An n -element cell array indicating types of surrogate splits at each node in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutType{k}` is a cell array with the types of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutType` contains an empty cell. A surrogate split type can be either `'continuous'` if the cut is defined in the form $Z < V$ for a variable Z and cut point V or `'categorical'` if the cut is defined by whether Z takes a value in a set of categories.

SurrogateCutPredictor

An n -element cell array of the names of the variables used for surrogate splits in each node in `tree`, where n is the number of nodes in `tree`. Every element of `SurrogateCutPredictor` is a cell array with the names of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutPredictor` contains an empty cell.

SurrogatePredictorAssociation

An n -element cell array of the predictive measures of association for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogatePredictorAssociation{k}` is a numeric vector. The length of `SurrogatePredictorAssociation{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogatePredictorAssociation{k}` gives the predictive measure of association between the optimal split and this surrogate split. The order of the surrogate split variables at each node is the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogatePredictorAssociation` contains an empty cell.

W

The scaled weights, a vector with length n , the number of rows in X .

X

A matrix or table of predictor values. Each column of X represents one variable, and each row represents one observation.

Y

A numeric column vector with the same number of rows as X . Each entry in Y is the response to the data in the corresponding row of X .

Methods

compact	Compact regression tree
crossval	Cross-validated decision tree
cvloss	Regression error by cross validation
prune	Produce sequence of regression subtrees by pruning
resubLoss	Regression error by resubstitution
resubPredict	Predict resubstitution response of tree

Inherited Methods

loss	Regression error
surrogateAssociation	Mean predictive measure of association for surrogate splits in regression tree
predict	Predict responses using regression tree
predictorImportance	Estimates of predictor importance for regression tree
view	View regression tree

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Construct Regression Tree

Load the sample data.

```
load carsmall
```

Construct a regression tree using the sample data. The response variable is miles per gallon, MPG.

```
tree = fitrtree([Weight, Cylinders],MPG,...
               'CategoricalPredictors',2,'MinParentSize',20,...
               'PredictorNames',{'W','C'})
```

```
tree =
  RegressionTree
    PredictorNames: {'W' 'C'}
    ResponseName: 'Y'
  CategoricalPredictors: 2
    ResponseTransform: 'none'
    NumObservations: 94
```

Properties, Methods

Predict the mileage of 4,000-pound cars with 4, 6, and 8 cylinders.

```
MPG4Kpred = predict(tree,[4000 4; 4000 6; 4000 8])
```

```
MPG4Kpred = 3×1
    19.2778
    19.2778
    14.3889
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `update` functions support code generation.
- When you train a regression tree model by using `fitrtree`, the following restrictions apply.
 - Code generation does not support categorical predictors (`logical`, `categorical`, `char`, `string`, or `cell`). If you supply training data in a table, the predictors must be numeric (`double` or `single`). Also, you cannot use the `'CategoricalPredictors'` name-value pair argument. To include categorical predictors in a model, preprocess the categorical predictors by using `dummyvar` before fitting the model.
 - The value of the `'ResponseTransform'` name-value pair argument cannot be an anonymous function. For fixed-point code generation, the `'ResponseTransform'` value must be `'none'`.
 - You cannot use surrogate splits, that is, the value of the `'Surrogate'` name-value pair argument must be `'off'`.

For more information, see “Introduction to Code Generation” on page 31-2.

RegressionTreeCoderConfigurer

Coder configurer of binary decision tree model for regression

Description

A `RegressionTreeCoderConfigurer` object is a coder configurer of a binary decision tree model for regression (`RegressionTree` or `CompactRegressionTree`).

A coder configurer offers convenient features to configure code generation options, generate C/C++ code, and update model parameters in the generated code.

- Configure code generation options and specify the coder attributes for tree model parameters by using object properties.
- Generate C/C++ code for the `predict` and `update` functions of the regression tree model by using `generateCode`. Generating C/C++ code requires MATLAB Coder.
- Update model parameters in the generated C/C++ code without having to regenerate the code. This feature reduces the effort required to regenerate, redeploy, and reverify C/C++ code when you retrain the tree model with new data or settings. Before updating model parameters, use `validatedUpdateInputs` to validate and extract the model parameters to update.

This flow chart shows the code generation workflow using a coder configurer.

For the code generation usage notes and limitations of a regression tree model, see the Code Generation sections of `CompactRegressionTree`, `predict`, and `update`.

Creation

After training a regression tree model by using `fitrtree`, create a coder configurer for the model by using `learnerCoderConfigurer`. Use the properties of a coder configurer to specify the coder attributes of the `predict` and `update` arguments. Then, use `generateCode` to generate C/C++ code based on the specified coder attributes.

Properties

`predict` Arguments

The properties listed in this section specify the coder attributes of the `predict` function arguments in the generated code.

X — Coder attributes of predictor data

LearnerCoderInput object

Coder attributes of the predictor data to pass to the generated C/C++ code for the `predict` function of the regression tree model, specified as a `LearnerCoderInput` on page 32-4698 object.

When you create a coder configurer by using the `learnerCoderConfigurer` function, the input argument `X` determines the default values of the `LearnerCoderInput` coder attributes:

- `SizeVector` — The default value is the array size of the input `X`.
- `VariableDimensions` — This value is `[0 0]`(default) or `[1 0]`.
 - `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
 - `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is `single` or `double`. The default data type depends on the data type of the input `X`.
- `Tunability` — This value must be `true`, meaning that `predict` in the generated C/C++ code always includes predictor data as an input.

You can modify the coder attributes by using dot notation. For example, to generate C/C++ code that accepts predictor data with 100 observations of three predictor variables, specify these coder attributes of `X` for the coder configurer `configurer`:

```
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [0 0];
```

`[0 0]` indicates that the first and second dimensions of `X` (number of observations and number of predictor variables, respectively) have fixed sizes.

To allow the generated C/C++ code to accept predictor data with up to 100 observations, specify these coder attributes of `X`:

```
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [1 0];
```

`[1 0]` indicates that the first dimension of `X` (number of observations) has a variable size and the second dimension of `X` (number of predictor variables) has a fixed size. The specified number of observations, 100 in this example, becomes the maximum allowed number of observations in the generated C/C++ code. To allow any number of observations, specify the bound as `Inf`.

NumOutputs — Number of outputs in predict

1 (default) | 2

Number of output arguments to return from the generated C/C++ code for the `predict` function of the regression tree model, specified as 1 or 2.

The output arguments of `predict` are `Yfit` (predicted responses) and `node` (node numbers for predictions), in that order. `predict` in the generated C/C++ code returns the first `n` outputs of the `predict` function, where `n` is the `NumOutputs` value.

After creating the coder configurer `configurer`, you can specify the number of outputs by using dot notation.

```
configurer.NumOutputs = 2;
```

The `NumOutputs` property is equivalent to the `'-nargout'` compiler option of `codegen`. This option specifies the number of output arguments in the entry-point function of code generation. The object function `generateCode` generates two entry-point functions—`predict.m` and `update.m` for the `predict` and `update` functions of a regression tree model, respectively—and generates C/C++ code for the two entry-point functions. The specified value for the `NumOutputs` property corresponds to the number of output arguments in the entry-point function `predict.m`.

Data Types: `double`

update Arguments

The properties listed in this section specify the coder attributes of the `update` function arguments in the generated code. The `update` function takes a trained model and new model parameters as input arguments, and returns an updated version of the model that contains the new parameters. To enable updating the parameters in the generated code, you need to specify the coder attributes of the parameters before generating code. Use a `LearnerCoderInput` on page 32-4698 object to specify the coder attributes of each parameter. The default attribute values are based on the model parameters in the input argument `Mdl` of `learnerCoderConfigurer`.

Children — Coder attributes of child nodes for each node

`LearnerCoderInput` object

Coder attributes of the child nodes for each node in the tree (`Children` of a regression tree model), specified as a `LearnerCoderInput` on page 32-4698 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — The default value is `[nd 2]`, where `nd` is the number of nodes in `Mdl`.
- `VariableDimensions` — This value is `[0 0]` (default) or `[1 0]`.
 - `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
 - `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — This value must be `true`.

If you modify the first dimension of `SizeVector` to be `newnd`, then the software modifies the first dimension of the `SizeVector` attribute to be `newnd` for the properties `CutPoint`, `CutPredictorIndex`, and `NodeMean`. Similarly, if you modify the first dimension of `VariableDimensions` to be `1`, then the software modifies the first dimension of the `VariableDimensions` attribute to be `1` for these properties.

CutPoint — Coder attributes of cut point for each node

`LearnerCoderInput` object

Coder attributes of the cut point for each node in the tree (`CutPoint` of a regression tree model), specified as a `LearnerCoderInput` on page 32-4698 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — The default value is `[nd 1]`, where `nd` is the number of nodes in `Mdl`.
- `VariableDimensions` — This value is `[0 0]`(default) or `[1 0]`.
 - `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
 - `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — This value must be `true`.

If you modify the first dimension of `SizeVector` to be `newnd`, then the software modifies the first dimension of the `SizeVector` attribute to be `newnd` for the properties `Children`, `CutPredictorIndex`, and `NodeMean`. Similarly, if you modify the first dimension of `VariableDimensions` to be 1, then the software modifies the first dimension of the `VariableDimensions` attribute to be 1 for these properties.

CutPredictorIndex — Coder attributes of cut predictor index for each node

`LearnerCoderInput` object

Coder attributes of the cut predictor index for each node in the tree (`CutPredictorIndex` of a regression tree model), specified as a `LearnerCoderInput` on page 32-4698 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — The default value is `[nd 1]`, where `nd` is the number of nodes in `Mdl`.
- `VariableDimensions` — This value is `[0 0]`(default) or `[1 0]`.
 - `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
 - `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — This value must be `true`.

If you modify the first dimension of `SizeVector` to be `newnd`, then the software modifies the first dimension of the `SizeVector` attribute to be `newnd` for the properties `Children`, `CutPoint`, and `NodeMean`. Similarly, if you modify the first dimension of `VariableDimensions` to be 1, then the software modifies the first dimension of the `VariableDimensions` attribute to be 1 for these properties.

NodeMean — Coder attributes of mean response value for each node

`LearnerCoderInput` object

Coder attributes of the mean response value for each node in the tree (NodeMean of a regression tree model), specified as a LearnerCoderInput on page 32-4698 object.

The default attribute values of the LearnerCoderInput object are based on the input argument MdL of learnerCoderConfigurer:

- **SizeVector** — The default value is [nd 1], where nd is the number of nodes in MdL.
- **VariableDimensions** — This value is [0 0](default) or [1 0].
 - [0 0] indicates that the array size is fixed as specified in SizeVector.
 - [1 0] indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of SizeVector is the upper bound for the number of rows, and the second value of SizeVector is the number of columns.
- **DataType** — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train MdL.
- **Tunability** — This value must be true.

If you modify the first dimension of SizeVector to be newnd, then the software modifies the first dimension of the SizeVector attribute to be newnd for the properties Children, CutPoint, and CutPredictorIndex. Similarly, if you modify the first dimension of VariableDimensions to be 1, then the software modifies the first dimension of the VariableDimensions attribute to be 1 for these properties.

Other Configurer Options

OutputFileName — File name of generated C/C++ code

'RegressionTreeModel' (default) | character vector

File name of the generated C/C++ code, specified as a character vector.

The object function generateCode of RegressionTreeCoderConfigurer generates C/C++ code using this file name.

The file name must not contain spaces because they can lead to code generation failures in certain operating system configurations. Also, the name must be a valid MATLAB function name.

After creating the coder configurer configurer, you can specify the file name by using dot notation.

```
configurer.OutputFileName = 'myModel';
```

Data Types: char

Verbose — Verbosity level

true (logical 1) (default) | false (logical 0)

Verbosity level, specified as true (logical 1) or false (logical 0). The verbosity level controls the display of notification messages at the command line.

Value	Description
true (logical 1)	The software displays notification messages when your changes to the coder attributes of a parameter result in changes for other dependent parameters.

Value	Description
false (logical 0)	The software does not display notification messages.

To enable updating machine learning model parameters in the generated code, you need to configure the coder attributes of the parameters before generating code. The coder attributes of parameters are dependent on each other, so the software stores the dependencies as configuration constraints. If you modify the coder attributes of a parameter by using a coder configurer, and the modification requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters. The verbosity level determines whether or not the software displays notification messages for these subsequent changes.

After creating the coder configurer `configurer`, you can modify the verbosity level by using dot notation.

```
configurer.Verbose = false;
```

Data Types: `logical`

Options for Code Generation Customization

To customize the code generation workflow, use the `generateFiles` function and the following three properties with `codegen`, instead of using the `generateCode` function.

After generating the two entry-point function files (`predict.m` and `update.m`) by using the `generateFiles` function, you can modify these files according to your code generation workflow. For example, you can modify the `predict.m` file to include data preprocessing, or you can add these entry-point functions to another code generation project. Then, you can generate C/C++ code by using the `codegen` function and the `codegen` arguments appropriate for the modified entry-point functions or code generation project. Use the three properties described in this section as a starting point to set the `codegen` arguments.

CodeGenerationArguments — codegen arguments

cell array

This property is read-only.

codegen arguments, specified as a cell array.

This property enables you to customize the code generation workflow. Use the `generateCode` function if you do not need to customize your workflow.

Instead of using `generateCode` with the coder configurer `configurer`, you can generate C/C++ code as follows:

```
generateFiles(configurer)
cgArgs = configurer.CodeGenerationArguments;
codegen(cgArgs{:})
```

If you customize the code generation workflow, modify `cgArgs` accordingly before calling `codegen`.

If you modify other properties of `configurer`, the software updates the `CodeGenerationArguments` property accordingly.

Data Types: `cell`

PredictInputs — Input argument of predict

cell array of a `coder.PrimitiveType` object

This property is read-only.

Input argument of the entry-point function `predict.m` for code generation, specified as a cell array of a `coder.PrimitiveType` object. The `coder.PrimitiveType` object includes the coder attributes of the predictor data stored in the `X` property.

If you modify the coder attributes of the predictor data, then the software updates the `coder.PrimitiveType` object accordingly.

The `coder.PrimitiveType` object in `PredictInputs` is equivalent to `configurer.CodeGenerationArguments{6}` for the coder configurer `configurer`.

Data Types: `cell`

UpdateInputs — List of tunable input arguments of update

cell array of a structure including `coder.PrimitiveType` objects

This property is read-only.

List of the tunable input arguments of the entry-point function `update.m` for code generation, specified as a cell array of a structure including `coder.PrimitiveType` objects. Each `coder.PrimitiveType` object includes the coder attributes of a tunable machine learning model parameter.

If you modify the coder attributes of a model parameter by using the coder configurer properties (update Arguments on page 32-4689 properties), then the software updates the corresponding `coder.PrimitiveType` object accordingly. If you specify the `Tunability` attribute of a machine learning model parameter as `false`, then the software removes the corresponding `coder.PrimitiveType` object from the `UpdateInputs` list.

The structure in `UpdateInputs` is equivalent to `configurer.CodeGenerationArguments{3}` for the coder configurer `configurer`.

Data Types: `cell`

Object Functions

<code>generateCode</code>	Generate C/C++ code using coder configurer
<code>generateFiles</code>	Generate MATLAB files for code generation using coder configurer
<code>validatedUpdateInputs</code>	Validate and extract machine learning model parameters to update

Examples**Generate Code Using Coder Configurer**

Train a machine learning model, and then generate code for the `predict` and `update` functions of the model by using a coder configurer.

Load the `carbig` data set, which contains car data, and train a regression tree model.

```
load carbig
X = [Displacement Horsepower Weight];
```

```
Y = MPG;
Mdl = fitrtree(X,Y);
```

Mdl is a RegressionTree object.

Create a coder configurer for the RegressionTree model by using learnerCoderConfigurer. Specify the predictor data X. The learnerCoderConfigurer function uses the input X to configure the coder attributes of the predict function input.

```
configurer = learnerCoderConfigurer(Mdl,X)

configurer =
  RegressionTreeCoderConfigurer with properties:

    Update Inputs:
        Children: [1x1 LearnerCoderInput]
        NodeMean: [1x1 LearnerCoderInput]
        CutPoint: [1x1 LearnerCoderInput]
    CutPredictorIndex: [1x1 LearnerCoderInput]

    Predict Inputs:
        X: [1x1 LearnerCoderInput]

    Code Generation Parameters:
        NumOutputs: 1
        OutputFileName: 'RegressionTreeModel'
```

Properties, Methods

configurer is a RegressionTreeCoderConfigurer object, which is a coder configurer of a RegressionTree object.

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use mex -setup to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the predict and update functions of the regression tree model (Mdl) with default settings.

```
generateCode(configurer)
```

```
generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionTreeModel.mat'
```

The generateCode function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions predict.m and update.m for the predict and update functions of Mdl, respectively.
- Create a MEX function named RegressionTreeModel for the two entry-point functions.
- Create the code for the MEX function in the codegen\mex\RegressionTreeModel folder.
- Copy the MEX function to the current folder.

Display the contents of the predict.m, update.m, and initialize.m files by using the type function.

type predict.m

```
function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:53:37
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end
```

type update.m

```
function update(varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:53:37
initialize('update',varargin{:});
end
```

type initialize.m

```
function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:53:37
coder.inline('always')
persistent model
if isempty(model)
    model = loadLearnerForCoder('RegressionTreeModel.mat');
end
switch(command)
    case 'update'
        % Update struct fields: Children
        %                               NodeMean
        %                               CutPoint
        %                               CutPredictorIndex
        model = update(model,varargin{:});
    case 'predict'
        % Predict Inputs: X
        X = varargin{1};
        if nargin == 2
            [varargout{1:nargout}] = predict(model,X);
        else
            PVPairs = cell(1,nargin-2);
            for i = 1:nargin-2
                PVPairs{1,i} = varargin{i+1};
            end
            [varargout{1:nargout}] = predict(model,X,PVPairs{:});
        end
    end
end
end
```

Update Parameters of Regression Tree Model in Generated Code

Train a regression tree using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the model parameters. Use the object function of the coder configurer to generate C code that predicts responses for new predictor data. Then retrain the model using the entire data set, and update parameters in the generated code without regenerating the code.

Train Model

Load the `carbig` data set, and train a regression tree model using half of the observations.

```
load carbig
X = [Displacement Horsepower Weight];
Y = MPG;

rng('default') % For reproducibility
n = length(Y);
idxTrain = randsample(n,n/2);
XTrain = X(idxTrain,:);
YTrain = Y(idxTrain);

Mdl = fitrtree(XTrain,YTrain);
```

Mdl is a RegressionTree object.

Create Coder Configurer

Create a coder configurer for the RegressionTree model by using learnerCoderConfigurer. Specify the predictor data XTrain. The learnerCoderConfigurer function uses the input XTrain to configure the coder attributes of the predict function input. Also, set the number of outputs to 2 so that the generated code returns predicted responses and node numbers for the predictions.

```
configurer = learnerCoderConfigurer(Mdl,XTrain,'NumOutputs',2);
```

configurer is a RegressionTreeCoderConfigurer object, which is a coder configurer of a RegressionTree object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the regression tree model parameters so that you can update the parameters in the generated code after retraining the model.

Specify the coder attributes of the X property of configurer so that the generated code accepts any number of observations. Modify the SizeVector and VariableDimensions attributes. The SizeVector attribute specifies the upper bound of the predictor data size, and the VariableDimensions attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 3];
configurer.X.VariableDimensions
```

```
ans = 1x2 logical array
```

```
    1    0
```

The size of the first dimension is the number of observations. Setting the value of the SizeVector attribute to Inf causes the software to change the value of the VariableDimensions attribute to 1. In other words, the upper bound of the size is Inf and the size is variable, meaning that the predictor data can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. Because the predictor data contains 3 predictors, the value of the SizeVector attribute must be 3 and the value of the VariableDimensions attribute must be 0.

If you retrain the tree model using new data or different settings, the number of nodes in the tree can vary. Therefore, specify the first dimension of the SizeVector attribute of one of these properties so

that you can update the number of nodes in the generated code: `Children`, `CutPoint`, `CutPredictorIndex`, or `NodeMean`. The software then modifies the other properties automatically.

For example, set the first value of the `SizeVector` attribute of the `NodeMean` property to `Inf`. The software modifies the `SizeVector` and `VariableDimensions` attributes of `Children`, `CutPoint`, and `CutPredictorIndex` to match the new upper bound on the number of nodes in the tree. Additionally, the first value of the `VariableDimensions` attribute of `NodeMean` changes to 1.

```
configurer.NodeMean.SizeVector = [Inf 1];
```

```
SizeVector attribute for Children has been modified to satisfy configuration constraints.
SizeVector attribute for CutPoint has been modified to satisfy configuration constraints.
SizeVector attribute for CutPredictorIndex has been modified to satisfy configuration constraints.
VariableDimensions attribute for Children has been modified to satisfy configuration constraints.
VariableDimensions attribute for CutPoint has been modified to satisfy configuration constraints.
VariableDimensions attribute for CutPredictorIndex has been modified to satisfy configuration constraints.
```

```
configurer.NodeMean.VariableDimensions
```

```
ans = 1x2 logical array
```

```
    1    0
```

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the `predict` and `update` functions of the regression tree model (`Mdl`).

```
generateCode(configurer)
```

```
generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionTreeModel.mat'
```

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `RegressionTreeModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\RegressionTreeModel` folder.
- Copy the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same predicted responses. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
[Yfit,node] = predict(Mdl,XTrain);
[Yfit_mex,node_mex] = RegressionTreeModel('predict',XTrain);
```

Compare `Yfit` to `Yfit_mex` and `node` to `node_mex`.

```
max(abs(Yfit-Yfit_mex),[], 'all')
```

```
ans = 0

isequal(node,node_mex)

ans = logical
     1
```

In general, `Yfit_mex` might include round-off differences compared to `Yfit`. In this case, the comparison confirms that `Yfit` and `Yfit_mex` are equal.

`isequal` returns logical 1 (true) if all the input arguments are equal. The comparison confirms that the `predict` function of `Mdl` and the `predict` function in the MEX function return the same node numbers.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

```
retrainedMdl = fitrtree(X,Y);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
RegressionTreeModel('update',params)
```

Verify Generated Code

Compare the output arguments from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```
[Yfit,node] = predict(retrainedMdl,X);
[Yfit_mex,node_mex] = RegressionTreeModel('predict',X);

max(abs(Yfit-Yfit_mex),[],'all')

ans = 0

isequal(node,node_mex)

ans = logical
     1
```

The comparison confirms that the predicted responses and node numbers are equal.

More About

LearnerCoderInput Object

A coder configurer uses a `LearnerCoderInput` object to specify the coder attributes of `predict` and `update` input arguments.

A `LearnerCoderInput` object has the following attributes to specify the properties of an input argument array in the generated code.

Attribute Name	Description
<code>SizeVector</code>	<p>Array size if the corresponding <code>VariableDimensions</code> value is <code>false</code>.</p> <p>Upper bound of the array size if the corresponding <code>VariableDimensions</code> value is <code>true</code>. To allow an unbounded array, specify the bound as <code>Inf</code>.</p>
<code>VariableDimensions</code>	<p>Indicator specifying whether each dimension of the array has a variable size or fixed size, specified as <code>true</code> (logical 1) or <code>false</code> (logical 0):</p> <ul style="list-style-type: none"> A value of <code>true</code> (logical 1) means that the corresponding dimension has a variable size. A value of <code>false</code> (logical 0) means that the corresponding dimension has a fixed size.
<code>DataType</code>	Data type of the array
<code>Tunability</code>	<p>Indicator specifying whether or not <code>predict</code> or <code>update</code> includes the argument as an input in the generated code, specified as <code>true</code> (logical 1) or <code>false</code> (logical 0).</p> <p>If you specify other attribute values when <code>Tunability</code> is <code>false</code>, the software sets <code>Tunability</code> to <code>true</code>.</p>

After creating a coder configurer, you can modify the coder attributes by using dot notation. For example, specify the coder attributes of the `CutPoint` property of the coder configurer configurer:

```
configurer.CutPoint.SizeVector = [40 1];
configurer.CutPoint.VariableDimensions = [1 0];
```

If you specify the verbosity level (`Verbose`) as `true` (default), then the software displays notification messages when you modify the coder attributes of a machine learning model parameter and the modification changes the coder attributes of other dependent parameters.

regstats

Regression diagnostics

Syntax

```
regstats(y,X,model)
stats = regstats(...)
stats = regstats(y,X,model,whichstats)
```

Description

`regstats(y,X,model)` performs a multilinear regression of the responses in `y` on the predictors in `X`. `X` is an n -by- p matrix of p predictors at each of n observations. `y` is an n -by-1 vector of observed responses.

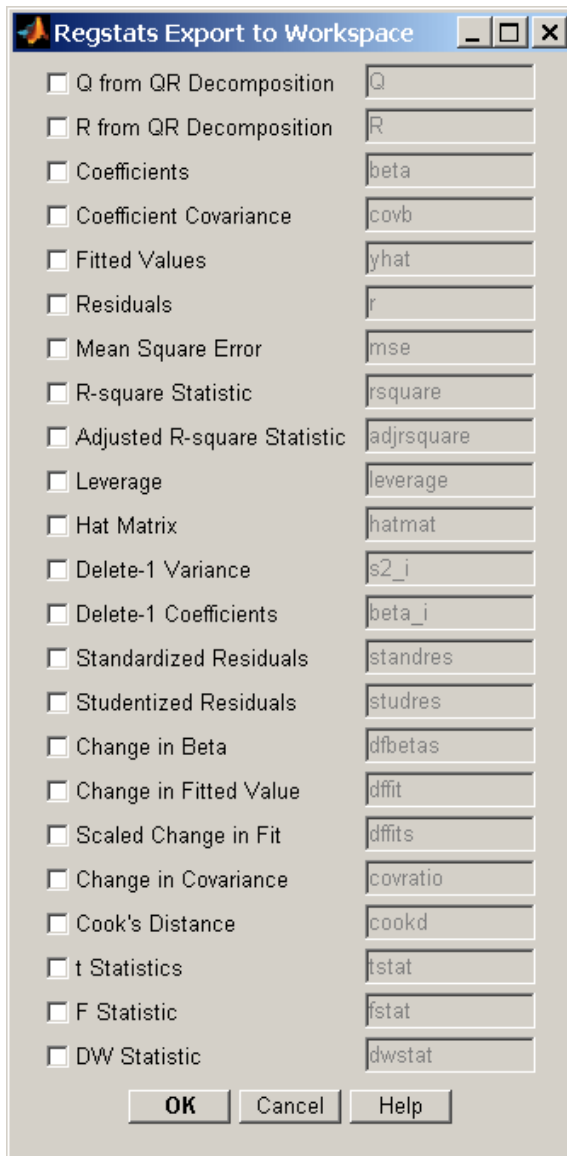

Note By default, `regstats` adds a first column of 1s to `X`, corresponding to a constant term in the model. Do not enter a column of 1s directly into `X`.

The optional input `model` controls the regression model. By default, `regstats` uses a linear additive model with a constant term. `model` can be any one of the following:

- 'linear' — Constant and linear terms (the default)
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

Alternatively, `model` can be a matrix of model terms accepted by the `x2fx` function. See `x2fx` for a description of this matrix and for a description of the order in which terms appear. You can use this matrix to specify other models including ones without a constant term.

With this syntax, the function displays a graphical user interface (GUI) with a list of diagnostic statistics, as shown in the following figure.

When you select check boxes corresponding to the statistics you want to compute and click **OK**, `regstats` returns the selected statistics to the MATLAB workspace. The names of the workspace variables are displayed on the right-hand side of the interface. You can change the name of the workspace variable to any valid MATLAB variable name.

`stats = regstats(...)` creates the structure `stats`, whose fields contain all of the diagnostic statistics for the regression. This syntax does not open the GUI. The fields of `stats` are listed in the following table.

Field	Description
Q	Q from the QR decomposition of the design matrix
R	R from the QR decomposition of the design matrix
beta	Regression coefficients

Field	Description
covb	Covariance of regression coefficients
yhat	Fitted values of the response data
r	Residuals
mse	Mean squared error
rsquare	R^2 statistic
adjrsquare	Adjusted R^2 statistic
leverage	Leverage
hatmat	Hat matrix
s2_i	Delete-1 variance
beta_i	Delete-1 coefficients
standres	Standardized residuals
studres	Studentized residuals
dfbetas	Scaled change in regression coefficients
dffit	Change in fitted values
dffits	Scaled change in fitted values
covratio	Change in covariance
cookd	Cook's distance
tstat	t statistics and p -values for coefficients
fstat	F statistic and p -value
dwstat	Durbin-Watson statistic and p -value

Note that the fields names of `stats` correspond to the names of the variables returned to the MATLAB workspace when you use the GUI. For example, `stats.beta` corresponds to the variable `beta` that is returned when you select **Coefficients** in the GUI and click **OK**.

`stats = regstats(y,X,model,whichstats)` returns only the statistics that you specify in `whichstats`. `whichstats` can be a single character vector such as `'leverage'`, a string array such as `["leverage", "standres", "studres"]`, or a cell array of character vectors such as `{'leverage', 'standres', 'studres'}`. Set `whichstats` to `'all'` to return all of the statistics.

Note The F statistic is computed under the assumption that the model contains a constant term. It is not correct for models without a constant. The R^2 statistic can be negative for models without a constant, which indicates that the model is not appropriate for the data.

Examples

Open the `regstats` GUI using data from `hald.mat`:

```
load hald
regstats(heat,ingredients,'linear');
```

Select **Fitted Values** and **Residuals** in the GUI:

Click **OK** to export the fitted values and residuals to the MATLAB workspace in variables named `yhat` and `r`, respectively.

You can create the same variables using the `stats` output, without opening the GUI:

```
whichstats = {'yhat','r'};  
stats = regstats(heat,ingredients,'linear',whichstats);  
yhat = stats.yhat;  
r = stats.r;
```

Introduced before R2006a

regularize

Find weights to minimize resubstitution error plus penalty term

Syntax

```
ens1 = regularize(ens)
ens1 = regularize(ens,Name,Value)
```

Description

`ens1 = regularize(ens)` finds optimal weights for learners in `ens` by lasso regularization. `regularize` returns a regression ensemble identical to `ens`, but with a populated `Regularization` property.

`ens1 = regularize(ens,Name,Value)` computes optimal weights with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

A regression ensemble, created by `fitrensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

lambda

Vector of nonnegative regularization parameter values for lasso. For the default setting of `lambda`, `regularize` calculates the smallest value `lambda_max` for which all optimal weights for learners are 0. The default value of `lambda` is a vector including 0 and nine exponentially-spaced numbers from `lambda_max/1000` to `lambda_max`.

Default: `[0 logspace(log10(lambda_max/1000),log10(lambda_max),9)]`

MaxIter

Maximum number of iterations allowed, specified as a positive integer. If the algorithm executes `MaxIter` iterations before reaching the convergence tolerance, then the function stops iterating and returns a warning message. The function can return more than one warning when either `npass` or the number of `lambda` values is greater than 1.

Default: `1e3`

npass

Maximal number of passes for lasso optimization, a positive integer.

Default: 10

reltol

Relative tolerance on the regularized loss for lasso, a numeric positive scalar.

Default: 1e-3

verbose

Verbosity level, either 0 or 1. When set to 1, `regularize` displays more information as it runs.

Default: 0

Output Arguments

ens1

A regression ensemble. Usually you set `ens1` to the same name as `ens`.

Examples

Regularize Ensemble of Bagged Trees

Regularize an ensemble of bagged trees.

Generate sample data.

```
rng(10,'twister') % For reproducibility
X = rand(2000,20);
Y = repmat(-1,2000,1);
Y(sum(X(:,1:5),2)>2.5) = 1;
```

You can create a bagged classification ensemble of 300 trees from the sample data.

```
bag = fitensemble(X,Y,'Method','Bag','NumLearningCycles',300);
```

`fitensemble` uses a default template tree object `templateTree()` as a weak learner when 'Method' is 'Bag'. In this example, for reproducibility, specify 'Reproducible', true when you create a tree template object, and then use the object as a weak learner.

```
t = templateTree('Reproducible',true); % For reproducibility of random predictor selections
bag = fitensemble(X,Y,'Method','Bag','NumLearningCycles',300,'Learners',t);
```

Regularize the ensemble of bagged regression trees.

```
bag = regularize(bag,'lambda',[0.001 0.1],'verbose',1);
```

Starting lasso minimization for Lambda=0.001. Initial MSE=0.110607.

```

MSE = 0.0788065
Relative change in MSE = 1.98213e-05
Number of learners with non-zero weights = 87
Completed lasso minimization for Lambda=0.1.
Resubstitution MSE changed from 0.110607 to 0.0788065.
Number of learners reduced from 300 to 87.

```

regularize reports on its progress.

Inspect the resulting regularization structure.

`bag.Regularization`

```

ans = struct with fields:
    Method: 'Lasso'
    TrainedWeights: [300x2 double]
    Lambda: [1.0000e-03 0.1000]
    ResubstitutionMSE: [0.0599 0.0788]
    CombineWeights: @classreg.learning.combiner.WeightedSum

```

Check how many learners in the regularized ensemble have positive weights. These are the learners included in a shrunken ensemble.

```
sum(bag.Regularization.TrainedWeights > 0)
```

```

ans = 1x2
    113    87

```

Shrink the ensemble using the weights from `Lambda = 0.1`.

```
cmp = shrink(bag, 'weightcolumn', 2)
```

```

cmp =
    classreg.learning.regr.CompactRegressionEnsemble
        ResponseName: 'Y'
        CategoricalPredictors: []
        ResponseTransform: 'none'
        NumTrained: 87

```

Properties, Methods

The compact ensemble contains 87 members, less than 1/3 of the original 300.

More About

Lasso

The lasso algorithm finds an optimal set of learner weights α_t that minimize

$$\sum_{n=1}^N w_n g\left(\left(\sum_{t=1}^T \alpha_t h_t(x_n)\right), y_n\right) + \lambda \sum_{t=1}^T |\alpha_t|.$$

Here

- $\lambda \geq 0$ is a parameter you provide, called the lasso parameter.
- h_t is a weak learner in the ensemble trained on N observations with predictors x_n , responses y_n , and weights w_n .
- $g(f,y) = (f - y)^2$ is the squared error.

Topics

“Ensemble Regularization” on page 18-69

relieff

Rank importance of predictors using ReliefF or RReliefF algorithm

Syntax

```
[idx,weights] = relieff(X,y,k)
[idx,weights] = relieff(X,y,k,Name,Value)
```

Description

`[idx,weights] = relieff(X,y,k)` ranks predictors using either the ReliefF or RReliefF algorithm with `k` nearest neighbors. The input matrix `X` contains predictor variables, and the vector `y` contains a response vector. The function returns `idx`, which contains the indices of the most important predictors, and `weights`, which contains the weights of the predictors.

If `y` is numeric, `relieff` performs RReliefF analysis for regression by default. Otherwise, `relieff` performs ReliefF analysis for classification using `k` nearest neighbors per class. For more information on ReliefF and RReliefF, see “Algorithms” on page 32-4714.

`[idx,weights] = relieff(X,y,k,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, `'updates',10` sets the number of observations randomly selected for computing weights to 10.

Examples

Determine Important Predictors

Load the sample data.

```
load fisheriris
```

Find the important predictors using 10 nearest neighbors.

```
[idx,weights] = relieff(meas,species,10)
```

```
idx = 1×4
```

```
    4    3    1    2
```

```
weights = 1×4
```

```
    0.1399    0.1226    0.3590    0.3754
```

`idx` shows the predictor numbers listed according to their ranking. The fourth predictor is the most important, and the second predictor is the least important. `weights` gives the weight values in the same order as the predictors. The first predictor has a weight of 0.1399, and the fourth predictor has a weight of 0.3754.

Rank Predictors by Importance

Load the sample data.

```
load ionosphere
```

Rank the predictors based on importance using 10 nearest neighbors.

```
[idx,weights] = relieff(X,Y,10);
```

Create a bar plot of predictor importance weights.

```
bar(weights(idx))
xlabel('Predictor rank')
ylabel('Predictor importance weight')
```

Select the top 5 most important predictors. Find the columns of these predictors in X.

```
idx(1:5)
```

```
ans = 1x5
```

```
24 3 8 5 14
```

The 24th column of X is the most important predictor of Y.

Determine Important Categorical Predictors

Rank categorical predictors using `relieff`.

Load the sample data.

```
load carbig
```

Convert the categorical predictor variables `Mfg`, `Model`, and `Origin` to numerical values, and combine them into an input matrix. Specify the response variable `MPG`.

```
X = [grp2idx(Mfg) grp2idx(Model) grp2idx(Origin)];
y = MPG;
```

Find the ranks and weights of the predictor variables using 10 nearest neighbors and treating the data in `X` as categorical.

```
[idx,weights] = relieff(X,y,10,'categoricalx','on')
```

```
idx = 1×3
```

```
    2    3    1
```

```
weights = 1×3
```

```
 -0.0019    0.0501    0.0114
```

The `Model` predictor is the most important in predicting `MPG`. The `Mfg` variable has a negative weight, indicating it is not a good predictor of `MPG`.

Input Arguments

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix. Each row of `X` corresponds to one observation, and each column corresponds to one variable.

Data Types: `single` | `double`

y — Response data

numeric vector | categorical vector | logical vector | character array | string array | cell array of character vectors

Response data, specified as a numeric vector, categorical vector, logical vector, character array, string array, or cell array of character vectors.

Data Types: `single` | `double` | `categorical` | `logical` | `char` | `string` | `cell`

k — Number of nearest neighbors

positive integer scalar

Number of nearest neighbors, specified as a positive integer scalar.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `relieff(X,y,5,'method','classification','categoricalx','on')` specifies 5 nearest neighbors and treats the response variable and predictor data as categorical.

`method` — Method for computing weights

`'regression'` | `'classification'`

Method for computing weights, specified as the comma-separated pair consisting of `'method'` and either `'regression'` or `'classification'`. If `y` is numeric, `'regression'` is the default method. Otherwise, `'classification'` is the default.

Example: `'method','classification'`

`prior` — Prior probabilities for each class

`'empirical'` (default) | `'uniform'` | numeric vector | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'prior'` and a value in this table.

Value	Description
<code>'empirical'</code>	The class probabilities are determined from class frequencies in <code>y</code> .
<code>'uniform'</code>	All class probabilities are equal.
numeric vector	One value exists for each distinct group name.
structure	A structure <code>S</code> with two fields: <ul style="list-style-type: none"> <code>S.group</code> contains the group names as a variable of the same type as <code>y</code>. <code>S.prob</code> contains a vector of corresponding probabilities.

Example: `'prior','uniform'`

Data Types: `single` | `double` | `char` | `string` | `struct`

`updates` — Number of observations for computing weights

`'all'` (default) | positive integer scalar

Number of observations to select at random for computing weights, specified as the comma-separated pair consisting of `'updates'` and either `'all'` or a positive integer scalar. By default, `relieff` uses all observations.

Example: `'updates',25`

Data Types: `single` | `double` | `char` | `string`

categoricalx — Categorical predictors flag

'off' (default) | 'on'

Categorical predictors flag, specified as the comma-separated pair consisting of 'categoricalx' and either 'on' or 'off'. If you specify 'on', then `relieff` treats all predictors in X as categorical. Otherwise, it treats all predictors in X as numeric. You cannot mix numeric and categorical predictors.

Example: 'categoricalx', 'on'

sigma — Distance scaling factor

numeric positive scalar

Distance scaling factor, specified as the comma-separated pair consisting of 'sigma' and a numeric positive scalar. For observation i , influence on the predictor weight from its nearest neighbor j is multiplied by $e^{-(\text{rank}(i,j)/\text{sigma})^2}$. $\text{rank}(i,j)$ is the position of the j th observation among the nearest neighbors of the i th observation, sorted by distance. The default is `Inf` for classification (all nearest neighbors have the same influence) and 50 for regression.

Example: 'sigma', 20

Data Types: `single` | `double`

Output Arguments**idx — Indices of predictors ordered by predictor importance**

numeric vector

Indices of predictors in X ordered by predictor importance, returned as a numeric vector. For example, if `idx(3)` is 5, then the third most important predictor is the fifth column in X .

Data Types: `double`

weights — Weights of predictors

numeric vector

Weights of the predictors, returned as a numeric vector. The values in `weights` have the same order as the predictors in X . `weights` range from -1 to 1 , with large positive weights assigned to important predictors.

Data Types: `double`

Tips

- Predictor ranks and weights usually depend on k . If you set k to 1, then the estimates can be unreliable for noisy data. If you set k to a value comparable with the number of observations (rows) in X , `relieff` can fail to find important predictors. You can start with $k = 10$ and investigate the stability and reliability of `relieff` ranks and weights for various values of k .
- `relieff` removes observations with NaN values.

Algorithms

ReliefF

ReliefF finds the weights of predictors in the case where y is a multiclass categorical variable. The algorithm penalizes the predictors that give different values to neighbors of the same class, and rewards predictors that give different values to neighbors of different classes.

ReliefF first sets all predictor weights W_j to 0. Then, the algorithm iteratively selects a random observation x_r , finds the k -nearest observations to x_r for each class, and updates, for each nearest neighbor x_q , all the weights for the predictors F_j as follows:

If x_r and x_q are in the same class,

$$W_j^i = W_j^{i-1} - \frac{\Delta_j(x_r, x_q)}{m} \cdot d_{rq}.$$

If x_r and x_q are in different classes,

$$W_j^i = W_j^{i-1} + \frac{p_{y_q}}{1 - p_{y_r}} \cdot \frac{\Delta_j(x_r, x_q)}{m} \cdot d_{rq}.$$

- W_j^i is the weight of the predictor F_j at the i th iteration step.
- p_{y_r} is the prior probability of the class to which x_r belongs, and p_{y_q} is the prior probability of the class to which x_q belongs.
- m is the number of iterations specified by 'updates'.
- $\Delta_j(x_r, x_q)$ is the difference in the value of the predictor F_j between observations x_r and x_q . Let x_{rj} denote the value of the j th predictor for observation x_r , and let x_{qj} denote the value of the j th predictor for observation x_q .

- For discrete F_j ,

$$\Delta_j(x_r, x_q) = \begin{cases} 0, & x_{rj} = x_{qj} \\ 1, & x_{rj} \neq x_{qj} \end{cases}.$$

- For continuous F_j ,

$$\Delta_j(x_r, x_q) = \frac{|x_{rj} - x_{qj}|}{\max(F_j) - \min(F_j)}.$$

- d_{rq} is a distance function of the form

$$d_{rq} = \frac{\tilde{d}_{rq}}{\sum_{l=1}^k \tilde{d}_{rl}}.$$

The distance is subject to the scaling

$$\tilde{d}_{rq} = e^{-(\text{rank}(r, q)/\text{sigma})^2}$$

where $\text{rank}(r, q)$ is the position of the q th observation among the nearest neighbors of the r th observation, sorted by distance. k is the number of nearest neighbors, specified by k . You can change the scaling by specifying 'sigma'.

RRelieff

RRelieff works with continuous y . Similar to ReliefF, RRelieff also penalizes the predictors that give different values to neighbors with the same response values, and rewards predictors that give different values to neighbors with different response values. However, RRelieff uses intermediate weights to compute the final predictor weights.

Given two nearest neighbors, assume the following:

- W_{dy} is the weight of having different values for the response y .
- W_{dj} is the weight of having different values for the predictor F_j .
- $W_{dy \wedge dj}$ is the weight of having different response values and different values for the predictor F_j .

RRelieff first sets the weights W_{dy} , W_{dj} , $W_{dy \wedge dj}$, and W_j equal to 0. Then, the algorithm iteratively selects a random observation x_r , finds the k -nearest observations to x_r , and updates, for each nearest neighbor x_q , all the intermediate weights as follows:

$$W_{dy}^i = W_{dy}^{i-1} + \Delta_y(x_r, x_q) \cdot d_{rq}.$$

$$W_{dj}^i = W_{dj}^{i-1} + \Delta_j(x_r, x_q) \cdot d_{rq}.$$

$$W_{dy \wedge dj}^i = W_{dy \wedge dj}^{i-1} + \Delta_y(x_r, x_q) \cdot \Delta_j(x_r, x_q) \cdot d_{rq}.$$

- The i and $i-1$ superscripts denote the iteration step number. m is the number of iterations specified by 'updates'.
- $\Delta_y(x_r, x_q)$ is the difference in the value of the continuous response y between observations x_r and x_q . Let y_r denote the value of the response for observation x_r , and let y_q denote the value of the response for observation x_q .

$$\Delta_y(x_r, x_q) = \frac{|y_r - y_q|}{\max(y) - \min(y)}.$$

- The $\Delta_j(x_r, x_q)$ and d_{rq} functions are the same as for "ReliefF" on page 32-4714.

RRelieff calculates the predictor weights W_j after fully updating all the intermediate weights.

$$W_j = \frac{W_{dy \wedge dj}}{W_{dy}} - \frac{W_{dj} - W_{dy \wedge dj}}{m - W_{dy}}.$$

For more information, see [2].

removeLearners

Remove members of compact classification ensemble

Syntax

```
cens1 = removeLearners(cens,idx)
```

Description

`cens1 = removeLearners(cens,idx)` creates a compact classification ensemble identical to `cens` only without the ensemble members in the `idx` vector.

Input Arguments

`cens`

Compact classification ensemble, constructed with `compact`.

`idx`

Vector of positive integers with entries from 1 to `cens.NumTrained`, where `cens.NumTrained` is the number of members in `cens`. `cens1` contains all members of `cens` except those with indices in `idx`.

Typically, you set `idx = j:cens.NumTrained` for some positive integer `j`.

Output Arguments

`cens1`

Compact classification ensemble, identical to `cens` except `cens1` does not contain those members of `cens` with indices in `idx`.

Examples

Remove Learners from an Ensemble

Create a compact classification ensemble. Compact it further by removing members of the ensemble.

Load the `ionosphere` data set.

```
load ionosphere
```

Train a classification ensemble for the `ionosphere` data using `AdaBoostM1`. Specify tree stumps as the weak learners.

```
t = templateTree('MaxNumSplits',1);  
ens = fitcensemble(X,Y,'Method','AdaBoostM1','Learners',t);
```

Create a compact classification ensemble `cens` from `ens`.

```
cens = compact(ens);
```

Remove the last 50 members of the ensemble.

```
idx = cens.NumTrained-49:cens.NumTrained;  
cens1 = removeLearners(cens,idx);
```

Tips

- Typically, set `cens1` equal to `cens` to retain just one ensemble.
- Removing learners reduces the memory used by the ensemble and speeds up its predictions.

removeLearners

Remove members of compact regression ensemble

Syntax

```
cens1 = removeLearners(cens,idx)
```

Description

`cens1 = removeLearners(cens,idx)` creates a compact regression ensemble identical to `cens` only without the ensemble members in the `idx` vector.

Input Arguments

cens

Compact regression ensemble, constructed with `compact`.

idx

Vector of positive integers with entries from 1 to `cens.NumTrained`, where `cens.NumTrained` is the number of members in `cens`. `cens1` contains the members of `cens` except those with indices in `idx`.

Typically, you set `idx = j:cens.NumTrained` for some positive integer `j`.

Output Arguments

cens1

Compact regression ensemble, identical to `cens` except `cens1` does not contain members of `cens` with indices in `idx`.

Examples

Remove Learners from an Ensemble

Create a compact regression ensemble. Compact it further by removing members of the ensemble.

Load the `carsmall` data set and select `Weight` and `Cylinders` as predictors.

```
load carsmall
X = [Weight Cylinders];
```

Train a regression ensemble using LSBoost. Specify tree stumps as the weak learners.

```
t = templateTree('MaxNumSplits',1);
ens = fitensemble(X,MPG,'Method','LSBoost','Learners',t,...
    'CategoricalPredictors',2);
```

Create a compact classification ensemble `cens` from `ens`.

```
cens = compact(ens);
```

Remove the last 50 members of the ensemble.

```
idx = cens.NumTrained-49:cens.NumTrained;  
cens1 = removeLearners(cens,idx);
```

Tips

- Typically, set `cens1` equal to `cens` to retain just one ensemble.
- Removing learners reduces the memory used by the ensemble and speeds up its predictions.

`CompactRegressionEnsemble`

removeTerms

Remove terms from generalized linear regression model

Syntax

```
NewMdl = removeTerms(mdl, terms)
```

Description

`NewMdl = removeTerms(mdl, terms)` returns a generalized linear regression model fitted using the input data and settings in `mdl` with the terms `terms` removed.

Examples

Remove Terms from Generalized Linear Regression Model

Create a generalized linear regression model using two predictors, and then remove one predictor.

Generate sample data using Poisson random numbers with two underlying predictors $X(:,1)$ and $X(:,2)$.

```
rng('default') % For reproducibility
rndvars = randn(100,2);
X = [2 + rndvars(:,1), rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','Distribution','poisson')
```

```
mdl =
Generalized linear regression model:
  log(y) ~ 1 + x1 + x2
  Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	1.0405	0.022122	47.034	0
x1	0.9968	0.003362	296.49	0
x2	1.987	0.0063433	313.24	0

100 observations, 97 error degrees of freedom

Dispersion: 1

Chi²-statistic vs. constant model: 2.95e+05, p-value = 0

Remove the second predictor from the model.

```
mdl1 = removeTerms(mdl, 'x2')
```

```
mdl1 =
Generalized linear regression model:
  log(y) ~ 1 + x1
  Distribution = Poisson

Estimated Coefficients:

```

	Estimate	SE	tStat	pValue
(Intercept)	2.7784	0.014043	197.85	0
x1	1.1732	0.0033653	348.6	0

```
100 observations, 98 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 1.25e+05, p-value = 0
```

Input Arguments

mdl — Generalized linear regression model

GeneralizedLinearModel object

Generalized linear regression model, specified as a GeneralizedLinearModel object created using fitglm or stepwiseglm.

terms — Terms to remove from regression model

character vector or string scalar formula in Wilkinson notation | *t*-by-*p* terms matrix

Terms to remove from the regression model mdl, specified as one of the following:

- Character vector or string scalar formula in “Wilkinson Notation” on page 32-4723 representing one or more terms. The variable names in the formula must be valid MATLAB identifiers.
- Terms matrix T of size *t*-by-*p*, where *t* is the number of terms and *p* is the number of predictor variables in mdl. The value of T(*i*, *j*) is the exponent of variable *j* in term *i*.

For example, suppose mdl has three variables A, B, and C in that order. Each row of T represents one term:

- [0 0 0] — Constant term or intercept
- [0 1 0] — B; equivalently, A⁰ * B¹ * C⁰
- [1 0 1] — A*C
- [2 0 0] — A²
- [0 1 2] — B*(C²)

removeTerms treats a group of indicator variables for a categorical predictor as a single variable. Therefore, you cannot specify an indicator variable to remove from the model. If you specify a categorical predictor to remove from the model, removeTerms removes a group of indicator variables for the predictor in one step.

Output Arguments

NewMdl — Generalized linear regression model with fewer terms

GeneralizedLinearModel object

Generalized linear regression model with fewer terms, returned as a GeneralizedLinearModel object. NewMdl is a newly fitted model that uses the input data and settings in mdl with the terms specified in terms removed from mdl.

To overwrite the input argument mdl, assign the newly fitted model to mdl:

```
mdl = removeTerms(mdl, terms);
```

More About

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- + means include the next variable.
- – means do not include the next variable.
- : defines an interaction, which is a product of terms.
- * defines an interaction and all lower-order terms.
- ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower-order terms as well.
- () groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Term in Standard Notation
1	Constant (intercept) term
A ^k , where k is a positive integer	A, A ² , ..., A ^k
A + B	A, B
A*B	A, B, A*B
A:B	A*B only
–B	Do not include B
A*B + C	A, B, C, A*B
A + B + C + A:B	A, B, C, A*B
A*B*C – A:B:C	A, B, C, A*B, A*C, B*C
A*(B + C)	A, B, C, A*B, A*C

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using –1.

For more details, see “Wilkinson Notation” on page 11-90.

Algorithms

- `removeTerms` treats a categorical predictor as follows:
 - A model with a categorical predictor that has L levels (categories) includes $L - 1$ indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level.
 - `removeTerms` treats the group of $L - 1$ indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor X , if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.
 - Interaction terms between a continuous predictor and a categorical predictor with L levels consist of the element-wise product of the $L - 1$ indicator variables with the continuous predictor.
 - Interaction terms between two categorical predictors with L and M levels consist of the $(L - 1) * (M - 1)$ indicator variables to include all possible combinations of the two categorical predictor levels.
 - You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.

Alternative Functionality

- Use `stepwiseglm` to specify terms in a starting model and continue improving the model until no single step of adding or removing a term is beneficial.
- Use `addTerms` to add specific terms to a model.
- Use `step` to optimally improve a model by adding or removing terms.

Introduced in R2012a

removeTerms

Remove terms from linear regression model

Syntax

```
NewMdl = removeTerms(mdl, terms)
```

Description

`NewMdl = removeTerms(mdl, terms)` returns a linear regression model fitted using the input data and settings in `mdl` with the terms `terms` removed.

Examples

Remove Terms from Linear Regression Model

Create a linear regression model using the `hald` data set. Remove terms that have high p -values.

Load the data set.

```
load hald
X = ingredients; % predictor variables
y = heat; % response variable
```

Fit a linear regression model to the data.

```
mdl = fitlm(X,y)
```

```
mdl =
Linear regression model:
    y ~ 1 + x1 + x2 + x3 + x4
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	62.405	70.071	0.8906	0.39913
x1	1.5511	0.74477	2.0827	0.070822
x2	0.51017	0.72379	0.70486	0.5009
x3	0.10191	0.75471	0.13503	0.89592
x4	-0.14406	0.70905	-0.20317	0.84407

```
Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 2.45
R-squared: 0.982, Adjusted R-Squared: 0.974
F-statistic vs. constant model: 111, p-value = 4.76e-07
```

Remove the `x3` and `x4` terms because their p -values are high.

```
terms = 'x3 + x4'; % terms to remove
NewMdl = removeTerms(mdl, terms)
```

```
NewMdl =
Linear regression model:
y ~ 1 + x1 + x2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	52.577	2.2862	22.998	5.4566e-10
x1	1.4683	0.1213	12.105	2.6922e-07
x2	0.66225	0.045855	14.442	5.029e-08

```
Number of observations: 13, Error degrees of freedom: 10
Root Mean Squared Error: 2.41
R-squared: 0.979, Adjusted R-Squared: 0.974
F-statistic vs. constant model: 230, p-value = 4.41e-09
```

`NewMdl` has the same adjusted R-squared value (0.974) as the previous model, meaning the fit is as good in the new model. All the terms in the new model have extremely low p -values.

Input Arguments

`mdl` — Linear regression model

LinearModel object

Linear regression model, specified as a `LinearModel` object created using `fitlm` or `stepwiselm`.

`terms` — Terms to remove from regression model

character vector or string scalar formula in Wilkinson notation | t -by- p terms matrix

Terms to remove from the regression model `mdl`, specified as one of the following:

- Character vector or string scalar formula in “Wilkinson Notation” on page 32-4727 representing one or more terms. The variable names in the formula must be valid MATLAB identifiers.
- Terms matrix T of size t -by- p , where t is the number of terms and p is the number of predictor variables in `mdl`. The value of $T(i, j)$ is the exponent of variable j in term i .

For example, suppose `mdl` has three variables A, B, and C in that order. Each row of T represents one term:

- $[0 \ 0 \ 0]$ — Constant term or intercept
- $[0 \ 1 \ 0]$ — B; equivalently, $A^0 * B^1 * C^0$
- $[1 \ 0 \ 1]$ — $A * C$
- $[2 \ 0 \ 0]$ — A^2
- $[0 \ 1 \ 2]$ — $B * (C^2)$

`removeTerms` treats a group of indicator variables for a categorical predictor as a single variable. Therefore, you cannot specify an indicator variable to remove from the model. If you specify a categorical predictor to remove from the model, `removeTerms` removes a group of indicator variables for the predictor in one step. See “Modify Linear Regression Model Using step” on page 32-5210 for an example that describes how to create indicator variables manually and treat each one as a separate variable.

Output Arguments

NewMdl — Linear regression model with fewer terms

LinearModel object

Linear regression model with fewer terms, returned as a LinearModel object. NewMdl is a newly fitted model that uses the input data and settings in mdl with the terms specified in terms removed from mdl.

To overwrite the input argument mdl, assign the newly fitted model to mdl:

```
mdl = removeTerms(mdl, terms);
```

More About

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- + means include the next variable.
- – means do not include the next variable.
- : defines an interaction, which is a product of terms.
- * defines an interaction and all lower-order terms.
- ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower-order terms as well.
- () groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Term in Standard Notation
1	Constant (intercept) term
A ^k , where k is a positive integer	A, A ² , ..., A ^k
A + B	A, B
A*B	A, B, A*B
A:B	A*B only
–B	Do not include B
A*B + C	A, B, C, A*B
A + B + C + A:B	A, B, C, A*B
A*B*C – A:B:C	A, B, C, A*B, A*C, B*C
A*(B + C)	A, B, C, A*B, A*C

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using –1.

For more details, see “Wilkinson Notation” on page 11-90.

Algorithms

- `removeTerms` treats a categorical predictor as follows:
 - A model with a categorical predictor that has L levels (categories) includes $L - 1$ indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level.
 - `removeTerms` treats the group of $L - 1$ indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor X , if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.
 - Interaction terms between a continuous predictor and a categorical predictor with L levels consist of the element-wise product of the $L - 1$ indicator variables with the continuous predictor.
 - Interaction terms between two categorical predictors with L and M levels consist of the $(L - 1)*(M - 1)$ indicator variables to include all possible combinations of the two categorical predictor levels.
 - You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.

Alternative Functionality

- Use `stepwiselm` to specify terms in a starting model and continue improving the model until no single step of adding or removing a term is beneficial.

reorderlevels

(Not Recommended) Reorder levels of nominal or ordinal arrays

Note The `nominal` and `ordinal` array data types are not recommended. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

Syntax

```
B = reorderlevels(A,newlevels)
```

Description

`B = reorderlevels(A,newlevels)` returns a `nominal` or `ordinal` array object of the same type as `A`, but with levels in the new order specified by `newlevels`.

For ordinal arrays, the order of the levels has significance for relational operators, finding minimum and maximum values, and sorting.

Input Arguments

A — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created with `nominal` or `ordinal`.

newlevels — New order of levels

string array | cell array of character vectors | 2-D character matrix

New order of levels, specified as a string array, cell array of character vectors, or 2-D character matrix. `newlevels` must be a reordering of the labels returned by `getlabels`.

Data Types: `char` | `string` | `cell`

Output Arguments

B — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, returned as a `nominal` or `ordinal` array object.

See Also

`addlevels` | `droplevels` | `getlabels` | `nominal` | `ordinal` | `reorderlevels`

repartition

Class: `cvpartition`

Repartition data for cross-validation

Syntax

```
cnew = repartition(c)
```

Description

`cnew = repartition(c)` constructs an object `cnew` of the `cvpartition` on page 32-983 class defining a random partition of the same type as `c`, where `c` is also an object of the `cvpartition` on page 32-983 class.

Repartitioning is useful for Monte-Carlo repetitions of cross-validation analyses. `repartition` is called by `crossval` when the `'mcreps'` parameter is specified.

Examples

Partition and repartition 100 observations for 3-fold cross-validation:

```
c = cvpartition(100,'kfold',3)
c =
K-fold cross validation partition
      N: 100
  NumTestSets: 3
  TrainSize: 67 66 67
  TestSize: 33 34 33
```

```
cnew = repartition(c)
cnew =
K-fold cross validation partition
      N: 100
  NumTestSets: 3
  TrainSize: 67 66 67
  TestSize: 33 34 33
```

Check for equality of the test data in the first fold:

```
isequal(test(c,1),test(cnew,1))
ans =
     0
```

See Also

`cvpartition`

RepeatedMeasuresModel class

Repeated measures model class

Description

A `RepeatedMeasuresModel` object represents a model fitted to data with multiple measurements per subject. The object comprises data, fitted coefficients, covariance parameters, design matrix, error degrees of freedom, and between- and within-subjects factor names for a repeated measures model. You can predict model responses using the `predict` method and generate random data at new design points using the `random` method.

Construction

You can fit a repeated measures model using `fitrm(t,modelspec)`.

Input Arguments

t — Input data

table

Input data, which includes the values of the response variables and the between-subject factors to use as predictors in the repeated measures model, specified as a table.

Data Types: table

modelspec — Formula for model specification

character vector or string scalar of the form 'y1-yk ~ terms'

Formula for model specification, specified as a character vector or string scalar of the form 'y1-yk ~ terms'. Specify the terms using Wilkinson notation. `fitrm` treats the variables used in model terms as categorical if they are categorical (nominal or ordinal), logical, character arrays, string arrays, or a cell array of character vectors.

Example: 'y1-y4 ~ x1 + x2 * x3'

Data Types: char | string

Properties

BetweenDesign — Design for between-subject factors

table

Design for between-subject factors and values of repeated measures, stored as a table.

Data Types: table

BetweenModel — Model for between-subjects factors

character vector

Model for between-subjects factors, stored as a character vector. This character vector is the text representation to the right of the tilde in the model specification you provide when fitting the repeated measures model using `fitrm`.

Data Types: `char`

BetweenFactorNames — Names of variables used as between-subject factors

cell array of character vectors

Names of variables used as between-subject factors in the repeated measures model, `rm`, stored as a cell array of character vectors.

Data Types: `cell`

ResponseNames — Names of variables used as response variables

cell array of character vectors

Names of variables used as response variables in the repeated measures model, `rm`, stored as a cell array of character vectors.

Data Types: `cell`

WithinDesign — Values of within-subject factors

table

Values of the within-subject factors, stored as a table.

Data Types: `table`

WithinModel — Model for within-subjects factors

character vector

Model for within-subjects factors, stored as a character vector.

You can specify `WithinModel` as a character vector or a string scalar using dot notation:

```
Mdl.WithinModel = newWithinModelValue.
```

WithinFactorNames — Names of within-subject factors

cell array of character vectors

Names of the within-subject factors, stored as a cell array of character vectors.

Data Types: `cell`

Coefficients — Values of estimated coefficients

table

Values of the estimated coefficients for fitting the repeated measures as a function of the terms in the between-subjects model, stored as a table.

`fitrm` defines the coefficients for a categorical term using 'effects' coding, which means coefficients sum to 0. There is one coefficient for each level except the first. The implied coefficient for the first level is the sum of the other coefficients for the term.

You can display the coefficient values as a matrix rather than a table using `coef = r.Coefficients{:, :}`.

You can display marginal means for all levels using the `margmean` method.

Data Types: `table`

Covariance — Estimated response covariances

`table`

Estimated response covariances, that is, covariance of the repeated measures, stored as a table. `fitrm` computes the covariances around the mean returned by the fitted repeated measures model `rm`.

You can display the covariance values as a matrix rather than a table using `coef = r.Covariance{:, :}`.

Data Types: `table`

DFE — Error degrees of freedom

scalar value

Error degrees of freedom, stored as a scalar value. DFE is the number of observations minus the number of estimated coefficients in the between-subjects model.

Data Types: `double`

Methods

<code>anova</code>	Analysis of variance for between-subject effects
<code>epsilon</code>	Epsilon adjustment for repeated measures anova
<code>grpstats</code>	Compute descriptive statistics of repeated measures data by group
<code>manova</code>	Multivariate analysis of variance
<code>margmean</code>	Estimate marginal means

<code>predict</code>	Compute predicted values given predictor values
<code>random</code>	Generate new random response values given predictor values
<code>ranova</code>	Repeated measures analysis of variance

Examples

Fit a Repeated Measures Model

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species: `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{ 'species', 'meas1', 'meas2', 'meas3', 'meas4' });
Meas = table([1 2 3 4], 'VariableNames', {'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t, 'meas1-meas4~species', 'WithinDesign', Meas)
```

```
rm =
  RepeatedMeasuresModel with properties:

  Between Subjects:
    BetweenDesign: [150x5 table]
    ResponseNames: {'meas1' 'meas2' 'meas3' 'meas4'}
    BetweenFactorNames: {'species'}
    BetweenModel: '1 + species'

  Within Subjects:
    WithinDesign: [4x1 table]
    WithinFactorNames: {'Measurements'}
    WithinModel: 'separatemeans'

  Estimates:
    Coefficients: [3x4 table]
    Covariance: [4x4 table]
```

Display the coefficients.

```
rm.Coefficients
```

```
ans=3x4 table
```

	meas1	meas2	meas3	meas4
(Intercept)	5.8433	3.0573	3.758	1.1993
species_setosa	-0.83733	0.37067	-2.296	-0.95333
species_versicolor	0.092667	-0.28733	0.502	0.12667

`fitrm` uses the 'effects' contrasts, which means that the coefficients sum to 0. The `rm.DesignMatrix` has one column of 1s for the intercept, and two other columns `species_setosa` and `species_versicolor`, which are as follows:

$$\text{species_setosa} = \begin{cases} 1, & \text{if setosa} \\ 0, & \text{if versicolor} \\ -1, & \text{if virginica} \end{cases}$$

and

$$\text{species_versicolor} = \begin{cases} 0, & \text{if setosa} \\ 1, & \text{if versicolor} \\ -1, & \text{if virginica} \end{cases} .$$

Display the covariance matrix.

```
rm.Covariance
```

```
ans=4x4 table
```

	meas1	meas2	meas3	meas4
meas1	0.26501	0.092721	0.16751	0.038401
meas2	0.092721	0.11539	0.055244	0.03271
meas3	0.16751	0.055244	0.18519	0.042665
meas4	0.038401	0.03271	0.042665	0.041882

Display the error degrees of freedom.

```
rm.DFE
```

```
ans = 147
```

The error degrees of freedom is the number of observations minus the number of estimated coefficients in the between-subjects model, e.g. $150 - 3 = 147$.

More About

Wilkinson Notation

Wilkinson notation describes the factors present in models. It does not describe the multipliers (coefficients) of those factors.

Use these rules to specify the responses in `model spec`.

Wilkinson Notation	Description
Y1, Y2, Y3	Specific list of variables
Y1-Y5	All table variables from Y1 through Y5

Use these rules to specify terms in `model spec`.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
X^k , where k is a positive integer	X, X^2, \dots, X^k
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1 * X2$
$X1 : X2$	$X1 * X2$ only
$-X2$	Do not include $X2$
$X1 * X2 + X3$	$X1, X2, X3, X1 * X2$
$X1 + X2 + X3 + X1 : X2$	$X1, X2, X3, X1 * X2$
$X1 * X2 * X3 - X1 : X2 : X3$	$X1, X2, X3, X1 * X2, X1 * X3, X2 * X3$
$X1 * (X2 + X3)$	$X1, X2, X3, X1 * X2, X1 * X3$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

Class Attributes (MATLAB)

Property Attributes (MATLAB)

replacedata

Class: dataset

(Not Recommended) Replace dataset variables

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
B = replacedata(A,X)
B = replacedata(A,X,vars)
B = replacedata(A,fun)
B = replacedata(A,fun,vars)
```

Description

`B = replacedata(A,X)` creates a dataset array `B` with the same variables as the dataset array `A`, but with the data for those variables replaced by the data in the array `X`. `replacedata` creates each variable in `B` using one or more columns from `X`, in order. `X` must have as many columns as the total number of columns in all of the variables in `A`, and as many rows as `A` has observations.

`B = replacedata(A,X,vars)` creates a dataset array `B` with the same variables as the dataset array `A`, but with the data for the variables specified in `vars` replaced by the data in the array `X`. The remaining variables in `B` are copies of the corresponding variables in `A`. `vars` is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector. Each variable in `B` has as many columns as the corresponding variable in `A`. `X` must have as many columns as the total number of columns in all the variables specified in `vars`.

`B = replacedata(A,fun)` or `B = replacedata(A,fun,vars)` creates a dataset array `B` by applying the function `fun` to the values in `A`'s variables. `replacedata` first horizontally concatenates `A`'s variables into a single array, then applies the function `fun`. The specified variables in `A` must have types and sizes compatible with the concatenation. `fun` is a function handle that accepts a single input array and returns an array with the same number of rows and columns as the input.

Examples

```
data = dataset({rand(3,3),'Var1','Var2','Var3'})

% Use ZSCORE to normalize each variable in a dataset array
% separately, by explicitly extracting and transforming the
% data, and then replacing it.
X = double(data);
X = zscore(X);
data = replacedata(data,X)

% Equivalently, provide a handle to ZSCORE.
data = replacedata(data,@zscore)
```

```
% Use ZSCORE to normalize each observation in a dataset  
% array separately by creating an anonymous function.  
data = replacedata(data,@(x) zscore(x,[],2))
```

See Also

dataset

replaceWithMissing

Class: dataset

(Not Recommended) Insert missing data indicators into a dataset array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
ds2 = replaceWithMissing(ds,Name,Value)
```

Description

`ds2 = replaceWithMissing(ds,Name,Value)` replaces specified values in a dataset array with standard missing data indicators using options specified by one or more `Name, Value` pair arguments. Use `replaceWithMissing` to specify:

- Which numeric missing value indicators to replace with `NaN`.
- Which character missing value indicators to replace with `' '`.
- Which categorical levels to replace with `<undefined>`.

Input Arguments

ds

dataset array.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

NumericValues

Vector of numeric values that `replaceWithMissing` replaces with `NaN`.

CategoricalLevels

Character vector or cell array of character vectors naming the categorical levels that `replaceWithMissing` replaces with `<undefined>`.

Strings

Character vector or cell array of character vectors containing the text that `replaceWithMissing` replaces with `' '`.

DataVars

Specified set of variables in `ds` for which `replaceWithMissing` replaces values. You can specify a positive integer or vector of positive integers indicating the variable column numbers, a variable name or a cell array of variables names, or a logical vector indicating which variables to replace missing values in.

Default: All variables in `ds`.

Output Arguments

`ds2`

dataset array that has the specified missing value indicators, in the specified variables of `ds`, replaced with standard missing value indicators.

Examples

Replace Nonstandard Missing Value Indicators

Replace nonstandard missing value indicators with standard missing value indicators.

Replace numeric missing values coded 99 with NaN, and character missing values coded '.' with ''.

```
ds = replaceWithMissing(ds, 'NumericValues', 99, 'Strings', '.');
```

Topics

“Clean Messy and Missing Data” on page 2-97

“Dataset Arrays” on page 2-112

reset

Class: grandstream

Reset state

Syntax

```
reset(q)
```

Description

`reset(q)` resets the state of the quasi-random number stream `q` of the `grandstream` on page 32-4386 class back to its initial state, 1. Subsequent points drawn from the stream will be the same as those drawn from a new stream. The command is equivalent to `q.State = 1`.

Examples

Use `grandstream` to construct a 3-D Halton stream, based on a point set that skips the first 1000 values and then retains every 101st point:

```
q = grandstream('halton',3,'Skip',1e3,'Leap',1e2)
```

```
q =  
  Halton quasi-random stream in 3 dimensions  
  Point set properties:  
    Skip : 1000  
    Leap : 100  
  ScrambleMethod : none
```

```
nextIdx = q.State
```

```
nextIdx =  
  1
```

Use `qrand` to generate two samples of size four:

```
X1 = qrand(q,4)
```

```
X1 =  
  0.0928    0.3475    0.0051  
  0.6958    0.2035    0.2371  
  0.3013    0.8496    0.4307  
  0.9087    0.5629    0.6166
```

```
nextIdx = q.State
```

```
nextIdx =  
  5
```

```
X2 = qrand(q,4)
```

```
X2 =  
  0.2446    0.0238    0.8102  
  0.5298    0.7540    0.0438  
  0.3843    0.5112    0.2758  
  0.8335    0.2245    0.4694
```

```
nextIdx = q.State
```

```
nextIdx =  
  9
```

Use `reset` to reset the stream, then generate another sample:

```
reset(q)
nextIdx = q.State
nextIdx =
    1

X = qrand(q,4)
X =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166
```

See Also

[qrand](#) | [qrandstream](#)

residuals

Class: GeneralizedLinearMixedModel

Residuals of fitted generalized linear mixed-effects model

Syntax

```
r = residuals(glme)
r = residuals(glme, Name, Value)
```

Description

`r = residuals(glme)` returns the raw conditional residuals from a fitted generalized linear mixed-effects model `glme`.

`r = residuals(glme, Name, Value)` returns the residuals using additional options specified by one or more `Name, Value` pair arguments. For example, you can specify to return Pearson residuals for the model.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Conditional — Indicator for conditional residuals

true (default) | false

Indicator for conditional residuals, specified as the comma-separated pair consisting of 'Conditional' and one of the following.

Value	Description
true	Contributions from both fixed effects and random effects (conditional)
false	Contribution from only fixed effects (marginal)

Conditional residuals include contributions from both fixed- and random-effects predictors. Marginal residuals include contribution from only fixed effects. To obtain marginal residual values, `residuals` computes the conditional mean of the response with the empirical Bayes predictor vector of random effects, `b`, set to 0.

Example: 'Conditional', false

ResidualType — Residual type

'raw' (default) | 'Pearson'

Residual type, specified as the comma-separated pair consisting of 'ResidualType' and one of the following.

Residual Type	Conditional	Marginal
'raw'	$r_{ci} = y_i - g^{-1}(x_i^T \hat{\beta} + z_i^T \hat{b} + \delta_i)$	$r_{mi} = y_i - g^{-1}(x_i^T \hat{\beta} + \delta_i)$
'Pearson'	$r_{ci}^{pearson} = \frac{r_{ci}}{\sqrt{\frac{\sigma^2}{w_i} v_i(\mu_i(\hat{\beta}, \hat{b}))}}$	$r_{mi}^{pearson} = \frac{r_{mi}}{\sqrt{\frac{\sigma^2}{w_i} v_i(\mu_i(\hat{\beta}, 0))}}$

In each of these equations:

- y_i is the i th element of the n -by-1 response vector, y , where $i = 1, \dots, n$.
- g^{-1} is the inverse link function for the model.
- x_i^T is the i th row of the fixed-effects design matrix X .
- z_i^T is the i th row of the random-effects design matrix Z .
- δ_i is the i th offset value.
- σ^2 is the dispersion parameter.
- w_i is the i th observation weight.
- v_i is the variance term for the i th observation.
- μ_i is the mean of the response for the i th observation.
- $\hat{\beta}$ and \hat{b} are estimated values of β and b .

Raw residuals from a generalized linear mixed-effects model have nonconstant variance. Pearson residuals are expected to have an approximately constant variance, and are generally used for analysis.

Example: 'ResidualType', 'Pearson'

Output Arguments

r — Residuals

n -by-1 vector

Residuals of the fitted generalized linear mixed-effects model `glme` returned as an n -by-1 vector, where n is the number of observations.

Examples

Plot Residuals Versus Fitted Values

Load the sample data.

load `mfr`

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglm(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', ...  
             'Distribution', 'Poisson', 'Link', 'log', 'FitMethod', 'Laplace', 'DummyVarCoding', 'effects');
```

Generate the conditional Pearson residuals and the conditional fitted values from the model.

```
r = residuals(glme, 'ResidualType', 'Pearson');  
mufit = fitted(glme);
```

Display the first ten rows of the Pearson residuals.

```
r(1:10)  
ans = 10×1  
  
    0.4530  
    0.4339  
    0.3833  
   -0.2653  
    0.2811  
   -0.0935  
   -0.2984  
   -0.2509  
    1.5547  
   -0.3027
```

Plot the Pearson residuals versus the fitted values, to check for signs of nonconstant variance among the residuals (heteroscedasticity).

```
figure  
scatter(mufit, r)  
title('Residuals versus Fitted Values')  
xlabel('Fitted Values')  
ylabel('Residuals')
```

The plot does not show a systematic dependence on the fitted values, so there are no signs of nonconstant variance among the residuals.

`GeneralizedLinearMixedModel | designMatrix | fitted | response`

residuals

Class: LinearMixedModel

Residuals of fitted linear mixed-effects model

Syntax

```
R = residuals(lme)
R = residuals(lme, Name, Value)
```

Description

`R = residuals(lme)` returns the raw conditional residuals from a fitted linear mixed-effects model `lme`.

`R = residuals(lme, Name, Value)` returns the residuals from the linear mixed-effects model `lme` with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify Pearson or standardized residuals, or residuals with contributions from only fixed effects.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a LinearMixedModel object constructed using `fitlme` or `fitlmematrix`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Conditional — Indicator for conditional residuals

True (default) | False

Indicator for conditional residuals, specified as the comma-separated pair consisting of 'Conditional' and one of the following.

True	Contribution from both fixed effects and random effects (conditional)
False	Contribution from only fixed effects (marginal)

Example: 'Conditional, 'False'

ResidualType — Residual type

'Raw' (default) | 'Pearson' | 'Standardized'

Residual type, specified by the comma-separated pair consisting of `ResidualType` and one of the following.

Residual Type	Conditional	Marginal
'Raw'	$r_i^C = [y - X\hat{\beta} - Z\hat{b}]_i$	$r_i^M = [y - X\hat{\beta}]_i$
'Pearson'	$pr_i^C = \frac{r_i^C}{\sqrt{[\widehat{\text{Var}}_{y,b}(y - X\hat{\beta} - Z\hat{b})]_{ii}}}$	$pr_i^M = \frac{r_i^M}{\sqrt{[\widehat{\text{Var}}_y(y - X\hat{\beta})]_{ii}}}$
'Standardized'	$st_i^C = \frac{r_i^C}{\sqrt{[\widehat{\text{Var}}_y(r^C)]_{ii}}}$	$st_i^M = \frac{r_i^M}{\sqrt{[\widehat{\text{Var}}_y(r^M)]_{ii}}}$

For more information on the conditional and marginal residuals and residual variances, see [Definitions](#) at the end of this page.

Example: `'ResidualType', 'Standardized'`

Output Arguments

R — Residuals

n-by-1 vector

Residuals of the fitted linear mixed-effects model `lme` returned as an *n*-by-1 vector, where *n* is the number of observations.

Examples

Plot Residuals vs. Fitted Values

Load the sample data.

```
load('weight.mat');
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight, Program, Subject, Week, y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl, 'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Compute the fitted values and raw residuals.

```
F = fitted(lme);  
R = residuals(lme);
```

Plot the residuals versus the fitted values.

```
plot(F,R,'bx')  
xlabel('Fitted Values')  
ylabel('Residuals')
```

Now, plot the residuals versus the fitted values, grouped by program.

```
figure();  
gscatter(F,R,Program)
```

The residuals seem to behave similarly across levels of the program as expected.

Compute Conditional and Marginal Pearson Residuals

Load the sample data.

```
load carbig
```

Store the variables for miles per gallon (MPG), acceleration, horsepower, cylinders, and model year in a table.

```
tbl = table(MPG,Acceleration,Horsepower,Cylinders,Model_Year);
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and the cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year.

```
lme = fitlme(tbl,'MPG ~ Acceleration + Horsepower + Cylinders + (Acceleration|Model_Year)');
```

Compute the conditional Pearson residuals and display the first five residuals.

```
PR = residuals(lme,'ResidualType','Pearson');
PR(1:5)
```

```
ans = 5×1
```

```
-0.0533  
0.0652  
0.3655  
-0.0106  
-0.3340
```

Compute the marginal Pearson residuals and display the first five residuals.

```
PRM = residuals(lme, 'ResidualType', 'Pearson', 'Conditional', false);  
PRM(1:5)
```

```
ans = 5×1
```

```
-0.1250  
0.0130  
0.3242  
-0.0861  
-0.3006
```

Examine Residuals

Load the sample data.

```
load carbig
```

Store the variables for miles per gallon (MPG), acceleration, horsepower, cylinders, and model year in a table.

```
tbl = table(MPG, Acceleration, Horsepower, Cylinders, Model_Year);
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and the cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year.

```
lme = fitlme(tbl, 'MPG ~ Acceleration + Horsepower + Cylinders + (Acceleration|Model_Year)');
```

Draw a histogram of the raw residuals with a normal fit.

```
r = residuals(lme);  
histfit(r)
```

Normal distribution seems to be a good fit for the residuals.

Compute the conditional Pearson and standardized residuals and create box plots of all three types of residuals.

```
pr = residuals(lme, 'ResidualType', 'Pearson');  
st = residuals(lme, 'ResidualType', 'Standardized');  
X = [r pr st];  
figure();  
boxplot(X)
```

Red plus signs show the observations with residuals above or below $q_3 + 1.5(q_3 - q_1)$ and $q_1 - 1.5(q_3 - q_1)$, where q_1 and q_3 are the 25th and 75th percentiles, respectively.

Find the observations with residuals that are 2.5 standard deviations above and below the mean.

```
find(r > nanmean(r) + 2.5*nanstd(r))
```

```
ans = 7×1
```

```
62
252
255
330
337
341
396
```

```
find(r < nanmean(r) - 2.5*nanstd(r))
```

```
ans = 3×1
```

```
119
324
375
```

More About

Conditional and Marginal Residuals

Conditional residuals include contributions from both fixed and random effects, whereas marginal residuals include contribution from only fixed effects.

Suppose the linear mixed-effects model `lme` has an n -by- p fixed-effects design matrix X and an n -by- q random-effects design matrix Z . Also, suppose the p -by-1 estimated fixed-effects vector is $\hat{\beta}$, and the q -by-1 estimated best linear unbiased predictor (BLUP) vector of random effects is \hat{b} . The fitted conditional response is

$$\hat{y}_{Cond} = X\hat{\beta} + Z\hat{b},$$

and the fitted marginal response is

$$\hat{y}_{Mar} = X\hat{\beta},$$

`residuals` can return three types of residuals: raw, Pearson, and standardized. For any type, you can compute the conditional or the marginal residuals. For example, the conditional raw residual is

$$r_{Cond} = y - X\hat{\beta} - Z\hat{b},$$

and the marginal raw residual is

$$r_{Mar} = y - X\hat{\beta}.$$

For more information on other types of residuals, see the `ResidualType` name-value pair argument.

`LinearMixedModel` | `fitted` | `plotResiduals` | `response`

response

Class: GeneralizedLinearMixedModel

Response vector of generalized linear mixed-effects model

Syntax

```
y = response(glme)
[y,binomialsize] = response(glme)
```

Description

`y = response(glme)` returns the response vector `y` used to fit the generalized linear mixed effects model `glme`.

`[y,binomialsize] = response(glme)` also returns the binomial size associated with each element of `y` if the conditional distribution of response given the random effects is binomial.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

Output Arguments

y — Response values

n-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

For an observation *i* with prior weights w_i^p and binomial size n_i (when applicable), the response values y_i can have the following values.

Distribution	Permitted Values	Notes
Binomial	$\left\{0, \frac{1}{w_i^p n_i}, \frac{2}{w_i^p n_i}, \dots, 1\right\}$	w_i^p and n_i are integer values > 0
Poisson	$\left\{0, \frac{1}{w_i^p}, \frac{2}{w_i^p}, \dots\right\}$	w_i^p is an integer value > 0
Gamma	$(0, \infty)$	$w_i^p \geq 0$
InverseGaussian	$(0, \infty)$	$w_i^p \geq 0$
normal	$(-\infty, \infty)$	$w_i^p \geq 0$

You can access the prior weights property w_i^p using dot notation. For example, to access the prior weights property for a model `glme`:

```
glme.ObservationInfo.Weights
```

binomialsize — Binomial size

vector

Binomial size associated with each element of y , returned as an n -by-1 vector, where n is the number of observations. `response` only returns `binomialsize` if the conditional distribution of response given the random effects is binomial. `binomialsize` is empty for other distributions.

Examples

Plot Response Versus Fitted Values

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is `log`. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglm(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', ...
             'Distribution', 'Poisson', 'Link', 'log', 'FitMethod', 'Laplace', 'DummyVarCoding', 'effects');
```

Extract the observed response values for the model, then use `fitted` to generate the fitted conditional mean values.

```
y = response(glme); % Observed response values
yfit = fitted(glme); % Fitted response values
```

Create a scatterplot of the observed response values versus fitted values. Add a reference line to improve the visualization.

```
figure
scatter(yfit, y)
xlim([0, 12])
ylim([0, 12])
refline(1, 0)
title('Response versus Fitted Values')
xlabel('Fitted Values')
ylabel('Response')
```

The plot shows a positive correlation between the fitted values and the observed response values.

See Also

`GeneralizedLinearMixedModel` | `fitted` | `residuals`

response

Class: LinearMixedModel

Response vector of the linear mixed-effects model

Syntax

```
y = response(lme)
```

Description

`y = response(lme)` returns the response vector `y` used to fit the linear mixed-effects model `lme`.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a LinearMixedModel object constructed using `fitlme` or `fitlmematrix`.

Output Arguments

y — Response values

n-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

Data Types: `single` | `double`

Examples

Plot Response versus Fitted Values

Load the sample data.

```
load('weight.mat');
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over two-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);  
tbl.Subject = nominal(tbl.Subject);  
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl, 'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Compute the fitted values and the response.

```
F = fitted(lme);  
y = response(lme);
```

Plot the response versus the fitted values.

```
plot(F,y,'bs')  
xlabel('Fitted Values')  
ylabel('Response')
```

See Also

[LinearMixedModel](#) | [fitted](#) | [residuals](#)

resubEdge

Class: ClassificationDiscriminant

Classification edge by resubstitution

Syntax

```
edge = resubEdge(obj)
```

Description

`edge = resubEdge(obj)` returns the classification edge obtained by `obj` on its training data.

Input Arguments

obj

Discriminant analysis classifier, produced using `fitcdiscr`.

Output Arguments

edge

Classification edge obtained by resubstituting the training data into the calculation of edge.

Examples

Estimate the Resubstitution Edge of Discriminant Analysis Classifiers

Estimate the quality of a discriminant analysis classifier for Fisher's iris data by resubstitution.

Load Fisher's iris data set.

```
load fisheriris
```

Train a discriminant analysis classifier.

```
Mdl = fitcdiscr(meas, species);
```

Compute the resubstitution edge.

```
redge = resubEdge(Mdl)
```

```
redge = 0.9454
```

More About

Edge

The edge is the weighted mean value of the classification margin. The weights are class prior probabilities. If you supply additional weights, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix X . A high value of margin indicates a more reliable prediction than a low value.

Score

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see "Posterior Probability" on page 20-6.

resubEdge

Resubstitution classification edge for multiclass error-correcting output codes (ECOC) model

Syntax

```
e = resubEdge(Mdl)
e = resubEdge(Mdl,Name,Value)
```

Description

`e = resubEdge(Mdl)` returns the resubstitution classification edge on page 32-4769 (**e**) for the multiclass error-correcting output codes (ECOC) model `Mdl` using the training data stored in `Mdl.X` and the corresponding class labels stored in `Mdl.Y`.

The classification edge is a scalar value that represents the weighted mean of the classification margins on page 32-4769.

`e = resubEdge(Mdl,Name,Value)` computes the resubstitution classification edge with additional options specified by one or more name-value pair arguments. For example, you can specify a decoding scheme, binary learner loss function, and verbosity level.

Examples

Resubstitution Edge of ECOC Model

Compute the resubstitution edge for an ECOC model with SVM binary learners.

Load Fisher's iris data set. Specify the predictor data `X` and the response data `Y`.

```
load fisheriris
X = meas;
Y = species;
```

Train an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
classOrder = unique(Y)
```

```
classOrder = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
```

```
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

`t` is an SVM template object. During training, the software uses default values for empty properties in `t`. `Mdl` is a `ClassificationECOC` model.

Compute the resubstitution edge, which is the mean of the training-sample margins.

```
e = resubEdge(Mdl)
e = 0.4961
```

Select ECOC Model Features by Comparing Training-Sample Edges

Perform feature selection by comparing training-sample edges from multiple models. Based solely on this comparison, the classifier with the greatest edge is the best classifier.

Load Fisher's iris data set. Define two data sets:

- `fullX` contains all four predictors.
- `partX` contains the sepal measurements only.

```
load fisheriris
X = meas;
fullX = X;
partX = X(:,1:2);
Y = species;
```

Train an ECOC model using SVM binary learners for each predictor set. Standardize the predictors using an SVM template, specify the class order, and compute the posterior probabilities.

```
t = templateSVM('Standardize',true);
classOrder = unique(Y)

classOrder = 3x1 cell
    {'setosa'   }
    {'versicolor'}
    {'virginica' }
```

```
FullMdl = fitcecoc(fullX,Y,'Learners',t,'ClassNames',classOrder,...
    'FitPosterior',true);
PartMdl = fitcecoc(partX,Y,'Learners',t,'ClassNames',classOrder,...
    'FitPosterior',true);
```

The default SVM score is the distance from the decision boundary. If you specify to compute posterior probabilities, then the software uses posterior probabilities as scores.

Compute the resubstitution edge for each classifier. The quadratic loss function operates on scores in the domain [0,1]. Specify to use quadratic loss when aggregating the binary learners for both models.

```
fullEdge = resubEdge(FullMdl,'BinaryLoss','quadratic')
fullEdge = 0.9896
partEdge = resubEdge(PartMdl,'BinaryLoss','quadratic')
partEdge = 0.5058
```

The edge for the classifier trained on the complete data set is greater, suggesting that the classifier trained with all the predictors has a better training-sample fit.

Input Arguments

Mdl — Full, trained multiclass ECOC model

ClassificationECOC model

Full, trained multiclass ECOC model, specified as a ClassificationECOC model trained with fitcecoc.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: resubEdge(Mdl, 'BinaryLoss', 'quadratic') specifies a quadratic binary learner loss function.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic'
| function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example customFunction, specify its function handle 'BinaryLoss', @customFunction.

customFunction has this form:

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in Mdl.CodingMatrix.
- s is the 1-by- L row vector of classification scores.

- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-4169.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	'hinge'
All binary learners are ensembles trained by <code>AdaboostM1</code> or <code>GentleBoost</code> .	'exponential'
All binary learners are ensembles trained by <code>LogitBoost</code> .	'binodeviance'
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting ' <code>FitPosterior</code> ', <code>true</code> in <code>fitcecoc</code> .	'quadratic'

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char | string | function_handle`

Decoding — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of '`Decoding`' and '`lossweighted`' or '`lossbased`'. For more information, see “Binary Loss” on page 32-4769.

Example: `'Decoding','lossbased'`

Options — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of '`Options`' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify '`Options`', `statset('UseParallel',true)`.

Verbose — Verbosity level

`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

More About

Classification Edge

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-189, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-189, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-189 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-189.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Tips

- To compare the margins or edges of several ECOC classifiers, use template objects to specify a common score transform function among the classifiers during training.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to `true`.

Set the 'UseParallel' field of the options structure to `true` using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the `'Options'` name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

resubEdge

Classification edge by resubstitution

Syntax

```
edge = resubEdge(ens)
edge = resubEdge(ens,Name,Value)
```

Description

`edge = resubEdge(ens)` returns the classification edge obtained by `ens` on its training data.

`edge = resubEdge(ens,Name,Value)` calculates edge with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

A classification ensemble created with `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `resubEdge` uses only these learners for calculating edge.

Default: `1:NumTrained`

mode

Character vector or string scalar representing the meaning of the output `edge`:

- `'ensemble'` — `edge` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `edge` is a vector with one element per trained learner.
- `'cumulative'` — `edge` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: `'ensemble'`

Output Arguments

edge

Classification edge obtained by `ens` by resubstituting the training data into the calculation of `edge`. Classification edge is classification margin averaged over the entire data. `edge` can be a scalar or vector, depending on the setting of the `mode` name-value pair.

Examples

Find Classification Edge by Resubstitution of Training Data

Find the resubstitution edge for an ensemble that classifies the Fisher iris data.

Load the sample data set.

```
load fisheriris
```

Train an ensemble of 100 boosted classification trees using `AdaBoostM2`.

```
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
ens = fitensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Find the resubstitution edge.

```
edge = resubEdge(ens)
```

```
edge = 3.2486
```

More About

Edge

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in `ens.Prior`.

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `ens.X`.

Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- `AdaBoostM1` scores range from $-\infty$ to ∞ .
- `Bag` scores range from 0 to 1.

See Also

resubEdge | resubLoss | resubMargin | resubPredict

resubEdge

Edge of k -nearest neighbor classifier by resubstitution

Syntax

```
E = resubEdge mdl
```

Description

`E = resubEdge(mdl)` returns the classification edge for `mdl` with the data used to train `mdl`.

The classification edge (`E`) is a scalar value that represents the mean of the classification margins on page 32-4776.

Examples

Resubstitution Edge Calculation

Create a k -nearest neighbor classifier for the Fisher iris data, where $k = 5$.

Load the Fisher iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Create a classifier for five nearest neighbors.

```
mdl = fitcknn(X,Y,'NumNeighbors',5);
```

Examine the resubstitution edge of the classifier.

```
E = resubEdge(mdl)
```

```
E = 0.9253
```

`E` is the mean of the training sample margins.

Input Arguments

mdl — k -nearest neighbor classifier model

ClassificationKNN object

k -nearest neighbor classifier model, specified as a ClassificationKNN object.

More About

Margin

The classification margin for each observation is the difference between the classification score for the true class and the maximal classification score for the false classes.

The classification margins form a column vector with the same number of rows as in the training data.

Score

The score of a classification is the posterior probability of the classification. The posterior probability is the number of neighbors with that classification divided by the number of neighbors. For a more detailed definition that includes weights and prior probabilities, see “Posterior Probability” on page 32-4144.

resubEdge

Class: ClassificationNaiveBayes

Classification edge for naive Bayes classifiers by resubstitution

Syntax

```
e = resubEdge(Mdl)
```

Description

`e = resubEdge(Mdl)` returns the resubstitution classification edge on page 32-4778 (`e`) for the naive Bayes classifier `Mdl` using the training data stored in `Mdl.X` and corresponding class labels stored in `Mdl.Y`.

Input Arguments

Mdl — Fully trained naive Bayes classifier

ClassificationNaiveBayes model

A fully trained naive Bayes classifier, specified as a ClassificationNaiveBayes model trained by `fitcnb`.

Output Arguments

e — Classification edge

scalar

Classification edge on page 32-4778, returned as a scalar. If you passed in weights when training the classifier, then `e` is the weighted classification edge. The software normalizes the weights so that they sum to the prior probability of their respective class.

Examples

Estimate the Resubstitution Edge of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'});
```

`Mdl` is a trained ClassificationNaiveBayes classifier.

Estimate the resubstitution edge.

```
e = resubEdge(Mdl)
e = 0.8944
```

The mean of the training sample margins is approximately 0.9, which indicates that the classifier classifies in-sample observations with high confidence.

Select Naive Bayes Classifier Features by Comparing In-Sample Edges

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare training sample edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load Fisher's iris data set. Define two data sets:

- `fullX` contains all predictors.
- `partX` contains the last two predictors.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
fullX = X;
partX = X(:,3:4);
```

Train naive Bayes classifiers for each predictor set.

```
FullMdl = fitcnb(fullX,Y);
PartMdl = fitcnb(partX,Y);
```

Estimate the training sample edge for each classifier.

```
fullEdge = resubEdge(FullMdl)
fullEdge = 0.8944
partEdge = resubEdge(PartMdl)
partEdge = 0.9169
```

The edge for the classifier trained on predictors 3 and 4 is greater, suggesting that the classifier trained using only those predictors has a better in-sample fit.

More About

Classification Edge

The classification edge is the weighted mean of the classification margins.

If you supply weights, then the software normalizes them to sum to the prior probability of their respective class. The software uses the normalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margins

The classification margins are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

Posterior Probability

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation (x_1, \dots, x_p) is

$$\widehat{P}(Y = k | x_1, \dots, x_p) = \frac{P(X_1, \dots, X_p | y = k)\pi(Y = k)}{P(X_1, \dots, X_p)},$$

where:

- $P(X_1, \dots, X_p | y = k)$ is the conditional joint density of the predictors given they are in class k . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- $P(X_1, \dots, X_p)$ is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_p) = \sum_{k=1}^K P(X_1, \dots, X_p | y = k)\pi(Y = k).$$

Prior Probability

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

Score

The naive Bayes score is the class posterior probability given the observation.

resubEdge

Find classification edge for support vector machine (SVM) classifier by resubstitution

Syntax

```
e = resubEdge(SVMModel)
```

Description

`e = resubEdge(SVMModel)` returns the resubstitution “Classification Edge” on page 32-4781 (`e`) for the support vector machine (SVM) classifier `SVMModel` using the training data stored in `SVMModel.X` and the corresponding class labels stored in `SVMModel.Y`.

The classification edge is a scalar value that represents the weighted mean of the classification margins on page 32-4781.

Examples

Estimate Resubstitution Edge of SVM Classifiers

Load the `ionosphere` data set.

```
load ionosphere
```

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class.

```
SVMModel = fitcsvm(X,Y,'Standardize',true,'ClassNames',{'b','g'});
```

`SVMModel` is a trained `ClassificationSVM` classifier.

Estimate the resubstitution edge. This is the mean of the training sample margins.

```
e = resubEdge(SVMModel)
```

```
e = 5.0998
```

Select SVM Classifier Features by Comparing In-Sample Edges

Perform feature selection by comparing training sample edges from multiple models. Based solely on this comparison, the classifier with the highest edge is the best classifier.

Load the `ionosphere` data set. Define two data sets:

- `fullX` contains all predictors (except the removed column of 0s).
- `partX` contains the last 20 predictors.

```
load ionosphere
fullX = X;
partX = X(:,end-20:end);
```

Train SVM classifiers for each predictor set.

```
FullSVMModel = fitcsvm(fullX,Y);
PartSVMModel = fitcsvm(partX,Y);
```

Estimate the training sample edge for each classifier.

```
fullEdge = resubEdge(FullSVMModel)
```

```
fullEdge = 3.3653
```

```
partEdge = resubEdge(PartSVMModel)
```

```
partEdge = 2.0471
```

The edge for the classifier trained on the complete data set is greater, suggesting that the classifier trained with all the predictors has a better in-sample fit.

Input Arguments

SVMModel — Full, trained SVM classifier

ClassificationSVM classifier

Full, trained SVM classifier, specified as a ClassificationSVM model trained with fitcsvm.

More About

Classification Edge

The edge is the weighted mean of the classification margins.

The weights are the prior class probabilities. If you supply weights, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to compute the weighted mean.

One way to choose among multiple classifiers, for example, to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation x . The classification margin is commonly defined as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

The SVM classification score for classifying observation x is the signed distance from x to the decision boundary ranging from $-\infty$ to $+\infty$. A positive score for a class indicates that x is predicted to be in that class. A negative score indicates otherwise.

The positive class classification score $f(x)$ is the trained SVM classification function. $f(x)$ is also the numerical, predicted response for x , or the score for predicting x into the positive class.

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, \dots, \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations. The negative class classification score for x , or the score for predicting x into the negative class, is $-f(x)$.

If $G(x_j, x) = x_j'x$ (the linear kernel), then the score function reduces to

$$f(x) = (x/s)' \beta + b.$$

s is the kernel scale and β is the vector of fitted linear coefficients.

For more details, see “Understanding Support Vector Machines” on page 18-145.

Algorithms

For binary classification, the software defines the margin for observation j , m_j , as

$$m_j = 2y_j f(x_j),$$

where $y_j \in \{-1, 1\}$, and $f(x_j)$ is the predicted score of observation j for the positive class. However, $m_j = y_j f(x_j)$ is commonly used to define the margin.

ClassificationSVM | CompactClassificationSVM | edge | fitcsvm | resubLoss | resubMargin

Introduced in R2014a

resubEdge

Class: ClassificationTree

Classification edge by resubstitution

Syntax

```
edge = resubEdge(tree)
```

Description

`edge = resubEdge(tree)` returns the classification edge obtained by `tree` on its training data.

Input Arguments

tree

A classification tree created using `fitctree`.

Output Arguments

edge

Classification edge obtained by resubstituting the training data into the calculation of edge.

Examples

Estimate the quality of a classification tree for the Fisher iris data by resubstitution.

```
load fisheriris
tree = fitctree(meas,species);
redge = resubEdge(tree)
```

```
redge =
    0.9384
```

More About

Edge

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in `tree.Prior`.

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `X`.

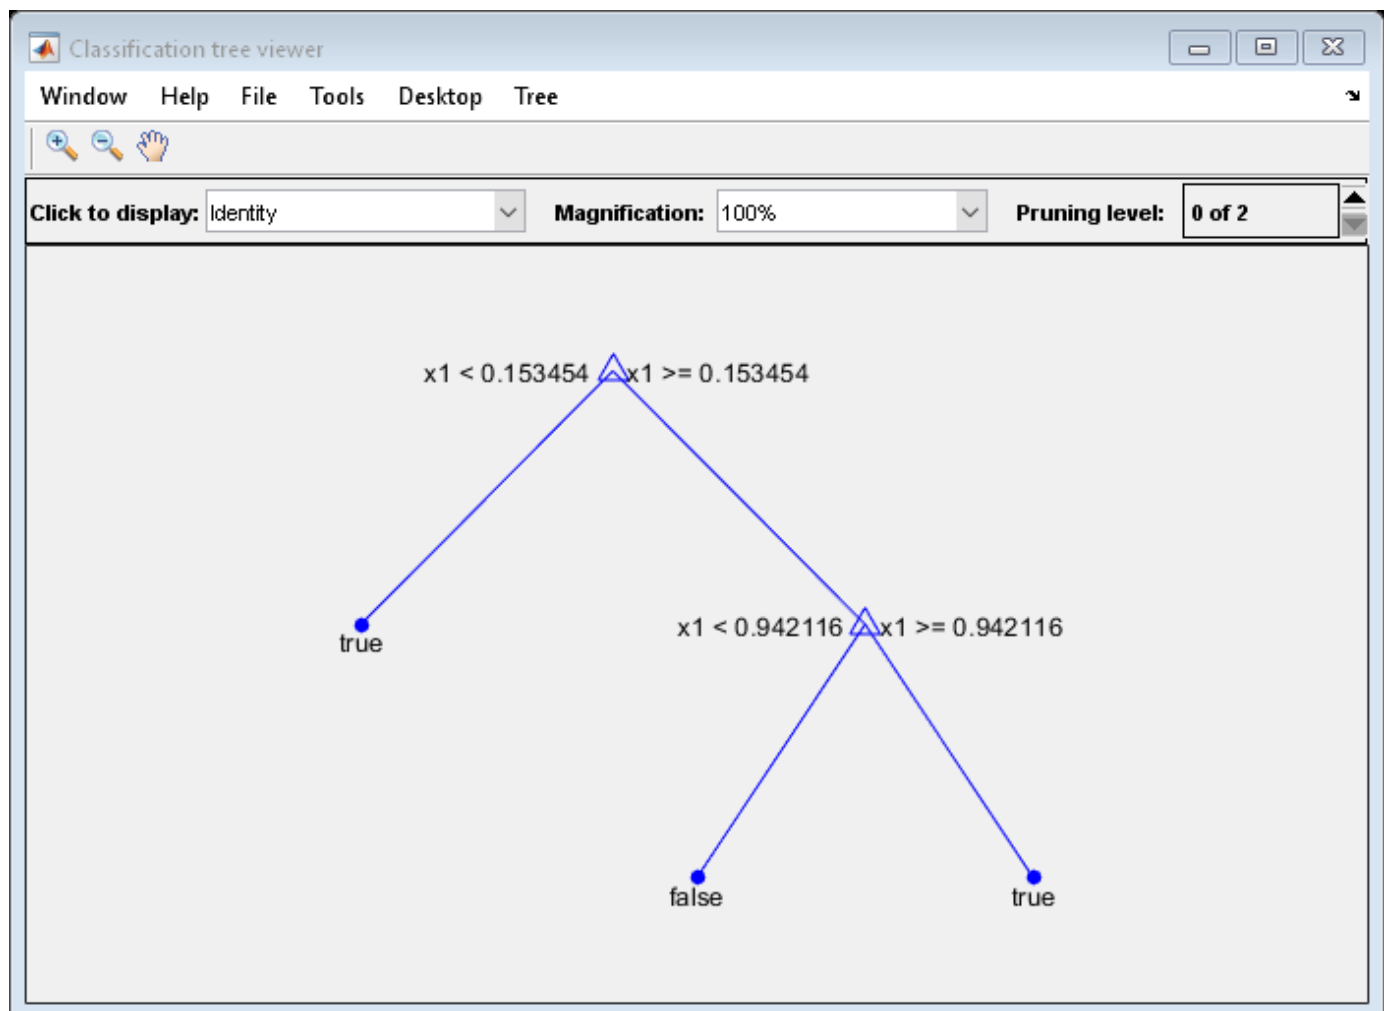

Score (tree)

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as `true` when $X < 0.15$ or $X > 0.95$, and X is false otherwise.

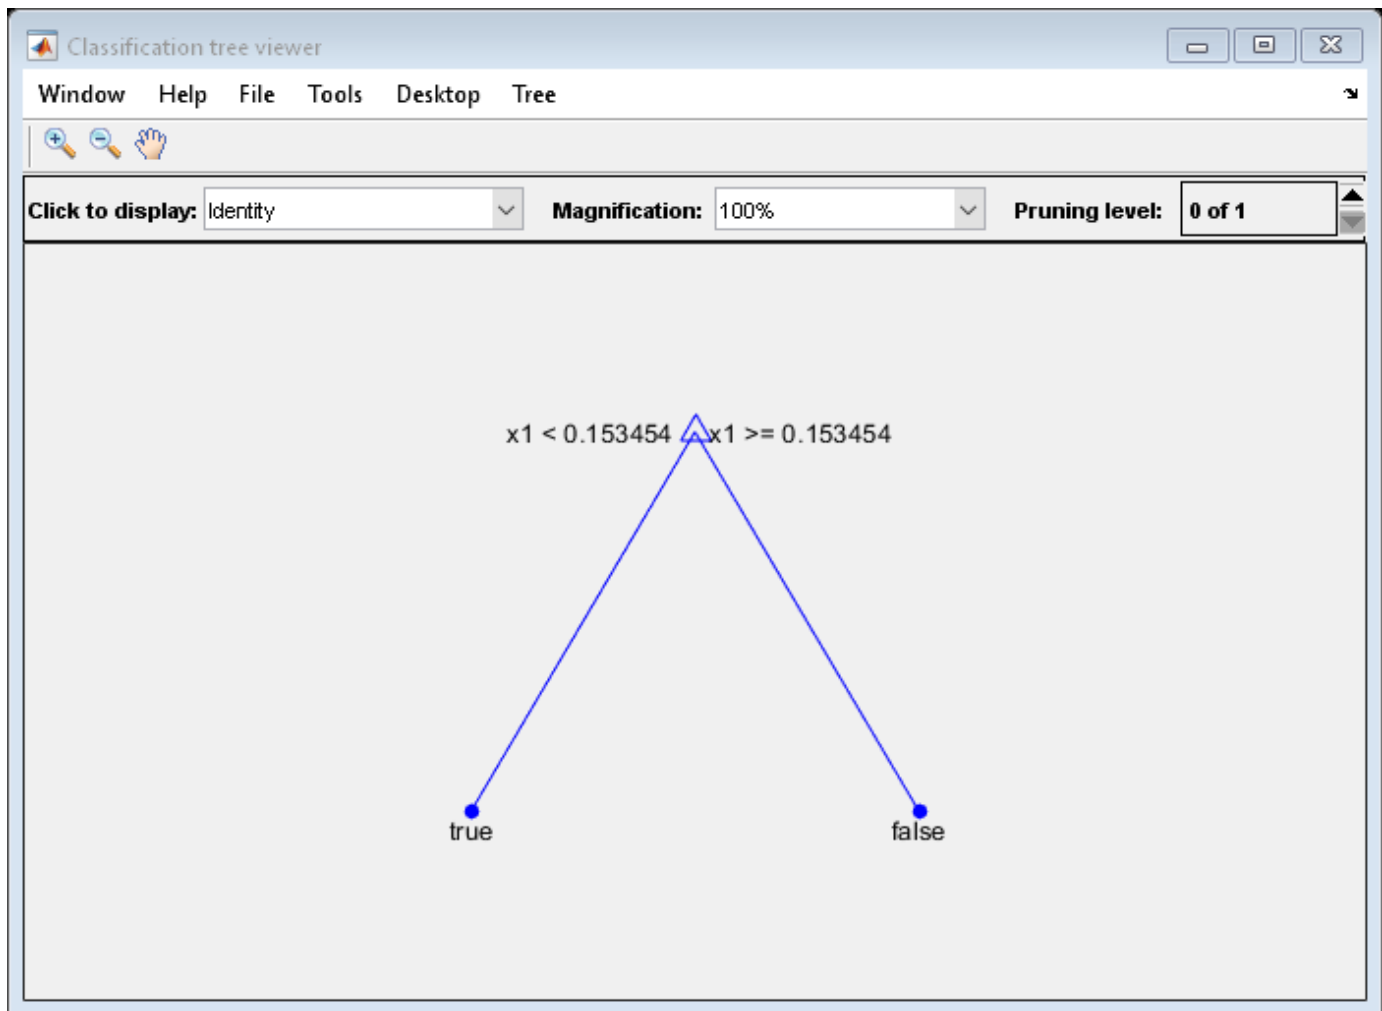

Generate 100 random points and classify them:

```
rng(0, 'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree, 'Mode', 'Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for `true`, and about $.8/.85=.94$ for `false`.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans = 10x3
```

```
    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0     1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0     1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
```

0.9059 0.0941 0.9649

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range $(.95, 1)$ instead of the expected 5 observations.

resubLoss

Class: ClassificationDiscriminant

Classification error by resubstitution

Syntax

```
L = resubLoss(obj)
L = resubLoss(obj,Name,Value)
```

Description

`L = resubLoss(obj)` returns the resubstitution loss, meaning the loss computed for the data that `fitcdiscr` used to create `obj`.

`L = resubLoss(obj,Name,Value)` returns loss statistics with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

obj

Discriminant analysis classifier, produced using `fitcdiscr`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

LossFun — Loss function

'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using the corresponding character vector or string scalar.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic

Value	Description
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. Discriminant analysis models return posterior probabilities as classification scores by default (see `predict`).

- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(obj.ClassNames)`). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `obj.ClassNames`.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `obj.ClassNames`. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

For more details on loss functions, see “Classification Loss” on page 32-4789.

Data Types: `char` | `string` | `function_handle`

Output Arguments

L

Classification error, a scalar. The meaning of the error depends on the values in `weights` and `lossfun`. See “Classification Loss” on page 32-4789.

Examples

Compute the resubstituted classification error for the Fisher iris data:

```
load fisheriris
obj = fitcdiscr(meas, species);
```

```
L = resubLoss(obj)
```

```
L =
    0.0200
```

More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$

Loss Function	Value of LossFun	Equation
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> Estimate the 1-by-K vector of expected classification costs for observation j: $\nu_j = f(X_j)C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j=1, \dots, K} (\nu_j).$ Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through [0,1].

Posterior Probability

The posterior probability that a point x belongs to class k is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with 1-by- d mean μ_k and d -by- d covariance Σ_k at a 1-by- d point x is

$$P(x|k) = \frac{1}{((2\pi)^d |\Sigma_k|)^{1/2}} \exp\left(-\frac{1}{2}(x - \mu_k)\Sigma_k^{-1}(x - \mu_k)^T\right),$$

where $|\Sigma_k|$ is the determinant of Σ_k , and Σ_k^{-1} is the inverse matrix.

Let $P(k)$ represent the prior probability of class k . Then the posterior probability that an observation x is of class k is

$$\hat{P}(k|x) = \frac{P(x|k)P(k)}{P(x)},$$

where $P(x)$ is a normalization constant, the sum over k of $P(x|k)P(k)$.

Prior Probability

The prior probability is one of three choices:

- 'uniform' — The prior probability of class k is one over the total number of classes.
- 'empirical' — The prior probability of class k is the number of training samples of class k divided by the total number of training samples.
- Custom — The prior probability of class k is the kth element of the prior vector. See `fitcdiscr`.

After creating a classification model (Mdl) you can set the prior using dot notation:

```
Mdl.Prior = v;
```

where `v` is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

Cost

The matrix of expected costs per observation is defined in “Cost” on page 20-7.

resubLoss

Resubstitution classification loss for multiclass error-correcting output codes (ECOC) model

Syntax

```
L = resubLoss(Mdl)
L = resubLoss(Mdl,Name,Value)
```

Description

`L = resubLoss(Mdl)` returns the classification loss by resubstitution (L) for the multiclass error-correcting output codes (ECOC) model `Mdl` using the training data stored in `Mdl.X` and the corresponding class labels stored in `Mdl.Y`. By default, `resubLoss` uses the classification error on page 32-4797 to compute L .

The classification loss (L) is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but in general, better classifiers yield smaller classification loss values.

`L = resubLoss(Mdl,Name,Value)` returns the classification loss with additional options specified by one or more name-value pair arguments. For example, you can specify the loss function, decoding scheme, and verbosity level.

Examples

Resubstitution Loss of ECOC Model

Compute the resubstitution loss for an ECOC model with SVM binary learners.

Load Fisher's iris data set. Specify the predictor data X and the response data Y .

```
load fisheriris
X = meas;
Y = species;
```

Train an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
classOrder = unique(Y)

classOrder = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
```

```
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

`t` is an SVM template object. During training, the software uses default values for empty properties in `t`. `Mdl` is a `ClassificationECOC` model.

Estimate the resubstitution classification error, which is the default classification loss.

```
L = resubLoss(Mdl)
```

```
L = 0.0267
```

The ECOC model misclassifies 2.67% of the training-sample irises.

Determine ECOC Model Quality Using Custom Resubstitution Loss

Determine the quality of an ECOC model by using a custom loss function that considers the minimal binary loss for each observation.

Load Fisher's iris data set. Specify the predictor data X , the response data Y , and the order of the classes in Y .

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y) % Class order
```

```
classOrder = 3x1 categorical
    setosa
    versicolor
    virginica
```

```
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

t is an SVM template object. During training, the software uses default values for empty properties in t . Mdl is a `ClassificationECOC` model.

Create a function that takes the minimal loss for each observation, then averages the minimal losses for all observations. S corresponds to the `NegLoss` output of `resubPredict`.

```
lossfun = @(~,S,~,~)mean(min(-S,[],2));
```

Compute the custom classification loss for the training data.

```
resubLoss(Mdl,'LossFun',lossfun)
```

```
ans = 0.0065
```

The average minimal binary loss for the training data is 0.0065.

Input Arguments

Mdl — Full, trained multiclass ECOC model

ClassificationECOC model

Full, trained multiclass ECOC model, specified as a ClassificationECOC model trained with fitcecoc.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: resubLoss(Mdl, 'BinaryLoss', 'hamming', 'LossFun', @lossfun) specifies 'hamming' as the binary learner loss function and the custom function handle @lossfun as the overall loss function.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example customFunction, specify its function handle 'BinaryLoss', @customFunction.

customFunction has this form:

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in Mdl.CodingMatrix.

- s is the 1-by- L row vector of classification scores.
- **bLoss** is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-4169.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	'hinge'
All binary learners are ensembles trained by <code>AdaboostM1</code> or <code>GentleBoost</code> .	'exponential'
All binary learners are ensembles trained by <code>LogitBoost</code> .	'binodeviance'
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting ' <code>FitPosterior</code> ', true in <code>fitcecoc</code> .	'quadratic'

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

Decoding — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of '`Decoding`' and '`lossweighted`' or '`lossbased`'. For more information, see “Binary Loss” on page 32-4798.

Example: `'Decoding','lossbased'`

LossFun — Loss function

`'classiferror'` (default) | `function_handle`

Loss function, specified as the comma-separated pair consisting of '`LossFun`' and '`classiferror`' or a function handle.

- Specify the built-in function '`classiferror`'. In this case, the loss function is the classification error on page 32-4797, which is the proportion of misclassified observations.
- Or, specify your own function using function handle notation.

Assume that $n = \text{size}(X,1)$ is the sample size and K is the number of classes. Your function must have the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

- The output argument `lossvalue` is a scalar.
- You specify the function name (*lossfun*).
- `C` is an n -by- K logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

Construct `C` by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- `S` is an n -by- K numeric matrix of negated loss values for the classes. Each row corresponds to an observation. The column order corresponds to the class order in `Mdl.ClassNames`. The input `S` resembles the output argument `NegLoss` of `resubPredict`.
- `W` is an n -by-1 numeric vector of observation weights. If you pass `W`, the software normalizes its elements to sum to 1.
- `Cost` is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

Data Types: `char` | `string` | `function_handle`

Options — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options', statset('UseParallel', true)`.

Verbose — Verbosity level

`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose', 1`

Data Types: `single` | `double`

More About

Classification Error

The classification error is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j e_j}{\sum_{j=1}^n w_j},$$

where:

- w_j is the weight for observation j . The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, the classification error is the proportion of observations misclassified by the classifier.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k, j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-189, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-189, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-189 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2 \log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$

Value	Description	Score Domain	$g(y_j, s_j)$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-189.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options', statset('UseParallel', true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see "Run MATLAB Functions with Automatic Parallel Support" (Parallel Computing Toolbox).

Introduced in R2014b

resubLoss

Classification error by resubstitution

Syntax

```
L = resubLoss(ens)
L = resubLoss(ens,Name,Value)
```

Description

`L = resubLoss(ens)` returns the resubstitution loss, meaning the loss computed for the data that `fitcensemble` used to create `ens`.

`L = resubLoss(ens,Name,Value)` calculates loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

A classification ensemble created with `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

learners

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `resubLoss` uses only these learners for calculating loss.

Default: `1:NumTrained`

lossfun

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential

Value	Description
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities.

- Bagged and subspace ensembles return posterior probabilities by default (`ens.Method` is 'Bag' or 'Subspace').
- If the ensemble method is 'AdaBoostM1', 'AdaBoostM2', GentleBoost, or 'LogitBoost', then, to use posterior probabilities as classification scores, you must specify the double-logit score transform by entering

```
ens.ScoreTransform = 'doublelogit';
```
- For all other ensemble methods, the software does not support posterior probabilities as classification scores.
- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(ens.ClassNames)`, `ens` is the input model). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `ens.ClassNames`.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `ens.ClassNames`. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using 'LossFun', `@lossfun`.

For more details on loss functions, see "Classification Loss" on page 32-4802.

Default: 'classiferror'

mode

Character vector or string scalar representing the meaning of the output `L`:

- `'ensemble'` — `L` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `L` is a vector with one element per trained learner.
- `'cumulative'` — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: `'ensemble'`

Output Arguments**L**

Classification loss on page 32-4802, by default the fraction of misclassified data. `L` can be a vector, and can mean different things, depending on the name-value pair settings.

Examples**Estimate Classification Error for Training Observations**

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification ensemble of 100 decision trees using `AdaBoostM2`. Specify tree stumps as the weak learners.

```
t = templateTree('MaxNumSplits',1);  
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Estimate the resubstitution classification error.

```
loss = resubLoss(ens)
```

```
loss = 0.0333
```

More About**Classification Loss**

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:

- y_j is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
- $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
- $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$

Loss Function	Value of LossFun	Equation
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> 1 Estimate the 1-by-K vector of expected classification costs for observation j: $\nu_j = f(X_j)'C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> 2 For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j=1, \dots, K} (\nu_j).$ 3 Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through [0,1].

resubLoss

Loss of k -nearest neighbor classifier by resubstitution

Syntax

```
L = resubLoss mdl
L = resubLoss mdl, 'LossFun', lossfun
```

Description

`L = resubLoss(mdl)` returns the classification loss on page 32-4807 by resubstitution, which is the loss computed for the data used by `fitcknn` to create `mdl`.

The classification loss (L) is a numeric scalar, whose interpretation depends on the loss function and the observation weights in `mdl`.

`L = resubLoss(mdl, 'LossFun', lossfun)` returns the resubstitution loss for the loss function `lossfun`, specified as a name-value pair argument.

Examples

Loss Calculation

Create a k -nearest neighbor classifier for the Fisher iris data, where $k = 5$.

Load the Fisher iris data set.

```
load fisheriris
```

Create a classifier for five nearest neighbors.

```
mdl = fitcknn(meas,species,'NumNeighbors',5);
```

Examine the resubstitution loss of the classifier.

```
L = resubLoss(mdl)
```

```
L = 0.0333
```

The classifier predicts incorrect classifications for 1/30 of its training data.

Input Arguments

mdl — k -nearest neighbor classifier model

ClassificationKNN object

k -nearest neighbor classifier model, specified as a ClassificationKNN object.

Lossfun — Loss function

'mincost' (default) | 'binodeviance' | 'classiferror' | 'exponential' | 'hinge' | 'logit' | 'quadratic' | function handle

Loss function, specified as a built-in loss function name or a function handle.

- The following table lists the available loss functions.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. By default, k -nearest neighbor models return posterior probabilities as classification scores (see `predict`).

- You can specify a function handle for a custom loss function using `@` (for example, `@lossfun`). Let n be the number of observations in X and K be the number of distinct classes (`numel mdl.ClassNames`). Your custom loss function must have this form:

```
function lossvalue = lossfun(C,S,W,Cost)
```

- C is an n -by- K logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `mdl.ClassNames`. Construct C by setting $C(p, q) = 1$, if observation p is in class q , for each row. Set all other elements of row p to 0 .
- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `mdl.ClassNames`. The argument S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes the weights to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, $Cost = ones(K) - eye(K)$ specifies a cost of 0 for correct classification and 1 for misclassification.
- The output argument `lossvalue` is a scalar.

For more details on loss functions, see "Classification Loss" on page 32-3149.

Data Types: `char` | `string` | `function_handle`

Algorithms**Classification Loss**

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1 , indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>

Loss Function	Value of LossFun	Equation
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> 1 Estimate the 1-by-K vector of expected classification costs for observation j: $v_j = f(X_j)C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> 2 For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j=1, \dots, K} (v_j).$ 3 Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through [0,1].

True Misclassification Cost

Two costs are associated with KNN classification: the true misclassification cost per class and the expected misclassification cost per observation.

You can set the true misclassification cost per class by using the 'Cost' name-value pair argument when you run `fitcknn`. The value $\text{Cost}(i, j)$ is the cost of classifying an observation into class j if its true class is i . By default, $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$. In other words, the cost is 0 for correct classification and 1 for incorrect classification.

Expected Cost

Two costs are associated with KNN classification: the true misclassification cost per class and the expected misclassification cost per observation. The third output of `resubPredict` is the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you classified with a trained classifier `mdl`, and you have `K` classes. The command

```
[label,score,cost] = resubPredict(mdl)
```

returns a matrix `cost` of size `Nobs`-by-`K`, among other outputs. Each row of the `cost` matrix contains the expected (average) cost of classifying the observation into each of the `K` classes. $\text{cost}(n, j)$ is

$$\sum_{i=1}^K \hat{P}(i|X(n))C(j|i),$$

where

- K is the number of classes.
- $\hat{P}(i|X(n))$ is the posterior probability on page 32-4900 of class i for observation $X(n)$.
- $C(j|i)$ is the true misclassification cost of classifying an observation as j when its true class is i .

Introduced in R2012a

resubLoss

Class: ClassificationNaiveBayes

Classification loss for naive Bayes classifiers by resubstitution

Syntax

```
L = resubLoss(Mdl)
L = resubLoss(Mdl, Name, Value)
```

Description

`L = resubLoss(Mdl)` returns the in-sample minimum misclassification cost loss (L), which is a scalar representing how well the trained naive Bayes classifier `Mdl` classifies the predictor data stored in `Mdl.X` as compared to the true class labels stored in `Mdl.Y`.

`L = resubLoss(Mdl, Name, Value)` returns the in-sample classification loss with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

Mdl — Fully trained naive Bayes classifier

ClassificationNaiveBayes model

A fully trained naive Bayes classifier, specified as a `ClassificationNaiveBayes` model trained by `fitcnb`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

LossFun — Loss function

'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge

Value	Description
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. Naive Bayes models return posterior probabilities as classification scores by default (see `predict`).

- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(Mdl.ClassNames)`, Mdl is the input model). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using 'LossFun', `@lossfun`.

For more details on loss functions, see "Classification Loss" on page 32-4814.

Data Types: `char` | `string` | `function_handle`

Output Arguments

L — Classification loss

scalar

Classification loss, returned as a scalar. L is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller loss values.

Examples

Determine the Resubstitution Loss of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'});
```

Mdl is a trained `ClassificationNaiveBayes` classifier.

Estimate the default resubstitution loss, which is the in-sample minimum misclassification cost.

```
L = resubLoss(Mdl)
```

```
L = 0.0400
```

The average, in-sample cost of classification is 0.04.

Determine Resubstitution Classification Error of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'});
```

Mdl is a trained `ClassificationNaiveBayes` classifier.

Estimate the in-sample proportion of misclassified observations.

```
L = resubLoss(Mdl,'LossFun','classiferror')
```

```
L = 0.0400
```

The naive Bayes classifier misclassifies 4% of the training observations.

More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>

Loss Function	Value of LossFun	Equation
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> Estimate the 1-by-K vector of expected classification costs for observation j: $v_j = f(X_j)C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j=1, \dots, K} (v_j).$ Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through [0,1].

Posterior Probability

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation (x_1, \dots, x_p) is

$$\hat{P}(Y = k | x_1, \dots, x_p) = \frac{P(X_1, \dots, X_p | y = k)\pi(Y = k)}{P(X_1, \dots, X_p)},$$

where:

- $P(X_1, \dots, X_p | y = k)$ is the conditional joint density of the predictors given they are in class k . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- $P(X_1, \dots, X_p)$ is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_p) = \sum_{k=1}^K P(X_1, \dots, X_p | y = k)\pi(Y = k).$$

Prior Probability

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

resubLoss

Find classification loss for support vector machine (SVM) classifier by resubstitution

Syntax

```
L = resubLoss(SVMModel)
L = resubLoss(SVMModel, 'LossFun', lossFun)
```

Description

`L = resubLoss(SVMModel)` returns the classification loss on page 32-4821 by resubstitution (`L`), the in-sample classification loss, for the support vector machine (SVM) classifier `SVMModel` using the training data stored in `SVMModel.X` and the corresponding class labels stored in `SVMModel.Y`.

The classification loss (`L`) is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller classification loss values.

`L = resubLoss(SVMModel, 'LossFun', lossFun)` returns the classification loss by resubstitution using the loss function supplied in `LossFun`.

Examples

Determine Resubstitution Loss of SVM Classifiers

Load the `ionosphere` data set.

```
load ionosphere
```

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class.

```
SVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

`SVMModel` is a trained `ClassificationSVM` classifier.

Estimate the resubstitution loss (that is, the in-sample classification error).

```
L = resubLoss(SVMModel)
```

```
L = 0.0570
```

The SVM classifier misclassifies 5.7% of the training sample radar returns.

Determine Resubstitution Hinge Loss of SVM Classifiers

Load the `ionosphere` data set.

```
load ionosphere
```

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class.

```
SVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

SVMModel is a trained ClassificationSVM classifier.

Estimate the in-sample hinge loss.

```
L = resubLoss(SVMModel,'LossFun','hinge')
```

```
L = 0.1603
```

The hinge loss is 0.1603. Classifiers with hinge losses close to 0 are preferred.

Input Arguments

SVMModel — Full, trained SVM classifier

ClassificationSVM classifier

Full, trained SVM classifier, specified as a ClassificationSVM model trained with fitcsvm.

LossFun — Loss function

'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as a built-in loss function name or a function handle.

- This table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. You can specify to use posterior probabilities as classification scores for SVM models by setting 'FitPosterior', true when you cross-validate the model using fitcsvm.

- Specify your own function by using function handle notation.

Suppose that n is the number of observations in X , and K is the number of distinct classes (`numel(SVMModel.ClassNames)`) used to create the input model (SVMModel). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (*lossfun*).
- `C` is an n -by- K logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `SVMMODEL.ClassNames`.

Construct `C` by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- `S` is an n -by- K numeric matrix of classification scores, similar to the output of `predict`. The column order corresponds to the class order in `SVMMODEL.ClassNames`.
- `W` is an n -by-1 numeric vector of observation weights. If you pass `W`, the software normalizes the weights to sum to 1.
- `Cost` is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

For more details on loss functions, see “Classification Loss” on page 32-4821.

Example: `'LossFun', 'binodeviance'`

Data Types: `char | string | function_handle`

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1 , indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.

- $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
- $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$

Loss Function	Value of LossFun	Equation
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> 1 Estimate the 1-by-K vector of expected classification costs for observation j: $v_j = f(X_j)'C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> 2 For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j=1, \dots, K} (v_j).$ 3 Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through [0,1].

Classification Score

The SVM classification score for classifying observation x is the signed distance from x to the decision boundary ranging from $-\infty$ to $+\infty$. A positive score for a class indicates that x is predicted to be in that class. A negative score indicates otherwise.

The positive class classification score $f(x)$ is the trained SVM classification function. $f(x)$ is also the numerical, predicted response for x , or the score for predicting x into the positive class.

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, \dots, \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations. The negative class classification score for x , or the score for predicting x into the negative class, is $-f(x)$.

If $G(x_j, x) = x_j'x$ (the linear kernel), then the score function reduces to

$$f(x) = (x/s)' \beta + b.$$

s is the kernel scale and β is the vector of fitted linear coefficients.

For more details, see “Understanding Support Vector Machines” on page 18-145.

`ClassificationSVM` | `fitcsvm` | `loss` | `resubPredict`

Introduced in R2014a

resubLoss

Class: ClassificationTree

Classification error by resubstitution

Syntax

```
L = resubLoss(tree)
L = resubLoss(tree,Name,Value)
L = resubLoss(tree,'Subtrees',subtreevector)
[L,se] = resubLoss(tree,'Subtrees',subtreevector)
[L,se,NLeaf] = resubLoss(tree,'Subtrees',subtreevector)
[L,se,NLeaf,bestlevel] = resubLoss(tree,'Subtrees',subtreevector)
[L,...] = resubLoss(tree,'Subtrees',subtreevector,Name,Value)
```

Description

`L = resubLoss(tree)` returns the resubstitution loss, meaning the loss computed for the data that `fitctree` used to create `tree`.

`L = resubLoss(tree,Name,Value)` returns the loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`L = resubLoss(tree,'Subtrees',subtreevector)` returns a vector of classification errors for the trees in the pruning sequence `subtreevector`.

`[L,se] = resubLoss(tree,'Subtrees',subtreevector)` returns the vector of standard errors of the classification errors.

`[L,se,NLeaf] = resubLoss(tree,'Subtrees',subtreevector)` returns the vector of numbers of leaf nodes in the trees of the pruning sequence.

`[L,se,NLeaf,bestlevel] = resubLoss(tree,'Subtrees',subtreevector)` returns the best pruning level as defined in the `TreeSize` name-value pair. By default, `bestlevel` is the pruning level that gives loss within one standard deviation of minimal loss.

`[L,...] = resubLoss(tree,'Subtrees',subtreevector,Name,Value)` returns loss statistics with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

tree

A classification tree constructed by `fitctree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

LossFun — Loss function

'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. Classification trees return posterior probabilities as classification scores by default (see `predict`).

- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(tree.ClassNames)`). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `tree.ClassNames`.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `tree.ClassNames`. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.

- `Cost` is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

For more details on loss functions, see “Classification Loss” on page 32-4832.

Data Types: `char | string | function_handle`

Name, Value arguments associated with pruning subtrees:

Subtrees — Pruning level

0 (default) | vector of nonnegative integers | `'all'`

Pruning level, specified as the comma-separated pair consisting of `'Subtrees'` and a vector of nonnegative integers in ascending order or `'all'`.

If you specify a vector, then all elements must be at least 0 and at most `max(tree.PruneList)`. 0 indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify `'all'`, then `resubLoss` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`resubLoss` prunes `tree` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `tree` must be nonempty. In other words, grow `tree` by setting `'Prune', 'on'`, or by pruning `tree` using `prune`.

Example: `'Subtrees', 'all'`

Data Types: `single | double | char | string`

TreeSize — Tree size

`'se'` (default) | `'min'`

Tree size, specified as the comma-separated pair consisting of `'TreeSize'` and one of the following values:

- `'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum ($L + se$, where L and se relate to the smallest value in `Subtrees`).
- `'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Output Arguments

L

Classification loss on page 32-4832, a vector the length of `Subtrees`. The meaning of the error depends on the values in `Weights` and `LossFun`.

se

Standard error of loss, a vector the length of `Subtrees`.

NLeaf

Number of leaves (terminal nodes) in the pruned subtrees, a vector the length of `Subtrees`.

bestLevel

A scalar whose value depends on `TreeSize`:

- `TreeSize = 'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum ($L+se$, where L and se relate to the smallest value in `Subtrees`).
- `TreeSize = 'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Examples**Compute the In-Sample Classification Error**

Compute the resubstitution classification error for the `ionosphere` data.

```
load ionosphere
tree = fitctree(X,Y);
L = resubLoss(tree)
```

```
L = 0.0114
```

Examine the Classification Error for Each Subtree

Unpruned decision trees tend to overfit. One way to balance model complexity and out-of-sample performance is to prune a tree (or restrict its growth) so that in-sample and out-of-sample performance are satisfactory.

Load Fisher's iris data set. Partition the data into training (50%) and validation (50%) sets.

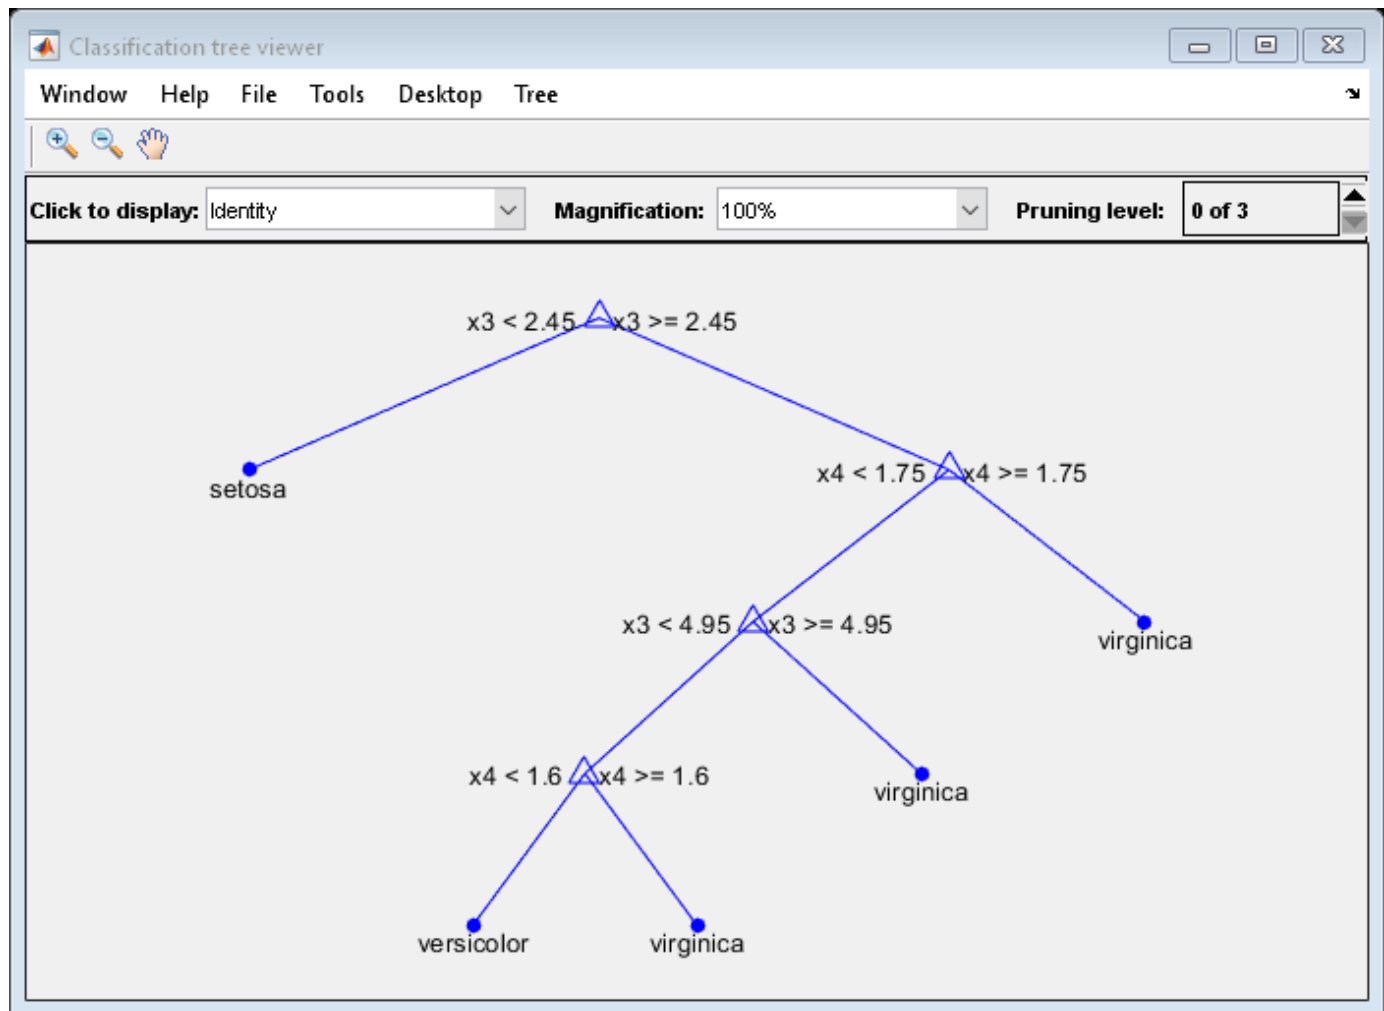

```
load fisheriris
n = size(meas,1);
rng(1) % For reproducibility
idxTrn = false(n,1);
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices
idxVal = idxTrn == false; % Validation set logical indices
```

Grow a classification tree using the training set.

```
Mdl = fitctree(meas(idxTrn,:),species(idxTrn));
```

View the classification tree.

```
view(Mdl,'Mode','graph');
```

The classification tree has four pruning levels. Level 0 is the full, unpruned tree (as displayed). Level 3 is just the root node (i.e., no splits).

Examine the training sample classification error for each subtree (or pruning level) excluding the highest level.

```
m = max(Mdl.PruneList) - 1;
trnLoss = resubLoss(Mdl, 'SubTrees', 0:m)
```

```
trnLoss = 3×1
```

```
0.0267
0.0533
0.3067
```

- The full, unpruned tree misclassifies about 2.7% of the training observations.
- The tree pruned to level 1 misclassifies about 5.3% of the training observations.
- The tree pruned to level 2 (i.e., a stump) misclassifies about 30.6% of the training observations.

Examine the validation sample classification error at each level excluding the highest level.

```

valLoss = loss(Mdl,meas(idxVal,:),species(idxVal),'SubTrees',0:m)
valLoss = 3×1
    0.0369
    0.0237
    0.3067

```

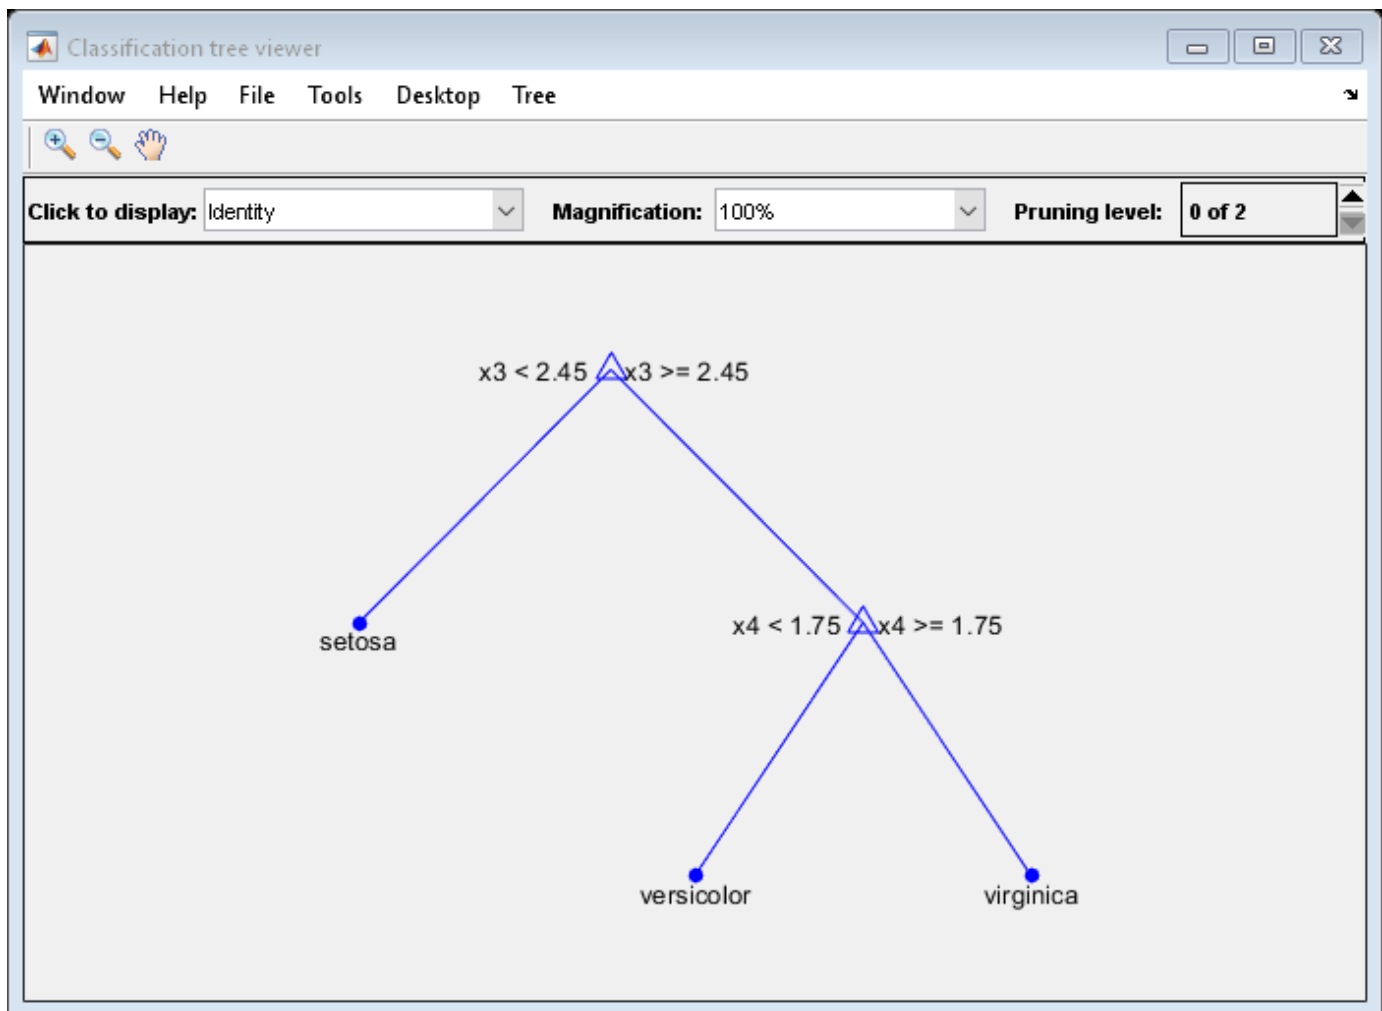

- The full, unpruned tree misclassifies about 3.7% of the validation observations.
- The tree pruned to level 1 misclassifies about 2.4% of the validation observations.
- The tree pruned to level 2 (i.e., a stump) misclassifies about 30.7% of the validation observations.

To balance model complexity and out-of-sample performance, consider pruning Mdl to level 1.

```

pruneMdl = prune(Mdl,'Level',1);
view(pruneMdl,'Mode','graph')

```

More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$

Loss Function	Value of LossFun	Equation
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> 1 Estimate the 1-by-K vector of expected classification costs for observation j: $\nu_j = f(X_j)C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> 2 For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j=1, \dots, K} (\nu_j).$ 3 Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through [0,1].

True Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you create the classifier using the `fitctree` method. `Cost(i, j)` is the cost of classifying an observation into class `j` if its true class is `i`. By default, `Cost(i, j)=1` if `i~j`, and `Cost(i, j)=0` if `i=j`. In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

Expected Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier. Suppose you have `K` classes. You place the observations into a matrix `Xnew` with one observation per row.

The expected cost matrix `CE` has size `Nobs-by-K`. Each row of `CE` contains the expected (average) cost of classifying the observation into each of the `K` classes. `CE(n, k)` is

$$\sum_{i=1}^K \widehat{P}(i|Xnew(n))C(k|i),$$

where

- K is the number of classes.
- $\hat{P}(i|X_{new}(n))$ is the posterior probability of class i for observation $X_{new}(n)$.
- $C(k|i)$ is the true misclassification cost of classifying an observation as k when its true class is i .

fitctree | loss | resubEdge | resubMargin | resubPredict

resubLoss

Regression error by resubstitution

Syntax

```
L = resubLoss(ens)
L = resubLoss(ens,Name,Value)
```

Description

`L = resubLoss(ens)` returns the resubstitution loss, meaning the mean squared error computed for the data that `fitrensemble` used to create `ens`.

`L = resubLoss(ens,Name,Value)` calculates loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

A regression ensemble created with `fitrensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `resubLoss` uses only these learners for calculating loss.

Default: `1:NumTrained`

lossfun

Function handle for loss function, or `'mse'`, meaning mean squared error. If you pass a function handle `fun`, `resubLoss` calls it as

```
FUN(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length. `Y` is the observed response, `Yfit` is the predicted response, and `W` is the observation weights.

Default: `'mse'`

mode

Character vector or string scalar representing the meaning of the output `L`:

- 'ensemble' — L is a scalar value, the loss for the entire ensemble.
- 'individual' — L is a vector with one element per trained learner.
- 'cumulative' — L is a vector in which element J is obtained by using learners 1:J from the input list of learners.

Default: 'ensemble'

Output Arguments

L

Loss, by default the mean squared error. L can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

Estimate Resubstitution Loss

Find the mean-squared difference between resubstitution predictions and training data.

Load the `carsmall` data set and select horsepower and vehicle weight as predictors.

```
load carsmall
X = [Horsepower Weight];
```

Train an ensemble of regression trees, and find the mean-squared difference of predictions from the training data.

```
ens = fitensemble(X,MPG);
MSE = resubLoss(ens)
```

```
MSE = 0.5836
```

`loss` | `resubLoss` | `resubPredict`

resubLoss

Class: RegressionGP

Resubstitution loss for a trained Gaussian process regression model

Syntax

```
L = resubLoss(gprMdl)
L = resubLoss(gprMdl, Name, Value)
```

Description

`L = resubLoss(gprMdl)` returns the resubstitution mean squared error for the Gaussian process regression (GPR) model, `gprMdl`.

`L = resubLoss(gprMdl, Name, Value)` returns the resubstitution loss for the GPR model, `gprMdl`, with additional options specified by one or more `Name, Value` pair arguments. For example, you can specify a custom loss function or the observation weights.

Input Arguments

gprMdl — Gaussian process regression model

RegressionGP object

Gaussian process regression model, specified as a RegressionGP object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

lossfun — Loss function

'mse' (default) | function handle

Loss function for the trained GPR model, specified as 'mse' or a function handle. 'mse' stands for the mean squared error.

If you pass a function handle, say `fun`, `resubLoss` calls it as `: fun(Y, Ypred, W)`, where `Y`, `Ypred`, and `W` are numeric vectors of length n , and n is the number of observations in the training data. `Y` is the observed response, `Ypred` is the predicted response, and `W` is the observation weights.

Example: `'lossfun', Fct` calls the loss function `Fct`.

Data Types: char | string | function_handle

weights — Observation weights

vector of 1s (default) | n -by-1 vector

Observation weights, specified as an n -by-1 vector, where n is the number of observations in the training data. By default, weight of each observation is 1.

Data Types: double | single

Output Arguments

L — Resubstitution error

scalar value

Resubstitution error for the GPR model, returned as a scalar value.

Examples

Compute the Resubstitution Loss

This example uses "Housing" data set [1] from the UCI machine learning archive [2] described in <http://archive.ics.uci.edu/ml/datasets/Housing>. Download the data and save it in your current directory as a data file named `housing.data`.

The dataset has 506 observations. The first 13 columns contain the predictor values and the last column contains the response values. The goal is to predict the median value of owner-occupied homes in the Boston suburb area as a function of 13 predictors.

Load the data and define the response vector and predictor matrix.

```
load('housing.data');
X = housing(:,1:13);
y = housing(:,end);
```

Fit a GPR model using subset of regressors ('sr') approximation method with Matern 3/2 ('Matern32') kernel function. Predict using the fully independent conditional ('fic') method.

```
gprMdl = fitrgp(X,y,'KernelFunction','Matern32',...
'FitMethod','sr','PredictMethod','fic');
```

Compute the resubstitution predictions.

```
ypred = resubPredict(gprMdl);
```

Plot the predicted response values along with the actual response values.

```
plot(y,'r'); % Plot original response values
hold on;
plot(ypred,'b--'); % Plot predicted response values
ylabel('y');
legend('Actual response','Predicted response','Location','SouthWest');
axis([0 510 -10 55]);
hold off
```

Compute the resubstitution loss.

```
L = resubLoss(gprMdl)
```

```
L =
```

```
4.8478
```

Manually compute the regression loss.

```
n = length(y);
```

```
L = (y-ypred)'*(y-ypred)/n
```

```
L =
```

```
4.8478
```

Compute Custom Resubstitution Loss

Load the sample data and store in a table.

```
load fisheriris
```

```
tbl = table(meas(:,1),meas(:,2),meas(:,3),meas(:,4),species,...  
'VariableNames',{'meas1','meas2','meas3','meas4','species'});
```

Fit a GPR model using the first measurement as the response and the other variables as the predictors.

```
mdl = fitrgp(tbl, 'meas1');
```

Predict the responses using the trained model.

```
ypred = predict(mdl, tbl);
```

Compute the mean absolute error.

```
n = height(tbl);  
y = tbl.meas1;  
fun = @(y, ypred, w) sum(abs(y-ypred))/n;  
L = resubLoss(mdl, 'lossfun', fun)
```

```
L = 0.2345
```

Alternatives

To compute the regression error for new data, use `loss`.

RegressionGP | fitrgp | loss | resubPredict

Introduced in R2015b

resubLoss

Class: RegressionSVM

Resubstitution loss for support vector machine regression model

Syntax

```
L = resubLoss mdl
L = resubLoss mdl, Name, Value
```

Description

`L = resubLoss(mdl)` returns the resubstitution loss for the support vector machine (SVM) regression model `mdl`, using the training data stored in `mdl.X` and corresponding response values stored in `mdl.Y`.

`L = resubLoss(mdl, Name, Value)` returns the resubstitution loss with additional options specified by one or more `Name, Value` pair arguments. For example, you can specify the loss function or observation weights.

Input Arguments

mdl — Full, trained SVM regression model

RegressionSVM model

Full, trained SVM regression model, specified as a RegressionSVM model returned by `fitrsvm`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

LossFun — Loss function

'mse' (default) | 'epsiloninsensitive' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and 'mse', 'epsiloninsensitive', or a function handle.

- The following table lists the available loss functions. Specify one using its corresponding value.

Value	Loss Function
'mse'	"Mean Squared Error" on page 32-4844
'epsiloninsensitive'	"Epsilon-Insensitive Loss Function" on page 32-4844

- Specify your own function using function handle notation.

Suppose that `n = size(X,1)` is the sample size. Your function must have the signature `lossvalue = lossfun(Y, Yfit, W)`, where:

- The output argument `lossvalue` is a numeric value.
- You choose the function name (*lossfun*).
- `Y` is an n -by-1 numeric vector of observed response values.
- `Yfit` is an n -by-1 numeric vector of predicted response values, calculated using the corresponding predictor values in `X` (similar to the output of `predict`).
- `W` is an n -by-1 numeric vector of observation weights.

Specify your function using `'LossFun',@lossfun`.

Example: `'LossFun','epsiloninsensitive'`

Data Types: `char` | `string` | `function_handle`

Weights — Observation weights

`ones(size(X,1),1)` (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector. `Weights` must be the same length as the number of rows in `X`. The software weighs the observations in each row of `X` using the corresponding weight value in `Weights`.

Data Types: `single` | `double`

Output Arguments

L — Resubstitution loss

scalar value

Resubstitution loss, returned as a scalar value.

The resubstitution loss is the loss calculated between the response training data and the model's predicted response values based on the input training data.

Resubstitution loss can be an overly optimistic estimate of the predictive error on new data. If the resubstitution loss is high, the model's predictions are not likely to be very good. However, having a low resubstitution loss does not guarantee good predictions for new data.

To better assess the predictive accuracy of your model, cross validate the model using `crossval`.

Examples

Resubstitution Loss for SVM Regression Model

This example shows how to train an SVM regression model, then calculate the resubstitution loss using mean square error (MSE) and epsilon-insensitive loss.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current directory with the name `'abalone.data'`.

Read the data into a table.

```
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);
rng default % for reproducibility
```

The sample data contains 4177 observations. All of the predictor variables are continuous except for sex, which is a categorical variable with possible values 'M' (for males), 'F' (for females), and 'I' (for infants). The goal is to predict the number of rings on the abalone, and thereby determine its age, using physical measurements.

Train an SVM regression model to the data, using a Gaussian kernel function with an automatic kernel scale. Standardize the data.

```
mdl = fitrsvm(tbl, 'Var9', 'KernelFunction', 'gaussian', 'KernelScale', 'auto', 'Standardize', true);
```

Calculate the resubstitution loss using mean square error (MSE).

```
mse_loss = resubLoss(mdl)
```

```
mse_loss =
```

```
4.0603
```

Calculate the epsilon-insensitive loss.

```
eps_loss = resubLoss(mdl, 'LossFun', 'epsiloninsensitive')
```

```
eps_loss =
```

```
1.1027
```

More About

Mean Squared Error

The weighted mean squared error is calculated as follows:

$$\text{mse} = \frac{\sum_{j=1}^n w_j (f(x_j) - y_j)^2}{\sum_{j=1}^n w_j},$$

where:

- n is the number of rows of data
- x_j is the j th row of data
- y_j is the true response to x_j
- $f(x_j)$ is the response prediction of the SVM regression model `mdl` to x_j
- w is the vector of weights.

The weights in w are all equal to one by default. You can specify different values for weights using the 'Weights' name-value pair argument. If you specify weights, each value is divided by the sum of all weights, such that the normalized weights add to one.

Epsilon-Insensitive Loss Function

The epsilon-insensitive loss function ignores errors that are within the distance epsilon (ϵ) of the function value. It is formally described as:

$$Loss_{\epsilon} = \begin{cases} 0, & \text{if } |y - f(x)| \leq \epsilon \\ |y - f(x)| - \epsilon, & \text{otherwise.} \end{cases}$$

The mean epsilon-insensitive loss is calculated as follows:

$$Loss = \frac{\sum_{j=1}^n w_j \max(0, |y_j - f(x_j)| - \epsilon)}{\sum_{j=1}^n w_j},$$

RegressionSVM | fitrsvm | loss | resubPredict

Introduced in R2015b

resubLoss

Class: RegressionTree

Regression error by resubstitution

Syntax

```
L = resubLoss(tree)
L = resubLoss(tree,Name,Value)
L = resubLoss(tree,'Subtrees',subtreevector)
[L,se] = resubLoss(tree,'Subtrees',subtreevector)
[L,se,NLeaf] = resubLoss(tree,'Subtrees',subtreevector)
[L,se,NLeaf,bestlevel] = resubLoss(tree,'Subtrees',subtreevector)
[L,...] = resubLoss(tree,'Subtrees',subtreevector,Name,Value)
```

Description

`L = resubLoss(tree)` returns the resubstitution loss, meaning the loss computed for the data that `fitrtree` used to create `tree`.

`L = resubLoss(tree,Name,Value)` returns the loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`L = resubLoss(tree,'Subtrees',subtreevector)` returns a vector of mean squared errors for the trees in the pruning sequence `subtreevector`.

`[L,se] = resubLoss(tree,'Subtrees',subtreevector)` returns the vector of standard errors of the classification errors.

`[L,se,NLeaf] = resubLoss(tree,'Subtrees',subtreevector)` returns the vector of numbers of leaf nodes in the trees of the pruning sequence.

`[L,se,NLeaf,bestlevel] = resubLoss(tree,'Subtrees',subtreevector)` returns the best pruning level as defined in the `TreeSize` name-value pair. By default, `bestlevel` is the pruning level that gives loss within one standard deviation of minimal loss.

`[L,...] = resubLoss(tree,'Subtrees',subtreevector,Name,Value)` returns loss statistics with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

tree — Regression tree

RegressionTree model object

A regression tree (RegressionTree model object) constructed using `fitrtree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

LossFun — Loss function

'mse' (default) | function handle

Loss function, specified as a function handle or 'mse' meaning mean squared error.

You can write your own loss function in the syntax described in “Loss Functions” on page 32-4851.

Data Types: char | string | function_handle

`Name`, `Value` arguments associated with pruning subtrees:

Subtrees — Pruning level

0 (default) | vector of nonnegative integers | 'all'

Pruning level, specified as the comma-separated pair consisting of 'Subtrees' and a vector of nonnegative integers in ascending order or 'all'.

If you specify a vector, then all elements must be at least 0 and at most `max(tree.PruneList)`. 0 indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify 'all', then `resubLoss` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`resubLoss` prunes `tree` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `tree` must be nonempty. In other words, grow `tree` by setting 'Prune', 'on', or by pruning `tree` using `prune`.

Example: 'Subtrees', 'all'

Data Types: single | double | char | string

TreeSize — Tree size

'se' (default) | 'min'

Tree size, specified as one of the following:

- 'se' — `loss` returns the highest pruning level with loss within one standard deviation of the minimum ($L + se$, where L and se relate to the smallest value in `Subtrees`).
- 'min' — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Output Arguments

L — Regression loss

numeric vector of positive values

Regression loss (mean squared error), a vector the length of `Subtrees`. The meaning of the error depends on the values in `Weights` and `LossFun`.

se — Standard error of loss

numeric vector of positive values

Standard error of loss, a vector the length of `Subtrees`.

NLeaf — Number of leaves

numeric vector of nonnegative integers

Number of leaves (terminal nodes) in the pruned subtrees, a vector the length of `Subtrees`.

bestlevel — Optimal pruning level

nonnegative numeric scalar

A scalar whose value depends on `TreeSize`:

- `TreeSize = 'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum ($L + se$, where L and se relate to the smallest value in `Subtrees`).
- `TreeSize = 'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Examples

Compute the In-Sample MSE

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using all observations.

```
Mdl = fitrtree(X,MPG);
```

Compute the resubstitution MSE.

```
resubLoss(Mdl)
```

```
ans = 4.8952
```

Examine the MSE for Each Subtree

Unpruned decision trees tend to overfit. One way to balance model complexity and out-of-sample performance is to prune a tree (or restrict its growth) so that in-sample and out-of-sample performance are satisfactory.

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];
Y = MPG;
```

Partition the data into training (50%) and validation (50%) sets.

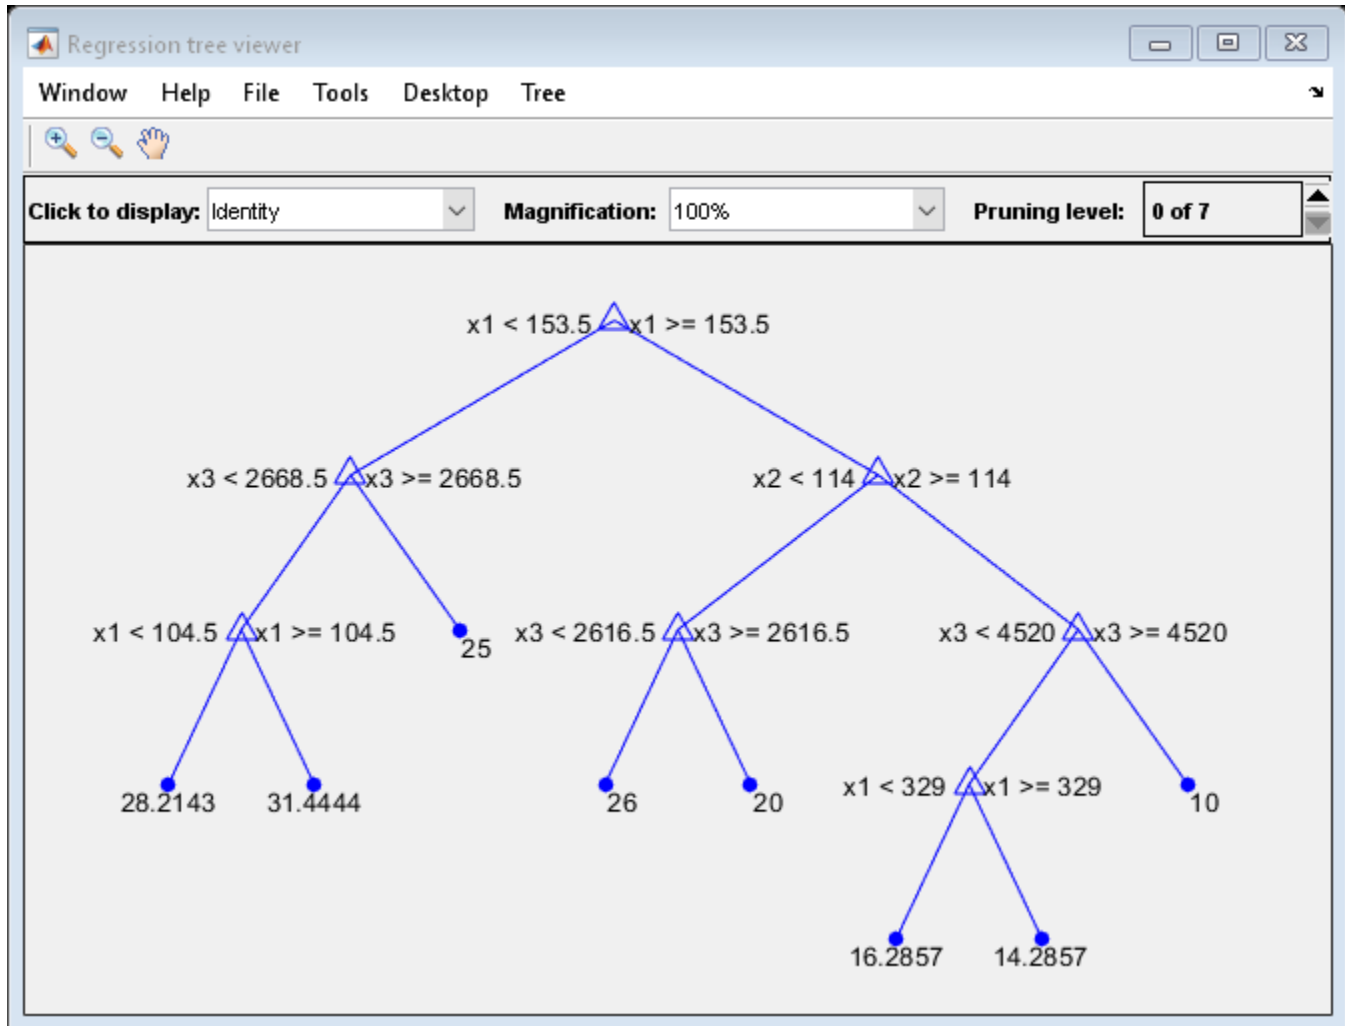

```
n = size(X,1);
rng(1) % For reproducibility
idxTrn = false(n,1);
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices
idxVal = idxTrn == false; % Validation set logical indices
```

Grow a regression tree using the training set.

```
Mdl = fitrtree(X(idxTrn,:),Y(idxTrn));
```

View the regression tree.

```
view(Mdl, 'Mode', 'graph');
```

The regression tree has seven pruning levels. Level 0 is the full, unpruned tree (as displayed). Level 7 is just the root node (i.e., no splits).

Examine the training sample MSE for each subtree (or pruning level) excluding the highest level.

```
m = max(Mdl.PruneList) - 1;  
trnLoss = resubLoss(Mdl, 'SubTrees', 0:m)
```

```
trnLoss = 7×1
```

```
5.9789  
6.2768  
6.8316  
7.5209  
8.3951  
10.7452  
14.8445
```

- The MSE for the full, unpruned tree is about 6 units.
- The MSE for the tree pruned to level 1 is about 6.3 units.
- The MSE for the tree pruned to level 6 (i.e., a stump) is about 14.8 units.

Examine the validation sample MSE at each level excluding the highest level.

```
valLoss = loss(Mdl, X(idxVal, :), Y(idxVal), 'SubTrees', 0:m)
```

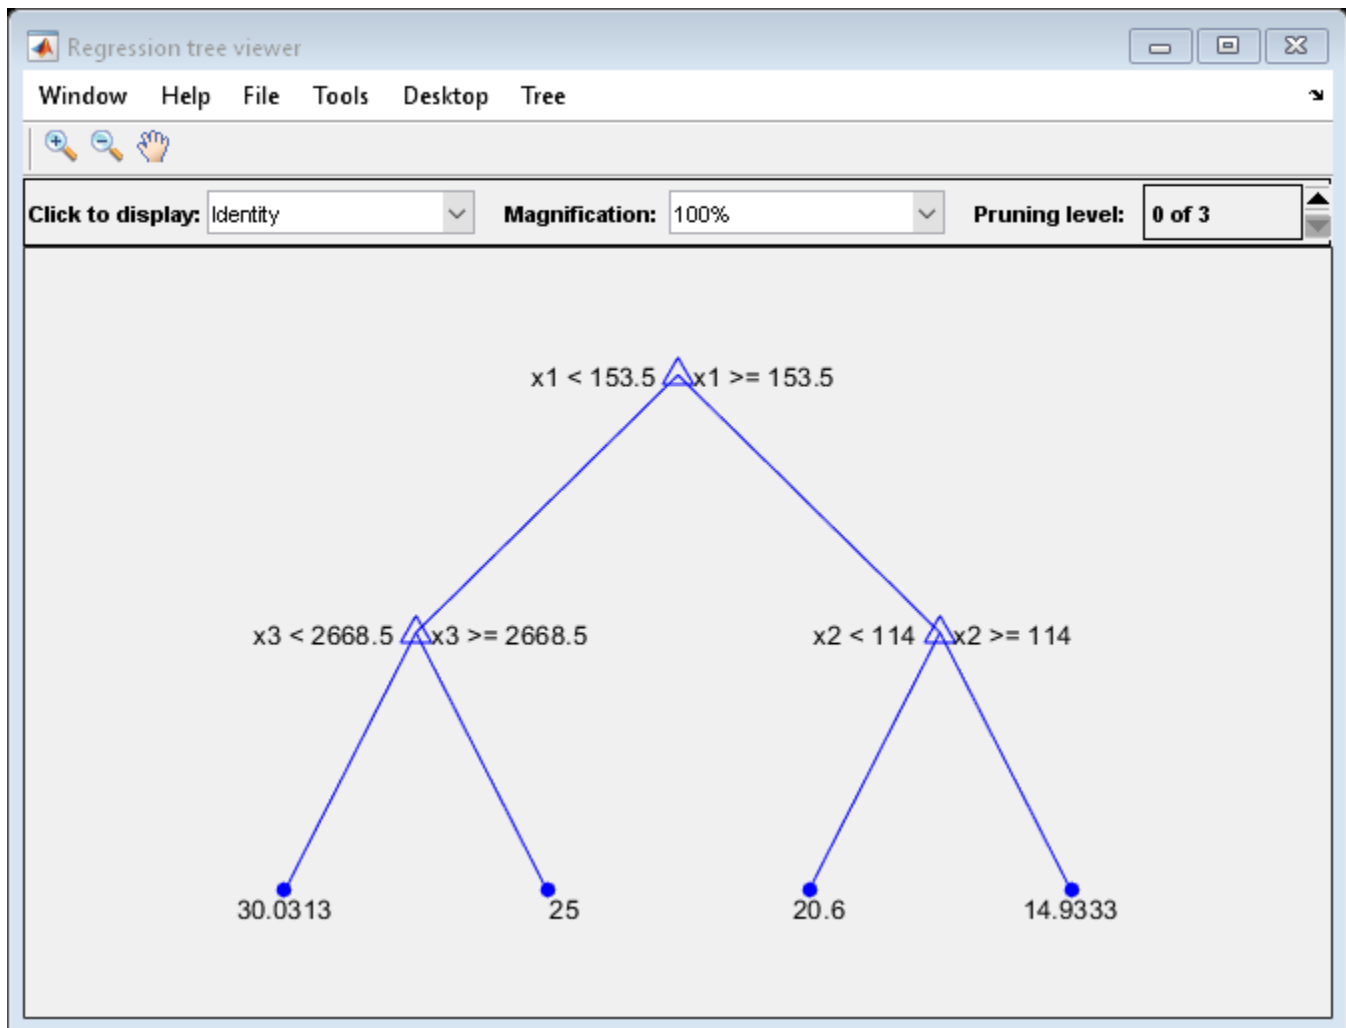

```
valLoss = 7×1
```

```
32.1205  
31.5035  
32.0541  
30.8183  
26.3535  
30.0137  
38.4695
```

- The MSE for the full, unpruned tree (level 0) is about 32.1 units.
- The MSE for the tree pruned to level 4 is about 26.4 units.
- The MSE for the tree pruned to level 5 is about 30.0 units.
- The MSE for the tree pruned to level 6 (i.e., a stump) is about 38.5 units.

To balance model complexity and out-of-sample performance, consider pruning Mdl to level 4.

```
pruneMdl = prune(Mdl, 'Level', 4);  
view(pruneMdl, 'Mode', 'graph')
```

More About

Loss Functions

The built-in loss function is 'mse', meaning mean squared error.

To write your own loss function, create a function file of the form

```
function loss = lossfun(Y,Yfit,W)
```

- N is the number of rows of `tree.X`.
- Y is an N-element vector representing the observed response.
- Yfit is an N-element vector representing the predicted responses.
- W is an N-element vector representing the observation weights.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `LossFun` name-value pair.

See Also

fitrtree | loss | resubPredict

resubMargin

Class: ClassificationDiscriminant

Classification margins by resubstitution

Syntax

```
M = resubMargin(obj)
```

Description

`M = resubMargin(obj)` returns resubstitution classification margins for `obj`.

Input Arguments

obj

Discriminant analysis classifier, produced using `fitcdiscr`.

Output Arguments

M

Numeric column-vector of length `size(obj.X,1)` containing the classification margins.

Examples

Estimate Resubstitution Margins for Discriminant Analysis Classifiers

Find the margins for a discriminant analysis classifier for Fisher's iris data by resubstitution. Examine several entries.

Load Fisher's iris data set.

```
load fisheriris
```

Train a discriminant analysis classifier.

```
Mdl = fitcdiscr(meas,species);
```

Compute the resubstitution margins, and display several of them.

```
m = resubMargin(Mdl);  
m(1:25:end)
```

```
ans = 6×1  
  
    1.0000  
    1.0000
```

```
0.9998  
0.9998  
1.0000  
0.9946
```

More About

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix X . A high value of margin indicates a more reliable prediction than a low value.

Score

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 20-6.

`ClassificationDiscriminant` | `fitcdiscr` | `margin`

Topics

“Discriminant Analysis Classification” on page 20-2

resubMargin

Resubstitution classification margins for multiclass error-correcting output codes (ECOC) model

Syntax

```
m = resubMargin(Mdl)
m = resubMargin(Mdl,Name,Value)
```

Description

`m = resubMargin(Mdl)` returns the resubstitution classification margins on page 32-4860 (`m`) for the multiclass error-correcting output codes (ECOC) model `Mdl` using the training data stored in `Mdl.X` and the corresponding class labels stored in `Mdl.Y`.

`m` is returned as a numeric column vector with the same length as `Mdl.Y`. The software estimates each entry of `m` using the trained ECOC model `Mdl`, the corresponding row of `Mdl.X`, and the true class label `Mdl.Y`.

`m = resubMargin(Mdl,Name,Value)` returns the classification margins with additional options specified by one or more name-value pair arguments. For example, you can specify a decoding scheme, binary learner loss function, and verbosity level.

Examples

Resubstitution Classification Margins of ECOC Model

Calculate the resubstitution classification margins for an ECOC model with SVM binary learners.

Load Fisher's iris data set. Specify the predictor data `X` and the response data `Y`.

```
load fisheriris
X = meas;
Y = species;
```

Train an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
classOrder = unique(Y)

classOrder = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
```

```
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

`t` is an SVM template object. During training, the software uses default values for empty properties in `t`. `Mdl` is a `ClassificationECOC` model.

Calculate the classification margins for the observations used to train `Mdl`. Display the distribution of the margins using a boxplot.

```
m = resubMargin(Mdl);
boxplot(m)
title('In-Sample Margins')
```

The classification margin of an observation is the positive-class negated loss minus the maximum negative-class negated loss. Choose classifiers that yield relatively large margins.

Select ECOC Model Features by Examining Training-Sample Margins

Perform feature selection by comparing training-sample margins from multiple models. Based solely on this comparison, the model with the greatest margins is the best model.

Load Fisher's iris data set. Define two data sets:

- `fullX` contains all four predictors.
- `partX` contains the sepal measurements only.

```
load fisheriris
X = meas;
fullX = X;
```

```
partX = X(:,1:2);
Y = species;
```

Train an ECOC model using SVM binary learners for each predictor set. Standardize the predictors using an SVM template, specify the class order, and compute posterior probabilities.

```
t = templateSVM('Standardize',true);
classOrder = unique(Y)
```

```
classOrder = 3x1 cell
    {'setosa'   }
    {'versicolor'}
    {'virginica' }
```

```
FullMdl = fitcecoc(fullX,Y,'Learners',t,'ClassNames',classOrder,...
    'FitPosterior',true);
PartMdl = fitcecoc(partX,Y,'Learners',t,'ClassNames',classOrder,...
    'FitPosterior',true);
```

Compute the resubstitution margins for each classifier. For each model, display the distribution of the margins using a boxplot.

```
fullMargins = resubMargin(FullMdl);
partMargins = resubMargin(PartMdl);
```

```
boxplot([fullMargins partMargins],'Labels',{'All Predictors','Two Predictors'})
title('Training-Sample Margins')
```

The margin distribution of `FullMdl` is situated higher and has less variability than the margin distribution of `PartMdl`. This result suggests that the model trained with all the predictors fits the training data better.

Input Arguments

Mdl — Full, trained multiclass ECOC model

ClassificationECOC model

Full, trained multiclass ECOC model, specified as a `ClassificationECOC` model trained with `fitcecoc`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `resubMargin(Mdl, 'Verbose', 1)` specifies to display diagnostic messages in the Command Window.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic'
| function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle `'BinaryLoss', @customFunction`.

`customFunction` has this form:

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-4169.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	'hinge'
All binary learners are ensembles trained by <code>AdaboostM1</code> or <code>GentleBoost</code> .	'exponential'
All binary learners are ensembles trained by <code>LogitBoost</code> .	'binodeviance'
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting <code>'FitPosterior', true</code> in <code>fitcecoc</code> .	'quadratic'

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss', 'binodeviance'`

Data Types: `char` | `string` | `function_handle`

Decoding – Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 32-4860.

Example: `'Decoding', 'lossbased'`

Options – Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.

- Specify 'Options', `statset('UseParallel',true)`.

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

More About

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-189, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-189, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-189 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0,1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0,1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-189.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Tips

- To compare the margins or edges of several ECOC classifiers, use template objects to specify a common score transform function among the classifiers during training.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to `true`.

Set the 'UseParallel' field of the options structure to `true` using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options', statset('UseParallel', true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

resubMargin

Classification margins by resubstitution

Syntax

```
margin = resubMargin(ens)
margin = resubMargin(ens,Name,Value)
```

Description

`margin = resubMargin(ens)` returns the classification margin obtained by `ens` on its training data.

`margin = resubMargin(ens,Name,Value)` calculates margins with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`ens`

A classification ensemble created with `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `resubMargin` uses only these learners for calculating margin.

Default: `1:NumTrained`

Output Arguments

`margin`

A numeric column-vector of length `size(ens.X,1)` containing the classification margins.

Examples

Compute Resubstitution Margins for Classification Ensemble

Find the resubstitution margins for an ensemble that classifies the Fisher iris data.

Load the Fisher iris data set.

```
load fisheriris
```

Train an ensemble of 100 boosted classification trees using AdaBoostM2.

```
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Find the resubstitution margins.

```
margin = resubMargin(ens);
[min(margin) mean(margin) max(margin)]
```

```
ans = 1×3
```

```
-0.5674    3.2486    4.6245
```

More About

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `ens.X`.

Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from $-\infty$ to ∞ .
- Bag scores range from 0 to 1.

resubMargin

Margin of k -nearest neighbor classifier by resubstitution

Syntax

```
m = resubMargin mdl
```

Description

`m = resubMargin(mdl)` returns the classification margins on page 32-4866 (`m`) of the data used to train `mdl`.

`m` is returned as a numeric vector of length `size(mdl.X,1)`, where `mdl.X` is the training data for `mdl`. Each entry in `m` represents the margin for the corresponding row of `mdl.X` and the corresponding true class label in `mdl.Y`.

Examples

Resubstitution Margin Calculation

Create a k -nearest neighbor classifier for the Fisher iris data, where $k = 5$.

Load the Fisher iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Create a classifier for five nearest neighbors.

```
mdl = fitcknn(X,Y,'NumNeighbors',5);
```

Examine some statistics of the resubstitution margin of the classifier.

```
m = resubMargin(mdl);
[max(m) min(m) mean(m)]

ans = 1×3

    1.0000    -0.6000    0.9253
```

The mean margin is over 0.9, indicating fairly high classification accuracy for resubstitution. For a more reliable assessment of model accuracy, consider cross-validation, such as `kfoldLoss`.

Input Arguments

mdl — k -nearest neighbor classifier model
ClassificationKNN object

k-nearest neighbor classifier model, specified as a `ClassificationKNN` object.

More About

Margin

The classification margin for each observation is the difference between the classification score for the true class and the maximal classification score for the false classes.

Score

The score of a classification is the posterior probability of the classification. The posterior probability is the number of neighbors with that classification divided by the number of neighbors. For a more detailed definition that includes weights and prior probabilities, see “Posterior Probability” on page 32-4144.

resubMargin

Class: ClassificationNaiveBayes

Classification margins for naive Bayes classifiers by resubstitution

Syntax

```
m = resubMargin(Mdl)
```

Description

`m = resubMargin(Mdl)` returns the resubstitution classification margins on page 32-4869 (`m`) for the naive Bayes classifier `Mdl` using the training data stored in `Mdl.X` and corresponding class labels stored in `Mdl.Y`.

Input Arguments

Mdl — Fully trained naive Bayes classifier

ClassificationNaiveBayes model

A fully trained naive Bayes classifier, specified as a ClassificationNaiveBayes model trained by `fitcnb`.

Output Arguments

m — Classification margins

numeric vector

Classification margins on page 32-4869, returned as a numeric vector.

`m` has the same length equal to `size(Mdl.X,1)`. Each entry of `m` is the classification margin of the corresponding observation (row) of `Mdl.X` and element of `Mdl.Y`.

Examples

Estimate In-Sample Classification Margins of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'});
```

`Mdl` is a ClassificationNaiveBayes classifier.

Estimate the in-sample classification margins. Display the distribution of the margins using a boxplot.

```
m = resubMargin(Mdl);

figure;
boxplot(m);
h = gca;
iqr = quantile(m,0.75) - quantile(m,0.25);
h.YLim = median(m) + iqr*[-4 4];
title 'Boxplot of the Margins';
```

An observation margin is the observed (true) class score minus the maximum false class score among all scores in the respective class. Classifiers that yield relatively large margins are desirable.

Select Naive Bayes Classifier Features by Examining In-Sample Margins

The classifier margins measure, for each observation, the difference between the true class observed score and the maximal false class score for a particular class. One way to perform feature selection is to compare in-sample margins from multiple models. Based solely on this criterion, the model with the highest margins is the best model.

Load Fisher's iris data set. Define two data sets:

- `fullX` contains all predictors (except the removed column of 0s).

- partX contains the last 20 predictors.

```
load fisheriris
X = meas; % Predictors
Y = species; % Response
fullX = X;
partX = X(:,3:4);
```

Train naive Bayes classifiers for each predictor set.

```
FullMdl = fitcnb(fullX,Y);
PartMdl = fitcnb(partX,Y);
```

Estimate the in-sample margins for each classifier. Compute confidence intervals for each sample.

```
fullM = resubMargin(FullMdl);
partM = resubMargin(PartMdl);
n = size(X,1);
fullMCI = mean(fullM) + 2*[-std(fullM)/n std(fullM)/n]
```

```
fullMCI = 1×2
```

```
    0.8898    0.8991
```

```
partMCI = mean(partM) + 2*[-std(partM)/n std(partM)/n]
```

```
partMCI = 1×2
```

```
    0.9129    0.9209
```

The confidence intervals are tight, and mutually exclusive. The margin confidence interval of the classifier trained using just predictors 3 and 4 has higher values than that of the full model. Therefore, the model trained on two predictors has better in-sample performance.

More About

Classification Edge

The classification edge is the weighted mean of the classification margins.

If you supply weights, then the software normalizes them to sum to the prior probability of their respective class. The software uses the normalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The classification margins are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

Posterior Probability

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation (x_1, \dots, x_p) is

$$\widehat{P}(Y = k | x_1, \dots, x_p) = \frac{P(X_1, \dots, X_p | y = k)\pi(Y = k)}{P(X_1, \dots, X_p)},$$

where:

- $P(X_1, \dots, X_p | y = k)$ is the conditional joint density of the predictors given they are in class k . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- $P(X_1, \dots, X_p)$ is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_p) = \sum_{k=1}^K P(X_1, \dots, X_p | y = k)\pi(Y = k).$$

Prior Probability

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

Score

The naive Bayes score is the class posterior probability given the observation.

resubMargin

Find classification margins for support vector machine (SVM) classifier by resubstitution

Syntax

```
m = resubMargin(SVMModel)
```

Description

`m = resubMargin(SVMModel)` returns the resubstitution classification margins on page 32-3364 (`m`) for the support vector machine (SVM) classifier `SVMModel` using the training data stored in `SVMModel.X` and the corresponding class labels stored in `SVMModel.Y`.

`m` is returned as a numeric vector with the same length as `Y`. The software estimates each entry of `m` using the trained SVM classifier `SVMModel`, the corresponding row of `X`, and the true class label `Y`.

Examples

Estimate In-Sample Classification Margins of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class.

```
SVMModel = fitsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

`SVMModel` is a `ClassificationSVM` classifier.

Estimate the in-sample classification margins.

```
m = resubMargin(SVMModel);
m(10:20)
```

```
ans = 11x1

    5.5622
    4.2918
    1.9993
    4.5520
   -1.4897
    3.2816
    4.0260
    4.5419
   16.4449
    2.0006
    :
```

An observation margin is the observed (true) class score minus the maximum false class score among all scores in the respective class. Classifiers that yield relatively large margins are preferred.

Select SVM Classifier Features by Examining In-Sample Margins

Perform feature selection by comparing in-sample margins from multiple models. Based solely on this comparison, the model with the highest margins is the best model.

Load the `ionosphere` data set. Define two data sets:

- `fullX` contains all predictors (except the removed column of 0s).
- `partX` contains the last 20 predictors.

```
load ionosphere
fullX = X;
partX = X(:,end-20:end);
```

Train SVM classifiers for each predictor set.

```
FullSVMModel = fitcsvm(fullX,Y);
PartSVMModel = fitcsvm(partX,Y);
```

Estimate the in-sample margins for each classifier.

```
fullMargins = resubMargin(FullSVMModel);
partMargins = resubMargin(PartSVMModel);
n = size(X,1);
p = sum(fullMargins < partMargins)/n

p = 0.2222
```

Approximately 22% of the margins from the full model are less than those from the model with fewer predictors. This suggests that the model trained with all the predictors is better.

Input Arguments

SVMModel — Full, trained SVM classifier

`ClassificationSVM` classifier

Full, trained SVM classifier, specified as a `ClassificationSVM` model trained with `fitcsvm`.

More About

Classification Edge

The edge is the weighted mean of the classification margins.

The weights are the prior class probabilities. If you supply weights, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to compute the weighted mean.

One way to choose among multiple classifiers, for example, to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation x . The classification margin is commonly defined as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

The SVM classification score for classifying observation x is the signed distance from x to the decision boundary ranging from $-\infty$ to $+\infty$. A positive score for a class indicates that x is predicted to be in that class. A negative score indicates otherwise.

The positive class classification score $f(x)$ is the trained SVM classification function. $f(x)$ is also the numerical, predicted response for x , or the score for predicting x into the positive class.

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, \dots, \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations. The negative class classification score for x , or the score for predicting x into the negative class, is $-f(x)$.

If $G(x_j, x) = x_j'x$ (the linear kernel), then the score function reduces to

$$f(x) = (x/s)'\beta + b.$$

s is the kernel scale and β is the vector of fitted linear coefficients.

For more details, see “Understanding Support Vector Machines” on page 18-145.

Algorithms

For binary classification, the software defines the margin for observation j , m_j , as

$$m_j = 2y_j f(x_j),$$

where $y_j \in \{-1, 1\}$, and $f(x_j)$ is the predicted score of observation j for the positive class. However, $m_j = y_j f(x_j)$ is commonly used to define the margin.

resubMargin

Class: ClassificationTree

Classification margins by resubstitution

Syntax

```
M = resubMargin(tree)
```

Description

`M = resubMargin(tree)` returns resubstitution classification margins for `tree`.

Input Arguments

tree

A classification tree created by `fitctree`.

Output Arguments

M

A numeric column-vector of length `size(tree.X,1)` containing the classification margins.

Examples

Find the margins for a classification tree for the Fisher iris data by resubstitution. Examine several entries:

```
load fisheriris
tree = fitctree(meas,species);
M = resubMargin(tree);
M(1:25:end)
```

```
ans =
    1.0000
    1.0000
    1.0000
    1.0000
    0.9565
    0.9565
```

More About

Margin

Classification margin is the difference between classification score for the true class and maximal classification score for the false classes. A high value of margin indicates a more reliable prediction than a low value.

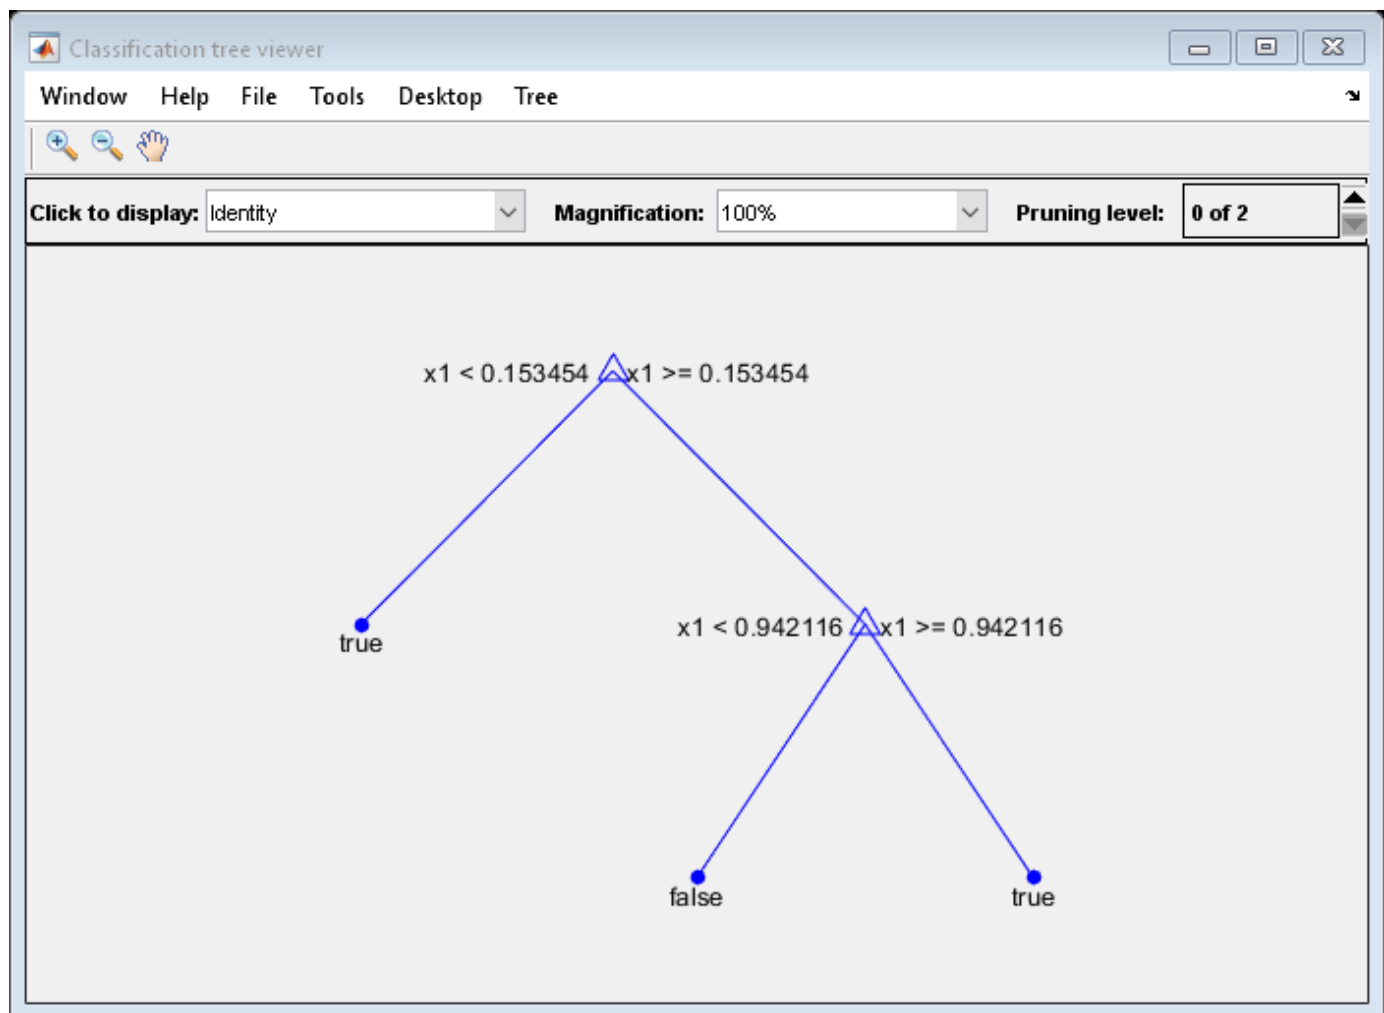

Score (tree)

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as `true` when $X < 0.15$ or $X > 0.95$, and X is false otherwise.

Generate 100 random points and classify them:

```
rng(0, 'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree, 'Mode', 'Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for `true`, and about $.8/.85=.94$ for `false`.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans = 10x3
```

```
    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0     1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0     1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
```

0.9059 0.0941 0.9649

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range $(.95, 1)$ instead of the expected 5 observations.

resubPredict

Class: ClassificationDiscriminant

Predict resubstitution labels of discriminant analysis classification model

Syntax

```
label = resubPredict(obj)
[label,posterior] = resubPredict(obj)
[label,posterior,cost] = resubPredict(obj)
```

Description

`label = resubPredict(obj)` returns the labels `obj` predicts for the data `obj.X`. `label` is the predictions of `obj` on the data that `fitcdiscr` used to create `obj`.

`[label,posterior] = resubPredict(obj)` returns the posterior class probabilities for the predictions.

`[label,posterior,cost] = resubPredict(obj)` returns the predicted misclassification costs per class for the resubstituted data.

Input Arguments

obj

Discriminant analysis classifier, produced using `fitcdiscr`.

Output Arguments

label

Response `obj` predicts for the training data. `label` is the same data type as the training response data `obj.Y`. The predicted class labels are those with minimal expected misclassification cost; see “Prediction Using Discriminant Analysis Models” on page 20-6.

posterior

N-by-K matrix of posterior probabilities for classes `obj` predicts, where N is the number of observations and K is the number of classes.

cost

N-by-K matrix of predicted misclassification costs. Each cost is the average misclassification cost with respect to the posterior probability.

Examples

Find the total number of misclassifications of the Fisher iris data for a discriminant analysis classifier:

```
load fisheriris
obj = fitcdiscr(meas,species);
Ypredict = resubPredict(obj); % the predictions
Ysame = strcmp(Ypredict,species); % true when ==
sum(~Ysame) % how many are different?
```

```
ans =
     3
```

More About

Posterior Probability

`posterior(i,k)` is the posterior probability of class `k` for observation `i`. For the mathematical definition, see “Posterior Probability” on page 20-6.

resubPredict

Classify observations in multiclass error-correcting output codes (ECOC) model

Syntax

```
label = resubPredict(Mdl)
label = resubPredict(Mdl,Name,Value)
[label,NegLoss,PBScore] = resubPredict(____)
[label,NegLoss,PBScore,Posterior] = resubPredict(____)
```

Description

`label = resubPredict(Mdl)` returns a vector of predicted class labels (`label`) for the trained multiclass error-correcting output codes (ECOC) model `Mdl` using the predictor data stored in `Mdl.X`.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`label = resubPredict(Mdl,Name,Value)` returns predicted class labels with additional options specified by one or more name-value pair arguments. For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

`[label,NegLoss,PBScore] = resubPredict(____)` uses any of the input argument combinations in the previous syntaxes and additionally returns the negated average binary loss on page 32-4891 per class (`NegLoss`) for observations, and the positive-class scores (`PBScore`) for the observations classified by each binary learner.

`[label,NegLoss,PBScore,Posterior] = resubPredict(____)` additionally returns posterior class probability estimates for observations (`Posterior`).

To obtain posterior class probabilities, you must set `'FitPosterior',true` when training the ECOC model using `fitcecoc`. Otherwise, `resubPredict` throws an error.

Examples

Predict Labels of Training Data Using ECOC Model

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
```

Train an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

`t` is an SVM template object. During training, the software uses default values for empty properties in `t`. `Mdl` is a `ClassificationECOC` model.

Predict the labels of the training data. Print a random subset of true and predicted labels.

```
labels = resubPredict(Mdl);

rng(1); % For reproducibility
n = numel(Y); % Sample size
idx = randsample(n,10);
table(Y(idx),labels(idx),'VariableNames',{'TrueLabels','PredictedLabels'})
```

```
ans=10x2 table
   TrueLabels   PredictedLabels
   _____   _____
   setosa       setosa
   versicolor   versicolor
   virginica    virginica
   setosa       setosa
   versicolor   versicolor
   setosa       setosa
   versicolor   versicolor
   versicolor   versicolor
   setosa       setosa
   setosa       setosa
```

`Mdl` correctly labels the observations with indices `idx`.

Predict Resubstitution Labels of ECOC Model Using Custom Binary Loss Function

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
```

Train an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

`t` is an SVM template object. During training, the software uses default values for empty properties in `t`. `Mdl` is a `ClassificationECOC` model.

SVM scores are signed distances from the observation to the decision boundary. Therefore, the domain is $(-\infty, \infty)$. Create a custom binary loss function that does the following:

- Map the coding design matrix (M) and positive-class classification scores (s) for each learner to the binary loss for each observation.

- Use linear loss.
- Aggregate the binary learner loss using the median.

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Or, you can specify an anonymous binary loss function. In this case, create a function handle (`customBL`) to an anonymous binary loss function.

```
customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;
```

Predict labels for the training data and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 observations.

```
[label,NegLoss] = resubPredict(Mdl, 'BinaryLoss',customBL);
```

```
rng(1); % For reproducibility
n = numel(Y); % Sample size
idx = randsample(n,10);
classOrder
```

```
classOrder = 3x1 categorical
    setosa
    versicolor
    virginica
```

```
table(Y(idx),label(idx),NegLoss(idx,:), 'VariableNames', ...
    {'TrueLabel', 'PredictedLabel', 'NegLoss'})
```

```
ans=10x3 table
```

TrueLabel	PredictedLabel	NegLoss		
setosa	versicolor	0.12376	1.9575	-3.5812
versicolor	versicolor	-1.0171	0.62948	-1.1123
virginica	virginica	-1.9088	-0.21759	0.62641
setosa	versicolor	0.43846	2.2448	-4.1833
versicolor	versicolor	-1.0735	0.3965	-0.82299
setosa	versicolor	0.26658	2.201	-3.9675
versicolor	versicolor	-1.1237	0.69927	-1.0756
versicolor	versicolor	-1.2716	0.51847	-0.74687
setosa	versicolor	0.35211	2.0683	-3.9204
setosa	versicolor	0.23342	2.1892	-3.9226

The order of the columns corresponds to the elements of `classOrder`. The software predicts the label based on the maximum negated loss. The results indicate that the median of the linear losses might not perform as well as other losses.

Estimate Posterior Probabilities Using ECOC Classifier

Train an ECOC classifier using SVM binary learners. First predict the training-sample labels and class posterior probabilities. Then predict the maximum class posterior probability at each point in a grid. Visualize the results.

Load Fisher's iris data set. Specify the petal dimensions as the predictors and the species names as the response.

```
load fisheriris
X = meas(:,3:4);
Y = species;
rng(1); % For reproducibility
```

Create an SVM template. Standardize the predictors, and specify the Gaussian kernel.

```
t = templateSVM('Standardize',true,'KernelFunction','gaussian');
```

`t` is an SVM template. Most of its properties are empty. When the software trains the ECOC classifier, it sets the applicable properties to their default values.

Train the ECOC classifier using the SVM template. Transform classification scores to class posterior probabilities (which are returned by `predict` or `resubPredict`) using the `'FitPosterior'` name-value pair argument. Specify the class order using the `'ClassNames'` name-value pair argument. Display diagnostic messages during training by using the `'Verbose'` name-value pair argument.

```
Mdl = fitcecoc(X,Y,'Learners',t,'FitPosterior',true,...
    'ClassNames',{'setosa','versicolor','virginica'},...
    'Verbose',2);
```

```
Training binary learner 1 (SVM) out of 3 with 50 negative and 50 positive observations.
Negative class indices: 2
Positive class indices: 1
```

```
Fitting posterior probabilities for learner 1 (SVM).
Training binary learner 2 (SVM) out of 3 with 50 negative and 50 positive observations.
Negative class indices: 3
Positive class indices: 1
```

```
Fitting posterior probabilities for learner 2 (SVM).
Training binary learner 3 (SVM) out of 3 with 50 negative and 50 positive observations.
Negative class indices: 3
Positive class indices: 2
```

```
Fitting posterior probabilities for learner 3 (SVM).
```

`Mdl` is a `ClassificationECOC` model. The same SVM template applies to each binary learner, but you can adjust options for each binary learner by passing in a cell vector of templates.

Predict the training-sample labels and class posterior probabilities. Display diagnostic messages during the computation of labels and class posterior probabilities by using the `'Verbose'` name-value pair argument.

```
[label,~,~,Posterior] = resubPredict(Mdl,'Verbose',1);
```

```
Predictions from all learners have been computed.
Loss for all observations has been computed.
Computing posterior probabilities...
```

```
Mdl.BinaryLoss
```

```
ans =
'quadratic'
```

The software assigns an observation to the class that yields the smallest average binary loss. Because all binary learners are computing posterior probabilities, the binary loss function is quadratic.

Display a random set of results.

```
idx = randsample(size(X,1),10,1);
Mdl.ClassNames
```

```
ans = 3x1 cell
    {'setosa' }
    {'versicolor'}
    {'virginica' }
```

```
table(Y(idx),label(idx),Posterior(idx,:),...
    'VariableNames',{'TrueLabel','PredLabel','Posterior'})
```

```
ans=10x3 table
    TrueLabel      PredLabel      Posterior
    _____  _____  _____
    {'virginica' } {'virginica' } 0.0039321    0.0039869    0.99208
    {'virginica' } {'virginica' } 0.017067    0.018263    0.96467
    {'virginica' } {'virginica' } 0.014948    0.015856    0.9692
    {'versicolor'} {'versicolor'} 2.2197e-14   0.87317     0.12683
    {'setosa' }    {'setosa' }    0.999       0.00025091  0.00074639
    {'versicolor'} {'virginica' } 2.2195e-14   0.059429    0.94057
    {'versicolor'} {'versicolor'} 2.2194e-14   0.97001     0.029986
    {'setosa' }    {'setosa' }    0.999       0.0002499   0.00074741
    {'versicolor'} {'versicolor'} 0.0085646   0.98259     0.008849
    {'setosa' }    {'setosa' }    0.999       0.00025013  0.00074718
```

The columns of `Posterior` correspond to the class order of `Mdl.ClassNames`.

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

```
xMax = max(X);
xMin = min(X);

x1Pts = linspace(xMin(1),xMax(1));
x2Pts = linspace(xMin(2),xMax(2));
[x1Grid,x2Grid] = meshgrid(x1Pts,x2Pts);

[~,~,~,PosteriorRegion] = predict(Mdl,[x1Grid(:),x2Grid(:)]);
```

For each coordinate on the grid, plot the maximum class posterior probability among all classes.

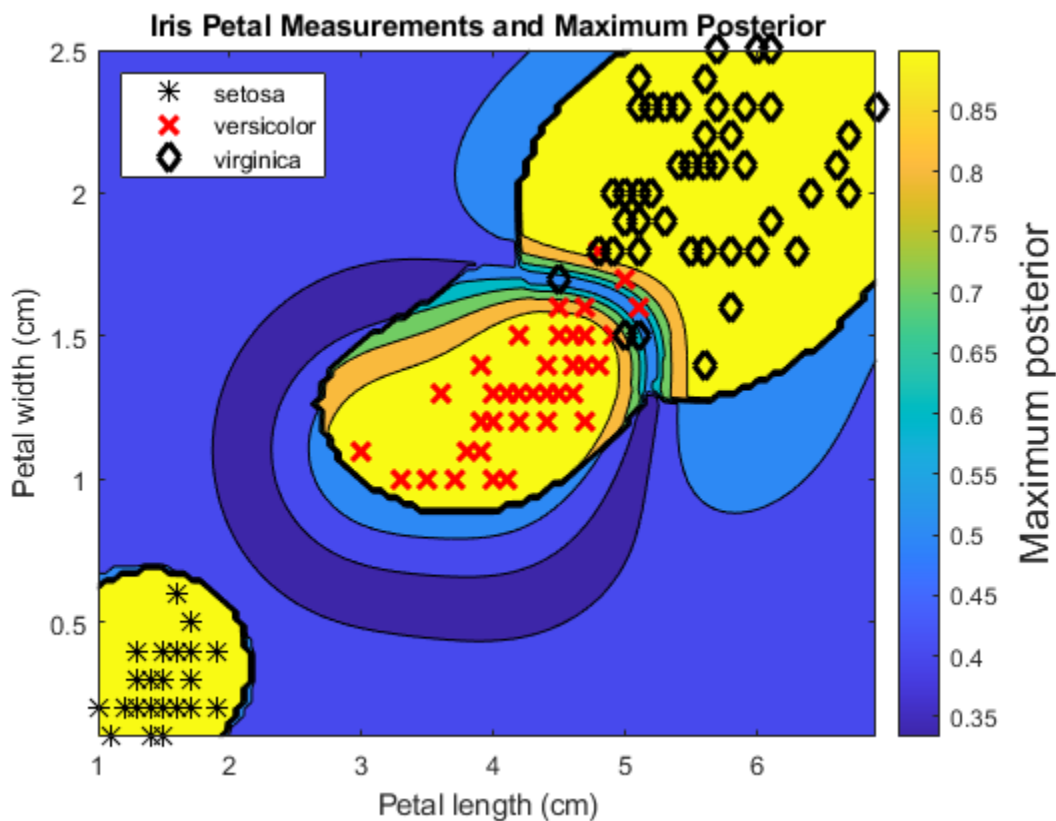

```
contourf(x1Grid,x2Grid,...
    reshape(max(PosteriorRegion,[],2),size(x1Grid,1),size(x1Grid,2)));
h = colorbar;
h.YLabel.String = 'Maximum posterior';
h.YLabel.FontSize = 15;

hold on
gh = gscatter(X(:,1),X(:,2),Y,'krk','*xd',8);
gh(2).LineWidth = 2;
gh(3).LineWidth = 2;
```

```

title('Iris Petal Measurements and Maximum Posterior')
xlabel('Petal length (cm)')
ylabel('Petal width (cm)')
axis tight
legend(gh, 'Location', 'NorthWest')
hold off

```

Estimate Posterior Probabilities Using Parallel Computing

Train a multiclass ECOC model and estimate the posterior probabilities using parallel computing.

Load the `arrhythmia` data set. Examine the response data `Y`, and determine the number of classes.

```

load arrhythmia
Y = categorical(Y);
tabulate(Y)

```

Value	Count	Percent
1	245	54.20%
2	44	9.73%
3	15	3.32%
4	15	3.32%
5	13	2.88%
6	25	5.53%

```

7         3         0.66%
8         2         0.44%
9         9         1.99%
10        50        11.06%
14        4         0.88%
15        5         1.11%
16        22        4.87%

```

```
K = numel(unique(Y));
```

Several classes are not represented in the data, and many other classes have low relative frequencies.

Specify an ensemble learning template that uses the GentleBoost method and 50 weak classification tree learners.

```
t = templateEnsemble('GentleBoost',50,'Tree');
```

`t` is a template object. Most of its properties are empty (`[]`). The software uses default values for all empty properties during training.

Because the response variable contains many classes, specify a sparse random coding design.

```
rng(1); % For reproducibility
Coding = designecoc(K,'sparseandom');
```

Train an ECOC model using parallel computing. Specify to fit posterior probabilities.

```
pool = parpool; % Invokes workers
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

```
options = statset('UseParallel',true);
Mdl = fitcecoc(X,Y,'Learner',t,'Options',options,'Coding',Coding,...
    'FitPosterior',true);
```

`Mdl` is a `ClassificationECOC` model. You can access its properties using dot notation.

The pool invokes six workers, although the number of workers might vary among systems.

Estimate posterior probabilities, and display the posterior probability of being classified as not having arrhythmia (class 1) given a random subset of the training data.

```
[~,~,~,posterior] = resubPredict(Mdl);
```

```
n = numel(Y);
idx = randsample(n,10,1);
table(idx,Y(idx),posterior(idx,1),...
    'VariableNames',{'ObservationIndex','TrueLabel','PosteriorNoArrythmia'})
```

```
ans=10x3 table
  ObservationIndex  TrueLabel  PosteriorNoArrythmia
  _____  _____  _____
           79             1           0.93436
          248             1           0.95574
          398            10           0.032378
          207             1           0.97965
```

340	1	0.93656
206	1	0.97795
345	10	0.015642
296	2	0.13433
391	1	0.9648
406	1	0.94861

Input Arguments

Mdl — Full, trained multiclass ECOC model

ClassificationECOC model

Full, trained multiclass ECOC model, specified as a `ClassificationECOC` model trained with `fitcecoc`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `resubPredict(Mdl, 'BinaryLoss', 'linear', 'Decoding', 'lossbased')` specifies a linear binary learner loss function and a loss-based decoding scheme for aggregating the binary losses.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic'
| function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle 'BinaryLoss', @customFunction.

`customFunction` has this form:

```
bLoss = customFunction(M,s)
```

where:

- `M` is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- `s` is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-4169.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	'hinge'
All binary learners are ensembles trained by <code>AdaboostM1</code> or <code>GentleBoost</code> .	'exponential'
All binary learners are ensembles trained by <code>LogitBoost</code> .	'binodeviance'
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting ' <code>FitPosterior</code> ', true in <code>fitcecoc</code> .	'quadratic'

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

```
Example: 'BinaryLoss', 'binodeviance'
```

```
Data Types: char | string | function_handle
```

Decoding — Decoding scheme

```
'lossweighted' (default) | 'lossbased'
```

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of '`Decoding`' and '`lossweighted`' or '`lossbased`'. For more information, see “Binary Loss” on page 32-4891.

```
Example: 'Decoding', 'lossbased'
```

NumKLInitializations — Number of random initial values

```
0 (default) | nonnegative integer scalar
```

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of '`NumKLInitializations`' and a nonnegative integer scalar.

If you do not request the fourth output argument (`Posterior`) and set `'PosteriorMethod'`, `'kl'` (the default), then the software ignores the value of `NumKLInitializations`.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-4892.

Example: `'NumKLInitializations',5`

Data Types: `single` | `double`

Options — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',true)`.

PosteriorMethod — Posterior probability estimation method

`'kl'` (default) | `'qp'`

Posterior probability estimation method, specified as the comma-separated pair consisting of `'PosteriorMethod'` and `'kl'` or `'qp'`.

- If `PosteriorMethod` is `'kl'`, then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-4892.
- If `PosteriorMethod` is `'qp'`, then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming” on page 32-4894.
- If you do not request the fourth output argument (`Posterior`), then the software ignores the value of `PosteriorMethod`.

Example: `'PosteriorMethod','qp'`

Verbose — Verbosity level

`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

label — Predicted class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of character vectors.

`label` has the same data type as `Mdl.ClassNames` and has the same number of rows as `Mdl.X`.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

NegLoss — Negated average binary losses

numeric matrix

Negated average binary losses on page 32-4891, returned as a numeric matrix. `NegLoss` is an n -by- K matrix, where n is the number of observations (`size(Mdl.X,1)`) and K is the number of unique classes (`size(Mdl.ClassNames,1)`).

PBScore — Positive-class scores

numeric matrix

Positive-class scores for each binary learner, returned as a numeric matrix. `PBScore` is an n -by- L matrix, where n is the number of observations (`size(Mdl.X,1)`) and L is the number of binary learners (`size(Mdl.CodingMatrix,2)`).

Posterior — Posterior class probabilities

numeric matrix

Posterior class probabilities, returned as a numeric matrix. `Posterior` is an n -by- K matrix, where n is the number of observations (`size(Mdl.X,1)`) and K is the number of unique classes (`size(Mdl.ClassNames,1)`).

To request `Posterior`, you must set `'FitPosterior', true` when training the ECOC model using `fitcecoc`. Otherwise, the software throws an error.

More About

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-189, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-189, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-189 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-189.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Algorithms

The software can estimate class posterior probabilities by minimizing the Kullback-Leibler divergence or by using quadratic programming. For the following descriptions of the posterior estimation algorithms, assume that:

- m_{kj} is the element (k, j) of the coding design matrix M .
- I is the indicator function.
- \hat{p}_k is the class posterior probability estimate for class k of an observation, $k = 1, \dots, K$.
- r_j is the positive-class posterior probability for binary learner j . That is, r_j is the probability that binary learner j classifies an observation into the positive class, given the training data.

Posterior Estimation Using Kullback-Leibler Divergence

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

$$\Delta(r, \hat{r}) = \sum_{j=1}^L w_j \left[r_j \log \frac{r_j}{\hat{r}_j} + (1 - r_j) \log \frac{1 - r_j}{1 - \hat{r}_j} \right],$$

where $w_j = \sum_{S_j} w_i^*$ is the weight for binary learner j .

- S_j is the set of observation indices on which binary learner j is trained.
- w_i^* is the weight of observation i .

The software minimizes the divergence iteratively. The first step is to choose initial values $\hat{p}_k^{(0)}$; $k = 1, \dots, K$ for the class posterior probabilities.

- If you do not specify 'NumKLIterations', then the software tries both sets of deterministic initial values described next, and selects the set that minimizes Δ .
 - $\hat{p}_k^{(0)} = 1/K$; $k = 1, \dots, K$.
 - $\hat{p}_k^{(0)}$; $k = 1, \dots, K$ is the solution of the system

$$M_{01} \hat{p}^{(0)} = r,$$

where M_{01} is M with all $m_{kj} = -1$ replaced with 0, and r is a vector of positive-class posterior probabilities returned by the L binary learners [Dietterich et al.] on page 18-189. The software uses `lsqnonneg` to solve the system.

- If you specify 'NumKLIterations', c , where c is a natural number, then the software does the following to choose the set $\hat{p}_k^{(0)}$; $k = 1, \dots, K$, and selects the set that minimizes Δ .
 - The software tries both sets of deterministic initial values as described previously.
 - The software randomly generates c vectors of length K using `rand`, and then normalizes each vector to sum to 1.

At iteration t , the software completes these steps:

- 1 Compute

$$\hat{r}_j^{(t)} = \frac{\sum_{k=1}^K \hat{p}_k^{(t)} I(m_{kj} = +1)}{\sum_{k=1}^K \hat{p}_k^{(t)} I(m_{kj} = +1 \cup m_{kj} = -1)}.$$

- 2 Estimate the next class posterior probability using

$$\hat{p}_k^{(t+1)} = \hat{p}_k^{(t)} \frac{\sum_{j=1}^L w_j [r_j I(m_{kj} = +1) + (1 - r_j) I(m_{kj} = -1)]}{\sum_{j=1}^L w_j [\hat{r}_j^{(t)} I(m_{kj} = +1) + (1 - \hat{r}_j^{(t)}) I(m_{kj} = -1)]}.$$

- 3 Normalize $\hat{p}_k^{(t+1)}$; $k = 1, \dots, K$ so that they sum to 1.
- 4 Check for convergence.

For more details, see [Hastie et al.] on page 18-190 and [Zadrozny] on page 18-191.

Posterior Estimation Using Quadratic Programming

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software completes these steps:

- 1 Estimate the positive-class posterior probabilities, r_j , for binary learners $j = 1, \dots, L$.
- 2 Using the relationship between r_j and \hat{p}_k [Wu et al.] on page 18-191, minimize

$$\sum_{j=1}^L \left[-r_j \sum_{k=1}^K \hat{p}_k I(m_{kj} = -1) + (1 - r_j) \sum_{k=1}^K \hat{p}_k I(m_{kj} = +1) \right]^2$$

with respect to \hat{p}_k and the restrictions

$$0 \leq \hat{p}_k \leq 1$$

$$\sum_k \hat{p}_k = 1.$$

The software performs minimization using `quadprog`.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to `true`.

Set the 'UseParallel' field of the options structure to `true` using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2014b

resubPredict

Classify observations in ensemble of classification models

Syntax

```
label = resubPredict(ens)
[label,score] = resubPredict(ens)
[label,score] = resubPredict(ens,Name,Value)
```

Description

`label = resubPredict(ens)` returns the labels `ens` predicts for the data `ens.X`. `label` is the predictions of `ens` on the data that `fitcensemble` used to create `ens`.

`[label,score] = resubPredict(ens)` also returns scores for all classes.

`[label,score] = resubPredict(ens,Name,Value)` finds resubstitution predictions with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`ens`

A classification ensemble created with `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `oobLoss` uses only these learners for calculating loss.

Default: `1:NumTrained`

Output Arguments

`label`

The response `ens` predicts for the training data. `label` is the same data type as the training response data `ens.Y`, and has the same number of entries as the number of rows in `ens.X`.

`score`

An `N`-by-`K` matrix, where `N` is the number of rows in `ens.X`, and `K` is the number of classes in `ens`. High score value indicates that an observation likely comes from this class.

Examples

Find Number of Ensemble Misclassifications

Find the total number of misclassifications of the `fisheriris` data for a classification ensemble.

Load the Fisher iris data set.

```
load fisheriris
```

Train an ensemble of 100 boosted classification trees using `AdaBoostM2`.

```
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Find the total number of misclassifications.

```
Ypredict = resubPredict(ens); % The predictions
Ysame = strcmp(Ypredict,species); % True when Ypredict and species are equal
sum(~Ysame) % Number of different predictions
```

```
ans = 5
```

More About

Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- `AdaBoostM1` scores range from $-\infty$ to ∞ .
- `Bag` scores range from 0 to 1.

resubPredict

Predict resubstitution labels of k -nearest neighbor classifier

Syntax

```
label = resubPredict mdl
[label, score] = resubPredict mdl
[label, score, cost] = resubPredict mdl
```

Description

`label = resubPredict(mdl)` returns the labels that `mdl` predicts for the training data `mdl.X`. The output `label` contains the predictions of `mdl` on the data used by `fitcknn` to create `mdl`.

`[label, score] = resubPredict(mdl)` also returns the posterior class probabilities for the predictions.

`[label, score, cost] = resubPredict(mdl)` also returns the misclassification costs.

Examples

Predict Labels for Training Data

Examine the quality of a classifier by its resubstitution predictions.

Load the Fisher iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Create a classifier for five nearest neighbors.

```
mdl = fitcknn(X, Y, 'NumNeighbors', 5);
```

Generate the resubstitution predictions.

```
label = resubPredict(mdl);
```

Calculate the number of differences between the predictions `label` and the original data `Y`.

```
mydiff = not(strcmp(Y, label)); % mydiff(i) = 1 means they differ
sum(mydiff) % Number of differences
```

```
ans = 5
```

A value of 1 in `mydiff` indicates that the observed label differs from the corresponding predicted label. This example has five misclassifications.

Input Arguments

mdl — *k*-nearest neighbor classifier model

ClassificationKNN object

k-nearest neighbor classifier model, specified as a ClassificationKNN object.

Output Arguments

label — Predicted class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Predicted class labels for the observations (rows) in the training data *X*, returned as a categorical array, character array, logical vector, numeric vector, or cell array of character vectors. `label` has length equal to the number of rows in *X*. The label is the class with minimal expected cost. See “Predicted Class Label” on page 32-4899.

score — Predicted class scores or posterior probabilities

numeric matrix

Predicted class scores or posterior probabilities, returned as a numeric matrix of size *n*-by-*K*. *n* is the number of observations (rows) in the training data *X*, and *K* is the number of classes (in `mdl.ClassNames`). `score(i, j)` is the posterior probability that observation *i* in *X* is of class *j* in `mdl.ClassNames`. See “Posterior Probability” on page 32-4900.

cost — Expected classification costs

numeric matrix

Expected classification costs, returned as a numeric matrix of size *n*-by-*K*. *n* is the number of observations (rows) in the training data *X*, and *K* is the number of classes (in `mdl.ClassNames`). `cost(i, j)` is the cost of classifying row *i* of *X* as class *j* in `mdl.ClassNames`. See “Expected Cost” on page 32-4900.

Tips

- If you standardize the predictor data, that is, `mdl.Mu` and `mdl.Sigma` are not empty (`[]`), then `resubPredict` standardizes the predictor data before predicting labels.

Algorithms

Predicted Class Label

`resubPredict` classifies by minimizing the expected classification cost:

$$\hat{y} = \underset{y=1, \dots, K}{\operatorname{argmin}} \sum_{j=1}^K \hat{P}(j|x)C(y|j),$$

where

- \hat{y} is the predicted classification.
- *K* is the number of classes.

- $\widehat{P}(j|x)$ is the posterior probability of class j for observation x .
- $C(y|j)$ is the cost of classifying an observation as y when its true class is j .

Posterior Probability

Consider a vector (single query point) x_{new} and a model mdl .

- k is the number of nearest neighbors used in prediction, $\text{mdl}.\text{NumNeighbors}$.
- $\text{nbr}(\text{mdl}, x_{\text{new}})$ specifies the k nearest neighbors to x_{new} in $\text{mdl}.X$.
- $Y(\text{nbr})$ specifies the classifications of the points in $\text{nbr}(\text{mdl}, x_{\text{new}})$, namely $\text{mdl}.Y(\text{nbr})$.
- $W(\text{nbr})$ specifies the weights of the points in $\text{nbr}(\text{mdl}, x_{\text{new}})$.
- prior specifies the priors of the classes in $\text{mdl}.Y$.

If the model contains a vector of prior probabilities, then the observation weights W are normalized by class to sum to the priors. This process might involve a calculation for the point x_{new} , because weights can depend on the distance from x_{new} to the points in $\text{mdl}.X$.

The posterior probability $p(j|x_{\text{new}})$ is

$$p(j|x_{\text{new}}) = \frac{\sum_{i \in \text{nbr}} W(i) 1_{Y(X(i))=j}}{\sum_{i \in \text{nbr}} W(i)}.$$

Here, $1_{Y(X(i))=j}$ is 1 when $\text{mdl}.Y(i) = j$, and 0 otherwise.

True Misclassification Cost

Two costs are associated with KNN classification: the true misclassification cost per class and the expected misclassification cost per observation.

You can set the true misclassification cost per class by using the 'Cost' name-value pair argument when you run `fitcknn`. The value $\text{Cost}(i, j)$ is the cost of classifying an observation into class j if its true class is i . By default, $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$. In other words, the cost is 0 for correct classification and 1 for incorrect classification.

Expected Cost

Two costs are associated with KNN classification: the true misclassification cost per class and the expected misclassification cost per observation. The third output of `resubPredict` is the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you classified with a trained classifier mdl , and you have K classes. The command

```
[label,score,cost] = resubPredict(mdl)
```

returns a matrix `cost` of size `Nobs-by-K`, among other outputs. Each row of the `cost` matrix contains the expected (average) cost of classifying the observation into each of the K classes. $\text{cost}(n, j)$ is

$$\sum_{i=1}^K \widehat{P}(i|X(n))C(j|i),$$

where

- K is the number of classes.
- $\hat{P}(i|X(n))$ is the posterior probability on page 32-4900 of class i for observation $X(n)$.
- $C(j|i)$ is the true misclassification cost of classifying an observation as j when its true class is i .

Introduced in R2012a

resubPredict

Class: ClassificationNaiveBayes

Predict resubstitution labels of naive Bayes classifier

Syntax

```
label = resubPredict(Mdl)
[label,Posterior,Cost] = predict(Mdl)
```

Description

`label = resubPredict(Mdl)` returns a vector of predicted class labels (`label`) for the trained naive Bayes classifier `Mdl` using the predictor data `Mdl.X`.

`[label,Posterior,Cost] = predict(Mdl)` additionally returns posterior probabilities on page 32-4905 (`Posterior`) and predicted (expected) misclassification costs on page 32-4905 (`Cost`) corresponding to the observations (rows) in `Mdl.X`.

Input Arguments

Mdl — Fully trained naive Bayes classifier

ClassificationNaiveBayes model

A fully trained naive Bayes classifier, specified as a `ClassificationNaiveBayes` model trained by `fitcnb`.

Output Arguments

label — Predicted class labels

categorical vector | character array | logical vector | numeric vector | cell array of character vectors

Predicted class labels, returned as a categorical vector, character array, logical or numeric vector, or cell array of character vectors.

`label`:

- Is the same data type as the observed class labels (`Y`) that trained `Mdl`. (The software treats string arrays as cell arrays of character vectors.)
- Has length equal to the number of rows of `X`.
- Is the class yielding the lowest expected misclassification cost (`Cost`).

Posterior — Class posterior probabilities

numeric matrix

Class posterior probabilities on page 32-4905, returned as a numeric matrix. `Posterior` has rows equal to the number of rows of `Mdl.X` and columns equal to the number of distinct classes in the training data (`size(Mdl.ClassNames,1)`).

$\text{Posterior}(j, k)$ is the predicted posterior probability of class k (i.e., in class $\text{Mdl.ClassNames}(k)$) given the observation in row j of Mdl.X .

Data Types: double

Cost — Expected misclassification costs

numeric matrix

Expected misclassification costs on page 32-4905, returned as a numeric matrix. `Cost` has rows equal to the number of rows of Mdl.X and columns equal to the number of distinct classes in the training data ($\text{size}(\text{Mdl.ClassNames}, 1)$).

$\text{Cost}(j, k)$ is the expected misclassification cost of the observation in row j of Mdl.X being predicted into class k (i.e., in class $\text{Mdl.ClassNames}(k)$).

Examples

Label Training Sample Observations for Naive Bayes

Load Fisher's iris data set.

```
load fisheriris
X = meas; % Predictors
Y = species; % Response
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X, Y, ...
    'ClassNames', {'setosa', 'versicolor', 'virginica'});
```

`Mdl` is a `ClassificationNaiveBayes` classifier.

Predict the training sample labels. Display the results for the 10 observations.

```
label = resubPredict(Mdl);
rng(1); % For reproducibility
idx = randsample(size(X, 1), 10);
table(Y(idx), label(idx), 'VariableNames', ...
    {'TrueLabel', 'PredictedLabel'})
```

```
ans=10x2 table
    TrueLabel    PredictedLabel
    _____    _____
    {'setosa'    }    {'setosa'    }
    {'versicolor'}    {'versicolor'}

    {'setosa'    }    {'setosa'    }
    {'setosa'    }    {'setosa'    }
```

Estimate In-Sample Posterior Probabilities of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas; % Predictors
Y = species; % Response
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X,Y,...
    'ClassNames',{'setosa','versicolor','virginica'});
```

Mdl is a ClassificationNaiveBayes classifier.

Estimate posterior probabilities and expected misclassification costs for the training data. Display the results for 10 observations.

```
[label,Posterior,MisclassCost] = resubPredict(Mdl);
rng(1); % For reproducibility
idx = randsample(size(X,1),10);
Mdl.ClassNames
```

```
ans = 3x1 cell
    {'setosa' }

0.0000    1.0000    1.0000
0.0000    1.0000    1.0000

```

The order of the columns of `Posterior` and `MisclassCost` corresponds to the order of the classes in `Mdl.ClassNames`.

More About

Misclassification Cost

A misclassification cost is the relative severity of a classifier labeling an observation into the wrong class.

There are two types of misclassification costs: true and expected. Let K be the number of classes.

- True misclassification cost — A K -by- K matrix, where element (i,j) indicates the misclassification cost of predicting an observation into class j if its true class is i . The software stores the misclassification cost in the property `Mdl.Cost`, and used in computations. By default, $\text{Mdl.Cost}(i, j) = 1$ if $i \neq j$, and $\text{Mdl.Cost}(i, j) = 0$ if $i = j$. In other words, the cost is 0 for correct classification, and 1 for any incorrect classification.
- Expected misclassification cost — A K -dimensional vector, where element k is the weighted average misclassification cost of classifying an observation into class k , weighted by the class posterior probabilities. In other words,

$$c_k = \sum_{j=1}^K \widehat{P}(Y = j | x_1, \dots, x_p) \text{Cost}_{jk}.$$

the software classifies observations to the class corresponding with the lowest expected misclassification cost.

Posterior Probability

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation (x_1, \dots, x_p) is

$$\widehat{P}(Y = k | x_1, \dots, x_p) = \frac{P(X_1, \dots, X_p | y = k) \pi(Y = k)}{P(X_1, \dots, X_p)},$$

where:

- $P(X_1, \dots, X_p | y = k)$ is the conditional joint density of the predictors given they are in class k . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.

- $P(X_1, \dots, X_P)$ is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_P) = \sum_{k=1}^K P(X_1, \dots, X_P \mid y = k) \pi(Y = k).$$

Prior Probability

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

resubPredict

Classify observations in support vector machine (SVM) classifier

Syntax

```
label = resubPredict(SVMModel)
[label,Score] = resubPredict(SVMModel)
```

Description

`label = resubPredict(SVMModel)` returns a vector of predicted class labels (`label`) for the trained support vector machine (SVM) classifier `SVMModel` using the predictor data `SVMModel.X`.

`[label,Score] = resubPredict(SVMModel)` additionally returns class likelihood measures, either scores or posterior probabilities.

Examples

Label Training Sample Observations for SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class.

```
SVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

`SVMModel` is a `ClassificationSVM` classifier.

Predict the training sample labels and scores. Display the results for the first 10 observations.

```
[label,score] = resubPredict(SVMModel);
table(Y(1:10),label(1:10),score(1:10,2),'VariableNames',...
    {'TrueLabel','PredictedLabel','Score'})
```

`ans=10×3 table`

TrueLabel	PredictedLabel	Score

Estimate In-Sample Posterior Probabilities of SVM Classifiers

Load the `ionosphere` data set.

```
load ionosphere
```

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class.

```
SVMMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

`SVMMModel` is a `ClassificationSVM` classifier.

Fit the optimal score-to-posterior-probability transformation function.

```
rng(1); % For reproducibility
ScoreSVMMModel = fitPosterior(SVMMModel)
```

```
ScoreSVMMModel =
  ClassificationSVM
      ResponseName: 'Y'
  CategoricalPredictors: []
      ClassNames: {'b' 'g'}
  ScoreTransform: '@(S)sigmoid(S,-9.481802e-01,-1.218745e-01)'
  NumObservations: 351

{'b'}	{'b'}	-2.7811	0.074805

Input Arguments

SVMMoDel — Full, trained SVM classifier

ClassificationSVM classifier

Full, trained SVM classifier, specified as a ClassificationSVM model trained with fitcsvm.

Output Arguments

label — Predicted class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of character vectors.

The predicted class labels have the following:

- Same data type as the observed class labels (SVMMoDel.Y)
- Length equal to the number of rows in SVMMoDel.X

For one-class learning, label contains the one class represented in SVMMoDel.Y.

Score — Predicted class scores or posterior probabilities

numeric column vector | numeric matrix

Predicted class scores on page 32-4910 or posterior probabilities on page 32-4910, returned as a numeric column vector or numeric matrix.

- For one-class learning, Score is a column vector with the same number of rows as SVMMoDel.X. The elements are the positive class scores for the corresponding observations. You cannot obtain posterior probabilities for one-class learning.
- For two-class learning, Score is a two-column matrix with the same number of rows as SVMMoDel.X.
 - If you fit the optimal score-to-posterior-probability transformation function using fitPosterior or fitSVMPosterior, then Score contains class posterior probabilities. That is, if the value of SVMMoDel.ScoreTransform is not none, then the first and second columns of Score contain the negative class (SVMMoDel.ClassNames{1}) and positive class (SVMMoDel.ClassNames{2}) posterior probabilities for the corresponding observations, respectively.
 - Otherwise, the first column contains the negative class scores and the second column contains the positive class scores for the corresponding observations.

If `SVMMoDel.KernelParameters.Function` is 'linear', then the classification score for the observation x is

$$f(x) = (x/s)\beta + b.$$

`SVMMoDel` stores β , b , and s in the properties `Beta`, `Bias`, and `KernelParameters.Scale`, respectively.

To estimate classification scores manually, you must first apply any transformations to the predictor data that were applied during training. Specifically, if you specify 'Standardize', true when using `fitsvm`, then you must standardize the predictor data manually by using the mean `SVMMoDel.Mu` and standard deviation `SVMMoDel.Sigma`, and then divide the result by the kernel scale in `SVMMoDel.KernelParameters.Scale`.

All SVM functions, such as `resubPredict` and `predict`, apply any required transformation before estimation.

If `SVMMoDel.KernelParameters.Function` is not 'linear', then `Beta` is empty (`[]`).

More About

Classification Score

The SVM classification score for classifying observation x is the signed distance from x to the decision boundary ranging from $-\infty$ to $+\infty$. A positive score for a class indicates that x is predicted to be in that class. A negative score indicates otherwise.

The positive class classification score $f(x)$ is the trained SVM classification function. $f(x)$ is also the numerical, predicted response for x , or the score for predicting x into the positive class.

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, \dots, \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations. The negative class classification score for x , or the score for predicting x into the negative class, is $-f(x)$.

If $G(x_j, x) = x_j'x$ (the linear kernel), then the score function reduces to

$$f(x) = (x/s)\beta + b.$$

s is the kernel scale and β is the vector of fitted linear coefficients.

For more details, see "Understanding Support Vector Machines" on page 18-145.

Posterior Probability

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For SVM, the posterior probability is a function of the score $P(s)$ that observation j is in class $k = \{-1, 1\}$.

- For separable classes, the posterior probability is the step function

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k = -1} s_k \\ \pi; & \max_{y_k = -1} s_k \leq s_j \leq \min_{y_k = +1} s_k, \\ 1; & s_j > \min_{y_k = +1} s_k \end{cases}$$

where:

- s_j is the score of observation j .
- $+1$ and -1 denote the positive and negative classes, respectively.
- π is the prior probability that an observation is in the positive class.
- For inseparable classes, the posterior probability is the sigmoid function

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)},$$

where the parameters A and B are the slope and intercept parameters, respectively.

Prior Probability

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

Tips

- If you are using a linear SVM model for classification and the model has many support vectors, then using `resubPredict` for the prediction method can be slow. To efficiently classify observations based on a linear SVM model, remove the support vectors from the model object by using `discardSupportVectors`.

Algorithms

- By default and irrespective of the model kernel function, MATLAB uses the dual representation of the score function to classify observations based on trained SVM models, specifically

$$\hat{f}(x) = \sum_{j=1}^n \hat{\alpha}_j y_j G(x, x_j) + \hat{b}.$$

This prediction method requires the trained support vectors and α coefficients (see the `SupportVectors` and `Alpha` properties of the SVM model).

- By default, the software computes optimal posterior probabilities using Platt's method [1]:

- 1 Perform 10-fold cross-validation.
- 2 Fit the sigmoid function parameters to the scores returned from the cross-validation.
- 3 Estimate the posterior probabilities by entering the cross-validation scores into the fitted sigmoid function.

- The software incorporates prior probabilities in the SVM objective function during training.
- For SVM, `predict` and `resubPredict` classify observations into the class yielding the largest score (the largest posterior probability). The software accounts for misclassification costs by

applying the average-cost correction before training the classifier. That is, given the class prior vector P , misclassification cost matrix C , and observation weight vector w , the software defines a new vector of observation weights (W) such that

$$W_j = w_j P_j \sum_{k=1}^K C_{jk}.$$

Introduced in R2014a

resubPredict

Class: ClassificationTree

Predict resubstitution labels of classification tree

Syntax

```
label = resubPredict(tree)
[label,posterior] = resubPredict(tree)
[label,posterior,node] = resubPredict(tree)
[label,posterior,node,cnum] = resubPredict(tree)
[label,...] = resubPredict(tree,Name,Value)
```

Description

`label = resubPredict(tree)` returns the labels `tree` predicts for the data `tree.X`. `label` is the predictions of `tree` on the data that `fitctree` used to create `tree`.

`[label,posterior] = resubPredict(tree)` returns the posterior class probabilities for the predictions.

`[label,posterior,node] = resubPredict(tree)` returns the node numbers of `tree` for the resubstituted data.

`[label,posterior,node,cnum] = resubPredict(tree)` returns the predicted class numbers for the predictions.

`[label,...] = resubPredict(tree,Name,Value)` returns resubstitution predictions with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

tree

A classification tree constructed by `fitctree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Subtrees — Pruning level

0 (default) | vector of nonnegative integers | 'all'

Pruning level, specified as the comma-separated pair consisting of 'Subtrees' and a vector of nonnegative integers in ascending order or 'all'.

If you specify a vector, then all elements must be at least 0 and at most `max(tree.PruneList)`. 0 indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify 'all', then `resubPredict` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`resubPredict` prunes `tree` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `tree` must be nonempty. In other words, grow `tree` by setting 'Prune', 'on', or by pruning `tree` using `prune`.

Example: 'Subtrees', 'all'

Data Types: `single` | `double` | `char` | `string`

Output Arguments

label

The response `tree` predicts for the training data. `label` is the same data type as the training response data `tree.Y`.

If the `Subtrees` name-value argument contains $m > 1$ entries, `label` has m columns, each of which represents the predictions of the corresponding subtree. Otherwise, `label` is a vector.

posterior

Matrix or array of posterior probabilities for classes `tree` predicts.

If the `Subtrees` name-value argument is a scalar or is missing, `posterior` is an n -by- k matrix, where n is the number of rows in the training data `tree.X`, and k is the number of classes.

If `Subtrees` contains $m > 1$ entries, `posterior` is an n -by- k -by- m array, where the matrix for each m gives posterior probabilities for the corresponding subtree.

node

The node numbers of `tree` where each data row resolves.

If the `Subtrees` name-value argument is a scalar or is missing, `node` is a numeric column vector with n rows, the same number of rows as `tree.X`.

If `Subtrees` contains $m > 1$ entries, `node` is a n -by- m matrix. Each column represents the node predictions of the corresponding subtree.

cnum

The class numbers that `tree` predicts for the resubstituted data.

If the `Subtrees` name-value argument is a scalar or is missing, `cnum` is a numeric column vector with n rows, the same number of rows as `tree.X`.

If `Subtrees` contains $m > 1$ entries, `cnum` is a n -by- m matrix. Each column represents the class predictions of the corresponding subtree.

Examples

Compute Number of Misclassified Observations

Find the total number of misclassifications of the Fisher iris data for a classification tree.

```
load fisheriris
tree = fitctree(meas,species);
Ypredict = resubPredict(tree); % The predictions
Ysame = strcmp(Ypredict,species); % True when ==
sum(~Ysame) % How many are different?

ans = 3
```

Compare In-Sample Posterior Probabilities for Each Subtree

Load Fisher's iris data set. Partition the data into training (50%)

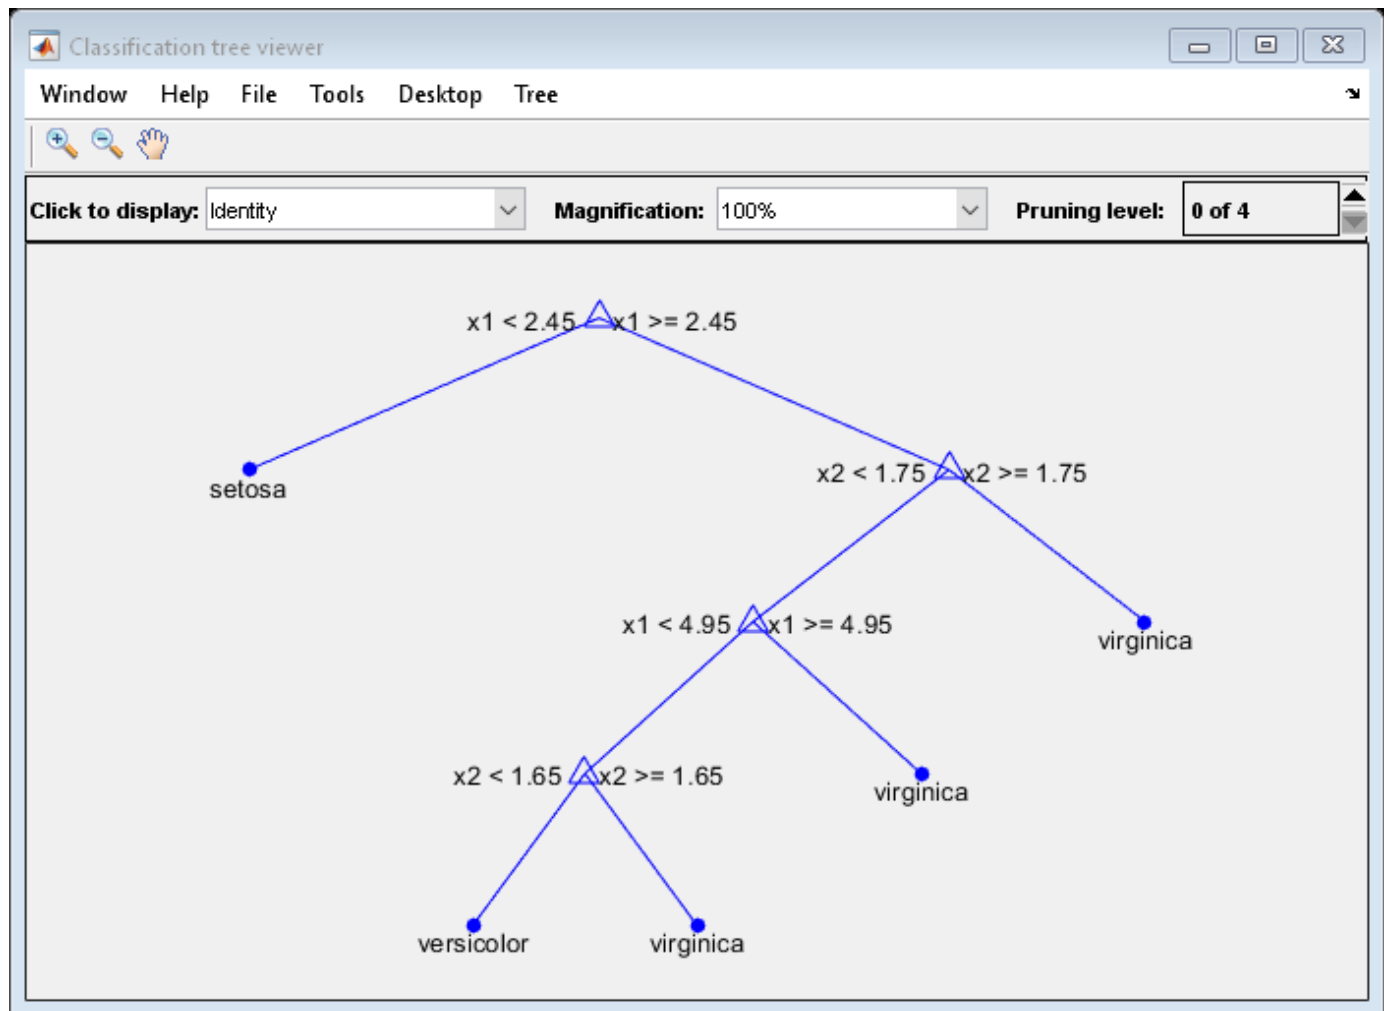

```
load fisheriris
```

Grow a classification tree using the all petal measurements.

```
Mdl = fitctree(meas(:,3:4),species);
n = size(meas,1); % Sample size
K = numel(Mdl.ClassNames); % Number of classes
```

View the classification tree.

```
view(Mdl, 'Mode', 'graph');
```

The classification tree has four pruning levels. Level 0 is the full, unpruned tree (as displayed). Level 4 is just the root node (i.e., no splits).

Estimate the posterior probabilities for each class using the subtrees pruned to levels 1 and 3.

```
[~,Posterior] = resubPredict(Mdl, 'SubTrees', [1 3]);
```

`Posterior` is an n -by- K -by- 2 array of posterior probabilities. Rows of `Posterior` correspond to observations, columns correspond to the classes with order `Mdl.ClassNames`, and pages correspond to pruning level.

Display the class posterior probabilities for iris 125 using each subtree.

```
Posterior(125, :, :)
```

```
ans =
ans(:, :, 1) =

    0    0.0217    0.9783
```

```
ans(:, :, 2) =
```

0 0.5000 0.5000

The decision stump (page 2 of `Posterior`) has trouble predicting whether iris 125 is versicolor or virginica.

More About

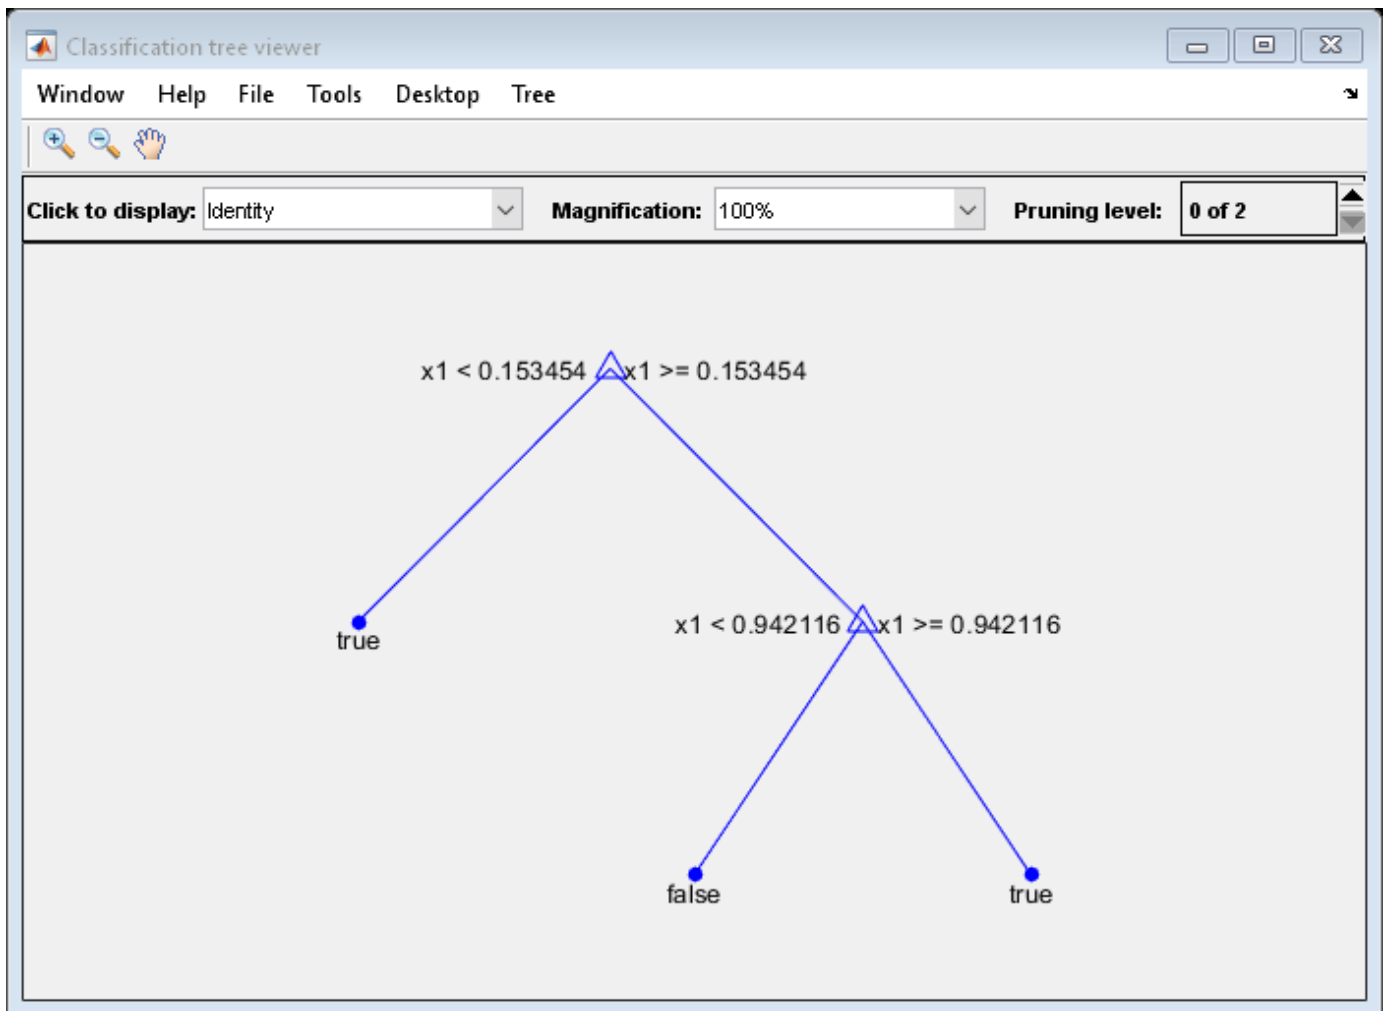

Posterior Probability

The posterior probability of the classification at a node is the number of training sequences that lead to that node with this classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor `X` as `true` when $X < 0.15$ or $X > 0.95$, and `X` is false otherwise.

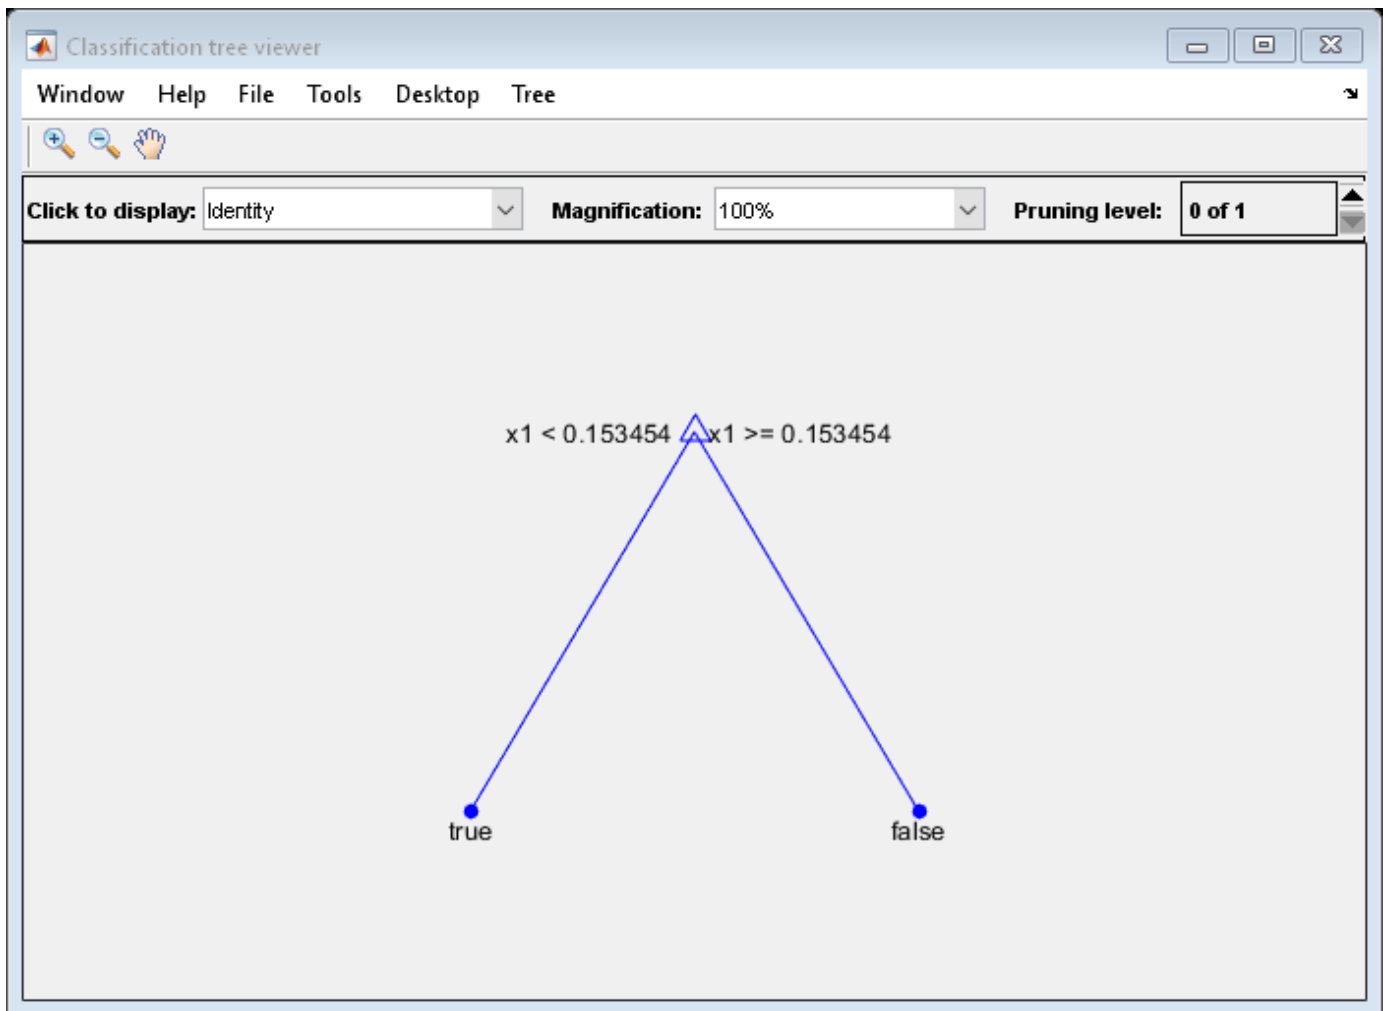

- 1 Generate 100 random points and classify them:

```
rng(0) % For reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree, 'Mode', 'graph')
```

2 Prune the tree:

```
tree1 = prune(tree,'Level',1);  
view(tree1,'Mode','graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations between .15 and .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore the score for observations that are greater than .15 should be about $.05/.85=.06$ for true, and about $.8/.85=.94$ for false.

- 3** Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans = 10x3
```

```
0.9059    0.0941    0.8147
0.9059    0.0941    0.9058
         0    1.0000    0.1270
0.9059    0.0941    0.9134
0.9059    0.0941    0.6324
         0    1.0000    0.0975
0.9059    0.0941    0.2785
0.9059    0.0941    0.5469
0.9059    0.0941    0.9575
```

0.9059 0.0941 0.9649

Indeed, every value of X (the rightmost column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.94 and 0.06.

resubPredict

Predict response of ensemble by resubstitution

Syntax

```
Yfit = resubPredict(ens)
Yfit = resubPredict(ens,Name,Value)
```

Description

`Yfit = resubPredict(ens)` returns the response `ens` predicts for the data `ens.X`. `Yfit` is the predictions of `ens` on the data that `fitrensemble` used to create `ens`.

`Yfit = resubPredict(ens,Name,Value)` predicts responses with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

`ens`

A regression ensemble created with `fitrensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `oobLoss` uses only these learners for calculating loss.

Default: `1:NumTrained`

Output Arguments

`Yfit`

A vector of predicted responses to the training data, with `ens.X` elements.

Examples

Find Mean-Squared Error of Resubstitution Predictions

Find the resubstitution predictions of mileage from the `carsmall` data, and look at their mean-squared difference from the training data.

Load the `carsmall` data set and select horsepower and vehicle weight as predictors.

```
load carsmall
X = [Horsepower Weight];
```

Train an ensemble of regression trees.

```
ens = fitensemble(X,MPG, 'Method', 'LSBoost', 'Learners', 'Tree');
```

Find the resubstitution predictions of MPG.

```
Yfit = resubPredict(ens);
```

Calculate the mean-squared difference of the resubstitution predictions from the training data.

```
MSE = mean((Yfit - ens.Y).^2)
```

```
MSE = 0.5836
```

Confirm that the result is the same as the result of `resubLoss`.

```
resubLoss(ens)
```

```
ans = 0.5836
```

See Also

`predict` | `resubLoss` | `resubPredict`

resubPredict

Class: RegressionGP

Resubstitution prediction from a trained Gaussian process regression model

Syntax

```
ypred = resubPredict(gprMdl)
[ypred,ysd] = resubPredict(gprMdl)
[ypred,ysd,yint] = predict(gprMdl)
[ypred,ysd,yint] = predict(gprMdl,Name,Value)
```

Description

`ypred = resubPredict(gprMdl)` returns the predicted responses, `ypred`, for the trained Gaussian process regression (GPR) model, `gprMdl`.

`[ypred,ysd] = resubPredict(gprMdl)` also returns the estimated standard deviations of the predicted responses corresponding to the rows of `gprMdl.X`.

`[ypred,ysd,yint] = predict(gprMdl)` also returns the 95% prediction intervals, `yint`, for the true responses corresponding to each row of training data, `gprMdl.X`.

`[ypred,ysd,yint] = predict(gprMdl,Name,Value)` returns the prediction intervals with additional options, specified by one or more `Name,Value` pair arguments. For example, you can specify the confidence level of the prediction interval.

Input Arguments

gprMdl — Gaussian process regression model

RegressionGP object

Gaussian process regression model, specified as a RegressionGP object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Alpha — Significance level

0.05 (default) | scalar value in the range from 0 to 1

Significance level for the prediction intervals, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range from 0 to 1.

Example: `'Alpha',0.01` specifies 99% prediction intervals.

Data Types: `single` | `double`

Output Arguments

ypred — Predicted response values

n-by-1 vector

Predicted response values, returned as an *n*-by-1 vector, where *n* is the number of observations in the training data.

ysd — Standard deviation of the predicted response values

n-by-1 vector

Standard deviation of the predicted response values corresponding to the rows of `gprMdl.X`, returned as an *n*-by-1 vector. `ysd(i)`, $i = 1, 2, \dots, n$, contains the estimated standard deviation of the new response corresponding to the predictor values at the i^{th} observation in the training data.

yint — Prediction intervals for the true response values

n-by-2 matrix

Prediction intervals for the true response values corresponding to the rows of `gprMdl.X`, returned as an *n*-by-2 matrix, where *n* is the number of observations in the training data. The first column of `yint` contains the lower limits and the second column contains the upper limits of the prediction intervals.

Examples

Plot Predicted Response and Prediction Intervals

This example uses "Housing" data set [1] from the UCI machine learning archive [2] described in <http://archive.ics.uci.edu/ml/datasets/Housing>. Download the data and save it in your current directory as a data file named `housing.data`.

The dataset has 506 observations. The first 13 columns contain the predictor values and the last column contains the response values. The goal is to predict the median value of owner-occupied homes in the Boston suburb area as a function of 13 predictors.

Load the data and define the response vector and predictor matrix.

```
load('housing.data');
X = housing(:,1:13);
y = housing(:,end);
```

Train a GPR model using subset of regressors ('sr') approximation method with Matern 3/2 ('Matern32') kernel function. Predict using the fully independent conditional ('fic') method.

```
gprMdl = fitrgp(X,y,'KernelFunction','Matern32',...
'FitMethod','sr','PredictMethod','fic');
```

Predict the responses using the trained GPR model. Compute the 99% prediction intervals.

```
[ypred,~,yint] = resubPredict(gprMdl,'Alpha',0.01);
```

Plot the actual response values along with predictions from the GPR model.

```
figure;
h1 = area([yint(:,1) yint(:,2)-yint(:,1)],-8,...
```

```

'FaceColor',[0.85,0.85,0.85], 'EdgeColor',[0.85,0.85,0.85]);
hold on;
h1(1).FaceColor = 'none'; % remove color from bottom area
h1(1).EdgeColor = 'none';
h2 = plot(y,'r'); % Plot original response values
h3 = plot(ypred,'b--'); % Plot predicted response values
legend([h2 h3 h1(2)], 'Actual response', 'Predicted response', ...
'Prediction intervals', 'Location', 'South');
axis([0 510 -7 65]);
hold off

```

The gray area shows the 99% prediction intervals.

Tips

- You can choose the prediction method while training the GPR model using the `PredictMethod` name-value pair argument in `fitrgp`. The default prediction method is 'exact' for $n \leq 10000$, where n is the number of observations in the training data, and 'bcd' (block coordinate descent), otherwise.
- Computation of standard deviations, `ysd`, and prediction intervals, `yint`, is not supported when `PredictMethod` is 'bcd'.

Alternatives

To compute the predicted responses for new data, use `predict`.

RegressionGP | fitrgp | predict | resubLoss

Introduced in R2015b

resubPredict

Class: RegressionSVM

Predict resubstitution response of support vector machine regression model

Syntax

```
yfit = resubPredict mdl
```

Description

`yfit = resubPredict(mdl)` returns a vector of predicted response values, `yfit`, for the trained support vector machine (SVM) regression model `mdl` using the predictor data stored in `mdl.X`.

Input Arguments

mdl — Full, trained SVM regression model

RegressionSVM model

Full, trained SVM regression model, specified as a RegressionSVM model returned by `fitrsvm`.

Output Arguments

yfit — Predicted response

vector of numeric values

Predicted responses, returned as a vector of numeric values. The length of `yfit` is equal to the number of observations in the training data, `mdl.NumObservations`.

For details about how to predict responses, see “Equation 25-1” and “Equation 25-2” in “Understanding Support Vector Machine Regression” on page 25-2.

Examples

Resubstitution Predictions for SVM Regression Model

This example shows how to train an SVM regression model, then use the model to generate predicted response values from the training data.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current directory with the name `'abalone.data'`. Read the data into a table.

```
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);  
rng default % for reproducibility
```

The sample data contains 4177 observations. All of the predictor variables are continuous except for `sex`, which is a categorical variable with possible values 'M' (for males), 'F' (for females), and 'I' (for infants). The goal is to predict the number of rings on the abalone, and thereby determine its age, using physical measurements.

Train an SVM regression model to the data, using a Gaussian kernel function with an automatic kernel scale. Standardize the data.

```
mdl = fitrsvm(tbl, 'Var9', 'KernelFunction', 'gaussian', 'KernelScale', 'auto', 'Standardize', true);
```

Use the trained model to predict response values based on the original data.

```
yfit = resubPredict(mdl);
```

Display the first ten predicted responses alongside the actual response values.

```
[mdl.Y(1:10), yfit(1:10)]
```

```
ans =
```

RegressionSVM | fitrsvm | predict | resubLoss

Introduced in R2015b

resubPredict

Class: RegressionTree

Predict resubstitution response of tree

Syntax

```
Yfit = resubPredict(tree)
[Yfit,node] = resubPredict(tree)
[Yfit,node] = resubPredict(tree,Name,Value)
```

Description

`Yfit = resubPredict(tree)` returns the responses `tree` predicts for the data `tree.X`. `Yfit` is the predictions of `tree` on the data that `fitrtree` used to create `tree`.

`[Yfit,node] = resubPredict(tree)` returns the node numbers of `tree` for the resubstituted data.

`[Yfit,node] = resubPredict(tree,Name,Value)` predicts with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

tree

A regression tree constructed using `fitrtree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Subtrees — Pruning level

0 (default) | vector of nonnegative integers | 'all'

Pruning level, specified as the comma-separated pair consisting of 'Subtrees' and a vector of nonnegative integers in ascending order or 'all'.

If you specify a vector, then all elements must be at least 0 and at most `max(tree.PruneList)`. 0 indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify 'all', then `resubPredict` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`resubPredict` prunes `tree` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `tree` must be nonempty. In other words, grow `tree` by setting `'Prune'`, `'on'`, or by pruning `tree` using `prune`.

Example: `'Subtrees','all'`

Data Types: `single | double | char | string`

Output Arguments

Yfit

The response `tree` predicts for the training data.

If the `Subtrees` name-value argument is a scalar or is missing, `label` is the same data type as the training response data `tree.Y`.

If `Subtrees` contains $m > 1$ entries, `label` has m columns, each of which represents the predictions of the corresponding subtree.

node

The `tree` node numbers where `tree` sends each data row.

If the `Subtrees` name-value argument is a scalar or is missing, `node` is a numeric column vector with n rows, the same number of rows as `tree.X`.

If `Subtrees` contains $m > 1$ entries, `node` is a n -by- m matrix. Each column represents the node predictions of the corresponding subtree.

Examples

Compute the In-Sample MSE

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using all observations.

```
Mdl = fitrtree(X,MPG);
```

Compute the resubstitution MSE.

```
Yfit = resubPredict(Mdl);
mean((Yfit - Mdl.Y).^2)
```

```
ans = 4.8952
```

You can get the same result using `resubLoss`.

```
resubLoss(Mdl)
```

```
ans = 4.8952
```

Estimate In-Sample Responses For Each Subtree

Load the `carsmall` data set. Consider `Weight` as a predictor of the response `MPG`.

```
load carsmall
idxNaN = isnan(MPG + Weight);
X = Weight(~idxNaN);
Y = MPG(~idxNaN);
n = numel(X);
```

Grow a regression tree using all observations.

```
Mdl = fitrtree(X,Y);
```

Compute resubstitution fitted values for the subtrees at several pruning levels.

```
m = max(Mdl.PruneList);
pruneLevels = 1:4:m; % Pruning levels to consider
z = numel(pruneLevels);
Yfit = resubPredict(Mdl, 'SubTrees',pruneLevels);
```

`Yfit` is an `n`-by-`z` matrix of fitted values in which the rows correspond to observations and the columns correspond to a subtree.

Plot several columns of `Yfit` and `Y` against `X`.

```
figure;
sortDat = sortrows([X Y Yfit],1); % Sort all data with respect to X
plot(repmat(sortDat(:,1),1,size(Yfit,2) + 1),sortDat(:,2:end))...
    % Vectorize for efficiency
lev = cellstr(num2str((pruneLevels)', 'Level %d MPG'));
legend(['Observed MPG'; lev])
title 'In-Sample Fitted Responses'
xlabel 'Weight (lbs)';
ylabel 'MPG';
h = findobj(gcf);
set(h(4:end), 'LineWidth',3) % Widen all lines
```

The values of `Yfit` for lower pruning levels tend to follow the data more closely than higher levels. Higher pruning levels tend to be flat for large `X` intervals.

`fitrtree` | `predict` | `resubLoss`

resume

Resume a Bayesian optimization

Syntax

```
newresults = resume(results,Name,Value)
```

Description

`newresults = resume(results,Name,Value)` resumes the optimization that produced `results` with additional options specified by one or more `Name,Value` pair arguments.

Examples

Resume a Bayesian Optimization

This example shows how to resume a Bayesian optimization. The optimization is for a deterministic function known as Rosenbrock's function, which is a well-known test case for nonlinear optimization. The function has a global minimum value of 0 at the point [1, 1].

Create two real variables bounded by -5 and 5.

```
x1 = optimizableVariable('x1',[-5,5]);
x2 = optimizableVariable('x2',[-5,5]);
vars = [x1,x2];
```

Create the objective function.

```
function f = rosenbrocks(x)
f = 100*(x.x2 - x.x1^2)^2 + (1 - x.x1)^2;
```

```
fun = @rosenbrocks;
```

For reproducibility, set the random seed, and set the acquisition function to 'expected-improvement-plus' in the optimization.

```
rng default
results = bayesopt(fun,vars,'Verbose',0,...
    'AcquisitionFunctionName','expected-improvement-plus');
```

View the best point found and the best modeled objective.

```
results.XAtMinObjective
results.MinEstimatedObjective
```

ans =

1x2 table

x1	x2
1.2421	1.5299

ans =

-9.5402

The best point is somewhat close to the optimum, but the function model is inaccurate. Resume the optimization for 30 more points (a total of 60 points), this time telling the optimizer that the objective function is deterministic.

```
newresults = resume(results, 'IsObjectiveDeterministic', true, 'MaxObjectiveEvaluations', 30);
newresults.XAtMinObjective
newresults.MinEstimatedObjective
```

ans =

1x2 table

x1	x2
1.0481	1.1027

ans =

-0.0040

The objective function model is much closer to the true function this time. The best point is closer to the true optimum.

Input Arguments

results — Bayesian optimization results

BayesianOptimization object

Bayesian optimization results, specified as a BayesianOptimization object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

You can use any name-value pair accepted by bayesopt except for those beginning with Initial. See the bayesopt “Input Arguments” on page 32-124.

Note The MaxObjectiveEvaluations and MaxTime name-value pairs mean *additional* time or evaluations, above the numbers stored in results. So, for example, the default number of evaluations is 30 in addition to the original specification.

Additionally, you can use the following name-value pair.

Example: `resume(results, 'MaxObjectiveEvaluations', 60)`

VariableDescriptions — Modify variable

`OptimizableVariable` object

Modify variable, specified as an `OptimizableVariable` object.

You can change only the following properties of a variable in an optimization.

- Range of real or integer variables. For example,

```
xvar = optimizableVariable('x', [-10, 10]);  
% Modify the range:  
xvar.Range = [1, 5];
```
- Type between 'integer' and 'real'. For example,

```
xvar.Type = 'integer';
```
- Transform of real or integer variables between 'log' and 'none'. For example,

```
xvar.Transform = 'log';
```

Output Arguments

newresults — Optimization results

`BayesianOptimization` object

Optimization results, returned as a `BayesianOptimization` object.

Introduced in R2016b

resume

Resume training ensemble

Syntax

```
ens1 = resume(ens,nlearn)
ens1 = resume(ens,nlearn,Name,Value)
```

Description

`ens1 = resume(ens,nlearn)` trains `ens` for `nlearn` more cycles. `resume` uses the same training options `fitcensemble` used to create `ens`.

Note You cannot resume training when `ens` is a `Subspace` ensemble created with `'AllPredictorCombinations'` number of learners.

`ens1 = resume(ens,nlearn,Name,Value)` trains `ens` with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

ens

A classification ensemble, created with `fitcensemble`.

nlearn

A positive integer, the number of cycles for additional training of `ens`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

nprint

Printout frequency, a positive integer scalar or `'off'` (no printouts). Returns to the command line the number of weak learners trained so far. Useful when you train ensembles with many learners on large data sets.

Default: `'off'`

Output Arguments

ens1

The classification ensemble `ens`, augmented with additional training.

Examples

Train Classification Ensemble for Additional Cycles

Train a classification ensemble for three cycles, and compare the resubstitution error obtained after training the ensemble for more cycles.

Load the `ionosphere` data set.

```
load ionosphere
```

Train a classification ensemble for three cycles and examine the resubstitution error.

```
ens = fitcensemble(X,Y,'Method','GentleBoost','NumLearningCycles',3);  
L = resubLoss(ens)
```

```
L = 0.0114
```

Train for three more cycles and examine the new resubstitution error.

```
ens1 = resume(ens,3);  
L = resubLoss(ens1)
```

```
L = 0
```

The resubstitution error is much lower in the new ensemble than the original.

See Also

`fitcensemble`

resume

Resume training learners on cross-validation folds

Syntax

```
ens1 = resume(ens,nlearn)
ens1 = resume(ens,nlearn,Name,Value)
```

Description

`ens1 = resume(ens,nlearn)` trains `ens` in every fold for `nlearn` more cycles. `resume` uses the same training options `fitcensemble` used to create `ens`.

`ens1 = resume(ens,nlearn,Name,Value)` trains `ens` with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`ens`

A cross-validated classification ensemble. `ens` is the result of either:

- The `fitcensemble` function with a cross-validation name-value pair. The names are 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'.
- The `crossval` method applied to a classification ensemble.

`nlearn`

A positive integer, the number of cycles for additional training of `ens`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`nprint`

Printout frequency, a positive integer scalar or 'off' (no printouts). Returns to the command line the number of weak learners trained so far. Useful when you train ensembles with many learners on large data sets.

Default: 'off'

Output Arguments

`ens1`

The cross-validated classification ensemble `ens`, augmented with additional training.

Examples

Train Partitioned Classification Ensemble for More Cycles

Train a partitioned classification ensemble for 10 cycles, and compare the classification loss obtained after training the ensemble for more cycles.

Load the `ionosphere` data set.

```
load ionosphere
```

Train a partitioned classification ensemble for 10 cycles and examine the error.

```
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
cvens = fitcensemble(X,Y,'Method','GentleBoost','NumLearningCycles',10,'Learners',t,'crossval','on',
rng(10,'twister') % For reproducibility
L = kfoldLoss(cvens)
```

```
L = 0.0940
```

Train for 10 more cycles and examine the new error.

```
cvens = resume(cvens,10);
L = kfoldLoss(cvens)
```

```
L = 0.0712
```

The cross-validation error is lower in the ensemble after training for 10 more cycles.

`kfoldEdge` | `kfoldLoss` | `kfoldMargin` | `kfoldPredict`

resume

Resume training support vector machine (SVM) classifier

Syntax

```
UpdatedSVMModel = resume(SVMModel,numIter)
UpdatedSVMModel = resume(SVMModel,numIter,Name,Value)
```

Description

`UpdatedSVMModel = resume(SVMModel,numIter)` returns an updated support vector machine (SVM) classifier `UpdatedSVMModel` by training the SVM classifier `SVMModel` for `numIter` more iterations. Like `SVMModel`, the updated SVM classifier is a `ClassificationSVM` classifier.

`resume` continues applying the training options set when `SVMModel` was trained with `fitsvm`.

`UpdatedSVMModel = resume(SVMModel,numIter,Name,Value)` returns `UpdatedSVMModel` with additional options specified by one or more name-value pair arguments. For example, you can specify the verbosity level.

Examples

Resume Training SVM Classifier

Train an SVM classifier and intentionally cause the solver to fail to converge onto a solution. Then resume training the classifier without having to restart the entire learning process.

Load the `ionosphere` data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify that the optimization routine uses at most 50 iterations.

```
SVMModel = fitsvm(X,Y,'IterationLimit',50);
DidConverge = SVMModel.ConvergenceInfo.Converged
```

```
DidConverge = logical
             0
```

```
Reason = SVMModel.ConvergenceInfo.ReasonForConvergence
```

```
Reason =
'NoConvergence'
```

`DidConverge = 0` indicates that the optimization routine did not converge onto a solution. `Reason` states the reason why the routine did not converge. Therefore, `SVMModel` is a partially trained SVM classifier.

Resume training the SVM classifier for another 1500 iterations.

```
UpdatedSVMModel = resume(SVMModel,1500);
DidConverge = UpdatedSVMModel.ConvergenceInfo.Converged
```

```
DidConverge = logical
            1
```

```
Reason = UpdatedSVMModel.ConvergenceInfo.ReasonForConvergence
```

```
Reason =
'DeltaGradient'
```

`DidConverge` indicates that the optimization routine converged onto a solution. `Reason` indicates that the gradient difference (`DeltaGradient`) reached its tolerance level (`DeltaGradientTolerance`). Therefore, `SVMModel` is a fully trained SVM classifier.

Monitor Training of SVM Classifier

Train an SVM classifier and intentionally cause the solver to fail to converge onto a solution. Then resume training the classifier without having to restart the entire learning process. Compare values of the resubstitution loss for the partially trained classifier and the fully trained classifier.

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. Specify that the optimization routine uses at most 100 iterations. Monitor the algorithm specifying that the software prints diagnostic information every 50 iterations.

```
SVMModel = fitcsvm(X,Y,'IterationLimit',100,'Verbose',1,'NumPrint',50);
```

```
=====
| Iteration | Set | Set Size | Feasibility | Delta | KKT | Number o |
|           |    |         | Gap          | Gradient | Violation | Supp. Vec |
|=====|=====|=====|=====|=====|=====|=====|
|           0 | active | 351 | 9.971591e-01 | 2.000000e+00 | 1.000000e+00 |
|           50 | active | 351 | 8.064425e-01 | 3.736929e+00 | 2.161317e+00 |
|=====|=====|=====|=====|=====|=====|
```

SVM optimization did not converge to the required tolerance.

The software prints an iterative display to the Command Window. The printout indicates that the optimization routine has not converged onto a solution.

Estimate the resubstitution loss of the partially trained SVM classifier.

```
partialLoss = resubLoss(SVMModel)
```

```
partialLoss = 0.1054
```

The training sample misclassification error is approximately 12%.

Resume training the classifier for another 1500 iterations. Specify that the software print diagnostic information every 250 iterations.

```
UpdatedSVMModel = resume(SVMModel,1500,'NumPrint',250)
```

Iteration	Set	Set Size	Feasibility Gap	Delta Gradient	KKT Violation	Number of Supp. Vec
250	active	351	1.441556e-01	1.701201e+00	1.015454e+00	
500	active	351	3.277736e-03	9.155364e-02	4.830095e-02	
750	active	351	3.928360e-04	1.367091e-02	9.155316e-03	
1000	active	351	4.802547e-05	1.551900e-03	7.765843e-04	
1044	active	351	3.602828e-05	9.382457e-04	5.182592e-04	

Exiting Active Set upon convergence due to DeltaGradient.

```
UpdatedSVMModel =
  ClassificationSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
    NumObservations: 351
    Alpha: [103x1 double]
    Bias: -3.8828
    KernelParameters: [1x1 struct]
    BoxConstraints: [351x1 double]
    ConvergenceInfo: [1x1 struct]
    IsSupportVector: [351x1 logical]
    Solver: 'SMO'
```

Properties, Methods

The software resumes at iteration 1000 and uses the same verbosity level as the one set when you trained the model using `fitsvm`. The printout indicates that the algorithm converged. Therefore, `UpdatedSVMModel` is a fully trained `ClassificationSVM` classifier.

```
updatedLoss = resubLoss(UpdatedSVMModel)
```

```
updatedLoss = 0.0769
```

The training sample misclassification error of the fully trained classifier is approximately 8%.

Input Arguments

SVMModel — Full, trained SVM classifier

`ClassificationSVM` classifier

Full, trained SVM classifier, specified as a `ClassificationSVM` model trained with `fitsvm`.

numIter — Number of iterations

positive integer

Number of iterations to continue training the SVM classifier, specified as a positive integer.

Data Types: double

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `resume(SVMModel, 500, 'Verbose', 2)` trains `SVMModel` for 500 more iterations and specifies displaying diagnostic messages and saving convergence criteria at every iteration.

Verbose – Verbosity level

0 | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and 0, 1, or 2. `Verbose` controls the amount of optimization information displayed in the Command Window and saved as a structure to `SVMModel.ConvergenceInfo.History`.

This table summarizes the verbosity level values.

Value	Description
0	The software does not display or save convergence information.
1	The software displays diagnostic messages and saves convergence criteria every <i>numprint</i> iterations, where <i>numprint</i> is the value of the <code>'NumPrint'</code> name-value pair argument.
2	The software displays diagnostic messages and saves convergence criteria at every iteration.

By default, `Verbose` is the value that `fitcsvm` uses to train `SVMModel`.

Example: `'Verbose', 1`

Data Types: `single`

NumPrint – Number of iterations between diagnostic message printouts

nonnegative integer

Number of iterations between diagnostic message printouts, specified as the comma-separated pair consisting of `'NumPrint'` and a nonnegative integer.

If you set `'Verbose', 1` and `'NumPrint', numprint`, then the software displays all optimization diagnostic messages from SMO [1] and ISDA [2] every *numprint* iterations in the Command Window.

By default, `NumPrint` is the value that `fitcsvm` uses to train `SVMModel`.

Example: `'NumPrint', 500`

Data Types: `single`

Tips

If optimization does not converge and the solver is `'SMO'` or `'ISDA'`, then try to resume training the SVM classifier.

resume

Resume training ensemble

Syntax

```
ens1 = resume(ens,nlearn)
ens1 = resume(ens,nlearn,Name,Value)
```

Description

`ens1 = resume(ens,nlearn)` trains `ens` for `nlearn` more cycles. `resume` uses the same training options `fitrensemble` used to create `ens`.

`ens1 = resume(ens,nlearn,Name,Value)` trains `ens` with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

ens

A regression ensemble, created with `fitrensemble`.

nlearn

A positive integer, the number of cycles for additional training of `ens`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

nprint

Printout frequency, a positive integer scalar or `'off'` (no printouts). Returns to the command line the number of weak learners trained so far. Useful when you train ensembles with many learners on large data sets.

Default: `'off'`

Output Arguments

ens1

The regression ensemble `ens`, augmented with additional training.

Examples

Train Regression Ensemble for Additional Cycles

Train a regression ensemble for 50 cycles, and compare the resubstitution error obtained after training the ensemble for more cycles.

Load the `carsmall` data set and select displacement, horsepower, and vehicle weight as predictors.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Train a regression ensemble for 50 cycles and examine the resubstitution error.

```
ens = fitensemble(X,MPG,'NumLearningCycles',50);
L = resubLoss(ens)
```

```
L = 0.5563
```

Train for 50 more cycles and examine the new resubstitution error.

```
ens = resume(ens,50);
L = resubLoss(ens)
```

```
L = 0.3463
```

The resubstitution error is lower in the new ensemble than in the original.

See Also

`fitensemble`

resume

Resume training ensemble

Syntax

```
ens1 = resume(ens,nlearn)
ens1 = resume(ens,nlearn,Name,Value)
```

Description

`ens1 = resume(ens,nlearn)` trains `ens` in every fold for `nlearn` more cycles. `resume` uses the same training options `fitrensemble` used to create `ens`.

`ens1 = resume(ens,nlearn,Name,Value)` trains `ens` with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

ens

A cross-validated regression ensemble. `ens` is the result of either:

- The `fitrensemble` function with a cross-validation name-value pair. The names are 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'.
- The `crossval` method applied to a regression ensemble.

nlearn

A positive integer, the number of cycles for additional training of `ens`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

nprint

Printout frequency, a positive integer scalar or 'off' (no printouts). Returns to the command line the number of weak learners trained so far. Useful when you train ensembles with many learners on large data sets.

Default: 'off'

Output Arguments

ens1

The cross-validated regression ensemble `ens`, augmented with additional training.

Examples

Cross-Validate Regression Ensemble Augmented with Additional Training

Examine the cross-validation error after training a regression ensemble for more cycles.

Load the `carsmall` data set and select displacement, horsepower, and vehicle weight as predictors.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Train a regression ensemble for 50 cycles.

```
ens = fitensemble(X,MPG,'NumLearningCycles',50);
```

Cross-validate the ensemble and examine the cross-validation error.

```
rng(10,'twister') % For reproducibility
cvens = crossval(ens);
L = kfoldLoss(cvens)
```

```
L = 27.9435
```

Train for 50 more cycles and examine the new cross-validation error.

```
cvens = resume(cvens,50);
L = kfoldLoss(cvens)
```

```
L = 28.7114
```

The additional training did not improve the cross-validation error.

See Also

resume

Class: RegressionSVM

Resume training support vector machine regression model

Syntax

```
updatedMdl = resume(mdl,numIter)
updatedMdl = resume(mdl,numIter,Name,Value)
```

Description

`updatedMdl = resume(mdl,numIter)` returns an updated support vector machine (SVM) regression model, `updatedMdl`, by training the model for an additional number of iterations as specified by `numIter`.

`resume` applies the same training options to `updatedMdl` that you set when using `fitrsvm` to train `mdl`.

`updatedMdl = resume(mdl,numIter,Name,Value)` returns an updated SVM regression model with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

mdl — Full, trained SVM regression model

RegressionSVM model

Full, trained SVM regression model, specified as a RegressionSVM model trained using `fitrsvm`.

numIter — Number of iterations

positive integer value

Number of iterations to continue training the SVM regression model, specified as a positive integer value.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Verbose — Verbosity level

0 | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and either 0, 1, or 2. `Verbose` controls the amount of optimization information that the software displays to the Command Window and is saved in the model as `mdl.ModelParameters.VerbosityLevel`.

By default, `Verbose` is the value that `fitrsvm` used to train `mdl`.

Example: 'Verbose',1

Data Types: single | double

NumPrint — Number of iterations between diagnostic message printouts

nonnegative integer value

Number of iterations between diagnostic message printouts, specified as the comma-separated pair consisting of 'NumPrint' and a nonnegative integer.

If you set 'Verbose',1 and 'NumPrint',*numprint*, then the software displays optimization diagnostic messages to the Command Window every *numprint* number of iterations .

By default, NumPrint is the value that `fitrsvm` used to train `mdl`.

Example: 'NumPrint',500

Data Types: single | double

Output Arguments

updatedMdl — Updated SVM regression model

RegressionSVM model

Updated SVM regression model, returned as a RegressionSVM model.

Examples

Resume Training an SVM Regression Model

This example shows how to resume training an SVM regression model that failed to converge without restarting the entire learning process.

Load the `carsmall` data set.

```
load carsmall
rng default % for reproducibility
```

Specify `Acceleration`, `Cylinders`, `Displacement`, `Horsepower`, and `Weight` as the predictor variables (X) and `MPG` as the response variable (Y).

```
X = [Acceleration,Cylinders,Displacement,Horsepower,Weight];
Y = MPG;
```

Train a linear SVM regression model. For illustration purposes, set the iteration limit to 50. Standardize the data.

```
mdl = fitrsvm(X,Y,'IterationLimit',50,'Standardize',true);
```

Check to confirm whether the model converged.

```
mdl.ConvergenceInfo.Converged
```

```
ans =
```

```
0
```

The returned value of 0 indicates that the model did not converge.

Resume training the model for up to an additional 100 iterations.

```
updatedMdl = resume mdl, 100;
```

Check to confirm whether the updated model converged.

```
updatedMdl.ConvergenceInfo.Converged
```

```
ans =
```

```
1
```

The returned value of 1 indicates that the updated model did converge.

Check the reason for convergence and the total number of iterations required.

```
updatedMdl.ConvergenceInfo.ReasonForConvergence  
updatedMdl.NumIterations
```

```
ans =
```

```
FeasibilityGap
```

```
ans =
```

```
97
```

The model converged because the feasibility gap reached its tolerance value after 97 iterations.

Tips

If optimization has not converged and 'Solver' is set to 'SMO' or 'ISDA', then try to resume training the SVM regression model.

Introduced in R2015b

rica

Feature extraction by using reconstruction ICA

Syntax

```
Mdl = rica(X,q)
Mdl = rica(X,q,Name,Value)
```

Description

`Mdl = rica(X,q)` returns a reconstruction independent component analysis (RICA) model object that contains the results from applying RICA to the table or matrix of predictor data `X` containing p variables. `q` is the number of features to extract from `X`, therefore `rica` learns a p -by- q matrix of transformation weights. For undercomplete or overcomplete feature representations, `q` can be less than or greater than the number of predictor variables, respectively.

- To access the learned transformation weights, use `Mdl.TransformWeights`.
- To transform `X` to the new set of features by using the learned transformation, pass `Mdl` and `X` to `transform`.

`Mdl = rica(X,q,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, you can standardize the predictor data or specify the value of the penalty coefficient in the reconstruction term of the objective function.

Examples

Create Reconstruction ICA Object

Create a `ReconstructionICA` object by using the `rica` function.

Load the `SampleImagePatches` image patches.

```
data = load('SampleImagePatches');
size(data.X)
```

```
ans = 1×2
```

```
    5000    363
```

There are 5,000 image patches, each containing 363 features.

Extract 100 features from the data.

```
rng default % For reproducibility
q = 100;
Mdl = rica(data.X,q,'IterationLimit',100)
```

Warning: Solver LBFGS was not able to converge to a solution.

```
Mdl =
  ReconstructionICA
    ModelParameters: [1x1 struct]
    NumPredictors: 363
    NumLearnedFeatures: 100
    Mu: []
    Sigma: []
    FitInfo: [1x1 struct]
    TransformWeights: [363x100 double]
    InitialTransformWeights: []
    NonGaussianityIndicator: [100x1 double]
```

Properties, Methods

`rica` issues a warning because it stopped due to reaching the iteration limit, instead of reaching a step-size limit or a gradient-size limit. You can still use the learned features in the returned object by calling the `transform` function.

Input Arguments

X — Predictor data

numeric matrix | table

Predictor data, specified as an n -by- p numeric matrix or table. Rows correspond to individual observations and columns correspond to individual predictor variables. If X is a table, then all of its variables must be numeric vectors.

Data Types: `single` | `double` | `table`

q — Number of features to extract

positive integer

Number of features to extract from the predictor data, specified as a positive integer.

`rica` stores a p -by- q transform weight matrix in `Mdl.TransformWeights`. Therefore, setting very large values for q can result in greater memory consumption and increased computation time.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `Mdl = rica(X,q,'IterationLimit',200,'Standardize',true)` runs `rica` with optimization iterations limited to 200 and standardized predictor data.

IterationLimit — Maximum number of iterations

1000 (default) | positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer.

Example: 'IterationLimit',1e6

Data Types: single | double

VerbosityLevel – Verbosity level

0 (default) | nonnegative integer

Verbosity level for monitoring algorithm convergence, specified as the comma-separated pair consisting of 'VerbosityLevel' and a value in this table.

Value	Description
0	rica does not display convergence information at the command line.
Positive integer	rica displays convergence information at the command line.

Convergence Information

Heading	Meaning
FUN VALUE	Objective function value.
NORM GRAD	Norm of the gradient of the objective function.
NORM STEP	Norm of the iterative step, meaning the distance between the previous point and the current point.
CURV	OK means the weak Wolfe condition is satisfied. This condition is a combination of sufficient decrease of the objective function and a curvature condition.
GAMMA	Inner product of the step times the gradient difference, divided by the inner product of the gradient difference with itself. The gradient difference is the gradient at the current point minus the gradient at the previous point. Gives diagnostic information on the objective function curvature.
ALPHA	Step direction multiplier, which differs from 1 when the algorithm performed a line search.
ACCEPT	YES means the algorithm found an acceptable step to take.

Example: 'VerbosityLevel',1

Data Types: single | double

Lambda – Regularization coefficient value

1 (default) | positive numeric scalar

Regularization coefficient value for the transform weight matrix, specified as the comma-separated pair consisting of 'Lambda' and a positive numeric scalar. If you specify 0, then there is no regularization term in the objective function.

Example: 'Lambda',0.1

Data Types: single | double

Standardize – Flag to standardize predictor data

false (default) | true

Flag to standardize the predictor data, specified as the comma-separated pair consisting of 'Standardize' and true (1) or false (0).

If Standardize is true, then:

- `rica` centers and scales each column of the predictor data (X) by the column mean and standard deviation, respectively.
- `rica` extracts new features by using the standardized predictor matrix, and stores the predictor variable means and standard deviations in properties `Mu` and `Sigma` of `Mdl`.

Example: 'Standardize', true

Data Types: logical

ContrastFcn — Contrast function

'logcosh' (default) | 'exp' | 'sqrt'

Contrast function, specified as 'logcosh', 'exp', or 'sqrt'. The contrast function is a smooth function that is similar to an absolute value function. The `rica` objective function contains a term

$$\sum_{j=1}^q \frac{1}{n} \sum_{i=1}^n g(w_j^T \tilde{x}_i),$$

where g represents the contrast function, the w_j are the variables over which the optimization takes place, and the \tilde{x}_i are data.

The three available contrast functions are:

- 'logcosh' — $g = \frac{1}{2} \log(\cosh(2x))$
- 'exp' — $g = -\exp\left(-\frac{x^2}{2}\right)$
- 'sqrt' — $g = \sqrt{x^2 + 10^{-8}}$

Example: 'ContrastFcn', 'exp'

InitialTransformWeights — Transformation weights that initialize optimization

`randn(p, q)` (default) | numeric matrix

Transformation weights that initialize optimization, specified as the comma-separated pair consisting of 'InitialTransformWeights' and a p -by- q numeric matrix. p must be the number of columns or variables in X and q is the value of q .

Tip You can continue optimizing a previously returned transform weight matrix by passing it as an initial value in another call to `rica`. The output model object `Mdl` stores a learned transform weight matrix in the `TransformWeights` property.

Example: 'InitialTransformWeights', `Mdl.TransformWeights`

Data Types: single | double

NonGaussianityIndicator — Non-Gaussianity of sources`ones(q, 1)` (default) | length-q vector of ± 1 Non-Gaussianity of sources, specified as a length-q vector of ± 1 .

- `NonGaussianityIndicator(k) = 1` means `rica` models the *k*th source as super-Gaussian, with a sharp peak at 0.
- `NonGaussianityIndicator(k) = -1` means `rica` models the *k*th source as sub-Gaussian.

Data Types: `single` | `double`**GradientTolerance — Relative convergence tolerance on gradient norm**`1e-6` (default) | positive numeric scalarRelative convergence tolerance on gradient norm, specified as the comma-separated pair consisting of `'GradientTolerance'` and a positive numeric scalar. This gradient is the gradient of the objective function.Example: `'GradientTolerance', 1e-4`Data Types: `single` | `double`**StepTolerance — Absolute convergence tolerance on step size**`1e-6` (default) | positive numeric scalarAbsolute convergence tolerance on the step size, specified as the comma-separated pair consisting of `'StepTolerance'` and a positive numeric scalar.Example: `'StepTolerance', 1e-4`Data Types: `single` | `double`**Output Arguments****Mdl — Learned reconstruction ICA model**`ReconstructionICA` model objectLearned reconstruction ICA model, returned as a `ReconstructionICA` model object.To access properties of `Mdl`, use dot notation. For example:

- To access the learned transform weights, use `Mdl.TransformWeights`.
- To access the structure of fitting information, use `Mdl.FitInfo`.

AlgorithmsThe `rica` function creates a linear transformation of input features to output features. The transformation is based on optimizing a nonlinear objective function that roughly balances statistical independence of the output features versus the ability to reconstruct the input data using the output features.

For details, see “Reconstruction ICA Algorithm” on page 15-132.

Introduced in R2017a

ridge

Ridge regression

Syntax

```
B = ridge(y,X,k)
B = ridge(y,X,k,scaled)
```

Description

`B = ridge(y,X,k)` returns coefficient estimates for ridge regression models on page 32-4965 of the predictor data `X` and the response `y`. Each column of `B` corresponds to a particular ridge parameter `k`. By default, the function computes `B` after centering and scaling the predictors to have mean 0 and standard deviation 1. Because the model does not include a constant term, do not add a column of 1s to `X`.

`B = ridge(y,X,k,scaled)` specifies the scaling for the coefficient estimates in `B`. When `scaled` is 1 (default), `ridge` does not restore the coefficients to the original data scale. When `scaled` is 0, `ridge` restores the coefficients to the scale of the original data. For more information, see “Coefficient Scaling” on page 32-4966.

Examples

Ridge Regression

Perform ridge regression for a range of ridge parameters and observe how the coefficient estimates change.

Load the `acetylene` data set.

```
load acetylene
```

`acetylene` contains observations for the predictor variables `x1`, `x2`, and `x3`, and the response variable `y`.

Plot the predictor variables against each other. Observe any correlation between the variables.

```
plotmatrix([x1 x2 x3])
```

For example, note the linear correlation between x_1 and x_3 .

Compute coefficient estimates for a multilinear model with interaction terms, for a range of ridge parameters. Use `x2fx` to create interaction terms and `ridge` to perform ridge regression.

```
X = [x1 x2 x3];
D = x2fx(X, 'interaction');
D(:,1) = []; % No constant term
k = 0:1e-5:5e-3;
B = ridge(y,D,k);
```

Plot the ridge trace.

```
figure
plot(k,B, 'LineWidth',2)
ylim([-100 100])
grid on
xlabel('Ridge Parameter')
ylabel('Standardized Coefficient')
title('Ridge Trace')
legend('x1', 'x2', 'x3', 'x1x2', 'x1x3', 'x2x3')
```

The estimates stabilize to the right of the plot. Note that the coefficient of the x_2x_3 interaction term changes sign at a value of the ridge parameter $\approx 5 \times 10^{-4}$.

Predict Values Using Ridge Regression

Predict miles per gallon (MPG) values using ridge regression.

Load the carbig data set.

```
load carbig
X = [Acceleration Weight Displacement Horsepower];
y = MPG;
```

Split the data into training and test sets.

```
n = length(y);
rng('default') % For reproducibility
c = cvpartition(n,'HoldOut',0.3);
idxTrain = training(c,1);
idxTest = ~idxTrain;
```

Find the coefficients of a ridge regression model (with $k = 5$).

```
k = 5;
b = ridge(y(idxTrain),X(idxTrain,:),k,0);
```

Predict MPG values for the test data using the model.

```
yhat = b(1) + X(idxTest,:)*b(2:end);
```

Compare the predicted values to the actual miles per gallon (MPG) values using a reference line.

```
scatter(y(idxTest),yhat)
hold on
plot(y(idxTest),y(idxTest))
xlabel('Actual MPG')
ylabel('Predicted MPG')
hold off
```

Input Arguments

y — Response data

numeric vector

Response data, specified as an n -by-1 numeric vector, where n is the number of observations.

Data Types: `single` | `double`

X — Predictor data

numeric matrix

Predictor data, specified as an n -by- p numeric matrix. The rows of X correspond to the n observations, and the columns of X correspond to the p predictors.

Data Types: `single` | `double`

k — Ridge parameters

numeric vector

Ridge parameters, specified as a numeric vector.

Example: `[0.2 0.3 0.4 0.5]`

Data Types: `single` | `double`

scaled — Scaling flag

1 (default) | 0

Scaling flag that determines whether the coefficient estimates in **B** are restored to the scale of the original data, specified as either 0 or 1. If `scaled` is 0, then `ridge` performs this additional transformation. In this case, **B** contains $p+1$ coefficients for each value of **k**, with the first row of **B** corresponding to a constant term in the model. If `scaled` is 1, then the software omits the additional transformation, and **B** contains p coefficients without a constant term coefficient.

Output Arguments

B — Coefficient estimates

numeric matrix

Coefficient estimates, returned as a numeric matrix. The rows of **B** correspond to the predictors in **X**, and the columns of **B** correspond to the ridge parameters **k**.

If `scaled` is 1, then **B** is a p -by- m matrix, where m is the number of elements in **k**. If `scaled` is 0, then **B** is a $(p+1)$ -by- m matrix.

More About

Ridge Regression

Ridge regression is a method for estimating coefficients of linear models that include linearly correlated predictors.

Coefficient estimates for multiple linear regression models rely on the independence of the model terms. When terms are correlated and the columns of the design matrix **X** have an approximate linear dependence, the matrix $(X^T X)^{-1}$ is close to singular. Therefore, the least-squares estimate

$$\hat{\beta} = (X^T X)^{-1} X^T y$$

is highly sensitive to random errors in the observed response **y**, producing a large variance. This situation of multicollinearity can arise, for example, when you collect data without an experimental design.

Ridge regression addresses the problem of multicollinearity by estimating regression coefficients using

$$\hat{\beta} = (X^T X + kI)^{-1} X^T y$$

where k is the ridge parameter and I is the identity matrix. Small, positive values of k improve the conditioning of the problem and reduce the variance of the estimates. While biased, the reduced

variance of ridge estimates often results in a smaller mean squared error when compared to least-squares estimates.

Coefficient Scaling

The scaling of the coefficient estimates for the ridge regression models depends on the value of the scaled input argument.

Suppose the ridge parameter k is equal to 0. The coefficients returned by `ridge`, when scaled is equal to 1, are estimates of the b_i^1 in the multilinear model

$$y - \mu_y = b_1^1 z_1 + \dots + b_p^1 z_p + \varepsilon$$

where $z_i = (x_i - \mu_i)/\sigma_i$ are the centered and scaled predictors, $y - \mu_y$ is the centered response, and ε is an error term. You can rewrite the model as

$$y = b_0^0 + b_1^0 x_1 + \dots + b_p^0 x_p + \varepsilon$$

with $b_0^0 = \mu_y - \sum_{i=1}^p \frac{b_i^1 \mu_i}{\sigma_i}$ and $b_i^0 = \frac{b_i^1}{\sigma_i}$. The b_i^0 terms correspond to the coefficients returned by `ridge` when scaled is equal to 0.

More generally, for any value of k , if `B1 = ridge(y,X,k,1)`, then

```
m = mean(X);
s = std(X,0,1)';
B1_scaled = B1./s;
B0 = [mean(y)-m*B1_scaled; B1_scaled]
```

where `B0 = ridge(y,X,k,0)`.

Tips

- `ridge` treats NaN values in X or y as missing values. `ridge` omits observations with missing values from the ridge regression fit.
- In general, set `scaled` equal to 1 to produce plots where the coefficients are displayed on the same scale. See “Ridge Regression” on page 32-4961 for an example using a ridge trace plot, where the regression coefficients are displayed as a function of the ridge parameter. When making predictions, set `scaled` equal to 0. For an example, see “Predict Values Using Ridge Regression” on page 32-4963.

Alternative Functionality

- Ridge, lasso, and elastic net regularization are all methods for estimating the coefficients of a linear model while penalizing large coefficients. The type of penalty depends on the method (see “More About” on page 32-2995 for more details). To perform lasso or elastic net regularization, use `lasso` instead.
- If you have high-dimensional full or sparse predictor data, you can use `fitrlinear` instead of `ridge`. When using `fitrlinear`, specify the 'Regularization', 'ridge' name-value pair argument. Set the value of the 'Lambda' name-value pair argument to a vector of the ridge parameters of your choice. `fitrlinear` returns a trained linear model `Mdl`. You can access the coefficient estimates stored in the `Beta` property of the model by using `Mdl.Beta`.

Introduced before R2006a

robustcov

Robust multivariate covariance and mean estimate

Syntax

```
sig = robustcov(x)
[ sig, mu ] = robustcov(x)
[ sig, mu, mah ] = robustcov(x)
[ sig, mu, mah, outliers ] = robustcov(x)
[ sig, mu, mah, outliers, s ] = robustcov(x)
[ ___ ] = robustcov(x, Name, Value)
```

Description

`sig = robustcov(x)` returns the robust covariance estimate `sig` of the multivariate data contained in `x`.

`[sig, mu] = robustcov(x)` also returns an estimate of the robust Minimum Covariance Determinant (MCD) mean, `mu`.

`[sig, mu, mah] = robustcov(x)` also returns the robust distances `mah`, computed as the Mahalanobis distances of the observations using the robust estimates of the mean and covariance.

`[sig, mu, mah, outliers] = robustcov(x)` also returns the indices of the observations retained as outliers in the sample data, `outliers`.

`[sig, mu, mah, outliers, s] = robustcov(x)` also returns a structure `s` that contains information about the estimate.

`[___] = robustcov(x, Name, Value)` returns any of the arguments shown in the previous syntaxes, using additional options specified by one or more `Name, Value` pair arguments. For example, you can specify which robust estimator to use or the start method to use for the attractors.

Examples

Detect Outliers Using Distance-Distance Plots

Use a Gaussian copula to generate random data points from a bivariate distribution.

```
rng default
rho = [1,0.05;0.05,1];
u = copularnd('Gaussian', rho, 50);
```

Modify 5 randomly selected observations to be outliers.

```
noise = randperm(50,5);
u(noise,1) = u(noise,1)*5;
```

Calculate the robust covariance matrices using the three available methods: Fast-MCD, Orthogonalized Gnanadesikan-Kettenring (OGK), and Olive-Hawkins.

```
[Sfmc, Mfmc, dfmc, Outfmc] = robustcov(u);
[Sogk, Mogk, dogk, Outogk] = robustcov(u, 'Method', 'ogk');
[Soh, Moh, doh, Outoh] = robustcov(u, 'Method', 'olivehawkins');
```

Calculate the classical distance values for the sample data using the Mahalanobis measure.

```
d_classical = pdist2(u, mean(u), 'mahal');
p = size(u,2);
chi2quantile = sqrt(chi2inv(0.975,p));
```

Create DD Plots for each robust covariance calculation method.

```
figure
subplot(2,2,1)
plot(d_classical, dfmc, 'o')
line([chi2quantile, chi2quantile], [0, 30], 'color', 'r')
line([0, 6], [chi2quantile, chi2quantile], 'color', 'r')
hold on
plot(d_classical(Outfmc), dfmc(Outfmc), 'r+')
xlabel('Mahalanobis Distance')
ylabel('Robust Distance')
title('DD Plot, FMCD method')
hold off

subplot(2,2,2)
plot(d_classical, dogk, 'o')
line([chi2quantile, chi2quantile], [0, 30], 'color', 'r')
line([0, 6], [chi2quantile, chi2quantile], 'color', 'r')
hold on
plot(d_classical(Outogk), dogk(Outogk), 'r+')
xlabel('Mahalanobis Distance')
ylabel('Robust Distance')
title('DD Plot, OGK method')
hold off

subplot(2,2,3)
plot(d_classical, doh, 'o')
line([chi2quantile, chi2quantile], [0, 30], 'color', 'r')
line([0, 6], [chi2quantile, chi2quantile], 'color', 'r')
hold on
plot(d_classical(Outoh), doh(Outoh), 'r+')
xlabel('Mahalanobis Distance')
ylabel('Robust Distance')
title('DD Plot, Olive-Hawkins method')
hold off
```

In a DD plot, the data points tend to cluster in a straight line that passes through the origin. Points that are far removed from this line are generally considered outliers. In each of the previous plots, the red '+' symbol indicates the data points that `robustcov` considers to be outliers.

Evaluate Data for Multivariate Normal Distribution

This example shows how to use `robustcov` to evaluate sample data for multivariate normal or other elliptically-contoured (EC) distributions.

Generate random sample data from a multivariate normal distribution. Calculate the Mahalanobis distances for the robust covariance estimates (using the Olive-Hawkins method) and the classical covariance estimates.

```
rng('default')
x1 = mvnrnd(zeros(1,3),eye(3),200);
[~, ~, d1] = robustcov(x1,'Method','olivehawkins');
d_classical1 = pdist2(x1,mean(x1),'mahalanobis');
```

Generate random sample data from an elliptically-contoured (EC) distribution. Calculate the Mahalanobis distances for the robust covariance estimates (using the Olive-Hawkins method) and the classical covariance estimates.

```
mu1 = [0 0 0];
sig1 = eye(3);
```

```

mu2 = [0 0 0];
sig2 = 25*eye(3);
x2 = [mvnrnd(mu1,sig1,120);mvnrnd(mu2,sig2,80)];
[~, ~, d2] = robustcov(x2, 'Method','olivehawkins');
d_classical2 = pdist2(x2, mean(x2), 'mahalanobis');

```

Generate random sample data from a multivariate lognormal distribution, which is neither multivariate normal or elliptically-contoured. Calculate the Mahalanobis distances for the robust covariance estimates (using the Olive-Hawkins method) and the classical covariance estimates.

```

x3 = exp(x1);
[~, ~, d3] = robustcov(x3, 'Method','olivehawkins');
d_classical3 = pdist2(x3, mean(x3), 'mahalanobis');

```

Create a D-D Plot for each of the three sets of sample data to compare.

```

figure
subplot(2,2,1)
plot(d_classical1,d1, 'o')
line([0 4.5], [0, 4.5])
xlabel('Mahalanobis Distance')
ylabel('Robust Distance')
title('DD Plot, Multivariate Normal')

subplot(2,2,2)
plot(d_classical2, d2, 'o')
line([0 18], [0, 18])
xlabel('Mahalanobis Distance')
ylabel('Robust Distance')
title('DD Plot, Elliptically-Contoured')

subplot(2,2,3)
plot(d_classical3, d3, 'o')
line([0 18], [0, 18])
xlabel('Mahalanobis Distance')
ylabel('Robust Distance')
title('DD Plot, 200 Lognormal cases')

```

For data with a multivariate normal distribution (as shown in the upper left), the plotted points follow a straight, 45-degree line extending from the origin. For data with an elliptically-contoured distribution (as shown in the upper right), the plotted points follow a straight line, but are not at a 45-degree angle to the origin. For the lognormal distribution (as shown in the lower left), the plotted points do not follow a straight line.

It is difficult to identify any pattern in the lognormal distribution plot because most of the points are in the lower left of the plot. Use a weighted DD plot to magnify this corner and reveal features that are obscured when large robust distances exist.

```
d3_weighted = d3(d3 < sqrt(chi2inv(0.975,3)));
d_classical_weighted = d_classical3(d3 < sqrt(chi2inv(0.975,3)));
```

Add a fourth subplot to the figure to show the results of the weighting process on the lognormally distributed data.

```
subplot(2,2,4)
plot(d_classical_weighted, d3_weighted, 'o')
line([0 3], [0, 3])
xlabel('Mahalanobis Distance')
ylabel('Robust Distance')
title('Weighted DD Plot, 200 Lognormal cases')
```

The scale on this plot indicates that it represents a magnified view of the original DD plot for the lognormal data. This view more clearly shows the lack of pattern to the plot, which indicates that the data is neither multivariate normal nor elliptically contoured.

Compute Robust Covariance and Plot the Outliers

Use a Gaussian copula to generate random data points from a bivariate distribution.

```
rng default
rho = [1,0.05;0.05,1];
u = copularnd('Gaussian',rho,50);
```

Modify 5 randomly selected observations to be outliers.

```
noise = randperm(50,5);
u(noise,1) = u(noise,1)*5;
```

Visualize the bivariate data using a scatter plot.

```
figure
scatter(u(:,1),u(:,2))
```

Most of the data points appear on the left side of the plot. However, some of the data points appear further to the right. These points are possible outliers that could affect the covariance matrix calculation.

Compare the classical and robust covariance matrices.

```
c = cov(u)
```

```
c = 2×2
```

```
    0.5523    0.0000
    0.0000    0.0913
```

```
rc = robustcov(u)
```

```
rc = 2×2
```

```
    0.1117    0.0364
    0.0364    0.1695
```

The classical and robust covariance matrices differ because the outliers present in the sample data influence the results.

Identify and plot the data points that `robustcov` considers outliers.

```
[sig,mu,mah,outliers] = robustcov(u);
figure
```

```
gscatter(u(:,1),u(:,2),outliers,'br','ox')
legend({'Not outliers','Outliers'})
```

`robustcov` identifies the data points on the right side of the plot as potential outliers, and treats them accordingly when calculating the robust covariance matrix.

Input Arguments

x — Sample data

matrix of numeric values

Sample data used to estimate the robust covariance matrix, specified as a matrix of numeric values. `x` is an n -by- p matrix where each row is an observation and each column is a variable.

`robustcov` removes any rows with missing predictor values when calculating the robust covariance matrix.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: 'Method', 'ogk', 'NumOGKIterations', 1 specifies the robust estimator as the Orthogonalized Gnanadesikan-Kettenring method and sets the number of orthogonalization iterations to 1.

For All Estimators

Method — Robust estimator

'fmcD' (default) | 'ogk' | 'olivehawkins'

Robust estimator, specified as one of the following.

Name	Value
'fmcD'	FAST-MCD (Minimum Covariance Determinant) on page 32-4979 method
'ogk'	Orthogonalized Gnanadesikan-Kettenring (OGK) on page 32-4980 estimate
'olivehawkins'	Concentration algorithm on page 32-4980 techniques, a family of fast, consistent and highly outlier-resistant methods

Example: 'Method', 'ogk'

For 'FMCD' and 'OliveHawkins' Estimators Only

OutlierFraction — Outlier fraction

0.5 (default) | numeric value in the range [0,0.5]

Outlier fraction, specified as the comma-separated pair consisting of 'OutlierFraction' and a numeric value in the range [0,0.5]. The value $1 - \text{OutlierFraction}$ specifies the fraction of observations over which to minimize the covariance determinant.

The algorithm chooses a subsample of size $h = \text{ceiling}(n + p + 1) / 2$, where n is the number of observations and p is the number of dimensions. `OutlierFraction` is the value for which the maximum possible breakdown is achieved, and controls the size of the subsets h over which the covariance determinant is minimized. The algorithm then chooses h to approximately equal $(1 - \text{OutlierFraction}) \times n$ observations per subset.

Example: 'OutlierFraction', 0.25

Data Types: single | double

NumTrials — Number of trials

positive integer value

Number of trials, specified as the comma-separated pair consisting of 'NumTrials' and a positive integer value.

If 'Method' is 'fmcD', then `NumTrials` is the number of random subsamples of size $(p + 1)$ drawn from the sample data as starting points in the algorithm. p is the number of dimensions in the sample data. In this case, the default value for `NumTrials` is 500.

If 'Method' is 'olivehawkins', then `NumTrials` is the number of trial fits, or attractors, to be used. In this case, the default value for `NumTrials` is 2. This option is only useful for non-deterministic starts.

Example: 'NumTrials',300

Data Types: single | double

For the FMCD Method Only

BiasCorrection — Flag to apply small-sample correction factor

1 (default) | 0

Flag to apply small-sample correction factor, specified as the comma-separated pair consisting of 'BiasCorrection' and either 1 or 0. A 1 value indicates that robustcov corrects for bias in the covariance estimate for small samples. A 0 value indicates that robustcov does not apply this correction.

Example: 'BiasCorrection',0

Data Types: logical

For the OGK Method Only

NumOGKIterations — Number of orthogonalization iterations

2 (default) | positive integer value

Number of orthogonalization iterations, specified as the comma-separated pair consisting of 'NumOGKIterations' and a positive integer value. Generally, this value is set to 1 or 2, and further steps are unlikely to improve the estimation.

Example: 'NumIter',1

Data Types: single | double

UnivariateEstimator — Function for computing univariate robust estimates

'tauscale' (default) | 'qn'

Function for computing univariate robust estimates, specified as the comma-separated pair consisting of 'UnivariateEstimator' and one of the following.

Name	Value
'tauscale'	Use the “tau-scale” estimate of Yohai and Zamar, which is a truncated standard deviation and a weighted mean.
'qn'	Use the Qn scale estimate of Croux and Rousseuw.

Example: 'UnivariateEstimator','qn'

For the OliveHawkins method only

ReweightingMethod — Method for reweighting

'rfch' (default) | 'rmvn'

Method for reweighting in the efficiency step, specified as the comma-separated pair consisting of 'ReweightingMethod' and one of the following.

Name	Value
'rfch'	Uses two reweighting steps. This is a standard method of reweighting to improve efficiency.
'rmvn'	Reweighted multivariate normal. Uses two reweighting steps that can be useful for estimating the true covariance matrix under a variety of outlier configurations when the clean data are multivariate normal.

Example: 'ReweightingMethod', 'rmvn'

NumConcentrationSteps — Number of concentration steps

10 (default) | positive integer value

Number of concentration steps, specified as the comma-separated pair consisting of 'NumConcentrationSteps' and a positive integer value.

Example: 'NumConcentrationSteps', 8

Data Types: single | double

StartMethod — Start method for each attractor

'classical' (default) | 'medianball' | 'elemental' | function handle | cell array

Start method for each attractor, specified as the comma-separated pair consisting of 'Start' and one of the following.

Name	Value
'classical'	Use the classical estimator as the start. This is the DGK attractor which, used on its own, is known as the DGK estimator.
'medianball'	Use the Median Ball as the start. The Median Ball is $(\text{med}(x), \text{eye}(p))$. So 50% of cases furthest in Euclidean distance from the sample median are trimmed for computing the MB start. This is the MB attractor which, used on its own, is known as the MB estimator.
'elemental'	The attractor is generated by concentration where the start is a randomly selected elemental start: the classical estimator applied to a randomly selected “elemental set” of $p + 1$ cases. This “elemental” attractor is computationally efficient, but suffers from theoretical drawbacks, as it is inconsistent and zero breakdown.

By default, the attractor is chosen as follows: If one of the attractors is 'medianball', then any attractor whose location estimate has greater Euclidean distance from $\text{median}(X)$ than half the data (in other words, is outside the median ball) is not used. Then the final attractor is chosen based on the MCD criterion.

You can also specify a function handle for a function that returns two output arguments used for computing the initial location and scatter estimates..

You can also specify a cell array containing any combination of the options given in the previous table and function handles. The number of attractors used is equal to the length of the cell array. This option allows more control over the algorithm and the ability to specify a custom number of attractors and starts.

Example: 'StartMethod','medianball'

Output Arguments

sig — Robust covariance matrix estimates

numeric matrix

Robust covariance matrix estimates, returned as a p -by- p numeric matrix. p is the number of predictors contained in the sample data.

mu — Robust mean estimates

array of numeric values

Robust mean estimates, returned as a 1-by- p array of numeric values. p is the number of predictors contained in the sample data.

mah — Robust distances

array of numeric values

Robust distances, returned as a 1-by- n array of numeric values. `robustcov` removes any rows of x that contain missing data, so the number of rows of `mah` might be smaller than the number of rows in x .

outliers — Indices of outliers

array of logical values

Indices of observations retained as outliers in the sample data x , returned as a 1-by- n array of logical values. A 0 value indicates that the observation is not an outlier. A 1 value indicates that the observation is an outlier.

`robustcov` removes any rows of x that contain missing data, so the number of rows of `outliers` might be smaller than the number of rows in x .

s — Structure containing estimate information

structure

Structure containing estimate information, returned as a structure.

Algorithms

Minimum Covariance Determinant Estimate

Minimum covariance determinant (MCD) is the fastest estimator of multivariate location and scatter that is both consistent and robust. However, an exact evaluation of the MCD is impractical because it is computationally expensive to evaluate all possible subsets of the sample data. `robustcov` uses the FAST-MCD method to implement MCD [3]

The FAST-MCD method selects h observations out of n (where $n/2 < h \leq n$) whose classical covariance matrix has the lowest possible determinant. The MCD mean is the mean of the h selected observations.

The MCD covariance is the covariance matrix of the h selected points, multiplied by a consistency factor to obtain consistency at the multivariate normal distribution, and by a correction factor to correct for bias at small sample sizes.

Orthogonalized Gnanadesikan-Kettenring Estimate

Orthogonalized Gnanadesikan-Kettenring (OGK) estimate is a positive definite estimate of the scatter starting from the Gnanadesikan and Kettenring (GK) estimator, a pairwise robust scatter matrix that may be non-positive definite [1]. The estimate uses a form of principal components called an orthogonalization iteration on the pairwise scatter matrix, replacing its eigenvalues, which could be negative, with robust variances. This procedure can be iterated for improved results, and convergence is usually obtained after 2 or 3 iterations.

Olive Hawkins Estimate

The Olive-Hawkins estimate uses the “concentration algorithm” techniques proposed by Olive and Hawkins. This is a family of fast, consistent, and highly outlier-resistant methods. The estimate is a robust root n -consistent estimator of covariance for elliptically contoured distributions with fourth moments. This estimate is obtained by first generating trial estimates, or starts, and then using the concentration technique from each trial fit to obtain attractors.

Suppose (T_{0j}, C_{0j}) is a start, then at the next iteration the classical mean and covariance estimators are computed from the approximately $n/2$ cases (where n is the number of observations) with the smallest Mahalanobis distances based on the estimates from the previous iteration. This iteration can be continued for a fixed number of steps k , with the estimate at the last step, k , being the attractor. The final estimate is chosen based on a given criterion.

By default, two attractors are used. The first attractor is the Devlin-Gnanadesikan-Kettering (DGK) attractor, where the start used is the classical estimator. The second attractor is the Median Ball (MB) attractor, where the start used is $(\text{median}(x), \text{eye}(p))$, in other words the half set of data closest to $\text{median}(x)$ in Euclidean distance. The MB attractor is used if the location estimator of the DGK attractor is outside of the median ball, and the attractor with the smallest determinant is used otherwise. The final mean estimate is the mean estimate of the chosen attractor, and the final covariance estimate is the covariance estimate of the chosen attractor, multiplied by a scaling factor to make the estimate consistent at the normal distribution.

Introduced in R2016a

robustdemo

Interactive robust regression

Syntax

```
robustdemo  
robustdemo(x, y)
```

Description

`robustdemo` shows the difference between ordinary least squares and robust regression for data with a single predictor. With no input arguments, `robustdemo` displays a scatter plot of a sample of roughly linear data with one outlier. The bottom of the figure displays equations of lines fitted to the data using ordinary least squares and robust methods, together with estimates of the root mean squared errors.

Use the right mouse button to click on a point and view its least-squares leverage and robust weight.

Use the left mouse button to click-and-drag a point. The displays will update.

`robustdemo(x, y)` uses `x` and `y` data vectors you supply, in place of the sample data supplied with the function.

Examples

The following steps show you how to use `robustdemo`.

- 1 Start the example.** To begin using `robustdemo` with the built-in data, simply type the function name:

```
robustdemo
```

Least squares:	$Y = -0.188327 + 1.10351 * X$	RMS error = 2.21375
Robust:	$Y = -1.77278 + 1.50415 * X$	RMS error = 1.43663

The resulting figure shows a scatter plot with two fitted lines. The red line is the fit using ordinary least-squares regression. The green line is the fit using robust regression. At the bottom of the figure are the equations for the fitted lines, together with the estimated root mean squared errors for each fit.

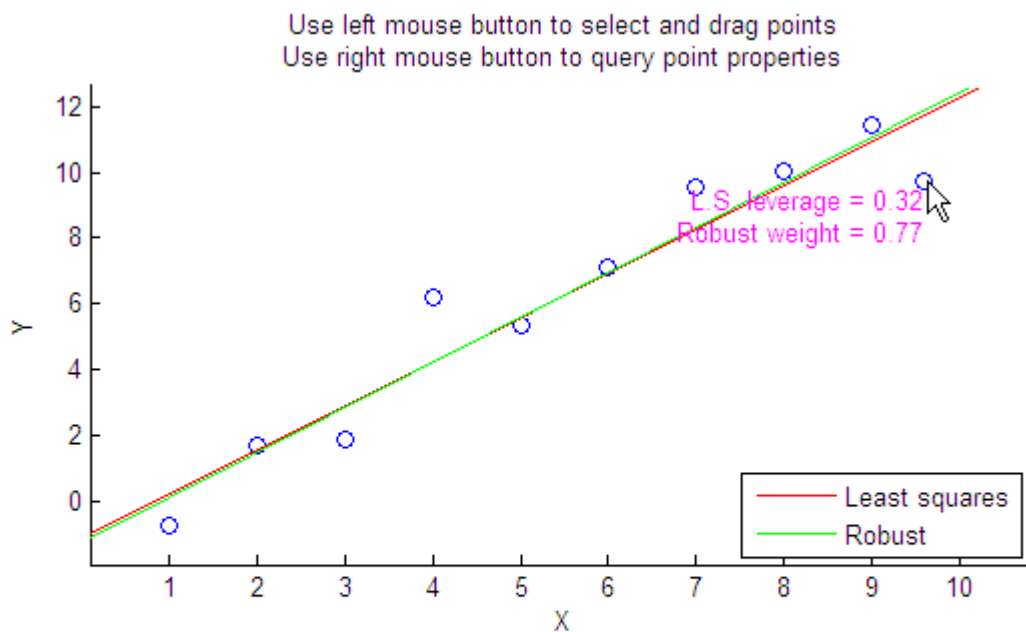

- View leverages and robust weights.** Right-click on any data point to see its least-squares leverage and robust weight:

Least squares:	$Y = -0.188327 + 1.10351 \cdot X$	RMS error = 2.21375
Robust:	$Y = -1.77278 + 1.50415 \cdot X$	RMS error = 1.43663

In the built-in data, the right-most point has a relatively high leverage of 0.35. The point exerts a large influence on the least-squares fit, but its small robust weight shows that it is effectively excluded from the robust fit.

- 3 See how changes in the data affect the fits.** With the left mouse button, click and hold on any data point and drag it to a new location. When you release the mouse button, the displays update:

Least squares:	$Y = -1.0661 + 1.33785 * X$	RMS error = 1.21477
Robust:	$Y = -1.18916 + 1.36459 * X$	RMS error = 1.27697

Bringing the right-most data point closer to the least-squares line makes the two fitted lines nearly identical. The adjusted right-most data point has significant weight in the robust fit.

leverage | robustfit

Introduced before R2006a

robustfit

Fit robust linear regression

Syntax

```
b = robustfit(X,y)
b = robustfit(X,y,wfun,tune,const)
[b,stats] = robustfit( ___ )
```

Description

`b = robustfit(X,y)` returns a vector `b` of coefficient estimates for a robust multiple linear regression of the responses in vector `y` on the predictors in matrix `X`.

`b = robustfit(X,y,wfun,tune,const)` specifies the fitting weight function options `wfun` and `tune`, and the indicator `const`, which determines if the model includes a constant term. You can pass in `[]` for `wfun`, `tune`, and `const` to use their default values.

`[b,stats] = robustfit(___)` also returns a structure `stats` containing estimated statistics, using any of the input argument combinations in previous syntaxes.

Examples

Estimate Robust Regression Coefficients

Estimate robust regression coefficients for a multiple linear model.

Load the `carsmall` data set. Specify car weight and horsepower as predictors and mileage per gallon as the response.

```
load carsmall
x1 = Weight;
x2 = Horsepower;
X = [x1 x2];
y = MPG;
```

Compute the robust regression coefficients.

```
b = robustfit(X,y)
```

```
b = 3×1
    47.1975
   -0.0068
   -0.0333
```

Plot the fitted model.

```
x1fit = linspace(min(x1),max(x1),20);
x2fit = linspace(min(x2),max(x2),20);
```

```
[X1FIT,X2FIT] = meshgrid(x1fit,x2fit);
YFIT = b(1) + b(2)*X1FIT + b(3)*X2FIT;
mesh(X1FIT,X2FIT,YFIT)
```

Plot the data.

```
hold on
scatter3(x1,x2,y,'filled')
hold off
xlabel('Weight')
ylabel('Horsepower')
zlabel('MPG')
legend('Model','Data')
view(50,10)
axis tight
```

Tune Robust Weight Function

Tune the weight function for robust regression by using different tuning constants.

Generate data with the trend $y = 10 - 2x$, and then change one value to simulate an outlier.

```
x = (1:10)';
rng('default') % For reproducibility
y = 10 - 2*x + randn(10,1);
y(10) = 0;
```

Compute the robust regression residuals using the bisquare weight function for three different tuning constants. The default tuning constant is 4.685.

```
tune_const = [3 4.685 6];

for i = 1:length(tune_const)
    [~,stats] = robustfit(x,y,'bisquare',tune_const(i));
    resids(:,i) = stats.resid;
end
```

Create a plot of the residuals.

```
scatter(x,resids(:,1),'b','filled')
hold on
plot(resids(:,2),'rx','MarkerSize',10,'LineWidth',2)
scatter(x,resids(:,3),'g','filled')
plot([min(x) max(x)],[0 0],'--k')
hold off
grid on
xlabel('x')
ylabel('Residuals')
legend('tune = 3','tune = 4.685','tune = 6','Location','best')
```

Compute the root mean squared error (RMSE) of residuals for the three different tuning constants.

```
rmse = sqrt(mean(resids.^2))
rmse = 1x3
```

```
3.2577    2.7576    2.7099
```

Because increasing the tuning constant decreases the downweight assigned to outliers, the RMSE decreases as the tuning constant increases.

Compare Robust and Least-Squares Regression

Generate data with the trend $y = 10 - 2x$, and then change one value to simulate an outlier.

```
x = (1:10)';
rng('default') % For reproducibility
y = 10 - 2*x + randn(10,1);
y(10) = 0;
```

Fit a straight line using ordinary least-squares regression. To compute coefficient estimates for a model with a constant term, include a column of ones in x .

```
bls = regress(y,[ones(10,1) x])
```

```
bls = 2×1
    7.8518
   -1.3644
```

Estimate a straight-line fit using robust regression. `robustfit` adds a constant term to the model by default.

```
[brob,stats] = robustfit(x,y);
brob
```

```
brob = 2×1
    8.4504
   -1.5278
```

Identify potential outliers by comparing the residuals to the median absolute deviation of the residuals.

```
outliers_ind = find(abs(stats.resid)>stats.mad_s);
```

Plot a bar graph of the residuals for robust regression.

```
bar(abs(stats.resid))
hold on
yline(stats.mad_s,'k--')
hold off
xlabel('x')
ylabel('Residuals')
```

Create a scatter plot of the data.

```
scatter(x,y,'filled')
```

Plot the outlier.

```
hold on
plot(x(outliers_ind),y(outliers_ind),'mo','LineWidth',2)
```

Plot the least-squares and robust fit.

```
plot(x,bls(1)+bls(2)*x,'r')
plot(x,brob(1)+brob(2)*x,'g')
hold off
xlabel('x')
ylabel('y')
legend('Data','Outlier','Ordinary Least Squares','Robust Regression')
grid on
```

The outlier influences the robust fit less than the least-squares fit.

Input Arguments

X — Predictor data

numeric matrix

Predictor data, specified as an n -by- p numeric matrix. Rows of X correspond to observations, and columns correspond to predictor variables. X must have the same number of rows as y .

By default, `robustfit` adds a constant term to the model, unless you explicitly remove it by specifying `const` as 'off'. So, do not include a column of 1s in X .

Data Types: `single` | `double`

y — Response data

numeric vector

Response data, specified as an n -by-1 numeric vector. Rows of y correspond to different observations. y must have the same number of rows as X .

Data Types: `single` | `double`

wfun — Robust fitting weight function

'bisquare' (default) | 'andrews' | 'cauchy' | 'fair' | function handle | ...

Robust fitting weight function, specified as the name of a weight function described in the following table, or a function handle. `robustfit` uses the corresponding default tuning constant, unless otherwise specified by `tune`.

Weight Function	Description	Default Tuning Constant
'andrews'	$w = (\text{abs}(r) < \pi) .* \sin(r) ./ r$	1.339
'bisquare'	$w = (\text{abs}(r) < 1) .* (1 - r.^2).^2$ (also called <code>biweight</code>)	4.685
'cauchy'	$w = 1 ./ (1 + r.^2)$	2.385
'fair'	$w = 1 ./ (1 + \text{abs}(r))$	1.400
'huber'	$w = 1 ./ \max(1, \text{abs}(r))$	1.345
'logistic'	$w = \tanh(r) ./ r$	1.205
'ols'	Ordinary least squares (no weighting function)	None
'talwar'	$w = 1 * (\text{abs}(r) < 1)$	2.795
'welsch'	$w = \exp(- (r.^2))$	2.985
function handle	Custom weight function that accepts a vector <code>r</code> of scaled residuals, and returns a vector of weights the same size as <code>r</code>	1

The value `r` in the weight functions is

$$r = \text{resid}/(\text{tune}*s*\text{sqrt}(1-h)),$$

where

- `resid` is the vector of residuals from the previous iteration.
- `tune` is the tuning constant.
- `h` is the vector of leverage values from a least-squares fit.
- `s` is an estimate of the standard deviation of the error term given by $s = \text{MAD}/0.6745$.

`MAD` is the median absolute deviation of the residuals from their median. The constant 0.6745 makes the estimate unbiased for the normal distribution. If `X` has p columns, the software excludes the smallest p absolute deviations when computing the median.

Data Types: `char` | `string` | `function handle`

tune — Tuning constant

positive scalar

Tuning constant, specified as a positive scalar. If you do not set `tune`, `robustfit` uses the corresponding default tuning constant for each weight function (see the table in `wfun`).

The default tuning constants of built-in weight functions give coefficient estimates that are approximately 95% as statistically efficient as the ordinary least-squares estimates, provided that the response has a normal distribution with no outliers. Decreasing the tuning constant increases the downweight assigned to large residuals; increasing the tuning constant decreases the downweight assigned to large residuals.

Data Types: `single` | `double`

const — Indicator for constant term

'on' (default) | 'off'

Indicator for a constant term in the fit, specified as 'on' or 'off'. If `const` is 'on', then `robustfit` adds a first column of 1s to the predictor matrix X , and the output b becomes a $(p + 1)$ -by-1 vector. If `const` is 'off', then X remains unchanged and b is a p -by-1 vector.

Data Types: char | string

Output Arguments**b — Coefficient estimates for robust multiple linear regression**

numeric vector

Coefficient estimates for robust multiple linear regression, returned as a numeric vector. b is a p -by-1 vector, where p is the number of predictors in X .

By default, `robustfit` adds a constant term to the model, unless you explicitly remove it by specifying `const` as 'off'.

stats — Model statistics

structure

Model statistics, returned as a structure. The following table describes the fields of the diagnostic statistics structure from the robust regression.

Field	Description
<code>ols_s</code>	Sigma estimate (root mean squared error) from ordinary least squares
<code>robust_s</code>	Robust estimate of sigma
<code>mad_s</code>	Estimate of sigma computed using the median absolute deviation of the residuals from their median; used for scaling residuals during iterative fitting
<code>s</code>	Final estimate of sigma, the largest between <code>robust_s</code> and a weighted average of <code>ols_s</code> and <code>robust_s</code>
<code>resid</code>	Residuals, observed minus fitted values (see "Raw Residuals" on page 11-79)
<code>rstud</code>	Studentized residuals, the residuals divided by an independent estimate of the residual standard deviation (see "Studentized Residuals" on page 11-79)
<code>se</code>	Standard error of the estimated coefficient value b
<code>covb</code>	Estimated covariance matrix for coefficient estimates
<code>coeffcorr</code>	Estimated correlation of coefficient estimates
<code>t</code>	t -statistic for each coefficient to test the null hypothesis that the corresponding coefficient is zero against the alternative that it is different from zero, given the other predictors in the model. Note that $t = b/se$.
<code>p</code>	p -values for the t -statistic of the hypothesis test that the corresponding coefficient is equal to zero or not
<code>w</code>	Vector of weights for a robust fit
<code>R</code>	R factor in the QR decomposition of X

Field	Description
dfc	Degrees of freedom for the error (residuals), equal to the number of observations minus the number of estimated coefficients
h	Vector of leverage values for a least-squares fit

More About

Leverage

Leverage is a measure of the effect of a particular observation on the regression predictions due to the position of that observation in the space of the inputs.

The leverage of observation i is the value of the i th diagonal term h_{ii} of the hat matrix H . The hat matrix H is defined in terms of the data matrix X :

$$H = X(X^T X)^{-1} X^T.$$

The hat matrix is also known as the *projection matrix* because it projects the vector of observations y onto the vector of predictions \hat{y} , thus putting the "hat" on y .

Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered an outlier if its leverage substantially exceeds p/n , where n is the number of observations.

For more details, see "Hat Matrix and Leverage" on page 11-76.

Tips

- `robustfit` treats NaN values in X or y as missing values. `robustfit` omits observations with missing values from the robust fit.

Algorithms

- `robustfit` uses iteratively reweighted least squares to compute the coefficients b . The input `wfun` specifies the weights.
- `robustfit` estimates the variance-covariance matrix of the coefficient estimates `stats.covb` using the formula `inv(X'*X)*stats.s^2`. This estimate produces the standard error `stats.se` and correlation `stats.coeffcorr`.
- In a linear model, observed values of y and their residuals are random variables. Residuals have normal distributions with zero mean but with different variances at different values of the predictors. To put residuals on a comparable scale, `robustfit` "Studentizes" the residuals. That is, `robustfit` divides the residuals by an estimate of their standard deviation that is independent of their value. Studentized residuals have t -distributions with known degrees of freedom. `robustfit` returns the Studentized residuals in `stats.rstud`.

Alternative Functionality

`robustfit` is useful when you simply need the output arguments of the function or when you want to repeat fitting a model multiple times in a loop. If you need to investigate a robust fitted regression model further, create a linear regression model object `LinearModel` by using `fitlm`. Set the value for the name-value pair argument 'RobustOpts' to 'on'.

rotatefactors

Rotate factor loadings

Syntax

```
B = rotatefactors(A)
B = rotatefactors(A, 'Method', 'orthomax', 'Coeff', gamma)
B = rotatefactors(A, 'Method', 'procrustes', 'Target', target)
B = rotatefactors(A, 'Method', 'pattern', 'Target', target)
B = rotatefactors(A, 'Method', 'promax')
[B, T] = rotatefactors(A, ...)
```

Description

`B = rotatefactors(A)` rotates the d -by- m loadings matrix A to maximize the varimax criterion, and returns the result in B . Rows of A and B correspond to variables and columns correspond to factors, for example, the (i, j) th element of A is the coefficient for the i th variable on the j th factor. The matrix A usually contains principal component coefficients created with `pca` or `pcacov`, or factor loadings estimated with `factoran`.

`B = rotatefactors(A, 'Method', 'orthomax', 'Coeff', gamma)` rotates A to maximize the orthomax criterion with the coefficient γ , i.e., B is the orthogonal rotation of A that maximizes $\text{sum}(D * \text{sum}(B.^4, 1) - \text{GAMMA} * \text{sum}(B.^2, 1).^2)$

The default value of 1 for γ corresponds to varimax rotation. Other possibilities include $\gamma = 0$, $m/2$, and $d(m-1)/(d+m-2)$, corresponding to quartimax, equamax, and parsimax. You can also supply 'varimax', 'quartimax', 'equamax', or 'parsimax' for the 'method' parameter and omit the 'Coeff' parameter.

If 'Method' is 'orthomax', 'varimax', 'quartimax', 'equamax', or 'parsimax', then additional parameters are

- 'Normalize' — Flag indicating whether the loadings matrix should be row-normalized for rotation. If 'on' (the default), rows of A are normalized prior to rotation to have unit Euclidean norm, and unnormalized after rotation. If 'off', the raw loadings are rotated and returned.
- 'Reltol' — Relative convergence tolerance in the iterative algorithm used to find T . The default is `sqrt(eps)`.
- 'Maxit' — Iteration limit in the iterative algorithm used to find T . The default is 250.

`B = rotatefactors(A, 'Method', 'procrustes', 'Target', target)` performs an oblique procrustes rotation of A to the d -by- m target loadings matrix `target`.

`B = rotatefactors(A, 'Method', 'pattern', 'Target', target)` performs an oblique rotation of the loadings matrix A to the d -by- m target pattern matrix `target`, and returns the result in B . `target` defines the "restricted" elements of B , i.e., elements of B corresponding to zero elements of `target` are constrained to have small magnitude, while elements of B corresponding to nonzero elements of `target` are allowed to take on any magnitude.

If 'Method' is 'procrustes' or 'pattern', an additional parameter is 'Type', the type of rotation. If 'Type' is 'orthogonal', the rotation is orthogonal, and the factors remain

uncorrelated. If 'Type' is 'oblique' (the default), the rotation is oblique, and the rotated factors might be correlated.

When 'Method' is 'pattern', there are restrictions on target. If A has m columns, then for orthogonal rotation, the j th column of target must contain at least $m - j$ zeros. For oblique rotation, each column of target must contain at least $m - 1$ zeros.

`B = rotatefactors(A, 'Method', 'promax')` rotates A to maximize the promax criterion, equivalent to an oblique Procrustes rotation with a target created by an orthomax rotation. Use the four orthomax parameters to control the orthomax rotation used internally by promax.

An additional parameter for 'promax' is 'Power', the exponent for creating promax target matrix. 'Power' must be 1 or greater. The default is 4.

`[B,T] = rotatefactors(A,...)` returns the rotation matrix T used to create B, that is, $B = A*T$. You can find the correlation matrix of the rotated factors by using `inv(T'*T)`. For orthogonal rotation, this is the identity matrix, while for oblique rotation, it has unit diagonal elements but nonzero off-diagonal elements.

Examples

```
rng('default') % for reproducibility
X = randn(100,10);

% Default (normalized varimax) rotation:
% first three principal components.
LPC = pca(X);
[L1,T] = rotatefactors(LPC(:,1:3));

% Equamax rotation:
% first three principal components.
[L2,T] = rotatefactors(LPC(:,1:3),...
    'method','equamax');

% Promax rotation:
% first three factors.
LFA = factoran(X,3,'Rotate','none');
[L3,T] = rotatefactors(LFA(:,1:3),...
    'method','promax',...
    'power',2);

% Pattern rotation:
% first three factors.
Tgt = [1 1 1 1 1 0 1 0 1 1; ...
    0 0 0 1 1 1 0 0 0 0; ...
    1 0 0 1 0 1 1 1 1 0]';
[L4,T] = rotatefactors(LFA(:,1:3),...
    'method','pattern',...
    'target',Tgt);
inv(T'*T) % Correlation matrix of the rotated factors
ans =

    1.0000    -0.9593   -0.7098
   -0.9593    1.0000    0.5938
   -0.7098    0.5938    1.0000
```

rowexch

Row exchange

Syntax

```
dRE = rowexch(nfactors,nruns)
[dRE,X] = rowexch(nfactors,nruns)
[dRE,X] = rowexch(nfactors,nruns,model)
[dRE,X] = rowexch(...,param1,val1,param2,val2,...)
```

Description

`dRE = rowexch(nfactors,nruns)` uses a row-exchange algorithm to generate a D -optimal design `dRE` with `nruns` runs (the rows of `dRE`) for a linear additive model with `nfactors` factors (the columns of `dRE`). The model includes a constant term.

`[dRE,X] = rowexch(nfactors,nruns)` also returns the associated design matrix `X`, whose columns are the model terms evaluated at each treatment (row) of `dRE`.

`[dRE,X] = rowexch(nfactors,nruns,model)` uses the linear regression model specified in `model`. `model` is one of the following:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

The order of the columns of `X` for a full quadratic model with n terms is:

- 1 The constant term
- 2 The linear terms in order 1, 2, ..., n
- 3 The interaction terms in order (1, 2), (1, 3), ..., (1, n), (2, 3), ..., ($n-1$, n)
- 4 The squared terms in order 1, 2, ..., n

Other models use a subset of these terms, in the same order.

Alternatively, `model` can be a matrix specifying polynomial terms of arbitrary order. In this case, `model` should have one column for each factor and one row for each term in the model. The entries in any row of `model` are powers for the factors in the columns. For example, if a model has factors X_1 , X_2 , and X_3 , then a row `[0 1 2]` in `model` specifies the term $(X_1.^0) .*(X_2.^1) .*(X_3.^2)$. A row of all zeros in `model` specifies a constant term, which can be omitted.

`[dRE,X] = rowexch(...,param1,val1,param2,val2,...)` specifies additional parameter/value pairs for the design. Valid parameters and their values are listed in the following table.

Parameter	Value
'bounds'	Lower and upper bounds for each factor, specified as a 2-by-nfactors matrix. Alternatively, this value can be a cell array containing nfactors elements, each element specifying the vector of allowable values for the corresponding factor.
'categorical'	Indices of categorical predictors.
'display'	Either 'on' or 'off' to control display of the iteration counter. The default is 'on'.
'excldefun'	Handle to a function that excludes undesirable runs. If the function is f , it must support the syntax $b = f(S)$, where S is a matrix of treatments with nfactors columns and b is a vector of Boolean values with the same number of rows as S . $b(i)$ is true if the i th row S should be excluded.
'init'	Initial design as an nruns-by-nfactors matrix. The default is a randomly selected set of points.
'levels'	Vector of number of levels for each factor.
'maxiter'	Maximum number of iterations. The default is 10.
options	A structure that specifies whether to run in parallel, and specifies the random stream or streams. Create the options structure with <code>statset</code> . This option requires Parallel Computing Toolbox. Option fields are: <ul style="list-style-type: none"> • <code>UseParallel</code> — Set to <code>true</code> to compute in parallel. Default is <code>false</code>. • <code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code>. • <code>Streams</code> — A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code>, <code>rowexch</code> uses the default stream or streams. If you choose to specify <code>Streams</code>, use a single object except in the case <ul style="list-style-type: none"> • <code>UseParallel</code> is <code>true</code> • <code>UseSubstreams</code> is <code>false</code> In that case, use a cell array the same size as the Parallel pool.
'tries'	Number of times to try to generate a design from a new starting point. The algorithm uses random points for each try, except possibly the first. The default is 1.

Examples

Suppose you want a design to estimate the parameters in the following three-factor, seven-term interaction model:

$$y = \beta_0 + \beta_1x_1 + \beta_2x_2 + \beta_3x_3 + \beta_{12}x_1x_2 + \beta_{13}x_1x_3 + \beta_{23}x_2x_3 + \varepsilon$$

Use `rowexch` to generate a D -optimal design with seven runs:

```
nfactors = 3;
nruns = 7;
[dRE,X] = rowexch(nfactors,nruns,'interaction','tries',10)
dRE =
```

```

-1  -1  1
 1  -1  1
 1  -1 -1
 1   1  1
-1  -1 -1
-1   1 -1
-1   1  1
X =
 1  -1  -1  1  1  -1  -1
 1   1  -1  1  -1  1  -1
 1   1  -1  -1 -1  -1  1
 1   1  1  1  1  1  1
 1  -1  -1  -1  1  1  1
 1  -1  1  -1  -1  1  -1
 1  -1  1  1  -1  -1  1

```

Columns of the design matrix X are the model terms evaluated at each row of the design dRE. The terms appear in order from left to right: constant term, linear terms (1, 2, 3), interaction terms (12, 13, 23). Use X to fit the model, as described in “Linear Regression” on page 11-8, to response data measured at the design points in dRE.

Algorithms

Both `cordexch` and `rowexch` use iterative search algorithms. They operate by incrementally changing an initial design matrix X to increase $D = |X^T X|$ at each step. In both algorithms, there is randomness built into the selection of the initial design and into the choice of the incremental changes. As a result, both algorithms may return locally, but not globally, D -optimal designs. Run each algorithm multiple times and select the best result for your final design. Both functions have a 'tries' parameter that automates this repetition and comparison.

At each step, the row-exchange algorithm exchanges an entire row of X with a row from a design matrix C evaluated at a candidate set of feasible treatments. The `rowexch` function automatically generates a C appropriate for a specified model, operating in two steps by calling the `candgen` and `candexch` functions in sequence. Provide your own C by calling `candexch` directly. In either case, if C is large, its static presence in memory can affect computation.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to `true`.

Set the 'UseParallel' field of the options structure to `true` using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

rsmdemo

Interactive response surface demonstration

Syntax

rsmdemo

Description

rsmdemo opens a group of three graphical user interfaces for interactively investigating response surface methodology (RSM), nonlinear fitting, and the design of experiments.

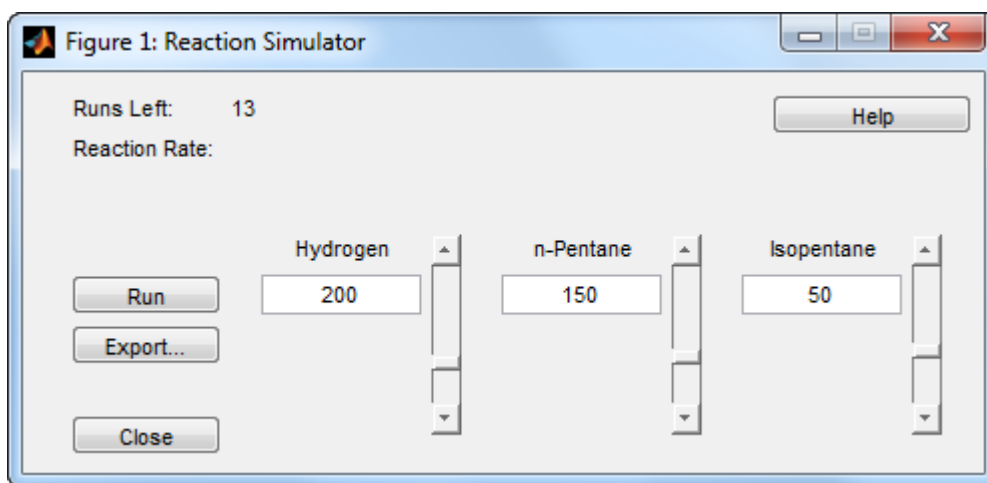

The interfaces allow you to collect and model data from a simulated chemical reaction. Experimental predictors are concentrations of three reactants (hydrogen, *n*-pentane, and isopentane) and the response is the reaction rate. The reaction rate is simulated by a Hougen-Watson model (Bates and Watts, [2] on page C-2, pp. 271–272):

$$rate = \frac{\beta_1 x_2 - x_3 / \beta_5}{1 + \beta_2 x_1 + \beta_3 x_2 + \beta_4 x_3}$$

where *rate* is the reaction rate, x_1 , x_2 , and x_3 are the concentrations of hydrogen, *n*-pentane, and isopentane, respectively, and $\beta_1, \beta_2, \dots, \beta_5$ are fixed parameters. Random errors are used to perturb the reaction rate for each combination of reactants.

Collect data using one of two methods:

- 1 Manually set reactant concentrations in the **Reaction Simulator** interface by editing the text boxes or by adjusting the associated sliders.

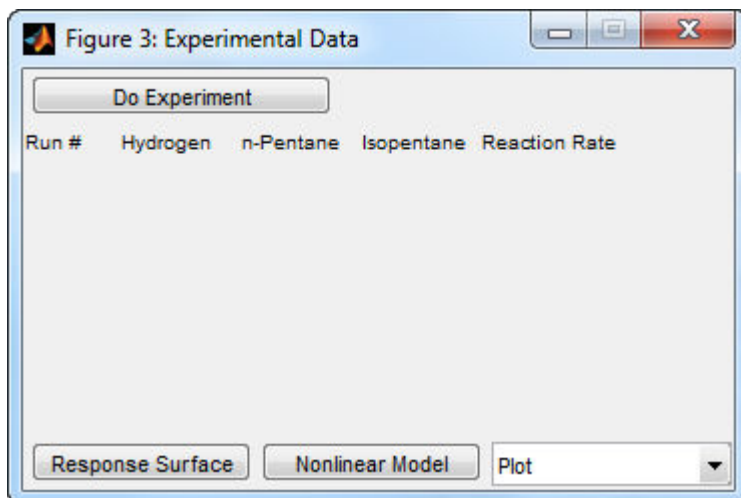

When you click **Run**, the concentrations and simulated reaction rate are recorded on the **Trial and Error Data** interface.

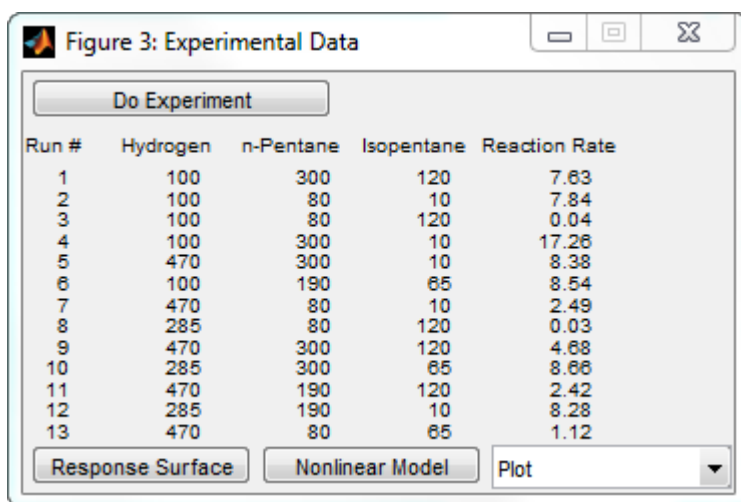

You are allowed up to 13 independent experimental runs for data collection.

- 2 Use a designed experiment to set reactant concentrations in the **Experimental Data** interface by clicking the **Do Experiment** button.

A 13-run *D*-optimal design for a full quadratic model is generated by the `cordexch` function, and the concentrations and simulated reaction rates are recorded on the same interface.

Run #	Hydrogen	n-Pentane	Isopentane	Reaction Rate
1	100	300	120	7.63
2	100	80	10	7.84
3	100	80	120	0.04
4	100	300	10	17.26
5	470	300	10	8.38
6	100	190	65	8.54
7	470	80	10	2.49
8	285	80	120	0.03
9	470	300	120	4.68
10	285	300	65	8.66
11	470	190	120	2.42
12	285	190	10	8.28
13	470	80	65	1.12

Once data is collected, scatter plots of reaction rates vs. individual predictors are generated by selecting one of the following from the **Plot** pop-up menu below the recorded data:

- **Hydrogen vs. Rate**
- **n-Pentane vs. Rate**
- **Isopentane vs. Rate**

Fit a response surface model to the data by clicking the **Analyze** button below the trial-and-error data or the **Response Surface** button below the experimental data. Both buttons load the data into the Response Surface Tool `rstool`. By default, trial-and-error data is fit with a linear additive model and experimental data is fit with a full quadratic model, but the models can be adjusted in the Response Surface Tool.

For experimental data, you have the additional option of fitting a Hougen-Watson model. Click the **Nonlinear Model** button to load the data and the model in `hougen` into the Nonlinear Fitting Tool `nlintool`.

`cordexch` | `hougen` | `nlintool` | `rstool`

Introduced before R2006a

rstool

Interactive response surface modeling

Syntax

```
rstool
rstool(X,Y,model)
rstool(x,y,model,alpha)
rstool(x,y,model,alpha,xname,yname)
```

Description

`rstool` opens a graphical user interface for interactively investigating one-dimensional contours of multidimensional response surface models.

By default, the interface opens with the data from `hald.mat` and a fitted response surface with constant, linear, and interaction terms.

A sequence of plots is displayed, each showing a contour of the response surface against a single predictor, with all other predictors held fixed. `rstool` plots a 95% simultaneous confidence band for the fitted response surface as two red curves. Predictor values are displayed in the text boxes on the horizontal axis and are marked by vertical dashed blue lines in the plots. Predictor values are changed by editing the text boxes or by dragging the dashed blue lines. When you change the value of a predictor, all plots update to show the new point in predictor space.

The pop-up menu at the lower left of the interface allows you to choose among the following models:

- Linear — Constant and linear terms (the default)
- Pure Quadratic — Constant, linear, and squared terms
- Interactions — Constant, linear, and interaction terms
- Full Quadratic — Constant, linear, interaction, and squared terms

Click **Export** to open the following dialog box:

The dialog allows you to save information about the fit to MATLAB workspace variables with valid names.

`rstool(X,Y,model)` opens the interface with the predictor data in *X*, the response data in *Y*, and the fitted model *model*. Distinct predictor variables should appear in different columns of *X*. *Y* can be a vector, corresponding to a single response, or a matrix, with columns corresponding to multiple responses. *Y* must have as many elements (or rows, if it is a matrix) as *X* has rows.

The optional input *model* can be any one of the following:

- 'linear' — Constant and linear terms (the default)
- 'purequadratic' — Constant, linear, and squared terms
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms

To specify a polynomial model of arbitrary order, or a model without a constant term, use a matrix for *model* as described in `x2fx`.

`rstool(x,y,model,alpha)` uses $100(1-\alpha)\%$ global confidence intervals for new observations in the plots.

`rstool(x,y,model,alpha,xname,yname)` labels the axes using *xname* and *yname*. To label each subplot differently, *xname* and *yname* can be string arrays or cell arrays of character vectors.

Examples

The following uses `rstool` to visualize a quadratic response surface model of the 3-D chemical reaction data in `reaction.mat`:

```
load reaction
alpha = 0.01; % Significance level
rstool(reactants,rate,'quadratic',alpha,xn,yn)
```

The `rstool` interface is used by `rsmdemo` to visualize the results of simulated experiments with data like that in `reaction.mat`. As described in “Response Surface Designs” on page 27-8, `rsmdemo` uses a response surface model to generate simulated data at combinations of predictors specified by either the user or by a designed experiment.

`nlintool` | `rsmdemo` | `x2fx`

Introduced before R2006a

runstest

Run test for randomness

Syntax

```
h = runstest(x)
h = runstest(x,v)
h = runstest(x,'ud')
h = runstest( ___,Name,Value)
[h,p,stats] = runstest( ___ )
```

Description

`h = runstest(x)` returns a test decision for the null hypothesis that the values in the data vector `x` come in random order, against the alternative that they do not. The test is based on the number of runs of consecutive values above or below the mean of `x`. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, or 0 otherwise.

`h = runstest(x,v)` returns a test decision based on the number of runs of consecutive values above or below the specified reference value `v`. Values exactly equal to `v` are discarded.

`h = runstest(x,'ud')` returns a test decision based on the number of runs up or down. Too few runs indicate a trend, while too many runs indicate an oscillation. Values exactly equal to the preceding value are discarded.

`h = runstest(___,Name,Value)` returns a test decision using additional options specified by one or more name-value pair arguments. For example, you can change the significance level of the test, specify the algorithm used to calculate the p -value, or conduct a one-sided test.

`[h,p,stats] = runstest(___)` also returns the p -value of the test `p`, and a structure `stats` containing additional data about the test.

Examples

Test Data for Randomness Using Sample Median

Generate a vector of 40 random numbers from a standard normal distribution.

```
rng default; % for reproducibility
x = randn(40,1);
```

Test whether the values in `x` appear in random order, using the sample median as the reference value.

```
[h,p] = runstest(x,median(x))
```

```
h = 0
```

```
p = 0.8762
```

The returned value of $h = 0$ indicates that `runstest` does not reject the null hypothesis that the values in `x` are in random order at the default 5% significance level.

Input Arguments

x — Data vector

vector of scalar values

Data vector, specified as a vector of scalar values. `runstest` treats NaN values in `x` as missing values, and ignores them.

Data Types: `single` | `double`

v — Reference value

mean of `x` (default) | scalar value

Reference value, specified as a scalar value. If you specify a value for `v`, then `runstest` performs the hypothesis test based on the number of runs of consecutive values above or below `v`. `runstest` discards values exactly equal to `v`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Alpha', 0.01, 'Method', 'Approximate', 'Tail', 'right'` specifies a right-tailed test with 1% significance level, which returns the approximate p-value.

Alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

Method — Method used to compute *p*-value

`'exact'` | `'approximate'`

Method used to compute *p*-value, specified as the comma-separated pair consisting of `'Method'` and either `'exact'` to use an exact algorithm, or `'approximate'` to use a normal approximation. The default is `'exact'` for runs above/below, and for runs up/down when the length of `x` is less than or equal to 50. If `runstest` tests for runs up/down and the length of `x` is greater than 50, then the default is `'approximate'`, and the `'exact'` method is not available.

Example: `'Method', 'approximate'`

Tail — Type of alternative hypothesis

`'both'` (default) | `'right'` | `'left'`

Type of alternative hypothesis, specified as the comma-separated pair consisting of 'Tail' and one of the following.

'both'	Two-tailed test (sequence is not random)
'right'	Right-tailed test (like values separate for runs above/below, direction alternates for runs up/down)
'left'	Left-tailed test (like values cluster for runs above/below, values trend for runs up/down)

Example: 'Tail', 'right'

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as 1 or 0.

- If $h = 1$, then `runstest` rejects the null hypothesis at the Alpha significance level.
- If $h = 0$, then `runstest` fails to reject the null hypothesis at the Alpha significance level.

The result in `runstest` is based on the number of runs of consecutive values above or below the mean of x . Too few runs indicate a tendency for high and low values to cluster. Too many runs indicate a tendency for high and low values to alternate.

`runstest` uses a test statistic which is the difference between the number of runs and its mean, divided by its standard deviation. The test statistic is approximately normally distributed when the null hypothesis is true.

p — *p*-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

p is computed from either the test statistic or the exact distribution of the number of runs, depending on the value specified for the 'Method' name-value pair argument.

stats — Test data

structure

Test data, returned as a structure with the following fields.

- `nruns` — The number of runs
- `n1` — The number of values above v
- `n0` — The number of values below v
- `z` — The test statistic

Introduced before R2006a

sampsizewr

Sample size and power of test

Syntax

```
nout = sampsizewr(testtype,p0,p1)
nout = sampsizewr(testtype,p0,p1,pwr)

pwrout = sampsizewr(testtype,p0,p1,[],n)

plout = sampsizewr(testtype,p0,[],pwr,n)

___ = sampsizewr(testtype,p0,p1,pwr,n,Name,Value)
```

Description

`sampsizewr` computes the sample size, power, or alternative parameter value for a hypothesis test, given the other two values. For example, you can compute the sample size required to obtain a particular power for a hypothesis test, given the parameter value of the alternative hypothesis.

`nout = sampsizewr(testtype,p0,p1)` returns the sample size, `nout`, required for a two-sided test of the type specified by `testtype` to have a power (probability of rejecting the null hypothesis when the alternative hypothesis is true) of 0.90 when the significance level (probability of rejecting the null hypothesis when the null hypothesis is true) is 0.05. `p0` specifies parameter values under the null hypothesis. `p1` specifies the value, or an array of values, of the single parameter being tested under the alternative hypothesis.

`nout = sampsizewr(testtype,p0,p1,pwr)` returns the sample size, `nout`, that corresponds to the specified power, `pwr`, and the parameter value under the alternative hypothesis, `p1`.

`pwrout = sampsizewr(testtype,p0,p1,[],n)` returns the power achieved for a sample size of `n` when the true parameter value is `p1`.

`plout = sampsizewr(testtype,p0,[],pwr,n)` returns the parameter value detectable with the specified sample size, `n`, and the specified power, `pwr`.

`___ = sampsizewr(testtype,p0,p1,pwr,n,Name,Value)` returns any of the previous arguments using one or more name-value pair arguments. For example, you can change the significance level of the test, or specify a right- or left-tailed test. The name-value pairs can appear in any order but must begin in the sixth argument position.

Examples

Compute Sample Size for Selected Power Value

A company runs a manufacturing process that fills empty bottles with 100 mL of liquid. To monitor quality, the company randomly selects several bottles and measures the volume of liquid inside.

Determine the sample size the company must use if it wants to detect a difference between 100 mL and 102 mL with a power of 0.80. Assume that prior evidence indicates a standard deviation of 5 mL.

```
nout = sampsizepwr('t',[100 5],102,0.80)
```

```
nout = 52
```

The company must test 52 bottles to detect the difference between a mean volume of 100 mL and 102 mL with a power of 0.80.

Generate a power curve to visualize how the sample size affects the power of the test.

```
nn = 1:100;  
pwrout = sampsizepwr('t',[100 5],102,[],nn);
```

```
figure;  
plot(nn,pwrout,'b-',nout,0.8,'ro')  
title('Power versus Sample Size')  
xlabel('Sample Size')  
ylabel('Power')
```

Compute Power and Sample Size for One-Sided Test

An employee wants to buy a house near her office. She decides to eliminate from consideration any house that has a mean morning commute time greater than 20 minutes. The null hypothesis for this

right-sided test is $H_0: \mu = 20$, and the alternative hypothesis is $H_A: \mu > 20$. The selected significance level is 0.05.

To determine the mean commute time, the employee takes a test drive from the house to her office during rush hour every morning for one week, so her total sample size is 5. She assumes that the standard deviation, σ , is equal to 5.

The employee decides that a true mean commute time of 25 minutes is too different from her targeted 20-minute limit, so she wants to detect a significant departure if the true mean is 25 minutes. Find the probability of incorrectly concluding that the mean commute time is no greater than 20 minutes.

Compute the power of the test, and then subtract the power from 1 to obtain β .

```
power = sampsizewr('t',[20 5],25,[],5,'Tail','right');
beta = 1 - power
```

```
beta = 0.4203
```

The β value indicates a probability of 0.4203 that the employee concludes incorrectly that the morning commute is not greater than 20 minutes.

The employee decides that this risk is too high, and she wants no more than a 0.01 probability of reaching an incorrect conclusion. Calculate the number of test drives the employee must take to obtain a power of 0.99.

```
nout = sampsizewr('t',[20 5],25,0.99,[],'Tail','right')
```

```
nout = 18
```

The results indicate that she must take 18 test drives from a candidate house to achieve this power level.

The employee decides that she only has time to take 10 test drives. She also accepts a 0.05 probability of making an incorrect conclusion. Calculate the smallest true parameter value that produces a detectable difference in mean commute time.

```
p1out = sampsizewr('t',[20 5],[],0.95,10,'Tail','right')
```

```
p1out = 25.6532
```

Given the employee's target power level and sample size, her test detects a significant difference from a mean commute time of at least 25.6532 minutes.

Compute Sample Size for a Binomial Test

Compute the sample size, n , required to distinguish $p = 0.30$ from $p = 0.36$, using a binomial test with a power of 0.8.

```
napprox = sampsizewr('p',0.30,0.36,0.8)
```

Warning: Values $N > 200$ are approximate. Plotting the power as a function of N may reveal lower N values that have the required power.

```
napprox = 485
```

The result indicates that a power of 0.8 requires a sample size of 485. However, this result is approximate.

Make a plot to see if any smaller n values provide the required power of 0.8.

```
nn = 1:500;
pwrout = sampsizepwr('p',0.3,0.36,[],nn);
nexact = min(nn(pwrout>=0.8))

nexact = 462
```

```
figure
plot(nn,pwrout,'b-',[napprox nexact],pwrout([napprox nexact]),'ro')
grid on
```

The result indicates that a sample size of 462 also provides a power of 0.8 for this test.

Compute Power for a Two-Sample t-Test

A farmer wants to test the impact of two different types of fertilizer on the yield of his bean crops. He currently uses Fertilizer A, but believes that Fertilizer B might improve crop yield. Because Fertilizer B is more expensive than Fertilizer A, the farmer wants to limit the number of plans he treats with Fertilizer B in this experiment.

The farmer uses a 2:1 ratio of plants in each treatment group. He tests 10 plants with Fertilizer A, and 5 plants with Fertilizer B. The mean yield using Fertilizer A is 1.4 kg per plant, with a standard deviation of 0.2. The mean yield using Fertilizer B is 1.7 kg per plant. The significance level of the test is 0.05.

Compute the power of the test.

```
pwr = sampsizewr('t2',[1.4 0.2],1.7,[],5,'Ratio',2)
pwr = 0.7165
```

The farmer wants to increase the power of the test to 0.90. Calculate how many plants he must treat with each type of fertilizer.

```
n = sampsizewr('t2',[1.4 0.2],1.7,0.9,[])
n = 11
```

To increase the power of the test to 0.90, the farmer must test 11 plants with each type of fertilizer.

The farmer wants to reduce the number of plants he must treat with Fertilizer B, but keep the power of the test at 0.90 and maintain the initial 2:1 ratio of plants in each treatment group

Using a 2:1 ratio of plants in each treatment group, calculate how many plants the farmer must test to obtain a power of 0.90. Use the mean and standard deviation values obtained in the previous test.

```
[n1out,n2out] = sampsizewr('t2',[1.4,0.2],1.7,0.9,[],'Ratio',2)
n1out = 8
n2out = 16
```

To obtain a power of 0.90, the farmer must treat 16 plants with Fertilizer A and 8 plants with Fertilizer B.

Input Arguments

testtype — Test type

'z' | 't' | 't2' | 'var' | 'p'

Test type, specified as one of the following.

- 'z' — z -test for normally distributed data with known standard deviation.
- 't' — t -test for normally distributed data with unknown standard deviation.
- 't2' — Two-sample pooled t -test for normally distributed data with unknown standard deviation and equal variances.
- 'var' — Chi-square test of variance for normally distributed data.
- 'p' — Test of the p parameter (success probability) for a binomial distribution. The 'p' test is a discrete test for which increasing the sample size does not always increase the power. For n values larger than 200, there may exist values smaller than the returned n value that also produce the specified power.

p0 — Parameter value under null hypothesis

scalar value | two-element array of scalar values

Parameter value under the null hypothesis, specified as a scalar value or a two-element array of scalar values.

- If `testtype` is 'z' or 't', then p_0 is a two-element array $[\mu_0, \sigma_0]$ of the mean and standard deviation, respectively, under the null hypothesis.
- If `testtype` is 't2', then p_0 is a two-element array $[\mu_0, \sigma_0]$ of the mean and standard deviation, respectively, of the first sample under the null and alternative hypotheses.
- If `testtype` is 'var', then p_0 is the variance under the null hypothesis.
- If `testtype` is 'p', then p_0 is the value of p under the null hypothesis.

Data Types: `single` | `double`

p1 — Parameter value under alternative hypothesis

scalar value | array of scalar values | []

Parameter value under the alternative hypothesis, specified as a scalar value or as an array of scalar values.

- If `testtype` is 'z' or 't', then p_1 is the value of the mean under the alternative hypothesis.
- If `testtype` is 't2', then p_1 is the value of the mean of the second sample under the alternative hypothesis.
- If `testtype` is 'var', then p_1 is the variance under the alternative hypothesis.
- If `testtype` is 'p', then p_1 is the value of p under the alternative hypothesis.

If you specify p_1 as an array, then `sampsizepwr` returns an array for `nout` or `pwrout` that is the same length as p_1 .

To return the alternative parameter value, `p1out`, specify p_1 using empty brackets ([]), as shown in the syntax description on page 32-5013.

Data Types: `single` | `double`

pwr — Power of the test

0.90 (default) | scalar value in the range (0,1) | array of scalar values in the range (0,1) | []

Power of the test, specified as a scalar value in the range (0,1) or as an array of scalar values in the range (0,1). The power of a test is the probability of rejecting the null hypothesis when the alternative hypothesis is true, given a particular significance level.

If you specify `pwr` as an array, then `sampsizepwr` returns an array for `nout` or `p1out` that is the same length as `pwr`.

To return a power value, `pwrout`, specify `pwr` using empty brackets ([]), as shown in the syntax description on page 32-5013.

Data Types: `single` | `double`

n — Sample size

positive integer value | array of positive integer values

Sample size, specified as a positive integer value or as an array of positive integer values.

If `testtype` is 't2', then `sampsizepwr` assumes that the two sample sizes are equal. For unequal sample sizes, specify `n` as the smaller of the two sample sizes, and use the 'Ratio' name-value pair

argument to indicate the sample size ratio. For example, if the smaller sample size is 5 and the larger sample size is 10, specify `n` as 5, and the `'Ratio'` name-value pair as 2.

If you specify `n` as an array, then `sampsizewr` returns an array for `pwrout` or `plout` that is the same length as `n`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Alpha', 0.01, 'Tail', 'right'` specifies a right-tailed test with a 0.01 significance level.

Alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance value of the test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

Ratio — Sample size ratio

1 (default) | scalar value greater than or equal to 1

Sample size ratio for a two-sample *t*-test, specified as the comma-separated pair consisting of `'Ratio'` and a scalar value greater than or equal to 1. The value of `Ratio` is equal to n_2/n_1 , where n_2 is the larger sample size, and n_1 is the smaller sample size.

To return the power, `pwrout`, or alternative parameter value, `plout`, specify the smaller of the two sample sizes for `n`, and use `'Ratio'` to indicate the sample size ratio.

Example: `'Ratio', 2`

Tail — Test type

`'both'` (default) | `'right'` | `'left'`

Test type, specified as the comma-separated pair consisting of `'Tail'` and one of the following:

- `'both'` — Two-sided test for an alternative not equal to p_0
- `'right'` — One-sided test for an alternative larger than p_0
- `'left'` — One-sided test for an alternative smaller than p_0

Example: `'Tail', 'right'`

Output Arguments

nout — Sample size

positive integer value | array of positive integer values

Sample size, returned as a positive integer value or as an array of positive integer values.

If `testtype` is `t2`, and you use the `'Ratio'` name-value pair argument to specify the ratio of the two unequal sample sizes, then `nout` returns the smaller of the two sample sizes.

Alternatively, to return both sample sizes, specify this argument as `[n1out, n2out]`. In this case, `sampsizepwr` returns the smaller sample size as `n1out`, and the larger sample size as `n2out`.

If you specify `pwr` or `p1` as an array, then `sampsizepwr` returns an array for `nout` that is the same length as `pwr` or `p1`.

pwrout – Power

scalar value in the range (0,1) | array of scalar values in the range (0,1)

Power achieved by the test, returned as a scalar value in the range (0,1) or as an array of scalar values in the range (0,1).

If you specify `n` or `p1` as an array, then `sampsizepwr` returns an array for `pwrout` that is the same length as `n` or `p1`.

p1out – Parameter value for the alternative hypothesis

scalar value | array of scalar values

Parameter value for the alternative hypothesis, returned as a scalar value or as an array of scalar values.

When computing `p1out` for the `'p'` test, if no alternative can be rejected for a given null hypothesis and significance level, the function displays a warning message and returns `NaN`.

Introduced in R2006b

saveCompactModel

(To be removed) Save model object in file for code generation

Note `saveCompactModel` will be removed in a future release. Use `saveLearnerForCoder` instead. To update your code, simply replace instances of `saveCompactModel` with `saveLearnerForCoder`.

Syntax

```
saveCompactModel(Mdl, filename)
```

Description

To generate C/C++ code for the object functions (`predict`, `random`, `knnsearch`, or `rangesearch`) of machine learning models, use `saveCompactModel`, `loadCompactModel`, and `codegen`. After training a machine learning model, save the model by using `saveCompactModel`. Define an entry-point function that loads the model by using `loadCompactModel` and calls an object function. Then use `codegen` or the MATLAB Coder app to generate C/C++ code. Generating C/C++ code requires MATLAB Coder.

This flow chart shows the code generation workflow for the object functions of machine learning models. Use `saveCompactModel` for the highlighted step.

`saveCompactModel(Mdl, filename)` prepares a classification model, regression model, or nearest neighbor searcher (`Mdl`) for code generation and saves it in the MATLAB formatted binary file (MAT-file) named `filename`. You can pass `filename` to `loadCompactModel` to reconstruct the model object from the `filename` file.

Examples

Generate C/C++ Code for Prediction

After training a machine learning model, save the model by using `saveCompactModel`. Define an entry-point function that loads the model by using `loadCompactModel` and calls the `predict` function of the trained model. Then use `codegen` to generate C/C++ code.

This example briefly explains the code generation workflow for the prediction of machine learning models at the command line. For more details, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 31-9. You can also generate code using the MATLAB Coder app. See “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 31-16 for details. To learn about the code generation for finding nearest neighbors using a nearest neighbor searcher model, see “Code Generation for Nearest Neighbor Searcher” on page 31-13.

Train Model

Load Fisher's iris data set. Remove all observed setosa irises data so that X and Y contain data for two classes only.

```
load fisheriris
inds = ~strcmp(species, 'setosa');
X = meas(inds, :);
Y = species(inds);
```

Train a support vector machine (SVM) classification model using the processed data set.

```
Mdl = fitcsvm(X, Y);
```

Mdl is a ClassificationSVM model.

Save Model

Save the SVM classification model to the file SVMIris.mat by using saveCompactModel.

```
saveCompactModel(Mdl, 'SVMIris');
```

Define Entry-Point Function

Define an entry-point function named classifyIris that does the following:

- Accept iris flower measurements with columns corresponding to meas, and return predicted labels.
- Load a trained SVM classification model.
- Predict labels using the loaded classification model for the iris flower measurements.

```
type classifyIris.m % Display contents of classifyIris.m file

function label = classifyIris(X) %#codegen
%CLASSIFYIRISES Classify iris species using SVM Model
% CLASSIFYIRISES classifies the iris flower measurements in X using the
% compact SVM model in the file SVMIris.mat, and then returns class
% labels in label.
CompactMdl = loadCompactModel('SVMIris');
label = predict(CompactMdl, X);
end
```

Add the %#codegen compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation.

Note: If you click the button located in the upper-right section of this example and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

Generate Code

Generate code for the entry-point function using codegen. Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. Pass X as the value of the -args option to specify that the generated code must accept an input that has the same data type and array size as the training data X. If the number of observations is

unknown at compile time, you can also specify the input as variable-size by using `coder.typeof`. For details, see “Specify Variable-Size Arguments for Code Generation” on page 31-38 and “Specify Properties of Entry-Point Function Inputs” (MATLAB Coder).

```
codegen classifyIris -args {X}
```

codegen generates the MEX function `classifyIris_mex` with a platform-dependent extension.

Verify Generated Code

Compare the labels classified using `predict`, `classifyIris`, and `classifyIris_mex`.

```
label1 = predict(Mdl,X);
label2 = classifyIris(X);
label3 = classifyIris_mex(X);
verify_label = isequal(label1,label2,label3)

verify_label = logical
    1
```

`isequal` returns logical 1 (true), which means all the inputs are equal. The labels classified all three ways are the same.

Input Arguments

Mdl — Machine learning model

full model object | compact model object

Machine learning model, specified as a full or compact model object, as given in the following tables of supported models.

- **Classification Model Object**

Model	Full/Compact Model Objects	Training Function
Binary decision tree for classification	ClassificationTree, CompactClassificationTree	fitctree
Discriminant analysis classification	ClassificationDiscriminant, CompactClassificationDiscriminant	fitcdiscr
Ensemble classifier	ClassificationEnsemble, CompactClassificationEnsemble, ClassificationBaggedEnsemble	fitcensemble
<i>k</i> -nearest neighbor classification	ClassificationKNN	fitcknn
Linear model for binary classification of high-dimensional data	ClassificationLinear	fitclinear
Multiclass model for support vector machines (SVMs) or other classifiers	ClassificationECOC, CompactClassificationECOC	fitcecoc
Naive Bayes classifier	ClassificationNaiveBayes, CompactClassificationNaiveBayes	fitcnb
SVM for one-class and binary classification	ClassificationSVM, CompactClassificationSVM	fitcsvm

- **Regression Model Object**

Model	Full/Compact Model Object	Training Function
Ensemble regression	RegressionEnsemble, CompactRegressionEnsemble, RegressionBaggedEnsemble	fitrensemble
Gaussian process regression	RegressionGP, CompactRegressionGP	fitrgp
Generalized linear model	GeneralizedLinearModel, CompactGeneralizedLinearModel	fitglm, stepwiseglm
Linear regression model	LinearModel, CompactLinearModel	fitlm, stepwiselm
Linear regression for high-dimensional data	RegressionLinear	fitrlinear
Regression tree	RegressionTree, CompactRegressionTree	fitrtree
SVM regression	RegressionSVM, CompactRegressionSVM	fitrsvm

- **Nearest Neighbor Searcher Object**

Model	Model Object	Training Function
Exhaustive nearest neighbor searcher	ExhaustiveSearcher	ExhaustiveSearcher, createns
Nearest neighbor searcher using Kd-tree	KDTreeSearcher	KDTreeSearcher, createns

filename – File name

character vector | string scalar

File name, specified as a character vector or string scalar.

If the filename file exists, then saveCompactModel overwrites the file.

The extension of the filename file must be .mat. If filename has no extension, then saveCompactModel appends .mat.

If filename does not include a full path, then saveCompactModel saves the file to the current folder.

Example: 'SVMmdl'

Data Types: char | string

Algorithms

saveCompactModel prepares a machine learning model (Mdl) for code generation. The function removes some properties that are not required for prediction.

- For a model that has a corresponding compact model, the `saveCompactModel` function applies the appropriate compact function to the model before saving it.
- For a model that does not have a corresponding compact model, such as `ClassificationKNN`, `ClassificationLinear`, `RegressionLinear`, `ExhaustiveSearcher`, and `KDTreeSearcher`, the `saveCompactModel` function removes properties such as hyperparameter optimization properties, training solver information, and others.

`loadCompactModel` loads the model saved by `saveCompactModel`.

Alternative Functionality

- Use a coder configurer created by `learnerCoderConfigurer` for the models listed in this table.

Model	Coder Configurer Object
Binary decision tree for multiclass classification	<code>ClassificationTreeCoderConfigurer</code>
SVM for one-class and binary classification	<code>ClassificationSVMCoderConfigurer</code>
Linear model for binary classification	<code>ClassificationLinearCoderConfigurer</code>
Multiclass model for SVMs and linear models	<code>ClassificationECOCCoderConfigurer</code>
Binary decision tree for regression	<code>RegressionTreeCoderConfigurer</code>
Support vector machine (SVM) regression	<code>RegressionSVMCoderConfigurer</code>
Linear regression	<code>RegressionLinearCoderConfigurer</code>

After training a machine learning model, create a coder configurer of the model. Use the object functions and properties of the configurer to configure code generation options and to generate code for the `predict` and `update` functions of the model. If you generate code using a coder configurer, you can update model parameters in the generated code without having to regenerate the code. For details, see “Code Generation for Prediction and Update Using Coder Configurer” on page 31-68.

Compatibility Considerations

`saveCompactModel` will be removed

Not recommended starting in R2019b

`saveCompactModel` will be removed in a future release. Use `saveLearnerForCoder` instead.

`saveLearnerForCoder` and `loadLearnerForCoder` provide broader functionality, including fixed-point code generation for supported models.

This table shows how to update your code to use `saveLearnerForCoder`.

Not Recommended	Recommended
<code>saveCompactModel(Model, 'MyModel');</code>	<code>saveLearnerForCoder(Model, 'MyModel');</code>

Introduced in R2016b

saveLearnerForCoder

Save model object in file for code generation

Syntax

```
saveLearnerForCoder(Mdl, filename)
```

Description

To generate C/C++ code for the object functions (`predict`, `random`, `knnsearch`, or `rangesearch`) of machine learning models, use `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen`. After training a machine learning model, save the model by using `saveLearnerForCoder`. Define an entry-point function that loads the model by using `loadLearnerForCoder` and calls an object function. Then use `codegen` or the MATLAB Coder app to generate C/C++ code. Generating C/C++ code requires MATLAB Coder.

This flow chart shows the code generation workflow for the object functions of machine learning models. Use `saveLearnerForCoder` for the highlighted step.

Fixed-point C/C++ code generation requires an additional step that defines the fixed-point data types of the variables required for prediction. Create a fixed-point data type structure by using the data type function generated by `generateLearnerDataTypeFcn`, and use the structure as an input argument of `loadLearnerForCoder` in an entry-point function. Generating fixed-point C/C++ code requires MATLAB Coder and Fixed-Point Designer.

This flow chart shows the fixed-point code generation workflow for the `predict` function of a machine learning model. Use `saveLearnerForCoder` for the highlighted step.

`saveLearnerForCoder(Mdl, filename)` prepares a classification model, regression model, or nearest neighbor searcher (`Mdl`) for code generation and saves it in the MATLAB formatted binary file (MAT-file) named `filename`. You can pass `filename` to `loadLearnerForCoder` to reconstruct the model object from the `filename` file.

Examples

Generate C/C++ Code for Prediction

After training a machine learning model, save the model by using `saveLearnerForCoder`. Define an entry-point function that loads the model by using `loadLearnerForCoder` and calls the `predict` function of the trained model. Then use `codegen` to generate C/C++ code.

This example briefly explains the code generation workflow for the prediction of machine learning models at the command line. For more details, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 31-9. You can also generate code using the MATLAB Coder app. See “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 31-16 for details. To learn about the code generation for finding nearest neighbors using a nearest neighbor searcher model, see “Code Generation for Nearest Neighbor Searcher” on page 31-13.

Train Model

Load Fisher's iris data set. Remove all observed setosa irises data so that X and Y contain data for two classes only.

```
load fisheriris
inds = ~strcmp(species,'setosa');
X = meas(inds,:);
Y = species(inds);
```

Train a support vector machine (SVM) classification model using the processed data set.

```
Mdl = fitcsvm(X,Y);
```

Mdl is a ClassificationSVM model.

Save Model

Save the SVM classification model to the file SVMIris.mat by using saveLearnerForCoder.

```
saveLearnerForCoder(Mdl,'SVMIris');
```

Define Entry-Point Function

Define an entry-point function named classifyIris that does the following:

- Accept iris flower measurements with columns corresponding to meas, and return predicted labels.
- Load a trained SVM classification model.
- Predict labels using the loaded classification model for the iris flower measurements.

```
type classifyIris.m % Display contents of classifyIris.m file
```

```
function label = classifyIris(X) %#codegen
%CLASSIFYIRIS Classify iris species using SVM Model
% CLASSIFYIRIS classifies the iris flower measurements in X using the SVM
% model in the file SVMIris.mat, and then returns class labels in label.
Mdl = loadLearnerForCoder('SVMIris');
label = predict(Mdl,X);
end
```

Add the %#codegen compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation.

Note: If you click the button located in the upper-right section of this example and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

Generate Code

Generate code for the entry-point function using `codegen`. Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. Pass `X` as the value of the `-args` option to specify that the generated code must accept an input that has the same data type and array size as the training data `X`. If the number of observations is unknown at compile time, you can also specify the input as variable-size by using `coder.typeof`. For details, see “Specify Variable-Size Arguments for Code Generation” on page 31-38 and “Specify Properties of Entry-Point Function Inputs” (MATLAB Coder).

```
codegen classifyIris -args {X}
```

`codegen` generates the MEX function `classifyIris_mex` with a platform-dependent extension.

Verify Generated Code

Compare the labels classified using `predict`, `classifyIris`, and `classifyIris_mex`.

```
label1 = predict(Mdl,X);
label2 = classifyIris(X);
label3 = classifyIris_mex(X);
verify_label = isequal(label1,label2,label3)

verify_label = logical
    1
```

`isequal` returns logical 1 (true), which means all the inputs are equal. The labels classified all three ways are the same.

Generate Fixed-Point C/C++ Code for Prediction

After training a machine learning model, save the model using `saveLearnerForCoder`. For fixed-point code generation, specify the fixed-point data types of the variables required for prediction by using the data type function generated by `generateLearnerDataTypeFcn`. Then, define an entry-point function that loads the model by using both `loadLearnerForCoder` and the specified fixed-point data types, and calls the `predict` function of the model. Use `codegen` to generate fixed-point C/C++ code for the entry-point function, and then verify the generated code.

Before generating code using `codegen`, you can use `buildInstrumentedMex` and `showInstrumentationResults` to optimize the fixed-point data types to improve the performance of the fixed-point code. Record minimum and maximum values of named and internal variables for prediction by using `buildInstrumentedMex`. View the instrumentation results using `showInstrumentationResults`; then, based on the results, tune the fixed-point data type properties of the variables. For details regarding this optional step, see “Fixed-Point Code Generation for Prediction of SVM” on page 31-75.

Train Model

Load the `ionosphere` data set and train a binary SVM classification model.

```
load ionosphere
Mdl = fitcsvm(X,Y,'KernelFunction','gaussian');
```

`Mdl` is a `ClassificationSVM` model.

Save Model

Save the SVM classification model to the file `myMdl.mat` by using `saveLearnerForCoder`.

```
saveLearnerForCoder(Mdl, 'myMdl');
```

Define Fixed-Point Data Types

Use `generateLearnerDataTypeFcn` to generate a function that defines the fixed-point data types of the variables required for prediction of the SVM model.

```
generateLearnerDataTypeFcn('myMdl', X)
```

`generateLearnerDataTypeFcn` generates the `myMdl_datatype` function.

Create a structure `T` that defines the fixed-point data types by using `myMdl_datatype`.

```
T = myMdl_datatype('Fixed')
```

```
T = struct with fields:
    XDataType: [0x0 embedded.fi]
    ScoreDataType: [0x0 embedded.fi]
    InnerProductDataType: [0x0 embedded.fi]
```

The structure `T` includes the fields for the named and internal variables required to run the `predict` function. Each field contains a fixed-point object, returned by `fi`. The fixed-point object specifies fixed-point data type properties, such as word length and fraction length. For example, display the fixed-point data type properties of the predictor data.

```
T.XDataType
```

```
ans =
```

```
[]

    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Signed
    WordLength: 16
    FractionLength: 14

    RoundingMethod: Floor
    OverflowAction: Wrap
    ProductMode: FullPrecision
    MaxProductWordLength: 128
    SumMode: FullPrecision
    MaxSumWordLength: 128
```

Define Entry-Point Function

Define an entry-point function named `myFixedPointPredict` that does the following:

- Accept the predictor data `X` and the fixed-point data type structure `T`.
- Load a fixed-point version of a trained SVM classification model by using both `loadLearnerForCoder` and the structure `T`.
- Predict labels and scores using the loaded model.

```
type myFixedPointPredict.m % Display contents of myFixedPointPredict.m file
```

```
function [label,score] = myFixedPointPredict(X,T) %#codegen
Mdl = loadLearnerForCoder('myMdl','DataType',T);
[label,score] = predict(Mdl,X);
end
```

Note: If you click the button located in the upper-right section of this example and open the example in MATLAB®, then MATLAB opens the example folder. This folder includes the entry-point function file.

Generate Code

The `XDataType` field of the structure `T` specifies the fixed-point data type of the predictor data. Convert `X` to the type specified in `T.XDataType` by using the `cast` function.

```
X_fx = cast(X,'like',T.XDataType);
```

Generate code for the entry-point function using `codegen`. Specify `X_fx` and constant folded `T` as input arguments of the entry-point function.

```
codegen myFixedPointPredict -args {X_fx,coder.Constant(T)}
```

`codegen` generates the MEX function `myFixedPointPredict_mex` with a platform-dependent extension.

Verify Generated Code

Pass predictor data to `predict` and `myFixedPointPredict_mex` to compare the outputs.

```
[labels,scores] = predict(Mdl,X);
[labels_fx,scores_fx] = myFixedPointPredict_mex(X_fx,T);
```

Compare the outputs from `predict` and `myFixedPointPredict_mex`.

```
verify_labels = isequal(labels,labels_fx)
```

```
verify_labels = logical
    1
```

`isequal` returns logical 1 (true), which means `labels` and `labels_fx` are equal. If the labels are not equal, you can compute the percentage of incorrectly classified labels as follows.

```
sum(strcmp(labels_fx,labels)==0)/numel(labels_fx)*100
```

```
ans = 0
```

Find the maximum of the relative differences between the score outputs.

```
relDiff_scores = max(abs((scores_fx.double(:,1)-scores(:,1))./scores(:,1)))
```

```
relDiff_scores = 0.0055
```

If you are not satisfied with the comparison results and want to improve the precision of the generated code, you can tune the fixed-point data types and regenerate the code. For details, see

“Tips” on page 32-2392 in `generateLearnerDataTypeFcn`, “Data Type Function” on page 32-2391, and “Fixed-Point Code Generation for Prediction of SVM” on page 31-75.

Input Arguments

Mdl — Machine learning model

full model object | compact model object

Machine learning model, specified as a full or compact model object, as given in the following tables of supported models.

- **Classification Model Object**

Model	Full/Compact Model Objects	Training Function
Binary decision tree for classification	<code>ClassificationTree</code> , <code>CompactClassificationTree</code>	<code>fitctree</code>
Discriminant analysis classification	<code>ClassificationDiscriminant</code> , <code>CompactClassificationDiscriminant</code>	<code>fitcdiscr</code>
Ensemble classifier	<code>ClassificationEnsemble</code> , <code>CompactClassificationEnsemble</code> , <code>ClassificationBaggedEnsemble</code>	<code>fitcensemble</code>
<i>k</i> -nearest neighbor classification	<code>ClassificationKNN</code>	<code>fitcknn</code>
Linear model for binary classification of high-dimensional data	<code>ClassificationLinear</code>	<code>fitclinear</code>
Multiclass model for support vector machines (SVMs) or other classifiers	<code>ClassificationECOC</code> , <code>CompactClassificationECOC</code>	<code>fitcecoc</code>
Naive Bayes classifier	<code>ClassificationNaiveBayes</code> , <code>CompactClassificationNaiveBayes</code>	<code>fitcnb</code>
SVM for one-class and binary classification	<code>ClassificationSVM</code> , <code>CompactClassificationSVM</code>	<code>fitcsvm</code>

- **Regression Model Object**

Model	Full/Compact Model Object	Training Function
Ensemble regression	RegressionEnsemble, CompactRegressionEnsemble, RegressionBaggedEnsemble	fitrensemble
Gaussian process regression	RegressionGP, CompactRegressionGP	fitrgp
Generalized linear model	GeneralizedLinearModel, CompactGeneralizedLinearModel	fitglm, stepwiseglm
Linear regression model	LinearModel, CompactLinearModel	fitlm, stepwiselm
Linear regression for high-dimensional data	RegressionLinear	fitrlinear
Regression tree	RegressionTree, CompactRegressionTree	fitrtree
SVM regression	RegressionSVM, CompactRegressionSVM	fitrsvm

- **Nearest Neighbor Searcher Object**

Model	Model Object	Training Function
Exhaustive nearest neighbor searcher	ExhaustiveSearcher	ExhaustiveSearcher, createns
Nearest neighbor searcher using Kd-tree	KDTreeSearcher	KDTreeSearcher, createns

filename – File name

character vector | string scalar

File name, specified as a character vector or string scalar.

If the filename file exists, then saveLearnerForCoder overwrites the file.

The extension of the filename file must be .mat. If filename has no extension, then saveLearnerForCoder appends .mat.

If filename does not include a full path, then saveLearnerForCoder saves the file to the current folder.

Example: 'SVMmdl'

Data Types: char | string

Algorithms

saveLearnerForCoder prepares a machine learning model (Mdl) for code generation. The function removes some properties that are not required for prediction.

- For a model that has a corresponding compact model, the `saveLearnerForCoder` function applies the appropriate compact function to the model before saving it.
- For a model that does not have a corresponding compact model, such as `ClassificationKNN`, `ClassificationLinear`, `RegressionLinear`, `ExhaustiveSearcher`, and `KDTreeSearcher`, the `saveLearnerForCoder` function removes properties such as hyperparameter optimization properties, training solver information, and others.

`loadLearnerForCoder` loads the model saved by `saveLearnerForCoder`.

Alternative Functionality

- Use a coder configurer created by `learnerCoderConfigurer` for the models listed in this table.

Model	Coder Configurer Object
Binary decision tree for multiclass classification	<code>ClassificationTreeCoderConfigurer</code>
SVM for one-class and binary classification	<code>ClassificationSVMCoderConfigurer</code>
Linear model for binary classification	<code>ClassificationLinearCoderConfigurer</code>
Multiclass model for SVMs and linear models	<code>ClassificationECOCCoderConfigurer</code>
Binary decision tree for regression	<code>RegressionTreeCoderConfigurer</code>
Support vector machine (SVM) regression	<code>RegressionSVMCoderConfigurer</code>
Linear regression	<code>RegressionLinearCoderConfigurer</code>

After training a machine learning model, create a coder configurer of the model. Use the object functions and properties of the configurer to configure code generation options and to generate code for the `predict` and `update` functions of the model. If you generate code using a coder configurer, you can update model parameters in the generated code without having to regenerate the code. For details, see “Code Generation for Prediction and Update Using Coder Configurer” on page 31-68.

Introduced in R2019b

scatterhist

Scatter plot with marginal histograms

Syntax

```
scatterhist(x,y)  
scatterhist(x,y,Name,Value)
```

```
h = scatterhist( ___ )
```

Description

`scatterhist(x,y)` creates a 2-D scatter plot of the data in vectors `x` and `y`, and displays the marginal distributions of `x` and `y` as univariate histograms on the horizontal and vertical axes of the scatter plot, respectively.

`scatterhist(x,y,Name,Value)` creates the plot using additional options specified by one or more name-value pair arguments. For example, you can specify a grouping variable or change the display options.

`h = scatterhist(___)` returns a vector of three axis handles for the scatter plot, the histogram along the horizontal axis, and the histogram along the vertical axis, respectively, using any of the input arguments in the previous syntaxes.

Examples

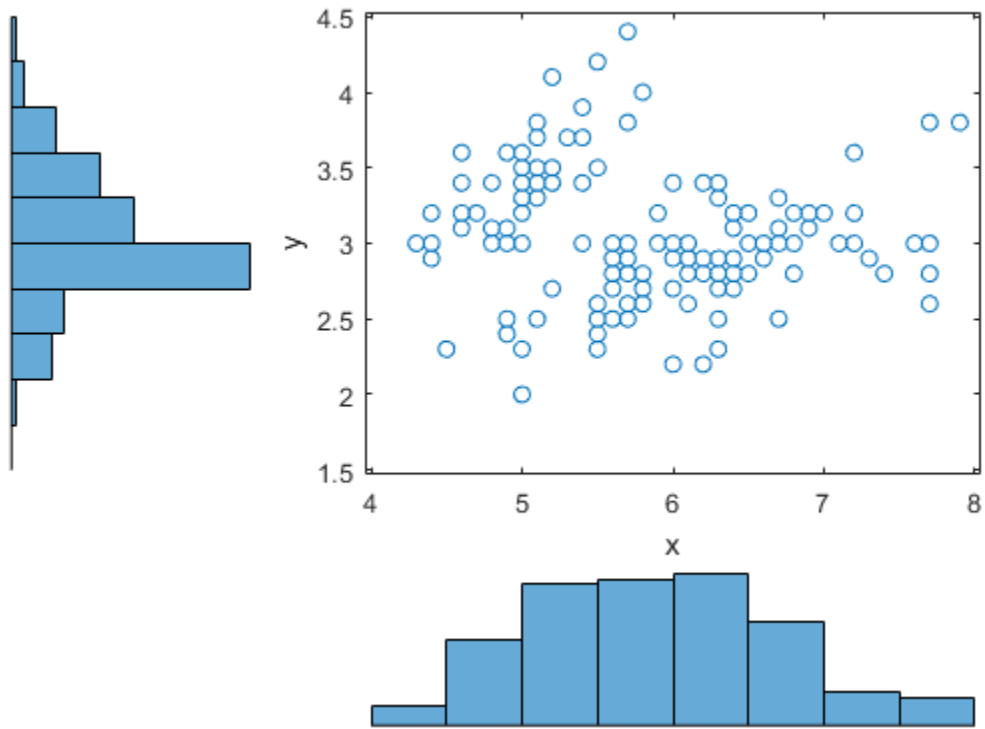

Create a scatterhist Plot

Load the sample data. Create data vector `x` from the first column of the data matrix, which contains sepal length measurements from iris flowers. Create data vector `y` from the second column of the data matrix, which contains sepal width measurements from the same flowers.

```
load fisheriris.mat;  
x = meas(:,1);  
y = meas(:,2);
```

Create a scatter plot and two marginal histograms to visualize the relationship between sepal length and sepal width.

```
scatterhist(x,y)
```

Display a data tip for a bin in a histogram. A data tip appears when you hover over a bin in a histogram.

The data tip displays the probability density function estimate of the selected bin and the lower and upper values for the bin edges.

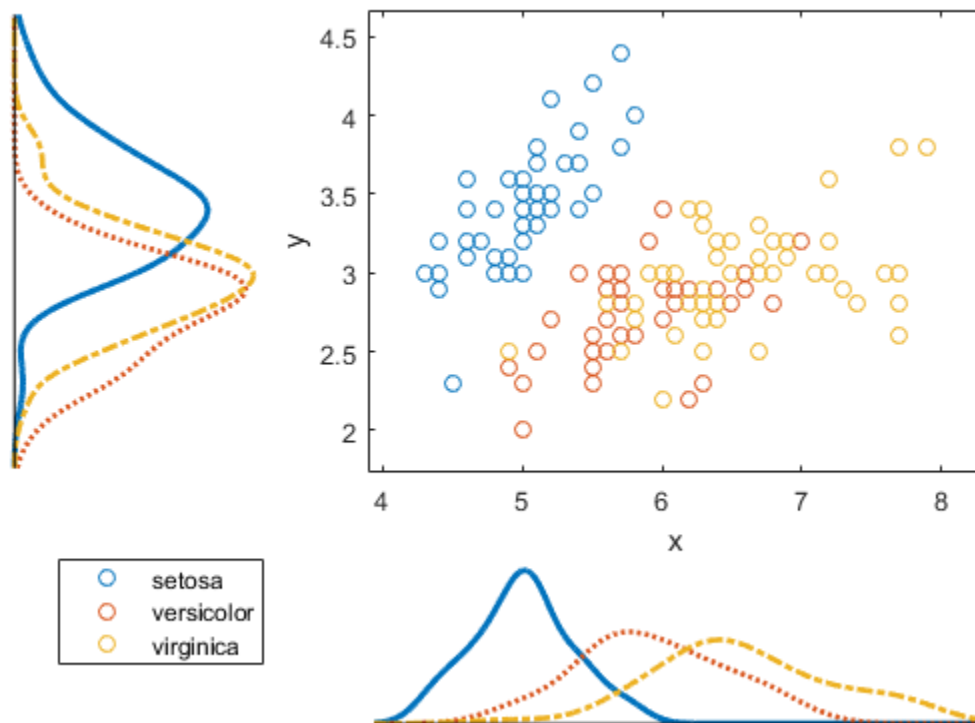

Plot Grouped Data

Load the sample data. Create data vector `x` from the first column of the data matrix, which contains sepal length measurements from three species of iris flowers. Create data vector `y` from the second column of the data matrix, which contains sepal width measurements from the same flowers.

```
load fisheriris.mat;
x = meas(:,1);
y = meas(:,2);
```

Create a scatter plot and six kernel density plots to visualize the relationship between sepal length and sepal width, grouped by species.

```
scatterhist(x,y,'Group',species,'Kernel','on')
```

The plot shows that the relationship between sepal length and width varies depending on the flower species.

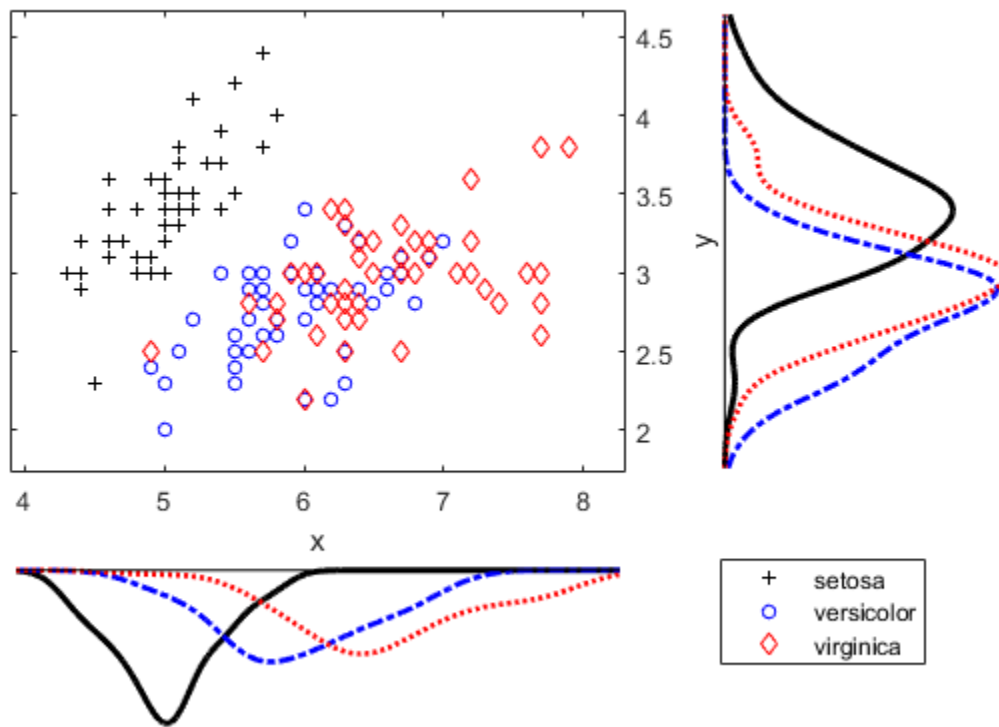

Customize the Plot Display

Load the sample data. Create data vector `x` from the first column of the data matrix, which contains sepal length measurements from three different species of iris flowers. Create data vector `y` from the second column of the data matrix, which contains sepal width measurements from the same flowers.

```
load fisheriris.mat;
x = meas(:,1);
y = meas(:,2);
```

Create a scatter plot and six kernel density plots to visualize the relationship between sepal length and sepal width as measured on three species of iris flowers, grouped by species. Customize the appearance of the plots.

```
scatterhist(x,y,'Group',species,'Kernel','on','Location','SouthEast',...
'Direction','out','Color','kbr','LineStyle',{'-','-',':'},...
'LineWidth',[2,2,2],'Marker','+od','MarkerSize',[4,5,6]);
```

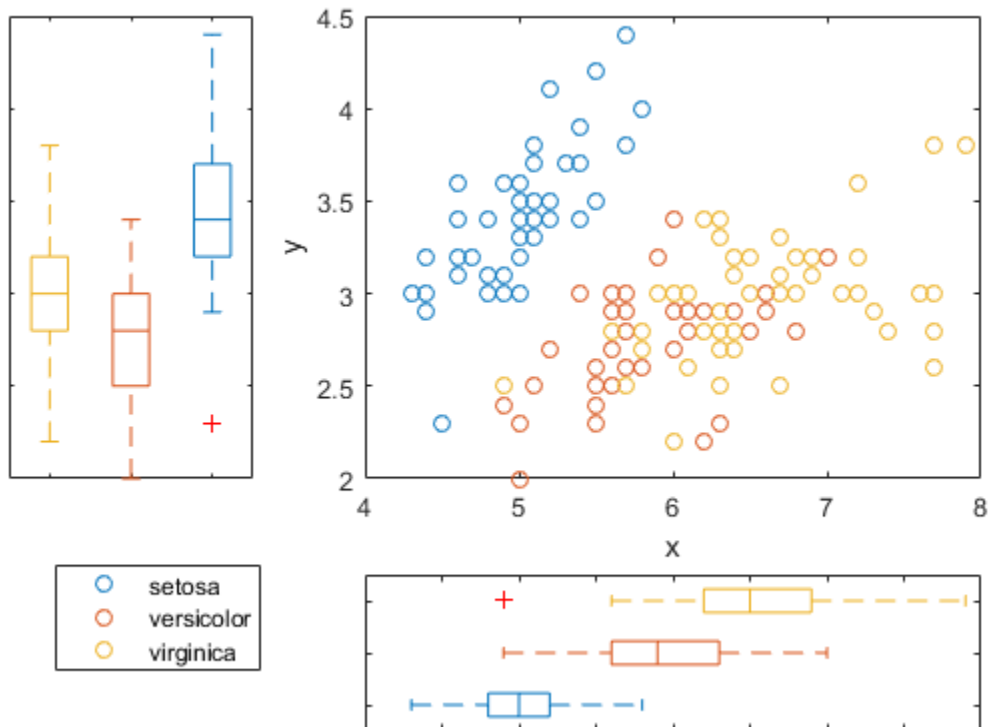

Customize Plots Using Axes Handles

Load the sample data. Create data vector `x` from the first column of the data matrix, which contains sepal length measurements from three species of iris flowers. Create data vector `y` from the second column of the data matrix, which contains sepal width measurements from the same flowers.

```
load fisheriris.mat;
x = meas(:,1);
y = meas(:,2);
```

Use axis handles to replace the marginal histograms with box plots.

```
h = scatterhist(x,y,'Group',species);
hold on;
clr = get(h(1),'colororder');
boxplot(h(2),x,species,'orientation','horizontal',...
        'label',{' ',' ',' '},'color',clr);
boxplot(h(3),y,species,'orientation','horizontal',...
        'label',{' ',' ',' '},'color',clr);
set(h(2:3),'XTickLabel','');
view(h(3),[270,90]); % Rotate the Y plot
axis(h(1),'auto'); % Sync axes
hold off;
```

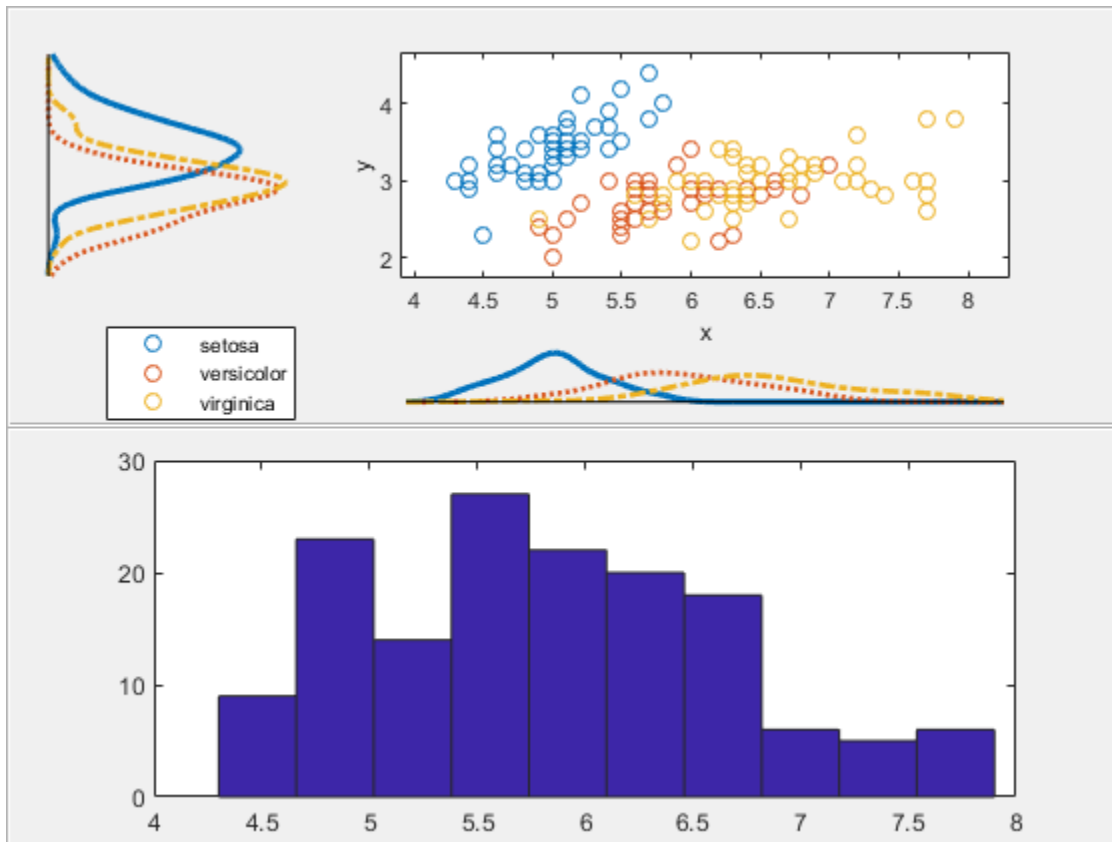

Create a scatterhist Plot in a Specified Parent Container

Load the sample data. Create data vector `x` from the first column of the data matrix, which contains sepal length measurements from iris flowers. Create data vector `y` from the second column of the data matrix, which contains sepal width measurements from the same flowers.

```
load fisheriris
x = meas(:,1);
y = meas(:,2);
```

Create a new figure and define two `uipanel` objects to divide the figure into two parts. In the upper half of the figure, plot the sample data using `scatterhist`. Include marginal kernel density plots grouped by species. In the lower half of the figure, plot a histogram of the sepal length measurements contained in `x`.

```
figure
hp1 = uipanel('position',[0 .5 1 .5]);
hp2 = uipanel('position',[0 0 1 .5]);
scatterhist(x,y,'Group',species,'Kernel','on','Parent',hp1);
axes('Parent',hp2);
hist(x);
```

Input Arguments

x — Sample data

vector

Sample data, specified as a vector. The data vectors **x** and **y** must be the same length.

If **x** or **y** contain NaN values, then `scatterhist`:

- Removes rows with NaN values in either **x** or **y** from both data vectors when generating the scatter plot
- Removes rows with NaN values only from the corresponding **x** or **y** data vector when generating the marginal histograms

Data Types: `single` | `double`

y — Sample data

vector

Sample data, specified as a vector. The data vectors **x** and **y** must be the same length.

If **x** or **y** contain NaN values, then `scatterhist`:

- Removes rows with NaN values in either **x** or **y** from both data vectors when generating the scatter plot

- Removes rows with NaN values only from the corresponding x or y data vector when generating the marginal histograms

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Location', 'SouthEast', 'Direction', 'out'` specifies a plot with histograms located below and to the right of the scatter plot, with the bars directed away from the scatter plot.

NBins — Number of bins for histograms

positive integer value | vector

Number of bins for histograms, specified as the comma-separated pair consisting of `'NBins'` and a positive integer value greater than or equal to 2, or vector of two such values. If the number of bins is specified as a positive integer value, that value is the number of bins for both the x and y histograms. If the number of bins is specified by a vector, the first value is the number of bins for the x data, and the second value is the number of bins for the y data. By default, the number of bins is computed based on the sample standard deviation using Scott's rule.

Example: `'NBins', [5,7]`

Data Types: `single` | `double`

Location — Location of marginal histograms

`'SouthWest'` (default) | `'SouthEast'` | `'NorthEast'` | `'NorthWest'`

Location of the marginal histograms in the figure, specified as the comma-separated pair consisting of `'Location'` and one of the following.

`'SouthWest'` Plot the histograms below and to the left of the scatter plot.

,

`'SouthEast'` Plot the histograms below and to the right of the scatter plot.

,

`'NorthEast'` Plot the histograms above and to the right of the scatter plot.

,

`'NorthWest'` Plot the histograms above and to the left of the scatter plot.

,

Example: `'Location', 'SouthEast'`

Direction — Direction of marginal histograms

`'in'` (default) | `'out'`

Direction of the marginal histograms, specified as the comma-separated pair consisting of `'Direction'` and one of the following.

`'in'` Plot the histograms with the bars directed toward the scatter plot.

`'out'` Plot the histograms with the bars directed away from the scatter plot.

Example: `'Direction', 'out'`

Group — Grouping variable

categorical array | logical or numeric vector | character array | string array | cell array of character vectors

Grouping variable, specified as the comma-separated pair consisting of 'Group' and a categorical array, logical or numeric vector, character array, string array, or cell array of character vectors. Each unique value in a grouping variable defines a group.

For example, if Gender is a cell array of character vectors with values 'Male' and 'Female', you can use Gender as a grouping variable to plot your data by gender.

The number of rows in the grouping variable must be equal to the length of x.

Example: 'Group', Gender

Data Types: categorical | single | double | logical | char | string | cell

PlotGroup — Grouped plot indicator

'on' | 'off'

Grouped plot indicator, specified as the comma-separated pair consisting of 'PlotGroup' and one of the following.

- 'on' Display grouped histograms or grouped kernel density plots. This is the default if a Group parameter is specified.
- 'off' Display histograms or kernel density plots of the whole data set. This is the default if a Group parameter is not specified.

Example: 'PlotGroup', 'off'

Style — Histogram display style

'stairs' | 'bar'

Histogram display style, specified as the comma-separated pair consisting of 'PlotGroup' and one of the following.

- 'stairs' Display a staircase plot that shows the outline of the histogram without filling the bars. This is the default if you specify a grouping variable that contains more than one group.
- 'bar' Display a histogram bar plot. This is the default if you specify a grouping variable that contains only one group or if PlotGroup is specified as 'off'.

Example: 'Style', 'bar'

Kernel — Kernel density plot indicator

'off' (default) | 'on' | 'overlay'

Kernel density plot indicator, specified as the comma-separated pair consisting of 'Kernel' and one of the following.

- 'off' Display the marginal distributions as histograms.
- 'on' Display the marginal distributions as kernel density plots.

'overlay' Display the marginal distributions as kernel density plots overlaid onto histograms, similar to `histfit`.

Example: 'Kernel', 'overlay'

Bandwidth — Bandwidth of kernel smoothing window

matrix

Bandwidth of kernel smoothing window, specified as the comma-separated pair consisting of 'Bandwidth' and a matrix of size 2-by- K , where K is the number of unique groups. The first row of the matrix gives the bandwidth of each group in x , and the second row gives the bandwidth of each group in y . By default, `scatterhist` finds the optimal bandwidth for estimating normal densities. Specifying a different bandwidth value changes the smoothing characteristics of the resulting kernel density plot. The value specified is a scaling factor for the normal distribution used to generate the kernel density plot.

Example: 'Bandwidth', [.5, .2, .1; .15, .25, .35]

Data Types: single | double

Legend — Legend visibility indicator

'on' | 'off'

Legend visibility indicator, specified as the comma-separated pair consisting of 'Legend' and one of the following.

'on' Set legend visible. This is the default if a Group parameter is specified.
 'off' Set legend invisible. This is the default if a Group parameter is not specified.

Example: 'Legend', 'on'

Parent — Parent container of the plot

uipanel container object | figure container object

Parent container for the plot, specified as a `uipanel` container object or `figure` container object. You can create panel container objects using `uipanel` or `figure`, respectively.

For example, if `h1` is a panel container object, specify the parent container of the plot as follows.

Example: 'Parent', h1

LineStyle — Style of kernel density plot line

valid line style | string array or cell array of line styles

Style of kernel density plot line, specified as the comma-separated pair consisting of 'LineStyle' and a valid line style or a string array or cell array of valid line styles. See `plot` for valid line styles. The default is a solid line. Use a string array or cell array to specify different line styles for each group. When the total number of groups exceeds the number of specified values, `scatterhist` cycles through the specified values.

Example: 'LineStyle', {'-', ':', '-.'}

Data Types: char | string | cell

LineWidth — Width of kernel density plot line

0.5 (default) | nonnegative scalar value | vector

Width of kernel density plot line, specified as the comma-separated pair consisting of `'LineWidth'` and a nonnegative scalar value or vector of nonnegative scalar values. The specified value is the size of the kernel density plot line measured in points. The default size is 0.5 points. Use a vector to specify different line widths for each group. When the total number of groups is greater than the number of specified values, `scatterhist` cycles through the specified values.

Example: `'LineWidth', [0.5, 1, 2]`

Data Types: `single` | `double`

Color — Marker color for each scatter plot group

character vector or string scalar of color names | matrix of RGB values

Marker color for each scatter plot group, specified as the comma-separated pair consisting of `'Color'` and a character vector or string scalar of color names, or a three-column matrix of RGB values in the range [0,1]. If you specify colors using a matrix, then each row of the matrix is an RGB triplet that represents a group. The three columns of the matrix represent the R value, G value, and B value, respectively. When the total number of groups exceeds the number of specified colors, `scatterhist` cycles through the specified colors.

This table lists the predefined colors and their equivalent RGB triplet values.

Option	Description	Equivalent RGB Triplet
'red' or 'r'	Red	[1 0 0]
'green' or 'g'	Green	[0 1 0]
'blue' or 'b'	Blue	[0 0 1]
'yellow' or 'y'	Yellow	[1 1 0]
'magenta' or 'm'	Magenta	[1 0 1]
'cyan' or 'c'	Cyan	[0 1 1]
'white' or 'w'	White	[1 1 1]
'black' or 'k'	Black	[0 0 0]

Example: `'Color', 'kcm'`

Example: `'Color', [.5, 0, 1; 0, .5, .5]`

Data Types: `single` | `double` | `char` | `string`

Marker — Marker symbol for each scatterplot group

'o' (default) | character vector | string scalar

Marker symbol for each scatter plot group, specified as the comma-separated pair consisting of `'Marker'` and a character vector or string scalar of one or more valid marker symbols. See `plot` for valid symbols. The default is 'o', a circle. When the total number of groups exceeds the number of specified symbols, `scatterhist` cycles through the specified symbols.

Example: `'Marker', '+do'`

Data Types: `char` | `string`

MarkerSize — Marker size for each scatter plot group

6 (default) | nonnegative scalar value | vector

Marker size for each scatter plot group, specified as the comma-separated pair consisting of 'MarkerSize' and a nonnegative scalar value or a vector of nonnegative scalar values, measured in points. When the total number of groups exceeds the number of specified values, `scatterhist` cycles through the specified values.

Example: 'MarkerSize',10

Data Types: `single` | `double`

Output Arguments

h — Axes handles

vector

Axes handles for the three plots, returned as a vector. The vector contains the handles for the scatter plot, the histogram along the horizontal axis, and the histogram along the vertical axis, respectively.

Alternative Functionality

Alternatively, you can create a `ScatterHistogramChart` object by using the `scatterhistogram` function.

- Explore the data interactively in the object by panning, zooming, and using data tips. Unlike the `scatterhist` function, `scatterhistogram` updates the marginal histograms based on the data within the current scatter plot limits.
- Control the appearance and behavior of the scatter histogram chart by changing the `ScatterHistogramChart` Properties.

“Grouping Variables” on page 2-45

Introduced in R2007a

scramble

Scramble quasirandom point set

Syntax

```
ps = scramble(p,type)
ps = scramble(p,'clear')
ps = scramble(p)
```

Description

`ps = scramble(p,type)` returns a scrambled copy `ps` of the point set `p`, created using the scramble type specified by `type`. The point set `p` is either a `haltonset` or `sobolset` object, and each type of point set supports a different scramble type.

The scrambled point set `ps` is the same kind of object as `p`.

`ps = scramble(p,'clear')` removes the scramble setting from `p` and returns the result in `ps`.

`ps = scramble(p)` reapplies the existing scramble setting to `p`, which typically results in a different point set because of the randomness of the scrambling algorithms.

Examples

Create Halton Point Set

Generate a three-dimensional Halton point set, skip the first 1000 values, and then retain every 101st point.

```
p = haltonset(3,'Skip',1e3,'Leap',1e2)

p =
Halton point set in 3 dimensions (89180190640991 points)

Properties:
    Skip : 1000
    Leap : 100
    ScrambleMethod : none
```

Apply reverse-radix scrambling by using `scramble`.

```
p = scramble(p,'RR2')

p =
Halton point set in 3 dimensions (89180190640991 points)

Properties:
    Skip : 1000
    Leap : 100
```

```
ScrambleMethod : RR2
```

Generate the first four points by using net.

```
X0 = net(p,4)
```

```
X0 = 4x3
```

```
0.0928    0.6950    0.0029
0.6958    0.2958    0.8269
0.3013    0.6497    0.4141
0.9087    0.7883    0.2166
```

Generate every third point, up to the eleventh point, by using parenthesis indexing.

```
X = p(1:3:11, :)
```

```
X = 4x3
```

```
0.0928    0.6950    0.0029
0.9087    0.7883    0.2166
0.3843    0.9840    0.9878
0.6831    0.7357    0.7923
```

Scramble and Unscramble Sobol Point Set

Create and scramble a five-dimensional Sobol point set. Specify the 'MatousekAffineOwen' scramble type.

```
p = sobolset(5);
ps = scramble(p, 'MatousekAffineOwen');
```

Compare the first four points in the two point sets.

```
X = net(p,4)
```

```
X = 4x5
```

```
0          0          0          0          0
0.5000    0.5000    0.5000    0.5000    0.5000
0.2500    0.7500    0.2500    0.7500    0.2500
0.7500    0.2500    0.7500    0.2500    0.7500
```

```
X2 = net(ps,4)
```

```
X2 = 4x5
```

```
0.6681    0.2784    0.2476    0.5688    0.0513
0.4485    0.6735    0.5417    0.3285    0.9719
0.9940    0.9606    0.3515    0.1586    0.4742
0.1550    0.1202    0.9226    0.9262    0.5491
```

Remove the scramble setting from `ps` by using the `'clear'` option. The point set `clearps` matches the original point set `p`.

```
clearps = scramble(ps, 'clear');
clearX = net(clearps, 4)
```

```
clearX = 4×5
```

```
      0      0      0      0      0
0.5000  0.5000  0.5000  0.5000  0.5000
0.2500  0.7500  0.2500  0.7500  0.2500
0.7500  0.2500  0.7500  0.2500  0.7500
```

Pass `ps` to the `scramble` function without additional input arguments. The software removes the scramble setting from `ps` and then reapplies it. Because of the randomness of the scrambling algorithm, the new scrambled point set `newps` differs from the original scrambled point set `ps`.

```
newps = scramble(ps);
newX = net(newps, 4)
```

```
newX = 4×5
```

```
0.6882  0.6261  0.9298  0.3314  0.4169
0.2442  0.1978  0.4307  0.6286  0.8666
0.7827  0.2868  0.5172  0.8430  0.1261
0.2772  0.8576  0.0164  0.1404  0.5905
```

Input Arguments

p — Point set

haltonset object | sobolset object

Point set, specified as either a `haltonset` or `sobolset` object.

Example: `sobolset(5)`

type — Scramble type

'RR2' | 'MatousekAffineOwen'

Scramble type, specified as `'RR2'` or `'MatousekAffineOwen'`. Different point sets support different scramble types, as indicated in this table.

Object	Scramble Type
haltonset	'RR2' — A permutation of the radical inverse coefficients derived by applying a reverse-radix operation to all of the possible coefficient values. The scramble is described in [1].
sobolset	'MatousekAffineOwen' — A random linear scramble combined with a random digital shift. The scramble is described in [2].

Introduced in R2008a

segment

Piecewise distribution segments containing input values

Syntax

```
s = segment(pd,x)
s = segment(pd,[],p)
```

Description

`s = segment(pd,x)` returns a vector `s` of positive integers indicating which segment in the piecewise distribution `pd` contains each quantile value in `x`.

The values 1, 2, and 3 in `s` indicate the lower tail, center, and upper tail segments in `pd`, respectively. If `pd` does not include a lower tail segment, then 1 and 2 indicate the center and upper tail segments, respectively.

`s = segment(pd,[],p)` returns a vector `s` of positive integers indicating which segment in the piecewise distribution `pd` contains each cumulative probability value in `p`.

Examples

Find Segment in `paretotails` Object

Generate a sample data set and create a `paretotails` object by fitting a piecewise distribution with Pareto tails to the generated data. Find the segment containing the specified quantile values by using the object function `segment`.

Generate a sample data set containing 20% outliers.

```
rng('default'); % For reproducibility
left_tail = -exprnd(1,100,1);
right_tail = exprnd(5,100,1);
center = randn(800,1);
x = [left_tail;center;right_tail];
```

Create a `paretotails` object by fitting a piecewise distribution to `x`. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities so that a fitted object consists of the empirical distribution for the middle 80% of the data set and generalized Pareto distributions (GPDs) for the lower and upper 10% of the data set.

```
pd = paretotails(x,0.1,0.9)
```

```
pd =
Piecewise distribution with 3 segments
  -Inf < x < -1.33251    (0 < p < 0.1): lower tail, GPD(-0.0063504,0.567017)
 -1.33251 < x < 1.80149 (0.1 < p < 0.9): interpolated empirical cdf
  1.80149 < x < Inf    (0.9 < p < 1): upper tail, GPD(0.24874,3.00974)
```

Find the segment containing the specified points by using the `segment` function.

```
xpts = -3:3;
s = segment(pd,xpts)

s = 1x7
     1     1     2     2     2     3     3
```

1, 2, and 3 indicate the lower tail, center, and upper tail segments in pd, respectively.

Draw the scatter plot of the points (xpts) grouped by their segments over the cumulative distribution function (cdf) plot. Plot the cdf of pd.

```
xgrid = linspace(icdf(pd,.01), icdf(pd,.99));
ygrid = cdf(pd,xgrid);
plot(xgrid,ygrid)
```

Superimpose the scatter plot of xpts by using gscatter.

```
hold on
gscatter(xpts,cdf(pd,xpts),s)
legend('cdf','Lower tail','Center','Upper tail')
hold off
```

Find Segment Containing Boundary Points

Generate a sample data set and create a `paretotails` object by fitting a piecewise distribution with Pareto tails to the generated data. Find the segment containing the boundary points by using the object function `segment`.

Generate a sample data set containing 20% outliers.

```
rng('default'); % For reproducibility
left_tail = -exprnd(1,100,1);
right_tail = exprnd(5,100,1);
center = randn(800,1);
x = [left_tail;center;right_tail];
```

Create a `paretotails` object by fitting a piecewise distribution to `x`. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities so that a fitted object consists of the empirical distribution for the middle 80% of the data set and generalized Pareto distributions (GPDs) for the lower and upper 10% of the data set.

```
pd = paretotails(x,0.1,0.9)

pd =
Piecewise distribution with 3 segments
    -Inf < x < -1.33251    (0 < p < 0.1): lower tail, GPD(-0.0063504,0.567017)
    -1.33251 < x < 1.80149 (0.1 < p < 0.9): interpolated empirical cdf
    1.80149 < x < Inf    (0.9 < p < 1): upper tail, GPD(0.24874,3.00974)
```

Return the boundary values between the piecewise segments by using the `boundary` function.

```
[p,q] = boundary(pd)
```

```
p = 2×1

    0.1000
    0.9000
```

```
q = 2×1

   -1.3325
    1.8015
```

The values in `p` are the cumulative probabilities at the boundaries, and the values in `q` are the corresponding quantiles.

Find the segment containing the boundary points by using the quantile values.

```
s1 = segment(pd,q)

s1 = 2×1

     2
     3
```

1, 2, and 3 indicate the lower tail, center, and upper tail segments in `pd`, respectively. The output `s1` implies that the first boundary between the lower tail segment and the center segment belongs to the

center segment, and the second boundary between the center segment and the upper tail segment belongs to the upper tail segment.

You can also use the cumulative probability values to find the corresponding segments.

```
s2 = segment(pd, [], [0;p;1])
```

```
s2 = 4×1
```

```
1
2
3
3
```

Input Arguments

pd — Piecewise distribution with Pareto tails

paretotails object

Piecewise distribution with Pareto tails, specified as a `paretotails` object.

x — Quantile

numeric vector

Quantile values, specified as a numeric vector.

Data Types: `single` | `double`

p — Cumulative probability

numeric vector of range `[0,1]` values

Cumulative probability values, specified as a numeric vector of range `[0,1]` values.

Data Types: `single` | `double`

Introduced in R2007a

selectModels

Class: ClassificationLinear

Choose subset of regularized, binary linear classification models

Syntax

```
SubMdl = selectModels(Mdl,idx)
```

Description

`SubMdl = selectModels(Mdl,idx)` returns a subset of trained, binary linear classification models from a set of binary linear classification models (`Mdl`) trained using various regularization strengths. The indices (`idx`) correspond to the regularization strengths in `Mdl.Lambda`, and specify which models to return.

Input Arguments

Mdl — Binary linear classification models trained using various regularization strengths

ClassificationLinear model object

Binary linear classification models trained using various regularization strengths, specified as a ClassificationLinear model object. You can create a ClassificationLinear model object using `fitclinear`.

Although `Mdl` is one model object, if `numel(Mdl.Lambda) = L ≥ 2`, then you can think of `Mdl` as L trained models.

idx — Indices corresponding to regularization strengths

numeric vector of positive integers

Indices corresponding to regularization strengths, specified as a numeric vector of positive integers. Values of `idx` must be in the interval $[1,L]$, where $L = \text{numel}(Mdl.Lambda)$.

Data Types: double | single

Output Arguments

SubMdl — Subset of binary linear classification models trained using various regularization strengths

ClassificationLinear model object

Subset of binary linear classification models trained using various regularization strengths, returned as a ClassificationLinear model object.

Examples

Find Good Lasso Penalty Using Classification Loss

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare test-sample classification error rates.

Load the NLP data set. Preprocess the data as in “Specify Custom Classification Loss” on page 32-3157.

```
load nlpdata
Ystats = Y == 'stats';
X = X';

rng(10); % For reproducibility
Partition = cvpartition(Ystats, 'Holdout', 0.30);
testIdx = test(Partition);
XTest = X(:, testIdx);
YTest = Ystats(testIdx);
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-6} through $10^{-0.5}$.

```
Lambda = logspace(-6, -0.5, 11);
```

Train binary, linear classification models that use each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```
CVMDL = fitlinear(X, Ystats, 'ObservationsIn', 'columns', ...
    'CVPartition', Partition, 'Learner', 'logistic', 'Solver', 'sparsa', ...
    'Regularization', 'lasso', 'Lambda', Lambda, 'GradientTolerance', 1e-8)
```

```
CVMDL =
  classreg.learning.partition.ClassificationPartitionedLinear
    CrossValidatedModel: 'Linear'
      ResponseName: 'Y'
    NumObservations: 31572
      KFold: 1
    Partition: [1x1 cvpartition]
    ClassNames: [0 1]
    ScoreTransform: 'none'
```

Properties, Methods

Extract the trained linear classification model.

```
Mdl = CVMDL.Trained{1}
```

```
Mdl =
  ClassificationLinear
    ResponseName: 'Y'
    ClassNames: [0 1]
    ScoreTransform: 'logit'
      Beta: [34023x11 double]
      Bias: [1x11 double]
      Lambda: [1x11 double]
    Learner: 'logistic'
```

Properties, Methods

Mdl is a `ClassificationLinear` model object. Because `Lambda` is a sequence of regularization strengths, you can think of Mdl as 11 models, one for each regularization strength in `Lambda`.

Estimate the test-sample classification error.

```
ce = loss(Mdl,X(:,testIdx),Ystats(testIdx),'ObservationsIn','columns');
```

Because there are 11 regularization strengths, `ce` is a 1-by-11 vector of classification error rates.

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitclinear(X,Ystats,'ObservationsIn','columns',...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8);
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the test-sample error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(ce),...
    log10(Lambda),log10(numNZCoeff + 1));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} classification error')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
title('Test-Sample Statistics')
hold off
```

Choose the index of the regularization strength that balances predictor variable sparsity and low classification error. In this case, a value between 10^{-4} to 10^{-1} should suffice.

```
idxFinal = 7;
```

Select the model from `Mdl` with the chosen regularization strength.

```
MdlFinal = selectModels(Mdl,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Tip

One way to build several predictive, binary linear classification models is:

- 1 Hold out a portion of the data for testing.
- 2 Train a binary, linear classification model using `fitclinear`. Specify a grid of regularization strengths using the 'Lambda' name-value pair argument and supply the training data. `fitclinear` returns one `ClassificationLinear` model object, but it contains a model for each regularization strength.
- 3 To determine the quality of each regularized model, pass the returned model object and the held-out data to, for example, `loss`.

- 4 Identify the indices (`idx`) of a satisfactory subset of regularized models, and then pass the returned model and the indices to `selectModels`. `selectModels` returns one `ClassificationLinear` model object, but it contains `numel(idx)` regularized models.
- 5 To predict class labels for new data, pass the data and the subset of regularized models to `predict`.

`ClassificationLinear` | `fitlinear` | `loss` | `predict`

Introduced in R2016a

selectModels

Package: `classreg.learning.classif`

Choose subset of multiclass ECOC models composed of binary `ClassificationLinear` learners

Syntax

```
SubMdl = selectModels(Mdl,idx)
```

Description

`SubMdl = selectModels(Mdl,idx)` returns a subset of trained error-correcting output codes (ECOC) models composed of `ClassificationLinear` binary models from a set of multiclass ECOC models (`Mdl`) trained using various regularization strengths. The indices (`idx`) correspond to the regularization strengths in `Mdl.BinaryLearners{1}.Lambda` and specify which models to return.

`SubMdl` is returned as a `CompactClassificationECOC` model object.

Examples

Select Best Regularized Models

Choose a subset of trained ECOC models composed of linear binary learners with various regularization strengths.

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels.

Create a set of 11 logarithmically spaced regularization strengths from 10^{-8} through 10^{-1} .

```
Lambda = logspace(-8,-1,11);
```

Create a linear classification model template that specifies optimizing the objective function using Sparsa. Use lasso penalties with the strengths specified in `Lambda`.

```
t = templateLinear('Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda);
```

Hold out 30% of the data for testing. Identify the test-sample indices.

```
rng(1); % For reproducibility
cvp = cvpartition(Y,'Holdout',0.30);
idxTest = test(cvp);
```

Train an ECOC model composed of linear classification models. For quicker execution time, orient the predictor data so that individual observations correspond to columns.

```
X = X';
PMdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','CVPartition',cvp);
Mdl = PMdl.Trained{1};
numel(Mdl.BinaryLearners{1}.Lambda)
```

```
ans = 11
```

Mdl is a CompactClassificationECOC model object. Because Lambda is an 11-dimensional vector of regularization strengths, you can think of Mdl as eleven trained models, each corresponding to a regularization strength.

Estimate the test-sample misclassification rates for each regularized model.

```
ce = loss(Mdl,X(:,idxTest),Y(idxTest),'ObservationsIn','columns');
```

Plot the misclassification rates with respect to regularization strength on the log scale.

```
figure
plot(log10(Lambda),log10(ce),'-o')
ylabel('log_{10} misclassification rates')
xlabel('log_{10} Lambda')
[~,minCEIdx] = min(ce);
minLambda = Lambda(minCEIdx);
hold on
plot(log10(minLambda),log10(ce(minCEIdx)),'ro');
hold off
```

Several values of `Lambda` yield similarly small classification error values. Consider choosing greater values of `Lambda` (that still yield good classification rates) because they lead to predictor variable sparsity.

Select the four models with regularization strengths that occur around the point at which the classification error starts increasing.

```
idx = 7:10;
MdlFinal = selectModels(Mdl,idx)

MdlFinal =
  classreg.learning.classif.CompactClassificationECOC
    ResponseName: 'Y'
    ClassNames: [comm dsp ecoder fixedpoint hdlcoder phased physmod sim]
    ScoreTransform: 'none'
    BinaryLearners: {78x1 cell}
    CodingMatrix: [13x78 double]
```

Properties, Methods

```
LambdaFinal = MdlFinal.BinaryLearners{1}.Lambda
```

```
LambdaFinal = 1x4
    0.0002    0.0008    0.0040    0.0200
```

`MdlFinal` is a `CompactClassificationECOC` model object. You can think of it as four models trained using the four regularization strengths in `LambdaFinal`.

Input Arguments

Mdl — Multiclass ECOC model composed of binary linear classifiers

`CompactClassificationECOC` model object

Multiclass ECOC model composed of binary linear classifiers, trained using various regularization strengths, specified as a `CompactClassificationECOC` model object.

When creating `Mdl`, you must:

- Use `fitcecoc`.
- Specify `ClassificationLinear` binary learners (see `Learners`).
- Specify the same regularization strengths for each linear binary learner.

Although `Mdl` is one model object, if `numel(Mdl.BinaryLearners{1}.Lambda) = L ≥ 2`, then you can think of `Mdl` as L trained models.

idx — Indices corresponding to regularization strengths

positive integer vector

Indices corresponding to regularization strengths, specified as a positive integer vector. Values of `idx` must be in the interval $[1,L]$, where $L = \text{numel}(\text{Mdl.BinaryLearners}\{1\}.\text{Lambda})$.

Data Types: `double` | `single`

Tips

- One way to build several predictive ECOC models composed of binary linear classification models is:
 - 1 Create a linear classification model template using `templateLinear` and specify a grid of regularization strengths using the `'Lambda'` name-value pair argument.
 - 2 Hold out a portion of the data for testing.
 - 3 Train an ECOC model using `fitcecoc`. Specify the template using the `'Learners'` name-value pair argument and supply the training data. `fitcecoc` returns one `CompactClassificationECOC` model object containing `ClassificationLinear` binary learners, but all binary learners contain a model for each regularization strength.
 - 4 To determine the quality of each regularized model, pass the returned model object and the held-out data to, for example, `loss`.
 - 5 Identify the indices (`idx`) of a satisfactory subset of regularized models, and then pass the returned model and the indices to `selectModels`. The function `selectModels` returns one `CompactClassificationECOC` model object, but it contains `numel(idx)` regularized models.
 - 6 To predict class labels for new data, pass the data and the subset of regularized models to `predict`.

Introduced in R2016a

selectModels

Class: RegressionLinear

Select fitted regularized linear regression models

Syntax

```
SubMdl = selectModels(Mdl,idx)
```

Description

`SubMdl = selectModels(Mdl,idx)` returns a subset of trained linear regression models from a set of linear regression models (`Mdl`) trained using various regularization strengths. The indices `idx` correspond to the regularization strengths in `Mdl.Lambda`, and specify which models to return.

Input Arguments

Mdl — Linear regression models trained using various regularization strengths

RegressionLinear model object

Linear regression models trained using various regularization strengths, specified as a RegressionLinear model object. You can create a RegressionLinear model object using `fitrlinear`.

Although `Mdl` is one model object, if `numel(Mdl.Lambda) = L ≥ 2`, then you can think of `Mdl` as L trained models.

idx — Indices corresponding to regularization strengths

numeric vector of positive integers

Indices corresponding to regularization strengths, specified as a numeric vector of positive integers. Values of `idx` must be in the interval $[1,L]$, where $L = \text{numel}(Mdl.Lambda)$.

Data Types: double | single

Output Arguments

SubMdl — Subset of linear regression models trained using various regularization strengths

RegressionLinear model object

Subset of linear regression models trained using various regularization strengths, returned as a RegressionLinear model object.

Examples

Find Good Lasso Penalty Using Regression Loss

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \dots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from 10^{-4} through 10^{-1} .

```
Lambda = logspace(-4,-1,15);
```

Hold out 30% of the data for testing. Identify the test-sample indices.

```
cvp = cvpartition(numel(Y),'Holdout',0.30);
idxTest = test(cvp);
```

Train a linear regression model using lasso penalties with the strengths in `Lambda`. Specify the regularization strengths, optimizing the objective function using `SpaRSA`, and the data partition. To increase execution speed, transpose the predictor data and specify that the observations are in columns.

```
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...
    'Solver','sparsa','Regularization','lasso','CVPartition',cvp);
Mdl1 = CVMdl.Trained{1};
numel(Mdl1.Lambda)
```

```
ans = 15
```

`Mdl1` is a `RegressionLinear` model. Because `Lambda` is a 15-dimensional vector of regularization strengths, you can think of `Mdl1` as 15 trained models, one for each regularization strength.

Estimate the test-sample mean squared error for each regularized model.

```
mse = loss(Mdl1,X(:,idxTest),Y(idxTest),'ObservationsIn','columns');
```

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a regression model. Retrain the model using the entire data set and all options used previously, except the data-partition specification. Determine the number of nonzero coefficients per model.

```
Mdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...
    'Solver','sparsa','Regularization','lasso');
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(mse),...
    log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
```

```

hL2.Marker = 'o';
ylabel(h(1), 'log_{10} MSE')
ylabel(h(2), 'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
hold off

```

Select the index or indices of `Lambda` that balance minimal classification error and predictor-variable sparsity (for example, `Lambda(11)`).

```

idx = 11;
MdlFinal = selectModels(Mdl,idx);

```

`MdlFinal` is a trained `RegressionLinear` model object that uses `Lambda(11)` as a regularization strength.

Tip

One way to build several predictive linear regression models is:

- 1 Hold out a portion of the data for testing.
- 2 Train a linear regression model using `fitrlinear`. Specify a grid of regularization strengths using the '`Lambda`' name-value pair argument and supply the training data. `fitrlinear` returns one `RegressionLinear` model object, but it contains a model for each regularization strength.

- 3** To determine the quality of each regularized model, pass the returned model object and the held-out data to, for example, `loss`.
- 4** Identify the indices (`idx`) of a satisfactory subset of regularized models, and then pass the returned model and the indices to `selectModels`. `selectModels` returns one `RegressionLinear` model object, but it contains `numel(idx)` regularized models.
- 5** To predict class labels for new data, pass the data and the subset of regularized models to `predict`.

`RegressionLinear` | `fitrlinear` | `loss` | `predict`

Introduced in R2016a

sequentialfs

Sequential feature selection using custom criterion

Syntax

```
inmodel = sequentialfs(fun,X,y)
inmodel = sequentialfs(fun,X,Y,Z,...)
[inmodel,history] = sequentialfs(fun,X,...)
[] = sequentialfs(...,param1,val1,param2,val2,...)
```

Description

`inmodel = sequentialfs(fun,X,y)` selects a subset of features from the data matrix `X` that best predict the data in `y` by sequentially selecting features until there is no improvement in prediction. Rows of `X` correspond to observations; columns correspond to variables or features. `y` is a column vector of response values or class labels for each observation in `X`. `X` and `y` must have the same number of rows. `fun` is a function handle to a function that defines the criterion used to select features and to determine when to stop. The output `inmodel` is a logical vector indicating which features are finally chosen.

Starting from an empty feature set, `sequentialfs` creates candidate feature subsets by sequentially adding each of the features not yet selected. For each candidate feature subset, `sequentialfs` performs 10-fold cross-validation by repeatedly calling `fun` with different training subsets of `X` and `y`, `XTRAIN` and `ytrain`, and test subsets of `X` and `y`, `XTEST` and `ytest`, as follows:

```
criterion = fun(XTRAIN,ytrain,XTEST,ytest)
```

`XTRAIN` and `ytrain` contain the same subset of rows of `X` and `Y`, while `XTEST` and `ytest` contain the complementary subset of rows. `XTRAIN` and `XTEST` contain the data taken from the columns of `X` that correspond to the current candidate feature set.

Each time it is called, `fun` must return a scalar value `criterion`. Typically, `fun` uses `XTRAIN` and `ytrain` to train or fit a model, then predicts values for `XTEST` using that model, and finally returns some measure of distance, or loss, of those predicted values from `ytest`. In the cross-validation calculation for a given candidate feature set, `sequentialfs` sums the values returned by `fun` and divides that sum by the total number of test observations. It then uses that mean value to evaluate each candidate feature subset.

Typical loss measures include sum of squared errors for regression models (`sequentialfs` computes the mean-squared error in this case), and the number of misclassified observations for classification models (`sequentialfs` computes the misclassification rate in this case).

Note `sequentialfs` divides the sum of the values returned by `fun` across all test sets by the total number of test observations. Accordingly, `fun` should not divide its output value by the number of test observations.

After computing the mean `criterion` values for each candidate feature subset, `sequentialfs` chooses the candidate feature subset that minimizes the mean criterion value. This process continues until adding more features does not decrease the criterion.

`inmodel = sequentialfs(fun,X,Y,Z,...)` allows any number of input variables X, Y, Z, \dots . `sequentialfs` chooses features (columns) only from X , but otherwise imposes no interpretation on X, Y, Z, \dots . All data inputs, whether column vectors or matrices, must have the same number of rows. `sequentialfs` calls `fun` with training and test subsets of X, Y, Z, \dots as follows:

```
criterion = fun(XTRAIN,YTRAIN,ZTRAIN,...,
               XTEST,YTEST,ZTEST,...)
```

`sequentialfs` creates `XTRAIN, YTRAIN, ZTRAIN, ... , XTEST, YTEST, ZTEST, ...` by selecting subsets of the rows of X, Y, Z, \dots . `fun` must return a scalar value `criterion`, but may compute that value in any way. Elements of the logical vector `inmodel` correspond to columns of X and indicate which features are finally chosen.

`[inmodel,history] = sequentialfs(fun,X,...)` returns information on which feature is chosen at each step. `history` is a scalar structure with the following fields:

- `Crit` — A vector containing the criterion values computed at each step.
- `In` — A logical matrix in which row i indicates the features selected at step i .

`[] = sequentialfs(...,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs from the following table.

Parameter	Value
'cv'	<p>The validation method used to compute the criterion for each candidate feature subset.</p> <ul style="list-style-type: none"> • When the value is a positive integer k, <code>sequentialfs</code> uses k-fold cross-validation without stratification. • When the value is an object of the <code>cvpartition</code> on page 32-983 class, other forms of cross-validation can be specified. • When the value is 'resubstitution', the original data are passed to <code>fun</code> as both the training and test data to compute the criterion. • When the value is 'none', <code>sequentialfs</code> calls <code>fun</code> as <code>criterion = fun(X,Y,Z,...)</code>, without separating test and training sets. <p>The default value is 10, that is, 10-fold cross-validation without stratification.</p> <p>So-called wrapper methods use a function <code>fun</code> that implements a learning algorithm. These methods usually apply cross-validation to select features. So-called filter methods use a function <code>fun</code> that measures characteristics of the data (such as correlation) to select features.</p>
'mcreps'	A positive integer indicating the number of Monte-Carlo repetitions for cross-validation. The default value is 1. The value must be 1 if the value of 'cv' is 'resubstitution' or 'none'.
'direction'	The direction of the sequential search. The default is 'forward'. A value of 'backward' specifies an initial candidate set including all features and an algorithm that removes features sequentially until the criterion increases.

Parameter	Value
'keepin'	A logical vector or a vector of column numbers specifying features that must be included. The default is empty.
'keepout'	A logical vector or a vector of column numbers specifying features that must be excluded. The default is empty.
'nfeatures'	The number of features at which <code>sequentialfs</code> should stop. <code>inmodel</code> includes exactly this many features. The default value is empty, indicating that <code>sequentialfs</code> should stop when a local minimum of the criterion is found. A nonempty value overrides values of 'MaxIter' and 'TolFun' in 'options'.
'nullmodel'	A logical value, indicating whether or not the null model (containing no features from X) should be included in feature selection and in the history output. The default is <code>false</code> .
'options'	<p>Options structure for the iterative sequential search algorithm, as created by <code>statset</code>.</p> <p><code>sequentialfs</code> uses the following <code>statset</code> parameters:</p> <ul style="list-style-type: none"> • <code>Display</code> — Amount of information displayed by the algorithm. The default is 'off'. • <code>MaxIter</code> — Maximum number of iterations allowed. The default is <code>Inf</code>. • <code>TolFun</code> — Termination tolerance for the objective function value. The default is <code>1e-6</code> if 'direction' is 'forward'; <code>0</code> if 'direction' is 'backward'. • <code>TolTypeFun</code> — Use absolute or relative objective function tolerances. The default is 'rel'. • <code>UseParallel</code> — Set to <code>true</code> to compute in parallel. Default is <code>false</code>. • <code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'. • <code>Streams</code> — A <code>RandStream</code> object or cell array consisting of one such object. If you do not specify <code>Streams</code>, <code>sequentialfs</code> uses the default stream. <p>To compute in parallel, you need Parallel Computing Toolbox.</p>

Examples

Perform sequential feature selection for classification of noisy features:

```
load fisheriris
rng('default') % For reproducibility
X = randn(150,10);
X(:,[1 3 5 7])= meas;
y = species;
```

```

c = cvpartition(y,'k',10);
opts = statset('Display','iter');
fun = @(XT,yT,Xt,yt)loss(fitcecoc(XT,yT),Xt,yt);

[fs,history] = sequentialfs(fun,X,y,'cv',c,'options',opts)

```

```

Start forward sequential feature selection:
Initial columns included: none
Columns that can not be included: none
Step 1, added column 5, criterion value 0.00266667
Step 2, added column 7, criterion value 0.00222222
Step 3, added column 1, criterion value 0.00177778
Step 4, added column 3, criterion value 0.000888889
Final columns included: 1 3 5 7

```

```

fs =

    1×10 logical array

     1     0     1     0     1     0     1     0     0     0

```

```

history =

    struct with fields:

        In: [4×10 logical]
        Crit: [0.0027 0.0022 0.0018 8.8889e-04]

```

```

history.In

```

```

ans =

    4×10 logical array

     0     0     0     0     1     0     0     0     0     0
     0     0     0     0     1     0     1     0     0     0
     1     0     0     0     1     0     1     0     0     0
     1     0     1     0     1     0     1     0     0     0

```

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

set

Class: dataset

(Not Recommended) Set and display properties

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
set(A)
set(A,PropertyName)
A = set(A,PropertyName,PropertyValue,...)
B = set(A,PropertyName,value)
```

Description

`set(A)` displays all properties of the dataset array `A` and their possible values.

`set(A,PropertyName)` displays possible values for the property specified by `PropertyName`.

`A = set(A,PropertyName,PropertyValue,...)` sets property name/value pairs.

`B = set(A,PropertyName,value)` returns a dataset array `B` that is a copy of `A`, but with the property `'PropertyName'` set to the value `value`.

Note Using `set(A,'PropertyName',value)` without assigning to a variable does not modify `A`'s properties. Use `A = set(A,'PropertyName',value)` to modify `A`.

Examples

Create a dataset array from Fisher's iris data and add a description:

```
load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs)','%-d'));
iris = dataset({nominal(species),'species'},...
              {meas,'SL','SW','PL','PW'},...
              'ObsNames',NameObs);
iris = set(iris,'Description','Fisher''s Iris Data');
get(iris)
Description: 'Fisher's Iris Data'
Units: {}
DimNames: {'Observations' 'Variables'}
UserData: []
ObsNames: {150x1 cell}
VarNames: {'species' 'SL' 'SW' 'PL' 'PW'}
```

get | summary

setDefaultYfit

Class: CompactTreeBagger

Set default value for predict

Syntax

`B = setDefaultYfit(B,Yfit)`

Description

`B = setDefaultYfit(B,Yfit)` sets the default prediction for ensemble `B` to `Yfit`. The default prediction must be specified as a character vector or string scalar for classification or as a numeric scalar for regression. This setting controls what predicted value `CompactTreeBagger` returns when no prediction is possible, for example when the `predict` method needs to predict for an observation which has only false values in the matrix supplied through `'UseInstanceForTree'` argument.

See Also

`predict`

setdiff

Class: dataset

(Not Recommended) Set difference for dataset array observations

Note The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
C = setdiff(A,B)
C = setdiff(A,B,vars)
C = setxor(A,B,vars,setOrder)
[C,iA] = setxor( ___ )
```

Description

`C = setdiff(A,B)` for dataset arrays A and B returns the set of observations that are in A but not B, with repetitions removed. The observations in the dataset array C are sorted.

`C = setdiff(A,B,vars)` returns the set of observations that are in A but not B, considering only the variables specified in `vars`, with repetitions removed. The observations in the dataset array C are sorted by these variables. The values for variables not specified in `vars` for each observation in C are taken from the corresponding observation in A. If there are multiple observations in A that correspond to an observation in C, those values are taken from the first occurrence.

`C = setxor(A,B,vars,setOrder)` returns the observations in C in the order specified by `setOrder`.

`[C,iA] = setxor(___)` also returns the index vector `iA` such that `C = A(iA, :)`. If there are repeated observations in A, then `setxor` returns the index of the first occurrence. You can use any of the previous input arguments.

Input Arguments

A, B

Input dataset arrays.

vars

String array or cell array of character vectors containing variable names, or a vector of integers containing variable column numbers. `vars` indicates the variables that `setdiff` considers.

Specify `vars` as `[]` to use its default value of all variables.

setOrder

Flag indicating the sorting order for the observations in C. The possible values of `setOrder` are:

'sorted' Observations in C are in sorted order (default).
 'stable' Observations in C are in the same order that they appear in A.

Output Arguments

C

Dataset array with the observations that are in A but not B, with repetitions removed. C is in sorted order (by default), or the order specified by `setOrder`.

iA

Index vector, indicating the observations from A that are in C. The vector `iA` contains the index to the first occurrence of any repeated observations in A.

Examples

Set Difference of Two Dataset Arrays

Create a scalar structure array, and then convert it into two dataset arrays.

```
S(1,1).Name = 'CLARK';
S(1,1).Gender = 'M';
S(1,1).SystolicBP = 124;
S(1,1).DiastolicBP = 93;
```

```
S(2,1).Name = 'BROWN';
S(2,1).Gender = 'F';
S(2,1).SystolicBP = 122;
S(2,1).DiastolicBP = 80;
```

```
S(3,1).Name = 'MARTIN';
S(3,1).Gender = 'M';
S(3,1).SystolicBP = 130;
S(3,1).DiastolicBP = 92;
```

```
A = struct2dataset(S(1:2));
B = struct2dataset(S(2:3));
```

The intersection of A and B is the second observation, with last name BROWN.

Return the set difference of A and B.

```
[C,iA] = setdiff(A,B)
```

```
C =
   Name           Gender   SystolicBP   DiastolicBP
   {'CLARK'}      {'M'}        124          93
```

```
iA = 1
```

The first observation in A is not present in B.

setlabels

(Not Recommended) Assign labels to levels of nominal or ordinal arrays

Note The `nominal` and `ordinal` array data types are not recommended. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

Syntax

```
B = setlabels(A, labels)
B = setlabels(A, labels, levels)
```

Description

`B = setlabels(A, labels)` returns a `nominal` or `ordinal` array object of the same type as `A`, but with levels labeled in the order specified by `labels`.

`B = setlabels(A, labels, levels)` labels only the levels specified in `levels`.

Input Arguments

A — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created with `nominal` or `ordinal`.

labels — Labels to assign

string array | cell array of character vectors | 2-D character matrix

Labels to assign to levels, specified as a string array, cell array of character vectors, or 2-D character matrix.

Data Types: `char` | `string` | `cell`

levels — Levels to assign labels

string array | cell array of character vectors | 2-D character matrix

Level to assign labels to, specified as a string array, cell array of character vectors, or 2-D character matrix.

Data Types: `char` | `string` | `cell`

Output Arguments

B — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, returned as a `nominal` or `ordinal` array object.

See Also

getlabels | nominal | ordinal

“Change Category Labels” on page 2-7

Introduced in R2007a

setxor

Class: dataset

(Not Recommended) Set exclusive or for dataset array observations

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
C = setxor(A,B)
C = setxor(A,B,vars)
C = setxor(A,B,vars,setOrder)
[C,iA,iB] = setxor( ___ )
```

Description

`C = setxor(A,B)` for `dataset` arrays `A` and `B` returns the set of observations that are not in the intersection of the two arrays, with repetitions removed. The observations in the `dataset` array `C` are sorted.

`C = setxor(A,B,vars)` returns the set of observations that are not in the intersection of the two arrays, considering only the variables specified in `vars`, with repetitions removed. The observations in the `dataset` array `C` are sorted by these variables. The values for variables not specified in `vars` for each observation in `C` are taken from the corresponding observation in `A` or `B`. If there are multiple observations in `A` or `B` that correspond to an observation in `C`, those values are taken from the first occurrence.

`C = setxor(A,B,vars,setOrder)` returns the observations in `C` in the order specified by `setOrder`.

`[C,iA,iB] = setxor(___)` also returns index vectors `iA` and `iB` such that `C` is a sorted combination of the values `A(iA,:)` and `B(iB,:)`. If there are repeated observations in `A` or `B`, then `setxor` returns the index of the first occurrence. You can use any of the previous input arguments.

Input Arguments

A,B

Input `dataset` arrays.

vars

String array or cell array of character vectors containing variable names, or a vector of integers containing variable column numbers. `vars` indicates the variables in `A` and `B` that `setxor` considers.

Specify `vars` as `[]` to use its default value of all variables.

setOrder

Flag indicating the sorting order for the observations in C. The possible values of `setOrder` are:

'sorted'	Observations in C are in sorted order (default).
'stable'	Observations in C are in the same order that they appear in A, then B.

Output Arguments**C**

Dataset array with the observations not in the intersection of A and B, with repetitions removed. C is in sorted order (by default), or the order specified by `setOrder`.

iA

Index vector, indicating the observations from A that are in C. The vector `iA` contains the index to the first occurrence of any repeated observations in A.

iB

Index vector, indicating the observations from B that are in C. The vector `iB` contains the index to the first occurrence of any repeated observations in B.

Examples**Symmetric Difference of Two Dataset Arrays**

Create a scalar structure array, and then convert it into two dataset arrays.

```
S(1,1).Name = 'CLARK';
S(1,1).Gender = 'M';
S(1,1).SystolicBP = 124;
S(1,1).DiastolicBP = 93;
```

```
S(2,1).Name = 'BROWN';
S(2,1).Gender = 'F';
S(2,1).SystolicBP = 122;
S(2,1).DiastolicBP = 80;
```

```
S(3,1).Name = 'MARTIN';
S(3,1).Gender = 'M';
S(3,1).SystolicBP = 130;
S(3,1).DiastolicBP = 92;
```

```
A = struct2dataset(S(1:2));
B = struct2dataset(S(2:3));
```

The intersection of A and B is the second observation, with last name BROWN.

Return the symmetric difference of A and B.

```
[C,iA,iB] = setxor(A,B);
C
```

```
C =
  Name           Gender   SystolicBP   DiastolicBP
  {'CLARK' }     {'M' }       124          93
  {'MARTIN' }    {'M' }       130          92
```

```
[iA iB]
```

```
ans = 1×2
```

```
    1    2
```

The symmetric difference contains the first observation from A, and the second observation from B.

Topics

“Dataset Arrays” on page 2-112

shrink

Prune ensemble

Syntax

```
cmp = shrink(ens)
cmp = shrink(ens,Name,Value)
```

Description

`cmp = shrink(ens)` returns a compact shrunken version of `ens`, a regularized ensemble. `cmp` retains only learners with weights above a threshold.

`cmp = shrink(ens,Name,Value)` returns an ensemble with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

A regression ensemble created with `fitrensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

lambda

Vector of nonnegative regularization parameter values for lasso. If `ens.Regularization` is nonempty (populate it with `regularize`), `shrink` regularizes `ens` using `lambda`. If `ens` contains a `Regularization` structure, you cannot pass `lambda`.

Default: []

threshold

Lower cutoff on weights for weak learners, a numeric nonnegative scalar. `shrink` creates `cmp` from those learners with weights above `threshold`.

Default: 0

weightcolumn

Column index of `ens.Regularization.TrainedWeights`, a positive integer. `shrink` creates `cmp` with learner weights from this column.

Default: 1

Output Arguments

cmp

A regression ensemble of class `CompactRegressionEnsemble`. Use `cmp` for making predictions exactly as you use `ens`, with the `predict` method.

`shrink` orders the members of `cmp` from largest to smallest.

Examples

Shrink Bagged Regression Ensemble

Shrink a 300-member bagged regression ensemble, and view the number of members of the resulting ensemble.

Generate sample data.

```
X = rand(2000,20);
Y = repmat(-1,2000,1);
Y(sum(X(:,1:5),2)>2.5) = 1;
```

Shrink a 300-member bagged regression ensemble using 0.1 for the parameter `lambda`.

```
bag = fitensemble(X,Y,'Method','Bag','NumLearningCycles',300);
cmp = shrink(bag,'lambda',0.1);
```

View the number of members of the resulting ensemble.

```
cmp.NumTrained
```

```
ans = 68
```

`cvshrink` | `predict` | `regularize`

Topics

“Ensemble Regularization” on page 18-69

signrank

Wilcoxon signed rank test

Syntax

```
p = signrank(x)
p = signrank(x,y)
p = signrank(x,y,Name,Value)
[p,h] = signrank( ___ )
[p,h,stats] = signrank( ___ )

[ ___ ] = signrank(x,m)
[ ___ ] = signrank(x,m,Name,Value)
```

Description

`p = signrank(x)` returns the p -value of a two-sided Wilcoxon signed rank test on page 32-5092.

`signrank` tests the null hypothesis that data in the vector `x` come from a distribution whose median is zero at the 5% significance level. The test assumes that the data in `x` come from a continuous distribution symmetric about its median.

`p = signrank(x,y)` returns the p -value of a paired, two-sided test for the null hypothesis that $x - y$ comes from a distribution with zero median.

`p = signrank(x,y,Name,Value)` returns the p -value for the sign test with additional options specified by one or more `Name,Value` pair arguments.

`[p,h] = signrank(___)` also returns a logical value indicating the test decision. $h = 1$ indicates a rejection of the null hypothesis, and $h = 0$ indicates a failure to reject the null hypothesis at the 5% significance level. You can use any of the input arguments in the previous syntaxes.

`[p,h,stats] = signrank(___)` also returns the structure `stats` with information about the test statistic.

`[___] = signrank(x,m)` returns any of the output arguments in the previous syntaxes for the null hypothesis that the data in `x` are observations from a distribution with median `m`.

`[___] = signrank(x,m,Name,Value)` returns any of the output arguments in the previous syntaxes for the signed rank test with additional options specified by one or more `Name,Value` pair arguments.

Examples

Test for Zero Median of a Single Population

Test the hypothesis of zero median.

Generate the sample data.

```
rng('default') % for reproducibility
x = randn(1,25) + 1.30;
```

Test the hypothesis that the data in `x` has zero median.

```
[p,h] = signrank(x)
p = 3.2229e-05
h = logical
    1
```

At the default 5% significance level, the value `h = 1` indicates that the test rejects the null hypothesis of zero median.

Test the Median of Differences of Paired Samples

Test the hypothesis of zero median for the difference between paired samples.

Generate the sample data.

```
rng('default') % for reproducibility
x = lognrnd(2, .25,10,1);
y = x + trnd(2,10,1);
```

Test the hypothesis that `x - y` has zero median.

```
[p,h] = signrank(x,y)
p = 0.3223
h = logical
    0
```

The results indicate that the test fails to reject the null hypothesis of zero median in the difference at the default 5% significance level.

Signed Rank Test for Large Samples

Conduct a -sided test on a large sample using approximation.

Load the sample data.

```
load('gradespaired.mat');
```

Test the null hypothesis that the median of the grade differences of students before and after participating in a tutoring program is 0 against the alternate that it is less than 0.

```
[p,h,stats] = signrank(gradespaired(:,1),...
    gradespaired(:,2), 'tail', 'left')
p = 0.0047
```

```

h = logical
    1

stats = struct with fields:
    zval: -2.5982
    signedrank: 2.0175e+03

```

Because the sample size is greater than 15, `signrank` uses an approximate method to calculate the p -value and also returns the value of the z -statistic. The value $h = 1$ indicates that the test rejects the null hypothesis that there is no difference between the grade medians at the 5% significance level. There is enough statistical evidence to conclude that the median grade before the tutoring program is less than the median grade after the tutoring program.

Repeat the test using the exact method.

```

[p,h,stats] = signrank(gradespaired(:,1),gradespaired(:,2),...
    'tail','left','method','exact')

p = 0.0045

h = logical
    1

stats = struct with fields:
    signedrank: 2.0175e+03

```

The results obtained using the approximate method are consistent with the exact method.

Two-Sided Test for the Median of a Single Population

Load the sample data.

```
load mileage
```

The data contains the mileages per gallon for three different types of cars in columns 1 to 3.

Test the hypothesis that the median mileage for the type of cars in the second column differs from 33.

```

[p,h,stats] = signrank(mileage(:,2),33)

p = 0.0313

h = logical
    1

stats = struct with fields:
    signedrank: 21

```

At the 5% significance level, the results indicate that the median mileage for the second type of cars differs from 33. Note that `signrank` uses an exact method to calculate the p -value for small samples and does not return the z -statistic.

Right-Sided Test for the Median of a Single Population

Use the name-value pair arguments in `signrank`.

Load the sample data.

```
load mileage
```

The data contains the mileage per gallon for three different types of cars in columns 1 to 3.

Test the hypothesis that the median mileage for the type of cars in the second row are larger than 33.

```
[p,h,stats] = signrank(mileage(:,2),33,'tail','right')
```

```
p = 0.0156
```

```
h = logical  
    1
```

```
stats = struct with fields:  
    signedrank: 21
```

Repeat the same test at the 1% significance level using the approximate method.

```
[p,h,stats] = signrank(mileage(:,2),33,'tail','right',...  
    'alpha',0.01,'method','approximate')
```

```
p = 0.0180
```

```
h = logical  
    0
```

```
stats = struct with fields:  
    zval: 2.0966  
    signedrank: 21
```

This result, $h = 0$, indicates that the null hypothesis cannot be rejected at the 1% significance level.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

y — Sample data

vector

Sample data, specified as a vector. y must be the same length as x .

Data Types: single | double

m – Hypothesized value of the median

scalar

Hypothesized value of the median, specified as a scalar.

Example: `signrank(x,10)`

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'alpha',0.01,'method','approximate','tail','right'` specifies a right-tailed signed rank test with 1% significance level, which returns the approximate *p*-value.

alpha – Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level of the decision of a hypothesis test, specified as the comma-separated pair consisting of `'alpha'` and a scalar value in the range 0 to 1. Significance level of *h* is $100 * \alpha\%$.

Example: `'alpha',0.01`

Data Types: double | single

method – Computation method of *p*

`'exact'` | `'approximate'`

Computation method of *p*, specified as the comma-separated pair consisting of `'method'` and one of the following.

<code>'exact'</code>	Exact computation of the <i>p</i> -value, <i>p</i> . Default value for 15 or fewer observations in <i>x</i> , <i>x - m</i> , or <i>x - y</i> when <code>method</code> is unspecified.
<code>'approximate'</code>	Normal approximation while computing the <i>p</i> -value, <i>p</i> . Default value for more than 15 observations in <i>x</i> , <i>x - m</i> , or <i>x - y</i> when <code>'method'</code> is unspecified because the exact method can be slow on large samples.

Example: `'method','exact'`

tail – Type of test

`'both'` (default) | `'right'` | `'left'`

Type of test, specified as the comma-separated pair consisting of `'tail'` and one of the following:

<code>'both'</code>	Two-sided hypothesis test, which is the default test type. <ul style="list-style-type: none"> For a one-sample test, the alternate hypothesis states that the data in <i>x</i> come from a continuous distribution with median different than 0 or <i>m</i>. For a two-sample test, the alternate hypothesis states that the data in <i>x - y</i> come from a distribution with median different than 0.
---------------------	--

'right'	Right-tailed hypothesis test. <ul style="list-style-type: none"> For a one-sample test, the alternate hypothesis states that the data in x come from a continuous distribution with median greater than 0 or m. For a two-sample test, the alternate hypothesis states the data in $x - y$ come from a distribution with median greater than 0.
'left'	Left-tailed hypothesis test. <ul style="list-style-type: none"> For a one-sample test, the alternate hypothesis states that the data in x come from a continuous distribution with median less than 0 or m. For a two-sample test, the alternate hypothesis states the data in $x - y$ come from a distribution with median less than 0.

Example: 'tail','left'

Output Arguments

p — *p*-value of the test

nonnegative scalar

p-value of the test, returned as a nonnegative scalar from 0 to 1. *p* is the probability of observing a test statistic as or more extreme than the observed value under the null hypothesis. `signrank` computes the two-sided *p*-value by doubling the most significant one-sided value.

h — Result of the hypothesis test

1 | 0

Result of the hypothesis test, returned as a logical value.

- If $h = 1$, this indicates the rejection of the null hypothesis at the $100 * \alpha\%$ significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the $100 * \alpha\%$ significance level.

stats — Test statistics

structure

Test statistics, returned as a structure. The test statistics stored in `stats` are:

- `signrank`: Value of the sign rank test statistic.
- `zval`: Value of the *z*-statistic on page 32-5093 (computed when 'method' is 'approximate').

More About

Wilcoxon Signed Rank Test

The Wilcoxon signed rank test is a nonparametric test for two populations when the observations are paired. In this case, the test statistic, W , is the sum of the ranks of positive differences between the observations in the two samples (that is, $x - y$). When you use the test for one sample, then W is the sum of the ranks of positive differences between the observations and the hypothesized median value M_0 (which is 0 when you use `signrank(x)` and m when you use `signrank(x,m)`).

z-Statistic

For large samples, or when `method` is `approximate`, the `signrank` function calculates the p -value using the z -statistic, given by

$$z = \frac{(W - n(n + 1)/4)}{\sqrt{\frac{n(n + 1)(2n + 1) - \text{tieadj}}{24}}}$$

where n is the sample size of the difference $x - y$ or $x - m$. For the two-sample case, `signrank` uses `[tie_rank, tieadj] = tiedrank(abs(diffxy), 0, 0, epsdiff)` to obtain the tie adjustment value `tieadj`.

Algorithms

`signrank` treats NaNs in x and y as missing values and ignores them.

For the two-sample case, `signrank` uses a tolerance based on the values `epsdiff = eps(x) + eps(y)`. `signrank` computes the absolute values of the differences (`abs(d(i))` where `d(i) = x(i) - y(i)`) and compares them to `epsdiff`. Values with an absolute value less than `epsdiff` (`abs(d(i)) < epsdiff(i)`) are treated as ties.

Introduced before R2006a

signtest

Sign test

Syntax

```
p = signtest(x)
p = signtest(x,y)
p = signtest(x,y,Name,Value)
[p,h] = signtest(____)
[p,h,stats] = signtest(____)

[____] = signtest(x,m)
[____] = signtest(x,m,Name,Value)
```

Description

`p = signtest(x)` returns the p -value for a two-sided sign test on page 32-5100.

`signtest` tests the hypothesis that data in `x` has a continuous distribution with zero median against the alternative that the distribution does not have zero median at the 5% significance level.

`p = signtest(x,y)` returns the p -value of a two-sided sign test on page 32-5100. Here, `signtest` tests for the hypothesis that the data in `x - y` has a distribution with zero median against the alternative that the distribution does not have zero median. Note that a hypothesis of zero median for `x - y` is not equivalent to a hypothesis of equal median for `x` and `y`.

`p = signtest(x,y,Name,Value)` returns the p -value for the sign test with additional options specified by one or more `Name,Value` pair arguments.

`[p,h] = signtest(____)` also returns a logical value indicating the test decision. The value `h = 1` indicates a rejection of the null hypothesis, and `h = 0` indicates a failure to reject the null hypothesis at the 5% significance level. You can use any of the input arguments in the previous syntaxes.

`[p,h,stats] = signtest(____)` also returns the structure `stats` containing information about the test statistic.

`[____] = signtest(x,m)` returns any of the output arguments in the previous syntaxes for the test whether the data in `x` are observations from a distribution with median `m` against the alternative that the median is different from `m`.

`[____] = signtest(x,m,Name,Value)` returns any of the output arguments in the previous syntaxes for the sign test with additional options specified by one or more `Name,Value` pair arguments.

Examples

Test for Zero Median of a Single Population

Test the hypothesis of zero median.

Generate the sample data.

```
rng('default') % for reproducibility
x = randn(1,25);
```

The sampling distribution of x is symmetric with zero median.

Test the null hypothesis that x comes from a distribution with a median different from zero median.

```
[p,h,stats] = signtest(x,0)
```

```
p = 0.1078
```

```
h = logical
    0
```

```
stats = struct with fields:
    zval: NaN
    sign: 17
```

At the default 5% significance level, the result $h = 0$ indicates that `signtest` fails to reject to the null hypothesis of zero median. `signtest` calculates the p -value using the exact method, hence it does not calculate `zval` and returns it as a `NaN`.

Test for Zero Median for the Difference of Paired Samples

Test the hypothesis of zero median for the difference between paired samples.

Generate the sample data.

```
rng('default') % for reproducibility
before = lognrnd(2,.25,10,1);
after = before + (lognrnd(0,.5,10,1) - 1);
```

The sampling distribution of the difference between `before` and `after` is symmetric with zero median.

Test the null hypothesis that the difference of `before` and `after` has zero median.

```
[p,h] = signtest(before,after)
```

```
p = 0.7539
```

```
h = logical
    0
```

At the default 5% significance level, the value $h = 0$ indicates that `signtest` fails to reject to the null hypothesis of zero median in the difference.

Medians of Paired Samples

Test the hypothesis of zero median for the difference between two paired samples using the exact and approximate methods.

Generate the sample data.

```
rng('default') % for reproducibility
x = lognrnd(2, .25, 15, 1);
y = x + trnd(2, 15, 1);
display([x y])
```

```
8.4521    7.8047
11.6869   11.4094
 4.2009    5.1133
 9.1664   12.1655
 8.0020   10.0300
 5.3285    6.0153
 6.6300    5.1235
 8.0499    8.6737
18.0763   19.2164
14.7665   15.3380
 5.2726    8.4187
15.7798   16.2093
 8.8583    8.5575
 7.2735    7.4783
 8.8347    7.8894
```

Test the hypothesis that $x - y$ has zero median.

```
[p,h,stats] = signtest(x,y)
```

```
p = 0.3018
```

```
h = logical
    0
```

```
stats = struct with fields:
    zval: NaN
    sign: 5
```

At the default 5% significance level, the value $h = 0$ indicates that the test fails to reject the null hypothesis of zero median in the difference.

Repeat the test using the approximate method.

```
[p,h,stats] = signtest(x,y, 'Method', 'approximate')
```

```
p = 0.3017
```

```
h = logical
    0
```

```
stats = struct with fields:
    zval: -1.0328
    sign: 5
```

The approximate p -value, which `signtest` obtains using the z -statistic, is really close to the exact p -value.

Test for Large Samples

Perform a left-sided sign test for large samples.

Load the sample data.

```
load gradespaired
```

Test the null hypothesis that the median of the grade differences before and after the tutoring program is 0 against the alternate that it is less than 0.

```
[p,h,stats] = signtest(gradespaired(:,1),gradespaired(:,2),'Tail','left')
```

```
p = 0.0013
```

```
h = logical
    1
```

```
stats = struct with fields:
    zval: -3.0110
    sign: 37
```

Because the sample size is large (greater than 100), `signtest` uses an approximate method to calculate the p -value and also returns the value of the z -statistic. The test rejects the null hypothesis that there is no difference between the grade medians at the 5% significance level.

Test for Median of a Single Population

Test the hypothesis that the population median is different from a specified value.

Load the sample data.

```
load lawdata
```

The data set has 15 observations for variables `gpa` and `lsat`.

Test the hypothesis that the median `lsat` score is higher than 570.

```
[p,h,stats] = signtest(lsat,570,'Tail','right')
```

```
p = 0.0176
```

```
h = logical
    1
```

```
stats = struct with fields:
    zval: NaN
```

sign: 12

Both the p -value, 0.0176, and $h = 1$ indicate that at the 5% significance level the test concludes in favor of the alternate hypothesis.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

y — Sample data

vector

Sample data, specified as a vector. y must be the same length as x .

Data Types: `single` | `double`

m — Hypothesized value of the median

scalar

Hypothesized value of the median, specified as a scalar.

Example: `signtest(x,35)`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'Alpha',0.01,'Method','approximate','Tail','right'` specifies a right-tailed sign test with 1% significance level, which returns the approximate p -value.

Alpha — Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range 0 to 1. The default value of `Alpha` is 0.05. Significance level of h is $100 * Alpha\%$.

Example: `'Alpha',0.01`

Data Types: `double` | `single`

Method — p -value computation method

`'exact'` | `'approximate'`

p -value computation method, specified as the comma-separated pair consisting of `'Method'` and one of the following:

'exact'	Exact computation of the p -value, p .
'approximate'	Normal approximation for computing the p -value, p .

The default computation method is 'exact', if there are fewer than 100 observations and 'approximate' if there are 100 observations or more.

Example: 'Method','exact'

Tail – Type of test

'both' (default) | 'right' | 'left'

Type of test, specified as the comma-separated pair consisting of 'Tail' and one of the following:

'both'	Two-sided hypothesis test, which is the default test type. <ul style="list-style-type: none"> For a one-sample test, the alternate hypothesis states that the data in x come from a continuous distribution with median different than zero (or m). For a two-sample test, the alternate hypothesis states that the data in $x - y$ come from a distribution with median different than zero.
'right'	Right-tailed hypothesis test. <ul style="list-style-type: none"> For a one-sample test, the alternate hypothesis states that the data in x come from a continuous distribution with median greater than zero (or m). For a two-sample test, the alternate hypothesis states the data in $x - y$ come from a distribution with median greater than zero.
'left'	Left-tailed hypothesis test. <ul style="list-style-type: none"> For a one-sample test, the alternate hypothesis states that the data in x come from a continuous distribution with median less than zero (or m). For a two-sample test, the alternative hypothesis states the data in $x - y$ come from a distribution with median less than zero.

Example: 'Tail','left'

Output Arguments

p – p -value of the test

nonnegative scalar

p -value of the test, returned as a nonnegative scalar from 0 to 1. p is the probability of observing a test statistic as or more extreme than the observed value under the null hypothesis. `signtest` computes the two-sided p -value by doubling the most significant one-sided value.

h – Result of the hypothesis test

1 | 0

Result of the hypothesis test, returned as a logical value.

- If $h = 1$, this indicates rejection of the null hypothesis at the $100 * \text{Alpha}\%$ significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the $100 * \text{Alpha}\%$ significance level.

stats — Test statistics

structure

Test statistics, returned as a structure. The test statistics stored in `stats` are:

- `sign`: Value of the sign test statistic.
- `zval`: Value of the z-statistic on page 32-5100 (computed only for large samples).

More About**Sign Test**

The sign test is a nonparametric test for the median of a population or median of the difference of two populations.

For example, for tests on a single population median:

- If the test is two-sided, then the test statistic, S , is the minimum of the number of observations that are smaller or larger than the hypothesized median value, M_0 .
- If the test is right-sided, then S is the number of observations that are larger than the hypothesized median value M_0 .
- If the test is left-sided, then S is the number of observations that are smaller than the hypothesized median value M_0 .

z-Statistic

For a large sample, `signtest` uses the z-statistic to approximate the p -value.

The `signtest` test statistic is the number of elements that are greater than 0 (for `signtest(x)` or `signtest(x-y)`), or m (for `signtest(x,m)`). Hence, the z-statistic of the sign test, with the continuity correction, is:

$$z = \frac{(S - E(S))}{\sqrt{V(S)}} = \frac{(S - (0.5)n - 0.5\text{sign}(npos - nneg))}{\sqrt{(0.5)(0.5)n}}$$

where $npos$ and $nneg$ are the number of positive and negative differences from the hypothesized median value, respectively.

Algorithms

For a one-sample test, `signtest` omits values in x that are zero or NaN.

For a two-sample test, `signtest` omits values in $x - y$ that are zero or NaN.

Introduced before R2006a

silhouette

Silhouette plot

Syntax

```
silhouette(X,clust)
silhouette(X,clust,Distance)
silhouette(X,clust,Distance,DistParameter)
```

```
s = silhouette( ___ )
[s,h] = silhouette( ___ )
```

Description

`silhouette(X,clust)` plots cluster silhouettes for the n -by- p input data matrix X , given the cluster assignment `clust` of each point (observation) in X .

`silhouette(X,clust,Distance)` plots the silhouettes using the inter-point distance metric specified in `Distance`.

`silhouette(X,clust,Distance,DistParameter)` accepts one or more additional distance metric parameter values when you specify `Distance` as a custom distance function handle `@distfun` that accepts the additional parameter values.

`s = silhouette(___)` returns the silhouette values in `s` for any of the input argument combinations in the previous syntaxes without plotting the cluster silhouettes.

`[s,h] = silhouette(___)` plots the silhouettes and returns the figure handle `h` in addition to the silhouette values in `s`.

Examples

Create Silhouette Plot

Create silhouette plots from clustered data using different distance metrics.

Generate random sample data.

```
rng('default') % For reproducibility
X = [randn(10,2)+3;randn(10,2)-3];
```

Create a scatter plot of the data.

```
scatter(X(:,1),X(:,2));
title('Randomly Generated Data');
```

The scatter plot shows that the data appears to be split into two clusters of equal size.

Partition the data into two clusters using `kmeans` with the default squared Euclidean distance metric.

```
clust = kmeans(X,2);
```

`clust` contains the cluster indices of the data.

Create a silhouette plot from the clustered data using the default squared Euclidean distance metric.

```
silhouette(X,clust)
```

The silhouette plot shows that the data is split into two clusters of equal size. All the points in the two clusters have large silhouette values (0.8 or greater), indicating that the clusters are well separated.

Create a silhouette plot from the clustered data using the Euclidean distance metric.

```
silhouette(X, clust, 'Euclidean')
```

The silhouette plot shows that the data is split into two clusters of equal size. All the points in the two clusters have large silhouette values (0.6 or greater), indicating that the clusters are well separated.

Compute Silhouette Values

Compute the silhouette values from clustered data.

Generate random sample data.

```
rng('default') % For reproducibility
X = [randn(10,2)+1;randn(10,2)-1];
```

Cluster the data in X based on the sum of absolute differences in distance by using kmeans.

```
clust = kmeans(X,2,'distance','cityblock');
```

clust contains the cluster indices of the data.

Compute the silhouette values from the clustered data. Specify the distance metric as 'cityblock' to indicate that the kmeans clustering is based on the sum of absolute differences.

```
s = silhouette(X,clust,'cityblock')
```

```
s = 20x1

Find Silhouette Values Using Custom Distance Metric

Find silhouette values from clustered data using a custom chi-square distance metric. Verify that the chi-square distance metric is equivalent to the Euclidean distance metric, but with an optional scaling parameter.

Generate random sample data.

```
rng('default'); % For reproducibility
X = [randn(10,2)+3;randn(10,2)-3];
```

Cluster the data in *X* using `kmeans` with the default squared Euclidean distance metric.

```
clust = kmeans(X,2);
```

Find silhouette values and create a silhouette plot from the clustered data using the Euclidean distance metric.

```
[s,h] = silhouette(X,clust,'Euclidean')
```

s = 20×1

```

Position: [360 502 560 420]
Units: 'pixels'

```

Show all properties

The chi-square distance between J -dimensional points x and z is

$$\chi(x, z) = \sqrt{\sum_{j=1}^J w_j (x_j - z_j)^2},$$

where w_j is the weight associated with dimension j .

Set weights for each dimension and specify the chi-square distance function. The distance function must:

- Take as input arguments the n -by- p input data matrix X , one row of X (for example, x), and a scaling (or weight) parameter w .
- Calculate the distance from x to each row of X .
- Return a vector of length n . Each element of the vector is the distance between the observation corresponding to x and the observations corresponding to each row of X .

```
w = [0.4; 0.6]; % Set arbitrary weights for illustration
chiSqrDist = @(x,Z,w) sqrt((bsxfun(@minus,x,Z).^2)*w);
```

Find silhouette values from the clustered data using the custom distance metric `chiSqrDist`.

```
s1 = silhouette(X,clust,chiSqrDist,w)
```

```
s1 = 20×1
```

```
    0.6288

    0.7223
    0.7572
    :
```

Set the weight for both dimensions to 1 to use `chiSqrDist` as the Euclidean distance metric. Find silhouette values and verify that they are the same as the values in `s`.

```
w2 = [1; 1];
s2 = silhouette(X,clust,chiSqrDist,w2);
AreValuesEqual = isequal(s2,s)
```

```
AreValuesEqual = logical
    1
```

The silhouette values are the same in `s` and `s2`.

Input Arguments

X — Input data
numeric matrix

Input data, specified as a numeric matrix of size n -by- p . Rows correspond to points, and columns correspond to coordinates.

Data Types: `single` | `double`

cclus – Cluster assignment

categorical variable | numeric vector | character matrix | string array | cell array of character vectors

Cluster assignment, specified as a categorical variable, numeric vector, character matrix, string array, or cell array of character vectors containing a cluster name for each point in X .

`silhouette` treats NaNs and empty values in `cclus` as missing values and ignores the corresponding rows of X .

Data Types: `single` | `double` | `char` | `string` | `cell` | `categorical`

Distance – Distance metric

'sqEuclidean' (default) | 'Euclidean' | 'cityblock' | function handle | vector of pairwise distances | ...

Distance metric, specified as a character vector, string scalar, or function handle, as described in this table.

Metric	Description
'Euclidean'	Euclidean distance
'sqEuclidean'	Squared Euclidean distance (default)
'cityblock'	Sum of absolute differences
'cosine'	One minus the cosine of the included angle between points (treated as vectors)
'correlation'	One minus the sample correlation between points (treated as sequences of values)
'Hamming'	Percentage of coordinates that differ
'Jaccard'	Percentage of nonzero coordinates that differ
Vector	A numeric row vector of pairwise distances, in the form created by the <code>pdist</code> function. X is not used in this case, and can safely be set to <code>[]</code> .
@ <i>distfun</i>	<p>Custom distance function handle. A distance function has the form</p> <pre>function D = distfun(X0,X,DistParameter) % calculation of distance ...</pre> <p>where</p> <ul style="list-style-type: none"> $X0$ is a 1-by-p vector containing a single point (observation) of the input data matrix X. X is an n-by-p matrix of points. <code>DistParameter</code> represents one or more additional parameter values specific to <code>@distfun</code>. D is an n-by-1 vector of distances, and $D(k)$ is the distance between observations $X0$ and $X(k, :)$.

For more information, see “Distance Metrics” on page 18-11.

Example: 'cosine'

Data Types: char | string | function_handle | single | double

DistParameter — Distance metric parameter value

positive scalar | numeric vector | numeric matrix

Distance metric parameter value, specified as a positive scalar, numeric vector, or numeric matrix. This argument is valid only when you specify a custom distance function handle *@distfun* that accepts one or more parameter values in addition to the input parameters *X0* and *X*.

Example: *silhouette(X, clust, distfun, p1, p2)* where *p1* and *p2* are additional distance metric parameter values for *@distfun*

Data Types: single | double

Output Arguments

s — Silhouette values

n-by-1 vector of values ranging from -1 to 1

Silhouette values, returned as an *n*-by-1 vector of values ranging from -1 to 1. A silhouette value measures how similar a point is to points in its own cluster, when compared to points in other clusters. Values range from -1 to 1. A high silhouette value indicates that a point is well matched to its own cluster, and poorly matched to other clusters.

Data Types: single | double

h — Figure handle

scalar

Figure handle, returned as a scalar. You can use the figure handle to query and modify figure properties. For more information, see [Figure](#).

More About

Silhouette Value

The silhouette value for each point is a measure of how similar that point is to points in its own cluster, when compared to points in other clusters. The silhouette value *S_i* for the *i*th point is defined as

$$S_i = (b_i - a_i) / \max(a_i, b_i)$$

where *a_i* is the average distance from the *i*th point to the other points in the same cluster as *i*, and *b_i* is the minimum average distance from the *i*th point to points in a different cluster, minimized over clusters.

The silhouette value ranges from -1 to 1. A high silhouette value indicates that *i* is well matched to its own cluster, and poorly matched to other clusters. If most points have a high silhouette value, then the clustering solution is appropriate. If many points have a low or negative silhouette value, then the clustering solution might have too many or too few clusters. You can use silhouette values as a clustering evaluation criterion with any distance metric.

Silhouette criterion clustering evaluation object

Description

`SilhouetteEvaluation` is an object consisting of sample data, clustering data, and silhouette criterion values used to evaluate the optimal number of data clusters. Create a silhouette criterion clustering evaluation object using `evalclusters`.

Construction

`eva = evalclusters(x, clust, 'Silhouette')` creates a silhouette criterion clustering evaluation object.

`eva = evalclusters(x, clust, 'Silhouette', Name, Value)` creates a silhouette criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

Input Arguments

x — Input data

matrix

Input data, specified as an N -by- P matrix. N is the number of observations, and P is the number of variables.

Data Types: `single` | `double`

clust — Clustering algorithm

'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

'kmeans'	Cluster the data in <code>x</code> using the <code>kmeans</code> clustering algorithm, with 'EmptyAction' set to 'singleton' and 'Replicates' set to 5.
'linkage'	Cluster the data in <code>x</code> using the <code>clusterdata</code> agglomerative clustering algorithm, with 'Linkage' set to 'ward'.
'gmdistribution'	Cluster the data in <code>x</code> using the <code>gmdistribution</code> Gaussian mixture distribution algorithm, with 'SharedCov' set to <code>true</code> and 'Replicates' set to 5.

If `criterion` is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can specify a clustering algorithm using a function handle (MATLAB). The function must be of the form `C = clustfun(DATA, K)`, where `DATA` is the data to be clustered, and `K` is the number of clusters. The output of `clustfun` must be one of the following:

- A vector of integers representing the cluster index for each observation in `DATA`. There must be `K` unique values in this vector.
- A numeric n -by- K matrix of score for n observations and K classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If `criterion` is `'CalinskiHarabasz'`, `'DaviesBouldin'`, or `'silhouette'`, you can also specify `clust` as a n -by- K matrix containing the proposed clustering solutions. n is the number of observations in the sample data, and K is the number of proposed clustering solutions. Column j contains the cluster indices for each of the N points in the j th clustering solution.

Data Types: `single` | `double` | `char` | `string` | `function_handle`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'KList', [1:5], 'Distance', 'cityblock'` specifies to test 1, 2, 3, 4, and 5 clusters using the city block distance metric.

ClusterPriors — Prior probabilities for each cluster

`'empirical'` (default) | `'equal'`

Prior probabilities for each cluster, specified as the comma-separated pair consisting of `'ClusterPriors'` and one of the following.

<code>'empirical'</code>	Compute the overall silhouette value for the clustering solution by averaging the silhouette values for all points. Each cluster contributes to the overall silhouette value proportionally to its size.
<code>'equal'</code>	Compute the overall silhouette value for the clustering solution by averaging the silhouette values for all points within each cluster, and then averaging those values across all clusters. Each cluster contributes equally to the overall silhouette value, regardless of its size.

Example: `'ClusterPriors', 'empirical'`

Distance — Distance metric

`'sqEuclidean'` (default) | `'Euclidean'` | `'cityblock'` | `vector` | `function` | ...

Distance metric used for computing the criterion values, specified as the comma-separated pair consisting of `'Distance'` and one of the following.

<code>'sqEuclidean'</code>	Squared Euclidean distance
<code>'Euclidean'</code>	Euclidean distance. This option is not valid for the <code>kmeans</code> clustering algorithm.
<code>'cityblock'</code>	Sum of absolute differences
<code>'cosine'</code>	One minus the cosine of the included angle between points (treated as vectors)
<code>'correlation'</code>	One minus the sample correlation between points (treated as sequences of values)

'Hamming'	Percentage of coordinates that differ. This option is only valid for the Silhouette criterion.
'Jaccard'	Percentage of nonzero coordinates that differ. This option is only valid for the Silhouette criterion.

For detailed information about each distance metric, see `pdist`.

You can also specify a function for the distance metric using a function handle (MATLAB). The distance function must be of the form `d2 = distfun(XI,XJ)`, where `XI` is a 1-by- n vector corresponding to a single row of the input matrix `X`, and `XJ` is an m_2 -by- n matrix corresponding to multiple rows of `X`. `distfun` must return an m_2 -by-1 vector of distances `d2`, whose k th element is the distance between `XI` and `XJ(k, :)`.

`Distance` only accepts a function handle if the clustering algorithm `clust` accepts a function handle as the distance metric. For example, the `kmeans` clustering algorithm does not accept a function handle as the distance metric. Therefore, if you use the `kmeans` algorithm and then specify a function handle for `Distance`, the software errors.

- If `criterion` is 'silhouette', you can also specify `Distance` as the output vector created by the function `pdist`.
- When `clust` is 'kmeans' or 'gmdistribution', `evalclusters` uses the distance metric specified for `Distance` to cluster the data.
- If `clust` is 'linkage', and `Distance` is either 'sqEuclidean' or 'Euclidean', then the clustering algorithm uses the Euclidean distance and Ward linkage.
- If `clust` is 'linkage' and `Distance` is any other metric, then the clustering algorithm uses the specified distance metric and average linkage.
- In all other cases, the distance metric specified for `Distance` must match the distance metric used in the clustering algorithm to obtain meaningful results.

Example: 'Distance', 'Euclidean'

Data Types: single | double | char | string | function_handle

KList — List of number of clusters to evaluate

vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of 'KList' and a vector of positive integer values. You must specify `KList` when `clust` is a clustering algorithm name or a function handle. When `criterion` is 'gap', `clust` must be a character vector, a string scalar, or a function handle, and you must specify `KList`.

Example: 'KList', [1:6]

Data Types: single | double

Properties

ClusteringFunction

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name or function handle. If the clustering solutions are provided in the input, `ClusteringFunction` is empty.

ClusterPriors

Prior probabilities for each cluster, stored as valid prior probability name.

ClusterSilhouettes

Silhouette values corresponding to each proposed number of clusters in `InspectedK`, stored as a cell array of vectors.

CriterionName

Name of the criterion used for clustering evaluation, stored as a valid criterion name.

CriterionValues

Criterion values corresponding to each proposed number of clusters in `InspectedK`, stored as a vector of numerical values.

Distance

Distance metric used for clustering data, stored as a valid distance metric name.

InspectedK

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

Missing

Logical flag for excluded data, stored as a column vector of logical values. If `Missing` equals `true`, then the corresponding value in the data matrix `x` is not used in the clustering solution.

NumObservations

Number of observations in the data matrix `X`, minus the number of missing (NaN) values in `X`, stored as a positive integer value.

OptimalK

Optimal number of clusters, stored as a positive integer value.

OptimalY

Optimal clustering solution corresponding to `OptimalK`, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, `OptimalY` is empty.

X

Data used for clustering, stored as a matrix of numerical values.

Methods

Inherited Methods

addK	Evaluate additional numbers of clusters
plot	Plot clustering evaluation object criterion values
compact	Compact clustering evaluation object

Examples

Evaluate the Clustering Solution Using Silhouette Criterion

Evaluate the optimal number of clusters using the silhouette clustering evaluation criterion.

Generate sample data containing random numbers from three multivariate distributions with different parameter values.

```
rng('default'); % For reproducibility
mu1 = [2 2];
sigma1 = [0.9 -0.0255; -0.0255 0.9];

mu2 = [5 5];
sigma2 = [0.5 0 ; 0 0.3];

mu3 = [-2, -2];
sigma3 = [1 0 ; 0 0.9];

N = 200;

X = [mvnrnd(mu1,sigma1,N);...
     mvnrnd(mu2,sigma2,N);...
     mvnrnd(mu3,sigma3,N)];
```

Evaluate the optimal number of clusters using the silhouette criterion. Cluster the data using `kmeans`.

```
E = evalclusters(X,'kmeans','silhouette','klist',[1:6])
```

```
E =
SilhouetteEvaluation with properties:
    NumObservations: 600
    InspectedK: [1 2 3 4 5 6]
    CriterionValues: [NaN 0.8055 0.8551 0.7155 0.6071 0.6232]
    OptimalK: 3
```

The `OptimalK` value indicates that, based on the silhouette criterion, the optimal number of clusters is three.

Plot the silhouette criterion values for each number of clusters tested.

```
figure;
plot(E)
```

The plot shows that the highest silhouette value occurs at three clusters, suggesting that the optimal number of clusters is three.

Create a grouped scatter plot to visually examine the suggested clusters.

```
figure;  
gscatter(X(:,1),X(:,2),E.OptimalY,'rbg','xod')
```

The plot shows three distinct clusters within the data: Cluster 1 is in the lower-left corner, cluster 2 is in the upper-right corner, and cluster 3 is near the center of the plot.

More About

Silhouette Value

The silhouette value for each point is a measure of how similar that point is to points in its own cluster, when compared to points in other clusters. The silhouette value S_i for the i th point is defined as

$$S_i = (b_i - a_i) / \max(a_i, b_i)$$

where a_i is the average distance from the i th point to the other points in the same cluster as i , and b_i is the minimum average distance from the i th point to points in a different cluster, minimized over clusters.

The silhouette value ranges from -1 to 1 . A high silhouette value indicates that i is well matched to its own cluster, and poorly matched to other clusters. If most points have a high silhouette value, then the clustering solution is appropriate. If many points have a low or negative silhouette value, then the clustering solution might have too many or too few clusters. You can use silhouette values as a clustering evaluation criterion with any distance metric.

Topics

[Class Attributes \(MATLAB\)](#)
[Property Attributes \(MATLAB\)](#)

single

Class: dataset

(Not Recommended) Convert dataset variables to single array

Note The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
B = single(A)
B = single(A,vars)
```

Description

`B = single(A)` returns the contents of the dataset `A`, converted to one single array. The classes of the variables in the dataset must support the conversion.

`B = single(A,vars)` returns the contents of the dataset variables specified by `vars`. `vars` is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector.

See Also

dataset | double | replacdata

size

Class: dataset

(Not Recommended) Size of dataset array

Note The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
D = SIZE(A)
[NOBS,NVARS] = SIZE(A)
[M1,M2,M3,...,MN] = SIZE(A)
M = size(A,dim)
```

Description

`D = SIZE(A)` returns the two-element row vector `D = [NOBS,NVARS]` containing the number of observations and number of variables in the dataset `A`. A dataset array always has two dimensions.

`[NOBS,NVARS] = SIZE(A)` returns the numbers of observations and variables in the dataset `A` as separate output variables.

`[M1,M2,M3,...,MN] = SIZE(A)`, for `N > 2`, returns `M1 = NOBS`, `M2 = NVARS`, and `M3,...,MN = 1`.

`M = size(A,dim)` returns the length of the dimension specified by the scalar `dim`:

- `M = size(A,1)` returns `NOBS`
- `M = size(A,2)` returns `NVARS`
- `M = size(A,k)` returns `1` for `k > 2`

`length` | `ndims` | `numel`

slicesample

Slice sampler

Syntax

```
rnd = slicesample(initial,nsamples,'pdf',pdf)
rnd = slicesample(initial,nsamples,'logpdf',logpdf)
[rnd,neval] = slicesample(initial,...)
[rnd,neval] = slicesample(initial,...,Name,Value)
```

Description

`rnd = slicesample(initial,nsamples,'pdf',pdf)` generates `nsamples` random samples using the slice sampling method (see “Algorithms” on page 32-5125). `pdf` gives the target probability density function (`pdf`). `initial` is a row vector or scalar containing the initial value of the random sample sequences.

`rnd = slicesample(initial,nsamples,'logpdf',logpdf)` generates samples using the logarithm of the `pdf`.

`[rnd,neval] = slicesample(initial,...)` returns the average number of function evaluations that occurred in the slice sampling.

`[rnd,neval] = slicesample(initial,...,Name,Value)` generates random samples with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

initial

Initial point, a scalar or row vector. Set `initial` so `pdf(initial)` is a strictly positive scalar. `length(initial)` is the number of dimensions of each sample.

nsamples

Positive integer, the number of samples that `slicesample` generates.

pdf

Handle to a function that generates the probability density function, specified with `@`. `pdf` can be unnormalized, meaning it need not integrate to 1.

logpdf

Handle to a function that generates the logarithm of the probability density function, specified with `@`. `logpdf` can be the logarithm of an unnormalized `pdf`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

burnin

Nonnegative integer, the number of samples to generate and discard before generating the samples to return. The slice sampling algorithm is a Markov chain whose stationary distribution is proportional to that of the `pdf` argument. Set `burnin` to a high enough value that you believe the Markov chain approximately reaches stationarity after `burnin` samples.

Default: 0

thin

Positive integer, where `slicesample` discards every `thin - 1` samples and returns the next. The slice sampling algorithm is a Markov chain, so the samples are serially correlated. To reduce the serial correlation, choose a larger value of `thin`.

Default: 1

width

Width of the interval around the current sample, a scalar or vector of positive values. `slicesample` begins with this interval and searches for an appropriate region containing the points of `pdf` that evaluate to a large enough value.

- If `width` is a scalar and the samples have multiple dimensions, `slicesample` uses `width` for each dimension.
- If `width` is a vector, it should have the same length as `initial`.

Default: 10

Output Arguments

rnd

`nsamples-by-length(initial)` matrix, where each row is one sample.

neval

Scalar, the mean number of function evaluations per sample. `neval` includes the `burnin` and `thin` evaluations, not just the evaluations of samples returned in `rnd`. Therefore the total number of function evaluations is

$$\text{neval} * (\text{nsamples} * \text{thin} + \text{burnin}).$$

Examples

Generate Random Samples From a Multimodal Density

This example shows how to generate random samples from a multimodal density using `slicesample`.

Define a function proportional to a multimodal density.

```
rng default % For reproducibility
f = @(x) exp(-x.^2/2).*(1 + (sin(3*x)).^2).*...
    (1 + (cos(5*x).^2));
area = integral(f,-5,5);
```

Generate 2000 samples from the density, using a burn-in period of 1000, and keeping one in five samples.

```
N = 2000;
x = slicesample(1,N,'pdf',f,'thin',5,'burnin',1000);
```

Plot a histogram of the sample.

```
[binheight,bincenter] = hist(x,50);
h = bar(bincenter,binheight,'hist');
h.FaceColor = [.8 .8 1];
```

Scale the density to have the same area as the histogram, and superimpose it on the histogram.

```
hold on
h = gca;
```

```

xd = h.XLim;
xgrid = linspace(xd(1),xd(2),1000);
binwidth = (bincenter(2)-bincenter(1));
y = (N*binwidth/area) * f(xgrid);
plot(xgrid,y,'r','LineWidth',2)
hold off

```

The samples seem to fit the theoretical distribution well, so the `burnin` value seems adequate.

Tips

- There are no definitive suggestions for choosing appropriate values for `burnin`, `thin`, or `width`. Choose starting values of `burnin` and `thin`, and increase them, if necessary, to give the requisite independence and marginal distributions. See Neal [1] for details of the effect of adjusting `width`.

Algorithms

At each point in the sequence of random samples, `slicesample` selects the next point by “slicing” the density to form a neighborhood around the previous point where the density is above some value. Consequently, the sample points are not independent. Nearby points in the sequence tend to be closer together than they would be from a sample of independent values. For many purposes, the entire set of points can be used as a sample from the target distribution. However, when this type of serial correlation is a problem, the `burnin` and `thin` parameters can help reduce that correlation.

`slice_sample` uses the slice sampling algorithm of Neal [1]. For numerical stability, it converts a pdf function into a `logpdf` function. The algorithm to resize the support region for each level, called “stepping-out” and “stepping-in,” was suggested by Neal.

Topics

“Representing Sampling Distributions Using Markov Chain Samplers” on page 7-10

Introduced in R2006a

skewness

Skewness

Syntax

```
y = skewness(X)
y = skewness(X,flag)
y = skewness(X,flag,'all')
y = skewness(X,flag,dim)
y = skewness(X,flag,vecdim)
```

Description

`y = skewness(X)` returns the sample skewness of `X`.

- If `X` is a vector, then `skewness(X)` returns a scalar value that is the skewness of the elements in `X`.
- If `X` is a matrix, then `skewness(X)` returns a row vector containing the sample skewness of each column in `X`.
- If `X` is a multidimensional array, then `skewness(X)` operates along the first nonsingleton dimension of `X`.

`y = skewness(X,flag)` specifies whether to correct for bias (`flag = 0`) or not (`flag = 1`, the default). When `X` represents a sample from a population, the skewness of `X` is biased, meaning it tends to differ from the population skewness by a systematic amount based on the sample size. You can set `flag` to `0` to correct for this systematic bias.

`y = skewness(X,flag,'all')` returns the skewness of all elements of `X`.

`y = skewness(X,flag,dim)` returns the skewness along the operating dimension `dim` of `X`.

`y = skewness(X,flag,vecdim)` returns the skewness over the dimensions specified in the vector `vecdim`. For example, if `X` is a 2-by-3-by-4 array, then `skewness(X,1,[1 2])` returns a 1-by-1-by-4 array. Each element of the output array is the biased skewness of the elements on the corresponding page of `X`.

Examples

Find Skewness of Matrix

Set the random seed for reproducibility of the results.

```
rng('default')
```

Generate a matrix with 5 rows and 4 columns.

```
X = randn(5,4)
```

```
X = 5×4
```

```
0.5377 -1.3077 -1.3499 -0.2050
1.8339 -0.4336 3.0349 -0.1241
-2.2588 0.3426 0.7254 1.4897
0.8622 3.5784 -0.0631 1.4090
0.3188 2.7694 0.7147 1.4172
```

Find the sample skewness of X.

```
y = skewness(X)
```

```
y = 1×4
```

```
-0.9362 0.2333 0.4363 -0.4075
```

y is a row vector containing the sample skewness of each column in X.

Correct for Bias in Sample Skewness

For an input vector, correct for bias in the calculation of skewness by specifying the `flag` input argument.

Set the random seed for reproducibility of the results.

```
rng('default')
```

Generate a vector of length 10.

```
x = randn(10,1)
```

```
x = 10×1
```

```
0.5377
1.8339
-2.2588
0.8622
0.3188
-1.3077
-0.4336
0.3426
3.5784
2.7694
```

Find the biased skewness of x. By default, `skewness` sets the value of `flag` to 1 for computing the biased skewness.

```
y1 = skewness(x) % flag is 1 by default
```

```
y1 = 0.1061
```

Find the bias-corrected skewness of x by setting the value of `flag` to 0.

```
y2 = skewness(x,0)
```

```
y2 = 0.1258
```

Find Skewness Along Given Dimension

Find the skewness along different dimensions for a multidimensional array.

Set the random seed for reproducibility of the results.

```
rng('default')
```

Create a 4-by-3-by-2 array of random numbers.

```
X = randn([4,3,2])
```

```
X =
```

```
X(:,:,1) =
```

```
    0.5377    0.3188    3.5784
    1.8339   -1.3077    2.7694
   -2.2588   -0.4336   -1.3499
    0.8622    0.3426    3.0349
```

```
X(:,:,2) =
```

```
    0.7254   -0.1241    0.6715
   -0.0631    1.4897   -1.2075
    0.7147    1.4090    0.7172
   -0.2050    1.4172    1.6302
```

Find the skewness of X along the default dimension.

```
Y1 = skewness(X)
```

```
Y1 =
```

```
Y1(:,:,1) =
```

```
   -0.8084   -0.5578   -1.0772
```

```
Y1(:,:,2) =
```

```
   -0.0403   -1.1472   -0.6632
```

By default, skewness operates along the first dimension of X whose size does not equal 1. In this case, this dimension is the first dimension of X. Therefore, Y1 is a 1-by-3-by-2 array.

Find the biased skewness of X along the second dimension.

```
Y2 = skewness(X,1,2)
```

```
Y2 =
```

```
Y2(:,:,1) =
```

```
    0.6956
   -0.5575
```

```
0.0049
0.6033
```

```
Y2(:,:,2) =
```

```
-0.6969
0.1828
0.7071
-0.6714
```

Y2 is a 4-by-1-by-2 array.

Find the biased skewness of X along the third dimension.

```
Y3 = skewness(X,1,3)
```

```
Y3 = 4×3
10-15 ×
```

```
0 0.1597 0.5062
0.1952 0 0
0 -0.2130 0
0.3654 0 0.4807
```

Y3 is a 4-by-3 matrix.

Find Skewness Along Vector of Dimensions

Find the skewness over multiple dimensions by using the 'all' and vecdim input arguments.

Set the random seed for reproducibility of the results.

```
rng('default')
```

Create a 4-by-3-by-2 array of random numbers.

```
X = randn([4 3 2])
```

```
X =
X(:,:,1) =
```

```
0.5377 0.3188 3.5784
1.8339 -1.3077 2.7694
-2.2588 -0.4336 -1.3499
0.8622 0.3426 3.0349
```

```
X(:,:,2) =
```

```
0.7254 -0.1241 0.6715
-0.0631 1.4897 -1.2075
0.7147 1.4090 0.7172
```

```
-0.2050    1.4172    1.6302
```

Find the biased skewness of X .

```
yall = skewness(X,1,'all')
```

```
yall = 0.0916
```

`yall` is the biased skewness of the entire input data set X .

Find the biased skewness of each page of X by specifying the first and second dimensions.

```
ypage = skewness(X,1,[1 2])
```

```
ypage =  
ypage(:,:,1) =
```

```
    0.1070
```

```
ypage(:,:,2) =
```

```
   -0.6263
```

For example, `ypage(1,1,2)` is the biased skewness of the elements in $X(:, :, 2)$.

Find the biased skewness of the elements in each $X(:, i, :)$ slice by specifying the first and third dimensions.

```
ycol = skewness(X,1,[1 3])
```

```
ycol = 1×3
```

```
   -1.0755   -0.3108   -0.2209
```

For example, `ycol(3)` is the biased skewness of the elements in $X(:, 3, :)$.

Input Arguments

X — Input data

vector | matrix | multidimensional array

Input data that represents a sample from a population, specified as a vector, matrix, or multidimensional array.

- If X is a vector, then `skewness(X)` returns a scalar value that is the skewness of the elements in X .
- If X is a matrix, then `skewness(X)` returns a row vector containing the sample skewness of each column in X .
- If X is a multidimensional array, then `skewness(X)` operates along the first nonsingleton dimension of X .

To specify the operating dimension when X is a matrix or an array, use the `dim` input argument.

`skewness` treats NaN values in X as missing values and removes them.

Data Types: `single` | `double`

flag — Indicator for bias

1 (default) | 0

Indicator for the bias, specified as 0 or 1.

- If `flag` is 1 (default), then the skewness of X is biased, meaning it tends to differ from the population skewness by a systematic amount based on the sample size.
- If `flag` is 0, then `skewness` corrects for the systematic bias.

Data Types: `single` | `double` | `logical`

dim — Dimension

positive integer

Dimension along which to operate, specified as a positive integer. If you do not specify a value for `dim`, then the default is the first dimension of X whose size does not equal 1.

Consider the skewness of a matrix X :

- If `dim` is equal to 1, then `skewness` returns a row vector that contains the sample skewness of each column in X .
- If `dim` is equal to 2, then `skewness` returns a column vector that contains the sample skewness of each row in X .

If `dim` is greater than `ndims(X)` or if `size(X,dim)` is 1, then `skewness` returns an array of NaNs the same size as X .

Data Types: `single` | `double`

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array X . The output y has length 1 in the specified operating dimensions. The other dimension lengths are the same for X and y .

For example, if X is a 2-by-3-by-3 array, then `skewness(X,1,[1 2])` returns a 1-by-1-by-3 array. Each element of the output array is the biased skewness of the elements on the corresponding page of X .

Data Types: `single` | `double`

Output Arguments

y — Skewness

scalar | vector | matrix | multidimensional array

Skewness, returned as a scalar, vector, matrix, or multidimensional array.

Algorithms

Skewness is a measure of the asymmetry of the data around the sample mean. If skewness is negative, the data spreads out more to the left of the mean than to the right. If skewness is positive, the data spreads out more to the right. The skewness of the normal distribution on page B-119 (or any perfectly symmetric distribution) is zero.

The skewness of a distribution is defined as

$$s = \frac{E(x - \mu)^3}{\sigma^3},$$

where μ is the mean of x , σ is the standard deviation of x , and $E(t)$ represents the expected value of the quantity t . The `skewness` function computes a sample version of this population value.

When you set `flag` to 1, the skewness is biased, and the following equation applies:

$$s_1 = \frac{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^3}{\left(\sqrt{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2} \right)^3}.$$

When you set `flag` to 0, `skewness` corrects for the systematic bias, and the following equation applies:

$$s_0 = \frac{\sqrt{n(n-1)}}{n-2} s_1.$$

This bias-corrected equation requires that X contain at least three elements.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The 'all' and `vecdim` input arguments are not supported.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'all' and `vecdim` input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

sobolset

Sobol quasirandom point set

Description

`sobolset` is a quasirandom point set object that produces points from the Sobol sequence. The Sobol sequence is a base-2 digital sequence that fills space in a highly uniform manner.

Creation

Syntax

```
p = sobolset(d)
p = sobolset(d,Name,Value)
```

Description

`p = sobolset(d)` constructs a d -dimensional point set `p`, which is a `sobolset` object with default property settings. The input argument `d` corresponds to the `Dimensions` property of `p`.

`p = sobolset(d,Name,Value)` sets properties on page 32-5135 of `p` using one or more name-value pair arguments. Enclose each property name in quotes. For example, `sobolset(5, 'Leap', 2)` creates a five-dimensional point set from the first point, fourth point, seventh point, tenth point, and so on.

The returned object `p` encapsulates properties of a Sobol quasirandom sequence. The point set is finite, with a length determined by the `Skip` and `Leap` properties and by limits on the size of the point set indices (maximum value of 2^{53}). Values of the point set are generated whenever you access `p` using `net` or parenthesis indexing. Values are not stored within `p`.

Properties

Dimensions — Number of dimensions

positive integer scalar in interval [1,1111]

This property is read-only.

Number of dimensions of the points in the point set, specified as a positive integer scalar in the interval [1,1111]. For example, each point in the point set `p` with `p.Dimensions = 5` has five values.

Use the `d` input argument to specify the number of dimensions when you create a point set using the `sobolset` function.

Use the `reduceDimensions` object function to reduce the number of dimensions after you create a point set.

Leap — Interval between points

0 (default) | positive integer scalar

Interval between points in the sequence, specified as a positive integer scalar. In other words, the `Leap` property of a point set specifies the number of points in the sequence to leap over and omit for every point taken. The default `Leap` value is 0, which corresponds to taking every point from the sequence.

Leaping is a technique used to improve the quality of a point set. However, you must choose the `Leap` values with care. Many `Leap` values create sequences that fail to touch on large sub-hyper-rectangles of the unit hypercube and, therefore, fail to be a uniform quasirandom point set. For more information, see [4].

```
Example: p = sobolset(__, 'Leap', 50);
```

```
Example: p.Lean = 100;
```

PointOrder — Point generation method

'standard' (default) | 'graycode'

Point generation method, specified as 'standard' or 'graycode'. The `PointOrder` property specifies the order in which the Sobol sequence points are produced. When `PointOrder` is set to 'standard', the points produced match the original Sobol sequence implementation. When `PointOrder` is set to 'graycode', the sequence is generated by an implementation that uses the Gray code of the index instead of the index itself.

You can use the 'graycode' option for faster sequence generation, but the software then changes the order of the generated points. For more information on the Gray code implementation, see [1].

```
Example: p = sobolset(__, 'PointOrder', 'graycode');
```

```
Example: p.PointOrder = 'standard';
```

ScrambleMethod — Settings that control scrambling

0x0 structure (default) | structure with `Type` and `Options` fields

Settings that control the scrambling of the sequence, specified as a structure with these fields:

- `Type` — A character vector containing the name of the scramble
- `Options` — A cell array of parameter values for the scramble

Use the `scramble` object function to set scrambles. For a list of valid scramble types, see the type input argument of `scramble`. An error occurs if you set an invalid scramble type for a given point set.

The `ScrambleMethod` property also accepts an empty matrix as a value. The software then clears all scrambling and sets the property to contain a 0x0 structure.

Skip — Number of initial points in sequence to omit

0 (default) | positive integer scalar

Number of initial points in the sequence to omit from the point set, specified as a positive integer scalar.

Initial points of a sequence sometimes exhibit undesirable properties. For example, the first point is often $(0, 0, 0, \dots)$, which can cause the sequence to be unbalanced because the counterpart of the point, $(1, 1, 1, \dots)$, never appears. Also, initial points often exhibit correlations among different dimensions, and these correlations disappear later in the sequence.

```
Example: p = sobolset(__, 'Skip', 2e3);
```

Example: `p.Skip = 1e3;`

Type — Sequence type

'Sobol' (default)

This property is read-only.

Sequence type on which the quasirandom point set `p` is based, specified as 'Sobol'.

Object Functions

<code>net</code>	Generate quasirandom point set
<code>reduceDimensions</code>	Reduce dimensions of Sobol point set
<code>scramble</code>	Scramble quasirandom point set

You can also use the following MATLAB functions with a `sobolset` object. The software treats the point set object like a matrix of multidimensional points.

<code>length</code>	Length of largest array dimension
<code>size</code>	Array size

Examples

Create Sobol Point Set

Generate a three-dimensional Sobol point set, skip the first 1000 values, and then retain every 101st point.

```
p = sobolset(3, 'Skip', 1e3, 'Leap', 1e2)
```

```
p =
Sobol point set in 3 dimensions (89180190640991 points)
```

Properties:

```
      Skip : 1000
      Leap : 100
ScrambleMethod : none
      PointOrder : standard
```

Apply a random linear scramble combined with a random digital shift by using `scramble`.

```
p = scramble(p, 'MatousekAffineOwen')
```

```
p =
Sobol point set in 3 dimensions (89180190640991 points)
```

Properties:

```
      Skip : 1000
      Leap : 100
ScrambleMethod : MatousekAffineOwen
      PointOrder : standard
```

Generate the first four points by using `net`.

```
X0 = net(p,4)
```

```
X0 = 4x3

    0.7601    0.5919    0.9529
    0.1795    0.0856    0.0491
    0.5488    0.0785    0.8483
    0.3882    0.8771    0.8755
```

Generate every third point, up to the eleventh point, by using parenthesis indexing.

```
X = p(1:3:11, :)

X = 4x3

    0.7601    0.5919    0.9529
    0.3882    0.8771    0.8755
    0.6905    0.4951    0.8464
    0.1955    0.5679    0.3192
```

Tips

- The `Skip` and `Leap` properties are useful for parallel applications. For example, if you have a Parallel Computing Toolbox license, you can partition a sequence of points across N different workers by using the function `labindex`. On each n th worker, set the `Skip` property of the point set to $n - 1$ and the `Leap` property to $N - 1$. The following code shows how to partition a sequence across three workers.

```
Nworkers = 3;
p = sobolset(10, 'Leap', Nworkers-1);
spmd(Nworkers)
    p.Skip = labindex - 1;

    % Compute something using points 1,4,7...
    % or points 2,5,8... or points 3,6,9...
end
```

Algorithms

Sobol Sequence Generation

Consider a default `sobolset` object `p` that contains d -dimensional points. Each `p(i, :)` is a point in a Sobol sequence. The j th coordinate of the i th point, `p(i, j)`, is equal to

$$\begin{cases} 0, & i = 1 \\ \gamma_i(1)v_j(1) \oplus \gamma_i(2)v_j(2) \oplus \dots, & i > 1. \end{cases}$$

- The $\gamma_i(n)$ values are 0s or 1s such that

$$i - 1 = \sum_{n=1} \gamma_i(n)2^{n-1}.$$

In other words, the $\gamma_i(n)$ values are the binary digits of the integer $i - 1$.

- The $v_j(n)$ values are called direction numbers. They are uniquely defined for each coordinate j . For more details on these values, see “Direction Numbers Generation” on page 32-5139.
- The \oplus operator is the bitwise exclusive-or operator. For two numbers expressed in binary, the \oplus operator compares the digits in each position. For a given digit position, the \oplus operator returns a 1 if the digits in that position differ and returns a 0 if the digits in that position are the same.
 - For example, $19 \oplus 24 = (10011)_2 \oplus (11000)_2 = (01011)_2 = 11$.
 - Similarly, $\frac{1}{2} \oplus \frac{3}{4} = (0.1)_2 \oplus (0.11)_2 = (0.01)_2 = \frac{1}{4}$.

For more information, see [3].

Direction Numbers Generation

The set of direction numbers $v_j(n)$ depends on the coordinate j . Define the direction numbers in terms of $m_j(n)$ values:

$$v_j(n) = \frac{m_j(n)}{2^n}.$$

For each j , you can generate the direction numbers by selecting the following:

- A primitive polynomial in \mathbb{Z}_2 of some degree s_j

$$x^{s_j} + a_j(1)x^{s_j-1} + a_j(2)x^{s_j-2} + \dots + a_j(s_j-1)x + 1.$$

Each coefficient in the polynomial is either 0 or 1.

- s_j initial direction numbers. For each initial direction number, the corresponding $m_j(n)$ value must be either 1 or an odd number less than 2^n .

The remaining direction numbers are determined by the following recurrence relation, which uses the coefficients of the primitive polynomial, the previous direction numbers, and the \oplus bitwise exclusive-or operator.

$$m_j(n) = 2a_j(1)m_j(n-1) \oplus 2^2a_j(2)m_j(n-2) \oplus \dots \oplus 2^{s_j-1}a_j(s_j-1)m_j(n-s_j+1) \oplus 2^{s_j}m_j(n-s_j) \oplus m_j(n-s_j).$$

`sobolset` uses the same primitive polynomials and initial direction numbers described in [3]. These parameters are provided for the first 1111 dimensions.

Topics

"Generating Quasi-Random Numbers" on page 7-13

Introduced in R2008a

sortClasses

Package: `mlearnlib.graphics.chart`

Sort classes of confusion matrix chart

Syntax

```
sortClasses(cm, order)
```

Description

`sortClasses(cm, order)` sorts the classes of the confusion matrix chart `cm` in the order specified by `order`. You can sort the classes in their natural order, by the values along the diagonal of the confusion matrix, or in fixed order that you specify.

Examples

Sort Classes by Precision or Recall

Create a confusion matrix chart and sort the classes of the chart according to the class-wise true positive rate (recall) or the class-wise positive predictive value (precision).

Load and inspect the `arrhythmia` data set.

```
load arrhythmia
isLabels = unique(Y);
nLabels = numel(isLabels)
```

```
nLabels = 13
```

```
tabulate(categorical(Y))
```

Value	Count	Percent
1	245	54.20%
2	44	9.73%
3	15	3.32%
4	15	3.32%
5	13	2.88%
6	25	5.53%
7	3	0.66%
8	2	0.44%
9	9	1.99%
10	50	11.06%
14	4	0.88%
15	5	1.11%
16	22	4.87%

The data contains 16 distinct labels that describe various degrees of arrhythmia, but the response (`Y`) includes only 13 distinct labels.

Train a classification tree and predict the resubstitution response of the tree.

```
Mdl = fitctree(X,Y);
predictedY = resubPredict(Mdl);
```

Create a confusion matrix chart from the true labels Y and the predicted labels predictedY. Specify 'RowSummary' as 'row-normalized' to display the true positive rates and false positive rates in the row summary. Also, specify 'ColumnSummary' as 'column-normalized' to display the positive predictive values and false discovery rates in the column summary.

```
fig = figure;
cm = confusionchart(Y,predictedY,'RowSummary','row-normalized','ColumnSummary','column-normalized');
```

Resize the container of the confusion chart so percentages appear in the row summary.

```
fig_Position = fig.Position;
fig_Position(3) = fig_Position(3)*1.5;
fig.Position = fig_Position;
```

To sort the confusion matrix according to the true positive rate, normalize the cell values across each row by setting the Normalization property to 'row-normalized' and then use sortClasses. After sorting, reset the Normalization property back to 'absolute' to display the total number of observations in each cell.

```
cm.Normalization = 'row-normalized';
sortClasses(cm,'descending-diagonal')
cm.Normalization = 'absolute';
```

To sort the confusion matrix according to the positive predictive value, normalize the cell values across each column by setting the `Normalization` property to `'column-normalized'` and then use `sortClasses`. After sorting, reset the `Normalization` property back to `'absolute'` to display the total number of observations in each cell.

```
cm.Normalization = 'column-normalized';
sortClasses(cm, 'descending-diagonal')
cm.Normalization = 'absolute';
```

Sort Classes to Cluster Similar Classes

Create a confusion matrix chart by using the `confusionchart` function, and sort the classes to cluster similar classes by using the `'cluster'` option of the `sortClasses` function. This example also shows how to cluster by using the `pdist`, `linkage`, and `optimalleaforder` functions.

Generate a sample data set that contains eight distinct classes.

```
rng('default') % For reproducibility
trueLabels = randi(8,1000,1);
predictedLabels = trueLabels;
```

Insert confusion among classes {1,4,7}, {2,8}, and {5,6} for the first 200 samples.

```
rename = [4 8 3 7 6 5 1 2];
predictedLabels(1:100) = rename(predictedLabels(1:100));
rename = [7 8 3 1 6 5 4 2];
predictedLabels(101:200) = rename(predictedLabels(101:200));
```

Create a confusion matrix chart from the true labels `trueLabels` and the predicted labels `predictedLabels`.

```
figure
cm1 = confusionchart(trueLabels,predictedLabels);
```

A confusion matrix with 8 rows (True Class) and 8 columns (Predicted Class). The diagonal elements are highlighted in blue, and off-diagonal elements are highlighted in orange. The counts are as follows:

True Class \ Predicted Class	1	2	3	4	5	6	7	8
1	106			10			14	
2		105						29
3			116					
4	14			107			11	
5					99	21		
6					21	121		
7	16			14			89	
8		26						81

Cluster Using 'cluster'

Sort the classes to cluster similar classes by using the 'cluster' option.

```
sortClasses(cm1, 'cluster')
```

3	116							
4		107	11	14				
7		14	89	16				
1		10	14	106				
2					105	29		
8					26	81		
5							99	21
6							21	121
	3	4	7	1	2	8	5	6

Cluster Using pdist, linkage, and optimalleaforder

Instead of using the 'cluster' option, you can use the `pdist`, `linkage`, and `optimalleaforder` functions to cluster confusion matrix values. You can customize clustering by using the options of these functions. For details, see the corresponding function reference pages.

Suppose you have a confusion matrix and class labels.

```
m = confusionmat(trueLabels,predictedLabels);
labels = [1 2 3 4 5 6 7 8];
```

Compute the clustered matrix and find the corresponding class labels by using `pdist`, `linkage`, and `optimalleaforder`. The `pdist` function computes the Euclidean distance D between pairs of the confusion matrix values. The `optimalleaforder` function returns an optimal leaf ordering for the hierarchical binary cluster tree `linkage(D)` using the distance D .

```
D = pdist(m);
idx = optimalleaforder(linkage(D),D);
clusteredM = m(idx,idx);
clusteredLabels = labels(idx);
```

Create a confusion matrix chart using the clustered matrix and the corresponding class labels. Then, sort the classes using the class labels.

```
cm2 = confusionchart(clusteredM,clusteredLabels);
sortClasses(cm2,clusteredLabels)
```

The sorted confusion matrix chart `cm2`, which you created by using `pdist`, `linkage`, and `optimalleaforder`, is identical to the sorted confusion matrix chart `cm1`, which you created by using the `'cluster'` option.

Sort Classes in Fixed Order

Create a confusion matrix chart and sort the classes of the chart in a fixed order.

Load Fisher's iris data set.

```
load fisheriris
X = meas([51:150,1:50],:);
Y = species([51:150,1:50],:);
```

`X` is a numeric matrix that contains four petal measurements for 150 irises. `Y` is a cell array of character vectors that contains the corresponding iris species.

Train a k -nearest neighbor (KNN) classifier, where the number of nearest neighbors in the predictors (k) is 5. A good practice is to standardize numeric predictor data.

```
Mdl = fitcknn(X,Y,'NumNeighbors',5,'Standardize',1);
```

Predict the labels of the training data.

```
predictedY = resubPredict(Mdl);
```

Create a confusion matrix chart from the true labels `Y` and the predicted labels `predictedY`.

```
cm = confusionchart(Y,predictedY);
```

By default, `confusionchart` sorts the classes into their natural order as defined by `sort`. In this example, the class labels are character vectors, so `confusionchart` sorts the classes alphabetically. Reorder the classes of the confusion matrix chart in a fixed order.

```
sortClasses(cm,["versicolor","setosa","virginica"])
```

Input Arguments

cm — Confusion matrix chart

ConfusionMatrixChart object

Confusion matrix chart, specified as a ConfusionMatrixChart object. To create a confusion matrix chart, use `confusionchart`,

order — Order in which to sort classes

'auto' | 'ascending-diagonal' | 'descending-diagonal' | 'cluster' | array

Order in which to sort the classes of the confusion matrix chart, specified as one of these values:

- 'auto' — Sorts the classes into their natural order as defined by the `sort` function. For example, if the class labels of the confusion matrix chart are a string vector, then sort alphabetically. If the class labels are an ordinal categorical vector, then use the order of the class labels.
- 'ascending-diagonal' — Sort the classes so that the values along the diagonal of the confusion matrix increase from top left to bottom right.
- 'descending-diagonal' — Sort the classes so that the values along the diagonal of the confusion matrix decrease from top left to bottom right.
- 'cluster' — Sort the classes to cluster similar classes. You can customize clustering by using the `pdist`, `linkage`, and `optimalleaforder` functions. For details, see “Sort Classes to Cluster Similar Classes” on page 32-5144.

- **Array** — Sort the classes in a unique order specified by a categorical vector, numeric vector, string vector, character array, cell array of character vectors, or logical vector. The array must be a permutation of the `ClassLabels` property of the confusion matrix chart.

Example: `sortClasses(cm, 'ascending-diagonal')`

Example: `sortClasses(cm, ["owl", "cat", "toad"])`

Properties

`ConfusionMatrixChart` Properties

Introduced in R2018b

sortrows

Class: dataset

(Not Recommended) Sort rows of dataset array

Note The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
B = sortrows(A)
B = sortrows(A,vars)
B = sortrows(A,'obsnames')
B = sortrows(A,vars,mode)
[B,idx] = sortrows(A)
```

Description

`B = sortrows(A)` returns a copy of the dataset array `A`, with the observations sorted in ascending order by all of the variables in `A`. The observations in `B` are sorted first by the first variable, next by the second variable, and so on. Each variable in `A` must be a valid input to `sort`, or, if a variable has multiple columns, to the MATLAB `sortrows` function or to its `sortrows` method.

`B = sortrows(A,vars)` sorts the observations in `A` by the variables specified by `vars`. `vars` is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector.

`B = sortrows(A,'obsnames')` sorts the observations in `A` by observation name.

`B = sortrows(A,vars,mode)` sorts in the direction specified by `mode`. When `mode` is `'ascend'` (the default) or `'descend'`, `sortrows` sorts `A` by the variables specified by `vars` in ascending or descending order, respectively. `mode` can also be a string array or cell array containing `'ascend'` or `'descend'`, to specify a different sorting direction for each variable in `vars`. Specify `[]` for `vars` to sort using all variables.

`[B,idx] = sortrows(A)` also returns an index vector `idx` such that `B = A(idx,:)`.

Examples

Sort the data in `hospital.mat` by age and then by last name:

```
load hospital
hospital(1:5,1:3)
ans =
    LastName    Sex    Age
    YPL-320    'SMITH'    Male    38
    GLI-532    'JOHNSON'    Male    43
    PNI-258    'WILLIAMS'    Female    38
    MIJ-579    'JONES'    Female    40
```

```

XLK-030    'BROWN'          Female    49

hospital = sortrows(hospital,{'Age','LastName'});
hospital(1:5,1:3)
ans =
          LastName      Sex      Age
REV-997    'ALEXANDER'    Male    25
FZR-250    'HALL'         Male    25
LIM-480    'HILL'         Female  25
XUE-826    'JACKSON'       Male    25
SCQ-914    'JAMES'         Male    25

```

Sort the data in `hospital` by gender in ascending order, and age in descending order.

```

hospital = sortrows(hospital,{'Sex','Age'},{'ascend','descend'});
hospital(1:5,1:3)
ans =
          LastName      Sex      Age
XLK-030    'BROWN'          Female    49
GGU-691    'HUGHES'         Female    49

sparsefilt

Feature extraction by using sparse filtering

Syntax

```
Mdl = sparsefilt(X,q)
Mdl = sparsefilt(X,q,Name,Value)
```

Description

`Mdl = sparsefilt(X,q)` returns a sparse filtering model object that contains the results from applying sparse filtering to the table or matrix of predictor data X containing p variables. q is the number of features to extract from X , therefore `sparsefilt` learns a p -by- q matrix of transformation weights. For undercomplete or overcomplete feature representations, q can be less than or greater than the number of predictor variables, respectively.

- To access the learned transformation weights, use `Mdl.TransformWeights`.
- To transform X to the new set of features by using the learned transformation, pass `Mdl` and X to `transform`.

`Mdl = sparsefilt(X,q,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, you can standardize the predictor data or apply L^2 regularization.

Examples

Create Sparse Filter

Create a `SparseFiltering` object by using the `sparsefilt` function.

Load the `SampleImagePatches` image patches.

```
data = load('SampleImagePatches');
size(data.X)
```

```
ans = 1×2
```

```
    5000    363
```

There are 5,000 image patches, each containing 363 features.

Extract 100 features from the data.

```
rng default % For reproducibility
Q = 100;
obj = sparsefilt(data.X,Q,'IterationLimit',100)
```

Warning: Solver LBFGS was not able to converge to a solution.

```
obj =
  SparseFiltering
    ModelParameters: [1x1 struct]
    NumPredictors: 363
    NumLearnedFeatures: 100
    Mu: []
    Sigma: []
    FitInfo: [1x1 struct]
    TransformWeights: [363x100 double]
    InitialTransformWeights: []
```

Properties, Methods

`sparsefilt` issues a warning because it stopped due to reaching the iteration limit, instead of reaching a step-size limit or a gradient-size limit. You can still use the learned features in the returned object by calling the `transform` function.

Restart `sparsefilt`

Continue optimizing a sparse filter.

Load the `SampleImagePatches` image patches.

```
data = load('SampleImagePatches');
size(data.X)
```

```
ans = 1x2
```

```
    5000    363
```

There are 5,000 image patches, each containing 363 features.

Extract 100 features from the data and use an iteration limit of 20.

```
rng default % For reproducibility
q = 100;
Mdl = sparsefilt(data.X,q,'IterationLimit',20);
```

Warning: Solver LBFGS was not able to converge to a solution.

View the resulting transformation matrix as image patches.

```
wts = Mdl.TransformWeights;
W = reshape(wts,[11,11,3,q]);
[dx,dy,~,~] = size(W);
for f = 1:q
    Wvec = W(:,:,,f);
    Wvec = Wvec(:);
    Wvec = (Wvec - min(Wvec))/(max(Wvec) - min(Wvec));
    W(:,:,,f) = reshape(Wvec,dx,dy,3);
end
m = ceil(sqrt(q));
n = m;
```

```

img = zeros(m*dx,n*dy,3);
f = 1;
for i = 1:m
    for j = 1:n
        if (f <= q)
            img((i-1)*dx+1:i*dx,(j-1)*dy+1:j*dy,:) = W(:,:,f);
            f = f+1;
        end
    end
end
imshow(img, 'InitialMagnification',300);

```

The image patches appear noisy. To clean up the noise, try more iterations. Restart the optimization from where it stopped for another 40 iterations.

```
Mdl = sparsefilt(data.X,q, 'IterationLimit',40, 'InitialTransformWeights',wts);
```

Warning: Solver LBFGS was not able to converge to a solution.

View the updated transformation matrix as image patches.

```

wts = Mdl.TransformWeights;
W = reshape(wts,[11,11,3,q]);
[dx,dy,~,~] = size(W);
for f = 1:q
    Wvec = W(:,:,f);
    Wvec = Wvec(:);
    Wvec = (Wvec - min(Wvec))/(max(Wvec) - min(Wvec));

```

```

    W(:,:,:,f) = reshape(Wvec,dx,dy,3);
end
m = ceil(sqrt(q));
n = m;
img = zeros(m*dx,n*dy,3);
f = 1;
for i = 1:m
    for j = 1:n
        if (f <= q)
            img((i-1)*dx+1:i*dx,(j-1)*dy+1:j*dy,:) = W(:,:,:,f);
            f = f+1;
        end
    end
end
end
imshow(img,'InitialMagnification',300);

```

These images are less noisy.

Input Arguments

X — Predictor data

numeric matrix | table

Predictor data, specified as an n -by- p numeric matrix or table. Rows correspond to individual observations and columns correspond to individual predictor variables. If X is a table, then all of its variables must be numeric vectors.

Data Types: `single` | `double` | `table`

q — Number of features to extract

positive integer

Number of features to extract from the predictor data, specified as a positive integer.

`sparsefilt` stores a p -by- q transform weight matrix in `Mdl.TransformWeights`. Therefore, setting very large values for q can result in greater memory consumption and increased computation time.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Standardize', true, 'Lambda', 1` standardizes the predictor data and applies a penalty of 1 to the transform weight matrix.

IterationLimit — Maximum number of iterations

1000 (default) | positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer.

Example: `'IterationLimit', 1e6`

Data Types: `single` | `double`

VerbosityLevel — Verbosity level

0 (default) | nonnegative integer

Verbosity level for monitoring algorithm convergence, specified as the comma-separated pair consisting of `'VerbosityLevel'` and a value in this table.

Value	Description
0	<code>sparsefilt</code> does not display convergence information at the command line.
Positive integer	<code>sparsefilt</code> displays convergence information at the command line.

Convergence Information

Heading	Meaning
FUN VALUE	Objective function value.
NORM GRAD	Norm of the gradient of the objective function.
NORM STEP	Norm of the iterative step, meaning the distance between the previous point and the current point.
CURV	OK means the weak Wolfe condition is satisfied. This condition is a combination of sufficient decrease of the objective function and a curvature condition.
GAMMA	Inner product of the step times the gradient difference, divided by the inner product of the gradient difference with itself. The gradient difference is the gradient at the current point minus the gradient at the previous point. Gives diagnostic information on the objective function curvature.
ALPHA	Step direction multiplier, which differs from 1 when the algorithm performed a line search.
ACCEPT	YES means the algorithm found an acceptable step to take.

Example: 'VerbosityLevel',1

Data Types: single | double

Lambda — L^2 regularization coefficient value

0 (default) | positive numeric scalar

L^2 regularization coefficient value for the transform weight matrix, specified as the comma-separated pair consisting of 'Lambda' and a positive numeric scalar. If you specify 0, the default, then there is no regularization term in the objective function.

Example: 'Lambda',0.1

Data Types: single | double

Standardize — Flag to standardize predictor data

false (default) | true

Flag to standardize the predictor data, specified as the comma-separated pair consisting of 'Standardize' and true (1) or false (0).

If Standardize is true, then:

- `sparsefilt` centers and scales each column of the predictor data (X) by the column mean and standard deviation, respectively.
- `sparsefilt` extracts new features by using the standardized predictor matrix, and stores the predictor variable means and standard deviations in properties `Mu` and `Sigma` of `Mdl`.

Example: 'Standardize',true

Data Types: logical

InitialTransformWeights — Transformation weights that initialize optimization

`randn(p,q)` (default) | numeric matrix

Transformation weights that initialize optimization, specified as the comma-separated pair consisting of 'InitialTransformWeights' and a p -by- q numeric matrix. p must be the number of columns or variables in X and q is the value of q .

Tip You can continue optimizing a previously returned transform weight matrix by passing it as an initial value in another call to `sparsefilt`. The output model object `Mdl` stores a learned transform weight matrix in the `TransformWeights` property.

Example: 'InitialTransformWeights',Mdl.TransformWeights

Data Types: single | double

GradientTolerance — Relative convergence tolerance on gradient norm

1e-6 (default) | positive numeric scalar

Relative convergence tolerance on gradient norm, specified as the comma-separated pair consisting of 'GradientTolerance' and a positive numeric scalar. This gradient is the gradient of the objective function.

Example: 'GradientTolerance',1e-4

Data Types: single | double

StepTolerance — Absolute convergence tolerance on step size

1e-6 (default) | positive numeric scalar

Absolute convergence tolerance on the step size, specified as the comma-separated pair consisting of 'StepTolerance' and a positive numeric scalar.

Example: 'StepTolerance',1e-4

Data Types: single | double

Output Arguments

Mdl — Learned sparse filtering model

SparseFiltering model object

Learned sparse filtering model, returned as a `SparseFiltering` model object.

To access properties of `Mdl`, use dot notation. For example:

- To access the learned transform weights, use `Mdl.TransformWeights`.
- To access the fitting information structure, use `Mdl.FitInfo`.

To find sparse filtering coefficients for new data, use the `transform` function.

Algorithms

The `sparsefilt` function creates a nonlinear transformation of input features to output features. The transformation is based on optimizing an objective function that encourages the representation of each example by as few output features as possible while at the same time keeping the output features equally active across examples.

For details, see “Sparse Filtering Algorithm” on page 15-130.

Introduced in R2017a

SparseFiltering

Feature extraction by sparse filtering

Description

SparseFiltering uses sparse filtering to learn a transformation that maps input predictors to new predictors.

Creation

Create a SparseFiltering object using the `sparsefilt` function.

Properties

FitInfo — Fitting history

structure

This property is read-only.

Fitting history, returned as a structure with two fields:

- **Iteration** — Iteration numbers from 0 through the final iteration.
- **Objective** — Objective function value at each corresponding iteration. Iteration 0 corresponds to the initial values, before any fitting.

Data Types: `struct`

InitialTransformWeights — Initial feature transformation weights

p-by-q matrix

This property is read-only.

Initial feature transformation weights, returned as a p-by-q matrix, where p is the number of predictors passed in X and q is the number of features that you want. These weights are the initial weights passed to the creation function. The data type is `single` when the training data X is `single`.

Data Types: `single` | `double`

ModelParameters — Parameters used for training model

structure

This property is read-only.

Parameters used for training the model, returned as a structure. The structure contains a subset of the fields that corresponds to the `sparsefilt` name-value pairs that were in effect during model creation:

- `IterationLimit`

- `VerbosityLevel`
- `Lambda`
- `Standardize`
- `GradientTolerance`
- `StepTolerance`

For details, see the `sparsefilt` name-value pairs in the documentation.

Data Types: `struct`

Mu — Predictor means when standardizing

`p`-by-1 vector

This property is read-only.

Predictor means when standardizing, returned as a `p`-by-1 vector. This property is nonempty when the `Standardize` name-value pair is `true` at model creation. The value is the vector of predictor means in the training data. The data type is `single` when the training data `X` is `single`.

Data Types: `single` | `double`

NumLearnedFeatures — Number of output features

positive integer

This property is read-only.

Number of output features, returned as a positive integer. This value is the `q` argument passed to the creation function, which is the requested number of features to learn.

Data Types: `double`

NumPredictors — Number of input predictors

positive integer

This property is read-only.

Number of input predictors, returned as a positive integer. This value is the number of predictors passed in `X` to the creation function.

Data Types: `double`

Sigma — Predictor standard deviations when standardizing

`p`-by-1 vector

This property is read-only.

Predictor standard deviations when standardizing, returned as a `p`-by-1 vector. This property is nonempty when the `Standardize` name-value pair is `true` at model creation. The value is the vector of predictor standard deviations in the training data. The data type is `single` when the training data `X` is `single`.

Data Types: `single` | `double`

TransformWeights — Feature transformation weights

`p`-by-`q` matrix

This property is read-only.

Feature transformation weights, returned as a p-by-q matrix, where p is the number of predictors passed in X and q is the number of features that you want. The data type is single when the training data X is single.

Data Types: single | double

Object Functions

`transform` Transform predictors into extracted features

Examples

Create Sparse Filter

Create a SparseFiltering object by using the `sparsefilt` function.

Load the `SampleImagePatches` image patches.

```
data = load('SampleImagePatches');
size(data.X)
```

```
ans = 1x2
```

```
    5000    363
```

There are 5,000 image patches, each containing 363 features.

Extract 100 features from the data.

```
rng default % For reproducibility
Q = 100;
obj = sparsefilt(data.X,Q,'IterationLimit',100)
```

Warning: Solver LBFGS was not able to converge to a solution.

```
obj =
  SparseFiltering
      ModelParameters: [1x1 struct]
      NumPredictors: 363
      NumLearnedFeatures: 100
              Mu: []
              Sigma: []
      FitInfo: [1x1 struct]
      TransformWeights: [363x100 double]
      InitialTransformWeights: []
```

Properties, Methods

`sparsefilt` issues a warning because it stopped due to reaching the iteration limit, instead of reaching a step-size limit or a gradient-size limit. You can still use the learned features in the returned object by calling the `transform` function.

“Feature Extraction” on page 15-130

Introduced in R2017a

spectralcluster

Spectral clustering

Syntax

```
idx = spectralcluster(X,k)
idx = spectralcluster(S,k,'Distance','precomputed')
idx = spectralcluster(___,Name,Value)
[idx,V] = spectralcluster(___)
[idx,V,D] = spectralcluster(___)

```

Description

`idx = spectralcluster(X,k)` partitions observations in the n -by- p data matrix X into k clusters using the spectral clustering algorithm (see Algorithms on page 32-5179). `spectralcluster` returns an n -by-1 vector `idx` containing cluster indices of each observation.

`idx = spectralcluster(S,k,'Distance','precomputed')` returns a vector of cluster indices for S , the similarity matrix on page 32-5178 (or adjacency matrix) of a similarity graph on page 32-5178. S can be the output of `adjacency`.

To use a similarity matrix as the first input, you must specify `'Distance','precomputed'`.

`idx = spectralcluster(___,Name,Value)` specifies additional options using one or more name-value pair arguments in addition to the input arguments in previous syntaxes. For example, you can specify `'SimilarityGraph','epsilon'` to construct a similarity graph using the radius search method.

`[idx,V] = spectralcluster(___)` also returns the eigenvectors V corresponding to the k smallest eigenvalues of the Laplacian matrix on page 32-5179.

`[idx,V,D] = spectralcluster(___)` also returns a vector D containing the k smallest eigenvalues of the Laplacian matrix.

Examples

Perform Spectral Clustering on Input Data

Cluster a 2-D circular data set using spectral clustering with the default Euclidean distance metric.

Generate synthetic data that contains two noisy circles.

```
rng('default') % For reproducibility

% Parameters for data generation
N = 300; % Size of each cluster
r1 = 2; % Radius of first circle
r2 = 4; % Radius of second circle

```

```
theta = linspace(0,2*pi,N)';  
X1 = r1*[cos(theta),sin(theta)]+ rand(N,1);  
X2 = r2*[cos(theta),sin(theta)]+ rand(N,1);  
X = [X1;X2]; % Noisy 2-D circular data set
```

Find two clusters in the data by using spectral clustering.

```
idx = spectralcluster(X,2);
```

Visualize the result of clustering.

```
gscatter(X(:,1),X(:,2),idx);
```

The `spectralcluster` function correctly identifies the two clusters in the data set.

Perform Spectral Clustering on Similarity Matrix

Compute a similarity matrix from Fisher's iris data set and perform spectral clustering on the similarity matrix.

Load Fisher's iris data set. Use the petal lengths and widths as features to consider for clustering.

```
load fisheriris
X = meas(:,3:4);
gscatter(X(:,1),X(:,2),species);
```

Find the distance between each pair of observations in X by using the `pdist` and `squareform` functions with the default Euclidean distance metric.

```
dist_temp = pdist(X);
dist = squareform(dist_temp);
```

Construct the similarity matrix and confirm that it is symmetric.

```
S = exp(-dist.^2);
issymmetric(S)
```

```
ans = logical
     1
```

Perform spectral clustering. Specify `'Distance'`, `'precomputed'` to perform clustering using the similarity matrix. Specify `k=3` clusters, and set the `'LaplacianNormalization'` name-value pair argument to use the normalized symmetric Laplacian matrix.

```
k = 3; % Number of clusters
rng('default') % For reproducibility
idx = spectralcluster(S,k,'Distance','precomputed','LaplacianNormalization','symmetric');
```

`idx` contains the cluster indices for each observation in X .

Visualize the result of clustering.

```
gscatter(X(:,1),X(:,2),idx);
```

Tabulate the clustering results.

```
tabulate(idx)
```

Value	Count	Percent
1	48	32.00%
2	50	33.33%
3	52	34.67%

The Percent column shows the percentage of data points assigned to the three clusters.

Repeat spectral clustering using the data as input to `spectralcluster`. Specify `'NumNeighbors'` as `size(X,1)`, which corresponds to creating the similarity matrix `S` by connecting each point to all the remaining points.

```
idx2 = spectralcluster(X,k,'NumNeighbors',size(X,1),'LaplacianNormalization','symmetric');
gscatter(X(:,1),X(:,2),idx2);
```

```
tabulate(idx2)
```

Value	Count	Percent
1	50	33.33%
2	52	34.67%
3	48	32.00%

The clustering results for both approaches are the same. The order of cluster assignments is different, even though the data points are clustered in the same way.

Cluster Using Radius Search for Similarity Graph

Find clusters in a data set, based on a specified search radius for creating a similarity graph.

Create data with 3 clusters, each containing 500 points.

```
rng('default') % For reproducibility
N = 500;
X = [mvnrnd([0 0],eye(2),N); ...
     mvnrnd(5*[1 -1],eye(2),N); ...
     mvnrnd(5*[1 1],eye(2),N)];
```

Specify a search radius of 2 for creating a similarity graph, and find 3 clusters in the data.

```
idx = spectralcluster(X,3,'SimilarityGraph','epsilon','Radius',2);
```

Visualize the result of clustering.

```
gscatter(X(:,1),X(:,2),idx);
```

Find Eigenvalues and Eigenvectors of Laplacian Matrix

Find the eigenvalues and eigenvectors of the Laplacian matrix and use the values to confirm clustering results.

Randomly generate sample data with three well-separated clusters, each containing 100 points.

```
rng('default'); % For reproducibility
n = 100;
X = [randn(n,2)*0.5+3;
     randn(n,2)*0.5
     randn(n,2)*0.5-3];
```

Estimate the number of clusters in the data by using the eigenvalues of the Laplacian matrix. Compute the five smallest eigenvalues (in magnitude) of the Laplacian matrix.

```
[~,~,D_temp] = spectralcluster(X,5)
```

```
D_temp = 5×1
```

```
-0.0000
```

that do not belong to a particular cluster, and nonzero values for points that belong to a particular cluster.

Visualize the result of clustering.

```
gscatter(X(:,1),X(:,2),idx);
```

Input Arguments

X — Input data

numeric matrix

Input data, specified as an n -by- p numeric matrix. The rows of X correspond to observations (or points), and the columns correspond to variables.

The software treats NaNs in X as missing data and ignores any row of X containing at least one NaN. The `spectralcluster` function returns NaN values for the corresponding row in the output arguments `idx` and `V`.

Data Types: `single` | `double`

S — Similarity matrix

symmetric matrix

Similarity matrix, specified as an n -by- n symmetric matrix, where n is the number of observations. A similarity matrix (or adjacency matrix) represents the input data by modeling local neighborhood

relationships among the data points. The values in a similarity matrix represent the edges (or connections) between nodes (data points) that are connected in a similarity graph on page 32-5178. For more information, see “Similarity Matrix” on page 32-5178.

S must not contain any NaN values.

To use a similarity matrix as the first input of `spectralcluster`, you must specify 'Distance', 'precomputed'.

Data Types: single | double

k — Number of clusters

positive integer

Number of clusters in the data, specified as a positive integer.

For details about how to estimate the number of clusters, see “Tips” on page 32-5179.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `spectralcluster(X,3,'SimilarityGraph','epsilon','Radius',5)` specifies 3 clusters and uses the radius search method with a search radius of 5 to construct a similarity graph.

Distance — Distance metric

character vector | string scalar | function handle

Distance metric, specified as the comma-separated pair consisting of 'Distance' and a character vector, string scalar, or function handle, as described in this table.

Value	Description
'precomputed'	Precomputed distance. You must specify this option if the first input to <code>spectralcluster</code> is a similarity matrix S .
'euclidean'	Euclidean distance (default)
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between observations is scaled by dividing by the corresponding element of the standard deviation computed from X . Use the <code>Scale</code> name-value pair argument to specify a different scaling factor.
'mahalanobis'	Mahalanobis distance using the sample covariance of X , $C = \text{nancov}(X)$. Use the <code>Cov</code> name-value pair argument to specify a different covariance matrix.
'cityblock'	City block distance
'minkowski'	Minkowski distance. The default exponent is 2. Use the <code>P</code> name-value pair argument to specify a different exponent, where P is a positive scalar value.
'chebychev'	Chebychev distance (maximum coordinate difference)

Value	Description
'cosine'	One minus the cosine of the included angle between observations (treated as vectors)
'correlation'	One minus the sample correlation between observations (treated as sequences of values)
'hamming'	Hamming distance, which is the percentage of coordinates that differ
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values)
@ <i>distfun</i>	<p>Custom distance function handle. A distance function has the form</p> <pre>function D2 = distfun(ZI,ZJ) % calculation of distance ...</pre> <p>where</p> <ul style="list-style-type: none"> • ZI is a 1-by-n vector containing a single observation. • ZJ is an m2-by-n matrix containing multiple observations. <code>distfun</code> must accept a matrix ZJ with an arbitrary number of observations. • D2 is an m2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(k, :). <p>If your data is not sparse, you can generally compute distance more quickly by using a built-in distance instead of a function handle.</p>

For more information, see “Distance Metrics” on page 18-11.

When you use the 'seuclidean', 'minkowski', or 'mahalanobis' distance metric, you can specify the additional name-value pair argument 'Scale', 'P', or 'Cov', respectively, to control the distance metric.

Example: `spectralcluster(X,5,'Distance','minkowski','P',3)` specifies 5 clusters and uses of the Minkowski distance metric with an exponent of 3 to perform the clustering algorithm.

P — Exponent for Minkowski distance metric

2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of 'P' and a positive scalar.

This argument is valid only if 'Distance' is 'minkowski'.

Example: 'P',3

Data Types: single | double

Cov — Covariance matrix for Mahalanobis distance metric

nancov(X) (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix.

This argument is valid only if 'Distance' is 'mahalanobis'.

Example: 'Cov', eye(4)

Data Types: single | double

Scale — Scaling factors for standardized Euclidean distance metric

nanstd(X) (default) | numeric vector of nonnegative values

Scaling factors for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of 'Scale' and a numeric vector of nonnegative values.

Scale has length p (the number of columns in X), because each dimension (column) of X has a corresponding value in Scale. For each dimension of X , spectralcluster uses the corresponding value in Scale to standardize the difference between observations.

This argument is valid only if 'Distance' is 'seuclidean'.

Data Types: single | double

SimilarityGraph — Type of similarity graph

'knn' (default) | 'epsilon'

Type of similarity graph to construct from the input data X , specified as the comma-separated pair consisting of 'SimilarityGraph' and one of these values.

Value	Description	Graph-Specific Name-Value Pair Arguments
'knn'	(Default) Construct the graph using nearest neighbors.	'NumNeighbors' — Number of nearest neighbors used to construct the similarity graph 'KNNGraphType' — Type of nearest neighbor graph
'epsilon'	Construct the graph using a radius search. You must specify a value for Radius if you use this option.	'Radius' — Search radius for the nearest neighbors used to construct the similarity graph

For more information, see “Similarity Graph” on page 32-5178.

This argument is valid only if 'Distance' is not 'precomputed'.

Example: 'SimilarityGraph', 'epsilon'

NumNeighbors — Number of nearest neighbors

log(size(X,1)) (default) | positive integer

Number of nearest neighbors used to construct the similarity graph, specified as the comma-separated pair consisting of 'NumNeighbors' and a positive integer.

This argument is valid only if 'SimilarityGraph' is 'knn'. For more information, see “Similarity Graph” on page 32-5178.

Example: 'NumNeighbors', 10

Data Types: single | double

KNNGraphType — Type of nearest neighbor graph

'complete' (default) | 'mutual'

Type of nearest neighbor graph, specified as the comma-separated pair consisting of 'KNNGraphType' and one of these values.

Value	Description
'complete'	(Default) Connects two points i and j , when either i is a nearest neighbor of j or j is a nearest neighbor of i . This option leads to a denser representation of the similarity matrix.
'mutual'	Connects two points i and j , when i is a nearest neighbor of j and j is a nearest neighbor of i . This option leads to a sparser representation of the similarity matrix.

This argument is valid only if 'SimilarityGraph' is 'knn'.

Example: 'KNNGraphType', 'mutual'

Radius — Search radius

nonnegative scalar

Search radius for the nearest neighbors used to construct the similarity graph, specified as the comma-separated pair consisting of 'Radius' and a nonnegative scalar.

You must specify this argument if 'SimilarityGraph' is 'epsilon'. For more information, see “Similarity Graph” on page 32-5178.

Example: 'Radius', 5

Data Types: single | double

KernelScale — Scale factor

1 (default) | 'auto' | positive scalar

Scale factor for the kernel, specified as the comma-separated pair consisting of 'KernelScale' and 'auto' or a positive scalar. The software uses the scale factor to transform distances to similarity measures. For more information, see “Similarity Graph” on page 32-5178.

- The 'auto' option is supported only for the 'euclidean' and 'seuclidean' distance metrics.
- If you specify 'auto', then the software selects an appropriate scale factor using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. To reproduce results, set a random number seed using `rng` before calling `spectralcluster`.

This argument is valid only if 'Distance' is not 'precomputed'.

Example: 'KernelScale', 'auto'

Data Types: double | single | char | string

LaplacianNormalization — Method to normalize Laplacian matrix

'randomwalk' (default) | 'symmetric' | 'none'

Method to normalize the Laplacian matrix L , specified as the comma-separated pair consisting of 'LaplacianNormalization' and one of these values.

Value	Description
'none'	Use Laplacian matrix L without normalization.
'randomwalk'	(Default) Use the normalized random-walk Laplacian matrix L_{rw} (Shi-Malik [2]). $L_{rw} = D_g^{-1}L.$ The matrix D_g is the degree matrix on page 32-5179.
'symmetric'	Use the normalized symmetric Laplacian matrix L_s (Ng-Jordan-Weiss [3]). $L_s = D_g^{-1/2}LD_g^{-1/2}.$ The matrix D_g is the degree matrix.

For more information, see “Laplacian Matrix” on page 32-5179.

Example: 'LaplacianNormalization', 'randomwalk'

ClusterMethod — Clustering method

'kmeans' (default) | 'kmedoids'

Clustering method to cluster the eigenvectors of the Laplacian matrix, specified as the comma-separated pair consisting of 'ClusterMethod' and either 'kmeans' or 'kmedoids'.

- 'kmeans' — Perform k -means clustering by using the `kmeans` function.
- 'kmedoids' — Perform k -medoids clustering by using the `kmedoids` function.

`kmeans` and `kmedoids` involve randomness in their algorithms. Therefore, to reproduce the results of `spectralcluster`, you must set the seed of the random number generator by using `rng`.

Example: 'ClusterMethod', 'kmedoids'

Output Arguments

idx — Cluster indices

numeric column vector

Cluster indices, returned as a numeric column vector. `idx` has n rows, and each row of `idx` indicates the cluster assignment of the corresponding row (or observation) in X .

Data Types: double

V — Eigenvectors

numeric matrix

Eigenvectors, returned as an n -by- k numeric matrix. The columns of V are the eigenvectors corresponding to the k smallest eigenvalues of the Laplacian matrix on page 32-5179. These eigenvectors are a low-dimensional representation of the input data X in a new space where clusters are more widely separated.

For well-separated clusters, the eigenvectors are indicator vectors. That is, the eigenvectors have values of zero (or close to zero) for points that do not belong to a given cluster, and nonzero values for points that belong to a particular cluster.

Data Types: `single` | `double`

D — Eigenvalues

numeric vector

Eigenvalues, returned as a k -by-1 numeric vector that contains the k smallest eigenvalues of the Laplacian matrix. The number of zero eigenvalues in D is an indicator of the number of connected components in the similarity graph and, therefore, is a good estimate of the number of clusters in your data.

Data Types: `single` | `double`

More About

Similarity Graph

A similarity graph models the local neighborhood relationships between data points in X as an undirected graph. The nodes in the graph represent data points, and the edges, which are directionless, represent the connections between the data points.

If the pairwise distance $Dist_{i,j}$ between any two nodes i and j is positive (or larger than a certain threshold), then the similarity graph connects the two nodes using an edge [1]. The edge between the two nodes is weighted by the pairwise similarity $S_{i,j}$, where $S_{i,j} = \exp\left(-\left(\frac{Dist_{i,j}}{\sigma}\right)^2\right)$, for a specified kernel scale σ value.

`spectralcluster` supports these two methods of constructing a similarity graph:

- *Nearest neighbor* method (if 'SimilarityGraph' is 'knn' (default)): `spectralcluster` connects points in X that are nearest neighbors. You can use the 'NumNeighbors' and 'KNNGraphType' name-value pair arguments to specify the options for constructing the nearest neighbor graph.
 - Use 'NumNeighbors' to specify the number of nearest neighbors.
 - Use 'KNNGraphType' to specify whether to make a 'complete' or 'mutual' connection of points.
- *Radius search* method (if 'SimilarityGraph' is 'epsilon'): `spectralcluster` connects points whose pairwise distances are smaller than a search radius. You must specify the search radius for nearest neighbors used to construct the similarity graph by using the 'Radius' name-value pair argument.

Similarity Matrix

A similarity matrix is a matrix representation of a similarity graph on page 32-5178. The n -by- n matrix $S = (S_{i,j})_{i,j=1,\dots,n}$ contains pairwise similarity values between connected nodes in the similarity graph. The similarity matrix of a graph is also called an adjacency matrix.

The similarity matrix is symmetric because the edges of the similarity graph are directionless. A value of $S_{i,j} = 0$ means that nodes i and j of the similarity graph are not connected.

Degree Matrix

A degree matrix D_g is an n -by- n diagonal matrix obtained by summing the rows of the similarity

matrix on page 32-5178 S . That is, the i th diagonal element of D_g is $D_g(i, i) = \sum_{j=1}^n S_{i,j}$.

Laplacian Matrix

A Laplacian matrix is one way of representing a similarity graph on page 32-5178. The `spectralcluster` function supports the unnormalized Laplacian matrix, the normalized Laplacian matrix using the Shi-Malik method [2], and the normalized Laplacian matrix using the Ng-Jordan-Weiss method [3].

- The *unnormalized Laplacian matrix* L is the difference between the degree matrix on page 32-5179 and the similarity matrix on page 32-5178.

$$L = D_g - S.$$

- The *normalized random-walk Laplacian matrix (Shi-Malik)* is defined as:

$$L_{rw} = D_g^{-1}L.$$

To derive L_{rw} , solve the generalized eigenvalue problem $Lv = \lambda D_g v$, where v is a column vector of length n , and λ is a scalar. The values of λ that satisfy the equation are the generalized eigenvalues of the matrix $L_{rw} = D_g^{-1}L$.

You can use the MATLAB function `eigs` to solve the generalized eigenvalue problem.

- The *normalized symmetric Laplacian matrix (Ng-Jordan-Weiss)* is defined as:

$$L_s = D_g^{-1/2} L D_g^{-1/2}.$$

Use the 'LaplacianNormalization' name-value pair argument to specify the method to normalize the Laplacian matrix.

Tips

- Consider using spectral clustering when the clusters in your data do not naturally correspond to convex regions.
- From the spectral clustering algorithm, you can estimate the number of clusters k as:
 - The number of eigenvalues of the Laplacian matrix that are equal to 0.
 - The number of connected components in your similarity graph representation. Use `graph` to create a similarity graph from a similarity matrix, and use `conncomp` to find the number of connected components in the graph.

For an example, see “Estimate Number of Clusters and Perform Spectral Clustering” on page 16-27.

Algorithms

Spectral clustering is a graph-based algorithm for clustering data points (or observations in X). The algorithm involves constructing a graph, finding its Laplacian matrix on page 32-5179, and using this

matrix to find k eigenvectors to split the graph k ways. By default, the algorithm for `spectralcluster` computes the normalized random-walk Laplacian matrix using the method described by Shi-Malik [2]. `spectralcluster` also supports the unnormalized Laplacian matrix and the normalized symmetric Laplacian matrix which uses the Ng-Jordan-Weiss method [3]. `spectralcluster` implements clustering as follows:

- 1 For each data point in X , define a local neighborhood using either the radius search method or nearest neighbor method, as specified by the 'SimilarityGraph' name-value pair argument (see "Similarity Graph" on page 32-5178). Then, find the pairwise distances $Dist_{i,j}$ for all points i and j in the neighborhood.
- 2 Convert the distances to similarity measures using the kernel transformation $S_{i,j} = \exp\left(-\left(\frac{Dist_{i,j}}{\sigma}\right)^2\right)$. The matrix S is the similarity matrix on page 32-5178, and σ is the scale factor for the kernel, as specified using the 'KernelScale' name-value pair argument.
- 3 Calculate the unnormalized Laplacian matrix on page 32-5179 L , the normalized random-walk Laplacian matrix L_{rw} , or the normalized symmetric Laplacian matrix L_s , depending on the value of the 'LaplacianNormalization' name-value pair argument.
- 4 Create a matrix $V \in \mathbb{R}^{n \times k}$ containing columns v_1, \dots, v_k , where the columns are the k eigenvectors that correspond to the k smallest eigenvalues of the Laplacian matrix. If using L_s , normalize each row of V to have unit length.
- 5 Treating each row of V as a point, cluster the n points using k -means clustering (default) or k -medoids clustering, as specified by the 'ClusterMethod' name-value pair argument.
- 6 Assign the original points in X to the same clusters as their corresponding rows in V .

Topics

"Partition Data Using Spectral Clustering" on page 16-26

Introduced in R2019b

squareform

Format distance matrix

Syntax

```
ZOut = squareform(yIn)
yOut = squareform(ZIn)
```

```
ZOut = squareform(yIn, 'tomatrix')
yOut = squareform(ZIn, 'tovector')
```

Description

`ZOut = squareform(yIn)` converts `yIn`, a pairwise distance vector of length $m(m-1)/2$ for m observations, into `ZOut`, an m -by- m symmetric matrix with zeros along the diagonal.

The pairwise distances in `yIn` are arranged in the order (2,1), (3,1), ..., (m,1), (3,2), ..., (m,2), ..., (m,m-1). The pairwise distance between the i th and j th observations is in `ZOut(i,j)` and `yIn((i-1)*(m-i)/2+j-i)` for $i \leq j$.

`yOut = squareform(ZIn)` converts `ZIn`, a square, symmetric matrix with zeros along the diagonal, into `yOut`, a vector containing the `ZIn` elements below the diagonal.

`ZOut = squareform(yIn, 'tomatrix')` forces `squareform` to treat `yIn` as a vector and converts `yIn` into a matrix.

`yOut = squareform(ZIn, 'tovector')` forces `squareform` to treat `ZIn` as a matrix and converts `ZIn` into a vector. If `ZIn` is a scalar (1-by-1), then `ZIn` must be zero.

The previous two syntaxes are useful when the input argument is a scalar. If you do not specify either 'tomatrix' or 'tovector', then the default is 'tomatrix'.

Examples

Compute Euclidean Distance and Convert Distance Vector to Matrix

Compute the Euclidean distance between pairs of observations, and convert the distance vector to a matrix using `squareform`.

Create a matrix with three observations and two variables.

```
rng('default') % For reproducibility
X = rand(3,2);
```

Compute the Euclidean distance.

```
D = pdist(X)
```

```
D = 1x3
```

```
0.2954    1.0670    0.9448
```

The pairwise distances are arranged in the order (2,1), (3,1), (3,2). You can easily locate the distance between observations *i* and *j* by using `squareform`.

```
Z = squareform(D)
```

```
Z = 3×3
```

```
      0    0.2954    1.0670
0.2954    0    0.9448
1.0670    0.9448    0
```

`squareform` returns a symmetric matrix where $Z(i, j)$ corresponds to the pairwise distance between observations *i* and *j*. For example, you can find the distance between observations 2 and 3.

```
Z(2,3)
```

```
ans = 0.9448
```

Pass *Z* to the `squareform` function to reproduce the output of the `pdist` function.

```
y = squareform(Z)
```

```
y = 1×3
```

```
0.2954    1.0670    0.9448
```

The outputs *y* from `squareform` and *D* from `pdist` are the same.

Input Arguments

yIn — Input distance vector

numeric vector | logical vector

Input distance vector, specified as a numeric or logical vector of length $m(m-1)/2$, where *m* is the number of observations.

The pairwise distances in *yIn* are arranged in the order (2,1), (3,1), ..., (*m*,1), (3,2), ..., (*m*,2), ..., (*m*,*m*-1), i.e., the lower-left triangle of the *m*-by-*m* distance matrix in column order. The pairwise distance between observations *i* and *j* is in *yIn*((*i*-1)*(*m*-*i*/2)+*j*-*i*) for $i \leq j$.

You can create *yIn* by using the `pdist` function. *m* is the number of observations in the input data of `pdist`.

Data Types: `single` | `double` | `logical`

ZIn — Input distance matrix

numeric matrix | logical matrix

Input distance matrix, specified as a numeric or logical matrix. *ZIn* is an *m*-by-*m* symmetric matrix with zeros along the diagonal, where *m* is the number of observations. *ZIn*(*i*, *j*) denotes the distance between the *i*th and *j*th observations.

Data Types: `single` | `double` | `logical`

Output Arguments

yOut — Distance vector

numeric vector | logical vector

Distance vector, returned as a numeric or logical vector of length $m(m-1)/2$, where m is the number of observations.

The pairwise distances in `yOut` are arranged in the order $(2,1)$, $(3,1)$, ..., $(m,1)$, $(3,2)$, ..., $(m,2)$, ..., $(m,m-1)$, i.e., the lower-left triangle of the m -by- m distance matrix in column order. The pairwise distance between observations i and j is in `yOut((i-1)*(m-i/2)+j-i)` for $i \leq j$.

`yOut` has the same format as the output from the `pdist` function.

ZOut — Distance matrix

numeric matrix | logical matrix

Distance matrix, returned as a numeric or logical matrix. `ZOut` is an m -by- m symmetric matrix with zeros along the diagonal, where m is the number of observations. `ZOut(i,j)` denotes the distance between the i th and j th observations.

Tips

- You can use `squareform` to format a vector or matrix that is similar to a distance vector or matrix, such as the correlation coefficient matrix (`corrcoef`).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations: The conversion direction `'tomatrix'` or `'tovector'` must be a compile-time constant. For example, to specify the conversion direction as `'tovector'`, include `coder.Constant('tovector')` in the `-args` value of `codegen`.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

stack

Class: dataset

(Not Recommended) Stack data from multiple variables into single variable

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
B = stack(A,datavars)
[B,iA] = stack(A,datavars)
B = stack(A,datavars,Parameter,value)
```

Description

`B = stack(A,datavars)` stacks multiple variables in dataset array `A` into a single variable in `B`. In general, `B` contains fewer variables but more observations than `A`.

`datavars` specifies a group of `m` data variables in `A`. `stack` creates a single data variable in `B` by interleaving their values, and if `A` has `n` observations, then `B` has `m`-by-`n` observations. In other words, `stack` takes the `m` data values from each observation in `A` and stacks them up to create `m` observations in `B`. `datavars` is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector. `stack` also creates a grouping variable in `B` to indicate which of the `m` data variables in `A` each observation in `B` corresponds to.

`stack` assigns values for the "per-variable properties (e.g., `Units` and `VarDescription`) for the new data variable in `B` from the corresponding property values for the first variable listed in `datavars`.

`stack` copies the remaining variables from `A` to `B` without stacking, by replicating each of their values `m` times. These variables are typically grouping variables. Because their values are constant across each group of `m` observations in `B`, they identify which observation in `A` an observation in `B` came from.

`[B,iA] = stack(A,datavars)` returns an index vector `iA` indicating the correspondence between observations in `B` and those in `A`. `stack` creates `B(j,:)` using `A(iA(j),datavars)`.

For more information on grouping variables, see "Grouping Variables" on page 2-45.

Input Arguments

`B = stack(A,datavars,Parameter,value)` uses the following parameter name/value pairs to control how `stack` converts variables in `A` to variables in `B`:

'ConstVars'	Variables in A to copy to B without stacking. ConstVars is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector. The default is all variables in A not specified in datavars.
'NewDataVarName'	A name for the data variable to be created in B. The default is a concatenation of the names of the m variables that are stacked up.
'IndVarName'	A name for the grouping variable to create in B to indicate the source of each value in the new data variable. The default is based on the 'NewDataVarName' parameter.

You can also specify multiple groups of data variables in A, each of which becomes a variable in B. All groups must contain the same number of variables. Use a string array or cell array of character vectors to contain multiple parameter values for datavars or to contain multiple values for 'NewDataVarName'.

Examples

Combine several variables for estimated influenza rates into a single variable. Then unstack the estimated influenza rates by date.

```
load flu

% FLU has a 'Date' variable, and 10 variables for estimated influenza rates
% (in 9 different regions, estimated from Google searches, plus a
% nationwide estimate from the CDC). Combine those 10 variables into an
% array that has a single data variable, 'FluRate', and an indicator
% variable, 'Region', that says which region each estimate is from.
[flu2,iflu] = stack(flu, 2:11, 'NewDataVarName','FluRate', ...
    'IndVarName','Region')

% The second observation in FLU is for 10/16/2005. Find the observations
% in FLU2 that correspond to that date.
flu(2,:)
flu2(iflu==2,:)

% Use the 'Date' variable from that array to split 'FluRate' into 52
% separate variables, each containing the estimated influenza rates for
% each unique date. The new array has one observation for each region. In
% effect, this is the original array FLU "on its side".
dateNames = cellstr(datestr(flu.Date,'mmm_DD_YYYY'));
[flu3,iflu2] = unstack(flu2, 'FluRate', 'Date', ...
    'NewDataVarNames',dateNames)

% Since observations in FLU3 represent regions, IFLU2 indicates the first
% occurrence in FLU2 of each region.
flu2(iflu2,:)
```

“Grouping Variables” on page 2-45

State property

Class: grandstream

Current state of the stream

Description

The State property of a quasi-random stream contains the index into the associated point set of the next point to draw in the stream. Getting and resetting the State property allows you to return a stream to a previous state. The initial value of State is 1.

Examples

```
Q = grandstream('sobol', 5);  
s = Q.State;  
u1 = grand(Q, 10)  
Q.State = s;  
u2 = grand(Q, 10) % contains exactly the same values as u1
```

See Also

grand

statget

Access values in statistics options structure

Syntax

```
val = statget(options,param)
val = statget(options,param,default)
```

Description

`val = statget(options,param)` returns the value of the parameter specified by `param` in the statistics options structure `options`. The input `param` is a character vector or a string scalar of the parameter name. If the parameter is undefined in `options`, `statget` returns `[]`. You need to type only enough leading characters to define the parameter name uniquely. `statget` ignores case for parameter names. For available options, see Inputs.

`val = statget(options,param,default)` returns `default` if the specified parameter is undefined in the optimization options structure `options`.

Input Arguments

DerivStep

Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics and Machine Learning Toolbox function using the options structure.

Display

Amount of information displayed by the algorithm.

- 'off' — Displays no information.
- 'final' — Displays the final output.
- 'iter' — Displays iterative output to the command window for some functions; otherwise displays the final output.

FunValCheck

Check for invalid values, such as NaN or Inf, from the objective function.

- 'off'
- 'on'

GradObj

Flags whether the objective function returns a gradient vector as a second output.

- 'off'
- 'on'

Jacobian

Flags whether the objective function returns a Jacobian as a second output.

- 'off'
- 'on'

MaxFunEvals

Maximum number of objective function evaluations allowed. Positive integer.

MaxIter

Maximum number of iterations allowed. Positive integer.

OutputFcn

The solver calls all output functions after each iteration.

- Function handle specified using @
- a cell array with function handles
- an empty array (default)

Robust

Invoke robust fitting option.

- 'off'
- 'on'

RobustWgtFun

A weight function for robust fitting. Valid only when `Robust` is 'on'. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output.

- 'bisquare'
- 'andrews'
- 'cauchy'
- 'fair'
- 'huber'
- 'logistic'
- 'talwar'
- 'welsch'

Streams

A single instance of the `RandStream` class, or a cell array of `RandStream` instances. The `Streams` option is accepted by some functions to govern what stream(s) to use in generating random numbers within the function. If `'UseSubstreams'` is `true`, the `Streams` value must be a scalar, or must be empty. If `'UseParallel'` is `true` and `'UseSubstreams'` is `false`, then the `Streams` argument must either be empty, or its length must match the number of processors used in the computation: equal to the `parpool` size if a `parpool` is open, a scalar otherwise.

TolBnd

Parameter bound tolerance. Positive scalar.

TolFun

Termination tolerance for the objective function value. Positive scalar.

TolTypeFun

Use `TolFun` for absolute or relative objective function tolerances.

- 'abs'
- 'rel'

TolTypeX

Use `TolX` for absolute or relative parameter tolerances.

- 'abs'
- 'rel'

TolX

Termination tolerance for the parameters. Positive scalar.

Tune

The tuning constant used in robust fitting to normalize the residuals before applying the weight function. The default value depends upon the weight function. This parameter is necessary if you specify the weight function as a function handle. Positive scalar.

UseParallel

Flag indicating whether eligible functions should use capabilities of the Parallel Computing Toolbox (PCT), if the capabilities are available. That is, if the PCT is installed, and a PCT `parpool` is in effect. Valid values are `false` (the default), for serial computation, and `true`, for parallel computation.

UseSubstreams

Flag indicating whether the random number generator in eligible functions should use `Substream` property of the `RandStream` class. `false` (default) or `true`. When `true`, high level iterations within the function will set the `Substream` property to the value of the iteration. This behavior helps to generate reproducible random number streams in parallel and/or serial mode computation.

WgtFun

A weight function for robust fitting. Valid only when `Robust` is 'on'. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output.

- 'bisquare'
- 'andrews'
- 'cauchy'
- 'fair'

- 'huber'
- 'logistic'
- 'talwar'
- 'welsch'

Examples

This statement returns the value of the `Display` statistics options parameter from the structure called `my_options`.

```
val = statget(my_options,'Display')
```

Return the value of the `Display` statistics options parameter from the structure called `my_options` (as in the previous example). If the `Display` parameter is undefined, `statget` returns the value 'final'.

```
optnew = statget(my_options,'Display','final');
```

See Also

`statset`

Introduced before R2006a

statset

Create statistics options structure

Syntax

```
statset
statset(statfun)
options = statset(...)
options = statset(fieldname1, val1, fieldname2, val2, ...)
options = statset(olddopts, fieldname1, val1, fieldname2, val2, ...)
options = statset(olddopts, newopts)
```

Description

`statset` with no input arguments and no output arguments displays all fields of a statistics options structure and their possible values.

`statset(statfun)` displays fields and default values used by the Statistics and Machine Learning Toolbox function `statfun`. Specify `statfun` using a character vector, a string scalar, or a function handle.

`options = statset(...)` creates a statistics options structure `options`. With no input arguments, all fields of the options structure are an empty array (`[]`). With a specified `statfun`, function-specific fields are default values and the remaining fields are `[]`. Function-specific fields set to `[]` indicate that the function is to use its default value for that parameter. For available options, see Inputs.

`options = statset(fieldname1, val1, fieldname2, val2, ...)` creates an options structure in which the named fields have the specified values. Any unspecified values are `[]`. Use character vectors or string scalars for field names. For named values, you must input the complete character vector or string scalar for the value. If you provide an invalid character vector or string scalar for a value, `statset` uses the default.

`options = statset(olddopts, fieldname1, val1, fieldname2, val2, ...)` creates a copy of `olddopts` with the named parameters changed to the specified values.

`options = statset(olddopts, newopts)` combines an existing options structure, `olddopts`, with a new options structure, `newopts`. Any parameters in `newopts` with nonempty values overwrite corresponding parameters in `olddopts`.

Input Arguments

DerivStep

Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics and Machine Learning Toolbox function using the options structure.

Display

Amount of information displayed by the algorithm.

- 'off' — Displays no information.
- 'final' — Displays the final output.
- 'iter' — Displays iterative output to the command window for some functions; otherwise displays the final output.

FunValCheck

Check for invalid values, such as NaN or Inf, from the objective function.

- 'off'
- 'on'

GradObj

Flags whether the objective function returns a gradient vector as a second output.

- 'off'
- 'on'

Jacobian

Flags whether the objective function returns a Jacobian as a second output.

- 'off'
- 'on'

MaxFunEvals

Maximum number of objective function evaluations allowed. Positive integer.

MaxIter

Maximum number of iterations allowed. Positive integer.

OutputFcn

The solver calls all output functions after each iteration.

- Function handle specified using @
- a cell array with function handles
- an empty array (default)

Robust

Invoke robust fitting option.

- 'off'
- 'on'

Robust will be removed in a future software release. Use RobustWgtFun for robust fitting.

RobustWgtFun

Weight function for robust fitting. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. If you use a function handle, give a Tune constant. See “Robust Options” on page 32-5196.

Streams

A single instance of the `RandStream` class, or a cell array of `RandStream` instances. The `Streams` option is accepted by some functions to govern what stream(s) to use in generating random numbers within the function. If `'UseSubstreams'` is `true`, the `Streams` value must be a scalar, or must be empty. If `'UseParallel'` is `true` and `'UseSubstreams'` is `false`, then the `Streams` argument must either be empty, or its length must match the number of processors used in the computation: equal to the `parpool` size if a `parpool` is open, a scalar otherwise.

TolBnd

Parameter bound tolerance. Positive scalar.

TolFun

Termination tolerance for the objective function value. Positive scalar.

TolTypeFun

Use `TolFun` for absolute or relative objective function tolerances.

- `'abs'`
- `'rel'`

TolTypeX

Use `TolX` for absolute or relative parameter tolerances.

- `'abs'`
- `'rel'`

TolX

Termination tolerance for the parameters. Positive scalar.

Tune

Tuning constant used in robust fitting to normalize the residuals before applying the weight function. The default value depends upon the weight function. This parameter is necessary if you specify the weight function as a function handle. Positive scalar. See “Robust Options” on page 32-5196.

UseParallel

Flag indicating whether eligible functions should use capabilities of the Parallel Computing Toolbox (PCT), if the capabilities are available. That is, if the PCT is installed, and a PCT `parpool` is in effect. Valid values are `false` (the default), for serial computation, and `true`, for parallel computation.

UseSubstreams

Flag indicating whether the random number generator in eligible functions should use `Substream` property of the `RandStream` class. `false` (default) or `true`. When `true`, high level iterations within

the function will set the `Substream` property to the value of the iteration. This behavior helps to generate reproducible random number streams in parallel and/or serial mode computation.

WgtFun

Weight function for robust fitting. Valid only when `Robust` is 'on'. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. See “Robust Options” on page 32-5196.

`WgtFun` will be removed in a future software release. Use `RobustWgtFun` instead.

Examples

Suppose you want to change the default parameter values for the function `evfit`, which fits an extreme value distribution to data. The default parameter values are:

```
statset('evfit')
ans =
    Display: 'off'
    MaxFunEvals: []
    MaxIter: []
    TolBnd: []
    TolFun: []
    TolTypeFun: []
    TolX: 1.0000e-06
    TolTypeX: []
    GradObj: []
    Jacobian: []
    DerivStep: []
    FunValCheck: []
    Robust: []
    RobustWgtFun: []
    WgtFun: []
    Tune: []
    UseParallel: []
    UseSubstreams: []
    Streams: []
    OutputFcn: []
```

The only parameters that `evfit` uses are `Display` and `TolX`. To create an options structure with the value of `TolX` set to `1e-8`, enter:

```
options = statset('TolX',1e-8)
% Pass options to evfit:
mu = 1;
sigma = 1;
data = evrnd(mu,sigma,1,100);

paramhat = evfit(data,[],[],[],options)
```

Introduced before R2006a

std

Package: prob

Standard deviation of probability distribution

Syntax

```
s = std(pd)
```

Description

`s = std(pd)` returns the standard deviation `s` of the probability distribution `pd`.

Examples

Standard Deviation of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x, 'Normal')
```

```
pd =
  NormalDistribution

  Normal distribution
      mu = 75.0083   [73.4321, 76.5846]
      sigma =  8.7202   [7.7391, 9.98843]
```

Compute the standard deviation of the fitted distribution.

```
s = std(pd)
```

```
s = 8.7202
```

For a normal distribution, the standard deviation is equal to the parameter `sigma`.

Standard Deviation of a Skewed Distribution

Create a Weibull probability distribution object

```
pd = makedist('Weibull', 'a', 5, 'b', 2)
```

```
pd =
  WeibullDistribution
```

```
Weibull distribution
A = 5
B = 2
```

Compute the standard deviation of the distribution.

```
s = std(pd)
s = 2.3163
```

Standard Deviation of a Triangular Distribution

Create a triangular distribution object.

```
pd = makedist('Triangular','a',-3,'b',1,'c',3)
pd =
  TriangularDistribution
A = -3, B = 1, C = 3
```

Compute the standard deviation of the distribution.

```
s = std(pd)
s = 1.2472
```

Standard Deviation of a Kernel Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;
x = grades(:,1);
```

Create a probability distribution object by fitting a kernel distribution to the data.

```
pd = fitdist(x,'Kernel')
pd =
  KernelDistribution

  Kernel = normal
  Bandwidth = 3.61677
  Support = unbounded
```

Compute the standard deviation of the fitted distribution.

```
s = std(pd)
s = 9.4069
```

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

Function or App	Description
<code>makedist</code>	Create a probability distribution object using specified parameter values.
<code>fitdist</code>	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.

Output Arguments

s — Standard deviation

nonnegative scalar value

Standard deviation of the probability distribution, returned as a nonnegative scalar value.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument `pd` can be a fitted probability distribution object for beta, exponential, extreme value, lognormal, normal, and Weibull distributions. Create `pd` by fitting a probability distribution to sample data from the `fitdist` function. For an example, see “Code Generation for Probability Distribution Objects” on page 31-70.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

Introduced in R2013a

step

Improve generalized linear regression model by adding or removing terms

Syntax

```
NewMdl = step mdl
NewMdl = step mdl, Name, Value
```

Description

`NewMdl = step(mdl)` returns a generalized linear regression model based on `mdl` using stepwise regression to add or remove one predictor.

`NewMdl = step(mdl, Name, Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the criterion to use to add or remove terms and the maximum number of steps to take.

Examples

Modify Generalized Linear Regression Model Using step

Fit a Poisson regression model using random data and a single predictor, and then use `step` to improve the model by adding or removing predictor terms.

Generate sample data that has 20 predictor variables. Use three of the predictors to generate the Poisson response variable.

```
rng('default') % For reproducibility
X = randn(100,20);
mu = exp(X(:, [5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data using `X(:,2)` as the only predictor.

```
mdl = fitglm(X,y,'y ~ x2','Distribution','poisson')
```

```
mdl =
Generalized linear regression model:
    log(y) ~ 1 + x2
    Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	1.1386	0.056722	20.073	1.2817e-89
x2	0.010768	0.056564	0.19037	0.84902

100 observations, 98 error degrees of freedom

Dispersion: 1
 Chi²-statistic vs. constant model: 0.0362, p-value = 0.849

Improve mdl by using `step`. Specify `'NSteps'` as 5 to allow at most 5 steps of stepwise regression.

```
mdl1 = step(mdl, 'NSteps', 5)
```

1. Adding x5, Deviance = 134.4375, Chi2Stat = 52.21338, PValue = 4.978574e-13
2. Adding x15, Deviance = 106.1925, Chi2Stat = 28.24496, PValue = 1.068927e-07
3. Adding x10, Deviance = 94.708, Chi2Stat = 11.4845, PValue = 0.000701792
4. Removing x2, Deviance = 95.021, Chi2Stat = 0.31263, PValue = 0.57607

```
mdl1 =
Generalized linear regression model:
  log(y) ~ 1 + x5 + x10 + x15
  Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	1.0115	0.064275	15.737	8.4217e-56
x5	0.39508	0.066665	5.9263	3.0977e-09
x10	0.18863	0.05534	3.4085	0.0006532
x15	0.29295	0.053269	5.4995	3.8089e-08

100 observations, 96 error degrees of freedom
 Dispersion: 1
 Chi²-statistic vs. constant model: 91.7, p-value = 9.61e-20

`step` adds the three predictor variables used to generate the response variable to the model and removes $X(:, 2)$ from the model.

Input Arguments

mdl — Generalized linear regression model

GeneralizedLinearModel object

Generalized linear regression model, specified as a `GeneralizedLinearModel` object created using `fitglm` or `stepwiseglm`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Criterion', 'aic', 'Upper', 'quadratic', 'Verbose', 2` instructs `step` to use the Akaike information criterion, include (at most) the quadratic terms in the model, and display the evaluation process and the decision taken at each step.

Criterion — Criterion to add or remove terms

`'Deviance'` (default) | `'sse'` | `'aic'` | `'bic'` | `'rsquared'` | `'adjrsquared'`

Criterion to add or remove terms, specified as the comma-separated pair consisting of 'Criterion' and one of these values:

- 'Deviance' — p -value for an F -test or chi-squared test of the change in the deviance that results from adding or removing the term. The F -test tests a single model, and the chi-squared test compares two different models.
- 'sse' — p -value for an F -test of the change in the sum of squared error that results from adding or removing the term.
- 'aic' — Change in the value of the Akaike information criterion (AIC).
- 'bic' — Change in the value of the Bayesian information criterion (BIC).
- 'rsquared' — Increase in the value of R^2 .
- 'adjrsquared' — Increase in the value of adjusted R^2 .

Example: 'Criterion', 'bic'

Lower — Model specification describing terms that cannot be removed

'constant' (default) | character vector or string scalar naming the model | t -by- $(p + 1)$ terms matrix | character vector or string scalar formula in the form 'Y ~ terms'

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of 'Lower' and one of these values:

- A character vector or string scalar naming the model.

Value	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear term for each predictor.
'interactions'	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept term and linear and squared terms for each predictor.
'quadratic'	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 through 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, 'poly13' has an intercept and x_1 , x_2 , x_2^2 , x_2^3 , x_1*x_2 , and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

- A t -by- $(p + 1)$ matrix, or a "Terms Matrix" on page 32-5206, specifying terms in the model, where t is the number of terms, p is the number of predictor variables, and $+1$ accounts for the response variable. A terms matrix is convenient when the number of predictors is large and you want to generate the terms programmatically.

- A character vector or string scalar representing a “Formula” on page 32-5206 in the form 'Y ~ terms', where the terms are in “Wilkinson Notation” on page 32-5206. The variable names in the formula must be valid MATLAB identifiers.

Example: 'Lower', 'linear'

Data Types: char | string | single | double

NSteps — Maximum number of steps to take

1 (default) | positive integer

Maximum number of steps to take, specified as the comma-separated pair consisting of 'NSteps' and a positive integer.

Example: 'NSteps', 5

Data Types: single | double

PEnter — Threshold for criterion to add term

scalar value

Threshold for the criterion to add a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'Deviance'	0.05	If the p -value of the F -statistic or chi-squared statistic is less than PEnter (p -value to enter), add the term to the model.
'SSE'	0.05	If the p -value of the F -statistic is less than PEnter, add the term to the model.
'AIC'	0	If the change in the AIC of the model is less than PEnter, add the term to the model.
'BIC'	0	If the change in the BIC of the model is less than PEnter, add the term to the model.
'Rsquared'	0.1	If the increase in the R-squared value of the model is greater than PEnter, add the term to the model.
'AdjRsquared'	0	If the increase in the adjusted R-squared value of the model is greater than PEnter, add the term to the model.

For more information, see the Criterion name-value pair argument.

Example: 'PEnter', 0.075

PRemove — Threshold for criterion to remove term

scalar value

Threshold for the criterion to remove a term, specified as the comma-separated pair consisting of 'PRemove' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'Deviance'	0.10	If the p -value of the F -statistic or chi-squared statistic is greater than PRemove (p -value to remove), remove the term from the model.
'SSE'	0.10	If the p -value of the F -statistic is greater than PRemove, remove the term from the model.
'AIC'	0.01	If the change in the AIC of the model is greater than PRemove, remove the term from the model.
'BIC'	0.01	If the change in the BIC of the model is greater than PRemove, remove the term from the model.
'Rsquared'	0.05	If the increase in the R-squared value of the model is less than PRemove, remove the term from the model.
'AdjRsquared'	-0.05	If the increase in the adjusted R-squared value of the model is less than PRemove, remove the term from the model.

At each step, the `step` function also checks whether a term is redundant (linearly dependent) with other terms in the current model. When a term is linearly dependent on other terms in the current model, the `step` function removes the redundant term, regardless of the criterion value.

For more information, see the `Criterion` name-value pair argument.

Example: 'PRemove', 0.05

Upper — Model specification describing largest set of terms in fit

'interactions' (default) | character vector or string scalar naming the model | t -by- $(p + 1)$ terms matrix | character vector or string scalar formula in the form 'Y ~ terms'

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of 'Upper' and one of these values:

- A character vector or string scalar naming the model.

Value	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear term for each predictor.

Value	Model Type
'interactions'	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept term and linear and squared terms for each predictor.
'quadratic'	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 through 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, 'poly13' has an intercept and x_1 , x_2 , x_2^2 , x_2^3 , x_1*x_2 , and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

- A t -by- $(p + 1)$ matrix, or a “Terms Matrix” on page 32-5206, specifying terms in the model, where t is the number of terms, p is the number of predictor variables, and $+1$ accounts for the response variable. A terms matrix is convenient when the number of predictors is large and you want to generate the terms programmatically.
- A character vector or string scalar representing a “Formula” on page 32-5206 in the form 'Y ~ terms', where the terms are in “Wilkinson Notation” on page 32-5206. The variable names in the formula must be valid MATLAB identifiers.

Example: 'Upper', 'quadratic'

Data Types: char | string | single | double

Verbose — Control for display of information

1 (default) | 0 | 2

Control for the display of information, specified as the comma-separated pair consisting of 'Verbose' and one of these values:

- 0 — Suppress all display.
- 1 — Display the action taken at each step.
- 2 — Display the evaluation process and the action taken at each step.

Example: 'Verbose', 2

Output Arguments

NewMd1 — Generalized linear regression model

GeneralizedLinearModel object

Generalized linear regression model, returned as a GeneralizedLinearModel object.

To overwrite the input argument md1, assign the new model to md1.

```
mdl = step(mdl);
```

More About

Terms Matrix

A terms matrix T is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and $+1$ accounts for the response variable. The value of $T(i, j)$ is the exponent of variable j in term i .

For example, suppose that an input includes three predictor variables A , B , and C and the response variable Y in the order A , B , C , and Y . Each row of T represents one term:

- $[0 \ 0 \ 0 \ 0]$ — Constant term or intercept
- $[0 \ 1 \ 0 \ 0]$ — B ; equivalently, $A^0 * B^1 * C^0$
- $[1 \ 0 \ 1 \ 0]$ — $A * C$
- $[2 \ 0 \ 0 \ 0]$ — A^2
- $[0 \ 1 \ 2 \ 0]$ — $B * (C^2)$

The 0 at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable in the last column of each row.

Formula

A formula for model specification is a character vector or string scalar of the form ' $Y \sim terms$ '.

- Y is the response name.
- $terms$ represents the predictor terms in a model using Wilkinson notation.

For example:

- ' $Y \sim A + B + C$ ' specifies a three-variable linear model with intercept.
- ' $Y \sim A + B + C - 1$ ' specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include -1 in the formula.

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- $+$ means include the next variable.
- $-$ means do not include the next variable.
- $:$ defines an interaction, which is a product of terms.
- $*$ defines an interaction and all lower-order terms.
- $^$ raises the predictor to a power, exactly as in $*$ repeated, so $^$ includes lower-order terms as well.

- () groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Term in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1 .

For more details, see “Wilkinson Notation” on page 11-90.

Algorithms

- Stepwise regression is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

The `step` function uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add to the model or remove from the model based on the value of the 'Criterion' name-value pair argument.

The default value of 'Criterion' for a linear regression model is 'sse'. In this case, `stepwiselm` and `step` of `LinearModel` use the p -value of an F -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the function adds the term to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the function removes the term from the model.

Stepwise regression takes these steps when 'Criterion' is 'sse':

- 1 Fit the initial model.
- 2 Examine a set of available terms not in the model. If any of the terms have p -values less than an entrance tolerance (that is, if it is unlikely a term would have a zero coefficient if added to the model), add the term with the smallest p -value and repeat this step; otherwise, go to step 3.

- 3 If any of the available terms in the model have p -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient cannot be rejected), remove the term with the largest p -value and return to step 2; otherwise, end the process.

At any stage, the function will not add a higher-order term if the model does not also include all lower-order terms that are subsets of the higher-order term. For example, the function will not try to add the term $X1:X2^2$ unless both $X1$ and $X2^2$ are already in the model. Similarly, the function will not remove lower-order terms that are subsets of higher-order terms that remain in the model. For example, the function will not try to remove $X1$ or $X2^2$ if $X1:X2^2$ remains in the model.

The default value of 'Criterion' for a generalized linear model is 'Deviance'. `stepwiseglm` and `step` of `GeneralizedLinearModel` follow a similar procedure for adding or removing terms.

You can specify other criteria by using the 'Criterion' name-value pair argument. For example, you can specify the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, or adjusted R-squared as the criterion to add or remove terms.

Depending on the terms included in the initial model, and the order in which the function adds and removes terms, the function might build different models from the same set of potential terms. The function terminates when no single step improves the model. However, a different initial model or a different sequence of steps does not guarantee a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

- `step` treats a categorical predictor as follows:
 - A model with a categorical predictor that has L levels (categories) includes $L - 1$ indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level.
 - `step` treats the group of $L - 1$ indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor X , if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.
 - Interaction terms between a continuous predictor and a categorical predictor with L levels consist of the element-wise product of the $L - 1$ indicator variables with the continuous predictor.
 - Interaction terms between two categorical predictors with L and M levels consist of the $(L - 1) * (M - 1)$ indicator variables to include all possible combinations of the two categorical predictor levels.
 - You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.

Therefore, if `step` adds or removes a categorical predictor, the function actually adds or removes the group of indicator variables in one step. Similarly, if `step` adds or removes an interaction term with a categorical predictor, the function actually adds or removes the group of interaction terms including the categorical predictor.

- `step` considers `NaN`, '' (empty character vector), "" (empty string), `<missing>`, and `<undefined>` values in `tbl`, X , and Y to be missing values. `step` does not use observations with

missing values in the fit. The `ObservationInfo` property of a fitted model indicates whether or not `step` uses each observation in the fit.

Alternative Functionality

- Use `stepwiseglm` to specify terms in a starting model and continue improving the model until no single step of adding or removing a term is beneficial.
- Use `addTerms` or `removeTerms` to add or remove specific terms.

“Generalized Linear Models” on page 12-9

Introduced in R2012a

step

Improve linear regression model by adding or removing terms

Syntax

```
NewMdl = step mdl
NewMdl = step mdl, Name, Value)
```

Description

`NewMdl = step(mdl)` returns a linear regression model based on `mdl` using stepwise regression to add or remove one predictor.

`NewMdl = step(mdl, Name, Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the criterion to use to add or remove terms and the maximum number of steps to take.

Examples

Modify Linear Regression Model Using step

Fit a linear regression model and use `step` to improve the model by adding or removing terms. This example also describes how the `step` function treats a categorical predictor.

Load the `carsmall` data set, and create a table using the `Weight`, `Model_Year`, and `MPG` variables.

```
load carsmall
tbl1 = table(MPG,Weight);
tbl1.Year = categorical(Model_Year);
```

Create a linear regression model of `MPG` as a function of `Weight`.

```
mdl1 = fitlm(tbl1, 'MPG ~ Weight')
```

```
mdl1 =
Linear regression model:
    MPG ~ 1 + Weight
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
Weight	-0.0086119	0.0005348	-16.103	1.6434e-28

```
Number of observations: 94, Error degrees of freedom: 92
Root Mean Squared Error: 4.13
R-squared: 0.738, Adjusted R-Squared: 0.735
F-statistic vs. constant model: 259, p-value = 1.64e-28
```

Adjust the model to include up to 'quadratic' terms by using `step`. Specify 'NSteps' as 5 to allow at most 5 steps of stepwise regression. Specify 'Verbose' as 2 to display the evaluation process and the decision taken at each step.

```
NewMdl1 = step(mdl1, 'Upper', 'quadratic', 'NSteps', 5, 'Verbose', 2)
```

```
pValue for adding Year is 8.2284e-15
pValue for adding Weight^2 is 0.15454
1. Adding Year, FStat = 47.5136, pValue = 8.22836e-15
pValue for adding Weight:Year is 0.0071637
pValue for adding Weight^2 is 0.0022303
2. Adding Weight^2, FStat = 9.9164, pValue = 0.0022303
pValue for adding Weight:Year is 0.19519
pValue for removing Year is 2.9042e-16
```

```
NewMdl1 =
Linear regression model:
MPG ~ 1 + Weight + Year + Weight^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	54.206	4.7117	11.505	2.6648e-19
Weight	-0.016404	0.0031249	-5.2493	1.0283e-06
Year_76	2.0887	0.71491	2.9215	0.0044137
Year_82	8.1864	0.81531	10.041	2.6364e-16
Weight^2	1.5573e-06	4.9454e-07	3.149	0.0022303

```
Number of observations: 94, Error degrees of freedom: 89
Root Mean Squared Error: 2.78
R-squared: 0.885, Adjusted R-Squared: 0.88
F-statistic vs. constant model: 172, p-value = 5.52e-41
```

`step` creates two indicator variables, `Year_76` and `Year_82`, because `Year` includes three distinct values. `step` does not consider the square terms of indicator variables because the square of an indicator variable is itself.

Because 'Verbose' is 2, `step` displays the evaluation process:

- `step` computes the p -values for adding `Year` or `Weight^2`. The p -value for `Year` is less than both the p -value for `Weight^2` and the default threshold value of 0.05; therefore, `step` adds `Year` to the model.
- `step` computes the p -values for adding `Weight:Year` or `Weight^2`. Because the p -value for `Weight^2` is less than the p -value for `Weight:Year`, the `step` function adds `Weight^2` to the model.
- After adding the quadratic term, `step` computes the p -value for adding `Weight:Year` again, but the p -value is greater than the threshold value. Therefore, `step` does not add the term to the model. `step` does not examine adding `Weight^3` because of the upper bound specified by the 'Upper' name-value pair argument.
- `step` looks for terms to remove. `step` already examined `Weight^2`, so it computes only the p -value for removing `Year`. Because the p -value is less than the default threshold value of 0.10, `step` does not remove the term.
- Although the maximum allowed number of steps is 5, `step` terminates the process after two steps because the model does not improve by adding or removing a term.

`step` treats the two indicator variables as one predictor variable and adds `Year` in one step. To treat the two indicator variables as two distinct predictor variables, use `dummyvar` to create separate categorical variables.

```
temp_Year = dummyvar(tbl1.Year);
Year_76 = temp_Year(:,2);
Year_82 = temp_Year(:,3);
```

Create a table containing `MPG`, `Weight`, `Year_76`, and `Year_82`.

```
tbl2 = table(MPG,Weight,Year_76,Year_82);
```

Create a linear regression model of `MPG` as a function of `Weight`, and use `step` to improve the model.

```
mdl2 = fitlm(tbl2,'MPG ~ Weight');
NewMdl2 = step(mdl2,'Upper','quadratic','NSteps',5)
```

1. Adding `Year_82`, `FStat` = 83.1956, `pValue` = 1.76163e-14
2. Adding `Weight:Year_82`, `FStat` = 8.0641, `pValue` = 0.0055818
3. Adding `Year_76`, `FStat` = 8.1284, `pValue` = 0.0054157

```
NewMdl2 =
Linear regression model:
  MPG ~ 1 + Year_76 + Weight*Year_82
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	38.844	1.5294	25.397	1.503e-42
Weight	-0.006272	0.00042673	-14.698	1.5622e-25
Year_76	2.0395	0.71537	2.851	0.0054157
Year_82	19.607	3.8731	5.0623	2.2163e-06
Weight:Year_82	-0.0046268	0.0014979	-3.0888	0.0026806

```
Number of observations: 94, Error degrees of freedom: 89
Root Mean Squared Error: 2.79
R-squared: 0.885, Adjusted R-Squared: 0.88
F-statistic vs. constant model: 171, p-value = 6.54e-41
```

The model `NewMdl2` includes the interaction term `Weight:Year_82` instead of `Weight^2`, the term included in `NewMdl1`.

Input Arguments

`mdl` — Linear regression model

`LinearModel` object

Linear regression model, specified as a `LinearModel` object created using `fitlm` or `stepwiselm`.

You can use `step` only if you create `mdl` by using `fitlm` with the `'RobustOpts'` name-value pair argument set to the default `'off'`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'Criterion', 'aic', 'Upper', 'quadratic', 'Verbose', 2` instructs `step` to use the Akaike information criterion, include (at most) the quadratic terms in the model, and display the evaluation process and the decision taken at each step.

Criterion — Criterion to add or remove terms

`'sse'` (default) | `'aic'` | `'bic'` | `'rsquared'` | `'adjrsquared'`

Criterion to add or remove terms, specified as the comma-separated pair consisting of `'Criterion'` and one of these values:

- `'sse'` — p -value for an F -test of the change in the sum of squared error that results from adding or removing the term
- `'aic'` — Change in the value of Akaike information criterion (AIC)
- `'bic'` — Change in the value of Bayesian information criterion (BIC)
- `'rsquared'` — Increase in the value of R^2
- `'adjrsquared'` — Increase in the value of adjusted R^2

Example: `'Criterion', 'bic'`

Lower — Model specification describing terms that cannot be removed

`'constant'` (default) | character vector or string scalar naming the model | t -by- $(p + 1)$ terms matrix | character vector or string scalar formula in the form `'Y ~ terms'`

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of `'Lower'` and one of these values:

- A character vector or string scalar naming the model.

Value	Model Type
<code>'constant'</code>	Model contains only a constant (intercept) term.
<code>'linear'</code>	Model contains an intercept and linear term for each predictor.
<code>'interactions'</code>	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
<code>'purequadratic'</code>	Model contains an intercept term and linear and squared terms for each predictor.
<code>'quadratic'</code>	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.

Value	Model Type
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 through 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, 'poly13' has an intercept and x_1 , x_2 , x_2^2 , x_2^3 , x_1*x_2 , and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

- A t -by- $(p + 1)$ matrix, or a “Terms Matrix” on page 32-5217, specifying terms in the model, where t is the number of terms, p is the number of predictor variables, and $+1$ accounts for the response variable. A terms matrix is convenient when the number of predictors is large and you want to generate the terms programmatically.
- A character vector or string scalar representing a “Formula” on page 32-5217 in the form 'Y ~ terms', where the terms are in “Wilkinson Notation” on page 32-5218. The variable names in the formula must be valid MATLAB identifiers.

Example: 'Lower', 'linear'

Data Types: single | double | char | string

NSteps — Maximum number of steps to take

1 (default) | positive integer

Maximum number of steps to take, specified as the comma-separated pair consisting of 'NSteps' and a positive integer.

Example: 'NSteps', 5

Data Types: single | double

PEnter — Threshold for criterion to add term

scalar value

Threshold for the criterion to add a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'SSE'	0.05	If the p -value of the F -statistic is less than PEnter (p -value to enter), add the term to the model.
'AIC'	0	If the change in the AIC of the model is less than PEnter, add the term to the model.
'BIC'	0	If the change in the BIC of the model is less than PEnter, add the term to the model.

Criterion	Default Value	Decision
'Rsquared'	0.1	If the increase in the R-squared value of the model is greater than PEnter, add the term to the model.
'AdjRsquared'	0	If the increase in the adjusted R-squared value of the model is greater than PEnter, add the term to the model.

For more information, see the `Criterion` name-value pair argument.

Example: 'PEnter', 0.075

PRemove — Threshold for criterion to remove term

scalar value

Threshold for the criterion to remove a term, specified as the comma-separated pair consisting of 'PRemove' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'SSE'	0.10	If the p -value of the F -statistic is greater than PRemove (p -value to remove), remove the term from the model.
'AIC'	0.01	If the change in the AIC of the model is greater than PRemove, remove the term from the model.
'BIC'	0.01	If the change in the BIC of the model is greater than PRemove, remove the term from the model.
'Rsquared'	0.05	If the increase in the R-squared value of the model is less than PRemove, remove the term from the model.
'AdjRsquared'	-0.05	If the increase in the adjusted R-squared value of the model is less than PRemove, remove the term from the model.

At each step, the `step` function also checks whether a term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, the `step` function removes the redundant term, regardless of the criterion value.

For more information, see the `Criterion` name-value pair argument.

Example: 'PRemove', 0.05

Upper — Model specification describing largest set of terms in fit

'interactions' (default) | character vector or string scalar naming the model | t -by- $(p + 1)$ terms matrix | character vector or string scalar formula in the form 'Y ~ terms'

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of 'Upper' and one of these values:

- A character vector or string scalar naming the model.

Value	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear term for each predictor.
'interactions'	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept term and linear and squared terms for each predictor.
'quadratic'	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 through 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, 'poly13' has an intercept and x_1 , x_2 , x_2^2 , x_2^3 , x_1*x_2 , and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

- A t -by- $(p + 1)$ matrix, or a “Terms Matrix” on page 32-5217, specifying terms in the model, where t is the number of terms, p is the number of predictor variables, and +1 accounts for the response variable. A terms matrix is convenient when the number of predictors is large and you want to generate the terms programmatically.
- A character vector or string scalar representing a “Formula” on page 32-5217 in the form 'Y ~ terms', where the terms are in “Wilkinson Notation” on page 32-5218. The variable names in the formula must be valid MATLAB identifiers.

Example: 'Upper', 'quadratic'

Data Types: single | double | char | string

Verbose — Control for display of information

1 (default) | 0 | 2

Control for the display of information, specified as the comma-separated pair consisting of 'Verbose' and one of these values:

- 0 — Suppress all display.

- 1 — Display the action taken at each step.
- 2 — Display the evaluation process and the action taken at each step.

Example: 'Verbose', 2

Output Arguments

NewMdl — Linear regression model

LinearModel object

Linear regression model, returned as a LinearModel object

To overwrite the input argument mdl, assign the new model to mdl.

```
mdl = step(mdl);
```

More About

Terms Matrix

A terms matrix T is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and $+1$ accounts for the response variable. The value of $T(i, j)$ is the exponent of variable j in term i .

For example, suppose that an input includes three predictor variables A , B , and C and the response variable Y in the order A , B , C , and Y . Each row of T represents one term:

- $[0 \ 0 \ 0 \ 0]$ — Constant term or intercept
- $[0 \ 1 \ 0 \ 0]$ — B ; equivalently, $A^0 * B^1 * C^0$
- $[1 \ 0 \ 1 \ 0]$ — $A * C$
- $[2 \ 0 \ 0 \ 0]$ — A^2
- $[0 \ 1 \ 2 \ 0]$ — $B * (C^2)$

The 0 at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable in the last column of each row.

Formula

A formula for model specification is a character vector or string scalar of the form ' $Y \sim terms$ '.

- Y is the response name.
- $terms$ represents the predictor terms in a model using Wilkinson notation.

For example:

- ' $Y \sim A + B + C$ ' specifies a three-variable linear model with intercept.
- ' $Y \sim A + B + C - 1$ ' specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include -1 in the formula.

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- + means include the next variable.
- – means do not include the next variable.
- : defines an interaction, which is a product of terms.
- * defines an interaction and all lower-order terms.
- ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower-order terms as well.
- () groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Term in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1 .

For more details, see “Wilkinson Notation” on page 11-90.

Algorithms

- Stepwise regression is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

The `step` function uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add to the model or remove from the model based on the value of the 'Criterion' name-value pair argument.

The default value of 'Criterion' for a linear regression model is 'sse'. In this case, `stepwiselm` and `step` of `LinearModel` use the p -value of an F -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to

reject the null hypothesis, the function adds the term to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the function removes the term from the model.

Stepwise regression takes these steps when 'Criterion' is 'sse':

- 1 Fit the initial model.
- 2 Examine a set of available terms not in the model. If any of the terms have p -values less than an entrance tolerance (that is, if it is unlikely a term would have a zero coefficient if added to the model), add the term with the smallest p -value and repeat this step; otherwise, go to step 3.
- 3 If any of the available terms in the model have p -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient cannot be rejected), remove the term with the largest p -value and return to step 2; otherwise, end the process.

At any stage, the function will not add a higher-order term if the model does not also include all lower-order terms that are subsets of the higher-order term. For example, the function will not try to add the term $X1:X2^2$ unless both $X1$ and $X2^2$ are already in the model. Similarly, the function will not remove lower-order terms that are subsets of higher-order terms that remain in the model. For example, the function will not try to remove $X1$ or $X2^2$ if $X1:X2^2$ remains in the model.

The default value of 'Criterion' for a generalized linear model is 'Deviance'. `stepwiseglm` and `step` of `GeneralizedLinearModel` follow a similar procedure for adding or removing terms.

You can specify other criteria by using the 'Criterion' name-value pair argument. For example, you can specify the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, or adjusted R-squared as the criterion to add or remove terms.

Depending on the terms included in the initial model, and the order in which the function adds and removes terms, the function might build different models from the same set of potential terms. The function terminates when no single step improves the model. However, a different initial model or a different sequence of steps does not guarantee a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

- `step` treats a categorical predictor as follows:
 - A model with a categorical predictor that has L levels (categories) includes $L - 1$ indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level.
 - `step` treats the group of $L - 1$ indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor X , if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.
 - Interaction terms between a continuous predictor and a categorical predictor with L levels consist of the element-wise product of the $L - 1$ indicator variables with the continuous predictor.

- Interaction terms between two categorical predictors with L and M levels consist of the $(L - 1) * (M - 1)$ indicator variables to include all possible combinations of the two categorical predictor levels.
- You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.

Therefore, if `step` adds or removes a categorical predictor, the function actually adds or removes the group of indicator variables in one step. Similarly, if `step` adds or removes an interaction term with a categorical predictor, the function actually adds or removes the group of interaction terms including the categorical predictor.

Alternative Functionality

- Use `stepwiselm` to specify terms in a starting model and continue improving the model until no single step of adding or removing a term is beneficial.
- Use `addTerms` or `removeTerms` to add or remove specific terms.

Introduced in R2012a

stepwise

Interactive stepwise regression

Syntax

```
stepwise
stepwise(X,y)
stepwise(X,y,inmodel,penter,premove)
```

Description

stepwise uses the sample data in `hald.mat` to display a graphical user interface for performing stepwise regression of the response values in `heat` on the predictive terms in `ingredients`.

The upper left of the interface displays estimates of the coefficients for all potential terms, with horizontal bars indicating 90% (colored) and 95% (grey) confidence intervals. The red color indicates that, initially, the terms are not in the model. Values displayed in the table are those that would result if the terms were added to the model.

The middle portion of the interface displays summary statistics for the entire model. These statistics are updated with each step.

The lower portion of the interface, **Model History**, displays the RMSE for the model. The plot tracks the RMSE from step to step, so you can compare the optimality of different models. Hover over the blue dots in the history to see which terms were in the model at a particular step. Click on a blue dot in the history to open a copy of the interface initialized with the terms in the model at that step.

Initial models, as well as entrance/exit tolerances for the p -values of F -statistics, are specified using additional input arguments to `stepwise`. Defaults are an initial model with no terms, an entrance tolerance of 0.05, and an exit tolerance of 0.10.

To center and scale the input data (compute z -scores) to improve conditioning of the underlying least-squares problem, select **Scale Inputs** from the **Stepwise** menu.

You proceed through a stepwise regression in one of two ways:

- 1 Click **Next Step** to select the recommended next step. The recommended next step either adds the most significant term or removes the least significant term. When the regression reaches a local minimum of RMSE, the recommended next step is “Move no terms.” You can perform all of the recommended steps at once by clicking **All Steps**.
- 2 Click a line in the plot or in the table to toggle the state of the corresponding term. Clicking a red line, corresponding to a term not currently in the model, adds the term to the model and changes the line to blue. Clicking a blue line, corresponding to a term currently in the model, removes the term from the model and changes the line to red.

To call `addedvarplot` and produce an added variable plot from the `stepwise` interface, select **Added Variable Plot** from the **Stepwise** menu. A list of terms is displayed. Select the term you want to add, and then click **OK**.

Click **Export** to display a dialog box that allows you to select information from the interface to save to the MATLAB workspace. Check the information you want to export and, optionally, change the names of the workspace variables to be created. Click **OK** to export the information.

`stepwise(X,y)` displays the interface using the p predictive terms in the n -by- p matrix X and the response values in the n -by-1 vector y . Distinct predictive terms should appear in different columns of X .

Note `stepwise` automatically includes a constant term in all models. Do not enter a column of 1s directly into X .

`stepwise` treats NaN values in either X or y as missing values, and ignores them.

`stepwise(X,y,inmodel,penter,remove)` additionally specifies the initial model (`inmodel`) and the entrance (`penter`) and exit (`remove`) tolerances for the p -values of F -statistics. `inmodel` is either a logical vector with length equal to the number of columns of X , or a vector of indices, with values ranging from 1 to the number of columns in X . The value of `penter` must be less than or equal to the value of `remove`.

Algorithms

Stepwise regression is a systematic method for adding and removing terms from a multilinear model based on their statistical significance in a regression. The method begins with an initial model and

then compares the explanatory power of incrementally larger and smaller models. At each step, the p value of an F -statistic is computed to test models with and without a potential term. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model. The method proceeds as follows:

- 1** Fit the initial model.
- 2** If any terms not in the model have p -values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest p value and repeat this step; otherwise, go to step 3.
- 3** If any terms in the model have p -values greater than an exit tolerance (that is, if it is unlikely that the hypothesis of a zero coefficient can be rejected), remove the one with the largest p value and go to step 2; otherwise, end.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method may build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but may not be globally optimal.

GeneralizedLinearModel.stepwise

(Not Recommended) Create generalized linear regression model by stepwise regression

Note `GeneralizedLinearModel.stepwise` is not recommended. Use `stepwiseglm` instead.

Syntax

```
mdl = GeneralizedLinearModel.stepwise(tbl,modelspec)
mdl = GeneralizedLinearModel.stepwise(X,y,modelspec)
mdl = GeneralizedLinearModel.stepwise(...,modelspec,Name,Value)
```

Description

`mdl = GeneralizedLinearModel.stepwise(tbl,modelspec)` creates a generalized linear model of a table or dataset array `tbl`, using stepwise regression to add or remove predictors. `modelspec` is the starting model for the stepwise procedure.

`mdl = GeneralizedLinearModel.stepwise(X,y,modelspec)` creates a generalized linear model of the responses `y` to a data matrix `X`, using stepwise regression to add or remove predictors.

`mdl = GeneralizedLinearModel.stepwise(...,modelspec,Name,Value)` creates a generalized linear model with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

tbl — Input data

table | dataset array

Input data including predictor and response variables, specified as a table or dataset array. The predictor variables and response variable can be numeric, logical, categorical, character, or string. The response variable can have a data type other than numeric only if 'Distribution' is 'binomial'.

- By default, `GeneralizedLinearModel.stepwise` takes the last variable as the response variable and the others as the predictor variables.
- To set a different column as the response variable, use the `ResponseVar` name-value pair argument.
- To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.
- To define a model specification, set the `modelspec` argument using a formula or terms matrix. The formula or terms matrix specifies which columns to use as the predictor or response variables.

The variable names in a table do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:

- You cannot specify `modelspec` using a formula.

- You cannot use a formula to specify the terms to add or remove when you use the `addTerms` function or the `removeTerms` function, respectively.
- You cannot use a formula to specify the lower and upper bounds of the model when you use the `step` or `stepwiseglm` function with the name-value pair arguments `'Lower'` and `'Upper'`, respectively.

You can verify the variable names in `tbl` by using the `isvarname` function. The following code returns logical 1 (`true`) for each variable that has a valid variable name.

```
cellfun(@isvarname,tbl.Properties.VariableNames)
```

If the variable names in `tbl` are not valid, then convert them by using the `matlab.lang.makeValidName` function.

```
tbl.Properties.VariableNames = matlab.lang.makeValidName(tbl.Properties.VariableNames);
```

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double`

y — Response variable

vector | matrix

Response variable, specified as a vector or matrix.

- If `'Distribution'` is not `'binomial'`, then `y` must be an n -by-1 vector, where n is the number of observations. Each entry in `y` is the response for the corresponding row of `X`. The data type must be `single` or `double`.
- If `'Distribution'` is `'binomial'`, then `y` can be an n -by-1 vector or n -by-2 matrix with counts in column 1 and `BinomialSize` in column 2.

Data Types: `single` | `double` | `logical` | `categorical`

modelspec — Starting model

`'constant'` (default) | character vector or string scalar naming the model | t -by- $(p + 1)$ terms matrix | character vector or string scalar formula in the form `'Y ~ terms'`

Starting model, specified as one of the following:

- Character vector or string scalar specifying the type of model.

Value	Model Type
<code>'constant'</code>	Model contains only a constant (intercept) term.
<code>'linear'</code>	Model contains an intercept and linear term for each predictor.

Value	Model Type
'interactions'	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept term and linear and squared terms for each predictor.
'quadratic'	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 through 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, 'poly13' has an intercept and x_1 , x_2 , x_2^2 , x_2^3 , x_1*x_2 , and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

- t -by- $(p+1)$ matrix, namely terms matrix on page 32-5234, specifying terms to include in model, where t is the number of terms and p is the number of predictor variables, and plus one is for the response variable.
- Character vector or string scalar representing a formula on page 32-5234 in the form

'Y ~ terms',

where the terms are in “Wilkinson Notation” on page 32-5234.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

BinomialSize — Number of trials for binomial distribution

1 (default) | numeric scalar | numeric vector | character vector | string scalar

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of 'BinomialSize' and the variable name in tbl, a numeric scalar, or a numeric vector of the same length as the response. This is the parameter n for the fitted binomial distribution. BinomialSize applies only when the Distribution parameter is 'binomial'.

If BinomialSize is a scalar value, that means all observations have the same number of trials.

As an alternative to BinomialSize, you can specify the response as a two-column matrix with counts in column 1 and BinomialSize in column 2.

Data Types: single | double | char | string

CategoricalVars — Categorical variable list

string array | cell array of character vectors | logical or numeric index vector

Categorical variable list, specified as the comma-separated pair consisting of 'CategoricalVars' and either a string array or cell array of character vectors containing categorical variable names in

the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then, by default, `GeneralizedLinearModel.stepwise` treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix `X`, then the default value of `'CategoricalVars'` is an empty matrix `[]`. That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: `'CategoricalVars',[2,3]`

Example: `'CategoricalVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `string` | `cell`

Criterion — Criterion to add or remove terms

`'Deviance'` (default) | `'sse'` | `'aic'` | `'bic'` | `'rsquared'` | `'adjrsquared'`

Criterion to add or remove terms, specified as the comma-separated pair consisting of `'Criterion'` and one of these values:

- `'Deviance'` — p -value for an F -test or chi-squared test of the change in the deviance that results from adding or removing the term. The F -test tests a single model, and the chi-squared test compares two different models.
- `'sse'` — p -value for an F -test of the change in the sum of squared error that results from adding or removing the term.
- `'aic'` — Change in the value of the Akaike information criterion (AIC).
- `'bic'` — Change in the value of the Bayesian information criterion (BIC).
- `'rsquared'` — Increase in the value of R^2 .
- `'adjrsquared'` — Increase in the value of adjusted R^2 .

Example: `'Criterion','bic'`

DispersionFlag — Indicator to compute dispersion parameter

`false` for `'binomial'` and `'poisson'` distributions (default) | `true`

Indicator to compute dispersion parameter for `'binomial'` and `'poisson'` distributions, specified as the comma-separated pair consisting of `'DispersionFlag'` and one of the following.

<code>true</code>	Estimate a dispersion parameter when computing standard errors. The estimated dispersion parameter value is the sum of squared Pearson residuals divided by the degrees of freedom for error (DFE).
<code>false</code>	Default. Use the theoretical value when computing standard errors.

The fitting function always estimates the dispersion for other distributions.

Example: `'DispersionFlag',true`

Distribution — Distribution of the response variable

`'normal'` (default) | `'binomial'` | `'poisson'` | `'gamma'` | `'inverse gaussian'`

Distribution of the response variable, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

'normal'	Normal distribution
'binomial'	Binomial distribution
'poisson'	Poisson distribution
'gamma'	Gamma distribution
'inverse gaussian'	Inverse Gaussian distribution

Example: 'Distribution', 'gamma'

Exclude – Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude', [2,3]

Example: 'Exclude', logical([0 1 1 0 0 0])

Data Types: single | double | logical

Intercept – Indicator for constant term

true (default) | false

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: 'Intercept', false

Link – Link function

canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

Link Function Name	Link Function	Mean (Inverse) Function
'identity'	$f(\mu) = \mu$	$\mu = Xb$
'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'probit'	$f(\mu) = \Phi^{-1}(\mu)$	$\mu = \Phi(Xb)$
'comprolog'	$f(\mu) = \log(-\log(1 - \mu))$	$\mu = 1 - \exp(-\exp(Xb))$
'reciprocal'	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
p (a number)	$f(\mu) = \mu^p$	$\mu = Xb^{1/p}$

Link Function Name	Link Function	Mean (Inverse) Function
<p>S (a structure) with three fields. Each field holds a function handle that accepts a vector of inputs and returns a vector of the same size:</p> <ul style="list-style-type: none"> • <code>S.Link</code> — The link function • <code>S.Inverse</code> — The inverse link function • <code>S.Derivative</code> — The derivative of the link function 	$f(\mu) = S.Link(\mu)$	$\mu = S.Inverse(Xb)$

The link function defines the relationship $f(\mu) = X*b$ between the mean response μ and the linear combination of predictors $X*b$.

For more information on the canonical link functions, see “Canonical Link Function” on page 32-5235.

Example: 'Link', 'probit'

Data Types: char | string | single | double | struct

Lower — Model specification describing terms that cannot be removed from model

'constant' (default) | character vector | string scalar | terms matrix

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of 'Lower' and one of the options for `modelspec` naming the model.

Example: 'Lower', 'linear'

Offset — Offset variable

[] (default) | numeric vector | character vector | string scalar

Offset variable in the fit, specified as the comma-separated pair consisting of 'Offset' and the variable name in `tbl` or a numeric vector with the same length as the response.

`GeneralizedLinearModel.stepwise` uses `Offset` as an additional predictor with a coefficient value fixed at 1. In other words, the formula for fitting is

$$f(\mu) = \text{Offset} + X*b,$$

where f is the link function, μ is the mean response, and $X*b$ is the linear combination of predictors X . The `Offset` predictor has coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor `A`. By using the log link function and by specifying `log(A)` as an offset, you can force the model to satisfy this theoretical constraint.

Data Types: single | double | char | string

PEnter — Threshold for criterion to add term

scalar value

Threshold for the criterion to add a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'Deviance'	0.05	If the p -value of the F -statistic or chi-squared statistic is less than PEnter (p -value to enter), add the term to the model.
'SSE'	0.05	If the p -value of the F -statistic is less than PEnter, add the term to the model.
'AIC'	0	If the change in the AIC of the model is less than PEnter, add the term to the model.
'BIC'	0	If the change in the BIC of the model is less than PEnter, add the term to the model.
'Rsquared'	0.1	If the increase in the R-squared value of the model is greater than PEnter, add the term to the model.
'AdjRsquared'	0	If the increase in the adjusted R-squared value of the model is greater than PEnter, add the term to the model.

For more information, see the Criterion name-value pair argument.

Example: 'PEnter', 0.075

PredictorVars — Predictor variables

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in X , or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars', [2,3]

Example: 'PredictorVars', logical([0 1 1 0 0 0])

Data Types: single | double | logical | string | cell

PRemove — Threshold for criterion to remove term

scalar value

Threshold for the criterion to remove a term, specified as the comma-separated pair consisting of 'PRemove' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'Deviance'	0.10	If the p -value of the F -statistic or chi-squared statistic is greater than PRemove (p -value to remove), remove the term from the model.
'SSE'	0.10	If the p -value of the F -statistic is greater than PRemove, remove the term from the model.
'AIC'	0.01	If the change in the AIC of the model is greater than PRemove, remove the term from the model.
'BIC'	0.01	If the change in the BIC of the model is greater than PRemove, remove the term from the model.
'Rsquared'	0.05	If the increase in the R-squared value of the model is less than PRemove, remove the term from the model.
'AdjRsquared'	-0.05	If the increase in the adjusted R-squared value of the model is less than PRemove, remove the term from the model.

At each step, the `GeneralizedLinearModel.stepwise` function also checks whether a term is redundant (linearly dependent) with other terms in the current model. When a term is linearly dependent on other terms in the current model, the `GeneralizedLinearModel.stepwise` function removes the redundant term, regardless of the criterion value.

For more information, see the `Criterion` name-value pair argument.

Example: `'PRemove', 0.05`

ResponseVar — Response variable

last column in `tbl` (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a character vector or string scalar containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar','yield'`

Example: `'ResponseVar',[4]`

Example: `'ResponseVar',logical([0 0 0 1 0 0])`

Data Types: `single | double | logical | char | string`

Upper — Model specification describing largest set of terms in fit

`'interactions'` (default) | character vector | string scalar | terms matrix

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of `'Upper'` and one of the options for `modelspec` naming the model.

Example: `'Upper','quadratic'`

VarNames — Names of variables

`{'x1','x2',..., 'xn','y'}` (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of `'VarNames'` and a string array or cell array of character vectors including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

The variable names do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:

- You cannot use a formula to specify the terms to add or remove when you use the `addTerms` function or the `removeTerms` function, respectively.
- You cannot use a formula to specify the lower and upper bounds of the model when you use the `step` or `stepwiseglm` function with the name-value pair arguments `'Lower'` and `'Upper'`, respectively.

Before specifying `'VarNames'`, `varNames`, you can verify the variable names in `varNames` by using the `isvarname` function. The following code returns logical 1 (`true`) for each variable that has a valid variable name.

```
cellfun(@isvarname,varNames)
```

If the variable names in `varNames` are not valid, then convert them by using the `matlab.lang.makeValidName` function.

```
varNames = matlab.lang.makeValidName(varNames);
```

Example: `'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}`

Data Types: `string | cell`

Weights — Observation weights

`ones(n,1)` (default) | n -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and an n -by-1 vector of nonnegative scalar values, where n is the number of observations.

Data Types: single | double

Output Arguments

mdl — Generalized linear regression model

GeneralizedLinearModel object

Generalized linear regression model, specified as a GeneralizedLinearModel object created using fitglm or stepwiseglm.

Examples

Create Generalized Linear Regression Model Using Stepwise Regression

Create response data using three of 20 predictor variables, and create a generalized linear model using stepwise regression from a constant model to see if stepwiseglm finds the correct predictors.

Generate sample data that has 20 predictor variables. Use three of the predictors to generate the Poisson response variable.

```
rng default % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Fit a generalized linear regression model using the Poisson distribution. Specify the starting model as a model that contains only a constant (intercept) term. Also, specify a model with an intercept and linear term for each predictor as the largest model to consider as the fit by using the 'Upper' name-value pair argument.

```
mdl = stepwiseglm(X,y,'constant','Upper','linear','Distribution','poisson')
```

1. Adding x5, Deviance = 134.439, Chi2Stat = 52.24814, PValue = 4.891229e-13
2. Adding x15, Deviance = 106.285, Chi2Stat = 28.15393, PValue = 1.1204e-07
3. Adding x10, Deviance = 95.0207, Chi2Stat = 11.2644, PValue = 0.000790094

```
mdl =
Generalized linear regression model:
  log(y) ~ 1 + x5 + x10 + x15
  Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	1.0115	0.064275	15.737	8.4217e-56
x5	0.39508	0.066665	5.9263	3.0977e-09
x10	0.18863	0.05534	3.4085	0.0006532
x15	0.29295	0.053269	5.4995	3.8089e-08

100 observations, 96 error degrees of freedom

Dispersion: 1

Chi^2-statistic vs. constant model: 91.7, p-value = 9.61e-20

`stepwiseglm` finds the three correct predictors: `x5`, `x10`, and `x15`.

More About

Terms Matrix

A terms matrix T is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and $+1$ accounts for the response variable. The value of $T(i, j)$ is the exponent of variable j in term i .

For example, suppose that an input includes three predictor variables A , B , and C and the response variable Y in the order A , B , C , and Y . Each row of T represents one term:

- $[0 \ 0 \ 0 \ 0]$ — Constant term or intercept
- $[0 \ 1 \ 0 \ 0]$ — B ; equivalently, $A^0 * B^1 * C^0$
- $[1 \ 0 \ 1 \ 0]$ — $A*C$
- $[2 \ 0 \ 0 \ 0]$ — A^2
- $[0 \ 1 \ 2 \ 0]$ — $B*(C^2)$

The 0 at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable in the last column of each row.

Formula

A formula for model specification is a character vector or string scalar of the form `'Y ~ terms'`.

- Y is the response name.
- $terms$ represents the predictor terms in a model using Wilkinson notation.

For example:

- `'Y ~ A + B + C'` specifies a three-variable linear model with intercept.
- `'Y ~ A + B + C - 1'` specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include -1 in the formula.

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- $+$ means include the next variable.
- $-$ means do not include the next variable.
- $:$ defines an interaction, which is a product of terms.
- $*$ defines an interaction and all lower-order terms.
- $^$ raises the predictor to a power, exactly as in $*$ repeated, so $^$ includes lower-order terms as well.

- () groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Term in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1 .

For more details, see “Wilkinson Notation” on page 11-90.

Canonical Link Function

The default link function for a generalized linear model is the canonical link function.

Distribution	Canonical Link Function Name	Link Function	Mean (Inverse) Function
'normal'	'identity'	$f(\mu) = \mu$	$\mu = Xb$
'binomial'	'logit'	$f(\mu) = \log(\mu/(1 - \mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'poisson'	'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

Tips

- The generalized linear model `mdl` is a standard linear model unless you specify otherwise with the `Distribution` name-value pair.
- For other methods such as `devianceTest`, or properties of the `GeneralizedLinearModel` object, see `GeneralizedLinearModel`.

Algorithms

Stepwise regression is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

The `GeneralizedLinearModel.stepwise` function uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add to the model or remove from the model based on the value of the 'Criterion' name-value pair argument.

The default value of 'Criterion' for a linear regression model is 'sse'. In this case, `stepwiselm` and `step` of `LinearModel` use the p -value of an F -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the function adds the term to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the function removes the term from the model.

Stepwise regression takes these steps when 'Criterion' is 'sse':

- 1 Fit the initial model.
- 2 Examine a set of available terms not in the model. If any of the terms have p -values less than an entrance tolerance (that is, if it is unlikely a term would have a zero coefficient if added to the model), add the term with the smallest p -value and repeat this step; otherwise, go to step 3.
- 3 If any of the available terms in the model have p -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient cannot be rejected), remove the term with the largest p -value and return to step 2; otherwise, end the process.

At any stage, the function will not add a higher-order term if the model does not also include all lower-order terms that are subsets of the higher-order term. For example, the function will not try to add the term $X1:X2^2$ unless both $X1$ and $X2^2$ are already in the model. Similarly, the function will not remove lower-order terms that are subsets of higher-order terms that remain in the model. For example, the function will not try to remove $X1$ or $X2^2$ if $X1:X2^2$ remains in the model.

The default value of 'Criterion' for a generalized linear model is 'Deviance'. `stepwiseglm` and `step` of `GeneralizedLinearModel` follow a similar procedure for adding or removing terms.

You can specify other criteria by using the 'Criterion' name-value pair argument. For example, you can specify the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, or adjusted R-squared as the criterion to add or remove terms.

Depending on the terms included in the initial model, and the order in which the function adds and removes terms, the function might build different models from the same set of potential terms. The function terminates when no single step improves the model. However, a different initial model or a different sequence of steps does not guarantee a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

Alternatives

You can also create a stepwise generalized linear model using `stepwiseglm`.

Use `fitglm` to create a model with a fixed specification. Use `step`, `addTerms`, or `removeTerms` to adjust a fitted model.

LinearModel.stepwise

(Not Recommended) Create linear regression model by stepwise regression

Note `LinearModel.stepwise` is not recommended. Use `stepwiselm` instead.

Syntax

```
mdl = LinearModel.stepwise(tbl,modelspec)
mdl = LinearModel.stepwise(X,y,modelspec)
mdl = LinearModel.stepwise( ____,modelspec,Name,Value)
```

Description

`mdl = LinearModel.stepwise(tbl,modelspec)` returns a linear model of a table or dataset array `tbl`, using stepwise regression to add or remove predictors. `modelspec` is the starting model for the stepwise procedure.

`mdl = LinearModel.stepwise(X,y,modelspec)` creates a linear model of the responses `y` to a data matrix `X`, using stepwise regression to add or remove predictors. `modelspec` is the starting model for the stepwise procedure.

`mdl = LinearModel.stepwise(____,modelspec,Name,Value)` creates a linear model for any of the inputs in the previous syntaxes, with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the categorical variables, the smallest or largest set of terms to use in the model, the maximum number of steps to take, or the criterion `LinearModel.stepwise` uses to add or remove terms.

Input Arguments

tbl — Input data

table | dataset array

Input data including predictor and response variables, specified as a table or dataset array. The predictor variables can be numeric, logical, categorical, character, or string. The response variable must be numeric or logical.

- By default, `LinearModel.stepwise` takes the last variable as the response variable and the others as the predictor variables.
- To set a different column as the response variable, use the `ResponseVar` name-value pair argument.
- To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.
- To define a model specification, set the `modelspec` argument using a formula or terms matrix. The formula or terms matrix specifies which columns to use as the predictor or response variables.

The variable names in a table do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:

- You cannot specify `modelspec` using a formula.
- You cannot use a formula to specify the terms to add or remove when you use the `addTerms` function or the `removeTerms` function, respectively.
- You cannot use a formula to specify the lower and upper bounds of the model when you use the `step` or `stepwiselm` function with the name-value pair arguments 'Lower' and 'Upper', respectively.

You can verify the variable names in `tbl` by using the `isvarname` function. The following code returns logical 1 (true) for each variable that has a valid variable name.

```
cellfun(@isvarname,tbl.Properties.VariableNames)
```

If the variable names in `tbl` are not valid, then convert them by using the `matlab.lang.makeValidName` function.

```
tbl.Properties.VariableNames = matlab.lang.makeValidName(tbl.Properties.VariableNames);
```

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in X .

Data Types: `single` | `double`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X .

Data Types: `single` | `double` | `logical`

modelspec — Starting model

'constant' (default) | character vector or string scalar naming the model | t -by- $(p + 1)$ terms matrix | character vector or string scalar formula in the form 'Y ~ terms'

Starting model for the stepwise regression, specified as one of the following:

- Character vector or string scalar specifying the type of starting model.

Value	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear term for each predictor.

Value	Model Type
'interactions'	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept term and linear and squared terms for each predictor.
'quadratic'	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 through 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, 'poly13' has an intercept and x_1 , x_2 , x_2^2 , x_2^3 , x_1*x_2 , and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

If you want to specify the smallest or largest set of terms in the model, use the `Lower` and `Upper` name-value pair arguments.

- t -by- $(p+1)$ matrix, namely a terms matrix on page 32-5247, specifying terms to include in model, where t is the number of terms and p is the number of predictor variables, and plus one is for the response variable.
- Character vector or string scalar representing a formula on page 32-5247 in the form

`'Y ~ terms'`,

where the terms are in “Wilkinson Notation” on page 32-5247.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

CategoricalVars — Categorical variable list

string array | cell array of character vectors | logical or numeric index vector

Categorical variable list, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a string array or cell array of character vectors containing categorical variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then, by default, `LinearModel.stepwise` treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix `X`, then the default value of `'CategoricalVars'` is an empty matrix `[]`. That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: `'CategoricalVars',[2,3]`

Example: `'CategoricalVars',logical([0 1 1 0 0 0])`

Data Types: `single | double | logical | string | cell`

Criterion – Criterion to add or remove terms

`'sse' (default) | 'aic' | 'bic' | 'rsquared' | 'adjrsquared'`

Criterion to add or remove terms, specified as the comma-separated pair consisting of `'Criterion'` and one of these values:

- `'sse'` – p -value for an F -test of the change in the sum of squared error that results from adding or removing the term
- `'aic'` – Change in the value of Akaike information criterion (AIC)
- `'bic'` – Change in the value of Bayesian information criterion (BIC)
- `'rsquared'` – Increase in the value of R^2
- `'adjrsquared'` – Increase in the value of adjusted R^2

Example: `'Criterion','bic'`

Exclude – Observations to exclude

`logical or numeric index vector`

Observations to exclude from the fit, specified as the comma-separated pair consisting of `'Exclude'` and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: `'Exclude',[2,3]`

Example: `'Exclude',logical([0 1 1 0 0 0])`

Data Types: `single | double | logical`

Intercept – Indicator for constant term

`true (default) | false`

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of `'Intercept'` and either `true` to include or `false` to remove the constant term from the model.

Use `'Intercept'` only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: `'Intercept',false`

Lower – Model specification describing terms that cannot be removed from model

`'constant' (default) | character vector | string scalar | terms matrix`

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of `'Lower'` and one of the options for `modelspec` naming the model.

Example: `'Lower','linear'`

NSteps — Maximum number of steps to take

no limit (default) | positive integer

Maximum number of steps to take, specified as the comma-separated pair consisting of 'NSteps' and a positive integer.

Example: 'NSteps',5

Data Types: single | double

PEnter — Threshold for criterion to add term

scalar value

Threshold for the criterion to add a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'SSE'	0.05	If the p -value of the F -statistic is less than PEnter (p -value to enter), add the term to the model.
'AIC'	0	If the change in the AIC of the model is less than PEnter, add the term to the model.
'BIC'	0	If the change in the BIC of the model is less than PEnter, add the term to the model.
'Rsquared'	0.1	If the increase in the R-squared value of the model is greater than PEnter, add the term to the model.
'AdjRsquared'	0	If the increase in the adjusted R-squared value of the model is greater than PEnter, add the term to the model.

For more information, see the Criterion name-value pair argument.

Example: 'PEnter',0.075

PredictorVars — Predictor variables

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the variable names in the table or dataset array tbl, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in tbl, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in X, or all variables in tbl except for ResponseVar.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: `'PredictorVars',[2,3]`

Example: `'PredictorVars',logical([0 1 1 0 0 0])`

Data Types: `single | double | logical | string | cell`

PRemove — Threshold for criterion to remove term

scalar value

Threshold for the criterion to remove a term, specified as the comma-separated pair consisting of `'PRemove'` and a scalar value, as described in this table.

Criterion	Default Value	Decision
'SSE'	0.10	If the p -value of the F -statistic is greater than <code>PRemove</code> (p -value to remove), remove the term from the model.
'AIC'	0.01	If the change in the AIC of the model is greater than <code>PRemove</code> , remove the term from the model.
'BIC'	0.01	If the change in the BIC of the model is greater than <code>PRemove</code> , remove the term from the model.
'Rsquared'	0.05	If the increase in the R-squared value of the model is less than <code>PRemove</code> , remove the term from the model.
'AdjRsquared'	-0.05	If the increase in the adjusted R-squared value of the model is less than <code>PRemove</code> , remove the term from the model.

At each step, the `LinearModel.stepwise` function also checks whether a term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, the `LinearModel.stepwise` function removes the redundant term, regardless of the criterion value.

For more information, see the `Criterion` name-value pair argument.

Example: `'PRemove',0.05`

ResponseVar — Response variable

last column in `tbl` (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a character vector or string scalar containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the

response variable. You typically need to use 'ResponseVar' when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: 'ResponseVar', 'yield'

Example: 'ResponseVar', [4]

Example: 'ResponseVar', logical([0 0 0 1 0 0])

Data Types: `single` | `double` | `logical` | `char` | `string`

Upper — Model specification describing largest set of terms in fit

'interactions' (default) | character vector | string scalar | terms matrix

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of 'Upper' and one of the options for `modelspec` naming the model.

Example: 'Upper', 'quadratic'

VarNames — Names of variables

{'x1', 'x2', ..., 'xn', 'y'} (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors including the names for the columns of X first, and the name for the response variable y last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

The variable names do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:

- You cannot use a formula to specify the terms to add or remove when you use the `addTerms` function or the `removeTerms` function, respectively.
- You cannot use a formula to specify the lower and upper bounds of the model when you use the `step` or `stepwiselm` function with the name-value pair arguments 'Lower' and 'Upper', respectively.

Before specifying 'VarNames', `varNames`, you can verify the variable names in `varNames` by using the `isvarname` function. The following code returns logical 1 (`true`) for each variable that has a valid variable name.

```
cellfun(@isvarname, varNames)
```

If the variable names in `varNames` are not valid, then convert them by using the `matlab.lang.makeValidName` function.

```
varNames = matlab.lang.makeValidName(varNames);
```

Example: 'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}

Data Types: `string` | `cell`

Verbose — Control for display of information

1 (default) | 0 | 2

Control for the display of information, specified as the comma-separated pair consisting of 'Verbose' and one of these values:

- 0 — Suppress all display.
- 1 — Display the action taken at each step.
- 2 — Display the evaluation process and the action taken at each step.

Example: 'Verbose',2

Weights — Observation weights

`ones(n,1)` (default) | n -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an n -by-1 vector of nonnegative scalar values, where n is the number of observations.

Data Types: single | double

Output Arguments

mdl — Linear model

LinearModel object

Linear model representing a least-squares fit of the response to the data, returned as a LinearModel object.

For the properties and methods of the linear model object, mdl, see the LinearModel class page.

Examples

Fit Linear Model Using Stepwise Regression

Load the `hald` data set, which measures the effect of cement composition on its hardening heat.

```
load hald
```

This data set includes the variables `ingredients` and `heat`. The matrix `ingredients` contains the percent composition of four chemicals present in the cement. The vector `heat` contains the values for the heat hardening after 180 days for each cement sample.

Fit a stepwise linear regression model to the data. Specify 0.06 as the threshold for the criterion to add a term to the model.

```
mdl = stepwiselm(ingredients,heat,'PEnter',0.06)

1. Adding x4, FStat = 22.7985, pValue = 0.000576232
2. Adding x1, FStat = 108.2239, pValue = 1.105281e-06
3. Adding x2, FStat = 5.0259, pValue = 0.051687
4. Removing x4, FStat = 1.8633, pValue = 0.2054

mdl =
Linear regression model:
    y ~ 1 + x1 + x2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	52.577	2.2862	22.998	5.4566e-10
x1	1.4683	0.1213	12.105	2.6922e-07
x2	0.66225	0.045855	14.442	5.029e-08

Number of observations: 13, Error degrees of freedom: 10
 Root Mean Squared Error: 2.41
 R-squared: 0.979, Adjusted R-Squared: 0.974
 F-statistic vs. constant model: 230, p-value = 4.41e-09

By default, the starting model is a constant model. `stepwiselm` performs forward selection and adds the `x4`, `x1`, and `x2` terms (in that order), because the corresponding p -values are less than the `PEnter` value of 0.06. `stepwiselm` then uses backward elimination and removes `x4` from the model because, once `x2` is in the model, the p -value of `x4` is greater than the default value of `PRemove`, 0.1.

Stepwise Regression Using Specified Model Formula and Variables

Perform stepwise regression using variables stored in a dataset array. Specify the starting model using Wilkinson notation, and identify the response and predictor variables using optional arguments.

Load the sample data.

```
load hospital
```

The hospital dataset array includes the gender, age, weight, and smoking status of patients.

Fit a linear model with a starting model of a constant term and `Smoker` as the predictor variable. Specify the response variable, `Weight`, and categorical predictor variables, `Sex`, `Age`, and `Smoker`.

```
mdl = stepwiselm(hospital, 'Weight~1+Smoker', ...
  'ResponseVar', 'Weight', 'PredictorVars', {'Sex', 'Age', 'Smoker'}, ...
  'CategoricalVar', {'Sex', 'Smoker'})
```

1. Adding Sex, FStat = 770.0158, pValue = 6.262758e-48
2. Removing Smoker, FStat = 0.21224, pValue = 0.64605

```
mdl =
Linear regression model:
  Weight ~ 1 + Sex
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	130.47	1.1995	108.77	5.2762e-104
Sex_Male	50.06	1.7496	28.612	2.2464e-49

Number of observations: 100, Error degrees of freedom: 98
 Root Mean Squared Error: 8.73
 R-squared: 0.893, Adjusted R-Squared: 0.892
 F-statistic vs. constant model: 819, p-value = 2.25e-49

At each step, `stepwise1m` searches for terms to add and remove. At first step, stepwise algorithm adds `Sex` to the model with a p -value of $6.26e-48$. Then, removes `Smoker` from the model, since given `Sex` in the model, the variable `Smoker` becomes redundant. `stepwise1m` only includes `Sex` in the final linear model. The weight of the patients do not seem to differ significantly according to age or the status of smoking.

More About

Terms Matrix

A terms matrix T is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and $+1$ accounts for the response variable. The value of $T(i, j)$ is the exponent of variable j in term i .

For example, suppose that an input includes three predictor variables A , B , and C and the response variable Y in the order A , B , C , and Y . Each row of T represents one term:

- $[0 \ 0 \ 0 \ 0]$ — Constant term or intercept
- $[0 \ 1 \ 0 \ 0]$ — B ; equivalently, $A^0 * B^1 * C^0$
- $[1 \ 0 \ 1 \ 0]$ — $A * C$
- $[2 \ 0 \ 0 \ 0]$ — A^2
- $[0 \ 1 \ 2 \ 0]$ — $B * (C^2)$

The 0 at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable in the last column of each row.

Formula

A formula for model specification is a character vector or string scalar of the form `'Y ~ terms'`.

- Y is the response name.
- `terms` represents the predictor terms in a model using Wilkinson notation.

For example:

- `'Y ~ A + B + C'` specifies a three-variable linear model with intercept.
- `'Y ~ A + B + C - 1'` specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include -1 in the formula.

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- $+$ means include the next variable.
- $-$ means do not include the next variable.

- `:` defines an interaction, which is a product of terms.
- `*` defines an interaction and all lower-order terms.
- `^` raises the predictor to a power, exactly as in `*` repeated, so `^` includes lower-order terms as well.
- `()` groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Term in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

For more details, see “Wilkinson Notation” on page 11-90.

Tips

- You cannot use robust regression with stepwise regression. Check your data for outliers before using `LinearModel.stepwise`.
- For other methods or properties of the `LinearModel` object, see `LinearModel`.

Algorithms

Stepwise regression is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

The `LinearModel.stepwise` function uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add to the model or remove from the model based on the value of the 'Criterion' name-value pair argument.

The default value of 'Criterion' for a linear regression model is 'sse'. In this case, `stepwiselm` and `step` of `LinearModel` use the p -value of an F -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the function adds the term to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the function removes the term from the model.

Stepwise regression takes these steps when 'Criterion' is 'sse':

- 1 Fit the initial model.
- 2 Examine a set of available terms not in the model. If any of the terms have p -values less than an entrance tolerance (that is, if it is unlikely a term would have a zero coefficient if added to the model), add the term with the smallest p -value and repeat this step; otherwise, go to step 3.
- 3 If any of the available terms in the model have p -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient cannot be rejected), remove the term with the largest p -value and return to step 2; otherwise, end the process.

At any stage, the function will not add a higher-order term if the model does not also include all lower-order terms that are subsets of the higher-order term. For example, the function will not try to add the term $X1:X2^2$ unless both $X1$ and $X2^2$ are already in the model. Similarly, the function will not remove lower-order terms that are subsets of higher-order terms that remain in the model. For example, the function will not try to remove $X1$ or $X2^2$ if $X1:X2^2$ remains in the model.

The default value of 'Criterion' for a generalized linear model is 'Deviance'. `stepwiseglm` and `step` of `GeneralizedLinearModel` follow a similar procedure for adding or removing terms.

You can specify other criteria by using the 'Criterion' name-value pair argument. For example, you can specify the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, or adjusted R-squared as the criterion to add or remove terms.

Depending on the terms included in the initial model, and the order in which the function adds and removes terms, the function might build different models from the same set of potential terms. The function terminates when no single step improves the model. However, a different initial model or a different sequence of steps does not guarantee a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

Alternatives

You can also construct a stepwise linear model using `stepwiselm`.

You can construct a model using `fitlm`, then manually adjust the model using `step`, `addTerms`, or `removeTerms`. Use `fitlm` for robust regression. You cannot use robust regression and stepwise regression together.

stepwiseglm

Create generalized linear regression model by stepwise regression

Syntax

```
mdl = stepwiseglm(tbl)
mdl = stepwiseglm(X,y)
mdl = stepwiseglm(___,modelspec)
mdl = stepwiseglm(___,modelspec,Name,Value)
```

Description

`mdl = stepwiseglm(tbl)` creates a generalized linear model of a table or dataset array `tbl` using stepwise regression to add or remove predictors, starting from a constant model. `stepwiseglm` uses the last variable of `tbl` as the response variable. `stepwiseglm` uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add the model to or remove from the model, based on the value of the 'Criterion' argument.

`mdl = stepwiseglm(X,y)` creates a generalized linear model of the responses `y` to a data matrix `X`.

`mdl = stepwiseglm(___,modelspec)` specifies the starting model `modelspec` using any of the input argument combinations in previous syntaxes.

`mdl = stepwiseglm(___,modelspec,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the categorical variables, the smallest or largest set of terms to use in the model, the maximum number of steps to take, or the criterion that `stepwiseglm` uses to add or remove terms.

Examples

Generalized Linear Model Using Stepwise Algorithm

Create response data using just three of 20 predictors, and create a generalized linear model using stepwise algorithm to see if it uses just the correct predictors.

Create data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```
rng('default') % for reproducibility
X = randn(100,20);
mu = exp(X(:, [5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Fit a generalized linear model using the Poisson distribution.

```
mdl = stepwiseglm(X,y,...
    'constant','upper','linear','Distribution','poisson')
```

1. Adding x5, Deviance = 134.439, Chi2Stat = 52.24814, PValue = 4.891229e-13
2. Adding x15, Deviance = 106.285, Chi2Stat = 28.15393, PValue = 1.1204e-07
3. Adding x10, Deviance = 95.0207, Chi2Stat = 11.2644, PValue = 0.000790094

```
mdl =
Generalized linear regression model:
  log(y) ~ 1 + x5 + x10 + x15
  Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	1.0115	0.064275	15.737	8.4217e-56
x5	0.39508	0.066665	5.9263	3.0977e-09
x10	0.18863	0.05534	3.4085	0.0006532
x15	0.29295	0.053269	5.4995	3.8089e-08

```
100 observations, 96 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 91.7, p-value = 9.61e-20
```

The starting model is the constant model. `stepwiseglm` by default uses deviance of the model as the criterion. It first adds `x5` into the model, as the p -value for the test statistic, deviance (the differences in the deviances of the two models), is less than the default threshold value 0.05. Then, it adds `x15` because given `x5` is in the model, when `x15` is added, the p -value for chi-squared test is smaller than 0.05. It then adds `x10` because given `x5` and `x15` are in the model, when `x10` is added, the p -value for the chi-square test statistic is again less than 0.05.

Input Arguments

tbl — Input data

table | dataset array

Input data including predictor and response variables, specified as a table or dataset array. The predictor variables and response variable can be numeric, logical, categorical, character, or string. The response variable can have a data type other than numeric only if 'Distribution' is 'binomial'.

- By default, `stepwiseglm` takes the last variable as the response variable and the others as the predictor variables.
- To set a different column as the response variable, use the `ResponseVar` name-value pair argument.
- To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.
- To define a model specification, set the `modelspec` argument using a formula or terms matrix. The formula or terms matrix specifies which columns to use as the predictor or response variables.

The variable names in a table do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:

- You cannot specify `modelspec` using a formula.

- You cannot use a formula to specify the terms to add or remove when you use the `addTerms` function or the `removeTerms` function, respectively.
- You cannot use a formula to specify the lower and upper bounds of the model when you use the `step` or `stepwiseglm` function with the name-value pair arguments 'Lower' and 'Upper', respectively.

You can verify the variable names in `tbl` by using the `isvarname` function. The following code returns logical 1 (true) for each variable that has a valid variable name.

```
cellfun(@isvarname,tbl.Properties.VariableNames)
```

If the variable names in `tbl` are not valid, then convert them by using the `matlab.lang.makeValidName` function.

```
tbl.Properties.VariableNames = matlab.lang.makeValidName(tbl.Properties.VariableNames);
```

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in X .

Data Types: `single` | `double`

y — Response variable

vector | matrix

Response variable, specified as a vector or matrix.

- If 'Distribution' is not 'binomial', then y must be an n -by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X . The data type must be single or double.
- If 'Distribution' is 'binomial', then y can be an n -by-1 vector or n -by-2 matrix with counts in column 1 and `BinomialSize` in column 2.

Data Types: `single` | `double` | `logical` | `categorical`

modelspec — Starting model

'constant' (default) | character vector or string scalar naming the model | t -by- $(p + 1)$ terms matrix | character vector or string scalar formula in the form 'Y ~ terms'

Starting model for `stepwiseglm`, specified as one of the following:

- A character vector or string scalar naming the model.

Value	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear term for each predictor.

Value	Model Type
'interactions'	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept term and linear and squared terms for each predictor.
'quadratic'	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 through 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, 'poly13' has an intercept and x_1 , x_2 , x_2^2 , x_2^3 , x_1*x_2 , and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

- A t -by- $(p + 1)$ matrix, or a “Terms Matrix” on page 32-5261, specifying terms in the model, where t is the number of terms and p is the number of predictor variables, and +1 accounts for the response variable. A terms matrix is convenient when the number of predictors is large and you want to generate the terms programmatically.
- A character vector or string scalar representing a “Formula” on page 32-5261 in the form 'Y ~ terms', where the terms are in “Wilkinson Notation” on page 32-5261. The variable names in the formula must be valid MATLAB identifiers.

The software determines the order of terms in a fitted model by using the order of terms in `tbl` or `X`. Therefore, the order of terms in the model can be different from the order of terms in the specified formula.

If you want to specify the smallest or largest set of terms in the model that `stepwiselm` fits, use the Lower and Upper name-value pair arguments.

Data Types: `char` | `string` | `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: 'Criterion', 'aic', 'Distribution', 'poisson', 'Upper', 'interactions' specifies Akaike Information Criterion as the criterion to add or remove variables to the model, Poisson distribution as the distribution of the response variable, and a model with all possible interactions as the largest model to consider as the fit.

BinomialSize — Number of trials for binomial distribution

1 (default) | numeric scalar | numeric vector | character vector | string scalar

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of 'BinomialSize' and the variable name in `tbl`, a numeric scalar, or a numeric

vector of the same length as the response. This is the parameter n for the fitted binomial distribution. `BinomialSize` applies only when the `Distribution` parameter is `'binomial'`.

If `BinomialSize` is a scalar value, that means all observations have the same number of trials.

As an alternative to `BinomialSize`, you can specify the response as a two-column matrix with counts in column 1 and `BinomialSize` in column 2.

Data Types: `single` | `double` | `char` | `string`

CategoricalVars — Categorical variable list

`string array` | `cell array of character vectors` | `logical or numeric index vector`

Categorical variable list, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a string array or cell array of character vectors containing categorical variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then, by default, `stepwiseglm` treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix `X`, then the default value of `'CategoricalVars'` is an empty matrix `[]`. That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: `'CategoricalVars',[2,3]`

Example: `'CategoricalVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `string` | `cell`

Criterion — Criterion to add or remove terms

`'Deviance'` (default) | `'sse'` | `'aic'` | `'bic'` | `'rsquared'` | `'adjrsquared'`

Criterion to add or remove terms, specified as the comma-separated pair consisting of `'Criterion'` and one of these values:

- `'Deviance'` — p -value for an F -test or chi-squared test of the change in the deviance that results from adding or removing the term. The F -test tests a single model, and the chi-squared test compares two different models.
- `'sse'` — p -value for an F -test of the change in the sum of squared error that results from adding or removing the term.
- `'aic'` — Change in the value of the Akaike information criterion (AIC).
- `'bic'` — Change in the value of the Bayesian information criterion (BIC).
- `'rsquared'` — Increase in the value of R^2 .
- `'adjrsquared'` — Increase in the value of adjusted R^2 .

Example: `'Criterion','bic'`

DispersionFlag — Indicator to compute dispersion parameter

`false` for `'binomial'` and `'poisson'` distributions (default) | `true`

Indicator to compute dispersion parameter for 'binomial' and 'poisson' distributions, specified as the comma-separated pair consisting of 'DispersionFlag' and one of the following.

<code>true</code>	Estimate a dispersion parameter when computing standard errors. The estimated dispersion parameter value is the sum of squared Pearson residuals divided by the degrees of freedom for error (DFE).
<code>false</code>	Default. Use the theoretical value when computing standard errors.

The fitting function always estimates the dispersion for other distributions.

Example: `'DispersionFlag',true`

Distribution — Distribution of the response variable

`'normal'` (default) | `'binomial'` | `'poisson'` | `'gamma'` | `'inverse gaussian'`

Distribution of the response variable, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

<code>'normal'</code>	Normal distribution
<code>'binomial'</code>	Binomial distribution
<code>'poisson'</code>	Poisson distribution
<code>'gamma'</code>	Gamma distribution
<code>'inverse gaussian'</code>	Inverse Gaussian distribution

Example: `'Distribution','gamma'`

Exclude — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: `'Exclude',[2,3]`

Example: `'Exclude',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

Intercept — Indicator for constant term

`true` (default) | `false`

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either `true` to include or `false` to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: `'Intercept',false`

Link — Link function

canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

Link Function Name	Link Function	Mean (Inverse) Function
'identity'	$f(\mu) = \mu$	$\mu = Xb$
'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'probit'	$f(\mu) = \Phi^{-1}(\mu)$	$\mu = \Phi(Xb)$
'comloglog'	$f(\mu) = \log(-\log(1 - \mu))$	$\mu = 1 - \exp(-\exp(Xb))$
'reciprocal'	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
p (a number)	$f(\mu) = \mu^p$	$\mu = Xb^{1/p}$
S (a structure) with three fields. Each field holds a function handle that accepts a vector of inputs and returns a vector of the same size: <ul style="list-style-type: none"> • S.Link — The link function • S.Inverse — The inverse link function • S.Derivative — The derivative of the link function 	$f(\mu) = S.Link(\mu)$	$\mu = S.Inverse(Xb)$

The link function defines the relationship $f(\mu) = X*b$ between the mean response μ and the linear combination of predictors $X*b$.

For more information on the canonical link functions, see “Canonical Function” on page 32-5262.

Example: 'Link', 'probit'

Data Types: char | string | single | double | struct

Lower — Model specification describing terms that cannot be removed from model

'constant' (default) | character vector | string scalar | terms matrix

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of 'Lower' and one of the options for modelSpec naming the model.

Example: 'Lower', 'linear'

NSteps — Maximum number of steps to take

no limit (default) | positive integer

Maximum number of steps to take, specified as the comma-separated pair consisting of 'NSteps' and a positive integer.

Example: 'NSteps', 5

Data Types: single | double

Offset — Offset variable

[] (default) | numeric vector | character vector | string scalar

Offset variable in the fit, specified as the comma-separated pair consisting of 'Offset' and the variable name in `tbl` or a numeric vector with the same length as the response.

`stepwiseglm` uses `Offset` as an additional predictor with a coefficient value fixed at 1. In other words, the formula for fitting is

$$f(\mu) = \text{Offset} + X*b,$$

where f is the link function, μ is the mean response, and $X*b$ is the linear combination of predictors X . The `Offset` predictor has coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor `A`. By using the log link function and by specifying `log(A)` as an offset, you can force the model to satisfy this theoretical constraint.

Data Types: `single` | `double` | `char` | `string`

PEnter — Threshold for criterion to add term

scalar value

Threshold for the criterion to add a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'Deviance'	0.05	If the p -value of the F -statistic or chi-squared statistic is less than <code>PEnter</code> (p -value to enter), add the term to the model.
'SSE'	0.05	If the p -value of the F -statistic is less than <code>PEnter</code> , add the term to the model.
'AIC'	0	If the change in the AIC of the model is less than <code>PEnter</code> , add the term to the model.
'BIC'	0	If the change in the BIC of the model is less than <code>PEnter</code> , add the term to the model.
'Rsquared'	0.1	If the increase in the R-squared value of the model is greater than <code>PEnter</code> , add the term to the model.
'AdjRsquared'	0	If the increase in the adjusted R-squared value of the model is greater than <code>PEnter</code> , add the term to the model.

For more information, see the `Criterion` name-value pair argument.

Example: 'PEnter', 0.075

PredictorVars – Predictor variables

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars',[2,3]

Example: 'PredictorVars',logical([0 1 1 0 0 0])

Data Types: single | double | logical | string | cell

PRemove – Threshold for criterion to remove term

scalar value

Threshold for the criterion to remove a term, specified as the comma-separated pair consisting of 'PRemove' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'Deviance'	0.10	If the p -value of the F -statistic or chi-squared statistic is greater than PRemove (p -value to remove), remove the term from the model.
'SSE'	0.10	If the p -value of the F -statistic is greater than PRemove, remove the term from the model.
'AIC'	0.01	If the change in the AIC of the model is greater than PRemove, remove the term from the model.
'BIC'	0.01	If the change in the BIC of the model is greater than PRemove, remove the term from the model.
'Rsquared'	0.05	If the increase in the R-squared value of the model is less than PRemove, remove the term from the model.

Criterion	Default Value	Decision
'AdjRsquared'	-0.05	If the increase in the adjusted R-squared value of the model is less than PRemove, remove the term from the model.

At each step, the `stepwiseglm` function also checks whether a term is redundant (linearly dependent) with other terms in the current model. When a term is linearly dependent on other terms in the current model, the `stepwiseglm` function removes the redundant term, regardless of the criterion value.

For more information, see the `Criterion` name-value pair argument.

Example: `'PRemove', 0.05`

ResponseVar — Response variable

last column in `tbl` (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a character vector or string scalar containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar', 'yield'`

Example: `'ResponseVar', [4]`

Example: `'ResponseVar', logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char` | `string`

Upper — Model specification describing largest set of terms in fit

`'interactions'` (default) | character vector | string scalar | terms matrix

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of `'Upper'` and one of the options for `modelspec` naming the model.

Example: `'Upper', 'quadratic'`

VarNames — Names of variables

`{'x1', 'x2', ..., 'xn', 'y'}` (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of `'VarNames'` and a string array or cell array of character vectors including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

The variable names do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:

- You cannot use a formula to specify the terms to add or remove when you use the `addTerms` function or the `removeTerms` function, respectively.
- You cannot use a formula to specify the lower and upper bounds of the model when you use the `step` or `stepwiseglm` function with the name-value pair arguments `'Lower'` and `'Upper'`, respectively.

Before specifying `'VarNames'`, `varNames`, you can verify the variable names in `varNames` by using the `isvarname` function. The following code returns logical 1 (`true`) for each variable that has a valid variable name.

```
cellfun(@isvarname,varNames)
```

If the variable names in `varNames` are not valid, then convert them by using the `matlab.lang.makeValidName` function.

```
varNames = matlab.lang.makeValidName(varNames);
```

Example: `'VarNames',{ 'Horsepower','Acceleration','Model_Year','MPG'}`

Data Types: `string` | `cell`

Verbose — Control for display of information

1 (default) | 0 | 2

Control for the display of information, specified as the comma-separated pair consisting of `'Verbose'` and one of these values:

- 0 — Suppress all display.
- 1 — Display the action taken at each step.
- 2 — Display the evaluation process and the action taken at each step.

Example: `'Verbose',2`

Weights — Observation weights

`ones(n,1)` (default) | n -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and an n -by-1 vector of nonnegative scalar values, where n is the number of observations.

Data Types: `single` | `double`

Output Arguments

mdl — Generalized linear regression model

`GeneralizedLinearModel` object

Generalized linear regression model, specified as a `GeneralizedLinearModel` object created using `fitglm` or `stepwiseglm`.

More About

Terms Matrix

A terms matrix T is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and $+1$ accounts for the response variable. The value of $T(i, j)$ is the exponent of variable j in term i .

For example, suppose that an input includes three predictor variables A , B , and C and the response variable Y in the order A , B , C , and Y . Each row of T represents one term:

- $[0 \ 0 \ 0 \ 0]$ — Constant term or intercept
- $[0 \ 1 \ 0 \ 0]$ — B ; equivalently, $A^0 * B^1 * C^0$
- $[1 \ 0 \ 1 \ 0]$ — $A*C$
- $[2 \ 0 \ 0 \ 0]$ — A^2
- $[0 \ 1 \ 2 \ 0]$ — $B*(C^2)$

The 0 at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable in the last column of each row.

Formula

A formula for model specification is a character vector or string scalar of the form ' $Y \sim terms$ '.

- Y is the response name.
- $terms$ represents the predictor terms in a model using Wilkinson notation.

For example:

- ' $Y \sim A + B + C$ ' specifies a three-variable linear model with intercept.
- ' $Y \sim A + B + C - 1$ ' specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include -1 in the formula.

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- $+$ means include the next variable.
- $-$ means do not include the next variable.
- $:$ defines an interaction, which is a product of terms.
- $*$ defines an interaction and all lower-order terms.
- $^$ raises the predictor to a power, exactly as in $*$ repeated, so $^$ includes lower-order terms as well.
- $()$ groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Term in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1 .

For more details, see “Wilkinson Notation” on page 11-90.

Canonical Function

The default link function for a generalized linear model is the canonical link function.

Distribution	Canonical Link Function Name	Link Function	Mean (Inverse) Function
'normal'	'identity'	$f(\mu) = \mu$	$\mu = Xb$
'binomial'	'logit'	$f(\mu) = \log(\mu/(1 - \mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'poisson'	'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

Tips

- The generalized linear model `mdl` is a standard linear model unless you specify otherwise with the `Distribution` name-value pair.
- For other methods such as `devianceTest`, or properties of the `GeneralizedLinearModel` object, see `GeneralizedLinearModel`.
- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

- Stepwise regression is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

The `stepwiseglm` function uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add to the model or remove from the model based on the value of the 'Criterion' name-value pair argument.

The default value of 'Criterion' for a linear regression model is 'sse'. In this case, `stepwiselm` and `step` of `LinearModel` use the p -value of an F -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the function adds the term to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the function removes the term from the model.

Stepwise regression takes these steps when 'Criterion' is 'sse':

- 1 Fit the initial model.
- 2 Examine a set of available terms not in the model. If any of the terms have p -values less than an entrance tolerance (that is, if it is unlikely a term would have a zero coefficient if added to the model), add the term with the smallest p -value and repeat this step; otherwise, go to step 3.
- 3 If any of the available terms in the model have p -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient cannot be rejected), remove the term with the largest p -value and return to step 2; otherwise, end the process.

At any stage, the function will not add a higher-order term if the model does not also include all lower-order terms that are subsets of the higher-order term. For example, the function will not try to add the term $X1 : X2^2$ unless both $X1$ and $X2^2$ are already in the model. Similarly, the function will not remove lower-order terms that are subsets of higher-order terms that remain in the model. For example, the function will not try to remove $X1$ or $X2^2$ if $X1 : X2^2$ remains in the model.

The default value of 'Criterion' for a generalized linear model is 'Deviance'. `stepwiseglm` and `step` of `GeneralizedLinearModel` follow a similar procedure for adding or removing terms.

You can specify other criteria by using the 'Criterion' name-value pair argument. For example, you can specify the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, or adjusted R-squared as the criterion to add or remove terms.

Depending on the terms included in the initial model, and the order in which the function adds and removes terms, the function might build different models from the same set of potential terms. The function terminates when no single step improves the model. However, a different initial model or a different sequence of steps does not guarantee a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

- `stepwiseglm` treats a categorical predictor as follows:
 - A model with a categorical predictor that has L levels (categories) includes $L - 1$ indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level.
 - `stepwiseglm` treats the group of $L - 1$ indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually

by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor X , if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.

- Interaction terms between a continuous predictor and a categorical predictor with L levels consist of the element-wise product of the $L - 1$ indicator variables with the continuous predictor.
- Interaction terms between two categorical predictors with L and M levels consist of the $(L - 1) * (M - 1)$ indicator variables to include all possible combinations of the two categorical predictor levels.
- You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.

Therefore, if `stepwiseglm` adds or removes a categorical predictor, the function actually adds or removes the group of indicator variables in one step. Similarly, if `stepwiseglm` adds or removes an interaction term with a categorical predictor, the function actually adds or removes the group of interaction terms including the categorical predictor.

- `stepwiseglm` considers `NaN`, `' '` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `tbl`, X , and Y to be missing values. `stepwiseglm` does not use observations with missing values in the fit. The `ObservationInfo` property of a fitted model indicates whether or not `stepwiseglm` uses each observation in the fit.

Alternatives

- Use `fitglm` to create a model with a fixed specification. Use `step`, `addTerms`, or `removeTerms` to adjust a fitted model.

```

Description

`mdl = stepwiselm(tbl)` creates a linear model for the variables in the table or dataset array `tbl` using stepwise regression to add or remove predictors, starting from a constant model. `stepwiselm` uses the last variable of `tbl` as the response variable. `stepwiselm` uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add the model to or remove from the model, based on the value of the 'Criterion' argument.

`mdl = stepwiselm(X,y)` creates a linear model of the responses `y` to the predictor variables in the data matrix `X`.

`mdl = stepwiselm(___,modelspec)` specifies the starting model `modelspec` using any of the input argument combinations in previous syntaxes.

`mdl = stepwiselm(___,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the categorical variables, the smallest or largest set of terms to use in the model, the maximum number of steps to take, or the criterion that `stepwiselm` uses to add or remove terms.

Examples

Fit Linear Model Using Stepwise Regression

Load the `hald` data set, which measures the effect of cement composition on its hardening heat.

```
load hald
```

This data set includes the variables `ingredients` and `heat`. The matrix `ingredients` contains the percent composition of four chemicals present in the cement. The vector `heat` contains the values for the heat hardening after 180 days for each cement sample.

Fit a stepwise linear regression model to the data. Specify 0.06 as the threshold for the criterion to add a term to the model.

```
mdl = stepwiselm(ingredients,heat,'PEnter',0.06)
```

1. Adding x4, FStat = 22.7985, pValue = 0.000576232
2. Adding x1, FStat = 108.2239, pValue = 1.105281e-06
3. Adding x2, FStat = 5.0259, pValue = 0.051687
4. Removing x4, FStat = 1.8633, pValue = 0.2054

```
mdl =
Linear regression model:
  y ~ 1 + x1 + x2

Estimated Coefficients:
              Estimate      SE      tStat      pValue
-----
(Intercept)  52.577        2.2862   22.998   5.4566e-10
x1           1.4683        0.1213   12.105   2.6922e-07
x2           0.66225       0.045855 14.442   5.029e-08
```

```
Number of observations: 13, Error degrees of freedom: 10
Root Mean Squared Error: 2.41
R-squared: 0.979, Adjusted R-Squared: 0.974
F-statistic vs. constant model: 230, p-value = 4.41e-09
```

By default, the starting model is a constant model. `stepwiselm` performs forward selection and adds the `x4`, `x1`, and `x2` terms (in that order), because the corresponding p -values are less than the `PEnter` value of 0.06. `stepwiselm` then uses backward elimination and removes `x4` from the model because, once `x2` is in the model, the p -value of `x4` is greater than the default value of `PRemove`, 0.1.

Stepwise Regression Using Specified Model Formula and Variables

Perform stepwise regression using variables stored in a dataset array. Specify the starting model using Wilkinson notation, and identify the response and predictor variables using optional arguments.

Load the sample data.

```
load hospital
```

The `hospital` dataset array includes the gender, age, weight, and smoking status of patients.

Fit a linear model with a starting model of a constant term and `Smoker` as the predictor variable. Specify the response variable, `Weight`, and categorical predictor variables, `Sex`, `Age`, and `Smoker`.

```
mdl = stepwiselm(hospital, 'Weight~1+Smoker', ...
'ResponseVar', 'Weight', 'PredictorVars', {'Sex', 'Age', 'Smoker'}, ...
'CategoricalVar', {'Sex', 'Smoker'})
```

1. Adding `Sex`, $F_{\text{Stat}} = 770.0158$, $p_{\text{Value}} = 6.262758e-48$
2. Removing `Smoker`, $F_{\text{Stat}} = 0.21224$, $p_{\text{Value}} = 0.64605$

```
mdl =
Linear regression model:
  Weight ~ 1 + Sex

Estimated Coefficients:
              Estimate      SE      tStat      pValue
-----
(Intercept)  130.47        1.1995   108.77   5.2762e-104
Sex_Male     50.06        1.7496   28.612   2.2464e-49
```

Number of observations: 100, Error degrees of freedom: 98
 Root Mean Squared Error: 8.73
 R-squared: 0.893, Adjusted R-Squared: 0.892
 F-statistic vs. constant model: 819, p-value = 2.25e-49

At each step, `stepwiselm` searches for terms to add and remove. At first step, stepwise algorithm adds `Sex` to the model with a p -value of $6.26e-48$. Then, removes `Smoker` from the model, since given `Sex` in the model, the variable `Smoker` becomes redundant. `stepwiselm` only includes `Sex` in the final linear model. The weight of the patients do not seem to differ significantly according to age or the status of smoking.

Stepwise Regression Using Terms Matrix

Load a sample data set and define the matrix of predictors.

```
load carsmall
X = [Acceleration,Weight];
```

Define the starting model and the upper model using terms matrices.

```
T_starting = [0 0 0] % a constant model
```

```
T_starting = 1x3
    0    0    0
```

```
T_upper = [0 0 0;1 0 0;0 1 0;1 1 0] % a linear model with interactions
```

```
T_upper = 4x3
    0    0    0
    1    0    0
    0    1    0
    1    1    0
```

Create a linear regression model using stepwise regression. Specify the starting model and the upper bound of the model using the terms matrices, and specify 'Verbose' as 2 to display the evaluation process and the decision taken at each step.

```
mdl = stepwiselm(X,MPG,T_starting,'upper',T_upper,'Verbose',2)
```

```
    pValue for adding x1 is 4.0973e-06
    pValue for adding x2 is 1.6434e-28
1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28
    pValue for adding x1 is 0.18493
    No candidate terms to remove
```

```
mdl =
Linear regression model:
    y ~ 1 + x2
```

```
Estimated Coefficients:
                Estimate          SE          tStat          pValue
```

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
x2	-0.0086119	0.0005348	-16.103	1.6434e-28

Number of observations: 94, Error degrees of freedom: 92
 Root Mean Squared Error: 4.13
 R-squared: 0.738, Adjusted R-Squared: 0.735
 F-statistic vs. constant model: 259, p-value = 1.64e-28

Stepwise Regression with Categorical Predictor

Fit a linear regression model with a categorical predictor using stepwise regression. `stepwiselm` adds or removes a group of indicator variables in one step to add or removes a categorical predictor. This example also shows how to create indicator variables manually and pass them to `stepwiselm` so that `stepwiselm` treats each indicator variable as a separate predictor.

Load the `carsmall` data set, and create a table using the `Weight`, `Model_Year`, and `MPG` variables.

```
load carsmall
Year = categorical(Model_Year);
tbl1 = table(MPG,Weight,Year);
```

Fit a linear regression model of `MPG` using stepwise regression. Specify the starting model as a function of `Weight`. Set the upper bound of the model to `'poly21'`, meaning the model can include (at most) a constant and the terms `Weight`, `Weight^2`, `Year`, and `Weight*Year`. Specify `'Verbose'` as 2 to display the evaluation process and the decision taken at each step.

```
mdl1 = stepwiselm(tbl1, 'MPG ~ Weight', 'Upper', 'poly21', 'Verbose', 2)
```

```
pValue for adding Year is 8.2284e-15
pValue for adding Weight^2 is 0.15454
1. Adding Year, FStat = 47.5136, pValue = 8.22836e-15
pValue for adding Weight^2 is 0.0022303
pValue for adding Weight:Year is 0.0071637
2. Adding Weight^2, FStat = 9.9164, pValue = 0.0022303
pValue for adding Weight:Year is 0.19519
pValue for removing Year is 2.9042e-16
```

```
mdl1 =
Linear regression model:
MPG ~ 1 + Weight + Year + Weight^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	54.206	4.7117	11.505	2.6648e-19
Weight	-0.016404	0.0031249	-5.2493	1.0283e-06
Year_76	2.0887	0.71491	2.9215	0.0044137
Year_82	8.1864	0.81531	10.041	2.6364e-16
Weight^2	1.5573e-06	4.9454e-07	3.149	0.0022303

```

Number of observations: 94, Error degrees of freedom: 89
Root Mean Squared Error: 2.78
R-squared: 0.885, Adjusted R-Squared: 0.88
F-statistic vs. constant model: 172, p-value = 5.52e-41

```

`stepwiselm` creates two indicator variables, `Year_76` and `Year_82`, because `Year` includes three distinct values.

Because `'Verbose'` is 2, `stepwiselm` displays the evaluation process:

- `stepwiselm` creates a model as a function of `Weight`.
- `stepwiselm` computes the p -values for adding `Year` or `Weight^2`. The p -value for `Year` is less than both the p -value for `Weight^2` and the default threshold value of 0.05; therefore, `stepwiselm` adds `Year` to the model.
- `stepwiselm` computes the p -values for adding `Weight:Year` or `Weight^2`. Because the p -value for `Weight^2` is less than the p -value for `Weight:Year`, the `stepwiselm` function adds `Weight^2` to the model.
- After adding the quadratic term, `stepwiselm` computes the p -value for adding `Weight:Year` again, but the p -value is greater than the threshold value. Therefore, `stepwiselm` does not add the term to the model. `stepwiselm` does not examine adding `Weight^3` because of the upper bound specified by the `'Upper'` name-value pair argument.
- `stepwiselm` looks for terms to remove. `stepwiselm` already examined `Weight^2`, so it computes only the p -value for removing `Year`. Because the p -value is less than the default threshold value of 0.10, `stepwiselm` does not remove the term.
- Although the maximum allowed number of steps is 5, `stepwiselm` terminates the process after two steps because the model does not improve by adding or removing a term.

`stepwiselm` treats the two indicator variables as one predictor variable and adds `Year` in one step. To treat the two indicator variables as two distinct predictor variables, use `dummyvar` to create separate categorical variables.

```

temp_Year = dummyvar(Year);
Year_76 = logical(temp_Year(:,2));
Year_82 = logical(temp_Year(:,3));

```

Create a table containing `MPG`, `Weight`, `Year_76`, and `Year_82`.

```
tbl2 = table(MPG,Weight,Year_76,Year_82);
```

Create a stepwise linear regression model from the same starting model used for `mdl1`.

```
mdl2 = stepwiselm(tbl2,'MPG ~ Weight','Upper','poly211')
```

1. Adding `Year_82`, $FStat = 83.1956$, $pValue = 1.76163e-14$
2. Adding `Weight:Year_82`, $FStat = 8.0641$, $pValue = 0.0055818$
3. Adding `Year_76`, $FStat = 8.1284$, $pValue = 0.0054157$

```

mdl2 =
Linear regression model:
    MPG ~ 1 + Year_76 + Weight*Year_82

```

Estimated Coefficients:

Estimate	SE	tStat	pValue
_____	_____	_____	_____

(Intercept)	38.844	1.5294	25.397	1.503e-42
Weight	-0.006272	0.00042673	-14.698	1.5622e-25
Year_76_1	2.0395	0.71537	2.851	0.0054157
Year_82_1	19.607	3.8731	5.0623	2.2163e-06
Weight:Year_82_1	-0.0046268	0.0014979	-3.0888	0.0026806

Number of observations: 94, Error degrees of freedom: 89
 Root Mean Squared Error: 2.79
 R-squared: 0.885, Adjusted R-Squared: 0.88
 F-statistic vs. constant model: 171, p-value = 6.54e-41

The model `mdl2` includes the interaction term `Weight:Year_82_1` instead of `Weight^2`, the term included in `mdl1`.

Input Arguments

tbl — Input data

table | dataset array

Input data including predictor and response variables, specified as a table or dataset array. The predictor variables can be numeric, logical, categorical, character, or string. The response variable must be numeric or logical.

- By default, `stepwiselm` takes the last variable as the response variable and the others as the predictor variables.
- To set a different column as the response variable, use the `ResponseVar` name-value pair argument.
- To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.
- To define a model specification, set the `modelspec` argument using a formula or terms matrix. The formula or terms matrix specifies which columns to use as the predictor or response variables.

The variable names in a table do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:

- You cannot specify `modelspec` using a formula.
- You cannot use a formula to specify the terms to add or remove when you use the `addTerms` function or the `removeTerms` function, respectively.
- You cannot use a formula to specify the lower and upper bounds of the model when you use the `step` or `stepwiselm` function with the name-value pair arguments `'Lower'` and `'Upper'`, respectively.

You can verify the variable names in `tbl` by using the `isvarname` function. The following code returns logical 1 (`true`) for each variable that has a valid variable name.

```
cellfun(@isvarname,tbl.Properties.VariableNames)
```

If the variable names in `tbl` are not valid, then convert them by using the `matlab.lang.makeValidName` function.

```
tbl.Properties.VariableNames = matlab.lang.makeValidName(tbl.Properties.VariableNames);
```

X – Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in X .

Data Types: `single` | `double`**y – Response variable**

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X .

Data Types: `single` | `double` | `logical`**modelspec – Starting model**

'constant' (default) | character vector or string scalar naming the model | t -by- $(p + 1)$ terms matrix | character vector or string scalar formula in the form 'Y ~ terms'

Starting model for the stepwise regression, specified as one of the following:

- A character vector or string scalar naming the model.

Value	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear term for each predictor.
'interactions'	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept term and linear and squared terms for each predictor.
'quadratic'	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 through 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, 'poly13' has an intercept and x_1 , x_2 , x_2^2 , x_2^3 , x_1*x_2 , and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

- A t -by- $(p + 1)$ matrix, or a “Terms Matrix” on page 32-5277, specifying terms in the model, where t is the number of terms and p is the number of predictor variables, and +1 accounts for the

response variable. A terms matrix is convenient when the number of predictors is large and you want to generate the terms programmatically.

- A character vector or string scalar representing a “Formula” on page 32-5277 in the form `'Y ~ terms'`, where the terms are in “Wilkinson Notation” on page 32-5277. The variable names in the formula must be valid MATLAB identifiers.

The software determines the order of terms in a fitted model by using the order of terms in `tbl` or `X`. Therefore, the order of terms in the model can be different from the order of terms in the specified formula.

If you want to specify the smallest or largest set of terms in the model that `stepwiselm` fits, use the `Lower` and `Upper` name-value pair arguments.

Data Types: `char` | `string` | `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Criterion','aic','Upper','interactions','Verbose',1` instructs `stepwiselm` to use the Akaike information criterion, display the action it takes at each step, and include at most the interaction terms in the model.

CategoricalVars — Categorical variable list

string array | cell array of character vectors | logical or numeric index vector

Categorical variable list, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a string array or cell array of character vectors containing categorical variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then, by default, `stepwiselm` treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix `X`, then the default value of `'CategoricalVars'` is an empty matrix `[]`. That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: `'CategoricalVars',[2,3]`

Example: `'CategoricalVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `string` | `cell`

Criterion — Criterion to add or remove terms

`'sse'` (default) | `'aic'` | `'bic'` | `'rsquared'` | `'adjrsquared'`

Criterion to add or remove terms, specified as the comma-separated pair consisting of `'Criterion'` and one of these values:

- `'sse'` — p -value for an F -test of the change in the sum of squared error that results from adding or removing the term

- 'aic' — Change in the value of Akaike information criterion (AIC)
- 'bic' — Change in the value of Bayesian information criterion (BIC)
- 'rsquared' — Increase in the value of R^2
- 'adjrsquared' — Increase in the value of adjusted R^2

Example: 'Criterion','bic'

Exclude — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude',[2,3]

Example: 'Exclude',logical([0 1 1 0 0 0])

Data Types: single | double | logical

Intercept — Indicator for constant term

true (default) | false

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: 'Intercept',false

Lower — Model specification describing terms that cannot be removed from model

'constant' (default) | character vector | string scalar | terms matrix

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of 'Lower' and one of the options for modelspec naming the model.

Example: 'Lower','linear'

NSteps — Maximum number of steps to take

no limit (default) | positive integer

Maximum number of steps to take, specified as the comma-separated pair consisting of 'NSteps' and a positive integer.

Example: 'NSteps',5

Data Types: single | double

PEnter — Threshold for criterion to add term

scalar value

Threshold for the criterion to add a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'SSE'	0.05	If the p -value of the F -statistic is less than <code>PEnter</code> (p -value to enter), add the term to the model.
'AIC'	0	If the change in the AIC of the model is less than <code>PEnter</code> , add the term to the model.
'BIC'	0	If the change in the BIC of the model is less than <code>PEnter</code> , add the term to the model.
'Rsquared'	0.1	If the increase in the R-squared value of the model is greater than <code>PEnter</code> , add the term to the model.
'AdjRsquared'	0	If the increase in the adjusted R-squared value of the model is greater than <code>PEnter</code> , add the term to the model.

For more information, see the `Criterion` name-value pair argument.

Example: `'PEnter',0.075`

PredictorVars — Predictor variables

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of `'PredictorVars'` and either a string array or cell array of character vectors of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in `tbl`, or the names you specify using the `'VarNames'` name-value pair argument.

The default is all variables in X , or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: `'PredictorVars',[2,3]`

Example: `'PredictorVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `string` | `cell`

PRemove — Threshold for criterion to remove term

scalar value

Threshold for the criterion to remove a term, specified as the comma-separated pair consisting of `'PRemove'` and a scalar value, as described in this table.

Criterion	Default Value	Decision
'SSE'	0.10	If the p -value of the F -statistic is greater than PRemove (p -value to remove), remove the term from the model.
'AIC'	0.01	If the change in the AIC of the model is greater than PRemove, remove the term from the model.
'BIC'	0.01	If the change in the BIC of the model is greater than PRemove, remove the term from the model.
'Rsquared'	0.05	If the increase in the R-squared value of the model is less than PRemove, remove the term from the model.
'AdjRsquared'	-0.05	If the increase in the adjusted R-squared value of the model is less than PRemove, remove the term from the model.

At each step, the `stepwiselm` function also checks whether a term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, the `stepwiselm` function removes the redundant term, regardless of the criterion value.

For more information, see the `Criterion` name-value pair argument.

Example: `'PRemove', 0.05`

ResponseVar — Response variable

last column in `tbl` (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a character vector or string scalar containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar', 'yield'`

Example: `'ResponseVar', [4]`

Example: `'ResponseVar', logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char` | `string`

Upper — Model specification describing largest set of terms in fit

`'interactions'` (default) | character vector | string scalar | terms matrix

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of 'Upper' and one of the options for `modelspec` naming the model.

Example: 'Upper','quadratic'

VarNames — Names of variables

{'x1','x2',..., 'xn','y'} (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors including the names for the columns of X first, and the name for the response variable y last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

The variable names do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:

- You cannot use a formula to specify the terms to add or remove when you use the `addTerms` function or the `removeTerms` function, respectively.
- You cannot use a formula to specify the lower and upper bounds of the model when you use the `step` or `stepwiselm` function with the name-value pair arguments 'Lower' and 'Upper', respectively.

Before specifying 'VarNames', `varNames`, you can verify the variable names in `varNames` by using the `isvarname` function. The following code returns logical 1 (`true`) for each variable that has a valid variable name.

```
cellfun(@isvarname,varNames)
```

If the variable names in `varNames` are not valid, then convert them by using the `matlab.lang.makeValidName` function.

```
varNames = matlab.lang.makeValidName(varNames);
```

Example: 'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}

Data Types: `string` | `cell`

Verbose — Control for display of information

1 (default) | 0 | 2

Control for the display of information, specified as the comma-separated pair consisting of 'Verbose' and one of these values:

- 0 — Suppress all display.
- 1 — Display the action taken at each step.
- 2 — Display the evaluation process and the action taken at each step.

Example: 'Verbose',2

Weights — Observation weights

`ones(n,1)` (default) | n -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an n -by-1 vector of nonnegative scalar values, where n is the number of observations.

Data Types: `single` | `double`

Output Arguments

`mdl` — Linear model

`LinearModel` object

Linear model representing a least-squares fit of the response to the data, returned as a `LinearModel` object.

For the properties and methods of the linear model object, `mdl`, see the `LinearModel` class page.

More About

Terms Matrix

A terms matrix T is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and $+1$ accounts for the response variable. The value of $T(i, j)$ is the exponent of variable j in term i .

For example, suppose that an input includes three predictor variables A , B , and C and the response variable Y in the order A , B , C , and Y . Each row of T represents one term:

- $[0 \ 0 \ 0 \ 0]$ — Constant term or intercept
- $[0 \ 1 \ 0 \ 0]$ — B ; equivalently, $A^0 * B^1 * C^0$
- $[1 \ 0 \ 1 \ 0]$ — $A * C$
- $[2 \ 0 \ 0 \ 0]$ — A^2
- $[0 \ 1 \ 2 \ 0]$ — $B * (C^2)$

The 0 at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable in the last column of each row.

Formula

A formula for model specification is a character vector or string scalar of the form ' $Y \sim terms$ '.

- Y is the response name.
- $terms$ represents the predictor terms in a model using Wilkinson notation.

For example:

- ' $Y \sim A + B + C$ ' specifies a three-variable linear model with intercept.
- ' $Y \sim A + B + C - 1$ ' specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include -1 in the formula.

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- + means include the next variable.
- – means do not include the next variable.
- : defines an interaction, which is a product of terms.
- * defines an interaction and all lower-order terms.
- ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower-order terms as well.
- () groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Term in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

For more details, see “Wilkinson Notation” on page 11-90.

Tips

- You cannot use robust regression with stepwise regression. Check your data for outliers before using `stepwiselm`.
- For other methods such as `anova`, or properties of the `LinearModel` object, see `LinearModel`.
- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

- Stepwise regression is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

The `stepwiselm` function uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add to the model or remove from the model based on the value of the 'Criterion' name-value pair argument.

The default value of 'Criterion' for a linear regression model is 'sse'. In this case, `stepwiselm` and `step` of `LinearModel` use the p -value of an F -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the function adds the term to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the function removes the term from the model.

Stepwise regression takes these steps when 'Criterion' is 'sse':

- 1 Fit the initial model.
- 2 Examine a set of available terms not in the model. If any of the terms have p -values less than an entrance tolerance (that is, if it is unlikely a term would have a zero coefficient if added to the model), add the term with the smallest p -value and repeat this step; otherwise, go to step 3.
- 3 If any of the available terms in the model have p -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient cannot be rejected), remove the term with the largest p -value and return to step 2; otherwise, end the process.

At any stage, the function will not add a higher-order term if the model does not also include all lower-order terms that are subsets of the higher-order term. For example, the function will not try to add the term $X1:X2^2$ unless both $X1$ and $X2^2$ are already in the model. Similarly, the function will not remove lower-order terms that are subsets of higher-order terms that remain in the model. For example, the function will not try to remove $X1$ or $X2^2$ if $X1:X2^2$ remains in the model.

The default value of 'Criterion' for a generalized linear model is 'Deviance'. `stepwiseglm` and `step` of `GeneralizedLinearModel` follow a similar procedure for adding or removing terms.

You can specify other criteria by using the 'Criterion' name-value pair argument. For example, you can specify the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, or adjusted R-squared as the criterion to add or remove terms.

Depending on the terms included in the initial model, and the order in which the function adds and removes terms, the function might build different models from the same set of potential terms. The function terminates when no single step improves the model. However, a different initial model or a different sequence of steps does not guarantee a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

- `stepwiselm` treats a categorical predictor as follows:
 - A model with a categorical predictor that has L levels (categories) includes $L - 1$ indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level.
 - `stepwiselm` treats the group of $L - 1$ indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor X , if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.

- Interaction terms between a continuous predictor and a categorical predictor with L levels consist of the element-wise product of the $L - 1$ indicator variables with the continuous predictor.
- Interaction terms between two categorical predictors with L and M levels consist of the $(L - 1) * (M - 1)$ indicator variables to include all possible combinations of the two categorical predictor levels.
- You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.

Therefore, if `stepwiselm` adds or removes a categorical predictor, the function actually adds or removes the group of indicator variables in one step. Similarly, if `stepwiselm` adds or removes an interaction term with a categorical predictor, the function actually adds or removes the group of interaction terms including the categorical predictor.

- `stepwiselm` considers `NaN`, `' '` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `tbl`, `X`, and `Y` to be missing values. `stepwiselm` does not use observations with missing values in the fit. The `ObservationInfo` property of a fitted model indicates whether or not `stepwiselm` uses each observation in the fit.

Alternative Functionality

- You can construct a model using `fitlm`, and then manually adjust the model using `step`, `addTerms`, or `removeTerms`.

Introduced in R2013b

stepwisefit

Fit linear regression model using stepwise regression

Syntax

```
b = stepwisefit(X,y)
b = stepwisefit(X,y,Name,Value)
[b,se,pval] = stepwisefit(____)
[b,se,pval,finalmodel,stats] = stepwisefit(____)
[b,se,pval,finalmodel,stats,nextstep,history] = stepwisefit(____)
```

Description

`b = stepwisefit(X,y)` returns a vector `b` of coefficient estimates from stepwise regression of the response vector `y` on the predictor variables in matrix `X`. `stepwisefit` begins with an initial constant model and takes forward or backward steps to add or remove variables, until a stopping criterion is satisfied.

`b = stepwisefit(X,y,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify a nonconstant initial model, or a maximum number of steps that `stepwisefit` can take.

`[b,se,pval] = stepwisefit(____)` returns the coefficient estimates `b`, standard errors `se`, and `p`-values `pval` using any of the input argument combinations in previous syntaxes.

`[b,se,pval,finalmodel,stats] = stepwisefit(____)` also returns a specification of the variables in the final regression model `finalmodel`, and statistics `stats` about the final model.

`[b,se,pval,finalmodel,stats,nextstep,history] = stepwisefit(____)` also returns the recommended next step `nextstep` and information `history` about all the steps taken.

Examples

Stepwise Regression with Default Arguments

Perform a basic stepwise regression and obtain the coefficient estimates.

Load the `hald` data set.

```
load hald
whos % Check variables loaded in workspace
```

Name	Size	Bytes	Class	Attributes
Description	22x58	2552	char	
hald	13x5	520	double	
heat	13x1	104	double	
ingredients	13x4	416	double	

This data set contains observations of the heat evolved during cement hardening for various mixtures of four cement ingredients. The response variable is `heat`. The matrix `ingredients` contains four columns of predictors.

Run `stepwisefit` beginning with only a constant term in the model and using the default entry and exit tolerances of 0.05 and 0.10, respectively.

```
b = stepwisefit(ingredients,heat)
```

```
Initial columns included: none
Step 1, added column 4, p=0.000576232
Step 2, added column 1, p=1.10528e-06
Final columns included: 1 4
    {'Coeff' }    {'Std.Err.'}    {'Status'}    {'P'          }
    {[ 1.4400]}    {[ 0.1384]}    {'In'   }     {[1.1053e-06]}
    {[ 0.4161]}    {[ 0.1856]}    {'Out'  }     {[ 0.0517]}
    {[ -0.4100]}    {[ 0.1992]}    {'Out'  }     {[ 0.0697]}
    {[ -0.6140]}    {[ 0.0486]}    {'In'   }     {[1.8149e-07]}
```

```
b = 4×1

    1.4400
    0.4161
   -0.4100
   -0.6140
```

The `stepwisefit` display shows that columns 1 and 4 are included in the final model. The output `b` includes estimates for all columns, even those that do not appear in the final model. `stepwisefit` computes the estimate for column 2 (or 3) by fitting a model consisting of the final model plus column 2 (or 3).

Tune the Stepwise Procedure

Load the `carsmall` data set, which contains various car measurements.

```
load carsmall
whos
```

Name	Size	Bytes	Class	Attributes
Acceleration	100×1	800	double	
Cylinders	100×1	800	double	
Displacement	100×1	800	double	
Horsepower	100×1	800	double	
MPG	100×1	800	double	
Mfg	100×13	2600	char	
Model	100×33	6600	char	
Model_Year	100×1	800	double	
Origin	100×7	1400	char	
Weight	100×1	800	double	

Perform stepwise regression with four continuous variables and the response variable MPG.

```
X = [Acceleration Cylinders Displacement Horsepower];
y = MPG;
b4_default = stepwisefit(X,y) % Stepwise regression with default arguments
```

```
Initial columns included: none
Step 1, added column 2, p=1.59001e-25
Step 2, added column 4, p=0.00364266
Step 3, added column 1, p=0.0161414
Final columns included: 1 2 4
    {'Coeff' }      {'Std.Err.'}      {'Status'}      {'P'           }
    {[ -0.4517]}    {[ 0.1842]}    {'In'         }    {[ 0.0161]}
    {[ -2.6407]}    {[ 0.4823]}    {'In'         }    {[4.0003e-07]}
    {[ 0.0148]}     {[ 0.0157]}    {'Out'        }    {[ 0.3472]}
    {[ -0.0772]}    {[ 0.0204]}    {'In'         }    {[2.6922e-04]}
```

```
b4_default = 4×1
```

```
-0.4517
-2.6407
0.0148
-0.0772
```

The term **Displacement** never enters the model. Determine if it is highly correlated with the other three terms by computing the term correlation matrix.

```
corrcoef(X, 'Rows', 'complete') % To exclude rows with missing values from calculation
```

```
ans = 4×4
```

```
1.0000    -0.6438    -0.6968    -0.6968
-0.6438    1.0000    0.9517    0.8622
-0.6968    0.9517    1.0000    0.9134
-0.6968    0.8622    0.9134    1.0000
```

The third row of the correlation matrix corresponds to **Displacement**. This term is highly correlated with the other three terms, especially **Cylinders** (0.95) and **Horsepower** (0.91).

Redefine the input matrix **X** to include **Weight**. Specify an initial model containing the terms **Displacement** and **Horsepower** by using the **'InModel'** name-value pair argument.

```
X = [Acceleration Cylinders Displacement Horsepower Weight];
inmodel = [false false true true false];
b5_inmodel = stepwisefit(X,y, 'InModel', inmodel)
```

```
Initial columns included: 3 4
Step 1, added column 5, p=1.06457e-06
Step 2, added column 2, p=0.00410234
Final columns included: 2 3 4 5
    {'Coeff' }      {'Std.Err.'}      {'Status'}      {'P'           }
    {[ -0.0912]}    {[ 0.2032]}    {'Out'         }    {[ 0.6548]}
    {[ -2.3223]}    {[ 0.7879]}    {'In'          }    {[ 0.0041]}
    {[ 0.0252]}     {[ 0.0145]}    {'In'          }    {[ 0.0862]}
    {[ -0.0449]}    {[ 0.0231]}    {'In'          }    {[ 0.0555]}
    {[ -0.0050]}    {[ 0.0012]}    {'In'          }    {[1.0851e-04]}
```

```
b5_inmodel = 5×1
```

```
-0.0912
-2.3223
 0.0252
-0.0449
-0.0050
```

The final model consists of terms 2–5. However, `Displacement` and `Horsepower` estimates have p -values greater than 0.05 in the final model. You can tune the stepwise algorithm to behave more conservatively by using the `'PRemove'` name-value pair argument. For example, setting `'PRemove'` to 0.05 (instead of the default 0.1) results in a smaller final model with only two terms, each with a p -value less than 0.05.

```
b5_inmodel_remove = stepwisefit(X,y,'InModel',inmodel,'PRemove',0.05)
```

```
Initial columns included: 3 4
```

```
Step 1, added column 5, p=1.06457e-06
```

```
Step 2, added column 2, p=0.00410234
```

```
Step 3, removed column 3, p=0.0862131
```

```
Step 4, removed column 4, p=0.239239
```

```
Final columns included: 2 5
```

{'Coeff' }	{'Std.Err.'}	{'Status'}	{'P' }
{[-0.0115]}	{[0.1656]}	{'Out' }	{[0.9449]}
{[-1.6037]}	{[0.5146]}	{'In' }	{[0.0025]}
{[0.0101]}	{[0.0124]}	{'Out' }	{[0.4186]}
{[-0.0234]}	{[0.0198]}	{'Out' }	{[0.2392]}
{[-0.0055]}	{[0.0011]}	{'In' }	{[3.9038e-06]}

```
b5_inmodel_remove = 5×1
```

```
-0.0115
-1.6037
 0.0101
-0.0234
-0.0055
```

Center and scale each column (compute the z -scores) before fitting by using the `'Scale'` name-value pair argument. The scaling does not change the model selected, the signs of coefficient estimates, or their p -values. However, the scaling does scale the coefficient estimates.

```
b5_inmodel_remove_scale = stepwisefit(X,y,'InModel',inmodel,'PRemove',0.05,'Scale','on')
```

```
Initial columns included: 3 4
```

```
Step 1, added column 5, p=1.06457e-06
```

```
Step 2, added column 2, p=0.00410234
```

```
Step 3, removed column 3, p=0.0862131
```

```
Step 4, removed column 4, p=0.239239
```

```
Final columns included: 2 5
```

{'Coeff' }	{'Std.Err.'}	{'Status'}	{'P' }
{[-0.0370]}	{[0.5339]}	{'Out' }	{[0.9449]}
{[-2.8136]}	{[0.9028]}	{'In' }	{[0.0025]}
{[1.1155]}	{[1.3726]}	{'Out' }	{[0.4186]}
{[-1.0617]}	{[0.8961]}	{'Out' }	{[0.2392]}
{[-4.4406]}	{[0.9028]}	{'In' }	{[3.9038e-06]}

```
b5_inmodel_remove_scale = 5×1
```

```
-0.0370
-2.8136
 1.1155
-1.0617
-4.4406
```

Usually, you scale to compare estimates of terms that are measured in different scales, such as Horsepower and Weight. In this case, increasing Horsepower by one standard deviation leads to an expected drop of 1 in MPG, whereas increasing Weight by one standard deviation leads to an expected drop of 4.4 in MPG.

Retrieve Detailed Output from Stepwise Regression

Load the `imports-85` data set. This data set contains characteristics of cars imported in 1985. For a list of all column names, see the variable `Description` in the workspace or type `Description` at the command line.

```
load imports-85
whos
```

Name	Size	Bytes	Class	Attributes
Description	9x79	1422	char	
X	205x26	42640	double	

Choose a subset of continuous variables to use in stepwise regression, consisting of the predictor variables `engine-size`, `bore`, `stroke`, `compression-ratio`, `horsepower`, `peak-rpm`, `city-mpg`, and `highway-mpg`, and the response variable `price`.

```
varnames = ["engine-size", "bore", "stroke", "compression-ratio", "horsepower", "peak-rpm", "city-mpg", "highway-mpg"];
dataTbl = array2table(X(:,8:16), 'VariableNames', varnames); % Create data table with variable names
Xstepw = dataTbl(:, {'engine-size', 'bore', 'stroke', 'compression-ratio', 'horsepower', 'peak-rpm', 'city-mpg', 'highway-mpg'});
ystepw = dataTbl(:, {'price'}); % Response vector
```

Run `stepwisefit` of the variable `price` on the other eight variables, first with the default constant initial model and then with an initial model including `highway-mpg`. Omit the display of step information.

```
[betahat_def, se_def, pval_def, finalmodel_def, stats_def] = stepwisefit(Xstepw, ystepw, 'Display', 'off');
inmodel = [false false false false false false false true];
[betahat_in, se_in, pval_in, finalmodel_in, stats_in] = stepwisefit(Xstepw, ystepw, 'InModel', inmodel, 'Display', 'off');
```

Inspect the final models returned by `stepwisefit`.

```
finalmodel_def
```

```
finalmodel_def = 1x8 logical array
```

```
 1  0  1  1  0  1  1  0
```

```
finalmodel_in
```

```
finalmodel_in = 1x8 logical array
```

```
1 0 1 1 0 1 0 1
```

The default model drops `highway-mpg` (term 8) from the model and includes `city-mpg` (term 7) instead. Compare the root mean squared errors (RMSEs) of these two final models.

```
stats_def.rmse
```

```
ans = 3.3033e+03
```

```
stats_in.rmse
```

```
ans = 3.3324e+03
```

The model resulting from the default arguments has a slightly lower RMSE. Note that a full specification of the final model consists of the term estimates plus the intercept estimate.

```
betahat_def % Term estimates
```

```
betahat_def = 8x1
103 ×
```

```
0.1559
-0.2242
-2.8578
0.3904
0.0222
0.0024
-0.2414
0.0793
```

```
stats_def.intercept % Intercept estimate
```

```
ans = -7.3506e+03
```

Retrieve the history of the default run of `stepwisefit` and the recommended next step. Omit the display of step information.

```
[~,~,~,~,~,nextstep_def,history_def]=stepwisefit(Xstepw,ystepw,'Display','off');
nextstep_def
```

```
nextstep_def = 0
```

No further steps are recommended (`nextstep_def` is 0).

```
history_def('in')
```

```
ans = 7x8 logical array
```

```
1 0 0 0 0 0 0 0
1 0 0 0 1 0 0 0
1 0 0 1 1 0 0 0
1 0 1 1 1 0 0 0
1 0 1 1 1 1 0 0
1 0 1 1 1 1 1 0
1 0 1 1 0 1 1 0
```

The algorithm performs a total of seven steps. The output shows that `engine-size` (term 1) is added in step 1, `horsepower` (term 5) is added in step 2, and so on.

Input Arguments

X — Predictor variables

numeric matrix

Predictor variables, specified as an n -by- p numeric matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

`stepwisefit` always includes a constant term in the model. Therefore, do not include a column of 1s in X .

Data Types: `single` | `double`

y — Response variable

numeric or logical vector

Response variable, specified as an n -by-1 numeric or logical vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X .

Data Types: `single` | `double` | `logical`

Note `stepwisefit` treats NaN values in either X or y as missing and ignores all rows containing these values.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'PEnter', 0.10, 'PRemove', 0.15, 'MaxIter', 8` instructs `stepwisefit` to use entry and exit tolerances of 0.10 and 0.15, respectively, and to take a maximum of 8 steps.

InModel — Terms for initial model

logical vector

Terms for the initial model, specified as the comma-separated pair consisting of `'InModel'` and a logical vector specifying terms to include in the initial model. The default is to include no terms.

Example: `'InModel', [true false false true]`

Data Types: `logical`

PEnter — Tolerance for adding terms to model

0.05 (default) | positive scalar

Tolerance for adding terms to the model, specified as the comma-separated pair consisting of `'PEnter'` and a positive scalar specifying the maximum p -value for a term to be added. The default is 0.05.

Example: 'PEnter',0.10

Data Types: single | double

PRemove — Tolerance for removing terms from model

maximum of PEnter and 0.10 (default) | positive scalar

Tolerance for removing terms from the model, specified as the comma-separated pair consisting of 'PRemove' and a positive scalar specifying the minimum p -value for a term to be removed. The default is the maximum of PEnter and 0.10.

Note PRemove is not allowed to be smaller than PEnter because that would cause `stepwisefit` to enter an infinite loop, where a variable is repeatedly added to the model and removed from the model.

Example: 'PRemove',0.15

Data Types: single | double

Display — Indicator for displaying step information

'on' (default) | 'off'

Indicator for displaying step information, specified as the comma-separated pair consisting of 'Display' and 'on' or 'off'.

- 'on' displays information about each step in the Command Window (default).
- 'off' omits the display.

Example: 'Display','off'

MaxIter — Maximum number of steps

Inf (default) | positive integer

Maximum number of steps, specified as the comma-separated pair consisting of 'MaxIter' and a positive integer or Inf (default). Inf allows the algorithm to run until no single step improves the model.

Example: 'MaxIter',12

Data Types: double

Keep — Terms to keep in their initial state

logical vector

Terms to keep in their initial state, specified as the comma-separated pair consisting of 'Keep' and a logical vector. The value `true` for a term specified to be in (or out of) the initial model forces that term to remain in (or out of) the final model. The value `false` for a term does not force that term to remain in (or out of) the final model. The default is to specify no terms to keep in their initial state.

Example: 'Keep',[true true false false]

Data Types: logical

Scale — Indicator for centering and scaling terms

'off' (default) | 'on'

Indicator for centering and scaling terms, specified as the comma-separated pair consisting of 'Scale' and 'off' or 'on'.

- 'off' does not center and scale the terms (default).
- 'on' centers and scales each column of X (computes the z-scores) before fitting.

Example: 'Scale', 'on'

Output Arguments

b — Estimated coefficients

numeric vector

Estimated coefficients, returned as a numeric vector corresponding to the terms in X. The `stepwisefit` function calculates the values in **b** as follows:

- If a term is included in the final model, then its corresponding value in **b** is the estimate resulting from fitting the final model.
- If a term is excluded from the final model, then its corresponding value in **b** is the estimate resulting from fitting the final model plus that term.

Note To obtain a full specification of the fitted model, you also need the estimated intercept in addition to **b**. The estimated intercept is provided as a field in the output argument `stats`. For more details see “stepwisefit Fitted Model” on page 32-5291.

se — Standard errors

numeric vector

Standard errors, returned as a numeric vector corresponding to the estimates in **b**.

pval — *p*-values

numeric vector

p-values, returned as a numeric vector that results from testing whether elements of **b** are 0.

finalmodel — Final model

logical vector

Final model, returned as a logical vector with length equal to the number of columns in X, indicating which terms are in the final model.

stats — Additional statistics

structure

Additional statistics, returned as a structure with the following fields. All statistics pertain to the final model except where noted.

Field	Description
source	Character vector 'stepwisefit'
dfe	Degrees of freedom for error

Field	Description
df0	Degrees of freedom for the regression
SStotal	Total sum of squares of the response
SSresid	Sum of squares of the residuals
fstat	<i>F</i> -statistic for testing the final model vs. no model (mean only)
pval	<i>p</i> -value of the <i>F</i> -statistic
rmse	Root mean squared error
xr	Residuals for terms not in the final model, computed by subtracting from each term the predicted response of the final model
yr	Residuals for the response using predictors in the final model
B	Coefficients for terms in the final model, with the value for each term not in the model set to the value that would be obtained by adding that term to the model
SE	Standard errors for coefficient estimates
TSTAT	<i>t</i> statistics for coefficient estimates
PVAL	<i>p</i> -values for coefficient estimates
intercept	Estimated intercept
wasnan	Rows in the data that contain NaN values

nextstep — Recommended next step

nonnegative integer

Recommended next step, returned as a nonnegative integer equal to the index of the next term to add to or remove from the model, or 0 if no further steps are recommended.

history — Information on steps taken

structure

Information on steps taken, returned as a structure with the following fields.

Field	Description
B	Matrix of regression coefficients, where each column is one step and each row is one coefficient vector
rmse	Root mean squared errors for the model at each step
df0	Degrees of freedom for the regression at each step
in	Logical array indicating which predictors are in the model at each step, where each row is one step and each column is one predictor

More About

stepwisefit Fitted Model

The final `stepwisefit` fitted model is

$$\hat{y} = \text{stats.intercept} + X(:, \text{finalmodel}) * b(\text{finalmodel}).$$

Here,

- \hat{y} is the predicted mean response.
- `stats.intercept` is the estimated intercept.
- `X(:, finalmodel)` is the input matrix for the terms in the final model.
- `b(finalmodel)` is the vector of coefficient estimates for the terms in the final model.

Algorithms

Stepwise regression is a method for adding terms to and removing terms from a multilinear model based on their statistical significance. This method begins with an initial model and then takes successive steps to modify the model by adding or removing terms. At each step, the p -value of an F -statistic is computed to test models with and without a potential term. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model. The method proceeds as follows:

- 1 Fit the initial model.
- 2 If any terms not in the model have p -values less than an entry tolerance, add the one with the smallest p -value and repeat this step. For example, assume the initial model is the default constant model and the entry tolerance is the default `0.05`. The algorithm first fits all models consisting of the constant plus another term and identifies the term that has the smallest p -value, for example term 4. If the term 4 p -value is less than `0.05`, then term 4 is added to the model. Next, the algorithm performs a search among all models consisting of the constant, term 4, and another term. If a term not in the model has a p -value less than `0.05`, the term with the smallest p -value is added to the model and the process is repeated. When no further terms exist that can be added to the model, the algorithm proceeds to step 3.
- 3 If any terms in the model have p -values greater than an exit tolerance, remove the one with the largest p -value and go to step 2; otherwise, end.

In each step of the algorithm, `stepwisefit` uses the method of least squares to estimate the model coefficients. After adding a term to the model at an earlier stage, the algorithm might subsequently drop that term if it is no longer helpful in combination with other terms added later. The method terminates when no single step improves the model. However, the final model is not guaranteed to be optimal, which means having the best fit to the data. A different initial model or a different sequence of steps might lead to a better fit. In this sense, stepwise models are locally optimal, but are not necessarily globally optimal.

Alternative Functionality

- You can create a model using `fitlm`, and then manually adjust the model using `step`, `addTerms`, and `removeTerms`.
- Use `stepwiselm` if you have data in a table, you have a mix of continuous and categorical predictors, or you want to specify model formulas that can potentially include higher-order and interaction terms.
- Use `stepwiseglm` to create stepwise generalized linear models (for example, if you have a binary response variable and want to fit a classification model).

Introduced before R2006a

subsasgn

Class: dataset

(Not Recommended) Subscripted assignment to dataset array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Description

`A = subsasgn(A,S,B)` is called for the syntax `A(i,j)=B`, `A{i,j}=B`, or `A.var=B` when `A` is a dataset array. `S` is a structure array with the fields:

<code>type</code>	'()', '{ }', or '.' specifying the subscript type.
<code>subs</code>	Cell array or character vector containing the actual subscripts.

`A(i,j) = B` assigns the contents of the dataset array `B` to a subset of the observations and variables in the dataset array `A`. `i` and `j` are one of the following types:

- positive integers
- vectors of positive integers
- observation/variable names
- cell arrays containing one or more observation/variable names
- logical vectors

The assignment does not use observation names, variable names, or any other properties of `B` to modify properties of `A`; however properties of `A` are extended with default values if the assignment expands the number of observations or variables in `A`. Elements of `B` are assigned into `A` by position, not by matching names.

`A{i,j} = B` assigns the value `B` into an element of the dataset array `A`. `i` and `J` are positive integers, or logical vectors. Cell indexing cannot assign into multiple dataset elements, that is, the subscripts `i` and `j` must each refer to only a single observation or variable. `B` is cast to the type of the target variable if necessary. If the dataset element already exists, `A{i,j}` may also be followed by further subscripting as supported by the variable.

For dataset variables that are cell arrays, assignments such as `A{1,'CellVar'} = B` assign into the contents of the target dataset element in the same way that `{}`-indexing of an ordinary cell array does.

For dataset variables that are n-D arrays, i.e., each observation is a matrix or array, an assignment such as `A{1,'ArrayVar'} = B` assigns into the second and following dimensions of the target dataset element, i.e., the assignment adds a leading singleton dimension to `B` to account for the observation dimension of the dataset variable.

`A.var = B` or `A.(varname) = B` assigns `B` to a dataset variable. `var` is a variable name literal, or `varname` is a character variable containing a variable name. If the dataset variable already exists, the

assignment completely replaces that variable. To assign into an element of the variable, `A.var` or `A.(varname)` may be followed by further subscripting as supported by the variable. In particular, `A.var(obsnames,...) = B` and `A.var{obsnames,...} = B` (when supported by `var`) provide assignment into a dataset variable using observation names.

`A.properties.propertyname = P` assigns to a dataset property. `propertyname` is one of the following:

- 'ObsNames'
- 'VarNames'
- 'Description'
- 'Units'
- 'DimNames'
- 'UserData'
- 'VarDescription'

To assign into an element of the property, `A.properties.propertyname` may also be followed by further subscripting as supported by the property.

You cannot assign multiple values into dataset variables or properties using assignments such as `[A.CellVar{1:2}] = B`, `[A.StructVar(1:2).field] = B`, or `[A.Properties.ObsNames{1:2}] = B`. Use multiple assignments of the form `A.CellVar{1} = B` instead.

Similarly, if a dataset variable is a cell array with multiple columns or is an n-D cell array, then the contents of that variable for a single observation consists of multiple cells, and you cannot assign to all of them using the syntax `A{1,'CellVar'} = B`. Use multiple assignments of the form `[A.CellVar{1,1}] = B` instead.

`dataset` | `set` | `subsref`

suboref

Class: dataset

(Not Recommended) Subscripted reference for dataset array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

`B = suboref(A,S)`

Description

`B = suboref(A,S)` is called for the syntax `A(i,j)`, `A{ i,j }`, or `A.var` when `A` is a dataset array. `S` is a structure array with the fields:

<code>type</code>	Character vector containing '()', '{}', or '.' specifying the subscript type.
<code>subs</code>	Cell array or character vector containing the actual subscripts.

`B = A(i,j)` returns a dataset array that contains a subset of the observations and variables in the dataset array `A`. `i` and `j` are one of the following types:

- positive integers
- vectors of positive integers
- observation/variable names
- cell arrays containing one or more observation/variable names
- logical vectors

`B` contains the same property values as `A`, subsetted for observations or variables where appropriate.

`B = A{ i,j }` returns an element of a dataset variable. `i` and `j` are positive integers, or logical vectors. Cell indexing cannot return multiple dataset elements, that is, the subscripts `i` and `j` must each refer to only a single observation or variable. `A{ i,j }` may also be followed by further subscripting as supported by the variable.

For dataset variables that are cell arrays, expressions such as `A{1, 'CellVar'}` return the contents of the referenced dataset element in the same way that `{}`-indexing on an ordinary cell array does. If the dataset variable is a single column of cells, the contents of a single cell is returned. If the dataset variable has multiple columns or is n-D, multiple outputs containing the contents of multiple cells are returned.

For dataset variables that are n-D arrays, i.e., each observation is a matrix or an array, expressions such as `A{1, 'ArrayVar'}` return `A.ArrayVar(1, :, ...)` with the leading singleton dimension squeezed out.

`B = A.var` or `A.(varname)` returns a dataset variable. `var` is a variable name literal, or `varname` is a character variable containing a variable name. `A.var` or `A.(varname)` may also be followed by further subscripting as supported by the variable. In particular, `A.var(obsnames, ...)` and `A.var{obsnames, ...}` (when supported by `var`) provide subscripting into a dataset variable using observation names.

`P = A.Properties.propertyname` returns a dataset property. `propertyname` is one of the following:

- 'ObsNames'
- 'VarNames'
- 'Description'
- 'Units'
- 'DimNames'
- 'UserData'
- 'VarDescription'

`A.properties.propertyname` may also be followed by further subscripting as supported by the property.

Limitations

Subscripting expressions such as `A.CellVar{1:2}`, `A.StructVar(1:2).field`, or `A.Properties.ObsNames{1:2}` are valid, but result in `subsref` returning multiple outputs in the form of a comma-separated list. If you explicitly assign to output arguments on the left-hand side of an assignment, for example, `[cellval1, cellval2] = A.CellVar{1:2}`, those variables will receive the corresponding values. However, if there are no output arguments, only the first output in the comma-separated list is returned.

Similarly, if a dataset variable is a cell array with multiple columns or is an n-D cell array, then subscripting expressions such as `A{1, 'CellVar'}` result in `subsref` returning the contents of multiple cells. You should explicitly assign to output arguments on the left-hand side of an assignment, for example, `[cellval1, cellval2] = A{1, 'CellVar'}`.

See Also

`dataset` | `set` | `subsasgn`

summary

Class: dataset

(Not Recommended) Print summary of dataset array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
summary(A)  
s = summary(A)
```

Description

`summary(A)` prints a summary of a dataset array and the variables that it contains.

`s = summary(A)` returns a scalar structure `s` that contains a summary of the dataset `A` and the variables that `A` contains. For more information on the fields in `s`, see [Outputs](#).

Summary information depends on the type of the variables in the data set:

- For numerical variables, `summary` computes a five-number summary of the data, giving the minimum, the first quartile, the median, the third quartile, and the maximum.
- For logical variables, `summary` counts the number of `true`s and `false`s in the data.
- For categorical variables, `summary` counts the number of data at each level.

Output Arguments

The following list describes the fields in the structure `s`:

- **Description** — A character array containing the dataset description.
- **Variables** — A structure array with one element for each dataset variable in `A`. Each element has the following fields:
 - **Name** — A character vector containing the name of the variable.
 - **Description** — A character vector containing the variable's description.
 - **Units** — A character vector containing the variable's units.
 - **Size** — A numeric vector containing the size of the variable.
 - **Class** — A character vector containing the class of the variable.
 - **Data** — A scalar structure containing the following fields.

For numeric variables:

- **Probabilities** — A numeric vector containing the probabilities [0.0 .25 .50 .75 1.0] and NaN (if any are present in the corresponding dataset variable).

- **Quantiles** — A numeric vector containing the values that correspond to 'Probabilities' for the corresponding dataset variable, and a count of NaNs (if any are present).

For logical variables:

- **Values** — The logical vector [true false].
- **Counts** — A numeric vector of counts for each logical value.

For categorical variables:

- **Levels** — A cell array containing the labels for each level of the corresponding dataset variable.
- **Counts** — A numeric vector of counts for each level.

'Data' is empty if variable is not numeric, categorical, or logical. If a dataset variable has more than one column, then the corresponding 'Quantiles' or 'Counts' field is a matrix or an array.

Examples

Summarize Fisher's iris data:

```
load fisheriris
species = nominal(species);
data = dataset(species,meas);
summary(data)
species: [150x1 nominal]
   setosa  versicolor  virginica
       50         50         50
meas: [150x4 double]
   min    4.3000    2         1    0.1000
   1st Q    5.1000    2.8000    1.6000    0.3000
   median  5.8000    3         4.3500    1.3000
   3rd Q    6.4000    3.3000    5.1000    1.8000
   max     7.9000    4.4000    6.9000    2.5000
```

Summarize the data in hospital.mat:

```
load hospital
summary(hospital)
```

Dataset array created from the data file hospital.dat.

The first column of the file ("id") is used for observation names. Other columns ("sex" and "smoke") have been converted from their original coded values into categorical and logical variables. Two sets of columns ("sys" and "dia", "trial1" through "trial4") have been combined into single variables with multivariate observations. Column headers have been replaced with more descriptive variable names. Units have been added where appropriate.

```
LastName: [100x1 cell array of character vectors]
Sex: [100x1 nominal]
      Female      Male
```

53 47

Age: [100x1 double, Units = Yrs]

min	1st Q	median	3rd Q	max
25	32	39	44	50

Weight: [100x1 double, Units = Lbs]

min	1st Q	median	3rd Q	max
111	130.5000	142.5000	180.5000	202

Smoker: [100x1 logical]

true	false
34	66

BloodPressure: [100x2 double, Units = mm Hg]

Systolic/Diastolic

min	109	68
1st Q	117.5000	77.5000
median	122	81.5000
3rd Q	127.5000	89
max	138	99

Trials: [100x1 cell, Units = Counts]

From zero to four measurement trials performed

struct2dataset

(Not Recommended) Convert structure array to dataset array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
ds = struct2dataset(S)
ds = struct2dataset(S,Name,Value)
```

Description

`ds = struct2dataset(S)` converts a structure array to a dataset array.

`ds = struct2dataset(S,Name,Value)` performs the conversion using additional options specified by one or more `Name,Value` pair arguments.

Examples

Convert Scalar Structure Array to Dataset Array

Convert a scalar structure array to a dataset array using the default options.

Create a structure array to convert.

```
S.Name = {'CLARK';'BROWN';'MARTIN'};
S.Gender = {'M';'F';'M'};
S.SystolicBP = [124;122;130];
S.DiastolicBP = [93;80;92];
S
```

```
S = struct with fields:
    Name: {3x1 cell}
    Gender: {3x1 cell}
    SystolicBP: [3x1 double]
    DiastolicBP: [3x1 double]
```

The scalar structure array has four fields, each with three rows.

Convert the structure array to a dataset array.

```
ds = struct2dataset(S)

ds =
    Name          Gender          SystolicBP    DiastolicBP
    {'CLARK' }    {'M' }          124           93
    {'BROWN' }    {'F' }          122           80
```

```

    {'MARTIN'}      {'M'}      130      92

```

The structure field names in `S` become the variable names in the output dataset array. The size of `ds` is 3-by-4.

Convert Nonscalar Structure Array to Dataset Array

Convert a nonscalar structure array to a dataset array, using one of the structure fields for observation names.

Create a nonscalar structure array to convert.

```

S(1,1).Name = 'CLARK';
S(1,1).Gender = 'M';
S(1,1).SystolicBP = 124;
S(1,1).DiastolicBP = 93;

S(2,1).Name = 'BROWN';
S(2,1).Gender = 'F';
S(2,1).SystolicBP = 122;
S(2,1).DiastolicBP = 80;

S(3,1).Name = 'MARTIN';
S(3,1).Gender = 'M';
S(3,1).SystolicBP = 130;
S(3,1).DiastolicBP = 92;

```

`S`

```

S=3x1 struct array with fields:
    Name
    Gender
    SystolicBP
    DiastolicBP

```

This is a 3-by-1 structure array with 4 fields.

Convert the structure array to a dataset array, using the `Name` field for observation names.

```

ds = struct2dataset(S, 'ReadObsNames', 'Name')

```

```

ds =
    CLARK      Gender      SystolicBP      DiastolicBP
    BROWN      {'F'}        122             80
    MARTIN     {'M'}        130             92

```

The size of `ds` is 3-by-3 because the structure field `Name` is used for observation names, and not as a dataset array variable.

```

ds.Properties.DimNames

```

```
ans = 1x2 cell
    {'Name'}    {'Variables'}
```

```
ds.Properties.ObsNames
```

```
ans = 3x1 cell
    {'CLARK' }
    {'BROWN' }
    {'MARTIN' }
```

Input Arguments

S — Input structure array

structure array

Input structure array to convert to a dataset array, specified as a scalar structure array with N fields, each with M rows, or a nonscalar M -by-1 structure array with N fields.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'ReadObsNames', 'myField'` specifies that the structure field, `myField`, contains observation names.

ReadObsNames — Name of structure field containing observation names for dataset array

`false` (default) | character vector | string scalar

Name of structure field containing observation names for the output dataset array, specified as the comma-separated pair consisting of `'ReadObsNames'` and a character vector or string scalar containing a field name from the input structure array, `S`. When you specify a field name, `struct2dataset` uses that field to create observation names, and sets `ds.Properties.DimNames` equal to `{ReadObsNames, 'Variables'}`.

For example, to specify that observation names are in the structure field, `Names`, use

Example: `'ReadObsNames', 'Names'`

By default, or if `ReadObsNames` is equal to `false`, `struct2dataset` does not create observation names unless you specify names using the name-value pair argument `ObsNames`.

ObsNames — Observation names for dataset array

string array | cell array of character vectors

Observation names for the output dataset array, specified as the comma-separated pair consisting of `'ObsNames'` and a string array or cell array of character vectors containing observation names. The names do not need to be valid MATLAB identifiers, but they must be unique.

AsScalar — Indicator for how to treat scalar structure

`false` | `true`

Indicator for how to treat a scalar input structure array, specified as the comma-separated pair consisting of 'AsScalar' and either `true` or `false`. The default value is `true` if `S` is a scalar structure array, and `false` otherwise.

By default, `struct2dataset` converts a scalar structure array with N fields, each with M rows, into an M -by- N dataset array.

If instead you set `AsScalar` equal to `false` for a scalar input structure array, then `struct2dataset` converts `S` to a dataset array with N observations.

Output Arguments

ds — Output dataset array

dataset array

Output dataset array, returned by default with M observations and N variables.

- If `S` is a scalar structure array with N fields, each with M rows, then `ds` is an M -by- N dataset array.
- If `S` is a nonscalar M -by-1 structure array with N fields, then `ds` is an M -by- N dataset array.
- If `S` is a scalar structure array with N fields, each with M rows, and `AsScalar` is set equal to `false`, then `ds` is a dataset array with N observations.

“Dataset Arrays” on page 2-112

Introduced in R2012b

surfht

Interactive contour plot

Syntax

```
surfht(z)  
surfht(x,y,z)
```

Description

`surfht(z)` creates an interactive contour plot of the data in matrix `z`. `surfht` treats the values in `z` as the height above the plane.

`surfht(x,y,z)` creates an interactive contour plot of the data in matrix `z`, using the `x`-axis values contained in `x` and the `y`-axis values contained in `y`.

Examples

Create an Interactive Contour Plot

This example shows how to use `surfht` to create an interactive contour plot.

Create a grid of the (x,y) domain from $(-2,-2)$ to $(2,2)$ using `meshgrid`.

```
[x,y] = meshgrid(-2:0.2:2, -2:0.2:2);
```

Evaluate the function $z(x,y) = x \times \exp(-x^2 - y^2)$ over this domain.

```
z = x.*exp(-x.^2 - y.^2);
```

Open an interactive contour plot. Since `meshgrid` creates a grid of the `x` and `y` values, open the plot using the first row of `x` and the first column of `y`.

```
surfht(x(1,:),y(:,1),z)
```

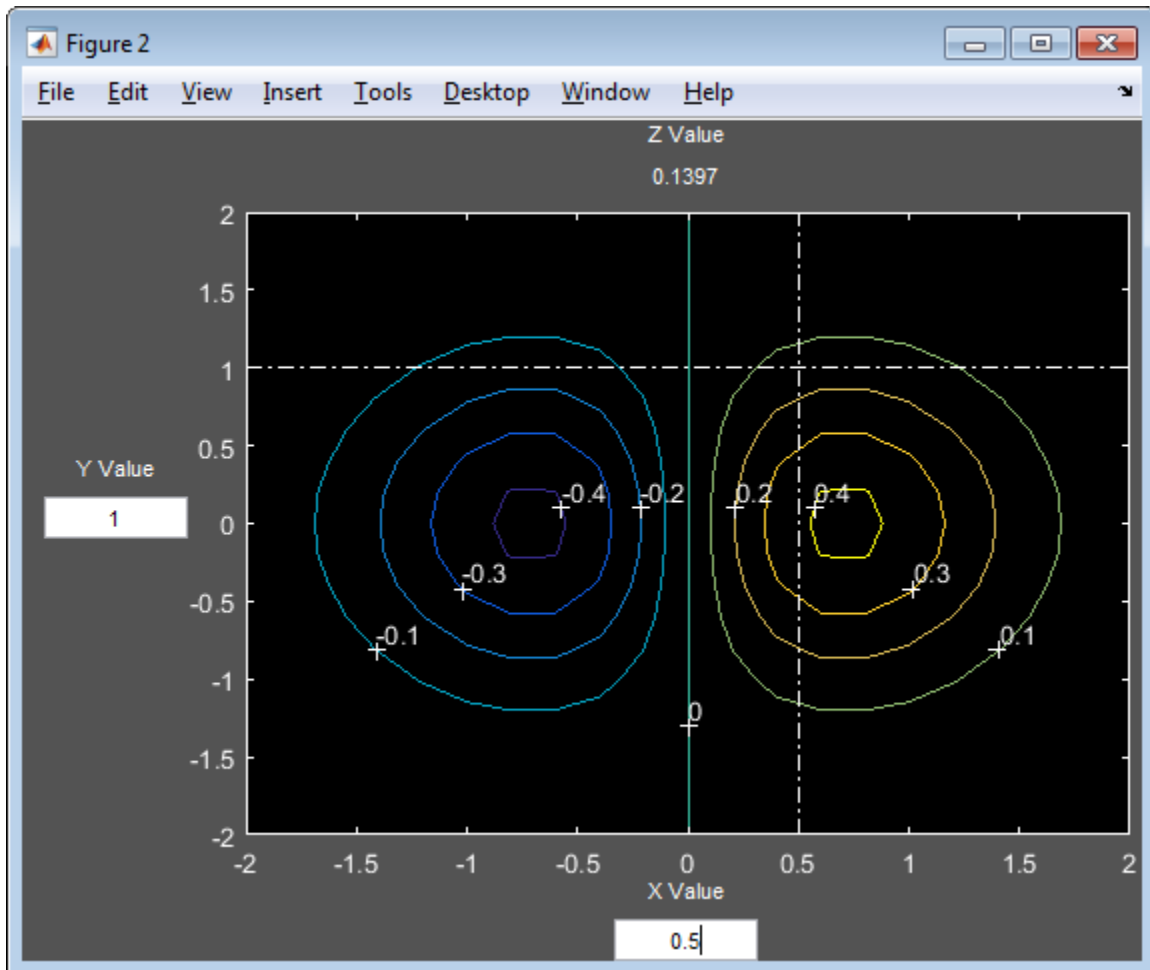

The figure shows a contour plot of the z values along the specified x- and y-axes.

Click the plot to evaluate z at the (x,y) coordinates indicated by the intersecting white lines.

For example, at $x = 0.71041$ and $y = 0.025723$, the value of z is 0.41827 .

Alternatively, enter values in the fields labeled **X Value** and **Y Value** to evaluate z at the specified coordinates. For example, evaluate z at $x = 0.5$ and $y = 1$.

The value of z is 0.1397.

Input Arguments

z — z-axis values for contour plot

numeric matrix

z -axis values for contour plot, specified as a numeric matrix.

`surfht` treats the values in z as the height above the plane. By default, the x -axis values of the plot are the column indices of z , and the y -axis values of the plot are the row indices of z . To change the x - and y -axis values, specify x and y , respectively.

Data Types: `single` | `double`

x — x-axis values for contour plot

column indices of z (default) | numeric vector

x -axis values for contour plot, specified as a numeric vector. The length of x must match the number of columns in z .

Data Types: `single` | `double`

y — y-axis values for contour plotrow indices of *z* (default) | numeric vector

y-axis values for contour plot, specified as a numeric vector. The length of *y* must match the number of rows in *z*.

Data Types: single | double

Tips

- The intersection of the vertical and horizontal reference lines on the interactive plot defines the current *x* value and *y* value.
- Drag the dotted white reference lines to watch the interpolated *z* value (at the top of the plot) update simultaneously.
- Alternatively, obtain a specific interpolated *z* value by typing the *x* value and *y* value into editable text fields on the *x*-axis and *y*-axis, respectively.

Introduced before R2006a

table2dataset

(Not Recommended) Convert table to dataset array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
ds = table2dataset(t)
```

Description

`ds = table2dataset(t)` converts a table to a dataset array.

Examples

Convert a Table to a Dataset Array

Load the sample data, which contains nutritional information for 77 cereals.

```
load cereal;
```

Create a table containing the calorie, protein, fat, and name data for the first five cereals. Label the variables.

```
Calories = Calories(1:5);
Protein = Protein(1:5);
Fat = Fat(1:5);
Name = Name(1:5);
```

```
cereal = table(Calories,Protein,Fat, 'RowNames',Name)
```

```
cereal=5x3 table
```

	Calories	Protein	Fat
100% Bran	70	4	1
100% Natural Bran	120	3	5
All-Bran	70	4	1
All-Bran with Extra Fiber	50	4	0
Almond Delight	110	2	2

Convert the table to a dataset array.

```
ds = table2dataset(cereal)
```

```
ds =
```

	Calories	Protein	Fat
100% Bran	70	4	1

100% Natural Bran	120	3	5
All-Bran	70	4	1
All-Bran with Extra Fiber	50	4	0
Almond Delight	110	2	2

Input Arguments

t — Input table

table

Input table to convert to a dataset array, specified as a table. Each variable in **t** becomes a variable in the output dataset array **ds**.

Data Types: table

Output Arguments

ds — Output dataset array

dataset array

Output dataset array, returned as a dataset array containing the variables from the input table **t**.

“Tables” (MATLAB)

Introduced in R2013b

tabulate

Frequency table

Syntax

```
tabulate(x)
tbl = tabulate(x)
```

Description

`tabulate(x)` displays a frequency table of the data in the vector `x`. For each unique value in `x`, the `tabulate` function shows the number of instances and percentage of that value in `x`. See `tbl`.

`tbl = tabulate(x)` returns the frequency table `tbl` as a numeric matrix when `x` is numeric and as a cell array otherwise.

Examples

Tabulate Data Vector

Create a frequency table for a vector of data.

Load the `patients` data set. Display the first five entries of the `Gender` variable. Each value indicates the gender of a patient.

```
load patients
Gender(1:5)
```

```
ans = 5x1 cell
    {'Male' }
    {'Male' }
    {'Female'}
    {'Female'}
    {'Female'}
```

Generate a frequency table that shows the number and percentage of `Male` and `Female` patients in the data set.

```
tabulate(Gender)
```

Value	Count	Percent
Male	47	47.00%
Female	53	53.00%

Tabulate Positive Integer Vector

Create a frequency table for a vector of positive integers. By default, if a vector `x` contains only positive integers, then `tabulate` returns 0 counts for the integers between 1 and `max(x)` that do not

appear in `x`. To avoid this behavior, convert the vector `x` to a `categorical` vector before calling `tabulate`.

Load the `patients` data set. Display the first five entries of the `Height` variable. Each value indicates the height, in inches, of a patient.

```
load patients
Height(1:5)
```

```
ans = 5×1
```

```
71
69
64
67
64
```

Create a frequency table that shows, in its second and third columns, the number and percentage of patients in the data set that have a particular height. Display the first five entries and the last five entries of the matrix that `tabulate` returns. `tbl` contains one row for each height between 1 and 72 inches, where 72 is the maximum height value in `Height`.

```
tbl = tabulate(Height);
first = tbl(1:5,:)
```

```
first = 5×3
```

```
1    0    0
2    0    0
3    0    0
4    0    0
5    0    0
```

```
last = tbl(end-4:end,:)
```

```
last = 5×3
```

```
68    15    15
69     8     8
70    11    11
71    10    10
72     4     4
```

Generate a frequency table that shows `Count` and `Percent` values only for heights that appear in the `Height` variable. Convert `Height` to a `categorical` variable, and then call the `tabulate` function.

```
newHeight = categorical(Height);
tabulate(newHeight)
```

Value	Count	Percent
60	1	1.00%
62	3	3.00%
63	7	7.00%
64	12	12.00%
65	8	8.00%

66	15	15.00%
67	6	6.00%
68	15	15.00%
69	8	8.00%
70	11	11.00%
71	10	10.00%
72	4	4.00%

Create Table Array from Tabulated Data

Create a frequency table from a character array by using `tabulate`. Convert the resulting cell array to a table array, and visualize the results.

Load the `carsmall` data set. Tabulate the data in the `Origin` variable, which shows the country of origin of each car in the data set. Convert the resulting cell array `tbl` to a table array `t`. Change the `Value` column to a categorical vector.

```
load carsmall
tbl = tabulate(Origin);
t = cell2table(tbl, 'VariableNames', ...
    {'Value', 'Count', 'Percent'});
t.Value = categorical(t.Value)
```

```
t=6x3 table
    Value    Count    Percent
    _____  _____  _____
    USA         69         69
    France        4          4
    Japan        15         15
    Germany       9          9
    Sweden        2          2
    Italy         1          1
```

Create a bar graph from the frequency table.

```
bar(t.Value,t.Count)
xlabel('Country of Origin')
ylabel('Number of Cars')
```

Tabulate Data with Missing Values

Create a frequency table from a numeric vector with NaN values.

Load the `carsmall` data set. The `MPG` variable contains the miles per gallon measurement of 100 cars. For six of the cars, the `MPG` value is missing (NaN).

```
load carsmall
numcars = length(MPG)

numcars = 100

nanindex = isnan(MPG);
numMissingMPG = length(MPG(nanindex))

numMissingMPG = 6
```

Create a frequency table using `MPG`. Convert the matrix output from `tabulate` to a table, and label the table columns.

```
tbl = tabulate(MPG);
t = array2table(tbl, 'VariableNames', ...
    {'Value', 'Count', 'Percent'})

t=37×3 table
    Value    Count    Percent
```

9	1	1.0638
10	2	2.1277
11	1	1.0638
13	4	4.2553
14	5	5.3191
14.5	1	1.0638
15	5	5.3191
15.5	1	1.0638
16	2	2.1277
16.5	2	2.1277
17	1	1.0638
17.5	2	2.1277
18	4	4.2553
18.5	1	1.0638
19	2	2.1277
20	2	2.1277
⋮		

The frequency table displays data only for the 94 cars with numeric MPG values. `tabulate` calculates the percentage of each MPG value in this subset of cars, not the entire set of 100 cars.

```
tnumcars = sum(t.Count)
```

```
tnumcars = 94
```

Input Arguments

x — Input data

numeric vector | logical vector | categorical vector | character array | string array | cell array of character vectors

Input data, specified as a numeric vector, logical vector, categorical vector, character array, string array, or cell array of character vectors.

- If `x` is a numeric vector, then `tbl` is a numeric matrix.
- If `x` is a logical vector, categorical vector, character array, string array, or cell array of character vectors, then `tbl` is a cell array.

Note If the elements of `x` are positive integers, then the frequency table includes 0 counts for the integers between 1 and `max(x)` that do not appear in `x`. For an example, see “Tabulate Positive Integer Vector” on page 32-5311.

Data Types: `single` | `double` | `logical` | `categorical` | `char` | `string` | `cell`

Output Arguments

tbl — Frequency table

numeric matrix | cell array

Frequency table, returned as a numeric matrix or cell array. `tbl` includes the following information.

Column	Description
1st column (Value)	Unique values of x
2nd column (Count)	Number of instances of each value
3rd column (Percent)	Percentage of each value

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

Introduced before R2006a

tblread

Read tabular data from file

Syntax

```
[data,varnames,casenames] = tblread
[data,varnames,casenames] = tblread(filename)
[data,varnames,casenames] = tblread(filename,delimiter)
```

Description

`[data,varnames,casenames] = tblread` displays the File Open dialog box for interactive selection of a tabular data file. The file format has variable names in the first row, case names in the first column and data starting in the (2, 2) position. Outputs are:

- `data` — Numeric matrix with a value for each variable-case pair
- `varnames` — Character matrix containing the variable names in the first row of the file
- `casenames` — Character matrix containing the names of each case in the first column of the file

`[data,varnames,casenames] = tblread(filename)` allows command line specification of the name of a file in the current folder, or the complete path name of any file, using the character vector or string scalar `filename`.

`[data,varnames,casenames] = tblread(filename,delimiter)` reads from the file using `delimiter` as the delimiting character. Accepted values for `delimiter` are:

- ' ' or 'space'
- '\t' or 'tab'
- ',' or 'comma'
- ';' or 'semi'
- '|' or 'bar'

The default value of `delimiter` is 'space'.

Examples

```
[data,varnames,casenames] = tblread('sat.dat')
data =
    470  530
    520  480

varnames =
Male
Female

casenames =
Verbal
Quantitative
```

See Also

caseread | readtable | tblwrite | tdfread

Introduced before R2006a

tblwrite

Write tabular data to file

Syntax

```
tblwrite(data,varnames,casenames)
tblwrite(data,varnames,casenames,filename)
tblwrite(data,varnames,casenames,filename,delimiter)
```

Description

`tblwrite(data,varnames,casenames)` displays the **File Open** dialog box for interactive specification of the tabular data output file. The file format has variable names in the first row, case names in the first column and data starting in the (2,2) position.

`varnames` is a character matrix or string array containing the variable names. `casenames` is a character matrix or string array containing the names of each case in the first column. `data` is a character matrix or string array with a value for each variable-case pair.

`tblwrite(data,varnames,casenames,filename)` specifies a file in the current folder, or the complete path name of any file in the character vector or string scalar `filename`.

`tblwrite(data,varnames,casenames,filename,delimiter)` writes to the file using `delimiter` as the delimiting character. The following table lists the accepted values for `delimiter` and their equivalent names.

Value	Name
' '	'space'
'\t'	'tab'
','	'comma'
';'	'semi'
' '	'bar'

The default value of `delimiter` is 'space'.

Examples

Continuing the example from `tblread`:

```
tblwrite(data,varnames,casenames,'sattest.dat')
type sattest.dat
```

	Male	Female
Verbal	470	530
Quantitative	520	480

`casewrite` | `tblread` | `writetable`

Introduced before R2006a

tcdf

Student's t cumulative distribution function

Syntax

```
p = tcdf(x,nu)
```

```
p = tcdf(x,nu,'upper')
```

Description

`p = tcdf(x,nu)` returns the cumulative distribution function (cdf) of the Student's t distribution with nu degrees of freedom, evaluated at the values in x .

`p = tcdf(x,nu,'upper')` returns the complement of the cdf, evaluated at the values in x with nu degrees of freedom, using an algorithm that more accurately computes the extreme upper-tail probabilities than subtracting the lower tail value from 1.

Examples

Compute Student's t Distribution cdf

Generate a random sample of size 100 from a normally distributed population with mean 1 and standard deviation 2.

```
rng default % For reproducibility
mu = 1;
n = 100;
sigma = 2;
x = normrnd(mu,sigma,n,1);
```

Compute the sample mean, sample standard deviation, and t -score of the sample.

```
xbar = mean(x);
s = std(x);
t = (xbar-mu)/(s/sqrt(n))
```

```
t = 1.0589
```

Use `tcdf` to compute the probability of a sample of size 100 having a larger t -score than the t -score of the sample.

```
p = 1-tcdf(t,n-1)
```

```
p = 0.1461
```

This probability is the same as the p value returned by a t test with null hypothesis that the sample comes from a normal population with mean 1 and alternative hypothesis that the mean is greater than 1.

```
[h,ptest] = ttest(x,mu,0.05,'right');
ptest

ptest = 0.1461
```

Compute Complementary cdf (Tail Distribution)

Determine the probability that an observation from the Student's t distribution with degrees of freedom 99 falls on the interval $[10 \text{ } \text{Inf}]$.

```
p1 = 1 - tcdf(10,99)
```

```
p1 = 0
```

`tcdf(10,99)` is nearly 1, so `p1` becomes 0. Specify 'upper' so that `tcdf` computes the extreme upper-tail probabilities more accurately.

```
p2 = tcdf(10,99,'upper')
```

```
p2 = 5.4699e-17
```

You can also use 'upper' to compute a right-tailed p -value.

Input Arguments

x — Values at which to evaluate cdf

scalar value | array of scalar values

Values at which to evaluate the cdf, specified as a scalar value or an array of scalar values.

- To evaluate the cdf at multiple values, specify `x` using an array.
- To evaluate the cdfs of multiple distributions, specify `nu` using an array.

If either or both of the input arguments `x` and `nu` are arrays, then the array sizes must be the same. In this case, `tcdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding element in `x`.

Example: `[-1,0,3,4]`

Data Types: `single` | `double`

nu — Degrees of freedom

positive scalar value | array of positive scalar values

Degrees of freedom for the Student's t distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the cdf at multiple values, specify `x` using an array.
- To evaluate the cdfs of multiple distributions, specify `nu` using an array.

If either or both of the input arguments `x` and `nu` are arrays, then the array sizes must be the same. In this case, `tcdf` expands each scalar input into a constant array of the same size as the array

inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding element in `x`.

Example: [9, 19, 49, 99]

Data Types: `single` | `double`

Output Arguments

`p` — cdf values

scalar value | array of scalar values

cdf values evaluated at the values in `x`, returned as a scalar value or an array of scalar values. `p` is the same size as `x` and `nu` after any necessary scalar expansion. Each element in `p` is the cdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding element in `x`.

More About

Student's t cdf

The Student's t distribution is a one-parameter family of curves. The parameter ν is the degrees of freedom. The Student's t distribution has zero mean.

The cdf of the Student's t distribution is

$$p = F(x | \nu) = \int_{-\infty}^x \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu\pi}} \frac{1}{\left(1 + \frac{t^2}{\nu}\right)^{\frac{\nu+1}{2}}} dt,$$

where ν is the degrees of freedom and $\Gamma(\cdot)$ is the Gamma function. The result p is the probability that a single observation from the t distribution with ν degrees of freedom falls in the interval $[-\infty, x]$.

For more information, see "Student's t Distribution" on page B-149.

Alternative Functionality

- `tcdf` is a function specific to the Student's t distribution. Statistics and Machine Learning Toolbox also offers the generic function `cdf`, which supports various probability distributions. To use `cdf`, specify the probability distribution name and its parameters. Note that the distribution-specific function `tcdf` is faster than the generic function `cdf`.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

“Student's t Distribution” on page B-149

Introduced before R2006a

tdfread

Read tab-delimited file

Syntax

```
tdfread
tdfread(filename)
tdfread(filename,delimiter)

s = tdfread( ___ )
```

Description

`tdfread` opens the Select File to Open dialog box for interactive selection of a data file, and reads the data from the file you select. `tdfread` can read data from tab-delimited text files with `.txt`, `.dat`, or `.csv` file extensions.

Select a file that has variable names in the first row and values separated by tabs in the remaining rows. `tdfread` creates a variable in the workspace for each column of the file, and names each variable according to its first row value.

- If a column contains only numeric data in all rows except the first, then `tdfread` creates a `double` variable.
- Otherwise, `tdfread` creates a `char` variable.

After importing all values, `tdfread` displays information about the imported variables, such as their size, bytes, and class.

`tdfread(filename)` creates variables from the data in `filename`, which is either the name of a file in the current folder or the complete path name of a file.

`tdfread(filename,delimiter)` indicates that the character specified by `delimiter` separates values in the file.

`s = tdfread(___)` returns a structure `s` in which each field contains a variable. Specify any of the input argument combinations in the previous syntaxes.

Examples

Create Workspace Variables from Text File

Display the contents of the `sat2.dat` file. Note that the first row of the file contains the variable names.

```
type sat2.dat
```

```
Test,Gender,Score
Verbal,Male,470
Verbal,Female,530
```

```
Quantitative, Male, 520
Quantitative, Female, 480
```

In the workspace, create the variables `Gender`, `Score`, and `Test` from the columns of the file. Because commas separate the values in the file, specify `' , '` as the delimiter.

```
tdfread('sat2.dat', ',')
```

Name	Size	Bytes	Class	Attributes
Gender	4x6	48	char	
Score	4x1	32	double	
Test	4x12	96	char	

Input Arguments

filename — Name of file to read

character vector | string scalar

Name of the file to read, specified as a character vector or string scalar.

Depending on the location of the file, `filename` has one of these forms.

Location of File	Form
Current folder or folder on the MATLAB path	Specify the name of the file in <code>filename</code> . Example: <code>'myTextFile.txt'</code>
Folder that is not the current folder or a folder on the MATLAB path	Specify the full or relative path name in <code>filename</code> . Example: <code>'C:\myFolder\myTextFile.txt'</code>

Example: `'sat2.dat'`

Data Types: `char` | `string`

delimiter — Delimiter character

`'\t'` or `'tab'` (default) | `'bar'` | `'comma'` | `'semi'` | `'space'` | ...

Delimiter character, specified as one of the values in this table.

Value	Description
<code>' '</code>	Vertical bar
<code>'bar'</code>	
<code>' , '</code>	Comma
<code>'comma'</code>	
<code>' ; '</code>	Semicolon
<code>'semi'</code>	

Value	Description
' '	Space
'space'	
'\t'	Tab
'tab'	

Example: ' , '

Data Types: char | string

Alternative Functionality

Consider using the `readtable`, `readmatrix`, or `readcell` MATLAB functions to import data. These functions provide more flexible data importing options than `tdfread`.

See Also

Import Tool | `readcell` | `readmatrix` | `readtable` | `textscan`

Introduced before R2006a

ClassificationDiscriminant.template

Class: ClassificationDiscriminant

(Not Recommended) Discriminant analysis classifier template for ensemble

Note ClassificationDiscriminant.template is not recommended. Use templateDiscriminant instead.

Syntax

```
t = ClassificationDiscriminant.template()
t = ClassificationDiscriminant.template(Name,Value)
```

Description

t = ClassificationDiscriminant.template() returns a learner template suitable to use in the fitcensemble function.

t = ClassificationDiscriminant.template(Name,Value) creates a template with additional options specified by one or more Name,Value pair arguments.

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Delta — Linear coefficient threshold

0 (default) | nonnegative scalar value

Linear coefficient threshold, specified as the comma-separated pair consisting of 'Delta' and a nonnegative scalar value. If a coefficient of Mdl has magnitude smaller than Delta, Mdl sets this coefficient to 0, and you can eliminate the corresponding predictor from the model. Set Delta to a higher value to eliminate more predictors.

Delta must be 0 for quadratic discriminant models.

Data Types: single | double

DiscrimType — Discriminant type

'linear' (default) | 'quadratic' | 'diaglinear' | 'diagquadratic' | 'pseudolinear' | 'pseudoquadratic'

Discriminant type, specified as the comma-separated pair consisting of 'DiscrimType' and a character vector in this table.

Value	Description	Predictor Covariance Treatment
'linear'	Regularized linear discriminant analysis (LDA)	<ul style="list-style-type: none"> All classes have the same covariance matrix. $\widehat{\Sigma}_\gamma = (1 - \gamma)\widehat{\Sigma} + \gamma\text{diag}(\widehat{\Sigma})$. <p>$\widehat{\Sigma}$ is the empirical, pooled covariance matrix and γ is the amount of regularization.</p>
'diaglinear'	LDA	All classes have the same, diagonal covariance matrix.
'pseudolinear'	LDA	All classes have the same covariance matrix. The software inverts the covariance matrix using the pseudo inverse.
'quadratic'	Quadratic discriminant analysis (QDA)	The covariance matrices can vary among classes.
'diagquadratic'	QDA	The covariance matrices are diagonal and can vary among classes.
'pseudoquadratic'	QDA	The covariance matrices can vary among classes. The software inverts the covariance matrix using the pseudo inverse.

Note To use regularization, you must specify 'linear'. To specify the amount of regularization, use the **Gamma** name-value pair argument.

Example: 'DiscrimType', 'quadratic'

FillCoeffs — Coeffs property flag

'on' | 'off'

Coeffs property flag, specified as the comma-separated pair consisting of 'FillCoeffs' and 'on' or 'off'. Setting the flag to 'on' populates the **Coeffs** property in the classifier object. This can be computationally intensive, especially when cross-validating. The default is 'on', unless you specify a cross-validation name-value pair, in which case the flag is set to 'off' by default.

Example: 'FillCoeffs', 'off'

Gamma — Amount of regularization

scalar value in the interval [0,1]

Amount of regularization to apply when estimating the covariance matrix of the predictors, specified as the comma-separated pair consisting of 'Gamma' and a scalar value in the interval [0,1]. **Gamma** provides finer control over the covariance matrix structure than **DiscrimType**.

- If you specify 0, then the software does not use regularization to adjust the covariance matrix. That is, the software estimates and uses the unrestricted, empirical covariance matrix.

- For linear discriminant analysis, if the empirical covariance matrix is singular, then the software automatically applies the minimal regularization required to invert the covariance matrix. You can display the chosen regularization amount by entering `Mdl.Gamma` at the command line.
- For quadratic discriminant analysis, if at least one class has an empirical covariance matrix that is singular, then the software throws an error.
- If you specify a value in the interval (0,1), then you must implement linear discriminant analysis, otherwise the software throws an error. Consequently, the software sets `DiscrimType` to `'linear'`.
- If you specify 1, then the software uses maximum regularization for covariance matrix estimation. That is, the software restricts the covariance matrix to be diagonal. Alternatively, you can set `DiscrimType` to `'diagLinear'` or `'diagQuadratic'` for diagonal covariance matrices.

Example: `'Gamma',1`

Data Types: `single | double`

SaveMemory — Flag to save covariance matrix

`'off'` (default) | `'on'`

Flag to save covariance matrix, specified as the comma-separated pair consisting of `'SaveMemory'` and either `'on'` or `'off'`. If you specify `'on'`, then `fitcdiscr` does not store the full covariance matrix, but instead stores enough information to compute the matrix. The `predict` method computes the full covariance matrix for prediction, and does not store the matrix. If you specify `'off'`, then `fitcdiscr` computes and stores the full covariance matrix in `Mdl`.

Specify `SaveMemory` as `'on'` when the input matrix contains thousands of predictors.

Example: `'SaveMemory','on'`

Output Arguments

t — Discriminant analysis classification template

classification template object

Discriminant analysis classification template suitable to use in the `fitcensemble` function, returned as a classification template object. In an ensemble, `t` specifies how to create the discriminant analysis classifier.

Examples

Discriminant Analysis Template for Nondefault Options

Create a nondefault discriminant analysis template for use in `fitcensemble`.

Create a template for pseudolinear discriminant analysis.

```
t = ClassificationDiscriminant.template('discrimType','pseudoLinear')
```

```
t =  
Fit template for classification Discriminant.
```

```
DiscrimType: 'pseudoLinear'
```

```
Gamma: []  
Delta: []  
FillCoeffs: []  
SaveMemory: []  
Version: 1  
Method: 'Discriminant'  
Type: 'classification'
```

You can use `t` for ensemble learning.

See Also

`ClassificationDiscriminant` | `fitcensemble` | `templateDiscriminant`

ClassificationKNN.template

(Not Recommended) *k*-nearest neighbor classifier template for ensemble

Note ClassificationKNN.template is not recommended. Use templateKNN instead.

Syntax

```
t = ClassificationKNN.template()
t = ClassificationKNN.template(Name,Value)
```

Description

`t = ClassificationKNN.template()` returns a learner template suitable to use in the `fitcensemble` function.

`t = ClassificationKNN.template(Name,Value)` creates a template with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

BreakTies — Tie-breaking algorithm

'smallest' (default) | 'nearest' | 'random'

Tie-breaking algorithm used by the `predict` method if multiple classes have the same smallest cost, specified as the comma-separated pair consisting of `'BreakTies'` and one of the following:

- `'smallest'` — Use the smallest index among tied groups.
- `'nearest'` — Use the class with the nearest neighbor among tied groups.
- `'random'` — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the `K` nearest neighbors.

Example: `'BreakTies','nearest'`

BucketSize — Maximum data points in node

50 (default) | positive integer value

Maximum number of data points in the leaf node of the *kd*-tree, specified as the comma-separated pair consisting of `'BucketSize'` and a positive integer value. This argument is meaningful only when `NSMethod` is `'kdtree'`.

Example: `'BucketSize',40`

Data Types: single | double

Cov — Covariance matrix

nancov(X) (default) | positive definite matrix of scalar values

Covariance matrix, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix of scalar values representing the covariance matrix when computing the Mahalanobis distance. This argument is only valid when 'Distance' is 'mahalanobis'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: single | double

Distance — Distance metric

'cityblock' | 'chebychev' | 'correlation' | 'cosine' | 'euclidean' | 'hamming' | function handle | ...

Distance metric, specified as the comma-separated pair consisting of 'Distance' and a valid distance metric name or function handle. The allowable distance metric names depend on your choice of a neighbor-searcher method (see NSMethod).

NSMethod	Distance Metric Names
exhaustive	Any distance metric of ExhaustiveSearcher
kdtree	'cityblock', 'chebychev', 'euclidean', or 'minkowski'

This table includes valid distance metrics of ExhaustiveSearcher.

Distance Metric Names	Description
'cityblock'	City block distance.
'chebychev'	Chebychev distance (maximum coordinate difference).
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'cosine'	One minus the cosine of the included angle between observations (treated as vectors).
'euclidean'	Euclidean distance.
'hamming'	Hamming distance, percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix C. The default value of C is the sample covariance matrix of X, as computed by nancov(X). To specify a different value for C, use the 'Cov' name-value pair argument.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'Exponent' name-value pair argument.

Distance Metric Names	Description
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between X and a query point is scaled, meaning divided by a scale value S . The default value of S is the standard deviation computed from X , $S = \text{nanstd}(X)$. To specify another value for S , use the <code>Scale</code> name-value pair argument.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
@ <i>distfun</i>	Distance function handle. <i>distfun</i> has the form <pre>function D2 = distfun(ZI,ZJ) % calculation of distance ... </pre> where <ul style="list-style-type: none"> • ZI is a 1-by-N vector containing one row of X or Y. • ZJ is an $M2$-by-N matrix containing multiple rows of X or Y. • $D2$ is an $M2$-by-1 vector of distances, and $D2(k)$ is the distance between observations ZI and $ZJ(k, :)$.

If you specify `CategoricalPredictors` as 'all', then the default distance metric is 'hamming'. Otherwise, the default distance metric is 'euclidean'.

For definitions, see “Distance Metrics” on page 18-11.

Example: 'Distance', 'minkowski'

Data Types: char | function_handle

DistanceWeight — Distance weighting function

'equal' (default) | 'inverse' | 'squaredinverse' | function handle

Distance weighting function, specified as the comma-separated pair consisting of 'DistanceWeight' and either a function handle or one of the values in this table.

Value	Description
'equal'	No weighting
'inverse'	Weight is $1/\text{distance}$
'squaredinverse'	Weight is $1/\text{distance}^2$
@ <i>fcn</i>	<i>fcn</i> is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to $@(d)d.^{-2}$.

Example: 'DistanceWeight', 'inverse'

Data Types: char | function_handle

Exponent — Minkowski distance exponent

2 (default) | positive scalar value

Minkowski distance exponent, specified as the comma-separated pair consisting of 'Exponent' and a positive scalar value. This argument is only valid when 'Distance' is 'minkowski'.

Example: 'Exponent',3

Data Types: single | double

IncludeTies — Tie inclusion flag

false (default) | true

Tie inclusion flag, specified as the comma-separated pair consisting of 'IncludeTies' and a logical value indicating whether `predict` includes all the neighbors whose distance values are equal to the `K`th smallest distance. If `IncludeTies` is true, `predict` includes all these neighbors. Otherwise, `predict` uses exactly `K` neighbors.

Example: 'IncludeTies',true

Data Types: logical

NSMethod — Nearest neighbor search method

'kdtree' | 'exhaustive'

Nearest neighbor search method, specified as the comma-separated pair consisting of 'NSMethod' and 'kdtree' or 'exhaustive'.

- 'kdtree' — Creates and uses a *kd*-tree to find nearest neighbors. 'kdtree' is valid when the distance metric is one of the following:
 - 'euclidean'
 - 'cityblock'
 - 'minkowski'
 - 'chebychev'
- 'exhaustive' — Uses the exhaustive search algorithm. When predicting the class of a new point `xnew`, the software computes the distance values from all points in `X` to `xnew` to find nearest neighbors.

The default is 'kdtree' when `X` has 10 or fewer columns, `X` is not sparse, and the distance metric is a 'kdtree' type; otherwise, 'exhaustive'.

Example: 'NSMethod','exhaustive'

NumNeighbors — Number of nearest neighbors to find

1 (default) | positive integer value

Number of nearest neighbors in `X` to find for classifying each point when predicting, specified as the comma-separated pair consisting of 'NumNeighbors' and a positive integer value.

Example: 'NumNeighbors',3

Data Types: single | double

Scale — Distance scale

nanstd(`X`) (default) | vector of nonnegative scalar values

Distance scale, specified as the comma-separated pair consisting of 'Scale' and a vector containing nonnegative scalar values with length equal to the number of columns in `X`. Each coordinate

difference between X and a query point is scaled by the corresponding element of `Scale`. This argument is only valid when `'Distance'` is `'seuclidean'`.

You cannot simultaneously specify `'Standardize'` and either of `'Scale'` or `'Cov'`.

Data Types: `single` | `double`

Output Arguments

t — Classification template

classification template object

K -nearest neighbor classification template suitable to use in the `fitcensemble` function. In an ensemble, `t` specifies how to create the KNN classifier.

Examples

KNN template for nondefault options

Create a nondefault k -nearest neighbor template for use in `fitcensemble`.

Create a template for 5-nearest neighbor search.

```
t = ClassificationKNN.template('NumNeighbors',5)
```

```
t =  
Fit template for classification KNN.
```

```
    NumNeighbors: 5  
      NSMethod: ''  
      Distance: ''  
    BucketSize: ''  
    IncludeTies: []  
    DistanceWeight: []  
      BreakTies: []  
      Exponent: []  
         Cov: []  
        Scale: []  
StandardizeData: []  
      Version: 1  
      Method: 'KNN'  
      Type: 'classification'
```

You can use `t` for ensemble learning.

Topics

“Random Subspace Classification” on page 18-103

ClassificationTree.template

Class: ClassificationTree

(Not Recommended) Create classification template

Note ClassificationTree.template is not recommended. Use templateTree instead.

Syntax

```
t = ClassificationTree.template
t = ClassificationTree.template(Name,Value)
```

Description

`t = ClassificationTree.template` returns a learner template suitable to use in the `fitcensemble` function.

`t = ClassificationTree.template(Name,Value)` creates a template with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

AlgorithmForCategorical

Algorithm to find the best split on a categorical predictor for data with $K = 3$ or more classes. The available algorithms are:

'Exact'

For a categorical predictor with C categories, consider all $2^{C-1} - 1$ combinations.

'PullLeft'

Start with all C categories on the right branch. Consider moving each category to the left branch as it achieves the minimum impurity for the K classes among the remaining categories. Out of this sequence, choose the split that has the lowest impurity.

'PCA'	Compute a score for each category using the inner product between the first principal component of a weighted covariance matrix (of the centered class probability matrix) and the vector of class probabilities for that category. Sort the scores in ascending order, and consider all $C - 1$ splits.
'OVAbyClass'	Start with all C categories on the right branch. For each class, order the categories based on their probability for that class. For the first class, consider moving each category to the left branch in order, recording the impurity criterion at each move. Repeat for the remaining classes. Out of this sequence, choose the split that has the minimum impurity.

Default: `ClassificationTree` selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For two classes, `ClassificationTree` always performs the exact search.

MaxCat

`ClassificationTree` splits a categorical predictor using the exact search algorithm if the predictor has at most `MaxCat` levels in the split node. Otherwise, `ClassificationTree` finds the best categorical split using one of the inexact algorithms.

Specify `MaxCat` as a numeric nonnegative scalar value. Passing a small value can lead to long computation time and memory overload.

Default: 10

MergeLeaves

Character vector that specifies whether to merge leaves after the tree is grown. Values are 'on' or 'off'.

When 'on', `ClassificationTree` merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When 'off', `ClassificationTree` does not merge leaves.

Default: 'off'

MinLeaf

Each leaf has at least `MinLeaf` observations per tree leaf. If you supply both `MinParent` and `MinLeaf`, `ClassificationTree` uses the setting that gives larger leaves: $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$.

Default: Half the number of training observations for boosting, 1 for bagging

MinParent

Each branch node in the tree has at least `MinParent` observations. If you supply both `MinParent` and `MinLeaf`, `ClassificationTree` uses the setting that gives larger leaves: $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$.

Default: Number of training observations for boosting, 2 for bagging

NVarToSample

Number of predictors to select at random for each split. Can be a positive integer or 'all', which means use all available predictors.

Default: 'all' for boosting, square root of number of predictors for bagging

Prune

When 'on', `ClassificationTree` grows the classification tree and computes the optimal sequence of pruned subtrees. When 'off' `ClassificationTree` grows the tree without pruning.

Default: 'off'

PruneCriterion

Character vector with the pruning criterion, either 'error' or 'impurity'.

Default: 'error'

SplitCriterion

Criterion for choosing a split. One of 'gdi' (Gini's diversity index), 'twoing' for the twoing rule, or 'deviance' for maximum deviance reduction (also known as cross entropy).

Default: 'gdi'

Surrogate

Character vector describing whether to find surrogate decision splits at each branch node. Specify as 'on', 'off', 'all', or a positive scalar value.

- When 'on', `ClassificationTree` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, `ClassificationTree` finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', `ClassificationTree` finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Default: 'off'

Output Arguments

t

Classification tree template suitable to use in the `fitcensemble` function. In an ensemble, `t` specifies how to grow the classification trees.

Examples

Construct a Classification Template with Surrogate Splits

Create a classification template with surrogate splits, and train an ensemble for the Fisher iris model with the template.

Load Fisher's iris data set.

```
load fisheriris
```

Create a decision tree template with surrogate splits and at least 50 observations per tree leaf.

```
t = ClassificationTree.template('surrogate', 'on', 'MinLeaf', 50)
```

```
t =
```

```
Fit template for classification Tree.
```

```

    SplitCriterion: []
        MinParent: []
            MinLeaf: 50
                MaxSplits: []
                    NVarToSample: []
                        MergeLeaves: []
                            Prune: []
                                PruneCriterion: []
                                    QEToler: []
                                        NSurrogate: 'on'
                                            MaxCat: []
                                                AlgCat: []
                                                    PredictorSelection: []
                                                        UseChisqTest: []
                                                            Stream: []
                                                                Reproducible: []
                                                                    Version: 2
                                                                        Method: 'Tree'
                                                                            Type: 'classification'
```

Specify `t` as a weak learner for a classification ensemble.

```
ens = fitcensemble(meas, species, 'Method', 'AdaBoostM2', 'Learners', t);
```

How well does the ensemble classify the training data? This can be an underestimate of the loss on new data, but is nonetheless interesting.

```
loss = resubLoss(ens)
```

```
loss = 0.0400
```

ClassificationTree | fitcensemble | fitctree | templateTree

RegressionTree.template

Class: RegressionTree

(Not Recommended) Create regression template

Note RegressionTree.template is not recommended. Use templateTree instead.

Syntax

```
t = RegressionTree.template
t = RegressionTree.template(Name, Value)
```

Description

t = RegressionTree.template returns a learner template suitable to use in the fitrensemble function.

t = RegressionTree.template(Name, Value) creates a template with additional options specified by one or more Name, Value pair arguments. You can specify several name-value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

MergeLeaves

Character vector that specifies whether to merge leaves after the tree is grown. Values are 'on' or 'off'.

When 'on', RegressionTree merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When 'off', RegressionTree does not merge leaves.

Default: 'off'

MinLeaf

Each leaf has at least MinLeaf observations per tree leaf. If you supply both MinParent and MinLeaf, RegressionTree uses the setting that gives larger leaves:
MinParent=max(MinParent, 2*MinLeaf).

Default: Half the number of training observations for boosting, 5 for bagging

MinParent

Each branch node in the tree has at least `MinParent` observations. If you supply both `MinParent` and `MinLeaf`, `RegressionTree` uses the setting that gives larger leaves: $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$.

Default: Number of training observations for boosting, 10 for bagging

NVarToSample

Number of predictors to select at random for each split. Can be a positive integer or 'all', which means use all available predictors.

Default: 'all' for boosting, one third of the number of predictors for bagging

Prune

When 'on', `RegressionTree` grows the regression tree and computes the optimal sequence of pruned subtrees. When 'off' `RegressionTree` grows the tree without pruning.

Default: 'off'

Surrogate

Character vector describing whether to find surrogate decision splits at each branch node. Specify as 'on', 'off', 'all', or a positive scalar value.

- When 'on', `RegressionTree` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, `RegressionTree` finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', `RegressionTree` finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Default: 'off'

Output Arguments

t

Regression tree template suitable to use in the `fitensemble` function. In an ensemble, `t` specifies how to grow the regression trees.

Examples

Create a Regression Template

Create a regression template with surrogate splits, and train an ensemble for the `carsmall` data with the template.

```
load carsmall
t = RegressionTree.template('surrogate','on');
```

```
X = [Acceleration Displacement Horsepower Weight];  
Y = MPG;  
ens = fitrensemble(X,Y,'Learners',t);
```

[RegressionTree](#) | [fitrensemble](#) | [fitrtree](#) | [templateTree](#)

templateDiscriminant

Discriminant analysis classifier template

Syntax

```
t = templateDiscriminant()
t = templateDiscriminant(Name,Value)
```

Description

`t = templateDiscriminant()` returns a discriminant analysis learner template suitable for training ensembles or error-correcting output code (ECOC) multiclass models.

If you specify a default template, then the software uses default values for all input arguments during training.

Specify `t` as a learner in `fitcensemble` or `fitcecoc`.

`t = templateDiscriminant(Name,Value)` creates a template with additional options specified by one or more name-value pair arguments.

For example, you can specify the discriminant type or the regularization parameter.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Create a Discriminant Analysis Template for Ensemble Learning

Create a nondefault discriminant analysis template for use in `fitcensemble`.

Load Fisher's iris data set.

```
load fisheriris
```

Create a template for pseudolinear discriminant analysis.

```
t = templateDiscriminant('DiscrimType','pseudoLinear')
```

```
t =
Fit template for classification Discriminant.
```

```
DiscrimType: 'pseudoLinear'
    Gamma: []
    Delta: []
  FillCoeffs: []
  SaveMemory: []
    Version: 1
    Method: 'Discriminant'
```

```
Type: 'classification'
```

All properties of the template object are empty except for `DiscrimType`, `Method`, and `Type`. When trained on, the software fills in the empty properties with their respective default values.

Specify `t` as a weak learner for a classification ensemble.

```
Mdl = fitensemble(meas,species,'Method','Subspace','Learners',t);
```

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl)
```

```
L = 0.0400
```

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'DiscrimType','pseudoLinear','SaveMemory','on'` specifies a template for pseudolinear discriminant analysis that does not store the full covariance matrix.

Delta — Linear coefficient threshold

0 (default) | nonnegative scalar value

Linear coefficient threshold, specified as the comma-separated pair consisting of `'Delta'` and a nonnegative scalar value. If a coefficient of `Mdl` has magnitude smaller than `Delta`, `Mdl` sets this coefficient to 0, and you can eliminate the corresponding predictor from the model. Set `Delta` to a higher value to eliminate more predictors.

`Delta` must be 0 for quadratic discriminant models.

Data Types: `single` | `double`

DiscrimType — Discriminant type

`'linear'` (default) | `'quadratic'` | `'diaglinear'` | `'diagquadratic'` | `'pseudolinear'` | `'pseudoquadratic'`

Discriminant type, specified as the comma-separated pair consisting of `'DiscrimType'` and a character vector or string scalar in this table.

Value	Description	Predictor Covariance Treatment
'linear'	Regularized linear discriminant analysis (LDA)	<ul style="list-style-type: none"> All classes have the same covariance matrix. $\widehat{\Sigma}_\gamma = (1 - \gamma)\widehat{\Sigma} + \gamma\text{diag}(\widehat{\Sigma})$. <p>$\widehat{\Sigma}$ is the empirical, pooled covariance matrix and γ is the amount of regularization.</p>
'diaglinear'	LDA	All classes have the same, diagonal covariance matrix.
'pseudolinear'	LDA	All classes have the same covariance matrix. The software inverts the covariance matrix using the pseudo inverse.
'quadratic'	Quadratic discriminant analysis (QDA)	The covariance matrices can vary among classes.
'diagquadratic'	QDA	The covariance matrices are diagonal and can vary among classes.
'pseudoquadratic'	QDA	The covariance matrices can vary among classes. The software inverts the covariance matrix using the pseudo inverse.

Note To use regularization, you must specify 'linear'. To specify the amount of regularization, use the **Gamma** name-value pair argument.

Example: 'DiscrimType', 'quadratic'

FillCoeffs — Coeffs property flag

'on' | 'off'

Coeffs property flag, specified as the comma-separated pair consisting of 'FillCoeffs' and 'on' or 'off'. Setting the flag to 'on' populates the **Coeffs** property in the classifier object. This can be computationally intensive, especially when cross-validating. The default is 'on', unless you specify a cross-validation name-value pair, in which case the flag is set to 'off' by default.

Example: 'FillCoeffs', 'off'

Gamma — Amount of regularization

scalar value in the interval [0,1]

Amount of regularization to apply when estimating the covariance matrix of the predictors, specified as the comma-separated pair consisting of 'Gamma' and a scalar value in the interval [0,1]. **Gamma** provides finer control over the covariance matrix structure than **DiscrimType**.

- If you specify 0, then the software does not use regularization to adjust the covariance matrix. That is, the software estimates and uses the unrestricted, empirical covariance matrix.

- For linear discriminant analysis, if the empirical covariance matrix is singular, then the software automatically applies the minimal regularization required to invert the covariance matrix. You can display the chosen regularization amount by entering `Mdl.Gamma` at the command line.
- For quadratic discriminant analysis, if at least one class has an empirical covariance matrix that is singular, then the software throws an error.
- If you specify a value in the interval (0,1), then you must implement linear discriminant analysis, otherwise the software throws an error. Consequently, the software sets `DiscrimType` to `'linear'`.
- If you specify 1, then the software uses maximum regularization for covariance matrix estimation. That is, the software restricts the covariance matrix to be diagonal. Alternatively, you can set `DiscrimType` to `'diagLinear'` or `'diagQuadratic'` for diagonal covariance matrices.

Example: `'Gamma',1`

Data Types: `single | double`

SaveMemory — Flag to save covariance matrix

`'off'` (default) | `'on'`

Flag to save covariance matrix, specified as the comma-separated pair consisting of `'SaveMemory'` and either `'on'` or `'off'`. If you specify `'on'`, then `fitcdiscr` does not store the full covariance matrix, but instead stores enough information to compute the matrix. The `predict` method computes the full covariance matrix for prediction, and does not store the matrix. If you specify `'off'`, then `fitcdiscr` computes and stores the full covariance matrix in `Mdl`.

Specify `SaveMemory` as `'on'` when the input matrix contains thousands of predictors.

Example: `'SaveMemory','on'`

Output Arguments

t — Discriminant analysis classification template

template object

Discriminant analysis classification template suitable for training ensembles or error-correcting output code (ECOC) multiclass models, returned as a template object. Pass `t` to `fitcensemble` or `fitcecoc` to specify how to create the discriminant analysis classifier for the ensemble or ECOC model, respectively.

If you display `t` to the Command Window, then all unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

See Also

`ClassificationDiscriminant` | `fitcecoc` | `fitcensemble` | `predict`

Introduced in R2014a

templateECOC

Error-correcting output codes learner template

Syntax

```
t = templateECOC()
t = templateECOC(Name,Value)
```

Description

`t = templateECOC()` returns an error-correcting output codes (ECOC) classification learner template.

If you specify a default template, then the software uses default values for all input arguments during training.

`t = templateECOC(Name,Value)` returns a template with additional options specified by one or more name-value pair arguments.

For example, you can specify a coding design, whether to fit posterior probabilities, or the types of binary learners.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Create a Default ECOC Classification Learner Template

Use `templateECOC` to create a default ECOC template.

```
t = templateECOC()

t =
Fit template for classification ECOC.

    BinaryLearners: ''
           Coding: ''
    FitPosterior: []
           Options: []
    VerbosityLevel: []
    NumConcurrent: []
           Version: 1
           Method: 'ECOC'
           Type: 'classification'
```

All properties of the template object are empty except for `Method` and `Type`. When you pass `t` to `testckfold`, the software fills in the empty properties with their respective default values. For

example, the software fills the `BinaryLearners` property with `'SVM'`. For details on other default values, see `fitcecoc`.

`t` is a plan for an ECOC learner. When you create it, no computation occurs. You can pass `t` to `testckfold` to specify a plan for an ECOC classification model to statistically compare with another model.

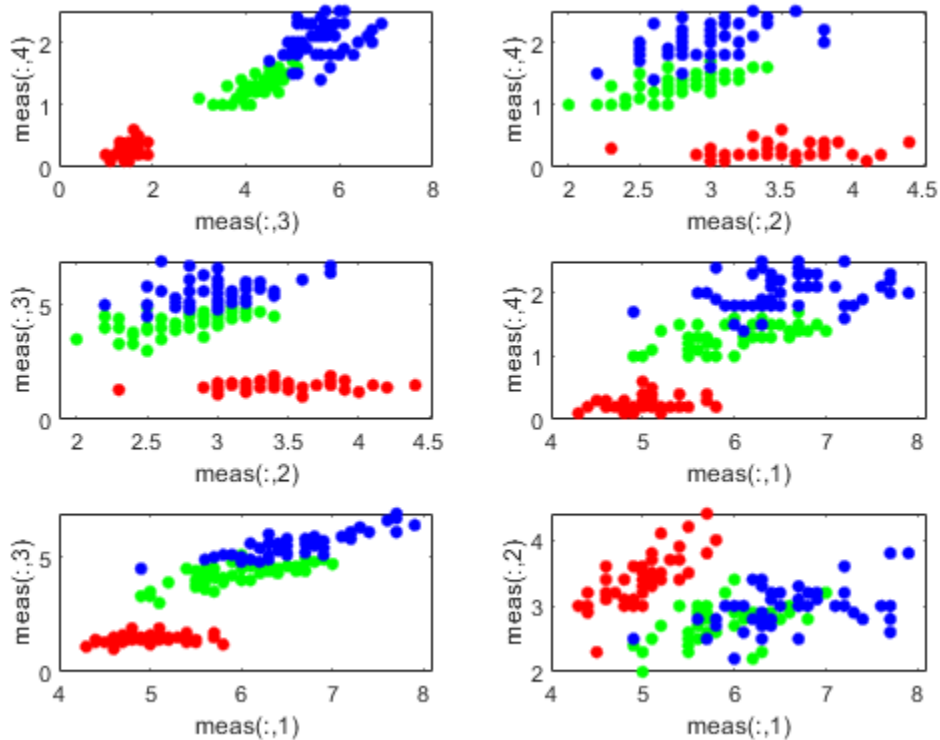

Statistically Compare Performance of Two ECOC Classification Models

One way to select predictors or features is to train two models where one that uses a subset of the predictors that trained the other. Statistically compare the predictive performances of the models. If there is sufficient evidence that model trained on fewer predictors performs better than the model trained using more of the predictors, then you can proceed with a more efficient model.

Load Fisher's iris data set. Plot all 2-dimensional combinations of predictors.

```
load fisheriris
d = size(meas,2); % Number of predictors
pairs = combnk(1:d,2);

figure;
for j = 1:size(pairs,1);
    subplot(3,2,j);
    gscatter(meas(:,pairs(j,1)),meas(:,pairs(j,2)),species);
    xlabel(sprintf('meas(:,%d)',pairs(j,1)));
    ylabel(sprintf('meas(:,%d)',pairs(j,2)));
    legend off;
end
```

Based on the scatterplot, `meas(:,3)` and `meas(:,4)` seem like they separate the groups well.

Create an ECOC template. Specify to use a one-versus-all coding design.

```
t = templateECOC('Coding','onevsall');
```

By default, the ECOC model uses linear SVM binary learners. You can choose other, supported algorithms by specifying them using the 'Learners' name-value pair argument.

Test whether an ECOC model that is just trained using predictors 3 and 4 performs at most as well as an ECOC model that is trained using all predictors. Rejecting this null hypothesis means that the ECOC model trained using predictors 3 and 4 performs better than the ECOC model trained using all predictors. Suppose C_1 represents the classification error of the ECOC model trained using predictors 3 and 4 and C_2 represents the classification error of the ECOC model trained using all predictors, then the test is:

$$H_0: C_1 \geq C_2$$

$$H_1: C_1 < C_2$$

By default, `testckfold` conducts a 5-by-2 k -fold F test, which is not appropriate as a one-tailed test. Specify to conduct a 5-by-2 k -fold t test.

```
rng(1); % For reproducibility
[h,pValue] = testckfold(t,t,meas(:,pairs(1,:)),meas,species,...
    'Alternative','greater','Test','5x2t')
```

```
h = logical
    0
```

```
pValue = 0.8940
```

The $h = 0$ indicates that there is not enough evidence to suggest that the model trained using predictors 3 and 4 is more accurate than the model trained using all predictors.

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'Coding', 'ternarycomplete', 'FitPosterior', true, 'Learners', 'tree'` specifies a ternary complete coding design, to transform scores to posterior probabilities, and to grow classification trees for all binary learners.

Coding — Coding design

`'onevsone'` (default) | `'allpairs'` | `'binarycomplete'` | `'denserandom'` | `'onevsall'` | `'ordinal'` | `'sparserandom'` | `'ternarycomplete'` | numeric matrix

Coding design name, specified as the comma-separated pair consisting of `'Coding'` and a numeric matrix or a value in this table.

Value	Number of Binary Learners	Description
<code>'allpairs'</code> and <code>'onevsone'</code>	$K(K - 1)/2$	For each binary learner, one class is positive, another is negative, and the software ignores the rest. This design exhausts all combinations of class pair assignments.
<code>'binarycomplete'</code>	$2^{(K - 1)} - 1$	This design partitions the classes into all binary combinations, and does not ignore any classes. For each binary learner, all class assignments are -1 and 1 with at least one positive and negative class in the assignment.
<code>'denserandom'</code>	Random, but approximately $10 \log_2 K$	For each binary learner, the software randomly assigns classes into positive or negative classes, with at least one of each type. For more details, see “Random Coding Design Matrices” on page 32-1532.

Value	Number of Binary Learners	Description
'onevsall'	K	For each binary learner, one class is positive and the rest are negative. This design exhausts all combinations of positive class assignments.
'ordinal'	$K - 1$	For the first binary learner, the first class is negative, and the rest positive. For the second binary learner, the first two classes are negative, the rest positive, and so on.
'sparserandom'	Random, but approximately $15 \log_2 K$	For each binary learner, the software randomly assigns classes as positive or negative with probability 0.25 for each, and ignores classes with probability 0.5. For more details, see "Random Coding Design Matrices" on page 32-1532.
'ternarycomplete'	$(3^K - 2^{(K+1)} + 1)/2$	This design partitions the classes into all ternary combinations. All class assignments are 0, -1, and 1 with at least one positive and one negative class in the assignment.

You can also specify a coding design using a custom coding matrix. The custom coding matrix is a K -by- L matrix. Each row corresponds to a class and each column corresponds to a binary learner. The class order (rows) corresponds to the order in `ClassNames`. Compose the matrix by following these guidelines:

- Every element of the custom coding matrix must be -1, 0, or 1, and the value must correspond to a dichotomous class assignment. This table describes the meaning of `Coding(i, j)`, that is, the class that learner j assigns to observations in class i .

Value	Dichotomous Class Assignment
-1	Learner j assigns observations in class i to a negative class.
0	Before training, learner j removes observations in class i from the data set.
1	Learner j assigns observations in class i to a positive class.

- Every column must contain at least one -1 or 1.
- For all column indices i, j such that $i \neq j$, `Coding(:, i)` cannot equal `Coding(:, j)` and `Coding(:, i)` cannot equal `-Coding(:, j)`.

- All rows of the custom coding matrix must be different.

For more details on the form of custom coding design matrices, see “Custom Coding Design Matrices” on page 32-1531.

Example: 'Coding', 'ternarycomplete'

Data Types: char | string | double | single | int16 | int32 | int64 | int8

FitPosterior — Flag indicating whether to transform scores to posterior probabilities

false or 0 (default) | true or 1

Flag indicating whether to transform scores to posterior probabilities, specified as the comma-separated pair consisting of 'FitPosterior' and a true (1) or false (0).

If `FitPosterior` is true, then the software transforms binary-learner classification scores to posterior probabilities. You can obtain posterior probabilities by using `kfoldPredict`, `predict`, or `resubPredict`.

`fitcecoc` does not support fitting posterior probabilities if:

- The ensemble method is `AdaBoostM2`, `LPBoost`, `RUSBoost`, `RobustBoost`, or `TotalBoost`.
- The binary learners (`Learners`) are linear or kernel classification models that implement SVM. To obtain posterior probabilities for linear or kernel classification models, implement logistic regression instead.

Example: 'FitPosterior', true

Data Types: logical

Learners — Binary learner templates

'svm' (default) | 'discriminant' | 'kernel' | 'knn' | 'linear' | 'naivebayes' | 'tree' | template object | cell vector of template objects

Binary learner templates, specified as the comma-separated pair consisting of 'Learners' and a character vector, string scalar, template object, or cell vector of template objects. Specifically, you can specify binary classifiers such as SVM, and the ensembles that use `GentleBoost`, `LogitBoost`, and `RobustBoost`, to solve multiclass problems. However, `fitcecoc` also supports multiclass models as binary classifiers.

- If `Learners` is a character vector or string scalar, then the software trains each binary learner using the default values of the specified algorithm. This table summarizes the available algorithms.

Value	Description
'discriminant'	Discriminant analysis. For default options, see <code>templateDiscriminant</code> .
'kernel'	Kernel classification model. For default options, see <code>templateKernel</code> .
'knn'	<i>k</i> -nearest neighbors. For default options, see <code>templateKNN</code> .
'linear'	Linear classification model. For default options, see <code>templateLinear</code> .

Value	Description
'naivebayes'	Naive Bayes. For default options, see <code>templateNaiveBayes</code> .
'svm'	SVM. For default options, see <code>templateSVM</code> .
'tree'	Classification trees. For default options, see <code>templateTree</code> .

- If `Learners` is a template object, then each binary learner trains according to the stored options. You can create a template object using:
 - `templateDiscriminant`, for discriminant analysis.
 - `templateEnsemble`, for ensemble learning. You must at least specify the learning method (`Method`), the number of learners (`NLearn`), and the type of learner (`Learners`). You cannot use the `AdaBoostM2` ensemble method for binary learning.
 - `templateKernel`, for kernel classification.
 - `templateKNN`, for k -nearest neighbors.
 - `templateLinear`, for linear classification.
 - `templateNaiveBayes`, for naive Bayes.
 - `templateSVM`, for SVM.
 - `templateTree`, for classification trees.
- If `Learners` is a cell vector of template objects, then:
 - Cell j corresponds to binary learner j (in other words, column j of the coding design matrix), and the cell vector must have length L . L is the number of columns in the coding design matrix. For details, see `Coding`.
 - To use one of the built-in loss functions for prediction, then all binary learners must return a score in the same range. For example, you cannot include default SVM binary learners with default naive Bayes binary learners. The former returns a score in the range $(-\infty, \infty)$, and the latter returns a posterior probability as a score. Otherwise, you must provide a custom loss as a function handle to functions such as `predict` and `loss`.
 - You cannot specify linear classification model learner templates with any other template.
 - Similarly, you cannot specify kernel classification model learner templates with any other template.

By default, the software trains learners using default SVM templates.

Example: `'Learners', 'tree'`

Output Arguments

t — ECOC classification template

template object

ECOC classification template, returned as a template object. Pass `t` to `testckfold` to specify how to create an ECOC classifier whose predictive performance you want to compare with another classifier.

If you display `t` to the Command Window, then all, unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

ClassificationECOC | designecoc | fitcecoc | predict | templateDiscriminant |
templateEnsemble | templateKNN | templateSVM | templateTree | testckfold

Introduced in R2015a

templateEnsemble

Ensemble learning template

Syntax

```
t = templateEnsemble(Method,NLearn,Learners)
t = templateEnsemble(Method,NLearn,Learners,Name,Value)
```

Description

`t = templateEnsemble(Method,NLearn,Learners)` returns an ensemble learning template that specifies to use the ensemble aggregation method `Method`, `NLearn` learning cycles, and weak learners `Learners`.

All other options of the template (`t`) specific to ensemble learning appear empty, but the software uses their corresponding default values during training.

`t = templateEnsemble(Method,NLearn,Learners,Name,Value)` returns an ensemble template with additional options specified by one or more name-value pair arguments.

For example, you can specify the number of predictors in each random subspace learner, learning rate for shrinkage, or the target classification error for `RobustBoost`.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those options that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Create an Ensemble Learning Template

Use `templateEnsemble` to specify an ensemble learning template. You must specify the ensemble method, the number of learning cycles, and the type of weak learners. For this example, specify the `AdaBoostM1` method, 100 learners, and classification tree weak learners.

```
t = templateEnsemble('AdaBoostM1',100,'tree')
```

```
t =
Fit template for classification AdaBoostM1.
```

```

      Type: 'classification'
      Method: 'AdaBoostM1'
LearnerTemplates: 'Tree'
      NLearn: 100
      LearnRate: []
```

All properties of the template object are empty except for `Method`, `Type`, `LearnerTemplates`, and `NLearn`. When trained on, the software fills in the empty properties with their respective default values. For example, the software fills the `LearnRate` property with 1.

`t` is a plan for an ensemble learner, and no computation takes place when you specify it. You can pass `t` to `fitcecoc` to specify ensemble binary learners for ECOC multiclass learning.

Create an Ensemble Template for ECOC Multiclass Learning

Create an ensemble template for use in `fitcecoc`.

Load the arrhythmia data set.

```
load arrhythmia
tabulate(categorical(Y));
```

Value	Count	Percent
1	245	54.20%
2	44	9.73%
3	15	3.32%
4	15	3.32%
5	13	2.88%
6	25	5.53%
7	3	0.66%
8	2	0.44%
9	9	1.99%
10	50	11.06%
14	4	0.88%
15	5	1.11%
16	22	4.87%

```
rng(1); % For reproducibility
```

Some classes have small relative frequencies in the data.

Create a template for a AdaBoostM1 ensemble of classification trees, and specify to use 100 learners and a shrinkage of 0.1. By default, boosting grows stumps (i.e., one node having a set of leaves). Since there are classes with small frequencies, the trees must be leafy enough to be sensitive to the minority classes. Specify the minimum number of leaf node observations to 3.

```
tTree = templateTree('MinLeafSize',20);
t = templateEnsemble('AdaBoostM1',100,tTree,'LearnRate',0.1);
```

All properties of the template objects are empty except for `Method` and `Type`, and the corresponding properties of the name-value pair argument values in the function calls. When you pass `t` to the training function, the software fills in the empty properties with their respective default values.

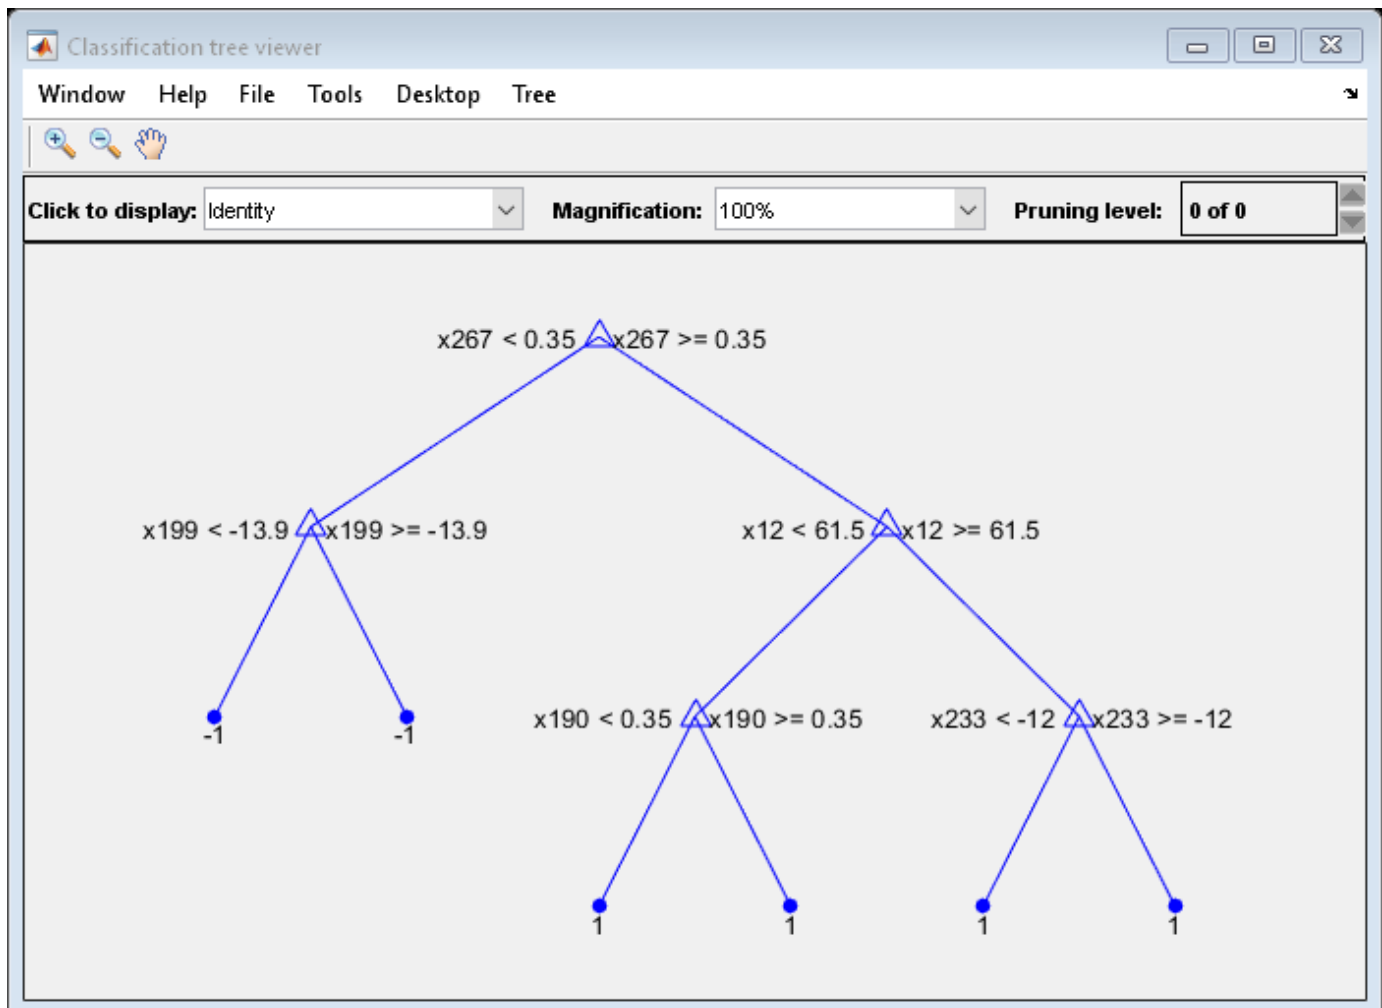

Specify `t` as a binary learner for an ECOC multiclass model. Train using the default one-versus-one coding design.

```
Mdl = fitcecoc(X,Y,'Learners',t);
```

- `Mdl` is a `ClassificationECOC` multiclass model.
- `Mdl.BinaryLearners` is a 78-by-1 cell array of `CompactClassificationEnsemble` models.
- `Mdl.BinaryLearners{j}.Trained` is a 100-by-1 cell array of `CompactClassificationTree` models, for $j = 1, \dots, 78$.

You can verify that one of the binary learners contains a weak learner that isn't a stump by using `view`.

```
view(Mdl.BinaryLearners{1}.Trained{1}, 'Mode', 'graph')
```

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl, 'LossFun', 'classiferror')
```

```
L = 0.0597
```

Speed Up Training ECOC Classifiers Using Binning and Parallel Computing

Train a one-versus-all ECOC classifier using a `GentleBoost` ensemble of decision trees with surrogate splits. To speed up training, bin numeric predictors and use parallel computing. Binning is valid only when `fitcecoc` uses a tree learner. After training, estimate the classification error using 10-fold cross-validation. Note that parallel computing requires Parallel Computing Toolbox™.

Load Sample Data

Load and inspect the `arrhythmia` data set.

```
load arrhythmia
[n,p] = size(X)

n = 452

p = 279

isLabels = unique(Y);
nLabels = numel(isLabels)

nLabels = 13

tabulate(categorical(Y))
```

Value	Count	Percent
1	245	54.20%
2	44	9.73%
3	15	3.32%
4	15	3.32%
5	13	2.88%
6	25	5.53%
7	3	0.66%
8	2	0.44%
9	9	1.99%
10	50	11.06%
14	4	0.88%
15	5	1.11%
16	22	4.87%

The data set contains 279 predictors, and the sample size of 452 is relatively small. Of the 16 distinct labels, only 13 are represented in the response (Y). Each label describes various degrees of arrhythmia, and 54.20% of the observations are in class 1.

Train One-Versus-All ECOC Classifier

Create an ensemble template. You must specify at least three arguments: a method, a number of learners, and the type of learner. For this example, specify `'GentleBoost'` for the method, `100` for the number of learners, and a decision tree template that uses surrogate splits because there are missing observations.

```
tTree = templateTree('surrogate','on');
tEnsemble = templateEnsemble('GentleBoost',100,tTree);
```

`tEnsemble` is a template object. Most of its properties are empty, but the software fills them with their default values during training.

Train a one-versus-all ECOC classifier using the ensembles of decision trees as binary learners. To speed up training, use binning and parallel computing.

- Binning (`'NumBins',50`) — When you have a large training data set, you can speed up training (a potential decrease in accuracy) by using the `'NumBins'` name-value pair argument. This argument is valid only when `fitcecoc` uses a tree learner. If you specify the `'NumBins'` value, then the software bins every numeric predictor into a specified number of equiprobable bins, and

then grows trees on the bin indices instead of the original data. You can try 'NumBins', 50 first, and then change the 'NumBins' value depending on the accuracy and training speed.

- Parallel computing ('Options', statset('UseParallel', true)) — With a Parallel Computing Toolbox license, you can speed up the computation by using parallel computing, which sends each binary learner to a worker in the pool. The number of workers depends on your system configuration. When you use decision trees for binary learners, fitcecoc parallelizes training using Intel® Threading Building Blocks (TBB) for dual-core systems and above. Therefore, specifying the 'UseParallel' option is not helpful on a single computer. Use this option on a cluster.

Additionally, specify that the prior probabilities are $1/K$, where $K = 13$ is the number of distinct classes.

```
options = statset('UseParallel', true);
Mdl = fitcecoc(X, Y, 'Coding', 'onevsall', 'Learners', tEnsemble, ...
    'Prior', 'uniform', 'NumBins', 50, 'Options', options);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

Mdl is a ClassificationECOC model.

Cross-Validation

Cross-validate the ECOC classifier using 10-fold cross-validation.

```
CVMDL = crossval(Mdl, 'Options', options);
```

```
Warning: One or more folds do not contain points from all the groups.
```

CVMDL is a ClassificationPartitionedECOC model. The warning indicates that some classes are not represented while the software trains at least one fold. Therefore, those folds cannot predict labels for the missing classes. You can inspect the results of a fold using cell indexing and dot notation. For example, access the results of the first fold by entering CVMDL.Trained{1}.

Use the cross-validated ECOC classifier to predict validation-fold labels. You can compute the confusion matrix by using confusionchart. Move and resize the chart by changing the inner position property to ensure that the percentages appear in the row summary.

```
oofLabel = kfoldPredict(CVMDL, 'Options', options);
ConfMat = confusionchart(Y, oofLabel, 'RowSummary', 'total-normalized');
ConfMat.InnerPosition = [0.10 0.12 0.85 0.85];
```

1	212	13			1	2				8			9	46.9%	7.3%	
2	19	20		1		1				1		1	1	4.4%	5.3%	
3		1	14											3.1%	0.2%	
4	3	1		10	1									2.2%	1.1%	
5	7				3					2			1	0.7%	2.2%	
6	1	1				22							1	4.9%	0.7%	
7	2		1												0.7%	
8	2														0.4%	
9									9					2.0%		
10	15				2	1				27			5	6.0%	5.1%	
14	3												1		0.9%	
15	1	1	1	1	1										1.1%	
16	14	2	1			2	1					1	1		4.9%	
	1	2	3	4	5	6	7	8	9	10	14	15	16			
	Predicted Class															

Reproduce Binned Data

Reproduce binned predictor data by using the `BinEdges` property of the trained model and the `discretize` function.

```
X = Mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = Mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

Xbinned contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. Xbinned values are 0 for categorical predictors. If X contains NaNs, then the corresponding Xbinned values are NaNs.

Input Arguments

Method — Ensemble aggregation method

'AdaBoostM1' | 'LogitBoost' | 'GentleBoost' | 'RUSBoost' | 'Subspace' | 'Bag' | 'AdaBoostM2' | 'LSBoost' | ...

Ensemble aggregation method, specified as one of the method names in this list.

- For classification with two classes:
 - 'AdaBoostM1'
 - 'LogitBoost'
 - 'GentleBoost'
 - 'RobustBoost' (requires Optimization Toolbox)
 - 'LPBoost' (requires Optimization Toolbox)
 - 'TotalBoost' (requires Optimization Toolbox)
 - 'RUSBoost'
 - 'Subspace'
 - 'Bag'
- For classification with three or more classes:
 - 'AdaBoostM2'
 - 'LPBoost' (requires Optimization Toolbox)
 - 'TotalBoost' (requires Optimization Toolbox)
 - 'RUSBoost'
 - 'Subspace'
 - 'Bag'
- For regression:
 - 'LSBoost'
 - 'Bag'

If you specify 'Method', 'Bag', then specify the problem type using the Type name-value pair argument, because you can specify 'Bag' for classification and regression problems.

For details about ensemble aggregation algorithms and examples, see “Ensemble Algorithms” on page 18-38 and “Choose an Applicable Ensemble Aggregation Method” on page 18-31.

NLearn — Number of ensemble learning cycles

positive integer | 'AllPredictorCombinations'

Number of ensemble learning cycles, specified as a positive integer or 'AllPredictorCombinations'.

- If you specify a positive integer, then, at every learning cycle, the software trains one weak learner for every template object in `Learners`. Consequently, the software trains $NLearn * numel(Learners)$ learners.
- If you specify `'AllPredictorCombinations'`, then set `Method` to `'Subspace'` and specify one learner only in `Learners`. With these settings, the software trains learners for all possible combinations of predictors taken `NPredToSample` at a time. Consequently, the software trains $nchoosek(size(X,2), NPredToSample)$ learners.

For more details, see “Tips” on page 32-5368.

Data Types: `single` | `double` | `char` | `string`

Learners — Weak learners to use in ensemble

weak-learner name | weak-learner template object | cell vector of weak-learner template objects

Weak learners to use in the ensemble, specified as a weak-learner name, weak-learner template object, or cell array of weak-learner template objects.

Weak Learner	Weak-Learner Name	Template Object Creation Function	Method Settings
Discriminant analysis	'Discriminant'	<code>templateDiscriminant</code>	Recommended for 'Subspace'
k nearest neighbors	'KNN'	<code>templateKNN</code>	For 'Subspace' only
Decision tree	'Tree'	<code>templateTree</code>	All methods except 'Subspace'

For more details, see `NLearn` and “Tips” on page 32-5368.

Example: For an ensemble composed of two types of classification trees, supply `{t1 t2}`, where `t1` and `t2` are classification tree templates.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'LearningRate', 0.05, 'NPrint', 5` specifies to use 0.05 as the learning rate and to display a message to the command line every time it trains 5 learners.

General Ensemble Options

NPrint — Printout frequency

'off' (default) | positive integer

Printout frequency, specified as the comma-separated pair consisting of `'NPrint'` and a positive integer or `'off'`.

To track the number of *weak learners* or *folds* that the software trained so far, specify a positive integer. That is, if you specify the positive integer m and:

- Do not specify any cross-validation option of the fitting function (for example, `CrossVal`), then the software displays a message to the command line every time it completes training m weak learners.

- A cross-validation option, then the software displays a message to the command line every time it finishes training m folds.

If you specify 'off', then the software does not display a message when it completes training weak learners.

Tip When training an ensemble of many weak learners on a large data set, specify a positive integer for `NPrint`.

Example: 'NPrint',5

Data Types: single | double | char | string

Type — Supervised learning type

'classification' | 'regression'

Supervised learning type, specified as the comma-separated pair consisting of 'Type' and 'classification' or 'regression'.

- If Method is 'bag', then the supervised learning type is ambiguous. Therefore, specify Type when bagging.
- Otherwise, the value of Method determines the supervised learning type.

Example: 'Type', 'classification'

Sampling Options for Boosting Methods and Bagging

FResample — Fraction of training set to resample

1 (default) | positive scalar in (0,1]

Fraction of the training set to resample for every weak learner, specified as the comma-separated pair consisting of 'FResample' and a positive scalar in (0,1].

To use 'FResample', specify 'bag' for Method or set Resample to 'on'.

Example: 'FResample',0.75

Data Types: single | double

Replace — Flag indicating to sample with replacement

'on' (default) | 'off'

Flag indicating sampling with replacement, specified as the comma-separated pair consisting of 'Replace' and 'off' or 'on'.

- For 'on', the software samples the training observations with replacement.
- For 'off', the software samples the training observations without replacement. If you set Resample to 'on', then the software samples training observations assuming uniform weights. If you also specify a boosting method, then the software boosts by reweighting observations.

Unless you set Method to 'bag' or set Resample to 'on', Replace has no effect.

Example: 'Replace', 'off'

Resample — Flag indicating to resample

'off' | 'on'

Flag indicating to resample, specified as the comma-separated pair consisting of 'Resample' and 'off' or 'on'.

- If Method is a boosting method, then:
 - 'Resample', 'on' specifies to sample training observations using updated weights as the multinomial sampling probabilities.
 - 'Resample', 'off' (default) specifies to reweight observations at every learning iteration.
- If Method is 'bag', then 'Resample' must be 'on'. The software resamples a fraction of the training observations (see FResample) with or without replacement (see Replace).

If you specify to resample using Resample, then it is good practice to resample to entire data set. That is, use the default setting of 1 for FResample.

AdaBoostM1, AdaBoostM2, LogitBoost, GentleBoost, and LSBoost Method Options**LearnRate — Learning rate for shrinkage**

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set LearnRate to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: 'LearnRate', 0.1

Data Types: single | double

RUSBoost Method Options**LearnRate — Learning rate for shrinkage**

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set LearnRate to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: 'LearnRate', 0.1

Data Types: single | double

RatioToSmallest — Sampling proportion with respect to lowest-represented class

positive numeric scalar | numeric vector of positive values

Sampling proportion with respect to the lowest-represented class, specified as the comma-separated pair consisting of 'RatioToSmallest' and a numeric scalar or numeric vector of positive values with length equal to the number of distinct classes in the training data.

Suppose that there are K classes in the training data and the lowest-represented class has m observations in the training data.

- If you specify the positive numeric scalar s , then the software samples $s*m$ observations from each class, that is, it uses the same sampling proportion for each class. For more details, see “Algorithms” on page 32-5369.
- If you specify the numeric vector $[s_1, s_2, \dots, s_K]$, then the software samples s_i*m observations from class i , $i = 1, \dots, K$. The elements of `RatioToSmallest` correspond to the order of the class names specified using the `ClassNames` name-value pair argument of the fitting function (see “Tips” on page 32-5368).

The default value is `ones(K, 1)`, which specifies to sample m observations from each class.

Example: `'RatioToSmallest', [2, 1]`

Data Types: `single` | `double`

LPBoost and TotalBoost Method Options

MarginPrecision — Margin precision to control convergence speed

0.1 (default) | numeric scalar in [0,1]

Margin precision to control convergence speed, specified as the comma-separated pair consisting of `'MarginPrecision'` and a numeric scalar in the interval [0,1]. `MarginPrecision` affects the number of boosting iterations required for convergence.

Tip To train an ensemble using many learners, specify a small value for `MarginPrecision`. For training using a few learners, specify a large value.

Example: `'MarginPrecision', 0.5`

Data Types: `single` | `double`

RobustBoost Method Options

RobustErrorGoal — Target classification error

0.1 (default) | nonnegative numeric scalar

Target classification error, specified as the comma-separated pair consisting of `'RobustErrorGoal'` and a nonnegative numeric scalar. The upper bound on possible values depends on the values of `RobustMarginSigma` and `RobustMaxMargin`. However, the upper bound cannot exceed 1.

Tip For a particular training set, usually there is an optimal range for `RobustErrorGoal`. If you set it too low or too high, then the software can produce a model with poor classification accuracy. Try cross-validating to search for the appropriate value.

Example: `'RobustErrorGoal', 0.05`

Data Types: `single` | `double`

RobustMarginSigma — Classification margin distribution spread

0.1 (default) | positive numeric scalar

Classification margin distribution spread over the training data, specified as the comma-separated pair consisting of 'RobustMarginSigma' and a positive numeric scalar. Before specifying RobustMarginSigma, consult the literature on RobustBoost, for example, [19].

Example: 'RobustMarginSigma',0.5

Data Types: single | double

RobustMaxMargin — Maximal classification margin

0 (default) | nonnegative numeric scalar

Maximal classification margin in the training data, specified as the comma-separated pair consisting of 'RobustMaxMargin' and a nonnegative numeric scalar. The software minimizes the number of observations in the training data having classification margins below RobustMaxMargin.

Example: 'RobustMaxMargin',1

Data Types: single | double

Random Subspace Method Options

NPredToSample — Number of predictors to sample

1 (default) | positive integer

Number of predictors to sample for each random subspace learner, specified as the comma-separated pair consisting of 'NPredToSample' and a positive integer in the interval $1, \dots, p$, where p is the number of predictor variables (`size(X,2)` or `size(Tbl,2)`).

Data Types: single | double

Output Arguments

t — Classification template for ensemble learning

classification template object

Classification template for ensemble learning, returned as a template object. You can pass `t` to, for example, `fitcecoc` to specify how to create the ensemble learning classifier for the ECOC model.

If you display `t` in the Command Window, then all, unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

Tips

- `NLearn` can vary from a few dozen to a few thousand. Usually, an ensemble with good predictive power requires from a few hundred to a few thousand weak learners. However, you do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and then, if necessary, train more weak learners using `resume` for classification problems, or `resume` for regression problems.
- Ensemble performance depends on the ensemble setting and the setting of the weak learners. That is, if you specify weak learners with default parameters, then the ensemble can perform. Therefore, like ensemble settings, it is good practice to adjust the parameters of the weak learners using templates, and to choose values that minimize generalization error.
- If you specify to resample using `Resample`, then it is good practice to resample to entire data set. That is, use the default setting of 1 for `FResample`.

- In classification problems (that is, `Type` is `'classification'`):
 - If the ensemble aggregation method (`Method`) is `'bag'` and:
 - The misclassification cost is highly imbalanced, then, for in-bag samples, the software oversamples unique observations from the class that has a large penalty.
 - The class prior probabilities are highly skewed, the software oversamples unique observations from the class that has a large prior probability.

For smaller sample sizes, these combinations can result in a very low relative frequency of out-of-bag observations from the class that has a large penalty or prior probability. Consequently, the estimated out-of-bag error is highly variable and it might be difficult to interpret. To avoid large estimated out-of-bag error variances, particularly for small sample sizes, set a more balanced misclassification cost matrix using the `Cost` name-value pair argument of the fitting function, or a less skewed prior probability vector using `Prior` name-value pair argument of the fitting function.

- Because the order of some input and output arguments correspond to the distinct classes in the training data, it is good practice to specify the class order using the `ClassNames` name-value pair argument of the fitting function.
 - To quickly determine the class order, remove all observations from the training data that are unclassified (that is, have a missing label), obtain and display an array of all the distinct classes, and then specify the array for `ClassNames`. For example, suppose the response variable (`Y`) is a cell array of labels. This code specifies the class order in the variable `classNames`.

```
Ycat = categorical(Y);
classNames = categories(Ycat)
```

`categorical` assigns `<undefined>` to unclassified observations and `categories` excludes `<undefined>` from its output. Therefore, if you use this code for cell arrays of labels or similar code for categorical arrays, then you do not have to remove observations with missing labels to obtain a list of the distinct classes.

- To specify that order should be from lowest-represented label to most-represented, then quickly determine the class order (as in the previous bullet), but arrange the classes in the list by frequency before passing the list to `ClassNames`. Following from the previous example, this code specifies the class order from lowest- to most-represented in `classNamesLH`.

```
Ycat = categorical(Y);
classNames = categories(Ycat);
freq = countcats(Ycat);
[~,idx] = sort(freq);
classNamesLH = classNames(idx);
```

Algorithms

- For details of ensemble aggregation algorithms, see “Ensemble Algorithms” on page 18-38.
- If you specify `Method` to be a boosting algorithm and `Learners` to be decision trees, then the software grows stumps by default. A decision stump is one root node connected to two terminal, leaf nodes. You can adjust tree depth by specifying the `MaxNumSplits`, `MinLeafSize`, and `MinParentSize` name-value pair arguments using `templateTree`.

- The software generates in-bag samples by oversampling classes with large misclassification costs and undersampling classes with small misclassification costs. Consequently, out-of-bag samples have fewer observations from classes with large misclassification costs and more observations from classes with small misclassification costs. If you train a classification ensemble using a small data set and a highly skewed cost matrix, then the number of out-of-bag observations per class might be very low. Therefore, the estimated out-of-bag error might have a large variance and might be difficult to interpret. The same phenomenon can occur for classes with large prior probabilities.
- For the RUSBoost ensemble aggregation method (`Method`), the name-value pair argument `RatioToSmallest` specifies the sampling proportion for each class with respect to the lowest-represented class. For example, suppose that there are 2 classes in the training data, *A* and *B*. *A* have 100 observations and *B* have 10 observations. Also, suppose that the lowest-represented class has *m* observations in the training data.
 - If you set `'RatioToSmallest', 2`, then $s_1 * m = 2 * 10 = 20$. Consequently, the software trains every learner using 20 observations from class *A* and 20 observations from class *B*. If you set `'RatioToSmallest', [2 2]`, then you will obtain the same result.
 - If you set `'RatioToSmallest', [2, 1]`, then $s_1 * m = 2 * 10 = 20$ and $s_2 * m = 1 * 10 = 10$. Consequently, the software trains every learner using 20 observations from class *A* and 10 observations from class *B*.
- For ensembles of decision trees, and for dual-core systems and above, `fitcensemble` and `fitrensemble` parallelize training using Intel Threading Building Blocks (TBB). For details on Intel TBB, see <https://software.intel.com/en-us/intel-tbb>.

Topics

“Supervised Learning Workflow and Algorithms” on page 18-2

“Framework for Ensemble Learning” on page 18-30

Introduced in R2014b

templateKernel

Kernel model template

Syntax

```
t = templateKernel()
t = templateKernel(Name,Value)
```

Description

`templateKernel` creates a template suitable for fitting a Gaussian kernel classification model for nonlinear classification.

The template specifies the binary learner model, number of dimensions of expanded space, kernel scale, box constraint, and regularization strength, among other parameters. After creating the template, train the model by passing the template and data to `fitcecoc`.

`t = templateKernel()` returns a kernel model template.

If you create a default template, then the software uses default values for all input arguments during training.

`t = templateKernel(Name,Value)` returns a template with additional options specified by one or more name-value pair arguments. For example, you can implement logistic regression or specify the number of dimensions of the expanded space.

If you display `t` in the Command Window, then some properties of `t` appear empty (`[]`). During training, the software uses default values for the empty properties.

Examples

Create Default Kernel Model Template

Create a default kernel model template and use it to train an error-correcting output codes (ECOC) multiclass model.

Load Fisher's iris data set.

```
load fisheriris
```

Create a default kernel model template.

```
t = templateKernel()

t =
Fit template for classification Kernel.

    BetaTolerance: []
    BlockSize: []
    BoxConstraint: []
```

```

        Epsilon: []
    NumExpansionDimensions: []
        GradientTolerance: []
        HessianHistorySize: []
        IterationLimit: []
        KernelScale: []
        Lambda: []
        Learner: 'svm'
        LossFunction: []
        Stream: []
    VerbosityLevel: []
        Version: 1
        Method: 'Kernel'
        Type: 'classification'

```

During training, the software fills in the empty properties with their respective default values.

Specify `t` as a binary learner for an ECOC multiclass model.

```
Mdl = fitcecoc(meas,species,'Learners',t)
```

```

Mdl =
    classreg.learning.classif.CompactClassificationECOC
        ResponseName: 'Y'
        ClassNames: {'setosa' 'versicolor' 'virginica'}
        ScoreTransform: 'none'
        BinaryLearners: {3x1 cell}
        CodingMatrix: [3x3 double]

```

Properties, Methods

`Mdl` is a `CompactClassificationECOC` multiclass classifier.

Specify Kernel Model Template Options

Create a kernel model template with additional options to implement logistic regression with a kernel scale parameter selected by a heuristic procedure.

```
t = templateKernel('Learner','logistic','KernelScale','auto')
```

```

t =
    Fit template for classification Kernel.

```

```

        BetaTolerance: []
        BlockSize: []
        BoxConstraint: []
        Epsilon: []
    NumExpansionDimensions: []
        GradientTolerance: []
        HessianHistorySize: []
        IterationLimit: []
        KernelScale: 'auto'
        Lambda: []

```

```

Learner: 'logistic'
LossFunction: []
Stream: []
VerbosityLevel: []
Version: 1
Method: 'Kernel'
Type: 'classification'

```

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

`'Learner', 'logistic', 'NumExpansionDimensions', 2^15, 'KernelScale', 'auto'` specifies to implement logistic regression after mapping the predictor data to the 2^{15} dimensional space using feature expansion with a kernel scale parameter selected by a heuristic procedure.

Kernel Classification Options

Learner — Linear classification model type

`'svm'` (default) | `'logistic'`

Linear classification model type, specified as the comma-separated pair consisting of `'Learner'` and `'svm'` or `'logistic'`.

In the following table, $f(x) = T(x)\beta + b$.

- x is an observation (row vector) from p predictor variables.
- $T(\cdot)$ is a transformation of an observation (row vector) for feature expansion. $T(x)$ maps x in \mathbb{R}^p to a high-dimensional space (\mathbb{R}^m).
- β is a vector of m coefficients.
- b is the scalar bias.

Value	Algorithm	Response Range	Loss Function
<code>'svm'</code>	Support vector machine	$y \in \{-1, 1\}$; 1 for the positive class and -1 otherwise	Hinge: $\ell[y, f(x)] = \max[0, 1 - yf(x)]$
<code>'logistic'</code>	Logistic regression	Same as <code>'svm'</code>	Deviance (logistic): $\ell[y, f(x)] = \log\{1 + \exp[-yf(x)]\}$

Example: `'Learner', 'logistic'`

NumExpansionDimensions — Number of dimensions of expanded space

`'auto'` (default) | positive integer

Number of dimensions of the expanded space, specified as the comma-separated pair consisting of `'NumExpansionDimensions'` and `'auto'` or a positive integer. For `'auto'`, the `templateKernel`

function selects the number of dimensions using $2^{\lceil \min(\log_2(p)+5, 15) \rceil}$, where p is the number of predictors.

For details, see “Random Feature Expansion” on page 32-5377.

Example: 'NumExpansionDimensions', 2^15

Data Types: char | string | single | double

KernelScale — Kernel scale parameter

1 (default) | 'auto' | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of 'KernelScale' and 'auto' or a positive scalar. The software obtains a random basis for random feature expansion by using the kernel scale parameter. For details, see “Random Feature Expansion” on page 32-5377.

If you specify 'auto', then the software selects an appropriate kernel scale parameter using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. Therefore, to reproduce results, set a random number seed by using `rng` before training.

Example: 'KernelScale', 'auto'

Data Types: char | string | single | double

BoxConstraint — Box constraint

1 (default) | positive scalar

Box constraint, specified as the comma-separated pair consisting of 'BoxConstraint' and a positive scalar.

This argument is valid only when 'Learner' is 'svm' (default) and you do not specify a value for the regularization term strength 'Lambda'. You can specify either 'BoxConstraint' or 'Lambda' because the box constraint (C) and the regularization term strength (λ) are related by $C = 1/(\lambda n)$, where n is the number of observations.

Example: 'BoxConstraint', 100

Data Types: single | double

Lambda — Regularization term strength

'auto' (default) | nonnegative scalar

Regularization term strength, specified as the comma-separated pair consisting of 'Lambda' and 'auto' or a nonnegative scalar.

For 'auto', the value of 'Lambda' is $1/n$, where n is the number of observations.

You can specify either 'BoxConstraint' or 'Lambda' because the box constraint (C) and the regularization term strength (λ) are related by $C = 1/(\lambda n)$.

Example: 'Lambda', 0.01

Data Types: char | string | single | double

Convergence Controls

BetaTolerance — Relative tolerance on linear coefficients and bias term

1e-5 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If you also specify GradientTolerance, then optimization terminates when the software satisfies either stopping criterion.

Example: 'BetaTolerance', 1e-6

Data Types: single | double

GradientTolerance — Absolute gradient tolerance

1e-6 (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of 'GradientTolerance' and a nonnegative scalar.

Let $\nabla \mathcal{L}_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t . If $\|\nabla \mathcal{L}_t\|_\infty = \max |\nabla \mathcal{L}_t| < \text{GradientTolerance}$, then optimization terminates.

If you also specify BetaTolerance, then optimization terminates when the software satisfies either stopping criterion.

Example: 'GradientTolerance', 1e-5

Data Types: single | double

IterationLimit — Maximum number of optimization iterations

positive integer

Maximum number of optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer.

The default value is 1000 if the transformed data fits in memory, as specified by the BlockSize name-value pair argument. Otherwise, the default value is 100.

Example: 'IterationLimit', 500

Data Types: single | double

Other Kernel Classification Options

BlockSize — Maximum amount of allocated memory

4e^3 (4GB) (default) | positive scalar

Maximum amount of allocated memory (in megabytes), specified as the comma-separated pair consisting of 'BlockSize' and a positive scalar.

If templateKernel requires more memory than the value of 'BlockSize' to hold the transformed predictor data, then the software uses a block-wise strategy. For details about the block-wise strategy, see "Algorithms" on page 32-5933.

Example: 'BlockSize', 1e4

Data Types: single | double

RandomStream — Random number stream

global stream (default) | random stream object

Random number stream for reproducibility of data transformation, specified as the comma-separated pair consisting of 'RandomStream' and a random stream object. For details, see “Random Feature Expansion” on page 32-5377.

Use 'RandomStream' to reproduce the random basis functions that `templateKernel` uses to transform the predictor data to a high-dimensional space. For details, see “Managing the Global Stream” (MATLAB) and “Creating and Controlling a Random Number Stream” (MATLAB).

Example: 'RandomStream', `RandStream('mlfg6331_64')`

HessianHistorySize — Size of history buffer for Hessian approximation

15 (default) | positive integer

Size of the history buffer for Hessian approximation, specified as the comma-separated pair consisting of 'HessianHistorySize' and a positive integer. At each iteration, `templateKernel` composes the Hessian approximation by using statistics from the latest `HessianHistorySize` iterations.

Example: 'HessianHistorySize', 10

Data Types: single | double

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and either 0 or 1. `Verbose` controls the display of diagnostic information at the command line.

Value	Description
0	<code>templateKernel</code> does not display diagnostic information.
1	<code>templateKernel</code> displays the value of the objective function, gradient magnitude, and other diagnostic information.

Example: 'Verbose', 1

Data Types: single | double

Output Arguments**t — Kernel model template**

template object

Kernel model template, returned as a template object. To train a kernel classification model for multiclass problems, pass `t` to `fitcecoc`.

If you display `t` in the Command Window, then some properties appear empty (`[]`). The software replaces the empty properties with their corresponding default values during training.

More About

Random Feature Expansion

Random feature expansion, such as Random Kitchen Sinks[1] and Fastfood[2], is a scheme to approximate Gaussian kernels of the kernel classification algorithm to use for big data in a computationally efficient way. Random feature expansion is more practical for big data applications that have large training sets, but can also be applied to smaller data sets that fit in memory.

The kernel classification algorithm searches for an optimal hyperplane that separates the data into two classes after mapping features into a high-dimensional space. Nonlinear features that are not linearly separable in a low-dimensional space can be separable in the expanded high-dimensional space. All the calculations for hyperplane classification use only dot products. You can obtain a nonlinear classification model by replacing the dot product x_1x_2' with the nonlinear kernel function $G(x_1, x_2) = \langle \varphi(x_1), \varphi(x_2) \rangle$, where x_i is the i th observation (row vector) and $\varphi(x_i)$ is a transformation that maps x_i to a high-dimensional space (called the “kernel trick”). However, evaluating $G(x_1, x_2)$ (Gram matrix) for each pair of observations is computationally expensive for a large data set (large n).

The random feature expansion scheme finds a random transformation so that its dot product approximates the Gaussian kernel. That is,

$$G(x_1, x_2) = \langle \varphi(x_1), \varphi(x_2) \rangle \approx T(x_1)T(x_2)',$$

where $T(x)$ maps x in \mathbb{R}^p to a high-dimensional space (\mathbb{R}^m). The Random Kitchen Sink scheme uses the random transformation

$$T(x) = m^{-1/2} \exp(iZx)',$$

where $Z \in \mathbb{R}^{m \times p}$ is a sample drawn from $N(0, \sigma^{-2})$ and σ^2 is a kernel scale. This scheme requires $O(mp)$ computation and storage. The Fastfood scheme introduces another random basis V instead of Z using Hadamard matrices combined with Gaussian scaling matrices. This random basis reduces the computation cost to $O(m \log p)$ and reduces storage to $O(m)$.

The `templateKernel` function uses the Fastfood scheme for random feature expansion and uses linear classification to train a Gaussian kernel classification model. Unlike solvers in the `templateSVM` function, which require computation of the n -by- n Gram matrix, the solver in `templateKernel` only needs to form a matrix of size n -by- m , with m typically much less than n for big data.

Box Constraint

A box constraint is a parameter that controls the maximum penalty imposed on margin-violating observations, and aids in preventing overfitting (regularization). Increasing the box constraint can lead to longer training times.

The box constraint (C) and the regularization term strength (λ) are related by $C = 1/(\lambda n)$, where n is the number of observations.

Algorithms

`templateKernel` minimizes the regularized objective function using a Limited-memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) solver with ridge (L_2) regularization. To find the type of LBFGS solver used for training, type `FitInfo.Solver` in the Command Window.

- 'LBFGS-fast' — LBFGS solver.
- 'LBFGS-blockwise' — LBFGS solver with a block-wise strategy. If `templateKernel` requires more memory than the value of `BlockSize` to hold the transformed predictor data, then it uses a block-wise strategy.
- 'LBFGS-tall' — LBFGS solver with a block-wise strategy for tall arrays.

When `templateKernel` uses a block-wise strategy, `templateKernel` implements LBFGS by distributing the calculation of the loss and gradient among different parts of the data at each iteration. Also, `templateKernel` refines the initial estimates of the linear coefficients and the bias term by fitting the model locally to parts of the data and combining the coefficients by averaging. If you specify 'Verbose', 1, then `templateKernel` displays diagnostic information for each data pass and stores the information in the `History` field of `FitInfo`.

When `templateKernel` does not use a block-wise strategy, the initial estimates are zeros. If you specify 'Verbose', 1, then `templateKernel` displays diagnostic information for each iteration and stores the information in the `History` field of `FitInfo`.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations when you train a model by passing a kernel model template and tall arrays to `fitcecoc`:

- The default values for these name-value pair arguments are different when you work with tall arrays.
 - 'Verbose' — Default value is 1.
 - 'BetaTolerance' — Default value is relaxed to $1e-3$.
 - 'GradientTolerance' — Default value is relaxed to $1e-5$.
 - 'IterationLimit' — Default value is relaxed to 20.

- If 'KernelScale' is 'auto', then `templateKernel` uses the random stream controlled by `ta1rng` for subsampling. For reproducibility, you must set a random number seed for both the global stream and the random stream controlled by `ta1rng`.
- If 'Lambda' is 'auto', then `templateKernel` might take an extra pass through the data to calculate the number of observations.
- `templateKernel` uses a block-wise strategy. For details, see “Algorithms” on page 32-5378.

For more information, see “Tall Arrays” (MATLAB).

Introduced in R2018b

templateKNN

k-nearest neighbor classifier template

Syntax

```
t = templateKNN()  
t = templateKNN(Name,Value)
```

Description

`t = templateKNN()` returns a *k*-nearest neighbor (KNN) learner template suitable for training ensembles or error-correcting output code (ECOC) multiclass models.

If you specify a default template, then the software uses default values for all input arguments during training.

Specify `t` as a learner in `fitcensemble` or `fitcecoc`.

`t = templateKNN(Name,Value)` creates a template with additional options specified by one or more name-value pair arguments.

For example, you can specify the nearest neighbor search method, the number of nearest neighbors to find, or the distance metric.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Create a *k*-Nearest Neighbor Template for Ensemble

Create a nondefault *k*-nearest neighbor template for use in `fitcensemble`.

Load Fisher's iris data set.

```
load fisheriris
```

Create a template for a 5-nearest neighbor search, and specify to standardize the predictors.

```
t = templateKNN('NumNeighbors',5,'Standardize',1)
```

```
t =  
Fit template for classification KNN.
```

```
NumNeighbors: 5  
NSMethod: ''  
Distance: ''  
BucketSize: ''  
IncludeTies: []
```

```

DistanceWeight: []
BreakTies: []
Exponent: []
Cov: []
Scale: []
StandardizeData: 1
Version: 1
Method: 'KNN'
Type: 'classification'

```

All properties of the template object are empty except for `NumNeighbors`, `Method`, `StandardizeData`, and `Type`. When you specify `t` as a learner, the software fills in the empty properties with their respective default values.

Specify `t` as a weak learner for a classification ensemble.

```
Mdl = fitcensemble(meas,species,'Method','Subspace','Learners',t);
```

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl)
```

```
L = 0.0600
```

Create a *k*-Nearest Neighbor Template for ECOC Multiclass Learning

Create a nondefault *k*-nearest neighbor template for use in `fitcecoc`.

Load Fisher's iris data set.

```
load fisheriris
```

Create a template for a 5-nearest neighbor search, and specify to standardize the predictors.

```
t = templateKNN('NumNeighbors',5,'Standardize',1)
```

```
t =
```

```
Fit template for classification KNN.
```

```

NumNeighbors: 5
NSMethod: ''
Distance: ''
BucketSize: ''
IncludeTies: []
DistanceWeight: []
BreakTies: []
Exponent: []
Cov: []
Scale: []
StandardizeData: 1
Version: 1
Method: 'KNN'
Type: 'classification'

```

All properties of the template object are empty except for `NumNeighbors`, `Method`, `StandardizeData`, and `Type`. When you specify `t` as a learner, the software fills in the empty properties with their respective default values.

Specify `t` as a binary learner for an ECOC multiclass model.

```
Mdl = fitcecoc(meas,species,'Learners',t);
```

By default, the software trains `Mdl` using the one-versus-one coding design.

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl,'LossFun','classiferror')
```

```
L = 0.0467
```

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'NumNeighbors',4,'Distance','minkowski'` specifies a 4-nearest neighbor classifier template using the Minkowski distance measure.

BreakTies — Tie-breaking algorithm

`'smallest'` (default) | `'nearest'` | `'random'`

Tie-breaking algorithm used by the `predict` method if multiple classes have the same smallest cost, specified as the comma-separated pair consisting of `'BreakTies'` and one of the following:

- `'smallest'` — Use the smallest index among tied groups.
- `'nearest'` — Use the class with the nearest neighbor among tied groups.
- `'random'` — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the `K` nearest neighbors.

Example: `'BreakTies','nearest'`

BucketSize — Maximum data points in node

50 (default) | positive integer value

Maximum number of data points in the leaf node of the *kd*-tree, specified as the comma-separated pair consisting of `'BucketSize'` and a positive integer value. This argument is meaningful only when `NSMethod` is `'kdtree'`.

Example: `'BucketSize',40`

Data Types: `single` | `double`

Cov — Covariance matrix

`nancov(X)` (default) | positive definite matrix of scalar values

Covariance matrix, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix of scalar values representing the covariance matrix when computing the Mahalanobis distance. This argument is only valid when 'Distance' is 'mahalanobis'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: single | double

Distance — Distance metric

'cityblock' | 'chebychev' | 'correlation' | 'cosine' | 'euclidean' | 'hamming' | function handle | ...

Distance metric, specified as the comma-separated pair consisting of 'Distance' and a valid distance metric name or function handle. The allowable distance metric names depend on your choice of a neighbor-searcher method (see NSMethod).

NSMethod	Distance Metric Names
exhaustive	Any distance metric of ExhaustiveSearcher
kdtree	'cityblock', 'chebychev', 'euclidean', or 'minkowski'

This table includes valid distance metrics of ExhaustiveSearcher.

Distance Metric Names	Description
'cityblock'	City block distance.
'chebychev'	Chebychev distance (maximum coordinate difference).
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'cosine'	One minus the cosine of the included angle between observations (treated as vectors).
'euclidean'	Euclidean distance.
'hamming'	Hamming distance, percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix C. The default value of C is the sample covariance matrix of X, as computed by <code>nancov(X)</code> . To specify a different value for C, use the 'Cov' name-value pair argument.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'Exponent' name-value pair argument.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between X and a query point is scaled, meaning divided by a scale value S. The default value of S is the standard deviation computed from X, <code>S = nanstd(X)</code> . To specify another value for S, use the <code>Scale</code> name-value pair argument.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).

Distance Metric Names	Description
@ <i>distfun</i>	<p>Distance function handle. <i>distfun</i> has the form</p> <pre>function D2 = distfun(ZI,ZJ) % calculation of distance ...</pre> <p>where</p> <ul style="list-style-type: none"> • ZI is a 1-by-N vector containing one row of X or Y. • ZJ is an M2-by-N matrix containing multiple rows of X or Y. • D2 is an M2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(k,:).

If you specify CategoricalPredictors as 'all', then the default distance metric is 'hamming'. Otherwise, the default distance metric is 'euclidean'.

For definitions, see “Distance Metrics” on page 18-11.

Example: 'Distance','minkowski'

Data Types: char | string | function_handle

DistanceWeight – Distance weighting function

'equal' (default) | 'inverse' | 'squaredinverse' | function handle

Distance weighting function, specified as the comma-separated pair consisting of 'DistanceWeight' and either a function handle or one of the values in this table.

Value	Description
'equal'	No weighting
'inverse'	Weight is 1/distance
'squaredinverse'	Weight is 1/distance ²
@ <i>fcn</i>	<i>fcn</i> is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to @(d)d.^(-2).

Example: 'DistanceWeight','inverse'

Data Types: char | string | function_handle

Exponent – Minkowski distance exponent

2 (default) | positive scalar value

Minkowski distance exponent, specified as the comma-separated pair consisting of 'Exponent' and a positive scalar value. This argument is only valid when 'Distance' is 'minkowski'.

Example: 'Exponent',3

Data Types: single | double

IncludeTies – Tie inclusion flag

false (default) | true

Tie inclusion flag, specified as the comma-separated pair consisting of `'IncludeTies'` and a logical value indicating whether `predict` includes all the neighbors whose distance values are equal to the `K`th smallest distance. If `IncludeTies` is true, `predict` includes all these neighbors. Otherwise, `predict` uses exactly `K` neighbors.

Example: `'IncludeTies',true`

Data Types: logical

NSMethod — Nearest neighbor search method

`'kdtree' | 'exhaustive'`

Nearest neighbor search method, specified as the comma-separated pair consisting of `'NSMethod'` and `'kdtree'` or `'exhaustive'`.

- `'kdtree'` — Creates and uses a *kd*-tree to find nearest neighbors. `'kdtree'` is valid when the distance metric is one of the following:
 - `'euclidean'`
 - `'cityblock'`
 - `'minkowski'`
 - `'chebychev'`
- `'exhaustive'` — Uses the exhaustive search algorithm. When predicting the class of a new point `xnew`, the software computes the distance values from all points in `X` to `xnew` to find nearest neighbors.

The default is `'kdtree'` when `X` has 10 or fewer columns, `X` is not sparse, and the distance metric is a `'kdtree'` type; otherwise, `'exhaustive'`.

Example: `'NSMethod','exhaustive'`

NumNeighbors — Number of nearest neighbors to find

1 (default) | positive integer value

Number of nearest neighbors in `X` to find for classifying each point when predicting, specified as the comma-separated pair consisting of `'NumNeighbors'` and a positive integer value.

Example: `'NumNeighbors',3`

Data Types: single | double

Scale — Distance scale

`nanstd(X)` (default) | vector of nonnegative scalar values

Distance scale, specified as the comma-separated pair consisting of `'Scale'` and a vector containing nonnegative scalar values with length equal to the number of columns in `X`. Each coordinate difference between `X` and a query point is scaled by the corresponding element of `Scale`. This argument is only valid when `'Distance'` is `'seuclidean'`.

You cannot simultaneously specify `'Standardize'` and either of `'Scale'` or `'Cov'`.

Data Types: single | double

Standardize — Flag to standardize predictors

false (default) | true

Flag to standardize the predictors, specified as the comma-separated pair consisting of 'Standardize' and true (1) or false (0).

If you set 'Standardize', true, then the software centers and scales each column of the predictor data (X) by the column mean and standard deviation, respectively.

The software does not standardize categorical predictors, and throws an error if all predictors are categorical.

You cannot simultaneously specify 'Standardize', 1 and either of 'Scale' or 'Cov'.

It is good practice to standardize the predictor data.

Example: 'Standardize', true

Data Types: logical

Output Arguments

t — kNN classification template

template object

kNN classification template suitable for training ensembles or error-correcting output code (ECOC) multiclass models, returned as a template object. Pass **t** to `fitcensemble` or `fitcecoc` to specify how to create the KNN classifier for the ensemble or ECOC model, respectively.

If you display **t** to the Command Window, then all, unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

`ClassificationKNN` | `ExhaustiveSearcher` | `fitcecoc` | `fitcensemble`

Topics

“Random Subspace Classification” on page 18-103

Introduced in R2014a

templateLinear

Linear classification learner template

Syntax

```
t = templateLinear()  
t = templateLinear(Name,Value)
```

Description

`templateLinear` creates a template suitable for fitting a linear classification model to high-dimensional data for multiclass problems.

The template specifies the binary learner model, regularization type and strength, and solver, among other things. After creating the template, train the model by passing the template and data to `fitcecoc`.

`t = templateLinear()` returns a linear classification learner template.

If you specify a default template, then the software uses default values for all input arguments during training.

`t = templateLinear(Name,Value)` returns a template with additional options specified by one or more name-value pair arguments. For example, you can specify to implement logistic regression, specify the regularization type or strength, or specify the solver to use for objective-function minimization.

If you display `t` in the Command Window, then all options appear empty (`[]`) except options that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Train Multiclass Linear Classification Model

Train an ECOC model composed of multiple binary, linear classification models.

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels. There are more than two classes in the data.

Create a default linear-classification-model template.

```
t = templateLinear();
```

To adjust the default values, see the “Name-Value Pair Arguments” on page 32-5388 on `templateLinear` page.

Train an ECOC model composed of multiple binary, linear classification models that can identify the product given the frequency distribution of words on a documentation web page. For faster training time, transpose the predictor data, and specify that observations correspond to columns.

```
X = X';
rng(1); % For reproducibility
Mdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns')
```

```
Mdl =
  classreg.learning.classif.CompactClassificationECOC
    ResponseName: 'Y'
    ClassNames: [1x13 categorical]
    ScoreTransform: 'none'
    BinaryLearners: {78x1 cell}
    CodingMatrix: [13x78 double]
```

Properties, Methods

Alternatively, you can train an ECOC model composed of default linear classification models using 'Learners','Linear'.

To conserve memory, `fitcecoc` returns trained ECOC models composed of linear classification learners in `CompactClassificationECOC` model objects.

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: 'Learner','logistic','Regularization','lasso','CrossVal','on' specifies to implement logistic regression with a lasso penalty, and to implement 10-fold cross-validation.

Linear Classification Options

Lambda — Regularization term strength

'auto' (default) | nonnegative scalar | vector of nonnegative values

Regularization term strength, specified as the comma-separated pair consisting of 'Lambda' and 'auto', a nonnegative scalar, or a vector of nonnegative values.

- For 'auto', $\text{Lambda} = 1/n$.
 - If you specify a cross-validation, name-value pair argument (e.g., `CrossVal`), then n is the number of in-fold observations.
 - Otherwise, n is the training sample size.
- For a vector of nonnegative values, the software sequentially optimizes the objective function for each distinct value in `Lambda` in ascending order.

- If Solver is 'sgd' or 'asgd' and Regularization is 'lasso', then the software does not use the previous coefficient estimates as a warm start on page 32-1625 for the next optimization iteration. Otherwise, the software uses warm starts.
- If Regularization is 'lasso', then any coefficient estimate of 0 retains its value when the software optimizes using subsequent values in Lambda.

Returns coefficient estimates for all optimization iterations.

Example: 'Lambda', 10.^(-(10:-2:2))

Data Types: char | string | double | single

Learner – Linear classification model type

'svm' (default) | 'logistic'

Linear classification model type, specified as the comma-separated pair consisting of 'Learner' and 'svm' or 'logistic'.

In this table, $f(x) = x\beta + b$.

- β is a vector of p coefficients.
- x is an observation from p predictor variables.
- b is the scalar bias.

Value	Algorithm	Response Range	Loss Function
'svm'	Support vector machine	$y \in \{-1,1\}$; 1 for the positive class and -1 otherwise	Hinge: $\ell[y, f(x)] = \max[0, 1 - yf(x)]$
'logistic'	Logistic regression	Same as 'svm'	Deviance (logistic): $\ell[y, f(x)] = \log\{1 + \exp[-yf(x)]\}$

Example: 'Learner', 'logistic'

Regularization – Complexity penalty type

'lasso' | 'ridge'

Complexity penalty type, specified as the comma-separated pair consisting of 'Regularization' and 'lasso' or 'ridge'.

The software composes the objective function for minimization from the sum of the average loss function (see Learner) and the regularization term in this table.

Value	Description
'lasso'	Lasso (L1) penalty: $\lambda \sum_{j=1}^p \beta_j $
'ridge'	Ridge (L2) penalty: $\frac{\lambda}{2} \sum_{j=1}^p \beta_j^2$

To specify the regularization term strength, which is λ in the expressions, use Lambda.

The software excludes the bias term (β_0) from the regularization penalty.

If `Solver` is `'sparsa'`, then the default value of `Regularization` is `'lasso'`. Otherwise, the default is `'ridge'`.

Tip

- For predictor variable selection, specify `'lasso'`. For more on variable selection, see “Introduction to Feature Selection” on page 15-49.
 - For optimization accuracy, specify `'ridge'`.
-

Example: `'Regularization','lasso'`

Solver — Objective function minimization technique

`'sgd' | 'asgd' | 'dual' | 'bfgs' | 'lbfgs' | 'sparsa'` | string array | cell array of character vectors

Objective function minimization technique, specified as the comma-separated pair consisting of `'Solver'` and a character vector or string scalar, a string array, or a cell array of character vectors with values from this table.

Value	Description	Restrictions
<code>'sgd'</code>	Stochastic gradient descent (SGD) [5][3]	
<code>'asgd'</code>	Average stochastic gradient descent (ASGD) [8]	
<code>'dual'</code>	Dual SGD for SVM [2][7]	Regularization must be <code>'ridge'</code> and Learner must be <code>'svm'</code> .
<code>'bfgs'</code>	Broyden-Fletcher-Goldfarb-Shanno quasi-Newton algorithm (BFGS) [4]	Inefficient if X is very high-dimensional.
<code>'lbfgs'</code>	Limited-memory BFGS (LBFGS) [4]	Regularization must be <code>'ridge'</code> .
<code>'sparsa'</code>	Sparse Reconstruction by Separable Approximation (SpaRSA) [6]	Regularization must be <code>'lasso'</code> .

If you specify:

- A ridge penalty (see `Regularization`) and the predictor data set contains 100 or fewer predictor variables, then the default solver is `'bfgs'`.
- An SVM model (see `Learner`), a ridge penalty, and the predictor data set contains more than 100 predictor variables, then the default solver is `'dual'`.
- A lasso penalty and the predictor data set contains 100 or fewer predictor variables, then the default solver is `'sparsa'`.

Otherwise, the default solver is `'sgd'`.

For more details on which solver to choose, see “Tips” on page 32-5398.

Example: 'Solver', {'sgd', 'lbfgs'}

Beta — Initial linear coefficient estimates

zeros($p, 1$) (default) | numeric vector | numeric matrix

Initial linear coefficient estimates (β), specified as the comma-separated pair consisting of 'Beta' and a p -dimensional numeric vector or a p -by- L numeric matrix. p is the number of predictor variables in X and L is the number of regularization-strength values (for more details, see Lambda).

- If you specify a p -dimensional vector, then the software optimizes the objective function L times using this process.
 - 1 The software optimizes using Beta as the initial value and the minimum value of Lambda as the regularization strength.
 - 2 The software optimizes again using the resulting estimate from the previous optimization as a warm start on page 32-1625, and the next smallest value in Lambda as the regularization strength.
 - 3 The software implements step 2 until it exhausts all values in Lambda.
- If you specify a p -by- L matrix, then the software optimizes the objective function L times. At iteration j , the software uses Beta($:$, j) as the initial value and, after it sorts Lambda in ascending order, uses Lambda(j) as the regularization strength.

If you set 'Solver', 'dual', then the software ignores Beta.

Data Types: single | double

Bias — Initial intercept estimate

numeric scalar | numeric vector

Initial intercept estimate (b), specified as the comma-separated pair consisting of 'Bias' and a numeric scalar or an L -dimensional numeric vector. L is the number of regularization-strength values (for more details, see Lambda).

- If you specify a scalar, then the software optimizes the objective function L times using this process.
 - 1 The software optimizes using Bias as the initial value and the minimum value of Lambda as the regularization strength.
 - 2 The uses the resulting estimate as a warm start to the next optimization iteration, and uses the next smallest value in Lambda as the regularization strength.
 - 3 The software implements step 2 until it exhausts all values in Lambda.
- If you specify an L -dimensional vector, then the software optimizes the objective function L times. At iteration j , the software uses Bias(j) as the initial value and, after it sorts Lambda in ascending order, uses Lambda(j) as the regularization strength.
- By default:
 - If Learner is 'logistic', then let g_j be 1 if $Y(j)$ is the positive class, and -1 otherwise. Bias is the weighted average of the g for training or, for cross-validation, in-fold observations.
 - If Learner is 'svm', then Bias is 0.

Data Types: single | double

FitBias – Linear model intercept inclusion flag

true (default) | false

Linear model intercept inclusion flag, specified as the comma-separated pair consisting of 'FitBias' and true or false.

Value	Description
true	The software includes the bias term b in the linear model, and then estimates it.
false	The software sets $b = 0$ during estimation.

Example: 'FitBias',false

Data Types: logical

PostFitBias – Flag to fit linear model intercept after optimization

false (default) | true

Flag to fit the linear model intercept after optimization, specified as the comma-separated pair consisting of 'PostFitBias' and true or false.

Value	Description
false	The software estimates the bias term b and the coefficients β during optimization.
true	To estimate b , the software: <ol style="list-style-type: none"> 1 Estimates β and b using the model 2 Estimates classification scores 3 Refits b by placing the threshold on the classification scores that attains maximum accuracy

If you specify true, then FitBias must be true.

Example: 'PostFitBias',true

Data Types: logical

Verbose – Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and either 0 or 1. Verbose controls the display of diagnostic information at the command line.

Value	Description
0	templateLinear does not display diagnostic information.
1	templateLinear periodically displays the value of the objective function, gradient magnitude, and other diagnostic information.

Example: 'Verbose',1

Data Types: single | double

SGD and ASGD Solver Options**BatchSize — Mini-batch size**

positive integer

Mini-batch size, specified as the comma-separated pair consisting of 'BatchSize' and a positive integer. At each iteration, the software estimates the gradient using BatchSize observations from the training data.

- If the predictor data is a numeric matrix, then the default value is 10.
- If the predictor data is a sparse matrix, then the default value is $\max([10, \text{ceil}(\text{sqrt}(\text{ff}))])$, where $\text{ff} = \text{numel}(X)/\text{nnz}(X)$, that is, the fullness factor of X .

Example: 'BatchSize', 100

Data Types: single | double

LearnRate — Learning rate

positive scalar

Learning rate, specified as the comma-separated pair consisting of 'LearnRate' and a positive scalar. LearnRate specifies how many steps to take per iteration. At each iteration, the gradient specifies the direction and magnitude of each step.

- If Regularization is 'ridge', then LearnRate specifies the initial learning rate γ_0 . The software determines the learning rate for iteration t , γ_t , using

$$\gamma_t = \frac{\gamma_0}{(1 + \lambda \gamma_0 t)^c}.$$

- λ is the value of Lambda.
- If Solver is 'sgd', then $c = 1$.
- If Solver is 'asgd', then c is 0.75 [7].
- If Regularization is 'lasso', then, for all iterations, LearnRate is constant.

By default, LearnRate is $1/\text{sqrt}(1+\max((\text{sum}(X.^2, \text{obsDim}))))$, where obsDim is 1 if the observations compose the columns of the predictor data X , and 2 otherwise.

Example: 'LearnRate', 0.01

Data Types: single | double

OptimizeLearnRate — Flag to decrease learning rate

true (default) | false

Flag to decrease the learning rate when the software detects divergence (that is, over-stepping the minimum), specified as the comma-separated pair consisting of 'OptimizeLearnRate' and true or false.

If OptimizeLearnRate is 'true', then:

- 1 For the few optimization iterations, the software starts optimization using LearnRate as the learning rate.
- 2 If the value of the objective function increases, then the software restarts and uses half of the current value of the learning rate.

3 The software iterates step 2 until the objective function decreases.

Example: 'OptimizeLearnRate', true

Data Types: logical

TruncationPeriod — Number of mini-batches between lasso truncation runs

10 (default) | positive integer

Number of mini-batches between lasso truncation runs, specified as the comma-separated pair consisting of 'TruncationPeriod' and a positive integer.

After a truncation run, the software applies a soft threshold to the linear coefficients. That is, after processing $k = \text{TruncationPeriod}$ mini-batches, the software truncates the estimated coefficient j using

$$\widehat{\beta}_j^* = \begin{cases} \widehat{\beta}_j - u_t & \text{if } \widehat{\beta}_j > u_t, \\ 0 & \text{if } |\widehat{\beta}_j| \leq u_t, \\ \widehat{\beta}_j + u_t & \text{if } \widehat{\beta}_j < -u_t. \end{cases}$$

- For SGD, $\widehat{\beta}_j$ is the estimate of coefficient j after processing k mini-batches. $u_t = k\gamma_t\lambda$. γ_t is the learning rate at iteration t . λ is the value of Lambda.
- For ASGD, $\widehat{\beta}_j$ is the averaged estimate coefficient j after processing k mini-batches, $u_t = k\lambda$.

If Regularization is 'ridge', then the software ignores TruncationPeriod.

Example: 'TruncationPeriod', 100

Data Types: single | double

SGD and ASGD Convergence Controls

BatchLimit — Maximal number of batches

positive integer

Maximal number of batches to process, specified as the comma-separated pair consisting of 'BatchLimit' and a positive integer. When the software processes BatchLimit batches, it terminates optimization.

- By default:
 - The software passes through the data PassLimit times.
 - If you specify multiple solvers, and use (A)SGD to get an initial approximation for the next solver, then the default value is $\text{ceil}(1e6/\text{BatchSize})$. BatchSize is the value of the 'BatchSize' name-value pair argument.
- If you specify 'BatchLimit' and 'PassLimit', then the software chooses the argument that results in processing the fewest observations.
- If you specify 'BatchLimit' but not 'PassLimit', then the software processes enough batches to complete up to one entire pass through the data.

Example: 'BatchLimit', 100

Data Types: single | double

BetaTolerance — Relative tolerance on linear coefficients and bias term

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t . If

$$\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}, \text{ then optimization terminates.}$$

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: 'BetaTolerance', 1e-6

Data Types: single | double

NumCheckConvergence — Number of batches to process before next convergence check

positive integer

Number of batches to process before next convergence check, specified as the comma-separated pair consisting of 'NumCheckConvergence' and a positive integer.

To specify the batch size, see `BatchSize`.

The software checks for convergence about 10 times per pass through the entire data set by default.

Example: 'NumCheckConvergence', 100

Data Types: single | double

PassLimit — Maximal number of passes

1 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of 'PassLimit' and a positive integer.

The software processes all observations when it completes one pass through the data.

When the software passes through the data `PassLimit` times, it terminates optimization.

If you specify 'BatchLimit' and `PassLimit`, then the software chooses the argument that results in processing the fewest observations.

Example: 'PassLimit', 5

Data Types: single | double

Dual SGD Convergence Controls**BetaTolerance — Relative tolerance on linear coefficients and bias term**

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t . If

$$\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}, \text{ then optimization terminates.}$$

If you also specify `DeltaGradientTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'BetaTolerance', 1e-6`

Data Types: `single | double`

DeltaGradientTolerance — Gradient-difference tolerance

1 (default) | nonnegative scalar

Gradient-difference tolerance between upper and lower pool Karush-Kuhn-Tucker (KKT) complementarity conditions on page 32-1690 violators, specified as the comma-separated pair consisting of `'DeltaGradientTolerance'` and a nonnegative scalar.

- If the magnitude of the KKT violators is less than `DeltaGradientTolerance`, then the software terminates optimization.
- If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'DeltaGapTolerance', 1e-2`

Data Types: `double | single`

NumCheckConvergence — Number of passes through entire data set to process before next convergence check

5 (default) | positive integer

Number of passes through entire data set to process before next convergence check, specified as the comma-separated pair consisting of `'NumCheckConvergence'` and a positive integer.

Example: `'NumCheckConvergence', 100`

Data Types: `single | double`

PassLimit — Maximal number of passes

10 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of `'PassLimit'` and a positive integer.

When the software completes one pass through the data, it has processed all observations.

When the software passes through the data `PassLimit` times, it terminates optimization.

Example: `'PassLimit', 5`

Data Types: `single | double`

BFGS, LBFGS, and SpARSA Convergence Controls

BetaTolerance — Relative tolerance on linear coefficients and bias term

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of `'BetaTolerance'` and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If you also specify `GradientTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'BetaTolerance', 1e-6`

Data Types: `single` | `double`

GradientTolerance — Absolute gradient tolerance

1e-6 (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of `'GradientTolerance'` and a nonnegative scalar.

Let $\nabla \mathcal{L}_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t . If $\|\nabla \mathcal{L}_t\|_\infty = \max|\nabla \mathcal{L}_t| < \text{GradientTolerance}$, then optimization terminates.

If you also specify `BetaTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in the software, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'GradientTolerance', 1e-5`

Data Types: `single` | `double`

HessianHistorySize — Size of history buffer for Hessian approximation

15 (default) | positive integer

Size of history buffer for Hessian approximation, specified as the comma-separated pair consisting of `'HessianHistorySize'` and a positive integer. That is, at each iteration, the software composes the Hessian using statistics from the latest `HessianHistorySize` iterations.

The software does not support `'HessianHistorySize'` for `SpaRSA`.

Example: `'HessianHistorySize', 10`

Data Types: `single` | `double`

IterationLimit — Maximal number of optimization iterations

1000 (default) | positive integer

Maximal number of optimization iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer. `IterationLimit` applies to these values of `Solver`: `'bfgs'`, `'lbfgs'`, and `'sparsa'`.

Example: `'IterationLimit', 500`

Data Types: `single` | `double`

Output Arguments

t — Linear classification model learner template

template object

Linear classification model learner template, returned as a template object. To train a linear classification model using high-dimensional data for multiclass problems, pass **t** to `fitcecoc`.

If you display **t** to the Command Window, then all, unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

More About

Warm Start

A warm start is initial estimates of the beta coefficients and bias term supplied to an optimization routine for quicker convergence.

Tips

- It is a best practice to orient your predictor matrix so that observations correspond to columns and to specify `'ObservationsIn'`, `'columns'`. As a result, you can experience a significant reduction in optimization-execution time.
- For better optimization accuracy if the predictor data is high-dimensional and `Regularization` is `'ridge'`, set any of these combinations for `Solver`:
 - `'sgd'`
 - `'asgd'`
 - `'dual'` if `Learner` is `'svm'`
 - `{'sgd','lbfgs'}`
 - `{'asgd','lbfgs'}`
 - `{'dual','lbfgs'}` if `Learner` is `'svm'`

Other combinations can result in poor optimization accuracy.

- For better optimization accuracy if the predictor data is moderate- through low-dimensional and `Regularization` is `'ridge'`, set `Solver` to `'bfgs'`.
- If `Regularization` is `'lasso'`, set any of these combinations for `Solver`:
 - `'sgd'`
 - `'asgd'`
 - `'sparsa'`
 - `{'sgd','sparsa'}`
 - `{'asgd','sparsa'}`
- When choosing between SGD and ASGD, consider that:
 - SGD takes less time per iteration, but requires more iterations to converge.
 - ASGD requires fewer iterations to converge, but takes more time per iteration.

- If the predictor data has few observations, but many predictor variables, then:
 - Specify 'PostFitBias', true.
 - For SGD or ASGD solvers, set PassLimit to a positive integer that is greater than 1, for example, 5 or 10. This setting often results in better accuracy.
- For SGD and ASGD solvers, BatchSize affects the rate of convergence.
 - If BatchSize is too small, then the software achieves the minimum in many iterations, but computes the gradient per iteration quickly.
 - If BatchSize is too large, then the software achieves the minimum in fewer iterations, but computes the gradient per iteration slowly.
- Large learning rate (see LearnRate) speed-up convergence to the minimum, but can lead to divergence (that is, over-stepping the minimum). Small learning rates ensure convergence to the minimum, but can lead to slow termination.
- If Regularization is 'lasso', then experiment with various values of TruncationPeriod. For example, set TruncationPeriod to 1, 10, and then 100.
- For efficiency, the software does not standardize predictor data. To standardize the predictor data (X), enter

```
X = bsxfun(@rdivide,bsxfun(@minus,X,mean(X,2)),std(X,0,2));
```

The code requires that you orient the predictors and observations as the rows and columns of X, respectively. Also, for memory-usage economy, the code replaces the original predictor data the standardized data.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations when you train a model by passing a linear model template and tall arrays to `fitcecoc`:

- The default values for these name-value pair arguments are different when you work with tall arrays.
 - 'Lambda' — Can be 'auto' (default) or a scalar
 - 'Regularization' — Supports only 'ridge'
 - 'Solver' — Supports only 'lbfgs'
 - 'FitBias' — Supports only true
 - 'Verbose' — Default value is 1
 - 'BetaTolerance' — Default value is relaxed to 1e-3
 - 'GradientTolerance' — Default value is relaxed to 1e-3
 - 'IterationLimit' — Default value is relaxed to 20
- When `fitcecoc` uses a `templateLinear` object with tall arrays, the only available solver is LBFGS. The software implements LBFGS by distributing the calculation of the loss and gradient among different parts of the tall array at each iteration. If you do not specify initial values for `Beta` and `Bias`, the software refines the initial estimates of the parameters by fitting the model locally to parts of the data and combining the coefficients by averaging.

For more information, see “Tall Arrays” (MATLAB).

Introduced in R2016a

templateNaiveBayes

Naive Bayes classifier template

Syntax

```
t = templateNaiveBayes()
t = templateNaiveBayes(Name,Value)
```

Description

`t = templateNaiveBayes()` returns a naive Bayes on page 32-5405 template suitable for training error-correcting output code (ECOC) multiclass models.

If you specify a default template, then the software uses default values for all input arguments during training.

Specify `t` as a learner in `fitcecoc`.

`t = templateNaiveBayes(Name,Value)` returns a template with additional options specified by one or more name-value pair arguments. All properties of `t` are empty, except those you specify using `Name,Value` pair arguments.

For example, you can specify distributions for the predictors.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Create a Default Naive Bayes Template

Use `templateNaiveBayes` to specify a default naive Bayes template.

```
t = templateNaiveBayes()
t =
Fit template for classification NaiveBayes.

    DistributionNames: [1x0 double]
           Kernel: []
          Support: []
           Width: []
          Version: 1
           Method: 'NaiveBayes'
           Type: 'classification'
```

All properties of the template object are empty except for `Method` and `Type`. When you pass `t` to the training function, the software fills in the empty properties with their respective default values. For

example, the software fills the `DistributionNames` property with a 1-by-`D` cell array of character vectors with 'normal' in each cell, where `D` is the number of predictors. For details on other default values, see `fitcnb`.

`t` is a plan for a naive Bayes learner, and no computation occurs when you specify it. You can pass `t` to `fitcecoc` to specify naive Bayes binary learners for ECOC multiclass learning.

Create a Naive Bayes Template for ECOC Multiclass Learning

Create a nondefault naive Bayes template for use in `fitcecoc`.

Load Fisher's iris data set.

```
load fisheriris
```

Create a template for naive Bayes binary classifiers, and specify kernel distributions for all predictors.

```
t = templateNaiveBayes('DistributionNames','kernel')
```

```
t =  
Fit template for classification NaiveBayes.
```

```
    DistributionNames: 'kernel'  
           Kernel: []  
           Support: []  
           Width: []  
           Version: 1  
           Method: 'NaiveBayes'  
           Type: 'classification'
```

All properties of the template object are empty except for `DistributionNames`, `Method`, and `Type`. When you pass `t` to the training function, the software fills in the empty properties with their respective default values.

Specify `t` as a binary learner for an ECOC multiclass model.

```
Mdl = fitcecoc(meas,species,'Learners',t);
```

By default, the software trains `Mdl` using the one-versus-one coding design.

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl,'LossFun','classiferror')
```

```
L = 0.0333
```

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'DistributionNames', 'mn'` specifies to treat all predictors as token counts for a multinomial model.

DistributionNames — Data distributions

`'kernel' | 'mn' | 'mvmn' | 'normal' | string array | cell array of character vectors`

Data distributions `fitcnb` uses to model the data, specified as the comma-separated pair consisting of `'DistributionNames'` and a character vector or string scalar, a string array, or a cell array of character vectors with values from this table.

Value	Description
<code>'kernel'</code>	Kernel smoothing density estimate.
<code>'mn'</code>	Multinomial distribution. If you specify <code>mn</code> , then all features are components of a multinomial distribution. Therefore, you cannot include <code>'mn'</code> as an element of a string array or a cell array of character vectors. For details, see “Algorithms” on page 32-1657.
<code>'mvmn'</code>	Multivariate multinomial distribution. For details, see “Algorithms” on page 32-1657.
<code>'normal'</code>	Normal (Gaussian) distribution.

If you specify a character vector or string scalar, then the software models all the features using that distribution. If you specify a 1-by- P string array or cell array of character vectors, then the software models feature j using the distribution in element j of the array.

By default, the software sets all predictors specified as categorical predictors (using the `CategoricalPredictors` name-value pair argument) to `'mvmn'`. Otherwise, the default distribution is `'normal'`.

You must specify that at least one predictor has distribution `'kernel'` to additionally specify `Kernel`, `Support`, or `Width`.

Example: `'DistributionNames', 'mn'`

Example: `'DistributionNames', {'kernel', 'normal', 'kernel'}`

Kernel — Kernel smoother type

`'normal' (default) | 'box' | 'epanechnikov' | 'triangle' | string array | cell array of character vectors`

Kernel smoother type, specified as the comma-separated pair consisting of `'Kernel'` and a character vector or string scalar, a string array, or a cell array of character vectors.

This table summarizes the available options for setting the kernel smoothing density region. Let $I\{u\}$ denote the indicator function.

Value	Kernel	Formula
'box'	Box (uniform)	$f(x) = 0.5I\{ x \leq 1\}$
'epanechnikov'	Epanechnikov	$f(x) = 0.75(1 - x^2)I\{ x \leq 1\}$
'normal'	Gaussian	$f(x) = \frac{1}{\sqrt{2\pi}}\exp(-0.5x^2)$
'triangle'	Triangular	$f(x) = (1 - x)I\{ x \leq 1\}$

If you specify a 1-by- P string array or cell array, with each element of the array containing any value in the table, then the software trains the classifier using the kernel smoother type in element j for feature j in X . The software ignores elements of `Kernel` not corresponding to a predictor whose distribution is 'kernel'.

You must specify that at least one predictor has distribution 'kernel' to additionally specify `Kernel`, `Support`, or `Width`.

Example: 'Kernel', {'epanechnikov', 'normal'}

Support — Kernel smoothing density support

'unbounded' (default) | 'positive' | string array | cell array | numeric row vector

Kernel smoothing density support, specified as the comma-separated pair consisting of 'Support' and 'positive', 'unbounded', a string array, a cell array, or a numeric row vector. The software applies the kernel smoothing density to the specified region.

This table summarizes the available options for setting the kernel smoothing density region.

Value	Description
1-by-2 numeric row vector	For example, [L,U], where L and U are the finite lower and upper bounds, respectively, for the density support.
'positive'	The density support is all positive real values.
'unbounded'	The density support is all real values.

If you specify a 1-by- P string array or cell array, with each element in the string array containing any text value in the table and each element in the cell array containing any value in the table, then the software trains the classifier using the kernel support in element j for feature j in X . The software ignores elements of `Kernel` not corresponding to a predictor whose distribution is 'kernel'.

You must specify that at least one predictor has distribution 'kernel' to additionally specify `Kernel`, `Support`, or `Width`.

Example: 'KSSupport', {[-10,20], 'unbounded'}

Data Types: char | string | cell | double

Width — Kernel smoothing window width

matrix of numeric values | numeric column vector | numeric row vector | scalar

Kernel smoothing window width, specified as the comma-separated pair consisting of 'Width' and a matrix of numeric values, numeric column vector, numeric row vector, or scalar.

Suppose there are K class levels and P predictors. This table summarizes the available options for setting the kernel smoothing window width.

Value	Description
K -by- P matrix of numeric values	Element (k,j) specifies the width for predictor j in class k .
K -by-1 numeric column vector	Element k specifies the width for all predictors in class k .
1-by- P numeric row vector	Element j specifies the width in all class levels for predictor j .
scalar	Specifies the bandwidth for all features in all classes.

By default, the software selects a default width automatically for each combination of predictor and class by using a value that is optimal for a Gaussian distribution. If you specify `Width` and it contains NaNs, then the software selects widths for the elements containing NaNs.

You must specify that at least one predictor has distribution 'kernel' to additionally specify `Kernel`, `Support`, or `Width`.

Example: 'Width', [NaN NaN]

Data Types: double | struct

Output Arguments

t — Naive Bayes classification template

template object

Naive Bayes classification template suitable for training error-correcting output code (ECOC) multiclass models, returned as a template object. Pass `t` to `fitcecoc` to specify how to create the naive Bayes classifier for the ECOC model.

If you display `t` to the Command Window, then all, unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

More About

Naive Bayes

Naive Bayes is a classification algorithm that applies density estimation to the data.

The algorithm leverages Bayes theorem, and (naively) assumes that the predictors are conditionally independent, given the class. Though the assumption is usually violated in practice, naive Bayes classifiers tend to yield posterior distributions that are robust to biased class density estimates, particularly where the posterior is 0.5 (the decision boundary) [1].

Naive Bayes classifiers assign observations to the most probable class (in other words, the maximum a posteriori decision rule). Explicitly, the algorithm:

- 1 Estimates the densities of the predictors within each class.
- 2 Models posterior probabilities according to Bayes rule. That is, for all $k = 1, \dots, K$,

$$\hat{P}(Y = k | X_1, \dots, X_P) = \frac{\pi(Y = k) \prod_{j=1}^P P(X_j | Y = k)}{\sum_{k=1}^K \pi(Y = k) \prod_{j=1}^P P(X_j | Y = k)},$$

where:

- Y is the random variable corresponding to the class index of an observation.
 - X_1, \dots, X_P are the random predictors of an observation.
 - $\pi(Y = k)$ is the prior probability that a class index is k .
- 3** Classifies an observation by estimating the posterior probability for each class, and then assigns the observation to the class yielding the maximum posterior probability.

If the predictors compose a multinomial distribution, then the posterior probability $\hat{P}(Y = k | X_1, \dots, X_P) \propto \pi(Y = k)P_{mn}(X_1, \dots, X_P | Y = k)$, where $P_{mn}(X_1, \dots, X_P | Y = k)$ is the probability mass function of a multinomial distribution.

Algorithms

- If you specify 'DistributionNames', 'mn' when training MdI using `fitcnb`, then the software fits a multinomial distribution using the bag-of-tokens model on page 32-1656. The software stores the probability that token j appears in class k in the property `DistributionParameters{k,j}`. Using additive smoothing [2], the estimated probability is

$$P(\text{token } j \mid \text{class } k) = \frac{1 + c_{j|k}}{P + c_k},$$

where:

- $c_{j|k} = n_k \frac{\sum_{i: y_i \in \text{class } k} x_{ij} w_i}{\sum_{i: y_i \in \text{class } k} w_i}$; which is the weighted number of occurrences of token j in class k .
 - n_k is the number of observations in class k .
 - w_i is the weight for observation i . The software normalizes weights within a class such that they sum to the prior probability for that class.
 - $c_k = \sum_{j=1}^P c_{j|k}$; which is the total weighted number of occurrences of all tokens in class k .
- If you specify 'DistributionNames', 'mvmn' when training MdI using `fitcnb`, then:
 - 1** For each predictor, the software collects a list of the unique levels, stores the sorted list in `CategoricalLevels`, and considers each level a bin. Each predictor/class combination is a separate, independent multinomial random variable.
 - 2** For predictor j in class k , the software counts instances of each categorical level using the list stored in `CategoricalLevels{j}`.
 - 3** The software stores the probability that predictor j , in class k , has level L in the property `DistributionParameters{k,j}`, for all levels in `CategoricalLevels{j}`. Using additive smoothing [2], the estimated probability is

$$P(\text{predictor } j = L \mid \text{class } k) = \frac{1 + m_{j|k}(L)}{m_j + m_k},$$

where:

- $$m_{j|k}(L) = n_k \frac{\sum_{i: y_i \in \text{class } k} I\{x_{ij} = L\} w_i}{\sum_{i: y_i \in \text{class } k} w_i};$$
 which is the weighted number of observations for which predictor j equals L in class k .
- n_k is the number of observations in class k .
- $I\{x_{ij} = L\} = 1$ if $x_{ij} = L$, 0 otherwise.
- w_i is the weight for observation i . The software normalizes weights within a class such that they sum to the prior probability for that class.
- m_j is the number of distinct levels in predictor j .
- m_k is the weighted number of observations in class k .

Introduced in R2014b

templateSVM

Support vector machine template

Syntax

```
t = templateSVM()  
t = templateSVM(Name,Value)
```

Description

`t = templateSVM()` returns a support vector machine (SVM) learner template suitable for training error-correcting output code (ECOC) multiclass models.

If you specify a default template, then the software uses default values for all input arguments during training.

Specify `t` as a binary learner, or one in a set of binary learners, in `fitcecoc` to train an ECOC multiclass classifier.

`t = templateSVM(Name,Value)` returns a template with additional options specified by one or more name-value pair arguments.

For example, you can specify the box constraint, the kernel function, or whether to standardize the predictors.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Create a Default Support Vector Machine Template

Use `templateSVM` to specify a default SVM template.

```
t = templateSVM()  
  
t =  
Fit template for classification SVM.  
  
          Alpha: [0x1 double]  
BoxConstraint: []  
  CacheSize: []  
CachingMethod: ''  
   ClipAlphas: []  
DeltaGradientTolerance: []  
      Epsilon: []  
   GapTolerance: []  
   KKTolerance: []  
IterationLimit: []
```

```

KernelFunction: ''
KernelScale: []
KernelOffset: []
KernelPolynomialOrder: []
NumPrint: []
Nu: []
OutlierFraction: []
RemoveDuplicates: []
ShrinkagePeriod: []
Solver: ''
StandardizeData: []
SaveSupportVectors: []
VerbosityLevel: []
Version: 2
Method: 'SVM'
Type: 'classification'

```

All properties of the template object are empty except for `Method` and `Type`. When you pass `t` to the training function, the software fills in the empty properties with their respective default values. For example, the software fills the `KernelFunction` property with `'linear'`. For details on other default values, see `fitcsvm`.

`t` is a plan for an SVM learner, and no computation occurs when you specify it. You can pass `t` to `fitcecoc` to specify SVM binary learners for ECOC multiclass learning. However, by default, `fitcecoc` uses default SVM binary learners.

Create an SVM Template for ECOC Multiclass Learning

Create a nondefault SVM template for use in `fitcecoc`.

Load Fisher's iris data set.

```
load fisheriris
```

Create a template for SVM binary classifiers, and specify to use a Gaussian kernel function.

```
t = templateSVM('KernelFunction','gaussian')
```

```
t =
Fit template for classification SVM.
```

```

Alpha: [0x1 double]
BoxConstraint: []
CacheSize: []
CachingMethod: ''
ClipAlphas: []
DeltaGradientTolerance: []
Epsilon: []
GapTolerance: []
KKTolerance: []
IterationLimit: []
KernelFunction: 'gaussian'
KernelScale: []
KernelOffset: []

```

```

KernelPolynomialOrder: []
    NumPrint: []
        Nu: []
    OutlierFraction: []
    RemoveDuplicates: []
    ShrinkagePeriod: []
        Solver: ''
    StandardizeData: []
    SaveSupportVectors: []
    VerbosityLevel: []
    Version: 2
    Method: 'SVM'
    Type: 'classification'

```

All properties of the template object are empty except for `DistributionNames`, `Method`, and `Type`. When trained on, the software fills in the empty properties with their respective default values.

Specify `t` as a binary learner for an ECOC multiclass model.

```
Mdl = fitcecoc(meas,species,'Learners',t);
```

`Mdl` is a `ClassificationECOC` multiclass classifier. By default, the software trains `Mdl` using the one-versus-one coding design.

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl,'LossFun','classiferror')
```

```
L = 0.0200
```

Retain and Discard Support Vectors of SVM Binary Learners

When you train an ECOC model with linear SVM binary learners, `fitcecoc` empties the `Alpha`, `SupportVectorLabels`, and `SupportVectors` properties of the binary learners by default. You can choose instead to retain the support vectors and related values, and then discard them from the model later.

Load Fisher's iris data set.

```
load fisheriris
rng(1); % For reproducibility
```

Train an ECOC model using the entire data set. Specify retaining the support vectors by passing in the appropriate SVM template.

```
t = templateSVM('SaveSupportVectors',true);
MdlSV = fitcecoc(meas,species,'Learners',t);
```

`MdlSV` is a trained `ClassificationECOC` model with linear SVM binary learners. By default, `fitcecoc` implements a one-versus-one coding design, which requires three binary learners for three-class learning.

Access the estimated α (alpha) values using dot notation.

```
alpha = cell(3,1);
alpha{1} = MdLSV.BinaryLearners{1}.Alpha;
alpha{2} = MdLSV.BinaryLearners{2}.Alpha;
alpha{3} = MdLSV.BinaryLearners{3}.Alpha;
alpha
```

```
alpha=3x1 cell array
    { 3x1 double}
    { 3x1 double}
    {23x1 double}
```

`alpha` is a 3-by-1 cell array that stores the estimated values of α .

Discard the support vectors and related values from the ECOC model.

```
Mdl = discardSupportVectors(MdLSV);
```

`Mdl` is similar to `MdLSV`, except that the `Alpha`, `SupportVectorLabels`, and `SupportVectors` properties of all the linear SVM binary learners are empty (`[]`).

```
areAllEmpty = @(x)isempty([x.Alpha x.SupportVectors x.SupportVectorLabels]);
cellfun(areAllEmpty,Mdl.BinaryLearners)
```

```
ans = 3x1 logical array
```

```
1
1
1
```

Compare the sizes of the two ECOC models.

```
vars = whos('Mdl','MdLSV');
100*(1 - vars(1).bytes/vars(2).bytes)
```

```
ans = 4.8394
```

`Mdl` is about 5% smaller than `MdLSV`.

Reduce your memory usage by compacting `Mdl` and then clearing `Mdl` and `MdLSV` from the workspace.

```
CompactMdl = compact(Mdl);
clear Mdl MdLSV;
```

Predict the label for a random row of the training data using the more efficient SVM model.

```
idx = randsample(size(meas,1),1)
```

```
idx = 63
```

```
predictedLabel = predict(CompactMdl,meas(idx,:))
```

```
predictedLabel = 1x1 cell array
    {'versicolor'}
```

```
trueLabel = species(idx)
```

```
truelabel = 1x1 cell array
    {'versicolor'}
```

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: `'BoxConstraint',0.1,'KernelFunction','gaussian','Standardize',1` specifies a box constraint of 0.1, to use the Gaussian (RBF) kernel, and to standardize the predictors.

BoxConstraint — Box constraint

1 (default) | positive scalar

Box constraint on page 32-1689, specified as the comma-separated pair consisting of `'BoxConstraint'` and a positive scalar.

For one-class learning, the software always sets the box constraint to 1.

For more details on the relationships and algorithmic behavior of `BoxConstraint`, `Cost`, `Prior`, `Standardize`, and `Weights`, see “Algorithms” on page 32-1693.

Example: `'BoxConstraint',100`

Data Types: double | single

CacheSize — Cache size

1000 (default) | 'maximal' | positive scalar

Cache size, specified as the comma-separated pair consisting of `'CacheSize'` and `'maximal'` or a positive scalar.

If `CacheSize` is `'maximal'`, then the software reserves enough memory to hold the entire n -by- n Gram matrix on page 32-1689.

If `CacheSize` is a positive scalar, then the software reserves `CacheSize` megabytes of memory for training the model.

Example: `'CacheSize','maximal'`

Data Types: double | single | char | string

ClipAlphas — Flag to clip alpha coefficients

true (default) | false

Flag to clip alpha coefficients, specified as the comma-separated pair consisting of `'ClipAlphas'` and either `true` or `false`.

Suppose that the alpha coefficient for observation j is α_j and the box constraint of observation j is C_j , $j = 1, \dots, n$, where n is the training sample size.

Value	Description
true	At each iteration, if α_j is near 0 or near C_j , then MATLAB sets α_j to 0 or to C_j , respectively.
false	MATLAB does not change the alpha coefficients during optimization.

MATLAB stores the final values of α in the Alpha property of the trained SVM model object.

`ClipAlphas` can affect SMO and ISDA convergence.

Example: 'ClipAlphas', false

Data Types: logical

DeltaGradientTolerance — Tolerance for gradient difference

nonnegative scalar

Tolerance for the gradient difference between upper and lower violators obtained by Sequential Minimal Optimization (SMO) or Iterative Single Data Algorithm (ISDA), specified as the comma-separated pair consisting of 'DeltaGradientTolerance' and a nonnegative scalar.

If `DeltaGradientTolerance` is 0, then the software does not use the tolerance for the gradient difference to check for optimization convergence.

The default values are:

- 1e-3 if the solver is SMO (for example, you set 'Solver', 'SMO')
- 0 if the solver is ISDA (for example, you set 'Solver', 'ISDA')

Example: 'DeltaGradientTolerance', 1e-2

Data Types: double | single

GapTolerance — Feasibility gap tolerance

0 (default) | nonnegative scalar

Feasibility gap tolerance obtained by SMO or ISDA, specified as the comma-separated pair consisting of 'GapTolerance' and a nonnegative scalar.

If `GapTolerance` is 0, then the software does not use the feasibility gap tolerance to check for optimization convergence.

Example: 'GapTolerance', 1e-2

Data Types: double | single

IterationLimit — Maximal number of numerical optimization iterations

1e6 (default) | positive integer

Maximal number of numerical optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer.

The software returns a trained model regardless of whether the optimization routine successfully converges. `Mdl.ConvergenceInfo` contains convergence information.

Example: 'IterationLimit', 1e8

Data Types: double | single

KernelFunction — Kernel function

'linear' | 'gaussian' | 'rbf' | 'polynomial' | function name

Kernel function used to compute the elements of the Gram matrix on page 32-1689, specified as the comma-separated pair consisting of 'KernelFunction' and a kernel function name. Suppose $G(x_j, x_k)$ is element (j, k) of the Gram matrix, where x_j and x_k are p -dimensional vectors representing observations j and k in X . This table describes supported kernel function names and their functional forms.

Kernel Function Name	Description	Formula
'gaussian' or 'rbf'	Gaussian or Radial Basis Function (RBF) kernel, default for one-class learning	$G(x_j, x_k) = \exp(-\ x_j - x_k\ ^2)$
'linear'	Linear kernel, default for two-class learning	$G(x_j, x_k) = x_j'x_k$
'polynomial'	Polynomial kernel. Use 'PolynomialOrder', q to specify a polynomial kernel of order q .	$G(x_j, x_k) = (1 + x_j'x_k)^q$

You can set your own kernel function, for example, `kernel`, by setting 'KernelFunction', 'kernel'. The value `kernel` must have this form.

```
function G = kernel(U,V)
```

where:

- U is an m -by- p matrix. Columns correspond to predictor variables, and rows correspond to observations.
- V is an n -by- p matrix. Columns correspond to predictor variables, and rows correspond to observations.
- G is an m -by- n Gram matrix on page 32-1689 of the rows of U and V .

`kernel.m` must be on the MATLAB path.

It is a good practice to avoid using generic names for kernel functions. For example, call a sigmoid kernel function 'mysigmoid' rather than 'sigmoid'.

Example: 'KernelFunction', 'gaussian'

Data Types: char | string

KernelOffset — Kernel offset parameter

nonnegative scalar

Kernel offset parameter, specified as the comma-separated pair consisting of 'KernelOffset' and a nonnegative scalar.

The software adds `KernelOffset` to each element of the Gram matrix.

The defaults are:

- 0 if the solver is SMO (that is, you set 'Solver', 'SMO')

- 0.1 if the solver is ISDA (that is, you set 'Solver', 'ISDA')

Example: 'KernelOffset',0

Data Types: double | single

KernelScale — Kernel scale parameter

1 (default) | 'auto' | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of 'KernelScale' and 'auto' or a positive scalar. The software divides all elements of the predictor matrix X by the value of KernelScale. Then, the software applies the appropriate kernel norm to compute the Gram matrix.

- If you specify 'auto', then the software selects an appropriate scale factor using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. Therefore, to reproduce results, set a random number seed using rng before training.
- If you specify KernelScale and your own kernel function, for example, 'KernelFunction', 'kernel', then the software throws an error. You must apply scaling within kernel.

Example: 'KernelScale', 'auto'

Data Types: double | single | char | string

KKTTolerance — Karush-Kuhn-Tucker complementarity conditions violation tolerance

nonnegative scalar

Karush-Kuhn-Tucker (KKT) complementarity conditions on page 32-1690 violation tolerance, specified as the comma-separated pair consisting of 'KKTTolerance' and a nonnegative scalar.

If KKTTolerance is 0, then the software does not use the KKT complementarity conditions violation tolerance to check for optimization convergence.

The default values are:

- 0 if the solver is SMO (for example, you set 'Solver', 'SMO')
- 1e-3 if the solver is ISDA (for example, you set 'Solver', 'ISDA')

Example: 'KKTTolerance', 1e-2

Data Types: double | single

NumPrint — Number of iterations between optimization diagnostic message output

1000 (default) | nonnegative integer

Number of iterations between optimization diagnostic message output, specified as the comma-separated pair consisting of 'NumPrint' and a nonnegative integer.

If you specify 'Verbose', 1 and 'NumPrint', numprint, then the software displays all optimization diagnostic messages from SMO and ISDA every numprint iterations in the Command Window.

Example: 'NumPrint', 500

Data Types: double | single

OutlierFraction — Expected proportion of outliers in training data

0 (default) | numeric scalar in the interval [0,1)

Expected proportion of outliers in the training data, specified as the comma-separated pair consisting of 'OutlierFraction' and a numeric scalar in the interval [0,1).

Suppose that you set 'OutlierFraction', `outlierfraction`, where `outlierfraction` is a value greater than 0.

- For two-class learning, the software implements robust learning. In other words, the software attempts to remove $100 \times \text{outlierfraction}\%$ of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.
- For one-class learning, the software finds an appropriate bias term such that `outlierfraction` of the observations in the training set have negative scores.

Example: 'OutlierFraction',0.01

Data Types: double | single

PolynomialOrder — Polynomial kernel function order

3 (default) | positive integer

Polynomial kernel function order, specified as the comma-separated pair consisting of 'PolynomialOrder' and a positive integer.

If you set 'PolynomialOrder' and `KernelFunction` is not 'polynomial', then the software throws an error.

Example: 'PolynomialOrder',2

Data Types: double | single

SaveSupportVectors — Store support vectors, their labels, and the estimated α coefficients

true | false

Store support vectors, their labels, and the estimated α coefficients as properties of the resulting model, specified as the comma-separated pair consisting of 'SaveSupportVectors' and true or false.

If `SaveSupportVectors` is true, the resulting model stores the support vectors in the `SupportVectors` property, their labels in the `SupportVectorLabels` property, and the estimated α coefficients in the `Alpha` property of the compact, SVM learners.

If `SaveSupportVectors` is false and `KernelFunction` is 'linear', the resulting model does not store the support vectors and the related estimates.

To reduce memory consumption by compact SVM models, specify `SaveSupportVectors`.

For linear, SVM binary learners in an ECOC model, the default value is false. Otherwise, the default value is true.

Example: 'SaveSupportVectors',true

Data Types: logical

ShrinkagePeriod — Number of iterations between reductions of active set

0 (default) | nonnegative integer

Number of iterations between reductions of the active set, specified as the comma-separated pair consisting of 'ShrinkagePeriod' and a nonnegative integer.

If you set 'ShrinkagePeriod', 0, then the software does not shrink the active set.

Example: 'ShrinkagePeriod', 1000

Data Types: double | single

Solver — Optimization routine

'ISDA' | 'LIQP' | 'SMO'

Optimization routine, specified as the comma-separated pair consisting of 'Solver' and a value in this table.

Value	Description
'ISDA'	Iterative Single Data Algorithm (see [30])
'LIQP'	Uses <code>quadprog</code> to implement <i>L1</i> soft-margin minimization by quadratic programming. This option requires an Optimization Toolbox license. For more details, see “Quadratic Programming Definition” (Optimization Toolbox).
'SMO'	Sequential Minimal Optimization (see [17])

The default value is 'ISDA' if you set 'OutlierFraction' to a positive value for two-class learning, and 'SMO' otherwise.

Example: 'Solver', 'ISDA'

Standardize — Flag to standardize predictor data

false (default) | true

Flag to standardize the predictor data, specified as the comma-separated pair consisting of 'Standardize' and true (1) or false (0).

If you set 'Standardize', true:

- The software centers and scales each column of the predictor data (X) by the weighted column mean and standard deviation, respectively (for details on weighted standardizing, see “Algorithms” on page 32-1693). MATLAB does not standardize the data contained in the dummy variable columns generated for categorical predictors.
- The software trains the classifier using the standardized predictor matrix, but stores the unstandardized data in the classifier property X.

Example: 'Standardize', true

Data Types: logical

Verbose — Verbosity level

0 (default) | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0, 1, or 2. The value of `Verbose` controls the amount of optimization information that the software displays in the Command Window and saves the information as a structure to `Mdl.ConvergenceInfo.History`.

This table summarizes the available verbosity level options.

Value	Description
0	The software does not display or save convergence information.
1	The software displays diagnostic messages and saves convergence criteria every <code>numprint</code> iterations, where <code>numprint</code> is the value of the name-value pair argument 'NumPrint'.
2	The software displays diagnostic messages and saves convergence criteria at every iteration.

Example: 'Verbose',1

Data Types: double | single

Output Arguments

t — SVM classification template

template object

SVM classification template suitable for training error-correcting output code (ECOC) multiclass models, returned as a template object. Pass `t` to `fitcecoc` to specify how to create the SVM classifier for the ECOC model.

If you display `t` to the Command Window, then all, unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

Tip

By default and for efficiency, `fitcecoc` empties the `Alpha`, `SupportVectorLabels`, and `SupportVectors` properties for all linear SVM binary learners. `fitcecoc` lists `Beta`, rather than `Alpha`, in the model display.

To store `Alpha`, `SupportVectorLabels`, and `SupportVectors`, pass a linear SVM template that specifies storing support vectors to `fitcecoc`. For example, enter:

```
t = templateSVM('SaveSupportVectors',true)
Mdl = fitcecoc(X,Y,'Learners',t);
```

You can remove the support vectors and related values by passing the resulting `ClassificationECOC` model to `discardSupportVectors`.

Introduced in R2014b

templateTree

Create decision tree template

Syntax

```
t = templateTree
t = templateTree(Name,Value)
```

Description

`t = templateTree` returns a default decision tree learner template suitable for training an ensemble (boosted and bagged decision trees) or error-correcting output code (ECOC) multiclass model. Specify `t` as a learner using:

- `fitensemble` for classification ensembles
- `fitrensemble` for regression ensembles
- `fitcecoc` for ECOC model classification

If you specify a default decision tree template, then the software uses default values for all input arguments during training. It is good practice to specify the type of decision tree, e.g., for a classification tree template, specify `'Type', 'classification'`. If you specify the type of decision tree and display `t` in the Command Window, then all options except `Type` appear empty (`[]`).

`t = templateTree(Name,Value)` creates a template with additional options specified by one or more name-value pair arguments.

For example, you can specify the algorithm used to find the best split on a categorical predictor, the split criterion, or the number of predictors selected for each split.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Create a Classification Template with Surrogate Splits

Create a decision tree template with surrogate splits, and use the template to train an ensemble using sample data.

Load Fisher's iris data set.

```
load fisheriris
```

Create a decision tree template of tree stumps with surrogate splits.

```
t = templateTree('Surrogate','on','MaxNumSplits',1)
t =
Fit template for Tree.
```

```

    Surrogate: 'on'
    MaxNumSplits: 1

```

Options for the template object are empty except for `Surrogate` and `MaxNumSplits`. When you pass `t` to the training function, the software fills in the empty options with their respective default values.

Specify `t` as a weak learner for a classification ensemble.

```
Mdl = fitensemble(meas,species,'Method','AdaBoostM2','Learners',t)
```

```

Mdl =
    classreg.learning.classif.ClassificationEnsemble
        ResponseName: 'Y'
    CategoricalPredictors: []
        ClassNames: {'setosa' 'versicolor' 'virginica'}
        ScoreTransform: 'none'
        NumObservations: 150
        NumTrained: 100
        Method: 'AdaBoostM2'
        LearnerNames: {'Tree'}
    ReasonForTermination: 'Terminated normally after completing the requested number of training
        FitInfo: [100x1 double]
    FitInfoDescription: {2x1 cell}

```

Properties, Methods

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl)
```

```
L = 0.0333
```

Optimize Regression Ensemble Using Cross-Validation

One way to create an ensemble of boosted regression trees that has satisfactory predictive performance is to tune the decision tree complexity level using cross-validation. While searching for an optimal complexity level, tune the learning rate to minimize the number of learning cycles as well.

This example manually finds optimal parameters by using the cross-validation option (the `'KFold'` name-value pair argument) and the `kfoldLoss` function. Alternatively, you can use the `'OptimizeHyperparameters'` name-value pair argument to optimize hyperparameters automatically. See “Optimize Regression Ensemble” on page 32-2080.

Load the `carsmall` data set. Choose the number of cylinders, volume displaced by the cylinders, horsepower, and weight as predictors of fuel economy.

```

load carsmall
Tbl = table(Cylinders,Displacement,Horsepower,Weight,MPG);

```

The default values of the tree depth controllers for boosting regression trees are:

- 10 for `MaxNumSplits`.

- 5 for MinLeafSize
- 10 for MinParentSize

To search for the optimal tree-complexity level:

- 1 Cross-validate a set of ensembles. Exponentially increase the tree-complexity level for subsequent ensembles from decision stump (one split) to at most $n - 1$ splits. n is the sample size. Also, vary the learning rate for each ensemble between 0.1 to 1.
- 2 Estimate the cross-validated mean-squared error (MSE) for each ensemble.
- 3 For tree-complexity level j , $j = 1 \dots J$, compare the cumulative, cross-validated MSE of the ensembles by plotting them against number of learning cycles. Plot separate curves for each learning rate on the same figure.
- 4 Choose the curve that achieves the minimal MSE, and note the corresponding learning cycle and learning rate.

Cross-validate a deep regression tree and a stump. Because the data contain missing values, use surrogate splits. These regression trees serve as benchmarks.

```
rng(1) % For reproducibility
MdlDeep = fitrtree(Tbl, 'MPG', 'CrossVal', 'on', 'MergeLeaves', 'off', ...
    'MinParentSize', 1, 'Surrogate', 'on');
MdlStump = fitrtree(Tbl, 'MPG', 'MaxNumSplits', 1, 'CrossVal', 'on', ...
    'Surrogate', 'on');
```

Cross-validate an ensemble of 150 boosted regression trees using 5-fold cross-validation. Using a tree template:

- Vary the maximum number of splits using the values in the sequence $\{2^0, 2^1, \dots, 2^m\}$. m is such that 2^m is no greater than $n - 1$.
- Turn on surrogate splits.

For each variant, adjust the learning rate using each value in the set $\{0.1, 0.25, 0.5, 1\}$.

```
n = size(Tbl, 1);
m = floor(log2(n - 1));
learnRate = [0.1 0.25 0.5 1];
numLR = numel(learnRate);
maxNumSplits = 2.^(0:m);
numMNS = numel(maxNumSplits);
numTrees = 150;
Mdl = cell(numMNS, numLR);

for k = 1:numLR
    for j = 1:numMNS
        t = templateTree('MaxNumSplits', maxNumSplits(j), 'Surrogate', 'on');
        Mdl{j, k} = fitrensemble(Tbl, 'MPG', 'NumLearningCycles', numTrees, ...
            'Learners', t, 'KFold', 5, 'LearnRate', learnRate(k));
    end
end
```

Estimate the cumulative, cross-validated MSE of each ensemble.

```
kflAll = @(x) kfoldLoss(x, 'Mode', 'cumulative');
errorCell = cellfun(kflAll, Mdl, 'Uniform', false);
```

```

error = reshape(cell2mat(errorCell),[numTrees numel(maxNumSplits) numel(learnRate)]);
errorDeep = kfoldLoss(MdlDeep);
errorStump = kfoldLoss(MdlStump);

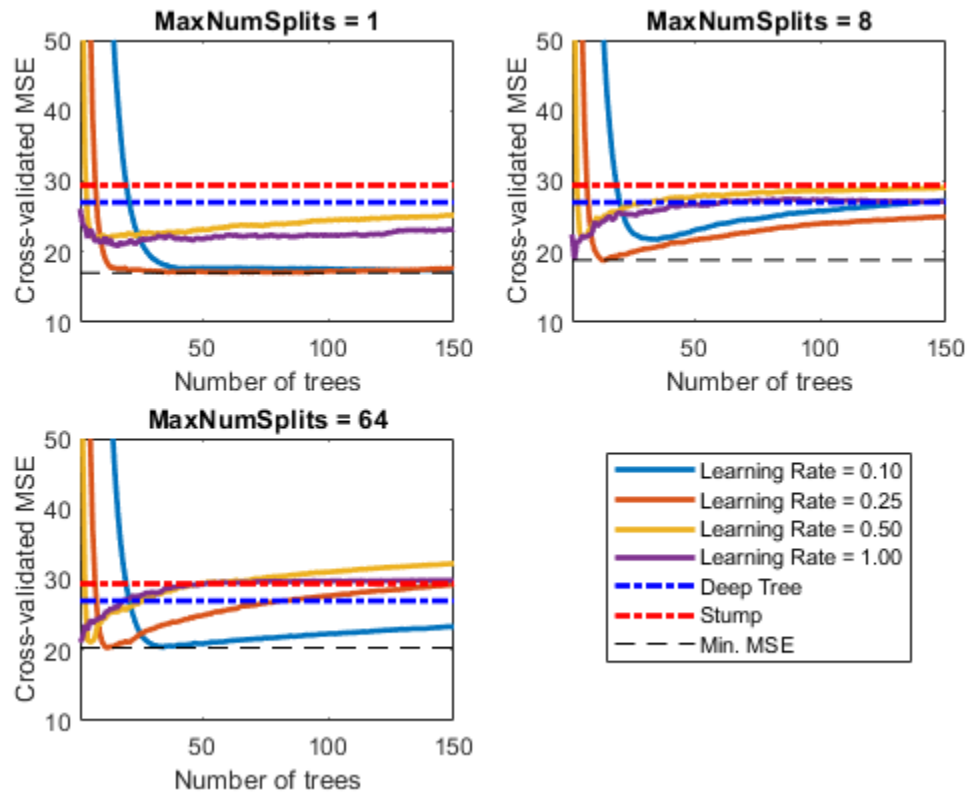

```

Plot how the cross-validated MSE behaves as the number of trees in the ensemble increases. Plot the curves with respect to learning rate on the same plot, and plot separate plots for varying tree-complexity levels. Choose a subset of tree complexity levels to plot.

```

mnsPlot = [1 round(numel(maxNumSplits)/2) numel(maxNumSplits)];
figure;
for k = 1:3
    subplot(2,2,k)
    plot(squeeze(error(:,mnsPlot(k),:)), 'LineWidth', 2)
    axis tight
    hold on
    h = gca;
    plot(h.XLim,[errorDeep errorDeep], '-.b', 'LineWidth', 2)
    plot(h.XLim,[errorStump errorStump], '-.r', 'LineWidth', 2)
    plot(h.XLim,min(min(error(:,mnsPlot(k),:))).*[1 1], '--k')
    h.YLim = [10 50];
    xlabel('Number of trees')
    ylabel('Cross-validated MSE')
    title(sprintf('MaxNumSplits = %0.3g', maxNumSplits(mnsPlot(k))))
    hold off
end
hL = legend([cellstr(num2str(learnRate', 'Learning Rate = %0.2f')); ...
            'Deep Tree'; 'Stump'; 'Min. MSE']);
hL.Position(1) = 0.6;

```

Each curve contains a minimum cross-validated MSE occurring at the optimal number of trees in the ensemble.

Identify the maximum number of splits, number of trees, and learning rate that yields the lowest MSE overall.

```
[minErr,minErrIdxLin] = min(error(:));
[idxNumTrees,idxMNS,idxLR] = ind2sub(size(error),minErrIdxLin);
fprintf('\nMin. MSE = %0.5f',minErr)
```

```
Min. MSE = 17.00516
```

```
fprintf('\nOptimal Parameter Values:\nNum. Trees = %d',idxNumTrees);
```

```
Optimal Parameter Values:
Num. Trees = 38
```

```
fprintf('\nMaxNumSplits = %d\nLearning Rate = %0.2f\n',...
    maxNumSplits(idxMNS),learnRate(idxLR))
```

```
MaxNumSplits = 4
Learning Rate = 0.10
```

Create a predictive ensemble based on the optimal hyperparameters and the entire training set.

```
tFinal = templateTree('MaxNumSplits',maxNumSplits(idxMNS),'Surrogate','on');
MdlFinal = fitensemble(Tbl,'MPG','NumLearningCycles',idxNumTrees,...
    'Learners',tFinal,'LearnRate',learnRate(idxLR))
```

```

MdlFinal =
  classreg.learning.regr.RegressionEnsemble
    PredictorNames: {'Cylinders' 'Displacement' 'Horsepower' 'Weight'}
    ResponseName: 'MPG'
    CategoricalPredictors: []
    ResponseTransform: 'none'
    NumObservations: 94
    NumTrained: 38
    Method: 'LSBoost'
    LearnerNames: {'Tree'}
    ReasonForTermination: 'Terminated normally after completing the requested number of training iterations'
    FitInfo: [38x1 double]
    FitInfoDescription: {2x1 cell}
    Regularization: []

```

Properties, Methods

`MdlFinal` is a `RegressionEnsemble`. To predict the fuel economy of a car given its number of cylinders, volume displaced by the cylinders, horsepower, and weight, you can pass the predictor data and `MdlFinal` to `predict`.

Instead of searching optimal values manually by using the cross-validation option (`'KFold'`) and the `kfoldLoss` function, you can use the `'OptimizeHyperparameters'` name-value pair argument. When you specify `'OptimizeHyperparameters'`, the software finds optimal parameters automatically using Bayesian optimization. The optimal values obtained by using `'OptimizeHyperparameters'` can be different from those obtained using manual search.

```

t = templateTree('Surrogate','on');
mdl = fitensemble(Tbl,'MPG','Learners',t, ...
    'OptimizeHyperparameters',{ 'NumLearningCycles','LearnRate','MaxNumSplits'})

```

Properties, Methods

Unbiased Estimates of Predictor Importance Using Parallel Computing

Load the `carsmall` data set. Consider a model that predicts the mean fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower, manufacturer, model year, and weight. Consider `Cylinders`, `Mfg`, and `Model_Year` as categorical variables.

```

load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
    Model_Year,Weight,MPG);

```

Display the number of categories represented in the categorical variables.

```

numCylinders = numel(categories(Cylinders))

numCylinders = 3

numMfg = numel(categories(Mfg))

numMfg = 28

numModelYear = numel(categories(Model_Year))

numModelYear = 3

```

Because there are 3 categories only in `Cylinders` and `Model_Year`, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over these two variables.

Train a random forest of 500 regression trees using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing values in the data, specify usage of surrogate splits. To reproduce random predictor selections, set the seed of the random number generator by using `rng` and specify `'Reproducible', true`.

```

rng('default'); % For reproducibility
t = templateTree('PredictorSelection','curvature','Surrogate','on', ...
    'Reproducible',true); % For reproducibility of random predictor selections

```

```
Mdl = fitrensemble(X, 'MPG', 'Method', 'bag', 'NumLearningCycles', 500, ...
    'Learners', t);
```

Estimate predictor importance measures by permuting out-of-bag observations. Perform calculations in parallel.

```
options = statset('UseParallel', true);
imp = oobPermutedPredictorImportance(Mdl, 'Options', options);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

Compare the estimates using a bar graph.

```
figure;
bar(imp);
title('Out-of-Bag Permuted Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```

In this case, Model_Year is the most important predictor, followed by Cylinders. Compare these results to the results in “Estimate Importance of Predictors” on page 32-3802.

Create an Ensemble Template for ECOC Multiclass Learning

Create an ensemble template for use in `fitcecoc`.

Load the arrhythmia data set.

```
load arrhythmia
tabulate(categorical(Y));
```

Value	Count	Percent
1	245	54.20%
2	44	9.73%
3	15	3.32%
4	15	3.32%
5	13	2.88%
6	25	5.53%
7	3	0.66%
8	2	0.44%
9	9	1.99%
10	50	11.06%
14	4	0.88%
15	5	1.11%
16	22	4.87%

```
rng(1); % For reproducibility
```

Some classes have small relative frequencies in the data.

Create a template for a AdaBoostM1 ensemble of classification trees, and specify to use 100 learners and a shrinkage of 0.1. By default, boosting grows stumps (i.e., one node having a set of leaves). Since there are classes with small frequencies, the trees must be leafy enough to be sensitive to the minority classes. Specify the minimum number of leaf node observations to 3.

```
tTree = templateTree('MinLeafSize',20);
t = templateEnsemble('AdaBoostM1',100,tTree,'LearnRate',0.1);
```

All properties of the template objects are empty except for `Method` and `Type`, and the corresponding properties of the name-value pair argument values in the function calls. When you pass `t` to the training function, the software fills in the empty properties with their respective default values.

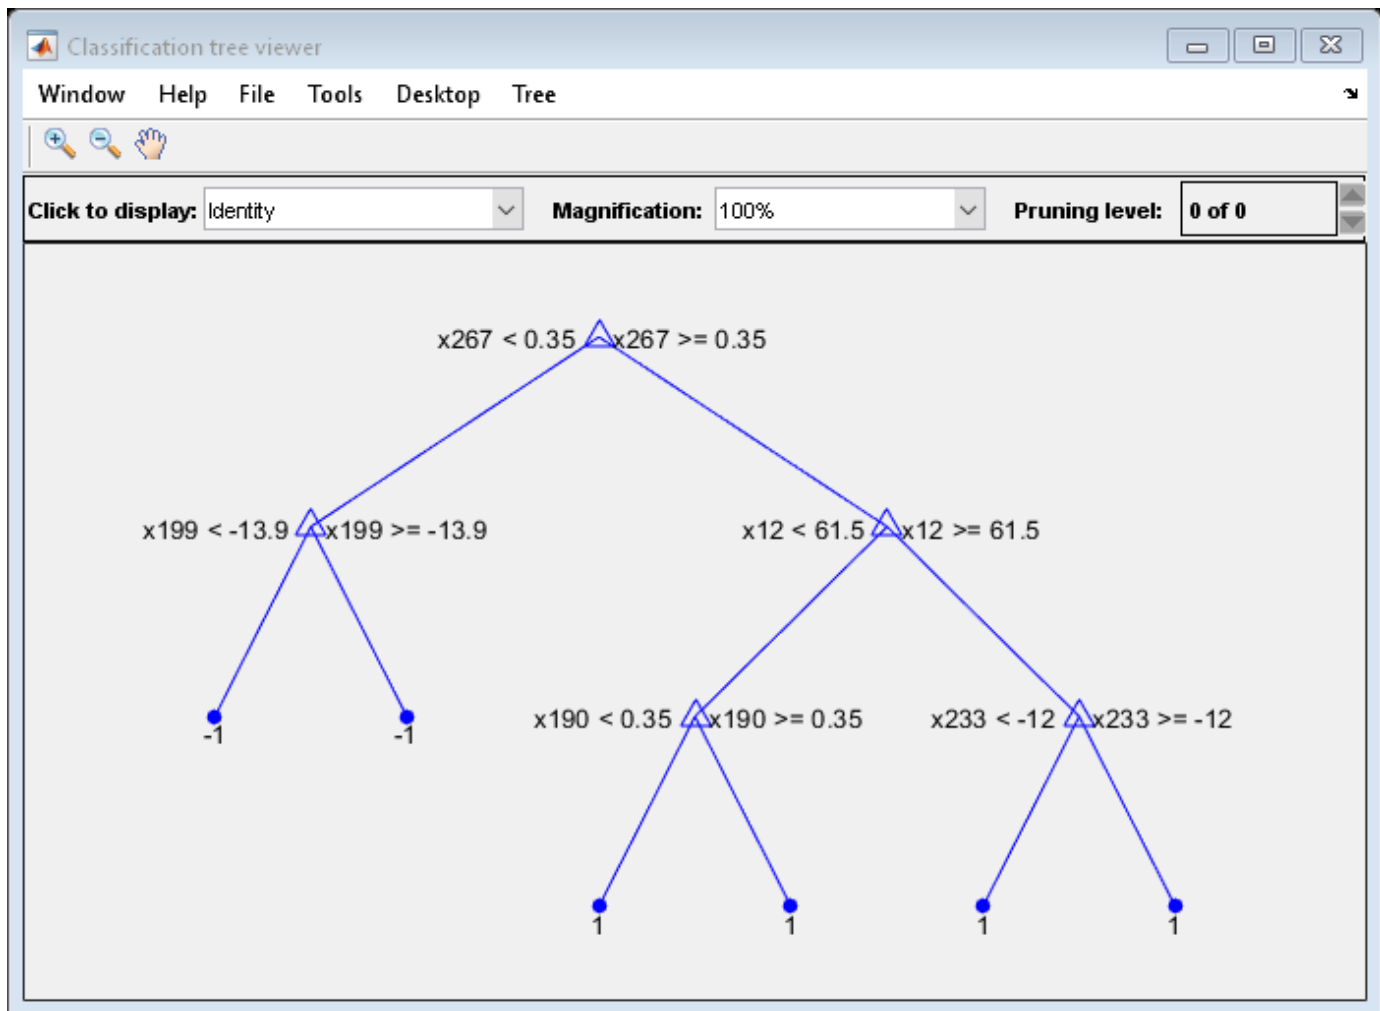

Specify `t` as a binary learner for an ECOC multiclass model. Train using the default one-versus-one coding design.

```
Mdl = fitcecoc(X,Y,'Learners',t);
```

- `Mdl` is a `ClassificationECOC` multiclass model.
- `Mdl.BinaryLearners` is a 78-by-1 cell array of `CompactClassificationEnsemble` models.
- `Mdl.BinaryLearners{j}.Trained` is a 100-by-1 cell array of `CompactClassificationTree` models, for $j = 1, \dots, 78$.

You can verify that one of the binary learners contains a weak learner that isn't a stump by using `view`.

```
view(Mdl.BinaryLearners{1}.Trained{1}, 'Mode', 'graph')
```

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl, 'LossFun', 'classiferror')
```

```
L = 0.0597
```

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: 'Surrogate', 'on', 'NumVariablesToSample', 'all' specifies a template with surrogate splits, and uses all available predictors at each split.

For Classification Trees and Regression Trees

MaxNumSplits — Maximal number of decision splits

positive integer

Maximal number of decision splits (or branch nodes) per tree, specified as the comma-separated pair consisting of `'MaxNumSplits'` and a positive integer. `templateTree` splits `MaxNumSplits` or fewer branch nodes. For more details on splitting behavior, see “Algorithms” on page 32-5437.

For bagged decision trees and decision tree binary learners in ECOC models, the default is $n - 1$, where n is the number of observations in the training sample. For boosted decision trees, the default is 10.

Example: `'MaxNumSplits',5`

Data Types: `single | double`

MergeLeaves — Leaf merge flag

`'off' | 'on'`

Leaf merge flag, specified as the comma-separated pair consisting of `'MergeLeaves'` and either `'on'` or `'off'`.

When `'on'`, the decision tree merges leaves that originate from the same parent node, and that provide a sum of risk values greater or equal to the risk associated with the parent node. When `'off'`, the decision tree does not merge leaves.

For boosted and bagged decision trees, the defaults are `'off'`. For decision tree binary learners in ECOC models, the default is `'on'`.

Example: `'MergeLeaves','on'`

MinLeafSize — Minimum observations per leaf

positive integer value

Minimum observations per leaf, specified as the comma-separated pair consisting of `'MinLeafSize'` and a positive integer value. Each leaf has at least `MinLeafSize` observations per tree leaf. If you supply both `MinParentSize` and `MinLeafSize`, the decision tree uses the setting that gives larger leaves: `MinParentSize = max(MinParentSize,2*MinLeafSize)`.

For boosted and bagged decision trees, the defaults are 1 for classification and 5 for regression. For decision tree binary learners in ECOC models, the default is 1.

Example: `'MinLeafSize',2`

MinParentSize — Minimum observations per branch node

positive integer value

Minimum observations per branch node, specified as the comma-separated pair consisting of `'MinParentSize'` and a positive integer value. Each branch node in the tree has at least `MinParentSize` observations. If you supply both `MinParentSize` and `MinLeafSize`, the decision tree uses the setting that gives larger leaves: `MinParentSize = max(MinParentSize,2*MinLeafSize)`.

For boosted and bagged decision trees, the defaults are 2 for classification and 10 for regression. For decision tree binary learners in ECOC models, the default is 10.

Example: `'MinParentSize',4`

NumVariablesToSample — Number of predictors to select at random for each split

positive integer value | `'all'`

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of 'NumVariablesToSample' and a positive integer value. Alternatively, you can specify 'all' to use all available predictors.

If the training data includes many predictors and you want to analyze predictor importance, then specify 'NumVariablesToSample' as 'all'. Otherwise, the software might not select some predictors, underestimating their importance.

To reproduce the random selections, you must set the seed of the random number generator by using `rng` and specify 'Reproducible', `true`.

For boosted decision trees and decision tree binary learners in ECOC models, the default is 'all'. The default for bagged decision trees is the square root of the number of predictors for classification, or one third of the number of predictors for regression.

Example: 'NumVariablesToSample',3

Data Types: `single` | `double` | `char` | `string`

PredictorSelection — Algorithm used to select the best split predictor

'allsplits' (default) | 'curvature' | 'interaction-curvature'

Algorithm used to select the best split predictor at each node, specified as the comma-separated pair consisting of 'PredictorSelection' and a value in this table.

Value	Description
'allsplits'	Standard CART — Selects the split predictor that maximizes the split-criterion gain over all possible splits of all predictors [1].
'curvature'	Curvature test — Selects the split predictor that minimizes the p -value of chi-square tests of independence between each predictor and the response [3][4]. Training speed is similar to standard CART.
'interaction-curvature'	Interaction test — Chooses the split predictor that minimizes the p -value of chi-square tests of independence between each predictor and the response, and that minimizes the p -value of a chi-square test of independence between each pair of predictors and response [3]. Training speed can be slower than standard CART.

For 'curvature' and 'interaction-curvature', if all tests yield p -values greater than 0.05, then MATLAB stops splitting nodes.

Tip

- The curvature and interaction tests are not recommended for boosting decision trees. To train an ensemble of boosted trees that has greater accuracy, use standard CART instead.
- Standard CART tends to select split predictors containing many distinct values, e.g., continuous variables, over those containing few distinct values, e.g., categorical variables [4]. If the predictor data set is heterogeneous, or if there are predictors that have relatively fewer distinct values than other variables, then consider specifying the curvature or interaction test.
 - If there are predictors that have relatively fewer distinct values than other predictors, for example, if the predictor data set is heterogeneous.
 - If an analysis of predictor importance is your goal. For more on predictor importance estimation, see `oobPermutedPredictorImportance` for classification problems,

`oobPermutedPredictorImportance` for regression problems, and “Introduction to Feature Selection” on page 15-49.

- Trees grown using standard CART are not sensitive to predictor variable interactions. Also, such trees are less likely to identify important variables in the presence of many irrelevant predictors than the application of the interaction test. Therefore, to account for predictor interactions and identify importance variables in the presence of many irrelevant variables, specify the interaction test [3].
- Prediction speed is unaffected by the value of `'PredictorSelection'`.

For details on how `templateTree` selects split predictors, see “Node Splitting Rules” on page 32-1791 (classification), “Node Splitting Rules” on page 32-2180 (regression), and “Choose Split Predictor Selection Technique” on page 19-14.

Example: `'PredictorSelection', 'curvature'`

Prune — Flag to estimate optimal sequence of pruned subtrees

`'off' | 'on'`

Flag to estimate the optimal sequence of pruned subtrees, specified as the comma-separated pair consisting of `'Prune'` and `'on'` or `'off'`.

If `Prune` is `'on'`, then the software trains the classification tree learners without pruning them, but estimates the optimal sequence of pruned subtrees for each learner in the ensemble or decision tree binary learner in ECOC models. Otherwise, the software trains the classification tree learners without estimating the optimal sequence of pruned subtrees.

For boosted and bagged decision trees, the default is `'off'`.

For decision tree binary learners in ECOC models, the default is `'on'`.

Example: `'Prune', 'on'`

PruneCriterion — Pruning criterion

`'error' | 'impurity' | 'mse'`

Pruning criterion, specified as the comma-separated pair consisting of `'PruneCriterion'` and a pruning criterion valid for the tree type.

- For classification trees, you can specify `'error'` (default) or `'impurity'`. If you specify `'impurity'`, then `templateTree` uses the impurity measure specified by the `'SplitCriterion'` name-value pair argument.
- For regression trees, you can specify only `'mse'` (default).

Example: `'PruneCriterion', 'impurity'`

Reproducible — Flag to enforce reproducibility

`false` (logical 0) (default) | `true` (logical 1)

Flag to enforce reproducibility over repeated runs of training a model, specified as the comma-separated pair consisting of `'Reproducible'` and either `false` or `true`.

If `'NumVariablesToSample'` is not `'all'`, then the software selects predictors at random for each split. To reproduce the random selections, you must specify `'Reproducible', true` and set the seed

of the random number generator by using `rng`. Note that setting `'Reproducible'` to `true` can slow down training.

Example: `'Reproducible', true`

Data Types: `logical`

SplitCriterion — Split criterion

`'gdi' | 'twoing' | 'deviance' | 'mse'`

Split criterion, specified as the comma-separated pair consisting of `'SplitCriterion'` and a split criterion valid for the tree type.

- For classification trees:
 - `'gdi'` for Gini's diversity index (default)
 - `'twoing'` for the twoing rule
 - `'deviance'` for maximum deviance reduction (also known as cross entropy)
- For regression trees:
 - `'mse'` for mean squared error (default)

Example: `'SplitCriterion', 'deviance'`

Surrogate — Surrogate decision splits

`'off' (default) | 'on' | 'all' | positive integer value`

Surrogate decision splits flag, specified as the comma-separated pair consisting of `'Surrogate'` and one of `'off'`, `'on'`, `'all'`, or a positive integer value.

- When `'off'`, the decision tree does not find surrogate splits at the branch nodes.
- When `'on'`, the decision tree finds at most 10 surrogate splits at each branch node.
- When set to `'all'`, the decision tree finds all surrogate splits at each branch node. The `'all'` setting can consume considerable time and memory.
- When set to a positive integer value, the decision tree finds at most the specified number of surrogate splits at each branch node.

Use surrogate splits to improve the accuracy of predictions for data with missing values. This setting also lets you compute measures of predictive association between predictors.

Example: `'Surrogate', 'on'`

Data Types: `single | double | char | string`

For Classification Trees Only

AlgorithmForCategorical — Algorithm for best categorical predictor split

`'Exact' | 'PullLeft' | 'PCA' | 'OVAbyClass'`

Algorithm to find the best split on a categorical predictor for data with C categories for data and $K \geq 3$ classes, specified as the comma-separated pair consisting of `'AlgorithmForCategorical'` and one of the following.

Value	Description
'Exact'	Consider all $2^{C-1} - 1$ combinations.
'PullLeft'	Start with all C categories on the right branch. Consider moving each category to the left branch as it achieves the minimum impurity for the K classes among the remaining categories. From this sequence, choose the split that has the lowest impurity.
'PCA'	Compute a score for each category using the inner product between the first principal component of a weighted covariance matrix (of the centered class probability matrix) and the vector of class probabilities for that category. Sort the scores in ascending order, and consider all $C - 1$ splits.
'OVAbyClass'	Start with all C categories on the right branch. For each class, order the categories based on their probability for that class. For the first class, consider moving each category to the left branch in order, recording the impurity criterion at each move. Repeat for the remaining classes. From this sequence, choose the split that has the minimum impurity.

The software selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For two classes, it always performs the exact search. Use the 'AlgorithmForCategorical' name-value pair argument to specify a particular algorithm.

For more details, see “Splitting Categorical Predictors in Classification Trees” on page 19-25.

Example: 'AlgorithmForCategorical', 'PCA'

MaxNumCategories — Maximum category levels in split node

10 (default) | nonnegative scalar value

Maximum category levels in the split node, specified as the comma-separated pair consisting of 'MaxNumCategories' and a nonnegative scalar value. A classification tree splits a categorical predictor using the exact search algorithm if the predictor has at most MaxNumCategories levels in the split node. Otherwise, it finds the best categorical split using one of the inexact algorithms. Note that passing a small value can increase computation time and memory overload.

Example: 'MaxNumCategories', 8

For Regression Trees Only

QuadraticErrorTolerance — Quadratic error tolerance

1e-6 (default) | positive scalar value

Quadratic error tolerance per node, specified as the comma-separated pair consisting of 'QuadraticErrorTolerance' and a positive scalar value. A regression tree stops splitting nodes when the weighted mean squared error per node drops below QuadraticErrorTolerance* ϵ , where ϵ is the weighted mean squared error of all n responses computed before growing the decision tree.

$$\varepsilon = \sum_{i=1}^n w_i (y_i - \bar{y})^2.$$

w_i is the weight of observation i , given that the weights of all the observations sum to one

($\sum_{i=1}^n w_i = 1$), and

$$\bar{y} = \sum_{i=1}^n w_i y_i$$

is the weighted average of all the responses.

Example: 'QuadraticErrorTolerance', 1e-4

Output Arguments

t — Decision tree template for classification or regression

template object

Decision tree template for classification or regression suitable for training an ensemble (boosted and bagged decision trees) or error-correcting output code (ECOC) multiclass model, returned as a template object. Pass **t** to `fitcensemble`, or `fitrensemble`, or `fitcecoc` to specify how to create the decision tree for the classification ensemble, regression ensemble, or ECOC model, respectively.

If you display **t** in the Command Window, then all unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

Algorithms

- To accommodate `MaxNumSplits`, the software splits all nodes in the current layer, and then counts the number of branch nodes. A layer is the set of nodes that are equidistant from the root node. If the number of branch nodes exceeds `MaxNumSplits`, then the software follows this procedure.
 - 1 Determine how many branch nodes in the current layer need to be unsplit so that there would be at most `MaxNumSplits` branch nodes.
 - 2 Sort the branch nodes by their impurity gains.
 - 3 Unsplit the desired number of least successful branches.
 - 4 Return the decision tree grown so far.

This procedure aims at producing maximally balanced trees.

- The software splits branch nodes layer by layer until at least one of these events occurs.
 - There are `MaxNumSplits + 1` branch nodes.
 - A proposed split causes the number of observations in at least one branch node to be fewer than `MinParentSize`.
 - A proposed split causes the number of observations in at least one leaf node to be fewer than `MinLeafSize`.

- The algorithm cannot find a good split within a layer (i.e., the pruning criterion (see `PruneCriterion`), does not improve for all proposed splits in a layer). A special case of this event is when all nodes are pure (i.e., all observations in the node have the same class).
- For values `'curvature'` or `'interaction-curvature'` of `PredictorSelection`, all tests yield p -values greater than 0.05.

`MaxNumSplits` and `MinLeafSize` do not affect splitting at their default values. Therefore, if you set `'MaxNumSplits'`, then splitting might stop due to the value of `MinParentSize` before `MaxNumSplits` splits occur.

- For details on selecting split predictors and node-splitting algorithms when growing decision trees, see “Algorithms” on page 32-1791 for classification trees and “Algorithms” on page 32-2180 for regression trees.

Introduced in R2014a

test

Class: cvpartition

Test indices for cross-validation

Syntax

```
idx = test(c)
idx = test(c,i)
```

Description

`idx = test(c)` returns the logical vector `idx` of test indices for an object `c` of the `cvpartition` on page 32-983 class of type 'holdout' or 'resubstitution'.

If `c.Type` is 'holdout', `idx` specifies the observations in the test set.

If `c.Type` is 'resubstitution', `idx` specifies all observations.

`idx = test(c,i)` returns the logical vector `idx` of test indices for repetition `i` of an object `c` of the `cvpartition` on page 32-983 class of type 'kfold' or 'leaveout'.

If `c.Type` is 'kfold', `idx` specifies the observations in the test set in fold `i`.

If `c.Type` is 'leaveout', `idx` specifies the observation left out at repetition `i`.

Examples

Identify the test indices in the first fold of a partition of 10 observations for 3-fold cross-validation:

```
c = cvpartition(10,'kfold',3)
c =
K-fold cross validation partition
      N: 10
  NumTestSets: 3
   TrainSize: 7  6  7
   TestSize:  3  4  3

test(c,1)
ans =
     1
     1
     0
     0
     0
     0
     0
     0
     1
     0
```

See Also

`cvpartition` | `training`

testcholdout

Compare predictive accuracies of two classification models

Syntax

```
h = testcholdout(YHat1,YHat2,Y)
h = testcholdout(YHat1,YHat2,Y,Name,Value)
[h,p,e1,e2] = testcholdout( ___ )
```

Description

`testcholdout` statistically assesses the accuracies of two classification models. The function first compares their predicted labels against the true labels, and then it detects whether the difference between the misclassification rates is statistically significant.

You can assess whether the accuracies of the classification models are different, or whether one classification model performs better than another. `testcholdout` can conduct several McNemar test on page 32-5451 variations, including the asymptotic test, the exact-conditional test, and the mid- p -value test. For cost-sensitive assessment on page 32-5449, available tests include a chi-square test (requires an Optimization Toolbox license) and a likelihood ratio test.

`h = testcholdout(YHat1,YHat2,Y)` returns the test decision, by conducting the mid- p -value McNemar test on page 32-5451, from testing the null hypothesis that the predicted class labels `YHat1` and `YHat2` have equal accuracy for predicting the true class labels `Y`. The alternative hypothesis is that the labels have unequal accuracy.

`h = 1` indicates to reject the null hypothesis at the 5% significance level. `h = 0` indicates to not reject the null hypothesis at 5% level.

`h = testcholdout(YHat1,YHat2,Y,Name,Value)` returns the result of the hypothesis test with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the type of alternative hypothesis, specify the type of test, or supply a cost matrix.

`[h,p,e1,e2] = testcholdout(___)` returns the p -value for the hypothesis test (p) and the respective classification loss on page 32-5453 of each set of predicted class labels ($e1$ and $e2$) using any of the input arguments in the previous syntaxes.

Examples

Compare Accuracies of Two Different Classification Models

Train two classification models using different algorithms. Conduct a statistical test comparing the misclassification rates of the two models on a held-out set.

Load the ionosphere data set.

```
load ionosphere
```

Create a partition that evenly splits the data into training and testing sets.

```

rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices

```

CVP is a cross-validation partition object that specifies the training and test sets.

Train an SVM model and an ensemble of 100 bagged classification trees. For the SVM model, specify to use the radial basis function kernel and a heuristic procedure to determine the kernel scale.

```

MdlSVM = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true,...
    'KernelFunction','RBF','KernelScale','auto');
t = templateTree('Reproducible',true); % For reproducibility of random predictor selections
MdlBag = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','Bag','Learners',t);

```

MdlSVM is a trained ClassificationSVM model. MdlBag is a trained ClassificationBaggedEnsemble model.

Label the test-set observations using the trained models.

```

YhatSVM = predict(MdlSVM,X(idxTest,:));
YhatBag = predict(MdlBag,X(idxTest,:));

```

YhatSVM and YhatBag are vectors containing the predicted class labels of the respective models.

Test whether the two models have equal predictive accuracies.

```

h = testcholdout(YhatSVM,YhatBag,Y(idxTest))

h = logical
    0

```

$h = 0$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Assess Whether One Classification Model Classifies Better Than Another

Train two classification models using the same algorithm, but adjust a hyperparameter to make the algorithm more complex. Conduct a statistical test to assess whether the simpler model has better accuracy in held-out data than the more complex model.

Load the ionosphere data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```

rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices

```

CVP is a cross-validation partition object that specifies the training and test sets.

Train two SVM models: one that uses a linear kernel (the default for binary classification) and one that uses the radial basis function kernel. Use the default kernel scale of 1.

```
MdlLinear = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true);
MdlRBF = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true,...
    'KernelFunction','RBF');
```

MdlLinear and MdlRBF are trained ClassificationSVM models.

Label the test-set observations using the trained models.

```
YhatLinear = predict(MdlLinear,X(idxTest,:));
YhatRBF = predict(MdlRBF,X(idxTest,:));
```

YhatLinear and YhatRBF are vectors containing the predicted class labels of the respective models.

Test the null hypothesis that the simpler model (MdlLinear) is at most as accurate as the more complex model (MdlRBF). Because the test-set size is large, conduct the asymptotic McNemar test, and compare the results with the mid- p -value test (the cost-insensitive testing default). Request to return p -values and misclassification rates.

```
Asymp = zeros(4,1); % Preallocation
MidP = zeros(4,1);
```

```
[Asymp(1),Asymp(2),Asymp(3),Asymp(4)] = testcholdout(YhatLinear,YhatRBF,Y(idxTest),...
    'Alternative','greater','Test','asymptotic');
[MidP(1),MidP(2),MidP(3),MidP(4)] = testcholdout(YhatLinear,YhatRBF,Y(idxTest),...
    'Alternative','greater');
table(Asymp,MidP,'RowNames',{'h' 'p' 'e1' 'e2'})
```

```
ans=4x2 table
           Asymp           MidP
           _____           _____
h           1             1
p    7.2801e-09    2.7649e-10
e1     0.13714     0.13714
e2     0.33143     0.33143
```

The p -value is close to zero for both tests, which indicates strong evidence to reject the null hypothesis that the simpler model is less accurate than the more complex model. No matter what test you specify, testcholdout returns the same type of misclassification measure for both models.

Conduct Cost-Sensitive Comparison of Two Classification Models

For data sets with imbalanced class representations, or if the false-positive and false-negative costs are imbalanced, you can statistically compare the predictive performance of two classification models by including a cost matrix in the analysis.

Load the arrhythmia data set. Determine the class representations in the data.

```
load arrhythmia;
Y = categorical(Y);
tabulate(Y);
```

Value	Count	Percent
1	245	54.20%
2	44	9.73%
3	15	3.32%
4	15	3.32%
5	13	2.88%
6	25	5.53%
7	3	0.66%
8	2	0.44%
9	9	1.99%
10	50	11.06%
14	4	0.88%
15	5	1.11%
16	22	4.87%

There are 16 classes, however some are not represented in the data set (for example, class 13). Most observations are classified as not having arrhythmia (class 1). The data set is highly discrete with imbalanced classes.

Combine all observations with arrhythmia (classes 2 through 15) into one class. Remove those observations with unknown arrhythmia status (class 16) from the data set.

```
idx = (Y ~= '16');
Y = Y(idx);
X = X(idx,:);
Y(Y ~= '1') = 'WithArrhythmia';
Y(Y == '1') = 'NoArrhythmia';
Y = removecats(Y);
```

Create a partition that evenly splits the data into training and test sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Create a cost matrix such that misclassifying a patient with arrhythmia into the "no arrhythmia" class is five times worse than misclassifying a patient without arrhythmia into the arrhythmia class. Classifying correctly incurs no cost. The rows indicate the true class and the columns indicate predicted class. When you conduct a cost-sensitive analysis, a good practice is to specify the order of the classes.

```
Cost = [0 1;5 0];
ClassNames = {'NoArrhythmia','WithArrhythmia'};
```

Train two boosting ensembles of 50 classification trees, one that uses AdaBoostM1 and another that uses LogitBoost. Because there are missing values in the data set, specify to use surrogate splits. Train the models using the cost matrix.

```
t = templateTree('Surrogate','on');
numTrees = 50;
MdlAda = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','AdaBoostM1',...
    'NumLearningCycles',numTrees,'Learners',t,...
    'Cost',Cost,'ClassNames',ClassNames);
MdlLogit = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','LogitBoost',...
```

```
'NumLearningCycles', numTrees, 'Learners', t, ...
'Cost', Cost, 'ClassNames', ClassNames);
```

MdlAda and MdlLogit are trained ClassificationEnsemble models.

Label the test-set observations using the trained models.

```
YhatAda = predict(MdlAda,X(idxTest,:));
YhatLogit = predict(MdlLogit,X(idxTest,:));
```

YhatLinear and YhatRBF are vectors containing the predicted class labels of the respective models.

Test whether the AdaBoostM1 ensemble (MdlAda) and the LogitBoost ensemble (MdlLogit) have equal predictive accuracy. Supply the cost matrix. Conduct the asymptotic, likelihood ratio, cost-sensitive test (the default when you pass in a cost matrix). Request to return p -values and misclassification costs.

```
[h,p,e1,e2] = testcholdout(YhatAda,YhatLogit,Y(idxTest),'Cost',Cost)
```

```
h = logical
    0
```

```
p = 0.4488
```

```
e1 = 0.5302
```

```
e2 = 0.4698
```

$h = 0$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Input Arguments

YHat1 — Predicted class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Predicted class labels of the first classification model, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

If YHat1 is a character array, then each element must correspond to one row of the array.

YHat1, YHat2, and Y must have equal lengths.

It is a best practice for YHat1, YHat2, and Y to share the same data type.

Data Types: categorical | char | string | logical | single | double | cell

YHat2 — Predicted class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Predicted class labels of the second classification model, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

If YHat2 is a character array, then each element must correspond to one row of the array.

YHat1, YHat2, and Y must have equal lengths.

It is a best practice for YHat1, YHat2, and Y to share the same data type.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Y — True class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

True class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

If Y is a character array, then each element must correspond to one row of the array.

YHat1, YHat2, and Y must have equal lengths.

It is a best practice for YHat1, YHat2, and Y to share the same data type.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'Alternative', 'greater', 'Test', 'asymptotic', 'Cost', [0 2; 1 0]` specifies to test whether the first set of first predicted class labels is more accurate than the second set, to conduct the asymptotic McNemar test, and to penalize misclassifying observations with the true label `ClassNames{1}` twice as much as for misclassifying observations with the true label `ClassNames{2}`.

Alpha — Hypothesis test significance level

0.05 (default) | scalar value in the interval (0,1)

Hypothesis test significance level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the interval (0,1).

Example: `'Alpha', 0.1`

Data Types: `single` | `double`

Alternative — Alternative hypothesis to assess

`'unequal'` (default) | `'greater'` | `'less'`

Alternative hypothesis to assess, specified as the comma-separated pair consisting of `'Alternative'` and one of the values listed in the table.

Value	Alternative hypothesis
<code>'unequal'</code> (default)	For predicting Y, YHat1 and YHat2 have unequal accuracies.
<code>'greater'</code>	For predicting Y, YHat1 is more accurate than YHat2.
<code>'less'</code>	For predicting Y, YHat1 is less accurate than YHat2.

Example: `'Alternative', 'greater'`

ClassNames — Class names

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class names, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. You must set ClassNames using the data type of Y.

If ClassNames is a character array, then each element must correspond to one row of the array.

Use ClassNames to:

- Specify the order of any input argument dimension that corresponds to class order. For example, use ClassNames to specify the order of the dimensions of Cost.
- Select a subset of classes for testing. For example, suppose that the set of all distinct class names in Y is {'a', 'b', 'c'}. To train and test models using observations from classes 'a' and 'c' only, specify 'ClassNames', {'a', 'c'}.

The default is the set of all distinct class names in Y.

Example: 'ClassNames', {'b', 'g'}

Data Types: single | double | logical | char | string | cell | categorical

Cost — Misclassification cost

square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure array.

- If you specify the square matrix Cost, then $\text{Cost}(i, j)$ is the cost of classifying a point into class j if its true class is i. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of Cost, additionally specify the ClassNames name-value pair argument.
- If you specify the structure S, then S must have two fields:
 - S.ClassNames, which contains the class names as a variable of the same data type as Y. You can use this field to specify the order of the classes.
 - S.ClassificationCosts, which contains the cost matrix, with rows and columns ordered as in S.ClassNames.

If you specify Cost, then testcholdout cannot conduct one-sided, exact, or mid-p tests. You must also specify 'Alternative', 'unequal', 'Test', 'asymptotic'. For cost-sensitive testing options, see the CostTest name-value pair argument.

A best practice is to supply the same cost matrix used to train the classification models.

The default is $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$.

Example: 'Cost', [0 1 2 ; 1 0 2; 2 2 0]

Data Types: single | double | struct

CostTest — Cost-sensitive test type

'likelihood' (default) | 'chisquare'

Cost-sensitive test type, specified as the comma-separated pair consisting of 'CostTest' and 'chisquare' or 'likelihood'. Unless you specify a cost matrix using the Cost name-value pair argument, testcholdout ignores CostTest.

This table summarizes the available options for cost-sensitive testing.

Value	Asymptotic test type	Requirements
'chisquare'	Chi-square test	Optimization Toolbox license to implement quadprog
'likelihood'	Likelihood ratio test	None

For more details, see “Cost-Sensitive Testing” on page 32-5449.

Example: 'CostTest','chisquare'

Test — Test to conduct

'asymptotic' | 'exact' | 'midp'

Test to conduct, specified as the comma-separated pair consisting of 'Test' and 'asymptotic', 'exact', and 'midp'. This table summarizes the available options for cost-insensitive testing.

Value	Description
'asymptotic'	Asymptotic McNemar test
'exact'	Exact-conditional McNemar test
'midp' (default)	Mid- p -value McNemar test

For more details, see “McNemar Tests” on page 32-5451.

For cost-sensitive testing, Test must be 'asymptotic'. When you specify the Cost name-value pair argument, and choose a cost-sensitive test using the CostTest name-value pair argument, 'asymptotic' is the default.

Example: 'Test','asymptotic'

Note NaNs, <undefined> values, empty character vectors (' '), empty strings (""), and <missing> values indicate missing data values. testcholdout:

- Treats missing values in YHat1 and YHat2 as misclassified observations.
- Removes missing values in Y and the corresponding values of YHat1 and YHat2

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

h = 1 indicates the rejection of the null hypothesis at the Alpha significance level.

h = 0 indicates failure to reject the null hypothesis at the Alpha significance level.

Data Types: `logical`

p – p-value

scalar in the interval [0,1]

p-value of the test, returned as a scalar in the interval [0,1]. p is the probability that a random test statistic is at least as extreme as the observed test statistic, given that the null hypothesis is true.

`testcholdout` estimates p using the distribution of the test statistic, which varies with the type of test. For details on test statistics derived from the available variants of the McNemar test, see “McNemar Tests” on page 32-5451. For details on test statistics derived from cost-sensitive tests, see “Cost-Sensitive Testing” on page 32-5449.

e1 – Classification loss

scalar

Classification loss on page 32-5453 that summarizes the accuracy of the first set of class labels (\hat{Y}_1) predicting the true class labels (Y), returned as a scalar.

For cost-insensitive testing, e1 is the misclassification rate. That is, e1 is the proportion of misclassified observations, which is a scalar in the interval [0,1].

For cost-sensitive testing, e1 is the misclassification cost. That is, e1 is the weighted average of the misclassification costs, in which the weights are the respective estimated proportions of misclassified observations.

e2 – Classification loss

scalar

Classification loss on page 32-5453 that summarizes the accuracy of the second set of class labels (\hat{Y}_2) predicting the true class labels (Y), returned as a scalar.

For cost-insensitive testing, e2 is the misclassification rate. That is, e2 is the proportion of misclassified observations, which is a scalar in the interval [0,1].

For cost-sensitive testing, e2 is the misclassification cost. That is, e2 is the weighted average of the costs of misclassification, in which the weights are the respective estimated proportions of misclassified observations.

More About

Cost-Sensitive Testing

Conduct cost-sensitive testing when the cost of misclassification is imbalanced. By conducting a cost-sensitive analysis, you can account for the cost imbalance when you train the classification models and when you statistically compare them.

If the cost of misclassification is imbalanced, then the misclassification rate tends to be a poorly performing classification loss. Use misclassification cost instead to compare classification models.

Misclassification costs are often imbalanced in applications. For example, consider classifying subjects based on a set of predictors into two categories: healthy and sick. Misclassifying a sick subject as healthy poses a danger to the subject's life. However, misclassifying a healthy subject as sick typically causes some inconvenience, but does not pose significant danger. In this situation, you

assign misclassification costs such that misclassifying a sick subject as healthy is more costly than misclassifying a healthy subject as sick.

The definitions that follow summarize the cost-sensitive tests. In the definitions:

- n_{ijk} and $\widehat{\pi}_{ijk}$ are the number and estimated proportion of test-sample observations with the following characteristics. k is the true class, i is the label assigned by the first classification model, and j is the label assigned by the second classification model. The unknown true value of $\widehat{\pi}_{ijk}$ is π_{ijk} . The test-set sample size is $\sum_{i,j,k} n_{ijk} = n_{test}$. Additionally, $\sum_{i,j,k} \pi_{ijk} = \sum_{i,j,k} \widehat{\pi}_{ijk} = 1$.
- c_{ij} is the relative cost of assigning label j to an observation with true class i . $c_{ii} = 0$, $c_{ij} \geq 0$, and, for at least one (i,j) pair, $c_{ij} > 0$.
- All subscripts take on integer values from 1 through K , which is the number of classes.
- The expected difference in the misclassification costs of the two classification models is

$$\delta = \sum_{i=1}^K \sum_{j=1}^K \sum_{k=1}^K (c_{ki} - c_{kj}) \pi_{ijk}.$$

- The hypothesis test is

$$H_0: \delta = 0$$

$$H_1: \delta \neq 0$$

The available cost-sensitive tests are appropriate for two-tailed testing.

Available asymptotic tests that address imbalanced costs are a chi-square test and a likelihood ratio test.

- Chi-square test — The chi-square test statistic is based on the Pearson and Neyman chi-square test statistics, but with a Laplace correction factor to account for any $n_{ijk} = 0$. The test statistic is

$$t_{\chi^2}^* = \sum_{i \neq j} \sum_k \frac{(n_{ijk} + 1 - (n_{test} + K^3) \widehat{\pi}_{ijk}^{(1)})^2}{n_{ijk} + 1}.$$

If $1 - F_{\chi^2}(t_{\chi^2}^*; 1) < \alpha$, then reject H_0 .

- $\widehat{\pi}_{ijk}^{(1)}$ are estimated by minimizing $t_{\chi^2}^*$ under the constraint that $\delta = 0$.
- $F_{\chi^2}(x; 1)$ is the χ^2 cdf with one degree of freedom evaluated at x .
- Likelihood ratio test — The likelihood ratio test is based on N_{ijk} , which are binomial random variables with sample size n_{test} and success probability π_{ijk} . The random variables represent the random number of observations with: true class k , label i assigned by the first classification model, and label j assigned by the second classification model. Jointly, the distribution of the random variables is multinomial.

The test statistic is

$$t_{LRT}^* = 2 \log \left[\frac{P\left(\bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \widehat{\pi}_{ijk} = \widehat{\pi}_{ijk}^{(2)} \right)}{P\left(\bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \widehat{\pi}_{ijk} = \widehat{\pi}_{ijk}^{(3)} \right)} \right].$$

If $1 - F_{\chi^2}(t_{LRT}^*; 1) < \alpha$, then reject H_0 .

- $\hat{\pi}_{ijk}^{(2)} = \frac{n_{ijk}}{n_{test}}$ is the unrestricted MLE of π_{ijk} .
- $\hat{\pi}_{ijk}^{(3)} = \frac{n_{ijk}}{n_{test} + \lambda(C_{ki} - C_{kj})}$ is the MLE under the null hypothesis that $\delta = 0$. λ is the solution to

$$\sum_{i,j,k} \frac{n_{ijk}(C_{ki} - C_{kj})}{n_{test} + \lambda(C_{ki} - C_{kj})} = 0.$$
- $F_{\chi^2}(x; 1)$ is the χ^2 cdf with one degree of freedom evaluated at x .

McNemar Tests

McNemar Tests are hypothesis tests that compare two population proportions while addressing the issues resulting from two dependent, matched-pair samples.

One way to compare the predictive accuracies of two classification models is:

- 1 Partition the data into training and test sets.
- 2 Train both classification models using the training set.
- 3 Predict class labels using the test set.
- 4 Summarize the results in a two-by-two table similar to this figure.

		Model 2		
		Correct	Incorrect	
Model 1	Correct	n_{11}	n_{12}	$n_{1\bullet}$
	Incorrect	n_{21}	n_{22}	$n_{2\bullet}$
		$n_{\bullet 1}$	$n_{\bullet 2}$	n_{test}

n_{ii} are the number of concordant pairs, that is, the number of observations that both models classify the same way (correctly or incorrectly). $n_{ij}, i \neq j$, are the number of discordant pairs, that is, the number of observations that models classify differently (correctly or incorrectly).

The misclassification rates for Models 1 and 2 are $\hat{\pi}_{2\bullet} = n_{2\bullet}/n$ and $\hat{\pi}_{\bullet 2} = n_{\bullet 2}/n$, respectively. A two-sided test for comparing the accuracy of the two models is

$$H_0: \pi_{\bullet 2} = \pi_{2\bullet}$$

$$H_1: \pi_{\bullet 2} \neq \pi_{2\bullet}$$

The null hypothesis suggests that the population exhibits marginal homogeneity, which reduces the null hypothesis to $H_0: \pi_{12} = \pi_{21}$. Also, under the null hypothesis, $N_{12} \sim \text{Binomial}(n_{12} + n_{21}, 0.5)$ [1].

These facts are the basis for the available McNemar test variants: the asymptotic, exact-conditional, and mid- p -value McNemar tests. The definitions that follow summarize the available variants.

- Asymptotic — The asymptotic McNemar test statistics and rejection regions (for significance level α) are:

- For one-sided tests, the test statistic is

$$t_{d1}^* = \frac{n_{12} - n_{21}}{\sqrt{n_{12} + n_{21}}}.$$

If $1 - \Phi(|t_1^*|) < \alpha$, where Φ is the standard Gaussian cdf, then reject H_0 .

- For two-sided tests, the test statistic is

$$t_{d2}^* = \frac{(n_{12} - n_{21})^2}{n_{12} + n_{21}}.$$

If $1 - F_{\chi^2}(t_2^*; m) < \alpha$, where $F_{\chi^2}(x; m)$ is the χ_m^2 cdf evaluated at x , then reject H_0 .

The asymptotic test requires large-sample theory, specifically, the Gaussian approximation to the binomial distribution.

- The total number of discordant pairs, $n_d = n_{12} + n_{21}$, must be greater than 10 ([1], Ch. 10.1.4).
- In general, asymptotic tests do not guarantee nominal coverage. The observed probability of falsely rejecting the null hypothesis can exceed α , as suggested in simulation studies in [18]. However, the asymptotic McNemar test performs well in terms of statistical power.
- Exact-Conditional — The exact-conditional McNemar test statistics and rejection regions (for significance level α) are ([36], [38]):

- For one-sided tests, the test statistic is

$$t_1^* = n_{12}.$$

If $F_{\text{Bin}}(t_1^*; n_d, 0.5) < \alpha$, where $F_{\text{Bin}}(x; n, p)$ is the binomial cdf with sample size n and success probability p evaluated at x , then reject H_0 .

- For two-sided tests, the test statistic is

$$t_2^* = \min(n_{12}, n_{21}).$$

If $F_{\text{Bin}}(t_2^*; n_d, 0.5) < \alpha/2$, then reject H_0 .

The exact-conditional test always attains nominal coverage. Simulation studies in [18] suggest that the test is conservative, and then show that the test lacks statistical power compared to other variants. For small or highly discrete test samples, consider using the mid- p -value test ([1], Ch. 3.6.3).

- Mid- p -value test — The mid- p -value McNemar test statistics and rejection regions (for significance level α) are ([32]):

- For one-sided tests, the test statistic is

$$t_1^* = n_{12}.$$

If $F_{\text{Bin}}(t_1^* - 1; n_{12} + n_{21}, 0.5) + 0.5f_{\text{Bin}}(t_1^*; n_{12} + n_{21}, 0.5) < \alpha$, where $F_{\text{Bin}}(x; n, p)$ and $f_{\text{Bin}}(x; n, p)$ are the binomial cdf and pdf, respectively, with sample size n and success probability p evaluated at x , then reject H_0 .

- For two-sided tests, the test statistic is

$$t_2^* = \min(n_{12}, n_{21}).$$

If $F_{\text{Bin}}(t_2^* - 1; n_{12} + n_{21} - 1, 0.5) + 0.5f_{\text{Bin}}(t_2^*; n_{12} + n_{21}, 0.5) < \alpha/2$, then reject H_0 .

The mid- p -value test addresses the over-conservative behavior of the exact-conditional test. The simulation studies in [18] demonstrate that this test attains nominal coverage, and has good statistical power.

Classification Loss

Classification losses indicate the accuracy of a classification model or set of predicted labels. Two classification losses are the misclassification rate and cost.

`testcholdout` returns the classification losses (see `e1` and `e2`) under the alternative hypothesis (that is, the unrestricted classification losses). n_{ijk} is the number of test-sample observations with: true class k , label i assigned by the first classification model, and label j assigned by the second classification model. The corresponding estimated proportion is $\hat{\pi}_{ijk} = \frac{n_{ijk}}{n_{\text{test}}}$. The test-set sample size is $\sum_{i,j,k} n_{ijk} = n_{\text{test}}$. The indices are taken from 1 through K , the number of classes.

- The misclassification rate, or classification error, is a scalar in the interval $[0,1]$ representing the proportion of misclassified observations. That is, the misclassification rate for the first classification model is

$$e_1 = \sum_{j=1}^K \sum_{k=1}^K \sum_{i \neq k} \hat{\pi}_{ijk}.$$

For the misclassification rate of the second classification model (e_2), switch the indices i and j in the formula.

Classification accuracy decreases as the misclassification rate increases to 1.

- The misclassification cost is a nonnegative scalar that is a measure of classification quality relative to the values of the specified cost matrix. Its interpretation depends on the specified costs of misclassification. The misclassification cost is the weighted average of the costs of misclassification (specified in a cost matrix, C) in which the weights are the respective estimated proportions of misclassified observations. The misclassification cost for the first classification model is

$$e_1 = \sum_{j=1}^K \sum_{k=1}^K \sum_{i \neq k} \hat{\pi}_{ijk} c_{ki}.$$

where c_{kj} is the cost of classifying an observation into class j if its true class is k . For the misclassification cost of the second classification model (e_2), switch the indices i and j in the formula.

In general, for a fixed cost matrix, classification accuracy decreases as the misclassification cost increases.

Tips

- It is a good practice to obtain predicted class labels by passing any trained classification model and new predictor data to the `predict` method. For example, for predicted labels from an SVM model, see `predict`.
- Cost-sensitive tests perform numerical optimization, which requires additional computational resources. The likelihood ratio test conducts numerical optimization indirectly by finding the root of a Lagrange multiplier in an interval. For some data sets, if the root lies close to the boundaries of the interval, then the method can fail. Therefore, if you have an Optimization Toolbox license, consider conducting the cost-sensitive chi-square test instead. For more details, see `CostTest` and “Cost-Sensitive Testing” on page 32-5449.

`testckfold`

Topics

“Hypothesis Tests”

Introduced in R2015a

testckfold

Compare accuracies of two classification models by repeated cross-validation

Syntax

```
h = testckfold(C1,C2,X1,X2)
h = testckfold(C1,C2,X1,X2,Y)
h = testckfold( ___,Name,Value)
[h,p,e1,e2] = testckfold( ___ )
```

Description

`testckfold` statistically assesses the accuracies of two classification models by repeatedly cross-validating the two models, determining the differences in the classification loss, and then formulating the test statistic by combining the classification loss differences. This type of test is particularly appropriate when sample size is limited.

You can assess whether the accuracies of the classification models are different, or whether one classification model performs better than another. Available tests include a 5-by-2 paired *t* test, a 5-by-2 paired *F* test, and a 10-by-10 repeated cross-validation *t* test. For more details, see “Repeated Cross-Validation Tests” on page 32-5471. To speed up computations, `testckfold` supports parallel computing (requires a Parallel Computing Toolbox license).

`h = testckfold(C1,C2,X1,X2)` returns the test decision that results from conducting a 5-by-2 paired *F* cross-validation test. The null hypothesis is the classification models `C1` and `C2` have equal accuracy in predicting the true class labels using the predictor and response data in the tables `X1` and `X2`. `h = 1` indicates to reject the null hypothesis at the 5% significance level.

`testckfold` conducts the cross-validation test by applying `C1` and `C2` to all predictor variables in `X1` and `X2`, respectively. The true class labels in `X1` and `X2` must be the same. The response variable names in `X1`, `X2`, `C1.ResponseName`, and `C2.ResponseName` must be the same.

For examples of ways to compare models, see “Tips” on page 32-5473.

`h = testckfold(C1,C2,X1,X2,Y)` applies the full classification model or classification templates `C1` and `C2` to all predictor variables in the tables or matrices of data `X1` and `X2`, respectively. `Y` is the table variable name corresponding to the true class labels, or an array of true class labels.

`h = testckfold(___,Name,Value)` uses any of the input arguments in the previous syntaxes and additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the type of alternative hypothesis, the type of test, or the use of parallel computing.

`[h,p,e1,e2] = testckfold(___)` also returns the *p*-value for the hypothesis test (`p`) and the respective classification losses on page 32-5472 for each cross-validation run and fold (`e1` and `e2`).

Examples

Compare Classification Tree Predictor-Selection Algorithms

At each node, `fitctree` chooses the best predictor to split using an exhaustive search by default. Alternatively, you can choose to split the predictor that shows the most evidence of dependence with the response by conducting curvature tests. This example statistically compares classification trees grown via exhaustive search for the best splits and grown by conducting curvature tests with interaction.

Load the `census1994` data set.

```
load census1994.mat
rng(1) % For reproducibility
```

Grow a default classification tree using the training set, `adulthood`, which is a table. The response-variable name is `'salary'`.

```
C1 = fitctree(adulthood, 'salary')
```

```
C1 =
ClassificationTree
    PredictorNames: {1x14 cell}
    ResponseName: 'salary'
    CategoricalPredictors: [2 4 6 7 8 9 10 14]
    ClassNames: [<=50K >50K]
    ScoreTransform: 'none'
    NumObservations: 32561
```

Properties, Methods

`C1` is a full `ClassificationTree` model. Its `ResponseName` property is `'salary'`. `C1` uses an exhaustive search to find the best predictor to split on based on maximal splitting gain.

Grow another classification tree using the same data set, but specify to find the best predictor to split using the curvature test with interaction.

```
C2 = fitctree(adulthood, 'salary', 'PredictorSelection', 'interaction-curvature')
```

```
C2 =
ClassificationTree
    PredictorNames: {1x14 cell}
    ResponseName: 'salary'
    CategoricalPredictors: [2 4 6 7 8 9 10 14]
    ClassNames: [<=50K >50K]
    ScoreTransform: 'none'
    NumObservations: 32561
```

Properties, Methods

`C2` also is a full `ClassificationTree` model with `ResponseName` equal to `'salary'`.

Conduct a 5-by-2 paired F test to compare the accuracies of the two models using the training set. Because the response-variable names in the data sets and the `ResponseName` properties are all equal, and the response data in both sets are equal, you can omit supplying the response data.

```
h = testckfold(C1,C2,adultdata,adultdata)
h = logical
    0
```

$h = 0$ indicates to not reject the null hypothesis that C1 and C2 have the same accuracies at 5% level.

Compare Accuracies of Two Different Classification Models

Conduct a statistical test comparing the misclassification rates of the two models using a 5-by-2 paired F test.

Load Fisher's iris data set.

```
load fisheriris;
```

Create a naive Bayes template and a classification tree template using default options.

```
C1 = templateNaiveBayes;
C2 = templateTree;
```

C1 and C2 are template objects corresponding to the naive Bayes and classification tree algorithms, respectively.

Test whether the two models have equal predictive accuracies. Use the same predictor data for each model. `testckfold` conducts a 5-by-2, two-sided, paired F test by default.

```
rng(1); % For reproducibility
h = testckfold(C1,C2,meas,meas,species)
h = logical
    0
```

$h = 0$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Compare Classification Accuracies of Simple and Complex Models

Conduct a statistical test to assess whether a simpler model has better accuracy than a more complex model using a 10-by-10 repeated cross-validation t test.

Load Fisher's iris data set. Create a cost matrix that penalizes misclassifying a setosa iris twice as much as misclassifying a virginica iris as a versicolor.

```
load fisheriris;
tabulate(species)
```

Value	Count	Percent
setosa	50	33.33%

```
versicolor    50    33.33%
virginica     50    33.33%
```

```
Cost = [0 2 2;2 0 1;2 1 0];
ClassNames = {'setosa' 'versicolor' 'virginica'};...
% Specifies the order of the rows and columns in Cost
```

The empirical distribution of the classes is uniform, and the classification cost is slightly imbalanced.

Create two ECOC templates: one that uses linear SVM binary learners and one that uses SVM binary learners equipped with the RBF kernel.

```
tSVMLinear = templateSVM('Standardize',true); % Linear SVM by default
tSVMRBF = templateSVM('KernelFunction','RBF','Standardize',true);
C1 = templateECOC('Learners',tSVMLinear);
C2 = templateECOC('Learners',tSVMRBF);
```

C1 and C2 are ECOC template objects. C1 is prepared for linear SVM. C2 is prepared for SVM with an RBF kernel training.

Test the null hypothesis that the simpler model (C1) is at most as accurate as the more complex model (C2) in terms of classification costs. Conduct the 10-by-10 repeated cross-validation test. Request to return p -values and misclassification costs.

```
rng(1); % For reproducibility
[h,p,e1,e2] = testckfold(C1,C2,meas,meas,species,...
    'Alternative','greater','Test','10x10t','Cost',Cost,...
    'ClassNames',ClassNames)
```

```
h = logical
    0
```

```
p = 0.1077
```

```
e1 = 10x10
```

0	0	0	0.0667	0	0.0667	0.1333	0	0.1333	0
0.0667	0.0667	0	0	0	0	0.0667	0	0.0667	0.0667
0	0	0	0	0	0.0667	0.0667	0.0667	0.0667	0.0667
0.0667	0.0667	0	0.0667	0	0.0667	0	0	0.0667	0.0667
0.0667	0.0667	0.0667	0	0.0667	0.0667	0	0	0	0
0	0	0.1333	0	0	0.0667	0	0	0.0667	0.0667
0.0667	0.0667	0	0	0.0667	0	0	0.0667	0	0.0667
0.0667	0	0.0667	0.0667	0	0.1333	0	0.0667	0	0.0667
0	0.0667	0.1333	0.0667	0.0667	0	0	0	0	0
0	0.0667	0.0667	0.0667	0.0667	0	0	0.0667	0	0

```
e2 = 10x10
```

0	0	0	0.1333	0	0.0667	0.1333	0	0.2667	0
0.0667	0.0667	0	0.1333	0	0	0	0.1333	0.1333	0.0667
0.1333	0.1333	0	0	0	0.0667	0	0.0667	0.0667	0.0667
0	0.1333	0	0.0667	0.1333	0.1333	0	0	0.0667	0.0667
0.0667	0.0667	0.0667	0	0.0667	0.1333	0.1333	0	0	0.0667
0.0667	0	0.0667	0.0667	0	0.0667	0.1333	0	0.0667	0.0667
0.2000	0.0667	0	0	0.0667	0	0	0.1333	0	0.0667
0.2000	0	0	0.1333	0	0.1333	0	0.0667	0	0

```

      0      0.0667      0.0667      0.0667      0.1333      0      0.2000      0      0
0.0667      0.0667      0      0.0667      0.1333      0      0      0.0667      0.1333      0

```

The p -value is slightly greater than 0.10, which indicates to retain the null hypothesis that the simpler model is at most as accurate as the more complex model. This result is consistent for any significance level (Alpha) that is at most 0.10.

$e1$ and $e2$ are 10-by-10 matrices containing misclassification costs. Row r corresponds to run r of the repeated cross validation. Column k corresponds to test-set fold k within a particular cross-validation run. For example, element (2,4) of $e2$ is 0.1333. This value means that in cross-validation run 2, when the test set is fold 4, the estimated test-set misclassification cost is 0.1333.

Select Features Using Statistical Accuracy Comparison

Reduce classification model complexity by selecting a subset of predictor variables (features) from a larger set. Then, statistically compare the accuracy between the two models.

Load the `ionosphere` data set.

```
load ionosphere;
```

Train an ensemble of 100 boosted classification trees using `AdaBoostM1` and the entire set of predictors. Inspect the importance measure for each predictor.

```

t = templateTree('MaxNumSplits',1); % Weak-learner template tree object
C = fitcensemble(X,Y,'Method','AdaBoostM1','Learners',t);
predImp = predictorImportance(C);

figure;
bar(predImp);
h = gca;
h.XTick = 1:2:h.XLim(2);
title('Predictor Importances');
xlabel('Predictor');
ylabel('Importance measure');

```

Identify the top five predictors in terms of their importance.

```
[~,idxSort] = sort(predImp,'descend');
idx5 = idxSort(1:5);
```

Test whether the two models have equal predictive accuracies. Specify the reduced data set and then the full predictor data. Use parallel computing to speed up computations.

```
s = RandStream('mlfg6331_64');
Options = statset('UseParallel',true,'Streams',s,'UseSubstreams',true);
```

```
[h,p,e1,e2] = testckfold(C,C,X(:,idx5),X,Y,'Options',Options)
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 12).
```

```
h = logical
    0
```

```
p = 0.4161
```

```
e1 = 5×2
```

```
    0.0686    0.0795
    0.0800    0.0625
    0.0914    0.0568
    0.0400    0.0739
```

```
0.0914 0.0966
```

```
e2 = 5×2
```

```
0.0914 0.0625
0.1257 0.0682
0.0971 0.0625
0.0800 0.0909
0.0914 0.1193
```

`testckfold` treats trained classification models as templates, and so it ignores all fitted parameters in `C`. That is, `testckfold` cross validates `C` using only the specified options and the predictor data to estimate the out-of-fold classification losses.

`h = 0` indicates to not reject the null hypothesis that the two models have equal predictive accuracies. This result favors the simpler ensemble.

Input Arguments

C1 — Classification model template or trained classification model

classification model template object | trained classification model object

Classification model template or trained classification model, specified as any classification model template object or trained classification model object described in these tables.

Template Type	Returned By
Classification tree	templateTree
Discriminant analysis	templateDiscriminant
Ensemble (boosting, bagging, and random subspace)	templateEnsemble
Error-correcting output codes (ECOC), multiclass classification model	templateECOC
kNN	templateKNN
Naive Bayes	templateNaiveBayes
Support Vector Machine (SVM)	templateSVM

Trained Model Type	Model Object	Returned By
Classification tree	ClassificationTree	fitctree
Discriminant analysis	ClassificationDiscriminant	fitcdiscr
Ensemble of bagged classification models	ClassificationBaggedEnsemble	fitcensemble
Ensemble of classification models	ClassificationEnsemble	fitcensemble
ECOC model	ClassificationECOC	fitcecoc
kNN	ClassificationKNN	fitcknn

Trained Model Type	Model Object	Returned By
Naive Bayes	ClassificationNaiveBayes	fitcnb
SVM	ClassificationSVM	fitcsvm

For efficiency, supply a classification model template object instead of a trained classification model object.

C2 — Classification model template or trained model

classification model template object | trained classification model object

Classification model template or trained classification model, specified as any classification model template object or trained classification model object described in these tables.

Template Type	Returned By
Classification tree	templateTree
Discriminant analysis	templateDiscriminant
Ensemble (boosting, bagging, and random subspace)	templateEnsemble
Error-correcting output codes (ECOC), multiclass classification model	templateECOC
kNN	templateKNN
Naive Bayes	templateNaiveBayes
Support Vector Machine (SVM)	templateSVM

Trained Model Type	Model Object	Returned By
Classification tree	ClassificationTree	fitctree
Discriminant analysis	ClassificationDiscriminant	fitcdiscr
Ensemble of bagged classification models	ClassificationBaggedEnsemble	fitcensemble
Ensemble of classification models	ClassificationEnsemble	fitcensemble
ECOC model	ClassificationECOC	fitcecoc
kNN	ClassificationKNN	fitcknn
Naive Bayes	ClassificationNaiveBayes	fitcnb
SVM	ClassificationSVM	fitcsvm

For efficiency, supply a classification model template object instead of a trained classification model object.

X1 — Data used to apply to first full classification model or template

numeric matrix | table

Data used to apply to the first full classification model or template, C1, specified as a numeric matrix or table.

Each row of `X1` corresponds to one observation, and each column corresponds to one variable. `testckfold` does not support multi-column variables and cell arrays other than cell arrays of character vectors.

`X1` and `X2` must be of the same data type, and `X1`, `X2`, `Y` must have the same number of observations.

If you specify `Y` as an array, then `testckfold` treats all columns of `X1` as separate predictor variables.

Data Types: `double` | `single` | `table`

X2 — Data used to apply to second full classification model or template

numeric matrix | table

Data used to apply to the second full classification model or template, `C2`, specified as a numeric matrix or table.

Each row of `X2` corresponds to one observation, and each column corresponds to one variable. `testckfold` does not support multi-column variables and cell arrays other than cell arrays of character vectors.

`X1` and `X2` must be of the same data type, and `X1`, `X2`, `Y` must have the same number of observations.

If you specify `Y` as an array, then `testckfold` treats all columns of `X2` as separate predictor variables.

Data Types: `double` | `single` | `table`

Y — True class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors | character vector | string scalar

True class labels, specified as a categorical, character, or string array, a logical or numeric vector, a cell array of character vectors, or a character vector or string scalar.

- For a character vector or string scalar, `X1` and `X2` must be tables, their response variables must have the same name and values, and `Y` must be the common variable name. For example, if `X1.Labels` and `X2.Labels` are the response variables, then `Y` is `'Labels'` and `X1.Labels` and `X2.Labels` must be equivalent.
- For all other supported data types, `Y` is an array of true class labels.
 - If `Y` is a character array, then each element must correspond to one row of the array.
 - `X1`, `X2`, `Y` must have the same number of observations (rows).
- If both of these statements are true, then you can omit supplying `Y`.
 - `X1` and `X2` are tables containing the same response variable (values and name).
 - `C1` and `C2` are full classification models containing `ResponseName` properties specifying the response variable names in `X1` and `X2`.

Consequently, `testckfold` uses the common response variable in the tables. For example, if the response variables in the tables are `X1.Labels` and `X2.Labels`, and the values of `C1.ResponseName` and `C2.ResponseName` are `'Labels'`, then you do not have to supply `Y`.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

```
'Alternative', 'greater', 'Test', '10x10t', 'Options', statsset('UseParallel', true)
) specifies to test whether the first set of first predicted class labels is more accurate than the second set, to conduct the 10-by-10 t test, and to use parallel computing for cross-validation.
```

Alpha — Hypothesis test significance level

0.05 (default) | scalar value in the interval (0,1)

Hypothesis test significance level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the interval (0,1).

Example: `'Alpha', 0.1`

Data Types: `single` | `double`

Alternative — Alternative hypothesis to assess

'unequal' (default) | 'greater' | 'less'

Alternative hypothesis to assess, specified as the comma-separated pair consisting of `'Alternative'` and one of the values listed in the table.

Value	Alternative Hypothesis Description	Supported Tests
'unequal' (default)	For predicting Y, the set of predictions resulting from C1 applied to X1 and C2 applied to X2 have unequal accuracies.	'5x2F', '5x2t', and '10x10t'
'greater'	For predicting Y, the set of predictions resulting from C1 applied to X1 is more accurate than C2 applied to X2.	'5x2t' and '10x10t'
'less'	For predicting Y, the set of predictions resulting from C1 applied to X1 is less accurate than C2 applied to X2.	'5x2t' and '10x10t'

For details on supported tests, see `Test`.

Example: `'Alternative', 'greater'`

X1CategoricalPredictors — Flag identifying categorical predictors

[] (default) | logical vector | numeric vector | 'all'

Flag identifying categorical predictors in the first test-set predictor data (X1), specified as the comma-separated pair consisting of `'X1CategoricalPredictors'` and one of the following:

- A numeric vector with indices from 1 through `p`, where `p` is the number of columns of X1.
- A logical vector of length `p`, where a `true` entry means that the corresponding column of X1 is a categorical variable.
- `'all'`, meaning all predictors are categorical.

Specification of `X1CategoricalPredictors` is appropriate if:

- At least one predictor is categorical and `C1` is a classification tree, an ensemble of classification trees, an ECOC model, or a naive Bayes classification model.
- All predictors are categorical and `C1` is a *k*NN classification model.

If you specify `X1CategoricalPredictors` for any other case, then `testckfold` throws an error. For example, the function cannot train SVM learners using categorical predictors.

The default is `[]`, which indicates that there are no categorical predictors.

Example: `'X1CategoricalPredictors','all'`

Data Types: `single | double | logical | char | string`

X2CategoricalPredictors — Flag identifying categorical predictors

`[]` (default) | logical vector | numeric vector | `'all'`

Flag identifying categorical predictors in the second test-set predictor data (`X2`), specified as the comma-separated pair consisting of `'X2CategoricalPredictors'` and one of the following:

- A numeric vector with indices from 1 through `p`, where `p` is the number of columns of `X2`.
- A logical vector of length `p`, where a `true` entry means that the corresponding column of `X2` is a categorical variable.
- `'all'`, meaning all predictors are categorical.

Specification of `X2CategoricalPredictors` is appropriate if:

- At least one predictor is categorical and `C2` is a classification tree, an ensemble of classification trees, an ECOC model, or a naive Bayes classification model.
- All predictors are categorical and `C2` is a *k*NN classification model.

If you specify `X2CategoricalPredictors` for any other case, then `testckfold` throws an error. For example, the function cannot train SVM learners using categorical predictors.

The default is `[]`, which indicates that there are no categorical predictors.

Example: `'X2CategoricalPredictors','all'`

Data Types: `single | double | logical | char | string`

ClassNames — Class names

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class names, specified as the comma-separated pair consisting of `'ClassNames'` and a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. You must set `ClassNames` using the data type of `Y`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `ClassNames` to:

- Specify the order of any input argument dimension that corresponds to class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost`.
- Select a subset of classes for testing. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train and test models using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default is the set of all distinct class names in Y .

Example: `'ClassNames', {'b', 'g'}`

Data Types: `single | double | logical | char | string | cell | categorical`

Cost — Classification cost

`square matrix | structure array`

Classification cost, specified as the comma-separated pair consisting of `'Cost'` and a square matrix or structure array.

- If you specify the square matrix `Cost`, then `Cost(i, j)` is the cost of classifying a point into class j if its true class is i . That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of `Cost`, additionally specify the `ClassNames` name-value pair argument.
- If you specify the structure `S`, then `S` must have two fields:
 - `S.ClassNames`, which contains the class names as a variable of the same data type as Y . You can use this field to specify the order of the classes.
 - `S.ClassificationCosts`, which contains the cost matrix, with rows and columns ordered as in `S.ClassNames`

For cost-sensitive testing use, `testcholdout`.

It is a best practice to supply the same cost matrix used to train the classification models.

The default is `Cost(i, j) = 1` if $i \neq j$, and `Cost(i, j) = 0` if $i = j$.

Example: `'Cost', [0 1 2 ; 1 0 2; 2 2 0]`

Data Types: `double | single | struct`

LossFun — Loss function

`'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | function handle`

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and `'classiferror'`, `'binodeviance'`, `'exponential'`, `'hinge'`, or a function handle.

- The following table lists the available loss functions.

Value	Loss Function
<code>'binodeviance'</code>	Binomial deviance
<code>'classiferror'</code>	Classification error
<code>'exponential'</code>	Exponential loss
<code>'hinge'</code>	Hinge loss

- Specify your own function using function handle notation.

Suppose that $n = \text{size}(X, 1)$ is the sample size and there are K unique classes. Your function must have the signature `lossvalue = lossfun(C, S, W, Cost)`, where:

- The output argument `lossvalue` is a scalar.
- `lossfun` is the name of your function.

- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs to. The column order corresponds to the class order in the `ClassNames` name-value pair argument.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in the `ClassNames` name-value pair argument. S is a matrix of classification scores.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes the weights to sum to 1.
- $Cost$ is a K -by- K numeric matrix of classification costs. For example, $Cost = ones(K) - eye(K)$ specifies a cost of 0 for correct classification and a cost of 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

Options – Parallel computing options

`[]` (default) | structure array returned by `statset`

Parallel computing options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`. These options require Parallel Computing Toolbox. `testckfold` uses `'Streams'`, `'UseParallel'`, and `'UseSubstreams'` fields.

This table summarizes the available options.

Option	Description
<code>'Streams'</code>	<p>A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code>, the software uses the default stream or streams. If you specify <code>Streams</code>, use a single object except when the following are true:</p> <ul style="list-style-type: none"> • You have an open parallel pool. • <code>UseParallel</code> is <code>true</code>. • <code>UseSubstreams</code> is <code>false</code>. <p>In that case, use a cell array of the same size as the parallel pool. If a parallel pool is not open, then the software tries to open one (depending on your preferences), and <code>Streams</code> must supply a single random number stream.</p>
<code>'UseParallel'</code>	<p>If you have Parallel Computing Toolbox, then you can invoke a pool of workers by setting <code>'UseParallel', true</code>.</p>
<code>'UseSubstreams'</code>	<p>Set to <code>true</code> to compute in parallel using the stream specified by <code>'Streams'</code>. Default is <code>false</code>. For example, set <code>Streams</code> to a type allowing substreams, such as <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code>.</p>

Example: `'Options', statset('UseParallel', true)`

Data Types: struct

Prior — Prior probabilities

'empirical' (default) | 'uniform' | numeric vector | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and 'empirical', 'uniform', a numeric vector, or a structure.

This table summarizes the available options for setting prior probabilities.

Value	Description
'empirical'	The class prior probabilities are the class relative frequencies in Y .
'uniform'	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements such that they sum to 1.
structure	A structure S with two fields: <ul style="list-style-type: none"> S.<code>ClassNames</code> contains the class names as a variable of the same type as Y. S.<code>ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.

Example: `'Prior', struct('ClassNames', {'setosa', 'versicolor'}, 'ClassProbs', [1, 2])`

Data Types: char | string | single | double | struct

Test — Test to conduct

'5x2F' (default) | '5x2t' | '10x10t'

Test to conduct, specified as the comma-separated pair consisting of 'Test' and one of the following: '5x2F', '5x2t', '10x10t'.

Value	Description	Supported Alternative Hypothesis
'5x2F' (default)	5-by-2 paired F test. Appropriate for two-sided testing only.	'unequal'
'5x2t'	5-by-2 paired t test	'unequal', 'less', 'greater'
'10x10t'	10-by-10 repeated cross-validation t test	'unequal', 'less', 'greater'

For details on the available tests, see “Repeated Cross-Validation Tests” on page 32-5471. For details on supported alternative hypotheses, see `Alternative`.

Example: 'Test', '10x10t'

Verbose – Verbosity level

0 (default) | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0, 1, or 2. Verbose controls the amount of diagnostic information that the software displays in the Command Window during training of each cross-validation fold.

This table summarizes the available verbosity level options.

Value	Description
0	The software does not display diagnostic information.
1	The software displays diagnostic messages every time it implements a new cross-validation run.
2	The software displays diagnostic messages every time it implements a new cross-validation run, and every time it trains on a particular fold.

Example: 'Verbose', 1

Data Types: double | single

Weights – Observation weights

ones(size(X,1),1) (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector.

The size of Weights must equal the number of rows of X1. The software weighs the observations in each row of X with the corresponding weight in Weights.

The software normalizes Weights to sum up to the value of the prior probability in the respective class.

Data Types: double | single

Notes:

- testckfold treats trained classification models as templates. Therefore, it ignores all fitted parameters in the model. That is, testckfold cross-validates using only the options specified in the model and the predictor data.
- The repeated cross-validation tests depend on the assumption that the test statistics are asymptotically normal under the null hypothesis. Highly imbalanced cost matrices (for example, Cost = [0 100; 1 0]) and highly discrete response distributions (that is, most of the observations are in a small number of classes) might violate the asymptotic normality assumption. For cost-sensitive testing, use testcholdout.
- NaNs, <undefined> values, empty character vectors (' '), empty strings (""), and <missing> values indicate missing data values.

- For the treatment of missing values in X1 and X2, see the appropriate classification model training function reference page: `fitctree`, `fitcdiscr`, `fitcensemble`, `fitcecoc`, `fitcknn`, `fitcnb`, or `fitcsvm`.
 - `testckfold` removes missing values in Y and the corresponding rows of X1 and X2.
-

Output Arguments

h – Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

`h = 1` indicates the rejection of the null hypothesis at the Alpha significance level.

`h = 0` indicates failure to reject the null hypothesis at the Alpha significance level.

Data Types: `logical`

p – *p*-value

scalar in the interval [0,1]

p-value of the test, returned as a scalar in the interval [0,1]. *p* is the probability that a random test statistic is at least as extreme as the observed test statistic, given that the null hypothesis is true.

`testckfold` estimates *p* using the distribution of the test statistic, which varies with the type of test. For details on test statistics, see “Repeated Cross-Validation Tests” on page 32-5471.

e1 – Classification losses

numeric matrix

Classification losses on page 32-5472, returned as a numeric matrix. The rows of `e1` correspond to the cross-validation run and the columns correspond to the test fold.

`testckfold` applies the first test-set predictor data (X1) to the first classification model (C1) to estimate the first set of class labels.

`e1` summarizes the accuracy of the first set of class labels predicting the true class labels (Y) for each cross-validation run and fold. The meaning of the elements of `e1` depends on the type of classification loss.

e2 – Classification losses

numeric matrix

Classification losses on page 32-5472, returned as a numeric matrix. The rows of `e2` correspond to the cross-validation run and the columns correspond to the test fold.

`testckfold` applies the second test-set predictor data (X2) to the second classification model (C2) to estimate the second set of class labels.

`e2` summarizes the accuracy of the second set of class labels predicting the true class labels (Y) for each cross-validation run and fold. The meaning of the elements of `e2` depends on the type of classification loss.

More About

Repeated Cross-Validation Tests

Repeated cross-validation tests form the test statistic for comparing the accuracies of two classification models by combining the classification loss differences resulting from repeatedly cross-validating the data. Repeated cross-validation tests are useful when sample size is limited.

To conduct an R -by- K test:

- 1 Randomly divide (stratified by class) the predictor data sets and true class labels into K sets, R times. Each division is called a run and each set within a run is called a fold. Each run contains the complete, but divided, data sets.
- 2 For runs $r = 1$ through R , repeat these steps for $k = 1$ through K :
 - a Reserve fold k as a test set, and train the two classification models using their respective predictor data sets on the remaining $K - 1$ folds.
 - b Predict class labels using the trained models and their respective fold k predictor data sets.
 - c Estimate the classification loss by comparing the two sets of estimated labels to the true labels. Denote e_{crk} as the classification loss when the test set is fold k in run r of classification model c .
 - d Compute the difference between the classification losses of the two models:

$$\widehat{\delta}_{rk} = e_{1rk} - e_{2rk}.$$

At the end of a run, there are K classification losses per classification model.

- 3 Combine the results of step 2. For each $r = 1$ through R :
 - Estimate the within-fold averages of the differences and their average: $\bar{\delta}_r = \frac{1}{K} \sum_{k=1}^K \widehat{\delta}_{rk}$.
 - Estimate the overall average of the differences: $\bar{\delta} = \frac{1}{KR} \sum_{r=1}^R \sum_{k=1}^K \widehat{\delta}_{rk}$.
 - Estimate the within-fold variances of the differences: $s_r^2 = \frac{1}{K} \sum_{k=1}^K (\widehat{\delta}_{rk} - \bar{\delta}_r)^2$.
 - Estimate the average of the within-fold differences: $\bar{s}^2 = \frac{1}{R} \sum_{r=1}^R s_r^2$.
 - Estimate the overall sample variance of the differences: $S^2 = \frac{1}{KR-1} \sum_{r=1}^R \sum_{k=1}^K (\widehat{\delta}_{rk} - \bar{\delta})^2$.

Compute the test statistic. All supported tests described here assume that, under H_0 , the estimated differences are independent and approximately normally distributed, with mean 0 and a finite, common standard deviation. However, these tests violate the independence assumption, and so the test-statistic distributions are approximate.

- For $R = 2$, the test is a paired test. The two supported tests are a paired t and F test.

- The test statistic for the paired t test is

$$t_{paired}^* = \frac{\widehat{\delta}_{11}}{\sqrt{S^2}}.$$

t_{paired}^* has a t -distribution with R degrees of freedom under the null hypothesis.

To reduce the effects of correlation between the estimated differences, the quantity $\widehat{\delta}_{11}$ occupies the numerator rather than $\bar{\delta}$.

5-by-2 paired t tests can be slightly conservative [4].

- The test statistic for the paired F test is

$$F_{paired}^* = \frac{\frac{1}{RK} \sum_{r=1}^R \sum_{k=1}^K (\widehat{\delta}_{rk})^2}{\bar{S}^2}.$$

F_{paired}^* has an F distribution with RK and R degrees of freedom.

A 5-by-2 paired F test has comparable power to the 5-by-2 t test, but is more conservative [1].

- For $R > 2$, the test is a repeated cross-validation test. The test statistic is

$$t_{CV}^* = \frac{\bar{\delta}}{S/\sqrt{\nu+1}}.$$

t_{CV}^* has a t distribution with ν degrees of freedom. If the differences were truly independent, then $\nu = RK - 1$. In this case, the degrees of freedom parameter must be optimized.

For a 10-by-10 repeated cross-validation t test, the optimal degrees of freedom between 8 and 11 ([2] and [3]). `testckfold` uses $\nu = 10$.

The advantage of repeated cross-validation tests over paired tests is that the results are more repeatable [3]. The disadvantage is that they require high computational resources.

Classification Loss

Classification losses indicate the accuracy of a classification model or set of predicted labels. In general, for a fixed cost matrix, classification accuracy decreases as classification loss increases.

`testckfold` returns the classification losses (see `e1` and `e2`) under the alternative hypothesis (that is, the unrestricted classification losses). In the definitions that follow:

- The classification losses focus on the first classification model. The classification losses for the second model are similar.
- n_{test} is the test-set sample size.
- $I(x)$ is the indicator function. If x is a true statement, then $I(x) = 1$. Otherwise, $I(x) = 0$.
- \widehat{p}_{1j} is the predicted class assignment of classification model 1 for observation j .
- y_j is the true class label of observation j .

- Binomial deviance has the form

$$e_1 = \frac{\sum_{j=1}^{n_{test}} w_j \log(1 + \exp(-2y_j f(X_j)))}{\sum_{j=1}^{n_{test}} w_j}$$

where:

- $y_j = 1$ for the positive class and -1 for the negative class.
- $f(X_j)$ is the classification score.

The binomial deviance has connections to the maximization of the binomial likelihood function. For details on binomial deviance, see [5].

- Exponential loss is similar to binomial deviance and has the form

$$e_1 = \frac{\sum_{j=1}^{n_{test}} w_j \exp(-y_j f(X_j))}{\sum_{j=1}^{n_{test}} w_j}.$$

y_j and $f(X_j)$ take the same forms here as in the binomial deviance formula.

- Hinge loss has the form

$$e_1 = \frac{\sum_{j=1}^n w_j \max\{0, 1 - y_j f(X_j)\}}{\sum_{j=1}^n w_j},$$

y_j and $f(X_j)$ take the same forms here as in the binomial deviance formula.

Hinge loss linearly penalizes for misclassified observations and is related to the SVM objective function used for optimization. For more details on hinge loss, see [5].

- Misclassification rate, or classification error, is a scalar in the interval $[0,1]$ representing the proportion of misclassified observations. That is, the misclassification rate for the first classification model is

$$e_1 = \frac{\sum_{j=1}^{n_{test}} w_j I(\hat{p}_{1j} \neq y_j)}{\sum_{j=1}^{n_{test}} w_j}.$$

Tips

- Examples of ways to compare models include:

- Compare the accuracies of a simple classification model and a more complex model by passing the same set of predictor data.
- Compare the accuracies of two different models using two different sets of predictors.
- Perform various types of Feature Selection on page 15-49. For example, you can compare the accuracy of a model trained using a set of predictors to the accuracy of one trained on a subset or different set of predictors. You can arbitrarily choose the set of predictors, or use a feature selection technique like PCA or sequential feature selection (see `pca` and `sequentialfs`).
- If both of these statements are true, then you can omit supplying `Y`.
 - `X1` and `X2` are tables containing the response variable and use the same response variable name.
 - `C1` and `C2` are full classification models containing equal `ResponseName` properties (e.g. `strcmp(C1.ResponseName, C2.ResponseName) = 1`).

Consequently, `testckfold` uses the common response variable in the tables.

- One way to perform cost-insensitive feature selection is:
 - 1 Create a classification model template that characterizes the first classification model (`C1`).
 - 2 Create a classification model template that characterizes the second classification model (`C2`).
 - 3 Specify two predictor data sets. For example, specify `X1` as the full predictor set and `X2` as a reduced set.
 - 4 Enter `testckfold(C1,C2,X1,X2,Y,'Alternative','less')`. If `testckfold` returns `1`, then there is enough evidence to suggest that the classification model that uses fewer predictors performs better than the model that uses the full predictor set.

Alternatively, you can assess whether there is a significant difference between the accuracies of the two models. To perform this assessment, remove the `'Alternative','less'` specification in step 4. `testckfold` conducts a two-sided test, and `h = 0` indicates that there is not enough evidence to suggest a difference in the accuracy of the two models.

- The tests are appropriate for the misclassification rate classification loss on page 32-5472, but you can specify other loss functions (see `LossFun`). The key assumptions are that the estimated classification losses are independent and normally distributed with mean 0 and finite common variance under the two-sided null hypothesis. Classification losses other than the misclassification rate can violate this assumption.
- Highly discrete data, imbalanced classes, and highly imbalanced cost matrices can violate the normality assumption of classification loss differences.

Algorithms

If you specify to conduct the 10-by-10 repeated cross-validation *t* test using `'Test','10x10t'`, then `testckfold` uses 10 degrees of freedom for the *t* distribution to find the critical region and estimate the *p*-value. For more details, see [2] and [3].

Alternatives

Use `testcholdout`:

- For test sets with larger sample sizes

- To implement variants of the McNemar test to compare two classification model accuracies
- For cost-sensitive testing using a chi-square or likelihood ratio test. The chi-square test uses `quadprog`, which requires an Optimization Toolbox license.

Topics

"Hypothesis Tests"

Introduced in R2015a

TestSize property

Class: cvpartition

Size of each test set

Description

Value is a vector in partitions of type 'kfold' and 'leaveout'.

Value is a scalar in partitions of type 'holdout' and 'resubstitution'.

tiedrank

Rank adjusted for ties

Syntax

```
[R,TIEADJ] = tiedrank(X)
[R,TIEADJ] = tiedrank(X,1)
[R,TIEADJ] = tiedrank(X,0,1)
```

Description

`[R,TIEADJ] = tiedrank(X)` computes the ranks of the values in the vector `X`. If any `X` values are tied, `tiedrank` computes their average rank. The return value `TIEADJ` is an adjustment for ties required by the nonparametric tests `signrank` and `ranksum`, and for the computation of Spearman's rank correlation.

`[R,TIEADJ] = tiedrank(X,1)` computes the ranks of the values in the vector `X`. `TIEADJ` is a vector of three adjustments for ties required in the computation of Kendall's tau. `tiedrank(X,0)` is the same as `tiedrank(X)`.

`[R,TIEADJ] = tiedrank(X,0,1)` computes the ranks from each end, so that the smallest and largest values get rank 1, the next smallest and largest get rank 2, etc. These ranks are used in the Ansari-Bradley test.

Examples

Counting from smallest to largest, the two 20 values are 2nd and 3rd, so they both get rank 2.5 (average of 2 and 3):

```
tiedrank([10 20 30 40 20])
ans =
    1.0000    2.5000    4.0000    5.0000    2.5000
```

Algorithms

`tiedrank` treats NaNs in `X` as missing values and ignores them. The rank of NaNs in the output argument `R` is NaN.

tinv

Student's *t* inverse cumulative distribution function

Syntax

```
x = tinv(p,nu)
```

Description

`x = tinv(p,nu)` returns the inverse cumulative distribution function (icdf) of the Student's *t* distribution evaluated at the probability values in `p` using the corresponding degrees of freedom in `nu`.

Examples

Compute Student's *t* icdf

Find the 95th percentile of the Student's *t* distribution with 50 degrees of freedom.

```
p = .95;
nu = 50;
x = tinv(p,nu)

x = 1.6759
```

Compute Student's *t* icdf for Multiple Distributions

Compute the 99th percentile of the Student's *t* distribution for 1 to 6 degrees of freedom.

```
percentile = tinv(0.99,1:6)

percentile = 1×6

    31.8205    6.9646    4.5407    3.7469    3.3649    3.1427
```

Compute Confidence Interval Using Student's *t* icdf

Find a 95% confidence interval estimating the mean of a population by using `tinv`.

Generate a random sample of size 100 drawn from a normal population with mean 10 and standard deviation 2.

```
mu = 10;
sigma = 2;
n = 100;
```

```
rng default % For reproducibility
x = normrnd(mu,sigma,n,1);
```

Compute the sample mean, standard error, and degrees of freedom.

```
xbar = mean(x);
se = std(x)/sqrt(n);
nu = n - 1;
```

Find the upper and lower confidence bounds for the 95% confidence interval.

```
conf = 0.95;
alpha = 1 - conf;
pLo = alpha/2;
pUp = 1 - alpha/2;
```

Compute the critical values for the confidence bounds.

```
crit = tinv([pLo pUp], nu);
```

Determine the confidence interval for the population mean.

```
ci = xbar + crit*se
```

```
ci = 1×2
    9.7849    10.7075
```

This confidence interval is the same as the `ci` value returned by a `t` test of a null hypothesis that the sample comes from a normal population with mean `mu`.

```
[h,p,ci2] = ttest(x,mu,'Alpha',alpha);
ci2
```

```
ci2 = 2×1
    9.7849
   10.7075
```

Input Arguments

p — Probability values at which to evaluate icdf

scalar value in $[0, 1]$ | array of scalar values

Probability values at which to evaluate the icdf, specified as a scalar value or an array of scalar values, where each element is in the range $[0, 1]$.

- To evaluate the icdf at multiple values, specify `p` using an array.
- To evaluate the icdfs of multiple distributions, specify `nu` using an array.

If either or both of the input arguments `p` and `nu` are arrays, then the array sizes must be the same. In this case, `tinv` expands each scalar input into a constant array of the same size as the array inputs. Each element in `x` is the icdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding probability in `p`.

Example: [0.1 0.5 0.9]

Data Types: single | double

nu — Degrees of freedom

positive scalar value | array of positive scalar values

Degrees of freedom for the Student's t distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the icdf at multiple values, specify p using an array.
- To evaluate the icdfs of multiple distributions, specify nu using an array.

If either or both of the input arguments p and nu are arrays, then the array sizes must be the same. In this case, `tinv` expands each scalar input into a constant array of the same size as the array inputs. Each element in x is the icdf value of the distribution specified by the corresponding element in nu , evaluated at the corresponding probability in p .

Example: [9 19 49 99]

Data Types: single | double

Output Arguments

x — icdf values

scalar value | array of scalar values

icdf values evaluated at the probabilities in p , returned as a scalar value or an array of scalar values. x is the same size as p and nu after any necessary scalar expansion. Each element in x is the icdf value of the distribution specified by the corresponding element in nu , evaluated at the corresponding probability in p .

More About

Student's t icdf

The Student's t distribution is a one-parameter family of curves. The parameter ν is the degrees of freedom. The Student's t distribution has zero mean.

The t inverse function is defined in terms of the Student's t cdf as

$$x = F^{-1}(p | \nu) = \{x : F(x | \nu) = p\},$$

where

$$p = F(x | \nu) = \int_{-\infty}^x \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu\pi}} \frac{1}{\left(1 + \frac{t^2}{\nu}\right)^{\frac{\nu+1}{2}}} dt,$$

ν is the degrees of freedom, and $\Gamma(\cdot)$ is the Gamma function. The result x is the solution of the integral equation where you supply the probability p .

For more information, see “Student's *t* Distribution” on page B-149.

Alternative Functionality

- `tinv` is a function specific to the Student's *t* distribution. Statistics and Machine Learning Toolbox also offers the generic function `icdf`, which supports various probability distributions. To use `icdf`, specify the probability distribution name and its parameters. Note that the distribution-specific function `tinv` is faster than the generic function `icdf`.

Topics

“Student's *t* Distribution” on page B-149

Introduced before R2006a

tpdf

Student's t probability density function

Syntax

```
y = tpdf(x,nu)
```

Description

`y = tpdf(x,nu)` returns the probability density function (pdf) of the Student's t distribution with `nu` degrees of freedom, evaluated at the values in `x`.

Examples

Compute Student's t Distribution pdf

The value of the pdf at the mode is an increasing function of the degrees of freedom.

The mode of the Student's t distribution is at $x = 0$. Compute the pdf at the mode for degrees of freedom 1 to 6.

```
tpdf(0,1:6)
ans = 1×6
    0.3183    0.3536    0.3676    0.3750    0.3796    0.3827
```

The t distribution converges to the standard normal distribution as the degrees of freedom approach infinity.

Compute the difference between the pdfs of the standard normal distribution and the Student's t distribution pdf with 30 degrees of freedom.

```
difference = tpdf(-2.5:2.5,30)-normpdf(-2.5:2.5)
difference = 1×6
    0.0035   -0.0006   -0.0042   -0.0042   -0.0006    0.0035
```

Input Arguments

x — Values at which to evaluate pdf

scalar value | array of scalar values

Values at which to evaluate the pdf, specified as a scalar value or an array of scalar values.

- To evaluate the pdf at multiple values, specify `x` using an array.

- To evaluate the pdfs of multiple distributions, specify `nu` using an array.

If either or both of the input arguments `x` and `nu` are arrays, then the array sizes must be the same. In this case, `tpdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `y` is the pdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding element in `x`.

Example: [-1 0 3 4]

Data Types: `single` | `double`

nu — degrees of freedom

positive scalar value | array of positive scalar values

Degrees of freedom for the Student's *t* distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the pdf at multiple values, specify `x` using an array.
- To evaluate the pdfs of multiple distributions, specify `nu` using an array.

If either or both of the input arguments `x` and `nu` are arrays, then the array sizes must be the same. In this case, `tpdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `y` is the pdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding element in `x`.

Example: [9 19 49 99]

Data Types: `single` | `double`

Output Arguments

y — pdf values

scalar value | array of scalar values

pdf values evaluated at the values in `x`, returned as a scalar value or an array of scalar values. `p` is the same size as `x` and `nu` after any necessary scalar expansion. Each element in `y` is the pdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding element in `x`.

More About

Student's *t* pdf

The Student's *t* distribution is a one-parameter family of curves. The parameter ν is the degrees of freedom. The Student's *t* distribution has zero mean.

The pdf of the Student's *t* distribution is

$$y = f(x) \Bigg|_{\nu} = \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu\pi}} \frac{1}{\left(1 + \frac{x^2}{\nu}\right)^{\frac{\nu+1}{2}}}$$

where ν is the degrees of freedom and $\Gamma(\cdot)$ is the Gamma function. The result y is the probability of observing a particular value of x from the Student's t distribution with ν degrees of freedom.

For more information, see “Student's t Distribution” on page B-149.

Alternative Functionality

- `tpdf` is a function specific to the Student's t distribution. Statistics and Machine Learning Toolbox also offers the generic function `pdf`, which supports various probability distributions. To use `pdf`, specify the probability distribution name and its parameters. Note that the distribution-specific function `tpdf` is faster than the generic function `pdf`.

training

Class: cvpartition

Training indices for cross-validation

Syntax

```
idx = training(c)
idx = training(c,i)
```

Description

`idx = training(c)` returns the logical vector `idx` of training indices for an object `c` of the `cvpartition` on page 32-983 class of type 'holdout' or 'resubstitution'.

If `c.Type` is 'holdout', `idx` specifies the observations in the training set.

If `c.Type` is 'resubstitution', `idx` specifies all observations.

`idx = training(c,i)` returns the logical vector `idx` of training indices for repetition `i` of an object `c` of the `cvpartition` on page 32-983 class of type 'kfold' or 'leaveout'.

If `c.Type` is 'kfold', `idx` specifies the observations in the training set in fold `i`.

If `c.Type` is 'leaveout', `idx` specifies the observations left in at repetition `i`.

Examples

Identify the training indices in the first fold of a partition of 10 observations for 3-fold cross-validation:

```
c = cvpartition(10,'kfold',3)
c =
K-fold cross validation partition
      N: 10
  NumTestSets: 3
   TrainSize: 7 6 7
   TestSize: 3 4 3

training(c,1)
ans =
     0
     0
     1
     1
     1
     1
     1
     1
     1
     0
     1
```

Transform predictors into extracted features

Syntax

```
z = transform(Mdl,x)
```

Description

`z = transform(Mdl,x)` transforms the data `x` into the features `z` via the model `Mdl`.

Examples

Transform Data to Learned Features

Create a feature transformation model with 100 features from the `SampleImagePatches` data.

```
rng('default') % For reproducibility
data = load('SampleImagePatches');
q = 100;
X = data.X;
Mdl = sparsefilt(X,q)
```

Warning: Solver LBFGS was not able to converge to a solution.

```
Mdl =
  SparseFiltering
    ModelParameters: [1x1 struct]
      NumPredictors: 363
    NumLearnedFeatures: 100
           Mu: []
           Sigma: []
      FitInfo: [1x1 struct]
    TransformWeights: [363x100 double]
  InitialTransformWeights: []
```

Properties, Methods

`sparsefilt` issues a warning because it stopped due to reaching the iteration limit, instead of reaching a step-size limit or a gradient-size limit. You can still use the learned features in the returned object by calling the `transform` function.

Transform the first five rows of the input data `X` to the new feature space.

```
y = transform(Mdl,X(1:5,:));
size(y)
```

```
ans = 1x2
```

5 100

Input Arguments

Mdl — Feature extraction model

SparseFiltering object | ReconstructionICA object

Feature extraction model, specified as a `SparseFiltering` object or as a `ReconstructionICA` object. Create `Mdl` by using the `sparsefilt` function or the `rica` function.

x — Predictor data

matrix with p columns | table of numeric values with p columns

Predictor data, specified as a matrix with `p` columns or as a table of numeric values with `p` columns. Here, `p` is the number of predictors in the model, which is `Mdl.NumPredictors`. Each row of the input matrix or table represents one data point to transform.

Data Types: single | double | table

Output Arguments

z — Transformed data

n-by-q matrix

Transformed data, returned as an `n`-by-`q` matrix. Here, `n` is the number of rows in the input data `x`, and `q` is the number of features, which is `Mdl.NumLearnedFeatures`.

Algorithms

`transform` converts data to predicted features by using the learned weight matrix `W` to map input predictors to output features.

- For `rica`, input data `X` maps linearly to output features `XW`. See “Reconstruction ICA Algorithm” on page 15-132.
- For `sparsefilt`, input data maps nonlinearly to output features $\widehat{F}(X,W)$. See “Sparse Filtering Algorithm” on page 15-130.

Caution The result of `transform` for sparse filtering depends on the number of data points. In particular, the result of applying `transform` to each row of a matrix separately differs from the result of applying `transform` to the entire matrix at once.

TreeBagger class

Bag of decision trees

Description

`TreeBagger` bags an ensemble of decision trees for either classification or regression. Bagging stands for bootstrap aggregation. Every tree in the ensemble is grown on an independently drawn bootstrap replica of input data. Observations not included in this replica are "out of bag" for this tree.

`TreeBagger` relies on the `ClassificationTree` and `RegressionTree` functionality for growing individual trees. In particular, `ClassificationTree` and `RegressionTree` accepts the number of features selected at random for each decision split as an optional input argument. That is, `TreeBagger` implements the random forest algorithm [1].

For regression problems, `TreeBagger` supports mean and quantile regression (that is, quantile regression forest [2]).

- To predict mean responses or estimate the mean-squared error given data, pass a `TreeBagger` model and the data to `predict` or `error`, respectively. To perform similar operations for out-of-bag observations, use `oobPredict` or `oobError`.
- To estimate quantiles of the response distribution or the quantile error given data, pass a `TreeBagger` model and the data to `quantilePredict` or `quantileError`, respectively. To perform similar operations for out-of-bag observations, use `oobQuantilePredict` or `oobError`.

Construction

`TreeBagger` Create bag of decision trees

Methods

<code>append</code>	Append new trees to ensemble
<code>compact</code>	Compact ensemble of decision trees
<code>error</code>	Error (misclassification probability or MSE)
<code>fillprox</code>	Proximity matrix for training data
<code>growTrees</code>	Train additional trees and add to ensemble
<code>margin</code>	Classification margin
<code>mdsprox</code>	Multidimensional scaling of proximity matrix
<code>meanMargin</code>	Mean classification margin
<code>oobError</code>	Out-of-bag error
<code>oobMargin</code>	Out-of-bag margins
<code>oobMeanMargin</code>	Out-of-bag mean margins
<code>oobPredict</code>	Ensemble predictions for out-of-bag observations
<code>oobQuantileError</code>	Out-of-bag quantile loss of bag of regression trees
<code>oobQuantilePredict</code>	Quantile predictions for out-of-bag observations from bag of regression trees
<code>predict</code>	Predict responses using ensemble of bagged decision trees
<code>quantileError</code>	Quantile loss using bag of regression trees
<code>quantilePredict</code>	Predict response quantile using bag of regression trees

Properties

ClassNames

A cell array containing the class names for the response variable Y. This property is empty for regression trees.

ComputeOOBPrediction

A logical flag specifying whether out-of-bag predictions for training observations should be computed. The default is `false`.

If this flag is `true`, the following properties are available:

- `OOBIndices`
- `OOBInstanceWeight`

If this flag is `true`, the following methods can be called:

- `oobError`
- `oobMargin`
- `oobMeanMargin`

ComputeOOBPredictorImportance

A logical flag specifying whether out-of-bag estimates of variable importance should be computed. The default is `false`. If this flag is `true`, then `ComputeOOBPrediction` is `true` as well.

If this flag is `true`, the following properties are available:

- `OoBPermutedPredictorDeltaError`
- `OoBPermutedPredictorDeltaMeanMargin`
- `OoBPermutedPredictorCountRaiseMargin`

Cost

Square matrix, where `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i` (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`. The number of rows and columns in `Cost` is the number of unique classes in the response.

This property is:

- read-only
- empty (`[]`) for ensembles of regression trees

DefaultYfit

Default value returned by `predict` and `oobPredict`. The `DefaultYfit` property controls what predicted value is returned when no prediction is possible. For example, when `oobPredict` needs to predict for an observation that is in-bag for all trees in the ensemble.

- For classification, you can set this property to either `' '` or `'MostPopular'`. If you choose `'MostPopular'` (the default), the property value becomes the name of the most probably class in the training data. If you choose `' '`, the in-bag observations are excluded from computation of the out-of-bag error and margin.
- For regression, you can set this property to any numeric scalar. The default value is the mean of the response for the training data. If you set this property to `NaN`, the in-bag observations are excluded from computation of the out-of-bag error and margin.

DeltaCriterionDecisionSplit

A numeric array of size 1-by-`Nvars` of changes in the split criterion summed over splits on each variable, averaged across the entire ensemble of grown trees.

InBagFraction

Fraction of observations that are randomly selected with replacement for each bootstrap replica. The size of each replica is `Nobs×InBagFraction`, where `Nobs` is the number of observations in the training set. The default value is 1.

MergeLeaves

A logical flag specifying whether decision tree leaves with the same parent are merged for splits that do not decrease the total risk. The default value is `false`.

Method

Method used by trees. The possible values are `'classification'` for classification ensembles, and `'regression'` for regression ensembles.

MinLeafSize

Minimum number of observations per tree leaf. By default, `MinLeafSize` is 1 for classification and 5 for regression. For decision tree training, the `MinParent` value is set equal to $2 * \text{MinLeafSize}$.

NumTrees

Scalar value equal to the number of decision trees in the ensemble.

NumPredictorSplit

A numeric array of size 1-by-*Nvars*, where every element gives a number of splits on this predictor summed over all trees.

NumPredictorsToSample

Number of predictor or feature variables to select at random for each decision split. By default, `NumPredictorsToSample` is equal to the square root of the total number of variables for classification, and one third of the total number of variables for regression.

OOBIndices

Logical array of size *Nobs*-by-*NumTrees*, where *Nobs* is the number of observations in the training data and *NumTrees* is the number of trees in the ensemble. A `true` value for the (i,j) element indicates that observation *i* is out-of-bag for tree *j*. In other words, observation *i* was not selected for the training data used to grow tree *j*.

OOBInstanceWeight

Numeric array of size *Nobs*-by-1 containing the number of trees used for computing the out-of-bag response for each observation. *Nobs* is the number of observations in the training data used to create the ensemble.

OOBPermutedPredictorCountRaiseMargin

A numeric array of size 1-by-*Nvars* containing a measure of variable importance for each predictor variable (feature). For any variable, the measure is the difference between the number of raised margins and the number of lowered margins if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble. This property is empty for regression trees.

OOBPermutedPredictorDeltaError

A numeric array of size 1-by-*Nvars* containing a measure of importance for each predictor variable (feature). For any variable, the measure is the increase in prediction error if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble.

OOBPermutedPredictorDeltaMeanMargin

A numeric array of size 1-by-*Nvars* containing a measure of importance for each predictor variable (feature). For any variable, the measure is the decrease in the classification margin if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every

tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble. This property is empty for regression trees.

OutlierMeasure

A numeric array of size *Nobs*-by-1, where *Nobs* is the number of observations in the training data, containing outlier measures for each observation.

Prior

Numeric vector of prior probabilities for each class. The order of the elements of **Prior** corresponds to the order of the classes in **ClassNames**.

This property is:

- read-only
- empty ([]) for ensembles of regression trees

Proximity

A numeric matrix of size *Nobs*-by-*Nobs*, where *Nobs* is the number of observations in the training data, containing measures of the proximity between observations. For any two observations, their proximity is defined as the fraction of trees for which these observations land on the same leaf. This is a symmetric matrix with 1s on the diagonal and off-diagonal elements ranging from 0 to 1.

Prune

The **Prune** property is true if decision trees are pruned and false if they are not. Pruning decision trees is not recommended for ensembles. The default value is false.

SampleWithReplacement

A logical flag specifying if data are sampled for each decision tree with replacement. This property is true if **TreeBagger** samples data with replacement and false otherwise. Default value is true.

TreeArguments

Cell array of arguments for **fitctree** or **fitrtree**. These arguments are used by **TreeBagger** when growing new trees for the ensemble.

Trees

A cell array of size *NumTrees*-by-1 containing the trees in the ensemble.

SurrogateAssociation

A matrix of size *Nvars*-by-*Nvars* with predictive measures of variable association, averaged across the entire ensemble of grown trees. If you grew the ensemble setting 'surrogate' to 'on', this matrix for each tree is filled with predictive measures of association averaged over the surrogate splits. If you grew the ensemble setting 'surrogate' to 'off' (default), **SurrogateAssociation** is diagonal.

PredictorNames

A cell array containing the names of the predictor variables (features). **TreeBagger** takes these names from the optional 'names' parameter. The default names are 'x1', 'x2', etc.

W

Numeric vector of weights of length *Nobs*, where *Nobs* is the number of observations (rows) in the training data. `TreeBagger` uses these weights for growing every decision tree in the ensemble. The default `W` is `ones(Nobs, 1)`.

X

A table or numeric matrix of size *Nobs*-by-*Nvars*, where *Nobs* is the number of observations (rows) and *Nvars* is the number of variables (columns) in the training data. If you train the ensemble using a table of predictor values, then `X` is a table. If you train the ensemble using a matrix of predictor values, then `X` is a matrix. This property contains the predictor (or feature) values.

Y

A size *Nobs* array of response data. Elements of `Y` correspond to the rows of `X`. For classification, `Y` is the set of true class labels. Labels can be any grouping variable on page 2-45, that is, a numeric or logical vector, character matrix, string array, cell array of character vectors, or categorical vector. `TreeBagger` converts labels to a cell array of character vectors for classification. For regression, `Y` is a numeric vector.

Examples

Train Ensemble of Bagged Classification Trees

Load Fisher's iris data set.

```
load fisheriris
```

Train an ensemble of bagged classification trees using the entire data set. Specify 50 weak learners. Store which observations are out of bag for each tree.

```
rng(1); % For reproducibility
Mdl = TreeBagger(50,meas,species,'OOBPrediction','On',...
    'Method','classification')
```

```
Mdl =
    TreeBagger
Ensemble with 50 bagged decision trees:
    Training X:      [150x4]
    Training Y:      [150x1]
    Method:          classification
    NumPredictors:   4
    NumPredictorsToSample: 2
    MinLeafSize:     1
    InBagFraction:   1
    SampleWithReplacement: 1
    ComputeOOBPrediction: 1
    ComputeOOBPredictorImportance: 0
    Proximity:       []
    ClassNames:      'setosa' 'versicolor' 'virginica'

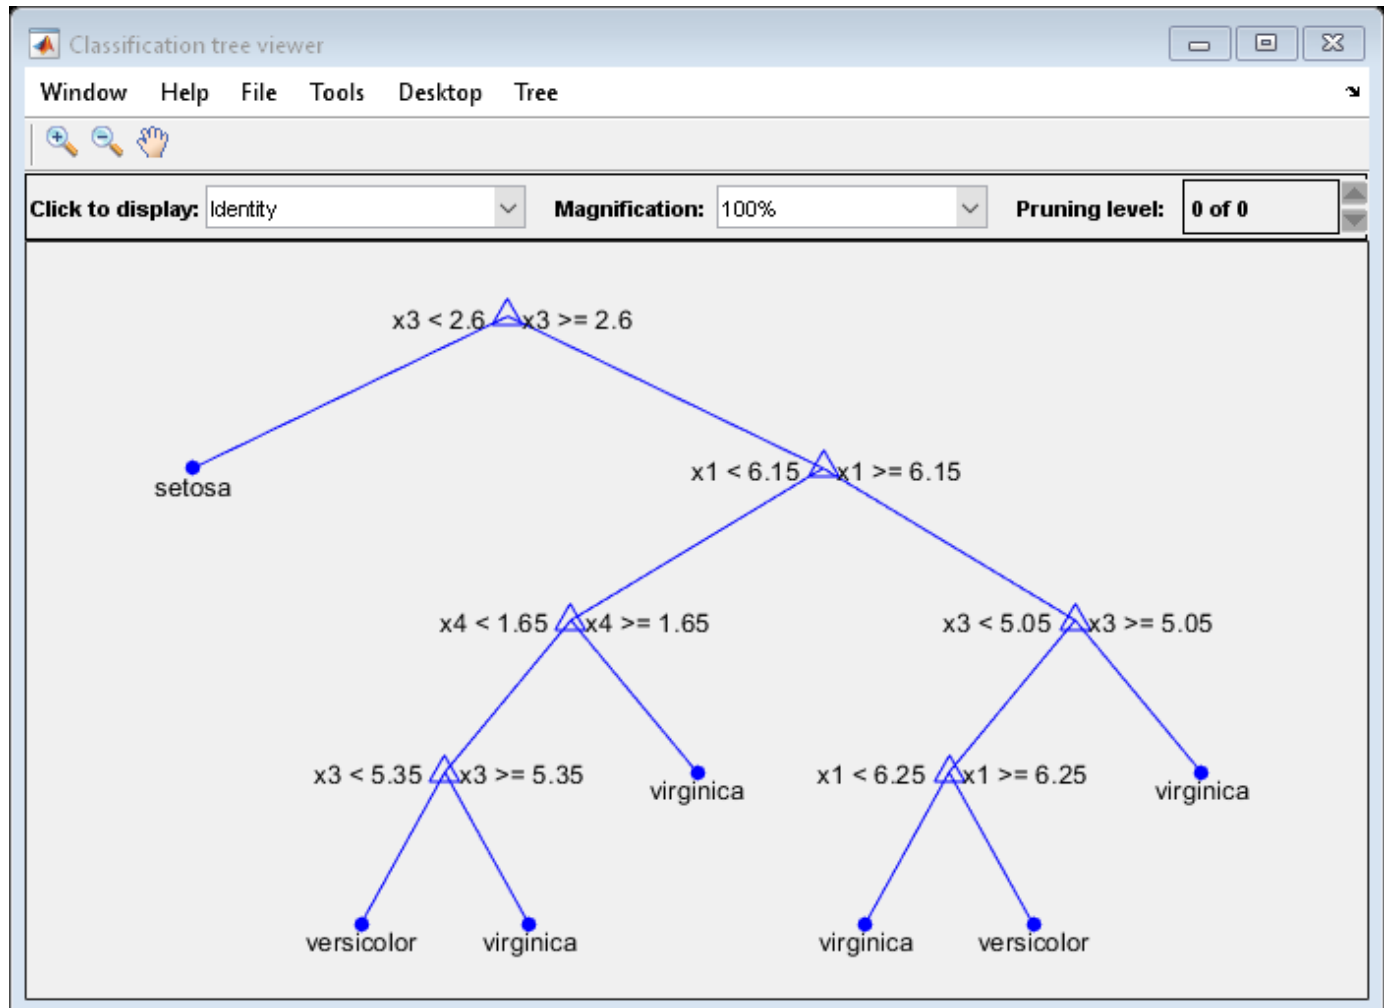

Properties, Methods
```

`Mdl` is a `TreeBagger` ensemble.

Mdl.Trees stores a 50-by-1 cell vector of the trained classification trees (CompactClassificationTree model objects) that compose the ensemble.

Plot a graph of the first trained classification tree.

```
view(Mdl.Trees{1}, 'Mode', 'graph')
```

By default, TreeBagger grows deep trees.

Mdl.OOBIndices stores the out-of-bag indices as a matrix of logical values.

Plot the out-of-bag error over the number of grown classification trees.

```
figure;
oobErrorBaggedEnsemble = oobError(Mdl);
plot(oobErrorBaggedEnsemble)
xlabel 'Number of grown trees';
ylabel 'Out-of-bag classification error';
```

The out-of-bag error decreases with the number of grown trees.

To label out-of-bag observations, pass `Mdl` to `oobPredict`.

Train Ensemble of Bagged Regression Trees

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement.

```
load carsmall
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100, Displacement, MPG, 'Method', 'regression');
```

`Mdl` is a `TreeBagger` ensemble.

Using a trained bag of regression trees, you can estimate conditional mean responses or perform quantile regression to predict conditional quantiles.

For ten equally-spaced engine displacements between the minimum and maximum in-sample displacement, predict conditional mean responses and conditional quartiles.

```

predX = linspace(min(Displacement),max(Displacement),10)';
mpgMean = predict(Mdl,predX);
mpgQuartiles = quantilePredict(Mdl,predX,'Quantile',[0.25,0.5,0.75]);

```

Plot the observations, and estimated mean responses and quartiles in the same figure.

```

figure;
plot(Displacement,MPG,'o');
hold on
plot(predX,mpgMean);
plot(predX,mpgQuartiles);
ylabel('Fuel economy');
xlabel('Engine displacement');
legend('Data','Mean Response','First quartile','Median','Third quartile');

```

Unbiased Predictor Importance Estimates

Load the `carsmall` data set. Consider a model that predicts the mean fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower, manufacturer, model year, and weight. Consider `Cylinders`, `Mfg`, and `Model_Year` as categorical variables.

```

load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);

```

```
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
          Model_Year,Weight,MPG);
rng('default'); % For reproducibility
```

Display the number of categories represented in the categorical variables.

```
numCylinders = numel(categories(Cylinders))
```

```
numCylinders = 3
```

```
numMfg = numel(categories(Mfg))
```

```
numMfg = 28
```

```
numModelYear = numel(categories(Model_Year))
```

```
numModelYear = 3
```

Because there are 3 categories only in `Cylinders` and `Model_Year`, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over these two variables.

Train a random forest of 200 regression trees using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing values in the data, specify usage of surrogate splits. Store the out-of-bag information for predictor importance estimation.

```
Mdl = TreeBagger(200,X,'MPG','Method','regression','Surrogate','on',...
                'PredictorSelection','curvature','OOBPredictorImportance','on');
```

`TreeBagger` stores predictor importance estimates in the property `OOBPermutedPredictorDeltaError`. Compare the estimates using a bar graph.

```
imp = Mdl.OOBPermutedPredictorDeltaError;
```

```
figure;
bar(imp);
title('Curvature Test');
ylabel('Predictor importance estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```

In this case, Model_Year is the most important predictor, followed by Weight.

Compare the `imp` to predictor importance estimates computed from a random forest that grows trees using standard CART.

```
MdlCART = TreeBagger(200,X,'MPG','Method','regression','Surrogate','on',...
    'OOBPredictorImportance','on');
```

```
impCART = MdlCART.OOBPermutedPredictorDeltaError;
```

```
figure;
bar(impCART);
title('Standard CART');
ylabel('Predictor importance estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```

In this case, `Weight`, a continuous predictor, is the most important. The next two most importance predictor are `Model_Year` followed closely by `Horsepower`, which is a continuous predictor.

Copy Semantics

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes \(MATLAB\)](#) in the MATLAB Object-Oriented Programming documentation.

Tip

For a `TreeBagger` model object `B`, the `Trees` property stores a cell vector of `B.NumTrees` `CompactClassificationTree` or `CompactRegressionTree` model objects. For a textual or graphical display of tree `t` in the cell vector, enter

```
view(B.Trees{t})
```

Alternative Functionality

Statistics and Machine Learning Toolbox offers three objects for bagging and random forest:

- `ClassificationBaggedEnsemble` created by `fitcensemble` for classification
- `RegressionBaggedEnsemble` created by `fitrensemble` for regression

- `TreeBagger` created by `TreeBagger` for classification and regression

For details about the differences between `TreeBagger` and bagged ensembles (`ClassificationBaggedEnsemble` and `RegressionBaggedEnsemble`), see “Comparison of `TreeBagger` and Bagged Ensembles” on page 18-43.

TreeBagger

Class: TreeBagger

Create bag of decision trees

Individual decision trees tend to overfit. Bootstrap-aggregated (bagged) decision trees combine the results of many decision trees, which reduces the effects of overfitting and improves generalization. `TreeBagger` grows the decision trees in the ensemble using bootstrap samples of the data. Also, `TreeBagger` selects a random subset of predictors to use at each decision split as in the random forest algorithm [1].

By default, `TreeBagger` bags classification trees. To bag regression trees instead, specify `'Method', 'regression'`.

For regression problems, `TreeBagger` supports mean and quantile regression (that is, quantile regression forest [5]).

Syntax

`Mdl = TreeBagger(NumTrees, Tbl, ResponseVarName)`

`Mdl = TreeBagger(NumTrees, Tbl, formula)`

`Mdl = TreeBagger(NumTrees, Tbl, Y)`

`B = TreeBagger(NumTrees, X, Y)`

`B = TreeBagger(NumTrees, X, Y, Name, Value)`

Description

`Mdl = TreeBagger(NumTrees, Tbl, ResponseVarName)` returns an ensemble of `NumTrees` bagged classification trees trained using the sample data in the table `Tbl`. `ResponseVarName` is the name of the response variable in `Tbl`.

`Mdl = TreeBagger(NumTrees, Tbl, formula)` returns an ensemble of bagged classification trees trained using the sample data in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`. Specify `Formula` using Wilkinson notation. For more information, see “Wilkinson Notation” on page 11-90.

`Mdl = TreeBagger(NumTrees, Tbl, Y)` returns an ensemble of classification trees using the predictor variables in table `Tbl` and class labels in vector `Y`.

`Y` is an array of response data. Elements of `Y` correspond to the rows of `Tbl`. For classification, `Y` is the set of true class labels. Labels can be any grouping variable on page 2-45, that is, a numeric or logical vector, character matrix, string array, cell array of character vectors, or categorical vector. `TreeBagger` converts labels to a cell array of character vectors. For regression, `Y` is a numeric vector. To grow regression trees, you must specify the name-value pair `'Method', 'regression'`.

`B = TreeBagger(NumTrees, X, Y)` creates an ensemble `B` of `NumTrees` decision trees for predicting response `Y` as a function of predictors in the numeric matrix of training data, `X`. Each row in `X` represents an observation and each column represents a predictor or feature.

`B = TreeBagger(NumTrees, X, Y, Name, Value)` specifies optional parameter name-value pairs:

'InBagFraction'	Fraction of input data to sample with replacement from the input data for growing each new tree. Default value is 1.
'Cost'	<p>Square matrix C, where $C(i, j)$ is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of $Cost$ corresponds to the order of the classes in the <code>ClassNames</code> property of the trained <code>TreeBagger</code> model B.</p> <p>Alternatively, <code>cost</code> can be a structure S having two fields:</p> <ul style="list-style-type: none"> • $S.ClassNames$ containing the group names as a categorical variable, character array, string array, or cell array of character vectors • $S.ClassificationCosts$ containing the cost matrix C <p>The default value is $C(i, j) = 1$ if $i \neq j$, and $C(i, j) = 0$ if $i = j$.</p> <p>If $Cost$ is highly skewed, then, for in-bag samples, the software oversamples unique observations from the class that has a large penalty. For smaller sample sizes, this might cause a very low relative frequency of out-of-bag observations from the class that has a large penalty. Therefore, the estimated out-of-bag error is highly variable, and might be difficult to interpret.</p>
'SampleWithReplacement'	'on' to sample with replacement or 'off' to sample without replacement. If you sample without replacement, you need to set 'InBagFraction' to a value less than one. Default is 'on'.
'OOBPrediction'	'on' to store info on what observations are out of bag for each tree. This info can be used by <code>oobPrediction</code> to compute the predicted class probabilities for each tree in the ensemble. Default is 'off'.
'OOBPredictorImportance'	'on' to store out-of-bag estimates of feature importance in the ensemble. Default is 'off'. Specifying 'on' also sets the 'OOBPrediction' value to 'on'. If an analysis of predictor importance is your goal, then also specify 'PredictorSelection', 'curvature' or 'PredictorSelection', 'interaction-curvature'. For more details, see <code>fitctree</code> or <code>fitrtree</code> .
'Method'	Either 'classification' or 'regression'. Regression requires a numeric Y .
'NumPredictorsToSample'	Number of variables to select at random for each decision split. Default is the square root of the number of variables for classification and one third of the number of variables for regression. Valid values are 'all' or a positive integer. Setting this argument to any valid value but 'all' invokes Breiman's random forest algorithm [1].
'NumPrint'	Number of training cycles (grown trees) after which <code>TreeBagger</code> displays a diagnostic message showing training progress. Default is no diagnostic messages.
'MinLeafSize'	Minimum number of observations per tree leaf. Default is 1 for classification and 5 for regression.

'Options'	<p>A structure that specifies options that govern the computation when growing the ensemble of decision trees. One option requests that the computation of decision trees on multiple bootstrap replicates uses multiple processors, if the Parallel Computing Toolbox is available. Two options specify the random number streams to use in selecting bootstrap replicates. You can create this argument with a call to <code>statset</code>. You can retrieve values of the individual fields with a call to <code>statget</code>. Applicable <code>statset</code> parameters are:</p> <ul style="list-style-type: none"> • 'UseParallel' — If <code>true</code> and if a <code>parpool</code> of the Parallel Computing Toolbox is open, compute decision trees drawn on separate bootstrap replicates in parallel. If the Parallel Computing Toolbox is not installed, or a <code>parpool</code> is not open, computation occurs in serial mode. Default is <code>false</code>, or serial computation. <p>For dual-core systems and above, <code>TreeBagger</code> parallelizes training using Intel Threading Building Blocks (TBB). Therefore, using the 'UseParallel' option is not helpful on a single computer. Use this option on a cluster. For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.</p> <ul style="list-style-type: none"> • 'UseSubstreams' — If <code>true</code> select each bootstrap replicate using a separate Substream of the random number generator (aka Stream). This option is available only with <code>RandStream</code> types that support Substreams: 'mlfg6331_64' or 'mrg32k3a'. Default is <code>false</code>, do not use a different Substream to compute each bootstrap replicate. • Streams — A <code>RandStream</code> object or cell array of such objects. If you do not specify Streams, <code>TreeBagger</code> uses the default stream or streams. If you choose to specify Streams, use a single object except in the case <ul style="list-style-type: none"> • UseParallel is <code>true</code> • UseSubstreams is <code>false</code> <p>In that case, use a cell array the same size as the Parallel pool.</p>
-----------	---

'Prior'	<p>Prior probabilities for each class. Specify as one of:</p> <ul style="list-style-type: none">• A character vector or string scalar:<ul style="list-style-type: none">• 'Empirical' determines class probabilities from class frequencies in Y. If you pass observation weights, they are used to compute the class probabilities. This is the default.• 'Uniform' sets all class probabilities equal.• A vector (one scalar value for each class). The order of the elements <code>Prior</code> corresponds to the order of the classes in the <code>ClassNames</code> property of the trained <code>TreeBagger</code> model <code>B</code>.• A structure <code>S</code> with two fields:<ul style="list-style-type: none">• <code>S.ClassNames</code> containing the class names as a categorical variable, character array, string array, or cell array of character vectors• <code>S.ClassProbs</code> containing a vector of corresponding probabilities <p>If you set values for both <code>Weights</code> and <code>Prior</code>, the weights are renormalized to add up to the value of the prior probability in the respective class.</p> <p>If <code>Prior</code> is highly skewed, then, for in-bag samples, the software oversamples unique observations from the class that has a large prior probability. For smaller sample sizes, this might cause a very low relative frequency of out-of-bag observations from the class that has a large prior probability. Therefore, the estimated out-of-bag error is highly variable, and might be difficult to interpret.</p>

Examples

Train Ensemble of Bagged Classification Trees

Load Fisher's iris data set.

```
load fisheriris
```

Train an ensemble of bagged classification trees using the entire data set. Specify 50 weak learners. Store which observations are out of bag for each tree.

```
rng(1); % For reproducibility
Mdl = TreeBagger(50,meas,species,'OOBPrediction','On',...
    'Method','classification')

Mdl =
    TreeBagger
    Ensemble with 50 bagged decision trees:
        Training X: [150x4]
        Training Y: [150x1]
        Method:      classification
        NumPredictors: 4
        NumPredictorsToSample: 2
        MinLeafSize: 1
        InBagFraction: 1
        SampleWithReplacement: 1
        ComputeOOBPrediction: 1
        ComputeOOBPredictorImportance: 0
        Proximity: []
        ClassNames: 'setosa' 'versicolor' 'virginica'

    Properties, Methods
```

`Mdl` is a `TreeBagger` ensemble.

Mdl.Trees stores a 50-by-1 cell vector of the trained classification trees (CompactClassificationTree model objects) that compose the ensemble.

Plot a graph of the first trained classification tree.

```
view(Mdl.Trees{1}, 'Mode', 'graph')
```

By default, TreeBagger grows deep trees.

Mdl.OOBIndices stores the out-of-bag indices as a matrix of logical values.

Plot the out-of-bag error over the number of grown classification trees.

```
figure;
oobErrorBaggedEnsemble = oobError(Mdl);
plot(oobErrorBaggedEnsemble)
xlabel 'Number of grown trees';
ylabel 'Out-of-bag classification error';
```

The out-of-bag error decreases with the number of grown trees.

To label out-of-bag observations, pass `Mdl` to `oobPredict`.

Train Ensemble of Bagged Regression Trees

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement.

```
load carsmall
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100, Displacement, MPG, 'Method', 'regression');
```

`Mdl` is a `TreeBagger` ensemble.

Using a trained bag of regression trees, you can estimate conditional mean responses or perform quantile regression to predict conditional quantiles.

For ten equally-spaced engine displacements between the minimum and maximum in-sample displacement, predict conditional mean responses and conditional quartiles.

```

predX = linspace(min(Displacement),max(Displacement),10)';
mpgMean = predict(Mdl,predX);
mpgQuartiles = quantilePredict(Mdl,predX,'Quantile',[0.25,0.5,0.75]);

```

Plot the observations, and estimated mean responses and quartiles in the same figure.

```

figure;
plot(Displacement,MPG,'o');
hold on
plot(predX,mpgMean);
plot(predX,mpgQuartiles);
ylabel('Fuel economy');
xlabel('Engine displacement');
legend('Data','Mean Response','First quartile','Median','Third quartile');

```

Unbiased Predictor Importance Estimates

Load the `carsmall` data set. Consider a model that predicts the mean fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower, manufacturer, model year, and weight. Consider `Cylinders`, `Mfg`, and `Model_Year` as categorical variables.

```

load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);

```

```
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
          Model_Year,Weight,MPG);
rng('default'); % For reproducibility
```

Display the number of categories represented in the categorical variables.

```
numCylinders = numel(categories(Cylinders))
```

```
numCylinders = 3
```

```
numMfg = numel(categories(Mfg))
```

```
numMfg = 28
```

```
numModelYear = numel(categories(Model_Year))
```

```
numModelYear = 3
```

Because there are 3 categories only in `Cylinders` and `Model_Year`, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over these two variables.

Train a random forest of 200 regression trees using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing values in the data, specify usage of surrogate splits. Store the out-of-bag information for predictor importance estimation.

```
Mdl = TreeBagger(200,X,'MPG','Method','regression','Surrogate','on',...
                'PredictorSelection','curvature','OOBPredictorImportance','on');
```

`TreeBagger` stores predictor importance estimates in the property `OOBPermutedPredictorDeltaError`. Compare the estimates using a bar graph.

```
imp = Mdl.OOBPermutedPredictorDeltaError;
```

```
figure;
bar(imp);
title('Curvature Test');
ylabel('Predictor importance estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```

In this case, Model_Year is the most important predictor, followed by Weight.

Compare the `imp` to predictor importance estimates computed from a random forest that grows trees using standard CART.

```
MdlCART = TreeBagger(200,X,'MPG','Method','regression','Surrogate','on',...
    'OOBPredictorImportance','on');
```

```
impCART = MdlCART.OOBPermutedPredictorDeltaError;
```

```
figure;
bar(impCART);
title('Standard CART');
ylabel('Predictor importance estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```

In this case, `Weight`, a continuous predictor, is the most important. The next two most importance predictor are `Model_Year` followed closely by `Horsepower`, which is a continuous predictor.

Train Ensemble of Bagged Classification Trees on Tall Array

Train an ensemble of bagged classification trees for observations in a tall array, and find the misclassification probability of each tree in the model for weighted observations. The sample data set `airlinesmall.csv` is a large data set that contains a tabular file of airline flight data.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

Create a datastore that references the location of the folder containing the data set. Select a subset of the variables to work with, and treat 'NA' values as missing data so that `datastore` replaces them with NaN values. Create a tall table that contains the data in the datastore.

```
ds = datastore('airlinesmall.csv');
ds.SelectedVariableNames = {'Month', 'DayofMonth', 'DayOfWeek', ...
    'DepTime', 'ArrDelay', 'Distance', 'DepDelay'};
ds.TreatAsMissing = 'NA';
tt = tall(ds) % Tall table
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 12).
```

```
tt =
```

```
Mx7 tall table
```

Month	DayofMonth	DayOfWeek	DepTime	ArrDelay	Distance	DepDelay

      :           :           :           :           :           :
      :           :           :           :           :           :

```

Create a tall array for the observation weights by arbitrarily assigning double weights to the observations in class 1.

```
W = Y+1; % Weights
```

Remove rows in X, Y, and W that contain missing data.

```
R = rmmissing([X Y W]); % Data with missing entries removed
X = R(:,1:end-2);
Y = R(:,end-1);
W = R(:,end);
```

Train an ensemble of 20 bagged decision trees using the entire data set. Specify a weight vector and uniform prior probabilities. For reproducibility, set the seeds of the random number generators using `rng` and `tallrng`. The results can vary depending on the number of workers and the execution environment for the tall arrays. For details, see “Control Where Your Code Runs” (MATLAB).

```
rng('default')
tallrng('default')
tMdl = TreeBagger(20,X,Y,'Weights',W,'Prior','Uniform')

Evaluating tall expression using the Parallel Pool 'local':

Evaluation completed in 22 sec
```

```
tMdl =
  CompactTreeBagger
Ensemble with 20 bagged decision trees:
      Method:      classification
NumPredictors:      6
ClassNames: '0' '1'
```

Properties, Methods

`tMdl` is a `CompactTreeBagger` ensemble with 20 bagged decision trees.

Calculate the misclassification probability of each tree in the model. Attribute a weight contained in the vector `W` to each observation by using the `'Weights'` name-value pair argument.

```
tterr = error(tMdl,X,Y,'Weights',W)
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 20 sec
Evaluation completed in 21 sec
```

0.0982
0.0982
⋮

```

Find the average misclassification probability for the ensemble of decision trees.

```
avg_terr = mean(terr)
```

```
avg_terr = 0.1025
```

Tips

- Avoid large estimated out-of-bag error variances by setting a more balanced misclassification cost matrix or a less skewed prior probability vector.
- The `Trees` property of `B` stores a cell array of `B.NumTrees CompactClassificationTree` or `CompactRegressionTree` model objects. For a textual or graphical display of tree `t` in the cell array, enter

```
view(B.Trees{t})
```

- Standard CART tends to select split predictors containing many distinct values, e.g., continuous variables, over those containing few distinct values, e.g., categorical variables [4]. Consider specifying the curvature or interaction test if any of the following are true:
 - If there are predictors that have relatively fewer distinct values than other predictors, for example, if the predictor data set is heterogeneous.
 - If an analysis of predictor importance is your goal. `TreeBagger` stores predictor importance estimates in the `OOBPermutedPredictorDeltaError` property of `Mdl`.

For more information on predictor selection, see `PredictorSelection` for classification trees or `PredictorSelection` for regression trees.

Algorithms

- `TreeBagger` generates in-bag samples by oversampling classes with large misclassification costs and undersampling classes with small misclassification costs. Consequently, out-of-bag samples have fewer observations from classes with large misclassification costs and more observations from classes with small misclassification costs. If you train a classification ensemble using a small data set and a highly skewed cost matrix, then the number of out-of-bag observations per class might be very low. Therefore, the estimated out-of-bag error might have a large variance and might be difficult to interpret. The same phenomenon can occur for classes with large prior probabilities.
- For details on selecting split predictors and node-splitting algorithms when growing decision trees, see “Algorithms” on page 32-1791 for classification trees and “Algorithms” on page 32-2180 for regression trees.

Alternative Functionality

Statistics and Machine Learning Toolbox offers three objects for bagging and random forest:

- `ClassificationBaggedEnsemble` created by `fitcensemble` for classification
- `RegressionBaggedEnsemble` created by `fitrensemble` for regression
- `TreeBagger` created by `TreeBagger` for classification and regression

For details about the differences between `TreeBagger` and bagged ensembles (`ClassificationBaggedEnsemble` and `RegressionBaggedEnsemble`), see “Comparison of `TreeBagger` and Bagged Ensembles” on page 18-43.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with the limitations:

- Supported syntaxes for tall `X`, `Y`, `Tbl` are:
 - `B = TreeBagger(NumTrees, Tbl, Y)`
 - `B = TreeBagger(NumTrees, X, Y)`
 - `B = TreeBagger(__, Name, Value)`
- For tall arrays, `TreeBagger` supports classification but does not support regression.
- Supported name-value pairs are:
 - `'NumPredictorsToSample'` — Default value is the square root of the number of variables for classification.
 - `'MinLeafSize'` — Default value is 1 if the number of observations is less than 50,000. If the number of observations is 50,000 or greater, then the default value is `max(1, min(5, floor(0.01*NobsChunk)))`, where `NobsChunk` is the number of observations in a chunk.
 - `'ChunkSize'` (only for tall arrays) — Default value is 50000.

In addition, TreeBagger supports these optional arguments of `fitctree`:

- 'AlgorithmForCategorical'
- 'CategoricalPredictors'
- 'Cost' — The columns of the cost matrix C cannot contain Inf or NaN values.
- 'MaxNumCategories'
- 'MaxNumSplits'
- 'MergeLeaves'
- 'PredictorNames'
- 'PredictorSelection'
- 'Prior'
- 'Prune'
- 'PruneCriterion'
- 'SplitCriterion'
- 'Surrogate'
- 'Weights'
- For tall data, TreeBagger returns a CompactTreeBagger object that contains most of the same properties as a full TreeBagger object. The main difference is that the compact object is more memory efficient. The compact object does not include properties that include the data, or that include an array of the same size as the data.
- The number of trees contained in the returned CompactTreeBagger object can differ from the number of trees specified as input to the TreeBagger function. TreeBagger determines the number of trees to return based on factors that include the size of the input data set and the number of data chunks available to grow trees.
- Supported CompactTreeBagger methods are:
 - combine
 - error
 - margin
 - meanMargin
 - predict
 - setDefaultYfit

The error, margin, meanMargin, and predict methods do not support the name-value pair arguments 'Trees', 'TreeWeights', or 'UseInstanceForTree'. The meanMargin method additionally does not support 'Weights'.

- TreeBagger creates a random forest by generating trees on disjoint chunks of the data. When more data is available than is required to create the random forest, the data is subsampled. For a similar example, see Random Forests for Big Data (Genuer, Poggi, Tuleau-Malot, Villa-Vialaneix 2015).

Depending on how the data is stored, it is possible that some chunks of data contain observations from only a few classes out of all the classes. In this case, TreeBagger might produce inferior results compared to the case where each chunk of data contains observations from most of the classes.

- During training of the `TreeBagger` algorithm, the speed, accuracy, and memory usage depend on a number of factors. These factors include values for `NumTrees`, `'ChunkSize'`, `'MinLeafSize'`, and `'MaxNumSplits'`.

For an n -by- p tall array X , `TreeBagger` implements sampling during training. This sampling depends on these variables:

- Number of trees `NumTrees`
- Chunk size `'ChunkSize'`
- Number of observations n
- Number of chunks r (approximately equal to $n / \text{'ChunkSize'}$)

Because the value of n is fixed for a given X , your settings for `NumTrees` and `'ChunkSize'` determine how `TreeBagger` samples X .

- 1 If $r > \text{NumTrees}$, then `TreeBagger` samples `'ChunkSize' * NumTrees` observations from X , and trains one tree per chunk (with each chunk containing `'ChunkSize'` number of observations). This scenario is the most common when you work with tall arrays.
 - 2 If $r \leq \text{NumTrees}$, then `TreeBagger` trains approximately $\text{NumTrees}/r$ trees in each chunk, using bootstrapping within the chunk.
 - 3 If $n \leq \text{'ChunkSize'}$, then `TreeBagger` uses bootstrapping to generate samples (each of size n) on which to train individual trees.
- When specifying a value for `NumTrees`, consider the following:
 - If you run your code on Apache Spark, and your data set is distributed with Hadoop® Distributed File System (HDFS™), start by specifying a value for `NumTrees` that is at least twice the number of partitions in HDFS for your data set. This setting prevents excessive data communication among Apache Spark executors and can improve performance of the `TreeBagger` algorithm.
 - `TreeBagger` copies fitted trees into the client memory in the resulting `CompactTreeBagger` model. Therefore, the amount of memory available to the client creates an upper bound on the value you can set for `NumTrees`. You can tune the values of `'MinLeafSize'` and `'MaxNumSplits'` for more efficient speed and memory usage at the expense of some predictive accuracy. After tuning, if the value of `NumTrees` is less than twice the number of partitions in HDFS for your data set, then consider repartitioning your data in HDFS to have larger partitions.

After specifying a value for `NumTrees`, set `'ChunkSize'` to ensure that `TreeBagger` uses most of the data to grow trees. Ideally, `'ChunkSize' * NumTrees` should approximate n , the number of rows in your data. Note that the memory available in the workers for training individual trees can also determine an upper bound for `'ChunkSize'`.

You can adjust the Apache Spark memory properties to avoid out-of-memory errors and support your workflow. See `parallel_cluster.Hadoop` for more information.

For more information, see “Tall Arrays for Out-of-Memory Data” (MATLAB).

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the `'UseParallel'` option to `true`.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2009a

trimmean

Mean, excluding outliers

Syntax

```
m = trimmean(X,percent)
m = trimmean(X,percent,flag)
m = trimmean( ____, 'all' )
m = trimmean( ____, dim)
m = trimmean( ____, vecdim)
```

Description

`m = trimmean(X,percent)` returns the mean of values of `X`, computed after removing the outliers of `X`. For example, if `X` is a vector that has `n` values, `m` is the mean of `X` excluding the highest and lowest `k` data values, where $k = n * (\text{percent}/100) / 2$.

- If `X` is a vector, then `trimmean(X,percent)` is the mean of all the values of `X`, computed after removing the outliers.
- If `X` is a matrix, then `trimmean(X,percent)` is a row vector of column means, computed after removing the outliers.
- If `X` is a multidimensional array, then `trimmean` operates along the first nonsingleton dimension of `X`.

`m = trimmean(X,percent,flag)` specifies how to trim when `k` (half the number of outliers) is not an integer.

`m = trimmean(____, 'all')` returns the trimmed mean of all the values in `X` using any of the input argument combinations in the previous syntaxes.

`m = trimmean(____, dim)` returns the trimmed mean along the operating dimension `dim` of `X`.

`m = trimmean(____, vecdim)` returns the trimmed mean over the dimensions specified in the vector `vecdim`. For example, if `X` is a 2-by-3-by-4 array, then `trimmean(X,10,[1 2])` returns a 1-by-1-by-4 array. Each value of the output array is the mean of the middle 90% of the values on the corresponding page of `X`.

Examples

Efficiency of Trimmed Mean

Find the relative efficiency of the 10% trimmed mean to the sample mean for a given data set.

Generate a 100-by-100 matrix of random numbers from the standard normal distribution. This matrix represents 100 samples, each containing 100 data points.

```
rng default; % For reproducibility
X = normrnd(0,1,100,100);
```

Compute the sample mean and the 10% trimmed mean for each column of the data matrix.

```
m = mean(X); % Sample mean
trim = trimmean(X,10); % Trimmed mean
```

Compute the relative efficiency of the trimmed mean to the sample mean. The relative efficiency is the variance of the sample mean divided by the variance of the trimmed mean.

```
vm = var(m) % Variance of the sample mean
vm = 0.0094
```

```
vtrim = var(trim) % Variance of the trimmed mean
vtrim = 0.0097
```

```
efficiency = vm/vtrim % Relative efficiency of the trimmed mean to the sample mean
efficiency = 0.9663
```

The sample mean has a smaller variance than the trimmed mean ($\text{efficiency} < 1$). Therefore, the trimmed mean is less efficient than the sample mean.

Control Trimming for Distribution with Outliers

Control the trimming for a distribution with outliers when k (half the number of outliers to be trimmed) is not an integer.

Generate a vector of random numbers from the Student's t distribution with degrees of freedom equal to 1. The Student's t distribution tends to have outliers.

```
rng default; % For reproducibility
nu = 1; % Degrees of freedom
n = 60; % Number of rows
m = 1; % Number of columns
x = trnd(nu,n,m); % Vector
```

Visualize the distribution using a normal probability plot.

```
probplot(x)
```

Although the distribution is symmetric around zero, several outliers affect the mean.

Find the mean of the data.

```
mn = mean(x)
```

```
mn = 1.6452
```

Find the 33% trimmed mean of the data.

```
trim = trimmean(x,33)
```

```
trim = 0.4940
```

The 33% trimmed mean is closer to zero, which is more representative of the data. For the 33% trimmed mean, k is not an integer ($k = 60 \cdot (33/100) / 2$ gives a value of 9.9). Therefore, `trimmean` rounds k to the nearest integer (10) by default.

Control trimming by rounding k down to the next smaller integer (9). Specify the control for trimming to `'floor'`.

```
trim = trimmean(x,33,'floor')
```

```
trim = 0.4933
```

Find Trimmed Mean Along Given Dimension

Find the trimmed mean along different dimensions for a matrix.

Generate a matrix of random numbers from the Student's t distribution. The Student's t distribution tends to have outliers.

```
rng('default')
nu = 1; % Degrees of freedom
n = 2; % Number of rows
m = 100; % Number of columns
X = trnd(nu,n,m);
```

Visualize the distribution for each row of X using a normal probability plot.

```
for i = 1:n
    figure()
    probplot(X(i,:))
end
```

Find the mean for each row of X.

```
mn = mean(X,2)
```

```
mn = 2×1
```

```
-2.7379  
2.0087
```

Find the 30% trimmed mean for each row of X. Specify `dim = 2` as the operating dimension.

```
trim = trimmean(X,30,2)
```

```
trim = 2×1
```

```
-0.0868  
0.1115
```

The 30% trimmed mean of each row is closer to zero, which is more representative of the data.

Trimmed Mean Along Vector of Dimensions

Calculate the trimmed mean over multiple dimensions by using the 'all' and `vecdim` input arguments.

Create a 5-by-4-by-2 array with some outlier values.

```
X = reshape(1:40,[5 4 2]);
X([3 37]) = -100
```

```
X =
X(:,:,1) =
     1     6    11    16
     2     7    12    17
    -100     8    13    18
     4     9    14    19
     5    10    15    20
```

```
X(:,:,2) =
    21    26    31    36
    22    27    32   -100
    23    28    33    38
    24    29    34    39
    25    30    35    40
```

Find the 10% trimmed mean of X.

```
mall = trimmean(X,10,'all')
```

```
mall = 19.4722
```

`mall` is the mean of the middle 90% of the values in X.

Find the 10% trimmed mean for each page of X.

```
mpage = trimmean(X,10,[1 2])
```

```
mpage =
mpage(:,:,1) =
```

```
    10.3889
```

```
mpage(:,:,2) =
```

```
    29.6111
```

For example, `mpage(1,1,2)` is the mean of the middle 90% of the values in `X(:,:,2)`.

Input Arguments

X — Input data

vector | matrix | multidimensional array

Input data that represents a sample from a population, specified as a vector, matrix, or multidimensional array.

- If X is a vector, then `trimmean(X,percent)` is the mean of all the values of X , computed after removing the outliers.
- If X is a matrix, then `trimmean(X,percent)` is a row vector of column means, computed after removing the outliers.
- If X is a multidimensional array, then `trimmean` operates along the first nonsingleton dimension of X .

To specify the operating dimension when X is a matrix or an array, use the `dim` input argument.

`trimmean` treats NaN values in X as missing values and removes them.

Data Types: `single` | `double`

percent — Percentage

scalar

Percentage of input data to be trimmed, specified as a scalar between 0 and 100.

`trimmean` uses the value of `percent` to determine the number of outliers (highest and lowest k values in X) to remove from X before computing the mean. For X with n values, $k = n * (\text{percent} / 100) / 2$.

Data Types: `single` | `double`

flag — Control for trimming

'round' (default) | 'floor' | 'weighted'

Control for trimming when k (half the number of outliers) is not an integer, specified as one of the values in this table.

Value	Description
'round'	Round k to the nearest integer (round to a smaller integer if k is a half integer). This value is the default.
'floor'	Round k down to the next smaller integer.
'weighted'	If $k = i + f$, where i is an integer and f is a fraction, compute a weighted mean with weight $(1 - f)$ for the $(i + 1)$ th and $(n - i)$ th values, and full weight for the values between them.

Data Types: `char` | `string`

dim — Dimension

positive integer scalar

Dimension along which to operate, specified as a positive integer scalar. If you do not specify a value, then the default value is the first array dimension of X whose size does not equal 1.

Consider a two-dimensional array X :

- If `dim` is equal to 1, then `trimmean(X,percent,1)` returns a row vector containing the trimmed mean for each column in X .
- If `dim` is equal to 2, then `trimmean(X,percent,2)` returns a column vector containing the trimmed mean for each row in X .

If `dim` is greater than `ndims(X)` or if `size(X,dim)` is 1, then `trimmean` returns X .

Data Types: `single` | `double`

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. The output `m` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `m`.

For example, if `X` is a 2-by-3-by-3 array, then `trimmean(X,10,[1 2])` returns a 1-by-1-by-3 array. Each element of the output is the mean of the middle 90% of the values on the corresponding page of `X`.

Data Types: `single` | `double`

Output Arguments

m — Trimmed mean

scalar | vector | matrix | multidimensional array

Trimmed mean values, returned as a scalar, vector, matrix, or multidimensional array.

Tips

- The trimmed mean is a robust estimate of the location of a data sample. If the data contains outliers, then the trimmed mean represents the center of the data better than the sample mean. However, if all the data is from the same probability distribution, then the trimmed mean is less efficient than the sample mean as an estimator of the data location.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'all' and `vecdim` input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

trnd

Student's t random numbers

Syntax

```
r = trnd(nu)
r = trnd(nu,sz1,...,szN)
r = trnd(nu,sz)
```

Description

`r = trnd(nu)` generates a random number from the Student's t distribution with `nu` degrees of freedom.

`r = trnd(nu,sz1,...,szN)` generates an array of random numbers from the Student's t distribution, where `sz1,...,szN` indicates the size of each dimension.

`r = trnd(nu,sz)` generates an array of random numbers from the Student's t distribution, where size vector `sz` specifies `size(r)`.

Examples

Generate Student's t Distribution Random Number

Generate a single random number from the Student's t distribution with 10 degrees of freedom.

```
nu = 10;
r = trnd(nu)

r = 1.0585
```

Generate Student's t Distribution Random Numbers

Generate a 1-by-6 array of Student's t random numbers with 1 degree of freedom.

```
nu1 = ones(1,6); % 1-by-6 array of ones
r1 = trnd(nu1)

r1 = 1×6

    0.2108    7.8450   -11.0511    0.4134    4.3293   -0.8323
```

If you specify `nu` as a scalar, it expands into a constant array with dimensions specified by `sz1,...,szn`.

Generate a 2-by-6 array of Student's t random numbers with 3 degrees of freedom

```

nu2 = 3;
sz1 = 2;
sz2 = 6;
r2 = trnd(nu2,sz1,sz2)

r2 = 2×6

    0.9257    0.3379    0.6477   -2.2792   -2.8371    0.3632
   -0.2996   -0.6845   -1.2554   -0.5134    1.0458   -0.5521

```

If you specify both `nu` and `sz` as arrays, then the dimensions specified by `sz` must match the dimension of `nu`.

Generate a 1-by-6 array of Student's t random numbers with 1 to 6 degrees of freedom.

```

nu3 = 1:6;
sz = [1 6];
r3 = trnd(nu3,sz)

r3 = 1×6

    1.3609    0.1845   -4.0246   -0.8724   -0.7507    2.3493

```

Input Arguments

nu — Degrees of freedom

scalar value | array of scalar values

Degrees of freedom for the Student's t distribution, specified as a scalar value or an array of scalar values.

To generate random numbers from multiple distributions, specify `nu` using an array. Each element in `r` is the random number generated from the distribution specified by the corresponding degrees of freedom in `nu`.

Example: [9 19 49 99]

Data Types: `single` | `double`

sz1, ..., szN — Size of each dimension (as separate arguments)

integers

Size of each dimension, specified as separate arguments of integers.

If `nu` is an array, then the specified dimensions `sz1, ..., szN` must match the dimensions of `nu`. The default values of `sz1, ..., szN` are the dimensions of `nu`.

- If you specify a single value `sz1`, then `r` is a square matrix of size `sz1`-by-`sz1`.
- If the size of any dimension is 0 or negative, then `r` is an empty array.
- Beyond the second dimension, `trnd` ignores trailing dimensions with a size of 1. For example, `trnd(5,3,1,1,1)` produces a 3-by-1 vector of random numbers from the distribution with 5 degrees of freedom.

Example: 3,5

Data Types: `single` | `double`

sz — Size of each dimension (as a row vector)

row vector of integers

Size of each dimension, specified as a row vector of integers.

If `nu` is an array, then the specified dimensions `sz` must match the dimensions of `nu`. The default values of `sz` are the dimensions of `nu`.

- If you specify a single value [`sz1`], then `r` is a square matrix of size `sz1`-by-`sz1`.
- If the size of any dimension is 0 or negative, then `r` is an empty array.
- Beyond the second dimension, `trnd` ignores trailing dimensions with a size of 1. For example, `trnd(5, [3 1 1 1])` produces a 3-by-1 vector of random numbers from the distribution with 5 degrees of freedom.

Example: `[3 5]`

Data Types: `single` | `double`

Output Arguments

r — Student's *t* random numbers

scalar value | array of scalar values

Student's *t* random numbers, returned as a scalar value or an array of scalar values with the dimensions specified by `sz1, . . . , szN` or `sz`. Each element in `r` is the random number generated from the distribution specified by the corresponding degrees of freedom in `nu`.

Alternative Functionality

- `trnd` is a function specific to the Student's *t* distribution. Statistics and Machine Learning Toolbox also offers the generic function `random`, which supports various probability distributions. To use `random`, specify the probability distribution name and its parameters. Note that the distribution-specific function `trnd` is faster than the generic function `random`.
- To generate random numbers interactively, use `randtool`, a user interface for random number generation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers from the sequence of numbers returned by MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

“Student's t Distribution” on page B-149

Introduced before R2006a

truncate

Package: prob

Truncate probability distribution object

Syntax

```
t = truncate(pd, lower, upper)
```

Description

`t = truncate(pd, lower, upper)` returns a probability distribution `t`, which is the probability distribution `pd` truncated to the specified interval with lower limit, `lower`, and upper limit, `upper`.

Examples

Truncate a Probability Distribution

Create a standard normal probability distribution object.

```
pd = makedist('Normal')
```

```
pd =  
  NormalDistribution  
  
  Normal distribution  
    mu = 0  
    sigma = 1
```

Truncate the distribution to have a lower limit of -2 and an upper limit of 2.

```
t = truncate(pd, -2, 2)  
  
t =  
  NormalDistribution  
  
  Normal distribution  
    mu = 0  
    sigma = 1  
  Truncated to the interval [-2, 2]
```

Plot the pdf of the original and truncated distributions for a visual comparison.

```
x = linspace(-3, 3, 1000);  
figure  
plot(x, pdf(pd, x))  
hold on  
plot(x, pdf(t, x), 'LineStyle', '--')  
legend('Normal', 'Truncated')  
hold off
```

Generate Random Numbers from a Truncated Distribution

Create a standard normal probability distribution object.

```
pd = makedist('Normal')
```

```
pd =  
NormalDistribution  
  
Normal distribution  
mu = 0  
sigma = 1
```

Truncate the distribution by restricting it to positive values. Set the lower limit to 0 and the upper limit to infinity.

```
t = truncate(pd,0,inf)
```

```
t =  
NormalDistribution  
  
Normal distribution  
mu = 0  
sigma = 1
```

Truncated to the interval [0, Inf]

Generate random numbers from the truncated distribution and visualize with a histogram.

```
r = random(t,10000,1);  
histogram(r,100)
```

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object.

Create a probability distribution object with specified parameter values using `makedist`.

Alternatively, for a fittable distribution, create a probability distribution object by fitting it to data using `fitdist` or the **Distribution Fitter** app.

Lower — Lower truncation limit

scalar value

Lower truncation limit, specified as a scalar value.

Data Types: `single` | `double`

upper — Upper truncation limit

scalar value

Upper truncation limit, specified as a scalar value.

Data Types: `single` | `double`

Output Arguments**t — Truncated distribution**

probability distribution object

Truncated distribution, returned as a probability distribution object. The probability distribution function (pdf) of `t` is 0 outside the truncation interval. Inside the truncation interval, the pdf of `t` is equal to the pdf of `pd`, but divided by the probability assigned to that interval by `pd`.

The object properties of `t` are the same as those of `pd` with these exceptions:

- The `Truncation` property of `t` stores the truncation interval.
- The `IsTruncated` property of `t` is 1.
- The `InputData` property of `t` is empty. For a fitted distribution object, the `InputData` property stores the data used for distribution fitting. The truncated distribution object does not store the input data.

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument `pd` can be a fitted probability distribution object for beta, exponential, extreme value, lognormal, normal, and Weibull distributions. Create `pd` by fitting a probability distribution to sample data from the `fitdist` function. For an example, see “Code Generation for Probability Distribution Objects” on page 31-70.
- A truncated probability distribution object cannot be an input argument of an entry-point function. To evaluate a truncated distribution using object functions such as `cdf`, `pdf`, `mean`, and so on, call `t.truncate` and one or more of these object functions within a single entry-point function.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

Introduced in R2013a

tsne

t-Distributed Stochastic Neighbor Embedding

Syntax

```
Y = tsne(X)
Y = tsne(X,Name,Value)
[Y,loss] = tsne(____)
```

Description

`Y = tsne(X)` returns a matrix of two-dimensional embeddings of the high-dimensional rows of `X`.

`Y = tsne(X,Name,Value)` modifies the embeddings using options specified by one or more name-value pair arguments.

`[Y,loss] = tsne(____)`, for any input arguments, also returns the Kullback-Leibler divergence between the joint distributions that model the data `X` and the embedding `Y`.

Examples

Visualize Fisher Iris Data

The Fisher iris data set has four-dimensional measurements of irises, and corresponding classification into species. Visualize this data by reducing the dimension using `tsne`.

```
load fisheriris
rng default % for reproducibility
Y = tsne(meas);
gscatter(Y(:,1),Y(:,2),species)
```

Compare Distance Metrics

Use various distance metrics to try to obtain a better separation between species in the Fisher iris data.

```
load fisheriris
```

```
rng('default') % for reproducibility
Y = tsne(meas, 'Algorithm', 'exact', 'Distance', 'mahalanobis');
subplot(2,2,1)
gscatter(Y(:,1), Y(:,2), species)
title('Mahalanobis')
```

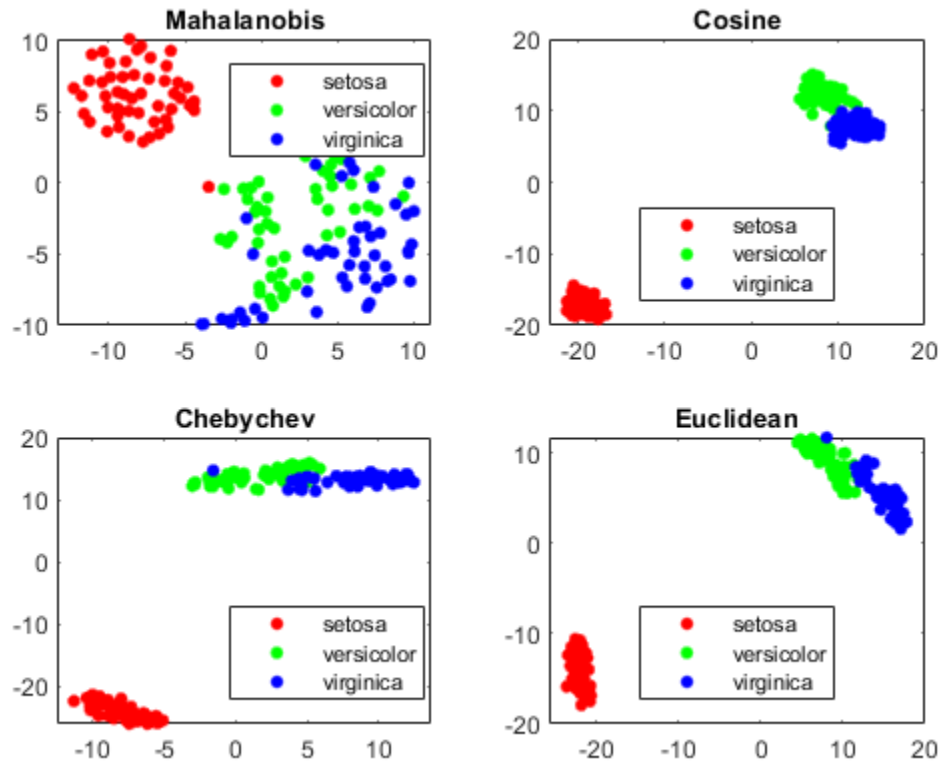

```
rng('default') % for fair comparison
Y = tsne(meas, 'Algorithm', 'exact', 'Distance', 'cosine');
subplot(2,2,2)
gscatter(Y(:,1), Y(:,2), species)
title('Cosine')
```

```
rng('default') % for fair comparison
Y = tsne(meas, 'Algorithm', 'exact', 'Distance', 'chebychev');
subplot(2,2,3)
gscatter(Y(:,1), Y(:,2), species)
title('Chebychev')
```

```

rng('default') % for fair comparison
Y = tsne(meas,'Algorithm','exact','Distance','euclidean');
subplot(2,2,4)
gscatter(Y(:,1),Y(:,2),species)
title('Euclidean')

```

In this case, the cosine, Chebychev, and Euclidean distance metrics give reasonably good separation of clusters. But the Mahalanobis distance metric does not give a good separation.

Plot Results with NaN Input Data

`tsne` removes input data rows that contain any NaN entries. Therefore, you must remove any such rows from your classification data before plotting.

For example, change a few random entries in the Fisher iris data to NaN.

```

load fisheriris
rng default % for reproducibility
meas(rand(size(meas)) < 0.05) = NaN;

```

Embed the four-dimensional data into two dimensions using `tsne`.

```

Y = tsne(meas,'Algorithm','exact');

```

Warning: Rows with NaN missing values in X or 'InitialY' values are removed.

Determine how many rows were eliminated from the embedding.

```
length(species) - length(Y)
```

```
ans = 22
```

Prepare to plot the result by locating the rows of meas that have no NaN values.

```
goodrows = not(any(isnan(meas),2));
```

Plot the results using only the rows of species that correspond to rows of meas with no NaN values.

```
gscatter(Y(:,1),Y(:,2),species(goodrows))
```

Compare t-SNE Loss

Find both 2-D and 3-D embeddings of the Fisher iris data, and compare the loss for each embedding. It is likely that the loss is lower for a 3-D embedding, because this embedding has more freedom to match the original data.

```
load fisheriris
rng default % for reproducibility
[Y,loss] = tsne(meas,'Algorithm','exact');
rng default % for fair comparison
[Y2,loss2] = tsne(meas,'Algorithm','exact','NumDimensions',3);
fprintf('2-D embedding has loss %g, and 3-D embedding has loss %g.\n',loss,loss2)
```

2-D embedding has loss 0.129953, and 3-D embedding has loss 0.0968597.

As expected, the 3-D embedding has lower loss.

View the embeddings. Use RGB colors [1 0 0], [0 1 0], and [0 0 1].

For the 3-D plot, convert the species to numeric values using the `categorical` command, then convert the numeric values to RGB colors using the `sparse` function as follows. If `v` is a vector of positive integers 1, 2, or 3, corresponding to the species data, then the command

```
sparse(1:numel(v),v,ones(size(v)))
```

is a sparse matrix whose rows are the RGB colors of the species.

```
gscatter(Y(:,1),Y(:,2),species,eye(3))
title('2-D Embedding')
```

```
figure
v = double(categorical(species));
c = full(sparse(1:numel(v),v,ones(size(v)),numel(v),3));
scatter3(Y2(:,1),Y2(:,2),Y2(:,3),15,c,'filled')
title('3-D Embedding')
view(-50,8)
```

Input Arguments

X — Data points

n-by-m matrix

Data points, specified as an n-by-m matrix, where each row is one m-dimensional point.

`tsne` removes rows of X that contain any NaN values before creating an embedding. See “Plot Results with NaN Input Data” on page 32-5543.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `Y = tsne(X, 'Algorithm', 'Exact', 'NumPCAComponents', 50)`

Algorithm Control

Algorithm — tsne algorithm

'barneshut' (default) | 'exact'

`tsne` algorithm, specified as 'barneshut' or 'exact'. The 'exact' algorithm optimizes the Kullback-Leibler divergence of distributions between the original space and the embedded space. The

'barneshut' algorithm performs an approximate optimization that is faster and uses less memory when the number of data rows is large.

Note For the 'barneshut' algorithm, tsne uses knnsearch to find the nearest neighbors.

Example: 'exact'

Distance – Distance metric

'euclidean' (default) | 'seuclidean' | 'cityblock' | 'chebychev' | 'minkowski' | 'mahalanobis' | 'cosine' | 'correlation' | 'spearman' | 'hamming' | 'jaccard' | function handle

Distance metric, specified by one of the following. For definitions of the distance metrics, see `pdist`.

- 'euclidean' — Euclidean distance.
- 'seuclidean' — Standardized Euclidean distance. Each coordinate difference between rows in X and the query matrix is scaled by dividing by the corresponding element of the standard deviation computed from `S = nanstd(X)`.
- 'cityblock' — City block distance.
- 'chebychev' — Chebychev distance, which is the maximum coordinate difference.
- 'minkowski' — Minkowski distance with exponent 2. This is the same as Euclidean distance.
- 'mahalanobis' — Mahalanobis distance, computed using the positive definite covariance matrix `nancov(X)`.
- 'cosine' — 1 minus the cosine of the included angle between observations (treated as vectors).
- 'correlation' — One minus the sample linear correlation between observations (treated as sequences of values).
- 'spearman' — One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
- 'hamming' — Hamming distance, which is the percentage of coordinates that differ.
- 'jaccard' — One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
- custom distance function — A distance function specified using @ (for example, `@distfun`). For details, see “More About” on page 32-5550.

In all cases, tsne uses squared pairwise distances to calculate the Gaussian kernel in the joint distribution of X.

Example: 'mahalanobis'

Exaggeration – Size of natural clusters in data

4 (default) | scalar value 1 or greater

Size of natural clusters in data, specified as a scalar value 1 or greater.

A large exaggeration makes tsne learn larger joint probabilities of Y and creates relatively more space between clusters in Y. tsne uses exaggeration in the first 99 optimization iterations.

If the value of Kullback-Leibler divergence increases in the early stage of the optimization, try reducing the exaggeration. See “tsne Settings” on page 15-117.

Example: 10

Data Types: `single` | `double`

NumDimensions — Dimension of the output Y

2 (default) | positive integer

Dimension of the output Y, specified as a positive integer. Generally, set `NumDimensions` to 2 or 3.

Example: 3

Data Types: `single` | `double`

NumPCAComponents — PCA dimension reduction

0 (default) | nonnegative integer

PCA dimension reduction, specified as a nonnegative integer. Before `tsne` embeds the high-dimensional data, it first reduces the dimensionality of the data to `NumPCAComponents` using the `pca` function. When `NumPCAComponents` is 0, `tsne` does not use PCA.

Example: 50

Data Types: `single` | `double`

Perplexity — Effective number of local neighbors of each point

30 (default) | positive scalar

Effective number of local neighbors of each point, specified as a positive scalar. See “t-SNE Algorithm” on page 15-104.

Larger perplexity causes `tsne` to use more points as nearest neighbors. Use a larger value of `Perplexity` for a large dataset. Typical `Perplexity` values are from 5 to 50. In the Barnes-Hut algorithm, `tsne` uses $\min(3*\text{Perplexity}, N-1)$ as the number of nearest neighbors. See “`tsne` Settings” on page 15-117.

Example: 10

Data Types: `single` | `double`

Standardize — Normalize input data

`false` (default) | `true`

Normalize input data, specified as `false` or `true`. When `true`, `tsne` centers and scales X by dividing the columns by their standard deviations.

When features in X are on different scales, set '`Standardize`' to `true`. Do this because the learning process is based on nearest neighbors, so features with large scales can override the contribution of features with small scales.

Example: `true`

Data Types: `logical`

Optimization Control

InitialY — Initial embedded points

`1e-4*randn(N, NumDimensions)` (default) | n-by-`NumDimensions` real matrix

Initial embedded points, specified as an n-by-`NumDimensions` real matrix, where n is the number of rows of X. The `tsne` optimization algorithm uses these points as initial values.

Data Types: `single` | `double`

LearnRate — Learning rate for optimization process

500 (default) | positive scalar

Learning rate for optimization process, specified as a positive scalar. Typically, set values from 100 through 1000.

When `LearnRate` is too small, `tsne` can converge to a poor local minimum. When `LearnRate` is too large, the optimization can initially have the Kullback-Leibler divergence increase rather than decrease. See “tsne Settings” on page 15-117.

Example: 1000

Data Types: `single` | `double`

NumPrint — Iterative display frequency

20 (default) | positive integer

Iterative display frequency, specified as a positive integer. When the `Verbose` name-value pair is not 0, `tsne` returns iterative display after every `NumPrint` iterations. If the `Options` name-value pair contains a nonempty `'OutputFcn'` entry, then output functions run after every `NumPrint` iterations.

Example: 20

Data Types: `single` | `double`

Options — Optimization options

structure containing the fields `'MaxIter'`, `'OutputFcn'`, and `'TolFun'`

Optimization options, specified as a structure containing the fields `'MaxIter'`, `'OutputFcn'`, and `'TolFun'`. Create `'Options'` using `statset` or `struct`.

- `'MaxIter'` — Positive integer specifying the maximum number of optimization iterations. Default: 1000.
- `'OutputFcn'` — Function handle or cell array of function handles specifying one or more functions to call after every `NumPrint` optimization iterations. For syntax details, see “t-SNE Output Function” on page 15-110. Default: `[]`.
- `'TolFun'` — Stopping criterion for the optimization. The optimization exits when the norm of the gradient of the Kullback-Leibler divergence is less than `'TolFun'`. Default: `1e-10`.

Example: `options = statset('MaxIter',500)`

Data Types: `struct`

Theta — Barnes-Hut tradeoff parameter

0.5 (default) | scalar from 0 through 1

Barnes-Hut tradeoff parameter, specified as a scalar from 0 through 1. Higher values give a faster but less accurate optimization. Applies only when `Algorithm` is `'barneshut'`.

Example: 0.1

Data Types: `single` | `double`

Verbose — Iterative display

0 (default) | 1 | 2

Iterative display, specified as 0, 1, or 2. When `Verbose` is not 0, `tsne` prints a summary table of the Kullback-Leibler divergence and the norm of its gradient every `NumPrint` iterations.

When `Verbose` is 2, `tsne` also prints the variances of Gaussian kernels. `tsne` uses these kernels in its computation of the joint probability of X . If you see a large difference in the scales of the minimum and maximum variances, you can sometimes get more suitable results by rescaling X .

Example: 2

Data Types: `single` | `double`

Output Arguments

Y — Embedded points

`n`-by-`NumDimensions` matrix

Embedded points, returned as an `n`-by-`NumDimensions` matrix. Each row represents one embedded point. `n` is the number of rows of data X that do not contain any NaN entries. See “Plot Results with NaN Input Data” on page 32-5543.

Loss — Kullback-Leibler divergence

nonnegative scalar

Kullback-Leibler divergence between modeled input and output distributions, returned as a nonnegative scalar. For details, see “t-SNE Algorithm” on page 15-104.

More About

Custom Distance Function

The syntax of a custom distance function is as follows.

```
function D2 = distfun(ZI,ZJ)
```

`tsne` passes `ZI` and `ZJ` to your function, and your function computes the distance.

- `ZI` is a 1-by-`n` vector containing a single row from X or Y .
- `ZJ` is an `m`-by-`n` matrix containing multiple rows of X or Y .

Your function returns `D2`, which is an `m`-by-1 vector of distances. The `j`th element of `D2` is the distance between the observations `ZI` and `ZJ(j, :)`.

Tip If your data are not sparse, then usually the built-in distance functions are faster than a function handle.

Algorithms

`tsne` constructs a set of embedded points in a low-dimensional space whose relative similarities mimic those of the original high-dimensional points. The embedded points show the clustering in the original data.

Roughly, the algorithm models the original points as coming from a Gaussian distribution, and the embedded points as coming from a Student's t distribution. The algorithm tries to minimize the Kullback-Leibler divergence between these two distributions by moving the embedded points.

For details, see “t-SNE” on page 15-104.

Introduced in R2017a

tstat

Student's t mean and variance

Syntax

```
[m,v] = tstat(nu)
```

Description

`[m,v] = tstat(nu)` returns the mean and variance of the Student's t distribution with nu degrees of freedom.

Examples

Compute Mean and Variance of Student's t Distribution

Compute the mean and variance for Student's t distribution with degrees of freedom nu equal to 1 to 30.

```
nu = reshape(1:30,6,5);
[m,v] = tstat(nu)
```

$m = 6 \times 5$

```
NaN    0    0    0    0
  0    0    0    0    0
  0    0    0    0    0
  0    0    0    0    0
  0    0    0    0    0
  0    0    0    0    0
```

$v = 6 \times 5$

```
NaN    1.4000    1.1818    1.1176    1.0870
NaN    1.3333    1.1667    1.1111    1.0833
3.0000    1.2857    1.1538    1.1053    1.0800
2.0000    1.2500    1.1429    1.1000    1.0769
1.6667    1.2222    1.1333    1.0952    1.0741
1.5000    1.2000    1.1250    1.0909    1.0714
```

Note that the mean is undefined for 1 degree of freedom, and variance is undefined for 1 and 2 degrees of freedom.

Input Arguments

nu — Degrees of freedom

positive scalar value | array of positive scalar values

Degrees of freedom for the Student's t distribution, specified as a positive scalar value or an array of positive scalar values.

Example: [9, 19, 49, 99]

Data Types: `single` | `double`

Output Arguments

m — Mean

scalar value | array of scalar values

Mean of the Student's t distribution with the degrees of freedom specified in `nu`, returned as a scalar value or an array of scalar values. `m` is the same size as `nu`.

v — Variance

scalar value | array of scalar values

Variance of the Student's t distribution with the degrees of freedom specified in `nu`, returned as a scalar value or an array of scalar values. `v` is the same size as `nu`.

More About

Mean and Variance of Student's t Distribution

The parameters of the Student's t distribution depend on the degrees of freedom.

The mean of the Student's t distribution is $\mu = 0$ for degrees of freedom ν greater than 1. If ν equals 1, then the mean is undefined.

The variance of the Student's t distribution is $\frac{\nu}{\nu - 2}$ for degrees of freedom ν greater than 2. If ν is less than or equal to 2, then the variance is undefined.

For more information, see "Student's t Distribution" on page B-149.

ttest

One-sample and paired-sample *t*-test

Syntax

```
h = ttest(x)
```

```
h = ttest(x,y)
h = ttest(x,y,Name,Value)
```

```
h = ttest(x,m)
h = ttest(x,m,Name,Value)
```

```
[h,p] = ttest( ___ )
[h,p,ci,stats] = ttest( ___ )
```

Description

`h = ttest(x)` returns a test decision for the null hypothesis that the data in `x` comes from a normal distribution with mean equal to zero and unknown variance, using the one-sample *t*-test on page 32-5560. The alternative hypothesis is that the population distribution does not have a mean equal to zero. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = ttest(x,y)` returns a test decision for the null hypothesis that the data in `x - y` comes from a normal distribution with mean equal to zero and unknown variance, using the paired-sample *t*-test.

`h = ttest(x,y,Name,Value)` returns a test decision for the paired-sample *t*-test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`h = ttest(x,m)` returns a test decision for the null hypothesis that the data in `x` comes from a normal distribution with mean `m` and unknown variance. The alternative hypothesis is that the mean is not `m`.

`h = ttest(x,m,Name,Value)` returns a test decision for the one-sample *t*-test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = ttest(___)` also returns the *p*-value, `p`, of the test, using any of the input arguments from the previous syntax groups.

`[h,p,ci,stats] = ttest(___)` also returns the confidence interval `ci` for the mean of `x`, or of `x - y` for the paired *t*-test, and the structure `stats` containing information about the test statistic.

Examples

t-Test for Mean Equal to Zero

Load the sample data. Create a vector containing the third column of the stock returns data.

```
load stockreturns
x = stocks(:,3);
```

Test the null hypothesis that the sample data comes from a population with mean equal to zero.

```
[h,p,ci,stats] = ttest(x)
```

```
h = 1
```

```
p = 0.0106
```

```
ci = 2×1
```

```
    -0.7357
```

```
    -0.0997
```

```
stats = struct with fields:
```

```
    tstat: -2.6065
```

```
     df: 99
```

```
     sd: 1.6027
```

The returned value `h = 1` indicates that `ttest` rejects the null hypothesis at the 5% significance level.

t-Test at Different Significance Level

Load the sample data. Create a vector containing the third column of the stock returns data.

```
load stockreturns
x = stocks(:,3);
```

Test the null hypothesis that the sample data are from a population with mean equal to zero at the 1% significance level.

```
h = ttest(x,0,'Alpha',0.01)
```

```
h = 0
```

The returned value `h = 0` indicates that `ttest` does not reject the null hypothesis at the 1% significance level.

Paired-Sample t-Test

Load the sample data. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades
x = grades(:,1);
y = grades(:,2);
```

Test the null hypothesis that the pairwise difference between data vectors x and y has a mean equal to zero.

```
[h,p] = ttest(x,y)
```

```
h = 0
```

```
p = 0.9805
```

The returned value of $h = 0$ indicates that `ttest` does not reject the null hypothesis at the default 5% significance level.

Paired-Sample t-Test at Different Significance Level

Load the sample data. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades
x = grades(:,1);
y = grades(:,2);
```

Test the null hypothesis that the pairwise difference between data vectors x and y has a mean equal to zero at the 1% significance level.

```
[h,p] = ttest(x,y,'Alpha',0.01)
```

```
h = 0
```

```
p = 0.9805
```

The returned value of $h = 0$ indicates that `ttest` does not reject the null hypothesis at the 1% significance level.

t-Test for a Hypothesized Mean

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades
x = grades(:,1);
```

Test the null hypothesis that sample data comes from a distribution with mean $m = 75$.

```
h = ttest(x,75)
```

```
h = 0
```

The returned value of $h = 0$ indicates that `ttest` does not reject the null hypothesis at the 5% significance level.

One-Sided t-Test

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades
x = grades(:,1);
```

Test the null hypothesis that the data comes from a population with mean equal to 65, against the alternative that the mean is greater than 65.

```
h = ttest(x,65,'Tail','right')
h = 1
```

The returned value of `h = 1` indicates that `ttest` rejects the null hypothesis at the 5% significance level, in favor of the alternate hypothesis that the data comes from a population with a mean greater than 65.

Input Arguments

x — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array on page 32-5560. `ttest` performs a separate *t*-test along each column and returns a vector of results. If *y* sample data is specified, *x* and *y* must be the same size.

Data Types: `single` | `double`

y — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array on page 32-5560. If *y* sample data is specified, *x* and *y* must be the same size.

Data Types: `single` | `double`

m — Hypothesized population mean

0 (default) | scalar value

Hypothesized population mean, specified as a scalar value.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Tail', 'right', 'Alpha', 0.01` conducts a right-tailed hypothesis test at the 1% significance level.

Alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

Example: 'Alpha',0.01

Data Types: single | double

Dim — Dimension

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix along which to test the means, specified as the comma-separated pair consisting of 'Dim' and a positive integer value. For example, specifying 'Dim',1 tests the column means, while 'Dim',2 tests the row means.

Example: 'Dim',2

Data Types: single | double

Tail — Type of alternative hypothesis

'both' (default) | 'right' | 'left'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of:

- 'both' — Test against the alternative hypothesis that the population mean is not m .
- 'right' — Test against the alternative hypothesis that the population mean is greater than m .
- 'left' — Test against the alternative hypothesis that the population mean is less than m .

ttest tests the null hypothesis that the population mean is m against the specified alternative hypothesis.

Example: 'Tail','right'

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as 1 or 0.

- If $h = 1$, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p — p-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

ci — Confidence interval

vector

Confidence interval for the true population mean, returned as a two-element vector containing the lower and upper boundaries of the $100 \times (1 - \text{Alpha})\%$ confidence interval.

stats — Test statistics

structure

Test statistics, returned as a structure containing the following:

- `tstat` — Value of the test statistic.
- `df` — Degrees of freedom of the test.
- `sd` — Estimated population standard deviation. For a paired *t*-test, `sd` is the standard deviation of $x - y$.

More About**One-Sample t-Test**

The one-sample *t*-test is a parametric test of the location parameter when the population standard deviation is unknown.

The test statistic is

$$t = \frac{\bar{x} - \mu}{s/\sqrt{n}},$$

where \bar{x} is the sample mean, μ is the hypothesized population mean, s is the sample standard deviation, and n is the sample size. Under the null hypothesis, the test statistic has Student's *t* distribution with $n - 1$ degrees of freedom.

Multidimensional Array

A multidimensional array has more than two dimensions. For example, if `x` is a 1-by-3-by-4 array, then `x` is a three-dimensional array.

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if `x` is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of `x`.

Tips

- Use `sampsizepwr` to calculate:
 - The sample size that corresponds to specified power and parameter values;
 - The power achieved for a particular sample size, given the true parameter value;
 - The parameter value detectable with the specified sample size and power.

Extended Capabilities**GPU Arrays**

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

sampsizepwr | ttest2 | ztest

Introduced before R2006a

ttest2

Two-sample *t*-test

Syntax

```
h = ttest2(x,y)
h = ttest2(x,y,Name,Value)
[h,p] = ttest2(____)
[h,p,ci,stats] = ttest2(____)
```

Description

`h = ttest2(x,y)` returns a test decision for the null hypothesis that the data in vectors `x` and `y` comes from independent random samples from normal distributions with equal means and equal but unknown variances, using the two-sample *t*-test on page 32-5566. The alternative hypothesis is that the data in `x` and `y` comes from populations with unequal means. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = ttest2(x,y,Name,Value)` returns a test decision for the two-sample *t*-test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct the test without assuming equal variances.

`[h,p] = ttest2(____)` also returns the *p*-value, `p`, of the test, using any of the input arguments in the previous syntaxes.

`[h,p,ci,stats] = ttest2(____)` also returns the confidence interval on the difference of the population means, `ci`, and the structure `stats` containing information about the test statistic.

Examples

Two-Sample *t*-Test for Equal Means

Load the data set. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades
x = grades(:,1);
y = grades(:,2);
```

Test the null hypothesis that the two data samples are from populations with equal means.

```
[h,p,ci,stats] = ttest2(x,y)

h = 0

p = 0.9867

ci = 2×1

    -1.9438
```

```
1.9771
```

```
stats = struct with fields:
    tstat: 0.0167
    df: 238
    sd: 7.7084
```

The returned value of $h = 0$ indicates that `ttest2` does not reject the null hypothesis at the default 5% significance level.

t-Test for Equal Means Without Assuming Equal Variances

Load the data set. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades
x = grades(:,1);
y = grades(:,2);
```

Test the null hypothesis that the two data vectors are from populations with equal means, without assuming that the populations also have equal variances.

```
[h,p] = ttest2(x,y,'Vartype','unequal')
h = 0
p = 0.9867
```

The returned value of $h = 0$ indicates that `ttest2` does not reject the null hypothesis at the default 5% significance level even if equal variances are not assumed.

Input Arguments

x — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array. `ttest2` treats NaN values as missing data and ignores them.

- If x and y are specified as vectors, they do not need to be the same length.
- If x and y are specified as matrices, they must have the same number of columns. `ttest2` performs a separate t -test along each column and returns a vector of results.
- If x and y are specified as multidimensional arrays on page 32-5566, they must have the same size along all but the first nonsingleton dimension on page 32-5566.

Data Types: `single` | `double`

y — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array. `ttest2` treats NaN values as missing data and ignores them.

- If `x` and `y` are specified as vectors, they do not need to be the same length.
- If `x` and `y` are specified as matrices, they must have the same number of columns. `ttest2` performs a separate *t*-test along each column and returns a vector of results.
- If `x` and `y` are specified as multidimensional arrays on page 32-5566, they must have the same size along all but the first nonsingleton dimension on page 32-5566. `ttest2` works along the first nonsingleton dimension.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'Tail', 'right', 'Alpha', 0.01, 'Vartype', 'unequal'` specifies a right-tailed test at the 1% significance level, and does not assume that `x` and `y` have equal population variances.

Alpha — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

Dim — Dimension

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix along which to test the means, specified as the comma-separated pair consisting of `'Dim'` and a positive integer value. For example, specifying `'Dim', 1` tests the column means, while `'Dim', 2` tests the row means.

Example: `'Dim', 2`

Data Types: `single` | `double`

Tail — Type of alternative hypothesis

`'both'` (default) | `'right'` | `'left'`

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of `'Tail'` and one of:

- `'both'` — Test against the alternative hypothesis that the population means are not equal.
- `'right'` — Test against the alternative hypothesis that the population mean of `x` is greater than the population mean of `y`.
- `'left'` — Test against the alternative hypothesis that the population mean of `x` is less than the population mean of `y`.

`ttest2` tests the null hypothesis that the population means are equal against the specified alternative hypothesis.

Example: 'Tail', 'right'

Vartype — Variance type

'equal' (default) | 'unequal'

Variance type, specified as the comma-separated pair consisting of 'Vartype' and one of the following.

'equal'	Conduct test using the assumption that x and y are from normal distributions with unknown but equal variances.
'unequal'	Conduct test using the assumption that x and y are from normal distributions with unknown and unequal variances. This is called the Behrens-Fisher problem. <code>ttest2</code> uses Satterthwaite's approximation for the effective degrees of freedom.

Vartype must be a single variance type, even when x is a matrix or a multidimensional array.

Example: 'Vartype', 'unequal'

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as 1 or 0.

- If $h = 1$, this indicates the rejection of the null hypothesis at the α significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the α significance level.

p — p-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

ci — Confidence interval

vector

Confidence interval for the difference in population means of x and y , returned as a two-element vector containing the lower and upper boundaries of the $100 \times (1 - \alpha)\%$ confidence interval.

stats — Test statistics

structure

Test statistics for the two-sample t -test, returned as a structure containing the following:

- `tstat` — Value of the test statistic.
- `df` — Degrees of freedom of the test.
- `sd` — Pooled estimate of the population standard deviation (for the equal variance case) or a vector containing the unpooled estimates of the population standard deviations (for the unequal variance case).

More About

Two-Sample *t*-test

The two-sample *t*-test is a parametric test that compares the location parameter of two independent data samples.

The test statistic is

$$t = \frac{\bar{x} - \bar{y}}{\sqrt{\frac{s_x^2}{n} + \frac{s_y^2}{m}}},$$

where \bar{x} and \bar{y} are the sample means, s_x and s_y are the sample standard deviations, and n and m are the sample sizes.

In the case where it is assumed that the two data samples are from populations with equal variances, the test statistic under the null hypothesis has Student's *t* distribution with $n + m - 2$ degrees of freedom, and the sample standard deviations are replaced by the pooled standard deviation

$$s = \sqrt{\frac{(n-1)s_x^2 + (m-1)s_y^2}{n+m-2}}.$$

In the case where it is not assumed that the two data samples are from populations with equal variances, the test statistic under the null hypothesis has an approximate Student's *t* distribution with a number of degrees of freedom given by Satterthwaite's approximation. This test is sometimes called Welch's *t*-test.

Multidimensional Array

A multidimensional array has more than two dimensions. For example, if x is a 1-by-3-by-4 array, then x is a three-dimensional array.

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if x is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of x .

Tips

- Use `sampsizepwr` to calculate:
 - The sample size that corresponds to specified power and parameter values;
 - The power achieved for a particular sample size, given the true parameter value;
 - The parameter value detectable with the specified sample size and power.

BetaDistribution

Beta probability distribution object

Description

A `BetaDistribution` object consist of parameters, a model description, and sample data for a beta probability distribution.

The beta distribution describes a family of curves that are unique in that they are nonzero only on the interval (0,1). A more general version of the distribution assigns parameters to the endpoints of the interval.

The beta distribution uses the following parameters.

Parameter	Description	Support
a	First shape parameter	$a > 0$
b	Second shape parameter	$b > 0$

Creation

There are several ways to create a `BetaDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

a — First shape parameter

positive scalar value

First shape parameter of the beta distribution, specified as a positive scalar value.

Data Types: `single` | `double`

b — Second shape parameter

positive scalar value

Second shape parameter of the beta distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: char

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

Data Types: struct

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: char

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: char

Object Functions

cdf	Cumulative distribution function
icdf	Inverse cumulative distribution function
iqr	Interquartile range
mean	Mean of probability distribution
median	Median of probability distribution
negloglik	Negative loglikelihood of probability distribution
paramci	Confidence intervals for probability distribution parameters
pdf	Probability density function
proflik	Profile likelihood function for probability distribution
random	Random numbers

std Standard deviation of probability distribution
truncate Truncate probability distribution object
var Variance of probability distribution

Examples

Create a Beta Distribution Object Using Default Parameters

Create a beta distribution object using the default parameter values.

```
pd = makedist('Beta')  
  
pd =  
BetaDistribution  
  
Beta distribution  
a = 1  
b = 1
```

Create a Beta Distribution Object Using Specified Parameters

Create a beta distribution object by specifying the parameter values.

```
pd = makedist('Beta','a',2,'b',4)  
  
pd =  
BetaDistribution  
  
Beta distribution  
a = 2  
b = 4
```

Compute the mean of the distribution.

```
m = mean(pd)  
  
m = 0.3333
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- You must create a probability distribution object by fitting a probability distribution to sample data from the `fitdist` function. For the usage notes and limitations of `fitdist`, see “Code Generation” on page 32-1996 of `fitdist`.
- These object functions support code generation: `cdf`, `icdf`, `iqr`, `mean`, `median`, `pdf`, `std`, `truncate`, and `var`.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “Code Generation for Probability Distribution Objects” on page 31-70.

BinomialDistribution

Binomial probability distribution object

Description

A `BinomialDistribution` object consists of parameters, a model description, and sample data for a binomial probability distribution

The binomial distribution models the total number of successes in repeated trials from an infinite population under the following conditions:

- Only two outcomes are possible for each of n trials.
- The probability of success for each trial is constant.
- All trials are independent of each other.

The binomial distribution uses the following parameters.

Parameter	Description	Support
N	Number of trials	positive integer
p	Probability of success	$0 \leq p \leq 1$

Creation

There are several ways to create a `BinomialDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

N — Number of trials

positive integer value

Number of trials for the binomial distribution, specified as a positive integer value.

Data Types: `single` | `double`

p — Probability of success

positive scalar value in the range $[0, 1]$

Probability of success of any individual trial for the binomial distribution, specified as a positive scalar value in the range $[0, 1]$.

Data Types: `single` | `double`

Distribution Characteristics**IsTruncated — Logical flag for truncated distribution**

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

Object Functions

var	Variance of probability distribution

Examples

Create a Negative Binomial Distribution Object Using Default Parameters

Create a negative binomial distribution object using the default parameter values.

```
pd = makedist('NegativeBinomial')

pd =
  NegativeBinomialDistribution

  Negative Binomial distribution
  R = 1
  P = 0.5
```

Create a Binomial Distribution Object Using Specified Parameters

Create a binomial distribution object by specifying the parameter values.

```
pd = makedist('Binomial', 'N', 30, 'p', 0.25)

pd =
  BinomialDistribution

  Binomial distribution
  N = 30
  p = 0.25
```

Compute the mean of the distribution.

```
m = mean(pd)

m = 7.5000
```

BirnbaumSaundersDistribution

Birnbaum-Saunders probability distribution object

Description

A `BirnbaumSaundersDistribution` object consists of parameters, a model description, and sample data for a Birnbaum-Saunders probability distribution.

The Birnbaum-Saunders distribution was originally proposed as a lifetime model for materials subject to cyclic patterns of stress and strain, where the ultimate failure of the material comes from the growth of a prominent flaw. In materials science, Miner's Rule suggests that the damage occurring after n cycles, at a stress level with an expected lifetime of N cycles, is proportional to n / N . Whenever Miner's Rule applies, the Birnbaum-Saunders model is a reasonable choice for a lifetime distribution model.

The Birnbaum-Saunders distribution uses the following parameters.

Parameter	Description	Support
beta	scale parameter	$\beta > 0$
gamma	shape parameter	$\gamma > 0$

Creation

There are several ways to create a `BirnbaumSaundersDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

beta — Scale parameter

positive scalar value

Scale parameter of the Birnbaum-Saunders distribution, specified as a positive scalar value.

Data Types: `single` | `double`

gamma — Shape parameter

positive scalar value

Shape parameter of the Birnbaum-Saunders distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

<code>mean</code>	Mean of probability distribution
<code>median</code>	Median of probability distribution
<code>negloglik</code>	Negative loglikelihood of probability distribution

paramci	Confidence intervals for probability distribution parameters
pdf	Probability density function
profilik	Profile likelihood function for probability distribution
random	Random numbers
std	Standard deviation of probability distribution
truncate	Truncate probability distribution object
var	Variance of probability distribution

Examples

Create a Birnbau-Saunders Distribution Object Using Default Parameters

Create a Birnbau-Saunders distribution object using the default parameter values.

```
pd = makedist('BirnbauSaunders')

pd =
  BirnbauSaundersDistribution

  Birnbau-Saunders distribution
    beta = 1
    gamma = 1
```

Create a Birnbau-Saunders Distribution Object Using Specified Parameter Values

Create a Birnbau-Saunders distribution object by specifying the parameter values.

```
pd = makedist('BirnbauSaunders', 'beta', 2, 'gamma', 5)

pd =
  BirnbauSaundersDistribution

  Birnbau-Saunders distribution
    beta = 2
    gamma = 5
```

Compute the mean of the distribution.

```
m = mean(pd)

m = 27
```

BurrDistribution

Burr probability distribution object

Description

A `BurrDistribution` object consists of parameters, a model description, and sample data for a Burr probability distribution.

The Burr distribution is a three-parameter family of distributions on the positive real line. It can fit a wide range of empirical data, and is used in various fields such as finance, hydrology, and reliability to model a variety of data types.

The Burr distribution uses the following parameters.

Parameter	Description	Support
alpha	Scale parameter	$\alpha > 0$
c	First shape parameter	$c > 0$
k	Second shape parameter	$k > 0$

Creation

There are several ways to create a `BurrDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

alpha — Scale parameter

positive scalar value

Scale parameter of the Burr distribution, specified as a positive scalar value.

Data Types: `single` | `double`

c — First shape parameter

positive scalar value

First shape parameter of the Burr distribution, specified as a positive scalar value.

Data Types: `single` | `double`

k — Second shape parameter

positive scalar value

Second shape parameter of the Burr distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`**Other Object Properties****DistributionName — Probability distribution name**

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

ExponentialDistribution

Exponential probability distribution object

Description

An `ExponentialDistribution` object consists of parameters, a model description, and sample data for an exponential probability distribution.

The exponential distribution is used to model events that occur randomly over time, and its main application area is studies of lifetimes. It is a special case of the gamma distribution with the shape parameter $a = 1$.

The exponential distribution uses the following parameters.

Parameter	Description	Support
mu	Mean	$\mu > 0$

Creation

There are several ways to create a `ExponentialDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameter

mu — Mean

positive scalar value

Mean of the exponential distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: double

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: double

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: logical

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: single | double

Other Object Properties**DistributionName — Probability distribution name**

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.

ExtremeValueDistribution

Extreme value probability distribution object

Description

An `ExtremeValueDistribution` object consists of parameters, a model description, and sample data for an extreme value probability distribution.

The extreme value distribution is appropriate for modeling the smallest value from a distribution whose tails decay exponentially fast, for example, the normal distribution. It can also model the largest value from a distribution, such as the normal or exponential distributions, by using the negative of the original values.

The extreme value distribution uses the following parameters.

Parameter	Description	Support
<code>mu</code>	Location parameter	$-\infty < \mu < \infty$
<code>sigma</code>	Scale parameter	$\sigma \geq 0$

Creation

There are several ways to create a `ExtremeValueDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

mu — Location parameter

scalar value

Location parameter of the extreme value distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

nonnegative scalar value

Scale parameter of the extreme value distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

paramci	Confidence intervals for probability distribution parameters
pdf	Probability density function
proflk	Profile likelihood function for probability distribution
random	Random numbers
std	Standard deviation of probability distribution
truncate	Truncate probability distribution object
var	Variance of probability distribution

Examples

Create an Extreme Value Distribution Object Using Default Parameters

Create an extreme value distribution object using the default parameter values.

```
pd = makedist('ExtremeValue')

pd =
    ExtremeValueDistribution

    Extreme Value distribution
         mu = 0
         sigma = 1
```

Create an Extreme Value Distribution Object Using Specified Parameters

Create an extreme value distribution object by specifying the parameter values.

```
pd = makedist('ExtremeValue','mu',-1,'sigma',2)

pd =
    ExtremeValueDistribution

    Extreme Value distribution
         mu = -1
         sigma = 2
```

Compute the standard deviation for the distribution.

```
s = std(pd)

s = 2.5651
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- You must create a probability distribution object by fitting a probability distribution to sample data from the `fitdist` function. For the usage notes and limitations of `fitdist`, see “Code Generation” on page 32-1996 of `fitdist`.

- These object functions support code generation: `cdf`, `icdf`, `iqr`, `mean`, `median`, `pdf`, `std`, `truncate`, and `var`.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “Code Generation for Probability Distribution Objects” on page 31-70.

GammaDistribution

Gamma probability distribution object

Description

A `GammaDistribution` object consists of parameters, a model description, and sample data for a gamma probability distribution.

The gamma distribution is a two-parameter family of distributions used to model sums of exponentially distributed random variables. The chi-square and the exponential distributions, which are special cases of the gamma distribution, are one-parameter distributions that fix one of the two gamma parameters.

The gamma distribution uses the following parameters.

Parameter	Description	Support
a	Shape parameter	$a > 0$
b	Scale parameter	$b > 0$

Creation

There are several ways to create a `GammaDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

a — Shape parameter

positive scalar value

Shape parameter for the gamma distribution, specified as a positive scalar value.

Data Types: `single` | `double`

b — Scale parameter

nonnegative scalar value

Scale parameter for the gamma distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

Distribution Characteristics**IsTruncated — Logical flag for truncated distribution**

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

Object Functions

<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>iqr</code>	Interquartile range
<code>mean</code>	Mean of probability distribution
<code>median</code>	Median of probability distribution
<code>negloglik</code>	Negative loglikelihood of probability distribution

paramci	Confidence intervals for probability distribution parameters
pdf	Probability density function
proflk	Profile likelihood function for probability distribution
random	Random numbers
std	Standard deviation of probability distribution
truncate	Truncate probability distribution object
var	Variance of probability distribution

Examples

Create a Gamma Distribution Object Using Default Parameters

Create a gamma distribution object using the default parameter values.

```
pd = makedist('Gamma')

pd =
  GammaDistribution

  Gamma distribution
  a = 1
  b = 1
```

Create a Gamma Distribution Object Using Specified Parameters

Create a gamma distribution object by specifying the parameter values.

```
pd = makedist('Gamma','a',2,'b',4)

pd =
  GammaDistribution

  Gamma distribution
  a = 2
  b = 4
```

Compute the mean of the distribution.

```
m = mean(pd)

m = 8
```

GeneralizedExtremeValueDistribution

Generalized extreme value probability distribution object

Description

A `GeneralizedExtremeValueDistribution` object consists of parameters, a model description, and sample data for a generalized extreme value probability distribution.

The generalized extreme value distribution is often used to model the smallest or largest value among a large set of independent, identically distributed random values representing measurements or observations. It combines three simpler distributions into a single form, allowing a continuous range of possible shapes that include all three of the simpler distributions.

The three distribution types correspond to the limiting distribution of block maxima from different classes of underlying distributions:

- Type 1 — Distributions whose tails decrease exponentially, such as the normal distribution
- Type 2 — Distributions whose tails decrease as a polynomial, such as Student's t distribution
- Type 3 — Distributions whose tails are finite, such as the beta distribution

The generalized extreme value distribution uses the following parameters.

Parameter	Description	Support
<code>k</code>	Shape parameter	$-\infty \leq k \leq \infty$
<code>sigma</code>	Scale parameter	$\sigma \geq 0$
<code>mu</code>	Location parameter	$-\infty \leq \mu \leq \infty$

Creation

There are several ways to create a `GeneralizedExtremeValueDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

k — Shape parameter

scalar value

Shape parameter of the generalized extreme value distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

nonnegative scalar value

Scale parameter of the generalized extreme value distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`**mu — Location parameter**

scalar value

Location parameter of the generalized extreme value distribution, specified as a scalar value.

Data Types: `single` | `double`**Distribution Characteristics****IsTruncated — Logical flag for truncated distribution**

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`**NumParameters — Number of parameters**

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`**ParameterCovariance — Covariance matrix of the parameter estimates**

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`**ParameterIsFixed — Logical flag for fixed parameters**

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties**DistributionName — Probability distribution name**

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: char

Object Functions

cdf	Cumulative distribution function

Examples

Create a Generalized Extreme Value Distribution Object Using Default Parameters

Create a generalized extreme value distribution object using the default parameter values.

```
pd = makedist('GeneralizedExtremeValue')

pd =
    GeneralizedExtremeValueDistribution

    Generalized Extreme Value distribution
         k = 0
        sigma = 1
         mu = 0
```

Create a Generalized Extreme Value Distribution Object Using Specified Parameters

Create a generalized extreme value distribution object by specifying values for the parameters.

```
pd = makedist('GeneralizedExtremeValue','k',0,'sigma',2,'mu',1)

pd =
    GeneralizedExtremeValueDistribution

    Generalized Extreme Value distribution
         k = 0
        sigma = 2
         mu = 1
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m = 2.1544
```

GeneralizedParetoDistribution

Generalized Pareto probability distribution object

Description

A `GeneralizedParetoDistribution` object consists of parameters, a model description, and sample data for a generalized Pareto probability distribution.

The generalized Pareto distribution is used to model the tails of another distribution. It allows a continuous range of possible shapes that include both the exponential and Pareto distributions as special cases. It has three basic forms, each corresponding to a limiting distribution of exceedance data from a different class of underlying distributions.

- Distributions whose tails decrease exponentially, such as the normal, lead to a generalized Pareto shape parameter of zero.
- Distributions whose tails decrease polynomially, such as the Student's t , lead to a positive shape parameter.
- Distributions whose tails are finite, such as the beta, lead to a negative shape parameter.

The generalized Pareto distribution uses the following parameters.

Parameter	Description	Support
<code>k</code>	Shape parameter	$-\infty < k < \infty$
<code>sigma</code>	Scale parameter	$\sigma \geq 0$
<code>theta</code>	Location parameter	$-\infty < \theta < \infty$

Creation

There are several ways to create a `GeneralizedParetoDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

k — Shape parameter

scalar value

Shape parameter for the generalized Pareto distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

nonnegative scalar value

Scale parameter for the generalized Pareto distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`**theta — Location parameter**

scalar value

Location parameter for the generalized Pareto distribution, specified as a scalar value.

Data Types: `single` | `double`**Distribution Characteristics****IsTruncated — Logical flag for truncated distribution**

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`**NumParameters — Number of parameters**

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`**ParameterCovariance — Covariance matrix of the parameter estimates**

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`**ParameterIsFixed — Logical flag for fixed parameters**

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties**DistributionName — Probability distribution name**

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: char

Examples

Create a Generalized Pareto Distribution Object Using Default Parameters

Create a generalized Pareto distribution object using the default parameter values.

```
pd = makedist('GeneralizedPareto')

pd =
  GeneralizedParetoDistribution

  Generalized Pareto distribution
      k = 1
      sigma = 1
      theta = 1
```

Create a Generalized Pareto Distribution Object Using Specified Parameters

Create a generalized Pareto distribution object by specifying parameter values.

```
pd = makedist('GeneralizedPareto','k',0,'sigma',2,'theta',1)

pd =
  GeneralizedParetoDistribution

  Generalized Pareto distribution
      k = 0
      sigma = 2
      theta = 1
```

Compute the mean of the distribution.

```
m = mean(pd)
```

$m = 3$

HalfNormalDistribution

Half-normal probability distribution object

Description

A `HalfNormalDistribution` object consists of parameters, a model description, and sample data for a half-normal probability distribution.

The half-normal distribution is a special case of the folded normal and truncated normal distribution. Applications of the half-normal distribution include modeling measurement data and lifetime data.

The half-normal distribution uses the following parameters:

Parameter	Description	Support
<code>mu</code>	Location	$-\infty < \mu < \infty$
<code>sigma</code>	Scale	$\sigma \geq 0$

For more information about the half-normal distribution, see “Half-Normal Distribution” on page B-68.

Creation

There are several ways to create a `HalfNormalDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

`mu` — Location parameter

scalar value

Location parameter of the half-normal distribution, specified as a scalar value. The `mu` parameter is also the lower limit of the half-normal distribution.

The Statistics and Machine Learning Toolbox implementation of the half-normal distribution assumes a fixed value for the location parameter μ . You can specify a value for the μ parameter when creating a `HalfNormalDistribution` object.

Data Types: `single` | `double`

`sigma` — Scale parameter

nonnegative scalar value

Scale parameter of the half-normal distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

Object Functions

<code>cdf</code>	Cumulative distribution function

var	Variance of probability distribution

Examples

Create a Half-Normal Distribution Object Using Default Parameters

```
pd = makedist('HalfNormal')  
  
pd =  
  HalfNormalDistribution  
  
  Half Normal distribution  
    mu = 0  
    sigma = 1
```

Create a Half-Normal Distribution Object Using Specified Parameters

Create a half-normal distribution object. Specify mu equal to 0 and sigma equal to 1.5.

```
pd = makedist('HalfNormal', 'mu', 0, 'sigma', 1.5)  
  
pd =  
  HalfNormalDistribution  
  
  Half Normal distribution  
    mu = 0  
    sigma = 1.5
```

Compute the mean and standard deviation of the distribution.

```
m = mean(pd)  
  
m = 1.1968  
  
s = std(pd)  
  
s = 0.9042
```

Fit a Half-Normal Distribution Object

Generate 100 random numbers from a standard normal distribution and compute their absolute value.

```
rng default % For reproducibility
x = abs(random(makedist('Normal'),100,1));
```

Fit a half-normal distribution object to the sample data.

```
pd = fitdist(x, 'HalfNormal')

pd =
  HalfNormalDistribution

  Half Normal distribution
      mu =          0
      sigma = 1.1631 [1.02184, 1.35006]
```

Calculate the mean of the fitted half-normal distribution using the probability distribution object.

```
m = mean(pd)

m = 0.9280
```

Calculate the mean of the half-normal distribution by substituting the fitted mu and sigma parameter values into the formula

$$mean = \mu + \sigma \sqrt{\frac{2}{\pi}}$$

```
mcalc = pd.mu + pd.sigma*(sqrt(2/pi))

mcalc = 0.9280
```

InverseGaussianDistribution

Inverse Gaussian probability distribution object

Description

An `InverseGaussianDistribution` object consists of parameters, a model description, and sample data for an inverse Gaussian probability distribution.

Also known as the Wald distribution, the inverse Gaussian is used to model nonnegative positively skewed data. Inverse Gaussian distributions have many similarities to standard Gaussian (normal) distributions, which lead to applications in inferential statistics.

The inverse Gaussian distribution uses the following parameters.

Parameter	Description	Support
<code>mu</code>	Scale parameter	$\mu > 0$
<code>lambda</code>	Shape parameter	$\lambda > 0$

Creation

There are several ways to create a `InverseGaussianDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

`mu` — Scale parameter

positive scalar value

Scale parameter for the inverse Gaussian distribution, specified as a positive scalar value.

Data Types: `single` | `double`

`lambda` — Shape parameter

positive scalar value

Shape parameter for the inverse Gaussian distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics

`IsTruncated` — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: char

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

Data Types: struct

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: char

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: char

KernelDistribution

Kernel probability distribution object

Description

A `KernelDistribution` object consists of parameters, a model description, and sample data for a nonparametric kernel-smoothing distribution.

The kernel distribution is a nonparametric estimation of the probability density function (pdf) of a random variable.

The kernel distribution uses the following options.

Option	Description	Possible Values
Kernel	Kernel function type	normal, box, triangle, epanechnikov
BandWidth	Kernel smoothing parameter	BandWidth > 0

Creation

There are several ways to create a `KernelDistribution` probability distribution object.

- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

Kernel — Kernel smoother type

'normal' | 'box' | 'triangle' | 'epanechnikov'

Kernel function type, specified as a valid kernel function type name.

BandWidth — Bandwidth of kernel smoothing window

positive scalar value

Bandwidth of the kernel smoothing window, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

Object Functions

<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>iqr</code>	Interquartile range
<code>mean</code>	Mean of probability distribution
<code>median</code>	Median of probability distribution
<code>negloglik</code>	Negative loglikelihood of probability distribution
<code>pdf</code>	Probability density function
<code>random</code>	Random numbers
<code>std</code>	Standard deviation of probability distribution
<code>truncate</code>	Truncate probability distribution object
<code>var</code>	Variance of probability distribution

Examples

Fit a Kernel Distribution Object to Data

Load the sample data. Visualize the patient weight data using a histogram.

```
load hospital
histogram(hospital.Weight)
```

The histogram shows that the data has two modes, one for female patients and one for male patients.

Create a probability distribution object by fitting a kernel distribution to the patient weight data.

```
pd_kernel = fitdist(hospital.Weight, 'Kernel')

pd_kernel =
  KernelDistribution

  Kernel = normal
  Bandwidth = 14.3792
  Support = unbounded
```

For comparison, create another probability distribution object by fitting a normal distribution to the patient weight data.

```
pd_normal = fitdist(hospital.Weight, 'Normal')
```

```
pd_normal =  
    NormalDistribution  
  
Normal distribution  
    mu =      154    [148.728, 159.272]  
    sigma = 26.5714 [23.3299, 30.8674]
```

Define the x values and compute the pdf of each distribution.

```
x = 50:1:250;  
pdf_kernel = pdf(pd_kernel,x);  
pdf_normal = pdf(pd_normal,x);
```

Plot the pdf of each distribution.

```
plot(x,pdf_kernel,'Color','b','LineWidth',2);  
hold on;  
plot(x,pdf_normal,'Color','r','LineStyle',':','LineWidth',2);  
legend('Kernel Distribution','Normal Distribution','Location','SouthEast');  
hold off;
```

Fitting a kernel distribution instead of a unimodal distribution such as the normal reveals the separate modes for the female and male patients.

LogisticDistribution

Logistic probability distribution object

Description

A `LogisticDistribution` object consists of parameters, a model description, and sample data for a logistic probability distribution.

The logistic distribution is used for growth models and in logistic regression. It has longer tails and a higher kurtosis than the normal distribution.

The logistic distribution uses the following parameters.

Parameter	Description	Support
<code>mu</code>	Mean	$-\infty < \mu < \infty$
<code>sigma</code>	Scale parameter	$\sigma \geq 0$

Creation

There are several ways to create a `LogisticDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

mu — Mean

scalar value

Mean of the logistic distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

nonnegative scalar value

Scale parameter of the logistic distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: char

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

Data Types: struct

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: char

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: char

Object Functions

cdf	Cumulative distribution function
icdf	Inverse cumulative distribution function
iqr	Interquartile range
mean	Mean of probability distribution
median	Median of probability distribution
negloglik	Negative loglikelihood of probability distribution
paramci	Confidence intervals for probability distribution parameters
pdf	Probability density function
proflik	Profile likelihood function for probability distribution
random	Random numbers

std Standard deviation of probability distribution
truncate Truncate probability distribution object
var Variance of probability distribution

Examples

Create a Logistic Distribution Object Using Default Parameters

Create a logistic distribution object using the default parameter values.

```
pd = makedist('Logistic')  
  
pd =  
  LogisticDistribution  
  
  Logistic distribution  
    mu = 0  
    sigma = 1
```

Create a Logistic Distribution Object Using Specified Parameters

Create a logistic distribution object by specifying parameter values.

```
pd = makedist('Logistic','mu',2,'sigma',4)  
  
pd =  
  LogisticDistribution  
  
  Logistic distribution  
    mu = 2  
    sigma = 4
```

Compute the standard deviation of the distribution.

```
s = std(pd)  
s = 7.2552
```

LoglogisticDistribution

Loglogistic probability distribution object

Description

A `LoglogisticDistribution` object consists of parameters, a model description, and sample data for a loglogistic probability distribution.

The loglogistic distribution is closely related to the logistic distribution. If x is distributed loglogistically with parameters μ and σ , then $\log(x)$ is distributed logistically with mean and standard deviation. This distribution is often used in survival analysis to model events that experience an initial rate increase, followed by a rate decrease.

The loglogistic distribution uses the following parameters.

Parameter	Description	Support
<code>mu</code>	Mean of logarithmic values	$\mu > 0$
<code>sigma</code>	Scale parameter of logarithmic values	$\sigma > 0$

Creation

There are several ways to create a `LoglogisticDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

`mu` — Mean of logarithmic values

positive scalar value

Mean of logarithmic values for the loglogistic distribution, specified as a positive scalar value.

Data Types: `single` | `double`

`sigma` — Scale parameter of logarithmic values

positive scalar value

Scale parameter of logarithmic values for the loglogistic distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics**IsTruncated — Logical flag for truncated distribution**

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

Object Functions

<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>iqr</code>	Interquartile range
<code>mean</code>	Mean of probability distribution
<code>median</code>	Median of probability distribution
<code>negloglik</code>	Negative loglikelihood of probability distribution

paramci	Confidence intervals for probability distribution parameters
pdf	Probability density function
proflk	Profile likelihood function for probability distribution
random	Random numbers
std	Standard deviation of probability distribution
truncate	Truncate probability distribution object
var	Variance of probability distribution

Examples

Create a Loglogistic Distribution Object Using Default Parameters

Create a loglogistic distribution object using the default parameter values.

```
pd = makedist('Loglogistic')

pd =
  LoglogisticDistribution

  Log-Logistic distribution
      mu = 0
      sigma = 1
```

Create a Loglogistic Distribution Object Using Specified Parameters

Create a loglogistic distribution object by specifying the parameter values.

```
pd = makedist('Loglogistic','mu',5,'sigma',2)

pd =
  LoglogisticDistribution

  Log-Logistic distribution
      mu = 5
      sigma = 2
```

Generate random numbers from the loglogistic distribution and compute their log values.

```
rng(19) % for reproducibility
x = random(pd,10000,1);
logx = log(x);
```

Compute the mean of the log values.

```
m = mean(logx)

m = 4.9828
```

The mean of the log of x is equal to the μ parameter of x , since x has a loglogistic distribution.

Plot $\log x$.

```
histogram(logx,50)
```

The plot shows that the log values of x have a logistic distribution.

LognormalDistribution

Lognormal probability distribution object

Description

A `LognormalDistribution` object consists of parameters, a model description, and sample data for a lognormal probability distribution.

The lognormal distribution, sometimes called the Galton distribution, is a probability distribution whose logarithm has a normal distribution. The lognormal distribution is applicable when the quantity of interest must be positive, because $\log(x)$ exists only when x is positive.

The lognormal distribution uses the following parameters.

Parameter	Description	Support
<code>mu</code> (μ)	Mean of logarithmic values	$-\infty < \mu < \infty$
<code>sigma</code> (σ)	Standard deviation of logarithmic values	$\sigma \geq 0$

Creation

There are several ways to create a `LognormalDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

mu — Mean of logarithmic values

scalar value

Mean of logarithmic values for the lognormal distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Standard deviation of logarithmic values

nonnegative scalar value

Standard deviation of logarithmic values for the lognormal distribution, specified as a nonnegative scalar value.

You can specify `sigma` to be zero when you create an object by using `makedist`. Some object functions support an object `pd` with zero standard deviation. For example, `random(pd)` always returns `exp(mu)`.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

`0` | `1`

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If `0`, the corresponding parameter in the `ParameterNames` array is not fixed. If `1`, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

Object Functions

<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>iqr</code>	Interquartile range
<code>mean</code>	Mean of probability distribution

median	Median of probability distribution

paramci	Confidence intervals for probability distribution parameters
pdf	Probability density function
proflik	Profile likelihood function for probability distribution
random	Random numbers
std	Standard deviation of probability distribution
truncate	Truncate probability distribution object
var	Variance of probability distribution

Examples

Create a Lognormal Distribution Object Using Default Parameters

Create a lognormal distribution object using the default parameter values.

```
pd = makedist('Lognormal')

pd =
  LognormalDistribution

  Lognormal distribution
      mu = 0
      sigma = 1
```

Create Lognormal Distribution Object Using Specified Parameters

Create a lognormal distribution object by specifying the parameter values.

```
pd = makedist('Lognormal','mu',5,'sigma',2)

pd =
  LognormalDistribution

  Lognormal distribution
      mu = 5
      sigma = 2
```

Compute the mean of the lognormal distribution.

```
mean(pd)

ans = 1.0966e+03
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- You must create a probability distribution object by fitting a probability distribution to sample data from the `fitdist` function. For the usage notes and limitations of `fitdist`, see “Code Generation” on page 32-1996 of `fitdist`.
- These object functions support code generation: `cdf`, `icdf`, `iqr`, `mean`, `median`, `pdf`, `std`, `truncate`, and `var`.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “Code Generation for Probability Distribution Objects” on page 31-70.

MultinomialDistribution

Multinomial probability distribution object

Description

A `MultinomialDistribution` object consists of parameters and a model description for a multinomial probability distribution.

The multinomial distribution is a generalization of the binomial distribution. While the binomial distribution gives the probability of the number of “successes” in n independent trials of a two-outcome process, the multinomial distribution gives the probability of each combination of outcomes in n independent trials of a k -outcome process. The probability of each outcome in any one trial is given by the fixed probabilities p_1, \dots, p_k .

The multinomial distribution uses the following parameters.

Parameter	Description	Support
<code>probabilities</code>	Outcome probabilities	$0 \leq \text{probabilities}(i) \leq 1 ; \sum_{\text{all}(i)} \text{probabilities}(i) = 1$

Creation

Create a `MultinomialDistribution` probability distribution with specified parameter values object using `makedist`.

Properties

Distribution Parameter

Probabilities — outcome probabilities

vector of scalar values in the range $[0, 1]$

Outcome probabilities for the multinomial distribution, stored as a vector of scalar values in the range $[0, 1]$. The values in `probabilities` must sum to 1.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

`0` | `1`

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: double

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: single | double

Other Object Properties**DistributionName — Probability distribution name**

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: char

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: char

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: char

Object Functions

cdf	Cumulative distribution function
icdf	Inverse cumulative distribution function
iqr	Interquartile range
mean	Mean of probability distribution
median	Median of probability distribution
pdf	Probability density function
random	Random numbers
std	Standard deviation of probability distribution
truncate	Truncate probability distribution object
var	Variance of probability distribution

Examples

Create a Multinomial Distribution Object Using Default Parameters

Create a multinomial distribution object using the default parameter values.

```
pd = makedist('Multinomial')

pd =
  MultinomialDistribution

  Probabilities:
    0.5000    0.5000
```

Create a Multinomial Distribution Object Using Specified Parameters

Create a multinomial distribution object for a distribution with three possible outcomes. Outcome 1 has a probability of 1/2, outcome 2 has a probability of 1/3, and outcome 3 has a probability of 1/6.

```
pd = makedist('Multinomial','probabilities',[1/2 1/3 1/6])

pd =
  MultinomialDistribution

  Probabilities:
    0.5000    0.3333    0.1667
```

Generate a random outcome from the distribution.

```
rng('default'); % for reproducibility
r = random(pd)

r = 2
```

The result of this trial is outcome 2. By default, the number of trials in each experiment, n , equals 1.

Generate random outcomes from the distribution when the number of trials in each experiment, n , equals 1, and the experiment is repeated ten times.

```
rng('default'); % for reproducibility
r = random(pd,10,1)
```

```
r = 10×1
```

```
2
3
1
3
2
1
1
2
3
3
```

Each element in the array is the outcome of an individual experiment that contains one trial.

Generate random outcomes from the distribution when the number of trials in each experiment, n , equals 5, and the experiment is repeated ten times.

```
rng('default'); % for reproducibility
r = random(pd,10,5)
```

```
r = 10×5
```

```
2 1 2 2 1
3 3 1 1 1
1 3 3 1 2
3 1 3 1 2
2 2 2 1 1
1 1 2 2 1
1 1 2 2 1
2 3 1 1 2
3 2 2 3 2
3 3 1 1 2
```

Each element in the resulting matrix is the outcome of one trial. The columns correspond to the five trials in each experiment, and the rows correspond to the ten experiments. For example, in the first experiment (corresponding to the first row), 2 of the 5 trials resulted in outcome 1, and 3 of the 5 trials resulted in outcome 2.

NakagamiDistribution

Nakagami probability distribution object

Description

A `NakagamiDistribution` object consists of parameters, a model description, and sample data for a Nakagami probability distribution.

The Nakagami distribution is commonly used in communication theory to model scattered signals that reach a receiver using multiple paths.

The Nakagami distribution uses the following parameters.

Parameter	Description	Support
<code>mu</code>	Shape parameter	$\mu > 0$
<code>omega</code>	Scale parameter	$\omega > 0$

Creation

There are several ways to create a `NakagamiDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

`mu` — Shape parameter

positive scalar value

Shape parameter for the Nakagami distribution, specified as a positive scalar value.

Data Types: `single` | `double`

`omega` — Scale parameter

positive scalar value

Scale parameter for the Nakagami distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics

`IsTruncated` — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: char

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

Data Types: struct

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: char

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: char

Object Functions

icdf	Inverse cumulative distribution function
iqr	Interquartile range
mean	Mean of probability distribution
median	Median of probability distribution
negloglik	Negative loglikelihood of probability distribution
paramci	Confidence intervals for probability distribution parameters
pdf	Probability density function
proflik	Profile likelihood function for probability distribution
random	Random numbers

std Standard deviation of probability distribution
truncate Truncate probability distribution object
var Variance of probability distribution

Examples

Create a Nakagami Distribution Object Using Default Parameters

Create a Nakagami distribution object using the default parameter values.

```
pd = makedist('Nakagami')  
  
pd =  
  NakagamiDistribution  
  
  Nakagami distribution  
    mu = 1  
    omega = 1
```

Create a Nakagami Distribution Object Using Specified Parameters

Create a Nakagami distribution object by specifying parameter values.

```
pd = makedist('Nakagami', 'mu', 5, 'omega', 2)  
  
pd =  
  NakagamiDistribution  
  
  Nakagami distribution  
    mu = 5  
    omega = 2
```

Compute the mean of the distribution.

```
m = mean(pd)  
  
m = 1.3794
```

NegativeBinomialDistribution

Negative binomial distribution object

Description

A `NegativeBinomialDistribution` object consists of parameters, a model description, and sample data for a negative binomial probability distribution.

The negative binomial distribution models the number of failures x before a specified number of successes, R , is reached in a series of independent, identical trials. This distribution can also model count data, in which case R does not need to be an integer value.

The negative binomial distribution uses the following parameters.

Parameter	Description	Support
R	Number of successes	$r > 0$
p	Probability of success	$0 < p \leq 1$

Creation

There are several ways to create a `NegativeBinomialDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

R — Number of successes

positive scalar value

Number of successes for the negative binomial distribution, specified as a positive scalar value.

Data Types: `single` | `double`

p — Probability of success

positive scalar value in the range (0,1]

Probability of success of any individual trial for the negative binomial distribution, specified as a positive scalar value in the range (0,1].

Data Types: `single` | `double`

Distribution Characteristics**IsTruncated — Logical flag for truncated distribution**

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

Object Functions

<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>iqr</code>	Interquartile range

truncate	Truncate probability distribution object
var	Variance of probability distribution

Examples

Create a Negative Binomial Distribution Object Using Default Parameters

Create a negative binomial distribution object using the default parameter values.

```
pd = makedist('NegativeBinomial')

pd =
  NegativeBinomialDistribution

  Negative Binomial distribution
  R = 1
  P = 0.5
```

Create a Negative Binomial Distribution Object Using Specified Parameters

Create a negative binomial distribution object by specifying the parameter values.

```
pd = makedist('NegativeBinomial', 'R', 5, 'p', .1)

pd =
  NegativeBinomialDistribution

  Negative Binomial distribution
  R = 5
  P = 0.1
```

Compute the mean of the distribution.

```
m = mean(pd)

m = 45
```

NormalDistribution

Normal probability distribution object

Description

A `NormalDistribution` object consists of parameters, a model description, and sample data for a normal probability distribution.

The normal distribution, sometimes called the Gaussian distribution, is a two-parameter family of curves. The usual justification for using the normal distribution for modeling is the Central Limit theorem, which states (roughly) that the sum of independent samples from any distribution with finite mean and variance converges to the normal distribution as the sample size goes to infinity.

The normal distribution uses the following parameters.

Parameter	Description	Support
<code>mu</code> (μ)	Mean	$-\infty < \mu < \infty$
<code>sigma</code> (σ)	Standard deviation	$\sigma \geq 0$

Creation

There are several ways to create a `NormalDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

mu — Mean

scalar value

Mean of the normal distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Standard deviation

nonnegative scalar value

Standard deviation of the normal distribution, specified as a nonnegative scalar value.

You can specify `sigma` to be zero when you create an object by using `makedist`. Some object functions support an object `pd` with zero standard deviation. For example, `random(pd)` always returns `mu`, and `cdf(pd,x)` returns either 0 or 1. The output is 0 if `x` is smaller than `mu`, and 1 otherwise. `mean`, `std`, and `var` return the mean, standard deviation, and variance of `pd`, respectively.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

Object Functions

<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>iqr</code>	Interquartile range
<code>mean</code>	Mean of probability distribution

median	Median of probability distribution
negloglik	Negative loglikelihood of probability distribution
paramci	Confidence intervals for probability distribution parameters
pdf	Probability density function
proflik	Profile likelihood function for probability distribution
random	Random numbers
std	Standard deviation of probability distribution
truncate	Truncate probability distribution object
var	Variance of probability distribution

Examples

Create a Normal Distribution Object Using Default Parameters

Create a normal distribution object using the default parameter values.

```
pd = makedist('Normal')

pd =
  NormalDistribution

  Normal distribution
    mu = 0
    sigma = 1
```

Create a Normal Distribution Object Using Specified Parameters

Create a normal distribution object by specifying the parameter values.

```
pd = makedist('Normal','mu',75,'sigma',10)

pd =
  NormalDistribution

  Normal distribution
    mu = 75
    sigma = 10
```

Compute the interquartile range of the distribution.

```
r = iqr(pd)

r = 13.4898
```

Fit Normal Distribution Object

Load the sample data and create a vector containing the first column of student exam grade data.

```
load examgrades
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =  
    NormalDistribution  
  
    Normal distribution  
        mu = 75.0083    [73.4321, 76.5846]  
        sigma = 8.7202    [7.7391, 9.98843]
```

The intervals next to the parameter estimates are the 95% confidence intervals for the distribution parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- You must create a probability distribution object by fitting a probability distribution to sample data from the `fitdist` function. For the usage notes and limitations of `fitdist`, see “Code Generation” on page 32-1996 of `fitdist`.
- These object functions support code generation: `cdf`, `icdf`, `iqr`, `mean`, `median`, `pdf`, `std`, `truncate`, and `var`.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “Code Generation for Probability Distribution Objects” on page 31-70.

PiecewiseLinearDistribution

Piecewise linear probability distribution object

Description

A `PiecewiseLinearDistribution` object consists of a model description for a piecewise linear probability distribution.

The piecewise linear distribution is a nonparametric probability distribution created using a piecewise linear representation of the cumulative distribution function (cdf). The options specified for the piecewise linear distribution specify the form of the cdf. The probability density function (pdf) is a step function.

The piecewise linear distribution uses the following parameters.

Parameter	Description
<code>x</code>	Vector of <code>x</code> values at which the cdf changes slope
<code>Fx</code>	Vector of cdf values that correspond to each value in <code>x</code>

Creation

Create a `PiecewiseLinearDistribution` probability distribution with specified parameter values object using `makedist`.

Properties

Distribution Parameters

x — Data values

vector of scalar values

Data values at which the cumulative distribution function (cdf) changes slope, specified as a vector of scalar values.

Data Types: `single` | `double`

Fx — cdf value

vector of scalar values

cdf value at each value in `x`, specified as a vector of scalar values.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: char

Object Functions

cdf	Cumulative distribution function
icdf	Inverse cumulative distribution function
iqr	Interquartile range
mean	Mean of probability distribution
median	Median of probability distribution
pdf	Probability density function
random	Random numbers
std	Standard deviation of probability distribution
truncate	Truncate probability distribution object
var	Variance of probability distribution

Examples

Create a Piecewise Linear Distribution Object Using Default Parameters

Create a piecewise linear distribution object using the default parameter values.

```
pd = makedist('PiecewiseLinear')
```

```
pd =
    PiecewiseLinearDistribution
```

```
F(0) = 0
F(1) = 1
```

Create a Piecewise Linear Distribution Object Using Specified Parameters

Load the sample data. Visualize the patient weight data using a histogram.

```
load hospital
histogram(hospital.Weight)
```

The histogram shows that the data has two modes, one for female patients and one for male patients.

Compute the empirical cumulative distribution function (ecdf) for the data.

```
[f,x] = ecdf(hospital.Weight);
```

Construct a piecewise linear approximation to the ecdf and plot both functions.

```
f = f(1:5:end); % keep a less dense grid of points
x = x(1:5:end);
```

```
figure;
ecdf(hospital.Weight)
hold on
plot(x,f,'ro','MarkerFace','r') % overlay grid
plot(x,f,'k') % show interpolation
```

Create a piecewise linear probability distribution object using the piecewise approximation of the ecdf.

```
pd = makedist('PiecewiseLinear', 'x', x, 'Fx', f)
```

```
pd =  
PiecewiseLinearDistribution
```

```
F(111) = 0  
F(118) = 0.05  
F(124) = 0.13  
F(130) = 0.25  
F(135) = 0.37  
F(142) = 0.5  
F(163) = 0.55  
F(171) = 0.61  
F(178) = 0.7  
F(183) = 0.82  
F(189) = 0.94  
F(202) = 1
```

Generate 100 random numbers from the distribution.

```
rw = random(pd, 100, 1);
```

Plot the random numbers to visually compare their distribution to the original data.

```
figure;  
histogram(rw)
```

The random numbers generated from the piecewise linear distribution have the same bimodal distribution as the original data.

PoissonDistribution

Poisson probability distribution object

Description

A `PoissonDistribution` object consists of parameters, a model description, and sample data for a Poisson probability distribution.

The Poisson distribution is appropriate for applications that involve counting the number of times a random event occurs in a given amount of time, distance, area, etc. If the number of counts follows the Poisson distribution, then the interval between individual counts follows the exponential distribution.

The Poisson distribution uses the following parameters.

Parameter	Description	Support
<code>lambda</code>	Mean	$\lambda \geq 0$

Creation

There are several ways to create a `PoissonDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameter

`lambda` — Mean

nonnegative scalar value

Mean of the Poisson distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

Distribution Characteristics

`IsTruncated` — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: double

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: double

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: logical

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: single | double

Other Object Properties**DistributionName — Probability distribution name**

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: char

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

Data Types: struct

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: char

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: char

Object Functions

cdf	Cumulative distribution function
icdf	Inverse cumulative distribution function
iqr	Interquartile range
mean	Mean of probability distribution
median	Median of probability distribution
negloglik	Negative loglikelihood of probability distribution
paramci	Confidence intervals for probability distribution parameters
pdf	Probability density function
proflik	Profile likelihood function for probability distribution
random	Random numbers
std	Standard deviation of probability distribution
truncate	Truncate probability distribution object
var	Variance of probability distribution

Examples

Create a Poisson Distribution Object Using Default Parameters

Create a Poisson distribution object using the default parameter values.

```
pd = makedist('Poisson')  
  
pd =  
  PoissonDistribution  
  
  Poisson distribution  
    lambda = 1
```

Create a Poisson Distribution Object Using Specified Parameters

Create a Poisson distribution object by specifying the parameter values.

```
pd = makedist('Poisson', 'lambda', 5)  
  
pd =  
  PoissonDistribution  
  
  Poisson distribution  
    lambda = 5
```

Compute the variance of the distribution.

```
v = var(pd)  
  
v = 5
```

For the Poisson distribution, both the mean and variance are equal to the parameter lambda.

RayleighDistribution

Rayleigh probability distribution object

Description

A `RayleighDistribution` object consists of parameters, a model description, and sample data for a normal probability distribution.

The Rayleigh distribution is a special case of the Weibull distribution. It is often used in communication theory to model scattered signals that reach a receiver by multiple paths.

The Rayleigh distribution uses the following parameter.

Parameter	Description	Support
<code>b</code>	Defining parameter	$b > 0$

Creation

There are several ways to create a `RayleighDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameter

`b` — Defining parameter

positive scalar value

Defining parameter for the Rayleigh distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics

`IsTruncated` — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

`NumParameters` — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

Object Functions

<code>cdf</code>	Cumulative distribution function

RicianDistribution

Rician probability distribution object

Description

A `RicianDistribution` object consists of parameters, a model description, and sample data for a Rician probability distribution.

The Rician distribution is used in communications theory to model scattered signals that reach a receiver using multiple paths.

The Rician distribution uses the following parameters.

Name	Description	Support
<code>s</code>	Noncentrality parameter	$s \geq 0$
<code>sigma</code>	Scale parameter	$\sigma > 0$

Creation

There are several ways to create a `RicianDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

s — Noncentrality parameter

nonnegative scalar value

Noncentrality parameter of the Rician distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

sigma — scale parameter

positive scalar value

Scale parameter for the Rician distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: char

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

Data Types: struct

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: char

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: char

Object Functions

<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>iqr</code>	Interquartile range
<code>mean</code>	Mean of probability distribution
<code>median</code>	Median of probability distribution
<code>negloglik</code>	Negative loglikelihood of probability distribution
<code>paramci</code>	Confidence intervals for probability distribution parameters
<code>pdf</code>	Probability density function
<code>proflik</code>	Profile likelihood function for probability distribution
<code>random</code>	Random numbers

std Standard deviation of probability distribution
truncate Truncate probability distribution object
var Variance of probability distribution

Examples

Create a Rician Distribution Object Using Default Parameters

Create a Rician distribution object using the default parameter values.

```
pd = makedist('Rician')  
  
pd =  
  RicianDistribution  
  
  Rician distribution  
    s = 1  
  sigma = 1
```

Create a Rician Distribution Object Using Specified Parameters

Create a Rician distribution object by specifying the parameter values.

```
pd = makedist('Rician', 's', 0, 'sigma', 2)  
  
pd =  
  RicianDistribution  
  
  Rician distribution  
    s = 0  
  sigma = 2
```

Compute the mean of the distribution.

```
m = mean(pd)  
m = 2.5066
```

StableDistribution

Stable probability distribution object

Description

`StableDistribution` is an object consisting of parameters, a model description, and sample data for a stable probability distribution.

The stable distribution uses the following parameters.

Parameter	Description	Support
alpha	First shape parameter	$0 < \alpha \leq 2$
beta	Second shape parameter	$-1 \leq \beta \leq 1$
gam	Scale parameter	$0 < \gamma < \infty$
delta	Location parameter	$-\infty < \delta < \infty$

Creation

There are several ways to create a `StableDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

alpha — First shape parameter

scalar value in the range (0,2]

First shape parameter of the stable distribution, specified as a scalar value in the range (0,2].

Data Types: `single` | `double`

beta — Second shape parameter

scalar value in the range [-1,1]

Second shape parameter of the stable distribution, specified as a scalar value in the range [-1,1].

Data Types: `single` | `double`

gam — Scale parameter

scalar value in the range (0,∞)

Scale parameter of the stable distribution, specified as a scalar value in the range (0,∞).

Data Types: `single` | `double`

delta — Location parameter

scalar value

Location parameter of the stable distribution, specified as a scalar value.

Data Types: `single` | `double`

Distribution Characteristics**IsTruncated — Logical flag for truncated distribution**

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

Object Functions

<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>iqr</code>	Interquartile range
<code>mean</code>	Mean of probability distribution
<code>median</code>	Median of probability distribution
<code>negloglik</code>	Negative loglikelihood of probability distribution
<code>paramci</code>	Confidence intervals for probability distribution parameters
<code>pdf</code>	Probability density function
<code>proflik</code>	Profile likelihood function for probability distribution
<code>random</code>	Random numbers
<code>std</code>	Standard deviation of probability distribution
<code>truncate</code>	Truncate probability distribution object
<code>var</code>	Variance of probability distribution

Examples

Create a Stable Distribution Object Using Default Parameters

Create a stable distribution object using the default parameter values.

```
pd = makedist('Stable')

pd =
  StableDistribution

  Stable distribution
  alpha = 2
  beta = 0
  gam = 1
  delta = 0
```

Create a Stable Distribution Object Using Specified Parameters

Create a stable distribution object by specifying the parameter values $\alpha = 0.5$, $\beta = 0$, $\text{gam} = 1$, and $\text{delta} = 0$.

```
pd = makedist('Stable','alpha',0.5,'beta',0,'gam',1,'delta',0);
```

Calculate the mean of the distribution.

```
m = mean(pd)

m = NaN
```

The mean of the stable distribution is undefined for values of `alpha` less than or equal to 1.

tLocationScaleDistribution

t Location-Scale probability distribution object

Description

A `tLocationScaleDistribution` object consists of parameters, a model description, and sample data for a *t* location-scale probability distribution.

The *t* location-scale distribution is useful for modeling data distributions with heavier tails (more prone to outliers) than the normal distribution. It approaches the normal distribution as ν approaches infinity, and smaller values of ν yield heavier tails.

The *t* location-scale distribution uses the following parameters.

Parameter	Description	Support
<code>mu</code>	Location parameter	$-\infty < \mu < \infty$
<code>sigma</code>	Scale parameter	$\sigma > 0$
<code>nu</code>	Shape parameter	$\nu > 0$

Creation

There are several ways to create a `tLocationScaleDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

mu — Location parameter

scalar value

Location parameter of the *t* location-scale distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

positive scalar value

Scale parameter of the *t* location-scale distribution, specified as a positive scalar value.

Data Types: `single` | `double`

nu — Degrees of freedom

positive scalar value

Degrees of freedom of the t location-scale distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`**Other Object Properties****DistributionName — Probability distribution name**

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`**InputData — Data used for distribution fitting**

TriangularDistribution

Triangular probability distribution object

Description

A `TriangularDistribution` object consists of parameters and a model description for a triangular probability distribution.

The triangular distribution is frequently used in simulations when limited sample data is available. The lower and upper limits represent the smallest and largest values, and the location of the peak represents an estimate of the mode.

The triangular distribution uses the following parameters.

Parameter	Description	Support
a	Lower limit	$a \leq b$
b	Peak location	$a \leq b \leq c$
c	Upper limit	$c \geq b$

Creation

Create a `TriangularDistribution` probability distribution with specified parameter values object using `makedist`.

Properties

Distribution Parameters

a — Lower limit

scalar value

Lower limit for the triangular distribution, specified as a scalar value.

Data Types: `single` | `double`

b — Peak location

scalar value

Location of the peak for the triangular distribution, specified as a scalar value greater than or equal to a.

Data Types: `single` | `double`

c — Upper limit

scalar value

Upper limit for the triangular distribution, specified as a scalar value greater than or equal to b.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: char

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: char

Object Functions

cdf	Cumulative distribution function
icdf	Inverse cumulative distribution function
iqr	Interquartile range
mean	Mean of probability distribution
median	Median of probability distribution
pdf	Probability density function
random	Random numbers
std	Standard deviation of probability distribution
truncate	Truncate probability distribution object
var	Variance of probability distribution

Examples

Create a Triangular Distribution Object Using Default Parameters

Create a triangular distribution object using the default parameter values.

```
pd = makedist('Triangular')
```

```
pd =  
    TriangularDistribution
```

```
A = 0, B = 0.5, C = 1
```

Create a Triangular Distribution Object Using Specified Parameters

Create a triangular distribution object by specifying parameter values.

```
pd = makedist('Triangular','a',-2,'b',1,'c',5)
```

```
pd =  
    TriangularDistribution
```

```
A = -2, B = 1, C = 5
```

Compute the mean of the distribution.

```
m = mean(pd)
```

m = 1.3333

UniformDistribution

Uniform probability distribution object

Description

A `UniformDistribution` object consists of parameters and a model description for a uniform probability distribution.

The uniform distribution has a constant probability density function between its two parameters, `lower` (the minimum) and `upper` (the maximum). This distribution is appropriate for representing round-off errors in values tabulated to a particular number of decimal places.

The uniform distribution uses the following parameters.

Parameter	Description	Support
<code>lower</code>	Lower parameter	$-\infty < lower < upper$
<code>upper</code>	Upper parameter	$lower < upper < \infty$

Creation

Create a `UniformDistribution` probability distribution with specified parameter values object using `makedist`.

Properties

Distribution Parameters

lower — Lower parameter

scalar value

Lower parameter for the uniform distribution, specified as a scalar value.

Data Types: `single` | `double`

upper — Upper parameter

scalar value

Upper parameter for the uniform distribution, specified as a scalar value greater than `lower`.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties**DistributionName — Probability distribution name**

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: char

Object Functions

<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>iqr</code>	Interquartile range
<code>mean</code>	Mean of probability distribution
<code>median</code>	Median of probability distribution
<code>pdf</code>	Probability density function
<code>random</code>	Random numbers
<code>std</code>	Standard deviation of probability distribution
<code>truncate</code>	Truncate probability distribution object
<code>var</code>	Variance of probability distribution

Examples

Create a Uniform Distribution Object Using Default Parameters

Create a uniform distribution object using the default parameter values.

```
pd = makedist('Uniform')  
  
pd =  
    UniformDistribution  
  
    Uniform distribution  
    Lower = 0  
    Upper = 1
```

Create a Uniform Distribution Object Using Specified Parameters

Create a uniform distribution object by specifying parameter values.

```
pd = makedist('Uniform', 'Lower', -4, 'Upper', 2)  
  
pd =  
    UniformDistribution  
  
    Uniform distribution  
    Lower = -4  
    Upper = 2
```

Compute the interquartile range of the distribution

```
r = iqr(pd)  
  
r = 3
```

WeibullDistribution

Weibull probability distribution object

Description

A `WeibullDistribution` object consists of parameters, a model description, and sample data for a Weibull probability distribution.

The Weibull distribution is used in reliability and lifetime modeling, and to model the breaking strength of materials.

The Weibull distribution uses the following parameters.

Parameter	Description	Support
<code>a</code>	Scale parameter	$a > 0$
<code>b</code>	Shape parameter	$b > 0$

Creation

There are several ways to create a `WeibullDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

a — Scale parameter

positive scalar value

Scale parameter of the Weibull distribution, specified as a positive scalar value.

Data Types: `single` | `double`

b — Shape parameter

positive scalar value

Shape parameter of the Weibull distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: char

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

Data Types: struct

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: char

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: char

Object Functions

cdf	Cumulative distribution function
icdf	Inverse cumulative distribution function
iqr	Interquartile range
mean	Mean of probability distribution
median	Median of probability distribution
negloglik	Negative loglikelihood of probability distribution
paramci	Confidence intervals for probability distribution parameters
pdf	Probability density function
proflik	Profile likelihood function for probability distribution
random	Random numbers

std Standard deviation of probability distribution
truncate Truncate probability distribution object
var Variance of probability distribution

Examples

Create a Weibull Distribution Object Using Default Parameters

Create a Weibull distribution object using the default parameter values.

```
pd = makedist('Weibull')  
  
pd =  
  WeibullDistribution  
  
  Weibull distribution  
  A = 1  
  B = 1
```

Create a Weibull Distribution Object Using Specified Parameter Values

Create a Weibull distribution object by specifying the parameter values.

```
pd = makedist('Weibull','a',2,'b',5)  
  
pd =  
  WeibullDistribution  
  
  Weibull distribution  
  A = 2  
  B = 5
```

Compute the mean of the distribution.

```
m = mean(pd)  
  
m = 1.8363
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- You must create a probability distribution object by fitting a probability distribution to sample data from the `fitdist` function. For the usage notes and limitations of `fitdist`, see “Code Generation” on page 32-1996 of `fitdist`.
- These object functions support code generation: `cdf`, `icdf`, `iqr`, `mean`, `median`, `pdf`, `std`, `truncate`, and `var`.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “Code Generation for Probability Distribution Objects” on page 31-70.

Introduced in R2013a

union

Class: dataset

(Not Recommended) Set union for dataset array observations

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
C = union(A,B)
C = union(A,B,vars)
C = union(A,B,vars,setOrder)
[C,iA,iB] = union( ___ )
```

Description

`C = union(A,B)` for dataset arrays `A` and `B` returns the combined set of observations from the two arrays, with repetitions removed. The observations in the dataset array `C` are sorted.

`C = union(A,B,vars)` returns the combined set of observations from the two arrays, with repetitions of unique combinations of the variables specified in `vars` removed. The observations in the dataset array `C` are sorted by those variables.

The values for variables not specified in `vars` for each observation in `C` are taken from the corresponding observation in `A` or `B`, or from `A` if there are common observations in both `A` and `B`. If there are multiple observations in `A` or `B` that correspond to an observation in `C`, those values are taken from the first occurrence.

`C = union(A,B,vars,setOrder)` returns the observations in `C` in the order specified by `setOrder`.

`[C,iA,iB] = union(___)` also returns index vectors `iA` and `iB` such that `C` is a sorted combination of the values `A(iA,:)` and `B(iB,:)`. If there are common observations in `A` and `B`, then `union` returns only the index from `A`, in `iA`. If there are repeated observations in `A` or `B`, then the index of the first occurrence is returned. You can use any of the previous input arguments.

Input Arguments

A,B

Input dataset arrays.

vars

String array or cell array of character vectors containing variable names, or a vector of integers containing variable column numbers. `vars` indicates the variables for which `union` removes repetitions of unique combinations of the variables.

Specify vars as [] to use its default value of all variables.

setOrder

Flag indicating the sorting order for the observations in C. The possible values of setOrder are:

'sorted'	Observations in C are in sorted order (default).
'stable'	Observations in C are in the same order that they appear in A, then B.

Output Arguments

C

Dataset array with the combined observations of A and B, with repetitions removed. C is in sorted order (by default), or the order specified by setOrder.

iA

Index vector, indicating the observations in A that contribute to the union. iA contains the index to the first occurrence of any repeated observations in A.

iB

Index vector, indicating the observations in B that contribute to the union. If there are common observations in A and B, then union returns only the index from A, in iA. iB contains the index to the first occurrence of any repeated observations in B.

Examples

Union of Two Dataset Arrays

Load sample data.

```
A = dataset('XLSFile',fullfile(matlabroot,'help/toolbox/stats/examples','hospitalSmall.xlsx'));
B = dataset('XLSFile',fullfile(matlabroot,'help/toolbox/stats/examples','hospitalSmall.xlsx'),'S'
[length(A) length(B)]
```

```
ans =
    14     8
```

The first dataset array, A, has 14 observations. The second dataset array, B, has 8 observations.

Return the union.

```
C = union(A,B);
length(C)
```

```
ans =
    21
```

The union of the two dataset arrays has 21 observations, indicating that there was one observation replicated in A and B.

“Dataset Arrays” on page 2-112

unique

Class: dataset

(Not Recommended) Unique observations in dataset array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
C = unique(A)
[C,ia,ic] = unique(A)
C = unique(A,vars)
[C,ia,ic] = unique(A,vars)
[...] = unique(A,vars,occurrence)
[...] = unique(...,'R2012a')
[...] = unique(...,'legacy')
[...] = unique(A,vars,setOrder)
```

Description

Note The behavior of `dataset.unique` is consistent with the MATLAB function `unique`. For a demonstration of using the `'legacy'` flag to preserve the behavior from R2012b and prior in your existing code, see the documentation for `unique`.

`C = unique(A)` returns a copy of the dataset `A` that contains only the sorted unique observations. `A` must contain only variables whose class has a `unique` method, including:

- numeric
- character
- logical
- categorical
- string
- cell arrays of character vectors

For a variable with multiple columns, its class's `unique` method must support the `'rows'` flag.

`[C,ia,ic] = unique(A)` also returns index vectors `ia` and `ic` such that `C = A(ia,:)` and `A = C(ic,:)`.

`C = unique(A,vars)` returns a dataset that contains only one observation for each unique combination of values for the variables in `A` specified in `vars`. `vars` is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector. `C` includes all variables from `A`. The values in `C` for the variables not specified in `vars` are taken from the last occurrence among observations in `A` with each unique combination of values for the variables specified in `vars`.

`[C,ia,ic] = unique(A,vars)` also returns index vectors `ia` and `ic` such that `C = A(ia,:)` and `A(:,vars) = C(ic,vars)`.

`[...] = unique(A,vars,occurrence)` specifies which index is returned in `ia` in the case of repeated observations in `A`. The default value is `occurrence='first'`, which returns the index of the first occurrence of each repeated observation in `A`. `occurrence='last'` returns the index of the last occurrence of each repeated observation in `A`. The values in `C` for variables not specified in `vars` are taken from the observations `A(ia,:)`. Specify `vars` as `[]` to use the default value of all variables.

`[...] = unique(...,'R2012a')` adopts the future behavior of `unique`. You can specify the flag as the final argument with any previous syntax that accepts `A`, `vars`, or `occurrence`.

`[...] = unique(...,'legacy')` preserves the current behavior of `unique`. You can specify the flag as the final argument with any previous syntax that accepts `A`, `vars`, or `occurrence`.

`[...] = unique(A,vars,setOrder)` returns the observations of `C` in a specific order. `setOrder='sorted'` returns the values of `C` in sorted order. `setOrder='stable'` returns the values of `C` in the same order as `A`. If there are repeated observations in `A`, then `ia` returns the index of the first occurrence of each repeated observation. Specify `vars` as `[]` to use the default value of all variables.

Units property

Class: dataset

(Not Recommended) Units of variables in data set

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Description

A cell array of character vectors giving the units of the variables in the data set. This property may be empty, but if not empty, the number of character vectors must equal the number of variables. Any individual character vector may be empty for a variable that does not have units defined. The default is an empty cell array.

unidcdf

Discrete uniform cumulative distribution function

Syntax

```
p = unidcdf(x,N)
p = unidcdf(x,N,'upper')
```

Description

`p = unidcdf(x,N)` returns the discrete uniform cdf at each value in `x` using the corresponding maximum observable value in `N`. `x` and `N` can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The maximum observable values in `N` must be positive integers.

`p = unidcdf(x,N,'upper')` returns the complement of the discrete uniform cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The discrete uniform cdf is

$$p = F(x|N) = \frac{\text{floor}(x)}{N} I_{(1, \dots, N)}(x)$$

The result, p , is the probability that a single observation from the discrete uniform distribution with maximum N will be a positive integer less than or equal to x . The values x do not need to be integers.

Examples

Compute Discrete Uniform Distribution cdf

What is the probability of drawing a number 20 or less from a hat with the numbers from 1 to 50 inside?

```
probability = unidcdf(20,50)
```

```
probability = 0.4000
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Topics

“Uniform Distribution (Discrete)” on page B-168

Introduced before R2006a

unidinv

Discrete uniform inverse cumulative distribution function

Syntax

```
X = unidinv(P,N)
```

Description

`X = unidinv(P,N)` returns the smallest positive integer `X` such that the discrete uniform cdf evaluated at `X` is equal to or exceeds `P`. You can think of `P` as the probability of drawing a number as large as `X` out of a hat with the numbers 1 through `N` inside.

`P` and `N` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `X`. A scalar input for `N` or `P` is expanded to a constant array with the same dimensions as the other input. The values in `P` must lie on the interval `[0 1]` and the values in `N` must be positive integers.

Examples

```
x = unidinv(0.7,20)
x =
    14
```

```
y = unidinv(0.7 + eps,20)
y =
    15
```

A small change in the first parameter produces a large jump in output. The cdf and its inverse are both step functions. The example shows what happens at a step.

Topics

“Uniform Distribution (Discrete)” on page B-168

Introduced before R2006a

unidpdf

Discrete uniform probability density function

Syntax

```
Y = unidpdf(X,N)
```

Description

`Y = unidpdf(X,N)` computes the discrete uniform pdf at each of the values in `X` using the corresponding maximum observable value in `N`. `X` and `N` can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `N` must be positive integers.

The discrete uniform pdf is

$$y = f(x|N) = \frac{1}{N}I_{(1, \dots, N)}(x)$$

You can think of `y` as the probability of observing any one number between 1 and `n`.

Examples

For fixed `n`, the uniform discrete pdf is a constant.

```
y = unidpdf(1:6,10)
y =
    0.1000    0.1000    0.1000    0.1000    0.1000    0.1000
```

Now fix `x`, and vary `n`.

```
likelihood = unidpdf(5,4:9)
likelihood =
    0    0.2000    0.1667    0.1429    0.1250    0.1111
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Topics

“Uniform Distribution (Discrete)” on page B-168

Introduced before R2006a

unidrnd

Random numbers from discrete uniform distribution

Syntax

```
r = unidrnd(n)
r = unidrnd(n,sz1,...,szN)
r = unidrnd(n,sz)
```

Description

`r = unidrnd(n)` generates random numbers from the discrete uniform distribution specified by its maximum value `n`.

`n` can be a scalar, vector, matrix, or multidimensional array.

`r = unidrnd(n,sz1,...,szN)` generates an array of random numbers from the discrete uniform distribution with the scalar maximum value `n`, where `sz1,...,szN` indicates the size of each dimension.

`r = unidrnd(n,sz)` generates an array of random numbers from the discrete uniform distribution with the scalar maximum value `n`, where vector `sz` specifies `size(r)`.

Examples

Array of Random Numbers from Several Discrete Uniform Distributions

Generate an array of random numbers from the discrete uniform distributions. For each distribution, specify its maximum value.

Specify the maximum values of the distributions.

```
n = 1:10:100;
```

Generate random numbers from the discrete uniform distributions.

```
r = unidrnd(n)
```

```
r = 1×10
```

```
    1    10     3    29    26     5    17    39    78    88
```

Array of Random Numbers from One Discrete Uniform Distribution

Generate an array of random numbers from one discrete uniform distribution. Here, the maximum value `n` is a scalar.

Use the `unidrnd` function to generate random numbers from the discrete uniform distribution with the maximum value 100. The function returns one number.

```
R_scalar = unidrnd(100)
```

```
R_scalar = 82
```

Generate a 2-by-3 array of random numbers from the same distribution by specifying the required array dimensions.

```
R_array = unidrnd(100,2,3)
```

```
R_array = 2×3
```

```
    91    92    10
    13    64    28
```

Alternatively, specify the required array dimensions as a vector.

```
R_array = unidrnd(100,[2,3])
```

```
R_array = 2×3
```

```
    55    97    98
    96    16    96
```

Input Arguments

n — Maximum value

positive integer | array of positive integers

Maximum value, specified as a positive integer or array of positive integers.

Example: `unidrnd(10)`

Data Types: `single` | `double`

sz1, ..., szN — Size of each dimension (as separate arguments)

integers

Size of each dimension, specified as separate arguments of integers. For example, specifying `5,3,2` generates a 5-by-3-by-2 array of random numbers from the discrete uniform distribution.

If `n` is an array, then the specified dimensions `sz1, ..., szN` must match the dimensions of `n`.

- If you specify a single value `sz1`, then `r` is a square matrix of size `sz1`-by-`sz1`.
- If the size of any dimension is 0 or negative, then `r` is an empty array.
- Beyond the second dimension, `unidrnd` ignores trailing dimensions with a size of 1. For example, `unidrnd(n,3,1,1,1)` produces a 3-by-1 vector of random numbers.

Example: `5,3,2`

Data Types: `single` | `double`

sz — Size of each dimension (as a row vector)

row vector of integers

Size of each dimension, specified as a row vector of integers. For example, specifying [5 3 2] generates a 5-by-3-by-2 array of random numbers from the discrete uniform distribution.

If *n* is an array, then the specified dimensions *sz* must match the dimensions of *n*.

- If you specify a single value [*sz1*], then *r* is a square matrix of size *sz1*-by-*sz1*.
- If the size of any dimension is 0 or negative, then *r* is an empty array.
- Beyond the second dimension, `unidrnd` ignores trailing dimensions with a size of 1. For example, `unidrnd(n,[3 1 1 1])` produces a 3-by-1 vector of random numbers.

Example: [5 3 2]

Data Types: `single` | `double`

Output Arguments**r — Random numbers from discrete uniform distribution**

scalar value | array of scalar values

Random numbers from the discrete uniform distribution, returned as a scalar value or an array of scalar values.

Data Types: `single` | `double`

Alternative Functionality

- `unidrnd` is a function specific to discrete uniform distribution. Statistics and Machine Learning Toolbox also offers the generic function `random`, which supports various probability distributions. To use `random`, specify the probability distribution name and its parameters. Note that the distribution-specific function `unidrnd` is faster than the generic function `random`.
- To generate random numbers interactively, use `randtool`, a user interface for random number generation.

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Uniform Distribution (Discrete)” on page B-168

Introduced before R2006a

unidstat

Discrete uniform mean and variance

Syntax

```
[M,V] = unidstat(N)
```

Description

`[M,V] = unidstat(N)` returns the mean and variance of the discrete uniform distribution with minimum value 1 and maximum value N .

The mean of the discrete uniform distribution with parameter N is $(N + 1)/2$. The variance is $(N^2 - 1)/12$.

Examples

```
[m,v] = unidstat(1:6)
m =
    1.0000    1.5000    2.0000    2.5000    3.0000    3.5000
v =
    0    0.2500    0.6667    1.2500    2.0000    2.9167
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Uniform Distribution (Discrete)” on page B-168

Introduced before R2006a

unifcdf

Continuous uniform cumulative distribution function

Syntax

```
p = unifcdf(x,a,b)
p = unifcdf(x,a,b,'upper')
```

Description

`p = unifcdf(x,a,b)` returns the uniform cdf at each value in `x` using the corresponding lower endpoint (minimum), `a` and upper endpoint (maximum), `b`. `x`, `a`, and `b` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant matrix with the same dimensions as the other inputs.

`p = unifcdf(x,a,b,'upper')` returns the complement of the uniform cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The uniform cdf is

$$p = F(x|a,b) = \frac{x-a}{b-a} I_{[a,b]}(x)$$

The standard uniform distribution has `a = 0` and `b = 1`.

Examples

Compute Uniform Distribution cdf

What is the probability that an observation from a standard uniform distribution will be less than 0.75?

```
probability = unifcdf(0.75)
probability = 0.7500
```

What is the probability that an observation from a uniform distribution with `a = -1` and `b = 1` will be less than 0.75?

```
probability = unifcdf(0.75,-1,1)
probability = 0.8750
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Introduced before R2006a

unifinv

Continuous uniform inverse cumulative distribution function

Syntax

```
X = unifinv(P,A,B)
```

Description

`X = unifinv(P,A,B)` computes the inverse of the uniform cdf with parameters A and B (the minimum and maximum values, respectively) at the corresponding probabilities in P. P, A, and B can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

The inverse of the uniform cdf is

$$x = F^{-1}(p|a,b) = a + p(a - b)I_{[0,1]}(p)$$

The standard uniform distribution has $A = 0$ and $B = 1$.

Examples

What is the median of the standard uniform distribution?

```
median_value = unifinv(0.5)
median_value =
    0.5000
```

What is the 99th percentile of the uniform distribution between -1 and 1?

```
percentile = unifinv(0.99,-1,1)
percentile =
    0.9800
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Topics

“Uniform Distribution (Continuous)” on page B-163

Introduced before R2006a

unifit

Continuous uniform parameter estimates

Syntax

```
[ahat,bhat] = unifit(data)
[ahat,bhat,ACI,BCI] = unifit(data)
[ahat,bhat,ACI,BCI] = unifit(data,alpha)
```

Description

`[ahat,bhat] = unifit(data)` returns the maximum likelihood estimates (MLEs) of the parameters of the uniform distribution given the data in `data`.

`[ahat,bhat,ACI,BCI] = unifit(data)` also returns 95% confidence intervals, `ACI` and `BCI`, which are matrices with two rows. The first row contains the lower bound of the interval for each column of the matrix `data`. The second row contains the upper bound of the interval.

`[ahat,bhat,ACI,BCI] = unifit(data,alpha)` controls the confidence level by using `alpha`. For example, if `alpha = 0.01`, then `ACI` and `BCI` are 99% confidence intervals.

Examples

```
r = unifrnd(10,12,100,2);
[ahat,bhat,aci,bci] = unifit(r)
ahat =
    10.0154    10.0060
bhat =
    11.9989    11.9743
aci =
     9.9551     9.9461
    10.0154    10.0060
bci =
    11.9989    11.9743
    12.0592    12.0341
```

Topics

“Uniform Distribution (Continuous)” on page B-163

Introduced before R2006a

unifpdf

Continuous uniform probability density function

Syntax

```
y = unifpdf(x)
y = unifpdf(x,a,b)
```

Description

`y = unifpdf(x)` returns the probability density function (pdf) of the standard uniform distribution, evaluated at the values in `x`.

`y = unifpdf(x,a,b)` returns the pdf of the continuous uniform distribution on the interval `[a, b]`, evaluated at the values in `x`.

Examples

Compute Standard and Continuous Uniform pdf

The pdf of the standard uniform distribution is constant on the interval `[0, 1]`.

Compute the pdf of 0.2, 0.4,...,1 in the standard uniform distribution.

```
x = 0.2:0.2:1;
y = unifpdf(x)

y = 1×5
    1    1    1    1    1
```

If `x` is not between `a` and `b`, `unifpdf` returns 0.

Compute the pdf of 1 through 5 in the continuous uniform distribution on the interval `[2, 4]`.

```
x2 = 1:5;
unifpdf(x2,2,4)

ans = 1×5
    0    0.5000    0.5000    0.5000    0
```

If the parameter `a` is larger than `b`, `unifpdf` returns NaN regardless of the `x` input.

```
unifpdf(5,10,1)

ans = NaN
```

Input Arguments

x — Values at which to evaluate pdf

nonnegative scalar value | array of nonnegative scalar values

Values at which to evaluate the pdf, specified as a nonnegative scalar value or an array of nonnegative scalar values.

- To evaluate the pdf at multiple values, specify **x** using an array.
- To evaluate the pdfs of multiple distributions, specify **a** and **b** using arrays.

If one or more of the input arguments **x**, **a**, and **b** are arrays, then the array sizes must be the same. In this case, `unifpdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in **y** is the pdf value of the distribution specified by the corresponding elements in **a** and **b**, evaluated at the corresponding element in **x**.

Example: [3 4 7 9]

Data Types: `single` | `double`

a — Lower endpoint

scalar value | array of scalar values

Lower endpoint of the uniform distribution, specified as a scalar value or an array of scalar values.

- To evaluate the pdf at multiple values, specify **x** using an array.
- To evaluate the pdfs of multiple distributions, specify **a** and **b** using arrays.

If one or more of the input arguments **x**, **a**, and **b** are arrays, then the array sizes must be the same. In this case, `unifpdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in **y** is the pdf value of the distribution specified by the corresponding elements in **a** and **b**, evaluated at the corresponding element in **x**.

Example: [0 -1 7 9]

Data Types: `single` | `double`

b — Upper endpoint

scalar value | array of scalar values

Upper endpoint of the uniform distribution, specified as a scalar value or an array of scalar values.

- To evaluate the pdf at multiple values, specify **x** using an array.
- To evaluate the pdfs of multiple distributions, specify **a** and **b** using arrays.

If one or more of the input arguments **x**, **a**, and **b** are arrays, then the array sizes must be the same. In this case, `unifpdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in **y** is the pdf value of the distribution specified by the corresponding elements in **a** and **b**, evaluated at the corresponding element in **x**.

Example: [1 1 10 10]

Data Types: `single` | `double`

Output Arguments

y — pdf values

scalar value | array of scalar values

pdf values evaluated at the values in **x**, returned as a scalar value or an array of scalar values. **y** is the same size as **x**, **a**, and **b** after any necessary scalar expansion. Each element in **y** is the pdf value of the distribution specified by the corresponding elements in **a** and **b**, evaluated at the corresponding element in **x**.

More About

Continuous Uniform pdf

The continuous uniform distribution is a two-parameter family of curves with a constant pdf on its interval of support, $[a, b]$. The parameters a and b are the endpoints of the interval.

The continuous uniform pdf is

$$y = f(x|a, b) = \frac{1}{b-a}I_{[a, b]}(x).$$

The standard uniform distribution occurs when $a = 0$ and $b = 1$.

For more information, see “Uniform Distribution (Continuous)” on page B-163.

Alternative Functionality

- `unifpdf` is a function specific to the continuous uniform distribution. Statistics and Machine Learning Toolbox also offers the generic function `pdf`, which supports various probability distributions. To use `pdf`, create a `UniformDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `unifpdf` is faster than the generic function `pdf`.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Extended Capabilities

Topics

“Uniform Distribution (Continuous)” on page B-163

Introduced before R2006a

unifrnd

Continuous uniform random numbers

Syntax

```
r = unifrnd(a,b)
r = unifrnd(a,b,sz1,...,szN)
r = unifrnd(a,b,sz)
```

Description

`r = unifrnd(a,b)` generates a random number from the continuous uniform distribution with the lower endpoints `a` and upper endpoint `b`.

`r = unifrnd(a,b,sz1,...,szN)` generates an array of uniform random numbers, where `sz1,...,szN` indicates the size of each dimension.

`r = unifrnd(a,b,sz)` generates an array of uniform random numbers, where the size vector `sz` specifies `size(r)`.

Examples

Generate Uniform Random Number

Generate a random number from the continuous uniform distribution with the lower parameter 0 and upper parameter 1.

```
r = unifrnd(0,1)
r = 0.8147
```

Generate Uniform Random Numbers

Generate 5 random numbers from the continuous uniform distributions on the intervals (0,1), (0,2),..., (0,5).

```
a1 = 0;
b1 = 1:5;
r1 = unifrnd(a1,b1)

r1 = 1×5
    0.8147    1.8116    0.3810    3.6535    3.1618
```

By default, `unifrnd` generates an array that is the same size as `a` and `b` after any necessary scalar expansion so that all scalars are expanded to match the dimensions of the other inputs.

If you specify array dimensions sz_1, \dots, sz_N , they must match the dimensions of **a** and **b** after any necessary scalar expansion.

Generate a 2-by-3 array of random numbers from the continuous uniform distribution with the lower parameter 0 and upper parameter 1.

```
sz = [2 3];
r2 = unifrnd(0,1,sz)

r2 = 2×3

    0.0975    0.5469    0.9649
    0.2785    0.9575    0.1576
```

Generate 6 random numbers on the intervals (0,1), (1,2),..., (5,6).

```
a3 = 0:5;
b3 = 1:6;
r3 = unifrnd(a3,b3,1,6)

r3 = 1×6

    0.9706    1.9572    2.4854    3.8003    4.1419    5.4218
```

Input Arguments

a — Lower endpoint

scalar value | array of scalar values

Lower endpoint of the uniform distribution, specified as a scalar value or an array of scalar values.

To generate random numbers from multiple distributions, specify **a** and **b** using arrays. If both **a** and **b** are arrays, then the array sizes must be the same. If either **a** or **b** is a scalar, then `unifrnd` expands the scalar argument into a constant array of the same size as the other argument. Each element in **r** is the random number generated from the distribution specified by the corresponding elements in **a** and **b**.

Example: [0 -1 7 9]

Data Types: `single` | `double`

b — Upper endpoint

scalar value | array of scalar values

Upper endpoint of the uniform distribution, specified as a scalar value or an array of scalar values.

To generate random numbers from multiple distributions, specify **a** and **b** using arrays. If both **a** and **b** are arrays, then the array sizes must be the same. If either **a** or **b** is a scalar, then `unifrnd` expands the scalar argument into a constant array of the same size as the other argument. Each element in **r** is the random number generated from the distribution specified by the corresponding elements in **a** and **b**.

Example: [1 1 10 10]

Data Types: `single` | `double`

sz1, ..., szN — Size of each dimension (as separate arguments)

integers

Size of each dimension, specified as separate arguments of integers.

If either **a** or **b** is an array, then the specified dimensions **sz1, ..., szN** must match the common dimensions of **a** and **b** after any necessary scalar expansion. The default values of **sz1, ..., szN** are the common dimensions.

- If you specify a single value **sz1**, then **r** is a square matrix of size **sz1-by-sz1**.
- If the size of any dimension is 0 or negative, then **r** is an empty array.
- Beyond the second dimension, **unifrnd** ignores trailing dimensions with a size of 1. For example, **unifrnd(-3,5,3,1,1,1)** produces a 3-by-1 vector of random numbers from the uniform distribution with lower endpoint -3 and upper endpoint 5.

Example: 2,3

Data Types: `single` | `double`

sz — Size of each dimension (as a row vector)

row vector of integers

Size of each dimension, specified as a row vector of integers.

If either **a** or **b** is an array, then the specified dimensions **sz** must match the common dimensions of **a** and **b** after any necessary scalar expansion. The default values of **sz** are the common dimensions.

- If you specify a single value [**sz1**], then **r** is a square matrix of size **sz1-by-sz1**.
- If the size of any dimension is 0 or negative, then **r** is an empty array.
- Beyond the second dimension, **unifrnd** ignores trailing dimensions with a size of 1. For example, **unifrnd(-3,5,[3 1 1 1])** produces a 3-by-1 vector of random numbers from the uniform distribution with lower endpoint -3 and upper endpoint 5.

Example: [2 3]

Data Types: `single` | `double`

Output Arguments**r — Uniform random numbers**

scalar value | array of scalar values

Uniform random numbers, returned as a scalar value or an array of scalar values with the dimensions specified by **sz1, ..., szN** or **sz**. Each element in **r** is the random number generated from the distribution specified by the corresponding elements in **a** and **b**.

Alternative Functionality

- **unifrnd** is a function specific to the continuous uniform distribution. Statistics and Machine Learning Toolbox also offers the generic function **random**, which supports various probability distributions. To use **random**, create a **UniformDistribution** probability distribution object and pass the object as an input argument or specify the probability distribution name and its

parameters. Note that the distribution-specific function `unifrnd` is faster than the generic function `random`.

- Use `rand` to generate numbers from the uniform distribution on the interval (0,1).
- To generate random numbers interactively, use `randtool`, a user interface for random number generation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers from the sequence returned by MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

unifstat

Continuous uniform mean and variance

Syntax

```
[M,V] = unifstat(A,B)
```

Description

`[M,V] = unifstat(A,B)` returns the mean of and variance for the continuous uniform distribution using the corresponding lower endpoint (minimum), `A` and upper endpoint (maximum), `B`. Vector or matrix inputs for `A` and `B` must have the same size, which is also the size of `M` and `V`. A scalar input for `A` or `B` is expanded to a constant matrix with the same dimensions as the other input.

The mean of the continuous uniform distribution with parameters a and b is $(a + b)/2$, and the variance is $(a - b)^2/12$.

Examples

```
a = 1:6;
b = 2.*a;
[m,v] = unifstat(a,b)
m =
    1.5000    3.0000    4.5000    6.0000    7.5000    9.0000
v =
    0.0833    0.3333    0.7500    1.3333    2.0833    3.0000
```

unstack

Class: dataset

(Not Recommended) Unstack data from single variable into multiple variables

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
A = unstack(B,datavar,indvar)
[A,iB] = unstack(B,datavar,indvar)
A = unstack(B,datavar,indvar,'Parameter',value)
```

Description

`A = unstack(B,datavar,indvar)` unstacks a single variable in dataset array `B` into multiple variables in `A`. In general `A` contains more variables, but fewer observations, than `B`.

`datavar` specifies the data variable in `B` to unstack. `indvar` specifies an indicator variable in `B` that determines which variable in `A` each value in `datavar` is unstacked into. `unstack` treats the remaining variables in `B` as grouping variables. Each unique combination of their values defines a group of observations in `B` that will be unstacked into a single observation in `A`.

`unstack` creates `m` data variables in `A`, where `m` is the number of group levels in `indvar`. The values in `indvar` indicate which of those `m` variables receive which values from `datavar`. The `j`-th data variable in `A` contains the values from `datavar` that correspond to observations whose `indvar` value was the `j`-th of the `m` possible levels. Elements of those `m` variables for which no corresponding data value in `B` exists contain a default value.

`datavar` is a positive integer, a character vector, a string scalar, or a logical vector containing a single true value. `indvar` is a positive integer, a variable name, or a logical vector containing a single true value.

`[A,iB] = unstack(B,datavar,indvar)` returns an index vector `iB` indicating the correspondence between observations in `A` and those in `B`. For each observation in `A`, `iB` contains the index of the first in the corresponding group of observations in `B`.

For more information on grouping variables, see “Grouping Variables” on page 2-45.

Input Arguments

`A = unstack(B,datavar,indvar,'Parameter',value)` uses the following parameter name/value pairs to control how `unstack` converts variables in `B` to variables in `A`:

'GroupVars'	Grouping variables in B that define groups of observations. <code>groupvars</code> is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector. The default is all variables in B not listed in <code>datavar</code> or <code>indvar</code> .
'NewDataVarNames'	A string array or cell array of character vectors containing names for the data variables <code>unstack</code> should create in A. Default is the group names of the grouping variable specified in <code>indvar</code> .
'AggregationFun'	A function handle that accepts a subset of values from <code>datavar</code> and returns a single value. <code>stack</code> applies this function to observations from the same group that have the same value of <code>indvar</code> . The function must aggregate the data values into a single value, and in such cases it is not possible to recover B from A using <code>stack</code> . The default is <code>@sum</code> for numeric data variables. For non-numeric variables, there is no default, and you must specify 'AggregationFun' if multiple observations in the same group have the same values of <code>indvar</code> .
'ConstVars'	Variables in B to copy to A without unstacking. The values for these variables in A are taken from the first observation in each group in B, so these variables should typically be constant within each group. <code>ConstVars</code> is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector. The default is no variables.

You can also specify more than one data variable in B, each of which becomes a set of *m* variables in A. In this case, specify `datavar` as a vector of positive integers, a string array or cell array containing variable names, or a logical vector. You may specify only one variable with `indvar`. The names of each set of data variables in A are the name of the corresponding data variable in B concatenated with the names specified in 'NewDataVarNames'. The function specified in 'AggregationFun' must return a value with a single row.

Examples

Combine several variables for estimated influenza rates into a single variable. Then unstack the estimated influenza rates by date.

```
load flu

% FLU has a 'Date' variable, and 10 variables for estimated influenza rates
% (in 9 different regions, estimated from Google searches, plus a
% nationwide estimate from the CDC). Combine those 10 variables into an
% array that has a single data variable, 'FluRate', and an indicator
% variable, 'Region', that says which region each estimate is from.
[flu2,iflu] = stack(flu, 2:11, 'NewDataVarName','FluRate', ...
    'IndVarName','Region')

% The second observation in FLU is for 10/16/2005. Find the observations
% in FLU2 that correspond to that date.
flu2(:, :)
flu2(iflu==2, :)

% Use the 'Date' variable from that array to split 'FluRate' into 52
```

```
% separate variables, each containing the estimated influenza rates for
% each unique date. The new array has one observation for each region. In
% effect, this is the original array FLU "on its side".
dateNames = cellstr(datestr(flu.Date,'mmm_DD_YYYY'));
[flu3,iflu2] = unstack(flu2, 'FluRate', 'Date', ...
    'NewDataVarNames',dateNames)

% Since observations in FLU3 represent regions, IFLU2 indicates the first
% occurrence in FLU2 of each region.
flu2(iflu2,:)
```

"Grouping Variables" on page 2-45

update

Package: `classreg.learning.classif`

Update model parameters for code generation

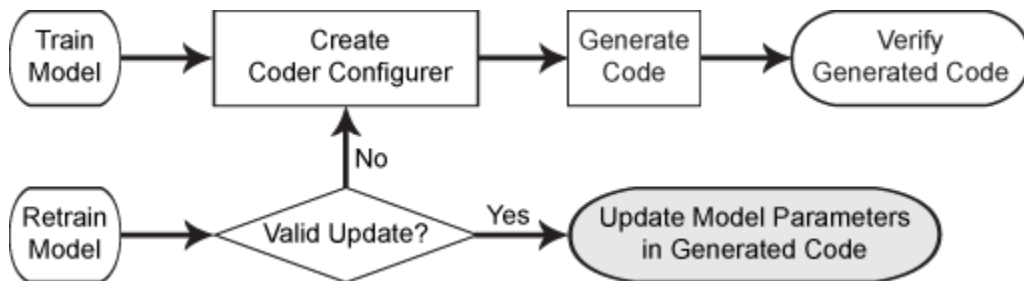

Syntax

```
updatedMdl = update(Mdl,params)
```

Description

Generate C/C++ code for the `predict` and `update` functions of a machine learning model by using a coder configurer object. Create this object by using `learnerCoderConfigurer` and its object function `generateCode`. Then you can use the `update` function to update model parameters in the generated code without having to regenerate the code. This feature reduces the effort required to regenerate, redeploy, and reverify C/C++ code when you retrain a model with new data or settings.

This flow chart shows the code generation workflow using a coder configurer. Use `update` for the highlighted step.

If you do not generate code, then you do not need to use the `update` function. When you retrain a model in MATLAB, the returned model already includes modified parameters.

`updatedMdl = update(Mdl,params)` returns an updated version of `Mdl` that contains new parameters in `params`.

After retraining a model, use the `validatedUpdateInputs` function to detect modified parameters in the retrained model and validate whether the modified parameter values satisfy the coder attributes of the parameters. Use the output of `validatedUpdateInputs`, the validated parameters, as the input `params` to update model parameters.

Examples

Update Parameters of SVM Classification Model in Generated Code

Train a SVM model using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the SVM model parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data.

Then retrain the model using the whole data set and update parameters in the generated code without regenerating the code.

Train Model

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g'). Train a binary SVM classification model using the first 50 observations.

```
load ionosphere
Mdl = fitcsvm(X(1:50,:),Y(1:50));
```

`Mdl` is a `ClassificationSVM` object.

Create Coder Configurer

Create a coder configurer for the `ClassificationSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input. Also, set the number of outputs to 2 so that the generated code returns predicted labels and scores.

```
configurer = learnerCoderConfigurer(Mdl,X(1:50:),'NumOutputs',2);
```

`configurer` is a `ClassificationSVMCoderConfigurer` object, which is a coder configurer of a `ClassificationSVM` object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the SVM classification model parameters so that you can update the parameters in the generated code after retraining the model. This example specifies the coder attributes of predictor data that you want to pass to the generated code and the coder attributes of the support vectors of the SVM model.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 34];
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. `X` contains 34 predictors, so the value of the `SizeVector` attribute must be 34 and the value of the `VariableDimensions` attribute must be `false`.

If you retrain the SVM model using new data or different settings, the number of support vectors can vary. Therefore, specify the coder attributes of `SupportVectors` so that you can update the support vectors in the generated code.

```
configurer.SupportVectors.SizeVector = [250 34];
```

SizeVector attribute for Alpha has been modified to satisfy configuration constraints.
 SizeVector attribute for SupportVectorLabels has been modified to satisfy configuration constraints.

```
configurer.SupportVectors.VariableDimensions = [true false];
```

VariableDimensions attribute for Alpha has been modified to satisfy configuration constraints.
 VariableDimensions attribute for SupportVectorLabels has been modified to satisfy configuration constraints.

If you modify the coder attributes of `SupportVectors`, then the software modifies the coder attributes of `Alpha` and `SupportVectorLabels` to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use `generateCode` to generate code for the `predict` and `update` functions of the SVM classification model (Mdl) with default settings.

```
generateCode(configurer)
```

`generateCode` creates these files in output folder:
 'initialize.m', 'predict.m', 'update.m', 'ClassificationSVMModel.mat'

`generateCode` generates the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of Mdl, respectively. Then `generateCode` creates a MEX function named `ClassificationSVMModel` for the two entry-point functions in the `codegen\mex\ClassificationSVMModel` folder and copies the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of Mdl and the `predict` function in the MEX function return the same labels. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
[label,score] = predict(Mdl,X);  
[label_mex,score_mex] = ClassificationSVMModel('predict',X);
```

Compare `label` and `label_mex` by using `isequal`.

```
isequal(label,label_mex)
```

```
ans = logical  
     1
```

`isequal` returns logical 1 (true) if all the inputs are equal. The comparison confirms that the `predict` function of Mdl and the `predict` function in the MEX function return the same labels.

`score_mex` might include round-off differences compared with `score`. In this case, compare `score_mex` and `score`, allowing a small tolerance.

```
find(abs(score-score_mex) > 1e-8)
```

```
ans =
    0x1 empty double column vector
```

The comparison confirms that `score` and `score_mex` are equal within the tolerance $1e-8$.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

```
retrainedMdl = fitcsvm(X,Y);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
ClassificationSVMModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```
[label,score] = predict(retrainedMdl,X);
[label_mex,score_mex] = ClassificationSVMModel('predict',X);
isequal(label,label_mex)
```

```
ans = logical
     1
```

```
find(abs(score-score_mex) > 1e-8)
```

```
ans =
    0x1 empty double column vector
```

The comparison confirms that `labels` and `labels_mex` are equal, and the score values are equal within the tolerance.

Update Parameters of ECOC Classification Model in Generated Code

Train an error-correcting output codes (ECOC) model using SVM binary learners and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the ECOC model parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data. Then retrain the model using different settings, and update parameters in the generated code without regenerating the code.

Train Model

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Create an SVM binary learner template to use a Gaussian kernel function and to standardize predictor data.

```
t = templateSVM('KernelFunction','gaussian','Standardize',true);
```

Train a multiclass ECOC model using the template `t`.

```
Mdl = fitcecoc(X,Y,'Learners',t);
```

`Mdl` is a `ClassificationECOC` object.

Create Coder Configurer

Create a coder configurer for the `ClassificationECOC` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input. Also, set the number of outputs to 2 so that the generated code returns the first two outputs of the `predict` function, which are the predicted labels and negated average binary losses.

```
configurer = learnerCoderConfigurer(Mdl,X,'NumOutputs',2)
```

```
configurer =
  ClassificationECOCoderConfigurer with properties:

  Update Inputs:
    BinaryLearners: [1x1 ClassificationSVMCoderConfigurer]
    Prior: [1x1 LearnerCoderInput]
    Cost: [1x1 LearnerCoderInput]

  Predict Inputs:
    X: [1x1 LearnerCoderInput]

  Code Generation Parameters:
    NumOutputs: 2
    OutputFileName: 'ClassificationECOCModel'
```

Properties, Methods

`configurer` is a `ClassificationECOCoderConfigurer` object, which is a coder configurer of a `ClassificationECOC` object. The display shows the tunable input arguments of `predict` and `update`: `X`, `BinaryLearners`, `Prior`, and `Cost`.

Specify Coder Attributes of Parameters

Specify the coder attributes of `predict` arguments (predictor data and the name-value pair arguments `'Decoding'` and `'BinaryLoss'`) and `update` arguments (support vectors of the SVM learners) so that you can use these arguments as the input arguments of `predict` and `update` in the generated code.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector`

attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 4];
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. `X` contains 4 predictors, so the second value of the `SizeVector` attribute must be 4 and the second value of the `VariableDimensions` attribute must be `false`.

Next, modify the coder attributes of `BinaryLoss` and `Decoding` to use the `'BinaryLoss'` and `'Decoding'` name-value pair arguments in the generated code. Display the coder attributes of `BinaryLoss`.

```
configurer.BinaryLoss

ans =
    EnumeratedInput with properties:

        Value: 'hinge'
    SelectedOption: 'Built-in'
    BuiltInOptions: {1x7 cell}
        IsConstant: 1
        Tunability: 0
```

To use a nondefault value in the generated code, you must specify the value before generating the code. Specify the `Value` attribute of `BinaryLoss` as `'exponential'`.

```
configurer.BinaryLoss.Value = 'exponential';
configurer.BinaryLoss
```

```
ans =
    EnumeratedInput with properties:

        Value: 'exponential'
    SelectedOption: 'Built-in'
    BuiltInOptions: {1x7 cell}
        IsConstant: 1
        Tunability: 1
```

If you modify attribute values when `Tunability` is `false` (logical 0), the software sets the `Tunability` to `true` (logical 1).

Display the coder attributes of `Decoding`.

```
configurer.Decoding

ans =
    EnumeratedInput with properties:

        Value: 'lossweighted'
```

```

SelectedOption: 'Built-in'
BuiltInOptions: {'lossweighted' 'lossbased'}
IsConstant: 1
Tunability: 0

```

Specify the `IsConstant` attribute of `Decoding` as `false` so that you can use all available values in `BuiltInOptions` in the generated code.

```

configurer.Decoding.IsConstant = false;
configurer.Decoding

ans =
  EnumeratedInput with properties:

      Value: [1x1 LearnerCoderInput]
SelectedOption: 'NonConstant'
BuiltInOptions: {'lossweighted' 'lossbased'}
IsConstant: 0
Tunability: 1

```

The software changes the `Value` attribute of `Decoding` to a `LearnerCoderInput` object so that you can use both `'lossweighted'` and `'lossbased'` as the value of `'Decoding'`. Also, the software sets the `SelectedOption` to `'NonConstant'` and the `Tunability` to `true`.

Finally, modify the coder attributes of `SupportVectors` in `BinaryLearners`. Display the coder attributes of `SupportVectors`.

```

configurer.BinaryLearners.SupportVectors

ans =
  LearnerCoderInput with properties:

      SizeVector: [54 4]
VariableDimensions: [1 0]
      DataType: 'double'
Tunability: 1

```

The default value of `VariableDimensions` is `[true false]` because each learner has a different number of support vectors. If you retrain the ECOC model using new data or different settings, the number of support vectors in the SVM learners can vary. Therefore, increase the upper bound of the number of support vectors.

```

configurer.BinaryLearners.SupportVectors.SizeVector = [150 4];

```

```

SizeVector attribute for Alpha has been modified to satisfy configuration constraints.
SizeVector attribute for SupportVectorLabels has been modified to satisfy configuration constraints.

```

If you modify the coder attributes of `SupportVectors`, then the software modifies the coder attributes of `Alpha` and `SupportVectorLabels` to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Display the coder configurer.

configurer

```

configurer =
  ClassificationECOCoderConfigurer with properties:

  Update Inputs:
    BinaryLearners: [1x1 ClassificationSVMCoderConfigurer]
    Prior: [1x1 LearnerCoderInput]
    Cost: [1x1 LearnerCoderInput]

  Predict Inputs:

    NumOutputs: 2
    OutputFileName: 'ClassificationECOCModel'

```

Properties, Methods

The display now includes `BinaryLoss` and `Decoding` as well.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the `predict` and `update` functions of the ECOC classification model (`Mdl`).

```
generateCode(configurer)
```

```

generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationECOCModel.mat'

```

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `ClassificationECOCModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\ClassificationECOCModel` folder.
- Copy the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument. Because you specified `'Decoding'` as a tunable input argument by changing the `IsConstant` attribute before generating the code, you also need to specify it in the call to the MEX function, even though `'lossweighted'` is the default value of `'Decoding'`.

```

[label,NegLoss] = predict(Mdl,X,'BinaryLoss','exponential');
[label_mex,NegLoss_mex] = ClassificationECOCModel('predict',X,'BinaryLoss','exponential','Decoding');

```

Compare `label` to `label_mex` by using `isequal`.

```
isequal(label,label_mex)
```

```
ans = logical
      1
```

`isequal` returns logical 1 (true) if all the inputs are equal. The comparison confirms that the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels.

`NegLoss_mex` might include round-off differences compared to `NegLoss`. In this case, compare `NegLoss_mex` to `NegLoss`, allowing a small tolerance.

```
find(abs(NegLoss-NegLoss_mex) > 1e-8)
```

```
ans =
```

```
0x1 empty double column vector
```

The comparison confirms that `NegLoss` and `NegLoss_mex` are equal within the tolerance $1e-8$.

Retrain Model and Update Parameters in Generated Code

Retrain the model using a different setting. Specify `'KernelScale'` as `'auto'` so that the software selects an appropriate scale factor using a heuristic procedure.

```
t_new = templateSVM('KernelFunction','gaussian','Standardize',true,'KernelScale','auto');
retrainedMdl = fitcecoc(X,Y,'Learners',t_new);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
ClassificationECOCModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` to the outputs from the `predict` function in the updated MEX function.

```
[label,NegLoss] = predict(retrainedMdl,X,'BinaryLoss','exponential','Decoding','lossbased');
[label_mex,NegLoss_mex] = ClassificationECOCModel('predict',X,'BinaryLoss','exponential','Decoding');
isequal(label,label_mex)
```

```
ans = logical
      1
```

```
find(abs(NegLoss-NegLoss_mex) > 1e-8)
```

```
ans =
```

```
0x1 empty double column vector
```

The comparison confirms that `label` and `label_mex` are equal, and `NegLoss` and `NegLoss_mex` are equal within the tolerance.

Update Parameters of SVM Regression Model in Generated Code

Train a support vector machine (SVM) model using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the SVM model parameters. Use the object function of the coder configurer to generate C code that predicts responses for new predictor data. Then retrain the model using the whole data set and update parameters in the generated code without regenerating the code.

Train Model

Load the `carsmall` data set and train an SVM regression model using the first 50 observations.

```
load carsmall
X = [Horsepower,Weight];
Y = MPG;
Mdl = fitrsvm(X(1:50,:),Y(1:50));
```

`Mdl` is a `RegressionSVM` object.

Create Coder Configurer

Create a coder configurer for the `RegressionSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input.

```
configurer = learnerCoderConfigurer(Mdl,X(1:50,:));
```

`configurer` is a `RegressionSVMCoderConfigurer` object, which is a coder configurer of a `RegressionSVM` object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the SVM regression model parameters so that you can update the parameters in the generated code after retraining the model. This example specifies the coder attributes of predictor data that you want to pass to the generated code and the coder attributes of the support vectors of the SVM regression model.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 2];
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. `X` contains two predictors, so the value of the `SizeVector` attribute must be two and the value of the `VariableDimensions` attribute must be `false`.

If you retrain the SVM model using new data or different settings, the number of support vectors can vary. Therefore, specify the coder attributes of `SupportVectors` so that you can update the support vectors in the generated code.

```
configurer.SupportVectors.SizeVector = [250 2];
```

`SizeVector` attribute for Alpha has been modified to satisfy configuration constraints.

```
configurer.SupportVectors.VariableDimensions = [true false];
```

`VariableDimensions` attribute for Alpha has been modified to satisfy configuration constraints.

If you modify the coder attributes of `SupportVectors`, then the software modifies the coder attributes of `Alpha` to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use `generateCode` to generate code for the `predict` and `update` functions of the SVM regression model (`Mdl`) with default settings.

```
generateCode(configurer)
```

`generateCode` creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionSVMModel.mat'

`generateCode` generates the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively. Then `generateCode` creates a MEX function named `RegressionSVMModel` for the two entry-point functions in the `codegen\mex\RegressionSVMModel` folder and copies the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same predicted responses. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
yfit = predict(Mdl,X);
yfit_mex = RegressionSVMModel('predict',X);
```

`yfit_mex` might include round-off differences compared with `yfit`. In this case, compare `yfit` and `yfit_mex`, allowing a small tolerance.

```
find(abs(yfit-yfit_mex) > 1e-6)
```

```
ans =
```

```
0x1 empty double column vector
```

The comparison confirms that `yfit` and `yfit_mex` are equal within the tolerance $1e-6$.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

```
retrainedMdl = fitrsvm(X,Y);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
RegressionSVMModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```
yfit = predict(retrainedMdl,X);
yfit_mex = RegressionSVMModel('predict',X);
find(abs(yfit-yfit_mex) > 1e-6)
```

```
ans =
```

```
0x1 empty double column vector
```

The comparison confirms that `yfit` and `yfit_mex` are equal within the tolerance $1e-6$.

Update Parameters of Regression Tree Model in Generated Code

Train a regression tree using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the model parameters. Use the object function of the coder configurer to generate C code that predicts responses for new predictor data. Then retrain the model using the entire data set, and update parameters in the generated code without regenerating the code.

Train Model

Load the `carbig` data set, and train a regression tree model using half of the observations.

```
load carbig
X = [Displacement Horsepower Weight];
Y = MPG;

rng('default') % For reproducibility
n = length(Y);
idxTrain = randsample(n,n/2);
XTrain = X(idxTrain,:);
YTrain = Y(idxTrain);

Mdl = fitrtree(XTrain,YTrain);
```

Mdl is a RegressionTree object.

Create Coder Configurer

Create a coder configurer for the RegressionTree model by using learnerCoderConfigurer. Specify the predictor data XTrain. The learnerCoderConfigurer function uses the input XTrain to configure the coder attributes of the predict function input. Also, set the number of outputs to 2 so that the generated code returns predicted responses and node numbers for the predictions.

```
configurer = learnerCoderConfigurer(Mdl,XTrain,'NumOutputs',2);
```

configurer is a RegressionTreeCoderConfigurer object, which is a coder configurer of a RegressionTree object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the regression tree model parameters so that you can update the parameters in the generated code after retraining the model.

Specify the coder attributes of the X property of configurer so that the generated code accepts any number of observations. Modify the SizeVector and VariableDimensions attributes. The SizeVector attribute specifies the upper bound of the predictor data size, and the VariableDimensions attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 3];
configurer.X.VariableDimensions
```

```
ans = 1x2 logical array
```

```
    1    0
```

The size of the first dimension is the number of observations. Setting the value of the SizeVector attribute to Inf causes the software to change the value of the VariableDimensions attribute to 1. In other words, the upper bound of the size is Inf and the size is variable, meaning that the predictor data can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. Because the predictor data contains 3 predictors, the value of the SizeVector attribute must be 3 and the value of the VariableDimensions attribute must be 0.

If you retrain the tree model using new data or different settings, the number of nodes in the tree can vary. Therefore, specify the first dimension of the SizeVector attribute of one of these properties so that you can update the number of nodes in the generated code: Children, CutPoint, CutPredictorIndex, or NodeMean. The software then modifies the other properties automatically.

For example, set the first value of the SizeVector attribute of the NodeMean property to Inf. The software modifies the SizeVector and VariableDimensions attributes of Children, CutPoint, and CutPredictorIndex to match the new upper bound on the number of nodes in the tree. Additionally, the first value of the VariableDimensions attribute of NodeMean changes to 1.

```
configurer.NodeMean.SizeVector = [Inf 1];
```

```
SizeVector attribute for Children has been modified to satisfy configuration constraints.
SizeVector attribute for CutPoint has been modified to satisfy configuration constraints.
```

SizeVector attribute for CutPredictorIndex has been modified to satisfy configuration constraints
 VariableDimensions attribute for Children has been modified to satisfy configuration constraints
 VariableDimensions attribute for CutPoint has been modified to satisfy configuration constraints
 VariableDimensions attribute for CutPredictorIndex has been modified to satisfy configuration constraints

```
configurer.NodeMean.VariableDimensions
```

```
ans = 1x2 logical array
```

```
    1    0
```

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the `predict` and `update` functions of the regression tree model (`Mdl`).

```
generateCode(configurer)
```

`generateCode` creates these files in output folder:
 'initialize.m', 'predict.m', 'update.m', 'RegressionTreeModel.mat'

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `RegressionTreeModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\RegressionTreeModel` folder.
- Copy the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same predicted responses. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
[Yfit,node] = predict(Mdl,XTrain);  
[Yfit_mex,node_mex] = RegressionTreeModel('predict',XTrain);
```

Compare `Yfit` to `Yfit_mex` and `node` to `node_mex`.

```
max(abs(Yfit-Yfit_mex),[],'all')
```

```
ans = 0
```

```
isequal(node,node_mex)
```

```
ans = logical  
    1
```

In general, `Yfit_mex` might include round-off differences compared to `Yfit`. In this case, the comparison confirms that `Yfit` and `Yfit_mex` are equal.

`isequal` returns logical 1 (true) if all the input arguments are equal. The comparison confirms that the `predict` function of `Mdl` and the `predict` function in the MEX function return the same node numbers.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

```
retrainedMdl = fitrtree(X,Y);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
RegressionTreeModel('update',params)
```

Verify Generated Code

Compare the output arguments from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```
[Yfit,node] = predict(retrainedMdl,X);
[Yfit_mex,node_mex] = RegressionTreeModel('predict',X);

max(abs(Yfit-Yfit_mex),[],'all')

ans = 0

isequal(node,node_mex)

ans = logical
     1
```

The comparison confirms that the predicted responses and node numbers are equal.

Input Arguments

Mdl — Machine learning model

model object

Machine learning model, specified as a model object, as given in this table of supported models.

Model	Model Object
Binary decision tree for multiclass classification	<code>CompactClassificationTree</code>
SVM for one-class and binary classification	<code>CompactClassificationSVM</code>
Linear model for binary classification	<code>ClassificationLinear</code>
Multiclass model for SVMs and linear models	<code>CompactClassificationECOC</code>
Binary decision tree for regression	<code>CompactRegressionTree</code>

Model	Model Object
Support vector machine (SVM) regression	CompactRegressionSVM
Linear regression	RegressionLinear

For the code generation usage notes and limitations of a machine learning model, see the Code Generation section of the model object page.

params — Parameters to update

structure

Parameters to update in the machine learning model, specified as a structure with a field for each parameter to update.

Create `params` by using the `validatedUpdateInputs` function. This function detects modified parameters in the retrained model, validates whether the modified parameter values satisfy the coder attributes of the parameters, and returns the parameters to update as a structure.

The set of parameters that you can update varies depending on the machine learning model, as described in this table.

Model	Parameters to Update
Binary decision tree for multiclass classification	Children, ClassProbability, Cost, CutPoint, CutPredictorIndex, Prior
SVM for one-class and binary classification	<ul style="list-style-type: none"> If you train an SVM classification model (Mdl) with a linear kernel function and discard support vectors by using <code>discardSupportVectors</code>, then <code>params</code> can include <code>Beta</code>, <code>Bias</code>, <code>Cost</code>, <code>Mu</code>, <code>Prior</code>, <code>Scale</code> (kernel scale parameter in <code>KernelParameters</code>), and <code>Sigma</code>. Otherwise, <code>params</code> can include <code>Alpha</code>, <code>Beta</code>, <code>Cost</code>, <code>Mu</code>, <code>Prior</code>, <code>Scale</code> (kernel scale parameter in <code>KernelParameters</code>), <code>Sigma</code>, <code>SupportVectorLabels</code>, and <code>SupportVectors</code>. If Mdl is a one-class SVM classification model, then <code>params</code> cannot include <code>Cost</code> or <code>Prior</code>.
Linear model for binary classification	Beta, Bias, Cost, Prior
Multiclass model for SVMs and linear models	BinaryLearners, Cost, Prior
Binary decision tree for regression	Children, CutPoint, CutPredictorIndex, NodeMean
SVM regression	<ul style="list-style-type: none"> If you train an SVM regression model (Mdl) with a linear kernel function and discard support vectors by using <code>discardSupportVectors</code>, then <code>params</code> can include <code>Beta</code>, <code>Bias</code>, <code>Mu</code>, <code>Scale</code> (kernel scale parameter in <code>KernelParameters</code>), and <code>Sigma</code>. Otherwise, <code>params</code> can include <code>Alpha</code>, <code>Bias</code>, <code>Mu</code>, <code>Scale</code> (kernel scale parameter in <code>KernelParameters</code>), <code>Sigma</code>, and <code>SupportVectors</code>.
Linear regression	Beta, Bias

Output Arguments

updatedMdl — Updated machine learning model

model object

Updated machine learning model, returned as a model object that is the same type of object as Mdl. The output updatedMdl is an updated version of the input Mdl that contains new parameters in params.

Tips

- If you modify any of the name-value pair arguments listed in this table when you retrain a model, you cannot use `update` to update the parameters. You must generate C/C++ code again.

Model	Arguments Not Supported for Update
Binary decision tree for multiclass classification	Arguments of <code>fitctree</code> — 'ClassNames', 'ScoreTransform'
SVM for one-class and binary classification	Arguments of <code>fitcsvm</code> — 'ClassNames', 'KernelFunction', 'PolynomialOrder', 'ScoreTransform', 'Standardize'
Linear model for binary classification	Arguments of <code>fitclinear</code> — 'ClassNames', 'ScoreTransform'
Multiclass model for SVMs and linear models	Arguments of <code>fitcecoc</code> — 'ClassNames', 'Coding', 'ScoreTransform' If you specify the binary learners in <code>fitcecoc</code> as template objects (see 'Learners'), then for each binary learner, you cannot modify the following: <ul style="list-style-type: none"> Arguments of <code>templateSVM</code> — 'KernelFunction', 'PolynomialOrder', 'Standardize' Arguments of <code>templateLinear</code> — 'Learner' (because modifying the model type changes the score transform of the binary learner)
Binary decision tree for regression	Arguments of <code>fitrtree</code> — 'ResponseTransform'
SVM regression	Arguments of <code>fitrsvm</code> — 'KernelFunction', 'PolynomialOrder', 'ResponseTransform', 'Standardize'
Linear regression	Arguments of <code>fitrlinear</code> — 'ResponseTransform'

- In the coder configurer workflow, you use `generateCode` to create both the `update.m` entry-point function and the MEX function for the entry-point function. Assuming the name of the MEX function is `myModel`, you call `update` using this syntax.

```
myModel('update',params)
```

To see how the syntax described on this page is used in the entry-point function, display the contents of the `update.m` and `initialize.m` files by using the `type` function.

```
type update.m
type initialize.m
```

For an example that shows the contents of the `update.m` and `initialize.m` files, see “Generate Code Using Coder Configurer” on page 32-2370.

Algorithms

In the coder configurer workflow, the `Mdl` input argument of `update` is a model returned by `loadLearnerForCoder`. This model and the `updatedMdl` object are reduced classification or regression models that primarily contain properties required for prediction.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Create a coder configurer by using `learnerCoderConfigurer` and then generate code for `predict` and `update` by using the object function `generateCode`.
- For the code generation usage notes and limitations of the machine learning model `Mdl`, see the Code Generation section of the model object page.

Model	Model Object
Binary decision tree for multiclass classification	<code>CompactClassificationTree</code>
SVM for one-class and binary classification	<code>CompactClassificationSVM</code>
Linear model for binary classification	<code>ClassificationLinear</code>
Multiclass model for SVMs and linear models	<code>CompactClassificationECOC</code>
Binary decision tree for regression	<code>CompactRegressionTree</code>
Support vector machine (SVM) regression	<code>CompactRegressionSVM</code>
Linear regression	<code>RegressionLinear</code>

Introduced in R2018b

upperparams

Upper Pareto tail parameters

Syntax

```
params = upperparams(pd)
```

Description

`params = upperparams(pd)` returns the two-element vector `params`, which includes the shape and scale parameters of the generalized Pareto distribution (GPD) in the upper tail of `pd`.

`upperparams` does not return the location parameter of the GPD. The location parameter is the quantile value corresponding to the upper tail cumulative probability. Use the `boundary` function to return the location parameter.

Examples

Parameters of Upper Pareto Tail

Generate a sample data set and fit a piecewise distribution with Pareto tails to the data by using `paretotails`. Find the distribution parameters of the upper Pareto tail by using the object function `upperparams`.

Generate a sample data set containing 20% outliers.

```
rng('default'); % For reproducibility
left_tail = -exprnd(1,100,1);
right_tail = exprnd(5,100,1);
center = randn(800,1);
x = [left_tail;center;right_tail];
```

Create a `paretotails` object by fitting a piecewise distribution to `x`. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities so that a fitted object consists of the empirical distribution for the middle 80% of the data set and GPDs for the lower and upper 10% of the data set.

```
pd = paretotails(x,0.1,0.9)
```

```
pd =
Piecewise distribution with 3 segments
  -Inf < x < -1.33251    (0 < p < 0.1): lower tail, GPD(-0.0063504,0.567017)
  -1.33251 < x < 1.80149 (0.1 < p < 0.9): interpolated empirical cdf
   1.80149 < x < Inf    (0.9 < p < 1): upper tail, GPD(0.24874,3.00974)
```

Return the shape and scale parameters of the fitted GPD of the upper tail by using the `upperparams` function.

```
params = upperparams(pd)
```

```
params = 1×2
    0.2487    3.0097
```

You can also get the upper Pareto tail parameters by using the `UpperParameters` property. Access the `UpperParameters` property by using dot notation.

```
pd.UpperParameters
ans = 1×2
    0.2487    3.0097
```

The location parameter of the GPD is equal to the quantile value of the upper tail cumulative probability. Return the location parameter by using the `boundary` function.

```
[p,q] = boundary(pd)
```

```
p = 2×1
    0.1000
    0.9000
```

```
q = 2×1
   -1.3325
    1.8015
```

The values in `p` are the cumulative probabilities at the boundaries, and the values in `q` are the corresponding quantiles. `q(1)` is the location parameter of the GPD of the upper tail.

Use the `lowerparams` function or the `LowerParameters` property to get the lower Pareto tail parameters.

Input Arguments

pd — Piecewise distribution with Pareto tails

`paretotails` object

Piecewise distribution with Pareto tails, specified as a `paretotails` object.

UserData property

Class: dataset

(Not Recommended) Variable containing additional information associated with data set

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Description

Any variable containing additional information to be associated with the data set. The default is an empty array.

validatedUpdateInputs

Package: `classreg.learning.coder.config.svm`

Validate and extract machine learning model parameters to update

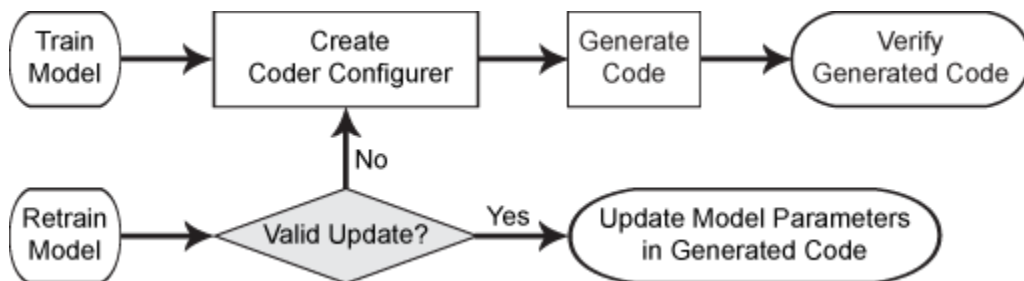

Syntax

```
params = validatedUpdateInputs(configurer,retrainedMdl)
```

Description

Generate C/C++ code for the `predict` and `update` functions of a machine learning model by using a coder configurer object. Create this object by using `learnerCoderConfigurer` and its object function `generateCode`. After retraining the model with new data or settings, you can update model parameters in the generated code without having to regenerate the code. Use `validatedUpdateInputs` to validate and extract the model parameters to update. This function helps you identify potential problems before you update the model parameters in the generated code. You can use the output of `validatedUpdateInputs`, the validated parameters, as an input argument of the `update` function to update model parameters.

This flow chart shows the code generation workflow using a coder configurer. Use `validatedUpdateInputs` for the highlighted step.

`params = validatedUpdateInputs(configurer,retrainedMdl)` returns the validated machine learning model parameters to update. `validatedUpdateInputs` detects the modified model parameters in `retrainedMdl` and validates whether they satisfy the coder attributes stored in `configurer`.

Examples

Update Parameters of SVM Classification Model in Generated Code

Train a SVM model using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the SVM model parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data. Then retrain the model using the whole data set and update parameters in the generated code without regenerating the code.

Train Model

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g'). Train a binary SVM classification model using the first 50 observations.

```
load ionosphere
Mdl = fitcsvm(X(1:50,:),Y(1:50));
```

`Mdl` is a `ClassificationSVM` object.

Create Coder Configurer

Create a coder configurer for the `ClassificationSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input. Also, set the number of outputs to 2 so that the generated code returns predicted labels and scores.

```
configurer = learnerCoderConfigurer(Mdl,X(1:50,:), 'NumOutputs',2);
```

`configurer` is a `ClassificationSVMCoderConfigurer` object, which is a coder configurer of a `ClassificationSVM` object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the SVM classification model parameters so that you can update the parameters in the generated code after retraining the model. This example specifies the coder attributes of predictor data that you want to pass to the generated code and the coder attributes of the support vectors of the SVM model.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 34];
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. `X` contains 34 predictors, so the value of the `SizeVector` attribute must be 34 and the value of the `VariableDimensions` attribute must be `false`.

If you retrain the SVM model using new data or different settings, the number of support vectors can vary. Therefore, specify the coder attributes of `SupportVectors` so that you can update the support vectors in the generated code.

```
configurer.SupportVectors.SizeVector = [250 34];
```

```
SizeVector attribute for Alpha has been modified to satisfy configuration constraints.
SizeVector attribute for SupportVectorLabels has been modified to satisfy configuration constraints.
```

```
configurer.SupportVectors.VariableDimensions = [true false];
```

VariableDimensions attribute for Alpha has been modified to satisfy configuration constraints. VariableDimensions attribute for SupportVectorLabels has been modified to satisfy configuration constraints.

If you modify the coder attributes of `SupportVectors`, then the software modifies the coder attributes of `Alpha` and `SupportVectorLabels` to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use `generateCode` to generate code for the `predict` and `update` functions of the SVM classification model (`Mdl`) with default settings.

```
generateCode(configurer)
```

`generateCode` creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationSVMModel.mat'

`generateCode` generates the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively. Then `generateCode` creates a MEX function named `ClassificationSVMModel` for the two entry-point functions in the `codegen\mex\ClassificationSVMModel` folder and copies the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
[label,score] = predict(Mdl,X);  
[label_mex,score_mex] = ClassificationSVMModel('predict',X);
```

Compare `label` and `label_mex` by using `isequal`.

```
isequal(label,label_mex)
```

```
ans = logical  
     1
```

`isequal` returns logical 1 (true) if all the inputs are equal. The comparison confirms that the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels.

`score_mex` might include round-off differences compared with `score`. In this case, compare `score_mex` and `score`, allowing a small tolerance.

```
find(abs(score-score_mex) > 1e-8)
```

```
ans =
```

```
     0x1 empty double column vector
```

The comparison confirms that `score` and `score_mex` are equal within the tolerance $1e-8$.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

```
retrainedMdl = fitcsvm(X,Y);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
ClassificationSVMModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```
[label,score] = predict(retrainedMdl,X);
[label_mex,score_mex] = ClassificationSVMModel('predict',X);
isequal(label,label_mex)
```

```
ans = logical
     1
```

```
find(abs(score-score_mex) > 1e-8)
```

```
ans =
```

```
     0x1 empty double column vector
```

The comparison confirms that `labels` and `labels_mex` are equal, and the score values are equal within the tolerance.

Update Parameters of ECOC Classification Model in Generated Code

Train an error-correcting output codes (ECOC) model using SVM binary learners and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the ECOC model parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data. Then retrain the model using different settings, and update parameters in the generated code without regenerating the code.

Train Model

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Create an SVM binary learner template to use a Gaussian kernel function and to standardize predictor data.

```
t = templateSVM('KernelFunction','gaussian','Standardize',true);
```

Train a multiclass ECOC model using the template `t`.

```
Mdl = fitcecoc(X,Y,'Learners',t);
```

`Mdl` is a `ClassificationECOC` object.

Create Coder Configurer

Create a coder configurer for the `ClassificationECOC` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input. Also, set the number of outputs to 2 so that the generated code returns the first two outputs of the `predict` function, which are the predicted labels and negated average binary losses.

```
configurer = learnerCoderConfigurer(Mdl,X,'NumOutputs',2)
```

```
configurer =
  ClassificationECOCoderConfigurer with properties:

  Update Inputs:
    BinaryLearners: [1x1 ClassificationSVMCoderConfigurer]
      Prior: [1x1 LearnerCoderInput]
      Cost: [1x1 LearnerCoderInput]

  Predict Inputs:
    X: [1x1 LearnerCoderInput]

  Code Generation Parameters:
    NumOutputs: 2
    OutputFileName: 'ClassificationECOCModel'
```

Properties, Methods

`configurer` is a `ClassificationECOCoderConfigurer` object, which is a coder configurer of a `ClassificationECOC` object. The display shows the tunable input arguments of `predict` and `update`: `X`, `BinaryLearners`, `Prior`, and `Cost`.

Specify Coder Attributes of Parameters

Specify the coder attributes of `predict` arguments (predictor data and the name-value pair arguments `'Decoding'` and `'BinaryLoss'`) and `update` arguments (support vectors of the SVM learners) so that you can use these arguments as the input arguments of `predict` and `update` in the generated code.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 4];
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. `X` contains 4 predictors, so the second value of the `SizeVector` attribute must be 4 and the second value of the `VariableDimensions` attribute must be `false`.

Next, modify the coder attributes of `BinaryLoss` and `Decoding` to use the `'BinaryLoss'` and `'Decoding'` name-value pair arguments in the generated code. Display the coder attributes of `BinaryLoss`.

```
configurer.BinaryLoss

ans =
    EnumeratedInput with properties:

        Value: 'hinge'
    SelectedOption: 'Built-in'
    BuiltInOptions: {1x7 cell}
        IsConstant: 1
        Tunability: 0
```

To use a nondefault value in the generated code, you must specify the value before generating the code. Specify the `Value` attribute of `BinaryLoss` as `'exponential'`.

```
configurer.BinaryLoss.Value = 'exponential';
configurer.BinaryLoss

ans =
    EnumeratedInput with properties:

        Value: 'exponential'
    SelectedOption: 'Built-in'
    BuiltInOptions: {1x7 cell}
        IsConstant: 1
        Tunability: 1
```

If you modify attribute values when `Tunability` is `false` (logical 0), the software sets the `Tunability` to `true` (logical 1).

Display the coder attributes of `Decoding`.

```
configurer.Decoding

ans =
    EnumeratedInput with properties:

        Value: 'lossweighted'
    SelectedOption: 'Built-in'
    BuiltInOptions: {'lossweighted' 'lossbased'}
        IsConstant: 1
        Tunability: 0
```

Specify the `IsConstant` attribute of `Decoding` as `false` so that you can use all available values in `BuiltInOptions` in the generated code.

```
configurer.Decoding.IsConstant = false;
configurer.Decoding

ans =
  EnumeratedInput with properties:

      Value: [1x1 LearnerCoderInput]
 SelectedOption: 'NonConstant'
 BuiltInOptions: {'lossweighted' 'lossbased'}
   IsConstant: 0
  Tunability: 1
```

The software changes the `Value` attribute of `Decoding` to a `LearnerCoderInput` object so that you can use both `'lossweighted'` and `'lossbased'` as the value of `'Decoding'`. Also, the software sets the `SelectedOption` to `'NonConstant'` and the `Tunability` to `true`.

Finally, modify the coder attributes of `SupportVectors` in `BinaryLearners`. Display the coder attributes of `SupportVectors`.

```
configurer.BinaryLearners.SupportVectors

ans =
  LearnerCoderInput with properties:

      SizeVector: [54 4]
 VariableDimensions: [1 0]
      DataType: 'double'
  Tunability: 1
```

The default value of `VariableDimensions` is `[true false]` because each learner has a different number of support vectors. If you retrain the ECOC model using new data or different settings, the number of support vectors in the SVM learners can vary. Therefore, increase the upper bound of the number of support vectors.

```
configurer.BinaryLearners.SupportVectors.SizeVector = [150 4];
```

```
SizeVector attribute for Alpha has been modified to satisfy configuration constraints.
SizeVector attribute for SupportVectorLabels has been modified to satisfy configuration constraints.
```

If you modify the coder attributes of `SupportVectors`, then the software modifies the coder attributes of `Alpha` and `SupportVectorLabels` to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Display the coder configurer.

```
configurer

configurer =
  ClassificationECOCConfigurer with properties:

  Update Inputs:
```

```

BinaryLearners: [1x1 ClassificationSVMCoderConfigurer]
  Prior: [1x1 LearnerCoderInput]
  Cost: [1x1 LearnerCoderInput]

Predict Inputs:
  X: [1x1 LearnerCoderInput]
  BinaryLoss: [1x1 EnumeratedInput]
  Decoding: [1x1 EnumeratedInput]

Code Generation Parameters:
  NumOutputs: 2
  OutputFileName: 'ClassificationECOCModel'

```

Properties, Methods

The display now includes `BinaryLoss` and `Decoding` as well.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the `predict` and `update` functions of the ECOC classification model (`Mdl`).

```
generateCode(configurer)
```

`generateCode` creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationECOCModel.mat'

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `ClassificationECOCModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\ClassificationECOCModel` folder.
- Copy the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument. Because you specified `'Decoding'` as a tunable input argument by changing the `IsConstant` attribute before generating the code, you also need to specify it in the call to the MEX function, even though `'lossweighted'` is the default value of `'Decoding'`.

```
[label,NegLoss] = predict(Mdl,X,'BinaryLoss','exponential');
[label_mex,NegLoss_mex] = ClassificationECOCModel('predict',X,'BinaryLoss','exponential','Decoding');
```

Compare `label` to `label_mex` by using `isequal`.

```
isequal(label,label_mex)
```

```
ans = logical
      1
```

`isequal` returns logical 1 (true) if all the inputs are equal. The comparison confirms that the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels.

`NegLoss_mex` might include round-off differences compared to `NegLoss`. In this case, compare `NegLoss_mex` to `NegLoss`, allowing a small tolerance.

```
find(abs(NegLoss-NegLoss_mex) > 1e-8)
```

```
ans =
```

```
0x1 empty double column vector
```

The comparison confirms that `NegLoss` and `NegLoss_mex` are equal within the tolerance $1e-8$.

Retrain Model and Update Parameters in Generated Code

Retrain the model using a different setting. Specify `KernelScale` as `'auto'` so that the software selects an appropriate scale factor using a heuristic procedure.

```
t_new = templateSVM('KernelFunction','gaussian','Standardize',true,'KernelScale','auto');
retrainedMdl = fitcecoc(X,Y,'Learners',t_new);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
ClassificationECOCModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` to the outputs from the `predict` function in the updated MEX function.

```
[label,NegLoss] = predict(retrainedMdl,X,'BinaryLoss','exponential','Decoding','lossbased');
[label_mex,NegLoss_mex] = ClassificationECOCModel('predict',X,'BinaryLoss','exponential','Decoding');
isequal(label,label_mex)
```

```
ans = logical
      1
```

```
find(abs(NegLoss-NegLoss_mex) > 1e-8)
```

```
ans =
```

```
0x1 empty double column vector
```

The comparison confirms that `label` and `label_mex` are equal, and `NegLoss` and `NegLoss_mex` are equal within the tolerance.

Update Parameters of SVM Regression Model in Generated Code

Train a support vector machine (SVM) model using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the SVM model parameters. Use the object function of the coder configurer to generate C code that predicts responses for new predictor data. Then retrain the model using the whole data set and update parameters in the generated code without regenerating the code.

Train Model

Load the `carsmall` data set and train an SVM regression model using the first 50 observations.

```
load carsmall
X = [Horsepower,Weight];
Y = MPG;
Mdl = fitrsvm(X(1:50,:),Y(1:50));
```

`Mdl` is a `RegressionSVM` object.

Create Coder Configurer

Create a coder configurer for the `RegressionSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input.

```
configurer = learnerCoderConfigurer(Mdl,X(1:50,:));
```

`configurer` is a `RegressionSVMCoderConfigurer` object, which is a coder configurer of a `RegressionSVM` object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the SVM regression model parameters so that you can update the parameters in the generated code after retraining the model. This example specifies the coder attributes of predictor data that you want to pass to the generated code and the coder attributes of the support vectors of the SVM regression model.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 2];
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. `X` contains two predictors, so the value of the `SizeVector` attribute must be two and the value of the `VariableDimensions` attribute must be `false`.

If you retrain the SVM model using new data or different settings, the number of support vectors can vary. Therefore, specify the coder attributes of `SupportVectors` so that you can update the support vectors in the generated code.

```
configurer.SupportVectors.SizeVector = [250 2];
```

SizeVector attribute for Alpha has been modified to satisfy configuration constraints.

```
configurer.SupportVectors.VariableDimensions = [true false];
```

VariableDimensions attribute for Alpha has been modified to satisfy configuration constraints.

If you modify the coder attributes of `SupportVectors`, then the software modifies the coder attributes of `Alpha` to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use `generateCode` to generate code for the `predict` and `update` functions of the SVM regression model (`Mdl`) with default settings.

```
generateCode(configurer)
```

`generateCode` creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionSVMModel.mat'

`generateCode` generates the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively. Then `generateCode` creates a MEX function named `RegressionSVMModel` for the two entry-point functions in the `codegen\mex\RegressionSVMModel` folder and copies the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same predicted responses. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
yfit = predict(Mdl,X);
yfit_mex = RegressionSVMModel('predict',X);
```

`yfit_mex` might include round-off differences compared with `yfit`. In this case, compare `yfit` and `yfit_mex`, allowing a small tolerance.

```
find(abs(yfit-yfit_mex) > 1e-6)
```

```
ans =
```

```
0x1 empty double column vector
```

The comparison confirms that `yfit` and `yfit_mex` are equal within the tolerance $1e-6$.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

```
retrainedMdl = fitcsvm(X,Y);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
RegressionSVMModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```
yfit = predict(retrainedMdl,X);
yfit_mex = RegressionSVMModel('predict',X);
find(abs(yfit-yfit_mex) > 1e-6)
```

```
ans =
```

```
0x1 empty double column vector
```

The comparison confirms that `yfit` and `yfit_mex` are equal within the tolerance `1e-6`.

Update Parameters of Regression Tree Model in Generated Code

Train a regression tree using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the model parameters. Use the `object` function of the coder configurer to generate C code that predicts responses for new predictor data. Then retrain the model using the entire data set, and update parameters in the generated code without regenerating the code.

Train Model

Load the `carbig` data set, and train a regression tree model using half of the observations.

```
load carbig
X = [Displacement Horsepower Weight];
Y = MPG;

rng('default') % For reproducibility
n = length(Y);
idxTrain = randsample(n,n/2);
XTrain = X(idxTrain,:);
YTrain = Y(idxTrain);
```

```
Mdl = fitrtree(XTrain,YTrain);
```

`Mdl` is a `RegressionTree` object.

Create Coder Configurer

Create a coder configurer for the `RegressionTree` model by using `learnerCoderConfigurer`. Specify the predictor data `XTrain`. The `learnerCoderConfigurer` function uses the input `XTrain`

to configure the coder attributes of the `predict` function input. Also, set the number of outputs to 2 so that the generated code returns predicted responses and node numbers for the predictions.

```
configurer = learnerCoderConfigurer(Mdl,XTrain,'NumOutputs',2);
```

`configurer` is a `RegressionTreeCoderConfigurer` object, which is a coder configurer of a `RegressionTree` object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the regression tree model parameters so that you can update the parameters in the generated code after retraining the model.

Specify the coder attributes of the `X` property of `configurer` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 3];
configurer.X.VariableDimensions
```

```
ans = 1x2 logical array
```

```
    1    0
```

The size of the first dimension is the number of observations. Setting the value of the `SizeVector` attribute to `Inf` causes the software to change the value of the `VariableDimensions` attribute to 1. In other words, the upper bound of the size is `Inf` and the size is variable, meaning that the predictor data can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. Because the predictor data contains 3 predictors, the value of the `SizeVector` attribute must be 3 and the value of the `VariableDimensions` attribute must be 0.

If you retrain the tree model using new data or different settings, the number of nodes in the tree can vary. Therefore, specify the first dimension of the `SizeVector` attribute of one of these properties so that you can update the number of nodes in the generated code: `Children`, `CutPoint`, `CutPredictorIndex`, or `NodeMean`. The software then modifies the other properties automatically.

For example, set the first value of the `SizeVector` attribute of the `NodeMean` property to `Inf`. The software modifies the `SizeVector` and `VariableDimensions` attributes of `Children`, `CutPoint`, and `CutPredictorIndex` to match the new upper bound on the number of nodes in the tree. Additionally, the first value of the `VariableDimensions` attribute of `NodeMean` changes to 1.

```
configurer.NodeMean.SizeVector = [Inf 1];
```

```
SizeVector attribute for Children has been modified to satisfy configuration constraints.
SizeVector attribute for CutPoint has been modified to satisfy configuration constraints.
SizeVector attribute for CutPredictorIndex has been modified to satisfy configuration constraints.
VariableDimensions attribute for Children has been modified to satisfy configuration constraints.
VariableDimensions attribute for CutPoint has been modified to satisfy configuration constraints.
VariableDimensions attribute for CutPredictorIndex has been modified to satisfy configuration constraints.
```

```
configurer.NodeMean.VariableDimensions
```

```
ans = 1x2 logical array
     1     0
```

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the `predict` and `update` functions of the regression tree model (`Mdl`).

```
generateCode(configurer)
```

```
generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionTreeModel.mat'
```

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `RegressionTreeModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\RegressionTreeModel` folder.
- Copy the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same predicted responses. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
[Yfit,node] = predict(Mdl,XTrain);
[Yfit_mex,node_mex] = RegressionTreeModel('predict',XTrain);
```

Compare `Yfit` to `Yfit_mex` and `node` to `node_mex`.

```
max(abs(Yfit-Yfit_mex),[],'all')
```

```
ans = 0
```

```
isequal(node,node_mex)
```

```
ans = logical
     1
```

In general, `Yfit_mex` might include round-off differences compared to `Yfit`. In this case, the comparison confirms that `Yfit` and `Yfit_mex` are equal.

`isequal` returns logical 1 (true) if all the input arguments are equal. The comparison confirms that the `predict` function of `Mdl` and the `predict` function in the MEX function return the same node numbers.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

```
retrainedMdl = fitrtree(X,Y);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
RegressionTreeModel('update',params)
```

Verify Generated Code

Compare the output arguments from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```
[Yfit,node] = predict(retrainedMdl,X);
[Yfit_mex,node_mex] = RegressionTreeModel('predict',X);

max(abs(Yfit-Yfit_mex),[],'all')

ans = 0

isequal(node,node_mex)

ans = logical
     1
```

The comparison confirms that the predicted responses and node numbers are equal.

Input Arguments

configurer — Coder configurer

coder configurer object

Coder configurer of a machine learning model, specified as a coder configurer object created by using `learnerCoderConfigurer`.

Model	Coder Configurer Object
Binary decision tree for multiclass classification	<code>ClassificationTreeCoderConfigurer</code>
SVM for one-class and binary classification	<code>ClassificationSVMCoderConfigurer</code>
Linear model for binary classification	<code>ClassificationLinearCoderConfigurer</code>
Multiclass model for SVMs and linear models	<code>ClassificationECOCCoderConfigurer</code>
Binary decision tree for regression	<code>RegressionTreeCoderConfigurer</code>
Support vector machine (SVM) regression	<code>RegressionSVMCoderConfigurer</code>
Linear regression	<code>RegressionLinearCoderConfigurer</code>

retrainedMdl — Retrained machine learning model

full model object | compact model object

Retrained machine learning model, specified as a full or compact model object, as given in this table of supported models.

Model	Full/Compact Model Object	Training Function
Binary decision tree for multiclass classification	ClassificationTree, CompactClassificationTree	fitctree
SVM for one-class and binary classification	ClassificationSVM, CompactClassificationSVM	fitcsvm
Linear model for binary classification	ClassificationLinear	fitclinear
Multiclass model for SVMs and linear models	ClassificationECOC, CompactClassificationECOC	fitcecoc
Binary decision tree for regression	RegressionTree, CompactRegressionTree	fitrtree
Support vector machine (SVM) regression	RegressionSVM, CompactRegressionSVM	fitrsvm
Linear regression	RegressionLinear	fitrlinear

Output Arguments

params — Validated parameters to update

structure

Validated parameters to update in the machine learning model, specified as a structure with a field for each parameter extracted from `retrainedMdl`.

The model parameters in `params` include all parameters listed in the `UpdateInputs` property of `configurer`, which is the list of tunable model parameters.

You can use `params` as an input argument of `update` to update model parameters.

Tips

- `validatedUpdateInputs` returns an error message if you modify any of the name-value pair arguments listed in this table when you retrain the model `retrainedMdl`. In this case, you cannot use `update` to update the parameters. You must generate C/C++ code again.

Model	Arguments Not Supported for Update
Binary decision tree for multiclass classification	Arguments of <code>fitctree</code> — 'ClassNames', 'ScoreTransform'
SVM for one-class and binary classification	Arguments of <code>fitcsvm</code> — 'ClassNames', 'KernelFunction', 'PolynomialOrder', 'ScoreTransform', 'Standardize'
Linear model for binary classification	Arguments of <code>fitclinear</code> — 'ClassNames', 'ScoreTransform'

Model	Arguments Not Supported for Update
Multiclass model for SVMs and linear models	<p>Arguments of <code>fitcecoc</code> — 'ClassNames', 'Coding', 'ScoreTransform'</p> <p>If you specify the binary learners in <code>fitcecoc</code> as template objects (see 'Learners'), then for each binary learner, you cannot modify the following:</p> <ul style="list-style-type: none"> Arguments of <code>templateSVM</code> — 'KernelFunction', 'PolynomialOrder', 'Standardize' Arguments of <code>templateLinear</code> — 'Learner' (because modifying the model type changes the score transform of the binary learner)
Binary decision tree for regression	Arguments of <code>fitrtree</code> — 'ResponseTransform'
SVM regression	Arguments of <code>fitrsvm</code> — 'KernelFunction', 'PolynomialOrder', 'ResponseTransform', 'Standardize'
Linear regression	Arguments of <code>fitrlinear</code> — 'ResponseTransform'

- `validatedUpdateInputs` displays a warning message if the machine learning model parameters in `configurer` and `retrainedMdl` are identical.

Introduced in R2018b

var

Package: prob

Variance of probability distribution

Syntax

```
v = var(pd)
```

Description

`v = var(pd)` returns the variance `v` of the probability distribution `pd`.

Examples

Variance of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x, 'Normal')
```

```
pd =
  NormalDistribution

  Normal distribution
      mu = 75.0083    [73.4321, 76.5846]
      sigma =  8.7202    [7.7391, 9.98843]
```

Compute the variance of the fitted distribution.

```
v = var(pd)
```

```
v = 76.0419
```

For a normal distribution, the variance is equal to the square of the parameter `sigma`.

Variance of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull', 'a', 5, 'b', 2)
```

```
pd =
  WeibullDistribution
```

```
Weibull distribution
A = 5
B = 2
```

Compute the variance of the distribution.

```
v = var(pd)
v = 5.3650
```

Variance of a Triangular Distribution

Create a triangular distribution object.

```
pd = makedist('Triangular','a',-3,'b',1,'c',3)
pd =
  TriangularDistribution
A = -3, B = 1, C = 3
```

Compute the variance of the distribution.

```
v = var(pd)
v = 1.5556
```

Variance of a Kernel Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;
x = grades(:,1);
```

Fit a kernel distribution object to the data.

```
pd = fitdist(x,'Kernel')
pd =
  KernelDistribution

  Kernel = normal
  Bandwidth = 3.61677
  Support = unbounded
```

Compute the variance of the fitted distribution.

```
v = var(pd)
v = 88.4893
```

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

Function or App	Description
<code>makedist</code>	Create a probability distribution object using specified parameter values.
<code>fitdist</code>	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.

Output Arguments

v — Variance

nonnegative scalar value

Variance of the probability distribution, returned as a nonnegative scalar value.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument `pd` can be a fitted probability distribution object for beta, exponential, extreme value, lognormal, normal, and Weibull distributions. Create `pd` by fitting a probability distribution to sample data from the `fitdist` function. For an example, see “Code Generation for Probability Distribution Objects” on page 31-70.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

Introduced in R2013a

VarDescription property

Class: dataset

(Not Recommended) Cell array of character vectors giving descriptions of variables in data set

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Description

A cell array of character vectors giving the descriptions of the variables in the data set. This property may be empty, but if not empty, the number of character vectors must equal the number of variables. Any individual character vector may be empty for a variable that does not have a description defined. The default is an empty cell array.

VarNames property

Class: dataset

(Not Recommended) Cell array giving names of variables in data set

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Description

A cell array of nonempty, distinct character vectors giving the names of the variables in the data set. The number of character vectors must equal the number of variables. The default is the cell array of names for the variables used to create the data set.

vartest

Chi-square variance test

Syntax

```
h = vartest(x,v)
h = vartest(x,v,Name,Value)
[h,p] = vartest(____)
[h,p,ci,stats] = vartest(____)
```

Description

`h = vartest(x,v)` returns a test decision for the null hypothesis that the data in vector `x` comes from a normal distribution with variance `v`, using the chi-square variance test on page 32-5779. The alternative hypothesis is that `x` comes from a normal distribution with a different variance. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = vartest(x,v,Name,Value)` performs the chi-square variance test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = vartest(____)` also returns the p -value of the test, `p`, using any of the input arguments in the previous syntaxes.

`[h,p,ci,stats] = vartest(____)` also returns the confidence interval for the true variance, `ci`, and the structure `stats` containing information about the test statistic.

Examples

Chi-Squared Test for Specified Variance

Load the sample data. Create a vector containing the first column of the students' exam grades matrix.

```
load examgrades
x = grades(:,1);
```

Test the null hypothesis that the data comes from a distribution with a variance of 25.

```
[h,p,ci,stats] = vartest(x,25)
```

```
h = 1
```

```
p = 0
```

```
ci = 2×1
```

```
59.8936
99.7688
```

```
stats = struct with fields:
    chisqstat: 361.9597
    df: 119
```

The returned value `h = 1` indicates that `vartest` rejects the null hypothesis at the default 5% significance level. `ci` shows the lower and upper boundaries of the 95% confidence interval for the true variance, and suggests that the true variance is greater than 25.

Chi-Squared Test Using One-Sided Hypothesis

Load the sample data. Create a vector containing the first column of the students' exam grades matrix.

```
load examgrades
x = grades(:,1);
```

Test the null hypothesis that the data comes from a distribution with a variance of 25, against the alternative hypothesis that the variance is greater than 25.

```
[h,p] = vartest(x,25,'Tail','right')
```

```
h = 1
```

```
p = 2.4269e-26
```

The returned value of `h = 1` indicates that `vartest` rejects the null hypothesis at the default 5% significance level, in favor of the alternative hypothesis that the variance is greater than 25.

Input Arguments

x — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array. For matrices, `vartest` performs separate tests along each column of `x`, and returns a row vector of results. For multidimensional arrays on page 32-5779, `vartest` works along the first nonsingleton dimension on page 32-5779 of `x`.

Data Types: `single` | `double`

v — Hypothesized variance

nonnegative scalar value

Hypothesized variance, specified as a nonnegative scalar value.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: 'Tail', 'right', 'Alpha', 0.01 specifies a right-tailed hypothesis test at the 1% significance level.

Alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

Example: 'Alpha', 0.01

Data Types: single | double

Dim — Dimension

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix to test along, specified as the comma-separated pair consisting of 'Dim' and a positive integer value. For example, specifying 'Dim', 1 tests the data in each column for equality to the hypothesized variance, while 'Dim', 2 tests the data in each row.

Example: 'Dim', 2

Data Types: single | double

Tail — Type of alternative hypothesis

'both' (default) | 'right' | 'left'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

'both'	Test the alternative hypothesis that the population variance is not v .
'right'	Test the alternative hypothesis that the population variance is greater than v .
'left'	Test the alternative hypothesis that the population variance is less than v .

Example: 'Tail', 'right'

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as 1 or 0.

- If $h = 1$, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p — p-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

ci — Confidence interval

vector

Confidence interval for the true variance, returned as a two-element vector containing the lower and upper boundaries of the $100 \times (1 - \text{Alpha})\%$ confidence interval.

stats — Test statistics

structure

Test statistics for the chi-square variance test, returned as a structure containing:

- `chisqstat` — Value of the test statistic.
- `df` — Degrees of freedom of the test.

More About

Chi-Square Variance Test

The chi-square variance test is used to test whether the variance of a population is equal to a hypothesized value.

The test statistic is

$$T = (n - 1) \left(\frac{s}{\sigma_0} \right)^2,$$

where n is the sample size, s is the sample standard deviation, and σ_0 is the hypothesized standard deviation. The denominator is the ratio of the sample standard deviation to the hypothesized standard deviation. The further this ratio deviates from 1, the more likely you are to reject the null hypothesis. The test statistic T has a chi-square distribution with $n - 1$ degrees of freedom under the null hypothesis.

Multidimensional Array

A multidimensional array has more than two dimensions. For example, if x is a 1-by-3-by-4 array, then x is a three-dimensional array.

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if x is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of x .

Tips

- Use `sampsizepwr` to calculate:
 - The sample size that corresponds to specified power and parameter values;
 - The power achieved for a particular sample size, given the true parameter value;
 - The parameter value detectable with the specified sample size and power.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

See Also

`sampsizepwr` | `vartest2` | `vartestn`

Introduced before R2006a

vartest2

Two-sample F -test for equal variances

Syntax

```
h = vartest2(x,y)
h = vartest2(x,y,Name,Value)
[h,p] = vartest2( ___ )
[h,p,ci,stats] = vartest2( ___ )
```

Description

`h = vartest2(x,y)` returns a test decision for the null hypothesis that the data in vectors `x` and `y` comes from normal distributions with the same variance, using the two-sample F -test on page 32-5784. The alternative hypothesis is that they come from normal distributions with different variances. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = vartest2(x,y,Name,Value)` returns a test decision for the two-sample F -test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = vartest2(___)` also returns the p -value of the test, `p`, using any of the input arguments in the previous syntaxes.

`[h,p,ci,stats] = vartest2(___)` also returns the confidence interval for the true variance ratio, `ci`, and the structure `stats` containing information about the test statistic.

Examples

Test for Equal Variances

Load the sample data. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades;
x = grades(:,1);
y = grades(:,2);
```

Test the null hypothesis that the data in `x` and `y` comes from distributions with the same variance.

```
[h,p,ci,stats] = vartest2(x,y)

h = 1

p = 0.0019

ci = 2×1

    1.2383
    2.5494
```

```
stats = struct with fields:
  fstat: 1.7768
  df1: 119
  df2: 119
```

The returned result `h = 1` indicates that `vartest2` rejects the null hypothesis at the default 5% significance level. `ci` contains the lower and upper boundaries of the 95% confidence interval for the true variance ratio. `stats` contains the value of the test statistic for the F -test and the numerator and denominator degrees of freedom.

One-Sided Hypothesis Test

Load the sample data. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades;
x = grades(:,1);
y = grades(:,2);
```

Test the null hypothesis that the data in `x` and `y` comes from distributions with the same variance, against the alternative that the population variance of `x` is greater than that of `y`.

```
vartest2(x,y,'Tail','right')

ans = 1
```

The returned result `h = 1` indicates that `vartest2` rejects the null hypothesis at the default 5% significance level, in favor of the alternative hypothesis that the population variance of `x` is greater than that of `y`.

Input Arguments

x — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array on page 32-5784.

- If `x` and `y` are vectors, they do not need to be the same length.
- If `x` and `y` are matrices, they must have the same number of columns, but do not need to have the same number of rows. `vartest2` performs separate tests along each column and returns a vector of the results.
- If `x` and `y` are multidimensional arrays, they must have the same number of dimensions, and the same size along all but the first nonsingleton dimension on page 32-5785.

Data Types: `single` | `double`

y — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array on page 32-5784.

- If x and y are vectors, they do not need to be the same length.
- If x and y are matrices, they must have the same number of columns, but do not need to have the same number of rows. `vartest2` performs separate tests along each column and returns a vector of the results.
- If x and y are multidimensional arrays, they must have the same number of dimensions, and the same size along all but the first nonsingleton dimension on page 32-5785.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'Tail', 'right', 'Alpha', 0.01` specifies a right-tailed hypothesis test at the 1% significance level.

Alpha — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

Dim — Dimension

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix to test along, specified as the comma-separated pair consisting of `'Dim'` and a positive integer value. For example, specifying `'Dim', 1` tests the data in each column for variance equality, while `'Dim', 2` tests the data in each row.

Example: `'Dim', 2`

Data Types: `single` | `double`

Tail — Type of alternative hypothesis

`'both'` (default) | `'right'` | `'left'`

Type of alternative hypothesis to evaluate using the F -test, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

<code>'both'</code>	Test the alternative hypothesis that the population variances are not equal.
<code>'right'</code>	Test the alternative hypothesis that the population variance of x is greater than that of y .
<code>'left'</code>	Test the alternative hypothesis that the population variance of x is less than that of y .

Example: `'Tail', 'right'`

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as 1 or 0.

- If $h = 1$, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p — *p*-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

ci — Confidence interval

vector

Confidence interval for the true ratio of the population variances, returned as a two-element vector containing the lower and upper boundaries of the $100 \times (1 - \text{Alpha})\%$ confidence interval.

stats — Test statistics

structure

Test statistics for the hypothesis test, returned as a structure containing:

- `fstat` — Value of the test statistic.
- `df1` — Numerator degrees of freedom of the test.
- `df2` — Denominator degrees of freedom of the test.

More About

Two-Sample *F*-Test

The two-sample *F*-test is used to test if the variances of two populations are equal.

The test statistic is

$$F = \frac{s_1^2}{s_2^2},$$

where s_1 and s_2 are the sample standard deviations. The test statistic is a ratio of the two sample variances. The further this ratio deviates from 1, the more likely you are to reject the null hypothesis. Under the null hypothesis, the test statistic F has a *F*-distribution with numerator degrees of freedom equal to $N_1 - 1$ and denominator degrees of freedom equal to $N_2 - 1$, where N_1 and N_2 are the sample sizes of the two data sets.

Multidimensional Array

A multidimensional array has more than two dimensions. For example, if x is a 1-by-3-by-4 array, then x is a three-dimensional array.

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if x is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of x .

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

vartest | vartestn

Introduced before R2006a

vartestn

Multiple-sample tests for equal variances

Syntax

```
vartestn(x)  
vartestn(x,Name,Value)
```

```
vartestn(x,group)  
vartestn(x,group,Name,Value)
```

```
p = vartestn( ___ )  
[p,stats] = vartestn( ___ )
```

Description

`vartestn(x)` returns a summary table of statistics and a box plot for a Bartlett test of the null hypothesis that the columns of data vector `x` come from normal distributions with the same variance. The alternative hypothesis is that not all columns of data have the same variance.

`vartestn(x,Name,Value)` returns a summary table of statistics and a box plot for a test of unequal variances with additional options specified by one or more name-value pair arguments. For example, you can specify a different type of hypothesis test or change the display settings for the test results.

`vartestn(x,group)` returns a summary table of statistics and a box plot for a Bartlett test of the null hypothesis that the data in each categorical group comes from normal distributions with the same variance. The alternative hypothesis is that not all groups have the same variance.

`vartestn(x,group,Name,Value)` returns a summary table of statistics and a box plot for a test of unequal variances with additional options specified by one or more name-value pair arguments. For example, you can specify a different type of hypothesis test or change the display settings for the test results.

`p = vartestn(___)` also returns the p -value of the test, `p`, using any of the input arguments in the previous syntaxes.

`[p,stats] = vartestn(___)` also returns the structure `stats` containing information about the test statistic.

Examples

Test Data for Equal Variances

Load the sample data.

```
load examgrades
```

Test the null hypothesis that the variances are equal across the five columns of data in the students' exam grades matrix, `grades`.

```
vartestn(grades)
```

Group Summary Table			
Group	Count	Mean	Std Dev
1	120	75.0083	8.7202
2	120	74.9917	6.54204
3	120	74.9917	7.43091
4	120	75.0333	8.60128
5	120	74.9917	5.25884
Pooled	600	75.0033	7.42558
Bartlett's statistic	38.7332		
Degrees of freedom	4		
p-value	0		

```
ans = 7.9086e-08
```

The low p -value, $p = 0$, indicates that `vartestn` rejects the null hypothesis that the variances are equal across all five columns, in favor of the alternative hypothesis that at least one column has a different variance.

Test Grouped Data for Equal Variances

Load the sample data.

```
load carsmall
```

Test the null hypothesis that the variances in miles per gallon (MPG) are equal across different model years.

```
vartestn(MPG,Model_Year)
```

Group Summary Table			
Group	Count	Mean	Std Dev
70	29	17.6897	5.33923
76	34	21.5735	5.8893
82	31	31.7097	5.39255
Pooled	94	23.7181	5.562
Bartlett's statistic	0.36619		
Degrees of freedom	2		
p-value	0.83269		

ans = 0.8327

The high p -value, $p = 0.83269$, indicates that `vartestn` does not reject the null hypothesis that the variances in miles per gallon (MPG) are equal across different model years.

Test for Equal Variances Using Levene's Test

Load the sample data.

```
load carsmall
```

Use Levene's test to test the null hypothesis that the variances in miles per gallon (MPG) are equal across different model years.

```
p = vartestn(MPG,Model_Year,'TestType','LeveneAbsolute')
```

Group Summary Table

Group	Count	Mean	Std Dev
70	29	17.6897	5.33923
76	34	21.5735	5.8893
82	31	31.7097	5.39255
Pooled	94	23.7181	5.562

Levene's statistic (absolute)	0.46126
Degrees of freedom	2, 91
p-value	0.63195

$p = 0.6320$

The high p -value, $p = 0.63195$, indicates that `vartestn` does not reject the null hypothesis that the variances in miles per gallon (MPG) are equal across different model years.

Test for Equal Variances Using the Brown-Forsythe Test

Load the sample data.

```
load examgrades
```

Test the null hypothesis that the variances are equal across the five columns of data in the students' exam grades matrix, `grades`, using the Brown-Forsythe test. Suppress the display of the summary table of statistics and the box plot.

```
[p,stats] = vartestn(grades, 'TestType', 'BrownForsythe', 'Display', 'off')
```

```
p = 1.3121e-06
```

```
stats = struct with fields:
    fstat: 8.4160
    df: [4 595]
```

The small p -value, $p = 1.3121e-06$, indicates that `vartestn` rejects the null hypothesis that the variances are equal across all five columns, in favor of the alternative hypothesis that at least one column has a different variance.

Input Arguments

x — Sample data

matrix | column vector

Sample data, specified as a matrix or column vector. If a grouping variable `group` is specified, then `x` must be a column vector. If a grouping variable is not specified, `x` must be a matrix. In either case, `vartestn` treats NaN values as missing values and ignores them.

Data Types: `single` | `double`

group — Grouping variable

categorical array | logical or numeric vector | character array | string array | cell array of character vectors

Grouping variable, specified as a categorical array, logical or numeric vector, character array, string array, or cell array of character vectors with one row for each element of `x`. Each unique value in a grouping variable defines a group. `vartestn` treats NaN values as missing values and ignores them.

For example, if `Gender` is a cell array of character vectors with values 'Male' and 'Female', you can use `Gender` as a grouping variable to test your data by gender.

Example: `Gender`

Data Types: `categorical` | `single` | `double` | `logical` | `string` | `cell` | `char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'TestType', 'BrownForsythe', 'Display', 'off'` specifies a Brown-Forsythe test and omits the plot of the results.

Display — Display settings for test results

`'on'` (default) | `'off'`

Display settings for test results, specified as the comma-separated pair consisting of `'Display'` and one of the following.

- `'on'` Display a box plot and table of summary statistics.
- `'off'` Do not display a box plot and table of summary statistics.

Example: `'display', 'off'`

TestType — Type of hypothesis test

`'Bartlett'` (default) | `'LeveneQuadratic'` | `'LeveneAbsolute'` | `'BrownForsythe'` | `'OBrien'`

Type of hypothesis test to perform, specified as the comma-separated pair consisting of 'TestType' and one of the following.

'Bartlett'	Bartlett's test.
'LeveneQuadratic'	Levene's test computed by performing ANOVA on the squared deviations of the data values from their group means.
'LeveneAbsolute'	Levene's test computed by performing ANOVA on the absolute deviations of the data values from their group means.
'BrownForsythe'	Brown-Forsythe test computed by performing ANOVA on the absolute deviations of the data values from the group medians.
'OBrien'	O'Brien's modification of Levene's test with $W = 0.5$.

Example: 'TestType', 'OBrien'

Output Arguments

p — p-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

stats — Test statistics

structure

Test statistics for the hypothesis test, returned as a structure containing:

- `chistat`: Value of the test statistic.
- `df`: Degrees of freedom of the test.

More About

Bartlett's Test

Bartlett's test is used to test whether multiple data samples have equal variances, against the alternative that at least two of the data samples do not have equal variances.

The test statistic is

$$T = \frac{(N - k) \ln s_p^2 - \sum_{i=1}^k (N_i - 1) \ln s_i^2}{1 + (1/(3(k - 1))) \left(\left(\sum_{i=1}^k 1/(N_i - 1) \right) - 1/(N - k) \right)},$$

where s_i^2 is the variance of the i th group, N is the total sample size, N_i is the sample size of the i th group, k is the number of groups, and s_p^2 is the pooled variance. The pooled variance is defined as

$$s_p^2 = \sum_{i=1}^k (N_i - 1) s_i^2 / (N - k).$$

The test statistic has a chi-square distribution with $k - 1$ degrees of freedom under the null hypothesis.

Bartlett's test is sensitive to departures from normality. If your data comes from a nonnormal distribution, Levene's test could provide a more accurate result.

Levene, Brown-Forsythe, and O'Brien Tests

The Levene, Brown-Forsythe, and O'Brien tests are used to test if multiple data samples have equal variances, against the alternative that at least two of the data samples do not have equal variances.

The test statistic is

$$W = \frac{(N - k) \sum_{i=1}^k N_i (\bar{Z}_{i.} - \bar{Z}_{..})^2}{(k - 1) \sum_{i=1}^k \sum_{j=1}^{N_i} (Z_{ij} - \bar{Z}_{i.})^2},$$

where N_i is the sample size of the i th group, and k is the number of groups. Depending on the type of test specified with the `TestType` name-value pair arguments, Z_{ij} can have one of four definitions:

- If you specify `LeveneAbsolute`, `vartestn` uses $Z_{ij} = |Y_{ij} - \bar{Y}_{i.}|$, where $\bar{Y}_{i.}$ is the mean of the i th subgroup.
- If you specify `LeveneQuadratic`, `vartestn` uses $Z_{ij}^2 = (Y_{ij} - \bar{Y}_{i.})^2$, where $\bar{Y}_{i.}$ is the mean of the i th subgroup.
- If you specify `BrownForsythe`, `vartestn` uses $Z_{ij} = |Y_{ij} - \tilde{Y}_{i.}|$, where $\tilde{Y}_{i.}$ is the median of the i th subgroup.
- If you specify `OBrien`, `vartestn` uses

$$Z_{ij} = \frac{(0.5 + n_i - 2)n_i(y_{ij} - \bar{y}_i)^2 - 0.5(n_i - 1)\sigma_i^2}{(n_i - 1)(n_i - 2)},$$

where n_i is the size of the i th group, σ_i^2 is its sample variance.

In all cases, the test statistic has an F -distribution with $k - 1$ numerator degrees of freedom, and $N - k$ denominator degrees of freedom.

The Levene, Brown-Forsythe, and O'Brien tests are less sensitive to departures from normality than Bartlett's test, so they are useful alternatives if you suspect the samples come from nonnormal distributions.

Introduced before R2006a

vertcat

Class: dataset

(Not Recommended) Vertical concatenation for dataset arrays

Note The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
ds = vertcat(ds1, ds2, ...)
```

Description

`ds = vertcat(ds1, ds2, ...)` vertically concatenates the dataset arrays `ds1`, `ds2`, Observation names, when present, must be unique across datasets. `vertcat` fills in default observation names for the output when some of the inputs have names and some do not.

Variable names for all dataset arrays must be identical except for order. `vertcat` concatenates by matching variable names. `vertcat` assigns values for the "per-variable" properties (e.g., Units and VarDescription) in `ds` from the corresponding property values in `ds1`.

See Also

`cat` | `horzcat`

compact

Class: `clustering.evaluation.ClusterCriterion`

Package: `clustering.evaluation`

Compact clustering evaluation object

Syntax

```
c = compact(eva)
```

Description

`c = compact(eva)` returns a compact clustering evaluation object, which contains a subset of information about the clustering solution in `eva`. Compacting a clustering evaluation object reduces the memory requirements of the object, which is useful when clustering a large data set.

Input Arguments

eva — Clustering evaluation data

clustering evaluation object

Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using `evalclusters`.

Output Arguments

c — Compact clustering evaluation object

clustering evaluation object

Compact clustering evaluation object, returned as a clustering evaluation object. The compact object includes the clustering evaluation results. In the compact object, the properties for the input data `X`, optimal clustering solution `OptimalY`, and the list of excluded data `Missing` are empty.

Examples

Create a Compact Clustering Evaluation Object

Create a compact clustering evaluation object from a full clustering evaluation object.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Create a clustering evaluation object. Cluster the data using `kmeans`, and evaluate the optimal number of clusters using the gap criterion.

```
rng('default'); % For reproducibility
eva = evalclusters(meas, 'kmeans', 'Gap', 'KList', [1:6])

eva =
  GapEvaluation with properties:

    NumObservations: 150
      InspectedK: [1 2 3 4 5 6]
    CriterionValues: [0.0720 0.5928 0.8762 1.0114 1.0534 1.0720]
      OptimalK: 5
```

Create a compact clustering evaluation object from `eva`.

```
c = compact(eva)

c =
  GapEvaluation with properties:

    NumObservations: 150
      InspectedK: [1 2 3 4 5 6]
    CriterionValues: [0.0720 0.5928 0.8762 1.0114 1.0534 1.0720]
      OptimalK: 5
```

The displayed output of the compact object `c` is the same as the original object `eva`, but some properties not shown in the display are different. For example, in the compact object, the properties `x`, `OptimalY`, and `Missing` are empty.

Display the optimal clustering solution `OptimalY` for `c`.

```
c.OptimalY
```

```
ans =
```

```
 []
```

`evalclusters`

view

View classification tree

Syntax

```
view(tree)
view(tree,Name,Value)
```

Description

`view(tree)` returns a text description of `tree`, a decision tree.

`view(tree,Name,Value)` describes `tree` with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`tree`

A classification tree or compact classification tree created by `fitctree` or `compact`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Mode

Value describing the display of `tree`, either `'graph'` or `'text'`. `'graph'` opens a user interface displaying `tree`, and containing controls for querying the tree. `'text'` sends output to the Command Window describing `tree`.

Default: `'text'`

Examples

View Trained Classification Tree

View textual and graphical displays of a trained classification tree.

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification tree using all measurements.

```
Mdl = fitctree(meas,species);
```

View textual display of the trained classification tree.

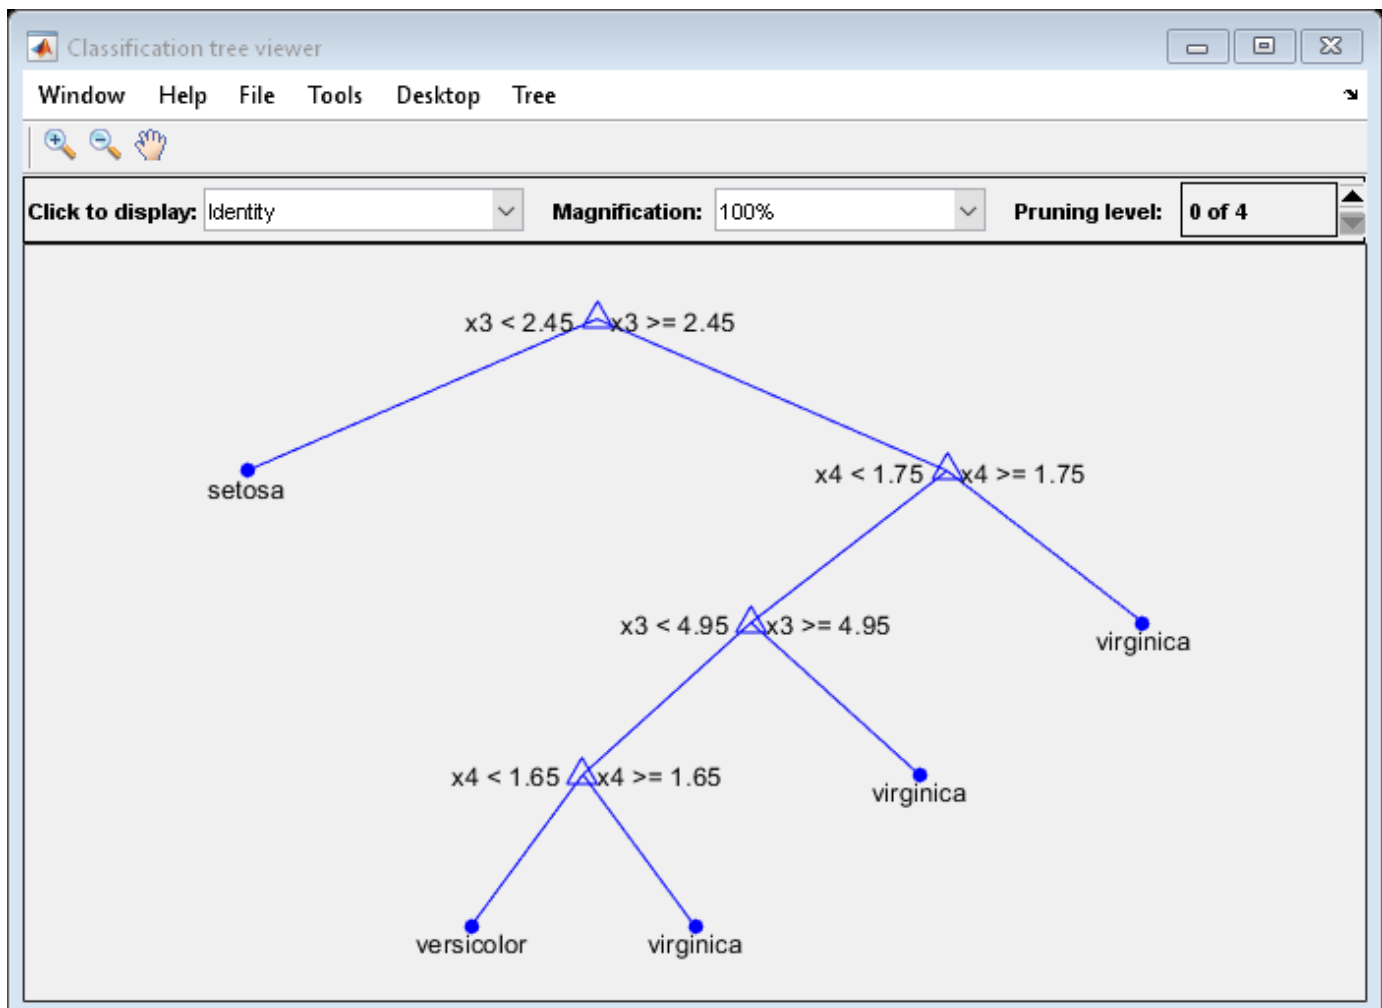

```
view(Mdl)
```

Decision tree for classification

```
1 if x3<2.45 then node 2 elseif x3>=2.45 then node 3 else setosa
2 class = setosa
3 if x4<1.75 then node 4 elseif x4>=1.75 then node 5 else versicolor
4 if x3<4.95 then node 6 elseif x3>=4.95 then node 7 else versicolor
5 class = virginica
6 if x4<1.65 then node 8 elseif x4>=1.65 then node 9 else versicolor
7 class = virginica
8 class = versicolor
9 class = virginica
```

View graphical display of the trained classification tree.

```
view(Mdl, 'Mode', 'graph');
```

View Tree from Bag of Trees

Load Fisher's iris data set.

```
load fisheriris
```

Grow a bag of 100 classification trees using all measurements.

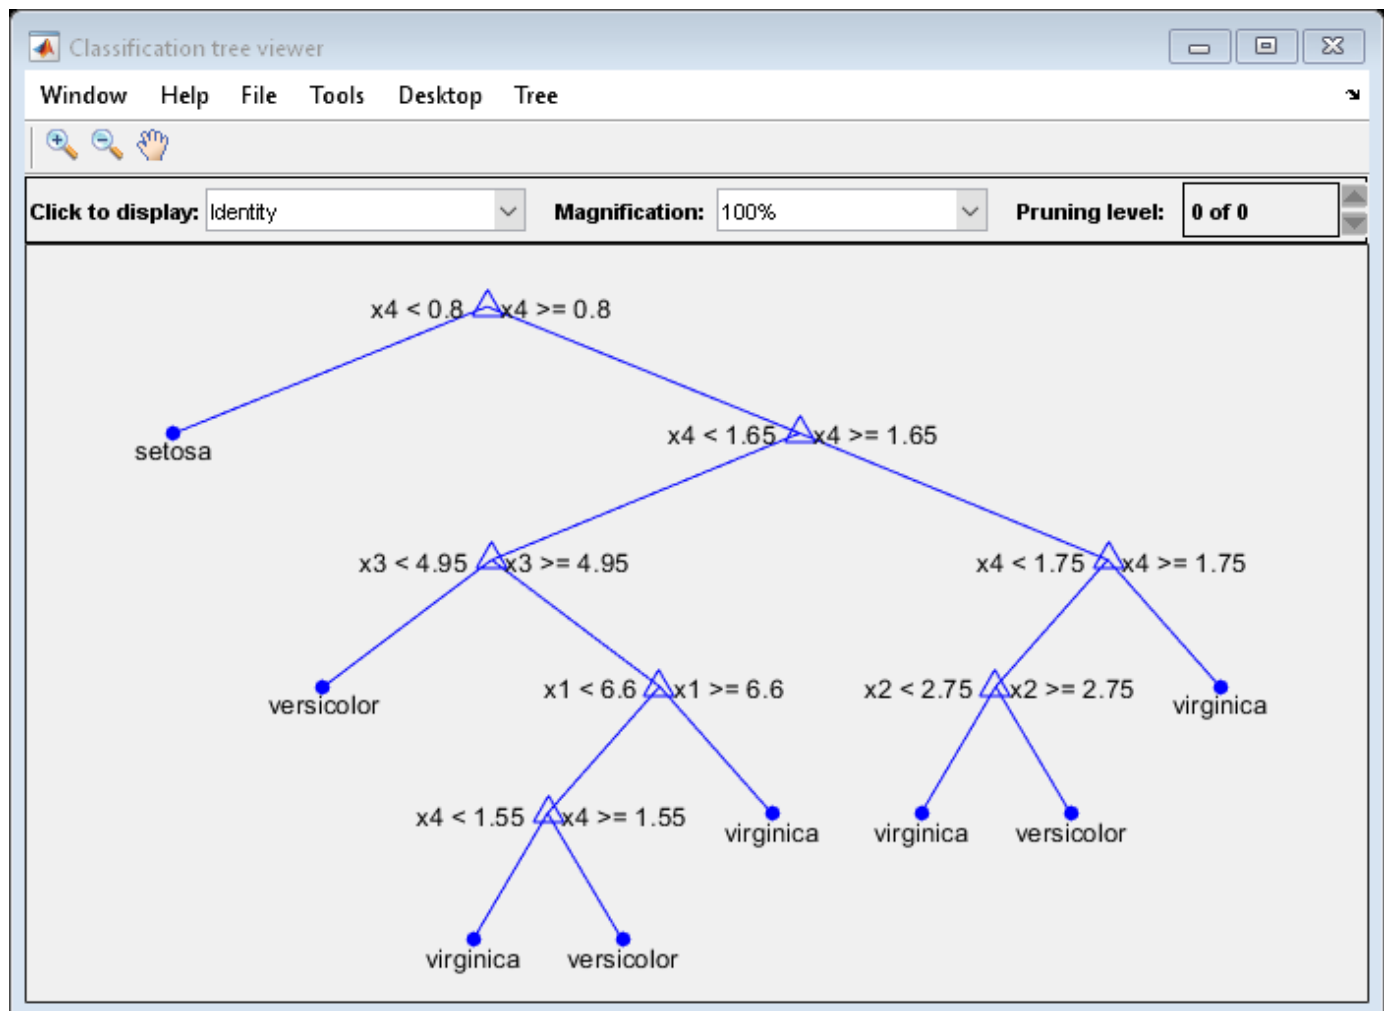

```
rng(1) % For reproducibility
Mdl = TreeBagger(100,meas,species);
```

Alternatively, you can use `fitcensemble` to grow a bag of classification trees.

`Mdl` is a `TreeBagger` model object. `Mdl.Trees` stores the bag of 100 trained classification trees in a 100-by-1 cell array. That is, each cell in `Mdl.Trees` contains a `CompactClassificationTree` model object.

View a graph of the 10th classification tree in the bag.

```
Tree10 = Mdl.Trees{10};
view(Tree10, 'Mode', 'graph');
```

By default, the software grows deep trees for bags of trees.

View Tree from Boosted Ensemble

Load Fisher's iris data set.

```
load fisheriris
```

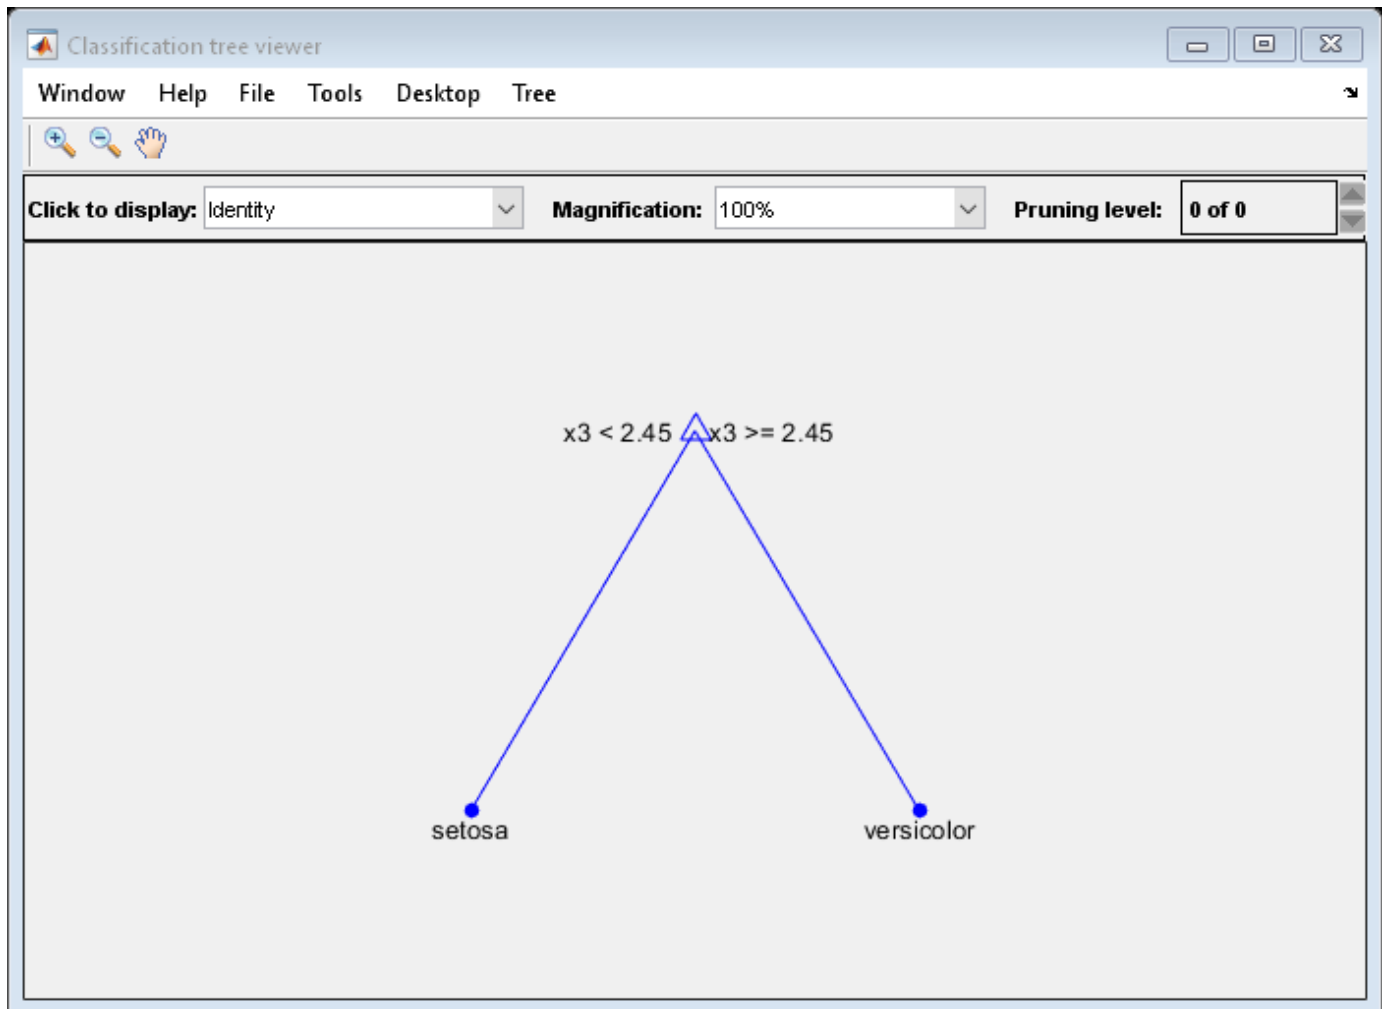

Boost an ensemble of 100 classification trees using all measurements. Specify tree stumps as the weak learners.

```
t = templateTree('MaxNumSplits',1);
Mdl = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Mdl is a ClassificationEnsemble model object. Mdl.Trained stores the ensemble of 100 trained classification trees in a 100-by-1 cell array. That is, each cell in Mdl.Trained contains a CompactClassificationTree model object.

View a graph of the 10th classification tree in the ensemble.

```
Tree10 = Mdl.Trained{10};
view(Tree10,'Mode','graph');
```

The graph shows a tree stump because you specified stumps as the weak learners for the ensemble. However, this behavior is not the default for fitcensemble. By default, fitcensemble grows

shallow trees for boosted ensembles of trees. That is, 'Learners' is `templateTree('MaxNumSplits',10)`.

Tip

To view tree t from an ensemble of trees, enter one of these lines of code

```
view(Ens.Trained{t})  
view(Bag.Trees{t})
```

- `Ens` is a full ensemble returned by `fitcensemble` or a compact ensemble returned by `compact`.
- `Bag` is a full bag of trees returned by `TreeBagger` or a compact bag of trees returned by `compact`.

To save tree in the Command Window, get a figure handle by using the `findall` and `setdiff` functions, and then save tree using the function `saveas`.

```
before = findall(groot,'Type','figure'); % Find all figures  
view(Mdl,'Mode','graph')  
after = findall(groot,'Type','figure');  
h = setdiff(after,before); % Get the figure handle of the tree viewer  
saveas(h,'a.png')
```

See Also

`ClassificationTree` | `fitctree`

view

View regression tree

Syntax

```
view(tree)
view(tree,Name,Value)
```

Description

`view(tree)` returns a text description of `tree`, a decision tree.

`view(tree,Name,Value)` describes `tree` with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`tree`

A regression tree or compact regression tree created by `fitrtree` or `compact`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Mode

Display of `tree`, either `'graph'` or `'text'`. `'graph'` opens a GUI displaying `tree`, and containing controls for querying the tree. `'text'` sends output to the Command Window describing `tree`.

Default: `'text'`

Examples

View Trained Regression Tree

View textual and graphical displays of a trained regression tree.

Load the `carsmall` data set. Consider a model that explains a car's fuel economy (MPG) using its weight (`Weight`) and number of cylinders (`Cylinders`).

```
load carsmall
X = [Weight Cylinders];
Y = MPG;
```

Train a regression tree using all measurements.

```
Mdl = fitrtree(X,Y);
```

View textual display of the trained regression tree.

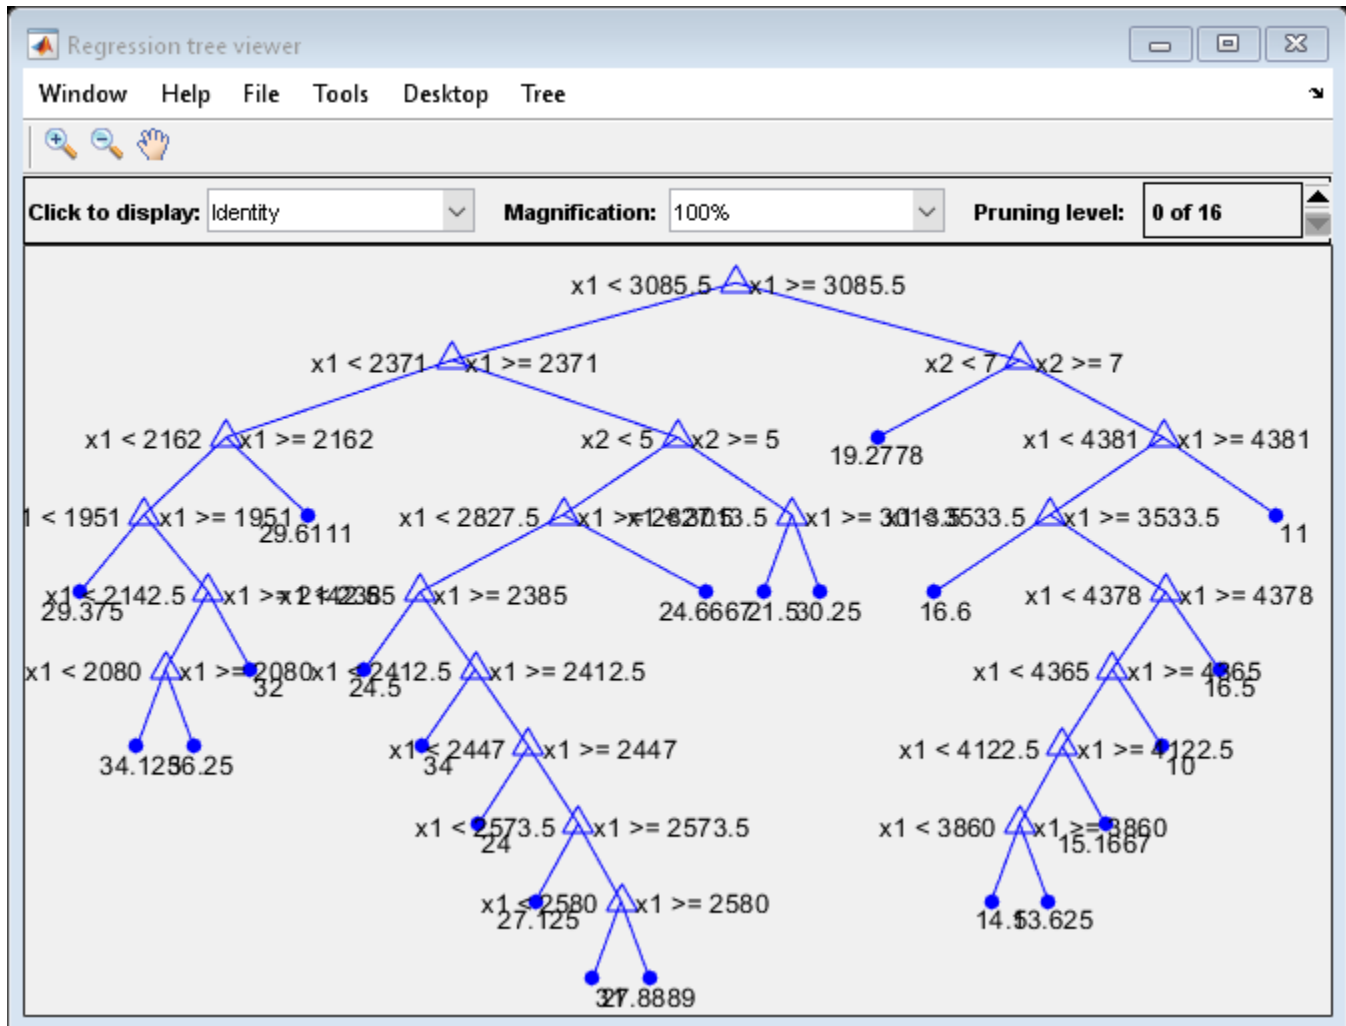

```
view(Mdl)
```

```
Decision tree for regression

33 fit = 10
34 fit = 24
35 if x1<2573.5 then node 38 elseif x1>=2573.5 then node 39 else 27.8929
36 if x1<3860 then node 40 elseif x1>=3860 then node 41 else 14.15
37 fit = 15.1667
38 fit = 27.125
39 if x1<2580 then node 42 elseif x1>=2580 then node 43 else 28.2
40 fit = 14.5
41 fit = 13.625
42 fit = 31
43 fit = 27.8889
```

View graphical display of the trained regression tree.

```
view(Mdl, 'Mode', 'graph');
```

View Tree from Bag of Trees

Load the `carsmall` data set. Consider a model that explains a car's fuel economy (MPG) using its weight (`Weight`) and number of cylinders (`Cylinders`).

```
load carsmall
X = [Weight Cylinders];
Y = MPG;
```

Grow a bag of 100 regression trees using all measurements.

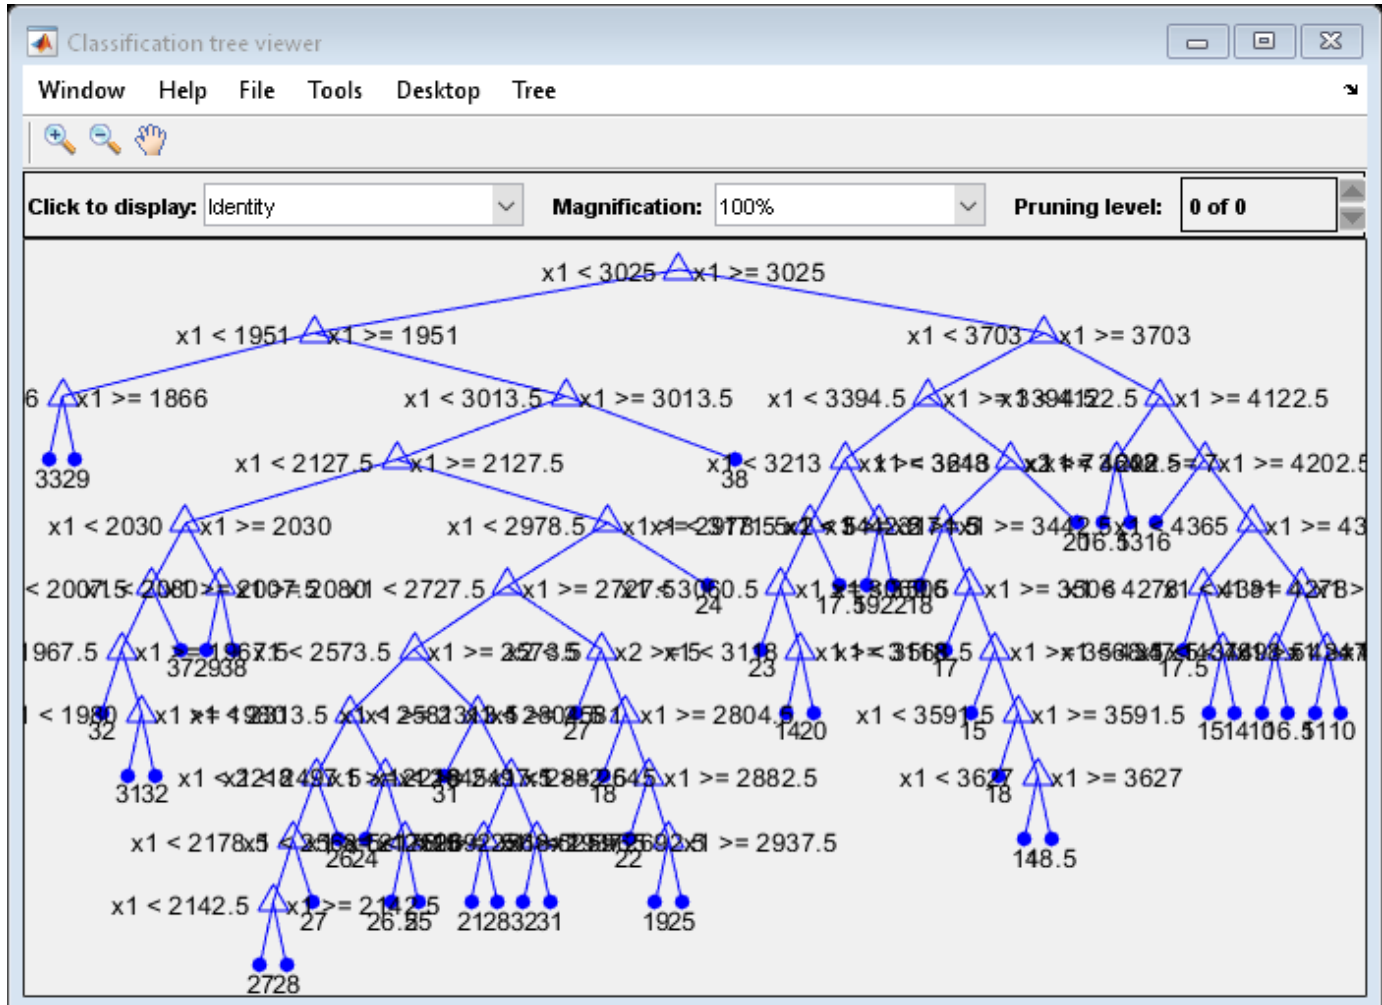

```
rng(1) % For reproducibility
Mdl = TreeBagger(100,X,Y);
```

Alternatively, you can use `fitensemble` to grow a bag of regression trees.

`Mdl` is a `TreeBagger` model object. `Mdl.Trees` stores the bag of 100 trained regression trees in a 100-by-1 cell array. That is, each cell in `Mdl.Trees` contains a `CompactRegressionTree` model object.

View a graph of the 10th regression tree in the bag.

```
Tree10 = Mdl.Trees{10};
view(Tree10, 'Mode', 'graph');
```

By default, the software grows deep trees for bags of trees.

View Tree from Boosted Ensemble

Load the `carsmall` data set. Consider a model that explains a car's fuel economy (MPG) using its weight (`Weight`) and number of cylinders (`Cylinders`).

```
load carsmall
X = [Weight Cylinders];
Y = MPG;
```

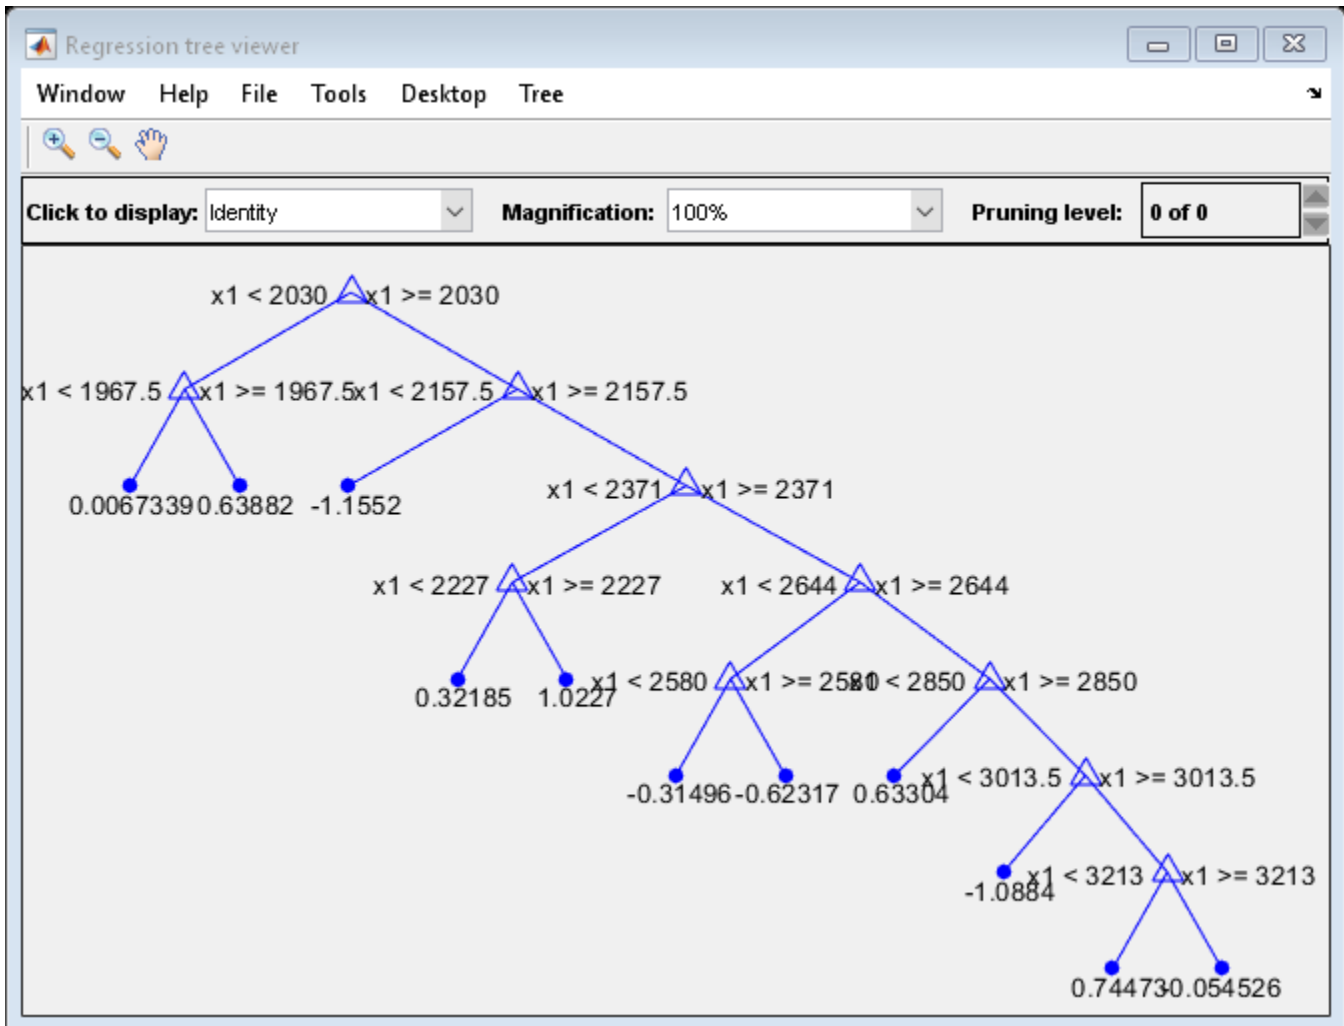

Boost an ensemble of 100 regression trees using all measurements.

```
Mdl = fitensemble(X,Y, 'Method', 'LSBoost');
```

Mdl is a RegressionEnsemble model object. Mdl.Trained stores the ensemble of 100 trained regression trees in a 100-by-1 cell array. That is, each cell in Mdl.Trained contains a CompactRegressionTree model object.

View a graph of the 10th regression tree in the ensemble.

```
Tree10 = Mdl.Trained{10};
view(Tree10, 'Mode', 'graph');
```

By default, fitrensemble grows shallow trees for boosted ensembles of trees. That is, 'Learners' is templateTree('MaxNumSplits', 10).

Tip

To view tree t from an ensemble of trees, enter one of these lines of code

```
view(Ens.Trained{t})
view(Bag.Trees{t})
```

- **Ens** is a full ensemble returned by `fitrensemble` or a compact ensemble returned by `compact`.
- **Bag** is a full bag of trees returned by `TreeBagger` or a compact bag of trees returned by `compact`.

To save `tree` in the Command Window, get a figure handle by using the `findall` and `setdiff` functions, and then save `tree` using the function `saveas`.

```
before = findall(groot,'Type','figure'); % Find all figures
view(Mdl,'Mode','graph')
after = findall(groot,'Type','figure');
h = setdiff(after,before); % Get the figure handle of the tree viewer
saveas(h,'a.png')
```

RegressionTree | `fitrtree`

wblcdf

Weibull cumulative distribution function

Syntax

```
p = wblcdf(x,a,b)
[p,plo,pup] = wblcdf(x,a,b,pcov,alpha)
[p,plo,pup] = wblcdf( ___, 'upper')
```

Description

`p = wblcdf(x,a,b)` returns the cdf of the Weibull distribution with scale parameter `a` and shape parameter `b`, at each value in `x`. `x`, `a`, and `b` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for `a` and `b` are both 1. The parameters `a` and `b` must be positive.

`[p,plo,pup] = wblcdf(x,a,b,pcov,alpha)` returns confidence bounds for `p` when the input parameters `a` and `b` are estimates. `pcov` is the 2-by-2 covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies 100(1 - `alpha`)% confidence bounds. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds.

`[p,plo,pup] = wblcdf(___, 'upper')` returns the complement of the Weibull cdf for each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use 'upper' with any of the previous syntaxes.

The function `wblcdf` computes confidence bounds for `p` using a normal approximation to the distribution of the estimate

$$\widehat{b} (\log x - \log \widehat{a})$$

and then transforms those bounds to the scale of the output `p`. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The Weibull cdf is

$$p = F(x|a,b) = \int_0^x b a^{-b} t^{b-1} e^{-\left(\frac{t}{a}\right)^b} dt = 1 - e^{-\left(\frac{x}{a}\right)^b}.$$

Examples

Weibull Distribution cdf

What is the probability that a value from a Weibull distribution with parameters `a = 0.15` and `b = 0.8` is less than 0.5?

```
probability = wblcdf(0.5, 0.15, 0.8)
```

```
probability = 0.9272
```

How sensitive is this result to small changes in the parameters?

```
[A, B] = meshgrid(0.1:0.05:0.2,0.2:0.05:0.3);
```

```
probability = wblcdf(0.5, A, B)
```

```
probability = 3×3
```

```
    0.7484    0.7198    0.6991  
    0.7758    0.7411    0.7156  
    0.8022    0.7619    0.7319
```

Topics

“Weibull Distribution” on page B-170

Introduced before R2006a

wblfit

Weibull parameter estimates

Syntax

```
parmHat = wblfit(x)
```

```
[parmHat,parmCI] = wblfit(x)
[parmHat,parmCI] = wblfit(x,alpha)
```

```
[ ___ ] = wblfit(x,alpha,censoring)
[ ___ ] = wblfit(x,alpha,censoring,freq)
[ ___ ] = wblfit(x,alpha,censoring,freq,options)
```

Description

`parmHat = wblfit(x)` returns the estimates of Weibull distribution parameters (shape and scale), given the sample data in `x`.

`[parmHat,parmCI] = wblfit(x)` also returns the 95% confidence intervals for the parameter estimates.

`[parmHat,parmCI] = wblfit(x,alpha)` specifies the confidence level for the confidence intervals to be $100(1-\alpha)\%$.

`[___] = wblfit(x,alpha,censoring)` specifies whether each value in `x` is right-censored or not. Use the logical vector `censoring` in which 1 indicates observations that are right-censored and 0 indicates observations that are fully observed.

`[___] = wblfit(x,alpha,censoring,freq)` specifies the frequency or weights of observations.

`[___] = wblfit(x,alpha,censoring,freq,options)` specifies optimization options for the iterative algorithm `wblfit` to use to compute maximum likelihood estimates (MLEs) with censoring. Create options by using the function `statset`.

You can pass in `[]` for `alpha`, `censoring`, and `freq` to use their default values.

Examples

Estimate Parameters of Weibull Distribution

Generate 100 random numbers from the Weibull distribution with scale 0.8 and shape 3.

```
x = wblrnd(0.8,3,100,1);
```

Estimate the parameters of the Weibull distribution from the data.

```
parmHat = wblfit(x)
```

```
parmHat = 1×2
```

```
0.7751    2.9433
```

Estimate Parameters of Weibull Distribution with Confidence Intervals

Generate 100 random numbers from the Weibull distribution with scale 1 and shape 2.

```
x = wblrnd(1,2,100,1);
```

Find the 95% confidence intervals estimating the parameters of the Weibull distribution from the data.

```
[parmHat,parmCI] = wblfit(x)
```

```
parmHat = 1×2
```

```
0.9536    1.9622
```

```
parmCI = 2×2
```

```
0.8583    1.6821  
1.0596    2.2890
```

The top row of `parmCI` contains the lower bounds of the confidence intervals and the bottom row contains the upper bounds of the confidence intervals.

Estimate Weibull Parameters with Algorithm Options

Generate 100 Weibull random variables from the distribution with scale 2 and shape 5.

```
x = wblrnd(2,5,100,1);
```

Display the algorithm parameters for `wblfit`.

```
statset('wblfit')
```

```
ans = struct with fields:
```

```
    Display: 'off'

```

Specify algorithm parameters using name-value pair arguments of the function `statset`. Change how results are displayed (`Display`), and set the termination tolerance for parameters (`TolX`).

```
options = statset('Display','iter','TolX',1e-4); % Optimization options
```

Find the MLEs using the new algorithm parameters.

```
parmhat = wblfit(x,[],[],[],options)
```

Func-count	x	f(x)	Procedure
2	0.193283	-0.0172927	initial
3	0.205467	0.00262429	interpolation
4	0.203862	2.99018e-05	interpolation
5	0.203862	2.99018e-05	interpolation

Zero found in the interval [0.193283, 0.386565]

```
parmhat = 1×2
```

```
    1.9624    4.9050
```

`wblfit` displays information about the iterations.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

alpha — Significance level

0.05 (default) | scalar in the range (0,1)

Significance level for the confidence intervals, specified as a scalar in the range (0,1). The confidence level is $100(1-\alpha)\%$, where `alpha` is the probability that the confidence intervals do not contain the true value.

Example: 0.01

Data Types: `single` | `double`

censoring — Indicator for censoring

array of 0s (default) | logical vector

Indicator for the censoring of each value in x , specified as a logical vector of the same size as x . Use 1 for observations that are right-censored and 0 for observations that are fully observed.

The default is an array of 0s, meaning that all observations are fully observed.

Data Types: `logical`

freq — Frequency or weights of observations

array of 1s (default) | nonnegative vector

Frequency or weights of observations, specified as a nonnegative vector that is the same size as x . The `freq` input argument typically contains nonnegative integer counts for the corresponding elements in x , but can contain any nonnegative values.

To obtain the weighted MLEs for a data set with censoring, specify weights of observations, normalized to the number of observations in x .

The default is an array of 1s, meaning one observation per element of x .

Data Types: `single` | `double`

options — Optimization options

`statset('wblfit')` (default) | structure

Optimization options, specified as a structure. `options` determines the control parameters for the iterative algorithm that `wblfit` uses to compute MLEs for censored data.

Create `options` by using the function `statset` or by creating a structure array containing the fields and values described in this table.

Field Name	Value	Default Value
<code>Display</code>	Amount of information displayed by the algorithm. <ul style="list-style-type: none"> <code>'off'</code> — Displays no information <code>'final'</code> — Displays the final output <code>'iter'</code> — Displays iterative output 	<code>'off'</code>
<code>TolX</code>	Termination tolerance for the parameters, specified as a positive scalar	<code>1e-8</code>

You can also enter `statset('wblfit')` in the Command Window to see the names and default values of the fields that `wblfit` includes in the `options` structure.

Example: `statset('Display','iter')` specifies to display the information from each step of the iterative algorithm.

Data Types: `struct`

Output Arguments

parmHat — Estimate of parameters

1-by-2 row vector

Estimate of the parameters a (scale) and b (shape) of the Weibull distribution, returned as a row vector.

parmCI — Confidence intervals for parameters

2-by-2 matrix

Confidence intervals for the mean parameters of the Weibull distribution, returned as a 2-by-2 matrix vector containing the lower and upper bounds of the $100(1-\alpha)\%$ confidence interval.

The first and second rows correspond to the lower and upper bounds of the confidence intervals, respectively.

Alternative Functionality

`wblfit` is a function specific to Weibull distribution. Statistics and Machine Learning Toolbox also offers the generic functions `mle`, `fitdist`, and `paramci` and the **Distribution Fitter** app, which support various probability distributions.

- `mle` returns MLEs and the confidence intervals of MLEs for the parameters of various probability distributions. You can specify the probability distribution name or a custom probability density function.
- Create a `WeibullDistribution` probability distribution object by fitting the distribution to data using the `fitdist` function or the **Distribution Fitter** app. The object properties `a` and `b` store the parameter estimates. To obtain the confidence intervals for the parameter estimates, pass the object to `paramci`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

wblinv

Weibull inverse cumulative distribution function

Syntax

```
X = wblinv(P,A,B)
[X,XLO,XUP] = wblinv(P,A,B,PCOV,alpha)
```

Description

`X = wblinv(P,A,B)` returns the inverse cumulative distribution function (cdf) for a Weibull distribution with scale parameter `A` and shape parameter `B`, evaluated at the values in `P`. `P`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for `A` and `B` are both 1.

`[X,XLO,XUP] = wblinv(P,A,B,PCOV,alpha)` returns confidence bounds for `X` when the input parameters `A` and `B` are estimates. `PCOV` is a 2-by-2 matrix containing the covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies 100(1 - `alpha`)% confidence bounds. `XLO` and `XUP` are arrays of the same size as `X` containing the lower and upper confidence bounds.

The function `wblinv` computes confidence bounds for `X` using a normal approximation to the distribution of the estimate

$$\log \hat{a} + \frac{\log q}{\hat{b}}$$

where q is the P th quantile from a Weibull distribution with scale and shape parameters both equal to 1. The computed bounds give approximately the desired confidence level when you estimate μ , σ , and `PCOV` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The inverse of the Weibull cdf is

$$x = F^{-1}(p | a, b) = -a[\ln(1 - p)]^{1/b}.$$

Examples

The lifetimes (in hours) of a batch of light bulbs has a Weibull distribution with parameters $a = 200$ and $b = 6$.

Find the median lifetime of the bulbs:

```
life = wblinv(0.5, 200, 6)
life =
    188.1486
```

Generate 100 random values from this distribution, and estimate the 90th percentile (with confidence bounds) from the random sample

```
x = wblrnd(200,6,100,1);  
p = wblfit(x)  
[nlogl,pcov] = wbllike(p,x)  
[q90,q90lo,q90up] = wblinv(0.9,p(1),p(2),pcov)  
p =
```

```
    204.8918    6.3920
```

```
nlogl =
```

```
    496.8915
```

```
pcov =
```

```
    11.3392    0.5233  
     0.5233    0.2573
```

```
q90 =
```

```
    233.4489
```

```
q90lo =
```

```
    226.0092
```

```
q90up =
```

```
    241.1335
```

Topics

“Weibull Distribution” on page B-170

Introduced before R2006a

wbllike

Weibull negative log-likelihood

Syntax

```
nlogL = wbllike(params,data)
[logL,AVAR] = wbllike(params,data)
[...] = wbllike(params,data,censoring)
[...] = wbllike(params,data,censoring,freq)
```

Description

`nlogL = wbllike(params,data)` returns the Weibull log-likelihood. `params(1)` is the scale parameter, `A`, and `params(2)` is the shape parameter, `B`.

`[logL,AVAR] = wbllike(params,data)` also returns `AVAR`, which is the asymptotic variance-covariance matrix of the parameter estimates if the values in `params` are the maximum likelihood estimates. `AVAR` is the inverse of Fisher's information matrix. The diagonal elements of `AVAR` are the asymptotic variances of their respective parameters.

`[...] = wbllike(params,data,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = wbllike(params,data,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. `freq` typically contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `censoring` to use its default value.

The Weibull negative log-likelihood for uncensored data is

$$(-\log L) = -\log \prod_{i=1}^n f(a,b|x_i) = -\sum_{i=1}^n \log f(a,b|x_i)$$

where f is the Weibull pdf.

`wbllike` is a utility function for maximum likelihood estimation.

Examples

This example continues the example from `wblfit`.

```
r = wblrnd(0.5,0.8,100,1);
[logL, AVAR] = wbllike(wblfit(r),r)
logL =
    47.3349
AVAR =
    0.0048    0.0014
    0.0014    0.0040
```

Introduced before R2006a

wblpdf

Weibull probability density function

Syntax

```
y = wblpdf(x)
y = wblpdf(x,a)
y = wblpdf(x,a,b)
```

Description

`y = wblpdf(x)` returns the probability density function (pdf) of the Weibull distribution with unit parameters, evaluated at the values in `x`.

`y = wblpdf(x,a)` returns the pdf of the Weibull distribution with scale parameter `a` and unit shape, evaluated at the values in `x`. This is equivalent to the pdf of the exponential distribution.

`y = wblpdf(x,a,b)` returns the pdf of the Weibull distribution with scale parameter `a` and shape parameter `b`, evaluated at the values in `x`.

Examples

Compute Weibull pdf

Compute the density of the observed value 3 in the Weibull distribution unit scale and shape.

```
y1 = wblpdf(3)
y1 = 0.0498
```

Compute the density of the observed value 3 in the Weibull distributions with scale parameter 2 and shape parameters 1 through 5.

```
y2 = wblpdf(3,2,1:5)
y2 = 1×5
    0.1116    0.1581    0.1155    0.0427    0.0064
```

Compare Weibull and Exponential pdfs

The exponential distribution with parameter `mu` is a special case of the Weibull distribution, where `a = mu` and `b = 1`.

Compute the density of sample observations in the exponential distributions with means 1 through 5 using `expcdf`.

```
x = 0.2:0.2:1;
mu = 1:5;
y1 = exppdf(x,mu)

y1 = 1×5

    0.8187    0.4094    0.2729    0.2047    0.1637
```

Compute the density of the same sample observations using `wblpdf` where the scale parameter is equal to `mu` and the shape parameter is `1`.

```
y2 = wblpdf(x,mu)

y2 = 1×5

    0.8187    0.4094    0.2729    0.2047    0.1637
```

The two functions return the same values.

Input Arguments

x — Values at which to evaluate pdf

nonnegative scalar value | array of nonnegative scalar values

Values at which to evaluate the pdf, specified as a nonnegative scalar value or an array of nonnegative scalar values.

- To evaluate the pdf at multiple values, specify `x` using an array.
- To evaluate the pdfs of multiple distributions, specify `a` and `b` using arrays.

If one or more of the input arguments `x`, `a`, and `b` are arrays, then the array sizes must be the same. In this case, `wblpdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `y` is the pdf value of the distribution specified by the corresponding elements in `a` and `b`, evaluated at the corresponding element in `x`.

Example: `[3 4 7 9]`

Data Types: `single` | `double`

a — Scale parameter

1 (default) | positive scalar value | array of positive scalar values

Scale parameter of the Weibull distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the pdf at multiple values, specify `x` using an array.
- To evaluate the pdfs of multiple distributions, specify `a` and `b` using arrays.

If one or more of the input arguments `x`, `a`, and `b` are arrays, then the array sizes must be the same. In this case, `wblpdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `y` is the pdf value of the distribution specified by the corresponding elements in `a` and `b`, evaluated at the corresponding element in `x`.

Example: `[1 2 3 5]`

Data Types: `single` | `double`

b — Shape parameter

1 (default) | positive scalar value | array of positive scalar values

Shape parameter of the Weibull distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the pdf at multiple values, specify `x` using an array.
- To evaluate the pdfs of multiple distributions, specify `a` and `b` using arrays.

If one or more of the input arguments `x`, `a`, and `b` are arrays, then the array sizes must be the same. In this case, `wblpdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `y` is the pdf value of the distribution specified by the corresponding elements in `a` and `b`, evaluated at the corresponding element in `x`.

Example: `[1 1 2 2]`

Data Types: `single` | `double`

Output Arguments

y — pdf values

scalar value | array of scalar values

pdf values evaluated at the values in `x`, returned as a scalar value or an array of scalar values. `y` is the same size as `x`, `a`, and `b` after any necessary scalar expansion. Each element in `y` is the pdf value of the distribution specified by the corresponding elements in `a` and `b`, evaluated at the corresponding element in `x`.

More About

Weibull pdf

The Weibull distribution is a two-parameter family of curves. The parameters `a` and `b` are scale and shape, respectively.

The Weibull pdf is

$$f(x|a, b) = \frac{b}{a} \left(\frac{x}{a}\right)^{b-1} e^{-(x/a)^b}.$$

Some instances refer to the Weibull distribution with a single parameter, which corresponds to `wblpdf` with `a = 1`.

For more information, see “Weibull Distribution” on page B-170.

Alternative Functionality

- `wblpdf` is a function specific to the Weibull distribution. Statistics and Machine Learning Toolbox also offers the generic function `pdf`, which supports various probability distributions. To use `pdf`, create a `WeibullDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `wblpdf` is faster than the generic function `pdf`.

- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Topics

“Weibull Distribution” on page B-170

Introduced before R2006a

wblplot

Weibull probability plot

Syntax

```
wblplot(x)
wblplot(ax,x)
h = wblplot( ___ )
```

Description

`wblplot(x)` creates a Weibull probability plot comparing the distribution of the data in `x` to the Weibull distribution.

`wblplot` plots each data point in `x` using plus sign ('+') markers and draws two reference lines that represent the theoretical distribution. A solid reference line connects the first and third quartiles of the data, and a dashed reference line extends the solid line to the ends of the data. If the sample data has a Weibull distribution, then the data points appear along the reference line. A distribution other than Weibull introduces curvature in the data plot.

`wblplot(ax,x)` adds a Weibull probability plot into the axes specified by `ax`.

`h = wblplot(___)` returns graphics handles corresponding to the plotted lines, using any of the input arguments in the previous syntaxes.

Examples

Create Weibull Probability Plot

Generate a vector `r` containing 50 random numbers from the Weibull distribution with the scale parameter 1.2 and the shape parameter 1.5.

```
rng('default') % For reproducibility
r = wblrnd(1.2,1.5,50,1);
```

Create a Weibull probability plot to visually determine if the data comes from a Weibull distribution.

```
wblplot(r)
```

The plot indicates that the data likely comes from a Weibull distribution.

Test for Weibull Distribution

Generate two sample data sets, one from a Weibull distribution and another from a lognormal distribution. Perform the Lilliefors test to assess whether each data set is from a Weibull distribution. Confirm the test decision by performing a visual comparison using a Weibull probability plot (`wblplot`).

Generate samples from a Weibull distribution.

```
rng('default')
data1 = wblrnd(0.5,2,[500,1]);
```

Perform the Lilliefors test by using the `lillietest`. To test data for a Weibull distribution, test if the logarithm of the data has an extreme value distribution.

```
h1 = lillietest(log(data1),'Distribution','extreme value')
h1 = 0
```

The returned value of `h1 = 0` indicates that `lillietest` fails to reject the null hypothesis at the default 5% significance level. Confirm the test decision using a Weibull probability plot.

```
wblplot(data1)
```

The plot indicates that the data follows a Weibull distribution.

Generate samples from a lognormal distribution.

```
data2 =lognrnd(5,2,[500,1]);
```

Perform the Lilliefors test.

```
h2 = lillietest(log(data2),'Distribution','extreme value')
```

```
h2 = 1
```

The returned value of $h2 = 1$ indicates that `lillietest` rejects the null hypothesis at the default 5% significance level. Confirm the test decision using a Weibull probability plot.

```
wblplot(data2)
```

The plot indicates that the data does not follow a Weibull distribution.

Input Arguments

x — Sample data

numeric vector | numeric matrix

Sample data, specified as a numeric vector or numeric matrix. `wblplot` displays each value in `x` using the symbol '+'. If `x` is a matrix, then `wblplot` displays a separate line for each column of `x`.

Data Types: `single` | `double`

ax — Target axes

Axes object | UIAxes object

Target axes, specified as an Axes object or a UIAxes object. `wblplot` adds an additional plot into the axes specified by `ax`. For details, see Axes Properties and UIAxes Properties.

Use `gca` to return the current axes for the current figure.

Output Arguments

h — Graphics handles for line objects

vector of Line graphics handles

Graphics handles for line objects, returned as a vector of `Line` graphics handles. Graphics handles are unique identifiers that you can use to query and modify the properties of a specific line on the plot. For each column of `x`, `wblplot` returns three handles:

- The line representing the data points. `wblplot` represents each data point in `x` using plus sign ('+') markers.
- The line joining the first and third quartiles of each column of `x`, represented as a solid line.
- The extrapolation of the quartile line, extended to the minimum and maximum values of `x`, represented as a dashed line.

To view and set properties of line objects, use dot notation. For information on using dot notation, see “Access Property Values” (MATLAB). For information on the `Line` properties that you can set, see `Primitive Line`.

Algorithms

`wblplot` matches the quantiles of sample data to the quantiles of a Weibull distribution. The sample data is sorted, scaled logarithmically, and plotted on the x-axis. The y-axis represents the quantiles of the Weibull distribution, converted into probability values. Therefore, the y-axis scaling is not linear.

Where the x-axis value is the i th sorted value from a sample of size N , the y-axis value is the midpoint between evaluation points of the empirical cumulative distribution function of the data. The midpoint is equal to $\frac{(i - 0.5)}{N}$.

`wblplot` superimposes a reference line to assess the linearity of the plot. The line goes through the first and third quartiles of the data.

Alternative Functionality

You can use the `probplot` function to create a probability plot. The `probplot` function enables you to indicate censored data and specify the distribution for a probability plot.

wblrnd

Weibull random numbers

Syntax

```
r = wblrnd(a,b)
r = wblrnd(a,b,sz1,...,szN)
r = wblrnd(a,b,sz)
```

Description

`r = wblrnd(a,b)` generates a random number from the Weibull distribution with scale `a` and shape `b`.

`r = wblrnd(a,b,sz1,...,szN)` generates an array of random numbers from the Weibull distribution, where `sz1,...,szN` indicates the size of each dimension.

`r = wblrnd(a,b,sz)` generates an array of random numbers from the Weibull distribution where size vector `sz` specifies `size(r)`.

Examples

Generate Weibull Random Number

Generate a single random number from the Weibull distribution with scale 4 and shape 3.

```
r = wblrnd(4,3)
```

```
r = 2.3582
```

Generate Weibull Random Numbers

Generate a 1-by-5 array of random numbers drawn from the Weibull distributions with scale 3 and shape values 1 through 5.

```
a1 = 3;
b1 = 1:5;
r1 = wblrnd(a1,b1)
```

```
r1 = 1×5
```

```
    0.6147    0.9437    3.8195    1.6459    2.5666
```

If you specify array dimensions, they must match the dimensions of `a` and `b` after any scalar expansion.

Generate a 1-by-6 array of random numbers drawn from the Weibull distributions with scale values 1 through 6 and shape values 5 through 10, respectively.

```
a2 = 1:6;  
b2 = 5:10;  
sz1 = 1;  
sz2 = 6;  
r2 = wblrnd(a2,b2,sz1,sz2)
```

```
r2 = 1×6
```

```
    1.1841    2.0836    2.7912    2.7026    3.4531    6.3799
```

Generate a 2-by-3 array of random numbers from the Weibull distribution with scale 4 and shape 5.

```
sz = [2 3];  
r3 = wblrnd(4,5,sz)
```

```
r3 = 2×3
```

```
    1.9817    3.7486    4.5729  
    2.1395    2.9624    3.8841
```

Input Arguments

a — Scale parameter

positive scalar value | array of positive scalar values

Scale parameter of the Weibull distribution, specified as a positive scalar value or an array of positive scalar values.

To generate random numbers from multiple distributions, specify **a** and **b** using arrays. If either or both of the input arguments **a** and **b** are arrays, then the array sizes must be the same. In this case, `wblrnd` expands each scalar input into a constant array of the same size as the array inputs. Each element in **r** is the random number generated from the distribution specified by the corresponding elements in **a** and **b**.

Example: [1 2 3 5]

Data Types: `single` | `double`

b — Shape parameter

positive scalar value | array of positive scalar values

Shape parameter of the Weibull distribution, specified as a positive scalar value or an array of positive scalar values.

To generate random numbers from multiple distributions, specify **a** and **b** using arrays. If either or both of the input arguments **a** and **b** are arrays, then the array sizes must be the same. In this case, `wblrnd` expands each scalar input into a constant array of the same size as the array inputs. Each element in **r** is the random number generated from the distribution specified by the corresponding elements in **a** and **b**.

Example: [1 1 2 2]

Data Types: `single` | `double`

sz1, ..., szN — Size of each dimension (as separate arguments)

integers

Size of each dimension, specified as separate arguments of integers.

If **a** and **b** are arrays, then the specified dimensions `sz1, ..., szN` must match the dimensions of **a** and **b**. The default values of `sz1, ..., szN` are the dimensions of **a** and **b**.

- If you specify a single value `sz1`, then **r** is a square matrix of size `sz1-by-sz1`.
- If the size of any dimension is 0 or negative, then **r** is an empty array.
- Beyond the second dimension, `wblrnd` ignores trailing dimensions with a size of 1. For example, `wblrnd(2,5,3,1,1,1)` produces a 3-by-1 vector of random numbers from the distribution with scale 2 and shape 5.

Example: `3,5`

Data Types: `single` | `double`

sz — Size of each dimension (as a row vector)

row vector of integers

Size of each dimension, specified as a row vector of integers.

If **a** and **b** are arrays, then the specified dimensions `sz` must match the dimensions of **a** and **b**. The default values of `sz` are the dimensions of **a** and **b**.

- If you specify a single value `[sz1]`, then **r** is a square matrix of size `sz1-by-sz1`.
- If the size of any dimension is 0 or negative, then **r** is an empty array.
- Beyond the second dimension, `wblrnd` ignores trailing dimensions with a size of 1. For example, `wblrnd(2,5,[3 1 1 1])` produces a 3-by-1 vector of random numbers from the distribution with scale 2 and shape 5.

Example: `[3 5]`

Data Types: `single` | `double`

Output Arguments

r — Weibull random numbers

scalar value | array of scalar values

Weibull random numbers, returned as a scalar value or an array of scalar values with the dimensions specified by `sz1, ..., szN` or `sz`. Each element in **r** is the random number generated from the distribution specified by the corresponding elements in **a** and **b**.

Alternative Functionality

- `wblrnd` is a function specific to the Weibull distribution. Statistics and Machine Learning Toolbox also offers the generic function `random`, which supports various probability distributions. To use `random`, specify the probability distribution name and its parameters. Note that the distribution-specific function `wblrnd` is faster than the generic function `random`.

- To generate random numbers interactively, use `randtool`, a user interface for random number generation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers from the sequence returned by MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

wblstat

Weibull mean and variance

Syntax

```
[M,V] = wblstat(A,B)
```

Description

`[M,V] = wblstat(A,B)` returns the mean of and variance for the Weibull distribution with scale parameter, *A* and shape parameter, *B*. Vector or matrix inputs for *A* and *B* must have the same size, which is also the size of *M* and *V*. A scalar input for *A* or *B* is expanded to a constant matrix with the same dimensions as the other input.

The mean of the Weibull distribution with parameters *a* and *b* is

$$a[\Gamma(1 + b^{-1})]$$

and the variance is

$$a^2[\Gamma(1 + 2b^{-1}) - \Gamma(1 + b^{-1})^2]$$

Examples

```
[m,v] = wblstat(1:4,1:4)
m =
    1.0000    1.7725    2.6789    3.6256
v =
    1.0000    0.8584    0.9480    1.0346

wblstat(0.5,0.7)
ans =
    0.6329
```

wishrnd

Wishart random numbers

Syntax

```
W = wishrnd(Sigma,df)
W = wishrnd(Sigma,df,D)
[W,D] = wishrnd(Sigma,df)
```

Description

`W = wishrnd(Sigma,df)` generates a random matrix `W` having the Wishart distribution with covariance matrix `Sigma` and with `df` degrees of freedom. The inverse of `W` has the Inverse Wishart distribution with parameters `Tau = inv(Sigma)` and `df` degrees of freedom.

`W = wishrnd(Sigma,df,D)` expects `D` to be the Cholesky factor of `Sigma`. If you call `wishrnd` multiple times using the same value of `Sigma`, it's more efficient to supply `D` instead of computing it each time.

`[W,D] = wishrnd(Sigma,df)` returns `D` so you can provide it as input in future calls to `wishrnd`.

This function defines the parameter `Sigma` so that the mean of the output matrix is `Sigma*df`

xptread

Create table from data stored in SAS XPORT format file

Syntax

```
data = xptread
data = xptread(filename)
[data,missing] = xptread(filename)
xptread(...,'ReadObsNames',true)
```

Description

`data = xptread` displays a dialog box for selecting a file, then reads data from the file into a table. The file must be in the SAS XPORT format.

`data = xptread(filename)` retrieves data from a SAS XPORT format file `filename`. For example, to open a SAS XPORT file named `sample.xpt`, type `data = xptread('sample.xpt')` at the command prompt.

`[data,missing] = xptread(filename)` returns a nominal array, `missing`, that contains the missing data type information from the XPORT format file.

The XPORT format allows for 28 missing data types, represented in the file by an upper case letter or the characters `'.'` or `'_'`. If the XPORT file contains missing values, `xptread` converts them to NaN values in the output table, `data`. However, if you need the specific missing types, you can recover this information by specifying a second output, `missing`. The entries in `missing` are one of the 28 missing data type values from the XPORT format file (`'.'`, `'_'`, `'A'`, ..., `'Z'`), or are undefined for values that are not present at all in the XPORT format file. The outputs `missing` and `data` are the same size.

`xptread(...,'ReadObsNames',true)` treats the first variable in the file as observation names. The default value is `false`.

`xptread` only supports single data sets per file. `xptread` does not support compressed files.

Introduced in R2009b

x2fx

Convert predictor matrix to design matrix

Syntax

```
D = x2fx(X,model)
D = x2fx(X,model,categ)
D = x2fx(X,model,categ,catlevels)
```

Description

$D = \text{x2fx}(X, \text{model})$ converts a matrix of predictors X to a design matrix D for regression analysis. Distinct predictor variables should appear in different columns of X .

The optional input *model* controls the regression model. By default, `x2fx` returns the design matrix for a linear additive model with a constant term. *model* is one of the following:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

If X has n columns, the order of the columns of D for a full quadratic model is:

- 1 The constant term
- 2 The linear terms (the columns of X , in order 1, 2, ..., n)
- 3 The interaction terms (pairwise products of the columns of X , in order (1, 2), (1, 3), ..., (1, n), (2, 3), ..., ($n-1$, n))
- 4 The squared terms (in order 1, 2, ..., n)

Other models use a subset of these terms, in the same order.

Alternatively, *model* can be a matrix specifying polynomial terms of arbitrary order. In this case, *model* should have one column for each column in X and one row for each term in the model. The entries in any row of *model* are powers for the corresponding columns of X . For example, if X has columns X_1 , X_2 , and X_3 , then a row $[0 \ 1 \ 2]$ in *model* specifies the term $(X_1.^0) .* (X_2.^1) .* (X_3.^2)$. A row of all zeros in *model* specifies a constant term, which can be omitted.

$D = \text{x2fx}(X, \text{model}, \text{categ})$ treats columns with numbers listed in the vector *categ* as categorical variables. Terms involving categorical variables produce dummy variable columns in D . Dummy variables are computed under the assumption that possible categorical levels are completely enumerated by the unique values that appear in the corresponding column of X .

$D = \text{x2fx}(X, \text{model}, \text{categ}, \text{catlevels})$ accepts a vector *catlevels* the same length as *categ*, specifying the number of levels in each categorical variable. In this case, values in the corresponding column of X must be integers in the range from 1 to the specified number of levels. Not all of the levels need to appear in X .

Examples

Example 1

The following converts 2 predictors X1 and X2 (the columns of X) into a design matrix for a full quadratic model with terms constant, X1, X2, X1.*X2, X1.^2, and X2.^2.

```
X = [1 10
     2 20
     3 10
     4 20
     5 15
     6 15];
```

```
D = x2fx(X, 'quadratic')
```

```
D =
     1     1    10    10     1   100
     1     2    20    40     4   400
     1     3    10    30     9   100
     1     4    20    80    16   400
     1     5    15    75    25   225
     1     6    15    90    36   225
```

Example 2

The following converts 2 predictors X1 and X2 (the columns of X) into a design matrix for a quadratic model with terms constant, X1, X2, X1.*X2, and X1.^2.

```
X = [1 10
     2 20
     3 10
     4 20
     5 15
     6 15];
model = [0 0
         1 0
         0 1
         1 1
         2 0];
```

```
D = x2fx(X, model)
```

```
D =
     1     1    10    10     1
     1     2    20    40     4
     1     3    10    30     9
     1     4    20    80    16
     1     5    15    75    25
     1     6    15    90    36
```

Introduced before R2006a

zscore

Standardized z-scores

Syntax

```
Z = zscore(X)
Z = zscore(X, flag)
Z = zscore(X, flag, 'all')
Z = zscore(X, flag, dim)
Z = zscore(X, flag, vecdim)
[Z, mu, sigma] = zscore( ___ )
```

Description

`Z = zscore(X)` returns the z-score on page 32-5844 for each element of `X` such that columns of `X` are centered to have mean 0 and scaled to have standard deviation 1. `Z` is the same size as `X`.

- If `X` is a vector, then `Z` is a vector of z-scores.
- If `X` is a matrix, then `Z` is a matrix of the same size as `X`, and each column of `Z` has mean 0 and standard deviation 1.
- For multidimensional arrays on page 32-5845, z-scores in `Z` are computed along the first nonsingleton dimension on page 32-5845 of `X`.

`Z = zscore(X, flag)` scales `X` using the standard deviation indicated by `flag`.

- If `flag` is 0 (default), then `zscore` scales `X` using the sample standard deviation on page 32-5845, with $n - 1$ in the denominator of the standard deviation formula. `zscore(X, 0)` is the same as `zscore(X)`.
- If `flag` is 1, then `zscore` scales `X` using the population standard deviation on page 32-5845, with n in the denominator of standard deviation formula.

`Z = zscore(X, flag, 'all')` standardizes `X` by using the mean and standard deviation of all the values in `X`.

`Z = zscore(X, flag, dim)` standardizes `X` along the operating dimension `dim`. For example, for a matrix `X`, if `dim = 1`, then `zscore` uses the means and standard deviations along the columns of `X`, if `dim = 2`, then `zscore` uses the means and standard deviations along the rows of `X`.

`Z = zscore(X, flag, vecdim)` standardizes `X` over the dimensions specified by the vector `vecdim`. For example, if `X` is a matrix, then `zscore(X, 0, [1 2])` is equivalent to `zscore(X, 0, 'all')` because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.

`[Z, mu, sigma] = zscore(___)` also returns the means and standard deviations used for centering and scaling, `mu` and `sigma`, respectively. You can use any of the input arguments in the previous syntaxes.

Examples

Z-Scores of Two Data Vectors

Compute and plot the z-scores of two data vectors, and then compare the results.

Load the sample data.

```
load lawdata
```

Two variables load into the workspace: `gpa` and `lsat`.

Plot both variables on the same axes.

```
plot([gpa,lsat])
legend('gpa','lsat','Location','East')
```

It is difficult to compare these two measures because they are on a very different scale.

Plot the z-scores of `gpa` and `lsat` on the same axes.

```
Zgpa = zscore(gpa);
Zlsat = zscore(lsat);
plot([Zgpa, Zlsat])
legend('gpa z-scores','lsat z-scores','Location','Northeast')
```

Now, you can see the relative performance of individuals with respect to both their `gpa` and `lsat` results. For example, the third individual's `gpa` and `lsat` results are both one standard deviation below the sample mean. The eleventh individual's `gpa` is around the sample mean but has an `lsat` score almost 1.25 standard deviations above the sample average.

Check the mean and standard deviation of the z-scores you created.

```
mean([Zgpa,Zlsat])
ans = 1×2
10-14 ×
    -0.1088    0.0357

std([Zgpa,Zlsat])
ans = 1×2
     1     1
```

By definition, z-scores of `gpa` and `lsat` have mean 0 and standard deviation 1.

Z-Scores for a Population vs. Sample

Load the sample data.

```
load lawdata
```

Two variables load into the workspace: `gpa` and `lsat`.

Compute the z-scores of `gpa` using the population formula for standard deviation.

```
Z1 = zscore(gpa,1); % population formula
Z0 = zscore(gpa,0); % sample formula
disp([Z1 Z0])
```

```
    1.2554    1.2128
    0.8728    0.8432
   -1.2100   -1.1690
   -0.2749   -0.2656
    1.4679    1.4181
   -0.1049   -0.1013
   -0.4024   -0.3888
    1.4254    1.3771
    1.1279    1.0896
    0.1502    0.1451
    0.1077    0.1040
   -1.5076   -1.4565
   -1.4226   -1.3743
   -0.9125   -0.8815
   -0.5724   -0.5530
```

For a sample from a population, the population standard deviation formula with n in the denominator corresponds to the maximum likelihood estimate of the population standard deviation, and might be biased. The sample standard deviation formula, on the other hand, is the unbiased estimator of the population standard deviation for a sample.

Z-Scores of a Data Matrix

Compute z-scores using the mean and standard deviation computed along the columns or rows of a data matrix.

Load the sample data.

```
load flu
```

The dataset array `flu` is loaded in the workplace. `flu` has 52 observations on 11 variables. The first variable contains dates (in weeks). The other variables contain the flu estimates for different regions in the U.S.

Convert the dataset array to a data matrix.

```
flu2 = double(flu(:,2:end));
```

The new data matrix, `flu2`, is a 52-by-10 double data matrix. The rows correspond to the weeks and the columns correspond to the U.S. regions in the data set array `flu`.

Standardize the flu estimate for each region (the *columns* of `flu2`).

```
Z1 = zscore(flu2,[ ],1);
```

You can see the z-scores in the variable editor by double-clicking on the matrix `Z1` created in the workspace.

Standardize the flu estimate for each week (the *rows* of `flu2`).

```
Z2 = zscore(flu2,[ ],2);
```

Z-Scores of Multidimensional Array

Find the z-scores of a multidimensional array by specifying to standardize the data along different dimensions. Compare the results when using the `'all'`, `dim`, and `vecdim` input arguments.

Create a 3-by-4-by-2 array.

```
X = reshape(1:24,[3 4 2])
```

```
X =
```

```
X(:,:,1) =
```

```
     1     4     7    10
     2     5     8    11
     3     6     9    12
```

```
X(:,:,2) =
```

```
    13    16    19    22
    14    17    20    23
    15    18    21    24
```

Standardize `X` by using the mean and standard deviation of all the values in `X`.

```
Zall = zscore(X,0,'all')
```

```
Zall =
```

```
Zall(:,:,1) =
```

```
   -1.6263   -1.2021   -0.7778   -0.3536
   -1.4849   -1.0607   -0.6364   -0.2121
   -1.3435   -0.9192   -0.4950   -0.0707
```

```
Zall(:,:,2) =
```

```
    0.0707    0.4950    0.9192    1.3435
    0.2121    0.6364    1.0607    1.4849
    0.3536    0.7778    1.2021    1.6263
```

The resulting multidimensional array of z-scores has mean 0 and standard deviation 1. For example, compute the mean and standard deviation of `Zall`.

```
mZall = mean(Zall(:,:,:), 'all')
```

```
mZall = -9.2519e-18
```

```
sZall = std(Zall(:,:,:),0, 'all')
```

```
sZall = 1.0000
```

Now standardize X along the second dimension.

```
Zdim = zscore(X,0,2)
```

```
Zdim =
```

```
Zdim(:,:,1) =
```

```

-1.1619  -0.3873   0.3873   1.1619
-1.1619  -0.3873   0.3873   1.1619
-1.1619  -0.3873   0.3873   1.1619

```

```
Zdim(:,:,2) =
```

```

-1.1619  -0.3873   0.3873   1.1619
-1.1619  -0.3873   0.3873   1.1619
-1.1619  -0.3873   0.3873   1.1619

```

The elements in each row of each page of Zdim have mean 0 and standard deviation 1. For example, compute the mean and standard deviation of the first row of the second page of Zdim.

```
mZdim = mean(Zdim(1,:,2), 'all')
```

```
mZdim = 0
```

```
sZdim = std(Zdim(1,:,2),0, 'all')
```

```
sZdim = 1
```

Finally, standardize X based on the second and third dimensions.

```
Zvecdim = zscore(X,0,[2 3])
```

```
Zvecdim =
```

```
Zvecdim(:,:,1) =
```

```

-1.4289  -1.0206  -0.6124  -0.2041
-1.4289  -1.0206  -0.6124  -0.2041
-1.4289  -1.0206  -0.6124  -0.2041

```

```
Zvecdim(:,:,2) =
```

```

 0.2041   0.6124   1.0206   1.4289
 0.2041   0.6124   1.0206   1.4289
 0.2041   0.6124   1.0206   1.4289

```

The elements in each Zvecdim(i, :, :) slice have mean 0 and standard deviation 1. For example, compute the mean and standard deviation of the elements in Zvecdim(1, :, :).

```
mZvecdim = mean(Zvecdim(1,:,:),'all')
mZvecdim = 2.7756e-17
sZvecdim = std(Zvecdim(1,:,:),0,'all')
sZvecdim = 1
```

Z-Scores, Mean, and Standard Deviation

Return the mean and standard deviation used to compute the z-scores.

Load the sample data.

```
load lawdata
```

Two variables load into the workspace: `gpa` and `lsat`.

Return the z-scores, mean, and standard deviation of `gpa`.

```
[Z,gpamean,gpastdev] = zscore(gpa)
```

```
Z = 15×1
    1.2128
    0.8432
   -1.1690
   -0.2656
    1.4181
   -0.1013
   -0.3888
    1.3771
    1.0896
    0.1451
    ⋮
```

```
gpamean = 3.0947
```

```
gpastdev = 0.2435
```

Input Arguments

X — Input data

vector | matrix | multidimensional array

Input data, specified as a vector, matrix, or multidimensional array.

Data Types: double | single

flag — Indicator for the standard deviation

0 (default) | 1

Indicator for the standard deviation used to compute the z-scores, specified as 0 or 1.

- If `flag` is 0 (default), then `zscore` scales `X` using the sample standard deviation on page 32-5845. `zscore(X,0)` is the same as `zscore(X)`.
- If `flag` is 1, then `zscore` scales `X` using the population standard deviation on page 32-5845.

dim — Dimension

positive integer scalar

Dimension along which to calculate the z-scores of `X`, specified as a positive integer scalar. If you do not specify a value, then the default value is the first array dimension whose size does not equal 1.

For example, for a matrix `X`, if `dim = 1`, then `zscore` uses the means and standard deviations along the columns of `X`, and if `dim = 2`, then `zscore` uses the means and standard deviations along the rows of `X`.

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions along which to calculate the z-scores of `X`, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. The output `Z` has the same dimensions as `X`, but the mean `mu` and standard deviation `sigma` each have length 1 in the operating dimensions. The other dimension lengths are the same for `X`, `mu`, and `sigma`.

For example, if `X` is a 2-by-3-by-3 array, then `zscore(X,0,[1 2])` uses the means and standard deviations along the pages of `X` to standardize the values of `X`.

Data Types: `single` | `double`

Output Arguments

Z — z-scores

vector | matrix | multidimensional array

z-scores, returned as a vector, matrix, or multidimensional array. `Z` has the same dimensions as `X`.

The values of `Z` depend on whether you specify `'all'`, `dim`, or `vecdim`. If you do not specify any of these input arguments, then the following conditions apply:

- If `X` is a vector, then `Z` is a vector of z-scores with mean 0 and variance 1.
- If `X` is an array, then `zscore` standardizes along the first nonsingleton dimension of `X`.

For an example that demonstrates the differences in `Z` when you use `'all'`, `dim`, and `vecdim`, see “Z-Scores of Multidimensional Array” on page 32-5840.

mu — Mean

scalar | vector | matrix | multidimensional array

Mean of `X` used to compute the z-scores, returned as a scalar, vector, matrix, or multidimensional array. `mu` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `mu`.

For example, if `X` is a 2-by-3-by-3 array and `vecdim` is `[1 2]`, then `mu` is a 1-by-1-by-3 array of means. Each value in `mu` corresponds to the mean of a page in `X`.

sigma — Standard deviation

scalar | vector | matrix | multidimensional array

Standard deviation of X used to compute the z -scores, returned as a scalar, vector, matrix, or multidimensional array. `sigma` has length 1 in the specified operating dimensions. The other dimension lengths are the same for X and `sigma`.

For example, if X is a 2-by-3-by-3 array and `vecdim` is `[1 2]`, then `sigma` is a 1-by-1-by-3 array of standard deviations. Each value in `sigma` corresponds to the standard deviation of a page in X .

More About

Z-Score

For a random variable X with mean μ and standard deviation σ , the z -score of a value x is

$$z = \frac{(x - \mu)}{\sigma}.$$

For sample data with mean \bar{X} and standard deviation S , the z -score of a data point x is

$$z = \frac{(x - \bar{X})}{S}.$$

z -scores measure the distance of a data point from the mean in terms of the standard deviation. This is also called *standardization* of data. The standardized data set has mean 0 and standard deviation 1, and retains the shape properties of the original data set (same skewness and kurtosis).

You can use z -scores to put data on the same scale before further analysis. This lets you to compare two or more data sets with different units.

Multidimensional Array

A *multidimensional array* is an array with more than two dimensions. For example, if X is a 1-by-3-by-4 array, then X is a three-dimensional array.

First Nonsingleton Dimension

A *first nonsingleton dimension* is the first dimension of an array whose size is not equal to 1. For example, if X is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of X .

Sample Standard Deviation

The *sample standard deviation* S is given by

$$S = \sqrt{\frac{\sum_{i=1}^n (x_i - \bar{X})^2}{n-1}}.$$

S is the square root of an unbiased estimator of the variance of the population from which X is drawn, as long as X consists of independent, identically distributed samples. \bar{X} is the sample mean.

Notice that the denominator in this variance formula is $n - 1$.

Population Standard Deviation

If the data is the entire population of values, then you can use the *population standard deviation*,

$$\sigma = \sqrt{\frac{\sum_{i=1}^n (x_i - \mu)^2}{n}}.$$

If X is a random sample from a population, then the mean μ is estimated by the sample mean, and σ is the biased maximum likelihood estimator of the population standard deviation.

Notice that the denominator in this variance formula is n .

Algorithms

`zscore` returns NaNs for any sample containing NaNs.

`zscore` returns 0s for any sample that is constant (all values are the same). For example, if X is a vector of the same numeric value, then Z is a vector of 0s.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The 'all' and `vecdim` input arguments are not supported.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'all' and `vecdim` input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

ztest

z-test

Syntax

```
h = ztest(x,m,sigma)
h= ztest(x,m,sigma,Name,Value)
[h,p] = ztest(____)
[h,p,ci,zval] = ztest(____)
```

Description

`h = ztest(x,m,sigma)` returns a test decision for the null hypothesis that the data in the vector `x` comes from a normal distribution with mean `m` and a standard deviation `sigma`, using the z-test on page 32-5850. The alternative hypothesis is that the mean is not `m`. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h= ztest(x,m,sigma,Name,Value)` returns a test decision for the z-test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = ztest(____)` also returns the *p*-value of the test, using any of the input arguments from previous syntaxes.

`[h,p,ci,zval] = ztest(____)` also returns the confidence interval of the population mean, `ci`, and the value of the test statistic, `zval`.

Examples

z-Test for a Hypothesized Mean

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades
x = grades(:,1);
```

Test the null hypothesis that the data comes from a normal distribution with mean `m = 75` and standard deviation `sigma = 10`.

```
[h,p,ci,zval] = ztest(x,75,10)
```

```
h = 0
```

```
p = 0.9927
```

```
ci = 2×1
```

```
73.2191
76.7975
```

```
zval = 0.0091
```

The returned value of `h = 0` indicates that `ztest` does not reject the null hypothesis at the default 5% significance level.

One-Sided z-Test

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades  
x = grades(:,1);
```

Test the null hypothesis that the data comes from a normal distribution with mean $m = 65$ and standard deviation $\sigma = 10$, against the alternative that the mean is greater than 65.

```
[h,p] = ztest(x,65,10,'Tail','right')
```

```
h = 1
```

```
p = 2.8596e-28
```

The returned value of `h = 1` indicates that `ztest` rejects the null hypothesis at the default 5% significance level, in favor of the alternative hypothesis that the population mean is greater than 65.

Input Arguments

x — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array.

- If `x` is specified as a vector, `ztest` returns a single value for each output argument.
- If `x` is specified as a matrix, `ztest` performs a separate *z*-test along each column of `x` and returns a vector of results.
- If `x` is specified as a multidimensional array on page 32-5850, `ztest` works along the first nonsingleton dimension on page 32-5850 of `x`.

In all cases, `ztest` treats NaN values as missing data and ignores them.

Data Types: `single` | `double`

m — Hypothesized mean

scalar value

Hypothesized mean, specified as a scalar value.

Data Types: `single` | `double`

sigma — Population standard deviation

scalar value

Population standard deviation, specified as a scalar value.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'Tail', 'right', 'Alpha', 0.01` specifies a right-tailed hypothesis test at the 1% significance level.

Alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: single | double

Dim — Dimension

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix along which to test the means, specified as the comma-separated pair consisting of `'Dim'` and a positive integer value. For example, specifying `'Dim', 1` tests the column means, while `'Dim', 2` tests the row means.

Example: `'Dim', 2`

Data Types: single | double

Tail — Type of alternative hypothesis

'both' (default) | 'right' | 'left'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of `'Tail'` and one of:

- `'both'` — Test against the alternative hypothesis that the population mean is not m .
- `'right'` — Test against the alternative hypothesis that the population mean is greater than m .
- `'left'` — Test against the alternative hypothesis that the population mean is less than m .

`ztest` tests the null hypothesis that the population mean is m against the specified alternative hypothesis.

Example: `'Tail', 'right'`

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as 1 or 0.

- If $h = 1$, this indicates the rejection of the null hypothesis at the `Alpha` significance level.

- If $h = 0$, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p – p-value

scalar value in the range [0,1]

p -value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

ci – Confidence interval

vector

Confidence interval for the true population mean, returned as a two-element vector containing the lower and upper boundaries of the $100 \times (1 - \text{Alpha})\%$ confidence interval.

zval – Test statistic

nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

More About**z-Test**

The z -test is a parametric hypothesis test used to determine whether a sample data set comes from a population with a particular mean. The test assumes that the sample data comes from a population with a normal distribution and a known standard deviation.

The test statistic is

$$z = \frac{\bar{x} - \mu}{\sigma/\sqrt{n}},$$

where \bar{x} is the sample mean, μ is the population mean, σ is the population standard deviation, and n is the sample size. Under the null hypothesis, the test statistic has a standard normal distribution.

Multidimensional Array

A multidimensional array has more than two dimensions. For example, if x is a 1-by-3-by-4 array, then x is a three-dimensional array.

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if x is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of x .

Tips

- Use `sampsizepwr` to calculate:
 - The sample size that corresponds to specified power and parameter values;
 - The power achieved for a particular sample size, given the true parameter value;

- The parameter value detectable with the specified sample size and power.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

hmcSampler

Hamiltonian Monte Carlo (HMC) sampler

Syntax

```
hmc = hmcSampler(logpdf,startpoint)
hmc = hmcSampler( ____,Name,Value)
```

Description

`hmc = hmcSampler(logpdf,startpoint)` creates a Hamiltonian Monte Carlo (HMC) sampler, returned as a `HamiltonianSampler` object. `logpdf` is a function handle that evaluates the logarithm of the probability density of the equilibrium distribution and its gradient. The column vector `startpoint` is the initial point from which to start HMC sampling.

After you create the sampler, you can compute MAP (maximum-a-posteriori) point estimates, tune the sampler, draw samples, and check convergence diagnostics using the methods of the `HamiltonianSampler` class. For an example of this workflow, see [Bayesian Linear Regression Using Hamiltonian Monte Carlo](#) on page 7-27.

`hmc = hmcSampler(____,Name,Value)` specifies additional options using one or more name-value pair arguments. Specify name-value pair arguments after all other input arguments.

Examples

Create Hamiltonian Monte Carlo Sampler

Create a Hamiltonian Monte Carlo (HMC) sampler to sample from a normal distribution.

First, save a function `normalDistGrad` on the MATLAB® path that returns the multivariate normal log probability density and its gradient (`normalDistGrad` is defined at the end of this example). Then, call the function with arguments to define the `logpdf` input argument to the `hmcSampler` function.

```
means = [1;-3];
standevs = [1;2];
logpdf = @(theta)normalDistGrad(theta,means,standevs);
```

Choose a starting point for the HMC sampler.

```
startpoint = randn(2,1);
```

Create the HMC sampler and display its properties.

```
smp = hmcSampler(logpdf,startpoint);
```

```
smp
```

```
smp =
  HamiltonianSampler with properties:
```

```

        StepSize: 0.1000
        NumSteps: 50
        MassVector: [2x1 double]
        JitterMethod: 'jitter-both'
        StepSizeTuningMethod: 'dual-averaging'
        MassVectorTuningMethod: 'iterative-sampling'
        LogPDF: @(theta)normalDistGrad(theta,means,standevs)
        VariableNames: {2x1 cell}
        StartPoint: [2x1 double]

```

The `normalDistGrad` function returns the logarithm of the multivariate normal probability density with means in `Mu` and standard deviations in `Sigma`, specified as scalars or columns vectors the same length as `startpoint`. The second output argument is the corresponding gradient.

```

function [lpdf,glpdf] = normalDistGrad(X,Mu,Sigma)
Z = (X - Mu)./Sigma;
lpdf = sum(-log(Sigma) - .5*log(2*pi) - .5*(Z.^2));
glpdf = -Z./Sigma;
end

```

Input Arguments

logpdf — Logarithm of target density and its gradient

function handle

Logarithm of target density and its gradient, specified as a function handle.

`logpdf` must return two output arguments: `[lpdf,glpdf] = logpdf(X)`. Here, `lpdf` is the base-e log probability density (up to an additive constant), `glpdf` is the gradient of the log density, and the point `X` is a column vector with the same number of elements as `startpoint`.

The input argument `X` to `logpdf` must be unconstrained, meaning that every element of `X` can be any real number. Transform any constrained sampling parameters into unconstrained variables before using the HMC sampler.

If the `'UseNumericalGradient'` value is set to `true`, then `logpdf` does not need to return the gradient as the second output. Using a numerical gradient can be easier since `logpdf` does not need to compute the gradient, but it can make sampling slower.

Data Types: `function_handle`

startpoint — Initial point to start sampling from

numeric column vector

Initial point to start sampling from, specified as a numeric column vector.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'VariableNames', {'Intercept', 'Beta'}, 'MassVectorTuningMethod', 'hessian'` specifies sampling variable names and the mass vector tuning method to be `'hessian'`.

StepSize — Step size of Hamiltonian dynamics

0.1 (default) | positive scalar

Step size of Hamiltonian dynamics, specified as the comma-separated pair consisting of `'StepSize'` and a positive scalar.

To propose a new state for the Markov chain, the HMC sampler integrates the Hamiltonian dynamics using leapfrog integration. This argument controls the step size of that leapfrog integration.

You can automatically tune the step size using `tuneSampler`.

Example: `'StepSize', 0.2`

Data Types: `single` | `double`

NumSteps — Number of steps of Hamiltonian dynamics

50 (default) | positive integer

Number of steps of Hamiltonian dynamics, specified as the comma-separated pair consisting of `'NumSteps'` and a positive integer.

To propose a new state for the Markov chain, the HMC sampler integrates the Hamiltonian dynamics using leapfrog integration. This argument controls the number of steps of that leapfrog integration.

You can automatically tune the number of steps using `tuneSampler`.

Example: `'NumSteps', 20`

Data Types: `single` | `double`

MassVector — Mass vector of momentum variables

`ones(size(startpoint,1),1)` (default) | numeric column vector

Mass vector of momentum variables, specified as the comma-separated pair consisting of `'MassVector'` and a numeric column vector with positive values and the same length as `startpoint`.

The “masses” of the momentum variables associated with the variables of interest control the Hamiltonian dynamics in each Markov chain proposal.

You can automatically tune the mass vector using `tuneSampler`.

Example: `'MassVector', rand(3,1)`

Data Types: `single` | `double`

JitterMethod — Method for jittering step size and number of steps

`'jitter-both'` (default) | `'jitter-numsteps'` | `'none'`

Method for jittering the step size and the number of steps, specified as the comma-separated pair consisting of `'JitterMethod'` and one of the following values.

Value	Description
'jitter-both'	Randomly jitter the step size and number of steps for each leapfrog trajectory.
'jitter-numsteps'	Jitter only the number of steps of each leapfrog trajectory.
'none'	Perform no jittering.

With jittering, the sampler randomly selects the step size or the number of steps of each leapfrog trajectory as values smaller than the 'StepSize' and 'NumSteps' values. Use jittering to improve the stability of the leapfrog integration of the Hamiltonian dynamics.

Example: 'JitterMethod', 'jitter-both'

StepSizeTuningMethod — Method for tuning sampler step size

'dual-averaging' (default) | 'none'

Method for tuning the sampler step size, specified as the comma-separated pair consisting of 'StepSizeTuningMethod' and 'dual-averaging' or 'none'.

If the 'StepSizeTuningMethod' value is set to 'dual-averaging', then `tuneSampler` tunes the leapfrog step size of the HMC sampler to achieve a certain acceptance ratio for a fixed value of the simulation length. The simulation length equals the step size multiplied by the number of steps. To set the target acceptance ratio, use the 'TargetAcceptanceRatio' name-value pair argument of the `tuneSampler` method.

Example: 'StepSizeTuningMethod', 'none'

MassVectorTuningMethod — Method for tuning sampler mass vector

'iterative-sampling' (default) | 'hessian' | 'none'

Method for tuning the sampler mass vector, specified as the comma-separated pair consisting of 'MassVectorTuningMethod' and one of the following values.

Value	Description
'iterative-sampling'	Tune the <code>MassVector</code> via successive approximations by drawing samples using a sequence of mass vector estimates.
'hessian'	Set the <code>MassVector</code> equal to the negative diagonal Hessian of the logpdf at the startpoint.
'none'	Perform no tuning of the <code>MassVector</code> .

To perform the tuning, use the `tuneSampler` method.

Example: 'MassVectorTuningMethod', 'hessian'

CheckGradient — Flag for checking analytical gradient

true (or 1) (default) | false (or 0)

Flag for checking the analytical gradient, specified as the comma-separated pair consisting of 'CheckGradient' and either true (or 1) or false (or 0).

If `'CheckGradient'` is `true`, then the sampler calculates the numerical gradient at the `startpoint` and compares it to the analytical gradient returned by `logpdf`.

Example: `'CheckGradient',true`

VariableNames — Sampling variable names

`{'x1','x2',...}` (default) | string array | cell array of character vectors

Sampling variable names, specified as the comma-separated pair consisting of `'VariableNames'` and a string array or a cell array of character vectors. Elements of the array must be unique. The length of the array must be the same as the length of `startpoint`.

Supply a `'VariableNames'` value to label the components of the vector you want to sample using the HMC sampler.

Example: `'VariableNames',{'Intercept','Beta'}`

Data Types: `string` | `cell`

UseNumericalGradient — Flag for using numerical gradient

`false` (or `0`) (default) | `true` (or `1`)

Flag for using numerical gradient, specified as the comma-separated pair consisting of `'UseNumericalGradient'` and either `true` (or `1`) or `false` (or `0`).

If you set the `'UseNumericalGradient'` value to `true`, then the HMC sampler numerically estimates the gradient from the log density returned by `logpdf`. In this case, the `logpdf` function does not need to return the gradient of the log density as the second output. Using a numerical gradient makes HMC sampling slower.

Example: `'UseNumericalGradient',true`

Output Arguments

hmc — Hamiltonian Monte Carlo sampler

`HamiltonianSampler` object

Hamiltonian Monte Carlo sampler, returned as a `HamiltonianSampler` object.

Introduced in R2017a

HamiltonianSampler class

Hamiltonian Monte Carlo (HMC) sampler

Description

A Hamiltonian Monte Carlo (HMC) sampler is a gradient-based Markov Chain Monte Carlo sampler that you can use to generate samples from a probability density $P(x)$. HMC sampling requires specification of $\log P(x)$ and its gradient.

The parameter vector x must be unconstrained, meaning that every element of x can be any real number. To sample constrained parameters, transform these parameters into unconstrained variables before using the HMC sampler.

After creating a sampler, you can compute MAP (maximum-a-posteriori) point estimates, tune the sampler, draw samples, and check convergence diagnostics using the methods of this class. For an example of this workflow, see Bayesian Linear Regression Using Hamiltonian Monte Carlo on page 7-27.

Construction

`hmc = hmcSampler(logpdf, startpoint)` creates a Hamiltonian Monte Carlo (HMC) sampler, returned as a `HamiltonianSampler` object. `logpdf` is a function handle that evaluates the logarithm of the probability density of the equilibrium distribution and its gradient. The column vector `startpoint` is the initial point from which to start HMC sampling.

`hmc = hmcSampler(___, Name, Value)` specifies additional options using one or more name-value pair arguments. Specify name-value pair arguments after all other input arguments.

Input Arguments

logpdf — Logarithm of target density and its gradient

function handle

Logarithm of target density and its gradient, specified as a function handle.

`logpdf` must return two output arguments: `[lpdf, glpdf] = logpdf(X)`. Here, `lpdf` is the base- e log probability density (up to an additive constant), `glpdf` is the gradient of the log density, and the point X is a column vector with the same number of elements as `startpoint`.

The input argument X to `logpdf` must be unconstrained, meaning that every element of X can be any real number. Transform any constrained sampling parameters into unconstrained variables before using the HMC sampler.

If the `'UseNumericalGradient'` value is set to `true`, then `logpdf` does not need to return the gradient as the second output. Using a numerical gradient can be easier since `logpdf` does not need to compute the gradient, but it can make sampling slower.

Data Types: `function_handle`

startpoint — Initial point to start sampling from

numeric column vector

Initial point to start sampling from, specified as a numeric column vector.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'VariableNames', {'Intercept', 'Beta'}, 'MassVectorTuningMethod', 'hessian'` specifies sampling variable names and the mass vector tuning method to be `'hessian'`.

StepSize — Step size of Hamiltonian dynamics

`0.1` (default) | positive scalar

Step size of Hamiltonian dynamics, specified as the comma-separated pair consisting of `'StepSize'` and a positive scalar.

To propose a new state for the Markov chain, the HMC sampler integrates the Hamiltonian dynamics using leapfrog integration. This argument controls the step size of that leapfrog integration.

You can automatically tune the step size using `tuneSampler`.

Example: `'StepSize', 0.2`

NumSteps — Number of steps of Hamiltonian dynamics

`50` (default) | positive integer

Number of steps of Hamiltonian dynamics, specified as the comma-separated pair consisting of `'NumSteps'` and a positive integer.

To propose a new state for the Markov chain, the HMC sampler integrates the Hamiltonian dynamics using leapfrog integration. This argument controls the number of steps of that leapfrog integration.

You can automatically tune the number of steps using `tuneSampler`.

Example: `'NumSteps', 20`

MassVector — Mass vector of momentum variables

`ones(size(startpoint,1),1)` (default) | numeric column vector

Mass vector of momentum variables, specified as the comma-separated pair consisting of `'MassVector'` and a numeric column vector with positive values and the same length as `startpoint`.

The “masses” of the momentum variables associated with the variables of interest control the Hamiltonian dynamics in each Markov chain proposal.

You can automatically tune the mass vector using `tuneSampler`.

Example: `'MassVector', rand(3,1)`

JitterMethod — Method for jittering step size and number of steps

`'jitter-both'` (default) | `'jitter-numsteps'` | `'none'`

Method for jittering the step size and number of steps, specified as the comma-separated pair consisting of 'JitterMethod' and one of the following:

Value	Description
'jitter-both'	Randomly jitter the step size and number of steps for each leapfrog trajectory.
'jitter-numsteps'	Jitter only the number of steps of each leapfrog trajectory.
'none'	Perform no jittering.

With jittering, the sampler randomly selects the step size or the number of steps of each leapfrog trajectory as values smaller than the 'StepSize' and 'NumSteps' values. Use jittering to improve the stability of the leapfrog integration of the Hamiltonian dynamics.

Example: 'JitterMethod', 'jitter-both'

StepSizeTuningMethod – Method for tuning sampler step size

'dual-averaging' (default) | 'none'

Method for tuning the sampler step size, specified as the comma-separated pair consisting of 'StepSizeTuningMethod' and 'dual-averaging' or 'none'.

If the 'StepSizeTuningMethod' value is set to 'dual-averaging', then tuneSampler tunes the leapfrog step size of the HMC sampler to achieve a certain acceptance ratio for a fixed value of the simulation length. The simulation length equals the step size multiplied by the number of steps. To set the target acceptance ratio, use the 'TargetAcceptanceRatio' name-value pair argument of the tuneSampler method.

Example: 'StepSizeTuningMethod', 'none'

MassVectorTuningMethod – Method for tuning sampler mass vector

'iterative-sampling' (default) | 'hessian' | 'none'

Method for tuning the sampler mass vector, specified as the comma-separated pair consisting of 'MassVectorTuningMethod' and one of the following values

Value	Description
'iterative-sampling'	Tune the MassVector via successive approximations by drawing samples using a sequence of mass vector estimates.
'hessian'	Set the MassVector equal to the negative diagonal Hessian of the logpdf at the startpoint.
'none'	Perform no tuning of the MassVector.

To perform the tuning, use the tuneSampler method.

Example: 'MassVectorTuningMethod', 'hessian'

CheckGradient – Flag for checking analytical gradient

true (or 1) (default) | false (or 0)

Flag for checking the analytical gradient, specified as the comma-separated pair consisting of `'CheckGradient'` and either `true` (or 1) or `false` (or 0).

If `'CheckGradient'` is `true`, then the sampler calculates the numerical gradient at the `startpoint` and compares it to the analytical gradient returned by `logpdf`.

Example: `'CheckGradient',true`

VariableNames — Sampling variable names

`{'x1','x2',...}` (default) | string array | cell array of character vectors

Sampling variable names, specified as the comma-separated pair consisting of `'VariableNames'` and a string array or cell array of character vectors. Elements of the array must be unique. The length of the array must be the same as the length of `startpoint`.

Supply a `'VariableNames'` value to label the components of the vector you want to sample using the HMC sampler.

Example: `'VariableNames',{'Intercept','Beta'}`

UseNumericalGradient — Flag for using numerical gradient

`false` (or 0) (default) | `true` (or 1)

Flag for using numerical gradient, specified as the comma-separated pair consisting of `'UseNumericalGradient'` and either `true` (or 1) or `false` (or 0).

If you set the `'UseNumericalGradient'` value to `true`, then the HMC sampler numerically estimates the gradient from the log density returned by `logpdf`. In this case, the `logpdf` function does not need to return the gradient of the log density as the second output. Using a numerical gradient makes HMC sampling slower.

Example: `'UseNumericalGradient',true`

Properties

StepSize — Step size of Hamiltonian dynamics

0.1 (default) | positive scalar

Step size of Hamiltonian dynamics, specified as a positive scalar.

To propose a new state for the Markov chain, the HMC sampler integrates the Hamiltonian dynamics using leapfrog integration. The value of this property controls the step size of that leapfrog integration.

NumSteps — Number of steps of Hamiltonian dynamics

50 (default) | positive integer

Number of steps of Hamiltonian dynamics, specified as a positive integer.

To propose a new state for the Markov chain, the HMC sampler integrates the Hamiltonian dynamics using leapfrog integration. The value of this property controls the number of steps of that leapfrog integration.

MassVector — Mass vector of momentum variables

`ones(size(startpoint,1),1)` (default) | numeric column vector

Mass vector of momentum variables, specified as a numeric column vector with positive values and the same length as `startpoint`.

The “masses” of the momentum variables associated with the variables of interest control the Hamiltonian dynamics in each Markov chain proposal.

JitterMethod — Method for jittering step size and number of steps

'jitter-both' (default) | 'jitter-numsteps' | 'none'

Method for jittering the step size and the number of steps, specified as one of the following values.

Value	Description
'jitter-both'	Randomly jitter the step size and number of steps of each leapfrog trajectory.
'jitter-numsteps'	Jitter only the number of steps of each leapfrog trajectory.
'none'	Perform no jittering.

With jittering, the sampler randomly selects the step size or the number of steps of each leapfrog trajectory as values smaller than the `StepSize` and `NumSteps` values. Use jittering to improve the stability of the leapfrog integration of the Hamiltonian dynamics.

StepSizeTuningMethod — Method for tuning sampler step size

'dual-averaging' (default) | 'none'

Method for tuning the sampler step size, specified as `'dual-averaging'` or `'none'`.

If `StepSizeTuningMethod` equals `'dual-averaging'`, then `tuneSampler` tunes the leapfrog step size of the HMC sampler to achieve a certain acceptance ratio for a fixed value of the simulation length. The simulation length equals the step size multiplied by the number of steps. To set the target acceptance ratio, use the `'TargetAcceptanceRatio'` name-value pair argument of the `tuneSampler` method.

MassVectorTuningMethod — Method for tuning sampler mass vector

'iterative-sampling' (default) | 'hessian' | 'none'

Method for tuning the sampler mass vector, specified as one of the following values.

Value	Description
'iterative-sampling'	Tune the <code>MassVector</code> via successive approximations by drawing samples using a sequence of mass vector estimates.
'hessian'	Set the <code>MassVector</code> equal to the negative diagonal Hessian of the <code>logpdf</code> at the <code>startpoint</code> .
'none'	Perform no tuning of the <code>MassVector</code> .

To perform the tuning, use the `tuneSampler` method.

LogPDF — Logarithm of target density and its gradient

function handle

Logarithm of target density and its gradient, specified as a function handle.

`LogPDF` returns two output arguments: `[lpdf,glpdf] = LogPDF(X)`. Here, `lpdf` is the base-e log probability density (up to an additive constant) and `glpdf` is the gradient of the log density at the point `X`. The input argument `X` must be a column vector with the same number of elements as the `StartPoint` property.

If you set the `'UseNumericalGradient'` value to `true` when creating the sampler, then `LogPDF` returns the numerical gradient in `glpdf`.

StartPoint — Initial point to start sampling from

numeric column vector

Initial point to start sampling from, specified as a numeric column vector.

VariableNames — Sampling variable names

`{'x1','x2',...}` (default) | cell array of unique character vectors

Sampling variable names, specified as a cell array of unique character vectors.

Methods

<code>estimateMAP</code>	Estimate maximum of log probability density
<code>tuneSampler</code>	Tune Hamiltonian Monte Carlo (HMC) sampler
<code>drawSamples</code>	Generate Markov chain using Hamiltonian Monte Carlo (HMC)
<code>diagnostics</code>	Markov Chain Monte Carlo diagnostics

Examples

Create Hamiltonian Monte Carlo Sampler

Create a Hamiltonian Monte Carlo (HMC) sampler to sample from a normal distribution.

First, save a function `normalDistGrad` on the MATLAB® path that returns the multivariate normal log probability density and its gradient (`normalDistGrad` is defined at the end of this example). Then, call the function with arguments to define the `logpdf` input argument to the `hmcSampler` function.

```
means = [1;-3];
standevs = [1;2];
logpdf = @(theta)normalDistGrad(theta,means,standevs);
```

Choose a starting point for the HMC sampler.

```
startpoint = randn(2,1);
```

Create the HMC sampler and display its properties.

```
smp = hmcSampler(logpdf,startpoint);
smp
```

```
smp =  
  HamiltonianSampler with properties:  
  
      StepSize: 0.1000  
      NumSteps: 50  
      MassVector: [2x1 double]  
      JitterMethod: 'jitter-both'  
      StepSizeTuningMethod: 'dual-averaging'  
      MassVectorTuningMethod: 'iterative-sampling'  
      LogPDF: @(theta)normalDistGrad(theta,means,standevs)  
      VariableNames: {2x1 cell}  
      StartPoint: [2x1 double]
```

The `normalDistGrad` function returns the logarithm of the multivariate normal probability density with means in `Mu` and standard deviations in `Sigma`, specified as scalars or columns vectors the same length as `startpoint`. The second output argument is the corresponding gradient.

```
function [lpdf,glpdf] = normalDistGrad(X,Mu,Sigma)  
Z = (X - Mu)./Sigma;  
lpdf = sum(-log(Sigma) - .5*log(2*pi) - .5*(Z.^2));  
glpdf = -Z./Sigma;  
end
```

“Bayesian Linear Regression Using Hamiltonian Monte Carlo” on page 7-27

Introduced in R2017a

estimateMAP

Class: HamiltonianSampler

Estimate maximum of log probability density

Syntax

```
xhat = estimateMAP(smp)
[xhat,fitinfo] = estimateMAP(smp)
[xhat,fitinfo] = estimateMAP( ____,Name,Value)
```

Description

`xhat = estimateMAP(smp)` returns the maximum-a-posteriori (MAP) estimate of the log probability density of the Monte Carlo sampler `smp`.

`[xhat,fitinfo] = estimateMAP(smp)` returns additional fitting information in `fitinfo`.

`[xhat,fitinfo] = estimateMAP(____,Name,Value)` specifies additional options using one or more name-value pair arguments. Specify name-value pair arguments after all other input arguments.

Input Arguments

smp — Hamiltonian Monte Carlo sampler

HamiltonianSampler object

Hamiltonian Monte Carlo sampler, specified as a HamiltonianSampler object.

`estimateMAP` estimates the maximum of the log probability density specified in `smp.LogPDF`.

Use the `hmcSampler` function to create a sampler.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'IterationLimit',100,'StepTolerance',1e-5` estimates the MAP point using an iteration limit of 100 and a step size convergence tolerance of $1e-5$.

StartPoint — Initial point to start optimization from

`smp.StartPoint` (default) | numeric column vector

Initial point to start optimization from, specified as a numeric column vector with the same number of elements as the `StartPoint` property of the sampler `smp`.

Example: `'StartPoint',randn(size(smp.StartPoint))`

IterationLimit — Maximum number of optimization iterations

1000 (default) | positive integer

Maximum number of optimization iterations, specified as a positive integer.

Example: 'IterationLimit',100

VerbosityLevel – Verbosity level of Command Window output

0 (default) | positive integer

Verbosity level of Command Window output during function maximization, specified as 0 or a positive integer.

- With the value set to 0, estimateMAP displays no details on the optimization.
- With the value set to a positive integer, estimateMAP displays convergence information at each iteration.

Convergence Information

Heading	Meaning
FUN VALUE	Objective function value.
NORM GRAD	Norm of the gradient of the objective function.
NORM STEP	Norm of the iterative step, meaning the distance between the previous point and the current point.
CURV	OK means the weak Wolfe condition is satisfied. This condition is a combination of sufficient decrease of the objective function and a curvature condition.
GAMMA	Inner product of the step times the gradient difference, divided by the inner product of the gradient difference with itself. The gradient difference is the gradient at the current point minus the gradient at the previous point. Gives diagnostic information on the objective function curvature.
ALPHA	Step direction multiplier, which differs from 1 when the algorithm performed a line search.
ACCEPT	YES means the algorithm found an acceptable step to take.

Example: 'VerbosityLevel',1

GradientTolerance – Relative gradient convergence tolerance

1e-6 (default) | positive scalar

Relative gradient convergence tolerance, specified as a positive scalar.

Let $\tau = \max(1, \min(\text{abs}(f), \text{infnormg0}))$, where f is the current objective function value and infnormg0 is the initial gradient norm. If the norm of the objective function gradient is smaller than τ times the 'GradientTolerance' value, then the maximization is considered to have converged to a local optimum.

Example: 'GradientTolerance',1e-4

StepTolerance – Step size convergence tolerance

1e-6 (default) | positive scalar

Step size convergence tolerance, specified as a positive scalar.

If the proposed step size is smaller than the 'StepTolerance' value, then the maximization is considered to have converged to a local optimum.

Example: 'StepTolerance', 1e-5

Output Arguments

xhat — MAP point estimate

numeric vector

MAP point estimate, returned as a numeric vector of the same size as `smp.StartPoint`.

fitinfo — Fitting information

structure

Fitting information for the MAP computation, returned as a structure with these fields:

Field	Description
Iteration	Iteration indices from 0 through the final iteration.
Objective	Negative log probability density at each iteration. The MAP point is computed by minimizing the negative log probability density. You can check that the final values are all similar, indicating that the function optimization has converged to a local optimum.
Gradient	Gradient of the negative log probability density at the final iteration.

Data Types: `struct`

Examples

Estimate MAP Point of HMC Sampler

Create a Hamiltonian Monte Carlo sampler for a normal distribution and estimate the maximum-a-posteriori (MAP) point of the log probability density.

First, save a function `normalDistGrad` on the MATLAB® path that returns the multivariate normal log probability density and its gradient (`normalDistGrad` is defined at the end of this example). Then, call the function with arguments to define the `logpdf` input argument to the `hmcSampler` function.

```
means = [1;-1];
standevs = [1;0.3];
logpdf = @(theta)normalDistGrad(theta,means,standevs);
```

Choose a starting point and create the HMC sampler.

```
startpoint = zeros(2,1);
smp = hmcSampler(logpdf,startpoint);
```

Estimate the MAP point (the point where the probability density has its maximum). Show more information during optimization by setting the 'VerbosityLevel' value to 1.

```
[xhat,fitinfo] = estimateMAP(smp,'VerbosityLevel',1);
```

```
o Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe
```

ITER	FUN VALUE	NORM GRAD	NORM STEP	CURV	GAMMA	ALPHA	AC
0	6.689460e+00	1.111e+01	0.000e+00		9.000e-03	0.000e+00	
1	4.671622e+00	8.889e+00	2.008e-01	OK	9.006e-02	2.000e+00	
2	9.759850e-01	8.268e-01	8.215e-01	OK	9.027e-02	1.000e+00	
3	9.158025e-01	7.496e-01	7.748e-02	OK	5.910e-01	1.000e+00	
4	6.339508e-01	3.104e-02	7.472e-01	OK	9.796e-01	1.000e+00	
5	6.339043e-01	3.668e-05	3.762e-03	OK	9.599e-02	1.000e+00	
6	6.339043e-01	2.488e-08	3.333e-06	OK	9.015e-02	1.000e+00	

```
Infinity norm of the final gradient = 2.488e-08
```

```
Two norm of the final step = 3.333e-06, TolX = 1.000e-06
```

```
Relative infinity norm of the final gradient = 2.488e-08, TolFun = 1.000e-06
```

```
EXIT: Local minimum found.
```

To further check that the optimization has converged to a local minimum, plot the `fitinfo.Objective` field. This field contains the values of the negative log density at each iteration of the function optimization. The final values are all very similar, so the optimization has converged.

```
fitinfo
```

```
fitinfo = struct with fields:
```

```
Iteration: [7x1 double]
```

```
Objective: [7x1 double]
```

```
Gradient: [2x1 double]
```

```
plot(fitinfo.Iteration,fitinfo.Objective,'ro-');
```

```
xlabel('Iteration');
```

```
ylabel('Negative log density');
```

Display the MAP estimate. It is indeed equal to the means variable, which is the exact maximum.

```
xhat
```

```
xhat = 2×1
    1.0000
   -1.0000
```

```
means
```

```
means = 2×1
    1
   -1
```

The `normalDistGrad` function returns the logarithm of the multivariate normal probability density with means in `Mu` and standard deviations in `Sigma`, specified as scalars or column vectors the same length as `startpoint`. The second output argument is the corresponding gradient.

```
function [lpdf,glpdf] = normalDistGrad(X,Mu,Sigma)
Z = (X - Mu)./Sigma;
lpdf = sum(-log(Sigma) - .5*log(2*pi) - .5*(Z.^2));
glpdf = -Z./Sigma;
end
```

Tips

- First create a Hamiltonian Monte Carlo sampler using the `hmcSampler` function, and then use `estimateMAP` to estimate the MAP point.
- After creating an HMC sampler, you can tune the sampler, draw samples, and check convergence diagnostics using the other methods of the `HamiltonianSampler` class. Using the MAP estimate as a starting point in the `tuneSampler` and `drawSamples` methods can lead to more efficient tuning and sampling. For an example of this workflow, see [Bayesian Linear Regression Using Hamiltonian Monte Carlo](#) on page 7-27.

Algorithms

- `estimateMAP` uses a limited memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) quasi-Newton optimizer to search for the maximum of the log probability density. See Nocedal and Wright [1].

tuneSampler

Class: HamiltonianSampler

Tune Hamiltonian Monte Carlo (HMC) sampler

Syntax

```
tunedSmp = tuneSampler(smp)
[tunedSmp,tuningInfo] = tuneSampler(smp)
[tunedSmp,tuningInfo] = tuneSampler( ____,Name,Value)
```

Description

`tunedSmp = tuneSampler(smp)` returns a tuned Hamiltonian Monte Carlo (HMC) sampler.

First, `tuneSampler` tunes the mass vector of the HMC sampler `smp`. Then, it tunes the step size and number of steps of the leapfrog integrations to achieve a certain target acceptance ratio.

You can use the tuned sampler to create Markov chains using the `drawSamples` method.

`[tunedSmp,tuningInfo] = tuneSampler(smp)` returns additional tuning information in `tuningInfo`.

`[tunedSmp,tuningInfo] = tuneSampler(____,Name,Value)` specifies additional options using one or more name-value pair arguments. Specify name-value pair arguments after all other input arguments.

Input Arguments

smp — Hamiltonian Monte Carlo sampler

HamiltonianSampler object

Hamiltonian Monte Carlo sampler to tune, specified as a HamiltonianSampler object.

Use the `hmcSampler` function to create a sampler.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'StepSizeTuningMethod','dual-averaging','MassVectorTuningMethod','hessian'` tunes an HMC sampler using the specified methods for tuning the step size and mass vector of the sampler.

StartPoint — Initial point to start tuning from

`smp.StartPoint` (default) | numeric column vector

Initial point to start tuning from, specified as a numeric column vector with the same number of elements as the `StartPoint` property of the sampler `smp`.

Example: `'StartPoint', randn(size(smp.StartPoint))`

StepSizeTuningMethod — Method for tuning sampler step size

`smp.StepSizeTuningMethod` (default) | 'dual-averaging' | 'none'

Method for tuning sampler step size, specified as the comma-separated pair consisting of 'StepSizeTuningMethod' and 'dual-averaging' or 'none'.

If 'StepSizeTuningMethod' is set to 'dual-averaging', then `tuneSampler` tunes the leapfrog step size of the HMC sampler to achieve a target acceptance ratio for a fixed value of the simulation length. The simulation length equals the step size multiplied by the number of steps. To specify the target acceptance ratio, set the 'TargetAcceptanceRatio' value.

To change the simulation length, set `smp.StepSize` = a and `smp.NumSteps` = b, for some values of a and b. This gives a simulation length of a*b.

Example: `'StepSizeTuningMethod', 'none'`

MassVectorTuningMethod — Method for tuning sampler mass vector

`smp.MassVectorTuningMethod` (default) | 'iterative-sampling' | 'hessian' | 'none'

Method for tuning the sampler mass vector, specified as the comma-separated pair consisting of 'MassVectorTuningMethod' and one of the following values.

Value	Description
'iterative-sampling'	Tune the <code>MassVector</code> via successive approximations by drawing samples using a sequence of mass vector estimates.
'hessian'	Set the <code>MassVector</code> equal to the negative diagonal Hessian of the logpdf at the startpoint.
'none'	Perform no tuning of the <code>MassVector</code> .

Example: `'MassVectorTuningMethod', 'hessian'`

NumStepSizeTuningIterations — Number of step size tuning iterations

100 (default) | positive integer

Number of step size tuning iterations, specified as a positive integer.

If the 'StepSizeTuningMethod' value is 'none', then `tuneSampler` does not tune the step size.

Example: `'NumStepSizeTuningIterations', 50`

TargetAcceptanceRatio — Target acceptance ratio

0.65 (default) | scalar from 0 through 1

Target acceptance ratio of the Markov chain, specified as a scalar from 0 through 1.

`tuneSampler` tunes the step size and number of steps of the leapfrog integration to achieve the specified target acceptance ratio for a fixed value of the simulation length. The simulation length is the leapfrog integration step size multiplied by the number of integration steps.

If the 'StepSizeTuningMethod' value is 'none', then `tuneSampler` does not tune the step size.

To change the simulation length, set `smp.StepSize = a` and `smp.NumSteps = b`, for some values of `a` and `b`. This gives a simulation length of `a*b`.

Example: `'TargetAcceptanceRatio', 0.55`

NumStepsLimit – Maximum number of leapfrog steps

2000 (default) | positive integer

Maximum number of leapfrog steps allowed during step size tuning, specified as a positive integer.

If the `'StepSizeTuningMethod'` value is `'none'`, then `tuneSampler` does not tune the step size.

Example: `'NumStepsLimit', 1000`

VerbosityLevel – Verbosity level of Command Window output

0 (default) | nonnegative integer

Verbosity level of Command Window output during sampler tuning, specified as a nonnegative integer.

- With the value set to 0, `tuneSampler` displays no details of the tuning.
- With the value set to 1, `tuneSampler` displays details of the step size tuning.
- With the value set to 2 or larger, `tuneSampler` displays details of the step size and mass vector tuning.

Heading	Description
ITER	Iteration number.
LOG PDF	Log probability density at the current iteration.
STEP SIZE	Leapfrog integration step size at the current iteration.
NUM STEPS	Number of leapfrog integration steps at the current iteration.
ACC RATIO	Acceptance ratio, that is, the fraction of proposals which are accepted.
DIVERGENT	Number of times the sampler failed to generate a valid proposal due to the leapfrog iterations generating NaNs or Infs. <code>tuneSampler</code> searches for a good value of the integration step size. While doing so, the algorithm can encounter regions of instability and report nonzero values in the DIVERGENT column. This behavior is normal and is not a problem in itself.

Example: `'VerbosityLevel', 1`

NumPrint – Verbose output frequency

100 (default) | positive integer

Verbose output frequency, specified as a positive integer.

If the `'VerbosityLevel'` value is a positive integer, `tuneSampler` outputs tuning details every `'NumPrint'` iterations.

Example: 'NumPrint',50

Output Arguments

tunedSmp — Tuned Hamiltonian Monte Carlo sampler

HamiltonianSampler object

Tuned Hamiltonian Monte Carlo sampler, returned as a HamiltonianSampler object.

tuningInfo — Tuning information

structure

Tuning information, returned as a structure with these fields.

Field	Description
MassVector	Tuned mass vector
StepSize	Tuned leapfrog step size
NumSteps	Tuned value of the number of leapfrog integration steps
MassVectorTuningInfo	Structure with additional information on the mass vector tuning
StepSizeTuningInfo	Structure with additional information on the step size tuning

If you tune the mass vector using the 'iterative-sampling' method, then MassVectorTuningInfo has the following fields.

Field	Description
MassVector	Tuned mass vector
IterativeSamplingMassVectorProfile	P -by- K matrix of mass vectors used during the K iterations, where P is the number of sampling variables
IterativeSamplingNumSamples	K -by-1 vector of the number of samples drawn for each of the K iterations

If you tune the mass vector using the 'hessian' method, then MassVectorTuningInfo has the following fields.

Field	Description
MassVector	Tuned mass vector
NegativeDiagonalHessian	Negative diagonal Hessian of logpdf at the tuning start point. If some elements are negative, this field can be different from the MassVector field.
HessianPoint	Point at which the Hessian is evaluated

If the MassVectorTuningMethod value is 'none', then MassVectorTuningInfo is empty.

If you tune the step size using the 'dual-averaging' method, then `StepSizeTuningInfo` has the following fields.

Field	Description
<code>StepSize</code>	Tuned step size
<code>NumSteps</code>	Tuned value of the number of steps
<code>StepSizeProfile</code>	Column vector containing the step sizes at each tuning iteration
<code>AcceptanceRatio</code>	Final acceptance ratio achieved during tuning

If the step size is not tuned, then `StepSizeTuningInfo` is empty.

Data Types: `struct`

Examples

Tune Hamiltonian Monte Carlo Sampler

Tune the parameters of a Hamiltonian Monte Carlo (HMC) sampler.

Define the number of parameters to sample and their means.

```
NumParams = 9;
means = [1:NumParams]';
standevs = 1;
```

First, save a function `normalDistGrad` on the MATLAB® path that returns the multivariate normal log probability density and its gradient (`normalDistGrad` is defined at the end of this example). Then, call the function with arguments to define the `logpdf` input argument to the `hmcSampler` function.

```
logpdf = @(theta)normalDistGrad(theta,means,standevs);
```

Choose a starting point and create the HMC sampler.

```
startpoint = randn(NumParams,1);
smp = hmcSampler(logpdf,startpoint);
```

It is important to select good values for the sampler parameters to get efficient sampling. The best way to find good values is to automatically tune the `MassVector`, `StepSize`, and `NumSteps` parameters using `tuneSampler`. The method:

1. Tunes the `MassVector` of the sampler.
2. Tunes `StepSize` and `NumSteps` for a fixed simulation length to achieve a certain acceptance ratio. The default target acceptance ratio of 0.65 is good in most cases.

```
[smp,info] = tuneSampler(smp,'NumStepSizeTuningIterations',50,'VerbosityLevel',1,'NumPrint',10);
```

```
o Tuning mass vector using method: iterative-sampling
Finished mass vector tuning iteration 1 of 5.
Finished mass vector tuning iteration 2 of 5.
Finished mass vector tuning iteration 3 of 5.
```

Finished mass vector tuning iteration 4 of 5.
 Finished mass vector tuning iteration 5 of 5.

o Tuning step size using method: dual-averaging. Target acceptance ratio = 0.65

o Initial step size for dual-averaging = 2

ITER	LOG PDF	STEP SIZE	NUM STEPS	ACC RATIO	DIVERGENT
10	-1.710457e+01	1.193e+00	4	5.000e-01	0
20	-9.152514e+00	9.527e-01	5	5.500e-01	0
30	-1.068923e+01	8.856e-01	6	5.333e-01	0
40	-1.290816e+01	8.506e-01	6	5.750e-01	0
50	-1.770386e+01	8.581e-01	6	6.000e-01	0

Plot the evolution of the step size during tuning to ensure that the step size tuning has converged.
 Display the achieved acceptance ratio.

```
figure;
plot(info.StepSizeTuningInfo.StepSizeProfile);
xlabel('Iteration');
ylabel('Step Size');
```

```
accratio = info.StepSizeTuningInfo.AcceptanceRatio
```

```
accratio = 0.6000
```

The `normalDistGrad` function returns the logarithm of the multivariate normal probability density with means in `Mu` and standard deviations in `Sigma`, specified as scalars or columns vectors the same length as `startpoint`. The second output argument is the corresponding gradient.

```
function [lpdf,glpdf] = normalDistGrad(X,Mu,Sigma)
Z = (X - Mu)./Sigma;
lpdf = sum(-log(Sigma) - .5*log(2*pi) - .5*(Z.^2));
glpdf = -Z./Sigma;
end
```

Tips

- After creating an HMC sampler using the `hmcSampler` function, you can compute MAP (maximum-a-posteriori) point estimates, tune the sampler, draw samples, and check convergence diagnostics using the methods of the `HamiltonianSampler` class. For an example of this workflow, see [Bayesian Linear Regression Using Hamiltonian Monte Carlo](#) on page 7-27.

`HamiltonianSampler`

Topics

“[Bayesian Linear Regression Using Hamiltonian Monte Carlo](#)” on page 7-27

Introduced in R2017a

drawSamples

Class: HamiltonianSampler

Generate Markov chain using Hamiltonian Monte Carlo (HMC)

Syntax

```
chain = drawSamples(smp)
[chain,endpoint,accratio] = drawSamples(smp)
[chain,endpoint,accratio] = drawSamples( ____,Name,Value)
```

Description

`chain = drawSamples(smp)` generates a Markov chain by drawing samples using the Hamiltonian Monte Carlo sampler `smp`.

`[chain,endpoint,accratio] = drawSamples(smp)` also returns the final state of the Markov chain in `endpoint` and the fraction of accepted proposals in `accratio`.

`[chain,endpoint,accratio] = drawSamples(____,Name,Value)` specifies additional options using one or more name-value pair arguments. Specify name-value pair arguments after all other input arguments.

Input Arguments

smp — Hamiltonian Monte Carlo sampler

HamiltonianSampler object

Hamiltonian Monte Carlo sampler, specified as a HamiltonianSampler object.

`drawSamples` draws samples from the target log probability density in `smp.LogPDF`. Use the `hmcSampler` function to create a sampler.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Burnin',500,'NumSamples',2000` generates a Markov chain by discarding 500 burn-in samples and then drawing 2000 samples.

Burnin — Number of burn-in samples to discard

1000 (default) | positive integer

Number of burn-in samples to discard from the beginning of the Markov chain, specified as a positive integer.

Example: `'Burnin',500`

NumSamples — Number of samples to draw

1000 (default) | positive integer

Number of samples to draw from the Markov chain using the HMC sampler, specified as a positive integer.

The `drawSamples` method generates this number of samples after the burn-in period.

Example: `'NumSamples', 2000`

ThinSize — Markov chain thinning size

1 (default) | positive integer

Markov chain thinning size, specified as a positive integer.

Only one out of the `'ThinSize'` number of samples are kept. The rest of the samples are discarded.

Example: `'ThinSize', 5`

StartPoint — Initial point to start sampling from`smp.StartPoint` (default) | numeric column vector

Initial point to start sampling from, specified as a numeric column vector with the same number of elements as the `StartPoint` property of the sampler `smp`.

Example: `'StartPoint', randn(5,1)`

VerbosityLevel — Verbosity level of Command Window output

0 (default) | positive integer

Verbosity level of Command Window output during sampling, specified as 0 or a positive integer.

With the value set to 0, `drawSamples` displays no details during sampling.

With the value set to a positive integer, `drawSamples` displays details of the sampling. To set the output frequency, use the `'NumPrint'` name-value pair argument.

`drawSamples` displays the output as a table with these columns.

Heading	Description
ITER	Iteration number
LOG PDF	Log probability density at the current iteration
STEP SIZE	Leapfrog integration step size at the current iteration. If the step size is jittered, it can vary between iterations.
NUM STEPS	Number of leapfrog integration steps at the current iteration. If the number of steps is jittered, it can vary between iterations
ACC RATIO	Acceptance ratio, that is, the fraction of proposals that are accepted. The acceptance ratio is calculated from the beginning of sampling, including the burn-in period.

Heading	Description
DIVERGENT	Number of times the sampler failed to generate a valid proposal due to the leapfrog iterations generating NaNs or Infs. When drawing samples, a nonzero value in the DIVERGENT column indicates that the chosen step size is above the stability threshold for some region of state space. To fix this issue, try to set the StepSize to a smaller value, draw new samples, and check that all values in the DIVERGENT column equal 0.

Example: `'VerbosityLevel',1`

NumPrint – Verbose output frequency

100 (default) | positive integer

Verbose output frequency, specified as a positive integer.

If the `'VerbosityLevel'` value is a positive integer, then `drawSamples` outputs sampling details every `'NumPrint'` iterations.

Example: `'NumPrint',200`

Output Arguments

chain – Markov chain generated using Hamiltonian Monte Carlo

numeric matrix

Markov chain generated using Hamiltonian Monte Carlo, returned as a numeric matrix.

Each row of `chain` is a sample, and each column represents one sampling variable.

endpoint – Final state of Markov chain

numeric column vector

Final state of the Markov chain, returned as a numeric column vector of the same length as `smp.StartPoint`.

accratio – Acceptance ratio

numeric scalar

Acceptance ratio of the Markov chain proposals, returned as a numeric scalar. The acceptance ratio is calculated from the beginning of sampling, including the burn-in period.

Examples

Draw Samples Using HMC Sampler

Create MCMC chains for a multivariate normal distribution using a Hamiltonian Monte Carlo (HMC) sampler.

Define the number of parameters to sample and their means.

```
NumParams = 100;
means = randn(NumParams,1);
standevs = 0.1;
```

First, save a function `normalDistGrad` on the MATLAB® path that returns the multivariate normal log probability density and its gradient (`normalDistGrad` is defined at the end of this example). Then, call the function with arguments to define the `logpdf` input argument to the `hmcSampler` function.

```
logpdf = @(theta)normalDistGrad(theta,means,standevs);
```

Choose a starting point of the sampler. Create the HMC sampler and tune its parameters.

```
startpoint = randn(NumParams,1);
smp = hmcSampler(logpdf,startpoint);
smp = tuneSampler(smp);
```

Draw samples from the posterior density, using a few independent chains. Choose different, randomly distributed starting points for each chain. Specify the number of burn-in samples to discard from the beginning of the Markov chain and the number of samples to generate after the burn-in. Set the `'VerbosityLevel'` to print details during sampling for the first chain.

```
NumChains = 4;
chains = cell(NumChains,1);
Burnin = 500;
NumSamples = 2000;
for c = 1:NumChains
    if c == 1
        showOutput = 1;
    else
        showOutput = 0;
    end
    chains{c} = drawSamples(smp,'Burnin',Burnin,'NumSamples',NumSamples,...
        'Start',randn(size(startpoint)),'VerbosityLevel',showOutput,'NumPrint',500);
end
```

ITER	LOG PDF	STEP SIZE	NUM STEPS	ACC RATIO	DIVERGENT
500	8.017202e+01	5.303e-01	4	8.820e-01	0
1000	7.756258e+01	5.303e-01	8	8.500e-01	0
1500	9.227175e+01	5.303e-01	2	8.547e-01	0
2000	8.073805e+01	3.128e-02	6	8.610e-01	0
2500	9.672952e+01	5.161e-01	2	8.600e-01	0

After obtaining a random sample, investigate issues such as convergence and mixing to determine whether the samples represent a reasonable set of random realizations from the target distribution. To examine the output, plot the trace plots of the samples for the first few variables using the first chain.

A number of burn-in samples have been removed to reduce the effect of the sampling starting point. Furthermore, the trace plots look like high-frequency noise, without any visible long-range correlation between the samples. This indicates that the chain is well mixed.

```
for p = 1:3
    subplot(3,1,p);
    plot(chains{1}(:,p));
```

```

        ylabel(smp.VariableNames(p))
        axis tight
    end
    xlabel('Iteration')

```

The `normalDistGrad` function returns the logarithm of the multivariate normal probability density with means in `Mu` and standard deviations in `Sigma`, specified as scalars or column vectors the same length as the `startpoint`. The second output argument is the corresponding gradient.

```

function [lpdf,glpdf] = normalDistGrad(X,Mu,Sigma)
Z = (X - Mu)./Sigma;
lpdf = sum(-log(Sigma) - .5*log(2*pi) - .5*(Z.^2));
glpdf = -Z./Sigma;
end

```

Tips

- After creating an HMC sampler using the `hmcSampler` function, you can compute MAP (maximum-a-posteriori) point estimates, tune the sampler, draw samples, and check convergence diagnostics using the methods of the `HamiltonianSampler` class. For an example of this workflow, see [Bayesian Linear Regression Using Hamiltonian Monte Carlo](#) on page 7-27.

diagnostics

Class: HamiltonianSampler

Markov Chain Monte Carlo diagnostics

Syntax

```
tbl = diagnostics(smp,chains)
tbl = diagnostics(smp,chains,'MaxLag',maxlag)
```

Description

`tbl = diagnostics(smp,chains)` returns Markov Chain Monte Carlo diagnostics for the chains in `chains`.

`tbl = diagnostics(smp,chains,'MaxLag',maxlag)` specifies the maximum number of autocorrelation lags to use for computing effective sample sizes.

Input Arguments

smp — Hamiltonian Monte Carlo sampler

HamiltonianSampler object

Hamiltonian Monte Carlo sampler, specified as a HamiltonianSampler object.

Use the `hmcSampler` function to create a sampler.

chains — MCMC chains

matrix | cell array

MCMC chains, specified as one of the following:

- A matrix, where each row is a sample and each column a parameter.
- A cell array of matrices, where the chain `chains{i}` is a matrix where each row is a sample and each column a parameter.

The number of parameters (that is, matrix columns) must equal the number of elements of the `StartPoint` property of the `smp` sampler.

maxlag — Maximum number of autocorrelation lags

100 (default) | positive integer

Maximum number of autocorrelation lags for computing effective sample sizes, specified as a positive integer.

The effective sample size calculation uses lags of $1, 2, \dots, \text{maxlag}$ for each chain in `chains` that has more than `maxlag` samples.

For chains with `maxlag` or fewer samples, the calculation uses $N_i - 1$ lags, where N_i is the number of samples of chain i .

Example: 'MaxLag',50

Output Arguments

tbl — MCMC diagnostics

table

MCMC diagnostics, computed using all the chains in `chains` and returned as a table with these columns.

Column	Description
Name	Variable name
Mean	Posterior mean estimate
MCSE	Estimate of the Monte Carlo standard error (the standard deviation of the posterior mean estimate)
SD	Estimate of the posterior standard deviation
Q5	Estimate of the 5th quantile of the marginal posterior distribution
Q95	Estimate of the 95th quantile of the marginal posterior distribution
ESS	Effective sample size for the posterior mean estimate. Larger effective sample sizes lead to more accurate results. If the samples are independent, then the effective sample size is equal to the number of samples.
RHat	Gelman-Rubin convergence statistic. As a rule of thumb, values of <code>RHat</code> less than 1.1 are interpreted as a sign that the chains have converged to the target distribution. If <code>RHat</code> for any variable is larger than 1.1, try drawing more Monte Carlo samples.

Examples

Compute Markov Chain Monte Carlo Diagnostics

Create MCMC chains using a Hamiltonian Monte Carlo (HMC) sampler and compute MCMC diagnostics.

First, save a function on the MATLAB® path that returns the multivariate normal log probability density and its gradient. In this example, that function is called `normalDistGrad` and is defined at the end of the example. Then, call this function with arguments to define the `logpdf` input argument to the `hmcSampler` function.

```
means = [1;-2;2];
standevs = [1;2;0.5];
logpdf = @(theta)normalDistGrad(theta,means,standevs);
```

Choose a starting point. Create the HMC sampler and tune its parameters.

```
startpoint = randn(3,1);
smp = hmcSampler(logpdf,startpoint);
smp = tuneSampler(smp);
```

Draw samples from the posterior density, using a few independent chains. Choose different, randomly distributed starting points for each chain. Specify the number of burn-in samples to discard from the beginning of the Markov chain and the number of samples to generate after the burn-in.

```
NumChains = 4;
chains = cell(NumChains,1);
Burnin = 500;
NumSamples = 1000;
for c = 1:NumChains
    chains{c} = drawSamples(smp, 'Burnin', Burnin, 'NumSamples', NumSamples, ...
        'Start', randn(size(startpoint)));
end
```

Compute MCMC diagnostics and display the results. Compare the true means in means with the column titled Mean in the MCMCdiagnostics table. The true posterior means are within a few Monte Carlo standard errors (MCSEs) of the estimated posterior means. The HMC sampler has accurately recovered the true means. Similarly, the estimated standard deviations in the column SD are very near the true standard deviations in standev.

```
MCMCdiagnostics = diagnostics(smp,chains)
```

MCMCdiagnostics=3×8 table

Name	Mean	MCSE	SD	Q5	Q95	ESS	RHat
{'x1'}	1.0038	0.016474	0.96164	-0.58601	2.563	3407.4	1
{'x2'}	-2.0435	0.034933	1.999	-5.3476	1.1851	3274.5	1
{'x3'}	1.9957	0.008209	0.49693	1.2036	2.8249	3664.5	1

2
```

standevs

```
standevs = 3×1
```

```
1.0000
2.0000
0.5000
```

The normalDistGrad function returns the logarithm of the multivariate normal probability density with means in Mu and standard deviations in Sigma, specified as scalars or column vectors the same length as the startpoint. The second output argument is the corresponding gradient.

```
function [lpdf,glpdf] = normalDistGrad(X,Mu,Sigma)
Z = (X - Mu)./Sigma;
lpdf = sum(-log(Sigma) - .5*log(2*pi) - .5*(Z.^2));
glpdf = -Z./Sigma;
end
```

Tips

- After creating an HMC sampler using the `hmcSampler` function, you can compute MAP (maximum-a-posteriori) point estimates, tune the sampler, draw samples, and check convergence diagnostics using the methods of the `HamiltonianSampler` class. For an example of this workflow, see [Bayesian Linear Regression Using Hamiltonian Monte Carlo](#) on page 7-27.

Classification Learner

Train models to classify data using supervised machine learning

Description

The **Classification Learner** app trains models to classify data. Using this app, you can explore supervised machine learning using various classifiers. You can explore your data, select features, specify validation schemes, train models, and assess results. You can perform automated training to search for the best classification model type, including decision trees, discriminant analysis, support vector machines, logistic regression, nearest neighbors, naive Bayes, and ensemble classification.

You can perform supervised machine learning by supplying a known set of input data (observations or examples) and known responses to the data (e.g., labels or classes). You use the data to train a model that generates predictions for the response to new data. To use the model with new data, or to learn about programmatic classification, you can export the model to the workspace or generate MATLAB code to recreate the trained model.

Tip To get started, in the Classifier list, try **All Quick-To-Train** to train a selection of models. See “Automated Classifier Training” on page 23-10.

Required Products

- MATLAB
- Statistics and Machine Learning Toolbox

Note: Classification Learner does not provide data import from file, code generation, or parallel model training in MATLAB Online.

Open the Classification Learner App

- MATLAB Toolstrip: On the **Apps** tab, under **Machine Learning**, click the app icon.
- MATLAB command prompt: Enter `classificationLearner`.

Examples

- “Train Classification Models in Classification Learner App” on page 23-10
- “Select Data and Validation for Classification Problem” on page 23-16
- “Automated Classifier Training” on page 23-10
- “Feature Selection and Feature Transformation Using Classification Learner App” on page 23-37
- “Choose Classifier Options” on page 23-20
- “Assess Classifier Performance in Classification Learner” on page 23-59

Regression Learner

Train regression models to predict data using supervised machine learning

Description

The **Regression Learner** app trains regression models to predict data. Using this app, you can explore your data, select features, specify validation schemes, train models, and assess results. You can perform automated training to search for the best regression model type, including linear regression models, regression trees, Gaussian process regression models, support vector machines, and ensembles of regression trees.

Perform supervised machine learning by supplying a known set of observations of input data (predictors) and known responses. Use the observations to train a model that generates predicted responses for new input data. To use the model with new data, or to learn about programmatic regression, you can export the model to the workspace or generate MATLAB code to recreate the trained model.

Required Products

- MATLAB
- Statistics and Machine Learning Toolbox

Note: Regression Learner does not provide data import from file, code generation, or parallel model training in MATLAB Online.

Open the Regression Learner App

- MATLAB Toolstrip: On the **Apps** tab, under **Machine Learning**, click the app icon.
- MATLAB command prompt: Enter `regressionLearner`.

Distribution Fitter

Fit probability distributions to data

Description

The **Distribution Fitter** app interactively fits probability distributions to data imported from the MATLAB workspace. You can choose from 22 built-in probability distributions or create your own custom distribution. The app displays plots of the fitted distribution superimposed on a histogram of the data. Available plots include probability density function (pdf), cumulative distribution function (cdf), probability plots, and survivor functions. You can export the fitted parameter values to the workspace as a probability distribution object, and use object functions to perform further analyses. For more information on working with these objects, see “Working with Probability Distributions” on page 5-2. For the programmatic work flow of the Distribution Fitter app, see `distributionFitter`.

Required Products

- MATLAB
- Statistics and Machine Learning Toolbox

Note: Distribution Fitter does not provide printing, custom distribution defining, or code generating functionality in MATLAB Online.

Open the Distribution Fitter App

- MATLAB Toolstrip: On the **Apps** tab, under **Math, Statistics and Optimization**, click the app icon.
- MATLAB command prompt: Enter `distributionFitter`.

Examples

- “Fit a Distribution Using the Distribution Fitter App” on page 5-69

Parameters

Data

Data — Data to import from the workspace

list of variables | valid MATLAB expression

Specify the data to import by selecting a variable from the drop-down list. If the variable is a matrix, the app imports the first column of the matrix by default. To select a different column or row of the matrix, click **Select Column or Row**. Alternatively, you can enter any valid MATLAB expression in the field.

Censoring — Variable containing censoring data

list of variables

Specify the censoring data by selecting a variable from the drop-down list. If the variable is a matrix, the app imports the first column of the matrix by default. To select a different column or row of the matrix, click **Select Column or Row**. This parameter is optional.

Frequency — Variable containing frequency data

list of variables

Specify the frequency data by selecting a variable from the drop-down list. If the variable is a matrix, the app imports the first column of the matrix by default. To select a different column or row of the matrix, click **Select Column or Row**. This parameter is optional.

Data set name — Data set name

character vector

Specify a name for the data set as a character vector, or accept the default name.

Manage data sets — Manage previously imported data sets

list of data sets

Manage previously imported data sets. Click the data set of interest, then click the buttons below this pane to view the data (**View**), set the bin rules (**Set Bin Rules**), rename the data set (**Rename**), or delete the data set (**Delete**).

Data preview — Preview plot of data

histogram plot

Display a preview plot of the variable selected from the **Data** drop-down menu.

New fit**Fit name — Name of fit**

character vector

Specify a name for the fit or accept the default name.

Data — Data set to fit

list of data sets

Specify the data to fit by selecting a data set from the drop-down list.

Distribution — Distribution to fit

Normal (default) | Exponential | Weibull | Non-parametric | ...

Specify the distribution to fit by selecting a distribution name from the drop-down list.

Exclusion rule — Data exclusion rule

list of exclusion rules

Specify a rule to exclude some data values by selecting an exclusion rule from the drop-down list. To populate this drop-down list, you must first define exclusion rules by clicking **Exclude** in the main window of the app. This parameter is optional

Manage fits**Plot — Flag to plot fitted distribution**

checked (default) | unchecked

Specify which fit or fits to plot in the main window by selecting the **Plot** check box next to each fit. Clear the **Plot** check box to remove a fit from the plot.

Conf bounds – Flag to plot confidence bounds

unchecked (default) | checked

If you select **Plot** for a particular fit, you can select **Conf bounds** to display the confidence bounds for that fit on the plot in the main window. Clearing the **Conf bounds** check box removes the confidence intervals from the plot. The Distribution Fitter app displays confidence bounds only if the Display Type in the main window is set to **Cumulative probability (CDF)**, **Quantile (inverse CDF)**, **Survivor function**, or **Cumulative hazard**.

Evaluate

Fit – Fit to evaluate

list of fits

Select one or more fits from the list to evaluate.

Function – Available functions to fit

Density (PDF) (default) | Cumulative probability (CDF) | Quantile (inverse CDF) | Survivor function | Cumulative hazard | Hazard rate

Specify the type of probability function to evaluate from the drop-down list. Available probability functions include the probability density function (pdf), cumulative distribution function (cdf), quantile (inverse cdf), survival function, cumulative hazard, and hazard rate.

At x = – Values at which to evaluate function

numeric vector

Specify a numeric vector of values at which to evaluate the function. If you specify **Function** as **Quantile (inverse CDF)**, this field name changes to **At p =** and you enter a vector of probability values.

Compute confidence bounds – Flag to compute confidence bounds

unchecked (default) | checked

Select **Compute confidence bounds** to compute the confidence bounds for the selected fit. This check box is enabled only if you specify **Function** as **Cumulative probability (CDF)**, **Quantile (inverse CDF)**, **Survivor function**, or **Cumulative hazard**. This parameter is optional.

Level – Level for confidence bounds

95% (default) | numeric value

Specify the level at which to compute the confidence bounds. This check box is enabled only if you specify **Function** as **Cumulative probability (CDF)**, **Quantile (inverse CDF)**, **Survivor function**, or **Cumulative hazard**.

Plot function – Flag to plot function

unchecked (default) | checked

Select **Plot function** to display a plot of the distribution function, evaluated at the points that you enter in the **At x =** field, in a new window. This parameter is optional.

Exclude

Exclusion rule name — Name of exclusion rule

character vector

Specify a name for the exclusion rule as a character vector.

Exclude sections — Define data exclusion rules numerically

numeric value

Specify lower and upper limits for the data numerically.

Exclude graphically — Define data exclusion rules graphically

list of variables

Specify lower and upper limits for the data by selecting a variable from the **Select data** drop-down list and clicking **Exclude graphically**. An interactive plot opens in a new window, where you can add lower or upper limits by clicking and dragging a boundary on the plot.

Existing exclusion rules — List of existing exclusion rules

list of exclusion rules

Select an existing exclusion rule from the list. You can copy, view, rename, or delete exclusion rules by clicking the appropriate button.

Programmatic Use

`distributionFitter` opens the Distribution Fitter app, or brings focus to the app if it is already open.

`distributionFitter(y)` opens the Distribution Fitter app populated with the data specified by the vector `y`.

`distributionFitter(y, cens)` uses the vector `cens` to specify whether the observation `y(j)` is censored, (`cens(j)==1`), or observed exactly, (`cens(j)==0`). If `cens` is omitted or empty, then no `y` values are censored.

`distributionFitter(y, cens, freq)` uses the vector `freq` to specify the frequency of each element contained in `y`. If `freq` is omitted or empty, then all values in `y` have a frequency of 1.

`distributionFitter(y, cens, freq, dsname)` creates a data set with the name `dsname` using the data vector, `y`, censoring indicator, `cens`, and frequency vector, `freq`. Specify `dsname` as a character vector or string scalar, for example, `'mydata'`.

Introduced before R2006a

plotPartialDependence

Package:

Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots

Syntax

```
plotPartialDependence(Mdl,Vars)
plotPartialDependence(Mdl,Vars,X)
plotPartialDependence( ____,Name,Value)
ax = plotPartialDependence( ____ )
```

Description

`plotPartialDependence(Mdl,Vars)` creates a PDP between features listed in `Vars` and responses predicted by using predictor data and a trained regression model in `Mdl`.

`plotPartialDependence(Mdl,Vars,X)` creates a PDP by using new predictor data in `X`.

`plotPartialDependence(____,Name,Value)` uses additional options specified by one or more name-value pair arguments in addition to any of the arguments in the previous syntaxes. For example, if you specify 'Conditional', 'absolute', the `plotPartialDependence` function creates a figure including a PDP, a scatter plot of the selected feature and predicted responses, and an ICE plot for each observation.

`ax = plotPartialDependence(____)` returns the axes of the plot using any of the input arguments combinations in the previous syntaxes.

Examples

Create Partial Dependence Plot

Train a regression tree using the `carsmall` data set, and create a PDP that shows the relationship between a feature and the predicted responses in the trained regression tree.

Load the `carsmall` data set.

```
load carsmall
```

Specify `Weight`, `Cylinders`, and `Horsepower` as the predictor variables (`X`), and `MPG` as the response variable (`Y`).

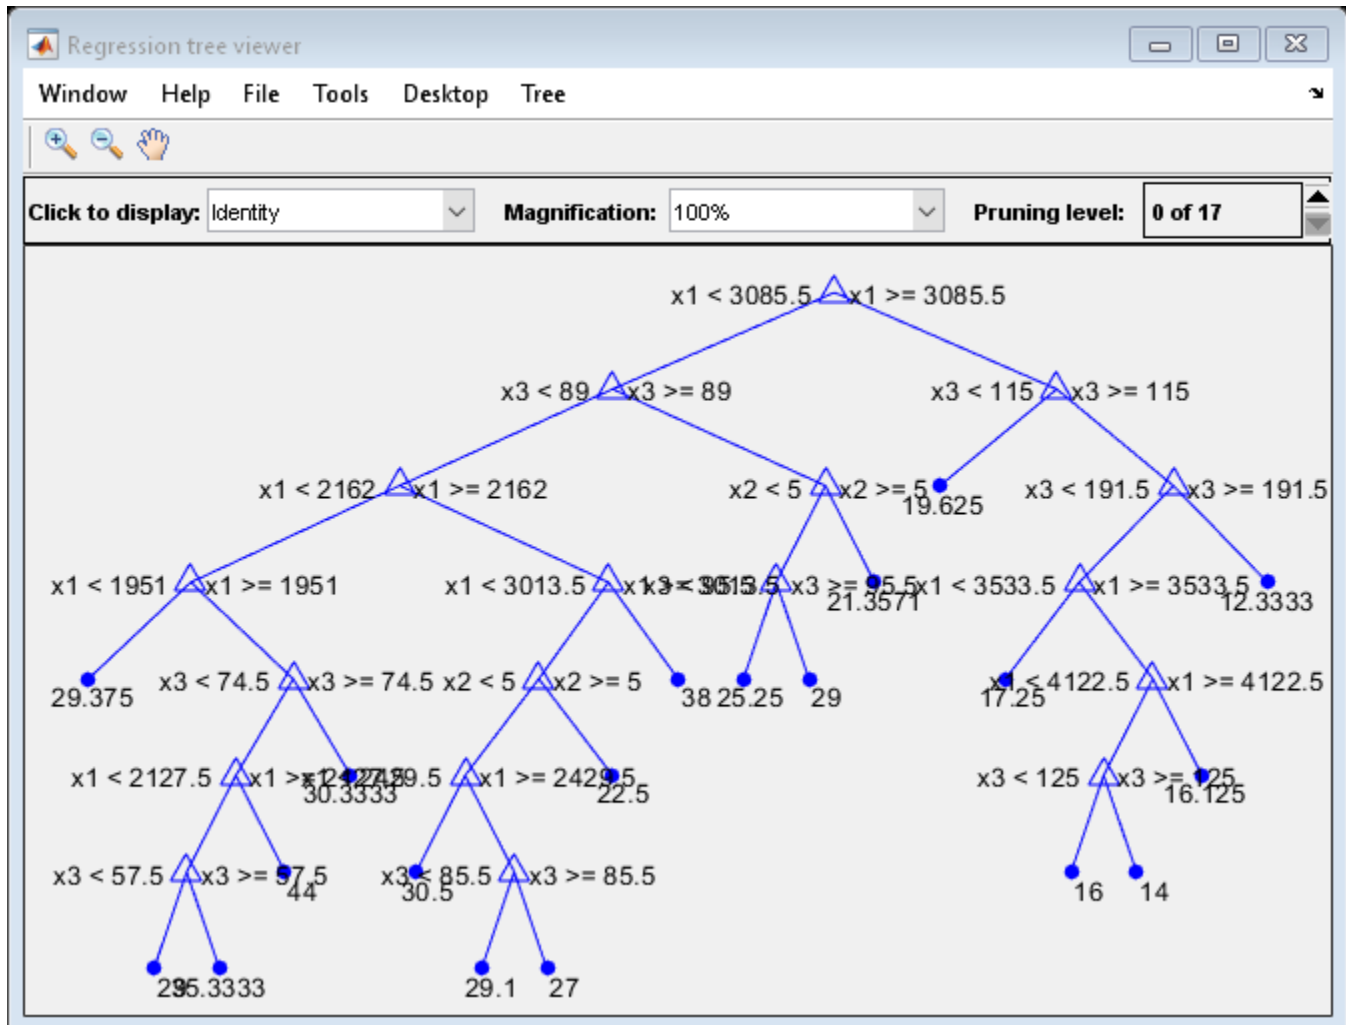

```
X = [Weight,Cylinders,Horsepower];
Y = MPG;
```

Construct a regression tree using `X` and `Y`.

```
Mdl = fitrtree(X,Y);
```

View a graphical display of the trained regression tree.

```
view(Mdl, 'Mode', 'graph')
```

Create a PDP of the first predictor variable, Weight.

```
plotPartialDependence(Mdl, 1)
```

The blue line represents averaged partial relationships between `Weight` (labeled as `x1`) and `MPG` (labeled as `Y`) in the trained regression tree `Mdl`.

The regression tree viewer shows that the first decision is whether `x1` is smaller than 3085.5. The PDP also shows a large change near `x1 = 3085.5`. The tree viewer visualizes each decision at each node based on predictor variables. You can find several nodes split based on the values of `x1`, but it is not easy to figure out the dependence of `Y` on `x1`. However, the PDP plots averaged predicted responses against `x1`, so you can clearly see the partial dependence of `Y` on `x1`.

The labels `x1` and `Y` are the default values of the predictor names and the response name. You can modify these names by specifying the name-value pair arguments `'PredictorNames'` and `'ResponseName'` when you train `Mdl` using `fitrtree`. You can also modify axis labels by using the `xlabel` and `ylabel` functions.

Create Individual Conditional Expectation Plots

Train a Gaussian process regression model using generated sample data where a response variable includes interactions between predictor variables. Then, create ICE plots that show the relationship between a feature and the predicted responses for each observation.

Generate sample predictor data `x1` and `x2`.

```
rng('default') % For reproducibility
n = 200;
```

```
x1 = rand(n,1)*2-1;
x2 = rand(n,1)*2-1;
```

Generate response values that include interactions between x_1 and x_2 .

```
Y = x1-2*x1.*(x2>0)+0.1*rand(n,1);
```

Construct a Gaussian process regression model using $[x_1 \ x_2]$ and Y .

```
Mdl = fitrgp([x1 x2],Y);
```

Create a figure including a PDP (red line) for the first predictor x_1 , a scatter plot (black circle markers) of x_1 and predicted responses, and a set of ICE plots (gray lines) by specifying 'Conditional' as 'centered'.

```
plotPartialDependence(Mdl,1,'Conditional','centered')
```

When 'Conditional' is 'centered', `plotPartialDependence` offsets plots so that all plots start from zero, which is helpful in examining the cumulative effect of the selected feature.

A PDP finds averaged relationships, so it does not reveal hidden dependencies especially when responses include interactions between features. However, the ICE plots clearly show two different dependencies of responses on x_1 .

Compare Importance of Predictor Variables

Train a regression ensemble using the `carsmall` data set, and create a PDP plot and ICE plots for each predictor variable using a new data set, `carbig`. Then, compare the figures to analyze the importance of predictor variables. Also, compare the results with the estimates of predictor importance returned by the `predictorImportance` function.

Load the `carsmall` data set.

```
load carsmall
```

Specify `Weight`, `Cylinders`, `Horsepower`, and `Model_Year` as the predictor variables (X), and `MPG` as the response variable (Y).

```
X = [Weight,Cylinders,Horsepower,Model_Year];
Y = MPG;
```

Train a regression ensemble using X and Y.

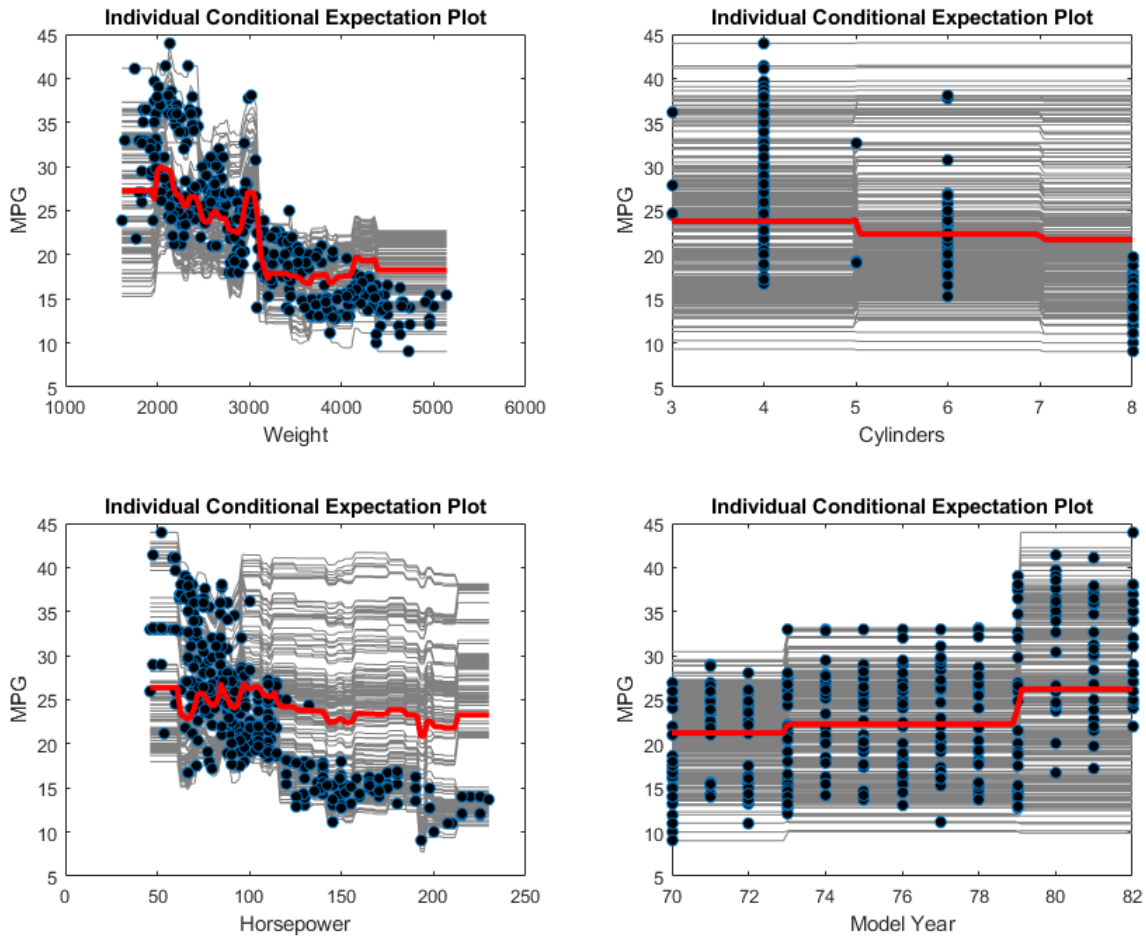

```
Mdl = fitensemble(X,Y, ...
    'PredictorNames',{'Weight','Cylinders','Horsepower','Model Year'}, ...
    'ResponseName','MPG');
```

Compare the importance of predictor variables by using the `plotPartialDependence` and `predictorImportance` functions. The `plotPartialDependence` function visualizes the relationships between a selected predictor and predicted responses. `predictorImportance` summarizes the importance of a predictor with a single value.

Create a figure including a PDP plot (red line) and ICE plots (gray lines) for each predictor by using `plotPartialDependence` and specifying `'Conditional'`, `'absolute'`. Each figure also includes a scatter plot (black circle markers) of the selected predictor and predicted responses. Also, load the `carbig` data set and use it as new predictor data, `Xnew`. When you provide `Xnew`, the `plotPartialDependence` function uses `Xnew` instead of the predictor data in `Mdl`.

```
load carbig
Xnew = [Weight,Cylinders,Horsepower,Model_Year];

f = figure;
f.Position = [100 100 1.75*f.Position(3:4)]; % Enlarge figure for visibility.
for i = 1 : 4
    subplot(2,2,i)
    plotPartialDependence(Mdl,i,Xnew,'Conditional','absolute')
end
```

Compute estimates of predictor importance by using `predictorImportance`. This function sums changes in the mean-squared error (MSE) due to splits on every predictor, and then divides the sum by the number of branch nodes.

```
imp = predictorImportance(Mdl);
figure;
bar(imp);
title('Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
ax = gca;
ax.XTickLabel = Mdl.PredictorNames;
```

The variable `Weight` has the most impact on MPG according to predictor importance. The PDP of `Weight` also shows that MPG has high partial dependence on `Weight`. The variable `Cylinders` has the least impact on MPG according to predictor importance. The PDP of `Cylinders` also shows that MPG does not change much depending on `Cylinders`.

Extract Partial Dependence Estimates from Plots

Train a support vector machine (SVM) regression model using the `carsmall` data set, and create a PDP for two predictor variables. Then, extract partial dependence estimates from the output of `plotPartialDependence`.

Load the `carsmall` data set.

```
load carsmall
```

Specify `Weight`, `Cylinders`, and `Horsepower` as the predictor variables (`Tbl`).

```
Tbl = table(Weight,Cylinders,Horsepower);
```

Construct a support vector machine (SVM) regression model using `Tbl` and the response variable `MPG`. Use a Gaussian kernel function with an automatic kernel scale.

```
Mdl = fitcsvm(Tbl,MPG,'ResponseName','MPG', ...
    'KernelFunction','gaussian','KernelScale','auto');
```

Create a PDP that visualizes partial dependence of predicted responses (MPG) on the predictor variables Weight and Horsepower. Use the QueryPoints name-value pair argument to specify the points to compute partial dependence.

```
pt1 = linspace(min(Weight),max(Weight),50)';
pt2 = linspace(min(Horsepower),max(Horsepower),50)';
ax = plotPartialDependence(Mdl,{'Weight','Horsepower'},'QueryPoints',[pt1 pt2]);
view(140,30) % Modify the viewing angle
```

The PDP shows an interaction effect between Weight and Horsepower.

Extract the estimated partial dependence of MPG on Weight and Horsepower. The XData, YData, and ZData values of ax.Children are x-axis values (the first selected predictor values), y-axis values (the second selected predictor values), and z-axis values (the corresponding partial dependence values), respectively.

```
xval = ax.Children.XData;
yval = ax.Children.YData;
zval = ax.Children.ZData;
```

If you specify 'Conditional' as 'absolute', plotPartialDependence creates a figure including a PDP, a scatter plot, and a set of ICE plots. ax.Children(1) and ax.Children(2) correspond to the PDP and scatter plot, respectively. The remaining elements of ax.Children correspond to the ICE plots. The XData and YData values of ax.Children(i) are x-axis values (the selected predictor values) and y-axis values (the corresponding partial dependence values), respectively.

Input Arguments

Mdl — Trained regression model

full regression model object | compact regression model object

Trained regression model, specified as a full or compact regression model object described in the following table.

Trained Model Type	Regression Model Object	Returned By
Bootstrap aggregation for ensemble of decision trees	TreeBagger, CompactTreeBagger	TreeBagger, compact
Ensemble of regression models	RegressionEnsemble, RegressionBaggedEnsemble, CompactRegressionEnsemble	fitrensemble, compact
Gaussian process regression	RegressionGP, CompactRegressionGP	fitrgp, compact
Generalized linear mixed-effect model	GeneralizedLinearMixedModel	fitglme
Generalized linear model	GeneralizedLinearModel, CompactGeneralizedLinearModel	fitglm, stepwiseglm, compact
Linear mixed-effect model	LinearMixedModel	fitlme, fitlmematrix
Linear regression	LinearModel, CompactLinearModel	fitlm, stepwiselm, compact
Linear regression for high-dimensional data	RegressionLinear	fitrlinear
Nonlinear regression	NonLinearModel	fitnlm
Regression tree	RegressionTree, CompactRegressionTree	fitrtree, compact
Support vector machine regression	RegressionSVM, CompactRegressionSVM	fitsvm, compact

If Mdl is a compact regression model object, you must provide X.

plotPartialDependence does not support a trained model object with a sparse matrix. If you train Mdl by using fitrlinear, use a full numeric matrix for predictor data where rows correspond to individual observations.

Vars — Features to visualize

vector of positive integers | character vector | string scalar | string array | cell array of character vectors

Features to visualize, specified as a vector of positive integers, character vector or string scalar, string array, or cell array of character vectors. You can choose one or two features, as shown in the following tables.

One Feature

Value	Description
positive integer	Index value corresponding to the column of the predictor data to visualize.
character vector or string scalar	Name of a predictor variable to visualize. The name must match the entry in <code>Mdl.PredictorNames</code> .

Two Features

Value	Description
vector of two positive integers	Index values corresponding to the columns of the predictor data to visualize.
string array or cell array of character vectors	Names of the predictor variables to visualize. Each element in the array is the name of a predictor variable. The names must match the entries in <code>Mdl.PredictorNames</code> .

Example: `{'x1', 'x3'}`

Data Types: `single` | `double` | `char` | `string` | `cell`

X — Predictor data

numeric matrix | table

Predictor data, specified as a numeric matrix or table. Each row of `X` corresponds to one observation, and each column corresponds to one variable.

- If `Mdl` is a full regression model object, `plotPartialDependence` uses the predictor data in `Mdl`. If you provide `X`, then `plotPartialDependence` does not use the predictor data in `Mdl` and uses `X` only.
- If `Mdl` is a compact regression model object, you must provide `X`.

`X` must be consistent with the predictor data that trained `Mdl`, stored in either `Mdl.X` or `Mdl.Variables`.

- If you trained `Mdl` using a numeric matrix, then `X` must be a numeric matrix. The variables making up the columns of `X` must have the same number and order as the predictor variables that trained `Mdl`.
- If you trained `Mdl` using a table (for example, `Tbl`), then `X` must be a table. All predictor variables in `X` must have the same variable names and data types as the names and types in `Tbl`. However, the column order of `X` does not need to correspond to the column order of `Tbl`.
- `plotPartialDependence` does not support a sparse matrix.

Data Types: `single` | `double` | `table`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

```
plotPartialDependence(Mdl, Vars, X, 'NumObservationsToSample', 100, 'UseParallel',
```

true) creates a PDP by using 100 sampled observations in X and executing for-loop iterations in parallel.

Conditional – Plot type

'none' (default) | 'absolute' | 'centered'

Plot type, specified as the comma-separated pair consisting of 'Conditional' and 'none', 'absolute', or 'centered'.

Value	Description
'none'	<p><code>plotPartialDependence</code> creates a PDP.</p> <ul style="list-style-type: none"> If you select one numeric feature in <code>Vars</code>, <code>plotPartialDependence</code> computes partial dependence at values between the minimum and maximum of the selected feature and creates a PDP with a solid blue line. If you select one categorical feature in <code>Vars</code>, <code>plotPartialDependence</code> computes predicted responses at all categorical values and plots partial dependence with blue circle markers connected with a dotted line. If you select two features in <code>Vars</code>, <code>plotPartialDependence</code> creates a surface plot.
'absolute'	<p><code>plotPartialDependence</code> creates a figure including the following three types of plots:</p> <ul style="list-style-type: none"> PDP with a solid red line Scatter plot of the selected feature and predicted responses with black circle markers ICE plot for each observation with a solid gray line <p>This value is valid when you select only one feature.</p>
'centered'	<p><code>plotPartialDependence</code> creates a figure including the same three types of plots as 'absolute'. <code>plotPartialDependence</code> offsets plots so that all plots start from zero.</p> <p>This value is valid when you select only one feature.</p>

For details, see “Partial Dependence Plot” on page 32-5908 and “Individual Conditional Expectation Plots” on page 32-5908.

Example: 'Conditional', 'absolute'

NumObservationsToSample – Number of observations to sample

number of total observations (default) | positive integer

Number of observations to sample, specified as the comma-separated pair consisting of 'NumObservationsToSample' and a positive integer. The default value is the number of total observations in either `Mdl` or `X`. If you specify a value larger than the number of total observations, then `plotPartialDependence` uses all observations.

`plotPartialDependence` samples observations without replacement by using the function `datasample` and uses the sampled observations to compute partial dependence. If you specify 'Conditional' as either 'absolute' or 'centered', `plotPartialDependence` creates a figure including an ICE plot for each sampled observation.

Example: 'NumObservationsToSample', 100

Data Types: single | double

ParentAxisHandle — Axes in which to plot

gca (default) | axes object

Axes in which to plot, specified as the comma-separated pair consisting of 'ParentAxisHandle' and an axes object. If you do not specify the axes and if the current axes are Cartesian, then plotPartialDependence uses the current axes (gca). If axes do not exist, plotPartialDependence plots in a new figure.

Example: 'ParentAxisHandle',ax

QueryPoints — Points to compute partial dependence

numeric column vector | numeric two column matrix | cell array of two numeric column vectors

Points to compute partial dependence, specified as the comma-separated pair consisting of 'QueryPoints' and a numeric column vector, a numeric two-column matrix, or a cell array of two numeric column vectors.

The default value is a numeric column vector or a numeric two-column matrix, depending on the number of selected features, where a column contains 100 evenly spaced points between the minimum and maximum values of the selected feature.

- If you select one feature in Vars, use a numeric column vector.
- If you select two features in Vars:
 - Use a numeric two-column matrix to specify the same number of points for each feature.
 - Use a cell array of two numeric column vectors to specify a different number of points for each feature.

The default values for a categorical feature are all categorical values in the selected feature. You cannot modify 'QueryPoints' for a categorical feature. If you select one numeric feature and one categorical feature, you can specify 'QueryPoints' for a numeric feature by using a cell array consisting of a numeric column vector and an empty array.

Example: 'QueryPoints',{pt,[]}

Data Types: single | double | cell

UseParallel — Flag to run in parallel

false (default) | true

Flag to run in parallel, specified as the comma-separated pair consisting of 'UseParallel' and true or false. If you specify 'UseParallel' as true, plotPartialDependence executes for-loop iterations in parallel by using parfor when predicting responses for each observation and averaging them.

Example: 'UseParallel',true

Data Types: logical

Output Arguments**ax — Axes of the plot**

axes object

Axes of the plot, returned as an axes object. For details on how to modify the appearance of the axes and extract data from plots, see “Axes Appearance” (MATLAB) and “Extract Partial Dependence Estimates from Plots” on page 32-5902.

More About

Partial Dependence Plot

A partial dependence plot[1] (PDP) visualizes relationships between features and predicted responses in a trained regression model. `plotPartialDependence` creates either a line plot or a surface plot of predicted responses against a single feature or a pair of features, respectively, by marginalizing over the other variables.

Consider a PDP for a subset X^S of the whole feature set $X = \{x_1, x_2, \dots, x_m\}$. A subset X^S includes either one feature or two features: $X^S = \{x_{S1}\}$ or $X^S = \{x_{S1}, x_{S2}\}$. Let X^C be the complementary set of X^S in X . A predicted response $f(X)$ depends on all features in X :

$$f(X) = f(X^S, X^C).$$

The partial dependence of predicted responses on X^S is defined by the expectation of predicted responses with respect to X^C :

$$f^S(X^S) = E_C[f(X^S, X^C)] = \int f(X^S, X^C) p_C(X^C) dX^C,$$

where $p_C(X^C)$ is the marginal probability of X^C , that is, $p_C(X^C) \approx \int p(X^S, X^C) dX^S$. Assuming that each observation is equally likely, and the dependence between X^S and X^C and the interactions of X^S and X^C in responses are not strong, `plotPartialDependence` estimates the partial dependence by using observed predictor data as follows:

$$f^S(X^S) \approx \frac{1}{N} \sum_{i=1}^N f(X^S, X_i^C), \quad (32-1)$$

where N is the number of observations and $X_i = (X_i^S, X_i^C)$ is the i th observation.

`plotPartialDependence` creates a PDP by using “Equation 32-1”. Input a trained model ($f(\cdot)$) and select features (X^S) to visualize by using the input arguments `Mdl` and `Vars`, respectively. `plotPartialDependence` computes partial dependence at 100 evenly spaced points of X^S or the points that you specify by using the 'QueryPoints' name-value pair argument. You can specify the number (N) of observations to sample from given predictor data by using the 'NumObservationsToSample' name-value pair argument.

Individual Conditional Expectation Plots

An individual conditional expectation (ICE) plot[2], as an extension of a PDP, visualizes the relationship between a feature and the predicted responses for each observation. While a PDP visualizes the averaged relationship between features and predicted responses, a set of ICE plots disaggregates the averaged information and visualizes an individual dependence for each observation.

`plotPartialDependence` creates an ICE plot for each observation. A set of ICE plots is useful to investigate heterogeneities of partial dependence originating from different observations. `plotPartialDependence` can also create ICE plots with any predictor data provided through the input argument `X`. You can use this feature to explore predicted response space.

Consider an ICE plot for a selected feature x_S with a given observation X_i^C , where $X^S = \{x_S\}$, X^C is the complementary set of X^S in the whole feature set X , and $X_i = (X_i^S, X_i^C)$ is the i th observation. The ICE plot corresponds to the summand of the summation in “Equation 32-1”:

$$f_i^S(X^S) = f(X^S, X_i^C).$$

`plotPartialDependence` plots $f_i^S(X^S)$ for each observation i when you specify 'Conditional' as 'absolute'. If you specify 'Conditional' as 'centered', `plotPartialDependence` draws all plots after removing level effects due to different observations:

$$f_{i, \text{centered}}^S(X^S) = f(X^S, X_i^C) - f(\min(X^S), X_i^C).$$

This subtraction ensures that each plot starts from zero, so that you can examine the cumulative effect of X^S and the interactions between X^S and X^C .

Weighted Traversal Algorithm

The weighted traversal algorithm[1] is a method to estimate partial dependence for a tree-based regression model. The estimated partial dependence is the weighted average of response values corresponding to the leaf nodes visited during the tree traversal.

Let X^S be a subset of the whole feature set X and X^C be the complementary set of X^S in X . For each X^S value to compute partial dependence, the algorithm traverses a tree from the root (beginning) node down to leaf (terminal) nodes and finds the weights of leaf nodes. The traversal starts by assigning a weight value of one at the root node. If a node splits by X^S , the algorithm traverses to the appropriate child node depending on the X^S value. The weight of the child node becomes the same value as its parent node. If a node splits by X^C , the algorithm traverses to both child nodes. The weight of each child node becomes a value of its parent node multiplied by the fraction of observations corresponding to each child node. After completing the tree traversal, the algorithm computes the weighted average by using the assigned weights.

For an ensemble of regression trees, the estimated partial dependence is an average of the weighted averages over the individual regression trees.

Algorithms

`plotPartialDependence` uses a `predict` function to predict responses. `plotPartialDependence` chooses the proper `predict` function according to `Mdl` and runs `predict` with its default settings. For details about each `predict` function, see the `predict` function in the following table. If `Mdl` is a tree-based model (not including a boosted ensemble of trees) and 'Conditional' is 'none', then `plotPartialDependence` uses the weighted traversal algorithm instead of the `predict` function. For details, see “Weighted Traversal Algorithm” on page 32-5909.

Trained Model Type	Regression Model Object	Function to Predict Responses
Bootstrap aggregation for ensemble of decision trees	<code>CompactTreeBagger</code>	<code>predict</code>

Trained Model Type	Regression Model Object	Function to Predict Responses
Bootstrap aggregation for ensemble of decision trees	TreeBagger	predict
Ensemble of regression models	RegressionEnsemble, RegressionBaggedEnsemble, CompactRegressionEnsemble	predict
Gaussian process regression	RegressionGP, CompactRegressionGP	predict
Generalized linear mixed-effect model	GeneralizedLinearMixedModel	predict
Generalized linear model	GeneralizedLinearModel, CompactGeneralizedLinearModel	predict
Linear mixed-effect model	LinearMixedModel	predict
Linear regression	LinearModel, CompactLinearModel	predict
Linear regression for high-dimensional data	RegressionLinear	predict
Nonlinear regression	NonLinearModel	predict
Regression tree	RegressionTree, CompactRegressionTree	predict
Support vector machine regression	RegressionSVM, CompactRegressionSVM	predict

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel', true name-value pair argument in the call to this function.

For more general information about parallel computing, see "Run MATLAB Functions with Automatic Parallel Support" (Parallel Computing Toolbox).

Topics

“Introduction to Feature Selection” on page 15-49

Introduced in R2017b

fitckernel

Fit Gaussian kernel classification model using random feature expansion

Syntax

```
Mdl = fitckernel(X,Y)
Mdl = fitckernel(X,Y,Name,Value)
[Mdl,FitInfo] = fitckernel(____)
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitckernel(____)
```

Description

`fitckernel` trains or cross-validates a binary Gaussian kernel classification model for nonlinear classification. `fitckernel` is more practical for big data applications that have large training sets but can also be applied to smaller data sets that fit in memory.

`fitckernel` maps data in a low-dimensional space into a high-dimensional space, then fits a linear model in the high-dimensional space by minimizing the regularized objective function. Obtaining the linear model in the high-dimensional space is equivalent to applying the Gaussian kernel to the model in the low-dimensional space. Available linear classification models include regularized support vector machine (SVM) and logistic regression models.

To train a nonlinear SVM model for binary classification of in-memory data, see `fitsvm`.

`Mdl = fitckernel(X,Y)` returns a binary Gaussian kernel classification model trained using the predictor data in `X` and the corresponding class labels in `Y`. The `fitckernel` function maps the predictors in a low-dimensional space into a high-dimensional space, then fits a binary SVM model to the transformed predictors and class labels. This linear model is equivalent to the Gaussian kernel classification model in the low-dimensional space.

`Mdl = fitckernel(X,Y,Name,Value)` returns a kernel classification model with additional options specified by one or more name-value pair arguments. For example, you can implement logistic regression, specify the number of dimensions of the expanded space, or specify to cross-validate.

`[Mdl,FitInfo] = fitckernel(____)` also returns the fit information in the structure array `FitInfo` using any of the input arguments in the previous syntaxes. You cannot request `FitInfo` for cross-validated models.

`[Mdl,FitInfo,HyperparameterOptimizationResults] = fitckernel(____)` also returns the hyperparameter optimization results `HyperparameterOptimizationResults` when you optimize hyperparameters by using the `'OptimizeHyperparameters'` name-value pair argument.

Examples

Train Kernel Classification Model

Train a binary kernel classification model using SVM.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
[n,p] = size(X)

n = 351

p = 34

resp = unique(Y)

resp = 2x1 cell
    {'b'}
    {'g'}
```

Train a binary kernel classification model that identifies whether the radar return is bad ('b') or good ('g'). Extract a fit summary to determine how well the optimization algorithm fits the model to the data.

```
rng('default') % For reproducibility
[Mdl,FitInfo] = fitckernel(X,Y)

Mdl =
    ClassificationKernel
        ResponseName: 'Y'
        ClassNames: {'b' 'g'}
        Learner: 'svm'
        NumExpansionDimensions: 2048
        KernelScale: 1
        Lambda: 0.0028
        BoxConstraint: 1
```

Properties, Methods

```
FitInfo = struct with fields:
    Solver: 'LBFGS-fast'
    LossFunction: 'hinge'
    Lambda: 0.0028
    BetaTolerance: 1.0000e-04
    GradientTolerance: 1.0000e-06
    ObjectiveValue: 0.2604
    GradientMagnitude: 0.0028
    RelativeChangeInBeta: 8.2512e-05
    FitTime: 0.3910
    History: []
```

`Mdl` is a `ClassificationKernel` model. To inspect the in-sample classification error, you can pass `Mdl` and the training data or new data to the `loss` function. Or, you can pass `Mdl` and new predictor data to the `predict` function to predict class labels for new observations. You can also pass `Mdl` and the training data to the `resume` function to continue training.

`FitInfo` is a structure array containing optimization information. Use `FitInfo` to determine whether optimization termination measurements are satisfactory.

For better accuracy, you can increase the maximum number of optimization iterations ('IterationLimit') and decrease the tolerance values ('BetaTolerance' and 'GradientTolerance') by using the name-value pair arguments. Doing so can improve measures like ObjectiveValue and RelativeChangeInBeta in FitInfo. You can also optimize model parameters by using the 'OptimizeHyperparameters' name-value pair argument.

Cross-Validate Kernel Classification Model

Load the ionosphere data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
rng('default') % For reproducibility
```

Cross-validate a binary kernel classification model. By default, the software uses 10-fold cross-validation.

```
CVMdl = fitckernel(X,Y,'CrossVal','on')
CVMdl =
    classreg.learning.partition.ClassificationPartitionedKernel
        CrossValidatedModel: 'Kernel'
           ResponseName: 'Y'
      NumObservations: 351
                KFold: 10
           Partition: [1x1 cvpartition]
        ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
```

Properties, Methods

```
numel(CVMdl.Trained)
```

```
ans = 10
```

CVMdl is a ClassificationPartitionedKernel model. Because fitckernel implements 10-fold cross-validation, CVMdl contains 10 ClassificationKernel models that the software trains on training-fold (in-fold) observations.

Estimate the cross-validated classification error.

```
kfoldLoss(CVMdl)
```

```
ans = 0.0940
```

The classification error rate is approximately 9%.

Optimize Kernel Classifier

Optimize hyperparameters automatically using the 'OptimizeHyperparameters' name-value pair argument.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization. Specify 'OptimizeHyperparameters' as 'auto' so that `fitckernel` finds optimal values of the 'KernelScale' and 'Lambda' name-value pair arguments. For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```
rng('default')
```

```
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitckernel(X,Y,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName','expected-improvement-plus'))
```

For big data, the optimization procedure can take a long time. If the data set is too large to run the optimization procedure, you can try to optimize the parameters using only partial data. Use the `datasample` function and specify `'Replace', 'false'` to sample data without replacement.

Input Arguments

X — Predictor data

numeric matrix

Predictor data, specified as an n -by- p numeric matrix, where n is the number of observations and p is the number of predictors.

The length of Y and the number of observations in X must be equal.

Data Types: `single` | `double`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

- `fitckernel` supports only binary classification. Either Y must contain exactly two distinct classes, or you must specify two classes for training by using the `ClassNames` name-value pair argument.
- If Y is a character array, then each element must correspond to one row of the array.
- The length of Y and the number of observations in X must be equal.
- A good practice is to specify the class order by using the `ClassNames` name-value pair argument.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Note `fitckernel` removes missing observations, that is, observations with any of these characteristics:

- `NaN`, empty character vector (`' '`), empty string (`""`), `<missing>`, and `<undefined>` elements in the response (Y)
 - At least one `NaN` value in a predictor observation (row in X)
 - `NaN` value or 0 weight (`'Weights'`)
-

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example: `Mdl = fitckernel(X,Y,'Learner','logistic','NumExpansionDimensions',2^15,'KernelScale','auto')` implements logistic regression after mapping the predictor data to the 2^{15} dimensional space using feature expansion with a kernel scale parameter selected by a heuristic procedure.

Kernel Classification Options

Learner — Linear classification model type

`'svm'` (default) | `'logistic'`

Linear classification model type, specified as the comma-separated pair consisting of `'Learner'` and `'svm'` or `'logistic'`.

In the following table, $f(x) = T(x)\beta + b$.

- x is an observation (row vector) from p predictor variables.
- $T(\cdot)$ is a transformation of an observation (row vector) for feature expansion. $T(x)$ maps x in \mathbb{R}^p to a high-dimensional space (\mathbb{R}^m).
- β is a vector of m coefficients.
- b is the scalar bias.

Value	Algorithm	Response Range	Loss Function
<code>'svm'</code>	Support vector machine	$y \in \{-1, 1\}$; 1 for the positive class and -1 otherwise	Hinge: $\ell[y, f(x)] = \max[0, 1 - yf(x)]$
<code>'logistic'</code>	Logistic regression	Same as <code>'svm'</code>	Deviance (logistic): $\ell[y, f(x)] = \log\{1 + \exp[-yf(x)]\}$

Example: `'Learner','logistic'`

NumExpansionDimensions — Number of dimensions of expanded space

`'auto'` (default) | positive integer

Number of dimensions of the expanded space, specified as the comma-separated pair consisting of `'NumExpansionDimensions'` and `'auto'` or a positive integer. For `'auto'`, the `fitckernel` function selects the number of dimensions using $2.^{\text{ceil}(\min(\log_2(p)+5, 15))}$, where p is the number of predictors.

For details, see “Random Feature Expansion” on page 32-5932.

Example: 'NumExpansionDimensions', 2^15

Data Types: char | string | single | double

KernelScale — Kernel scale parameter

1 (default) | 'auto' | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of 'KernelScale' and 'auto' or a positive scalar. The software obtains a random basis for random feature expansion by using the kernel scale parameter. For details, see “Random Feature Expansion” on page 32-5932.

If you specify 'auto', then the software selects an appropriate kernel scale parameter using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. Therefore, to reproduce results, set a random number seed by using rng before training.

Example: 'KernelScale', 'auto'

Data Types: char | string | single | double

BoxConstraint — Box constraint

1 (default) | positive scalar

Box constraint, specified as the comma-separated pair consisting of 'BoxConstraint' and a positive scalar.

This argument is valid only when 'Learner' is 'svm' (default) and you do not specify a value for the regularization term strength 'Lambda'. You can specify either 'BoxConstraint' or 'Lambda' because the box constraint (C) and the regularization term strength (λ) are related by $C = 1/(\lambda n)$, where n is the number of observations.

Example: 'BoxConstraint', 100

Data Types: single | double

Lambda — Regularization term strength

'auto' (default) | nonnegative scalar

Regularization term strength, specified as the comma-separated pair consisting of 'Lambda' and 'auto' or a nonnegative scalar.

For 'auto', the value of 'Lambda' is $1/n$, where n is the number of observations.

You can specify either 'BoxConstraint' or 'Lambda' because the box constraint (C) and the regularization term strength (λ) are related by $C = 1/(\lambda n)$.

Example: 'Lambda', 0.01

Data Types: char | string | single | double

Cross-Validation Options

CrossVal — Flag to train cross-validated classifier

'off' (default) | 'on'

Flag to train a cross-validated classifier, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software trains a cross-validated classifier with 10 folds.

You can override this cross-validation setting using the `CVPartition`, `Holdout`, `KFold`, or `Leaveout` name-value pair argument. You can use only one cross-validation name-value pair argument at a time to create a cross-validated model.

Example: 'Crossval', 'on'

CVPartition — Cross-validation partition

[] (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500, 'KFold', 5)`. Then, you can specify the cross-validated model by using 'CVPartition', `cvp`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', `p`, then the software completes these steps:

- 1 Randomly select and reserve $p \times 100\%$ of the data as validation data, and train the model using the rest of the data.
- 2 Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'Holdout', 0.1

Data Types: double | single

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold', `k`, then the software completes these steps:

- 1 Randomly partition the data into `k` sets.
- 2 For each set, reserve the set as validation data, and train the model using the other `k - 1` sets.
- 3 Store the `k` compact, trained models in the cells of a `k-by-1` cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'KFold', 5

Data Types: single | double

Leaveout — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the n observations (where n is the number of observations excluding missing observations), the software completes these steps:

- 1 Reserve the observation as validation data, and train the model using the other $n - 1$ observations.
- 2 Store the n compact, trained models in the cells of an n -by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Leaveout', 'on'

Convergence Controls

BetaTolerance — Relative tolerance on linear coefficients and bias term

1e-5 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If you also specify GradientTolerance, then optimization terminates when the software satisfies either stopping criterion.

Example: 'BetaTolerance', 1e-6

Data Types: single | double

GradientTolerance — Absolute gradient tolerance

1e-6 (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of 'GradientTolerance' and a nonnegative scalar.

Let $\nabla \mathcal{L}_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t . If $\|\nabla \mathcal{L}_t\|_\infty = \max |\nabla \mathcal{L}_t| < \text{GradientTolerance}$, then optimization terminates.

If you also specify BetaTolerance, then optimization terminates when the software satisfies either stopping criterion.

Example: 'GradientTolerance', 1e-5

Data Types: single | double

IterationLimit — Maximum number of optimization iterations

positive integer

Maximum number of optimization iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer.

The default value is 1000 if the transformed data fits in memory, as specified by the `BlockSize` name-value pair argument. Otherwise, the default value is 100.

Example: `'IterationLimit',500`

Data Types: `single` | `double`

Other Kernel Classification Options

BlockSize — Maximum amount of allocated memory

`4e^3` (4GB) (default) | positive scalar

Maximum amount of allocated memory (in megabytes), specified as the comma-separated pair consisting of `'BlockSize'` and a positive scalar.

If `fitckernel` requires more memory than the value of `'BlockSize'` to hold the transformed predictor data, then the software uses a block-wise strategy. For details about the block-wise strategy, see “Algorithms” on page 32-5933.

Example: `'BlockSize',1e4`

Data Types: `single` | `double`

RandomStream — Random number stream

global stream (default) | random stream object

Random number stream for reproducibility of data transformation, specified as the comma-separated pair consisting of `'RandomStream'` and a random stream object. For details, see “Random Feature Expansion” on page 32-5932.

Use `'RandomStream'` to reproduce the random basis functions that `fitckernel` uses to transform the predictor data to a high-dimensional space. For details, see “Managing the Global Stream” (MATLAB) and “Creating and Controlling a Random Number Stream” (MATLAB).

Example: `'RandomStream',RandStream('mlfg6331_64')`

HessianHistorySize — Size of history buffer for Hessian approximation

15 (default) | positive integer

Size of the history buffer for Hessian approximation, specified as the comma-separated pair consisting of `'HessianHistorySize'` and a positive integer. At each iteration, `fitckernel` composes the Hessian approximation by using statistics from the latest `HessianHistorySize` iterations.

Example: `'HessianHistorySize',10`

Data Types: `single` | `double`

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and either 0 or 1. `Verbose` controls the display of diagnostic information at the command line.

Value	Description
0	fitckernel does not display diagnostic information.
1	fitckernel displays and stores the value of the objective function, gradient magnitude, and other diagnostic information. FitInfo.History contains the diagnostic information.

Example: 'Verbose',1

Data Types: single | double

Other Classification Options

ClassNames — Names of classes to use for training

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. ClassNames must have the same data type as Y.

If ClassNames is a character array, then each element must correspond to one row of the array.

Use 'ClassNames' to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use 'ClassNames' to specify the order of the dimensions of Cost or the column order of classification scores returned by predict.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in Y is {'a', 'b', 'c'}. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames', {'a', 'c'}.

The default value for ClassNames is the set of all distinct class names in Y.

Example: 'ClassNames', {'b', 'g'}

Data Types: categorical | char | string | logical | single | double | cell

Cost — Misclassification cost

square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure.

- If you specify the square matrix cost ('Cost', cost), then cost(i, j) is the cost of classifying a point into class j if its true class is i. That is, the rows correspond to the true class, and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of cost, use the ClassNames name-value pair argument.
- If you specify the structure S ('Cost', S), then it must have two fields:
 - S.ClassNames, which contains the class names as a variable of the same data type as Y
 - S.ClassificationCosts, which contains the cost matrix with rows and columns ordered as in S.ClassNames

The default value for `Cost` is $\text{ones}(K) - \text{eye}(K)$, where K is the number of distinct classes.

`fitckernel` uses `Cost` to adjust the prior class probabilities specified in `Prior`. Then, `fitckernel` uses the adjusted prior probabilities for training and resets the cost matrix to its default.

Example: `'Cost',[0 2; 1 0]`

Data Types: `single` | `double` | `struct`

Prior — Prior probabilities

`'empirical'` (default) | `'uniform'` | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and `'empirical'`, `'uniform'`, a numeric vector, or a structure array.

This table summarizes the available options for setting prior probabilities.

Value	Description
<code>'empirical'</code>	The class prior probabilities are the class relative frequencies in Y .
<code>'uniform'</code>	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to their order in Y . If you specify the order using the <code>'ClassNames'</code> name-value pair argument, then order the elements accordingly.
structure array	A structure S with two fields: <ul style="list-style-type: none"> <code>S.ClassNames</code> contains the class names as a variable of the same type as Y. <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities.

`fitckernel` normalizes the prior probabilities in `Prior` to sum to 1.

Example: `'Prior',struct('ClassNames',{'setosa','versicolor'}),'ClassProbs',1:2)`

Data Types: `char` | `string` | `double` | `single` | `struct`

ScoreTransform — Score transformation

`'none'` (default) | `'doublelogit'` | `'invlogit'` | `'ismax'` | `'logit'` | function handle | ...

Score transformation, specified as the comma-separated pair consisting of `'ScoreTransform'` and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

Value	Description
<code>'doublelogit'</code>	$1/(1 + e^{-2x})$
<code>'invlogit'</code>	$\log(x / (1 - x))$

Value	Description
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for the score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform', 'logit'

Data Types: char | string | function_handle

Weights — Observation weights

positive numeric vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a positive numeric vector of length n , where n is the number of observations in X . The `fitckernel` function weighs the observations in X with the corresponding values in `Weights`.

The default value is `ones(n,1)`.

`fitckernel` normalizes `Weights` to sum up to the value of the prior probability in the respective class.

Example: 'Weights', w

Data Types: single | double

Hyperparameter Optimization Options

OptimizeHyperparameters — Parameters to optimize

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of these values:

- 'none' — Do not optimize.
- 'auto' — Use {'KernelScale', 'Lambda'}.
- 'all' — Optimize all eligible parameters.
- Cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for `fitkernel` by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair argument.

Note 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for `fitkernel` are:

- `KernelScale` — `fitkernel` searches among positive values, by default log-scaled in the range `[1e-3, 1e3]`.
- `Lambda` — `fitkernel` searches among positive values, by default log-scaled in the range `[1e-3, 1e3]/n`, where `n` is the number of observations.
- `Learner` — `fitkernel` searches among 'svm' and 'logistic'.
- `NumExpansionDimensions` — `fitkernel` searches among positive integers, by default log-scaled in the range `[100, 10000]`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example:

```
load fisheriris
params = hyperparameters('fitkernel', meas, species);
params(2).Range = [1e-4, 1e6];
```

Pass `params` as the value of 'OptimizeHyperparameters'.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the 'HyperparameterOptimizationOptions' name-value pair argument. To control the plots, set the `ShowPlots` field of the 'HyperparameterOptimizationOptions' name-value pair argument.

For an example, see “Optimize Kernel Classifier” on page 32-5914.

Example: 'OptimizeHyperparameters', 'auto'

HyperparameterOptimizationOptions — Options for optimization

structure

Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> 'bayesopt' — Use Bayesian optimization. Internally, this setting calls bayesopt. 'gridsearch' — Use grid search with NumGridDivisions values per dimension. 'randomsearch' — Search at random among MaxObjectiveEvaluations points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command <code>sortrows(Mdl.HyperparameterOptimizationResults)</code>.</p>	'bayesopt'
AcquisitionFunctionName	<ul style="list-style-type: none"> 'expected-improvement-per-second-plus' 'expected-improvement' 'expected-improvement-plus' 'expected-improvement-per-second' 'lower-confidence-bound' 'probability-of-improvement' <p>Acquisition functions whose names include per-second do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include plus modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-3.</p>	'expected-improvement-per-second-plus'
MaxObjectiveEvaluations	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
MaxTime	Time limit, specified as a positive real. The time limit is in seconds, as measured by <code>tic</code> and <code>toc</code> . Run time can exceed MaxTime because MaxTime does not interrupt function evaluations.	Inf
NumGridDivisions	For 'gridsearch', the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	10

Field Name	Values	Default
ShowPlots	Logical value indicating whether to show plots. If <code>true</code> , this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if <code>Optimizer</code> is <code>'bayesopt'</code> , then <code>ShowPlots</code> also plots a model of the objective function against the parameters.	<code>true</code>
SaveIntermediateResults	Logical value indicating whether to save results when <code>Optimizer</code> is <code>'bayesopt'</code> . If <code>true</code> , this field overwrites a workspace variable named <code>'BayesoptResults'</code> at each iteration. The variable is a <code>BayesianOptimization</code> object.	<code>false</code>
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesopt</code> <code>Verbose</code> name-value pair argument.	1
UseParallel	Logical value indicating whether to run Bayesian optimization in parallel, which requires <code>Parallel Computing Toolbox</code> . Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. For details, see “Parallel Bayesian Optimization” on page 10-7.	<code>false</code>
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.	<code>false</code>
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code> .	<code>'Kfold'</code> , 5 if you do not specify any cross-validation field
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example:

```
'HyperparameterOptimizationOptions', struct('MaxObjectiveEvaluations', 60)
```

Data Types: `struct`

Output Arguments

Mdl — Trained kernel classification model

ClassificationKernel model object | ClassificationPartitionedKernel cross-validated model object

Trained kernel classification model, returned as a ClassificationKernel model object or ClassificationPartitionedKernel cross-validated model object.

If you set any of the name-value pair arguments CrossVal, CVPartition, Holdout, KFold, or Leaveout, then Mdl is a ClassificationPartitionedKernel cross-validated classifier. Otherwise, Mdl is a ClassificationKernel classifier.

To reference properties of Mdl, use dot notation. For example, enter Mdl.NumExpansionDimensions in the Command Window to display the number of dimensions of the expanded space.

Note Unlike other classification models, and for economical memory usage, a ClassificationKernel model object does not store the training data or training process details (for example, convergence history).

FitInfo — Optimization details

structure array

Optimization details, returned as a structure array including fields described in this table. The fields contain final values or name-value pair argument specifications.

Field	Description
Solver	Objective function minimization technique: 'LBFGS-fast', 'LBFGS-blockwise', or 'LBFGS-tall'. For details, see "Algorithms" on page 32-5933.
LossFunction	Loss function. Either 'hinge' or 'logit' depending on the type of linear classification model. See Learner.
Lambda	Regularization term strength. See Lambda.
BetaTolerance	Relative tolerance on the linear coefficients and the bias term. See BetaTolerance.
GradientTolerance	Absolute gradient tolerance. See GradientTolerance.
ObjectiveValue	Value of the objective function when optimization terminates. The classification loss plus the regularization term compose the objective function.
GradientMagnitude	Infinite norm of the gradient vector of the objective function when optimization terminates. See GradientTolerance.
RelativeChangeInBeta	Relative changes in the linear coefficients and the bias term when optimization terminates. See BetaTolerance.
FitTime	Elapsed, wall-clock time (in seconds) required to fit the model to the data.

Field	Description
History	History of optimization information. This field is empty ([]) if you specify 'Verbose', 0. For details, see Verbose and "Algorithms" on page 32-5933.

To access fields, use dot notation. For example, to access the vector of objective function values for each iteration, enter `FitInfo.ObjectiveValue` in the Command Window.

A good practice is to examine `FitInfo` to assess whether convergence is satisfactory.

HyperparameterOptimizationResults — Cross-validation optimization of hyperparameters

`BayesianOptimization` object | table of hyperparameters and associated values

Cross-validation optimization of hyperparameters, returned as a `BayesianOptimization` object or a table of hyperparameters and associated values. The output is nonempty when the value of 'OptimizeHyperparameters' is not 'none'. The output value depends on the `Optimizer` field value of the 'HyperparameterOptimizationOptions' name-value pair argument:

Value of Optimizer Field	Value of HyperparameterOptimizationResults
'bayesopt' (default)	Object of class <code>BayesianOptimization</code>
'gridsearch' or 'randomsearch'	Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

Limitations

- `fitkernel` does not accept initial conditions for the vector of coefficients β and bias term (b) used to determine the decision function, $f(x) = T(x)\beta + b$.
- `fitkernel` does not support standardization and cross-validation options.
- `fitkernel` does not accept table inputs.

More About

Random Feature Expansion

Random feature expansion, such as Random Kitchen Sinks[1] and Fastfood[2], is a scheme to approximate Gaussian kernels of the kernel classification algorithm to use for big data in a computationally efficient way. Random feature expansion is more practical for big data applications that have large training sets, but can also be applied to smaller data sets that fit in memory.

The kernel classification algorithm searches for an optimal hyperplane that separates the data into two classes after mapping features into a high-dimensional space. Nonlinear features that are not linearly separable in a low-dimensional space can be separable in the expanded high-dimensional space. All the calculations for hyperplane classification use only dot products. You can obtain a nonlinear classification model by replacing the dot product x_1x_2' with the nonlinear kernel function $G(x_1, x_2) = \langle \varphi(x_1), \varphi(x_2) \rangle$, where x_i is the i th observation (row vector) and $\varphi(x_i)$ is a transformation that maps x_i to a high-dimensional space (called the "kernel trick"). However, evaluating $G(x_1, x_2)$

(Gram matrix) for each pair of observations is computationally expensive for a large data set (large n).

The random feature expansion scheme finds a random transformation so that its dot product approximates the Gaussian kernel. That is,

$$G(x_1, x_2) = \langle \varphi(x_1), \varphi(x_2) \rangle \approx T(x_1)T(x_2)',$$

where $T(x)$ maps x in \mathbb{R}^p to a high-dimensional space (\mathbb{R}^m). The Random Kitchen Sink scheme uses the random transformation

$$T(x) = m^{-1/2} \exp(iZx)',$$

where $Z \in \mathbb{R}^{m \times p}$ is a sample drawn from $N(0, \sigma^{-2})$ and σ^2 is a kernel scale. This scheme requires $O(mp)$ computation and storage. The Fastfood scheme introduces another random basis V instead of Z using Hadamard matrices combined with Gaussian scaling matrices. This random basis reduces the computation cost to $O(m \log p)$ and reduces storage to $O(m)$.

The `fitckernel` function uses the Fastfood scheme for random feature expansion and uses linear classification to train a Gaussian kernel classification model. Unlike solvers in the `fitsvm` function, which require computation of the n -by- n Gram matrix, the solver in `fitckernel` only needs to form a matrix of size n -by- m , with m typically much less than n for big data.

Box Constraint

A box constraint is a parameter that controls the maximum penalty imposed on margin-violating observations, and aids in preventing overfitting (regularization). Increasing the box constraint can lead to longer training times.

The box constraint (C) and the regularization term strength (λ) are related by $C = 1/(\lambda n)$, where n is the number of observations.

Algorithms

`fitckernel` minimizes the regularized objective function using a Limited-memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) solver with ridge (L_2) regularization. To find the type of LBFGS solver used for training, type `FitInfo.Solver` in the Command Window.

- 'LBFGS-fast' — LBFGS solver.
- 'LBFGS-blockwise' — LBFGS solver with a block-wise strategy. If `fitckernel` requires more memory than the value of `BlockSize` to hold the transformed predictor data, then it uses a block-wise strategy.
- 'LBFGS-tall' — LBFGS solver with a block-wise strategy for tall arrays.

When `fitckernel` uses a block-wise strategy, `fitckernel` implements LBFGS by distributing the calculation of the loss and gradient among different parts of the data at each iteration. Also, `fitckernel` refines the initial estimates of the linear coefficients and the bias term by fitting the model locally to parts of the data and combining the coefficients by averaging. If you specify 'Verbose', 1, then `fitckernel` displays diagnostic information for each data pass and stores the information in the `History` field of `FitInfo`.

When `fitkernel` does not use a block-wise strategy, the initial estimates are zeros. If you specify `'Verbose', 1`, then `fitkernel` displays diagnostic information for each iteration and stores the information in the `History` field of `FitInfo`.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Some name-value pair arguments have different defaults compared to the default values for the in-memory `fitkernel` function. Supported name-value pair arguments, and any differences, are:
 - `'Learner'`
 - `'NumExpansionDimensions'`
 - `'KernelScale'`
 - `'BoxConstraint'`
 - `'Lambda'`
 - `'BetaTolerance'` — Default value is relaxed to `1e-3`.
 - `'GradientTolerance'` — Default value is relaxed to `1e-5`.
 - `'IterationLimit'` — Default value is relaxed to `20`.
 - `'BlockSize'`
 - `'RandomStream'`
 - `'HessianHistorySize'`
 - `'Verbose'` — Default value is `1`.
 - `'ClassNames'`
 - `'Cost'`
 - `'Prior'`
 - `'ScoreTransform'`
 - `'Weights'` — Value must be a tall array.
 - `'OptimizeHyperparameters'`
 - `'HyperparameterOptimizationOptions'` — For cross-validation, tall optimization supports only `'Holdout'` validation. For example, you can specify

```
fitckernel(X,Y,'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',struct('Holdout',0.2)).
```

- If 'KernelScale' is 'auto', then `fitckernel` uses the random stream controlled by `tallrng` for subsampling. For reproducibility, you must set a random number seed for both the global stream and the random stream controlled by `tallrng`.
- If 'Lambda' is 'auto', then `fitckernel` might take an extra pass through the data to calculate the number of observations in X .
- `fitckernel` uses a block-wise strategy. For details, see “Algorithms” on page 32-5933.

For more information, see “Tall Arrays” (MATLAB).

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to `true`.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', `struct('UseParallel',true)` name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

ClassificationKernel

Gaussian kernel classification model using random feature expansion

Description

`ClassificationKernel` is a trained model object for a binary Gaussian kernel classification model using random feature expansion. `ClassificationKernel` is more practical for big data applications that have large training sets but can also be applied to smaller data sets that fit in memory.

Unlike other classification models, and for economical memory usage, `ClassificationKernel` model objects do not store the training data. However, they do store information such as the number of dimensions of the expanded space, the kernel scale parameter, prior-class probabilities, and the regularization strength.

You can use trained `ClassificationKernel` models to continue training using the training data and to predict labels or classification scores for new data. For details, see `resume` and `predict`.

Creation

Create a `ClassificationKernel` object using the `fitkernel` function. This function maps data in a low-dimensional space into a high-dimensional space, then fits a linear model in the high-dimensional space by minimizing the regularized objective function. The linear model in the high-dimensional space is equivalent to the model with a Gaussian kernel in the low-dimensional space. Available linear classification models include regularized support vector machine (SVM) and logistic regression models.

Properties

Kernel Classification Properties

Learner — Linear classification model type

'logistic' | 'svm'

Linear classification model type, specified as 'logistic' or 'svm'.

In the following table, $f(x) = T(x)\beta + b$.

- x is an observation (row vector) from p predictor variables.
- $T(\cdot)$ is a transformation of an observation (row vector) for feature expansion. $T(x)$ maps x in \mathbb{R}^p to a high-dimensional space (\mathbb{R}^m).
- β is a vector of m coefficients.
- b is the scalar bias.

Value	Algorithm	Loss Function	FittedLoss Value
'logistic'	Logistic regression	Deviance (logistic): $\ell[y, f(x)] = \log \{1 + \exp[-yf(x)]\}$	'logit'
'svm'	Support vector machine	Hinge: $\ell[y, f(x)] = \max [0, 1 - yf(x)]$	'hinge'

NumExpansionDimensions — Number of dimensions of expanded space

positive integer

Number of dimensions of the expanded space, specified as a positive integer.

Data Types: single | double

KernelScale — Kernel scale parameter

positive scalar

Kernel scale parameter, specified as a positive scalar.

Data Types: char | single | double

BoxConstraint — Box constraint

positive scalar

Box constraint, specified as a positive scalar.

Data Types: double | single

Lambda — Regularization term strength

nonnegative scalar

Regularization term strength, specified as a nonnegative scalar.

Data Types: single | double

FittedLoss — Loss function used to fit linear model

'hinge' | 'logit'

Loss function used to fit the linear model, specified as 'hinge' or 'logit'.

Value	Algorithm	Loss Function	Learner Value
'hinge'	Support vector machine	Hinge: $\ell[y, f(x)] = \max [0, 1 - yf(x)]$	'svm'
'logit'	Logistic regression	Deviance (logistic): $\ell[y, f(x)] = \log \{1 + \exp[-yf(x)]\}$	'logistic'

Regularization — Complexity penalty type

'ridge (L2)'

Complexity penalty type, which is always 'ridge (L2)'.

The software composes the objective function for minimization from the sum of the average loss function (see FittedLoss) and the regularization term, ridge (L_2) penalty.The ridge (L_2) penalty is

$$\frac{\lambda}{2} \sum_{j=1}^p \beta_j^2$$

where λ specifies the regularization term strength (see `Lambda`). The software excludes the bias term (β_0) from the regularization penalty.

Other Classification Properties

CategoricalPredictors — Indices of categorical predictors

[]

Indices of categorical predictors, whose value is always empty ([]) because a `ClassificationKernel` model does not support categorical predictors.

ClassNames — Unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` has the same data type as the class labels `Y`. (The software treats string arrays as cell arrays of character vectors.) `ClassNames` also determines the class order.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Cost — Misclassification costs

square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. `Cost` has K rows and columns, where K is the number of classes.

`Cost(i, j)` is the cost of classifying a point into class j if its true class is i . The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`.

Data Types: `double`

ModelParameters — Parameters used for training model

structure

Parameters used for training the `ClassificationKernel` model, specified as a structure.

Access fields of `ModelParameters` using dot notation. For example, access the relative tolerance on the linear coefficients and the bias term by using `Mdl.ModelParameters.BetaTolerance`.

Data Types: `struct`

PredictorNames — Predictor names

cell array of character vectors

Predictor names in order of their appearance in the predictor data `X`, specified as a cell array of character vectors. The length of `PredictorNames` is equal to the number of columns in `X`.

Data Types: `cell`

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

Expanded predictor names, specified as a cell array of character vectors.

Because a `ClassificationKernel` model does not support categorical predictors, `ExpandedPredictorNames` and `PredictorNames` are equal.

Data Types: `cell`

Prior — Prior class probabilities

numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. `Prior` has as many elements as classes in `ClassNames`, and the order of the elements corresponds to the elements of `ClassNames`.

Data Types: `double`

ScoreTransform — Score transformation function to apply to predicted scores

'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'none' | function handle | ...

Score transformation function to apply to predicted scores, specified as a function name or function handle.

For kernel classification models and before the score transformation, the predicted classification score for the observation x (row vector) is $f(x) = T(x)\beta + b$.

- $T(\cdot)$ is a transformation of an observation for feature expansion.
- β is the estimated column vector of coefficients.
- b is the estimated scalar bias.

To change the score transformation function to *function*, for example, use dot notation.

- For a built-in function, enter this code and replace *function* with a value from the table.

```
Mdl.ScoreTransform = 'function';
```

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

- For a MATLAB function, or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function must accept a matrix of the original scores for each class, and then return a matrix of the same size representing the transformed scores for each class.

Data Types: char | function_handle

ResponseName — Response variable name

character vector

Response variable name, specified as a character vector.

Data Types: char

Object Functions

edge	Classification edge for Gaussian kernel classification model
loss	Classification loss for Gaussian kernel classification model
margin	Classification margins for Gaussian kernel classification model
predict	Predict labels for Gaussian kernel classification model
resume	Resume training of Gaussian kernel classification model

Examples

Train Kernel Classification Model

Train a binary kernel classification model using SVM.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
[n,p] = size(X)

n = 351
p = 34

resp = unique(Y)

resp = 2x1 cell
    {'b'}
    {'g'}
```

Train a binary kernel classification model that identifies whether the radar return is bad ('b') or good ('g'). Extract a fit summary to determine how well the optimization algorithm fits the model to the data.

```
rng('default') % For reproducibility
[Mdl,FitInfo] = fitkernel(X,Y)

Mdl =
    ClassificationKernel
        ResponseName: 'Y'
```

```

        ClassNames: {'b' 'g'}
        Learner: 'svm'
    NumExpansionDimensions: 2048
        KernelScale: 1
            Lambda: 0.0028
        BoxConstraint: 1

```

Properties, Methods

```

FitInfo = struct with fields:
    Solver: 'LBFGS-fast'
    LossFunction: 'hinge'
    Lambda: 0.0028
    BetaTolerance: 1.0000e-04
    GradientTolerance: 1.0000e-06
    ObjectiveValue: 0.2604
    GradientMagnitude: 0.0028
    RelativeChangeInBeta: 8.2512e-05
    FitTime: 0.3910
    History: []

```

`Mdl` is a `ClassificationKernel` model. To inspect the in-sample classification error, you can pass `Mdl` and the training data or new data to the `loss` function. Or, you can pass `Mdl` and new predictor data to the `predict` function to predict class labels for new observations. You can also pass `Mdl` and the training data to the `resume` function to continue training.

`FitInfo` is a structure array containing optimization information. Use `FitInfo` to determine whether optimization termination measurements are satisfactory.

For better accuracy, you can increase the maximum number of optimization iterations (`'IterationLimit'`) and decrease the tolerance values (`'BetaTolerance'` and `'GradientTolerance'`) by using the name-value pair arguments. Doing so can improve measures like `ObjectiveValue` and `RelativeChangeInBeta` in `FitInfo`. You can also optimize model parameters by using the `'OptimizeHyperparameters'` name-value pair argument.

Predict Class Labels and Resume Training

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Partition the data set into training and test sets. Specify a 20% holdout sample for the test set.

```

rng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',0.20);
trainingInds = training(Partition); % Indices for the training set
XTrain = X(trainingInds,:);
YTrain = Y(trainingInds);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds);

```

Train a binary kernel classification model that identifies whether the radar return is bad ('b') or good ('g').

```
Mdl = fitckernel(XTrain,YTrain,'IterationLimit',5,'Verbose',1);
```

Solver	Pass	Iteration	Objective	Step	Gradient magnitude	Relative change in Beta
LBFGS	1	0	1.000000e+00	0.000000e+00	2.811388e-01	
LBFGS	1	1	7.585395e-01	4.000000e+00	3.594306e-01	1.000000e+00
LBFGS	1	2	7.160994e-01	1.000000e+00	2.028470e-01	6.923988e-01
LBFGS	1	3	6.825272e-01	1.000000e+00	2.846975e-02	2.388909e-01
LBFGS	1	4	6.699435e-01	1.000000e+00	1.779359e-02	1.325304e-01
LBFGS	1	5	6.535619e-01	1.000000e+00	2.669039e-01	4.112952e-01

Mdl is a ClassificationKernel model.

Predict the test-set labels, construct a confusion matrix for the test set, and estimate the classification error for the test set.

```
label = predict(Mdl,XTest);
ConfusionTest = confusionchart(YTest,label);
```

```
L = loss(Mdl,XTest,YTest)
```

```
L = 0.3594
```

MdL misclassifies all bad radar returns as good returns.

Continue training by using resume. This function continues training with the same options used for training MdL.

```
UpdatedMdL = resume(MdL,XTrain,YTrain);
```

Solver	Pass	Iteration	Objective	Step	Gradient magnitude	Relative change in Beta

LBFGS	1	116	2.452691e-01	1.000000e+00	2.135231e-02	9.941716e-04

Predict the test-set labels, construct a confusion matrix for the test set, and estimate the classification error for the test set.

```
UpdatedLabel = predict(UpdatedMdl,XTest);
UpdatedConfusionTest = confusionchart(YTest,UpdatedLabel);
```

```
UpdatedL = loss(UpdatedMdl, XTest, YTest)
```

```
UpdatedL = 0.1284
```

The classification error decreases after resume updates the classification model with more iterations.

Introduced in R2017b

edge

Classification edge for Gaussian kernel classification model

Syntax

```
e = edge(Mdl,X,Y)
e = edge(Mdl,X,Y,'Weights',weights)
```

Description

`e = edge(Mdl,X,Y)` returns the classification edge on page 32-5949 for the binary Gaussian kernel classification model `Mdl` using the predictor data in `X` and the corresponding class labels in `Y`.

`e = edge(Mdl,X,Y,'Weights',weights)` returns the weighted classification edges for the observation weights supplied in `weights`.

Examples

Estimate Test-Set Edge

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Partition the data set into training and test sets. Specify a 15% holdout sample for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',0.15);
trainingInds = training(Partition); % Indices for the training set
testInds = test(Partition); % Indices for the test set
```

Train a binary kernel classification model using the training set.

```
Mdl = fitckernel(X(trainingInds,:),Y(trainingInds));
```

Estimate the training-set edge and the test-set edge.

```
eTrain = edge(Mdl,X(trainingInds,:),Y(trainingInds))
```

```
eTrain = 2.1703
```

```
eTest = edge(Mdl,X(testInds,:),Y(testInds))
```

```
eTest = 1.5643
```

Feature Selection Using Test-Set Edges

Perform feature selection by comparing test-set edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Partition the data set into training and test sets. Specify a 15% holdout sample for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',0.15);
trainingInds = training(Partition); % Indices for the training set
XTrain = X(trainingInds,:);
YTrain = Y(trainingInds);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds);
```

Randomly choose half of the predictor variables.

```
p = size(X,2); % Number of predictors
idxPart = randsample(p,ceil(0.5*p));
```

Train two binary kernel classification models: one that uses all of the predictors, and one that uses half of the predictors.

```
Mdl = fitckernel(XTrain,YTrain);
PMdl = fitckernel(XTrain(:,idxPart),YTrain);
```

`Mdl` and `PMdl` are `ClassificationKernel` models.

Estimate the test-set edge for each classifier.

```
fullEdge = edge(Mdl,XTest,YTest)
fullEdge = 1.6335
partEdge = edge(PMdl,XTest(:,idxPart),YTest)
partEdge = 2.0205
```

Based on the test-set edges, the classifier that uses half of the predictors is the better model.

Input Arguments

Mdl — Binary kernel classification model

`ClassificationKernel` model object

Binary kernel classification model, specified as a `ClassificationKernel` model object. You can create a `ClassificationKernel` model object using `fitckernel`.

X — Predictor data

n -by- p numeric matrix

Predictor data, specified as an n -by- p numeric matrix, where n is the number of observations and p is the number of predictors used to train `Mdl`.

The length of `Y` and the number of observations in `X` must be equal.

Data Types: `single` | `double`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

- The data type of `Y` must be the same as the data type of `Mdl.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)
- The distinct classes in `Y` must be a subset of `Mdl.ClassNames`.
- If `Y` is a character array, then each element must correspond to one row of the array.
- The length of `Y` and the number of observations in `X` must be equal.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

weights — Observation weights

positive numeric vector

Observation weights, specified as a positive numeric vector of length n , where n is the number of observations in `X`. If you supply weights, `edge` computes the weighted classification edge on page 32-5949.

The default value is `ones(n, 1)`.

`edge` normalizes `weights` to sum up to the value of the prior probability in the respective class.

Data Types: `double` | `single`

Output Arguments

e — Classification edge

numeric scalar

Classification edge on page 32-5949, returned as a numeric scalar.

More About

Classification Edge

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation x . The classification margin is commonly defined as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

For kernel classification models, the raw classification score for classifying the observation x , a row vector, into the positive class is defined by

$$f(x) = T(x)\beta + b.$$

- $T(\cdot)$ is a transformation of an observation for feature expansion.
- β is the estimated column vector of coefficients.
- b is the estimated scalar bias.

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields a positive score.

If the kernel classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see `ScoreTransform`).

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

`ClassificationKernel` | `fitckernel` | `margin` | `predict`

Introduced in R2017b

loss

Classification loss for Gaussian kernel classification model

Syntax

```
L = loss(Mdl,X,Y)
L = loss(Mdl,X,Y,Name,Value)
```

Description

`L = loss(Mdl,X,Y)` returns the classification loss on page 32-5955 for the binary Gaussian kernel classification model `Mdl` using the predictor data in `X` and the corresponding class labels in `Y`.

`L = loss(Mdl,X,Y,Name,Value)` uses additional options specified by one or more name-value pair arguments. For example, you can specify a classification loss function and observation weights. Then, `loss` returns the weighted classification loss using the specified loss function.

Examples

Estimate Test-Set Classification Loss

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Partition the data set into training and test sets. Specify a 15% holdout sample for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',0.15);
trainingInds = training(Partition); % Indices for the training set
testInds = test(Partition); % Indices for the test set
```

Train a binary kernel classification model using the training set.

```
Mdl = fitckernel(X(trainingInds,:),Y(trainingInds));
```

Estimate the training-set classification error and the test-set classification error.

```
ceTrain = loss(Mdl,X(trainingInds,:),Y(trainingInds))
ceTrain = 0.0067
ceTest = loss(Mdl,X(testInds,:),Y(testInds))
ceTest = 0.1140
```

Specify Custom Classification Loss

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Partition the data set into training and test sets. Specify a 15% holdout sample for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',0.15);
trainingInds = training(Partition); % Indices for the training set
testInds = test(Partition); % Indices for the test set
```

Train a binary kernel classification model using the training set.

```
Mdl = fitckernel(X(trainingInds,:),Y(trainingInds));
```

Create an anonymous function that measures linear loss, that is,

$$L = \frac{\sum_j -w_j y_j f_j}{\sum_j w_j}.$$

w_j is the weight for observation j , y_j is response j (-1 for the negative class, and 1 otherwise), and f_j is the raw classification score of observation j .

```
linearloss = @(C,S,W,Cost)sum(-W.*sum(S.*C,2))/sum(W);
```

Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the 'LossFun' name-value pair argument.

Estimate the training-set classification loss and the test-set classification loss using the linear loss function.

```
ceTrain = loss(Mdl,X(trainingInds,:),Y(trainingInds),'LossFun',linearloss)
ceTrain = -1.0851
ceTest = loss(Mdl,X(testInds,:),Y(testInds),'LossFun',linearloss)
ceTest = -0.7821
```

Input Arguments

Mdl — Binary kernel classification model

ClassificationKernel model object

Binary kernel classification model, specified as a `ClassificationKernel` model object. You can create a `ClassificationKernel` model object using `fitckernel`.

X — Predictor data

n -by- p numeric matrix

Predictor data, specified as an n -by- p numeric matrix, where n is the number of observations and p is the number of predictors used to train `Mdl`.

The length of `Y` and the number of observations in `X` must be equal.

Data Types: `single` | `double`

Y – Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

- The data type of `Y` must be the same as the data type of `Mdl.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)
- The distinct classes in `Y` must be a subset of `Mdl.ClassNames`.
- If `Y` is a character array, then each element must correspond to one row of the array.
- The length of `Y` and the number of observations in `X` must be equal.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `L = loss(Mdl,X,Y,'LossFun','quadratic','Weights',weights)` returns the weighted classification loss using the quadratic loss function.

LossFun – Loss function

'`classiferror`' (default) | '`binodeviance`' | '`exponential`' | '`hinge`' | '`logit`' | '`mincost`' | '`quadratic`' | function handle

Loss function, specified as the comma-separated pair consisting of '`LossFun`' and a built-in loss function name or a function handle.

- This table lists the available loss functions. Specify one using its corresponding value.

Value	Description
' <code>binodeviance</code> '	Binomial deviance
' <code>classiferror</code> '	Classification error
' <code>exponential</code> '	Exponential
' <code>hinge</code> '	Hinge
' <code>logit</code> '	Logistic
' <code>mincost</code> '	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
' <code>quadratic</code> '	Quadratic

'`mincost`' is appropriate for classification scores that are posterior probabilities. For kernel classification models, logistic regression learners return posterior probabilities as classification scores by default, but SVM learners do not (see `predict`).

- Specify your own function by using function handle notation.

Let n be the number of observations in X and K be the number of distinct classes (`numel(Mdl.ClassNames)`), where `Mdl` is the input model). Your function must have this signature:

```
lossvalue = lossfun(C,S,W,Cost)
```

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

Construct C by setting $C(p, q) = 1$, if observation p is in class q , for each row. Set all other elements of row p to 0 .

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes the weights to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Example: `'LossFun',@lossfun`

Data Types: `char` | `string` | `function_handle`

Weights — Observation weights

positive numeric vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a positive numeric vector of length n , where n is the number of observations in X . If you supply weights, `loss` computes the weighted classification loss on page 32-5955.

The default value is `ones(n, 1)`.

`loss` normalizes weights to sum up to the value of the prior probability in the respective class.

Data Types: `double` | `single`

Output Arguments

L — Classification loss

numeric scalar

Classification loss on page 32-5955, returned as a numeric scalar. The interpretation of L depends on `Weights` and `LossFun`.

More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Suppose the following:

- L is the weighted average classification loss.
- n is the sample size.
- y_j is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
- $f(X_j)$ is the raw classification score for the transformed observation (row) j of the predictor data X using feature expansion.
- $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute to the average loss.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so that they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

This table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>The classification error is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$

Loss Function	Value of LossFun	Equation
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$
Minimal cost	'mincost'	<p>The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> 1 Estimate the 1-by-K vector of expected classification costs for observation j: $v_j = f(X_j)'C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> 2 For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j=1, \dots, K} (v_j).$ 3 Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except minimal cost) for one observation over m . Some functions are normalized to pass through $[0,1]$.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

See Also

`ClassificationKernel` | `fitckernel` | `predict`

Introduced in R2017b

margin

Classification margins for Gaussian kernel classification model

Syntax

```
m = margin(Mdl,X,Y)
```

Description

`m = margin(Mdl,X,Y)` returns the classification margins on page 32-5961 for the binary Gaussian kernel classification model `Mdl` using the predictor data in `X` and the corresponding class labels in `Y`.

Examples

Estimate Test-Set Margins

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Partition the data set into training and test sets. Specify a 30% holdout sample for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',0.30);
trainingInds = training(Partition); % Indices for the training set
testInds = test(Partition); % Indices for the test set
```

Train a binary kernel classification model using the training set.

```
Mdl = fitckernel(X(trainingInds,:),Y(trainingInds));
```

Estimate the training-set margins and test-set margins.

```
mTrain = margin(Mdl,X(trainingInds,:),Y(trainingInds));
mTest = margin(Mdl,X(testInds,:),Y(testInds));
```

Plot both sets of margins using box plots.

```
boxplot([mTrain; mTest],[zeros(size(mTrain,1),1); ones(size(mTest,1),1)], ...
    'Labels',{'Training set','Test set'});
title('Training-Set and Test-Set Margins')
```

The margin distribution of the training set is situated higher than the margin distribution of the test set.

Feature Selection Using Test-Set Margins

Perform feature selection by comparing test-set margins from multiple models. Based solely on this criterion, the classifier with the larger margins is the better classifier.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Partition the data set into training and test sets. Specify a 15% holdout sample for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',0.15);
trainingInds = training(Partition); % Indices for the training set
XTrain = X(trainingInds,:);
YTrain = Y(trainingInds);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds);
```

Randomly choose 10% of the predictor variables.

```
p = size(X,2); % Number of predictors
idxPart = randsample(p,ceil(0.1*p));
```

Train two binary kernel classification models: one that uses all of the predictors, and one that uses the random 10%.

```
Mdl = fitckernel(XTrain,YTrain);
PMdl = fitckernel(XTrain(:,idxPart),YTrain);
```

Mdl and PMdl are ClassificationKernel models.

Estimate the test-set margins for each classifier.

```
fullMargins = margin(Mdl,XTest,YTest);
partMargins = margin(PMdl,XTest(:,idxPart),YTest);
```

Plot the distribution of the margin sets using box plots.

```
boxplot([fullMargins partMargins], ...
        'Labels',{'All Predictors','10% of the Predictors'});
title('Test-Set Margins')
```

The margin distribution of PMdl is situated higher than the margin distribution of Mdl. Therefore, the PMdl model is the better classifier.

Input Arguments

Mdl — Binary kernel classification model

ClassificationKernel model object

Binary kernel classification model, specified as a ClassificationKernel model object. You can create a ClassificationKernel model object using fitckernel.

X — Predictor data

n-by-*p* numeric matrix

Predictor data, specified as an *n*-by-*p* numeric matrix, where *n* is the number of observations and *p* is the number of predictors used to train Mdl.

The length of Y and the number of observations in X must be equal.

Data Types: single | double

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

- The data type of Y must be the same as the data type of Mdl.ClassNames. (The software treats string arrays as cell arrays of character vectors.)
- The distinct classes in Y must be a subset of Mdl.ClassNames.
- If Y is a character array, then each element must correspond to one row of the array.
- The length of Y and the number of observations in X must be equal.

Data Types: categorical | char | string | logical | single | double | cell

Output Arguments

m — Classification margins

numeric column vector

Classification margins on page 32-5961, returned as an *n*-by-1 numeric column vector, where *n* is the number of observations in X.

More About

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation x . The classification margin is commonly defined as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

For kernel classification models, the raw classification score for classifying the observation x , a row vector, into the positive class is defined by

$$f(x) = T(x)\beta + b.$$

- $T(\cdot)$ is a transformation of an observation for feature expansion.
- β is the estimated column vector of coefficients.
- b is the estimated scalar bias.

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields a positive score.

If the kernel classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see `ScoreTransform`).

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

`ClassificationKernel` | `edge` | `fitckernel` | `predict`

Introduced in R2017b

predict

Predict labels for Gaussian kernel classification model

Syntax

```
Label = predict(Mdl,X)
[Label,Score] = predict(Mdl,X)
```

Description

`Label = predict(Mdl,X)` returns predicted class labels for each observation in the predictor data `X` based on the binary Gaussian kernel classification model `Mdl`.

`[Label,Score] = predict(Mdl,X)` also returns classification scores on page 32-5968 for both classes.

Examples

Predict Training Set Labels

Predict the training set labels using a binary kernel classification model, and display the confusion matrix for the resulting classification.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Train a binary kernel classification model that identifies whether the radar return is bad ('b') or good ('g').

```
rng('default') % For reproducibility
Mdl = fitckernel(X,Y);
```

`Mdl` is a `ClassificationKernel` model.

Predict the training set, or resubstitution, labels.

```
label = predict(Mdl,X);
```

Construct a confusion matrix.

```
ConfusionTrain = confusionchart(Y,label);
```

The model misclassifies one radar return for each class.

Predict Test Set Labels

Predict the test set labels using a binary kernel classification model, and display the confusion matrix for the resulting classification.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Partition the data set into training and test sets. Specify a 15% holdout sample for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',0.15);
trainingInds = training(Partition); % Indices for the training set
testInds = test(Partition); % Indices for the test set
```

Train a binary kernel classification model using the training set. A good practice is to define the class order.

```
Mdl = fitkernel(X(trainingInds,:),Y(trainingInds),'ClassNames',{'b','g'});
```

Predict the training-set labels and the test set labels.

```
labelTrain = predict(Mdl,X(trainingInds,:));  
labelTest = predict(Mdl,X(testInds,:));
```

Construct a confusion matrix for the training set.

```
ConfusionTrain = confusionchart(Y(trainingInds),labelTrain);
```

The model misclassifies only one radar return for each class.

Construct a confusion matrix for the test set.

```
ConfusionTest = confusionchart(Y(testInds),labelTest);
```

The model misclassifies one bad radar return as being a good return, and five good radar returns as being bad returns.

Estimate Posterior Class Probabilities

Estimate posterior class probabilities for a test set, and determine the quality of the model by plotting a receiver operating characteristic (ROC) curve. Kernel classification models return posterior probabilities for logistic regression learners only.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Partition the data set into training and test sets. Specify a 30% holdout sample for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',0.30);
trainingInds = training(Partition); % Indices for the training set
testInds = test(Partition); % Indices for the test set
```

Train a binary kernel classification model. Fit logistic regression learners.

```
Mdl = fitckernel(X(trainingInds,:),Y(trainingInds), ...
    'ClassNames',{'b','g'},'Learner','logistic');
```

Predict the posterior class probabilities for the test set.

```
[~,posterior] = predict(Mdl,X(testInds,:));
```

Because `Mdl` has one regularization strength, the output `posterior` is a matrix with two columns and rows equal to the number of test-set observations. Column `i` contains posterior probabilities of `Mdl.ClassNames(i)` given a particular observation.

Obtain false and true positive rates, and estimate the area under the curve (AUC). Specify that the second class is the positive class.

```
[fpr,tpr,~,auc] = perfcurve(Y(testInds),posterior(:,2),Mdl.ClassNames(2));
auc
```

```
auc = 0.9042
```

The AUC is close to 1, which indicates that the model predicts labels well.

Plot an ROC curve.

```
figure;
plot(fpr,tpr)
h = gca;
h.XLim(1) = -0.1;
h.YLim(2) = 1.1;
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve')
```

Input Arguments

Mdl — Binary kernel classification model

ClassificationKernel model object

Binary kernel classification model, specified as a ClassificationKernel model object. You can create a ClassificationKernel model object using `fitckernel`.

X — Predictor data

n-by-*p* numeric matrix

Predictor data, specified as an *n*-by-*p* numeric matrix, where *n* is the number of observations and *p* is the number of predictors used to train Mdl.

Data Types: `single` | `double`

Output Arguments

Label — Predicted class labels

categorical array | character array | logical matrix | numeric matrix | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric matrix, or cell array of character vectors.

Label has *n* rows, where *n* is the number of observations in X, and has the same data type as the observed class labels (Y) used to train Mdl. (The software treats string arrays as cell arrays of character vectors.)

`predict` classifies observations into the class yielding the highest score.

Score — Classification scores

numeric array

Classification scores on page 32-5968, returned as an *n*-by-2 numeric array, where *n* is the number of observations in X. `Score(i,j)` is the score for classifying observation *i* into class *j*.

Mdl.ClassNames stores the order of the classes.

If Mdl.Learner is `'logistic'`, then classification scores are posterior probabilities.

More About

Classification Score

For kernel classification models, the raw classification score for classifying the observation *x*, a row vector, into the positive class is defined by

$$f(x) = T(x)\beta + b.$$

- $T(\cdot)$ is a transformation of an observation for feature expansion.
- β is the estimated column vector of coefficients.
- b is the estimated scalar bias.

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields a positive score.

If the kernel classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see `ScoreTransform`).

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

`ClassificationKernel` | `confusionchart` | `fitckernel` | `perfcurve` | `resume`

Introduced in R2017b

resume

Resume training of Gaussian kernel classification model

Syntax

```
UpdatedMdl = resume(Mdl,X,Y)
UpdatedMdl = resume(Mdl,X,Y,Name,Value)
[UpdatedMdl,FitInfo] = resume(____)
```

Description

`UpdatedMdl = resume(Mdl,X,Y)` continues training with the same options used to train `Mdl`, including the training data (predictor data in `X` and class labels in `Y`) and the feature expansion. The training starts at the current estimated parameters in `Mdl`. The function returns a new binary Gaussian kernel classification model `UpdatedMdl`.

`UpdatedMdl = resume(Mdl,X,Y,Name,Value)` returns a new binary Gaussian kernel classification model with additional options specified by one or more name-value pair arguments. For example, you can modify convergence control options, such as convergence tolerances and the maximum number of additional optimization iterations.

`[UpdatedMdl,FitInfo] = resume(____)` also returns the fit information in the structure array `FitInfo` using any of the previous input arguments in the syntaxes.

Examples

Predict Class Labels and Resume Training

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Partition the data set into training and test sets. Specify a 20% holdout sample for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',0.20);
trainingInds = training(Partition); % Indices for the training set
XTrain = X(trainingInds,:);
YTrain = Y(trainingInds);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds);
```

Train a binary kernel classification model that identifies whether the radar return is bad ('b') or good ('g').

```
Mdl = fitkernel(XTrain,YTrain,'IterationLimit',5,'Verbose',1);
```

```
|=====|
| Solver | Pass | Iteration | Objective | Step | Gradient | Relative
```

						magnitude	change in Beta

Mdl is a ClassificationKernel model.

Predict the test-set labels, construct a confusion matrix for the test set, and estimate the classification error for the test set.

```
label = predict(Mdl,XTest);
ConfusionTest = confusionchart(YTest,label);
```

```
L = loss(Mdl,XTest,YTest)
```

```
L = 0.3594
```

Mdl misclassifies all bad radar returns as good returns.

Continue training by using resume. This function continues training with the same options used for training Mdl.

```
UpdatedMdl = resume(Mdl,XTrain,YTrain);
```

=====						

Predict the test-set labels, construct a confusion matrix for the test set, and estimate the classification error for the test set.

```
UpdatedLabel = predict(UpdatedMdl,XTest);
UpdatedConfusionTest = confusionchart(YTest,UpdatedLabel);
```

```
UpdatedL = loss(UpdatedMdl,XTest,YTest)
```

```
UpdatedL = 0.1284
```

The classification error decreases after `resume` updates the classification model with more iterations.

Resume Training with Modified Convergence Control Training Options

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Partition the data set into training and test sets. Specify a 20% holdout sample for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',0.20);
trainingInds = training(Partition); % Indices for the training set
XTrain = X(trainingInds,:);
YTrain = Y(trainingInds);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds);
```

Train a binary kernel classification model with relaxed convergence control training options by using the name-value pair arguments `'BetaTolerance'` and `'GradientTolerance'`.

```
[Mdl,FitInfo] = fitkernel(XTrain,YTrain,'Verbose',1, ...
    'BetaTolerance',1e-1,'GradientTolerance',1e-1);
```

Solver	Pass	Iteration	Objective	Step	Gradient magnitude	Relative change in Beta
LBFGS	1	0	1.000000e+00	0.000000e+00	2.811388e-01	
LBFGS	1	1	7.585395e-01	4.000000e+00	3.594306e-01	1.000000e+00
LBFGS	1	2	7.160994e-01	1.000000e+00	2.028470e-01	6.923988e-01
LBFGS	1	3	6.825272e-01	1.000000e+00	2.846975e-02	2.388909e-01

Mdl is a ClassificationKernel model.

Predict the test-set labels, construct a confusion matrix for the test set, and estimate the classification error for the test set

```
label = predict(Mdl,XTest);
ConfusionTest = confusionchart(YTest,label);
```

```
L = loss(Mdl,XTest,YTest)
```

```
L = 0.3594
```

Mdl misclassifies all bad radar returns as good returns.

Continue training by using resume with modified convergence control training options.

```
[UpdatedMdl,UpdatedFitInfo] = resume(Mdl,XTrain,YTrain, ...
    'BetaTolerance',1e-2,'GradientTolerance',1e-2);
```

Solver	Pass	Iteration	Objective	Step	Gradient magnitude	Relative change in Beta

LBFGS	1	20	2.552954e-01	1.000000e+00	1.769940e-03	1.899895e-02

Predict the test-set labels, construct a confusion matrix for the test set, and estimate the classification error for the test set.

```
UpdatedLabel = predict(UpdatedMdl,XTest);
UpdatedConfusionTest = confusionchart(YTest,UpdatedLabel);
```

```
UpdatedL = loss(UpdatedMdl,XTest,YTest)
```

```
UpdatedL = 0.1140
```

The classification error decreases after `resume` updates the classification model with smaller convergence tolerances.

Display the outputs `FitInfo` and `UpdatedFitInfo`.

`FitInfo`

```
FitInfo = struct with fields:
    Solver: 'LBFGS-fast'
    LossFunction: 'hinge'
    Lambda: 0.0036
    BetaTolerance: 0.1000
    GradientTolerance: 0.1000
    ObjectiveValue: 0.6825
    GradientMagnitude: 0.0285
    RelativeChangeInBeta: 0.2389
    FitTime: 0.0504
    History: [1x1 struct]
```

`UpdatedFitInfo`

```
UpdatedFitInfo = struct with fields:
    Solver: 'LBFGS-fast'
```

```

LossFunction: 'hinge'
Lambda: 0.0036
BetaTolerance: 0.0100
GradientTolerance: 0.0100
ObjectiveValue: 0.2553
GradientMagnitude: 0.0018
RelativeChangeInBeta: 0.0190
FitTime: 0.1221
History: [1x1 struct]

```

Both trainings terminate because the software satisfies the absolute gradient tolerance.

Plot the gradient magnitude versus the number of iterations by using `UpdatedFitInfo.History.GradientMagnitude`. Note that the `History` field of `UpdatedFitInfo` includes the information in the `History` field of `FitInfo`.

```

semilogy(UpdatedFitInfo.History.GradientMagnitude, 'o-')
ax = gca;
ax.XTick = 1:25;
ax.XTickLabel = UpdatedFitInfo.History.IterationNumber;
grid on
xlabel('Number of Iterations')
ylabel('Gradient Magnitude')

```

The first training terminates after three iterations because the gradient magnitude becomes less than $1e-1$. The second training terminates after 20 iterations because the gradient magnitude becomes less than $1e-2$.

Input Arguments

Mdl — Binary kernel classification model

ClassificationKernel model object

Binary kernel classification model, specified as a ClassificationKernel model object. You can create a ClassificationKernel model object using fitckernel.

X — Predictor data used to train Mdl

n -by- p numeric matrix

Predictor data used to train Mdl, specified as an n -by- p numeric matrix, where n is the number of observations and p is the number of predictors.

Data Types: single | double

Y — Class labels used to train Mdl

categorical array | character array | string array | logical vector | vector of numeric values | cell array of character vectors

Class labels used to train Mdl, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

Data Types: categorical | char | string | logical | single | double | cell

Note resume should run only on the same training data (X and Y) and the same observation weights used to train Mdl. The resume function uses the same training options used to train Mdl, including feature expansion.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: UpdatedMdl = resume(Mdl, X, Y, 'GradientTolerance', 1e-5) resumes training with the same options used to train Mdl, except the absolute gradient tolerance.

Weights — Observation weights used to train Mdl

positive numeric vector

Observation weights used to train Mdl, specified as the comma-separated pair consisting of 'Weights' and a positive numeric vector of length n , where n is the number of observations in X. The resume function weighs the observations in X with the corresponding values in Weights.

The default value is ones(n , 1).

resume normalizes Weights to sum up to the value of the prior probability in the respective class.

Example: 'Weights', w

Data Types: single | double

BetaTolerance — Relative tolerance on linear coefficients and bias term

BetaTolerance value used to train MdL (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t . If

$$\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}, \text{ then optimization terminates.}$$

If you also specify GradientTolerance, then optimization terminates when the software satisfies either stopping criterion.

By default, the value is the same BetaTolerance value used to train MdL.

Example: 'BetaTolerance', 1e-6

Data Types: single | double

GradientTolerance — Absolute gradient tolerance

GradientTolerance value used to train MdL (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of 'GradientTolerance' and a nonnegative scalar.

Let $\nabla \mathcal{L}_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t . If $\|\nabla \mathcal{L}_t\|_\infty = \max |\nabla \mathcal{L}_t| < \text{GradientTolerance}$, then optimization terminates.

If you also specify BetaTolerance, then optimization terminates when the software satisfies either stopping criterion.

By default, the value is the same GradientTolerance value used to train MdL.

Example: 'GradientTolerance', 1e-5

Data Types: single | double

IterationLimit — Maximum number of additional optimization iterations

positive integer

Maximum number of additional optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer.

The default value is 1000 if the transformed data fits in memory (MdL.ModelParameters.BlockSize), which you specify by using the name-value pair argument when training MdL. Otherwise, the default value is 100.

Note that the default value is not the value used to train MdL.

Example: 'IterationLimit', 500

Data Types: single | double

Output Arguments**UpdatedMdL — Updated kernel classification model**

ClassificationKernel model object

Updated kernel classification model, returned as a `ClassificationKernel` model object.

FitInfo — Optimization details

structure array

Optimization details, returned as a structure array including fields described in this table. The fields contain final values or name-value pair argument specifications.

Field	Description
<code>Solver</code>	Objective function minimization technique: 'LBFGS-fast', 'LBFGS-blockwise', or 'LBFGS-tall'. For details, see "Algorithms" on page 32-5933 of <code>fitckernel</code> .
<code>LossFunction</code>	Loss function. Either 'hinge' or 'logit' depending on the type of linear classification model. See <code>Learner</code> of <code>fitckernel</code> .
<code>Lambda</code>	Regularization term strength. See <code>Lambda</code> of <code>fitckernel</code> .
<code>BetaTolerance</code>	Relative tolerance on the linear coefficients and the bias term. See <code>BetaTolerance</code> .
<code>GradientTolerance</code>	Absolute gradient tolerance. See <code>GradientTolerance</code> .
<code>ObjectiveValue</code>	Value of the objective function when optimization terminates. The classification loss plus the regularization term compose the objective function.
<code>GradientMagnitude</code>	Infinite norm of the gradient vector of the objective function when optimization terminates. See <code>GradientTolerance</code> .
<code>RelativeChangeInBeta</code>	Relative changes in the linear coefficients and the bias term when optimization terminates. See <code>BetaTolerance</code> .
<code>FitTime</code>	Elapsed, wall-clock time (in seconds) required to fit the model to the data.
<code>History</code>	History of optimization information. This field also includes the optimization information from training <code>Mdl</code> . This field is empty (<code>[]</code>) if you specify 'Verbose', <code>0</code> when training <code>Mdl</code> . For details, see <code>Verbose</code> and "Algorithms" on page 32-5933 of <code>fitckernel</code> .

To access fields, use dot notation. For example, to access the vector of objective function values for each iteration, enter `FitInfo.ObjectiveValue` in the Command Window.

A good practice is to examine `FitInfo` to assess whether convergence is satisfactory.

More About

Random Feature Expansion

Random feature expansion, such as `Random Kitchen Sinks`[1] and `Fastfood`[2], is a scheme to approximate Gaussian kernels of the kernel classification algorithm to use for big data in a computationally efficient way. Random feature expansion is more practical for big data applications that have large training sets, but can also be applied to smaller data sets that fit in memory.

The kernel classification algorithm searches for an optimal hyperplane that separates the data into two classes after mapping features into a high-dimensional space. Nonlinear features that are not linearly separable in a low-dimensional space can be separable in the expanded high-dimensional space. All the calculations for hyperplane classification use only dot products. You can obtain a

nonlinear classification model by replacing the dot product x_1x_2' with the nonlinear kernel function $G(x_1, x_2) = \langle \varphi(x_1), \varphi(x_2) \rangle$, where x_i is the i th observation (row vector) and $\varphi(x_i)$ is a transformation that maps x_i to a high-dimensional space (called the “kernel trick”). However, evaluating $G(x_1, x_2)$ (Gram matrix) for each pair of observations is computationally expensive for a large data set (large n).

The random feature expansion scheme finds a random transformation so that its dot product approximates the Gaussian kernel. That is,

$$G(x_1, x_2) = \langle \varphi(x_1), \varphi(x_2) \rangle \approx T(x_1)T(x_2)',$$

where $T(x)$ maps x in \mathbb{R}^p to a high-dimensional space (\mathbb{R}^m). The Random Kitchen Sink scheme uses the random transformation

$$T(x) = m^{-1/2} \exp(iZx)',$$

where $Z \in \mathbb{R}^{m \times p}$ is a sample drawn from $N(0, \sigma^{-2})$ and σ^2 is a kernel scale. This scheme requires $O(mp)$ computation and storage. The Fastfood scheme introduces another random basis V instead of Z using Hadamard matrices combined with Gaussian scaling matrices. This random basis reduces the computation cost to $O(m \log p)$ and reduces storage to $O(m)$.

The `fitckernel` function uses the Fastfood scheme for random feature expansion and uses linear classification to train a Gaussian kernel classification model. Unlike solvers in the `fitcsvm` function, which require computation of the n -by- n Gram matrix, the solver in `fitckernel` only needs to form a matrix of size n -by- m , with m typically much less than n for big data.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- The default value for the 'IterationLimit' name-value pair argument is relaxed to 20 when working with tall arrays.
- `resume` uses a block-wise strategy. For details, see “Algorithms” on page 32-5933 of `fitckernel`.
- You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

Introduced in R2017b

fitrkernel

Fit Gaussian kernel regression model using random feature expansion

Syntax

```
Mdl = fitrkernel(X,Y)
Mdl = fitrkernel(X,Y,Name,Value)
[Mdl,FitInfo] = fitrkernel(____)
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrkernel(____)
```

Description

`fitrkernel` trains or cross-validates a Gaussian kernel regression model for nonlinear regression. `fitrkernel` is more practical to use for big data applications that have large training sets, but can also be applied to smaller data sets that fit in memory.

`fitrkernel` maps data in a low-dimensional space into a high-dimensional space, then fits a linear model in the high-dimensional space by minimizing the regularized objective function. Obtaining the linear model in the high-dimensional space is equivalent to applying the Gaussian kernel to the model in the low-dimensional space. Available linear regression models include regularized support vector machine (SVM) and least-squares regression models.

To train a nonlinear SVM regression model on in-memory data, see `fitrsvm`.

`Mdl = fitrkernel(X,Y)` returns a compact Gaussian kernel regression model trained using the predictor data in `X` and the corresponding responses in `Y`.

`Mdl = fitrkernel(X,Y,Name,Value)` returns a kernel regression model with additional options specified by one or more name-value pair arguments. For example, you can implement least-squares regression, specify the number of dimension of the expanded space, or specify cross-validation options.

`[Mdl,FitInfo] = fitrkernel(____)` also returns the fit information in the structure array `FitInfo` using any of the input arguments in the previous syntaxes. You cannot request `FitInfo` for cross-validated models.

`[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrkernel(____)` also returns the hyperparameter optimization results when you optimize hyperparameters by using the `'OptimizeHyperparameters'` name-value pair argument.

Examples

Train Gaussian Kernel Regression Model

Train a kernel regression model for a tall array by using SVM.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example

using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

Create a datastore that references the folder location with the data. The data can be contained in a single file, a collection of files, or an entire folder. Treat 'NA' values as missing data so that `datastore` replaces them with NaN values. Select a subset of the variables to use. Create a tall table on top of the datastore.

```
varnames = {'ArrTime','DepTime','ActualElapsedTime'};
ds = datastore('airlinesmall.csv','TreatAsMissing','NA',...
    'SelectedVariableNames',varnames);
t = tall(ds);
```

Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 12).

Specify `DepTime` and `ArrTime` as the predictor variables (X) and `ActualElapsedTime` as the response variable (Y). Select the observations for which `ArrTime` is later than `DepTime`.

```
daytime = t.ArrTime>t.DepTime;
Y = t.ActualElapsedTime(daytime); % Response data
X = t{daytime,{'DepTime' 'ArrTime'}}; % Predictor data
```

Standardize the predictor variables.

```
Z = zscore(X); % Standardize the data
```

Train a default Gaussian kernel regression model with the standardized predictors. Extract a fit summary to determine how well the optimization algorithm fits the model to the data.

```
[Mdl,FitInfo] = fitrkernel(Z,Y)
```

    FitTime: 237.4500
    History: [1x1 struct]
```

`Mdl` is a `RegressionKernel` model. To inspect the regression error, you can pass `Mdl` and the training data or new data to the `loss` function. Or, you can pass `Mdl` and new predictor data to the `predict` function to predict responses for new observations. You can also pass `Mdl` and the training data to the `resume` function to continue training.

`FitInfo` is a structure array containing optimization information. Use `FitInfo` to determine whether optimization termination measurements are satisfactory.

For improved accuracy, you can increase the maximum number of optimization iterations (`'IterationLimit'`) and decrease the tolerance values (`'BetaTolerance'` and `'GradientTolerance'`) by using the name-value pair arguments of `fitrkernel`. Doing so can improve measures like `ObjectiveValue` and `RelativeChangeInBeta` in `FitInfo`. You can also optimize model parameters by using the `'OptimizeHyperparameters'` name-value pair argument.

Cross-Validate Kernel Regression Model

Load the carbig data set.

```
load carbig
```

Specify the predictor variables (X) and the response variable (Y).

```
X = [Acceleration,Cylinders,Displacement,Horsepower,Weight];
Y = MPG;
```

Delete rows of X and Y where either array has NaN values. Removing rows with NaN values before passing data to `fitrkernel` can speed up training and reduce memory usage.

```
R = rmmissing([X Y]); % Data with missing entries removed
X = R(:,1:5);
Y = R(:,end);
```

Standardize the predictor variables.

```
Z = zscore(X);
```

Cross-validate a kernel regression model using 5-fold cross-validation.

```
Mdl = fitrkernel(Z,Y,'Kfold',5)
```

```
Mdl =
  classreg.learning.partition.RegressionPartitionedKernel
    CrossValidatedModel: 'Kernel'
      ResponseName: 'Y'
    NumObservations: 392
          KFold: 5
      Partition: [1x1 cvpartition]
    ResponseTransform: 'none'
```

Properties, Methods

```
numel(Mdl.Trained)
```

```
ans = 5
```

Mdl is a `RegressionPartitionedKernel` model. Because `fitrkernel` implements five-fold cross-validation, Mdl contains five `RegressionKernel` models that the software trains on training-fold (in-fold) observations.

Examine the cross-validation loss (mean squared error) for each fold.

```
kfoldLoss(Mdl,'mode','individual')
```

```
ans = 5x1

    13.0610
    14.0975
    24.0104
    21.1223
    24.3979
```

Optimize Kernel Regression

Optimize hyperparameters automatically using the 'OptimizeHyperparameters' name-value pair argument.

Load the carbig data set.

```
load carbig
```

Specify the predictor variables (X) and the response variable (Y).

```
X = [Acceleration,Cylinders,Displacement,Horsepower,Weight];
Y = MPG;
```

Delete rows of X and Y where either array has NaN values. Removing rows with NaN values before passing data to fitrkernel can speed up training and reduce memory usage.

```
R = rmmissing([X Y]); % Data with missing entries removed
X = R(:,1:5);
Y = R(:,end);
```

Standardize the predictor variables.

```
Z = zscore(X);
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization. Specify 'OptimizeHyperparameters' as 'auto' so that fitrkernel finds the optimal values of the 'KernelScale', 'Lambda', and 'Epsilon' name-value pair arguments. For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```
rng('default')
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrkernel(Z,Y,'OptimizeHyperparameters','auto',
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName','expected-improvement-plus'))
```

```

For big data, the optimization procedure can take a long time. If the data set is too large to run the optimization procedure, you can try to optimize the parameters using only partial data. Use the `datasample` function and specify 'Replace', 'false' to sample data without replacement.

Input Arguments

X — Predictor data

numeric matrix

Predictor data to which the regression model is fit, specified as an n -by- p numeric matrix, where n is the number of observations and p is the number of predictor variables.

The length of Y and the number of observations in X must be equal.

Data Types: `single` | `double`

Y — Response data

numeric vector

Response data, specified as an n -dimensional numeric vector. The length of Y and the number of observations in X must be equal.

Data Types: `single` | `double`

Note `fitrkernel` removes missing observations, that is, observations with any of these characteristics:

- NaN elements in the response (Y)
 - At least one NaN value in a predictor observation (row in X)
 - NaN value or 0 weight (`'Weights'`)
-

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example: `Mdl = fitrkernel(X,Y,'Learner','leastsquares','NumExpansionDimensions',2^15,'KernelScale','auto')` implements least-squares regression after mapping the predictor data to the 2^{15} dimensional space using feature expansion with a kernel scale parameter selected by a heuristic procedure.

Kernel Regression Options

BoxConstraint — Box constraint

1 (default) | positive scalar

Box constraint on page 32-6005, specified as the comma-separated pair consisting of `'BoxConstraint'` and a positive scalar.

This argument is valid only when 'Learner' is 'svm' (default) and you do not specify a value for the regularization term strength 'Lambda'. You can specify either 'BoxConstraint' or 'Lambda' because the box constraint (C) and the regularization term strength (λ) are related by $C = 1/(\lambda n)$, where n is the number of observations (rows in X).

Example: 'BoxConstraint',100

Data Types: single | double

Epsilon — Half width of epsilon-insensitive band

'auto' (default) | nonnegative scalar value

Half the width of the epsilon-insensitive band, specified as the comma-separated pair consisting of 'Epsilon' and 'auto' or a nonnegative scalar value.

For 'auto', the `fitrkernel` function determines the value of Epsilon as $\text{iqr}(Y)/13.49$, which is an estimate of a tenth of the standard deviation using the interquartile range of the response variable Y . If $\text{iqr}(Y)$ is equal to zero, then `fitrkernel` sets the value of Epsilon to 0.1.

'Epsilon' is valid only when Learner is svm.

Example: 'Epsilon',0.3

Data Types: single | double

NumExpansionDimensions — Number of dimensions of expanded space

'auto' (default) | positive integer

Number of dimensions of the expanded space, specified as the comma-separated pair consisting of 'NumExpansionDimensions' and 'auto' or a positive integer. For 'auto', the `fitrkernel` function selects the number of dimensions using $2.^{\text{ceil}(\min(\log_2(p)+5, 15))}$, where p is the number of predictors.

Example: 'NumExpansionDimensions',2^15

Data Types: char | string | single | double

KernelScale — Kernel scale parameter

1 (default) | 'auto' | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of 'KernelScale' and 'auto' or a positive scalar. MATLAB obtains the random basis for random feature expansion by using the kernel scale parameter. For details, see “Random Feature Expansion” on page 32-6004.

If you specify 'auto', then MATLAB selects an appropriate kernel scale parameter using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. Therefore, to reproduce results, set a random number seed by using `rng` before training.

Example: 'KernelScale','auto'

Data Types: char | string | single | double

Lambda — Regularization term strength

'auto' (default) | nonnegative scalar

Regularization term strength, specified as the comma-separated pair consisting of 'Lambda' and 'auto' or a nonnegative scalar.

For 'auto', the value of 'Lambda' is $1/n$, where n is the number of observations (rows in X).

You can specify either 'BoxConstraint' or 'Lambda' because the box constraint (C) and the regularization term strength (λ) are related by $C = 1/(\lambda n)$.

Example: 'Lambda', 0.01

Data Types: char | string | single | double

Learner – Linear regression model type

'svm' (default) | 'leastsquares'

Linear regression model type, specified as the comma-separated pair consisting of 'Learner' and 'svm' or 'leastsquares'.

In the following table, $f(x) = T(x)\beta + b$.

- x is an observation (row vector) from p predictor variables.
- $T(\cdot)$ is a transformation of an observation (row vector) for feature expansion. $T(x)$ maps x in \mathbb{R}^p to a high-dimensional space (\mathbb{R}^m).
- β is a vector of m coefficients.
- b is the scalar bias.

Value	Algorithm	Response range	Loss function
'leastsquares'	Linear regression via ordinary least squares	$y \in (-\infty, \infty)$	Mean squared error (MSE): $\ell[y, f(x)] = \frac{1}{2}[y - f(x)]^2$
'svm'	Support vector machine regression	Same as 'leastsquares'	Epsilon-insensitive: $\ell[y, f(x)] = \max[0, y - f(x) - \varepsilon]$

Example: 'Learner', 'leastsquares'

Verbose – Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and either 0 or 1. Verbose controls the amount of diagnostic information fitrkernel displays at the command line.

Value	Description
0	fitrkernel does not display diagnostic information.
1	fitrkernel displays and stores the value of the objective function, gradient magnitude, and other diagnostic information. FitInfo.History contains the diagnostic information.

Example: 'Verbose', 1

Data Types: single | double

BlockSize – Maximum amount of allocated memory

4e^3 (4GB) (default) | positive scalar

Maximum amount of allocated memory (in megabytes), specified as the comma-separated pair consisting of 'BlockSize' and a positive scalar.

If `fitrkernel` requires more memory than the value of `BlockSize` to hold the transformed predictor data, then MATLAB uses a block-wise strategy. For details about the block-wise strategy, see “Algorithms” on page 32-6005.

Example: `'BlockSize',1e4`

Data Types: `single` | `double`

RandomStream — Random number stream

`global stream` (default) | random stream object

Random number stream for reproducibility of data transformation, specified as the comma-separated pair consisting of `'RandomStream'` and a random stream object. For details, see “Random Feature Expansion” on page 32-6004.

Use `'RandomStream'` to reproduce the random basis functions that `fitrkernel` uses to transform the data in `X` to a high-dimensional space. For details, see “Managing the Global Stream” (MATLAB) and “Creating and Controlling a Random Number Stream” (MATLAB).

Example: `'RandomStream',RandStream('mlfg6331_64')`

ResponseTransform — Response transformation

`'none'` (default) | function handle

Response transformation, specified as the comma-separated pair consisting of `'ResponseTransform'` and either `'none'` or a function handle. The default is `'none'`, which means $@(y)y$, or no transformation. For a MATLAB function or a function you define, use its function handle. The function handle must accept a vector (the original response values) and return a vector of the same size (the transformed response values).

Example: Suppose you create a function handle that applies an exponential transformation to an input vector by using `myfunction = @(y)exp(y)`. Then, you can specify the response transformation as `'ResponseTransform',myfunction`.

Data Types: `char` | `string` | `function_handle`

Weights — Observation weights

`ones(n,1)/n` (default) | numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector of positive values. `fitrkernel` weighs the observations in `X` with the corresponding values in `Weights`. The size of `Weights` must equal `n`, the number of observations (rows in `X`).

`fitrkernel` normalizes `Weights` to sum to 1.

Data Types: `double` | `single`

Cross-Validation Options

CrossVal — Cross-validation flag

`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software implements 10-fold cross-validation.

You can override this cross-validation setting using the `CVPartition`, `Holdout`, `KFold`, or `Leaveout` name-value pair argument. You can use only one cross-validation name-value pair argument at a time to create a cross-validated model.

Example: `'Crossval','on'`

CVPartition — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500,'KFold',5)`. Then, you can specify the cross-validated model by using `'CVPartition',cvp`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). If you specify `'Holdout',p`, then the software completes these steps:

- 1 Randomly select and reserve $p \times 100\%$ of the data as validation data, and train the model using the rest of the data.
- 2 Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1. If you specify `'KFold',k`, then the software completes these steps:

- 1 Randomly partition the data into k sets.
- 2 For each set, reserve the set as validation data, and train the model using the other $k - 1$ sets.
- 3 Store the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

Leaveout — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the n observations (where n is the number of observations excluding missing observations), the software completes these steps:

- 1 Reserve the observation as validation data, and train the model using the other $n - 1$ observations.
- 2 Store the n compact, trained models in the cells of an n -by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Leaveout', 'on'

Convergence Controls**BetaTolerance — Relative tolerance on linear coefficients and bias term**

1e-5 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t . If

$\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If you also specify GradientTolerance, then optimization terminates when the software satisfies either stopping criterion.

Example: 'BetaTolerance', 1e-6

Data Types: single | double

GradientTolerance — Absolute gradient tolerance

1e-6 (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of 'GradientTolerance' and a nonnegative scalar.

Let $\nabla \mathcal{L}_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t . If $\|\nabla \mathcal{L}_t\|_\infty = \max |\nabla \mathcal{L}_t| < \text{GradientTolerance}$, then optimization terminates.

If you also specify BetaTolerance, then optimization terminates when the software satisfies either stopping criterion.

Example: 'GradientTolerance', 1e-5

Data Types: single | double

HessianHistorySize — Size of history buffer for Hessian approximation

15 (default) | positive integer

Size of the history buffer for Hessian approximation, specified as the comma-separated pair consisting of 'HessianHistorySize' and a positive integer. At each iteration, `fitrkernel` composes the Hessian by using statistics from the latest `HessianHistorySize` iterations.

Example: 'HessianHistorySize',10

Data Types: single | double

IterationLimit — Maximum number of optimization iterations

positive integer

Maximum number of optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer.

The default value is 1000 if the transformed data fits in memory, as specified by `BlockSize`. Otherwise, the default value is 100.

Example: 'IterationLimit',500

Data Types: single | double

Hyperparameter Optimization Options

OptimizeHyperparameters — Parameters to optimize

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of these values:

- 'none' — Do not optimize.
- 'auto' — Use {'KernelScale', 'Lambda', 'Epsilon'}.
- 'all' — Optimize all eligible parameters.
- Cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for `fitrkernel` by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair argument.

Note 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for `fitrkernel` are:

- `Epsilon` — `fitrkernel` searches among positive values, by default log-scaled in the range $[1e-3, 1e2] * \text{iqr}(Y) / 1.349$.
- `KernelScale` — `fitrkernel` searches among positive values, by default log-scaled in the range $[1e-3, 1e3]$.
- `Lambda` — `fitrkernel` searches among positive values, by default log-scaled in the range $[1e-3, 1e3] / n$, where n is the number of observations.

- **Learner** — `fitrkernel` searches among 'svm' and 'leastsquares'.
- **NumExpansionDimensions** — `fitrkernel` searches among positive integers, by default log-scaled in the range [100,10000].

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example:

```
load carsmall
params = hyperparameters('fitrkernel',[Horsepower,Weight],MPG);
params(2).Range = [1e-4,1e6];
```

Pass `params` as the value of 'OptimizeHyperparameters'.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the 'HyperparameterOptimizationOptions' name-value pair argument. To control the plots, set the `ShowPlots` field of the 'HyperparameterOptimizationOptions' name-value pair argument.

For an example, see “Optimize Kernel Regression” on page 32-5989.

Example: 'OptimizeHyperparameters','auto'

HyperparameterOptimizationOptions — Options for optimization structure

Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> • 'bayesopt' — Use Bayesian optimization. Internally, this setting calls <code>bayesopt</code>. • 'gridsearch' — Use grid search with <code>NumGridDivisions</code> values per dimension. • 'randomsearch' — Search at random among <code>MaxObjectiveEvaluations</code> points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command <code>sortrows(Mdl.HyperparameterOptimizationResults)</code>.</p>	'bayesopt'

Field Name	Values	Default
AcquisitionFunctionName	<ul style="list-style-type: none"> • 'expected-improvement-per-second-plus' • 'expected-improvement' • 'expected-improvement-plus' • 'expected-improvement-per-second' • 'lower-confidence-bound' • 'probability-of-improvement' <p>Acquisition functions whose names include per-second do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include plus modify their behavior when they are overexploiting an area. For more details, see "Acquisition Function Types" on page 10-3.</p>	'expected-improvement-per-second-plus'
MaxObjectiveEvaluations	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
MaxTime	Time limit, specified as a positive real. The time limit is in seconds, as measured by tic and toc. Run time can exceed MaxTime because MaxTime does not interrupt function evaluations.	Inf
NumGridDivisions	For 'gridsearch', the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	10
ShowPlots	Logical value indicating whether to show plots. If true, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if Optimizer is 'bayesopt', then ShowPlots also plots a model of the objective function against the parameters.	true
SaveIntermediateResults	Logical value indicating whether to save results when Optimizer is 'bayesopt'. If true, this field overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a BayesianOptimization object.	false

Field Name	Values	Default
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesopt</code> <code>Verbose</code> name-value pair argument.	1
UseParallel	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. For details, see “Parallel Bayesian Optimization” on page 10-7.	false
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If false, the optimizer uses a single partition for the optimization. true usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, true requires at least twice as many function evaluations.	false
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code> .	'Kfold', 5 if you do not specify any cross-validation field
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example:

```
'HyperparameterOptimizationOptions', struct('MaxObjectiveEvaluations', 60)
```

Data Types: struct

Output Arguments

Mdl — Trained kernel regression model

RegressionKernel model object | RegressionPartitionedKernel cross-validated model object

Trained kernel regression model, returned as a `RegressionKernel` model object or `RegressionPartitionedKernel` cross-validated model object.

If you set any of the name-value pair arguments `CrossVal`, `CVPartition`, `Holdout`, `KFold`, or `Leaveout`, then `Mdl` is a `RegressionPartitionedKernel` cross-validated model. Otherwise, `Mdl` is a `RegressionKernel` model.

To reference properties of `Mdl`, use dot notation. For example, enter `Mdl.NumExpansionDimensions` in the Command Window to display the number of dimensions of the expanded space.

Note Unlike other regression models, and for economical memory usage, a `RegressionKernel` model object does not store the training data or training process details (for example, convergence history).

FitInfo – Optimization details

structure array

Optimization details, returned as a structure array including fields described in this table. The fields contain final values or name-value pair argument specifications.

Field	Description
<code>Solver</code>	Objective function minimization technique: 'LBFGS-fast', 'LBFGS-blockwise', or 'LBFGS-tall'. For details, see "Algorithms" on page 32-6005.
<code>LossFunction</code>	Loss function. Either mean squared error (MSE) or epsilon-insensitive, depending on the type of linear regression model. See <code>Learner</code> .
<code>Lambda</code>	Regularization term strength. See <code>Lambda</code> .
<code>BetaTolerance</code>	Relative tolerance on the linear coefficients and the bias term. See <code>BetaTolerance</code> .
<code>GradientTolerance</code>	Absolute gradient tolerance. See <code>GradientTolerance</code> .
<code>ObjectiveValue</code>	Value of the objective function when optimization terminates. The regression loss plus the regularization term compose the objective function.
<code>GradientMagnitude</code>	Infinite norm of the gradient vector of the objective function when optimization terminates. See <code>GradientTolerance</code> .
<code>RelativeChangeInBeta</code>	Relative changes in the linear coefficients and the bias term when optimization terminates. See <code>BetaTolerance</code> .
<code>FitTime</code>	Elapsed, wall-clock time (in seconds) required to fit the model to the data.
<code>History</code>	History of optimization information. This field also includes the optimization information from training <code>Mdl</code> . This field is empty (<code>[]</code>) if you specify 'Verbose', <code>0</code> . For details, see <code>Verbose</code> and "Algorithms" on page 32-6005.

To access fields, use dot notation. For example, to access the vector of objective function values for each iteration, enter `FitInfo.ObjectiveValue` in the Command Window.

Examine the information provided by `FitInfo` to assess whether convergence is satisfactory.

HyperparameterOptimizationResults – Cross-validation optimization of hyperparameters

`BayesianOptimization` object | table of hyperparameters and associated values

Cross-validation optimization of hyperparameters, returned as a `BayesianOptimization` object or a table of hyperparameters and associated values. The output is nonempty when the value of

'OptimizeHyperparameters' is not 'none'. The output value depends on the `Optimizer` field value of the 'HyperparameterOptimizationOptions' name-value pair argument:

Value of Optimizer Field	Value of HyperparameterOptimizationResults
'bayesopt' (default)	Object of class <code>BayesianOptimization</code>
'gridsearch' or 'randomsearch'	Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

Limitations

- `fitrkernel` does not accept initial conditions for the linear coefficients β and bias term (b) used to determine the decision function, $f(x) = T(x)\beta + b$.
- `fitrkernel` does not support standardization and cross-validation options.
- `fitrkernel` does not accept table inputs.

More About

Random Feature Expansion

Random feature expansion, such as Random Kitchen Sinks[1] and Fastfood[2], is a scheme to approximate Gaussian kernels of the kernel regression algorithm for big data in a computationally efficient way. Random feature expansion is more practical for big data applications that have large training sets but can also be applied to smaller data sets that fit in memory.

The kernel regression algorithm searches for an optimal function that deviates from each response data point (y_i) by values no greater than the epsilon margin (ϵ) after mapping the predictor data into a high-dimensional space.

Some regression problems cannot be described adequately using a linear model. In such cases, obtain a nonlinear regression model by replacing the dot product x_1x_2' with a nonlinear kernel function $G(x_1, x_2) = \langle \varphi(x_1), \varphi(x_2) \rangle$, where x_i is the i th observation (row vector) and $\varphi(x_i)$ is a transformation that maps x_i to a high-dimensional space (called the "kernel trick"). However, evaluating $G(x_1, x_2)$, the Gram matrix, for each pair of observations is computationally expensive for a large data set (large n).

The random feature expansion scheme finds a random transformation so that its dot product approximates the Gaussian kernel. That is,

$$G(x_1, x_2) = \langle \varphi(x_1), \varphi(x_2) \rangle \approx T(x_1)T(x_2)',$$

where $T(x)$ maps x in \mathbb{R}^p to a high-dimensional space (\mathbb{R}^m). The Random Kitchen Sink[1] scheme uses the random transformation

$$T(x) = m^{-1/2} \exp(iZx'),$$

where $Z \in \mathbb{R}^{m \times p}$ is a sample drawn from $N(0, \sigma^{-2})$ and σ^2 is a kernel scale. This scheme requires $O(mp)$ computation and storage. The Fastfood[2] scheme introduces another random basis V instead

of Z using Hadamard matrices combined with Gaussian scaling matrices. This random basis reduces computation cost to $O(m \log p)$ and reduces storage to $O(m)$.

You can specify values for m and σ^2 , using the `NumExpansionDimensions` and `KernelScale` name-value pair arguments of `fitrkernel`, respectively.

The `fitrkernel` function uses the Fastfood scheme for random feature expansion and uses linear regression to train a Gaussian kernel regression model. Unlike solvers in the `fitrsvm` function, which require computation of the n -by- n Gram matrix, the solver in `fitrkernel` only needs to form a matrix of size n -by- m , with m typically much less than n for big data.

Box Constraint

A box constraint is a parameter that controls the maximum penalty imposed on observations that lie outside the epsilon margin (ϵ), and helps to prevent overfitting (regularization). Increasing the box constraint can lead to longer training times.

The box constraint (C) and the regularization term strength (λ) are related by $C = 1/(\lambda n)$, where n is the number of observations.

Algorithms

`fitrkernel` minimizes the regularized objective function using a Limited-memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) solver with ridge (L_2) regularization. To find the type of LBFGS solver used for training, type `FitInfo.Solver` in the Command Window.

- 'LBFGS-fast' — LBFGS solver.
- 'LBFGS-blockwise' — LBFGS solver with a block-wise strategy. If `fitrkernel` requires more memory than the value of `BlockSize` to hold the transformed predictor data, then it uses a block-wise strategy.
- 'LBFGS-tall' — LBFGS solver with a block-wise strategy for tall arrays.

When `fitrkernel` uses a block-wise strategy, `fitrkernel` implements LBFGS by distributing the calculation of the loss and gradient among different parts of the data at each iteration. Also, `fitrkernel` refines the initial estimates of the linear coefficients and the bias term by fitting the model locally to parts of the data and combining the coefficients by averaging. If you specify 'Verbose', 1, then `fitrkernel` displays diagnostic information for each data pass and stores the information in the `History` field of `FitInfo`.

When `fitrkernel` does not use a block-wise strategy, the initial estimates are zeros. If you specify 'Verbose', 1, then `fitrkernel` displays diagnostic information for each iteration and stores the information in the `History` field of `FitInfo`.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Some name-value pair arguments have different defaults compared to the default values for the in-memory `fitrkernel` function. Supported name-value pair arguments, and any differences, are:
 - 'BoxConstraint'
 - 'Epsilon'
 - 'NumExpansionDimensions'
 - 'KernelScale'
 - 'Lambda'
 - 'Learner'
 - 'Verbose' — Default value is 1.
 - 'BlockSize'
 - 'RandomStream'
 - 'ResponseTransform'
 - 'Weights' — Value must be a tall array.
 - 'BetaTolerance' — Default value is relaxed to $1e-3$.
 - 'GradientTolerance' — Default value is relaxed to $1e-5$.
 - 'HessianHistorySize'
 - 'IterationLimit' — Default value is relaxed to 20.
 - 'OptimizeHyperparameters'
 - 'HyperparameterOptimizationOptions' — For cross-validation, tall optimization supports only 'Holdout' validation. For example, you can specify `fitrkernel(X,Y,'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',struct('Holdout',0.2))`.
- If 'KernelScale' is 'auto', then `fitrkernel` uses the random stream controlled by `ta1rng` for subsampling. For reproducibility, you must set a random number seed for both the global stream and the random stream controlled by `ta1rng`.
- If 'Lambda' is 'auto', then `fitrkernel` might take an extra pass through the data to calculate the number of observations in X.
- `fitrkernel` uses a block-wise strategy. For details, see "Algorithms" on page 32-6005.

For more information, see "Tall Arrays" (MATLAB).

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to `true`.

To perform parallel hyperparameter optimization, use the `'HyperparameterOptions'`, `struct('UseParallel',true)` name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2018a

RegressionKernel

Gaussian kernel regression model using random feature expansion

Description

`RegressionKernel` is a trained model object for Gaussian kernel regression using random feature expansion. `RegressionKernel` is more practical for big data applications that have large training sets but can also be applied to smaller data sets that fit in memory.

Unlike other regression models, and for economical memory usage, `RegressionKernel` model objects do not store the training data. However, they do store information such as the dimension of the expanded space, the kernel scale parameter, and the regularization strength.

You can use trained `RegressionKernel` models to continue training using the training data, predict responses for new data, and compute the mean squared error or epsilon-insensitive loss. For details, see `resume`, `predict`, and `loss`.

Creation

Create a `RegressionKernel` object using the `fitrkernel` function. This function maps data in a low-dimensional space into a high-dimensional space, then fits a linear model in the high-dimensional space by minimizing the regularized objective function. Obtaining the linear model in the high-dimensional space is equivalent to applying the Gaussian kernel to the model in the low-dimensional space. Available linear regression models include regularized support vector machines (SVM) and least-squares regression models.

Properties

Kernel Regression Properties

Epsilon — Half width of epsilon-insensitive band

nonnegative scalar

Half the width of the epsilon-insensitive band, specified as a nonnegative scalar.

If `Learner` is not `'svm'`, then `Epsilon` is an empty array (`[]`).

Data Types: `single` | `double`

Learner — Linear regression model type

`'svm'` (default) | `'leastsquares'`

Linear regression model type, specified as `'leastsquares'` or `'svm'`.

In the following table, $f(x) = T(x)\beta + b$.

- x is an observation (row vector) from p predictor variables.

- $T(\cdot)$ is a transformation of an observation (row vector) for feature expansion. $T(x)$ maps x in \mathbb{R}^p to a high-dimensional space (\mathbb{R}^m).
- β is a vector of m coefficients.
- b is the scalar bias.

Value	Algorithm	Loss function	FittedLoss Value
'leastsquares'	Linear regression via ordinary least squares	Mean squared error (MSE): $\ell[y, f(x)] = \frac{1}{2}[y - f(x)]^2$	'mse'
'svm'	Support vector machine regression	Epsilon-insensitive: $\ell[y, f(x)] = \max[0, y - f(x) - \varepsilon]$	'epsiloninsensitive'

NumExpansionDimensions — Number of dimensions of expanded space

positive integer

Number of dimensions of the expanded space, specified as a positive integer.

Data Types: single | double

KernelScale — Kernel scale parameter

positive scalar

Kernel scale parameter, specified as a positive scalar.

Data Types: single | double

BoxConstraint — Box constraint

positive scalar

Box constraint, specified as a positive scalar.

Data Types: double | single

Lambda — Regularization term strength

nonnegative scalar

Regularization term strength, specified as a nonnegative scalar.

Data Types: single | double

FittedLoss — Loss function used to fit linear model

'epsiloninsensitive' | 'mse'

Loss function used to fit the linear model, specified as 'epsiloninsensitive' or 'mse'.

Value	Algorithm	Loss function	Learner Value
'epsiloninsensitive'	Support vector machine regression	Epsilon-insensitive: $\ell[y, f(x)] = \max[0, y - f(x) - \varepsilon]$	'svm'

Value	Algorithm	Loss function	Learner Value
'mse'	Linear regression via ordinary least squares	Mean squared error (MSE): $\ell[y, f(x)] = \frac{1}{2}[y - f(x)]^2$	'least squares'

Regularization — Complexity penalty type

'lasso (L1)' | 'ridge (L2)'

Complexity penalty type, specified as 'lasso (L1)' or 'ridge (L2)'.

The software composes the objective function for minimization from the sum of the average loss function (see `FittedLoss`) and a regularization value from this table.

Value	Description
'lasso (L1)'	Lasso (L_1) penalty: $\lambda \sum_{j=1}^p \beta_j $
'ridge (L2)'	Ridge (L_2) penalty: $\frac{\lambda}{2} \sum_{j=1}^p \beta_j^2$

λ specifies the regularization term strength (see `Lambda`).

The software excludes the bias term (β_0) from the regularization penalty.

Other Regression Properties

CategoricalPredictors — Indices of categorical predictors

[]

Indices of categorical predictors, whose value is always empty ([]) because a `RegressionKernel` model does not support categorical predictors.

ModelParameters — Parameters used for training model

structure

Parameters used for training the `RegressionKernel` model, specified as a structure.

Access fields of `ModelParameters` using dot notation. For example, access the relative tolerance on the linear coefficients and the bias term by using `Mdl.ModelParameters.BetaTolerance`.

Data Types: `struct`

PredictorNames — Predictor names

cell array of character vectors

Predictor names in order of their appearance in the predictor data X , specified as a cell array of character vectors. The length of `PredictorNames` is equal to the number of columns in X .

Data Types: `cell`

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

Expanded predictor names, specified as a cell array of character vectors.

Because a `RegressionKernel` model does not support categorical predictors, `ExpandedPredictorNames` and `PredictorNames` are equal.

Data Types: `cell`

ResponseName — Response variable name

character vector

Response variable name, specified as a character vector.

Data Types: `char`

ResponseTransform — Response transformation function to apply to predicted responses

'none' | function handle

Response transformation function to apply to predicted responses, specified as 'none' or a function handle.

For kernel regression models and before the response transformation, the predicted response for the observation x (row vector) is $f(x) = T(x)\beta + b$.

- $T(\cdot)$ is a transformation of an observation for feature expansion.
- β corresponds to `Mdl.Beta`.
- b corresponds to `Mdl.Bias`.

For a MATLAB function or a function that you define, enter its function handle. For example, you can enter `Mdl.ResponseTransform = @function`, where *function* accepts a numeric vector of the original responses and returns a numeric vector of the same size containing the transformed responses.

Data Types: `char` | `function_handle`

Object Functions

`loss` Regression loss for Gaussian kernel regression model
`predict` Predict responses for Gaussian kernel regression model
`resume` Resume training of Gaussian kernel regression model

Examples

Train Gaussian Kernel Regression Model

Train a kernel regression model for a tall array by using SVM.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

Create a datastore that references the folder location with the data. The data can be contained in a single file, a collection of files, or an entire folder. Treat 'NA' values as missing data so that

datastore replaces them with NaN values. Select a subset of the variables to use. Create a tall table on top of the datastore.

```
varnames = {'ArrTime','DepTime','ActualElapsedTime'};
ds = datastore('airlinesmall.csv','TreatAsMissing','NA',...
    'SelectedVariableNames',varnames);
t = tall(ds);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 12).
```

Specify `DepTime` and `ArrTime` as the predictor variables (X) and `ActualElapsedTime` as the response variable (Y). Select the observations for which `ArrTime` is later than `DepTime`.

```
daytime = t.ArrTime>t.DepTime;
Y = t.ActualElapsedTime(daytime); % Response data
X = t{daytime,{'DepTime' 'ArrTime'}}; % Predictor data
```

Standardize the predictor variables.

```
Z = zscore(X); % Standardize the data
```

Train a default Gaussian kernel regression model with the standardized predictors. Extract a fit summary to determine how well the optimization algorithm fits the model to the data.

```
[Mdl,FitInfo] = fitrkernel(Z,Y)
```

`Mdl` is a `RegressionKernel` model. To inspect the regression error, you can pass `Mdl` and the training data or new data to the `loss` function. Or, you can pass `Mdl` and new predictor data to the `predict` function to predict responses for new observations. You can also pass `Mdl` and the training data to the `resume` function to continue training.

`FitInfo` is a structure array containing optimization information. Use `FitInfo` to determine whether optimization termination measurements are satisfactory.

For improved accuracy, you can increase the maximum number of optimization iterations (`'IterationLimit'`) and decrease the tolerance values (`'BetaTolerance'` and `'GradientTolerance'`) by using the name-value pair arguments of `fitrkernel`. Doing so can improve measures like `ObjectiveValue` and `RelativeChangeInBeta` in `FitInfo`. You can also optimize model parameters by using the `'OptimizeHyperparameters'` name-value pair argument.

Estimate Sample Loss and Resume Training

Resume training a Gaussian kernel regression model for more iterations to improve the regression loss.

Load the `carbig` data set.

```
load carbig
```

Specify the predictor variables (X) and the response variable (Y).

```
X = [Acceleration,Cylinders,Displacement,Horsepower,Weight];
Y = MPG;
```

Delete rows of X and Y where either array has NaN values. Removing rows with NaN values before passing data to `fitrkernel` can speed up training and reduce memory usage.

```
R = rmmissing([X Y]); % Data with missing entries removed
X = R(:,1:5);
Y = R(:,end);
```

Reserve 10% of the observations as a holdout sample. Extract the training and test indices from the partition definition.

```
rng(10) % For reproducibility
N = length(Y);
cvp = cvpartition(N,'Holdout',0.1);
idxTrn = training(cvp); % Training set indices
idxTest = test(cvp); % Test set indices
```

Standardize the training data and train a kernel regression model. Set the iteration limit to 5 and specify 'Verbose', 1 to display diagnostic information.

```
Xtrain = X(idxTrn,:);
Ytrain = Y(idxTrn);
[Ztrain,tr_mu,tr_sigma] = zscore(Xtrain); % Standardize the training data
tr_sigma(tr_sigma==0) = 1;
Mdl = fitrkernel(Ztrain,Ytrain,'IterationLimit',5,'Verbose',1)
```

Solver	Pass	Iteration	Objective	Step	Gradient magnitude	Relative change in Beta

LBFGS	1	5	3.063978e+00	1.000000e+00	1.475038e-02	3.314455e-02

```
Mdl =
  RegressionKernel
      ResponseName: 'Y'
        Learner: 'svm'
  NumExpansionDimensions: 256
        KernelScale: 1
            Lambda: 0.0028
      BoxConstraint: 1
        Epsilon: 0.8617
```

Properties, Methods

Mdl is a `RegressionKernel` model.

Standardize the test data using the same mean and standard deviation of the training data columns.
Estimate the epsilon-insensitive error for the test set.

```
Xtest = X(idxTest,:);
Ztest = (Xtest-tr_mu)./tr_sigma; % Standardize the test data
Ytest = Y(idxTest);
```

```
L = loss(Mdl,Ztest,Ytest,'LossFun','epsiloninsensitive')
```

```
L = 2.0674
```

Continue training the model by using `resume`. This function continues training with the same options used for training `Mdl`.

```
UpdatedMdl = resume(Mdl,Ztrain,Ytrain);
```

=====							

Estimate the epsilon-insensitive error for the test set using the updated model.

```
UpdatedL = loss(UpdatedMdl,Ztest,Ytest,'LossFun','epsiloninsensitive')
```

```
UpdatedL = 1.8933
```

The regression error decreases by a factor of about 0.08 after resume updates the regression model with more iterations.

Introduced in R2018a

loss

Regression loss for Gaussian kernel regression model

Syntax

```
L = loss(Mdl,X,Y)
L = loss(Mdl,X,Y,Name,Value)
```

Description

`L = loss(Mdl,X,Y)` returns the mean squared error (MSE) for the Gaussian kernel regression model `Mdl` using the predictor data in `X` and the corresponding responses in `Y`.

`L = loss(Mdl,X,Y,Name,Value)` uses additional options specified by one or more name-value pair arguments. For example, you can specify a regression loss function and observation weights. Then, `loss` returns the weighted regression loss using the specified loss function.

Examples

Calculate Sample Loss for Gaussian Kernel Regression Model

Train a Gaussian kernel regression model for a tall array, then calculate the resubstitution mean squared error and epsilon-insensitive error.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

Create a datastore that references the folder location with the data. The data can be contained in a single file, a collection of files, or an entire folder. Treat 'NA' values as missing data so that `datastore` replaces them with NaN values. Select a subset of the variables to use. Create a tall table on top of the datastore.

```
varnames = {'ArrTime','DepTime','ActualElapsedTime'};
ds = datastore('airlinesmall.csv','TreatAsMissing','NA',...
    'SelectedVariableNames',varnames);
t = tall(ds);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 12).
```

Specify `DepTime` and `ArrTime` as the predictor variables (`X`) and `ActualElapsedTime` as the response variable (`Y`). Select the observations for which `ArrTime` is later than `DepTime`.

```
daytime = t.ArrTime>t.DepTime;
Y = t.ActualElapsedTime(daytime);    % Response data
X = t{daytime,{'DepTime' 'ArrTime'}}; % Predictor data
```

Standardize the predictor variables.

```
Z = zscore(X); % Standardize the data
```

Train a default Gaussian kernel regression model with the standardized predictors. Set 'Verbose', 0 to suppress diagnostic messages.

```
[Mdl,FitInfo] = fitrkernel(Z,Y,'Verbose',0)
```

```
Mdl =
  RegressionKernel
    PredictorNames: {'x1' 'x2'}
    ResponseName: 'Y'
    Learner: 'svm'
    NumExpansionDimensions: 64
    KernelScale: 1
    Lambda: 8.5385e-06
    BoxConstraint: 1
    Epsilon: 5.9303
```

Properties, Methods

```
FitInfo = struct with fields:
    Solver: 'LBFGS-tall'
    LossFunction: 'epsiloninsensitive'
    Lambda: 8.5385e-06
    BetaTolerance: 1.0000e-03
    GradientTolerance: 1.0000e-05
    ObjectiveValue: 31.3687
    GradientMagnitude: 0.0468
    RelativeChangeInBeta: 0.0360
    FitTime: 205.8170
    History: []
```

Mdl is a trained RegressionKernel model, and the structure array FitInfo contains optimization details.

Determine how well the trained model generalizes to new predictor values by estimating the resubstitution mean squared error and epsilon-insensitive error.

```
lossMSE = loss(Mdl,Z,Y) % Resubstitution mean squared error
```

```
lossMSE =
```

```
MxNx... tall array
```

```
? ? ? ...
? ? ? ...
? ? ? ...
: : :
: : :
```

```
lossEI = loss(Mdl,Z,Y,'LossFun','epsiloninsensitive') % Resubstitution epsilon-insensitive error
```

```
lossEI =
```

```
MxNx... tall array
```

```

? ? ? ...
? ? ? ...
? ? ? ...
: : :
: : :

```

Evaluate the tall arrays and bring the results into memory by using `gather`.

```
[lossMSE,lossEI] = gather(lossMSE,lossEI)
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 3.9 sec
Evaluation completed in 4.5 sec
```

```
lossMSE = 2.8927e+03
```

```
lossEI = 28.2703
```

Specify Custom Regression Loss

Specify a custom regression loss (Huber loss) for a Gaussian kernel regression model.

Load the `carbig` data set.

```
load carbig
```

Specify the predictor variables (X) and the response variable (Y).

```
X = [Weight,Cylinders,Horsepower,Model_Year];
Y = MPG;
```

Delete rows of X and Y where either array has NaN values. Removing rows with NaN values before passing data to `fitrkernel` can speed up training and reduce memory usage.

```
R = rmmissing([X Y]);
X = R(:,1:4);
Y = R(:,end);
```

Reserve 10% of the observations as a holdout sample. Extract the training and test indices from the partition definition.

```
rng(10) % For reproducibility
N = length(Y);
cvp = cvpartition(N,'Holdout',0.1);
idxTrn = training(cvp); % Training set indices
idxTest = test(cvp); % Test set indices
```

Standardize the training data and train the regression kernel model.

```
Xtrain = X(idxTrn,:);
Ytrain = Y(idxTrn);
[Ztrain,tr_mu,tr_sigma] = zscore(Xtrain); % Standardize the training data
tr_sigma(tr_sigma==0) = 1;
Mdl = fitrkernel(Ztrain,Ytrain)
```

```
Mdl =
  RegressionKernel
```

```

        ResponseName: 'Y'
        Learner: 'svm'
    NumExpansionDimensions: 128
        KernelScale: 1
            Lambda: 0.0028
        BoxConstraint: 1
            Epsilon: 0.8617

```

Properties, Methods

Mdl is a `RegressionKernel` model.

Create an anonymous function that measures Huber loss ($\delta = 1$), that is,

$$L = \frac{1}{\sum w_j} \sum_{j=1}^n w_j \ell_j,$$

where

$$\ell_j = \begin{cases} 0.5\widehat{e}_j^2; & |\widehat{e}_j| \leq 1 \\ |\widehat{e}_j| - 0.5; & |\widehat{e}_j| > 1 \end{cases}.$$

\widehat{e}_j is the residual for observation j . Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the 'LossFun' name-value pair argument.

```

huberloss = @(Y,Yhat,W)sum(W.*((0.5*(abs(Y-Yhat)<=1).*(Y-Yhat).^2) + ...
    ((abs(Y-Yhat)>1).*abs(Y-Yhat)-0.5)))/sum(W);

```

Estimate the training set regression loss using the Huber loss function.

```
eTrain = loss(Mdl,Ztrain,Ytrain,'LossFun',huberloss)
```

```
eTrain = 1.7210
```

Standardize the test data using the same mean and standard deviation of the training data columns. Estimate the test set regression loss using the Huber loss function.

```

Xtest = X(idxTest,:);
Ztest = (Xtest-tr_mu)./tr_sigma; % Standardize the test data
Ytest = Y(idxTest);

```

```
eTest = loss(Mdl,Ztest,Ytest,'LossFun',huberloss)
```

```
eTest = 1.3062
```

Input Arguments

Mdl — Kernel regression model

`RegressionKernel` model object

Kernel regression model, specified as a `RegressionKernel` model object. You can create a `RegressionKernel` model object using `fitrkernel`.

X — Predictor data*n*-by-*p* numeric matrix

Predictor data, specified as an *n*-by-*p* numeric matrix, where *n* is the number of observations and *p* is the number of predictors. *p* must be equal to the number of predictors used to train `Mdl`.

Data Types: `single` | `double`**Y — Response data**

numeric vector

Response data, specified as an *n*-dimensional numeric vector. The length of *Y* and the number of observations in *X* must be equal.

Data Types: `single` | `double`**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `L = loss(Mdl,X,Y,'LossFun','epsiloninsensitive','Weights',weights)` returns the weighted regression loss using the epsilon-insensitive loss function.

LossFun — Loss function`'mse'` (default) | `'epsiloninsensitive'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in loss function name or a function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar. Also, in the table, $f(x) = T(x)\beta + b$.
 - x is an observation (row vector) from p predictor variables.
 - $T(\cdot)$ is a transformation of an observation (row vector) for feature expansion. $T(x)$ maps x in \mathbb{R}^p to a high-dimensional space (\mathbb{R}^m).
 - β is a vector of m coefficients.
 - b is the scalar bias.

Value	Description
<code>'epsiloninsensitive'</code>	Epsilon-insensitive loss: $\ell[y, f(x)] = \max[0, y - f(x) - \epsilon]$
<code>'mse'</code>	MSE: $\ell[y, f(x)] = [y - f(x)]^2$

- `'epsiloninsensitive'` is appropriate for SVM learners only.
- Specify your own function by using function handle notation.

Let n be the number of observations in *X*. Your function must have this signature:

```
lossvalue = lossfun(Y, Yhat, W)
```

- The output argument `lossvalue` is a scalar.

- You choose the function name (*lossfun*).
- Y is an n -dimensional vector of observed responses. `loss` passes the input argument Y in for Y .
- \hat{Y} is an n -dimensional vector of predicted responses, which is similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights.

Specify your function using 'LossFun', @*lossfun*.

Data Types: char | string | function_handle

Weights — Observation weights

ones($n, 1$)/ n (default) | numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values. `loss` weighs the observations in X with the corresponding values in `Weights`. The size of `Weights` must equal n , the number of observations (rows in X). If you supply the observation weights, `loss` computes the weighted regression loss, that is, the “Weighted Mean Squared Error” on page 32-6022 or “Epsilon-Insensitive Loss Function” on page 32-6023.

`loss` normalizes `Weights` to sum to 1.

Data Types: double | single

Output Arguments

L — Regression loss

numeric scalar

Regression loss, returned as a numeric scalar. The interpretation of L depends on `Weights` and `LossFun`. For example, if you use the default observation weights and specify 'epsiloninsensitive' as the loss function, then L is the epsilon-insensitive loss.

More About

Weighted Mean Squared Error

The weighted mean squared error is calculated as follows:

$$\text{mse} = \frac{\sum_{j=1}^n w_j (f(x_j) - y_j)^2}{\sum_{j=1}^n w_j},$$

where:

- n is the number of observations.
- x_j is the j th observation (row of predictor data).
- y_j is the observed response to x_j .
- $f(x_j)$ is the response prediction of the Gaussian kernel regression model `Mdl` to x_j .
- w is the vector of observation weights.

Each observation weight in w is equal to $\text{ones}(n, 1)/n$ by default. You can specify different values for the observation weights by using the 'Weights' name-value pair argument. `loss` normalizes `Weights` to sum to 1.

Epsilon-Insensitive Loss Function

The epsilon-insensitive loss function ignores errors that are within the distance epsilon (ε) of the function value. The function is formally described as:

$$Loss_{\varepsilon} = \begin{cases} 0, & \text{if } |y - f(x)| \leq \varepsilon \\ |y - f(x)| - \varepsilon, & \text{otherwise.} \end{cases}$$

The mean epsilon-insensitive loss is calculated as follows:

$$Loss = \frac{\sum_{j=1}^n w_j \max(0, |y_j - f(x_j)| - \varepsilon)}{\sum_{j=1}^n w_j},$$

where:

- n is the number of observations.
- x_j is the j th observation (row of predictor data).
- y_j is the observed response to x_j .
- $f(x_j)$ is the response prediction of the Gaussian kernel regression model `Mdl` to x_j .
- w is the vector of observation weights.

Each observation weight in w is equal to $\text{ones}(n, 1)/n$ by default. You can specify different values for the observation weights by using the 'Weights' name-value pair argument. `loss` normalizes `Weights` to sum to 1.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

`RegressionKernel` | `fitrkernel` | `predict` | `resume`

Introduced in R2018a

predict

Predict responses for Gaussian kernel regression model

Syntax

```
YFit = predict(Mdl,X)
```

Description

`YFit = predict(Mdl,X)` returns predicted responses for each observation in the predictor data `X` based on the binary Gaussian kernel regression model `Mdl`.

Examples

Predict Test Set Responses

Predict the test set responses using a Gaussian kernel regression model for the `carbig` data set.

Load the `carbig` data set.

```
load carbig
```

Specify the predictor variables (`X`) and the response variable (`Y`).

```
X = [Weight,Cylinders,Horsepower,Model_Year];  
Y = MPG;
```

Delete rows of `X` and `Y` where either array has `NaN` values. Removing rows with `NaN` values before passing data to `fitrkernel` can speed up training and reduce memory usage.

```
R = rmmissing([X Y]);  
X = R(:,1:4);  
Y = R(:,end);
```

Reserve 10% of the observations as a holdout sample. Extract the training and test indices from the partition definition.

```
rng(10) % For reproducibility  
N = length(Y);  
cvp = cvpartition(N,'Holdout',0.1);  
idxTrn = training(cvp); % Training set indices  
idxTest = test(cvp); % Test set indices
```

Standardize the training data and train the regression kernel model.

```
Xtrain = X(idxTrn,:);  
Ytrain = Y(idxTrn);  
[Ztrain,tr_mu,tr_sigma] = zscore(Xtrain); % Standardize the training data  
tr_sigma(tr_sigma==0) = 1;  
Mdl = fitrkernel(Ztrain,Ytrain)
```

```
Mdl =
  RegressionKernel
      ResponseName: 'Y'
      Learner: 'svm'
      NumExpansionDimensions: 128
      KernelScale: 1
      Lambda: 0.0028
      BoxConstraint: 1
      Epsilon: 0.8617
```

Properties, Methods

Mdl is a RegressionKernel model.

Standardize the test data using the same mean and standard deviation of the training data columns. Predict responses for the test set.

```
Xtest = X(idxTest,:);
Ztest = (Xtest-tr_mu)./tr_sigma; % Standardize the test data
Ytest = Y(idxTest);
```

```
YFit = predict(Mdl,Ztest);
```

Create a table containing the first 10 observed response values and predicted response values.

```
table(Ytest(1:10),YFit(1:10),'VariableNames',...
      {'ObservedValue','PredictedValue'})
```

```
ans=10x2 table
  ObservedValue PredictedValue
  _____  _____

           13           13.324
```

Estimate the test set regression loss using the mean squared error loss function.

```
L = loss(Mdl,Ztest,Ytest)
```

```
L = 9.2664
```

Input Arguments

Mdl — Kernel regression model

RegressionKernel model object

Kernel regression model, specified as a `RegressionKernel` model object. You can create a `RegressionKernel` model object using `fitrkernel`.

X — Predictor data

n-by-*p* numeric matrix

Predictor data, specified as an *n*-by-*p* numeric matrix, where *n* is the number of observations and *p* is the number of predictors. *p* must be equal to the number of predictors used to train `Mdl`.

Data Types: `single` | `double`

Output Arguments**YFit — Predicted responses**

numeric vector

Predicted responses, returned as a numeric vector.

`YFit` is an *n*-by-1 vector of the same data type as the response data (`Y`) used to train `Mdl`, where *n* is the number of observations in `X`.

Extended Capabilities**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

See Also

`RegressionKernel` | `fitrkernel` | `loss` | `resume`

Introduced in R2018a

resume

Resume training of Gaussian kernel regression model

Syntax

```
UpdatedMdl = resume(Mdl,X,Y)
UpdatedMdl = resume(Mdl,X,Y,Name,Value)
[UpdatedMdl,FitInfo] = resume(____)
```

Description

`UpdatedMdl = resume(Mdl,X,Y)` continues training with the same options used to train `Mdl`, including the training data (predictor data in `X` and response data in `Y`) and the feature expansion. The training starts at the current estimated parameters in `Mdl`. The function returns a new Gaussian kernel regression model `UpdatedMdl`.

`UpdatedMdl = resume(Mdl,X,Y,Name,Value)` returns a new kernel regression model with additional options specified by one or more name-value pair arguments. For example, you can modify convergence control options, such as convergence tolerances and the maximum number of additional optimization iterations.

`[UpdatedMdl,FitInfo] = resume(____)` also returns the fit information in the structure array `FitInfo` using any of the input arguments in the previous syntaxes.

Examples

Estimate Sample Loss and Resume Training

Resume training a Gaussian kernel regression model for more iterations to improve the regression loss.

Load the `carbig` data set.

```
load carbig
```

Specify the predictor variables (`X`) and the response variable (`Y`).

```
X = [Acceleration,Cylinders,Displacement,Horsepower,Weight];
Y = MPG;
```

Delete rows of `X` and `Y` where either array has NaN values. Removing rows with NaN values before passing data to `fitrkernl` can speed up training and reduce memory usage.

```
R = rmmissing([X Y]); % Data with missing entries removed
X = R(:,1:5);
Y = R(:,end);
```

Reserve 10% of the observations as a holdout sample. Extract the training and test indices from the partition definition.

```

rng(10) % For reproducibility
N = length(Y);
cvp = cvpartition(N,'Holdout',0.1);
idxTrn = training(cvp); % Training set indices
idxTest = test(cvp); % Test set indices

```

Standardize the training data and train a kernel regression model. Set the iteration limit to 5 and specify 'Verbose', 1 to display diagnostic information.

```

Xtrain = X(idxTrn,:);
Ytrain = Y(idxTrn);
[Ztrain,tr_mu,tr_sigma] = zscore(Xtrain); % Standardize the training data
tr_sigma(tr_sigma==0) = 1;
Mdl = fitrkernel(Ztrain,Ytrain,'IterationLimit',5,'Verbose',1)

```

        Lambda: 0.0028
  BoxConstraint: 1
        Epsilon: 0.8617

```

Properties, Methods

Mdl is a `RegressionKernel` model.

Standardize the test data using the same mean and standard deviation of the training data columns. Estimate the epsilon-insensitive error for the test set.

```

Xtest = X(idxTest,:);
Ztest = (Xtest-tr_mu)./tr_sigma; % Standardize the test data
Ytest = Y(idxTest);

```

```
L = loss(Mdl,Ztest,Ytest,'LossFun','epsiloninsensitive')
```

```
L = 2.0674
```

Continue training the model by using `resume`. This function continues training with the same options used for training Mdl.

```
UpdatedMdl = resume(Mdl,Ztrain,Ytrain);
```

Estimate the epsilon-insensitive error for the test set using the updated model.

```
UpdatedL = loss(UpdatedMdl,Ztest,Ytest,'LossFun','epsiloninsensitive')
```

```
UpdatedL = 1.8933
```

The regression error decreases by a factor of about 0.08 after resume updates the regression model with more iterations.

Resume Training with Modified Convergence Control Training Options

Load the carbig data set.

```
load carbig
```

Specify the predictor variables (X) and the response variable (Y).

```
X = [Acceleration,Cylinders,Displacement,Horsepower,Weight];
Y = MPG;
```

Delete rows of X and Y where either array has NaN values. Removing rows with NaN values before passing data to `fitrkernel` can speed up training and reduce memory usage.

```
R = rmmissing([X Y]); % Data with missing entries removed
X = R(:,1:5);
Y = R(:,end);
```

Reserve 10% of the observations as a holdout sample. Extract the training and test indices from the partition definition.

```
rng(10) % For reproducibility
N = length(Y);
cvp = cvpartition(N,'Holdout',0.1);
idxTrn = training(cvp); % Training set indices
idxTest = test(cvp); % Test set indices
```

Standardize the training data and train a kernel regression model with relaxed convergence control training options by using the name-value pair arguments 'BetaTolerance' and 'GradientTolerance'. Specify 'Verbose', 1 to display diagnostic information.

```
Xtrain = X(idxTrn,:);
Ytrain = Y(idxTrn);
[Ztrain,tr_mu,tr_sigma] = zscore(Xtrain); % Standardize the training data
tr_sigma(tr_sigma==0) = 1;
[Mdl,FitInfo] = fitrkernel(Ztrain,Ytrain,'Verbose',1, ...
    'BetaTolerance',2e-2,'GradientTolerance',2e-2);
```

Solver	Pass	Iteration	Objective	Step	Gradient magnitude	Relative change in Beta
LBFGS	1	0	5.691016e+00	0.000000e+00	5.852758e-02	
LBFGS	1	1	5.086537e+00	8.000000e+00	5.220869e-02	9.846711e-02
LBFGS	1	2	3.862301e+00	5.000000e-01	3.796034e-01	5.998808e-02
LBFGS	1	3	3.460613e+00	1.000000e+00	3.257790e-01	1.615091e-01
LBFGS	1	4	3.136228e+00	1.000000e+00	2.832861e-02	8.006254e-02
LBFGS	1	5	3.063978e+00	1.000000e+00	1.475038e-02	3.314455e-02

Mdl is a RegressionKernel model.

Standardize the test data using the same mean and standard deviation of the training data columns. Estimate the epsilon-insensitive error for the test set.

```
Xtest = X(idxTest,:);
Ztest = (Xtest-tr_mu)./tr_sigma; % Standardize the test data
Ytest = Y(idxTest);
```

```
L = loss(Mdl,Ztest,Ytest,'LossFun','epsiloninsensitive')
```

L = 2.0674

Continue training the model by using resume with modified convergence control options.

```
[UpdatedMdl,UpdatedFitInfo] = resume(Mdl,Ztrain,Ytrain, ...
    'BetaTolerance',2e-3,'GradientTolerance',2e-3);
```

Solver	Pass	Iteration	Objective	Step	Gradient magnitude	Relative change in Beta

LBFGS	1	6	2.738163e+00	1.000000e+00	5.949008e-02	9.476263e-02
LBFGS	1	7	2.719146e+00	1.000000e+00	1.699717e-02	1.849972e-02
LBFGS	1	8	2.705941e+00	1.000000e+00	3.116147e-02	4.152590e-02
LBFGS	1	9	2.701162e+00	1.000000e+00	5.665722e-03	9.401466e-02
LBFGS	1	10	2.695341e+00	5.000000e-01	3.116147e-02	4.968046e-02
LBFGS	1	11	2.691277e+00	1.000000e+00	8.498584e-03	1.017446e-02
LBFGS	1	12	2.689972e+00	1.000000e+00	1.983003e-02	9.938921e-02
LBFGS	1	13	2.688979e+00	1.000000e+00	1.416431e-02	6.606316e-02
LBFGS	1	14	2.687787e+00	1.000000e+00	1.621956e-03	7.089542e-02

Estimate the epsilon-insensitive error for the test set using the updated model.

```
UpdatedL = loss(UpdatedMdl,Ztest,Ytest,'LossFun','epsiloninsensitive')
```

```
UpdatedL = 1.8891
```

The regression error decreases after resume updates the regression model with smaller convergence tolerances.

Display the outputs `FitInfo` and `UpdatedFitInfo`.

`FitInfo`

```
FitInfo = struct with fields:
    Solver: 'LBFGS-fast'
    LossFunction: 'epsiloninsensitive'
    Lambda: 0.0028
    BetaTolerance: 0.0200
    GradientTolerance: 0.0200
    ObjectiveValue: 3.0640
    GradientMagnitude: 0.0148
    RelativeChangeInBeta: 0.0331
    FitTime: 0.0853
    History: [1x1 struct]
```

`UpdatedFitInfo`

```
UpdatedFitInfo = struct with fields:
    Solver: 'LBFGS-fast'
    LossFunction: 'epsiloninsensitive'
    Lambda: 0.0028
    BetaTolerance: 0.0020
    GradientTolerance: 0.0020
    ObjectiveValue: 2.6878
    GradientMagnitude: 0.0016
    RelativeChangeInBeta: 0.0071
    FitTime: 0.2580
    History: [1x1 struct]
```

Both trainings terminate because the software satisfies the absolute gradient tolerance.

Plot the gradient magnitude versus the number of iterations by using `UpdatedFitInfo.History.GradientMagnitude`. Note that the `History` field of `UpdatedFitInfo` includes the information in the `History` field of `FitInfo`.

```
semilogy(UpdatedFitInfo.History.GradientMagnitude,'o-')
ax = gca;
ax.XTick = 1:21;
ax.XTickLabel = UpdatedFitInfo.History.IterationNumber;
grid on
xlabel('Number of Iterations')
ylabel('Gradient Magnitude')
```

The first training terminates after five iterations because the gradient magnitude becomes less than $2e-2$. The second training terminates after 14 iterations because the gradient magnitude becomes less than $2e-3$.

Input Arguments

Mdl — Kernel regression model

`RegressionKernel` model object

Kernel regression model, specified as a `RegressionKernel` model object. You can create a `RegressionKernel` model object using `fitrkernel`.

X — Predictor data used to train Mdl

n -by- p numeric matrix

Predictor data used to train Mdl, specified as an n -by- p numeric matrix, where n is the number of observations and p is the number of predictors.

Data Types: `single` | `double`

Y — Response data used to train Mdl

numeric vector

Response data used to train Mdl, specified as a numeric vector.

Data Types: `double` | `single`

Note `resume` should run only on the same training data (X and Y) and the same observation weights (`Weights`) used to train `Mdl`. The `resume` function uses the same training options, such as feature expansion, used to train `Mdl`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `UpdatedMdl = resume(Mdl, X, Y, 'BetaTolerance', 1e-3)` resumes training with the same options used to train `Mdl`, except the relative tolerance on the linear coefficients and the bias term.

Weights — Observation weights used to train Mdl

positive numeric vector

Observation weights used to train `Mdl`, specified as the comma-separated pair consisting of `'Weights'` and a positive numeric vector of length n , where n is the number of observations in `X`. The `resume` function weighs the observations in `X` with the corresponding values in `Weights`.

The default value is `ones(n, 1)/n`.

`resume` normalizes `Weights` to sum to 1.

Example: `'Weights', w`

Data Types: `single` | `double`

BetaTolerance — Relative tolerance on linear coefficients and bias term

`BetaTolerance` value used to train `Mdl` (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of `'BetaTolerance'` and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t . If

$$\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}, \text{ then optimization terminates.}$$

If you also specify `GradientTolerance`, then optimization terminates when the software satisfies either stopping criterion.

By default, the value is the same `BetaTolerance` value used to train `Mdl`.

Example: `'BetaTolerance', 1e-6`

Data Types: `single` | `double`

GradientTolerance — Absolute gradient tolerance

`GradientTolerance` value used to train `Mdl` (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of `'GradientTolerance'` and a nonnegative scalar.

Let $\nabla \mathcal{L}_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t . If $\|\nabla \mathcal{L}_t\|_\infty = \max |\nabla \mathcal{L}_t| < \text{GradientTolerance}$, then optimization terminates.

If you also specify `BetaTolerance`, then optimization terminates when the software satisfies either stopping criterion.

By default, the value is the same `GradientTolerance` value used to train `Mdl`.

Example: `'GradientTolerance', 1e-5`

Data Types: `single` | `double`

IterationLimit – Maximum number of additional optimization iterations

positive integer

Maximum number of additional optimization iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer.

The default value is 1000 if the transformed data fits in memory (`Mdl.ModelParameters.BlockSize`), which you specify by using the `'BlockSize'` name-value pair argument when training `Mdl` with `fitrkernel`. Otherwise, the default value is 100.

Note that the default value is not the value used to train `Mdl`.

Example: `'IterationLimit', 500`

Data Types: `single` | `double`

Output Arguments

UpdatedMdl – Updated kernel regression model

`RegressionKernel` model object

Updated kernel regression model, returned as a `RegressionKernel` model object.

FitInfo – Optimization details

structure array

Optimization details, returned as a structure array including fields described in this table. The fields contain final values or name-value pair argument specifications.

Field	Description
<code>Solver</code>	Objective function minimization technique: <code>'LBFGS-fast'</code> , <code>'LBFGS-blockwise'</code> , or <code>'LBFGS-tall'</code> . For details, see the “Algorithms” on page 32-6005 section of <code>fitrkernel</code> .
<code>LossFunction</code>	Loss function. Either mean squared error (MSE) or epsilon-insensitive, depending on the type of linear regression model. See <code>Learner</code> of <code>fitrkernel</code> .
<code>Lambda</code>	Regularization term strength. See <code>Lambda</code> of <code>fitrkernel</code> .
<code>BetaTolerance</code>	Relative tolerance on the linear coefficients and the bias term. See <code>BetaTolerance</code> .
<code>GradientTolerance</code>	Absolute gradient tolerance. See <code>GradientTolerance</code> .
<code>ObjectiveValue</code>	Value of the objective function when optimization terminates. The regression loss plus the regularization term compose the objective function.

Field	Description
GradientMagnitude	Infinite norm of the gradient vector of the objective function when optimization terminates. See GradientTolerance.
RelativeChangeInBeta	Relative changes in the linear coefficients and the bias term when optimization terminates. See BetaTolerance.
FitTime	Elapsed, wall-clock time (in seconds) required to fit the model to the data.
History	History of optimization information. This field also includes the optimization information from training Mdl. This field is empty ([]) if you specify 'Verbose', 0 when training Mdl. For details, see Verbose and the "Algorithms" on page 32-6005 section of fitrkernel.

To access fields, use dot notation. For example, to access the vector of objective function values for each iteration, enter `FitInfo.ObjectiveValue` in the Command Window.

Examine the information provided by `FitInfo` to assess whether convergence is satisfactory.

More About

Random Feature Expansion

Random feature expansion, such as Random Kitchen Sinks[1] and Fastfood[2], is a scheme to approximate Gaussian kernels of the kernel regression algorithm for big data in a computationally efficient way. Random feature expansion is more practical for big data applications that have large training sets but can also be applied to smaller data sets that fit in memory.

The kernel regression algorithm searches for an optimal function that deviates from each response data point (y_i) by values no greater than the epsilon margin (ϵ) after mapping the predictor data into a high-dimensional space.

Some regression problems cannot be described adequately using a linear model. In such cases, obtain a nonlinear regression model by replacing the dot product $x_1 x_2'$ with a nonlinear kernel function $G(x_1, x_2) = \langle \varphi(x_1), \varphi(x_2) \rangle$, where x_i is the i th observation (row vector) and $\varphi(x_i)$ is a transformation that maps x_i to a high-dimensional space (called the "kernel trick"). However, evaluating $G(x_1, x_2)$, the Gram matrix, for each pair of observations is computationally expensive for a large data set (large n).

The random feature expansion scheme finds a random transformation so that its dot product approximates the Gaussian kernel. That is,

$$G(x_1, x_2) = \langle \varphi(x_1), \varphi(x_2) \rangle \approx T(x_1)T(x_2)',$$

where $T(x)$ maps x in \mathbb{R}^p to a high-dimensional space (\mathbb{R}^m). The Random Kitchen Sink[1] scheme uses the random transformation

$$T(x) = m^{-1/2} \exp(iZx)',$$

where $Z \in \mathbb{R}^{m \times p}$ is a sample drawn from $N(0, \sigma^{-2})$ and σ^2 is a kernel scale. This scheme requires $O(mp)$ computation and storage. The Fastfood[2] scheme introduces another random basis V instead of Z using Hadamard matrices combined with Gaussian scaling matrices. This random basis reduces computation cost to $O(m \log p)$ and reduces storage to $O(m)$.

You can specify values for m and σ^2 , using the `NumExpansionDimensions` and `KernelScale` name-value pair arguments of `fitrkernel`, respectively.

The `fitrkernel` function uses the Fastfood scheme for random feature expansion and uses linear regression to train a Gaussian kernel regression model. Unlike solvers in the `fitrsvm` function, which require computation of the n -by- n Gram matrix, the solver in `fitrkernel` only needs to form a matrix of size n -by- m , with m typically much less than n for big data.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- The default value for the `'IterationLimit'` name-value pair argument is relaxed to 20 when you work with tall arrays.
- `resume` uses a block-wise strategy. For details, see the “Algorithms” on page 32-6005 section of `fitrkernel`.
- You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

Introduced in R2018a

RegressionPartitionedKernel

Cross-validated kernel model for regression

Description

`RegressionPartitionedKernel` is a set of kernel regression models trained on cross-validated folds. To obtain a cross-validated, kernel regression model, use `fitrkernel` and specify one of the cross-validation options. You can estimate the predictive quality of the model, or how well the linear regression model generalizes, using one or more of these “kfold” methods: `kfoldPredict` and `kfoldLoss`.

Every “kfold” method uses models trained on *training-fold* observations to predict the response for *validation-fold* observations. For example, suppose that you cross-validate using five folds. In this case, the software randomly assigns each observation into five groups of equal size (roughly). The training fold contains four of the groups (that is, roughly 4/5 of the data) and the validation fold contains the other group (that is, roughly 1/5 of the data). In this case, cross-validation proceeds as follows:

- 1 The software trains the first model (stored in `CVMdl.Trained{1}`) using the observations in the last four groups and reserves the observations in the first group for validation.
- 2 The software trains the second model (stored in `CVMdl.Trained{2}`) using the observations in the first group and the last three groups. The software reserves the observations in the second group for validation.
- 3 The software proceeds in a similar fashion for the third through the fifth models.

If you validate by calling `kfoldPredict`, it computes predictions for the observations in group 1 using the first model, group 2 for the second model, and so on. In short, the software estimates a response for every observation using the model trained without that observation.

Note `RegressionPartitionedKernel` model objects do not store the predictor data set.

Creation

Create a `RegressionPartitionedKernel` object using the `fitrkernel` function. Use one of the 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout' name-value pair arguments in the call to `fitrkernel`. For details, see the `fitrkernel` function reference page.

Properties

Cross-Validation Properties

CrossValidatedModel — Cross-validated model name

character vector

This property is read-only.

Cross-validated model name, specified as a character vector.

For example, 'Kernel' specifies a cross-validated kernel model.

Data Types: char

KFold — Number of cross-validated folds

positive integer scalar

This property is read-only.

Number of cross-validated folds, specified as a positive integer scalar.

Data Types: double

ModelParameters — Cross-validation parameter values

object

This property is read-only.

Cross-validation parameter values, specified as an object. The parameter values correspond to the name-value pair argument values used to cross-validate the kernel regression model.

ModelParameters does not contain estimated parameters.

NumObservations — Number of observations

positive numeric scalar

This property is read-only.

Number of observations in the training data, specified as a positive numeric scalar.

Data Types: double

Partition — Data partition

cvpartition model

This property is read-only.

Data partition indicating how the software splits the data into cross-validation folds, specified as a cvpartition model.

Trained — Kernel regression models trained on cross-validation folds

cell array of RegressionKernel models

This property is read-only.

Kernel regression models trained on cross-validation folds, specified as a cell array of RegressionKernel models. Trained has k cells, where k is the number of folds.

Data Types: cell

W — Observation weights

numeric vector

This property is read-only.

Observation weights used to cross-validate the model, specified as a numeric vector. W has NumObservations elements.

The software normalizes the weights used for training so that $\text{nansum}(W)$ is 1.

Data Types: `single` | `double`

Y — Observed response values

numeric vector

This property is read-only.

Observed response values used to cross-validate the model, specified as a numeric vector. Y has `NumObservations` elements.

Each row of Y represents the observed response of the corresponding observation in the predictor data.

Data Types: `single` | `double`

Other Regression Properties

CategoricalPredictors — Categorical predictor indices

`[]`

This property is read-only.

Categorical predictor indices, specified as an empty numeric value. In general, `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. Because `RegressionKernel` models can only be trained on numeric predictor data, this property is empty (`[]`).

PredictorNames — Predictor names

`{'x1', 'x2', ...}`

This property is read-only.

Predictor names in order of their appearance in predictor data (X), specified as a cell array of character vectors of the form `{'x1', 'x2', ...}`. The length of `PredictorNames` is equal to the number of columns in X.

Data Types: `cell`

ResponseName — Response variable name

`'Y'`

This property is read-only.

Response variable name, specified as `'Y'`. Because `RegressionKernel` models cannot be trained using tabular data, this property is always `'Y'`.

Data Types: `char`

ResponseTransform — Response transformation function

`'none'` | function handle

Response transformation function, specified as `'none'` or a function handle. `ResponseTransform` describes how the software transforms raw response values predicted by the model.

For a MATLAB function, or a function that you define, enter its function handle. For example, you can enter `Mdl.ResponseTransform = @function`, where *function* accepts a numeric vector of the

original responses and returns a numeric vector of the same size containing the transformed responses.

Data Types: `char` | `string` | `function_handle`

Object Functions

`kfoldLoss` Regression loss for cross-validated kernel regression model

`kfoldPredict` Predict responses for observations in cross-validated kernel regression model

Examples

Create Cross-Validated Kernel Regression Model

Simulate sample data.

```
rng(0,'twister'); % For reproducibility
n = 1000;
x = linspace(-10,10,n)';
y = 1 + x*2e-2 + sin(x)./x + 0.2*randn(n,1);
```

Cross-validate a kernel regression model.

```
CVMDL = fitrkernel(x,y,'Kfold',5);
```

`CVMDL` is a `RegressionPartitionedKernel` 5-fold cross-validated model. `CVMDL.Trained` contains a cell vector of five `RegressionKernel` models. Display the trained property.

`CVMDL.Trained`

```
ans=5x1 cell array
    {1x1 RegressionKernel}
    {1x1 RegressionKernel}
    {1x1 RegressionKernel}
    {1x1 RegressionKernel}
    {1x1 RegressionKernel}
```

Each cell contains a kernel regression model trained on four folds, then tested on the remaining fold.

Predict responses for observations in the validation folds and estimate the generalization error by passing `CVMDL` to `kfoldPredict` and `kfoldLoss`, respectively.

```
yHat = kfoldPredict(CVMDL);
L = kfoldLoss(CVMDL)
```

```
L = 0.1887
```

`kfoldLoss` computes the average mean squared error for all the folds by default. The estimated mean squared error is 0.1887.

Introduced in R2018b

kfoldLoss

Package: classreg.learning.partition

Regression loss for cross-validated kernel regression model

Syntax

```
L = kfoldLoss(CVMdl)
L = kfoldLoss(CVMdl,Name,Value)
```

Description

`L = kfoldLoss(CVMdl)` returns the regression loss obtained by the cross-validated kernel regression model `CVMdl`. For every fold, `kfoldLoss` computes the regression loss for observations in the validation fold, using a model trained on observations in the training fold.

`L = kfoldLoss(CVMdl,Name,Value)` returns the mean squared error (MSE) with additional options specified by one or more name-value pair arguments. For example, you can specify the regression-loss function or which folds to use for loss calculation.

Examples

Compute Loss for Cross-Validated Kernel Regression Models

Simulate sample data:

```
rng(0,'twister'); % For reproducibility
n = 1000;
x = linspace(-10,10,n)';
y = 1 + x*2e-2 + sin(x)./x + 0.2*randn(n,1);
```

Cross-validate a kernel regression model.

```
CVMdl = fitrkernel(x,y,'Kfold',5);
```

`fitrkernel` implements 5-fold cross-validation. `CVMdl` is a `RegressionPartitionedKernel` model. It contains the property `Trained`, which is a 5-by-1 cell array holding 5 `RegressionKernel` models that the software trained using the training set.

Compute the epsilon-insensitive loss for each fold for observations that `fitrkernel` did not use in training the folds.

```
L = kfoldLoss(CVMdl,'LossFun','epsiloninsensitive','Mode','individual')
```

```
L = 5×1
    0.2812
    0.3223
    0.3073
    0.3117
```

0.2576

Input Arguments

CVMdl — Cross-validated kernel regression model

RegressionPartitionedKernel model object

Cross-validated kernel regression model, specified as a RegressionPartitionedKernel model object. You can create a RegressionPartitionedKernel model using fitrkernel and specifying any of the cross-validation name-value pair arguments, for example, CrossVal.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'LossFun', 'epsiloninsensitive', 'Mode', 'individual' specifies kfoldLoss to return the epsilon-insensitive loss for each fold.

Folds — Fold indices to use for response prediction

1: CVMdl.KFold (default) | numeric vector of positive integers

Fold indices to use for response prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must range from 1 through CVMdl.KFold.

Example: 'Folds', [1 4 10]

Data Types: single | double

LossFun — Loss function

'mse' (default) | 'epsiloninsensitive' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar. Also, in the table, $f(x) = x\beta + b$.
 - β is a vector of p coefficients.
 - x is an observation from p predictor variables.
 - b is the scalar bias.

Value	Description
'epsiloninsensitive'	Epsilon-insensitive loss: $\ell[y, f(x)] = \max[0, y - f(x) - \varepsilon]$
'mse'	MSE: $\ell[y, f(x)] = [y - f(x)]^2$

'epsiloninsensitive' is appropriate for SVM learners only.

- Specify your own function using function handle notation.

Assume that n is the number of observations in X . Your function must have this signature

```
lossvalue = lossfun(Y,Yhat,W)
```

where:

- The output argument `lossvalue` is a scalar.
- You specify the function name (`lossfun`).
- Y is an n -dimensional vector of observed responses. `kfoldLoss` passes the input argument Y in for Y .
- $Yhat$ is an n -dimensional vector of predicted responses, which is similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights.

Data Types: `char` | `string` | `function_handle`

Mode — Loss aggregation level

'average' (default) | 'individual'

Loss aggregation level, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

Value	Description
'average'	Returns losses averaged over all folds
'individual'	Returns losses for each fold

Example: 'Mode','individual'

Output Arguments

L — Cross-validated regression losses

numeric scalar | numeric vector

Cross-validated regression losses, returned as a numeric scalar or vector. The interpretation of L depends on `LossFun`.

- If `Mode` is 'average', then L is a scalar.
- Otherwise, L is a k -by-1 vector, where k is the number of folds. $L(j)$ is the average regression loss over fold j .

To estimate L , `kfoldLoss` uses the data that created `CVMdl`.

`RegressionKernel` | `RegressionPartitionedKernel` | `fitrkernel` | `kfoldPredict`

Introduced in R2018b

kfoldPredict

Package: `classreg.learning.partition`

Predict responses for observations in cross-validated kernel regression model

Syntax

```
YHat = kfoldPredict(CVMdl)
```

Description

`YHat = kfoldPredict(CVMdl)` returns cross-validated predicted responses by the cross-validated kernel regression model `CVMdl`. That is, for every fold, `kfoldPredict` predicts the responses for observations that it holds out in validation fold while it trains using all other observations in the training fold.

Examples

Predict Responses from Cross-Validated Kernel Regression Models

Simulate sample data:

```
rng(0, 'twister'); % For reproducibility
n = 1000;
x = linspace(-10,10,n)';
y = 1 + x*2e-2 + sin(x)./x + 0.2*randn(n,1);
```

Cross-validate a kernel regression model.

```
CVMdl = fitrkernel(x,y,'CrossVal','on');
```

By default, `fitrkernel` implements 10-fold cross-validation. `CVMdl` is a `RegressionPartitionedKernel` model. It contains the property `Trained`, which is a 10-by-1 cell array holding 10 `RegressionKernel` models that the software trained using the training set.

Predict responses for observations that `fitrkernel` did not use in training the folds.

```
yHat = kfoldPredict(CVMdl);
```

`yHat` is a numeric vector. Display the first five predicted responses.

```
yHat(1:5)
```

```
ans = 5×1
```

```
1.0767
1.0744
1.0758
1.0779
1.0798
```

Input Arguments

CVMd1 — Cross-validated kernel regression model

`RegressionPartitionedKernel` model object

Cross-validated kernel regression model, specified as a `RegressionPartitionedKernel` model object. You can create a `RegressionPartitionedKernel` model using `fitrkernel` and specifying any of the one of the cross-validation name-value pair arguments, for example, `CrossVal`.

To obtain estimates, `kfoldPredict` applies the same data used to cross-validate the kernel regression model (see `X` input argument on `fitrkernel` page).

Output Arguments

YHat — Cross-validated predicted responses

numeric vector

Cross-validated predicted responses, returned as an n -by-1 numeric array, where n is the number of observations in the predictor data used to create `CVMd1` (see `X` input argument on `fitrkernel` page).

Sample Data Sets

Sample Data Sets

Statistics and Machine Learning Toolbox software includes the sample data sets in the following table.

To load a data set into the MATLAB workspace, type:

```
load filename
```

where *filename* is one of the files listed in the table.

Data sets contain individual data variables, description variables with references, and dataset arrays encapsulating the data set and its description, as appropriate.

Probability Distributions

Bernoulli Distribution

In this section...

“Overview” on page B-2

“Parameters” on page B-2

“Probability Density Function” on page B-2

“Cumulative Distribution Function” on page B-2

“Descriptive Statistics” on page B-2

“Examples” on page B-3

“Related Distributions” on page B-4

Overview

The Bernoulli distribution is a discrete probability distribution with only two possible values for the random variable. Each instance of an event with a Bernoulli distribution is called a Bernoulli trial.

Parameters

The Bernoulli distribution uses the following parameter.

Parameter	Description	Support
p	Probability of success	$0 \leq p \leq 1$

Probability Density Function

The probability density function (pdf) of the Bernoulli distribution is

$$f(x|p) = \begin{cases} 1 - p, & x = 0 \\ p, & x = 1 \end{cases}.$$

For discrete distributions, the pdf is also known as the probability mass function (pmf).

For an example, see “Compute Bernoulli Distribution pdf” on page B-3.

Cumulative Distribution Function

The cumulative distribution function (cdf) of the Bernoulli distribution is

$$F(x|p) = \begin{cases} 1 - p, & x = 0 \\ 1, & x = 1 \end{cases}.$$

For an example, see “Compute Bernoulli Distribution cdf” on page B-3.

Descriptive Statistics

The mean of the Bernoulli distribution is p .

The variance of the Bernoulli distribution is $p(1 - p)$.

Examples

Compute Bernoulli Distribution pdf

The Bernoulli distribution is a special case of the binomial distribution, where $N = 1$. Use `binopdf` to compute the pdf of the Bernoulli distribution with the probability of success 0.75 .

```
p = 0.75;  
x = 0:1;  
y = binopdf(0:1,1,p);
```

Plot the pdf with bars of width 1.

```
figure  
bar(x,y,1)  
xlabel('Observation')  
ylabel('Probability')
```

Compute Bernoulli Distribution cdf

The Bernoulli distribution is a special case of the binomial distribution, where $N = 1$. Use `binocdf` to compute the cdf of the Bernoulli distribution with the probability of success 0.75 .

```
p = 0.75;  
y = binocdf(-1:2,1,p);
```

Plot the cdf.

```
figure  
stairs(-1:2,y)  
xlabel('Observation')  
ylabel('Cumulative Probability')
```

Related Distributions

- Binomial Distribution on page B-10 — The binomial distribution is a two-parameter discrete distribution that models the total number of successes in repeated Bernoulli trials. The Bernoulli distribution occurs as a binomial distribution with $N = 1$.
- Geometric Distribution on page B-63 — The geometric distribution is a one-parameter discrete distribution that models the total number of failures before the first success in repeated Bernoulli trials.

Beta Distribution

In this section...

- “Overview” on page B-6
- “Parameters” on page B-6
- “Probability Density Function” on page B-6
- “Cumulative Distribution Function” on page B-8
- “Example” on page B-8

Overview

The beta distribution describes a family of curves that are unique in that they are nonzero only on the interval (0 1). A more general version of the function assigns parameters to the endpoints of the interval.

Statistics and Machine Learning Toolbox provides several ways to work with the beta distribution. You can use the following approaches to estimate parameters from sample data, compute the pdf, cdf, and icdf, generate random numbers, and more.

- Fit a probability distribution object to sample data, or create a probability distribution object with specified parameter values. See [Using BetaDistribution Objects](#) for more information.
- Work with data input from matrices, tables, and dataset arrays using probability distribution functions. See “Supported Distributions” on page 5-13 for a list of beta distribution functions.
- Interactively fit, explore, and generate random numbers from the distribution using an app or user interface.

For more information on each of these options, see “Working with Probability Distributions” on page 5-2.

Parameters

The beta distribution uses the following parameters.

Parameter	Description	Support
a	First shape parameter	$a > 0$
b	Second shape parameter	$b > 0$

Probability Density Function

Definition

The probability density function (pdf) of the beta distribution is

$$y = f(x | a, b) = \frac{1}{B(a, b)} x^{a-1} (1-x)^{b-1} I_{[0,1]}(x)$$

where $B(\cdot)$ is the Beta function. The indicator function $I_{(0,1)}(x)$ ensures that only values of x in the range (0,1) have nonzero probability.

Plot

This plot shows how changing the value of the parameters alters the shape of the pdf. The constant pdf (the flat line) shows that the standard uniform distribution is a special case of the beta distribution, which occurs when $a = b = 1$.

```
X = 0:.01:1;
y1 = betapdf(X,0.75,0.75);
y2 = betapdf(X,1,1);
y3 = betapdf(X,4,4);

figure
plot(X,y1,'Color','r','LineWidth',2)
hold on
plot(X,y2,'LineStyle','-','Color','b','LineWidth',2)
plot(X,y3,'LineStyle',':','Color','g','LineWidth',2)
legend({'a = b = 0.75','a = b = 1','a = b = 4'},'Location','NorthEast');
hold off
```

Relationship to Other Distributions

The beta distribution has a functional relationship with the t distribution. If Y is an observation from Student's t distribution with ν degrees of freedom, then the following transformation generates X , which is beta distributed.

$$X = \frac{1}{2} + \frac{1}{2} \frac{Y}{\sqrt{\nu + Y^2}}$$

If $Y \sim t(\nu)$, then $X \sim \beta\left(\frac{\nu}{2}, \frac{\nu}{2}\right)$

This relationship is used to compute values of the t cdf and inverse function as well as generating t distributed random numbers.

Cumulative Distribution Function

The beta cdf is the same as the incomplete beta function.

Example

Suppose you are collecting data that has hard lower and upper bounds of zero and one respectively. Parameter estimation is the process of determining the parameters of the beta distribution that fit this data best in some sense.

One popular criterion of goodness is to maximize the likelihood function. The likelihood has the same form as the beta pdf. But for the pdf, the parameters are known constants and the variable is x . The likelihood function reverses the roles of the variables. Here, the sample values (the x 's) are already observed. So they are the fixed constants. The variables are the unknown parameters. Maximum likelihood estimation (MLE) involves calculating the values of the parameters that give the highest likelihood given the particular set of data.

The function `betafit` returns the MLEs and confidence intervals for the parameters of the beta distribution. Here is an example using random numbers from the beta distribution with $a = 5$ and $b = 0.2$.

```
rng default % For reproducibility
r = betarnd(5,0.2,100,1);
[phat, pci] = betafit(r)

phat = 1x2
    7.4911    0.2135

pci = 2x2
    5.0861    0.1744
   11.0334    0.2614
```

The MLE for parameter a is 7.4911, compared to the true value of 5. The 95% confidence interval for a goes from 5.0861 to 11.0334, which does not include the true value. While this is an unlikely result, it does sometimes happen when estimating distribution parameters.

Similarly the MLE for parameter b is 0.2135, compared to the true value of 0.2. The 95% confidence interval for b goes from 0.1744 to 0.2614, which does include the true value. In this made-up example you know the “true value.” In experimentation you do not.

Binomial Distribution

In this section...
“Overview” on page B-10
“Parameters” on page B-10
“Probability Density Function” on page B-10
“Cumulative Distribution Function” on page B-11
“Descriptive Statistics” on page B-11
“Example” on page B-11
“Related Distributions” on page B-16

Overview

The binomial distribution is a two-parameter family of curves. The binomial distribution is used to model the total number of successes in a fixed number of independent trials that have the same probability of success, such as modeling the probability of a given number of heads in ten flips of a fair coin.

Statistics and Machine Learning Toolbox offers several ways to work with the binomial distribution.

- Create a probability distribution object `BinomialDistribution` by fitting a probability distribution to sample data (`fitdist`) or by specifying parameter values (`makedist`). Then, use object functions to evaluate the distribution, generate random numbers, and so on.
- Work with the binomial distribution interactively by using the **Distribution Fitter** app. You can export an object from the app and use the object functions.
- Use distribution-specific functions (`binocdf`, `binopdf`, `binoinv`, `binostat`, `binofit`, `binornd`) with specified distribution parameters. The distribution-specific functions can accept parameters of multiple binomial distributions.
- Use generic distribution functions (`cdf`, `icdf`, `pdf`, `random`) with a specified distribution name ('`Binomial`') and parameters.

Parameters

The binomial distribution uses the following parameters.

Parameter	Description	Support
N	Number of trials	Positive integer
p	Probability of success in a single trial	$0 \leq p \leq 1$

The sum of two binomial random variables that both have the same parameter p is also a binomial random variable with N equal to the sum of the number of trials.

Probability Density Function

The probability density function (pdf) of the binomial distribution is

$$f(x|N, p) = \binom{N}{x} p^x (1-p)^{N-x} \quad ; \quad x = 0, 1, 2, \dots, N,$$

where x is the number of successes in N trials of a Bernoulli process with the probability of success p . The result is the probability of exactly x successes in N trials. For discrete distributions, the pdf is also known as the probability mass function (pmf).

For an example, see “Compute Binomial Distribution pdf” on page B-12.

Cumulative Distribution Function

The cumulative distribution function (cdf) of the binomial distribution is

$$F(x|N, p) = \sum_{i=0}^x \binom{N}{i} p^i (1-p)^{N-i} \quad ; \quad x = 0, 1, 2, \dots, N,$$

where x is the number of successes in N trials of a Bernoulli process with the probability of success p . The result is the probability of at most x successes in N trials.

For an example, see “Compute Binomial Distribution cdf” on page B-13.

Descriptive Statistics

The mean of the binomial distribution is Np .

The variance of the binomial distribution is $Np(1-p)$.

Example

Fit Binomial Distribution to Data

Generate a binomial random number that counts the number of successes in 100 trials with the probability of success 0.9 in each trial.

```
x = binornd(100,0.9)
```

```
x = 85
```

Fit a binomial distribution to data using `fitdist`.

```
pd = fitdist(x, 'Binomial', 'NTrials', 100)
```

```
pd =
```

```
BinomialDistribution
```

```
Binomial distribution
```

```
N = 100
```

```
p = 0.85 [0.764692, 0.913546]
```

`fitdist` returns a `BinomialDistribution` object. The interval next to `p` is the 95% confidence interval estimating `p`.

Estimate the parameter `p` using the distribution functions.

```
[phat,pci] = binofit(x,100) % Distribution-specific function
```

```
phat = 0.8500
```

```
pci = 1×2
```

```
    0.7647    0.9135
```

```
[phat2,pci2] = mle(x,'distribution','Binomial','NTrials',100) % Generic distribution function
```

```
phat2 = 0.8500
```

```
pci2 = 2×1
```

```
    0.7647
```

```
    0.9135
```

Compute Binomial Distribution pdf

Compute the pdf of the binomial distribution with 10 trials and the probability of success 0.5.

```
x = 0:10;
```

```
y = binopdf(x,10,0.5);
```

Plot the pdf with bars of width 1.

```
figure
```

```
bar(x,y,1)
```

```
xlabel('Observation')
```

```
ylabel('Probability')
```

Compute Binomial Distribution cdf

Compute the cdf of the binomial distribution with 10 trials and the probability of success 0.5.

```
x = 0:10;  
y = binocdf(x,10,0.5);
```

Plot the cdf.

```
figure  
stairs(x,y)  
xlabel('Observation')  
ylabel('Cumulative Probability')
```

Compare Binomial and Normal Distribution pdfs

When N is large, the binomial distribution with parameters N and p can be approximated by the normal distribution with mean $N \cdot p$ and variance $N \cdot p \cdot (1 - p)$ provided that p is not too large or too small.

Compute the pdf of the binomial distribution counting the number of successes in 50 trials with the probability 0.6 in a single trial .

```
N = 50;  
p = 0.6;  
x1 = 0:N;  
y1 = binopdf(x1,N,p);
```

Compute the pdf of the corresponding normal distribution.

```
mu = N*p;  
sigma = sqrt(N*p*(1-p));  
x2 = 0:0.1:N;  
y2 = normpdf(x2,mu,sigma);
```

Plot the pdfs on the same axis.

```
figure  
bar(x1,y1,1)  
hold on  
plot(x2,y2,'LineWidth',2)
```

```

xlabel('Observation')
ylabel('Probability')
title('Binomial and Normal pdfs')
legend('Binomial Distribution','Normal Distribution','location','northwest')
hold off

```

The pdf of the normal distribution closely approximates the pdf of the binomial distribution.

Compare Binomial and Poisson Distribution pdfs

When p is small, the binomial distribution with parameters N and p can be approximated by the Poisson distribution with mean $N \cdot p$, provided that $N \cdot p$ is also small.

Compute the pdf of the binomial distribution counting the number of successes in 20 trials with the probability of success 0.05 in a single trial.

```

N = 20;
p = 0.05;
x = 0:N;
y1 = binopdf(x,N,p);

```

Compute the pdf of the corresponding Poisson distribution.

```

mu = N*p;
y2 = poisspdf(x,mu);

```

Plot the pdfs on the same axis.

```
figure
bar(x,[y1; y2])
xlabel('Observation')
ylabel('Probability')
title('Binomial and Poisson pdfs')
legend('Binomial Distribution','Poisson Distribution','location','northeast')
```

The pdf of the Poisson distribution closely approximates the pdf of the binomial distribution.

Birnbaum-Saunders Distribution

In this section...
“Definition” on page B-18
“Background” on page B-18
“Parameters” on page B-18

Definition

The Birnbaum-Saunders distribution has the density function

$$\frac{1}{\sqrt{2\pi}} \exp\left\{-\frac{(\sqrt{x/\beta} - \sqrt{\beta/x})^2}{2\gamma^2}\right\} \left(\frac{\sqrt{x/\beta} + \sqrt{\beta/x}}{2\gamma x}\right)$$

with scale parameter $\beta > 0$ and shape parameter $\gamma > 0$, for $x > 0$.

If x has a Birnbaum-Saunders distribution with parameters β and γ , then

$$\frac{(\sqrt{x/\beta} - \sqrt{\beta/x})}{\gamma}$$

has a standard normal distribution.

Background

The Birnbaum-Saunders distribution was originally proposed as a lifetime model for materials subject to cyclic patterns of stress and strain, where the ultimate failure of the material comes from the growth of a prominent flaw. In materials science, Miner's Rule suggests that the damage occurring after n cycles, at a stress level with an expected lifetime of N cycles, is proportional to n / N . Whenever Miner's Rule applies, the Birnbaum-Saunders model is a reasonable choice for a lifetime distribution model.

Parameters

To estimate distribution parameters, use `mle` or the Distribution Fitter app.

Burr Type XII Distribution

In this section...

“Definition” on page B-19

“Background” on page B-19

“Parameters” on page B-20

“Fit a Burr Distribution and Draw the cdf” on page B-21

“Compare Lognormal and Burr Distribution pdfs” on page B-22

“Burr pdf for Various Parameters” on page B-23

“Survival and Hazard Functions of Burr Distribution” on page B-25

“Divergence of Parameter Estimates” on page B-26

Definition

The Burr type XII distribution is a three-parameter family of distributions on the positive real line. The cumulative distribution function (cdf) of the Burr distribution is

$$F(x) \left| \alpha, c, k \right. = 1 - \frac{1}{\left(1 + \left(\frac{x}{\alpha}\right)^c\right)^k}, \quad x > 0, \alpha > 0, c > 0, k > 0,$$

where c and k are the shape parameters and α is the scale parameter. The probability density function (pdf) is

$$f(x) \left| \alpha, c, k \right. = \frac{\frac{kc}{\alpha} \left(\frac{x}{\alpha}\right)^{c-1}}{\left(1 + \left(\frac{x}{\alpha}\right)^c\right)^{k+1}}, \quad x > 0, \alpha > 0, c > 0, k > 0.$$

The density of the Burr type XII distribution is L-shaped if $c \leq 1$ and unimodal, otherwise.

Background

Burr distribution was first discussed by Burr (1942) as a two-parameter family. An additional scale parameter was introduced by Tadikamalla (1980). It is a flexible distribution family that can express a wide range of distribution shapes. The Burr distribution includes, overlaps, or has as a limiting case, many commonly used distributions such as gamma, lognormal, loglogistic, bell-shaped, and J-shaped beta distributions (but not U-shaped). Some compound distributions also correspond to the Burr distribution. For example, compounding a Weibull distribution with a gamma distribution for its scale parameter results in a Burr distribution. Similarly, compounding an exponential distribution with a gamma distribution for its rate parameter, $1/\mu$, also yields a Burr distribution. The Burr distribution also has two asymptotic limiting cases: Weibull and Pareto Type I.

The Burr distribution can fit a wide range of empirical data. Different values of its parameters cover a broad set of skewness and kurtosis. Hence, it is used in various fields such as finance, hydrology, and reliability to model a variety of data types. Examples of data modeled by the Burr distribution are household income, crop prices, insurance risk, travel time, flood levels, and failure data.

The survival and hazard functions of Burr type XII distribution are, respectively,

$$S(x|\alpha, c, k) = \frac{1}{\left[1 + \left(\frac{x}{\alpha}\right)^c\right]^k}$$

and

$$h(x|\alpha, c, k) = \frac{\frac{kc}{\alpha} \left(\frac{x}{\alpha}\right)^{c-1}}{1 + \left(\frac{x}{\alpha}\right)^c}.$$

If $c > 1$, the hazard function $h(x)$ is non-monotonic with a mode at $x = \alpha(c - 1)^{1/c}$.

Parameters

The three-parameter Burr distribution is defined by its scale parameter α and shape parameters c and k . You can estimate the parameters using `mle` or `fitdist`. Both functions support censored data for Burr distribution.

Generate sample data from a Burr distribution with scale parameter 0.5 and shape parameters 2 and 5.

```
rng('default')
R = random('burr', 0.5, 2, 5, 1000, 1);
```

Estimate the parameters and the confidence intervals.

```
[phat, pci] = mle(R, 'distribution', 'burr')
```

```
phat =
```

```
    0.4154    2.1217    4.0550
```

```
pci =
```

```
    0.2985    1.9560    2.4079
    0.5782    2.3014    6.8288
```

The default 95% confidence intervals for the parameters include the true parameter values.

The three-parameter Burr distribution converges asymptotically to one of the two limiting forms as its parameters diverge:

- If $k \rightarrow 0$, $c \rightarrow \infty$, $ck = \lambda$, then the Burr distribution reduces to a two-parameter Pareto distribution with the cdf

$$F_P = 1 - \left(\frac{x}{\alpha}\right)^{-\lambda}, \quad x \geq \alpha.$$

- If $k \rightarrow \infty$, $\alpha \rightarrow \infty$, $\alpha/k^{1/c} = \theta$, then the Burr distribution reduces to a two-parameter Weibull distribution with the cdf

$$F_W(x|c, \theta) = 1 - \exp\left[-\left(\frac{x}{\theta}\right)^c\right].$$

If `mle` or `fitdist` detects such divergence, it returns an error message, but informs you of the limiting distribution and corresponding parameter estimates for that distribution.

Fit a Burr Distribution and Draw the cdf

This example shows how to fit a Burr distribution to data, draw the cdf, and construct a histogram with a Burr distribution fit.

1. Load the sample data.

```
load arrhythmia
```

The fifth column in `X` contains a measurement obtained from electrocardiograms, called QRS duration.

2. Fit a Burr distribution to the QRS duration data, and get the parameter estimates.

```
PD = fitdist(X(:,5), 'burr');
```

`PD` has the maximum likelihood estimates of the Burr distribution parameters in the property `Param`. The estimates are $\alpha = 80.4515$, $c = 18.9251$, $k = 0.4492$.

3. Plot the cdf of the QRS duration data.

```
QRScdf=cdf('burr',sortrows(X(:,5)),80.4515,18.9251,0.4492);
plot(sortrows(X(:,5)),QRScdf)
title('QRS duration data')
xlabel('QRS Duration')
```

4. Draw the histogram of QRS duration data with 15 bins and the pdf of the Burr distribution fit.

```
histfit(X(:,5),15,'burr')  
title('Histogram of QRS data with a Burr distribution fit')  
xlabel('QRS Duration')
```

Compare Lognormal and Burr Distribution pdfs

Compare the lognormal pdf to the Burr pdf using income data generated from a lognormal distribution.

Generate the income data.

```
rng('default') % For reproducibility  
y = random('Lognormal',log(25000),0.65,[500,1]);
```

Fit a Burr distribution.

```
pd = fitdist(y,'burr')
```

```
pd =  
BurrDistribution  
  
Burr distribution  
alpha = 26007.2 [21165.5, 31956.4]  
c = 2.63743 [2.3053, 3.0174]
```

```
k = 1.09658 [0.775479, 1.55064]
```

Plot both the Burr and lognormal pdfs of income data on the same figure.

```
p_burr = pdf(pd,sortrows(y));
p_lognormal = pdf('Lognormal',sortrows(y),log(25000),0.65);
plot(sortrows(y),p_burr,'-',sortrows(y),p_lognormal,'-.-')
title('Burr and Lognormal pdfs Fit to Income Data')
legend('Burr Distribution','Lognormal Distribution')
```

Burr pdf for Various Parameters

This example shows how to create a variety of shapes for probability density functions of the Burr distribution.

```
X = 0:0.01:5;
c = [0.5 0.95 2 5];
k = [0.5 0.75 2 5];
alpha = [0.5 1 2 5];
colors = ['b'; 'g'; 'r'; 'k'];

figure
for i = 1:1:4
pdf1(i,:) = pdf('burr',X,1,c(i),0.5);
pdf2(i,:) = pdf('burr',X,1,2,k(i));
```

```

pdf3(i,:) = pdf('burr',X,alpha(i),2,0.5);

axC = subplot(3,1,1);
pC(i) = plot(X,pdf1(i,:),colors(i),'LineWidth',2);
title('Effect of c, \alpha = 1, k = 0.5'),xlabel('x')
hold on

axK = subplot(3,1,2);
pK(i) = plot(X,pdf2(i,:),colors(i),'LineWidth',2);
title('Effect of k, \alpha = 1, c = 2'),xlabel('x')
hold on

axAlpha = subplot(3,1,3);
pAlpha(i) = plot(X,pdf3(i,:),colors(i),'LineWidth',2);
title('Effect of \alpha, c = 2, k = 0.5'),xlabel('x')
hold on
end

set(axC,'XLim',[0 3],'YLim',[0 1.2]);
set(axK,'XLim',[0 3],'YLim',[0 2.1]);
set(axAlpha,'XLim',[0 5],'YLim',[0 1]);

legend(axC,'c=0.5','c=0.95','c=2','c=5');
legend(axK,'k=0.5','k=0.75','k=2','k=5');
legend(axAlpha,'\alpha=0.5','\alpha=1','\alpha=2','\alpha=5');

```

This figure illustrates how the shape and scale of the Burr distribution changes for different values of its parameters.

Survival and Hazard Functions of Burr Distribution

This example shows how to find and plot the survival and hazard functions for a sample coming from a Burr distribution.

Generate the data.

```
X = 0:0.015:2.5;
```

Evaluate the pdf and cdf of data in X.

```
Xpdf = pdf('burr',X,0.2,5,0.5);  
Xcdf = cdf('burr',X,0.2,5,0.5);
```

Evaluate and plot the survival function of data in X.

```
S = 1.-Xcdf; % survival function  
plot(X,S,'LineWidth',2)  
title('Survival function')  
xlabel('x')
```

Evaluate and plot the hazard function of data in X.

```
H = Xpdf./S; % hazard function
plot(X,H,'r','LineWidth',2)
title('Hazard function')
xlabel('x')
```

Divergence of Parameter Estimates

This example shows how to interpret the display when the parameter estimates diverge when fitting a Burr distribution to input data.

1. Generate sample data from the Weibull distribution with parameters 0.5 and 2.

```
rng('default') % for reproducibility
X = wblrnd(0.5,2,100,1);
```

2. Fit a Burr distribution.

```
PD = fitdist(X,'burr');
```

```
Error using addburr>burrfit (line 566)
The data are not fit by a Burr distribution with finite parameters.
The maximum likelihood fit is provided by the k->Inf, alpha->Inf
limiting form of the Burr distribution: a Weibull distribution
with the parameters below.
```

```
    a (scale): 0.476817
    b (shape): 1.96219
```

```
Error in prob.BurrDistribution.fit (line 246)
      p = burrfit(x,0.05,cens,freq,opt);

Error in fitdist>localfit (line 238)
pd = feval(fitter,x,'cens',c,'freq',f,varargin{:});

Error in fitdist (line 185)
      pd = localfit(dist,fitter,x,cens,freq,args{:});
```

The error message tells you that the Weibull family seems to fit the data better and gives you the parameter estimates from a Weibull fit. You can use those estimates directly. If you need covariance estimates for the parameters or other information about the fit, you can refit a Weibull distribution to the data.

3. Fit a Weibull distribution to the data and find the confidence intervals for the parameter estimates.

```
PD = fitdist(X,'weibull');
paramci(PD)

ans =

      0.4291      1.6821
      0.5298      2.2890
```

These are the 95% confidence intervals of the parameter estimates for the Weibull distribution fit.

Chi-Square Distribution

In this section...
“Overview” on page B-28
“Parameters” on page B-28
“Probability Density Function” on page B-28
“Cumulative Distribution Function” on page B-29
“Inverse Cumulative Distribution Function” on page B-29
“Descriptive Statistics” on page B-29
“Examples” on page B-29
“Related Distributions” on page B-31

Overview

The chi-square (χ^2) distribution is a one-parameter family of curves. The chi-square distribution is commonly used in hypothesis testing, particularly the chi-square test for goodness of fit.

Statistics and Machine Learning Toolbox offers multiple ways to work with the chi-square distribution.

- Use distribution-specific functions (`chi2cdf`, `chi2inv`, `chi2pdf`, `chi2rnd`, `chi2stat`) with specified distribution parameters. The distribution-specific functions can accept parameters of multiple chi-square distributions.
- Use generic distribution functions (`cdf`, `icdf`, `pdf`, `random`) with a specified distribution name ('`Chisquare`') and parameters.

Parameters

The chi-square distribution uses the following parameter.

Parameter	Description	Support
<code>nu</code> (ν)	Degrees of freedom	$\nu = 1, 2, 3, \dots$

The degrees of freedom parameter is typically an integer, but chi-square functions accept any positive value.

The sum of two chi-square random variables with degrees of freedom ν_1 and ν_2 is a chi-square random variable with degrees of freedom $\nu = \nu_1 + \nu_2$.

Probability Density Function

The probability density function (pdf) of the chi-square distribution is

$$y = f(x|\nu) = \frac{x^{(\nu-2)/2} e^{-x/2}}{2^{\nu/2} \Gamma(\nu/2)},$$

where ν is the degrees of freedom and $\Gamma(\cdot)$ is the Gamma function.

For an example, see “Compute Chi-Square Distribution pdf” on page B-29.

Cumulative Distribution Function

The cumulative distribution function (cdf) of the chi-square distribution is

$$p = F(x | \nu) = \int_0^x \frac{t^{(\nu-2)/2} e^{-t/2}}{2^{\nu/2} \Gamma(\nu/2)} dt,$$

where ν is the degrees of freedom and $\Gamma(\cdot)$ is the Gamma function. The result p is the probability that a single observation from the chi-square distribution with ν degrees of freedom falls in the interval $[0, x]$.

For an example, see “Compute Chi-Square Distribution cdf” on page B-30.

Inverse Cumulative Distribution Function

The inverse cumulative distribution function (icdf) of the chi-square distribution is

$$x = F^{-1}(p | \nu) = \{x: F(x | \nu) = p\},$$

where

$$p = F(x | \nu) = \int_0^x \frac{t^{(\nu-2)/2} e^{-t/2}}{2^{\nu/2} \Gamma(\nu/2)} dt,$$

ν is the degrees of freedom, and $\Gamma(\cdot)$ is the Gamma function. The result p is the probability that a single observation from the chi-square distribution with ν degrees of freedom falls in the interval $[0, x]$.

Descriptive Statistics

The mean of the chi-square distribution is ν .

The variance of the chi-square distribution is 2ν .

Examples

Compute Chi-Square Distribution pdf

Compute the pdf of a chi-square distribution with 4 degrees of freedom.

```
x = 0:0.2:15;
y = chi2pdf(x,4);
```

Plot the pdf.

```
figure;
plot(x,y)
xlabel('Observation')
ylabel('Probability Density')
```

The chi-square distribution is skewed to the right, especially for few degrees of freedom.

Compute Chi-Square Distribution cdf

Compute the cdf of a chi-square distribution with 4 degrees of freedom.

```
x = 0:0.2:15;  
y = chi2cdf(x,4);
```

Plot the cdf.

```
figure;  
plot(x,y)  
xlabel('Observation')  
ylabel('Cumulative Probability')
```

Related Distributions

- “F Distribution” on page B-45 — The F distribution is a two-parameter distribution that has parameters ν_1 (numerator degrees of freedom) and ν_2 (denominator degrees of freedom). The F distribution can be defined as the ratio $F = \frac{x_1^2/\nu_1}{x_2^2/\nu_2}$, where χ^2_1 and χ^2_2 are both chi-square distributed with ν_1 and ν_2 degrees of freedom, respectively.
- “Gamma Distribution” on page B-47 — The gamma distribution is a two-parameter continuous distribution that has parameters a (shape) and b (scale). The chi-square distribution is equal to the gamma distribution with $2a = \nu$ and $b = 2$.
- “Noncentral Chi-Square Distribution” on page B-113 — The noncentral chi-square distribution is a two-parameter continuous distribution that has parameters ν (degrees of freedom) and δ (noncentrality). The noncentral chi-square distribution is equal to the chi-square distribution when $\delta = 0$.
- “Normal Distribution” on page B-119 — The normal distribution is a two-parameter continuous distribution that has parameters μ (mean) and σ (standard deviation). The standard normal distribution occurs when $\mu = 0$ and $\sigma = 1$.

If Z_1, Z_2, \dots, Z_n are standard normal random variables, then $\sum_{i=1}^n Z_i^2$ has a chi-square distribution with degrees of freedom $\nu = n - 1$.

If a set of n observations is normally distributed with variance σ^2 and sample variance s^2 , then $\frac{(n-1)s^2}{\sigma^2}$ has a chi-square distribution with degrees of freedom $\nu = n - 1$. This relationship is used to calculate confidence intervals for the estimate of the normal parameter σ^2 in the function `normfit`.

- “Student's t Distribution” on page B-149 — The Student's t distribution is a one-parameter continuous distribution that has parameter ν (degrees of freedom). If Z has a standard normal distribution and χ^2 has a chi-square distribution with degrees of freedom ν , then $t = \frac{Z}{\sqrt{\chi^2/\nu}}$ has a Student's t distribution with degrees of freedom ν .
- “Wishart Distribution” on page B-178 — The Wishart distribution is a higher dimensional analog of the chi-square distribution.

 "Cumulative Distribution Function" on page B-34
 "Inverse Cumulative Distribution Function" on page B-34
 "Hazard Function" on page B-34
 "Examples" on page B-35
 "Related Distributions" on page B-38

Overview

The exponential distribution is a one-parameter family of curves. The exponential distribution models wait times when the probability of waiting an additional period of time is independent of how long you have already waited. For example, the probability that a light bulb will burn out in its next minute of use is relatively independent of how many minutes it has already burned.

Statistics and Machine Learning Toolbox offers several ways to work with the exponential distribution.

- Create a probability distribution object `ExponentialDistribution` by fitting a probability distribution to sample data (`fitdist`) or by specifying parameter values (`makedist`). Then, use object functions to evaluate the distribution, generate random numbers, and so on.
- Work with the exponential distribution interactively by using the **Distribution Fitter** app. You can export an object from the app and use the object functions.
- Use distribution-specific functions (`expcdf`, `exppdf`, `expinv`, `explike`, `expstat`, `expfit`, `exprnd`) with specified distribution parameters. The distribution-specific functions can accept parameters of multiple exponential distributions.
- Use generic distribution functions (`cdf`, `icdf`, `pdf`, `random`) with a specified distribution name (`'Exponential'`) and parameters.

Parameters

The exponential distribution uses the following parameter.

Parameter	Description	Support
μ (μ)	Mean	$\mu > 0$

The parameter μ is also equal to the standard deviation of the exponential distribution.

The standard exponential distribution has $\mu=1$.

A common alternative parameterization of the exponential distribution is to use λ defined as the mean number of events in an interval as opposed to μ , which is the mean wait time for an event to occur. λ and μ are reciprocals.

Parameter Estimation

The *likelihood function* is the probability density function (pdf) viewed as a function of the parameters. The *maximum likelihood estimates* (MLEs) are the parameter estimates that maximize the likelihood function for fixed values of \mathbf{x} .

The maximum likelihood estimator of μ for the exponential distribution is $\bar{x} = \sum_{i=1}^n \frac{x_i}{n}$, where \bar{x} is the sample mean for samples x_1, x_2, \dots, x_n . The sample mean is an unbiased estimator of the parameter μ .

To fit the exponential distribution to data and find a parameter estimate, use `expfit`, `fitdist`, or `mle`. Unlike `expfit` and `mle`, which return parameter estimates, `fitdist` returns the fitted probability distribution object `ExponentialDistribution`. The object property `mu` stores the parameter estimate.

For an example, see “Fit Exponential Distribution to Data” on page B-35.

Probability Density Function

The pdf of the exponential distribution is

$$y = f(x|\mu) = \frac{1}{\mu} e^{-\frac{x}{\mu}}.$$

For an example, see “Compute Exponential Distribution pdf” on page B-35.

Cumulative Distribution Function

The cumulative distribution function (cdf) of the exponential distribution is

$$p = F(x|u) = \int_0^x \frac{1}{\mu} e^{-\frac{t}{\mu}} dt = 1 - e^{-\frac{x}{\mu}}.$$

The result p is the probability that a single observation from the exponential distribution with mean μ falls in the interval $[0, x]$.

For an example, see “Compute Exponential Distribution cdf” on page B-36.

Inverse Cumulative Distribution Function

The inverse cumulative distribution function (icdf) of the exponential distribution is

$$x = F^{-1}(p|\mu) = -\mu \ln(1 - p).$$

The result x is the value such that an observation from an exponential distribution with parameter μ falls in the range $[0, x]$ with probability p .

Hazard Function

The hazard function (instantaneous failure rate) is the ratio of the pdf and the complement of the cdf. If $f(t)$ and $F(t)$ are the pdf and cdf of a distribution (respectively), then the hazard rate is

$h(t) = \frac{f(t)}{1 - F(t)}$. Substituting the pdf and cdf of the exponential distribution for $f(t)$ and $F(t)$ yields a constant λ . The exponential distribution is the only continuous distribution with a constant hazard function. λ is the reciprocal of μ and can be interpreted as the rate at which events occur in any given interval. Consequently, when you model survival times, the probability that an item will survive an extra unit of time is independent of the current age of the item.

For an example, see “Exponentially Distributed Lifetimes” on page B-37.

Examples

Fit Exponential Distribution to Data

Generate a sample of 100 of exponentially distributed random numbers with mean 700.

```
x = exprnd(700,100,1); % Generate sample
```

Fit an exponential distribution to data using `fitdist`.

```
pd = fitdist(x,'exponential')
pd =
    ExponentialDistribution

    Exponential distribution
    mu = 641.934    [532.598, 788.966]
```

`fitdist` returns an `ExponentialDistribution` object. The interval next to the parameter estimate is the 95% confidence interval for the distribution parameter.

Estimate the parameter using the distribution functions.

```
[muhat,muci] = expfit(x) % Distribution specific function
muhat = 641.9342
muci = 2x1

    532.5976
    788.9660
```

```
[muhat2,muci2] = mle(x,'distribution','exponential') % Generic distribution function
muhat2 = 641.9342
muci2 = 2x1

    532.5976
    788.9660
```

Compute Exponential Distribution pdf

Compute the pdf of an exponential distribution with parameter $\mu = 2$.

```
x = 0:0.1:10;  
y = exppdf(x,2);
```

Plot the pdf.

```
figure;  
plot(x,y)  
xlabel('Observation')  
ylabel('Probability Density')
```

Compute Exponential Distribution cdf

Compute the cdf of an exponential distribution with parameter $\mu = 2$.

```
x = 0:0.1:10;  
y = expcdf(x,2);
```

Plot the cdf.

```
figure;  
plot(x,y)  
xlabel('Observation')  
ylabel('Cumulative Probability')
```

Exponentially Distributed Lifetimes

Compute the hazard function of the exponential distribution with mean $\mu = 2$ at the values one through five.

```
x = 1:5;
lambda1 = exppdf(x,2)./(1-expcdf(x,2))

lambda1 = 1x5
    0.5000    0.5000    0.5000    0.5000    0.5000
```

The hazard function (instantaneous rate of failure to survival) of the exponential distribution is constant and always equals $1/\mu$. This constant is often denoted by λ .

Evaluate the hazard functions of the exponential distributions with means one through five at $x = 3$.

```
mu = 1:5;
lambda2 = exppdf(3,mu)./(1-expcdf(3,mu))

lambda2 = 1x5
    1.0000    0.5000    0.3333    0.2500    0.2000
```

The probability that an item with an exponentially distributed lifetime survive one more unit of time is independent of how long it has survived.

Compute the probability of an item surviving one more year at various ages when the mean survival time is 10 years.

```
x2 = 5:5:25;
x3 = x2 + 1;
deltap = (expcdf(x3,10) - expcdf(x2,10)) ./ (1 - expcdf(x2,10))
```

```
deltap = 1x5
```

```
    0.0952    0.0952    0.0952    0.0952    0.0952
```

The probability of surviving one more year is the same regardless of how long an item has already survived.

Related Distributions

- “Burr Type XII Distribution” on page B-19 — The Burr distribution is a three-parameter continuous distribution. An exponential distribution compounded with a gamma distribution on the mean yields a Burr distribution.
- “Gamma Distribution” on page B-47 — The gamma distribution is a two-parameter continuous distribution that has parameters a (shape) and b (scale). When $a = 1$, the gamma distribution is equal to the exponential distribution with mean $\mu = b$. The sum of k exponentially distributed random variables with mean μ has a gamma distribution with parameters $a = k$ and $\mu = b$.
- “Geometric Distribution” on page B-63 — The geometric distribution is a one-parameter discrete distribution that models the total number of failures before the first success in repeated Bernoulli trials. The geometric distribution is a discrete analog of the exponential distribution and is the only discrete distribution with a constant hazard function.
- “Generalized Pareto Distribution” on page B-59 — The generalized Pareto distribution is a three-parameter continuous distribution that has parameters k (shape), σ (scale), and θ (threshold). When both $k = 0$ and $\theta = 0$, the generalized Pareto distribution is equal to the exponential distribution with mean $\mu = \sigma$.
- “Poisson Distribution” on page B-131 — The Poisson distribution is a one-parameter discrete distribution that takes nonnegative integer values. The parameter λ is both the mean and the variance of the distribution. The Poisson distribution models counts of the number of times a random event occurs in a given amount of time. In such a model, the amount of time between occurrences is modeled by the exponential distribution with mean $\frac{1}{\lambda}$.
- “Weibull Distribution” on page B-170 — The Weibull distribution is a two-parameter continuous distribution that has parameters a (scale) and b (shape). The Weibull distribution is also used to model lifetimes, but it does not have a constant hazard rate. When $b = 1$, the Weibull distribution is equal to the exponential distribution with mean $\mu = a$.

For an example, see “Compare Exponential and Weibull Distribution Hazard Functions” on page B-174.

Extreme Value Distribution

In this section...

“Definition” on page B-40

“Background” on page B-40

“Parameters” on page B-42

“Examples” on page B-43

Definition

The probability density function for the extreme value distribution with location parameter μ and scale parameter σ is

$$y = f(x|\mu, \sigma) = \sigma^{-1} \exp\left(\frac{x - \mu}{\sigma}\right) \exp\left(-\exp\left(\frac{x - \mu}{\sigma}\right)\right)$$

This form of the probability density function is suitable for modeling the minimum value. To model the maximum value, use the negative of the original values.

If T has a Weibull distribution on page B-170 with parameters a and b , then $\log T$ has an extreme value distribution with parameters $\mu = \log a$ and $\sigma = 1/b$.

Background

Extreme value distributions are often used to model the smallest or largest value among a large set of independent, identically distributed random values representing measurements or observations. The extreme value distribution is appropriate for modeling the smallest value from a distribution whose tails decay exponentially fast, such as, the normal distribution. It can also model the largest value from a distribution, such as the normal or exponential distributions, by using the negative of the original values.

For example, the following fits an extreme value distribution to minimum values taken over 1000 sets of 500 observations from a normal distribution.

```
rng default; % For reproducibility
xMinima = min(randn(1000,500), [], 2);
paramEstsMinima = evfit(xMinima);
y = linspace(-5, -1.5, 1001);
histogram(xMinima, -4.75:.25:-1.75);
p = evpdf(y, paramEstsMinima(1), paramEstsMinima(2));
line(y, .25*length(xMinima)*p, 'color', 'r')
```

The following fits an extreme value distribution to the maximum values in each set of observations.

```
rng default; % For reproducibility
xMaxima = max(randn(1000,500), [], 2);
paramEstsMaxima = evfit(-xMaxima);
y = linspace(1.5,5,1001);
histogram(xMaxima,1.75:.25:4.75);
p = evpdf(-y,paramEstsMaxima(1),paramEstsMaxima(2));
line(y,.25*length(xMaxima)*p,'color','r')
```

Although the extreme value distribution is most often used as a model for extreme values, you can also use it as a model for other types of continuous data. For example, extreme value distributions are closely related to the Weibull distribution. If T has a Weibull distribution, then $\log(T)$ has a type 1 extreme value distribution.

Parameters

The function `evfit` returns the maximum likelihood estimates (MLEs) and confidence intervals for the parameters of the extreme value distribution. The following example shows how to fit some sample data using `evfit`, including estimates of the mean and variance from the fitted distribution.

Suppose you want to model the size of the smallest washer in each batch of 1000 from a manufacturing process. If you believe that the sizes are independent within and between each batch, you can fit an extreme value distribution to measurements of the minimum diameter from a series of eight experimental batches. The following code returns the MLEs of the distribution parameters as `parmhat` and the confidence intervals as the columns of `parmci`.

```
x = [19.774 20.141 19.44 20.511 21.377 19.003 19.66 18.83];
[parmhat, parmci] = evfit(x)

parmhat =
    20.2506    0.8223

parmci =
    19.644 0.49861
    20.857 1.3562
```

You can find mean and variance of the extreme value distribution with these parameters using the function `evstat`.

```
[meanfit, varfit] = evstat(parmhat(1),parmhat(2))
```

```
meanfit =  
    19.776
```

```
varfit =  
    1.1123
```

Examples

Compute the Extreme Value Distribution pdf

Compute the pdf of an extreme value distribution.

```
t = [-5:.01:2];  
y = evpdf(t);
```

Plot the pdf.

```
figure;  
plot(t,y)
```

The extreme value distribution is skewed to the left, and its general shape remains the same for all parameter values. The location parameter, μ , shifts the distribution along the real line, and the scale parameter, σ , expands or contracts the distribution.

The following plots the probability function for different combinations of μ and σ .

```
x = -15:.01:5;
plot(x,evpdf(x,2,1),'-', ...
     x,evpdf(x,0,2),':', ...
     x,evpdf(x,-2,4),'-.');
legend({'mu = 2, sigma = 1', ...
       'mu = 0, sigma = 2', ...
       'mu = -2, sigma = 4'}, ...
       'Location', 'NW')
xlabel('x')
ylabel('f(x|mu,sigma)')
```

F Distribution

In this section...

“Definition” on page B-45

“Background” on page B-45

“Examples” on page B-45

Definition

The pdf for the F distribution is

$$y = f(x | \nu_1, \nu_2) = \frac{\Gamma\left(\frac{\nu_1 + \nu_2}{2}\right)}{\Gamma\left(\frac{\nu_1}{2}\right)\Gamma\left(\frac{\nu_2}{2}\right)} \left(\frac{\nu_1}{\nu_2}\right)^{\frac{\nu_1}{2}} \frac{x^{\frac{\nu_1 - 2}{2}}}{\left[1 + \left(\frac{\nu_1}{\nu_2}\right)x\right]^{\frac{\nu_1 + \nu_2}{2}}}$$

where $\Gamma(\cdot)$ is the Gamma function.

Background

The F distribution has a natural relationship with the chi-square distribution. If χ_1 and χ_2 are both chi-square with ν_1 and ν_2 degrees of freedom respectively, then the statistic F below is F -distributed.

$$F(\nu_1, \nu_2) = \frac{x_1/\nu_1}{x_2/\nu_2}$$

The two parameters, ν_1 and ν_2 , are the numerator and denominator degrees of freedom. That is, ν_1 and ν_2 are the number of independent pieces of information used to calculate χ_1 and χ_2 , respectively.

Examples

Compute the F Distribution pdf

Compute the pdf of an F distribution with 5 numerator degrees of freedom and 3 denominator degrees of freedom.

```
x = 0:0.01:10;
y = fpdf(x,5,3);
```

Plot the pdf.

```
figure;
plot(x,y)
```

The plot shows that the F distribution exists on positive real numbers and is skewed to the right.

Gamma Distribution

In this section...

“Overview” on page B-47
 “Parameters” on page B-47
 “Probability Density Function” on page B-48
 “Cumulative Distribution Function” on page B-48
 “Inverse Cumulative Distribution Function” on page B-49
 “Descriptive Statistics” on page B-49
 “Examples” on page B-49
 “Related Distributions” on page B-53

Overview

The gamma distribution is a two-parameter family of curves. The gamma distribution models sums of exponentially distributed random variables and generalizes both the chi-square and exponential distributions.

Statistics and Machine Learning Toolbox offers several ways to work with the gamma distribution.

- Create a probability distribution object `GammaDistribution` by fitting a probability distribution to sample data (`fitdist`) or by specifying parameter values (`makedist`). Then, use object functions to evaluate the distribution, generate random numbers, and so on.
- Work with the gamma distribution interactively by using the **Distribution Fitter** app. You can export an object from the app and use the object functions.
- Use distribution-specific functions (`gamcdf`, `gampdf`, `gaminv`, `gamlike`, `gamstat`, `gamfit`, `gamrnd`, `randg`) with specified distribution parameters. The distribution-specific functions can accept parameters of multiple gamma distributions.
- Use generic distribution functions (`cdf`, `icdf`, `pdf`, `random`) with a specified distribution name (`'Gamma'`) and parameters.

Parameters

The gamma distribution uses the following parameters.

Parameter	Description	Support
a	Shape	$a > 0$
b	Scale	$b > 0$

The standard gamma distribution has unit scale.

The sum of two gamma random variables with shape parameters a_1 and a_2 both with scale parameter b is a gamma random variable with shape parameter $a = a_1 + a_2$ and scale parameter b .

Parameter Estimation

The *likelihood function* is the probability density function (pdf) viewed as a function of the parameters. The *maximum likelihood estimates* (MLEs) are the parameter estimates that maximize the likelihood function for fixed values of x .

The maximum likelihood estimators of a and b for the gamma distribution are the solutions to the simultaneous equations

$$\begin{aligned} \log \hat{a} - \psi(\hat{a}) &= \log \left(\bar{x} / \left(\prod_{i=1}^n x_i \right)^{1/n} \right) \\ \hat{b} &= \frac{\bar{x}}{\hat{a}} \end{aligned}$$

where \bar{x} is the sample mean for the sample x_1, x_2, \dots, x_n , and Ψ is the digamma function `psi`.

To fit the gamma distribution to data and find parameter estimates, use `gamfit`, `fitdist`, or `mle`. Unlike `gamfit` and `mle`, which return parameter estimates, `fitdist` returns the fitted probability distribution object `GammaDistribution`. The object properties `a` and `b` store the parameter estimates.

For an example, see “Fit Gamma Distribution to Data” on page B-49.

Probability Density Function

The pdf of the gamma distribution is

$$y = f(x | a, b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-x/b},$$

where $\Gamma(\cdot)$ is the Gamma function.

For an example, see “Compute Gamma Distribution pdf” on page B-50.

Cumulative Distribution Function

The cumulative distribution function (cdf) of the gamma distribution is

$$p = F(x | a, b) = \frac{1}{b^a \Gamma(a)} \int_0^x t^{a-1} e^{-t/b} dt.$$

The result p is the probability that a single observation from the gamma distribution with parameters a and b falls in the interval $[0, x]$.

For an example, see “Compute Gamma Distribution cdf” on page B-51.

The gamma cdf is related to the incomplete gamma function `gammainc` by

$$f(x | a, b) = \text{gammainc}\left(\frac{x}{b}, a\right).$$

Inverse Cumulative Distribution Function

The inverse cumulative distribution function (icdf) of the gamma distribution in terms of the gamma cdf is

$$x = F^{-1}(p|a, b) = \{x: F(x|a, b) = p\},$$

where

$$p = F(x|a, b) = \frac{1}{b^a \Gamma(a)} \int_0^x t^{a-1} e^{-\frac{t}{b}} dt.$$

The result x is the value such that an observation from the gamma distribution with parameters a and b falls in the range $[0, x]$ with probability p .

The preceding integral equation has no known analytical solution. `gaminv` uses an iterative approach (Newton's method) to converge on the solution.

Descriptive Statistics

The mean of the gamma distribution is $\mu = ab$.

The standard deviation of the gamma distribution is $\sigma = ab^2$.

Examples

Fit Gamma Distribution to Data

Generate a sample of 100 gamma random numbers with shape 3 and scale 5.

```
x = gamrnd(3,5,100,1);
```

Fit a gamma distribution to data using `fitdist`.

```
pd = fitdist(x, 'gamma')
```

```
pd =
```

```
GammaDistribution
```

```
Gamma distribution
```

```
 a = 2.7783 [2.1374, 3.61137]
```

```
 b = 5.73438 [4.30198, 7.64372]
```

`fitdist` returns a `GammaDistribution` object. The intervals next to the parameter estimates are the 95% confidence intervals for the distribution parameters.

Estimate the parameters a and b using the distribution functions.

```
[muhat,muci] = gamfit(x) % Distribution specific function
```

```
muhat = 1x2
```

```
2.7783    5.7344

muci = 2x2

2.1374    4.3020
3.6114    7.6437

[muhat2,muci2] = mle(x,'distribution','gamma') % Generic function
muhat2 = 1x2

2.7783    5.7344

muci2 = 2x2

2.1374    4.3020
3.6114    7.6437
```

Compute Gamma Distribution pdf

Compute the pdfs of the gamma distribution with several shape and scale parameters.

```
x = 0:0.1:50;
y1 = gampdf(x,1,10);
y2 = gampdf(x,3,5);
y3 = gampdf(x,6,4);
```

Plot the pdfs.

```
figure;
plot(x,y1)
hold on
plot(x,y2)
plot(x,y3)
hold off
xlabel('Observation')
ylabel('Probability Density')
legend('a = 1, b = 10', 'a = 3, b = 5', 'a = 6, b = 4')
```

Compute Gamma Distribution cdf

Compute the cdfs of the gamma distribution with several shape and scale parameters.

```
x = 0:0.1:50;
y1 = gamcdf(x,1,10);
y2 = gamcdf(x,3,5);
y3 = gamcdf(x,6,4);
```

Plot the cdfs.

```
figure;
plot(x,y1)
hold on
plot(x,y2)
plot(x,y3)
hold off
xlabel('Observation')
ylabel('Cumulative Probability')
legend('a = 1, b = 10','a = 3, b = 5','a = 6, b = 4','Location','northwest')
```

Compare Gamma and Normal Distribution pdfs

The gamma distribution has the shape parameter a and the scale parameter b . For a large a , the gamma distribution closely approximates the normal distribution with mean $\mu = ab$ and variance $\sigma^2 = ab^2$.

Compute the pdf of a gamma distribution with parameters $a = 100$ and $b = 5$.

```
a = 100;  
b = 5;  
x = 250:750;  
y_gam = gampdf(x,a,b);
```

For comparison, compute the mean, standard deviation, and pdf of the normal distribution that gamma approximates.

```
mu = a*b  
mu = 500  
sigma = sqrt(a*b^2)  
sigma = 50  
y_norm = normpdf(x,mu,sigma);
```

Plot the pdfs of the gamma distribution and the normal distribution on the same figure.

```

plot(x,y_gam,'-',x,y_norm,'-.-')
title('Gamma and Normal pdfs')
xlabel('Observation')
ylabel('Probability Density')
legend('Gamma Distribution','Normal Distribution')

```

The pdf of the normal distribution approximates the pdf of the gamma distribution.

Related Distributions

- “Beta Distribution” on page B-6 — The beta distribution is a two-parameter continuous distribution that has parameters a (first shape parameter) and b (second shape parameter). If X_1 and X_2 have standard gamma distributions with shape parameters a_1 and a_2 respectively, then $Y = \frac{X_1}{X_1 + X_2}$ has a beta distribution with shape parameters a_1 and a_2 .
- “Chi-Square Distribution” on page B-28 — The chi-square distribution is a one-parameter continuous distribution that has parameter ν (degrees of freedom). The chi-square distribution is equal to the gamma distribution with $2a = \nu$ and $b = 2$.
- “Exponential Distribution” on page B-33 — The exponential distribution is a one-parameter continuous distribution that has parameter μ (mean). The exponential distribution is equal to the gamma distribution with $a = 1$ and $b = \mu$. The sum of k exponentially distributed random variables with mean μ is the gamma distribution with parameters $a = k$ and $\mu = b$.

- “Nakagami Distribution” on page B-108 — The Nakagami distribution is a two-parameter continuous distribution with shape parameter μ and scale parameter ω . If x has a Nakagami distribution, then x^2 has a gamma distribution with $a = \mu$ and $ab = \omega$.
- “Normal Distribution” on page B-119 — The normal distribution is a two-parameter continuous distribution that has parameters μ (mean) and σ (standard deviation). When a is large, the gamma distribution closely approximates a normal distribution with $\mu = ab$ and $\sigma = ab^2$. For an example, see “Compare Gamma and Normal Distribution pdfs” on page B-52.

Generalized Extreme Value Distribution

In this section...

“Definition” on page B-55

“Background” on page B-55

“Parameters” on page B-56

“Examples” on page B-57

Definition

The probability density function for the generalized extreme value distribution with location parameter μ , scale parameter σ , and shape parameter $k \neq 0$ is

$$y = f(x|k, \mu, \sigma) = \left(\frac{1}{\sigma}\right) \exp\left(-\left(1 + k\frac{(x-\mu)}{\sigma}\right)^{-\frac{1}{k}}\right) \left(1 + k\frac{(x-\mu)}{\sigma}\right)^{-1 - \frac{1}{k}}$$

for

$$1 + k\frac{(x-\mu)}{\sigma} > 0$$

$k > 0$ corresponds to the Type II case, while $k < 0$ corresponds to the Type III case. For $k = 0$, corresponding to the Type I case, the density is

$$y = f(x|0, \mu, \sigma) = \left(\frac{1}{\sigma}\right) \exp\left(-\exp\left(-\frac{(x-\mu)}{\sigma}\right) - \frac{(x-\mu)}{\sigma}\right)$$

Background

Like the extreme value distribution, the generalized extreme value distribution is often used to model the smallest or largest value among a large set of independent, identically distributed random values representing measurements or observations. For example, you might have batches of 1000 washers from a manufacturing process. If you record the size of the largest washer in each batch, the data are known as block maxima (or minima if you record the smallest). You can use the generalized extreme value distribution as a model for those block maxima.

The generalized extreme value combines three simpler distributions into a single form, allowing a continuous range of possible shapes that includes all three of the simpler distributions. You can use any one of those distributions to model a particular dataset of block maxima. The generalized extreme value distribution allows you to “let the data decide” which distribution is appropriate.

The three cases covered by the generalized extreme value distribution are often referred to as the Types I, II, and III. Each type corresponds to the limiting distribution of block maxima from a different class of underlying distributions. Distributions whose tails decrease exponentially, such as the normal, lead to the Type I. Distributions whose tails decrease as a polynomial, such as Student's t , lead to the Type II. Distributions whose tails are finite, such as the beta, lead to the Type III.

Types I, II, and III are sometimes also referred to as the Gumbel, Fréchet, and Weibull types, though this terminology can be slightly confusing. The Type I (Gumbel) and Type III (Weibull) cases actually correspond to the mirror images of the usual Gumbel and Weibull distributions, for example, as

computed by the functions `evcdf` and `evfit`, or `wblcdf` and `wblfit`, respectively. Finally, the Type II (Frechet) case is equivalent to taking the reciprocal of values from a standard Weibull distribution.

Parameters

If you generate 250 blocks of 1000 random values drawn from Student's t distribution with 5 degrees of freedom, and take their maxima, you can fit a generalized extreme value distribution to those maxima.

```
blocksize = 1000;
nblocks = 250;
rng default % For reproducibility
t = trnd(5,blocksize,nblocks);
x = max(t); % 250 column maxima
paramEsts = gevfit(x)
```

```
paramEsts = 1×3
    0.1185    1.4530    5.8929
```

Notice that the shape parameter estimate (the first element) is positive, which is what you would expect based on block maxima from a Student's t distribution.

```
histogram(x,2:20,'FaceColor',[.8 .8 1]);
xgrid = linspace(2,20,1000);
line(xgrid,nblocks*...
     gevpdf(xgrid,paramEsts(1),paramEsts(2),paramEsts(3)));
```

Examples

Compute the Generalized Extreme Value Distribution pdf

Generate examples of probability density functions for the three basic forms of the generalized extreme value distribution.

```
x = linspace(-3,6,1000);
y1 = gevpdf(x,-.5,1,0);
y2 = gevpdf(x,0,1,0);
y3 = gevpdf(x,.5,1,0);
plot(x,y1,'-', x,y2,'--', x,y3,':')
legend({'K < 0, Type III' 'K = 0, Type I' 'K > 0, Type II'})
```

Notice that for $k > 0$, the distribution has zero probability density for x such that $x < -\sigma/k + \mu$.

For $k < 0$, the distribution has zero probability density for $x > -\sigma/k + \mu$.

For $k = 0$, there is no upper or lower bound.

Generalized Pareto Distribution

In this section...

“Definition” on page B-59

“Background” on page B-59

“Parameters” on page B-60

“Examples” on page B-61

Definition

The probability density function for the generalized Pareto distribution with shape parameter $k \neq 0$, scale parameter σ , and threshold parameter θ , is

$$y = f(x|k, \sigma, \theta) = \left(\frac{1}{\sigma}\right) \left(1 + k \frac{(x - \theta)}{\sigma}\right)^{-1 - \frac{1}{k}}$$

for $\theta < x$, when $k > 0$, or for $\theta < x < \theta - \sigma/k$ when $k < 0$.

For $k = 0$, the density is

$$y = f(x|0, \sigma, \theta) = \left(\frac{1}{\sigma}\right) e^{-\frac{(x - \theta)}{\sigma}}$$

for $\theta < x$.

If $k = 0$ and $\theta = 0$, the generalized Pareto distribution is equivalent to the exponential distribution. If $k > 0$ and $\theta = \sigma/k$, the generalized Pareto distribution is equivalent to the Pareto distribution with a scale parameter equal to σ/k and a shape parameter equal to $1/k$.

Background

Like the exponential distribution, the generalized Pareto distribution is often used to model the tails of another distribution. For example, you might have washers from a manufacturing process. If random influences in the process lead to differences in the sizes of the washers, a standard probability distribution, such as the normal, could be used to model those sizes. However, while the normal distribution might be a good model near its mode, it might not be a good fit to real data in the tails and a more complex model might be needed to describe the full range of the data. On the other hand, only recording the sizes of washers larger (or smaller) than a certain threshold means you can fit a separate model to those tail data, which are known as *exceedances*. You can use the generalized Pareto distribution in this way, to provide a good fit to extremes of complicated data.

The generalized Pareto distribution allows a continuous range of possible shapes that includes both the exponential and Pareto distributions as special cases. You can use either of those distributions to model a particular dataset of exceedances. The generalized Pareto distribution allows you to “let the data decide” which distribution is appropriate.

The generalized Pareto distribution has three basic forms, each corresponding to a limiting distribution of exceedance data from a different class of underlying distributions.

- Distributions whose tails decrease exponentially, such as the normal, lead to a generalized Pareto shape parameter of zero.
- Distributions whose tails decrease as a polynomial, such as Student's t , lead to a positive shape parameter.
- Distributions whose tails are finite, such as the beta, lead to a negative shape parameter.

The generalized Pareto distribution is used in the tails of distribution fit objects of the `paretotails` object.

Parameters

If you generate a large number of random values from a Student's t distribution with 5 degrees of freedom, and then discard everything less than 2, you can fit a generalized Pareto distribution to those exceedances.

```
rng default % For reproducibility
t = trnd(5,5000,1);
y = t(t > 2) - 2;
paramEsts = gpfitt(y)

paramEsts = 1x2

    0.1445    0.7225
```

Notice that the shape parameter estimate (the first element) is positive, which is what you would expect based on exceedances from a Student's t distribution.

```
hist(y+2,2.25:.5:11.75);
h = findobj(gca,'Type','patch');
h.FaceColor = [.8 .8 1];
xgrid = linspace(2,12,1000);
line(xgrid,.5*length(y)*...
      gppdf(xgrid,paramEsts(1),paramEsts(2),2));
```

Examples

Compute Generalized Pareto Distribution pdf

Compute the pdf of three generalized Pareto distributions. The first has shape parameter $k = -0.25$, the second has $k = 0$, and the third has $k = 1$.

```
x = linspace(0,10,1000);
y1 = gppdf(x,-.25,1,0);
y2 = gppdf(x,0,1,0);
y3 = gppdf(x,1,1,0);
```

Plot the three pdfs on the same figure.

```
figure;
plot(x,y1,'-', x,y2,'--', x,y3,':')
legend({'K < 0' 'K = 0' 'K > 0'});
```

Geometric Distribution

In this section...
“Overview” on page B-63
“Parameters” on page B-63
“Probability Density Function” on page B-63
“Cumulative Distribution Function” on page B-64
“Descriptive Statistics” on page B-64
“Hazard Function” on page B-64
“Examples” on page B-64
“Related Distributions” on page B-66

Overview

The geometric distribution is a one-parameter family of curves that models the number of failures before one success in a series of independent trials, where each trial results in either success or failure, and the probability of success in any individual trial is constant. For example, if you toss a coin, the geometric distribution models the number of tails observed before the result is heads. The geometric distribution is discrete, existing only on the nonnegative integers.

Statistics and Machine Learning Toolbox offers multiple ways to work with the geometric distribution.

- Use distribution-specific functions (`geocdf`, `geopdf`, `geoinv`, `geostat`, `geornd`) with specified distribution parameters. The distribution-specific functions can accept parameters of multiple geometric distributions.
- Use generic distribution functions (`cdf`, `icdf`, `pdf`, `mle`, `random`) with a specified distribution name ('Geometric') and parameters.

Parameters

The geometric distribution uses the following parameter.

Parameter	Description	Support
p	Probability of success	$0 \leq p \leq 1$

Probability Density Function

The probability density function (pdf) of the geometric distribution is

$$y = f(x|p) = p(1-p)^x \quad ; \quad x = 0, 1, 2, \dots,$$

where p is the probability of success, and x is the number of failures before the first success. The result y is the probability of observing exactly x trials before a success, when the probability of success in any given trial is p . For discrete distributions, the pdf is also known as the probability mass function (pmf).

For an example, see “Compute Geometric Distribution pdf” on page B-64.

Cumulative Distribution Function

The cumulative distribution function (cdf) of the geometric distribution is

$$y = F(x|p) = 1 - (1 - p)^{x+1}; x = 0, 1, 2, \dots,$$

where p is the probability of success, and x is the number of failures before the first success. The result y is the probability of observing up to x trials before a success, when the probability of success in any given trial is p .

For an example, see “Compute Geometric Distribution cdf” on page B-65.

Descriptive Statistics

The mean of the geometric distribution is $\text{mean} = \frac{1-p}{p}$, and the variance of the geometric distribution is $\text{var} = \frac{1-p}{p^2}$, where p is the probability of success.

Hazard Function

The hazard function (instantaneous failure rate) is the ratio of the pdf and the complement of the cdf. If $f(t)$ and $F(t)$ are the pdf and cdf of a distribution (respectively), then the hazard rate is

$h(t) = \frac{f(t)}{1 - F(t)}$. Substituting the pdf and cdf of the geometric distribution for $f(t)$ and $F(t)$ above yields a constant equal to the reciprocal of the mean. The geometric distribution is the only discrete distribution with constant hazard function. Consequently, the probability of observing a success is independent of the number of failures already observed.

Examples

Compute Geometric Distribution pdf

Compute the pdf of the geometric distribution with the probability of success 0.25.

```
x = 0:20;  
y = geopdf(x,0.25);
```

Plot the pdf with bars of width 1.

```
figure  
bar(x,y,1)  
xlabel('Observation')  
ylabel('Probability')
```

Compute Geometric Distribution cdf

Compute the cdf of the geometric distribution with the probability of success 0.25.

```
x = 0:20;  
y = geocdf(x,0.25);
```

Plot the cdf.

```
figure  
stairs(x,y)  
xlabel('Observation')  
ylabel('Cumulative Probability')
```

Compute Geometric Distribution Probabilities

Assume that the probability of a five-year-old car battery not starting in cold weather is 0.03. The driver attempts to start the car every morning during a span of cold weather lasting 25 days. Model this scenario with a geometric distribution, where the event to observe is the car not starting.

Compute the cdf of 25 to find the probability of the car not starting during one of the 25 days.

```
x = 25;
p = 0.03;
notstart = geocdf(x,p)
notstart = 0.5470
```

Compute the complement to find the probability of the car starting every day for all 25 days.

```
start = 1 - notstart
start = 0.4530
```

Related Distributions

- “Exponential Distribution” on page B-33 — The exponential distribution is a one-parameter continuous distribution that has parameter μ (mean). The exponential distribution is a continuous analog of the geometric and is the only distribution other than geometric with a constant hazard function.

- Negative Binomial Distribution on page B-109 — The negative binomial distribution is a two-parameter discrete distribution that has parameters r and p , and models the number of failures observed before r successes with probability p of success in a single trial. The geometric distribution occurs as the negative binomial distribution with $r = 1$.

Half-Normal Distribution

In this section...

“Overview” on page B-68

“Parameters” on page B-68

“Probability Density Function” on page B-68

“Cumulative Distribution Function” on page B-70

“Descriptive Statistics” on page B-71

“Relationship to Other Distributions” on page B-72

Overview

The half-normal distribution is a special case of the folded normal and truncated normal distributions. Some applications of the half-normal distribution include modeling measurement data and lifetime data.

Parameters

The half-normal distribution uses the following parameters:

Parameter	Description
$-\infty < \mu < \infty$	Location parameter
$\sigma \geq 0$	Scale parameter

The support for the half-normal distribution is $x \geq \mu$.

Use `makedist` with specified parameter values to create a half-normal probability distribution object `HalfNormalDistribution`. Use `fitdist` to fit a half-normal probability distribution object to sample data. Use `mle` to estimate the half-normal distribution parameter values from sample data without creating a probability distribution object. For more information about working with probability distributions, see “Working with Probability Distributions” on page 5-2.

The Statistics and Machine Learning Toolbox implementation of the half-normal distribution assumes a fixed value for the location parameter μ . Therefore, neither `fitdist` nor `mle` estimates the value of the parameter μ when fitting a half-normal distribution to sample data. You can specify a value for the μ parameter by using the name-value pair argument `'mu'`. The default value for the `'mu'` argument is 0 in both `fitdist` and `mle`.

Probability Density Function

The probability density function (pdf) of the half-normal distribution is

$$y = f(x|\mu, \sigma) = \sqrt{\frac{2}{\pi}} \frac{1}{\sigma} e^{-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2}; x \geq \mu,$$

where μ is the location parameter and σ is the scale parameter. If $x \leq \mu$, then the pdf is undefined.

To compute the pdf of the half-normal distribution, create a `HalfNormalDistribution` probability distribution object using `fitdist` or `makedist`, then use the `pdf` method to work with the object.

PDF of Half-Normal Probability Distribution

This example shows how changing the values of the `mu` and `sigma` parameters alters the shape of the pdf.

Create four probability distribution objects with different parameters.

```
pd1 = makedist('HalfNormal');  
pd2 = makedist('HalfNormal','mu',0,'sigma',2);  
pd3 = makedist('HalfNormal','mu',0,'sigma',3);  
pd4 = makedist('HalfNormal','mu',0,'sigma',5);
```

Compute the probability density functions (pdfs) of each distribution.

```
x = 0:0.1:10;  
pdf1 = pdf(pd1,x);  
pdf2 = pdf(pd2,x);  
pdf3 = pdf(pd3,x);  
pdf4 = pdf(pd4,x);
```

Plot the pdfs on the same figure.

```
figure;  
plot(x,pdf1,'r','LineWidth',2)  
hold on;  
plot(x,pdf2,'k:', 'LineWidth',2);  
plot(x,pdf3,'b-.','LineWidth',2);  
plot(x,pdf4,'g--','LineWidth',2);  
legend({'mu = 0, sigma = 1','mu = 0, sigma = 2',...  
       'mu = 0, sigma = 3','mu = 0, sigma = 5'}, 'Location','NE');  
hold off;
```

As σ increases, the curve flattens and the peak value becomes smaller.

Cumulative Distribution Function

The cumulative distribution function (cdf) of the half-normal distribution is

$$y = F(x) = \operatorname{erf}\left(\frac{x - \mu}{\sqrt{2}\sigma}\right) = 2\Phi\left(\frac{x - \mu}{\sigma}\right) - 1; x \geq \mu,$$

where μ is the location parameter, σ is the scale parameter, $\operatorname{erf}(\bullet)$ is the error function, and $\Phi(\bullet)$ is the cdf of the standard normal distribution. If $x \leq \mu$, then the cdf is undefined.

To compute the cdf of the half-normal distribution, create a `HalfNormalDistribution` probability distribution object using `fitdist` or `makedist`, then use the `cdf` method to work with the object.

CDF of Half-Normal Probability Distribution

This example shows how changing the values of the μ and σ parameters alters the shape of the cdf.

Create four probability distribution objects with different parameters.

```
pd1 = makedist('HalfNormal');
pd2 = makedist('HalfNormal', 'mu', 0, 'sigma', 2);
pd3 = makedist('HalfNormal', 'mu', 0, 'sigma', 3);
pd4 = makedist('HalfNormal', 'mu', 0, 'sigma', 5);
```

Compute the cumulative distribution functions (cdf) for each probability distribution.

```
x = 0:0.1:10;
cdf1 = cdf(pd1,x);
cdf2 = cdf(pd2,x);
cdf3 = cdf(pd3,x);
cdf4 = cdf(pd4,x);
```

Plot all four cdfs on the same figure.

```
figure;
plot(x,cdf1,'r','LineWidth',2)
hold on;
plot(x,cdf2,'k:','LineWidth',2);
plot(x,cdf3,'b-.','LineWidth',2);
plot(x,cdf4,'g--','LineWidth',2);
legend({'mu = 0, sigma = 1','mu = 0, sigma = 2',...
      'mu = 0, sigma = 3','mu = 0, sigma = 5'},'Location','SE');
hold off;
```

As sigma increases, the curve of the cdf flattens.

Descriptive Statistics

The mean of the half-normal distribution is

$$\text{mean} = \mu + \sigma\sqrt{\frac{2}{\pi}},$$

where μ is the location parameter and σ is the scale parameter.

The variance of the half-normal distribution is

$$\text{var} = \sigma^2\left(1 - \frac{2}{\pi}\right),$$

where σ is the scale parameter.

Relationship to Other Distributions

If a random variable Z has a standard normal distribution with a mean μ equal to zero and standard deviation σ equal to one, then $X = \mu + \sigma|Z|$ has a half-normal distribution with parameters μ and σ .

Hypergeometric Distribution

In this section...

“Definition” on page B-73

“Background” on page B-73

“Examples” on page B-73

Definition

The hypergeometric pdf is

$$y = f(x) \left| M, K, n \right. = \frac{\binom{K}{x} \binom{M-K}{n-x}}{\binom{M}{n}}$$

Background

The hypergeometric distribution models the total number of successes in a fixed-size sample drawn without replacement from a finite population.

The distribution is discrete, existing only for nonnegative integers less than the number of samples or the number of possible successes, whichever is greater. The hypergeometric distribution differs from the binomial only in that the population is finite and the sampling from the population is without replacement.

The hypergeometric distribution has three parameters that have direct physical interpretations.

- M is the size of the population.
- K is the number of items with the desired characteristic in the population.
- n is the number of samples drawn.

Sampling “without replacement” means that once a particular sample is chosen, it is removed from the relevant population for all subsequent selections.

Examples

Compute and Plot Hypergeometric Distribution CDF

This example shows how to compute and plot the cdf of a hypergeometric distribution.

Compute the cdf of a hypergeometric distribution that draws 20 samples from a group of 1000 items, when the group contains 50 items of the desired type.

```
x = 0:10;
y = hygecdf(x, 1000, 50, 20);
```

Plot the cdf.

```
stairs(x,y)
```

The x-axis of the plot shows the number of items drawn that are of the desired type. The y-axis shows the corresponding cdf values.

Inverse Gaussian Distribution

In this section...

“Definition” on page B-75

“Background” on page B-75

“Parameters” on page B-75

Definition

The inverse Gaussian distribution has the density function

$$\sqrt{\frac{\lambda}{2\pi x^3}} \exp\left\{-\frac{\lambda}{2\mu^2 x}(x - \mu)^2\right\}$$

Background

Also known as the Wald distribution, the inverse Gaussian is used to model nonnegative positively skewed data. The distribution originated in the theory of Brownian motion, but has been used to model diverse phenomena. Inverse Gaussian distributions have many similarities to standard Gaussian (normal) distributions, which lead to applications in inferential statistics.

Parameters

To estimate distribution parameters, use `mle` or the Distribution Fitter app.

Inverse Wishart Distribution

Definition

The probability density function of the d -dimensional Inverse Wishart distribution is given by

$$y = f(X, \Sigma, \nu) = \frac{|T|^{(\nu/2)} e\left(-\frac{1}{2}\text{trace}(TX^{-1})\right)}{2^{(\nu d)/2} \pi^{(d(d-1))/4} |X|^{(\nu+d+1)/2} \Gamma(\nu/2) \dots \Gamma(\nu-(d-1))/2'}$$

where X and T are d -by- d symmetric positive definite matrices, and ν is a scalar greater than or equal to d . While it is possible to define the Inverse Wishart for singular T , the density cannot be written as above.

If a random matrix has a Wishart distribution with parameters T^{-1} and ν , then the inverse of that random matrix has an inverse Wishart distribution with parameters T and ν . The mean of the distribution is given by

$$\frac{1}{\nu - d - 1} T$$

where d is the number of rows and columns in T .

Only random matrix generation is supported for the inverse Wishart, including both singular and nonsingular T .

Background

The inverse Wishart distribution is based on the Wishart distribution on page B-178. In Bayesian statistics it is used as the conjugate prior for the covariance matrix of a multivariate normal distribution.

Example

Notice that the sampling variability is quite large when the degrees of freedom is small.

```
Tau = [1 .5; .5 2];
df = 10; S1 = iwishrnd(Tau,df)*(df-2-1)
```

```
S1 =
    1.7959    0.64107
    0.64107    1.5496
```

```
df = 1000; S2 = iwishrnd(Tau,df)*(df-2-1)

Kernel Distribution

In this section...

“Overview” on page B-78

“Kernel Density Estimator” on page B-78

“Kernel Smoothing Function” on page B-78

“Bandwidth” on page B-82

Overview

A kernel distribution is a nonparametric representation of the probability density function (pdf) of a random variable. You can use a kernel distribution when a parametric distribution cannot properly describe the data, or when you want to avoid making assumptions about the distribution of the data. A kernel distribution is defined by a smoothing function and a bandwidth value, which control the smoothness of the resulting density curve.

Kernel Density Estimator

The kernel density estimator is the estimated pdf of a random variable. For any real values of x , the kernel density estimator's formula is given by

$$\hat{f}_h(x) = \frac{1}{nh} \sum_{i=1}^n K\left(\frac{x - x_i}{h}\right),$$

where x_1, x_2, \dots, x_n are random samples from an unknown distribution, n is the sample size, $K(\cdot)$ is the kernel smoothing function, and h is the bandwidth.

Kernel Smoothing Function

The kernel smoothing function defines the shape of the curve used to generate the pdf. Similar to a histogram, the kernel distribution builds a function to represent the probability distribution using the sample data. But unlike a histogram, which places the values into discrete bins, a kernel distribution sums the component smoothing functions for each data value to produce a smooth, continuous probability curve. The following plots show a visual comparison of a histogram and a kernel distribution generated from the same sample data.

A histogram represents the probability distribution by establishing bins and placing each data value in the appropriate bin.

```
SixMPG = [13;15;23;29;32;34];  
figure  
histogram(SixMPG)
```

Because of this bin count approach, the histogram produces a discrete probability density function. This might be unsuitable for certain applications, such as generating random numbers from a fitted distribution.

Alternatively, the kernel distribution builds the pdf by creating an individual probability density curve for each data value, then summing the smooth curves. This approach creates one smooth, continuous probability density function for the data set.

```
figure
pdSix = fitdist(SixMPG,'Kernel','BandWidth',4);
x = 0:.1:45;
ySix = pdf(pdSix,x);
plot(x,ySix,'k-','LineWidth',2)

% Plot each individual pdf and scale its appearance on the plot
hold on
for i=1:6
    pd = makedist('Normal','mu',SixMPG(i),'sigma',4);
    y = pdf(pd,x);
    y = y/6;
    plot(x,y,'b:')
end
hold off
```

The smaller dashed curves are the probability distributions for each value in the sample data, scaled to fit the plot. The larger solid curve is the overall kernel distribution of the SixMPG data. The kernel smoothing function refers to the shape of those smaller component curves, which have a normal distribution in this example.

You can choose one of several options for the kernel smoothing function. This plot shows the shapes of the available smoothing functions.

Set plot specifications

```
hname = {'normal' 'epanechnikov' 'box' 'triangle'};
colors = {'r' 'b' 'g' 'm'};
lines = {'-', '-.', '--', ':'};

% Generate a sample of each kernel smoothing function and plot
data = [0];
figure
for j=1:4
    pd = fitdist(data,'kernel','Kernel',hname{j});
    x = -3:.1:3;
    y = pdf(pd,x);
    plot(x,y,'Color',colors{j},'LineStyle',lines{j})
    hold on
end
legend(hname)
hold off
```

To understand the effect of different kernel smoothing functions on the shape of the resulting pdf estimate, compare plots of the mileage data (MPG) from `carbig.mat` using each available kernel function.

```
load carbig
% Set plot specifications
hname = {'normal' 'epanechnikov' 'box' 'triangle'};
colors = {'r' 'b' 'g' 'm'};
lines = {'-' '---' '---' ':'};

% Generate kernel distribution objects and plot
figure
for j=1:4
    pd = fitdist(MPG, 'kernel', 'Kernel', hname{j});
    x = -10:1:60;
    y = pdf(pd, x);
    plot(x, y, 'Color', colors{j}, 'LineStyle', lines{j})
    hold on
end
legend(hname)
hold off
```

Each density curve uses the same input data, but applies a different kernel smoothing function to generate the pdf. The density estimates are roughly comparable, but the shape of each curve varies slightly. For example, the box kernel produces a density curve that is less smooth than the others.

Bandwidth

The choice of bandwidth value controls the smoothness of the resulting probability density curve. This plot shows the density estimate for the same MPG data, using a normal kernel smoothing function with three different bandwidths.

Create kernel distribution objects

```
pd1 = fitdist(MPG, 'kernel');
pd2 = fitdist(MPG, 'kernel', 'BandWidth', 1);
pd3 = fitdist(MPG, 'kernel', 'BandWidth', 5);
```

```
% Compute each pdf
```

```
x = -10:1:60;
y1 = pdf(pd1, x);
y2 = pdf(pd2, x);
y3 = pdf(pd3, x);
```

```
% Plot each pdf
```

```
plot(x, y1, 'Color', 'r', 'LineStyle', '-');
hold on
plot(x, y2, 'Color', 'k', 'LineStyle', '-');
```

```

plot(x,y3,'Color','b','LineStyle','--')
legend({'BandWidth = Default','BandWidth = 1','BandWidth = 5'})
hold off

```

The default bandwidth, which is theoretically optimal for estimating densities for the normal distribution [1], produces a reasonably smooth curve. Specifying a smaller bandwidth produces a very rough curve, but reveals that there might be two major peaks in the data. Specifying a larger bandwidth produces a curve nearly identical to the kernel function, and is so smooth that it obscures potentially important features of the data.

Logistic Distribution

In this section...

“Overview” on page B-85
 “Parameters” on page B-85
 “Probability Density Function” on page B-85
 “Relationship to Other Distributions” on page B-85

Overview

The logistic distribution is used for growth models and in logistic regression. It has longer tails and a higher kurtosis than the normal distribution.

Parameters

The logistic distribution uses the following parameters.

Parameter	Description	Support
mu	Mean	$-\infty < \mu < \infty$
sigma	Scale parameter	$\sigma \geq 0$

Probability Density Function

The probability density function (pdf) is

$$f(x) \Big|_{\mu, \sigma} = \frac{\exp\left\{\frac{x-\mu}{\sigma}\right\}}{\sigma\left(1 + \exp\left\{\frac{x-\mu}{\sigma}\right\}\right)^2} ; \quad -\infty < x < \infty .$$

Relationship to Other Distributions

The loglogistic distribution is closely related to the logistic distribution. If x is distributed loglogistically with parameters μ and σ , then $\log(x)$ is distributed logistically with parameters μ and σ .

Loglogistic Distribution

In this section...
“Overview” on page B-86
“Parameters” on page B-86
“Probability Density Function” on page B-86
“Relationship to Other Distributions” on page B-86

Overview

The loglogistic distribution is a probability distribution whose logarithm has a logistic distribution. This distribution is often used in survival analysis to model events that experience an initial rate increase, followed by a rate decrease. It is also known as the Fisk distribution in economics applications.

Parameters

The loglogistic distribution uses the following parameters.

Parameter	Description	Support
mu	Mean of logarithmic values	$\mu > 0$
sigma	Scale parameter of logarithmic values	$\sigma > 0$

Probability Density Function

The probability density function (pdf) is

$$f(x | \mu, \sigma) = \frac{1}{\sigma} \frac{1}{x} \frac{e^z}{(1 + e^z)^2} ; \quad x \geq 0,$$

where $z = \frac{\log(x) - \mu}{\sigma}$.

Relationship to Other Distributions

The loglogistic distribution is closely related to the logistic distribution. If x is distributed loglogistically with parameters μ and σ , then $\log(x)$ is distributed logistically with parameters μ and σ . The relationship is similar to that between the lognormal on page B-88 and normal on page B-119 distribution.

Lognormal Distribution

In this section...
“Overview” on page B-88
“Parameters” on page B-88
“Probability Density Function” on page B-89
“Cumulative Distribution Function” on page B-89
“Examples” on page B-89
“Related Distributions” on page B-94

Overview

The lognormal distribution, sometimes called the Galton distribution, is a probability distribution whose logarithm has a normal distribution. The lognormal distribution is applicable when the quantity of interest must be positive, because $\log(x)$ exists only when x is positive.

Statistics and Machine Learning Toolbox offers several ways to work with the lognormal distribution.

- Create a probability distribution object `LognormalDistribution` by fitting a probability distribution to sample data (`fitdist`) or by specifying parameter values (`makedist`). Then, use object functions to evaluate the distribution, generate random numbers, and so on.
- Work with the lognormal distribution interactively by using the **Distribution Fitter** app. You can export an object from the app and use the object functions.
- Use distribution-specific functions (`logncdf`, `lognpdf`, `logninv`, `lognlike`, `lognstat`, `lognfit`, `lognrnd`) with specified distribution parameters. The distribution-specific functions can accept parameters of multiple lognormal distributions.
- Use generic distribution functions (`cdf`, `icdf`, `pdf`, `random`) with a specified distribution name (`'Lognormal'`) and parameters.

Parameters

The lognormal distribution uses these parameters.

Parameter	Description	Support
μ (μ)	Mean of logarithmic values	$-\infty < \mu < \infty$
σ (σ)	Standard deviation of logarithmic values	$\sigma \geq 0$

If X follows the lognormal distribution with parameters μ and σ , then $\log(X)$ follows the normal distribution with mean μ and standard deviation σ .

Parameter Estimation

To fit the lognormal distribution to data and find the parameter estimates, use `lognfit`, `fitdist`, or `mle`.

- For uncensored data, `lognfit` and `fitdist` find the unbiased estimates of the distribution parameters, and `mle` finds the maximum likelihood estimates.

- For censored data, `lognfit`, `fitdist`, and `mle` find the maximum likelihood estimates.

Unlike `lognfit` and `mle`, which return parameter estimates, `fitdist` returns the fitted probability distribution object `LognormalDistribution`. The object properties `mu` and `sigma` store the parameter estimates.

Descriptive Statistics

The mean m and variance v of a lognormal random variable are functions of the lognormal distribution parameters μ and σ :

$$m = \exp(\mu + \sigma^2/2)$$

$$v = \exp(2\mu + \sigma^2)(\exp(\sigma^2) - 1)$$

Also, you can compute the lognormal distribution parameters μ and σ from the mean m and variance v :

$$\mu = \log(m^2/\sqrt{v + m^2})$$

$$\sigma = \sqrt{\log(v/m^2 + 1)}$$

Probability Density Function

The probability density function (pdf) of the lognormal distribution is

$$y = f(x) \left| \mu, \sigma \right. = \frac{1}{x\sigma\sqrt{2\pi}} \exp\left\{-\frac{(\log x - \mu)^2}{2\sigma^2}\right\}, \quad \text{for } x > 0.$$

For an example, see “Compute Lognormal Distribution pdf” on page B-89.

Cumulative Distribution Function

The cumulative distribution function (cdf) of the lognormal distribution is

$$p = F(x) \left| \mu, \sigma \right. = \frac{1}{\sigma\sqrt{2\pi}} \int_0^x \frac{1}{t} \exp\left\{-\frac{(\log t - \mu)^2}{2\sigma^2}\right\} dt, \quad \text{for } x > 0.$$

For an example, see “Compute Lognormal Distribution cdf” on page B-90.

Examples

Compute Lognormal Distribution pdf

Suppose the income of a family of four in the United States follows a lognormal distribution with $\mu = \log(20,000)$ and $\sigma = 1$. Compute and plot the income density.

Create a lognormal distribution object by specifying the parameter values.

```
pd = makedist('Lognormal', 'mu', log(20000), 'sigma', 1)
```

```
pd =
  LognormalDistribution
```

```
Lognormal distribution
mu = 9.90349
sigma = 1
```

Compute the pdf values.

```
x = (10:1000:125010)';
y = pdf(pd,x);
```

Plot the pdf.

```
plot(x,y)
h = gca;
h.XTick = [0 30000 60000 90000 120000];
h.XTickLabel = {'0', '$30,000', '$60,000', ...
                '$90,000', '$120,000'};
```

Compute Lognormal Distribution cdf

Compute the cdf values evaluated at the values in x for the lognormal distribution with mean μ and standard deviation σ .

```
x = 0:0.2:10;
mu = 0;
sigma = 1;
p = logncdf(x,mu,sigma);
```

Plot the cdf.

```
plot(x,p)
grid on
xlabel('x')
ylabel('p')
```

Relationship Between Normal and Lognormal Distributions

If X follows the lognormal distribution with parameters μ and σ , then $\log(X)$ follows the normal distribution with mean μ and standard deviation σ . Use distribution objects to inspect the relationship between normal and lognormal distributions.

Create a lognormal distribution object by specifying the parameter values.

```
pd = makedist('Lognormal', 'mu', 5, 'sigma', 2)
```

```
pd =
  LognormalDistribution

  Lognormal distribution
    mu = 5
    sigma = 2
```

Compute the mean of the lognormal distribution.

```
mean(pd)
```

```
ans = 1.0966e+03
```

The mean of the lognormal distribution is not equal to the μ parameter. The mean of the logarithmic values is equal to μ . Confirm this relationship by generating random numbers.

Generate random numbers from the lognormal distribution and compute their log values.

```
rng('default'); % For reproducibility
x = random(pd,10000,1);
logx = log(x);
```

Compute the mean of the logarithmic values.

```
m = mean(logx)
```

```
m = 5.0033
```

The mean of the log of x is close to the μ parameter of x , because x has a lognormal distribution.

Construct a histogram of $\log x$ with a normal distribution fit.

```
histfit(logx)
```

The plot shows that the log values of x are normally distributed.

`histfit` uses `fitdist` to fit a distribution to data. Use `fitdist` to obtain parameters used in fitting.

```
pd_normal = fitdist(logx,'Normal')
pd_normal =
    NormalDistribution

    Normal distribution
        mu = 5.00332    [4.96445, 5.04219]
        sigma = 1.98296    [1.95585, 2.01083]
```

The estimated normal distribution parameters are close to the lognormal distribution parameters 5 and 2.

Compare Lognormal and Burr Distribution pdfs

Compare the lognormal pdf to the Burr pdf using income data generated from a lognormal distribution.

Generate the income data.

```
rng('default') % For reproducibility
y = random('Lognormal',log(25000),0.65,[500,1]);
```

Fit a Burr distribution.

```
pd = fitdist(y,'burr')
pd =
    BurrDistribution

    Burr distribution
        alpha = 26007.2    [21165.5, 31956.4]
        c = 2.63743    [2.3053, 3.0174]
        k = 1.09658    [0.775479, 1.55064]
```

Plot both the Burr and lognormal pdfs of income data on the same figure.

```
p_burr = pdf(pd,sortrows(y));
p_lognormal = pdf('Lognormal',sortrows(y),log(25000),0.65);
plot(sortrows(y),p_burr,'-',sortrows(y),p_lognormal,'-.')
title('Burr and Lognormal pdfs Fit to Income Data')
legend('Burr Distribution','Lognormal Distribution')
```

Related Distributions

- “Normal Distribution” on page B-119 — The lognormal distribution is closely related to the normal distribution. If X is distributed lognormally with parameters μ and σ , then $\log(x)$ is distributed normally with mean μ and standard deviation σ . See “Relationship Between Normal and Lognormal Distributions” on page B-91.
- “Burr Type XII Distribution” on page B-19 — The Burr distribution is a flexible distribution family that can express a wide range of distribution shapes. It has as a limiting case many commonly used distributions such as gamma, lognormal, loglogistic, bell-shaped, and J-shaped beta distributions (but not U-shaped). See “Compare Lognormal and Burr Distribution pdfs” on page B-93.

Multinomial Distribution

In this section...
“Overview” on page B-96
“Parameter” on page B-96
“Probability Density Function” on page B-96
“Descriptive Statistics” on page B-96
“Relationship to Other Distributions” on page B-97

Overview

Multinomial distribution models the probability of each combination of successes in a series of independent trials. Use this distribution when there are more than two possible mutually exclusive outcomes for each trial, and each outcome has a fixed probability of success.

Parameter

Multinomial distribution uses the following parameter.

Parameter	Description	Constraints
probabilities	Outcome probabilities	$0 \leq \text{probabilities}(i) \leq 1 ; \sum_{\text{all}(i)} \text{probabilities}(i) = 1$

Probability Density Function

The multinomial pdf is

$$f(x|n, p) = \frac{n!}{x_1! \dots x_k!} p_1^{x_1} \dots p_k^{x_k},$$

where k is the number of possible mutually exclusive outcomes for each trial, and n is the total number of trials. The vector $x = (x_1 \dots x_k)$ is the number of observations of each k outcome, and contains nonnegative integer components that sum to n . The vector $p = (p_1 \dots p_k)$ is the fixed probability of each k outcome, and contains nonnegative scalar components that sum to 1.

Descriptive Statistics

The expected number of observations of outcome i in n trials is

$$E\{x_i\} = np_i,$$

where p_i is the fixed probability of outcome i .

The variance is of outcome i is

$$\text{var}(x_i) = np_i(1 - p_i).$$

The covariance of outcomes i and j is

$$\text{cov}(x_i, x_j) = -np_i p_j, \quad i \neq j.$$

Relationship to Other Distributions

The multinomial distribution is a generalization of the binomial distribution on page B-10. While the binomial distribution gives the probability of the number of “successes” in n independent trials of a two-outcome process, the multinomial distribution gives the probability of each combination of outcomes in n independent trials of a k -outcome process. The probability of each outcome in any one trial is given by the fixed probabilities p_1, \dots, p_k .

Multivariate Normal Distribution

In this section...

“Overview” on page B-98
 “Parameters” on page B-98
 “Probability Density Function” on page B-98
 “Cumulative Distribution Function” on page B-99
 “Examples” on page B-99

Overview

The multivariate normal distribution is a generalization of the univariate normal distribution on page B-119 to two or more variables. It is a distribution for random vectors of correlated variables, where each vector element has a univariate normal distribution. In the simplest case, no correlation exists among variables, and elements of the vectors are independent univariate normal random variables.

Because it is easy to work with, the multivariate normal distribution is often used as a model for multivariate data.

Statistics and Machine Learning Toolbox provides several functionalities related to the multivariate normal distribution.

- Generate random numbers from the distribution using `mvnrnd`.
- Evaluate the probability density function (pdf) at specific values using `mvnpdf`.
- Evaluate the cumulative distribution function (cdf) at specific values using `mvncdf`.

Parameters

The multivariate normal distribution uses the parameters in this table.

Parameter	Description	Univariate Normal Analogue
μ	Mean vector	Mean μ (scalar)
Σ	Covariance matrix — Diagonal elements contain the variances for each variable, and off-diagonal elements contain the covariances between variables	Variance σ^2 (scalar)

Note that in the one-dimensional case, Σ is the variance, not the standard deviation. For more information on the parameters of the univariate normal distribution, see “Parameters” on page B-119.

Probability Density Function

The probability density function (pdf) of the d -dimensional multivariate normal distribution is

$$y = f(x, \mu, \Sigma) = \frac{1}{\sqrt{|\Sigma|(2\pi)^d}} \exp\left(-\frac{1}{2}(x-\mu) \Sigma^{-1}(x-\mu)'\right)$$

where x and μ are 1-by- d vectors and Σ is a d -by- d symmetric, positive definite matrix.

Note that Statistics and Machine Learning Toolbox:

- Supports singular Σ for random vector generation only. The pdf cannot be written in the same form when Σ is singular.
- Uses x and μ oriented as row vectors rather than column vectors.

For an example, see “Bivariate Normal Distribution pdf” on page B-99.

Cumulative Distribution Function

The multivariate normal cumulative distribution function (cdf) evaluated at x is defined as the probability that a random vector v , distributed as multivariate normal, lies within the semi-infinite rectangle with upper limits defined by x ,

$$\Pr\{v(1) \leq x(1), v(2) \leq x(2), \dots, v(d) \leq x(d)\}.$$

Although the multivariate normal cdf has no closed form, `mvncdf` can compute cdf values numerically.

For an example, see “Bivariate Normal Distribution cdf” on page B-100.

Examples

Bivariate Normal Distribution pdf

Compute and plot the pdf of a bivariate normal distribution with parameters $\mu = [0 \ 0]$ and $\sigma = [0.25 \ 0.3; \ 0.3 \ 1]$.

Define the parameters μ and σ .

```
mu = [0 0];
sigma = [0.25 0.3; 0.3 1];
```

Create a grid of evenly spaced points in two-dimensional space.

```
x1 = -3:0.2:3;
x2 = -3:0.2:3;
[X1,X2] = meshgrid(x1,x2);
X = [X1(:) X2(:)];
```

Evaluate the pdf of the normal distribution at the grid points.

```
y = mvnpdf(X,mu,sigma);
y = reshape(y,length(x2),length(x1));
```

Plot the pdf values.

```
surf(x1,x2,y)
caxis([min(y(:))-0.5*range(y(:)),max(y(:))])
axis([-3 3 -3 3 0 0.4])
xlabel('x1')
ylabel('x2')
zlabel('Probability Density')
```

Bivariate Normal Distribution cdf

Compute and plot the cdf of a bivariate normal distribution.

Define the mean vector μ and the covariance matrix σ .

```
mu = [1 -1];  
sigma = [.9 .4; .4 .3];
```

Create a grid of 625 evenly spaced points in two-dimensional space.

```
[X1,X2] = meshgrid(linspace(-1,3,25)',linspace(-3,1,25)');  
X = [X1(:) X2(:)];
```

Evaluate the cdf of the normal distribution at the grid points.

```
p = mvncdf(X,mu,sigma);
```

Plot the cdf values.

```
Z = reshape(p,25,25);  
surf(X1,X2,Z)
```

Probability over Rectangular Region

Compute the probability over the unit square of a bivariate normal distribution, and create a contour plot of the results.

Define the bivariate normal distribution parameters μ and σ .

```
mu = [0 0];
sigma = [0.25 0.3; 0.3 1];
```

Compute the probability over the unit square.

```
p = mvncdf([0 0],[1 1],mu,sigma)
p = 0.2097
```

To visualize the result, first create a grid of evenly spaced points in two-dimensional space.

```
x1 = -3:.2:3;
x2 = -3:.2:3;
[X1,X2] = meshgrid(x1,x2);
X = [X1(:) X2(:)];
```

Then, evaluate the pdf of the normal distribution at the grid points.

```
y = mvnpdf(X,mu,sigma);
y = reshape(y,length(x2),length(x1));
```

Finally, create a contour plot of the multivariate normal distribution that includes the unit square.

```
contour(x1,x2,y,[0.0001 0.001 0.01 0.05 0.15 0.25 0.35])  
xlabel('x')  
ylabel('y')  
line([0 0 1 1 0],[1 0 0 1 1], 'LineStyle','--','Color','k')
```

Computing a multivariate cumulative probability requires significantly more work than computing a univariate probability. By default, the `mvncdf` function computes values to less than full machine precision, and returns an estimate of the error as an optional second output. View the error estimate in this case.

```
[p,err] = mvncdf([0 0],[1 1],mu,sigma)
```

```
p = 0.2097
```

```
err = 1.0000e-08
```

“Example” on page B-104

Definition

The probability density function of the d -dimensional multivariate Student's t distribution is given by

$$f(x, \Sigma, \nu) = \frac{1}{|\Sigma|^{1/2}} \frac{1}{\sqrt{(\nu\pi)^d}} \frac{\Gamma((\nu+d)/2)}{\Gamma(\nu/2)} \left(1 + \frac{x \Sigma^{-1} x}{\nu}\right)^{-(\nu+d)/2}.$$

where x is a 1-by- d vector, Σ is a d -by- d symmetric, positive definite matrix, and ν is a positive scalar. While it is possible to define the multivariate Student's t for singular Σ , the density cannot be written as above. For the singular case, only random number generation is supported. Note that while most textbooks define the multivariate Student's t with x oriented as a column vector, for the purposes of data analysis software, it is more convenient to orient x as a row vector, and Statistics and Machine Learning Toolbox software uses that orientation.

Background

The multivariate Student's t distribution is a generalization of the univariate Student's t to two or more variables. It is a distribution for random vectors of correlated variables, each element of which has a univariate Student's t distribution. In the same way as the univariate Student's t distribution can be constructed by dividing a standard univariate normal random variable by the square root of a univariate chi-square random variable, the multivariate Student's t distribution can be constructed by dividing a multivariate normal random vector having zero mean and unit variances by a univariate chi-square random variable.

The multivariate Student's t distribution is parameterized with a correlation matrix, Σ , and a positive scalar degrees of freedom parameter, ν . ν is analogous to the degrees of freedom parameter of a univariate Student's t distribution. The off-diagonal elements of Σ contain the correlations between variables. Note that when Σ is the identity matrix, variables are uncorrelated; however, they are not independent.

The multivariate Student's t distribution is often used as a substitute for the multivariate normal distribution in situations where it is known that the marginal distributions of the individual variables have fatter tails than the normal.

Example

Plot PDF and CDF of Multivariate t-Distribution

Plot the pdf of a bivariate Student's t distribution. You can use this distribution for a higher number of dimensions as well, although visualization is not easy.

```
Rho = [1 .6; .6 1];
nu = 5;
```

```

x1 = -3:.2:3; x2 = -3:.2:3;
[X1,X2] = meshgrid(x1,x2);
F = mvtpdf([X1(:) X2(:)],Rho,nu);
F = reshape(F,length(x2),length(x1));
surf(x1,x2,F);
caxis([min(F(:))-.5*range(F(:)),max(F(:))]);
axis([-3 3 -3 3 0 .2])
xlabel('x1'); ylabel('x2'); zlabel('Probability Density');

```

Plot the cdf of a bivariate Student's t distribution.

```

F = mvtcdf([X1(:) X2(:)],Rho,nu);
F = reshape(F,length(x2),length(x1));
surf(x1,x2,F);
caxis([min(F(:))-.5*range(F(:)),max(F(:))]);
axis([-3 3 -3 3 0 1])
xlabel('x1'); ylabel('x2'); zlabel('Cumulative Probability');

```

Since the bivariate Student's *t* distribution is defined on the plane, you can also compute cumulative probabilities over rectangular regions. For example, this contour plot illustrates the computation that follows, of the probability contained within the unit square shown in the figure.

```
contour(x1,x2,F,[.0001 .001 .01 .05:.1:.95 .99 .999 .9999]);
xlabel('x'); ylabel('y');
line([0 0 1 1 0],[1 0 0 1 1], 'linestyle','--', 'color','k');
```

Compute the value of the probability contained within the unit square.

```
F = mvtcdf([0 0],[1 1],Rho,nu)
```

```
F = 0.1401
```

Computing a multivariate cumulative probability requires significantly more work than computing a univariate probability. By default, the `mvtcdf` function computes values to less than full machine precision and returns an estimate of the error, as an optional second output.

```
[F,err] = mvtcdf([0 0],[1 1],Rho,nu)
```

```
F = 0.1401
```

```
err = 1.0000e-08
```

Nakagami Distribution

In this section...
“Definition” on page B-108
“Background” on page B-108
“Parameters” on page B-108

Definition

The Nakagami distribution has the density function

$$2\left(\frac{\mu}{\omega}\right)^{\mu} \frac{1}{\Gamma(\mu)} x^{(2\mu-1)} e^{-\frac{\mu}{\omega}x^2}$$

with shape parameter μ and scale parameter $\omega > 0$, for $x > 0$. If x has a Nakagami distribution with parameters μ and ω , then x^2 has a gamma distribution with shape parameter μ and scale parameter ω/μ .

Background

In communications theory, Nakagami distributions, Rician distributions on page B-139, and Rayleigh distributions on page B-137 are used to model scattered signals that reach a receiver by multiple paths. Depending on the density of the scatter, the signal will display different fading characteristics. Rayleigh and Nakagami distributions are used to model dense scatters, while Rician distributions model fading with a stronger line-of-sight. Nakagami distributions can be reduced to Rayleigh distributions, but give more control over the extent of the fading.

Parameters

To estimate distribution parameters, use `mle` or the Distribution Fitter app.

Negative Binomial Distribution

In this section...

“Definition” on page B-109

“Background” on page B-109

“Parameters” on page B-109

“Example” on page B-111

Definition

When the r parameter is an integer, the negative binomial pdf is

$$y = f(x | r, p) = \binom{r + x - 1}{x} p^r q^x I_{(0, 1, \dots)}(x)$$

where $q = 1 - p$. When r is not an integer, the binomial coefficient in the definition of the pdf is replaced by the equivalent expression

$$\frac{\Gamma(r + x)}{\Gamma(r)\Gamma(x + 1)}$$

Background

In its simplest form (when r is an integer), the negative binomial distribution models the number of failures x before a specified number of successes is reached in a series of independent, identical trials. Its parameters are the probability of success in a single trial, p , and the number of successes, r . A special case of the negative binomial distribution, when $r = 1$, is the geometric distribution on page B-63, which models the number of failures before the first success.

More generally, r can take on non-integer values. This form of the negative binomial distribution has no interpretation in terms of repeated trials, but, like the Poisson distribution on page B-131, it is useful in modeling count data. The negative binomial distribution is more general than the Poisson distribution because it has a variance that is greater than its mean, making it suitable for count data that do not meet the assumptions of the Poisson distribution. In the limit, as r increases to infinity, the negative binomial distribution approaches the Poisson distribution.

Parameters

Suppose you are collecting data on the number of auto accidents on a busy highway, and would like to be able to model the number of accidents per day. Because these are count data, and because there are a very large number of cars and a small probability of an accident for any specific car, you might think to use the Poisson distribution. However, the probability of having an accident is likely to vary from day to day as the weather and amount of traffic change, and so the assumptions needed for the Poisson distribution are not met. In particular, the variance of this type of count data sometimes exceeds the mean by a large amount. The data below exhibit this effect: most days have few or no accidents, and a few days have a large number.

```
accident = [2 3 4 2 3 1 12 8 14 31 23 1 10 7 0];
m = mean(accident)
```

```
m = 8.0667
```

```
v = var(accident)
```

```
v = 79.3524
```

The negative binomial distribution is more general than the Poisson, and is often suitable for count data when the Poisson is not. The function `nbinfit` returns the maximum likelihood estimates (MLEs) and confidence intervals for the parameters of the negative binomial distribution. Here are the results from fitting the `accident` data:

```
[phat,pci] = nbinfit(accident)
```

```
phat = 1×2
```

```
    1.0060    0.1109
```

```
pci = 2×2
```

```
    0.2152    0.0171  
    1.7968    0.2046
```

It is difficult to give a physical interpretation in this case to the individual parameters. However, the estimated parameters can be used in a model for the number of daily accidents. For example, a plot of the estimated cumulative probability function shows that while there is an estimated 10% chance of no accidents on a given day, there is also about a 10% chance that there will be 20 or more accidents.

```
plot(0:50,nbincdf(0:50,phat(1),phat(2)),'.-');  
xlabel('Accidents per Day')  
ylabel('Cumulative Probability')
```

Example

Compute and Plot Negative Binomial Distribution PDF

Compute and plot the pdf using four different values for the parameter r , the desired number of successes: .1, 1, 3, and 6. In each case, the probability of success p is .5.

```
x = 0:10;
plot(x,nbinpdf(x,.1,.5),'s-', ...
      x,nbinpdf(x,1,.5),'o-', ...
      x,nbinpdf(x,3,.5),'d-', ...
      x,nbinpdf(x,6,.5),'^-');
legend({'r = .1' 'r = 1' 'r = 3' 'r = 6'})
xlabel('x')
ylabel('f(x|r,p)')
```

The plot shows that the negative binomial distribution can take on a variety of shapes, ranging from very skewed to nearly symmetric, depending on the value of r .

Noncentral Chi-Square Distribution

In this section...

“Definition” on page B-113

“Background” on page B-113

“Examples” on page B-113

Definition

There are many equivalent formulas for the noncentral chi-square distribution function. One formulation uses a modified Bessel function of the first kind. Another uses the generalized Laguerre polynomials. The cumulative distribution function is computed using a weighted sum of χ^2 probabilities with the weights equal to the probabilities of a Poisson distribution. The Poisson parameter is one-half of the noncentrality parameter of the noncentral chi-square

$$F(x | \nu, \delta) = \sum_{j=0}^{\infty} \left(\frac{\left(\frac{1}{2}\delta\right)^j}{j!} e^{-\frac{\delta}{2}} \right) \Pr[\chi_{\nu+2j}^2 \leq x]$$

where δ is the noncentrality parameter.

Background

The χ^2 distribution is actually a simple special case of the noncentral chi-square distribution. One way to generate random numbers with a χ^2 distribution (with ν degrees of freedom) is to sum the squares of ν standard normal random numbers (mean equal to zero.)

What if the normally distributed quantities have a mean other than zero? The sum of squares of these numbers yields the noncentral chi-square distribution. The noncentral chi-square distribution requires two parameters: the degrees of freedom and the noncentrality parameter. The noncentrality parameter is the sum of the squared means of the normally distributed quantities.

The noncentral chi-square has scientific application in thermodynamics and signal processing. The literature in these areas may refer to it as the “Rician Distribution” on page B-139 or generalized “Rayleigh Distribution” on page B-137.

Examples

Compute Noncentral Chi-Square Distribution pdf

Compute the pdf of a noncentral chi-square distribution with degrees of freedom $V = 4$ and noncentrality parameter $\text{DELTA} = 2$. For comparison, also compute the pdf of a chi-square distribution with the same degrees of freedom.

```
x = (0:0.1:10)';
ncx2 = ncx2pdf(x,4,2);
chi2 = chi2pdf(x,4);
```

Plot the pdf of the noncentral chi-square distribution on the same figure as the pdf of the chi-square distribution.

```
figure;  
plot(x,ncx2,'b-','LineWidth',2)  
hold on  
plot(x,chi2,'g--','LineWidth',2)  
legend('ncx2','chi2')
```

Noncentral F Distribution

In this section...

“Definition” on page B-115

“Background” on page B-115

“Examples” on page B-115

Definition

Similar to the noncentral χ^2 distribution, the toolbox calculates noncentral F distribution probabilities as a weighted sum of incomplete beta functions using Poisson probabilities as the weights.

$$F(x | \nu_1, \nu_2, \delta) = \sum_{j=0}^{\infty} \left(\frac{\left(\frac{1}{2}\delta\right)^j}{j!} e^{-\frac{\delta}{2}} \right) I\left(\frac{\nu_1 \cdot x}{\nu_2 + \nu_1 \cdot x} \middle| \frac{\nu_1}{2} + j, \frac{\nu_2}{2}\right)$$

$I(x|a,b)$ is the incomplete beta function with parameters a and b , and δ is the noncentrality parameter.

Background

As with the χ^2 distribution, the F distribution is a special case of the noncentral F distribution. The F distribution is the result of taking the ratio of χ^2 random variables each divided by its degrees of freedom.

If the numerator of the ratio is a noncentral chi-square random variable divided by its degrees of freedom, the resulting distribution is the noncentral F distribution.

The main application of the noncentral F distribution is to calculate the power of a hypothesis test relative to a particular alternative.

Examples

Compute Noncentral F Distribution pdf

Compute the pdf of a noncentral F distribution with degrees of freedom $\text{NU1} = 5$ and $\text{NU2} = 20$, and noncentrality parameter $\text{DELTA} = 10$. For comparison, also compute the pdf of an F distribution with the same degrees of freedom.

```
x = (0.01:0.1:10.01)';
p1 = ncfpdf(x,5,20,10);
p = fpdf(x,5,20);
```

Plot the pdf of the noncentral F distribution and the pdf of the F distribution on the same figure.

```
figure;
plot(x,p1,'b-','LineWidth',2)
hold on
plot(x,p,'g--','LineWidth',2)
legend('Noncentral F','F distribution')
```

Noncentral t Distribution

In this section...

“Definition” on page B-117

“Background” on page B-117

“Examples” on page B-117

Definition

The most general representation of the noncentral t distribution is quite complicated. Johnson and Kotz [66] give a formula for the probability that a noncentral t variate falls in the range $[-u, u]$.

$$P(-u < x < u | \nu, \delta) = \sum_{j=0}^{\infty} \left(\frac{\left(\frac{1}{2}\delta^2\right)^j}{j!} e^{-\frac{\delta^2}{2}} \right) I\left(\frac{u^2}{\nu + u^2} \middle| \frac{1}{2} + j, \frac{\nu}{2}\right)$$

$I(x|\nu, \delta)$ is the incomplete beta function with parameters ν and δ . δ is the noncentrality parameter, and ν is the number of degrees of freedom.

Background

The noncentral t distribution is a generalization of Student's t distribution.

Student's t distribution with $n - 1$ degrees of freedom models the t -statistic

$$t = \frac{\bar{x} - \mu}{s/\sqrt{n}}$$

where \bar{x} is the sample mean and s is the sample standard deviation of a random sample of size n from a normal population with mean μ . If the population mean is actually μ_0 , then the t -statistic has a noncentral t distribution with noncentrality parameter

$$\delta = \frac{\mu_0 - \mu}{\sigma/\sqrt{n}}$$

The noncentrality parameter is the normalized difference between μ_0 and μ .

The noncentral t distribution gives the probability that a t test will correctly reject a false null hypothesis of mean μ when the population mean is actually μ_0 ; that is, it gives the power of the t test. The power increases as the difference $\mu_0 - \mu$ increases, and also as the sample size n increases.

Examples

Compute Noncentral t Distribution pdf

Compute the pdf of a noncentral t distribution with degrees of freedom $V = 10$ and noncentrality parameter $\text{DELTA} = 1$. For comparison, also compute the pdf of a t distribution with the same degrees of freedom.

```
x = (-5:0.1:5)';  
nct = nctpdf(x,10,1);  
t = tpdf(x,10);
```

Plot the pdf of the noncentral t distribution and the pdf of the t distribution on the same figure.

```
plot(x,nct,'b-','LineWidth',2)  
hold on  
plot(x,t,'g--','LineWidth',2)  
legend('nct','t')
```

Normal Distribution

In this section...

“Overview” on page B-119
 “Parameters” on page B-119
 “Probability Density Function” on page B-120
 “Cumulative Distribution Function” on page B-120
 “Examples” on page B-121
 “Related Distributions” on page B-127

Overview

The normal distribution, sometimes called the Gaussian distribution, is a two-parameter family of curves. The usual justification for using the normal distribution for modeling is the Central Limit theorem, which states (roughly) that the sum of independent samples from any distribution with finite mean and variance converges to the normal distribution as the sample size goes to infinity.

Statistics and Machine Learning Toolbox offers several ways to work with the normal distribution.

- Create a probability distribution object `NormalDistribution` by fitting a probability distribution to sample data (`fitdist`) or by specifying parameter values (`makedist`). Then, use object functions to evaluate the distribution, generate random numbers, and so on.
- Work with the normal distribution interactively by using the **Distribution Fitter** app. You can export an object from the app and use the object functions.
- Use distribution-specific functions (`normcdf`, `normpdf`, `norminv`, `normlike`, `normstat`, `normfit`, `normrnd`) with specified distribution parameters. The distribution-specific functions can accept parameters of multiple normal distributions.
- Use generic distribution functions (`cdf`, `icdf`, `pdf`, `random`) with a specified distribution name (`'Normal'`) and parameters.

Parameters

The normal distribution uses these parameters.

Parameter	Description	Support
μ (μ)	Mean	$-\infty < \mu < \infty$
σ (σ)	Standard deviation	$\sigma \geq 0$

The standard normal distribution has zero mean and unit standard deviation. If z is standard normal, then $\sigma z + \mu$ is also normal with mean μ and standard deviation σ . Conversely, if x is normal with mean μ and standard deviation σ , then $z = (x - \mu) / \sigma$ is standard normal.

Parameter Estimation

The *maximum likelihood estimates* (MLEs) are the parameter estimates that maximize the likelihood function. The maximum likelihood estimators of μ and σ^2 for the normal distribution, respectively, are

$$\bar{x} = \sum_{i=1}^n \frac{x_i}{n}$$

and

$$s_{\text{MLE}}^2 = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2.$$

\bar{x} is the sample mean for samples x_1, x_2, \dots, x_n . The sample mean is an unbiased estimator of the parameter μ . However, s_{MLE}^2 is a biased estimator of the parameter σ^2 , meaning that its expected value does not equal the parameter.

The *minimum variance unbiased estimator* (MVUE) is commonly used to estimate the parameters of the normal distribution. The MVUE is the estimator that has the minimum variance of all unbiased estimators of a parameter. The MVUEs of the parameters μ and σ^2 for the normal distribution are the sample mean \bar{x} and sample variance s^2 , respectively.

$$s^2 = \frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})^2$$

To fit the normal distribution to data and find the parameter estimates, use `normfit`, `fitdist`, or `mle`.

- For uncensored data, `normfit` and `fitdist` find the unbiased estimates, and `mle` finds the maximum likelihood estimates.
- For censored data, `normfit`, `fitdist`, and `mle` find the maximum likelihood estimates.

Unlike `normfit` and `mle`, which return parameter estimates, `fitdist` returns the fitted probability distribution object `NormalDistribution`. The object properties `mu` and `sigma` store the parameter estimates.

For an example, see “Fit Normal Distribution Object” on page B-121.

Probability Density Function

The normal probability density function (pdf) is

$$y = f(x) \left| \mu, \sigma \right. = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}, \quad \text{for } x \in \mathbb{R}.$$

The *likelihood function* is the pdf viewed as a function of the parameters. The maximum likelihood estimates (MLEs) are the parameter estimates that maximize the likelihood function for fixed values of x .

For an example, see “Compute and Plot the Normal Distribution pdf” on page B-121.

Cumulative Distribution Function

The normal cumulative distribution function (cdf) is

$$p = F(x) \left| \mu, \sigma \right. = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{(t-\mu)^2}{2\sigma^2}} dt, \quad \text{for } x \in \mathbb{R}.$$

p is the probability that a single observation from a normal distribution with parameters μ and σ falls in the interval $(-\infty, x]$.

The standard normal cumulative distribution function $\Phi(x)$ is functionally related to the error function erf .

$$\Phi(x) = \frac{1}{2} \left(1 - \text{erf} \left(-\frac{x}{\sqrt{2}} \right) \right)$$

where

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt = 2\Phi(\sqrt{2}x) - 1.$$

For an example, see “Plot Standard Normal Distribution cdf” on page B-122

Examples

Fit Normal Distribution Object

Load the sample data and create a vector containing the first column of student exam grade data.

```
load examgrades
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x, 'Normal')

pd =
    NormalDistribution

    Normal distribution
        mu = 75.0083    [73.4321, 76.5846]
        sigma = 8.7202    [7.7391, 9.98843]
```

The intervals next to the parameter estimates are the 95% confidence intervals for the distribution parameters.

Compute and Plot the Normal Distribution pdf

Compute the pdf of a standard normal distribution, with parameters μ equal to 0 and σ equal to 1.

```
x = [-3:.1:3];
y = normpdf(x,0,1);
```

Plot the pdf.

```
plot(x,y)
```

**Plot Standard Normal Distribution cdf**

Create a standard normal distribution object.

```
pd = makedist('Normal')
```

```
pd =  
  NormalDistribution  
  
  Normal distribution  
    mu = 0  
    sigma = 1
```

Specify the x values and compute the cdf.

```
x = -3:.1:3;  
p = cdf(pd,x);
```

Plot the cdf of the standard normal distribution.

```
plot(x,p)
```

Compare Gamma and Normal Distribution pdfs

The gamma distribution has the shape parameter a and the scale parameter b . For a large a , the gamma distribution closely approximates the normal distribution with mean $\mu = ab$ and variance $\sigma^2 = ab^2$.

Compute the pdf of a gamma distribution with parameters $a = 100$ and $b = 5$.

```
a = 100;
b = 5;
x = 250:750;
y_gam = gampdf(x,a,b);
```

For comparison, compute the mean, standard deviation, and pdf of the normal distribution that gamma approximates.

```
mu = a*b
mu = 500

sigma = sqrt(a*b^2)
sigma = 50

y_norm = normpdf(x,mu,sigma);
```

Plot the pdfs of the gamma distribution and the normal distribution on the same figure.

```

plot(x,y_gam,'-',x,y_norm,'-.')
title('Gamma and Normal pdfs')
xlabel('Observation')
ylabel('Probability Density')
legend('Gamma Distribution','Normal Distribution')

```

The pdf of the normal distribution approximates the pdf of the gamma distribution.

Relationship Between Normal and Lognormal Distributions

If X follows the lognormal distribution with parameters μ and σ , then $\log(X)$ follows the normal distribution with mean μ and standard deviation σ . Use distribution objects to inspect the relationship between normal and lognormal distributions.

Create a lognormal distribution object by specifying the parameter values.

```

pd = makedist('Lognormal','mu',5,'sigma',2)

pd =
  LognormalDistribution

  Lognormal distribution
    mu = 5
    sigma = 2

```

Compute the mean of the lognormal distribution.

```
mean(pd)
```

```
ans = 1.0966e+03
```

The mean of the lognormal distribution is not equal to the μ parameter. The mean of the logarithmic values is equal to μ . Confirm this relationship by generating random numbers.

Generate random numbers from the lognormal distribution and compute their log values.

```
rng('default'); % For reproducibility
x = random(pd,10000,1);
logx = log(x);
```

Compute the mean of the logarithmic values.

```
m = mean(logx)
```

```
m = 5.0033
```

The mean of the log of x is close to the μ parameter of x , because x has a lognormal distribution.

Construct a histogram of $\log x$ with a normal distribution fit.

```
histfit(logx)
```

The plot shows that the log values of x are normally distributed.

`histfit` uses `fitdist` to fit a distribution to data. Use `fitdist` to obtain parameters used in fitting.

```
pd_normal = fitdist(logx, 'Normal')
pd_normal =
  NormalDistribution

  Normal distribution
    mu = 5.00332    [4.96445, 5.04219]
    sigma = 1.98296 [1.95585, 2.01083]
```

The estimated normal distribution parameters are close to the lognormal distribution parameters 5 and 2.

Compare Student's t and Normal Distribution pdfs

The Student's t distribution is a family of curves depending on a single parameter ν (the degrees of freedom). As the degrees of freedom ν approach infinity, the t distribution approaches the standard normal distribution.

Compute the pdfs for the Student's t distribution with the parameter $\nu = 5$ and the Student's t distribution with the parameter $\nu = 15$.

```
x = [-5:0.1:5];
y1 = tpdf(x,5);
y2 = tpdf(x,15);
```

Compute the pdf for a standard normal distribution.

```
z = normpdf(x,0,1);
```

Plot the Student's t pdfs and the standard normal pdf on the same figure.

```
plot(x,y1,'-.',x,y2,'--',x,z,'-')
legend('Student's t Distribution with \nu=5', ...
       'Student's t Distribution with \nu=15', ...
       'Standard Normal Distribution','Location','best')
xlabel('Observation')
ylabel('Probability Density')
title('Student's t and Standard Normal pdfs')
```

The standard normal pdf has shorter tails than the Student's t pdfs.

Related Distributions

- “Binomial Distribution” on page B-10 — The binomial distribution models the total number of successes in n repeated trials with the probability of success p . As n increases, the binomial distribution can be approximated by a normal distribution with $\mu = np$ and $\sigma^2 = np(1-p)$. See “Compare Binomial and Normal Distribution pdfs” on page B-14.
- “Birnbbaum-Saunders Distribution” on page B-18 — If x has a Birnbbaum-Saunders distribution with parameters β and γ , then

$$\frac{(\sqrt{x/\beta} - \sqrt{\beta/x})}{\gamma}$$

has a standard normal distribution.

- “Chi-Square Distribution” on page B-28 — The chi-square distribution is the distribution of the sum of squared, independent, standard normal random variables. If a set of n observations is normally distributed with variance σ^2 , and s^2 is the sample variance, then $(n-1)s^2/\sigma^2$ has a chi-square distribution with $n-1$ degrees of freedom. The `normfit` function uses this relationship to calculate confidence intervals for the estimate of the normal parameter σ^2 .
- “Extreme Value Distribution” on page B-40 — The extreme value distribution is appropriate for modeling the smallest or largest value from a distribution whose tails decay exponentially fast, such as, the normal distribution.

- “Gamma Distribution” on page B-47 — The gamma distribution has the shape parameter a and the scale parameter b . For a large a , the gamma distribution closely approximates the normal distribution with mean $\mu = ab$ and variance $\sigma^2 = ab^2$. The gamma distribution has density only for positive real numbers. See “Compare Gamma and Normal Distribution pdfs” on page B-123.
- “Half-Normal Distribution” on page B-68 — The half-normal distribution is a special case of the folded normal and truncated normal distributions. If a random variable Z has a standard normal distribution, then $X = \mu + \sigma|Z|$ has a half-normal distribution with parameters μ and σ .
- “Logistic Distribution” on page B-85 — The logistic distribution is used for growth models and in logistic regression. It has longer tails and a higher kurtosis than the normal distribution.
- “Lognormal Distribution” on page B-88 — If X follows the lognormal distribution with parameters μ and σ , then $\log(X)$ follows the normal distribution with mean μ and standard deviation σ . See “Relationship Between Normal and Lognormal Distributions” on page B-124.
- “Multivariate Normal Distribution” on page B-98 — The multivariate normal distribution is a generalization of the univariate normal to two or more variables. It is a distribution for random vectors of correlated variables, in which each element has a univariate normal distribution. In the simplest case, there is no correlation among variables, and elements of the vectors are independent, univariate normal random variables.
- “Poisson Distribution” on page B-131 — The Poisson distribution is a one-parameter discrete distribution that takes nonnegative integer values. The parameter, λ , is both the mean and the variance of the distribution. As λ increase, the Poisson distribution can be approximated by a normal distribution with $\mu = \lambda$ and $\sigma^2 = \lambda$.
- “Rayleigh Distribution” on page B-137 — The Rayleigh distribution is a special case of the Weibull distribution with applications in communications theory. If the component velocities of a particle in the x and y directions are two independent normal random variables with zero means and equal variances, then the distance the particle travels per unit time follows the Rayleigh distribution.
- “Stable Distribution” on page B-140 — The normal distribution is a special case of the stable distribution. The stable distribution with the first shape parameter $\alpha = 2$ corresponds to the normal distribution.

$$N(\mu, \sigma^2) = S\left(2, 0, \frac{\sigma}{\sqrt{2}}, \mu\right).$$

- “Student's t Distribution” on page B-149 — The Student's t distribution is a family of curves depending on a single parameter ν (the degrees of freedom). As the degrees of freedom ν goes to infinity, the t distribution approaches the standard normal distribution. See “Compare Student's t and Normal Distribution pdfs” on page B-126.

If x is a random sample of size n from a normal distribution with mean μ , then the statistic

$$t = \frac{\bar{x} - \mu}{s/\sqrt{n}}$$

where \bar{x} is the sample mean and s is the sample standard deviation, has the Student's t distribution with $n-1$ degrees of freedom.

- “ t Location-Scale Distribution” on page B-156 — The t location-scale distribution is useful for modeling data distributions with heavier tails (more prone to outliers) than the normal distribution. It approaches the normal distribution as the shape parameter ν approaches infinity.

Piecewise Linear Distribution

In this section...
“Overview” on page B-130
“Parameters” on page B-130
“Cumulative Distribution Function” on page B-130
“Relationship to Other Distributions” on page B-130

Overview

The piecewise linear distribution creates a nonparametric representation of the cumulative distribution function (cdf) by linearly connecting the known cdf values from the sample data.

Parameters

The piecewise linear distribution uses the following parameters.

Parameter	Description
x	Vector of x values at which the cdf changes slope
F_x	Vector of cdf values that correspond to each value in x

Cumulative Distribution Function

The piecewise linear distribution constructs a continuous cumulative distribution function (cdf) by connecting the empirical cdf values such that the cdf increases linearly between $x(j)$ and $x(j + 1)$.

Relationship to Other Distributions

The piecewise linear distribution is a continuous version of the discrete empirical cumulative distribution function (ecdf).

Poisson Distribution

In this section...

“Overview” on page B-131
 “Parameters” on page B-131
 “Probability Density Function” on page B-131
 “Cumulative Distribution Function” on page B-132
 “Examples” on page B-132
 “Related Distributions” on page B-135

Overview

The Poisson distribution is a one-parameter family of curves that models the number of times a random event occurs. This distribution is appropriate for applications that involve counting the number of times a random event occurs in a given amount of time, distance, area, and so on. Sample applications that involve Poisson distributions include the number of Geiger counter clicks per second, the number of people walking into a store in an hour, and the number of packets lost over a network per minute.

Statistics and Machine Learning Toolbox offers several ways to work with the Poisson distribution.

- Create a probability distribution object `PoissonDistribution` by fitting a probability distribution to sample data or by specifying parameter values. Then, use object functions to evaluate the distribution, generate random numbers, and so on.
- Work with the Poisson distribution interactively by using the **Distribution Fitter** app. You can export an object from the app and use the object functions.
- Use distribution-specific functions (`poisscdf`, `poisspdf`, `poissinv`, `poisstat`, `poissfit`, `poissrnd`) with specified distribution parameters. The distribution-specific functions can accept parameters of multiple Poisson distributions.
- Use generic distribution functions (`cdf`, `icdf`, `pdf`, `random`) with a specified distribution name ('Poisson') and parameters.

Parameters

The Poisson distribution uses the following parameter.

Parameter	Description	Support
lambda (λ)	Mean	$\lambda \geq 0$

The parameter λ is also equal to the variance of the Poisson distribution.

The sum of two Poisson random variables with parameters λ_1 and λ_2 is a Poisson random variable with parameter $\lambda = \lambda_1 + \lambda_2$.

Probability Density Function

The probability density function (pdf) of the Poisson distribution is

$$f(x|\lambda) = \frac{\lambda^x}{x!} e^{-\lambda}; x = 0, 1, 2, \dots, \infty .$$

The result is the probability of exactly x occurrences of the random event. For discrete distributions, the pdf is also known as the probability mass function (pdf).

For an example, see “Compute Poisson Distribution pdf” on page B-132.

Cumulative Distribution Function

The cumulative distribution function (cdf) of the Poisson distribution is

$$p = F(x|\lambda) = e^{-\lambda} \sum_{i=0}^{\text{floor}(x)} \frac{\lambda^i}{i!} .$$

The result is the probability of at most x occurrences of the random event.

For an example, see “Compute Poisson Distribution cdf” on page B-133.

Examples

Compute Poisson Distribution pdf

Compute the pdf of the Poisson distribution with parameter `lambda = 4`.

```
x = 0:15;  
y = poisspdf(x,4);
```

Plot the pdf with bars of width 1.

```
figure  
bar(x,y,1)  
xlabel('Observation')  
ylabel('Probability')
```

Compute Poisson Distribution cdf

Compute the cdf of the Poisson distribution with parameter $\lambda = 4$.

```
x = 0:15;  
y = poisscdf(x,4);
```

Plot the cdf.

```
figure  
stairs(x,y)  
xlabel('Observation')  
ylabel('Cumulative Probability')
```

Compare Poisson and Normal Distribution pdfs

When λ is large, the Poisson distribution can be approximated by the normal distribution with mean λ and variance λ .

Compute the pdf of the Poisson distribution with parameter $\lambda = 50$.

```
lambda = 50;  
x1 = 0:100;  
y1 = poisspdf(x1,lambda);
```

Compute the pdf of the corresponding normal distribution.

```
mu = lambda;  
sigma = sqrt(lambda);  
x2 = 0:0.1:100;  
y2 = normpdf(x2,mu,sigma);
```

Plot the pdfs on the same axis.

```
figure  
bar(x1,y1,1)  
hold on  
plot(x2,y2,'LineWidth',2)  
xlabel('Observation')  
ylabel('Probability')  
title('Poisson and Normal pdfs')
```

```
legend('Poisson Distribution', 'Normal Distribution', 'location', 'northwest')
hold off
```

The pdf of the normal distribution closely approximates the pdf of the Poisson distribution.

Related Distributions

- “Binomial Distribution” on page B-10 — The binomial distribution is a two-parameter discrete distribution that counts the number of successes in N independent trials with the probability of success p . The Poisson distribution is the limiting case of a binomial distribution where N approaches infinity and p goes to zero while $Np = \lambda$. See “Compare Binomial and Poisson Distribution pdfs” on page B-15.
- “Exponential Distribution” on page B-33 — The exponential distribution is a one-parameter continuous distribution that has parameter μ (mean). The Poisson distribution models counts of the number of times a random event occurs in a given amount of time. In such a model, the amount of time between occurrences is modeled by the exponential distribution with mean $\frac{1}{\lambda}$.
- “Normal Distribution” on page B-119 — The normal distribution is a two-parameter continuous distribution that has parameters μ (mean) and σ (standard deviation). When λ is large, the Poisson distribution can be approximated by the normal distribution with $\mu = \lambda$ and $\sigma^2 = \lambda$. See “Compare Poisson and Normal Distribution pdfs” on page B-134.

Rayleigh Distribution

In this section...

“Definition” on page B-137

“Background” on page B-137

“Parameters” on page B-137

“Examples” on page B-137

Definition

The Rayleigh pdf is

$$y = f(x|b) = \frac{x}{b^2} e^{\left(\frac{-x^2}{2b^2}\right)}$$

Background

The Rayleigh distribution is a special case of the Weibull distribution on page B-170. If A and B are the parameters of the Weibull distribution, then the Rayleigh distribution with parameter b is equivalent to the Weibull distribution with parameters $A = \sqrt{2}b$ and $B = 2$.

If the component velocities of a particle in the x and y directions are two independent normal random variables with zero means and equal variances, then the distance the particle travels per unit time is distributed Rayleigh.

In communications theory, Nakagami distributions on page B-108, Rician distributions on page B-139, and Rayleigh distributions are used to model scattered signals that reach a receiver by multiple paths. Depending on the density of the scatter, the signal will display different fading characteristics. Rayleigh and Nakagami distributions are used to model dense scatters, while Rician distributions model fading with a stronger line-of-sight. Nakagami distributions can be reduced to Rayleigh distributions, but give more control over the extent of the fading.

Parameters

The `raylfit` function returns the MLE of the Rayleigh parameter. This estimate is

$$b = \sqrt{\frac{1}{2n} \sum_{i=1}^n x_i^2}$$

Examples

Compute and Plot Rayleigh Distribution pdf

Compute the pdf of a Rayleigh distribution with parameter $B = 0.5$.

```
x = [0:0.01:2];
p = raylpdf(x,0.5);
```

Plot the pdf.

```
figure;  
plot(x,p)
```

Rician Distribution

In this section...

“Definition” on page B-139

“Background” on page B-139

“Parameters” on page B-139

Definition

The Rician distribution has the density function

$$I_0\left(\frac{x s}{\sigma^2}\right) \frac{x}{\sigma^2} e^{-\left(\frac{x^2 + s^2}{2\sigma^2}\right)}$$

with noncentrality parameter $s \geq 0$ and scale parameter $\sigma > 0$, for $x > 0$. I_0 is the zero-order modified Bessel function of the first kind. If x has a Rician distribution with parameters s and σ , then $(x/\sigma)^2$ has a noncentral chi-square distribution with two degrees of freedom and noncentrality parameter $(s/\sigma)^2$.

Background

In communications theory, Nakagami distributions on page B-108, Rician distributions, and Rayleigh distributions on page B-137 are used to model scattered signals that reach a receiver by multiple paths. Depending on the density of the scatter, the signal will display different fading characteristics. Rayleigh and Nakagami distributions are used to model dense scatters, while Rician distributions model fading with a stronger line-of-sight. Nakagami distributions can be reduced to Rayleigh distributions, but give more control over the extent of the fading.

Parameters

To estimate distribution parameters, use `mle` or the Distribution Fitter app.

Stable Distribution

In this section...
“Overview” on page B-140
“Parameters” on page B-140
“Probability Density Function” on page B-141
“Cumulative Distribution Function” on page B-143
“Descriptive Statistics” on page B-145
“Relationship to Other Distributions” on page B-146

Overview

Stable distributions are a class of probability distributions suitable for modeling heavy tails and skewness. A linear combination of two independent, identically-distributed stable-distributed random variables has the same distribution as the individual variables. In other words, if X_1, X_2, \dots, X_n are independent and identically distributed stable random variables, then for every n

$$X_1 + X_2 + \dots + X_n \stackrel{d}{=} c_n X + d_n$$

where the constant $c_n > 0$ and $d_n \in \mathbb{R}$.

The stable distribution is an application of the Generalized Central Limit Theorem, which states that the limit of normalized sums of independent identically distributed variables is stable.

Several different parameterizations exist for the stable distribution. The implementation in Statistics and Machine Learning Toolbox uses the parameterization described in [2]. In this case, a random variable X has the stable distribution $S(\alpha, \beta, \gamma, \delta_0; 0)$ if its characteristic function is given by:

$$E(e^{itX}) = \begin{cases} \exp\left(-\gamma^\alpha |t|^\alpha \left[1 + i\beta \text{sign}(t) \tan\frac{\pi\alpha}{2} \left((\gamma|t|)^{1-\alpha} - 1\right)\right] + i\delta_0 t\right) & \text{for } \alpha \neq 1, \\ \exp\left(-\gamma |t| \left[1 + i\beta \text{sign}(t) \frac{2}{\pi} \ln(\gamma|t|)\right] + i\delta_0 t\right) & \text{for } \alpha = 1 \end{cases}$$

Parameters

The stable distribution uses the following parameters.

Parameter	Description	Support
alpha	First shape parameter	$0 < \alpha \leq 2$
beta	Second shape parameter	$-1 \leq \beta \leq 1$
gam	Scale parameter	$0 < \gamma < \infty$
delta	Location parameter	$-\infty < \delta < \infty$

The first shape parameter, α , describes the tails of the distribution. The software computes the densities of the stable distribution using the direct integration method. As explained in [1], numerical difficulties exist with accurately computing the pdf and cdf when the α parameter is close to 1 or 0. If

α is close to 1 (specifically, $0 < |\alpha - 1| < 0.02$), then the software rounds α to 1. If α is close to 0, then the densities may not be accurate.

The second shape parameter, β , describes the skewness of the distribution. If $\beta = 0$, then the distribution is symmetric. If $\beta > 0$, then the distribution is right-skewed. If $\beta < 0$, then the distribution is left-skewed. When α is small, the skewness of β is significant. As α increases, the effect of β decreases.

Probability Density Function

Definition

Most members of the stable distribution family do not have an explicit probability density function (pdf). Instead, the pdf is described in terms of the characteristic function [2].

Some special cases of the stable distribution, such as the normal, Cauchy, and Lévy distributions, have closed-form density functions. See Relationship to Other Distributions on page B-146 for more information.

Use `pdf` to calculate the probability density function for the stable distribution. The software computes the pdf using the direct integration method. As explained in [1], numerical difficulties exist with accurately computing the pdf when the α parameter is close to 1 or 0. If α is close to 1 (specifically, $0 < |\alpha - 1| < 0.02$), then the software rounds α to 1. If α is close to 0, then the densities may not be accurate.

Compare PDFs of Stable Distributions

The following plot compares the probability density functions for stable distributions with different alpha values. In each case, $\beta = 0$, $\text{gam} = 1$, and $\text{delta} = 0$.

```
pd1 = makedist('Stable','alpha',2,'beta',0,'gam',1,'delta',0);
pd2 = makedist('Stable','alpha',1,'beta',0,'gam',1,'delta',0);
pd3 = makedist('Stable','alpha',0.5,'beta',0,'gam',1,'delta',0);
```

Calculate the pdf for each distribution.

```
x = -5:.1:5;
pdf1 = pdf(pd1,x);
pdf2 = pdf(pd2,x);
pdf3 = pdf(pd3,x);
```

Plot all three pdf functions on the same figure for visual comparison.

```
figure
plot(x,pdf1,'b-');
hold on
plot(x,pdf2,'r-.');
plot(x,pdf3,'k--');
title('Compare Alpha Parameters in Stable Distribution PDF Plots')
legend('\alpha = 2','\alpha = 1','\alpha = 0.5','Location','northwest')
hold off
```

The plot illustrates the effect of the α parameter on the tails of the distribution.

The next plot compares the probability density functions for stable distributions with different β values. In each case, $\alpha = 0.5$, $\gamma = 1$, and $\delta = 0$.

```
pd1 = makedist('Stable', 'alpha', 0.5, 'beta', 0, 'gam', 1, 'delta', 0);
pd2 = makedist('Stable', 'alpha', 0.5, 'beta', 0.5, 'gam', 1, 'delta', 0);
pd3 = makedist('Stable', 'alpha', 0.5, 'beta', 1, 'gam', 1, 'delta', 0);
```

Calculate the pdf for each distribution.

```
x = -5:.1:5;
pdf1 = pdf(pd1,x);
pdf2 = pdf(pd2,x);
pdf3 = pdf(pd3,x);
```

Plot all three pdf functions on the same figure for visual comparison.

```
figure
plot(x,pdf1, 'b-');
hold on
plot(x,pdf2, 'r-.');
plot(x,pdf3, 'k--');
title('Compare Beta Parameters in Stable Distribution PDF Plots')
legend('\beta = 0', '\beta = 0.5', '\beta = 1', 'Location', 'northwest')
hold off
```

Random Number Generation

Use `random` to generate random numbers from the stable distribution. The software generates random numbers for the stable distribution using the method proposed in [3]

Cumulative Distribution Function

Definition

Most members of the stable distribution family do not have an explicit cumulative distribution function (cdf). Instead, the cdf is described in terms of the characteristic function [2].

Use `cdf` to calculate the cumulative distribution function for the stable distribution. The software computes the cdf using the direct integration method. As explained in [1], numerical difficulties exist with accurately computing the cdf when the α parameter is close to 1 or 0. If α is close to 1 (specifically, $0 < |\alpha - 1| < 0.02$), then the software rounds α to 1. If α is close to 0, then the densities may not be accurate.

Compare CDFs of Stable Distributions

The following plot compares the cumulative distribution functions for stable distributions with different alpha values. In each case, $\beta = 0$, $\text{gam} = 1$, and $\text{delta} = 0$.

```
pd1 = makedist('Stable', 'alpha', 2, 'beta', 0, 'gam', 1, 'delta', 0);  
pd2 = makedist('Stable', 'alpha', 1, 'beta', 0, 'gam', 1, 'delta', 0);  
pd3 = makedist('Stable', 'alpha', 0.5, 'beta', 0, 'gam', 1, 'delta', 0);
```

Calculate the cdf for each distribution.

```
x = -5:.1:5;  
cdf1 = cdf(pd1,x);  
cdf2 = cdf(pd2,x);  
cdf3 = cdf(pd3,x);
```

Plot all three cdf functions on the same figure for visual comparison.

```
figure  
plot(x,cdf1,'b-');  
hold on  
plot(x,cdf2,'r-.');  
plot(x,cdf3,'k--');  
title('Compare Alpha Parameters in Stable Distribution CDF Plots')  
legend('\alpha = 2', '\alpha = 1', '\alpha = 0.5', 'Location', 'northwest')  
hold off
```

The plot illustrates the effect of the alpha parameter on the shape of the cdf.

The next plot compares the cumulative distribution functions for stable distributions with different beta values. In all cases, alpha = 0.5, gam = 1, and delta = 0.

```
pd1 = makedist('Stable', 'alpha', 0.5, 'beta', 0, 'gam', 1, 'delta', 0);
pd2 = makedist('Stable', 'alpha', 0.5, 'beta', 0.5, 'gam', 1, 'delta', 0);
pd3 = makedist('Stable', 'alpha', 0.5, 'beta', 1, 'gam', 1, 'delta', 0);
```

Calculate the cdf for each distribution.

```
x = -5:.1:5;
cdf1 = cdf(pd1,x);
cdf2 = cdf(pd2,x);
cdf3 = cdf(pd3,x);
```

Plot all three pdf functions on the same figure for visual comparison.

```
figure
plot(x,cdf1,'b-');
hold on
plot(x,cdf2,'r-.');
plot(x,cdf3,'k--');
title('Compare Beta Parameters in Stable Distribution CDF Plots')
legend('\beta = 0', '\beta = 0.5', '\beta = 1', 'Location', 'northwest')
hold off
```

Descriptive Statistics

The mean of the stable distribution is undefined for values of $\alpha \leq 1$. For $\alpha > 1$, the mean of the stable distribution is

$$\text{mean} = \delta - \beta \gamma \tan\left(\frac{\pi\alpha}{2}\right).$$

Use `mean` to calculate the mean of the stable distribution.

The variance of the stable distribution is undefined for values of $\alpha < 2$. For $\alpha = 2$, the variance of the stable distribution is

$$\text{var} = 2\gamma^2.$$

Use `var` to calculate the variance of the stable distribution.

Relationship to Other Distributions

The stable distribution has three special cases: The normal distribution, the Cauchy distribution, and the Lévy distribution. These distributions are notable because they have closed-form probability density functions.

Normal Distribution

The normal, or Gaussian, distribution is a special case of the stable distribution. The stable distribution with $\alpha = 2$ corresponds to the normal distribution. In other words,

$$N(\mu, \sigma^2) = S\left(2, 0, \frac{\sigma}{\sqrt{2}}, \mu\right).$$

μ is the mean and σ is the standard deviation of the normal distribution.

Although the value of β has no effect when $\alpha = 2$, the normal distribution is usually associated with $\beta = 0$.

The probability density function for the normal distribution is

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right), \quad -\infty < x < \infty.$$

A plot of the density for a normal distribution is symmetric and has a bell-shaped curve.

Cauchy Distribution

The Cauchy distribution is a special case of the stable distribution with $\alpha = 1$ and $\beta = 0$. In other words,

$$\text{Cauchy}(\delta, \gamma) = S(1, 0, \gamma, \delta),$$

where γ is the scale parameter and δ is location parameter of the Cauchy distribution.

The probability density function for the Cauchy distribution is

$$f(x) = \frac{1}{\pi} \frac{\gamma}{\gamma^2 + (x-\delta)^2}, \quad -\infty < x < \infty.$$

A plot of the density for a Cauchy distribution is symmetric and has a bell-shaped curve, but has heavier tails than the density of a normal distribution.

Lévy Distribution

The Lévy distribution is a special case of the stable distribution where $\alpha = 0.5$ and $\beta = 1$. In other words,

$$Lévy(\delta, \gamma) = S(0.5, 1, \gamma, \gamma + \delta) .$$

where γ is the scale parameter and δ is location parameter of the Lévy distribution.

The probability density function for the Lévy distribution is

$$f(x) = \sqrt{\frac{\gamma}{2\pi}} \frac{1}{(x - \delta)^{3/2}} \exp\left(-\frac{\gamma}{2(x - \delta)}\right), \delta < x < \infty .$$

A plot of the density for a Lévy distribution is highly skewed and has heavy tails.

Comparison Plot for Stable Distributions

The following plot compares the probability density functions for the standard normal, Cauchy, and Lévy distributions.

Create a probability distribution object for the standard normal, Cauchy, and Lévy distributions.

```
pd_norm = makedist('Stable', 'alpha', 2, 'beta', 0, 'gam', 1/sqrt(2), 'delta', 0);
pd_cauchy = makedist('Stable', 'alpha', 1, 'beta', 0, 'gam', 1, 'delta', 0);
pd_levy = makedist('Stable', 'alpha', 0.5, 'beta', 1, 'gam', 1, 'delta', 0);
```

Calculate the pdf for each distribution.

```
x = -5:.1:5;
pdf_norm = pdf(pd_norm, x);
pdf_cauchy = pdf(pd_cauchy, x);
pdf_levy = pdf(pd_levy, x);
```

Plot all three pdf functions on the same figure for visual comparison.

```
figure
plot(x, pdf_norm, 'b-');
hold on
plot(x, pdf_cauchy, 'r. ');
plot(x, pdf_levy, 'k--');
title('Compare Stable Distributions pdf Plots')
legend('Normal', 'Cauchy', 'Levy', 'Location', 'northwest')
hold off
```

 “Related Distributions” on page B-153

Overview

The Student's *t* distribution is a one-parameter family of curves. This distribution is typically used to test a hypothesis regarding the population mean when the population standard deviation is unknown.

Statistics and Machine Learning Toolbox offers multiple ways to work with the Student's *t* distribution.

- Use distribution-specific functions (`tcdf`, `tinvs`, `tpdf`, `trnd`, `tstat`) with specified distribution parameters. The distribution-specific functions can accept parameters of multiple Student's *t* distributions.
- Use generic distribution functions (`cdf`, `icdf`, `pdf`, `random`) with a specified distribution name ('`T`') and parameters.

Parameters

The Student's *t* distribution uses the following parameter.

Parameter	Description	Support
nu (ν)	Degrees of freedom	$\nu = 1, 2, 3, \dots$

Probability Density Function

The pdf of the Student's *t* distribution is

$$y = f(x | \nu) = \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu\pi}} \frac{1}{\left(1 + \frac{x^2}{\nu}\right)^{\frac{\nu+1}{2}}}$$

where ν is the degrees of freedom and $\Gamma(\cdot)$ is the Gamma function. The result y is the probability of observing a particular value of x from the Student's *t* distribution with ν degrees of freedom.

For an example, see “Compute and Plot Student's *t* Distribution pdf” on page B-150.

Cumulative Distribution Function

The cdf of the Student's *t* distribution is

$$p = F(x | \nu) = \int_{-\infty}^x \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu\pi}} \frac{1}{\left(1 + \frac{t^2}{\nu}\right)^{\frac{\nu+1}{2}}} dt,$$

where ν is the degrees of freedom and $\Gamma(\cdot)$ is the Gamma function. The result p is the probability that a single observation from the *t* distribution with ν degrees of freedom falls in the interval $[-\infty, x]$.

For an example, see "Compute and Plot Student's *t* Distribution cdf" on page B-151.

Inverse Cumulative Distribution Function

The *t* inverse function is defined in terms of the Student's *t* cdf as

$$x = F^{-1}(p | \nu) = \{x: F(x | \nu) = p\},$$

where

$$p = F(x | \nu) = \int_{-\infty}^x \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu\pi}} \frac{1}{\left(1 + \frac{t^2}{\nu}\right)^{\frac{\nu+1}{2}}} dt,$$

ν is the degrees of freedom, and $\Gamma(\cdot)$ is the Gamma function. The result x is the solution of the integral equation where you supply the probability p .

For an example, see "Compute Student's *t* icdf" on page B-152.

Descriptive Statistics

The mean of the Student's *t* distribution is $\mu = 0$ for degrees of freedom ν greater than 1. If ν equals 1, then the mean is undefined.

The variance of the Student's *t* distribution is $\frac{\nu}{\nu-2}$ for degrees of freedom ν greater than 2. If ν is less than or equal to 2, then the variance is undefined.

Examples

Compute and Plot Student's *t* Distribution pdf

Compute the pdf of a Student's *t* distribution with degrees of freedom equal to 5, 10, and 50.

```
x = [-5:.1:5];
y1 = tpdf(x,5);
```

```
y2 = tpdf(x,10);
y3 = tpdf(x,50);
```

Plot the pdf for all three choices ν on the same axis.

```
figure;
plot(x,y1,'Color','black','LineStyle','-')
hold on
plot(x,y2,'Color','red','LineStyle','-')
plot(x,y3,'Color','blue','LineStyle','-')
xlabel('Observation')
ylabel('Probability Density')
legend({'nu = 5','nu = 10','nu = 50'})
hold off
```

Compute and Plot Student's t Distribution cdf

Compute the cdf of a Student's t distribution with degrees of freedom equal to 5, 10, and 50.

```
x = [-5:.1:5];
y1 = tcdf(x,5);
y2 = tcdf(x,10);
y3 = tcdf(x,50);
```

Plot the cdf for all three choices of ν on the same axis.

```
figure;
plot(x,y1,'Color','black','LineStyle','-')
```

```
hold on
plot(x,y2,'Color','red','LineStyle','-')
plot(x,y3,'Color','blue','LineStyle','-')
xlabel('Observation')
ylabel('Cumulative Probability')
legend({'nu = 5','nu = 10','nu = 50'})
hold off
```

Compute Student's t icdf

Find the 95th percentile of the Student's t distribution with 50 degrees of freedom.

```
p = .95;
nu = 50;
x = tinv(p,nu)
```

```
x = 1.6759
```

Compare Student's t and Normal Distribution pdfs

The Student's t distribution is a family of curves depending on a single parameter ν (the degrees of freedom). As the degrees of freedom ν approach infinity, the t distribution approaches the standard normal distribution.

Compute the pdfs for the Student's t distribution with the parameter $\text{nu} = 5$ and the Student's t distribution with the parameter $\text{nu} = 15$.

```
x = [-5:0.1:5];
y1 = tpdf(x,5);
y2 = tpdf(x,15);
```

Compute the pdf for a standard normal distribution.

```
z = normpdf(x,0,1);
```

Plot the Student's t pdfs and the standard normal pdf on the same figure.

```
plot(x,y1,'-.-',x,y2,'--',x,z,'-')
legend('Student's t Distribution with \nu=5', ...
       'Student's t Distribution with \nu=15', ...
       'Standard Normal Distribution','Location','best')
xlabel('Observation')
ylabel('Probability Density')
title('Student's t and Standard Normal pdfs')
```

The standard normal pdf has shorter tails than the Student's t pdfs.

Related Distributions

- “Beta Distribution” on page B-6 — The beta distribution is a two-parameter continuous distribution that has parameters a (first shape parameter) and b (second shape parameter). If Y has a Student's t distribution with ν degrees of freedom, then $X = \frac{1}{2} + \frac{1}{2} \frac{Y}{\sqrt{\nu + Y^2}}$ has beta

distribution with the shape parameters $a = \nu/2$ and $b = \nu/2$. This relationship is used to compute values of the t cdf and inverse functions, and to generate t distributed random numbers.

- Cauchy Distribution — The Cauchy distribution is a two-parameter continuous distribution with the parameters γ (scale) and δ (location). It is a special case of the “Stable Distribution” on page B-140 with the shape parameters $\alpha = 1$ and $\beta = 0$. The standard Cauchy distribution (unit scale and location zero) is the Student's t distribution with degrees of freedom ν equal to 1. The standard Cauchy distribution has an undefined mean and variance.

For an example, see “Generate Cauchy Random Numbers Using Student's t ” on page 5-104.

- “Chi-Square Distribution” on page B-28 — The chi-square distribution is a one-parameter continuous distribution that has the parameter ν (degrees of freedom). If Z has a standard normal distribution and χ^2 has a chi-square distribution with degrees of freedom ν , then $t = \frac{Z}{\sqrt{\chi^2/\nu}}$ has a Student's t distribution with degrees of freedom ν .
- “Noncentral t Distribution” on page B-117 — The noncentral t distribution is a two-parameter continuous distribution that generalizes the Student's t distribution and has the parameters ν (degrees of freedom) and δ (noncentrality). Setting $\delta = 0$ yields the Student's t distribution.
- “Normal Distribution” on page B-119 — The normal distribution is a two-parameter continuous distribution with the parameters μ (mean) and σ (standard deviation).

As the degrees of freedom ν approach infinity, the Student's t distribution approaches the standard normal distribution (zero mean and unit standard deviation).

For an example, see “Compare Student's t and Normal Distribution pdfs” on page B-152

If x is a random sample of size n from a normal distribution with mean μ , then the statistic $t = \frac{\bar{x} - \mu}{s/\sqrt{n}}$, where \bar{x} is the sample mean and s is the sample standard deviation, has a Student's t distribution with $n - 1$ degrees of freedom.

For an example, see “Compute Student's t Distribution cdf” on page 32-5321.

- “ t Location-Scale Distribution” on page B-156 — The t location-scale distribution is a three-parameter continuous distribution with the parameters μ (mean), σ (scale), and ν (shape). If x has a t location-scale distribution with the parameters μ , σ , and ν , then $\frac{x - \mu}{\sigma}$ has a Student's t distribution with ν degrees of freedom.

t Location-Scale Distribution

In this section...
“Overview” on page B-156
“Parameters” on page B-156
“Probability Density Function” on page B-156
“Cumulative Distribution Function” on page B-157
“Descriptive Statistics” on page B-157
“Relationship to Other Distributions” on page B-157

Overview

The *t* location-scale distribution is useful for modeling data distributions with heavier tails (more prone to outliers) than the normal distribution. It approaches the normal distribution as ν approaches infinity, and smaller values of ν yield heavier tails.

Parameters

The *t* location-scale distribution uses the following parameters.

Parameter	Description	Support
μ	Location parameter	$-\infty < \mu < \infty$
σ	Scale parameter	$\sigma > 0$
ν	Shape parameter	$\nu > 0$

To estimate distribution parameters, use `mle`. Alternatively, fit a `tLocationScaleDistribution` object to data using `fitdist` or the **Distribution Fitter** app.

Probability Density Function

The probability density function (pdf) of the *t* location-scale distribution is

$$\frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\sigma\sqrt{\nu\pi}\Gamma\left(\frac{\nu}{2}\right)} \left[\nu + \frac{(x-\mu)^2}{\sigma^2} \right]^{-\left(\frac{\nu+1}{2}\right)}$$

where $\Gamma(\cdot)$ is the gamma function, μ is the location parameter, σ is the scale parameter, and ν is the shape parameter .

To compute the probability density function, use `pdf` and specify '`tLocationScale`'. Alternatively, you can create a `tLocationScaleDistribution` object using `fitdist` or `makedist`, then use the `pdf` to work with the object.

Cumulative Distribution Function

To compute the probability density function, use `cdf` and specify `'tLocationScale'`. Alternatively, you can create a `tLocationScaleDistribution` object using `fitdist` or `makedist`, then use the `cdf` to work with the object.

Descriptive Statistics

The mean of the t location-scale distribution is

$$\text{mean} = \mu,$$

where μ is the location parameter. The mean is only defined for shape parameter values $\nu > 1$. For other values of ν , the mean is undefined.

The variance of the t location-scale distribution is

$$\text{var} = \sigma^2 \frac{\nu}{\nu - 2},$$

where μ is the location parameter and ν is the shape parameter. The variance is only defined for values of $\nu > 2$. For other values of ν , the variance is undefined.

To compute the mean and variance, create a `tLocationScaleDistribution` object using `fitdist` or `makedist`. You can also use the **Distribution Fitter** app.

Relationship to Other Distributions

If x has a t location-scale distribution, with parameters μ , σ , and ν , then

$$\frac{x - \mu}{\sigma}$$

has a Student's t distribution with ν degrees of freedom.

Triangular Distribution

In this section...

- “Overview” on page B-158
- “Parameters” on page B-158
- “Probability Density Function” on page B-158
- “Cumulative Distribution Function” on page B-160
- “Descriptive Statistics” on page B-161

Overview

The triangular distribution provides a simplistic representation of the probability distribution when limited sample data is available. Its parameters are the minimum, maximum, and peak of the data. Common applications include business and economic simulations, project management planning, natural phenomena modeling, and audio dithering.

Parameters

The triangular distribution uses the following parameters.

Parameter	Description	Constraints
a	Lower limit	$a \leq b$
b	Peak location	$a \leq b \leq c$
c	Upper limit	$c \geq b$

Parameter Estimation

Typically, you estimate triangular distribution parameters using subjectively reasonable values based on the sample data. You can estimate the lower and upper limit parameters a and c using the minimum and maximum values of the sample data, respectively. You can estimate the peak location parameter b using the sample mean, median, mode, or any other subjectively reasonable estimate of the population mode.

Probability Density Function

The probability density function (pdf) of the triangular distribution is

$$f(x) \Big|_{a, b, c} = \begin{cases} \frac{2(x - a)}{(c - a)(b - a)} & ; \quad a \leq x \leq b \\ \frac{2(c - x)}{(c - a)(c - b)} & ; \quad b < x \leq c \\ 0 & ; \quad x < a, x > c \end{cases}$$

This plot shows how changing the value of the parameters a , b , and c alters the shape of the pdf.

```
% Create four distribution objects with different parameters
pd1 = makedist('Triangular');
pd2 = makedist('Triangular', 'a', -1, 'b', 0, 'c', 1);
```

```

pd3 = makedist('Triangular','a',-.5,'b',0,'c',1);
pd4 = makedist('Triangular','a',0,'b',0,'c',1);

% Compute the pdfs
x = -2:.01:2;
pdf1 = pdf(pd1,x);
pdf2 = pdf(pd2,x);
pdf3 = pdf(pd3,x);
pdf4 = pdf(pd4,x);

% Plot the pdfs
figure;
plot(x,pdf1,'r','LineWidth',2)
hold on;
plot(x,pdf2,'k:','LineWidth',2);
plot(x,pdf3,'b-.','LineWidth',2);
plot(x,pdf4,'g--','LineWidth',2);
legend({'a = 0, b = 0.5, c = 1','a = -1, b = 0, c = 1',...
'a = -0.5, b = 0, c = 1','a = 0, b = 0, c = 1'},'Location','NW');
hold off;

```

As the distance between a and c increases, the density at any particular value within the distribution boundaries decreases. Because the density function integrates to 1, the height of the pdf plot decreases as its width increases. The location of the peak parameter b determines whether the pdf skews right or left, or if it is symmetrical.

Cumulative Distribution Function

The cumulative distribution function (cdf) of the triangular distribution is

$$F(x|a,b,c) = \begin{cases} 0 & , x < a \\ \frac{(x-a)^2}{(c-a)(b-a)} & , a \leq x \leq b \\ 1 - \frac{(c-x)^2}{(c-a)(c-b)} & , b < x \leq c \\ 1 & , x > c \end{cases}$$

This plot shows how changing the value of the parameters a , b , and c alters the shape of the cdf.

```
% Create four distribution objects with different parameters
pd1 = makedist('Triangular');
pd2 = makedist('Triangular','a',-1,'b',0,'c',1);
pd3 = makedist('Triangular','a',-.5,'b',0,'c',1);
pd4 = makedist('Triangular','a',0,'b',0,'c',1);

% Compute the cdfs
x = -1.2:.01:1.2;
cdf1 = cdf(pd1,x);
cdf2 = cdf(pd2,x);
cdf3 = cdf(pd3,x);
cdf4 = cdf(pd4,x);

% Plot the cdfs
figure;
plot(x,cdf1,'r','LineWidth',2)
xlim([-1.2 1.2]);
ylim([0 1.1]);hold on;
plot(x,cdf2,'k:','LineWidth',2);
plot(x,cdf3,'b-.','LineWidth',2);
plot(x,cdf4,'g--','LineWidth',2);
legend({'a = 0, b = 0.5, c = 1','a = -1, b = 0, c = 1',...
       'a = -0.5, b = 0, c = 1','a = 0, b = 0, c = 1'},'Location','NW');
hold off;
```

Descriptive Statistics

The mean and variance of the triangular distribution are related to the parameters a , b , and c .

The mean is

$$\text{mean} = \left(\frac{a + b + c}{3} \right).$$

The variance is

$$\text{var} = \left(\frac{a^2 + b^2 + c^2 - ab - ac - bc}{18} \right).$$

Uniform Distribution (Continuous)

In this section...

“Overview” on page B-163
 “Parameters” on page B-163
 “Probability Density Function” on page B-164
 “Cumulative Distribution Function” on page B-164
 “Descriptive Statistics” on page B-164
 “Random Number Generation” on page B-164
 “Examples” on page B-164
 “Related Distributions” on page B-167

Overview

The uniform distribution (also called the rectangular distribution) is a two-parameter family of curves that is notable because it has a constant probability distribution function (pdf) between its two bounding parameters. This distribution is appropriate for representing the distribution of round-off errors in values tabulated to a particular number of decimal places. The uniform distribution is used in random number generating techniques such as the inversion method.

Statistics and Machine Learning Toolbox offers several ways to work with the uniform distribution.

- Create a probability distribution object `UniformDistribution` by specifying parameter values (`makedist`). Then, use object functions to evaluate the distribution, generate random numbers, and so on.
- Use distribution-specific functions (`unifcdf`, `unifpdf`, `unifinv`, `unifit`, `unifstat`, `unifrnd`) with specified distribution parameters. The distribution-specific functions can accept parameters of multiple uniform distributions.
- Use generic distribution functions (`cdf`, `icdf`, `pdf`, `random`) with a specified distribution name ('Uniform') and parameters.

Parameters

The uniform distribution uses the following parameters.

Parameter	Description	Support
<code>a</code>	Lower endpoint	$-\infty < a < b$
<code>b</code>	Upper endpoint	$a < b < \infty$

The standard uniform distribution has $a = 0$ and $b = 1$.

Parameter Estimation

The *maximum likelihood estimates* (MLEs) are the parameter estimates that maximize the likelihood function. The maximum likelihood estimators of a and b for the uniform distribution are the sample minimum and maximum, respectively.

To fit the uniform distribution to data and find parameter estimates, use `unifit` or `mle`.

Probability Density Function

The pdf of the uniform distribution is

$$f(x|a, b) = \begin{cases} \left(\frac{1}{b-a}\right) & ; \quad a \leq x \leq b \\ 0 & ; \quad \textit{otherwise} \end{cases} .$$

The pdf is constant between a and b .

For an example, see “Compute Continuous Uniform Distribution pdf” on page B-164.

Cumulative Distribution Function

The cumulative distribution function (cdf) of the uniform distribution is

$$F(x|a, b) = \begin{cases} 0 & ; \quad x < a \\ \frac{x-a}{b-a} & ; \quad a \leq x < b \\ 1 & ; \quad x \geq b \end{cases} .$$

The result p is the probability that a single observation from a uniform distribution with parameters a and b falls in the interval $[a, x]$.

For an example, see “Compute Continuous Uniform Distribution cdf” on page B-165.

Descriptive Statistics

The mean of the uniform distribution is $\mu = \frac{1}{2}(a + b)$.

The variance of the uniform distribution is $\sigma^2 = \frac{1}{12}(b - a)^2$.

Random Number Generation

You can use the standard uniform distribution to generate random numbers for any other continuous distribution by the inversion method. The inversion method relies on the principle that continuous cumulative distribution functions (cdfs) range uniformly over the open interval $(0, 1)$. If u is a uniform random number on $(0, 1)$, then $x = F^{-1}(u)$ generates a random number x from the continuous distribution with the specified cdf F .

For an example, see “Generate Random Numbers Using Uniform Distribution Inversion” on page 5-98.

Examples

Compute Continuous Uniform Distribution pdf

Create three uniform distribution objects with different parameters.

```

pd1 = makedist('Uniform'); % Standard uniform distribution
pd2 = makedist('Uniform','lower',-2,'upper',2); % Uniform distribution with a = -2 and b = 2
pd3 = makedist('Uniform','lower',-2,'upper',1); % Uniform distribution with a = -2 and b = 1

```

Compute the pdfs for the three uniform distributions.

```

x = -3:.01:3;
pdf1 = pdf(pd1,x);
pdf2 = pdf(pd2,x);
pdf3 = pdf(pd3,x);

```

Plot the pdfs on the same axis.

```

figure;
plot(x,pdf1,'r','LineWidth',2);
hold on;
plot(x,pdf2,'k:','LineWidth',2);
plot(x,pdf3,'b-','LineWidth',2);
legend({'a = 0, b = 1','a = -2, b = 2','a = -2, b = 1'},'Location','northwest');
xlabel('Observation')
ylabel('Probability Density')
hold off;

```

As the width of the interval (a, b) increases, the height of each pdf decreases.

Compute Continuous Uniform Distribution cdf

Create three uniform distribution objects with different parameters.

```
pd1 = makedist('Uniform'); % Standard uniform distribution
pd2 = makedist('Uniform','lower',-2,'upper',2); % Uniform distribution with a = -2 and b = 2
pd3 = makedist('Uniform','lower',-2,'upper',1); % Uniform distribution with a = -2 and b = 1
```

Compute the cdfs for the three uniform distributions.

```
x = -3:.01:3;
cdf1 = cdf(pd1,x);
cdf2 = cdf(pd2,x);
cdf3 = cdf(pd3,x);
```

Plot the cdfs on the same axis.

```
figure;
plot(x,cdf1,'r','LineWidth',2);
hold on;
plot(x,cdf2,'k:','LineWidth',2);
plot(x,cdf3,'b-.','LineWidth',2);
legend({'a = 0, b = 1','a = -2, b = 2','a = -2, b = 1'},'Location','NW');
xlabel('Observation')
ylabel('Cumulative Probability')
hold off;
```

As the width of the interval (a, b) increases, the slope of each cdf decreases.

Related Distributions

- “Beta Distribution” on page B-6 — The beta distribution is a two-parameter continuous distribution that has parameters a (first shape parameter) and b (second shape parameter). The standard uniform distribution is equal to the beta distribution with unit parameters.
- “Triangular Distribution” on page B-158 — The triangular distribution is a three-parameter continuous distribution that has parameters a (lower limit), b (peak), and c (upper limit). The sum of two random variables with a standard uniform distribution has a triangular distribution with $a = 0$, $b = 1$, and $c = 0$.

Uniform Distribution (Discrete)

In this section...
"Definition" on page B-168
"Background" on page B-168
"Examples" on page B-168

Definition

The discrete uniform pdf is

$$y = f(x|N) = \frac{1}{N}I_{(1, \dots, N)}(x)$$

Background

The discrete uniform distribution is a simple distribution that puts equal weight on the integers from one to N .

Examples

Plot a Discrete Uniform Distribution cdf

As for all discrete distributions, the cdf is a step function. The plot shows the discrete uniform cdf for $N = 10$.

```
x = 0:10;  
y = unidcdf(x,10);  
figure;  
stairs(x,y)  
h = gca;  
h.XLim = [0 11];
```

Generate Discrete Uniform Random Numbers

Pick a random sample of 10 from a list of 553 items.

```
rng default; % for reproducibility  
numbers = unidrnd(553,1,10)
```

```
numbers = 1×10
```

```
451 501 71 506 350 54 155 303 530 534

Weibull Distribution

In this section...
“Overview” on page B-170
“Parameters” on page B-170
“Probability Density Function” on page B-171
“Cumulative Distribution Function” on page B-171
“Inverse Cumulative Distribution Function” on page B-171
“Hazard Function” on page B-172
“Examples” on page B-172
“Related Distributions” on page B-176

Overview

The Weibull distribution is a two-parameter family of curves. This distribution is named for Waloddi Weibull, who offered it as an appropriate analytical tool for modeling the breaking strength of materials. Current usage also includes reliability and lifetime modeling. The Weibull distribution is more flexible than the exponential distribution for these purposes, because the exponential distribution has a constant hazard function.

Statistics and Machine Learning Toolbox offers several ways to work with the Weibull distribution.

- Create a probability distribution object `WeibullDistribution` by fitting a probability distribution to sample data (`fitdist`) or by specifying parameter values (`makedist`). Then, use object functions to evaluate the distribution, generate random numbers, and so on.
- Work with the Weibull distribution interactively by using the **Distribution Fitter** app. You can export an object from the app and use the object functions.
- Use distribution-specific functions (`wblcdf`, `wblpdf`, `wblinv`, `wbllike`, `wblstat`, `wblfit`, `wblrnd`, `wblplot`) with specified distribution parameters. The distribution-specific functions can accept parameters of multiple Weibull distributions.
- Use generic distribution functions (`cdf`, `icdf`, `pdf`, `random`) with a specified distribution name ('`Weibull`') and parameters.

Parameters

The Weibull distribution uses these parameters.

Parameter	Description	Support
a	Scale	$a > 0$
b	Shape	$b > 0$

The standard Weibull distribution has unit scale.

Parameter Estimation

The *likelihood function* is the probability density function (pdf) viewed as a function of the parameters. The *maximum likelihood estimates* (MLEs) are the parameter estimates that maximize

the likelihood function for fixed values of x . The maximum likelihood estimators of a and b for the Weibull distribution are the solution of the simultaneous equations

$$\hat{a} = \left[\left(\frac{1}{n} \right) \sum_{i=1}^n x_i^{\hat{b}} \right]^{\frac{1}{\hat{b}}}$$

$$\hat{b} = \frac{n}{\left(\frac{1}{\hat{a}} \right) \sum_{i=1}^n x_i^{\hat{b}} \log x_i - \sum_{i=1}^n \log x_i}.$$

\hat{a} and \hat{b} are unbiased estimators of the parameters a and b .

To fit the Weibull distribution to data and find parameter estimates, use `wblfit`, `fitdist`, or `mle`. Unlike `wblfit` and `mle`, which return parameter estimates, `fitdist` returns the fitted probability distribution object `WeibullDistribution`. The object properties `a` and `b` store the parameter estimates.

For an example, see “Fit Weibull Distribution to Data and Estimate Parameters” on page B-172.

Probability Density Function

The pdf of the Weibull distribution is

$$f(x|a, b) = \frac{b}{a} \left(\frac{x}{a} \right)^{b-1} e^{-(x/a)^b}.$$

For an example, see “Compute Weibull Distribution pdf” on page B-172.

Cumulative Distribution Function

The cumulative distribution function (cdf) of the Weibull distribution is

$$p = F(x|a, b) = \int_0^x b a^{-b} t^{b-1} e^{-\left(\frac{t}{a}\right)^b} dt = 1 - e^{-\left(\frac{x}{a}\right)^b}.$$

The result p is the probability that a single observation from a Weibull distribution with parameters a and b falls in the interval $[0, x]$.

For an example, see “Compute Weibull Distribution cdf” on page B-173.

Inverse Cumulative Distribution Function

The inverse cdf of the Weibull distribution is

$$x = F^{-1}(p|a, b) = -a[\ln(1-p)]^{1/b}.$$

The result x is the value where an observation from a Weibull distribution with parameters a and b falls in the range $[0, x]$ with probability p .

Hazard Function

The hazard function (instantaneous failure rate) is the ratio of the pdf and the complement of the cdf.

If $f(t)$ and $F(t)$ are the pdf and cdf of a distribution, then the hazard rate is $h(t) = \frac{f(t)}{1 - F(t)}$.

Substituting the pdf and cdf of the exponential distribution for $f(t)$ and $F(t)$ above yields the function $\frac{b}{a^b}x^{b-1}$.

For an example, see “Compare Exponential and Weibull Distribution Hazard Functions” on page B-174.

Examples

Fit Weibull Distribution to Data and Estimate Parameters

Simulate the tensile strength data of a thin filament using the Weibull distribution with the scale parameter value 0.5 and the shape parameter value 2.

```
rng('default'); % For reproducibility
strength = wblrnd(0.5,2,100,1); % Simulated strengths
```

Compute the MLEs and confidence intervals for the Weibull distribution parameters.

```
[param,ci] = wblfit(strength)
```

```
param = 1×2
```

```
    0.4768    1.9622
```

```
ci = 2×2
```

```
    0.4291    1.6821
    0.5298    2.2890
```

The estimated scale parameter is 0.4768, with the 95% confidence interval (0.4291, 0.5298).

The estimated shape parameter is 1.9622, with the 95% confidence interval (1.6821, 2.2890).

The default confidence interval for each parameter contains the true value.

Compute Weibull Distribution pdf

Compute the pdf of the Weibull distribution with the scale parameter value 3 and the shape parameter value 2.

```
x = 0:0.1:10;
y = wblpdf(x,3,2);
```

Plot the pdf.

```
figure;
plot(x,y)
```

```
xlabel('Observation')  
ylabel('Probability Density')
```

Compute Weibull Distribution cdf

Compute the cdf of the Weibull distribution with the scale parameter value 3 and the shape parameter value 2.

```
x = 0:0.1:10;  
y = wblcdf(x,3,2);
```

Plot the cdf.

```
figure;  
plot(x,y)  
xlabel('Observation')  
ylabel('Cumulative Probability')
```

Compare Exponential and Weibull Distribution Hazard Functions

The exponential distribution has a constant hazard function, which is not generally the case for the Weibull distribution. In this example, the Weibull hazard rate increases with age (a reasonable assumption).

Compute the hazard function for the Weibull distribution with the scale parameter value 1 and the shape parameter value 2.

```
t = 0:0.1:4.5;  
h1 = wblpdf(t,1,2)./(1-wblcdf(t,1,2));
```

Compute the mean of the Weibull distribution with scale parameter value 1 and shape parameter value 2.

```
mu = wblstat(1,2)
```

```
mu = 0.8862
```

Compute the hazard function for the exponential distribution with mean mu.

```
h2 = exppdf(t,mu)./(1-expcdf(t,mu));
```

Plot both hazard functions on the same axis.

```
plot(t,h1,'-',t,h2,'--')  
xlabel('Observation')
```

```
ylabel('Hazard Rate')
legend('Weibull','Exponential','location','northwest')
```

Estimate Parameters of Three-Parameter Weibull Distribution

Statistics and Machine Learning Toolbox™ uses a two-parameter Weibull distribution with a scale parameter a and a shape parameter b . The Weibull distribution can take one more parameter, a location parameter c . The pdf becomes

$$f(x) \Big|_{a,b,c} = \begin{cases} \frac{b}{a} \left(\frac{x-c}{a}\right)^{b-1} \exp\left(-\left(\frac{x-c}{a}\right)^b\right) & \text{if } x > c, \\ 0 & \text{if } x \leq c, \end{cases}$$

where a and b are positive values, and c is a real value.

Generate sample data of size 1000 from a three-parameter Weibull distribution with the scale parameter 1, shape parameter 1, and location parameter 10.

```
rng('default') % For reproducibility
data = wblrnd(1,1,[1000,1]) + 10;
```

Define a probability density function for a three-parameter Weibull distribution.

```
custompdf = @(x,a,b,c) (x>c).*(b/a).*((x-c)/a).^(b-1).*exp(-((x-c)/a).^b);
```

`mle` estimates the parameters from data. If `mle` does not converge with default statistics options, modify them by using the name-value pair argument `'Options'`.

Create a statistics options structure `opt` by using the function `statset`.

```
opt = statset('MaxIter',1e5,'MaxFunEvals',1e5,'FunValCheck','off');
```

The option `opt` includes the following options:

- `'MaxIter', 1e5` — Increase the maximum number of iterations to `1e5`.
- `'MaxFunEvals', 1e5` — Increase the maximum number of object function evaluations to `1e5`.
- `'FunValCheck', 'off'` — Turn off checking for invalid object function values.

For a distribution with a region that has zero probability density, `mle` might try some parameters that have zero density, and it will fail to estimate parameters. To avoid this problem, you can turn off the option that checks for invalid function values by using `'FunValCheck', 'off'`.

Use `mle` to estimate the parameters. Note that the Weibull probability density function is positive only for $x > c$. This constraint also implies that a location parameter c is smaller than the minimum of the sample data. Include the lower and upper bounds of parameters by using the name-value pair arguments `'LowerBound'` and `'UpperBound'`, respectively.

```
params = mle(data,'pdf',custompdf,'start',[5 5 5],...
    'Options',opt,'LowerBound',[0 0 -Inf],'UpperBound',[Inf Inf min(data)])
```

```
params = 1×3
```

```
    1.0258    1.0618    10.0004
```

If the scale parameter b is smaller than 1, the probability density of the Weibull distribution approaches infinity as x goes to c , where c is the location parameter. The maximum of the likelihood function is infinite. `mle` may find satisfactory estimates in some cases, but the global maximum is degenerate when $b < 1$.

Related Distributions

- “Exponential Distribution” on page B-33 — The exponential distribution is a one-parameter continuous distribution that has parameter μ (mean). This distribution is also used for lifetime modeling. When $b = 1$, the Weibull distribution is equal to the exponential distribution with mean $\mu = a$.
- “Extreme Value Distribution” on page B-40 — The extreme value distribution is a two-parameter continuous distribution with parameters μ (location) and σ (scale). If X has a Weibull distribution with parameters a and b , then $\log X$ has an extreme value distribution with parameters $\mu = \log a$ and $\sigma = 1/b$. This relationship is used to fit data to a Weibull distribution.
- “Rayleigh Distribution” on page B-137 — The Rayleigh distribution is a one-parameter continuous distribution that has parameter b (scale). If A and B are the parameters of the Weibull distribution, then the Rayleigh distribution with parameter b is equivalent to the Weibull distribution with parameters $A = \sqrt{2}b$ and $B = 2$.
- Three-Parameter Weibull Distribution — The three-parameter Weibull distribution adds a location parameter that is zero in the two-parameter case. If X has a two-parameter Weibull distribution, then $Y = X + c$ has a three-parameter Weibull distribution with the added location parameter c .

For an example, see “Estimate Parameters of Three-Parameter Weibull Distribution” on page B-175.

Wishart Distribution

In this section...

“Overview” on page B-178

“Parameters” on page B-178

“Probability Density Function” on page B-178

“Example” on page B-178

Overview

The Wishart distribution is a generalization of the univariate chi-square distribution to two or more variables. It is a distribution for symmetric positive semidefinite matrices, typically covariance matrices, the diagonal elements of which are each chi-square random variables. In the same way as the chi-square distribution can be constructed by summing the squares of independent, identically distributed, zero-mean univariate normal random variables, the Wishart distribution can be constructed by summing the inner products of independent, identically distributed, zero-mean multivariate normal random vectors. The Wishart distribution is often used as a model for the distribution of the sample covariance matrix for multivariate normal random data, after scaling by the sample size.

Only random matrix generation is supported for the Wishart distribution, including both singular and nonsingular Σ .

Parameters

The Wishart distribution is parameterized with a symmetric, positive semidefinite matrix, Σ , and a positive scalar degrees of freedom parameter, ν . ν is analogous to the degrees of freedom parameter of a univariate chi-square distribution, and $\Sigma\nu$ is the mean of the distribution.

Probability Density Function

The probability density function of the d -dimensional Wishart distribution is given by

$$y = f(X, \Sigma, \nu) = \frac{|X|^{(\nu-d-1)/2} e^{-\frac{1}{2}\text{trace}(\Sigma^{-1}X)}}{2^{(\nu d)/2} \pi^{(d(d-1))/4} |\Sigma|^{\nu/2} \Gamma(\nu/2) \dots \Gamma(\nu-(d-1))/2}$$

where X and Σ are d -by- d symmetric positive definite matrices, and ν is a scalar greater than $d - 1$. While it is possible to define the Wishart for singular Σ , the density cannot be written as above.

Example

If x is a bivariate normal random vector with mean zero and covariance matrix

$$\Sigma = \begin{pmatrix} 1 & .5 \\ .5 & 2 \end{pmatrix}$$

then you can use the Wishart distribution to generate a sample covariance matrix without explicitly generating x itself. Notice how the sampling variability is quite large when the degrees of freedom is small.

```
Sigma = [1 .5; .5 2];  
df = 10; S1 = wishrnd(Sigma,df)/df
```

```
S1 =  
    1.7959    0.64107  
    0.64107    1.5496
```

```
df = 1000; S2 = wishrnd(Sigma,df)/df
```

```
S2 =  
    0.9842    0.50158  
    0.50158    2.1682
```
