If you trained `Mdl` using sample data contained in a table, then the input data for this method must also be in a table.

Data Types: table

ResponseVarName — Response variable name

name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `y` is stored as `tbl.y`, then specify it as `'y'`. Otherwise, the software treats all columns of `tbl`, including `y`, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` should be the same as the variables that trained `Mdl`.

The length of `Y` and the number of rows of `X` must be equal.

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | string array | logical vector | vector of numeric values | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. `Y` must be the same as the data type of `Mdl.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)

The length of `Y` and the number of rows of `tbl` or `X` must be equal.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Output Arguments

m — Classification margins

numeric vector

Classification margins on page 32-3359, returned as a numeric vector.

`m` has the same length equal to `size(X,1)`. Each entry of `m` is the classification margin of the corresponding observation (row) of `X` and element of `Y`.

Examples

Estimate Test-Sample Classification Margins of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);
```

Train a naive Bayes classifier. Specify a 30% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

```

CVMdl = fitcnb(X,Y,'Holdout',0.30,...
    'ClassNames',{'setosa','versicolor','virginica'});
CMdl = CVMdl.Trained{1}; ...
    % Extract the trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds);

```

CVMdl is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Estimate the test sample classification margins. Display the distribution of the margins using a `boxplot`.

```

m = margin(CMdl,XTest,YTest);

figure;
boxplot(m);
title 'Distribution of the Test-Sample Margins';

```

An observation margin is the observed true class score minus the maximum false class score among all scores in the respective class. Classifiers that yield relatively large margins are desirable.

Select Naive Bayes Classifier Features by Examining Test Sample Margins

The classifier margins measure, for each observation, the difference between the true class observed score and the maximal false class score for a particular class. One way to perform feature selection is to compare test sample margins from multiple models. Based solely on this criterion, the model with the highest margins is the best model.

Load Fisher's iris data set.

```
load fisheriris
X = meas; % Predictors
Y = species; % Response
rng(1);
```

Partition the data set into training and test sets. Specify a 30% holdout sample for testing.

```
Partition = cvpartition(Y, 'Holdout', 0.30);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds, :);
YTest = Y(testInds);
```

Partition defines the data set partition.

Define these two data sets:

- fullX contains all predictors.
- partX contains the last 2 predictors.

```
fullX = X;
partX = X(:, 3:4);
```

Train naive Bayes classifiers for each predictor set. Specify the partition definition.

```
FCVMdl = fitcnb(fullX, Y, 'CVPartition', Partition);
PCVMdl = fitcnb(partX, Y, 'CVPartition', Partition);
FCMdl = FCVMdl.Trained{1};
PCMdl = PCVMdl.Trained{1};
```

FullCVMdl and PartCVMdl are ClassificationPartitionedModel classifiers. They contain the property Trained, which is a 1-by-1 cell array holding a CompactClassificationNaiveBayes classifier that the software trained using the training set.

Estimate the test sample margins for each classifier. Display the distributions of the margins for each model using boxplots.

```
fullM = margin(FCMdl, XTest, YTest);
partM = margin(PCMdl, XTest(:, 3:4), YTest);

figure;
boxplot([fullM partM], 'Labels', {'All Predictors', 'Two Predictors'})
h = gca;
h.YLim = [0.98 1.01]; % Modify axis to see boxes.
title 'Boxplots of Test-Sample Margins';
```

The margins have a similar distribution, but PCMDL is less complex.

More About

Classification Edge

The classification edge is the weighted mean of the classification margins.

If you supply weights, then the software normalizes them to sum to the prior probability of their respective class. The software uses the normalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The classification margins are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

Posterior Probability

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation (x_1, \dots, x_p) is

$$\widehat{P}(Y = k | x_1, \dots, x_p) = \frac{P(X_1, \dots, X_p | y = k)\pi(Y = k)}{P(X_1, \dots, X_p)},$$

where:

- $P(X_1, \dots, X_p | y = k)$ is the conditional joint density of the predictors given they are in class k . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- $P(X_1, \dots, X_p)$ is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_p) = \sum_{k=1}^K P(X_1, \dots, X_p | y = k)\pi(Y = k).$$

Prior Probability

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

Score

The naive Bayes score is the class posterior probability given the observation.

Topics

“Naive Bayes Classification” on page 21-2

margin

Package: `classreg.learning.classif`

Find classification margins for support vector machine (SVM) classifier

Syntax

```
m = margin(SVMModel,TBL,ResponseVarName)
```

```
m = margin(SVMModel,TBL,Y)
```

```
m = margin(SVMModel,X,Y)
```

Description

`m = margin(SVMModel,TBL,ResponseVarName)` returns the classification margins on page 32-3364 (`m`) for the trained support vector machine (SVM) classifier `SVMModel` using the sample data in table `TBL` and the class labels in `TBL.ResponseVarName`.

`m` is returned as a numeric vector with the same length as `Y`. The software estimates each entry of `m` using the trained SVM classifier `SVMModel`, the corresponding row of `X`, and the true class label `Y`.

`m = margin(SVMModel,TBL,Y)` returns the classification margins (`m`) for the trained SVM classifier `SVMModel` using the sample data in table `TBL` and the class labels in `Y`.

`m = margin(SVMModel,X,Y)` returns the classification margins for `SVMModel` using the predictor data in matrix `X` and the class labels in `Y`.

Examples

Estimate Test Sample Classification Margins of SVM Classifiers

Load the `ionosphere` data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing, standardize the data, and specify that 'g' is the positive class.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
    'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; ...
    % Extract the trained, compact classifier
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`CVSVMModel` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Estimate the test sample classification margins.

```
m = margin(CompactSVMModel,XTest,YTest);
m(10:20)
```

```
ans = 11×1
```

```
    3.5461
    5.5939
    4.9948
    4.5611
   -4.7963
    5.5127
   -2.8776
    1.8673
    9.4986
    9.5018
    :
```

An observation margin is the observed true class score minus the maximum false class score among all scores in the respective class. Classifiers that yield relatively large margins are preferred.

Select SVM Classifier Features by Examining Test Sample Margins

Perform feature selection by comparing test sample margins from multiple models. Based solely on this comparison, the model with the highest margins is the best model.

Load the `ionosphere` data set.

```
load ionosphere
rng(1); % For reproducibility
```

Partition the data set into training and test sets. Specify a 15% holdout sample for testing.

```
Partition = cvpartition(Y,'Holdout',0.15);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`Partition` defines the data set partition.

Define these two data sets:

- `fullX` contains all predictors (except the removed column of 0s).
- `partX` contains the last 20 predictors.

```
fullX = X;
partX = X(:,end-20:end);
```

Train SVM classifiers for each predictor set. Specify the partition definition.

```
FullCVSVMModel = fitcsvm(fullX,Y,'CVPartition',Partition);
PartCVSVMModel = fitcsvm(partX,Y,'CVPartition',Partition);
FCSVMModel = FullCVSVMModel.Trained{1};
PCSVMModel = PartCVSVMModel.Trained{1};
```

`FullCVSVMModel` and `PartCVSVMModel` are `ClassificationPartitionedModel` classifiers. They contain the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Estimate the test sample margins for each classifier.

```
fullM = margin(FCSVMModel,XTest,YTest);
partM = margin(PCSVModel,XTest(:,end-20:end),YTest);
n = size(XTest,1);
p = sum(fullM < partM)/n
```

```
p = 0.2500
```

Approximately 25% of the margins from the full model are less than those from the model with fewer predictors. This result suggests that the model trained with all the predictors is better.

Input Arguments

SVModel — SVM classification model

`ClassificationSVM` model object | `CompactClassificationSVM` model object

SVM classification model, specified as a `ClassificationSVM` model object or `CompactClassificationSVM` model object returned by `fitcsvm` or `compact`, respectively.

TBL — Sample data

`table`

Sample data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor variable. Optionally, TBL can contain additional columns for the response variable and observation weights. TBL must contain all of the predictors used to train `SVModel`. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If TBL contains the response variable used to train `SVModel`, then you do not need to specify `ResponseVarName` or `Y`.

If you trained `SVModel` using sample data contained in a table, then the input data for `margin` must also be in a table.

If you set `'Standardize',true` in `fitcsvm` when training `SVModel`, then the software standardizes the columns of the predictor data using the corresponding means in `SVModel.Mu` and the standard deviations in `SVModel.Sigma`.

Data Types: `table`

X — Predictor data

`numeric matrix`

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables in the columns of `X` must be the same as the variables that trained the `SVModel` classifier.

The length of `Y` and the number of rows in `X` must be equal.

If you set `'Standardize', true` in `fitcsvm` to train `SVMModel`, then the software standardizes the columns of `X` using the corresponding means in `SVMModel.Mu` and the standard deviations in `SVMModel.Sigma`.

Data Types: `double` | `single`

ResponseVarName — Response variable name

name of variable in TBL

Response variable name, specified as the name of a variable in TBL. If TBL contains the response variable used to train `SVMModel`, then you do not need to specify `ResponseVarName`.

If you specify `ResponseVarName`, then you must do so as a character vector or string scalar. For example, if the response variable is stored as `TBL.Response`, then specify `ResponseVarName` as `'Response'`. Otherwise, the software treats all columns of TBL, including `TBL.Response`, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. `Y` must be the same as the data type of `SVMModel.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)

The length of `Y` must equal the number of rows in TBL or the number of rows in `X`.

More About

Classification Edge

The edge is the weighted mean of the classification margins.

The weights are the prior class probabilities. If you supply weights, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to compute the weighted mean.

One way to choose among multiple classifiers, for example, to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation x . The classification margin is commonly defined as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

The SVM classification score for classifying observation x is the signed distance from x to the decision boundary ranging from $-\infty$ to $+\infty$. A positive score for a class indicates that x is predicted to be in that class. A negative score indicates otherwise.

The positive class classification score $f(x)$ is the trained SVM classification function. $f(x)$ is also the numerical, predicted response for x , or the score for predicting x into the positive class.

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, \dots, \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations. The negative class classification score for x , or the score for predicting x into the negative class, is $-f(x)$.

If $G(x_j, x) = x_j'x$ (the linear kernel), then the score function reduces to

$$f(x) = (x/s)'\beta + b.$$

s is the kernel scale and β is the vector of fitted linear coefficients.

For more details, see “Understanding Support Vector Machines” on page 18-145.

Algorithms

For binary classification, the software defines the margin for observation j , m_j , as

$$m_j = 2y_j f(x_j),$$

where $y_j \in \{-1, 1\}$, and $f(x_j)$ is the predicted score of observation j for the positive class. However, $m_j = y_j f(x_j)$ is commonly used to define the margin.

margin

Classification margins

Syntax

```
m = margin(tree, TBL, ResponseVarName)
m = margin(tree, TBL, Y)
m = margin(tree, X, Y)
```

Description

`m = margin(tree, TBL, ResponseVarName)` returns the classification margins for the table of predictors `TBL` and class labels `TBL . ResponseVarName`. For the definition, see “Margin” on page 32-3369.

`m = margin(tree, TBL, Y)` returns the classification margins for the table of predictors `TBL` and class labels `Y`.

`m = margin(tree, X, Y)` returns the classification margins for the matrix of predictors `X` and class labels `Y`.

Input Arguments

tree — Trained classification tree

`ClassificationTree` model object | `CompactClassificationTree` model object

Trained classification tree, specified as a `ClassificationTree` or `CompactClassificationTree` model object. That is, `tree` is a trained classification model returned by `fitctree` or `compact`.

TBL — Sample data

`table`

Sample data, specified as a table. Each row of `TBL` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `TBL` can contain additional columns for the response variable and observation weights. `TBL` must contain all the predictors used to train `tree`. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If `TBL` contains the response variable used to train `tree`, then you do not need to specify `ResponseVarName` or `Y`.

If you train `tree` using sample data contained in a `table`, then the input data for this method must also be in a table.

Data Types: `table`

X — Data to classify

`numeric matrix`

Data to classify, specified as a numeric matrix. Each row of `X` represents one observation, and each column represents one predictor. `X` must have the same number of columns as the data used to train `tree`. `X` must have the same number of rows as the number of elements in `Y`.

Data Types: `single` | `double`

ResponseVarName — Response variable name

name of a variable in TBL

Response variable name, specified as the name of a variable in TBL. If TBL contains the response variable used to train `tree`, then you do not need to specify `ResponseVarName`.

If you specify `ResponseVarName`, then you must do so as a character vector or string scalar. For example, if the response variable is stored as `TBL.Response`, then specify it as `'Response'`. Otherwise, the software treats all columns of TBL, including `TBL.ResponseVarName`, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Y must be of the same type as the classification used to train `tree`, and its number of elements must equal the number of rows of X.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Output Arguments

m — Margin

numeric column vector

Margin, returned as a numeric column vector of length `size(X,1)`. Each entry in `m` represents the margin for the corresponding rows of X and (true class) Y, computed using `tree`.

Examples

Compute the classification margin for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries.

```
load fisheriris
X = meas(:,1:2);
tree = fitctree(X,species);
M = margin(tree,X,species);
M(end-10:end)
```

```
ans =
    0.1111
    0.1111
    0.1111
   -0.2857
    0.6364
    0.6364
    0.1111
```

```

0.7500
1.0000
0.6364
0.2000

```

The classification tree trained on all the data is better.

```

tree = fitctree(meas,species);
M = margin(tree,meas,species);
M(end-10:end)

```

```

ans =
0.9565
0.9565
0.9565
0.9565
0.9565

```

More About

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix X .

Score (tree)

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

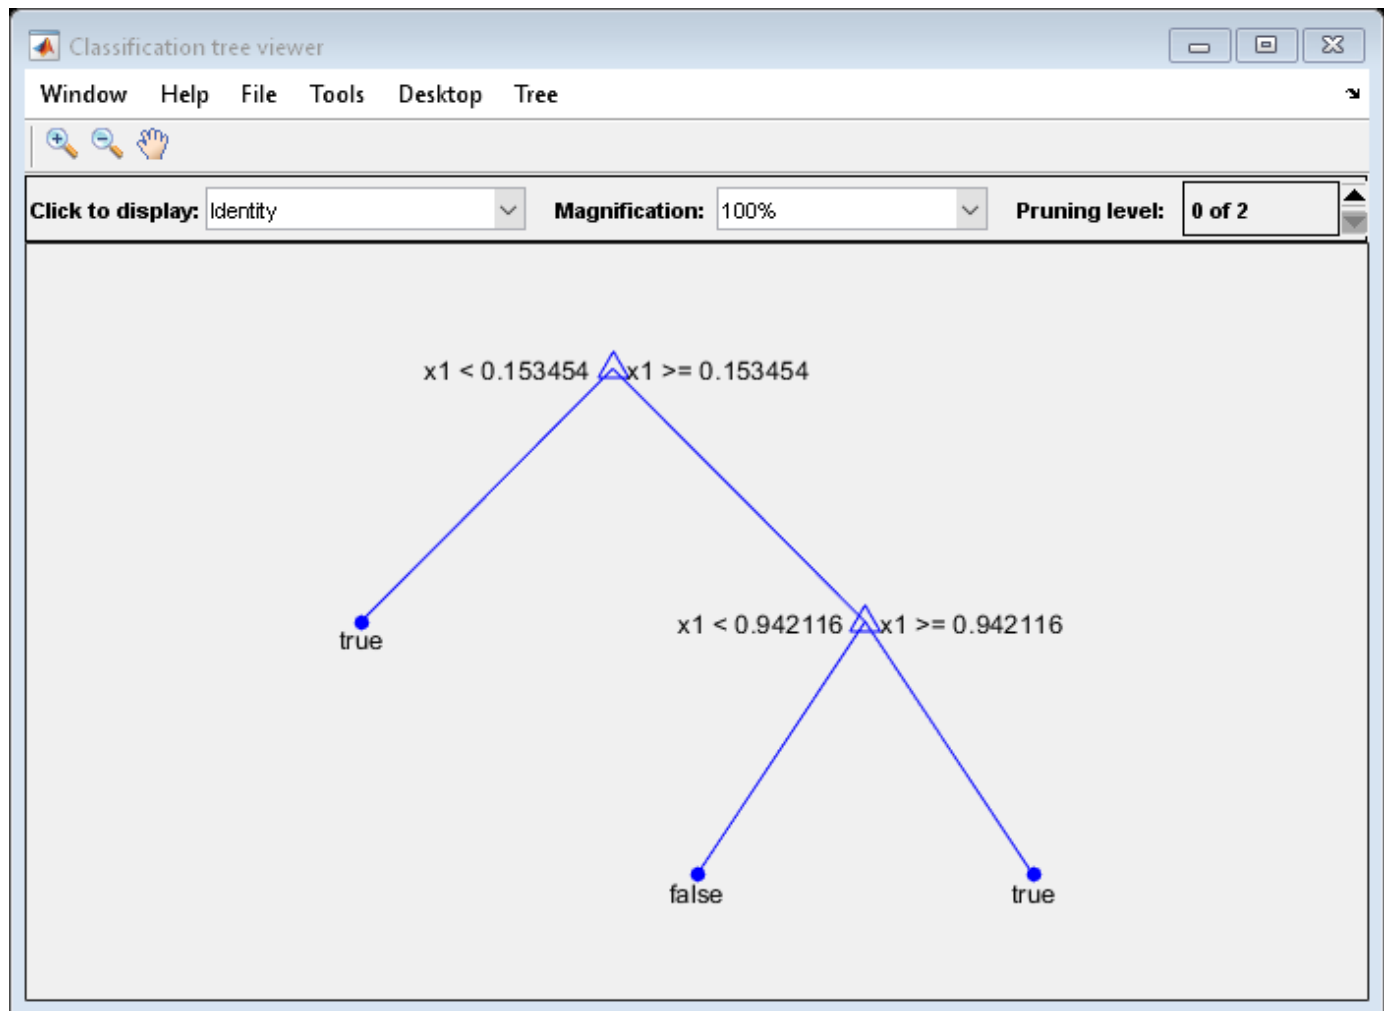

For example, consider classifying a predictor X as true when $X < 0.15$ or $X > 0.95$, and X is false otherwise.

Generate 100 random points and classify them:

```

rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')

```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for `true`, and about $.8/.85=.94$ for `false`.

Compute the prediction scores for the first 10 rows of `X`:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans = 10x3
```

```
    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0     1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0     1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
```

0.9059 0.0941 0.9649

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range $(.95, 1)$ instead of the expected 5 observations.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

`edge` | `fitctree` | `loss` | `predict`

margin

Class: CompactTreeBagger

Classification margin

Syntax

```
mar = margin(B,TBLnew,Ynew)
mar = margin(B,Xnew,Ynew)
mar = margin(B,TBLnew,Ynew,'param1',val1,'param2',val2,...)
mar = margin(B,Xnew,Ynew,'param1',val1,'param2',val2,...)
```

Description

`mar = margin(B,TBLnew,Ynew)` computes the classification margins for the predictors contained in the table `TBLnew` given true response `Ynew`. You can omit `Ynew` if `TBLnew` contains the response variable. If you trained `B` using sample data contained in a table, then the input data for this method must also be in a table.

`mar = margin(B,Xnew,Ynew)` computes the classification margins for the predictors contained in the matrix `Xnew` given true response `Ynew`.

`Ynew` can be a numeric vector, character matrix, string array, cell array of character vectors, categorical vector or logical vector. `mar` is a numeric array of size `Nobs-by-NTrees`, where `Nobs` is the number of rows of `TBLnew` and `Ynew`, and `NTrees` is the number of trees in the ensemble `B`. For observation `I` and tree `J`, `mar(I,J)` is the difference between the score for the true class and the largest score for other classes. This method is available for classification ensembles only.

`mar = margin(B,TBLnew,Ynew,'param1',val1,'param2',val2,...)` or `mar = margin(B,Xnew,Ynew,'param1',val1,'param2',val2,...)` specifies optional parameter name-value pairs:

'Mode'	How the method computes errors. If set to 'cumulative' (default), <code>margin</code> computes cumulative errors and <code>mar</code> is an <code>Nobs-by-NTrees</code> matrix, where the first column gives error from <code>trees(1)</code> , second column gives error from <code>trees(1:2)</code> etc., up to <code>trees(1:NTrees)</code> . If set to 'individual', <code>mar</code> is a <code>Nobs-by-NTrees</code> matrix, where each element is an error from each tree in the ensemble. If set to 'ensemble', <code>mar</code> a single column of length <code>Nobs</code> showing the cumulative margins for the entire ensemble.
'Trees'	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'Trees' is a numeric vector, the method returns a vector of length <code>NTrees</code> for 'cumulative' and 'individual' modes, where <code>NTrees</code> is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives error from <code>trees(1)</code> , the second element gives error from <code>trees(1:2)</code> etc.

'TreeWeights'	Vector of tree weights. This vector must have the same length as the 'Trees' vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the 'individual' mode.
'UseInstanceForTree'	Logical matrix of size Nobs-by-NTrees indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.

mar = margin(B,Xnew,Ynew)
mar = margin(B,TBLnew,Ynew,'param1',val1,'param2',val2,...)
mar = margin(B,Xnew,Ynew,'param1',val1,'param2',val2,...)
```

Description

`mar = margin(B,TBLnew,Ynew)` computes the classification margins for the predictors contained in the table `TBLnew` given true response `Ynew`. You can omit `Ynew` if `TBLnew` contains the response variable. If you trained `B` using sample data contained in a table, then the input data for this method must also be in a table.

`mar = margin(B,Xnew,Ynew)` computes the classification margins for the predictors contained in the matrix `Xnew` given true response `Ynew`. If you trained `B` using sample data contained in a matrix, then the input data for this method must also be in a matrix.

`Ynew` can be a numeric vector, character matrix, string array, cell array of character vectors, categorical vector or logical vector. `mar` is a numeric array of size `Nobs-by-NTrees`, where `Nobs` is the number of rows of `TBLnew` and `Ynew`, and `NTrees` is the number of trees in the ensemble `B`. For observation `I` and tree `J`, `mar(I,J)` is the difference between the score for the true class and the largest score for other classes. This method is available for classification ensembles only.

`mar = margin(B,TBLnew,Ynew,'param1',val1,'param2',val2,...)` or `mar = margin(B,Xnew,Ynew,'param1',val1,'param2',val2,...)` specifies optional parameter name-value pairs:

'Mode'	Character vector or string scalar indicating how the method computes errors. If set to 'cumulative' (default), <code>margin</code> computes cumulative errors and <code>mar</code> is an <code>Nobs-by-NTrees</code> matrix, where the first column gives error from <code>trees(1)</code> , second column gives error from <code>trees(1:2)</code> etc., up to <code>trees(1:NTrees)</code> . If set to 'individual', <code>mar</code> is a <code>Nobs-by-NTrees</code> matrix, where each element is an error from each tree in the ensemble. If set to 'ensemble', <code>mar</code> a single column of length <code>Nobs</code> showing the cumulative margins for the entire ensemble.
'Trees'	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'Trees' is a numeric vector, the method returns a vector of length <code>NTrees</code> for 'cumulative' and 'individual' modes, where <code>NTrees</code> is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives error from <code>trees(1)</code> , the second element gives error from <code>trees(1:2)</code> etc.

'TreeWeights'	Vector of tree weights. This vector must have the same length as the 'Trees' vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the 'individual' mode.
'UseInstanceForTree'	Logical matrix of size Nobs-by-NTrees indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.

margin

margmean

Class: RepeatedMeasuresModel

Estimate marginal means

Syntax

```
tbl = margmean(rm,vars)
tbl = margmean(rm,vars,'alpha',alpha)
```

Description

`tbl = margmean(rm,vars)` returns the estimated marginal means for the variables `vars`, in the table `tbl`.

`tbl = margmean(rm,vars,'alpha',alpha)` returns the $100*(1-\alpha)\%$ confidence intervals for the marginal means.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

vars — Variables for which to compute the marginal means

character vector | string scalar | string array | cell array of character vectors

Variables for which to compute the marginal means, specified as a character vector or string scalar representing the name of a between or within-subjects factor in `rm`, or a string array or cell array of character vectors representing the names of multiple variables. Each between-subjects factor must be categorical.

For example, if you want to compute the marginal means for the variables `Drug` and `Gender`, then you can specify as follows.

Example: `{'Drug','Gender'}`

Data Types: `char` | `string` | `cell`

alpha — Significance level

0.05 (default) | scalar value in the range of 0 to 1

Significance level of the confidence intervals for population marginal means, specified as a scalar value in the range of 0 to 1. The confidence level is $100*(1-\alpha)\%$.

For example, you can specify a 99% confidence level as follows.

Example: `'alpha',0.01`

Data Types: `double` | `single`

Output Arguments

`tbl` — Estimated marginal means

table

Estimated marginal means, returned as a table. `tbl` contains one row for each combination of the groups of the variables you specify in `vars`, one column for each variable, and the following columns.

Column name	Description
Mean	Estimated marginal means
StdErr	Standard errors of the estimates
Lower	Lower limit of a 95% confidence interval for the true population mean
Upper	Upper limit of a 95% confidence interval for the true population mean

Examples

Compute Marginal Means Grouped by Two Factors

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` to `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` to `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the `group-gender` interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Compute the marginal means grouped by the factors `Group` and `Gender`.

```
M = margmean(rm, {'Group' 'Gender'})
```

M=6×6 table

Group	Gender	Mean	StdErr	Lower	Upper
A	Female	15.946	5.6153	4.3009	27.592
A	Male	8.0726	5.7236	-3.7973	19.943
B	Female	11.758	5.7091	-0.08189	23.598
B	Male	2.2858	5.6748	-9.483	14.055
C	Female	-8.6183	5.871	-20.794	3.5574
C	Male	-13.551	5.7283	-25.431	-1.6712

Display the description for table `M`.

```
M.Properties.Description
```

```
ans =
  'Estimated marginal means
  Means computed with Age=13.7, IQ=98.2667'
```

Compute Estimated Marginal Means and Confidence Intervals

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
  'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4-species','WithinDesign',Meas);
```

Compute the marginal means grouped by the factor species.

```
margmean(rm,'species')
```

```
ans=3x5 table
      species      Mean      StdErr      Lower      Upper
-----
{'setosa'   }  2.5355  0.042807  2.4509  2.6201
{'versicolor'}  3.573  0.042807  3.4884  3.6576
{'virginica' }  4.285  0.042807  4.2004  4.3696
```

`StdError` field shows the standard errors of the estimated marginal means. The `Lower` and `Upper` fields show the lower and upper bounds for the 95% confidence intervals of the group marginal means, respectively. None of the confidence intervals overlap, which indicates that marginal means differ with species. You can also plot the estimated marginal means using the `plotprofile` method.

Compute the 99% confidence intervals for the marginal means.

```
margmean(rm,'species','alpha',0.01)
```

```
ans=3x5 table
      species      Mean      StdErr      Lower      Upper
-----
{'setosa'   }  2.5355  0.042807  2.4238  2.6472
{'versicolor'}  3.573  0.042807  3.4613  3.6847
{'virginica' }  4.285  0.042807  4.1733  4.3967
```

See Also

`multcompare` | `fitrm` | `plotprofile`

mauchly

Class: RepeatedMeasuresModel

Mauchly's test for sphericity

Syntax

```
tbl = mauchly(rm)
tbl = mauchly(rm,C)
```

Description

`tbl = mauchly(rm)` returns the result of the Mauchly's test for sphericity for the repeated measures model `rm`.

It tests the null hypothesis that the sphericity assumption is true for the response variables in `rm`.

For more information, see "Mauchly's Test of Sphericity" on page 9-57.

`tbl = mauchly(rm,C)` returns the result of the Mauchly's test based on the contrast matrix `C`.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

C — Contrasts

matrix

Contrasts, specified as a matrix. The default value of `C` is the `Q` factor in a QR decomposition of the matrix `M`, where `M` is defined so that `Y*M` is the difference between all successive pairs of columns of the repeated measures matrix `Y`.

Data Types: `single` | `double`

Output Arguments

tbl — Results of Mauchly's test of sphericity

table

Results of Mauchly's test for sphericity for the repeated measures model `rm`, returned as a table.

`tbl` contains the following columns.

Column Name	Definition
W	Value of Mauchly's W statistic
ChiStat	Chi-square statistic value
DF	Degrees of freedom of the Chi-square statistic
pValue	p -value corresponding to the Chi-square statistic

Data Types: table

Examples

Perform Mauchly's Test

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4-species','WithinDesign',Meas);
```

Perform Mauchly's test to assess the sphericity assumption.

```
mauchly(rm)
```

```
ans=1x4 table
      W      ChiStat      DF      pValue
-----
0.55814  84.976      5      7.6149e-17
```

The small p -value (in the `pValue` field) indicates that the sphericity, hence the compound symmetry assumption, does not hold. You should use epsilon corrections to compute the p -values for a repeated measures anova. You can compute the epsilon corrections using the `epsilon` method and perform the repeated measures anova with the corrected p -values using the `ranova` method.

mat2dataset

(Not Recommended) Convert matrix to dataset array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
ds = mat2dataset(X)
ds = mat2dataset(X,Name,Value)
```

Description

`ds = mat2dataset(X)` converts a matrix to a dataset array.

`ds = mat2dataset(X,Name,Value)` performs the conversion using additional options specified by one or more `Name,Value` pair arguments.

Examples

Convert Matrix to Dataset Array

Convert a matrix to a dataset array using the default options.

Load sample data.

```
load('fisheriris')
X = meas;
size(X)
```

```
ans = 1×2
```

```
    150     4
```

Convert the matrix to a dataset array.

```
ds = mat2dataset(X);
size(ds)
```

```
ans = 1×2
```

```
    150     4
```

```
ds(1:5,:)
ans =
```

```
    X1    X2    X3    X4
    5.1    3.5    1.4    0.2
```

```

4.9    3    1.4    0.2
4.7    3.2  1.3    0.2
4.6    3.1  1.5    0.2
5      3.6  1.4    0.2

```

When you do not specify variable names, `mat2dataset` uses the matrix name and column numbers to create default variable names.

Convert Matrix to Dataset Array with Variable Names

Load sample data.

```

load('fisheriris')
X = meas;
size(X)

```

```
ans = 1×2
```

```
150    4
```

Convert the matrix to a dataset array, providing a variable name for each of the four column of X.

```

ds = mat2dataset(X, 'VarNames', {'SLength', ...
'SWidth', 'PLength', 'PWidth'});
size(ds)

```

```
ans = 1×2
```

```
150    4
```

```
ds(1:5, :)
```

```

ans =
SLength    SWidth    PLength    PWidth
5.1         3.5        1.4         0.2
4.9         3          1.4         0.2
4.7         3.2        1.3         0.2
4.6         3.1        1.5         0.2
5           3.6        1.4         0.2

```

Create a Dataset Array with Multicolumn Variables

Convert a matrix to a dataset array containing multicolumn variables.

Load sample data.

```

load('fisheriris')
X = meas;
size(X)

```

```
ans = 1×2
    150     4
```

Convert the matrix to a dataset array, combining the sepal measurements (the first two columns) into one variable named `SepalMeas`, and the petal measurements (third and fourth columns) into one variable names `PetalMeas`.

```
ds = mat2dataset(X, 'NumCols', [2,2], ...
    'VarNames', {'SepalMeas', 'PetalMeas'});
ds(1:5,:)
```

```
ans =
    SepalMeas      PetalMeas
    5.1          3.5      1.4      0.2
    4.9           3      1.4      0.2
    4.7          3.2      1.3      0.2
    4.6          3.1      1.5      0.2
     5           3.6      1.4      0.2
```

The output dataset array has 150 observations and 2 variables.

```
size(ds)
ans = 1×2
    150     2
```

Input Arguments

X — Input matrix

matrix

Input matrix to convert to a dataset array, specified as an M -by- N numeric matrix. Each column of X becomes a variable in the output M -by- N dataset array.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'NumCols', [1,1,2,1]` specifies that the 3rd and 4th columns of the input matrix should be combined into a single variable.

VarNames — Variable names for output dataset array

string array | cell array of character vectors

Variable names for the output dataset array, specified as the comma-separated pair consisting of `'VarNames'` and a string array or cell array of character vectors. You must provide a variable name for each variable in `ds`. The names must be valid MATLAB identifiers, and must be unique.

Example: 'VarNames', {'myVar1', 'myVar2', 'myVar3'}

ObsNames — Observation names for output dataset array

string array | cell array of character vectors

Observation names for the output dataset array, specified as the comma-separated pair consisting of 'ObsNames' and a string array or cell array of character vectors. The names do not need to be valid MATLAB identifiers, but they must be unique.

NumCols — Number of columns for each variable

vector of nonnegative integers

Number of columns for each variable in `ds`, specified as the comma-separated pair consisting of 'NumCols' and a vector of nonnegative integers. When the number of columns for a variable is greater than one, `mat2dataset` combines multiple columns in `X` into a single variable in `ds`. The vector you assign to `NumCols` must sum to `size(X,2)`.

For example, to convert a matrix with eight columns into a dataset array with five variables, specify a vector with five elements that sum to eight, such as 'NumCols', [1,1,3,1,2].

Output Arguments

ds — Output dataset array

dataset array

Output dataset array, returned by default with a variable for each column of `X`, and an observation for each row of `X`. If you specify `NumCols`, then the number of variables in `ds` is equal to the length of the specified vector of column numbers.

Introduced in R2012b

mdscale

Nonclassical multidimensional scaling

Syntax

```
Y = mdscale(D,p)
[Y, stress] = mdscale(D,p)
[Y, stress, disparities] = mdscale(D,p)
[...] = mdscale(D,p, 'Name', value)
```

Description

`Y = mdscale(D,p)` performs nonmetric multidimensional scaling on the n -by- n dissimilarity matrix `D`, and returns `Y`, a configuration of n points (rows) in p dimensions (columns). The Euclidean distances between points in `Y` approximate a monotonic transformation of the corresponding dissimilarities in `D`. By default, `mdscale` uses Kruskal's normalized stress1 criterion.

You can specify `D` as either a full n -by- n matrix, or in upper triangle form such as is output by `pdist`. A full dissimilarity matrix must be real and symmetric, and have zeros along the diagonal and non-negative elements everywhere else. A dissimilarity matrix in upper triangle form must have real, non-negative entries. `mdscale` treats NaNs in `D` as missing values, and ignores those elements. `Inf` is not accepted.

You can also specify `D` as a full similarity matrix, with ones along the diagonal and all other elements less than one. `mdscale` transforms a similarity matrix to a dissimilarity matrix in such a way that distances between the points returned in `Y` approximate `sqrt(1-D)`. To use a different transformation, transform the similarities prior to calling `mdscale`.

`[Y, stress] = mdscale(D,p)` returns the minimized stress, i.e., the stress evaluated at `Y`.

`[Y, stress, disparities] = mdscale(D,p)` returns the disparities, that is, the monotonic transformation of the dissimilarities `D`.

`[...] = mdscale(D,p, 'Name', value)` specifies one or more optional parameter name/value pairs that control further details of `mdscale`. Specify *Name* in single quotes. Available parameters are

- **Criterion**— The goodness-of-fit criterion to minimize. This also determines the type of scaling, either non-metric or metric, that `mdscale` performs. Choices for non-metric scaling are:
 - `'stress'` — Stress normalized by the sum of squares of the inter-point distances, also known as stress1. This is the default.
 - `'sstress'` — Squared stress, normalized with the sum of 4th powers of the inter-point distances.

Choices for metric scaling are:

- `'metricstress'` — Stress, normalized with the sum of squares of the dissimilarities.
- `'metricsstress'` — Squared stress, normalized with the sum of 4th powers of the dissimilarities.

- 'sammon' — Sammon's nonlinear mapping criterion. Off-diagonal dissimilarities must be strictly positive with this criterion.
- 'strain' — A criterion equivalent to that used in classical multidimensional scaling.
- **Weights** — A matrix or vector the same size as *D*, containing nonnegative dissimilarity weights. You can use these to weight the contribution of the corresponding elements of *D* in computing and minimizing stress. Elements of *D* corresponding to zero weights are effectively ignored.

Note When you specify weights as a full matrix, its diagonal elements are ignored and have no effect, since the corresponding diagonal elements of *D* do not enter into the stress calculation.

- **Start** — Method used to choose the initial configuration of points for *Y*. The choices are
 - 'cmdscale' — Use the classical multidimensional scaling solution. This is the default. 'cmdscale' is not valid when there are zero weights.
 - 'random' — Choose locations randomly from an appropriately scaled *p*-dimensional normal distribution with uncorrelated coordinates.
 - An *n*-by-*p* matrix of initial locations, where *n* is the size of the matrix *D* and *p* is the number of columns of the output matrix *Y*. In this case, you can pass in [] for *p* and `mdscale` infers *p* from the second dimension of the matrix. You can also supply a 3-D array, implying a value for 'Replicates' from the array's third dimension.
- **Replicates** — Number of times to repeat the scaling, each with a new initial configuration. The default is 1.
- **Options** — Options for the iterative algorithm used to minimize the fitting criterion. Pass in an options structure created by `statset`. For example,

```
opts = statset(param1,val1,param2,val2, ...);
[...] = mdscale(...,'Options',opts)
```

The choices of `statset` parameters are

- 'Display' — Level of display output. The choices are 'off' (the default), 'iter', and 'final'.
- 'MaxIter' — Maximum number of iterations allowed. The default is 200.
- 'TolFun' — Termination tolerance for the stress criterion and its gradient. The default is 1e-4.
- 'TolX' — Termination tolerance for the configuration location step size. The default is 1e-4.

Examples

```
load cereal.mat
X = [Calories Protein Fat Sodium Fiber ...
     Carbo Sugars Shelf Potass Vitamins];

% Take a subset from a single manufacturer.
X = X(strcmp('K',cellstr(Mfg)),:);

% Create a dissimilarity matrix.
dissimilarities = pdist(X);

% Use non-metric scaling to recreate the data in 2D,
% and make a Shepard plot of the results.
```

```

[Y, stress, disparities] = mdscale(dissimilarities, 2);
distances = pdist(Y);
[dum, ord] = sortrows([disparities(:) dissimilarities(:)]);
plot(dissimilarities, distances, 'bo', ...
     dissimilarities(ord), disparities(ord), 'r.-');
xlabel('Dissimilarities'); ylabel('Distances/Disparities')
legend({'Distances' 'Disparities'}, 'Location', 'NW');

```

```

% Do metric scaling on the same dissimilarities.
figure
[Y, stress] = ...
mdscale(dissimilarities, 2, 'criterion', 'metricsstress');
distances = pdist(Y);
plot(dissimilarities, distances, 'bo', ...
     [0 max(dissimilarities)], [0 max(dissimilarities)], 'r.-');
xlabel('Dissimilarities'); ylabel('Distances')

```

Introduced before R2006a

mdsprox

Class: CompactTreeBagger

Multidimensional scaling of proximity matrix

Syntax

```
[SC,EIGEN] = mdsprox(B,X)
[SC,EIGEN] = mdsprox(B,X,'param1',val1,'param2',val2,...)
```

Description

[SC,EIGEN] = mdsprox(B,X) applies classical multidimensional scaling to the proximity matrix computed for the data in the matrix X, and returns scaled coordinates SC and eigenvalues EIGEN of the scaling transformation. The method applies multidimensional scaling to the matrix of distances defined as 1-prox, where prox is the proximity matrix returned by the proximity method.

You can supply the proximity matrix directly by using the 'Data' parameter.

[SC,EIGEN] = mdsprox(B,X,'param1',val1,'param2',val2,...) specifies optional parameter name/value pairs:

'Data'	Flag indicating how the method treats the X input argument. If set to 'predictors' (default), mdsprox assumes X to be a matrix of predictors and used for computation of the proximity matrix. If set to 'proximity', the method treats X as a proximity matrix returned by the proximity method.
'Colors'	If you supply this argument, mdsprox makes overlaid scatter plots of two scaled coordinates using specified colors for different classes. You must supply the colors as a character vector or a string scalar with one letter for each color. If there are more classes in the data than letters in the supplied value, mdsprox plots only the first C classes, where C is the number of letters in the supplied value. For regression or if you do not provide the vector of true class labels, the method uses the first color for all observations in X.
'Labels'	Vector of true class labels for a classification ensemble. True class labels can be a numeric vector, character matrix, string array, or cell array of character vectors. If supplied, this vector must have as many elements as there are observations (rows) in X. This argument has no effect unless you also supply the 'Colors' argument.
'MDSCoordinates'	Indices of the two scaled coordinates to plot. By default, mdsprox makes a scatter plot of the first and second scaled coordinates which correspond to the two largest eigenvalues. You can specify any other two or three indices not exceeding the dimensionality of the scaled data. This argument has no effect unless you also supply the 'Colors' argument.

cmdscale | mdsprox | proximity

mdsprox

Class: TreeBagger

Multidimensional scaling of proximity matrix

Syntax

```
[S,E] = mdsprox(B)
[S,E] = mdsprox(B, 'param1',val1, 'param2',val2,...)
```

Description

`[S,E] = mdsprox(B)` returns scaled coordinates, S, and eigenvalues, E, for the proximity matrix in the ensemble B. An earlier call to `fillprox(B)` must create the proximity matrix.

`[S,E] = mdsprox(B, 'param1',val1, 'param2',val2,...)` specifies optional parameter name/value pairs:

'Keep'	Array of indices of observations in the training data to use for multidimensional scaling. By default, this argument is set to 'all'. If you provide numeric or logical indices, the method uses only the subset of the training data specified by these indices to compute the scaled coordinates and eigenvalues.
'Colors'	If you supply this argument, <code>mdsprox</code> makes overlaid scatter plots of two scaled coordinates using specified colors for different classes. You must supply the colors as a character vector or a string scalar with one letter for each color. If there are more classes in the data than letters in the supplied value, <code>mdsprox</code> plots only the first C classes, where C is the number of letters in the supplied value. For regression, the method uses the first color for all observations in X.
'MDSCoordinates'	Indices of the two scaled coordinates to plot. By default, <code>mdsprox</code> makes a scatter plot of the first and second scaled coordinates which correspond to the two largest eigenvalues. You can specify any other two or three indices not exceeding the dimensionality of the scaled data. This argument has no effect unless you also supply the 'Colors' argument.

mean

Package: prob

Mean of probability distribution

Syntax

```
m = mean(pd)
```

Description

`m = mean(pd)` returns the mean `m` of the probability distribution `pd`.

Examples

Mean of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x, 'Normal')

pd =
  NormalDistribution

  Normal distribution
      mu = 75.0083   [73.4321, 76.5846]
      sigma =  8.7202   [7.7391, 9.98843]
```

Compute the mean of the fitted distribution.

```
m = mean(pd)
m = 75.0083
```

The mean of the normal distribution is equal to the parameter `mu`.

Mean of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull', 'a', 5, 'b', 2)

pd =
  WeibullDistribution
```

```
Weibull distribution
A = 5
B = 2
```

Compute the mean of the distribution.

```
mean = mean(pd)
```

```
mean = 4.4311
```

Mean of a Uniform Distribution

Create a uniform distribution object

```
pd = makedist('Uniform', 'lower', -3, 'upper', 5)
```

```
pd =
  UniformDistribution

  Uniform distribution
  Lower = -3
  Upper = 5
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m = 1
```

Mean of a Kernel Distribution

Load the sample data. Create a probability distribution object by fitting a kernel distribution to the miles per gallon (MPG) data.

```
load carsmall;
pd = fitdist(MPG, 'Kernel')
```

```
pd =
  KernelDistribution

  Kernel = normal
  Bandwidth = 4.11428
  Support = unbounded
```

Compute the mean of the distribution.

```
mean(pd)
```

```
ans = 23.7181
```

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

Function or App	Description
<code>makedist</code>	Create a probability distribution object using specified parameter values.
<code>fitdist</code>	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.

Output Arguments

m — Mean

scalar value

Mean of the probability distribution, returned as a scalar value.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument `pd` can be a fitted probability distribution object for beta, exponential, extreme value, lognormal, normal, and Weibull distributions. Create `pd` by fitting a probability distribution to sample data from the `fitdist` function. For an example, see “Code Generation for Probability Distribution Objects” on page 31-70.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

Introduced in R2013a

meanMargin

Class: CompactTreeBagger

Mean classification margin

Syntax

```
mar = meanMargin(B,TBLnew,Ynew)
mar = meanMargin(B,Xnew,Ynew)
mar = meanMargin(B,TBLnew,Ynew,'param1',val1,'param2',val2,...)
mar = meanMargin(B,Xnew,Ynew,'param1',val1,'param2',val2,...)
```

Description

`mar = meanMargin(B,TBLnew,Ynew)` computes average classification margins for the predictors contained in the table `TBLnew` given the true response `Ynew`. You can omit `Ynew` if `TBLnew` contains the response variable. If you trained `B` using sample data contained in a table, then the input data for this method must also be in a table.

`mar = meanMargin(B,Xnew,Ynew)` computes average classification margins for the predictors contained in the matrix `Xnew` given true response `Ynew`. If you trained `B` using sample data contained in a matrix, then the input data for this method must also be in a matrix.

`Ynew` can be a numeric vector, character matrix, string array, cell array of character vectors, categorical vector, or logical vector. `meanMargin` averages the margins over all observations (rows) in `TBLnew` or `Xnew` for each tree. `mar` is a matrix of size 1-by-`NTrees`, where `NTrees` is the number of trees in the ensemble `B`. This method is available for classification ensembles only.

`mar = meanMargin(B,TBLnew,Ynew,'param1',val1,'param2',val2,...)` or `mar = meanMargin(B,Xnew,Ynew,'param1',val1,'param2',val2,...)` specifies optional parameter name-value pairs:

'Mode'	How <code>meanMargin</code> computes errors. If set to 'cumulative' (default), is a vector of length <code>NTrees</code> where the first element gives mean margin from <code>trees(1)</code> , second column gives mean margins from <code>trees(1:2)</code> etc., up to <code>trees(1:NTrees)</code> . If set to 'individual', <code>mar</code> is a vector of length <code>NTrees</code> , where each element is a mean margin from each tree in the ensemble. If set to 'ensemble', <code>mar</code> is a scalar showing the cumulative mean margin for the entire ensemble.
'Trees'	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'Trees' is a numeric vector, the method returns a vector of length <code>NTrees</code> for 'cumulative' and 'individual' modes, where <code>NTrees</code> is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives mean margin from <code>trees(1)</code> , the second element gives mean margin from <code>trees(1:2)</code> etc.

'TreeWeights'	Vector of tree weights. This vector must have the same length as the 'Trees' vector. <code>meanMargin</code> uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the 'individual' mode.

meanMargin

Class: TreeBagger

Mean classification margin

Syntax

```
mar = meanMargin(B,TBLnew,Ynew)
mar = meanMargin(B,Xnew,Ynew)
mar = meanMargin(B,TBLnew,Ynew,'param1',val1,'param2',val2,...)
mar = meanMargin(B,Xnew,Ynew,'param1',val1,'param2',val2,...)
```

Description

`mar = meanMargin(B,TBLnew,Ynew)` computes average classification margins for the predictors contained in the table `TBLnew` given the true response `Ynew`. You can omit `Ynew` if `TBLnew` contains the response variable. If you trained `B` using sample data contained in a table, then the input data for this method must also be in a table.

`mar = meanMargin(B,Xnew,Ynew)` computes average classification margins for the predictors contained in the matrix `Xnew` given true response `Ynew`. If you trained `B` using sample data contained in a matrix, then the input data for this method must also be in a matrix.

`Ynew` can be a numeric vector, character matrix, string array, cell array of character vectors, categorical vector or logical vector. `meanMargin` averages the margins over all observations (rows) in `TBLnew` or `Xnew` for each tree. `mar` is a matrix of size 1-by-`NTrees`, where `NTrees` is the number of trees in the ensemble `B`. This method is available for classification ensembles only.

`mar = meanMargin(B,TBLnew,Ynew,'param1',val1,'param2',val2,...)` or `mar = meanMargin(B,Xnew,Ynew,'param1',val1,'param2',val2,...)` specifies optional parameter name-value pairs:

'Mode'	Character vector or string scalar indicating how <code>meanMargin</code> computes errors. If set to 'cumulative' (default), is a vector of length <code>NTrees</code> where the first element gives mean margin from trees (1), second column gives mean margins from trees (1:2) etc, up to trees (1:NTrees). If set to 'individual', <code>mar</code> is a vector of length <code>NTrees</code> , where each element is a mean margin from each tree in the ensemble. If set to 'ensemble', <code>mar</code> is a scalar showing the cumulative mean margin for the entire ensemble.
'Trees'	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'Trees' is a numeric vector, the method returns a vector of length <code>NTrees</code> for 'cumulative' and 'individual' modes, where <code>NTrees</code> is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives mean margin from trees (1), the second element gives mean margin from trees (1:2) etc.

'TreeWeights'	Vector of tree weights. This vector must have the same length as the 'Trees' vector. <code>meanMargin</code> uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the 'individual' mode.
'Weights'	Vector of observation weights to use for margin averaging. By default the weight of every observation is set to 1. The length of this vector must be equal to the number of rows in <i>X</i> .
'UseInstanceForTree'	Logical matrix of size Nobs-by-NumTrees indicating which trees to use to make predictions for each observation. By default the method uses all trees for all observations.

surrogateAssociation

Mean predictive measure of association for surrogate splits in classification tree

Syntax

```
ma = surrogateAssociation(tree)
ma = surrogateAssociation(tree,N)
```

Description

`ma = surrogateAssociation(tree)` returns a matrix of predictive measures of association for the predictors in `tree`.

`ma = surrogateAssociation(tree,N)` returns a matrix of predictive measures of association averaged over the nodes in vector `N`.

Input Arguments

tree

A classification tree constructed with `fitctree`, or a compact regression tree constructed with `compact`.

N

Vector of node numbers in `tree`.

Output Arguments

ma

- `ma = surrogateAssociation(tree)` returns a P-by-P matrix, where P is the number of predictors in `tree`. `ma(i,j)` is the predictive measure of association on page 32-3402 between the optimal split on variable `i` and a surrogate split on variable `j`. For more details, see “Algorithms” on page 32-3403.
- `ma = surrogateAssociation(tree,N)` returns a P-by-P representing the predictive measure of association between variables averaged over nodes in the vector `N`. `N` contains node numbers from 1 to `max(tree.NumNodes)`.

Examples

Estimate Predictive Measures of Association for Surrogate Splits

Load Fisher's iris data set.

```
load fisheriris
```

Grow a classification tree using `species` as the response. Specify to use surrogate splits for missing values.

```
tree = fitctree(meas,species,'surrogate','on');
```

Find the mean predictive measure of association between the predictor variables.

```
ma = surrogateAssociation(tree)
```

```
ma = 4×4
```

```
1.0000    0    0    0

More About

Predictive Measure of Association

The predictive measure of association is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split (found by growing the tree), the best surrogate decision split on page 32-1791 yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose x_j and x_k are predictor variables j and k , respectively, and $j \neq k$. At node t , the predictive measure of association between the optimal split $x_j < u$ and a surrogate split $x_k < v$ is

$$\lambda_{jk} = \frac{\min(P_L, P_R) - (1 - P_{L_j L_k} - P_{R_j R_k})}{\min(P_L, P_R)}.$$

- P_L is the proportion of observations in node t , such that $x_j < u$. The subscript L stands for the left child of node t .
- P_R is the proportion of observations in node t , such that $x_j \geq u$. The subscript R stands for the right child of node t .
- $P_{L_j L_k}$ is the proportion of observations at node t , such that $x_j < u$ and $x_k < v$.
- $P_{R_j R_k}$ is the proportion of observations at node t , such that $x_j \geq u$ and $x_k \geq v$.

- Observations with missing values for x_j or x_k do not contribute to the proportion calculations.

λ_{jk} is a value in $(-\infty, 1]$. If $\lambda_{jk} > 0$, then $x_k < v$ is a worthwhile surrogate split for $x_j < u$.

Surrogate Decision Splits

A surrogate decision split is an alternative to the optimal decision split at a given node in a decision tree. The optimal split is found by growing the tree; the surrogate split uses a similar or correlated predictor variable and split criterion.

When the value of the optimal split predictor for an observation is missing, the observation is sent to the left or right child node using the best surrogate predictor. When the value of the best surrogate split predictor for the observation is also missing, the observation is sent to the left or right child node using the second-best surrogate predictor, and so on. Candidate splits are sorted in descending order by their predictive measure of association on page 32-2179.

Algorithms

Element $ma(i, j)$ is the predictive measure of association averaged over surrogate splits on predictor j for which predictor i is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor i and surrogate splits on predictor j and dividing by the total number of optimal splits on predictor i , including splits for which the predictive measure of association between predictors i and j is negative.

surrogateAssociation

Mean predictive measure of association for surrogate splits in regression tree

Syntax

```
ma = surrogateAssociation(tree)
ma = surrogateAssociation(tree,N)
```

Description

`ma = surrogateAssociation(tree)` returns a matrix of predictive measures of association for the predictors in `tree`.

`ma = surrogateAssociation(tree,N)` returns a matrix of predictive measures of association averaged over the nodes in vector `N`.

Input Arguments

`tree`

A regression tree constructed with `fitrtree`, or a compact regression tree constructed with `compact`.

`N`

Vector of node numbers in `tree`.

Output Arguments

`ma`

- `ma = surrogateAssociation(tree)` returns a P-by-P matrix, where P is the number of predictors in `tree`. `ma(i,j)` is the predictive measure of association on page 32-3405 between the optimal split on variable `i` and a surrogate split on variable `j`. For more details, see “Algorithms” on page 32-3406.
- `ma = surrogateAssociation(tree,N)` returns a P-by-P representing the predictive measure of association between variables averaged over nodes in the vector `N`. `N` contains node numbers from 1 to `max(tree.NumNodes)`.

Examples

Estimate Predictive Measures of Association for Surrogate Splits

Load the `carsmall` data set. Specify `Displacement`, `Horsepower`, and `Weight` as predictor variables.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using MPG as the response. Specify to use surrogate splits for missing values.

```
tree = fitrtree(X,MPG,'surrogate','on');
```

Find the mean predictive measure of association between the predictor variables.

```
ma = surrogateAssociation(tree)
```

```
ma = 3×3
```

```
    1.0000    0.2167    0.5083

RegressionTree | fitrtree | prune

median

Package: prob

Median of probability distribution

Syntax

```
m = median(pd)
```

Description

`m = median(pd)` returns the median `m` for the probability distribution `pd`

Examples

Median of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x, 'Normal')

pd =
  NormalDistribution

  Normal distribution
      mu = 75.0083    [73.4321, 76.5846]
      sigma =  8.7202    [7.7391, 9.98843]
```

Compute the median of the fitted distribution.

```
m = median(pd)
m = 75.0083
```

For a symmetrical distribution such as the normal distribution, the median is equal to the mean, `mu`.

Median of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull', 'a', 5, 'b', 2)

pd =
  WeibullDistribution
```

```
Weibull distribution  
A = 5  
B = 2
```

Compute the median of the distribution.

```
m = median(pd)  
m = 4.1628
```

For a skewed distribution such as the Weibull distribution, the median and the mean may not be equal.

Calculate the mean of the Weibull distribution and compare it to the median.

```
mean = mean(pd)  
mean = 4.4311
```

The mean of the distribution is greater than the median.

Plot the pdf to visualize the distribution.

```
x = [0:.1:15];  
pdf = pdf(pd,x);  
plot(x,pdf)
```

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

Function or App	Description
<code>makedist</code>	Create a probability distribution object using specified parameter values.
<code>fitdist</code>	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.

Output Arguments

m — Median

scalar value

Median of the probability distribution, returned as a scalar value. The value of `m` is the 50th percentile of the probability distribution.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument `pd` can be a fitted probability distribution object for beta, exponential, extreme value, lognormal, normal, and Weibull distributions. Create `pd` by fitting a probability distribution to sample data from the `fitdist` function. For an example, see “Code Generation for Probability Distribution Objects” on page 31-70.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

mergelevels

(Not Recommended) Merge levels of nominal or ordinal arrays

Note The `nominal` and `ordinal` array data types are not recommended. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

Syntax

```
B = mergelevels(A,oldlevels)
B = mergelevels(A,oldlevels,newlevel)
```

Description

`B = mergelevels(A,oldlevels)` merges two or more levels of `A`.

- If `A` is a nominal array, `mergelevels` uses the first label in `oldlevels` as the new level.
- If `A` is an ordinal array, the levels specified by `oldlevels` must be consecutive, and `mergelevels` uses the label corresponding to the lowest level in `oldlevels` as the label for the new level.

`B = mergelevels(A,oldlevels,newlevel)` merges two or more levels into the new level with label `newlevel`.

Examples

Create New Category From Merged Levels

Create a nominal array from data in a cell array.

```
colors = nominal({'r','b','g';'g','r','b';'b','r','g'},...
                {'blue','green','red'})
```

```
colors = 3x3 nominal
    red     blue     green
    green   red      blue
    blue    red      green
```

Merge the elements of the 'red' and 'blue' levels into a new level labeled 'purple'.

```
colors = mergelevels(colors,{'red','blue'},'purple')
```

```
colors = 3x3 nominal
    purple   purple   green
    green    purple   purple
    purple   purple   green
```

Display the levels of `colors`.

```
getlevels(colors)
ans = 1x2 nominal
      purple      green
```

Input Arguments

A — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created with `nominal` or `ordinal`.

oldlevels — Levels to merge

string array | cell array of character vectors | 2-D character array

Levels to merge, specified as a string array, cell array of character vectors, or 2-D character array. For ordinal arrays, the levels in `oldlevels` must be consecutive.

Data Types: `char` | `string` | `cell`

newlevel — Level to create

character vector | string scalar

Level to create from the merged levels, specified as a character vector or string scalar that gives the label for the new level.

Data Types: `char` | `string`

Output Arguments

B — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, returned as a `nominal` or `ordinal` array object.

See Also

`addlevels` | `droplevels` | `nominal` | `ordinal` | `reorderlevels`

mhsample

Metropolis-Hastings sample

Syntax

```
smdl = mhsample(start,nsamples,'pdf',pdf,'proppdf',proppdf,
'proprnd',proprnd)
smdl = mhsample(...,'symmetric',sym)
smdl = mhsample(...,'burnin',K)
smdl = mhsample(...,'thin',m)
smdl = mhsample(...,'nchain',n)
[smdl,accept] = mhsample(...)
```

Description

`smdl = mhsample(start,nsamples,'pdf',pdf,'proppdf',proppdf,'proprnd',proprnd)` draws `nsamples` random samples from a target stationary distribution `pdf` using the Metropolis-Hastings algorithm.

`start` is a row vector containing the start value of the Markov Chain, `nsamples` is an integer specifying the number of samples to be generated, and `pdf`, `proppdf`, and `proprnd` are function handles created using `@`. `proppdf` defines the proposal distribution density, and `proprnd` defines the random number generator for the proposal distribution. `pdf` and `proprnd` take one argument as an input with the same type and size as `start`. `proppdf` takes two arguments as inputs with the same type and size as `start`.

`smdl` is a column vector or matrix containing the samples. If the log density function is preferred, `'pdf'` and `'proppdf'` can be replaced with `'logpdf'` and `'logproppdf'`. The density functions used in Metropolis-Hastings algorithm are not necessarily normalized.

The proposal distribution $q(x,y)$ gives the probability density for choosing x as the next point when y is the current point. It is sometimes written as $q(x|y)$.

If the `proppdf` or `logproppdf` satisfies $q(x,y) = q(y,x)$, that is, the proposal distribution is symmetric, `mhsample` implements Random Walk Metropolis-Hastings sampling. If the `proppdf` or `logproppdf` satisfies $q(x,y) = q(x)$, that is, the proposal distribution is independent of current values, `mhsample` implements Independent Metropolis-Hastings sampling.

`smdl = mhsample(...,'symmetric',sym)` draws `nsamples` random samples from a target stationary distribution `pdf` using the Metropolis-Hastings algorithm. `sym` is a logical value that indicates whether the proposal distribution is symmetric. The default value is false, which corresponds to the asymmetric proposal distribution. If `sym` is true, for example, the proposal distribution is symmetric, `proppdf` and `logproppdf` are optional.

`smdl = mhsample(...,'burnin',K)` generates a Markov chain with values between the starting point and the k^{th} point omitted in the generated sequence. Values beyond the k^{th} point are kept. `k` is a nonnegative integer with default value of 0.

`smdl = mhsample(...,'thin',m)` generates a Markov chain with $m-1$ out of m values omitted in the generated sequence. `m` is a positive integer with default value of 1.

`smpl = mhsample(..., 'nchain', n)` generates n Markov chains using the Metropolis-Hastings algorithm. n is a positive integer with a default value of 1. `smpl` is a matrix containing the samples. The last dimension contains the indices for individual chains.

`[smpl, accept] = mhsample(...)` also returns `accept`, the acceptance rate of the proposed distribution. `accept` is a scalar if a single chain is generated and is a vector if multiple chains are generated.

Examples

Estimate Moments Using Independent Metropolis-Hastings Sampling

Use Independent Metropolis-Hastings sampling to estimate the second order moment of a Gamma distribution.

```
rng default; % For reproducibility
alpha = 2.43;
beta = 1;
pdf = @(x)gampdf(x,alpha,beta); % Target distribution
proppdf = @(x,y)gampdf(x,floor(alpha),floor(alpha)/alpha);
proprnd = @(x)sum(...
    exprnd(floor(alpha)/alpha,floor(alpha),1));
nsamples = 5000;
smpl = mhsample(1,nsamples,'pdf',pdf,'proprnd',proprnd,...
    'proppdf',proppdf);
```

Plot the results.

```
xxhat = cumsum(smpl.^2)./(1:nsamples)';
figure;
plot(1:nsamples,xxhat)
```

Random Walk Metropolis-Hastings Sampling

Use Random Walk Metropolis-Hastings sampling to generate sample data from a standard normal distribution.

```
rng default % For reproducibility
delta = .5;
pdf = @(x) normpdf(x);
proppdf = @(x,y) unifpdf(y-x,-delta,delta);
proprnd = @(x) x + rand*2*delta - delta;
nsamples = 15000;
x = mhsample(1,nsamples,'pdf',pdf,'proprnd',proprnd,'symmetric',1);
```

Plot the sample data.

```
figure;
h = histfit(x,50);
h(1).FaceColor = [.8 .8 1];
```

mle

Maximum likelihood estimates

Syntax

```
phat = mle(data)
phat = mle(data, 'distribution', dist)

phat = mle(data, 'pdf', pdf, 'start', start)
phat = mle(data, 'pdf', pdf, 'start', start, 'cdf', cdf)

phat = mle(data, 'logpdf', logpdf, 'start', start)
phat = mle(data, 'logpdf', logpdf, 'start', start, 'logsf', logsf)

phat = mle(data, 'nloglf', nloglf, 'start', start)

phat = mle( ___, Name, Value)
[phat, pci] = mle( ___)
```

Description

`phat = mle(data)` returns maximum likelihood estimates (MLEs) for the parameters of a normal distribution, using the sample data in the vector `data`.

`phat = mle(data, 'distribution', dist)` returns parameter estimates for a distribution specified by `dist`.

`phat = mle(data, 'pdf', pdf, 'start', start)` returns parameter estimates for a custom distribution specified by the probability density function `pdf`. You must also specify the initial parameter values, `start`.

`phat = mle(data, 'pdf', pdf, 'start', start, 'cdf', cdf)` returns parameter estimates for a custom distribution specified by the probability density function `pdf` and custom cumulative distribution function `cdf`.

`phat = mle(data, 'logpdf', logpdf, 'start', start)` returns parameter estimates for a custom distribution specified by the log probability density function `logpdf`. You must also specify the initial parameter values, `start`.

`phat = mle(data, 'logpdf', logpdf, 'start', start, 'logsf', logsf)` returns parameter estimates for a custom distribution specified by the log probability density function `logpdf` and custom log survival function on page 32-3429 `logsf`.

`phat = mle(data, 'nloglf', nloglf, 'start', start)` returns parameter estimates for the custom distribution specified by the negative loglikelihood function `nloglf`. You must also specify the initial parameter values, `start`.

`phat = mle(___, Name, Value)` specifies options using name-value pair arguments in addition to any of the input arguments in previous syntaxes. For example, you can specify the censored data, frequency of observations, and confidence level.

`[phat,pci] = mle(___)` also returns the 95% confidence intervals for the parameters.

Examples

Estimate Parameters of Burr Distribution

Load the sample data.

```
load carbig
```

The variable MPG has the miles per gallon for different models of cars.

Draw a histogram of MPG data.

```
histogram(MPG)
```

The distribution is somewhat right skewed. A symmetric distribution, such as normal distribution, might not be a good fit.

Estimate the parameters of the Burr Type XII distribution for the MPG data.

```
phat = mle(MPG, 'distribution', 'burr')
```

```
phat = 1×3
```

```
34.6447    3.7898    3.5722
```

The maximum likelihood estimates for the scale parameter α is 34.6447. The estimates for the two shape parameters c and k of the Burr Type XII distribution are 3.7898 and 3.5722, respectively.

Estimate Parameters of a Noncentral Chi-Square Distribution

Generate sample data of size 1000 from a noncentral chi-square distribution with degrees of freedom 8 and noncentrality parameter 3.

```
rng default % for reproducibility
x = ncx2rnd(8,3,1000,1);
```

Estimate the parameters of the noncentral chi-square distribution from the sample data. To do this, custom define the noncentral chi-square pdf using the pdf input argument.

```
[phat,pci] = mle(x,'pdf',@(x,v,d)ncx2pdf(x,v,d),'start',[1,1])
```

```
phat = 1×2
```

```
8.1052    2.6693
```

```
pci = 2×2
```

```
7.1121    1.6025
9.0983    3.7362
```

The estimate for the degrees of freedom is 8.1052 and the noncentrality parameter is 2.6693. The 95% confidence interval for the degrees of freedom is (7.1121,9.0983) and the noncentrality parameter is (1.6025,3.7362). The confidence intervals include the true parameter values of 8 and 3, respectively.

Fit Custom Distribution to Censored Data

Load the sample data.

```
load('readmissiontimes.mat');
```

The data includes ReadmissionTime, which has readmission times for 100 patients. The column vector Censored has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom probability density and cumulative distribution function.

```
custpdf = @(data,lambda) lambda*exp(-lambda*data);
custcdf = @(data,lambda) 1-exp(-lambda*data);
```

Estimate the parameter, lambda, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime,'pdf',custpdf,'cdf',custcdf,'start',0.05,'Censoring',Censored)
```

```
phat = 0.1096
```

Fit Custom Log pdf and Survival Function

Load the sample data.

```
load('readmissiontimes.mat');
```

The data includes ReadmissionTime, which has readmission times for 100 patients. The column vector Censored has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom log probability density and survival function.

```
custlogpdf = @(data,lambda,k) log(k)-k*log(lambda)+(k-1)*log(data)-(data/lambda).^k;
custlogsf = @(data,lambda,k) -(data/lambda).^k;
```

Estimate the parameters, lambda and k, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime,'logpdf',custlogpdf,'logsf',custlogsf,...
    'start',[1,0.75],'Censoring',Censored)
```

```
phat = 1x2
```

```
    9.2090    1.4223
```

The scale and shape parameters of the custom-defined distribution are 9.2090 and 1.4223, respectively.

Fit Custom Log Negative Likelihood Function

Load the sample data.

```
load('readmissiontimes.mat');
```

The data includes ReadmissionTime, which has readmission times for 100 patients. This is simulated data.

Define a negative log likelihood function.

```
custnloglf = @(lambda,data,cens,freq) - length(data)*log(lambda) + nansum(lambda*data);
```

Estimate the parameters of the defined distribution.

```
phat = mle(ReadmissionTime,'nloglf',custnloglf,'start',0.05)
```

```
phat = 0.1462
```

Estimate Probability of Success

Generate 100 random observations from a binomial distribution with the number of trials, $n = 20$, and the probability of success, $p = 0.75$.

```
data = binornd(20,0.75,100,1);
```

Estimate the probability of success and 95% confidence limits using the simulated sample data.

```
[phat,pci] = mle(data,'distribution','binomial','alpha',.05,'ntrials',20)
```

```
phat = 0.7615
```

```
pci = 2×1
```

```
    0.7422
    0.7800
```

The estimate of probability of success is 0.7615 and the lower and upper limits of the 95% confidence interval are 0.7422 and 0.78. This interval covers the true value used to simulate the data.

Fit Distribution with Known Parameter

Generate sample data of size 1000 from a noncentral chi-square distribution with degrees of freedom 10 and noncentrality parameter 5.

```
rng default % for reproducibility
x = ncx2rnd(10,5,1000,1);
```

Suppose the noncentrality parameter is fixed at the value 5. Estimate the degrees of freedom of the noncentral chi-square distribution from the sample data. To do this, custom define the noncentral chi-square pdf using the pdf input argument.

```
[phat,pci] = mle(x,'pdf',@(x,v,d)ncx2pdf(x,v,5),'start',1)
```

```
phat = 9.9307
```

```
pci = 2×1
```

```
    9.5626
   10.2989
```

The estimate for the noncentrality parameter is 9.9307, with a 95% confidence interval of 9.5626 and 10.2989. The confidence interval includes the true parameter value of 10.

Fit Rician Distribution with Known Scale Parameter

Generate sample data of size 1000 from a Rician distribution with noncentrality parameter of 8 and scale parameter of 5. First create the Rician distribution.

```
r = makedist('Rician','s',8,'sigma',5);
```

Now, generate sample data from the distribution you created above.

```
rng default % For reproducibility
x = random(r,1000,1);
```

Suppose the scale parameter is known, and estimate the noncentrality parameter from sample data. To do this using `mle`, you must custom define the Rician probability density function.

```
[phat,pci] = mle(x,'pdf',@(x,s,sigma) pdf('rician',x,s,5),'start',10)

phat = 7.8953

pci = 2×1

    7.5405
    8.2501
```

The estimate for the noncentrality parameter is 7.8953, with a 95% confidence interval of 7.5404 and 8.2501. The confidence interval includes the true parameter value of 8.

Fit a Distribution with Additional Parameter

Add a scale parameter to the chi-square distribution for adapting to the scale of data and fit it. First, generate sample data of size 1000 from a chi-square distribution with degrees of freedom 5, and scale it by the factor of 100.

```
rng default % For reproducibility
x = 100*chi2rnd(5,1000,1);
```

Estimate the degrees of freedom and the scaling factor. To do this, custom define the chi-square probability density function using the `pdf` input argument. The density function requires a $1/s$ factor for data scaled by s .

```
[phat,pci] = mle(x,'pdf',@(x,v,s)chi2pdf(x/s,v)/s,'start',[1,200])

phat = 1×2

    5.1079    99.1681

pci = 2×2

    4.6862    90.1215
    5.5297   108.2146
```

The estimate for the degrees of freedom is 5.1079 and the scale is 99.1681. The 95% confidence interval for the degrees of freedom is (4.6862,5.5279) and the scale parameter is (90.1215,108.2146). The confidence intervals include the true parameter values of 5 and 100, respectively.

Input Arguments

data — Sample data

vector

Sample data `mle` uses to estimate the distribution parameters, specified as a vector.

Data Types: `single` | `double`

dist — Distribution type

'normal' (default) | character vector or string scalar of distribution type

Distribution type to estimate parameters for, specified as one of the following.

dist	Description	Parameter 1	Parameter 2	Parameter 3	Parameter 4
'Bernoulli'	"Bernoulli Distribution" on page B-2	p : probability of success for each trial	—	—	—
'Beta'	"Beta Distribution" on page B-6	a : first shape parameter	b : second shape parameter	—	—
'bino' or 'Binomial'	"Binomial Distribution" on page B-10	n : number of trials	p : probability of success for each trial	—	—
'BirnbaumSaunders'	"Birnbaum-Saunders Distribution" on page B-18	β : scale parameter	γ : shape parameter	—	—
'Burr'	"Burr Type XII Distribution" on page B-19	α : scale parameter	c : first shape parameter	k : second shape parameter	—
'Discrete Uniform' or 'unid'	"Uniform Distribution (Discrete)" on page B-168	n : maximum observable value	—	—	—
'exp' or 'Exponential'	"Exponential Distribution" on page B-33	μ : mean	—	—	—
'ev' or 'Extreme Value'	"Extreme Value Distribution" on page B-40	μ : location parameter	σ : scale parameter	—	—
'gam' or 'Gamma'	"Gamma Distribution" on page B-47	a : shape parameter	b : scale parameter	—	—
'gev' or 'Generalized Extreme Value'	"Generalized Extreme Value Distribution" on page B-55	k : shape parameter	σ : scale parameter	μ : location parameter	—
'gp' or 'Generalized Pareto'	"Generalized Pareto Distribution" on page B-59	k : tail index (shape) parameter	σ : scale parameter	θ : threshold (location) parameter	—

dist	Description	Parameter 1	Parameter 2	Parameter 3	Parameter 4
'geo' or 'Geometric'	"Geometric Distribution" on page B-63	ρ : probability parameter	—	—	—
'hn' or 'Half Normal'	"Half-Normal Distribution" on page B-68	μ : location parameter	σ : scale parameter	—	—
'InverseGaussian'	"Inverse Gaussian Distribution" on page B-75	μ : scale parameter	λ : shape parameter	—	—
'Logistic'	"Logistic Distribution" on page B-85	μ : mean	σ : scale parameter	—	—
'LogLogistic'	"Loglogistic Distribution" on page B-86	μ : mean of logarithmic values	σ : scale parameter of logarithmic values	—	—
'logn' or 'LogNormal'	"Lognormal Distribution" on page B-88	μ : mean of logarithmic values	σ : standard deviation of logarithmic values	—	—
'Nakagami'	"Nakagami Distribution" on page B-108	μ : shape parameter	ω : scale parameter	—	—
'nbin' or 'Negative Binomial'	"Negative Binomial Distribution" on page B-109	r : number of successes	p : probability of success in a single trial	—	—
'norm' or 'Normal'	"Normal Distribution" on page B-119	μ : mean	σ : standard deviation	—	—
'poiss' or 'Poisson'	"Poisson Distribution" on page B-131	λ : mean	—	—	—
'rayl' or 'Rayleigh'	"Rayleigh Distribution" on page B-137	b : scale parameter	—	—	—
'Rician'	"Rician Distribution" on page B-139	s : noncentrality parameter	σ : scale parameter	—	—
'Stable'	"Stable Distribution" on page B-140	α : first shape parameter	β : second shape parameter	γ : scale parameter	δ : location parameter
'tLocationScale'	"t Location-Scale Distribution" on page B-156	μ : location parameter	σ : scale parameter	ν : shape parameter	—
'unif' or 'Uniform'	"Uniform Distribution (Continuous)" on page B-163	a : lower endpoint (minimum)	b : upper endpoint (maximum)	—	—
'wbl' or 'Weibull'	"Weibull Distribution" on page B-170	a : scale parameter	b : shape parameter	—	—

Example: 'rician'

pdf — Custom probability density function

function handle

Custom probability distribution function, specified as a function handle created using @.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of probability density values.

For example, if the name of the custom probability density function is `newpdf`, then you can specify the function handle in `mle` as follows.

Example: `@newpdf`

Data Types: `function_handle`

cdf — Custom cumulative distribution function

function handle

Custom cumulative distribution function, specified as a function handle created using @.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of cumulative probability values.

You must define `cdf` with `pdf` if data is censored and you use the 'Censoring' name-value pair argument. If 'Censoring' is not present, you do not have to specify `cdf` while using `pdf`.

For example, if the name of the custom cumulative distribution function is `newcdf`, then you can specify the function handle in `mle` as follows.

Example: `@newcdf`

Data Types: `function_handle`

logpdf — Custom log probability density function

function handle

Custom log probability density function, specified as a function handle created using @.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of log probability values.

For example, if the name of the custom log probability density function is `customlogpdf`, then you can specify the function handle in `mle` as follows.

Example: `@customlogpdf`

Data Types: `function_handle`

logsf — Custom log survival function

function handle

Custom log survival function on page 32-3429, specified as a function handle created using @.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of log survival probability values.

You must define `logsf` with `logpdf` if data is censored and you use the 'Censoring' name-value pair argument. If 'Censoring' is not present, you do not have to specify `logsf` while using `logpdf`.

For example, if the name of the custom log survival function is `logsurvival`, then you can specify the function handle in `mle` as follows.

Example: `@logsurvival`

Data Types: `function_handle`

nloglf – Custom negative loglikelihood function

function handle

Custom negative loglikelihood function, specified as a function handle created using `@`.

This custom function accepts the following input arguments.

<code>params</code>	Vector of distribution parameter values. <code>mle</code> detects the number of parameters from the number of elements in <code>start</code> .
<code>data</code>	Vector of data.
<code>cens</code>	Boolean vector of censored values.
<code>freq</code>	Vector of integer data frequencies.

`nloglf` must accept all four arguments even if you do not use the 'Censoring' or 'Frequency' name-value pair arguments. You can write '`nloglf`' to ignore `cens` and `freq` arguments in that case.

`nloglf` returns a scalar negative loglikelihood value and optionally, a negative loglikelihood gradient vector (see the '`GradObj`' field in '`Options`').

If the name of the custom negative log likelihood function is `negloglik`, then you can specify the function handle in `mle` as follows.

Example: `@negloglik`

Data Types: `function_handle`

start – Initial parameter values

scalar | vector

Initial parameter values for the custom functions, specified as a scalar value or a vector of scalar values.

Use `start` when you fit custom distributions, that is, when you use `pdf` and `cdf`, `logpdf` and `logsf`, or `nloglf` input arguments.

Example: `0.05`

Example: `[100,2]`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: '`Censoring`', `Cens`, '`Alpha`', `0.01`, '`Options`', `Opt` specifies that `mle` estimates the parameters for the distribution of censored data specified by array `Cens`, computes the 99%

confidence limits for the parameter estimates, and uses the algorithm control parameters specified by the structure `Opt`.

Censoring — Indicator for censoring

array of 0s (default) | array of 0s and 1s

Indicator for censoring, specified as the comma-separated pair consisting of 'Censoring' and a Boolean array of the same size as `data`. Use 1 for observations that are right censored and 0 for observations that are fully observed. The default is all observations are fully observed.

For example, if the censored data information is in the binary array called `Censored`, then you can specify the censored data as follows.

Example: 'Censoring', `Censored`

`mle` supports censoring for the following distributions:

Birnbaum-Saunders	Logistic
Burr	Lognormal
Exponential	Nakagami
Extreme Value	Normal
Gamma	Rician
Inverse Gaussian	t Location-Scale
Kernel	Weibull
Log-Logistic	

Data Types: `logical`

Frequency — Frequency of observations

array of 1s (default) | vector of nonnegative integer counts

Frequency of observations, specified as the comma-separated pair consisting of 'Frequency' and an array containing nonnegative integer counts, which is the same size as `data`. The default is one observation per element of `data`.

For example, if the observation frequencies are stored in an array named `Freq`, you can specify the frequencies as follows.

Example: 'Frequency', `Freq`

Data Types: `single` | `double`

Alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level for the confidence interval of parameter estimates, `p_ci`, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1). The confidence level of `p_ci` is $100(1-\text{Alpha})\%$. The default is 0.05 for 95% confidence.

For example, for 99% confidence limits, you can specify the confidence level as follows.

Example: 'Alpha', 0.01

Data Types: `single` | `double`

NTrials — Number of trials

scalar value | vector

Number of trials for the corresponding element of data, specified as the comma-separated pair consisting of 'Ntrials' and a scalar or a vector of the same size as data.

Applies only to binomial distribution.

Example: 'Ntrials',total

Data Types: single | double

mu — Location parameter

0 (default) | scalar value

Location parameter for the half-normal distribution, specified as the comma-separated pair consisting of 'mu' and a scalar value.

Applies only to half-normal distribution.

Example: 'mu',1

Data Types: single | double

Options — Fitting algorithm control parameters

structure

Fitting algorithm control parameters, specified as the comma-separated pair consisting of 'Options' and a structure returned by `statset`.

Not applicable to all distributions.

Use the 'Options' name-value pair argument to control details of the maximum likelihood optimization when fitting a custom distribution. For parameter names and default values, type `statset('mlecustom')`. You can set the options under a new name and use that in the name-value pair argument. `mle` interprets the following `statset` parameters for custom distribution fitting.

Parameter	Value
'GradObj'	<p>Default is 'off'.</p> <p>'on' or 'off', indicating whether or not <code>fmincon</code> can expect the custom function provided with the <code>nloglf</code> input argument to return the gradient vector of the negative log-likelihood as a second output.</p> <p><code>mle</code> ignores 'GradObj' when using <code>fminsearch</code>.</p>
'DerivStep'	<p>Default is $\text{eps}^{(1/3)}$.</p> <p>The relative difference, specified as a scalar or a vector the same size as <code>start</code>, used in finite difference derivative approximations when using <code>fmincon</code>, and 'GradObj' is 'off'.</p> <p><code>mle</code> ignores 'DerivStep' when using <code>fminsearch</code>.</p>

Parameter	Value
'FunValCheck'	<p>Default is 'on'.</p> <p>'on' or 'off', indicating whether or not mle should check the values returned by the custom distribution functions for validity.</p> <p>A poor choice of starting point can sometimes cause these functions to return NaNs, infinite values, or out-of-range values if they are written without suitable error checking.</p>
'TolBnd'	<p>Default is 1e-6.</p> <p>An offset for lower and upper bounds when using fmincon.</p> <p>mle treats lower and upper bounds as strict inequalities, that is, open bounds. With fmincon, this is approximated by creating closed bounds inset from the specified lower and upper bounds by TolBnd.</p>

Example: 'Options',statset('mlecustom')

Data Types: struct

LowerBound — Lower bounds for distribution parameters

-∞ (default) | vector

Lower bounds for distribution parameters, specified as the comma-separated pair consisting of 'Lowerbound' and a vector the same size as start.

This name-value pair argument is valid only when you use the pdf and cdf, logpdf and logcdf, or nloglf input arguments.

Example: 'Lowerbound',0

Data Types: single | double

UpperBound — Upper bounds for distribution parameters

∞ (default) | vector

Upper bounds for distribution parameters, specified as the comma-separated pair consisting of 'Upperbound' and a vector the same size as start.

This name-value pair argument is valid only when you use the pdf and cdf, logpdf and logsf, or nloglf input arguments.

Example: 'Upperbound',1

Data Types: single | double

OptimFun — Optimization function

'fminsearch' (default) | 'fmincon'

Optimization function mle uses in maximizing the likelihood, specified as the comma-separated pair consisting of 'Optimfun' and either 'fminsearch' or 'fmincon'.

Default is 'fminsearch'.

You can only specify 'fmincon' if Optimization Toolbox is available.

The 'Optimfun' name-value pair argument is valid only when you fit custom distributions, that is, when you use the pdf and cdf, logpdf and logsf, or nloglf input arguments.

Example: 'Optimfun', 'fmincon'

Output Arguments

phat — Parameter estimates

scalar value | row vector

Parameter estimates, returned as a scalar value or a row vector.

pci — Confidence intervals for parameter estimates

2-by-*k* matrix

Confidence intervals for parameter estimates, returned as a column vector or a matrix depending on the number of parameters, hence the size of phat.

pci is a 2-by-*k* matrix, where *k* is the number of parameters mle estimates. The first and second rows of the pci show the lower and upper confidence limits, respectively.

More About

Survival Function

The survival function is the probability of survival as a function of time. It is also called the survivor function. It gives the probability that the survival time of an individual exceeds a certain value. Since the cumulative distribution function, $F(t)$, is the probability that the survival time is less than or equal to a given point in time, the survival function for a continuous distribution, $S(t)$, is the complement of the cumulative distribution function: $S(t) = 1 - F(t)$.

Tips

When you supply distribution functions, mle computes the parameter estimates using an iterative maximization algorithm. With some models and data, a poor choice of starting point can cause mle to converge to a local optimum that is not the global maximizer, or to fail to converge entirely. Even in cases for which the log-likelihood is well-behaved near the global maximum, the choice of starting point is often crucial to convergence of the algorithm. In particular, if the initial parameter values are far from the MLEs, underflow in the distribution functions can lead to infinite log-likelihoods.

“What Is Survival Analysis?” on page 14-2

“Estimate Parameters of Three-Parameter Weibull Distribution” on page B-175

Introduced before R2006a

mlecov

Asymptotic covariance of maximum likelihood estimators

Syntax

```
acov = mlecov(params,data,'pdf',pdf)
acov = mlecov(params,data,'pdf',pdf,'cdf',cdf)

acov = mlecov(params,data,'logpdf',logpdf)
acov = mlecov(params,data,'logpdf',logpdf,'logsf',logsf)

acov = mlecov(params,data,'nloglf',nloglf)

acov = mlecov( ____,Name,Value)
```

Description

`acov = mlecov(params,data,'pdf',pdf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom probability density function `pdf`.

`mlecov` computes a finite difference approximation to the Hessian of the log-likelihood at the maximum likelihood estimates `params`, given the observed `data`, and returns the negative inverse of that Hessian.

`acov = mlecov(params,data,'pdf',pdf,'cdf',cdf)` returns `acov` for a distribution specified by the custom probability density function `pdf` and cumulative distribution function `cdf`.

`acov = mlecov(params,data,'logpdf',logpdf)` returns `acov` for a distribution specified by the custom log probability density function `logpdf`.

`acov = mlecov(params,data,'logpdf',logpdf,'logsf',logsf)` returns `acov` for a distribution specified by the custom log probability density function `logpdf` and custom log survival function on page 32-3436 `logsf`.

`acov = mlecov(params,data,'nloglf',nloglf)` returns `acov` for a distribution specified by the custom negative loglikelihood function `nloglf`.

`acov = mlecov(____,Name,Value)` specifies options using name-value pair arguments in addition to any of the input arguments in previous syntaxes. For example, you can specify the censored data and frequency of observations.

Examples

Custom Probability Density Function

Load the sample data.

```
load carbig
```

The vector `Weight` shows the weights of 406 cars.

In the MATLAB Editor, create a function that returns the probability density function (pdf) of a lognormal distribution. Save the file in your current working folder as `lognormpdf.m`.

```
function newpdf = lognormpdf(data,mu,sigma)
newpdf = exp((- (log(data)-mu).^2)/(2*sigma^2))./(data*sigma*sqrt(2*pi));
```

Estimate the parameters, `mu` and `sigma`, of the custom-defined distribution.

```
phat = mle(Weight,'pdf',@lognormpdf,'start',[4.5 0.3])
```

```
phat =
    7.9600    0.2804
```

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat,Weight,'pdf',@lognormpdf)
```

```
acov =
    1.0e-03 *
    0.1937    -0.0000
   -0.0000    0.0968
```

Estimate the standard errors of estimates.

```
se = sqrt(diag(acov))
```

```
se =
    0.0139
    0.0098
```

The standard error of the estimates of `mu` and `sigma` are 0.0139 and 0.0098, respectively.

Custom Log Probability Density Function

In the MATLAB Editor, create a function that returns the log probability density function of a beta distribution. Save the file in your current working folder as `beta logpdf.m`.

```
function logpdf = beta logpdf(x,a,b)
logpdf = (a-1)*log(x)+(b-1)*log(1-x)-beta ln(a,b);
```

Generate sample data from a beta distribution with parameters 1.23 and 3.45 and estimate the parameters using the simulated data.

```
rng('default')
x = betarnd(1.23,3.45,25,1);
phat = mle(x,'dist','beta')
```

```
phat =
    1.1213    2.7182
```

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat,x,'logpdf',@betalogpdf)

acov =

    0.0810    0.1646
    0.1646    0.6074
```

Custom Log pdf and Survival Function

Load the sample data.

```
load('readmissiontimes.mat');
```

The sample data includes `ReadmissionTime`, which has readmission times for 100 patients. The column vector `Censored` has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom log probability density and survival function.

```
custlogpdf = @(data,lambda,k) log(k)-k*log(lambda)...
             +(k-1)*log(data)-(data/lambda).^k;
custlogsf = @(data,lambda,k) -(data/lambda).^k;
```

Estimate the parameters, `lambda` and `k`, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime,'logpdf',custlogpdf,...
           'logsf',custlogsf,'start',[1,0.75],'Censoring',Censored)

phat = 1×2

    9.2090    1.4223
```

The scale and shape parameters of the custom-defined distribution are 9.2090 and 1.4223, respectively.

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat,ReadmissionTime,...
             'logpdf',custlogpdf,'logsf',custlogsf,'Censoring',Censored)

acov = 2×2

    0.5653    0.0102
    0.0102    0.0163
```

Custom Log Negative Likelihood Function

Load the sample data.

```
load('readmissiontimes.mat');
```

The sample data includes `ReadmissionTime`, which has readmission times for 100 patients. This is simulated data.

Define a negative log likelihood function.

```
custnloglf = @(lambda,data,cens,freq) -length(data)*log(lambda)...
+ nansum(lambda*data);
```

Estimate the parameters of the defined distribution.

```
phat = mle(ReadmissionTime,'nloglf',custnloglf,'start',0.05)
```

```
phat = 0.1462
```

Compute the variance of the parameter estimate.

```
acov = mlecov(phat,ReadmissionTime,'nloglf',custnloglf)
```

```
acov = 2.1374e-04
```

Compute the standard error.

```
sqrt(acov)
```

```
ans = 0.0146
```

Input Arguments

params — Parameter estimates

scalar value | vector

Parameter estimates, specified as a scalar value or vector of scalar values. These parameter estimates must be maximum likelihood estimates. For example, you can specify parameter estimates returned by `mle`.

Data Types: `single` | `double`

data — Sample data

vector

Sample data `mle` uses to estimate the distribution parameters, specified as a vector.

Data Types: `single` | `double`

pdf — Custom probability density function

function handle

Custom probability distribution function, specified as a function handle created using `@`.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of probability density values.

For example, if the name of the custom probability density function is `newpdf`, then you can specify the function handle in `mlecov` as follows.

Example: `@newpdf`

Data Types: `function_handle`

cdf — Custom cumulative distribution function

function handle

Custom cumulative distribution function, specified as a function handle created using @.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of cumulative probability values.

You must define `cdf` with `pdf` if data is censored and you use the 'Censoring' name-value pair argument. If 'Censoring' is not present, you do not have to specify `cdf` while using `pdf`.

For example, if the name of the custom cumulative distribution function is `newcdf`, then you can specify the function handle in `mlecov` as follows.

Example: `@newcdf`

Data Types: `function_handle`

logpdf — Custom log probability density function

function handle

Custom log probability density function, specified as a function handle created using @.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of log probability values.

For example, if the name of the custom log probability density function is `customlogpdf`, then you can specify the function handle in `mlecov` as follows.

Example: `@customlogpdf`

Data Types: `function_handle`

logsf — Custom log survival function

function handle

Custom log survival function on page 32-3436, specified as a function handle created using @.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of log survival probability values.

You must define `logsf` with `logpdf` if data is censored and you use the 'Censoring' name-value pair argument. If 'Censoring' is not present, you do not have to specify `logsf` while using `logpdf`.

For example, if the name of the custom log survival function is `logsurvival`, then you can specify the function handle in `mlecov` as follows.

Example: `@logsurvival`

Data Types: `function_handle`

nloglf — Custom negative loglikelihood function

function handle

Custom negative loglikelihood function, specified as a function handle created using @.

This custom function accepts the following input arguments.

<code>params</code>	Vector of distribution parameter values
<code>data</code>	Vector of data
<code>cens</code>	Boolean vector of censored values
<code>freq</code>	Vector of integer data frequencies

`nloglf` must accept all four arguments even if you do not use the 'Censoring' or 'Frequency' name-value pair arguments. You can write '`nloglf`' to ignore `cens` and `freq` arguments in that case.

`nloglf` returns a scalar negative loglikelihood value and optionally, a negative loglikelihood gradient vector (see the 'GradObj' field in 'Options').

If the name of the custom negative log likelihood function is `negloglik`, then you can specify the function handle in `mlecov` as follows.

Example: `@negloglik`

Data Types: `function_handle`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: '`Censoring, cens, 'Options', opt`' specifies that `mlecov` reads the censored data information from the vector `cens` and performs according to the new options structure `opt`.

Censoring — Indicator for censoring

array of 0s (default) | array of 0s and 1s

Indicator for censoring, specified as the comma-separated pair consisting of 'Censoring' and a Boolean array of the same size as `data`. Use 1 for observations that are right censored and 0 for observations that are fully observed. The default is all observations are fully observed.

For censored data, you must use `cdf` with `pdf`, or `logsf` with `logpdf`, or `nloglf` must be defined to account for censoring.

For example, if the censored data information is in the binary array called `Censored`, then you can specify the censored data as follows.

Example: '`Censoring, Censored`'

Data Types: `logical`

Frequency — Frequency of observations

array of 1s (default) | vector of nonnegative integer counts

Frequency of observations, specified as the comma-separated pair consisting of 'Frequency' and an array containing nonnegative integer counts, which is the same size as `data`. The default is one observation per element of `data`.

For example, if the observation frequencies are stored in an array named `Freq`, you can specify the frequencies as follows.

Example: '`Frequency, Freq`'

Data Types: `single` | `double`

Options — Numerical options

structure

Numerical options for the finite difference Hessian calculation, specified as the comma-separated pair consisting of 'Options' and a structure returned by `statset`.

You can set the options under a new name and use it in the name-value pair argument. The applicable `statset` parameters are as follows.

Parameter	Value
'GradObj'	Default is 'off'. 'on' or 'off', indicating whether or not the function provided with the <code>nloglf</code> input argument can return the gradient vector of the negative log-likelihood as a second output.
'DerivStep'	Default is $\text{eps}^{(1/4)}$. Relative step size used in finite difference for Hessian calculations. It can be a scalar, or the same size as <code>params</code> . A smaller value than the default might be appropriate if 'GradObj' is 'on'.

Example: `'Options', statset('mlecov')`

Data Types: `struct`

Output Arguments

acov — Approximation to asymptotic covariance matrix

p-by-*p* matrix

Approximation to asymptotic covariance matrix, returned as a *p*-by-*p* matrix, where *p* is the number of parameters in `params`.

More About

Survival Function

The survival function is the probability of survival as a function of time. It is also called the survivor function. It gives the probability that the survival time of an individual exceeds a certain value. Since the cumulative distribution function, $F(t)$, is the probability that the survival time is less than or equal to a given point in time, the survival function for a continuous distribution, $S(t)$, is the complement of the cumulative distribution function: $S(t) = 1 - F(t)$.

mnpdf

Multinomial probability density function

Syntax

`Y = mnpdf(X,PROB)`

Description

`Y = mnpdf(X,PROB)` returns the pdf for the multinomial distribution with probabilities `PROB`, evaluated at each row of `X`. `X` and `PROB` are m -by- k matrices or 1-by- k vectors, where k is the number of multinomial bins or categories. Each row of `PROB` must sum to one, and the sample sizes for each observation (rows of `X`) are given by the row sums `sum(X,2)`. `Y` is an m -by-1 vector, and `mnpdf` computes each row of `Y` using the corresponding rows of the inputs, or replicates them if needed.

Examples

Compute the Multinomial Distribution pdf

Compute the pdf of a multinomial distribution with a sample size of $n = 10$. The probabilities are $p = 1/2$ for outcome 1, $p = 1/3$ for outcome 2, and $p = 1/6$ for outcome 3.

```
p = [1/2 1/3 1/6];
n = 10;
x1 = 0:n;
x2 = 0:n;
[X1,X2] = meshgrid(x1,x2);
X3 = n - (X1+X2);
```

Compute the pdf of the distribution.

```
Y = mnpdf([X1(:),X2(:),X3(:)], repmat(p, (n+1)^2, 1));
```

Plot the pdf on a 3-dimensional figure.

```
Y = reshape(Y, n+1, n+1);
bar3(Y)
h = gca;
h.XTickLabel = [0:n];
h.YTickLabel = [0:n];
xlabel('x_1')
ylabel('x_2')
zlabel('Probability Mass')
title('Trinomial Distribution')
```

Note that the visualization does not show x_3 , which is determined by the constraint $x_1 + x_2 + x_3 = n$.

mnrfit

Multinomial logistic regression

Syntax

```
B = mnrfi(X,Y)
B = mnrfi(X,Y,Name,Value)
[B,dev,stats] = mnrfi( ___ )
```

Description

`B = mnrfi(X,Y)` returns a matrix, `B`, of coefficient estimates for a multinomial logistic regression of the nominal responses in `Y` on the predictors in `X`.

`B = mnrfi(X,Y,Name,Value)` returns a matrix, `B`, of coefficient estimates for a multinomial model fit with additional options specified by one or more `Name,Value` pair arguments.

For example, you can fit a nominal, an ordinal, or a hierarchical model, or change the link function.

`[B,dev,stats] = mnrfi(___)` also returns the deviance of the fit, `dev`, and the structure `stats` for any of the previous input arguments. `stats` contains model statistics such as degrees of freedom, standard errors for coefficient estimates, and residuals.

Examples

Multinomial Regression for Nominal Responses

Fit a multinomial regression for nominal outcomes and interpret the results.

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable using a categorical array.

```
sp = categorical(species);
```

Fit a multinomial regression model to predict the species using the measurements.

```
[B,dev,stats] = mnrfi(meas,sp);
```

```
B
```

```
B = 5×2
103 ×
```

```
1.9722    0.0426
```

```

0.6584    0.0025
-0.5553   0.0067
-0.5045  -0.0094
-2.6981  -0.0183

```

This is a nominal model for the response category relative risks, with separate slopes on all four predictors, that is, each category of `meas`. The first row of `B` contains the intercept terms for the relative risk of the first two response categories, `setosa` and `versicolor` versus the reference category, `virginica`. The last four rows contain the slopes for the models for the first two categories. `mnrfit` accepts the third category as the reference category.

The relative risk of an iris flower being species 2 (`versicolor`) versus species 3 (`virginica`) is the ratio of the two probabilities (the probability of being species 2 and the probability of being species 3). The model for the relative risk is

$$\ln\left(\frac{\pi_{\text{versicolor}}}{\pi_{\text{virginica}}}\right) = 42.6 + 2.5X_1 + 6.7X_2 - 9.4X_3 - 18.3X_4.$$

The coefficients express both the effects of the predictor variables on the relative risk and the log odds of being in one category versus the reference category. For example, the estimated coefficient 2.5 indicates that the relative risk of being species 2 (`versicolor`) versus species 3 (`virginica`) increases $\exp(2.5)$ times for each unit increase in X_1 , the first measurement, given all else is equal. The relative log odds of being `versicolor` versus `virginica` increases 2.5 times with a one-unit increase in X_1 , given all else is equal.

If the coefficients are converging toward infinity or negative infinity, the estimated coefficients can vary slightly depending on your operating system.

Check the statistical significance of the model coefficients.

```
stats.p
```

```
ans = 5x2
```

```

0    0.0000
0    0.0281
0    0.0000
0    0.0000
0    0.0000

```

The small p -values indicate that all measures are significant on the relative risk of being a `setosa` versus a `virginica` (species 1 compared to species 3) and being a `versicolor` versus a `virginica` (species 2 compared to species 3).

Request the standard errors of coefficient estimates.

```

Multinomial Regression for Ordinal Responses

Fit a multinomial regression model for categorical responses with natural ordering among categories.

Load the sample data and define the predictor variables.

```
load carbig
X = [Acceleration Displacement Horsepower Weight];
```

The predictor variables are the acceleration, engine displacement, horsepower, and weight of the cars. The response variable is miles per gallon (mpg).

Create an ordinal response variable categorizing MPG into four levels from 9 to 48 mpg by labeling the response values in the range 9-19 as 1, 20-29 as 2, 30-39 as 3, and 40-48 as 4.

```
miles = ordinal(MPG,{'1','2','3','4'},[],[9,19,29,39,48]);
```

Fit an ordinal response model for the response variable miles.

```
[B,dev,stats] = mnrfit(X,miles,'model','ordinal');
B
```

```
B = 7×1
-16.6895
-11.7208
-8.0606
0.1048
0.0103
0.0645
0.0017
```

The first three elements of B are the intercept terms for the models, and the last four elements of B are the coefficients of the covariates, assumed common across all categories. This model corresponds to *parallel regression*, which is also called the *proportional odds* model, where there is a different intercept but common slopes among categories. You can specify this using the `'interactions', 'off'` name-value pair argument, which is the default for ordinal models.

```
[B(1:3)'; repmat(B(4:end),1,3)]
```

```
ans = 5×3
-16.6895 -11.7208 -8.0606
0.1048 0.1048 0.1048
0.0103 0.0103 0.0103
0.0645 0.0645 0.0645
0.0017 0.0017 0.0017
```

The link function in the model is `logit('link','logit')`, which is the default for an ordinal model. The coefficients express the relative risk or log odds of the mpg of a car being less than or equal to one value versus greater than that value.

The proportional odds model in this example is

$$\ln\left(\frac{P(\text{mpg} \leq 19)}{P(\text{mpg} > 19)}\right) = -16.6895 + 0.1048X_A + 0.0103X_D + 0.0645X_H + 0.0017X_W$$

$$\ln\left(\frac{P(\text{mpg} \leq 29)}{P(\text{mpg} > 29)}\right) = -11.7208 + 0.1048X_A + 0.0103X_D + 0.0645X_H + 0.0017X_W$$

$$\ln\left(\frac{P(\text{mpg} \leq 39)}{P(\text{mpg} > 39)}\right) = -8.0606 + 0.1048X_A + 0.0103X_D + 0.0645X_H + 0.0017X_W$$

For example, the coefficient estimate of 0.1048 indicates that a unit change in acceleration would impact the odds of the mpg of a car being less than or equal to 19 versus more than 19, or being less than or equal to 29 versus greater than 29, or being less than or equal to 39 versus greater than 39, by a factor of $\exp(0.1048)$ given all else is equal.

Assess the significance of the coefficients.

```
stats.p
ans = 7×1
0.0000
```

```

0.0000
0.0000
0.1899
0.0350
0.0000
0.0118

```

The p -values of 0.035, 0.0000, and 0.0118 for engine displacement, horsepower, and weight of a car, respectively, indicate that these factors are significant on the odds of mpg of a car being less than or equal to a certain value versus being greater than that value.

Hierarchical Multinomial Regression Model

Fit a hierarchical multinomial regression model.

Load the sample data.

```
load('smoking.mat');
```

The data set `smoking` contains five variables: `sex`, `age`, `weight`, and `systolic` and `diastolic` blood pressure. `Sex` is a binary variable where 1 indicates female patients, and 0 indicates male patients.

Define the response variable.

```
Y = categorical(smoking.Smoker);
```

The data in `Smoker` has four categories:

- 0: Nonsmoker, 0 cigarettes a day
- 1: Smoker, 1-5 cigarettes a day
- 2: Smoker, 6-10 cigarettes a day
- 3: Smoker, 11 or more cigarettes a day

Define the predictor variables.

```
X = [smoking.Sex smoking.Age smoking.Weight...
     smoking.SystolicBP smoking.DiastolicBP];
```

Fit a hierarchical multinomial model.

```
[B,dev,stats] = mnrfits(X,Y,'model','hierarchical');
B
```

```
B = 6×3
```

```

43.8148    5.9571   44.0712
 1.8709   -0.0230    0.0662
 0.0188    0.0625    0.1335
 0.0046   -0.0072   -0.0130
-0.2170    0.0416   -0.0324
-0.2273   -0.1449   -0.4824

```

The first column of B includes the intercept and the coefficient estimates for the model of the relative risk of being a nonsmoker versus a smoker. The second column includes the parameter estimates for modeling the log odds of smoking 1-5 cigarettes a day versus more than five cigarettes a day given that a person is a smoker. Finally, the third column includes the parameter estimates for modeling the log odds of a person smoking 6-10 cigarettes a day versus more than 10 cigarettes a day given he/she smokes more than 5 cigarettes a day.

The coefficients differ across categories. You can specify this using the 'interactions', 'on' name-value pair argument, which is the default for hierarchical models. So, the model in this example is

$$\ln\left(\frac{P(y=0)}{P(y>0)}\right) = 43.8148 + 1.8709X_S + 0.0188X_A + 0.0046X_W - 0.2170X_{SBP} - 0.2273X_{DBP}$$

$$\ln\left(\frac{P(1 \leq y \leq 5)}{P(y > 5)}\right) = 5.9571 - 0.0230X_S + 0.0625X_A - 0.0072X_W + 0.0416X_{SBP} - 0.1449X_{DBP}$$

$$\ln\left(\frac{P(6 \leq y \leq 10)}{P(y > 10)}\right) = 44.0712 + 0.0662X_S + 0.1335X_A - 0.0130X_W - 0.0324X_{SBP} - 0.4824X_{DBP}$$

For example, the coefficient estimate of 1.8709 indicates that the likelihood of being a smoker versus a nonsmoker increases by $\exp(1.8709) = 6.49$ times as the gender changes from female to male given everything else held constant.

Assess the statistical significance of the terms.

```
stats.p
```

```
ans = 6×3
```

0.0000	0.5363	0.2149
0.3549	0.9912	0.9835
0.6850	0.2676	0.2313
0.9032	0.8523	0.8514
0.0009	0.5187	0.8165
0.0004	0.0483	0.0545

Sex, age, or weight don't appear significant on any level. The p -values of 0.0009 and 0.0004 indicate that both types of blood pressure are significant on the relative risk of a person being a smoker versus a nonsmoker. The p -value of 0.0483 shows that only diastolic blood pressure is significant on the odds of a person smoking 0-5 cigarettes a day versus more than 5 cigarettes a day. Similarly, the p -value of 0.0545 indicates that diastolic blood pressure is significant on the odds of a person smoking 6-10 cigarettes a day versus more than 10 cigarettes a day.

Check if any nonsignificant factors are correlated to each other. Draw a scatterplot of age versus weight grouped by sex.

```
figure()
gscatter(smoking.Age, smoking.Weight, smoking.Sex)
legend('Male', 'Female')
xlabel('Age')
ylabel('Weight')
```

The range of weight of an individual seems to differ according to gender. Age does not seem to have any obvious correlation with sex or weight. Age is insignificant and weight seems to be correlated with sex, so you can eliminate both and reconstruct the model.

Eliminate age and weight from the model and fit a hierarchical model with sex, systolic blood pressure, and diastolic blood pressure as the predictor variables.

```
X = double([smoking.Sex smoking.SystolicBP...
smoking.DiastolicBP]);
[B,dev,stats] = mnrfits(X,Y,'model','hierarchical');
B
```

B = 4×3

44.8456	5.3230	25.0248
1.6045	0.2330	0.4982
-0.2161	0.0497	0.0179
-0.2222	-0.1358	-0.3092

Here, a coefficient estimate of 1.6045 indicates that the likelihood of being a nonsmoker versus a smoker increases by $\exp(1.6045) = 4.97$ times as sex changes from male to female. A unit increase in the systolic blood pressure indicates an $\exp(-.2161) = 0.8056$ decrease in the likelihood of being a nonsmoker versus a smoker. Similarly, a unit increase in the diastolic blood pressure indicates an $\exp(-.2222) = 0.8007$ decrease in the relative rate of being a nonsmoker versus being a smoker.

Assess the statistical significance of the terms.

```
stats.p
ans = 4x3
    0.0000    0.4715    0.2325
    0.0210    0.7488    0.6362
    0.0010    0.4107    0.8899
    0.0003    0.0483    0.0718
```

The p -values of 0.0210, 0.0010, and 0.0003 indicate that the terms sex and both types of blood pressure are significant on the relative risk of a person being a nonsmoker versus a smoker, given the other terms in the model. Based on the p -value of 0.0483, diastolic blood pressure appears significant on the relative risk of a person smoking 1–5 cigarettes versus more than 5 cigarettes a day, given that this person is a smoker. Because none of the p -values on the third column are less than 0.05, you can say that none of the variables are statistically significant on the relative risk of a person smoking from 6–10 cigarettes versus more than 10 cigarettes, given that this person smokes more than 5 cigarettes a day.

Input Arguments

X — Observations on predictor variables

n -by- p matrix

Observations on predictor variables, specified as an n -by- p matrix. X contains n observations for p predictors.

Note `mnrfit` automatically includes a constant term (intercept) in all models. Do not include a column of 1s in X .

Data Types: `single` | `double`

Y — Response values

n -by- k matrix | n -by-1 column vector

Response values, specified as a column vector or a matrix. Y can be one of the following:

- An n -by- k matrix, where $Y(i,j)$ is the number of outcomes of the multinomial category j for the predictor combinations given by $X(i,:)$. In this case, the number of observations are made at each predictor combination.
- An n -by-1 column vector of scalar integers from 1 to k indicating the value of the response for each observation. In this case, all sample sizes are 1.
- An n -by-1 categorical array indicating the nominal or ordinal value of the response for each observation. In this case, all sample sizes are 1.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: 'Model', 'ordinal', 'Link', 'probit' specifies an ordinal model with a probit link function.

Model — Type of model to fit

'nominal' (default) | 'ordinal' | 'hierarchical'

Type of model to fit, specified as the comma-separated pair consisting of 'Model' and one of the following.

'nominal'	Default. There is no ordering among the response categories.
'ordinal'	There is a natural ordering among the response categories.
'hierarchical'	The choice of response category is sequential/nested.

Example: 'Model', 'ordinal'

Interactions — Indicator for interaction between multinomial categories and coefficients

'on' | 'off'

Indicator for an interaction between the multinomial categories and coefficients, specified as the comma-separated pair consisting of 'Interactions' and one of the following.

'on'	Default for nominal and hierarchical models. Fit a model with different coefficients across categories.
'off'	Default for ordinal models. Fit a model with a common set of coefficients for the predictor variables, across all multinomial categories. This is often described as <i>parallel regression</i> or the <i>proportional odds model</i> .

In all cases, the model has different intercepts across categories. The choice of 'Interactions' determines the dimensions of the output array B.

Example: 'Interactions', 'off'

Link — Link function

'logit' (default) | 'probit' | 'comploglog' | 'loglog'

Link function to use for ordinal and hierarchical models, specified as the comma-separated pair consisting of 'Link' and one of the following.

'logit'	Default. $f(\gamma) = \ln(\gamma/(1 - \gamma))$
'probit'	$f(\gamma) = \Phi^{-1}(\gamma)$ — error term is normally distributed with variance 1
'comploglog'	Complementary log-log $f(\gamma) = \ln(-\ln(1 - \gamma))$
'loglog'	$f(\gamma) = \ln(-\ln(\gamma))$

The link function defines the relationship between response probabilities and the linear combination of predictors, $X\beta$. The link functions might be functions of cumulative or conditional probabilities based on whether the model is for an ordinal or a sequential/nested response. For example, for an ordinal model, γ represents the cumulative probability of being in categories 1 to j and the model with a logit link function as follows:

$$\ln\left(\frac{\gamma}{1 - \gamma}\right) = \ln\left(\frac{\pi_1 + \pi_2 + \dots + \pi_j}{\pi_{j+1} + \dots + \pi_k}\right) = \beta_{0j} + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_p X_p,$$

where k represents the last category.

You cannot specify the 'Link' parameter for nominal models; these always use a multinomial logit link,

$$\ln\left(\frac{\pi_j}{\pi_r}\right) = \beta_{j0} + \beta_{j1}X_{j1} + \beta_{j2}X_{j2} + \dots + \beta_{jp}X_{jp}, \quad j = 1, \dots, k - 1,$$

where π stands for a categorical probability, and r corresponds to the reference category. `mnrfit` uses the last category as the reference category for nominal models.

Example: 'Link', 'loglog'

EstDisp — Indicator for estimating dispersion parameter

'off' (default) | 'on'

Indicator for estimating a dispersion parameter, specified as the comma-separated pair consisting of 'EstDisp' and one of the following.

'off'	Default. Use the theoretical dispersion value of 1.
'on'	Estimate a dispersion parameter for the multinomial distribution in computing standard errors.

Example: 'EstDisp', 'on'

Output Arguments

B — Coefficient estimates

vector | matrix

Coefficient estimates for a multinomial logistic regression of the responses in Y , returned as a vector or a matrix.

- If 'Interaction' is 'off', then B is a $k - 1 + p$ vector. The first $k - 1$ rows of B correspond to the intercept terms, one for each $k - 1$ multinomial categories, and the remaining p rows correspond to the predictor coefficients, which are common for all of the first $k - 1$ categories.
- If 'Interaction' is 'on', then B is a $(p + 1)$ -by- $(k - 1)$ matrix. Each column of B corresponds to the estimated intercept term and predictor coefficients, one for each of the first $k - 1$ multinomial categories.

The estimates for the k th category are taken to be zero as `mnrfit` takes the last category as the reference category.

dev — Deviance of the fit

scalar value

Deviance of the fit, returned as a scalar value. It is twice the difference between the maximum achievable log likelihood and that attained under the fitted model. This corresponds to the sum of deviance residuals,

$$dev = 2 * \sum_i^n \sum_j^k y_{ij} * \log\left(\frac{y_{ij}}{\hat{\pi}_{ij} * m_i}\right) = \sum_i^n rd_i,$$

where rd_i are the deviance residuals. For deviance residuals see `stats`.

stats – Model statistics

structure

Model statistics, returned as a structure that contains the following fields.

beta	The coefficient estimates. These are the same as B.
dfe	Degrees of freedom for error <ul style="list-style-type: none"> • If 'Interactions' is 'off', then degrees of freedom is $n*(k - 1) - (k - 1 + p)$. • If 'Interactions' is 'on', then degrees of freedom is $(n - p + 1)*(k - 1)$.
sfit	Estimated dispersion parameter.
s	Theoretical or estimated dispersion parameter. <ul style="list-style-type: none"> • If 'Estdisp' is 'off', then s is the theoretical dispersion parameter, 1. • If 'Estdisp' is 'on', then s is equal to the estimated dispersion parameter, sfit.
estdisp	Indicator for a theoretical or estimated dispersion parameter.
se	Standard errors of coefficient estimates, B.
coeffcorr	Estimated correlation matrix for B.
covb	Estimated covariance matrix for B.
t	t statistics for B.
p	p-values for B.
resid	Raw residuals. Observed minus fitted values, $r_{ij} = y_{ij} - \hat{\pi}_{ij} * m_i, \quad \begin{cases} i = 1, \dots, n \\ j = 1, \dots, k' \end{cases}$ <p>where π_{ij} is the categorical, cumulative or conditional probability, and m_i is the corresponding sample size.</p>
residp	Pearson residuals, which are the raw residuals scaled by the estimated standard deviation: $rp_{ij} = \frac{r_{ij}}{\hat{\sigma}_{ij}} = \frac{y_{ij} - \hat{\pi}_{ij} * m_i}{\sqrt{\hat{\pi}_{ij} * (1 - \hat{\pi}_{ij}) * m_i}}, \quad \begin{cases} i = 1, \dots, n \\ j = 1, \dots, k' \end{cases}$ <p>where π_{ij} is the categorical, cumulative, or conditional probability, and m_i is the corresponding sample size.</p>
residd	Deviance residuals: $rd_i = 2 * \sum_j^k y_{ij} * \log\left(\frac{y_{ij}}{\hat{\pi}_{ij} * m_i}\right), \quad i = 1, \dots, n.$ <p>where π_{ij} is the categorical, cumulative, or conditional probability, and m_i is the corresponding sample size.</p>

Algorithms

mnrfit treats NaNs in either X or Y as missing values, and ignores them.

mnrnd

Multinomial random numbers

Syntax

```
r = mnrnd(n,p)
R = mnrnd(n,p,m)
R = mnrnd(N,P)
```

Description

`r = mnrnd(n,p)` returns random values `r` from the multinomial distribution with parameters `n` and `p`. `n` is a positive integer specifying the number of trials (sample size) for each multinomial outcome. `p` is a 1-by-`k` vector of multinomial probabilities, where `k` is the number of multinomial bins or categories. `p` must sum to one. (If `p` does not sum to one, `r` consists entirely of NaN values.) `r` is a 1-by-`k` vector, containing counts for each of the `k` multinomial bins.

`R = mnrnd(n,p,m)` returns `m` random vectors from the multinomial distribution with parameters `n` and `p`. `R` is a `m`-by-`k` matrix, where `k` is the number of multinomial bins or categories. Each row of `R` corresponds to one multinomial outcome.

`R = mnrnd(N,P)` generates outcomes from different multinomial distributions. `P` is a `m`-by-`k` matrix, where `k` is the number of multinomial bins or categories and each of the `m` rows contains a different set of multinomial probabilities. Each row of `P` must sum to one. (If any row of `P` does not sum to one, the corresponding row of `R` consists entirely of NaN values.) `N` is a `m`-by-1 vector of positive integers or a single positive integer (replicated by `mnrnd` to a `m`-by-1 vector). `R` is a `m`-by-`k` matrix. Each row of `R` is generated using the corresponding rows of `N` and `P`.

Examples

Generate 2 random vectors with the same probabilities:

```
n = 1e3;
p = [0.2,0.3,0.5];
R = mnrnd(n,p,2)
R =
    215    282    503
    194    303    503
```

Generate 2 random vectors with different probabilities:

```
n = 1e3;
P = [0.2, 0.3, 0.5; ...
     0.3, 0.4, 0.3];
R = mnrnd(n,P)
R =
    186    290    524
    290    389    321
```

Topics

“Multinomial Distribution” on page B-96

Introduced in R2006b

mnrval

Multinomial logistic regression values

Syntax

```

pihat = mnrvl(B,X)
[pihat,dlow,dhi] = mnrvl(B,X,stats)
[pihat,dlow,dhi] = mnrvl(B,X,stats,Name,Value)

yhat = mnrvl(B,X,ssize)
[yhat,dlow,dhi] = mnrvl(B,X,ssize,stats)
[yhat,dlow,dhi] = mnrvl(B,X,ssize,stats,Name,Value)

```

Description

`pihat = mnrvl(B,X)` returns the predicted probabilities for the multinomial logistic regression model with predictors, `X`, and the coefficient estimates, `B`.

`pihat` is an n -by- k matrix of predicted probabilities for each multinomial category. `B` is the vector or matrix that contains the coefficient estimates returned by `mnrfit`. And `X` is an n -by- p matrix which contains n observations for p predictors.

Note `mnrvl` automatically includes a constant term in all models. Do not enter a column of 1s in `X`.

`[pihat,dlow,dhi] = mnrvl(B,X,stats)` also returns 95% error bounds on the predicted probabilities, `pihat`, using the statistics in the structure, `stats`, returned by `mnrfit`.

The lower and upper confidence bounds for `pihat` are `pihat` minus `dlow` and `pihat` plus `dhi`, respectively. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

`[pihat,dlow,dhi] = mnrvl(B,X,stats,Name,Value)` returns the predicted probabilities and 95% error bounds on the predicted probabilities `pihat`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the model type, link function, and the type of probabilities to return.

`yhat = mnrvl(B,X,ssize)` returns the predicted category counts for sample sizes, `ssize`.

`[yhat,dlow,dhi] = mnrvl(B,X,ssize,stats)` also computes 95% error bounds on the predicted counts `yhat`, using the statistics in the structure, `stats`, returned by `mnrfit`.

The lower and upper confidence bounds for `yhat` are `yhat` minus `dlo` and `yhat` plus `dhi`, respectively. Confidence bounds are nonsimultaneous and they apply to the fitted curve, not to new observations.

`[yhat,dlow,dhi] = mnrvl(B,X,ssize,stats,Name,Value)` returns the predicted category counts and 95% error bounds on the predicted counts `yhat`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the model type, link function, and the type of predicted counts to return.

Examples

Estimate Category Probabilities for Nominal Responses

Fit a multinomial regression for nominal outcomes and estimate the category probabilities.

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable.

```
sp = nominal(species);
sp = double(sp);
```

Now in `sp`, 1, 2, and 3 indicate the species `setosa`, `versicolor`, and `virginica`, respectively.

Fit a nominal model to estimate the species using the flower measurements as the predictor variables.

```
[B,dev,stats] = mnrfits(meas,sp);
```

Estimate the probability of being a certain kind of species for an iris flower having the measurements (6.3, 2.8, 4.9, 1.7).

```
x = [6.3, 2.8, 4.9, 1.7];
pihat = mnrval(B,x);
pihat
```

```
pihat = 1x3
        0    0.3977    0.6023
```

The probability of an iris flower having the measurements (6.3, 2.8, 4.9, 1.7) being a `setosa` is 0, a `versicolor` is 0.3977, and a `virginica` is 0.6023.

Estimate Upper and Lower Error Bounds for Probability Estimates of Ordinal Responses

Fit a multinomial regression model for categorical responses with natural ordering among categories. Then estimate the upper and lower confidence bounds for the category probability estimates.

Load the sample data and define the predictor variables.

```
load('carbig.mat')
X = [Acceleration Displacement Horsepower Weight];
```

The predictor variables are the acceleration, engine displacement, horsepower, and the weight of the cars. The response variable is miles per gallon (MPG).

Create an ordinal response variable categorizing MPG into four levels from 9 to 48 mpg.

```
miles = ordinal(MPG,{'1','2','3','4'},[],[9,19,29,39,48]);
miles = double(miles);
```

Now in miles, 1 indicates the cars with miles per gallon from 9 to 19, and 2 indicates the cars with miles per gallon from 20 to 29. Similarly, 3 and 4 indicate the cars with miles per gallon from 30 to 39 and 40 to 48, respectively.

Fit a multinomial regression model for the response variable miles. For an ordinal model, the default 'link' is logit and the default 'interactions' is 'off'.

```
[B,dev,stats] = mnrfits(X,miles,'model','ordinal');
```

Compute the probability estimates and 95% error bounds for probability confidence intervals for miles per gallon of a car with $x = (12, 113, 110, 2670)$.

```
x = [12,113,110,2670];
[pihat,dlow,hi] = mnrfits(B,x,stats,'model','ordinal');
pihat
```

```
pihat = 1×4
```

```
    0.0615    0.8426    0.0932    0.0027
```

Calculate the confidence bounds for the category probability estimates.

```
LL = pihat - dlow;
UL = pihat + hi;
[LL;UL]
```

```
ans = 2×4
```

```
    0.0073    0.7829    0.0283   -0.0003
    0.1157    0.9022    0.1580    0.0057
```

Estimate Category Counts and Error Bounds for Nominal Responses

Fit a multinomial regression for nominal outcomes and estimate the category counts.

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable.

```
sp = nominal(species);
sp = double(sp);
```

Now in `sp`, 1, 2, and 3 indicate the species *setosa*, *versicolor*, and *virginica*, respectively.

Fit a nominal model to estimate the species based on the flower measurements.

```
[B,dev,stats] = mnrfit(meas,sp);
```

Estimate the number in each species category for a sample of 100 iris flowers all with the measurements (6.3, 2.8, 4.9, 1.7).

```
x = [6.3, 2.8, 4.9, 1.7];
yhat = mnrval(B,x,18)
```

```
yhat = 1×3
```

```
    0    7.1578    10.8422
```

Estimate the error bounds for the counts.

```
[yhat,dlow,hi] = mnrval(B,x,18,stats,'model','nominal');
```

Calculate the confidence bounds for the category probability estimates.

```
LL = yhat - dlow;
UL = yhat + hi;
[LL;UL]
```

```
ans = 2×3
```

```
    0    3.3019    6.9863
    0   11.0137   14.6981
```

Plot the Count Estimates

Create sample data with one predictor variable and a categorical response variable with three categories.

```
x = [-3 -2 -1 0 1 2 3]';
Y = [1 11 13; 2 9 14; 6 14 5; 5 10 10; ...
     5 14 6; 7 13 5; 8 11 6];
```

```
[Y x]
```

```
ans = 7×4
```

```
    1    11    13    -3
    2     9    14    -2
    6    14     5    -1
    5    10    10     0
    5    14     6     1
    7    13     5     2
    8    11     6     3
```

There are observations on seven different values of the predictor variable x . The response variable Y has three categories and the data shows how many of the 25 individuals are in each category of Y for each observation of x . For example, when x is -3, 1 of 25 individuals is observed in category 1, 11 observed in category 2, and 13 observed in category 3. Similarly, when x is 1, 5 of the individuals are observed in category 1, 14 are observed in category 2, and 6 are observed in category 3.

Plot the number in each category versus the x values, on a stacked bar graph.

```
bar(x,Y,'stacked');
ylim([0 25]);
```

Fit a nominal model for the individual response category probabilities, with separate slopes on the single predictor variable, x , for each category.

```
betaHatNom = mnrfi(x,Y,'model','nominal',...
    'interactions','on')
```

```
betaHatNom = 2x2
```

```
-0.6028    0.3832
 0.4068    0.1948
```

The first row of `betaHatOrd` contains the intercept terms for the first two response categories. The second row contains the slopes. `mnrfi` accepts the third category as the reference category and hence assumes the coefficients for the third category are zero.

Compute the predicted probabilities for the three response categories.

```
xx = linspace(-4,4)';
piHatNom = mnrval(betaHatNom,xx,'model','nominal',...
    'interactions','on');
```

The probability of being in the third category is simply $1 - P(y = 1) - P(y = 2)$.

Plot the estimated cumulative number in each category on the bar graph.

```
line(xx,cumsum(25*piHatNom,2),'LineWidth',2);
```

The cumulative probability for the third category is always 1.

Now, fit a "parallel" ordinal model for the cumulative response category probabilities, with a common slope on the single predictor variable, x , across all categories:

```
betaHatOrd = mnrfity(x,Y,'model','ordinal',...
    'interactions','off')
```

```
betaHatOrd = 3x1
```

```
-1.5001
 0.7266
 0.2642
```

The first two elements of `betaHatOrd` are the intercept terms for the first two response categories. The last element of `betaHatOrd` is the common slope.

Compute the predicted cumulative probabilities for the first two response categories. The cumulative probability for the third category is always 1.

```
piHatOrd = mnrvl(betaHatOrd,xx,'type','cumulative',...
    'model','ordinal','interactions','off');
```

Plot the estimated cumulative number on the bar graph of the observed cumulative number.

```
figure()
bar(x,cumsum(Y,2),'grouped');
ylim([0 25]);
line(xx,25*piHatOrd,'LineWidth',2);
```

Input Arguments

B — Coefficient estimates

vector or matrix returned by `mnrfit`

Coefficient estimates for the multinomial logistic regression model, specified as a vector or matrix returned by `mnrfit`. It is a vector or matrix depending on the model and interactions.

Example: `B = mnrfit(X,y); pihat = mnrvl(B,X)`

Data Types: `single` | `double`

X — Sample data

matrix

Sample data on predictors, specified as an n -by- p . X contains n observations for p predictors.

Note `mnrval` automatically includes a constant term in all models. Do not enter a column of 1s in X .

Example: `pihat = mnrval(B,X)`

Data Types: `single` | `double`

stats — Model statistics

structure returned by `mnrfit`

Model statistics, specified as a structure returned by `mnrfit`. You must use the `stats` input argument in `mnrval` to compute the lower and upper error bounds on the category probabilities and counts.

Example: `[B,dev,stats] = mnrfit(X,y); [pihat,dlo,dhi] = mnrval(B,X,stats)`

ssize — Sample sizes

column vector of positive integers

Sample sizes to return the number of items in response categories for each combination of the predictor variables, specified as an n -by-1 column vector of positive integers.

For example, for a response variable having three categories, if an observation of the number of individuals in each category is y_1 , y_2 , and y_3 , respectively, then the sample size, m , for that observation is $m = y_1 + y_2 + y_3$.

If the sample sizes for n observations are in vector `sample`, then you can enter the sample sizes as follows.

Example: `yhat = mnrval(B,X,sample)`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'model','ordinal','link','probit','type','cumulative'` specifies that `mnrval` returns the estimates for cumulative probabilities for an ordinal model with a probit link function.

model — Type of multinomial model

`'nominal'` (default) | `'ordinal'` | `'hierarchical'`

Type of multinomial model fit by `mnrfit`, specified as the comma-separated pair consisting of `'model'` and one of the following.

<code>'nominal'</code>	Default. Specify when there is no ordering among the response categories.
<code>'ordinal'</code>	Specify when there is a natural ordering among the response categories.
<code>'hierarchical'</code>	Specify when the choice of response category is sequential.

Example: `'model','ordinal'`

interactions — Indicator for interaction between multinomial categories and coefficients

'on' | 'off'

Indicator for an interaction between the multinomial categories and coefficients in the model fit by `mnrfit`, specified as the comma-separated pair consisting of 'interactions' and one of the following.

'on'	Default for nominal and hierarchical models. Specify to fit a model with different intercepts and coefficients across categories.
'off'	Default for ordinal models. Specify to fit a model with different intercepts, but a common set of coefficients for the predictor variables, across all multinomial categories. This is often described as <i>parallel regression</i> or <i>proportional odds model</i> .

Example: 'interactions','off'

Data Types: logical

link — Link function

'logit' (default) | 'probit' | 'comploglog' | 'loglog'

Link function `mnrfit` uses for ordinal and hierarchical models, specified as the comma-separated pair consisting of 'link' and one of the following.

'logit'	Default. $f(\gamma) = \ln(\gamma/(1 - \gamma))$
'probit'	$f(\gamma) = \Phi^{-1}(\gamma)$ — error term is normally distributed with variance 1
'comploglog'	Complementary log-log $f(\gamma) = \ln(-\ln(1 - \gamma))$
'loglog'	$f(\gamma) = \ln(-\ln(\gamma))$

The link function defines the relationship between response probabilities and the linear combination of predictors, $X\beta$.

γ might be cumulative or conditional probabilities based on whether the model is for an ordinal or a sequential/nested response.

You cannot specify the 'link' parameter for nominal models; these always use a multinomial logit link,

$$\ln\left(\frac{\pi_j}{\pi_r}\right) = \beta_{j0} + \beta_{j1}X_{j1} + \beta_{j2}X_{j2} + \dots + \beta_{jp}X_{jp}, \quad j = 1, \dots, k - 1,$$

where π stands for a categorical probability, and r corresponds to the reference category, k is the total number of response categories, p is the number of predictor variables. `mnrfit` uses the last category as the reference category for nominal models.

Example: 'link','loglog'

type — Type of probabilities or counts to estimate

'category' (default) | 'cumulative' | 'conditional'

Type of probabilities or counts to estimate, specified as the comma-separated pair including 'type' and one of the following.

'category'	Default. Specify to return predictions and error bounds for the probabilities (or counts) of the k multinomial categories.
'cumulative'	Specify to return predictions and confidence bounds for the cumulative probabilities (or counts) of the first $k - 1$ multinomial categories, as an n -by- $(k - 1)$ matrix. The predicted cumulative probability for the k th category is always 1.
'conditional'	Specify to return predictions and error bounds in terms of the first $k - 1$ conditional category probabilities (counts), i.e., the probability (count) for category j , given an outcome in category j or higher. When 'type' is 'conditional', and you supply the sample size argument <code>ssize</code> , the predicted counts at each row of X are conditioned on the corresponding element of <code>ssize</code> , across all categories.

Example: 'type','cumulative'

confidence — Confidence level

0.95 (default) | scalar value in the range (0,1)

Confidence level for the error bounds, specified as the comma-separated pair consisting of 'confidence' and a scalar value in the range (0,1).

For example, for 99% error bounds, you can specify the confidence as follows:

Example: 'confidence',0.99

Data Types: single | double

Output Arguments

pihat — Probability estimates

n -by- $(k - 1)$ matrix

Probability estimates for each multinomial category, returned as an n -by- $(k - 1)$ matrix, where n is the number of observations, and k is the number of response categories.

yhat — Count estimates

n -by- $k - 1$ matrix

Count estimates for the number in each response category, returned as an n -by- $k - 1$ matrix, where n is the number of observations, and k is the number of response categories.

dlow — Lower error bound

column vector

Lower error bound to compute the lower confidence bound for pihat or yhat, returned as a column vector.

The lower confidence bound for pihat is pihat minus dlow. Similarly, the lower confidence bound for yhat is yhat minus dlow. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

dhi — Upper error bound

column vector

Upper error bound to compute the upper confidence bound for `pihat` or `yhat`, returned as a column vector.

The upper confidence bound for `pihat` is `pihat` plus `dhi`. Similarly, the upper confidence bound for `yhat` is `yhat` plus `dhi`. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

Introduced in R2006b

moment

Central moment

Syntax

```
m = moment(X,order)
m = moment(X,order,'all')
m = moment(X,order,dim)
m = moment(X,order,vecdim)
```

Description

`m = moment(X,order)` returns the central moment of `X` for the order specified by `order`.

- If `X` is a vector, then `moment(X,order)` returns a scalar value that is the k -order central moment of the elements in `X`.
- If `X` is a matrix, then `moment(X,order)` returns a row vector containing the k -order central moment of each column in `X`.
- If `X` is a multidimensional array, then `moment(X,order)` operates along the first nonsingleton dimension of `X`.

`m = moment(X,order,'all')` returns the central moment of the specified order for all elements of `X`.

`m = moment(X,order,dim)` takes the central moment along the operating dimension `dim` of `X`.

`m = moment(X,order,vecdim)` returns the central moment over the dimensions specified in the vector `vecdim`. For example, if `X` is a 2-by-3-by-4 array, then `moment(X,1,[1 2])` returns a 1-by-1-by-4 array. Each element of the output array is the first-order central moment of the elements on the corresponding page of `X`.

Examples

Find Central Moment for Specified Order

Set the random seed for reproducibility of the results.

```
rng('default')
```

Generate a matrix with 6 rows and 5 columns.

```
X = randn(6,5)
```

```
X = 6×5
```

```
    0.5377    -0.4336     0.7254     1.4090     0.4889
    1.8339     0.3426    -0.0631     1.4172     1.0347
   -2.2588     3.5784     0.7147     0.6715     0.7269
    0.8622     2.7694    -0.2050    -1.2075    -0.3034
```

```

    0.3188   -1.3499   -0.1241    0.7172    0.2939
   -1.3077    3.0349    1.4897    1.6302   -0.7873

```

Find the third-order central moment of X.

```
m = moment(X,3)
```

```
m = 1×5
```

```

   -1.1143   -0.9973    0.1234   -1.1023   -0.1045

```

m is a row vector containing the third-order central moment of each column in X.

Find Central Moment Along Given Dimension

Find the central moment along different dimensions for a multidimensional array.

Set the random seed for reproducibility of the results.

```
rng('default')
```

Create a 4-by-3-by-2 array of random numbers.

```
X = randn([4,3,2])
```

```
X =
```

```
X(:,:,1) =
```

```

    0.5377    0.3188    3.5784
    1.8339   -1.3077    2.7694
   -2.2588   -0.4336   -1.3499
    0.8622    0.3426    3.0349

```

```
X(:,:,2) =
```

```

    0.7254   -0.1241    0.6715
   -0.0631    1.4897   -1.2075
    0.7147    1.4090    0.7172
   -0.2050    1.4172    1.6302

```

Find the fourth-order central moment of X along the default dimension.

```
m1 = moment(X,4)
```

```
m1 =
```

```
m1(:,:,1) =
```

```

   11.4427    0.3553   33.6733

```

```
m1(:,:,2) =
```

```
0.0360    0.4902    2.3821
```

By default, `moment` operates along the first dimension of `X` whose size does not equal 1. In this case, this dimension is the first dimension of `X`. Therefore, `m1` is a 1-by-3-by-2 array.

Find the fourth-order central moment of `X` along the second dimension.

```
m2 = moment(X,4,2)
```

```
m2 =
m2(:,:,1) =
```

```
7.3476
13.8702
0.4625
2.7741
```

```
m2(:,:,2) =
```

```
0.0341
2.2389
0.0171
0.6766
```

`m2` is a 4-by-1-by-2 array.

Find the fourth-order central moment of `X` along the third dimension.

```
m3 = moment(X,4,3)
```

```
m3 = 4×3
```

```
0.0001    0.0024    4.4627
0.8093    3.8273   15.6340
4.8866    0.7205    1.1412
0.0811    0.0833    0.2433
```

`m3` is a 4-by-3 matrix.

Find Central Moment Along Vector of Dimensions

Find the central moment over multiple dimensions by using the `'all'` and `vecdim` input arguments.

Set the random seed for reproducibility of the results.

```
rng('default')
```

Create a 4-by-3-by-2 array of random numbers.

```
X = randn([4 3 2])
```

```
X =
X(:,:,1) =
```

```
0.5377    0.3188    3.5784
1.8339   -1.3077    2.7694
-2.2588   -0.4336   -1.3499
0.8622    0.3426    3.0349
```

```
X(:,:,2) =
```

```
0.7254   -0.1241    0.6715
-0.0631    1.4897   -1.2075
0.7147    1.4090    0.7172
-0.2050    1.4172    1.6302
```

Find the third-order central moment of X.

```
mall = moment(X,3,'all')
```

```
mall = 0.2431
```

`mall` is the third-order central moment of the entire input data set X.

Find the third-order moment of each page of X by specifying the first and second dimensions.

```
mpage = moment(X,3,[1 2])
```

```
mpage =
mpage(:,:,1) =
```

```
0.6002
```

```
mpage(:,:,2) =
```

```
-0.3475
```

For example, `mpage(1,1,2)` is the third-order central moment of the elements in `X(:,:,2)`.

Find the third-order moment of the elements in each `X(i, :, :)` slice by specifying the second and third dimensions.

```
mrow = moment(X,3,[2 3])
```

```
mrow = 4×1
```

```
2.7552
0.0443
-0.7585
0.5340
```

For example, `mrow(1)` is the third-order central moment of the elements in `X(1, :, :)`.

Input Arguments

X — Input data

vector | matrix | multidimensional array

Input data that represents a sample from a population, specified as a vector, matrix, or multidimensional array.

- If X is a vector, then `moment(X, order)` returns a scalar value that is the k -order central moment of the elements in X .
- If X is a matrix, then `moment(X, order)` returns a row vector containing the k -order central moment of each column in X .
- If X is a multidimensional array, then `moment(X, order)` operates along the first nonsingleton dimension of X .

To specify the operating dimension when X is a matrix or an array, use the `dim` input argument.

Data Types: `single` | `double`

order — Order of central moment

positive integer

Order of the central moment, specified as a positive integer.

Data Types: `single` | `double`

dim — Dimension

positive integer

Dimension along which to operate, specified as a positive integer. If you do not specify a value for `dim`, then the default is the first nonsingleton dimension of X .

Consider the third-order central moment of a matrix X :

- If `dim` is equal to 1, then `moment(X, 3, 1)` returns a row vector that contains the third-order central moment of each column in X .
- If `dim` is equal to 2, then `moment(X, 3, 2)` returns a column vector that contains the third-order central moment of each row in X .

If `dim` is greater than `ndims(X)` or if `size(X, dim)` is 1, then `moment` returns an array of zeros the same size as X .

Data Types: `single` | `double`

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array X . The output m has length 1 in the specified operating dimensions. The other dimension lengths are the same for X and m .

For example, if X is a 2-by-3-by-3 array, then `moment(X, 1, [1 2])` returns a 1-by-1-by-3 array. Each element of the output array is the first-order central moment of the elements on the corresponding page of X .

Data Types: `single` | `double`

Output Arguments

m — Central moments

scalar | vector | matrix | multidimensional array

Central moments, returned as a scalar, vector, matrix, or multidimensional array.

Algorithms

The central moment of order k for a distribution is defined as

$$m_k = E(x - \mu)^k,$$

where μ is the mean of x , and $E(t)$ represents the expected value of the quantity t . The moment function computes a sample version of this population value.

$$m_k = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^k.$$

Note that the first-order central moment is zero, and the second-order central moment is the variance computed using a divisor of n rather than $n - 1$, where n is the length of the vector x or the number of rows in the matrix X .

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).
- If `order` is nonintegral and X is real, use `moment(complex(X), order)`.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'all' and vecdim input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

multcompare

Multiple comparison test

Syntax

```
c = multcompare(stats)
c = multcompare(stats,Name,Value)
[c,m] = multcompare(____)
[c,m,h] = multcompare(____)
[c,m,h,gnames] = multcompare(____)
```

Description

`c = multcompare(stats)` returns a matrix `c` of the pairwise comparison results from a multiple comparison test using the information contained in the `stats` structure. `multcompare` also displays an interactive graph of the estimates and comparison intervals. Each group mean is represented by a symbol, and the interval is represented by a line extending out from the symbol. Two group means are significantly different if their intervals are disjoint; they are not significantly different if their intervals overlap. If you use your mouse to select any group, then the graph will highlight all other groups that are significantly different, if any.

`c = multcompare(stats,Name,Value)` returns a matrix of pairwise comparison results, `c`, using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the confidence interval, or the type of critical value to use in the multiple comparison.

`[c,m] = multcompare(____)` also returns a matrix, `m`, which contains estimated values of the means (or whatever statistics are being compared) for each group and the corresponding standard errors. You can use any of the previous syntaxes.

`[c,m,h] = multcompare(____)` also returns a handle, `h`, to the comparison graph.

`[c,m,h,gnames] = multcompare(____)` also returns a cell array, `gnames`, which contains the names of the groups.

Examples

Multiple Comparison of Group Means

Load the sample data.

```
load carsmall
```

Perform a one-way analysis of variance (ANOVA) to see if there is any difference between the mileage of the cars by origin.

```
[p,t,stats] = anova1(MPG,Origin,'off');
```

Perform a multiple comparison of the group means.

```
[c,m,h,nms] = multcompare(stats);
```

multcompare displays the estimates with comparison intervals around them. You can click the graphs of each country to compare its mean to those of other countries.

Now display the mean estimates and the standard errors with the corresponding group names.

```
[nms num2cell(m)]
```

```
ans=6x3 cell array
```

```
{'USA' } {[21.1328]} {[0.8814]}
{'Japan' } {[31.8000]} {[1.8206]}
{'Germany' } {[28.4444]} {[2.3504]}
{'France' } {[23.6667]} {[4.0711]}
{'Sweden' } {[22.5000]} {[4.9860]}
{'Italy' } {[ 28]} {[7.0513]}
```

Multiple Comparisons for Two-Way ANOVA

Load the sample data.

```
load popcorn
popcorn
```

```
popcorn = 6x3
```

```

5.5000  4.5000  3.5000
5.5000  4.5000  4.0000
6.0000  4.0000  3.0000
6.5000  5.0000  4.0000
7.0000  5.5000  5.0000
7.0000  5.0000  4.5000

```

The data is from a study of popcorn brands and popper types (Hogg 1987). The columns of the matrix `popcorn` are brands (Gourmet, National, and Generic). The rows are popper types oil and air. In the study, researchers popped a batch of each brand three times with each popper. The values are the yield in cups of popped popcorn.

Perform a two-way ANOVA. Also compute the statistics that you need to perform a multiple comparison test on the main effects.

```
[~,~,stats] = anova2(popcorn,3,'off')
```

```
stats = struct with fields:
  source: 'anova2'
  sigmasq: 0.1389
  colmeans: [6.2500 4.7500 4]
  coln: 6
  rowmeans: [4.5000 5.5000]
  rown: 9
  inter: 1
  pval: 0.7462
  df: 12

```

The `stats` structure includes

- The mean squared error (`sigmasq`)
- The estimates of the mean yield for each popcorn brand (`colmeans`)
- The number of observations for each popcorn brand (`coln`)
- The estimate of the mean yield for each popper type (`rowmeans`)
- The number of observations for each popper type (`rown`)
- The number of interactions (`inter`)
- The p -value that shows the significance level of the interaction term (`pval`)
- The error degrees of freedom (`df`).

Perform a multiple comparison test to see if the popcorn yield differs between pairs of popcorn brands (columns).

```
c = multcompare(stats)
```

Note: Your model includes an interaction term. A test of main effects can be difficult to interpret when the model includes interactions.

`c = 3×6`

1.0000	2.0000	0.9260	1.5000	2.0740	0.0000
1.0000	3.0000	1.6760	2.2500	2.8240	0.0000
2.0000	3.0000	0.1760	0.7500	1.3240	0.0116

The first two columns of `c` show the groups that are compared. The fourth column shows the difference between the estimated group means. The third and fifth columns show the lower and upper limits for 95% confidence intervals for the true mean difference. The sixth column contains the p -value for a hypothesis test that the corresponding mean difference is equal to zero. All p -values (0, 0, and 0.0116) are very small, which indicates that the popcorn yield differs across all three brands.

The figure shows the multiple comparison of the means. By default, the group 1 mean is highlighted and the comparison interval is in blue. Because the comparison intervals for the other two groups do not intersect with the intervals for the group 1 mean, they are highlighted in red. This lack of intersection indicates that both means are different than group 1 mean. Select other group means to confirm that all group means are significantly different from each other.

Perform a multiple comparison test to see the popcorn yield differs between the two popper types (rows).

```
c = multcompare(stats, 'Estimate', 'row')
```

Note: Your model includes an interaction term. A test of main effects can be difficult to interpret when the model includes interactions.

```
c = 1x6
```

```
1.0000    2.0000   -1.3828   -1.0000   -0.6172    0.0001
```

The small p -value of 0.0001 indicates that the popcorn yield differs between the two popper types (air and oil). The figure shows the same results. The disjoint comparison intervals indicate that the group means are significantly different from each other.

Multiple Comparisons for Three-Way ANOVA

Load the sample data.

```
y = [52.7 57.5 45.9 44.5 53.0 57.0 45.9 44.0]';
g1 = [1 2 1 2 1 2 1 2];
g2 = {'hi'; 'hi'; 'lo'; 'lo'; 'hi'; 'hi'; 'lo'; 'lo'};
g3 = {'may'; 'may'; 'may'; 'may'; 'june'; 'june'; 'june'; 'june'};
```

y is the response vector and $g1$, $g2$, and $g3$ are the grouping variables (factors). Each factor has two levels, and every observation in y is identified by a combination of factor levels. For example, observation $y(1)$ is associated with level 1 of factor $g1$, level 'hi' of factor $g2$, and level 'may' of factor $g3$. Similarly, observation $y(6)$ is associated with level 2 of factor $g1$, level 'hi' of factor $g2$, and level 'june' of factor $g3$.

Test if the response is the same for all factor levels. Also compute the statistics required for multiple comparison tests.

```
[~,~,stats] = anovan(y,{g1 g2 g3},'model','interaction',...
    'varnames',{'g1','g2','g3'});
```

Analysis of Variance					
Source	Sum Sq.	d. f.	Mean Sq.	F	Prob>F
g1	3.781	1	3.781	336.11	0.0347
g2	199.001	1	199.001	17689	0.0048
g3	0.061	1	0.061	5.44	0.2578
g1*g2	18.301	1	18.301	1626.78	0.0158
g1*g3	0.211	1	0.211	18.78	0.1444
g2*g3	0.011	1	0.011	1	0.5
Error	0.011	1	0.011		
Total	221.379	7			

Constrained (Type III) sums of squares.

The p -value of 0.2578 indicates that the mean responses for levels 'may' and 'june' of factor g3 are not significantly different. The p -value of 0.0347 indicates that the mean responses for levels 1 and 2 of factor g1 are significantly different. Similarly, the p -value of 0.0048 indicates that the mean responses for levels 'hi' and 'lo' of factor g2 are significantly different.

Perform multiple comparison tests to find out which groups of the factors g1 and g2 are significantly different.

```
results = multcompare(stats,'Dimension',[1 2])
```

results = 6×6

1.0000	2.0000	-6.8604	-4.4000	-1.9396	0.0280
1.0000	3.0000	4.4896	6.9500	9.4104	0.0177
1.0000	4.0000	6.1396	8.6000	11.0604	0.0143
2.0000	3.0000	8.8896	11.3500	13.8104	0.0108
2.0000	4.0000	10.5396	13.0000	15.4604	0.0095
3.0000	4.0000	-0.8104	1.6500	4.1104	0.0745

`multcompare` compares the combinations of groups (levels) of the two grouping variables, `g1` and `g2`. In the `results` matrix, the number 1 corresponds to the combination of level 1 of `g1` and level `hi` of `g2`, the number 2 corresponds to the combination of level 2 of `g1` and level `hi` of `g2`. Similarly, the number 3 corresponds to the combination of level 1 of `g1` and level `lo` of `g2`, and the number 4 corresponds to the combination of level 2 of `g1` and level `lo` of `g2`. The last column of the matrix contains the p -values.

For example, the first row of the matrix shows that the combination of level 1 of `g1` and level `hi` of `g2` has the same mean response values as the combination of level 2 of `g1` and level `hi` of `g2`. The p -value corresponding to this test is 0.0280, which indicates that the mean responses are significantly different. You can also see this result in the figure. The blue bar shows the comparison interval for the mean response for the combination of level 1 of `g1` and level `hi` of `g2`. The red bars are the comparison intervals for the mean response for other group combinations. None of the red bars overlap with the blue bar, which means the mean response for the combination of level 1 of `g1` and level `hi` of `g2` is significantly different from the mean response for other group combinations.

You can test the other groups by clicking on the corresponding comparison interval for the group. The bar you click on turns to blue. The bars for the groups that are significantly different are red. The bars for the groups that are not significantly different are gray. For example, if you click on the comparison interval for the combination of level 1 of `g1` and level 10 of `g2`, the comparison interval for the combination of level 2 of `g1` and level 10 of `g2` overlaps, and is therefore gray. Conversely, the other comparison intervals are red, indicating significant difference.

Input Arguments

stats — Test data

structure

Test data, specified as a structure. You can create a structure using one of the following functions:

- `anova1` — One-way analysis of variance.
- `anova2` — Two-way analysis of variance.
- `anovan` — *N*-way analysis of variance.
- `aoctool` — Interactive analysis of covariance tool.
- `friedman` — Friedman's test.
- `kruskalwallis` — Kruskal-Wallis test.

`multcompare` does not support multiple comparisons using `anovan` output for a model that includes random or nested effects. The calculations for a random effects model produce a warning that all effects are treated as fixed. Nested models are not accepted.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Alpha', 0.01, 'CType', 'bonferroni', 'Display', 'off'` computes the Bonferroni critical values, conducts the hypothesis tests at the 1% significance level, and omits the interactive display.

Alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the multiple comparison test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1). The value specified for `'Alpha'` determines the $100 \times (1 - \alpha)$ confidence levels of the intervals returned in the matrix `c` and in the figure.

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

CType — Type of critical value

'tukey-kramer' (default) | 'hsd' | 'lsd' | 'bonferroni' | 'dunn-sidak' | 'scheffe'

Type of critical value to use for the multiple comparison, specified as the comma-separated pair consisting of `'CType'` and one of the following.

Value	Description
'tukey-kramer' or 'hsd'	Tukey's honest significant difference criterion on page 9-22
'bonferroni'	Bonferroni method on page 9-23
'dunn-sidak'	Dunn and Sidák's approach on page 9-23
'lsd'	Fisher's least significant difference procedure on page 9-23
'scheffe'	Scheffé's S procedure on page 9-24

Example: 'CType', 'bonferroni'

Display – Display toggle

'on' (default) | 'off'

Display toggle, specified as the comma-separated pair consisting of 'Display' and either 'on' or 'off'. If you specify 'on', then `multcompare` displays a graph of the estimates and their comparison intervals. If you specify 'off', then `multcompare` omits the graph.

Example: 'Display', 'off'

Dimension – Dimension over which to calculate marginal means

1 (default) | positive integer value | vector of positive integer values

A vector specifying the dimension or dimensions over which to calculate the population marginal means, specified as a positive integer value, or a vector of such values. Use the 'Dimension' name-value pair only if you create the input structure `stats` using the function `anovan`.

For example, if you specify 'Dimension' as 1, then `multcompare` compares the means for each value of the first grouping variable, adjusted by removing effects of the other grouping variables as if the design were balanced. If you specify 'Dimension' as [1,3], then `multcompare` computes the population marginal means for each combination of the first and third grouping variables, removing effects of the second grouping variable. If you fit a singular model, some cell means may not be estimable and any population marginal means that depend on those cell means will have the value NaN.

Population marginal means are described by Milliken and Johnson (1992) and by Searle, Speed, and Milliken (1980). The idea behind population marginal means is to remove any effect of an unbalanced design by fixing the values of the factors specified by 'Dimension', and averaging out the effects of other factors as if each factor combination occurred the same number of times. The definition of population marginal means does not depend on the number of observations at each factor combination. For designed experiments where the number of observations at each factor combination has no meaning, population marginal means can be easier to interpret than simple means ignoring other factors. For surveys and other studies where the number of observations at each combination does have meaning, population marginal means may be harder to interpret.

Example: 'Dimension', [1,3]

Data Types: single | double

Estimate – Estimates to be compared

'column' (default) | 'row' | 'slope' | 'intercept' | 'pmm'

Estimates to be compared, specified as the comma-separated pair consisting of 'Estimate' and an allowable value. The allowable values for 'Estimate' depend on the function used to generate the input structure `stats`, according to the following table.

Source	Values
anova1	None. This name-value pair is ignored, and <code>multcompare</code> always compares the group means.
anova2	Either 'column' to compare column means, or 'row' to compare row means.
anovan	None. This name-value pair is ignored, and <code>multcompare</code> always compares the population marginal means as specified by the 'Dimension' name-value pair argument.
aoctool	Either 'slope', 'intercept', or 'pmm' to compare slopes, intercepts, or population marginal means, respectively. If the analysis of covariance model did not include separate slopes, then 'slope' is not allowed. If it did not include separate intercepts, then no comparisons are possible.
friedman	None. This name-value pair is ignored, and <code>multcompare</code> always compares the average column ranks.
kruskalwallis	None. This name-value pair is ignored, and <code>multcompare</code> always compares the average group ranks.

Example: 'Estimate', 'row'

Output Arguments

c – Matrix of multiple comparison results

matrix of scalar values

Matrix of multiple comparison results, returned as an p -by-6 matrix of scalar values, where p is the number of pairs of groups. Each row of the matrix contains the result of one paired comparison test. Columns 1 and 2 contain the indices of the two samples being compared. Column 3 contains the lower confidence interval, column 4 contains the estimate, and column 5 contains the upper confidence interval. Column 6 contains the p -value for the hypothesis test that the corresponding mean difference is not equal to 0.

For example, suppose one row contains the following entries.

```
2.0000  5.0000  1.9442  8.2206  14.4971  0.0432
```

These numbers indicate that the mean of group 2 minus the mean of group 5 is estimated to be 8.2206, and a 95% confidence interval for the true difference of the means is [1.9442, 14.4971]. The p -value for the corresponding hypothesis test that the difference of the means of groups 2 and 5 is significantly different from zero is 0.0432.

In this example the confidence interval does not contain 0, so the difference is significant at the 5% significance level. If the confidence interval did contain 0, the difference would not be significant. The p -value of 0.0432 also indicates that the difference of the means of groups 2 and 5 is significantly different from 0.

m – Matrix of estimates

matrix of scalar values

Matrix of the estimates, returned as a matrix of scalar values. The first column of `m` contains the estimated values of the means (or whatever statistics are being compared) for each group, and the second column contains their standard errors.

h — Handle to the figure

handle

Handle to the figure containing the interactive graph, returned as a handle. The title of this graph contains instructions for interacting with the graph, and the *x*-axis label contains information about which means are significantly different from the selected mean. If you plan to use this graph for presentation, you may want to omit the title and the *x*-axis label. You can remove them using interactive features of the graph window, or you can use the following commands.

```
title('')
xlabel('')
```

gnames — Group names

cell array of character vectors

Group names, returned as a cell array of character vectors. Each row of `gnames` contains the name of a group.

More About

Multiple Comparison Tests

Analysis of variance compares the means of several groups to test the hypothesis that they are all equal, against the general alternative that they are not all equal. Sometimes this alternative may be too general. You may need information about which pairs of means are significantly different, and which are not. A *multiple comparison test* can provide this information.

When you perform a simple *t*-test of one group mean against another, you specify a significance level that determines the cutoff value of the *t*-statistic. For example, you can specify the value `alpha = 0.05` to insure that when there is no real difference, you will incorrectly find a significant difference no more than 5% of the time. When there are many group means, there are also many pairs to compare. If you applied an ordinary *t*-test in this situation, the `alpha` value would apply to each comparison, so the chance of incorrectly finding a significant difference would increase with the number of comparisons. Multiple comparison procedures are designed to provide an upper bound on the probability that *any* comparison will be incorrectly found significant.

Introduced before R2006a

multcompare

Class: RepeatedMeasuresModel

Multiple comparison of estimated marginal means

Syntax

```
tbl = multcompare(rm,var)
tbl = multcompare(rm,var,Name,Value)
```

Description

`tbl = multcompare(rm,var)` returns multiple comparisons of the estimated marginal means based on the variable `var` in the repeated measures model `rm`.

`tbl = multcompare(rm,var,Name,Value)` returns multiple comparisons of the estimated marginal means with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the comparison type or which variable to group by.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

var — Variables for which to compute marginal means

character vector | string scalar

Variables for which to compute the marginal means, specified as a character vector or string scalar representing the name of a between- or within-subjects factor in `rm`. If `var` is a between-subjects factor, it must be categorical.

Data Types: `char` | `string`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Alpha — Significance level

0.05 (default) | scalar value in the range of 0 through 1

Significance level of the confidence intervals for population marginal means, specified as the comma-separated pair consisting of `'alpha'` and a scalar value in the range of 0 through 1. The confidence level is $100*(1-\alpha)\%$.

Example: 'alpha',0.01

Data Types: double | single

By — Factor to perform comparisons by

character vector | string scalar

Factor to do the comparisons by, specified as the comma-separated pair consisting of 'By' and a character vector or string scalar. The comparison between levels of `var` occurs separately for each value of the factor you specify.

If you have more than one between-subjects factors, *A*, *B*, and *C*, and if you want to do the comparisons of *A* levels separately for each level of *C*, then specify *A* as the `var` argument and specify *C* using the 'By' argument as follows.

Example: 'By',C

Data Types: char | string

ComparisonType — Type of critical value to use

'tukey-kramer' (default) | 'dunn-sidak' | 'bonferroni' | 'scheffe' | 'lsd'

Type of critical value to use, specified as the comma-separated pair consisting of 'ComparisonType' and one of the following.

Comparison Type	Definition
'tukey-kramer'	Default. Also called Tukey's Honest Significant Difference procedure. It is based on the Studentized range distribution. According to the unproven Tukey-Kramer conjecture, it is also accurate for problems where the quantities being compared are correlated, as in analysis of covariance with unbalanced covariate values.
'dunn-sidak'	Use critical values from the <i>t</i> distribution, after an adjustment for multiple comparisons that was proposed by Dunn and proved accurate by Sidák. The critical value is $ t = \frac{ \bar{y}_i - \bar{y}_j }{\sqrt{MSE\left(\frac{1}{n_i} + \frac{1}{n_j}\right)}} > t_{1-\eta/2, v},$ where $\eta = 1 - (1 - \alpha)^{\frac{1}{\binom{k}{2}}}$ and <i>ng</i> is the number of groups (marginal means). This procedure is similar to, but less conservative than, the Bonferroni procedure.

Comparison Type	Definition
'bonferroni'	<p>Use critical values from the t distribution, after a Bonferroni adjustment to compensate for multiple comparisons. The critical value is</p> $t_{\alpha/2} \left(\frac{ng}{2} \right), v,$ <p>where ng is the number of groups (marginal means), and v is the error degrees of freedom. This procedure is conservative, but usually less so than the Scheffé procedure.</p>
'scheffe'	<p>Use critical values from Scheffé's S procedure, derived from the F distribution. The critical value is</p> $\sqrt{(ng - 1)F_{\alpha, ng - 1, v}},$ <p>where ng is the number of groups (marginal means), and v is the error degrees of freedom. This procedure provides a simultaneous confidence level for comparisons of all linear combinations of the means, and it is conservative for comparisons of simple differences of pairs.</p>
'lsd'	<p>Least significant difference. This option uses plain t-tests. The critical value is</p> $t_{\alpha/2, v},$ <p>where v is the error degrees of freedom. It provides no protection against the multiple comparison problem.</p>

Example: 'ComparisonType', 'dunn-sidak'

Output Arguments

tbl — Results of multiple comparison

table

Results of multiple comparisons of estimated marginal means, returned as a table. `tbl` has the following columns.

Column Name	Description
Difference	Estimated difference between the corresponding two marginal means
StdErr	Standard error of the estimated difference between the corresponding two marginal means
pValue	p -value for a test that the difference between the corresponding two marginal means is 0
Lower	Lower limit of simultaneous 95% confidence intervals for the true difference

Column Name	Description
Upper	Upper limit of simultaneous 95% confidence intervals for the true difference

Examples

Multiple Comparison of Estimated Marginal Means

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4-species','WithinDesign',Meas);
```

Perform a multiple comparison of the estimated marginal means of species.

```
tbl = multcompare(rm,'species')
```

```
tbl=6x7 table
   species_1      species_2      Difference      StdErr      pValue      Lower      Upper
   _____      _____      _____      _____      _____      _____      _____
   {'setosa'   }      {'versicolor'}      -1.0375      0.060539      9.5606e-10      -1.1794      -0.8956
   {'setosa'   }      {'virginica'  }      -1.7495      0.060539      9.5606e-10      -1.8914      -1.6076
   {'versicolor'}      {'setosa'   }      1.0375      0.060539      9.5606e-10      0.89562      1.1794
   {'versicolor'}      {'virginica' }      -0.712      0.060539      9.5606e-10      -0.85388      -0.56012
   {'virginica' }      {'setosa'   }      1.7495      0.060539      9.5606e-10      1.6076      1.8956
   {'virginica' }      {'versicolor'}      0.712      0.060539      9.5606e-10      0.57012      0.85388
```

The small p -values (in the `pValue` field) indicate that the estimated marginal means for the three species significantly differ from each other.

Perform Multiple Comparisons with Specified Options

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the `group-gender` interaction are the predictor variables. Also specify the within-subject design matrix.

```
R = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Perform a multiple comparison of the estimated marginal means based on the variable `Group`.

```
T = multcompare(R, 'Group')
```

T=6×7 table

Group_1	Group_2	Difference	StdErr	pValue	Lower	Upper
A	B	4.9875	5.6271	0.65436	-9.1482	19.123
A	C	23.094	5.9261	0.0021493	8.2074	37.981
B	A	-4.9875	5.6271	0.65436	-19.123	9.1482
B	C	18.107	5.8223	0.013588	3.4805	32.732
C	A	-23.094	5.9261	0.0021493	-37.981	-8.2074
C	B	-18.107	5.8223	0.013588	-32.732	-3.4805

The small p -value of 0.0021493 indicates that there is significant difference between the marginal means of groups A and C. The p -value of 0.65436 indicates that the difference between the marginal means for groups A and B is not significantly different from 0.

`multcompare` uses the Tukey-Kramer test statistic by default. Change the comparison type to the Scheffe procedure.

```
T = multcompare(R, 'Group', 'ComparisonType', 'Scheffe')
```

T=6×7 table

Group_1	Group_2	Difference	StdErr	pValue	Lower	Upper
A	B	4.9875	5.6271	0.67981	-9.7795	19.755
A	C	23.094	5.9261	0.0031072	7.5426	38.646
B	A	-4.9875	5.6271	0.67981	-19.755	9.7795
B	C	18.107	5.8223	0.018169	2.8273	33.386
C	A	-23.094	5.9261	0.0031072	-38.646	-7.5426
C	B	-18.107	5.8223	0.018169	-33.386	-2.8273

The Scheffe test produces larger p -values, but similar conclusions.

Perform multiple comparisons of estimated marginal means based on the variable `Group` for each gender separately.

```
T = multcompare(R, 'Group', 'By', 'Gender')
```

T=12×8 table

Gender	Group_1	Group_2	Difference	StdErr	pValue	Lower	Upper
--------	---------	---------	------------	--------	--------	-------	-------

Female	A	B	4.1883	8.0177	0.86128	-15.953	24.329
Female	A	C	24.565	8.2083	0.017697	3.9449	45.184
Female	B	A	-4.1883	8.0177	0.86128	-24.329	15.953
Female	B	C	20.376	8.1101	0.049957	0.0033459	40.749
Female	C	A	-24.565	8.2083	0.017697	-45.184	-3.9449
Female	C	B	-20.376	8.1101	0.049957	-40.749	-0.0033459
Male	A	B	5.7868	7.9498	0.74977	-14.183	25.757
Male	A	C	21.624	8.1829	0.038022	1.0676	42.179
Male	B	A	-5.7868	7.9498	0.74977	-25.757	14.183
Male	B	C	15.837	8.0511	0.14414	-4.3881	36.062
Male	C	A	-21.624	8.1829	0.038022	-42.179	-1.0676
Male	C	B	-15.837	8.0511	0.14414	-36.062	4.3881

The results indicate that the difference between marginal means for groups A and B is not significant from 0 for either gender (corresponding p -values are 0.86128 for females and 0.74977 for males). The difference between marginal means for groups A and C is significant for both genders (corresponding p -values are 0.017697 for females and 0.038022 for males). While the difference between marginal means for groups B and C is significantly different from 0 for females (p -value is 0.049957), it is not significantly different from 0 for males (p -value is 0.14414).

multivarichart

Multivari chart for grouped data

Syntax

```
multivarichart(y, GROUP)
multivarichart(Y)
multivarichart(..., param1, val1, param2, val2, ...)
[charthandle, AXESH] = multivarichart(...)
```

Description

`multivarichart(y, GROUP)` displays the multivari chart for the vector `y` grouped by entries in `GROUP` that can be a cell array or a matrix. If `GROUP` is a cell array, then each cell in `GROUP` must contain a grouping variable that is a categorical vector, numeric vector, character matrix, string array, or single-column cell array of character vectors. If `GROUP` is a numeric matrix, then its columns represent different grouping variables. Each grouping variable must have the same number of elements as `y`. The number of grouping variables must be 2, 3, or 4.

Each subplot of the plot matrix contains a multivari chart for the first and second grouping variables. The x-axis in each subplot indicates values of the first grouping variable. The legend at the bottom of the figure window indicates values of the second grouping variable. The subplot at position (i,j) is the multivari chart for the subset of `y` at the i th level of the third grouping variable and the j th level of the fourth grouping variable. If the third or fourth grouping variable is absent, it is considered to have only one level.

`multivarichart(Y)` displays the multivari chart for a matrix `Y`. The data in different columns represent changes in one factor. The data in different rows represent changes in another factor.

`multivarichart(..., param1, val1, param2, val2, ...)` specifies one or more of the following name/value pairs:

- `'varnames'` — Grouping variable names in a character matrix, a string array, or a cell array of character vectors, one per grouping variable. Default names are `'X1'`, `'X2'`,
- `'plotorder'` — `'sorted'` or a vector containing a permutation of the integers from 1 to the number of grouping variables.

If `'plotorder'` is `'sorted'`, the grouping variables are rearranged in descending order according to the number of levels in each variable.

If `'plotorder'` is a vector, it indicates the order in which each grouping variable should be plotted. For example, `[2, 3, 1, 4]` indicates that the second grouping variable should be used as the x-axis of each subplot, the third grouping variable should be used as the legend, the first grouping variable should be used as the columns of the plot, and the fourth grouping variable should be used as the rows of the plot.

`[charthandle, AXESH] = multivarichart(...)` returns a handle `charthandle` to the figure window and a matrix `AXESH` of handles to the subplot axes.

Examples

Multivari Chart for Grouped Data

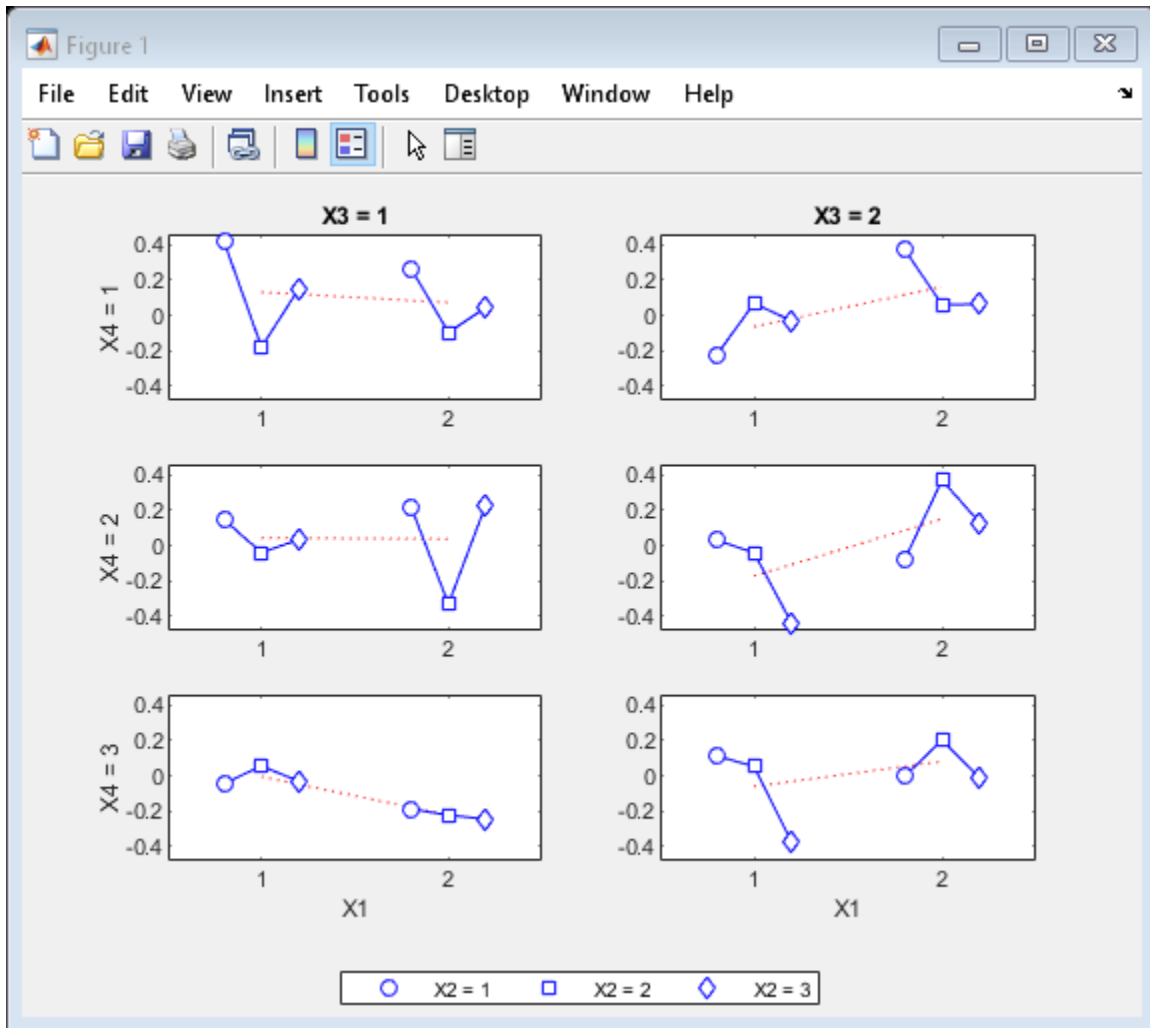

Display a multivari chart for data with two grouping variables.

```
rng default; % For reproducibility
y = randn(100,1); % Randomly generate response
group = [ceil(3*rand(100,1)) ceil(2*rand(100,1))];
multivarichart(y,group)
```

Display a multivari chart for data with four grouping variables.

```
y = randn(1000,1); % Randomly generate response
group = {ceil(2*rand(1000,1)),ceil(3*rand(1000,1)), ...
         ceil(2*rand(1000,1)),ceil(3*rand(1000,1))};
multivarichart(y,group)
```

Introduced in R2006b

mvksdensity

Kernel smoothing function estimate for multivariate data

Syntax

```
f = mvksdensity(x,pts,'Bandwidth',bw)
f = mvksdensity(x,pts,'Bandwidth',bw,Name,Value)
```

Description

`f = mvksdensity(x,pts,'Bandwidth',bw)` computes a probability density estimate of the sample data in the n -by- d matrix `x`, evaluated at the points in `pts` using the required name-value pair argument value `bw` for the bandwidth value. The estimation is based on a product Gaussian kernel function.

For univariate or bivariate data, use `ksdensity` instead.

`f = mvksdensity(x,pts,'Bandwidth',bw,Name,Value)` returns any of the previous output arguments, using additional options specified by one or more `Name,Value` pair arguments. For example, you can define the function type that `mvksdensity` evaluates, such as probability density, cumulative probability, or survivor function. You can also assign weights to the input values.

Examples

Estimate Multivariate Kernel Density

Load the Hald cement data.

```
load hald
```

The data measures the heat of hardening for 13 different cement compositions. The predictor matrix `ingredients` contains the percent composition for each of four cement ingredients. The response matrix `heat` contains the heat of hardening (in cal/g) after 180 days.

Estimate the kernel density for the first three observations in `ingredients`.

```
xi = ingredients(1:3,:);
f = mvksdensity(ingredients,xi,'Bandwidth',0.8);
```

Estimate Multivariate Kernel Density Using Grids

Load the Hald cement data.

```
load hald
```

The data measures the heat of hardening for 13 different cement compositions. The predictor matrix `ingredients` contains the percent composition for each of four cement ingredients. The response matrix `heat` contains the heat of hardening (in cal/g) after 180 days.

Create an array of points at which to estimate the density. First, define the range and spacing for each variable, using a similar number of points in each dimension.

```
gridx1 = 0:2:22;
gridx2 = 20:5:80;
gridx3 = 0:2:24;
gridx4 = 5:5:65;
```

Next, use `ndgrid` to generate a full grid of points using the defined range and spacing.

```
[x1,x2,x3,x4] = ndgrid(gridx1,gridx2,gridx3,gridx4);
```

Finally, transform and concatenate to create an array that contains the points at which to estimate the density. This array has one column for each variable.

```
x1 = x1(:,:,:)' ;
x2 = x2(:,:,:)' ;
x3 = x3(:,:,:)' ;
x4 = x4(:,:,:)' ;
xi = [x1(:) x2(:) x3(:) x4(:)];
```

Estimate the density.

```
f = mvksdensity(ingredients,xi,...
    'Bandwidth',[4.0579 10.7345 4.4185 11.5466],...
    'Kernel','normpdf');
```

View the size of `xi` and `f` to confirm that `mvksdensity` calculates the density at each point in `xi`.

```
size_xi = size(xi)
```

```
size_xi = 1×2
```

```
    26364    4
```

```
size_f = size(f)
```

```
size_f = 1×2
```

```
    26364    1
```

Input Arguments

x — Sample data

numeric matrix

Sample data for which `mvksdensity` returns the probability density estimate, specified as an n -by- d matrix of numeric values. n is the number of data points (rows) in `x`, and d is the number of dimensions (columns).

Data Types: `single` | `double`

pts — Points at which to evaluate `f`

matrix

Points at which to evaluate the probability density estimate `f`, specified as a matrix with the same number of columns as `x`. The returned estimate `f` and `pts` have the same number of rows.

Data Types: `single` | `double`

bw — Value for the bandwidth of the kernel smoothing window

scalar value | d -element vector

Value for the bandwidth of the kernel-smoothing window, specified as a scalar value or d -element vector. d is the number of dimensions (columns) in the sample data `x`. If `bw` is a scalar value, it applies to all dimensions.

If you specify `'BoundaryCorrection'` as `'log'` (default) and `'Support'` as either `'positive'` or a two-row matrix, `mvksdensity` converts bounded data to be unbounded by using log transformation. The value of `bw` is on the scale of the transformed values.

Silverman's rule of thumb for the bandwidth is

$$b_i = \sigma_i \left\{ \frac{4}{(d+2)n} \right\}^{1/(d+4)}, \quad i = 1, 2, \dots, d,$$

where d is the number of dimensions, n is the number of observations, and σ_i is the standard deviation of the i^{th} variate [4].

Example: `'Bandwidth', 0.8`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Kernel', 'triangle', 'Function', 'cdf'` specifies that `mvksdensity` estimates the cdf of the sample data using the triangle kernel function.

BoundaryCorrection — Boundary correction method

`'log'` (default) | `'reflection'`

Boundary correction method, specified as the comma-separated pair consisting of `'BoundaryCorrection'` and either `'log'` or `'reflection'`.

Value	Description
'log'	<p>mvksdensity converts bounded data to be unbounded by using one of the following transformations. Then, it transforms back to the original bounded scale after density estimation.</p> <ul style="list-style-type: none"> If you specify 'Support', 'positive', then mvksdensity applies $\log(x_j)$ for each dimension, where x_j is the jth column of the input argument x. If you specify 'Support' as a two-row matrix consisting of the lower and upper limits for each dimension, then mvksdensity applies $\log((x_j - L_j)/(U_j - x_j))$ for each dimension, where L_j and U_j are the lower and upper limits of the jth dimension, respectively. <p>The value of bw is on the scale of the transformed values.</p>
'reflection'	mvksdensity augments bounded data by adding reflected data near the boundaries, then it returns estimates corresponding to the original support. For details, see “Reflection Method” on page 32-3498.

mvksdensity applies boundary correction only when you specify 'Support' as a value other than 'unbounded'.

Example: 'BoundaryCorrection', 'reflection'

Function — Function to estimate

'pdf' (default) | 'cdf' | 'survivor'

Function to estimate, specified as the comma-separated pair consisting of 'Function' and one of the following.

Value	Description
'pdf'	Probability density function
'cdf'	Cumulative distribution function
'survivor'	Survivor function

Example: 'Function', 'cdf'

Kernel — Type of kernel smoother

'normal' (default) | 'box' | 'triangle' | 'epanechnikov' | function handle | character vector | string scalar

Type of kernel smoother, specified as the comma-separated pair consisting of 'Kernel' and one of the following.

Value	Description
'normal'	Normal (Gaussian) kernel
'box'	Box kernel
'triangle'	Triangular kernel
'epanechnikov'	Epanechnikov kernel

You can also specify a kernel function that is a custom or built-in function. Specify the function as a function handle (for example, @myfunction or @normpdf) or as a character vector or string scalar

(for example, 'myfunction' or 'normpdf'). The software calls the specified function with one argument that is an array of distances between data values and locations where the density is evaluated, normalized by the bandwidth in that dimension. The function must return an array of the same size containing the corresponding values of the kernel function.

mvksdensity applies the same kernel to each dimension.

Example: 'Kernel', 'box'

Support — Support for the density

'unbounded' (default) | 'positive' | 2-by-*d* matrix

Support for the density, specified as the comma-separated pair consisting of 'support' and one of the following.

Value	Description
'unbounded'	Allow the density to extend over the whole real line
'positive'	Restrict the density to positive values
2-by- <i>d</i> matrix	Specify the finite lower and upper bounds for the support of the density. The first row contains the lower limits and the second row contains the upper limits. Each column contains the limits for one dimension of <i>x</i> .

'Support' can also be a combination of positive, unbounded, and bounded variables specified as [0 -Inf L; Inf Inf U].

Example: 'Support', 'positive'

Data Types: single | double | char | string

Weights — Weights for sample data

vector

Weights for sample data, specified as the comma-separated pair consisting of 'Weights' and a vector of length $\text{size}(x, 1)$, where *x* is the sample data.

Example: 'Weights', *xw*

Data Types: single | double

Output Arguments

f — Estimated function values

vector

Estimated function values, returned as a vector. *f* and *pts* have the same number of rows.

More About

Multivariate Kernel Distribution

A multivariate kernel distribution is a nonparametric representation of the probability density function (pdf) of a random vector. You can use a kernel distribution when a parametric distribution

cannot properly describe the data, or when you want to avoid making assumptions about the distribution of the data. A multivariate kernel distribution is defined by a smoothing function and a bandwidth matrix, which control the smoothness of the resulting density curve.

The multivariate kernel density estimator is the estimated pdf of a random vector. Let $x = (x_1, x_2, \dots, x_d)'$ be a d -dimensional random vector with a density function f and let $y_i = (y_{i1}, y_{i2}, \dots, y_{id})'$ be a random sample drawn from f for $i = 1, 2, \dots, n$, where n is the number of random samples. For any real vectors of x , the multivariate kernel density estimator is given by

$$\hat{f}_H(x) = \frac{1}{n} \sum_{i=1}^n K_H(x - y_i),$$

where $K_H(x) = |H|^{-1/2} K(H^{-1/2}x)$, $K(\cdot)$ is the kernel smoothing function, and H is the d -by- d bandwidth matrix.

`mvksdensity` uses a diagonal bandwidth matrix and a product kernel. That is, $H^{1/2}$ is a square diagonal matrix with the elements of vector (h_1, h_2, \dots, h_d) on the main diagonal. $K(x)$ takes the product form $K(x) = k(x_1)k(x_2) \dots k(x_d)$, where $k(\cdot)$ is a one-dimensional kernel smoothing function. Then, the multivariate kernel density estimator becomes

$$\begin{aligned} \hat{f}_H(x) &= \frac{1}{n} \sum_{i=1}^n K_H(x - y_i) = \frac{1}{nh_1 h_2 \dots h_d} \sum_{i=1}^n K\left(\frac{x_1 - y_{i1}}{h_1}, \frac{x_2 - y_{i2}}{h_2}, \dots, \frac{x_d - y_{id}}{h_d}\right) \\ &= \frac{1}{nh_1 h_2 \dots h_d} \sum_{i=1}^n \prod_{j=1}^d k\left(\frac{x_j - y_{ij}}{h_j}\right). \end{aligned}$$

The kernel estimator for the cumulative distribution function (cdf), for any real vectors of x , is given by

$$\hat{F}_H(x) = \int_{-\infty}^{x_1} \int_{-\infty}^{x_2} \dots \int_{-\infty}^{x_d} \hat{f}_H(t) dt_d \dots dt_2 dt_1 = \frac{1}{n} \sum_{i=1}^n \prod_{j=1}^d G\left(\frac{x_j - y_{ij}}{h_j}\right),$$

where $G(x_j) = \int_{-\infty}^{x_j} k(t_j) dt_j$.

Reflection Method

The reflection method is a boundary correction method that accurately finds kernel density estimators when a random variable has bounded support. If you specify 'BoundaryCorrection', 'reflection', `mvksdensity` uses the reflection method.

If you additionally specify 'Support' as a two-row matrix consisting of the lower and upper limits for each dimension, then `mvksdensity` finds the kernel estimator as follows.

- If 'Function' is 'pdf', then the kernel density estimator is

$$\hat{f}_H(x) = \frac{1}{nh_1 h_2 \dots h_d} \sum_{i=1}^n \prod_{j=1}^d \left[k\left(\frac{x_j - y_{ij}^-}{h_j}\right) + k\left(\frac{x_j - y_{ij}}{h_j}\right) + k\left(\frac{x_j - y_{ij}^+}{h_j}\right) \right] \text{ for } L_j \leq x_j \leq U_j,$$

where $y_{ij}^- = 2L_j - y_{ij}$, $y_{ij}^+ = 2U_j - y_{ij}$, and y_{ij} is the j th element of the i th sample data corresponding to $x(i, j)$ of the input argument x . L_j and U_j are the lower and upper limits of the j th dimension, respectively.

- If 'Function' is 'cdf', then the kernel estimator for cdf is

$$\widehat{F}_H(x) = \frac{1}{n} \sum_{i=1}^n \prod_{j=1}^d \left[G\left(\frac{x_j - y_{ij}}{h_j}\right) + G\left(\frac{x_j - y_{ij}}{h_j}\right) + G\left(\frac{x_j - y_{ij}^+}{h_j}\right) - G\left(\frac{L_j - y_{ij}}{h_j}\right) - G\left(\frac{L_j - y_{ij}}{h_j}\right) - G\left(\frac{L_j - y_{ij}^+}{h_j}\right) \right]$$

for $L_j \leq x_j \leq U_j$.

- To obtain a kernel estimator for a survivor function (when 'Function' is 'survivor'), mvksdensity uses both $\widehat{f}_H(x)$ and $\widehat{F}_H(x)$.

If you additionally specify 'Support' as 'positive' or a matrix including [0 inf], then mvksdensity finds the kernel density estimator by replacing [$L_j U_j$] with [0 inf] in the above equations.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Names in name-value pair arguments, including 'Bandwidth', must be compile-time constants.
- Values in the following name-value pair arguments must also be compile-time constants: 'BoundaryCorrection', 'Function', and 'Kernel'. For example, to use the 'Function', 'cdf' name-value pair argument in the generated code, include `{coder.Constant('Function'), coder.Constant('cdf')}` in the -args value of codegen.
- The value of the 'Kernel' name-value pair argument cannot be a custom function handle. To specify a custom kernel function, use a character vector or string scalar.
- For the value of the 'Support' name-value pair argument, the compile-time data type must match the runtime data type.

For more information on code generation, see "Introduction to Code Generation" on page 31-2 and "General Code Generation Workflow" on page 31-5.

Introduced in R2016a

mvncdf

Multivariate normal cumulative distribution function

Syntax

```
p = mvncdf(X)
p = mvncdf(X,mu,sigma)

p = mvncdf(xl,xu,mu,sigma)

p = mvncdf(___,options)

[p,err] = mvncdf(___)
```

Description

`p = mvncdf(X)` returns the cumulative distribution function (cdf) of the multivariate normal distribution with zero mean and identity covariance matrix, evaluated at each row of `X`. For more information, see “Multivariate Normal Distribution” on page 32-3507.

`p = mvncdf(X,mu,sigma)` returns the cdf of the multivariate normal distribution with mean `mu` and covariance `sigma`, evaluated at each row of `X`.

Specify `[]` for `mu` to use its default value of zero when you want to specify only `sigma`.

`p = mvncdf(xl,xu,mu,sigma)` returns the multivariate normal cdf evaluated over the multidimensional rectangle with lower and upper limits defined by `xl` and `xu`, respectively.

`p = mvncdf(___,options)` specifies control parameters for the numerical integration used to compute `p`, using any of the input argument combinations in the previous syntaxes. Create the `options` argument using the `statset` function with any combination of the parameters `'TolFun'`, `'MaxFunEvals'`, and `'Display'`.

`[p,err] = mvncdf(___)` additionally returns an estimate of the error in `p`. For more information, see “Algorithms” on page 32-3507.

Examples

Standard Multivariate Normal Distribution cdf

Evaluate the cdf of a standard four-dimensional multivariate normal distribution at points with increasing coordinates in every dimension.

Create a matrix `X` of five four-dimensional points with increasing coordinates.

```
firstDim = (-2:2)';
X = repmat(firstDim,1,4)

X = 5×4
```

```
-2  -2  -2  -2
-1  -1  -1  -1
 0   0   0   0
 1   1   1   1
 2   2   2   2
```

Evaluate the cdf at the points in X .

```
p = mvncdf(X)
```

```
p = 5×1
```

```
0.0000
0.0006
0.0625
0.5011
0.9121
```

The cdf values increase because the coordinates of the points are increasing in every dimension.

Bivariate Normal Distribution cdf

Compute and plot the cdf of a bivariate normal distribution.

Define the mean vector μ and the covariance matrix σ .

```
mu = [1 -1];
sigma = [.9 .4; .4 .3];
```

Create a grid of 625 evenly spaced points in two-dimensional space.

```
[X1,X2] = meshgrid(linspace(-1,3,25)',linspace(-3,1,25)');
X = [X1(:) X2(:)];
```

Evaluate the cdf of the normal distribution at the grid points.

```
p = mvncdf(X,mu,sigma);
```

Plot the cdf values.

```
Z = reshape(p,25,25);
surf(X1,X2,Z)
```

Probability over Rectangular Region

Compute the probability over the unit square of a bivariate normal distribution, and create a contour plot of the results.

Define the bivariate normal distribution parameters μ and σ .

```
mu = [0 0];
sigma = [0.25 0.3; 0.3 1];
```

Compute the probability over the unit square.

```
p = mvncdf([0 0],[1 1],mu,sigma)
p = 0.2097
```

To visualize the result, first create a grid of evenly spaced points in two-dimensional space.

```
x1 = -3:.2:3;
x2 = -3:.2:3;
[X1,X2] = meshgrid(x1,x2);
X = [X1(:) X2(:)];
```

Then, evaluate the pdf of the normal distribution at the grid points.

```
y = mvnpdf(X,mu,sigma);
y = reshape(y,length(x2),length(x1));
```

Finally, create a contour plot of the multivariate normal distribution that includes the unit square.

```
contour(x1,x2,y,[0.0001 0.001 0.01 0.05 0.15 0.25 0.35])
xlabel('x')
ylabel('y')
line([0 0 1 1 0],[1 0 0 1 1],'LineStyle','--','Color','k')
```

Computing a multivariate cumulative probability requires significantly more work than computing a univariate probability. By default, the `mvncdf` function computes values to less than full machine precision, and returns an estimate of the error as an optional second output. View the error estimate in this case.

```
[p,err] = mvncdf([0 0],[1 1],mu,sigma)
p = 0.2097
err = 1.0000e-08
```

Error Estimates in cdf Calculation

Evaluate the cdf of a multivariate normal distribution at random points, and display the error estimates associated with the cdf calculation.

Generate four random points from a five-dimensional multivariate normal distribution with mean vector `mu` and covariance matrix `sigma`.

```
mu = [0.5 -0.3 0.2 0.1 -0.4];
sigma = 0.5*eye(5);
rng('default') % For reproducibility
X = mvnrnd(mu,sigma,4);
```

Find the cdf values `p` at the points in `X` and the associated error estimates `err`. Display a summary of the numerical calculations.

```
[p,err] = mvncdf(X,mu,sigma,statset('Display','final'))
```

```
Successfully satisfied error tolerance of 0.0001 in 8650 function evaluations.
Successfully satisfied error tolerance of 0.0001 in 8650 function evaluations.
Successfully satisfied error tolerance of 0.0001 in 8650 function evaluations.
Successfully satisfied error tolerance of 0.0001 in 8650 function evaluations.
```

```
p = 4x1

    0.1520
    0.0407
    0.0002
    0.1970
```

```
err = 4x1
10-16 x

         0
    0.0496
    0.0012
    0.5949
```

Input Arguments

X — Evaluation points

numeric matrix

Evaluation points, specified as an n -by- d numeric matrix, where n is a positive scalar integer and d is the dimension of a single multivariate normal distribution. The rows of `X` correspond to observations (or points), and the columns correspond to variables (or coordinates).

Data Types: `single` | `double`

mu — Mean vector of multivariate normal distribution

vector of zeros (default) | numeric vector | numeric scalar

Mean vector of a multivariate normal distribution, specified as a 1-by- d numeric vector or a numeric scalar, where d is the dimension of the multivariate normal distribution. If `mu` is a scalar, then `mvncdf` replicates the scalar to match the size of `X`.

Data Types: `single` | `double`

sigma — Covariance matrix of multivariate normal distribution

identity matrix (default) | symmetric, positive definite matrix | numeric vector of diagonal entries

Covariance matrix of a multivariate normal distribution, specified as a d -by- d symmetric, positive definite matrix, where d is the dimension of the multivariate normal distribution. If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off it, then you can also specify `sigma` as a 1-by- d vector containing just the diagonal entries.

Data Types: `single` | `double`

xl — Rectangle lower limit

numeric vector

Rectangle lower limit, specified as a 1-by- d numeric vector.

Data Types: `single` | `double`

xu — Rectangle upper limit

numeric vector

Rectangle upper limit, specified as a 1-by- d numeric vector.

Data Types: `single` | `double`

options — Numerical integration options

structure

Numerical integration options, specified as a structure. Create the `options` argument by calling the `statset` function with any combination of the following parameters:

- `'TolFun'` — Maximum absolute error tolerance. The default value is $1e-8$ when $d < 4$, and $1e-4$ when $d \geq 4$.
- `'MaxFunEvals'` — Maximum number of integrand evaluations allowed when $d \geq 4$. The default value is $1e7$. The function ignores `'MaxFunEvals'` when $d < 4$.
- `'Display'` — Level of display output. The choices are `'off'` (the default), `'iter'`, and `'final'`. The function ignores `'Display'` when $d < 4$.

Example: `statset('TolFun',1e-7,'Display','final')`

Data Types: `struct`

Output Arguments

p — cdf values

numeric vector | numeric scalar

cdf values, returned as either an n -by-1 numeric vector, where n is the number of rows in `X`, or a numeric scalar representing the probability over the rectangular region specified by `xl` and `xu`.

err — Absolute error tolerance

positive numeric scalar

Absolute error tolerance, returned as a positive numeric scalar. For bivariate and trivariate distributions, the default absolute error tolerance is $1e-8$. For four or more dimensions, the default absolute error tolerance is $1e-4$. For more information, see “Algorithms” on page 32-3507.

More About

Multivariate Normal Distribution

The multivariate normal distribution is a generalization of the univariate normal distribution to two or more variables. It has two parameters, a mean vector μ and a covariance matrix Σ , that are analogous to the mean and variance parameters of a univariate normal distribution. The diagonal elements of Σ contain the variances for each variable, and the off-diagonal elements of Σ contain the covariances between variables.

The probability density function (pdf) of the d -dimensional multivariate normal distribution is

$$y = f(x, \mu, \Sigma) = \frac{1}{\sqrt{|\Sigma|(2\pi)^d}} \exp\left(-\frac{1}{2}(x-\mu)' \Sigma^{-1}(x-\mu)\right)$$

where x and μ are 1-by- d vectors and Σ is a d -by- d symmetric, positive definite matrix. Only `mvnrnd` allows positive semi-definite Σ matrices, which can be singular. The pdf cannot have the same form when Σ is singular.

The multivariate normal cumulative distribution function (cdf) evaluated at x is the probability that a random vector v , distributed as multivariate normal, lies within the semi-infinite rectangle with upper limits defined by x :

$$\Pr\{v(1) \leq x(1), v(2) \leq x(2), \dots, v(d) \leq x(d)\}.$$

Although the multivariate normal cdf does not have a closed form, `mvncdf` can compute cdf values numerically.

Tips

- In the one-dimensional case, `sigma` is the variance, not the standard deviation. For example, `mvncdf(1, 0, 4)` is the same as `normcdf(1, 0, 2)`, where 4 is the variance and 2 is the standard deviation.

Algorithms

For bivariate and trivariate distributions, `mvncdf` uses adaptive quadrature on a transformation of the t density, based on methods developed by Drezner and Wesolowsky [1] [2] and by Genz [3]. For four or more dimensions, `mvncdf` uses a quasi-Monte Carlo integration algorithm based on methods developed by Genz and Bretz [4] [5].

Introduced in R2006a

mvnpdf

Multivariate normal probability density function

Syntax

```
y = mvnpdf(X)
y = mvnpdf(X,mu)
y = mvnpdf(X,mu,sigma)
```

Description

`y = mvnpdf(X)` returns an n -by-1 vector `y` containing the probability density function (pdf) of the d -dimensional multivariate normal distribution with zero mean and identity covariance matrix, evaluated at each row of the n -by- d matrix `X`. For more information, see “Multivariate Normal Distribution” on page 32-3515.

`y = mvnpdf(X,mu)` returns pdf values of points in `X`, where `mu` determines the mean of each associated multivariate normal distribution.

`y = mvnpdf(X,mu,sigma)` returns pdf values of points in `X`, where `sigma` determines the covariance of each associated multivariate normal distribution.

Specify `[]` for `mu` to use its default value of zero when you want to specify only `sigma`.

Examples

Standard Multivariate Normal pdf

Evaluate the pdf of a standard five-dimensional normal distribution at a set of random points.

Randomly sample eight points from the standard five-dimensional normal distribution.

```
mu = zeros(1,5);
sigma = eye(5);
rng('default') % For reproducibility
X = mvnrnd(mu,sigma,8)
```

`X = 8×5`

```

```

Find the point in X with the greatest pdf value.

```
[maxpdf,idx] = max(y)
```

```
maxpdf = 0.0054
```

```
idx = 5
```

```
maxPoint = X(idx,:)
```

```
maxPoint = 1×5
```

```
0.3188 0.7254 0.6715 0.2939 0.3252
```

The fifth point in X has a greater pdf value than any of the other randomly selected points.

Multivariate Normal pdfs Evaluated at Different Points

Create six three-dimensional normal distributions, each with a distinct mean. Evaluate the pdf of each distribution at a different random point.

Specify the means `mu` and covariances `sigma` of the distributions. Each distribution has the same covariance matrix—the identity matrix.

```
firstDim = (1:6)';
```

```
mu = repmat(firstDim,1,3)
```

```
mu = 6×3
```

```
1 1 1  
2 2 2  
3 3 3  
4 4 4  
5 5 5  
6 6 6
```

```
sigma = eye(3)
```

```
sigma = 3×3
```

```

1      0      0
0      1      0
0      0      1

```

Randomly sample once from each of the six distributions.

```

rng('default') % For reproducibility
X = mvnrnd(mu,sigma)

```

$X = 6 \times 3$

```

1.5377    0.5664    1.7254
3.8339    2.3426    1.9369
0.7412    6.5784    3.7147

0.0001

```

Multivariate Normal pdf

Evaluate the pdf of a two-dimensional normal distribution at a set of given points.

Specify the mean μ and covariance σ of the distribution.

```

mu = [1 -1];
sigma = [0.9 0.4; 0.4 0.3];

```

Randomly sample from the distribution 100 times. Specify X as the matrix of sampled points.

```

rng('default') % For reproducibility
X = mvnrnd(mu,sigma,100);

```

Evaluate the pdf of the distribution at the points in X .

```

y = mvnpdf(X,mu,sigma);

```

Plot the probability density values.

```

scatter3(X(:,1),X(:,2),y)
xlabel('X1')

```

```
ylabel('X2')
zlabel('Probability Density')
```

Multivariate Normal pdfs Evaluated at Same Point

Create ten different five-dimensional normal distributions, and compare the values of their pdfs at a specified point.

Set the dimensions n and d equal to 10 and 5, respectively.

```
n = 10;
d = 5;
```

Specify the means μ and the covariances σ of the multivariate normal distributions. Let all the distributions have the same mean vector, but vary the covariance matrices.

```
mu = ones(1,d)
```

```
mu = 1x5
```

```
1 1 1 1 1
```

```
mat = eye(d);
nMat = repmat(mat,1,1,n);
```

```
var = reshape(1:n,1,1,n);
sigma = nMat.*var;
```

Display the first two covariance matrices in `sigma`.

```
sigma(:,:,1:2)
```

```
ans =
```

```
ans(:,:,1) =
```

```

1     0     0     0     0
0     1     0     0     0
0     0     1     0     0
0     0     0     1     0
0     0     0     0     1
```

```
ans(:,:,2) =
```

```

2     0     0     0     0
0     2     0     0     0
0     0     2     0     0
0     0     0     2     0
0     0     0     0     2
```

Set `x` to be a random point in five-dimensional space.

```
rng('default') % For reproducibility
x = normrnd(0,1,1,5)
```

```
x = 1×5
```

```

0.5377    1.8339   -2.2588    0.8622    0.3188
```

Evaluate the pdf at `x` for each of the ten distributions.

```
y = mvnpdf(x,mu,sigma)
```

```
y = 10×1
10-4 ×
```

```

ylabel('Probability Density at x')
```

Input Arguments

X — Evaluation points

numeric vector | numeric matrix

Evaluation points, specified as a 1-by- d numeric vector or an n -by- d numeric matrix, where n is a positive scalar integer and d is the dimension of a single multivariate normal distribution. The rows of X correspond to observations (or points), and the columns correspond to variables (or coordinates).

If X is a vector, then `mvnpdf` replicates it to match the leading dimension of `mu` or the trailing dimension of `sigma`.

Data Types: `single` | `double`

mu — Means of multivariate normal distributions

vector of zeros (default) | numeric vector | numeric matrix

Means of multivariate normal distributions, specified as a 1-by- d numeric vector or an n -by- d numeric matrix.

- If `mu` is a vector, then `mvnpdf` replicates the vector to match the trailing dimension of `sigma`.
- If `mu` is a matrix, then each row of `mu` is the mean vector of a single multivariate normal distribution.

Data Types: `single` | `double`

sigma — Covariances of multivariate normal distributions

identity matrix (default) | symmetric, positive definite matrix | numeric array

Covariances of multivariate normal distributions, specified as a d -by- d symmetric, positive definite matrix or a d -by- d -by- n numeric array.

- If `sigma` is a matrix, then `mvnpdf` replicates the matrix to match the number of rows in `mu`.
- If `sigma` is an array, then each page of `sigma`, `sigma(:, :, i)`, is the covariance matrix of a single multivariate normal distribution and, therefore, is a symmetric, positive definite matrix.

If the covariance matrices are diagonal, containing variances along the diagonal and zero covariances off it, then you can also specify `sigma` as a 1-by- d vector or a 1-by- d -by- n array containing just the diagonal entries.

Data Types: `single` | `double`**Output Arguments****y — pdf values**

numeric vector

pdf values, returned as an n -by-1 numeric vector, where n is one of the following:

- Number of rows in `X` if `X` is a matrix
- Number of times `X` is replicated if `X` is a vector

If `X` is a matrix, `mu` is a matrix, and `sigma` is an array, then `mvnpdf` computes `y(i)` using `X(i, :)`, `mu(i, :)`, and `sigma(:, :, i)`.

Data Types: `double`**More About****Multivariate Normal Distribution**

The multivariate normal distribution is a generalization of the univariate normal distribution to two or more variables. It has two parameters, a mean vector μ and a covariance matrix Σ , that are analogous to the mean and variance parameters of a univariate normal distribution. The diagonal elements of Σ contain the variances for each variable, and the off-diagonal elements of Σ contain the covariances between variables.

The probability density function (pdf) of the d -dimensional multivariate normal distribution is

$$y = f(x, \mu, \Sigma) = \frac{1}{\sqrt{|\Sigma|(2\pi)^d}} \exp\left(-\frac{1}{2}(x-\mu)' \Sigma^{-1}(x-\mu)\right)$$

where x and μ are 1-by- d vectors and Σ is a d -by- d symmetric, positive definite matrix. Only `mvnrnd` allows positive semi-definite Σ matrices, which can be singular. The pdf cannot have the same form when Σ is singular.

The multivariate normal cumulative distribution function (cdf) evaluated at x is the probability that a random vector v , distributed as multivariate normal, lies within the semi-infinite rectangle with upper limits defined by x :

$$\Pr\{v(1) \leq x(1), v(2) \leq x(2), \dots, v(d) \leq x(d)\}.$$

Although the multivariate normal cdf does not have a closed form, `mvncdf` can compute cdf values numerically.

Tips

- In the one-dimensional case, `sigma` is the variance, not the standard deviation. For example, `mvnpdf(1,0,4)` is the same as `normpdf(1,0,2)`, where 4 is the variance and 2 is the standard deviation.

Topics

“Multivariate Normal Distribution” on page B-98

Introduced before R2006a

mvregress

Multivariate linear regression

Syntax

```
beta = mvregress(X,Y)
beta = mvregress(X,Y,Name,Value)
[beta,Sigma] = mvregress( ___ )
[beta,Sigma,E,CovB,logL] = mvregress( ___ )
```

Description

`beta = mvregress(X,Y)` returns the estimated coefficients for a multivariate normal regression on page 32-3528 of the d -dimensional responses in Y on the design matrices in X .

`beta = mvregress(X,Y,Name,Value)` returns the estimated coefficients using additional options specified by one or more name-value pair arguments. For example, you can specify the estimation algorithm, initial estimate values, or maximum number of iterations for the regression.

`[beta,Sigma] = mvregress(___)` also returns the estimated d -by- d variance-covariance matrix of Y , using any of the input arguments from the previous syntaxes.

`[beta,Sigma,E,CovB,logL] = mvregress(___)` also returns a matrix of residuals E , estimated variance-covariance matrix of the regression coefficients $CovB$, and the value of the log likelihood objective function after the last iteration $logL$.

Examples

Multivariate Regression Model for Panel Data with Different Intercepts

Fit a multivariate regression model to panel data, assuming different intercepts and common slopes.

Load the sample data.

```
load('flu')
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google® query data.

Extract the response and predictor data.

```
Y = double(flu(:,2:end-1));
[n,d] = size(Y);
x = flu.WtdILI;
```

The responses in Y are the nine regional flu estimates. Observations exist for every week over a one-year period, so $n = 52$. The dimension of the responses corresponds to the regions, so $d = 9$. The predictors in x are the weekly national flu estimates.

Plot the flu data, grouped by region.

```
figure;
regions = flu.Properties.VarNames(2:end-1);
plot(x,Y,'x')
legend(regions,'Location','NorthWest')
```

Fit the multivariate regression model $y_{ij} = \alpha_j + \beta x_{ij} + \epsilon_{ij}$, where $i = 1, \dots, n$ and $j = 1, \dots, d$, with between-region concurrent correlation $\text{COV}(\epsilon_{ij}, \epsilon_{ij}) = \sigma_{jj}$.

There are $K = 10$ regression coefficients to estimate: nine intercept terms and a common slope. The input argument X should be an n -element cell array of d -by- K design matrices.

```
X = cell(n,1);
for i = 1:n
    X{i} = [eye(d) repmat(x(i),d,1)];
end
[beta,Sigma] = mvregress(X,Y);
```

beta contains estimates of the K -dimensional coefficient vector $(\alpha_1, \alpha_2, \dots, \alpha_9, \beta)'$.

Sigma contains estimates of the d -by- d variance-covariance matrix $(\sigma_{ij})_{d \times d}$, $i, j = 1, \dots, d$ for the between-region concurrent correlations.

Plot the fitted regression model.

```
B = [beta(1:d)'; repmat(beta(end),1,d)];
xx = linspace(.5,3.5)';
fits = [ones(size(xx)),xx]*B;
```

```

figure;
h = plot(x,Y,'x',xx,fits,'-');
for i = 1:d
    set(h(d+i),'color',get(h(i),'color'));
end
legend(regions,'Location','NorthWest');

```

The plot shows that each regression line has a different intercept but the same slope. Upon visual inspection, some regression lines appear to fit the data better than others.

Multivariate Regression for Panel Data with Different Slopes

Fit a multivariate regression model to panel data using least squares, assuming different intercepts and slopes.

Load the sample data.

```
load('flu');
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google® queries.

Extract the response and predictor data.

```
Y = double(flu(:,2:end-1));
[n,d] = size(Y);
x = flu.WtdILI;
```

The responses in Y are the nine regional flu estimates. Observations exist for every week over a one-year period, so $n = 52$. The dimension of the responses corresponds to the regions, so $d = 9$. The predictors in x are the weekly national flu estimates.

Fit the multivariate regression model $y_{ij} = \alpha_j + \beta_j x_{ij} + \epsilon_{ij}$, where $i = 1, \dots, n$ and $j = 1, \dots, d$, with between-region concurrent correlation $COV(\epsilon_{ij}, \epsilon_{ij}) = \sigma_{jj}$.

There are $K = 18$ regression coefficients to estimate: nine intercept terms, and nine slope terms. X is an n -element cell array of d -by- K design matrices.

```
X = cell(n,1);
for i = 1:n
    X{i} = [eye(d) x(i)*eye(d)];
end
[beta,Sigma] = mvregress(X,Y, 'algorithm', 'cwls');
```

β contains estimates of the K -dimensional coefficient vector $(\alpha_1, \alpha_2, \dots, \alpha_9, \beta_1, \beta_2, \dots, \beta_9)'$.

Plot the fitted regression model.

```
B = [beta(1:d)';beta(d+1:end)'];
xx = linspace(.5,3.5)';
fits = [ones(size(xx)),xx]*B;

figure;
h = plot(x,Y,'x',xx,fits,'-');
for i = 1:d
    set(h(d+i),'color',get(h(i),'color'));
end

regions = flu.Properties.VarNames(2:end-1);
legend(regions, 'Location', 'NorthWest');
```

The plot shows that each regression line has a different intercept and slope.

Multivariate Regression With a Single Design Matrix

Fit a multivariate regression model using a single n -by- P design matrix for all response dimensions.

Load the sample data.

```
load('flu')
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google® queries.

Extract the response and predictor data.

```
Y = double(flu(:,2:end-1));
[n,d] = size(Y);
x = flu.WtdILI;
```

The responses in `Y` are the nine regional flu estimates. Observations exist for every week over a one-year period, so $n = 52$. The dimension of the responses corresponds to the regions, so $d = 9$. The predictors in `x` are the weekly national flu estimates.

Create an n -by- P design matrix `X`. Add a column of ones to include a constant term in the regression.

```
X = [ones(size(x)),x];
```

Fit the multivariate regression model

$$y_{ij} = \alpha_j + \beta_j x_{ij} + \epsilon_{ij},$$

where $i = 1, \dots, n$ and $j = 1, \dots, d$, with between-region concurrent correlation

$$COV(\epsilon_{ij}, \epsilon_{ij}) = \sigma_{jj}.$$

There are 18 regression coefficients to estimate: nine intercept terms, and nine slope terms.

```
[beta,Sigma,E,CovB,logL] = mvregress(X,Y);
```

beta contains estimates of the P -by- d coefficient matrix. **Sigma** contains estimates of the d -by- d variance-covariance matrix for the between-region concurrent correlations. **E** is a matrix of the residuals. **CovB** is the estimated variance-covariance matrix of the regression coefficients. **logL** is the value of the log likelihood objective function after the last iteration.

Plot the fitted regression model.

```
B = beta;
xx = linspace(.5,3.5)';
fits = [ones(size(xx)),xx]*B;

figure
h = plot(x,Y,'x', xx,fits,'-');
for i = 1:d
    set(h(d+i),'color',get(h(i),'color'))
end

regions = flu.Properties.VarNames(2:end-1);
legend(regions,'Location','NorthWest')
```

The plot shows that each regression line has a different intercept and slope.

Input Arguments

X — Design matrices

matrix | cell array of matrices

Design matrices for the multivariate regression, specified as a matrix or cell array of matrices. n is the number of observations in the data, K is the number of regression coefficients to estimate, p is the number of predictor variables, and d is the number of dimensions in the response variable matrix Y .

- If $d = 1$, then specify X as a single n -by- K design matrix.
- If $d > 1$ and all d dimensions have the same design matrix, then you can specify X as a single n -by- p design matrix (not in a cell array).
- If $d > 1$ and all n observations have the same design matrix, then you can specify X as a cell array containing a single d -by- K design matrix.
- If $d > 1$ and all n observations do not have the same design matrix, then specify X as a cell array of length n containing d -by- K design matrices.

To include a constant term in the regression model, each design matrix should contain a column of ones.

`mvregress` treats NaN values in X as missing values, and ignores rows in X with missing values.

Data Types: `single` | `double` | `cell`

Y — Response variables

matrix

Response variables, specified as an n -by- d matrix. n is the number of observations in the data, and d is the number of dimensions in the response. When $d = 1$, `mvregress` treats the values in Y like n independent response values.

`mvregress` treats NaN values in Y as missing values, and handles them according to the estimation algorithm specified using the name-value pair argument `algorithm`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'algorithm','cwlsl','covar0'`, `C` specifies covariance-weighted least squares estimation using the covariance matrix `C`.

algorithm — Estimation algorithm

`'mvn'` | `'ecm'` | `'cwlsl'`

Estimation algorithm, specified as the comma-separated pair consisting of `'algorithm'` and one of the following.

<code>'mvn'</code>	Ordinary multivariate normal maximum likelihood estimation.
<code>'ecm'</code>	Maximum likelihood estimation via the ECM algorithm.
<code>'cwlsl'</code>	Covariance-weighted least squares estimation.

The default algorithm depends on the presence of missing data.

- For complete data, the default is `'mvn'`.
- If there are any missing responses (indicated by NaN), the default is `'ecm'`, provided the sample size is sufficient to estimate all parameters. Otherwise, the default algorithm is `'cwlsl'`.

Note If `algorithm` has the value `'mvn'`, then `mvregress` removes observations with missing response values before estimation.

Example: `'algorithm','ecm'`

beta0 — Initial estimates for regression coefficients

vector

Initial estimates for the regression coefficients, specified as the comma-separated pair consisting of `'beta0'` and a vector with K elements. The default value is a vector of 0s.

The `beta0` argument is not used if the estimation `algorithm` is `'mvn'`.

covar0 — Initial estimate for variance-covariance matrix

matrix

Initial estimate for the variance-covariance matrix, Σ , specified as the comma-separated pair consisting of 'covar0' and a symmetric, positive definite, d -by- d matrix. The default value is the identity matrix.

If the estimation algorithm is 'cwcs', then mvregress uses covar0 as the weighting matrix at each iteration, without changing it.

covtype — Type of variance-covariance matrix

'full' (default) | 'diagonal'

Type of variance-covariance matrix to estimate for Y , specified as the comma-separated pair consisting of 'covtype' and one of the following.

'full'	Estimate all $d(d + 1)/2$ variance-covariance elements.
'diagonal'	Estimate only the d diagonal elements of the variance-covariance matrix.

Example: 'covtype', 'diagonal'

maxiter — Maximum number of iterations

100 (default) | positive integer

Maximum number of iterations for the estimation algorithm, specified as the comma-separated pair consisting of 'maxiter' and a positive integer.

Iterations continue until estimates are within the convergence tolerances tolbeta and tolobj, or the maximum number of iterations specified by maxiter is reached. If both tolbeta and tolobj are 0, then mvregress performs maxiter iterations with no convergence tests.

Example: 'maxiter', 50

outputfcn — Function to evaluate each iteration

function handle

Function to evaluate at each iteration, specified as the comma-separated pair consisting of 'outputfcn' and a function handle. The function must return a logical true or false. At each iteration, mvregress evaluates the function. If the result is true, iterations stop. Otherwise, iterations continue. For example, you could specify a function that plots or displays current iteration results, and returns true if you close the figure.

The function must accept three input arguments, in this order:

- Vector of current coefficient estimates
- Structure containing these three fields:

Covar	Current value of the variance-covariance matrix
iteration	Current iteration number
fval	Current value of the loglikelihood objective function

- Text that takes these three values:

'init'	When the function is called during initialization
'iter'	When the function is called after an iteration
'done'	When the function is called after completion

tolbeta — Convergence tolerance for regression coefficients

`sqrt(eps)` (default) | positive scalar value

Convergence tolerance for regression coefficients, specified as the comma-separated pair consisting of 'tolbeta' and a positive scalar value.

Let \mathbf{b}^t denote the estimate of the coefficient vector at iteration t , and τ_β be the tolerance specified by `tolbeta`. The convergence criterion for regression coefficient estimation is

$$\|\mathbf{b}^t - \mathbf{b}^{t-1}\| < \tau_\beta \sqrt{K}(1 + \|\mathbf{b}^t\|),$$

where K is the length of \mathbf{b}^t and $\|\mathbf{v}\|$ is the norm of a vector \mathbf{v} .

Iterations continue until estimates are within the convergence tolerances `tolbeta` and `tolobj`, or the maximum number of iterations specified by `maxiter` is reached. If both `tolbeta` and `tolobj` are 0, then `mvregress` performs `maxiter` iterations with no convergence tests.

Example: 'tolbeta', 1e-5

tolobj — Convergence tolerance for loglikelihood objective function

`eps^(3/4)` (default) | positive scalar value

Convergence tolerance for the loglikelihood objective function, specified as the comma-separated pair consisting of 'tolobj' and a positive scalar value.

Let L^t denote the value of the loglikelihood objective function at iteration t , and τ_ℓ be the tolerance specified by `tolobj`. The convergence criterion for the objective function is

$$|L^t - L^{t-1}| < \tau_\ell (1 + |L^t|).$$

Iterations continue until estimates are within the convergence tolerances `tolbeta` and `tolobj`, or the maximum number of iterations specified by `maxiter` is reached. If both `tolbeta` and `tolobj` are 0, then `mvregress` performs `maxiter` iterations with no convergence tests.

Example: 'tolobj', 1e-5

varformat — Format for parameter estimate variance-covariance matrix

'beta' (default) | 'full'

Format for the parameter estimate variance-covariance matrix, `CovB`, specified as the comma-separated pair consisting of 'varformat' and one of the following.

'beta'	Return the variance-covariance matrix for only the regression coefficient estimates, <code>beta</code> .
'full'	Return the variance-covariance matrix for both the regression coefficient estimates, <code>beta</code> , and the variance-covariance matrix estimate, <code>Sigma</code> .

Example: 'varformat', 'full'

vartype — Type of variance-covariance matrix for parameter estimates

'hessian' (default) | 'fisher'

Type of variance-covariance matrix for parameter estimates, specified as the comma-separated pair consisting of 'vartype' and either 'hessian' or 'fisher'.

- If the value is 'hessian', then `mvregress` uses the Hessian, or observed information, matrix to compute `CovB`.
- If the value is 'fisher', then `mvregress` uses the complete-data Fisher, or expected information, matrix to compute `CovB`.

The 'hessian' method takes into account the increase uncertainties due to missing data, while the 'fisher' method does not.

Example: 'vartype', 'fisher'

Output Arguments**beta — Estimated regression coefficients**

column vector | matrix

Estimated regression coefficients, returned as a column vector or matrix.

- If you specify X as a single n -by- K design matrix, then `mvregress` returns `beta` as a column vector of length K . For example, if X is a 20-by-5 design matrix, then `beta` is a 5-by-1 column vector.
- If you specify X as a cell array containing one or more d -by- K design matrices, then `mvregress` returns `beta` as a column vector of length K . For example, if X is a cell array containing 2-by-10 design matrices, then `beta` is a 10-by-1 column vector.
- If you specify X as a single n -by- p design matrix (not in a cell array), and Y has dimension $d > 1$, then `mvregress` returns `beta` as a p -by- d matrix. For example, if X is a 20-by-5 design matrix, and Y has two dimensions such that $d = 2$, then `beta` is a 5-by-2 matrix, and the fitted Y values are $X \times \text{beta}$.

Sigma — Estimated variance-covariance matrix

square matrix

Estimated variance-covariance matrix for the responses in Y , returned as a d -by- d square matrix.

Note The estimated variance-covariance matrix, `Sigma`, is not the sample covariance matrix of the residual matrix, `E`.

E — Residuals

matrix

Residuals for the fitted regression model, returned as an n -by- d matrix.

If `algorithm` has the value 'ecm' or 'cwlsl', then `mvregress` computes the residual values corresponding to missing values in Y as the difference between the conditionally imputed values on page 32-3528 and the fitted values.

Note If `algorithm` has the value 'mvn', then `mvregress` removes observations with missing response values before estimation.

CovB — Parameter estimate variance-covariance matrix

square matrix

Parameter estimate variance-covariance matrix, returned as a square matrix.

- If `varformat` has the value 'beta' (default), then `CovB` is the estimated variance-covariance matrix of the coefficient estimates in `beta`.
- If `varformat` has the value 'full', then `CovB` is the estimated variance-covariance matrix of the combined estimates in `beta` and `Sigma`.

LogL — Loglikelihood objective function value

scalar value

Loglikelihood objective function value after the last iteration, returned as a scalar value.

More About

Multivariate Normal Regression

Multivariate normal regression is the regression of a d -dimensional response on a design matrix of predictor variables, with normally distributed errors. The errors can be heteroscedastic and correlated.

The model is

$$\mathbf{y}_i = \mathbf{X}_i\boldsymbol{\beta} + \mathbf{e}_i, \quad i = 1, \dots, n,$$

where

- \mathbf{y}_i is a d -dimensional vector of responses.
- \mathbf{X}_i is a design matrix of predictor variables.
- $\boldsymbol{\beta}$ is vector or matrix of regression coefficients.
- \mathbf{e}_i is a d -dimensional vector of error terms, with multivariate normal distribution

$$\mathbf{e}_i \sim MVN_d(\mathbf{0}, \boldsymbol{\Sigma}).$$

Conditionally Imputed Values

The expectation/conditional maximization ('ecm') and covariance-weighted least squares ('cwlsl') estimation algorithms include imputation of missing response values.

Let $\tilde{\mathbf{y}}$ denote missing observations. The conditionally imputed values are the expected value of the missing observation given the observed data, $E(\tilde{\mathbf{y}}|\mathbf{y})$.

The joint distribution of the missing and observed responses is a multivariate normal distribution,

$$\begin{pmatrix} \tilde{\mathbf{y}} \\ \mathbf{y} \end{pmatrix} \sim MVN \left\{ \begin{pmatrix} \tilde{\mathbf{X}}\boldsymbol{\beta} \\ \mathbf{X}\boldsymbol{\beta} \end{pmatrix}, \begin{pmatrix} \boldsymbol{\Sigma}_{\tilde{\mathbf{y}}} & \boldsymbol{\Sigma}_{\tilde{\mathbf{y}}\mathbf{y}} \\ \boldsymbol{\Sigma}_{\mathbf{y}\tilde{\mathbf{y}}} & \boldsymbol{\Sigma}_{\mathbf{y}} \end{pmatrix} \right\}.$$

Using properties of the multivariate normal distribution, the imputed conditional expectation is given by

$$E(\tilde{\mathbf{y}}|\mathbf{y}) = \tilde{\mathbf{X}}\boldsymbol{\beta} + \Sigma_{\tilde{\mathbf{y}}\mathbf{y}}\Sigma_{\mathbf{y}}^{-1}(\mathbf{y} - \mathbf{X}\boldsymbol{\beta}).$$

Note `mvregress` only imputes missing response values. Observations with missing values in the design matrix are removed.

mvregresslike

Negative log-likelihood for multivariate regression

Syntax

```
nlogL = mvregresslike(X,Y,b,SIGMA,alg)
[nlogL,COVB] = mvregresslike(...)
[nlogL,COVB] = mvregresslike(...,type,format)
```

Description

`nlogL = mvregresslike(X,Y,b,SIGMA,alg)` computes the negative log-likelihood `nlogL` for a multivariate regression of the d -dimensional multivariate observations in the n -by- d matrix `Y` on the predictor variables in the matrix or cell array `X`, evaluated for the p -by-1 column vector `b` of coefficient estimates and the d -by- d matrix `SIGMA` specifying the covariance of a row of `Y`. If $d = 1$, `X` can be an n -by- p design matrix of predictor variables. For any value of d , `X` can also be a cell array of length n , with each cell containing a d -by- p design matrix for one multivariate observation. If all observations have the same d -by- p design matrix, `X` can be a single cell.

NaN values in `X` or `Y` are taken as missing. Observations with missing values in `X` are ignored. Treatment of missing values in `Y` depends on the algorithm specified by `alg`.

`alg` should match the algorithm used by `mvregress` to obtain the coefficient estimates `b`, and must be one of the following:

- 'ecm' — ECM algorithm
- 'cwlsl' — Least squares conditionally weighted by `SIGMA`
- 'mvn' — Multivariate normal estimates computed after omitting rows with any missing values in `Y`

`[nlogL,COVB] = mvregresslike(...)` also returns an estimated covariance matrix `COVB` of the parameter estimates `b`.

`[nlogL,COVB] = mvregresslike(...,type,format)` specifies the type and format of `COVB`.

`type` is either:

- 'hessian' — To use the Hessian or observed information. This method takes into account the increased uncertainties due to missing data. This is the default.
- 'fisher' — To use the Fisher or expected information. This method uses the complete data expected information, and does not include uncertainty due to missing data.

`format` is either:

- 'beta' — To compute `COVB` for `b` only. This is the default.
- 'full' — To compute `COVB` for both `b` and `SIGMA`.

Introduced in R2007a

mvnrnd

Multivariate normal random numbers

Syntax

```
R = mvnrnd(mu,sigma,n)
R = mvnrnd(mu,sigma)
```

Description

`R = mvnrnd(mu,sigma,n)` returns a matrix `R` of `n` random vectors chosen from the same multivariate normal distribution, with mean vector `mu` and covariance matrix `sigma`. For more information, see “Multivariate Normal Distribution” on page 32-3535.

`R = mvnrnd(mu,sigma)` returns an m -by- d matrix `R` of random vectors sampled from m separate d -dimensional multivariate normal distributions, with means and covariances specified by `mu` and `sigma`, respectively. Each row of `R` is a single multivariate normal random vector.

Examples

Generate Multivariate Normal Random Numbers

Generate random numbers from the same multivariate normal distribution.

Define `mu` and `sigma`, and generate 100 random numbers.

```
mu = [2 3];
sigma = [1 1.5; 1.5 3];
rng('default') % For reproducibility
R = mvnrnd(mu,sigma,100);
```

Plot the random numbers.

```
plot(R(:,1),R(:,2),'+')
```

Sample from Different Multivariate Normal Distributions

Randomly sample from five different three-dimensional normal distributions.

Specify the means μ and the covariances σ of the distributions. Let all the distributions share the same covariance matrix, but vary the mean vectors.

```
firstDim = (1:5)';
mu = repmat(firstDim,1,3)
```

```
mu = 5×3
```

```
1    1    1
2    2    2
3    3    3
4    4    4
5    5    5
```

```
sigma = eye(3)
```

```
sigma = 3×3
```

```
1    0    0
0    1    0
```

```
0 0 1
```

Randomly sample once from each of the five distributions.

```
rng('default') % For reproducibility  
R = mvnrnd(mu,sigma)
```

```
R = 5×3
```

```
1.5377 -0.3077 -0.3499  
3.8339 1.5664 5.0349  
0.7412 3.3426 3.7254  
4.8622 7.5784 3.9369  
5.3188 7.7694 5.7147
```

Plot the results.

```
scatter3(R(:,1),R(:,2),R(:,3))
```

Input Arguments

mu — Means of multivariate normal distributions
numeric vector | numeric matrix

Means of multivariate normal distributions, specified as a 1-by- d numeric vector or an m -by- d numeric matrix.

- If `mu` is a vector, then `mvnrnd` replicates the vector to match the trailing dimension of `sigma`.
- If `mu` is a matrix, then each row of `mu` is the mean vector of a single multivariate normal distribution.

Data Types: `single` | `double`

sigma — Covariances of multivariate normal distributions

symmetric, positive semi-definite matrix | numeric array

Covariances of multivariate normal distributions, specified as a d -by- d symmetric, positive semi-definite matrix or a d -by- d -by- m numeric array.

- If `sigma` is a matrix, then `mvnrnd` replicates the matrix to match the number of rows in `mu`.
- If `sigma` is an array, then each page of `sigma`, `sigma(:,:,i)`, is the covariance matrix of a single multivariate normal distribution and, therefore, is a symmetric, positive semi-definite matrix.

If the covariance matrices are diagonal, containing variances along the diagonal and zero covariances off it, then you can also specify `sigma` as a 1-by- d vector or a 1-by- d -by- m array containing just the diagonal entries.

Data Types: `single` | `double`

n — Number of multivariate random numbers

positive scalar integer

Number of multivariate random numbers, specified as a positive scalar integer. `n` specifies the number of rows in `R`.

Data Types: `single` | `double`

Output Arguments

R — Multivariate normal random numbers

numeric matrix

Multivariate normal random numbers, returned as one of the following:

- m -by- d numeric matrix, where m and d are the dimensions specified by `mu` and `sigma`
- n -by- d numeric matrix, where `n` is the specified input argument and d is the dimension specified by `mu` and `sigma`

If `mu` is a matrix and `sigma` is an array, then `mvnrnd` computes `R(i,:)` using `mu(i,:)` and `sigma(:,:,i)`.

More About

Multivariate Normal Distribution

The multivariate normal distribution is a generalization of the univariate normal distribution to two or more variables. It has two parameters, a mean vector μ and a covariance matrix Σ , that are analogous

to the mean and variance parameters of a univariate normal distribution. The diagonal elements of Σ contain the variances for each variable, and the off-diagonal elements of Σ contain the covariances between variables.

The probability density function (pdf) of the d -dimensional multivariate normal distribution is

$$y = f(x, \mu, \Sigma) = \frac{1}{\sqrt{|\Sigma|(2\pi)^d}} \exp\left(-\frac{1}{2}(x-\mu)' \Sigma^{-1}(x-\mu)\right)$$

where x and μ are 1-by- d vectors and Σ is a d -by- d symmetric, positive definite matrix. Only `mvnrnd` allows positive semi-definite Σ matrices, which can be singular. The pdf cannot have the same form when Σ is singular.

The multivariate normal cumulative distribution function (cdf) evaluated at x is the probability that a random vector v , distributed as multivariate normal, lies within the semi-infinite rectangle with upper limits defined by x :

$$\Pr\{v(1) \leq x(1), v(2) \leq x(2), \dots, v(d) \leq x(d)\}.$$

Although the multivariate normal cdf does not have a closed form, `mvncdf` can compute cdf values numerically.

Tips

- `mvnrnd` requires the matrix `sigma` to be symmetric. If `sigma` has only minor asymmetry, you can use `(sigma + sigma')/2` instead to resolve the asymmetry.
- In the one-dimensional case, `sigma` is the variance, not the standard deviation. For example, `mvnrnd(0,4)` is the same as `normrnd(0,2)`, where 4 is the variance and 2 is the standard deviation.

mvtcdf

Multivariate t cumulative distribution function

Syntax

```
y = mvtcdf(X,C,DF)
y = mvtcdf(xl,xu,C,DF)
[y,err] = mvtcdf(...)
[...] = mvntdf(...,options)
```

Description

`y = mvtcdf(X,C,DF)` returns the cumulative probability of the multivariate t distribution with correlation parameters C and degrees of freedom DF , evaluated at each row of X . Rows of the n -by- d matrix X correspond to observations or points, and columns correspond to variables or coordinates. y is an n -by-1 vector.

C is a symmetric, positive definite, d -by- d matrix, typically a correlation matrix. If its diagonal elements are not 1, `mvtcdf` scales C to correlation form. `mvtcdf` does not rescale X . DF is a scalar, or a vector with n elements.

The multivariate t cumulative probability at X is defined as the probability that a random vector T , distributed as multivariate t , will fall within the semi-infinite rectangle with upper limits defined by X , i.e., $\Pr\{T(1) \leq X(1), T(2) \leq X(2), \dots, T(d) \leq X(d)\}$.

`y = mvtcdf(xl,xu,C,DF)` returns the multivariate t cumulative probability evaluated over the rectangle with lower and upper limits defined by x_l and x_u , respectively.

`[y,err] = mvtcdf(...)` returns an estimate of the error in y . For bivariate and trivariate distributions, `mvtcdf` uses adaptive quadrature on a transformation of the t density, based on methods developed by Genz, as described in the references. The default absolute error tolerance for these cases is $1e-8$. For four or more dimensions, `mvtcdf` uses a quasi-Monte Carlo integration algorithm based on methods developed by Genz and Bretz, as described in the references. The default absolute error tolerance for these cases is $1e-4$.

`[...] = mvntdf(...,options)` specifies control parameters for the numerical integration used to compute y . This argument can be created by a call to `statset`. Choices of `statset` parameters are:

- `'TolFun'` — Maximum absolute error tolerance. Default is $1e-8$ when $d < 4$, or $1e-4$ when $d \geq 4$.
- `'MaxFunEvals'` — Maximum number of integrand evaluations allowed when $d \geq 4$. Default is $1e7$. `'MaxFunEvals'` is ignored when $d < 4$.
- `'Display'` — Level of display output. Choices are `'off'` (the default), `'iter'`, and `'final'`. `'Display'` is ignored when $d < 4$.

Examples

Compute the Multivariate t Distribution cdf

Compute the cdf of a multivariate t distribution with correlation parameters $C = \begin{bmatrix} 1 & .4 \\ .4 & 1 \end{bmatrix}$ and 2 degrees of freedom.

```
C = [1 .4; .4 1];  
df = 2;  
[X1,X2] = meshgrid(linspace(-2,2,25)',linspace(-2,2,25)');  
X = [X1(:) X2(:)];  
p = mvtcdf(X,C,df);
```

Plot the cdf.

```
figure;  
surf(X1,X2,reshape(p,25,25));
```

mvtpdf

Multivariate t probability density function

Syntax

```
y = mvtpdf(X,C,df)
```

Description

`y = mvtpdf(X,C,df)` returns the probability density of the multivariate t distribution with correlation parameters C and degrees of freedom df , evaluated at each row of X . Rows of the n -by- d matrix X correspond to observations or points, and columns correspond to variables or coordinates. C is a symmetric, positive definite, d -by- d matrix, typically a correlation matrix. If its diagonal elements are not 1, `mvtpdf` scales C to correlation form. `mvtcdf` does not rescale X . df is a scalar, or a vector with n elements. y is an n -by-1 vector.

Examples

Compute the Multivariate t Distribution pdf

Compute the pdf of a multivariate t distribution with correlation parameters $C = [1 \ .4; \ .4 \ 1]$ and 2 degrees of freedom.

```
[X1,X2] = meshgrid(linspace(-2,2,25)',linspace(-2,2,25)');  
X = [X1(:) X2(:)];  
C = [1 .4; .4 1];  
df = 2;  
p = mvtpdf(X,C,df);
```

Plot the pdf.

```
figure;  
surf(X1,X2,reshape(p,25,25))
```

Topics

"Multivariate t Distribution" on page B-104

Introduced in R2006b

mvtrnd

Multivariate t random numbers

Syntax

```
R = mvtrnd(C,df,cases)
R = mvtrnd(C,df)
```

Description

`R = mvtrnd(C,df,cases)` returns a matrix of random numbers chosen from the multivariate t distribution, where C is a correlation matrix. `df` is the degrees of freedom and is either a scalar or is a vector with `cases` elements. If p is the number of columns in C , then the output R has `cases` rows and p columns.

Let \mathbf{t} represent a row of R . Then the distribution of \mathbf{t} is that of a vector having a multivariate normal distribution with mean 0, variance 1, and covariance matrix C , divided by an independent chi-square random value having `df` degrees of freedom. The rows of R are independent.

C must be a square, symmetric and positive definite matrix. If its diagonal elements are not all 1 (that is, if C is a covariance matrix rather than a correlation matrix), `mvtrnd` rescales C to transform it to a correlation matrix before generating the random numbers.

`R = mvtrnd(C,df)` returns a single random number from the multivariate t distribution.

Examples

Generate Multivariate t Distribution Random Numbers

Generate random numbers from a multivariate t distribution with correlation parameters `SIGMA = [1 0.8;0.8 1]` and 3 degrees of freedom.

```
rng default; % For reproducibility
SIGMA = [1 0.8;0.8 1];
R = mvtrnd(SIGMA,3,100);
```

Plot the random numbers.

```
figure;
plot(R(:,1),R(:,2),'+')
```

NumObservations property

Class: cvpartition

Number of observations (including observations with missing group values)

Description

Number of observations (including observations with missing group values).

nancov

Covariance ignoring NaN values

Syntax

```
Y = nancov(X)
Y = nancov(X1,X2)
Y = nancov(...,1)
Y = nancov(...,'pairwise')
```

Description

$Y = \text{nancov}(X)$ is the covariance cov of X , computed after removing observations with NaN values.

For vectors x , $\text{nancov}(x)$ is the sample variance of the remaining elements, once NaN values are removed. For matrices X , $\text{nancov}(X)$ is the sample covariance of the remaining observations, once observations (rows) containing any NaN values are removed.

$Y = \text{nancov}(X1, X2)$, where $X1$ and $X2$ are matrices with the same number of elements, is equivalent to $\text{nancov}(X)$, where $X = [X1(:) \ X2(:)]$.

nancov removes the mean from each variable (column for matrix X) before calculating Y . If n is the number of remaining observations after removing observations with NaN values, nancov normalizes Y by either $n - 1$ or n , depending on whether $n > 1$ or $n = 1$, respectively. To specify normalization by n , use $Y = \text{nancov}(\dots, 1)$.

$Y = \text{nancov}(\dots, \text{'pairwise'})$ computes $Y(i, j)$ using rows with no NaN values in columns i or j . The result Y may not be a positive definite matrix.

Examples

Generate random data for two variables (columns) with random missing values:

```
X = rand(10,2);
p = randperm(numel(X));
X(p(1:5)) = NaN
X =
    0.8147    0.1576
    NaN      NaN
    0.1270    0.9572
    0.9134    NaN
    0.6324    NaN
    0.0975    0.1419
    0.2785    0.4218
    0.5469    0.9157
    0.9575    0.7922
    0.9649    NaN
```

Establish a correlation between a third variable and the other two variables:

```
X(:,3) = sum(X,2)
X =
```

```

0.8147    0.1576    0.9723
   NaN     NaN     NaN
0.1270    0.9572    1.0842
0.9134     NaN     NaN
0.6324     NaN     NaN
0.0975    0.1419    0.2394
0.2785    0.4218    0.7003
0.5469    0.9157    1.4626
0.9575    0.7922    1.7497
0.9649     NaN     NaN

```

Compute the covariance matrix for the three variables after removing observations (rows) with NaN values:

```

Y = nancov(X)
Y =
    0.1311    0.0096    0.1407
    0.0096    0.1388    0.1483
    0.1407    0.1483    0.2890

```

Alternative Functionality

Instead of using `nancov`, you can use the MATLAB function `cov` with the input argument `nanflag`. For example, instead of `nancov(X)`, use `cov(X, 'omitrows')`, and instead of `nancov(X, 'pairwise')`, use `cov(X, 'partialrows')`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- If the input is variable-size and is `[]` at run time, the generated code returns `[]` not NaN.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

NaN | cov | nanvar | var

Introduced before R2006a

nanmax

Maximum, ignoring NaN values

Syntax

```
y = nanmax(X)
y = nanmax(X,[],dim)
[y,indices] = nanmax( ___ )
```

```
y = nanmax(X,[],'all')
y = nanmax(X,[],vecdim)
```

```
Y = nanmax(X1,X2)
```

Description

`y = nanmax(X)` is the maximum max of `X`, computed after removing NaN values.

For vectors `x`, `nanmax(x)` is the maximum of the remaining elements, once NaN values are removed. For matrices `X`, `nanmax(X)` is a row vector of column maxima, once NaN values are removed. For multidimensional arrays `X`, `nanmax` operates along the first nonsingleton dimension.

`y = nanmax(X,[],dim)` operates along the dimension `dim` of `X`.

`[y,indices] = nanmax(___)` also returns the row indices of the maximum values for each column in the vector `indices`.

`y = nanmax(X,[],'all')` returns the maximum of all elements of `X`, computed after removing NaN values.

`y = nanmax(X,[],vecdim)` returns the maximum over the dimensions specified in the vector `vecdim`, computed after removing NaN values. Each element of `vecdim` represents a dimension of the input array `X`. The output `y` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `y`. For example, if `X` is a 2-by-3-by-4 array, then `nanmax(X,[],[1 2])` returns a 1-by-1-by-4 array. Each element of the output array is the maximum of the elements on the corresponding page of `X`.

`Y = nanmax(X1,X2)` returns an array `Y` the same size as `X1` and `X2` with `Y(i,j) = nanmax(X1(i,j),X2(i,j))`. Scalar inputs are expanded to an array of the same size as the other input.

Examples

Maximum of Matrix Data

Find the column maximum values and their indices for matrix data with missing values.

```
X = magic(3);
X([1 6:9]) = NaN
```

```
X = 3×3
```

```
NaN    1    NaN
 3     5    NaN
 4    NaN    NaN
```

```
[y,indices] = nanmax(X)
```

```
y = 1×3
```

```
4     5    NaN
```

```
indices = 1×3
```

```
3     2     1
```

Maximum of All Values

Find the maximum of all the values in an array, ignoring missing values.

Create a 2-by-5-by-3 array X with some missing values.

```
X = reshape(1:30,[2 5 3]);
X([10:12 25]) = NaN
```

```
X =
X(:,:,1) =
```

```
1     3     5     7     9
2     4     6     8    NaN
```

```
X(:,:,2) =
```

```
NaN    13    15    17    19
NaN    14    16    18    20
```

```
X(:,:,3) =
```

```
21    23    NaN    27    29
22    24    26    28    30
```

Find the maximum of the elements of X.

```
y = nanmax(X,[],'all')
```

```
y = 30
```

Alternative Functionality

Instead of using `nanmax`, you can use the MATLAB function `max` with the input argument `nanflag` specified as the value `'omitnan'`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

`NaN` | `max` | `nanmin`

Introduced before R2006a

nanmean

Mean, ignoring NaN values

Syntax

```
y = nanmean(X)
y = nanmean(X, 'all')
y = nanmean(X, dim)
y = nanmean(X, vecdim)
```

Description

`y = nanmean(X)` returns the mean of the elements of `X`, computed after removing all NaN values.

- If `X` is a vector, then `nanmean(X)` is the mean of all the non-NaN elements of `X`.
- If `X` is a matrix, then `nanmean(X)` is a row vector of column means, computed after removing NaN values.
- If `X` is a multidimensional array, then `nanmean` operates along the first nonsingleton dimension of `X`. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same. `nanmean` removes all NaN values.

For information on how `nanmean` treats arrays of all NaN values, see “Tips” on page 32-3554.

`y = nanmean(X, 'all')` returns the mean of all elements of `X`, computed after removing NaN values.

`y = nanmean(X, dim)` returns the mean along the operating dimension `dim` of `X`, computed after removing NaN values.

`y = nanmean(X, vecdim)` returns the mean over the dimensions specified in the vector `vecdim`. The function computes the means after removing NaN values. For example, if `X` is a matrix, then `nanmean(X, [1 2])` is the mean of all non-NaN elements of `X` because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.

Examples

Mean of Matrix Data

Find the column means for matrix data with missing values.

```
X = magic(3);
X([1 6:9]) = NaN
```

```
X = 3×3
```

```
NaN    1    NaN
  3     5    NaN
  4   NaN    NaN
```

```

y = nanmean(X)
y = 1×3
    3.5000    3.0000    NaN

```

Mean of All Values

Find the mean of all the values in an array, ignoring missing values.

Create a 2-by-5-by-3 array X with some missing values.

```

X = reshape(1:30,[2 5 3]);
X([10:12 25]) = NaN

X =
X(:,:,1) =
     1     3     5     7     9
     2     4     6     8    NaN

X(:,:,2) =
    NaN    13    15    17    19
    NaN    14    16    18    20

X(:,:,3) =
    21    23    NaN    27    29
    22    24    26    28    30

```

Find the mean of the elements of X.

```

y = nanmean(X, 'all')
y = 15.6538

```

Mean Along Scalar Dimension

Find the row means for matrix data with missing values by specifying to compute the means along the second dimension.

```

X = magic(3);
X([1 6:9]) = NaN

X = 3×3
    NaN     1    NaN
     3     5    NaN

```

```
4 NaN NaN
```

```
y = nanmean(X,2)
```

```
y = 3×1
```

```
1  
4  
4
```

Mean Along Vector Dimension

Find the mean of a multidimensional array over multiple dimensions.

Create a 2-by-5-by-3 array X with some missing values.

```
X = reshape(1:30,[2 5 3]);  
X([10:12 25]) = NaN
```

```
X =  
X(:,:,1) =
```

```
1 3 5 7 9  
2 4 6 8 NaN
```

```
X(:,:,2) =
```

```
NaN 13 15 17 19  
NaN 14 16 18 20
```

```
X(:,:,3) =
```

```
21 23 NaN 27 29  
22 24 26 28 30
```

Find the mean of each page of X by specifying dimensions 1 and 2 as the operating dimensions.

```
ypage = nanmean(X,[1 2])
```

```
ypage =  
ypage(:,:,1) =
```

```
5
```

```
ypage(:,:,2) =
```

```
16.5000
```

```
ypage(:,:,3) =
```

```
25.5556
```

For example, `ypage(1,1,1)` is the mean of the non-NaN elements in `X(:, :, 1)`.

Find the mean of the elements in each `X(i, :, :)` slice by specifying dimensions 2 and 3 as the operating dimensions.

```
yrow = nanmean(X,[2 3])
```

```
yrow = 2×1
```

```
14.5385
16.7692
```

For example, `yrow(2)` is the mean of the non-NaN elements in `X(2, :, :)`.

Input Arguments

X — Input data

scalar | vector | matrix | multidimensional array

Input data, specified as a scalar, vector, matrix, or multidimensional array.

If `X` is an empty array, then `nanmean(X)` is NaN. For more details, see “Tips” on page 32-3554.

Data Types: `single` | `double`

dim — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If you do not specify a value, then the default value is the first array dimension whose size does not equal 1.

`dim` indicates the dimension whose length reduces to 1. `size(y, dim)` is 1 while the sizes of all other dimensions remain the same.

Consider a two-dimensional array `X`:

- If `dim` is equal to 1, then `nanmean(X, 1)` returns a row vector containing the mean for each column.
- If `dim` is equal to 2, then `nanmean(X, 2)` returns a column vector containing the mean for each row.

If `dim` is greater than `ndims(X)` or if `size(X, dim)` is 1, then `nanmean` returns `X`.

Data Types: `single` | `double`

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. The output `y` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `y`.

For example, if X is a 2-by-3-by-3 array, then `nanmean(X, [1 2])` returns a 1-by-1-by-3 array. Each element of the output is the mean of the elements on the corresponding page of X .

Data Types: `single` | `double`

Output Arguments

y — Mean values

scalar | vector | matrix | multidimensional array

Mean values, returned as a scalar, vector, matrix, or multidimensional array.

Tips

- When `nanmean` computes the mean of an array of all NaN values, the array is empty once the NaN values are removed and, therefore, the sum of the remaining elements is 0. Because the mean calculation involves division by 0, the mean value is NaN. The output NaN is not a mean of NaN values.

Alternative Functionality

Instead of using `nanmean`, you can use the MATLAB function `mean` with the input argument `nanflag` specified as the value `'omitnan'`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'all' and vecdim input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

NaN | mean | nanmedian

Introduced before R2006a

nanmedian

Median, ignoring NaN values

Syntax

```
y = nanmedian(X)
y = nanmedian(X,'all')
y = nanmedian(X,dim)
y = nanmedian(X,vecdim)
```

Description

`y = nanmedian(X)` is the median of `X`, computed after removing NaN values.

For vectors `x`, `nanmedian(x)` is the median of the remaining elements, once NaN values are removed. For matrices `X`, `nanmedian(X)` is a row vector of column medians, once NaN values are removed. For multidimensional arrays `X`, `nanmedian` operates along the first nonsingleton dimension.

`y = nanmedian(X,'all')` returns the median of all elements of `X`, computed after removing NaN values.

`y = nanmedian(X,dim)` takes the median along the operating dimension `dim` of `X`.

`y = nanmedian(X,vecdim)` returns the median over the dimensions specified in the vector `vecdim`, computed after removing NaN values. Each element of `vecdim` represents a dimension of the input array `X`. The output `y` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `y`. For example, if `X` is a 2-by-3-by-4 array, then `nanmedian(X,[1 2])` returns a 1-by-1-by-4 array. Each element of the output array is the median of the elements on the corresponding page of `X`.

Examples

Median of Matrix Data

Find the column medians for matrix data with missing values.

```
X = magic(3);
X([1 6:9]) = NaN
```

```
X = 3×3
```

```
NaN     1     NaN
     3     5     NaN
     4    NaN     NaN
```

```
y = nanmedian(X)
```

```
y = 1×3
```

```
3.5000 3.0000 NaN
```

Median Along Vector Dimension

Find the median of a multidimensional array over multiple dimensions.

Create a 3-by-5-by-2 array X with some missing values.

```
X = reshape(1:30,[3 5 2]);
X([10:12 25]) = NaN
```

```
X =
X(:,:,1) =
```

```
1 4 7 NaN 13
2 5 8 NaN 14
3 6 9 NaN 15
```

```
X(:,:,2) =
```

```
16 19 22 NaN 28
17 20 23 26 29
18 21 24 27 30
```

Find the median of each page of X by specifying dimensions 1 and 2 as the operating dimensions.

```
ypage = nanmedian(X,[1 2])
```

```
ypage =
ypage(:,:,1) =
```

```
6.5000
```

```
ypage(:,:,2) =
```

```
22.5000
```

For example, `ypage(1,1,1)` is the median of the non-NaN elements in `X(:,:,1)`.

Find the median of the elements in each `X(:,i,:)` slice by specifying dimensions 1 and 3 as the operating dimensions.

```
ycol = nanmedian(X,[1 3])
```

```
ycol = 1x5
```

```
9.5000 12.5000 15.5000 26.5000 21.5000
```

For example, `ycol(4)` is the median of the non-NaN elements in `X(:,4,:)`.

Alternative Functionality

Instead of using `nanmedian`, you can use the MATLAB function `median` with the input argument `nanflag` specified as the value `'omitnan'`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

nanmin

Minimum, ignoring NaN values

Syntax

```
y = nanmin(X)
y = nanmin(X,[],dim)
[y,indices] = nanmin( ___ )
```

```
y = nanmin(X,[],'all')
y = nanmin(X,[],vecdim)
```

```
Y = nanmin(X1,X2)
```

Description

`y = nanmin(X)` is the minimum `min` of `X`, computed after removing NaN values.

For vectors `x`, `nanmin(x)` is the minimum of the remaining elements, once NaN values are removed. For matrices `X`, `nanmin(X)` is a row vector of column minima, once NaN values are removed. For multidimensional arrays `X`, `nanmin` operates along the first nonsingleton dimension.

`y = nanmin(X,[],dim)` operates along the dimension `dim` of `X`.

`[y,indices] = nanmin(___)` also returns the row indices of the minimum values for each column in the vector `indices`.

`y = nanmin(X,[],'all')` returns the minimum of all elements of `X`, computed after removing NaN values.

`y = nanmin(X,[],vecdim)` returns the minimum over the dimensions specified in the vector `vecdim`, computed after removing NaN values. Each element of `vecdim` represents a dimension of the input array `X`. The output `y` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `y`. For example, if `X` is a 2-by-3-by-4 array, then `nanmin(X,[],[1 2])` returns a 1-by-1-by-4 array. Each element of the output array is the minimum of the elements on the corresponding page of `X`.

`Y = nanmin(X1,X2)` returns an array `Y` the same size as `X1` and `X2` with `Y(i,j) = nanmin(X1(i,j),X2(i,j))`. Scalar inputs are expanded to an array of the same size as the other input.

Examples

Minimum of Matrix Data

Find the column minimum values and their indices for matrix data with missing values.

```
X = magic(3);
X([1 6:9]) = NaN
```

```
X = 3×3
```

```
NaN    1    NaN
 3     5    NaN
 4    NaN    NaN
```

```
[y,indices] = nanmin(X)
```

```
y = 1×3
```

```
3     1    NaN
```

```
indices = 1×3
```

```
2     1     1
```

Minimum of All Values

Find the minimum of all the values in an array, ignoring missing values.

Create a 2-by-5-by-3 array X with some missing values.

```
X = reshape(1:30,[2 5 3]);
X([10:12 25]) = NaN
```

```
X =
X(:,:,1) =
```

```
1     3     5     7     9
2     4     6     8    NaN
```

```
X(:,:,2) =
```

```
NaN    13    15    17    19
NaN    14    16    18    20
```

```
X(:,:,3) =
```

```
21    23    NaN    27    29
22    24    26    28    30
```

Find the minimum of the elements of X.

```
y = nanmin(X,[],'all')
```

```
y = 1
```

Alternative Functionality

Instead of using `nanmin`, you can use the MATLAB function `min` with the input argument `nanflag` specified as the value `'omitnan'`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

`NaN` | `min` | `nanmax`

Introduced before R2006a

nanstd

Standard deviation, ignoring NaN values

Syntax

```
y = nanstd(X)
y = nanstd(X,flag)
y = nanstd(X,flag,'all')
y = nanstd(X,flag,dim)
y = nanstd(X,flag,vecdim)
```

Description

`y = nanstd(X)` is the standard deviation `std` of `X`, computed after removing all NaN values.

- If `X` is a vector, then `nanstd(X)` is the sample standard deviation of all the non-NaN elements of `X`.
- If `X` is a matrix, then `nanstd(X)` is a row vector of column sample standard deviations, computed after removing NaN values.
- If `X` is a multidimensional array, then `nanstd` operates along the first nonsingleton dimension of `X`. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same. `nanstd` removes all NaN values.
- By default, `nanstd` normalizes `y` by $n - 1$, where n is the number of remaining observations after removing observations with NaN values.

`y = nanstd(X,flag)` returns the standard deviation of `X` based on the normalization specified by `flag`. The `flag` is 0 (default) or 1 to specify normalization by $n - 1$ or n , respectively, where n is the number of remaining observations after removing observations with NaN values.

`y = nanstd(X,flag,'all')` returns the standard deviation of all elements of `X`, computed after removing NaN values.

`y = nanstd(X,flag,dim)` returns the standard deviation along the operating dimension `dim` of `X`, computed after removing NaN values.

`y = nanstd(X,flag,vecdim)` returns the standard deviation over the dimensions specified in the vector `vecdim`. The function computes the standard deviations after removing NaN values. For example, if `X` is a matrix, then `nanstd(X,0,[1 2])` is the sample standard deviation of all non-NaN elements of `X` because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.

Examples

Standard Deviation of Matrix Data

Find the column standard deviations for matrix data with missing values.

```
X = magic(3);
X([1 6:9]) = NaN
```

```
X = 3×3
    NaN     1     NaN
     3     5     NaN
     4    NaN     NaN

y = nanstd(X)
y = 1×3
    0.7071    2.8284    NaN
```

Standard Deviation for Population vs. Sample

Load the `carsmall` data set.

```
load carsmall
```

Compute the population and sample standard deviations for the Horsepower data. The `nanstd` function ignores the missing value in Horsepower.

```
y1 = nanstd(Horsepower,1) % Population formula
y1 = 45.2963
y2 = nanstd(Horsepower,0) % Sample formula
y2 = 45.5268
```

Standard Deviation of All Values

Find the standard deviation of all the values in an array, ignoring missing values.

Create a 3-by-4-by-2 array `X` with some missing values.

```
X = reshape(1:24,[3 4 2]);
X([8:10 18]) = NaN

X =
X(:,:,1) =
     1     4     7     NaN
     2     5    NaN    11
     3     6    NaN    12

X(:,:,2) =
    13    16    19    22
    14    17    20    23
    15    NaN    21    24
```

Find the sample standard deviation of the elements of X.

```
y = nanstd(X,0, 'all')  
y = 7.5385
```

Standard Deviation Along Scalar Dimension

Find the row standard deviations for matrix data with missing values. Specify to compute the sample standard deviations along the second dimension.

```
X = magic(3);  
X([1 6:9]) = NaN
```

```
X = 3×3
```

```
NaN    1    NaN  
 3     5    NaN  
 4    NaN    NaN
```

```
y = nanstd(X,0,2)
```

```
y = 3×1
```

```
 0  
1.4142  
 0
```

Standard Deviation Along Vector Dimension

Find the standard deviation of a multidimensional array over multiple dimensions.

Create a 3-by-4-by-2 array X with some missing values.

```
X = reshape(1:24, [3 4 2]);  
X([8:10 18]) = NaN
```

```
X =  
X(:,:,1) =
```

```
 1     4     7    NaN  
 2     5    NaN    11  
 3     6    NaN    12
```

```
X(:,:,2) =
```

```
13    16    19    22  
14    17    20    23  
15    NaN    21    24
```

Find the sample standard deviation of each page of X by specifying dimensions 1 and 2 as the operating dimensions.

```
ypage = nanstd(X,0,[1 2])
```

```
ypage =  
ypage(:,:,1) =
```

```
    3.8079
```

```
ypage(:,:,2) =
```

```
    3.7779
```

For example, `ypage(1,1,2)` is the sample standard deviation of the non-NaN elements in $X(:,:,2)$.

Find the sample standard deviation of the elements in each $X(i, :, :)$ slice by specifying dimensions 2 and 3 as the operating dimensions.

```
yrow = nanstd(X,0,[2 3])
```

```
yrow = 3×1
```

```
    7.9102
```

```
    7.6904
```

```
    8.2158
```

For example, `yrow(3)` is the sample standard deviation of the non-NaN elements in $X(3, :, :)$.

Input Arguments

X — Input data

scalar | vector | matrix | multidimensional array

Input data, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double`

flag — Indicator for normalization

0 (default) | 1

Indicator for the normalization used to compute the standard deviation, specified as 0 or 1.

- If `flag` is 0 (default), then `nanstd` returns the sample standard deviation on page 32-3567 of X . `nanstd(X,0)` is the same as `nanstd(X)`.
- If `flag` is 1, then `nanstd` returns the population standard deviation on page 32-3567 of X .

Data Types: `single` | `double`

dim — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If you do not specify a value, then the default value is the first array dimension whose size does not equal 1.

`dim` indicates the dimension whose length reduces to 1. `size(y, dim)` is 1 while the sizes of all other dimensions remain the same.

Consider a two-dimensional array `X`:

- If `dim` is equal to 1, then `nanstd(X, 0, 1)` returns a row vector containing the sample standard deviation for each column.
- If `dim` is equal to 2, then `nanstd(X, 0, 2)` returns a column vector containing the sample standard deviation for each row.

If `dim` is greater than `ndims(X)` or if `size(X, dim)` is 1, then `nanstd` returns an array of zeros with the same dimensions and missing values as `X`.

Data Types: `single` | `double`

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. The output `y` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `y`.

For example, if `X` is a 2-by-3-by-3 array, then `nanstd(X, 0, [1 2])` returns a 1-by-1-by-3 array. Each element of the output array is the sample standard deviation of the elements on the corresponding page of `X`.

Data Types: `single` | `double`

Output Arguments

y — Standard deviation values

scalar | vector | matrix | multidimensional array

Standard deviation values, returned as a scalar, vector, matrix, or multidimensional array.

More About

Sample Standard Deviation

The *sample standard deviation* S is given by

$$S = \sqrt{\frac{\sum_{i=1}^n (x_i - \bar{X})^2}{n - 1}}.$$

S is the square root of an unbiased estimator of the variance of the population from which X is drawn, as long as X consists of independent, identically distributed samples. \bar{X} is the sample mean.

Notice that the denominator in this variance formula is $n - 1$.

Population Standard Deviation

If the data is the entire population of values, then you can use the *population standard deviation*,

$$\sigma = \sqrt{\frac{\sum_{i=1}^n (x_i - \mu)^2}{n}}.$$

If X is a random sample from a population, then the mean μ is estimated by the sample mean, and σ is the biased maximum likelihood estimator of the population standard deviation.

Notice that the denominator in this variance formula is n .

Alternative Functionality

Instead of using `nanstd`, you can use the MATLAB function `std` with the input argument `nanflag` specified as the value `'omitnan'`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

nansum

Sum, ignoring NaN values

Syntax

```
y = nansum(X)
y = nansum(X, 'all')
y = nansum(X, dim)
y = nansum(X, vecdim)
```

Description

`y = nansum(X)` returns the sum of the elements of `X`, computed after removing all NaN values.

- If `X` is a vector, then `nansum(X)` is the sum of all the non-NaN elements of `X`.
- If `X` is a matrix, then `nansum(X)` is a row vector of column sums, computed after removing NaN values.
- If `X` is a multidimensional array, then `nansum` operates along the first nonsingleton dimension of `X`. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same. `nansum` removes all NaN values.

For information on how `nansum` treats arrays of all NaN values, see “Tips” on page 32-3573.

`y = nansum(X, 'all')` returns the sum of all elements of `X`, computed after removing NaN values.

`y = nansum(X, dim)` returns the sum along the operating dimension `dim` of `X`, computed after removing NaN values.

`y = nansum(X, vecdim)` returns the sum over the dimensions specified in the vector `vecdim`. The function computes the sums after removing NaN values. For example, if `X` is a matrix, then `nansum(X, [1 2])` is the sum of all non-NaN elements of `X` because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.

Examples

Sum of Matrix Data

Find the column sums for matrix data with missing values.

```
X = magic(3);
X([1 6:9]) = NaN
```

```
X = 3×3
```

```
NaN     1     NaN
     3     5     NaN
     4    NaN     NaN
```

```
y = nansum(X)
```

```
y = 1×3
    7    6    0
```

Sum of All Values

Find the sum of all the values in an array, ignoring missing values.

Create a 2-by-4-by-3 array X with some missing values.

```
X = reshape(1:24,[2 4 3]);
X([5:6 20]) = NaN
```

```
X =
X(:,:,1) =
    1    3  NaN    7
    2    4  NaN    8
```

```
X(:,:,2) =
    9   11   13   15
   10   12   14   16
```

```
X(:,:,3) =
   17   19   21   23
   18  NaN   22   24
```

Find the sum of the elements of X.

```
y = nansum(X, 'all')
y = 269
```

Sum Along Scalar Dimension

Find the row sums for matrix data with missing values by specifying to compute the sums along the second dimension.

```
X = magic(3);
X([1 6:9]) = NaN
X = 3×3
    NaN    1    NaN
     3     5    NaN
     4    NaN    NaN
```

```
y = nansum(X,2)
```

```
y = 3×1
```

```
1
8
4
```

Sum Along Vector Dimension

Find the sum of a multidimensional array over multiple dimensions.

Create a 2-by-4-by-3 array X with some missing values.

```
X = reshape(1:24,[2 4 3]);
X([5:6 20]) = NaN
```

```
X =
X(:,:,1) =
```

```
1    3    NaN    7
2    4    NaN    8
```

```
X(:,:,2) =
```

```
9    11   13   15
10   12   14   16
```

```
X(:,:,3) =
```

```
17   19   21   23
18   NaN  22   24
```

Find the sum of each page of X by specifying dimensions 1 and 2 as the operating dimensions.

```
ypage = nansum(X,[1 2])
```

```
ypage =
ypage(:,:,1) =
```

```
25
```

```
ypage(:,:,2) =
```

```
100
```

```
ypage(:,:,3) =
```

```
144
```

For example, `ypage(1,1,1)` is the sum of the non-NaN elements in `X(:, :, 1)`.

Find the sum of the elements in each `X(i, :, :)` slice by specifying dimensions 2 and 3 as the operating dimensions.

```
yrow = nansum(X, [2 3])
```

```
yrow = 2×1
```

```
    139
    130
```

For example, `yrow(2)` is the sum of the non-NaN elements in `X(2, :, :)`.

Input Arguments

X — Input data

scalar | vector | matrix | multidimensional array

Input data, specified as a scalar, vector, matrix, or multidimensional array.

If `X` is an empty array, then `nansum(X)` is 0.

Data Types: `single` | `double`

dim — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If you do not specify a value, then the default value is the first array dimension whose size does not equal 1.

`dim` indicates the dimension whose length reduces to 1. `size(y, dim)` is 1 while the sizes of all other dimensions remain the same.

Consider a two-dimensional array `X`:

- If `dim` is equal to 1, then `nansum(X, 1)` returns a row vector containing the sum for each column.
- If `dim` is equal to 2, then `nansum(X, 2)` returns a column vector containing the sum for each row.

If `dim` is greater than `ndims(X)` or if `size(X, dim)` is 1, then `nansum` returns `X`, with 0 values in the place of any missing values.

Data Types: `single` | `double`

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. The output `y` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `y`.

For example, if `X` is a 2-by-3-by-3 array, then `nansum(X, [1 2])` returns a 1-by-1-by-3 array. Each element of the output array is the sum of the elements on the corresponding page of `X`.

Data Types: `single` | `double`

Output Arguments

y — Sum values

`scalar` | `vector` | `matrix` | `multidimensional array`

Sum values, returned as a scalar, vector, matrix, or multidimensional array.

Tips

- When `nansum` computes the sum of an array of all NaN values, the array is empty once the NaN values are removed and, therefore, the sum of the remaining elements is 0. The output 0 is not a sum of NaN values.

Alternative Functionality

Instead of using `nansum`, you can use the MATLAB function `sum` with the input argument `nanflag` specified as the value `'omitnan'`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'all' and `vecdim` input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

NaN | sum

Introduced before R2006a

nanvar

Variance, ignoring NaN values

Syntax

```
y = nanvar(X)
y = nanvar(X,w)
y = nanvar(X,w,'all')
y = nanvar(X,w,dim)
y = nanvar(X,w,vecdim)
```

Description

`y = nanvar(X)` is the variance `var` of `X`, computed after removing NaN values.

For vectors `x`, `nanvar(x)` is the sample variance of the remaining elements, once NaN values are removed. For matrices `X`, `nanvar(X)` is a row vector of column sample variances, once NaN values are removed. For multidimensional arrays `X`, `nanvar` operates along the first nonsingleton dimension.

`nanvar` removes the mean from each variable (column for matrix `X`) before calculating `y`. If `n` is the number of remaining observations after removing observations with NaN values, `nanvar` normalizes `y` by either `n - 1` or `n`, depending on whether `n > 1` or `n = 1`, respectively.

`y = nanvar(X,w)` computes the variance of `X` according to the weighting scheme `w`. When `w` is `0` (default), `X` is normalized by `n - 1`, where `n` is the number of non-NaN observations. When `w` is `1`, `w` is normalized by the number of non-NaN observations. Otherwise, `w` can be a weight vector containing nonnegative elements. The length of `w` must equal the length of the dimension over which `nanvar` operates. Elements of `X` corresponding to NaN values of `w` are ignored.

`y = nanvar(X,w,'all')` returns the variance over all elements of `X` when `w = 0` or `w = 1`. The `nanvar` function computes the variance after removing NaN values.

`y = nanvar(X,w,dim)` returns the variance along the operating dimension `dim` of `X`.

`y = nanvar(X,w,vecdim)` returns the variance over the dimensions specified in the vector `vecdim`, computed after removing NaN values. Each element of `vecdim` represents a dimension of the input array `X`. The output `y` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `y`. For example, if `X` is a 2-by-3-by-4 array, then `nanvar(X,[1,1,2])` returns a 1-by-1-by-4 array. Each element of the output array is the variance of the elements on the corresponding page of `X`. This syntax is supported when `w = 0` or `w = 1`.

Examples

Variance of Matrix Data

Find the column variances for matrix data with missing values.

```
X = magic(3);
X([1 6:9]) = NaN
```

```
X = 3×3
```

```
NaN    1    NaN
    3    5    NaN
    4   NaN   NaN
```

```
y = nanvar(X)
```

```
y = 1×3
```

```
    0.5000    8.0000    NaN
```

Variance Along Vector Dimension

Find the variance of a multidimensional array over multiple dimensions.

Create a 3-by-4-by-2 array X with some missing values.

```
X = reshape(1:24,[3 4 2]);
X([8:10 18]) = NaN
```

```
X =
X(:,:,1) =
```

```
    1    4    7   NaN
    2    5   NaN   11
    3    6   NaN   12
```

```
X(:,:,2) =
```

```
   13   16   19   22
   14   17   20   23
   15   NaN   21   24
```

Find the sample variance of each page of X by specifying dimensions 1 and 2 as the operating dimensions.

```
ypage = nanvar(X,0,[1 2])
```

```
ypage =
ypage(:,:,1) =
```

```
    14.5000
```

```
ypage(:,:,2) =
```

```
    14.2727
```

For example, `ypage(1,1,2)` is the sample variance of the non-`NaN` elements in `X(:,:,2)`.

Find the sample variance of the elements in each $X(:, i, :)$ slice by specifying dimensions 1 and 3 as the operating dimensions.

```
ycol = nanvar(X,0,[1 3])
```

```
ycol = 1x4
```

```
44.0000 40.3000 42.9167 40.3000
```

For example, `ycol(4)` is the sample variance of the non-NaN elements in $X(:, 4, :)$.

Alternative Functionality

Instead of using `nanvar`, you can use the MATLAB function `var` with the input argument `nanflag` specified as the value `'omitnan'`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

NaN | `nanmean` | `nanstd` | `var`

Introduced before R2006a

nearcorr

Compute nearest correlation matrix by minimizing Frobenius distance

Syntax

```
Y = nearcorr(A)
Y = nearcorr( ___,Name,Value)
```

Description

`Y = nearcorr(A)` returns the nearest correlation matrix `Y` by minimizing the Frobenius distance.

`Y = nearcorr(___,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute the Nearest Correlation Matrix

Find the nearest correlation matrix in the Frobenius norm for a given nonpositive semidefinite matrix.

Specify an N -by- N symmetric matrix with all elements in the interval $[-1, 1]$ and unit diagonal.

```
A = [1.0000  0         0         0         -0.9360
      0      1.0000  -0.5500  -0.3645  -0.5300
      0     -0.5500   1.0000  -0.0351   0.0875
      0     -0.3645  -0.0351   1.0000   0.4557
     -0.9360 -0.5300  0.0875  0.4557  1.0000];
```

Compute the eigenvalues of `A` using `eig`.

```
eig(A)

ans = 5×1

    -0.1244
     0.3396
     1.0284
     1.4457
     2.3107
```

The smallest eigenvalue is less than 0, which indicates that `A` is not a positive semidefinite matrix.

Compute the nearest correlation matrix using `nearcorr` with the default Newton algorithm.

```
B = nearcorr(A)

B = 5×5

    1.0000    0.0372    0.0100   -0.0219   -0.8478
```

```

0.0372    1.0000   -0.5449   -0.3757   -0.4849
0.0100   -0.5449    1.0000   -0.0381    0.0996
-0.0219  -0.3757   -0.0381    1.0000    0.4292
-0.8478  -0.4849    0.0996    0.4292    1.0000

```

Compute the eigenvalues of B.

```
eig(B)
```

```
ans = 5×1
```

```

0.0000
0.3266
1.0146
1.4113
2.2475

```

All of the eigenvalues are greater than or equal to 0, which means that B is a positive semidefinite matrix.

When you use `nearcorr`, you can specify the alternating projections algorithm by setting the name-value pair argument `'method'` to `'projection'`.

```
nearcorr(A, 'method', 'projection')
```

```
ans = 5×5
```

```

1.0000    0.0372    0.0100   -0.0219   -0.8478
0.0372    1.0000   -0.5449   -0.3757   -0.4849
0.0100   -0.5449    1.0000   -0.0381    0.0996
-0.0219  -0.3757   -0.0381    1.0000    0.4292
-0.8478  -0.4849    0.0996    0.4292    1.0000

```

You can also impose elementwise weights by specifying the `'Weights'` name-value pair argument. For more information on elementwise weights, see [“Weights” on page 32-0](#).

```

W = [0.0000  1.0000  0.1000  0.1500  0.2500
      1.0000  0.0000  0.0500  0.0250  0.1500
      0.1000  0.0500  0.0000  0.2500  1
      0.1500  0.0250  0.2500  0.0000  0.2500
      0.2500  0.1500  1  0.2500  0.0000];

```

```
nearcorr(A, 'Weights', W)
```

```
ans = 5×5
```

```

1.0000    0.0014    0.0287   -0.0222   -0.8777
0.0014    1.0000   -0.4980   -0.7268   -0.4567
0.0287   -0.4980    1.0000   -0.0358    0.0878
-0.0222  -0.7268   -0.0358    1.0000    0.4465
-0.8777  -0.4567    0.0878    0.4465    1.0000

```

In addition, you can impose N-by-1 vectorized weights by specifying the `'Weights'` name-value pair argument. For more information on vectorized weights, see [“Weights” on page 32-0](#).

```
W = linspace(0.1,0.01,5)'
```

```
W = 5×1
```

```
0.1000
0.0775
0.0550
0.0325
0.0100
```

```
C = nearcorr(A, 'Weights', W)
```

```
C = 5×5
```

```
1.0000    0.0051    0.0021   -0.0056   -0.8490
0.0051    1.0000   -0.5486   -0.3684   -0.4691
0.0021   -0.5486    1.0000   -0.0367    0.1119
-0.0056  -0.3684   -0.0367    1.0000    0.3890
-0.8490  -0.4691    0.1119    0.3890    1.0000
```

Compute the eigenvalues of C.

```
eig(C)
```

```
ans = 5×1
```

```
0.0000
0.3350
1.0272
1.4308
2.2070
```

All of the eigenvalues are greater than or equal to 0, which means that C is a positive semidefinite matrix.

Generate a Correlation Matrix for Stocks with Missing Values

Use `nearcorr` to create a positive semidefinite matrix for a correlation matrix for stocks with missing values.

Assume that you have stock values with missing values.

```
Stock_Missing = [59.875 42.734 47.938 60.359 NaN 69.625 61.500 62.125
53.188 49.000 39.500 64.813 34.750 56.625 83.000 44.500
55.750 50.000 38.938 62.875 30.188 43.375 NaN 29.938
65.500 51.063 45.563 69.313 48.250 62.375 85.250 46.875
69.938 47.000 52.313 71.016 37.500 59.359 61.188 48.219
61.500 44.188 NaN 57.000 35.313 55.813 51.500 62.188
59.230 48.210 62.190 61.390 54.310 70.170 61.750 91.080
NaN 48.700 60.300 68.580 61.250 70.340 61.590 90.350
52.900 52.690 54.230 61.670 68.170 NaN 57.870 88.640
57.370 59.040 59.870 62.090 61.620 66.470 65.370 85.840];
```

Use `corr` to compute the correlation matrix and then use `eig` to check if the correlation matrix is positive semidefinite.

```
A = corr(Stock_Missing, 'Rows', 'pairwise');
eig(A)
```

```
ans = 8×1

-0.1300
-0.0398
 0.0473
 0.2325
 0.6278
 1.6276
 1.7409
 3.8936
```

A has eigenvalues that are less than 0, which indicates that the correlation matrix is not positive semidefinite.

Use `nearcorr` with this correlation matrix to generate a positive semidefinite matrix where all eigenvalues are greater than or equal to 0.

```
B = nearcorr(A);
eigenvalues = eig(B)
```

```
eigenvalues = 8×1

 0.5863
 1.6026
 1.7258
 3.8469
```

Copyright 2019 The MathWorks, Inc.

Input Arguments

A — Input correlation matrix

matrix

Input correlation matrix, specified as an N -by- N symmetric approximate correlation matrix with all elements in the interval $[-1 \ 1]$ and unit diagonal. The A input may or may not be a positive semidefinite matrix.

```
Example: A = [1.0000 0 0 0 -0.9360 0 1.0000 -0.5500 -0.3645 -0.5300 0 -0.5500
1.0000 -0.0351 0.0875 0 -0.3645 -0.0351 1.0000 0.4557 -0.9360 -0.5300 0.0875
0.4557 1.0000]
```

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

```
nearcorr(A, 'Tolerance', 1e-7, 'MaxIterations', 500, 'Method', 'newton', 'Weights', w_eight_vector) returns .
```

Tolerance — Termination tolerance for algorithm

1e-6 (default) | positive scalar

Termination tolerance for the algorithm, specified as the comma-separated pair consisting of `'Tolerance'` and a positive scalar.

Example: `'Tolerance', 1e-7`

Data Types: `single` | `double`

MaxIterations — Maximum number of solver iterations

200 (default) | positive integer

Maximum number of solver iterations, specified as the comma-separated pair consisting of `'MaxIterations'` and a positive integer.

Example: `'MaxIterations', 500`

Data Types: `single` | `double`

Method — Method for solving nearest correlation matrix problem

`'newton'` (default) | `'projection'`

Method for solving nearest correlation matrix problem, specified as the comma-separated pair consisting of `'Method'` and one of the values in the following table.

Value	Description
<code>'newton'</code>	The Newton algorithm is quadratically convergent. If you specify the <code>'newton'</code> method, <code>Weights</code> can be either a symmetric matrix or an N-by-1 vector.
<code>'projection'</code>	The alternating projections algorithm can converge to the nearest correlation matrix with high accuracy, at best linearly. If you specify the <code>'projection'</code> method, <code>Weights</code> must be an N-by-1 vector.

Example: `'Method', 'projection'`

Data Types: `char` | `string`

Weights — Weights for confidence levels of entries in input matrix

[] (default) | matrix | vector

Weights for confidence levels of entries in the input matrix, specified as the comma-separated pair consisting of `'Weights'` and either a symmetric matrix or an N-by-1 vector.

- Symmetric matrix — When you specify `Weights` as a symmetric matrix W with all elements ≥ 0 to do elementwise weighting, the nearest correlation matrix Y is computed by minimizing the norm of $(W - (A-Y))$. Larger weight values place greater importance on the corresponding elements in A .
- N-by-1 vector — When you specify `Weights` as an N-by-1 vector w with positive numeric values, the nearest correlation matrix Y is computed by minimizing the norm of $(\text{diag}(w)^{0.5} \times (A-Y) \times \text{diag}(w)^{0.5})$.

Note Matrix weights put weight on individual entries of the correlation matrix. A full matrix must be specified, but you can control which entries are more important to match. Alternatively, vector weights put weight on a full column (and the corresponding row). Fewer weights need to be specified as compared to the matrix weights, but an entire column (and the corresponding row) is weighted by a single weight.

Example: `'Weights',W`

Data Types: `single | double`

Output Arguments

Y — Nearest correlation matrix to input A

positive semidefinite matrix

Nearest correlation matrix to the input A , returned as a positive semidefinite matrix.

Introduced in R2019b

nbincdf

Negative binomial cumulative distribution function

Syntax

```
y = nbincdf(x,R,p)
y = nbincdf(x,R,p,'upper')
```

Description

`y = nbincdf(x,R,p)` computes the negative binomial cdf at each of the values in `x` using the corresponding number of successes, `R` and probability of success in a single trial, `p`. `x`, `R`, and `p` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `y`. A scalar input for `x`, `R`, or `p` is expanded to a constant array with the same dimensions as the other inputs.

`y = nbincdf(x,R,p,'upper')` returns the complement of the negative binomial cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The negative binomial cdf is

$$y = F(x \mid r, p) = \sum_{i=0}^x \binom{r+i-1}{i} p^r q^i I_{(0,1,\dots)}(i)$$

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `p` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbincdf` allows `R` to be any positive value, including nonintegers. When `R` is noninteger, the binomial coefficient in the definition of the cdf is replaced by the equivalent expression

$$\frac{\Gamma(r+i)}{\Gamma(r)\Gamma(i+1)}$$

Examples

Compute Negative Binomial Distribution CDF

```
x = (0:15);
p = nbincdf(x,3,0.5);
stairs(x,p)
```

Topics

“Negative Binomial Distribution” on page B-109

Introduced before R2006a

nbinfit

Negative binomial parameter estimates

Syntax

```
parmhat = nbinfit(data)
[parmhat,parmci] = nbinfit(data,alpha)
[...] = nbinfit(data,alpha,options)
```

Description

`parmhat = nbinfit(data)` returns the maximum likelihood estimates (MLEs) of the parameters of the negative binomial distribution given the data in the vector `data`.

`[parmhat,parmci] = nbinfit(data,alpha)` returns MLEs and $100(1-\alpha)$ percent confidence intervals. By default, $\alpha = 0.05$, which corresponds to 95% confidence intervals.

`[...] = nbinfit(data,alpha,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The negative binomial fit function accepts an `options` structure which you can create using the function `statset`. Enter `statset('nbinfit')` to see the names and default values of the parameters that `nbinfit` accepts in the `options` structure. See the reference page for `statset` for more information about these options.

Note The variance of a negative binomial distribution is greater than its mean. If the sample variance of the data in `data` is less than its sample mean, `nbinfit` cannot compute MLEs. You should use the `poissfit` function instead.

Topics

“Negative Binomial Distribution” on page B-109

Introduced before R2006a

nbininv

Negative binomial inverse cumulative distribution function

Syntax

```
X = nbininv(Y,R,P)
```

Description

`X = nbininv(Y,R,P)` returns the inverse of the negative binomial cdf with corresponding number of successes, `R` and probability of success in a single trial, `P`. Since the binomial distribution is discrete, `nbininv` returns the least integer `X` such that the negative binomial cdf evaluated at `X` equals or exceeds `Y`. `Y`, `R`, and `P` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `X`. A scalar input for `Y`, `R`, or `P` is expanded to a constant array with the same dimensions as the other inputs.

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbininv` allows `R` to be any positive value, including nonintegers.

Examples

How many times would you need to flip a fair coin to have a 99% probability of having observed 10 heads?

```
flips = nbininv(0.99,10,0.5) + 10  
flips =  
    33
```

Note that you have to flip at least 10 times to get 10 heads. That is why the second term on the right side of the equals sign is a 10.

Introduced before R2006a

nbinpdf

Negative binomial probability density function

Syntax

`Y = nbinpdf(X,R,P)`

Description

`Y = nbinpdf(X,R,P)` returns the negative binomial pdf at each of the values in `X` using the corresponding number of successes, `R` and probability of success in a single trial, `P`. `X`, `R`, and `P` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `Y`. A scalar input for `X`, `R`, or `P` is expanded to a constant array with the same dimensions as the other inputs. Note that the density function is zero unless the values in `X` are integers.

The negative binomial pdf is

$$y = f(x|r, p) = \binom{r+x-1}{x} p^r q^x I_{(0,1,\dots)}(x)$$

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbinpdf` allows `R` to be any positive value, including nonintegers. When `R` is noninteger, the binomial coefficient in the definition of the pdf is replaced by the equivalent expression

$$\frac{\Gamma(r+x)}{\Gamma(r)\Gamma(x+1)}$$

Examples

Compute the Negative Binomial Distribution pdf

Compute the pdf of a negative binomial distribution with parameters `R = 3` and `p = 0.5`.

```
x = (0:10);
y = nbinpdf(x,3,0.5);
```

Plot the pdf.

```
figure;
plot(x,y, '+')
xlim([-0.5,10.5])
```

nbinrnd

Negative binomial random numbers

Syntax

```
RND = nbinrnd(R,P)
RND = nbinrnd(R,P,m,n,...)
RND = nbinrnd(R,P,[m,n,...])
```

Description

`RND = nbinrnd(R,P)` is a matrix of random numbers chosen from a negative binomial distribution with corresponding number of successes, `R` and probability of success in a single trial, `P`. `R` and `P` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `RND`. A scalar input for `R` or `P` is expanded to a constant array with the same dimensions as the other input.

`RND = nbinrnd(R,P,m,n,...)` or `RND = nbinrnd(R,P,[m,n,...])` generates an `m`-by-`n`-by-... array. The `R`, `P` parameters can each be scalars or arrays of the same size as `R`.

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbinrnd` allows `R` to be any positive value, including nonintegers.

Examples

Suppose you want to simulate a process that has a defect probability of 0.01. How many units might Quality Assurance inspect before finding three defective items?

```
r = nbinrnd(3,0.01,1,6)+3
r =
    496    142    420    396    851    178
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

nbinstat

Negative binomial mean and variance

Syntax

```
[M,V] = nbinstat(R,P)
```

Description

`[M,V] = nbinstat(R,P)` returns the mean of and variance for the negative binomial distribution with corresponding number of successes, R and probability of success in a single trial, P . R and P can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of M and V . A scalar input for R or P is expanded to a constant array with the same dimensions as the other input.

The mean of the negative binomial distribution with parameters r and p is rq / p , where $q = 1 - p$. The variance is rq / p^2 .

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability P of success. The number of *extra* trials you must perform in order to observe a given number R of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbinstat` allows R to be any positive value, including nonintegers.

Examples

```
p = 0.1:0.2:0.9;
r = 1:5;
[R,P] = meshgrid(r,p);
[M,V] = nbinstat(R,P)
M =

FeatureSelectionNCAClassification class

Feature selection for classification using neighborhood component analysis (NCA)

Description

`FeatureSelectionNCAClassification` object contains the data, fitting information, feature weights, and other parameters of a neighborhood component analysis (NCA) model. `fscnca` learns the feature weights using a diagonal adaptation of NCA and returns an instance of a `FeatureSelectionNCAClassification` object. The function achieves feature selection by regularizing the feature weights.

Construction

Create a `FeatureSelectionNCAClassification` object using `fscnca`.

Properties

NumObservations — Number of observations in the training data

scalar

Number of observations in the training data (X and Y) after removing NaN or Inf values, stored as a scalar.

Data Types: `double`

ModelParameters — Model parameters

structure

Model parameters used for training the model, stored as a structure.

You can access the fields of `ModelParameters` using dot notation.

For example, for a `FeatureSelectionNCAClassification` object named `mdl`, you can access the `LossFunction` value using `mdl.ModelParameters.LossFunction`.

Data Types: `struct`

Lambda — Regularization parameter

scalar

Regularization parameter used for training this model, stored as a scalar. For n observations, the best `Lambda` value that minimizes the generalization error of the NCA model is expected to be a multiple of $1/n$.

Data Types: `double`

FitMethod — Name of fitting method

'exact' | 'none' | 'average'

Name of the fitting method used to fit this model, stored as one of the following:

- 'exact' — Perform fitting using all of the data.
- 'none' — No fitting. Use this option to evaluate the generalization error of the NCA model using the initial feature weights supplied in the call to `fscnca`.
- 'average' — Divide the data into partitions (subsets), fit each partition using the `exact` method, and return the average of the feature weights. You can specify the number of partitions using the `NumPartitions` name-value pair argument.

Solver — Name of the solver used to fit this model

'lbfgs' | 'sgd' | 'minibatch-lbfgs'

Name of the solver used to fit this model, stored as one of the following:

- 'lbfgs' — Limited memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) algorithm
- 'sgd' — Stochastic gradient descent (SGD) algorithm
- 'minibatch-lbfgs' — stochastic gradient descent with LBFGS algorithm applied to mini-batches

GradientTolerance — Relative convergence tolerance on gradient norm

positive scalar

Relative convergence tolerance on the gradient norm for the 'lbfgs' and 'minibatch-lbfgs' solvers, stored as a positive scalar value.

Data Types: double

IterationLimit — Maximum number of iterations for optimization

positive integer

Maximum number of iterations for optimization, stored as a positive integer value.

Data Types: double

PassLimit — Maximum number of passes

positive integer

Maximum number of passes for 'sgd' and 'minibatch-lbfgs' solvers. Every pass processes all of the observations in the data.

Data Types: double

InitialLearningRate — Initial learning rate

positive real scalar

Initial learning rate for the 'sgd' and 'minibatch-lbfgs' solvers, stored as a positive real scalar. The learning rate decays over iterations starting at the value specified for `InitialLearningRate`.

Use the `NumTuningIterations` and `TuningSubsetSize` name-value pair arguments to control the automatic tuning of initial learning rate in the call to `fscnca`.

Data Types: double

Verbose — Verbosity level indicator

nonnegative integer

Verbosity level indicator, stored as a nonnegative integer. Possible values are:

- 0 — No convergence summary
- 1 — Convergence summary, including norm of gradient and objective function value
- >1 — More convergence information, depending on the fitting algorithm. When you use the 'minibatch-lbfgs' solver and verbosity level > 1, the convergence information includes the iteration log from intermediate minibatch LBFGS fits.

Data Types: double

InitialFeatureWeights — Initial feature weights

p -by-1 vector of positive real scalars

Initial feature weights, stored as a p -by-1 vector of positive real scalars, where p is the number of predictors in X .

Data Types: double

FeatureWeights — Feature weights

p -by-1 vector of real scalars

Feature weights, stored as a p -by-1 vector of real scalars, where p is the number of predictors in X .

If `FitMethod` is 'average', then `FeatureWeights` is a p -by- m matrix. m is the number of partitions specified via the 'NumPartitions' name-value pair argument in the call to `fscnca`.

The absolute value of `FeatureWeights(k)` is a measure of the importance of predictor k . A `FeatureWeights(k)` value that is close to 0 indicates that predictor k does not influence the response in Y .

Data Types: double

FitInfo — Fit information

structure

Fit information, stored as a structure with the following fields.

Field Name	Meaning
Iteration	Iteration index
Objective	Regularized objective function for minimization
UnregularizedObjective	Unregularized objective function for minimization
Gradient	Gradient of regularized objective function for minimization

- For classification, `UnregularizedObjective` represents the negative of the leave-one-out accuracy of the NCA classifier on the training data.
- For regression, `UnregularizedObjective` represents the leave-one-out loss between the true response and the predicted response when using the NCA regression model.
- For the 'lbfgs' solver, `Gradient` is the final gradient. For the 'sgd' and 'minibatch-lbfgs' solvers, `Gradient` is the final mini-batch gradient.
- If `FitMethod` is 'average', then `FitInfo` is an m -by-1 structure array, where m is the number of partitions specified via the 'NumPartitions' name-value pair argument.

You can access the fields of `FitInfo` using dot notation. For example, for a `FeatureSelectionNCAClassification` object named `mdl`, you can access the `Objective` field using `mdl.FitInfo.Objective`.

Data Types: `struct`

Mu — Predictor means

p -by-1 vector | []

Predictor means, stored as a p -by-1 vector for standardized training data. In this case, the `predict` method centers predictor matrix X by subtracting the respective element of `Mu` from every column.

If data is not standardized during training, then `Mu` is empty.

Data Types: `double`

Sigma — Predictor standard deviations

p -by-1 vector | []

Predictor standard deviations, stored as a p -by-1 vector for standardized training data. In this case, the `predict` method scales predictor matrix X by dividing every column by the respective element of `Sigma` after centering the data using `Mu`.

If data is not standardized during training, then `Sigma` is empty.

Data Types: `double`

X — Predictor values

n -by- p matrix

Predictor values used to train this model, stored as an n -by- p matrix. n is the number of observations and p is the number of predictor variables in the training data.

Data Types: `double`

Y — Response values

numeric vector of size n

Response values used to train this model, stored as a numeric vector of size n , where n is the number of observations.

Data Types: `double`

W — Observation weights

numeric vector of size n

Observation weights used to train this model, stored as a numeric vector of size n . The sum of observation weights is n .

Data Types: `double`

Methods

loss Evaluate accuracy of learned feature weights on test data
predict Predict responses using neighborhood component analysis (NCA) classifier
refit Refit neighborhood component analysis (NCA) model for classification

Examples

Explore FeatureSelectionNCAClassification Object

Load the sample data.

```
load ionosphere
```

The data set has 34 continuous predictors. The response variable is the radar returns, labeled as b (bad) or g (good).

Fit a neighborhood component analysis (NCA) model for classification to detect the relevant features.

```
mdl = fscnca(X,Y);
```

The returned NCA model, `mdl`, is a `FeatureSelectionNCAClassification` object. This object stores information about the training data, model, and optimization. You can access the object properties, such as the feature weights, using dot notation.

Plot the feature weights.

```
figure()  
plot(mdl.FeatureWeights,'ro')  
xlabel('Feature Index')  
ylabel('Feature Weight')  
grid on
```

The weights of the irrelevant features are zero. The 'Verbose', 1 option in the call to `fscnca` displays the optimization information on the command line. You can also visualize the optimization process by plotting the objective function versus the iteration number.

```
figure
plot mdl.FitInfo.Iteration, mdl.FitInfo.Objective, 'ro-'
grid on
xlabel('Iteration Number')
ylabel('Objective')
```

The `ModelParameters` property is a `struct` that contains more information about the model. You can access the fields of this property using dot notation. For example, see if the data was standardized or not.

```
mdl.ModelParameters.Standardize
```

```
ans = logical
      0
```

`0` means that the data was not standardized before fitting the NCA model. You can standardize the predictors when they are on very different scales using the `'Standardize', 1` name-value pair argument in the call to `fscnca`.

FeatureSelectionNCARegression class

Feature selection for regression using neighborhood component analysis (NCA)

Description

`FeatureSelectionNCARegression` contains the data, fitting information, feature weights, and other model parameters of a neighborhood component analysis (NCA) model. `fsrnca` learns the feature weights using a diagonal adaptation of NCA and returns an instance of `FeatureSelectionNCARegression` object. The function achieves feature selection by regularizing the feature weights.

Construction

Create a `FeatureSelectionNCARegression` object using `fsrnca`.

Properties

NumObservations — Number of observations in the training data

scalar

Number of observations in the training data (X and Y) after removing NaN or Inf values, stored as a scalar.

Data Types: `double`

ModelParameters — Model parameters

structure

Model parameters used for training the model, stored as a structure.

You can access the fields of `ModelParameters` using dot notation.

For example, for a `FeatureSelectionNCARegression` object named `mdl`, you can access the `LossFunction` value using `mdl.ModelParameters.LossFunction`.

Data Types: `struct`

Lambda — Regularization parameter

scalar

Regularization parameter used for training this model, stored as a scalar. For n observations, the best `Lambda` value that minimizes the generalization error of the NCA model is expected to be a multiple of $1/n$.

Data Types: `double`

FitMethod — Name of the fitting method used to fit this model

'exact' | 'none' | 'average'

Name of the fitting method used to fit this model, stored as one of the following:

- 'exact' — Perform fitting using all of the data.
- 'none' — No fitting. Use this option to evaluate the generalization error of the NCA model using the initial feature weights supplied in the call to `fsrnca`.
- 'average' — The software divides the data into partitions (subsets), fits each partition using the `exact` method, and returns the average of the feature weights. You can specify the number of partitions using the `NumPartitions` name-value pair argument.

Solver — Name of the solver used to fit this model

'lbfgs' | 'sgd' | 'minibatch-lbfgs'

Name of the solver used to fit this model, stored as one of the following:

- 'lbfgs' — Limited memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) algorithm
- 'sgd' — Stochastic gradient descent (SGD) algorithm
- 'minibatch-lbfgs' — stochastic gradient descent with LBFGS algorithm applied to mini-batches

GradientTolerance — Relative convergence tolerance on gradient norm

positive scalar

Relative convergence tolerance on the gradient norm for the 'lbfgs' and 'minibatch-lbfgs' solvers, stored as a positive scalar value.

Data Types: double

IterationLimit — Maximum number of iterations for optimization

positive integer

Maximum number of iterations for optimization, stored as a positive integer value.

Data Types: double

PassLimit — Maximum number of passes

positive integer

Maximum number of passes for 'sgd' and 'minibatch-lbfgs' solvers. Every pass processes all of the observations in the data.

Data Types: double

InitialLearningRate — Initial learning rate

positive real scalar

Initial learning rate for 'sgd' and 'minibatch-lbfgs' solvers. The learning rate decays over iterations starting at the value specified for `InitialLearningRate`.

Use the `NumTuningIterations` and `TuningSubsetSize` to control the automatic tuning of initial learning rate in the call to `fsrnca`.

Data Types: double

Verbose — Verbosity level indicator

nonnegative integer

Verbosity level indicator, stored as a nonnegative integer. Possible values are:

- 0 — No convergence summary
- 1 — Convergence summary, including norm of gradient and objective function value
- >1 — More convergence information, depending on the fitting algorithm. When you use the 'minibatch-lbfgs' solver and verbosity level > 1, the convergence information includes the iteration log from intermediate minibatch LBFGS fits.

Data Types: double

InitialFeatureWeights — Initial feature weights

p-by-1 vector of positive real scalars

Initial feature weights, stored as a *p*-by-1 vector of positive real scalars, where *p* is the number of predictors in *X*.

Data Types: double

FeatureWeights — Feature weights

p-by-1 vector of real scalar values

Feature weights, stored as a *p*-by-1 vector of real scalar values, where *p* is the number of predictors in *X*.

For 'FitMethod' equal to 'average', FeatureWeights is a *p*-by-*m* matrix, where *m* is the number of partitions specified via the 'NumPartitions' name-value pair argument in the call to `fsrnca`.

The absolute value of FeatureWeights(*k*) is a measure of the importance of predictor *k*. If FeatureWeights(*k*) is close to 0, then this indicates that predictor *k* does not influence the response in *Y*.

Data Types: double

FitInfo — Fit information

structure

Fit information, stored as a structure with the following fields.

Field Name	Meaning
Iteration	Iteration index
Objective	Regularized objective function for minimization
UnregularizedObjective	Unregularized objective function for minimization
Gradient	Gradient of regularized objective function for minimization

- For classification, UnregularizedObjective represents the negative of the leave-one-out accuracy of the NCA classifier on the training data.
- For regression, UnregularizedObjective represents the leave-one-out loss between the true response and the predicted response when using the NCA regression model.
- For the 'lbfgs' solver, Gradient is the final gradient. For the 'sgd' and 'minibatch-lbfgs' solvers, Gradient is the final mini-batch gradient.
- If FitMethod is 'average', then FitInfo is an *m*-by-1 structure array, where *m* is the number of partitions specified via the 'NumPartitions' name-value pair argument.

You can access the fields of `FitInfo` using dot notation. For example, for a `FeatureSelectionNCARegression` object named `mdl`, you can access the `Objective` field using `mdl.FitInfo.Objective`.

Data Types: `struct`

Mu — Predictor means

p-by-1 vector | []

Predictor means, stored as a *p*-by-1 vector for standardized training data. In this case, the `predict` method centers predictor matrix *X* by subtracting the respective element of `Mu` from every column.

If data is not standardized during training, then `Mu` is empty.

Data Types: `double`

Sigma — Predictor standard deviations

p-by-1 vector | []

Predictor standard deviations, stored as a *p*-by-1 vector for standardized training data. In this case, the `predict` method scales predictor matrix *X* by dividing every column by the respective element of `Sigma` after centering the data using `Mu`.

If data is not standardized during training, then `Sigma` is empty.

Data Types: `double`

X — Predictor values

n-by-*p* matrix

Predictor values used to train this model, stored as an *n*-by-*p* matrix. *n* is the number of observations and *p* is the number of predictor variables in the training data.

Data Types: `double`

Y — Response values

numeric vector of size *n*

Response values used to train this model, stored as a numeric vector of size *n*, where *n* is the number of observations.

Data Types: `double`

W — Observation weights

numeric vector of size *n*

Observation weights used to train this model, stored as a numeric vector of size *n*. The sum of observation weights is *n*.

Data Types: `double`

Methods

`loss` Evaluate accuracy of learned feature weights on test data
`predict` Predict responses using neighborhood component analysis (NCA) regression model
`refit` Refit neighborhood component analysis (NCA) model for regression

Examples

Explore FeatureSelectionNCARegression Object

Load the sample data.

```
load imports-85
```

The first 15 columns contain the continuous predictor variables, whereas the 16th column contains the response variable, which is the price of a car. Define the variables for the neighborhood component analysis model.

```
Predictors = X(:,1:15);  
Y = X(:,16);
```

Fit a neighborhood component analysis (NCA) model for regression to detect the relevant features.

```
mdl = fsrnca(Predictors,Y);
```

The returned NCA model, `mdl`, is a `FeatureSelectionNCARegression` object. This object stores information about the training data, model, and optimization. You can access the object properties, such as the feature weights, using dot notation.

Plot the feature weights.

```
figure()  
plot(mdl.FeatureWeights,'ro')  
xlabel('Feature Index')  
ylabel('Feature Weight')  
grid on
```

The weights of the irrelevant features are zero. The 'Verbose', 1 option in the call to `fsrnca` displays the optimization information on the command line. You can also visualize the optimization process by plotting the objective function versus the iteration number.

```
figure()
plot mdl.FitInfo.Iteration, mdl.FitInfo.Objective, 'ro-'
grid on
xlabel('Iteration Number')
ylabel('Objective')
```

The `ModelParameters` property is a `struct` that contains more information about the model. You can access the fields of this property using dot notation. For example, see if the data was standardized or not.

```
mdl.ModelParameters.Standardize
```

```
ans = logical
      0
```

`0` means that the data was not standardized before fitting the NCA model. You can standardize the predictors when they are on very different scales using the `'Standardize', 1` name-value pair argument in the call to `fsrnca`.

ncfcdf

Noncentral F cumulative distribution function

Syntax

```
p = ncfcdf(x, nu1, nu2, delta)
p = ncfcdf(x, nu1, nu2, delta, 'upper')
```

Description

`p = ncfcdf(x, nu1, nu2, delta)` computes the noncentral F cdf at each value in `x` using the corresponding numerator degrees of freedom in `nu1`, denominator degrees of freedom in `nu2`, and positive noncentrality parameters in `delta`. `nu1`, `nu2`, and `delta` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `p`. A scalar input for `x`, `nu1`, `nu2`, or `delta` is expanded to a constant array with the same dimensions as the other inputs.

`p = ncfcdf(x, nu1, nu2, delta, 'upper')` returns the complement of the noncentral F cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The noncentral F cdf is

$$F(x | \nu_1, \nu_2, \delta) = \sum_{j=0}^{\infty} \left(\frac{\left(\frac{1}{2}\delta\right)^j}{j!} e^{-\frac{\delta}{2}} \right) I\left(\frac{\nu_1 \cdot x}{\nu_2 + \nu_1 \cdot x} \middle| \frac{\nu_1}{2} + j, \frac{\nu_2}{2}\right)$$

where $I(x|a,b)$ is the incomplete beta function with parameters a and b .

Examples

Compute Noncentral F Distribution cdf

Compare the noncentral F cdf with $\delta = 10$ to the F cdf with the same number of numerator and denominator degrees of freedom (5 and 20 respectively).

```
x = (0.01:0.1:10.01)';
p1 = ncfcdf(x,5,20,10);
p = fcdf(x,5,20);
plot(x,p,'- ',x,p1,'- ')
```

Introduced before R2006a

ncfinv

Noncentral F inverse cumulative distribution function

Syntax

```
X = ncfinv(P,NU1,NU2,DELTA)
```

Description

`X = ncfinv(P,NU1,NU2,DELTA)` returns the inverse of the noncentral F cdf with numerator degrees of freedom `NU1`, denominator degrees of freedom `NU2`, and positive noncentrality parameter `DELTA` for the corresponding probabilities in `P`. `P`, `NU1`, `NU2`, and `DELTA` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `X`. A scalar input for `P`, `NU1`, `NU2`, or `DELTA` is expanded to a constant array with the same dimensions as the other inputs.

Examples

One hypothesis test for comparing two sample variances is to take their ratio and compare it to an F distribution. If the numerator and denominator degrees of freedom are 5 and 20 respectively, then you reject the hypothesis that the first variance is equal to the second variance if their ratio is less than that computed below.

```
critical = finv(0.95,5,20)
critical =
    2.7109
```

Suppose the truth is that the first variance is twice as big as the second variance. How likely is it that you would detect this difference?

```
prob = 1 - ncfcdf(critical,5,20,2)
prob =
    0.1297
```

If the true ratio of variances is 2, what is the typical (median) value you would expect for the F statistic?

```
ncfinv(0.5,5,20,2)
ans =
    1.2786
```

Topics

“Noncentral F Distribution” on page B-115

Introduced before R2006a

ncfpdf

Noncentral F probability density function

Syntax

```
Y = ncfpdf(X,NU1,NU2,DELTA)
```

Description

`Y = ncfpdf(X,NU1,NU2,DELTA)` computes the noncentral F pdf at each of the values in X using the corresponding numerator degrees of freedom in $NU1$, denominator degrees of freedom in $NU2$, and positive noncentrality parameters in $DELTA$. X , $NU1$, $NU2$, and $DELTA$ can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of Y . A scalar input for $NU1$, $NU2$, or $DELTA$ is expanded to a constant array with the same dimensions as the other inputs.

The F distribution is a special case of the noncentral F where $\delta = 0$. As δ increases, the distribution flattens like the plot in the example.

Examples

Compute Noncentral F Distribution pdf

Compute the pdf of a noncentral F distribution with degrees of freedom $NU1 = 5$ and $NU2 = 20$, and noncentrality parameter $DELTA = 10$. For comparison, also compute the pdf of an F distribution with the same degrees of freedom.

```
x = (0.01:0.1:10.01)';  
p1 = ncfpdf(x,5,20,10);  
p = fpdf(x,5,20);
```

Plot the pdf of the noncentral F distribution and the pdf of the F distribution on the same figure.

```
figure;  
plot(x,p1,'b-','LineWidth',2)  
hold on  
plot(x,p,'g--','LineWidth',2)  
legend('Noncentral F','F distribution')
```

ncfrnd

Noncentral F random numbers

Syntax

```
R = ncfrnd(NU1,NU2,DELTA)
R = ncfrnd(NU1,NU2,DELTA,m,n,...)
R = ncfrnd(NU1,NU2,DELTA,[m,n,...])
```

Description

`R = ncfrnd(NU1,NU2,DELTA)` returns a matrix of random numbers chosen from the noncentral F distribution with corresponding numerator degrees of freedom in `NU1`, denominator degrees of freedom in `NU2`, and positive noncentrality parameters in `DELTA`. `NU1`, `NU2`, and `DELTA` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `NU1`, `NU2`, or `DELTA` is expanded to a constant matrix with the same dimensions as the other inputs.

`R = ncfrnd(NU1,NU2,DELTA,m,n,...)` or `R = ncfrnd(NU1,NU2,DELTA,[m,n,...])` generates an `m`-by-`n`-by-... array. The `NU1`, `NU2`, `DELTA` parameters can each be scalars or arrays of the same size as `R`.

Examples

Compute six random numbers from a noncentral F distribution with 10 numerator degrees of freedom, 100 denominator degrees of freedom and a noncentrality parameter, δ , of 4.0. Compare this to the F distribution with the same degrees of freedom.

```
r = ncfrnd(10,100,4,1,6)
r =
    2.5995    0.8824    0.8220    1.4485    1.4415    1.4864
```

```
r1 = frnd(10,100,1,6)
r1 =
    0.9826    0.5911    1.0967    0.9681    2.0096    0.6598
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

ncfstat

Noncentral F mean and variance

Syntax

`[M,V] = ncfstat(NU1,NU2,DELTA)`

Description

`[M,V] = ncfstat(NU1,NU2,DELTA)` returns the mean of and variance for the noncentral F pdf with corresponding numerator degrees of freedom in `NU1`, denominator degrees of freedom in `NU2`, and positive noncentrality parameters in `DELTA`. `NU1`, `NU2`, and `DELTA` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `NU1`, `NU2`, or `DELTA` is expanded to a constant array with the same dimensions as the other input.

The mean of the noncentral F distribution with parameters ν_1 , ν_2 , and δ is

$$\frac{\nu_2(\delta + \nu_1)}{\nu_1(\nu_2 - 2)}$$

where $\nu_2 > 2$.

The variance is

$$2\left(\frac{\nu_2}{\nu_1}\right)^2 \left[\frac{(\delta + \nu_1)^2 + (2\delta + \nu_1)(\nu_2 - 2)}{(\nu_2 - 2)^2(\nu_2 - 4)} \right]$$

where $\nu_2 > 4$.

Examples

```
[m,v]= ncfstat(10,100,4)
m =
    1.4286
v =
    0.4252
```

nctcdf

Noncentral t cumulative distribution function

Syntax

```
p = nctcdf(x,nu,delta)
p = nctcdf(x,nu,delta,'upper')
```

Description

`p = nctcdf(x,nu,delta)` computes the noncentral t cdf at each value in `x` using the corresponding degrees of freedom in `nu` and noncentrality parameters in `delta`. `x`, `nu`, and `delta` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `p`. A scalar input for `x`, `nu`, or `delta` is expanded to a constant array with the same dimensions as the other inputs.

`p = nctcdf(x,nu,delta,'upper')` returns the complement of the noncentral t cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

Examples

Compute Noncentral t Distribution cdf

Compare the noncentral t cdf with `DELTA = 1` to the t cdf with the same number of degrees of freedom (10).

```
x = (-5:0.1:5)';
p1 = nctcdf(x,10,1);
p = tcdf(x,10);
plot(x,p,'- ',x,p1,':')
```

nctpdf

Noncentral t probability density function

Syntax

```
Y = nctpdf(X,V,DELTA)
```

Description

`Y = nctpdf(X,V,DELTA)` computes the noncentral t pdf at each of the values in X using the corresponding degrees of freedom in V and noncentrality parameters in $DELTA$. Vector or matrix inputs for X , V , and $DELTA$ must have the same size, which is also the size of Y . A scalar input for X , V , or $DELTA$ is expanded to a constant matrix with the same dimensions as the other inputs.

Examples

Compute Noncentral t Distribution pdf

Compute the pdf of a noncentral t distribution with degrees of freedom $V = 10$ and noncentrality parameter $DELTA = 1$. For comparison, also compute the pdf of a t distribution with the same degrees of freedom.

```
x = (-5:0.1:5)';  
nct = nctpdf(x,10,1);  
t = tpdf(x,10);
```

Plot the pdf of the noncentral t distribution and the pdf of the t distribution on the same figure.

Noncentral t random numbers

Syntax

```
R = nctrnd(V,DELTA)
R = nctrnd(V,DELTA,m,n,...)
R = nctrnd(V,DELTA,[m,n,...])
```

Description

`R = nctrnd(V,DELTA)` returns a matrix of random numbers chosen from the noncentral T distribution using the corresponding degrees of freedom in `V` and noncentrality parameters in `DELTA`. `V` and `DELTA` can be vectors, matrices, or multidimensional arrays. A scalar input for `V` or `DELTA` is expanded to a constant array with the same dimensions as the other input.

`R = nctrnd(V,DELTA,m,n,...)` or `R = nctrnd(V,DELTA,[m,n,...])` generates an m -by- n -by-... array. The `V`, `DELTA` parameters can each be scalars or arrays of the same size as `R`.

Examples

```
nctrnd(10,1,5,1)
ans =
    1.6576
    1.0617
    1.4491
    0.2930
    3.6297
```

nctstat

Noncentral t mean and variance

Syntax

`[M,V] = nctstat(NU,DELTA)`

Description

`[M,V] = nctstat(NU,DELTA)` returns the mean of and variance for the noncentral t pdf with `NU` degrees of freedom and noncentrality parameter `DELTA`. `NU` and `DELTA` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `NU` or `DELTA` is expanded to a constant array with the same dimensions as the other input.

The mean of the noncentral t distribution with parameters ν and δ is

$$\frac{\delta(\nu/2)^{1/2}\Gamma((\nu-1)/2)}{\Gamma(\nu/2)}$$

where $\nu > 1$.

The variance is

$$\frac{\nu}{(\nu-2)}(1+\delta^2) - \frac{\nu}{2}\delta^2\left[\frac{\Gamma((\nu-1)/2)}{\Gamma(\nu/2)}\right]^2$$

where $\nu > 2$.

Examples

```
[m,v] = nctstat(10,1)
```

```
m =  
  1.0837
```

```
v =  
  1.3255
```

ncx2cdf

Noncentral chi-square cumulative distribution function

Syntax

```
p = ncx2cdf(x,v,delta)
p = ncx2cdf(x,v,delta,'upper')
```

Description

`p = ncx2cdf(x,v,delta)` computes the noncentral chi-square cdf at each value in `x` using the corresponding degrees of freedom in `v` and positive noncentrality parameters in `delta`. `x`, `v`, and `delta` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `p`. A scalar input for `x`, `v`, or `delta` is expanded to a constant array with the same dimensions as the other inputs.

`p = ncx2cdf(x,v,delta,'upper')` returns the complement of the noncentral chi-square cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

Some texts refer to this distribution as the generalized Rayleigh, Rayleigh-Rice, or Rice distribution.

The noncentral chi-square cdf is

$$F(x \mid \nu, \delta) = \sum_{j=0}^{\infty} \left(\frac{\left(\frac{1}{2}\delta\right)^j}{j!} e^{-\frac{\delta}{2}} \right) \Pr[\chi_{\nu+2j}^2 \leq x]$$

Examples

Compute Noncentral Chi-Square cdf

Compare the noncentral chi-square cdf with `DELTA = 2` to the chi-square cdf with the same number of degrees of freedom (4):

```
x = (0:0.1:10)';
ncx2 = ncx2cdf(x,4,2);
chi2 = chi2cdf(x,4);

plot(x,ncx2,'b-','LineWidth',2)
hold on
plot(x,chi2,'g--','LineWidth',2)
legend('ncx2','chi2','Location','NW')
```

ncx2pdf

Noncentral chi-square probability density function

Syntax

```
Y = ncx2pdf(X,V,DELTA)
```

Description

`Y = ncx2pdf(X,V,DELTA)` computes the noncentral chi-square pdf at each of the values in `X` using the corresponding degrees of freedom in `V` and positive noncentrality parameters in `DELTA`. Vector or matrix inputs for `X`, `V`, and `DELTA` must have the same size, which is also the size of `Y`. A scalar input for `X`, `V`, or `DELTA` is expanded to a constant array with the same dimensions as the other inputs.

Some texts refer to this distribution as the generalized Rayleigh, Rayleigh-Rice, or Rice distribution.

Examples

Compute Noncentral Chi-Square Distribution pdf

Compute the pdf of a noncentral chi-square distribution with degrees of freedom $V = 4$ and noncentrality parameter $DELTA = 2$. For comparison, also compute the pdf of a chi-square distribution with the same degrees of freedom.

```
x = (0:0.1:10)';  
ncx2 = ncx2pdf(x,4,2);  
chi2 = chi2pdf(x,4);
```

Plot the pdf of the noncentral chi-square distribution on the same figure as the pdf of the chi-square distribution.

```
figure;  
plot(x,ncx2,'b-','LineWidth',2)  
hold on  
plot(x,chi2,'g--','LineWidth',2)  
legend('ncx2','chi2')
```

Topics

“Noncentral Chi-Square Distribution” on page B-113

Introduced before R2006a

ncx2rnd

Noncentral chi-square random numbers

Syntax

```
R = ncx2rnd(V,DELTA)
R = ncx2rnd(V,DELTA,m,n,...)
R = ncx2rnd(V,DELTA,[m,n,...])
```

Description

`R = ncx2rnd(V,DELTA)` returns a matrix of random numbers chosen from the noncentral chi-square distribution using the corresponding degrees of freedom in `V` and positive noncentrality parameters in `DELTA`. `V` and `DELTA` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `V` or `DELTA` is expanded to a constant array with the same dimensions as the other input.

`R = ncx2rnd(V,DELTA,m,n,...)` or `R = ncx2rnd(V,DELTA,[m,n,...])` generates an `m`-by-`n`-by-... array. The `V`, `DELTA` parameters can each be scalars or arrays of the same size as `R`.

Examples

```
ncx2rnd(4,2,6,3)
ans =
    6.8552    5.9650   11.2961
    5.2631    4.2640    5.9495
    9.1939    6.7162    3.8315
   10.3100    4.4828    7.1653
    2.1142    1.9826    4.6400
    3.8852    5.3999    0.9282
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Noncentral Chi-Square Distribution” on page B-113

Introduced before R2006a

ncx2stat

Noncentral chi-square mean and variance

Syntax

```
[M,V] = ncx2stat(NU,DELTA)
```

Description

`[M,V] = ncx2stat(NU,DELTA)` returns the mean of and variance for the noncentral chi-square pdf with `NU` degrees of freedom and noncentrality parameter `DELTA`. `NU` and `DELTA` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `NU` or `DELTA` is expanded to a constant array with the same dimensions as the other input.

The mean of the noncentral chi-square distribution with parameters ν and δ is $\nu+\delta$, and the variance is $2(\nu+2\delta)$.

Examples

```
[m,v] = ncx2stat(4,2)
m =
    6
v =
   16
```

ndims

Class: dataset

(Not Recommended) Number of dimensions of dataset array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the `MATLAB® table` data type instead. See `MATLAB table` documentation for more information.

Syntax

`n = ndims(A)`

Description

`n = ndims(A)` returns the number of dimensions in the dataset A. The number of dimensions in an array is always 2.

See Also

`size`

ne

Class: grandstream

Not equal relation for handles

Syntax

`h1 ~= h2`

Description

Handles are equal if they are handles for the same object and are unequal otherwise.

`h1 ~= h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `~=` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = ne(h1, h2)` stores the result in a logical array of the same dimensions.

`eq` | `ge` | `gt` | `le` | `lt` | `grandstream`

negloglik

Package: prob

Negative loglikelihood of probability distribution

Syntax

```
nll = negloglik(pd)
```

Description

`nll = negloglik(pd)` returns the value of the negative loglikelihood function for the data used to fit the probability distribution `pd`.

Examples

Negative Log Likelihood for a Fitted Distribution

Load the sample data.

```
load carsmall
```

Create a Weibull distribution object by fitting it to the mile per gallon (MPG) data.

```
pd = fitdist(MPG, 'Weibull')
```

```
pd =  
  WeibullDistribution  
  
  Weibull distribution  
  A = 26.5079 [24.8333, 28.2954]  
  B = 3.27193 [2.79441, 3.83104]
```

Compute the negative log likelihood for the fitted Weibull distribution.

```
wnll = negloglik(pd)
```

```
wnll = 327.4942
```

Negative Loglikelihood for a Kernel Distribution

Load the sample data. Fit a kernel distribution to the miles per gallon (MPG) data.

```
load carsmall;  
pd = fitdist(MPG, 'Kernel')
```

```
pd =  
  KernelDistribution  
  
  Kernel = normal
```

```
Bandwidth = 4.11428
Support = unbounded
```

Compute the negative loglikelihood.

```
nll = negloglik(pd)
```

```
nll = 327.3139
```

Input Arguments

pd – Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

Function or App	Description
<code>fitdist</code>	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.

Output Arguments

nll – Negative loglikelihood

numeric value

Negative loglikelihood value for the data used to fit the distribution, returned as a numeric value.

net

Generate quasirandom point set

Syntax

```
X = net(p,n)
```

Description

`X = net(p,n)` returns the first n points from the point set p , which is either a `haltonset` or `sobolset` object. X is an n -by- d matrix, where d is the number of dimensions of the points in p .

The object p encapsulates properties of a specified quasirandom sequence. Values of the point set are generated whenever you access p using `net` or parenthesis indexing. Values are not stored within p .

Examples

Create Halton Point Set

Generate a three-dimensional Halton point set, skip the first 1000 values, and then retain every 101st point.

```
p = haltonset(3, 'Skip', 1e3, 'Leap', 1e2)
```

```
p =  
Halton point set in 3 dimensions (89180190640991 points)
```

```
Properties:  
      Skip : 1000  
      Leap : 100  
ScrambleMethod : none
```

Apply reverse-radix scrambling by using `scramble`.

```
p = scramble(p, 'RR2')
```

```
p =  
Halton point set in 3 dimensions (89180190640991 points)
```

```
Properties:  
      Skip : 1000  
      Leap : 100  
ScrambleMethod : RR2
```

Generate the first four points by using `net`.

```
X0 = net(p,4)
```

```
X0 = 4×3
```

```
0.0928 0.6950 0.0029
0.6958 0.2958 0.8269
0.3013 0.6497 0.4141
0.9087 0.7883 0.2166
```

Generate every third point, up to the eleventh point, by using parenthesis indexing.

```
X = p(1:3:11, :)
```

```
X = 4×3
```

```
0.0928 0.6950 0.0029
0.9087 0.7883 0.2166
0.3843 0.9840 0.9878
0.6831 0.7357 0.7923
```

Input Arguments

p — Point set

haltonset object | sobolset object

Point set, specified as either a `haltonset` or `sobolset` object.

Example: `haltonset(4)`

n — Number of points to return

positive integer scalar

Number of points to return from the point set, specified as a positive integer scalar. `n` must be between 1 and `length(p)`, the number of points in `p`.

`net` always returns the first `n` points in `p`. To select a different set of `n` points from the quasirandom sequence, you can change `p` by using its `Leap` and `Skip` properties or the `scramble` object function. Alternatively, you can access points in `p` by using parenthesis indexing rather than the `net` object function.

Example: 1024

Data Types: `single` | `double`

Introduced in R2008a

nLinearCoeffs

Number of nonzero linear coefficients

Syntax

```
ncoeffs = nLinearCoeffs(obj)
ncoeffs = nLinearCoeffs(obj,delta)
```

Description

`ncoeffs = nLinearCoeffs(obj)` returns the number of nonzero linear coefficients in the linear discriminant model `obj`.

`ncoeffs = nLinearCoeffs(obj,delta)` returns the number of nonzero linear coefficients for threshold parameter `delta`.

Input Arguments

obj

Discriminant analysis classifier, produced using `fitcdiscr`.

delta

Scalar or vector value of the `Delta` parameter. See “Gamma and Delta” on page 32-3644.

Output Arguments

ncoeffs

Nonnegative integer, the number of nonzero coefficients in the discriminant analysis model `obj`.

If you call `nLinearCoeffs` with a `delta` argument, `ncoeffs` is the number of nonzero linear coefficients for threshold parameter `delta`. If `delta` is a vector, `ncoeffs` is a vector with the same number of elements.

If `obj` is a quadratic discriminant model, `ncoeffs` is the number of predictors in `obj`.

Examples

Find the Number of Nonzero Coefficients in a Discriminant Analysis Classifier

Find the number of nonzero coefficients in a discriminant analysis classifier for various `Delta` values.

Create a discriminant analysis classifier from the `fishseriris` data.

```
load fisheriris
obj = fitcdiscr(meas,species);
```

Find the number of nonzero coefficients in `obj`.

```
ncoeffs = nLinearCoeffs(obj)
```

```
ncoeffs = 4
```

Find the number of nonzero coefficients for `delta = 1, 2, 4, and 8`.

```
delta = [1 2 4 8];
```

```
ncoeffs = nLinearCoeffs(obj,delta)
```

```
ncoeffs = 4×1
```

```
4
4
3
0
```

The `DeltaPredictor` property gives the values of `delta` where the number of nonzero coefficients changes.

```
ncoeffs2 = nLinearCoeffs(obj,obj.DeltaPredictor)
```

```
ncoeffs2 = 4×1
```

```
4
3
1
2
```

More About

Gamma and Delta

Regularization is the process of finding a small set of predictors that yield an effective predictive model. For linear discriminant analysis, there are two parameters, γ and δ , that control regularization as follows. `cvshrink` helps you select appropriate values of the parameters.

Let Σ represent the covariance matrix of the data X , and let \widehat{X} be the centered data (the data X minus the mean by class). Define

$$D = \text{diag}(\widehat{X}^T * \widehat{X}).$$

The regularized covariance matrix $\widetilde{\Sigma}$ is

$$\widetilde{\Sigma} = (1 - \gamma)\Sigma + \gamma D.$$

Whenever $\gamma \geq \text{MinGamma}$, $\widetilde{\Sigma}$ is nonsingular.

Let μ_k be the mean vector for those elements of X in class k , and let μ_0 be the global mean vector (the mean of the rows of X). Let C be the correlation matrix of the data X , and let \widetilde{C} be the regularized correlation matrix:

$$\tilde{C} = (1 - \gamma)C + \gamma I,$$

where I is the identity matrix.

The linear term in the regularized discriminant analysis classifier for a data point x is

$$(x - \mu_0)^T \tilde{\Sigma}^{-1} (\mu_k - \mu_0) = [(x - \mu_0)^T D^{-1/2}] [\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0)].$$

The parameter δ enters into this equation as a threshold on the final term in square brackets. Each component of the vector $[\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0)]$ is set to zero if it is smaller in magnitude than the threshold δ . Therefore, for class k , if component j is thresholded to zero, component j of x does not enter into the evaluation of the posterior probability.

The `DeltaPredictor` property is a vector related to this threshold. When $\delta \geq \text{DeltaPredictor}(i)$, all classes k have

$$|\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0)| \leq \delta.$$

Therefore, when $\delta \geq \text{DeltaPredictor}(i)$, the regularized classifier does not use predictor i .

nlinfit

Nonlinear regression

Syntax

```
beta = nlinfit(X,Y,modelfun,beta0)
beta = nlinfit(X,Y,modelfun,beta0,options)
beta = nlinfit( ___,Name,Value)
[beta,R,J,CovB,MSE,ErrorModelInfo] = nlinfit( ___ )
```

Description

`beta = nlinfit(X,Y,modelfun,beta0)` returns a vector of estimated coefficients for the nonlinear regression of the responses in *Y* on the predictors in *X* using the model specified by `modelfun`. The coefficients are estimated using iterative least squares estimation, with initial values specified by `beta0`.

`beta = nlinfit(X,Y,modelfun,beta0,options)` fits the nonlinear regression using the algorithm control parameters in the structure `options`. You can return any of the output arguments in the previous syntaxes.

`beta = nlinfit(___,Name,Value)` uses additional options specified by one or more name-value pair arguments. For example, you can specify observation weights or a nonconstant error model. You can use any of the input arguments in the previous syntaxes.

`[beta,R,J,CovB,MSE,ErrorModelInfo] = nlinfit(___)` additionally returns the residuals, *R*, the Jacobian of `modelfun`, *J*, the estimated variance-covariance matrix for the estimated coefficients, *CovB*, an estimate of the variance of the error term, *MSE*, and a structure containing details about the error model, `ErrorModelInfo`.

Examples

Nonlinear Regression Model Using Default Options

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the initial values in `beta0`.

```
beta = nlinfit(X,y,@hougen,beta0)
```

```
beta = 5×1
    1.2526
    0.0628
    0.0400
```

```
0.1124
1.1914
```

Nonlinear Regression Using Robust Options

Generate sample data from the nonlinear regression model $y = b_1 + b_2 \cdot \exp\{-b_3x\} + \epsilon$, where b_1 , b_2 , and b_3 are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.1.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
```

```
rng('default') % for reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.1,100,1);
```

Set robust fitting options.

```
opts = statset('nlinfit');
opts.RobustWgtFun = 'bisquare';
```

Fit the nonlinear model using the robust fitting options.

```
beta0 = [2;2;2];
beta = nlinfit(x,y,modelfun,beta0,opts)
```

```
beta = 3×1
```

```
1.0041
3.0997
2.1483
```

Nonlinear Regression Using Observation Weights

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Specify a vector of known observation weights.

```
W = [8 2 1 6 12 9 12 10 10 12 2 10 8]';
```

Fit the Hougen-Watson model to the rate data using the specified observation weights.

```
[beta,R,J,CovB] = nlinfit(X,y,@hougen,beta0,'Weights',W);
beta

Nonlinear Regression Using Weights Function Handle

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```
a = 1; b = 1;
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
[beta,R,J,CovB] = nlinfit(X,y,@hougen,beta0,'Weights',weights);
beta
```

```

    ScheffeSimPred: 6
    WeightFunction: 0
    FixedWeights: 0
    RobustWeightFunction: 0

```

Input Arguments

X — Predictor variables

matrix

Predictor variables for the nonlinear regression function, specified as a matrix. Typically, X is a design matrix of predictor (independent variable) values, with one row for each value in Y, and one column for each predictor. However, X can be any array that `modelfun` can accept.

Data Types: `single` | `double`

Y — Response values

vector

Response values (dependent variable) for fitting the nonlinear regression function, specified as a vector with the same number of rows as X.

Data Types: `single` | `double`**modelfun — Nonlinear regression model function**

function handle

Nonlinear regression model function, specified as a function handle. `modelfun` must accept two input arguments, a coefficient vector and an array X—in that order—and return a vector of fitted response values.

For example, to specify the `hougen` nonlinear regression function, use the function handle `@hougen`.

Data Types: `function_handle`**beta0 — Initial coefficient values**

vector

Initial coefficient values for the least squares estimation algorithm, specified as a vector.

Note Poor starting values can lead to a solution with large residual error.

Data Types: `single` | `double`**options — Estimation algorithm options**structure created using `statset`

Estimation algorithm options, specified as a structure you create using `statset`. The following `statset` parameters are applicable to `nlinfit`.

DerivStep — Relative difference for finite difference gradient`eps^(1/3)` (default) | positive scalar value | vector

Relative difference for the finite difference gradient calculation, specified as a positive scalar value, or a vector the same size as `beta`. Use a vector to specify a different relative difference for each coefficient.

Display — Level of output display`'off'` (default) | `'iter'` | `'final'`

Level of output display during estimation, specified as one of `'off'`, `'iter'`, or `'final'`. If you specify `'iter'`, output is displayed at each iteration. If you specify `'final'`, output is displayed after the final iteration.

FunValCheck — Indicator for whether to check for invalid values`'on'` (default) | `'off'`

Indicator for whether to check for invalid values such as NaN or Inf from the objective function, specified as `'on'` or `'off'`.

MaxIter — Maximum number of iterations

100 (default) | positive integer

Maximum number of iterations for the estimation algorithm, specified as a positive integer. Iterations continue until estimates are within the convergence tolerance, or the maximum number of iterations specified by `MaxIter` is reached.

RobustWgtFun — Weight function

character vector | string scalar | function handle | []

Weight function for robust fitting, specified as a valid character vector, string scalar, or function handle.

Note `RobustWgtFun` must have value [] when you use observation weights, `W`.

The following table describes the possible character vectors and string scalars. Let r denote normalized residuals and w denote robust weights. The indicator function $I[x]$ is equal to 1 if the expression x is true, and 0 otherwise.

Weight Function	Equation	Default Tuning Constant
' ' (default)	No robust fitting	—
'andrews'	$w = I[r < \pi] \times \sin(r)/r$	1.339
'bisquare'	$w = I[r < 1] \times (1 - r^2)^2$	4.685
'cauchy'	$w = 1/(1 + r^2)$	2.385
'fair'	$w = 1/(1 + r)$	1.400
'huber'	$w = 1/\max(1, r)$	1.345
'logistic'	$w = \tanh(r)/r$	1.205
'talwar'	$w = I[r < 1]$	2.795
'welsch'	$w = \exp\{-r^2\}$	2.985

You can alternatively specify a function handle that accepts a vector of normalized residuals as input, and returns a vector of robust weights as output. If you use a function handle, you must provide a `Tune` constant.

Tune — Tuning constant

positive scalar value

Tuning constant for robust fitting, specified as a positive scalar value. The tuning constant is used to normalize residuals before applying a robust weight function. The default tuning constant depends on the function specified by `RobustWgtFun`.

If you use a function handle to specify `RobustWgtFun`, then you must specify a value for `Tune`.

TolFun — Termination tolerance on residual sum of squares

1e-8 (default) | positive scalar value

Termination tolerance for the residual sum of squares, specified as a positive scalar value. Iterations continue until estimates are within the convergence tolerance, or the maximum number of iterations specified by `MaxIter` is reached.

ToLX — Termination tolerance on estimated coefficients

1e-8 (default) | positive scalar value

Termination tolerance on the estimated coefficients, `beta`, specified as a positive scalar value. Iterations continue until estimates are within the convergence tolerance, or the maximum number of iterations specified by `MaxIter` is reached.

Robust — Indicator for robust fitting

'off' (default) | 'on'

Indicator for robust fitting, specified as 'off' or 'on'.

Note `Robust` will be removed in a future software release. Use `RobustWgtFun` for robust fitting.

WgtFun — Weight function for robust fitting

character vector | string scalar | function handle

Weight function for robust fitting, specified as a character vector or string scalar indicating a weight function, or a function handle. `WgtFun` is valid only when `Robust` has value 'on'.

Note `WgtFun` will be removed in a future software release. Use `RobustWgtFun` instead.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'ErrorModel', 'proportional', 'ErrorParameters', 0.5` specifies a proportional error model, with initial value 0.5 for the error parameter estimation

ErrorModel — Form of error term

'constant' (default) | 'proportional' | 'combined'

Form of the error term, specified as the comma-separated pair consisting of `'ErrorModel'` and `'constant'`, `'proportional'`, or `'combined'` indicating the error model. Each model defines the error using a standard mean-zero and unit-variance variable e in combination with independent components: the function value f , and one or two parameters a and b .

'constant' (default)	$y = f + ae$
'proportional'	$y = f + bfe$
'combined'	$y = f + (a + b f)e$

The only allowed error model when using `Weights` is 'constant'.

Note `options.RobustWgtFun` must have value `[]` when using an error model other than `'constant'`.

ErrorParameters — Initial estimates for error model parameters

1 or `[1,1]` (default) | scalar value | two-element vector

Initial estimates for the error model parameters in the chosen `ErrorModel`, specified as the comma-separated pair consisting of `'ErrorParameters'` and a scalar value or two-element vector.

Error Model	Parameters	Default Values
'constant'	a	1
'proportional'	b	1
'combined'	a, b	<code>[1,1]</code>

For example, if `'ErrorModel'` has the value `'combined'`, you can specify the starting value 1 for a and the starting value 2 for b as follows.

Example: `'ErrorParameters',[1,2]`

You can only use the `'constant'` error model when using `Weights`.

Note `options.RobustWgtFun` must have value `[]` when using an error model other than `'constant'`.

Data Types: `double` | `single`

Weights — Observation weights

vector | function handle

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of real positive weights or a function handle. You can use observation weights to down-weight the observations that you want to have less influence on the fitted model.

- If W is a vector, then it must be the same size as Y .
- If W is a function handle, then it must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Note `options.RobustWgtFun` must have value `[]` when you use observation weights.

Data Types: `double` | `single` | `function_handle`

Output Arguments

beta — Estimated regression coefficients

vector

Estimated regression coefficients, returned as a vector. The number of elements in `beta` equals the number of elements in `beta0`.

Let $f(\mathbf{X}_i, \mathbf{b})$ denote the nonlinear function specified by `model fun`, where \mathbf{x}_i are the predictors for observation i , $i = 1, \dots, N$, and \mathbf{b} are the regression coefficients. The vector of coefficients returned in `beta` minimizes the weighted least squares equation,

$$\sum_{i=1}^N w_i [y_i - f(\mathbf{x}_i, \mathbf{b})]^2.$$

For unweighted nonlinear regression, all of the weight terms are equal to 1.

R — Residuals

vector

Residuals for the fitted model, returned as a vector.

- If you specify observation weights using the name-value pair argument `Weights`, then `R` contains weighted residuals on page 32-3655.
- If you specify an error model other than 'constant' using the name-value pair argument `ErrorModel`, then you can no longer interpret `R` as model fit residuals.

J — Jacobian

matrix

Jacobian of the nonlinear regression model, `model fun`, returned as an N -by- p matrix, where N is the number of observations and p is the number of estimated coefficients.

- If you specify observation weights using the name-value pair argument `Weights`, then `J` is the weighted model function Jacobian on page 32-3655.
- If you specify an error model other than 'constant' using the name-value pair argument `ErrorModel`, then you can no longer interpret `J` as the model function Jacobian.

CovB — Estimated variance-covariance matrix

matrix

Estimated variance-covariance matrix for the fitted coefficients, `beta`, returned as a p -by- p matrix, where p is the number of estimated coefficients. If the model Jacobian, `J`, has full column rank, then $\text{CovB} = \text{inv}(\mathbf{J}' * \mathbf{J}) * \text{MSE}$, where `MSE` is the mean squared error.

MSE — Mean squared error

scalar value

Mean squared error (MSE) of the fitted model, returned as a scalar value. MSE is an estimate of the variance of the error term. If the model Jacobian, `J`, has full column rank, then $\text{MSE} = (\mathbf{R}' * \mathbf{R}) / (N - p)$, where N is the number of observations, and p is the number of estimated coefficients.

ErrorModelInfo — Information about error model fit

structure

Information about the error model fit, returned as a structure with the following fields:

<code>ErrorModel</code>	Chosen error model
<code>ErrorParameters</code>	Estimated error parameters

ErrorVariance	Function handle that accepts an N -by- p matrix, \mathbf{X} , and returns an N -by-1 vector of error variances using the estimated error model
MSE	Mean squared error
ScheffeSimPred	Scheffé parameter for simultaneous prediction intervals when using the estimated error model
WeightFunction	Logical with value <code>true</code> if you used a custom weight function previously in <code>nlinfit</code>
FixedWeights	Logical with value <code>true</code> if you used fixed weights previously in <code>nlinfit</code>
RobustWeightFunction	Logical with value <code>true</code> if you used robust fitting previously in <code>nlinfit</code>

More About

Weighted Residuals

A weighted residual is a residual multiplied by the square root of the corresponding observation weight.

Given estimated regression coefficients, \mathbf{b} , the residual for observation i is

$$r_i = y_i - f(\mathbf{x}_i, \mathbf{b}),$$

where y_i is the observed response and $f(\mathbf{x}_i, \mathbf{b})$ is the fitted response at predictors \mathbf{x}_i .

When you fit a weighted nonlinear regression with weights w_i , $i = 1, \dots, N$, `nlinfit` returns the weighted residuals,

$$r_i^* = \sqrt{w_i}(y_i - f(\mathbf{x}_i, \mathbf{b})).$$

Weighted Model Function Jacobian

The weighted model function Jacobian is the nonlinear model Jacobian multiplied by the square root of the observation weight matrix.

Given estimated regression coefficients, \mathbf{b} , the estimated model Jacobian, \mathbf{J} , for the nonlinear function $f(\mathbf{x}_i, \mathbf{b})$ has elements

$$\mathbf{J}_{ij} = \frac{\partial f(\mathbf{x}_i, \mathbf{b})}{\partial b_j},$$

where b_j is the j th element of \mathbf{b} .

When you fit a weighted nonlinear regression with diagonal weights matrix \mathbf{W} , `nlinfit` returns the weighted Jacobian matrix,

$$\mathbf{J}^* = \mathbf{W}^{1/2}\mathbf{J}.$$

Tips

- To produce error estimates on predictions, use the optional output arguments `R`, `J`, `CovB`, or `MSE` as inputs to `nlpredci`.
- To produce error estimates on the estimated coefficients, `beta`, use the optional output arguments `R`, `J`, `CovB`, or `MSE` as inputs to `nlparci`.
- If you use the robust fitting option, `RobustWgtFun`, you must use `CovB`—and might need `MSE`—as inputs to `nlpredci` or `nlparci` to ensure that the confidence intervals take the robust fit properly into account.

Algorithms

- `nlfit` treats NaN values in `Y` or `modelfun(beta0,X)` as missing data, and ignores the corresponding observations.
- For nonrobust estimation, `nlfit` uses the Levenberg-Marquardt nonlinear least squares algorithm [1].
- For robust estimation, `nlfit` uses an iterative reweighted least squares algorithm ([2], [3]). At each iteration, the robust weights are recalculated based on each observation's residual from the previous iteration. These weights downweight outliers, so that their influence on the fit is decreased. Iterations continue until the weights converge.
- When you specify a function handle for observation weights, the weights depend on the fitted model. In this case, `nlfit` uses an iterative generalized least squares algorithm to fit the nonlinear regression model.

Topics

"Nonlinear Regression" on page 13-2

Introduced before R2006a

nlintool

Interactive nonlinear regression

Syntax

```
nlintool(X,y,fun,beta0)
nlintool(X,y,fun,beta0,alpha)
nlintool(X,y,fun,beta0,alpha,'xname','yname')
```

Description

`nlintool(X,y,fun,beta0)` is a graphical user interface to the `nlinfit` function, and uses the same input arguments. The interface displays plots of the fitted response against each predictor, with the other predictors held fixed. The fixed values are in the text boxes below each predictor axis. Change the fixed values by typing in a new value or by dragging the vertical lines in the plots to new positions. When you change the value of a predictor, all plots update to display the model at the new point in predictor space. Dashed red curves show 95% simultaneous confidence bands for the function.

`nlintool(X,y,fun,beta0,alpha)` shows $100(1-\alpha)\%$ confidence bands. These are simultaneous confidence bounds for the function value. Using the **Bounds** menu you can switch between simultaneous and non-simultaneous bounds, and between bounds on the function and bounds for predicting a new observation.

`nlintool(X,y,fun,beta0,alpha,'xname','yname')` labels the plots using the character matrix or string array 'xname' for the predictors and the character vector or string scalar 'yname' for the response.

Examples

The data in `reaction.mat` are partial pressures of three chemical reactants and the corresponding reaction rates. The function `hougen` implements the nonlinear Hougen-Watson model for reaction rates. The following fits the model to the data:

```
load reaction
nlintool(reactants,rate,@hougen,beta,0.01,xn,yn)
```

`nlinfit` | `polytool` | `rstool`

Introduced before R2006a

nlmefit

Nonlinear mixed-effects estimation

Syntax

```
beta = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI] = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI,stats] = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0,'Name',value)
```

Description

`beta = nlmefit(X,y,group,V,fun,beta0)` fits a nonlinear mixed-effects regression model and returns estimates of the fixed effects in `beta`. By default, `nlmefit` fits a model in which each parameter is the sum of a fixed and a random effect, and the random effects are uncorrelated (their covariance matrix is diagonal).

`X` is an n -by- h matrix of n observations on h predictors.

`y` is an n -by-1 vector of responses.

`group` is a grouping variable indicating m groups in the observations. `group` is a categorical variable, a numeric vector, a character matrix with rows for group names, a string array, or a cell array of character vectors. For more information on grouping variables, see “Grouping Variables” on page 2-45.

`V` is an m -by- g matrix or cell array of g group-specific predictors. These are predictors that take the same value for all observations in a group. The rows of `V` are assigned to groups using `grp2idx`, according to the order specified by `grp2idx(group)`. Use a cell array for `V` if group predictors vary in size across groups. Use `[]` for `V` if there are no group-specific predictors.

`fun` is a handle to a function that accepts predictor values and model parameters and returns fitted values. `fun` has the form

```
yfit = modelfun(PHI,XFUN,VFUN)
```

The arguments are:

- `PHI` — A 1-by- p vector of model parameters.
- `XFUN` — A k -by- h array of predictors, where:
 - $k = 1$ if `XFUN` is a single row of `X`.
 - $k = n_i$ if `XFUN` contains the rows of `X` for a single group of size n_i .
 - $k = n$ if `XFUN` contains all rows of `X`.
- `VFUN` — Group-specific predictors given by one of:
 - A 1-by- g vector corresponding to a single group and a single row of `V`.
 - An n -by- g array, where the j th row is `V(I,:)` if the j th observation is in group `I`.

If `V` is empty, `nlmefit` calls `modelfun` with only two inputs.

- `yfit` — A k -by-1 vector of fitted values

When either `PHI` or `VFUN` contains a single row, it corresponds to all rows in the other two input arguments.

Note If `modelfun` can compute `yfit` for more than one vector of model parameters per call, use the 'Vectorization' parameter (described later) for improved performance.

`beta0` is a q -by-1 vector with initial estimates for q fixed effects. By default, q is the number of model parameters p .

`nlmefit` fits the model by maximizing an approximation to the marginal likelihood with random effects integrated out, assuming that:

- Random effects are multivariate normally distributed and independent between groups.
- Observation errors are independent, identically normally distributed, and independent of the random effects.

`[beta,PSI] = nlmefit(X,y,group,V,fun,beta0)` also returns `PSI`, an r -by- r estimated covariance matrix for the random effects. By default, r is equal to the number of model parameters p .

`[beta,PSI,stats] = nlmefit(X,y,group,V,fun,beta0)` also returns `stats`, a structure with fields:

- `dfe` — The error degrees of freedom for the model
- `logl` — The maximized loglikelihood for the fitted model
- `rmse` — The square root of the estimated error variance (computed on the log scale for the exponential error model)
- `errorparam` — The estimated parameters of the error variance model
- `aic` — The Akaike information criterion, calculated as $\text{aic} = -2 * \text{logl} + 2 * \text{numParam}$, where `numParam` is the number of fitting parameters, including the degree of freedom for covariance matrix of the random effects, the number of fixed effects and the number of parameters of the error model, and `logl` is a field in the `stats` structure
- `bic` — The Bayesian information criterion, calculated as $\text{bic} = -2 * \text{logl} + \log(M) * \text{numParam}$
 - `M` is the number of groups.
 - `numParam` and `logl` are defined as in `aic`.

Note that some literature suggests that the computation of `bic` should be , $\text{bic} = -2 * \text{logl} + \log(N) * \text{numParam}$, where `N` is the number of observations.

- `covb` — The estimated covariance matrix of the parameter estimates
- `sebeta` — The standard errors for `beta`
- `ires` — The population residuals ($y - y_{\text{population}}$), where `y_population` is the individual predicted values
- `pres` — The population residuals ($y - y_{\text{population}}$), where `y_population` is the population predicted values
- `iwres` — The individual weighted residuals

- `pwres` — The population weighted residuals
- `cwres` — The conditional weighted residuals

`[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0)` also returns `B`, an r -by- m matrix of estimated random effects for the m groups. By default, r is equal to the number of model parameters p .

`[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0,'Name',value)` specifies one or more optional parameter name/value pairs. Specify *Name* inside single quotes.

Use the following parameters to fit a model different from the default. (The default model is obtained by setting both `FEConstDesign` and `REConstDesign` to `eye(p)`, or by setting both `FEPARAMSSELECT` and `REPARAMSSELECT` to `1:p`.) Use at most one parameter with an 'FE' prefix and one parameter with an 'RE' prefix. The `nlmefit` function requires you to specify at least one fixed effect and one random effect.

Parameter	Value
<code>FEPARAMSSELECT</code>	A vector specifying which elements of the parameter vector <code>PHI</code> include a fixed effect, given as a numeric vector of indices from 1 to p or as a 1-by- p logical vector. If q is the specified number of elements, then the model includes q fixed effects.
<code>FEConstDesign</code>	A p -by- q design matrix <code>ADESIGN</code> , where <code>ADESIGN*beta</code> are the fixed components of the p elements of <code>PHI</code> .
<code>FEGroupDesign</code>	A p -by- q -by- m array specifying a different p -by- q fixed-effects design matrix for each of the m groups.
<code>FEObsDesign</code>	A p -by- q -by- n array specifying a different p -by- q fixed-effects design matrix for each of the n observations.
<code>REPARAMSSELECT</code>	A vector specifying which elements of the parameter vector <code>PHI</code> include a random effect, given as a numeric vector of indices from 1 to p or as a 1-by- p logical vector. The model includes r random effects, where r is the specified number of elements.
<code>REConstDesign</code>	A p -by- r design matrix <code>BDESIGN</code> , where <code>BDESIGN*B</code> are the random components of the p elements of <code>PHI</code> .
<code>REGroupDesign</code>	A p -by- r -by- m array specifying a different p -by- r random-effects design matrix for each of m groups.
<code>REObsDesign</code>	A p -by- r -by- n array specifying a different p -by- r random-effects design matrix for each of n observations.

Use the following parameters to control the iterative algorithm for maximizing the likelihood:

Parameter	Value
<code>RefineBeta0</code>	Determines whether <code>nlmefit</code> makes an initial refinement of <code>beta0</code> by first fitting <code>modelfun</code> without random effects and replacing <code>beta0</code> with <code>beta</code> . Choices are 'on' and 'off'. The default value is 'on'.

Parameter	Value
ErrorModel	<p>A character vector or string scalar specifying the form of the error term. Default is 'constant'. Each model defines the error using a standard normal (Gaussian) variable e, the function value f, and one or two parameters a and b. Choices are:</p> <ul style="list-style-type: none"> • 'constant': $y = f + a*e$ • 'proportional': $y = f + b*f*e$ • 'combined': $y = f + (a+b*f)*e$ • 'exponential': $y = f*\exp(a*e)$, or equivalently $\log(y) = \log(f) + a*e$ <p>If this parameter is given, the output <code>stats.errorparam</code> field has the value</p> <ul style="list-style-type: none"> • a for 'constant' and 'exponential' • b for 'proportional' • $[a\ b]$ for 'combined'
ApproximationType	<p>The method used to approximate the likelihood of the model. Choices are:</p> <ul style="list-style-type: none"> • 'LME' — Use the likelihood for the linear mixed-effects model at the current conditional estimates of <code>beta</code> and <code>B</code>. This is the default. • 'RELME' — Use the restricted likelihood for the linear mixed-effects model at the current conditional estimates of <code>beta</code> and <code>B</code>. • 'FO' — First-order Laplacian approximation without random effects. • 'FOCE' — First-order Laplacian approximation at the conditional estimates of <code>B</code>.

Parameter	Value
Vectorization	<p>Indicates acceptable sizes for the PHI, XFUN, and VFUN input arguments to <code>modelfun</code>. Choices are:</p> <ul style="list-style-type: none"> • 'SinglePhi' — <code>modelfun</code> can only accept a single set of model parameters at a time, so PHI must be a single row vector in each call. <code>nlmefit</code> calls <code>modelfun</code> in a loop, if necessary, with a single PHI vector and with XFUN containing rows for a single observation or group at a time. VFUN may be a single row that applies to all rows of XFUN, or a matrix with rows corresponding to rows in XFUN. This is the default. • 'SingleGroup' — <code>modelfun</code> can only accept inputs corresponding to a single group in the data, so XFUN must contain rows of X from a single group in each call. Depending on the model, PHI is a single row that applies to the entire group or a matrix with one row for each observation. VFUN is a single row. • 'Full' — <code>modelfun</code> can accept inputs for multiple parameter vectors and multiple groups in the data. Either PHI or VFUN may be a single row that applies to all rows of XFUN or a matrix with rows corresponding to rows in XFUN. This option can improve performance by reducing the number of calls to <code>modelfun</code>, but may require <code>modelfun</code> to perform singleton expansion on PHI or V.
CovParameterization	<p>Specifies the parameterization used internally for the scaled covariance matrix. Choices are 'chol' for the Cholesky factorization or 'logm' the matrix logarithm. The default is 'logm'.</p>
CovPattern	<p>Specifies an r-by-r logical or numeric matrix P that defines the pattern of the random-effects covariance matrix PSI. <code>nlmefit</code> estimates the variances along the diagonal of PSI and the covariances specified by nonzeros in the off-diagonal elements of P. Covariances corresponding to zero off-diagonal elements in P are constrained to be zero. If P does not specify a row-column permutation of a block diagonal matrix, <code>nlmefit</code> adds nonzero elements to P as needed. The default value of P is <code>eye(r)</code>, corresponding to uncorrelated random effects.</p> <p>Alternatively, P may be a 1-by-r vector containing values in $1:r$, with equal values specifying groups of random effects. In this case, <code>nlmefit</code> estimates covariances only within groups, and constrains covariances across groups to be zero.</p>

Parameter	Value
ParamTransform	<p>A vector of p-values specifying a transformation function $f()$ for each of the P parameters: $XB = ADESIGN*BETA + BDESIGN*B$ $PHI = f(XB)$. Each element of the vector must be one of the following integer codes specifying the transformation for the corresponding value of PHI:</p> <ul style="list-style-type: none"> • 0: $PHI = XB$ (default for all parameters) • 1: $\log(PHI) = XB$ • 2: $\text{probit}(PHI) = XB$ • 3: $\text{logit}(PHI) = XB$
Options	<p>A structure of the form returned by <code>statset.nlmefit</code> uses the following <code>statset</code> parameters:</p> <ul style="list-style-type: none"> • 'DerivStep' — Relative difference used in finite difference gradient calculation. May be a scalar, or a vector whose length is the number of model parameters p. The default is $\text{eps}^{(1/3)}$. • 'Display' — Level of iterative display during estimation. Choices are: <ul style="list-style-type: none"> • 'off' (default) — Displays no information • 'final' — Displays information after the final iteration • 'iter' — Displays information at each iteration • 'FunValCheck' — Check for invalid values, such as NaN or Inf, from <code>modelfun</code>. Choices are 'on' and 'off'. The default is 'on'. • 'MaxIter' — Maximum number of iterations allowed. The default is 200. • 'OutputFcn' — Function handle specified using @, a cell array with function handles or an empty array (default). The solver calls all output functions after each iteration. • 'TolFun' — Termination tolerance on the loglikelihood function. The default is $1e-4$. • 'TolX' — Termination tolerance on the estimated fixed and random effects. The default is $1e-4$.
OptimFun	<p>Specifies the optimization function used in maximizing the likelihood. Choices are 'fminsearch' to use <code>fminsearch</code> or 'fminunc' to use <code>fminunc</code>. The default is 'fminsearch'. You can specify 'fminunc' only if Optimization Toolbox software is installed.</p>

Examples

Nonlinear Mixed-Effects Model

Enter and display data on the growth of five orange trees.

```

CIRC = [30 58 87 115 120 142 145;
        33 69 111 156 172 203 203;
        30 51 75 108 115 139 140;
        32 62 112 167 179 209 214;
        30 49 81 125 142 174 177];
time = [118 484 664 1004 1231 1372 1582];

h = plot(time,CIRC','o','LineWidth',2);
xlabel('Time (days)')
ylabel('Circumference (mm)')
title('\bf Orange Tree Growth')
legend([repmat('Tree ',5,1),num2str((1:5)')],...
       'Location','NW')
grid on
hold on

```

Use an anonymous function to specify a logistic growth model.

```
model = @(PHI,t)(PHI(:,1))./(1+exp(-(t-PHI(:,2))./PHI(:,3))));
```

Fit the model using `nlmefit` with default settings (that is, assuming each parameter is the sum of a fixed and a random effect, with no correlation among the random effects):

```

TIME = repmat(time,5,1);
NUMS = repmat((1:5)',size(time));

beta0 = [100 100 100];

```

```
[beta1,PSI1,stats1] = nlmeFit(TIME(:),CIRC(:),NUMS(:),...
                             [],model,beta0)
```

```
beta1 = 3×1
```

```
191.3189
723.7608
346.2517
```

```
PSI1 = 3×3
```

```
962.1535    0    0
    0    0.0000    0
    0    0    297.9880
```

```
stats1 = struct with fields:
```

```
  dfe: 28
  logl: -131.5457
  mse: 59.7882
  rmse: 7.9016
  errorparam: 7.7323
  aic: 277.0913
  bic: 274.3574
  covb: [3×3 double]
  sebeta: [15.2249 33.1579 26.8235]

```

The loglikelihood `logl` is unaffected, and both the Akaike and Bayesian information criteria (`aic` and `bic`) are reduced, supporting the decision to drop the second random effect from the model.

Use the estimated fixed effects in `beta2` and the estimated random effects for each tree in `b2` to plot the model through the data.

```

PHI = repmat(beta2,1,5) + ...           % Fixed effects
      [b2(1,:);zeros(1,5);b2(2,:)];    % Random effects

tplot = 0:0.1:1600;
for I = 1:5
    fitted_model=@(t)(PHI(1,I))./(1+exp(-(t-PHI(2,I))./ ...
        PHI(3,I)));
    plot(tplot,fitted_model(tplot),'Color',h(I).Color, ...
        'LineWidth',2)
end

```

Introduced in R2008b

nlmefitsa

Fit nonlinear mixed-effects model with stochastic EM algorithm

Syntax

```
[BETA,PSI,STATS,B] = nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0)
[BETA,PSI,STATS,B] = nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0,'Name',Value)
```

Description

`[BETA,PSI,STATS,B] = nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0)` fits a nonlinear mixed-effects regression model and returns estimates of the fixed effects in BETA. By default, `nlmefitsa` fits a model where each model parameter is the sum of a corresponding fixed and random effect, and the covariance matrix of the random effects is diagonal, i.e., uncorrelated random effects.

The BETA, PSI, and other values this function returns are the result of a random (Monte Carlo) simulation designed to converge to the maximum likelihood estimates of the parameters. Because the results are random, it is advisable to examine the plot of simulation to results to be sure that the simulation has converged. It may also be helpful to run the function multiple times, using multiple starting values, or use the 'Replicates' parameter to perform multiple simulations.

`[BETA,PSI,STATS,B] = nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0,'Name',Value)` accepts one or more comma-separated parameter name/value pairs. Specify *Name* inside single quotes.

Input Arguments

Definitions:

In the following list of arguments, the following variable definitions apply:

- n — number of observations
- h — number of predictor variables
- m — number of groups
- g — number of group-specific predictor variables
- p — number of parameters
- f — number of fixed effects

X

An n -by- h matrix of n observations on h predictor variables.

Y

An n -by-1 vector of responses.

GROUP

A grouping variable indicating to which of m groups each observation belongs. **GROUP** can be a categorical variable, a numeric vector, a character matrix with rows for group names, a string array, or a cell array of character vectors.

V

An m -by- g matrix of g group-specific predictor variables for each of the m groups in the data. These are predictor values that take on the same value for all observations in a group. Rows of **V** are ordered according to `GRP2IDX(GROUP)`. Use an m -by- g cell array for **V** if any of the group-specific predictor values vary in size across groups. Specify `[]` for **V** if there are no group predictors.

MODELFUN

A handle to a function that accepts predictor values and model parameters, and returns fitted values. **MODELFUN** has the form `YFIT = MODELFUN(PHI, XFUN, VFUN)` with input arguments

- **PHI** — A 1-by- p vector of model parameters.
- **XFUN** — An l -by- h array of predictor variables where
 - l is 1 if **XFUN** is a single row of **X**
 - l is n_i if **XFUN** contains the rows of **X** for a single group of size n_i
 - l is n if **XFUN** contains all rows of **X**.
- **VFUN** — Either
 - A 1-by- g vector of group-specific predictors for a single group, corresponding to a single row of **V**
 - An n -by- g matrix, where the k -th row of **VFUN** is $V(i,:)$ if the k -th observation is in group i .

If **V** is empty, `nlmefitsa` calls **MODELFUN** with only two inputs.

MODELFUN returns an l -by-1 vector of fitted values **YFIT**. When either **PHI** or **VFUN** contains a single row, that one row corresponds to all rows in the other two input arguments. For improved performance, use the 'Vectorization' parameter name/value pair (described below) if **MODELFUN** can compute **YFIT** for more than one vector of model parameters in one call.

BETA0

An f -by-1 vector with initial estimates for the f fixed effects. By default, f is equal to the number of model parameters p . **BETA0** can also be an f -by-**REPS** matrix, and the estimation is repeated **REPS** times using each column of **BETA0** as a set of starting values.

Name-Value Pair Arguments

By default, `nlmefitsa` fits a model where each model parameter is the sum of a corresponding fixed and random effect. Use the following parameter name/value pairs to fit a model with a different number of or dependence on fixed or random effects. Use at most one parameter name with an 'FE' prefix and one parameter name with an 'RE' prefix. Note that some choices change the way `nlmefitsa` calls **MODELFUN**, as described further below.

FEParamsSelect

A vector specifying which elements of the model parameter vector PHI include a fixed effect, as a numeric vector with elements in 1:p, or as a 1-by-p logical vector. The model will include *f* fixed effects, where *f* is the specified number of elements.

FEConstDesign

A *p*-by-*f* design matrix ADESIGN, where ADESIGN*BETA are the fixed components of the *p* elements of PHI.

FEGroupDesign

A *p*-by-*f*-by-*m* array specifying a different *p*-by-*f* fixed effects design matrix for each of the *m* groups.

REParamsSelect

A vector specifying which elements of the model parameter vector PHI include a random effect, as a numeric vector with elements in 1:p, or as a 1-by-p logical vector. The model will include *r* random effects, where *r* is the specified number of elements.

REConstDesign

A *p*-by-*r* design matrix BDESIGN, where BDESIGN*B are the random components of the *p* elements of PHI. This matrix must consist of 0s and 1s, with at most one 1 per row.

The default model is equivalent to setting both FEConstDesign and REConstDesign to `eye(p)`, or to setting both FEParamsSelect and REParamsSelect to 1:p.

Additional optional parameter name/value pairs control the iterative algorithm used to maximize the likelihood:

CovPattern

Specifies an *r*-by-*r* logical or numeric matrix PAT that defines the pattern of the random effects covariance matrix PSI. `nlmefitsa` computes estimates for the variances along the diagonal of PSI as well as covariances that correspond to non-zeroes in the off-diagonal of PAT. `nlmefitsa` constrains the remaining covariances, i.e., those corresponding to off-diagonal zeroes in PAT, to be zero. PAT must be a row-column permutation of a block diagonal matrix, and `nlmefitsa` adds non-zero elements to PAT as needed to produce such a pattern. The default value of PAT is `eye(r)`, corresponding to uncorrelated random effects.

Alternatively, specify PAT as a 1-by-*r* vector containing values in 1:r. In this case, elements of PAT with equal values define groups of random effects, `nlmefitsa` estimates covariances only within groups, and constrains covariances across groups to be zero.

Cov0

Initial value for the covariance matrix PSI. Must be an *r*-by-*r* positive definite matrix. If empty, the default value depends on the values of BETA0.

ComputeStdErrors

`true` to compute standard errors for the coefficient estimates and store them in the output STATS structure, or `false` (default) to omit this computation.

ErrorModel

A character vector or string scalar specifying the form of the error term. Default is 'constant'. Each model defines the error using a standard normal (Gaussian) variable e , the function value f , and one or two parameters a and b . Choices are

- 'constant' — $y = f + a*e$
- 'proportional' — $y = f + b*f*e$
- 'combined' — $y = f + (a+b*f)*e$
- 'exponential' — $y = f*\exp(a*e)$, or equivalently $\log(y) = \log(f) + a*e$

If this parameter is given, the output `STATS.errorparam` field has the value

- a for 'constant' and 'exponential'
- b for 'proportional'
- $[a\ b]$ for 'combined'

ErrorParameters

A scalar or two-element vector specifying starting values for parameters of the error model. This specifies the a , b , or $[a\ b]$ values depending on the `ErrorModel` parameter.

LogLikMethod

Specifies the method for approximating the loglikelihood. Choices are:

- 'is' — Importance sampling
- 'gq' — Gaussian quadrature
- 'lin' — Linearization
- 'none' — Omit the loglikelihood approximation (default)

NBurnIn

Number of initial burn-in iterations during which the parameter estimates are not recomputed. Default is 5.

NChains

Number c of "chains" simulated. Default is 1. Setting $c > 1$ causes c simulated coefficient vectors to be computed for each group during each iteration. Default depends on the data, and is chosen to provide about 100 groups across all chains.

NIterations

Number of iterations. This can be a scalar or a three-element vector. Controls how many iterations are performed for each of three phases of the algorithm:

- 1 simulated annealing
- 2 full step size
- 3 reduced step size

Default is `[150 150 100]`. A scalar is distributed across the three phases in the same proportions as the default.

NMCMCIterations

Number of Markov Chain Monte Carlo (MCMC) iterations. This can be a scalar or a three-element vector. Controls how many of three different types of MCMC updates are performed during each phase of the main iteration:

- 1 full multivariate update
- 2 single coordinate update
- 3 multiple coordinate update

Default is [2 2 2]. A scalar value is treated as a three-element vector with all elements equal to the scalar.

OptimFun

Either 'fminsearch' or 'fminunc', specifying the optimization function to be used during the estimation process. Default is 'fminsearch'. Use of 'fminunc' requires Optimization Toolbox.

Options

A structure created by a call to `statset.nlmefitsa` uses the following `statset` parameters:

- 'DerivStep' — Relative difference used in finite difference gradient calculation. May be a scalar, or a vector whose length is the number of model parameters p . The default is $\text{eps}^{(1/3)}$.
- Display — Level of display during estimation.
 - 'off' (default) — Displays no information
 - 'final' — Displays information after the final iteration of the estimation algorithm
 - 'iter' — Displays information at each iteration
- FunValCheck
 - 'on' (default) — Check for invalid values (such as NaN or Inf) from MODELFUN
 - 'off' — Skip this check
- OutputFcn — Function handle specified using @, a cell array with function handles or an empty array. `nlmefitsa` calls all output functions after each iteration. See `nlmefitoutputfcn.m` (the default output function for `nlmefitsa`) for an example of an output function.

ParamTransform

A vector of p -values specifying a transformation function $f()$ for each of the p parameters:

```
XB = ADESIGN*BETA + BDESIGN*B
PHI = f(XB)
```

Each element of the vector must be one of the following integer codes specifying the transformation for the corresponding value of PHI:

- 0: $\text{PHI} = \text{XB}$ (default for all parameters)
- 1: $\log(\text{PHI}) = \text{XB}$
- 2: $\text{probit}(\text{PHI}) = \text{XB}$
- 3: $\text{logit}(\text{PHI}) = \text{XB}$

Replicates

Number REPS of estimations to perform starting from the starting values in the vector BETA0. If BETA0 is a matrix, REPS must match the number of columns in BETA0. Default is the number of columns in BETA0.

Vectorization

Determines the possible sizes of the PHI, XFUN, and VFUN input arguments to MODELFUN. Possible values are:

- 'SinglePhi' — MODELFUN is a function (such as an ODE solver) that can only compute YFIT for a single set of model parameters at a time, i.e., PHI must be a single row vector in each call. nlmefitsa calls MODELFUN in a loop if necessary using a single PHI vector and with XFUN containing rows for a single observation or group at a time. VFUN may be a single row that applies to all rows of XFUN, or a matrix with rows corresponding to rows in XFUN.
- 'SingleGroup' — MODELFUN can only accept inputs corresponding to a single group in the data, i.e., XFUN must contain rows of X from a single group in each call. Depending on the model, PHI is a single row that applies to the entire group, or a matrix with one row for each observation. VFUN is a single row.
- 'Full' — MODELFUN can accept inputs for multiple parameter vectors and multiple groups in the data. Either PHI or VFUN may be a single row that applies to all rows of XFUN, or a matrix with rows corresponding to rows in XFUN. Using this option can improve performance by reducing the number of calls to MODELFUN, but may require MODELFUN to perform singleton expansion on PHI or V.

The default for 'Vectorization' is 'SinglePhi'. In all cases, if V is empty, nlmefitsa calls MODELFUN with only two inputs.

Output Arguments

BETA

Estimates of the fixed effects

PSI

An r -by- r estimated covariance matrix for the random effects. By default, r is equal to the number of model parameters p .

STATS

A structure with the following fields:

- logl — The maximized loglikelihood for the fitted model; empty if the LogLikMethod parameter has its default value of 'none'
- rmse — The square root of the estimated error variance (computed on the log scale for the exponential error model)
- errorparam — The estimated parameters of the error variance model
- aic — The Akaike information criterion (empty if logl is empty), calculated as $aic = -2 * \log l + 2 * \text{numParam}$, where

- `logl` is the maximized loglikelihood.
- `numParam` is the number of fitting parameters, including the degree of freedom for covariance matrix of the random effects, the number of fixed effects and the number of parameters of the error model.
- `bic` — The Bayesian information criterion (empty if `logl` is empty), calculated as `bic = -2*logl + log(M) * numParam`
 - `M` is the number of groups.
 - `logl` and `numParam` are defined as in `aic`.

Note that some literature suggests that the computation of `bic` should be , `bic = -2*logl + log(N) * numParam`, where `N` is the number of observations. To adjust the value of the output you can redefine `bic` as follows: `bic = bic - numel(unique(group)) + numel(Y)`

- `sebeta` — The standard errors for BETA (empty if the `ComputeStdErrors` parameter has its default value of false)
- `covb` — The estimated covariance of the parameter estimates (empty if `ComputeStdErrors` is false)
- `dfe` — The error degrees of freedom
- `pres` — The population residuals (`y-y_population`), where `y_population` is the population predicted values
- `ires` — The population residuals (`y-y_population`), where `y_population` is the individual predicted values
- `pwres` — The population weighted residuals
- `cwres` — The conditional weighted residuals
- `iwres` — The individual weighted residuals

Examples

Nonlinear Mixed-Effects Model with Stochastic EM Algorithm

Load the sample data.

```
load indomethacin
```

Fit a model to data on concentrations of the drug indomethacin in the bloodstream of six subjects over eight hours.

```
model = @(phi,t)(phi(:,1).*exp(-phi(:,2).*t)+phi(:,3).*exp(-phi(:,4).*t));
phi0 = [1 1 1 1];
xform = [0 1 0 1]; % log transform for 2nd and 4th parameters
[beta,PSI,stats,br] = nlmefitsa(time,concentration,...
    subject,[],model,phi0,'ParamTransform',xform)
```

```
beta =
```

```
    0.8563
   -0.7950
    2.7744
    1.0772
```

PSI =

0.0529	0	0	0
0	0.0220	0	0
0	0	0.4762	0
0	0	0	0.0120

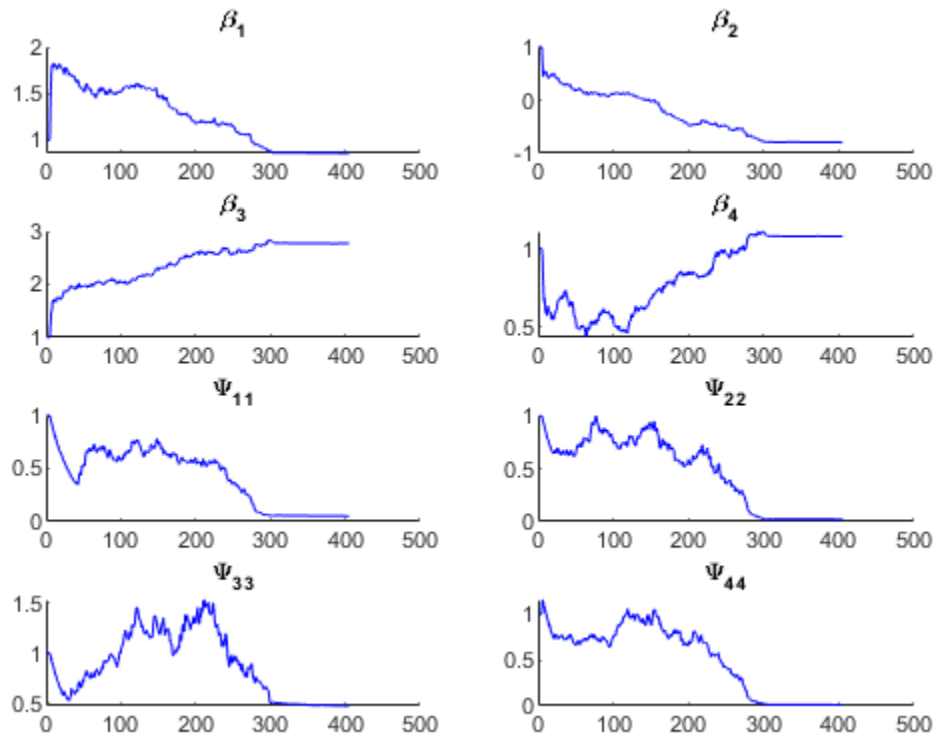

stats =

struct with fields:

```
logl: []
aic: []
bic: []
sebeta: []
dfe: 57
covb: []
errorparam: 0.0809
rmse: 0.0775
ires: [66x1 double]
pres: [66x1 double]
iwres: [66x1 double]
pwres: [66x1 double]
cwres: [66x1 double]
```

br =

-0.2255	0.0063	0.1600	0.1773	-0.3269	0.1157
0.0350	-0.1384	0.0058	0.0431	0.0093	-0.0453

-0.0010	-0.0198	0.0137	-0.0757	0.0478	-0.0076

Plot the data along with an overall population fit

```
clf
phi = [beta(1), exp(beta(2)), beta(3), exp(beta(4))];
h = gscatter(time, concentration, subject);
xlabel('Time (hours)')
ylabel('Concentration (mcg/ml)')
title('{\bf Indomethacin Elimination}')
xx = linspace(0,8);
line(xx,model(phi,xx), 'linewidth',2, 'color', 'k')
```

Plot individual curves based on random-effect estimates.

```
for j=1:6
    phir = [beta(1)+br(1,j), exp(beta(2)+br(2,j)), ...
            beta(3)+br(3,j), exp(beta(4)+br(4,j))];
    line(xx,model(phir,xx),'color',get(h(j),'color'))
end
```

Algorithms

In order to estimate the parameters of a nonlinear mixed effects model, we would like to choose the parameter values that maximize a likelihood function. These values are called the maximum likelihood estimates. The likelihood function can be written in the form

$$p(y|\beta, \sigma^2, \Sigma) = \int p(y|\beta, b, \sigma^2)p(b|\Sigma)db$$

where

- y is the response data
- β is the vector of population coefficients
- σ^2 is the residual variance
- Σ is the covariance matrix for the random effects
- b is the set of unobserved random effects

Each $p()$ function on the right-hand-side is a normal (Gaussian) likelihood function that may depend on covariates.

Since the integral does not have a closed form, it is difficult to find parameters that maximize it. Delyon, Lavielle, and Moulines [1] proposed to find the maximum likelihood estimates using an Expectation-Maximization (EM) algorithm in which the E step is replaced by a stochastic procedure. They called their algorithm SAEM, for Stochastic Approximation EM. They demonstrated that this

algorithm has desirable theoretical properties, including convergence under practical conditions and convergence to a local maximum of the likelihood function. Their proposal involves three steps:

- 1 Simulation: Generate simulated values of the random effects b from the posterior density $p(b|\Sigma)$ given the current parameter estimates.
- 2 Stochastic approximation: Update the expected value of the loglikelihood function by taking its value from the previous step, and moving part way toward the average value of the loglikelihood calculated from the simulated random effects.
- 3 Maximization step: Choose new parameter estimates to maximize the loglikelihood function given the simulated values of the random effects.

`nlinfit` | `nlmefit` | `nlpredci`

Topics

“Mixed-Effects Models” on page 13-17

“Grouping Variables” on page 2-45

Introduced in R2010a

nlparci

Nonlinear regression parameter confidence intervals

Syntax

```
ci = nlparci(beta,resid,'covar',sigma)
ci = nlparci(beta,resid,'jacobian',J)
ci = nlparci(...,'alpha',alpha)
```

Description

`ci = nlparci(beta,resid,'covar',sigma)` returns the 95% confidence intervals `ci` for the nonlinear least squares parameter estimates `beta`. Before calling `nlparci`, use `nlinfit` to fit a nonlinear regression model and get the coefficient estimates `beta`, residuals `resid`, and estimated coefficient covariance matrix `sigma`.

`ci = nlparci(beta,resid,'jacobian',J)` is an alternative syntax that also computes 95% confidence intervals. `J` is the Jacobian computed by `nlinfit`. If the `'robust'` option is used with `nlinfit`, use the `'covar'` input rather than the `'jacobian'` input so that the required `sigma` parameter takes the robust fitting into account.

`ci = nlparci(...,'alpha',alpha)` returns $100(1-\text{alpha})\%$ confidence intervals.

`nlparci` treats NaNs in `resid` or `J` as missing values, and ignores the corresponding observations.

The confidence interval calculation is valid for systems where the length of `resid` exceeds the length of `beta` and `J` has full column rank. When `J` is ill-conditioned, confidence intervals may be inaccurate.

Examples

Fit to exponential decay

Suppose you have data, and want to fit a model of the form

$$y_i = a_1 + a_2 \exp(-a_3 x_i) + \varepsilon_i.$$

Here the a_i are the parameters you want to estimate, x_i are the data points, the y_i are the responses, and the ε_i are noise terms.

- 1 Write a function handle that represents the model:

```
mdl = @(a,x)(a(1) + a(2)*exp(-a(3)*x));
```

- 2 Generate synthetic data with parameters `a = [1;3;2]`, with the `x` data points distributed exponentially with parameter 2, and normally distributed noise with standard deviation `0.1`:

```
rng(9845,'twister') % for reproducibility
a = [1;3;2];
x = exprnd(2,100,1);
epsn = normrnd(0,0.1,100,1);
y = mdl(a,x) + epsn;
```

- 3 Fit the model to data starting from the arbitrary guess $a_0 = [2;2;2]$:

```
a0 = [2;2;2];  
[ahat,r,J,cov,mse] = nlinfit(x,y,mdl,a0);  
ahat
```

```
ahat =  
    1.0153  
    3.0229  
    2.1070
```

- 4 Check whether $[1;3;2]$ is in a 95% confidence interval using the Jacobian argument in `nlparci`:

```
ci = nlparci(ahat,r,'Jacobian',J)
```

```
ci =  
    0.9869    1.0438  
    2.9401    3.1058  
    1.9963    2.2177
```

- 5 You can obtain the same result using the covariance argument:

```
ci = nlparci(ahat,r,'covar',cov)
```

```
ci =  
    0.9869    1.0438  
    2.9401    3.1058  
    1.9963    2.2177
```

See Also

`nlinfit` | `nlpredci`

Introduced before R2006a

nlpredci

Nonlinear regression prediction confidence intervals

Syntax

```
[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB)
[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB,Name,Value)
```

```
[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J)
[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J,Name,Value)
```

Description

`[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB)` returns predictions, `Ypred`, and 95% confidence interval half-widths, `delta`, for the nonlinear regression model `modelfun` at input values `X`. Before calling `nlpredci`, use `nlinfit` to fit `modelfun` and get the estimated coefficients, `beta`, residuals, `R`, and variance-covariance matrix, `CovB`.

`[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB,Name,Value)` uses additional options specified by one or more name-value pair arguments.

`[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J)` returns predictions, `Ypred`, and 95% confidence interval half-widths, `delta`, for the nonlinear regression model `modelfun` at input values `X`. Before calling `nlpredci`, use `nlinfit` to fit `modelfun` and get the estimated coefficients, `beta`, residuals, `R`, and Jacobian, `J`.

If you use a robust option with `nlinfit`, then you should use the `Covar` syntax rather than the `Jacobian` syntax. The variance-covariance matrix, `CovB`, is required to properly take the robust fitting into account.

`[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J,Name,Value)` uses additional options specified by one or more name-value pair arguments.

Examples

Confidence Interval for Nonlinear Regression Curve

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the initial values in `beta0`.

```
[beta,R,J] = nlinfit(X,y,@hougen,beta0);
```

Obtain the predicted response and 95% confidence interval half-width for the value of the curve at average reactant levels.

```
[ypred,delta] = nlpredci(@hougen,mean(X),beta,R,'Jacobian',J)
ypred = 5.4622
delta = 0.1921
```

Compute the 95% confidence interval for the value of the curve.

```
[ypred-delta,ypred+delta]
ans = 1×2
    5.2702    5.6543
```

Prediction Interval for New Observation

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the initial values in beta0.

```
[beta,R,J] = nlinfit(X,y,@hougen,beta0);
```

Obtain the predicted response and 95% prediction interval half-width for a new observation with reactant levels [100,100,100].

```
[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,...
    'PredOpt','observation')
ypred = 1.8346
delta = 0.5101
```

Compute the 95% prediction interval for the new observation.

```
[ypred-delta,ypred+delta]
ans = 1×2
    1.3245    2.3447
```

Simultaneous Confidence Intervals for Robust Fit Curve

Generate sample data from the nonlinear regression model $y = b_1 + b_2 \cdot \exp\{b_3 x\} + \epsilon$, where b_1 , b_2 , and b_3 are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
```

```
rng('default') % for reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Fit the nonlinear model using robust fitting options.

```
opts = statset('nlinfit');
opts.RobustWgtFun = 'bisquare';
beta0 = [2;2;2];
[beta,R,J,CovB,MSE] = nlinfit(x,y,modelfun,beta0,opts);
```

Plot the fitted regression model and simultaneous 95% confidence bounds.

```
xrange = min(x):.01:max(x);
[ypred,delta] = nlpredci(modelfun,xrange,beta,R,'Covar',CovB,...
    'MSE',MSE,'SimOpt','on');
lower = ypred - delta;
upper = ypred + delta;

figure()
plot(x,y,'ko') % observed data
hold on
plot(xrange,ypred,'k','LineWidth',2)
plot(xrange,[lower;upper],'r--','LineWidth',1.5)
```

Confidence Interval Using Observation Weights

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Specify a function handle for observation weights, then fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
a = 1; b = 1;
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
[beta,R,J,CovB] = nlinfit(X,y,@hougen,beta0,'Weights',weights);
```

Compute the 95% prediction interval for a new observation with reactant levels [100,100,100] using the observation weight function.

```
[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,...
                        'PredOpt','observation','Weights',weights);
[ypred-delta,ypred+delta]
```

```
ans = 1x2
```

```
    1.5264    2.1033
```

Confidence Interval Using Nonconstant Error Model

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error variance model.

```
[beta,R,J,CovB,MSE,S] = nlinfit(X,y,@hougen,beta0,'ErrorModel','combined');
```

Compute the 95% prediction interval for a new observation with reactant levels [100,100,100] using the fitted error variance model.

```
[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,...
                        'PredOpt','observation','ErrorModelInfo',S);
[ypred-delta,ypred+delta]
```

```
ans = 1x2
```

```
    1.3245    2.3447
```

Input Arguments

modelfun — Nonlinear regression model function

function handle

Nonlinear regression model function, specified as a function handle. `modelfun` must accept two input arguments, a coefficient vector and an array X —in that order—and return a vector of fitted response values.

For example, to specify the `hougen` nonlinear regression function, use the function handle `@hougen`.

Data Types: `function_handle`

X — Input values for predictions

matrix

Input values for predictions, specified as a matrix. `nlpredci` makes a prediction for the covariates in each row of X . There should be a column in X for each coefficient in the model.

Data Types: `single` | `double`

beta — Estimated regression coefficients

vector returned by `nlinfit`

Estimated regression coefficients, specified as the vector of fitted coefficients returned by a previous call to `nlinfit`.

Data Types: `single` | `double`

R — Residuals

vector returned by `nlinfit`

Residuals for the fitted `modelfun`, specified as the vector of residuals returned by a previous call to `nlinfit`.

CovB — Estimated variance-covariance matrix

matrix returned by `nlinfit`

Estimated variance-covariance matrix for the fitted coefficients, `beta`, specified as the variance-covariance matrix returned by a previous call to `nlinfit`.

J — Estimated Jacobian

matrix returned by `nlinfit`

Estimated Jacobian of the nonlinear regression model, `modelfun`, specified as the Jacobian matrix returned by a previous call to `nlinfit`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Alpha', 0.1, 'PredOpt', 'observation'` specifies 90% prediction intervals for new observations.

Alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level for the confidence interval, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1). If Alpha has value α , then `nlpredci` returns intervals with $100 \times (1 - \alpha)\%$ confidence level.

The default confidence level is 95% ($\alpha = 0.05$).

Example: 'Alpha', 0.1

Data Types: single | double

ErrorModelInfo — Information about error model fit

structure returned by `nlinfit`

Information about the error model fit, specified as the comma-separated pair consisting of 'ErrorModelInfo' and a structure returned by a previous call to `nlinfit`.

`ErrorModelInfo` only has an effect on the returned prediction interval when `PredOpt` has the value 'observation'. If you do not use `ErrorModelInfo`, then `nlpredci` assumes the error variance model is 'constant'.

The error model structure returned by `nlinfit` has the following fields:

<code>ErrorModel</code>	Chosen error model
<code>ErrorParameters</code>	Estimated error parameters
<code>ErrorVariance</code>	Function handle that accepts an N -by- p matrix, X , and returns an N -by-1 vector of error variances using the estimated error model
<code>MSE</code>	Mean squared error
<code>ScheffeSimPred</code>	Scheffé parameter for simultaneous prediction intervals when using the estimated error model
<code>WeightFunction</code>	Logical with value <code>true</code> if you used a custom weight function previously in <code>nlinfit</code>
<code>FixedWeights</code>	Logical with value <code>true</code> if you used fixed weights previously in <code>nlinfit</code>
<code>RobustWeightFunction</code>	Logical with value <code>true</code> if you used robust fitting previously in <code>nlinfit</code>

MSE — Mean squared error

MSE returned by `nlinfit`

Mean squared error (MSE) for the fitted nonlinear regression model, specified as the comma-separated pair consisting of 'MSE' and the MSE value returned by a previous call to `nlinfit`.

If you use a robust option with `nlinfit`, then you must specify the MSE when predicting new observations to properly take the robust fitting into account. If you do not specify the MSE, then `nlpredci` computes the MSE from the residuals, R , and does not take the robust fitting into account.

For example, if `mse` is the MSE value returned by `nlinfit`, then you can specify 'MSE', `mse`.

Data Types: single | double

PredOpt — Prediction interval to compute

'curve' (default) | 'observation'

Prediction interval to compute, specified as the comma-separated pair consisting of 'PredOpt' and either 'curve' or 'observation'.

- If you specify the value 'curve', then `nlpredci` returns confidence intervals for the estimated curve (function value) at the observations X .
- If you specify the value 'observation', then `nlpredci` returns prediction intervals for new observations at X .

If you specify 'observation' after using a robust option with `nlfit`, then you must also specify a value for MSE to provide the robust estimate of the mean squared error.

Example: 'PredOpt', 'observation'

SimOpt — Indicator for specifying simultaneous bounds

'off' (default) | 'on'

Indicator for specifying simultaneous bounds, specified as the comma-separated pair consisting of 'SimOpt' and either 'off' or 'on'. Use the value 'off' to compute nonsimultaneous bounds, and 'on' for simultaneous bounds.

Weights — Observation weights

vector | function handle

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of positive scalar values or a function handle. The default is no weights.

- If you specify a vector of weights, then it must have the same number of elements as the number of observations (rows) in X .
- If you specify a function handle for the weights, then it must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, W , `nlpredci` estimates the error variance at observation i by $mse * (1/W(i))$, where `mse` is the mean squared error value specified using MSE.

Example: 'Weights', @WFun

Data Types: double | single | function_handle

Output Arguments**Ypred — Predicted responses**

vector

Predicted responses, returned as a vector with the same number of rows as X .

delta — Confidence interval half-widths

vector

Confidence interval half-widths, returned as a vector with the same number of rows as X . By default, `delta` contains the half-widths for nonsimultaneous 95% confidence intervals for `model fun` at the observations in X . You can compute the lower and upper bounds of the confidence intervals as `Ypred-delta` and `Ypred+delta`, respectively.

If 'PredOpt' has value 'observation', then delta contains the half-widths for prediction intervals of new observations at the values in X.

More About

Confidence Intervals for Estimable Predictions

When the estimated model Jacobian is not of full rank, then it might not be possible to construct sensible confidence intervals at all prediction points. In this case, `nlpredci` still tries to construct confidence intervals for any estimable prediction points.

For example, suppose you fit the linear function $f(\mathbf{x}_i, \beta) = \beta_1 x_{i1} + \beta_2 x_{i2} + \beta_3 x_{i3}$ at the points in the design matrix

$$\mathbf{X} = \begin{pmatrix} 1 & 1 & 0 \\ 1 & 1 & 0 \\ 1 & 1 & 0 \\ 1 & 0 & 1 \\ 1 & 0 & 1 \\ 1 & 0 & 1 \end{pmatrix}.$$

The estimated Jacobian at the values in \mathbf{X} is the design matrix itself, $\mathbf{J} = \mathbf{X}$. Thus, the Jacobian is not of full rank:

```
rng('default') % For reproducibility
y = randn(6,1);

linfun = @(b,x) x*b;
beta0 = [1;1;1];
X = [repmat([1 1 0],3,1); repmat([1 0 1],3,1)];

[beta,R,J] = nlinfit(X,y,linfun,beta0);

Warning: The Jacobian at the solution is ill-conditioned, and
some model parameters may not be estimated well (they are not
identifiable). Use caution in making predictions.
> In nlinfit at 283
```

In this example, `nlpredci` can only compute prediction intervals at points that satisfy the linear relationship

$$x_{i1} = x_{i2} + x_{i3}.$$

If you try to compute confidence intervals for predictions at nonidentifiable points, `nlpredci` returns NaN for the corresponding interval half-widths:

```
xpred = [1 1 1;0 1 -1;2 1 1];
[ypred,delta] = nlpredci(linfun,xpred,beta,R,'Jacobian',J)

ypred =

-0.0035
 0.0798
-0.0047
```

```
delta =  
  
      NaN  
      3.8102  
      3.8102
```

Here, the first element of `delta` is `NaN` because the first row in `xpred` does not satisfy the required linear dependence, and is therefore not an estimable contrast.

Tips

- To compute confidence intervals for complex parameters or data, you need to split the problem into its real and imaginary parts. When calling `nlinfit`:
 - 1 Define your parameter vector `beta` as the concatenation of the real and imaginary parts of the original parameter vector.
 - 2 Concatenate the real and imaginary parts of the response vector `Y` as a single vector.
 - 3 Modify your model function `modelfun` to accept `X` and the purely real parameter vector, and return a concatenation of the real and imaginary parts of the fitted values.

With the problem formulated this way, `nlinfit` computes real estimates, and confidence intervals are feasible.

Algorithms

- `nlpredci` treats `NaN` values in the residuals, `R`, or the Jacobian, `J`, as missing values, and ignores the corresponding observations.
- If the Jacobian, `J`, does not have full column rank, then some of the model parameters might be nonidentifiable. In this case, `nlpredci` tries to construct confidence intervals for estimable predictions on page 32-3691, and returns `NaN` for those that are not.

`NonLinearModel` | `nlinfit` | `nlparci`

Introduced before R2006a

nnmf

Nonnegative matrix factorization

Syntax

```
[W,H] = nnmf(A,k)
[W,H] = nnmf(A,k,param1,val1,param2,val2,...)
[W,H,D] = nnmf(...)
```

Description

`[W,H] = nnmf(A,k)` factors the nonnegative n -by- m matrix A into nonnegative factors W (n -by- k) and H (k -by- m). The factorization is not exact; $W*H$ is a lower-rank approximation to A . The factors W and H are chosen to minimize the root-mean-squared residual D between A and $W*H$:

$$D = \text{norm}(A-W*H, 'fro')/\text{sqrt}(N*M)$$

The factorization uses an iterative method starting with random initial values for W and H . Because the root-mean-squared residual D may have local minima, repeated factorizations may yield different W and H . Sometimes the algorithm converges to a solution of lower rank than k , which may indicate that the result is not optimal.

W and H are normalized so that the rows of H have unit length. The columns of W are ordered by decreasing length.

`[W,H] = nnmf(A,k,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs from the following table.

Parameter	Value
'algorithm'	Either 'als' (the default) to use an alternating least-squares algorithm, or 'mult' to use a multiplicative update algorithm. In general, the 'als' algorithm converges faster and more consistently. The 'mult' algorithm is more sensitive to initial values, which makes it a good choice when using 'replicates' to find W and H from multiple random starting values.
'w0'	An n -by- k matrix to be used as the initial value for W .
'h0'	A k -by- m matrix to be used as the initial value for H .

Parameter	Value
'options'	<p>An options structure as created by the <code>statset</code> function. <code>nnmf</code> uses the following fields of the options structure:</p> <ul style="list-style-type: none"> • <code>Display</code> — Level of display. Choices: <ul style="list-style-type: none"> • 'off' (default) — No display • 'final' — Display final result • 'iter' — Iterative display of intermediate results • <code>MaxIter</code> — Maximum number of iterations. Default is 100. Unlike in optimization settings, reaching <code>MaxIter</code> iterations is treated as convergence. • <code>TolFun</code> — Termination tolerance on change in size of the residual. Default is $1e-4$. • <code>TolX</code> — Termination tolerance on relative change in the elements of <code>W</code> and <code>H</code>. Default is $1e-4$. • <code>UseParallel</code> — Set to <code>true</code> to compute in parallel. Default is <code>false</code>. • <code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'. • <code>Streams</code> — A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code>, <code>nnmf</code> uses the default stream or streams. If you choose to specify <code>Streams</code>, use a single object except in the case <ul style="list-style-type: none"> • <code>UseParallel</code> is <code>true</code> • <code>UseSubstreams</code> is <code>false</code> <p>In that case, use a cell array the same size as the <code>Parallel</code> pool.</p> <p>To compute in parallel, you need <code>Parallel Computing Toolbox</code>.</p>
'replicates'	<p>The number of times to repeat the factorization, using new random starting values for <code>W</code> and <code>H</code>, except at the first replication if 'w0' and 'h0' are given. This is most beneficial with the 'mult' algorithm. The default is 1.</p>

`[W,H,D] = nnmf(...)` also returns `D`, the root mean square residual.

Examples

Nonnegative Rank-Two Approximation and Biplot

Load the sample data.

```
load fisheriris
```

Compute a nonnegative rank-two approximation of the measurements of the four variables in Fisher's iris data.

```
rng(1) % For reproducibility
[W,H] = nnmf(meas,2);
H
```

```
H = 2×4
```

```
    0.6945    0.2856    0.6220    0.2218
    0.8020    0.5683    0.1834    0.0149
```

The first and third variables in `meas` (sepal length and petal length, with coefficients 0.6945 and 0.6220, respectively) provide relatively strong weights to the first column of `W`. The first and second variables in `meas` (sepal length and sepal width, with coefficients 0.8020 and 0.5683) provide relatively strong weights to the second column of `W`.

Create a biplot of the data and the variables in `meas` in the column space of `W`.

```
biplot(H', 'scores', W, 'varlabels', {'sl', 'sw', 'pl', 'pw'});
axis([0 1.1 0 1.1])
xlabel('Column 1')
ylabel('Column 2')
```

Change Algorithm

Starting from a random array X with rank 20, try a few iterations at several replicates using the multiplicative algorithm:

```
X = rand(100,20)*rand(20,50);
opt = statset('MaxIter',5,'Display','final');
[W0,H0] = nnmf(X,5,'replicates',10,...
               'options',opt,...
               'algorithm','mult');
```

rep	iteration	rms resid	delta x
1	5	0.560887	0.0245182
2	5	0.66418	0.0364471
3	5	0.609125	0.0358355
4	5	0.608894	0.0415491
5	5	0.619291	0.0455135
6	5	0.621549	0.0299965
7	5	0.640549	0.0438758
8	5	0.673015	0.0366856
9	5	0.606835	0.0318931
10	5	0.633526	0.0319591

Final root mean square residual = 0.560887

Continue with more iterations from the best of these results using alternating least squares:

```
opt = statset('Maxiter',1000,'Display','final');
[W,H] = nnmf(X,5,'w0',W0,'h0',H0,...
              'options',opt,...
              'algorithm','als');
```

rep	iteration	rms resid	delta x
1	24	0.257336	0.00271859

Final root mean square residual = 0.257336

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2008a

nominal

(Not Recommended) Arrays for nominal data

Note The `nominal` and `ordinal` array data types are not recommended. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

Description

Nominal data are discrete, nonnumeric values that do not have a natural ordering. `nominal` array objects provide efficient storage and convenient manipulation of such data, while also maintaining meaningful labels for the values.

You can manipulate `nominal` arrays like ordinary numeric arrays, by subscripting, concatenating, and reshaping. Use `nominal` arrays as grouping variables when the elements indicate the group to which an observation belongs.

Creation

Syntax

```
B = nominal(X)
B = nominal(X,labels)
B = nominal(X,labels,levels)

B = nominal(X,labels,[],edges)
```

Description

`B = nominal(X)` creates a nominal array `B` from the array `X`. `nominal` creates the levels of `B` from the sorted unique values in `X`, and creates default labels for the levels.

`B = nominal(X,labels)` labels the levels in `B` according to `labels`.

`B = nominal(X,labels,levels)` creates a nominal array with possible levels defined by `levels`.

`B = nominal(X,labels,[],edges)` creates a nominal array by binning the numeric array `X` with bin edges given by the numeric vector `edges`.

Input Arguments

X — Input array

numeric | logical | character | string | categorical | cell array of character vectors

Input array to convert to `nominal`, specified as a numeric, logical, character, string, or categorical array, or a cell array of character vectors. The levels of the resulting `nominal` array correspond to the sorted unique values in `X`.

labels — Labels for discrete levels

character array | string array | cell array of character vectors

Labels for the discrete levels, specified as a character array, string array, or cell array of character vectors. By default, `nominal` assigns labels to the levels in `B` in order of the sorted unique values in `X`.

You can include duplicate labels in `labels` to merge multiple values in `X` into a single level in `B`.

Data Types: `char` | `string` | `cell`

levels — Possible nominal levels

vector

Possible nominal levels for the output `nominal` array, specified as a vector whose values can be compared to those in `X` using the equality operator. `nominal` assigns labels to each level from the corresponding elements of `labels`. If `X` contains any values not present in `levels`, the levels of the corresponding elements of `B` are undefined.

edges — Bin edges

numeric vector

Bin edges used to create the nominal array by binning a numeric array, specified as a numeric vector. The uppermost bin includes values equal to the rightmost edge. `nominal` assigns labels to each level in the resulting nominal array from the corresponding elements of `labels`. When you specify the `edges` input argument, it must have one more element than `labels`.

Output Arguments**B — Nominal array**

`nominal` array object

Nominal array, returned as a `nominal` array object.

By default, an element of `B` is undefined if the corresponding element of `X` is `NaN` (when `X` is numeric), an empty character vector (when `X` is a character), an empty or missing string (when `X` is a string), or undefined (when `X` is categorical). `nominal` treats such elements as undefined or missing and does not include entries for them among the possible levels. To create an explicit level for such elements instead of treating them as undefined, use the `levels` input argument and include `NaN`, the empty character vector, the empty or missing string, or an undefined element.

Properties**labels — Level labels**

cell array of character vectors

This property is read-only.

Level labels, specified as a cell array of character vectors. Access labels using `getLabels`.

Data Types: `cell`

undefLabel — Label for undefined levels

'<undefined>' (default)

This property is read-only.

Label for undefined levels, specified as '<undefined>'. You can find undefined elements in categorical arrays by using `isundefined`.

Object Functions

<code>addlevels</code>	(Not Recommended) Add levels to nominal or ordinal arrays
<code>droplevels</code>	(Not Recommended) Drop levels from a nominal or ordinal array
<code>getlabels</code>	(Not Recommended) Access nominal or ordinal array labels
<code>getlevels</code>	(Not Recommended) Access nominal or ordinal array levels
<code>islevel</code>	(Not Recommended) Determine if levels are in nominal or ordinal array
<code>levelcounts</code>	(Not Recommended) Element counts by level of a nominal or ordinal array
<code>mergelevels</code>	(Not Recommended) Merge levels of nominal or ordinal arrays
<code>reorderlevels</code>	(Not Recommended) Reorder levels of nominal or ordinal arrays
<code>setlabels</code>	(Not Recommended) Assign labels to levels of nominal or ordinal arrays

The following is a partial list of the many other MATLAB array functions you can use with nominal arrays. For a complete list, see “Other MATLAB Functions Supporting Nominal and Ordinal Arrays” on page 2-2.

<code>double</code>	Double-precision arrays
<code>histogram</code>	Histogram plot
<code>isequal</code>	Determine array equality
<code>isundefined</code>	Find undefined elements in categorical array
<code>pie</code>	Pie chart
<code>summary</code>	Print summary of table, timetable, or categorical array
<code>times</code>	Multiplication

Examples

Create and Label Nominal Arrays

Create nominal arrays from a cell array of character vectors and from integer data. Provide explicit labels.

Create a nominal array from a cell array of character vectors with values 'r', 'g', and 'b'. Label these levels 'red', 'green', and 'blue', respectively. `nominal` assigns the labels according to the sorted (alphabetical) order of the elements in `X`.

```
X = {'r' 'b' 'g'; 'g' 'r' 'b'; 'b' 'r' 'g'}
```

```
X = 3x3 cell
    {'r'}    {'b'}    {'g'}
    {'g'}    {'r'}    {'b'}
    {'b'}    {'r'}    {'g'}
```

```
labels = {'blue', 'green', 'red'};
B = nominal(X, labels)
```

```
B = 3x3 nominal
    red    blue    green
    green  red     blue
    blue   red     green
```

Create a nominal array from integer data with values 1 to 4, merging odd and even values into two nominal levels with the labels 'odd' and 'even'. Merge the values by duplicating the labels.

```
X = randi([1 4],5,2)
```

```
X = 5x2
```

```
 4     1
 4     2
 1     3
 4     4
 3     4
```

```
labels = {'odd','even','odd','even'};
```

```
B = nominal(X,labels)
```

```
B = 5x2 nominal
```

```
 even     odd
 even     even
 odd      odd
 even     even
 odd      even
```

Create and Manipulate Nominal Arrays

Create a nominal array from data in a cell array.

```
X = {'r','b','g';'g','r','b';'b','r','g'};
```

```
labels = {'blue','green','red'};
```

```
colors = nominal(X,labels)
```

```
colors = 3x3 nominal
```

```
 red     blue     green
 green   red      blue
 blue    red      green
```

Identify the elements in `colors` that are members of the level 'red'. A value of 1 in the resulting array indicates that the corresponding element of `colors` is a member of 'red'.

```
colors == 'red'
```

```
ans = 3x3 logical array
```

```
 1     0     0
 0     1     0
 0     1     0
```

Identify the elements in `colors` that are members of either the level 'red' or 'blue'.

```
ismember(colors,{'red','blue'})
```

```
ans = 3x3 logical array
```

```
1 1 0
0 1 1
1 1 0
```

Merge the elements of the 'red' and 'blue' levels into a new level labeled 'purple'.

```
colors = mergelevels(colors,{'red','blue'},'purple')
```

```
colors = 3x3 nominal
  purple    purple    green
  green     purple    purple
  purple    purple    green
```

Display the levels of colors.

```
getlevels(colors)
```

```
ans = 1x2 nominal
  purple    green
```

Summarize the number of elements in each level. By default, `summary` returns counts for each column of the input array.

```
summary(colors)
```

```
  purple    2    3    1
  green     1    0    2
```

Create a pie chart for the data in colors.

```
pie(colors)
```

notify

Class: grandstream

Notify listeners of event

Syntax

```
notify(h, 'eventname')  
notify(h, 'eventname', data)
```

Description

`notify(h, 'eventname')` notifies listeners added to the event named `eventname` on handle object array `h` that the event is taking place. `h` is the array of handles to objects triggering the event, and `eventname` must be a character vector.

`notify(h, 'eventname', data)` provides a way of encapsulating information about an event which can then be accessed by each registered listener. `data` must belong to the `event.eventdata` class.

See Also

`addlistener` | `event.EventData` | `events` | `grandstream`

NonLinearModel class

Nonlinear regression model class

Description

An object comprising training data, model description, diagnostic information, and fitted coefficients for a nonlinear regression. Predict model responses with the `predict` or `feval` methods.

Construction

Create a `NonLinearModel` object using `fitnlm`.

Properties

CoefficientCovariance — Covariance matrix of coefficient estimates

numeric matrix

This property is read-only.

Covariance matrix of coefficient estimates, specified as a p -by- p matrix of numeric values. p is the number of coefficients in the fitted model.

For details, see “Coefficient Standard Errors and Confidence Intervals” on page 11-57.

Data Types: `single` | `double`

CoefficientNames — Coefficient names

cell array of character vectors

This property is read-only.

Coefficient names, specified as a cell array of character vectors, each containing the name of the corresponding term.

Data Types: `cell`

Coefficients — Coefficient values

table

This property is read-only.

Coefficient values, specified as a table. `Coefficients` contains one row for each coefficient and these columns:

- `Estimate` — Estimated coefficient value
- `SE` — Standard error of the estimate
- `tStat` — t -statistic for a test that the coefficient is zero
- `pValue` — p -value for the t -statistic

Use `anova` (only for a linear regression model) or `coefTest` to perform other tests on the coefficients. Use `coefCI` to find the confidence intervals of the coefficient estimates.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the estimated coefficient vector in the model `mdl`:

```
beta = mdl.Coefficients.Estimate
```

Data Types: `table`

Diagnosics — Diagnostic information

`table`

This property is read-only.

Diagnostic information for the model, specified as a table. Diagnostics can help identify outliers and influential observations. `Diagnosics` contains the following fields.

Field	Meaning	Utility
Leverage	Diagonal elements of <code>HatMatrix</code>	Leverage indicates to what extent the predicted value for an observation is determined by the observed value for that observation. A value close to 1 indicates that the prediction is largely determined by that observation, with little contribution from the other observations. A value close to 0 indicates the fit is largely determined by the other observations. For a model with <code>P</code> coefficients and <code>N</code> observations, the average value of <code>Leverage</code> is <code>P/N</code> . An observation with <code>Leverage</code> larger than <code>2*P/N</code> can be regarded as having high leverage.
CooksDistance	Cook's measure of scaled change in fitted values	<code>CooksDistance</code> is a measure of scaled change in fitted values. An observation with <code>CooksDistance</code> larger than three times the mean Cook's distance can be an outlier.
HatMatrix	Projection matrix to compute fitted from observed responses	<code>HatMatrix</code> is an <code>N</code> -by- <code>N</code> matrix such that <code>Fitted = HatMatrix*Y</code> , where <code>Y</code> is the response vector and <code>Fitted</code> is the vector of fitted response values.

Data Types: `table`

DFE — Degrees of freedom for error

positive integer

This property is read-only.

Degrees of freedom for the error (residuals), equal to the number of observations minus the number of estimated coefficients, specified as a positive integer.

Data Types: `double`

Fitted — Fitted response values based on input data

numeric vector

This property is read-only.

Fitted (predicted) values based on the input data, specified as a numeric vector. `fitnlm` attempts to make `Fitted` as close as possible to the response data.

Data Types: `single` | `double`

Formula — Model information

`NonLinearFormula` object

This property is read-only.

Model information, specified as a `NonLinearFormula` object.

Display the formula of the fitted model `mdl` by using dot notation.

`mdl.Formula`

Iterative — Information about fitting process

structure

This property is read-only.

Information about the fitting process, specified as a structure with the following fields:

- `InitialCoefs` — Initial coefficient values (the `beta0` vector)
- `IterOpts` — Options included in the `Options` name-value pair argument for `fitnlm`.

Data Types: `struct`

LogLikelihood — Loglikelihood

numeric value

This property is read-only.

Loglikelihood of the model distribution at the response values, specified as a numeric value. The mean is fitted from the model, and other parameters are estimated as part of the model fit.

Data Types: `single` | `double`

ModelCriterion — Criterion for model comparison

structure

This property is read-only.

Criterion for model comparison, specified as a structure with these fields:

- `AIC` — Akaike information criterion. $AIC = -2 \cdot \log L + 2 \cdot m$, where $\log L$ is the loglikelihood and m is the number of estimated parameters.
- `AICc` — Akaike information criterion corrected for the sample size. $AICc = AIC + (2 \cdot m \cdot (m + 1)) / (n - m - 1)$, where n is the number of observations.
- `BIC` — Bayesian information criterion. $BIC = -2 \cdot \log L + m \cdot \log(n)$.
- `CAIC` — Consistent Akaike information criterion. $CAIC = -2 \cdot \log L + m \cdot (\log(n) + 1)$.

Information criteria are model selection tools that you can use to compare multiple models fit to the same data. These criteria are likelihood-based measures of model fit that include a penalty for complexity (specifically, the number of parameters). Different information criteria are distinguished by the form of the penalty.

When you compare multiple models, the model with the lowest information criterion value is the best-fitting model. The best-fitting model can vary depending on the criterion used for model comparison.

To obtain any of the criterion values as a scalar, index into the property using dot notation. For example, obtain the AIC value `aic` in the model `mdl`:

```
aic = mdl.ModelCriterion.AIC
```

Data Types: `struct`

MSE — Mean squared error

numeric value

This property is read-only.

Mean squared error, specified as a numeric value. The mean squared error is an estimate of the variance of the error term in the model.

Data Types: `single` | `double`

NumCoefficients — Number of model coefficients

positive integer

This property is read-only.

Number of coefficients in the fitted model, specified as a positive integer. `NumCoefficients` is the same as `NumEstimatedCoefficients` for `NonLinearModel` objects. `NumEstimatedCoefficients` is equal to the degrees of freedom for regression.

Data Types: `double`

NumEstimatedCoefficients — Number of estimated coefficients

positive integer

This property is read-only.

Number of estimated coefficients in the fitted model, specified as a positive integer. `NumEstimatedCoefficients` is the same as `NumCoefficients` for `NonLinearModel` objects. `NumEstimatedCoefficients` is equal to the degrees of freedom for regression.

Data Types: `double`

NumPredictors — Number of predictor variables

positive integer

This property is read-only.

Number of predictor variables used to fit the model, specified as a positive integer.

Data Types: `double`

NumVariables — Number of variables

positive integer

This property is read-only.

Number of variables in the input data, specified as a positive integer. `NumVariables` is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector.

`NumVariables` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: `double`

ObservationInfo – Observation information

table

This property is read-only.

Observation information, specified as an n -by-4 table, where n is equal to the number of rows of input data. `ObservationInfo` contains the columns described in this table.

Column	Description
Weights	Observation weights, specified as a numeric value. The default value is 1.
Excluded	Indicator of excluded observations, specified as a logical value. The value is <code>true</code> if you exclude the observation from the fit by using the 'Exclude' name-value pair argument.
Missing	Indicator of missing observations, specified as a logical value. The value is <code>true</code> if the observation is missing.
Subset	Indicator of whether or not the fitting function uses the observation, specified as a logical value. The value is <code>true</code> if the observation is not excluded or missing, meaning the fitting function uses the observation.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the weight vector `w` of the model `mdl`:

```
w = mdl.ObservationInfo.Weights
```

Data Types: `table`

ObservationNames – Observation names

cell array of character vectors

This property is read-only.

Observation names, specified as a cell array of character vectors containing the names of the observations used in the fit.

- If the fit is based on a table or dataset containing observation names, `ObservationNames` uses those names.
- Otherwise, `ObservationNames` is an empty cell array.

Data Types: `cell`

PredictorNames – Names of predictors used to fit model

cell array of character vectors

This property is read-only.

Names of predictors used to fit the model, specified as a cell array of character vectors.

Data Types: `cell`

Residuals — Residuals for fitted model

table

This property is read-only.

Residuals for the fitted model, specified as a table that contains one row for each observation and the columns described in this table.

Column	Description
Raw	Observed minus fitted values
Pearson	Raw residuals divided by the root mean squared error (RMSE)
Standardized	Raw residuals divided by their estimated standard deviation
Studentized	Raw residual divided by an independent estimate of the residual standard deviation. The residual for observation i is divided by an estimate of the error standard deviation based on all observations except observation i .

Use `plotResiduals` to create a plot of the residuals. For details, see “Residuals” on page 11-79.

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) or excluded values (in `ObservationInfo.Excluded`) contain NaN values.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the raw residual vector `r` in the model `mdl`:

```
r = mdl.Residuals.Raw
```

Data Types: `table`

ResponseName — Response variable name

character vector

This property is read-only.

Response variable name, specified as a character vector.

Data Types: `char`

RMSE — Root mean squared error

numeric value

This property is read-only.

Root mean squared error, specified as a numeric value. The root mean squared error is an estimate of the standard deviation of the error term in the model.

Data Types: `single` | `double`

Robust — Robust fit information

structure

This property is read-only.

Robust fit information, specified as a structure with the following fields:

Field	Description
WgtFun	Robust weighting function, such as 'bisquare' (see <code>robustfit</code>)
Tune	Value specified for tuning parameter (can be [])
Weights	Vector of weights used in final iteration of robust fit

This structure is empty unless `fitnlm` constructed the model using robust regression.

Data Types: `struct`

Rsquared — R-squared value for model

structure

This property is read-only.

R-squared value for the model, specified as a structure with two fields:

- **Ordinary** — Ordinary (unadjusted) R-squared
- **Adjusted** — R-squared adjusted for the number of coefficients

The R-squared value is the proportion of the total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:

$$Rsquared = SSR/SST,$$

where SST is the total sum of squares, and SSR is the regression sum of squares.

For details, see “Coefficient of Determination (R-Squared)” on page 11-60.

To obtain either of these values as a scalar, index into the property using dot notation. For example, obtain the adjusted R-squared value in the model `mdl`:

```
r2 = mdl.Rsquared.Adjusted
```

Data Types: `struct`

SSE — Sum of squared errors

numeric value

This property is read-only.

Sum of squared errors (residuals), specified as a numeric value.

Data Types: `single` | `double`

SSR — Regression sum of squares

numeric value

This property is read-only.

Regression sum of squares, specified as a numeric value. The regression sum of squares is equal to the sum of squared deviations of the fitted values from their mean.

Data Types: `single` | `double`

SST — Total sum of squares

numeric value

This property is read-only.

Total sum of squares, specified as a numeric value. The total sum of squares is equal to the sum of squared deviations of the response vector y from the mean (\bar{y}).

Data Types: `single` | `double`

VariableInfo — Information about variables

table

This property is read-only.

Information about variables contained in `Variables`, specified as a table with one row for each variable and the columns described in this table.

Column	Description
<code>Class</code>	Variable class, specified as a cell array of character vectors, such as <code>'double'</code> and <code>'categorical'</code>
<code>Range</code>	Variable range, specified as a cell array of vectors <ul style="list-style-type: none"> • Continuous variable — Two-element vector $[min, max]$, the minimum and maximum values • Categorical variable — Vector of distinct variable values
<code>InModel</code>	Indicator of which variables are in the fitted model, specified as a logical vector. The value is <code>true</code> if the model includes the variable.
<code>IsCategorical</code>	Indicator of categorical variables, specified as a logical vector. The value is <code>true</code> if the variable is categorical.

`VariableInfo` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: `table`

VariableNames — Names of variables

cell array of character vectors

This property is read-only.

Names of variables, specified as a cell array of character vectors.

- If the fit is based on a table or dataset, this property provides the names of the variables in the table or dataset.
- If the fit is based on a predictor matrix and response vector, `VariableNames` contains the values specified by the `'VarNames'` name-value pair argument of the fitting method. The default value of `'VarNames'` is `{'x1', 'x2', ..., 'xn', 'y'}`.

`VariableNames` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: `cell`

Variables — Input data

table

This property is read-only.

Input data, specified as a table. `Variables` contains both predictor and response values. If the fit is based on a table or dataset array, `Variables` contains all the data from the table or dataset array. Otherwise, `Variables` is a table created from the input data matrix X and the response vector y .

`Variables` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: table

Methods

<code>coefCI</code>	Confidence intervals of coefficient estimates of nonlinear regression model
<code>coefTest</code>	Linear hypothesis test on nonlinear regression model coefficients
<code>disp</code>	Display nonlinear regression model
<code>feval</code>	Evaluate nonlinear regression model prediction
<code>fit</code>	(Not Recommended) Fit nonlinear regression model
<code>plotDiagnostics</code>	Plot diagnostics of nonlinear regression model
<code>plotResiduals</code>	Plot residuals of nonlinear regression model
<code>plotSlice</code>	Plot of slices through fitted nonlinear regression surface
<code>predict</code>	Predict response of nonlinear regression model
<code>random</code>	Simulate responses for nonlinear regression model

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Fit a Nonlinear Regression Model

Fit a nonlinear regression model for auto mileage based on the `carbig` data. Predict the mileage of an average car.

Load the sample data. Create a matrix X containing the measurements for the horsepower (Horsepower) and weight (Weight) of each car. Create a vector y containing the response values in miles per gallon (MPG).

```
load carbig
X = [Horsepower,Weight];
y = MPG;
```

Fit a nonlinear regression model.

```
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
```

```
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(X,y,modelfun,beta0)
```

```
mdl =
Nonlinear regression model:
    y ~ b1 + b2*x1^b3 + b4*x2^b5
```

Estimated Coefficients:				
	Estimate	SE	tStat	pValue
b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

```
Number of observations: 392, Error degrees of freedom: 387
Root Mean Squared Error: 3.96
R-Squared: 0.745, Adjusted R-Squared 0.743
F-statistic vs. constant model: 283, p-value = 1.79e-113
```

Find the predicted mileage of an average auto. Since the sample data contains some missing (NaN) observations, compute the mean using `nanmean`.

```
Xnew = nanmean(X)
```

```
Xnew = 1×2
103 ×
```

```
    0.1051    2.9794
```

```
MPGnew = predict(mdl,Xnew)
```

```
MPGnew = 21.8073
```

More About

Hat Matrix

The hat matrix H is defined in terms of the data matrix X and the Jacobian matrix J :

$$J_{i,j} = \left. \frac{\partial f}{\partial \beta_j} \right|_{x_i, \beta}$$

Here f is the nonlinear model function, and β is the vector of model coefficients.

The Hat Matrix H is

$$H = J(J^T J)^{-1} J^T.$$

The diagonal elements H_{ii} satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Leverage

Leverage is a measure of the effect of a particular observation on the regression predictions due to the position of that observation in the space of the inputs.

The leverage of observation i is the value of the i th diagonal term h_{ii} of the hat matrix H . Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered an outlier if its leverage substantially exceeds p/n , where n is the number of observations.

Cook's Distance

The Cook's distance D_i of observation i is

$$D_i = \frac{\sum_{j=1}^n (\hat{y}_j - \hat{y}_{j(i)})^2}{p \text{MSE}},$$

where

- \hat{y}_j is the j th fitted response value.
- $\hat{y}_{j(i)}$ is the j th fitted response value, where the fit does not include observation i .
- MSE is the mean squared error.
- p is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{p \text{MSE}} \left(\frac{h_{ii}}{(1 - h_{ii})^2} \right),$$

where e_i is the i th residual.

"Nonlinear Regression" on page 13-2

normcdf

Normal cumulative distribution function

Syntax

```
p = normcdf(x)
p = normcdf(x,mu)
p = normcdf(x,mu,sigma)

[p,pLo,pUp] = normcdf(x,mu,sigma,pCov)
[p,pLo,pUp] = normcdf(x,mu,sigma,pCov,alpha)

___ = normcdf( ___, 'upper' )
```

Description

`p = normcdf(x)` returns the cumulative distribution function (cdf) of the standard normal distribution, evaluated at the values in `x`.

`p = normcdf(x,mu)` returns the cdf of the normal distribution with mean `mu` and unit standard deviation, evaluated at the values in `x`.

`p = normcdf(x,mu,sigma)` returns the cdf of the normal distribution with mean `mu` and standard deviation `sigma`, evaluated at the values in `x`.

`[p,pLo,pUp] = normcdf(x,mu,sigma,pCov)` also returns the 95% confidence bounds `[pLo,pUp]` of `p` when `mu` and `sigma` are estimates. `pCov` is the covariance matrix of the estimated parameters.

`[p,pLo,pUp] = normcdf(x,mu,sigma,pCov,alpha)` specifies the confidence level for the confidence interval `[pLo,pUp]` to be $100(1-\alpha)\%$.

`___ = normcdf(___, 'upper')` returns the complement of the cdf, evaluated at the values in `x`, using an algorithm that more accurately computes the extreme upper-tail probabilities. 'upper' can follow any of the input arguments in the previous syntaxes.

Examples

Standard Normal Distribution cdf

Compute the probability that an observation from a standard normal distribution falls on the interval `[-1 1]`.

```
p = normcdf([-1 1]);
p(2)-p(1)

ans = 0.6827
```

About 68% of the observations from a normal distribution fall within one standard deviation of the mean 0.

Normal Distribution cdf

Compute the cdf values evaluated at the values in `x` for the normal distribution with mean `mu` and standard deviation `sigma`.

```
x = [-2,-1,0,1,2];
mu = 2;
sigma = 1;
p = normcdf(x,mu,sigma)

p = 1x5

    0.0000    0.0013    0.0228    0.1587    0.5000
```

Compute the cdf values evaluated at zero for various normal distributions with different mean parameters.

```
mu = [-2,-1,0,1,2];
sigma = 1;
p = normcdf(0,mu,sigma)

p = 1x5

    0.9772    0.8413    0.5000    0.1587    0.0228
```

Confidence Interval of Normal cdf Value

Find the maximum likelihood estimates (MLEs) of the normal distribution parameters, and then find the confidence interval of the corresponding cdf value.

Generate 1000 normal random numbers from the normal distribution with mean 5 and standard deviation 2.

```
rng('default') % For reproducibility
n = 1000; % Number of samples
x = normrnd(5,2,n,1);
```

Find the MLEs for the distribution parameters (mean and standard deviation) by using `mle`.

```
phat = mle(x)

phat = 1x2

    4.9347    1.9969
```

```
muHat = phat(1);
sigmaHat = phat(2);
```

Estimate the covariance of the distribution parameters by using `normlike`. The function `normlike` returns an approximation to the asymptotic covariance matrix if you pass the MLEs and the samples used to estimate the MLEs.

```
[~,pCov] = normlike([muHat,sigmaHat],x)
pCov = 2x2
    0.0040    -0.0000
   -0.0000     0.0020
```

Find the cdf value at zero and its 95% confidence interval.

```
[p,pLo,pUp] = normcdf(0,muHat,sigmaHat,pCov)
p = 0.0067
pLo = 0.0047
pUp = 0.0095
```

`p` is the cdf value using the normal distribution with the parameters `muHat` and `sigmaHat`. The interval `[pLo,pUp]` is the 95% confidence interval of the cdf evaluated at 0, considering the uncertainty of `muHat` and `sigmaHat` using `pCov`. The 95% confidence interval means the probability that `[pLo,pUp]` contains the true cdf value is 0.95.

Complementary cdf (Tail Distribution)

Determine the probability that an observation from a standard normal distribution will fall on the interval `[10,Inf]`.

```
p1 = 1 - normcdf(10)
p1 = 0
```

`normcdf(10)` is nearly 1, so `p1` becomes 0. Specify `'upper'` so that `normcdf` computes the extreme upper-tail probabilities more accurately.

```
p2 = normcdf(10,'upper')
p2 = 7.6199e-24
```

You can also use `'upper'` to compute a right-tailed p -value.

Test for Normal Distribution Using Function Handle

Use the probability distribution function `normcdf` as a function handle in the chi-square goodness-of-fit test (`chi2gof`).

Test the null hypothesis that the sample data in the input vector `x` comes from a normal distribution with parameters μ and σ equal to the mean (`mean`) and standard deviation (`std`) of the sample data, respectively.

```
rng('default') % For reproducibility
x = normrnd(50,5,100,1);
h = chi2gof(x,'cdf',{@normcdf,mean(x),std(x)})
h = 0
```

The returned result $h = 0$ indicates that `chi2gof` does not reject the null hypothesis at the default 5% significance level.

Input Arguments

x — Values at which to evaluate cdf

scalar value | array of scalar values

Values at which to evaluate the cdf, specified as a scalar value or an array of scalar values.

If you specify `pCov` to compute the confidence interval `[pLo, pUp]`, then `x` must be a scalar value.

To evaluate the cdf at multiple values, specify `x` using an array. To evaluate the cdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `x`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `normcdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Example: `[-1, 0, 3, 4]`

Data Types: `single` | `double`

mu — Mean

0 (default) | scalar value | array of scalar values

Mean of the normal distribution, specified as a scalar value or an array of scalar values.

If you specify `pCov` to compute the confidence interval `[pLo, pUp]`, then `mu` must be a scalar value.

To evaluate the cdf at multiple values, specify `x` using an array. To evaluate the cdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `x`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `normcdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Example: `[0 1 2; 0 1 2]`

Data Types: `single` | `double`

sigma — Standard deviation

1 (default) | nonnegative scalar value | array of nonnegative scalar values

Standard deviation of the normal distribution, specified as a nonnegative scalar value or an array of nonnegative scalar values.

If `sigma` is zero, then the output `p` is either 0 or 1. `p` is 0 if `x` is smaller than `mu`, or 1 otherwise.

If you specify `pCov` to compute the confidence interval `[pLo, pUp]`, then `sigma` must be a scalar value.

To evaluate the cdf at multiple values, specify `x` using an array. To evaluate the cdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `x`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `normcdf` expands each scalar

input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Example: [1 1 1; 2 2 2]

Data Types: `single` | `double`

pCov — Covariance of estimates

2-by-2 numeric matrix

Covariance of the estimates `mu` and `sigma`, specified as a 2-by-2 matrix.

If you specify `pCov` to compute the confidence interval [`pLo`, `pUp`], then `x`, `mu`, and `sigma` must be scalar values.

You can estimate `mu` and `sigma` by using `mle`, and estimate the covariance of `mu` and `sigma` by using `normlike`. For an example, see “Confidence Interval of Normal cdf Value” on page 32-3717.

Data Types: `single` | `double`

alpha — Significance level

0.05 (default) | scalar in the range (0,1)

Significance level for the confidence interval, specified as a scalar in the range (0,1). The confidence level is $100(1-\alpha)\%$, where `alpha` is the probability that the confidence interval does not contain the true value.

Example: 0.01

Data Types: `single` | `double`

Output Arguments

p — cdf values

scalar value | array of scalar values

cdf values, evaluated at the values in `x`, returned as a scalar value or an array of scalar values. `p` is the same size as `x`, `mu`, and `sigma` after any necessary scalar expansion. Each element in `p` is the cdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

pLo — Lower confidence bound for p

scalar value | array of scalar values

Lower confidence bound for `p`, returned as a scalar value or an array of scalar values. `pLo` has the same size as `p`.

pUp — Upper confidence bound for p

scalar value | array of scalar values

Upper confidence bound for `p`, returned as a scalar value or an array of scalar values. `pUp` has the same size as `p`.

More About

Normal Distribution

The normal distribution is a two-parameter family of curves. The first parameter, μ , is the mean. The second parameter, σ , is the standard deviation.

The standard normal distribution has zero mean and unit standard deviation.

The normal cumulative distribution function (cdf) is

$$p = F(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{(t-\mu)^2}{2\sigma^2}} dt, \quad \text{for } x \in \mathbb{R}.$$

p is the probability that a single observation from a normal distribution with parameters μ and σ falls in the interval $(-\infty, x]$.

Algorithms

- The `normcdf` function uses the complementary error function `erfc`. The relationship between `normcdf` and `erfc` is

$$\text{normcdf}(x) = \frac{1}{2} \text{erfc}\left(-\frac{x}{\sqrt{2}}\right).$$

The complementary error function `erfc`(x) is defined as

$$\text{erfc}(x) = 1 - \text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-t^2} dt.$$

- The `normcdf` function computes confidence bounds for p by using the delta method. `normcdf(x, mu, sigma)` is equivalent to `normcdf((x-mu)/sigma, 0, 1)`. Therefore, the `normcdf` function estimates the variance of $(x-\mu)/\sigma$ using the covariance matrix of μ and σ by the delta method, and finds the confidence bounds of $(x-\mu)/\sigma$ using the estimates of this variance. Then, the function transforms the bounds to the scale of p . The computed bounds give approximately the desired confidence level when you estimate μ , σ , and `pCov` from large samples.

Alternative Functionality

- `normcdf` is a function specific to normal distribution. Statistics and Machine Learning Toolbox also offers the generic function `cdf`, which supports various probability distributions. To use `cdf`, create a `NormalDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `normcdf` is faster than the generic function `cdf`.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Introduced before R2006a

normfit

Normal parameter estimates

Syntax

```
[muHat,sigmaHat] = normfit(x)
[muHat,sigmaHat,muCI,sigmaCI] = normfit(x)
[muHat,sigmaHat,muCI,sigmaCI] = normfit(x,alpha)
[ ___ ] = normfit(x,alpha,censoring)
[ ___ ] = normfit(x,alpha,censoring,freq)
[ ___ ] = normfit(x,alpha,censoring,freq,options)
```

Description

`[muHat,sigmaHat] = normfit(x)` returns estimates of normal distribution parameters (the mean `muHat` and standard deviation `sigmaHat`), given the sample data in `x`. `muHat` is the sample mean, and `sigmaHat` is the square root of the unbiased estimator of the variance.

`[muHat,sigmaHat,muCI,sigmaCI] = normfit(x)` also returns 95% confidence intervals for the parameter estimates on the mean and standard deviation in the arrays `muCI` and `sigmaCI`, respectively.

`[muHat,sigmaHat,muCI,sigmaCI] = normfit(x,alpha)` specifies the confidence level for the confidence intervals to be $100(1-\alpha)\%$.

`[___] = normfit(x,alpha,censoring)` specifies whether each value in `x` is right-censored or not. Use the logical vector `censoring` in which 1 indicates observations that are right-censored and 0 indicates observations that are fully observed. With `censoring`, `muHat` and `sigmaHat` are the maximum likelihood estimates (MLEs).

`[___] = normfit(x,alpha,censoring,freq)` specifies the frequency or weights of observations.

`[___] = normfit(x,alpha,censoring,freq,options)` specifies optimization options for the iterative algorithm `normfit` to use to compute MLEs with censoring. Create `options` by using the function `statset`.

You can pass in `[]` for `alpha`, `censoring`, and `freq` to use their default values.

Examples

Estimate Parameters and Confidence Intervals

Generate 1000 normal random numbers from the normal distribution with mean 3 and standard deviation 5.

```
rng('default') % For reproducibility
x = normrnd(3,5,[1000,1]);
```

Find the parameter estimates and the 99% confidence intervals.

```
[muHat,sigmaHat,muCI,sigmaCI] = normfit(x,0.01)
```

```
muHat = 2.8368
```

```
sigmaHat = 4.9948
```

```
muCI = 2×1
```

```
    2.4292
    3.2445
```

```
sigmaCI = 2×1
```

```
    4.7218
    5.2989
```

`muHat` is the sample mean, and `sigmaHat` is the square root of the unbiased estimator of the variance. `muCI` and `sigmaCI` contain the 99% confidence intervals of the mean and standard deviation parameters, respectively. The first row is the lower bound, and the second row is the upper bound.

Change Algorithm Options

Find the MLEs of a data set with censoring by using `normfit`. Use `statset` to specify the iterative algorithm options that `normfit` uses to compute MLEs for censored data, and then find the MLEs again.

Load the sample data.

```
load lightbulb
```

The first column of the data contains the lifetime (in hours) of two types of bulbs. The second column contains the binary variable indicating whether the bulb is fluorescent or incandescent. 1 indicates that the bulb is fluorescent, and 0 indicates that the bulb is incandescent. The third column contains the censorship information, where 0 indicates the bulb is observed until failure, and 1 indicates the item (bulb) is censored.

Find the indices for fluorescent bulbs.

```
idx = find(lightbulb(:,2) == 0);
```

Assume that the lifetime follows the normal distribution, and find the MLEs of the normal distribution parameters. The second input argument of `normfit` specifies the confidence level. Pass in `[]` to use its default value 0.05. The third input argument specifies the censorship information.

```
censoring = lightbulb(idx,3) == 1;
[muHat1,sigmaHat1] = normfit(lightbulb(idx,1),[],censoring)
```

```
muHat1 = 9.4966e+03
```

```
sigmaHat1 = 3.0640e+03
```

Display the default algorithm parameters that `normfit` uses to estimate the normal distribution parameters.

```
statset('normfit')
ans = struct with fields:
    Display: 'off'
    MaxFunEvals: 200
    MaxIter: 100
    TolBnd: 1.0000e-06
    TolFun: 1.0000e-08
    TolTypeFun: []
    TolX: 1.0000e-08
    TolTypeX: []
    GradObj: []
    Jacobian: []
    DerivStep: []
    FunValCheck: []
    Robust: []
    RobustWgtFun: []
    WgtFun: []
    Tune: []
    UseParallel: []
    UseSubstreams: []
    Streams: {}
    OutputFcn: []
```

Save the options using a different name. Change how the results are displayed (`Display`) and the termination tolerance for the objective function (`TolFun`).

```
options = statset('normfit');
options.Display = 'final';
options.TolFun = 1e-10;
```

Alternatively, you can specify algorithm parameters by using the name-value pair arguments of the function `statset`.

```
options = statset('Display','final','TolFun',1e-10);
```

Find the MLEs with the new algorithm parameters.

```
[muHat2,sigmaHat2] = normfit(lightbulb(idx,1),[],censoring,[],options)
```

```
Successful convergence: Norm of gradient less than OPTIONS.TolFun
```

```
muHat2 = 9.4966e+03
```

```
sigmaHat2 = 3.0640e+03
```

`normfit` displays a report on the final iteration.

Convert Unbiased Estimator to MLE

The function `normfit` finds the sample mean and the square root of the unbiased estimator of the variance with no censoring. The sample mean is equal to the MLE of the mean parameter, but the

square root of the unbiased estimator of the variance is not equal to the MLE of the standard deviation parameter.

Find the normal distribution parameters by using `normfit`, convert them into MLEs, and then compare the negative log likelihoods of the estimates by using `normlike`.

Generate 100 normal random numbers from the standard normal distribution.

```
rng('default') % For reproducibility
n = 100;
x = normrnd(0,1,[n,1]);
```

Find the sample mean and the square root of the unbiased estimator of the variance.

```
[muHat,sigmaHat] = normfit(x)
muHat = 0.1231
sigmaHat = 1.1624
```

Convert the square root of the unbiased estimator of the variance into the MLE of the standard deviation parameter.

```
sigmaHat_MLE = sqrt((n-1)/n)*sigmaHat
sigmaHat_MLE = 1.1566
```

The difference between `sigmaHat` and `sigmaHat_MLE` is negligible for large n .

Alternatively, you can find the MLEs by using the function `mle`.

```
phat = mle(x)
phat = 1×2
    0.1231    1.1566
```

`phat(1)` and `phat(2)` are the MLEs of the mean and the standard deviation parameter, respectively.

Confirm that the log likelihood of the MLEs (`muHat` and `sigmaHat_MLE`) is greater than the log likelihood of the unbiased estimators (`muHat` and `sigmaHat`) by using the `normlike` function.

```
logL = -normlike([muHat,sigmaHat],x)
logL = -156.4424
logL_MLE = -normlike([muHat,sigmaHat_MLE],x)
logL_MLE = -156.4399
```

Input Arguments

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

alpha — Significance level

0.05 (default) | scalar in the range (0,1)

Significance level for the confidence intervals, specified as a scalar in the range (0,1). The confidence level is $100(1-\alpha)\%$, where `alpha` is the probability that the confidence intervals do not contain the true value.

Example: `0.01`

Data Types: `single` | `double`

censoring — Indicator for censoring

array of 0s (default) | logical vector

Indicator for the censoring of each value in `x`, specified as a logical vector of the same size as `x`. Use 1 for observations that are right-censored and 0 for observations that are fully observed.

The default is an array of 0s, meaning that all observations are fully observed.

Data Types: `logical`

freq — Frequency or weights of observations

array of 1s (default) | nonnegative vector

Frequency or weights of observations, specified as a nonnegative vector that is the same size as `x`. The `freq` input argument typically contains nonnegative integer counts for the corresponding elements in `x`, but can contain any nonnegative values.

To obtain the weighted MLEs for a data set with censoring, specify weights of observations, normalized to the number of observations in `x`.

The default is an array of 1s, meaning one observation per element of `x`.

Data Types: `single` | `double`

options — Optimization options

`statset('normfit')` (default) | structure

Optimization options, specified as a structure. `options` determines the control parameters for the iterative algorithm that `normfit` uses to compute MLEs for censored data.

Create `options` by using the function `statset` or by creating a structure array containing the fields and values described in this table.

Field Name	Value	Default Value
<code>Display</code>	Amount of information displayed by the algorithm. <ul style="list-style-type: none"> <code>'off'</code> — Displays no information. <code>'final'</code> — Displays the final output. 	<code>'off'</code>
<code>MaxFunEvals</code>	Maximum number of objective function evaluations allowed, specified as a positive integer.	200

Field Name	Value	Default Value
MaxIter	Maximum number of iterations allowed, specified as a positive integer.	100
TolBnd	Lower bound of the standard deviation parameter estimate, specified as a positive scalar. The bounds for the mean and standard deviation parameter estimates are $[-\text{Inf}, \text{Inf}]$ and $[\text{TolBnd}, \text{Inf}]$, respectively.	1e-6
TolFun	Termination tolerance for the objective function value, specified as a positive scalar.	1e-8
TolX	Termination tolerance for the parameters, specified as a positive scalar.	1e-8

You can also enter `statset('normfit')` in the Command Window to see the names and default values of the fields that `normfit` accepts in the `options` structure.

Example: `statset('Display','final','MaxIter',1000)` specifies to display the final information of the iterative algorithm results, and change the maximum number of iterations allowed to 1000.

Data Types: `struct`

Output Arguments

muHat — Estimate of mean

scalar

Estimate of the mean parameter of the normal distribution, returned as a scalar.

- With no censoring, `muHat` is the sample mean.
- With censoring, `muHat` is the MLE. To compute the weighted MLE, specify the weights of observations by using `freq`.

sigmaHat — Estimate of standard deviation

scalar

Estimate of the standard deviation parameter of the normal distribution, returned as a scalar.

- With no censoring, `sigmaHat` is the square root of the unbiased estimator of the variance. To compute the MLE with no censoring, use the `mle` function.
- With censoring, `sigmaHat` is the MLE. To compute the weighted MLE, specify the weights of observations by using `freq`.

muCI — Confidence interval for mean

2-by-1 column vector

Confidence interval for the mean parameter of the normal distribution, returned as a 2-by-1 column vector containing the lower and upper bounds of the $100(1-\alpha)\%$ confidence interval.

The first and second rows correspond to the lower and upper bounds of the confidence intervals, respectively.

sigmaCI — Confidence interval for standard deviation

2-by-1 column vector

Confidence interval for the standard deviation parameter of the normal distribution, returned as a 2-by-1 column vector containing the lower and upper bounds of the $100(1-\alpha)\%$ confidence interval.

The first and second rows correspond to the lower and upper bounds of the confidence intervals, respectively.

Algorithms

To compute the confidence intervals, `normfit` uses the exact method for uncensored data and the Wald method for censored data. The exact method provides exact coverage for uncensored samples based on t and chi-square distributions.

Alternative Functionality

`normfit` is a function specific to normal distribution. Statistics and Machine Learning Toolbox also offers the generic functions `mle`, `fitdist`, and `paramci` and the **Distribution Fitter** app, which support various probability distributions.

- `mle` returns MLEs and the confidence intervals of MLEs for the parameters of various probability distributions. You can specify the probability distribution name or a custom probability density function.
- Create a `NormalDistribution` probability distribution object by fitting the distribution to data using the `fitdist` function or the **Distribution Fitter** app. The object properties `mu` and `sigma` store the parameter estimates. To obtain the confidence intervals for the parameter estimates, pass the object to `paramci`.

Topics

“Normal Distribution” on page B-119

Introduced before R2006a

norminv

Normal inverse cumulative distribution function

Syntax

```
x = norminv(p)
x = norminv(p,mu)
x = norminv(p,mu,sigma)

[x,xLo,xUp] = norminv(p,mu,sigma,pCov)
[x,xLo,xUp] = norminv(p,mu,sigma,pCov,alpha)
```

Description

`x = norminv(p)` returns the inverse of the standard normal cumulative distribution function (cdf), evaluated at the probability values in `p`.

`x = norminv(p,mu)` returns the inverse of the normal cdf with mean `mu` and the unit standard deviation, evaluated at the probability values in `p`.

`x = norminv(p,mu,sigma)` returns the inverse of the normal cdf with mean `mu` and standard deviation `sigma`, evaluated at the probability values in `p`.

`[x,xLo,xUp] = norminv(p,mu,sigma,pCov)` also returns the 95% confidence bounds `[xLo,xUp]` of `x` when `mu` and `sigma` are estimates. `pCov` is the covariance matrix of the estimated parameters.

`[x,xLo,xUp] = norminv(p,mu,sigma,pCov,alpha)` specifies the confidence level for the confidence interval `[xLo,xUp]` to be $100(1-\alpha)\%$.

Examples

Inverse of Standard Normal cdf

Find an interval that contains 95% of the values from a standard normal distribution.

```
x = norminv([0.025 0.975])
x = 1x2
    -1.9600    1.9600
```

Note that the interval `x` is not the only such interval, but it is the shortest. Find another interval.

```
x1 = norminv([0.01 0.96])
x1 = 1x2
    -2.3263    1.7507
```

The interval $x1$ also contains 95% of the probability, but it is longer than x .

Inverse of Normal Distribution cdf

Compute the inverse of cdf values evaluated at the probability values in p for the normal distribution with mean μ and standard deviation σ .

```
p = 0:0.25:1;
mu = 2;
sigma = 1;
x = norminv(p,mu,sigma)

x = 1x5

    -Inf    1.3255    2.0000    2.6745    Inf
```

Compute the inverse of cdf values evaluated at 0.5 for various normal distributions with different mean parameters.

```
mu = [-2,-1,0,1,2];
sigma = 1;
x = norminv(0.5,mu,sigma)

x = 1x5

    -2    -1     0     1     2
```

Confidence Interval of Inverse Normal cdf Value

Find the maximum likelihood estimates (MLEs) of the normal distribution parameters, and then find the confidence interval of the corresponding inverse cdf value.

Generate 1000 normal random numbers from the normal distribution with mean 5 and standard deviation 2.

```
rng('default') % For reproducibility
n = 1000; % Number of samples
x = normrnd(5,2,[n,1]);
```

Find the MLEs for the distribution parameters (mean and standard deviation) by using `mle`.

```
phat = mle(x)

phat = 1x2

    4.9347    1.9969

muHat = phat(1);
sigmaHat = phat(2);
```

Estimate the covariance of the distribution parameters by using `normlike`. The function `normlike` returns an approximation to the asymptotic covariance matrix if you pass the MLEs and the samples used to estimate the MLEs.

```
[~,pCov] = normlike([muHat,sigmaHat],x)
```

```
pCov = 2x2
```

```
    0.0040    -0.0000
   -0.0000     0.0020
```

Find the inverse cdf value at 0.5 and its 99% confidence interval.

```
[x,xLo,xUp] = norminv(0.5,muHat,sigmaHat,pCov,0.01)
```

```
x = 4.9347
```

```
xLo = 4.7721
```

```
xUp = 5.0974
```

`x` is the inverse cdf value using the normal distribution with the parameters `muHat` and `sigmaHat`. The interval `[xLo,xUp]` is the 99% confidence interval of the inverse cdf value evaluated at 0.5, considering the uncertainty of `muHat` and `sigmaHat` using `pCov`. The 99% confidence interval means the probability that `[xLo,xUp]` contains the true inverse cdf value is 0.99.

Input Arguments

p — Probability values at which to evaluate inverse of cdf

scalar value in `[0,1]` | array of scalar values

Probability values at which to evaluate the inverse of the cdf (icdf), specified as a scalar value or an array of scalar values, where each element is in the range `[0,1]`.

If you specify `pCov` to compute the confidence interval `[xLo,xUp]`, then `p` must be a scalar value.

To evaluate the icdf at multiple values, specify `p` using an array. To evaluate the icdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `p`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `norminv` expands each scalar input into a constant array of the same size as the array inputs. Each element in `x` is the icdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `p`.

Example: `[0.1,0.5,0.9]`

Data Types: `single` | `double`

mu — Mean

0 (default) | scalar value | array of scalar values

Mean of the normal distribution, specified as a scalar value or an array of scalar values.

If you specify `pCov` to compute the confidence interval `[xLo,xUp]`, then `mu` must be a scalar value.

To evaluate the icdf at multiple values, specify `p` using an array. To evaluate the icdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `p`, `mu`, and

`sigma` are arrays, then the array sizes must be the same. In this case, `norminv` expands each scalar input into a constant array of the same size as the array inputs. Each element in `x` is the icdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `p`.

Example: [0 1 2; 0 1 2]

Data Types: `single` | `double`

sigma — Standard deviation

1 (default) | positive scalar value | array of positive scalar values

Standard deviation of the normal distribution, specified as a positive scalar value or an array of positive scalar values.

If you specify `pCov` to compute the confidence interval [`xLo`, `xUp`], then `sigma` must be a scalar value.

To evaluate the icdf at multiple values, specify `p` using an array. To evaluate the icdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `p`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `norminv` expands each scalar input into a constant array of the same size as the array inputs. Each element in `x` is the icdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `p`.

Example: [1 1 1; 2 2 2]

Data Types: `single` | `double`

pCov — Covariance of estimates

2-by-2 numeric matrix

Covariance of the estimates `mu` and `sigma`, specified as a 2-by-2 matrix.

If you specify `pCov` to compute the confidence interval [`xLo`, `xUp`], then `p`, `mu`, and `sigma` must be scalar values.

You can estimate `mu` and `sigma` by using `mle`, and estimate the covariance of `mu` and `sigma` by using `normlike`. For an example, see “Confidence Interval of Inverse Normal cdf Value” on page 32-3732.

Data Types: `single` | `double`

alpha — Significance level

0.05 (default) | scalar in the range (0,1)

Significance level for the confidence interval, specified as a scalar in the range (0,1). The confidence level is $100(1-\alpha)\%$, where `alpha` is the probability that the confidence interval does not contain the true value.

Example: 0.01

Data Types: `single` | `double`

Output Arguments

x — icdf values

scalar value | array of scalar values

icdf values, evaluated at the probability values in `p`, returned as a scalar value or an array of scalar values. `x` is the same size as `p`, `mu`, and `sigma` after any necessary scalar expansion. Each element in `x` is the icdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `p`.

xLo — Lower confidence bound for x

scalar value | array of scalar values

Lower confidence bound for `x`, returned as a scalar value or an array of scalar values. `xLo` has the same size as `x`.

xUp — Upper confidence bound for x

scalar value | array of scalar values

Upper confidence bound for `x`, returned as a scalar value or an array of scalar values. `xUp` has the same size as `x`.

More About

Normal Distribution

The normal distribution is a two-parameter family of curves. The first parameter, μ , is the mean. The second parameter, σ , is the standard deviation.

The standard normal distribution has zero mean and unit standard deviation.

The normal inverse function is defined in terms of the normal cdf as

$$x = F^{-1}(p | \mu, \sigma) = \{x: F(x | \mu, \sigma) = p\},$$

where

$$p = F(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{(t-\mu)^2}{2\sigma^2}} dt.$$

The result `x` is the solution of the integral equation where you supply the desired probability `p`.

Algorithms

- The `norminv` function uses the inverse complementary error function `erfcinv`. The relationship between `norminv` and `erfcinv` is

$$\text{norminv}(p) = -\sqrt{2}\text{erfcinv}(2p)$$

The inverse complementary error function `erfcinv(x)` is defined as `erfcinv(erfc(x))=x`, and the complementary error function `erfc(x)` is defined as

$$\text{erfc}(x) = 1 - \text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-t^2} dt.$$

- The `norminv` function computes confidence bounds for `x` by using the delta method. `norminv(p, mu, sigma)` is equivalent to `mu + sigma*norminv(p, 0, 1)`. Therefore, the `norminv` function estimates the variance of `mu + sigma*norminv(p, 0, 1)` using the covariance

matrix of `mu` and `sigma` by the delta method, and finds the confidence bounds using the estimates of this variance. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pCov` from large samples.

Alternative Functionality

- `norminv` is a function specific to normal distribution. Statistics and Machine Learning Toolbox also offers the generic function `icdf`, which supports various probability distributions. To use `icdf`, create a `NormalDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `norminv` is faster than the generic function `icdf`.

Topics

“Normal Distribution” on page B-119

Introduced before R2006a

normlike

Normal negative loglikelihood

Syntax

```
nlogL = normlike(params,x)
nlogL = normlike(params,x,censoring)
nlogL = normlike(params,x,censoring,freq)
```

```
[nlogL,aVar] = normlike( ___ )
```

Description

`nlogL = normlike(params,x)` returns the normal negative loglikelihood of the distribution parameters (`params`) given the sample data (`x`). `params(1)` and `params(2)` correspond to the mean and standard deviation of the normal distribution, respectively.

`nlogL = normlike(params,x,censoring)` specifies whether each value in `x` is right-censored or not. Use the logical vector `censoring` in which 1 indicates observations that are right-censored and 0 indicates observations that are fully observed.

`nlogL = normlike(params,x,censoring,freq)` specifies the frequency or weights of observations. To specify `freq` without specifying `censoring`, you can pass `[]` for `censoring`.

`[nlogL,aVar] = normlike(___)` also returns the inverse of the Fisher information matrix `aVar`, using any of the input argument combinations in the previous syntaxes. If values in `params` are the maximum likelihood estimates (MLEs) of the parameters, `aVar` is an approximation to the asymptotic covariance matrix.

Examples

Negative Loglikelihood of MLEs

Find the MLEs of a data set with censoring by using `normfit`, and then find the negative loglikelihood of the MLEs by using `normlike`.

Load the sample data.

```
load lightbulb
```

The first column of the data contains the lifetime (in hours) of two types of bulbs. The second column contains the binary variable indicating whether the bulb is fluorescent or incandescent. 1 indicates that the bulb is fluorescent, and 0 indicates that the bulb is incandescent. The third column contains the censorship information, where 0 indicates the bulb is observed until failure, and 1 indicates the item (bulb) is censored.

Find the indices for fluorescent bulbs.

```
idx = find(lightbulb(:,2) == 0);
```

Find the MLEs of the normal distribution parameters. The second input argument of `normfit` specifies the confidence level. Pass in `[]` to use its default value 0.05. The third input argument specifies the censorship information.

```
ensoring = lightbulb(idx,3) == 1;
[muHat,sigmaHat] = normfit(lightbulb(idx,1),[],ensoring)

muHat = 9.4966e+03
sigmaHat = 3.0640e+03
```

Find the negative loglikelihood of the MLEs.

```
nlogL = normlike([muHat,sigmaHat],lightbulb(idx,1),ensoring)

nlogL = 376.2305
```

Convert Unbiased Estimator to MLE

The function `normfit` finds the sample mean and the square root of the unbiased estimator of the variance with no censoring. The sample mean is equal to the MLE of the mean parameter, but the square root of the unbiased estimator of the variance is not equal to the MLE of the standard deviation parameter.

Find the normal distribution parameters by using `normfit`, convert them into MLEs, and then compare the negative log likelihoods of the estimates by using `normlike`.

Generate 100 normal random numbers from the standard normal distribution.

```
rng('default') % For reproducibility
n = 100;
x = normrnd(0,1,[n,1]);
```

Find the sample mean and the square root of the unbiased estimator of the variance.

```
[muHat,sigmaHat] = normfit(x)

muHat = 0.1231
sigmaHat = 1.1624
```

Convert the square root of the unbiased estimator of the variance into the MLE of the standard deviation parameter.

```
sigmaHat_MLE = sqrt((n-1)/n)*sigmaHat

sigmaHat_MLE = 1.1566
```

The difference between `sigmaHat` and `sigmaHat_MLE` is negligible for large `n`.

Alternatively, you can find the MLEs by using the function `mle`.

```
phat = mle(x)

phat = 1×2
```

```
0.1231    1.1566
```

phat(1) and phat(2) are the MLEs of the mean and the standard deviation parameter, respectively.

Confirm that the log likelihood of the MLEs (muHat and sigmaHat_MLE) is greater than the log likelihood of the unbiased estimators (muHat and sigmaHat) by using the normlike function.

```
logL = -normlike([muHat,sigmaHat],x)
logL = -156.4424
logL_MLE = -normlike([muHat,sigmaHat_MLE],x)
logL_MLE = -156.4399
```

Confidence Interval of Inverse Normal cdf Value

Find the maximum likelihood estimates (MLEs) of the normal distribution parameters, and then find the confidence interval of the corresponding inverse cdf value.

Generate 1000 normal random numbers from the normal distribution with mean 5 and standard deviation 2.

```
rng('default') % For reproducibility
n = 1000; % Number of samples
x = normrnd(5,2,[n,1]);
```

Find the MLEs for the distribution parameters (mean and standard deviation) by using mle.

```
phat = mle(x)
phat = 1x2
    4.9347    1.9969
```

```
muHat = phat(1);
sigmaHat = phat(2);
```

Estimate the covariance of the distribution parameters by using normlike. The function normlike returns an approximation to the asymptotic covariance matrix if you pass the MLEs and the samples used to estimate the MLEs.

```
[~,pCov] = normlike([muHat,sigmaHat],x)
pCov = 2x2
    0.0040    -0.0000
   -0.0000    0.0020
```

Find the inverse cdf value at 0.5 and its 99% confidence interval.

```
[x,xLo,xUp] = norminv(0.5,muHat,sigmaHat,pCov,0.01)
x = 4.9347
```

```
xLo = 4.7721
```

```
xUp = 5.0974
```

`x` is the inverse cdf value using the normal distribution with the parameters `muHat` and `sigmaHat`. The interval `[xLo, xUp]` is the 99% confidence interval of the inverse cdf value evaluated at 0.5, considering the uncertainty of `muHat` and `sigmaHat` using `pCov`. The 99% confidence interval means the probability that `[xLo, xUp]` contains the true inverse cdf value is 0.99.

Input Arguments

params — Normal distribution parameters

vector of two numeric values

Normal distribution parameters consisting of the mean and standard deviation, specified as a vector of two numeric values. `params(1)` and `params(2)` correspond to the mean and standard deviation of the normal distribution, respectively. `params(2)` must be positive.

Example: `[0, 1]`

Data Types: `single` | `double`

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

censoring — Indicator for censoring

array of 0s (default) | logical vector

Indicator for the censoring of each value in `x`, specified as a logical vector of the same size as `x`. Use 1 for observations that are right-censored and 0 for observations that are fully observed.

The default is an array of 0s, meaning that all observations are fully observed.

Data Types: `logical`

freq — Frequency or weights of observations

array of 1s (default) | nonnegative vector

Frequency or weights of observations, specified as a nonnegative vector that is the same size as `x`. The `freq` input argument typically contains nonnegative integer counts for the corresponding elements in `x`, but can contain any nonnegative values.

To obtain the weighted negative loglikelihood for a data set with censoring, specify weights of observations, normalized to the number of observations in `x`.

The default is an array of 1s, meaning one observation per element of `x`.

Data Types: `single` | `double`

Output Arguments

nLogL — Negative loglikelihood

numeric scalar

Negative loglikelihood value of the distribution parameters (`params`) given the sample data (`x`), returned as a numeric scalar.

aVar — Inverse of Fisher information matrix

numeric matrix

Inverse of the Fisher information matrix, returned as a 2-by-2 numeric matrix. `aVar` is based on the observed Fisher information given the observed data (`x`), not the expected information.

If values in `params` are the MLEs of the parameters, `aVar` is an approximation to the asymptotic variance-covariance matrix (also known as the asymptotic covariance matrix). To find the MLEs, use `mle`.

Alternative Functionality

`normlike` is a function specific to normal distribution. Statistics and Machine Learning Toolbox also offers the generic functions `mlecov`, `fitdist`, `negloglik`, and `proflk` and the **Distribution Fitter** app, which support various probability distributions.

- `mlecov` returns the asymptotic covariance matrix of the MLEs of the parameters for a distribution specified by a custom probability density function. For example, `mlecov(params,x,'pdf',@normpdf)` returns the asymptotic covariance matrix of the MLEs for the normal distribution.
- Create a `NormalDistribution` probability distribution object by fitting the distribution to data using the `fitdist` function or the **Distribution Fitter** app. The object property `ParameterCovariance` stores the covariance matrix of the parameter estimates. To obtain the negative loglikelihood of the parameter estimates and the profile of the likelihood function, pass the object to `negloglik` and `proflk`, respectively.

normpdf

Normal probability density function

Syntax

```
y = normpdf(x)
y = normpdf(x,mu)
y = normpdf(x,mu,sigma)
```

Description

`y = normpdf(x)` returns the probability density function (pdf) of the standard normal distribution, evaluated at the values in `x`.

`y = normpdf(x,mu)` returns the pdf of the normal distribution with mean `mu` and the unit standard deviation, evaluated at the values in `x`.

`y = normpdf(x,mu,sigma)` returns the pdf of the normal distribution with mean `mu` and standard deviation `sigma`, evaluated at the values in `x`.

Examples

Standard Normal Distribution pdf

Compute the pdf values for the standard normal distribution at the values in `x`.

```
x = [-2,-1,0,1,2];
y = normpdf(x)

y = 1×5
    0.0540    0.2420    0.3989    0.2420    0.0540
```

Normal Distribution pdf

Compute the pdf values evaluated at the values in `x` for the normal distribution with mean `mu` and standard deviation `sigma`.

```
x = [-2,-1,0,1,2];
mu = 2;
sigma = 1;
y = normpdf(x,mu,sigma)

y = 1×5
    0.0001    0.0044    0.0540    0.2420    0.3989
```

Compute the pdf values evaluated at zero for various normal distributions with different mean parameters.

```
mu = [-2,-1,0,1,2];  
sigma = 1;  
y = normpdf(0,mu,sigma)  
  
y = 1×5  
    0.0540    0.2420    0.3989    0.2420    0.0540
```

Input Arguments

x — Values at which to evaluate pdf

scalar value | array of scalar values

Values at which to evaluate the pdf, specified as a scalar value or an array of scalar values.

To evaluate the pdf at multiple values, specify **x** using an array. To evaluate the pdfs of multiple distributions, specify **mu** and **sigma** using arrays. If one or more of the input arguments **x**, **mu**, and **sigma** are arrays, then the array sizes must be the same. In this case, `normpdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in **y** is the pdf value of the distribution specified by the corresponding elements in **mu** and **sigma**, evaluated at the corresponding element in **x**.

Example: [-1,0,3,4]

Data Types: `single` | `double`

mu — Mean

0 (default) | scalar value | array of scalar values

Mean of the normal distribution, specified as a scalar value or an array of scalar values.

To evaluate the pdf at multiple values, specify **x** using an array. To evaluate the pdfs of multiple distributions, specify **mu** and **sigma** using arrays. If one or more of the input arguments **x**, **mu**, and **sigma** are arrays, then the array sizes must be the same. In this case, `normpdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in **y** is the pdf value of the distribution specified by the corresponding elements in **mu** and **sigma**, evaluated at the corresponding element in **x**.

Example: [0 1 2; 0 1 2]

Data Types: `single` | `double`

sigma — Standard deviation

1 (default) | positive scalar value | array of positive scalar values

Standard deviation of the normal distribution, specified as a positive scalar value or an array of positive scalar values.

To evaluate the pdf at multiple values, specify **x** using an array. To evaluate the pdfs of multiple distributions, specify **mu** and **sigma** using arrays. If one or more of the input arguments **x**, **mu**, and **sigma** are arrays, then the array sizes must be the same. In this case, `normpdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in **y** is the pdf value of

the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Example: [1 1 1; 2 2 2]

Data Types: `single` | `double`

Output Arguments

y — pdf values

scalar value | array of scalar values

pdf values, evaluated at the values in `x`, returned as a scalar value or an array of scalar values. `y` is the same size as `x`, `mu`, and `sigma` after any necessary scalar expansion. Each element in `y` is the pdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

More About

Normal Distribution

The normal distribution is a two-parameter family of curves. The first parameter, μ , is the mean. The second parameter, σ , is the standard deviation.

The standard normal distribution has zero mean and unit standard deviation.

The normal probability density function (pdf) is

$$y = f(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}, \quad \text{for } x \in \mathbb{R}.$$

The *likelihood function* is the pdf viewed as a function of the parameters. The maximum likelihood estimates (MLEs) are the parameter estimates that maximize the likelihood function for fixed values of `x`.

Alternative Functionality

- `normpdf` is a function specific to normal distribution. Statistics and Machine Learning Toolbox also offers the generic function `pdf`, which supports various probability distributions. To use `pdf`, create a `NormalDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `normpdf` is faster than the generic function `pdf`.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Introduced before R2006a

normplot

Normal probability plot

Syntax

```
normplot(x)
normplot(ax,x)
h = normplot( ___ )
```

Description

`normplot(x)` creates a normal probability plot comparing the distribution of the data in `x` to the normal distribution.

`normplot` plots each data point in `x` using plus sign ('+') markers and draws two reference lines that represent the theoretical distribution. A solid reference line connects the first and third quartiles of the data, and a dashed reference line extends the solid line to the ends of the data. If the sample data has a normal distribution, then the data points appear along the reference line. A distribution other than normal introduces curvature in the data plot.

`normplot(ax,x)` adds a normal probability plot into the axes specified by `ax`.

`h = normplot(___)` returns graphics handles corresponding to the plotted lines, using any of the previous syntaxes.

Examples

Generate a Normal Probability Plot

Generate random sample data from a normal distribution with $\mu = 10$ and $\sigma = 1$.

```
rng default; % For reproducibility
x = normrnd(10,1,25,1);
```

Create a normal probability plot of the sample data.

```
figure;
normplot(x)
```

The plot indicates that the data follows a normal distribution.

Assess Normality Using a Normal Probability Plot

Generate 50 random numbers from each of four different distributions: A standard normal distribution; a Student's-t distribution with five degrees of freedom (a "fat-tailed" distribution); a set of Pearson random numbers with μ equal to 0, σ equal to 1, skewness equal to 0.5, and kurtosis equal to 3 (a "right-skewed" distribution); and a set of Pearson random numbers with μ equal to 0, σ equal to 1, skewness equal to -0.5, and kurtosis equal to 3 (a "left-skewed" distribution).

```
rng(11) % For reproducibility
x1 = normrnd(0,1,[50,1]);
x2 = trnd(5,[50,1]);
x3 = pearsrnd(0,1,0.5,3,[50,1]);
x4 = pearsrnd(0,1,-0.5,3,[50,1]);
```

Plot four histograms on the same figure for a visual comparison of the pdf of each distribution.

```
figure
subplot(2,2,1)
histogram(x1,10)
title('Normal')
axis([-4,4,0,15])
```

```

subplot(2,2,2)
histogram(x2,10)
title('Fat Tails')
axis([-4,4,0,15])

subplot(2,2,3)
histogram(x3,10)
title('Right-Skewed')
axis([-4,4,0,15])

subplot(2,2,4)
histogram(x4,10)
title('Left-Skewed')
axis([-4,4,0,15])

```

The histograms show how each sample differs from the normal distribution.

Create a normal probability plot for each sample.

```

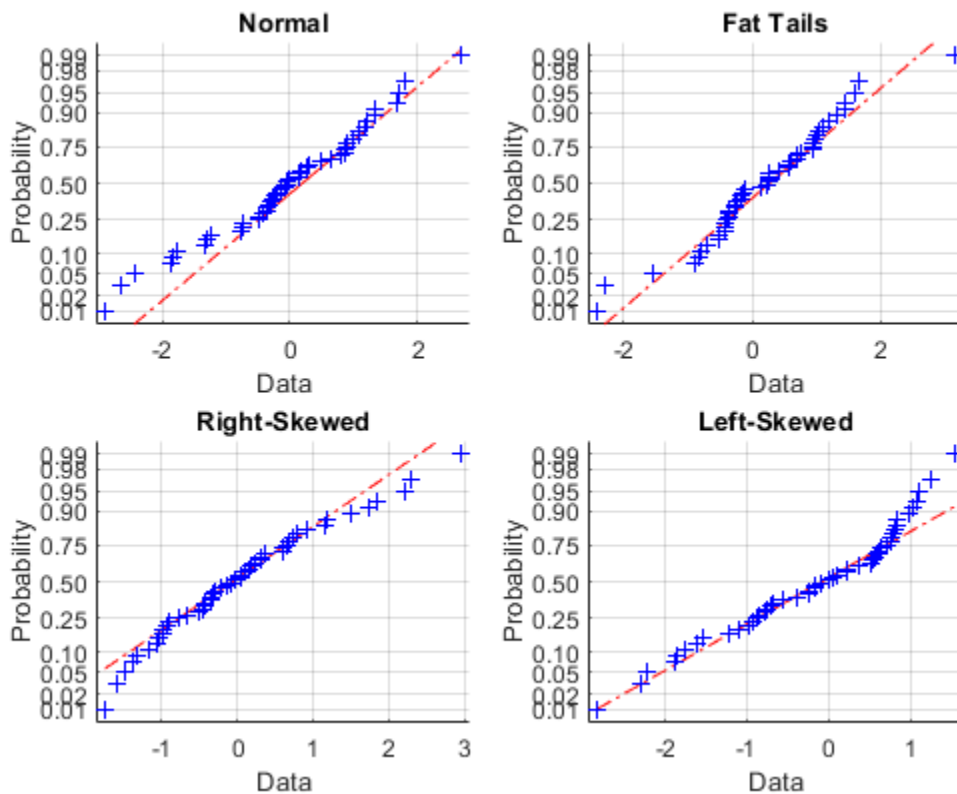

figure
subplot(2,2,1)
normplot(x1)
title('Normal')

subplot(2,2,2)
normplot(x2)
title('Fat Tails')

```

```
subplot(2,2,3)
normplot(x3)
title('Right-Skewed')

subplot(2,2,4)
normplot(x4)
title('Left-Skewed')
```

Adjust Normal Probability Plot Line Properties

Create a 50-by-2 matrix containing 50 random numbers from each of two different distributions: A standard normal distribution in column 1, and a set of Pearson random numbers with μ equal to 0, σ equal to 1, skewness equal to 0.5, and kurtosis equal to 3 (a "right-skewed" distribution) in column 2.

```
rng default % For reproducibility
x = [normrnd(0,1,[50,1]) pearsrnd(0,1,0.5,3,[50,1])];
```

Create a normal probability plot for both samples on the same figure. Return the plot line graphic handles.

```
figure
h = normplot(x)

h =
    6x1 Line array:
```

```

Line
Line
Line
Line
Line
Line
Line

```

```

legend({'Normal', 'Right-Skewed'}, 'Location', 'southeast')

```

The handles h(1) and h(2) correspond to the data points for the normal and skewed distributions, respectively. The handles h(3) and h(4) correspond to the second and third quartile line fit to the sample data. The handles h(5) and h(6) correspond to the extrapolated line that extends to the minimum and maximum of each set of sample data.

To illustrate, increase the line width of the second and third quartile line for the normally distributed data sample (represented by h(3)) to 2.

```

h(3).LineWidth = 2;
h(4).LineWidth = 2;

```

Input Arguments

x — Sample data

numeric vector | numeric matrix

Sample data, specified as a numeric vector or numeric matrix. `normplot` displays each value in `x` using the symbol '+'. If `x` is a matrix, then `normplot` displays a separate line for each column of `x`.

Data Types: `single` | `double`

ax — Target axes

Axes object | UIAxes object

Target axes, specified as an Axes object or a UIAxes object. `normplot` adds an additional plot into the axes specified by `ax`. For details, see Axes Properties and UIAxes Properties.

Use `gca` to return the current axes for the current figure.

Output Arguments

h — Graphics handles for line objects

vector of Line graphics handles

Graphics handles for line objects, returned as a vector of `Line` graphics handles. Graphics handles are unique identifiers that you can use to query and modify the properties of a specific line on the plot. For each column of `x`, `normplot` returns three handles:

- The line representing the data points. `normplot` represents each data point in `x` using plus sign ('+') markers.
- The line joining the first and third quartiles of each column of `x`, represented as a solid line.
- The extrapolation of the quartile line, extended to the minimum and maximum values of `x`, represented as a dashed line.

To view and set properties of line objects, use dot notation. For information on using dot notation, see “Access Property Values” (MATLAB). For information on the `Line` properties that you can set, see `Primitive Line`.

Algorithms

`normplot` matches the quantiles of sample data to the quantiles of a normal distribution. The sample data is sorted and plotted on the x-axis. The y-axis represents the quantiles of the normal distribution, converted into probability values. Therefore, the y-axis scaling is not linear.

Where the x-axis value is the i th sorted value from a sample of size N , the y-axis value is the midpoint between evaluation points of the empirical cumulative distribution function of the data. The midpoint is equal to $\frac{(i - 0.5)}{N}$.

`normplot` superimposes a reference line to assess the linearity of the plot. The line goes through the first and third quartiles of the data.

Alternative Functionality

You can use the `probplot` function to create a probability plot. The `probplot` function enables you to indicate censored data and specify the distribution for a probability plot.

Introduced before R2006a

normrnd

Normal random numbers

Syntax

```
r = normrnd(mu, sigma)
r = normrnd(mu, sigma, sz1, ..., szN)
r = normrnd(mu, sigma, sz)
```

Description

`r = normrnd(mu, sigma)` generates a random number from the normal distribution with mean parameter `mu` and standard deviation parameter `sigma`.

`r = normrnd(mu, sigma, sz1, ..., szN)` generates an array of normal random numbers, where `sz1, ..., szN` indicates the size of each dimension.

`r = normrnd(mu, sigma, sz)` generates an array of normal random numbers, where vector `sz` specifies `size(r)`.

Examples

Generate Normal Random Number

Generate a single random value from the standard normal distribution.

```
rng('default') % For reproducibility
r = normrnd(0,1)

r = 0.5377
```

Reset Random Number Generator

Save the current state of the random number generator. Then create a 1-by-5 vector of normal random numbers from the normal distribution with mean 3 and standard deviation 10.

```
s = rng;
r = normrnd(3,10,[1,5])

r = 1×5

    8.3767    21.3389   -19.5885    11.6217     6.1877
```

Restore the state of the random number generator to `s`, and then create a new 1-by-5 vector of random numbers. The values are the same as before.

```
rng(s);
r1 = normrnd(3,10,[1,5])
```

```
r1 = 1×5
    8.3767    21.3389   -19.5885    11.6217     6.1877
```

Clone Size from Existing Array

Create a matrix of normally distributed random numbers with the same size as an existing array.

```
A = [3 2; -2 1];
sz = size(A);
R = normrnd(0,1,sz)
```

```
R = 2×2
    0.5377   -2.2588
    1.8339    0.8622
```

You can combine the previous two lines of code into a single line.

```
R = normrnd(1,0,size(A));
```

Input Arguments

mu — Mean

scalar value | array of scalar values

Mean of the normal distribution, specified as a scalar value or an array of scalar values.

To generate random numbers from multiple distributions, specify `mu` and `sigma` using arrays. If both `mu` and `sigma` are arrays, then the array sizes must be the same. If either `mu` or `sigma` is a scalar, then `normrnd` expands the scalar argument into a constant array of the same size as the other argument. Each element in `r` is the random number generated from the distribution specified by the corresponding elements in `mu` and `sigma`.

Example: [0 1 2; 0 1 2]

Data Types: `single` | `double`

sigma — Standard deviation

nonnegative scalar value | array of nonnegative scalar values

Standard deviation of the normal distribution, specified as a nonnegative scalar value or an array of nonnegative scalar values.

If `sigma` is zero, then the output `r` is always equal to `mu`.

To generate random numbers from multiple distributions, specify `mu` and `sigma` using arrays. If both `mu` and `sigma` are arrays, then the array sizes must be the same. If either `mu` or `sigma` is a scalar, then `normrnd` expands the scalar argument into a constant array of the same size as the other argument. Each element in `r` is the random number generated from the distribution specified by the corresponding elements in `mu` and `sigma`.

Example: [1 1 1; 2 2 2]

Data Types: `single` | `double`

sz1, ..., szN — Size of each dimension (as separate arguments)

integers

Size of each dimension, specified as integers. For example, specifying `5,3,2` generates a 5-by-3-by-2 array of random numbers from the probability distribution.

If either `mu` or `sigma` is an array, then the specified dimensions `sz1, ..., szN` must match the common dimensions of `mu` and `sigma` after any necessary scalar expansion. The default values of `sz1, ..., szN` are the common dimensions.

- If you specify a single value `sz1`, then `r` is a square matrix of size `sz1`-by-`sz1`.
- If the size of any dimension is `0` or negative, then `r` is an empty array.
- Beyond the second dimension, `normrnd` ignores trailing dimensions with a size of 1. For example, specifying `3,1,1,1` produces a 3-by-1 vector of random numbers.

Example: `5,3,2`

Data Types: `single` | `double`

sz — Size of each dimension (as a row vector)

row vector of integers

Size of each dimension, specified as a row vector of integers. For example, specifying `[5,3,2]` generates a 5-by-3-by-2 array of random numbers from the probability distribution.

If either `mu` or `sigma` is an array, then the specified dimensions `sz` must match the common dimensions of `mu` and `sigma` after any necessary scalar expansion. The default values of `sz` are the common dimensions.

- If you specify a single value `[sz1]`, then `r` is a square matrix of size `sz1`-by-`sz1`.
- If the size of any dimension is `0` or negative, then `r` is an empty array.
- Beyond the second dimension, `normrnd` ignores trailing dimensions with a size of 1. For example, specifying `[3,1,1,1]` produces a 3-by-1 vector of random numbers.

Example: `[5,3,2]`

Data Types: `single` | `double`

Output Arguments

r — Normal random numbers

scalar value | array of scalar values

Normal random numbers, returned as a scalar value or an array of scalar values with the dimensions specified by `sz1, ..., szN` or `sz`. Each element in `r` is the random number generated from the distribution specified by the corresponding elements in `mu` and `sigma`.

Alternative Functionality

- `normrnd` is a function specific to normal distribution. Statistics and Machine Learning Toolbox also offers the generic function `random`, which supports various probability distributions. To use

random, create a `NormalDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `normrnd` is faster than the generic function `random`.

- Use `randn` to generate random numbers from the standard normal distribution.
- To generate random numbers interactively, use `randtool`, a user interface for random number generation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see "Introduction to Code Generation" on page 31-2 and "General Code Generation Workflow" on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see "Run MATLAB Functions on a GPU" (Parallel Computing Toolbox).

Introduced before R2006a

normspec

Normal density plot shading between specifications

Syntax

```
p = normspec(specs)
p = normspec(specs,mu,sigma)
p = normspec(specs,mu,sigma,region)
[p,h] = normspec(____)
```

Description

`p = normspec(specs)` plots the standard normal density, shading the portion inside the specification limits given by the two-element vector `specs`, and returns the probability `p` of the shaded area. If `spec` has no lower limit, then set `specs(1)` to `-Inf`; if `spec` has no upper limit, then set `specs(2)` to `Inf`.

`p = normspec(specs,mu,sigma)` uses a normal density with parameters `mu` and `sigma`.

`p = normspec(specs,mu,sigma,region)` specifies the shading region as either `'inside'` or `'outside'` the specification limits. The default is `'inside'`.

`[p,h] = normspec(____)` also returns a column vector of chart line objects using any of the input arguments in the previous syntaxes. Use `h` to modify properties of a specific chart line after you create it. For a list of properties, see `Line`.

Examples

Create Standard Normal Density Plot Shading Inside of Limits

Create a standard normal density plot, shading the portion inside the specification limits `[-1,1]`.

```
p = normspec([-1,1])
```

$p = 0.6827$

Create Normal Density Plot Shading Outside of Limits

Create a normal density plot, shading the portion outside the specification limits.

For example, consider a production process that fills cans of paint. The average amount of paint in any can is 1 gallon, but variability in the process produces a standard deviation of 2 ounces ($2/128$ gallons). Create a normal density plot, shading the portion corresponding to the probability that the cans will be filled under specification by 3 or more ounces.

```
p = normspec([1-3/128, Inf], 1, 2/128, 'outside')
```

$$p = 0.0668$$

Input Arguments

specs — Specification limits

two-element numeric vector

Specification limits, specified as a two-element numeric vector. Set `specs(1)` to `-Inf` if there is no lower limit; set `specs(2)` to `Inf` if there is no upper limit.

Data Types: `single` | `double`

mu — Mean

0 (default) | scalar value

Mean of the normal distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Standard deviation

1 (default) | positive scalar value

Standard deviation of the normal distribution, specified as a positive scalar value.

Data Types: `single` | `double`

region — Shading region`'inside' (default) | 'outside'`

Shading region, specified as either `'inside'` or `'outside'`. The function `normspec` shades the region either `'inside'` or `'outside'` the specification limits.

Output Arguments**p — Probability of shaded area**`nonnegative scalar value`

Probability of the shaded area, returned as a nonnegative scalar value.

h — One or more chart line objects`scalar | vector`

One or more chart line objects, returned as a scalar or vector. These objects are unique identifiers that you use to query and modify properties of a specific chart line. For a list of properties, see [Chart Line](#).

“Normal Distribution” on page B-119

Introduced before R2006a

normstat

Normal mean and variance

Syntax

```
[m,v] = normstat(mu,sigma)
```

Description

`[m,v] = normstat(mu,sigma)` returns the mean and variance of the normal distribution with mean `mu` and standard deviation `sigma`.

The mean of the normal distribution with parameters μ and σ is μ , and the variance is σ^2 .

Examples

Compute Mean and Variance

Compute the mean and variance of the normal distribution with parameters `mu` and `sigma`.

```
mu = 1;
sigma = 1:5;
[m,v] = normstat(mu,sigma)

m = 1x5
    1    1    1    1    1

v = 1x5
    1    4    9   16   25
```

Input Arguments

mu — Mean

scalar value | array of scalar values

Mean of the normal distribution, specified as a scalar value or an array of scalar values.

To compute the means and variances of multiple distributions, specify distribution parameters using an array of scalar values. If both `mu` and `sigma` are arrays, then the array sizes must be the same. If either `mu` or `sigma` is a scalar, then `normstat` expands the scalar argument into a constant array of the same size as the other argument. Each element in `m` and `v` is the mean and variance of the distribution specified by the corresponding elements in `mu` and `sigma`.

Example: `[0 1 2; 0 1 2]`

Data Types: `single` | `double`

sigma — Standard deviation

positive scalar value | array of positive scalar values

Standard deviation of the normal distribution, specified as a positive scalar value or an array of positive scalar values.

To compute the means and variances of multiple distributions, specify distribution parameters using an array of scalar values. If both `mu` and `sigma` are arrays, then the array sizes must be the same. If either `mu` or `sigma` is a scalar, then `normstat` expands the scalar argument into a constant array of the same size as the other argument. Each element in `m` and `v` is the mean and variance of the distribution specified by the corresponding elements in `mu` and `sigma`.

Example: [1 1 1; 2 2 2]

Data Types: `single` | `double`

Output Arguments

m — Mean

scalar value | array of scalar values

Mean of the normal distribution, returned as a scalar value or an array of scalar values. `m` is the same size as `mu` and `sigma` after any necessary scalar expansion. Each element in `m` is the mean of the normal distribution specified by the corresponding elements in `mu` and `sigma`.

v — Variance

scalar value | array of scalar values

Variance of the normal distribution, returned as a scalar value or an array of scalar values. `v` is the same size as `mu` and `sigma` after any necessary scalar expansion. Each element in `v` is the variance of the normal distribution specified by the corresponding elements in `mu` and `sigma`.

Alternative Functionality

- `normstat` is a function specific to normal distribution. Statistics and Machine Learning Toolbox also offers generic functions to compute summary statistics, including mean (`mean`), median (`median`), interquartile range (`iqr`), variance (`var`), and standard deviation (`std`). These generic functions support various probability distributions. To use these functions, create a `NormalDistribution` probability distribution object and pass the object as an input argument.

nsegments

Number of segments in piecewise distribution

Syntax

```
n = nsegments(pd)
```

Description

`n = nsegments(pd)` returns the number of segments in the piecewise distribution object `pd`.

Examples

Number of Segments in `paretotails` Object

Generate a sample data set and fit a piecewise distribution with a Pareto tail to the data by using `paretotails`. Find the number of segments in the fitted distribution by using the object function `nsegments`.

Generate a sample data set containing 10% outliers in the right tail.

```
rng('default'); % For reproducibility
right_tail = exprnd(5,100,1);
center = randn(900,1);
x = [center;right_tail];
```

Create a `paretotails` object by fitting a piecewise distribution to `x`. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities. Pass in 0 and 0.9 so that a fitted object does not contain a lower tail segment, and consists of the empirical distribution for the lower 90% of the data set and a generalized Pareto distribution (GPD) for the upper 10% of the data set.

```
pd = paretotails(x,0,0.9)
```

```
pd =
Piecewise distribution with 2 segments
  -Inf < x < 1.73931 (0 < p < 0.9): interpolated empirical cdf
  1.73931 < x < Inf (0.9 < p < 1): upper tail, GPD(0.643752,1.62246)
```

Return the number of segments in `pd` by using the `nsegments` function.

```
n = nsegments(pd)
```

```
n = 2
```

You can also get the number of segments by using the `NumSegments` property. Access the `NumSegments` property by using dot notation.

```
pd.NumSegments
```

```
ans = 2
```

Input Arguments

pd – Piecewise distribution with Pareto tails

`paretotails` object

Piecewise distribution with Pareto tails, specified as a `paretotails` object.

numel

Class: dataset

(Not Recommended) Number of elements in dataset array

Note The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
n = numel(A)
n = numel(A, varargin)
```

Description

`n = numel(A)` returns 1. To find the number of elements, `n`, in the dataset array `A`, use `prod(size(A))` or `numel(A, ':', ':')`.

`n = numel(A, varargin)` returns the number of subscripted elements, `n`, in `A(index1, index2, ..., indexn)`, where `varargin` is a string array or cell array whose elements are `index1, index2, ... indexn`.

See Also

`length` | `size`

NumTestSets property

Class: cvpartition

Number of test sets

Description

Value is the number of folds in partitions of type 'kfold' and 'leaveout'.

Value is 1 in partitions of type 'holdout' and 'resubstitution'.

ObsNames property

Class: dataset

(Not Recommended) Cell array of nonempty, distinct character vectors giving names of observations in data set

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the `MATLAB® table` data type instead. See `MATLAB table` documentation for more information.

Description

A cell array of nonempty, distinct character vectors giving the names of the observations in the data set. This property may be empty, but if not empty, the number of character vectors must equal the number of observations.

optimalleaforder

Optimal leaf ordering for hierarchical clustering

Syntax

```
leafOrder = optimalleaforder(tree,D)  
leafOrder = optimalleaforder(tree,D,Name,Value)
```

Description

`leafOrder = optimalleaforder(tree,D)` returns an optimal leaf ordering for the hierarchical binary cluster tree, `tree`, using the distances, `D`. An optimal leaf ordering of a binary tree maximizes the sum of the similarities between adjacent leaves by flipping tree branches without dividing the clusters.

`leafOrder = optimalleaforder(tree,D,Name,Value)` returns the optimal leaf ordering using one or more name-value pair arguments.

Examples

Plot Dendrogram With Optimal Leaf Order

Create a hierarchical binary cluster tree using `linkage`. Then, compare the dendrogram plot with the default ordering to a dendrogram with an optimal leaf ordering.

Generate sample data.

```
rng('default') % For reproducibility  
X = rand(10,2);
```

Create a distance vector and a hierarchical binary clustering tree. Use the distances and clustering tree to determine an optimal leaf order.

```
D = pdist(X);  
tree = linkage(D,'average');  
leafOrder = optimalleaforder(tree,D);
```

Plot the dendrogram with the default ordering and the dendrogram with the optimal leaf ordering.

```
figure()  
subplot(2,1,1)  
dendrogram(tree)  
title('Default Leaf Order')  
  
subplot(2,1,2)  
dendrogram(tree,'reorder',leafOrder)  
title('Optimal Leaf Order')
```

The order of the leaves in the bottom figure corresponds to the elements in leafOrder.

leafOrder

```
leafOrder = 1x10
```

```
1 4 9 10 2 5 8 3 7 6
```

Optimal Leaf Order Using Inverse Distance Similarity

Generate sample data.

```
rng('default') % For reproducibility
X = rand(10,2);
```

Create a distance vector and a hierarchical binary clustering tree.

```
D = pdist(X);
tree = linkage(D, 'average');
```

Use the inverse distance similarity transformation to determine an optimal leaf order.

```
leafOrder = optimalleaforder(tree,D, 'Transformation', 'inverse')
```

```
leafOrder = 1×10
```

```
    1     4     9    10     2     5     8     3     7     6
```

Input Arguments

tree — Hierarchical binary cluster tree

matrix returned by `linkage`

Hierarchical binary cluster tree, specified as an $(M - 1)$ -by-3 matrix that you generate using `linkage`, where M is the number of leaves.

D — Distances

matrix | vector

Distances for determining similarities between leaves, specified as a matrix or vector of distances. For example, you can generate distances using `pdist`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Criteria', 'group', 'Transformation', 'inverse'` specifies that the sum of similarities be maximized between every leaf and all other leaves in adjacent clusters, using an inverse similarity transformation.

Criteria — Optimization criterion

'adjacent' (default) | 'group'

Optimization criterion for determining an optimal leaf ordering, specified as the comma-separated pair consisting of `'criteria'` and one of these values:

'adjacent'	Maximize the sum of similarities between adjacent leaves.
'group'	Maximize the sum of similarities between every leaf and all other leaves in the adjacent clusters at the same level of the dendrogram.

Example: `'Criteria', 'group'`

Transformation — Method for transforming distances to similarities

'linear' (default) | 'inverse' | function handle

Method for transforming distances to similarities, specified as the comma-separated pair consisting of `'Transformation'` and one of `'linear'`, `'inverse'`, or a function handle.

Let $d_{i,j}$ and $Sim_{i,j}$ denote the distance and similarity between leaves i and j , respectively. The included similarity transformations are:

'linear'	$Sim_{i,j} = \max_{i,j} (d_{i,j}) - d_{i,j}$
'inverse'	$Sim_{i,j} = 1/d_{i,j}$

To use a custom transformation function, specify a handle to a function that accepts a matrix of distances, D , and returns a matrix of similarities, S . The function should be monotonic decreasing in the range of distance values. S must have the same size as D , with $S(i, j)$ being the similarity computed based on $D(i, j)$.

Example: 'Transformation',@myTransform

Output Arguments

leafOrder – Optimal leaf order

vector

Optimal leaf order, returned as a length- M vector, where M is the number of leaves. `leafOrder` is a permutation of the vector $1:M$, giving an optimal leaf ordering based on the specified distances and similarity transformation.

References

[1] Bar-Joseph, Z., Gifford, D.K., and Jaakkola, T.S. (2001). Fast optimal leaf ordering for hierarchical clustering. *Bioinformatics* 17, Suppl 1:S22-9. PMID: 11472989.

Introduced in R2012b

oobEdge

Out-of-bag classification edge

Syntax

```
edge = oobEdge(ens)
edge = oobEdge(ens,Name,Value)
```

Description

`edge = oobEdge(ens)` returns out-of-bag classification edge for `ens`.

`edge = oobEdge(ens,Name,Value)` computes classification edge with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

A classification bagged ensemble, constructed with `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

Default: `1:NumTrained`

mode

Character vector or string scalar representing the meaning of the output `L`:

- `'ensemble'` — `L` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `L` is a vector with one element per trained learner.
- `'cumulative'` — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: `'ensemble'`

Output Arguments

edge

Classification edge, a weighted average of the classification margin.

Examples

Estimate Out-of-Bag Edge

Load Fisher's iris data set.

```
load fisheriris
```

Train an ensemble of 100 bagged classification trees using the entire data set.

```
Mdl = fitcensemble(meas,species,'Method','Bag');
```

Estimate the out-of-bag edge.

```
edge = oobEdge(Mdl)
```

```
edge = 0.8704
```

More About

Edge

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in `ens.Prior`.

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `ens.X`.

Out of Bag

Bagging, which stands for "bootstrap aggregation", is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitcensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitcensemble` obtains each bootstrap replica by randomly selecting N observations out of N with replacement, where N is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing N out of N observations with replacement omits on average 37% ($1/e$) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

See Also

[oobLoss](#) | [oobMargin](#) | [oobPredict](#)

oobError

Class: TreeBagger

Out-of-bag error

Syntax

```
err = oobError(B)
err = oobError(B, 'param1', val1, 'param2', val2, ...)
```

Description

`err = oobError(B)` computes the misclassification probability (for classification trees) or mean squared error (for regression trees) for out-of-bag observations in the training data, using the trained bagger `B`. `err` is a vector of length `NTrees`, where `NTrees` is the number of trees in the ensemble.

`err = oobError(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

<code>'Mode'</code>	Character vector or string scalar indicating how <code>oobError</code> computes errors. If set to <code>'cumulative'</code> (default), the method computes cumulative errors and <code>err</code> is a vector of length <code>NTrees</code> , where the first element gives error from <code>trees(1)</code> , second element gives error from <code>trees(1:2)</code> etc., up to <code>trees(1:NTrees)</code> . If set to <code>'individual'</code> , <code>err</code> is a vector of length <code>NTrees</code> , where each element is an error from each tree in the ensemble. If set to <code>'ensemble'</code> , <code>err</code> is a scalar showing the cumulative error for the entire ensemble.
<code>'Trees'</code>	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to <code>'all'</code> and the method uses all trees. If <code>'Trees'</code> is a numeric vector, the method returns a vector of length <code>NTrees</code> for <code>'cumulative'</code> and <code>'individual'</code> modes, where <code>NTrees</code> is the number of elements in the input vector, and a scalar for <code>'ensemble'</code> mode. For example, in the <code>'cumulative'</code> mode, the first element gives error from <code>trees(1)</code> , the second element gives error from <code>trees(1:2)</code> etc.
<code>'TreeWeights'</code>	Vector of tree weights. This vector must have the same length as the <code>'Trees'</code> vector. <code>oobError</code> uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the <code>'individual'</code> mode.

Algorithms

`oobError` estimates the weighted ensemble error for out-of-bag observations. That is, `oobError` applies error to the training data stored in the input `TreeBagger` model `B`, and selects the out-of-bag observations for each tree to compose the ensemble error.

- `B.X` and `B.Y` are the training data predictors and responses, respectively.

- `B.OOBIndices` specifies which observations are out-of-bag for each tree in the ensemble.
- `B.W` specifies the observation weights.
- Optionally:
 - Using the `'Mode'` name-value pair argument, you can specify to return the individual, weighted ensemble error for each tree, or the entire, weighted ensemble error. By default, `oobError` returns the cumulative, weighted ensemble error.
 - Using the `'Trees'` name-value pair argument, you can choose which trees to use in the ensemble error calculations.
 - Using the `'TreeWeights'` name-value pair argument, you can attribute each tree with a weight.

`oobError` applies the algorithms described below. For more details, see `error` and `predict`.

For regression problems, `oobError` returns the weighted MSE.

- 1 `oobError` predicts responses for all out-of-bag observations.
- 2 The MSE estimate depends on the value of `'Mode'`.
 - If you specify `'Mode', 'Individual'`, then `oobError` sets any in bag observations within a selected tree to the weighted sample average of the observed, training data responses. Then, `oobError` computes the weighted MSE for each selected tree.
 - If you specify `'Mode', 'Cumulative'`, then `oobError` returns a vector of cumulative, weighted MSEs, where MSE_t is the cumulative, weighted MSE for selected tree t . To compute MSE_t , for each observation that is out of bag for at least one tree through tree t , `oobError` computes the cumulative, weighted mean of the predicted responses through tree t . `oobError` sets observations that are in bag for all selected trees through tree t to the weighted sample average of the observed, training data responses. Then, `oobError` computes MSE_t .
 - If you specify `'Mode', 'Ensemble'`, then, for each observation that is out of bag for at least one tree, `oobError` computes the weighted mean over all selected trees. `oobError` sets observations that are in bag for all selected trees to the weighted sample average of the observed, training data responses. Then, `oobError` computes the weighted MSE, which is the same as the final, cumulative, weighted MSE.

In classification problems, `oobError` returns the weighted misclassification rate.

- 1 `oobError` predicts classes for all out-of-bag observations.
- 2 The weighted misclassification rate estimate depends on the value of `'Mode'`.
 - If you specify `'Mode', 'Individual'`, then `oobError` sets any in bag observations within a selected tree to the predicted, weighted, most popular class over all training responses. If there are multiple most popular classes, `error` considers the one listed first in the `ClassNames` property of the `TreeBagger` model the most popular. Then, `oobError` computes the weighted misclassification rate for each selected tree.
 - If you specify `'Mode', 'Cumulative'`, then `oobError` returns a vector of cumulative, weighted misclassification rates, where e_t^* is the cumulative, weighted misclassification rate for selected tree t . To compute e_t^* , for each observation that is out of bag for at least one tree through tree t , `oobError` finds the predicted, cumulative, weighted most popular class through tree t . `oobError` sets observations that are in bag for all selected trees through tree t to the weighted, most popular class over all training responses. If there are multiple most

popular classes, `error` considers the one listed first in the `ClassNames` property of the `TreeBagger` model the most popular. Then, `oobError` computes e_t^* .

- If you specify `'Mode'`, `'Ensemble'`, then, for each observation that is out of bag for at least one tree, `oobError` computes the weighted, most popular class over all selected trees. `oobError` sets observations that are in bag for all selected trees through tree t to the predicted, weighted, most popular class over all training responses. If there are multiple most popular classes, `error` considers the one listed first in the `ClassNames` property of the `TreeBagger` model the most popular. Then, `oobError` computes the weighted misclassification rate, which is the same as the final, cumulative, weighted misclassification rate.

oobLoss

Out-of-bag classification error

Syntax

```
L = oobloss(ens)
L = oobloss(ens,Name,Value)
```

Description

`L = oobloss(ens)` returns the classification error for `ens` computed for out-of-bag data.

`L = oobloss(ens,Name,Value)` computes error with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

A classification bagged ensemble, constructed with `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `oobLoss` uses only these learners for calculating loss.

Default: `1:NumTrained`

Lossfun

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
<code>'binodeviance'</code>	Binomial deviance
<code>'classiferror'</code>	Classification error
<code>'exponential'</code>	Exponential
<code>'hinge'</code>	Hinge

Value	Description
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. Bagged ensembles return posterior probabilities as classification scores by default.

- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes ($\text{numel}(\text{ens}.\text{ClassNames})$, ens is the input model). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (*lossfun*).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in $\text{ens}.\text{ClassNames}$.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in $\text{ens}.\text{ClassNames}$. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.
- Cost is a K -by- K numeric matrix of misclassification costs. For example, $\text{Cost} = \text{ones}(K) - \text{eye}(K)$ specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using 'LossFun', @*lossfun*.

For more details on loss functions, see "Classification Loss" on page 32-3782.

Default: 'classiferror'

mode

Character vector or string scalar representing the meaning of the output L :

- 'ensemble' — L is a scalar value, the loss for the entire ensemble.
- 'individual' — L is a vector with one element per trained learner.
- 'cumulative' — L is a vector in which element J is obtained by using learners $1:J$ from the input list of learners.

Default: 'ensemble'

Output Arguments

L

Classification loss on page 32-3782 of the out-of-bag observations, a scalar. L can be a vector, or can represent a different quantity, depending on the name-value settings.

Examples

Estimate Out-Of-Bag Error

Load Fisher's iris data set.

```
load fisheriris
```

Grow a bag of 100 classification trees.

```
ens = fitcensemble(meas,species,'Method','Bag');
```

Estimate the out-of-bag classification error.

```
L = oobLoss(ens)
```

```
L = 0.0667
```

More About

Out of Bag

Bagging, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitcensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitcensemble` obtains each bootstrap replica by randomly selecting N observations out of N with replacement, where N is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing N out of N observations with replacement omits on average 37% ($1/e$) of observations for each decision tree. These are “out-of-bag” observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.

- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>

Loss Function	Value of LossFun	Equation
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> Estimate the 1-by-K vector of expected classification costs for observation j: $v_j = f(X_j)C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j=1, \dots, K} (v_j).$ Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through [0,1].

oobLoss

Out-of-bag regression error

Syntax

```
L = oobLoss(ens)
L = oobLoss(ens,Name,Value)
```

Description

`L = oobLoss(ens)` returns the mean squared error for `ens` computed for out-of-bag data.

`L = oobLoss(ens,Name,Value)` computes error with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

A regression bagged ensemble, constructed with `fitrensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `oobLoss` uses only these learners for calculating loss.

Default: `1:NumTrained`

lossfun

Function handle for loss function, or `'mse'`, meaning mean squared error. If you pass a function handle `fun`, `oobLoss` calls it as

```
FUN(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length. `Y` is the observed response, `Yfit` is the predicted response, and `W` is the observation weights.

Default: `'mse'`

mode

Character vector or string scalar representing the meaning of the output `L`:

- 'ensemble' — L is a scalar value, the loss for the entire ensemble.
- 'individual' — L is a vector with one element per trained learner.
- 'cumulative' — L is a vector in which element J is obtained by using learners 1:J from the input list of learners.

Default: 'ensemble'

Output Arguments

L

Mean squared error of the out-of-bag observations, a scalar. L can be a vector, or can represent a different quantity, depending on the name-value settings.

Examples

Find Out-of-Bag Regression Error

Compute the out-of-bag error for the `carsmall` data.

Load the `carsmall` data set and select engine displacement, horsepower, and vehicle weight as predictors.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Train an ensemble of bagged regression trees.

```
ens = fitensemble(X,MPG,'Method','Bag');
```

Find the out-of-bag error.

```
L = oobLoss(ens)
L = 19.4890
```

oobMargin

Out-of-bag classification margins

Syntax

```
margin = oobMargin(ens)
margin = oobMargin(ens,Name,Value)
```

Description

`margin = oobMargin(ens)` returns out-of-bag classification margins.

`margin = oobMargin(ens,Name,Value)` calculates margins with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`ens`

A classification bagged ensemble, constructed with `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

Default: `1:NumTrained`

Output Arguments

`margin`

A numeric column vector of length `size(ens.X,1)`.

Examples

Find Out-of-Bag Classification Margins

Find the out-of-bag margins for a bagged ensemble from the Fisher iris data.

Load the sample data set.

```
load fisheriris
```

Train an ensemble of bagged classification trees.

```
ens = fitcensemble(meas,species,'Method','Bag');
```

Find the number of out-of-bag margins that are equal to 1.

```
margin = oobMargin(ens);  
sum(margin == 1)
```

```
ans = 114
```

Drawing N out of N observations with replacement omits on average 37% ($1/e$) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `ens.X`.

oobMargin

Class: TreeBagger

Out-of-bag margins

Syntax

```
mar = oobMargin(B)
mar = oobMargin(B, 'param1', val1, 'param2', val2, ...)
```

Description

`mar = oobMargin(B)` computes an `Nobs-by-NTrees` matrix of classification margins for out-of-bag observations in the training data, using the trained bagger `B`.

`mar = oobMargin(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

'Mode'	Character vector or string scalar indicating how <code>oobMargin</code> computes errors. If set to <code>'cumulative'</code> (default), the method computes cumulative margins and <code>mar</code> is an <code>Nobs-by-NTrees</code> matrix, where the first column gives margins from <code>trees(1)</code> , second column gives margins from <code>trees(1:2)</code> etc., up to <code>trees(1:NTrees)</code> . If set to <code>'individual'</code> , <code>mar</code> is an <code>Nobs-by-NTrees</code> matrix, where each column gives margins from each tree in the ensemble. If set to <code>'ensemble'</code> , <code>mar</code> is a single column of length <code>Nobs</code> showing the cumulative margins for the entire ensemble.
'Trees'	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to <code>'all'</code> and the method uses all trees. If <code>'Trees'</code> is a numeric vector, the method returns an <code>Nobs-by-NTrees</code> matrix for <code>'cumulative'</code> and <code>'individual'</code> modes, where <code>NTrees</code> is the number of elements in the input vector, and a single column for <code>'ensemble'</code> mode. For example, in the <code>'cumulative'</code> mode, the first column gives margins from <code>trees(1)</code> , the second column gives margins from <code>trees(1:2)</code> etc.
'TreeWeights'	Vector of tree weights. This vector must have the same length as the <code>'Trees'</code> vector. <code>oobMargin</code> uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the <code>'individual'</code> mode.

margin

oobMeanMargin

Class: TreeBagger

Out-of-bag mean margins

Syntax

```
mar = oobMeanMargin(B)
mar = oobMeanMargin(B, 'param1', val1, 'param2', val2, ...)
```

Description

`mar = oobMeanMargin(B)` computes average classification margins for out-of-bag observations in the training data, using the trained bagger `B`. `oobMeanMargin` averages the margins over all out-of-bag observations. `mar` is a row-vector of length `NTrees`, where `NTrees` is the number of trees in the ensemble.

`mar = oobMeanMargin(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

'Mode'	Character vector or string scalar indicating how <code>oobMeanMargin</code> computes errors. If set to 'cumulative' (default), is a vector of length <code>NTrees</code> where the first element gives mean margin from <code>trees(1)</code> , second column gives mean margins from <code>trees(1:2)</code> etc., up to <code>trees(1:NTrees)</code> . If set to 'individual', <code>mar</code> is a vector of length <code>NTrees</code> , where each element is a mean margin from each tree in the ensemble. If set to 'ensemble', <code>mar</code> is a scalar showing the cumulative mean margin for the entire ensemble.
'Trees'	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'Trees' is a numeric vector, the method returns a vector of length <code>NTrees</code> for 'cumulative' and 'individual' modes, where <code>NTrees</code> is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives mean margin from <code>trees(1)</code> , the second element gives mean margin from <code>trees(1:2)</code> etc.
'TreeWeights'	Vector of tree weights. This vector must have the same length as the 'Trees' vector. <code>oobMeanMargin</code> uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the 'individual' mode.

`meanMargin`

oobPermutedPredictorImportance

Predictor importance estimates by permutation of out-of-bag predictor observations for random forest of classification trees

Syntax

```
Imp = oobPermutedPredictorImportance(Mdl)
Imp = oobPermutedPredictorImportance(Mdl,Name,Value)
```

Description

`Imp = oobPermutedPredictorImportance(Mdl)` returns a vector of out-of-bag, predictor importance estimates by permutation on page 32-3798 using the random forest of classification trees `Mdl`. `Mdl` must be a `ClassificationBaggedEnsemble` model object.

`Imp = oobPermutedPredictorImportance(Mdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, you can speed up computation using parallel computing or indicate which trees to use in the predictor importance estimation.

Input Arguments

Mdl — Random forest of classification trees

`ClassificationBaggedEnsemble` model object

Random forest of classification trees, specified as a `ClassificationBaggedEnsemble` model object created by `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Learners — Indices of learners to use in predictor importance estimation

`1:Mdl.NumTrained` (default) | numeric vector of positive integers

Indices of learners to use in predictor importance estimation, specified as the comma-separated pair consisting of `'Learners'` and a numeric vector of positive integers. Values must be at most `Mdl.NumTrained`. When `oobPermutedPredictorImportance` estimates the predictor importance, it includes the learners in `Mdl.Trained(learners)` only, where `learners` is the value of `'Learners'`.

Example: `'Learners',[1:2:Mdl.NumTrained]`

Options — Parallel computing options

`[]` (default) | structure array returned by `statset`

Parallel computing options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`. `'Options'` requires a Parallel Computing Toolbox license.

`oobPermutedPredictorImportance` uses the `'UseParallel'` field only. `statset('UseParallel',true)` invokes a pool of workers.

Example: `'Options',statset('UseParallel',true)`

Output Arguments

Imp — Out-of-bag, predictor importance estimates by permutation

numeric vector

Out-of-bag, predictor importance estimates by permutation on page 32-3798, returned as a 1-by- p numeric vector. p is the number of predictor variables in the training data (`size(Mdl.X,2)`). `Imp(j)` is the predictor importance of the predictor `Mdl.PredictorNames(j)`.

Examples

Estimate Importance of Predictors

Load the census1994 data set. Consider a model that predicts a person's salary category given their age, working class, education level, marital status, race, sex, capital gain and loss, and number of working hours per week.

```
load census1994
X = adu1tdata(:,{'age','workClass','education_num','marital_status','race',...
    'sex','capital_gain','capital_loss','hours_per_week','salary'});
```

You can train a random forest of 50 classification trees using the entire data set.

```
Mdl = fitcensemble(X,'salary','Method','Bag','NumLearningCycles',50);
```

`fitcensemble` uses a default template tree object `templateTree()` as a weak learner when `'Method'` is `'Bag'`. In this example, for reproducibility, specify `'Reproducible',true` when you create a tree template object, and then use the object as a weak learner.

```
rng('default') % For reproducibility
t = templateTree('Reproducible',true); % For reproducibility of random predictor selections
Mdl = fitcensemble(X,'salary','Method','Bag','NumLearningCycles',50,'Learners',t);
```

`Mdl` is a `ClassificationBaggedEnsemble` model.

Estimate predictor importance measures by permuting out-of-bag observations. Compare the estimates using a bar graph.

```
imp = oobPermutedPredictorImportance(Mdl);

figure;
bar(imp);
title('Out-of-Bag Permuted Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```

`imp` is a 1-by-9 vector of predictor importance estimates. Larger values indicate predictors that have a greater influence on predictions. In this case, `marital_status` is the most important predictor, followed by `capital_gain`.

Unbiased Estimates of Predictor Importance Using Parallel Computing

Load the `census1994` data set. Consider a model that predicts a person's salary category given their age, working class, education level, marital status, race, sex, capital gain and loss, and number of working hours per week.

```
load census1994
X = adu1tdata(:, {'age', 'workClass', 'education_num', 'marital_status', 'race', ...
    'sex', 'capital_gain', 'capital_loss', 'hours_per_week', 'salary'});
```

Display the number of categories represented in the categorical variables using `summary`.

```
summary(X)
```

```
Variables:
```

```
age: 32561×1 double
```

```
Values:
```

```

sex: 32561×1 categorical

Values:

Female	10771
Male	21790

capital_gain: 32561×1 double

Values:

```

        Min            0
        Median         0
        Max           99999

capital_loss: 32561x1 double

    Values:

        Min            0
        Median         0
        Max           4356

hours_per_week: 32561x1 double

    Values:

        Min            1
        Median         40
        Max            99

salary: 32561x1 categorical

    Values:

        <=50K        24720
        >50K          7841

```

Because there are few categories represented in the categorical variables compared to levels in the continuous variables, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over the categorical variables.

Train a random forest of 50 classification trees using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing values in the data, specify usage of surrogate splits. To reproduce random predictor selections, set the seed of the random number generator by using `rng` and specify `'Reproducible', true`.

```

rng('default') % For reproducibility
t = templateTree('PredictorSelection','curvature','Surrogate','on', ...
    'Reproducible',true); % For reproducibility of random predictor selections
Mdl = fitcensemble(X,'salary','Method','bag','NumLearningCycles',50, ...
    'Learners',t);

```

Estimate predictor importance measures by permuting out-of-bag observations. Perform calculations in parallel.

```

options = statset('UseParallel',true);
imp = oobPermutedPredictorImportance(Mdl,'Options',options);

```

```

Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).

```

Compare the estimates using a bar graph.

```

figure
bar(imp)
title('Out-of-Bag Permuted Predictor Importance Estimates')
ylabel('Estimates')
xlabel('Predictors')

```

```

h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';

```

In this case, `capital_gain` is the most important predictor, followed by `marital_status`. Compare these results to the results in “Estimate Importance of Predictors” on page 32-3794.

More About

Out-of-Bag, Predictor Importance Estimates by Permutation

Out-of-bag, predictor importance estimates by permutation measure how influential the predictor variables in the model are at predicting the response. The influence of a predictor increases with the value of this measure.

If a predictor is influential in prediction, then permuting its values should affect the model error. If a predictor is not influential, then permuting its values should have little to no effect on the model error.

The following process describes the estimation of out-of-bag predictor importance values by permutation. Suppose that R is a random forest of T learners and p is the number of predictors in the training data.

- 1 For tree t , $t = 1, \dots, T$:

- a Identify the out-of-bag observations and the indices of the predictor variables that were split to grow tree t , $s_t \subseteq \{1, \dots, p\}$.
 - b Estimate the out-of-bag error ε_t .
 - c For each predictor variable $x_j, j \in s_t$:
 - i Randomly permute the observations of x_j .
 - ii Estimate the model error, ε_{tj} , using the out-of-bag observations containing the permuted values of x_j .
 - iii Take the difference $d_{tj} = \varepsilon_{tj} - \varepsilon_t$. Predictor variables not split when growing tree t are attributed a difference of 0.
- 2 For each predictor variable in the training data, compute the mean, \bar{d}_j , and standard deviation, σ_j , of the differences over the learners, $j = 1, \dots, p$.
 - 3 The out-of-bag predictor importance by permutation for x_j is \bar{d}_j/σ_j .

Tips

When growing a random forest using `fitcensemble`:

- Standard CART tends to select split predictors containing many distinct values, e.g., continuous variables, over those containing few distinct values, e.g., categorical variables [3]. If the predictor data set is heterogeneous, or if there are predictors that have relatively fewer distinct values than other variables, then consider specifying the curvature or interaction test.
- Trees grown using standard CART are not sensitive to predictor variable interactions. Also, such trees are less likely to identify important variables in the presence of many irrelevant predictors than the application of the interaction test. Therefore, to account for predictor interactions and identify importance variables in the presence of many irrelevant variables, specify the interaction test [2].
- If the training data includes many predictors and you want to analyze predictor importance, then specify 'NumVariablesToSample' of the `templateTree` function as 'all' for the tree learners of the ensemble. Otherwise, the software might not select some predictors, underestimating their importance.

For more details, see `templateTree` and "Choose Split Predictor Selection Technique" on page 19-14.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to `true`.

Set the 'UseParallel' field of the options structure to `true` using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

oobPermutedPredictorImportance

Predictor importance estimates by permutation of out-of-bag predictor observations for random forest of regression trees

Syntax

```
Imp = oobPermutedPredictorImportance(Mdl)
Imp = oobPermutedPredictorImportance(Mdl,Name,Value)
```

Description

`Imp = oobPermutedPredictorImportance(Mdl)` returns a vector of out-of-bag, predictor importance estimates by permutation on page 32-3805 using the random forest of regression trees `Mdl`. `Mdl` must be a `RegressionBaggedEnsemble` model object.

`Imp = oobPermutedPredictorImportance(Mdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, you can speed up computation using parallel computing or indicate which trees to use in the predictor importance estimation.

Input Arguments

Mdl — Random forest of regression trees

`RegressionBaggedEnsemble` model object

Random forest of regression trees, specified as a `RegressionBaggedEnsemble` model object created by `fitrensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Learners — Indices of learners to use in predictor importance estimation

`1:Mdl.NumTrained` (default) | numeric vector of positive integers

Indices of learners to use in predictor importance estimation, specified as the comma-separated pair consisting of `'Learners'` and a numeric vector of positive integers. Values must be at most `Mdl.NumTrained`. When `oobPermutedPredictorImportance` estimates the predictor importance, it includes the learners in `Mdl.Trained(learners)` only, where `learners` is the value of `'Learners'`.

Example: `'Learners',[1:2:Mdl.NumTrained]`

Options — Parallel computing options

`[]` (default) | structure array returned by `statset`

Parallel computing options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`. `'Options'` requires a Parallel Computing Toolbox license.

`oobPermutedPredictorImportance` uses the `'UseParallel'` field only. `statset('UseParallel',true)` invokes a pool of workers.

Example: `'Options',statset('UseParallel',true)`

Output Arguments

Imp — Out-of-bag, predictor importance estimates by permutation

numeric vector

Out-of-bag, predictor importance estimates by permutation on page 32-3805, returned as a 1-by- p numeric vector. p is the number of predictor variables in the training data (`size(Mdl.X,2)`). `Imp(j)` is the predictor importance of the predictor `Mdl.PredictorNames(j)`.

Examples

Estimate Importance of Predictors

Load the `carsmall` data set. Consider a model that predicts the mean fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower, manufacturer, model year, and weight. Consider `Cylinders`, `Mfg`, and `Model_Year` as categorical variables.

```
load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
    Model_Year,Weight,MPG);
```

You can train a random forest of 500 regression trees using the entire data set.

```
Mdl = fitrensemble(X,'MPG','Method','Bag','NumLearningCycles',500);
```

`fitrensemble` uses a default template tree object `templateTree()` as a weak learner when `'Method'` is `'Bag'`. In this example, for reproducibility, specify `'Reproducible',true` when you create a tree template object, and then use the object as a weak learner.

```
rng('default') % For reproducibility
t = templateTree('Reproducible',true); % For reproducibility of random predictor selections
Mdl = fitrensemble(X,'MPG','Method','Bag','NumLearningCycles',500,'Learners',t);
```

`Mdl` is a `RegressionBaggedEnsemble` model.

Estimate predictor importance measures by permuting out-of-bag observations. Compare the estimates using a bar graph.

```
imp = oobPermutedPredictorImportance(Mdl);

figure;
bar(imp);
title('Out-of-Bag Permuted Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
```

```
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```

`imp` is a 1-by-7 vector of predictor importance estimates. Larger values indicate predictors that have a greater influence on predictions. In this case, `Weight` is the most important predictor, followed by `Model_Year`.

Unbiased Estimates of Predictor Importance Using Parallel Computing

Load the `carsmall` data set. Consider a model that predicts the mean fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower, manufacturer, model year, and weight. Consider `Cylinders`, `Mfg`, and `Model_Year` as categorical variables.

```
load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
    Model_Year,Weight,MPG);
```

Display the number of categories represented in the categorical variables.

```
numCylinders = numel(categories(Cylinders))
```

```
numCylinders = 3
```

```

numMfg = numel(categories(Mfg))
numMfg = 28
numModelYear = numel(categories(Model_Year))
numModelYear = 3

```

Because there are 3 categories only in Cylinders and Model_Year, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over these two variables.

Train a random forest of 500 regression trees using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing values in the data, specify usage of surrogate splits. To reproduce random predictor selections, set the seed of the random number generator by using `rng` and specify `'Reproducible', true`.

```

rng('default'); % For reproducibility
t = templateTree('PredictorSelection','curvature','Surrogate','on', ...
    'Reproducible',true); % For reproducibility of random predictor selections
Mdl = fitensemble(X,'MPG','Method','bag','NumLearningCycles',500, ...
    'Learners',t);

```

Estimate predictor importance measures by permuting out-of-bag observations. Perform calculations in parallel.

```

options = statset('UseParallel',true);
imp = oobPermutedPredictorImportance(Mdl,'Options',options);

```

```

Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).

```

Compare the estimates using a bar graph.

```

figure;
bar(imp);
title('Out-of-Bag Permuted Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';

```

In this case, `Model_Year` is the most important predictor, followed by `Cylinders`. Compare these results to the results in “Estimate Importance of Predictors” on page 32-3802.

More About

Out-of-Bag, Predictor Importance Estimates by Permutation

Out-of-bag, predictor importance estimates by permutation measure how influential the predictor variables in the model are at predicting the response. The influence of a predictor increases with the value of this measure.

If a predictor is influential in prediction, then permuting its values should affect the model error. If a predictor is not influential, then permuting its values should have little to no effect on the model error.

The following process describes the estimation of out-of-bag predictor importance values by permutation. Suppose that R is a random forest of T learners and p is the number of predictors in the training data.

- 1 For tree t , $t = 1, \dots, T$:
 - a Identify the out-of-bag observations and the indices of the predictor variables that were split to grow tree t , $s_t \subseteq \{1, \dots, p\}$.
 - b Estimate the out-of-bag error ε_t .

- c For each predictor variable $x_j, j \in s_t$:
 - i Randomly permute the observations of x_j .
 - ii Estimate the model error, ε_{tj} , using the out-of-bag observations containing the permuted values of x_j .
 - iii Take the difference $d_{tj} = \varepsilon_{tj} - \varepsilon_t$. Predictor variables not split when growing tree t are attributed a difference of 0.
- 2 For each predictor variable in the training data, compute the mean, \bar{d}_j , and standard deviation, σ_j , of the differences over the learners, $j = 1, \dots, p$.
- 3 The out-of-bag predictor importance by permutation for x_j is \bar{d}_j/σ_j .

Tips

When growing a random forest using `fitrensemble`:

- Standard CART tends to select split predictors containing many distinct values, e.g., continuous variables, over those containing few distinct values, e.g., categorical variables [3]. If the predictor data set is heterogeneous, or if there are predictors that have relatively fewer distinct values than other variables, then consider specifying the curvature or interaction test.
- Trees grown using standard CART are not sensitive to predictor variable interactions. Also, such trees are less likely to identify important variables in the presence of many irrelevant predictors than the application of the interaction test. Therefore, to account for predictor interactions and identify importance variables in the presence of many irrelevant variables, specify the interaction test [2].
- If the training data includes many predictors and you want to analyze predictor importance, then specify 'NumVariablesToSample' of the `templateTree` function as 'all' for the tree learners of the ensemble. Otherwise, the software might not select some predictors, underestimating their importance.

For more details, see `templateTree` and “Choose Split Predictor Selection Technique” on page 19-14.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to `true`.

Set the 'UseParallel' field of the options structure to `true` using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

oobPredict

Predict out-of-bag response of ensemble

Syntax

```
[label,score] = oobPredict(ens)
[label,score] = oobPredict(ens,Name,Value)
```

Description

`[label,score] = oobPredict(ens)` returns class labels and scores for `ens` for out-of-bag data.

`[label,score] = oobPredict(ens,Name,Value)` computes labels and scores with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

ens

A classification bagged ensemble, constructed with `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

Default: `1:NumTrained`

Output Arguments

label

Classification labels of the same data type as the training data `Y`. (The software treats string arrays as cell arrays of character vectors.) There are `N` elements or rows, where `N` is the number of training observations. The label is the class with the highest score. In case of a tie, the label is earliest in `ens.ClassNames`.

score

An `N`-by-`K` numeric matrix for `N` observations and `K` classes. A high score indicates that an observation is likely to come from this class. Scores are in the range 0 to 1.

Examples

Find Out-of-Bag Response of Classification Ensemble

Find the out-of-bag predictions and scores for the Fisher iris data. Find the scores with notable uncertainty in the resulting classifications.

Load the sample data set.

```
load fisheriris
```

Train an ensemble of bagged classification trees.

```
ens = fitcensemble(meas,species,'Method','Bag');
```

Find the out-of-bag predictions and scores.

```
[label,score] = oobPredict(ens);
```

Find the scores in the range (0.2, 0.8). These scores have notable uncertainty in the resulting classifications.

```
unsure = ((score > .2) & (score < .8));
sum(sum(unsure)) % Number of uncertain predictions
```

```
ans = 18
```

More About

Out of Bag

Bagging, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting N observations out of N with replacement, where N is the dataset size. To find the predicted response of a trained ensemble, `predict` takes an average over predictions from individual trees.

Drawing N out of N observations with replacement omits on average 37% ($1/e$) of observations for each decision tree. These are “out-of-bag” observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from $-\infty$ to ∞ .
- Bag scores range from 0 to 1.

oobPredict

Predict out-of-bag response of ensemble

Syntax

```
Yfit = oobPredict(ens)
Yfit = oobPredict(ens,Name,Value)
```

Description

`Yfit = oobPredict(ens)` returns the predicted responses for the out-of-bag data in `ens`.

`Yfit = oobPredict(ens,Name,Value)` predicts responses with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`ens`

A regression bagged ensemble, constructed with `fitensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `oobLoss` uses only these learners for calculating loss.

Default: `1:NumTrained`

Output Arguments

`Yfit`

A vector of predicted responses for out-of-bag data. `Yfit` has `size(ens.X,1)` elements.

You can find the indices of out-of-bag observations for weak learner `L` with the command

```
~ens.UseObsForLearner(:,L)
```

Examples

Find Out-of-Bag Response of Regression Ensemble

Compute the out-of-bag predictions for the `carsmall` data set. Display the first three terms of the fit.

Load the `carsmall` data set and select displacement, horsepower, and vehicle weight as predictors.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Train an ensemble of bagged regression trees.

```
ens = fitrensemble(X,MPG,'Method','Bag');
```

Find the out-of-bag predictions, and display the first three terms of the fit.

```
Yfit = oobPredict(ens);
Yfit(1:3) % First three terms
```

```
ans = 3×1
    14.9663
    14.6543
    15.0019
```

`oobLoss` | `predict`

oobPredict

Class: TreeBagger

Ensemble predictions for out-of-bag observations

Syntax

```
Y = oobPredict(B)
Y = oobPredict(B,Name,Value)
[Y,stdevs] = oobPredict(____)
[Y,scores] = oobPredict(____)
[Y,scores,stdevs] = oobPredict(____)
```

Description

`Y = oobPredict(B)` computes predicted responses using the trained bagger `B` for out-of-bag observations in the training data. The output has one prediction for each observation in the training data. The returned `Y` is a cell array of character vectors for classification and a numeric array for regression.

`Y = oobPredict(B,Name,Value)` specifies additional options using one or both name-value pair arguments:

- `'Trees'` — Array of tree indices to use for computation of responses. The default is `'all'`.
- `'TreeWeights'` — Array of `NTrees` weights for weighting votes from the specified trees, where `NTrees` is the number of trees in the ensemble.

For regression, `[Y,stdevs] = oobPredict(____)` also returns standard deviations of the computed responses over the ensemble of the grown trees using any of the input argument combinations in previous syntaxes.

For classification, `[Y,scores] = oobPredict(____)` also returns scores for all classes. `scores` is a matrix with one row per observation and one column per class. For each out-of-bag observation and each class, the score generated by each tree is the probability of the observation originating from the class, computed as the fraction of observations of the class in a tree leaf. `oobPredict` averages these scores over all trees in the ensemble.

`[Y,scores,stdevs] = oobPredict(____)` also returns standard deviations of the computed scores for classification. `stdevs` is a matrix with one row per observation and one column per class, with standard deviations taken over the ensemble of the grown trees.

Algorithms

`oobPredict` and `predict` similarly predict classes and responses.

- In regression problems:
 - For each observation that is out of bag for at least one tree, `oobPredict` composes the weighted mean by selecting responses of trees in which the observation is out of bag. For this computation, the `'TreeWeights'` name-value pair argument specifies the weights.

- For each observation that is in bag for all trees, the predicted response is the weighted mean of all of the training responses. For this computation, the `W` property of the `TreeBagger` model (i.e., the observation weights) specify the weights.
- In classification problems:
 - For each observation that is out of bag for at least one tree, `oobPredict` composes the weighted mean of the class posterior probabilities by selecting the trees in which the observation is out of bag. Consequently, the predicted class is the class corresponding to the largest weighted mean. For this computation, the `'TreeWeights'` name-value pair argument specifies the weights.
 - For each observation that is in bag for all trees, the predicted class is the weighted, most popular class over all training responses. For this computation, the `W` property of the `TreeBagger` model (i.e., the observation weights) specify the weights. If there are multiple most popular classes, `oobPredict` considers the one listed first in the `ClassNames` property of the `TreeBagger` model the most popular.

oobQuantileError

Class: TreeBagger

Out-of-bag quantile loss of bag of regression trees

Syntax

```
err = quantileError(Mdl)
err = quantileError(Mdl,Name,Value)
```

Description

`err = quantileError(Mdl)` returns half of the out-of-bag on page 32-3819 mean absolute deviation (MAD) from comparing the true responses in `Mdl.Y` to the predicted, out-of-bag medians at `Mdl.X`, the predictor data, and using the bag of regression trees `Mdl`. `Mdl` must be a `TreeBagger` model object.

`err = quantileError(Mdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, specify quantile probabilities, the error type, or which trees to include in the quantile-regression-error estimation.

Input Arguments

Mdl — Bag of regression trees

`TreeBagger` model object (default)

Bag of regression trees, specified as a `TreeBagger` model object created by `TreeBagger`.

- The value of `Mdl.Method` must be `regression`.
- When you train `Mdl` using `TreeBagger`, you must specify the name-value pair `'OOBPrediction','on'`. Consequently, `TreeBagger` saves required out-of-bag observation index matrix in `Mdl.OOBIndices`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Mode — Ensemble error type

`'ensemble'` (default) | `'cumulative'` | `'individual'`

Ensemble error type, specified as the comma-separated pair consisting of `'Mode'` and a value in this table. Suppose τ is the value of `Quantile`.

Value	Description
'cumulative'	err is a <code>Mdl.NumTrees</code> -by- <code>numel(tau)</code> numeric matrix of cumulative quantile regression errors. <code>err(j,k)</code> is the $\tau(k)$ quantile regression error using the learners in <code>Mdl.Trees(1:j)</code> only.
'ensemble'	err is a 1-by- <code>numel(tau)</code> numeric vector of cumulative quantile regression errors for the entire ensemble. <code>err(k)</code> is the $\tau(k)$ ensemble quantile regression error.
'individual'	err is a <code>Mdl.NumTrees</code> -by- <code>numel(tau)</code> numeric matrix of quantile regression errors from individual learners. <code>err(j,k)</code> is the $\tau(k)$ quantile regression error using the learner in <code>Mdl.Trees(j)</code> only.

For 'cumulative' and 'individual', if you choose to include fewer trees in quantile estimation using `Trees`, then this action affects the number of rows in `err` and corresponding row indices.

Example: 'Mode', 'cumulative'

Quantile — Quantile probability

0.5 (default) | numeric vector containing values in [0,1]

Quantile probability, specified as the comma-separated pair consisting of 'Quantile' and a numeric vector containing values in the interval [0,1]. For each observation (row) in `Mdl.X`, `oobQuantileError` estimates corresponding quantiles for all probabilities in `Quantile`.

Example: 'Quantile',[0 0.25 0.5 0.75 1]

Data Types: single | double

Trees — Indices of trees to use in response estimation

'all' (default) | numeric vector of positive integers

Indices of trees to use in response estimation, specified as the comma-separated pair consisting of 'Trees' and 'all' or a numeric vector of positive integers. Indices correspond to the cells of `Mdl.Trees`; each cell therein contains a tree in the ensemble. The maximum value of `Trees` must be less than or equal to the number of trees in the ensemble (`Mdl.NumTrees`).

For 'all', `oobQuantileError` uses all trees in the ensemble (that is, the indices `1:Mdl.NumTrees`).

Values other than the default can affect the number of rows in `err`.

Example: 'Trees',[1 10 Mdl.NumTrees]

Data Types: char | string | single | double

TreeWeights — Weights to attribute to responses from individual trees

ones(Mdl.NumTrees,1) (default) | numeric vector of nonnegative values

Weights to attribute to responses from individual trees, specified as the comma-separated pair consisting of 'TreeWeights' and a numeric vector of `numel(trees)` nonnegative values. `trees` is the value of `Trees`.

If you specify 'Mode', 'individual', then `oobQuantileError` ignores `TreeWeights`.

Data Types: single | double

Output Arguments

err — Half of out-of-bag quantile regression error

numeric scalar | numeric matrix

Half of the out-of-bag quantile regression error on page 32-3819, returned as a numeric scalar or T -by- $\text{numel}(\tau)$ matrix. τ is the value of `Quantile`.

T depends on the values of `Mode`, `Trees`, and `Quantile`. Suppose that you specify `'Quantile'`, τ and `'Trees'`, $trees$.

- For `'Mode'`, `'cumulative'`, `err` is a $\text{numel}(trees)$ -by- $\text{numel}(\tau)$ numeric matrix. `err(j,k)` is the $\tau(k)$ cumulative, out-of-bag quantile regression error using the learners in `Mdl.Trees(trees(1:j))`.
- For `'Mode'`, `'ensemble'`, `err` is a 1-by- $\text{numel}(\tau)$ numeric vector. `err(k)` is the $\tau(k)$ cumulative, out-of-bag quantile regression error using the learners in `Mdl.Trees(trees)`.
- For `'Mode'`, `'individual'`, `err` is a $\text{numel}(trees)$ -by- $\text{numel}(\tau)$ numeric matrix. `err(j,k)` is the $\tau(k)$ out-of-bag quantile regression error using the learner in `Mdl.Trees(trees(j))`.

Examples

Estimate Out-of-Bag Quantile Regression Error

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement, weight, and number of cylinders. Consider `Cylinders` a categorical variable.

```
load carsmall
Cylinders = categorical(Cylinders);
X = table(Displacement,Weight,Cylinders,MPG);
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners and save the out-of-bag indices.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100,X,'MPG','Method','regression','OOBPrediction','on');
```

`Mdl` is a `TreeBagger` ensemble.

Perform quantile regression, and out-of-bag estimate the MAD of the entire ensemble using the predicted conditional medians.

```
oobErr = oobQuantileError(Mdl)
```

```
oobErr = 1.5321
```

`oobErr` is an unbiased estimate of the quantile regression error for the entire ensemble.

Find Appropriate Ensemble Size Using Out-of-Bag Quantile Regression Error

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement, weight, and number of cylinders.

```
load carsmall
X = table(Displacement,Weight,Cylinders,MPG);
```

Train an ensemble of bagged regression trees using the entire data set. Specify 250 weak learners and save the out-of-bag indices.

```
rng('default'); % For reproducibility
Mdl = TreeBagger(250,X,'MPG','Method','regression',...
    'OOBPrediction','on');
```

Estimate the cumulative; out-of-bag; 0.25, 0.5, and 0.75 quantile regression errors.

```
err = oobQuantileError(Mdl,'Quantile',[0.25 0.5 0.75],'Mode','cumulative');
```

`err` is an 250-by-3 matrix of cumulative, out-of-bag, quantile regression errors. Columns correspond to quantile probabilities and rows correspond to trees in the ensemble. The errors are cumulative, so they incorporate aggregated predictions from previous trees.

Plot the cumulative, out-of-bag, quantile errors on the same plot.

```
figure;
plot(err);
legend('0.25 quantile error','0.5 quantile error','0.75 quantile error');
ylabel('Out-of-bag quantile error');
xlabel('Tree index');
title('Cumulative, Out-of-Bag, Quantile Regression Error')
```

All quantile error curves appear to level off after training about 50 trees. So, training 50 trees appears to be sufficient to achieve minimal quantile error for the three quantile probabilities.

More About

Out-of-Bag

In a bagged ensemble, observations are out-of-bag when they are left out of the training sample for a particular learner. Observations are in-bag when they are used to train a particular learner.

When bagging learners, a practitioner takes a bootstrap sample (that is, a random sample with replacement) of size n for each learner, and then trains the learners using their respective bootstrap samples. Drawing n out of n observations with replacement omits on average about 37% of observations for each learner.

The out-of-bag ensemble error, the ensemble error estimated using out-of-bag observations only, is an unbiased estimator of the true ensemble error.

Quantile Regression Error

The quantile regression error of a model given observed predictor data and responses is the weighted mean absolute deviation (MAD). If the model under-predicts the response, then deviation weights are τ , the quantile probability. If the model over-predicts, then deviation weights are $1 - \tau$.

That is, the τ quantile regression error is

$$L_\tau = \tau \frac{\sum_{\{j: y_j \geq \hat{y}_{\tau, j}\}} w_j (y_j - \hat{y}_{\tau, j})}{\sum_{j=1}^n w_j} + (1 - \tau) \frac{\sum_{\{j: y_j < \hat{y}_{\tau, j}\}} w_j (\hat{y}_{\tau, j} - y_j)}{\sum_{j=1}^n w_j} .$$

y_j is true response j , $\hat{y}_{\tau, j}$ is the τ quantile that the model predicts, and w_j is observation weight j .

Tip

The out-of-bag ensemble error estimator is unbiased for the true ensemble error. So, to tune parameters of a random forest, estimate the out-of-bag ensemble error instead of implementing cross-validation.

Introduced in R2016b

oobQuantilePredict

Class: TreeBagger

Quantile predictions for out-of-bag observations from bag of regression trees

Syntax

```
YFit = oobQuantilePredict(Mdl)
YFit = oobQuantilePredict(Mdl,Name,Value)
[YFit,YW] = oobQuantilePredict(____)
```

Description

`YFit = oobQuantilePredict(Mdl)` returns a vector of medians of the predicted responses at all out-of-bag on page 32-3828 observations in `Mdl.X`, the predictor data, and using `Mdl`, which is a bag of regression trees. `Mdl` must be a `TreeBagger` model object and `Mdl.OOBIndices` must be nonempty.

`YFit = oobQuantilePredict(Mdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, specify quantile probabilities or trees to include for quantile estimation.

`[YFit,YW] = oobQuantilePredict(____)` also returns a sparse matrix of response weights on page 32-3829 using any of the previous syntaxes.

Input Arguments

Mdl — Bag of regression trees

`TreeBagger` model object (default)

Bag of regression trees, specified as a `TreeBagger` model object created by `TreeBagger`.

- The value of `Mdl.Method` must be `regression`.
- When you train `Mdl` using `TreeBagger`, you must specify the name-value pair `'OOBPrediction','on'`. Consequently, `TreeBagger` saves required out-of-bag observation index matrix in `Mdl.OOBIndices`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Quantile — Quantile probability

0.5 (default) | numeric vector containing values in [0,1]

Quantile probability, specified as the comma-separated pair consisting of `'Quantile'` and a numeric vector containing values in the interval [0,1]. For each observation (row) in `Mdl.X`, `oobQuantilePredict` estimates corresponding quantiles for all probabilities in `Quantile`.

Example: 'Quantile',[0 0.25 0.5 0.75 1]

Data Types: single | double

Trees — Indices of trees to use in response estimation

'all' (default) | numeric vector of positive integers

Indices of trees to use in response estimation, specified as the comma-separated pair consisting of 'Trees' and 'all' or a numeric vector of positive integers. Indices correspond to the cells of `Mdl.Trees`; each cell therein contains a tree in the ensemble. The maximum value of `Trees` must be less than or equal to the number of trees in the ensemble (`Mdl.NumTrees`).

For 'all', `oobQuantilePredict` uses the indices `1:Mdl.NumTrees`.

Example: 'Trees',[1 10 Mdl.NumTrees]

Data Types: char | string | single | double

TreeWeights — Weights to attribute to responses from individual trees

numeric vector of nonnegative values

Weights to attribute to responses from individual trees, specified as the comma-separated pair consisting of 'TreeWeights' and a numeric vector of `numel(trees)` nonnegative values. `trees` is the value of the `Trees` name-value pair argument.

The default is `ones(size(trees))`.

Data Types: single | double

Output Arguments

YFit — Estimated quantiles

numeric matrix

Estimated quantiles for out-of-bag observations, returned as an n -by-`numel(tau)` numeric matrix. n is the number of observations in the training data (`numel(Mdl.Y)`) and `tau` is the value of the `Quantile` name-value pair argument. That is, `YFit(j,k)` is the estimated $100 \cdot \text{tau}(k)$ percentile of the response distribution given `X(j,:)` and using `Mdl`.

YW — Response weights

sparse matrix

Response weights on page 32-3829, returned as an n -by- n sparse matrix. n is the number of responses in the training data (`numel(Mdl.Y)`). `YW(:,j)` specifies the response weights for the observation in `Mdl.X(j,:)`.

`oobQuantilePredict` predicts quantiles using linear interpolation of the empirical cumulative distribution function (cdf). For a particular observation, you can use its response weights to estimate quantiles using alternative methods, such as approximating the cdf using kernel smoothing on page B-78.

Examples

Predict Out-of-Bag Medians Using Quantile Regression

Load the `carsmall` data set. Consider a model that predicts the fuel economy (in MPG) of a car given its engine displacement.

```
load carsmall
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners and save out-of-bag indices.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100, Displacement, MPG, 'Method', 'regression', ...
    'OOBPrediction', 'on');
```

`Mdl` is a `TreeBagger` ensemble.

Perform quantile regression to predict the out-of-bag median fuel economy for all training observations.

```
oobMedianMPG = oobQuantilePredict(Mdl);
```

`oobMedianMPG` is an n -by-1 numeric vector of medians corresponding to the conditional distribution of the response given the sorted observations in `Mdl.X`. n is the number of observations, `size(Mdl.X,1)`.

Sort the observations in ascending order. Plot the observations and the estimated medians on the same figure. Compare the out-of-bag median and mean responses.

```
[sX, idx] = sort(Mdl.X);
oobMeanMPG = oobPredict(Mdl);

figure;
plot(Displacement, MPG, 'k. ');
hold on
plot(sX, oobMedianMPG(idx));
plot(sX, oobMeanMPG(idx), 'r--');
ylabel('Fuel economy');
xlabel('Engine displacement');
legend('Data', 'Out-of-bag median', 'Out-of-bag mean');
hold off;
```

Estimate Out-of-Bag Prediction Intervals Using Percentiles

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car (in MPG) given its engine displacement.

```
load carsmall
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners and save out-of-bag indices.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100, Displacement, MPG, 'Method', 'regression', ...
    'OOBPrediction', 'on');
```

Perform quantile regression to predict the out-of-bag 2.5% and 97.5% percentiles.

```
oobQuantPredInts = oobQuantilePredict(Mdl, 'Quantile', [0.025, 0.975]);
```

`oobQuantPredInts` is an n -by-2 numeric matrix of prediction intervals corresponding to the out-of-bag observations in `Mdl.X`. n is number of observations, `size(Mdl.X, 1)`. The first column contains the 2.5% percentiles and the second column contains the 97.5% percentiles.

Plot the observations and the estimated medians on the same figure. Compare the percentile prediction intervals and the 95% prediction intervals, assuming the conditional distribution of MPG is Gaussian.

```

[oobMeanMPG,oobSTEMeanMPG] = oobPredict(Mdl);
STDNPredInts = oobMeanMPG + [-1 1]*norminv(0.975).*oobSTEMeanMPG;
[sX,idx] = sort(Mdl.X);

figure;
h1 = plot(Displacement,MPG,'k.');
```

hold on

```

h2 = plot(sX,oobQuantPredInts(idx,:), 'b');
h3 = plot(sX,STDNPredInts(idx,:), 'r--');
```

ylabel('Fuel economy');

xlabel('Engine displacement');

```

legend([h1,h2(1),h3(1)], {'Data', '95% percentile prediction intervals', ...
    '95% Gaussian prediction intervals'});
```

hold off;

Estimate Out-of-Bag Conditional Cumulative Distribution Using Quantile Regression

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car (in MPG) given its engine displacement.

```
load carsmall
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners and save the out-of-bag indices.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100,Displacement,MPG,'Method','regression',...
    'OOBPrediction','on');
```

Estimate the out-of-bag response weights.

```
[~,YW] = oobQuantilePredict(Mdl);
```

YW is an n-by-n sparse matrix containing the response weights. n is the number of training observations, numel(Y). The response weights for the observation in Mdl.X(j,:) are in YW(:,j). Response weights are independent of any specified quantile probabilities.

Estimate the out-of-bag, conditional cumulative distribution function (ccdf) of the responses by:

- 1 Sorting the responses in ascending order, and then sorting the response weights using the indices induced by sorting the responses.
- 2 Computing the cumulative sums over each column of the sorted response weights.

```
[sortY,sortIdx] = sort(Mdl.Y);
cpdf = full(YW(sortIdx,:));
ccdf = cumsum(cpdf);
```

ccdf(:,j) is the empirical out-of-bag ccdf of the response, given observation j.

Choose a random sample of four training observations. Plot the training sample and identify the chosen observations.

```
[randX,idx] = datasample(Mdl.X,4);
figure;
plot(Mdl.X,Mdl.Y,'o');
hold on
plot(randX,Mdl.Y(idx),'*','MarkerSize',10);
text(randX-10,Mdl.Y(idx)+1.5,{'obs. 1' 'obs. 2' 'obs. 3' 'obs. 4'});
legend('Training Data','Chosen Observations');
xlabel('Engine displacement')
ylabel('Fuel economy')
hold off
```

Plot the out-of-bag ccdf for the four chosen responses in the same figure.

```
figure;
plot(sortY,ccdf(:,idx));
legend('ccdf given obs. 1','ccdf given obs. 2',...
       'ccdf given obs. 3','ccdf given obs. 4',...
       'Location','SouthEast')
title('Out-of-Bag Conditional Cumulative Distribution Functions')
xlabel('Fuel economy')
ylabel('Empirical CDF')
```

More About

Out-of-Bag

In a bagged ensemble, observations are out-of-bag when they are left out of the training sample for a particular learner. Observations are in-bag when they are used to train a particular learner.

When bagging learners, a practitioner takes a bootstrap sample (that is, a random sample with replacement) of size n for each learner, and then trains the learners using their respective bootstrap samples. Drawing n out of n observations with replacement omits on average about 37% of observations for each learner.

The out-of-bag ensemble error, the ensemble error estimated using out-of-bag observations only, is an unbiased estimator of the true ensemble error.

Quantile Random Forest

Quantile random forest [2] is a quantile-regression method that uses a random forest [1] of regression trees to model the conditional distribution of a response variable, given the value of predictor variables. You can use a fitted model to estimate quantiles in the conditional distribution of the response.

Besides quantile estimation, you can use quantile regression to estimate prediction intervals or detect outliers. For example:

- To estimate 95% quantile prediction intervals, estimate the 0.025 and 0.975 quantiles.
- To detect outliers, estimate the 0.01 and 0.99 quantiles. All observations smaller than the 0.01 quantile and larger than the 0.99 quantile are outliers. All observations that are outside the interval $[L, U]$ can be considered outliers:

$$L = Q_1 - 1.5 * IQR$$

and

$$U = Q_3 + 1.5 * IQR,$$

where:

- Q_1 is the 0.25 quantile.
- Q_3 is the 0.75 quantile.
- $IQR = Q_3 - Q_1$ (the interquartile range).

Response Weights

Response weights are scalars that represent the conditional distribution of the response given a value in the predictor space. The observations in the bootstrap samples and the leaves that the training and test observations share induce response weights.

Given the observation x , the response weight for observation j in the training sample using tree t in the ensemble is

$$w_{t,j}(x) = \frac{I\{X_j \in S_t(x)\}}{\sum_{k=1}^{n_{\text{train}}} I\{X_k \in S_t(x)\}},$$

where:

- $I\{h\}$ is the indicator function.
- $S_t(x)$ is the leaf of tree t containing x .
- n_{train} is the number of training observations.

In other words, the response weights of a particular tree form the conditional relative frequency distribution of the response.

The response weights for the entire ensemble are averaged over the trees:

$$w_j^*(x) = \frac{1}{T} \sum_{t=1}^T w_{t,j}(x).$$

Algorithms

`oobQuantilePredict` estimates out-of-bag quantiles by applying `quantilePredict` to all observations in the training data ($\text{Mdl}.X$). For each observation, the method uses only the trees for which the observation is out-of-bag.

For observations that are in-bag for all trees in the ensemble, `oobQuantilePredict` assigns the sample quantile of the response data. In other words, `oobQuantilePredict` does not use quantile

regression for out-of-bag observations. Instead, it assigns `quantile(Mdl.Y, tau)`, where `tau` is the value of the `Quantile` name-value pair argument.

Introduced in R2016b

optimizableVariable

Variable description for bayesopt or other optimizers

Description

Create variables for optimizers.

Creation

Syntax

```
variable = optimizableVariable(Name,Range)
variable = optimizableVariable(Name,Range,Name,Value)
```

Description

`variable = optimizableVariable(Name,Range)` creates a variable with the specified name and range of values.

`variable = optimizableVariable(Name,Range,Name,Value)` sets properties on page 32-3831 using name-value pair arguments. For example, `optimizableVariable('xvar',[1 1000],'Type','integer')` creates an integer variable from 1 to 1000. You can specify multiple name-value pair arguments. Enclose each property name in quotes.

Properties

Name — Variable name

character vector | string scalar

Variable name, specified as a character vector or string scalar. The name must be unique, meaning different from those of other variables in the optimization.

Note

- There are two names associated with an `optimizableVariable`:
 - The MATLAB workspace variable name
 - The name of the variable in the optimization

For example,

```
xvar = optimizableVariable('spacevar',[1,100]);
```

`xvar` is the MATLAB workspace variable, and `'spacevar'` is the variable in the optimization.

Use these names as follows:

- Use `xvar` as an element in the vector of variables you pass to `bayesopt`. For example,

```
results = bayesopt(fun,[xvar,tvar])
```
- Use `'spacevar'` as the name of the variable in the optimization. For example, in an objective function,

```
function objective = mysvmfun(x,cdata,grp)
SVMModel = fitcsvm(cdata,grp,'KernelFunction','rbf',...
    'BoxConstraint',x.spacevar,...
    'KernelScale',x.tvar);
objective = kfoldLoss(crossval(SVMModel));
```

Example: `'X1'`

Data Types: `char` | `string`

Range — Variable range

2-element increasing real vector | string array or cell array of names of categorical variables

Variable range, specified as a 2-element finite increasing real vector, or as a string array or cell array of names of categorical variables:

- For real or integer variables, **Range** gives the lower bound and upper bound of that variable.
- For categorical variables, **Range** gives the possible values.

Example: `[-10,1]`

Example: `{'red','blue','black'}`

Data Types: `double` | `string` | `cell`

Type — Variable type

`'real'` (default) | `'integer'` | `'categorical'`

Variable type, specified as `'real'` (real variable), `'integer'` (integer variable), or `'categorical'` (categorical variable).

Note The MATLAB data type of both `'real'` and `'integer'` variables is the standard double-precision floating point number. The data type of `'categorical'` variables is categorical. So, for example, to read a value of a categorical variable named `'colorv'` in a table of variables named `x`, use the command `char(x.colorv)`. For an example, see the objective function in “Custom Output Functions” on page 10-19.

Example: `'Type','categorical'`

Transform — Transform applied to variable

`'none'` (default) | `'log'`

Transform applied to variable, specified as `'none'` (no transform) or `'log'` (logarithmic transform).

For `'log'`, the variable must be `'real'` or `'integer'` and positive. The variable is searched and modeled on a log scale.

Example: `'Transform','log'`

Optimize — Indication to use variable in optimization

true (default) | false

Indication to use variable in optimization, specified as `true` (use the variable) or `false` (do not use the variable).

Example: `'Optimize',false`

Data Types: `logical`

Note You can use dot notation to change the following properties after creation.

- Range of real or integer variables. For example,

```
xvar = optimizableVariable('x',[-10,10]);
% Modify the range:
xvar.Range = [1,5];
```

- Type between `'integer'` and `'real'`. For example,

```
xvar.Type = 'integer';
```

- Transform of real or integer variables between `'log'` and `'none'`. For example,

```
xvar.Transform = 'log';
```

You can use this flexibility, for example, to tweak an optimization that you want to continue. Update the range or transform using dot notation and then call `resume`.

Object Functions

`bayesopt` Select optimal machine learning hyperparameters using Bayesian optimization

Examples**Variables for Optimization Examples**

Real variable from 0 to 1:

```
var1 = optimizableVariable('xvar',[0 1])
```

```
var1 =
    optimizableVariable with properties:
```

```
    Name: 'xvar'
    Range: [0 1]
    Type: 'real'
    Transform: 'none'
    Optimize: 1
```

Integer variable from 1 to 1000 on a log scale:

```
var2 = optimizableVariable('ivar',[1 1000],'Type','integer','Transform','log')
```

```
var2 =
    optimizableVariable with properties:
```

```
Name: 'ivar'  
Range: [1 1000]  
Type: 'integer'  
Transform: 'log'  
Optimize: 1
```

Categorical variable of rainbow colors:

```
var3 = optimizableVariable('rvar',{ 'r' 'o' 'y' 'g' 'b' 'i' 'v'}, 'Type','categorical')
```

```
var3 =  
  optimizableVariable with properties:  
  
    Name: 'rvar'  
    Range: {'r' 'o' 'y' 'g' 'b' 'i' 'v'}  
    Type: 'categorical'  
    Transform: 'none'  
    Optimize: 1
```

Introduced in R2016b

ordinal

(Not Recommended) Arrays for ordinal data

Note The `nominal` and `ordinal` array data types are not recommended. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

Description

Ordinal data are discrete, nonnumeric values that have a natural ordering. `ordinal` array objects provide efficient storage and convenient manipulation of such data, while also maintaining meaningful labels for the values.

You can manipulate `ordinal` arrays like ordinary numeric arrays, by subscripting, concatenating, and reshaping. Use `ordinal` arrays as grouping variables when the elements indicate the group to which an observation belongs.

Creation

Syntax

```
B = ordinal(X)
B = ordinal(X,labels)
B = ordinal(X,labels,levels)

B = ordinal(X,labels,[],edges)
```

Description

`B = ordinal(X)` creates an ordinal array `B` from the array `X`. `ordinal` creates the levels of `B` from the sorted unique values in `X`, and creates default labels for the levels.

`B = ordinal(X,labels)` labels the levels in `B` according to `labels`.

`B = ordinal(X,labels,levels)` creates an ordinal array with possible levels defined by `levels`.

`B = ordinal(X,labels,[],edges)` creates an ordinal array by binning the numeric array `X` with bin edges given by the numeric vector `edges`.

Input Arguments

X — Input array

numeric | logical | character | string | categorical | cell array of character vectors

Input array to convert to `ordinal`, specified as a numeric, logical, character, string, or categorical array, or a cell array of character vectors. The levels of the resulting `ordinal` array correspond to the sorted unique values in `X`.

labels — Labels for discrete levels

character array | string array | cell array of character vectors

Labels for the discrete levels, specified as a character array, string array, or cell array of character vectors. By default, `ordinal` assigns labels to the levels in `B` in order of the sorted unique values in `X`.

You can include duplicate labels in `labels` to merge multiple values in `X` into a single level in `B`.

Data Types: `char` | `string` | `cell`**levels — Possible ordinal levels**

vector

Possible ordinal levels for the output `ordinal` array, specified as a vector whose values can be compared to those in `X` using the equality operator. `ordinal` assigns labels to each level from the corresponding elements of `labels`. If `X` contains any values not present in `levels`, the levels of the corresponding elements of `B` are undefined.

edges — Bin edges

numeric vector

Bin edges used to create the ordinal array by binning a numeric array, specified as a numeric vector. The uppermost bin includes values equal to the rightmost edge. `ordinal` assigns labels to each level in the resulting ordinal array from the corresponding elements of `labels`. When you specify the `edges` input argument, it must have one more element than `labels`.

Output Arguments**B — Ordinal array**

ordinal array object

Ordinal array, returned as an ordinal array object.

By default, an element of `B` is undefined if the corresponding element of `X` is `NaN` (when `X` is numeric), an empty character vector (when `X` is a character), an empty or missing string (when `X` is a string), or undefined (when `X` is categorical). `ordinal` treats such elements as undefined or missing and does not include entries for them among the possible levels. To create an explicit level for such elements instead of treating them as undefined, use the `levels` input argument and include `NaN`, the empty character vector, the empty or missing string, or an undefined element.

Properties**labels — Level labels**

cell array of character vectors

This property is read-only.

Level labels, specified as a cell array of character vectors. Access labels using `getLabels`.

Data Types: `cell`**undefLabel — Label for undefined levels**

'<undefined>' (default)

This property is read-only.

Label for undefined levels, specified as '<undefined>'. You can find undefined elements in categorical arrays by using `isundefined`.

Object Functions

<code>addlevels</code>	(Not Recommended) Add levels to nominal or ordinal arrays
<code>droplevels</code>	(Not Recommended) Drop levels from a nominal or ordinal array
<code>getlabels</code>	(Not Recommended) Access nominal or ordinal array labels
<code>getlevels</code>	(Not Recommended) Access nominal or ordinal array levels
<code>islevel</code>	(Not Recommended) Determine if levels are in nominal or ordinal array
<code>levelcounts</code>	(Not Recommended) Element counts by level of a nominal or ordinal array
<code>mergelevels</code>	(Not Recommended) Merge levels of nominal or ordinal arrays
<code>reorderlevels</code>	(Not Recommended) Reorder levels of nominal or ordinal arrays
<code>setlabels</code>	(Not Recommended) Assign labels to levels of nominal or ordinal arrays

The following is a partial list of the many other MATLAB array functions you can use with ordinal arrays. For a complete list, see “Other MATLAB Functions Supporting Nominal and Ordinal Arrays” on page 2-2.

<code>double</code>	Double-precision arrays
<code>histogram</code>	Histogram plot
<code>isequal</code>	Determine array equality
<code>isundefined</code>	Find undefined elements in categorical array
<code>pie</code>	Pie chart
<code>summary</code>	Print summary of table, timetable, or categorical array
<code>times</code>	Multiplication

Examples

Create and Label Ordinal Arrays

Create an ordinal array from integer data, providing explicit labels.

```
quality = ordinal([1 2 3 3 2 1 2 1 3],...
    {'low' 'medium' 'high'})

quality = 1x9 ordinal
Columns 1 through 7

    low    medium    high    high    medium    low    medium

Columns 8 through 9

    low    high
```

Show that the first element is less than the second element (low is less than medium).

```
quality(1) < quality(2)

ans = logical
     1
```

Create an ordinal array by binning values between 0 and 1 into thirds with labels 'small', 'medium', and 'large'.

```
X = rand(5,2)
```

```
X = 5x2
```

```
    0.8147    0.0975  
    0.9058    0.2785  
    0.1270    0.5469  
    0.9134    0.9575  
    0.6324    0.9649
```

```
A = ordinal(X,{'small' 'medium' 'large'},[],[0 1/3 2/3 1])
```

```
A = 5x2 ordinal
```

```
    large    small  
    large    small  
    small    medium  
    large    large  
    medium    large
```

Create and Manipulate Ordinal Arrays

Create an ordinal array from integer data.

```
quality = ordinal([1 2 3; 3 2 1; 2 1 3],{'low' 'medium' 'high'})
```

```
quality = 3x3 ordinal
```

```
    low    medium    high  
    high    medium    low  
    medium    low    high
```

Identify the elements in `quality` that are members of a level greater than or equal to 'medium'. A value of 1 in the resulting array indicates that the corresponding element of `quality` is a member of this level.

```
quality >= 'medium'
```

```
ans = 3x3 logical array
```

```
    0    1    1  
    1    1    0  
    1    0    1
```

Identify the elements in `quality` that are members of either the level 'low' or 'high'.

```
ismember(quality,{'low' 'high'})
```

```
ans = 3x3 logical array
```

```
    1    0    1  
    1    0    1  
    0    1    1
```

Merge the elements of the 'medium' and 'high' levels into a new level labeled 'ok'.

```
quality = mergelevels(quality,{'medium','high'},'ok')
```

```
quality = 3x3 ordinal
  low      ok      ok
  ok       ok      low
  ok       low     ok
```

Display the levels of quality.

```
getlevels(quality)
```

```
ans = 1x2 ordinal
  low      ok
```

Summarize the number of elements in each level. By default, `summary` returns counts for each column of the input array.

```
summary(quality)
```

```
  low      1      1      1
  ok       2      2      2
```

outlierMeasure

Class: CompactTreeBagger

Outlier measure for data

Syntax

```
out = outlierMeasure(B,X)
out = outlierMeasure(B,X,'param1',val1,'param2',val2,...)
```

Description

`out = outlierMeasure(B,X)` computes outlier measures for predictors `X` using trees in the ensemble `B`. The method computes the outlier measure for a given observation by taking an inverse of the average squared proximity between this observation and other observations. `outlierMeasure` then normalizes these outlier measures by subtracting the median of their distribution, taking the absolute value of this difference, and dividing by the median absolute deviation. A high value of the outlier measure indicates that this observation is an outlier.

You can supply the proximity matrix directly by using the 'Data' parameter.

`out = outlierMeasure(B,X,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

'Data'	Flag indicating how to treat the <code>X</code> input argument. If set to 'predictors' (default), the method assumes <code>X</code> is a matrix of predictors and uses it for computation of the proximity matrix. If set to 'proximity', the method treats <code>X</code> as a proximity matrix returned by the <code>proximity</code> method. If you do not supply the proximity matrix, <code>outlierMeasure</code> computes it internally. If you use the <code>proximity</code> method to compute a proximity matrix, supplying it as input to <code>outlierMeasure</code> reduces computing time.
'Labels'	Vector of true class labels. True class labels can be a numeric vector, character matrix, string array, or cell array of character vectors. When you supply this parameter, the method performs the outlier calculation for any observations using only other observations from the same class. This parameter must specify one label for each observation (row) in <code>X</code> .

`proximity`

parallelcoords

Parallel coordinates plot

Syntax

```
parallelcoords(x)
parallelcoords(x,Name,Value)

parallelcoords(ax, ___ )

h = parallelcoords( ___ )
```

Description

`parallelcoords(x)` creates a parallel coordinates plot of the multivariate data in the matrix `x`. Use a parallel coordinates plot to visualize high dimensional data, where each observation is represented by the sequence of its coordinate values plotted against their coordinate indices.

`parallelcoords(x,Name,Value)` creates a parallel coordinates plot with additional options specified by one or more `Name,Value` pair arguments. For example, you can standardize the data in `x` or label the coordinate tick marks along the horizontal axis of the plot.

`parallelcoords(ax, ___)` creates a parallel coordinates plot using the axes specified by the axes graphic object `ax`, using any of the previous syntaxes.

`h = parallelcoords(___)` returns a column vector of handles to the Line objects created by `parallelcoords`, with one handle for each row of `x`.

Examples

Parallel Coordinates Plot for Grouped Data

Load the Fisher iris sample data.

```
load fisheriris
```

The data contains four measurements (sepal length, sepal width, petal length, and petal width) from three species of iris flowers. The matrix `meas` contains all four measurements for each of 150 flowers. The cell array `species` contains the species name for each of the 150 flowers.

Create a cell array that contains the name of each measurement variable in the sample data.

```
labels = {'Sepal Length','Sepal Width','Petal Length','Petal Width'};
```

Create a parallel coordinate plot using the measurement data in `meas`. Use a different color for each group as identified in `species`, and label the horizontal axis using the variable names.

```
parallelcoords(meas,'Group',species,'Labels',labels)
```

The resulting plot contains one line for each observation (flower). The color of each line indicates the flower species.

Parallel Coordinates Plot with Quantile Values

Load the Fisher iris sample data.

```
load fisheriris
```

The data contains four measurements (sepal length, sepal width, petal length, and petal width) from three species of iris flowers. The matrix `meas` contains all four measurements for each of 150 flowers. The cell array `species` contains the species name for each of the 150 flowers.

Create a cell array that contains the name of each measurement variable in the sample data.

```
labels = {'Sepal Length', 'Sepal Width', 'Petal Length', 'Petal Width'};
```

Create a parallel coordinates plot using the measurement data in `meas`. Plot only the median, 25 percent, and 75 percent quartile values for each group identified in `species`. Label the horizontal axis using the variable names.

```
parallelcoords(meas, 'group', species, 'labels', labels, ...
               'quantile', .25)
```

The plot shows the median values for each group as a solid line and the quartile values as dotted lines of the same color. For example, the solid blue line shows the median value measured for each variable on *setosa* irises. The dotted blue line below the solid blue line shows the 25th percentile of measurements for each variable on *setosa* irises. The dotted blue line above the solid blue line shows the 75th percentile of measurements for each variable on *setosa* irises.

Adjust Line Properties in Parallel Coordinates Plot

Load the Fisher iris sample data.

```
load fisheriris
```

The data contains four measurements (sepal length, sepal width, petal length, and petal width) from three species of iris flowers. The matrix `meas` contains all four measurements for each of 150 flowers. The cell array `species` contains the species name for each of the 150 flowers.

Create a cell array that contains the name of each measurement variable in the sample data.

```
labels = {'Sepal Length', 'Sepal Width', 'Petal Length', 'Petal Width'};
```

Create a parallel coordinates plot using the measurement data in `meas`. Plot only the median, 25 percent, and 75 percent quartile values for each group identified in `species`. Label the horizontal axis using the variable names. Set the line width to 2.

```
parallelcoords(meas, 'group', species, 'labels', labels, ...
              'quantile', .25, 'LineWidth', 2)
```

Specifying 'LineWidth' in this way sets the width of every line in the plot to 2.

Recreate the parallel coordinates plot, but this time, use handles to increase the width of only the line representing the median value for each measurement made on irises in the setosa group.

```
h = parallelcoords(meas, 'group', species, 'labels', labels, ...
                  'quantile', .25)
```

```

h =
9x1 Line array:

Line (median)
Line (lower quantile)
Line (upper quantile)
Line (median)
Line (lower quantile)
Line (upper quantile)
Line (median)
Line (lower quantile)
Line (upper quantile)

```

The returned column vector `h` contains handles that correspond to each line object created by `parallelcoords`. For example, `h(1)` corresponds to the median line for the first grouping variable (`setosa`).

Use dot notation to increase the width of the line showing the median value for each measurement made on irises in the `setosa` group.

```
h(1).LineWidth = 2;
```

Input Arguments

x — Multivariate input data

numeric matrix

Multivariate input data, specified as an n -by- p matrix of numeric values. n is the number of rows of x , and each row corresponds to an observation in x . p is the number of columns in x , and each column corresponds to a variable in x .

`parallelcoords` treats NaN values in x as missing values and does not plot those coordinate values.

Data Types: `single` | `double`

ax — Axes for plot

axes graphic object

Axes for plot, specified as an axes graphic object. If you do not specify `ax`, then `parallelcoords` creates the plot using the current axis. For more information on creating an axes graphic object, see `axes` and `Axes`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: 'Group', species, 'Quantile', .25 plots the median, 25 percent, and 75 percent quartile values for the input data, using a different color for each group identified in the variable species.

Group — Grouping variable for input data

numeric array | categorical variable | character matrix | string array | cell array

Grouping variable for input data, specified as the comma-separated pair consisting of 'Group' and a numeric array containing a group index for each observation. Alternatively, the array can be a categorical variable, character matrix, string array, or cell array containing a group name for each observation.

Data Types: single | double | categorical | char | string | cell

Labels — Horizontal axis labels

character array | string array | cell array

Horizontal axis labels, specified as the comma-separated pair consisting of 'Labels' and a character array, string array, or cell array containing the label names.

Example: 'Labels', {'Sepal Width', 'Sepal Length'}

Data Types: char | string | cell

Quantile — Quantiles of input data to plot

numeric value in the range (0,1)

Quantiles of input data to plot, specified as the comma-separated pair consisting of 'Quantile' and a numeric value in the range (0,1). If you specify a value *alpha* for 'Quantile', then `parallelcoords` plots only the median, *alpha*, and 1 - *alpha* quantiles for each of the variables (columns) in *x*.

The quantile plot option provides a useful summary of the data when *x* contains many observations.

Example: 'Quantile', .25

Data Types: single | double

Standardize — Method to standardize input data

'on' | 'PCA' | 'PCAStd'

Method to standardize input data, specified as the comma-separated pair consisting of 'Standardize' and one of the following.

'on'	Scale each column of <i>x</i> to have a mean equal to 0 and a standard deviation equal to 1 before plotting.
'PCA'	Create plot from the principal component scores of <i>x</i> , in order of decreasing eigenvalues. <code>parallelcoords</code> removes rows of <i>x</i> containing missing values (NaN) for PCA standardization.
'PCAStd'	Create plot using the standardized principal component scores.

Example: 'Standardize', 'on'

Tips

- You can modify certain aspects of the plot lines by specifying a property name and value for any of the properties listed in Primitive Line. However, this approach applies the modification to all the

lines in the plot. To modify only certain plot lines, use the syntax that returns graphics handles and use dot notation to adjust each line property individually. For an illustration, see “Adjust Line Properties in Parallel Coordinates Plot” on page 32-3843.

Output Arguments

h — Graphic handles for line objects

vector of `Line` graphic handles

Graphic handles for line objects, returned as a vector of `Line` graphic handles. Graphic handles are unique identifiers that you can use to query and modify the properties of a specific line on the plot. To view and set properties of line objects, use dot notation. For information on using dot notation, see “Access Property Values” (MATLAB). For information on the `Line` properties that you can set, see `Primitive Line`.

If you use the `'Quantile'` name-value pair argument, then `h` contains one handle for each of the three lines objects created. If you use both the `'Quantile'` and the `'Group'` name-value pair arguments, then `h` contains three handles for each group.

Alternative Functionality

Alternatively, you can create a `ParallelCoordinatesPlot` object by using the `parallelplot` function.

- Unlike the `parallelcoords` function, `parallelplot` allows you to plot tabular data that includes categorical variables.
- `parallelplot` does not support the plotting of quantiles for numeric data. However, the `ParallelCoordinatesPlot` object contains the `DataNormalization` property, which provides several data normalization methods for coordinates with numeric values.

To control the appearance and behavior of the object, change the `ParallelCoordinatesPlot`.

Introduced before R2006a

paramci

Package: prob

Confidence intervals for probability distribution parameters

Syntax

```
ci = paramci(pd)
ci = paramci(pd,Name,Value)
```

Description

`ci = paramci(pd)` returns the array `ci` containing the lower and upper boundaries of the 95% confidence interval for each parameter in probability distribution `pd`.

`ci = paramci(pd,Name,Value)` returns confidence intervals with additional options specified by one or more name-value pair arguments. For example, you can specify a different percentage for the confidence interval, or compute confidence intervals only for selected parameters.

Examples

Parameter Confidence Intervals

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x,'Normal')

pd =
    NormalDistribution

    Normal distribution
        mu = 75.0083    [73.4321, 76.5846]
        sigma = 8.7202    [7.7391, 9.98843]
```

The intervals next to the parameter estimates are the 95% confidence intervals for the distribution parameters.

You can also obtain these intervals by using the function `paramci`.

```
ci = paramci(pd)

ci = 2×2

    73.4321    7.7391
    76.5846    9.9884
```

Column 1 of `ci` contains the lower and upper 95% confidence interval boundaries for the μ parameter, and column 2 contains the boundaries for the σ parameter.

Change Parameter Confidence Intervals

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x, 'Normal')

pd =
    NormalDistribution

    Normal distribution
         mu = 75.0083    [73.4321, 76.5846]
        sigma =  8.7202    [7.7391, 9.98843]
```

Compute the 99% confidence interval for the distribution parameters.

```
ci = paramci(pd, 'Alpha', .01)

ci = 2x2

    72.9245    7.4627
    77.0922   10.4403
```

Column 1 of `ci` contains the lower and upper 99% confidence interval boundaries for the μ parameter, and column 2 contains the boundaries for the σ parameter.

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

Function or App	Description
<code>makedist</code>	Create a probability distribution object using specified parameter values.
<code>fitdist</code>	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Alpha', 0.01` specifies a 99% confidence interval.

Alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level for the confidence interval, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1). The confidence level of `ci` is $100(1-\text{Alpha})\%$. The default value 0.05 corresponds to a 95% confidence interval.

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

Parameter — Parameter list

character vector | string array | cell array of character vectors

Parameter list for which to compute confidence intervals, specified as the comma-separated pair consisting of `'Parameter'` and a character vector, string array, or cell array of character vectors containing the parameter names. By default, `paramci` computes confidence intervals for all distribution parameters.

Example: `'Parameter', 'mu'`

Data Types: `char` | `string` | `cell`

Type — Computation method

`'exact'` | `'Wald'` | `'lr'`

Computation method for the confidence intervals, specified as the comma-separated pair consisting of `'Type'` and `'exact'`, `'Wald'`, or `'lr'`.

`'exact'` computes the confidence intervals using an exact method, and is available for the following distributions.

Distribution	Computation Method
Binomial	Compute using the Clopper-Pearson method based on exact probability calculations. This method does not provide exact coverage probabilities.
Exponential	Compute using a method based on a chi-square distribution. This method provides exact coverage for complete and Type 2 censored samples.
Normal	Computation method based on t and chi-square distributions for uncensored samples provides exact coverage for uncensored samples. For censored samples, <code>paramci</code> uses the Wald method if <code>Type</code> is <code>exact</code> .

Distribution	Computation Method
Lognormal	Computation method based on t and chi-square distributions for uncensored samples provides exact coverage. For censored samples, <code>paramci</code> uses the Wald method if <code>Type</code> is <code>exact</code> .
Poisson	Computation method based on a chi-square distribution provides exact coverage. For large degrees of freedom, the chi-square is approximated by a normal distribution for numerical efficiency.
Rayleigh	Computation method based on a chi-square distribution provides exact coverage probabilities.

'exact' is the default when it is available. Alternatively, you can specify 'Wald' to compute the confidence intervals using the Wald method, or 'lr' to compute the confidence intervals using the likelihood ratio method.

Example: 'Type', 'Wald'

LogFlag — Boolean flag for log scale

vector

Boolean flag for the log scale, specified as the comma-separated pair consisting of 'LogFlag' and a vector containing Boolean values corresponding to each distribution parameter. The flag specifies which Wald intervals to compute on a log scale. The default values depend on the distribution.

Example: 'LogFlag', [0,1]

Data Types: logical

Output Arguments

ci — Confidence interval

array

Confidence interval, returned as a p -by-2 array containing the lower and upper bounds of the $100(1-\text{Alpha})\%$ confidence interval for each distribution parameter. p is the number of distribution parameters.

If you create `pd` by using `makedist` and specifying the distribution parameters, the lower and upper bounds are equal to the specified parameters.

Introduced in R2013a

paretotails

Piecewise distribution with Pareto tails

Description

A `paretotails` object is a piecewise distribution with generalized Pareto distributions (GPDs) in the tails.

A `paretotails` object consists of one or two GPDs in the tails and another distribution in the center. You can specify the distribution type for the center by using the `cdffun` argument of `paretotails` when you create an object. Valid values are `'ecdf'`, `'kernel'`, and a function handle.

`paretotails` fits a distribution of type `cdffun` to the observations (`x`) and finds the quantiles corresponding to the lower and upper tail cumulative probabilities (`pl` and `pu`, respectively). Then, `paretotails` fits two GPDs to the lower $100*pl$ percent of the observations and the upper $100*(1-pu)$ percent of the observations, respectively. If `x` does not have at least two distinct observations in a tail, then `paretotails` does not create the corresponding tail segment.

Use the object functions `boundary`, `segment`, `upperparams`, and `lowerparams` to find distribution characteristics. `lowerparams` and `upperparams` return the parameters of the GPDs in the tails. `boundary` returns the boundary points between piecewise distribution segments, `segment` returns the segment of a piecewise distribution containing input values, and `nsegments` returns the number of segments in an object.

Use the object functions `cdf`, `icdf`, `pdf`, and `random` to evaluate the distribution. These functions are well suited to copula and other Monte Carlo simulations. `pdf` returns the GPD density in the tails and the slope of the cumulative distribution function (`cdf`) in the center. These probability density function (`pdf`) values in the center are generally not good estimates of the underlying density of the original data.

Creation

Create a piecewise distribution object using `paretotails`.

Syntax

```
pd = paretotails(x,pl,pu)
pd = paretotails(x,pl,pu,cdffun)
```

Description

`pd = paretotails(x,pl,pu)` returns the piecewise distribution object `pd`, which consists of the empirical distribution in the center and generalized Pareto distributions in the tails. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities `pl` and `pu`, respectively.

`pd = paretotails(x,pl,pu,cdffun)` specifies the type of center distribution segment using `cdffun`.

Input Arguments**x — Input data**

numeric vector

Input data, specified as a numeric vector.

Data Types: double

pL — Lower tail cumulative probabilitynumeric scalar in the range $[0, 1]$

Lower tail cumulative probability, specified as a numeric scalar in the range $[0, 1]$. The quantile of `pL` is the boundary of the lower tail observations.

If `pL` is 0 or `x` does not have at least two distinct observations in the lower tail, then `paretotails` divides the input data in `x` into two groups, center and upper tail. In this case, the fitted piecewise distribution object `pd` consists of two segments: the empirical distribution in the center and GPD in the upper tail.

Example: 0.1

Data Types: single | double

pu — Upper tail cumulative probabilitynumeric scalar in the range $[0, 1]$

Upper tail cumulative probability, specified as a numeric scalar in the range $[0, 1]$. The quantile of `pu` is the boundary of the upper tail observations.

If `pu` is 1 or `x` does not have at least two distinct observations in the upper tail, then `paretotails` divides the input data in `x` into two groups, center and lower tail. In this case, the fitted piecewise distribution object `pd` consists of two segments: the empirical distribution in the center and GPD in the lower tail.

Example: 0.9

Data Types: single | double

cdffun — Type of center distribution segment

'ecdf' (default) | 'kernel' | function handle

Type of center distribution segment, specified as 'ecdf', 'kernel', or a function handle.

Value	Description
'ecdf'	Interpolated empirical cdf. <code>paretotails</code> uses values in <code>x</code> as the midpoints in the vertical steps of the empirical cdf, and computes the estimates for the points between the values in <code>x</code> by linear interpolation. For details about how to find the interpolated empirical cdf, see A Piecewise Linear Nonparametric CDF Estimate .

Value	Description
'kernel'	<p>Interpolated kernel smoothing estimate of the cdf.</p> <p>paretotails uses the <code>ksdensity</code> function to find cdf estimates for 100 points in the range of <code>x</code>, and uses linear interpolation to compute the estimates for the points between the 100 points.</p> <p>'kernel' is equivalent to specifying a function handle <code>fun = @(x)ksdensity(x,'function','cdf');</code>.</p>
function handle	<p>Interpolated estimates using a specified function.</p> <p>paretotails uses a handle to a function of the form <code>[p,xi] = fun(x)</code> that accepts the input data vector <code>x</code> and returns a vector <code>p</code> of cdf values and a vector <code>xi</code> of evaluation points. Values in <code>xi</code> must be sorted and distinct but do not have to equal the values in <code>x</code>. The <code>paretotails</code> function computes the cdf estimates for the points between the values in <code>xi</code> by linear interpolation.</p>

paretotails uses `cdfun` to compute the quantiles corresponding to `pL` and `pU`.

Example: 'kernel'

Properties

NumSegments — Number of segments

3 | 2 | 1

This property is read-only.

Number of segments, including the center segment and tail segments in a `paretotail` object, specified as a scalar. `NumSegments` is 3, 2, or 1 if the number of the tail segments in the object is 2, 1, or 0, respectively.

Data Types: `double`

LowerParameters — Lower tail GPD parameters

numeric vector

This property is read-only.

Lower tail GPD parameters, fit to the lower extreme observations in `x`, specified as a numeric vector. The first value is the shape parameter and the second value is the scale parameter of the GPD.

The location parameter of the lower tail GPD is equal to the quantile of `pL`. Use the `boundary` function to return the location parameter. For example, run `[p,q] = boundary(pd)`, where `pd` is a `paretotails` object. `q(1)` is the location parameter.

Data Types: `single` | `double`

UpperParameters — Upper tail GPD parameters

numeric vector

This property is read-only.

Upper tail GPD parameters, fit to the upper extreme observations in x , specified as a numeric vector. The first value is the shape parameter and the second value is the scale parameter of the GPD.

The location parameter of the upper tail GPD is equal to the quantile of pu . Use the `boundary` function to return the location parameter. For example, run `[p, q] = boundary(pd)`, where `pd` is a `paretotails` object. `q(2)` is the location parameter.

Data Types: `single` | `double`

Object Functions

<code>boundary</code>	Piecewise distribution boundaries
<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>lowerparams</code>	Lower Pareto tail parameters
<code>nsegments</code>	Number of segments in piecewise distribution
<code>pdf</code>	Probability density function
<code>random</code>	Random numbers
<code>segment</code>	Piecewise distribution segments containing input values
<code>upperparams</code>	Upper Pareto tail parameters

Examples

Create `paretotails` with Empirical Distribution

Generate a sample data set and fit a piecewise distribution with Pareto tails to the data. Specify an empirical distribution for the center by using `paretotails` with its default settings.

Generate a sample data set containing 100 random numbers from a t distribution with 3 degrees of freedom.

```
rng('default'); % For reproducibility
t = trnd(3,100,1);
```

Create a `paretotails` object by fitting a piecewise distribution to `t`. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities so that a fitted object consists of the empirical distribution for the middle 80% of the data set and GPDs for the lower and upper 10% of the data set.

```
pd = paretotails(t,0.1,0.9)
```

```
pd =
Piecewise distribution with 3 segments
  -Inf < x < -1.84875   (0 < p < 0.1): lower tail, GPD(0.183032,1.00347)
 -1.84875 < x < 2.07662 (0.1 < p < 0.9): interpolated empirical cdf
  2.07662 < x < Inf    (0.9 < p < 1): upper tail, GPD(0.333239,1.19705)
```

Each line of the object display shows the summary of each segment, including the GPD parameters (shape and scale parameters) and the boundary values in the quantiles and cumulative probabilities. Use the object functions `boundary`, `lowerparams`, and `upperparams` to return these values.

You can use the `nsegments` function to return the number of segments and the `segment` function to return the segment that contains input values.

You can also use the distribution functions `cdf`, `icdf`, `pdf`, and `random` to evaluate the distribution and generate random samples.

Plot the cdf of the t distribution and the cdf of the `paretotails` object on the same figure.

```
x = linspace(-5,5);
plot(x,tcdf(x,3),'r--')
hold on
plot(x,cdf(pd,x),'b-')
```

Find the boundary points between the segments of the `paretotails` object by using `boundary`, and mark the points on the figure.

```
[p,q] = boundary(pd);
plot(q,p,'bo')
legend('t Distribution','Pareto Tails Object','Boundary Points','Location','best')
hold off
```

Create `paretotails` with Function Handle

Generate a sample data set and fit a piecewise distribution with Pareto tails to the data. Fit a center segment by using `paretotails` with a function handle.

Generate a sample data set containing 20% outliers.

```
rng('default'); % For reproducibility
left_tail = -exprnd(1,100,1);
right_tail = exprnd(5,100,1);
center = randn(800,1);
x = [left_tail;center;right_tail];
```

Define a function handle using `ksdensity` to specify a nondefault value of the bandwidth.

```
myfun1 = @(x)ksdensity(x, 'Bandwidth', .1, 'Function', 'cdf');
```

Create a `paretotails` object by fitting a piecewise distribution with the specified kernel smoothing estimator to `x`. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities so that a fitted object consists of the kernel estimator for the middle 80% of the data set and GPDs for the lower and upper 10% of the data set.

```
pd1 = paretotails(x,0.1,0.9,myfun1)
```

```
pd1 =
Piecewise distribution with 3 segments
  -Inf < x < -1.35204    (0 < p < 0.1): lower tail, GPD(0.0104112,0.54947)
 -1.35204 < x < 1.80824 (0.1 < p < 0.9): function: @(x)ksdensity(x,'Bandwidth',.1,'Function',
  1.80824 < x < Inf      (0.9 < p < 1): upper tail, GPD(0.227542,3.10586)
```

You can also use a parametric distribution for the center segment. Define a function that fits a normal distribution to data and returns the cdf values, and pass the function handle when you create a `paretotails` object.

```
pd2 = paretotails(x,0.1,0.9,@myfun2)
```

```
pd2 =
Piecewise distribution with 3 segments
  -Inf < x < -2.70875    (0 < p < 0.1): lower tail, GPD(-0.358104,0.831855)
 -2.70875 < x < 3.52195 (0.1 < p < 0.9): function: myfun2
  3.52195 < x < Inf      (0.9 < p < 1): upper tail, GPD(-0.0661815,5.04694)
```

```
function [p,xi] = myfun2(x)
    pd = fitdist(x, 'Normal');
    xi = linspace(min(x),max(x),length(x)*2);
    p = cdf(pd,xi);
end
```

Introduced in R2007a

partialcorr

Linear or rank partial correlation coefficients

Syntax

```
rho = partialcorr(x)
rho = partialcorr(x,z)
rho = partialcorr(x,y,z)
rho = partialcorr( ____,Name,Value)
[rho,pval] = partialcorr( ____)
```

Description

`rho = partialcorr(x)` returns the sample linear partial correlation coefficients between pairs of variables in `x`, controlling for the remaining variables in `x`.

`rho = partialcorr(x,z)` returns the sample linear partial correlation coefficients between pairs of variables in `x`, controlling for the variables in `z`.

`rho = partialcorr(x,y,z)` returns the sample linear partial correlation coefficients between pairs of variables in `x` and `y`, controlling for the variables in `z`.

`rho = partialcorr(____,Name,Value)` returns the sample linear partial correlation coefficients with additional options specified by one or more name-value pair arguments, using input arguments from any of the previous syntaxes. For example, you can specify whether to use Pearson or Spearman partial correlations, or specify how to treat missing values.

`[rho,pval] = partialcorr(____)` also returns a matrix `pval` of p -values for testing the hypothesis of no partial correlation against the one- or two-sided alternative that there is a nonzero partial correlation.

Examples

Compute Partial Correlation Coefficients

Compute partial correlation coefficients between pairs of variables in the input matrix.

Load the sample data. Convert the genders in `hospital.Sex` to numeric group identifiers.

```
load hospital;
hospital.SexID = grp2idx(hospital.Sex);
```

Create an input matrix containing the sample data.

```
x = [hospital.SexID hospital.Age hospital.Smoker hospital.Weight];
```

Each row in `x` contains a patient's gender, age, smoking status, and weight.

Compute partial correlation coefficients between pairs of variables in `x`, while controlling for the effects of the remaining variables in `x`.

```
rho = partialcorr(x)
rho = 4x4
    1.0000    -0.0105    0.0273    0.9421
   -0.0105    1.0000    0.0419    0.0369
    0.0273    0.0419    1.0000    0.0451
    0.9421    0.0369    0.0451    1.0000
```

The matrix `rho` indicates, for example, a correlation of 0.9421 between gender and weight after controlling for all other variables in `x`. You can return the p -values as a second output, and examine them to confirm whether these correlations are statistically significant.

For a clearer display, create a table with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'VariableNames', {'SexID', 'Age', 'Smoker', 'Weight'}, ...
    'RowNames', {'SexID', 'Age', 'Smoker', 'Weight'});
disp('Partial Correlation Coefficients')
Partial Correlation Coefficients
disp(rho)
```

	SexID	Age	Smoker	Weight
SexID	1	-0.01052	0.027324	0.9421
Age	-0.01052	1	0.041945	0.036873
Smoker	0.027324	0.041945	1	0.045106
Weight	0.9421	0.036873	0.045106	1

Test for Partial Correlations with Controlled Variables

Test for partial correlation between pairs of variables in the input matrix, while controlling for the effects of a second set of variables.

Load the sample data. Convert the genders in `hospital.Sex` to numeric group identifiers.

```
load hospital;
hospital.SexID = grp2idx(hospital.Sex);
```

Create two matrices containing the sample data.

```
x = [hospital.Age hospital.BloodPressure];
z = [hospital.SexID hospital.Smoker hospital.Weight];
```

The `x` matrix contains the variables to test for partial correlation. The `z` matrix contains the variables to control for. The measurements for `BloodPressure` are contained in two columns: The first column contains the upper (systolic) number, and the second column contains the lower (diastolic) number. `partialcorr` treats each column as a separate variable.

Test for partial correlation between pairs of variables in `x`, while controlling for the effects of the variables in `z`. Compute the correlation coefficients.

```
[rho,pval] = partialcorr(x,z)
```

```
rho = 3×3
```

```
    1.0000    0.1300    0.0462
    0.1300    1.0000    0.0012
    0.0462    0.0012    1.0000
```

```
pval = 3×3
```

```
    0    0.2044    0.6532
    0.2044    0    0.9903
    0.6532    0.9903    0
```

The large values in `pval` indicate that there is no significant correlation between age and either blood pressure measurement after controlling for gender, smoking status, and weight.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'VariableNames',{'Age','BPTop','BPBottom'},...
    'RowNames',{'Age','BPTop','BPBottom'});
```

```
pval = array2table(pval, ...
    'VariableNames',{'Age','BPTop','BPBottom'},...
    'RowNames',{'Age','BPTop','BPBottom'});
```

```
disp('Partial Correlation Coefficients')
```

```
Partial Correlation Coefficients
```

```
disp(rho)
```

	Age	BPTop	BPBottom
Age	1	0.13	0.046202
BPTop	0.13	1	0.0012475
BPBottom	0.046202	0.0012475	1

```
disp('p-values')
```

```
p-values
```

```
disp(pval)
```

	Age	BPTop	BPBottom
Age	0	0.20438	0.65316
BPTop	0.20438	0	0.99032
BPBottom	0.65316	0.99032	0

Test for Paired Partial Correlation Coefficients

Test for partial correlation between pairs of variables in the `x` and `y` input matrices, while controlling for the effects of a third set of variables.

Load the sample data. Convert the genders in `hospital.Sex` to numeric group identifiers.

```
load hospital;
hospital.SexID = grp2idx(hospital.Sex);
```

Create three matrices containing the sample data.

```
x = [hospital.BloodPressure];
y = [hospital.Weight hospital.Age];
z = [hospital.SexID hospital.Smoker];
```

`partialcorr` can test for partial correlation between the pairs of variables in `x` (the systolic and diastolic blood pressure measurements) and `y` (weight and age), while controlling for the variables in `z` (gender and smoking status). The measurements for `BloodPressure` are contained in two columns: The first column contains the upper (systolic) number, and the second column contains the lower (diastolic) number. `partialcorr` treats each column as a separate variable.

Test for partial correlation between pairs of variables in `x` and `y`, while controlling for the effects of the variables in `z`. Compute the correlation coefficients.

```
[rho,pval] = partialcorr(x,y,z)
```

```
rho = 2×2
```

```
    -0.0257    0.1289
     0.0292    0.0472
```

```
pval = 2×2
```

```
    0.8018    0.2058
    0.7756    0.6442
```

The results in `pval` indicate that, after controlling for gender and smoking status, there is no significant correlation between either of a patient's blood pressure measurements and that patient's weight or age.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'RowNames',{'BPTop','BPBottom'},...
    'VariableNames',{'Weight','Age'});

pval = array2table(pval, ...
    'RowNames',{'BPTop','BPBottom'},...
    'VariableNames',{'Weight','Age'});

disp('Partial Correlation Coefficients')

Partial Correlation Coefficients

disp(rho)
```

	Weight	Age
BPTop	-0.02568	0.12893
BPBottom	0.029168	0.047226

```
disp('p-values')
```

```
p-values
```

```
disp(pval)
```

	Weight	Age
BPTop	0.80182	0.2058
BPBottom	0.77556	0.64424

One-Tailed Partial Correlation Test

Test the hypothesis that pairs of variables have no correlation, against the alternative hypothesis that the correlation is greater than 0.

Load the sample data. Convert the genders in `hospital.Sex` to numeric group identifiers.

```
load hospital;
hospital.SexID = grp2idx(hospital.Sex);
```

Create three matrices containing the sample data.

```
x = [hospital.BloodPressure];
y = [hospital.Weight hospital.Age];
z = [hospital.SexID hospital.Smoker];
```

`partialcorr` can test for partial correlation between the pairs of variables in `x` (the systolic and diastolic blood pressure measurements) and `y` (weight and age), while controlling for the variables in `z` (gender and smoking status). The measurements for `BloodPressure` are contained in two columns: The first column contains the upper (systolic) number, and the second column contains the lower (diastolic) number. `partialcorr` treats each column as a separate variable.

Compute the correlation coefficients using a right-tailed test.

```
[rho,pval] = partialcorr(x,y,z,'Tail','right')
```

```
rho = 2×2
```

-0.0257	0.1289
0.0292	0.0472

```
pval = 2×2
```

0.5991	0.1029
0.3878	0.3221

The results in `pval` indicate that `partialcorr` does not reject the null hypothesis of nonzero correlations between the variables in `x` and `y`, after controlling for the variables in `z`, when the alternative hypothesis is that the correlations are greater than 0.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'RowNames', {'BPTop', 'BPBottom'}, ...
    'VariableNames', {'Weight', 'Age'});

pval = array2table(pval, ...
    'RowNames', {'BPTop', 'BPBottom'}, ...
    'VariableNames', {'Weight', 'Age'});

disp('Partial Correlation Coefficients')
```

Partial Correlation Coefficients

```
disp(rho)
```

	Weight	Age
BPTop	-0.02568	0.12893
BPBottom	0.029168	0.047226

```
disp('p-values')
```

p-values

```
disp(pval)
```

	Weight	Age
BPTop	0.59909	0.1029

Input Arguments

x — Data matrix

matrix

Data matrix, specified as an n -by- p_x matrix. The rows of `x` correspond to observations, and the columns correspond to variables.

Data Types: `single` | `double`

y — Data matrix

matrix

Data matrix, specified as an n -by- p_y matrix. The rows of `y` correspond to observations, and the columns correspond to variables.

Data Types: `single` | `double`

z — Data matrix

matrix

Data matrix, specified as an n -by- p_z matrix. The rows of z correspond to observations, and columns correspond to variables.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'Type', 'Spearman', 'Rows', 'complete'` computes Spearman partial correlations using only the data in rows that contain no missing values.

Type — Type of partial correlations

`'Pearson'` (default) | `'Spearman'`

Type of partial correlations to compute, specified as the comma-separated pair consisting of `'Type'` and one of the following.

<code>'Pearson'</code>	Compute Pearson (linear) partial correlations.
<code>'Spearman'</code>	Compute Spearman (rank) partial correlations.

Example: `'Type', 'Spearman'`

Rows — Rows to use in computation

`'all'` (default) | `'complete'` | `'pairwise'`

Rows to use in computation, specified as the comma-separated pair consisting of `'Rows'` and one of the following.

<code>'all'</code>	Use all rows of the input regardless of missing values (NaNs).
<code>'complete'</code>	Use only rows of the input with no missing values.
<code>'pairwise'</code>	Compute $\rho(i, j)$ using rows with no missing values in column i or j .

Example: `'Rows', 'complete'`

Tail — Alternative hypothesis

`'both'` (default) | `'right'` | `'left'`

Alternative hypothesis to test against, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

<code>'both'</code>	Test the alternative hypothesis that the correlation is not 0.
<code>'right'</code>	Test the alternative hypothesis that the correlation is greater than 0.
<code>'left'</code>	Test the alternative hypothesis that the correlation is less than 0.

Example: `'Tail', 'right'`

Output Arguments

rho — Sample linear partial correlation coefficients

matrix

Sample linear partial correlation coefficients, returned as a matrix.

- If you input only an x matrix, ρ is a symmetric p_x -by- p_x matrix. The (i,j) th entry is the sample linear partial correlation between the i -th and j -th columns in x .
- If you input x and z matrices, ρ is a symmetric p_x -by- p_x matrix. The (i,j) th entry is the sample linear partial correlation between the i th and j th columns in x , controlled for the variables in z .
- If you input x , y , and z matrices, ρ is a p_x -by- p_y matrix, where the (i,j) th entry is the sample linear partial correlation between the i th column in x and the j th column in y , controlled for the variables in z .

If the covariance matrix of $[x, z]$ is

$$S = \begin{pmatrix} S_{xx} & S_{xz} \\ S_{xz}^T & S_{zz} \end{pmatrix},$$

then the partial correlation matrix of x , controlling for z , can be defined formally as a normalized version of the covariance matrix: $S_{xx} - (S_{xz}S_{zz}^{-1}S_{xz}^T)$.

pval — *p*-values

matrix

p-values, returned as a matrix. Each element of `pval` is the *p*-value for the corresponding element of ρ .

If `pval(i, j)` is small, then the corresponding partial correlation $\rho(i, j)$ is statistically significantly different from 0.

`partialcorr` computes *p*-values for linear and rank partial correlations using a Student's *t* distribution for a transformation of the correlation. This is exact for linear partial correlation when x and z are normal, but is a large-sample approximation otherwise.

See Also

`corr` | `corrcoef` | `partialcorri` | `tiedrank`

Introduced before R2006a

partialcorri

Partial correlation coefficients adjusted for internal variables

Syntax

```
rho = partialcorri(y,x)
rho = partialcorri(y,x,z)
rho = partialcorri( ____,Name,Value)
[rho,pval] = partialcorri( ____,Name,Value)
```

Description

`rho = partialcorri(y,x)` returns the sample linear partial correlation coefficients between pairs of variables in `y` and `x`, adjusting for the remaining variables in `x`.

`rho = partialcorri(y,x,z)` returns the sample linear partial correlation coefficients between pairs of variables in `y` and `x`, adjusting for the remaining variables in `x`, after first controlling both `x` and `y` for the variables in `z`.

`rho = partialcorri(____,Name,Value)` returns the sample linear partial correlation coefficients with additional options specified by one or more name-value pair arguments, using input arguments from any of the previous syntaxes. For example, you can specify whether to use Pearson or Spearman partial correlations, or specify how to treat missing values.

`[rho,pval] = partialcorri(____,Name,Value)` also returns a matrix `pval` of p -values for testing the hypothesis of no partial correlation against the one- or two-sided alternative that there is a nonzero partial correlation.

Examples

Compute Partial Correlation Coefficients

Compute partial correlation coefficients for each pair of variables in the `x` and `y` input matrices, while controlling for the effects of the remaining variables in `x`.

Load the sample data.

```
load carsmall;
```

The data contains measurements from cars manufactured in 1970, 1976, and 1982. It includes `MPG` and `Acceleration` as performance measures, and `Displacement`, `Horsepower`, and `Weight` as design variables. `Acceleration` is the time required to accelerate from 0 to 60 miles per hour, so a high value for `Acceleration` corresponds to a vehicle with low acceleration.

Define the input matrices. The `y` matrix includes the performance measures, and the `x` matrix includes the design variables.

```
y = [MPG,Acceleration];
x = [Displacement,Horsepower,Weight];
```

Compute the correlation coefficients. Include only rows with no missing values in the computation.

```
rho = partialcorri(y,x,'Rows','complete')
```

```
rho = 2×3
```

```
-0.0537   -0.1520   -0.4856
-0.3994   -0.4008    0.4912
```

The results suggest, for example, a 0.4912 correlation between weight and acceleration after controlling for the effects of displacement and horsepower. You can return the p -values as a second output, and examine them to confirm whether these correlations are statistically significant.

For a clearer display, create a table with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'VariableNames',{ 'Displacement', 'Horsepower', 'Weight'}, ...
    'RowNames',{ 'MPG', 'Acceleration'});
```

```
disp('Partial Correlation Coefficients')
```

```
Partial Correlation Coefficients
```

```
disp(rho)
```

	Displacement	Horsepower	Weight
MPG	-0.053684	-0.15199	-0.48563
Acceleration	-0.39941	-0.40075	0.49123

Test Partial Correlations While Controlling for Additional Variables

Test for partial correlation between pairs of variables in the x and y input matrices, while controlling for the effects of the remaining variables in x plus additional variables in matrix z .

Load the sample data.

```
load carsmall;
```

The data contains measurements from cars manufactured in 1970, 1976, and 1982. It includes `MPG` and `Acceleration` as performance measures, and `Displacement`, `Horsepower`, and `Weight` as design variables. `Acceleration` is the time required to accelerate from 0 to 60 miles per hour, so a high value for `Acceleration` corresponds to a vehicle with low acceleration.

Create a new variable `Headwind`, and randomly generate data to represent the notion of an average headwind along the performance measurement route.

```
rng('default'); % For reproducibility
Headwind = (10:-0.2:-9.8)' + 5*randn(100,1);
```

Since headwind can affect the performance measures, control for its effects when testing for partial correlation between the remaining variables.

Define the input matrices. The y matrix includes the performance measures, and the x matrix includes the design variables. The z matrix contains additional variables to control for when computing the partial correlations, such as headwind.

```
y = [MPG,Acceleration];
x = [Displacement,Horsepower,Weight];
z = Headwind;
```

Compute the partial correlation coefficients. Include only rows with no missing values in the computation.

```
[rho,pval] = partialcorri(y,x,z,'Rows','complete')
```

```
rho = 2×3
```

```
    0.0572    -0.1055    -0.5736
   -0.3845    -0.3966     0.4674
```

```
pval = 2×3
```

```
    0.5923    0.3221    0.0000
    0.0002    0.0001    0.0000
```

The small returned *p*-value of 0.001 in `pval` indicates, for example, a significant negative correlation between horsepower and acceleration, after controlling for displacement, weight, and headwind.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'VariableNames',{'Displacement','Horsepower','Weight'}, ...
    'RowNames',{'MPG','Acceleration'});

pval = array2table(pval, ...
    'VariableNames',{'Displacement','Horsepower','Weight'}, ...
    'RowNames',{'MPG','Acceleration'});

disp('Partial Correlation Coefficients, Accounting for Headwind')
```

```
Partial Correlation Coefficients, Accounting for Headwind
```

```
disp(rho)
```

	Displacement	Horsepower	Weight
MPG	0.057197	-0.10555	-0.57358
Acceleration	-0.38452	-0.39658	0.4674

```
disp('p-values, Accounting for Headwind')
```

```
p-values, Accounting for Headwind
```

```
disp(pval)
```

	Displacement	Horsepower	Weight

MPG	0.59233	0.32212	3.4401e-09
Acceleration	0.00018272	0.00010902	3.4091e-06

Input Arguments

x — Data matrix

matrix

Data matrix, specified as an n -by- p_x matrix. The rows of **x** correspond to observations, and the columns correspond to variables.

Data Types: `single` | `double`

y — Data matrix

matrix

Data matrix, specified as an n -by- p_y matrix. The rows of **y** correspond to observations, and the columns correspond to variables.

Data Types: `single` | `double`

z — Data matrix

matrix

Data matrix, specified as an n -by- p_z matrix. The rows of **z** correspond to observations, and the columns correspond to variables.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Type', 'Spearman', 'Rows', 'complete'` computes Spearman partial correlations using only the data in rows that contain no missing values.

Type — Type of partial correlations

`'Pearson'` (default) | `'Spearman'`

Type of partial correlations to compute, specified as the comma-separated pair consisting of `'Type'` and either `'Pearson'` or `'Spearman'`. `Pearson` computes the Pearson (linear) partial correlations. `Spearman` computes the Spearman (rank) partial correlations.

Example: `'Type', 'Spearman'`

Rows — Rows to use in computation

`'all'` (default) | `'complete'` | `'pairwise'`

Rows to use in computation, specified as the comma-separated pair consisting of `'Rows'` and one of the following.

<code>'all'</code>	Use all rows regardless of missing (NaN) values.
<code>'complete'</code>	Use only rows with no missing values.

`'pairwise'` Use all available values in each column of y when computing the partial correlation coefficients and p -values corresponding to that column. For each column of y , rows will be dropped corresponding to missing values in x (and/or z , if supplied). However, remaining rows with valid values in that column of y are used, even if there are missing values in other columns of y .

Example: `'Rows', 'complete'`

Tail – Alternative hypothesis

`'both'` (default) | `'right'` | `'left'`

Alternative hypothesis to test against, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

<code>'both'</code>	Test the alternative hypothesis that the correlation is not zero.
<code>'right'</code>	Test the alternative hypothesis that the correlation is greater than 0.
<code>'left'</code>	Test the alternative hypothesis that the correlation is less than 0.

Example: `'Tail', 'right'`

Output Arguments

rho – Sample linear partial correlation coefficients

matrix

Sample linear partial correlation coefficients, returned as a p_y -by- p_x matrix.

- If you input x and y matrices, the (i,j) th entry is the sample linear partial correlation between the i th column in y and the j th column in x , controlled for all the columns of x except column j .
- If you input x , y , and z matrices, the (i,j) th entry is the sample linear partial correlation between the i th column in y and the j th column in x , adjusted for all the columns of x except column j , after first controlling both x and y for the variables in z .

pval – p -values

matrix

p -values, returned as a matrix. Each element of `pval` is the p -value for the corresponding element of `rho`. If `pval(i, j)` is small, then the corresponding partial correlation `rho(i, j)` is statistically significantly different from zero.

`partialcorri` computes p -values for linear and rank partial correlations using a Student's t distribution for a transformation of the correlation. This is exact for linear partial correlation when x and z are normal, but is a large-sample approximation otherwise.

`corr` | `partialcorr`

Introduced in R2013b

pca

Principal component analysis of raw data

Syntax

```
coeff = pca(X)
coeff = pca(X,Name,Value)
[coeff,score,latent] = pca( ___ )
[coeff,score,latent,tsquared] = pca( ___ )
[coeff,score,latent,tsquared,explained,mu] = pca( ___ )
```

Description

`coeff = pca(X)` returns the principal component coefficients, also known as loadings, for the n -by- p data matrix X . Rows of X correspond to observations and columns correspond to variables. The coefficient matrix is p -by- p . Each column of `coeff` contains coefficients for one principal component, and the columns are in descending order of component variance. By default, `pca` centers the data and uses the singular value decomposition (SVD) algorithm.

`coeff = pca(X,Name,Value)` returns any of the output arguments in the previous syntaxes using additional options for computation and handling of special data types, specified by one or more `Name,Value` pair arguments.

For example, you can specify the number of principal components `pca` returns or an algorithm other than SVD to use.

`[coeff,score,latent] = pca(___)` also returns the principal component scores in `score` and the principal component variances in `latent`. You can use any of the input arguments in the previous syntaxes.

Principal component scores are the representations of X in the principal component space. Rows of `score` correspond to observations, and columns correspond to components.

The principal component variances are the eigenvalues of the covariance matrix of X .

`[coeff,score,latent,tsquared] = pca(___)` also returns the Hotelling's T-squared statistic for each observation in X .

`[coeff,score,latent,tsquared,explained,mu] = pca(___)` also returns `explained`, the percentage of the total variance explained by each principal component and `mu`, the estimated mean of each variable in X .

Examples

Principal Components of a Data Set

Load the sample data set.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Find the principal components for the ingredients data.

```
coeff = pca(ingredients)
coeff = 4x4
    -0.0678    -0.6460     0.5673     0.5062
    -0.6785    -0.0200    -0.5440     0.4933
     0.0290     0.7553     0.4036     0.5156
     0.7309    -0.1085    -0.4684     0.4844
```

The rows of `coeff` contain the coefficients for the four ingredient variables, and its columns correspond to four principal components.

PCA in the Presence of Missing Data

Find the principal component coefficients when there are missing values in a data set.

Load the sample data set.

```
load imports-85
```

Data matrix `X` has 13 continuous variables in columns 3 to 15: wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg. The variables `bore` and `stroke` are missing four values in rows 56 to 59, and the variables `horsepower` and `peak-rpm` are missing two values in rows 131 and 132.

Perform principal component analysis.

```
coeff = pca(X(:,3:15));
```

By default, `pca` performs the action specified by the `'Rows'`, `'complete'` name-value pair argument. This option removes the observations with NaN values before calculation. Rows of NaNs are reinserted into `score` and `tsquared` at the corresponding locations, namely rows 56 to 59, 131, and 132.

Use `'pairwise'` to perform the principal component analysis.

```
coeff = pca(X(:,3:15), 'Rows', 'pairwise');
```

In this case, `pca` computes the (i,j) element of the covariance matrix using the rows with no NaN values in the columns i or j of `X`. Note that the resulting covariance matrix might not be positive definite. This option applies when the algorithm `pca` uses is eigenvalue decomposition. When you don't specify the algorithm, as in this example, `pca` sets it to `'eig'`. If you require `'svd'` as the algorithm, with the `'pairwise'` option, then `pca` returns a warning message, sets the algorithm to `'eig'` and continues.

If you use the `'Rows'`, `'all'` name-value pair argument, `pca` terminates because this option assumes there are no missing values in the data set.

```
coeff = pca(X(:,3:15), 'Rows', 'all');
```

Error using pca (line 180)
Raw data contains NaN missing value while 'Rows' option is set to 'all'. Consider using 'complete'

Weighted PCA

Use the inverse variable variances as weights while performing the principal components analysis.

Load the sample data set.

```
load hald
```

Perform the principal component analysis using the inverse of variances of the ingredients as variable weights.

```
[wcoeff,~,latent,~,explained] = pca(ingredients,...
'VariableWeights','variance')
```

```
wcoeff = 4×4
```

```
-2.7998    2.9940   -3.9736    1.4180
-8.7743   -6.4411    4.8927    9.9863
 2.5240   -3.8749   -4.0845    1.7196
 9.1714    7.5529    3.2710   11.3273

```

PCA Using ALS for Missing Data

Find the principal components using the alternating least squares (ALS) algorithm when there are missing values in the data.

Load the sample data.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Perform principal component analysis using the ALS algorithm and display the component coefficients.

```
[coeff,score,latent,tsquared,explained] = pca(ingredients);
coeff
```

```
coeff = 4x4
   -0.0678   -0.6460    0.5673    0.5062
   -0.6785   -0.0200   -0.5440    0.4933
    0.0290    0.7553    0.4036    0.5156
    0.7309   -0.1085   -0.4684    0.4844

```

Introduce missing values randomly.

```
y = ingredients;
rng('default'); % for reproducibility
ix = random('unif',0,1,size(y))<0.30;
y(ix) = NaN
```

```
y = 13x4
     7     26     6    NaN
     1     29    15     52
    NaN    NaN     8     20
    11     31    NaN     47
     7     52     6     33
    NaN     55    NaN    NaN
    NaN     71    NaN     6
     1     31    NaN     44
     2    NaN    NaN     22
    21     47     4     26
     :
```

Approximately 30% of the data has missing values now, indicated by NaN.

Perform principal component analysis using the ALS algorithm and display the component coefficients.

```
[coeff1,score1,latent,tsquared,explained,mu1] = pca(y,...
'algorithm','als');
```

```
coeff1
```

```
coeff1 = 4×4
```

```
-0.0362    0.8215   -0.5252    0.2190
-0.6831   -0.0998    0.1828    0.6999
 0.0169    0.5575    0.8215   -0.1185
 0.7292   -0.0657    0.1261    0.6694
```

Display the estimated mean.

```

```

```
mu1 = 1×4
```

```
 8.9956  47.9088   9.0451  28.5515
```

Reconstruct the observed data.

```
t = score1*coeff1' + repmat(mu1,13,1)
```

```
t = 13×4
```

```
 7.0000  26.0000   6.0000  51.5250
 1.0000  29.0000  15.0000  52.0000
10.7819  53.0230   8.0000  20.0000
11.0000  31.0000  13.5500  47.0000
 7.0000  52.0000   6.0000  33.0000
10.4818  55.0000   7.8328  17.9362
 3.0982  71.0000  11.9491   6.0000
 1.0000  31.0000  -0.5161  44.0000
 2.0000  53.7914   5.7710  22.0000
21.0000  47.0000   4.0000  26.0000
  :
```

The ALS algorithm estimates the missing values in the data.

Another way to compare the results is to find the angle between the two spaces spanned by the coefficient vectors. Find the angle between the coefficients found for complete data and data with missing values using ALS.

```
subspace(coeff,coeff1)
```

```
ans = 4.8688e-16
```

This is a small value. It indicates that the results if you use `pca` with `'Rows','complete'` name-value pair argument when there is no missing data and if you use `pca` with `'algorithm','als'` name-value pair argument when there is missing data are close to each other.

Perform the principal component analysis using 'Rows', 'complete' name-value pair argument and display the component coefficients.

```
[coeff2,score2,latent,tsquared,explained,mu2] = pca(y,...
'Rows','complete');
```

```
coeff2
```

```
coeff2 = 4×3
```

```
-0.2054    0.8587    0.0492
-0.6694   -0.3720    0.5510
 0.1474   -0.3513   -0.5187
 0.6986   -0.0298    0.6518
```

In this case, `pca` removes the rows with missing values, and `y` has only four rows with no missing values. `pca` returns only three principal components. You cannot use the 'Rows', 'pairwise' option because the covariance matrix is not positive semidefinite and `pca` returns an error message.

Find the angle between the coefficients found for complete data and data with missing values using listwise deletion (when 'Rows', 'complete').

```
subspace(coeff(:,1:3),coeff2)
```

```
ans = 0.3576
```

The angle between the two spaces is substantially larger. This indicates that these two results are different.

Display the estimated mean.

```
mu2
```

```
mu2 = 1×4
```

```
7.8889    46.9091    9.8750    29.6000
```

In this case, the mean is just the sample mean of `y`.

Reconstruct the observed data.

```
score2*coeff2'
```

```
ans = 13×4
```

```
NaN      NaN      NaN      NaN
-7.5162  -18.3545   4.0968   22.0056
NaN      NaN      NaN      NaN
NaN      NaN      NaN      NaN
-0.5644   5.3213   -3.3432   3.6040
NaN      NaN      NaN      NaN
NaN      NaN      NaN      NaN
NaN      NaN      NaN      NaN
NaN      NaN      NaN      NaN
12.8315  -0.1076  -6.3333  -3.7758
⋮
```

This shows that deleting rows containing NaN values does not work as well as the ALS algorithm. Using ALS is better when the data has too many missing values.

Principal Component Coefficients, Scores, and Variances

Find the coefficients, scores, and variances of the principal components.

Load the sample data set.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Find the principal component coefficients, scores, and variances of the components for the ingredients data.

```
[coeff,score,latent] = pca(ingredients)
```

```
coeff = 4×4
```

```

13.5385 -1.1538 -7.7692 -4.0000
  :
```

The new data in `Xcentered` is the original ingredients data centered by subtracting the column means from corresponding columns.

Visualize both the orthonormal principal component coefficients for each variable and the principal component scores for each observation in a single plot.

```
biplot(coeff(:,1:2), 'scores', score(:,1:2), 'varlabels', {'v_1', 'v_2', 'v_3', 'v_4'});
```

All four variables are represented in this biplot by a vector, and the direction and length of the vector indicate how each variable contributes to the two principal components in the plot. For example, the first principal component, which is on the horizontal axis, has positive coefficients for the third and

fourth variables. Therefore, vectors v_3 and v_4 are directed into the right half of the plot. The largest coefficient in the first principal component is the fourth, corresponding to the variable v_4 .

The second principal component, which is on the vertical axis, has negative coefficients for the variables v_1 , v_2 , and v_4 , and a positive coefficient for the variable v_3 .

This 2-D biplot also includes a point for each of the 13 observations, with coordinates indicating the score of each observation for the two principal components in the plot. For example, points near the left edge of the plot have the lowest scores for the first principal component. The points are scaled with respect to the maximum score value and maximum coefficient length, so only their relative locations can be determined from the plot.

T-Squared Statistic

Find the Hotelling's T-squared statistic values.

Load the sample data set.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Perform the principal component analysis and request the T-squared values.

Percent Variability Explained by Principal Components

Find the percent variability explained by the principal components. Show the data representation in the principal components space.

Load the sample data set.

```
load imports-85
```

Data matrix X has 13 continuous variables in columns 3 to 15: wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg.

Find the percent variability explained by principal components of these variables.

```
[coeff,score,latent,tsquared,explained] = pca(X(:,3:15));
```

```
explained
```

```
explained = 13×1
```

```
64.3429
35.4484
 0.1550
 0.0379
 0.0078
 0.0048
 0.0013
 0.0011
 0.0005
 0.0002
  :
```

The first three components explain 99.95% of all variability.

Visualize the data representation in the space of the first three principal components.

```
scatter3(score(:,1),score(:,2),score(:,3))
axis equal
xlabel('1st Principal Component')
ylabel('2nd Principal Component')
zlabel('3rd Principal Component')
```

The data shows the largest variability along the first principal component axis. This is the largest possible variance among all possible choices of the first axis. The variability along the second principal component axis is the largest among all possible remaining choices of the second axis. The third principal component axis has the third largest variability, which is significantly smaller than the variability along the second principal component axis. The fourth through thirteenth principal component axes are not worth inspecting, because they explain only 0.05% of all variability in the data.

To skip any of the outputs, you can use `~` instead in the corresponding element. For example, if you don't want to get the T-squared values, specify

```
[coeff,score,latent,~,explained] = pca(X(:,3:15));
```

Apply PCA to New Data and Generate C/C++ Code

Find the principal components for one data set and apply the PCA to another data set. This procedure is useful when you have a training data set and a test data set for a machine learning model. For example, you can preprocess the training data set by using PCA and then train a model. To test the trained model using the test data set, you need to apply the PCA transformation obtained from the training data to the test data set.

This example also describes how to generate C/C++ code. Because `pca` supports code generation, you can generate code that performs PCA using a training data set and applies the PCA to a test data

set. Then deploy the code to a device. In this workflow, you must pass training data, which can be of considerable size. To save memory on the device, you can separate training and prediction. Use `pca` in MATLAB® and apply PCA to new data in the generated code on the device.

Generating C/C++ code requires MATLAB® Coder™.

Apply PCA to New Data

Load the data set into a table by using `readtable`. The data set is in the file `CreditRating_Historical.dat`, which contains the historical credit rating data.

```
creditrating = readtable('CreditRating_Historical.dat');
creditrating(1:5,:)
```

ans=5×8 table

ID	WC_TA	RE_TA	EBIT_TA	MVE_BVTD	S_TA	Industry	Rating
62394	0.013	0.104	0.036	0.447	0.142	3	{'BB' }
48608	0.232	0.335	0.062	1.969	0.281	8	{'A' }
42444	0.311	0.367	0.074	1.935	0.366	1	{'A' }
48631	0.194	0.263	0.062	1.017	0.228	4	{'BBB' }
43768	0.121	0.413	0.057	3.647	0.466	12	{'AAA' }

The first column is an ID of each observation, and the last column is a rating. Specify the second to seventh columns as predictor data and specify the last column (Rating) as the response.

```
X = table2array(creditrating(:,2:7));
Y = creditrating.Rating;
```

Use the first 100 observations as test data and the rest as training data.

```
XTest = X(1:100,:);
XTrain = X(101:end,:);
YTest = Y(1:100);
YTrain = Y(101:end);
```

Find the principal components for the training data set `XTrain`.

```
[coeff,scoreTrain,~,~,explained,mu] = pca(XTrain);
```

This code returns four outputs: `coeff`, `scoreTrain`, `explained`, and `mu`. Use `explained` (percentage of total variance explained) to find the number of components required to explain at least 95% variability. Use `coeff` (principal component coefficients) and `mu` (estimated means of `XTrain`) to apply the PCA to a test data set. Use `scoreTrain` (principal component scores) instead of `XTrain` when you train a model.

Display the percent variability explained by the principal components.

```
explained
```

```
explained = 6×1
```

```
58.2614
41.2606
0.3875
0.0632
```

```
0.0269
0.0005
```

The first two components explain more than 95% of all variability. Programmatically find the number of components required to explain at least 95% variability by using a `while` loop.

```
sum_explained = 0;
idx = 0;
while sum_explained < 95
    idx = idx + 1;
    sum_explained = sum_explained + explained(idx);
end
idx

idx = 2
```

Train a classification tree using the first two components.

```
scoreTrain95 = scoreTrain(:,1:idx);
mdl = fitctree(scoreTrain95,YTrain);
```

`mdl` is a `ClassificationTree` model.

To use the trained model for the test set, you need to transform the test data set by using the PCA obtained from the training data set. Obtain the principal component scores of the test data set by subtracting `mu` from `XTest` and multiplying by `coeff`. Only the scores for the first two components are necessary, so use the first two coefficients `coeff(:,1:idx)`.

```
scoreTest95 = (XTest-mu)*coeff(:,1:idx);
```

Pass the trained model `mdl` and the transformed test data set `scoreTest` to the `predict` function to predict ratings for the test set.

```
YTest_predicted = predict(mdl,scoreTest95);
```

Generate Code

Generate code that applies PCA to data and predicts ratings using the trained model. Note that generating C/C++ code requires MATLAB® Coder™.

Save the classification model to the file `myMdl.mat` by using `saveLearnerForCoder`.

```
saveLearnerForCoder(mdl, 'myMdl');
```

Define an entry-point function named `myPCAPredict` that accepts a test data set (`XTest`) and PCA information (`coeff` and `mu`) and returns the ratings of the test data.

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would cause errors during code generation.

```
type myPCAPredict % Display contents of myPCAPredict.m

function label = myPCAPredict(XTest,coeff,mu) %#codegen
% Transform data using PCA
scoreTest = bsxfun(@minus,XTest,mu)*coeff;
```

```
% Load trained classification model
mdl = loadLearnerForCoder('myMdl');
% Predict ratings using the loaded model
label = predict(mdl,scoreTest);
```

`myPCAPredict` applies PCA to new data using `coeff` and `mu`, and then predicts ratings using the transformed data. In this way, you do not pass training data, which can be of considerable size.

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

Generate code by using `codegen`. Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. To specify the data type and exact input array size, pass a MATLAB® expression that represents the set of values with a certain data type and array size by using the `-args` option. If the number of observations is unknown at compile time, you can also specify the input as variable-size by using `coder.typeof`. For details, see “Specify Variable-Size Arguments for Code Generation” on page 31-38.

```
codegen myPCAPredict -args {coder.typeof(XTest,[Inf,6],[1,0]),coeff(:,1:idx),mu}
```

`codegen` generates the MEX function `myPCAPredict_mex` with a platform-dependent extension.

Verify the generated code.

```
YTest_predicted_mex = myPCAPredict_mex(XTest,coeff(:,1:idx),mu);
isequal(YTest_predicted,YTest_predicted_mex)
```

```
ans = logical
     1
```

`isequal` returns logical 1 (true), which means all the inputs are equal. The comparison confirms that the `predict` function of `mdl` and the `myPCAPredict_mex` function return the same ratings.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “Code Generation and Classification Learner App” on page 31-25. The latter describes how to perform PCA and train a model by using the Classification Learner app, and how to generate C/C++ code that predicts labels for new data based on the trained model.

Input Arguments

X — Input data

matrix

Input data for which to compute the principal components, specified as an n -by- p matrix. Rows of X correspond to observations and columns to variables.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: 'Algorithm', 'eig', 'Centered', false, 'Rows', 'all', 'NumComponents', 3 specifies that `pca` uses eigenvalue decomposition algorithm, not center the data, use all of the observations, and return only the first three principal components.

Algorithm – Principal component algorithm

'svd' (default) | 'eig' | 'als'

Principal component algorithm that `pca` uses to perform the principal component analysis, specified as the comma-separated pair consisting of 'Algorithm' and one of the following.

Value	Description
'svd'	Default. Singular value decomposition (SVD) of X .
'eig'	Eigenvalue decomposition (EIG) of the covariance matrix. The EIG algorithm is faster than SVD when the number of observations, n , exceeds the number of variables, p , but is less accurate because the condition number of the covariance is the square of the condition number of X .
'als'	Alternating least squares (ALS) algorithm. This algorithm finds the best rank- k approximation by factoring X into a n -by- k left factor matrix, L , and a p -by- k right factor matrix, R , where k is the number of principal components. The factorization uses an iterative method starting with random initial values. ALS is designed to better handle missing values. It is preferable to pairwise deletion ('Rows', 'pairwise') and deals with missing values without listwise deletion ('Rows', 'complete'). It can work well for data sets with a small percentage of missing data at random, but might not perform well on sparse data sets.

Example: 'Algorithm', 'eig'

Centered – Indicator for centering columns

true (default) | false

Indicator for centering the columns, specified as the comma-separated pair consisting of 'Centered' and one of these logical expressions.

Value	Description
true	Default. <code>pca</code> centers X by subtracting column means before computing singular value decomposition or eigenvalue decomposition. If X contains NaN missing values, <code>nanmean</code> is used to find the mean with any available data. You can reconstruct the centered data using <code>score*coeff</code> .
false	In this case <code>pca</code> does not center the data. You can reconstruct the original data using <code>score*coeff</code> .

Example: 'Centered', false

Data Types: logical

Economy – Indicator for economy size output

true (default) | false

Indicator for the economy size output when the degrees of freedom on page 32-3892, d , is smaller than the number of variables, p , specified as the comma-separated pair consisting of 'Economy' and one of these logical expressions.

Value	Description
true	Default. <code>pca</code> returns only the first d elements of <code>latent</code> and the corresponding columns of <code>coeff</code> and <code>score</code> . This option can be significantly faster when the number of variables p is much larger than d .
false	<code>pca</code> returns all elements of <code>latent</code> . The columns of <code>coeff</code> and <code>score</code> corresponding to zero elements in <code>latent</code> are zeros.

Note that when $d < p$, `score(:,d+1:p)` and `latent(d+1:p)` are necessarily zero, and the columns of `coeff(:,d+1:p)` define directions that are orthogonal to X .

Example: 'Economy', false

Data Types: logical

NumComponents — Number of components requested

number of variables (default) | scalar integer

Number of components requested, specified as the comma-separated pair consisting of 'NumComponents' and a scalar integer k satisfying $0 < k \leq p$, where p is the number of original variables in X . When specified, `pca` returns the first k columns of `coeff` and `score`.

Example: 'NumComponents', 3

Data Types: single | double

Rows — Action to take for NaN values

'complete' (default) | 'pairwise' | 'all'

Action to take for NaN values in the data matrix X , specified as the comma-separated pair consisting of 'Rows' and one of the following.

Value	Description
'complete'	Default. Observations with NaN values are removed before calculation. Rows of NaNs are reinserted into <code>score</code> and <code>tsquared</code> at the corresponding locations.
'pairwise'	This option only applies when the algorithm is 'eig'. If you don't specify the algorithm along with 'pairwise', then <code>pca</code> sets it to 'eig'. If you specify 'svd' as the algorithm, along with the option 'Rows', 'pairwise', then <code>pca</code> returns a warning message, sets the algorithm to 'eig' and continues. When you specify the 'Rows', 'pairwise' option, <code>pca</code> computes the (i,j) element of the covariance matrix using the rows with no NaN values in the columns i or j of X . Note that the resulting covariance matrix might not be positive definite. In that case, <code>pca</code> terminates with an error message.
'all'	X is expected to have no missing values. <code>pca</code> uses all of the data and terminates if any NaN value is found.

Example: 'Rows', 'pairwise'

Weights — Observation weights

ones (default) | row vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of length n containing all positive elements.

Data Types: `single` | `double`

VariableWeights — Variable weights

row vector | `'variance'`

Variable weights on page 32-3892, specified as the comma-separated pair consisting of `'VariableWeights'` and one of the following.

Value	Description
row vector	Vector of length p containing all positive elements.
<code>'variance'</code>	The variable weights are the inverse of sample variance. If you also assign weights to observations using <code>'Weights'</code> , then the variable weights become the inverse of weighted sample variance. If <code>'Centered'</code> is set to <code>true</code> at the same time, the data matrix X is centered and standardized. In this case, <code>pca</code> returns the principal components based on the correlation matrix.

Example: `'VariableWeights', 'variance'`

Data Types: `single` | `double` | `char` | `string`

Coeff0 — Initial value for coefficients

matrix of random values (default) | p -by- k matrix

Initial value for the coefficient matrix `coeff`, specified as the comma-separated pair consisting of `'Coeff0'` and a p -by- k matrix, where p is the number of variables, and k is the number of principal components requested.

Note You can use this name-value pair only when `'algorithm'` is `'als'`.

Data Types: `single` | `double`

Score0 — Initial value for scores

matrix of random values (default) | k -by- m matrix

Initial value for scores matrix `score`, specified as a comma-separated pair consisting of `'Score0'` and an n -by- k matrix, where n is the number of observations and k is the number of principal components requested.

Note You can use this name-value pair only when `'algorithm'` is `'als'`.

Data Types: `single` | `double`

Options — Options for iterations

structure

Options for the iterations, specified as a comma-separated pair consisting of `'Options'` and a structure created by the `statset` function. `pca` uses the following fields in the options structure.

Field Name	Description
'Display'	Level of display output. Choices are 'off', 'final', and 'iter'.
'MaxIter'	Maximum number steps allowed. The default is 1000. Unlike in optimization settings, reaching the MaxIter value is regarded as convergence.
'TolFun'	Positive number giving the termination tolerance for the cost function. The default is 1e-6.
'TolX'	Positive number giving the convergence threshold for the relative change in the elements of the left and right factor matrices, L and R, in the ALS algorithm. The default is 1e-6.

Note You can use this name-value pair only when 'algorithm' is 'als'.

You can change the values of these fields and specify the new structure in `pca` using the 'Options' name-value pair argument.

```
Example: opt = statset('pca'); opt.MaxIter = 2000; coeff =
pca(X, 'Options', opt);
```

Data Types: struct

Output Arguments

coeff — Principal component coefficients

matrix

Principal component coefficients, returned as a p -by- p matrix. Each column of `coeff` contains coefficients for one principal component. The columns are in the order of descending component variance, `latent`.

score — Principal component scores

matrix

Principal component scores, returned as a matrix. Rows of `score` correspond to observations, and columns to components.

latent — Principal component variances

column vector

Principal component variances, that is the eigenvalues of the covariance matrix of `X`, returned as a column vector.

tsquared — Hotelling's T-squared statistic

column vector

"Hotelling's T-Squared Statistic" on page 32-3892, which is the sum of squares of the standardized scores for each observation, returned as a column vector.

explained — Percentage of total variance explained

column vector

Percentage of the total variance explained by each principal component, returned as a column vector.

mu — Estimated means

row vector

Estimated means of the variables in X , returned as a row vector when `Centered` is set to `true`. When `Centered` is `false`, the software does not compute the means and returns a vector of zeros.

More About

Hotelling's T-Squared Statistic

Hotelling's T-squared statistic is a statistical measure of the multivariate distance of each observation from the center of the data set.

Even when you request fewer components than the number of variables, `pca` uses all principal components to compute the T-squared statistic (computes it in the full space). If you want the T-squared statistic in the reduced or the discarded space, do one of the following:

- For the T-squared statistic in the reduced space, use `mahal(score, score)`.
- For the T-squared statistic in the discarded space, first compute the T-squared statistic using `[coeff, score, latent, tsquared] = pca(X, 'NumComponents', k, ...)`, compute the T-squared statistic in the reduced space using `tsqreduced = mahal(score, score)`, and then take the difference: `tsquared - tsqreduced`.

Degrees of Freedom

The degrees of freedom, d , is equal to $n - 1$, if data is centered and n otherwise, where:

- n is the number of rows without any NaNs if you use `'Rows'`, `'complete'`.
- n is the number of rows without any NaNs in the column pair that has the maximum number of rows without NaNs if you use `'Rows'`, `'pairwise'`.

Variable Weights

Note that when variable weights are used, the coefficient matrix is not orthonormal. Suppose the variable weights vector you used is called `varwei`, and the principal component coefficients vector `pca` returned is `wcoeff`. You can then calculate the orthonormal coefficients using the transformation `diag(sqrt(varwei))*wcoeff`.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

- `pca` works directly with tall arrays by computing the covariance matrix and using the in-memory `pcacov` function to compute the principle components.
- Supported syntaxes are:
 - `coeff = pca(X)`
 - `[coeff,score,latent] = pca(X)`
 - `[coeff,score,latent,explained] = pca(X)`
 - `[coeff,score,latent,tsquared] = pca(X)`
 - `[coeff,score,latent,tsquared,explained] = pca(X)`
- Name-value pair arguments are not supported.

For more information, see "Tall Arrays for Out-of-Memory Data" (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- When 'Algorithm' is 'als', the 'Display' value for 'Options' is ignored.
- The values for the 'Weights' and 'VariableWeights' name-value pair arguments must be real.
- The value for the 'Economy' name-value pair argument must be a compile-time constant. For example, to use the 'Economy', `false` name-value pair argument in the generated code, include `{coder.Constant('Economy'),coder.Constant(false)}` in the `-args` value of `codegen`.
- Names in name-value pair arguments must be compile-time constants.
- The generated code always returns the fifth output `explained` as a column vector.
- The generated code always returns the sixth output `mu` as a row vector.
- If `mu` is empty, `pca` returns `mu` as a 1-by-0 array. `pca` does not convert `mu` to a 0-by-0 empty array.
- The generated code does not treat an input matrix `X` that has all NaN values as a special case. The output dimensions are commensurate with corresponding finite inputs.
- To save memory on the device to which you deploy generated code, you can separate training (constructing PCA components from input data) and prediction (performing PCA transformation). Construct PCA components in MATLAB. Then, define an entry-point function that performs PCA transformation using the principal component coefficients (`coeff`) and estimated means (`mu`), which are the outputs of `pca`. Finally, generate code for the entry-point function. For an example, see "Apply PCA to New Data and Generate C/C++ Code" on page 32-3884.

For more information on code generation, see "Introduction to Code Generation" on page 31-2 and "General Code Generation Workflow" on page 31-5.

Introduced in R2012b

pcacov

Principal component analysis on covariance matrix

Syntax

```
COEFF = pcacov(V)
[COEFF,latent] = pcacov(V)
[COEFF,latent,explained] = pcacov(V)
```

Description

`COEFF = pcacov(V)` performs principal components analysis on the p -by- p covariance matrix V and returns the principal component coefficients, also known as loadings. `COEFF` is a p -by- p matrix, with each column containing coefficients for one principal component. The columns are in order of decreasing component variance.

`pcacov` does not standardize V to have unit variances. To perform principal components analysis on standardized variables, use the correlation matrix $R = V ./ (SD * SD')$, where $SD = \text{sqrt}(\text{diag}(V))$, in place of V . To perform principal components analysis directly on the data matrix, use `pca`.

`[COEFF,latent] = pcacov(V)` returns `latent`, a vector containing the principal component variances, that is, the eigenvalues of V .

`[COEFF,latent,explained] = pcacov(V)` returns `explained`, a vector containing the percentage of the total variance explained by each principal component.

Examples

```
load hald
covx = cov(ingredients);
[COEFF,latent,explained] = pcacov(covx)
COEFF =
    0.0678 -0.6460  0.5673 -0.5062
    0.6785 -0.0200 -0.5440 -0.4933
   -0.0290  0.7553  0.4036 -0.5156
   -0.7309 -0.1085 -0.4684 -0.4844

latent =
    517.7969
     67.4964
     12.4054
      0.2372

explained =
     86.5974
     11.2882
      2.0747
      0.0397
```

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

`pcacov` and `factoran` do *not* work directly on tall arrays. Instead, use `C = gather(cov(X))` to compute the covariance matrix of a tall array. Then, you can use `pcacov` or `factoran` on the in-memory covariance matrix. Alternatively, you can use `pca` directly on a tall array.

For more information, see “Tall Arrays for Out-of-Memory Data” (MATLAB).

`barttest` | `biplot` | `factoran` | `pca` | `pcares` | `rotatefactors`

Introduced before R2006a

pcares

Residuals from principal component analysis

Syntax

```
residuals = pcares(X,ndim)
[residuals,reconstructed] = pcares(X,ndim)
```

Description

`residuals = pcares(X,ndim)` returns the `residuals` obtained by retaining `ndim` principal components of the `n`-by-`p` matrix `X`. Rows of `X` correspond to observations, columns to variables. `ndim` is a scalar and must be less than or equal to `p`. `residuals` is a matrix of the same size as `X`. Use the data matrix, *not* the covariance matrix, with this function.

`pcares` does not normalize the columns of `X`. To perform the principal components analysis based on standardized variables, that is, based on correlations, use `pcares(zscore(X), ndim)`. You can perform principal components analysis directly on a covariance or correlation matrix, but without constructing residuals, by using `pcacov`.

`[residuals,reconstructed] = pcares(X,ndim)` returns the reconstructed observations; that is, the approximation to `X` obtained by retaining its first `ndim` principal components.

Examples

This example shows the drop in the residuals from the first row of the Hald data as the number of component dimensions increases from one to three.

```
load hald
r1 = pcares(ingredients,1);
r2 = pcares(ingredients,2);
r3 = pcares(ingredients,3);

r11 = r1(1,:)
r11 =
    2.0350    2.8304   -6.8378    3.0879

r21 = r2(1,:)
r21 =
   -2.4037    2.6930   -1.6482    2.3425

r31 = r3(1,:)
r31 =
    0.2008    0.1957    0.2045    0.1921
```

factoran | pca | pcacov

Introduced before R2006a

ppca

Probabilistic principal component analysis

Syntax

```
[coeff,score,pcvar] = ppca(Y,K)
[coeff,score,pcvar] = ppca(Y,K,Name,Value)
[coeff,score,pcvar,mu] = ppca(____)
[coeff,score,pcvar,mu,v,S] = ppca(____)
```

Description

`[coeff,score,pcvar] = ppca(Y,K)` returns the principal component coefficients for the n -by- p data matrix Y based on a probabilistic principal component analysis on page 32-3905 (PPCA). It also returns the principal component scores, which are the representations of Y in the principal component space, and the principal component variances, which are the eigenvalues of the covariance matrix of Y , in `pcvar`.

Each column of `coeff` contains coefficients for one principal component, and the columns are in descending order of component variance. Rows of `score` correspond to observations, and columns correspond to components. Rows of Y correspond to observations and columns correspond to variables.

Probabilistic principal component analysis might be preferable to other algorithms that handle missing data, such as the alternating least squares algorithm when any data vector has one or more missing values. It assumes that the values are missing at random through the data set. An expectation-maximization algorithm is used for both complete and missing data.

`[coeff,score,pcvar] = ppca(Y,K,Name,Value)` returns the principal component coefficients, scores, and variances using additional options for computation and handling of special data types, specified by one or more `Name,Value` pair arguments.

For example, you can introduce initial values for the residual variance, v , or change the termination criteria.

`[coeff,score,pcvar,mu] = ppca(____)` also returns the estimated mean of each variable in Y . You can use any of the input arguments in the previous syntaxes.

`[coeff,score,pcvar,mu,v,S] = ppca(____)` also returns the isotropic residual variance in v and the final results at convergence in structure S .

Examples

Perform Probabilistic Principal Component Analysis

Load the sample data.

```
load fisheriris
```

The double matrix `meas` consists of four types of measurements on the flowers, which, respectively, are the length and width of sepals and petals.

Introduce missing values randomly.

```
y = meas;
rng('default'); % for reproducibility
ix = random('unif',0,1,size(y))<0.20;
y(ix) = NaN;
```

Now, approximately 20% of the data is missing, indicated by `NaN`.

Perform probabilistic principal component analysis and request the component coefficients and variances.

```
[coeff,score,pcvar,mu] = ppca(y,3);
coeff
```

```
coeff = 4×3
```

```
    0.3562    0.6709   -0.5518
   -0.0765    0.7120    0.6332
    0.8592   -0.1597    0.0596
    0.3592   -0.1318    0.5395
```

```
pcvar
```

```
pcvar = 3×1
```

```
    4.0914
    0.2125
    0.0617
```

Perform principal component analysis using the alternating least squares algorithm and request the component coefficients and variances.

```
[coeff2,score2,pcvar2,mu2] = pca(y,'algorithm','als',...
'NumComponents',3);
coeff2
```

```
coeff2 = 4×3
```

```
    0.3376    0.4952    0.7406
   -0.0731    0.8609   -0.4476
    0.8657   -0.1168   -0.1233
    0.3623   -0.0086   -0.4857
```

```
pcvar2
```

```
pcvar2 = 3×1
```

```
    4.0733
    0.2652
    0.1222
```

The coefficients and the variances of the first two principal components are similar.

Another way to compare the results is to find the angle between the two spaces spanned by the coefficient vectors.

```
subspace(coeff,coeff2)
ans = 0.0884
```

The angle between the two spaces is pretty small. This indicates that these two results are close to each other.

Change the Termination Criteria for Probabilistic Principal Component Analysis

Load the sample data set.

```
load imports-85
```

Data matrix X has 13 continuous variables in columns 3 to 15: wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg. The variables bore and stroke are missing four values in rows 56 to 59, and the variables horsepower and peak-rpm are missing two values in rows 131 and 132.

Perform probabilistic principal component analysis and display the first three principal components.

```
[coeff,score,pcvar] = ppca(X(:,3:15),3);
```

```
Warning: Maximum number of iterations 1000 reached.
```

Change the termination tolerance for the cost function to 0.01.

```
opt = statset('ppca');
opt.TolFun = 0.01;
```

Perform probabilistic principal component analysis.

```
[coeff,score,pcvar] = ppca(X(:,3:15),3,'Options',opt);
```

```
Warning: Maximum number of iterations 1000 reached.
```

ppca now terminates before the maximum number of iterations is reached because it meets the tolerance for the cost function.

Reconstruct Observations

Load the sample data.

```
load hald
y = ingredients;
```

The ingredients data has 13 observations for 4 variables.

Introduce missing values to the data.

```
y(2:16:end) = NaN;
```

Every 16th value is NaN. This corresponds to 7.69% of the data.

Find the first three principal components of data using PPCA and display the reconstructed observations.

```
[coeff,score,pcvar,mu,v,S] = ppca(y,3);
```

```
Warning: Maximum number of iterations 1000 reached.
```

```
S.Recon
```

```
ans = 13×4
```

```

    6.8536    25.8700     5.8389    59.8730
    1.0433    28.9710    14.9654    51.9738
   11.5770    56.5067     8.6352    20.5076
   11.0835    31.0722     8.0920    47.0748
    7.0679    52.2556     6.0748    33.0598
   11.0486    55.0430     9.0534    22.0423
    2.8493    70.8691    16.8339     5.8656
    1.0333    31.0281    19.6907    44.0306
    2.0400    54.0354    18.0440    22.0349
   20.7822    46.8091     3.7603    25.8081
      :
```

You can also reconstruct the observations using the principal components and the estimated mean.

```
t = score*coeff' + repmat(mu,13,1);
```

Results at Convergence

Load the data.

```
load hald
```

Here, `ingredients` is a real-valued matrix of predictor variables.

Perform the probabilistic principal components analysis and display coefficients.

```
[coeff,score,pcvariance,mu,v,S] = ppca(ingredients,3);
```

```
Warning: Maximum number of iterations 1000 reached.

Input Arguments

Y — Input data

n-by-*p* matrix

Input data for which to compute the principal components, specified as an *n*-by-*p* matrix. Rows of Y correspond to observations and columns correspond to variables.

Data Types: single | double

K — Number of principal components

positive integer value less than rank

Number of principal components to return, specified as an integer value less than the rank of data. The maximum possible rank is $\min(n,p)$, where *n* is the number of observations and *p* is the number of variables. However, if the data is correlated, the rank might be smaller than $\min(n,p)$.

ppca orders the components based on their variance.

If K is $\min(n,p)$, ppca sets K equal to $\min(n,p) - 1$, and 'W0' is truncated to $\min(p,n) - 1$ columns if you specify a *p*-by-*p* W0 matrix.

For example, you can request only the first three components, based on the component variance as follows.

Example: `coeff = ppca(Y,3)`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'W0', init, 'Options', opt` specifies that the initial values for `'W0'` are in matrix `init` and `ppca` uses the options defined by `opt`.

W0 — Initial value of *W*

matrix of random values (default) | *p*-by-*k* matrix

Initial value of *W* in the probabilistic principal component analysis on page 32-3905 algorithm, specified as a comma-separated pair consisting of `'W0'` and a *p*-by-*k* matrix.

Data Types: `single` | `double`

v0 — Initial value of residual variance

random number (default) | positive scalar value

Initial value of residual variance, specified as the comma-separated pair consisting of `'v0'` and a positive scalar value.

Data Types: `single` | `double`

Options — Options for iterations

structure

Options for the iterations, specified as a comma-separated pair `'Options'` and a structure created by the `statset` function. `ppca` uses the following fields in the options structure.

<code>'Display'</code>	Level of display output. Choices are <code>'off'</code> , <code>'final'</code> , and <code>'iter'</code> .
<code>'MaxIter'</code>	Maximum number of steps allowed. The default is 1000. Unlike in optimization settings, reaching the <code>MaxIter</code> value is regarded as convergence.
<code>'TolFun'</code>	Positive integer stating the termination tolerance for the cost function. The default is 1e-6.
<code>'TolX'</code>	Positive integer stating the convergence threshold for the relative change in the elements of <i>W</i> . The default is 1e-6.

You can change the values of these fields and specify the new structure in `ppca` using the `'Options'` name-value pair argument.

Example: `opt = statset('ppca'); opt.MaxIter = 2000; coeff = ppca(Y,3, 'Options', opt);`

Data Types: `struct`

Output Arguments

coeff — Principal component coefficients

p-by-*k* matrix

Principal component coefficients, returned as a *p*-by-*k* matrix. Each column of **coeff** contains coefficients for one principal component. The columns are in the order of descending component variance, **pcvar**.

score — Principal component scores

n-by-*k* matrix

Principal component scores, returned as an *n*-by-*k* matrix. Rows of **score** correspond to observations, and columns correspond to components.

pcvar — Principal component variances

column vector

Principal component variances, which are the eigenvalues of the covariance matrix of *Y*, returned as a column vector.

mu — Estimated mean

row vector

Estimated mean of each variable in *Y*, returned as a row vector.

v — Isotropic residual variance

scalar value

Isotropic residual variance, returned as a scalar value.

S — Final results at convergence

structure

Final results at convergence, returned as a structure containing the following fields.

W	<i>W</i> at convergence.
Xexp	Conditional expectation of the estimated latent variable <i>x</i> .
Recon	Reconstructed observations using <i>k</i> principal components. This is a low dimension approximation of the input data <i>Y</i> , and is equal to $\mu + \text{score} \cdot \text{coeff}'$.
v	Residual variance.
RMSResid	Root mean square of residuals.
NumIter	Number of iteration counts.
nloglk	Negative loglikelihood function value.

More About

Probabilistic Principal Component Analysis

Probabilistic principal component analysis (PPCA) is a method to estimate the principal axes when any data vector has one or more missing values.

PPCA is based on an isotropic error model. It seeks to relate a p -dimensional observation vector y to a corresponding k -dimensional vector of latent (or unobserved) variable x , which is normal with mean zero and covariance $I(k)$. The relationship is

$$y^T = W * x^T + \mu + \varepsilon,$$

where y is the row vector of observed variable, x is the row vector of latent variables, and ε is the isotropic error term. ε is Gaussian with mean zero and covariance of $v * I(k)$, where v is the residual variance. Here, k needs to be smaller than the rank for the residual variance to be greater than 0 ($v > 0$). Standard principal component analysis, where the residual variance is zero, is the limiting case of PPCA. The observed variables, y , are conditionally independent given the values of the latent variables, x . So, the latent variables explain the correlations between the observation variables and the error explains the variability unique to a particular y_i . The p -by- k matrix W relates the latent and observation variables, and the vector μ permits the model to have a nonzero mean. PPCA assumes that the values are missing at random through the data set. This means that whether a data value is missing or not does not depend on the latent variable given the observed data values.

Under this model,

$$y \sim N(\mu, W * W^T + v * I(k)).$$

There is no closed-form analytical solution for W and v , so their estimates are determined by iterative maximization of the corresponding loglikelihood using an expectation-maximization (EM) algorithm. This EM algorithm handles missing values by treating them as additional latent variables. At convergence, the columns of W spans the subspace, but they are not orthonormal. `ppca` obtains the orthonormal coefficients, `coef`, for the components by orthogonalization of W .

Introduced in R2013a

pdf

Package: prob

Probability density function

Syntax

```
y = pdf('name',x,A)
y = pdf('name',x,A,B)
y = pdf('name',x,A,B,C)
y = pdf('name',x,A,B,C,D)

y = pdf(pd,x)
```

Description

`y = pdf('name',x,A)` returns the probability density function (pdf) for the one-parameter distribution family specified by 'name' and the distribution parameter A, evaluated at the values in x.

`y = pdf('name',x,A,B)` returns the pdf for the two-parameter distribution family specified by 'name' and the distribution parameters A and B, evaluated at the values in x.

`y = pdf('name',x,A,B,C)` returns the pdf for the three-parameter distribution family specified by 'name' and the distribution parameters A, B, and C, evaluated at the values in x.

`y = pdf('name',x,A,B,C,D)` returns the pdf for the four-parameter distribution family specified by 'name' and the distribution parameters A, B, C, and D, evaluated at the values in x.

`y = pdf(pd,x)` returns the pdf of the probability distribution object pd, evaluated at the values in x.

Examples

Compute the Normal Distribution pdf

Create a standard normal distribution object with the mean μ equal to 0 and the standard deviation σ equal to 1.

```
mu = 0;
sigma = 1;
pd = makedist('Normal','mu',mu,'sigma',sigma);
```

Define the input vector x to contain the values at which to calculate the pdf.

```
x = [-2 -1 0 1 2];
```

Compute the pdf values for the standard normal distribution at the values in x.

```
y = pdf(pd,x)
```

```
y = 1x5
    0.0540    0.2420    0.3989    0.2420    0.0540
```

Each value in y corresponds to a value in the input vector x . For example, at the value x equal to 1, the corresponding pdf value y is equal to 0.2420.

Alternatively, you can compute the same pdf values without creating a probability distribution object. Use the `pdf` function, and specify a standard normal distribution using the same parameter values for μ and σ .

```
y2 = pdf('Normal',x,mu,sigma)
y2 = 1x5
    0.0540    0.2420    0.3989    0.2420    0.0540
```

The pdf values are the same as those computed using the probability distribution object.

Compute the Poisson Distribution pdf

Create a Poisson distribution object with the rate parameter, λ , equal to 2.

```
lambda = 2;
pd = makedist('Poisson','lambda',lambda);
```

Define the input vector x to contain the values at which to calculate the pdf.

```
x = [0 1 2 3 4];
```

Compute the pdf values for the Poisson distribution at the values in x .

```
y = pdf(pd,x)
y = 1x5
    0.1353    0.2707    0.2707    0.1804    0.0902
```

Each value in y corresponds to a value in the input vector x . For example, at the value x equal to 3, the corresponding pdf value in y is equal to 0.1804.

Alternatively, you can compute the same pdf values without creating a probability distribution object. Use the `pdf` function, and specify a Poisson distribution using the same value for the rate parameter, λ .

```
y2 = pdf('Poisson',x,lambda)
y2 = 1x5
    0.1353    0.2707    0.2707    0.1804    0.0902
```

The pdf values are the same as those computed using the probability distribution object.

Plot the pdf of a Standard Normal Distribution

Create a standard normal distribution object.

```
pd = makedist('Normal')
```

```
pd =  
NormalDistribution  
  
Normal distribution  
mu = 0  
sigma = 1
```

Specify the x values and compute the pdf.

```
x = -3:.1:3;  
pdf_normal = pdf(pd,x);
```

Plot the pdf.

```
plot(x,pdf_normal,'LineWidth',2)
```

Plot the pdf of a Weibull Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull','a',5,'b',2)
```

```
pd =  
WeibullDistribution  
  
Weibull distribution  
A = 5  
B = 2
```

Specify the x values and compute the pdf.

```
x = 0:.1:15;  
y = pdf(pd,x);
```

Plot the pdf.

```
plot(x,y,'LineWidth',2)
```

Input Arguments

'name' — Probability distribution name

character vector or string scalar of probability distribution name

Probability distribution name, specified as one of the probability distribution names in this table.

'name'	Distribution	Input Parameter A	Input Parameter B	Input Parameter C	Input Parameter D
'Beta'	"Beta Distribution" on page B-6	a first shape parameter	b second shape parameter	—	—
'Binomial'	"Binomial Distribution" on page B-10	n number of trials	p probability of success for each trial	—	—
'BirnbaumSaunders'	"Birnbaum-Saunders Distribution" on page B-18	β scale parameter	γ shape parameter	—	—

'Weibull'	"Weibull Distribution" on page B-170	a scale parameter	b shape parameter	—	—

Example: 'Normal'

x — Values at which to evaluate pdf

scalar value | array of scalar values

Values at which to evaluate the pdf, specified as a scalar value or an array of scalar values.

If one or more of the input arguments x , A , B , C , and D are arrays, then the array sizes must be the same. In this case, pdf expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A , B , C , and D for each distribution.

Example: [-1, 0, 3, 4]

Data Types: single | double

A — First probability distribution parameter

scalar value | array of scalar values

First probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments x , A , B , C , and D are arrays, then the array sizes must be the same. In this case, pdf expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A , B , C , and D for each distribution.

Data Types: single | double

B — Second probability distribution parameter

scalar value | array of scalar values

Second probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments x , A , B , C , and D are arrays, then the array sizes must be the same. In this case, pdf expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A , B , C , and D for each distribution.

Data Types: single | double

C — Third probability distribution parameter

scalar value | array of scalar values

Third probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments x , A , B , C , and D are arrays, then the array sizes must be the same. In this case, `pdf` expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A , B , C , and D for each distribution.

Data Types: `single` | `double`

D — Fourth probability distribution parameter

scalar value | array of scalar values

Fourth probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments x , A , B , C , and D are arrays, then the array sizes must be the same. In this case, `pdf` expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A , B , C , and D for each distribution.

Data Types: `single` | `double`

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created with a function or app in this table.

Function or App	Description
<code>makedist</code>	Create a probability distribution object using specified parameter values.
<code>fitdist</code>	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.
<code>paretotails</code>	Create a piecewise distribution object that has generalized Pareto distributions in the tails.

Output Arguments

y — pdf values

scalar value | array of scalar values

pdf values, returned as a scalar value or an array of scalar values. y is the same size as x after any necessary scalar expansion. Each element in y is the pdf value of the distribution, specified by the corresponding elements in the distribution parameters (A , B , C , and D) or specified by the probability distribution object (`pd`), evaluated at the corresponding element in x .

Alternative Functionality

- `pdf` is a generic function that accepts either a distribution by its name 'name' or a probability distribution object `pd`. It is faster to use a distribution-specific function, such as `normpdf` for the normal distribution and `binopdf` for the binomial distribution. For a list of distribution-specific functions, see "Supported Distributions" on page 5-13.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument 'name' must be a compile-time constant. For example, to use the normal distribution, include `coder.Constant('Normal')` in the `-args` value of `codegen`.
- The input argument `pd` can be a fitted probability distribution object for beta, exponential, extreme value, lognormal, normal, and Weibull distributions. Create `pd` by fitting a probability distribution to sample data from the `fitdist` function. For an example, see “Code Generation for Probability Distribution Objects” on page 31-70.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

pdf

Probability density function for Gaussian mixture distribution

Syntax

```
y = pdf(gm,X)
```

Description

`y = pdf(gm,X)` returns the probability density function (pdf) of the Gaussian mixture distribution `gm`, evaluated at the values in `X`.

Examples

Compute pdf Values

Create a `gmdistribution` object and compute its pdf values.

Define the distribution parameters (means and covariances) of a two-component bivariate Gaussian mixture distribution.

```
mu = [1 2;-3 -5];  
sigma = [1 1]; % shared diagonal covariance matrix
```

Create a `gmdistribution` object by using the `gmdistribution` function. By default, the function creates an equal proportion mixture.

```
gm = gmdistribution(mu,sigma)
```

```
gm =
```

```
Gaussian mixture distribution with 2 components in 2 dimensions
```

```
Component 1:
```

```
Mixing proportion: 0.500000
```

```
Mean:      1      2
```

```
Component 2:
```

```
Mixing proportion: 0.500000
```

```
Mean:     -3     -5
```

Compute the pdf values of `gm`.

```
X = [0 0;1 2;3 3;5 3];
```

```
pdf(gm,X)
```

```
ans = 4×1
```

```
    0.0065
```

```
    0.0796
```

```
    0.0065
```

```
    0.0000
```

Plot pdf

Create a `gmdistribution` object and plot its pdf.

Define the distribution parameters (means, covariances, and mixing proportions) of two bivariate Gaussian mixture components.

```
p = [0.4 0.6];           % Mixing proportions
mu = [1 2;-3 -5];      % Means
sigma = cat(3,[2 .5],[1 1]) % Covariances 1-by-2-by-2 array

sigma =
sigma(:,:,1) =

    2.0000    0.5000

sigma(:,:,2) =

    1    1
```

The `cat` function concatenates the covariances along the third array dimension. The defined covariance matrices are diagonal matrices. `sigma(1,:,i)` contains the diagonal elements of the covariance matrix of component `i`.

Create a `gmdistribution` object by using the `gmdistribution` function.

```
gm = gmdistribution(mu,sigma)

gm =

Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.500000
Mean:    1    2

Component 2:
Mixing proportion: 0.500000
Mean:   -3   -5
```

Plot the pdf of the Gaussian mixture distribution by using `fsurf`.

```
fsurf(@(x,y) reshape(pdf(gm,[x(:),y(:)]),size(x)),-10 10)
```

Input Arguments

gm — Gaussian mixture distribution

`gmdistribution` object

Gaussian mixture distribution, also called Gaussian mixture model (GMM), specified as a `gmdistribution` object.

You can create a `gmdistribution` object using `gmdistribution` or `fitgmdist`. Use the `gmdistribution` function to create a `gmdistribution` object by specifying the distribution parameters. Use the `fitgmdist` function to fit a `gmdistribution` model to data given a fixed number of components.

X — Values at which to evaluate pdf

n -by- m numeric matrix

Values at which to evaluate the pdf, specified as an n -by- m numeric matrix, where n is the number of observations and m is the number of variables in each observation.

Data Types: `single` | `double`

Output Arguments

y — pdf values

n -by-1 numeric vector

pdf values of the Gaussian mixture distribution `gm`, evaluated at `X`, returned as an n -by-1 numeric vector, where n is the number of observations in `X`.

The `pdf` function computes the pdf values by using the likelihood of each component given each observation and the component probabilities.

$$y(i) = \sum_{j=1}^k L(C_j|O_i)P(C_j),$$

where $L(C_j|O_i)$ is the likelihood of component j given observation i , and $P(C_j)$ is the probability of component j . The `pdf` function computes the likelihood term by using the multivariate normal pdf of the j th Gaussian mixture component evaluated at observation i . The component probabilities are the mixing proportions of mixture components, the `ComponentProportion` property of `gm`.

pdist

Pairwise distance between pairs of observations

Syntax

```
D = pdist(X)
D = pdist(X,Distance)
D = pdist(X,Distance,DistParameter)
```

Description

`D = pdist(X)` returns the Euclidean distance between pairs of observations in `X`.

`D = pdist(X,Distance)` returns the distance by using the method specified by `Distance`.

`D = pdist(X,Distance,DistParameter)` returns the distance by using the method specified by `Distance` and `DistParameter`. You can specify `DistParameter` only when `Distance` is 'seuclidean', 'minkowski', or 'mahalanobis'.

Examples

Compute Euclidean Distance and Convert Distance Vector to Matrix

Compute the Euclidean distance between pairs of observations, and convert the distance vector to a matrix using `squareform`.

Create a matrix with three observations and two variables.

```
rng('default') % For reproducibility
X = rand(3,2);
```

Compute the Euclidean distance.

```
D = pdist(X)

D = 1×3
    0.2954    1.0670    0.9448
```

The pairwise distances are arranged in the order (2,1), (3,1), (3,2). You can easily locate the distance between observations `i` and `j` by using `squareform`.

```
Z = squareform(D)

Z = 3×3
     0    0.2954    1.0670
 0.2954     0    0.9448
 1.0670    0.9448     0
```

`squareform` returns a symmetric matrix where $Z(i, j)$ corresponds to the pairwise distance between observations i and j . For example, you can find the distance between observations 2 and 3.

```
Z(2,3)
```

```
ans = 0.9448
```

Pass Z to the `squareform` function to reproduce the output of the `pdist` function.

```
y = squareform(Z)
```

```
y = 1×3
```

```
    0.2954    1.0670    0.9448
```

The outputs y from `squareform` and D from `pdist` are the same.

Compute Minkowski Distance

Create a matrix with three observations and two variables.

```
rng('default') % For reproducibility
X = rand(3,2);
```

Compute the Minkowski distance with the default exponent 2.

```
D1 = pdist(X, 'minkowski')
```

```
D1 = 1×3
```

```
    0.2954    1.0670    0.9448
```

Compute the Minkowski distance with an exponent of 1, which is equal to the city block distance.

```
D2 = pdist(X, 'minkowski', 1)
```

```
D2 = 1×3
```

```
    0.3721    1.5036    1.3136
```

```
D3 = pdist(X, 'cityblock')
```

```
D3 = 1×3
```

```
    0.3721    1.5036    1.3136
```

Compute Pairwise Distance with Missing Elements Using a Custom Distance Function

Define a custom distance function that ignores coordinates with NaN values, and compute pairwise distance by using the custom distance function.

Create a matrix with three observations and two variables.

```
rng('default') % For reproducibility
X = rand(3,2);
```

Assume that the first element of the first observation is missing.

```
X(1,1) = NaN;
```

Compute the Euclidean distance.

```
D1 = pdist(X)
```

```
D1 =
```

```
      NaN      NaN      0.9448
```

If observation *i* or *j* contains NaN values, the function `pdist` returns NaN for the pairwise distance between *i* and *j*. Therefore, `D1(1)` and `D1(2)`, the pairwise distances (2,1) and (3,1), are NaN values.

Define a custom distance function `naneucdist` that ignores coordinates with NaN values and returns the Euclidean distance.

```
function D2 = naneucdist(XI,XJ)
%NANEUCDIST Euclidean distance ignoring coordinates with NaNs
n = size(XI,2);
sqdx = (XI-XJ).^2;
nstar = sum(~isnan(sqdx),2); % Number of pairs that do not contain NaNs
nstar(nstar == 0) = NaN; % To return NaN if all pairs include NaNs
D2squared = nansum(sqdx,2).*n./nstar; % Correction for missing coordinates
D2 = sqrt(D2squared);
```

Compute the distance with `naneucdist` by passing the function handle as an input argument of `pdist`.

```
D2 = pdist(X,@naneucdist)
```

```
D2 =
```

```
      0.3974      1.1538      0.9448
```

Input Arguments

X — Input data

numeric matrix

Input data, specified as a numeric matrix of size *m*-by-*n*. Rows correspond to individual observations, and columns correspond to individual variables.

Data Types: `single` | `double`

Distance — Distance metric

character vector | string scalar | function handle

Distance metric, specified as a character vector, string scalar, or function handle, as described in the following table.

Value	Description
'euclidean'	Euclidean distance (default).
'squaredeuclidean'	Squared Euclidean distance. (This option is provided for efficiency only. It does not satisfy the triangle inequality.)
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between observations is scaled by dividing by the corresponding element of the standard deviation, $S = \text{nanstd}(X)$. Use <code>DistParameter</code> to specify another value for S .
'mahalanobis'	Mahalanobis distance using the sample covariance of X , $C = \text{nancov}(X)$. Use <code>DistParameter</code> to specify another value for C , where the matrix C is symmetric and positive definite.
'cityblock'	City block distance.
'minkowski'	Minkowski distance. The default exponent is 2. Use <code>DistParameter</code> to specify a different exponent P , where P is a positive scalar value of the exponent.
'chebychev'	Chebychev distance (maximum coordinate difference).
'cosine'	One minus the cosine of the included angle between points (treated as vectors).
'correlation'	One minus the sample correlation between points (treated as sequences of values).
'hamming'	Hamming distance, which is the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
@ <i>distfun</i>	<p>Custom distance function handle. A distance function has the form</p> <pre>function D2 = distfun(ZI,ZJ) % calculation of distance ...</pre> <p>where</p> <ul style="list-style-type: none"> • ZI is a 1-by-n vector containing a single observation. • ZJ is an $m2$-by-n matrix containing multiple observations. <code>distfun</code> must accept a matrix ZJ with an arbitrary number of observations. • $D2$ is an $m2$-by-1 vector of distances, and $D2(k)$ is the distance between observations ZI and $ZJ(k, :)$. <p>If your data is not sparse, you can generally compute distance more quickly by using a built-in distance instead of a function handle.</p>

For definitions, see “Distance Metrics” on page 32-3925.

When you use 'seuclidean', 'minkowski', or 'mahalanobis', you can specify an additional input argument `DistParameter` to control these metrics. You can also use these metrics in the same way as the other metrics with a default value of `DistParameter`.

Example: 'minkowski'

DistParameter — Distance metric parameter values

positive scalar | numeric vector | numeric matrix

Distance metric parameter values, specified as a positive scalar, numeric vector, or numeric matrix. This argument is valid only when you specify `Distance` as 'seuclidean', 'minkowski', or 'mahalanobis'.

- If `Distance` is 'seuclidean', `DistParameter` is a vector of scaling factors for each dimension, specified as a positive vector. The default value is `nanstd(X)`.
- If `Distance` is 'minkowski', `DistParameter` is the exponent of Minkowski distance, specified as a positive scalar. The default value is 2.
- If `Distance` is 'mahalanobis', `DistParameter` is a covariance matrix, specified as a numeric matrix. The default value is `nancov(X)`. `DistParameter` must be symmetric and positive definite.

Example: 'minkowski',3

Data Types: single | double

Output Arguments

D — Pairwise distances

numeric row vector

Pairwise distances, returned as a numeric row vector of length $m(m-1)/2$, corresponding to pairs of observations, where m is the number of observations in X .

The distances are arranged in the order (2,1), (3,1), ..., (m,1), (3,2), ..., (m,2), ..., (m,m-1), i.e., the lower-left triangle of the m -by- m distance matrix in column order. The pairwise distance between observations i and j is in $D((i-1)*(m-i/2)+j-i)$ for $i \leq j$.

You can convert D into a symmetric matrix by using the `squareform` function. $Z = \text{squareform}(D)$ returns an m -by- m matrix where $Z(i, j)$ corresponds to the pairwise distance between observations i and j .

If observation i or j contains NaNs, then the corresponding value in D is NaN for the built-in distance functions.

D is commonly used as a dissimilarity matrix in clustering or multidimensional scaling. For details, see “Hierarchical Clustering” on page 16-6 and the function reference pages for `cmdscale`, `cophenet`, `linkage`, `mdscale`, and `optimalleaforder`. These functions take D as an input argument.

More About

Distance Metrics

A distance metric is a function that defines a distance between two observations. `pdist` supports various distance metrics: Euclidean distance, standardized Euclidean distance, Mahalanobis distance, city block distance, Minkowski distance, Chebychev distance, cosine distance, correlation distance, Hamming distance, Jaccard distance, and Spearman distance.

Given an m -by- n data matrix X , which is treated as m (1-by- n) row vectors x_1, x_2, \dots, x_m , the various distances between the vector x_s and x_t are defined as follows:

- Euclidean distance

$$d_{st}^2 = (x_s - x_t)(x_s - x_t)'$$

The Euclidean distance is a special case of the Minkowski distance, where $p = 2$.

- Standardized Euclidean distance

$$d_{st}^2 = (x_s - x_t)V^{-1}(x_s - x_t)'$$

where V is the n -by- n diagonal matrix whose j th diagonal element is $(S(j))^2$, where S is a vector of scaling factors for each dimension.

- Mahalanobis distance

$$d_{st}^2 = (x_s - x_t)C^{-1}(x_s - x_t)'$$

where C is the covariance matrix.

- City block distance

$$d_{st} = \sum_{j=1}^n |x_{sj} - x_{tj}|$$

The city block distance is a special case of the Minkowski distance, where $p = 1$.

- Minkowski distance

$$d_{st} = \sqrt[p]{\sum_{j=1}^n |x_{sj} - x_{tj}|^p}$$

For the special case of $p = 1$, the Minkowski distance gives the city block distance. For the special case of $p = 2$, the Minkowski distance gives the Euclidean distance. For the special case of $p = \infty$, the Minkowski distance gives the Chebychev distance.

- Chebychev distance

$$d_{st} = \max_j \{|x_{sj} - x_{tj}|\}$$

The Chebychev distance is a special case of the Minkowski distance, where $p = \infty$.

- Cosine distance

$$d_{st} = 1 - \frac{x_s x_t'}{\sqrt{(x_s x_s')(x_t x_t')}}$$

- Correlation distance

$$d_{st} = 1 - \frac{(x_s - \bar{x}_s)(x_t - \bar{x}_t)'}{\sqrt{(x_s - \bar{x}_s)(x_s - \bar{x}_s)' \sqrt{(x_t - \bar{x}_t)(x_t - \bar{x}_t)'}}$$

where

$$\bar{x}_s = \frac{1}{n} \sum_j x_{sj} \text{ and } \bar{x}_t = \frac{1}{n} \sum_j x_{tj}.$$

- Hamming distance

$$d_{st} = (\# (x_{sj} \neq x_{tj})/n).$$

- Jaccard distance

$$d_{st} = \frac{\# [(x_{sj} \neq x_{tj}) \cap ((x_{sj} \neq 0) \cup (x_{tj} \neq 0))]}{\# [(x_{sj} \neq 0) \cup (x_{tj} \neq 0)]}.$$

- Spearman distance

$$d_{st} = 1 - \frac{(r_s - \bar{r}_s)(r_t - \bar{r}_t)'}{\sqrt{(r_s - \bar{r}_s)(r_s - \bar{r}_s)' \sqrt{(r_t - \bar{r}_t)(r_t - \bar{r}_t)'}}$$

where

- r_{sj} is the rank of x_{sj} taken over $x_{1j}, x_{2j}, \dots, x_{mj}$, as computed by `tiedrank`.
- r_s and r_t are the coordinate-wise rank vectors of x_s and x_t , i.e., $r_s = (r_{s1}, r_{s2}, \dots, r_{sn})$.
- $\bar{r}_s = \frac{1}{n} \sum_j r_{sj} = \frac{(n+1)}{2}$.
- $\bar{r}_t = \frac{1}{n} \sum_j r_{tj} = \frac{(n+1)}{2}$.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The distance input argument value (`Distance`) must be a compile-time constant. For example, to use the Minkowski distance, include `coder.Constant('Minkowski')` in the `-args` value of `codegen`.
- The distance input argument value (`Distance`) cannot be a custom distance function.
- The generated code of `pdist` uses `parfor` to create loops that run in parallel on supported shared-memory multicore platforms in the generated code. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the `parfor`-loops as `for`-loops. To find supported compilers, see https://www.mathworks.com/support/compilers/current_release/. To disable OpenMP library, set the `EnableOpenMP` property of the configuration object to `false`. For details, see `coder.CodeConfig`.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- The supported distance input argument values (`Distance`) for optimized CUDA code are 'euclidean', 'squaredeuclidean', 'seuclidean', 'cityblock', 'minkowski', 'chebychev', 'cosine', 'correlation', 'hamming', and 'jaccard'.
- `Distance` cannot be a custom distance function.
- `Distance` must be a compile-time constant.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The `Distance` argument must be specified as a character vector.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

pdist2

Pairwise distance between two sets of observations

Syntax

```
D = pdist2(X,Y,Distance)
```

```
D = pdist2(X,Y,Distance,DistParameter)
```

```
D = pdist2( ___,Name,Value)
```

```
[D,I] = pdist2( ___,Name,Value)
```

Description

`D = pdist2(X,Y,Distance)` returns the distance between each pair of observations in `X` and `Y` using the metric specified by `Distance`.

`D = pdist2(X,Y,Distance,DistParameter)` returns the distance using the metric specified by `Distance` and `DistParameter`. You can specify `DistParameter` only when `Distance` is `'seuclidean'`, `'minkowski'`, or `'mahalanobis'`.

`D = pdist2(___,Name,Value)` specifies an additional option using one of the name-value pair arguments `'Smallest'` or `'Largest'` in addition to any of the arguments in the previous syntaxes.

For example,

- `D = pdist2(X,Y,Distance,'Smallest',K)` computes the distance using the metric specified by `Distance` and returns the `K` smallest pairwise distances to observations in `X` for each observation in `Y` in ascending order.
- `D = pdist2(X,Y,Distance,DistParameter,'Largest',K)` computes the distance using the metric specified by `Distance` and `DistParameter` and returns the `K` largest pairwise distances in descending order.

`[D,I] = pdist2(___,Name,Value)` also returns the matrix `I`. The matrix `I` contains the indices of the observations in `X` corresponding to the distances in `D`.

Examples

Compute Euclidean Distance

Create two matrices with three observations and two variables.

```
rng('default') % For reproducibility
X = rand(3,2);
Y = rand(3,2);
```

Compute the Euclidean distance. The default value of the input argument `Distance` is `'euclidean'`. When computing the Euclidean distance without using a name-value pair argument, you do not need to specify `Distance`.

```
D = pdist2(X,Y)
```

```
D = 3×3
```

```
    0.5387    0.8018    0.1538
    0.7100    0.5951    0.3422
    0.8805    0.4242    1.2050
```

$D(i, j)$ corresponds to the pairwise distance between observation i in X and observation j in Y .

Compute Minkowski Distance

Create two matrices with three observations and two variables.

```
rng('default') % For reproducibility
```

```
X = rand(3,2);
```

```
Y = rand(3,2);
```

Compute the Minkowski distance with the default exponent 2.

```
D1 = pdist2(X,Y,'minkowski')
```

```
D1 = 3×3
```

```
    0.5387    0.8018    0.1538
    0.7100    0.5951    0.3422
    0.8805    0.4242    1.2050
```

Compute the Minkowski distance with an exponent of 1, which is equal to the city block distance.

```
D2 = pdist2(X,Y,'minkowski',1)
```

```
D2 = 3×3
```

```
    0.5877    1.0236    0.2000
    0.9598    0.8337    0.3899
    1.0189    0.4800    1.7036
```

```
D3 = pdist2(X,Y,'cityblock')
```

```
D3 = 3×3
```

```
    0.5877    1.0236    0.2000
    0.9598    0.8337    0.3899
    1.0189    0.4800    1.7036
```

Find the Two Smallest Pairwise Distances

Create two matrices with three observations and two variables.

```
rng('default') % For reproducibility
X = rand(3,2);
Y = rand(3,2);
```

Find the two smallest pairwise Euclidean distances to observations in X for each observation in Y.

```
[D,I] = pdist2(X,Y,'euclidean','Smallest',2)
```

```
D = 2×3
```

```
    0.5387    0.4242    0.1538
    0.7100    0.5951    0.3422
```

```
I = 2×3
```

```
    1    3    1
    2    2    2
```

For each observation in Y, `pdist2` finds the two smallest distances by computing and comparing the distance values to all the observations in X. The function then sorts the distances in each column of D in ascending order. I contains the indices of the observations in X corresponding to the distances in D.

Compute Pairwise Distance with Missing Elements Using a Custom Distance Function

Define a custom distance function that ignores coordinates with NaN values, and compute pairwise distance by using the custom distance function.

Create two matrices with three observations and three variables.

```
rng('default') % For reproducibility
X = rand(3,3)
Y = [X(:,1:2) rand(3,1)]
```

```
X =
```

```
    0.8147    0.9134    0.2785
    0.9058    0.6324    0.5469
    0.1270    0.0975    0.9575
```

```
Y =
```

```
    0.8147    0.9134    0.9649
    0.9058    0.6324    0.1576
    0.1270    0.0975    0.9706
```

The first two columns of X and Y are identical. Assume that X(1,1) is missing.

```
X(1,1) = NaN
```

```
X =
```

```

    NaN    0.9134    0.2785
0.9058    0.6324    0.5469
0.1270    0.0975    0.9575

```

Compute the Hamming distance.

```
D1 = pdist2(X,Y,'hamming')
```

D1 =

```

    NaN    NaN    NaN
1.0000    0.3333    1.0000
1.0000    1.0000    0.3333

```

If observation i in X or observation j in Y contains NaN values, the function `pdist2` returns NaN for the pairwise distance between i and j . Therefore, $D1(1,1)$, $D1(1,2)$, and $D1(1,3)$ are NaN values.

Define a custom distance function `nanhamdist` that ignores coordinates with NaN values and computes the Hamming distance. When working with a large number of observations, you can compute the distance more quickly by looping over coordinates of the data.

```

function D2 = nanhamdist(XI,XJ)
%NANHAMDIST Hamming distance ignoring coordinates with NaNs
[m,p] = size(XJ);
nesum = zeros(m,1);
pstar = zeros(m,1);
for q = 1:p
    notnan = ~(isnan(XI(q)) | isnan(XJ(:,q)));
    nesum = nesum + ((XI(q) ~= XJ(:,q)) & notnan);
    pstar = pstar + notnan;
end
D2 = nesum./pstar;

```

Compute the distance with `nanhamdist` by passing the function handle as an input argument of `pdist2`.

```
D2 = pdist2(X,Y,@nanhamdist)
```

D2 =

```

0.5000    1.0000    1.0000
1.0000    0.3333    1.0000
1.0000    1.0000    0.3333

```

Assign New Data to Existing Clusters and Generate C/C++ Code

`kmeans` performs k -means clustering to partition data into k clusters. When you have a new data set to cluster, you can create new clusters that include the existing data and the new data by using

`kmeans`. The `kmeans` function supports C/C++ code generation, so you can generate code that accepts training data and returns clustering results, and then deploy the code to a device. In this workflow, you must pass training data, which can be of considerable size. To save memory on the device, you can separate training and prediction by using `kmeans` and `pdist2`, respectively.

Use `kmeans` to create clusters in MATLAB® and use `pdist2` in the generated code to assign new data to existing clusters. For code generation, define an entry-point function that accepts the cluster centroid positions and the new data set, and returns the index of the nearest cluster. Then, generate code for the entry-point function.

Generating C/C++ code requires MATLAB® Coder™.

Perform *k*-Means Clustering

Generate a training data set using three distributions.

```
rng('default') % For reproducibility
X = [randn(100,2)*0.75+ones(100,2);
     randn(100,2)*0.5-ones(100,2);
     randn(100,2)*0.75];
```

Partition the training data into three clusters by using `kmeans`.

```
[idx,C] = kmeans(X,3);
```

Plot the clusters and the cluster centroids.

```
figure
gscatter(X(:,1),X(:,2),idx,'bgm')
hold on
plot(C(:,1),C(:,2),'kx')
legend('Cluster 1','Cluster 2','Cluster 3','Cluster Centroid')
```

Assign New Data to Existing Clusters

Generate a test data set.

```
Xtest = [randn(10,2)*0.75+ones(10,2);
         randn(10,2)*0.5-ones(10,2);
         randn(10,2)*0.75];
```

Classify the test data set using the existing clusters. Find the nearest centroid from each test data point by using `pdist2`.

```
[~,idx_test] = pdist2(C,Xtest,'euclidean','Smallest',1);
```

Plot the test data and label the test data using `idx_test` by using `gscatter`.

```
gscatter(Xtest(:,1),Xtest(:,2),idx_test,'bgm','ooo')
legend('Cluster 1','Cluster 2','Cluster 3','Cluster Centroid', ...
       'Data classified to Cluster 1','Data classified to Cluster 2', ...
       'Data classified to Cluster 3')
```

Generate Code

Generate C code that assigns new data to the existing clusters. Note that generating C/C++ code requires MATLAB® Coder™.

Define an entry-point function named `findNearestCentroid` that accepts centroid positions and new data, and then find the nearest cluster by using `pdist2`.

Add the `%codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would cause errors during code generation.

```
type findNearestCentroid % Display contents of findNearestCentroid.m

function idx = findNearestCentroid(C,X) %codegen
[~,idx] = pdist2(C,X,'euclidean','Smallest',1); % Find the nearest centroid
```

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

Generate code by using `codegen`. Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. To specify the data type and array size of the inputs of `findNearestCentroid`, pass a MATLAB expression that represents the set of values with a certain data type and array size by using the `-args` option. For details, see “Specify Variable-Size Arguments for Code Generation” on page 31-38.

```
codegen findNearestCentroid -args {C,Xtest}
```

codegen generates the MEX function `findNearestCentroid_mex` with a platform-dependent extension.

Verify the generated code.

```
myIdx = findNearestCentroid(C,Xtest);
myIndex_mex = findNearestCentroid_mex(C,Xtest);
verifyMEX = isequal(idx_test,myIdx,myIndex_mex)

verifyMEX = logical
    1
```

`isequal` returns logical 1 (true), which means all the inputs are equal. The comparison confirms that the `pdist2` function, the `findNearestCentroid` function, and the MEX function return the same index.

You can also generate optimized CUDA® code using GPU Coder™.

```
cfg = coder.gpuConfig('mex');
codegen -config cfg findNearestCentroid -args {C,Xtest}
```

For more information on code generation, see “General Code Generation Workflow” on page 31-5. For more information on GPU coder, see “Get Started with GPU Coder” (GPU Coder) and “Supported Functions” (GPU Coder).

Input Arguments

X, Y — Input data

numeric matrix

Input data, specified as a numeric matrix. X is an $m \times n$ matrix and Y is an $my \times n$ matrix. Rows correspond to individual observations, and columns correspond to individual variables.

Data Types: `single` | `double`

Distance — Distance metric

character vector | string scalar | function handle

Distance metric, specified as a character vector, string scalar, or function handle, as described in the following table.

Value	Description
'euclidean'	Euclidean distance (default).
'squaredeuclidean'	Squared Euclidean distance. (This option is provided for efficiency only. It does not satisfy the triangle inequality.)
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between observations is scaled by dividing by the corresponding element of the standard deviation, $S = \text{nanstd}(X)$. Use <code>DistParameter</code> to specify another value for S.

Value	Description
'mahalanobis'	Mahalanobis distance using the sample covariance of X, $C = \text{nancov}(X)$. Use <code>DistParameter</code> to specify another value for C, where the matrix C is symmetric and positive definite.
'cityblock'	City block distance.
'minkowski'	Minkowski distance. The default exponent is 2. Use <code>DistParameter</code> to specify a different exponent P, where P is a positive scalar value of the exponent.
'chebychev'	Chebychev distance (maximum coordinate difference).
'cosine'	One minus the cosine of the included angle between points (treated as vectors).
'correlation'	One minus the sample correlation between points (treated as sequences of values).
'hamming'	Hamming distance, which is the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
@ <i>distfun</i>	<p>Custom distance function handle. A distance function has the form</p> <pre>function D2 = distfun(ZI,ZJ) % calculation of distance ...</pre> <p>where</p> <ul style="list-style-type: none"> • ZI is a 1-by-n vector containing a single observation. • ZJ is an m2-by-n matrix containing multiple observations. <code>distfun</code> must accept a matrix ZJ with an arbitrary number of observations. • D2 is an m2-by-1 vector of distances, and $D2(k)$ is the distance between observations ZI and $ZJ(k, :)$. <p>If your data is not sparse, you can generally compute distance more quickly by using a built-in distance instead of a function handle.</p>

For definitions, see “Distance Metrics” on page 32-3938.

When you use 'seuclidean', 'minkowski', or 'mahalanobis', you can specify an additional input argument `DistParameter` to control these metrics. You can also use these metrics in the same way as the other metrics with a default value of `DistParameter`.

Example: 'minkowski'

DistParameter — Distance metric parameter values

positive scalar | numeric vector | numeric matrix

Distance metric parameter values, specified as a positive scalar, numeric vector, or numeric matrix. This argument is valid only when you specify `Distance` as 'seuclidean', 'minkowski', or 'mahalanobis'.

- If `Distance` is 'seuclidean', `DistParameter` is a vector of scaling factors for each dimension, specified as a positive vector. The default value is `nanstd(X)`.
- If `Distance` is 'minkowski', `DistParameter` is the exponent of Minkowski distance, specified as a positive scalar. The default value is 2.
- If `Distance` is 'mahalanobis', `DistParameter` is a covariance matrix, specified as a numeric matrix. The default value is `nancov(X)`. `DistParameter` must be symmetric and positive definite.

Example: 'minkowski',3

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: Either 'Smallest',K or 'Largest',K. You cannot use both 'Smallest' and 'Largest'.

Smallest — Number of smallest distances to find

positive integer

Number of smallest distances to find, specified as the comma-separated pair consisting of 'Smallest' and a positive integer. If you specify 'Smallest', then `pdist2` sorts the distances in each column of `D` in ascending order.

Example: 'Smallest',3

Data Types: single | double

Largest — Number of largest distances to find

positive integer

Number of largest distances to find, specified as the comma-separated pair consisting of 'Largest' and a positive integer. If you specify 'Largest', then `pdist2` sorts the distances in each column of `D` in descending order.

Example: 'Largest',3

Data Types: single | double

Output Arguments

D — Pairwise distances

numeric matrix

Pairwise distances, returned as a numeric matrix.

If you do not specify either 'Smallest' or 'Largest', then `D` is an m_x -by- m_y matrix, where m_x and m_y are the number of observations in `X` and `Y`, respectively. $D(i,j)$ is the distance between observation i in `X` and observation j in `Y`. If observation i in `X` or observation j in `Y` contains NaN, then $D(i,j)$ is NaN for the built-in distance functions.

If you specify either 'Smallest' or 'Largest' as `K`, then `D` is a K -by- m_y matrix. `D` contains either the K smallest or K largest pairwise distances to observations in `X` for each observation in `Y`. For each

observation in Y , `pdist2` finds the K smallest or largest distances by computing and comparing the distance values to all the observations in X . If K is greater than mx , `pdist2` returns an mx -by- my matrix.

I – Sort index

positive integer matrix

Sort index, returned as a positive integer matrix. I is the same size as D . I contains the indices of the observations in X corresponding to the distances in D .

More About

Distance Metrics

A distance metric is a function that defines a distance between two observations. `pdist2` supports various distance metrics: Euclidean distance, standardized Euclidean distance, Mahalanobis distance, city block distance, Minkowski distance, Chebychev distance, cosine distance, correlation distance, Hamming distance, Jaccard distance, and Spearman distance.

Given an mx -by- n data matrix X , which is treated as mx (1-by- n) row vectors x_1, x_2, \dots, x_{mx} , and an my -by- n data matrix Y , which is treated as my (1-by- n) row vectors y_1, y_2, \dots, y_{my} , the various distances between the vector x_s and y_t are defined as follows:

- Euclidean distance

$$d_{st}^2 = (x_s - y_t)(x_s - y_t)'$$

The Euclidean distance is a special case of the Minkowski distance, where $p = 2$.

- Standardized Euclidean distance

$$d_{st}^2 = (x_s - y_t)V^{-1}(x_s - y_t)'$$

where V is the n -by- n diagonal matrix whose j th diagonal element is $(S(j))^2$, where S is a vector of scaling factors for each dimension.

- Mahalanobis distance

$$d_{st}^2 = (x_s - y_t)C^{-1}(x_s - y_t)'$$

where C is the covariance matrix.

- City block distance

$$d_{st} = \sum_{j=1}^n |x_{sj} - y_{tj}|$$

The city block distance is a special case of the Minkowski distance, where $p = 1$.

- Minkowski distance

$$d_{st} = \sqrt[p]{\sum_{j=1}^n |x_{sj} - y_{tj}|^p}$$

For the special case of $p = 1$, the Minkowski distance gives the city block distance. For the special case of $p = 2$, the Minkowski distance gives the Euclidean distance. For the special case of $p = \infty$, the Minkowski distance gives the Chebychev distance.

- Chebychev distance

$$d_{st} = \max_j \{|x_{sj} - y_{tj}|\}.$$

The Chebychev distance is a special case of the Minkowski distance, where $p = \infty$.

- Cosine distance

$$d_{st} = \left(1 - \frac{x_s y_t}{\sqrt{(x_s x_s')(y_t y_t')}}\right).$$

- Correlation distance

$$d_{st} = 1 - \frac{(x_s - \bar{x}_s)(y_t - \bar{y}_t)'}{\sqrt{(x_s - \bar{x}_s)(x_s - \bar{x}_s)'(y_t - \bar{y}_t)(y_t - \bar{y}_t)'}}$$

where

$$\bar{x}_s = \frac{1}{n} \sum_j x_{sj}$$

and

$$\bar{y}_t = \frac{1}{n} \sum_j y_{tj}.$$

- Hamming distance

$$d_{st} = (\#(x_{sj} \neq y_{tj})/n).$$

- Jaccard distance

$$d_{st} = \frac{\#[(x_{sj} \neq y_{tj}) \cap ((x_{sj} \neq 0) \cup (y_{tj} \neq 0))]}{\#[(x_{sj} \neq 0) \cup (y_{tj} \neq 0)]}.$$

- Spearman distance

$$d_{st} = 1 - \frac{(r_s - \bar{r}_s)(r_t - \bar{r}_t)'}{\sqrt{(r_s - \bar{r}_s)(r_s - \bar{r}_s)'(r_t - \bar{r}_t)(r_t - \bar{r}_t)'}}$$

where

- r_{sj} is the rank of x_{sj} taken over $x_{1j}, x_{2j}, \dots, x_{mj}$, as computed by `tiedrank`.
- r_{tj} is the rank of y_{tj} taken over $y_{1j}, y_{2j}, \dots, y_{mj}$, as computed by `tiedrank`.
- r_s and r_t are the coordinate-wise rank vectors of x_s and y_t , i.e., $r_s = (r_{s1}, r_{s2}, \dots, r_{sn})$ and $r_t = (r_{t1}, r_{t2}, \dots, r_{tn})$.
- $\bar{r}_s = \frac{1}{n} \sum_j r_{sj} = \frac{(n+1)}{2}$.
- $\bar{r}_t = \frac{1}{n} \sum_j r_{tj} = \frac{(n+1)}{2}$.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- The first input `X` must be a tall array. Input `Y` cannot be a tall array.

For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The distance input argument value (`Distance`) must be a compile-time constant. For example, to use the Minkowski distance, include `coder.Constant('Minkowski')` in the `-args` value of `codegen`.
- The distance input argument value (`Distance`) cannot be a custom distance function.
- Names in name-value pair arguments must be compile-time constants. For example, to use the 'Smallest' name-value pair argument in the generated code, include `{coder.Constant('Smallest'), 0}` in the `-args` value of `codegen`.
- The sorted order of tied distances in the generated code can be different from the order in MATLAB due to numerical precision.
- The generated code of `pdist2` uses `parfor` to create loops that run in parallel on supported shared-memory multicore platforms in the generated code. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the `parfor`-loops as `for`-loops. To find supported compilers, see https://www.mathworks.com/support/compilers/current_release/. To disable OpenMP library, set the `EnableOpenMP` property of the configuration object to `false`. For details, see `coder.CodeConfig`.
- Starting in R2020a, `pdist2` returns integer-type (`int32`) indices, rather than double-precision indices, in generated standalone C/C++ code. Therefore, the function allows for strict single-precision support when you use single-precision inputs. For MEX code generation, the function still returns double-precision indices to match the MATLAB behavior.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- The supported distance input argument values (`Distance`) for optimized CUDA code are 'euclidean', 'squaredeuclidean', 'seuclidean', 'cityblock', 'minkowski', 'chebychev', 'cosine', 'correlation', 'hamming', and 'jaccard'.
- `Distance` cannot be a custom distance function.
- `Distance` must be a compile-time constant.
- Names in name-value pair arguments must be compile-time constants.

- The sorted order of tied distances in the generated code can be different from the order in MATLAB due to numerical precision.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The `Distance` argument must be specified as a character vector.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced in R2010a

pearsrnd

Pearson system random numbers

Syntax

```
r = pearsrnd(mu, sigma, skew, kurt, m, n)
r = pearsrnd(mu, sigma, skew, kurt)
r = pearsrnd(mu, sigma, skew, kurt, m, n, ...)
r = pearsrnd(mu, sigma, skew, kurt, [m, n, ...])
[r, type] = pearsrnd(...)
[r, type, coefs] = pearsrnd(...)
```

Description

`r = pearsrnd(mu, sigma, skew, kurt, m, n)` returns an m -by- n matrix of random numbers drawn from the distribution in the Pearson system with mean `mu`, standard deviation `sigma`, skewness `skew`, and kurtosis `kurt`. The parameters `mu`, `sigma`, `skew`, and `kurt` must be scalars.

Note Because `r` is a random sample, its sample moments, especially the skewness and kurtosis, typically differ somewhat from the specified distribution moments.

`pearsrnd` uses the definition of kurtosis for which a normal distribution has a kurtosis of 3. Some definitions of kurtosis subtract 3, so that a normal distribution has a kurtosis of 0. The `pearsrnd` function does not use this convention.

Some combinations of moments are not valid; in particular, the kurtosis must be greater than the square of the skewness plus 1. The kurtosis of the normal distribution is defined to be 3.

`r = pearsrnd(mu, sigma, skew, kurt)` returns a scalar value.

`r = pearsrnd(mu, sigma, skew, kurt, m, n, ...)` or `r = pearsrnd(mu, sigma, skew, kurt, [m, n, ...])` returns an m -by- n -by-... array.

`[r, type] = pearsrnd(...)` returns the type of the specified distribution within the Pearson system. `type` is a scalar integer from 0 to 7. Set `m` and `n` to 0 to identify the distribution type without generating any random values.

The seven distribution types in the Pearson system correspond to the following distributions:

- 0 — Normal on page B-119 distribution
- 1 — Four-parameter beta on page B-6 distribution
- 2 — Symmetric four-parameter beta on page B-6 distribution
- 3 — Three-parameter gamma on page B-47 distribution
- 4 — Not related to any standard distribution. The density is proportional to:

$$(1 + ((x - a)/b)^2)^{-c} \exp(-d \arctan((x - a)/b)).$$

- 5 — Inverse gamma on page B-47 location-scale distribution
- 6 — F on page B-45 location-scale distribution
- 7 — Student's t location-scale on page B-156 distribution

`[r,type,coefs] = pearsrnd(...)` returns the coefficients `coefs` of the quadratic polynomial that defines the distribution via the differential equation

$$\frac{d}{dx} \log(p(x)) = \frac{-(a+x)}{c(0) + c(1)x + c(2)x^2}.$$

Examples

Generate random values from the standard normal distribution:

```
r = pearsrnd(0,1,0,3,100,1); % Equivalent to randn(100,1)
```

Determine the distribution type:

```
[r,type] = pearsrnd(0,1,1,4,0,0);
r =
[]
type =
1
```

Introduced in R2006a

perfcurve

Receiver operating characteristic (ROC) curve or other performance curve for classifier output

Syntax

```
[X,Y] = perfcurve(labels,scores,posclass)
[X,Y,T] = perfcurve(labels,scores,posclass)
[X,Y,T,AUC] = perfcurve(labels,scores,posclass)
[X,Y,T,AUC,OPTROCPT] = perfcurve(labels,scores,posclass)
[X,Y,T,AUC,OPTROCPT,SUBY] = perfcurve(labels,scores,posclass)
[X,Y,T,AUC,OPTROCPT,SUBY,SUBYNAMES] = perfcurve(labels,scores,posclass)
[ ___ ] = perfcurve(labels,scores,posclass,Name,Value)
```

Description

`[X,Y] = perfcurve(labels,scores,posclass)` returns the X and Y coordinates of an ROC curve for a vector of classifier predictions, `scores`, given true class labels, `labels`, and the positive class label, `posclass`. You can visualize the performance curve using `plot(X,Y)`.

`[X,Y,T] = perfcurve(labels,scores,posclass)` returns an array of thresholds on classifier scores for the computed values of X and Y.

`[X,Y,T,AUC] = perfcurve(labels,scores,posclass)` returns the area under the curve for the computed values of X and Y.

`[X,Y,T,AUC,OPTROCPT] = perfcurve(labels,scores,posclass)` returns the optimal operating point of the ROC curve.

`[X,Y,T,AUC,OPTROCPT,SUBY] = perfcurve(labels,scores,posclass)` returns the Y values for negative subclasses.

`[X,Y,T,AUC,OPTROCPT,SUBY,SUBYNAMES] = perfcurve(labels,scores,posclass)` returns the negative class names.

`[___] = perfcurve(labels,scores,posclass,Name,Value)` returns the coordinates of a ROC curve and any other output argument from the previous syntaxes, with additional options specified by one or more `Name, Value` pair arguments.

For example, you can provide a list of negative classes, change the X or Y criterion, compute pointwise confidence bounds on page 32-3966 using cross validation or bootstrap, specify the misclassification cost, or compute the confidence bounds in parallel.

Examples

Plot ROC Curve for Classification by Logistic Regression

Load the sample data.

```
load fisheriris
```

Use only the first two features as predictor variables. Define a binary classification problem by using only the measurements that correspond to the species *versicolor* and *virginica*.

```
pred = meas(51:end,1:2);
```

Define the binary response variable.

```
resp = (1:100) '>50; % Versicolor = 0, virginica = 1
```

Fit a logistic regression model.

```
mdl = fitglm(pred,resp,'Distribution','binomial','Link','logit');
```

Compute the ROC curve. Use the probability estimates from the logistic regression model as scores.

```
scores = mdl.Fitted.Probability;  
[X,Y,T,AUC] = perfcurve(species(51:end,:),scores,'virginica');
```

`perfcurve` stores the threshold values in the array `T`.

Display the area under the curve.

AUC

```
AUC = 0.7918
```

The area under the curve is 0.7918. The maximum AUC is 1, which corresponds to a perfect classifier. Larger AUC values indicate better classifier performance.

Plot the ROC curve.

```
plot(X,Y)  
xlabel('False positive rate')  
ylabel('True positive rate')  
title('ROC for Classification by Logistic Regression')
```

Compare Classification Methods Using ROC Curve

Load the sample data.

```
load ionosphere
```

X is a 351x34 real-valued matrix of predictors. Y is a character array of class labels: 'b' for bad radar returns and 'g' for good radar returns.

Reformat the response to fit a logistic regression. Use the predictor variables 3 through 34.

```
resp = strcmp(Y,'b'); % resp = 1, if Y = 'b', or 0 if Y = 'g'
pred = X(:,3:34);
```

Fit a logistic regression model to estimate the posterior probabilities for a radar return to be a bad one.

```
mdl = fitglm(pred,resp,'Distribution','binomial','Link','logit');
score_log = mdl.Fitted.Probability; % Probability estimates
```

Compute the standard ROC curve using the probabilities for scores.

```
[Xlog,Ylog,Tlog,AUClog] = perfcurve(resp,score_log,'true');
```

Train an SVM classifier on the same sample data. Standardize the data.

```
mdlSVM = fitcsvm(pred,resp,'Standardize',true);
```

Compute the posterior probabilities (scores).

```
mdlSVM = fitPosterior(mdlSVM);  
[~,score_svm] = resubPredict(mdlSVM);
```

The second column of `score_svm` contains the posterior probabilities of bad radar returns.

Compute the standard ROC curve using the scores from the SVM model.

```
[Xsvm,Ysvm,Tsvm,AUCsvm] = perfcurve(resp,score_svm(:,mdlSVM.ClassNames),'true');
```

Fit a naive Bayes classifier on the same sample data.

```
mdlNB = fitcnb(pred,resp);
```

Compute the posterior probabilities (scores).

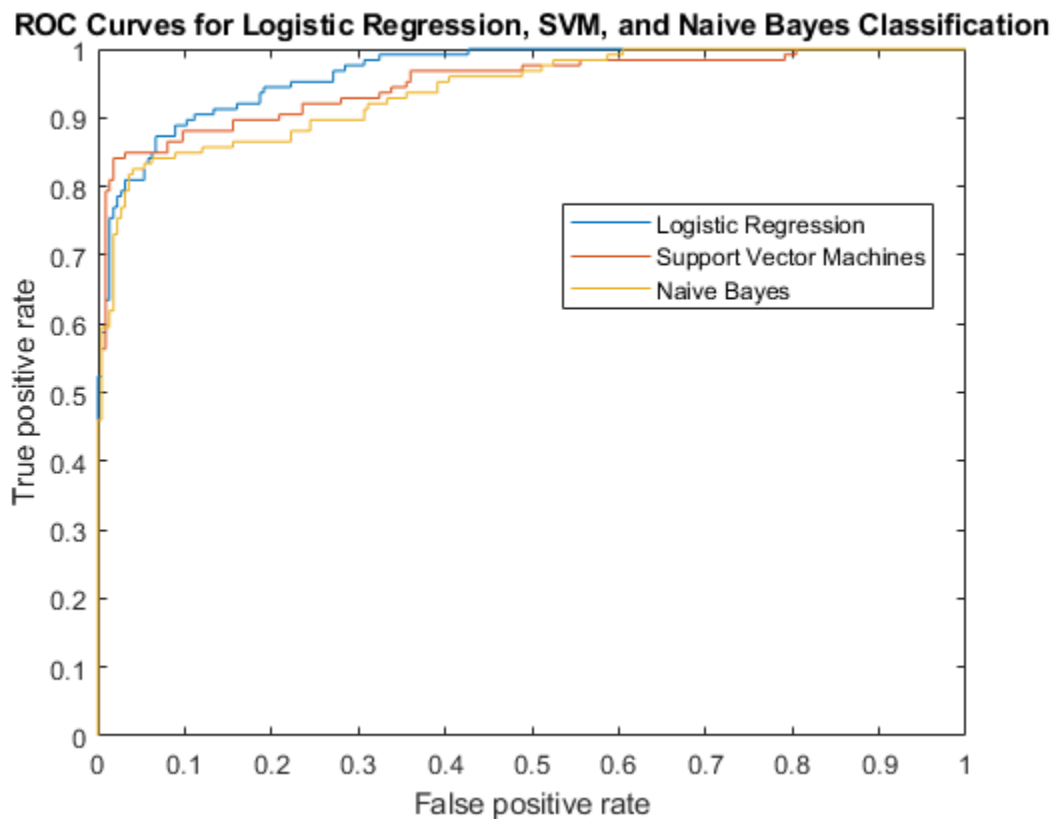

```
[~,score_nb] = resubPredict(mdlNB);
```

Compute the standard ROC curve using the scores from the naive Bayes classification.

```
[Xnb,Ynb,Tnb,AUCnb] = perfcurve(resp,score_nb(:,mdlNB.ClassNames),'true');
```

Plot the ROC curves on the same graph.

```
plot(Xlog,Ylog)  
hold on  
plot(Xsvm,Ysvm)  
plot(Xnb,Ynb)  
legend('Logistic Regression','Support Vector Machines','Naive Bayes','Location','Best')  
xlabel('False positive rate'); ylabel('True positive rate');  
title('ROC Curves for Logistic Regression, SVM, and Naive Bayes Classification')  
hold off
```

Although SVM produces better ROC values for higher thresholds, logistic regression is usually better at distinguishing the bad radar returns from the good ones. The ROC curve for naive Bayes is generally lower than the other two ROC curves, which indicates worse in-sample performance than the other two classifier methods.

Compare the area under the curve for all three classifiers.

AUC_{log}

AUC_{log} = 0.9659

AUC_{svm}

AUC_{svm} = 0.9488

AUC_{nb}

AUC_{nb} = 0.9393

Logistic regression has the highest AUC measure for classification and naive Bayes has the lowest. This result suggests that logistic regression has better in-sample average performance for this sample data.

Determine the Parameter Value for Custom Kernel Function

This example shows how to determine the better parameter value for a custom kernel function in a classifier using the ROC curves.

Generate a random set of points within the unit circle.

```
rng(1); % For reproducibility
n = 100; % Number of points per quadrant

r1 = sqrt(rand(2*n,1)); % Random radii
t1 = [pi/2*rand(n,1); (pi/2*rand(n,1)+pi)]; % Random angles for Q1 and Q3
X1 = [r1.*cos(t1) r1.*sin(t1)]; % Polar-to-Cartesian conversion

r2 = sqrt(rand(2*n,1));
t2 = [pi/2*rand(n,1)+pi/2; (pi/2*rand(n,1)-pi/2)]; % Random angles for Q2 and Q4
X2 = [r2.*cos(t2) r2.*sin(t2)];
```

Define the predictor variables. Label points in the first and third quadrants as belonging to the positive class, and those in the second and fourth quadrants in the negative class.

```
pred = [X1; X2];
resp = ones(4*n,1);
resp(2*n + 1:end) = -1; % Labels
```

Create the function `mysigmoid.m`, which accepts two matrices in the feature space as inputs, and transforms them into a Gram matrix using the sigmoid kernel.

```
function G = mysigmoid(U,V)
% Sigmoid kernel function with slope gamma and intercept c
gamma = 1;
c = -1;
G = tanh(gamma*U*V' + c);
end
```

Train an SVM classifier using the sigmoid kernel function. It is good practice to standardize the data.

```
SVMModel1 = fitcsvm(pred,resp,'KernelFunction','mysigmoid',...
    'Standardize',true);
SVMModel1 = fitPosterior(SVMModel1);
[~,scores1] = resubPredict(SVMModel1);
```

Set `gamma = 0.5`; within `mysigmoid.m` and save as `mysigmoid2.m`. And, train an SVM classifier using the adjusted sigmoid kernel.

```
function G = mysigmoid2(U,V)
% Sigmoid kernel function with slope gamma and intercept c
gamma = 0.5;
c = -1;
G = tanh(gamma*U*V' + c);
end
```

```
SVMModel2 = fitcsvm(pred,resp,'KernelFunction','mysigmoid2',...
    'Standardize',true);
```

```
SVMModel2 = fitPosterior(SVMModel2);
[~,scores2] = resubPredict(SVMModel2);
```

Compute the ROC curves and the area under the curve (AUC) for both models.

```
[x1,y1,~,auc1] = perfcurve(resp,scores1(:,2),1);
[x2,y2,~,auc2] = perfcurve(resp,scores2(:,2),1);
```

Plot the ROC curves.

```
plot(x1,y1)
hold on
plot(x2,y2)
hold off
legend('gamma = 1','gamma = 0.5','Location','SE');
xlabel('False positive rate'); ylabel('True positive rate');
title('ROC for classification by SVM');
```

The kernel function with the gamma parameter set to 0.5 gives better in-sample results.

Compare the AUC measures.

```
auc1
auc2
```

```
auc1 =
```

```
0.9518
```

```
auc2 =
```

```
0.9985
```

The area under the curve for gamma set to 0.5 is higher than that for gamma set to 1. This also confirms that gamma parameter value of 0.5 produces better results. For visual comparison of the classification performance with these two gamma parameter values, see “Train SVM Classifier Using Custom Kernel” on page 18-154.

Plot ROC Curve for Classification Tree

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species: `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: sepal length, sepal width, petal length, and petal width. All measures are in centimeters.

Train a classification tree using the sepal length and width as the predictor variables. It is a good practice to specify the class names.

```
Model = fitctree(meas(:,1:2),species, ...
    'ClassNames',{'setosa','versicolor','virginica'});
```

Predict the class labels and scores for the species based on the tree `Model`.

```
[~,score] = resubPredict(Model);
```

The scores are the posterior probabilities that an observation (a row in the data matrix) belongs to a class. The columns of `score` correspond to the classes specified by `'ClassNames'`. So, the first column corresponds to `setosa`, the second corresponds to `versicolor`, and the third column corresponds to `virginica`.

Compute the ROC curve for the predictions that an observation belongs to `versicolor`, given the true class labels `species`. Also compute the optimal operating point and `y` values for negative subclasses. Return the names of the negative classes.

Because this is a multiclass problem, you cannot merely supply `score(:,2)` as input to `perfcurve`. Doing so would not give `perfcurve` enough information about the scores for the two negative classes (`setosa` and `virginica`). This problem is unlike a binary classification problem, where knowing the scores of one class is enough to determine the scores of the other class. Therefore, you must supply `perfcurve` with a function that factors in the scores of the two negative classes. One such function is `score(:,2) - max(score(:,1),score(:,3))`.

```
diffscore = score(:,2) - max(score(:,1),score(:,3));
[X,Y,T,~,OPTROCPT,suby,subnames] = perfcurve(species,diffscore,'versicolor');
```

`X`, by default, is the false positive rate (fallout or 1-specificity) and `Y`, by default, is the true positive rate (recall or sensitivity). The positive class label is `versicolor`. Because a negative class is not

defined, `perfcurve` assumes that the observations that do not belong to the positive class are in one class. The function accepts it as the negative class.

```
OPTROCPT
```

```
OPTROCPT = 1×2
```

```
    0.1000    0.8000
```

```
suby
```

```
suby = 12×2
```

```
    0         0
    0.1800    0.1800
    0.4800    0.4800
    0.5800    0.5800
    0.6200    0.6200
    0.8000    0.8000
    0.8800    0.8800
    0.9200    0.9200
    0.9600    0.9600
    0.9800    0.9800
    ⋮
```

```
subnames
```

```
subnames = 1×2 cell
    {'setosa'}    {'virginica'}
```

Plot the ROC curve and the optimal operating point on the ROC curve.

```
plot(X,Y)
hold on
plot(OPTROCPT(1),OPTROCPT(2),'ro')
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve for Classification by Classification Trees')
hold off
```

Find the threshold that corresponds to the optimal operating point.

```
T((X==OPTROCPT(1))&(Y==OPTROCPT(2)))
```

```
ans = 0.2857
```

Specify *virginica* as the negative class and compute and plot the ROC curve for *versicolor*.

Again, you must supply *perfcurve* with a function that factors in the scores of the negative class. An example of a function to use is `score(:,2) - score(:,3)`.

```
diffscore = score(:,2) - score(:,3);
[X,Y,~,~,OPTROCPT] = perfcurve(species,diffscore,'versicolor', ...
    'negClass','virginica');
OPTROCPT
```

```
OPTROCPT = 1×2
```

```
    0.1800    0.8200
```

```
figure, plot(X,Y)
hold on
plot(OPTROCPT(1),OPTROCPT(2),'ro')
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve for Classification by Classification Trees')
hold off
```

Compute Pointwise Confidence Intervals for ROC Curve

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: sepal length, sepal width, petal length, and petal width. All measures are in centimeters.

Use only the first two features as predictor variables. Define a binary problem by using only the measurements that correspond to the `versicolor` and `virginica` species.

```
pred = meas(51:end,1:2);
```

Define the binary response variable.

```
resp = (1:100) '>50'; % Versicolor = 0, virginica = 1
```

Fit a logistic regression model.

```
mdl = fitglm(pred,resp,'Distribution','binomial','Link','logit');
```

Compute the pointwise confidence intervals on the true positive rate (TPR) by vertical averaging (VA) and sampling using bootstrap.

```
[X,Y,T] = perfcurve(species(51:end,:),mdl.Fitted.Probability,...
    'virginica','NBoot',1000,'XVals',[0:0.05:1]);
```

'NBoot', 1000 sets the number of bootstrap replicas to 1000. 'XVals', 'All' prompts perfcurve to return X, Y, and T values for all scores, and average the Y values (true positive rate) at all X values (false positive rate) using vertical averaging. If you do not specify XVals, then perfcurve computes the confidence bounds using threshold averaging by default.

Plot the pointwise confidence intervals.

```
errorbar(X,Y(:,1),Y(:,1)-Y(:,2),Y(:,3)-Y(:,1));
xlim([-0.02,1.02]); ylim([-0.02,1.02]);
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve with Pointwise Confidence Bounds')
legend('PCBwVA','Location','Best')
```

It might not always be possible to control the false positive rate (FPR, the X value in this example). So you might want to compute the pointwise confidence intervals on true positive rates (TPR) by threshold averaging.

```
[X1,Y1,T1] = perfcurve(species(51:end,:),mdl.Fitted.Probability,...
    'virginica','NBoot',1000);
```

If you set 'TVals' to 'All', or if you do not specify 'TVals' or 'Xvals', then perfcurve returns X, Y, and T values for all scores and computes pointwise confidence bounds for X and Y using threshold averaging.

Plot the confidence bounds.

```
figure()
errorbar(X1(:,1),Y1(:,1),Y1(:,1)-Y1(:,2),Y1(:,3)-Y1(:,1));
xlim([-0.02,1.02]); ylim([-0.02,1.02]);
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve with Pointwise Confidence Bounds')
legend('PCBwTA','Location','Best')
```

Specify the threshold values to fix and compute the ROC curve. Then plot the curve.

```
[X1,Y1,T1] = perfcurve(species(51:end,:),mdl.Fitted.Probability,...
'virginica','NBoot',1000,'TVals',0:0.05:1);
figure()
errorbar(X1(:,1),Y1(:,1),Y1(:,1)-Y1(:,2),Y1(:,3)-Y1(:,1));
xlim([-0.02,1.02]); ylim([-0.02,1.02]);
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve with Pointwise Confidence Bounds')
legend('PCBwTA','Location','Best')
```

Input Arguments

labels — True class labels

numeric vector | logical vector | character matrix | string array | cell array of character vectors | categorical array

True class labels, specified as a numeric vector, logical vector, character matrix, string array, cell array of character vectors, or categorical array. For more information, see “Grouping Variables” on page 2-45.

Example: {'hi','mid','hi','low',..., 'mid'}

Example: ['H','M','H','L',..., 'M']

Data Types: single | double | logical | char | string | cell | categorical

scores — Scores returned by a classifier

vector of floating points

Scores returned by a classifier for some sample data, specified as a vector of floating points. scores must have the same number of elements as labels.

Data Types: single | double

posclass — Positive class label

numeric scalar | logical scalar | character vector | string scalar | cell containing a character vector | categorical scalar

Positive class label, specified as a numeric scalar, logical scalar, character vector, string scalar, cell containing a character vector, or categorical scalar. The positive class must be a member of the input labels. The value of `posclass` that you can specify depends on the value of `labels`.

labels value	posclass value
Numeric vector	Numeric scalar
Logical vector	Logical scalar
Character matrix	Character vector
String array	String scalar
Cell array of character vectors	Character vector or cell containing character vector
Categorical vector	Categorical scalar

For example, in a cancer diagnosis problem, if a malignant tumor is the positive class, then specify `posclass` as `'malignant'`.

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell` | `categorical`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'NegClass', 'versicolor', 'XCrit', 'fn', 'NBoot', 1000, 'BootType', 'per'` specifies the species `versicolor` as the negative class, the criterion for the X-coordinate as false negative, the number of bootstrap samples as 1000. It also specifies that the pointwise confidence bounds are computed using the percentile method.

NegClass — List of negative classes

`'all'` (default) | numeric array | categorical array | string array | cell array of character vectors

List of negative classes, specified as the comma-separated pair consisting of `'NegClass'`, and a numeric array, a categorical array, a string array, or a cell array of character vectors. By default, `perfcurve` sets `NegClass` to `'all'` and considers all nonpositive classes found in the input array of labels to be negative.

If `NegClass` is a subset of the classes found in the input array of labels, then `perfcurve` discards the instances with labels that do not belong to either positive or negative classes.

Example: `'NegClass', {'versicolor', 'setosa'}`

Data Types: `single` | `double` | `categorical` | `char` | `string` | `cell`

XCrit — Criterion to compute for X

`'fpr'` (default) | `'fnr'` | `'tnr'` | `'ppv'` | `'ecost'` | ...

Criterion to compute for X, specified as the comma-separated pair consisting of `'XCrit'` and one of the following.

Criterion	Description
<code>tp</code>	Number of true positive instances

Criterion	Description
fn	Number of false negative instances.
fp	Number of false positive instances.
tn	Number of true negative instances.
tp+fp	Sum of true positive and false positive instances.
rpp	Rate of positive predictions. $rpp = (tp+fp)/(tp+fn+fp+tn)$
rnp	Rate of negative predictions. $rnp = (tn+fn)/(tp+fn+fp+tn)$
accu	Accuracy. $accu = (tp+tn)/(tp+fn+fp+tn)$
tpr, or sens, or reca	True positive rate, or sensitivity, or recall. $tpr = sens = reca = tp/(tp+fn)$
fnr, or miss	False negative rate, or miss. $fnr = miss = fn/(tp+fn)$
fpr, or fall	False positive rate, or fallout, or 1 - specificity. $fpr = fall = fp/(tn+fp)$
tnr, or spec	True negative rate, or specificity. $tnr = spec = tn/(tn+fp)$
ppv, or prec	Positive predictive value, or precision. $ppv = prec = tp/(tp+fp)$
npv	Negative predictive value. $npv = tn/(tn+fn)$
ecost	Expected cost. $ecost = (tp*Cost(P P)+fn*Cost(N P)+fp*Cost(P N)+tn*Cost(N N))/(tp+fn+fp+tn)$
Custom criterion	A custom-defined function with the input arguments (C, scale, cost), where C is a 2-by-2 confusion matrix, scale is a 2-by-1 array of class scales, and cost is a 2-by-2 misclassification cost matrix.

Caution Some of these criteria return NaN values at one of the two special thresholds, 'reject all' and 'accept all'.

Example: 'XCrit', 'ecost'

YCrit – Criterion to compute for Y

'tpr' (default) | same criteria options for X

Criterion to compute for Y, specified as the comma-separated pair consisting of 'YCrit' and one of the same criteria options as for X. This criterion does not have to be a monotone function of the positive class score.

Example: 'YCrit', 'ecost'

XVals — Values for the X criterion`'all'` (default) | numeric array

Values for the X criterion, specified as the comma-separated pair consisting of `'XVals'` and a numeric array.

- If you specify `XVals`, then `perfcurve` computes X and Y and the pointwise confidence bounds on page 32-3966 for Y (when applicable) only for the specified `XVals`.
- If you do not specify `XVals`, then `perfcurve`, computes X and Y and the values for all scores by default.

Note You cannot set `XVals` and `TVals` at the same time.

Example: `'XVals', [0:0.05:1]`

Data Types: `single` | `double` | `char` | `string`

TVals — Thresholds for the positive class score`'all'` (default) | numeric array

Thresholds for the positive class score, specified as the comma-separated pair consisting of `'TVals'` and either `'all'` or a numeric array.

- If `TVals` is set to `'all'` or not specified, and `XVals` is not specified, then `perfcurve` returns X, Y, and T values for all scores and computes pointwise confidence bounds on page 32-3966 for X and Y using threshold averaging.
- If `TVals` is set to a numeric array, then `perfcurve` returns X, Y, and T values for the specified thresholds and computes pointwise confidence bounds for X and Y at these thresholds using threshold averaging.

Note You cannot set `XVals` and `TVals` at the same time.

Example: `'TVals', [0:0.05:1]`

Data Types: `single` | `double` | `char` | `string`

UseNearest — Indicator to use the nearest values in the data`'on'` (default) | `'off'`

Indicator to use the nearest values in the data instead of the specified numeric `XVals` or `TVals`, specified as the comma-separated pair consisting of `'UseNearest'` and either `'on'` or `'off'`.

- If you specify numeric `XVals` and set `UseNearest` to `'on'`, then `perfcurve` returns the nearest unique X values found in the data, and it returns the corresponding values of Y and T.
- If you specify numeric `XVals` and set `UseNearest` to `'off'`, then `perfcurve` returns the sorted `XVals`.
- If you compute confidence bounds by cross validation or bootstrap, then this parameter is always `'off'`.

Example: `'UseNearest', 'off'`

ProcessNaN — perfcurve method for processing NaN scores

'ignore' (default) | 'addtofalse'

perfcurve method for processing NaN scores, specified as the comma-separated pair consisting of 'ProcessNaN' and 'ignore' or 'addtofalse'.

- If ProcessNaN is 'ignore', then perfcurve removes observations with NaN scores from the data.
- If ProcessNaN is 'addtofalse', then perfcurve adds instances with NaN scores to false classification counts in the respective class. That is, perfcurve always counts instances from the positive class as false negative (FN), and it always counts instances from the negative class as false positive (FP).

Example: 'ProcessNaN', 'addtofalse'

Prior — Prior probabilities for positive and negative classes

'empirical' (default) | 'uniform' | array with two elements

Prior probabilities for positive and negative classes, specified as the comma-separated pair consisting of 'Prior' and 'empirical', 'uniform', or an array with two elements.

If Prior is 'empirical', then perfcurve derives prior probabilities from class frequencies.

If Prior is 'uniform', then perfcurve sets all prior probabilities to be equal.

Example: 'Prior', [0.3,0.7]

Data Types: single | double | char | string

Cost — Misclassification costs

[0 0.5;0.5 0] (default) | 2-by-2 matrix

Misclassification costs, specified as the comma-separated pair consisting of 'Cost' and a 2-by-2 matrix, containing [Cost(P|P), Cost(N|P); Cost(P|N), Cost(N|N)].

Cost(N|P) is the cost of misclassifying a positive class as a negative class. Cost(P|N) is the cost of misclassifying a negative class as a positive class. Usually, Cost(P|P) = 0 and Cost(N|N) = 0, but perfcurve allows you to specify nonzero costs for correct classification as well.

Example: 'Cost', [0 0.7;0.3 0]

Data Types: single | double

Alpha — Significance level

0.05 (default) | scalar value in the range 0 through 1

Significance level for the confidence bounds, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range 0 through 1. perfcurve computes $100 \cdot (1 - \alpha)$ percent pointwise confidence bounds on page 32-3966 for X, Y, T, and AUC for a confidence level of $1 - \alpha$.

Example: 'Alpha', 0.01 specifies 99% confidence bounds

Data Types: single | double

Weights — Observation weights

vector of nonnegative scalar values | cell array of vectors of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of nonnegative scalar values. This vector must have as many elements as `scores` or `labels` do.

If `scores` and `labels` are in cell arrays and you need to supply `Weights`, the weights must be in a cell array as well. In this case, every element in `Weights` must be a numeric vector with as many elements as the corresponding element in `scores`. For example, `numel(weights{1}) == numel(scores{1})`.

When `perfcurve` computes the X, Y and T or confidence bounds using cross-validation, it uses these observation weights instead of observation counts.

When `perfcurve` computes confidence bounds using bootstrap, it samples N out of N observations with replacement, using these weights as multinomial sampling probabilities.

The default is a vector of 1s or a cell array in which each element is a vector of 1s.

Data Types: `single` | `double` | `cell`

NBoot — Number of bootstrap replicas

0 (default) | positive integer

Number of bootstrap replicas for computation of confidence bounds, specified as the comma-separated pair consisting of 'NBoot' and a positive integer. The default value 0 means the confidence bounds are not computed.

If `labels` and `scores` are cell arrays, this parameter must be 0 because `perfcurve` can use either cross-validation or bootstrap to compute confidence bounds.

Example: 'NBoot', 500

Data Types: `single` | `double`

BootType — Confidence interval type for bootci

'bca' (default) | 'norm' | 'per' | 'cper' | 'stud'

Confidence interval type for `bootci` to use to compute confidence bounds, specified as the comma-separated pair consisting of 'BootType' and one of the following:

- 'bca' — Bias corrected and accelerated percentile method
- 'norm' or 'normal' — Normal approximated interval with bootstrapped bias and standard error
- 'per' or 'percentile' — Percentile method
- 'cper' or 'corrected percentile' — Bias corrected percentile method
- 'stud' or 'student' — Studentized confidence interval

Example: 'BootType', 'cper'

BootArg — Optional input arguments for bootci

[] (default) | {'Nbootstd', nbootstd} | {'Stderr', stderr}

Optional input arguments for `bootci` to compute confidence bounds, specified as the comma-separated pair consisting of 'BootArg' and {'Nbootstd', nbootstd} or {'Stderr', stderr}, name-value pair arguments of `bootci`.

When you compute the studentized bootstrap confidence intervals ('BootType' is 'student'), you can additionally specify 'Nbootstd' or 'Stderr', name-value pair arguments of `bootci`, by using 'BootArg'.

- 'BootArg', {'Nbootstd', nbootstd} estimates the standard error of the bootstrap statistics using bootstrap with nbootstd data samples. nbootstd is a positive integer and its default is 100.
- 'BootArg', {'Stderr', stderr} evaluates the standard error of the bootstrap statistics by a user-defined function stderr that takes [1:numel(scores)]' as an input argument. stderr is a function handle.

Example: 'BootArg', {'Nbootstd', nbootstd}

Data Types: cell

Options — Options for controlling the computation of confidence intervals

[] (default) | structure array returned by `statset`

Options for controlling the computation of confidence intervals, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`. These options require Parallel Computing Toolbox. `perfcurve` uses this argument for computing pointwise confidence bounds only. To compute these bounds, you must pass cell arrays for `labels` and `scores` or set `NBoot` to a positive integer.

This table summarizes the available options.

Option	Description
'UseParallel'	<ul style="list-style-type: none"> • <code>false</code> — Serial computation (default). • <code>true</code> — Parallel computation. You need Parallel Computing Toolbox for this option to work.
'UseSubstreams'	<ul style="list-style-type: none"> • <code>false</code> — Do not use a separate substream for each iteration (default). • <code>true</code> — Use a separate substream for each iteration to compute in parallel in a reproducible fashion. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'.
'Streams'	<p>A <code>RandStream</code> object, or a cell array of such objects. If you specify <code>Streams</code>, use a single object, except when:</p> <ul style="list-style-type: none"> • <code>UseParallel</code> is <code>true</code>. • <code>UseSubstreams</code> is <code>false</code>. <p>In that case, use a cell array of the same size as the parallel pool. If a parallel pool is not open, then <code>Streams</code> must supply a single random number stream.</p>

If `'UseParallel'` is true and `'UseSubstreams'` is false, then the length of `'Streams'` must equal the number of workers used by `perfcurve`. If a parallel pool is already open, then the length of `'Streams'` is the size of the parallel pool. If a parallel pool is not already open, then MATLAB might open a pool for you, depending on your installation and preferences. To ensure more predictable results, use `parpool` and explicitly create a parallel pool before invoking `perfcurve` and setting `'Options'`, `statset('UseParallel',true)`.

Example: `'Options',statset('UseParallel',true)`

Data Types: `struct`

Output Arguments

X — x-coordinates for the performance curve

vector, `fpr` (default) | m -by-3 matrix

x-coordinates for the performance curve, returned as a vector or an m -by-3 matrix. By default, X values are the false positive rate, FPR (fallout or $1 - \text{specificity}$). To change X, use the `XCrit` name-value pair argument.

- If `perfcurve` does not compute the pointwise confidence bounds on page 32-3966, or if it computes them using vertical averaging, then X is a vector.
- If `perfcurve` computes the confidence bounds using threshold averaging, then X is an m -by-3 matrix, where m is the number of fixed threshold values. The first column of X contains the mean value. The second and third columns contain the lower bound and the upper bound, respectively, of the pointwise confidence bounds.

Y — y-coordinates for the performance curve

vector, `tpr` (default) | m -by-3 matrix

y-coordinates for the performance curve, returned as a vector or an m -by-3 matrix. By default, Y values are the true positive rate, TPR (recall or sensitivity). To change Y, use `YCrit` name-value pair argument.

- If `perfcurve` does not compute the pointwise confidence bounds on page 32-3966, then Y is a vector.
- If `perfcurve` computes the confidence bounds, then Y is an m -by-3 matrix, where m is the number of fixed X values or thresholds (T values). The first column of Y contains the mean value. The second and third columns contain the lower bound and the upper bound, respectively, of the pointwise confidence bounds.

T — Thresholds on classifier scores

vector | m -by-3 matrix

Thresholds on classifier scores for the computed values of X and Y, returned as a vector or m -by-3 matrix.

- If `perfcurve` does not compute the pointwise confidence bounds on page 32-3966, or computes them using threshold averaging, then T is a vector.
- If `perfcurve` computes the confidence bounds using vertical averaging, T is an m -by-3 matrix, where m is the number of fixed X values. The first column of T contains the mean value. The second and third columns contain the lower bound, and the upper bound, respectively, of the pointwise confidence bounds.

For each threshold, TP is the count of true positive observations with scores greater than or equal to this threshold, and FP is the count of false positive observations with scores greater than or equal to this threshold. `perfcurve` defines negative counts, TN and FN, in a similar way. The function then sorts the thresholds in the descending order that corresponds to the ascending order of positive counts.

For the m distinct thresholds found in the array of scores, `perfcurve` returns the X, Y and T arrays with $m + 1$ rows. `perfcurve` sets elements T(2:m+1) to the distinct thresholds, and T(1) replicates T(2). By convention, T(1) represents the highest 'reject all' threshold, and `perfcurve` computes the corresponding values of X and Y for TP = 0 and FP = 0. The T(end) value is the lowest 'accept all' threshold for which TN = 0 and FN = 0.

AUC — Area under the curve

scalar value | 3-by-1 vector

Area under the curve (AUC) for the computed values of X and Y, returned as a scalar value or a 3-by-1 vector.

- If `perfcurve` does not compute the pointwise confidence bounds on page 32-3966, AUC is a scalar value.
- If `perfcurve` computes the confidence bounds using vertical averaging, AUC is a 3-by-1 vector. The first column of AUC contains the mean value. The second and third columns contain the lower bound and the upper bound, respectively, of the confidence bound.

For a perfect classifier, AUC = 1. For a classifier that randomly assigns observations to classes, AUC = 0.5.

If you set XVals to 'all' (default), then `perfcurve` computes AUC using the returned X and Y values.

If XVals is a numeric array, then `perfcurve` computes AUC using X and Y values from all distinct scores in the interval, which are specified by the smallest and largest elements of XVals. More precisely, `perfcurve` finds X values for all distinct thresholds as if XVals were set to 'all', and then uses a subset of these (with corresponding Y values) between $\min(\text{XVals})$ and $\max(\text{XVals})$ to compute AUC.

`perfcurve` uses trapezoidal approximation to estimate the area. If the first or last value of X or Y are NaNs, then `perfcurve` removes them to allow calculation of AUC. This takes care of criteria that produce NaNs for the special 'reject all' or 'accept all' thresholds, for example, positive predictive value (PPV) or negative predictive value (NPV).

OPTRCPT — Optimal operating point of the ROC curve

1-by-2 array

Optimal operating point of the ROC curve, returned as a 1-by-2 array with false positive rate (FPR) and true positive rate (TPR) values for the optimal ROC operating point.

`perfcurve` computes OPTRCPT for the standard ROC curve only, and sets to NaNs otherwise. To obtain the optimal operating point for the ROC curve, `perfcurve` first finds the slope, S , using

$$S = \frac{\text{Cost}(P|N) - \text{Cost}(N|N)}{\text{Cost}(N|P) - \text{Cost}(P|P)} * \frac{N}{P}$$

- Cost(N|P) is the cost of misclassifying a positive class as a negative class. Cost(P|N) is the cost of misclassifying a negative class as a positive class.

- $P = TP + FN$ and $N = TN + FP$. They are the total instance counts in the positive and negative class, respectively.

`perfcurve` then finds the optimal operating point by moving the straight line with slope S from the upper left corner of the ROC plot ($FPR = 0$, $TPR = 1$) down and to the right, until it intersects the ROC curve.

SUBY — Values for negative subclasses

array

Values for negative subclasses, returned as an array.

- If you specify only one negative class, then `SUBY` is identical to `Y`.
- If you specify k negative classes, then `SUBY` is a matrix of size m -by- k , where m is the number of returned values for `X` and `Y`, and k is the number of negative classes. `perfcurve` computes `Y` values by summing counts over all negative classes.

`SUBY` gives values of the `Y` criterion for each negative class separately. For each negative class, `perfcurve` places a new column in `SUBY` and fills it with `Y` values for true negative (`TN`) and false positive (`FP`) counted just for this class.

SUBYNAMES — Negative class names

cell array

Negative class names, returned as a cell array.

- If you provide an input array of negative class names, `NegClass`, then `perfcurve` copies names into `SUBYNAMES`.
- If you do not provide `NegClass`, then `perfcurve` extracts `SUBYNAMES` from the input labels. The order of `SUBYNAMES` is the same as the order of columns in `SUBY`. That is, `SUBY(:, 1)` is for negative class `SUBYNAMES{1}`, `SUBY(:, 2)` is for negative class `SUBYNAMES{2}`, and so on.

Algorithms

Pointwise Confidence Bounds

If you supply cell arrays for `labels` and `scores`, or if you set `NBoot` to a positive integer, then `perfcurve` returns pointwise confidence bounds for `X`, `Y`, `T`, and `AUC`. You cannot supply cell arrays for `labels` and `scores` and set `NBoot` to a positive integer at the same time.

`perfcurve` resamples data to compute confidence bounds using either cross validation or bootstrap.

- Cross-validation — If you supply cell arrays for `labels` and `scores`, then `perfcurve` uses cross-validation and treats elements in the cell arrays as cross-validation folds. `labels` can be a cell array of numeric vectors, logical vectors, character matrices, cell arrays of character vectors, or categorical vectors. All elements in `labels` must have the same type. `scores` can be a cell array of numeric vectors. The cell arrays for `labels` and `scores` must have the same number of elements. The number of labels in cell j of `labels` must be equal to the number of scores in cell j of `scores` for any j in the range from 1 to the number of elements in `scores`.
- Bootstrap — If you set `NBoot` to a positive integer n , `perfcurve` generates n bootstrap replicas to compute pointwise confidence bounds. If you use `XCrit` or `YCrit` to set the criterion for `X` or `Y` to an anonymous function, `perfcurve` can compute confidence bounds only using bootstrap.

`perfcurve` estimates the confidence bounds using one of two methods:

- Vertical averaging (VA) — `perfcurve` estimates confidence bounds on Y and T at fixed values of X. That is, `perfcurve` takes samples of the ROC curves for fixed X values, averages the corresponding Y and T values, and computes the standard errors. You can use the `XVals` name-value pair argument to fix the X values for computing confidence bounds. If you do not specify `XVals`, then `perfcurve` computes the confidence bounds at all X values.
- Threshold averaging (TA) — `perfcurve` takes samples of the ROC curves at fixed thresholds T for the positive class score, averages the corresponding X and Y values, and estimates the confidence bounds. You can use the `TVals` name-value pair argument to use this method for computing confidence bounds. If you set `TVals` to 'all' or do not specify `TVals` or `XVals`, then `perfcurve` returns X, Y, and T values for all scores and computes pointwise confidence bounds for Y and X using threshold averaging.

When you compute the confidence bounds, Y is an m -by-3 array, where m is the number of fixed X values or thresholds (T values). The first column of Y contains the mean value. The second and third columns contain the lower bound and the upper bound, respectively, of the pointwise confidence bounds. AUC is a row vector with three elements, following the same convention. If `perfcurve` computes the confidence bounds using VA, then T is an m -by-3 matrix, and X is a column vector. If `perfcurve` uses TA, then X is an m -by-3 matrix and T is a column-vector.

`perfcurve` returns pointwise confidence bounds. It does not return a simultaneous confidence band for the entire curve.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to `true`.

Set the 'UseParallel' field of the options structure to `true` using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the `'Options'` name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2009a

plot

Class: clustering.evaluation.ClusterCriterion

Package: clustering.evaluation

Plot clustering evaluation object criterion values

Syntax

```
plot(eva)  
h = plot(eva)
```

Description

`plot(eva)` displays a plot of the criterion values versus the number of clusters, based on the values stored in the clustering evaluation object `eva`.

`h = plot(eva)` returns a handle to the plot line.

Input Arguments

eva — Clustering evaluation data

clustering evaluation object

Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using `evalclusters`.

Output Arguments

h — Handle to plot line

scalar value

Handle to the plot line, returned as a scalar value.

Examples

Plot the Clustering Evaluation Criterion Values

Plot the criterion values versus the number of clusters for each clustering solution stored in a clustering evaluation object.

Load the sample data.

```
load fisheriris
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Create a clustering evaluation object. Cluster the data using `kmeans`, and evaluate the optimal number of clusters using the Calinski-Harabasz criterion.

```
rng('default'); % For reproducibility
eva = evalclusters(meas, 'kmeans', 'CalinskiHarabasz', 'KList', [1:6]);
```

Plot the Calinski-Harabasz criterion values for each number of clusters tested.

```
figure;
plot(eva);
```

The plot shows that the highest Calinski-Harabasz value occurs at three clusters, suggesting that the optimal number of clusters is three.

`evalclusters`

plot

Scatter plot or added variable plot of linear regression model

Syntax

```
plot mdl
plot(ax, mdl)
h = plot( ___ )
```

Description

`plot(mdl)` creates a plot of the linear regression model `mdl`. The plot type depends on the number of predictor variables.

- If `mdl` includes multiple predictor variables, `plot` creates an “Added Variable Plot” on page 32-3976 for the whole model except the constant (intercept) term, equivalent to `plotAdded(mdl)`.
- If `mdl` includes a single predictor variable, `plot` creates a scatter plot of the data along with a fitted curve and confidence bounds.
- If `mdl` does not include a predictor, `plot` creates a histogram of the residuals, equivalent to `plotResiduals(mdl)`.

`plot(ax, mdl)` creates the plot in the axes specified by `ax` instead of the current axes.

`h = plot(___)` returns graphics objects for the lines or patch in the plot, using any of the input argument combinations in the previous syntaxes. Use `h` to modify the properties of a specific line or patch after you create the plot. For a list of properties, see [Chart Line and Patch Properties](#).

Examples

Create Added Variable Plot

Create a linear regression model of car mileage as a function of weight and model year. Then create an added variable plot to see the significance of the model.

Create a linear regression model of mileage from the `carsmall` data set.

```
load carsmall
Year = categorical(Model_Year);
tbl = table(MPG, Weight, Year);
mdl = fitlm(tbl, 'MPG ~ Year + Weight^2');
```

Create an added variable plot of the model.

```
plot(mdl)
```

The plot illustrates that the model is significant because a horizontal line does not fit between the confidence bounds.

Create the same plot by using the `plotAdded` function.

```
plotAdded mdl)
```

Create Scatter Plot for Simple Linear Regression

Create a scatter plot of data along with a fitted curve and confidence bounds for a simple linear regression model. A simple linear regression model includes only one predictor variable.

Create a simple linear regression model of mileage from the `carsmall` data set.

```
load carsmall
tbl = table(MPG,Weight);
mdl = fitlm(tbl,'MPG ~ Weight')
```

```
mdl =
Linear regression model:
MPG ~ 1 + Weight
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
Weight	-0.0086119	0.0005348	-16.103	1.6434e-28

```
Number of observations: 94, Error degrees of freedom: 92
Root Mean Squared Error: 4.13
```

R-squared: 0.738, Adjusted R-Squared: 0.735
F-statistic vs. constant model: 259, p-value = 1.64e-28

pValue of the Weight variable is very small, which means that the variable is statistically significant in the model. Visualize this result by creating a scatter plot of the data, along with a fitted curve and its 95% confidence bounds, using the `plot` function.

```
plot mdl
```

The plot illustrates that the model is significant because a horizontal line does not fit between the confidence bounds, which is consistent with the pValue result.

Create the same plot by using the `plotAdded` function.

```
plotAdded mdl
```

When a model includes only one term in addition to the constant term, an adjusted value is equivalent to its original value. Therefore, this added variable plot is the same as the scatter plot created by the `plot` function.

Input Arguments

mdl — Linear regression model

LinearModel object

Linear regression model, specified as a LinearModel object created using `fitlm` or `stepwiselm`.

ax — Target axes

Axes object

Target axes, specified as an Axes object.

If you do not specify the axes and the current axes are Cartesian, then `plot` uses the current axes (`gca`). For more information on creating an Axes object, see `axes` and `gca`.

Output Arguments

h — Graphics objects

graphics array

Graphics objects corresponding to the lines or patch in the plot, returned as a graphics array. Use dot notation to query and set properties of graphics objects. For details, see Line Properties and Patch Properties.

If `mdl` includes one or more predictors, then `h(1)`, `h(2)`, `h(3)`, and `h(4)` correspond to adjusted data points, the fitted line, and the lower and upper bounds of the fitted line, respectively.

If `mdl` does not include a predictor, then `h` corresponds to the histogram of residuals.

More About

Added Variable Plot

An added variable plot, also known as a partial regression leverage plot, illustrates the incremental effect on the response of specified terms caused by removing the effects of all other terms.

An added variable plot created by `plotAdded` with a single selected term corresponding to a single predictor variable includes these plots:

- Scatter plot of adjusted response values against adjusted predictor variable values
- Fitted line for adjusted response values as a function of adjusted predictor variable values
- 95% confidence bounds of the fitted line

The adjusted values are equal to the average of the variable plus the residuals of the variable fit to all predictors except the selected predictor. For example, consider an added variable plot for the first predictor variable x_1 . Fit the response variable y and the selected predictor variable x_1 to all predictors except x_1 as follows:

$$\begin{aligned} y_i &= g_y(x_{2i}, x_{3i}, \dots, x_{pi}) + r_{yi}, \\ x_{1i} &= g_x(x_{2i}, x_{3i}, \dots, x_{pi}) + r_{xi}, \end{aligned}$$

where g_y and g_x are the fit of y and x_1 , respectively, against all predictors except the selected predictor (x_1). r_y and r_x are the corresponding residual vectors. The subscript i represents the observation number. The adjusted value is the sum of the average value and the residual for each observation.

$$\begin{aligned} \tilde{y}_i &= \bar{y} + r_{yi}, \\ \tilde{x}_{1i} &= \bar{x}_1 + r_{xi}, \end{aligned}$$

where \bar{x}_1 and \bar{y} represent the average of x_1 and y , respectively.

`plotAdded` plots a scatter plot of $(\tilde{x}_{1i}, \tilde{y}_i)$, a fitted line for \tilde{y} as a function of \tilde{x}_1 (that is, $\beta_1 \tilde{x}_1$), and the 95% confidence bounds of the fitted line. The coefficient β_1 is the same as the coefficient estimate of x_1 in the full model, which includes all predictors.

r_{yi} represents the part of the response values unexplained by the predictors (except x_1), and r_{xi} represents the part of the x_1 values unexplained by the other predictors. Therefore, the fitted line represents how the new information introduced by adding x_1 can explain the unexplained part of the response values. If the slope of the fitted line is close to zero and the confidence bounds can include a horizontal line, then the plot indicates that the new information from x_1 does not explain the unexplained part of the response values well. That is, x_1 is not significant in the model fit.

`plotAdded` also supports an extension of the added variable plot so that you can select multiple terms instead of a single term. Therefore, you can also specify a categorical predictor, all terms that

involve a specific predictor, or the model as a whole (except a constant (intercept) term). Consider a set of predictors X with a coefficient vector β , where β_i is the coefficient estimate of x_i in the full model if you specify the i th coefficient for an added variable plot; otherwise, β_i is zero. Define a unit direction vector u as $u = \beta/s$ where $s = \text{norm}(\beta)$. Then, $X\beta = (Xu)s$. Treat Xu as a single predictor with a coefficient s , and create an added variable plot for Xu in the same way as creating the plot for a single term. The coefficient of the fitted line in the added variable plot corresponds to s .

`plot` creates an added variable plot for the model as a whole (except a constant term) if the model includes multiple terms.

Tips

- The data cursor displays the values of the selected plot point in a data tip (small text box located next to the data point). The data tip includes the x -axis and y -axis values for the selected point, along with the observation name or number.

Alternative Functionality

- A `LinearModel` object provides multiple plotting functions.
 - When creating a model, use `plotAdded` to understand the effect of adding or removing a predictor variable.
 - When verifying a model, use `plotDiagnostics` to find questionable data and to understand the effect of each observation. Also, use `plotResiduals` to analyze the residuals of the model.
 - After fitting a model, use `plotAdjustedResponse`, `plotPartialDependence`, and `plotEffects` to understand the effect of a particular predictor. Use `plotInteraction` to understand the interaction effect between two predictors. Also, use `plotSlice` to plot slices through the prediction surface.
- The `plot` function creates an added variable plot for the model as a whole (except a constant term) if the model includes multiple terms. Use `plotAdded` to select particular predictors for an added variable plot.

plot

Class: RepeatedMeasuresModel

Plot data with optional grouping

Syntax

```
plot(rm)
plot(rm, Name, Value)
H = plot( ___ )
```

Description

`plot(rm)` plots the measurements in the repeated measures model `rm` for each subject as a function of time. If there is a single numeric within-subjects factor, `plot` uses the values of that factor as the time values. Otherwise, `plot` uses the discrete values 1 through r as the time values, where r is the number of repeated measurements.

`plot(rm, Name, Value)` also plots the measurements in the repeated measures model `rm`, with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the factors to group by or change the line colors.

`H = plot(___)` returns handles, `H`, to the plotted lines.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Group — Name of between-subject factor or factors

character vector | string array | cell array of character vectors

Name of between-subject factor or factors, specified as the comma-separated pair consisting of `'Group'` and a character vector, string array, or cell array of character vectors. This name-value pair argument groups the lines according to the factor values.

For example, if you have two between-subject factors, `drug` and `sex`, and you want to group the lines in the plot according to them, you can specify these factors as follows.

Example: `'Group', {'Drug', 'Sex'}`

Data Types: `char` | `string` | `cell`

Marker — Marker to use for each group

`string array` | `cell array of character vectors`

Marker to use for each group, specified as the comma-separated pair consisting of `'Marker'` and a `string array` or `cell array of character vectors`.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify `o` as the marker for the groups of drug and `x` as the marker for the groups of sex as follows.

Example: `'Marker', {'o', 'o', 'x', 'x'}`

Data Types: `string` | `cell`

Color — Color for each group

`character vector` | `string array` | `cell array of character vectors` | `rows of a three-column RGB matrix`

Color for each group, specified as the comma-separated pair consisting of `'Color'` and a `character vector`, `string array`, `cell array of character vectors`, or `rows of a three-column RGB matrix`.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify `red` as the color for the groups of drug and `blue` as the color for the groups of sex as follows.

Example: `'Color', 'rbb'`

Data Types: `single` | `double` | `char` | `string` | `cell`

LineStyle — Line style for each group

`string array` | `cell array of character vectors`

Line style for each group, specified as the comma-separated pair consisting of `'LineStyle'` and a `string array` or `cell array of character vectors`.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify `-` as the line style of one group and `:` as the line style for the other group as follows.

Example: `'LineStyle', {'-' ':' '-' ':'}`

Data Types: `string` | `cell`

Output Arguments

H — Handle to plotted lines

`handle`

Handle to plotted lines, returned as a handle.

Examples

Plot Data by Group

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Plot data grouped by the factor species.

```
plot(rm,'group','species')
```

Change the line style for each group.

```
plot(rm,'group','species','LineStyle',{'-','--',':'})
```

Plot Data Grouped by Two Factors

Load the sample data.

load `repeatedmeas`

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the `group-gender` interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Plot data with `Group` coded by color and `Gender` coded by line type.

```
plot(rm, 'group', {'Group' 'Gender'}, 'Color', 'rbbgg', ...
      'LineStyle', {'-' ':' '-' ':' '-' ':'}, 'Marker', '.')
```

**See Also**

`fitrm` | `multcompare` | `plotprofile`

plotAdded

Added variable plot of linear regression model

Syntax

```
plotAdded mdl
plotAdded mdl,coef
plotAdded mdl,coef,Name,Value
```

```
plotAdded(ax, ___)
```

```
h = plotAdded( ___)
```

Description

`plotAdded(mdl)` creates an added variable plot on page 32-3992 for the whole model `mdl` except the constant (intercept) term.

`plotAdded(mdl,coef)` creates an added variable plot for the specified terms `coef`.

`plotAdded(mdl,coef,Name,Value)` specifies graphical properties of adjusted data points using one or more name-value pair arguments. For example, you can specify the marker symbol and size for the data points.

`plotAdded(ax, ___)` creates the plot in the axes specified by `ax` instead of the current axes, using any of the input argument combinations in the previous syntaxes.

`h = plotAdded(___)` returns line objects for the plot. Use `h` to modify the properties of a specific line after you create the plot. For a list of properties, see [Line Properties](#).

Examples

Create Added Variable Plot

Create a linear regression model of car mileage as a function of weight and model year. Then create an added variable plot to see the significance of the model.

Create a linear regression model of mileage from the `carsmall` data set.

```
load carsmall
Year = categorical(Model_Year);
tbl = table(MPG,Weight,Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Create an added variable plot of the model.

```
plot(mdl)
```

The plot illustrates that the model is significant because a horizontal line does not fit between the confidence bounds.

Create the same plot by using the `plotAdded` function.

```
plotAdded mdl)
```

Create Added Variable Plot for Specified Variables

Create a linear regression model of car mileage as a function of weight and model year. Then create an added variable plot to see the effect of the weight terms (`Weight` and `Weight^2`).

Create the linear regression model using the `carsmall` data set.

```
load carsmall
Year = categorical(Model_Year);
tbl = table(MPG,Weight,Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Find the terms in the model corresponding to `Weight` and `Weight^2`.

```
mdl.CoefficientNames
```

```
ans = 1x5 cell
      {'(Intercept)'}      {'Weight'}      {'Year_76'}      {'Year_82'}      {'Weight^2'}
```

The weight terms are 2 and 5.

Create an added variable plot with the weight terms.

```
coef = [2 5];
plotAdded mdl,coef)
```

The plot illustrates that the weight terms are significant because a horizontal line does not fit between the confidence bounds.

Create Scatter Plot for Simple Linear Regression

Create a scatter plot of data along with a fitted curve and confidence bounds for a simple linear regression model. A simple linear regression model includes only one predictor variable.

Create a simple linear regression model of mileage from the `carsmall` data set.

```
load carsmall
tbl = table(MPG,Weight);
mdl = fitlm(tbl,'MPG ~ Weight')
```

```
mdl =
Linear regression model:
MPG ~ 1 + Weight
```

Estimated Coefficients:

Estimate	SE	tStat	pValue
----------	----	-------	--------

(Intercept)	49.238	1.6411	30.002	2.7015e-49
Weight	-0.0086119	0.0005348	-16.103	1.6434e-28

Number of observations: 94, Error degrees of freedom: 92
 Root Mean Squared Error: 4.13
 R-squared: 0.738, Adjusted R-Squared: 0.735
 F-statistic vs. constant model: 259, p-value = 1.64e-28

pValue of the Weight variable is very small, which means that the variable is statistically significant in the model. Visualize this result by creating a scatter plot of the data, along with a fitted curve and its 95% confidence bounds, using the plot function.

```
plot mdl
```

The plot illustrates that the model is significant because a horizontal line does not fit between the confidence bounds, which is consistent with the pValue result.

Create the same plot by using the plotAdded function.

```
plotAdded mdl
```

When a model includes only one term in addition to the constant term, an adjusted value is equivalent to its original value. Therefore, this added variable plot is the same as the scatter plot created by the `plot` function.

Input Arguments

mdl — Linear regression model

LinearModel object

Linear regression model, specified as a LinearModel object created using `fitlm` or `stepwiselm`.

coef — Coefficients in regression model

character vector | string scalar | vector of positive integers

Coefficients in the regression model `mdl`, specified as one of the following:

- Character vector or string scalar of a single coefficient name in `mdl.CoefficientNames` (`CoefficientNames` property of `mdl`).
- Vector of positive integers representing the indexes of coefficients in `mdl.CoefficientNames`. Use a vector to specify multiple coefficients.

Data Types: `char` | `string` | `single` | `double`

ax — Target axes

Axes object

Target axes, specified as an `Axes` object.

If you do not specify the axes and the current axes are Cartesian, then `plotAdded` uses the current axes (`gca`). For more information on creating an `Axes` object, see `axes` and `gca`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Color', 'blue', 'Marker', '*'`

Note The graphical properties listed here are only a subset. For a complete list, see `Line Properties`. The specified properties determine the appearance of adjusted data points.

Color — Line color

RGB triplet | hexadecimal color code | color name | short name

Line color, specified as the comma-separated pair consisting of `'Color'` and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the following table.

The `'Color'` name-value pair argument also determines marker outline color and marker fill color if `'MarkerEdgeColor'` is `'auto'` (default) and `'MarkerFaceColor'` is `'auto'`.

For a custom color, specify an RGB triplet or a hexadecimal color code.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range $[0, 1]$; for example, $[0.4 \ 0.6 \ 0.7]$.
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (`#`) followed by three or six hexadecimal digits, which can range from `0` to `F`. The values are not case sensitive. Thus, the color codes `'#FF8800'`, `'#ff8800'`, `'#F80'`, and `'#f80'` are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'red'	'r'	[1 0 0]	'#FF0000'	
'green'	'g'	[0 1 0]	'#00FF00'	
'blue'	'b'	[0 0 1]	'#0000FF'	
'cyan'	'c'	[0 1 1]	'#00FFFF'	
'magenta'	'm'	[1 0 1]	'#FF00FF'	
'yellow'	'y'	[1 1 0]	'#FFFF00'	
'black'	'k'	[0 0 0]	'#000000'	
'white'	'w'	[1 1 1]	'#FFFFFF'	

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'none'	Not applicable	Not applicable	Not applicable	No color

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

Example: 'Color', 'blue'

LineWidth — Line width

positive value

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a positive value in points. If the line has markers, then the line width also affects the marker edges.

Example: 'LineWidth', 0.75

Marker — Marker symbol

'o' | '+' | '*' | '.' | 'x' | ...

Marker symbol, specified as the comma-separated pair consisting of 'Marker' and one of the values in this table.

Value	Description
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle

Value	Description
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: 'Marker', '+'

MarkerEdgeColor — Marker outline color

'auto' (default) | 'none' | RGB triplet | hexadecimal color code | color name | short name

Marker outline color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the Color name-value pair argument.

The default value of 'auto' uses the same color specified by using 'Color'.

Example: 'MarkerEdgeColor', 'blue'

MarkerFaceColor — Marker fill color

'none' (default) | 'auto' | RGB triplet | hexadecimal color code | color name | short name

Marker fill color, specified as the comma-separated pair consisting of 'MarkerFaceColor' and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the Color name-value pair argument.

The 'auto' value uses the same color specified by using 'Color'.

Example: 'MarkerFaceColor', 'blue'

MarkerSize — Marker size

6 (default) | positive value

Marker size, specified as the comma-separated pair consisting of 'MarkerSize' and a positive value in points.

Example: 'MarkerSize', 2

Output Arguments

h — Line objects

vector

Line objects, returned as a 3-by-1 vector. $h(1)$, $h(2)$, and $h(3)$ correspond to the adjusted data points, fitted line, and 95% confidence bounds of the fitted line, respectively. Use dot notation to query and set properties of the line objects. For details, see Line Properties.

You can use name-value pair arguments to specify the appearance of adjusted data points corresponding to the first graphics object $h(1)$.

More About

Added Variable Plot

An added variable plot, also known as a partial regression leverage plot, illustrates the incremental effect on the response of specified terms caused by removing the effects of all other terms.

An added variable plot created by `plotAdded` with a single selected term corresponding to a single predictor variable includes these plots:

- Scatter plot of adjusted response values against adjusted predictor variable values
- Fitted line for adjusted response values as a function of adjusted predictor variable values
- 95% confidence bounds of the fitted line

The adjusted values are equal to the average of the variable plus the residuals of the variable fit to all predictors except the selected predictor. For example, consider an added variable plot for the first predictor variable x_1 . Fit the response variable y and the selected predictor variable x_1 to all predictors except x_1 as follows:

$$y_i = g_y(x_{2i}, x_{3i}, \dots, x_{pi}) + r_{yi}$$

$$x_{1i} = g_x(x_{2i}, x_{3i}, \dots, x_{pi}) + r_{xi}$$

where g_y and g_x are the fit of y and x_1 , respectively, against all predictors except the selected predictor (x_1). r_y and r_x are the corresponding residual vectors. The subscript i represents the observation number. The adjusted value is the sum of the average value and the residual for each observation.

$$\tilde{y}_i = \bar{y} + r_{yi}$$

$$\tilde{x}_{1i} = \bar{x}_1 + r_{xi}$$

where \bar{x}_1 and \bar{y} represent the average of x_1 and y , respectively.

`plotAdded` plots a scatter plot of $(\tilde{x}_{1i}, \tilde{y}_i)$, a fitted line for \tilde{y} as a function of \tilde{x}_1 (that is, $\beta_1 \tilde{x}_1$), and the 95% confidence bounds of the fitted line. The coefficient β_1 is the same as the coefficient estimate of x_1 in the full model, which includes all predictors.

r_{yi} represents the part of the response values unexplained by the predictors (except x_1), and r_{xi} represents the part of the x_1 values unexplained by the other predictors. Therefore, the fitted line represents how the new information introduced by adding x_1 can explain the unexplained part of the response values. If the slope of the fitted line is close to zero and the confidence bounds can include a horizontal line, then the plot indicates that the new information from x_1 does not explain the unexplained part of the response values well. That is, x_1 is not significant in the model fit.

`plotAdded` also supports an extension of the added variable plot so that you can select multiple terms instead of a single term. Therefore, you can also specify a categorical predictor, all terms that involve a specific predictor, or the model as a whole (except a constant (intercept) term). Consider a set of predictors X with a coefficient vector β , where β_i is the coefficient estimate of x_i in the full model if you specify the i th coefficient for an added variable plot; otherwise, β_i is zero. Define a unit direction vector u as $u = \beta/s$ where $s = \text{norm}(\beta)$. Then, $X\beta = (Xu)s$. Treat Xu as a single predictor with a coefficient s , and create an added variable plot for Xu in the same way as creating the plot for a single term. The coefficient of the fitted line in the added variable plot corresponds to s .

Tips

- The data cursor displays the values of the selected plot point in a data tip (small text box located next to the data point). The data tip includes the x-axis and y-axis values for the selected point, along with the observation name or number.

Alternative Functionality

- A `LinearModel` object provides multiple plotting functions.
 - When creating a model, use `plotAdded` to understand the effect of adding or removing a predictor variable.
 - When verifying a model, use `plotDiagnostics` to find questionable data and to understand the effect of each observation. Also, use `plotResiduals` to analyze the residuals of the model.
 - After fitting a model, use `plotAdjustedResponse`, `plotPartialDependence`, and `plotEffects` to understand the effect of a particular predictor. Use `plotInteraction` to understand the interaction effect between two predictors. Also, use `plotSlice` to plot slices through the prediction surface.
- `plotAdded` shows the incremental effect on the response of specified terms by removing the effects of the other terms, whereas `plotAdjustedResponse` shows the effect of a selected predictor in the model fit with the other predictors averaged out by averaging the fitted values. Note that the definitions of adjusted values in `plotAdded` and `plotAdjustedResponse` are not the same.

plotAdjustedResponse

Adjusted response plot of linear regression model

Syntax

```
plotAdjustedResponse mdl, var  
plotAdjustedResponse mdl, var, Name, Value  
h = plotAdjustedResponse( ___ )
```

Description

`plotAdjustedResponse(mdl, var)` creates an adjusted response on page 32-3999 plot for the variable `var` in the linear regression model `mdl`.

`plotAdjustedResponse(mdl, var, Name, Value)` specifies graphical properties of adjusted response data points using one or more name-value pair arguments. For example, you can specify the marker symbol and size for the data points.

`h = plotAdjustedResponse(___)` returns line objects using any of the input argument combinations in the previous syntaxes. Use `h` to modify the properties of a specific line after you create the plot. For a list of properties, see [Line Properties](#).

Examples

Plot Adjusted Responses

Load the `carsmall` data set and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall  
tbl = table(MPG,Weight);  
tbl.Year = categorical(Model_Year);  
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Plot the effect of `Weight` averaged over `Year`.

```
plotAdjustedResponse(mdl, 'Weight')
```

Plot the effect of Year averaged over Weight.

```
plotAdjustedResponse mdl, 'Year';
```

Input Arguments

mdl — Linear regression model

LinearModel object

Linear regression model, specified as a LinearModel object created using `fitlm` or `stepwiselm`.

var — Variable for adjusted response plot

character vector | string array | positive integer

Variable for the adjusted response plot, specified as a character vector or string array of the variable name in `mdl.VariableNames`, or a positive integer representing the index of a variable in `mdl.VariableNames`.

Data Types: `char` | `string` | `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'Color','blue','Marker','*'`

Note The graphical properties listed here are only a subset. For a complete list, see Line Properties. The specified properties determine the appearance of adjusted response data points.

Color — Line color

RGB triplet | hexadecimal color code | color name | short name

Line color, specified as the comma-separated pair consisting of 'Color' and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the following table.

The 'Color' name-value pair argument also determines marker outline color and marker fill color if 'MarkerEdgeColor' is 'auto' (default) and 'MarkerFaceColor' is 'auto'.

For a custom color, specify an RGB triplet or a hexadecimal color code.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1]; for example, [0.4 0.6 0.7].
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (#) followed by three or six hexadecimal digits, which can range from 0 to F. The values are not case sensitive. Thus, the color codes '#FF8800', '#ff8800', '#F80', and '#f80' are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'red'	'r'	[1 0 0]	'#FF0000'	
'green'	'g'	[0 1 0]	'#00FF00'	
'blue'	'b'	[0 0 1]	'#0000FF'	
'cyan'	'c'	[0 1 1]	'#00FFFF'	
'magenta'	'm'	[1 0 1]	'#FF00FF'	
'yellow'	'y'	[1 1 0]	'#FFFF00'	
'black'	'k'	[0 0 0]	'#000000'	
'white'	'w'	[1 1 1]	'#FFFFFF'	
'none'	Not applicable	Not applicable	Not applicable	No color

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	

RGB Triplet	Hexadecimal Color Code	Appearance
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

Example: 'Color', 'blue'

LineWidth – Line width

positive value

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a positive value in points. If the line has markers, then the line width also affects the marker edges.

Example: 'LineWidth', 0.75

Marker – Marker symbol

'o' | '+' | '*' | '.' | 'x' | ...

Marker symbol, specified as the comma-separated pair consisting of 'Marker' and one of the values in this table.

Value	Description
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: 'Marker', '+'

MarkerEdgeColor – Marker outline color

'auto' (default) | 'none' | RGB triplet | hexadecimal color code | color name | short name

Marker outline color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the Color name-value pair argument.

The default value of 'auto' uses the same color specified by using 'Color'.

Example: 'MarkerEdgeColor', 'blue'

MarkerFaceColor — Marker fill color

'none' (default) | 'auto' | RGB triplet | hexadecimal color code | color name | short name

Marker fill color, specified as the comma-separated pair consisting of 'MarkerFaceColor' and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the Color name-value pair argument.

The 'auto' value uses the same color specified by using 'Color'.

Example: 'MarkerFaceColor', 'blue'

MarkerSize — Marker size

6 (default) | positive value

Marker size, specified as the comma-separated pair consisting of 'MarkerSize' and a positive value in points.

Example: 'MarkerSize', 2

Output Arguments

h — Line objects

vector

Line objects, returned as a 2-by-1 vector. $h(1)$ corresponds to the adjusted response data points, and $h(2)$ corresponds to the adjusted response function. Use dot notation to query and set properties of the line objects. For details, see Line Properties.

You can use name-value pair arguments to specify the appearance of adjusted response data points corresponding to the first graphics object $h(1)$.

More About

Adjusted Response

An adjusted response function describes the relationship between the fitted response and a single predictor, with the other predictors averaged out by averaging the fitted values over the data used in the fit.

A regression model for the predictor variables (x_1, x_2, \dots, x_p) and the response variable y has the form

$$y_i = f(x_{1i}, x_{2i}, \dots, x_{pi}) + r_i,$$

where f is a fitted regression function and r is a residual. The subscript i represents the observation number.

The adjusted response function for the first predictor variable x_1 , for example, is defined as

$$g(x_1) = \frac{1}{n} \sum_{i=1}^n f(x_1, x_{2i}, x_{3i}, \dots, x_{pi}),$$

where n is the number of observations. The adjusted response data value is the sum of the adjusted fitted value and the residual for each observation.

$$\tilde{y}_i = g(x_{1i}) + r_i.$$

`plotAdjustedResponse` plots the adjusted response function and the adjusted response data values for a selected predictor variable.

Tips

- The data cursor displays the values of the selected plot point in a data tip (small text box located next to the data point). The data tip includes the x-axis and y-axis values for the selected point, along with the observation name or number.

Alternative Functionality

- A `LinearModel` object provides multiple plotting functions.
 - When creating a model, use `plotAdded` to understand the effect of adding or removing a predictor variable.
 - When verifying a model, use `plotDiagnostics` to find questionable data and to understand the effect of each observation. Also, use `plotResiduals` to analyze the residuals of the model.
 - After fitting a model, use `plotAdjustedResponse`, `plotPartialDependence`, and `plotEffects` to understand the effect of a particular predictor. Use `plotInteraction` to understand the interaction effect between two predictors. Also, use `plotSlice` to plot slices through the prediction surface.
- `plotPartialDependence` creates either a line plot or a surface plot of predicted responses against a single feature or a pair of features, respectively, by marginalizing over the other variables. A line plot for a single feature from `plotPartialDependence` and an adjusted response function plot from `plotAdjustedResponse` are the same within numerical precision.
- `plotEffects` creates a summary plot that shows separate effects for all predictors.
- `plotAdded` shows the incremental effect on the response of specified terms by removing the effects of the other terms, whereas `plotAdjustedResponse` shows the effect of a selected predictor in the model fit with the other predictors averaged out by averaging the fitted values. Note that the definitions of adjusted values in `plotAdded` and `plotAdjustedResponse` are not the same.

plot

Plot Bayesian optimization results

Syntax

```
plot(results, 'all')
plot(results, plotFcn1, plotFcn2, ...)
```

Description

`plot(results, 'all')` calls all predefined plot functions on `results`.

`plot(results, plotFcn1, plotFcn2, ...)` calls the listed plot functions on `results`.

Examples

Plot After Optimization

This example shows how to plot the error model and the best objective trace after the optimization has finished. The objective function for this example throws an error for points with norm larger than 2.

```
function f = makeanerror(x)
f = x.x1 - x.x2 - sqrt(4-x.x1^2-x.x2^2);
```

```
fun = @makeanerror;
```

Create the variables for optimization.

```
var1 = optimizableVariable('x1', [-5,5]);
var2 = optimizableVariable('x2', [-5,5]);
vars = [var1, var2];
```

Run the optimization without any plots. For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function. Optimize for 60 iterations so the error model becomes well-trained.

```
rng default
results = bayesopt(fun, vars, 'MaxObjectiveEvaluations', 60, ...
    'AcquisitionFunctionName', 'expected-improvement-plus', ...
    'PlotFcn', [], 'Verbose', 0);
```

Plot the error model and the best objective trace.

```
plot(results, @plotConstraintModels, @plotMinObjective)
```

Input Arguments

results — Bayesian optimization results

BayesianOptimization object

Bayesian optimization results, specified as a BayesianOptimization object.

plotFcn — Plot function

function handle

Plot function, specified as a function handle.

There are several built-in plot functions:

Model Plots — Apply When $D \leq 2$	Description
@plotAcquisitionFunction	Plot the acquisition function surface.

Model Plots — Apply When $D \leq 2$	Description
@plotConstraintModels	Plot each constraint model surface. Negative values indicate feasible points. Also plot a $P(\text{feasible})$ surface. Also plot the error model, if it exists, which ranges from -1 to 1 . Negative values mean that the model probably does not error, positive values mean that it probably does error. The model is: Plotted error = $2 * \text{Probability}(\text{error}) - 1$.
@plotObjectiveEvaluationTimeModel	Plot the objective function evaluation time model surface.
@plotObjectiveModel	Plot the fun model surface, the estimated location of the minimum, and the location of the next proposed point to evaluate. For one-dimensional problems, plot envelopes one credible interval above and below the mean function, and envelopes one noise standard deviation above and below the mean.

Trace Plots — Apply to All D	Description
@plotObjective	Plot each observed function value versus the number of function evaluations.
@plotObjectiveEvaluationTime	Plot each observed function evaluation run time versus the number of function evaluations.
@plotMinObjective	Plot the minimum observed and estimated function values versus the number of function evaluations.
@plotElapsedTime	Plot three curves: the total elapsed time of the optimization, the total function evaluation time, and the total modeling and point selection time, all versus the number of function evaluations.

You can include a handle to your own plot functions. For details, see “Bayesian Optimization Plot Functions” on page 10-11.

Example: @plotObjective

Data Types: function_handle

Alternative Functionality

You can specify plot functions in the bayesopt PlotFcn name-value pair. This allows you to monitor the progress of the optimization.

plotDiagnostics

Plot observation diagnostics of generalized linear regression model

Syntax

```
plotDiagnostics mdl
plotDiagnostics mdl, plottype
plotDiagnostics mdl, plottype, Name, Value
h = plotDiagnostics( ___ )
```

Description

`plotDiagnostics` creates a plot of observation diagnostics, such as leverage and Cook's distance, to identify outliers and influential observations.

`plotDiagnostics(mdl)` creates a leverage plot of the generalized linear regression model (`mdl`) observations. A dotted line in the plot represents the recommended threshold values.

`plotDiagnostics(mdl, plottype)` specifies the type of observation diagnostics `plottype`.

`plotDiagnostics(mdl, plottype, Name, Value)` specifies the graphical properties of diagnostic data points using one or more name-value pair arguments. For example, you can specify the marker symbol and size for the data points.

`h = plotDiagnostics(___)` returns graphics objects for the lines or contour in the plot using any of the input argument combinations in the previous syntaxes. Use `h` to modify the properties of a specific line or contour after you create the plot. For a list of properties, see [Line Properties](#) and [Contour Properties](#).

Examples

Find Outliers Using Leverage and Cook's Distance

Create leverage and Cook's distance plots of a fitted generalized linear model, and find the outliers.

Generate sample data using Poisson random numbers with two underlying predictors $X(:, 1)$ and $X(:, 2)$.

```
rng('default') % For reproducibility
rndvars = randn(100,2);
X = [2 + rndvars(:,1), rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','Distribution','poisson');
```

Create a leverage plot.

```
plotDiagnostics mdl
legend('show') % Show the legend
```

The dotted line represents the recommended threshold value $2*p/n$, where p is the number of coefficients, and n is the number of observations. Find the threshold value using the `NumCoefficients` and `NumObservations` properties.

```
t_leverage = 2*mdl.NumCoefficients/mdl.NumObservations
```

```
t_leverage = 0.0600
```

Find the observations with leverage values that exceed the threshold value.

```
find(mdl.Diagnostics.Leverage > t_leverage)
```

```
ans = 5x1
```

```
9
21
64
65
70
```

You can also find an observation number by using a data tip. Select the data points above the threshold line to display their data tips. The data tip includes the x-axis and y-axis values for the selected point, along with the observation number.

Plot the Cook's distance values.

```
plotDiagnostics mdl, 'cookd')
```

The dotted line represents the recommended threshold value. Compute the threshold value t_{cookd} .

```
t_cookd = 3*mean mdl.Diagnostics.CooksDistance'
```

```
t_cookd = 0.0294
```

Find the observations with the Cook's distance values that exceed the threshold value.

```
find mdl.Diagnostics.CooksDistance > t_cookd
```

```
ans = 5×1
```

```
15
21
27
65
70
```

Three observations (21, 65, and 70) are outliers by both measures, but some points (9, 15, 27, and 64) are outliers by only one measure.

Input Arguments

mdl — Generalized linear regression model

GeneralizedLinearModel object

Generalized linear regression model, specified as a GeneralizedLinearModel object created using fitglm or stepwiseglm.

plottype — Type of plot

'leverage' (default) | 'contour' | 'cookd'

Type of plot, specified as one of the values in this table.

Value	Plot Type	Dotted Reference Line in Plot	Purpose
'contour'	Residual vs. leverage with overlaid contours of Cook's distance	Contours of Cook's distance	Identify observations with large residual values, high leverage, and large Cook's distance values.
'cookd'	Cook's distance	Recommended threshold, computed by $3 * \text{mean}(\text{mdl}.\text{Diagnostics}.\text{CooksDistance})$	Identify observations with large Cook's distance values.
'leverage'	Leverage	Recommended threshold, computed by $2 * p / n$, where p is the number of coefficients ($\text{mdl}.\text{NumCoefficients}$) and n is the number of observations ($\text{mdl}.\text{NumObservations}$)	Identify high leverage observations.

For 'cookd' and 'leverage', the x-axis is the row number (case order) of observations.

The Diagnostics property of mdl contains the diagnostic values used by plotDiagnostics to create plots.

For more information about observation diagnostics, see “Cook’s Distance” on page 32-4012 and “Leverage” on page 32-4013.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'Color', 'blue', 'Marker', 'o'

Note The graphical properties listed here are only a subset. For a complete list, see Line Properties. The specified properties determine the appearance of diagnostic data points.

Color — Line color

RGB triplet | hexadecimal color code | color name | short name

Line color, specified as the comma-separated pair consisting of 'Color' and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the following table.

The 'Color' name-value pair argument also determines marker outline color and marker fill color if 'MarkerEdgeColor' is 'auto' (default) and 'MarkerFaceColor' is 'auto'.

For a custom color, specify an RGB triplet or a hexadecimal color code.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1]; for example, [0.4 0.6 0.7].
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (#) followed by three or six hexadecimal digits, which can range from 0 to F. The values are not case sensitive. Thus, the color codes '#FF8800', '#ff8800', '#F80', and '#f80' are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'red'	'r'	[1 0 0]	'#FF0000'	
'green'	'g'	[0 1 0]	'#00FF00'	
'blue'	'b'	[0 0 1]	'#0000FF'	
'cyan'	'c'	[0 1 1]	'#00FFFF'	
'magenta'	'm'	[1 0 1]	'#FF00FF'	
'yellow'	'y'	[1 1 0]	'#FFFF00'	
'black'	'k'	[0 0 0]	'#000000'	
'white'	'w'	[1 1 1]	'#FFFFFF'	
'none'	Not applicable	Not applicable	Not applicable	No color

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	

RGB Triplet	Hexadecimal Color Code	Appearance
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

Example: 'Color', 'blue'

LineWidth – Line width

positive value

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a positive value in points. If the line has markers, then the line width also affects the marker edges.

Example: 'LineWidth', 0.75

Marker – Marker symbol

'o' | '+' | '*' | '.' | 'x' | ...

Marker symbol, specified as the comma-separated pair consisting of 'Marker' and one of the values in this table.

Value	Description
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: 'Marker', '+'

MarkerEdgeColor – Marker outline color

'auto' (default) | 'none' | RGB triplet | hexadecimal color code | color name | short name

Marker outline color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the Color name-value pair argument.

The default value of 'auto' uses the same color specified by using 'Color'.

Example: 'MarkerEdgeColor', 'blue'

MarkerFaceColor — Marker fill color

'none' (default) | 'auto' | RGB triplet | hexadecimal color code | color name | short name

Marker fill color, specified as the comma-separated pair consisting of 'MarkerFaceColor' and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the `Color` name-value pair argument.

The 'auto' value uses the same color specified by using 'Color'.

Example: 'MarkerFaceColor', 'blue'

MarkerSize — Marker size

6 (default) | positive value

Marker size, specified as the comma-separated pair consisting of 'MarkerSize' and a positive value in points.

Example: 'MarkerSize', 2

Output Arguments

h — Graphics objects

graphics array

Graphics objects corresponding to the lines or contour in the plot, returned as a graphics array. Use dot notation to query and set properties of the graphics objects. For details, see [Line Properties](#) and [Contour Properties](#).

You can use name-value pair arguments to specify the appearance of diagnostic data points corresponding to the first graphics object `h(1)`.

More About

Cook's Distance

The Cook's distance D_i of observation i is

$$D_i = w_i \frac{e_i^2}{p\hat{\varphi}} \frac{h_{ii}}{(1 - h_{ii})^2},$$

where

- $\hat{\varphi}$ is the dispersion parameter (estimated or theoretical).
- e_i is the linear predictor residual, $g(y_i) - x_i\hat{\beta}$, where
 - g is the link function.
 - y_i is the observed response.
 - x_i is the observation.
 - $\hat{\beta}$ is the estimated coefficient vector.

- p is the number of coefficients in the regression model.
- h_{ii} is the i th diagonal element of the Hat Matrix on page 32-4013 H .

Leverage

Leverage is a measure of the effect of a particular observation on the regression predictions due to the position of that observation in the space of the inputs.

The leverage of observation i is the value of the i th diagonal term h_{ii} of the hat matrix H . Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered an outlier if its leverage substantially exceeds p/n , where n is the number of observations.

Hat Matrix

The hat matrix H is defined in terms of the data matrix X and a diagonal weight matrix W :

$$H = X(X^T W X)^{-1} X^T W^T.$$

W has diagonal elements w_i :

$$w_i = \frac{g'(\mu_i)}{\sqrt{V(\mu_i)}},$$

where

- g is the link function mapping y_i to $x_i b$.
- g' is the derivative of the link function g .
- V is the variance function.
- μ_i is the i th mean.

The diagonal elements H_{ii} satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Tips

- The data cursor displays the values of the selected plot point in a data tip (small text box located next to the data point). The data tip includes the x-axis and y-axis values for the selected point, along with the observation name or number.
- Use `legend('show')` to show the pre-populated legend.

Alternative Functionality

A `GeneralizedLinearModel` object provides multiple plotting functions.

- When verifying a model, use `plotDiagnostics` to find questionable data and to understand the effect of each observation. Also, use `plotResiduals` to analyze the residuals of the model.
- After fitting a model, use `plotPartialDependence` to understand the effect of a particular predictor. Also, use `plotSlice` to plot slices through the prediction surface.

Topics

“Diagnostic Plots” on page 12-17

“Generalized Linear Models” on page 12-9

Introduced in R2012a

plotDiagnostics

Plot observation diagnostics of linear regression model

Syntax

```
plotDiagnostics mdl
plotDiagnostics mdl, plottype
plotDiagnostics mdl, plottype, Name, Value
h = plotDiagnostics( ___ )
```

Description

`plotDiagnostics` creates a plot of observation diagnostics such as leverage, Cook's distance, and delete-1 statistics to identify outliers and influential observations.

`plotDiagnostics(mdl)` creates a leverage plot of the linear regression model (`mdl`) observations. A dotted line in the plot represents the recommended threshold values.

`plotDiagnostics(mdl, plottype)` specifies the type of observation diagnostics `plottype`.

`plotDiagnostics(mdl, plottype, Name, Value)` specifies the graphical properties of diagnostic data points using one or more name-value pair arguments. For example, you can specify the marker symbol and size for the data points.

`h = plotDiagnostics(___)` returns graphics objects for the lines or contour in the plot using any of the input argument combination in the previous syntaxes. Use `h` to modify the properties of a specific line or contour after you create the plot. For a list of properties, see [Line Properties](#) and [Contour Properties](#).

Examples

Find Outliers Using Leverage and Cook's Distance

Plot the leverage values and Cook's distances of observations and find the outliers.

Load the `carsmall` data set and fit a linear regression model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
tbl = table(MPG, Weight);
tbl.Year = categorical(Model_Year);
mdl = fitlm(tbl, 'MPG ~ Year + Weight^2');
```

Plot the leverage values.

```
plotDiagnostics(mdl)
legend('show') % Show the legend
```

The dotted line represents the recommended threshold value $2*p/n$, where p is the number of coefficients, and n is the number of observations. Find the threshold value using the `NumCoefficients` and `NumObservations` properties.

```
t_leverage = 2*mdl.NumCoefficients/mdl.NumObservations
```

```
t_leverage = 0.1064
```

Find the observations with leverage values that exceed the threshold value.

```
find(mdl.Diagnostics.Leverage > t_leverage)
```

```
ans = 3×1
```

```
26
32
35
```

You can also find an observation number by using a data tip. Select the data points above the threshold line to display their data tips. The data tip includes the x-axis and y-axis values for the selected point, along with the observation number.

Plot the Cook's distance values.

```
plotDiagnostics(mdl, 'cookd')
```

The dotted line represents the recommended threshold value. Compute the threshold value t_{cookd} .

```
t_cookd = 3*mean mdl.Diagnostics.CooksDistance, 'omitnan')
```

```
t_cookd = 0.0320
```

Find the observations with the Cook's distance values that exceed the threshold value.

```
find(mdl.Diagnostics.CooksDistance > t_cookd)
```

```
ans = 6×1
```

```
26
35
80
90
92
97
```

Two observations (26 and 35) are outliers by both measures, but some points (32, 80, 90, 92, and 97) are outliers by only one measure.

Input Arguments

mdl — Linear regression model

LinearModel object

Linear regression model, specified as a `LinearModel` object created using `fitlm` or `stepwiselm`.

plottype – Type of plot

'leverage' (default) | 'contour' | 'cookd' | 'covratio' | 'dfbetas' | 'dffits' | 's2_i'

Type of plot, specified as one of the values in this table.

Value	Plot Type	Dotted Reference Line in Plot	Purpose
'contour'	Residual vs. leverage with overlaid contours of Cook's distance	Contours of Cook's distance	Identify observations with large residual values, high leverage, and large Cook's distance values.
'cookd'	Cook's distance	Recommended threshold, computed by $3 * \text{mean}(\text{mdl.Diagnostic}s.\text{CooksDistance})$	Identify observations with large Cook's distance values.
'covratio'	Delete-1 ratio of determinant of covariance	Recommended thresholds, computed by $1 \pm 3 * p/n$, where p is the number of coefficients (<code>mdl.NumCoefficients</code>) and n is the number of observations (<code>mdl.NumObservations</code>)	Identify observations where the delete-1 statistic value is not in the range of the recommended thresholds.
'dfbetas'	Delete-1 scaled differences in coefficient estimates	Recommended threshold, computed by $3 / \text{sqrt}(n)$	Identify observations with large delete-1 statistic values.
'dffits'	Delete-1 scaled differences in fitted values	Recommended threshold, computed by $2 * \text{sqrt}(p/n)$ in an absolute value	Identify observations with large delete-1 statistic values in an absolute value.
'leverage'	Leverage	Recommended threshold, computed by $2 * p/n$	Identify high leverage observations.
's2_i'	Delete-1 variance	Mean squared error (<code>mdl.MSE</code>)	Compare the delete-1 variance with the mean squared error.

For all plot types except 'contour', the x-axis is the row number (case order) of observations.

The `Diagnostics` property of `mdl` contains the diagnostic values used by `plotDiagnostics` to create plots.

For more information about observation diagnostics, see “Cook’s Distance” on page 32-4021, “Delete-1 Statistics” on page 32-4022, and “Leverage” on page 32-4022.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: 'Color', 'blue', 'Marker', 'o'

Note The graphical properties listed here are only a subset. For a complete list, see Line Properties. The specified properties determine the appearance of diagnostic data points.

Color — Line color

RGB triplet | hexadecimal color code | color name | short name

Line color, specified as the comma-separated pair consisting of 'Color' and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the following table.

The 'Color' name-value pair argument also determines marker outline color and marker fill color if 'MarkerEdgeColor' is 'auto' (default) and 'MarkerFaceColor' is 'auto'.

For a custom color, specify an RGB triplet or a hexadecimal color code.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1]; for example, [0.4 0.6 0.7].
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (#) followed by three or six hexadecimal digits, which can range from 0 to F. The values are not case sensitive. Thus, the color codes '#FF8800', '#ff8800', '#F80', and '#f80' are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'red'	'r'	[1 0 0]	'#FF0000'	
'green'	'g'	[0 1 0]	'#00FF00'	
'blue'	'b'	[0 0 1]	'#0000FF'	
'cyan'	'c'	[0 1 1]	'#00FFFF'	
'magenta'	'm'	[1 0 1]	'#FF00FF'	
'yellow'	'y'	[1 1 0]	'#FFFF00'	
'black'	'k'	[0 0 0]	'#000000'	
'white'	'w'	[1 1 1]	'#FFFFFF'	
'none'	Not applicable	Not applicable	Not applicable	No color

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	

RGB Triplet	Hexadecimal Color Code	Appearance
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

Example: 'Color', 'blue'

LineWidth — Line width

positive value

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a positive value in points. If the line has markers, then the line width also affects the marker edges.

Example: 'LineWidth', 0.75

Marker — Marker symbol

'o' | '+' | '*' | '.' | 'x' | ...

Marker symbol, specified as the comma-separated pair consisting of 'Marker' and one of the values in this table.

Value	Description
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: 'Marker', '+'

MarkerEdgeColor — Marker outline color

'auto' (default) | 'none' | RGB triplet | hexadecimal color code | color name | short name

Marker outline color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the Color name-value pair argument.

The default value of 'auto' uses the same color specified by using 'Color'.

Example: 'MarkerEdgeColor', 'blue'

MarkerFaceColor — Marker fill color

'none' (default) | 'auto' | RGB triplet | hexadecimal color code | color name | short name

Marker fill color, specified as the comma-separated pair consisting of 'MarkerFaceColor' and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the Color name-value pair argument.

The 'auto' value uses the same color specified by using 'Color'.

Example: 'MarkerFaceColor', 'blue'

MarkerSize — Marker size

6 (default) | positive value

Marker size, specified as the comma-separated pair consisting of 'MarkerSize' and a positive value in points.

Example: 'MarkerSize', 2

Output Arguments

h — Graphics objects

graphics array

Graphics objects corresponding to the lines or contour in the plot, returned as a graphics array. Use dot notation to query and set properties of the graphics objects. For details, see Line Properties and Contour Properties.

You can use name-value pair arguments to specify the appearance of diagnostic data points corresponding to the first graphics object `h(1)`. If `plottype` is 'dfbetas', the plot includes a line object for each coefficient. Name-value pair arguments specify the line object properties of all coefficients. You can modify the properties of each coefficient separately by using the corresponding graphics object.

More About

Cook's Distance

Cook's distance is the scaled change in fitted values, which is useful for identifying outliers in the X values (observations for predictor variables). Cook's distance shows the influence of each observation on the fitted response values. An observation with Cook's distance larger than three times the mean Cook's distance might be an outlier.

Each element in the Cook's distance D is the normalized change in the fitted response values due to the deletion of an observation. The Cook's distance of observation i is

$$D_i = \frac{\sum_{j=1}^n (\hat{Y}_j - \hat{Y}_{j(i)})^2}{p \text{MSE}},$$

where

- \hat{y}_j is the j th fitted response value.
- $\hat{y}_{j(i)}$ is the j th fitted response value, where the fit does not include observation i .
- MSE is the mean squared error.
- p is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{p MSE} \left(\frac{h_{ii}}{(1 - h_{ii})^2} \right),$$

where r_i is the i th residual, and h_{ii} is the i th leverage value.

For more details, see "Cook's Distance" on page 11-54.

Delete-1 Statistics

Delete-1 statistics are useful for finding the influence of each observation. These statistics capture the changes that would result from excluding each observation in turn from the fit. If the delete-1 statistics differ significantly from the model using all observations, then the observation is influential.

See "Delete-1 Statistics" on page 11-62 for the definitions and usages of the delete-1 statistics.

Leverage

Leverage is a measure of the effect of a particular observation on the regression predictions due to the position of that observation in the space of the inputs.

The leverage of observation i is the value of the i th diagonal term h_{ii} of the hat matrix H . The hat matrix H is defined in terms of the data matrix X :

$$H = X(X^T X)^{-1} X^T.$$

The hat matrix is also known as the *projection matrix* because it projects the vector of observations y onto the vector of predictions \hat{y} , thus putting the "hat" on y .

Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered an outlier if its leverage substantially exceeds p/n , where n is the number of observations.

For more details, see "Hat Matrix and Leverage" on page 11-76.

Tips

- The data cursor displays the values of the selected plot point in a data tip (small text box located next to the data point). The data tip includes the x-axis and y-axis values for the selected point, along with the observation name or number.
- Use `legend('show')` to show the pre-populated legend.

Alternative Functionality

- A `LinearModel` object provides multiple plotting functions.
 - When creating a model, use `plotAdded` to understand the effect of adding or removing a predictor variable.

- When verifying a model, use `plotDiagnostics` to find questionable data and to understand the effect of each observation. Also, use `plotResiduals` to analyze the residuals of the model.
- After fitting a model, use `plotAdjustedResponse`, `plotPartialDependence`, and `plotEffects` to understand the effect of a particular predictor. Use `plotInteraction` to understand the interaction effect between two predictors. Also, use `plotSlice` to plot slices through the prediction surface.

plotDiagnostics

Class: NonLinearModel

Plot diagnostics of nonlinear regression model

Syntax

```
plotDiagnostics mdl
plotDiagnostics mdl,plottype
h = plotDiagnostics(...)
h = plotDiagnostics mdl,plottype,Name,Value)
```

Description

`plotDiagnostics(mdl)` plots diagnostics from the `mdl` linear model using leverage as the plot type.

`plotDiagnostics(mdl,plottype)` plots diagnostics in a plot of type `plottype`.

`h = plotDiagnostics(...)` returns handles to the lines in the plot.

`h = plotDiagnostics(mdl,plottype,Name,Value)` plots with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`mdl`

Nonlinear regression model, constructed by `fitnlm`.

`plottype`

Character vector or string scalar specifying the type of plot:

'contour'	Residual vs. leverage with overlaid Cook's contours
'cookd'	Cook's distance
'leverage'	Leverage (diagonal of Hat matrix)

Default: 'leverage'

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note The plot property name-value pairs apply to the first returned handle `h(1)`.

Color

Color of the line or marker, specified as an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the following table.

For a custom color, specify an RGB triplet or a hexadecimal color code.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range $[0, 1]$; for example, $[0.4 \ 0.6 \ 0.7]$.
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (#) followed by three or six hexadecimal digits, which can range from 0 to F. The values are not case sensitive. Thus, the color codes '#FF8800', '#ff8800', '#F80', and '#f80' are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'red'	'r'	[1 0 0]	'#FF0000'	
'green'	'g'	[0 1 0]	'#00FF00'	
'blue'	'b'	[0 0 1]	'#0000FF'	
'cyan'	'c'	[0 1 1]	'#00FFFF'	
'magenta'	'm'	[1 0 1]	'#FF00FF'	
'yellow'	'y'	[1 1 0]	'#FFFF00'	
'black'	'k'	[0 0 0]	'#000000'	
'white'	'w'	[1 1 1]	'#FFFFFF'	

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

LineStyle

Type of line, a Chart Line specification. For details, see `linespec`.

LineWidth

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: 0.5

MarkerEdgeColor

Marker outline color, specified as an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the `Color` name-value pair argument.

MarkerFaceColor

Fill color for filled markers, specified as an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the `Color` name-value pair argument.

MarkerSize

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Examples

Nonlinear Model Leverage Plot

Create a leverage plot of a fitted nonlinear model, and find the points with high leverage.

Load the reaction data and fit a model of the reaction rate as a function of reactants.

```
load reaction
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
```

Create a leverage plot of the fitted model.

```
plotDiagnostics(mdl)
```

Use data tips to examine the observation with high leverage. A data tip appears when you hover over a data point.

Alternatively, find the high-leverage observation at the command line.

```
find mdl.Diagnostics.Leverage > 0.8)
```

```
ans =
```

```
6
```

More About

Hat Matrix

The hat matrix H is defined in terms of the data matrix X and the Jacobian matrix J :

$$J_{i,j} = \left. \frac{\partial f}{\partial \beta_j} \right|_{x_i, \beta}$$

Here f is the nonlinear model function, and β is the vector of model coefficients.

The Hat Matrix H is

$$H = J(J^T J)^{-1} J^T.$$

The diagonal elements H_{ii} satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Leverage

Leverage is a measure of the effect of a particular observation on the regression predictions due to the position of that observation in the space of the inputs.

The leverage of observation i is the value of the i th diagonal term h_{ii} of the hat matrix H . Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered an outlier if its leverage substantially exceeds p/n , where n is the number of observations.

Cook's Distance

The Cook's distance D_i of observation i is

$$D_i = \frac{\sum_{j=1}^n (\hat{y}_j - \hat{y}_{j(i)})^2}{p \text{MSE}},$$

where

- \hat{y}_j is the j th fitted response value.
- $\hat{y}_{j(i)}$ is the j th fitted response value, where the fit does not include observation i .
- MSE is the mean squared error.
- p is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{p \text{MSE}} \left(\frac{h_{ii}}{(1 - h_{ii})^2} \right),$$

where e_i is the i th residual.

Tips

- The data cursor displays the values of the selected plot point in a data tip (small text box located next to the data point). The data tip includes the x -axis and y -axis values for the selected point, along with the observation name or number.

“Nonlinear Regression” on page 13-2

plotEffects

Package:

Plot main effects of predictors in linear regression model

Syntax

```
plotEffects mdl  
h = plotEffects(mdl)
```

Description

`plotEffects(mdl)` creates an effects plot of the predictors in the linear regression model `mdl`. An effects plot shows the estimated main effect on page 32-4033 on the response from changing each predictor value, averaging out the effects of the other predictors. A horizontal line through an effect value indicates the 95% confidence interval for the effect value.

`h = plotEffects(mdl)` returns line objects. Use `h` to modify the properties of a specific line after you create the plot. For a list of properties, see [Line Properties](#).

Examples

Effects Plot for Linear Regression Model

Load the `carsmall` data set and fit a linear regression model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall  
tbl = table(MPG,Weight);  
tbl.Year = categorical(Model_Year);  
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Create an effects plot.

```
plotEffects(mdl)
```

The length of each horizontal line in the figure shows a 95% confidence interval for the effect on the response of the change shown for each predictor. For example, the estimated effect of changing Year from 70 to 82 is an increase of about 8, and is between 6 and 10 with 95% confidence.

Input Arguments

mdl — Linear regression model object

`LinearModel` object | `CompactLinearModel` object

Linear regression model object, specified as a `LinearModel` object created by using `fitlm` or `stepwiselm`, or a `CompactLinearModel` object created by using `compact`.

Output Arguments

h — Line objects

vector

Line objects, returned as a vector. `h(1)` corresponds to the circles that represent the effect estimates, and `h(j+1)` corresponds to the 95% confidence interval for the effect of predictor `j`. Use dot notation to query and set properties of line objects. For details, see [Line Properties](#).

More About

Main Effect

An effect, or main effect, of a predictor represents an effect of one predictor on the response from changing the predictor value while averaging out the effects of the other predictors.

For a predictor variable x_s , the effect is defined by

$$g(x_{si}) - g(x_{sj}) ,$$

where g is an “Adjusted Response” on page 32-4033 function. The `plotEffects` function chooses the observations i and j as follows. For a categorical variable that is not ordinal, x_{si} and x_{sj} are the predictor values that produce the maximum and minimum adjusted responses, respectively, so that the effect value is always positive. For a numeric variable or an ordinal categorical variable, the function chooses two predictor values that produce the minimum and maximum adjusted responses where $x_{si} < x_{sj}$.

`plotEffects` plots the effect value and the 95% confidence interval of the effect value for each predictor variable.

Adjusted Response

An adjusted response function describes the relationship between the fitted response and a single predictor, with the other predictors averaged out by averaging the fitted values over the data used in the fit.

A regression model for the predictor variables (x_1, x_2, \dots, x_p) and the response variable y has the form

$$y_i = f(x_{1i}, x_{2i}, \dots, x_{pi}) + r_i,$$

where f is a fitted regression function and r is a residual. The subscript i represents the observation number.

The adjusted response function for the first predictor variable x_1 , for example, is defined as

$$g(x_1) = \frac{1}{n} \sum_{i=1}^n f(x_1, x_{2i}, x_{3i}, \dots, x_{pi}),$$

where n is the number of observations. The adjusted response data value is the sum of the adjusted fitted value and the residual for each observation.

$$\tilde{y}_i = g(x_{1i}) + r_i.$$

`plotAdjustedResponse` plots the adjusted response function and the adjusted response data values for a selected predictor variable.

Tips

- The data cursor displays the values of the selected plot point in a data tip (small text box located next to the data point). The data tip includes the x -axis and y -axis values for the selected point. Use the x -axis values to view an estimated effect value and its confidence bounds.

Alternative Functionality

- A `LinearModel` object provides multiple plotting functions.

- When creating a model, use `plotAdded` to understand the effect of adding or removing a predictor variable.
- When verifying a model, use `plotDiagnostics` to find questionable data and to understand the effect of each observation. Also, use `plotResiduals` to analyze the residuals of the model.
- After fitting a model, use `plotAdjustedResponse`, `plotPartialDependence`, and `plotEffects` to understand the effect of a particular predictor. Use `plotInteraction` to understand the interaction effect between two predictors. Also, use `plotSlice` to plot slices through the prediction surface.

“Linear Regression with Interaction Effects” on page 11-43

“Interpret Linear Regression Results” on page 11-49

“Linear Regression Workflow” on page 11-34

“Linear Regression” on page 11-8

Introduced in R2012a

plotInteraction

Package:

Plot interaction effects of two predictors in linear regression model

Syntax

```
plotInteraction mdl, var1, var2)
plotInteraction mdl, var1, var2, ptype)
h = plotInteraction( ___ )
```

Description

`plotInteraction mdl, var1, var2` creates a plot of the main effects on page 32-4042 of the two selected predictors `var1` and `var2` and their conditional effects on page 32-4043 in the linear regression model `mdl`. Horizontal lines through the effect values indicate their 95% confidence intervals.

`plotInteraction mdl, var1, var2, ptype` specifies the plot type `ptype`. For example, if `ptype` is 'predictions', then `plotInteraction` plots the adjusted response function as a function of the second predictor, with the first predictor fixed at specific values. For details, see "Conditional Effect" on page 32-4043.

`h = plotInteraction(___)` returns line objects using any of the input argument combinations in the previous syntaxes. Use `h` to modify the properties of a specific line after you create the plot. For a list of properties, see Line Properties.

Examples

Interaction Plot of Main Effects and Conditional Effects

Fit a model with an interaction term and create an interaction plot that shows the main effects and conditional effects.

Using the data in the `carsmall` data set, create response values that include an interaction term. First, load the data set and normalize the predictor data.

```
load carsmall
Acceleration = normalize(Acceleration);
Horsepower = normalize(Horsepower);
Displacement = normalize(Displacement);
```

Define a response variable that includes the interaction term `Acceleration*Horsepower`.

```
y = Acceleration + 4*Horsepower + Acceleration.*Horsepower + Displacement;
```

Add some noise to the response values.

```
rng('default') % For reproducibility
y = y + normrnd(10,0.25*nanstd(y),size(y));
```

Create a table that includes the predictor data and response values.

```
tbl = table(Acceleration,Horsepower,Displacement,y);
```

Fit a linear regression model.

```
mdl = fitlm(tbl,'y ~ Acceleration + Horsepower + Acceleration*Horsepower + Displacement + Horsepower');
```

```
mdl =
```

```
Linear regression model:
```

```
y ~ 1 + Acceleration*Horsepower + Horsepower*Displacement
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	9.8652	0.16177	60.982	8.587e-77
Acceleration	0.63726	0.1626	3.9191	0.00016967
Horsepower	3.6168	0.34	10.638	9.273e-18
Displacement	0.95032	0.31828	2.9858	0.0036144
Acceleration:Horsepower	0.60108	0.1851	3.2473	0.0016209
Horsepower:Displacement	-0.0096069	0.20947	-0.045863	0.96352

Number of observations: 99, Error degrees of freedom: 93

Root Mean Squared Error: 1.07

R-squared: 0.93, Adjusted R-Squared: 0.927

F-statistic vs. constant model: 249, p-value = 3.3e-52

pValue of the interaction term `Acceleration*Horsepower` is very small, meaning that the interaction term is statistically significant.

Create an interaction plot that shows the main effects and conditional effects of Horsepower and Acceleration.

```
plotInteraction(mdl,'Horsepower','Acceleration')
```

For each predictor, the main effect point and its conditional effect points are not vertically aligned. Therefore, you cannot find any vertical lines that pass through the confidence intervals of the main and conditional effect points for each predictor. This plot indicates the existence of interaction effects on the response variable.

For comparison, create an interaction plot for Displacement and Horsepower. This p -value of this interaction term (Displacement*Horsepower) is large, meaning that the interaction term is not statistically significant.

```
plotInteraction mdl, 'Displacement', 'Horsepower')
```

For each predictor, the main effect point and its conditional effect points are aligned vertically. This plot indicates no interaction.

Interaction Plot of Adjusted Response Curve

Fit a model with an interaction term and create an interaction plot of adjusted response curves.

Using the data in the `carsmall` data set, create response values that include an interaction term. First, load the data set and normalize the predictor data.

```
load carsmall
Acceleration = normalize(Acceleration);
Horsepower = normalize(Horsepower);
Displacement = normalize(Displacement);
```

Define a response variable that includes the interaction term `Acceleration*Horsepower`.

```
y = Acceleration + 4*Horsepower + Acceleration.*Horsepower + Displacement;
```

Add some noise to the response values.

```
rng('default') % For reproducibility
y = y + normrnd(10,0.25*nanstd(y),size(y));
```

Create a table that includes the predictor data and response values.

```
tbl = table(Acceleration,Horsepower,Displacement,y);
```

Fit a linear regression model.

```
mdl = fitlm(tbl,'y ~ Acceleration + Horsepower + Acceleration*Horsepower + Displacement + Horsepower*Displacement');
```

```
mdl =
```

Linear regression model:

```
y ~ 1 + Acceleration*Horsepower + Horsepower*Displacement
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	9.8652	0.16177	60.982	8.587e-77
Acceleration	0.63726	0.1626	3.9191	0.00016967
Horsepower	3.6168	0.34	10.638	9.273e-18
Displacement	0.95032	0.31828	2.9858	0.0036144
Acceleration:Horsepower	0.60108	0.1851	3.2473	0.0016209
Horsepower:Displacement	-0.0096069	0.20947	-0.045863	0.96352

Number of observations: 99, Error degrees of freedom: 93

Root Mean Squared Error: 1.07

R-squared: 0.93, Adjusted R-Squared: 0.927

F-statistic vs. constant model: 249, p-value = 3.3e-52

pValue of the interaction term `Acceleration*Horsepower` is very small, meaning that the interaction term is statistically significant.

Create an interaction plot that shows the adjusted response function as a function of `Acceleration`, with `Horsepower` fixed at specific values.

```
plotInteraction(mdl, 'Horsepower', 'Acceleration', 'predictions')
```

The curves are not parallel. This plot indicates interactions between the predictors.

For comparison, create an interaction plot for the Displacement and Horsepower. The p -value of this interaction term (Displacement*Horsepower) is large, meaning that the interaction term is not statistically significant.

```
plotInteraction mdl, 'Displacement', 'Horsepower', 'predictions')
```

The curves are parallel, indicating no interaction.

Input Arguments

mdl — Linear regression model object

LinearModel object | CompactLinearModel object

Linear regression model object, specified as a LinearModel object created by using `fitlm` or `stepwiselm`, or a CompactLinearModel object created by using `compact`.

var1 — First variable for plot

character vector | string array | positive integer

First variable for the plot, specified as a character vector or string array of the variable name in `mdl.VariableNames` (VariableNames property of `mdl`), or a positive integer representing the index of a variable in `mdl.VariableNames`.

Data Types: `char` | `string` | `single` | `double`

var2 — Second variable for plot

character vector | string array | positive integer

Second variable for the plot, specified as a character vector or string array of the variable name in `mdl.VariableNames` (VariableNames property of `mdl`), or a positive integer representing the index of a variable in `mdl.VariableNames`.

Data Types: `char` | `string` | `single` | `double`

ptype — Plot type

'effects' (default) | 'predictions'

Plot type, specified as one of these values:

- 'effects' — `plotInteraction` creates a plot of the main effects of the two selected predictors `var1` and `var2` and their conditional effects. Horizontal lines through the effect values indicate their 95% confidence intervals.
- 'predictions' — `plotInteraction` plots the adjusted response function as a function of `var2`, with `var1` fixed at specific values.

For details, see “Main Effect” on page 32-4042 and “Conditional Effect” on page 32-4043.

Output Arguments

h — Line objects

vector

Line objects, returned as a vector. Use dot notation to query and set properties of the line objects. For details, see Line Properties.

If the plot type is 'effects' (default), `h(1)` corresponds to the circles that represent the main effect estimates, and `h(2)` and `h(3)` correspond to the 95% confidence intervals for the two main effects. The remaining entries in `h` correspond to the conditional effects and their confidence intervals. The line objects associated with the main effects have the tag 'main'. The line objects associated with the conditional effects of `var1` and `var2` have the tags 'conditional1' and 'conditional2', respectively.

If the plot type is 'predictions', each entry in `h` corresponds to each curve on the plot.

More About

Main Effect

An effect, or main effect, of a predictor represents an effect of one predictor on the response from changing the predictor value while averaging out the effects of the other predictors.

For a predictor variable x_s , the effect is defined by

$$g(x_{si}) - g(x_{sj}),$$

where g is an “Adjusted Response” on page 32-4043 function. The `plotEffects` function chooses the observations i and j as follows. For a categorical variable that is not ordinal, x_{si} and x_{sj} are the predictor values that produce the maximum and minimum adjusted responses, respectively, so that the effect value is always positive. For a numeric variable or an ordinal categorical variable, the function chooses two predictor values that produce the minimum and maximum adjusted responses where $x_{si} < x_{sj}$.

`plotEffects` plots the effect value and the 95% confidence interval of the effect value for each predictor variable.

Adjusted Response

An adjusted response function describes the relationship between the fitted response and a single predictor, with the other predictors averaged out by averaging the fitted values over the data used in the fit.

A regression model for the predictor variables (x_1, x_2, \dots, x_p) and the response variable y has the form

$$y_i = f(x_{1i}, x_{2i}, \dots, x_{pi}) + r_i,$$

where f is a fitted regression function and r is a residual. The subscript i represents the observation number.

The adjusted response function for the first predictor variable x_1 , for example, is defined as

$$g(x_1) = \frac{1}{n} \sum_{i=1}^n f(x_1, x_{2i}, x_{3i}, \dots, x_{pi}),$$

where n is the number of observations. The adjusted response data value is the sum of the adjusted fitted value and the residual for each observation.

$$\tilde{y}_i = g(x_{1i}) + r_i.$$

`plotAdjustedResponse` plots the adjusted response function and the adjusted response data values for a selected predictor variable.

Conditional Effect

When a model contains an interaction term, the main effect of one predictor depends on the value of another predictor that interacts with it. In this case, a conditional effect of one predictor given a specific value of another is helpful in understanding the actual effect of both predictors. You can examine whether the effect of one predictor depends on the value of another by using conditional effect values.

To define a conditional effect, define the adjusted response function as a function of two predictor variables. For example, the adjusted response function of x_1 and x_2 is

$$h(x_1, x_2) = \frac{1}{n} \sum_{i=1}^n f(x_1, x_2, x_{3i}, \dots, x_{pi}),$$

where f is a fitted regression function, and n is the number of observations.

The conditional effect of one predictor (x_2) given a specific value of another predictor (x_{1k}) is defined by

$$h(x_{1k}, x_{2i}) - h(x_{1k}, x_{2j}).$$

To compute conditional effect values, `plotInteraction` chooses the observations i and j of x_2 in the same way as when the function computes the "Main Effect" on page 32-4042 and chooses the x_{1k} values. If x_1 is a categorical variable, then `plotInteraction` computes the conditional effect for all levels of x_1 . If x_1 is a numeric variable, then `plotInteraction` computes the conditional effect for three values of x_1 : the minimum value of x_1 , the maximum value of x_1 , and the average value of the minimum and maximum.

If the plot type is 'effects' (default), `plotInteraction` plots the main effects of the two selected predictors, their conditional effects, and the 95% confidence bounds for the effect values.

If the plot type is 'predictions', `plotInteraction` plots the adjusted response function as a function of the second predictor, with the first predictor fixed at specific values. For example,

`plotInteraction(mdl, 'x1', 'x2', 'predictions')` plots the curve of $h(x_{1k}, x_2)$ for each x_{1k} value.

Tips

- The data cursor displays the values of the selected plot point in a data tip (small text box located next to the data point). The data tip includes the x-axis and y-axis values for the selected point, along with the observation name or number.

Alternative Functionality

- A `LinearModel` object provides multiple plotting functions.
 - When creating a model, use `plotAdded` to understand the effect of adding or removing a predictor variable.
 - When verifying a model, use `plotDiagnostics` to find questionable data and to understand the effect of each observation. Also, use `plotResiduals` to analyze the residuals of the model.
 - After fitting a model, use `plotAdjustedResponse`, `plotPartialDependence`, and `plotEffects` to understand the effect of a particular predictor. Use `plotInteraction` to understand the interaction effect between two predictors. Also, use `plotSlice` to plot slices through the prediction surface.

Introduced in R2012a

plotprofile

Class: RepeatedMeasuresModel

Plot expected marginal means with optional grouping

Syntax

```
plotprofile(rm,X)
plotprofile(rm,Name,Value)
H = plotprofile( ___ )
```

Description

`plotprofile(rm,X)` plots the expected marginal means computed from the repeated measures model `rm` as a function of the variable `X`.

`plotprofile(rm,Name,Value)` plots the expected marginal means computed from the repeated measures model `rm` with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the factors to group by or change the line colors.

`H = plotprofile(___)` returns handles, `H`, to the plotted lines.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

X — Name of between-subjects or within-subjects factor

character vector | string scalar

Name of a between-subjects or within-subjects factor, specified as a character vector or string scalar.

For example, if you want to plot the marginal means as a function of the groups of a between-subjects variable `drug`, you can specify it as follows.

Example: 'Drug'

Data Types: char | string

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Group — Name of between-subject factor or factors

character vector | string array | cell array of character vectors

Name of between-subject factor or factors, specified as the comma-separated pair consisting of 'Group' and a character vector, string array, or cell array of character vectors. This name-value pair argument groups the lines according to the factor values.

For example, if you have two between-subject factors, drug and sex, and you want to group the lines in the plot according to them, you can specify these factors as follows.

Example: 'Group', {'Drug', 'Sex'}

Data Types: char | string | cell

Marker — Marker to use for each group

string array | cell array of character vectors

Marker to use for each group, specified as the comma-separated pair consisting of 'Marker' and a string array or cell array of character vectors.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify o as the marker for the groups of drug and x as the marker for the groups of sex as follows.

Example: 'Marker', {'o', 'o', 'x', 'x'}

Data Types: string | cell

Color — Color for each group

character vector | string array | cell array of character vectors | rows of a three-column RGB matrix

Color for each group, specified as the comma-separated pair consisting of 'Color' and a character vector, string array, cell array of character vectors, or rows of a three-column RGB matrix.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify red as the color for the groups of drug and blue as the color for the groups of sex as follows.

Example: 'Color', 'rbbb'

Data Types: single | double | char | string | cell

LineStyle — Line style for each group

string array | cell array of character vectors

Line style for each group, specified as the comma-separated pair consisting of 'LineStyle' and a string array or cell array of character vectors.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify - as the line style of one group and : as the line style for the other group as follows.

Example: 'LineStyle', {'-' ':' '-' ':'}

Data Types: string | cell

Output Arguments

H — Handle to plotted lines

handle

Handle to plotted lines, returned as a handle.

Examples

Plot Expected Marginal Means

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: *setosa*, *versicolor*, and *virginica*. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4'],'VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4-species','WithinDesign',Meas);
```

Perform data grouped by the factor species.

```
plotprofile(rm,'species')
```

The estimated marginal means seem to differ with group. You can compute the standard error and the 95% confidence intervals for the marginal means using the `margmean` method.

Plot Marginal Means for Two Groups

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the `group-gender` interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Plot the estimated marginal means based on the factors `Group` and `Gender`.

```
ax1 = subplot(1,2,1);
plotprofile(rm, 'Group')
ax2 = subplot(1,2,2);
plotprofile(rm, 'Gender')
linkaxes([ax1 ax2], 'y')
```

Plot the estimated marginal means based on the factor Group and grouped by Gender.

```
figure()  
plotprofile(rm, 'Group', 'Group', 'Gender')
```

[fitrm](#) | [margmean](#) | [plot](#)

plotResiduals

Plot residuals of generalized linear regression model

Syntax

```
plotResiduals mdl
plotResiduals mdl, plottype
plotResiduals mdl, plottype, Name, Value
h = plotResiduals( ___ )
```

Description

`plotResiduals(mdl)` creates a histogram plot of the generalized linear regression model (`mdl`) residuals.

`plotResiduals(mdl, plottype)` specifies the residual plot type `plottype`.

`plotResiduals(mdl, plottype, Name, Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the residual type and the graphical properties of residual data points.

`h = plotResiduals(___)` returns graphics objects for the lines or patch in the plot using any of the input argument combinations in the previous syntaxes. Use `h` to modify the properties of a specific line or patch after you create the plot. For a list of properties, see [Chart Line and Patch Properties](#).

Examples

Create Residual Plots for Generalized Linear Regression Model

Create three plots of a fitted generalized linear regression model: a histogram of raw residuals, a normal probability plot of raw residuals, a normal probability plot of Anscombe type residuals.

Generate sample data using Poisson random numbers with two underlying predictors $X(:,1)$ and $X(:,2)$.

```
rng('default') % For reproducibility
rndvars = randn(100,2);
X = [2 + rndvars(:,1), rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','Distribution','poisson');
```

Create a histogram of the raw residuals using probability density function scaling.

```
plotResiduals(mdl)
```

The area of each bar is the relative number of observations. The sum of the bar areas is equal to 1.

Create a normal probability plot of the raw residuals.

```
plotResiduals mdl, 'probability'
```

The residuals do not match a normal distribution in the tails because the residuals are more spread out.

Create a normal probability plot of the Anscombe type residuals.

```
plotResiduals mdl, 'probability', 'ResidualType', 'Anscombe'
```

The Anscombe type residuals match a normal distribution.

Input Arguments

mdl — Generalized linear regression model

GeneralizedLinearModel object

Generalized linear regression model, specified as a GeneralizedLinearModel object created using fitglm or stepwiseglm.

plottype — Plot type

'histogram' (default) | 'caseorder' | 'fitted' | 'lagged' | 'probability' | 'symmetry'

Plot type, specified as one of the values in this table.

Value	Description
'caseorder'	Residuals vs. case order (row number)
'fitted'	Residuals vs. fitted values
'histogram'	Histogram of residuals using probability density function scaling. The area of each bar is the relative number of observations. The sum of the bar areas is equal to 1.
'lagged'	Residuals vs. lagged residuals ($r(t)$ vs. $r(t - 1)$)

Value	Description
'probability'	Normal probability plot of residuals. For details, see <code>probplot</code> .
'symmetry'	Symmetry plot of residuals around their median (residuals in upper tail - median vs. median - residuals in lower tail). This plot includes a dotted reference line of $y = x$ to examine the symmetry of residuals.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'Color', 'blue', 'Marker', 'o'`

Note The graphical properties listed here are only a subset. For a complete list, see `Chart Line` for lines and `Patch Properties` for histogram. The specified properties apply to the appearance of residual data points or the appearance of the histogram.

ResidualType — Type of residual

'Raw' (default) | 'Anscombe' | 'Deviance' | 'LinearPredictor' | 'Pearson'

Type of residual used in the plot, specified as the comma-separated pair consisting of `'ResidualType'` and one of the values in this table.

Value	Description
'Raw'	Observed minus fitted values
'LinearPredictor'	Residuals on the linear predictor scale, equal to the adjusted response value minus the fitted linear combination of the predictors
'Pearson'	Raw residuals divided by the estimated standard deviation of the response
'Anscombe'	Residuals defined on transformed data with the transformation selected to remove skewness
'Deviance'	Residuals based on the contribution of each observation to the deviance

The `Residuals` property of `mdl` contains the residual values used by `plotResiduals` to create plots.

Example: `'ResidualType', 'Pearson'`

Color — Line color

RGB triplet | hexadecimal color code | color name | short name

Line color, specified as the comma-separated pair consisting of `'Color'` and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the following table.

The 'Color' name-value pair argument also determines marker outline color and marker fill color if 'MarkerEdgeColor' is 'auto' (default) and 'MarkerFaceColor' is 'auto'.

For a custom color, specify an RGB triplet or a hexadecimal color code.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1]; for example, [0.4 0.6 0.7].
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (#) followed by three or six hexadecimal digits, which can range from 0 to F. The values are not case sensitive. Thus, the color codes '#FF8800', '#ff8800', '#F80', and '#f80' are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'red'	'r'	[1 0 0]	'#FF0000'	
'green'	'g'	[0 1 0]	'#00FF00'	
'blue'	'b'	[0 0 1]	'#0000FF'	
'cyan'	'c'	[0 1 1]	'#00FFFF'	
'magenta'	'm'	[1 0 1]	'#FF00FF'	
'yellow'	'y'	[1 1 0]	'#FFFF00'	
'black'	'k'	[0 0 0]	'#000000'	
'white'	'w'	[1 1 1]	'#FFFFFF'	
'none'	Not applicable	Not applicable	Not applicable	No color

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

Example: 'Color', 'blue'

LineWidth — Line width

positive value

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a positive value in points. If the line has markers, then the line width also affects the marker edges.

Example: `'LineWidth',0.75`

Marker — Marker symbol

`'o' | '+' | '*' | '.' | 'x' | ...`

Marker symbol, specified as the comma-separated pair consisting of `'Marker'` and one of the values in this table.

Value	Description
<code>'o'</code>	Circle
<code>'+'</code>	Plus sign
<code>'*'</code>	Asterisk
<code>'.'</code>	Point
<code>'x'</code>	Cross
<code>'square'</code> or <code>'s'</code>	Square
<code>'diamond'</code> or <code>'d'</code>	Diamond
<code>'^'</code>	Upward-pointing triangle
<code>'v'</code>	Downward-pointing triangle
<code>'>'</code>	Right-pointing triangle
<code>'<'</code>	Left-pointing triangle
<code>'pentagram'</code> or <code>'p'</code>	Five-pointed star (pentagram)
<code>'hexagram'</code> or <code>'h'</code>	Six-pointed star (hexagram)
<code>'none'</code>	No markers

Example: `'Marker','+'`

MarkerEdgeColor — Marker outline color

`'auto'` (default) | `'none'` | RGB triplet | hexadecimal color code | color name | short name

Marker outline color, specified as the comma-separated pair consisting of `'MarkerEdgeColor'` and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the `Color` name-value pair argument.

The default value of `'auto'` uses the same color specified by using `'Color'`.

Example: `'MarkerEdgeColor','blue'`

MarkerFaceColor — Marker fill color

`'none'` (default) | `'auto'` | RGB triplet | hexadecimal color code | color name | short name

Marker fill color, specified as the comma-separated pair consisting of `'MarkerFaceColor'` and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the `Color` name-value pair argument.

The `'auto'` value uses the same color specified by using `'Color'`.

Example: `'MarkerFaceColor','blue'`

MarkerSize — Marker size

6 (default) | positive value

Marker size, specified as the comma-separated pair consisting of 'MarkerSize' and a positive value in points.

Example: 'MarkerSize',2

Output Arguments

h — Graphics objects

graphics array

Graphics objects corresponding to the lines or patch in the plot, returned as a graphics array. Use dot notation to query and set properties of the graphics objects. For details, see [Line Properties](#) and [Patch Properties](#).

You can use name-value pair arguments to specify the appearance of residual data points or the appearance of the histogram, corresponding to the first graphics object `h(1)`.

More About

Deviance

Deviance is twice the loglikelihood of the model. Because this overall loglikelihood is a sum of loglikelihoods for each observation, a residual plot with the deviance type shows the loglikelihood per observation.

Tips

- The data cursor displays the values of the selected plot point in a data tip (small text box located next to the data point). The data tip includes the x-axis and y-axis values for the selected point, along with the observation name or number.

Alternative Functionality

A `GeneralizedLinearModel` object provides multiple plotting functions.

- When verifying a model, use `plotDiagnostics` to find questionable data and to understand the effect of each observation. Also, use `plotResiduals` to analyze the residuals of the model.
- After fitting a model, use `plotPartialDependence` to understand the effect of a particular predictor. Also, use `plotSlice` to plot slices through the prediction surface.

Introduced in R2012a

plotResiduals

Class: GeneralizedLinearMixedModel

Plot residuals of generalized linear mixed-effects model

Syntax

```
plotResiduals(glme, plottype)
plotResiduals(glme, plottype, Name, Value)
```

```
h = plotResiduals( ___ )
```

Description

`plotResiduals(glme, plottype)` plots the raw conditional residuals of the generalized linear mixed-effects model `glme` in a plot of the type specified by `plottype`.

`plotResiduals(glme, plottype, Name, Value)` plots the conditional residuals of `glme` using additional options specified by one or more `Name, Value` pair arguments. For example, you can specify to plot the Pearson residuals.

`h = plotResiduals(___)` returns a handle, `h`, to the lines or patches in the plot of residuals.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

plottype — Type of residual plot

'histogram' (default) | 'caseorder' | 'fitted' | 'lagged' | 'probability' | 'symmetry'

Type of residual plot, specified as one of the following.

Value	Description
'histogram'	Histogram of residuals
'caseorder'	Residuals versus case order. Case order is the same as the row order used in the input data <code>tbl</code> when fitting the model using <code>fitglme</code> .
'fitted'	Residuals versus fitted values
'lagged'	Residuals versus lagged residual ($r(t)$ versus $r(t - 1)$)
'probability'	Normal probability plot
'symmetry'	Symmetry plot

Example: `plotResiduals(glme, 'lagged')`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

ResidualType — Residual type

'raw' (default) | 'Pearson'

Residual type, specified by the comma-separated pair consisting of `ResidualType` and one of the following.

Residual Type	Formula
'raw'	$r_{ci} = y_i - g^{-1}(x_i^T \hat{\beta} + z_i^T \hat{b} + \delta_i)$
'Pearson'	$r_{ci}^{pearson} = \frac{r_{ci}}{\sqrt{\frac{\sigma^2}{w_i} v_i(\mu_i(\hat{\beta}, \hat{b}))}}$

In each of these equations:

- y_i is the i th element of the n -by-1 response vector, y , where $i = 1, \dots, n$.
- g^{-1} is the inverse link function for the model.
- x_i^T is the i th row of the fixed-effects design matrix X .
- z_i^T is the i th row of the random-effects design matrix Z .
- δ_i is the i th offset value.
- σ^2 is the dispersion parameter.
- w_i is the i th observation weight.
- v_i is the variance term for the i th observation.
- μ_i is the mean of the response for the i th observation.
- $\hat{\beta}$ and \hat{b} are estimated values of β and b .

Raw residuals from a generalized linear mixed-effects model have nonconstant variance. Pearson residuals are expected to have an approximately constant variance, and are generally used for analysis.

Example: 'ResidualType', 'Pearson'

Output Arguments

h — Handle to residual plot

graphics object

Handle to the residual plot, returned as a graphics object. You can use dot notation to change certain property values of the object, including face color for a histogram, and marker style and color for a scatterplot. For more information, see "Access Property Values" (MATLAB).

Examples

Create Plots of Residuals

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution:

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .

- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', 'Di
```

Create diagnostic plots using Pearson residuals to test the model assumptions.

Plot a histogram to visually confirm that the mean of the Pearson residuals is equal to 0. If the model is correct, we expect the Pearson residuals to be centered at 0.

```
plotResiduals(glme, 'histogram', 'ResidualType', 'Pearson')
```

The histogram shows that the Pearson residuals are centered at 0.

Plot the Pearson residuals versus the fitted values, to check for signs of nonconstant variance among the residuals (heteroscedasticity). We expect the conditional Pearson residuals to have a constant variance. Therefore, a plot of conditional Pearson residuals versus conditional fitted values should not reveal any systematic dependence on the conditional fitted values.

```
plotResiduals(glme, 'fitted', 'ResidualType', 'Pearson')
```

The plot does not show a systematic dependence on the fitted values, so there are no signs of nonconstant variance among the residuals.

Plot the Pearson residuals versus lagged residuals, to check for correlation among the residuals. The conditional independence assumption in GLME implies that the conditional Pearson residuals are approximately uncorrelated.

```
plotResiduals(glme, 'lagged', 'ResidualType', 'Pearson')
```

There is no pattern to the plot, so there are no signs of correlation among the residuals.

[GeneralizedLinearMixedModel](#) | [fitglm](#) | [fitted](#) | [plot](#) | [residuals](#)

plotResiduals

Plot residuals of linear regression model

Syntax

```
plotResiduals mdl  
plotResiduals mdl, plottype  
plotResiduals mdl, plottype, Name, Value
```

```
plotResiduals ax, ___  
h = plotResiduals( ___)
```

Description

`plotResiduals(mdl)` creates a histogram plot of the linear regression model (`mdl`) residuals.

`plotResiduals(mdl, plottype)` specifies the residual plot type `plottype`.

`plotResiduals(mdl, plottype, Name, Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the residual type and the graphical properties of residual data points.

`plotResiduals(ax, ___)` creates the plot in the axes specified by `ax` instead of the current axes, using any of the input argument combinations in the previous syntaxes.

`h = plotResiduals(___)` returns graphics objects for the lines or patch in the plot. Use `h` to modify the properties of a specific line or patch after you create the plot. For a list of properties, see [Chart Line and Patch Properties](#).

Examples

Histogram of Residuals

Plot a histogram of the residuals of a fitted linear regression model.

Load the `carsmall` data set and fit a linear regression model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall  
tbl = table(MPG, Weight);  
tbl.Year = categorical(Model_Year);  
mdl = fitlm(tbl, 'MPG ~ Year + Weight^2');
```

Create a histogram of the raw residuals using probability density function scaling.

```
plotResiduals(mdl)
```

The area of each bar is the relative number of observations. The sum of the bar areas is equal to 1.

Normal Probability Plot of Residuals

Create a normal probability plot of the residuals of a fitted linear regression model.

Load the `carsmall` data set and fit a linear regression model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
X = [Weight,Model_Year];
mdl = fitlm(X,MPG,...
    'y ~ x2 + x1^2','Categorical',2);
```

Create a normal probability plot of the residuals of the fitted model.

```
plotResiduals(mdl,'probability')
```

Input Arguments

mdl – Linear regression model

LinearModel object

Linear regression model, specified as a LinearModel object created using fitlm or stepwiselm.

plottype – Plot type

'histogram' (default) | 'caseorder' | 'fitted' | 'lagged' | 'probability' | 'symmetry'

Plot type, specified as one of the values in this table.

Value	Description
'caseorder'	Residuals vs. case order (row number)
'fitted'	Residuals vs. fitted values
'histogram'	Histogram of residuals using probability density function scaling. The area of each bar is the relative number of observations. The sum of the bar areas is equal to 1.
'lagged'	Residuals vs. lagged residuals ($r(t)$ vs. $r(t - 1)$)
'probability'	Normal probability plot of residuals. For details, see probplot.

Value	Description
'symmetry'	Symmetry plot of residuals around their median (residuals in upper tail - median vs. median - residuals in lower tail). This plot includes a dotted reference line of $y = x$ to examine the symmetry of residuals.

ax — Target axes

Axes object

Target axes, specified as an Axes object.

If you do not specify the axes and the current axes are Cartesian, then `plotResiduals` uses the current axes (`gca`). For more information on creating an Axes object, see `axes` and `gca`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'Color', 'blue', 'Marker', 'o'

Note The graphical properties listed here are only a subset. For a complete list, see Chart Line for lines and Patch Properties for histogram. The specified properties apply to the appearance of residual data points or the appearance of the histogram.

ResidualType — Type of residual

'raw' (default) | 'pearson' | 'standardized' | 'studentized'

Type of residual used in the plot, specified as the comma-separated pair consisting of 'ResidualType' and one of these values:

Value	Description
'raw'	Observed minus fitted values
'pearson'	Raw residuals divided by the root mean squared error (RMSE)
'standardized'	Raw residuals divided by their estimated standard deviation
'studentized'	Raw residuals divided by an independent (delete-1) estimate of their standard deviation

The `Residuals` property of `mdl` contains the residual values used by `plotResiduals` to create plots.

For details, see “Residuals” on page 11-79.

Example: 'ResidualType', 'Pearson'

Color — Line color

RGB triplet | hexadecimal color code | color name | short name

Line color, specified as the comma-separated pair consisting of 'Color' and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the following table.

The 'Color' name-value pair argument also determines marker outline color and marker fill color if 'MarkerEdgeColor' is 'auto' (default) and 'MarkerFaceColor' is 'auto'.

For a custom color, specify an RGB triplet or a hexadecimal color code.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range $[0, 1]$; for example, $[0.4 \ 0.6 \ 0.7]$.
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (#) followed by three or six hexadecimal digits, which can range from 0 to F. The values are not case sensitive. Thus, the color codes '#FF8800', '#ff8800', '#F80', and '#f80' are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'red'	'r'	[1 0 0]	'#FF0000'	
'green'	'g'	[0 1 0]	'#00FF00'	
'blue'	'b'	[0 0 1]	'#0000FF'	
'cyan'	'c'	[0 1 1]	'#00FFFF'	
'magenta'	'm'	[1 0 1]	'#FF00FF'	
'yellow'	'y'	[1 1 0]	'#FFFF00'	
'black'	'k'	[0 0 0]	'#000000'	
'white'	'w'	[1 1 1]	'#FFFFFF'	
'none'	Not applicable	Not applicable	Not applicable	No color

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

Example: 'Color', 'blue'

LineWidth — Line width

positive value

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a positive value in points. If the line has markers, then the line width also affects the marker edges.

Example: `'LineWidth',0.75`

Marker — Marker symbol

`'o' | '+' | '*' | '.' | 'x' | ...`

Marker symbol, specified as the comma-separated pair consisting of `'Marker'` and one of the values in this table.

Value	Description
<code>'o'</code>	Circle
<code>'+'</code>	Plus sign
<code>'*'</code>	Asterisk
<code>'.'</code>	Point
<code>'x'</code>	Cross
<code>'square'</code> or <code>'s'</code>	Square
<code>'diamond'</code> or <code>'d'</code>	Diamond
<code>'^'</code>	Upward-pointing triangle
<code>'v'</code>	Downward-pointing triangle
<code>'>'</code>	Right-pointing triangle
<code>'<'</code>	Left-pointing triangle
<code>'pentagram'</code> or <code>'p'</code>	Five-pointed star (pentagram)
<code>'hexagram'</code> or <code>'h'</code>	Six-pointed star (hexagram)
<code>'none'</code>	No markers

Example: `'Marker','+'`

MarkerEdgeColor — Marker outline color

`'auto'` (default) | `'none'` | RGB triplet | hexadecimal color code | color name | short name

Marker outline color, specified as the comma-separated pair consisting of `'MarkerEdgeColor'` and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the `Color` name-value pair argument.

The default value of `'auto'` uses the same color specified by using `'Color'`.

Example: `'MarkerEdgeColor','blue'`

MarkerFaceColor — Marker fill color

`'none'` (default) | `'auto'` | RGB triplet | hexadecimal color code | color name | short name

Marker fill color, specified as the comma-separated pair consisting of `'MarkerFaceColor'` and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the `Color` name-value pair argument.

The `'auto'` value uses the same color specified by using `'Color'`.

Example: `'MarkerFaceColor','blue'`

MarkerSize — Marker size

6 (default) | positive value

Marker size, specified as the comma-separated pair consisting of 'MarkerSize' and a positive value in points.

Example: 'MarkerSize',2

Output Arguments

h — Graphics objects

graphics array

Graphics objects corresponding to the lines or patch in the plot, returned as a graphics array. Use dot notation to query and set properties of the graphics objects. For details, see [Line Properties](#) and [Patch Properties](#).

You can use name-value pair arguments to specify the appearance of residual data points or the appearance of the histogram, corresponding to the first graphics object `h(1)`.

Tips

- The data cursor displays the values of the selected plot point in a data tip (small text box located next to the data point). The data tip includes the x-axis and y-axis values for the selected point, along with the observation name or number.

Alternative Functionality

- A `LinearModel` object provides multiple plotting functions.
 - When creating a model, use `plotAdded` to understand the effect of adding or removing a predictor variable.
 - When verifying a model, use `plotDiagnostics` to find questionable data and to understand the effect of each observation. Also, use `plotResiduals` to analyze the residuals of the model.
 - After fitting a model, use `plotAdjustedResponse`, `plotPartialDependence`, and `plotEffects` to understand the effect of a particular predictor. Use `plotInteraction` to understand the interaction effect between two predictors. Also, use `plotSlice` to plot slices through the prediction surface.

plotResiduals

Class: LinearMixedModel

Plot residuals of linear mixed-effects model

Syntax

```
plotResiduals(lme,plottype)
plotResiduals(lme,plottype,Name,Value)
```

```
h = plotResiduals( ___ )
```

Description

`plotResiduals(lme,plottype)` plots the raw conditional residuals of the linear mixed-effects model `lme` in a plot of the type specified by `plottype`.

`plotResiduals(lme,plottype,Name,Value)` also plots the residuals of the linear mixed-effects model `lme` with additional options specified by one or more name-value pair arguments. For example, you can specify the residual type to plot.

`plotResiduals` also accepts some other name-value pair arguments that specify the properties of the primary line in the plot. For those name-value pairs, see `plot`.

`h = plotResiduals(___)` returns a handle, `h`, to the lines or patches in the plot of residuals.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a `LinearMixedModel` object constructed using `fitlme` or `fitlmematrix`.

plottype — Type of residual plot

'histogram' (default) | 'caseorder' | 'fitted' | 'lagged' | 'probability' | 'symmetry'

Type of residual plot, specified as one of the following.

'histogram'	Default. Histogram of residuals
'caseorder'	Residuals versus case (row) order
'fitted'	Residuals versus fitted values
'lagged'	Residuals versus lagged residual ($r(t)$ versus $r(t - 1)$)
'probability'	Normal probability plot
'symmetry'	Symmetry plot

Example: `plotResiduals(lme,'lagged')`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

ResidualType — Residual type

'Raw' (default) | 'Pearson' | 'Standardized'

Residual type, specified by the comma-separated pair consisting of `ResidualType` and one of the following.

Residual Type	Conditional	Marginal
'Raw'	$r_i^C = [y - X\hat{\beta} - Zb]_i$	$r_i^M = [y - X\hat{\beta}]_i$
'Pearson'	$pr_i^C = \frac{r_i^C}{\sqrt{[\widehat{\text{Var}}_{y,b}(y - X\hat{\beta} - Zb)]_{ii}}}$	$pr_i^M = \frac{r_i^M}{\sqrt{[\widehat{\text{Var}}_y(y - X\hat{\beta})]_{ii}}}$
'Standardized'	$st_i^C = \frac{r_i^C}{\sqrt{[\widehat{\text{Var}}_y(r^C)]_{ii}}}$	$st_i^M = \frac{r_i^M}{\sqrt{[\widehat{\text{Var}}_y(r^M)]_{ii}}}$

For more information on the conditional and marginal residuals and residual variances, see [Definitions](#) at the end of this page.

Example: `'ResidualType', 'Standardized'`

Output Arguments

h — Handle to residual plot

handle

Handle to the residual plot, returned as a handle.

Examples

Examine Residuals

Load the sample data.

```
load('weight.mat');
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);  
tbl.Subject = nominal(tbl.Subject);  
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Plot the histogram of the raw residuals.

```
plotResiduals(lme)
```

Plot the residuals versus the fitted values.

```
figure();  
plotResiduals(lme,'fitted')
```

There is no obvious pattern, so there are no immediate signs of heteroscedasticity.

Create the normal probability plot of residuals.

```
figure();  
plotResiduals(lme, 'probability')
```

Data appears to be normal.

Find the observation number for the data that appears to be an outlier to the right of the plot.

```
find(residuals(lme)>0.25)
```

```
ans =
```

```
101
```

Create a box plot of the raw, Pearson, and standardized residuals.

```
r = residuals(lme);
pr = residuals(lme,'ResidualType','Pearson');
st = residuals(lme,'ResidualType','Standardized');
X = [r pr st];
boxplot(X,'labels',{'Raw','Pearson','Standardized'});
```

All three box plots point out the outlier on the right tail of the distribution. The box plots of raw and Pearson residuals also point out a second possible outlier on the left tail. Find the corresponding observation number.

```
find(pr<-2)
```

```
ans =
```

```
10
```

Plot the raw residuals versus lagged residuals.

```
plotResiduals(lme, 'lagged')
```

There is no obvious pattern in the graph. The residuals do not appear to be correlated.

See Also

`LinearMixedModel` | `fitted` | `residuals`

plotResiduals

Class: NonLinearModel

Plot residuals of nonlinear regression model

Syntax

```
plotResiduals mdl
plotResiduals mdl, plottype
h = plotResiduals(...)
h = plotResiduals(mdl, plottype, Name, Value)
```

Description

`plotResiduals(mdl)` gives a histogram plot of the residuals of the `mdl` nonlinear model.

`plotResiduals(mdl, plottype)` plots residuals in a plot of type `plottype`.

`h = plotResiduals(...)` returns handles to the lines in the plot.

`h = plotResiduals(mdl, plottype, Name, Value)` plots with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

`mdl`

Nonlinear regression model, constructed by `fitnlm`.

`plottype`

Character vector or string scalar specifying the type of plot:

'caseorder'	Residuals vs. case (row) order
'fitted'	Residuals vs. fitted values
'histogram'	Histogram
'lagged'	Residuals vs. lagged residual ($r(t)$ vs. $r(t-1)$)
'probability'	Normal probability plot
'symmetry'	Symmetry plot

Default: 'histogram'

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Note The plot property name-value pairs apply to the first returned handle `h(1)`.

Color

Color of the line or marker, specified as an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the following table.

For a custom color, specify an RGB triplet or a hexadecimal color code.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range $[0, 1]$; for example, $[0.4 \ 0.6 \ 0.7]$.
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (`#`) followed by three or six hexadecimal digits, which can range from `0` to `F`. The values are not case sensitive. Thus, the color codes `'#FF8800'`, `'#ff8800'`, `'#F80'`, and `'#f80'` are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'red'	'r'	[1 0 0]	'#FF0000'	
'green'	'g'	[0 1 0]	'#00FF00'	
'blue'	'b'	[0 0 1]	'#0000FF'	
'cyan'	'c'	[0 1 1]	'#00FFFF'	
'magenta'	'm'	[1 0 1]	'#FF00FF'	
'yellow'	'y'	[1 1 0]	'#FFFF00'	
'black'	'k'	[0 0 0]	'#000000'	
'white'	'w'	[1 1 1]	'#FFFFFF'	

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

LineStyle

Type of line, a Chart Line specification. For details, see `linespec`.

LineWidth

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: 0.5

MarkerEdgeColor

Marker outline color, specified as an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the `Color` name-value pair argument.

MarkerFaceColor

Fill color for filled markers, specified as an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the `Color` name-value pair argument.

MarkerSize

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

ResidualType

Type of residual used in the plot:

'Raw'	Observed minus fitted values
'Pearson'	Raw residuals divided by RMSE
'Standardized'	Raw residuals divided by their estimated standard deviation
'Studentized'	Raw residuals divided by an independent (delete-1) estimate of their standard deviation

Default: 'Raw'

Output Arguments

h

Vector of handles to lines or patches in the plot.

Examples**Residual Plot**

Plot the residuals of a fitted nonlinear model.

Load the reaction data and fit a model of the reaction rate as a function of reactants.

```
load reaction
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
```

Plot the residuals of the fitted model.

```
plotResiduals(mdl)
```

Residual Probability Plot

Create a normal probability plot of the residuals of a fitted nonlinear model.

Load the reaction data and fit a model of the reaction rate as a function of reactants.

```
load reaction
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
```

Create a normal probability plot of the residuals of the fitted model.

```
plotResiduals(mdl,'probability')
```

Tips

- The data cursor displays the values of the selected plot point in a data tip (small text box located next to the data point). The data tip includes the x-axis and y-axis values for the selected point, along with the observation name or number.

plotSlice

Package:

Plot of slices through fitted generalized linear regression surface

Syntax

```
plotSlice mdl
```

Description

`plotSlice mdl` creates a figure containing one or more plots, each representing a slice through the regression surface predicted by `mdl`. Each plot shows the fitted response values as a function of a single predictor variable, with the other predictor variables held constant.

`plotSlice` also displays the 95% confidence bounds for the response values. Use the **Bounds** menu to choose the type of confidence bounds, and use the **Predictors** menu to select which predictors to use for each slice plot. For details, see “Tips” on page 32-4085.

Examples

Slice Plot for Generalized Linear Regression Model

Plot slices through a fitted generalized linear regression model surface.

Generate sample data using Poisson random numbers with two underlying predictors $X(:,1)$ and $X(:,2)$.

```
rng('default') % For reproducibility
rndvars = randn(100,2);
X = [2 + rndvars(:,1), rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','Distribution','poisson');
```

Create a slice plot.

```
plotSlice(mdl)
```

The green line in each plot represents the predicted response values as a function of a single predictor variable, with the other predictor variables held constant. The red dotted lines are the 95% confidence bounds. The y-axis label includes the predicted response value and the corresponding confidence bound for the point selected by the vertical and horizontal lines. The x-axis label shows the predictor variable name and the predictor value for the selected point.

Move the vertical line in the x_1 plot to the right and observe the change in the y-axis label and the changes in the x_2 plot.

Input Arguments

mdl — Generalized linear regression model

GeneralizedLinearModel object | CompactGeneralizedLinearModel object

Generalized linear regression model, specified as a GeneralizedLinearModel object created using fitglm or stepwiseglm, or a CompactGeneralizedLinearModel object created using compact.

Tips

- Use the **Bounds** menu in the figure window to choose the type of confidence bounds. You can choose **Simultaneous** or **Non-Simultaneous**. You can also choose **No Bounds** to have no confidence bounds.
 - Simultaneous (default) — plotSlice computes confidence bounds for the curve of the response values using Scheffe's method. The range between the upper and lower confidence bounds contains the curve consisting of true response values with 95% confidence.
 - Non-Simultaneous — plotSlice computes confidence bounds for the response value at each observation. The confidence interval for a response value at a specific predictor value contains the true response value with 95% confidence.

Simultaneous bounds are wider than separate bounds, because requiring the entire curve of response values to be within the bounds is stricter than requiring the response value at a single predictor value to be within the bounds.

- Use the **Predictors** menu in the figure window to select which predictors to use for each slice plot. If the regression model mdl includes more than eight predictors, plotSlice creates plots for the first five predictors by default.

Alternative Functionality

- Use `predict` to return the predicted response values and confidence bounds. You can also specify the confidence level for confidence bounds by using the 'Alpha' name-value pair argument of the `predict` function. Note that `predict` finds nonsimultaneous bounds by default, whereas `plotSlice` finds simultaneous bounds by default.
- A `GeneralizedLinearModel` object provides multiple plotting functions.
 - When verifying a model, use `plotDiagnostics` to find questionable data and to understand the effect of each observation. Also, use `plotResiduals` to analyze the residuals of the model.
 - After fitting a model, use `plotPartialDependence` to understand the effect of a particular predictor. Also, use `plotSlice` to plot slices through the prediction surface.

plotSlice

Package:

Plot of slices through fitted linear regression surface

Syntax

```
plotSlice mdl
```

Description

`plotSlice(mdl)` creates a figure containing one or more plots, each representing a slice through the regression surface predicted by `mdl`. Each plot shows the fitted response values as a function of a single predictor variable, with the other predictor variables held constant.

`plotSlice` also displays the 95% confidence bounds for the response values. Use the **Bounds** menu to choose the type of confidence bounds, and use the **Predictors** menu to select which predictors to use for each slice plot. For details, see “Tips” on page 32-4089.

Examples

Slice Plot for Linear Regression Model

Plot slices through a fitted linear regression model surface.

Load the `carsmall` data set and fit a linear regression model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
Year = categorical(Model_Year);
tbl = table(MPG,Weight,Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Create a slice plot.

```
plotSlice(mdl)
```

The green line in each plot represents the predicted response values as a function of a single predictor variable, with the other predictor variables held constant. The red dotted lines are the 95% confidence bounds. The y-axis label includes the predicted response value and the corresponding confidence bound for the point selected by the vertical and horizontal lines. The x-axis label shows the predictor variable name and the predictor value for the selected point.

Note that `mdl` includes both the `Weight` and `Weight^2` terms, but `plotSlice` creates only one plot for the `Weight` term.

Move the vertical line in the `Weight` plot to the right and observe the change in the y-axis label and the changes in the `Year` plot.

Input Arguments

`mdl` — Linear regression model object

LinearModel object | CompactLinearModel object

Linear regression model object, specified as a `LinearModel` object created by using `fitlm` or `stepwiselm`, or a `CompactLinearModel` object created by using `compact`.

Tips

- Use the **Bounds** menu in the figure window to choose the type of confidence bounds. You can choose **Simultaneous** or **Non-Simultaneous**, and **Curve** or **Observation**. You can also choose **No Bounds** to have no confidence bounds.
 - **Simultaneous** or **Non-Simultaneous**
 - Simultaneous (default) — `plotSlice` computes confidence bounds for the curve of the response values using Scheffe's method. The range between the upper and lower confidence bounds contains the curve consisting of true response values with 95% confidence.
 - Non-Simultaneous — `plotSlice` computes confidence bounds for the response value at each observation. The confidence interval for a response value at a specific predictor value contains the true response value with 95% confidence.

Simultaneous bounds are wider than separate bounds, because requiring the entire curve of response values to be within the bounds is stricter than requiring the response value at a single predictor value to be within the bounds.

- **Curve** or **Observation**

A regression model for the predictor variables X and the response variable y has the form $y = f(X) + \varepsilon$, where f is a function of X and ε is a random noise term.

- **Curve** (default) — `plotSlice` predicts confidence bounds for the fitted responses $f(X)$.
- **Observation** — `plotSlice` predicts confidence bounds for the response observations y .

The bounds for y are wider than the bounds for $f(X)$ because of the additional variability of the noise term.

- Use the **Predictors** menu in the figure window to select which predictors to use for each slice plot. If the regression model `mdl` includes more than eight predictors, `plotSlice` creates plots for the first five predictors by default.

Alternative Functionality

- Use `predict` to return the predicted response values and confidence bounds. You can also specify the confidence level for confidence bounds by using the 'Alpha' name-value pair argument of the `predict` function. Note that `predict` finds nonsimultaneous bounds by default whereas `plotSlice` finds simultaneous bounds by default.
- A `LinearModel` object provides multiple plotting functions.
 - When creating a model, use `plotAdded` to understand the effect of adding or removing a predictor variable.
 - When verifying a model, use `plotDiagnostics` to find questionable data and to understand the effect of each observation. Also, use `plotResiduals` to analyze the residuals of the model.
 - After fitting a model, use `plotAdjustedResponse`, `plotPartialDependence`, and `plotEffects` to understand the effect of a particular predictor. Use `plotInteraction` to understand the interaction effect between two predictors. Also, use `plotSlice` to plot slices through the prediction surface.

plotSlice

Class: NonLinearModel

Plot of slices through fitted nonlinear regression surface

Syntax

```
plotSlice mdl  
h = plotSlice(mdl)
```

Description

`plotSlice(mdl)` creates a new figure containing a series of plots, each representing a slice through the regression surface predicted by `mdl`. For each plot, the surface slice is shown as a function of a single predictor variable, with the other predictor variables held constant.

`h = plotSlice(mdl)` returns handles to the lines in the plot.

Input Arguments

mdl

Nonlinear regression model, constructed by `fitnlm`.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Examples

Slice Plot

Plot slices of a fitted nonlinear model.

Load the `reaction` data and fit a model of the reaction rate as a function of reactants.

```
load reaction  
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
```

Create a slice plot.

```
plotSlice(mdl)
```

Drag the X1 prediction line to the right, and observe the change in the predicted response y and in the predicted response curves to X2 and X3.

Tips

- If there are more than eight predictors, `plotSlice` selects the first five for plotting. Use the **Predictors** menu to control which predictors are plotted.
- The **Bounds** menu lets you choose between simultaneous or non-simultaneous bounds, and between bounds on the function or bounds on a new observation.

plsregress

Partial least-squares regression

Syntax

```
[XL,YL] = plsregress(X,Y,ncomp)
[XL,YL,XS] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA] = plsregress(X,Y,ncomp,...)
[XL,YL,XS,YS,BETA,PCTVAR] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA,PCTVAR,MSE] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA,PCTVAR,MSE] = plsregress(...,param1,val1,param2,val2,...)
[XL,YL,XS,YS,BETA,PCTVAR,MSE,stats] = plsregress(X,Y,ncomp,...)
```

Description

`[XL,YL] = plsregress(X,Y,ncomp)` computes a partial least-squares (PLS) regression of Y on X , using $ncomp$ PLS components, and returns the predictor and response loadings in XL and YL , respectively. X is an n -by- p matrix of predictor variables, with rows corresponding to observations and columns to variables. Y is an n -by- m response matrix. XL is a p -by- $ncomp$ matrix of predictor loadings, where each row contains coefficients that define a linear combination of PLS components that approximate the original predictor variables. YL is an m -by- $ncomp$ matrix of response loadings, where each row contains coefficients that define a linear combination of PLS components that approximate the original response variables.

`[XL,YL,XS] = plsregress(X,Y,ncomp)` returns the predictor scores XS , that is, the PLS components that are linear combinations of the variables in X . XS is an n -by- $ncomp$ orthonormal matrix with rows corresponding to observations and columns to components.

`[XL,YL,XS,YS] = plsregress(X,Y,ncomp)` returns the response scores YS , that is, the linear combinations of the responses with which the PLS components XS have maximum covariance. YS is an n -by- $ncomp$ matrix with rows corresponding to observations and columns to components. YS is neither orthogonal nor normalized.

`plsregress` uses the SIMPLS algorithm, first centering X and Y by subtracting off column means to get centered variables X_0 and Y_0 . However, it does not rescale the columns. To perform PLS with standardized variables, use `zscore` to normalize X and Y .

If $ncomp$ is omitted, its default value is $\min(\text{size}(X,1)-1, \text{size}(X,2))$.

The relationships between the scores, loadings, and centered variables X_0 and Y_0 are:

$$XL = (XS \backslash X_0)' = X_0' * XS,$$

$$YL = (XS \backslash Y_0)' = Y_0' * XS,$$

XL and YL are the coefficients from regressing X_0 and Y_0 on XS , and $XS * XL'$ and $XS * YL'$ are the PLS approximations to X_0 and Y_0 .

`plsregress` initially computes YS as:

$$Y_0 = Y_0 * Y_L = Y_0 * Y_0' * X_S,$$

By convention, however, `plsregress` then orthogonalizes each column of `Y0` with respect to preceding columns of `XS`, so that `XS' * Y0` is lower triangular.

`[XL,YL,XS,YS,BETA] = plsregress(X,Y,ncomp,...)` returns the PLS regression coefficients `BETA`. `BETA` is a $(p+1)$ -by- m matrix, containing intercept terms in the first row:

$$Y = [\text{ones}(n,1),X]*\text{BETA} + Y_{\text{residuals}},$$

$Y_0 = X_0 * \text{BETA}(2:\text{end},:) + Y_{\text{residuals}}$. Here `Yresiduals` is the vector of response residuals.

`[XL,YL,XS,YS,BETA,PCTVAR] = plsregress(X,Y,ncomp)` returns a 2-by-`ncomp` matrix `PCTVAR` containing the percentage of variance explained by the model. The first row of `PCTVAR` contains the percentage of variance explained in `X` by each PLS component, and the second row contains the percentage of variance explained in `Y`.

`[XL,YL,XS,YS,BETA,PCTVAR,MSE] = plsregress(X,Y,ncomp)` returns a 2-by- $(ncomp+1)$ matrix `MSE` containing estimated mean-squared errors for PLS models with $0:ncomp$ components. The first row of `MSE` contains mean-squared errors for the predictor variables in `X`, and the second row contains mean-squared errors for the response variable(s) in `Y`.

`[XL,YL,XS,YS,BETA,PCTVAR,MSE] = plsregress(...,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs from the following table to control the calculation of `MSE`.

Parameter	Value
'cv'	<p>The method used to compute MSE.</p> <ul style="list-style-type: none"> When the value is a positive integer <code>k</code>, <code>plsregress</code> uses <code>k</code>-fold cross-validation. When the value is an object of the <code>cvpartition</code> on page 32-983 class, other forms of cross-validation can be specified. When the value is 'resubstitution', <code>plsregress</code> uses <code>X</code> and <code>Y</code> both to fit the model and to estimate the mean-squared errors, without cross-validation. <p>The default is 'resubstitution'.</p>
'mcreps'	<p>A positive integer indicating the number of Monte-Carlo repetitions for cross-validation. The default value is 1. The value must be 1 if the value of 'cv' is 'resubstitution'.</p>
options	<p>A structure that specifies whether to run in parallel, and specifies the random stream or streams. Create the <code>options</code> structure with <code>statset</code>. Option fields:</p> <ul style="list-style-type: none"> <code>UseParallel</code> — Set to <code>true</code> to compute in parallel. Default is <code>false</code>. <code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'. <code>Streams</code> — A <code>RandStream</code> object or cell array consisting of one such object. If you do not specify <code>Streams</code>, <code>plsregress</code> uses the default stream. <p>To compute in parallel, you need Parallel Computing Toolbox</p>

`[XL,YL,XS,YS,BETA,PCTVAR,MSE,stats] = plsregress(X,Y,ncomp,...)` returns a structure `stats` with the following fields:

- W — A p -by- n comp matrix of PLS weights so that $XS = X0*W$.
- T^2 — The T^2 statistic for each point in XS .
- $Xresiduals$ — The predictor residuals, that is, $X0 - XS*XL'$.
- $Yresiduals$ — The response residuals, that is, $Y0 - XS*YL'$.

Examples

Perform Partial Least-Squares Regression

Load data on near infrared (NIR) spectral intensities of 60 samples of gasoline at 401 wavelengths, and their octane ratings.

```
load spectra
X = NIR;
y = octane;
```

Perform PLS regression with ten components.

```
[XL,yL,XS,YS,beta,PCTVAR] = plsregress(X,y,10);
```

Plot the percent of variance explained in the response variable as a function of the number of components.

```
plot(1:10,cumsum(100*PCTVAR(2,:)),'-bo');
xlabel('Number of PLS components');
ylabel('Percent Variance Explained in y');
```

Compute the fitted response and display the residuals.

```
yfit = [ones(size(X,1),1) X]*beta;
residuals = y - yfit;
stem(residuals)
xlabel('Observation');
ylabel('Residual');
```

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to `true` using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

See Also

`regress` | `sequentialfs`

Introduced in R2008a

PointSet property

Class: `qrandstream`

Point set from which stream is drawn

Description

The `PointSet` property contains a copy of the point set from which the stream is providing points. The point set is specified during construction of a quasi-random stream and cannot subsequently be altered.

Examples

```
Q = qrandstream('sobol', 5, 'Skip', 8);  
% Create a new stream based on the same sequence as that in Q  
Q2 = qrandstream(Q.PointSet);  
u1 = qrand(Q, 10)  
u2 = qrand(Q2, 10) % contains exactly the same values as u1
```

poisscdf

Poisson cumulative distribution function

Syntax

```
y = poisscdf(x,lambda)
y = poisscdf(x,lambda,'upper')
```

Description

`y = poisscdf(x,lambda)` computes the Poisson cumulative distribution function at each of the values in `x` using the rate parameters in `lambda`.

`x` and `lambda` can be scalars, vectors, matrices, or multidimensional arrays that all have the same size. If only one argument is a scalar, `poisscdf` expands it to a constant array with the same dimensions as the other argument.

`y = poisscdf(x,lambda,'upper')` returns the complement of the Poisson cumulative distribution function at each value in `x`, using an algorithm that computes the extreme upper tail probabilities more accurately.

Examples

Compute and Plot Poisson Cumulative Distribution Function

Compute and plot the Poisson cumulative distribution function for the specified range of integer values and average rate.

A computer hard disk manufacturing facility performs random tests of individual hard disks. The policy is to shut down the manufacturing process if an inspector finds more than four bad sectors on a disk. Assuming that on average a disk has two bad sectors, find the probability of a manufacturing process shutdown after the first inspection.

```
1 - poisscdf(4,2)
```

```
ans = 0.0527
```

Compute the probabilities a manufacturing process shutdown after the first inspection if on average a disk has 0, 1, 2, ..., 10 bad sectors.

```
lambda = 0:10;
y = 1 - poisscdf(4,lambda);
```

Plot the results.

```
scatter(lambda,y,'Marker','o')
grid on
```

Compute Extreme Upper Tail Probabilities

Compute the complement of the Poisson cumulative distribution function with more accurate upper tail probabilities.

A computer hard disk manufacturing facility performs random tests of individual hard disks. Assuming that on average a disk has 10 bad sectors, find the probability that a disk has more than 100 bad sectors.

```
format long
1 - poisscdf(100,10)
```

```
ans =
     0
```

This result shows that `poisscdf(100,10)` is so close to 1 (within `eps`) that subtracting it from 1 gives 0. To approximate the extreme upper tail probabilities better, compute the complement of the Poisson cumulative distribution function directly instead of computing the difference.

```
poisscdf(100,10,'upper')
ans =
 5.339405460719755e-64
```

Input Arguments

x — Values at which to evaluate Poisson cdf

scalar value | array of scalar values

Values at which to evaluate the Poisson cdf, specified as a scalar value or array of scalar values.

Example: [0, 1, 3, 4]

Data Types: `single` | `double`

lambda — Rate parameters

positive value | array of positive values

Rate parameters, specified as a positive value or array of positive values. The rate parameter indicates the average number of events in a given time interval.

Example: 2

Data Types: `single` | `double`

Output Arguments

y — Poisson cdf values

scalar value | array of scalar values

Poisson cdf values, returned as a scalar value or array of scalar values. Each element in **y** is the Poisson cdf value of the distribution evaluated at the corresponding element in **x**.

More About

Poisson Cumulative Distribution Function

The Poisson cumulative distribution function lets you obtain the probability of an event occurring within a given time or space interval less than or equal to x times if on average the event occurs λ times within that interval.

The Poisson cumulative distribution function for the given values x and λ is

$$p = F(x | \lambda) = e^{-\lambda} \sum_{i=0}^{\text{floor}(x)} \frac{\lambda^i}{i!}.$$

Alternative Functionality

- `poisscdf` is a function specific to Poisson distribution. Statistics and Machine Learning Toolbox also offers the generic function `cdf`, which supports various probability distributions. To use `cdf`, specify the probability distribution name and its parameters. Alternatively, create a `PoissonDistribution` probability distribution object and pass the object as an input argument. Note that the distribution-specific function `poisscdf` is faster than the generic function `cdf`.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

PoissonDistribution | cdf | poissfit | poissinv | poisspdf | poissrnd | poisstat

Topics

“Poisson Distribution” on page B-131

Introduced before R2006a

poissfit

Poisson parameter estimates

Syntax

```
lambdahat = poissfit(data)
[lambdahat, lambdaci] = poissfit(data)
[lambdahat, lambdaci] = poissfit(data, alpha)
```

Description

`lambdahat = poissfit(data)` returns the maximum likelihood estimate (MLE) of the parameter of the Poisson distribution, λ , given the data `data`.

`[lambdahat, lambdaci] = poissfit(data)` also gives 95% confidence intervals in `lambdaci`.

`[lambdahat, lambdaci] = poissfit(data, alpha)` gives $100(1 - \alpha)\%$ confidence intervals. For example `alpha = 0.001` yields 99.9% confidence intervals.

The sample mean is the MLE of λ .

$$\hat{\lambda} = \frac{1}{n} \sum_{i=1}^n x_i$$

Examples

```
r = poissrnd(5,10,2);
[l, lci] = poissfit(r)
l =
    7.4000    6.3000
lci =
    5.8000    4.8000
    9.1000    7.9000
```

Topics

“Poisson Distribution” on page B-131

Introduced before R2006a

poissinv

Poisson inverse cumulative distribution function

Syntax

```
X = poissinv(P,lambda)
```

Description

`X = poissinv(P,lambda)` returns the smallest value X such that the Poisson cdf evaluated at X equals or exceeds P , using mean parameters in `lambda`. P and `lambda` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input.

Examples

If the average number of defects (λ) is two, what is the 95th percentile of the number of defects?

```
poissinv(0.95,2)
ans =
     5
```

What is the median number of defects?

```
median_defects = poissinv(0.50,2)
median_defects =
     2
```

Extended Capabilities

Topics

“Poisson Distribution” on page B-131

Introduced before R2006a

poisspdf

Poisson probability density function

Syntax

```
y = poisspdf(x,lambda)
```

Description

`y = poisspdf(x,lambda)` computes the Poisson probability density function at each of the values in `x` using the rate parameters in `lambda`.

`x` and `lambda` can be scalars, vectors, matrices, or multidimensional arrays that all have the same size. If only one argument is a scalar, `poisspdf` expands it to a constant array with the same dimensions as the other argument.

Examples

Compute and Plot Poisson Probability Density Function

Compute and plot the Poisson probability density function for the specified range of integer values and average rate.

In the computer hard disk manufacturing process, flaws occur randomly. Assuming that on average a 4 GB hard disk has two flaws, compute the probability that a disk has no flaws.

```
poisspdf(0,2)
```

```
ans = 0.1353
```

Compute the Poisson probability density function values at each value from 0 to 10. These values correspond to the probabilities that a disk has 0, 1, 2, ..., 10 flaws.

```
flaws = 0:10;  
y = poisspdf(flaws,2);
```

Plot the resulting probability values.

```
scatter(flaws,y,'Marker','o')  
grid on
```

Input Arguments

x — Values at which to evaluate Poisson pdf

scalar value | array of scalar values

Values at which to evaluate the Poisson pdf, specified as a scalar value or array of scalar values. For noninteger values x , the Poisson probability density function is zero.

Example: `[0,1,3,4]`

Data Types: `single` | `double`

lambda — Rate parameters

positive value | array of positive values

Rate parameters, specified as a positive value or array of positive values. The rate parameter indicates the average number of events in a given time interval.

Example: `2`

Data Types: `single` | `double`

Output Arguments

y — Poisson pdf values

scalar value | array of scalar values

Poisson pdf values, returned as a scalar value or array of scalar values. Each element in y is the Poisson pdf value of the distribution evaluated at the corresponding element in x .

Data Types: `single` | `double`

More About

Poisson Probability Density Function

The Poisson probability density function lets you obtain the probability of an event occurring within a given time or space interval exactly x times if on average the event occurs λ times within that interval.

The Poisson probability density function for the given values x and λ is

$$f(x|\lambda) = \frac{\lambda^x}{x!} e^{-\lambda}; x = 0, 1, 2, \dots, \infty.$$

Alternative Functionality

- `poisspdf` is a function specific to Poisson distribution. Statistics and Machine Learning Toolbox also offers the generic function `pdf`, which supports various probability distributions. To use `pdf`, specify the probability distribution name and its parameters. Alternatively, create a `PoissonDistribution` probability distribution object and pass the object as an input argument. Note that the distribution-specific function `poisspdf` is faster than the generic function `pdf`.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Extended Capabilities

Topics

“Poisson Distribution” on page B-131

Introduced before R2006a

poissrnd

Random numbers from Poisson distribution

Syntax

```
r = poissrnd(lambda)
r = poissrnd(lambda,sz1,...,szN)
r = poissrnd(lambda,sz)
```

Description

`r = poissrnd(lambda)` generates random numbers from the Poisson distribution specified by the rate parameter `lambda`.

`lambda` can be a scalar, vector, matrix, or multidimensional array.

`r = poissrnd(lambda,sz1,...,szN)` generates an array of random numbers from the Poisson distribution with the scalar rate parameter `lambda`, where `sz1,...,szN` indicates the size of each dimension.

`r = poissrnd(lambda,sz)` generates an array of random numbers from the Poisson distribution with the scalar rate parameter `lambda`, where vector `sz` specifies `size(r)`.

Examples

Array of Random Numbers from Several Poisson Distributions

Generate an array of random numbers from the Poisson distributions. Specify the average rate for each distribution.

```
lambda = 10:2:20
```

```
lambda = 1×6
```

```
    10    12    14    16    18    20
```

Generate random numbers from the Poisson distributions.

```
r = poissrnd(lambda)
```

```
r = 1×6
```

```
    14    13    14     9    14    31
```

Array of Random Numbers from One Poisson Distribution

Generate an array of random numbers from one Poisson distribution. Here, the distribution parameter `lambda` is a scalar.

Use the `poissrnd` function to generate random numbers from the Poisson distribution with the average rate 20. The function returns one number.

```
r_scalar = poissrnd(20)
```

```
r_scalar = 9
```

Generate a 2-by-3 array of random numbers from the same distribution by specifying the required array dimensions.

```
r_array = poissrnd(20,2,3)
```

```
r_array = 2×3
```

```
    13    14    18
    26    16    21
```

Alternatively, specify the required array dimensions as a vector.

```
r_array = poissrnd(20,[2 3])
```

```
r_array = 2×3
```

```
    22    27    22
    25    19    21
```

Input Arguments

lambda — Rate parameters

positive value | array of positive values

Rate parameters, specified as a positive value or array of positive values. The rate parameter indicates the average number of events in a given time interval.

Example: 2

Data Types: `single` | `double`

sz1, ..., szN — Size of each dimension (as separate arguments)

integers

Size of each dimension, specified as separate arguments of integers. For example, specifying 5, 3, 2 generates a 5-by-3-by-2 array of random numbers from the Poisson probability distribution.

If `lambda` is an array, then the specified dimensions `sz1, ..., szN` must match the dimensions of `lambda`.

- If you specify a single value `sz1`, then `r` is a square matrix of size `sz1`-by-`sz1`.
- If the size of any dimension is 0 or negative, then `r` is an empty array.

- Beyond the second dimension, `poissrnd` ignores trailing dimensions with a size of 1. For example, `poissrnd(5,3,1,1,1)` produces a 3-by-1 vector of random numbers from the Poisson distribution with rate parameter 5.

Example: 5,3,2

Data Types: `single` | `double`

sz — Size of each dimension (as a row vector)

row vector of integers

Size of each dimension, specified as a row vector of integers. For example, specifying `[5 3 2]` generates a 5-by-3-by-2 array of random numbers from the Poisson probability distribution.

If `lambda` is an array, then the specified dimensions `sz` must match the dimensions of `lambda`.

- If you specify a single value `[sz1]`, then `r` is a square matrix of size `sz1`-by-`sz1`.
- If the size of any dimension is 0 or negative, then `r` is an empty array.
- Beyond the second dimension, `poissrnd` ignores trailing dimensions with a size of 1. For example, `poissrnd(5,[3,1,1,1])` produces a 3-by-1 vector of random numbers from the Poisson distribution with rate parameter 5.

Example: `[5 3 2]`

Data Types: `single` | `double`

Output Arguments

r — Random numbers from Poisson distribution

scalar value | array of scalar values

Random numbers from the Poisson distribution, returned as a scalar value or an array of scalar values.

Data Types: `single` | `double`

Alternative Functionality

- `poissrnd` is a function specific to Poisson distribution. Statistics and Machine Learning Toolbox also offers the generic function `random`, which supports various probability distributions. To use `random`, specify the probability distribution name and its parameters. Alternatively, create a `PoissonDistribution` probability distribution object and pass the object as an input argument. Note that the distribution-specific function `poissrnd` is faster than the generic function `random`.
- To generate random numbers interactively, use `randtool`, a user interface for random number generation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

poisstat

Poisson mean and variance

Syntax

```
M = poisstat(lambda)
[M,V] = poisstat(lambda)
```

Description

`M = poisstat(lambda)` returns the mean of the Poisson distribution using mean parameters in `lambda`. The size of `M` is the size of `lambda`.

`[M,V] = poisstat(lambda)` also returns the variance `V` of the Poisson distribution.

For the Poisson distribution with parameter λ , both the mean and variance are equal to λ .

Examples

Find the mean and variance for the Poisson distribution with $\lambda = 2$.

```
[m,v] = poisstat([1 2; 3 4])
m =
     1     2
     3     4
v =
     1     2
     3     4
```

Introduced before R2006a

polyconf

Polynomial confidence intervals

Syntax

```
Y = polyconf(p,X)
[Y,DELTA] = polyconf(p,X,S)
[Y,DELTA] = polyconf(p,X,S,param1,val1,param2,val2,...)
```

Description

`Y = polyconf(p,X)` evaluates the polynomial `p` at the values in `X`. `p` is a vector of coefficients in descending powers.

`[Y,DELTA] = polyconf(p,X,S)` takes outputs `p` and `S` from `polyfit` and generates 95% prediction intervals $Y \pm \text{DELTA}$ for new observations at the values in `X`.

`[Y,DELTA] = polyconf(p,X,S,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs chosen from the following list.

Parameter	Value
'alpha'	A value between 0 and 1 specifying a confidence level of $100*(1-\text{alpha})\%$. The default is 0.05.
'mu'	A two-element vector containing centering and scaling parameters. With this option, <code>polyconf</code> uses $(X-\text{mu}(1))/\text{mu}(2)$ in place of <code>X</code> .
'predopt'	Either 'observation' (the default) to compute prediction intervals for new observations at the values in <code>X</code> , or 'curve' to compute confidence intervals for the fit evaluated at the values in <code>X</code> . See below.
'simopt'	Either 'off' (the default) for nonsimultaneous bounds, or 'on' for simultaneous bounds. See below.

The 'predopt' and 'simopt' parameters can be understood in terms of the following functions:

- $p(x)$ — the unknown mean function estimated by the fit
- $l(x)$ — the lower confidence bound
- $u(x)$ — the upper confidence bound

Suppose you make a new observation y_{n+1} at x_{n+1} , so that

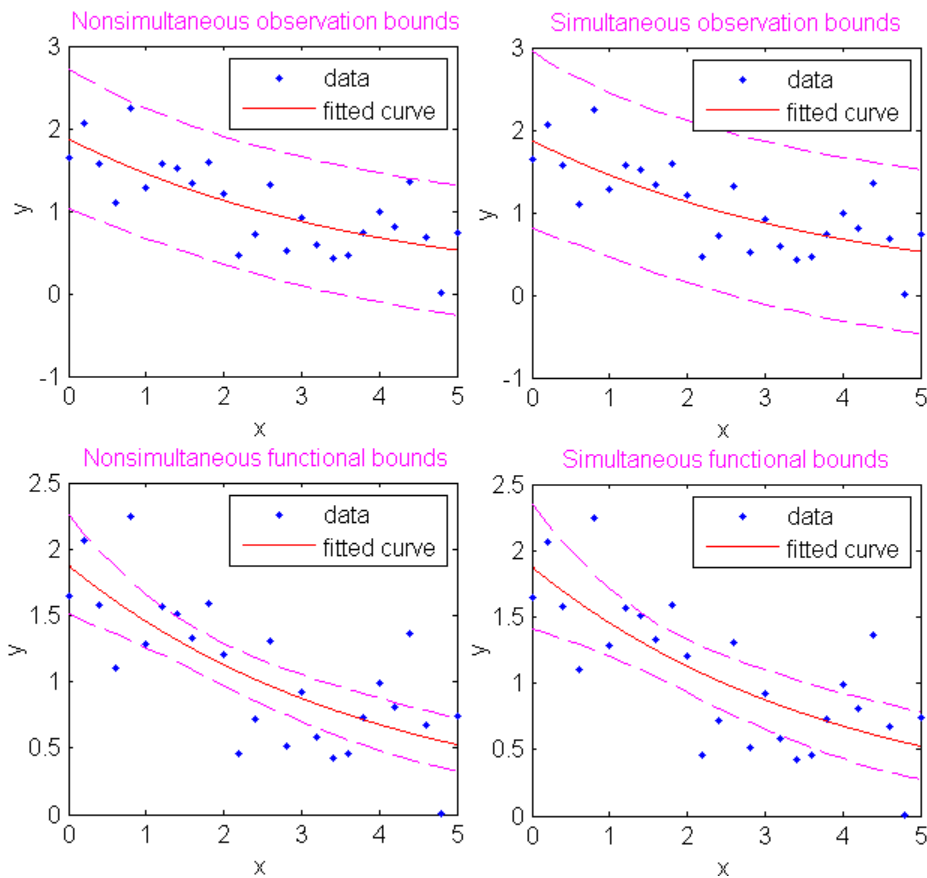

$$y_{n+1}(x_{n+1}) = p(x_{n+1}) + \varepsilon_{n+1}$$

By default, the interval $[l_{n+1}(x_{n+1}), u_{n+1}(x_{n+1})]$ is a 95% confidence bound on $y_{n+1}(x_{n+1})$.

The following combinations of the 'predopt' and 'simopt' parameters allow you to specify other bounds.

'simopt'	'predopt'	Bounded Quantity
'off'	'observation'	$y_{n+1}(x_{n+1})$ (default)
'off'	'curve'	$p(x_{n+1})$
'on'	'observation'	$y_{n+1}(x)$, for all x
'on'	'curve'	$p(x)$, for all x

In general, 'observation' intervals are wider than 'curve' intervals, because of the additional uncertainty of predicting a new response value (the curve plus random errors). Likewise, simultaneous intervals are wider than nonsimultaneous intervals, because of the additional uncertainty of bounding values for all predictors x .

Examples

This example uses code from the documentation example function `polydemo`, and calls the documentation example function `polystr` to convert the coefficient vector p into text for the polynomial expression displayed in the figure title. It combines the functions `polyfit`, `polyval`, `roots`, and `polyconf` to produce a formatted display of data with a polynomial fit.

Note Statistics and Machine Learning Toolbox documentation example files are located in the `\help\toolbox\stats\examples` subdirectory of your MATLAB root folder (`matlabroot`). This subdirectory is not on the MATLAB path at installation. To use the files in this subdirectory, either add

the subdirectory to the MATLAB path (`addpath`) or make the subdirectory your current working folder (`cd`).

Display simulated data with a quadratic trend, a fitted quadratic polynomial, and 95% prediction intervals for new observations:

```
xdata = -5:5;
ydata = xdata.^2 - 5*xdata - 3 + 5*randn(size(xdata));

degree = 2;          % Degree of the fit
alpha = 0.05;       % Significance level

% Compute the fit and return the structure used by
% POLYCONF.
[p,S] = polyfit(xdata,ydata,degree);

% Compute the real roots and determine the extent of the
% data.
r = roots(p)';          % Roots as a row vector.
real_r = r(imag(r) == 0); % Real roots.

% Assure that the data are row vectors.
xdata = reshape(xdata,1,length(xdata));
ydata = reshape(ydata,1,length(ydata));

% Extent of the data.
mx = min([real_r,xdata]);
Mx = max([real_r,xdata]);
my = min([ydata,0]);
My = max([ydata,0]);

% Scale factors for plotting.
sx = 0.05*(Mx-mx);
sy = 0.05*(My-my);

% Plot the data, the fit, and the roots.
hdata = plot(xdata,ydata,'md','MarkerSize',5,...
             'LineWidth',2);
hold on
xfit = mx-sx:0.01:Mx+sx;
yfit = polyval(p,xfit);
hfit = plot(xfit,yfit,'b-','LineWidth',2);
hroots = plot(real_r,zeros(size(real_r)),...
              'bo','MarkerSize',5,...
              'LineWidth',2,...
              'MarkerFaceColor','b');
grid on
plot(xfit,zeros(size(xfit)),'k-','LineWidth',2)
axis([mx-sx Mx+sx my-sy My+sy])

% Add prediction intervals to the plot.
[Y,DELTA] = polyconf(p,xfit,S,'alpha',alpha);
hconf = plot(xfit,Y+DELTA,'b--');
plot(xfit,Y-DELTA,'b--')

% Display the polynomial fit and the real roots.
```

```

approx_p = round(100*p)/100; % Round for display.
htitle = title(['\bf Fit:  '],...
              texlabel(polystr(approx_p)));
set(htitle,'Color','b')
approx_real_r = round(100*real_r)/100; % Round for display.
hxlabel = xlabel(['\bf Real Roots:  '],...
                num2str(approx_real_r));
set(hxlabel,'Color','b')

% Add a legend.
legend([hdata,hfit,hroots,hconf],...
      'Data','Fit','Real Roots of Fit',...
      '95% Prediction Intervals')

```

polyfit | polytool | polyval

Introduced before R2006a

polytool

Interactive polynomial fitting

Syntax

```
polytool(x,y)
polytool(x,y,n)
polytool(x,y,n,alpha)
polytool(x,y,n,alpha,xname,yname)
h = polytool(...)
```

Description

`polytool(x,y)` fits a line to the vectors `x` and `y` and displays an interactive plot of the result in a graphical interface. You can use the interface to explore the effects of changing the parameters of the fit and to export fit results to the workspace.

`polytool(x,y,n)` initially fits a polynomial of degree `n`. The default is 1, which produces a linear fit.

`polytool(x,y,n,alpha)` initially plots `100(1 - alpha)%` confidence intervals on the predicted values. The default is `0.05` which results in 95% confidence intervals.

`polytool(x,y,n,alpha,xname,yname)` labels the `x` and `y` values on the graphical interface using `xname` and `yname`. Specify `n` and `alpha` as `[]` to use their default values.

`h = polytool(...)` outputs a vector of handles, `h`, to the line objects in the plot. The handles are returned in the degree: data, fit, lower bounds, upper bounds.

Examples

Interactive polynomial fitting

This example shows how to start an interactive fitting session with `polytool`.

Generate data from a quadratic curve with added noise.

```
rng('default') % for reproducibility
x = -5:5;
y = x.^2 - 5*x - 3 + 5*randn(size(x));
```

Fit a quadratic (degree-2) model with `0.90` confidence intervals.

```
n = 2;
alpha = 0.1;
polytool(x,y,n,alpha)
```

Introduced before R2006a

posterior

Posterior probability of Gaussian mixture component

Syntax

```
P = posterior(gm,X)
[P,nlogL] = posterior(gm,X)
```

Description

`P = posterior(gm,X)` returns the posterior probability of each Gaussian mixture component in `gm` given each observation in `X`.

`[P,nlogL] = posterior(gm,X)` also returns the negative loglikelihood of the Gaussian mixture model `gm` given the data `X`.

Examples

Compute Posterior Probabilities

Generate random variates that follow a mixture of two bivariate Gaussian distributions by using the `mvnrnd` function. Fit a Gaussian mixture model (GMM) to the generated data by using the `fitgmdist` function, and then compute the posterior probabilities of the mixture components.

Define the distribution parameters (means and covariances) of two bivariate Gaussian mixture components.

```
mu1 = [2 2];           % Mean of the 1st component
sigma1 = [2 0; 0 1];  % Covariance of the 1st component
mu2 = [-2 -1];        % Mean of the 2nd component
sigma2 = [1 0; 0 1];  % Covariance of the 2nd component
```

Generate an equal number of random variates from each component, and combine the two sets of random variates.

```
rng('default') % For reproducibility
r1 = mvnrnd(mu1,sigma1,1000);
r2 = mvnrnd(mu2,sigma2,1000);
X = [r1; r2];
```

The combined data set `X` contains random variates following a mixture of two bivariate Gaussian distributions.

Fit a two-component GMM to `X`.

```
gm = fitgmdist(X,2)
```

```
gm =
```

```
Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
```

```
Mixing proportion: 0.500765
Mean:   -1.9675  -0.9654
```

```
Component 2:
Mixing proportion: 0.499235
Mean:    1.9657   2.0342
```

Plot X by using `scatter`. Visualize the fitted model `gm` by using `pdf` and `fcontour`.

```
figure
scatter(X(:,1),X(:,2),10, '.') % Scatter plot with points of size 10
hold on
gmPDF = @(x,y) reshape(pdf(gm,[x(:) y(:)]),size(x));
fcontour(gmPDF,[-6 8 -4 6])
c1 = colorbar;
ylabel(c1,'Probability Density Function')
```

Compute the posterior probabilities of the components.

```
P = posterior(gm,X);
```

$P(i, j)$ is the posterior probability of the j th Gaussian mixture component given observation i .

Plot the posterior probabilities of Component 1 by using the `scatter` function. Use the circle colors to visualize the posterior probability values.

```
figure
scatter(X(:,1),X(:,2),10,P(:,1))
```

```
c2 = colorbar;  
ylabel(c2, 'Posterior Probability of Component 1')
```

Plot the posterior probabilities of Component 2.

```
figure  
scatter(X(:,1),X(:,2),10,P(:,2))  
c3 = colorbar;  
ylabel(c3, 'Posterior Probability of Component 2')
```

Input Arguments

gm — Gaussian mixture distribution

`gmdistribution` object

Gaussian mixture distribution, also called Gaussian mixture model (GMM), specified as a `gmdistribution` object.

You can create a `gmdistribution` object using `gmdistribution` or `fitgmdist`. Use the `gmdistribution` function to create a `gmdistribution` object by specifying the distribution parameters. Use the `fitgmdist` function to fit a `gmdistribution` model to data given a fixed number of components.

X — Data

n -by- m numeric matrix

Data, specified as an n -by- m numeric matrix, where n is the number of observations and m is the number of variables in each observation.

If a row of X contains NaNs, then `posterior` excludes the row from the computation. The corresponding value in P is NaN.

Data Types: `single` | `double`

Output Arguments

P — Posterior probability

n-by-*k* numeric vector

Posterior probability of each Gaussian mixture component in `gm` given each observation in `X`, returned as an *n*-by-*k* numeric vector, where *n* is the number of observations in `X` and *k* is the number of mixture components in `gm`.

$P(i, j)$ is the posterior probability of the *j*th Gaussian mixture component given observation *i*, `Probability(component j | observation i)`.

nlogL — Negative loglikelihood

numeric value

Negative loglikelihood value of the Gaussian mixture model `gm` given the data `X`, returned as a numeric value.

Introduced in R2007b

postFitStatistics

Class: RegressionGP

Compute post-fit statistics for the exact Gaussian process regression model

Syntax

```
loores = postFitStatistics(gprMdl)
[loores,neff] = postFitStatistics(gprMdl)
```

Description

`loores = postFitStatistics(gprMdl)` returns the leave-one-out residuals, `loores`, for the trained Gaussian process regression (GPR) model.

`[loores,neff] = postFitStatistics(gprMdl)` also returns the number of effective parameters, `neff`.

Input Arguments

gprMdl — Gaussian process regression model

RegressionGP object

Gaussian process regression model, specified as a RegressionGP object.

Output Arguments

loores — Leave-one-out residuals

n-by-1 matrix

Leave-one-out residuals, returned as an *n*-by-1 matrix, where *n* is the number of observations in the training data.

neff — Number of effective parameters

n-by-1 matrix

Number of effective parameters, returned as an *n*-by-1 matrix, where *n* is the number of observations in the training data.

Examples

Compute Post-Fit Statistics

Generate sample data.

```
rng(0,'twister'); % For reproducibility
n = 1500;
x = linspace(-10,10,n)';
y = sin(3*x).*cos(3*x) + sin(2*x).*cos(2*x) + sin(x) + cos(x) + 0.2*randn(n,1);
```

Fit a GPR model using the exact method for fitting and prediction.

```
gprMdl = fitrgp(x,y,'Basis','linear','FitMethod','exact',...
    'PredictMethod','exact','KernelFunction','matern52');
```

Compute the leave-one-out residuals and the effective number of parameters in the trained model.

```
[loores,neff] = postFitStatistics(gprMdl);
```

Predict the responses using the trained model.

```
ypred = resubPredict(gprMdl);
```

Plot the true and predicted responses, and display effective number of parameters in the fit.

```
figure()
plot(x,y,'r. ');
hold on;
plot(x,ypred,'b');
xlabel('x');
ylabel('y');
legend('Data','GPR prediction','Location','Best');
title(['Effective number of parameters = ',num2str(neff)]);
hold off
```

Plot leave-one-out residuals.

```
figure()
plot(x,loores,'r.-');
```

```
xlabel('x');  
ylabel('leave-one-out residuals');
```

Tips

- You can only compute the post-fit statistics when `PredictMethod` is 'exact'.
- If `FitMethod` is 'exact', then `postFitStatistics` accounts for the fact that the fixed basis function coefficients are estimated from the data.
- If `FitMethod` is different than 'exact', then `postFitStatistics` treats the fixed basis function coefficients as known.
- For all `PredictMethod` and `FitMethod` options, `postFitStatistics` treats the estimated kernel parameters and noise standard deviation as known.

RegressionGP | fitrgp

Introduced in R2015b

prctile

Percentiles of a data set

Syntax

```
Y = prctile(X,p)
Y = prctile(X,p,'all')
Y = prctile(X,p,dim)
Y = prctile(X,p,vecdim)
Y = prctile( ____, 'Method', method)
```

Description

`Y = prctile(X,p)` returns percentiles of the elements in a data vector or array `X` for the percentages `p` in the interval `[0,100]`.

- If `X` is a vector, then `Y` is a scalar or a vector with the same length as the number of percentiles requested (`length(p)`). `Y(i)` contains the `p(i)` percentile.
- If `X` is a matrix, then `Y` is a row vector or a matrix, where the number of rows of `Y` is equal to the number of percentiles requested (`length(p)`). The `i`th row of `Y` contains the `p(i)` percentiles of each column of `X`.
- For multidimensional arrays on page 32-4136, `prctile` operates along the first nonsingleton dimension on page 32-4136 of `X`.

`Y = prctile(X,p,'all')` returns percentiles of all the elements of `X`.

`Y = prctile(X,p,dim)` returns percentiles along the operating dimension `dim`.

`Y = prctile(X,p,vecdim)` returns percentiles over the dimensions specified in the vector `vecdim`. For example, if `X` is a matrix, then `prctile(X,50,[1 2])` returns the 50th percentile of all the elements of `X` because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.

`Y = prctile(____, 'Method', method)` returns either exact or approximate percentiles based on the value of `method`, using any of the input argument combinations in the previous syntaxes.

Examples

Percentiles of a Data Vector

Generate a data set of size 10.

```
rng('default'); % for reproducibility
x = normrnd(5,2,1,10)
```

```
x = 1×10
```

```
    6.0753    8.6678    0.4823    6.7243    5.6375    2.3846    4.1328    5.6852    12.1568    10.5
```

Calculate the 42nd percentile.

```
Y = prctile(x,42)
```

```
Y = 5.6709
```

Percentiles of All Values

Find the percentiles of all the values in an array.

Create a 3-by-5-by-2 array X.

```
X = reshape(1:30,[3 5 2])
```

```
X =
```

```
X(:,:,1) =
```

```

     1     4     7    10    13
     2     5     8    11    14
     3     6     9    12    15
```

```
X(:,:,2) =
```

```

    16    19    22    25    28
    17    20    23    26    29
    18    21    24    27    30
```

Find the 40th and 60th percentiles of the elements of X.

```
Y = prctile(X,[40 60], 'all')
```

```
Y = 2x1
```

```

    12.5000
    18.5000
```

Y(1) is the 40th percentile of X, and Y(2) is the 60th percentile of X.

Percentiles of a Data Matrix

Calculate the percentiles along the columns and rows of a data matrix for specified percentages.

Generate a 5-by-5 data matrix.

```
X = (1:5)'*(2:6)
```

```
X = 5x5
```

```

     2     3     4     5     6
     4     6     8    10    12
```

```

6     9     12    15    18
8     12    16    20    24
10    15    20    25    30

```

Calculate the 25th, 50th, and 75th percentiles along the columns of X.

```
Y = prctile(X,[25 50 75],1)
```

```
Y = 3x5
```

```

3.5000    5.2500    7.0000    8.7500    10.5000
6.0000    9.0000   12.0000   15.0000   18.0000
8.5000   12.7500   17.0000   21.2500   25.5000

```

The rows of Y correspond to the percentiles of columns of X. For example, the 25th, 50th, and 75th percentiles of the third column of X with elements (4, 8, 12, 16, 20) are 7, 12, and 17, respectively. `Y = prctile(X,[25 50 75])` returns the same percentile matrix.

Calculate the 25th, 50th, and 75th percentiles along the rows of X.

```
Y = prctile(X,[25 50 75],2)
```

```
Y = 5x3
```

```

2.7500    4.0000    5.2500
5.5000    8.0000   10.5000
8.2500   12.0000   15.7500
11.0000   16.0000   21.0000
13.7500   20.0000   26.2500

```

The rows of Y correspond to the percentiles of rows of X. For example, the 25th, 50th, and 75th percentiles of the first row of X with elements (2, 3, 4, 5, 6) are 2.75, 4, and 5.25, respectively.

Percentiles of Multidimensional Array

Find the percentiles of a multidimensional array along multiple dimensions simultaneously.

Create a 3-by-5-by-2 array X.

```
X = reshape(1:30,[3 5 2])
```

```
X =
```

```
X(:,:,1) =
```

```

1     4     7    10    13
2     5     8    11    14
3     6     9    12    15

```

```
X(:,:,2) =
```

```

16    19    22    25    28
17    20    23    26    29

```

```
18    21    24    27    30
```

Calculate the 40th and 60th percentiles for each page of `X` by specifying dimensions 1 and 2 as the operating dimensions.

```
Ypage = prctile(X,[40 60],[1 2])
```

```
Ypage =
Ypage(:,:,1) =
```

```
6.5000
9.5000
```

```
Ypage(:,:,2) =
```

```
21.5000
24.5000
```

For example, `Ypage(1,1,1)` is the 40th percentile of the first page of `X`, and `Ypage(2,1,1)` is the 60th percentile of the first page of `X`.

Calculate the 40th and 60th percentiles of the elements in each `X(:,i,:)` slice by specifying dimensions 1 and 3 as the operating dimensions.

```
Ycol = prctile(X,[40 60],[1 3])
```

```
Ycol = 2x5
```

```
2.9000    5.9000    8.9000    11.9000    14.9000
16.1000   19.1000   22.1000   25.1000   28.1000
```

For example, `Ycol(1,4)` is the 40th percentile of the elements in `X(:,4,:)`, and `Ycol(2,4)` is the 60th percentile of the elements in `X(:,4,:)`.

Percentiles of Tall Vector for Given Percentage

Calculate exact and approximate percentiles of a tall column vector for a given percentage.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

Create a datastore for the `airlinesmall` data set. Treat 'NA' values as missing data so that `datastore` replaces them with NaN values. Specify to work with the `ArrTime` variable.

```
ds = datastore('airlinesmall.csv','TreatAsMissing','NA',...
    'SelectedVariableNames','ArrTime');
```

Create a tall table on top of the datastore, and extract the data from the tall table into a tall vector.

```
t = tall(ds) % Tall table
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 12).
```

```
t =
```

```
Mx1 tall table
```

```
ArrTime
```

```
-----
    735
   1124
   2218
   1431
    746
   1547
   1052
   1134
      :
      :
```

```
x = t{:, :} % Tall vector
```

```
x =
```

```
Mx1 tall double column vector
```

```
    735
   1124
   2218
   1431
    746
   1547
   1052
   1134
      :
      :
```

Calculate the exact 50th percentile of x . Because x is a tall column vector and p is a scalar, `prctile` returns the exact percentile value by default.

```
p = 50;
yExact = prctile(x,p)
```

```
yExact =
```

```
tall double
```

```
?
```

Calculate the approximate 50th percentile of x . Specify `'Method', 'approximate'` to use an approximation algorithm based on “T-Digest” on page 32-4137 for computing the percentile.

```
yApprox = prctile(x,p, 'Method', 'approximate')
```

```
yApprox =
```

```
MxNx... tall double array
```

```
? ? ? ...
? ? ? ...
? ? ? ...
: : :
: : :
```

Evaluate the tall arrays and bring the results into memory by using `gather`.

```
[yExact,yApprox] = gather(yExact,yApprox)
```

```
Evaluating tall expression using the Parallel Pool 'local':
```

```
- Pass 1 of 4: Completed in 11 sec
- Pass 2 of 4: Completed in 1.6 sec
- Pass 3 of 4: Completed in 3.2 sec
- Pass 4 of 4: Completed in 1.8 sec
Evaluation completed in 24 sec
```

```
yExact = 1522
```

```
yApprox = 1.5220e+03
```

The values of the approximate percentile and the exact percentile are the same to the four digits shown.

Percentiles of Tall Matrix Along Different Dimensions

Calculate exact and approximate percentiles of a tall matrix for specified percentages along different dimensions.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

Create a tall matrix `X` containing a subset of variables from the `airlinesmall` data set. See “Percentiles of Tall Vector for Given Percentage” on page 32-4131 for details about the steps to extract data from a tall array.

```
varnames = {'ArrDelay','ArrTime','DepTime','ActualElapsedTime'}; % Subset of variables in the da
ds = datastore('airlinesmall.csv','TreatAsMissing','NA',...
    'SelectedVariableNames',varnames); % Datastore
t = tall(ds); % Tall table
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 12).
```

```
X = t{:,varnames} % Tall matrix
```

```
X =
```

```
Mx4 tall double matrix
```

```
      8      735      642      53
      8     1124     1021      63
```

```

21      2218      2055      83
13      1431      1332      59
4        746      629      77
59      1547      1446      61
3        1052      928      84
11      1134      859      155
:        :        :        :
:        :        :        :

```

When operating along a dimension that is not 1, the `prctile` function calculates the exact percentiles only, so that it can perform the computation efficiently using a sorting-based algorithm (see “Algorithms” on page 32-4138) instead of an approximation algorithm based on “T-Digest” on page 32-4137.

Calculate the exact 25th, 50th, and 75th percentiles of `X` along the second dimension.

```

p = [25 50 75]; % Vector of percentages
Yexact = prctile(X,p,2)

```

```

Yexact =

```

```

MxNx... tall double array

```

```

? ? ? ...
? ? ? ...
? ? ? ...
: : :
: : :

```

When the function operates along the first dimension and `p` is a vector of percentages, you must use the approximation algorithm based on `t-digest` to compute the percentiles. Using the sorting-based algorithm to find the percentiles along the first dimension of a tall array is computationally intensive.

Calculate the approximate 25th, 50th, and 75th percentiles of `X` along the first dimension. Because the default dimension is 1, you do not need to specify a value for `dim`.

```

Yapprox = prctile(X,p,'Method','approximate')

```

```

Yapprox =

```

```

MxNx... tall double array

```

```

? ? ? ...
? ? ? ...
? ? ? ...
: : :
: : :

```

Evaluate the tall arrays and bring the results into memory by using `gather`.

```

[Yexact,Yapprox] = gather(Yexact,Yapprox);

```

```

Evaluating tall expression using the Parallel Pool 'local':

```

```

- Pass 1 of 1: Completed in 24 sec

```

```

Evaluation completed in 32 sec

```

Show the first five rows of the exact 25th, 50th, and 75th percentiles along the second dimension of `X`.

```
Yexact(1:5,:)

```

```
ans = 5x3
103 ×

```

```
    0.0305    0.3475    0.6885
    0.0355    0.5420    1.0725
    0.0520    1.0690    2.1365
    0.0360    0.6955    1.3815
    0.0405    0.3530    0.6875

```

Each row of the matrix `Yexact` contains the three percentiles of the corresponding row in `X`. For example, 30.5, 347.5, and 688.5 are the 25th, 50th, and 75th percentiles, respectively, of the first row in `X`.

Show the approximate 25th, 50th, and 75th percentiles of `X` along the first dimension.

```
Yapprox

```

```
Yapprox = 3x4
103 ×

```

```
   -0.0070    1.1149    0.9322    0.0700
         0     1.5220    1.3350    0.1020
    0.0110    1.9180    1.7400    0.1510

```

Each column of the matrix `Yapprox` corresponds to the three percentiles for each column of the matrix `X`. For example, the first column of `Yapprox` with elements (-7, 0, 11) contains the percentiles for the first column of `X`.

Input Arguments

X — Input data

vector | array

Input data, specified as a vector or array.

Data Types: double | single

p — Percentages

scalar | vector

Percentages for which to compute percentiles, specified as a scalar or vector of scalars from 0 to 100.

Example: 25

Example: [25, 50, 75]

Data Types: double | single

dim — Dimension

positive integer

Dimension along which the percentiles of `X` are requested, specified as a positive integer. For example, for a matrix `X`, when `dim = 1`, `prctile` returns the percentile(s) of the columns of `X`; when

$\text{dim} = 2$, `prctile` returns the percentile(s) of the rows of X . For a multidimensional array X , the length of the dimth dimension of Y is equal to the length of p .

Data Types: `double` | `single`

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array X . The output Y has length `length(p)` in the smallest specified operating dimension (that is, dimension `min(vecdim)`) and has length 1 in each of the remaining operating dimensions. The other dimension lengths are the same for X and Y .

For example, consider a 2-by-3-by-3 array X with $p = [20 \ 40 \ 60 \ 80]$. In this case, `prctile(X,p,[1 2])` returns an array, where each page of the array contains the 20th, 40th, 60th, and 80th percentiles of the elements of the corresponding page of X . Because 1 and 2 are the operating dimensions, with `min([1 2]) = 1` and `length(p) = 4`, the output is a 4-by-1-by-3 array.

Data Types: `single` | `double`

method — Method for calculating percentiles

'exact' (default) | 'approximate'

Method for calculating percentiles, specified as 'exact' or 'approximate'. By default, `prctile` returns the exact percentiles by implementing an algorithm on page 32-4138 that uses sorting. You can specify 'method', 'approximate' for `prctile` to return approximate percentiles by implementing an algorithm that uses T-Digest on page 32-4137.

Data Types: `char` | `string`

Output Arguments

Y — Percentiles

scalar | array

Percentiles of a data vector or array, returned as a scalar or array for one or more percentage values.

- If X is a vector, then Y is a scalar or a vector with the same length as the number of percentiles requested (`length(p)`). $Y(i)$ contains the $p(i)$ th percentile.
- If X is an array of dimension d , then Y is an array with the length of the smallest operating dimension equal to the number of percentiles requested (`length(p)`).

More About

Multidimensional Array

A *multidimensional array* is an array with more than two dimensions. For example, if X is a 1-by-3-by-4 array, then X is a 3-D array.

Nonsingleton Dimension

A *nonsingleton dimension* of an array is a dimension whose size is not equal to 1. A *first nonsingleton dimension* of an array is the first dimension that satisfies the nonsingleton condition. For example, if X is a 1-by-1-by-2-by-4 array, then the third dimension is the first nonsingleton dimension of X .

Linear Interpolation

Linear interpolation uses linear polynomials to find $y_i = f(x_i)$, the values of the underlying function $Y = f(X)$ at the points in the vector or array x . Given the data points (x_1, y_1) and (x_2, y_2) , where $y_1 = f(x_1)$ and $y_2 = f(x_2)$, linear interpolation finds $y = f(x)$ for a given x between x_1 and x_2 as follows:

$$y = f(x) = y_1 + \frac{(x - x_1)}{(x_2 - x_1)}(y_2 - y_1).$$

Similarly, if the $100(1.5/n)$ th percentile is $y_{1.5/n}$ and the $100(2.5/n)$ th percentile is $y_{2.5/n}$, then linear interpolation finds the $100(2.3/n)$ th percentile, $y_{2.3/n}$ as:

$$y_{\frac{2.3}{n}} = y_{\frac{1.5}{n}} + \frac{\left(\frac{2.3}{n} - \frac{1.5}{n}\right)}{\left(\frac{2.5}{n} - \frac{1.5}{n}\right)}\left(y_{\frac{2.5}{n}} - y_{\frac{1.5}{n}}\right).$$

T-Digest

T-digest[2] on page 32-4139 is a probabilistic data structure that is a sparse representation of the empirical cumulative distribution function (CDF) of a data set. T-digest is useful for computing approximations of rank-based statistics (such as percentiles and quantiles) from online or distributed data in a way that allows for controllable accuracy, particularly near the tails of the data distribution.

For data that is distributed in different partitions, t-digest computes quantile estimates (and percentile estimates) for each data partition separately, and then combines the estimates while maintaining a constant-memory bound and constant relative accuracy of computation ($q(1 - q)$ for the q th quantile). For these reasons, t-digest is practical for working with tall arrays.

To estimate quantiles of an array that is distributed in different partitions, first build a t-digest in each partition of the data. A t-digest clusters the data in the partition and summarizes each cluster by a centroid value and an accumulated weight that represents the number of samples contributing to the cluster. T-digest uses large clusters (widely spaced centroids) to represent areas of the CDF that are near $q = 0.5$ and uses small clusters (tightly spaced centroids) to represent areas of the CDF that are near $q = 0$ or $q = 1$.

T-digest controls the cluster size by using a scaling function that maps a quantile q to an index k with a compression parameter δ . That is,

$$k(q, \delta) = \delta \cdot \left(\frac{\sin^{-1}(2q - 1)}{\pi} + \frac{1}{2} \right),$$

where the mapping k is monotonic with minimum value $k(0, \delta) = 0$ and maximum value $k(1, \delta) = \delta$. The following figure shows the scaling function for $\delta = 10$.

The scaling function translates the quantile q to the scaling factor k in order to give variable size steps in q . As a result, cluster sizes are unequal (larger around the center quantiles and smaller near $q = 0$ or $q = 1$). The smaller clusters allow for better accuracy near the edges of the data.

To update a t-digest with a new observation that has a weight and location, find the cluster closest to the new observation. Then, add the weight and update the centroid of the cluster based on the weighted average, provided that the updated weight of the cluster does not exceed the size limitation.

You can combine independent t-digests from each partition of the data by taking a union of the t-digests and merging their centroids. To combine t-digests, first sort the clusters from all the independent t-digests in decreasing order of cluster weights. Then, merge neighboring clusters, when they meet the size limitation, to form a new t-digest.

Once you form a t-digest that represents the complete data set, you can estimate the end-points (or boundaries) of each cluster in the t-digest and then use interpolation between the end-points of each cluster to find accurate quantile estimates.

Algorithms

For an n -element vector X , `prctile` returns percentiles by using a sorting-based algorithm as follows:

- 1 The sorted elements in X are taken as the $100(0.5/n)$ th, $100(1.5/n)$ th, ..., $100([n - 0.5]/n)$ th percentiles. For example:

- For a data vector of five elements such as {6, 3, 2, 10, 1}, the sorted elements {1, 2, 3, 6, 10} respectively correspond to the 10th, 30th, 50th, 70th, and 90th percentiles.
 - For a data vector of six elements such as {6, 3, 2, 10, 8, 1}, the sorted elements {1, 2, 3, 6, 8, 10} respectively correspond to the (50/6)th, (150/6)th, (250/6)th, (350/6)th, (450/6)th, and (550/6)th percentiles.
- 2 `prctile` uses linear interpolation on page 32-4137 to compute percentiles for percentages between $100(0.5/n)$ and $100([n - 0.5]/n)$.
 - 3 `prctile` assigns the minimum or maximum values of the elements in `X` to the percentiles corresponding to the percentages outside that range.

`prctile` treats NaNs as missing values and removes them.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- `Y = prctile(X,p)` returns the exact percentiles (using a sorting-based algorithm on page 32-4138) only if `X` is a tall column vector.
- `Y = prctile(X,p,dim)` returns the exact percentiles only when *one* of these conditions exists:
 - `X` is a tall column vector.
 - `X` is a tall array and `dim` is not 1. For example, `prctile(X,p,2)` returns the exact percentiles along the rows of the tall array `X`.

If `X` is a tall array and `dim` is 1, then you must specify `'Method','approximate'` to use an approximation algorithm based on T-Digest on page 32-4137 for computing the percentiles. For example, `prctile(X,p,1,'Method','approximate')` returns the approximate percentiles along the columns of the tall array `X`.

- `Y = prctile(X,p,vecdim)` returns the exact percentiles only when *one* of these conditions exists:
 - `X` is a tall column vector.
 - `X` is a tall array and `vecdim` does not include 1. For example, if `X` is a 3-by-5-by-2 array, then `prctile(X,p,[2,3])` returns the exact percentiles of the elements in each `X(i,:,:) slice`.
 - `X` is a tall array and `vecdim` includes 1 and all the nonsingleton dimensions on page 32-4136 of `X`. For example, if `X` is a 10-by-1-by-4 array, then `prctile(X,p,[1 3])` returns the exact percentiles of the elements in `X(:,1,:)`.

If `X` is a tall array and `vecdim` includes 1 but does not include all the nonsingleton dimensions of `X`, then you must specify `'Method','approximate'` to use the approximation algorithm. For

example, if `X` is a 10-by-1-by-4 array, you can use `prctile(X,p,[1 2], 'Method', 'approximate')` to find the approximate percentiles of each page of `X`.

For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The 'all' and `vecdim` input arguments are not supported.
- The 'Method' name-value pair argument is not supported.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).
- If the output `Y` is a vector, the orientation of `Y` differs from MATLAB when all of the following are true:
 - You do not supply `dim`.
 - `X` is a variable-size array, and not a variable-size vector, at compile time, but `X` is a vector at run time.
 - The orientation of the vector `X` does not match the orientation of the vector `p`.

In this case, the output `Y` matches the orientation of `X`, not the orientation of `p`.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'all' and `vecdim` input arguments are not supported.
- The 'Method' name-value pair argument is not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Quantiles and Percentiles” on page 3-6

Introduced before R2006a

predict

Predict labels using *k*-nearest neighbor classification model

Syntax

```
label = predict mdl,X
[label,score,cost] = predict mdl,X
```

Description

`label = predict(mdl,X)` returns a vector of predicted class labels for the predictor data in the table or matrix *X*, based on the trained *k*-nearest neighbor classification model *mdl*. See “Predicted Class Label” on page 32-4143.

`[label,score,cost] = predict(mdl,X)` also returns:

- A matrix of classification scores (*score*) indicating the likelihood that a label comes from a particular class. For *k*-nearest neighbor, scores are posterior probabilities. See “Posterior Probability” on page 32-4144.
- A matrix of expected classification cost (*cost*). For each observation in *X*, the predicted class label corresponds to the minimum expected classification costs among all classes. See “Expected Cost” on page 32-4144.

Examples

k-Nearest Neighbor Classification Predictions

Create a *k*-nearest neighbor classifier for Fisher's iris data, where *k* = 5. Evaluate some model predictions on new data.

Load the Fisher iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Create a classifier for five nearest neighbors. Standardize the noncategorical predictor data.

```
mdl = fitcknn(X,Y,'NumNeighbors',5,'Standardize',1);
```

Predict the classifications for flowers with minimum, mean, and maximum characteristics.

```
Xnew = [min(X);mean(X);max(X)];
[label,score,cost] = predict(mdl,Xnew)
```

```
label = 3x1 cell
    {'versicolor'}
    {'versicolor'}
    {'virginica' }
```

```
score = 3×3
  0.4000  0.6000  0
  0      1.0000  0
  0      0      1.0000
```

```
cost = 3×3
  0.6000  0.4000  1.0000
  1.0000  0      1.0000
  1.0000  1.0000  0
```

The second and third rows of the score and cost matrices have binary values, which means all five nearest neighbors of the mean and maximum flower measurements have identical classifications.

Input Arguments

mdl — *k*-nearest neighbor classifier model

ClassificationKNN object

k-nearest neighbor classifier model, specified as a ClassificationKNN object.

X — Predictor data to be classified

numeric matrix | table

Predictor data to be classified, specified as a numeric matrix or table.

Each row of *X* corresponds to one observation, and each column corresponds to one variable.

- For a numeric matrix:
 - The variables that make up the columns of *X* must have the same order as the predictor variables used to train *mdl*.
 - If you train *mdl* using a table (for example, Tbl), then *X* can be a numeric matrix if Tbl contains all numeric predictor variables. *k*-nearest neighbor classification requires homogeneous predictors. Therefore, to treat all numeric predictors in Tbl as categorical during training, set 'CategoricalPredictors', 'all' when you train using `fitcknn`. If Tbl contains heterogeneous predictors (for example, numeric and categorical data types) and *X* is a numeric matrix, then `predict` throws an error.
- For a table:
 - `predict` does not support multicolumn variables and cell arrays other than cell arrays of character vectors.
 - If you train *mdl* using a table (for example, Tbl), then all predictor variables in *X* must have the same variable names and data types as those used to train *mdl* (stored in `mdl.PredictorNames`). However, the column order of *X* does not need to correspond to the column order of Tbl. Both Tbl and *X* can contain additional variables (response variables, observation weights, and so on), but `predict` ignores them.
 - If you train *mdl* using a numeric matrix, then the predictor names in `mdl.PredictorNames` and corresponding predictor variable names in *X* must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `fitcknn`. All

predictor variables in X must be numeric vectors. X can contain additional variables (response variables, observation weights, and so on), but `predict` ignores them.

If you set `'Standardize', true` in `fitcknn` to train `mdl`, then the software standardizes the columns of X using the corresponding means in `mdl.Mu` and standard deviations in `mdl.Sigma`.

Data Types: `double` | `single` | `table`

Output Arguments

label — Predicted class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Predicted class labels for the observations (rows) in X , returned as a categorical array, character array, logical vector, vector of numeric values, or cell array of character vectors. `label` has length equal to the number of rows in X . The label is the class with minimal expected cost. See “Predicted Class Label” on page 32-4143.

score — Predicted class scores or posterior probabilities

numeric matrix

Predicted class scores or posterior probabilities, returned as a numeric matrix of size n -by- K . n is the number of observations (rows) in X , and K is the number of classes (in `mdl.ClassNames`).

`score(i, j)` is the posterior probability that observation i in X is of class j in `mdl.ClassNames`. See “Posterior Probability” on page 32-4144.

Data Types: `single` | `double`

cost — Expected classification costs

numeric matrix

Expected classification costs, returned as a numeric matrix of size n -by- K . n is the number of observations (rows) in X , and K is the number of classes (in `mdl.ClassNames`). `cost(i, j)` is the cost of classifying row i of X as class j in `mdl.ClassNames`. See “Expected Cost” on page 32-4144.

Data Types: `single` | `double`

Algorithms

Predicted Class Label

`predict` classifies by minimizing the expected classification cost:

$$\hat{y} = \underset{y = 1, \dots, K}{\operatorname{argmin}} \sum_{j=1}^K \hat{P}(j|x)C(y|j),$$

where

- \hat{y} is the predicted classification.
- K is the number of classes.
- $\hat{P}(j|x)$ is the posterior probability of class j for observation x .

- $C(y|j)$ is the cost of classifying an observation as y when its true class is j .

Posterior Probability

Consider a vector (single query point) x_{new} and a model mdl .

- k is the number of nearest neighbors used in prediction, $\text{mdl}.\text{NumNeighbors}$.
- $\text{nb}(\text{mdl}, x_{\text{new}})$ specifies the k nearest neighbors to x_{new} in $\text{mdl}.X$.
- $Y(\text{nb})$ specifies the classifications of the points in $\text{nb}(\text{mdl}, x_{\text{new}})$, namely $\text{mdl}.Y(\text{nb})$.
- $W(\text{nb})$ specifies the weights of the points in $\text{nb}(\text{mdl}, x_{\text{new}})$.
- prior specifies the priors of the classes in $\text{mdl}.Y$.

If the model contains a vector of prior probabilities, then the observation weights W are normalized by class to sum to the priors. This process might involve a calculation for the point x_{new} , because weights can depend on the distance from x_{new} to the points in $\text{mdl}.X$.

The posterior probability $p(j|x_{\text{new}})$ is

$$p(j|x_{\text{new}}) = \frac{\sum_{i \in \text{nb}} W(i) 1_{Y(X(i))=j}}{\sum_{i \in \text{nb}} W(i)}.$$

Here, $1_{Y(X(i))=j}$ is 1 when $\text{mdl}.Y(i) = j$, and 0 otherwise.

True Misclassification Cost

Two costs are associated with KNN classification: the true misclassification cost per class and the expected misclassification cost per observation.

You can set the true misclassification cost per class by using the 'Cost' name-value pair argument when you run `fitcknn`. The value $\text{Cost}(i, j)$ is the cost of classifying an observation into class j if its true class is i . By default, $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$. In other words, the cost is 0 for correct classification and 1 for incorrect classification.

Expected Cost

Two costs are associated with KNN classification: the true misclassification cost per class and the expected misclassification cost per observation. The third output of `predict` is the expected misclassification cost per observation.

Suppose you have Nobs observations that you want to classify with a trained classifier mdl , and you have K classes. You place the observations into a matrix X_{new} with one observation per row. The command

```
[label, score, cost] = predict(mdl, Xnew)
```

returns a matrix `cost` of size Nobs -by- K , among other outputs. Each row of the `cost` matrix contains the expected (average) cost of classifying the observation into each of the K classes. $\text{cost}(n, j)$ is

$$\sum_{i=1}^K \hat{P}(i|X_{\text{new}}(n))C(j|i),$$

where

- K is the number of classes.
- $\hat{P}(i|X_{new}(n))$ is the posterior probability on page 32-4144 of class i for observation $X_{new}(n)$.
- $C(j|i)$ is the true misclassification cost of classifying an observation as j when its true class is i .

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen` to generate code for the `predict` function. Save a trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
mdl	<ul style="list-style-type: none"> • A <code>ClassificationKNN</code> model object is a full object that does not have a corresponding compact object. For this model, <code>saveLearnerForCoder</code> saves a compact version that does not include the hyperparameter optimization properties. • If <code>mdl</code> is a model trained using the <code>kd-tree</code> search algorithm, and the code generation build type is a MEX function, then <code>codegen</code> generates a MEX function using Intel Threading Building Blocks (TBB) for parallel computation. Otherwise, <code>codegen</code> generates code using <code>parfor</code>. <ul style="list-style-type: none"> • MEX function for the <code>kd-tree</code> search algorithm — <code>codegen</code> generates an optimized MEX function using Intel TBB for parallel computation on multicore platforms. You can use the MEX function to accelerate MATLAB algorithms. For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb. <p>If you generate the MEX function to test the generated code of the <code>parfor</code> version, you can disable the usage of Intel TBB. Set the <code>ExtrinsicCalls</code> property of the MEX configuration object to <code>false</code>. For details, see <code>coder.MexCodeConfig</code>.</p> • MEX function for the exhaustive search algorithm and standalone C/C++ code for both algorithms — The generated code of <code>predict</code> uses <code>parfor</code> to create loops that run in parallel on supported shared-memory multicore platforms in the generated code. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the <code>parfor</code>-loops as <code>for</code>-loops. To find supported compilers, see https://www.mathworks.com/support/compilers/current_release/. To disable OpenMP library, set the <code>EnableOpenMP</code> property of the configuration object to <code>false</code>. For details, see <code>coder.CodeConfig</code>. • For the usage notes and limitations of the model object, see “Code Generation” on page 32-382 of the <code>ClassificationKNN</code> object.

Argument	Notes and Limitations
X	<ul style="list-style-type: none"> For general code generation, X must be a single-precision or double-precision matrix or a table containing single or double predictor variables. <p>If you want to specify X as a table, then your model must be trained using a table, and you must ensure that your entry-point function for prediction:</p> <ul style="list-style-type: none"> Accepts data as arrays Creates a table from the data input arguments and specifies the variable names in the table Passes the table to <code>predict</code> <p>For an example of this table workflow, see “Generate Code to Classify Numeric Data in Table” on page 31-88. For more information on using tables in code generation, see “Code Generation for Tables” (MATLAB Coder) and “Table Limitations for Code Generation” (MATLAB Coder).</p> <ul style="list-style-type: none"> The number of rows, or observations, in X can be a variable size, but the number of columns in X must be fixed.

Introduced in R2012a

predict

Class: ClassificationLinear

Predict labels for linear classification models

Syntax

```
Label = predict(Mdl,X)
Label = predict(Mdl,X,Name,Value)
[Label,Score] = predict( ___ )
```

Description

`Label = predict(Mdl,X)` returns predicted class labels for each observation in the predictor data `X` based on the trained, binary, linear classification model `Mdl`. `Label` contains class labels for each regularization strength in `Mdl`.

`Label = predict(Mdl,X,Name,Value)` returns predicted class labels with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify that columns in the predictor data correspond to observations.

`[Label,Score] = predict(___)` also returns classification scores on page 32-4158 for both classes using any of the previous syntaxes. `Score` contains classification scores for each regularization strength in `Mdl`.

Input Arguments

Mdl — Binary, linear classification model

ClassificationLinear model object

Binary, linear classification model, specified as a `ClassificationLinear` model object. You can create a `ClassificationLinear` model object using `fitclinear`.

X — Predictor data

full matrix | sparse matrix

Predictor data, specified as an n -by- p full or sparse matrix. This orientation of `X` indicates that rows correspond to individual observations, and columns correspond to individual predictor variables.

Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in computation time.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

ObservationsIn — Predictor data observation dimension

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in optimization-execution time.

Output Arguments

Label — Predicted class labels

categorical array | character array | logical matrix | numeric matrix | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric matrix, or cell array of character vectors.

In most cases, `Label` is an n -by- L array of the same data type as the observed class labels (`Y`) used to train `Mdl`. (The software treats string arrays as cell arrays of character vectors.) n is the number of observations in `X` and L is the number of regularization strengths in `Mdl.Lambda`. That is, `Label(i, j)` is the predicted class label for observation i using the linear classification model that has regularization strength `Mdl.Lambda(j)`.

If `Y` is a character array and $L > 1$, then `Label` is a cell array of class labels.

Score — Classification scores

numeric array

Classification scores on page 32-4158, returned as a n -by-2-by- L numeric array. n is the number of observations in `X` and L is the number of regularization strengths in `Mdl.Lambda`. `Score(i, k, j)` is the score for classifying observation i into class k using the linear classification model that has regularization strength `Mdl.Lambda(j)`. `Mdl.ClassNames` stores the order of the classes.

If `Mdl.Learner` is 'logistic', then classification scores are posterior probabilities.

Examples

Predict Training-Sample Labels

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Train a binary, linear classification model using the entire data set, which can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```
rng(1); % For reproducibility  
Mdl = fitclinear(X,Ystats);
```

Mdl is a ClassificationLinear model.

Predict the training-sample, or resubstitution, labels.

```
label = predict(Mdl,X);
```

Because there is one regularization strength in Mdl, label is column vectors with lengths equal to the number of observations.

Construct a confusion matrix.

```
ConfusionTrain = confusionchart(Ystats,label);
```

The model misclassifies only one 'stats' documentation page as being outside of the Statistics and Machine Learning Toolbox documentation.

Predict Test-Sample Labels

Load the NLP data set and preprocess it as in “Predict Training-Sample Labels” on page 32-4149. Transpose the predictor data matrix.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Train a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation. Specify to hold out 30% of the observations. Optimize the objective function using SpARSA.

```
rng(1) % For reproducibility
CVMdl = fitclinear(X,Ystats,'Solver','sparsa','Holdout',0.30,...
    'ObservationsIn','columns');
Mdl = CVMdl.Trained{1};
```

CVMdl is a ClassificationPartitionedLinear model. It contains the property Trained, which is a 1-by-1 cell array holding a ClassificationLinear model that the software trained using the training set.

Extract the training and test data from the partition definition.

```
trainIdx = training(CVMdl.Partition);
testIdx = test(CVMdl.Partition);
```

Predict the training- and test-sample labels.

```
labelTrain = predict(Mdl,X(:,trainIdx),'ObservationsIn','columns');
labelTest = predict(Mdl,X(:,testIdx),'ObservationsIn','columns');
```

Because there is one regularization strength in Mdl, labelTrain and labelTest are column vectors with lengths equal to the number of training and test observations, respectively.

Construct a confusion matrix for the training data.

```
ConfusionTrain = confusionchart(Ystats(trainIdx),labelTrain);
```

The model misclassifies only three documentation pages as being outside of Statistics and Machine Learning Toolbox documentation.

Construct a confusion matrix for the test data.

```
ConfusionTest = confusionchart(Ystats(testIdx), labelTest);
```

True Class	false	9003	2
	true	3	463
		false	true
		Predicted Class	

The model misclassifies three documentation pages as being outside the Statistics and Machine Learning Toolbox, and two pages as being inside.

Estimate Posterior Class Probabilities

Estimate test-sample, posterior class probabilities, and determine the quality of the model by plotting a ROC curve. Linear classification models return posterior probabilities for logistic regression learners only.

Load the NLP data set and preprocess it as in “Predict Test-Sample Labels” on page 32-4151.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Randomly partition the data into training and test sets by specifying a 30% holdout sample. Identify the test-set indices.

```
cvp = cvpartition(Ystats, 'Holdout', 0.30);
idxTest = test(cvp);
```

Train a binary linear classification model. Fit logistic regression learners using SpARSA. To hold out the test set, specify the partitioned model.

```
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns','CVPartition',cvp,...  
    'Learner','logistic','Solver','sparsa');  
Mdl = CVMdl.Trained{1};
```

Mdl is a `ClassificationLinear` model trained using the training set specified in the partition `cvp` only.

Predict the test-sample posterior class probabilities.

```
[~,posterior] = predict(Mdl,X(:,idxTest),'ObservationsIn','columns');
```

Because there is one regularization strength in Mdl, `posterior` is a matrix with 2 columns and rows equal to the number of test-set observations. Column *i* contains posterior probabilities of `Mdl.ClassNames(i)` given a particular observation.

Obtain false and true positive rates, and estimate the AUC. Specify that the second class is the positive class.

```
[fpr,tpr,~,auc] = perfcurve(Ystats(idxTest),posterior(:,2),Mdl.ClassNames(2));  
auc
```

```
auc = 0.9985
```

The AUC is 1, which indicates a model that predicts well.

Plot an ROC curve.

```
figure;  
plot(fpr,tpr)  
h = gca;  
h.XLim(1) = -0.1;  
h.YLim(2) = 1.1;  
xlabel('False positive rate')  
ylabel('True positive rate')  
title('ROC Curve')
```

The ROC curve and AUC indicate that the model classifies the test-sample observations almost perfectly.

Find Good Lasso Penalty Using AUC

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare test-sample values of the AUC.

Load the NLP data set. Preprocess the data as in “Predict Test-Sample Labels” on page 32-4151.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create a data partition that specifies to holdout 10% of the observations. Extract test-sample indices.

```
rng(10); % For reproducibility
Partition = cvpartition(Ystats, 'Holdout', 0.10);
testIdx = test(Partition);
XTest = X(:, testIdx);
n = sum(testIdx)
```

```
n = 3157
```

```
YTest = Ystats(testIdx);
```

There are 3157 observations in the test sample.

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-6} through $10^{-0.5}$.

```
Lambda = logspace(-6, -0.5, 11);
```

Train binary, linear classification models that use each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```
CVMDL = fitlinear(X, Ystats, 'ObservationsIn', 'columns', ...
    'CVPartition', Partition, 'Learner', 'logistic', 'Solver', 'sparsa', ...
    'Regularization', 'lasso', 'Lambda', Lambda, 'GradientTolerance', 1e-8)
```

```
CVMDL =
  classreg.learning.partition.ClassificationPartitionedLinear
  CrossValidatedModel: 'Linear'
  ResponseName: 'Y'
  NumObservations: 31572
  KFold: 1
  Partition: [1x1 cvpartition]
  ClassNames: [0 1]
  ScoreTransform: 'none'
```

Properties, Methods

Extract the trained linear classification model.

```
Mdl1 = CVMDL.Trained{1}
```

```
Mdl1 =
  ClassificationLinear
  ResponseName: 'Y'
  ClassNames: [0 1]
  ScoreTransform: 'logit'
  Beta: [34023x11 double]
  Bias: [1x11 double]
  Lambda: [1x11 double]
  Learner: 'logistic'
```

Properties, Methods

`Mdl` is a `ClassificationLinear` model object. Because `Lambda` is a sequence of regularization strengths, you can think of `Mdl` as 11 models, one for each regularization strength in `Lambda`.

Estimate the test-sample predicted labels and posterior class probabilities.

```
[label, posterior] = predict(Mdl1, XTest, 'ObservationsIn', 'columns');
Mdl1.ClassNames;
posterior(3, 1, 5)

ans = 1.0000
```

`label` is a 3157-by-11 matrix of predicted labels. Each column corresponds to the predicted labels of the model trained using the corresponding regularization strength. `posterior` is a 3157-by-2-by-11

matrix of posterior class probabilities. Columns correspond to classes and pages correspond to regularization strengths. For example, `posterior(3,1,5)` indicates that the posterior probability that the first class (label 0) is assigned to observation 3 by the model that uses `Lambda(5)` as a regularization strength is 1.0000.

For each model, compute the AUC. Designate the second class as the positive class.

```
auc = 1:numel(Lambda); % Preallocation
for j = 1:numel(Lambda)
    [~,~,~,auc(j)] = perfcurve(YTest,posterior(:,2,j),Mdl1.ClassNames(2));
end
```

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you trained the model. Determine the number of nonzero coefficients per model.

```
Mdl = fitlinear(X,Ystats,'ObservationsIn','columns',...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8);
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the test-sample error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(auc),...
    log10(Lambda),log10(numNZCoeff + 1));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} AUC')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
title('Test-Sample Statistics')
hold off
```

Choose the index of the regularization strength that balances predictor variable sparsity and high AUC. In this case, a value between 10^{-2} to 10^{-1} should suffice.

```
idxFinal = 9;
```

Select the model from `Mdl` with the chosen regularization strength.

```
MdlFinal = selectModels(Mdl,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

More About

Classification Score

For linear classification models, the raw classification score for classifying the observation x , a row vector, into the positive class is defined by

$$f_j(x) = x\beta_j + b_j.$$

For the model with regularization strength j , β_j is the estimated column vector of coefficients (the model property `Beta(:,j)`) and b_j is the estimated, scalar bias (the model property `Bias(j)`).

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see `ScoreTransform`).

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- You can generate C/C++ code for both `predict` and `update` by using a coder configurer. Or, generate code only for `predict` by using `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen`.
 - Code generation for `predict` and `update` — Create a coder configurer by using `learnerCoderConfigurer` and then generate code by using `generateCode`. Then you can update model parameters in the generated code without having to regenerate the code.
 - Code generation for `predict` — Save a trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
Mdl	For the usage notes and limitations of the model object, see “Code Generation” on page 32-390 of the <code>ClassificationLinear</code> object.
X	<ul style="list-style-type: none"> Must be a single-precision or double-precision matrix and can be variable-size. If you specify 'ObservationsIn', 'rows' (default), then the number of columns in X must be <code>numel(Mdl.PredictorNames)</code>. Rows and columns must correspond to observations and predictors, respectively. If you specify 'ObservationsIn', 'columns', then the number of rows in X must be <code>numel(Mdl.PredictorNames)</code>. Rows and columns must correspond to predictors and observations, respectively.

Argument	Notes and Limitations
Name-value pair arguments	<ul style="list-style-type: none">Names in name-value pair arguments must be compile-time constants.The value for the 'ObservationsIn' name-value pair argument must be a compile-time constant. For example, to use the 'ObservationsIn', 'columns' name-value pair argument in the generated code, include <code>{coder.Constant('ObservationsIn'),coder.Constant('columns')}</code> in the <code>-args</code> value of <code>codegen</code>.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2016a

predict

Predict labels using discriminant analysis classification model

Syntax

```
label = predict(Mdl,X)
[label,score,cost] = predict(Mdl,X)
```

Description

`label = predict(Mdl,X)` returns a vector of predicted class labels for the predictor data in the table or matrix `X`, based on the trained discriminant analysis classification model `Mdl`.

`[label,score,cost] = predict(Mdl,X)` also returns:

- A matrix of classification scores (`score`) indicating the likelihood that a label comes from a particular class. For discriminant analysis, scores are posterior probabilities on page 32-4165.
- A matrix of expected classification cost on page 32-4166 (`cost`). For each observation in `X`, the predicted class label corresponds to the minimum expected classification cost among all classes.

Input Arguments

Mdl — Discriminant analysis classification model

ClassificationDiscriminant model object | CompactClassificationDiscriminant model object

Discriminant analysis classification model, specified as a `ClassificationDiscriminant` or `CompactClassificationDiscriminant` model object returned by `fitcdiscr`.

X — Predictor data to be classified

numeric matrix | table

Predictor data to be classified, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable. All predictor variables in `X` must be numeric vectors.

- For a numeric matrix, the variables that compose the columns of `X` must have the same order as the predictor variables that trained `Mdl`.
- For a table:
 - `predict` does not support multi-column variables and cell arrays other than cell arrays of character vectors.
 - If you trained `Mdl` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and data types as those that trained `Mdl` (stored in `Mdl.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. `Tbl` and `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.

- If you trained `Mdl` using a numeric matrix, then the predictor names in `Mdl.PredictorNames` and corresponding predictor variable names in `X` must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `fitcdiscr`. `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.

Data Types: `table` | `double` | `single`

Output Arguments

label — Predicted class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Predicted class labels on page 32-4166, returned as a categorical or character array, logical or numeric vector, or cell array of character vectors.

`label`:

- Is the same data type as the observed class labels (`Y`) that trained `Mdl`. (The software treats string arrays as cell arrays of character vectors.)
- Has length equal to the number of rows of `X`.

score — Predicted class posterior probabilities

numeric matrix

Predicted class posterior probabilities on page 32-4165, returned as a numeric matrix of size `N`-by-`K`. `N` is the number of observations (rows) in `X`, and `K` is the number of classes (in `Mdl.ClassNames`). `score(i,j)` is the posterior probability that observation `i` in `X` is of class `j` in `Mdl.ClassNames`.

cost — Expected classification costs

numeric matrix

Expected classification costs on page 32-4166, returned as a matrix of size `N`-by-`K`. `N` is the number of observations (rows) in `X`, and `K` is the number of classes (in `Mdl.ClassNames`). `cost(i,j)` is the cost of classifying row `i` of `X` as class `j` in `Mdl.ClassNames`.

Examples

Predict Class Labels Using Discriminant Analysis Model

Load Fisher's iris data set. Determine the sample size.

```
load fisheriris
N = size(meas,1);
```

Partition the data into training and test sets. Hold out 10% of the data for testing.

```
rng(1); % For reproducibility
cvp = cvpartition(N,'Holdout',0.1);
idxTrn = training(cvp); % Training set indices
idxTest = test(cvp); % Test set indices
```

Store the training data in a table.

```
tblTrn = array2table(meas(idxTrn,:));
tblTrn.Y = species(idxTrn);
```

Train a discriminant analysis model using the training set and default options.

```
Mdl = fitcdiscr(tblTrn, 'Y');
```

Predict labels for the test set. You trained `Mdl` using a table of data, but you can predict labels using a matrix.

```
labels = predict(Mdl, meas(idxTest,:));
```

Construct a confusion matrix for the test set.

```
confusionchart(species(idxTest), labels)
```

`Mdl` misclassifies one versicolor iris as virginica in the test set.

Plot Class Posterior Probability Regions

Load Fisher's iris data set. Consider training using the petal lengths and widths only.

```
load fisheriris
X = meas(:,3:4);
```

Train a quadratic discriminant analysis model using the entire data set.

```
Mdl = fitcdiscr(X,species,'DiscrimType','quadratic');
```

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

```
xMax = max(X);  
xMin = min(X);  
d = 0.01;  
[x1Grid,x2Grid] = meshgrid(xMin(1):d:xMax(1),xMin(2):d:xMax(2));
```

```
[~,score] = predict(Mdl,[x1Grid(:),x2Grid(:)]);  
Mdl.ClassNames
```

```
ans = 3x1 cell  
    {'setosa' }  
    {'versicolor'}  
    {'virginica' }
```

`score` is a matrix of class posterior probabilities. The columns correspond to the classes in `Mdl.ClassNames`. For example, `score(j,1)` is the posterior probability that observation `j` is a setosa iris.

Plot the posterior probability of versicolor classification for each observation in the grid and plot the training data.

```
figure;  
contourf(x1Grid,x2Grid,reshape(score(:,2),size(x1Grid,1),size(x1Grid,2)));  
h = colorbar;  
caxis([0 1]);  
colormap jet;  
hold on  
gscatter(X(:,1),X(:,2),species,'mcy','.x+');  
axis tight  
title('Posterior Probability of versicolor');  
hold off
```

The posterior probability region exposes a portion of the decision boundary.

More About

Posterior Probability

The posterior probability that a point x belongs to class k is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with 1-by- d mean μ_k and d -by- d covariance Σ_k at a 1-by- d point x is

$$P(x|k) = \frac{1}{((2\pi)^d |\Sigma_k|)^{1/2}} \exp\left(-\frac{1}{2}(x - \mu_k)\Sigma_k^{-1}(x - \mu_k)^T\right),$$

where $|\Sigma_k|$ is the determinant of Σ_k , and Σ_k^{-1} is the inverse matrix.

Let $P(k)$ represent the prior probability of class k . Then the posterior probability that an observation x is of class k is

$$\hat{P}(k|x) = \frac{P(x|k)P(k)}{P(x)},$$

where $P(x)$ is a normalization constant, the sum over k of $P(x|k)P(k)$.

Prior Probability

The prior probability is one of three choices:

- 'uniform' — The prior probability of class k is one over the total number of classes.
- 'empirical' — The prior probability of class k is the number of training samples of class k divided by the total number of training samples.
- Custom — The prior probability of class k is the k th element of the prior vector. See `fitcdiscr`.

After creating a classification model (Mdl) you can set the prior using dot notation:

```
Mdl.Prior = v;
```

where v is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

Cost

The matrix of expected costs per observation is defined in “Cost” on page 20-7.

Predicted Class Label

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \underset{y=1, \dots, K}{\operatorname{argmin}} \sum_{k=1}^K \hat{P}(k|x)C(y|k),$$

where

- \hat{y} is the predicted classification.
- K is the number of classes.
- $\hat{P}(k|x)$ is the posterior probability on page 20-6 of class k for observation x .
- $C(y|k)$ is the cost on page 20-7 of classifying an observation as y when its true class is k .

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen` to generate code for the `predict` function. Save a trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.

- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
<code>Mdl</code>	For the usage notes and limitations of the model object, see “Code Generation” on page 32-665 of the <code>CompactClassificationDiscriminant</code> object.
<code>X</code>	<ul style="list-style-type: none"> • For general code generation, <code>X</code> must be a single-precision or double-precision matrix or a table containing single or double predictor variables. <p>If you want to specify <code>X</code> as a table, then your model must be trained using a table, and you must ensure that your entry-point function for prediction:</p> <ul style="list-style-type: none"> • Accepts data as arrays • Creates a table from the data input arguments and specifies the variable names in the table • Passes the table to <code>predict</code> <p>For an example of this table workflow, see “Generate Code to Classify Numeric Data in Table” on page 31-88. For more information on using tables in code generation, see “Code Generation for Tables” (MATLAB Coder) and “Table Limitations for Code Generation” (MATLAB Coder).</p> <ul style="list-style-type: none"> • The number of rows, or observations, in <code>X</code> can be a variable size, but the number of columns in <code>X</code> must be fixed.

Introduced in R2011b

predict

Package:

Classify observations using multiclass error-correcting output codes (ECOC) model

Syntax

```
label = predict(Mdl,X)
label = predict(Mdl,X,Name,Value)
[label,NegLoss,PBScore] = predict( ___ )
[label,NegLoss,PBScore,Posterior] = predict( ___ )
```

Description

`label = predict(Mdl,X)` returns a vector of predicted class labels (`label`) for the predictor data in the table or matrix `X`, based on the trained multiclass error-correcting output codes (ECOC) model `Mdl`. The trained ECOC model can be either full or compact.

`label = predict(Mdl,X,Name,Value)` uses additional options specified by one or more name-value pair arguments. For example, you can specify the posterior probability estimation method, decoding scheme, and verbosity level.

`[label,NegLoss,PBScore] = predict(___)` uses any of the input argument combinations in the previous syntaxes and additionally returns:

- An array of negated average binary losses on page 32-4180 (`NegLoss`). For each observation in `X`, `predict` assigns the label of the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).
- An array of positive-class scores (`PBScore`) for the observations classified by each binary learner.

`[label,NegLoss,PBScore,Posterior] = predict(___)` additionally returns posterior class probability estimates for the observations (`Posterior`).

To obtain posterior class probabilities, you must set `'FitPosterior'`, `true` when training the ECOC model using `fitcecoc`. Otherwise, `predict` throws an error.

Examples

Predict Test-Sample Labels of Training Data Using ECOC Model

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers. Specify a 30% holdout sample, standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
PMdl = fitcecoc(X,Y,'Holdout',0.30,'Learners',t,'ClassNames',classOrder);
Mdl = PMdl.Trained{1}; % Extract trained, compact classifier
```

PMdl is a ClassificationPartitionedECOC model. It has the property Trained, a 1-by-1 cell array containing the CompactClassificationECOC model that the software trained using the training set.

Predict the test-sample labels. Print a random subset of true and predicted labels.

```
testInds = test(PMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
labels = predict(Mdl,XTest);
```

```
idx = randsample(sum(testInds),10);
table(YTest(idx),labels(idx),...
      'VariableNames',{'TrueLabels','PredictedLabels'})
```

```
ans=10x2 table
  TrueLabels PredictedLabels
  _____ _____
  setosa     setosa
  versicolor virginica
  setosa     setosa
  virginica  virginica
  versicolor versicolor
  setosa     setosa
  virginica  virginica
  virginica  virginica
  setosa     setosa
  setosa     setosa
```

Mdl correctly labels all except one of the test-sample observations with indices idx.

Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function

Load Fisher's iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify a 30% holdout sample. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
PMdl = fitcecoc(X,Y,'Holdout',0.30,'Learners',t,'ClassNames',classOrder);
Mdl = PMdl.Trained{1}; % Extract trained, compact classifier
```

PMdl is a ClassificationPartitionedECOC model. It has the property Trained, a 1-by-1 cell array containing the CompactClassificationECOC model that the software trained using the training set.

SVM scores are signed distances from the observation to the decision boundary. Therefore, $(-\infty, \infty)$ is the domain. Create a custom binary loss function that does the following:

- Map the coding design matrix (M) and positive-class classification scores (s) for each learner to the binary loss for each observation.
- Use linear loss.
- Aggregate the binary learner loss using the median.

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Or, you can specify an anonymous binary loss function. In this case, create a function handle (customBL) to an anonymous binary loss function.

```
customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;
```

Predict test-sample labels and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 test-sample observations.

```
testInds = test(PMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
[label,NegLoss] = predict(Mdl,XTest,'BinaryLoss',customBL);
```

```
idx = randsample(sum(testInds),10);
classOrder
```

```
classOrder = 3x1 categorical
    setosa
    versicolor
    virginica
```

```
table(YTest(idx),label(idx),NegLoss(idx,:), 'VariableNames',...
    {'TrueLabel','PredictedLabel','NegLoss'})
```

```
ans=10x3 table
```

TrueLabel	PredictedLabel	NegLoss		
setosa	versicolor	0.1857	1.9878	-3.6735
versicolor	virginica	-1.3316	-0.12333	-0.045053
setosa	versicolor	0.13898	1.9261	-3.5651
virginica	virginica	-1.5133	-0.38263	0.39592
versicolor	versicolor	-0.87209	0.74777	-1.3757
setosa	versicolor	0.48381	1.9972	-3.981
virginica	virginica	-1.9364	-0.67508	1.1114
virginica	virginica	-1.579	-0.83339	0.91235
setosa	versicolor	0.51001	2.1208	-4.1308
setosa	versicolor	0.36119	2.0594	-3.9206

The order of the columns corresponds to the elements of `classOrder`. The software predicts the label based on the maximum negated loss. The results indicate that the median of the linear losses might not perform as well as other losses.

Estimate Posterior Probabilities Using ECOC Classifier

Train an ECOC classifier using SVM binary learners. First predict the training-sample labels and class posterior probabilities. Then predict the maximum class posterior probability at each point in a grid. Visualize the results.

Load Fisher's iris data set. Specify the petal dimensions as the predictors and the species names as the response.

```
load fisheriris
X = meas(:,3:4);
Y = species;
rng(1); % For reproducibility
```

Create an SVM template. Standardize the predictors, and specify the Gaussian kernel.

```
t = templateSVM('Standardize',true,'KernelFunction','gaussian');
```

`t` is an SVM template. Most of its properties are empty. When the software trains the ECOC classifier, it sets the applicable properties to their default values.

Train the ECOC classifier using the SVM template. Transform classification scores to class posterior probabilities (which are returned by `predict` or `resubPredict`) using the `'FitPosterior'` name-value pair argument. Specify the class order using the `'ClassNames'` name-value pair argument. Display diagnostic messages during training by using the `'Verbose'` name-value pair argument.

```
Mdl = fitcecoc(X,Y,'Learners',t,'FitPosterior',true,...
    'ClassNames',{'setosa','versicolor','virginica'},...
    'Verbose',2);
```

```
Training binary learner 1 (SVM) out of 3 with 50 negative and 50 positive observations.
Negative class indices: 2
Positive class indices: 1
```

```
Fitting posterior probabilities for learner 1 (SVM).
Training binary learner 2 (SVM) out of 3 with 50 negative and 50 positive observations.
Negative class indices: 3
Positive class indices: 1
```

```
Fitting posterior probabilities for learner 2 (SVM).
Training binary learner 3 (SVM) out of 3 with 50 negative and 50 positive observations.
Negative class indices: 3
Positive class indices: 2
```

```
Fitting posterior probabilities for learner 3 (SVM).
```

`Mdl` is a `ClassificationECOC` model. The same SVM template applies to each binary learner, but you can adjust options for each binary learner by passing in a cell vector of templates.

Predict the training-sample labels and class posterior probabilities. Display diagnostic messages during the computation of labels and class posterior probabilities by using the 'Verbose' name-value pair argument.

```
[label,~,~,Posterior] = resubPredict(Mdl,'Verbose',1);
```

```
Predictions from all learners have been computed.
Loss for all observations has been computed.
Computing posterior probabilities...
```

```
Mdl.BinaryLoss
```

```
ans =
'quadratic'
```

The software assigns an observation to the class that yields the smallest average binary loss. Because all binary learners are computing posterior probabilities, the binary loss function is `quadratic`.

Display a random set of results.

```
idx = randsample(size(X,1),10,1);
Mdl.ClassNames
```

```
ans = 3x1 cell
{'setosa' }
{'versicolor' }
{'virginica' }
```

```
table(Y(idx),label(idx),Posterior(idx,:),...
'VariableNames',{'TrueLabel','PredLabel','Posterior'})
```

```
ans=10x3 table
   TrueLabel   PredLabel   Posterior
   _____   _____   _____
   {'virginica' }   {'virginica' }   0.0039321   0.0039869   0.99208
   {'virginica' }   {'virginica' }   0.017067   0.018263   0.96467
   {'virginica' }   {'virginica' }   0.014948   0.015856   0.9692
   {'versicolor' }   {'versicolor' }   2.2197e-14   0.87317   0.12683
   {'setosa' }   {'setosa' }   0.999   0.00025091   0.00074639
   {'versicolor' }   {'virginica' }   2.2195e-14   0.059429   0.94057
   {'versicolor' }   {'versicolor' }   2.2194e-14   0.97001   0.029986
   {'setosa' }   {'setosa' }   0.999   0.0002499   0.00074741
   {'versicolor' }   {'versicolor' }   0.0085646   0.98259   0.008849
   {'setosa' }   {'setosa' }   0.999   0.00025013   0.00074718
```

The columns of `Posterior` correspond to the class order of `Mdl.ClassNames`.

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

```
xMax = max(X);
xMin = min(X);

x1Pts = linspace(xMin(1),xMax(1));
x2Pts = linspace(xMin(2),xMax(2));
[x1Grid,x2Grid] = meshgrid(x1Pts,x2Pts);
```

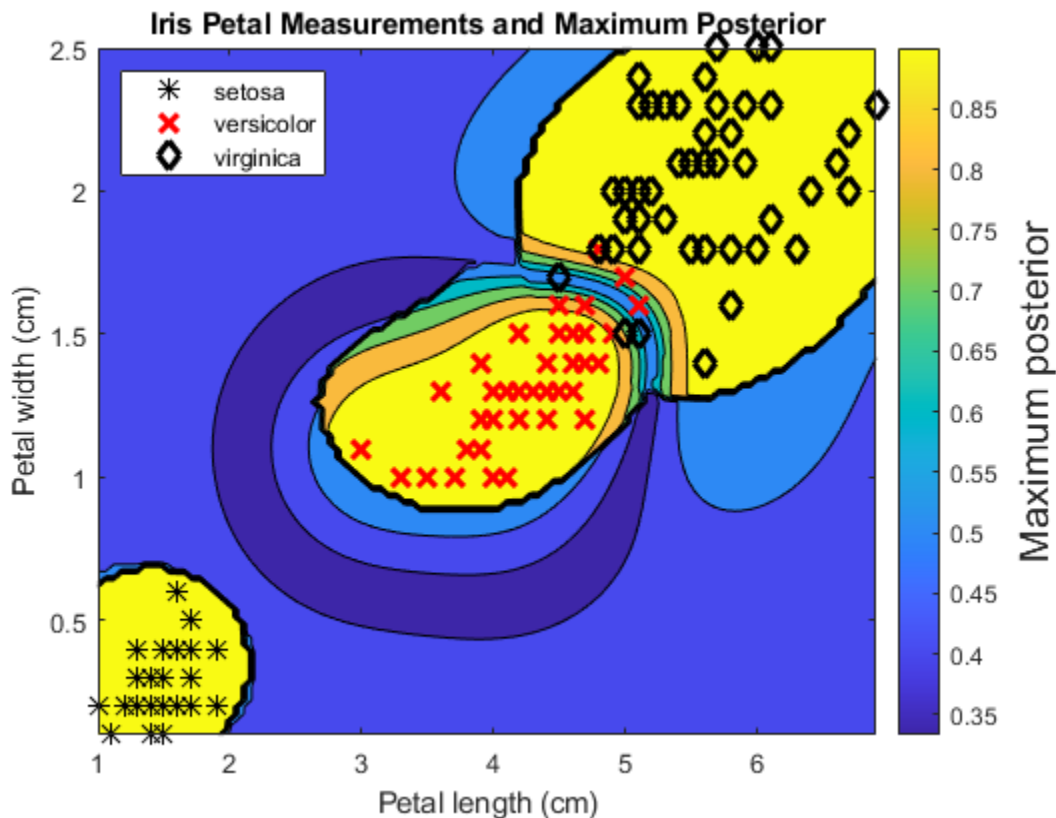

```
[~,~,~,PosteriorRegion] = predict(Mdl,[x1Grid(:),x2Grid(:)]);
```

For each coordinate on the grid, plot the maximum class posterior probability among all classes.

```
contourf(x1Grid,x2Grid,...
         reshape(max(PosteriorRegion,[],2),size(x1Grid,1),size(x1Grid,2)));
h = colorbar;
h.YLabel.String = 'Maximum posterior';
h.YLabel.FontSize = 15;

hold on
gh = gscatter(X(:,1),X(:,2),Y,'krk','*xd',8);
gh(2).LineWidth = 2;
gh(3).LineWidth = 2;

title('Iris Petal Measurements and Maximum Posterior')
xlabel('Petal length (cm)')
ylabel('Petal width (cm)')
axis tight
legend(gh,'Location','NorthWest')
hold off
```

Estimate Test-Sample Posterior Probabilities Using Parallel Computing

Train a multiclass ECOC model and estimate posterior probabilities using parallel computing.

Load the `arrhythmia` data set. Examine the response data `Y`, and determine the number of classes.

```
load arrhythmia
Y = categorical(Y);
tabulate(Y)
```

Value	Count	Percent
1	245	54.20%
2	44	9.73%
3	15	3.32%
4	15	3.32%
5	13	2.88%
6	25	5.53%
7	3	0.66%
8	2	0.44%
9	9	1.99%
10	50	11.06%
14	4	0.88%
15	5	1.11%
16	22	4.87%

```
K = numel(unique(Y));
```

Several classes are not represented in the data, and many of the other classes have low relative frequencies.

Specify an ensemble learning template that uses the GentleBoost method and 50 weak classification tree learners.

```
t = templateEnsemble('GentleBoost',50,'Tree');
```

`t` is a template object. Most of its properties are empty (`[]`). The software uses default values for all empty properties during training.

Because the response variable contains many classes, specify a sparse random coding design.

```
rng(1); % For reproducibility
Coding = designecoc(K,'sparseandom');
```

Train an ECOC model using parallel computing. Specify a 15% holdout sample, and fit posterior probabilities.

```
pool = parpool; % Invokes workers

Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).

options = statset('UseParallel',true);
PMdl = fitcecoc(X,Y,'Learner',t,'Options',options,'Coding',Coding,...
    'FitPosterior',true,'Holdout',0.15);
Mdl = PMdl.Trained{1}; % Extract trained, compact classifier
```

`PMdl` is a `ClassificationPartitionedECOC` model. It has the property `Trained`, a 1-by-1 cell array containing the `CompactClassificationECOC` model that the software trained using the training set.

The pool invokes six workers, although the number of workers might vary among systems.

Estimate posterior probabilities, and display the posterior probability of being classified as not having arrhythmia (class 1) given the data for a random set of test-sample observations.

```
testInds = test(PMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
[~,~,~,posterior] = predict(Mdl,XTest,'Options',options);

idx = randsample(sum(testInds),10);
table(idx,YTest(idx),posterior(idx,1),...
      'VariableNames',{'TestSampleIndex','TrueLabel','PosteriorNoArrhythmia'})
```

```
ans=10x3 table
  TestSampleIndex  TrueLabel  PosteriorNoArrhythmia
  _____  _____  _____
         11             6          0.60631
         41             4          0.23674
         51             2          0.13802
         33            10          0.43831
         12             1          0.94332
          8             1          0.97278
         37             1          0.62807
         24            10          0.96876
         56            16          0.29375
         30             1          0.64512
```

Input Arguments

Mdl — Full or compact multiclass ECOC model

ClassificationECOC model object | CompactClassificationECOC model object

Full or compact multiclass ECOC model, specified as a ClassificationECOC or CompactClassificationECOC model object.

To create a full or compact ECOC model, see ClassificationECOC or CompactClassificationECOC.

X — Predictor data to be classified

numeric matrix | table

Predictor data to be classified, specified as a numeric matrix or table.

Each row of X corresponds to one observation, and each column corresponds to one variable.

- For a numeric matrix:
 - The variables that constitute the columns of X must have the same order as the predictor variables that train Mdl.
 - If you train Mdl using a table (for example, Tbl), then X can be a numeric matrix if Tbl contains all numeric predictor variables. To treat numeric predictors in Tbl as categorical during training, identify categorical predictors using the CategoricalPredictors name-

value pair argument of `fitcecoc`. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types) and `X` is a numeric matrix, then `predict` throws an error.

- For a table:
 - `predict` does not support multicolumn variables and cell arrays other than cell arrays of character vectors.
 - If you train `Mdl` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and data types as the predictor variables that train `Mdl` (stored in `Mdl.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. Both `Tbl` and `X` can contain additional variables (response variables, observation weights, and so on), but `predict` ignores them.
 - If you train `Mdl` using a numeric matrix, then the predictor names in `Mdl.PredictorNames` and the corresponding predictor variable names in `X` must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `fitcecoc`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, and so on), but `predict` ignores them.

Note If `Mdl.BinaryLearners` contains linear or kernel classification models (`ClassificationLinear` or `ClassificationKernel` model objects), then you cannot specify sample data in a table. Instead, pass a matrix of predictor data.

When training `Mdl`, assume that you set `'Standardize', true` for a template object specified in the `'Learners'` name-value pair argument of `fitcecoc`. In this case, for the corresponding binary learner `j`, the software standardizes the columns of the new predictor data using the corresponding means in `Mdl.BinaryLearner{j}.Mu` and standard deviations in `Mdl.BinaryLearner{j}.Sigma`.

Data Types: `table` | `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `predict(Mdl, X, 'BinaryLoss', 'quadratic', 'Decoding', 'lossbased')` specifies a quadratic binary learner loss function and a loss-based decoding scheme for aggregating the binary losses.

BinaryLoss — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'`
| function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle 'BinaryLoss', @customFunction.

`customFunction` has this form:

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-4169.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	'hinge'
All binary learners are ensembles trained by <code>AdaboostM1</code> or <code>GentleBoost</code> .	'exponential'
All binary learners are ensembles trained by <code>LogitBoost</code> .	'binodeviance'
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting 'FitPosterior', true in <code>fitcecoc</code> .	'quadratic'

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char | string | function_handle`

Decoding – Decoding scheme

`'lossweighted' (default) | 'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 32-4180.

Example: `'Decoding','lossbased'`

NumKLInitializations – Number of random initial values

`0 (default) | nonnegative integer scalar`

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of `'NumKLInitializations'` and a nonnegative integer scalar.

If you do not request the fourth output argument (`Posterior`) and set `'PosteriorMethod','kl'` (the default), then the software ignores the value of `NumKLInitializations`.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-4182.

Example: `'NumKLInitializations',5`

Data Types: `single | double`

ObservationsIn – Predictor data observation dimension

`'rows' (default) | 'columns'`

Predictor data observation dimension, specified as the comma-separated pair consisting of `'ObservationsIn'` and `'columns'` or `'rows'`. `Mdl.BinaryLearners` must contain `ClassificationLinear` models.

Note If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn','columns'`, you can experience a significant reduction in execution time.

Options – Estimation options

`[] (default) | structure array returned by statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',true)`.

PosteriorMethod – Posterior probability estimation method

`'kl' (default) | 'qp'`

Posterior probability estimation method, specified as the comma-separated pair consisting of 'PosteriorMethod' and 'kl' or 'qp'.

- If `PosteriorMethod` is 'kl', then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-4182.
- If `PosteriorMethod` is 'qp', then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming” on page 32-4183.
- If you do not request the fourth output argument (`Posterior`), then the software ignores the value of `PosteriorMethod`.

Example: 'PosteriorMethod', 'qp'

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

Output Arguments

label — Predicted class labels

categorical array | character array | logical array | numeric array | cell array of character vectors

Predicted class labels, returned as a categorical, character, logical, or numeric array, or a cell array of character vectors. The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`label` has the same data type as the class labels used to train `Mdl` and has the same number of rows as `X`. (The software treats string arrays as cell arrays of character vectors.)

If `Mdl.BinaryLearners` contains `ClassificationLinear` models, then `label` is an m -by- L matrix, where m is the number of observations in `X`, and L is the number of regularization strengths in the linear classification models (`numel(Mdl.BinaryLearners{1}.Lambda)`). The value `label(i, j)` is the predicted label of observation `i` for the model trained using regularization strength `Mdl.BinaryLearners{1}.Lambda(j)`.

Otherwise, `label` is a column vector of length m .

NegLoss — Negated average binary losses

numeric matrix | numeric array

Negated average binary losses on page 32-4180, returned as a numeric matrix or array.

- If `Mdl.BinaryLearners` contains `ClassificationLinear` models, then `NegLoss` is an m -by- K -by- L array.
 - m is the number of observations in X .
 - K is the number of distinct classes in the training data (`numel(Mdl.ClassNames)`).
 - L is the number of regularization strengths in the linear classification models (`numel(Mdl.BinaryLearners{1}.Lambda)`).

`NegLoss(i, k, j)` is the negated average binary loss for observation i , corresponding to class `Mdl.ClassNames(k)`, for the model trained using regularization strength `Mdl.BinaryLearners{1}.Lambda(j)`.

- Otherwise, `NegLoss` is an m -by- K matrix.

PBScore — Positive-class scores

numeric matrix | numeric array

Positive-class scores for each binary learner, returned as a numeric matrix or array.

- If `Mdl.BinaryLearners` contains `ClassificationLinear` models, then `PBScore` is an m -by- B -by- L array.
 - m is the number of observations in X .
 - B is the number of binary learners (`numel(Mdl.BinaryLearners)`).
 - L is the number of regularization strengths in the linear classification models (`numel(Mdl.BinaryLearners{1}.Lambda)`).

`PBScore(i, b, j)` is the positive-class score for observation i , using binary learner b , for the model trained using regularization strength `Mdl.BinaryLearners{1}.Lambda(j)`.

- Otherwise, `PBScore` is an m -by- B matrix.

Posterior — Posterior class probabilities

numeric matrix | numeric array

Posterior class probabilities, returned as a numeric matrix or array.

- If `Mdl.BinaryLearners` contains `ClassificationLinear` models, then `Posterior` is an m -by- K -by- L array. For dimension definitions, see `NegLoss`. `Posterior(i, k, j)` is the posterior probability that observation i comes from class `Mdl.ClassNames(k)`, for the model trained using regularization strength `Mdl.BinaryLearners{1}.Lambda(j)`.
- Otherwise, `Posterior` is an m -by- K matrix.

More About

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k, j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).

- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-189, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-189, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-189 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-189.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Algorithms

The software can estimate class posterior probabilities by minimizing the Kullback-Leibler divergence or by using quadratic programming. For the following descriptions of the posterior estimation algorithms, assume that:

- m_{kj} is the element (k,j) of the coding design matrix M .
- I is the indicator function.
- \widehat{p}_k is the class posterior probability estimate for class k of an observation, $k = 1, \dots, K$.
- r_j is the positive-class posterior probability for binary learner j . That is, r_j is the probability that binary learner j classifies an observation into the positive class, given the training data.

Posterior Estimation Using Kullback-Leibler Divergence

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

$$\Delta(r, \widehat{r}) = \sum_{j=1}^L w_j \left[r_j \log \frac{r_j}{\widehat{r}_j} + (1 - r_j) \log \frac{1 - r_j}{1 - \widehat{r}_j} \right],$$

where $w_j = \sum_{S_j} w_i^*$ is the weight for binary learner j .

- S_j is the set of observation indices on which binary learner j is trained.
- w_i^* is the weight of observation i .

The software minimizes the divergence iteratively. The first step is to choose initial values $\widehat{p}_k^{(0)}$; $k = 1, \dots, K$ for the class posterior probabilities.

- If you do not specify 'NumKLIterations', then the software tries both sets of deterministic initial values described next, and selects the set that minimizes Δ .
 - $\widehat{p}_k^{(0)} = 1/K$; $k = 1, \dots, K$.
 - $\widehat{p}_k^{(0)}$; $k = 1, \dots, K$ is the solution of the system

$$M_{01} \widehat{p}^{(0)} = r,$$

where M_{01} is M with all $m_{kj} = -1$ replaced with 0, and r is a vector of positive-class posterior probabilities returned by the L binary learners [Dietterich et al.] on page 18-189. The software uses `lsqnonneg` to solve the system.

- If you specify 'NumKLIterations', c , where c is a natural number, then the software does the following to choose the set $\widehat{p}_k^{(0)}$; $k = 1, \dots, K$, and selects the set that minimizes Δ .
 - The software tries both sets of deterministic initial values as described previously.
 - The software randomly generates c vectors of length K using `rand`, and then normalizes each vector to sum to 1.

At iteration t , the software completes these steps:

- 1 Compute

$$\widehat{r}_j^{(t)} = \frac{\sum_{k=1}^K \widehat{p}_k^{(t)} I(m_{kj} = +1)}{\sum_{k=1}^K \widehat{p}_k^{(t)} I(m_{kj} = +1 \cup m_{kj} = -1)}.$$

- 2 Estimate the next class posterior probability using

$$\hat{p}_k^{(t+1)} = \hat{p}_k^{(t)} \frac{\sum_{j=1}^L w_j [r_j I(m_{kj} = +1) + (1 - r_j) I(m_{kj} = -1)]}{\sum_{j=1}^L w_j [\hat{r}_j^{(t)} I(m_{kj} = +1) + (1 - \hat{r}_j^{(t)}) I(m_{kj} = -1)]}.$$

- 3 Normalize $\hat{p}_k^{(t+1)}$; $k = 1, \dots, K$ so that they sum to 1.
- 4 Check for convergence.

For more details, see [Hastie et al.] on page 18-190 and [Zadrozny] on page 18-191.

Posterior Estimation Using Quadratic Programming

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software completes these steps:

- 1 Estimate the positive-class posterior probabilities, r_j , for binary learners $j = 1, \dots, L$.
- 2 Using the relationship between r_j and \hat{p}_k [Wu et al.] on page 18-191, minimize

$$\sum_{j=1}^L \left[-r_j \sum_{k=1}^K \hat{p}_k I(m_{kj} = -1) + (1 - r_j) \sum_{k=1}^K \hat{p}_k I(m_{kj} = +1) \right]^2$$

with respect to \hat{p}_k and the restrictions

$$0 \leq \hat{p}_k \leq 1$$

$$\sum_k \hat{p}_k = 1.$$

The software performs minimization using `quadprog`.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see "Tall Arrays" (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- You can generate C/C++ code for both `predict` and `update` by using a coder configurer. Or, generate code only for `predict` by using `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen`.
- Code generation for `predict` and `update` — Create a coder configurer by using `learnerCoderConfigurer` and then generate code by using `generateCode`. Then you can update model parameters in the generated code without having to regenerate the code.
- Code generation for `predict` — Save a trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
<code>Mdl</code>	For the usage notes and limitations of the model object, see "Code Generation" on page 32-673 of the <code>CompactClassificationECOC</code> object.

Argument	Notes and Limitations
X	<ul style="list-style-type: none"> For general code generation, X must be a single-precision or double-precision matrix or a table containing single or double predictor variables. <p>If you want to specify X as a table, then your model must be trained using a table, and you must ensure that your entry-point function for prediction:</p> <ul style="list-style-type: none"> Accepts data as arrays Creates a table from the data input arguments and specifies the variable names in the table Passes the table to <code>predict</code> <p>For an example of this table workflow, see “Generate Code to Classify Numeric Data in Table” on page 31-88. For more information on using tables in code generation, see “Code Generation for Tables” (MATLAB Coder) and “Table Limitations for Code Generation” (MATLAB Coder).</p> <ul style="list-style-type: none"> In the coder configurer workflow, X must be a single or double matrix. The number of observations in X can be a variable size, but the number of variables in X must be fixed.
Posterior	This output argument is not supported.
Name-value pair arguments	Names in name-value pair arguments must be compile-time constants.
BinaryLoss	<ul style="list-style-type: none"> The value for the 'BinaryLoss' name-value pair argument must be a compile-time constant. For example, to use the 'BinaryLoss', 'logit' name-value pair argument in the generated code, include <code>{coder.Constant('BinaryLoss'), coder.Constant('logit')}</code> in the <code>-args</code> value of <code>codegen</code>. To set the 'BinaryLoss' name-value pair argument to a custom binary loss function in the generated code, define a custom function on the MATLAB search path, and specify the name of the custom function instead of its function handle. The custom function name must be a compile-time constant. For example, if you define a custom function named <code>customFunction</code>, then include <code>{coder.Constant('BinaryLoss'), coder.Constant('customFunction')}</code> in the <code>-args</code> value of <code>codegen</code>.
NumKLInitializations	This name-value pair argument is not supported.
ObservationsIn	The value for the 'ObservationsIn' name-value pair argument must be a compile-time constant. For example, to use the 'ObservationsIn', 'columns' name-value pair argument in the generated code, include <code>{coder.Constant('ObservationsIn'), coder.Constant('columns')}</code> in the <code>-args</code> value of <code>codegen</code> .

Argument	Notes and Limitations
Options	This name-value pair argument is not supported.
PosteriorMethod	This name-value pair argument is not supported.
Verbose	If you plan to generate a MEX file without using a coder configurer, then you can specify Verbose. Otherwise, codegen does not support Verbose.

For more information, see “Introduction to Code Generation” on page 31-2.

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2014b

predict

Classify observations using ensemble of classification models

Syntax

```
labels = predict(Mdl,X)
labels = predict(Mdl,X,Name,Value)
[labels,score] = predict(____)
```

Description

`labels = predict(Mdl,X)` returns a vector of predicted class labels for the predictor data in the table or matrix `X`, based on the full or compact, trained classification ensemble `Mdl`.

`labels = predict(Mdl,X,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`[labels,score] = predict(____)` also returns a matrix of classification scores on page 32-4190 (`score`), indicating the likelihood that a label comes from a particular class, using any of the input arguments in the previous syntaxes. For each observation in `X`, the predicted class label corresponds to the maximum score among all classes.

Input Arguments

Mdl

A classification ensemble created by `fitcensemble` or a compact classification ensemble created by `compact`.

X

Predictor data to be classified, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

- For a numeric matrix:
 - The variables making up the columns of `X` must have the same order as the predictor variables that trained `Mdl`.
 - If you trained `Mdl` using a table (for example, `Tbl`), then `X` can be a numeric matrix if `Tbl` contains all numeric predictor variables. To treat numeric predictors in `Tbl` as categorical during training, identify categorical predictors using the `CategoricalPredictors` name-value pair argument of `fitcensemble`. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types) and `X` is a numeric matrix, then `predict` throws an error.
- For a table:
 - `predict` does not support multi-column variables and cell arrays other than cell arrays of character vectors.

- If you trained `Mdl` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and be of the same data types as those that trained `Mdl` (stored in `Mdl.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. `Tbl` and `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.
- If you trained `Mdl` using a numeric matrix, then the predictor names in `Mdl.PredictorNames` and corresponding predictor variable names in `X` must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `fitcensemble`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Learners

Indices of weak learners `predict` uses for computation of responses, a numeric vector.

Default: `1:T`, where `T` is the number of weak learners in `Mdl`

UseObsForLearner

A logical matrix of size `N-by-T`, where:

- `N` is the number of rows of `X`.
- `T` is the number of weak learners in `Mdl`.

When `UseObsForLearner(i, j)` is `true`, learner `j` is used in predicting the class of row `i` of `X`.

Default: `true(N, T)`

Output Arguments

labels

Vector of classification labels. `labels` has the same data type as the labels used in training `Mdl`. (The software treats string arrays as cell arrays of character vectors.)

score

A matrix with one row per observation and one column per class. For each observation and each class, the score generated by each tree is the probability of this observation originating from this class computed as the fraction of observations of this class in a tree leaf. `predict` averages these scores over all trees in the ensemble.

Examples

Predict Class Labels Using Classification Ensemble

Load Fisher's iris data set. Determine the sample size.

```
load fisheriris
N = size(meas,1);
```

Partition the data into training and test sets. Hold out 10% of the data for testing.

```
rng(1); % For reproducibility
cvp = cvpartition(N,'Holdout',0.1);
idxTrn = training(cvp); % Training set indices
idxTest = test(cvp); % Test set indices
```

Store the training data in a table.

```
tblTrn = array2table(meas(idxTrn,:));
tblTrn.Y = species(idxTrn);
```

Train a classification ensemble using AdaBoostM2 and the training set. Specify tree stumps as the weak learners.

```
t = templateTree('MaxNumSplits',1);
Mdl = fitensemble(tblTrn,'Y','Method','AdaBoostM2','Learners',t);
```

Predict labels for the test set. You trained model using a table of data, but you can predict labels using a matrix.

```
labels = predict(Mdl,meas(idxTest,:));
```

Construct a confusion matrix for the test set.

```
confusionchart(species(idxTest),labels)
```

Mdl misclassifies one versicolor iris as virginica in the test set.

More About

Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from $-\infty$ to ∞ .
- Bag scores range from 0 to 1.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen` to generate code for the `predict` function. Save a trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- You can also generate fixed-point C/C++ code for `predict`. Fixed-point code generation requires an additional step that defines the fixed-point data types of the variables required for prediction. Create a fixed-point data type structure by using the `dataType` function on page 32-2391 generated by `generateLearnerDataTypeFcn`, and use the structure as an input argument of `loadLearnerForCoder` in an entry-point function. Generating fixed-point C/C++ code requires MATLAB Coder and Fixed-Point Designer.
- Generating fixed-point code for `predict` includes propagating data types for individual learners and, therefore, can be time consuming.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
Mdl	For the usage notes and limitations of the model object, see “Code Generation” on page 32-680 of the CompactClassificationEnsemble object.

Argument	Notes and Limitations
X	<ul style="list-style-type: none"> For general code generation, X must be a single-precision or double-precision matrix or a table containing single or double predictor variables. <p>If you want to specify X as a table, then your model must be trained using a table, and you must ensure that your entry-point function for prediction:</p> <ul style="list-style-type: none"> Accepts data as arrays Creates a table from the data input arguments and specifies the variable names in the table Passes the table to <code>predict</code> <p>For an example of this table workflow, see “Generate Code to Classify Numeric Data in Table” on page 31-88. Introduced in R2011a

predict

Predict labels using naive Bayes classification model

Syntax

```
label = predict(Mdl,X)
[label,Posterior,Cost] = predict(Mdl,X)
```

Description

`label = predict(Mdl,X)` returns a vector of predicted class labels for the predictor data in the table or matrix `X`, based on the trained, full or compact naive Bayes classifier `Mdl`.

`[label,Posterior,Cost] = predict(Mdl,X)` also returns:

- A matrix of posterior probabilities on page 32-4199 (`Posterior`) indicating the likelihood that a label comes from a particular class.
- A matrix of misclassification costs on page 32-4198 (`Cost`). For each observation in `X`, the predicted class label corresponds to the minimum expected classification costs among all classes.

Input Arguments

Mdl — Naive Bayes classifier

`ClassificationNaiveBayes` model | `CompactClassificationNaiveBayes` model

Naive Bayes classifier, specified as a `ClassificationNaiveBayes` model or `CompactClassificationNaiveBayes` model returned by `fitcnb` or `compact`, respectively.

X — Predictor data to be classified

numeric matrix | table

Predictor data to be classified, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

- For a numeric matrix:
 - The variables making up the columns of `X` must have the same order as the predictor variables that trained `Mdl`.
 - If you trained `Mdl` using a table (for example, `Tbl`), then `X` can be a numeric matrix if `Tbl` contains all numeric predictor variables. To treat numeric predictors in `Tbl` as categorical during training, identify categorical predictors using the `CategoricalPredictors` name-value pair argument of `fitcnb`. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types) and `X` is a numeric matrix, then `predict` throws an error.
- For a table:
 - `predict` does not support multi-column variables and cell arrays other than cell arrays of character vectors.

- If you trained `Mdl` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and data types as those that trained `Mdl` (stored in `Mdl.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. `Tbl` and `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.
- If you trained `Mdl` using a numeric matrix, then the predictor names in `Mdl.PredictorNames` and corresponding predictor variable names in `X` must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `fitcnb`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.

Data Types: `table` | `double` | `single`

Notes:

- If `Mdl.DistributionNames` is `'mn'`, then the software returns NaNs corresponding to rows of `X` containing at least one NaN.
 - If `Mdl.DistributionNames` is not `'mn'`, then the software ignores NaN values when estimating misclassification costs and posterior probabilities. Specifically, the software computes the conditional density of the predictors given the class by leaving out the factors corresponding to missing predictor values.
 - For predictor distribution specified as `'mvmn'`, if `X` contains levels that are not represented in the training data (i.e., not in `Mdl.CategoricalLevels` for that predictor), then the conditional density of the predictors given the class is 0. For those observations, the software returns the corresponding value of `Posterior` as a NaN. The software determines the class label for such observations using the class prior probability, stored in `Mdl.Prior`.
-

Output Arguments

label — Predicted class labels

categorical vector | character array | logical vector | numeric vector | cell array of character vectors

Predicted class labels, returned as a categorical vector, character array, logical or numeric vector, or cell array of character vectors.

label:

- Is the same data type as the observed class labels (`Mdl.Y`) that trained `Mdl`
- Has length equal to the number of rows of `Mdl.X`
- Is the class yielding the lowest expected misclassification cost (`Cost`)

Posterior — Class posterior probabilities

numeric matrix

Class posterior probabilities on page 32-4199, returned as a numeric matrix. `Posterior` has rows equal to the number of rows of `X` and columns equal to the number of distinct classes in the training data (`size(Mdl.ClassNames, 1)`).

`Posterior(j, k)` is the predicted posterior probability of class `k` (i.e., in class `Mdl.ClassNames(k)`) given the observation in row `j` of `X`.

Data Types: double

Cost — Expected misclassification costs

numeric matrix

Expected misclassification costs on page 32-4198, returned as a numeric matrix. `Cost` has rows equal to the number of rows of `X` and columns equal to the number of distinct classes in the training data (`size(Mdl.ClassNames,1)`).

`Cost(j,k)` is the expected misclassification cost of the observation in row `j` of `X` being predicted into class `k` (i.e., in class `Mdl.ClassNames(k)`).

Examples

Label Test Sample Observations of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas; % Predictors
Y = species; % Response
rng(1);
```

Train a naive Bayes classifier and specify to holdout 30% of the data for a test sample. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
CVMdl = fitcnb(X,Y,'Holdout',0.30,...
    'ClassNames',{'setosa','versicolor','virginica'});
CMdl = CVMdl.Trained{1}; % Extract trained, compact classifier
testIdx = test(CVMdl.Partition); % Extract the test indices
XTest = X(testIdx,:);
YTest = Y(testIdx);
```

`CVMdl` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Label the test sample observations. Display the results for a random set of 10 observations in the test sample.

```
idx = randsample(sum(testIdx),10);
label = predict(CMdl,XTest);
table(YTest(idx),label(idx),'VariableNames',...
    {'TrueLabel','PredictedLabel'})
```

```
ans=10x2 table
    TrueLabel    PredictedLabel
    _____    _____
    {'setosa'    }    {'setosa'    }
    {'versicolor'}    {'versicolor'}
    {'setosa'    }    {'setosa'    }
    {'virginica' }    {'virginica' }
    {'versicolor'}    {'versicolor'}
```

```

{'setosa'   }    {'setosa'   }
{'virginica'}  {'virginica'}
{'virginica'}  {'virginica'}
{'setosa'   }    {'setosa'   }
{'setosa'   }    {'setosa'   }

```

Estimate Posterior Probabilities and Misclassification Costs

A goal of classification is to estimate posterior probabilities of new observations using a trained algorithm. Many applications train algorithms on large data sets, which can use resources that are better used elsewhere. This example shows how to efficiently estimate posterior probabilities of new observations using a Naive Bayes classifier.

Load Fisher's iris data set.

```

load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);

```

Partition the data set into two sets: one in the training set, and the other is new unobserved data. Reserve 10 observations for the new data set.

```

n = size(X,1);
newInds = randsample(n,10);
inds = ~ismember(1:n,newInds);
XNew = X(newInds,:);
YNew = Y(newInds);

```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label. Conserve memory by reducing the size of the trained SVM classifier.

```

Mdl = fitcnb(X(inds,:),Y(inds),...
    'ClassNames',{'setosa','versicolor','virginica'});
CMdl = compact(Mdl);
whos('Mdl','CMdl')

```

Name	Size	Bytes	Class
CMdl	1x1	5238	classreg.learning.classif.CompactClassificationNaiveBayes
Mdl	1x1	12539	ClassificationNaiveBayes

The `CompactClassificationNaiveBayes` classifier (CMdl) uses less space than the `ClassificationNaiveBayes` classifier (Mdl) because the latter stores the data.

Predict the labels, posterior probabilities, and expected class misclassification costs. Since true labels are available, compare them with the predicted labels.

CMdl.ClassNames

```

ans = 3x1 cell
    {'setosa'   }
    {'versicolor'}

```

```
{'virginica' }
```

```
[labels,PostProbs,MisClassCost] = predict(CMDL,XNew);
table(YNew,labels,PostProbs,'VariableNames',...
      {'TrueLabels','PredictedLabels',...
       'PosteriorProbabilities'})
```

```
ans=10×3 table
```

TrueLabels	PredictedLabels	PosteriorProbabilities		
{'setosa' }	{'setosa' }	1	4.1259e-16	1.1846e-23
{'versicolor' }	{'versicolor' }	1.0373e-60	0.99999	5.8053e-06
{'virginica' }	{'virginica' }	4.8708e-211	0.00085645	0.99914
{'setosa' }	{'setosa' }	1	1.4053e-19	2.2672e-26
{'versicolor' }	{'versicolor' }	2.9308e-75	0.99987	0.00012869
{'setosa' }	{'setosa' }	1	2.629e-18	4.4297e-25
{'versicolor' }	{'versicolor' }	1.4238e-67	0.99999	9.733e-06
{'versicolor' }	{'versicolor' }	2.0667e-110	0.94237	0.057625
{'setosa' }	{'setosa' }	1	4.3779e-19	3.5139e-26
{'setosa' }	{'setosa' }	1	1.1792e-17	2.2912e-24

MisClassCost

```
MisClassCost = 10×3
```

0.0000	1.0000	1.0000
1.0000	0.0000	1.0000
1.0000	0.9991	0.0009
0.0000	1.0000	1.0000
1.0000	0.0001	0.9999
0.0000	1.0000	1.0000
1.0000	0.0000	1.0000
1.0000	0.0576	0.9424
0.0000	1.0000	1.0000
0.0000	1.0000	1.0000

PostProbs and MisClassCost are 15-by-3 numeric matrices, where each row corresponds to a new observation and each column corresponds to a class. The order of the columns corresponds to the order of CMDL.ClassNames.

Plot Posterior Probability Regions for Naive Bayes Classifiers

Load Fisher's iris data set. Train the classifier using the petal lengths and widths.

```
load fisheriris
X = meas(:,3:4);
Y = species;
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X,Y,...
    'ClassNames',{'setosa','versicolor','virginica'});
```

Mdl is a ClassificationNaiveBayes model. You can access its properties using dot notation.

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

```
xMax = max(X);
xMin = min(X);
h = 0.01;
[x1Grid,x2Grid] = meshgrid(xMin(1):h:xMax(1),xMin(2):h:xMax(2));
```

```
[~,PosteriorRegion] = predict(Mdl,[x1Grid(:),x2Grid(:)]);
```

Plot the posterior probability regions and the training data.

```
figure;
% Plot posterior regions
scatter(x1Grid(:),x2Grid(:),1,PosteriorRegion);
% Adjust color bar options
h = colorbar;
h.Ticks = [0 0.5 1];
h.TickLabels = {'setosa','versicolor','virginica'};
h.YLabel.String = 'Posterior';
h.YLabel.Position = [-0.5 0.5 0];
% Adjust color map options
d = 1e-2;
cmap = zeros(201,3);
cmap(1:101,1) = 1:-d:0;
cmap(1:201,2) = [0:d:1 1-d:-d:0];
cmap(101:201,3) = 0:d:1;
colormap(cmap);
% Plot data
hold on
gh = gscatter(X(:,1),X(:,2),Y,'k','dx*');
title 'Iris Petal Measurements and Posterior Probabilities';
xlabel 'Petal length (cm)';
ylabel 'Petal width (cm)';
axis tight
legend(gh,'Location','Best')
hold off
```

More About

Misclassification Cost

A misclassification cost is the relative severity of a classifier labeling an observation into the wrong class.

There are two types of misclassification costs: true and expected. Let K be the number of classes.

- True misclassification cost — A K -by- K matrix, where element (i, j) indicates the misclassification cost of predicting an observation into class j if its true class is i . The software stores the misclassification cost in the property `Mdl.Cost`, and used in computations. By default, $\text{Mdl.Cost}(i, j) = 1$ if $i \neq j$, and $\text{Mdl.Cost}(i, j) = 0$ if $i = j$. In other words, the cost is 0 for correct classification, and 1 for any incorrect classification.
- Expected misclassification cost — A K -dimensional vector, where element k is the weighted average misclassification cost of classifying an observation into class k , weighted by the class posterior probabilities. In other words,

$$c_k = \sum_{j=1}^K \widehat{P}(Y = j | x_1, \dots, x_p) \text{Cost}_{jk}.$$

the software classifies observations to the class corresponding with the lowest expected misclassification cost.

Posterior Probability

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation (x_1, \dots, x_p) is

$$\hat{P}(Y = k | x_1, \dots, x_p) = \frac{P(X_1, \dots, X_p | y = k)\pi(Y = k)}{P(X_1, \dots, X_p)},$$

where:

- $P(X_1, \dots, X_p | y = k)$ is the conditional joint density of the predictors given they are in class k . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- $P(X_1, \dots, X_p)$ is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_p) = \sum_{k=1}^K P(X_1, \dots, X_p | y = k)\pi(Y = k).$$

Prior Probability

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen` to generate code for the `predict` function. Save a trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
Mdl	For the usage notes and limitations of the model object, see “Code Generation” on page 32-690 of the <code>CompactClassificationNaiveBayes</code> object.
X	<ul style="list-style-type: none"> For general code generation, X must be a single-precision or double-precision matrix or a table containing single or double predictor variables. <p>If you want to specify X as a table, then your model must be trained using a table, and you must ensure that your entry-point function for prediction:</p> <ul style="list-style-type: none"> Accepts data as arrays Creates a table from the data input arguments and specifies the variable names in the table Passes the table to <code>predict</code> <p>For an example of this table workflow, see “Generate Code to Classify Numeric Data in Table” on page 31-88. predict

Package: `classreg.learning.classif`

Classify observations using support vector machine (SVM) classifier

Syntax

```
label = predict(SVMModel,X)
[label,score] = predict(SVMModel,X)
```

Description

`label = predict(SVMModel,X)` returns a vector of predicted class labels for the predictor data in the table or matrix `X`, based on the trained support vector machine (SVM) classification model `SVMModel`. The trained SVM model can either be full or compact.

`[label,score] = predict(SVMModel,X)` also returns a matrix of scores (`score`) indicating the likelihood that a label comes from a particular class. For SVM, likelihood measures are either classification scores on page 32-4205 or class posterior probabilities on page 32-4206. For each observation in `X`, the predicted class label corresponds to the maximum score among all classes.

Examples

Label Test Sample Observations of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing, standardize the data, and specify that 'g' is the positive class.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
    'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; % Extract trained, compact classifier
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`CVSVMModel` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Label the test sample observations. Display the results for the first 10 observations in the test sample.

```
[label,score] = predict(CompactSVMModel,XTest);
table(YTest(1:10),label(1:10),score(1:10,2),'VariableNames',...
    {'TrueLabel','PredictedLabel','Score'})
```

```
ans=10x3 table
  TrueLabel   PredictedLabel   Score
  _____   _____   _____
    {'b'}      {'b'}           -1.7177
    {'g'}      {'g'}            2.0003
    {'b'}      {'b'}           -9.6841
    {'g'}      {'g'}            2.5618
    {'b'}      {'b'}           -1.548
    {'g'}      {'g'}            2.0984
    {'b'}      {'b'}           -2.7018
    {'b'}      {'b'}          -0.66291
    {'g'}      {'g'}            1.6046
    {'g'}      {'g'}            1.7731
```

Predict Labels and Posterior Probabilities of SVM Classifiers

Label new observations using an SVM classifier.

Load the ionosphere data set. Assume that the last 10 observations become available after you train the SVM classifier.

```
load ionosphere
rng(1); % For reproducibility
n = size(X,1); % Training sample size
isInds = 1:(n-10); % In-sample indices
oosInds = (n-9):n; % Out-of-sample indices
```

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class. Conserve memory by reducing the size of the trained SVM classifier.

```
SVMMModel = fitcsvm(X(isInds,:),Y(isInds),'Standardize',true,...
    'ClassNames',{'b','g'});
CompactSVMMModel = compact(SVMMModel);
whos('SVMMModel','CompactSVMMModel')
```

Name	Size	Bytes	Class
CompactSVMMModel	1x1	30314	classreg.learning.classif.CompactClassificationSVM
SVMMModel	1x1	137414	ClassificationSVM

The `CompactClassificationSVM` classifier (`CompactSVMMModel`) uses less space than the `ClassificationSVM` classifier (`SVMMModel`) because `SVMMModel` stores the data.

Estimate the optimal score-to-posterior-probability transformation function.

```
CompactSVMMModel = fitPosterior(CompactSVMMModel,...
    X(isInds,:),Y(isInds))

CompactSVMMModel =
    classreg.learning.classif.CompactClassificationSVM
        ResponseName: 'Y'
    CategoricalPredictors: []
        ClassNames: {'b' 'g'}
    ScoreTransform: '@(S)sigmoid(S,-1.968452e+00,3.121267e-01)'
```

```

        Alpha: [88x1 double]
        Bias: -0.2143
    KernelParameters: [1x1 struct]
        Mu: [1x34 double]
        Sigma: [1x34 double]
    SupportVectors: [88x34 double]
    SupportVectorLabels: [88x1 double]

```

Properties, Methods

The optimal score transformation function (`CompactSVMModel.ScoreTransform`) is the sigmoid function because the classes are inseparable.

Predict the out-of-sample labels and positive class posterior probabilities. Because true labels are available, compare them with the predicted labels.

```

[labels,PostProbs] = predict(CompactSVMModel,X(oosInds,:));
table(Y(oosInds),labels,PostProbs(:,2),'VariableNames',...
    {'TrueLabels','PredictedLabels','PosClassPosterior'})

```

```

ans=10x3 table
  TrueLabels PredictedLabels PosClassPosterior
  _____ _____
  {'g'}      {'g'}      0.98419
  {'g'}      {'g'}      0.95545
  {'g'}      {'g'}      0.67792
  {'g'}      {'g'}      0.94448
  {'g'}      {'g'}      0.98744
  {'g'}      {'g'}      0.92482
  {'g'}      {'g'}      0.97111
  {'g'}      {'g'}      0.96986
  {'g'}      {'g'}      0.97803
  {'g'}      {'g'}      0.94361

```

`PostProbs` is a 10-by-2 matrix, where the first column is the negative class posterior probabilities, and the second column is the positive class posterior probabilities corresponding to the new observations.

Input Arguments

SVMModel — SVM classification model

ClassificationSVM model object | CompactClassificationSVM model object

SVM classification model, specified as a `ClassificationSVM` model object or `CompactClassificationSVM` model object returned by `fitsvm` or `compact`, respectively.

X — Predictor data to be classified

numeric matrix | table

Predictor data to be classified, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

- For a numeric matrix:
 - The variables in the columns of `X` must have the same order as the predictor variables that trained `SVMMODEL`.
 - If you trained `SVMMODEL` using a table (for example, `Tbl`) and `Tbl` contains all numeric predictor variables, then `X` can be a numeric matrix. To treat numeric predictors in `Tbl` as categorical during training, identify categorical predictors by using the `CategoricalPredictors` name-value pair argument of `fitcsvm`. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types) and `X` is a numeric matrix, then `predict` throws an error.
- For a table:
 - `predict` does not support multicolumn variables and cell arrays other than cell arrays of character vectors.
 - If you trained `SVMMODEL` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and data types as those that trained `SVMMODEL` (stored in `SVMMODEL.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. Also, `Tbl` and `X` can contain additional variables (response variables, observation weights, and so on), but `predict` ignores them.
 - If you trained `SVMMODEL` using a numeric matrix, then the predictor names in `SVMMODEL.PredictorNames` and corresponding predictor variable names in `X` must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `fitcsvm`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, and so on), but `predict` ignores them.

If you set `'Standardize', true` in `fitcsvm` to train `SVMMODEL`, then the software standardizes the columns of `X` using the corresponding means in `SVMMODEL.Mu` and the standard deviations in `SVMMODEL.Sigma`.

Data Types: `table` | `double` | `single`

Output Arguments

label — Predicted class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of character vectors.

`label` has the same data type as the observed class labels (`Y`) that trained `SVMMODEL`, and its length is equal to the number of rows in `X`. (The software treats string arrays as cell arrays of character vectors.)

For one-class learning, `label` is the one class represented in the observed class labels.

score — Predicted class scores or posterior probabilities

numeric column vector | numeric matrix

Predicted class scores on page 32-4205 or posterior probabilities on page 32-4206, returned as a numeric column vector or numeric matrix.

- For one-class learning, `score` is a column vector with the same number of rows as the observations (`X`). The elements of `score` are the positive class scores for the corresponding observations. You cannot obtain posterior probabilities for one-class learning.
- For two-class learning, `score` is a two-column matrix with the same number of rows as `X`.
 - If you fit the optimal score-to-posterior-probability transformation function using `fitPosterior` or `fitSVMPosterior`, then `score` contains class posterior probabilities. That is, if the value of `SVMModel.ScoreTransform` is not `none`, then the first and second columns of `score` contain the negative class (`SVMModel.ClassNames{1}`) and positive class (`SVMModel.ClassNames{2}`) posterior probabilities for the corresponding observations, respectively.
 - Otherwise, the first column contains the negative class scores and the second column contains the positive class scores for the corresponding observations.

If `SVMModel.KernelParameters.Function` is `'linear'`, then the classification score for the observation `x` is

$$f(x) = (x/s)' \beta + b.$$

`SVMModel` stores β , b , and s in the properties `Beta`, `Bias`, and `KernelParameters.Scale`, respectively.

To estimate classification scores manually, you must first apply any transformations to the predictor data that were applied during training. Specifically, if you specify `'Standardize', true` when using `fitsvm`, then you must standardize the predictor data manually by using the mean `SVMModel.Mu` and standard deviation `SVMModel.Sigma`, and then divide the result by the kernel scale in `SVMModel.KernelParameters.Scale`.

All SVM functions, such as `resubPredict` and `predict`, apply any required transformation before estimation.

If `SVMModel.KernelParameters.Function` is not `'linear'`, then `Beta` is empty (`[]`).

More About

Classification Score

The SVM classification score for classifying observation x is the signed distance from x to the decision boundary ranging from $-\infty$ to $+\infty$. A positive score for a class indicates that x is predicted to be in that class. A negative score indicates otherwise.

The positive class classification score $f(x)$ is the trained SVM classification function. $f(x)$ is also the numerical, predicted response for x , or the score for predicting x into the positive class.

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, \dots, \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations. The negative class classification score for x , or the score for predicting x into the negative class, is $-f(x)$.

If $G(x_j, x) = x_j'x$ (the linear kernel), then the score function reduces to

$$f(x) = (x/s)'\beta + b.$$

s is the kernel scale and β is the vector of fitted linear coefficients.

For more details, see “Understanding Support Vector Machines” on page 18-145.

Posterior Probability

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For SVM, the posterior probability is a function of the score $P(s)$ that observation j is in class $k = \{-1, 1\}$.

- For separable classes, the posterior probability is the step function

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k = -1} s_k \\ \pi; & \max_{y_k = -1} s_k \leq s_j \leq \min_{y_k = +1} s_k, \\ 1; & s_j > \min_{y_k = +1} s_k \end{cases}$$

where:

- s_j is the score of observation j .
- $+1$ and -1 denote the positive and negative classes, respectively.
- π is the prior probability that an observation is in the positive class.
- For inseparable classes, the posterior probability is the sigmoid function

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)},$$

where the parameters A and B are the slope and intercept parameters, respectively.

Prior Probability

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

Tips

- If you are using a linear SVM model for classification and the model has many support vectors, then using `predict` for the prediction method can be slow. To efficiently classify observations based on a linear SVM model, remove the support vectors from the model object by using `discardSupportVectors`.

Algorithms

- By default and irrespective of the model kernel function, MATLAB uses the dual representation of the score function to classify observations based on trained SVM models, specifically

$$\hat{f}(x) = \sum_{j=1}^n \hat{\alpha}_j y_j G(x, x_j) + \hat{b}.$$

This prediction method requires the trained support vectors and α coefficients (see the `SupportVectors` and `Alpha` properties of the SVM model).

- By default, the software computes optimal posterior probabilities using Platt's method [1]:
 - 1 Perform 10-fold cross-validation.
 - 2 Fit the sigmoid function parameters to the scores returned from the cross-validation.
 - 3 Estimate the posterior probabilities by entering the cross-validation scores into the fitted sigmoid function.
- The software incorporates prior probabilities in the SVM objective function during training.
- For SVM, `predict` and `resubPredict` classify observations into the class yielding the largest score (the largest posterior probability). The software accounts for misclassification costs by applying the average-cost correction before training the classifier. That is, given the class prior vector P , misclassification cost matrix C , and observation weight vector w , the software defines a new vector of observation weights (W) such that

$$W_j = w_j P_j \sum_{k=1}^K C_{jk}.$$

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see "Tall Arrays" (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- You can generate C/C++ code for both `predict` and `update` by using a coder configurer. Or, generate code only for `predict` by using `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen`.
 - Code generation for `predict` and `update` — Create a coder configurer by using `learnerCoderConfigurer` and then generate code by using `generateCode`. Then you can update model parameters in the generated code without having to regenerate the code.
 - Code generation for `predict` — Save a trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.

- You can also generate fixed-point C/C++ code for `predict`. Fixed-point code generation requires an additional step that defines the fixed-point data types of the variables required for prediction. Create a fixed-point data type structure by using the data type function on page 32-2391 generated by `generateLearnerDataTypeFcn`, and use the structure as an input argument of `loadLearnerForCoder` in an entry-point function. Generating fixed-point C/C++ code requires MATLAB Coder and Fixed-Point Designer.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
SVMModel	<ul style="list-style-type: none"> If you use <code>saveLearnerForCoder</code> to save an SVM model that is equipped to predict posterior probabilities, and use <code>loadLearnerForCoder</code> to load the model, then <code>loadLearnerForCoder</code> cannot restore the <code>ScoreTransform</code> property into the MATLAB Workspace. However, <code>loadLearnerForCoder</code> can load the model, including the <code>ScoreTransform</code> property, at compile time for code generation, within an entry-point function. For the usage notes and limitations of the model object, see “Code Generation” on page 32-700 of the <code>CompactClassificationSVM</code> object.
X	<ul style="list-style-type: none"> For general code generation, X must be a single-precision or double-precision matrix or a table containing single or double predictor variables. <p>If you want to specify X as a table, then your model must be trained using a table, and you must ensure that your entry-point function for prediction:</p> <ul style="list-style-type: none"> Accepts data as arrays Creates a table from the data input arguments and specifies the variable names in the table Passes the table to <code>predict</code> <p>For an example of this table workflow, see “Generate Code to Classify Numeric Data in Table” on page 31-88. For more information on using tables in code generation, see “Code Generation for Tables” (MATLAB Coder) and “Table Limitations for Code Generation” (MATLAB Coder).</p> <ul style="list-style-type: none"> In the coder configurer workflow, X must be a single or double matrix. For fixed-point code generation, X must be a fixed-point matrix. The number of rows, or observations, in X can be a variable size, but the number of columns in X must be fixed.

For more information, see “Introduction to Code Generation” on page 31-2.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

predict

Predict labels using classification tree

Syntax

```
label = predict(Mdl,X)
label = predict(Mdl,X,Name,Value)
[label,score,node,cnum] = predict( ___ )
```

Description

`label = predict(Mdl,X)` returns a vector of predicted class labels for the predictor data in the table or matrix `X`, based on the trained, full or compact classification tree `Mdl`.

`label = predict(Mdl,X,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, you can specify to prune `Mdl` to a particular level before predicting labels.

`[label,score,node,cnum] = predict(___)` uses any of the input argument in the previous syntaxes and additionally returns:

- A matrix of classification scores (`score`) indicating the likelihood that a label comes from a particular class. For classification trees, scores are posterior probabilities. For each observation in `X`, the predicted class label on page 32-4215 corresponds to the minimum expected misclassification cost on page 32-4218 among all classes.
- A vector of predicted node numbers for the classification (`node`).
- A vector of predicted class number for the classification (`cnum`).

Input Arguments

Mdl — Trained classification tree

`ClassificationTree` model object | `CompactClassificationTree` model object

Trained classification tree, specified as a `ClassificationTree` or `CompactClassificationTree` model object. That is, `Mdl` is a trained classification model returned by `fitctree` or `compact`.

X — Predictor data to be classified

numeric matrix | table

Predictor data to be classified, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

- For a numeric matrix:
 - The variables making up the columns of `X` must have the same order as the predictor variables that trained `Mdl`.
 - If you trained `Mdl` using a table (for example, `Tbl`), then `X` can be a numeric matrix if `Tbl` contains all numeric predictor variables. To treat numeric predictors in `Tbl` as categorical

during training, identify categorical predictors using the `CategoricalPredictors` name-value pair argument of `fitctree`. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types) and `X` is a numeric matrix, then `predict` throws an error.

- For a table:
 - `predict` does not support multi-column variables and cell arrays other than cell arrays of character vectors.
 - If you trained `Mdl` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and data types as those that trained `Mdl` (stored in `Mdl.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. `Tbl` and `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.
 - If you trained `Mdl` using a numeric matrix, then the predictor names in `Mdl.PredictorNames` and corresponding predictor variable names in `X` must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `fitctree`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.

Data Types: `table` | `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Subtrees — Pruning level

0 (default) | vector of nonnegative integers | 'all'

Pruning level, specified as the comma-separated pair consisting of 'Subtrees' and a vector of nonnegative integers in ascending order or 'all'.

If you specify a vector, then all elements must be at least 0 and at most `max(Mdl.PruneList)`. 0 indicates the full, unpruned tree and `max(Mdl.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify 'all', then `predict` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(Mdl.PruneList)`.

`predict` prunes `Mdl` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `Mdl` must be nonempty. In other words, grow `Mdl` by setting 'Prune', 'on', or by pruning `Mdl` using `prune`.

Example: 'Subtrees', 'all'

Data Types: `single` | `double` | `char` | `string`

Output Arguments

label — Predicted class labels

vector | array

Predicted class labels on page 32-4215, returned as a vector or array. Each entry of `label` corresponds to the class with minimal expected cost for the corresponding row of `X`.

Suppose `Subtrees` is a numeric vector containing `T` elements (for 'all', see `Subtrees`), and `X` has `N` rows.

- If the response data type is `char` and:
 - `T = 1`, then `label` is a character matrix containing `N` rows. Each row contains the predicted label produced by subtree `Subtrees`.
 - `T > 1`, then `label` is an `N`-by-`T` cell array.
- Otherwise, `label` is an `N`-by-`T` array having the same data type as the response. (The software treats string arrays as cell arrays of character vectors.)

In the latter two cases, column `j` of `label` contains the vector of predicted labels produced by subtree `Subtrees(j)`.

score — Posterior probabilities

numeric matrix

Posterior probabilities, returned as a numeric matrix of size `N`-by-`K`, where `N` is the number of observations (rows) in `X`, and `K` is the number of classes (in `Mdl.ClassNames`). `score(i,j)` is the posterior probability that row `i` of `X` is of class `j`.

If `Subtrees` has `T` elements, and `X` has `N` rows, then `score` is an `N`-by-`K`-by-`T` array, and `node` and `cnum` are `N`-by-`T` matrices.

node — Node numbers

numeric vector

Node numbers for the predicted classes, returned as a numeric vector. Each entry corresponds to the predicted node in `Mdl` for the corresponding row of `X`.

cnum — Class numbers

numeric vector

Class numbers corresponding to the predicted `labels`, returned as a numeric vector. Each entry of `cnum` corresponds to a predicted class number for the corresponding row of `X`.

Examples

Predict Labels Using a Classification Tree

Examine predictions for a few rows in a data set left out of training.

Load Fisher's iris data set.

```
load fisheriris
```

Partition the data into training (50%) and validation (50%) sets.

```
n = size(meas,1);
rng(1) % For reproducibility
idxTrn = false(n,1);
```

```
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices
idxVal = idxTrn == false; % Validation set logical indices
```

Grow a classification tree using the training set.

```
Mdl = fitctree(meas(idxTrn,:),species(idxTrn));
```

Predict labels for the validation data. Count the number of misclassified observations.

```
label = predict(Mdl,meas(idxVal,:));
label(randsample(numel(label),5)) % Display several predicted labels
```

```
ans = 5x1 cell
    {'setosa' }
    {'setosa' }
    {'setosa' }
    {'virginica' }
    {'versicolor' }
```

```
numMisclass = sum(~strcmp(label,species(idxVal)))
```

```
numMisclass = 3
```

The software misclassifies three out-of-sample observations.

Estimate Class Posterior Probabilities Using a Classification Tree

Load Fisher's iris data set.

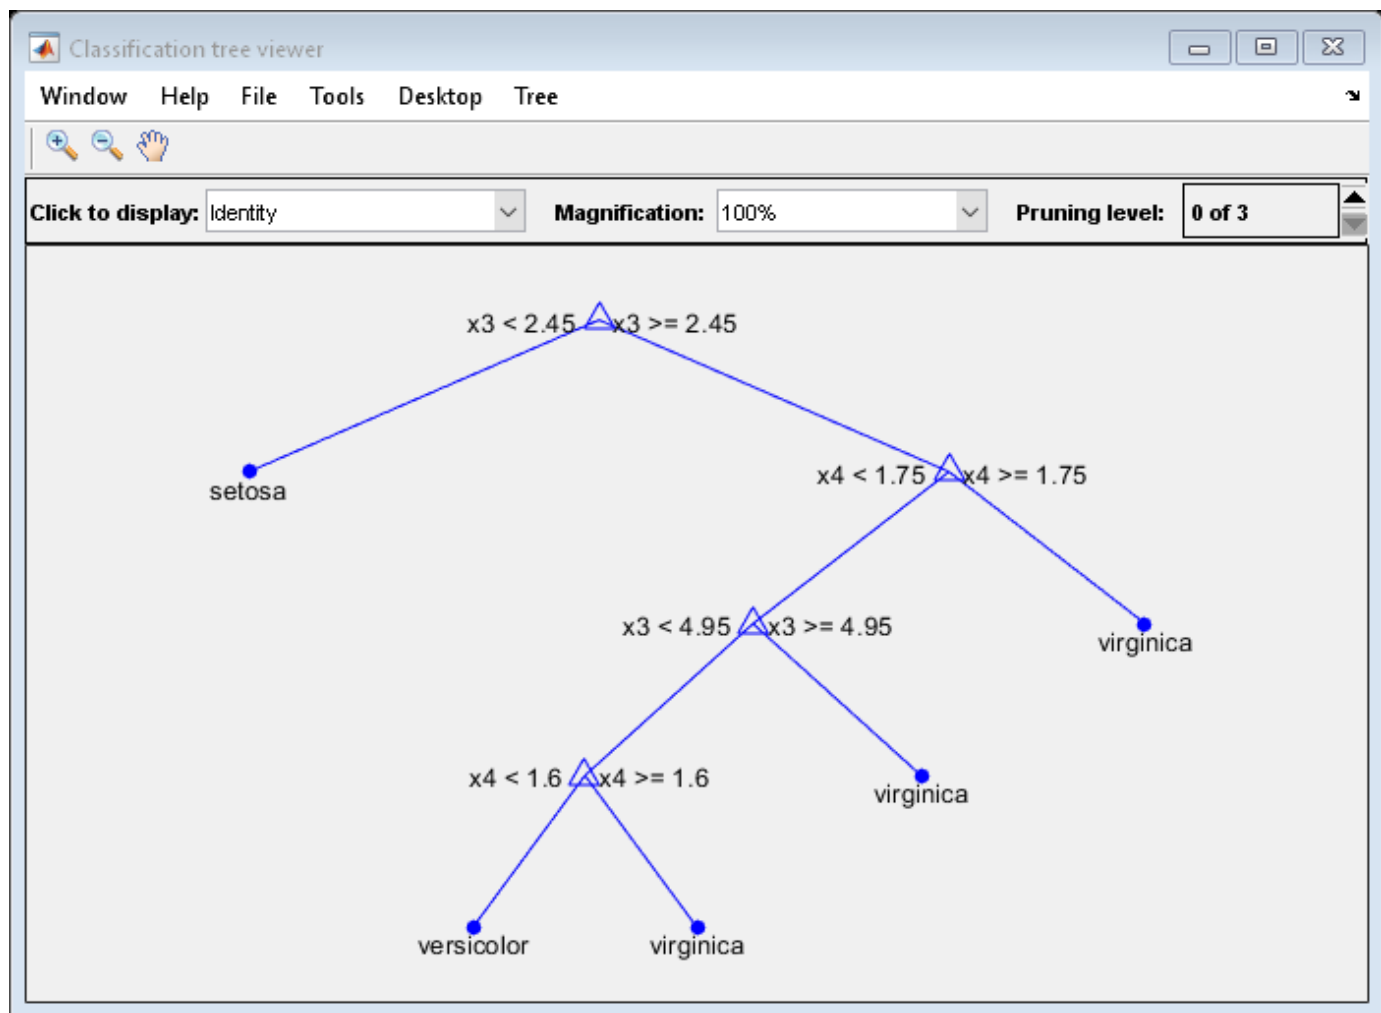

```
load fisheriris
```

Partition the data into training (50%) and validation (50%) sets.

```
n = size(meas,1);
rng(1) % For reproducibility
idxTrn = false(n,1);
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices
idxVal = idxTrn == false; % Validation set logical indices
```

Grow a classification tree using the training set, and then view it.

```
Mdl = fitctree(meas(idxTrn,:),species(idxTrn));
view(Mdl,'Mode','graph')
```

The resulting tree has four levels.

Estimate posterior probabilities for the test set using subtrees pruned to levels 1 and 3.

```
[~,Posterior] = predict(Mdl,meas(idxVal,:), 'SubTrees', [1 3]);
Mdl.ClassNames
```

```
ans = 3x1 cell
    {'setosa' }
    {'versicolor'}
    {'virginica' }
```

```
Posterior(randsample(size(Posterior,1),5),:,:) ,...
    % Display several posterior probabilities
```

```
ans =
ans(:, :, 1) =
```

```
1.0000    0    0
1.0000    0    0
1.0000    0    0
```

```

0      0      1.0000
0      0.8571  0.1429

```

```
ans(:, :, 2) =
```

```

0.3733  0.3200  0.3067
0.3733  0.3200  0.3067
0.3733  0.3200  0.3067
0.3733  0.3200  0.3067
0.3733  0.3200  0.3067

```

The elements of `Posterior` are class posterior probabilities:

- Rows correspond to observations in the validation set.
- Columns correspond to the classes as listed in `Mdl.ClassNames`.
- Pages correspond to the subtrees.

The subtree pruned to level 1 is more sure of its predictions than the subtree pruned to level 3 (i.e., the root node).

More About

Predicted Class Label

`predict` classifies by minimizing the expected classification cost:

$$\hat{y} = \operatorname{argmin}_{y=1, \dots, K} \sum_{j=1}^K \hat{P}(j|x)C(y|j),$$

where

- \hat{y} is the predicted classification.
- K is the number of classes.
- $\hat{P}(j|x)$ is the posterior probability of class j for observation x .
- $C(y|j)$ is the cost of classifying an observation as y when its true class is j .

Score (tree)

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as `true` when $X < 0.15$ or $X > 0.95$, and X is false otherwise.

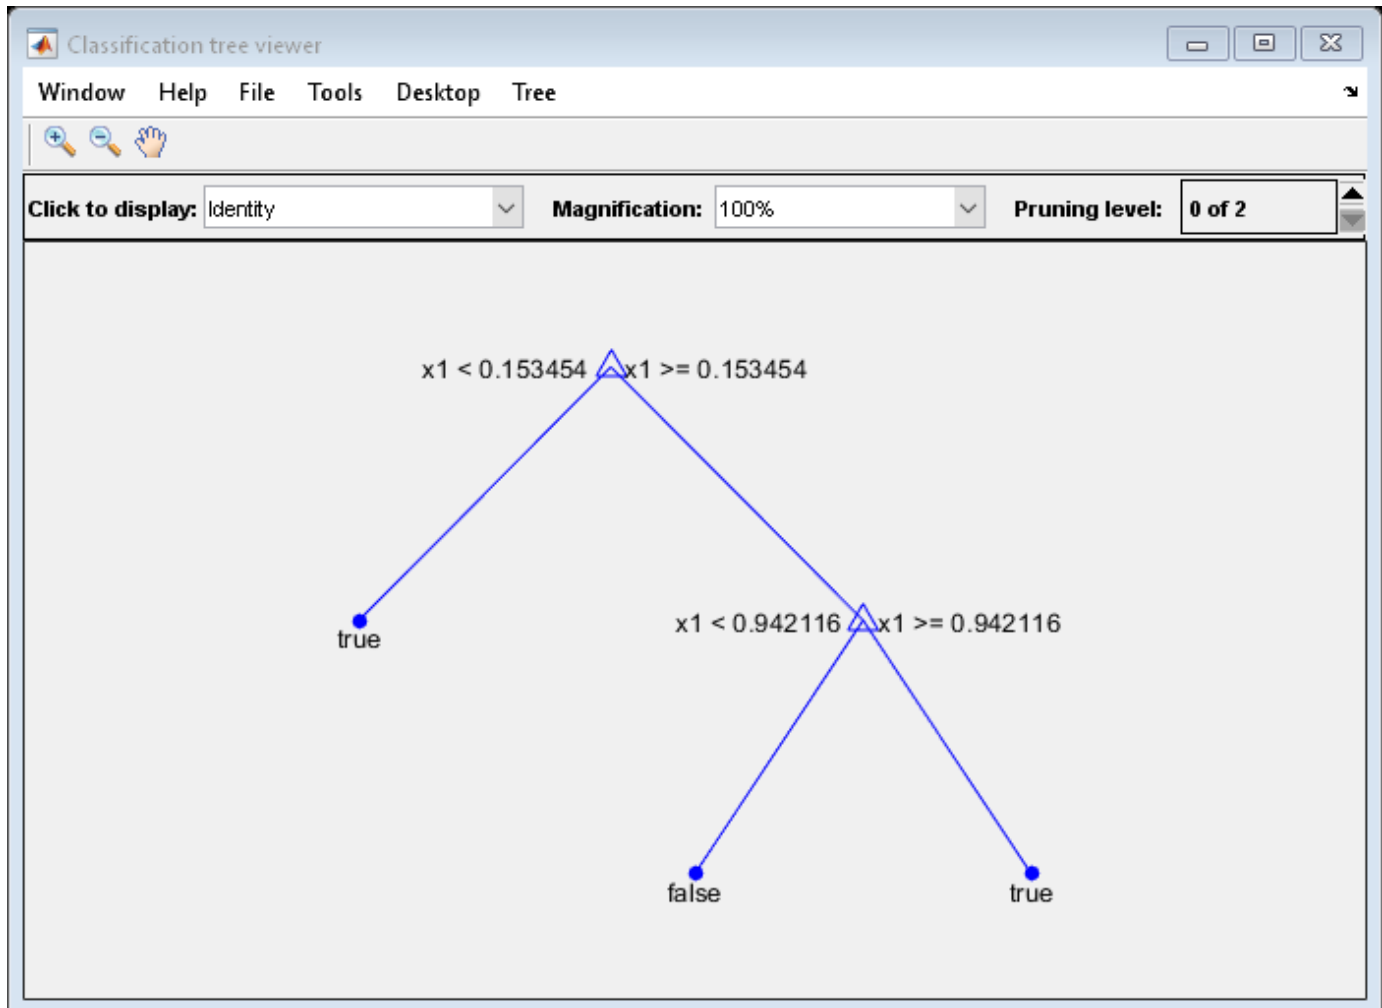

Generate 100 random points and classify them:

```

rng(0, 'twister') % for reproducibility
X = rand(100,1);

```

```
Y = (abs(X - .55) > .4);  
tree = fitctree(X,Y);  
view(tree, 'Mode', 'Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for `true`, and about $.8/.85=.94$ for `false`.

Compute the prediction scores for the first 10 rows of `X`:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans = 10x3
```

```
    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0     1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0     1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
```

0.9059 0.0941 0.9649

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range $(.95, 1)$ instead of the expected 5 observations.

True Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you create the classifier using the `fitctree` method. `Cost(i, j)` is the cost of classifying an observation into class j if its true class is i . By default, `Cost(i, j)=1` if $i \neq j$, and `Cost(i, j)=0` if $i=j$. In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

Expected Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier. Suppose you have K classes. You place the observations into a matrix `Xnew` with one observation per row.

The expected cost matrix `CE` has size `Nobs-by-K`. Each row of `CE` contains the expected (average) cost of classifying the observation into each of the K classes. `CE(n, k)` is

$$\sum_{i=1}^K \widehat{P}(i|Xnew(n))C(k|i),$$

where

- K is the number of classes.
- $\widehat{P}(i|Xnew(n))$ is the posterior probability of class i for observation `Xnew(n)`.
- $C(k|i)$ is the true misclassification cost of classifying an observation as k when its true class is i .

Predictive Measure of Association

The predictive measure of association is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split (found by growing the tree), the best surrogate decision split on page 32-1791 yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose x_j and x_k are predictor variables j and k , respectively, and $j \neq k$. At node t , the predictive measure of association between the optimal split $x_j < u$ and a surrogate split $x_k < v$ is

$$\lambda_{jk} = \frac{\min(P_L, P_R) - (1 - P_{L_j L_k} - P_{R_j R_k})}{\min(P_L, P_R)}.$$

- P_L is the proportion of observations in node t , such that $x_j < u$. The subscript L stands for the left child of node t .

- P_R is the proportion of observations in node t , such that $x_j \geq u$. The subscript R stands for the right child of node t .
- $P_{L_j L_k}$ is the proportion of observations at node t , such that $x_j < u$ and $x_k < v$.
- $P_{R_j R_k}$ is the proportion of observations at node t , such that $x_j \geq u$ and $x_k \geq v$.
- Observations with missing values for x_j or x_k do not contribute to the proportion calculations.

λ_{jk} is a value in $(-\infty, 1]$. If $\lambda_{jk} > 0$, then $x_k < v$ is a worthwhile surrogate split for $x_j < u$.

Algorithms

`predict` generates predictions by following the branches of `Mdl` until it reaches a leaf node or a missing value. If `predict` reaches a leaf node, it returns the classification of that node.

If `predict` reaches a node with a missing value for a predictor, its behavior depends on the setting of the `Surrogate` name-value pair when `fitctree` constructs `Mdl`.

- **Surrogate = 'off'** (default) — `predict` returns the label with the largest number of training samples that reach the node.
- **Surrogate = 'on'** — `predict` uses the best surrogate split at the node. If all surrogate split variables with positive predictive measure of association are missing, `predict` returns the label with the largest number of training samples that reach the node. For a definition, see “Predictive Measure of Association” on page 32-4218.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- You can generate C/C++ code for both `predict` and `update` by using a coder configurer. Or, generate code only for `predict` by using `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen`.
 - Code generation for `predict` and `update` — Create a coder configurer by using `learnerCoderConfigurer` and then generate code by using `generateCode`. Then you can update model parameters in the generated code without having to regenerate the code.
 - Code generation for `predict` — Save a trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- You can also generate fixed-point C/C++ code for `predict`. Fixed-point code generation requires an additional step that defines the fixed-point data types of the variables required for prediction.

Create a fixed-point data type structure by using the data type function on page 32-2391 generated by `generateLearnerDataTypeFcn`, and use the structure as an input argument of `loadLearnerForCoder` in an entry-point function. Generating fixed-point C/C++ code requires MATLAB Coder and Fixed-Point Designer.

- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
<code>Mdl</code>	For the usage notes and limitations of the model object, see “Code Generation” on page 32-709 of the <code>CompactClassificationTree</code> object.
<code>X</code>	<ul style="list-style-type: none"> • For general code generation, <code>X</code> must be a single-precision or double-precision matrix or a table containing single or double predictor variables. <p>If you want to specify <code>X</code> as a table, then your model must be trained using a table, and you must ensure that your entry-point function for prediction:</p> <ul style="list-style-type: none"> • Accepts data as arrays • Creates a table from the data input arguments and specifies the variable names in the table • Passes the table to <code>predict</code> <p>For an example of this table workflow, see “Generate Code to Classify Numeric Data in Table” on page 31-88. “Specify Variable-Size Arguments for Code Generation” on page 31-38

Introduced in R2011a

predict

Predict responses using ensemble of regression models

Syntax

```
Yfit = predict(Mdl,X)
Yfit = predict(Mdl,X,Name,Value)
```

Description

`Yfit = predict(Mdl,X)` returns predicted responses to the predictor data in the table or matrix `X`, based on the regression ensemble model `Mdl`.

`Yfit = predict(Mdl,X,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

Mdl

Regression ensemble created by `fitrensemble`, or by the `compact` method.

X

Predictor data used to generate responses, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

- For a numeric matrix:
 - The variables making up the columns of `X` must have the same order as the predictor variables that trained `Mdl`.
 - If you trained `Mdl` using a table (for example, `Tbl`), then `X` can be a numeric matrix if `Tbl` contains all numeric predictor variables. To treat numeric predictors in `Tbl` as categorical during training, identify categorical predictors using the `CategoricalPredictors` name-value pair argument of `fitrensemble`. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types) and `X` is a numeric matrix, then `predict` throws an error.
- For a table:
 - `predict` does not support multi-column variables and cell arrays other than cell arrays of character vectors.
 - If you trained `Mdl` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and data types as those that trained `Mdl` (stored in `Mdl.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. `Tbl` and `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.
 - If you trained `Mdl` using a numeric matrix, then the predictor names in `Mdl.PredictorNames` and corresponding predictor variable names in `X` must be the same. To specify predictor names

during training, see the `PredictorNames` name-value pair argument of `fitrensemble`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`, where `NumTrained` is the number of weak learners.

Default: `1:NumTrained`

UseObsForLearner

A logical matrix of size `N`-by-`NumTrained`, where `N` is the number of observations in `X`, and `NumTrained` is the number of weak learners. When `UseObsForLearner(I, J)` is `true`, `predict` uses learner `J` in predicting observation `I`.

Default: `true(N, NumTrained)`

Output Arguments

Yfit

A numeric column vector with the same number of rows as `TBLdata` or `Xdata`. Each row of `Yfit` gives the predicted response to the corresponding row of `TBLdata` or `Xdata`, based on the ensemble regression model.

Examples

Predict Responses Based on Regression Ensemble

Find the predicted mileage for a car based on regression ensemble trained on the `carsmall` data.

Load the `carsmall` data set and select the number of cylinders, engine displacement, horsepower, and vehicle weight as predictors.

```
load carsmall
X = [Cylinders Displacement Horsepower Weight];
```

Train an ensemble of regression trees and predict MPG for a four-cylinder car, with 200 cubic inch engine displacement, 150 horsepower, weighing 3000 lbs.

```
rens = fitrensemble(X,MPG);
Mileage = predict(rens,[4 200 150 3000])
```

```
Mileage = 25.6467
```

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen` to generate code for the `predict` function. Save a trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- You can also generate fixed-point C/C++ code for `predict`. Fixed-point code generation requires an additional step that defines the fixed-point data types of the variables required for prediction. Create a fixed-point data type structure by using the data type function on page 32-2391 generated by `generateLearnerDataTypeFcn`, and use the structure as an input argument of `loadLearnerForCoder` in an entry-point function. Generating fixed-point C/C++ code requires MATLAB Coder and Fixed-Point Designer.
- Generating fixed-point code for `predict` includes propagating data types for individual learners and, therefore, can be time consuming.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
<code>Mdl</code>	For the usage notes and limitations of the model object, see “Code Generation” on page 32-733 of the <code>CompactRegressionEnsemble</code> object.

Argument	Notes and Limitations
X	<ul style="list-style-type: none"> For general code generation, X must be a single-precision or double-precision matrix or a table containing single or double predictor variables. <p>If you want to specify X as a table, then your model must be trained using a table, and you must ensure that your entry-point function for prediction:</p> <ul style="list-style-type: none"> Accepts data as arrays Creates a table from the data input arguments and specifies the variable names in the table Passes the table to <code>predict</code> <p>For an example of this table workflow, see “Generate Code to Classify Numeric Data in Table” on page 31-88. For more information on using tables in code generation, see “Code Generation for Tables” (MATLAB Coder) and “Table Limitations for Code Generation” (MATLAB Coder).</p> <ul style="list-style-type: none"> For fixed-point code generation, X must be a fixed-point matrix. The number of rows, or observations, in X can be a variable size, but the number of columns in X must be fixed.
Name-value pair arguments	<p>Names in name-value pair arguments must be compile-time constants. For example, to allow user-defined indices up to 5 weak learners in the generated code, include</p> <pre>{coder.Constant('Learners'),coder.typeof(0,[1,5],[0,1])}</pre> <p>in the <code>-args</code> value of <code>codegen</code>.</p>
'Learners'	<p>For fixed-point code generation, the 'Learners' value must have an integer data type.</p>

predict

Predict response of Gaussian process regression model

Syntax

```
ypred = predict(gprMdl,Xnew)
[ypred,ysd] = predict(gprMdl,Xnew)
[ypred,ysd,yint] = predict(gprMdl,Xnew)
[ypred,ysd,yint] = predict(gprMdl,Xnew,Name,Value)
```

Description

`ypred = predict(gprMdl,Xnew)` returns the predicted responses `ypred` for the full or compact Gaussian process regression (GPR) model, `gprMdl`, and the predictor values in `Xnew`.

`[ypred,ysd] = predict(gprMdl,Xnew)` also returns the estimated standard deviations for the new responses at the predictor values in `Xnew` from a trained GPR model.

`[ypred,ysd,yint] = predict(gprMdl,Xnew)` also returns the 95% prediction intervals, `yint`, for the true responses corresponding to each row of `Xnew`.

`[ypred,ysd,yint] = predict(gprMdl,Xnew,Name,Value)` also returns the prediction intervals with additional options specified by one or more `Name, Value` pair arguments. For example, you can specify the confidence level of the prediction interval.

Input Arguments

gprMdl — Gaussian process regression model

RegressionGP object | CompactRegressionGP object

Gaussian process regression model, specified as a `RegressionGP` (full) or `CompactRegressionGP` (compact) object.

Xnew — New values for the predictors

table | *m*-by-*d* matrix

New values for the predictors that `fitrgp` uses in training the GPR model, specified as a `table` or an *m*-by-*d* matrix. *m* is the number of observations and *d* is the number of predictor variables in the training data.

If you trained `gprMdl` on a `table`, then `Xnew` must be a `table` that contains all the predictor variables used to train `gprMdl`.

If you trained `gprMdl` on a matrix, then `Xnew` must be a numeric matrix with *d* columns.

Data Types: `single` | `double` | `table`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Alpha — Significance level

0.05 (default) | scalar value in the range from 0 to 1

Significance level for the prediction intervals, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range from 0 to 1.

Example: `'Alpha', 0.01` specifies 99% prediction intervals.

Data Types: `single` | `double`

Output Arguments

ypred — Predicted response values

n-by-1 vector

Predicted response values, returned as an *n*-by-1 vector.

ysd — Estimated standard deviation of the new response values

n-by-1 vector

Estimated standard deviation of the new response values, returned as an *n*-by-1 vector, where `ysd(i)`, $i = 1, 2, \dots, n$, contains the estimated standard deviation of the new response corresponding to the predictor values at the *i*th row of `Xnew` from the trained GPR model.

yint — Prediction intervals for the true response values

n-by-2 matrix

Prediction intervals for the true response values corresponding to each row of `Xnew`, returned as an *n*-by-2 matrix. The first column of `yint` contains the lower limits and the second column contains the upper limits of the prediction intervals.

Examples

Compute Predicted Responses

Generate the sample data.

```
n = 10000;
rng(1) % For reproducibility
x = linspace(0.5,2.5,n)';
y = sin(10*pi.*x) ./ (2.*x)+(x-1).^4 + 1.5*rand(n,1);
```

Fit a GPR model using the Matern 3/2 kernel function with separate length scale for each predictor and an active set size of 100. Use the subset of regressors approximation method for parameter estimation and fully independent conditional method for prediction.

```
gprMdl = fitrgp(x,y,'KernelFunction','ardmatern32',...
'ActiveSetSize',100,'FitMethod','sr','PredictMethod','fic');
```

Compute the predictions.

```
[ypred,~,yci] = predict(gprMdl,x);
```

Plot the data along with the predictions and prediction intervals.

```
plot(x,y,'r. ');
hold on
plot(x,ypred);
plot(x,yci(:,1),'k--');
plot(x,yci(:,2),'k--');
xlabel('x');
ylabel('y');
```

Compute Predictions When Data in Table

Load the sample data and store in a table.

```
load fisheriris
tbl = table(meas(:,1),meas(:,2),meas(:,3),meas(:,4),species,...
'VariableNames',{'meas1','meas2','meas3','meas4','species'});
```

Fit a GPR model using the first measurement as the response and the other variables as the predictors.

```
mdl = fitrgp(tbl,'meas1');
```

Compute the predictions and the 99% confidence intervals.

```
[ypred,~,yci] = predict mdl, tbl, 'Alpha', 0.01;
```

Plot the true response and the predictions along with the prediction intervals.

```
figure();
plot mdl.Y, 'r.';
hold on;
plot(ypred);
plot(yci(:,1), 'k:');
plot(yci(:,2), 'k:');
legend('True response', 'GPR predictions', ...
'Lower prediction limit', 'Upper prediction limit', ...
'Location', 'Best');
```

Plot Predicted Response for Test Data

Load the sample data.

```
load('gprdata.mat');
```

The data contains training and test data. There are 500 observations in training data and 100 observations in test data. The data has 8 predictor variables. This is simulated data.

Fit a GPR model using the squared exponential kernel function with a separate length scale for each predictor. Standardize predictors in the training data. Use the exact fitting and prediction methods.

```
gprMdl = fitrgp(Xtrain,ytrain,'Basis','constant',...
'FitMethod','exact','PredictMethod','exact',...
'KernelFunction','ardsquaredexponential','Standardize',1);
```

Predict the responses for test data.

```
[ytestpred,~,ytestci] = predict(gprMdl,Xtest);
```

Plot the test response along with the predictions.

```
figure;
plot(ytest,'r');
hold on;
plot(ytestpred,'b');
plot(ytestci(:,1),'k:');
plot(ytestci(:,2),'k:');
legend('Actual response','GPR predictions',...
'95% lower','95% upper','Location','Best');
hold off
```

Tips

- You can choose the prediction method while training the GPR model using the `PredictMethod` name-value pair argument in `fitrgp`. The default prediction method is 'exact' for $n \leq 10000$,

where n is the number of observations in the training data, and 'bcd' (block coordinate descent), otherwise.

- Computation of standard deviations, `ysd`, and prediction intervals, `yint`, is not supported when `PredictMethod` is 'bcd'.
- If `gprMdl` is a `CompactRegressionGP` object, you cannot compute standard deviations, `ysd`, or prediction intervals, `yint`, for `PredictMethod` equal to 'sr' or 'fic'. To compute `ysd` and `yint` for `PredictMethod` equal to 'sr' or 'fic', use the full regression (`RegressionGP`) object.

Alternatives

You can use `resubPredict` to compute the predicted responses for the trained GPR model at the observations in the training data.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen` to generate code for the `predict` function. Save a trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
<code>Mdl</code>	For the usage notes and limitations of the model object, see “Code Generation” on page 32-738 of the <code>CompactRegressionGP</code> object.

Argument	Notes and Limitations
Xnew	<ul style="list-style-type: none"> For general code generation, Xnew must be a single-precision or double-precision matrix or a table containing single or double predictor variables. <p>If you want to specify Xnew as a table, then your model must be trained using a table, and you must ensure that your entry-point function for prediction:</p> <ul style="list-style-type: none"> Accepts data as arrays Creates a table from the data input arguments and specifies the variable names in the table Passes the table to <code>predict</code> <p>For an example of this table workflow, see “Generate Code to Classify Numeric Data in Table” on page 31-88. CompactRegressionGP | RegressionGP | compact | fitrgp | loss | resubPredict

Introduced in R2015b

predict

Predict responses using support vector machine regression model

Syntax

```
yfit = predict(Mdl,X)
```

Description

`yfit = predict(Mdl,X)` returns a vector of predicted responses for the predictor data in the table or matrix `X`, based on the full or compact, trained support vector machine (SVM) regression model `Mdl`.

Input Arguments

Mdl — SVM regression model

RegressionSVM object | CompactRegressionSVM object

SVM regression model, specified as a `RegressionSVM` model or a `CompactRegressionSVM` model, returned by `fitrsvm` or `compact`, respectively.

X — Predictor data used to generate responses

numeric matrix | table

Predictor data used to generate responses, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

- For a numeric matrix:
 - The variables making up the columns of `X` must have the same order as the predictor variables that trained `Mdl`.
 - If you trained `Mdl` using a table (for example, `Tbl`), then `X` can be a numeric matrix if `Tbl` contains all numeric predictor variables. To treat numeric predictors in `Tbl` as categorical during training, identify categorical predictors using the `CategoricalPredictors` name-value pair argument of `fitrsvm`. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types) and `X` is a numeric matrix, then `predict` throws an error.
- For a table:
 - `predict` does not support multi-column variables and cell arrays other than cell arrays of character vectors.
 - If you trained `Mdl` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and data types as those that trained `Mdl` (stored in `Mdl.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. `Tbl` and `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.
 - If you trained `Mdl` using a numeric matrix, then the predictor names in `Mdl.PredictorNames` and corresponding predictor variable names in `X` must be the same. To specify predictor names

during training, see the `PredictorNames` name-value pair argument of `fitrsvm`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.

If you set `'Standardize', true` in `fitrsvm` to train `Mdl`, then the software standardizes the columns of `X` using the corresponding means in `Mdl.Mu` and standard deviations in `Mdl.Sigma`.

Data Types: `table` | `double` | `single`

Output Arguments

yfit — Predicted responses

vector

Predicted responses, returned as a vector of length n , where n is the number of observations in the training data.

For details about how to predict responses, see “Equation 25-1” and “Equation 25-2” in “Understanding Support Vector Machine Regression” on page 25-2.

Examples

Predict Test Sample Response for SVM Regression Model

Load the `carsmall` data set. Consider a model that predicts a car's fuel efficiency given its horsepower and weight. Determine the sample size.

```
load carsmall
tbl = table(Horsepower,Weight,MPG);
N = size(tbl,1);
```

Partition the data into training and test sets. Hold out 10% of the data for testing.

```
rng(10); % For reproducibility
cvp = cvpartition(N,'Holdout',0.1);
idxTrn = training(cvp); % Training set indices
idxTest = test(cvp); % Test set indices
```

Train a linear SVM regression model. Standardize the data.

```
Mdl = fitrsvm(tbl(idxTrn,:), 'MPG', 'Standardize', true);
```

`Mdl` is a `RegressionSVM` model.

Predict responses for the test set.

```
YFit = predict(Mdl,tbl(idxTest,:));
```

Create a table containing the observed response values and the predicted response values side by side.

```
table(tbl.MPG(idxTest),YFit,'VariableNames',...
      {'ObservedValue','PredictedValue'})
```

```
ans=10×2 table
    ObservedValue    PredictedValue
```

14	9.4833
27	28.938
10	7.765
28	27.155
22	21.054
29	31.484
24.5	30.306
18.5	19.12
32	28.225
28	26.632

Tips

- If `mdl` is a cross-validated `RegressionPartitionedSVM` model, use `kfoldPredict` instead of `predict` to predict new response values.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- You can generate C/C++ code for both `predict` and `update` by using a coder configurer. Or, generate code only for `predict` by using `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen`.
 - Code generation for `predict` and `update` — Create a coder configurer by using `learnerCoderConfigurer` and then generate code by using `generateCode`. Then you can update model parameters in the generated code without having to regenerate the code.
 - Code generation for `predict` — Save a trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- You can also generate fixed-point C/C++ code for `predict`. Fixed-point code generation requires an additional step that defines the fixed-point data types of the variables required for prediction. Create a fixed-point data type structure by using the data type function on page 32-2391 generated by `generateLearnerDataTypeFcn`, and use the structure as an input argument of `loadLearnerForCoder` in an entry-point function. Generating fixed-point C/C++ code requires MATLAB Coder and Fixed-Point Designer.

- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
Mdl	For the usage notes and limitations of the model object, see “Code Generation” on page 32-745 of the <code>CompactRegressionSVM</code> object.
X	<ul style="list-style-type: none"> • For general code generation, X must be a single-precision or double-precision matrix or a table containing single or double predictor variables. <p>If you want to specify X as a table, then your model must be trained using a table, and you must ensure that your entry-point function for prediction:</p> <ul style="list-style-type: none"> • Accepts data as arrays • Creates a table from the data input arguments and specifies the variable names in the table • Passes the table to <code>predict</code> <p>For an example of this table workflow, see “Generate Code to Classify Numeric Data in Table” on page 31-88. For more information on using tables in code generation, see “Code Generation for Tables” (MATLAB Coder) and “Table Limitations for Code Generation” (MATLAB Coder).</p> <ul style="list-style-type: none"> • In the coder configurer workflow, X must be a single or double matrix. • For fixed-point code generation, X must be a fixed-point matrix. • The number of rows, or observations, in X can be a variable size, but the number of columns in X must be fixed.

`CompactRegressionSVM` | `RegressionSVM` | `fitrsvm` | `kfoldPredict`

Introduced in R2015b

predict

Predict responses using regression tree

Syntax

```
Yfit = predict(Mdl,X)
Yfit = predict(Mdl,X,Name,Value)
[Yfit,node] = predict( ___ )
```

Description

`Yfit = predict(Mdl,X)` returns a vector of predicted responses for the predictor data in the table or matrix `X`, based on the full or compact regression tree `Mdl`.

`Yfit = predict(Mdl,X,Name,Value)` predicts response values with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify to prune `Mdl` to a particular level before predicting responses.

`[Yfit,node] = predict(___)` also returns a vector of predicted node numbers for the responses, using any of the input arguments in the previous syntaxes.

Input Arguments

Mdl — Trained regression tree

RegressionTree model object | CompactRegressionTree model object

Trained classification tree, specified as a `RegressionTree` or `CompactRegressionTree` model object. That is, `Mdl` is a trained classification model returned by `fitrtree` or `compact`.

X — Predictor data to be classified

numeric matrix | table

Predictor data to be classified, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

- For a numeric matrix:
 - The variables making up the columns of `X` must have the same order as the predictor variables that trained `Mdl`.
 - If you trained `Mdl` using a table (for example, `Tbl`), then `X` can be a numeric matrix if `Tbl` contains all numeric predictor variables. To treat numeric predictors in `Tbl` as categorical during training, identify categorical predictors using the `CategoricalPredictors` name-value pair argument of `fitrtree`. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types) and `X` is a numeric matrix, then `predict` throws an error.
- For a table:
 - `predict` does not support multi-column variables and cell arrays other than cell arrays of character vectors.

- If you trained `Mdl` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and data types as those that trained `Mdl` (stored in `Mdl.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. `Tbl` and `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.
- If you trained `Mdl` using a numeric matrix, then the predictor names in `Mdl.PredictorNames` and corresponding predictor variable names in `X` must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `fitrtree`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.

Data Types: `table` | `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Subtrees — Pruning level

0 (default) | vector of nonnegative integers | `'all'`

Pruning level, specified as the comma-separated pair consisting of `'Subtrees'` and a vector of nonnegative integers in ascending order or `'all'`.

If you specify a vector, then all elements must be at least 0 and at most `max(Mdl.PruneList)`. 0 indicates the full, unpruned tree and `max(Mdl.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify `'all'`, then `predict` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(Mdl.PruneList)`.

`predict` prunes `Mdl` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `Mdl` must be nonempty. In other words, grow `Mdl` by setting `'Prune'`, `'on'`, or by pruning `Mdl` using `prune`.

Example: `'Subtrees', 'all'`

Data Types: `single` | `double` | `char` | `string`

Output Arguments

Yfit — Predicted response values

numeric column vector

Predicted response values, returned as a numeric column vector with the same number of rows as `X`. Each row of `Yfit` gives the predicted response to the corresponding row of `X`, based on the `Mdl`.

node — Node numbers

numeric vector

Node numbers for the predictions, specified as a numeric vector. Each entry corresponds to the predicted leaf node in `Mdl` for the corresponding row of `X`.

Examples

Predict a Response Using a Regression Tree

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using the entire data set.

```
Mdl = fitrtree(X,MPG);
```

Predict the MPG for a car with 200 cubic inch engine displacement, 150 horsepower, and that weighs 3000 lbs.

```
X0 = [200 150 3000];
MPG0 = predict(Mdl,X0)
```

```
MPG0 = 21.9375
```

The regression tree predicts the car's efficiency to be 21.94 mpg.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- You can generate C/C++ code for both `predict` and `update` by using a coder configurer. Or, generate code only for `predict` by using `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen`.
 - Code generation for `predict` and `update` — Create a coder configurer by using `learnerCoderConfigurer` and then generate code by using `generateCode`. Then you can update model parameters in the generated code without having to regenerate the code.
 - Code generation for `predict` — Save a trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- You can also generate fixed-point C/C++ code for `predict`. Fixed-point code generation requires an additional step that defines the fixed-point data types of the variables required for prediction.

Create a fixed-point data type structure by using the data type function on page 32-2391 generated by `generateLearnerDataTypeFcn`, and use the structure as an input argument of `loadLearnerForCoder` in an entry-point function. Generating fixed-point C/C++ code requires MATLAB Coder and Fixed-Point Designer.

- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
Mdl	For the usage notes and limitations of the model object, see “Code Generation” on page 32-751 of the <code>CompactRegressionTree</code> object.
X	<ul style="list-style-type: none"> • For general code generation, X must be a single-precision or double-precision matrix or a table containing single or double predictor variables. <p>If you want to specify X as a table, then your model must be trained using a table, and you must ensure that your entry-point function for prediction:</p> <ul style="list-style-type: none"> • Accepts data as arrays • Creates a table from the data input arguments and specifies the variable names in the table • Passes the table to <code>predict</code> <p>For an example of this table workflow, see “Generate Code to Classify Numeric Data in Table” on page 31-88. For more information on using tables in code generation, see “Code Generation for Tables” (MATLAB Coder) and “Table Limitations for Code Generation” (MATLAB Coder).</p> <ul style="list-style-type: none"> • In the coder configurer workflow, X must be a single or double matrix. • For fixed-point code generation, X must be a fixed-point matrix. • The number of rows, or observations, in X can be a variable size, but the number of columns in X must be fixed.
Subtrees	<ul style="list-style-type: none"> • Names in name-value pair arguments must be compile-time constants. For example, to allow user-defined pruning levels in the generated code, include <code>{coder.Constant('Subtrees'), coder.typeof(0, [1, n], [0, 1])}</code> in the <code>-args</code> value of <code>codegen</code>, where n is <code>max(Mdl.PruneList)</code>. • The 'Subtrees' name-value pair argument is not supported in the coder configurer workflow. • For fixed-point code generation, the 'Subtrees' value must be <code>coder.Constant('all')</code> or have an integer data type.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2011a

predict

Class: RegressionLinear

Predict response of linear regression model

Syntax

```
YHat = predict(Mdl,X)
YHat = predict(Mdl,X,Name,Value)
```

Description

`YHat = predict(Mdl,X)` returns predicted responses for each observation in the predictor data `X` based on the trained linear regression model `Mdl`. `YHat` contains responses for each regularization strength in `Mdl`.

`YHat = predict(Mdl,X,Name,Value)` returns predicted responses with additional options specified by one or more `Name,Value` pair arguments. For example, specify that columns in the predictor data correspond to observations.

Input Arguments

Mdl — Linear regression model

RegressionLinear model object

Linear regression model, specified as a RegressionLinear model object. You can create a RegressionLinear model object using `fitrlinear`.

X — Predictor data

full matrix | sparse matrix

Predictor data, specified as an n -by- p full or sparse matrix. This orientation of `X` indicates that rows correspond to individual observations, and columns correspond to individual predictor variables.

Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in computation time.

The length of `Y` and the number of observations in `X` must be equal.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

ObservationsIn — Predictor data observation dimension`'rows' (default) | 'columns'`

Predictor data observation dimension, specified as the comma-separated pair consisting of `'ObservationsIn'` and `'columns'` or `'rows'`.

Note If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn'`, `'columns'`, then you might experience a significant reduction in optimization-execution time.

Output Arguments**YHat — Predicted responses**

numeric matrix

Predicted responses, returned as a n -by- L numeric matrix. n is the number of observations in X and L is the number of regularization strengths in `Mdl.Lambda`. $YHat(i,j)$ is the response for observation i using the linear regression model that has regularization strength `Mdl.Lambda(j)`.

The predicted response using the model with regularization strength j is $\hat{y}_j = x\beta_j + b_j$.

- x is an observation from the predictor data matrix X , and is row vector.
- β_j is the estimated column vector of coefficients. The software stores this vector in `Mdl.Beta(:,j)`.
- b_j is the estimated, scalar bias, which the software stores in `Mdl.Bias(j)`.

Examples**Predict Test-Sample Responses**

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = x_1, \dots, x_{1000}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Train a linear regression model. Reserve 30% of the observations as a holdout sample.

```
CVMDL = fitrlinear(X,Y,'Holdout',0.3);
Mdl = CVMDL.Trained{1}
```

```
Mdl =
  RegressionLinear
```

```

    ResponseName: 'Y'
    ResponseTransform: 'none'
        Beta: [1000x1 double]
        Bias: -0.0066
        Lambda: 1.4286e-04
    Learner: 'svm'

```

Properties, Methods

CVMDL is a `RegressionPartitionedLinear` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `RegressionLinear` model that the software trained using the training set.

Extract the training and test data from the partition definition.

```

trainIdx = training(CVMdl.Partition);
testIdx = test(CVMdl.Partition);

```

Predict the training- and test-sample responses.

```

yHatTrain = predict(Mdl,X(trainIdx,:));
yHatTest = predict(Mdl,X(testIdx,:));

```

Because there is one regularization strength in `Mdl`, `yHatTrain` and `yHatTest` are numeric vectors.

Predict from Best-Performing Model

Predict responses from the best-performing, linear regression model that uses a lasso-penalty and least squares.

Simulate 10000 observations as in “Predict Test-Sample Responses” on page 32-4243.

```

rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);

```

Create a set of 15 logarithmically-spaced regularization strengths from 10^{-5} through 10^{-1} .

```

Lambda = logspace(-5,-1,15);

```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Optimize the objective function using `SparSA`.

```

X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','KFold',5,'Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');

```

```

numCLModels = numel(CVMdl.Trained)

```

```

numCLModels = 5

```

CVMDL is a `RegressionPartitionedLinear` model. Because `fitrlinear` implements 5-fold cross-validation, CVMDL contains 5 `RegressionLinear` models that the software trains on each fold.

Display the first trained linear regression model.

```
Mdl1 = CVMDL.Trained{1}
```

```
Mdl1 =
  RegressionLinear
    ResponseName: 'Y'
    ResponseTransform: 'none'
        Beta: [1000x15 double]
        Bias: [1x15 double]
        Lambda: [1x15 double]
    Learner: 'leastsquares'
```

Properties, Methods

`Mdl1` is a `RegressionLinear` model object. `fitrlinear` constructed `Mdl1` by training on the first four folds. Because `Lambda` is a sequence of regularization strengths, you can think of `Mdl1` as 11 models, one for each regularization strength in `Lambda`.

Estimate the cross-validated MSE.

```
mse = kfoldLoss(CVMDL);
```

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a regression model. For each regularization strength, train a linear regression model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...
  'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(mse),...
  log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} MSE')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
hold off
```

Choose the index of the regularization strength that balances predictor variable sparsity and low MSE (for example, $\text{Lambda}(10)$).

```
idxFinal = 10;
```

Extract the model with corresponding to the minimal MSE.

```
MdlFinal = selectModels(Mdl,idxFinal)
```

```
MdlFinal =
  RegressionLinear
    ResponseName: 'Y'
    ResponseTransform: 'none'
        Beta: [1000x1 double]
        Bias: -0.0050
        Lambda: 0.0037
    Learner: 'leastquares'
```

Properties, Methods

```
idxNZCoeff = find(MdlFinal.Beta~=0)
```

```
idxNZCoeff = 2x1
```

```
100
200
```

```
EstCoeff = Mdl.Beta(idxNZCoeff)
```

```
EstCoeff = 2×1
```

```
1.0051
```

```
1.9965
```

`MdlFinal` is a `RegressionLinear` model with one regularization strength. The nonzero coefficients `EstCoeff` are close to the coefficients that simulated the data.

Simulate 10 new observations, and predict corresponding responses using the best-performing model.

```
XNew = sprandn(d,10,nz);
```

```
YHat = predict(MdlFinal,XNew,'ObservationsIn','columns');
```

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- You can generate C/C++ code for both `predict` and `update` by using a coder configurer. Or, generate code only for `predict` by using `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen`.
 - Code generation for `predict` and `update` — Create a coder configurer by using `learnerCoderConfigurer` and then generate code by using `generateCode`. Then you can update model parameters in the generated code without having to regenerate the code.
 - Code generation for `predict` — Save a trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
<code>Mdl</code>	For the usage notes and limitations of the model object, see “Code Generation” on page 32-4618 of the <code>RegressionLinear</code> object.

Argument	Notes and Limitations
X	<ul style="list-style-type: none"> • Must be a single-precision or double-precision matrix and can be variable-size. • If you specify 'ObservationsIn', 'rows' (default), then the number of columns in X must be <code>numel(Mdl.PredictorNames)</code>. Rows and columns must correspond to observations and predictors, respectively. • If you specify 'ObservationsIn', 'columns', then the number of rows in X must be <code>numel(Mdl.PredictorNames)</code>. Rows and columns must correspond to predictors and observations, respectively.
Name-value pair arguments	<ul style="list-style-type: none"> • Names in name-value pair arguments must be compile-time constants. • The value for the 'ObservationsIn' name-value pair argument must be a compile-time constant. For example, to use the 'ObservationsIn', 'columns' name-value pair argument in the generated code, include <code>{coder.Constant('ObservationsIn'), coder.Constant('columns')}</code> in the <code>-args</code> value of <code>codegen</code>.

For more information, see “Introduction to Code Generation” on page 31-2.

RegressionLinear | fitrlinear

Introduced in R2016a

predict

Class: CompactTreeBagger

Predict responses using ensemble of bagged decision trees

Syntax

```
Yfit = predict(B,X)
Yfit = predict(B,X,Name,Value)
[Yfit,stdevs] = predict(____)
[Yfit,scores] = predict(____)
[Yfit,scores,stdevs] = predict(____)
```

Description

`Yfit = predict(B,X)` returns a vector of predicted responses for the predictor data in the table or matrix `X`, based on the compact ensemble of bagged decision trees `B`. `Yfit` is a cell array of character vectors for classification and a numeric array for regression. By default, `predict` takes a democratic (nonweighted) average vote from all trees in the ensemble.

`B` is a trained `CompactTreeBagger` model object, that is, a model returned by `compact`.

`X` is a table or matrix of predictor data used to generate responses. Rows represent observations and columns represent variables.

- If `X` is a numeric matrix:
 - The variables making up the columns of `X` must have the same order as the predictor variables that trained `B`.
 - If you trained `B` using a table (for example, `Tbl`), then `X` can be a numeric matrix if `Tbl` contains all numeric predictor variables. To treat numeric predictors in `Tbl` as categorical during training, identify categorical predictors using the `CategoricalPredictors` name-value pair argument of `TreeBagger`. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types) and `X` is a numeric matrix, then `predict` throws an error.
- If `X` is a table:
 - `predict` does not support multi-column variables and cell arrays other than cell arrays of character vectors.
 - If you trained `B` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and be of the same data types as those that trained `B` (stored in `B.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. `Tbl` and `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.
 - If you trained `B` using a numeric matrix, then the predictor names in `B.PredictorNames` and corresponding predictor variable names in `X` must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `TreeBagger`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.

`Yfit = predict(B,X,Name,Value)` specifies additional options using one or more name-value pair arguments:

- `'Trees'` — Array of tree indices to use for computation of responses. The default is `'all'`.
- `'TreeWeights'` — Array of `NTrees` weights for weighting votes from the specified trees, where `NTrees` is the number of trees in the ensemble.
- `'UseInstanceForTree'` — Logical matrix of size `Nobs`-by-`NTrees` indicating which trees to use to make predictions for each observation, where `Nobs` is the number of observations. By default all trees are used for all observations.

For regression, `[Yfit,stdevs] = predict(____)` also returns standard deviations of the computed responses over the ensemble of the grown trees using any of the input argument combinations in previous syntaxes.

For classification, `[Yfit,scores] = predict(____)` also returns scores for all classes. `scores` is a matrix with one row per observation and one column per class. For each observation and each class, the score generated by each tree is the probability of the observation originating from the class, computed as the fraction of observations of the class in a tree leaf. `predict` averages these scores over all trees in the ensemble.

`[Yfit,scores,stdevs] = predict(____)` also returns standard deviations of the computed scores for classification. `stdevs` is a matrix with one row per observation and one column per class, with standard deviations taken over the ensemble of the grown trees.

Algorithms

- For regression problems, the predicted response for an observation is the weighted average of the predictions using selected trees only. That is,

$$\hat{y}_{\text{bag}} = \frac{1}{\sum_{t=1}^T \alpha_t I(t \in S)} \sum_{t=1}^T \alpha_t \hat{y}_t I(t \in S).$$

- \hat{y}_t is the prediction from tree t in the ensemble.
 - S is the set of indices of selected trees that comprise the prediction (see `'Trees'` and `'UseInstanceForTree'`). $I(t \in S)$ is 1 if t is in the set S , and 0 otherwise.
 - α_t is the weight of tree t (see `'TreeWeights'`).
- For classification problems, the predicted class for an observation is the class that yields the largest weighted average of the class posterior probabilities (i.e., classification scores) computed using selected trees only. That is,
 - 1 For each class $c \in C$ and each tree $t = 1, \dots, T$, `predict` computes $\hat{P}_t(c|x)$, which is the estimated posterior probability of class c given observation x using tree t . C is the set of all distinct classes in the training data. For more details on classification tree posterior probabilities, see `fitctree` and `predict`.
 - 2 `predict` computes the weighted average of the class posterior probabilities over the selected trees.

$$\hat{P}_{\text{bag}}(c|x) = \frac{1}{\sum_{t=1}^T \alpha_t I(t \in S)} \sum_{t=1}^T \alpha_t \hat{P}_t(c|x) I(t \in S).$$

- 3 The predicted class is the class that yields the largest weighted average.

$$\hat{y}_{\text{bag}} = \operatorname{argmax}_{c \in C} \{ \hat{P}_{\text{bag}}(c|x) \}.$$

predict

Package:

Predict responses of generalized linear regression model

Syntax

```
ypred = predict mdl,Xnew
[ypred,yci] = predict mdl,Xnew
[ypred,yci] = predict mdl,Xnew,Name,Value
```

Description

`ypred = predict(mdl,Xnew)` returns the predicted response values of the generalized linear regression model `mdl` to the points in `Xnew`.

`[ypred,yci] = predict(mdl,Xnew)` also returns confidence intervals for the responses at `Xnew`.

`[ypred,yci] = predict(mdl,Xnew,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the confidence level of the confidence interval.

Examples

Predict Response Values

Create a generalized linear regression model, and predict its response to new data.

Generate sample data using Poisson random numbers with two underlying predictors `X(:,1)` and `X(:,2)`.

```
rng('default') % For reproducibility
rndvars = randn(100,2);
X = [2 + rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','Distribution','poisson');
```

Create data points for prediction.

```
[Xtest1,Xtest2] = meshgrid(-1:.5:3,-2:.5:2);
Xnew = [Xtest1(:),Xtest2(:)];
```

Predict responses at the data points.

```
ypred = predict(mdl,Xnew);
```

Plot the predictions.

```
surf(Xtest1,Xtest2,reshape(ypred,9,9))
```

Generate C/C++ Code for Prediction

Fit a generalized linear regression model, and then save the model by using `saveLearnerForCoder`. Define an entry-point function that loads the model by using `loadLearnerForCoder` and calls the `predict` function of the fitted model. Then use `codegen` to generate C/C++ code. Note that generating C/C++ code requires MATLAB® Coder™.

This example briefly explains the code generation workflow for the prediction of linear regression models at the command line. For more details, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 31-9. You can also generate code using the MATLAB Coder app. For details, see “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 31-16.

Train Model

Generate sample data using Poisson random numbers with two underlying predictors $X(:,1)$ and $X(:,2)$.

```
rng('default') % For reproducibility
rndvars = randn(100,2);
X = [2 + rndvars(:,1), rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model. Specify the Poisson distribution for the response.

```
mdl = fitglm(X,y,'y ~ x1 + x2','Distribution','poisson');
```

Save Model

Save the fitted generalized linear regression model to the file `GLMMdl.mat` by using `saveLearnerForCoder`.

```
saveLearnerForCoder(mdl,'GLMMdl');
```

Define Entry-Point Function

In your current folder, define an entry-point function named `mypredictGLM.m` that does the following:

- Accept new predictor input and valid name-value pair arguments.
- Load the fitted generalized linear regression model in `GLMMdl.mat` by using `loadLearnerForCoder`.
- Return predictions and confidence interval bounds.

```
function [yhat,ci] = mypredictGLM(x,varargin) %#codegen
%MYPREDICTGLM Predict responses using GLM model
% MYPREDICTGLM predicts responses for the n observations in the n-by-1
% vector x using the GLM model stored in the MAT-file GLMMdl.mat,
% and then returns the predictions in the n-by-1 vector yhat.
% MYPREDICTGLM also returns confidence interval bounds for the
% predictions in the n-by-2 vector ci.
CompactMdl = loadLearnerForCoder('GLMMdl');
narginchk(1,Inf);
[yhat,ci] = predict(CompactMdl,x,varargin{:});
end
```

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation.

Generate Code

Generate code for the entry-point function using `codegen`. Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. To specify the data type and exact input array size, pass a MATLAB® expression that represents the set of values with a certain data type and array size. Use `coder.Constant` for the names of name-value pair arguments.

Create points for prediction.

```
[Xtest1,Xtest2] = meshgrid(-1:.5:3,-2:.5:2);
Xnew = [Xtest1(:),Xtest2(:)];
```

Generate code and specify returning 90% simultaneous confidence intervals on the predictions.

```
codegen mypredictGLM -args {Xnew,coder.Constant('Alpha'),0.1,coder.Constant('Simultaneous')},true;
```

`codegen` generates the MEX function `mypredictGLM_mex` with a platform-dependent extension.

If the number of observations is unknown at compile time, you can also specify the input as variable-size by using `coder.typeof`. For details, see “Specify Variable-Size Arguments for Code Generation” on page 31-38 and “Specify Properties of Entry-Point Function Inputs” (MATLAB Coder).

Verify Generated Code

Compare predictions and confidence intervals using `predict` and `mypredictGLM_mex`. Specify name-value pair arguments in the same order as in the `-args` argument in the call to `codegen`.

```
[yhat1,ci1] = predict mdl,Xnew,'Alpha',0.1,'Simultaneous',true);
[yhat2,ci2] = mypredictGLM_mex(Xnew,'Alpha',0.1,'Simultaneous',true);
```

The returned values from `mypredictGLM_mex` might include round-off differences compared to the values from `predict`. In this case, compare the values allowing a small tolerance.

```
find(abs(yhat1-yhat2) > 1e-6)

ans =

    0x1 empty double column vector

find(abs(ci1-ci2) > 1e-6)

ans =

    0x1 empty double column vector
```

The comparison confirms that the returned values are equal within the tolerance $1e-6$.

Input Arguments

mdl — Generalized linear regression model

GeneralizedLinearModel object | CompactGeneralizedLinearModel object

Generalized linear regression model, specified as a `GeneralizedLinearModel` object created using `fitglm` or `stepwiseglm`, or a `CompactGeneralizedLinearModel` object created using `compact`.

Xnew — New predictor input values

table | dataset array | matrix

New predictor input values, specified as a table, dataset array, or matrix. Each row of `Xnew` corresponds to one observation, and each column corresponds to one variable.

- If `Xnew` is a table or dataset array, it must contain predictors that have the same predictor names as in the `PredictorNames` property of `mdl`.
- If `Xnew` is a matrix, it must have the same number of variables (columns) in the same order as the predictor input used to create `mdl`. Note that `Xnew` must also contain any predictor variables that are not used as predictors in the fitted model. Also, all variables used in creating `mdl` must be numeric. To treat numerical predictors as categorical, identify the predictors using the `'CategoricalVars'` name-value pair argument when you create `mdl`.

Data Types: `single` | `double` | `table`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[ypred, yci] = predict(Mdl, Xnew, 'Alpha', 0.01, 'Simultaneous', true)` returns the confidence interval `yci` with a 99% confidence level, computed simultaneously for all predictor values.

Alpha — Significance level

0.05 (default) | numeric value in the range [0,1]

Significance level for the confidence interval, specified as the comma-separated pair consisting of `'Alpha'` and a numeric value in the range [0,1]. The confidence level of `yci` is equal to $100(1 - \text{Alpha})\%$. `Alpha` is the probability that the confidence interval does not contain the true value.

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

BinomialSize — Number of trials for binomial distribution

1 (default) | scalar | vector

Number of trials for the binomial distribution, specified as the comma-separated pair consisting of `'BinomialSize'` and a scalar or vector of the same length as the response. `predict` expands the scalar input into a constant array of the same size as the response. The scalar input means that all observations have the same number of trials.

The meaning of the output values in `ypred` depends on the value of `'BinomialSize'`.

- If `'BinomialSize'` is 1 (default), then each value in the output `ypred` is the probability of success.
- If `'BinomialSize'` is not 1, then each value in the output `ypred` is the predicted number of successes in the trials.

Data Types: `single` | `double`

Offset — Offset value

`zeros(size(Xnew,1))` (default) | scalar | vector

Offset value for each row in `Xnew`, specified as the comma-separated pair consisting of `'Offset'` and a scalar or vector with the same length as the response. `predict` expands the scalar input into a constant array of the same size as the response.

Note that the default value of this argument is a vector of zeros even if you specify the `'Offset'` name-value pair argument when fitting a model. If you specify `'Offset'` for fitting, the software treats the offset as an additional predictor with a coefficient value fixed at 1. In other words, the formula for fitting is

$$f(\mu) = \text{Offset} + X*b,$$

where f is the link function, μ is the mean response, and $X*b$ is the linear combination of predictors X . The `Offset` predictor has coefficient 1.

Data Types: `single` | `double`

Simultaneous — Flag to compute simultaneous confidence bounds

false (default) | true

Flag to compute simultaneous confidence bounds, specified as the comma-separated pair consisting of 'Simultaneous' and either true or false.

- `true` — `predict` computes confidence bounds for the curve of response values corresponding to all predictor values in `Xnew`, using Scheffe's method. The range between the upper and lower bounds contains the curve consisting of true response values with $100(1 - \alpha)\%$ confidence.
- `false` — `predict` computes confidence bounds for the response value at each observation in `Xnew`. The confidence interval for a response value at a specific predictor value contains the true response value with $100(1 - \alpha)\%$ confidence.

Simultaneous bounds are wider than separate bounds, because requiring the entire curve of response values to be within the bounds is stricter than requiring the response value at a single predictor value to be within the bounds.

Example: 'Simultaneous', true

Output Arguments**ypred — Predicted response values**

numeric vector

Predicted response values at `Xnew`, returned as a numeric vector.

For a binomial model, the meaning of the output values in `ypred` depends on the value of the 'BinomialSize' name-value pair argument.

- If 'BinomialSize' is 1 (default), then each value in the output `ypred` is the probability of success.
- If 'BinomialSize' is not 1, then each value in the output `ypred` is the predicted number of successes in the trials.

For a model with an offset, specify the offset value by using the 'Offset' name-value pair argument. Otherwise, `predict` uses 0 as the offset value.

yci — Confidence intervals for responses

two-column numeric matrix

Confidence intervals for the responses, returned as a two-column matrix with each row providing one interval. The meaning of the confidence interval depends on the settings of the name-value pair arguments 'Alpha' and 'Simultaneous'.

Alternative Functionality

- `feval` returns the same predictions as `predict`. The `feval` function does not support the 'Offset' and 'BinomialSize' name-value pair arguments. `feval` uses 0 as the offset value, and the output values in `ypred` are predicted probabilities. The `feval` function can take multiple input arguments for new predictor input values, with one input for each predictor variable, which is simpler to use with a model created from a table or dataset array. Note that the `feval` function does not give confidence intervals on its predictions.

- `random` returns predictions with added noise.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen` to generate code for the `predict` function. Save a trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
<code>mdl</code>	For the usage notes and limitations of the model object, see “Code Generation” on page 32-727 of the <code>CompactGeneralizedLinearModel</code> object.
<code>Xnew</code>	<ul style="list-style-type: none"> • For general code generation, <code>Xnew</code> must be a single-precision or double-precision matrix or a table containing single or double predictor variables. <p>If you want to specify <code>Xnew</code> as a table, then your model must be trained using a table, and you must ensure that your entry-point function for prediction:</p> <ul style="list-style-type: none"> • Accepts data as arrays • Creates a table from the data input arguments and specifies the variable names in the table • Passes the table to <code>predict</code> <p>For an example of this table workflow, see “Generate Code to Classify Numeric Data in Table” on page 31-88. For more information on using tables in code generation, see “Code Generation for Tables” (MATLAB Coder) and “Table Limitations for Code Generation” (MATLAB Coder).</p> <ul style="list-style-type: none"> • The number of rows, or observations, in <code>Xnew</code> can be a variable size, but the number of columns in <code>Xnew</code> must be fixed.
Name-value pair arguments	Names in name-value pair arguments must be compile-time constants. For example, to allow a user-defined significance level in the generated code, include <code>{coder.Constant('Alpha'),0}</code> in the <code>-args</code> value of <code>codegen</code> .

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2012a

predict

Class: GeneralizedLinearMixedModel

Predict response of generalized linear mixed-effects model

Syntax

```
ypred = predict(glme)
ypred = predict(glme,tblnew)
ypred = predict( ___,Name,Value)
[ypred,ypredCI] = predict( ___ )
[ypred,ypredCI,DF] = predict( ___ )
```

Description

`ypred = predict(glme)` returns the predicted conditional means of the response, `ypred`, using the original predictor values used to fit the generalized linear mixed-effects model `glme`.

`ypred = predict(glme,tblnew)` returns the predicted conditional means using the new predictor values specified in `tblnew`.

If a grouping variable in `tblnew` has levels that are not in the original data, then the random effects for that grouping variable do not contribute to the 'Conditional' prediction at observations where the grouping variable has new levels.

`ypred = predict(___,Name,Value)` returns the predicted conditional means of the response using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the confidence level, simultaneous confidence bounds, or contributions from only fixed effects. You can use any of the input arguments in the previous syntaxes.

`[ypred,ypredCI] = predict(___)` also returns 95% point-wise confidence intervals, `ypredCI`, for each predicted value.

`[ypred,ypredCI,DF] = predict(___)` also returns the degrees of freedom, `DF`, used to compute the confidence intervals.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

tblnew — New input data

table | dataset array

New input data, which includes the response variable, predictor variables, and grouping variables on page 2-45, specified as a table or dataset array. The predictor variables can be continuous or

grouping variables. `tblnew` must have the same variables as the original table or dataset array used in `fitglme` to fit the generalized linear mixed-effects model `glme`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, `...`, `NameN`, `ValueN`.

Alpha — Significance level

0.05 (default) | scalar value in the range [0,1]

Significance level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range [0,1]. For a value α , the confidence level is $100 \times (1 - \alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

Conditional — Indicator for conditional predictions

`true` (default) | `false`

Indicator for conditional predictions, specified as the comma-separated pair consisting of `'Conditional'` and one of the following.

Value	Description
<code>true</code>	Contributions from both fixed effects and random effects (conditional)
<code>false</code>	Contribution from only fixed effects (marginal)

Example: `'Conditional', false`

DFMethod — Method for computing approximate degrees of freedom

`'residual'` (default) | `'none'`

Method for computing approximate degrees of freedom, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

Value	Description
<code>'residual'</code>	The degrees of freedom value is assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
<code>'none'</code>	The degrees of freedom is set to infinity.

Example: `'DFMethod', 'none'`

Offset — Model offset

`zeros(m, 1)` (default) | m -by-1 vector of scalar values

Model offset, specified as a vector of scalar values of length m , where m is the number of rows in `tblnew`. The offset is used as an additional predictor and has a coefficient value fixed at 1.

Simultaneous — Type of confidence bounds

false (default) | true

Type of confidence bounds, specified as the comma-separated pair consisting of 'Simultaneous' and either false or true.

- If 'Simultaneous' is false, then `predict` computes nonsimultaneous confidence bounds.
- If 'Simultaneous' is true, `predict` returns simultaneous confidence bounds.

Example: 'Simultaneous', true

Output Arguments**ypred — Predicted responses**

vector

Predicted responses, returned as a vector. If the 'Conditional' name-value pair argument is specified as true, `ypred` contains predictions for the conditional means of the responses given the random effects. Conditional predictions include contributions from both fixed and random effects. Marginal predictions include only contributions from fixed effects.

To compute marginal predictions, `predict` computes conditional predictions, but substitutes a vector of zeros in place of the empirical Bayes predictors (EBPs) of the random effects.

ypredCI — Point-wise confidence intervals

two-column matrix

Point-wise confidence intervals for the predicted values, returned as a two-column matrix. The first column of `ypredCI` contains the lower bound, and the second column contains the upper bound. By default, `ypredCI` contains the 95% nonsimultaneous confidence intervals for the predictions. You can change the confidence level using the `Alpha` name-value pair argument, and make them simultaneous using the `Simultaneous` name-value pair argument.

When fitting a GLME model using `fitglme` and one of the maximum likelihood fit methods ('Laplace' or 'ApproximateLaplace'), `predict` computes the confidence intervals using the conditional mean squared error of prediction (CMSEP) approach conditional on the estimated covariance parameters and the observed response. Alternatively, you can interpret the confidence intervals as approximate Bayesian credible intervals conditional on the estimated covariance parameters and the observed response.

When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods ('MPL' or 'REML'), `predict` bases the computations on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

DF — Degrees of freedom

vector | scalar value

Degrees of freedom used in computing the confidence intervals, returned as a vector or a scalar value.

- If 'Simultaneous' is false, then DF is a vector.
- If 'Simultaneous' is true, then DF is a scalar value.

Examples

Predict Responses at Original Design Values

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution:

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.

- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', 'Di
```

Predict the response values at the original design values. Display the first ten predictions along with the observed response values.

```
ypred = predict(glme);
[ypred(1:10), mfr.defects(1:10)]
```

```
ans = 10×2
```

```

4.9883    6.0000
5.9423    7.0000
5.1318    6.0000
5.6295    5.0000
5.3499    6.0000
5.2134    5.0000
4.6430    4.0000
4.5342    4.0000
5.3903    9.0000
4.6529    4.0000
```

Column 1 contains the predicted response values at the original design values. Column 2 contains the observed response values.

Predict Responses at Values in New Table

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is `log`. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution:

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', 'Di
```

Predict the response values at the original design values.

```
ypred = predict(glme);
```

Create a new table by copying the first 10 rows of `mfr` into `tblnew`.

```
tblnew = mfr(1:10, :);
```

The first 10 rows of `mfr` include data collected from trials 1 through 5 for factories 1 and 2. Both factories used the old process for all of their trials during the experiment, so `newprocess = 0` for all 10 observations.

Change the value of `newprocess` to 1 for the observations in `tblnew`.

```
tblnew.newprocess = ones(height(tblnew), 1);
```

Compute predicted response values and nonsimultaneous 99% confidence intervals using `tblnew`. Display the first 10 rows of the predicted values based on `tblnew`, the predicted values based on `mfr`, and the observed response values.

```
[ypred_new,ypredCI] = predict(glme,tblnew,'Alpha',0.01);
[ypred_new,ypred(1:10),mfr.defects(1:10)]
```

```
ans = 10x3
```

3.4536	4.9883	6.0000
4.1142	5.9423	7.0000
3.5530	5.1318	6.0000
3.8976	5.6295	5.0000
3.7040	5.3499	6.0000
3.6095	5.2134	5.0000
3.2146	4.6430	4.0000
3.1393	4.5342	4.0000
3.7320	5.3903	9.0000
3.2214	4.6529	4.0000

Column 1 contains predicted response values based on the data in `tblnew`, where `newprocess = 1`. Column 2 contains predicted response values based on the original data in `mfr`, where `newprocess = 0`. Column 3 contains the observed response values in `mfr`. Based on these results, if all other predictors retain their original values, the predicted number of defects appears to be smaller when using the new process.

Display the 99% confidence intervals for rows 1 through 10 corresponding to the new predicted response values.

```
ypredCI(1:10,1:2)
```

```
ans = 10x2
```

predict

Package:

Predict responses of linear regression model

Syntax

```
ypred = predict mdl, Xnew)
[ypred, yci] = predict mdl, Xnew)
[ypred, yci] = predict mdl, Xnew, Name, Value)
```

Description

`ypred = predict mdl, Xnew)` returns the predicted response values of the linear regression model `mdl` to the points in `Xnew`.

`[ypred, yci] = predict mdl, Xnew)` also returns confidence intervals for the responses at `Xnew`.

`[ypred, yci] = predict mdl, Xnew, Name, Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the confidence level of the confidence interval and the prediction type.

Examples

Predict Response Values

Create a quadratic model of car mileage as a function of weight from the `carsmall` data set.

```
load carsmall
X = Weight;
y = MPG;
mdl = fitlm(X, y, 'quadratic');
```

Create predicted responses to the data.

```
ypred = predict(mdl, X);
```

Plot the original responses and the predicted responses to see how they differ.

```
plot(X, y, 'o', X, ypred, 'x')
legend('Data', 'Predictions')
```

Generate C/C++ Code for Prediction

Fit a linear regression model, and then save the model by using `saveLearnerForCoder`. Define an entry-point function that loads the model by using `loadLearnerForCoder` and calls the `predict` function of the fitted model. Then use `codegen` to generate C/C++ code. Note that generating C/C++ code requires MATLAB® Coder™.

This example briefly explains the code generation workflow for the prediction of linear regression models at the command line. For more details, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 31-9. You can also generate code using the MATLAB Coder app. For details, see “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 31-16.

Train Model

Load the `carsmall` data set, and then fit the quadratic regression model.

```
load carsmall
X = Weight;
y = MPG;
mdl = fitlm(X,y,'quadratic');
```

Save Model

Save the fitted quadratic model to the file `QLMMdl.mat` by using `saveLearnerForCoder`.

```
saveLearnerForCoder mdl, 'QLMMdl');
```

Define Entry-Point Function

Define an entry-point function named `mypredictQLM` that does the following:

- Accept measurements corresponding to `X` and optional, valid name-value pair arguments.
- Load the fitted quadratic model in `QLMMdl.mat`.
- Return predictions and confidence interval bounds.

```
function [yhat,ci] = mypredictQLM(x,varargin) %#codegen
%MYPREDICTQLM Predict response using linear model
% MYPREDICTQLM predicts responses for the n observations in the n-by-1
% vector x using the linear model stored in the MAT-file QLMMdl.mat, and
% then returns the predictions in the n-by-1 vector yhat. MYPREDICTQLM
% also returns confidence interval bounds for the predictions in the
% n-by-2 vector ci.
CompactMdl = loadLearnerForCoder('QLMMdl');
[yhat,ci] = predict(CompactMdl,x,varargin{:});
end
```

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation.

Note: If you click the button located in the upper-right section of this example and open the example in MATLAB®, then MATLAB opens the example folder. This folder includes the entry-point function file.

Generate Code

Generate code for the entry-point function using `codegen`. Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. To specify the data type and exact input array size, pass a MATLAB® expression that represents the set of values with a certain data type and array size. Use `coder.Constant` for the names of name-value pair arguments.

If the number of observations is unknown at compile time, you can also specify the input as variable-size by using `coder.typeof`. For details, see “Specify Variable-Size Arguments for Code Generation” on page 31-38 and “Specify Properties of Entry-Point Function Inputs” (MATLAB Coder).

```
codegen mypredictQLM -args {X,coder.Constant('Alpha'),0.1,coder.Constant('Simultaneous'),true}
```

`codegen` generates the MEX function `mypredictQLM_mex` with a platform-dependent extension.

Verify Generated Code

Compare predictions and confidence intervals using `predict` and `mypredictQLM_mex`. Specify name-value pair arguments in the same order as in the `-args` argument in the call to `codegen`.

```
Xnew = sort(X);
[yhat1,ci1] = predict mdl,Xnew,'Alpha',0.1,'Simultaneous',true);
[yhat2,ci2] = mypredictQLM_mex(Xnew,'Alpha',0.1,'Simultaneous',true);
```

The returned values from `mypredictQLM_mex` might include round-off differences compared to the values from `predict`. In this case, compare the values allowing a small tolerance.

```
find(abs(yhat1-yhat2) > 1e-6)
ans =
    0x1 empty double column vector
find(abs(ci1-ci2) > 1e-6)
ans =
    0x1 empty double column vector
```

The comparison confirms that the returned values are equal within the tolerance $1e-6$.

Plot the returned values for comparison.

```
h1 = plot(X,y,'k. ');
hold on
h2 = plot(Xnew,yhat1,'ro',Xnew,yhat2,'gx');
h3 = plot(Xnew,ci1,'r-','LineWidth',4);
h4 = plot(Xnew,ci2,'g--','LineWidth',2);
legend([h1; h2; h3(1); h4(1)], ...
    {'Data','predict estimates','MEX estimates','predict CIs','MEX CIs'});
xlabel('Weight');
ylabel('MPG');
```

Input Arguments

mdl — Linear regression model object

LinearModel object | CompactLinearModel object

Linear regression model object, specified as a LinearModel object created by using `fitlm` or `stepwiselm`, or a CompactLinearModel object created by using `compact`.

Xnew — New predictor input values

table | dataset array | matrix

New predictor input values, specified as a table, dataset array, or matrix. Each row of Xnew corresponds to one observation, and each column corresponds to one variable.

- If Xnew is a table or dataset array, it must contain predictors that have the same predictor names as in the PredictorNames property of mdl.
- If Xnew is a matrix, it must have the same number of variables (columns) in the same order as the predictor input used to create mdl. Note that Xnew must also contain any predictor variables that are not used as predictors in the fitted model. Also, all variables used in creating mdl must be numeric. To treat numerical predictors as categorical, identify the predictors using the 'CategoricalVars' name-value pair argument when you create mdl.

Data Types: single | double | table

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[ypred, yci] = predict(Mdl, Xnew, 'Alpha', 0.01, 'Simultaneous', true)` returns the confidence interval `yci` with a 99% confidence level, computed simultaneously for all predictor values.

Alpha — Significance level

0.05 (default) | numeric value in the range [0,1]

Significance level for the confidence interval, specified as the comma-separated pair consisting of `'Alpha'` and a numeric value in the range [0,1]. The confidence level of `yci` is equal to $100(1 - \text{Alpha})\%$. `Alpha` is the probability that the confidence interval does not contain the true value.

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

Prediction — Prediction type

`'curve'` (default) | `'observation'`

Prediction type, specified as the comma-separated pair consisting of `'Prediction'` and either `'curve'` or `'observation'`.

A regression model for the predictor variables X and the response variable y has the form

$$y = f(X) + \varepsilon,$$

where f is a fitted regression function and ε is a random noise term.

- If `'Prediction'` is `'curve'`, then `predict` predicts confidence bounds for $f(X_{\text{new}})$, the fitted responses at X_{new} .
- If `'Prediction'` is `'observation'`, then `predict` predicts confidence bounds for y , the response observations at X_{new} .

The bounds for y are wider than the bounds for $f(X)$ because of the additional variability of the noise term.

Example: `'Prediction', 'observation'`

Simultaneous — Flag to compute simultaneous confidence bounds

`false` (default) | `true`

Flag to compute simultaneous confidence bounds, specified as the comma-separated pair consisting of `'Simultaneous'` and either `true` or `false`.

- `true` — `predict` computes confidence bounds for the curve of response values corresponding to all predictor values in X_{new} , using Scheffe's method. The range between the upper and lower bounds contains the curve consisting of true response values with $100(1 - \alpha)\%$ confidence.
- `false` — `predict` computes confidence bounds for the response value at each observation in X_{new} . The confidence interval for a response value at a specific predictor value contains the true response value with $100(1 - \alpha)\%$ confidence.

Simultaneous bounds are wider than separate bounds, because requiring the entire curve of response values to be within the bounds is stricter than requiring the response value at a single predictor value to be within the bounds.

Example: `'Simultaneous', true`

Output Arguments

ypred — Predicted response values

numeric vector

Predicted response values evaluated at X_{new} , returned as a numeric vector.

yaci — Confidence intervals for responses

two-column numeric matrix

Confidence intervals for the responses, returned as a two-column matrix with each row providing one interval. The meaning of the confidence interval depends on the settings of the name-value pair arguments `'Alpha'`, `'Prediction'`, and `'Simultaneous'`.

Alternative Functionality

- `feval` returns the same predictions as `predict`. The `feval` function can take multiple input arguments, with one input for each predictor variable, which is simpler to use with a model created from a table or dataset array. Note that the `feval` function does not give confidence intervals on its predictions.
- `random` returns predictions with added noise.
- Use `plotSlice` to create a figure containing a series of plots, each representing a slice through the predicted regression surface. Each plot shows the fitted response values as a function of a single predictor variable, with the other predictor variables held constant.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen` to generate code for the `predict` function. Save a trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
mdl	<ul style="list-style-type: none"> Suppose you train a linear model by using <code>fitlm</code> and specifying 'RobustOpts' as a structure with an anonymous function handle for the <code>RobustWgtFun</code> field, use <code>saveLearnerForCoder</code> to save the model, and then use <code>loadLearnerForCoder</code> to load the model. In this case, <code>loadLearnerForCoder</code> cannot restore the <code>Robust</code> property into the MATLAB Workspace. However, <code>loadLearnerForCoder</code> can load the model at compile time within an entry-point function for code generation. For the usage notes and limitations of the model object, see "Code Generation" on page 32-717 of the <code>CompactLinearModel</code> object.
Xnew	<ul style="list-style-type: none"> For general code generation, <code>Xnew</code> must be a single-precision or double-precision matrix or a table containing single or double predictor variables. <p>If you want to specify <code>Xnew</code> as a table, then your model must be trained using a table, and you must ensure that your entry-point function for prediction:</p> <ul style="list-style-type: none"> Accepts data as arrays Creates a table from the data input arguments and specifies the variable names in the table Passes the table to <code>predict</code> <p>For an example of this table workflow, see "Generate Code to Classify Numeric Data in Table" on page 31-88. For more information on using tables in code generation, see "Code Generation for Tables" (MATLAB Coder) and "Table Limitations for Code Generation" (MATLAB Coder).</p> <ul style="list-style-type: none"> The number of rows, or observations, in <code>Xnew</code> can be a variable size, but the number of columns in <code>Xnew</code> must be fixed.
Name-value pair arguments	Names in name-value pair arguments must be compile-time constants. For example, to allow a user-defined significance level in the generated code, include <code>{coder.Constant('Alpha'), 0}</code> in the <code>-args</code> value of <code>codegen</code> .

For more information, see "Introduction to Code Generation" on page 31-2.

predict

Class: LinearMixedModel

Predict response of linear mixed-effects model

Syntax

```
ypred = predict(lme)
ypred = predict(lme, tblnew)
ypred = predict(lme, Xnew, Znew)
ypred = predict(lme, Xnew, Znew, Gnew)
ypred = predict( ___, Name, Value)
[ypred, ypredCI] = predict( ___ )
[ypred, ypredCI, DF] = predict( ___ )
```

Description

`ypred = predict(lme)` returns a vector of conditional predicted responses on page 32-4285 `ypred` at the original predictors used to fit the linear mixed-effects model `lme`.

`ypred = predict(lme, tblnew)` returns a vector of conditional predicted responses `ypred` from the fitted linear mixed-effects model `lme` at the values in the new table or dataset array `tblnew`. Use a table or dataset array for `predict` if you use a table or dataset array for fitting the model `lme`.

If a particular grouping variable in `tblnew` has levels that are not in the original data, then the random effects for that grouping variable do not contribute to the 'Conditional' prediction at observations where the grouping variable has new levels.

`ypred = predict(lme, Xnew, Znew)` returns a vector of conditional predicted responses `ypred` from the fitted linear mixed-effects model `lme` at the values in the new fixed- and random-effects design matrices, `Xnew` and `Znew`, respectively. `Znew` can also be a cell array of matrices. In this case, the grouping variable `G` is `ones(n, 1)`, where n is the number of observations used in the fit.

Use the matrix format for `predict` if using design matrices for fitting the model `lme`.

`ypred = predict(lme, Xnew, Znew, Gnew)` returns a vector of conditional predicted responses `ypred` from the fitted linear mixed-effects model `lme` at the values in the new fixed- and random-effects design matrices, `Xnew` and `Znew`, respectively, and the grouping variable `Gnew`.

`Znew` and `Gnew` can also be cell arrays of matrices and grouping variables, respectively.

`ypred = predict(___, Name, Value)` returns a vector of predicted responses `ypred` from the fitted linear mixed-effects model `lme` with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the confidence level, simultaneous confidence bounds, or contributions from only fixed effects.

`[ypred, ypredCI] = predict(___)` also returns confidence intervals `ypredCI` for the predictions `ypred` for any of the input arguments in the previous syntaxes.

[ypred,ypredCI,DF] = predict(___) also returns the degrees of freedom DF used in computing the confidence intervals for any of the input arguments in the previous syntaxes.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a LinearMixedModel object constructed using fitlme or fitlmematrix.

tblnew — New input data

table | dataset array

New input data, which includes the response variable, predictor variables, and grouping variables on page 2-45, specified as a table or dataset array. The predictor variables can be continuous or grouping variables. tblnew must have the same variables as in the original table or dataset array used to fit the linear mixed-effects model lme.

Xnew — New fixed-effects design matrix

n-by-*p* matrix

New fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations and *p* is the number of fixed predictor variables. Each row of X corresponds to one observation and each column of X corresponds to one variable.

Data Types: single | double

Znew — New random-effects design

n-by-*q* matrix | cell array of length *R*

New random-effects design, specified as an *n*-by-*q* matrix or a cell array of *R* design matrices $Z\{r\}$, where $r = 1, 2, \dots, R$. If Znew is a cell array, then each $Z\{r\}$ is an *n*-by-*q*(*r*) matrix, where *n* is the number of observations, and *q*(*r*) is the number of random predictor variables.

Data Types: single | double | cell

Gnew — New grouping variable or variables

vector | cell array of grouping variables of length *R*

New grouping variable or variables on page 2-45, specified as a vector or a cell array, of length *R*, of grouping variables with the same levels or groups as the original grouping variables used to fit the linear mixed-effects model lme.

Data Types: single | double | categorical | logical | char | string | cell

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Alpha — Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range 0 to 1. For a value α , the confidence level is $100*(1-\alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha', 0.01

Data Types: single | double

Conditional — Indicator for conditional predictions

true (default) | false

Indicator for conditional prediction on page 32-4285s, specified as the comma-separated pair consisting of 'Conditional' and one of the following.

true	Contributions from both fixed effects and random effects (conditional)
false	Contribution from only fixed effects (marginal)

Example: 'Conditional', false

DFMethod — Method for computing approximate degrees of freedom

'residual' (default) | 'satterthwaite' | 'none'

Method for computing approximate degrees of freedom to use in the confidence interval computation, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

'residual'	Default. The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
'satterthwaite'	Satterthwaite approximation.
'none'	All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

Example: 'DFMethod', 'satterthwaite'

Simultaneous — Type of confidence bounds

false (default) | true

Type of confidence bounds, specified as the comma-separated pair consisting of 'Simultaneous' and one of the following.

false	Default. Nonsimultaneous bounds.
true	Simultaneous bounds.

Example: 'Simultaneous', true

Prediction — Type of prediction

'curve' (default) | 'observation'

Type of prediction, specified as the comma-separated pair consisting of 'Prediction' and one of the following.

'curve'	Default. Confidence bounds for the predictions based on the fitted function.
'observation'	Variability due to observation error for the new observations is also included in the confidence bound calculations and this results in wider bounds.

Example: 'Prediction', 'observation'

Output Arguments

ypred — Predicted responses

vector

Predicted responses, returned as a vector. `ypred` can contain the conditional or marginal responses, depending on the value choice of the 'Conditional' name-value pair argument. Conditional predictions include contributions from both fixed and random effects.

ypredCI — Point-wise confidence intervals

two-column matrix

Point-wise confidence intervals for the predicted values, returned as a two-column matrix. The first column of `yCI` contains the lower bounds, and the second column contains the upper bound. By default, `yCI` contains the 95% confidence intervals for the predictions. You can change the confidence level using the `Alpha` name-value pair argument, make them simultaneous using the `Simultaneous` name-value pair argument, and also make them for a new observation rather than for the curve using the `Prediction` name-value pair argument.

DF — Degrees of freedom

vector | scalar value

Degrees of freedom used in computing the confidence intervals, returned as a vector or a scalar value.

- If the 'Simultaneous' name-value pair argument is `false`, then `DF` is a vector.
- If the 'Simultaneous' name-value pair argument is `true`, then `DF` is a scalar value.

Examples

Predict Responses at the Original Design Values

Load the sample data.

```
load('fertilizer.mat');
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Predict the response values at the original design values. Display the first five predictions with the observed response values.

```
yhat = predict(lme);
[yhat(1:5) ds.Yield(1:5)]
```

```
ans = 5×2
```

```
115.4788 104.0000
135.1455 136.0000
152.8121 158.0000
160.4788 174.0000
58.0839 57.0000
```

Plot Predictions vs. Observed Responses

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, with a fixed effect for `Weight`, and a random intercept grouped by `Model_Year`. First, store the data in a table.

```
tbl = table(MPG,Weight,Model_Year);
lme = fitlme(tbl, 'MPG ~ Weight + (1|Model_Year)');
```

Create predicted responses to the data.

```
yhat = predict(lme,tbl);
```

Plot the original responses and the predicted responses to see how they differ. Group them by model year.

```
figure()
gscatter(Weight,MPG,Model_Year)
hold on
gscatter(Weight,yhat,Model_Year,[], 'o+x')
legend('70-data', '76-data', '82-data', '70-pred', '76-pred', '82-pred')
hold off
```

Predict Responses at Values in a New Dataset Array

Load the sample data.

```
load('fertilizer.mat');
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Create a new dataset array with design values. The new dataset array must have the same variables as the original dataset array you use for fitting the model `lme`.

```
dsnew = dataset();
dsnew.Soil = nominal({'Sandy'; 'Silty'});
dsnew.Tomato = nominal({'Cherry'; 'Vine'});
dsnew.Fertilizer = nominal([2;2]);
```

Predict the conditional and marginal responses at the original design points.

```
yhatC = predict(lme, dsnew);
yhatM = predict(lme, dsnew, 'Conditional', false);
[yhatC yhatM]
```

```
ans = 2×2
```

```
    92.7505    111.6667
    87.5891    82.6667
```

Predict Responses at the Values in New Design Matrices

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
Z = [ones(406,1) Acceleration];
Model_Year = nominal(Model_Year);
G = Model_Year;
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X, MPG, Z, G, 'FixedEffectPredictors', ...
{'Intercept', 'Acceleration', 'Horsepower'}, 'RandomEffectPredictors', ...
{'Intercept', 'Acceleration'}}, 'RandomEffectGroups', {'Model_Year'});
```

Create the design matrices that contain the data at which to predict the response values. `Xnew` must have three columns as in `X`. The first column must be a column of 1s. And the values in the last two columns must correspond to `Acceleration` and `Horsepower`, respectively. The first column of `Znew` must be a column of 1s, and the second column must contain the same `Acceleration` values as in `Xnew`. The original grouping variable in `G` is the model year. So, `Gnew` must contain values for the model year. Note that `Gnew` must contain nominal values.

```
Xnew = [1, 13.5, 185; 1, 17, 205; 1, 21.2, 193];
Znew = [1, 13.5; 1, 17; 1, 21.2]; % alternatively Znew = Xnew(:,1:2);
Gnew = nominal([73 77 82]);
```

Predict the responses for the data in the new design matrices.

```
yhat = predict(lme,Xnew,Znew,Gnew)
```

```
yhat = 3×1
```

```
8.7063
5.4423
12.5384
```

Now, repeat the same for a linear mixed-effects model with uncorrelated random-effects terms for intercept and acceleration. First, change the original random effects design and the random effects grouping variables. Then, refit the model.

```
Z = {ones(406,1),Acceleration};
G = {Model_Year,Model_Year};
```

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept'},{'Acceleration'}},'RandomEffectGroups',{'Model_Year','Model_Year'});
```

Now, recreate the new random effects design, Znew, and the grouping variable design, Gnew, using which to predict the response values.

```
Znew = {[1;1;1],[13.5;17;21.2]};
MY = nominal([73 77 82]);
Gnew = {MY,MY};
```

Predict the responses using the new design matrices.

```
yhat = predict(lme,Xnew,Znew,Gnew)
```

```
yhat = 3×1
```

```
8.6365
5.9199
12.1247
```

Compute Confidence Intervals for Predictions

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year. First, store the variables in a table.

```
tbl = table(MPG,Acceleration,Horsepower,Model_Year);
```

Now, fit the model using `fitlme` with the defined design matrices and grouping variables.

```
lme = fitlme(tbl,'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');
```

Create the new data and store it in a new table.

```
tblnew = table();
tblnew.Acceleration = linspace(8,25)';
tblnew.Horsepower = linspace(nanmin(Horsepower),nanmax(Horsepower))';
tblnew.Model_Year = repmat(70,100,1);
```

`linspace` creates 100 equally distanced values between the lower and the upper input limits. `Model_Year` is fixed at 70. You can repeat this for any model year.

Compute and plot the predicted values and 95% confidence limits (nonsimultaneous).

```
[ypred,yCI,DF] = predict(lme,tblnew);
figure();
h1 = line(tblnew.Acceleration,ypred);
hold on;
h2 = plot(tblnew.Acceleration,yCI,'g-.');
```

Display the degrees of freedom.

```
DF(1)
```

```
ans = 389
```

Compute and plot the simultaneous confidence bounds.

```
[ypred,yCI,DF] = predict(lme,tblnew,'Simultaneous',true);
h3 = plot(tblnew.Acceleration,yCI,'r--');
```

Display the degrees of freedom.

```
DF
```

```
DF = 389
```

Compute the simultaneous confidence bounds using the Satterthwaite method to compute the degrees of freedom.

```
[ypred,yCI,DF] = predict(lme,tblnew,'Simultaneous',true,'DFMethod','satterthwaite');
h4 = plot(tblnew.Acceleration,yCI,'k:');
hold off
xlabel('Acceleration')
ylabel('Response')
ylim([-50,60])
xlim([8,25])
legend([h1,h2(1),h3(1),h4(1)],'Predicted response','95%','95% Sim',...
'95% Sim-Satt','Location','Best')
```

Display the degrees of freedom.

DF

DF = 3.6001

More About

Conditional and Marginal Predictions

A conditional prediction includes contributions from both fixed and random effects, whereas a marginal model includes contribution from only fixed effects.

Suppose the linear mixed-effects model `lme` has an n -by- p fixed-effects design matrix X and an n -by- q random-effects design matrix Z . Also, suppose the estimated p -by-1 fixed-effects vector is $\hat{\beta}$, and the q -by-1 estimated best linear unbiased predictor (BLUP) vector of random effects is \hat{b} . The predicted conditional response is

$$\hat{y}_{Cond} = X\hat{\beta} + Z\hat{b},$$

which corresponds to the 'Conditional', 'true' name-value pair argument.

The predicted marginal response is

$$\hat{y}_{Mar} = X\hat{\beta},$$

which corresponds to the 'Conditional', 'false' name-value pair argument.

When making predictions, if a particular grouping variable has new levels (1s that were not in the original data), then the random effects for the grouping variable do not contribute to the 'Conditional' prediction at observations where the grouping variable has new levels.

`LinearMixedModel` | `fitted` | `random`

predict

Class: FeatureSelectionNCAClassification

Predict responses using neighborhood component analysis (NCA) classifier

Syntax

```
[labels,postprobs,classnames] = predict mdl,X
```

Description

`[labels,postprobs,classnames] = predict(mdl,X)` computes the predicted labels, `labels`, corresponding to the rows of `X`, using the model `mdl`.

Input Arguments

mdl — Neighborhood component analysis model for classification

FeatureSelectionNCAClassification object

Neighborhood component analysis model for classification, specified as a FeatureSelectionNCAClassification object.

X — Predictor variable values

n-by-*p* matrix

Predictor variable values, specified as an *n*-by-*p* matrix, where *n* is the number of observations and *p* is the number of predictor variables.

Data Types: `single` | `double`

Output Arguments

labels — Predicted class labels

categorical vector | logical vector | numeric vector | cell array of character vectors | character array

Predicted class labels corresponding to the rows of `X`, returned as a categorical, logical, or numeric vector, a cell array of character vectors of length *n*, or a character array with *n* rows. *n* is the number of observations. The type of `labels` is the same as `Y` used in training.

postprobs — Posterior probabilities

n-by-*c* matrix

Posterior probabilities, returned as an *n*-by-*c* matrix, where *n* is the number of observations and *c* is the number of classes. A posterior probability, `postprobs(i,:)`, represents the membership of an observation in `X(i,:)` in classes 1 through *c*.

classnames — Class names

cell array of character vectors

Class names corresponding to posterior probabilities, returned as a cell array of character vectors. Each character vector is the class name corresponding to a column of `postprobs`.

Examples

Tune NCA Model for Classification

Load the sample data.

```
load('twodimclassdata.mat');
```

This data set is simulated using the scheme described in [1]. This is a two-class classification problem in two dimensions. Data from the first class (class -1) are drawn from two bivariate normal distributions $N(\mu_1, \Sigma)$ or $N(\mu_2, \Sigma)$ with equal probability, where $\mu_1 = [-0.75, -1.5]$, $\mu_2 = [0.75, 1.5]$, and $\Sigma = I_2$. Similarly, data from the second class (class 1) are drawn from two bivariate normal distributions $N(\mu_3, \Sigma)$ or $N(\mu_4, \Sigma)$ with equal probability, where $\mu_3 = [1.5, -1.5]$, $\mu_4 = [-1.5, 1.5]$, and $\Sigma = I_2$. The normal distribution parameters used to create this data set result in tighter clusters in data than the data used in [1].

Create a scatter plot of the data grouped by the class.

```
figure  
gscatter(X(:,1),X(:,2),y)  
xlabel('x1')  
ylabel('x2')
```

Add 100 irrelevant features to X . First generate data from a Normal distribution with a mean of 0 and a variance of 20.

```
n = size(X,1);
rng('default')
XwithBadFeatures = [X,randn(n,100)*sqrt(20)];
```

Normalize the data so that all points are between 0 and 1.

```
XwithBadFeatures = bsxfun(@rdivide,...
    bsxfun(@minus,XwithBadFeatures,min(XwithBadFeatures,[],1)), ...
    range(XwithBadFeatures,1));
X = XwithBadFeatures;
```

```
Infinity norm of the final gradient = 9.404e-08
```

```
Two norm of the final step = 8.947e-04, TolX = 1.000e-06
```

```
Relative infinity norm of the final gradient = 9.404e-08, TolFun = 1.000e-06
```

```
EXIT: Local minimum found.
```

Plot the feature weights. The weights of the irrelevant features should be very close to zero.

```
figure
semilogx(ncaMdl.FeatureWeights,'ro')
xlabel('Feature index')
ylabel('Feature weight')
grid on
```

Predict the classes using the NCA model and compute the confusion matrix.

```
ypred = predict(ncaMdl,X);  
confusionchart(y,ypred)
```

Confusion matrix shows that 40 of the data that are in class -1 are predicted as belonging to class -1. 60 of the data from class -1 are predicted to be in class 1. Similarly, 94 of the data from class 1 are predicted to be from class 1 and 6 of them are predicted to be from class -1. The prediction accuracy for class -1 is not good.

All weights are very close to zero, which indicates that the value of λ used in training the model is too large. When $\lambda \rightarrow \infty$, all features weights approach to zero. Hence, it is important to tune the regularization parameter in most cases to detect the relevant features.

Use five-fold cross-validation to tune λ for feature selection by using `fscnca`. Tuning λ means finding the λ value that will produce the minimum classification loss. To tune λ using cross-validation:

1. Partition the data into five folds. For each fold, `cvpartition` assigns four-fifths of the data as a training set and one-fifth of the data as a test set. Again for each fold, `cvpartition` creates a stratified partition, where each partition has roughly the same proportion of classes.

```
cvp = cvpartition(y, 'kfold', 5);
numtestsets = cvp.NumTestSets;
lambdavalues = linspace(0, 2, 20)/length(y);
lossvalues = zeros(length(lambdavalues), numtestsets);
```

2. Train the neighborhood component analysis (nca) model for each λ value using the training set in each fold.

3. Compute the classification loss for the corresponding test set in the fold using the nca model. Record the loss value.

4. Repeat this process for all folds and all λ values.

```

for i = 1:length(lambdavalues)
    for k = 1:numtestsets

        % Extract the training set from the partition object
        Xtrain = X(cvp.training(k),:);
        ytrain = y(cvp.training(k),:);

        % Extract the test set from the partition object
        Xtest  = X(cvp.test(k),:);
        ytest  = y(cvp.test(k),:);

        % Train an NCA model for classification using the training set
        ncaMdl = fscnca(Xtrain,ytrain,'FitMethod','exact', ...
            'Solver','lbfgs','Lambda',lambdavalues(i));

        % Compute the classification loss for the test set using the NCA
        % model
        lossvalues(i,k) = loss(ncaMdl,Xtest,ytest, ...
            'LossFunction','quadratic');

    end
end

```

Plot the average loss values of the folds versus the λ values. If the λ value that corresponds to the minimum loss falls on the boundary of the tested λ values, the range of λ values should be reconsidered.

```

figure
plot(lambdavalues,mean(lossvalues,2),'ro-')
xlabel('Lambda values')
ylabel('Loss values')
grid on

```

Find the λ value that corresponds to the minimum average loss.

```
[~,idx] = min(mean(lossvalues,2)); % Find the index
bestlambda = lambdavalues(idx) % Find the best lambda value
```

```
bestlambda =
    0.0037
```

Fit the NCA model to all of the data using the best λ value. Use the LBFGS solver and display the convergence information.

```
ncaMdl = fscnca(X,y,'FitMethod','exact','Verbose',1, ...
    'Solver','lbfgs','Lambda',bestlambda);
```

```
o Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe
```

19	-6.149997e-01	1.574e-06	1.275e-03	OK	1.808e+02	1.000e+00	Y

ITER	FUN VALUE	NORM GRAD	NORM STEP	CURV	GAMMA	ALPHA	ACC
20	-6.149997e-01	5.764e-07	6.765e-04	OK	2.905e+02	1.000e+00	Y

Infinity norm of the final gradient = 5.764e-07

Two norm of the final step = 6.765e-04, TolX = 1.000e-06

Relative infinity norm of the final gradient = 5.764e-07, TolFun = 1.000e-06

EXIT: Local minimum found.

Plot the feature weights.

```
figure
semilogx(ncaMdl.FeatureWeights, 'ro')
xlabel('Feature index')
ylabel('Feature weight')
grid on
```

`fscnca` correctly figures out that the first two features are relevant and that the rest are not. The first two features are not individually informative, but when taken together result in an accurate classification model.

Predict the classes using the new model and compute the accuracy.

```
ypred = predict(ncaMdl,X);  
confusionchart(y,ypred)
```

Confusion matrix shows that prediction accuracy for class -1 has improved. 88 of the data from class -1 are predicted to be from -1, and 12 of them are predicted to be from class 1. 92 of the data from class 1 are predicted to be from class 1 and 8 of them are predicted to be from class -1.

`FeatureSelectionNCAClassification` | `fscnca` | `loss` | `refit`

Introduced in R2016b

predict

Class: FeatureSelectionNCARegression

Predict responses using neighborhood component analysis (NCA) regression model

Syntax

```
ypred = predict mdl, X
```

Description

`ypred = predict(mdl, X)` computes the predicted response values, `ypred`, corresponding to rows of `X`, using the model `mdl`.

Input Arguments

mdl — Neighborhood component analysis model for regression

FeatureSelectionNCARegression object

Neighborhood component analysis model for regression, specified as a FeatureSelectionNCARegression object.

X — Predictor variable values

n-by-*p* matrix

Predictor variable values, specified as an *n*-by-*p* matrix, where *n* is the number of observations and *p* is the number of predictor variables.

Data Types: single | double

Output Arguments

ypred — Predicted response values

n-by-1 vector

Predicted response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

Examples

Tune NCA Model for Regression Using `loss` and `predict`

Load the sample data.

Download the housing data [1], from the UCI Machine Learning Repository [2]. The dataset has 506 observations. The first 13 columns contain the predictor values and the last column contains the response values. The goal is to predict the median value of owner-occupied homes in suburban Boston as a function of 13 predictors.

Load the data and define the response vector and the predictor matrix.

```
load('housing.data');  
X = housing(:,1:13);  
y = housing(:,end);
```

Divide the data into training and test sets using the 4th predictor as the grouping variable for a stratified partitioning. This ensures that each partition includes similar amount of observations from each group.

```
rng(1) % For reproducibility  
cvp = cvpartition(X(:,4),'Holdout',56);  
Xtrain = X(cvp.training,:);  
ytrain = y(cvp.training,:);  
Xtest = X(cvp.test,:);  
ytest = y(cvp.test,:);
```

`cvpartition` randomly assigns 56 observations into a test set and the rest of the data into a training set.

Perform Feature Selection Using Default Settings

Perform feature selection using NCA model for regression. Standardize the predictor values.

```
nca = fsrnca(Xtrain,ytrain,'Standardize',1);
```

Plot the feature weights.

```
figure()  
plot(nca.FeatureWeights,'ro')
```

The weights of irrelevant features are expected to approach zero. `fsrnca` identifies two features as irrelevant.

Compute the regression loss.

```
L = loss(nca,Xtest,ytest,'LossFunction','mad')
L = 2.5394
```

Compute the predicted response values for the test set and plot them versus the actual response.

```
ypred = predict(nca,Xtest);
figure()
plot(ypred,ytest,'bo')
xlabel('Predicted response')
ylabel('Actual response')
```

A perfect fit versus the actual values forms a 45 degree straight line. In this plot, the predicted and actual response values seem to be scattered around this line. Tuning λ (regularization parameter) value usually helps improve the performance.

Tune the regularization parameter using 10-fold cross-validation

Tuning λ means finding the λ value that will produce the minimum regression loss. Here are the steps for tuning λ using 10-fold cross-validation:

1. First partition the data into 10 folds. For each fold, `cvpartition` assigns 1/10th of the data as a training set, and 9/10th of the data as a test set.

```
n = length(ytrain);
cvp = cvpartition(Xtrain(:,4), 'kfold', 10);
numvalidsets = cvp.NumTestSets;
```

Assign the λ values for the search. Create an array to store the loss values.

```
lambdaval = linspace(0,2,30)*std(ytrain)/n;
lossvals = zeros(length(lambdaval),numvalidsets);
```

2. Train the neighborhood component analysis (nca) model for each λ value using the training set in each fold.

3. Fit a Gaussian process regression (gpr) model using the selected features. Next, compute the regression loss for the corresponding test set in the fold using the gpr model. Record the loss value.

4. Repeat this for each λ value and each fold.

```
for i = 1:length(lambdaval)
    for k = 1:numvalidsets
        X = Xtrain(cvp.training(k),:);
        y = ytrain(cvp.training(k),:);
        Xvalid = Xtrain(cvp.test(k),:);
        yvalid = ytrain(cvp.test(k),:);

        nca = fsrnca(X,y,'FitMethod','exact',...
                    'Lambda',lambdaval(i),...
                    'Standardize',1,'LossFunction','mad');

        % Select features using the feature weights and a relative
        % threshold.
        tol = 1e-3;
        selidx = nca.FeatureWeights > tol*max(1,max(nca.FeatureWeights));

        % Fit a non-ARD GPR model using selected features.
        gpr = fitrgp(X(:,selidx),y,'Standardize',1,...
                    'KernelFunction','squaredexponential','Verbose',0);

        lossvals(i,k) = loss(gpr,Xvalid(:,selidx),yvalid);

    end
end
```

Compute the average loss obtained from the folds for each λ value. Plot the mean loss versus the λ values.

```
meanloss = mean(lossvals,2);
figure;
plot(lambdaval,meanloss,'ro-');
xlabel('Lambda');
ylabel('Loss (MSE)');
grid on;
```

Find the λ value that produces the minimum loss value.

```
[~,idx] = min(meanloss);
bestlambda = lambdaval(idx)
```

```
bestlambda = 0.0251
```

Perform feature selection for regression using the best λ value. Standardize the predictor values.

```
nca2 = fsrnca(Xtrain,ytrain,'Standardize',1,'Lambda',bestlambda,...
    'LossFunction','mad');
```

Plot the feature weights.

```
figure()
plot(nca.FeatureWeights,'ro')
```

Compute the loss using the new nca model on the test data, which is not used to select the features.

```
L2 = loss(nca2,Xtest,ytest,'LossFunction','mad')
```

```
L2 = 2.0560
```

Tuning the regularization parameter helps identify the relevant features and reduces the loss.

Plot the predicted versus the actual response values in the test set.

```
ypred = predict(nca2,Xtest);  
figure;  
plot(ypred,ytest,'bo');
```

The predicted response values seem to be closer to the actual values as well.

`FeatureSelectionNCARegression` | `fsrcna` | `loss` | `refit`

Introduced in R2016b

predict

Class: NonLinearModel

Predict response of nonlinear regression model

Syntax

```
ypred = predict mdl, Xnew  
[ypred, yci] = predict mdl, Xnew  
[ypred, yci] = predict mdl, Xnew, Name, Value
```

Description

`ypred = predict mdl, Xnew` returns the predicted response of the `mdl` nonlinear regression model to the points in `Xnew`.

`[ypred, yci] = predict mdl, Xnew` returns confidence intervals for the true mean responses.

`[ypred, yci] = predict mdl, Xnew, Name, Value` predicts responses with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

`mdl`

Nonlinear regression model, constructed by `fitnlm`.

`Xnew`

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Alpha

Positive scalar from 0 to 1. Confidence level of `yci` is $100(1 - \text{alpha})\%$.

Default: 0.05, meaning a 95% confidence interval.

Prediction

Type of prediction:

- 'curve' — `predict` predicts confidence bounds for the fitted mean values.
- 'observation' — `predict` predicts confidence bounds for the new observations. This results in wider bounds because the error in a new observation is equal to the error in the estimated mean value, plus the variability in the observation from the true mean.

For details, see `polyconf`.

Default: 'curve'

Simultaneous

Logical value specifying whether the confidence bounds are for all predictor values simultaneously (`true`), or hold for each individual predictor value (`false`). Simultaneous bounds are wider than separate bounds, because it is more stringent to require that the entire curve be within the bounds than to require that the curve at a single predictor value be within the bounds.

For details, see `polyconf`.

Default: `false`

Weights

Vector of real, positive value weights or a function handle.

- If you specify a vector, then it must have the same number of elements as the number of observations (or rows) in `Xnew`.
- If you specify a function handle, then the function must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, W , `predict` estimates the error variance at observation i by $MSE * (1/W(i))$, where MSE is the mean squared error.

Default: No weights

Output Arguments

`ypred`

Predicted mean values at `Xnew`. `ypred` is the same size as each component of `Xnew`.

`yci`

Confidence intervals, a two-column matrix with each row providing one interval. The meaning of the confidence interval depends on the settings of the name-value pairs.

Examples

Predict Responses

Create a nonlinear model of car mileage as a function of weight, and predict the response.

Create an exponential model of car mileage as a function of weight from the `carsmall` data. Scale the weight by a factor of 1000 so all the variables are roughly equal in size.

```
load carsmall
X = Weight;
y = MPG;
modelfun = 'y ~ b1 + b2*exp(-b3*x/1000)';
beta0 = [1 1 1];
mdl = fitnlm(X,y,modelfun,beta0);
```

Create predicted responses to the data.

```
Xnew = X;
ypred = predict(mdl,Xnew);
```

Plot the original responses and the predicted responses to see how they differ.

```
plot(X,y,'o',X,ypred,'x')
legend('Data','Predicted')
```

Confidence Intervals for Predictions

Create a nonlinear model of car mileage as a function of weight, and examine confidence intervals of some responses.

Create an exponential model of car mileage as a function of weight from the `carsmall` data. Scale the weight by a factor of 1000 so all the variables are roughly equal in size.

```
load carsmall
X = Weight;
y = MPG;
modelfun = 'y ~ b1 + b2*exp(-b3*x/1000)';
beta0 = [1 1 1];
mdl = fitnlm(X,y,modelfun,beta0);
```

Create predicted responses to the smallest, mean, and largest data points.

```
Xnew = [min(X);mean(X);max(X)];
[ypred,yci] = predict(mdl,Xnew)
```

```
ypred = 3×1
```

```
34.9469
22.6868
10.0617
```

```
ygi = 3×2
```

```
32.5212 37.3726
21.4061 23.9674
7.0148 13.1086
```

Simultaneous Confidence Intervals for Robust Fit Curve

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp(-b_3 x) + \epsilon$$

where b_1 , b_2 , and b_3 are coefficients, and the error term ϵ is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
```

```
rng('default') % For reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Fit the nonlinear model using robust fitting options.

```
opts = statset('nlinfit');
opts.RobustWgtFun = 'bisquare';
b0 = [2;2;2];
mdl = fitnlm(x,y,modelfun,b0,'Options',opts);
```

Plot the fitted regression model and simultaneous 95% confidence bounds.

```
xrange = [min(x):.01:max(x)];
[ypred,ygi] = predict(mdl,xrange,'Simultaneous',true);
```

```
figure()
plot(x,y,'ko') % observed data
```

```
hold on
plot(xrange,ypred,'k','LineWidth',2)
plot(xrange,yci,'r--','LineWidth',1.5)
```

Confidence Interval Using Observation Weights

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Specify a function handle for observation weights, then fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
a = 1; b = 1;
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
mdl = fitnlm(X,y,@hougen,beta0,'Weights',weights);
```

Compute the 95% prediction interval for a new observation with reactant levels [100,100,100] using the observation weight function.

```
[ypred,yci] = predict(mdl,[100,100,100],'Prediction','observation', ...
    'Weights',weights)
```

```
ypred = 1.8149
yci = 1×2
      1.5264    2.1033
```

Tips

- For predictions with added noise, use `random`.
- For a syntax that can be easier to use with models created from tables or dataset arrays, try `feval`.

predict

Class: RepeatedMeasuresModel

Compute predicted values given predictor values

Syntax

```
yPred = predict(rm,tnew)
yPred = predict(rm,tnew,Name,Value)
[yPred,yCI] = predict( ___ )
```

Description

`yPred = predict(rm,tnew)` returns the predicted values from the repeated measures model `rm` using the predictor values from the table `t`.

`yPred = predict(rm,tnew,Name,Value)` returns the predicted values from the repeated measures model `rm` with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the within-subjects design matrix.

`[yPred,yCI] = predict(___)` also returns the 95% confidence interval for the predicted values.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

tnew — New data

table used to create `rm` (default) | table

New data including the values of the response variables and the between-subject factors used as predictors in the repeated measures model, `rm`, specified as a table. `tnew` must contain all of the between-subject factors used to create `rm`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Alpha — Significance level

0.05 (default) | scalar value in the range of 0 through 1

Significance level of the confidence intervals for the predicted values, specified as the comma-separated pair consisting of 'alpha' and a scalar value in the range of 0 to 1. The confidence level is $100*(1-\alpha)\%$.

Example: 'alpha',0.01

Data Types: double | single

WithinModel — Model for within-subject factors

'separatemeans' | 'orthogonalcontrasts' | character vector | string scalar

Model for the within-subject factors, specified as the comma-separated pair consisting of 'WithinModel' and one of the following:

- 'separatemeans' — Compute a separate mean for each group.
- 'orthogonalcontrasts' — Valid when the within-subject design consists of a single numeric factor T . This specifies a model consisting of orthogonal polynomials up to order $T^{(r-1)}$, where r is the number of repeated measures.
- A character vector or string scalar that defines a model specification in the within-subject factors.

Example: 'WithinModel','orthogonalcontrasts'

Data Types: char | string

WithinDesign — Design for within-subject factors

vector | matrix | table

Design for within-subject factors, specified as the comma-separated pair consisting of 'WithinDesign' and a vector, matrix, or a table. It provides the values of the within-subject factors in the same form as the `RM.WithinDesign` property.

Example: 'WithinDesign','Time'

Data Types: single | double | table

Output Arguments

ypred — Predicted values

n -by- r matrix

Predicted values from the repeated measures model `rm`, returned as an n -by- r matrix, where n is the number of rows in `tnew` and r is the number of repeated measures in `rm`.

yci — Confidence intervals for predicted values

n -by- r -by-2 matrix

Confidence intervals for predicted values from the repeated measures model `rm`, returned as an n -by- r -by-2 matrix.

These are nonsimultaneous intervals for predicting the mean response at the specified predictor values. For predicted value `ypred(i,j)`, the lower limit of the interval is `yci(i,j,1)` and the upper limit is `yci(i,j,2)`.

Examples

Predict Response Values

Load the sample data.

```
load fisheriris
```

The column vector, `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4), ...
    'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Predict responses for the three species.

```
Y = predict(rm,t([1 51 101],:))
```

Y = 3×4

5.0060	3.4280	1.4620	0.2460
5.9360	2.7700	4.2600	1.3260
6.5880	2.9740	5.5520	2.0260

Predict Response Values and Plot Predictions

Load the sample data.

```
load longitudinalData
```

The matrix `Y` contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of `Y` corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M' 'M'];
```

Store the data in a proper table array format to perform repeated measures analysis.

```
t = table(Gender,Y(:,1),Y(:,2),Y(:,3),Y(:,4),Y(:,5), ...
    'VariableNames',{'Gender','t0','t2','t4','t6','t8'});
```

Define the within-subjects variable.

```
Time = [0 2 4 6 8]';
```

Fit a repeated measures model, where the blood levels are the responses and gender is the predictor variable.

```
rm = fitrm(t,'t0-t8 ~ Gender','WithinDesign',Time);
```

Predict the responses at intermediate times.

```
time = linspace(0,8)';
Y = predict(rm,t([1 5 8 12],:), ...
    'WithinModel','orthogonalcontrasts','WithinDesign',time);
```

Plot the predictions along with the estimated marginal means.

```
plotprofile(rm, 'Time', 'Group', {'Gender'})
hold on;
plot(time,Y,'Color','k','LineStyle',':');
legend('Gender=F','Gender=M','Predictions')
hold off
```

Compute and Plot Confidence Intervals

Load the sample data.

```
load longitudinalData
```

The matrix Y contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of Y corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M' 'M'];
```

Store the data in a proper table array format to perform repeated measures analysis.

```
t = table(Gender,Y(:,1),Y(:,2),Y(:,3),Y(:,4),Y(:,5), ...
    'VariableNames',{'Gender','t0','t2','t4','t6','t8'});
```

Define the within-subjects variable.

```
Time = [0 2 4 6 8]';
```

Fit a repeated measures model, where the blood levels are the responses and gender is the predictor variable.

```
rm = fitrm(t,'t0-t8 ~ Gender','WithinDesign',Time);
```

Predict the responses at intermediate times.

```
time = linspace(0,8)';
[ypred,ypredci] = predict(rm,t([1 5 8 12],:), ...
    'WithinModel','orthogonalcontrasts','WithinDesign',time);
```

Plot the predictions and the confidence intervals for predictions along with the estimated marginal means.

```
p1 = plotprofile(rm,'Time','Group',{'Gender'});
hold on;
p2 = plot(time,ypred,'Color','k','LineStyle',':');
p3 = plot(time,ypredci(:,:,1),'k--');
p4 = plot(time,ypredci(:,:,2),'k--');
legend([p1;p2(1);p3(1)],'Gender=F','Gender=M','Predictions','Confidence Intervals')
hold off
```

predict

Class: TreeBagger

Predict responses using ensemble of bagged decision trees

Syntax

```
Yfit = predict(B,X)
Yfit = predict(B,X,Name,Value)
[Yfit,stdevs] = predict(____)
[Yfit,scores] = predict(____)
[Yfit,scores,stdevs] = predict(____)
```

Description

`Yfit = predict(B,X)` returns a vector of predicted responses for the predictor data in the table or matrix `X`, based on the ensemble of bagged decision trees `B`. `Yfit` is a cell array of character vectors for classification and a numeric array for regression. By default, `predict` takes a democratic (nonweighted) average vote from all trees in the ensemble.

`B` is a trained `TreeBagger` model object, that is, a model returned by `TreeBagger`.

`X` is a table or matrix of predictor data used to generate responses. Rows represent observations and columns represent variables.

- If `X` is a numeric matrix:
 - The variables making up the columns of `X` must have the same order as the predictor variables that trained `B`.
 - If you trained `B` using a table (for example, `Tbl`), then `X` can be a numeric matrix if `Tbl` contains all numeric predictor variables. To treat numeric predictors in `Tbl` as categorical during training, identify categorical predictors using the `CategoricalPredictors` name-value pair argument of `TreeBagger`. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types) and `X` is a numeric matrix, then `predict` throws an error.
- If `X` is a table:
 - `predict` does not support multi-column variables and cell arrays other than cell arrays of character vectors.
 - If you trained `B` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and be of the same data types as those that trained `B` (stored in `B.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. `Tbl` and `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.
 - If you trained `B` using a numeric matrix, then the predictor names in `B.PredictorNames` and corresponding predictor variable names in `X` must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `TreeBagger`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.

`Yfit = predict(B,X,Name,Value)` specifies additional options using one or more name-value pair arguments:

- 'Trees' — Array of tree indices to use for computation of responses. The default is 'all'.
- 'TreeWeights' — Array of NTrees weights for weighting votes from the specified trees, where NTrees is the number of trees in the ensemble.
- 'UseInstanceForTree' — Logical matrix of size Nobs-by-NTrees indicating which trees to use to make predictions for each observation, where Nobs is the number of observations. By default all trees are used for all observations.

For regression, `[Yfit,stdevs] = predict(____)` also returns standard deviations of the computed responses over the ensemble of the grown trees using any of the input argument combinations in previous syntaxes.

For classification, `[Yfit,scores] = predict(____)` also returns scores for all classes. `scores` is a matrix with one row per observation and one column per class. For each observation and each class, the score generated by each tree is the probability of the observation originating from the class, computed as the fraction of observations of the class in a tree leaf. `predict` averages these scores over all trees in the ensemble.

`[Yfit,scores,stdevs] = predict(____)` also returns standard deviations of the computed scores for classification. `stdevs` is a matrix with one row per observation and one column per class, with standard deviations taken over the ensemble of the grown trees.

Algorithms

- For regression problems, the predicted response for an observation is the weighted average of the predictions using selected trees only. That is,

$$\hat{y}_{\text{bag}} = \frac{1}{\sum_{t=1}^T \alpha_t I(t \in S)} \sum_{t=1}^T \alpha_t \hat{y}_t I(t \in S).$$

- \hat{y}_t is the prediction from tree t in the ensemble.
 - S is the set of indices of selected trees that comprise the prediction (see 'Trees' and 'UseInstanceForTree'). $I(t \in S)$ is 1 if t is in the set S , and 0 otherwise.
 - α_t is the weight of tree t (see 'TreeWeights').
- For classification problems, the predicted class for an observation is the class that yields the largest weighted average of the class posterior probabilities (i.e., classification scores) computed using selected trees only. That is,
 - 1 For each class $c \in C$ and each tree $t = 1, \dots, T$, `predict` computes $\hat{P}_t(c|x)$, which is the estimated posterior probability of class c given observation x using tree t . C is the set of all distinct classes in the training data. For more details on classification tree posterior probabilities, see `fitctree` and `predict`.
 - 2 `predict` computes the weighted average of the class posterior probabilities over the selected trees.

$$\hat{P}_{\text{bag}}(c|x) = \frac{1}{\sum_{t=1}^T \alpha_t I(t \in S)} \sum_{t=1}^T \alpha_t \hat{P}_t(c|x) I(t \in S).$$

- 3 The predicted class is the class that yields the largest weighted average.

$$\hat{y}_{\text{bag}} = \operatorname{argmax}_{c \in C} \{ \hat{P}_{\text{bag}}(c|x) \}.$$

“Bootstrap Aggregation (Bagging) of Classification Trees Using TreeBagger” on page 18-119

predictConstraints

Predict coupled constraint violations at a set of points

Syntax

```
ConstraintViolations = predictConstraints(results,XTable)
[ConstraintViolations,sigma] = predictConstraints(results,XTable)
```

Description

`ConstraintViolations = predictConstraints(results,XTable)` returns the coupled constraint function violations at the points in `XTable`.

`[ConstraintViolations,sigma] = predictConstraints(results,XTable)` also returns the standard deviations of the coupled constraint functions.

Examples

Predict Coupled Constraints

This example shows how to predict the coupled constraints of an optimized SVM model. For details of this model, see “Optimize a Cross-Validated SVM Classifier Using bayesopt” on page 10-45.

```
rng default
grnpop = mvnrnd([1,0],eye(2),10);
redpop = mvnrnd([0,1],eye(2),10);
redpts = zeros(100,2);
grnpts = redpts;
for i = 1:100
    grnpts(i,:) = mvnrnd(grnpop(randi(10),:),eye(2)*0.02);
    redpts(i,:) = mvnrnd(redpop(randi(10),:),eye(2)*0.02);
end
cdata = [grnpts;redpts];
grp = ones(200,1);
grp(101:200) = -1;
c = cvpartition(200,'Kfold',10);
sigma = optimizableVariable('sigma',[1e-5,1e5],'Transform','log');
box = optimizableVariable('box',[1e-5,1e5],'Transform','log');
```

The objective function is the cross-validation loss of the SVM model for the partition `c`. The coupled constraint is the number of support vectors in the model minus 100. The model has 200 data points, so the coupled constraint values range from -100 to 100. Positive values mean the constraint is not satisfied.

```
function [objective,constraint] = mysvmfun(x,cdata,grp,c)
SVMModel = fitcsvm(cdata,grp,'KernelFunction','rbf',...
    'BoxConstraint',x.box,...
    'KernelScale',x.sigma);
cvModel = crossval(SVMModel,'CVPartition',c);
```

```
objective = kfoldLoss(cvModel);  
constraint = sum(SVMModel.IsSupportVector)-100.5;
```

Call the optimizer using this function and its one coupled constraint.

```
fun = @(x)mysvmfun(x,cdata,grp,c);  
results = bayesopt(fun,[sigma,box], 'IsObjectiveDeterministic',true,...  
    'NumCoupledConstraints',1,'PlotFcn',...  
    {@plotMinObjective,@plotConstraintModels,@plotObjectiveModel},...  
    'AcquisitionFunctionName','expected-improvement-plus','Verbose',0);
```

Constraint 1 model

The constraint model plot shows that most parameters in the range are infeasible, and are feasible only for relatively high values of the `box` parameter and a small range of the `sigma` parameter. Predict the coupled constraint values for several values of the control variables `box` and `sigma`.

```
sigma = logspace(-2,2,11)';
box = logspace(0,5,11)';
XTable = table(sigma,box);
cons = predictConstraints(results,XTable);
[XTable,table(cons)]
```

ans =

15.849	10000	39.465
39.811	31623	60.9
100	1e+05	71.906

Input Arguments

results — Bayesian optimization results

BayesianOptimization object

Bayesian optimization results, specified as a BayesianOptimization object.

XTable — Prediction points

table with D columns

Prediction points, specified as a table with D columns, where D is the number of variables in the problem. The function performs its predictions on these points.

Data Types: table

Output Arguments

ConstraintViolations — Constraint violations

N-by-K matrix

Constraint violations, returned as an N-by-K matrix, where there are N rows in XTable and K coupled constraints. The constraint violations are the posterior means of the Gaussian process model of the coupled constraints at the points in XTable.

sigma — Constraint standard deviations

N-by-K matrix

Constraint standard deviations, returned as an N-by-K matrix, where there are N rows in XTable and K coupled constraints. The standard deviations represent those of the posterior distribution at the points in XTable.

See Also

BayesianOptimization | bayesopt

Introduced in R2016b

predictError

Predict error value at a set of points

Syntax

```
error = predictError(results,XTable)
[error,sigma] = predictError(results,XTable)
```

Description

`error = predictError(results,XTable)` returns the posterior mean of the error coupled constraint at the points in `XTable`.

`[error,sigma] = predictError(results,XTable)` also returns the posterior standard deviations.

Examples

Error Prediction

This example shows optimizing a function that throws an error when the evaluation point has norm larger than 2. The error model for the objective function learns this behavior.

Create variables named `x1` and `x2` that range from -5 to 5.

```
var1 = optimizableVariable('x1',[-5,5]);
var2 = optimizableVariable('x2',[-5,5]);
vars = [var1,var2];
```

The following objective function throws an error when the norm of $x = [x1, x2]$ exceeds 2:

```
function f = makeanerror(x)
f = x.x1 - x.x2 - sqrt(4-x.x1^2-x.x2^2);
```

```
fun = @makeanerror;
```

Plot the error model and minimum objective as the optimization proceeds. Optimize for 60 iterations so the error model becomes well-trained. For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```
rng default
results = bayesopt(fun,vars,'Verbose',0,'MaxObjectiveEvaluations',60,...
    'AcquisitionFunctionName','expected-improvement-plus',...
    'PlotFcn',{@plotMinObjective,@plotConstraintModels});
```

Probability of feasibility

Predict the error at points on the line $x_1 = x_2$. If the error model were perfect, it would have value -1 at every point where the norm of x is no more than 2, and value 1 at all other points.

```
x1 = (-5:0.5:5)';
x2 = x1;
XTable = table(x1,x2);
error = predictError(results,XTable);
normx = sqrt(x1.^2 + x2.^2);
[XTable,table(normx,error)]
```

ans =

Input Arguments

results — Bayesian optimization results

BayesianOptimization object

Bayesian optimization results, specified as a BayesianOptimization object.

XTable — Prediction points

table with D columns

Prediction points, specified as a table with D columns, where D is the number of variables in the problem. The function performs its predictions on these points.

Data Types: table

Output Arguments

error — Mean of error coupled constraint

N-by-1 vector

Mean of error coupled constraint, returned as an N-by-1 vector, where N is the number of rows of XTable. The mean is the posterior mean of the error coupled constraint at the points in XTable.

bayesopt deems your objective function to return an error if it returns anything other than a finite real scalar. See “Objective Function Errors” on page 10-37.

sigma — Standard deviation of error coupled constraint

N-by-1 vector

Standard deviation of error coupled constraint, returned as an N-by-1 vector, where N is the number of rows of XTable.

predictObjective

Predict objective function at a set of points

Syntax

```
objective = predictObjective(results,XTable)
[objective,sigma] = predictObjective(results,XTable)
```

Description

`objective = predictObjective(results,XTable)` returns the estimated objective function value at the points in `XTable`.

`[objective,sigma] = predictObjective(results,XTable)` also returns estimated standard deviations.

Examples

Predict Cross-Validation Loss of an Optimized Classifier

This example shows how to estimate the cross-validation loss of an optimized classifier.

Optimize a KNN classifier for the ionosphere data, meaning find parameters that minimize the cross-validation loss. Minimize over nearest-neighborhood sizes from 1 to 30, and over the distance functions 'chebychev', 'euclidean', and 'minkowski'.

For reproducibility, set the random seed, and set the `AcquisitionFunctionName` option to 'expected-improvement-plus'.

```
load ionosphere
rng default
num = optimizableVariable('n',[1,30],'Type','integer');
dst = optimizableVariable('dst',{'chebychev','euclidean','minkowski'},'Type','categorical');
c = cvpartition(351,'Kfold',5);
fun = @(x)kfoldLoss(fitcknn(X,Y,'CVPartition',c,'NumNeighbors',x.n,...
    'Distance',char(x.dst),'NSMethod','exhaustive'));
results = bayesopt(fun,[num,dst],'Verbose',0,...
    'AcquisitionFunctionName','expected-improvement-plus');
```

Create a table of points to estimate.

```
b = categorical({'chebychev','euclidean','minkowski'});
n = [1;1;1;4;2;2];
dst = [b(1);b(2);b(3);b(1);b(1);b(3)];
XTable = table(n,dst);
```

Estimate the objective and standard deviation of the objective at these points.

```
[objective,sigma] = predictObjective(results,XTable);
[XTable,table(objective,sigma)]
```

ans=6×4 table

n	dst	objective	sigma
1	chebychev	0.12132	0.0068029
1	euclidean	0.14052	0.0079128
1	minkowski	0.14057	0.0079117

2	minkowski	0.1437	0.0075448

Input Arguments

results — Bayesian optimization results

BayesianOptimization object

Bayesian optimization results, specified as a BayesianOptimization object.

XTable — Prediction points

table with D columns

Prediction points, specified as a table with D columns, where D is the number of variables in the problem. The function performs its predictions on these points.

Data Types: table

Output Arguments

objective — Objective estimates

N-by-1 vector

Objective estimates, returned as an N-by-1 vector, where N is the number of rows of XTable. The estimates are the mean values of the posterior distribution of the Gaussian process model of the objective function.

sigma — Standard deviations of objective function

N-by-1 vector

Standard deviations of objective function, returned as an N-by-1 vector, where N is the number of rows of XTable. The standard deviations are those of the posterior distribution of the Gaussian process model of the objective function.

predictObjectiveEvaluationTime

Predict objective function run times at a set of points

Syntax

```
time = predictObjectiveEvaluationTime(results,XTable)
```

Description

`time = predictObjectiveEvaluationTime(results,XTable)` returns estimated objective evaluation times at the points in `XTable`.

Examples

Predict Evaluation Time of Objective In an Optimized Model

This example shows how to estimate the objective function evaluation time in an optimized Bayesian model of SVM classification.

Create an optimized SVM model. For details of this model, see “Optimize a Cross-Validated SVM Classifier Using `bayesopt`” on page 10-45.

```
rng default
grnpop = mvnrnd([1,0],eye(2),10);
redpop = mvnrnd([0,1],eye(2),10);
redpts = zeros(100,2);
grnpts = redpts;
for i = 1:100
    grnpts(i,:) = mvnrnd(grnpop(randi(10),:),eye(2)*0.02);
    redpts(i,:) = mvnrnd(redpop(randi(10),:),eye(2)*0.02);
end
cdata = [grnpts;redpts];
grp = ones(200,1);
grp(101:200) = -1;
c = cvpartition(200,'KFold',10);
sigma = optimizableVariable('sigma',[1e-5,1e5],'Transform','log');
box = optimizableVariable('box',[1e-5,1e5],'Transform','log');
minfn = @(z)kfoldLoss(fitcsvm(cdata,grp,'CVPartition',c,...
    'KernelFunction','rbf','BoxConstraint',z.box,...
    'KernelScale',z.sigma));
results = bayesopt(minfn,[sigma,box],'IsObjectiveDeterministic',true,...
    'AcquisitionFunctionName','expected-improvement-plus','Verbose',0);
```

Predict the evaluation time for various points.

```
sigma = logspace(-5,5,11)';
box = 1e5*ones(size(sigma));
XTable = table(sigma,box);
time = predictObjectiveEvaluationTime(results,XTable);
[XTable,table(time)]
```

Input Arguments

results — Bayesian optimization results

BayesianOptimization object

Bayesian optimization results, specified as a BayesianOptimization object.

XTable — Prediction points

table with D columns

Prediction points, specified as a table with D columns, where D is the number of variables in the problem. The function performs its predictions on these points.

Data Types: table

Output Arguments

time — Estimated objective evaluation times

N-by-1 vector

Estimated objective evaluation times, returned as an N-by-1 vector, where N is the number of rows of XTable. The estimated values are the means of the posterior distribution of the Gaussian process model of the evaluation times of the objective function.

predictorImportance

Estimates of predictor importance for classification ensemble of decision trees

Syntax

```
imp = predictorImportance(ens)
[imp,ma] = predictorImportance(ens)
```

Description

`imp = predictorImportance(ens)` computes estimates of predictor importance for `ens` by summing these estimates over all weak learners in the ensemble. `imp` has one element for each input predictor in the data used to train this ensemble. A high value indicates that this predictor is important for `ens`.

`[imp,ma] = predictorImportance(ens)` returns a P-by-P matrix with predictive measures of association for P predictors, when the learners in `ens` contain surrogate splits. See “More About” on page 32-4341.

Input Arguments

ens

A classification ensemble of decision trees, created by `fitcensemble`, or by the `compact` method.

Output Arguments

imp

A row vector with the same number of elements as the number of predictors (columns) in `ens.X`. The entries are the estimates of predictor importance, with 0 representing the smallest possible importance.

ma

A P-by-P matrix of predictive measures of association for P predictors. Element `ma(I,J)` is the predictive measure of association averaged over surrogate splits on predictor J for which predictor I is the optimal split predictor. `predictorImportance` averages this predictive measure of association over all trees in the ensemble.

Examples

Estimate Predictor Importance

Estimate the predictor importance for all variables in the Fisher iris data.

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification ensemble using AdaBoostM2. Specify tree stumps as the weak learners.

```
t = templateTree('MaxNumSplits',1);
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Estimate the predictor importance for all predictor variables.

```
imp = predictorImportance(ens)

imp = 1×4

    0.0004    0.0016    0.1266    0.0324
```

The first two predictors are not very important in the ensemble.

Predictor Importance and Surrogate Splits

Estimate the predictor importance for all variables in the Fisher iris data for an ensemble where the trees contain surrogate splits.

Load Fisher's iris data set.

```
load fisheriris
```

Grow an ensemble of 100 classification trees using AdaBoostM2. Specify tree stumps as the weak learners, and also identify surrogate splits.

```
t = templateTree('MaxNumSplits',1,'Surrogate','on');
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Estimate the predictor importance and predictive measures of association for all predictor variables.

```
[imp,ma] = predictorImportance(ens)

imp = 1×4

    0.0674    0.0417    0.1582    0.1537

ma = 4×4

    1.0000     0         0         0
    0.0115    1.0000    0.0022    0.0054
    0.3186    0.2137    1.0000    0.6391
    0.0392    0.0073    0.1137    1.0000
```

The first two predictors show much more importance than the analysis in “Estimate Predictor Importance” on page 32-4339.

More About

Predictor Importance

`predictorImportance` computes estimates of predictor importance for `ens` by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes. If `ens` is grown without surrogate splits, this sum is taken over best splits found at each branch node. If `ens` is grown with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. `imp` has one element for each input predictor in the data used to train `ens`. Predictor importance associated with this split is computed as the difference between the risk for the parent node and the total risk for the two children.

Impurity and Node Error

`ClassificationTree` splits nodes based on either impurity or node error.

Impurity means one of several things, depending on your choice of the `SplitCriterion` name-value pair argument:

- Gini's Diversity Index (`gdi`) — The Gini index of a node is

$$1 - \sum_i p^2(i),$$

where the sum is over the classes i at the node, and $p(i)$ is the observed fraction of classes with class i that reach the node. A node with just one class (a pure node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance ('deviance') — With $p(i)$ defined the same as for the Gini index, the deviance of a node is

$$-\sum_i p(i) \log_2 p(i).$$

A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule ('twoing') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let $L(i)$ denote the fraction of members of class i in the left child node after a split, and $R(i)$ denote the fraction of members of class i in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R) \left(\sum_i |L(i) - R(i)| \right)^2,$$

where $P(L)$ and $P(R)$ are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and therefore similar to the parent node. The split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If j is the class with the largest number of training samples at a node, the node error is

$$1 - p(j).$$

Predictive Measure of Association

The predictive measure of association is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split

(found by growing the tree), the best surrogate decision split on page 32-1791 yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose x_j and x_k are predictor variables j and k , respectively, and $j \neq k$. At node t , the predictive measure of association between the optimal split $x_j < u$ and a surrogate split $x_k < v$ is

$$\lambda_{jk} = \frac{\min(P_L, P_R) - (1 - P_{L_j L_k} - P_{R_j R_k})}{\min(P_L, P_R)}.$$

- P_L is the proportion of observations in node t , such that $x_j < u$. The subscript L stands for the left child of node t .
- P_R is the proportion of observations in node t , such that $x_j \geq u$. The subscript R stands for the right child of node t .
- $P_{L_j L_k}$ is the proportion of observations at node t , such that $x_j < u$ and $x_k < v$.
- $P_{R_j R_k}$ is the proportion of observations at node t , such that $x_j \geq u$ and $x_k \geq v$.
- Observations with missing values for x_j or x_k do not contribute to the proportion calculations.

λ_{jk} is a value in $(-\infty, 1]$. If $\lambda_{jk} > 0$, then $x_k < v$ is a worthwhile surrogate split for $x_j < u$.

Algorithms

Element $\text{ma}(i, j)$ is the predictive measure of association averaged over surrogate splits on predictor j for which predictor i is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor i and surrogate splits on predictor j and dividing by the total number of optimal splits on predictor i , including splits for which the predictive measure of association between predictors i and j is negative.

predictorImportance

Estimates of predictor importance for classification tree

Syntax

```
imp = predictorImportance(tree)
```

Description

`imp = predictorImportance(tree)` computes estimates of predictor importance for `tree` by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes.

Input Arguments

tree

A classification tree created by `fitctree`, or by the `compact` method.

Output Arguments

imp

A row vector with the same number of elements as the number of predictors (columns) in `tree.X`. The entries are the estimates of predictor importance, with 0 representing the smallest possible importance.

Examples

Estimate Predictor Importance Values

Load Fisher's iris data set.

```
load fisheriris
```

Grow a classification tree.

```
Mdl = fitctree(meas,species);
```

Compute predictor importance estimates for all predictor variables.

```
imp = predictorImportance(Mdl)
```

```
imp = 1×4
```

```
0         0         0.0907    0.0682
```

The first two elements of `imp` are zero. Therefore, the first two predictors do not enter into `Mdl` calculations for classifying irises.

Estimates of predictor importance do not depend on the order of predictors if you use surrogate splits, but do depend on the order if you do not use surrogate splits.

Permute the order of the data columns in the previous example, grow another classification tree, and then compute predictor importance estimates.

```
measPerm = meas(:,[4 1 3 2]);
MdlPerm = fitctree(measPerm,species);
impPerm = predictorImportance(MdlPerm)

impPerm = 1×4
    0.1515         0    0.0074         0
```

The estimates of predictor importance are not a permutation of `imp`.

Surrogate Splits and Predictor Importance

Load Fisher's iris data set.

```
load fisheriris
```

Grow a classification tree. Specify usage of surrogate splits.

```
Mdl = fitctree(meas,species,'Surrogate','on');
```

Compute predictor importance estimates for all predictor variables.

```
imp = predictorImportance(Mdl)

imp = 1×4
    0.0791    0.0374    0.1530    0.1529
```

All predictors have some importance. The first two predictors are less important than the final two.

Permute the order of the data columns in the previous example, grow another classification tree specifying usage of surrogate splits, and then compute predictor importance estimates.

```
measPerm = meas(:,[4 1 3 2]);
MdlPerm = fitctree(measPerm,species,'Surrogate','on');
impPerm = predictorImportance(MdlPerm)

impPerm = 1×4
    0.1529    0.0791    0.1530    0.0374
```

The estimates of predictor importance are a permutation of `imp`.

Unbiased Predictor Importance Estimates

Load the `census1994` data set. Consider a model that predicts a person's salary category given their age, working class, education level, marital status, race, sex, capital gain and loss, and number of working hours per week.

```
load census1994
X = adultdata(:, {'age', 'workClass', 'education_num', 'marital_status', 'race', ...
    'sex', 'capital_gain', 'capital_loss', 'hours_per_week', 'salary'});
```

Display the number of categories represented in the categorical variables using `summary`.

```
summary(X)
```

Variables:

age: 32561x1 double

Values:

Min	17
Median	37
Max	90

workClass: 32561x1 categorical

Values:

Federal-gov	960
Local-gov	2093
Never-worked	7
Private	22696
Self-emp-inc	1116
Self-emp-not-inc	2541
State-gov	1298
Without-pay	14
NumMissing	1836

education_num: 32561x1 double

Values:

Min	1
Median	10
Max	16

marital_status: 32561x1 categorical

Values:

Divorced	4443
Married-AF-spouse	23
Married-civ-spouse	14976
Married-spouse-absent	418
Never-married	10683
Separated	1025
Widowed	993

```
race: 32561x1 categorical
```

```
Values:
```

Amer-Indian-Eskimo	311
Asian-Pac-Islander	1039
Black	3124
Other	271
White	27816

```
sex: 32561x1 categorical
```

```
Values:
```

Female	10771
Male	21790

```
capital_gain: 32561x1 double
```

```
Values:
```

Min	0
Median	0
Max	99999

```
capital_loss: 32561x1 double
```

```
Values:
```

Min	0
Median	0
Max	4356

```
hours_per_week: 32561x1 double
```

```
Values:
```

Min	1
Median	40
Max	99

```
salary: 32561x1 categorical
```

```
Values:
```

<=50K	24720
>50K	7841

Because there are few categories represented in the categorical variables compared to levels in the continuous variables, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over the categorical variables.

Train a classification tree using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing observations in the data, specify usage of surrogate splits.

```
Mdl = fitctree(X, 'salary', 'PredictorSelection', 'curvature', ...  
    'Surrogate', 'on');
```

Estimate predictor importance values by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes. Compare the estimates using a bar graph.

```
imp = predictorImportance(Mdl);

figure;
bar(imp);
title('Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```

In this case, `capital_gain` is the most important predictor, followed by `education_num`.

More About

Predictor Importance

`predictorImportance` computes estimates of predictor importance for `tree` by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes. If `tree` is grown without surrogate splits, this sum is taken over best splits found at each branch node. If `tree` is grown with surrogate splits, this sum is taken over all splits at each branch node including

surrogate splits. `imp` has one element for each input predictor in the data used to train `tree`. Predictor importance associated with this split is computed as the difference between the risk for the parent node and the total risk for the two children.

Estimates of predictor importance do not depend on the order of predictors if you use surrogate splits, but do depend on the order if you do not use surrogate splits.

If you use surrogate splits, `predictorImportance` computes estimates before the tree is reduced by pruning or merging leaves. If you do not use surrogate splits, `predictorImportance` computes estimates after the tree is reduced by pruning or merging leaves. Therefore, reducing the tree by pruning affects the predictor importance for a tree grown without surrogate splits, and does not affect the predictor importance for a tree grown with surrogate splits.

Impurity and Node Error

`ClassificationTree` splits nodes based on either impurity or node error.

Impurity means one of several things, depending on your choice of the `SplitCriterion` name-value pair argument:

- Gini's Diversity Index (`gdi`) — The Gini index of a node is

$$1 - \sum_i p^2(i),$$

where the sum is over the classes i at the node, and $p(i)$ is the observed fraction of classes with class i that reach the node. A node with just one class (a pure node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance ('`deviance`') — With $p(i)$ defined the same as for the Gini index, the deviance of a node is

$$-\sum_i p(i) \log_2 p(i).$$

A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule ('`twoing`') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let $L(i)$ denote the fraction of members of class i in the left child node after a split, and $R(i)$ denote the fraction of members of class i in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R) \left(\sum_i |L(i) - R(i)| \right)^2,$$

where $P(L)$ and $P(R)$ are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and therefore similar to the parent node. The split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If j is the class with the largest number of training samples at a node, the node error is

$$1 - p(j).$$

predictorImportance

Estimates of predictor importance for regression ensemble

Syntax

```
imp = predictorImportance(ens)
[imp,ma] = predictorImportance(ens)
```

Description

`imp = predictorImportance(ens)` computes estimates of predictor importance for `ens` by summing these estimates over all weak learners in the ensemble. `imp` has one element for each input predictor in the data used to train this ensemble. A high value indicates that this predictor is important for `ens`.

`[imp,ma] = predictorImportance(ens)` returns a P-by-P matrix with predictive measures of association for P predictors.

Input Arguments

`ens`

A regression ensemble, created by `fitrensemble`, or by the `compact` method.

Output Arguments

`imp`

A row vector with the same number of elements as the number of predictors (columns) in `ens.X`. The entries are the estimates of predictor importance, with 0 representing the smallest possible importance.

`ma`

A P-by-P matrix of predictive measures of association for P predictors. Element `ma(I,J)` is the predictive measure of association averaged over surrogate splits on predictor J for which predictor I is the optimal split predictor. `predictorImportance` averages this predictive measure of association over all trees in the ensemble.

Examples

Estimate Predictor Importance

Estimate the predictor importance for all predictor variables in the data.

Load the `carsmall` data set.

```
load carsmall
```

Grow an ensemble of 100 regression trees for MPG using Acceleration, Cylinders, Displacement, Horsepower, Model_Year, and Weight as predictors. Specify tree stumps as the weak learners.

```
X = [Acceleration Cylinders Displacement Horsepower Model_Year Weight];
t = templateTree('MaxNumSplits',1);
ens = fitensemble(X,MPG,'Method','LSBoost','Learners',t);
```

Estimate the predictor importance for all predictor variables.

```
imp = predictorImportance(ens)

imp = 1×6

    0.0150         0    0.0066    0.1111    0.0437    0.5181
```

Weight, the last predictor, has the most impact on mileage. The second predictor has importance 0, which means that the number of cylinders has no impact on predictions made with `ens`.

Predictor Importance and Surrogate Splits

Estimate the predictor importance for all variables in the data and where the regression tree ensemble contains surrogate splits.

Load the `carsmall` data set.

```
load carsmall
```

Grow an ensemble of 100 regression trees for MPG using Acceleration, Cylinders, Displacement, Horsepower, Model_Year, and Weight as predictors. Specify tree stumps as the weak learners, and also identify surrogate splits.

```
X = [Acceleration Cylinders Displacement Horsepower Model_Year Weight];
t = templateTree('MaxNumSplits',1,'Surrogate','on');
ens = fitensemble(X,MPG,'Method','LSBoost','Learners',t);
```

Estimate the predictor importance and predictive measures of association for all predictor variables.

```
[imp,ma] = predictorImportance(ens)

imp = 1×6

    0.2065    0.3799    0.4100    0.6190    0.3670    0.5476

ma = 6×6

    1.0000    0.0098    0.0102    0.0098    0.0033    0.0067
         0    1.0000         0         0         0         0
    0.0056    0.0084    1.0000    0.0078    0.0022    0.0084
    0.2232    0.1574    0.2066    1.0000    0.0580    0.2059
    0.0061    0.0070    0.0063    0.0064    1.0000    0.0056
    0.0200    0.0368    0.0620    0.0521    0.0098    1.0000
```

Comparing `imp` to the results in “Estimate Predictor Importance” on page 32-4350, Horsepower has the greatest impact on mileage, with `Weight` having the second greatest impact.

More About

Predictor Importance

`predictorImportance` computes estimates of predictor importance for `ens` by summing changes in the mean squared error (MSE) due to splits on every predictor and dividing the sum by the number of branch nodes. If `ens` is grown without surrogate splits, this sum is taken over best splits found at each branch node. If `ens` is grown with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. `imp` has one element for each input predictor in the data used to train `ens`. At each node, MSE is estimated as node error weighted by the node probability. Variable importance associated with this split is computed as the difference between MSE for the parent node and the total MSE for the two children.

Predictive Measure of Association

The predictive measure of association is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split (found by growing the tree), the best surrogate decision split on page 32-1791 yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose x_j and x_k are predictor variables j and k , respectively, and $j \neq k$. At node t , the predictive measure of association between the optimal split $x_j < u$ and a surrogate split $x_k < v$ is

$$\lambda_{jk} = \frac{\min(P_L, P_R) - (1 - P_{L_j L_k} - P_{R_j R_k})}{\min(P_L, P_R)}.$$

- P_L is the proportion of observations in node t , such that $x_j < u$. The subscript L stands for the left child of node t .
- P_R is the proportion of observations in node t , such that $x_j \geq u$. The subscript R stands for the right child of node t .
- $P_{L_j L_k}$ is the proportion of observations at node t , such that $x_j < u$ and $x_k < v$.
- $P_{R_j R_k}$ is the proportion of observations at node t , such that $x_j \geq u$ and $x_k \geq v$.
- Observations with missing values for x_j or x_k do not contribute to the proportion calculations.

λ_{jk} is a value in $(-\infty, 1]$. If $\lambda_{jk} > 0$, then $x_k < v$ is a worthwhile surrogate split for $x_j < u$.

Algorithms

Element `ma(i, j)` is the predictive measure of association averaged over surrogate splits on predictor j for which predictor i is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor i and surrogate splits on predictor j and dividing by the total number of optimal splits on predictor i , including splits for which the predictive measure of association between predictors i and j is negative.

predictorImportance

Estimates of predictor importance for regression tree

Syntax

```
imp = predictorImportance(tree)
```

Description

`imp = predictorImportance(tree)` computes estimates of predictor importance for `tree` by summing changes in the mean squared error due to splits on every predictor and dividing the sum by the number of branch nodes.

Input Arguments

tree

A regression tree created by `fitrtree`, or by the `compact` method.

Output Arguments

imp

A row vector with the same number of elements as the number of predictors (columns) in `tree.X`. The entries are the estimates of predictor importance, with 0 representing the smallest possible importance.

Examples

Estimate Predictor Importance

Estimate the predictor importance for all predictor variables in the data.

Load the `carsmall` data set.

```
load carsmall
```

Grow a regression tree for MPG using Acceleration, Cylinders, Displacement, Horsepower, Model_Year, and Weight as predictors.

```
X = [Acceleration Cylinders Displacement Horsepower Model_Year Weight];  
tree = fitrtree(X,MPG);
```

Estimate the predictor importance for all predictor variables.

```
imp = predictorImportance(tree)
```

```
imp = 1×6
```

```
0.0647    0.1068    0.1155    0.1411    0.3348    2.6565
```

Weight, the last predictor, has the most impact on mileage. The predictor with the minimal impact on making predictions is the first variable, which is **Acceleration**.

Predictor Importance and Surrogate Splits

Estimate the predictor importance for all variables in the data and where the regression tree contains surrogate splits.

Load the `carsmall` data set.

```
load carsmall
```

Grow a regression tree for MPG using **Acceleration**, **Cylinders**, **Displacement**, **Horsepower**, **Model_Year**, and **Weight** as predictors. Specify to identify surrogate splits.

```
X = [Acceleration Cylinders Displacement Horsepower Model_Year Weight];
tree = fitrtree(X,MPG,'Surrogate','on');
```

Estimate the predictor importance for all predictor variables.

```
imp = predictorImportance(tree)
```

```
imp = 1×6
```

```
1.0449    2.4560    2.5570    2.5788    2.0832    2.8938
```

Comparing `imp` to the results in “Estimate Predictor Importance” on page 32-4354, **Weight** still has the most impact on mileage, but **Cylinders** is the fourth most important predictor.

Unbiased Predictor Importance Estimates

Load the `carsmall` data set. Consider a model that predicts the mean fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower, manufacturer, model year, and weight. Consider **Cylinders**, **Mfg**, and **Model_Year** as categorical variables.

```
load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
    Model_Year,Weight,MPG);
```

Display the number of categories represented in the categorical variables.

```
numCylinders = numel(categories(Cylinders))
```

```
numCylinders = 3
```

```
numMfg = numel(categories(Mfg))
```

```

numMfg = 28
numModelYear = numel(categories(Model_Year))
numModelYear = 3

```

Because there are 3 categories only in Cylinders and Model_Year, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over these two variables.

Train a regression tree using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing values in the data, specify usage of surrogate splits.

```
Mdl = fitrtree(X, 'MPG', 'PredictorSelection', 'curvature', 'Surrogate', 'on');
```

Estimate predictor importance values by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes. Compare the estimates using a bar graph.

```

imp = predictorImportance(Mdl);

figure;
bar(imp);
title('Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';

```

In this case, Displacement is the most important predictor, followed by Horsepower.

More About

Predictor Importance

`predictorImportance` computes estimates of predictor importance for `tree` by summing changes in the mean squared error (MSE) due to splits on every predictor and dividing the sum by the number of branch nodes. If the tree is grown without surrogate splits, this sum is taken over best splits found at each branch node. If the tree is grown with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. `imp` has one element for each input predictor in the data used to train this tree. At each node, MSE is estimated as node error weighted by the node probability. Variable importance associated with this split is computed as the difference between MSE for the parent node and the total MSE for the two children.

Estimates of predictor importance do not depend on the order of predictors if you use surrogate splits, but do depend on the order if you do not use surrogate splits.

If you use surrogate splits, `predictorImportance` computes estimates before the tree is reduced by pruning or merging leaves. If you do not use surrogate splits, `predictorImportance` computes estimates after the tree is reduced by pruning or merging leaves. Therefore, reducing the tree by pruning affects the predictor importance for a tree grown without surrogate splits, and does not affect the predictor importance for a tree grown with surrogate splits.

probplot

Probability plots

Syntax

```
probplot(y)
probplot(y, cens)
probplot(y, cens, freq)
probplot(dist, ___ )

probplot(ax, ___ )
probplot(ax, pd)
probplot(ax, fun, params)

probplot( ___ , 'noref' )

h = probplot( ___ )
```

Description

`probplot(y)` creates a normal probability plot comparing the distribution of the data in `y` to the normal distribution.

`probplot` plots each data point in `y` using marker symbols and draws a reference line that represents the theoretical distribution. If the sample data has a normal distribution, then the data points appear along the reference line. The reference line connects the first and third quartiles of the data and extends to the ends of the data. A distribution other than normal introduces curvature in the data plot.

`probplot(y, cens)` creates a probability plot using the censoring data in `cens`.

`probplot(y, cens, freq)` creates a probability plot using the censoring data in `cens` and the frequency data in `freq`.

`probplot(dist, ___)` creates a probability plot for the distribution specified by `dist`, using any of the input arguments in the previous syntaxes.

`probplot(ax, ___)` adds a probability plot into the existing probability plot axes specified by `ax`, using any of the input arguments in the previous syntaxes.

`probplot(ax, pd)` adds a fitted line on the existing probability plot axes specified by `ax` to represent the probability distribution `pd`.

`probplot(ax, fun, params)` adds a fitted line on the existing probability plot axes specified by `ax` to represent the function `fun` with the parameters `params`.

`probplot(___ , 'noref')` omits the reference line from the plot.

`h = probplot(___)` returns graphics handles corresponding to the plotted lines.

Examples

Create Weibull Probability Plot

Generate sample data and create a probability plot.

Generate sample data. The sample x1 contains 500 random numbers from a Weibull distribution with scale parameter $A = 3$ and shape parameter $B = 3$. The sample x2 contains 500 random numbers from a Rayleigh distribution with scale parameter $B = 3$.

```
rng('default'); % For reproducibility
x1 = wblrnd(3,3,[500,1]);
x2 = raylrnd(3,[500,1]);
```

Create a probability plot to assess whether the data in x1 and x2 comes from a Weibull distribution.

```
figure
probplot('weibull',[x1 x2])
legend('Weibull Sample','Rayleigh Sample','Location','best')
```

The probability plot shows that the data in x1 comes from a Weibull distribution, while the data in x2 does not.

Alternatively, you can use `wblplot` to create a Weibull probability plot.

Add Fitted Line to Probability Plot

Create a probability plot and an additional fitted line on the same figure.

Generate sample data containing about 20% outliers in the tails. The left tail of the sample data contains 10 values randomly generated from an exponential distribution with parameter $\mu = 1$. The right tail contains 10 values randomly generated from an exponential distribution with parameter $\mu = 5$. The center of the sample data contains 80 values randomly generated from a standard normal distribution.

```
rng('default') % For reproducibility
left_tail = -exprnd(1,10,1);
right_tail = exprnd(5,10,1);
center = randn(80,1);
data = [left_tail;center;right_tail];
```

Create a probability plot to assess whether the sample data comes from a normal distribution.

```
probplot(data)
```

Plot a t location-scale curve on the same figure to compare with data.

```
p = mle(data, 'distribution', 'tLocationScale');
t = @(data,mu,sig,df)cdf('tLocationScale',data,mu,sig,df);
h = probplot(gca,t,p);
h.Color = 'r';
h.LineStyle = '-';
title('\bf Probability Plot')
legend('Normal', 'Data', 't', 'Location', 'NW')
```

The plot shows that neither the normal line nor the t location-scale curve fits the tails very well because of the outliers.

Identify Significant Effects with Half-Normal Probability Plot

Create a half-normal probability distribution plot to identify significant effects in an experiment to study factors that might influence flow rate in a chemical manufacturing process. The four factors are reactants A, B, C, and D. Each factor is present at two levels (high and low concentration). The experiment contains only one replication at each factor level.

Load the sample data.

load flowrate

The first four columns of the table `flowrate` contain the design matrix for the factors and their interactions. The design matrix is coded to use 1 for the high factor level and -1 for the low factor level. The fifth column of `flowrate` contains the measured flow rate.

Fit a linear regression model using `rate` as the response variable. Use predictor variables A, B, C, D, and all of their interaction terms.

```
mdl = fitlm(flowrate, 'rate ~ A*B*C*D');
```

Calculate and store the absolute value of the factor effect estimates. To obtain the factor effect estimates, multiply the coefficient estimates obtained during the model fitting by two. This step is

necessary because the regression coefficients measure the effect of a one-unit change in x on the mean of y . However, the effects estimates measure a two-unit change in x due to the design matrix coding of -1 and 1. Exclude the baseline measurement. Note that the factor order in `mdl` may be different from the order in the original design matrix.

```
effects = abs(mdl.Coefficients{2:end,1}*2);
```

Create a half-normal probability plot using the absolute value of the effects estimates, excluding the baseline.

```
figure
h = probplot('halfnormal',effects);
```

Label the points and format the plot. First, return the index values for the sorted effects estimates (from lowest to highest). Then use these index values to sort the probability values stored in the graphics handle (`h(1).YData`).

```
[b,i] = sort(effects);
prob(i) = h(1).YData;
```

Add text labels to the plot at each point. For each point, the x-value is the effects estimate and the y-value is the corresponding probability.

```
text(effects,prob,mdl.CoefficientNames(2:end),'FontSize',8,...
    'VerticalAlignment','top')
h(1).Color = 'r';
```

The points located far from the reference line represent the significant effects.

Create a Normal Probability Plot Using Frequency Data

Generate simulated frequency data.

```
y = 1:10;
freq = [2 4 6 7 9 8 7 7 6 5];
```

Create a normal probability plot using the frequency data.

```
probplot(y, [], freq)
```

The normal probability plot shows that the data do not have a normal distribution.

Input Arguments

y — Sample data

numeric vector | numeric matrix

Sample data, specified as a numeric vector or numeric matrix. `probplot` displays each value in `y` using marker symbols including 'x' and 'o'. If `y` is a matrix, then `probplot` displays a separate line for each column of `y`.

Not all distributions are appropriate for all data sets. `probplot` errors if the data set is inappropriate for a specified distribution. See `dist` for appropriate data ranges for each distribution.

dist — Distribution for probability plot

probability distribution object | 'normal' | 'exponential' | 'extreme value' | 'half normal' | 'lognormal' | ...

Distribution for probability plot, specified as a probability distribution object or one of the following distribution names:

Name	Plot Type	Data Range
'normal'	Normal probability plot	All values

Name	Plot Type	Data Range
'exponential'	Exponential probability plot	Nonnegative values
'extreme value'	Extreme value probability plot	All values
'half normal'	Half-normal probability plot	All values
'lognormal'	Lognormal probability plot	Positive values
'logistic'	Logistic probability plot	All values
'loglogistic'	Loglogistic probability plot	Positive values
'rayleigh'	Rayleigh probability plot	Positive values
'weibull'	Weibull probability plot	Positive values

The default is 'normal' if you create a probability plot in a new figure. If you add a probability plot to a figure that already includes one by using the `ax` input argument, then the default is the plot type of the existing probability plot.

You can create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a probability distribution object to sample data using `fitdist`. For more information on probability distribution objects, see “Working with Probability Distributions” on page 5-2.

The y-axis scale is based on the selected distribution. The x-axis has a log scale for the Weibull, loglogistic, and lognormal distributions, and a linear scale for the others.

Not all distributions are appropriate for all data sets. `probplot` errors if the data set is inappropriate for a specified distribution.

Example: 'weibull'

cens — Censoring data

numeric vector

Censoring data, specified as a numeric vector. `cens` must be the same length as `y`, and contain a 1 value for observations that are right-censored and a 0 value for observations that are measured exactly.

Data Types: single | double

freq — Frequency data

vector of integer values

Frequency data, specified as a vector of integer values. `freq` must be the same length as `y`. `freq` contains the integer frequencies for the corresponding elements in `y`.

To create a probability plot using frequency data but not censoring data, specify empty brackets ([]) for `cens`.

Data Types: single | double

ax — Target axes

Axes object | UIAxes object

Target axes, specified as an Axes object or a UIAxes object. `probplot` adds an additional plot into the axes specified by `ax`. For details, see Axes Properties and UIAxes Properties.

Use `gca` to return the current axes for the current figure.

pd — Probability distribution for reference line

probability distribution object

Probability distribution for reference line, specified as a probability distribution object. `probplot` adds a fitted line to the axes specified by `ax` to represent the probability distribution specified by `pd`.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a probability distribution object to sample data using `fitdist`. For more information on probability distribution objects, see “Working with Probability Distributions” on page 5-2.

fun — Function for reference line

function handle

Function for reference line, specified as a function handle. `probplot` adds a fitted line to the axes specified by `ax` to represent the function specified by `fun`, evaluated at the parameters specified by `params`.

`fun` is a function handle to a cdf function, specified using the function handle operator `@`. The function must accept a vector of input values as its first argument, and return a vector containing the cdf evaluated at each input value. Specify the parameter values required to evaluate `fun` using the `params` argument. For more information on function handles, see “Create Function Handle” (MATLAB).

Example: `@wblpdf`

Data Types: `function_handle`

params — Reference line function parameters

vector of numeric values | cell array

Reference line function parameters, specified as a vector of numeric values or a cell array. `probplot` adds a fitted line to the axes specified by `ax` to represent the function specified by `fun`, evaluated at the parameters specified by `params`.

`fun` is a function handle to a cdf function, specified using the function handle operator `@`. The function must accept a vector of values as its first argument, and return a vector of cdf values evaluated at each value. Specify the parameter values required to evaluate `fun` using the `params` argument. For more information on function handles, see “Create Function Handle” (MATLAB).

Output Arguments**h — Graphic handles for line objects**

vector of Line graphic handles

Graphic handles for line objects, returned as a vector of Line graphic handles. Graphic handles are unique identifiers that you can use to query and modify the properties of a specific line on the plot. For each column of `y`, `probplot` returns two handles:

- The line representing the data points. `probplot` represents each data point in `y` using marker symbols such as `'+'` and `'o'`.
- The line showing the theoretical distribution for the probability plot, represented as a dashed line.

To view and set properties of line objects, use dot notation. For information on using dot notation, see “Access Property Values” (MATLAB). For information on the Line properties that you can set, see Primitive Line.

Algorithms

`probplot` matches the quantiles of sample data to the quantiles of a given probability distribution. The sample data is sorted, scaled according to the choice of `dist`, and plotted on the x-axis. When `dist` is `'lognormal'`, `'loglogistic'`, or `'weibull'`, the scaling is logarithmic. Otherwise, the scaling is linear. The y-axis represents the quantiles of the distribution specified in `dist`, converted into probability values. The scaling depends on the given distribution and is not linear.

Where the x-axis value is the i th sorted value from a sample of size N , the y-axis value is the midpoint between evaluation points of the empirical cumulative distribution function of the data. In the case of uncensored data, the midpoint is equal to $\frac{(i - 0.5)}{N}$.

`probplot` superimposes a reference line to assess the linearity of the plot. If the data is uncensored, then the line goes through the first and third quartiles of the data. If the data is censored, then the line shifts accordingly. If the data is uncensored and `dist` is `'half normal'`, then `probplot` uses the zeroth and second quartiles instead.

Introduced before R2006a

procrustes

Procrustes analysis

Syntax

```
d = procrustes(X,Y)
[d,Z] = procrustes(X,Y)
[d,Z,transform] = procrustes(X,Y)
[...] = procrustes(...,'scaling',flag)
[...] = procrustes(...,'reflection',flag)
```

Description

`d = procrustes(X,Y)` determines a linear transformation (translation, reflection, orthogonal rotation, and scaling) of the points in matrix `Y` to best conform them to the points in matrix `X`. The goodness-of-fit criterion is the sum of squared errors. `procrustes` returns the minimized value of this dissimilarity measure in `d`. `d` is standardized by a measure of the scale of `X`, given by:

```
sum(sum((X-repmat(mean(X,1),size(X,1),1)).^2,1))
```

That is, the sum of squared elements of a centered version of `X`. However, if `X` comprises repetitions of the same point, the sum of squared errors is not standardized.

`X` and `Y` must have the same number of points (rows), and `procrustes` matches `Y(i)` to `X(i)`. Points in `Y` can have smaller dimension (number of columns) than those in `X`. In this case, `procrustes` adds columns of zeros to `Y` as necessary.

`[d,Z] = procrustes(X,Y)` also returns the transformed `Y` values.

`[d,Z,transform] = procrustes(X,Y)` also returns the transformation that maps `Y` to `Z`. `transform` is a structure array with fields:

- `c` — Translation component
- `T` — Orthogonal rotation and reflection component
- `b` — Scale component

That is:

```
c = transform.c;
T = transform.T;
b = transform.b;
```

```
Z = b*Y*T + c;
```

`[...] = procrustes(...,'scaling',flag)`, when `flag` is false, allows you to compute the transformation without a scale component (that is, with `b` equal to 1). The default `flag` is true.

`[...] = procrustes(...,'reflection',flag)`, when `flag` is false, allows you to compute the transformation without a reflection component (that is, with `det(T)` equal to 1). The default `flag` is 'best', which computes the best-fitting transformation, whether or not it includes a

reflection component. A *flag* of `true` forces the transformation to be computed with a reflection component (that is, with $\det(T)$ equal to -1)

Examples

Procrustes Analysis

Generate the sample data in two dimensions.

```
rng('default')
n = 10;
X = normrnd(0,1,[n 2]);
```

Rotate, scale, translate, and add some noise to sample points.

```
S = [0.5 -sqrt(3)/2; sqrt(3)/2 0.5];
Y = normrnd(0.5*X*S+2,0.05,n,2);
```

Conform Y to X using procrustes analysis.

```
[d,Z,tr] = procrustes(X,Y);
```

Plot the original X and Y with the transformed Y.

```
plot(X(:,1),X(:,2),'rx',Y(:,1),Y(:,2),'b.',Z(:,1),Z(:,2),'bx');
```

Introduced before R2006a

proflik

Package: prob

Profile likelihood function for probability distribution

Syntax

```
[ll,param] = proflik(pd,pnum)
[ll,param] = proflik(pd,pnum,'Display',display)
[ll,param] = proflik(pd,pnum,setparam)
[ll,param] = proflik(pd,pnum,setparam,'Display',display)
[ll,param,other] = proflik(____)
```

Description

`[ll,param] = proflik(pd,pnum)` returns a vector `ll` of loglikelihood values and a vector `param` of corresponding parameter values for the parameter in the position indicated by `pnum`.

`[ll,param] = proflik(pd,pnum,'Display',display)` returns the loglikelihood values and corresponding parameter values, and plots the profile likelihood overlaid on an approximation of the loglikelihood.

`[ll,param] = proflik(pd,pnum,setparam)` returns the loglikelihood values and corresponding parameter values as specified by `setparam`.

`[ll,param] = proflik(pd,pnum,setparam,'Display',display)` returns the loglikelihood values and corresponding parameter values as specified by `setparam`, and plots the profile likelihood overlaid on an approximation of the loglikelihood.

`[ll,param,other] = proflik(____)` also returns a matrix `other` containing the values of the other parameters that maximize the likelihood, using any of the input arguments from the previous syntaxes.

Examples

Profile Likelihood of a Distribution Parameter

Load the sample data. Create a probability distribution object by fitting a Weibull distribution to the miles per gallon (MPG) data.

```
load carsmall
pd = fitdist(MPG,'Weibull')

pd =
    WeibullDistribution

    Weibull distribution
    A = 26.5079    [24.8333, 28.2954]
    B = 3.27193   [2.79441, 3.83104]
```

View the parameter names for the distribution.

```
pd.ParameterNames
ans = 1x2 cell
    {'A'}    {'B'}
```

For the Weibull distribution, A is in position 1, and B is in position 2.

Compute the profile likelihood for B, which is in position `pnum = 2`.

```
[ll,param] = proflik(pd,2);
```

Display the loglikelihood values for the estimated values of B.

```
[ll',param']
ans = 21x2
-329.9688    2.7132
-329.4312    2.7748
-328.9645    2.8365
-328.5661    2.8981
-328.2340    2.9597
-327.9658    3.0213
-327.7596    3.0830
-327.6135    3.1446
-327.5256    3.2062
-327.4943    3.2678
    ⋮
```

These results show that the profile log likelihood is maximized between the estimated B values of 3.2678 and 3.3295, which correspond to loglikelihood values -327.4943 and -327.5178. From the earlier fit, the MLE of B is 3.27193, which is in this interval as expected.

Profile Likelihood With Restricted Parameter Values

Load the sample data. Create a probability distribution object by fitting a generalized extreme value distribution to the miles per gallon (MPG) data.

```
load carsmall
pd = fitdist(MPG,'GeneralizedExtremeValue')

pd =
    GeneralizedExtremeValueDistribution

    Generalized Extreme Value distribution
        k = -0.207765    [-0.381674, -0.0338564]
        sigma = 7.49674    [6.31755, 8.89603]
        mu = 20.6233    [18.8859, 22.3606]
```

View the parameter names for the distribution.

```
pd.ParameterNames
```

```
ans = 1x3 cell
      {'k'}      {'sigma'}      {'mu'}
```

For the generalized extreme value distribution, k is in position 1, σ is in position 2, and μ is in position 3.

Compute the profile likelihood for μ , which is in position $\text{prnum} = 3$. Restrict the computation to parameter values from 20 to 22, and display the plot.

```
[ll,param,other] = proflik(pd,3,20:.1:22,'display','on');
```

The plot shows the estimated value for the parameter μ that maximizes the loglikelihood.

Display the loglikelihood values for the estimated values of μ , and the values of the other distribution parameters that maximize the corresponding loglikelihood.

```
[ll',param',other]
```

```
ans = 21x4
-327.5706    20.0000    -0.1803     7.4087
-327.4971    20.1000    -0.1846     7.4218
-327.4364    20.2000    -0.1890     7.4354
-327.3887    20.3000    -0.1934     7.4493
-327.3538    20.4000    -0.1978     7.4636
```

```

-327.3317  20.5000  -0.2023  7.4783
-327.3223  20.6000  -0.2067  7.4932
-327.3257  20.7000  -0.2112  7.5084
-327.3418  20.8000  -0.2156  7.5240
-327.3706  20.9000  -0.2201  7.5399
  ⋮

```

The first column contains the log likelihood value that corresponds to the estimate of μ in the second column. The log likelihood is maximized between the parameter values 20.6000 and 20.7000, corresponding to log likelihood values -327.3223 and -327.3257. The third column contains the value of k that maximizes the corresponding log likelihood for μ . The fourth column contains the value of σ that maximizes the corresponding log likelihood for μ .

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

Function or App	Description
<code>fitdist</code>	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.

pnum — Parameter number

positive integer value

Parameter number for which to compute the profile likelihood, specified as a positive integer value corresponding to the position of the desired parameter in the parameter name vector. For example, a Weibull distribution has a parameter name vector `{ 'A', 'B' }`, so specify `pnum` as 2 to compute the profile likelihood for B.

Data Types: `single` | `double`

setparam — Parameter value restriction

scalar value | vector of scalar values

Parameter value restriction, specified as a scalar value or a vector of such values. If you do not specify `setparam`, `proflk` chooses the values for output vector `param` based on the default confidence interval method for the probability distribution `pd`. If the parameter can take only restricted values, and if the confidence interval violates that restriction, you can use `setparam` to specify valid values.

Example: `[3,3.5,4]`

display — Display toggle

'off' (default) | 'on'

Display toggle, specified as either 'on' or 'off'. Specify 'on' to display the profile of the exact loglikelihood overlaid on the Wald approximation of the loglikelihood. Specify 'off' to omit the

display. The Wald approximation is based on a Taylor series expansion around the estimated parameter value, as a function of the parameter in position `pnum` or its logarithm. The intersection of the curves with the horizontal dotted line marks the endpoints of 95% confidence intervals.

Output Arguments

ll — Loglikelihood values

vector

Loglikelihood values, returned as a vector. The loglikelihood is the value of the likelihood with the parameter in position `pnum` set to the values in `param`, maximized over the remaining parameters.

param — Parameter values

vector

Parameter values corresponding to the loglikelihood values in `ll`, returned as a vector. If you specify parameter values using `setparam`, then `param` is equal to `setparam`.

other — Other parameter values

matrix

Other parameter values that maximize the likelihood, returned as a matrix. Each row of `other` contains the values for all parameters except the parameter in position `pnum`.

Topics

“Working with Probability Distributions” on page 5-2

“Supported Distributions” on page 5-13

Introduced in R2013a

proximity

Class: CompactTreeBagger

Proximity matrix for data

Syntax

```
prox = proximity(B,X)
```

Description

`prox = proximity(B,X)` computes a numeric matrix of size `Nobs`-by-`Nobs` of proximities for data `X`, where `Nobs` is the number of observations (rows) in `X`. Proximity between any two observations in the input data is defined as a fraction of trees in the ensemble `B` for which these two observations land on the same leaf. This is a symmetric matrix with ones on the diagonal and off-diagonal elements ranging from 0 to 1.

prune

Class: ClassificationTree

Produce sequence of classification subtrees by pruning

Syntax

```
tree1 = prune(tree)
tree1 = prune(tree, Name, Value)
```

Description

`tree1 = prune(tree)` creates a copy of the classification tree `tree` with its optimal pruning sequence filled in.

`tree1 = prune(tree, Name, Value)` creates a pruned tree with additional options specified by one `Name, Value` pair argument. You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Input Arguments

tree

A classification tree created with `fitctree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Alpha

A numeric scalar. `prune` prunes `tree` to the specified value of the pruning cost.

Level

A numeric scalar from 0 (no pruning) to the largest pruning level of this tree `max(tree.PruneList)`. `prune` returns the tree pruned to this level.

Nodes

A numeric vector with elements from 1 to `tree.NumNodes`. Any `tree` branch nodes listed in `nodes` become leaf nodes in `tree1`, unless their parent nodes are also pruned.

Output Arguments

tree1

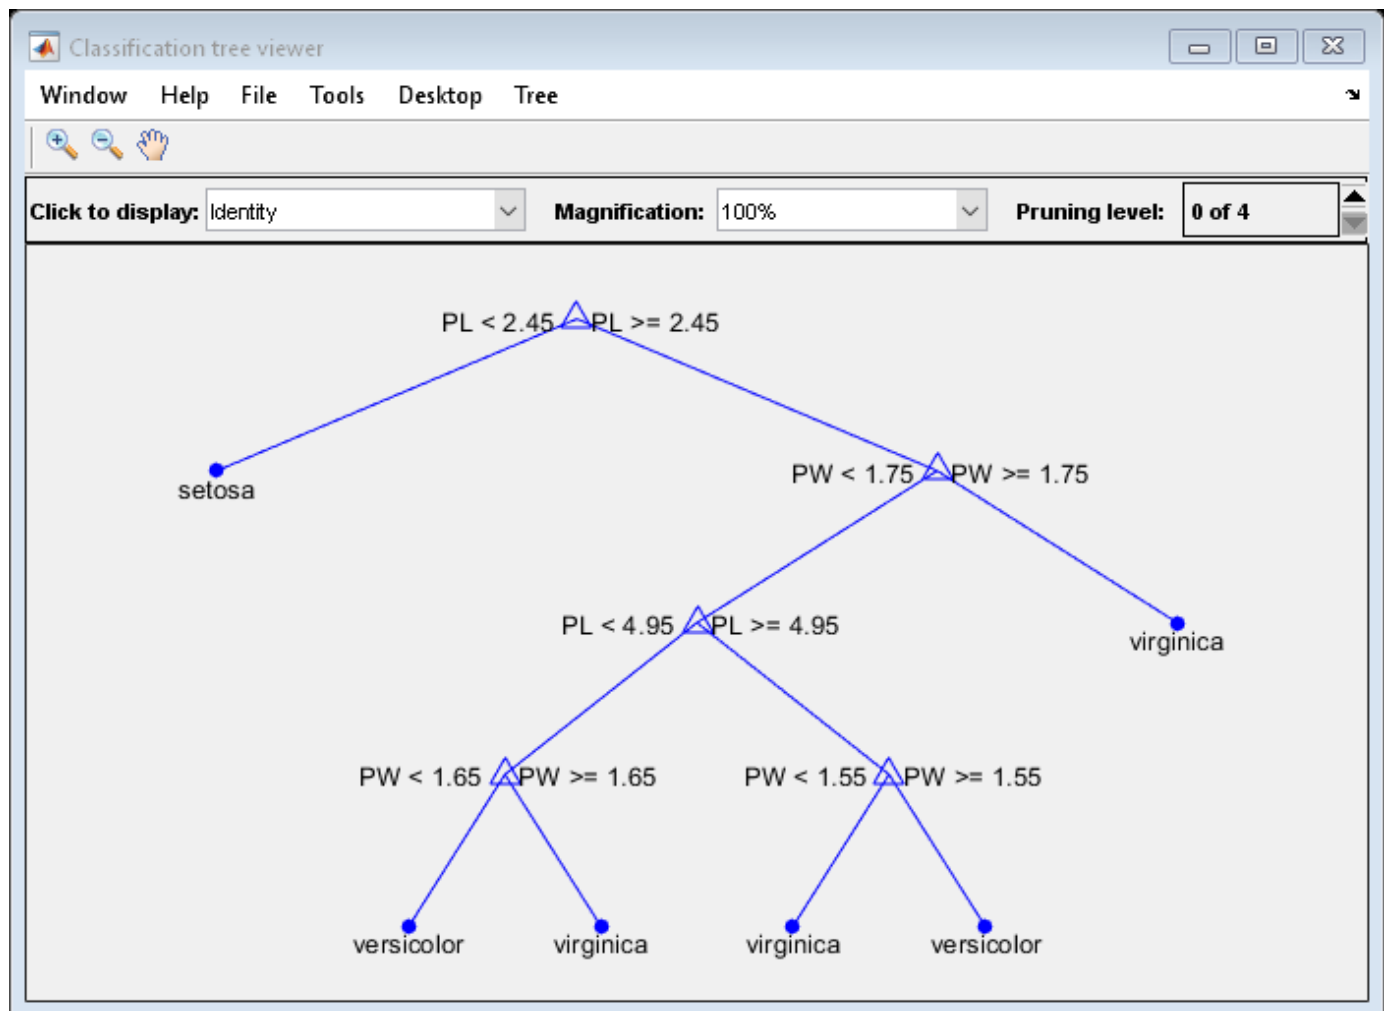

A classification tree.

Examples

Prune and Display a Classification Tree

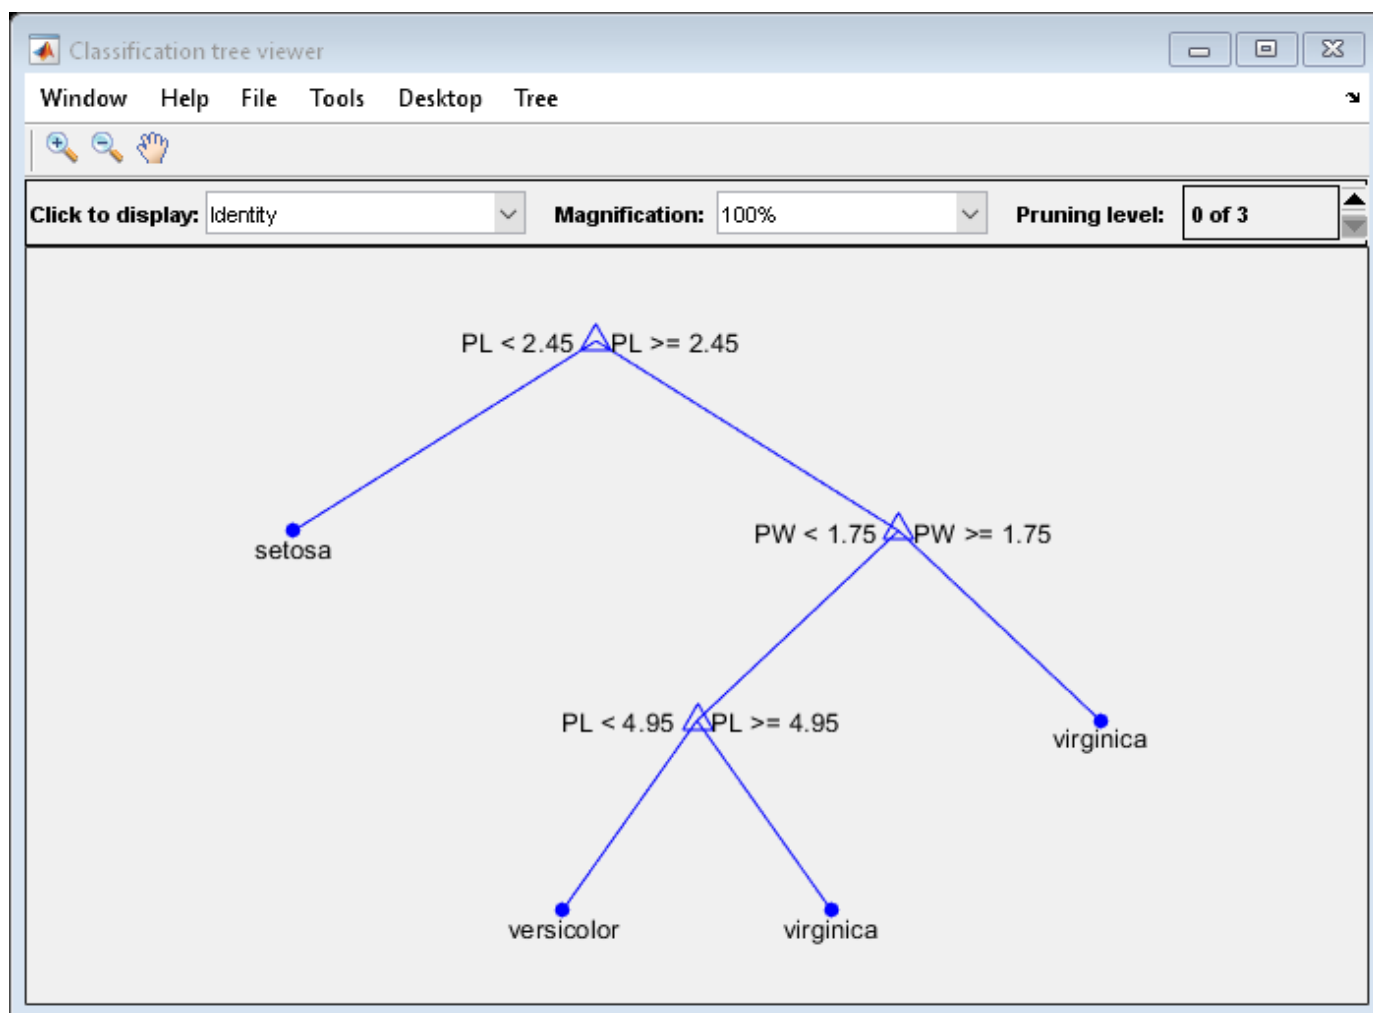

Construct and display a full classification tree for Fisher's iris data.

```
load fisheriris;
varnames = {'SL','SW','PL','PW'};
t1 = fitctree(meas,species,'MinParentSize',5,'PredictorNames',varnames);
view(t1,'Mode','graph');
```

Construct and display the next largest tree from the optimal pruning sequence.

```
t2 = prune(t1,'Level',1);
view(t2,'Mode','graph');
```

Tips

- `tree1 = prune(tree)` returns the decision tree `tree1` that is the full, unpruned `tree`, but with optimal pruning information added. This is useful only if you created `tree` by pruning another tree, or by using the `fitctree` function with pruning set `'off'`. If you plan to prune a tree multiple times along the optimal pruning sequence, it is more efficient to create the optimal pruning sequence first.

See Also

`fitctree`

prune

Class: RegressionTree

Produce sequence of regression subtrees by pruning

Syntax

```
tree1 = prune(tree)
tree1 = prune(tree,Name,Value)
```

Description

`tree1 = prune(tree)` creates a copy of the regression tree `tree` with its optimal pruning sequence filled in.

`tree1 = prune(tree,Name,Value)` creates a pruned tree with additional options specified by one `Name,Value` pair argument. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

tree

A regression tree created with `fitrtree`.

Name-Value Pair Arguments

Optional comma-separated pair of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`'`). You can specify only one name-value pair argument.

Alpha

A numeric scalar from 0 (no pruning) to 1 (prune to one node). Prunes to minimize the sum of (`Alpha` times the number of leaf nodes) and a cost (mean squared error).

Level

A numeric scalar from 0 (no pruning) to the largest pruning level of this tree `max(tree.PruneList)`. `prune` returns the tree pruned to this level.

Nodes

A numeric vector with elements from 1 to `tree.NumNodes`. Any `tree` branch nodes listed in `Nodes` become leaf nodes in `tree1`, unless their parent nodes are also pruned.

Output Arguments

tree1

A regression tree.

Examples

Prune Regression Tree

Load the `carsmall` data set. Consider Horsepower and Weight as predictor variables.

```
load carsmall;  
X = [Weight Horsepower];  
varNames = {'Weight' 'Horsepower'};
```

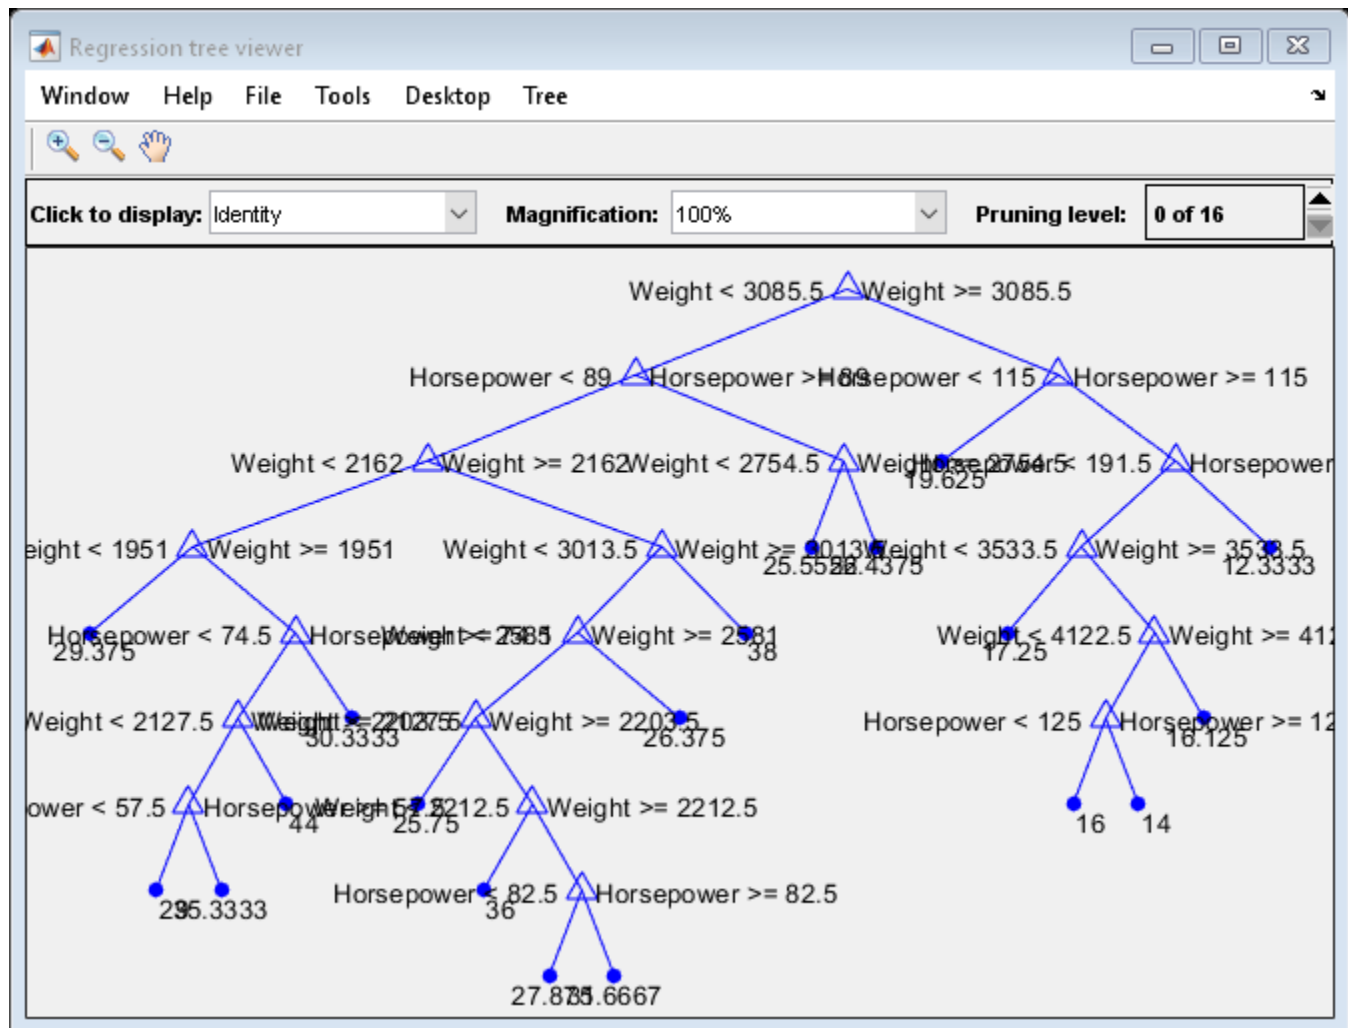

Grow a regression tree using the entire data set. View the tree.

```
Mdl = fitrtree(X,MPG,'PredictorNames',varNames)
```

```
Mdl =  
  RegressionTree  
      PredictorNames: {'Weight' 'Horsepower'}  
      ResponseName: 'Y'  
      CategoricalPredictors: []  
      ResponseTransform: 'none'  
      NumObservations: 94
```

Properties, Methods

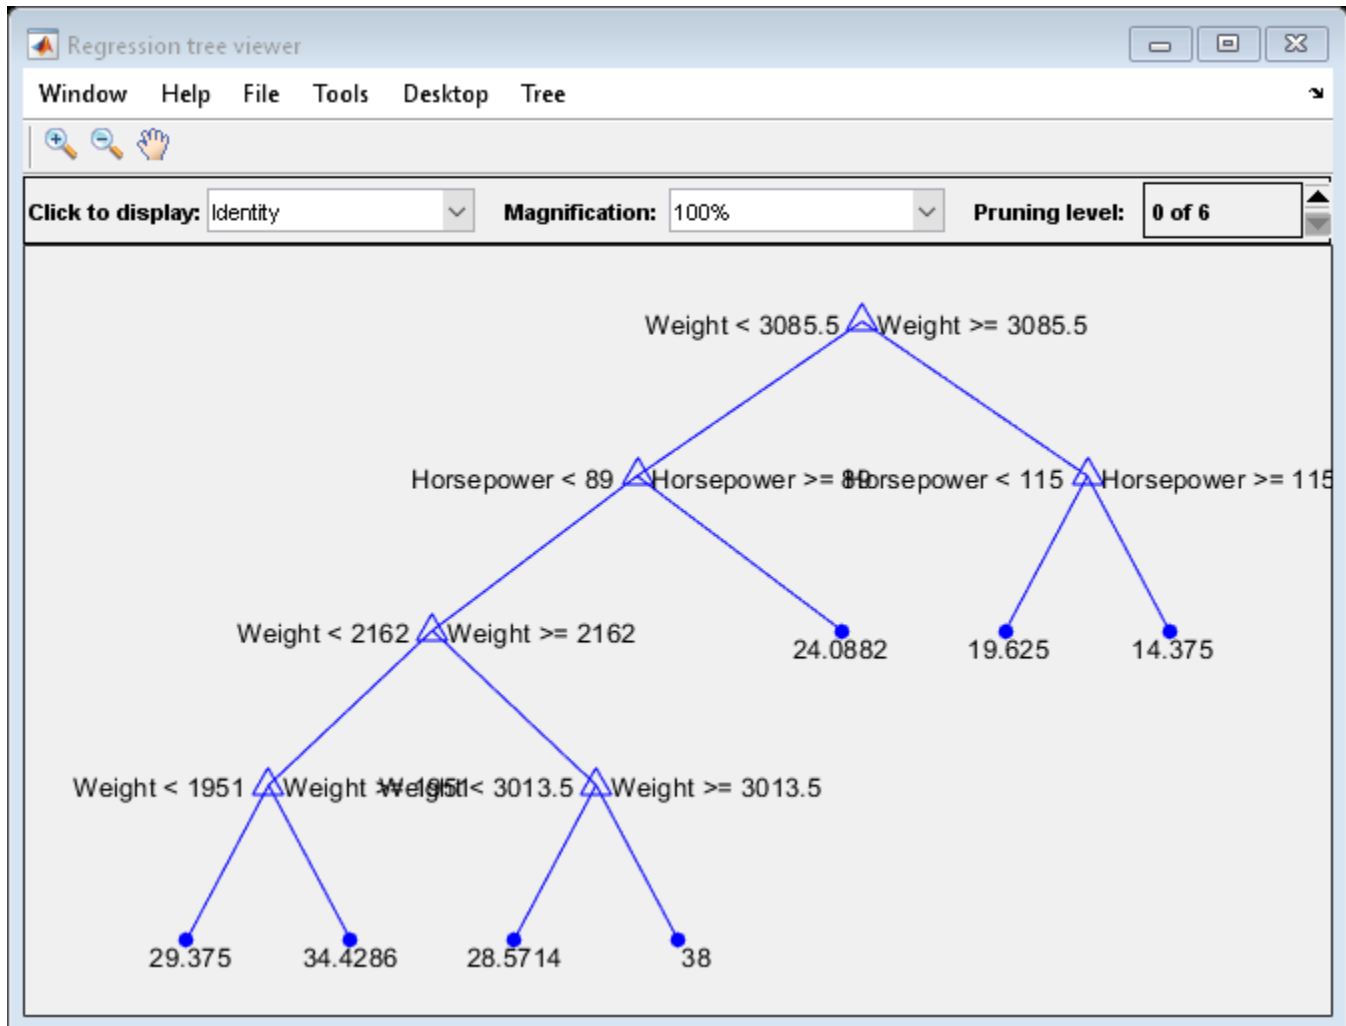

```
view(Mdl,'Mode','graph');
```

The regression tree has 16 pruning levels.

Prune the regression tree to pruning-level 10. View the pruned tree.

```
MdlPruned = prune(Mdl, 'Level', 10);
view(MdlPruned, 'Mode', 'graph');
```

The pruned tree has six pruning levels.

Alternatively, you can use the pruning-level field in the Regression tree viewer to prune the tree.

Tips

- `tree1 = prune(tree)` returns the decision tree `tree1` that is the full, unpruned `tree`, but with optimal pruning information added. This is useful only if you created `tree` by pruning another tree, or by using `fitrtree` with pruning set 'off'. If you plan to prune a tree multiple times along the optimal pruning sequence, it is more efficient to create the optimal pruning sequence first.

`fitrtree`

qrand

Class: qrandstream

Generate quasi-random points from stream

Syntax

```
x = qrand(q)
X = qrand(q,n)
```

Description

`x = qrand(q)` returns the next value x in the quasi-random number stream q of the `qrandstream` on page 32-4386 class. x is a 1-by- d vector, where d is the dimension of the stream. The command sets $q.State$ to the index in the underlying point set of the next value to be returned.

`X = qrand(q,n)` returns the next n values X in an n -by- d matrix.

Objects q of the `qrandstream` class encapsulate properties of a specified quasi-random number stream. Values of the stream are not generated and stored in memory until q is accessed using `qrand`.

Examples

Use `qrandstream` to construct a 3-D Halton stream, based on a point set that skips the first 1000 values and then retains every 101st point:

```
q = qrandstream('halton',3,'Skip',1e3,'Leap',1e2)
q =
    Halton quasi-random stream in 3 dimensions
    Point set properties:
        Skip : 1000
        Leap : 100
    ScrambleMethod : none
```

```
nextIdx = q.State
nextIdx =
    1
```

Use `qrand` to generate two samples of size four:

```
X1 = qrand(q,4)
X1 =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166
nextIdx = q.State
nextIdx =
    5
```

```
X2 = qrand(q,4)
```

```
X2 =
    0.2446    0.0238    0.8102
    0.5298    0.7540    0.0438
    0.3843    0.5112    0.2758
    0.8335    0.2245    0.4694
nextIdx = q.State
nextIdx =
     9
```

Use `reset` to reset the stream, then generate another sample:

```
reset(q)
nextIdx = q.State
nextIdx =
     1
```

```
X = grand(q,4)
X =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166
```

grandstream

Class: grandstream

Construct quasi-random number stream

Syntax

```
q = grandstream(type,d)
q = grandstream(type,d,prop1,val1,prop2,val2,...)
q = grandstream(p)
```

Description

`q = grandstream(type,d)` constructs a d -dimensional quasi-random number stream `q` of the grandstream on page 32-4386 class, of type specified by `type`. `type` is either 'halton' or 'sobol', and `q` is based on a point set from either the `haltonset` class or `sobolset` class, respectively, with default property settings.

`q = grandstream(type,d,prop1,val1,prop2,val2,...)` specifies property name/value pairs for the point set on which the stream is based. Applicable properties depend on `type`.

`q = grandstream(p)` constructs a stream based on the specified point set `p`. `p` must be a point set from either the `haltonset` class or `sobolset` class.

Examples

Construct a 3-D Halton stream, based on a point set that skips the first 1000 values and then retains every 101st point:

```
q = grandstream('halton',3,'Skip',1e3,'Leap',1e2)
q =
    Halton quasi-random stream in 3 dimensions
    Point set properties:
        Skip : 1000
        Leap : 100
        ScrambleMethod : none

nextIdx = q.State
nextIdx =
    1
```

Use `qrand` to generate two samples of size four:

```
X1 = qrand(q,4)
X1 =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166

nextIdx = q.State
nextIdx =
```

```
5
X2 = qrand(q,4)
X2 =
    0.2446    0.0238    0.8102
    0.5298    0.7540    0.0438
    0.3843    0.5112    0.2758
    0.8335    0.2245    0.4694
nextIdx = q.State
nextIdx =
    9
```

Use `reset` to reset the stream, and then generate another sample:

```
reset(q)
nextIdx = q.State
nextIdx =
    1

X = qrand(q,4)
X =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166
```

Introduced in R2008a

qqplot

Quantile-quantile plot

Syntax

```
qqplot(x)
qqplot(x,pd)

qqplot(x,y)

qqplot( ____,pvec)

h = qqplot( ____)
```

Description

`qqplot(x)` displays a quantile-quantile plot of the quantiles of the sample data `x` versus the theoretical quantile values from a normal distribution. If the distribution of `x` is normal, then the data plot appears linear.

`qqplot` plots each data point in `x` using plus sign ('+') markers and draws two reference lines that represent the theoretical distribution. A solid reference line connects the first and third quartiles of the data, and a dashed reference line extends the solid line to the ends of the data.

`qqplot(x,pd)` displays a quantile-quantile plot of the quantiles of the sample data `x` versus the theoretical quantiles of the distribution specified by the probability distribution object `pd`. If the distribution of `x` is the same as the distribution specified by `pd`, then the plot appears linear.

`qqplot(x,y)` displays a quantile-quantile plot of the quantiles of the sample data `x` versus the quantiles of the sample data `y`. If the samples come from the same distribution, then the plot appears linear.

`qqplot(____,pvec)` displays a quantile-quantile plot with the quantiles specified in the vector `pvec`, using any of the previous syntaxes.

`h = qqplot(____)` returns the handles (`h`) to the lines in the quantile-quantile plot.

Examples

Quantile-Quantile Plot for Normal Distribution

Use a quantile-quantile plot to determine whether gas prices in Massachusetts follow a normal distribution.

Load the sample data.

```
load gas
```

The sample data in `price1` and `price2` represent gasoline prices at 20 different gas stations in Massachusetts. The samples were collected during two different months.

Create a quantile-quantile plot to determine if the gas prices in `price1` follow a normal distribution.

```
figure
qqplot(price1)
```

The plot produces an approximately straight line, suggesting that the gas prices follow a normal distribution.

Quantile-Quantile Plot With Two Samples

Use a quantile-quantile plot to determine whether two sets of sample data come from the same distribution.

Load the sample data.

```
load gas
```

The sample data in `price1` and `price2` represent gasoline prices at 20 different gas stations in Massachusetts. The samples were collected during two different months.

Create a quantile-quantile plot using both sets of sample data, to assess whether prices at different times have the same distribution.

```
qqplot(price1,price2);
```

The plot produces an approximately straight line, suggesting that the two sets of sample data have the same distribution.

Quantile-Quantile Plot for Weibull Distribution

Use a quantile-quantile plot to determine whether sample data comes from a Weibull distribution.

Load the sample data.

```
load lightbulb
```

The first column of the data has the lifetime (in hours) of two types of light bulbs. The second column has information about the type of light bulb. 1 indicates fluorescent bulbs whereas 0 indicates the incandescent bulbs. The third column has censoring information. 1 indicates censored data, and 0 indicates the exact failure time. This is simulated data.

Remove the censored data.

```
lightbulb = [lightbulb(lightbulb(:,3)==0,1), ...
             lightbulb(lightbulb(:,3)==0,2)];
```

Create a variable for each light bulb type. Include only uncensored data.

```
fluo = [lightbulb(lightbulb(:,2)==0,1)];
insc = [lightbulb(lightbulb(:,2)==1,1)];
```

Create a Weibull probability distribution object using the default parameters of $A = 1$ and $B = 1$.

```
pd = makedist('Weibull');
```

Create a q-q plot to determine whether the lifetime of fluorescent bulbs has a Weibull distribution.

```
figure
qqplot(fluo,pd)
```

The plot is not a straight line, suggesting that the lifetime data for fluorescent bulbs does not follow a Weibull distribution.

Input Arguments

x — Sample data

numeric vector | numeric matrix

Sample data, specified as a numeric vector or numeric matrix. If x is a matrix, then `qqplot` displays a separate line for each column.

`qqplot` displays the sample data using the plot symbol '+'. A line joining the first and third quartiles of each distribution is superimposed on the plot. The line represents a robust linear fit of the order statistics for the data in x . This line is extrapolated out to the minimum and maximum values in x to help evaluate the linearity of the data.

Data Types: single | double

y — Second set of sample data

numeric vector | numeric matrix

Second set of sample data, specified as a numeric vector or numeric matrix. `x` and `y` do not need to be the same length. However, if `x` and `y` are matrices, they must contain the same number of columns. If `x` and `y` are matrices, then `qqplot` displays a separate line for each pair of columns.

`qqplot` selects the quantiles to plot based on the size of the smaller data set.

Data Types: `single` | `double`

pd — Hypothesized probability distribution

probability distribution object

Hypothesized probability distribution, specified as a probability distribution object. `qqplot` plots the quantiles of the input data `x` versus the theoretical quartiles of the distribution specified by `pd`.

Create a probability distribution object with specified parameter values using `makedist`, or fit a probability distribution object to data using `fitdist`.

pvec — Quantiles for plot

numeric value in the range [0,100] | vector of numeric values in the range [0,100]

Quantiles for plot, specified as a numeric value, or vector of numeric values, in the range [0,100].

For a single set of sample data (`x`), `qqplot` uses the quantiles in `x`. For two sets of sample data (`x` and `y`), `qqplot` uses the quantiles in the smaller of the two data sets.

Data Types: `single` | `double`

Output Arguments**h — Graphics handles for line objects**

vector of Line graphics handles

Graphics handles for line objects, returned as a vector of `Line` graphics handles. Graphics handles are unique identifiers that you can use to query and modify the properties of a specific line on the plot. For each column of `x`, `qqplot` returns three handles:

- The line representing the data points. `qqplot` represents each data point in `x` using plus sign ('+') markers.
- The line joining the first and third quartiles of each column of `x`, represented as a solid line.
- The extrapolation of the quartile line, extended to the minimum and maximum values of `x`, represented as a dashed line.

To view and set properties of line objects, use dot notation. For information on using dot notation, see "Access Property Values" (MATLAB). For information on the `Line` properties that you can set, see `Primitive Line`.

More About

Quantile-Quantile Plot

A *quantile-quantile plot* (also called a *q-q plot*) visually assesses whether sample data comes from a specified distribution. Alternatively, a q-q plot assesses whether two sets of sample data come from the same distribution.

A q-q plot orders the sample data values from smallest to largest, then plots these values against the expected value for the specified distribution at each quantile in the sample data. The quantile values of the input sample appear along the y -axis, and the theoretical values of the specified distribution at the same quantiles appear along the x -axis. If the resulting plot is linear, then the sample data likely comes from the specified distribution.

The q-q plot selects quantiles based on the number of values in the sample data. If the sample data contains n values, then the plot uses n quantiles. Plot the i th ordered value (also called the i th *order statistic*) against the $\frac{i - 0.5}{n}$ th quantile of the specified distribution.

A q-q plot can also assess whether two sets of sample data have the same distribution, even if you do not know the underlying distribution. The quantile values for the first data set appear on the x -axis and the corresponding quantile values for the second data set appear on the y -axis. Since q-q plots rely on quantiles, the number of data points in the two samples does not need to be equal. If the sample sizes are unequal, the q-q plot chooses the quantiles based on the smaller data set. If the resulting plot is linear, then the two sets of sample data likely come from the same distribution.

Introduced before R2006a

quantile

Quantiles of a data set

Syntax

```
Y = quantile(X,p)
```

```
Y = quantile(X,N)
```

```
Y = quantile( ____, 'all' )
```

```
Y = quantile( ____, dim)
```

```
Y = quantile( ____, vecdim)
```

```
Y = quantile( ____, 'Method', method)
```

Description

`Y = quantile(X,p)` returns quantiles of the elements in data vector or array `X` for the cumulative probability or probabilities `p` in the interval `[0,1]`.

- If `X` is a vector, then `Y` is a scalar or a vector having the same length as `p`.
- If `X` is a matrix, then `Y` is a row vector or a matrix where the number of rows of `Y` is equal to the length of `p`.
- For multidimensional arrays on page 32-4408, `quantile` operates along the first nonsingleton dimension on page 32-4408 of `X`.

`Y = quantile(X,N)` returns quantiles for `N` evenly spaced cumulative probabilities ($1/(N + 1)$, $2/(N + 1)$, ..., $N/(N + 1)$) for integer $N > 1$.

- If `X` is a vector, then `Y` is a scalar or a vector with length `N`.
- If `X` is a matrix, then `Y` is a matrix where the number of rows of `Y` is equal to `N`.
- For multidimensional arrays on page 32-4408, `quantile` operates along the first nonsingleton dimension on page 32-4408 of `X`.

`Y = quantile(____, 'all')` returns quantiles of all the elements of `X` for either of the first two syntaxes.

`Y = quantile(____, dim)` returns quantiles along the operating dimension `dim` for either of the first two syntaxes.

`Y = quantile(____, vecdim)` returns quantiles over the dimensions specified in the vector `vecdim` for either of the first two syntaxes. For example, if `X` is a matrix, then `quantile(X,0.5, [1 2])` returns the 0.5 quantile of all the elements of `X` because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.

`Y = quantile(____, 'Method', method)` returns either exact or approximate quantiles based on the value of `method`, using any of the input argument combinations in the previous syntaxes.

Examples

Quantiles for Given Probabilities

Calculate the quantiles of a data set for specified probabilities.

Generate a data set of size 10.

```
rng('default'); % for reproducibility
x = normrnd(0,1,1,10)
```

```
x = 1×10
```

```
    0.5377    1.8339   -2.2588    0.8622    0.3188   -1.3077   -0.4336    0.3426    3.5784    2.7
```

Calculate the 0.3 quantile.

```
y = quantile(x,0.30)
```

```
y = -0.0574
```

Calculate the quantiles for the cumulative probabilities 0.025, 0.25, 0.5, 0.75, and 0.975.

```
y = quantile(x,[0.025 0.25 0.50 0.75 0.975])
```

```
y = 1×5
```

```
   -2.2588   -0.4336    0.4401    1.8339    3.5784
```

Quantiles for N Evenly Spaced Cumulative Probabilities

Calculate the quantiles of a data set for a given number of quantiles.

Generate a data set of size 10.

```
rng('default'); % for reproducibility
x = normrnd(0,1,1,10)
```

```
x = 1×10
```

```
    0.5377    1.8339   -2.2588    0.8622    0.3188   -1.3077   -0.4336    0.3426    3.5784    2.7
```

Calculate four evenly spaced quantiles.

```
y = quantile(x,4)
```

```
y = 1×4
```

```
   -0.8706    0.3307    0.6999    2.3017
```

Using `y = quantile(x,[0.2,0.4,0.6,0.8])` is another way to return the four evenly spaced quantiles.

Quantiles of a Matrix for Given Probabilities

Calculate the quantiles along the columns and rows of a data matrix for specified probabilities.

Generate a 4-by-6 data matrix.

```
rng default % For reproducibility
X = normrnd(0,1,4,6)

X = 4x6

    0.5377    0.3188    3.5784    0.7254   -0.1241    0.6715
    1.8339   -1.3077    2.7694   -0.0631    1.4897   -1.2075
   -2.2588   -0.4336   -1.3499    0.7147    1.4090    0.7172
    0.8622    0.3426    3.0349   -0.2050    1.4172    1.6302
```

Calculate the 0.3 quantile for each column of X (dim = 1).

```
y = quantile(X,0.3,1)

y = 1x6

   -0.3013   -0.6958    1.5336   -0.1056    0.9491    0.1078
```

`quantile` returns a row vector `y` when calculating one quantile for each column of a matrix. For example, `-0.3013` is the 0.3 quantile of the first column of X with elements (0.5377, 1.8339, -2.2588, 0.8622). Because the default value of `dim` is 1, you can return the same result with `y = quantile(X,0.3)`.

Calculate the 0.3 quantile for each row of X (dim = 2).

```
y = quantile(X,0.3,2)

y = 4x1

    0.3844
   -0.8642
   -1.0750
    0.4985
```

`quantile` returns a column vector `y` when calculating one quantile for each row of a matrix. For example `0.3844` is the 0.3 quantile of the first row of X with elements (0.5377, 0.3188, 3.5784, 0.7254, -0.1241, 0.6715).

Quantiles of a Matrix for Given Number of Quantiles

Calculate the *N* evenly spaced quantiles along the columns and rows of a data matrix.

Generate a 6-by-10 data matrix.

```
rng('default'); % for reproducibility
X = unidrnd(10,6,7)
```

```
X = 6×7
```

```

     9     3    10     8     7     8     7
    10     6     5    10     8     1     4
     2    10     9     7     8     3    10
    10    10     2     1     4     1     1
     7     2     5     9     7     1     5
     1    10    10    10     2     9     4
```

Calculate three evenly spaced quantiles for each column of X (dim = 1).

```
y = quantile(X,3,1)
```

```
y = 3×7
```

```

    2.0000    3.0000    5.0000    7.0000    4.0000    1.0000    4.0000
    8.0000    8.0000    7.0000    8.5000    7.0000    2.0000    4.5000
   10.0000   10.0000   10.0000   10.0000    8.0000    8.0000    7.0000
```

Each column of matrix y corresponds to the three evenly spaced quantiles of each column of matrix X. For example, the first column of y with elements (2, 8, 10) has the quantiles for the first column of X with elements (9, 10, 2, 10, 7, 1). `y = quantile(X,3)` returns the same answer because the default value of dim is 1.

Calculate three evenly spaced quantiles for each row of X (dim = 2).

```
y = quantile(X,3,2)
```

```
y = 6×3
```

```

    7.0000    8.0000    8.7500
    4.2500    6.0000    9.5000
    4.0000    8.0000    9.7500
    1.0000    2.0000    8.5000
    2.7500    5.0000    7.0000
    2.5000    9.0000   10.0000
```

Each row of matrix y corresponds to the three evenly spaced quantiles of each row of matrix X. For example, the first row of y with elements (7, 8, 8.75) has the quantiles for the first row of X with elements (9, 3, 10, 8, 7, 8, 7).

Quantiles of Multidimensional Array for Given Probabilities

Calculate the quantiles of a multidimensional array for specified probabilities by using the 'all' and vecdim input arguments.

Create a 3-by-5-by-2 array X. Specify the vector of probabilities p.

```
X = reshape(1:30,[3 5 2])
```

```
X =
X(:,:,1) =
```

```

1     4     7     10    13
2     5     8     11    14
3     6     9     12    15

```

```
X(:,:,2) =
```

```

16    19    22    25    28
17    20    23    26    29
18    21    24    27    30

```

```
p = [0.25 0.75];
```

Calculate the 0.25 and 0.75 quantiles of all the elements in X.

```
Yall = quantile(X,p,'all')
```

```
Yall = 2×1
```

```

8
23

```

Yall(1) is the 0.25 quantile of X, and Yall(2) is the 0.75 quantile of X.

Calculate the 0.25 and 0.75 quantiles for each page of X by specifying dimensions 1 and 2 as the operating dimensions.

```
Ypage = quantile(X,p,[1 2])
```

```
Ypage =
Ypage(:,:,1) =
```

```

4.2500
11.7500

```

```
Ypage(:,:,2) =
```

```

19.2500
26.7500

```

For example, Ypage(1,1,1) is the 0.25 quantile of the first page of X, and Ypage(2,1,1) is the 0.75 quantile of the first page of X.

Calculate the 0.25 and 0.75 quantiles of the elements in each X(i, :, :) slice by specifying dimensions 2 and 3 as the operating dimensions.

```
Yrow = quantile(X,p,[2 3])
```

```
Yrow = 3×2
```

```

7     22
8     23
9     24

```

For example, `Yrow(3,1)` is the 0.25 quantile of the elements in `X(3, :, :)`, and `Yrow(3,2)` is the 0.75 quantile of the elements in `X(3, :, :)`.

Median and Quartiles for Even Number of Data Elements

Find median and quartiles of a vector, `x`, with even number of elements.

Enter the data.

```
x = [2 5 6 10 11 13]
```

```
x = 1×6
```

```
     2     5     6    10    11    13
```

Calculate the median of `x`.

```
y = quantile(x,0.50)
```

```
y = 8
```

Calculate the quartiles of `x`.

```
y = quantile(x,[0.25, 0.5, 0.75])
```

```
y = 1×3
```

```
     5     8    11
```

Using `y = quantile(x,3)` is another way to compute the quartiles of `x`.

These results might be different than the textbook definitions because `quantile` uses “Linear Interpolation” on page 32-4408 to find the median and quartiles.

Median and Quartiles for Odd Number of Data Elements

Find median and quartiles of a vector, `x`, with odd number of elements.

Enter the data.

```
x = [2 4 6 8 10 12 14]
```

```
x = 1×7
```

```
     2     4     6     8    10    12    14
```

Find the median of `x`.

```
y = quantile(x,0.50)
```

```
y = 8
```

Find the quartiles of x .

```
y = quantile(x,[0.25, 0.5, 0.75])
```

```
y = 1×3
```

```
    4.5000    8.0000   11.5000
```

Using `y = quantile(x,3)` is another way to compute the quartiles of x .

These results might be different than the textbook definitions because `quantile` uses “Linear Interpolation” on page 32-4408 to find the median and quartiles.

Quantiles of Tall Vector for Given Probability

Calculate exact and approximate quantiles of a tall column vector for a given probability.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

Create a datastore for the `airlinesmall` data set. Treat 'NA' values as missing data so that `datastore` replaces them with NaN values. Specify to work with the `ArrTime` variable.

```
ds = datastore('airlinesmall.csv','TreatAsMissing','NA',...
    'SelectedVariableNames','ArrTime');
```

Create a tall table on top of the datastore, and extract the data from the tall table into a tall vector.

```
t = tall(ds) % Tall table
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 12).
```

```
t =
```

```
Mx1 tall table
```

```
ArrTime
```

```

    1547
    1052
    1134
    :
    :
```

Calculate the exact quantile of x for $p = 0.5$. Because X is a tall column vector and p is a scalar, `quantile` returns the exact quantile value by default.

```
p = 0.5; % Cumulative probability
yExact = quantile(x,p)
```

```
yExact =
    tall double
    ?
```

Calculate the approximate quantile of x for $p = 0.5$. Specify `'Method','approximate'` to use an approximation algorithm based on “T-Digest” on page 32-4409 for computing the quantiles.

```
yApprox = quantile(x,p,'Method','approximate')
```

```
yApprox =
    MxNx... tall double array
    ? ? ? ...
    ? ? ? ...
    ? ? ? ...
    : : :
    : : :
```

Evaluate the tall arrays and bring the results into memory by using `gather`.

```
[yExact,yApprox] = gather(yExact,yApprox)
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 4: Completed in 16 sec
- Pass 2 of 4: Completed in 3.7 sec
- Pass 3 of 4: Completed in 5.1 sec
- Pass 4 of 4: Completed in 2.5 sec
Evaluation completed in 39 sec
```

```
yExact = 1522
```

```
yApprox = 1.5220e+03
```

The values of the approximate quantile and the exact quantile are the same to the four digits shown.

Quantiles of Tall Matrix Along Different Dimensions

Calculate exact and approximate quantiles of a tall matrix for specified cumulative probabilities along different dimensions.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

Create a tall matrix `X` containing a subset of variables from the `airlinesmall` data set. See “Quantiles of Tall Vector for Given Probability” on page 32-4401 for details about the steps to extract data from a tall array.

```
varnames = {'ArrDelay','ArrTime','DepTime','ActualElapsedTime'}; % Subset of variables in the da
ds = datastore('airlinesmall.csv','TreatAsMissing','NA',...
    'SelectedVariableNames',varnames); % Datastore
t = tall(ds); % Tall table
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 12).
```

```
X = t{:,varnames} % Tall matrix
```

```
X =
```

```
Mx4 tall double matrix
```

```
      8      735      642      53
      8      1124     1021     63
     21      2218     2055     83
     13      1431     1332     59
      4       746      629     77
     59      1547     1446     61
      3      1052      928     84
     11      1134      859    155
      :       :       :       :
      :       :       :       :
```

When operating along a dimension that is not 1, the `quantile` function calculates the exact quantiles only, so that it can perform the computation efficiently using a sorting-based algorithm (see “Algorithms” on page 32-4410) instead of an approximation algorithm based on “T-Digest” on page 32-4409.

Calculate the exact quantiles of `X` along the second dimension for the cumulative probabilities 0.25, 0.5, and 0.75.

```
p = [0.25 0.50 0.75]; % Vector of cumulative probabilities
Yexact = quantile(X,p,2)
```

```
Yexact =
```

```
MxNx... tall double array
```

```
 ? ? ? ...
 ? ? ? ...
```

```

?   ?   ?   ...
:   :   :
:   :   :

```

When the function operates along the first dimension and p is a vector of cumulative probabilities, you must use the approximation algorithm based on `t-digest` to compute the quantiles. Using the sorting-based algorithm to find the quantiles along the first dimension of a tall array is computationally intensive.

Calculate the approximate quantiles of X along the first dimension for the cumulative probabilities 0.25, 0.5, and 0.75. Because the default dimension is 1, you do not need to specify a value for `dim`.

```
Yapprox = quantile(X,p,'Method','approximate')
```

```
Yapprox =
```

```
MxNx... tall double array
```

```

?   ?   ?   ...
?   ?   ?   ...
?   ?   ?   ...
:   :   :
:   :   :

```

Evaluate the tall arrays and bring the results into memory by using `gather`.

```
[Yexact,Yapprox] = gather(Yexact,Yapprox);
```

```
Evaluating tall expression using the Parallel Pool 'local':
```

```
- Pass 1 of 1: Completed in 13 sec
```

```
Evaluation completed in 18 sec
```

Show the first five rows of the exact quantiles of X (along the second dimension) for the cumulative probabilities 0.25, 0.5, and 0.75.

```
Yexact(1:5,:)
```

```
ans = 5x3
```

```
103 ×
```

```

0.0305    0.3475    0.6885
0.0355    0.5420    1.0725
0.0520    1.0690    2.1365
0.0360    0.6955    1.3815
0.0405    0.3530    0.6875

```

Each row of the matrix `Yexact` contains the three quantiles of the corresponding row in X . For example, 30.5, 347.5, and 688.5 are the 0.25, 0.5, and 0.75 quantiles, respectively, of the first row in X .

Show the approximate quantiles of X (along the first dimension) for the cumulative probabilities 0.25, 0.5, and 0.75.

```
Yapprox
```

```
Yapprox = 3x4
```

```
103 ×
```

```

-0.0070    1.1149    0.9322    0.0700
         0    1.5220    1.3350    0.1020
 0.0110    1.9180    1.7400    0.1510

```

Each column of the matrix `Yapprox` corresponds to the three quantiles for each column of the matrix `X`. For example, the first column of `Yapprox` with elements `(-7, 0, 11)` contains the quantiles for the first column of `X`.

Quantiles of Tall Matrix for N Evenly Spaced Probabilities

Calculate exact and approximate quantiles along different dimensions of a tall matrix for `N` evenly spaced cumulative probabilities.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

Create a tall matrix `X` containing a subset of variables from the `airlinesmall` data set. See “Quantiles of Tall Vector for Given Probability” on page 32-4401 for details about the steps to extract data from a tall array.

```

varnames = {'ArrDelay', 'ArrTime', 'DepTime', 'ActualElapsedTime'}; % Subset of variables in the da
ds = datastore('airlinesmall.csv', 'TreatAsMissing', 'NA', ...
    'SelectedVariableNames', varnames); % Datastore
t = tall(ds); % Tall table
X = t{:, varnames}

```

`X =`

Mx4 tall double matrix

```

      8      735      642      53
      8     1124     1021      63
     21     2218     2055      83
     13     1431     1332      59
      4      746      629      77
     59     1547     1446      61
      3     1052      928      84
     11     1134      859     155
      :
      :
      :

```

To find evenly spaced quantiles along the first dimension, you must use the approximation algorithm based on “T-Digest” on page 32-4409. Using the sorting-based algorithm (see “Algorithms” on page 32-4410) to find quantiles along the first dimension of a tall array is computationally intensive.

Calculate three evenly spaced quantiles along the first dimension of `X`. Because the default dimension is 1, you do not need to specify a value for `dim`. Specify `'Method', 'approximate'` to use the approximation algorithm.

```

N = 3; % Number of quantiles
Yapprox = quantile(X, N, 'Method', 'approximate')

```

Yapprox =

MxNx... tall double array

```
? ? ? ...
? ? ? ...
? ? ? ...
: : :
: : :
```

To find evenly spaced quantiles along any other dimension (`dim` is not 1), `quantile` calculates the exact quantiles only, so that it can perform the computation efficiently by using the sorting-based algorithm.

Calculate three evenly spaced quantiles along the second dimension of `X`. Because `dim` is not 1, `quantile` returns the exact quantiles by default.

Yexact = `quantile(X,N,2)`

Yexact =

MxNx... tall double array

```
? ? ? ...
? ? ? ...
? ? ? ...
: : :
: : :
```

Evaluate the tall arrays and bring the results into memory by using `gather`.

`[Yapprox,Yexact] = gather(Yapprox,Yexact);`

Evaluating tall expression using the Local MATLAB Session:

- Pass 1 of 1: Completed in 8.7 sec

Evaluation completed in 11 sec

Show the approximate quantiles of `X` (along the first dimension) for the three evenly spaced cumulative probabilities.

Yapprox

Yapprox = 3×4
10³ ×

```
-0.0070    1.1149    0.9321    0.0700
         0    1.5220    1.3350    0.1020
 0.0110    1.9180    1.7400    0.1510
```

Each column of the matrix `Yapprox` corresponds to the three evenly spaced quantiles for each column of the matrix `X`. For example, the first column of `Yapprox` with elements `(-7, 0, 11)` contains the quantiles for the first column of `X`.

Show the first five rows of the exact quantiles of `X` (along the second dimension) for the three evenly spaced cumulative probabilities.

`Yexact(1:5,:)`

```
ans = 5×3
103 ×

    0.0305    0.3475    0.6885
    0.0355    0.5420    1.0725
    0.0520    1.0690    2.1365
    0.0360    0.6955    1.3815
    0.0405    0.3530    0.6875
```

Each row of the matrix `Yexact` contains the three evenly spaced quantiles of the corresponding row in `X`. For example, `30.5`, `347.5`, and `688.5` are the 0.25, 0.5, and 0.75 quantiles, respectively, of the first row in `X`.

Input Arguments

X — Input data

vector | array

Input data, specified as a vector or array.

Data Types: double | single

p — Cumulative probabilities

scalar | vector

Cumulative probabilities for which to compute the quantiles, specified as a scalar or vector of scalars from 0 to 1.

Example: 0.3

Example: [0.25, 0.5, 0.75]

Example: (0:0.25:1)

Data Types: double | single

N — Number of quantiles

positive integer

Number of quantiles to compute, specified as a positive integer. `quantile` returns `N` quantiles that divide the data set into evenly distributed `N+1` segments.

Data Types: double | single

dim — Dimension

positive integer

Dimension along which the quantiles of a matrix `X` are requested, specified as a positive integer. For example, for a matrix `X`, when `dim = 1`, `quantile` returns the quantile(s) of the columns of `X`; when `dim = 2`, `quantile` returns the quantile(s) of the rows of `X`. For a multidimensional array `X`, the length of the `dim`th dimension of `Y` is the same as the length of `p`.

Data Types: single | double

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. In the smallest specified operating dimension (that is, dimension `min(vecdim)`), the output `Y` has length equal to the number of quantiles requested (either `N` or `length(p)`). In each of the remaining operating dimensions, `Y` has length 1. The other dimension lengths are the same for `X` and `Y`.

For example, consider a 2-by-3-by-3 array `X` with `p = [0.2 0.4 0.6 0.8]`. In this case, `quantile(X,p,[1 2])` returns an array, where each page of the array contains the 0.2, 0.4, 0.6, and 0.8 quantiles of the elements on the corresponding page of `X`. Because 1 and 2 are the operating dimensions, with `min([1 2]) = 1` and `length(p) = 4`, the output is a 4-by-1-by-3 array.

Data Types: `single` | `double`

method — Method for calculating quantiles

'exact' (default) | 'approximate'

Method for calculating quantiles, specified as 'exact' or 'approximate'. By default, `quantile` returns the exact quantiles by implementing an algorithm on page 32-4410 that uses sorting. You can specify 'method', 'approximate' for `quantile` to return approximate quantiles by implementing an algorithm that uses T-Digest on page 32-4409.

Data Types: `char` | `string`

Output Arguments

Y — Quantiles

scalar | array

Quantiles of a data vector or array, returned as a scalar or array for one or multiple values of cumulative probabilities.

- If `X` is a vector, then `Y` is a scalar or a vector with the same length as the number of quantiles requested (`N` or `length(p)`). `Y(i)` contains the `p(i)` quantile.
- If `X` is an array of dimension `d`, then `Y` is an array with the length of the smallest operating dimension equal to the number of quantiles requested (`N` or `length(p)`).

More About

Multidimensional Array

A *multidimensional array* is an array with more than two dimensions. For example, if `X` is a 1-by-3-by-4 array, then `X` is a 3-D array.

Nonsingleton Dimension

A *nonsingleton dimension* of an array is a dimension whose size is not equal to 1. A *first nonsingleton dimension* of an array is the first dimension that satisfies the nonsingleton condition. For example, if `X` is a 1-by-1-by-2-by-4 array, then the third dimension is the first nonsingleton dimension of `X`.

Linear Interpolation

Linear interpolation uses linear polynomials to find $y_i = f(x_i)$, the values of the underlying function $Y = f(X)$ at the points in the vector or array `x`. Given the data points (x_1, y_1) and (x_2, y_2) , where $y_1 = f(x_1)$ and $y_2 = f(x_2)$, linear interpolation finds $y = f(x)$ for a given `x` between x_1 and x_2 as follows:

$$y = f(x) = y_1 + \frac{(x - x_1)}{(x_2 - x_1)}(y_2 - y_1).$$

Similarly, if the $1.5/n$ quantile is $y_{1.5/n}$ and the $2.5/n$ quantile is $y_{2.5/n}$, then linear interpolation finds the $2.3/n$ quantile $y_{2.3/n}$ as

$$y_{\frac{2.3}{n}} = y_{\frac{1.5}{n}} + \frac{\left(\frac{2.3}{n} - \frac{1.5}{n}\right)}{\left(\frac{2.5}{n} - \frac{1.5}{n}\right)} \left(y_{\frac{2.5}{n}} - y_{\frac{1.5}{n}}\right).$$

T-Digest

T-digest[2] on page 32-4411 is a probabilistic data structure that is a sparse representation of the empirical cumulative distribution function (CDF) of a data set. T-digest is useful for computing approximations of rank-based statistics (such as percentiles and quantiles) from online or distributed data in a way that allows for controllable accuracy, particularly near the tails of the data distribution.

For data that is distributed in different partitions, t-digest computes quantile estimates (and percentile estimates) for each data partition separately, and then combines the estimates while maintaining a constant-memory bound and constant relative accuracy of computation ($q(1 - q)$ for the q th quantile). For these reasons, t-digest is practical for working with tall arrays.

To estimate quantiles of an array that is distributed in different partitions, first build a t-digest in each partition of the data. A t-digest clusters the data in the partition and summarizes each cluster by a centroid value and an accumulated weight that represents the number of samples contributing to the cluster. T-digest uses large clusters (widely spaced centroids) to represent areas of the CDF that are near $q = 0.5$ and uses small clusters (tightly spaced centroids) to represent areas of the CDF that are near $q = 0$ or $q = 1$.

T-digest controls the cluster size by using a scaling function that maps a quantile q to an index k with a compression parameter δ . That is,

$$k(q, \delta) = \delta \cdot \left(\frac{\sin^{-1}(2q - 1)}{\pi} + \frac{1}{2} \right),$$

where the mapping k is monotonic with minimum value $k(0, \delta) = 0$ and maximum value $k(1, \delta) = \delta$. The following figure shows the scaling function for $\delta = 10$.

The scaling function translates the quantile q to the scaling factor k in order to give variable size steps in q . As a result, cluster sizes are unequal (larger around the center quantiles and smaller near $q = 0$ or $q = 1$). The smaller clusters allow for better accuracy near the edges of the data.

To update a t-digest with a new observation that has a weight and location, find the cluster closest to the new observation. Then, add the weight and update the centroid of the cluster based on the weighted average, provided that the updated weight of the cluster does not exceed the size limitation.

You can combine independent t-digests from each partition of the data by taking a union of the t-digests and merging their centroids. To combine t-digests, first sort the clusters from all the independent t-digests in decreasing order of cluster weights. Then, merge neighboring clusters, when they meet the size limitation, to form a new t-digest.

Once you form a t-digest that represents the complete data set, you can estimate the end-points (or boundaries) of each cluster in the t-digest and then use interpolation between the end-points of each cluster to find accurate quantile estimates.

Algorithms

For an n -element vector X , `quantile` computes quantiles by using a sorting-based algorithm as follows:

- 1 The sorted elements in X are taken as the $(0.5/n)$, $(1.5/n)$, ..., $([n - 0.5]/n)$ quantiles. For example:
 - For a data vector of five elements such as $\{6, 3, 2, 10, 1\}$, the sorted elements $\{1, 2, 3, 6, 10\}$ respectively correspond to the 0.1, 0.3, 0.5, 0.7, 0.9 quantiles.

- For a data vector of six elements such as {6, 3, 2, 10, 8, 1}, the sorted elements {1, 2, 3, 6, 8, 10} respectively correspond to the (0.5/6), (1.5/6), (2.5/6), (3.5/6), (4.5/6), (5.5/6) quantiles.
- 2 `quantile` uses “Linear Interpolation” on page 32-4408 to compute quantiles for probabilities between $(0.5/n)$ and $([n - 0.5]/n)$.
 - 3 For the quantiles corresponding to the probabilities outside that range, `quantile` assigns the minimum or maximum values of the elements in `X`.

`quantile` treats NaNs as missing values and removes them.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- `Y = quantile(X,p)` and `Y = quantile(X,N)` return the exact quantiles (using a sorting-based algorithm on page 32-4410) only if `X` is a tall column vector.
- `Y = quantile(__,dim)` returns the exact quantiles only when *one* of these conditions exists:
 - `X` is a tall column vector.
 - `X` is a tall array and `dim` is not 1. For example, `quantile(X,p,2)` returns the exact quantiles along the rows of the tall array `X`.

If `X` is a tall array and `dim` is 1, then you must specify `'Method', 'approximate'` to use an approximation algorithm based on T-Digest on page 32-4409 for computing the quantiles. For example, `quantile(X,p,1,'Method','approximate')` returns the approximate quantiles along the columns of the tall array `X`.

- `Y = quantile(__,vecdim)` returns the exact quantiles only when *one* of these conditions exists:
 - `X` is a tall column vector.
 - `X` is a tall array and `vecdim` does not include 1. For example, if `X` is a 3-by-5-by-2 array, then `quantile(X,p,[2,3])` returns the exact quantiles of the elements in each `X(i, :, :)` slice.
 - `X` is a tall array and `vecdim` includes 1 and all the nonsingleton dimensions on page 32-4408 of `X`. For example, if `X` is a 10-by-1-by-4 array, then `quantile(X,p,[1 3])` returns the exact quantiles of the elements in `X(:,1,:)`.

If `X` is a tall array and `vecdim` includes 1 but does not include all the nonsingleton dimensions of `X`, then you must specify `'Method', 'approximate'` to use the approximation algorithm. For example, if `X` is a 10-by-1-by-4 array, you can use `quantile(X,p,[1 2], 'Method', 'approximate')` to find the approximate quantiles of each page of `X`.

For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The 'all' and `vecdim` input arguments are not supported.
- The 'Method' name-value pair argument is not supported.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).
- If the output `Y` is a vector, the orientation of `Y` differs from MATLAB when all of the following are true:
 - You do not supply `dim`.
 - `X` is a variable-size array, and not a variable-size vector, at compile time, but `X` is a vector at run time.
 - The orientation of the vector `X` does not match the orientation of the vector `p`.

In this case, the output `Y` matches the orientation of `X`, not the orientation of `p`.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'all' and `vecdim` input arguments are not supported.
- The 'Method' name-value pair argument is not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Quantiles and Percentiles” on page 3-6

Introduced before R2006a

rand

Class: `qrandstream`

Generate quasi-random points from stream

Syntax

```
rand
rand(q,n)
rand(q)
rand(q,m,n)
rand(q,[m,n])
rand(q,m,n,p,...)
rand(q,[m,n,p,...])
```

Description

`rand` returns a matrix of quasi-random values and is intended to allow objects of the `qrandstream` on page 32-4386 class to be used in code that contains calls to the `rand` method of the MATLAB pseudo-random `randstream` class. Due to the multidimensional nature of quasi-random numbers, only some syntaxes of `rand` are supported by the `qrandstream` class.

`rand(q,n)` returns an n -by- n matrix only when n is equal to the number of dimensions. Any other value of n produces an error.

`rand(q)` returns a scalar only when the stream is in one dimension. Having more than one dimension in q produces an error.

`rand(q,m,n)` or `rand(q,[m,n])` returns an m -by- n matrix only when n is equal to the number of dimensions in the stream. Any other value of n produces an error.

`rand(q,m,n,p,...)` or `rand(q,[m,n,p,...])` produces an error unless p and all following dimensions sizes are equal to one.

Examples

Generate the first 256 points from a 5-D Sobol sequence:

```
q = qrandstream('sobol',5);
X = rand(q,256,5);
```

`qrand` | `qrandstream` | `rand`

quantileError

Class: TreeBagger

Quantile loss using bag of regression trees

Syntax

```
err = quantileError(Mdl,X)
err = quantileError(Mdl,X,ResponseVarName)
err = quantileError(Mdl,X,Y)
err = quantileError( ____,Name,Value)
```

Description

`err = quantileError(Mdl,X)` returns half of the mean absolute deviation (MAD) from comparing the true responses in the table `X` to the predicted medians resulting from applying the bag of regression trees `Mdl` to the observations of the predictor data in `X`.

- `Mdl` must be a `TreeBagger` model object.
- The response variable name in `X` must have the same name as the response variable in the table containing the training data.

`err = quantileError(Mdl,X,ResponseVarName)` uses the true response and predictor variables contained in the table `X`. `ResponseVarName` is the name of the response variable and `Mdl.PredictorNames` contain the names of the predictor variables.

`err = quantileError(Mdl,X,Y)` uses the predictor data in the table or matrix `X` and the response data in the vector `Y`.

`err = quantileError(____,Name,Value)` uses any of the previous syntaxes and additional options specified by one or more `Name,Value` pair arguments. For example, specify quantile probabilities, the error type, or which trees to include in the quantile-regression-error estimation.

Input Arguments

Mdl — Bag of regression trees

`TreeBagger` model object (default)

Bag of regression trees, specified as a `TreeBagger` model object created by `TreeBagger`. The value of `Mdl.Method` must be `regression`.

X — Sample data

numeric matrix | table

Sample data used to estimate quantiles, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable. If you specify `Y`, then the number of rows in `X` must be equal to the length of `Y`.

- For a numeric matrix:
 - The variables making up the columns of X must have the same order as the predictor variables that trained Mdl (stored in $Mdl.PredictorNames$).
 - If you trained Mdl using a table (for example, Tbl), then X can be a numeric matrix if Tbl contains all numeric predictor variables. If Tbl contains heterogeneous predictor variables (for example, numeric and categorical data types), then `quantileError` throws an error.
 - Specify Y for the true responses.
- For a table:
 - `quantileError` does not support multi-column variables and cell arrays other than cell arrays of character vectors.
 - If you trained Mdl using a table (for example, Tbl), then all predictor variables in X must have the same variable names and data types as those variables that trained Mdl (stored in $Mdl.PredictorNames$). However, the column order of X does not need to correspond to the column order of Tbl . Tbl and X can contain additional variables (response variables, observation weights, etc.).
 - If you trained Mdl using a numeric matrix, then the predictor names in $Mdl.PredictorNames$ and corresponding predictor variable names in X must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `TreeBagger`. All predictor variables in X must be numeric vectors. X can contain additional variables (response variables, observation weights, etc.).
 - If X contains the response variable:
 - If the response variable has the same name as the response variable that trained Mdl , then you do not have to supply the response variable name or vector of true responses. `quantileError` uses that variable for the true responses by default.
 - You can specify `ResponseVarName` or Y for the true responses.

Data Types: `table` | `double` | `single`

ResponseVarName — Response variable name

character vector | string scalar

Response variable name, specified as a character vector or string scalar. `ResponseVarName` must be the name of the response variable in the table of sample data X .

If the table X contains the response variable, and it has the same name as the response variable used to train Mdl , then you do not have to specify `ResponseVarName`. `quantileError` uses that variable for the true responses by default.

Data Types: `char` | `string`

Y — True responses

numeric vector

True responses, specified as a numeric vector. The number of rows in X must be equal to the length of Y .

Data Types: `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Mode — Ensemble error type

'ensemble' (default) | 'cumulative' | 'individual'

Ensemble error type, specified as the comma-separated pair consisting of 'Mode' and a value in this table. Suppose τ is the value of `Quantile`.

Value	Description
'cumulative'	<code>err</code> is a <code>Mdl.NumTrees-by-numel(τ)</code> numeric matrix of cumulative quantile regression errors. <code>err(j,k)</code> is the $\tau(k)$ quantile regression error using the learners in <code>Mdl.Trees(1:j)</code> only.
'ensemble'	<code>err</code> is a 1-by- <code>numel(τ)</code> numeric vector of cumulative quantile regression errors for the entire ensemble. <code>err(k)</code> is the $\tau(k)$ ensemble quantile regression error.
'individual'	<code>err</code> is a <code>Mdl.NumTrees-by-numel(τ)</code> numeric matrix of quantile regression errors from individual learners. <code>err(j,k)</code> is the $\tau(k)$ quantile regression error using the learner in <code>Mdl.Trees(j)</code> only.

For 'cumulative' and 'individual', if you include fewer trees in quantile estimation using `Trees` or `UseInstanceForTree`, then the number of rows in `err` decreases from `Mdl.NumTrees`.

Example: 'Mode', 'cumulative'

Weights — Observation weights

`ones(size(X,1),1)` (default) | numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values with length equal to `size(X,1)`. `quantileError` uses `Weights` to compute the weighted average of the deviations when estimating the quantile regression error.

By default, `quantileError` attributes a weight of 1 to each observation, which yields an unweighted average of the deviations.

Quantile — Quantile probability

0.5 (default) | numeric vector containing values in [0,1]

Quantile probability, specified as the comma-separated pair consisting of 'Quantile' and a numeric vector containing values in the interval [0,1]. For each element in `Quantile`, `quantileError` returns corresponding quantile regression errors for all probabilities in `Quantile`.

Example: 'Quantile', [0 0.25 0.5 0.75 1]

Data Types: single | double

Trees — Indices of trees to use in response estimation

'all' (default) | numeric vector of positive integers

Indices of trees to use in response estimation, specified as the comma-separated pair consisting of 'Trees' and 'all' or a numeric vector of positive integers. Indices correspond to the cells of

`Mdl.Trees`; each cell therein contains a tree in the ensemble. The maximum value of `Trees` must be less than or equal to the number of trees in the ensemble (`Mdl.NumTrees`).

For 'all', `quantileError` uses all trees in the ensemble (that is, the indices `1:Mdl.NumTrees`).

Values other than the default can affect the number of rows in `err`.

Example: 'Trees', [1 10 Mdl.NumTrees]

Data Types: char | string | single | double

TreeWeights — Weights to attribute to responses from individual trees

`ones(Mdl.NumTrees,1)` (default) | numeric vector of nonnegative values

Weights to attribute to responses from individual trees, specified as the comma-separated pair consisting of 'TreeWeights' and a numeric vector of `numel(trees)` nonnegative values. `trees` is the value of `Trees`.

If you specify 'Mode', 'individual', then `quantileError` ignores `TreeWeights`.

Data Types: single | double

UseInstanceForTree — Indicators specifying which trees to use to make predictions for each observation

'all' (default) | logical matrix

Indicators specifying which trees to use to make predictions for each observation, specified as the comma-separated pair consisting of 'UseInstanceForTree' and an n -by-`Mdl.Trees` logical matrix. n is the number of observations (rows) in `X`. Rows of `UseInstanceForTree` correspond to observations and columns correspond to learners in `Mdl.Trees`. 'all' indicates to use all trees for all observations when estimating the quantiles.

If `UseInstanceForTree(j,k) = true`, then `quantileError` uses the tree in `Mdl.Trees(k)` when it predicts the response for the observation `X(j,:)`.

You can estimate quantiles using the response data in `Mdl.Y` directly instead of using the predictions from the random forest by specifying a row composed entirely of false values. For example, to estimate the quantile for observation j using the response data, and to use the predictions from the random forest for all other observations, specify this matrix:

```
UseInstanceForTree = true(size(Mdl.X,2),Mdl.NumTrees);
UseInstanceForTree(j,:) = false(1,Mdl.NumTrees);
```

Values other than the default can affect the number of rows in `err`. Also, the value of `Trees` affects the value of `UseInstanceForTree`. Suppose that U is the value of `UseInstanceForTree`. `quantileError` ignores the columns of U corresponding to trees not being used in estimation from the specification of `Trees`. That is, `quantileError` resets the value of 'UseInstanceForTree' to `U(:,trees)`, where `trees` is the value of 'Trees'.

Data Types: char | string | logical

Output Arguments

err — Half of quantile regression error

numeric scalar | numeric matrix

Half of the quantile regression error on page 32-4420, returned as a numeric scalar or T -by- $\text{numel}(\text{tau})$ matrix. tau is the value of `Quantile`.

T depends on the values of `Mode`, `Trees`, `UseInstanceForTree`, and `Quantile`. Suppose that you specify `'Trees'`, trees and you use the default value of `'UseInstanceForTree'`.

- For `'Mode'`, `'cumulative'`, `err` is a $\text{numel}(\text{trees})$ -by- $\text{numel}(\text{tau})$ numeric matrix. `err(j,k)` is the $\text{tau}(k)$ cumulative quantile regression error using the learners in `Mdl.Trees(trees(1:j))`.
- For `'Mode'`, `'ensemble'`, `err` is a 1-by- $\text{numel}(\text{tau})$ numeric vector. `err(k)` is the $\text{tau}(k)$ cumulative quantile regression error using the learners in `Mdl.Trees(trees)`.
- For `'Mode'`, `'individual'`, `err` is a $\text{numel}(\text{trees})$ -by- $\text{numel}(\text{tau})$ numeric matrix. `err(j,k)` is the $\text{tau}(k)$ quantile regression error using the learner in `Mdl.Trees(trees(j))`.

Examples

Estimate In-Sample Quantile Regression Error

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement, weight, and number of cylinders. Consider `Cylinders` a categorical variable.

```
load carsmall
Cylinders = categorical(Cylinders);
X = table(Displacement,Weight,Cylinders,MPG);
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100,X,'MPG','Method','regression');
```

`Mdl` is a `TreeBagger` ensemble.

Perform quantile regression, and estimate the MAD of the entire ensemble using the predicted conditional medians.

```
err = quantileError(Mdl,X)
err = 1.2586
```

Because `X` is a table containing the response and commensurate variable names, you do not have to specify the response variable name or data. However, you can specify the response using this syntax.

```
err = quantileError(Mdl,X,'MPG')
err = 1.2586
```

Find Appropriate Ensemble Size Using Quantile Regression Error

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement, weight, and number of cylinders.

```
load carsmall
X = table(Displacement,Weight,Cylinders,MPG);
```

Randomly split the data into two sets: 75% training and 25% testing. Extract the subset indices.

```
rng(1); % For reproducibility
cvp = cvpartition(size(X,1),'Holdout',0.25);
idxTrn = training(cvp);
idxTest = test(cvp);
```

Train an ensemble of bagged regression trees using the training set. Specify 250 weak learners.

```
Mdl = TreeBagger(250,X{idxTrn,:},'MPG','Method','regression');
```

Estimate the cumulative 0.25, 0.5, and 0.75 quantile regression errors for the test set. Pass the predictor data in as a numeric matrix, and the response data in as a vector.

```
err = quantileError(Mdl,X{idxTest,1:3},MPG{idxTest},'Quantile',[0.25 0.5 0.75],...
    'Mode','cumulative');
```

`err` is a 250-by-3 matrix of cumulative quantile regression errors. Columns correspond to quantile probabilities and rows correspond to trees in the ensemble. The errors are cumulative, so they incorporate aggregated predictions from previous trees. Although, `Mdl` was trained using a table, if all predictor variables in the table are numeric, then you can supply a matrix of predictor data instead.

Plot the cumulative quantile errors on the same plot.

```
figure;
plot(err);
legend('0.25 quantile error','0.5 quantile error','0.75 quantile error');
ylabel('Quantile error');
xlabel('Tree index');
title('Cumulative Quantile Regression Error')
```

Training using about 60 trees appears to be enough for the first two quantiles, but the third quartile requires about 150 trees.

More About

Quantile Regression Error

The quantile regression error of a model given observed predictor data and responses is the weighted mean absolute deviation (MAD). If the model under-predicts the response, then deviation weights are τ , the quantile probability. If the model over-predicts, then deviation weights are $1 - \tau$.

That is, the τ quantile regression error is

$$L_\tau = \tau \frac{\sum_{\{j: y_j \geq \hat{y}_{\tau, j}\}} w_j (y_j - \hat{y}_{\tau, j})}{\sum_{j=1}^n w_j} + (1 - \tau) \frac{\sum_{\{j: y_j < \hat{y}_{\tau, j}\}} w_j (\hat{y}_{\tau, j} - y_j)}{\sum_{j=1}^n w_j} .$$

y_j is true response j , $\hat{y}_{\tau, j}$ is the τ quantile that the model predicts, and w_j is observation weight j .

Tips

- To tune the number of trees in the ensemble, set 'Mode', 'cumulative' and plot the quantile regression errors with respect to tree indices. The maximal number of required trees is the tree index where the quantile regression error appears to level off.
- To investigate the performance of a model when the training sample is small, use `oobQuantileError` instead.

`TreeBagger` | `error` | `oobQuantileError` | `quantilePredict`

Introduced in R2016b

quantilePredict

Class: TreeBagger

Predict response quantile using bag of regression trees

Syntax

```
YFit = quantilePredict(Mdl,X)
YFit = quantilePredict(Mdl,X,Name,Value)
[YFit,YW] = quantilePredict( ___ )
```

Description

`YFit = quantilePredict(Mdl,X)` returns a vector of medians of the predicted responses at `X`, a table or matrix of predictor data, and using the bag of regression trees `Mdl`. `Mdl` must be a `TreeBagger` model object.

`YFit = quantilePredict(Mdl,X,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, specify quantile probabilities or which trees to include for quantile estimation.

`[YFit,YW] = quantilePredict(___)` also returns a sparse matrix of response weights on page 32-4429.

Input Arguments

Mdl — Bag of regression trees

`TreeBagger` model object (default)

Bag of regression trees, specified as a `TreeBagger` model object created by `TreeBagger`. The value of `Mdl.Method` must be `regression`.

X — Predictor data

numeric matrix | table

Predictor data used to estimate quantiles, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

- For a numeric matrix:
 - The variables making up the columns of `X` must have the same order as the predictor variables that trained `Mdl`.
 - If you trained `Mdl` using a table (for example, `Tbl`), then `X` can be a numeric matrix if `Tbl` contains all numeric predictor variables. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types) and `X` is a numeric matrix, then `quantilePredict` throws an error.
- For a table:

- `quantilePredict` does not support multi-column variables and cell arrays other than cell arrays of character vectors.
- If you trained `Mdl` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and data types as those variables that trained `Mdl` (stored in `Mdl.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. `Tbl` and `X` can contain additional variables (response variables, observation weights, etc.), but `quantilePredict` ignores them.
- If you trained `Mdl` using a numeric matrix, then the predictor names in `Mdl.PredictorNames` and corresponding predictor variable names in `X` must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `TreeBagger`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, etc.), but `quantilePredict` ignores them.

Data Types: `table` | `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Quantile — Quantile probability

0.5 (default) | numeric vector containing values in [0,1]

Quantile probability, specified as the comma-separated pair consisting of `'Quantile'` and a numeric vector containing values in the interval [0,1]. For each observation (row) in `X`, `quantilePredict` returns corresponding quantiles for all probabilities in `Quantile`.

Example: `'Quantile',[0 0.25 0.5 0.75 1]`

Data Types: `single` | `double`

Trees — Indices of trees to use in response estimation

'all' (default) | numeric vector of positive integers

Indices of trees to use in response estimation, specified as the comma-separated pair consisting of `'Trees'` and `'all'` or a numeric vector of positive integers. Indices correspond to the cells of `Mdl.Trees`; each cell therein contains a tree in the ensemble. The maximum value of `Trees` must be less than or equal to the number of trees in the ensemble (`Mdl.NumTrees`).

For `'all'`, `quantilePredict` uses the indices `1:Mdl.NumTrees`.

Example: `'Trees',[1 10 Mdl.NumTrees]`

Data Types: `char` | `string` | `single` | `double`

TreeWeights — Weights to attribute to responses from individual trees

numeric vector of nonnegative values

Weights to attribute to responses from individual trees, specified as the comma-separated pair consisting of `'TreeWeights'` and a numeric vector of `numel(trees)` nonnegative values. `trees` is the value of the `Trees` name-value pair argument.

The default is `ones(size(trees))`.

Data Types: `single` | `double`

UseInstanceForTree — Indicators specifying which trees to use to make predictions for each observation`'all'` (default) | logical matrix

Indicators specifying which trees to use to make predictions for each observation, specified as the comma-separated pair consisting of `'UseInstanceForTree'` and an n -by-`Mdl.Trees` logical matrix. n is the number of observations (rows) in `X`. Rows of `UseInstanceForTree` correspond to observations and columns correspond to learners in `Mdl.Trees`. `'all'` indicates to use all trees for all observations when estimating the quantiles.

If `UseInstanceForTree(j,k) = true`, then `quantilePredict` uses the tree in `Mdl.Trees(trees(k))` when it predicts the response for the observation `X(j,:)`.

You can estimate the quantile using the response data in `Mdl.Y` directly instead of using the predictions from the random forest by specifying a row composed entirely of false values. For example, to estimate the quantile for observation j using the response data, and to use the predictions from the random forest for all other observations, specify this matrix:

```
UseInstanceForTree = true(size(Mdl.X,2),Mdl.NumTrees);
UseInstanceForTree(j,:) = false(1,Mdl.NumTrees);
```

Data Types: `char` | `string` | `logical`

Output Arguments**YFit** — Estimated quantiles

numeric matrix

Estimated quantiles, returned as an n -by-`numel(tau)` numeric matrix. n is the number of observations in `X` (`size(X,1)`) and `tau` is the value of `Quantile`. That is, `YFit(j,k)` is the estimated $100*tau(k)\%$ percentile of the response distribution given `X(j,:)` and using `Mdl`.

YW — Response weights

sparse matrix

Response weights on page 32-4429, returned as an n_{train} -by- n sparse matrix. n_{train} is the number of responses in the training data (`numel(Mdl.Y)`) and n is the number of observations in `X` (`size(X,1)`).

`quantilePredict` predicts quantiles using linear interpolation of the empirical cumulative distribution function (C.D.F.). For a particular observation, you can use its response weights to estimate quantiles using alternative methods, such as approximating the C.D.F. using kernel smoothing.

Note `quantilePredict` derives response weights by passing an observation through the trees in the ensemble. If you specify `UseInstanceForTree` and you compose row j entirely of false values, then `YW(:,j) = Mdl.W` instead, that is, the observation weights.

Examples

Predict Training Sample Medians

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement.

```
load carsmall
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100,Displacement,MPG,'Method','regression');
```

`Mdl` is a `TreeBagger` ensemble.

Perform quantile regression to predict the median MPG for all sorted training observations.

```
medianMPG = quantilePredict(Mdl,sort(Displacement));
```

`medianMPG` is an `n`-by-1 numeric vector of medians corresponding to the conditional distribution of the response given the sorted observations in `Displacement`. `n` is the number of observations in `Displacement`.

Plot the observations and the estimated medians on the same figure. Compare the median and mean responses.

```
meanMPG = predict(Mdl,sort(Displacement));

figure;
plot(Displacement,MPG,'k. ');
hold on
plot(sort(Displacement),medianMPG);
plot(sort(Displacement),meanMPG,'r--');
ylabel('Fuel economy');
xlabel('Engine displacement');
legend('Data','Median','Mean');
hold off;
```

Estimate Prediction Intervals Using Percentiles

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement.

```
load carsmall
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100, Displacement, MPG, 'Method', 'regression');
```

Perform quantile regression to predict the 2.5% and 97.5% percentiles for ten equally-spaced engine displacements between the minimum and maximum in-sample displacement.

```
predX = linspace(min(Displacement), max(Displacement), 10)';
quantPredInts = quantilePredict(Mdl, predX, 'Quantile', [0.025, 0.975]);
```

`quantPredInts` is a 10-by-2 numeric matrix of prediction intervals corresponding to the observations in `predX`. The first column contains the 2.5% percentiles and the second column contains the 97.5% percentiles.

Plot the observations and the estimated medians on the same figure. Compare the percentile prediction intervals and the 95% prediction intervals assuming the conditional distribution of MPG is Gaussian.

```

[meanMPG,steMeanMPG] = predict(Mdl,predX);
stndPredInts = meanMPG + [-1 1]*norminv(0.975).*steMeanMPG;

figure;
h1 = plot(Displacement,MPG,'k.');
```

hold on

```

h2 = plot(predX,quantPredInts,'b');
h3 = plot(predX,stndPredInts,'r--');
```

ylabel('Fuel economy');

xlabel('Engine displacement');

```

legend([h1,h2(1),h3(1)],{'Data','95% percentile prediction intervals',...
'95% Gaussian prediction intervals'});
```

hold off;

Estimate Conditional Cumulative Distribution Using Quantile Regression

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement.

```
load carsmall
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100,Displacement,MPG,'Method','regression');
```

Estimate the response weights for a random sample of four training observations. Plot the training sample and identify the chosen observations.

```
[predX,idx] = datasample(Mdl.X,4);
[~,YW] = quantilePredict(Mdl,predX);
n = numel(Mdl.Y);

figure;
plot(Mdl.X,Mdl.Y,'o');
hold on
plot(predX,Mdl.Y(idx),'*','MarkerSize',10);
text(predX-10,Mdl.Y(idx)+1.5,{'obs. 1' 'obs. 2' 'obs. 3' 'obs. 4'});
legend('Training Data','Chosen Observations');
xlabel('Engine displacement')
ylabel('Fuel economy')
hold off
```

YW is an n -by-4 sparse matrix containing the response weights. Columns correspond to test observations and rows correspond to responses in the training sample. Response weights are independent of the specified quantile probability.

Estimate the conditional cumulative distribution function (C.C.D.F.) of the responses by:

- 1 Sorting the responses in ascending order, and then sorting the response weights using the indices induced by sorting the responses.
- 2 Computing the cumulative sums over each column of the sorted response weights.

```
[sortY,sortIdx] = sort(Mdl.Y);
cpdf = full(YW(sortIdx,:));
ccdf = cumsum(cpdf);
```

`ccdf(:,j)` is the empirical C.C.D.F. of the response given test observation j .

Plot the four empirical C.C.D.F. in the same figure.

```
figure;
plot(sortY,ccdf);
legend('C.C.D.F. given test obs. 1','C.C.D.F. given test obs. 2',...
       'C.C.D.F. given test obs. 3','C.C.D.F. given test obs. 4',...
       'Location','SouthEast')
title('Conditional Cumulative Distribution Functions')
xlabel('Fuel economy')
ylabel('Empirical CDF')
```

More About

Response Weights

Response weights are scalars that represent the conditional distribution of the response given a value in the predictor space. The observations in the bootstrap samples and the leaves that the training and test observations share induce response weights.

Given the observation x , the response weight for observation j in the training sample using tree t in the ensemble is

$$w_{tj}(x) = \frac{I\{X_j \in S_t(x)\}}{n_{\text{train}} \sum_{k=1} I\{X_k \in S_t(x)\}},$$

where:

- $I\{h\}$ is the indicator function.
- $S_t(x)$ is the leaf of tree t containing x .
- n_{train} is the number of training observations.

In other words, the response weights of a particular tree form the conditional relative frequency distribution of the response.

The response weights for the entire ensemble are averaged over the trees:

$$w_j^*(x) = \frac{1}{T} \sum_{t=1}^T w_{tj}(x).$$

Quantile Random Forest

Quantile random forest [2] is a quantile-regression method that uses a random forest [1] of regression trees to model the conditional distribution of a response variable, given the value of predictor variables. You can use a fitted model to estimate quantiles in the conditional distribution of the response.

Besides quantile estimation, you can use quantile regression to estimate prediction intervals or detect outliers. For example:

- To estimate 95% quantile prediction intervals, estimate the 0.025 and 0.975 quantiles.
- To detect outliers, estimate the 0.01 and 0.99 quantiles. All observations smaller than the 0.01 quantile and larger than the 0.99 quantile are outliers. All observations that are outside the interval $[L, U]$ can be considered outliers:

$$L = Q_1 - 1.5 * IQR$$

and

$$U = Q_3 + 1.5 * IQR,$$

where:

- Q_1 is the 0.25 quantile.
- Q_3 is the 0.75 quantile.
- $IQR = Q_3 - Q_1$ (the interquartile range).

Tip

`quantilePredict` estimates the conditional distribution of the response using the training data every time you call it. To predict many quantiles efficiently, or quantiles for many observations

efficiently, you should pass X as a matrix or table of observations and specify all quantiles in a vector using the `Quantile` name-value pair argument. That is, avoid calling `quantilePredict` within a loop.

Algorithms

- `TreeBagger` grows a random forest of regression trees using the training data. Then, to implement quantile random forest on page 32-4430, `quantilePredict` predicts quantiles using the empirical conditional distribution of the response given an observation from the predictor variables. To obtain the empirical conditional distribution of the response:
 - 1 `quantilePredict` passes all the training observations in `Mdl.X` through all the trees in the ensemble, and stores the leaf nodes of which the training observations are members.
 - 2 `quantilePredict` similarly passes each observation in X through all the trees in the ensemble.
 - 3 For each observation in X , `quantilePredict`:
 - a Estimates the conditional distribution of the response by computing response weights on page 32-4429 for each tree.
 - b For observation k in X , aggregates the conditional distributions for the entire ensemble:

$$\widehat{F}(y|X = x_k) = \sum_{j=1}^n \sum_{t=1}^T \frac{1}{T} w_{tj}(x_k) I\{Y_j \leq y\}.$$

n is the number of training observations (`size(Y,1)`) and T is the number of trees in the ensemble (`Mdl.NumTrees`).

- 4 For observation k in X , the τ quantile or, equivalently, the $100\tau\%$ percentile, is $Q_\tau(x_k) = \inf\{y: \widehat{F}(y|X = x_k) \geq \tau\}$.
- This process describes how `quantilePredict` uses all specified weights.
 - 1 For all training observations $j = 1, \dots, n$ and all chosen trees $t = 1, \dots, T$, `quantilePredict` attributes the product $v_{tj} = b_{tj} w_{j, \text{obs}}$ to training observation j (stored in `Mdl.X(j, :)` and `Mdl.Y(j)`). b_{tj} is the number of times observation j is in the bootstrap sample for tree t . $w_{j, \text{obs}}$ is the observation weight in `Mdl.W(j)`.
 - 2 For each chosen tree, `quantilePredict` identifies the leaves in which each training observation falls. Let $S_t(x_j)$ be the set of all observations contained in the leaf of tree t of which observation j is a member.
 - 3 For each chosen tree, `quantilePredict` normalizes all weights within a particular leaf to sum to 1, that is,

$$v_{tj}^* = \frac{v_{tj}}{\sum_{i \in S_t(x_j)} v_{ti}}.$$
 - 4 For each training observation and tree, `quantilePredict` incorporates tree weights ($w_{t, \text{tree}}$) specified by `TreeWeights`, that is, $w_{tj, \text{tree}}^* = w_{t, \text{tree}} v_{tj}^*$. Trees not chosen for prediction have 0 weight.
 - 5 For all test observations $k = 1, \dots, K$ in X and all chosen trees $t = 1, \dots, T$, `quantilePredict` predicts the unique leaves in which the observations fall, and then identifies all training

observations within the predicted leaves. `quantilePredict` attributes the weight u_{tj} such that

$$u_{tj} = \begin{cases} w_{tj, \text{tree}}^* & \text{if } x_k \in S_t(x_j) \\ 0 & \text{otherwise} \end{cases}.$$

6 `quantilePredict` sums the weights over all chosen trees, that is,

$$u_j = \sum_{t=1}^T u_{tj}.$$

7 `quantilePredict` creates response weights by normalizing the weights so that they sum to 1, that is,

$$w_j^* = \frac{u_j}{\sum_{j=1}^n u_j}.$$

Introduced in R2016b

randg

Gamma random numbers with unit scale

Syntax

```
Y = randg
Y = randg(A)
Y = randg(A,m)
Y = randg(A,m,n,p,...)
Y = randg(A,[m,n,p,...])
Y = randg(...,classname)
Y = randg(...,'like',X)
Y = randg(...,'like',classname)
```

Description

`Y = randg` returns a scalar random value chosen from a gamma distribution with unit scale and shape.

`Y = randg(A)` returns a matrix of random values chosen from gamma distributions with unit scale. `Y` is the same size as `A`, and `randg` generates each element of `Y` using a shape parameter equal to the corresponding element of `A`.

`Y = randg(A,m)` returns an `m`-by-`m` matrix of random values chosen from gamma distributions with shape parameters `A`. `A` is either an `m`-by-`m` matrix or a scalar. If `A` is a scalar, `randg` uses that single shape parameter value to generate all elements of `Y`.

`Y = randg(A,m,n,p,...)` or `Y = randg(A,[m,n,p,...])` returns an `m`-by-`n`-by-`p`-by-... array of random values chosen from gamma distributions with shape parameters `A`. `A` is either an `m`-by-`n`-by-`p`-by-... array or a scalar.

`Y = randg(...,classname)` returns an array of random values chosen from gamma distributions of the specified class. `classname` can be `double` or `single`.

`Y = randg(...,'like',X)` or `Y = randg(...,'like',classname)` returns an array of random values chosen from gamma distributions of the same class as `X` or `classname`, respectively. `X` is a numeric array.

`randg` produces pseudo-random numbers using the MATLAB functions `rand` and `randn`. The sequence of numbers generated is determined by the settings of the uniform random number generator that underlies `rand` and `randn`. Control that shared random number generator using `rng`. See the `rng` documentation for more information.

Note To generate gamma random numbers and specify both the scale and shape parameters, you should call `gamrnd`.

Examples

Example 1

Generate a 100-by-1 array of values drawn from a gamma distribution with shape parameter 3.

```
r = randg(3,100,1);
```

Example 2

Generate a 100-by-2 array of values drawn from gamma distributions with shape parameters 3 and 2.

```
A = [ones(100,1)*3,ones(100,1)*2];  
r = randg(A,[100,2]);
```

Example 3

To create reproducible output from `randg`, reset the random number generator used by `rand` and `randn` to its default startup settings. This way `randg` produces the same random numbers as if you restarted MATLAB.

```
rng('default')  
randg(3,1,5)
```

ans =

```
6.9223 4.3369 1.0505 3.2662 11.3269
```

Example 4

Save the settings for the random number generator used by `rand` and `randn`, generate 5 values from `randg`, restore the settings, and repeat those values.

```
s = rng; % Obtain the current state of the random stream  
r1 = randg(10,1,5)
```

r1 =

```
9.4719 9.0433 15.0774 14.7763 6.3775
```

```
rng(s); % Reset the stream to the previous state  
r2 = randg(10,1,5)
```

r2 =

```
9.4719 9.0433 15.0774 14.7763 6.3775
```

r2 contains exactly the same values as r1.

Example 5

Reinitialize the random number generator used by `rand` and `randn` with a seed based on the current time. `randg` returns different values each time you do this. Note that it is usually not necessary to do this more than once per MATLAB session.

```
rng('shuffle');  
randg(2,1,5);
```

gamrnd

Introduced before R2006a

random

Package: prob

Random numbers

Syntax

```
R = random('name',A)
R = random('name',A,B)
R = random('name',A,B,C)
R = random('name',A,B,C,D)

R = random(pd)

R = random(____,sz1,...,szN)
R = random(____,sz)
```

Description

`R = random('name',A)` returns a random number from the one-parameter distribution family specified by 'name' and the distribution parameter A.

`R = random('name',A,B)` returns a random number from the two-parameter distribution family specified by 'name' and the distribution parameters A and B.

`R = random('name',A,B,C)` returns a random number from the three-parameter distribution family specified by 'name' and the distribution parameters A, B, and C.

`R = random('name',A,B,C,D)` returns a random number from the four-parameter distribution family specified by 'name' and the distribution parameters A, B, C, and D.

`R = random(pd)` returns a random number from the probability distribution object pd.

`R = random(____,sz1,...,szN)` generates an array of random numbers from the specified probability distribution using input arguments from any of the previous syntaxes, where `sz1,...,szN` indicates the size of each dimension.

`R = random(____,sz)` generates an array of random numbers from the specified probability distribution using input arguments from any of the previous syntaxes, where vector `sz` specifies `size(r)`.

Examples

Generate One Random Number

Create a standard normal probability distribution object.

```
pd = makedist('Normal')
pd =
  NormalDistribution
```

```
Normal distribution
    mu = 0
    sigma = 1
```

Generate one random number from the distribution.

```
rng('default') % For reproducibility
r1 = random(pd)

r1 = 0.5377
```

Alternatively, you can generate a standard normal random number by specifying its name and parameters.

```
r2 = random('Normal',0,1)

r2 = 1.8339
```

Reset Random Number Generator

Save the current state of the random number generator. Then generate a random number from the Poisson distribution with rate parameter 5.

```
s = rng;
r = random('Poisson',5)

r = 5
```

Restore the state of the random number generator to s, and then create a new random number. The value is the same as before.

```
rng(s);
r1 = random('Poisson',5)

r1 = 5
```

Clone Size from Existing Array

Create a matrix of random numbers with the same size as an existing array. Use the stable distribution with shape parameters 2 and 0, scale parameter 1, and location parameter 0.

```
A = [3 2; -2 1];
sz = size(A);
R = random('Stable',2,0,1,0,sz)

R = 2×2

    0.7604    -3.1945
    2.5935     1.2193
```

You can combine the previous two lines of code into a single line.

```
R = random('Stable',2,0,1,0,size(A))  
R = 2x2  
    0.4508    -0.6132  
   -1.8494     0.4845
```

Generate Multiple Random Numbers

Create a Weibull probability distribution object using the default parameter values.

```
pd = makedist('Weibull')  
pd =  
    WeibullDistribution  
  
    Weibull distribution  
    A = 1  
    B = 1
```

Generate random numbers from the distribution.

```
rng('default') % For reproducibility  
r = random(pd,10000,1);
```

Construct a histogram using 100 bins with a Weibull distribution fit.

```
histfit(r,100,'weibull')
```

Generate Multidimensional Array of Random Numbers

Create a standard normal probability distribution object.

```
pd = makedist('Normal')
```

```
pd =  
NormalDistribution  
  
Normal distribution  
mu = 0  
sigma = 1
```

Generate a 2-by-3-by-2 array of random numbers from the distribution.

```
r = random(pd, [2, 3, 2])
```

```
r =  
r(:, :, 1) =  
  
0.5377    -2.2588    0.3188  
1.8339     0.8622   -1.3077
```

```
r(:, :, 2) =
    -0.4336    3.5784   -1.3499
     0.3426    2.7694    3.0349
```

Input Arguments

'name' — Probability distribution name

character vector or string scalar of probability distribution name

Probability distribution name, specified as one of the probability distribution names in this table.

'name'	Distribution	Input Parameter A	Input Parameter B	Input Parameter C	Input Parameter D
'Beta'	"Beta Distribution" on page B-6	a first shape parameter	b second shape parameter	—	—

Example: 'Normal'

A — First probability distribution parameter

scalar value | array of scalar values

First probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments A, B, C, and D are arrays, then the array sizes must be the same. In this case, `random` expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A, B, C, and D for each distribution.

Data Types: single | double

B — Second probability distribution parameter

scalar value | array of scalar values

Second probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments A, B, C, and D are arrays, then the array sizes must be the same. In this case, `random` expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A, B, C, and D for each distribution.

Data Types: single | double

C — Third probability distribution parameter

scalar value | array of scalar values

Third probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments A, B, C, and D are arrays, then the array sizes must be the same. In this case, `random` expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A, B, C, and D for each distribution.

Data Types: single | double

D — Fourth probability distribution parameter

scalar value | array of scalar values

Fourth probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments A, B, C, and D are arrays, then the array sizes must be the same. In this case, `random` expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A, B, C, and D for each distribution.

Data Types: `single` | `double`**pd — Probability distribution**

probability distribution object

Probability distribution, specified as a probability distribution object created with a function or app in this table.

Function or App	Description
<code>makedist</code>	Create a probability distribution object using specified parameter values.
<code>fitdist</code>	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.
<code>paretotails</code>	Create a piecewise distribution object that has generalized Pareto distributions in the tails.

sz1, ..., szN — Size of each dimension (as separate arguments)

integer values

Size of each dimension, specified as integer values. For example, specifying `5,3,2` generates a 5-by-3-by-2 array of random numbers from the specified probability distribution.

If one or more of the input arguments A, B, C, and D are arrays, then the specified dimensions `sz1, ..., szN` must match the common dimensions of A, B, C, and D after any necessary scalar expansion. The default values of `sz1, ..., szN` are the common dimensions.

- If you specify a single value `sz1`, then R is a square matrix of size `sz1`-by-`sz1`.
- If the size of any dimension is 0 or negative, then R is an empty array.
- Beyond the second dimension, `random` ignores trailing dimensions with a size of 1. For example, specifying `3,1,1,1` produces a 3-by-1 vector of random numbers.

Example: `5,3,2`Data Types: `single` | `double`**sz — Size of each dimension (as a row vector)**

row vector of integers

Size of each dimension, specified as a row vector of integers. For example, specifying `[5 3 2]` generates a 5-by-3-by-2 array of random numbers from the specified probability distribution.

If one or more of the input arguments A, B, C, and D are arrays, then the specified dimensions `sz` must match the common dimensions of A, B, C, and D after any necessary scalar expansion. The default values of `sz` are the common dimensions.

- If you specify a single value [*sz1*], then *R* is a square matrix of size *sz1*-by-*sz1*.
- If the size of any dimension is 0 or negative, then *R* is an empty array.
- Beyond the second dimension, `random` ignores trailing dimensions with a size of 1. For example, specifying [3 1 1 1] produces a 3-by-1 vector of random numbers.

Example: [5 3 2]

Data Types: `single` | `double`

Output Arguments

R — Random number

scalar value | array of scalar values

Random number generated from the specified probability distribution, returned as a scalar value or an array of scalar values with the dimensions specified by *sz1*, . . . , *szN* or *sz*.

If you specify distribution parameters *A*, *B*, *C*, or *D*, then each element in *R* is the random number generated from the distribution specified by the corresponding elements in *A*, *B*, *C*, and *D*.

Alternative Functionality

- `random` is a generic function that accepts either a distribution by its name 'name' or a probability distribution object *pd*. It is faster to use a distribution-specific function, such as `randn` and `normrnd` for the normal distribution and `binornd` for the binomial distribution. For a list of distribution-specific functions, see “Supported Distributions” on page 5-13.
- To generate random numbers interactively, use `randtool`, a user interface for random number generation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument 'name' must be a compile-time constant. For example, to use the normal distribution, include `coder.Constant('Normal')` in the `-args` value of `codegen`.
- Code generation does not support the probability distribution object (*pd*) input argument.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

random

Package:

Simulate responses with random noise for generalized linear regression model

Syntax

```
ysim = random mdl, Xnew)
ysim = random mdl, Xnew, Name, Value)
```

Description

`ysim = random mdl, Xnew)` simulates responses to the predictor data in `Xnew` using the generalized linear regression model `mdl`, adding random noise.

`ysim = random mdl, Xnew, Name, Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the number of trials for binomial distribution or the offset value used for fitting.

Examples

Simulate Response Data with Random Noise

Create a generalized linear regression model, and simulate its response with random noise to new data.

Generate sample data using Poisson random numbers with one underlying predictor `X`.

```
rng('default') % For reproducibility
X = rand(20,1);
mu = exp(1 + 2*X);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1','Distribution','poisson');
```

Create data points for prediction.

```
Xnew = (0:.05:1)';
```

Simulate responses with random noise at the data points.

```
ysim = random(mdl,Xnew);
```

Plot the simulated values and the original values.

```
plot(X,y,'rx',Xnew,ysim,'bo',Xnew,feval(mdl,Xnew),'g-')
legend('Data','Simulated Response with Noise','Predicted Response', ...
      'Location','best')
```

Generate C/C++ Code That Simulates Responses

Fit a generalized linear regression model, and then save the model by using `saveLearnerForCoder`. Define an entry-point function that loads the model by using `loadLearnerForCoder` and calls the `predict` function of the fitted model. Then use `codegen` to generate C/C++ code. Note that generating C/C++ code requires MATLAB® Coder™.

This example briefly explains the code generation workflow for the prediction of linear regression models at the command line. For more details, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 31-9. You can also generate code using the MATLAB Coder app. For details, see “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 31-16.

Train Model

Generate sample data of the predictor x and response y with the following distributions:

- $x \sim N(1, 0.5^2)$.
- $\beta_0 = 1$ and $\beta = -2$.
- $y \sim \text{Binomial}\left(10, \frac{\exp(1 + x\beta)}{1 + \exp(1 + x\beta)}\right)$.

```
rng('default') % For reproducibility
x = 1 + randn(100,1)*0.5;
beta = -2;
p = exp(1 + x*beta)./(1 + exp(1 + x*beta)); % Inverse logit
n = 10;
y = binornd(n,p,100,1);
```

Create a generalized linear regression model of binomial data. Specify a binomial sample size of 10.

```
mdl = fitglm(x,y,'y ~ x1','Distribution','Binomial','BinomialSize',n);
```

Save Model

Save the fitted generalized linear regression model to the file `GLMMdl.mat` by using `saveLearnerForCoder`.

```
saveLearnerForCoder(mdl,'GLMMdl');
```

Define Entry-Point Function

In your current folder, define an entry-point function named `myrandomGLM.m` that does the following:

- Accept new predictor input and valid name-value pair arguments.
- Load the fitted generalized linear regression model in `GLMMdl.mat` by using `loadLearnerForCoder`.
- Simulate responses from the loaded GLM model.

```
function y = myrandomGLM(x,varargin) %#codegen
%MYRANDOMGLM Simulate responses using GLM model
% MYRANDOMGLM simulates responses for the n observations in the n-by-1
% vector x using the GLM model stored in the MAT-file GLMMdl.mat, and
% then returns the simulations in the n-by-1 vector y.
CompactMdl = loadLearnerForCoder('GLMMdl');
narginchk(1,Inf);
y = random(CompactMdl,x,varargin{:});
end
```

Add the `%codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation.

Generate Code

Generate code for the entry-point function using `codegen`. Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. To specify the data type and exact input array size, pass a MATLAB® expression that represents the set of values with a certain data type and array size. Use `coder.Constant` for the names of name-value pair arguments.

Specify the predictor data `x` and binomial parameter `n`.

```
codegen -config:mex myrandomGLM -args {x,coder.Constant('BinomialSize'),coder.Constant(n)}
```

`codegen` generates the MEX function `myrandomGLM_mex` with a platform-dependent extension.

If the number of observations is unknown at compile time, you can also specify the input as variable-size by using `coder.typeof`. For details, see “Specify Variable-Size Arguments for Code Generation” on page 31-38 and “Specify Properties of Entry-Point Function Inputs” (MATLAB Coder).

Verify Generated Code

Simulate responses using the MEX function. Specify the predictor data `x` and binomial parameter `n`.

```
ysim = myrandomGLM_mex(x, 'BinomialSize', n);
```

Plot the simulated values and the data in the same figure.

```
figure
plot(x,y,'bo',x,ysim,'r*')
legend('Observed responses','Simulated responses')
xlabel('x')
ylabel('y')
```

The observed and simulated responses appear to be similarly distributed.

Input Arguments

mdl — Generalized linear regression model

GeneralizedLinearModel object | CompactGeneralizedLinearModel object

Generalized linear regression model, specified as a `GeneralizedLinearModel` object created using `fitglm` or `stepwiseglm`, or a `CompactGeneralizedLinearModel` object created using `compact`.

Xnew — New predictor input values

table | dataset array | matrix

New predictor input values, specified as a table, dataset array, or matrix. Each row of `Xnew` corresponds to one observation, and each column corresponds to one variable.

- If `Xnew` is a table or dataset array, it must contain predictors that have the same predictor names as in the `PredictorNames` property of `mdl`.
- If `Xnew` is a matrix, it must have the same number of variables (columns) in the same order as the predictor input used to create `mdl`. Note that `Xnew` must also contain any predictor variables that are not used as predictors in the fitted model. Also, all variables used in creating `mdl` must be numeric. To treat numerical predictors as categorical, identify the predictors using the `'CategoricalVars'` name-value pair argument when you create `mdl`.

Data Types: single | double | table

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `ysim = random(Mdl, Xnew, 'BinomialSize', 50)` returns the numbers of success, perturbed by random noise, using the number of trials specified by `'BinomialSize'`.

BinomialSize — Number of trials for binomial distribution

1 (default) | scalar | vector

Number of trials for the binomial distribution, specified as the comma-separated pair consisting of `'BinomialSize'` and a scalar or vector of the same length as the response. `random` expands the scalar input into a constant array of the same size as the response. The scalar input means that all observations have the same number of trials.

The meaning of the output values in `ysim` depends on the value of `'BinomialSize'`.

- If `'BinomialSize'` is 1 (default), then each value in the output `ysim` is the probability of success.
- If `'BinomialSize'` is not 1, then each value in the output `ysim` is the predicted number of successes in the trials.

Data Types: single | double

Offset — Offset value`zeros(size(Xnew,1))` (default) | scalar | vector

Offset value for each row in `Xnew`, specified as the comma-separated pair consisting of `'Offset'` and a scalar or vector with the same length as the response. `random` expands the scalar input into a constant array of the same size as the response.

Note that the default value of this argument is a vector of zeros even if you specify the `'Offset'` name-value pair argument when fitting a model. If you specify `'Offset'` for fitting, the software treats the offset as an additional predictor with a coefficient value fixed at 1. In other words, the formula for fitting is

$$f(\mu) = \text{Offset} + X*b,$$

where f is the link function, μ is the mean response, and $X*b$ is the linear combination of predictors X . The `Offset` predictor has coefficient 1.

Data Types: `single` | `double`

Output Arguments

ysim — Simulated response values

numeric vector

Simulated response values, returned as a numeric vector. The simulated values are the predicted response values at X_{new} perturbed by random noise with the distribution given by the fitted model. The values in `ysim` are independent, conditional on the predictors. For binomial and Poisson fits, `random` generates `ysim` with the specified distribution and no adjustment for any estimated dispersion.

- If `'BinomialSize'` is 1 (default), then each value in the output `ysim` is the probability of success.
- If `'BinomialSize'` is not 1, then each value in the output `ysim` is the predicted number of successes in the trials.

Alternative Functionality

For predictions without random noise, use `predict` or `feval`.

- `predict` accepts a single input argument containing all predictor variables, and gives confidence intervals on its predictions.
- `feval` accepts multiple input arguments with one input for each predictor variable, which is simpler to use with a model created from a table or dataset array. The `feval` function does not support the name-value pair arguments `'Offset'` and `'BinomialSize'`. The function uses 0 as the offset value, and the output values are predicted probabilities.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen` to generate code for the `random` function. Save a trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `random` function. Then use `codegen` to generate code for the entry-point function.
- `random` can return a different sequence of numbers than MATLAB if either of the following is true:
 - The output is nonscalar.
 - An input parameter is invalid for the distribution.
- This table contains notes about the arguments of `random`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
mdl	For the usage notes and limitations of the model object, see “Code Generation” on page 32-727 of the <code>CompactGeneralizedLinearModel</code> object.
Xnew	<ul style="list-style-type: none"> For general code generation, Xnew must be a single-precision or double-precision matrix or a table containing single or double predictor variables. <p>If you want to specify Xnew as a table, then your model must be trained using a table, and you must ensure that your entry-point function for prediction:</p> <ul style="list-style-type: none"> Accepts data as arrays Creates a table from the data input arguments and specifies the variable names in the table Passes the table to random <p>For an example of this table workflow, see “Generate Code to Classify Numeric Data in Table” on page 31-88. For more information on using tables in code generation, see “Code Generation for Tables” (MATLAB Coder) and “Table Limitations for Code Generation” (MATLAB Coder).</p> <ul style="list-style-type: none"> The number of rows, or observations, in Xnew can be a variable size, but the number of columns in Xnew must be fixed.
Name-value pair arguments	Names in name-value pair arguments must be compile-time constants. For example, to use the 'BinomialSize' name-value pair argument in the generated code, include <code>{coder.Constant('BinomialSize'),0}</code> in the -args value of codegen.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2012a

random

Class: `GeneralizedLinearMixedModel`

Generate random responses from fitted generalized linear mixed-effects model

Syntax

```
ysim = random(glme)
ysim = random(glme,tblnew)
ysim = random( ____,Name,Value)
```

Description

`ysim = random(glme)` returns simulated responses, `ysim`, from the fitted generalized linear mixed-effects model `glme`, at the original design points.

`ysim = random(glme,tblnew)` returns simulated responses using new input values specified in the table or dataset array, `tblnew`.

`ysim = random(____,Name,Value)` returns simulated responses using additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes. For example, you can specify observation weights, binomial sizes, or offsets for the model.

Input Arguments

`glme` — Generalized linear mixed-effects model

`GeneralizedLinearMixedModel` object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

`tblnew` — New input data

table | dataset array

New input data, which includes the response variable, predictor variables, and grouping variables on page 2-45, specified as a table or dataset array. The predictor variables can be continuous or grouping variables. `tblnew` must contain the same variables as the original table or dataset array, `tbl`, used to fit the generalized linear mixed-effects model `glme`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1, . . . ,NameN,ValueN`.

`BinomialSize` — Number of trials for binomial distribution

`ones(m,1)` (default) | m -by-1 vector of positive integer values

Number of trials for binomial distribution, specified as the comma-separated pair consisting of `'BinomialSize'` and an m -by-1 vector of positive integer values, where m is the number of rows in

`tblnew`. The 'BinomialSize' name-value pair applies only to the binomial distribution. The value specifies the number of binomial trials when generating the random response values.

Data Types: `single` | `double`

Offset — Model offset

`zeros(m,1)` (default) | vector of scalar values

Model offset, specified as a vector of scalar values of length m , where m is the number of rows in `tblnew`. The offset is used as an additional predictor and has a coefficient value fixed at 1.

Weights — Observation weights

m -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an m -by-1 vector of nonnegative scalar values, where m is the number of rows in `tblnew`. If the response distribution is binomial or Poisson, then 'Weights' must be a vector of positive integers.

Data Types: `single` | `double`

Output Arguments

`ysim` — Simulated response values

m -by-1 vector

Simulated response values, returned as an m -by-1 vector, where m is the number of rows in `tblnew`. `random` creates `ysim` by first generating the random-effects vector based on its fitted prior distribution. `random` then generates `ysim` from its fitted conditional distribution given the random effects. `random` takes into account the effect of observation weights specified when fitting the model using `fitglm`, if any.

Examples

Simulate Random Responses From a GLME Model

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)

- Number of defects in the batch (defects)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', 'Di
```

Use `random` to simulate a new response vector from the fitted model.

```
rng(0, 'twister'); % For reproducibility
ynew = random(glme);
```

Display the first 10 rows of the simulated response vector.

```
ynew(1:10)
```

```
ans = 10×1
```

```
3
3
1
7
5
```

```
8
7
9
5
9
```

Simulate a new response vector using new input values. Create a new table by copying the first 10 rows of `mfr` into `tblnew`.

```
tblnew = mfr(1:10,:);
```

The first 10 rows of `mfr` include data collected from trials 1 through 5 for factories 1 and 2. Both factories used the old process for all of their trials during the experiment, so `newprocess = 0` for all 10 observations.

Change the value of `newprocess` to 1 for the observations in `tblnew`.

```
tblnew.newprocess = ones(height(tblnew),1);
```

Simulate new responses using the new input values in `tblnew`.

```
ynew2 = random(glme,tblnew)
```

```
ynew2 = 10×1
```

```
2
3
5
4

2
2
1
2
0
```

More About

Conditional Distribution Method

`random` generates random data from the fitted generalized linear mixed-effects model as follows:

- Sample $b_{sim} \sim P(b | \hat{\theta}, \hat{\sigma}^2)$, where $P(b | \hat{\theta}, \hat{\sigma}^2)$ is the estimated prior distribution of random effects, and $\hat{\theta}$ is a vector of estimated covariance parameters, and $\hat{\sigma}^2$ is the estimated dispersion parameter.
- Given b_{sim} , for $i = 1$ to m , sample $y_{sim_i} \sim P(y_{new_i} | b_{sim}, \hat{\beta}, \hat{\theta}, \hat{\sigma}^2)$, where $P(y_{new_i} | b_{sim}, \hat{\beta}, \hat{\theta}, \hat{\sigma}^2)$ is the conditional distribution of the i th new response y_{new_i} given b_{sim} and the model parameters.

GeneralizedLinearMixedModel | fitglme | fitted | predict

random

Random variate from Gaussian mixture distribution

Syntax

```
Y = random(gm)
Y = random(gm,n)
[Y,compIdx] = random( ___ )
```

Description

`Y = random(gm)` generates a 1-by- m random variate from the m -dimensional Gaussian mixture distribution `gm`.

`Y = random(gm,n)` returns n random variates. Each row of `Y` is a random variate generated from the m -dimensional Gaussian mixture distribution `gm`.

`[Y,compIdx] = random(___)` also returns an n -by-1 index vector `compIdx` for any of the input arguments in previous syntaxes. `compIdx(i)` indicates the mixture component used to generate the i th random variate `Y(i,:)`.

Examples

Generate Random Variates

Create a `gmdistribution` object and generate random variates.

Define the distribution parameters (means and covariances) of a two-component bivariate Gaussian mixture distribution.

```
mu = [1 2;-3 -5];
sigma = [1 1]; % shared diagonal covariance matrix
```

Create a `gmdistribution` object by using the `gmdistribution` function. By default, the function creates an equal proportion mixture.

```
gm = gmdistribution(mu,sigma)
```

```
gm =
```

```
Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.500000
Mean:      1      2
```

```
Component 2:
Mixing proportion: 0.500000
Mean:     -3     -5
```

Generate 1000 random variates.

```
rng('default'); % For reproducibility
[Y,compIdx] = random(gm,1000);
```

`compIdx(i)` indicates the mixture component used to generate the i th random variate $Y(i, :)$. Count the number of random variates generated by Component 1.

```
numIdx1 = sum(compIdx == 1)
```

```
numIdx1 = 512
```

`random` generates about half of the random variates using Component 1 because `gm` has equal mixing proportions.

Plot the generated random variates by using `scatter`.

```
scatter(Y(:,1),Y(:,2),10, '.') % Scatter plot with points of size 10
```

Reset Random Number Generator

Reset the random number generator to generate the same random variate.

Define the distribution parameters (means, covariances, and mixing proportions) of two bivariate Gaussian mixture components.

```

p = [0.4 0.6];           % Mixing proportions
mu = [1 2;-3 -5];      % Means
sigma = cat(3,[2 .5],[1 1]) % Covariances 1-by-2-by-2 array

sigma =
sigma(:,:,1) =

    2.0000    0.5000

sigma(:,:,2) =

    1    1

```

The `cat` function concatenates the covariances along the third array dimension. The defined covariance matrices are diagonal matrices. `sigma(1,:,i)` contains the diagonal elements of the covariance matrix of component `i`.

Create a `gmdistribution` object by using the `gmdistribution` function.

```
gm = gmdistribution(mu,sigma);
```

Save the current state of the random number generator, and then generate a random variate using `gm`.

```

s = rng;
r = random(gm)

r = 1×2

   -1.1661   -7.2588

```

Restore the state of the random number generator to `s`, and then generate a random variate using `gm`. The values are the same as before.

```

rng(s);
r1 = random(gm)

r1 = 1×2

   -1.1661   -7.2588

```

Input Arguments

gm — Gaussian mixture distribution

`gmdistribution` object

Gaussian mixture distribution, also called Gaussian mixture model (GMM), specified as a `gmdistribution` object.

You can create a `gmdistribution` object using `gmdistribution` or `fitgmdist`. Use the `gmdistribution` function to create a `gmdistribution` object by specifying the distribution parameters. Use the `fitgmdist` function to fit a `gmdistribution` model to data given a fixed number of components.

n — Number of random variates

1 (default) | positive integer

Number of random variates to generate, specified as a positive integer.

Data Types: single | double

Output Arguments**Y — Random variate**1-by-*m* numeric vector | *n*-by-*m* numeric matrixRandom variate, returned as a 1-by-*m* numeric vector or an *n*-by-*m* numeric matrix. Each row of *Y* is a random variate generated from the *m*-dimensional Gaussian mixture distribution *gm*.**compIdx — Component index**positive integer | *n*-by-1 numeric vectorComponent index, returned as a positive integer or an *n*-by-1 index vector, where `compIdx(i)` indicates the mixture component used to generate the *i*th random variate $Y(i, :)$.**See Also**

random

Package:

Simulate responses with random noise for linear regression model

Syntax

```
ysim = random mdl, Xnew
```

Description

`ysim = random(mdl, Xnew)` simulates responses to the predictor data in `Xnew` using the linear model `mdl`, adding random noise.

Examples

Simulate Response Data with Random Noise

Create a quadratic model of car mileage as a function of weight from the `carsmall` data set.

```
load carsmall
X = Weight;
y = MPG;
mdl = fitlm(X,y, 'quadratic');
```

Create simulated responses to the data with random noise.

```
ysim = random(mdl,X);
```

Plot the original responses and the simulated responses to see how they differ.

```
plot(X,y, 'o', X, ysim, 'x')
legend('Data', 'Simulated')
```

Input Arguments

mdl — Linear regression model object

LinearModel object | CompactLinearModel object

Linear regression model object, specified as a LinearModel object created by using `fitlm` or `stepwiselm`, or a CompactLinearModel object created by using `compact`.

Xnew — New predictor input values

table | dataset array | matrix

New predictor input values, specified as a table, dataset array, or matrix. Each row of `Xnew` corresponds to one observation, and each column corresponds to one variable.

- If `Xnew` is a table or dataset array, it must contain predictors that have the same predictor names as in the `PredictorNames` property of `mdl`.
- If `Xnew` is a matrix, it must have the same number of variables (columns) in the same order as the predictor input used to create `mdl`. Note that `Xnew` must also contain any predictor variables that are not used as predictors in the fitted model. Also, all variables used in creating `mdl` must be numeric. To treat numerical predictors as categorical, identify the predictors using the `'CategoricalVars'` name-value pair argument when you create `mdl`.

Data Types: single | double | table

Output Arguments

ysim — Simulated response values

numeric vector

Simulated response value, returned as a numeric vector. The simulated value is the predicted response values at X_{new} perturbed by random noise. The noise is independent and normally distributed, with mean equal to zero and variance equal to the estimated error variance of the model.

Alternative Functionality

For predictions without random noise, use `predict` or `feval`. These two functions give the same predictions.

- `predict` accepts a single input argument containing all predictor variables, and gives confidence intervals on its predictions.
- `feval` accepts multiple input arguments with one input for each predictor variable.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen` to generate code for the `random` function. Save a trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `random` function. Then use `codegen` to generate code for the entry-point function.
- `random` can return a different sequence of numbers than MATLAB if either of the following is true:
 - The output is nonscalar.
 - An input parameter is invalid for the distribution.
- This table contains notes about the arguments of `random`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
<code>mdl</code>	<ul style="list-style-type: none"> • Suppose you train a linear model by using <code>fitlm</code> and specifying 'RobustOpts' as a structure with an anonymous function handle for the <code>RobustWgtFun</code> field, use <code>saveLearnerForCoder</code> to save the model, and then use <code>loadLearnerForCoder</code> to load the model. In this case, <code>loadLearnerForCoder</code> cannot restore the <code>Robust</code> property into the MATLAB Workspace. However, <code>loadLearnerForCoder</code> can load the model at compile time within an entry-point function for code generation. • For the usage notes and limitations of the model object, see "Code Generation" on page 32-717 of the <code>CompactLinearModel</code> object.

Argument	Notes and Limitations
Xnew	<ul style="list-style-type: none"> For general code generation, Xnew must be a single-precision or double-precision matrix or a table containing single or double predictor variables. <p>If you want to specify Xnew as a table, then your model must be trained using a table, and you must ensure that your entry-point function for prediction:</p> <ul style="list-style-type: none"> Accepts data as arrays Creates a table from the data input arguments and specifies the variable names in the table Passes the table to random <p>For an example of this table workflow, see “Generate Code to Classify Numeric Data in Table” on page 31-88. For more information on using tables in code generation, see “Code Generation for Tables” (MATLAB Coder) and “Table Limitations for Code Generation” (MATLAB Coder).</p> <ul style="list-style-type: none"> The number of rows, or observations, in Xnew can be a variable size, but the number of columns in Xnew must be fixed.

Introduced in R2012a

random

Class: LinearMixedModel

Generate random responses from fitted linear mixed-effects model

Syntax

```
ysim = random(lme)
ysim = random(lme,tblnew)
ysim = random(lme,Xnew,Znew)
ysim = random(lme,Xnew,Znew,Gnew)
```

Description

`ysim = random(lme)` returns a vector of simulated responses `ysim` from the fitted linear mixed-effects model `lme` at the original fixed- and random-effects design points, used to fit `lme`.

`random` simulates new random-effects vector and new observation errors. So, the simulated response is

$$y_{sim} = X\hat{\beta} + Z\hat{b} + \varepsilon,$$

where $\hat{\beta}$ is the estimated fixed-effects coefficients, \hat{b} is the new random effects, and ε is the new observation error.

`random` also accounts for the effect of observation weights, if you use any when fitting the model.

`ysim = random(lme,tblnew)` returns a vector of simulated responses `ysim` from the fitted linear mixed-effects model `lme` at the values in the new table or dataset array `tblnew`. Use a table or dataset array for `random` if you use a table or dataset array for fitting the model `lme`.

`ysim = random(lme,Xnew,Znew)` returns a vector of simulated responses `ysim` from the fitted linear mixed-effects model `lme` at the values in the new fixed- and random-effects design matrices, `Xnew` and `Znew`, respectively. `Znew` can also be a cell array of matrices. Use the matrix format for `random` if you use design matrices for fitting the model `lme`.

`ysim = random(lme,Xnew,Znew,Gnew)` returns a vector of simulated responses `ysim` from the fitted linear mixed-effects model `lme` at the values in the new fixed- and random-effects design matrices, `Xnew` and `Znew`, respectively, and the grouping variable `Gnew`.

`Znew` and `Gnew` can also be cell arrays of matrices and grouping variables, respectively.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a LinearMixedModel object constructed using `fitlme` or `fitlmematrix`.

tblnew — New input data

table | dataset array

New input data, which includes the response variable, predictor variables, and grouping variables on page 2-45, specified as a table or dataset array. The predictor variables can be continuous or grouping variables. `tblnew` must have the same variables as in the original table or dataset array used to fit the linear mixed-effects model `lme`.

Xnew — New fixed-effects design matrix*n*-by-*p* matrix

New fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations and *p* is the number of fixed predictor variables. Each row of *X* corresponds to one observation and each column of *X* corresponds to one variable.

Data Types: single | double

Znew — New random-effects design*n*-by-*q* matrix | cell array of length *R*

New random-effects design, specified as an *n*-by-*q* matrix or a cell array of *R* design matrices $Z\{r\}$, where $r = 1, 2, \dots, R$. If *Znew* is a cell array, then each $Z\{r\}$ is an *n*-by-*q*(*r*) matrix, where *n* is the number of observations, and *q*(*r*) is the number of random predictor variables.

Data Types: single | double | cell

Gnew — New grouping variable or variablesvector | cell array of grouping variables of length *R*

New grouping variable or variables on page 2-45, specified as a vector or a cell array, of length *R*, of grouping variables used to fit the linear mixed-effects model, `lme`.

`random` treats all levels of each grouping variable as new levels. It draws an independent random effects vector for each level of each grouping variable.

Data Types: single | double | categorical | logical | char | string | cell

Output Arguments**ysim — Simulated response values***n*-by-1 vector

Simulated response values, returned as an *n*-by-1 vector, where *n* is the number of observations.

Examples**Generate Random Responses at the Original Design Values**

Load the sample data.

```
load('fertilizer.mat');
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five

different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Generate random response values at the original design points. Display the first five values.

```
rng(123, 'twister') % For reproducibility
ysim = random(lme);
ysim(1:5)
```

```
ans = 5×1
```

```
114.8785
134.2018
154.2818
169.7554
84.6089
```

Plot Randomly Generated vs. Observed Response Values

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, with a fixed-effects for `Weight`, and a random intercept grouped by `Model_Year`. First, store the data in a table.

```
tbl = table(MPG, Weight, Model_Year);
lme = fitlme(tbl, 'MPG ~ Weight + (1|Model_Year)');
```

Randomly generate responses using the original data.

```
rng(123, 'twister') % For reproducibility
ysim = random(lme, tbl);
```

Plot the original and the randomly generated responses to see how they differ. Group them by model year.

```
figure()
gscatter(Weight, MPG, Model_Year)
```

```
hold on
gscatter(Weight,ysim,Model_Year,[],'o+x')
legend('70-data','76-data','82-data','70-sim','76-sim','82-sim')
hold off
```

Note that the simulated random response values for year 82 are lower than the original data for that year. This might be due to a lower simulated random effect for year 82 than the estimated random effect in the original data.

Generate Responses Using a New Dataset Array

Load the sample data.

```
load('fertilizer.mat');
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where Fertilizer and Tomato are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Create a new dataset array with design values. The new dataset array must have the same variables as the original dataset array you use for fitting the model lme.

```
dsnew = dataset();
dsnew.Soil = nominal({'Sandy'; 'Silty'; 'Silty'});
dsnew.Tomato = nominal({'Cherry'; 'Vine'; 'Plum'});
dsnew.Fertilizer = nominal([2; 2; 4]);
```

Generate random responses at the new points.

```
rng(123, 'twister') % For reproducibility
ysim = random(lme, dsnew)
```

```
ysim = 3×1
```

```
    99.6006
   101.9911
   161.4026
```

Generate Random Responses Using New Design Matrices

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and cylinders, and potentially correlated random effect for intercept and acceleration grouped by model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
Z = [ones(406,1) Acceleration];
Model_Year = nominal(Model_Year);
G = Model_Year;
```

Now, fit the model using fitlmematrix with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X, MPG, Z, G, 'FixedEffectPredictors', ...
{'Intercept', 'Acceleration', 'Horsepower'}, 'RandomEffectPredictors', ...
{{'Intercept', 'Acceleration'}}, 'RandomEffectGroups', {'Model_Year'});
```

Create the design matrices that contain the data at which to predict the response values. Xnew must have three columns as in X. The first column must be a column of 1s. And the values in the last two

columns must correspond to `Acceleration` and `Horsepower`, respectively. The first column of `Znew` must be a column of 1s, and the second column must contain the same `Acceleration` values as in `Xnew`. The original grouping variable in `G` is the model year. So, `Gnew` must contain values for the model year. Note that `Gnew` must contain nominal values.

```
Xnew = [1,13.5,185; 1,17,205; 1,21.2,193];
Znew = [1,13.5; 1,17; 1,21.2];
Gnew = nominal([73 77 82]);
```

Generate random responses for the data in the new design matrices.

```
rng(123,'twister') % For reproducibility
ysim = random(lme,Xnew,Znew,Gnew)

ysim = 3×1

    15.7416
    10.6085
     6.8796
```

Now, repeat the same for a linear mixed-effects model with uncorrelated random-effects terms for intercept and acceleration. First, change the original random effects design and the random effects grouping variables. Then, fit the model.

```
Z = {ones(406,1),Acceleration};
G = {Model_Year,Model_Year};

lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{'Intercept'},{'Acceleration'}},'RandomEffectGroups',{'Model_Year','Model_Year'});
```

Now, recreate the new random effects design, `Znew`, and the grouping variable design, `Gnew`, using which to predict the response values.

```
Znew = {[1;1;1],[13.5;17;21.2]};
MY = nominal([73 77 82]);
Gnew = {MY,MY};
```

Generate random responses using the new design matrices.

```
rng(123,'twister') % For reproducibility
ysim = random(lme,Xnew,Znew,Gnew)

ysim = 3×1

    16.8280
    10.4375
     4.1027
```

`LinearMixedModel` | `fitlme` | `fitlmematrix` | `predict`

random

Class: NonLinearModel

Simulate responses for nonlinear regression model

Syntax

```
ysim = random mdl
ysim = random mdl, Xnew
ysim = random mdl, Xnew, 'Weights', W
```

Description

`ysim = random(mdl)` simulates responses from the fitted nonlinear model `mdl` at the original design points.

`ysim = random(mdl, Xnew)` simulates responses from the fitted nonlinear model `mdl` to the data in `Xnew`, adding random noise.

`ysim = random(mdl, Xnew, 'Weights', W)` simulates responses using the observation weights, `W`.

Input Arguments

mdl

Nonlinear regression model, constructed by `fitnlm`.

Xnew

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

W

Vector of real, positive value weights or a function handle.

- If you specify a vector, then it must have the same number of elements as the number of observations (or rows) in `Xnew`.
- If you specify a function handle, the function must accept a vector of predicted response values as input, and returns a vector of real positive weights as output.

Given weights, `W`, `random` estimates the error variance at observation `i` by $MSE * (1/W(i))$, where `MSE` is the mean squared error.

Default: No weights

Output Arguments

`ysim`

Vector of predicted mean values at `Xnew`, perturbed by random noise. The noise is independent, normally distributed, with mean zero, and variance equal to the estimated error variance of the model.

Examples

Simulate Responses

Create a nonlinear model of car mileage as a function of weight, and simulate the response.

Create an exponential model of car mileage as a function of weight from the `carsmall` data. Scale the weight by a factor of 1000 so all the variables are roughly equal in size.

```
load carsmall
X = Weight;
y = MPG;
modelfun = 'y ~ b1 + b2*exp(-b3*x/1000)';
beta0 = [1 1 1];
mdl = fitnlm(X,y,modelfun,beta0);
```

Create simulated responses to the data.

```
Xnew = X;
ysim = random(mdl,Xnew);
```

Plot the original responses and the simulated responses to see how they differ.

```
plot(X,y,'o',X,ysim,'x')
legend('Data','Simulated')
```

Alternatives

For predictions without added noise, use `predict`.

random

Class: RepeatedMeasuresModel

Generate new random response values given predictor values

Syntax

```
ysim = random(rm, tnew)
```

Description

`ysim = random(rm, tnew)` generates random response values from the repeated measures model `rm` using the predictor variables from table `tnew`.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

tnew — New data

table used to create `rm` (default) | table

New data including the values of the response variables and the between-subject factors used as predictors in the repeated measures model, `rm`, specified as a table. `tnew` must contain all of the between-subject factors used to create `rm`.

Output Arguments

ysim — Random response values

n-by-*r* matrix

Random response values random generates, returned as an *n*-by-*r* matrix, where *n* is the number of rows in `tnew`, and *r* is the number of repeated measures in `rm`.

Examples

Randomly Generate New Response Values

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the `species` is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Randomly generate new response values.

```
ysim = random(rm);
```

`random` uses the predictor values in the original sample data you use to fit the repeated measures model `rm` in table `t`.

Randomly Generate Response Values Using New Data

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the `group-gender` interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between,'y1-y8 ~ Group*Gender + Age + IQ','WithinDesign',within);
```

Define a table with new values for the predictor variables.

```
tnew = table(16,93,{'B'},{'Male'},'VariableNames',{'Age','IQ','Group','Gender'})
```

```
tnew=1x4 table
  Age    IQ    Group    Gender
  ---    ---    ---      ---
  16     93    {'B'}    {'Male'}
```

Randomly generate new response values using the values in the new table `tnew`.

```
ysim = random(rm,tnew)
```

```
ysim = 1x8
```

```
46.2252    66.8003   -40.4987   -1.9930    27.5213   -37.9809    4.8905   -3.7568
```

Algorithms

random computes `ysim` by creating predicted values and adding random noise values. For each row, the noise has a multivariate normal distribution with covariance the same as `rm.Covariance`.

`fitrm` | `predict`

randomEffects

Class: GeneralizedLinearMixedModel

Estimates of random effects and related statistics

Syntax

```
B = randomEffects(glme)
[B,BNames] = randomEffects(glme)
[B,BNames,stats] = randomEffects(glme)
[B,BNames,stats] = randomEffects(glme,Name,Value)
```

Description

`B = randomEffects(glme)` returns the estimates of the empirical Bayes predictors (EPBs) of random effects in the generalized linear mixed-effects model `glme` conditional on the estimated covariance parameters and the observed response.

`[B,BNames] = randomEffects(glme)` also returns the names of the coefficients, `BNames`. Each name corresponds to a coefficient in `B`.

`[B,BNames,stats] = randomEffects(glme)` also returns related statistics, `stats`, for the estimated EPBs of random effects in `glme`.

`[B,BNames,stats] = randomEffects(glme,Name,Value)` returns any of the above output arguments using additional options specified by one or more `Name, Value` pair arguments. For example, you can specify the confidence interval level, or the method for computing the approximate degrees of freedom.

Input Arguments

`glme` — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Alpha — Significance level

0.05 (default) | scalar value in the range [0,1]

Significance level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range [0,1]. For a value α , the confidence level is $100 \times (1 - \alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha', 0.01

Data Types: single | double

DFMethod — Method for computing approximate degrees of freedom

'residual' (default) | 'none'

Method for computing approximate degrees of freedom, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

Value	Description
'residual'	The degrees of freedom value is assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
'none'	The degrees of freedom is set to infinity.

Example: 'DFMethod', 'none'

Output Arguments

B — Estimated empirical Bayes predictors for the random effects

column vector

Estimated empirical Bayes predictors (EBPs) for the random effects in the generalized linear mixed-effects model `glme`, returned as a column vector. The EBPs in `B` are approximated by the mode of the empirical posterior distribution of the random effects given the estimated covariance parameters and the observed response.

Suppose `glme` has R grouping variables g_1, g_2, \dots, g_R , with levels m_1, m_2, \dots, m_R , respectively. Also suppose q_1, q_2, \dots, q_R are the lengths of the random-effects vectors that are associated with g_1, g_2, \dots, g_R , respectively. Then, `B` is a column vector of length $q_1*m_1 + q_2*m_2 + \dots + q_R*m_R$.

`randomEffects` creates `B` by concatenating the empirical Bayes predictors of random-effects vectors corresponding to each level of each grouping variable as `[g1level1; g1level2; ...; g1levelm1; g2level1; g2level2; ...; g2levelm2; ...; gRlevel1; gRlevel2; ...; gRlevelmR]`'.

BNames — Names of random-effects coefficients

table

Names of random-effects coefficients in `B`, returned as a table.

stats — Estimated empirical Bayes predictors and related statistics

table

Estimated empirical Bayes predictors (EBPs) and related statistics for the random effects in the generalized linear mixed-effects model `glme`, returned as a table. `stats` has one row for each of the random effects, and one column for each of the following statistics.

Column Name	Description
Group	Grouping variable associated with the random effect

Column Name	Description
Level	Level within the grouping variable corresponding to the random effect
Name	Name of the random-effect coefficient
Estimate	Empirical Bayes predictor (EBP) of random effect
SEPred	Square root of the conditional mean squared error of prediction (CMSEP) given covariance parameters and response
tStat	<i>t</i> -statistic for a test that the random-effects coefficient is equal to 0
DF	Estimated degrees of freedom for the <i>t</i> -statistic
pValue	<i>p</i> -value for the <i>t</i> -statistic
Lower	Lower limit of a 95% confidence interval for the random-effects coefficient
Upper	Upper limit of a 95% confidence interval for the random-effects coefficient

`randomEffects` computes the confidence intervals using the conditional mean squared error of prediction (CMSEP) approach conditional on the estimated covariance parameters and the observed response. An alternative interpretation of the confidence intervals is that they are approximate Bayesian credible intervals conditional on the estimated covariance parameters and the observed response.

When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods ('MPL' or 'REMP'), `randomEffects` computes confidence intervals and related statistics based on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Examples

Compute and Plot Estimated Random Effects

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)

- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', 'Di

Each row of **B** contains the estimated EPB for the random-effects coefficient named in the corresponding row of **Bnames**. For example, the value -0.2633 in row 3 of **B** is the estimated EPB for '(Intercept)' for level '3' of factory.

Compute 99% Confidence Intervals for Random Effects

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (**newprocess**)
- Processing time for each batch, in hours (**time**)
- Temperature of the batch, in degrees Celsius (**temp**)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (**supplier**)
- Number of defects in the batch (**defects**)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is `log`. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', ...
              'Distribution', 'Poisson', 'Link', 'log', 'FitMethod', 'Laplace', 'DummyVarCoding', 'effects');
```

Compute and display the 99% confidence intervals for the random-effects coefficients.

0.27195	94	0.78626	-0.50635	0.62319

The first three columns of `stats` contain the group name, level, and random-effects coefficient name. Column 4 contains the estimated EBP of the random-effects coefficient. The last two columns of `stats`, `Lower` and `Upper`, contain the lower and upper bounds of the 99% confidence interval, respectively. For example, for the coefficient for `'(Intercept)'` for level 3 of `factory`, the estimated EBP is -0.26325, and the 99% confidence interval is [-0.82191,0.29541].

randomEffects

Class: LinearMixedModel

Estimates of random effects and related statistics

Syntax

```
B = randomEffects(lme)
[B,Bnames] = randomEffects(lme)
[B,Bnames,stats] = randomEffects(lme)
[B,Bnames,stats] = randomEffects(lme,Name,Value)
```

Description

`B = randomEffects(lme)` returns the estimates of the best linear unbiased predictors (BLUPs) of random effects in the linear mixed-effects model `lme`.

`[B,Bnames] = randomEffects(lme)` also returns the names of the coefficients in `Bnames`. Each name corresponds to a coefficient in `B`.

`[B,Bnames,stats] = randomEffects(lme)` also returns the estimated BLUPs of random effects in the linear mixed-effects model `lme` and related statistics.

`[B,Bnames,stats] = randomEffects(lme,Name,Value)` also returns the BLUPs of random effects in the linear mixed-effects model `lme` and related statistics with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a LinearMixedModel object constructed using `fitlme` or `fitlmematrix`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Alpha — Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range 0 to 1. For a value α , the confidence level is $100*(1-\alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha',0.01

Data Types: single | double

DFMethod — Method for computing approximate degrees of freedom

'residual' (default) | 'satterthwaite' | 'none'

Method for computing approximate degrees of freedom for the t -statistics that test the random-effects coefficients against 0, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

'residual'	Default. The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
'satterthwaite'	Satterthwaite approximation.
'none'	All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

Example: 'DFMethod', 'satterthwaite'

Output Arguments

B — Estimated best linear unbiased predictors of random effects

column vector

Estimated best linear unbiased predictors of random effects of linear mixed-effects model `lme`, returned as a column vector.

Suppose `lme` has R grouping variables g_1, g_2, \dots, g_R , with levels m_1, m_2, \dots, m_R , respectively. Also suppose q_1, q_2, \dots, q_R are the lengths of the random-effects vectors that are associated with g_1, g_2, \dots, g_R , respectively. Then, `B` is a column vector of length $q_1*m_1 + q_2*m_2 + \dots + q_R*m_R$.

`randomEffects` creates `B` by concatenating the best linear unbiased predictors of random-effects vectors corresponding to each level of each grouping variable as `[g1level1; g1level2; ...; g1levelm1; g2level1; g2level2; ...; g2levelm2; ...; gRlevel1; gRlevel2; ...; gRlevelmR]`.

Bnames — Names of random-effects coefficients

table

Names of random-effects coefficients in `B`, returned as a table.

stats — Estimates of random effects BLUPs and related statistics

dataset array

Estimates of random effects BLUPs and related statistics, returned as a dataset array that has one row for each of the fixed effects and one column for each of the following statistics.

Group	Grouping variable associated with the random effect
Level	Level within the grouping variable corresponding to the random effect

Name	Name of the random-effect coefficient
Estimate	Best linear unbiased predictor (BLUP) of random effect
SEPred	Standard error of the estimate (BLUP minus random effect)
tStat	<i>t</i> -statistic for a test that the random effect is zero
DF	Estimated degrees of freedom for the <i>t</i> -statistic
pValue	<i>p</i> -value for the <i>t</i> -statistic
Lower	Lower limit of a 95% confidence interval for the random effect
Upper	Upper limit of a 95% confidence interval for the random effect

Examples

Display Random-Effects Estimates and Coefficient Names

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and potentially correlated random effects for intercept and acceleration, grouped by the model year. First, store the data in a table.

```
tbl = table(Acceleration,Horsepower,Model_Year,MPG);
```

Fit the model.

```
lme = fitlme(tbl, 'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');
```

Compute the BLUPs of the random-effects coefficients and display the names of the corresponding random effects.

```
[B,Bnames] = randomEffects(lme)
```

```
B = 26×1

Model_Year	{'(Intercept)' }	{'(Intercept)' }	{'std' }
Model_Year	{'Acceleration'}	{'(Intercept)' }	{'corr'}
Model_Year	{'Acceleration'}	{'Acceleration'}	{'std' }

Estimate	Lower	Upper
3.3475	1.2862	8.7119
-0.87971	-0.98501	-0.29675
0.33789	0.1825	0.62558

The correlation value suggests that random effects seem negatively correlated. Plot the random effects for intercept versus acceleration to confirm this.

```
plot(B(1:2:end),B(2:2:end),'r*')
```

Compute Random-Effects Estimates and Related Statistics

Load the sample data.

```
load('fertilizer.mat');
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Compute the BLUPs and related statistics for random effects.

```
[~,~,stats] = randomEffects(lme)
```

```
stats =
```

```
Random effect coefficients: DFMethod = 'Residual', Alpha = 0.05
```

The first three rows contain the random-effects estimates and the statistics for the three levels, Loamy, Sandy, and Silty of the grouping variable Soil. The corresponding p -values 0.66918, 0.51825, and 0.82593 indicate that these random-effects are not significantly different from 0. The following 15 rows include the BLUPs of random-effects estimates for the intercept, grouped by the variable Tomato nested in Soil, i.e. interaction of Tomato and Soil.

Compute Confidence Intervals with Specified Options

Load the sample data.

```
load shift
```

Fit a linear mixed-effects model with a random intercept grouped by operator, to assess if there is a significant difference in the performance according to the time of the shift. Use the restricted maximum likelihood method.

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)');
```

Compute the 99% confidence intervals for random effects using the residuals option to compute the degrees of freedom. This is the default method.

```
[~,~,stats] = randomEffects(lme, 'Alpha', 0.01)
```

```
stats =
```

```
Random effect coefficients: DFMethod = 'Residual', Alpha = 0.01
```

{'Operator'}	{'4'}	{'(Intercept)'}	2.3655	0.90378
{'Operator'}	{'5'}	{'(Intercept)'}	-1.9472	0.90378

tStat	DF	pValue	Lower	Upper
0.63902	6.4253	0.5449	-2.684	3.839
1.3009	6.4253	0.23799	-2.0858	4.4372
-2.4027	6.4253	0.050386	-5.433	1.09
2.6174	6.4253	0.037302	-0.89598	5.627
-2.1546	6.4253	0.071626	-5.2087	1.3142

The Satterthwaite method usually produces smaller values for the degrees of freedom (DF), which results in larger p-values (pValue) and larger confidence intervals (Lower and Upper) for the random-effects estimates.

randsample

Random sample

Syntax

```
y = randsample(n,k)
y = randsample(population,k)
y = randsample( ___, replacement)
y = randsample(n,k,true,w)
y = randsample(population,k,true,w)
y = randsample(s, ___)
```

Description

`y = randsample(n,k)` returns `k` values sampled uniformly at random, without replacement, from the integers 1 to `n`.

`y = randsample(population,k)` returns a vector of `k` values sampled uniformly at random, without replacement, from the values in the vector `population`.

`y = randsample(___, replacement)` returns a sample taken with replacement if `replacement` is `true`, or without replacement if `replacement` is `false`. Specify `replacement` following any of the input argument combinations in the previous syntaxes.

`y = randsample(n,k,true,w)` uses a vector of non-negative weights, `w`, whose length is `n`, to determine the probability that an integer `i` is selected as an entry for `y`.

`y = randsample(population,k,true,w)` uses a vector of nonnegative weights, `w`, of the same length as the vector `population`, to determine the probability that a value `population(i)` is selected as an entry for `y`.

`y = randsample(s, ___)` uses the stream `s` for random number generation. The option `s` can precede any of the input arguments in the previous syntaxes. `s` is a member of the `RandStream` class.

Examples

Sample Unique Value from Range

Draw a single value from the integers 1 through 10.

```
n = 10;
x = randsample(n,1)
```

```
x = 9
```

Sample from Population Vector

Create the random seed for reproducibility of the results.

```
s = RandStream('mlfg6331_64');
```

Draw a single value from the vector [10:20].

```
population = 10:20;
y = randsample(s,population,1)
```

```
y = 17
```

Generate Random Sequence for Specified Probabilities

Create the random number stream for reproducibility.

```
s = RandStream('mlfg6331_64');
```

Choose 48 characters randomly and with replacement from the sequence ACGT, according to the specified probabilities.

```
R = randsample(s,'ACGT',48,true,[0.15 0.35 0.35 0.15])
```

```
R =
'GGCGGCGCAAGGCGCCGGACCTGGCTGCACGCCGTTCCCTGCTACTCG'
```

Set Random Number Stream

Create the random number stream for reproducibility.

```
s = RandStream('mlfg6331_64');
```

Draw five values with replacement from the integers 1:10.

```
y = randsample(s,10,5,true)
```

```
y = 5×1
```

```
7
8
5
7
8
```

Input Arguments

n — Upper limit of range

positive integer

Upper limit of the range (1 to n) from which to sample, specified as a positive integer. By default, `randSample` samples uniformly at random, without replacement, from the values in the range 1 to n.

Data Types: `single` | `double`

population — Input data

vector

Input data from which to sample, specified as a vector. By default, `randSample` samples uniformly at random, without replacement, from the values in `population`. The orientation of `y` (row or column) is the same as that of `population`.

If `population` is a numeric vector containing only nonnegative integer values, and `population` can have the length 1, then use `y = population(randSample(length(population),k))` instead of `y = randSample(population,k)`.

Example: `y = randSample([50:100],20)` returns a vector of 20 values sampled uniformly at random, without replacement, from the `population` vector consisting of integers from 50 to 100.

Data Types: `single` | `double` | `logical` | `char` | `string` | `categorical`

k — Number of samples

positive integer

Number of samples, specified as a positive integer.

Example: `randSample(20,10)` returns a vector of 10 values sampled uniformly at random, without replacement, from the integers 1 to 20.

Data Types: `single` | `double`

replacement — Indicator for sampling with replacement

`false` (default) | `true`

Indicator for sampling with replacement, specified as either `false` or `true`.

Example: `randSample(10,2,true)` returns two values with replacement from the integers 1 to 10.

Data Types: `logical`

w — Sampling weights

`ones(n,1)` (default) | vector of nonnegative scalar values

Sampling weights, specified as a vector of nonnegative scalar values. The length of `w` must be equal to the range of integers to sample or the length of `population`. The vector `w` must have at least one positive value. If `w` contains negative values or NaN values, `randSample` displays an error message. The `randSample` function samples with probability proportional to $w(i)/\text{sum}(w)$. Usually, `w` is a vector of probabilities. The `randSample` function supports specifying weights only for sampling with replacement.

Example: `[0.1 0.5 0.35 0.46]`

Data Types: `single` | `double`

s — Random number stream

MATLAB default random number stream (default) | `RandStream`

Random number stream, specified as the MATLAB default random number stream or `RandStream`. For details, see “Creating and Controlling a Random Number Stream” (MATLAB).

Example: `s = RandStream('mlfg6331_64')` creates a random number stream that uses the multiplicative lagged Fibonacci generator algorithm.

Output Arguments

y – Sample

vector | scalar

Sample, returned as a vector or scalar.

- If $k = 1$, then y is a scalar.
- If $k > 1$, then y is a k -by-1 vector.

Tips

To sample data randomly, with or without replacement, use `datasample`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- When you sample without replacement, the order of the output values might not match the order in MATLAB.
- Code generation does not support the random number stream input argument `s`.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

Introduced before R2006a

randtool

Interactive random number generation

Syntax

`randtool`

Description

`randtool` opens the Random Number Generation Tool.

The Random Number Generation Tool is a graphical user interface that generates random samples from specified probability distributions and displays the samples as histograms. Use the tool to explore the effects of changing parameters and sample size on the distributions.

Start by selecting a distribution, then enter the desired sample size.

You can also

- Use the controls at the bottom of the window to set parameter values for the distribution and to change their upper and lower bounds.
- Draw another sample from the same distribution, with the same size and parameters.
- Export the current sample to your workspace. A dialog box enables you to provide a name for the sample.

`randttool` does not provide printing functionality in MATLAB Online.

Introduced before R2006a

range

Range of values

Syntax

```
y = range(X)
y = range(X, 'all')
y = range(X, dim)
y = range(X, vecdim)
```

Description

`y = range(X)` returns the difference between the maximum and minimum values of sample data in `X`.

- If `X` is a vector, then `range(X)` is the range of the values in `X`.
- If `X` is a matrix, then `range(X)` is a row vector containing the range of each column in `X`.
- If `X` is a multidimensional array, then `range` operates along the first nonsingleton dimension of `X`, treating the values as vectors. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same. If `X` is an empty array with first dimension 0, then `range(X)` returns an empty array with the same size as `X`.

`y = range(X, 'all')` returns the range of all elements in `X`.

`y = range(X, dim)` returns the range along the operating dimension `dim` of `X`. For example, if `X` is a matrix, then `range(X, 2)` is a column vector containing the range value of each row.

`y = range(X, vecdim)` returns the range over the dimensions specified in the vector `vecdim`. For example, if `X` is a matrix, then `range(X, [1 2])` is the range of all elements in `X` because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.

Examples

Range of Standard Normal Random Numbers

Generate five large samples of standard normal random numbers.

```
rng('default') % For reproducibility
rv = normrnd(0, 1, 1000, 5);
```

Find the range values of the samples.

```
near6 = range(rv)
```

```
near6 = 1×5
```

```
    6.8104    6.6420    6.9578    6.0860    6.8165
```

The range value is approximately 6 for each sample.

Range of Exam Scores

Find the range of exam scores over the course of five exams.

Load the examgrades data set.

```
load examgrades
```

Find the range of all exam scores.

```
y = range(grades, 'all')
```

```
y = 46
```

Range of Exam Scores by Student

Find the range of exam scores for each student over the course of five exams.

Load the examgrades data set.

```
load examgrades
```

Find the range of exam scores for the first 10 students. For example, the difference between the eighth student's best and worst exam scores is 7 points.

```
X = grades(1:10, :);
```

```
y = range(X, 2)
```

```
y = 10×1
```

```
12
13
10
12
8
16
14
7
12
10
```

Range Along Vector Dimension

Find the range of a multidimensional array over multiple dimensions.

Create a 3-by-5-by-2 array of normal random numbers with mean $\mu = 2$ and standard deviation $\sigma = 7$.

```
rng('default') % For reproducibility
mu = 2;
```

```
sigma = 7;
X = normrnd(mu,sigma,[3 5 2])

X =
X(:,:,1) =

    5.7637    8.0352   -1.0351   21.3861    7.0778
   14.8372    4.2314    4.3984   -7.4492    1.5586
  -13.8119   -7.1538   27.0488   23.2445    7.0032

X(:,:,2) =

    0.5652   11.8632   -6.4524    5.4223   -0.1241
    1.1310   11.9203    7.0207    9.2429    4.0571
   12.4279    6.7005   13.4116    7.0882   -3.5110
```

Find the range of each page of X by specifying dimensions 1 and 2 as the operating dimensions.

```
ypage = range(X,[1 2])
```

```
ypage =
ypage(:,:,1) =

    40.8607
```

```
ypage(:,:,2) =

    19.8641
```

For example, `ypage(1,1,2)` is the range of all the elements in $X(:,:,2)$.

Find the range of the elements in each $X(i, :, :)$ slice by specifying dimensions 2 and 3 as the operating dimensions.

```
yrow = range(X,[2 3])
```

```
yrow = 3×1

    27.8385
    22.2864
    40.8607
```

For example, `yrow(3)` is the range of all the elements in $X(3, :, :)$.

Input Arguments

X — Data sample

scalar | vector | matrix | multidimensional array

Data sample, specified as a scalar, vector, matrix, or multidimensional array.

- If X is a scalar, then $\text{range}(X)$ is 0.
- If X is a 0-by-0 empty array, then $\text{range}(X)$ is also an empty array.

Data Types: `single` | `double` | `logical` | `datetime` | `duration`

dim — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If you do not specify a value, then the default value is the first array dimension whose size does not equal 1.

dim indicates the dimension whose length reduces to 1. $\text{size}(y, \text{dim})$ is 1, while the sizes of all other dimensions remain the same unless $\text{size}(X, \text{dim})$ is 0. If $\text{size}(X, \text{dim})$ is 0, then $\text{range}(X, \text{dim})$ returns an empty array of the same size as X .

Consider a two-dimensional data sample X :

- If dim is equal to 1, then $\text{range}(X, 1)$ returns a row vector containing the range for each column.
- If dim is equal to 2, then $\text{range}(X, 2)$ returns a column vector containing the range for each row.

If dim is greater than $\text{ndims}(X)$, range returns an array of zeros with the same dimensions and missing values as X .

Data Types: `single` | `double`

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of vecdim represents a dimension of the input array X . The output y has length 1 in the specified operating dimensions. The other dimension lengths are the same for X and y .

For example, if X is a 2-by-3-by-3 array, then $\text{range}(X, [1\ 2])$ returns a 1-by-1-by-3 array. Each element of the output array is the range of the elements on the corresponding page of X .

Data Types: `single` | `double`

Output Arguments

y — Difference between maximum and minimum values

scalar | vector | matrix | multidimensional array

Difference between the maximum and minimum values, returned as a scalar, vector, matrix, or multidimensional array.

Tips

- `range` treats NaNs as missing values and ignores them.
- `range` provides an easily calculated estimate of the spread of a sample. Avoid using `range` with data that has outliers because they have an undue influence on this statistic.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

`iqr` | `mad` | `std`

Introduced before R2006a

rangesearch

Find all neighbors within specified distance using searcher object

Syntax

```
Idx = rangesearch(Mdl,Y,r)
Idx = rangesearch(Mdl,Y,r,Name,Value)
[Idx,D] = rangesearch( ___ )
```

Description

`Idx = rangesearch(Mdl,Y,r)` searches for all neighbors (i.e., points, rows, or observations) in `Mdl.X` within radius `r` of each point (i.e., row or observation) in the query data `Y` using an exhaustive search or a *Kd*-tree. `rangesearch` returns `Idx`, which is a column vector of the indices of `Mdl.X` within `r` units.

`Idx = rangesearch(Mdl,Y,r,Name,Value)` returns the indices of the observation in `Mdl.X` within radius `r` of each observation in `Y` with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify to use a different distance metric than is stored in `Mdl.Distance` or a different distance metric parameter than is stored in `Mdl.DistanceParameter`.

`[Idx,D] = rangesearch(___)` additionally returns the matrix `D` using any of the input arguments in the previous syntaxes. `D` contains the distances between the observations in `Mdl.X` within radius `r` of each observation in `Y`. By default, the function arranges the columns of `D` in ascending order by closeness, with respect to the distance metric.

Examples

Search for Neighbors Within a Radius Using *Kd*-tree and Exhaustive Search

`rangesearch` accepts `ExhaustiveSearcher` or `KDTreeSearcher` model objects to search the training data for the nearest neighbors to the query data. An `ExhaustiveSearcher` model invokes the exhaustive searcher algorithm, and a `KDTreeSearcher` model defines a *Kd*-tree, which `rangesearch` uses to search for nearest neighbors.

Load Fisher's iris data set. Randomly reserve five observations from the data for query data. Focus on the petal dimensions.

```
load fisheriris
rng(1); % For reproducibility
n = size(meas,1);
idx = randsample(n,5);
X = meas(~ismember(1:n,idx),3:4); % Training data
Y = meas(idx,3:4); % Query data
```

Grow a default two-dimensional *Kd*-tree.

```
MdlKDT = KDTreeSearcher(X)
```

```
MdlKDT =
  KDTreeSearcher with properties:

    BucketSize: 50
    Distance: 'euclidean'
    DistParameter: []
    X: [145x2 double]
```

MdlKDT is a KDTreeSearcher model object. You can alter its writable properties using dot notation.

Prepare an exhaustive nearest neighbor searcher.

```
MdlES = ExhaustiveSearcher(X)

MdlES =
  ExhaustiveSearcher with properties:

    Distance: 'euclidean'
    DistParameter: []
    X: [145x2 double]
```

MdlES is an ExhaustiveSearcher model object. It contains the options, such as the distance metric, to use to find nearest neighbors.

Alternatively, you can grow a Kd-tree or prepare an exhaustive nearest neighbor searcher using `createns`.

Search training data for the nearest neighbor indices that correspond to each query observation that are within a 0.5 cm radius. Conduct both types of searches and use the default settings.

```
r = 0.15; % Search radius
IdxKDT = rangesearch(MdlKDT,Y,r);
IdxES = rangesearch(MdlES,Y,r);
[IdxKDT IdxES]

ans=5x2 cell array
    {1x27 double}    {1x27 double}
    {[          13]}    {[          13]}
    {1x27 double}    {1x27 double}
    {1x2 double}     {1x2 double}
    {1x0 double}     {1x0 double}
```

IdxKDT and IdxES are cell arrays of vectors corresponding to the indices of X that are within 0.15 cm of the observations in Y. Each row of the index matrices corresponds to a query observation.

Compare the results between the methods.

```
cellfun(@isequal,IdxKDT,IdxES)

ans = 5x1 logical array

    1
    1
    1
    1
```

1

In this case, the results are the same.

Plot the results for the setosa irises.

```

setosaIdx = strcmp(species(~ismember(1:n,idx)), 'setosa');
XSetosa = X(setosaIdx, :);
ySetosaIdx = strcmp(species(idx), 'setosa');
YSetosa = Y(ySetosaIdx, :);

figure;
plot(XSetosa(:,1), XSetosa(:,2), '.k');
hold on;
plot(YSetosa(:,1), YSetosa(:,2), '*r');
for j = 1:sum(ySetosaIdx)
    c = YSetosa(j, :);
    circleFun = @(x1,x2)r^2 - (x1 - c(1)).^2 - (x2 - c(2)).^2;
    fimplicit(circleFun, [c(1) + [-1 1]*r, c(2) + [-1 1]*r], 'b-')
end
xlabel 'Petal length (cm)';
ylabel 'Petal width (cm)';
title 'Setosa Petal Measurements';
legend('Observations', 'Query Data', 'Search Radius');
axis equal
hold off

```

Search for Neighbors Within a Radius Using the Mahalanobis Distance

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(1); % For reproducibility
n = size(meas,1); % Sample size
qIdx = randsample(n,5); % Indices of query data
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);
```

Prepare a default exhaustive nearest neighbor searcher.

```
Mdl = ExhaustiveSearcher(X)
```

```
Mdl =
ExhaustiveSearcher with properties:
    Distance: 'euclidean'
  DistParameter: []
           X: [145x4 double]
```

Mdl is an ExhaustiveSearcher model.

Find the indices of the training data (X) that are within 0.15 cm of each point in the query data (Y). Specify that the distances are with respect to the Mahalanobis metric.

```
r = 1;
Idx = rangesearch(Mdl,Y,r,'Distance','mahalanobis')
```

```
Idx=5x1 cell array
    {1x15 double}
    {1x5 double}
    {1x6 double}
    {[ 84]}
    {[ 69]}
```

```
Idx{3}
```

```
ans = 1x6
     1    34    33    22    24     2
```

Each cell of Idx corresponds to a query data observation and contains in X a vector of indices of the neighbors within 0.15cm of the query data. rangesearch arranges the indices in ascending order by distance. For example, using the Mahalanobis distance, the second nearest neighbor of Y(3,:) is X(34,).

Compute Distances of Neighbors Within a Radius

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(4); % For reproducibility
n = size(meas,1); % Sample size
qIdx = randsample(n,5); % Indices of query data
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);
```

Grow a four-dimensional Kd-tree using the training data. Specify to use the Minkowski distance for finding nearest neighbors.

```
Mdl = KDTreeSearcher(X);
```

Mdl is a KDTreeSearcher model. By default, the distance metric for finding nearest neighbors is the Euclidean metric.

Find the indices of the training data (X) that are within 0.5 cm from each point in the query data (Y).

```
r = 0.5;
[Idx,D] = rangesearch(Mdl,Y,r);
```

Idx and D are five-element cell arrays of vectors. The vector values in Idx are the indices in X. The X indices represent the observations that are within 0.5 cm of the query data, Y. D contains the distances that correspond to the observations.

Display the results for query observation 3.

```
Idx{3}
```

```
ans = 1×2
    127    122
```

```
D{3}
```

```
ans = 1×2
    0.2646    0.4359
```

The closest observation to Y(3,:) is X(127,:), which is 0.2646 cm away. The next closest is X(122,:), which is 0.4359 cm away. All other observations are greater than 0.5 cm away from Y(5, :).

Input Arguments

Mdl — Nearest neighbor searcher

ExhaustiveSearcher model object | KDTreeSearcher model object

Nearest neighbor searcher, specified as an `ExhaustiveSearcher` or `KDTreeSearcher` model object, respectively.

If `Mdl` is an `ExhaustiveSearcher` model, then `rangesearch` searches for nearest neighbors using an exhaustive search. Otherwise, `rangesearch` uses the grown Kd-tree to search for nearest neighbors.

Y – Query data

numeric matrix

Query data, specified as a numeric matrix.

Y is an m -by- K matrix. Rows of Y correspond to observations (i.e., examples), and columns correspond to predictors (i.e., variables or features). Y must have the same number of columns as the training data stored in `Mdl.X`.

Data Types: `single` | `double`

r – Search radius

nonnegative scalar

Search radius around each point in the query data, specified as a nonnegative scalar.

`rangesearch` finds all observations in `Mdl.X` that are within distance `r` of each observation in Y. The property `Mdl.Distance` stores the distance.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Distance', 'minkowski', 'P', 3` specifies to find all observations in `Mdl.X` within distance `r` of each observation in Y, using the Minkowski distance metric with exponent 3.

For Both Nearest Neighbor Searchers

Distance – Distance metric

`Mdl.Distance` (default) | `'cityblock'` | `'euclidean'` | `'mahalanobis'` | `'minkowski'` | `'seuclidean'` | function handle | ...

Distance metric used to find neighbors of the training data to the query observations, specified as the comma-separated pair consisting of `'Distance'` and a character vector, string scalar, or function handle.

For both types of nearest neighbor searchers, `rangesearch` supports these distance metrics.

Value	Description
<code>'chebychev'</code>	Chebychev distance (maximum coordinate difference).
<code>'cityblock'</code>	City block distance.
<code>'euclidean'</code>	Euclidean distance.

Value	Description
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument.

If `Mdl` is an `ExhaustiveSearcher` model object, then `rangearch` also supports these distance metrics.

Value	Description
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'cosine'	One minus the cosine of the included angle between observations (treated as row vectors).
'hamming'	Hamming distance, which is the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix. To change the value of the covariance matrix, use the 'Cov' name-value pair argument.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between rows in <code>Mdl.X</code> and the query matrix is scaled by dividing by the corresponding element of the standard deviation computed from <code>Mdl.X</code> . To specify another scaling, use the 'Scale' name-value pair argument.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).

If `Mdl` is an `ExhaustiveSearcher` model object, then you can also specify a function handle for a custom distance metric by using `@` (for example, `@distfun`). The custom distance function must:

- Have the form `function D2 = distfun(ZI,ZJ)`.
- Take as arguments:
 - A 1-by- K vector `ZI` containing a single row from `Mdl.X` or `Y`, where K is the number of columns of `Mdl.X`.
 - An m -by- K matrix `ZJ` containing multiple rows of `Mdl.X` or `Y`, where m is a positive integer.
- Return an m -by-1 vector of distances `D2`, where `D2(j)` is the distance between the observations `ZI` and `ZJ(j,:)`.

For more details, see “Distance Metrics” on page 18-11.

Example: 'Distance', 'minkowski'

P — Exponent for Minkowski distance metric

2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of 'P' and a positive scalar. This argument is valid only if 'Distance' is 'minkowski'.

Example: 'P',3

Data Types: single | double

SortIndices — Flag to sort returned indices according to distance

true (1) (default) | false (0)

Flag to sort returned indices according to distance, specified as the comma-separated pair consisting of 'SortIndices' and either true (1) or false (0).

For faster performance when Y contains many observations that have many nearest points, you can set SortIndices to false. In this case, rangearch returns the indices of the nearest points in no particular order. When SortIndices is true, the function arranges the indices of the nearest points in ascending order by distance.

Example: 'SortIndices',false

Data Types: logical

For Exhaustive Nearest Neighbor Searchers

Cov — Covariance matrix for Mahalanobis distance metric

nancov(Mdl.X) (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix. Cov is a K -by- K matrix, where K is the number of columns of Mdl.X. If you specify Cov and do not specify 'Distance', 'mahalanobis', then rangearch returns an error message.

Example: 'Cov',eye(3)

Data Types: single | double

Scale — Scale parameter value for standardized Euclidean distance metric

nanstd(Mdl.X) (default) | nonnegative numeric vector

Scale parameter value for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of 'Scale' and a nonnegative numeric vector. Scale has length K , where K is the number of columns of Mdl.X.

The software scales each difference between the training and query data using the corresponding element of Scale. If you specify Scale and do not specify 'Distance', 'seuclidean', then rangearch returns an error message.

Example: 'Scale',quantile(Mdl.X,0.75) - quantile(Mdl.X,0.25)

Data Types: single | double

Note If you specify 'Distance', 'Cov', 'P', or 'Scale', then Mdl.Distance and Mdl.DistanceParameter do not change value.

Output Arguments

Idx — Training data indices of nearest neighbors

cell array of numeric vectors

Training data indices of nearest neighbors, returned as a cell array of numeric vectors.

Idx is an m -by-1 cell array such that cell j (Idx{j}) contains an m_j -dimensional vector of indices of the observations in $Mdl.X$ that are within r units to the query observation $Y(j, :)$. If SortIndices is true, then rangearch arranges the elements of the vectors in ascending order by distance.

D — Distances of nearest neighbors to the query data

cell array of numeric vectors

Distances of the neighbors to the query data, returned as a numeric matrix or cell array of numeric vectors.

D is an m -by-1 cell array such that cell j (D{j}) contains an m_j -dimensional vector of the distances that the observations in $Mdl.X$ are from the query observation $Y(j, :)$. All elements of the vector are less than r . If SortIndices is true, then rangearch arranges the elements of the vectors in ascending order.

Tips

knnsearch finds the k (positive integer) points in $Mdl.X$ that are k -nearest for each Y point. In contrast, rangearch finds all the points in $Mdl.X$ that are within distance r (positive scalar) of each Y point.

Alternative Functionality

rangearch is an object function that requires an ExhaustiveSearcher or a KDTreeSearcher model object, query data, and a distance. Under equivalent conditions, rangearch returns the same results as rangearch when you specify the name-value pair argument 'NSMethod', 'exhaustive' or 'NSMethod', 'kdtree', respectively.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- This table contains notes about the arguments of rangearch. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
Mdl	<p>There are two ways to use Mdl in code generation. For an example, see “Code Generation for Nearest Neighbor Searcher” on page 31-13.</p> <ul style="list-style-type: none"> Use <code>saveLearnerForCoder</code>, <code>loadLearnerForCoder</code>, and <code>codegen</code> to generate code for the <code>rangesearch</code> function. Save a trained model by using <code>saveLearnerForCoder</code>. Define an entry-point function that loads the saved model by using <code>loadLearnerForCoder</code> and calls the <code>rangesearch</code> function. Then use <code>codegen</code> to generate code for the entry-point function. Include <code>coder.Constant(Mdl)</code> in the <code>-args</code> value of <code>codegen</code>. <p>If Mdl is a <code>KDTreeSearcher</code> object, and the code generation build type is a MEX function, then <code>codegen</code> generates a MEX function using Intel Threading Building Blocks (TBB) for parallel computation. Otherwise, <code>codegen</code> generates code using <code>parfor</code>.</p> <ul style="list-style-type: none"> MEX function for the kd-tree search algorithm — <code>codegen</code> generates an optimized MEX function using Intel TBB for parallel computation on multicore platforms. You can use the MEX function to accelerate MATLAB algorithms. For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb. <p>If you generate the MEX function to test the generated code of the <code>parfor</code> version, you can disable the usage of Intel TBB. Set the <code>ExtrinsicCalls</code> property of the MEX configuration object to <code>false</code>. For details, see <code>coder.MexCodeConfig</code>.</p> <ul style="list-style-type: none"> MEX function for the exhaustive search algorithm and standalone C/C++ code for both algorithms — The generated code of <code>rangesearch</code> uses <code>parfor</code> to create loops that run in parallel on supported shared-memory multicore platforms in the generated code. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the <code>parfor</code>-loops as <code>for</code>-loops. To find supported compilers, see https://www.mathworks.com/support/compilers/current_release/. To disable OpenMP library, set the <code>EnableOpenMP</code> property of the configuration object to <code>false</code>. For details, see <code>coder.CodeConfig</code>.
'Distance'	<ul style="list-style-type: none"> Cannot be a custom distance function. Must be a compile-time constant; its value cannot change in the generated code.
'SortIndices'	Not supported. The output arguments are always sorted.
Name-value pair arguments	<p>Names in name-value pair arguments must be compile-time constants. For example, to allow a user-defined exponent for the Minkowski distance in the generated code, include <code>{coder.Constant('Distance'), coder.Constant('Minkowski'), coder.Constant('P'), 0}</code> in the <code>-args</code> value of <code>codegen</code>.</p>

Argument	Notes and Limitations
Idx	<ul style="list-style-type: none">• The sorted order of tied distances in the generated code can be different from the order in MATLAB due to numerical precision.• Starting in R2020a, rangesearch returns integer-type (int32) indices, rather than double-precision indices, in generated standalone C/C++ code. Therefore, the function allows for strict single-precision support when you use single-precision inputs. For MEX code generation, the function still returns double-precision indices to match the MATLAB behavior.

For more information, see “Introduction to Code Generation” on page 31-2 and “Code Generation for Nearest Neighbor Searcher” on page 31-13.

Topics

“k-Nearest Neighbor Search and Radius Search” on page 18-13

“Distance Metrics” on page 18-11

Introduced in R2011b

rangesearch

Find all neighbors within specified distance using input data

Syntax

```
Idx = rangesearch(X,Y,r)
[Idx,D] = rangesearch(X,Y,r)
[Idx,D] = rangesearch(X,Y,r,Name,Value)
```

Description

`Idx = rangesearch(X,Y,r)` finds all the X points that are within distance `r` of the Y points. The rows of X and Y correspond to observations, and the columns correspond to variables.

`[Idx,D] = rangesearch(X,Y,r)` also returns the distances between the Y points and the X points that are within a distance of `r`.

`[Idx,D] = rangesearch(X,Y,r,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the nearest neighbor search method and the distance metric used in the search.

Examples

Find All Points Within Specified Distance

Find the X points that are within a Euclidean distance 1.5 of each Y point. Both X and Y are samples of five-dimensional normally distributed variables.

```
rng('default') % For reproducibility
X = randn(100,5);
Y = randn(10,5);
[Idx,D] = rangesearch(X,Y,1.5)
```

```
Idx=10x1 cell array
    {1x7 double}
    {1x2 double}
    {1x11 double}
    {1x2 double}
    {1x12 double}
    {1x9 double}
    {[      89]}
    {1x0 double}
    {1x0 double}
    {1x0 double}
```

```
D=10x1 cell array
    {1x7 double}
    {1x2 double}
    {1x11 double}
    {1x2 double}
```

```
{1x12 double}
{1x9 double}
{[ 1.1739]}
{1x0 double}
{1x0 double}
{1x0 double}
```

In this case, the last three Y points are more than 1.5 distance away from any X point. X(89,:) is 1.1739 distance away from Y(7,:), and no other X point is within distance 1.5 of Y(7,:). X contains 12 points within distance 1.5 of Y(5,:).

Find Nearest Points in Clustered Data

Generate 5000 random points from each of three distinct multivariate normal distributions. Shift the means of the distributions so that the randomly generated points are likely to form three separate clusters.

```
rng('default') % For reproducibility
N = 5000;
dist = 10;
X = [mvnrnd([0 0],eye(2),N);
     mvnrnd(dist*[1 1],eye(2),N);
     mvnrnd(dist*[-1 -1],eye(2),N)];
```

For each point in X, find the points in X that are within a radius `dist` away from the point. For faster computation, specify to keep the indices of the nearest neighbors unsorted. Select the first point in X, and find its nearest neighbors.

```
Idx = rangesearch(X,X,dist,'SortIndices',false);
x = X(1,:);
nearestPoints = X(Idx{1},:);
```

Find the values in X that are not the nearest neighbors of x. Display those points in one color and the nearest neighbors of x in a different color. Label the point x with a black, filled circle.

```
nonNearestIdx = true(size(X,1),1);
nonNearestIdx(Idx{1}) = false;

scatter(X(nonNearestIdx,1),X(nonNearestIdx,2))
hold on
scatter(nearestPoints(:,1),nearestPoints(:,2))
scatter(x(1),x(2),'black','filled')
hold off
```

Find Nearest Points Using Custom Distance Function

Find the patients in the `patients` data set that are within a certain age and weight range of the patients in `Y`.

Load the `patients` data set. The `Age` values are in years, and the `Weight` values are in pounds.

```
load patients
X = [Age Weight];
Y = [20 162; 30 169; 40 168]; % New patients
```

Create a custom distance function `distfun` that determines the distance between patients in terms of age and weight. For example, according to `distfun`, two patients that are one year apart in age and have the same weight are one distance unit apart. Similarly, two patients that have the same age and are five pounds apart in weight are also one distance unit apart.

```
type distfun.m % Display contents of distfun.m file
```

```
function D2 = distfun(ZI,ZJ)
ageDifference = abs(ZI(1)-ZJ(:,1));
weightDifference = abs(ZI(2)-ZJ(:,2));
D2 = ageDifference + 0.2*weightDifference;
end
```

Note: If you click the button located in the upper-right section of this example and open the example in MATLAB®, then MATLAB opens the example folder. This folder includes the function file `distfun.m`.

Find the patients in X that are within the distance 2 of the patients in Y.

```
[Idx,D] = rangesearch(X,Y,2,'Distance',@distfun)
```

```
Idx=3×1 cell array
    {1×0 double}
    {1×0 double}
    {[         41]}
```

```
D=3×1 cell array
    {1×0 double}
    {1×0 double}
    {[ 1.8000]}
```

The third patient in Y is the only one to have a patient in X within a distance of 2.

Display the Age and Weight values for the nearest patient in X to the patient with age 40 and weight 168.

```
X(Idx{3},:)
```

```
ans = 1×2
     39    164
```

Input Arguments

X — Input data

numeric matrix

Input data, specified as an $m \times n$ numeric matrix, where each row represents one n -dimensional point. The number of columns n must equal the number of columns in Y.

Data Types: `single` | `double`

Y — Query points

numeric matrix

Query points, specified as an $m \times n$ numeric matrix, where each row represents one n -dimensional point. The number of columns n must equal the number of columns in X.

Data Types: `single` | `double`

r — Search radius

nonnegative scalar

Search radius around each query point, specified as a nonnegative scalar. `rangesearch` finds all X points (rows) that are within distance `r` of each Y point. The meaning of distance depends on the 'Distance' name-value pair argument.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `rangesearch(X,Y,1.4,'Distance','seuclidean','Scale',iqr(X))` specifies to find all the observations in `X` within distance 1.4 of each observation in `Y`, using a standardized Euclidean distance scaled by the interquartile range of `X`.

NSMethod — Nearest neighbor search method

`'kdtree'` | `'exhaustive'`

Nearest neighbor search method, specified as the comma-separated pair consisting of `'NSMethod'` and one of these values.

Value	Description
<code>'kdtree'</code>	Create and use a Kd-tree to find nearest neighbors. <code>'kdtree'</code> is valid only when the distance metric is one of these options: <ul style="list-style-type: none"> <code>'chebychev'</code> <code>'cityblock'</code> <code>'euclidean'</code> <code>'minkowski'</code>
<code>'exhaustive'</code>	Use the exhaustive search algorithm. The software computes the distances from all <code>X</code> points to each <code>Y</code> point to find nearest neighbors.

`'kdtree'` is the default value when the number of columns in `X` is less than or equal to 10, `X` is not sparse, and the distance metric is one of the valid `'kdtree'` metrics. Otherwise, the default value is `'exhaustive'`.

Example: `'NSMethod','exhaustive'`

Distance — Distance metric

`'euclidean'` (default) | `'seuclidean'` | `'mahalanobis'` | `'cityblock'` | `'minkowski'` | `'chebychev'` | function handle | ...

Distance metric that `rangesearch` uses, specified as the comma-separated pair consisting of `'Distance'` and one of the values in this table.

Value	Description
<code>'euclidean'</code>	Euclidean distance.
<code>'seuclidean'</code>	Standardized Euclidean distance. Each coordinate difference between a row in <code>X</code> and a query point is scaled by dividing by the corresponding element of the standard deviation computed from <code>X</code> , <code>nanstd(X)</code> . To specify another scaling, use the <code>'Scale'</code> name-value pair argument.

Value	Description
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix C. The default value of C is the sample covariance matrix of X, as computed by <code>nancov(X)</code> . To specify a different value for C, use the 'Cov' name-value pair argument.
'cityblock'	City block distance.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument.
'chebychev'	Chebychev distance (maximum coordinate difference).
'cosine'	One minus the cosine of the included angle between observations (treated as vectors).
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'hamming'	Hamming distance, the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
@distfun	<p>Custom distance function handle. A distance function has the form</p> <pre>function D2 = distfun(ZI,ZJ) % calculation of distance ...</pre> <p>where</p> <ul style="list-style-type: none"> • ZI is a 1-by-n vector containing one row of X or Y. • ZJ is an m-by-n matrix containing multiple rows of X or Y. • D2 is an m-by-1 vector of distances, and D2(j) is the distance between the observations ZI and ZJ(j,:).

For more information, see “Distance Metrics” on page 18-11.

Example: 'Distance', 'minkowski'

P — Exponent for Minkowski distance metric

2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of 'P' and a positive scalar. This argument is valid only if 'Distance' is 'minkowski'.

Example: 'P', 4

Data Types: single | double

Cov — Covariance matrix for Mahalanobis distance metric

`nancov(X)` (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix. This argument is valid only when 'Distance' is 'mahalanobis'.

Example: 'Cov', eye(4)

Data Types: single | double

Scale — Scale parameter value for standardized Euclidean distance metric

nanstd(X) (default) | nonnegative vector

Scale parameter value for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of 'Scale' and a nonnegative vector. Scale has length equal to the number of columns in X. Each coordinate difference between a row in X and a query point is scaled by the corresponding element of Scale. This argument is valid only when 'Distance' is 'seuclidean'.

Example: 'Scale', iqr(X)

Data Types: single | double

BucketSize — Maximum number of data points in leaf node of Kd-tree

50 (default) | positive integer scalar

Maximum number of data points in the leaf node of the Kd-tree, specified as the comma-separated pair consisting of 'BucketSize' and a positive integer scalar. This argument is valid only when NSMethod is 'kdtree'.

Example: 'BucketSize', 20

Data Types: single | double

SortIndices — Flag to sort returned indices according to distance

true (1) (default) | false (0)

Flag to sort returned indices according to distance, specified as the comma-separated pair consisting of 'SortIndices' and either true (1) or false (0).

For faster performance when Y contains many observations that have many nearest points in X, you can set SortIndices to false. In this case, rangesearch returns the indices of the nearest points in no particular order. When SortIndices is true, the function arranges the indices of the nearest points in ascending order by distance.

Example: 'SortIndices', false

Data Types: logical

Output Arguments

Idx — Indices of nearest points

cell array of numeric vectors

Indices of nearest points, returned as a cell array of numeric vectors.

Idx is an *my*-by-1 cell array, where *my* is the number of rows in Y. The vector Idx{j} contains the indices of points (rows) in X whose distances to Y(j, :) are not greater than r. If SortIndices is true, then rangesearch arranges the indices in ascending order by distance.

D — Distances of nearest points to query points

cell array of numeric vectors

Distances of the nearest points to the query points, returned as a cell array of numeric vectors.

D is an $m \times j$ cell array, where m is the number of rows in Y . $D\{j\}$ contains the distance values between $Y(j, :)$ and the points (rows) in $X(\text{Idx}\{j\}, :)$. If `SortIndices` is `true`, then `rangesearch` arranges the distances in ascending order.

Tips

- For a fixed positive real value r , `rangesearch` finds all the X points that are within a distance r of each Y point. To find the k points in X that are nearest to each Y point, for a fixed positive integer k , use `knnsearch`.
- `rangesearch` does not save a search object. To create a search object, use `createns`.

Algorithms

- For an overview of the kd-tree algorithm, see “k-Nearest Neighbor Search Using a Kd-Tree” on page 18-14.
- The exhaustive search algorithm finds the distance from each point in X to each point in Y .

Alternative Functionality

If you set the `rangesearch` function `'NSMethod'` name-value pair argument to the appropriate value (`'exhaustive'` for an exhaustive search algorithm or `'kdtree'` for a Kd-tree algorithm), then the search results are equivalent to the results obtained by conducting a distance search using the `rangesearch` object function. Unlike the `rangesearch` function, the `rangesearch` object function requires an `ExhaustiveSearcher` or `KDTreeSearcher` model object.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- If X is a tall array, then Y cannot be a tall array. Similarly, if Y is a tall array, then X cannot be a tall array.

For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- For code generation, the default value of the `'NSMethod'` name-value pair argument is `'exhaustive'` when the number of columns in X is greater than 7.
- The value of the `'Distance'` name-value pair argument must be a compile-time constant and cannot be a custom distance function.
- The `'SortIndices'` name-value pair argument is not supported. The output arguments are always sorted.
- Names in name-value pair arguments must be compile-time constants. For example, to allow a user-defined exponent for the Minkowski distance in the generated code, include

`{coder.Constant('Distance'), coder.Constant('Minkowski'), coder.Constant('P'), 0}` in the `-args` value of `codegen`.

- The sorted order of tied distances in the generated code can be different from the order in MATLAB due to numerical precision.
- When `rangesearch` uses the `kd-tree` search algorithm, and the code generation build type is a MEX function, `codegen` generates a MEX function using Intel Threading Building Blocks (TBB) for parallel computation. Otherwise, `codegen` generates code using `parfor`.
 - MEX function for the `kd-tree` search algorithm — `codegen` generates an optimized MEX function using Intel TBB for parallel computation on multicore platforms. You can use the MEX function to accelerate MATLAB algorithms. For details on Intel TBB, see <https://software.intel.com/en-us/intel-tbb>.

If you generate the MEX function to test the generated code of the `parfor` version, you can disable the usage of Intel TBB. Set the `ExtrinsicCalls` property of the MEX configuration object to `false`. For details, see `coder.MexCodeConfig`.

- MEX function for the exhaustive search algorithm and standalone C/C++ code for both algorithms — The generated code of `rangesearch` uses `parfor` to create loops that run in parallel on supported shared-memory multicore platforms in the generated code. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the `parfor`-loops as `for`-loops. To find supported compilers, see https://www.mathworks.com/support/compilers/current_release/. To disable OpenMP library, set the `EnableOpenMP` property of the configuration object to `false`. For details, see `coder.CodeConfig`.
- Starting in R2020a, `rangesearch` returns integer-type (`int32`) indices, rather than double-precision indices, in generated standalone C/C++ code. Therefore, the function allows for strict single-precision support when you use single-precision inputs. For MEX code generation, the function still returns double-precision indices to match the MATLAB behavior.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

Topics

“k-Nearest Neighbor Search and Radius Search” on page 18-13

“Distance Metrics” on page 18-11

Introduced in R2011b

ranksum

Wilcoxon rank sum test

Syntax

```
p = ranksum(x,y)
[p,h] = ranksum(x,y)
[p,h,stats] = ranksum(x,y)
[ ___ ] = ranksum(x,y,Name,Value)
```

Description

`p = ranksum(x,y)` returns the p -value of a two-sided Wilcoxon rank sum test on page 32-4527. `ranksum` tests the null hypothesis that data in `x` and `y` are samples from continuous distributions with equal medians, against the alternative that they are not. The test assumes that the two samples are independent. `x` and `y` can have different lengths.

This test is equivalent to a Mann-Whitney U-test.

`[p,h] = ranksum(x,y)` also returns a logical value indicating the test decision. The result `h = 1` indicates a rejection of the null hypothesis, and `h = 0` indicates a failure to reject the null hypothesis at the 5% significance level.

`[p,h,stats] = ranksum(x,y)` also returns the structure `stats` with information about the test statistic.

`[___] = ranksum(x,y,Name,Value)` returns any of the output arguments in the previous syntaxes, for a rank sum test with additional options specified by one or more `Name,Value` pair arguments.

Examples

Test for Equal Median of Two Populations

Test the hypothesis of equal medians for two independent unequal-sized samples.

Generate sample data.

```
rng('default') % for reproducibility
x = unifrnd(0,1,10,1);
y = unifrnd(0.25,1.25,15,1);
```

These samples come from populations with identical distributions except for a shift of 0.25 in the location.

Test the equality of medians of `x` and `y`.

```
p = ranksum(x,y)
```

```
p = 0.0375
```

The p -value of 0.0375 indicates that `ranksum` rejects the null hypothesis of equal medians at the default 5% significance level.

Statistics of the Test for Two Population Medians

Obtain the statistics of the test for the equality of two population medians.

Load the sample data.

```
load mileage
```

Test if the mileage per gallon is the same for the first and second type of cars.

```
[p,h,stats] = ranksum(mileage(:,1),mileage(:,2))
```

```
p = 0.0043
```

```
h = logical  
    1
```

```
stats = struct with fields:  
    ranksum: 21.5000
```

Both the p -value, 0.043, and $h = 1$ indicate the rejection of the null hypothesis of equal medians at the default 5% significance level. Because the sample sizes are small (six each), `ranksum` calculates the p -value using the exact method. The structure `stats` includes only the value of the rank sum test statistic.

Increase in the Median

Test the hypothesis of an increase in the population median.

Load the sample data.

```
load('weather.mat');
```

The weather data shows the daily high temperatures taken in the same month in two consecutive years.

Perform a left-sided test to assess the increase in the median at the 1% significance level.

```
[p,h,stats] = ranksum(year1,year2,'alpha',0.01,...  
'tail','left')
```

```
p = 0.1271
```

```
h = logical  
    0
```

```
stats = struct with fields:  
    zval: -1.1403
```

```
ranksum: 837.5000
```

Both the p -value of 0.1271 and $h = 0$ indicate that there is not enough evidence to reject the null hypothesis and conclude that there is a positive shift in the median of observed high temperatures in the same month from year 1 to year 2 at the 1% significance level. Notice that ranksum uses the approximate method to calculate the p -value due to the large sample sizes.

Use the exact method to calculate the p -value.

```
[p,h,stats] = ranksum(year1,year2,'alpha',0.01,...
'tail','left','method','exact')
```

```
p = 0.1273
```

```
h = logical
    0
```

```
stats = struct with fields:
    ranksum: 837.5000
```

The results of the approximate and exact methods are consistent with each other.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

y — Sample data

vector

Sample data, specified as a vector. The length of y does not have to be the same as the length of x .

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'alpha', 0.01, 'method', 'approximate', 'tail', 'right'` specifies a right-tailed rank sum test with 1% significance level, which returns the approximate p -value.

alpha — Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level of the decision of a hypothesis test, specified as the comma-separated pair consisting of `'alpha'` and a scalar value in the range 0 to 1. The significance level of h is $100 * \alpha\%$.

Example: 'alpha', 0.01

Data Types: double | single

method — Computation method of the p -value

'exact' | 'approximate'

Computation method of the p -value, p , specified as the comma-separated pair consisting of 'method' and one of the following:

'exact'	Exact computation of the p -value, p .
'approximate'	Normal approximation while computing the p -value, p .

When 'method' is unspecified, the default is:

- 'exact' if $\min(n_x, n_y) < 10$ and $n_x + n_y < 20$
- 'approximate' otherwise

n_x and n_y are the sizes of the samples in x and y , respectively.

Example: 'method', 'exact'

tail — Type of test

'both' (default) | 'right' | 'left'

Type of test, specified as the comma-separated pair consisting of 'tail' and one of the following:

'both'	Two-sided hypothesis test, where the alternative hypothesis states that x and y have different medians. Default test type if 'tail' is not specified.
'right'	Right-tailed hypothesis test, where the alternative hypothesis states that the median of x is greater than the median of y .
'left'	Left-tailed hypothesis test, where the alternative hypothesis states that the median of x is less than the median of y .

Example: 'tail', 'left'

Output Arguments

p — p -value of the test

nonnegative scalar

p -value of the test, returned as a positive scalar from 0 to 1. p is the probability of observing a test statistic as or more extreme than the observed value under the null hypothesis. `ranksum` computes the two-sided p -value by doubling the most significant one-sided value.

h — Result of the hypothesis test

1 | 0

Result of the hypothesis test, returned as a logical value.

- If $h = 1$, this indicates rejection of the null hypothesis at the $100 * \alpha\%$ significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the $100 * \alpha\%$ significance level.

stats – Test statistics

structure

Test statistics, returned as a structure. The test statistics stored in `stats` are:

- `ranksum` : Value of the rank sum test statistic
- `zval` : Value of the z-statistic on page 32-4527 (computed when 'method' is 'approximate')

More About**Wilcoxon Rank Sum Test**

The Wilcoxon rank sum test is a nonparametric test for two populations when samples are independent. If X and Y are independent samples with different sample sizes, the test statistic which `ranksum` returns is the rank sum of the first sample.

The Wilcoxon rank sum test is equivalent to the Mann-Whitney U-test. The Mann-Whitney U-test is a nonparametric test for equality of population medians of two independent samples X and Y .

The Mann-Whitney U-test statistic, U , is the number of times a y precedes an x in an ordered arrangement of the elements in the two independent samples X and Y . It is related to the Wilcoxon rank sum statistic in the following way: If X is a sample of size n_X , then

$$U = W - \frac{n_X(n_X + 1)}{2}.$$

z-Statistic

For large samples, `ranksum` uses a z-statistic to compute the approximate p -value of the test.

If X and Y are two independent samples of size n_X and n_Y , where $n_X < n_Y$ the z-statistic is

$$z = \frac{W - E(W)}{\sqrt{V(W)}} = \frac{W - \left[\frac{n_X n_Y + n_X(n_X + 1)}{2} \right] - 0.5 * \text{sign}(W - E(W))}{\sqrt{\frac{n_X n_Y (n_X + n_Y + 1) - \text{tiescor}}{12}}},$$

with continuity correction and tie adjustment. Here `tiescor` is given by

$$\text{tiescor} = \frac{2 * \text{tiedj}}{(n_X + n_Y)(n_X + n_Y - 1)},$$

where `ranksum` uses `[ranks, tiedj] = tiedrank(x, y)` to obtain tie adjustments. The standard normal distribution gives the p -value for this z-statistic.

Algorithms

`ranksum` treats NaNs in x and y as missing values and ignores them.

For a two-sided test of medians with unequal sample sizes, the test statistic that `ranksum` returns is the rank sum of the first sample.

Introduced before R2006a

ranova

Class: RepeatedMeasuresModel

Repeated measures analysis of variance

Syntax

```
ranovatbl = ranova(rm)
ranovatbl = ranova(rm, 'WithinModel', WM)
[ranovatbl, A, C, D] = ranova( ___ )
```

Description

`ranovatbl = ranova(rm)` returns the results of repeated measures analysis of variance for a repeated measures model `rm` in table `ranovatbl`.

`ranovatbl = ranova(rm, 'WithinModel', WM)` returns the results of repeated measures analysis of variance using the responses specified by the within-subject model `WM`.

`[ranovatbl, A, C, D] = ranova(___)` also returns arrays `A`, `C`, and `D` for the hypotheses tests of the form $A*B*C = D$, where `D` is zero.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

WM — Model specifying responses

'separatemeans' (default) | *r*-by-*nc* contrast matrix | character vector or string scalar that defines a model specification

Model specifying the responses, specified as one of the following:

- 'separatemeans' — Compute a separate mean for each group.
- *C* — *r*-by-*nc* contrast matrix specifying the *nc* contrasts among the *r* repeated measures. If *Y* represents a matrix of repeated measures, `ranova` tests the hypothesis that the means of $Y*C$ are zero.
- A character vector or string scalar that defines a model specification in the within-subject factors. You can define the model based on the rules for the `terms` in the `modelspec` argument of `fitrm`. Also see “Model Specification for Repeated Measures Models” on page 9-54.

For example, if there are three within-subject factors `w1`, `w2`, and `w3`, then you can specify a model for the within-subject factors as follows.

Example: 'WithinModel', 'w1+w2+w2*w3'

Data Types: `single` | `double` | `char` | `string`

Output Arguments

ranovatbl — Results of repeated measures anova

table

Results of repeated measures anova, returned as a table.

`ranovatbl` includes a term representing all differences across the within-subjects factors. This term has either the name of the within-subjects factor if specified while fitting the model, or the name `Time` if the name of the within-subjects factor is not specified while fitting the model or there are more than one within-subjects factors. `ranovatbl` also includes all interactions between the terms in the within-subject model and all between-subject model terms. It contains the following columns.

Column Name	Definition
SumSq	Sum of squares.
DF	Degrees of freedom.
MeanSq	Mean squared error.
F	F -statistic.
pValue	p -value for the corresponding F -statistic. A small p -value indicates significant term effect.
pValueGG	p -value with Greenhouse-Geisser adjustment.
pValueHF	p -value with Huynh-Feldt adjustment.
pValueLB	p -value with Lower bound adjustment.

The last three p -values are the adjusted p -values for use when the compound symmetry assumption is not satisfied. For details, see “Compound Symmetry Assumption and Epsilon Corrections” on page 9-55. The `mauchy` method tests for sphericity (hence, compound symmetry) and `epsilon` method returns the epsilon adjustment values.

A — Specification based on between-subjects model

matrix | cell array

Specification based on the between-subjects model, returned as a matrix or a cell array. It permits the hypothesis on the elements within given columns of `B` (within time hypothesis). If `ranovatbl` contains multiple hypothesis tests, `A` might be a cell array.

Data Types: `single` | `double` | `cell`

C — Specification based on within-subjects model

matrix | cell array

Specification based on the within-subjects model, returned as a matrix or a cell array. It permits the hypotheses on the elements within given rows of `B` (between time hypotheses). If `ranovatbl` contains multiple hypothesis tests, `C` might be a cell array.

Data Types: `single` | `double` | `cell`

D — Hypothesis value

0

Hypothesis value, returned as 0.

Examples

Repeated Measures Analysis of Variance

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = table([1 2 3 4]','VariableNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform repeated measures analysis of variance.

```
ranovatbl = ranova(rm)
```

```
ranovatbl=3x8 table
```

	SumSq	DF	MeanSq	F	pValue	pValueGG
(Intercept):Measurements	1656.3	3	552.09	6873.3	0	9.4491e-279
species:Measurements	282.47	6	47.078	586.1	1.4271e-206	4.9313e-150
Error(Measurements)	35.423	441	0.080324			

There are four measurements, three types of species, and 150 observations. So, degrees of freedom for measurements is $(4-1) = 3$, for species-measurements interaction it is $(4-1)*(3-1) = 6$, and for error it is $(150-3)*(4-1) = 441$. `ranova` computes the last three p -values using Greenhouse-Geisser, Huynh-Feldt, and Lower bound corrections, respectively. You can check the compound symmetry (sphericity) assumption using the `mauchly` method, and display the epsilon corrections using the `epsilon` method.

Longitudinal Data

Load the sample data.

```
load('longitudinalData.mat');
```

The matrix `Y` contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (`time = 0, 2, 4, 6, and 8`). Each row of `Y` corresponds to an individual,

and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M' 'M'];
```

Store the data in a proper table array format to do repeated measures analysis.

```
t = table(Gender, Y(:,1), Y(:,2), Y(:,3), Y(:,4), Y(:,5), ...
'VariableNames', {'Gender', 't0', 't2', 't4', 't6', 't8'});
```

Define the within-subjects variable.

```
Time = [0 2 4 6 8]';
```

Fit a repeated measures model, where the blood levels are the responses and gender is the predictor variable.

```
rm = fitrm(t, 't0-t8 ~ Gender', 'WithinDesign', Time);
```

Perform repeated measures analysis of variance.

```
ranovatbl = ranova(rm)
```

```
ranovatbl=3×8 table
```

	SumSq	DF	MeanSq	F	pValue	pValueGG	pValueL
(Intercept):Time	881.7	4	220.43	37.539	3.0348e-15	4.7325e-09	2.4439e-05
Gender:Time	17.65	4	4.4125	0.75146	0.56126	0.4877	0.5000
Error(Time)	328.83	56	5.872				

There are 5 time points, 2 genders, and 16 observations. So, the degrees of freedom for time is $(5-1) = 4$, for gender-time interaction it is $(5-1)*(2-1) = 4$, and for error it is $(16-2)*(5-1) = 56$. The small p -value of $2.6198e-05$ indicates that there is a significant effect of time on blood pressure. The p -value of 0.40063 indicates that there is no significant gender-time interaction.

Specify the Within-Subjects Model

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data. Hypothetically, the response can be results of a memory test. The within-subject variable `w1` can be the type of exercise the subject does before the test and `w2` can be the different points in the day the subject takes the memory test. So, one subject does two different type of exercises A and B before taking the test and takes the test at four different times on different days. For each subject, the measurements are taken under these conditions:

Exercise to perform before the test: A B A B A B A B

Test time: 1 1 2 2 3 3 4 4

Fit a repeated measures model, where the repeated measures y1 through y8 are the responses, and age, IQ, group, gender, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between,'y1-y8 ~ Group*Gender + Age + IQ','WithinDesign',within);
```

Perform repeated measures analysis of variance.

```
ranovatbl = ranova(rm)
```

ranovatbl=7x8 table

	SumSq	DF	MeanSq	F	pValue	pValueGG	pValueHF
(Intercept):Time	6645.2	7	949.31	2.2689	0.031674	0.071235	0.056257
Age:Time	5824.3	7	832.05	1.9887	0.059978	0.10651	0.09012
IQ:Time	5188.3	7	741.18	1.7715	0.096749	0.14492	0.1289
Group:Time	15800	14	1128.6	2.6975	0.0014425	0.011884	0.006434

Algorithms

`ranova` computes the regular p -value (in the `pValue` column of the `rmanova` table) using the F -statistic cumulative distribution function:

$$p\text{-value} = 1 - \text{fcdf}(F, v_1, v_2).$$

When the compound symmetry assumption is not satisfied, `ranova` uses a correction factor ϵ , to compute the corrected p -values as follows:

$$p\text{-value}_{\text{corrected}} = 1 - \text{fcdf}(F, \epsilon * v_1, \epsilon * v_2).$$

The `mauchly` method tests for sphericity (hence, compound symmetry) and `epsilon` method returns the epsilon adjustment values.

raylcdf

Rayleigh cumulative distribution function

Syntax

```
p = raylcdf(x,b)
p = raylcdf(x,b,'upper')
```

Description

`p = raylcdf(x,b)` returns the Rayleigh cdf at each value in `x` using the corresponding scale parameter, `b`. `x` and `b` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `x` or `b` is expanded to a constant array with the same dimensions as the other input.

`p = raylcdf(x,b,'upper')` returns the complement of the Rayleigh cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The Rayleigh cdf is

$$y = F(x|b) = \int_0^x \frac{t}{b^2} e^{\left(\frac{-t^2}{2b^2}\right)} dt$$

Examples

Compute and Plot Rayleigh Distribution cdf

Compute the cdf of a Rayleigh distribution with parameter `B = 1`.

```
x = 0:0.1:3;
p = raylcdf(x,1);
```

Plot the cdf.

```
figure;
plot(x,p)
```

raylfit

Rayleigh parameter estimates

Syntax

```
raylfit(data,alpha)  
[phat,pci] = raylfit(data,alpha)
```

Description

`raylfit(data,alpha)` returns the maximum likelihood estimates of the parameter of the Rayleigh distribution given the data in the vector `data`.

`[phat,pci] = raylfit(data,alpha)` returns the maximum likelihood estimate and $100(1 - \alpha)\%$ confidence interval given the data. The default value of the optional parameter `alpha` is 0.05, corresponding to 95% confidence intervals.

raylinv

Rayleigh inverse cumulative distribution function

Syntax

```
X = raylinv(P,B)
```

Description

`X = raylinv(P,B)` returns the inverse of the Rayleigh cumulative distribution function using the corresponding scale parameter, `B` at the corresponding probabilities in `P`. `P` and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `P` or `B` is expanded to a constant array with the same dimensions as the other input.

Examples

```
x = raylinv(0.9,1)
x =
    2.1460
```

raylpdf

Rayleigh probability density function

Syntax

```
Y = raylpdf(X,B)
```

Description

`Y = raylpdf(X,B)` computes the Rayleigh pdf at each of the values in `X` using the corresponding scale parameter, `B`. `X` and `B` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `Y`. A scalar input for `X` or `B` is expanded to a constant array with the same dimensions as the other input.

The Rayleigh pdf is

$$y = f(x|b) = \frac{x}{b^2} e^{\left(\frac{-x^2}{2b^2}\right)}$$

Examples

Compute and Plot Rayleigh Distribution pdf

Compute the pdf of a Rayleigh distribution with parameter `B = 0.5`.

```
x = [0:0.01:2];  
p = raylpdf(x,0.5);
```

Plot the pdf.

```
figure;  
plot(x,p)
```

raylrnd

Rayleigh random numbers

Syntax

```
R = raylrnd(B)
R = raylrnd(B,v)
R = raylrnd(B,m,n)
```

Description

`R = raylrnd(B)` returns a matrix of random numbers chosen from the Rayleigh distribution with scale parameter, `B`. `B` can be a vector, a matrix, or a multidimensional array. The size of `R` is the size of `B`.

`R = raylrnd(B,v)` returns a matrix of random numbers chosen from the Rayleigh distribution with parameter `B`, where `v` is a row vector. If `v` is a 1-by-2 vector, `R` is a matrix with `v(1)` rows and `v(2)` columns. If `v` is 1-by-`n`, `R` is an `n`-dimensional array.

`R = raylrnd(B,m,n)` returns a matrix of random numbers chosen from the Rayleigh distribution with parameter `B`, where scalars `m` and `n` are the row and column dimensions of `R`.

Examples

```
r = raylrnd(1:5)
r =
    1.7986    0.8795    3.3473    8.9159    3.5182
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Rayleigh Distribution” on page B-137

Introduced before R2006a

raylstat

Rayleigh mean and variance

Syntax

```
[M,V] = raylstat(B)
```

Description

`[M,V] = raylstat(B)` returns the mean of and variance for the Rayleigh distribution with scale parameter B.

The mean of the Rayleigh distribution with parameter b is $b\sqrt{\pi/2}$ and the variance is

$$\frac{4 - \pi}{2} b^2$$

Examples

```
[mn,v] = raylstat(1)
mn =
    1.2533
v =
    0.4292
```

Extended Capabilities

rcoplot

Residual case order plot

Syntax

```
rcoplot(r,rint)
```

Description

`rcoplot(r,rint)` displays an error bar plot of the confidence intervals on the residuals from a regression. The residuals appear in the plot in case order. Inputs `r` and `rint` are outputs from the `regress` function.

Examples

The following plots residuals and prediction intervals from a regression of a linearly additive model to the data in `moore.mat`:

```
load moore
X = [ones(size(moore,1),1) moore(:,1:5)];
y = moore(:,6);
alpha = 0.05;
[betahat,Ibeta,res,Ires,stats] = regress(y,X,alpha);
rcoplot(res,Ires)
```

The interval around the first residual, shown in red, does not contain zero. This indicates that the residual is larger than expected in 95% of new observations, and suggests the data point is an outlier.

`regress`

Introduced before R2006a

ReconstructionICA

Feature extraction by reconstruction ICA

Description

`ReconstructionICA` applies reconstruction independent component analysis (RICA) to learn a transformation that maps input predictors to new predictors.

Creation

Create a `ReconstructionICA` object by using the `rica` function.

Properties

FitInfo — Fitting history

structure

This property is read-only.

Fitting history, returned as a structure with two fields:

- `Iteration` — Iteration numbers from 0 through the final iteration.
- `Objective` — Objective function value at each corresponding iteration. Iteration 0 corresponds to the initial values, before any fitting.

Data Types: `struct`

InitialTransformWeights — Initial feature transformation weights

p-by-q matrix

This property is read-only.

Initial feature transformation weights, returned as a p-by-q matrix, where p is the number of predictors passed in X and q is the number of features that you want. These weights are the initial weights passed to the creation function. The data type is `single` when the training data X is `single`.

Data Types: `single` | `double`

ModelParameters — Parameters for training model

structure

This property is read-only.

Parameters for training the model, returned as a structure. The structure contains a subset of the fields that correspond to the `rica` name-value pairs that were in effect during model creation:

- `IterationLimit`
- `VerbosityLevel`

- `Lambda`
- `Standardize`
- `ContrastFcn`
- `GradientTolerance`
- `StepTolerance`

For details, see the `rica Name, Value` on page 32-4956 pairs.

Data Types: `struct`

Mu — Predictor means when standardizing

`p-by-1` vector

This property is read-only.

Predictor means when standardizing, returned as a `p-by-1` vector. This property is nonempty when the `Standardize` name-value pair is `true` at model creation. The value is the vector of predictor means in the training data. The data type is `single` when the training data `X` is `single`.

Data Types: `single` | `double`

NonGaussianityIndicator — Non-Gaussianity of sources

`length-q` vector of ± 1

This property is read-only.

Non-Gaussianity of sources, returned as a `length-q` vector of ± 1 .

- `NonGaussianityIndicator(k) = 1` means `rica` models the `k`th source as sub-Gaussian.
- `NonGaussianityIndicator(k) = -1` means `rica` models the `k`th source as super-Gaussian, with a sharp peak at 0.

Data Types: `double`

NumLearnedFeatures — Number of output features

positive integer

This property is read-only.

Number of output features, returned as a positive integer. This value is the `q` argument passed to the creation function, which is the requested number of features to learn.

Data Types: `double`

NumPredictors — Number of input predictors

positive integer

This property is read-only.

Number of input predictors, returned as a positive integer. This value is the number of predictors passed in `X` to the creation function.

Data Types: `double`

Sigma — Predictor standard deviations when standardizing

`p-by-1` vector

This property is read-only.

Predictor standard deviations when standardizing, returned as a p-by-1 vector. This property is nonempty when the `Standardize` name-value pair is `true` at model creation. The value is the vector of predictor standard deviations in the training data. The data type is `single` when the training data `X` is `single`.

Data Types: `single` | `double`

TransformWeights — Feature transformation weights

p-by-q matrix

This property is read-only.

Feature transformation weights, returned as a p-by-q matrix, where `p` is the number of predictors passed in `X` and `q` is the number of features that you want. The data type is `single` when the training data `X` is `single`.

Data Types: `single` | `double`

Object Functions

`transform` Transform predictors into extracted features

Examples

Create Reconstruction ICA Object

Create a `ReconstructionICA` object by using the `rica` function.

Load the `SampleImagePatches` image patches.

```
data = load('SampleImagePatches');
size(data.X)
```

```
ans = 1×2
```

```
5000    363
```

There are 5,000 image patches, each containing 363 features.

Extract 100 features from the data.

```
rng default % For reproducibility
q = 100;
Mdl = rica(data.X,q,'IterationLimit',100)
```

Warning: Solver LBFGS was not able to converge to a solution.

```
Mdl =
  ReconstructionICA
      ModelParameters: [1x1 struct]
      NumPredictors: 363
      NumLearnedFeatures: 100
      Mu: []
```

```
      Sigma: []  
      FitInfo: [1x1 struct]  
      TransformWeights: [363x100 double]  
      InitialTransformWeights: []  
      NonGaussianityIndicator: [100x1 double]
```

Properties, Methods

`rica` issues a warning because it stopped due to reaching the iteration limit, instead of reaching a step-size limit or a gradient-size limit. You can still use the learned features in the returned object by calling the `transform` function.

Introduced in R2017a

refcurve

Add reference curve to plot

Syntax

```
refcurve(p)
refcurve
refcurve(ax,p)
hcurve = refcurve(...)
```

Description

`refcurve(p)` adds a polynomial reference curve with coefficients `p` to the current axes. If `p` is a vector with `n+1` elements, the curve is:

$$y = p(1)*x^n + p(2)*x^{(n-1)} + \dots + p(n)*x + p(n+1)$$

`refcurve` with no input arguments adds a line along the `x` axis.

`refcurve(ax,p)` uses the plot axes specified in `ax`, an `Axes` object. For more information, see `axes`.

`hcurve = refcurve(...)` returns the handle `hcurve` to the curve using any of the input argument combinations in the previous syntaxes.

Examples

Add Population and Fitted Mean Functions

Generate data with a polynomial trend.

```
p = [1 -2 -1 0];
t = 0:0.1:3;
rng default % For reproducibility
y = polyval(p,t) + 0.5*randn(size(t));
```

Plot data and add the population mean function using `refcurve`.

```
plot(t,y,'ro')
h = refcurve(p);
h.Color = 'r';
```

Also add the fitted mean function.

```
q = polyfit(t,y,3);  
refcurve(q)  
legend('Data', 'Population Mean', 'Fitted Mean', ...  
       'Location', 'NW')
```

Plot Trajectories of a Batted Baseball Using refcurve

Introduce the relevant physical constants.

```
M = 0.145;      % Mass (kg)
R = 0.0366;    % Radius (m)
A = pi*R^2;    % Area (m^2)
rho = 1.2;     % Density of air (kg/m^3)
C = 0.5;       % Drag coefficient
D = rho*C*A/2; % Drag proportional to the square of the speed
g = 9.8;       % Acceleration due to gravity (m/s^2)
```

Simulate the trajectory with drag proportional to the square of the speed, assuming constant acceleration in each time interval.

```
dt = 1e-2;     % Simulation time interval (s)
r0 = [0 1];    % Initial position (m)
s0 = 50;       % Initial speed (m/s)
alpha0 = 35;   % Initial angle (deg)
v0 = s0*[cosd(alpha0) sind(alpha0)]; % Initial velocity (m/s)

r = r0;
v = v0;
trajectory = r0;
while r(2) > 0
```

```

a = [0 -g] - (D/M)*norm(v)*v;
v = v + a*dt;
r = r + v*dt + (1/2)*a*(dt^2);
trajectory = [trajectory;r];
end

```

Plot trajectory and use `refcurve` to add the drag-free parabolic trajectory (found analytically) to the plot of trajectory.

```

figure
plot(trajectory(:,1),trajectory(:,2),'m','LineWidth',2)
xlim([0,250])
h = refcurve([-g/(2*v0(1)^2),...
    (g*r0(1)/v0(1)^2) + (v0(2)/v0(1)),...
    (-g*r0(1)^2/(2*v0(1)^2) - (v0(2)*r0(1)/v0(1)) + r0(2)]);
h.Color = 'c';
h.LineWidth = 2;
axis equal
ylim([0,50])
grid on
xlabel('Distance (m)')
ylabel('Height (m)')
title('\bf Baseball Trajectories')
legend('With Drag','Without Drag')

```

Introduced before R2006a

refit

Class: GeneralizedLinearMixedModel

Refit generalized linear mixed-effects model

Syntax

```
glmenew = refit(glme,ynew)
```

Description

`glmenew = refit(glme,ynew)` returns a refitted generalized linear mixed-effects model, `glmenew`, based on the input model `glme`, using a new response vector, `ynew`.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

ynew — New response vector

n -by-1 vector of scalar values

New response vector, specified as an n -by-1 vector of scalar values, where n is the number of observations used to fit `glme`.

For an observation i with prior weights w_i^p and binomial size n_i (when applicable), the response values y_i contained in `ynew` can have the following values.

Distribution	Permitted Values	Notes
Binomial	$\left\{0, \frac{1}{w_i^p n_i}, \frac{2}{w_i^p n_i}, \dots, 1\right\}$	w_i^p and n_i are integer values > 0
Poisson	$\left\{0, \frac{1}{w_i^p}, \frac{2}{w_i^p}, \dots, 1\right\}$	w_i^p is an integer value > 0
Gamma	$(0, \infty)$	$w_i^p \geq 0$
InverseGaussian	$(0, \infty)$	$w_i^p \geq 0$
Normal	$(-\infty, \infty)$	$w_i^p \geq 0$

You can access the prior weights property w_i^p using dot notation.

```
glme.ObservationInfo.Weights
```

Data Types: single | double

Output Arguments

`glmnew` — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, returned as a GeneralizedLinearMixedModel object. `glmnew` is an updated version of the generalized linear mixed-effects model `glm`, refit to the values in the response vector `ynew`.

For properties and methods of this object, see GeneralizedLinearMixedModel.

Examples

Refit Model to New Response Vector

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is `log`. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', 'Di
```

Use random to simulate a new response vector from the fitted model.

```
rng(0, 'twister'); % For reproducibility
ynew = random(glme);
```

Refit the model using the new response vector.

```
glme = refit(glme, ynew)
```

```
glme =
Generalized linear mixed-effects model fit by ML
```

refit

Class: FeatureSelectionNCAClassification

Refit neighborhood component analysis (NCA) model for classification

Syntax

```
mdlrefit = refit(mdl,Name,Value)
```

Description

`mdlrefit = refit(mdl,Name,Value)` refits the model `mdl`, with modified parameters specified by one or more `Name,Value` pair arguments.

Input Arguments

mdl — Neighborhood component analysis model for classification

FeatureSelectionNCAClassification object

Neighborhood component analysis model or classification, specified as a FeatureSelectionNCAClassification object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Fitting Options

FitMethod — Method for fitting the model

`mdl.FitMethod` (default) | 'exact' | 'none' | 'average'

Method for fitting the model, specified as the comma-separated pair consisting of 'FitMethod' and one of the following.

- 'exact' — Performs fitting using all of the data.
- 'none' — No fitting. Use this option to evaluate the generalization error of the NCA model using the initial feature weights supplied in the call to `fscnca`.
- 'average' — The function divides the data into partitions (subsets), fits each partition using the exact method, and returns the average of the feature weights. You can specify the number of partitions using the `NumPartitions` name-value pair argument.

Example: 'FitMethod', 'none'

Lambda — Regularization parameter

`mdl.Lambda` (default) | non-negative scalar value

Regularization parameter, specified as the comma-separated pair consisting of 'Lambda' and a non-negative scalar value.

For n observations, the best Lambda value that minimizes the generalization error of the NCA model is expected to be a multiple of $1/n$

Example: 'Lambda', 0.01

Data Types: double | single

Solver — Solver type

`mdl.Solver` (default) | 'lbfgs' | 'sgd' | 'minibatch-lbfgs'

Solver type for estimating feature weights, specified as the comma-separated pair consisting of 'Solver' and one of the following.

- 'lbfgs' — Limited memory BFGS (Broyden-Fletcher-Goldfarb-Shanno) algorithm (LBFGS algorithm)
- 'sgd' — Stochastic gradient descent
- 'minibatch-lbfgs' — Stochastic gradient descent with LBFGS algorithm applied to mini-batches

Example: 'solver', 'minibatch-lbfgs'

InitialFeatureWeights — Initial feature weights

`mdl.InitialFeatureWeights` (default) | p -by-1 vector of real positive scalar values

Initial feature weights, specified as the comma-separated pair consisting of 'InitialFeatureWeights' and a p -by-1 vector of real positive scalar values.

Data Types: double | single

Verbose — Indicator for verbosity level

`mdl.Verbose` (default) | 0 | 1 | >1

Indicator for verbosity level for the convergence summary display, specified as the comma-separated pair consisting of 'Verbose' and one of the following.

- 0 — No convergence summary
- 1 — Convergence summary including iteration number, norm of the gradient, and objective function value.
- >1 — More convergence information depending on the fitting algorithm

When using solver 'minibatch-lbfgs' and verbosity level >1, the convergence information includes iteration log from intermediate minibatch LBFGS fits.

Example: 'Verbose', 2

Data Types: double | single

LBFGS or Mini-Batch LBFGS Options

GradientTolerance — Relative convergence tolerance

`mdl.GradientTolerance` (default) | positive real scalar value

Relative convergence tolerance on the gradient norm for solver lbfgs, specified as the comma-separated pair consisting of 'GradientTolerance' and a positive real scalar value.

Example: 'GradientTolerance', 0.00001

Data Types: double | single

SGD or Mini-Batch LBFGS Options

InitialLearningRate — Initial learning rate for solver `sgd`

`mdl.InitialLearningRate` (default) | positive real scalar value

Initial learning rate for solver `sgd`, specified as the comma-separated pair consisting of `'InitialLearningRate'` and a positive scalar value.

When using solver type `'sgd'`, the learning rate decays over iterations starting with the value specified for `'InitialLearningRate'`.

Example: `'InitialLearningRate',0.8`

Data Types: double | single

PassLimit — Maximum number of passes for solver `'sgd'`

`mdl.PassLimit` (default) | positive integer value

Maximum number of passes for solver `'sgd'` (stochastic gradient descent), specified as the comma-separated pair consisting of `'PassLimit'` and a positive integer. Every pass processes `size(mdl.X,1)` observations.

Example: `'PassLimit',10`

Data Types: double | single

SGD or LBFGS or Mini-Batch LBFGS Options

IterationLimit — Maximum number of iterations

`mdl.IterationLimit` (default) | positive integer value

Maximum number of iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer.

Example: `'IterationLimit',250`

Data Types: double | single

Output Arguments

`mdlrefit` — Neighborhood component analysis model for classification

`FeatureSelectionNCAClassification` object

Neighborhood component analysis model for classification, returned as a `FeatureSelectionNCAClassification` object. You can either save the results as a new model or update the existing model as `mdl = refit(mdl,Name,Value)`.

Examples

Refit NCA Model for Classification with Modified Settings

Generate checkerboard data using the `generateCheckerBoardData.m` function.

```
rng(2016,'twister'); % For reproducibility
pps = 1375;
```

```
[X,y] = generateCheckerBoardData(pps);  
X = X + 2;
```

Plot the data.

```
figure  
plot(X(y==1,1),X(y==1,2), 'rx')  
hold on  
plot(X(y==-1,1),X(y==-1,2), 'bx')
```

```
[n,p] = size(X)
```

```
n =
```

```
22000
```

```
p =
```

```
2
```

Add irrelevant predictors to the data.

```
Q = 98;  
Xrnd = unifrnd(0,4,n,Q);  
Xobs = [X,Xrnd];
```

This piece of code creates 98 additional predictors, all uniformly distributed between 0 and 4.

Partition the data into training and test sets. To create stratified partitions, so that each partition has similar proportion of classes, use `y` instead of `length(y)` as the partitioning criteria.

```
cvp = cvpartition(y, 'holdout', 2000);
```

`cvpartition` randomly chooses 2000 of the observations to add to the test set and the rest of the data to add to the training set. Create the training and validation sets using the assignments stored in the `cvpartition` object `cvp`.

```
Xtrain = Xobs(cvp.training(1),:);
ytrain = y(cvp.training(1),:);
```

```
Xval = Xobs(cvp.test(1),:);
yval = y(cvp.test(1),:);
```

Compute the misclassification error without feature selection.

```
nca = fscnca(Xtrain,ytrain,'FitMethod','none','Standardize',true, ...
            'Solver','lbfgs');
loss_nofs = loss(nca,Xval,yval)
```

```
loss_nofs =
    0.5165
```

'FitMethod', 'none' option uses the default weights (all 1s), which means all features are equally important.

This time, perform feature selection using neighborhood component analysis for classification, with $\lambda = 1/n$.

```
w0 = rand(100,1);
n = length(ytrain)
lambda = 1/n;
nca = refit(nca,'InitialFeatureWeights',w0,'FitMethod','exact', ...
            'Lambda',lambda,'solver','sgd');
```

```
n =
    20000
```

Plot the objective function value versus the iteration number.

```
figure()
plot(nca.FitInfo.Iteration,nca.FitInfo.Objective,'ro')
hold on
plot(nca.FitInfo.Iteration,movmean(nca.FitInfo.Objective,10),'k.-')
xlabel('Iteration number')
ylabel('Objective value')
```

Compute the misclassification error with feature selection.

```
loss_withfs = loss(nca,Xval,yval)
```

```
loss_withfs =
```

```
0.0115
```

Plot the selected features.

```
figure  
semilogx(nca.FeatureWeights,'ro')  
xlabel('Feature index')  
ylabel('Feature weight')  
grid on
```

Select features using the feature weights and a relative threshold.

```
tol = 0.15;
selidx = find(nca.FeatureWeights > tol*max(1,max(nca.FeatureWeights)))
```

```
selidx =
```

```
1
2
```

Feature selection improves the results and `fscnca` detects the correct two features as relevant.

Introduced in R2016b

refit

Class: FeatureSelectionNCARegression

Refit neighborhood component analysis (NCA) model for regression

Syntax

```
mdlrefit = refit(mdl,Name,Value)
```

Description

`mdlrefit = refit(mdl,Name,Value)` refits the model `mdl`, with modified parameters specified by one or more `Name,Value` pair arguments.

Input Arguments

mdl — Neighborhood component analysis model for regression

FeatureSelectionNCARegression object

Neighborhood component analysis model or classification, specified as a FeatureSelectionNCARegression object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Fitting Options

FitMethod — Method for fitting the model

`mdl.FitMethod` (default) | 'exact' | 'none' | 'average'

Method for fitting the model, specified as the comma-separated pair consisting of 'FitMethod' and one of the following.

- 'exact' — Performs fitting using all of the data.
- 'none' — No fitting. Use this option to evaluate the generalization error of the NCA model using the initial feature weights supplied in the call to `fsrnca`.
- 'average' — The function divides the data into partitions (subsets), fits each partition using the exact method, and returns the average of the feature weights. You can specify the number of partitions using the `NumPartitions` name-value pair argument.

Example: 'FitMethod','none'

Lambda — Regularization parameter

`mdl.Lambda` (default) | non-negative scalar value

Regularization parameter, specified as the comma-separated pair consisting of 'Lambda' and a non-negative scalar value.

For n observations, the best Lambda value that minimizes the generalization error of the NCA model is expected to be a multiple of $1/n$

Example: 'Lambda',0.01

Data Types: double | single

Solver — Solver type

`mdl.Solver` (default) | 'lbfgs' | 'sgd' | 'minibatch-lbfgs'

Solver type for estimating feature weights, specified as the comma-separated pair consisting of 'Solver' and one of the following.

- 'lbfgs' — Limited memory BFGS (Broyden-Fletcher-Goldfarb-Shanno) algorithm (LBFGS algorithm)
- 'sgd' — Stochastic gradient descent
- 'minibatch-lbfgs' — Stochastic gradient descent with LBFGS algorithm applied to mini-batches

Example: 'solver','minibatch-lbfgs'

InitialFeatureWeights — Initial feature weights

`mdl.InitialFeatureWeights` (default) | p -by-1 vector of real positive scalar values

Initial feature weights, specified as the comma-separated pair consisting of 'InitialFeatureWeights' and a p -by-1 vector of real positive scalar values.

Data Types: double | single

Verbose — Indicator for verbosity level

`mdl.Verbose` (default) | 0 | 1 | >1

Indicator for verbosity level for the convergence summary display, specified as the comma-separated pair consisting of 'Verbose' and one of the following.

- 0 — No convergence summary
- 1 — Convergence summary including iteration number, norm of the gradient, and objective function value.
- >1 — More convergence information depending on the fitting algorithm

When using solver 'minibatch-lbfgs' and verbosity level >1, the convergence information includes iteration log from intermediate minibatch LBFGS fits.

Example: 'Verbose',2

Data Types: double | single

LBFGS or Mini-Batch LBFGS Options

GradientTolerance — Relative convergence tolerance

`mdl.GradientTolerance` (default) | positive real scalar value

Relative convergence tolerance on the gradient norm for solver lbfgs, specified as the comma-separated pair consisting of 'GradientTolerance' and a positive real scalar value.

Example: 'GradientTolerance',0.00001

Data Types: double | single

SGD or Mini-Batch LBFGS Options

InitialLearningRate — Initial learning rate for solver `sgd`

`mdl.InitialLearningRate` (default) | positive real scalar value

Initial learning rate for solver `sgd`, specified as the comma-separated pair consisting of `'InitialLearningRate'` and a positive scalar value.

When using solver type `'sgd'`, the learning rate decays over iterations starting with the value specified for `'InitialLearningRate'`.

Example: `'InitialLearningRate',0.8`

Data Types: double | single

PassLimit — Maximum number of passes for solver `'sgd'`

`mdl.PassLimit` (default) | positive integer value

Maximum number of passes for solver `'sgd'` (stochastic gradient descent), specified as the comma-separated pair consisting of `'PassLimit'` and a positive integer. Every pass processes `size(mdl.X,1)` observations.

Example: `'PassLimit',10`

Data Types: double | single

SGD or LBFGS or Mini-Batch LBFGS Options

IterationLimit — Maximum number of iterations

`mdl.IterationLimit` (default) | positive integer value

Maximum number of iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer.

Example: `'IterationLimit',250`

Data Types: double | single

Output Arguments

`mdlrefit` — Neighborhood component analysis model for regression

`FeatureSelectionNCARegression` object

Neighborhood component analysis model or classification, returned as a `FeatureSelectionNCARegression` object. You can either save the results as a new model or update the existing model as `mdl = refit(mdl,Name,Value)`.

Examples

Refit NCA Model for Regression with Modified Settings

Load the sample data.

```
load('robotarm.mat')
```

The `robotarm` (`pumadyn32nm`) dataset is created using a robot arm simulator with 7168 training and 1024 test observations with 32 features [1], [2]. This is a preprocessed version of the original data set. Data are preprocessed by subtracting off a linear regression fit followed by normalization of all features to unit variance.

Compute the generalization error without feature selection.

```
nca = fsrnca(Xtrain,ytrain,'FitMethod','none','Standardize',1);
L = loss(nca,Xtest,ytest)
```

```
L = 0.9017
```

Now, refit the model and compute the prediction loss with feature selection, with $\lambda = 0$ (no regularization term) and compare to the previous loss value, to determine feature selection seems necessary for this problem. For the settings that you do not change, `refit` uses the settings of the initial model `nca`. For example, it uses the feature weights found in `nca` as the initial feature weights.

```
nca2 = refit(nca,'FitMethod','exact','Lambda',0);
L2 = loss(nca2,Xtest,ytest)
```

```
L2 = 0.1088
```

The decrease in the loss suggests that feature selection is necessary.

Plot the feature weights.

```
figure()
plot(nca2.FeatureWeights,'ro')
```

Tuning the regularization parameter usually improves the results. Suppose that, after tuning λ using cross-validation as in “Tune Regularization Parameter in NCA for Regression” on page 32-2269, the best λ value found is 0.0035. Refit the nca model using this λ value and stochastic gradient descent as the solver. Compute the prediction loss.

```
nca3 = refit(nca2, 'FitMethod', 'exact', 'Lambda', 0.0035, ...
            'Solver', 'sgd');
L3 = loss(nca3, Xtest, ytest)

L3 = 0.0573
```

Plot the feature weights.

```
figure()
plot(nca3.FeatureWeights, 'ro')
```

After tuning the regularization parameter, the loss decreased even more and the software identified four of the features as relevant.

Introduced in R2016b

reduceDimensions

Reduce dimensions of Sobol point set

Syntax

```
pr = reduceDimensions(p,d)
```

Description

`pr = reduceDimensions(p,d)` reduces the Sobol quasirandom point set `p` to the first `d` dimensions. `d` must be less than or equal to the number of dimensions in `p`.

The reduced point set `pr` is a `sobolset` object.

Examples

Reduce Dimensions of Sobol Point Set

Generate a seven-dimensional Sobol point set and scramble the points.

```
p = sobolset(7);
ps = scramble(p, 'MatousekAffineOwen')

ps =
Sobol point set in 7 dimensions (9007199254740992 points)

Properties:
      Skip : 0
      Leap : 0
ScrambleMethod : MatousekAffineOwen
      PointOrder : standard
```

Split the first 7168 points in `ps` into seven levels of 1024 points each. Reduce the first 1024 points to be one-dimensional, the second 1024 points to be two-dimensional, and so on. For each level, compute the variance of the point values in each dimension.

```
variance = NaN(7);
for level = 1:7
    pr = reduceDimensions(ps,level);
    pr.Skip = (level-1)*1024;
    pts = pr(1:1024,:);
    variance(level,1:level) = var(pts);
end
```

Plot the variances. The dark blue bars show the variance of the points in the first dimension, the dark orange bars show the variance of the points in the second dimension, and so on.

```
bar(variance)
xlabel('Level')
ylabel('Variances')
```

Input Arguments

p – Sobol point set

`sobolset` object

Sobol point set, specified as a `sobolset` object.

d – Number of dimensions to retain

positive integer scalar

Number of dimensions to retain from the point set `p`, specified as a positive integer scalar between 1 and the number of dimensions in `p`. The function always retains the first `d` dimensions of `p`.

Data Types: `single` | `double`

Introduced in R2019a

refline

Add reference line to plot

Syntax

```
refline(m,b)
refline(coeffs)
refline
refline(ax, ___)
hline = refline( ___ )
```

Description

`refline(m,b)` adds a reference line with slope `m` and intercept `b` to the current axes.

`refline(coeffs)` adds the line defined by the elements of the vector `coeffs` to the figure.

`refline` with no input arguments is equivalent to `lsline`.

`refline(ax, ___)` adds a reference line to the plot in the axis specified by `ax`, using any of the input arguments in the previous syntaxes.

`hline = refline(___)` returns the reference line object `hline` using any of the input arguments in the previous syntaxes. Use `hline` to modify properties of a specific reference line after you create it. For a list of properties, see [Line Properties](#).

Examples

Add Reference Line at the Mean

Generate sample data for an independent variable `x` and a dependent variable `y`.

```
x = 1:10;
y = x + randn(1,10);
```

Create a scatter plot of `x` and `y`.

```
scatter(x,y,25, 'b', '*')
```

Superimpose a least-squares line on the scatter plot.

refline

Add a reference line at the mean of the scatter plot.

```
mu = mean(y);  
hline = refline([0 mu]);  
hline.Color = 'r';
```

The red line is the reference line at the mean of the data.

Specify Axes for Least-Squares and Reference Lines

Define the x-variable and two different y-variables to use for the plots.

```
rng default % For reproducibility
x = 1:10;
y1 = x + randn(1,10);
y2 = 2*x + randn(1,10);
```

Define `ax1` as the top half of the figure, and `ax2` as the bottom half of the figure. Create the first scatter plot on the top axis using `y1`, and the second scatter plot on the bottom axis using `y2`.

```
figure
ax1 = subplot(2,1,1);
ax2 = subplot(2,1,2);

scatter(ax1,x,y1)
scatter(ax2,x,y2)
```

Superimpose a least-squares line on the top plot, and a reference line at the mean of the y2 values in the bottom plot.

```
lsline(ax1) % This is equivalent to refline(ax1)
```

```
mu = mean(y2);  
refline(ax2,[0 mu])
```

Input Arguments

m — Slope of reference line

numeric scalar

Slope of the reference line, specified as a numeric scalar. The function uses *m* to define the line

$$y = m*x + b.$$

Example: `refline(-1,1)`

Data Types: `single` | `double`

b — Intercept of reference line

numeric scalar

Intercept of the reference line, specified as a numeric scalar. The function uses *b* to define the line

$$y = m*x + b.$$

Example: `refline(2,-10)`

Data Types: `single` | `double`

coeffs — Linear coefficients

length-two numeric vector

Linear coefficients, specified as a length-two numeric vector. `coeffs` contains the coefficients of a line defined as

$$y = \text{coeffs}(1)*x + \text{coeffs}(2).$$

Example: `refline([-1,2])`

Data Types: `single` | `double`

ax — Target axes

`gca` (default) | axes object

Target axes, specified as an axes object. If you do not specify the axes and if the current axes are Cartesian axes, then the `refline` function uses the current axes.

Output Arguments

hline — One or more reference line objects

scalar | vector

One or more reference line objects, returned as a scalar or a vector. These objects are unique identifiers, which you can use to query and modify properties of a specific reference line. For a list of properties, see [Chart Line](#).

`gline` | `lslines` | `refcurve`

Introduced before R2006a

regress

Multiple linear regression

Syntax

```
b = regress(y,X)
[b,bint] = regress(y,X)
[b,bint,r] = regress(y,X)
[b,bint,r,rint] = regress(y,X)
[b,bint,r,rint,stats] = regress(y,X)
[ ___ ] = regress(y,X,alpha)
```

Description

`b = regress(y,X)` returns a vector `b` of coefficient estimates for a multiple linear regression of the responses in vector `y` on the predictors in matrix `X`. To compute coefficient estimates for a model with a constant term (intercept), include a column of ones in the matrix `X`.

`[b,bint] = regress(y,X)` also returns a matrix `bint` of 95% confidence intervals for the coefficient estimates.

`[b,bint,r] = regress(y,X)` also returns an additional vector `r` of residuals.

`[b,bint,r,rint] = regress(y,X)` also returns a matrix `rint` of intervals that can be used to diagnose outliers.

`[b,bint,r,rint,stats] = regress(y,X)` also returns a vector `stats` that contains the R^2 statistic, the F -statistic and its p -value, and an estimate of the error variance. The matrix `X` must include a column of ones for the software to compute the model statistics correctly.

`[___] = regress(y,X,alpha)` uses a $100*(1-\alpha)\%$ confidence level to compute `bint` and `rint`. Specify any of the output argument combinations in the previous syntaxes.

Examples

Estimate Multiple Linear Regression Coefficients

Load the `carsmall` data set. Identify weight and horsepower as predictors and mileage as the response.

```
load carsmall
x1 = Weight;
x2 = Horsepower;    % Contains NaN data
y = MPG;
```

Compute the regression coefficients for a linear model with an interaction term.

```
X = [ones(size(x1)) x1 x2 x1.*x2];
b = regress(y,X)    % Removes NaN data
```

```
b = 4x1  
  
60.7104  
-0.0102  
-0.1882  
0.0000
```

Plot the data and the model.

```
scatter3(x1,x2,y,'filled')  
hold on  
x1fit = min(x1):100:max(x1);  
x2fit = min(x2):10:max(x2);  
[X1FIT,X2FIT] = meshgrid(x1fit,x2fit);  
YFIT = b(1) + b(2)*X1FIT + b(3)*X2FIT + b(4)*X1FIT.*X2FIT;  
mesh(X1FIT,X2FIT,YFIT)  
xlabel('Weight')  
ylabel('Horsepower')  
zlabel('MPG')  
view(50,10)  
hold off
```

Diagnose Outliers Using Residuals

Load the examgrades data set.

```
load examgrades
```

Use the last exam scores as response data and the first two exam scores as predictor data.

```
y = grades(:,5);
X = [ones(size(grades(:,1))) grades(:,1:2)];
```

Perform multiple linear regression with $\alpha = 0.01$.

```
[~,~,r,rint] = regress(y,X,0.01);
```

Diagnose outliers by finding the residual intervals rint that do not contain 0.

```
contain0 = (rint(:,1)<0 & rint(:,2)>0);
idx = find(contain0==false)
```

```
idx = 2×1
```

```
53
```

```
54
```

Observations 53 and 54 are possible outliers.

Create a scatter plot of the residuals. Fill in the points corresponding to the outliers.

```
hold on
scatter(y,r)
scatter(y(idx),r(idx),'b','filled')
xlabel("Last Exam Grades")
ylabel("Residuals")
hold off
```

Determine Significance of Linear Regression Relationship

Load the `hald` data set. Use `heat` as the response variable and `ingredients` as the predictor data.

```
load hald
y = heat;
X1 = ingredients;
x1 = ones(size(X1,1),1);
X = [x1 X1];    % Includes column of ones
```

Perform multiple linear regression and generate model statistics.

```
[~,~,~,~,stats] = regress(y,X)

stats = 1x4

    0.9824    111.4792     0.0000     5.9830
```

Because the R^2 value of 0.9824 is close to 1, and the p -value of 0.0000 is less than the default significance level of 0.05, a significant linear regression relationship exists between the response y and the predictor variables in X .

Input Arguments

y — Response data

numeric vector

Response data, specified as an n -by-1 numeric vector. Rows of y correspond to different observations. y must have the same number of rows as X .

Data Types: `single` | `double`

X — Predictor data

numeric matrix

Predictor data, specified as an n -by- p numeric matrix. Rows of X correspond to observations, and columns correspond to predictor variables. X must have the same number of rows as y .

Data Types: `single` | `double`

alpha — Significance level

0.05 (default) | positive scalar

Significance level, specified as a positive scalar. α must be between 0 and 1.

Data Types: `single` | `double`

Output Arguments

b — Coefficient estimates for multiple linear regression

numeric vector

Coefficient estimates for multiple linear regression, returned as a numeric vector. \mathbf{b} is a p -by-1 vector, where p is the number of predictors in X . If the columns of X are linearly dependent, `regress` sets the maximum number of elements of \mathbf{b} to zero.

Data Types: `double`

bint — Lower and upper confidence bounds for coefficient estimates

numeric matrix

Lower and upper confidence bounds for coefficient estimates, returned as a numeric matrix. \mathbf{bint} is a p -by-2 matrix, where p is the number of predictors in X . The first column of \mathbf{bint} contains lower confidence bounds for each of the coefficient estimates; the second column contains upper confidence bounds. If the columns of X are linearly dependent, `regress` returns zeros in elements of \mathbf{bint} corresponding to the zero elements of \mathbf{b} .

Data Types: `double`

r — Residuals

numeric vector

Residuals, returned as a numeric vector. \mathbf{r} is an n -by-1 vector, where n is the number of observations, or rows, in X .

Data Types: `single` | `double`

rint — Intervals to diagnose outliers

numeric matrix

Intervals to diagnose outliers, returned as a numeric matrix. `rint` is an n -by-2 matrix, where n is the number of observations, or rows, in X . If the interval `rint(i, :)` for observation i does not contain zero, the corresponding residual is larger than expected in $100*(1-\alpha)\%$ of new observations, suggesting an outlier. For more information, see “Algorithms” on page 32-4588.

Data Types: `single` | `double`

stats – Model statistics

numeric vector

Model statistics, returned as a numeric vector including the R^2 statistic, the F -statistic and its p -value, and an estimate of the error variance.

- X must include a column of ones so that the model contains a constant term. The F -statistic and its p -value are computed under this assumption and are not correct for models without a constant.
- The F -statistic is the test statistic of the F -test on the regression model. The F -test looks for a significant linear regression relationship between the response variable and the predictor variables.
- The R^2 statistic can be negative for models without a constant, indicating that the model is not appropriate for the data.

Data Types: `single` | `double`

Tips

- `regress` treats NaN values in X or y as missing values. `regress` omits observations with missing values from the regression fit.

Algorithms

Residual Intervals

In a linear model, observed values of y and their residuals are random variables. Residuals have normal distributions with zero mean but with different variances at different values of the predictors. To put residuals on a comparable scale, `regress` “Studentizes” the residuals. That is, `regress` divides the residuals by an estimate of their standard deviation that is independent of their value. Studentized residuals have t -distributions with known degrees of freedom. The intervals returned in `rint` are shifts of the $100*(1-\alpha)\%$ confidence intervals of these t -distributions, centered at the residuals.

Alternative Functionality

`regress` is useful when you simply need the output arguments of the function and when you want to repeat fitting a model multiple times in a loop. If you need to investigate a fitted regression model further, create a linear regression model object `LinearModel` by using `fitlm` or `stepwiselm`. A `LinearModel` object provides more features than `regress`.

- Use the properties of `LinearModel` to investigate a fitted linear regression model. The object properties include information about coefficient estimates, summary statistics, fitting method, and input data.
- Use the object functions of `LinearModel` to predict responses and to modify, evaluate, and visualize the linear regression model.

- Unlike `regress`, the `fitlm` function does not require a column of ones in the input data. A model created by `fitlm` always includes an intercept term unless you specify not to include it by using the 'Intercept' name-value pair argument.
- You can find the information in the output of `regress` using the properties and object functions of `LinearModel`.

Output of regress	Equivalent Values in LinearModel
<code>b</code>	See the Estimate column of the Coefficients property.
<code>bint</code>	Use the <code>coefCI</code> function.
<code>r</code>	See the Raw column of the Residuals property.
<code>rint</code>	Not supported. Instead, use studentized residuals (Residuals property) and observation diagnostics (Diagnostics property) to find outliers.
<code>stats</code>	See the model display in the Command Window. You can find the statistics in the model properties (MSE and Rsquared) and by using the <code>anova</code> function.

Introduced before R2006a

RegressionBaggedEnsemble

Package: classreg.learning.regr

Superclasses: RegressionEnsemble

Regression ensemble grown by resampling

Description

RegressionBaggedEnsemble combines a set of trained weak learner models and data on which these learners were trained. It can predict ensemble response for new data by aggregating predictions from its weak learners.

Construction

Create a bagged regression ensemble object using `fitensemble`. Set the name-value pair argument 'Method' of `fitensemble` to 'Bag' to use bootstrap aggregation (bagging, for example, random forest).

Properties

BinEdges

Bin edges for numeric predictors, specified as a cell array of p numeric vectors, where p is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the 'NumBins' name-value pair argument as a positive integer scalar when training a model with tree learners. The BinEdges property is empty if the 'NumBins' value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the BinEdges property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
```

```

    Xbinned(:,j) = xbinned;
end

```

Xbinned contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. Xbinned values are 0 for categorical predictors. If X contains NaNs, then the corresponding Xbinned values are NaNs.

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. CategoricalPredictors contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

CombineWeights

A character vector describing how the ensemble combines learner predictions.

ExpandedPredictorNames

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then ExpandedPredictorNames includes the names that describe the expanded variables. Otherwise, ExpandedPredictorNames is the same as PredictorNames.

FitInfo

A numeric array of fit information. The FitInfoDescription property describes the content of this array.

FitInfoDescription

Character vector describing the meaning of the FitInfo array.

FResample

A numeric scalar between 0 and 1. FResample is the fraction of training data fitrensemble resampled at random for every weak learner when constructing the ensemble.

HyperparameterOptimizationResults

Description of the cross-validation optimization of hyperparameters, stored as a BayesianOptimization object or a table of hyperparameters and associated values. Nonempty when the OptimizeHyperparameters name-value pair is nonempty at creation. Value depends on the setting of the HyperparameterOptimizationOptions name-value pair at creation:

- 'bayesopt' (default) — Object of class BayesianOptimization
- 'gridsearch' or 'randomsearch' — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

LearnerNames

Cell array of character vectors with names of the weak learners in the ensemble. The name of each learner appears just once. For example, if you have an ensemble of 100 trees, LearnerNames is {'Tree'}.

Method

A character vector with the name of the algorithm `fitrensemble` used for training the ensemble.

ModelParameters

Parameters used in training `ens`.

NumObservations

Numeric scalar containing the number of observations in the training data.

NumTrained

Number of trained learners in the ensemble, a positive scalar.

PredictorNames

A cell array of names for the predictor variables, in the order in which they appear in `X`.

ReasonForTermination

A character vector describing the reason `fitrensemble` stopped adding weak learners to the ensemble.

Regularization

A structure containing the result of the `regularize` method. Use `Regularization` with `shrink` to lower resubstitution error and shrink the ensemble.

Replace

Boolean flag indicating if training data for weak learners in this ensemble were sampled with replacement. `Replace` is `true` for sampling with replacement, `false` otherwise.

ResponseName

A character vector with the name of the response variable `Y`.

ResponseTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means $@(x)x$.

Add or change a `ResponseTransform` function using dot notation:

```
ens.ResponseTransform = @function
```

Trained

The trained learners, a cell array of compact regression models.

TrainedWeights

A numeric vector of weights the ensemble assigns to its learners. The ensemble computes predicted response by aggregating weighted predictions from its learners.

UseObsForLearner

A logical matrix of size N-by-NumTrained, where N is the number of rows (observations) in the training data X, and NumTrained is the number of trained weak learners. UseObsForLearner(I, J) is true if observation I was used for training learner J, and is false otherwise.

W

The scaled weights, a vector with length n, the number of rows in X. The sum of the elements of W is 1.

X

The matrix or table of predictor values that trained the ensemble. Each column of X represents one variable, and each row represents one observation.

Y

The numeric column vector with the same number of rows as X that trained the ensemble. Each entry in Y is the response to the data in the corresponding row of X.

Methods

oobLoss	Out-of-bag regression error
oobPermutedPredictorImportance	Predictor importance estimates by permutation of out-of-bag predictor observations for random forest of regression trees
oobPredict	Predict out-of-bag response of ensemble

Inherited Methods

compact	Create compact regression ensemble
crossval	Cross validate ensemble
cvshrink	Cross validate shrinking (pruning) ensemble
regularize	Find weights to minimize resubstitution error plus penalty term
resubLoss	Regression error by resubstitution
resubPredict	Predict response of ensemble by resubstitution
resume	Resume training ensemble
shrink	Prune ensemble
loss	Regression error
predict	Predict responses using ensemble of regression models
predictorImportance	Estimates of predictor importance for regression ensemble
removeLearners	Remove members of compact regression ensemble

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Train Bagged Ensemble of Regression Trees

Load the `carsmall` data set. Consider a model that explains a car's fuel economy (MPG) using its weight (`Weight`) and number of cylinders (`Cylinders`).

```
load carsmall
X = [Weight Cylinders];
Y = MPG;
```

Train a bagged ensemble of 100 regression trees using all measurements.

```
Mdl = fitensemble(X,Y,'Method','bag')
```

```
Mdl =
  classreg.learning.regr.RegressionBaggedEnsemble
      ResponseName: 'Y'
  CategoricalPredictors: []
      ResponseTransform: 'none'
      NumObservations: 94
      NumTrained: 100
      Method: 'Bag'
      LearnerNames: {'Tree'}
  ReasonForTermination: 'Terminated normally after completing the requested number of training iterations'
      FitInfo: []
  FitInfoDescription: 'None'
      Regularization: []
      FResample: 1
      Replace: 1
      UseObsForLearner: [94x100 logical]
```

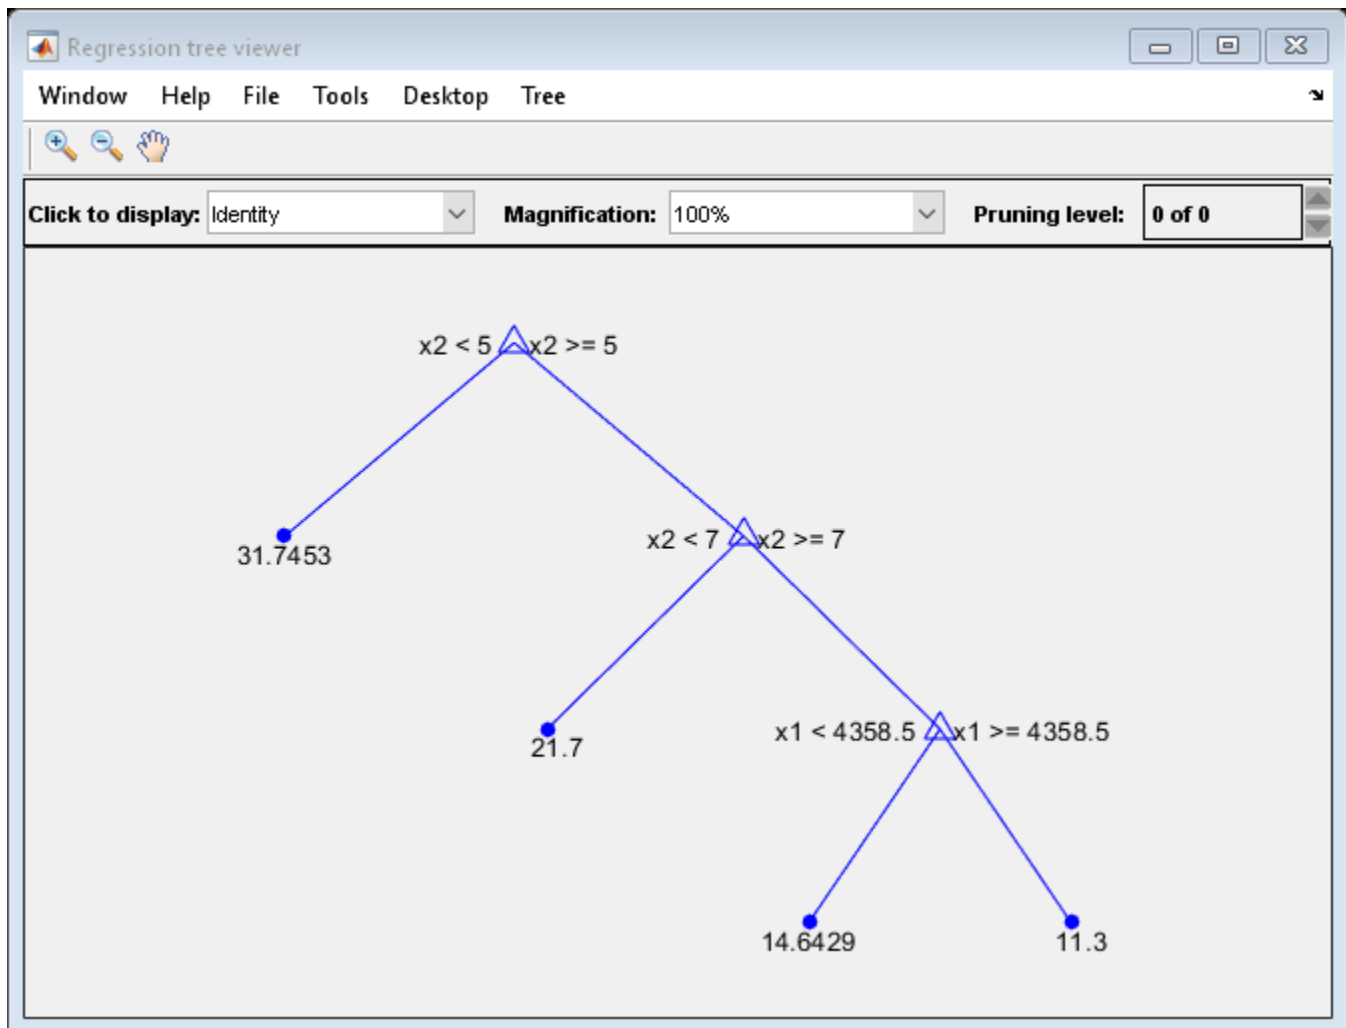

Properties, Methods

`Mdl` is a `RegressionBaggedEnsemble` model object.

`Mdl.Trained` is the property that stores a 100-by-1 cell vector of the trained, compact regression trees (`CompactRegressionTree` model objects) that compose the ensemble.

Plot a graph of the first trained regression tree.

```
view(Mdl.Trained{1}, 'Mode', 'graph')
```

By default, `fitensemble` grows deep trees for bags of trees.

Estimate the in-sample mean-squared error (MSE).

```
L = resubLoss(Mdl)
```

```
L = 18.7221
```

Tip

For a bagged ensemble of regression trees, the `Trained` property of `ens` stores a cell vector of `ens.NumTrained CompactRegressionTree` model objects. For a textual or graphical display of tree `t` in the cell vector, enter

```
view(ens.Trained{t})
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.
- When you train an ensemble by using `fitensemble`, code generation limitations for regression trees also apply to ensembles of regression trees. For more details, see “Code Generation” on page 32-751 of the `CompactRegressionTree` class.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2011a

RegressionEnsemble

Package: classreg.learning.regr

Superclasses: CompactRegressionEnsemble

Ensemble regression

Description

RegressionEnsemble combines a set of trained weak learner models and data on which these learners were trained. It can predict ensemble response for new data by aggregating predictions from its weak learners.

Construction

Create a regression ensemble object using `fitrensemble`.

Properties

BinEdges

Bin edges for numeric predictors, specified as a cell array of p numeric vectors, where p is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the 'NumBins' name-value pair argument as a positive integer scalar when training a model with tree learners. The BinEdges property is empty if the 'NumBins' value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the BinEdges property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

Xbinned contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. Xbinned values are 0 for categorical predictors. If X contains NaNs, then the corresponding Xbinned values are NaNs.

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. CategoricalPredictors contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

CombineWeights

A character vector describing how the ensemble combines learner predictions.

ExpandedPredictorNames

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then ExpandedPredictorNames includes the names that describe the expanded variables. Otherwise, ExpandedPredictorNames is the same as PredictorNames.

FitInfo

A numeric array of fit information. The FitInfoDescription property describes the content of this array.

FitInfoDescription

Character vector describing the meaning of the FitInfo array.

LearnerNames

Cell array of character vectors with names of the weak learners in the ensemble. The name of each learner appears just once. For example, if you have an ensemble of 100 trees, LearnerNames is {'Tree'}.

HyperparameterOptimizationResults

Description of the cross-validation optimization of hyperparameters, stored as a BayesianOptimization object or a table of hyperparameters and associated values. Nonempty when the OptimizeHyperparameters name-value pair is nonempty at creation. Value depends on the setting of the HyperparameterOptimizationOptions name-value pair at creation:

- 'bayesopt' (default) — Object of class BayesianOptimization
- 'gridsearch' or 'randomsearch' — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

Method

A character vector with the name of the algorithm fitrensemble used for training the ensemble.

ModelParameters

Parameters used in training ens.

NumObservations

Numeric scalar containing the number of observations in the training data.

NumTrained

Number of trained learners in the ensemble, a positive scalar.

PredictorNames

A cell array of names for the predictor variables, in the order in which they appear in X .

ReasonForTermination

A character vector describing the reason `fitensemble` stopped adding weak learners to the ensemble.

Regularization

A structure containing the result of the `regularize` method. Use `Regularization` with `shrink` to lower resubstitution error and shrink the ensemble.

ResponseName

A character vector with the name of the response variable Y .

ResponseTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means $@(x)x$.

Add or change a `ResponseTransform` function using dot notation:

```
ens.ResponseTransform = @function
```

Trained

The trained learners, a cell array of compact regression models.

TrainedWeights

A numeric vector of weights the ensemble assigns to its learners. The ensemble computes predicted response by aggregating weighted predictions from its learners.

W

The scaled weights, a vector with length n , the number of rows in X . The sum of the elements of W is 1.

X

The matrix or table of predictor values that trained the ensemble. Each column of X represents one variable, and each row represents one observation.

Y

The numeric column vector with the same number of rows as *X* that trained the ensemble. Each entry in *Y* is the response to the data in the corresponding row of *X*.

Methods

<code>compact</code>	Create compact regression ensemble
<code>crossval</code>	Cross validate ensemble
<code>cvshrink</code>	Cross validate shrinking (pruning) ensemble
<code>regularize</code>	Find weights to minimize resubstitution error plus penalty term
<code>resubLoss</code>	Regression error by resubstitution
<code>resubPredict</code>	Predict response of ensemble by resubstitution
<code>resume</code>	Resume training ensemble
<code>shrink</code>	Prune ensemble

Inherited Methods

<code>loss</code>	Regression error
<code>predict</code>	Predict responses using ensemble of regression models
<code>predictorImportance</code>	Estimates of predictor importance for regression ensemble
<code>removeLearners</code>	Remove members of compact regression ensemble

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples**Train Boosted Regression Ensemble**

Load the `carsmall` data set. Consider a model that explains a car's fuel economy (MPG) using its weight (`Weight`) and number of cylinders (`Cylinders`).

```
load carsmall
X = [Weight Cylinders];
Y = MPG;
```

Train a boosted ensemble of 100 regression trees using the `LSBoost` method. Specify that `Cylinders` is a categorical variable.

```
Mdl = fitensemble(X,Y,'Method','LSBoost',...
    'PredictorNames',{'W','C'},'CategoricalPredictors',2)
```

```
Mdl =
    classreg.learning.regr.RegressionEnsemble
    PredictorNames: {'W' 'C'}
    ResponseName: 'Y'
```

```
CategoricalPredictors: 2
  ResponseTransform: 'none'
  NumObservations: 94
  NumTrained: 100
    Method: 'LSBoost'
    LearnerNames: {'Tree'}
  ReasonForTermination: 'Terminated normally after completing the requested number of training iterations'
  FitInfo: [100x1 double]
  FitInfoDescription: {2x1 cell}
  Regularization: []
```

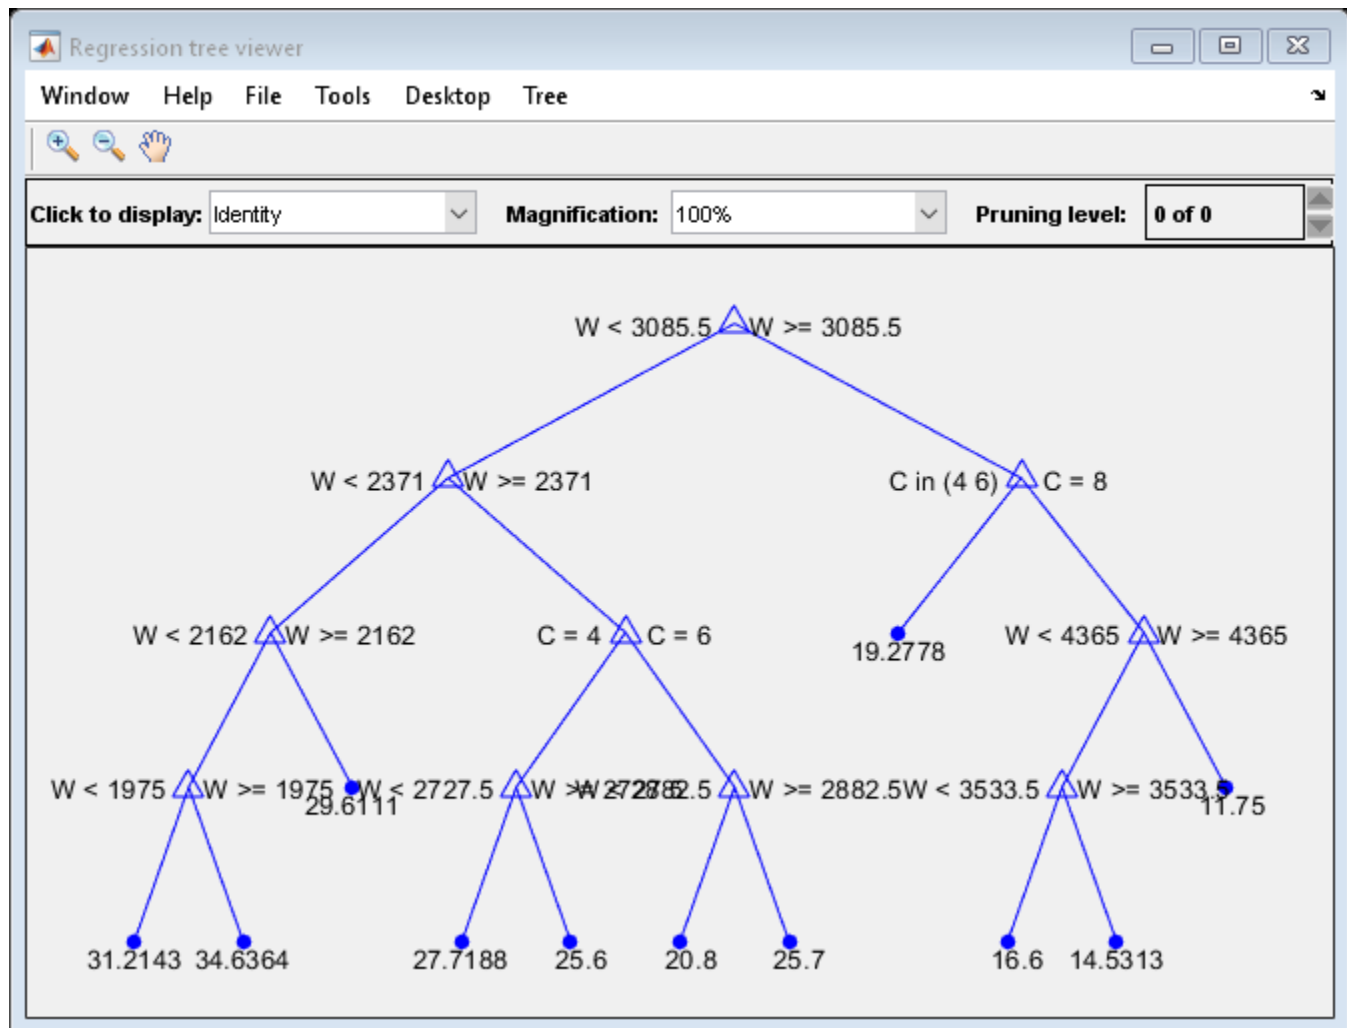

Properties, Methods

`Mdl` is a `RegressionEnsemble` model object that contains the training data, among other things.

`Mdl.Trained` is the property that stores a 100-by-1 cell vector of the trained regression trees (`CompactRegressionTree` model objects) that compose the ensemble.

Plot a graph of the first trained regression tree.

```
view(Mdl.Trained{1}, 'Mode', 'graph')
```

By default, `fitensemble` grows shallow trees for boosted ensembles of trees.

Predict the fuel economy of 4,000 pound cars with 4, 6, and 8 cylinders.

```
XNew = [4000*ones(3,1) [4; 6; 8]];
mpgNew = predict(Mdl,XNew)
```

```
mpgNew = 3×1
```

```
19.5926
18.6388
15.4810
```

Tip

For an ensemble of regression trees, the `Trained` property contains a cell vector of `ens.NumTrained CompactRegressionTree` model objects. For a textual or graphical display of tree t in the cell vector, enter

```
view(ens.Trained{t})
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.
- When you train an ensemble by using `fitensemble`, code generation limitations for regression trees also apply to ensembles of regression trees. For more details, see “Code Generation” on page 32-751 of the `CompactRegressionTree` class.

Introduced in R2011a

RegressionGP class

Superclasses: CompactRegressionGP

Gaussian process regression model class

Description

RegressionGP is a Gaussian process regression (GPR) model. You can train a GPR model, using `fitrgp`. Using the trained model, you can

- Predict responses for training data using `resubPredict` or new predictor data using `predict`. You can also compute the prediction intervals.
- Compute the regression loss for training data using `resubLoss` or new data using `loss`.

Construction

Create a RegressionGP object by using `fitrgp`.

Properties

Fitting

FitMethod — Method used to estimate the parameters

'none' | 'exact' | 'sd' | 'sr' | 'fic'

Method used to estimate the basis function coefficients, β ; noise standard deviation, σ ; and kernel parameters, θ , of the GPR model, stored as a character vector. It can be one of the following.

Fit Method	Description
'none'	No estimation. <code>fitrgp</code> uses the initial parameter values as the parameter values.
'exact'	Exact Gaussian process regression.
'sd'	Subset of data points approximation.
'sr'	Subset of regressors approximation.
'fic'	Fully independent conditional approximation.

BasisFunction — Explicit basis function

'none' | 'constant' | 'linear' | 'pureQuadratic' | function handle

Explicit basis function used in the GPR model, stored as a character vector or a function handle. It can be one of the following. If n is the number of observations, the basis function adds the term $\mathbf{H}\boldsymbol{\beta}$ to the model, where \mathbf{H} is the basis matrix and $\boldsymbol{\beta}$ is a p -by-1 vector of basis coefficients.

Explicit Basis	Basis Matrix
'none'	Empty matrix.

Explicit Basis	Basis Matrix
'constant'	$H = 1$ (n -by-1 vector of 1s, where n is the number of observations)
'linear'	$H = [1, X]$
'pureQuadratic'	$H = [1, X, X_2]$, where $X_2 = \begin{bmatrix} x_{11}^2 & x_{12}^2 & \cdots & x_{1d}^2 \\ x_{21}^2 & x_{22}^2 & \cdots & x_{2d}^2 \\ \vdots & \vdots & \vdots & \vdots \\ x_{n1}^2 & x_{n2}^2 & \cdots & x_{nd}^2 \end{bmatrix}.$
Function handle	Function handle, <i>hfcn</i> , that <code>fitrgp</code> calls as: $H = hfcn(X)$, where X is an n -by- d matrix of predictors and H is an n -by- p matrix of basis functions.

Data Types: char | function_handle

Beta – Estimated coefficients

vector

Estimated coefficients for the explicit basis functions, stored as a vector. You can define the explicit basis function by using the `BasisFunction` name-value pair argument in `fitrgp`.

Data Types: double

Sigma – Estimated noise standard deviation

scalar value

Estimated noise standard deviation of the GPR model, stored as a scalar value.

Data Types: double

CategoricalPredictors – Indices of categorical predictors

vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: single | double

HyperparameterOptimizationResults – Description of cross-validation optimization of hyperparameters

BayesianOptimization object | table

Description of the cross-validation optimization of hyperparameters, specified as a `BayesianOptimization` object or a table of hyperparameters and associated values. This property

is nonempty if the 'OptimizeHyperparameters' name-value pair argument is nonempty when you create the model. The value of HyperparameterOptimizationResults depends on the setting of the Optimizer field in the HyperparameterOptimizationOptions structure when you create the model, as described in this table.

Value of Optimizer Field	Value of HyperparameterOptimizationResults
'bayesopt' (default)	Object of class BayesianOptimization
'gridsearch' or 'randomsearch'	Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

LogLikelihood — Maximized marginal log likelihood

scalar value | []

Maximized marginal log likelihood of the GPR model, stored as a scalar value if the FitMethod is different from 'none'. If FitMethod is 'none', then LogLikelihood is empty.

If FitMethod is 'sd', 'sr', or 'fic', then LogLikelihood is the maximized approximation of the marginal log likelihood of the GPR model.

Data Types: double

ModelParameters — Parameters used for training

GPParams object

Parameters used for training the GPR model, stored as a GPParams object.

Kernel Function

KernelFunction — Form of the covariance function

'squaredExponential' | 'matern32' | 'matern52' | 'ardsquaredexponential' | 'ardmatern32' | 'ardmatern52' | function handle

Form of the covariance function used in the GPR model, stored as a character vector containing the name of the built-in covariance function or a function handle. It can be one of the following.

Function	Description
'squaredexponential'	Squared exponential kernel.
'matern32'	Matern kernel with parameter 3/2.
'matern52'	Matern kernel with parameter 5/2.
'ardsquaredexponential'	Squared exponential kernel with a separate length scale per predictor.
'ardmatern32'	Matern kernel with parameter 3/2 and a separate length scale per predictor.
'ardmatern52'	Matern kernel with parameter 5/2 and a separate length scale per predictor.

Function	Description
Function handle	A function handle that <code>fitrgp</code> can call like this: $K_{mn} = \text{kfcn}(X_m, X_n, \text{theta})$ where X_m is an m -by- d matrix, X_n is an n -by- d matrix and K_{mn} is an m -by- n matrix of kernel products such that $K_{mn}(i,j)$ is the kernel product between $X_m(i,:)$ and $X_n(j,:)$. theta is the r -by-1 unconstrained parameter vector for <code>kfcn</code> .

Data Types: char | function_handle

KernelInformation — Information about the parameters of the kernel function structure

Information about the parameters of the kernel function used in the GPR model, stored as a structure with the following fields.

Field Name	Description
Name	Name of the kernel function
KernelParameters	Vector of the estimated kernel parameters
KernelParameterNames	Names associated with the elements of KernelParameters.

Data Types: struct

Prediction

PredictMethod — Method used to make predictions

'exact' | 'bcd' | 'sd' | 'sr' | 'fic'

Method that `predict` uses to make predictions from the GPR model, stored as a character vector. It can be one of the following.

PredictMethod	Description
'exact'	Exact Gaussian process regression
'bcd'	Block Coordinate Descent
'sd'	Subset of Data points approximation
'sr'	Subset of Regressors approximation
'fic'	Fully Independent Conditional approximation

Alpha — Weights

numeric vector

Weights used to make predictions from the trained GPR model, stored as a numeric vector. `predict` computes the predictions for a new predictor matrix X_{new} by using the product

$$K(X_{new}, A) * \alpha .$$

$K(X_{new}, A)$ is the matrix of kernel products between X_{new} and active set vector A and α is a vector of weights.

Data Types: `double`

BCDInformation — Information on BCD-based computation of Alpha

structure | []

Information on block coordinate descent (BCD)-based computation of Alpha when `PredictMethod` is 'bcd', stored as a structure containing the following fields.

Field Name	Description
Gradient	n -by-1 vector containing the gradient of the BCD objective function at convergence.
Objective	Scalar containing the BCD objective function at convergence.
SelectionCounts	n -by-1 integer vector indicating the number of times each point was selected into a block during BCD.

Alpha property contains the Alpha vector computed from BCD.

If `PredictMethod` is not 'bcd', then `BCDInformation` is empty.

Data Types: `struct`

ResponseTransform — Transformation applied to predicted response

'none' (default)

Transformation applied to the predicted response, stored as a character vector describing how the response values predicted by the model are transformed. In `RegressionGP`, `ResponseTransform` is 'none' by default, and `RegressionGP` does not use `ResponseTransform` when making predictions.

Active Set Selection

ActiveSetVectors — Subset of training data

matrix

Subset of training data used to make predictions from the GPR model, stored as a matrix.

`predict` computes the predictions for a new predictor matrix X_{new} by using the product

$$K(X_{new}, A) * \alpha .$$

$K(X_{new}, A)$ is the matrix of kernel products between X_{new} and active set vector A and α is a vector of weights.

`ActiveSetVectors` is equal to the training data X for exact GPR fitting and a subset of the training data X for sparse GPR methods. When there are categorical predictors in the model, `ActiveSetVectors` contains dummy variables for the corresponding predictors.

Data Types: `double`

ActiveSetHistory — History of active set selection and parameter estimation

structure

History of interleaved active set selection and parameter estimation on page 32-4611 for `FitMethod` equal to 'sd', 'sr', or 'fic', stored as a structure with the following fields.

Field Name	Description
ParameterVector	Cell array containing the parameter vectors: basis function coefficients, β , kernel function parameters θ , and noise standard deviation σ .
ActiveSetIndices	Cell array containing the active set indices.
Loglikelihood	Vector containing the maximized log likelihoods.
CriterionProfile	Cell array containing the active set selection criterion values as the active set grows from size 0 to its final size.

Data Types: struct

ActiveSetMethod — Method used to select the active set

'sgma' | 'entropy' | 'likelihood' | 'random'

Method used to select the active set for sparse methods ('sd', 'sr', or 'fic'), stored as a character vector. It can be one of the following.

ActiveSetMethod	Description
'sgma'	Sparse greedy matrix approximation
'entropy'	Differential entropy-based selection
'likelihood'	Subset of regressors log likelihood-based selection
'random'	Random selection

The selected active set is used in parameter estimation or prediction, depending on the choice of `FitMethod` and `PredictMethod` in `fitrgp`.

ActiveSetSize — Size of the active set

integer value

Size of the active set for sparse methods ('sd', 'sr', or 'fic'), stored as an integer value.

Data Types: double

IsActiveSetVector — Indicators for selected active set

logical vector

Indicators for selected active set for making predictions from the trained GPR model, stored as a logical vector. These indicators mark the subset of training data that `fitrgp` selects as the active set. For example, if X is the original training data, then `ActiveSetVectors = X(IsActiveSetVector, :)`.

Data Types: logical

Training Data

NumObservations — Number of observations in training data

scalar value

Number of observations in training data, stored as a scalar value.

Data Types: `double`

X — Training data

n-by-*d* table | *n*-by-*d* matrix

Training data, stored as an *n*-by-*d* table or matrix, where *n* is the number of observations and *d* is the number of predictor variables (columns) in the training data. If the GPR model is trained on a table, then *X* is a table. Otherwise, *X* is a matrix.

Data Types: `double` | `table`

Y — Observed response values

n-by-1 vector

Observed response values used to train the GPR model, stored as an *n*-by-1 vector, where *n* is the number of observations.

Data Types: `double`

PredictorNames — Names of predictors

cell array of character vectors

Names of predictors used in the GPR model, stored as a cell array of character vectors. Each name (cell) corresponds to a column in *X*.

Data Types: `cell`

ExpandedPredictorNames — Names of expanded predictors

cell array of character vectors

Names of expanded predictors for the GPR model, stored as a cell array of character vectors. Each name (cell) corresponds to a column in `ActiveSetVectors`.

If the model uses dummy variables for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

Data Types: `cell`

ResponseName — Name of the response variable

character vector

Name of the response variable in the GPR model, stored as a character vector.

Data Types: `char`

PredictorLocation — Means of predictors

1-by-*d* vector | []

Means of predictors used for training the GPR model if the training data is standardized, stored as a 1-by-*d* vector. If the training data is not standardized, `PredictorLocation` is empty.

If `PredictorLocation` is not empty, then the `predict` method centers the predictor values by subtracting the respective element of `PredictorLocation` from every column of *X*.

If there are categorical predictors, then `PredictorLocation` includes a 0 for each dummy variable corresponding to those predictors. The dummy variables are not centered or scaled.

Data Types: `double`

PredictorScale — Standard deviations of predictors

1-by- d vector | []

Standard deviations of predictors used for training the GPR model if the training data is standardized, stored as a 1-by- d vector. If the training data is not standardized, `PredictorScale` is empty.

If `PredictorScale` is not empty, the `predict` method scales the predictors by dividing every column of X by the respective element of `PredictorScale` (after centering using `PredictorLocation`).

If there are categorical predictors, then `PredictorLocation` includes a 1 for each dummy variable corresponding to those predictors. The dummy variables are not centered or scaled.

Data Types: `double`

RowsUsed — Indicators for rows used in training

logical vector | []

Indicators for rows used in training the GPR model, stored as a logical vector. If all rows are used in training the model, then `RowsUsed` is empty.

Data Types: `logical`

Methods

<code>compact</code>	Create compact Gaussian process regression model
<code>crossval</code>	Cross-validate Gaussian process regression model
<code>postFitStatistics</code>	Compute post-fit statistics for the exact Gaussian process regression model
<code>resubLoss</code>	Resubstitution loss for a trained Gaussian process regression model
<code>resubPredict</code>	Resubstitution prediction from a trained Gaussian process regression model

Inherited Methods

<code>loss</code>	Regression error for Gaussian process regression model
<code>predict</code>	Predict response of Gaussian process regression model

More About

Active Set Selection and Parameter Estimation

For subset of data, subset of regressors, or fully independent conditional approximation fitting methods (`FitMethod` equal to `'sd'`, `'sr'`, or `'fic'`), if you do not provide the active set, `fitrgp` selects the active set and computes the parameter estimates in a series of iterations.

In the first iteration, the software uses the initial parameter values in vector $\eta_0 = [\beta_0, \sigma_0, \theta_0]$ to select an active set A_1 . It maximizes the GPR marginal log likelihood or its approximation using η_0 as the initial values and A_1 to compute the new parameter estimates η_1 . Next, it computes the new log likelihood L_1 using η_1 and A_1 .

In the second iteration, the software selects the active set A_2 using the parameter values in η_1 . Then, using η_1 as the initial values and A_2 , it maximizes the GPR marginal log likelihood or its approximation and estimates the new parameter values η_2 . Then using η_2 and A_2 , computes the new log likelihood value L_2 .

The following table summarizes the iterations and what is computed at each iteration.

Iteration Number	Active Set	Parameter Vector	Log Likelihood
1	A_1	η_1	L_1
2	A_2	η_2	L_2
3	A_3	η_3	L_3
...

The software iterates similarly for a specified number of repetitions. You can specify the number of replications for active set selection using the `NumActiveSetRepeats` name-value pair argument.

Tips

- You can access the properties of this class using dot notation. For example, `KernelInformation` is a structure holding the kernel parameters and their names. Hence, to access the kernel function parameters of the trained model `gprMdl`, use `gprMdl.KernelInformation.KernelParameters`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.
- When you train a Gaussian process regression model by using `fitrgp` and you supply training data in a table, the predictors must be numeric (`double` or `single`). Code generation does not support categorical predictors (`logical`, `categorical`, `char`, `string`, or `cell`). Also, you cannot use the `'CategoricalPredictors'` name-value pair argument. To include categorical predictors in a model, preprocess the categorical predictors by using `dummyvar` before fitting the model.

For more information, see “Introduction to Code Generation” on page 31-2.

RegressionLinear class

Linear regression model for high-dimensional data

Description

`RegressionLinear` is a trained linear model object for regression; the linear model is a support vector machine regression (SVM) or linear regression model. `fitrlinear` fits a `RegressionLinear` model by minimizing the objective function using techniques that reduce computation time for high-dimensional data sets (e.g., stochastic gradient descent). The regression loss plus the regularization term compose the objective function.

Unlike other regression models, and for economical memory usage, `RegressionLinear` model objects do not store the training data. However, they do store, for example, the estimated linear model coefficients, estimated coefficients, and the regularization strength.

You can use trained `RegressionLinear` models to predict responses for new data. For details, see `predict`.

Construction

Create a `RegressionLinear` object by using `fitrlinear`.

Properties

Linear Regression Properties

Epsilon — Half of width of epsilon-insensitive band

nonnegative scalar

Half of the width of the epsilon-insensitive-band, specified as a nonnegative scalar.

If `Learner` is not `'svm'`, then `Epsilon` is an empty array (`[]`).

Data Types: `single` | `double`

Lambda — Regularization term strength

nonnegative scalar | vector of nonnegative values

Regularization term strength, specified as a nonnegative scalar or vector of nonnegative values.

Data Types: `double` | `single`

Learner — Linear regression model type

`'leastsquares'` | `'svm'`

Linear regression model type, specified as `'leastsquares'` or `'svm'`.

In this table, $f(x) = x\beta + b$.

- β is a vector of p coefficients.

- x is an observation from p predictor variables.
- b is the scalar bias.

Value	Algorithm	Loss function	FittedLoss Value
'leastsquares'	Linear regression via ordinary least squares	Mean squared error (MSE): $\ell[y, f(x)] = \frac{1}{2}[y - f(x)]^2$	'mse'
'svm'	Support vector machine regression	Epsilon-insensitive: $\ell[y, f(x)] = \max[0, y - f(x) - \varepsilon]$	'epsiloninsensitive'

Beta – Linear coefficient estimates

numeric vector

Linear coefficient estimates, specified as a numeric vector with length equal to the number of predictors.

Data Types: double

Bias – Estimated bias term

numeric scalar

Estimated bias term or model intercept, specified as a numeric scalar.

Data Types: double

FittedLoss – Loss function used to fit the linear model

'epsiloninsensitive' | 'mse'

Loss function used to fit the model, specified as 'epsiloninsensitive' or 'mse'.

Value	Algorithm	Loss function	Learner Value
'epsiloninsensitive'	Support vector machine regression	Epsilon-insensitive: $\ell[y, f(x)] = \max[0, y - f(x) - \varepsilon]$	'svm'
'mse'	Linear regression via ordinary least squares	Mean squared error (MSE): $\ell[y, f(x)] = \frac{1}{2}[y - f(x)]^2$	'leastsquares'

Regularization – Complexity penalty type

'lasso (L1)' | 'ridge (L2)'

Complexity penalty type, specified as 'lasso (L1)' or 'ridge (L2)'.

The software composes the objective function for minimization from the sum of the average loss function (see FittedLoss) and a regularization value from this table.

Value	Description
'lasso (L1)'	Lasso (L_1) penalty: $\lambda \sum_{j=1}^p \beta_j $
'ridge (L2)'	Ridge (L_2) penalty: $\frac{\lambda}{2} \sum_{j=1}^p \beta_j^2$

λ specifies the regularization term strength (see Lambda).

The software excludes the bias term (β_0) from the regularization penalty.

Other Regression Properties

ModelParameters — Parameters used for training model

structure

Parameters used for training the RegressionLinear model, specified as a structure.

Access fields of ModelParameters using dot notation. For example, access the relative tolerance on the linear coefficients and the bias term by using `Mdl.ModelParameters.BetaTolerance`.

Data Types: `struct`

PredictorNames — Predictor names

cell array of character vectors

Predictor names in order of their appearance in the predictor data X, specified as a cell array of character vectors. The length of PredictorNames is equal to the number of columns in X.

Data Types: `cell`

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

Expanded predictor names, specified as a cell array of character vectors.

Because a RegressionLinear model does not support categorical predictors, ExpandedPredictorNames and PredictorNames are equal.

Data Types: `cell`

ResponseName — Response variable name

character vector

Response variable name, specified as a character vector.

Data Types: `char`

ResponseTransform — Response transformation function

'none' | function handle

Response transformation function, specified as 'none' or a function handle. ResponseTransform describes how the software transforms raw response values.

For a MATLAB function, or a function that you define, enter its function handle. For example, you can enter `Mdl.ResponseTransform = @function`, where *function* accepts a numeric vector of the

original responses and returns a numeric vector of the same size containing the transformed responses.

Data Types: char | function_handle

Methods

loss	Regression loss for linear regression models
predict	Predict response of linear regression model
selectModels	Select fitted regularized linear regression models

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Train Linear Regression Model

Train a linear regression model using SVM, dual SGD, and ridge regularization.

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = x_1, \dots, x_{1000}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Train a linear regression model. By default, `fitrlinear` uses support vector machines with a ridge penalty, and optimizes using dual SGD for SVM. Determine how well the optimization algorithm fit the model to the data by extracting a fit summary.

```
[Mdl,FitInfo] = fitrlinear(X,Y)
```

```
Mdl =
  RegressionLinear
    ResponseName: 'Y'
  ResponseTransform: 'none'
           Beta: [1000x1 double]
           Bias: -0.0056
           Lambda: 1.0000e-04
           Learner: 'svm'
```

Properties, Methods

```

FitInfo = struct with fields:
    Lambda: 1.0000e-04
    Objective: 0.2725
    PassLimit: 10
    NumPasses: 10
    BatchLimit: []
    NumIterations: 100000
    GradientNorm: NaN
    GradientTolerance: 0
    RelativeChangeInBeta: 0.4907
    BetaTolerance: 1.0000e-04
    DeltaGradient: 1.5816
    DeltaGradientTolerance: 0.1000
    TerminationCode: 0
    TerminationStatus: {'Iteration limit exceeded.'}
    Alpha: [10000x1 double]
    History: []
    FitTime: 0.1552
    Solver: {'dual'}

```

`Mdl` is a `RegressionLinear` model. You can pass `Mdl` and the training or new data to `loss` to inspect the in-sample mean-squared error. Or, you can pass `Mdl` and new predictor data to `predict` to predict responses for new observations.

`FitInfo` is a structure array containing, among other things, the termination status (`TerminationStatus`) and how long the solver took to fit the model to the data (`FitTime`). It is good practice to use `FitInfo` to determine whether optimization-termination measurements are satisfactory. In this case, `fitrlinear` reached the maximum number of iterations. Because training time is fast, you can retrain the model, but increase the number of passes through the data. Or, try another solver, such as LBFSGS.

Predict Responses Using Linear Regression Model

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \dots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```

rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);

```

Hold out 5% of the data.

```

rng(1); % For reproducibility
cvp = cvpartition(n,'Holdout',0.05)

```

```

cvp =
Hold-out cross validation partition
  NumObservations: 10000
  NumTestSets: 1
  TrainSize: 9500
  TestSize: 500

```

`cvp` is a `CVPartition` object that defines the random partition of n data into training and test sets.

Train a linear regression model using the training set. For faster training time, orient the predictor data matrix so that the observations are in columns.

```

idxTrain = training(cvp); % Extract training set indices
X = X';
Mdl = fitrlinear(X(:,idxTrain),Y(idxTrain),'ObservationsIn','columns');

```

Predict observations and the mean squared error (MSE) for the hold out sample.

```

idxTest = test(cvp); % Extract test set indices
yHat = predict(Mdl,X(:,idxTest),'ObservationsIn','columns');
L = loss(Mdl,X(:,idxTest),Y(idxTest),'ObservationsIn','columns')

```

```
L = 0.1851
```

The hold-out sample MSE is 0.1852.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `update` functions support code generation.
- When you train a linear regression model by using `fitrlinear`, the following restrictions apply.
 - The predictor data input argument value (X) must be a full numeric matrix.
 - You can specify only one regularization strength, either `'auto'` or a nonnegative scalar for the `'Lambda'` name-value pair argument.
 - The value of the `'ResponseTransform'` name-value pair argument cannot be an anonymous function.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2016a

RegressionLinearCoderConfigurer

Coder configurer for linear regression model with high-dimensional data

Description

A `RegressionLinearCoderConfigurer` object is a coder configurer of a linear regression model (`RegressionLinear`) with high-dimensional data.

A coder configurer offers convenient features to configure code generation options, generate C/C++ code, and update model parameters in the generated code.

- Configure code generation options and specify the coder attributes for linear model parameters by using object properties.
- Generate C/C++ code for the `predict` and `update` functions of the linear regression model by using `generateCode`. Generating C/C++ code requires MATLAB Coder.
- Update model parameters in the generated C/C++ code without having to regenerate the code. This feature reduces the effort required to regenerate, redeploy, and reverify C/C++ code when you retrain the linear model with new data or settings. Before updating model parameters, use `validatedUpdateInputs` to validate and extract the model parameters to update.

This flow chart shows the code generation workflow using a coder configurer.

For the code generation usage notes and limitations of a linear regression model, see the Code Generation sections of `RegressionLinear`, `predict`, and `update`.

Creation

After training a linear regression model by using `fitrlinear`, create a coder configurer for the model by using `learnerCoderConfigurer`. Use the properties of a coder configurer to specify the coder attributes of the `predict` and `update` arguments. Then, use `generateCode` to generate C/C++ code based on the specified coder attributes.

Properties

`predict` Arguments

The properties listed in this section specify the coder attributes of the `predict` function arguments in the generated code.

X — Coder attributes of predictor data

LearnerCoderInput object

Coder attributes of the predictor data to pass to the generated C/C++ code for the `predict` function of the linear regression model, specified as a `LearnerCoderInput` on page 32-4629 object.

When you create a coder configurer by using the `learnerCoderConfigurer` function, the input argument `X` determines the default values of the `LearnerCoderInput` coder attributes:

- **SizeVector** — The default value is the array size of the input `X`.
 - If the `Value` attribute of the `ObservationsIn` property for the `RegressionLinearCoderConfigurer` is `'rows'`, then this `SizeVector` value is `[n p]`, where `n` corresponds to the number of observations and `p` corresponds to the number of predictors.
 - If the `Value` attribute of the `ObservationsIn` property for the `RegressionLinearCoderConfigurer` is `'columns'`, then this `SizeVector` value is `[p n]`.

To switch the elements of `SizeVector` (for example, to change `[n p]` to `[p n]`), modify the `Value` attribute of the `ObservationsIn` property for the `RegressionLinearCoderConfigurer` accordingly. You cannot modify the `SizeVector` value directly.

- **VariableDimensions** — The default value is `[0 0]`, which indicates that the array size is fixed as specified in `SizeVector`.

You can set this value to `[1 0]` if the `SizeVector` value is `[n p]` or to `[0 1]` if it is `[p n]`, which indicates that the array has variable-size rows and fixed-size columns. For example, `[1 0]` specifies that the first value of `SizeVector` (`n`) is the upper bound for the number of rows, and the second value of `SizeVector` (`p`) is the number of columns.

- **DataType** — This value is `single` or `double`. The default data type depends on the data type of the input `X`.
- **Tunability** — This value must be `true`, meaning that `predict` in the generated C/C++ code always includes predictor data as an input.

You can modify the coder attributes by using dot notation. For example, to generate C/C++ code that accepts predictor data with 100 observations (in rows) of three predictor variables (in columns), specify these coder attributes of `X` for the coder configurer `configurer`:

```
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [0 0];
```

`[0 0]` indicates that the first and second dimensions of `X` (number of observations and number of predictor variables, respectively) have fixed sizes.

To allow the generated C/C++ code to accept predictor data with up to 100 observations, specify these coder attributes of `X`:

```
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [1 0];
```

`[1 0]` indicates that the first dimension of `X` (number of observations) has a variable size and the second dimension of `X` (number of predictor variables) has a fixed size. The specified number of

observations, 100 in this example, becomes the maximum allowed number of observations in the generated C/C++ code. To allow any number of observations, specify the bound as `Inf`.

ObservationsIn — Coder attributes of predictor data observation dimension

EnumeratedInput object

Coder attributes of the predictor data observation dimension ('`ObservationsIn`' name-value pair argument of `predict`), specified as an EnumeratedInput on page 32-4630 object.

When you create a coder configurer by using the `learnerCoderConfigurer` function, the '`ObservationsIn`' name-value pair argument determines the default values of the EnumeratedInput coder attributes:

- **Value** — The default value is the predictor data observation dimension you use when creating the coder configurer, specified as '`rows`' or '`columns`'. If you do not specify '`ObservationsIn`' when creating the coder configurer, the default value is '`rows`'.
- **SelectedOption** — This value is always '`Built-in`'. This attribute is read-only.
- **BuiltInOptions** — Cell array of '`rows`' and '`columns`'. This attribute is read-only.
- **IsConstant** — This value must be `true`.
- **Tunability** — The default value is `false` if you specify '`ObservationsIn`', '`rows`' when creating the coder configurer, and `true` if you specify '`ObservationsIn`', '`columns`'. If you set `Tunability` to `false`, the software sets `Value` to '`rows`'. If you specify other attribute values when `Tunability` is `false`, the software sets `Tunability` to `true`.

NumOutputs — Number of outputs in predict

1 (default)

Number of output arguments to return from the generated C/C++ code for the `predict` function of the linear regression model, specified as 1. `predict` returns `YHat` (predicted responses) in the generated C/C++ code.

The `NumOutputs` property is equivalent to the '`-nargout`' compiler option of `codegen`. This option specifies the number of output arguments in the entry-point function of code generation. The object function `generateCode` generates two entry-point functions—`predict.m` and `update.m` for the `predict` and `update` functions of a linear regression model, respectively—and generates C/C++ code for the two entry-point functions. The specified value for the `NumOutputs` property corresponds to the number of output arguments in the entry-point function `predict.m`.

Data Types: `double`

update Arguments

The properties listed in this section specify the coder attributes of the `update` function arguments in the generated code. The `update` function takes a trained model and new model parameters as input arguments, and returns an updated version of the model that contains the new parameters. To enable updating the parameters in the generated code, you need to specify the coder attributes of the parameters before generating code. Use a `LearnerCoderInput` on page 32-4629 object to specify the coder attributes of each parameter. The default attribute values are based on the model parameters in the input argument `Mdl` of `learnerCoderConfigurer`.

Beta — Coder attributes of linear predictor coefficients

LearnerCoderInput object

Coder attributes of the linear predictor coefficients (Beta of a linear regression model), specified as a `LearnerCoderInput` on page 32-4629 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — This value must be `[p 1]`, where `p` is the number of predictors in `Mdl`.
- `VariableDimensions` — This value must be `[0 0]`, indicating that the array size is fixed as specified in `SizeVector`.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — This value must be `true`.

Bias — Coder attributes of bias term

`LearnerCoderInput` object

Coder attributes of the bias term (Bias of a linear regression model), specified as a `LearnerCoderInput` on page 32-4629 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — This value must be `[1 1]`.
- `VariableDimensions` — This value must be `[0 0]`, indicating that the array size is fixed as specified in `SizeVector`.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — This value must be `true`.

Other Configurer Options

OutputFileName — File name of generated C/C++ code

`'RegressionLinearModel'` (default) | character vector

File name of the generated C/C++ code, specified as a character vector.

The object function `generateCode` of `RegressionLinearCoderConfigurer` generates C/C++ code using this file name.

The file name must not contain spaces because they can lead to code generation failures in certain operating system configurations. Also, the name must be a valid MATLAB function name.

After creating the coder configurer `configurer`, you can specify the file name by using dot notation.

```
configurer.OutputFileName = 'myModel';
```

Data Types: `char`

Verbose — Verbosity level

`true` (logical 1) (default) | `false` (logical 0)

Verbosity level, specified as `true` (logical 1) or `false` (logical 0). The verbosity level controls the display of notification messages at the command line.

Value	Description
true (logical 1)	The software displays notification messages when your changes to the coder attributes of a parameter result in changes for other dependent parameters.
false (logical 0)	The software does not display notification messages.

To enable updating machine learning model parameters in the generated code, you need to configure the coder attributes of the parameters before generating code. The coder attributes of parameters are dependent on each other, so the software stores the dependencies as configuration constraints. If you modify the coder attributes of a parameter by using a coder configurer, and the modification requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters. The verbosity level determines whether or not the software displays notification messages for these subsequent changes.

After creating the coder configurer `configurer`, you can modify the verbosity level by using dot notation.

```
configurer.Verbose = false;
```

Data Types: `logical`

Options for Code Generation Customization

To customize the code generation workflow, use the `generateFiles` function and the following three properties with `codegen`, instead of using the `generateCode` function.

After generating the two entry-point function files (`predict.m` and `update.m`) by using the `generateFiles` function, you can modify these files according to your code generation workflow. For example, you can modify the `predict.m` file to include data preprocessing, or you can add these entry-point functions to another code generation project. Then, you can generate C/C++ code by using the `codegen` function and the `codegen` arguments appropriate for the modified entry-point functions or code generation project. Use the three properties described in this section as a starting point to set the `codegen` arguments.

CodeGenerationArguments — codegen arguments

cell array

This property is read-only.

`codegen` arguments, specified as a cell array.

This property enables you to customize the code generation workflow. Use the `generateCode` function if you do not need to customize your workflow.

Instead of using `generateCode` with the coder configurer `configurer`, you can generate C/C++ code as follows:

```
generateFiles(configurer)
cgArgs = configurer.CodeGenerationArguments;
codegen(cgArgs{:})
```

If you customize the code generation workflow, modify `cgArgs` accordingly before calling `codegen`.

If you modify other properties of `configurer`, the software updates the `CodeGenerationArguments` property accordingly.

Data Types: `cell`

PredictInputs — List of tunable input arguments of predict

cell array

This property is read-only.

List of tunable input arguments of the entry-point function `predict.m` for code generation, specified as a cell array. The cell array contains another cell array that includes `coder.PrimitiveType` objects and `coder.Constant` objects.

If you modify the coder attributes of `predict` arguments on page 32-4619, then the software updates the corresponding objects accordingly. If you specify the `Tunability` attribute as `false`, then the software removes the corresponding objects from the `PredictInputs` list.

The cell array in `PredictInputs` is equivalent to `configurer.CodeGenerationArguments{6}` for the coder configurer `configurer`.

Data Types: `cell`

UpdateInputs — List of tunable input arguments of update

cell array of a structure including `coder.PrimitiveType` objects

This property is read-only.

List of the tunable input arguments of the entry-point function `update.m` for code generation, specified as a cell array of a structure including `coder.PrimitiveType` objects. Each `coder.PrimitiveType` object includes the coder attributes of a tunable machine learning model parameter.

If you modify the coder attributes of a model parameter by using the coder configurer properties (`update Arguments` on page 32-4621 properties), then the software updates the corresponding `coder.PrimitiveType` object accordingly. If you specify the `Tunability` attribute of a machine learning model parameter as `false`, then the software removes the corresponding `coder.PrimitiveType` object from the `UpdateInputs` list.

The structure in `UpdateInputs` is equivalent to `configurer.CodeGenerationArguments{3}` for the coder configurer `configurer`.

Data Types: `cell`

Object Functions

<code>generateCode</code>	Generate C/C++ code using coder configurer
<code>generateFiles</code>	Generate MATLAB files for code generation using coder configurer
<code>validatedUpdateInputs</code>	Validate and extract machine learning model parameters to update

Examples

Generate Code Using Coder Configurer

Train a machine learning model, and then generate code for the `predict` and `update` functions of the model by using a coder configurer.

Simulate 10,000 observations from the model

$$y = x_{100} + 2x_{200} + e.$$

- $X = x_1, \dots, x_{1000}$ is a 10,000-by-1000 numeric matrix with standard normal elements.
- e is a random normal error with mean 0 and standard deviation 0.3.

```
rng('default') % For reproducibility
n = 10000;
p = 1000;
X = randn(n,p);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Train a linear regression model using the simulated data. Pass the transposed predictor matrix `Xnew` to `fitrlinear`, and use the `'ObservationsIn'` name-value pair argument to specify that the columns of `Xnew` correspond to observations.

```
Xnew = X';
Mdl = fitrlinear(Xnew,Y,'ObservationsIn','columns');
```

`Mdl` is a `RegressionLinear` object.

Create a coder configurer for the `RegressionLinear` model by using `learnerCoderConfigurer`. Specify the predictor data `Xnew`, and use the `'ObservationsIn'` name-value pair argument to specify the observation dimension of `Xnew`. The `learnerCoderConfigurer` function uses these input arguments to configure the coder attributes of the corresponding input arguments of `predict`.

```
configurer = learnerCoderConfigurer(Mdl,Xnew,'ObservationsIn','columns')
```

```
configurer =
  RegressionLinearCoderConfigurer with properties:
```

```
  Update Inputs:
      Beta: [1x1 LearnerCoderInput]
      Bias: [1x1 LearnerCoderInput]
```

```
  Predict Inputs:
      X: [1x1 LearnerCoderInput]
  ObservationsIn: [1x1 EnumeratedInput]
```

```
  Code Generation Parameters:
      NumOutputs: 1
      OutputFileName: 'RegressionLinearModel'
```

Properties, Methods

`configurer` is a `RegressionLinearCoderConfigurer` object, which is a coder configurer of a `RegressionLinear` object.

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the `predict` and `update` functions of the linear regression model (`Mdl`) with default settings.

```
generateCode(configurer)
```

generateCode creates these files in output folder:
 'initialize.m', 'predict.m', 'update.m', 'RegressionLinearModel.mat'

The generateCode function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `RegressionLinearModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\RegressionLinearModel` folder.
- Copy the MEX function to the current folder.

Display the contents of the `predict.m`, `update.m`, and `initialize.m` files by using the `type` function.

type `predict.m`

```
function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:47:03
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end
```

type `update.m`

```
function update(varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:47:03
initialize('update',varargin{:});
end
```

type `initialize.m`

```
function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:47:03
coder.inline('always')
persistent model
if isempty(model)
    model = loadLearnerForCoder('RegressionLinearModel.mat');
end
switch(command)
    case 'update'
        % Update struct fields: Beta
        %                               Bias
        model = update(model,varargin{:});
    case 'predict'
        % Predict Inputs: X, ObservationsIn
        X = varargin{1};
        if nargin == 2
            [varargout{1:nargout}] = predict(model,X);
        else
            PVPairs = cell(1,nargin-2);
            for i = 1:nargin-2
                PVPairs{1,i} = varargin{i+1};
            end
            [varargout{1:nargout}] = predict(model,X,PVPairs{:});
        end
    end
end
end
```

Update Parameters of Linear Regression Model in Generated Code

Train a linear regression model using a partial data set, and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the linear regression model parameters. Use the object function of the coder configurer to generate C code that predicts responses for new predictor data. Then retrain the model using the entire data set, and update parameters in the generated code without regenerating the code.

Train Model

Simulate 10,000 observations from the model

$$y = x_{100} + 2x_{200} + e.$$

- $X = x_1, \dots, x_{1000}$ is a 10,000-by-1000 numeric matrix with standard normal elements.
- e is a random normal error with mean 0 and standard deviation 0.3.

```
rng('default') % For reproducibility
n = 10000;
p = 1000;
X = randn(n,p);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Train a linear regression model using the first 500 observations. Transpose the predictor data, and use the 'ObservationsIn' name-value pair argument to specify that the columns of XTrain correspond to observations.

```
XTrain = X(1:500,:);
YTrain = Y(1:500);
Mdl = fitrlinear(XTrain,YTrain,'ObservationsIn','columns');
```

Mdl is a RegressionLinear object.

Create Coder Configurer

Create a coder configurer for the RegressionLinear model by using learnerCoderConfigurer. Specify the predictor data XTrain, and use the 'ObservationsIn' name-value pair argument to specify the observation dimension of XTrain. The learnerCoderConfigurer function uses these input arguments to configure the coder attributes of the corresponding input arguments of predict.

```
configurer = learnerCoderConfigurer(Mdl,XTrain,'ObservationsIn','columns');
```

configurer is a RegressionLinearCoderConfigurer object, which is a coder configurer of a RegressionLinear object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the linear regression model parameters so that you can update the parameters in the generated code after retraining the model. This example specifies the coder attributes of the predictor data that you want to pass to the generated code.

Specify the coder attributes of the X property of configurer so that the generated code accepts any number of observations. Modify the SizeVector and VariableDimensions attributes. The SizeVector attribute specifies the upper bound of the predictor data size, and the

`VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [1000 Inf];
configurer.X.VariableDimensions
```

```
ans = 1x2 logical array
```

```
    0    1
```

The size of the first dimension is the number of predictor variables. This value must be fixed for a machine learning model. Because the predictor data contains 1000 predictors, the value of the `SizeVector` attribute must be 1000 and the value of the `VariableDimensions` attribute must be 0.

The size of the second dimension is the number of observations. Setting the value of the `SizeVector` attribute to `Inf` causes the software to change the value of the `VariableDimensions` attribute to 1. In other words, the upper bound of the size is `Inf` and the size is variable, meaning that the predictor data can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The order of the dimensions in `SizeVector` and `VariableDimensions` depends on the coder attributes of `ObservationsIn`.

```
configurer.ObservationsIn
```

```
ans =
```

```
EnumeratedInput with properties:
```

```
    Value: 'columns'
SelectedOption: 'Built-in'
BuiltInOptions: {'rows' 'columns'}
    IsConstant: 1
    Tunability: 1
```

When the `Value` attribute of the `ObservationsIn` property is `'columns'`, the first dimension of the `SizeVector` and `VariableDimensions` attributes of `X` corresponds to the number of predictors, and the second dimension corresponds to the number of observations. When the `Value` attribute of `ObservationsIn` is `'rows'`, the order of the dimensions is switched.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the `predict` and `update` functions of the linear regression model (`Mdl`).

```
generateCode(configurer)
```

```
generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionLinearModel.mat'
```

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.

- Create a MEX function named `RegressionLinearModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\RegressionLinearModel` folder.
- Copy the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same predicted responses. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
YHat = predict(Mdl,XTrain,'ObservationsIn','columns');
YHat_mex = RegressionLinearModel('predict',XTrain,'ObservationsIn','columns');
```

Compare `YHat` and `YHat_mex`.

```
max(abs(YHat-YHat_mex))
```

```
ans = 0
```

In general, `YHat_mex` might include round-off differences compared to `YHat`. In this case, the comparison confirms that `YHat` and `YHat_mex` are equal.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

```
retrainedMdl = fitrlinear(X',Y,'ObservationsIn','columns');
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
RegressionLinearModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```
YHat = predict(retrainedMdl,X', 'ObservationsIn','columns');
YHat_mex = RegressionLinearModel('predict',X', 'ObservationsIn','columns');
max(abs(YHat-YHat_mex))
```

```
ans = 0
```

The comparison confirms that `YHat` and `YHat_mex` are equal.

More About

LearnerCoderInput Object

A coder configurer uses a `LearnerCoderInput` object to specify the coder attributes of `predict` and `update` input arguments.

A `LearnerCoderInput` object has the following attributes to specify the properties of an input argument array in the generated code.

Attribute Name	Description
<code>SizeVector</code>	<p>Array size if the corresponding <code>VariableDimensions</code> value is <code>false</code>.</p> <p>Upper bound of the array size if the corresponding <code>VariableDimensions</code> value is <code>true</code>. To allow an unbounded array, specify the bound as <code>Inf</code>.</p>
<code>VariableDimensions</code>	<p>Indicator specifying whether each dimension of the array has a variable size or fixed size, specified as <code>true</code> (logical 1) or <code>false</code> (logical 0):</p> <ul style="list-style-type: none"> • A value of <code>true</code> (logical 1) means that the corresponding dimension has a variable size. • A value of <code>false</code> (logical 0) means that the corresponding dimension has a fixed size.
<code>DataType</code>	Data type of the array
<code>Tunability</code>	<p>Indicator specifying whether or not <code>predict</code> or <code>update</code> includes the argument as an input in the generated code, specified as <code>true</code> (logical 1) or <code>false</code> (logical 0).</p> <p>If you specify other attribute values when <code>Tunability</code> is <code>false</code>, the software sets <code>Tunability</code> to <code>true</code>.</p>

After creating a coder configurer, you can modify the coder attributes by using dot notation. For example, specify the data type of the bias term `Bias` of the coder configurer `configurer`:

```
configurer.Bias.DataType = 'single';
```

If you specify the verbosity level (`Verbose`) as `true` (default), then the software displays notification messages when you modify the coder attributes of a machine learning model parameter and the modification changes the coder attributes of other dependent parameters.

EnumeratedInput Object

A coder configurer uses an `EnumeratedInput` object to specify the coder attributes of `predict` input arguments that have a finite set of available values.

An `EnumeratedInput` object has the following attributes to specify the properties of an input argument array in the generated code.

Attribute Name	Description
Value	<p>Value of the <code>predict</code> argument in the generated code, specified as a character vector or a <code>LearnerCoderInput</code> on page 32-4629 object.</p> <ul style="list-style-type: none"> • Character vector in <code>BuiltInOptions</code> — You can specify one of the <code>BuiltInOptions</code> using either the option name or its index value. For example, to choose the first option, specify <code>Value</code> as either the first character vector in <code>BuiltInOptions</code> or <code>1</code>. • Character vector designating a custom function name — To use a custom option, define a custom function on the MATLAB search path, and specify <code>Value</code> as the name of the custom function. • <code>LearnerCoderInput</code> on page 32-4629 object — If you set <code>IsConstant</code> to <code>false</code> (logical <code>0</code>), then the software changes <code>Value</code> to a <code>LearnerCoderInput</code> on page 32-4629 object with the following read-only coder attribute values. These values indicate that the input in the generated code is a variable-size, tunable character vector that is one of the available values in <code>BuiltInOptions</code>. <ul style="list-style-type: none"> • <code>SizeVector</code> — <code>[1 c]</code>, indicating the upper bound of the array size, where <code>c</code> is the length of the longest available character vector in <code>Option</code> • <code>VariableDimensions</code> — <code>[0 1]</code>, indicating that the array is a variable-size vector • <code>DataType</code> — <code>'char'</code> • <code>Tunability</code> — <code>1</code> <p>The default value of <code>Value</code> is consistent with the default value of the corresponding <code>predict</code> argument, which is one of the character vectors in <code>BuiltInOptions</code>.</p>
SelectedOption	<p>Status of the selected option, specified as <code>'Built-in'</code>, <code>'Custom'</code>, or <code>'NonConstant'</code>. The software sets <code>SelectedOption</code> according to <code>Value</code>:</p> <ul style="list-style-type: none"> • <code>'Built-in'</code> (default) — When <code>Value</code> is one of the character vectors in <code>BuiltInOptions</code> • <code>'Custom'</code> — When <code>Value</code> is a character vector that is not in <code>BuiltInOptions</code> • <code>'NonConstant'</code> — When <code>Value</code> is a <code>LearnerCoderInput</code> on page 32-4629 object <p>This attribute is read-only.</p>
BuiltInOptions	<p>List of available character vectors for the corresponding <code>predict</code> argument, specified as a cell array.</p> <p>This attribute is read-only.</p>

Attribute Name	Description
IsConstant	<p>Indicator specifying whether or not the array value is a compile-time constant (<code>coder.Constant</code>) in the generated code, specified as <code>true</code> (logical 1, default) or <code>false</code> (logical 0).</p> <p>If you set this value to <code>false</code>, then the software changes <code>Value</code> to a <code>LearnerCoderInput</code> on page 32-4629 object.</p>
Tunability	<p>Indicator specifying whether or not <code>predict</code> includes the argument as an input in the generated code, specified as <code>true</code> (logical 1) or <code>false</code> (logical 0, default).</p> <p>If you specify other attribute values when <code>Tunability</code> is <code>false</code>, the software sets <code>Tunability</code> to <code>true</code>.</p>

After creating a coder configurer, you can modify the coder attributes by using dot notation. For example, specify the coder attributes of `ObservationsIn` of the coder configurer `configurer`:

```
configurer.ObservationsIn.Value = 'columns';
```

RegressionPartitionedEnsemble

Package: `classreg.learning.partition`

Superclasses: `RegressionPartitionedModel`

Cross-validated regression ensemble

Description

`RegressionPartitionedEnsemble` is a set of regression ensembles trained on cross-validated folds. Estimate the quality of classification by cross validation using one or more “kfold” methods: `kfoldfun`, `kfoldLoss`, or `kfoldPredict`. Every “kfold” method uses models trained on in-fold observations to predict response for out-of-fold observations. For example, suppose you cross validate using five folds. In this case, every training fold contains roughly 4/5 of the data and every test fold contains roughly 1/5 of the data. The first model stored in `Trained{1}` was trained on X and Y with the first 1/5 excluded, the second model stored in `Trained{2}` was trained on X and Y with the second 1/5 excluded, and so on. When you call `kfoldPredict`, it computes predictions for the first 1/5 of the data using the first model, for the second 1/5 of data using the second model and so on. In short, response for every observation is computed by `kfoldPredict` using the model trained without this observation.

Construction

`cvens = crossval(ens)` creates a cross-validated ensemble from `ens`, a regression ensemble. For syntax details, see the `crossval` method reference page.

`cvens = fitrensemble(X,Y,Name,Value)` creates a cross-validated ensemble when `Name` is one of `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. For syntax details, see the `fitrensemble` function reference page.

Input Arguments

ens

A regression ensemble constructed with `fitrensemble`.

Properties

BinEdges

Bin edges for numeric predictors, specified as a cell array of p numeric vectors, where p is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the `'NumBins'` name-value pair argument as a positive integer scalar when training a model with tree learners. The `BinEdges` property is empty if the `'NumBins'` value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the `BinEdges` property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

Xbinned contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. Xbinned values are 0 for categorical predictors. If X contains NaNs, then the corresponding Xbinned values are NaNs.

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. CategoricalPredictors contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

CrossValidatedModel

Name of the cross-validated model, a character vector.

Kfold

Number of folds used in a cross-validated tree, a positive integer.

ModelParameters

Object holding parameters of tree.

NumObservations

Numeric scalar containing the number of observations in the training data.

NTrainedPerFold

Vector of Kfold elements. Each entry contains the number of trained learners in this cross-validation fold.

Partition

The partition of class cvpartition used in creating the cross-validated ensemble.

PredictorNames

A cell array of names for the predictor variables, in the order in which they appear in X.

ResponseName

Name of the response variable Y , a character vector.

ResponseTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means $@(x)x$.

Add or change a ResponseTransform function using dot notation:

```
ens.ResponseTransform = @function
```

Trainable

Cell array of ensembles trained on cross-validation folds. Every ensemble is full, meaning it contains its training data and weights.

Trained

Cell array of compact ensembles trained on cross-validation folds.

W

The scaled weights, a vector with length n , the number of rows in X .

X

A matrix or table of predictor values. Each column of X represents one variable, and each row represents one observation.

Y

A numeric column vector with the same number of rows as X . Each entry in Y is the response to the data in the corresponding row of X .

Methods

kfoldLoss	Cross-validation loss of partitioned regression ensemble
resume	Resume training ensemble

Inherited Methods

kfoldfun	Cross validate function
kfoldLoss	Cross-validation loss of partitioned regression model
kfoldPredict	Predict response for observations not used for training

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Construct Partitioned Regression Ensemble

Construct a partitioned regression ensemble, and examine the cross-validation losses for the folds.

Load the `carsmall` data set.

```
load carsmall;
```

Create a subset of variables.

```
XX = [Cylinders Displacement Horsepower Weight];  
YY = MPG;
```

Construct the ensemble model.

```
rens = fitrensemble(XX,YY);
```

Create a cross-validated ensemble from `rens`.

```
rng(10,'twister') % For reproducibility  
cvrens = crossval(rens);
```

Examine the cross-validation losses.

```
L = kfoldLoss(cvrens,'mode','individual')
```

```
L = 10×1
```

```
21.4489  
48.4388  
28.2223  
17.5354  
29.9441  
49.5254  
43.8872  
31.0152  
31.6388  
8.9607
```

`L` is a vector containing the cross-validation loss for each trained learner in the ensemble.

RegressionPartitionedLinear

Package: `classreg.learning.partition`

Superclasses: `RegressionPartitionedModel`

Cross-validated linear regression model for high-dimensional data

Description

`RegressionPartitionedLinear` is a set of linear regression models trained on cross-validated folds. To obtain a cross-validated, linear regression model, use `fitrlinear` and specify one of the cross-validation options. You can estimate the predictive quality of the model, or how well the linear regression model generalizes, using one or more of these “kfold” methods: `kfoldPredict` and `kfoldLoss`.

Every “kfold” method uses models trained on in-fold observations to predict the response for out-of-fold observations. For example, suppose that you cross-validate using five folds. In this case, the software randomly assigns each observation into five roughly equally sized groups. The training fold contains four of the groups (that is, roughly 4/5 of the data) and the test fold contains the other group (that is, roughly 1/5 of the data). In this case, cross-validation proceeds as follows:

- 1 The software trains the first model (stored in `CVMDL.Trained{1}`) using the observations in the last four groups and reserves the observations in the first group for validation.
- 2 The software trains the second model (stored in `CVMDL.Trained{2}`) using the observations in the first group and last three groups. The software reserves the observations in the second group for validation.
- 3 The software proceeds in a similar fashion for the third through fifth models.

If you validate by calling `kfoldPredict`, it computes predictions for the observations in group 1 using the first model, group 2 for the second model, and so on. In short, the software estimates a response for every observation using the model trained without that observation.

Note Unlike other cross-validated, regression models, `RegressionPartitionedLinear` model objects do not store the predictor data set.

Construction

`CVMDL = fitrlinear(X,Y,Name,Value)` creates a cross-validated, linear regression model when `Name` is either `'CrossVal'`, `'CVPartition'`, `'Holdout'`, or `'KFold'`. For more details, see `fitrlinear`.

Properties

Cross-Validation Properties

CrossValidatedModel — Cross-validated model name

character vector

Cross-validated model name, specified as a character vector.

For example, 'Linear' specifies a cross-validated linear model for binary classification or regression.

Data Types: char

KFold — Number of cross-validated folds

positive integer

Number of cross-validated folds, specified as a positive integer.

Data Types: double

ModelParameters — Cross-validation parameter values

object

Cross-validation parameter values, e.g., the name-value pair argument values used to cross-validate the linear model, specified as an object. ModelParameters does not contain estimated parameters.

Access properties of ModelParameters using dot notation.

NumObservations — Number of observations

positive numeric scalar

Number of observations in the training data, specified as a positive numeric scalar.

Data Types: double

Partition — Data partition

cvpartition model

Data partition indicating how the software splits the data into cross-validation folds, specified as a cvpartition model.

Trained — Linear regression models trained on cross-validation folds

cell array of RegressionLinear model objects

Linear regression models trained on cross-validation folds, specified as a cell array of RegressionLinear models. Trained has k cells, where k is the number of folds.

Data Types: cell

W — Observation weights

numeric vector

Observation weights used to cross-validate the model, specified as a numeric vector. W has NumObservations elements.

The software normalizes the weights used for training so that `nansum(W)` is 1.

Data Types: single | double

Y — Observed responses

numeric vector

Observed responses used to cross-validate the model, specified as a numeric vector containing NumObservations elements.

Each row of Y represents the observed response of the corresponding observation in the predictor data.

Data Types: `single` | `double`

Other Regression Properties

CategoricalPredictors — Categorical predictor indices

vector of positive integers | []

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

Data Types: `single` | `double`

PredictorNames — Predictor names

cell array of character vectors

Predictor names in their order of appearance in predictor data used to train `CVML`, specified as a cell array of character vectors. `PredictorNames` has length equal to the number of predictor variables in the predictor data.

Data Types: `cell`

ResponseName — Response variable name

character vector

Response variable name, specified as a character vector.

Data Types: `char`

ResponseTransform — Response transformation function

'none' | function handle

Response transformation function, specified as 'none' or a function handle. `ResponseTransform` describes how the software transforms raw response values.

For a MATLAB function, or a function that you define, enter its function handle. For example, you can enter `Mdl.ResponseTransform = @function`, where *function* accepts a numeric vector of the original responses and returns a numeric vector of the same size containing the transformed responses.

Data Types: `char` | `function_handle`

Methods

<code>kfoldLoss</code>	Regression loss for observations not used in training
<code>kfoldPredict</code>	Predict responses for observations not used for training

Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects \(MATLAB\)](#).

Examples

Create Cross-Validated Linear Regression Model

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \dots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Cross-validate a linear regression model. To increase execution speed, transpose the predictor data and specify that the observations are in columns.

```
X = X';
CVMdl = fitrlinear(X,Y,'CrossVal','on','ObservationsIn','columns');
```

`CVMdl` is a `RegressionPartitionedLinear` cross-validated model. Because `fitrlinear` implements 10-fold cross-validation by default, `CVMdl.Trained` contains a cell vector of ten `RegressionLinear` models. Each cell contains a linear regression model trained on nine folds, and then tested on the remaining fold.

Predict responses for out-of-fold observations and estimate the generalization error by passing `CVMdl` to `kfoldPredict` and `kfoldLoss`, respectively.

```
oofYHat = kfoldPredict(CVMdl);
ge = kfoldLoss(CVMdl)

ge = 0.1748
```

The estimated, generalization, mean squared error is 0.1748.

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for a linear regression model that uses least squares, implement 5-fold cross-validation.

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \dots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.

- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from 10^{-5} through 10^{-1} .

```
Lambda = logspace(-5,-1,15);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Optimize the objective function using SpARSA.

```
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','KFold',5,'Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
```

```
numCLModels = numel(CVMdl.Trained)
```

```
numCLModels = 5
```

CVMdl is a RegressionPartitionedLinear model. Because fitrlinear implements 5-fold cross-validation, CVMdl contains 5 RegressionLinear models that the software trains on each fold.

Display the first trained linear regression model.

```
Mdl1 = CVMdl.Trained{1}
```

```
Mdl1 =
  RegressionLinear
    ResponseName: 'Y'
  ResponseTransform: 'none'
           Beta: [1000x15 double]
           Bias: [1x15 double]
           Lambda: [1x15 double]
           Learner: 'leastsquares'
```

Properties, Methods

Mdl1 is a RegressionLinear model object. fitrlinear constructed Mdl1 by training on the first four folds. Because Lambda is a sequence of regularization strengths, you can think of Mdl1 as 15 models, one for each regularization strength in Lambda.

Estimate the cross-validated MSE.

```
mse = kfoldLoss(CVMdl);
```

Higher values of Lambda lead to predictor variable sparsity, which is a good quality of a regression model. For each regularization strength, train a linear regression model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure
[h,hL1,hL2] = plotyy(log10(Lambda),log10(mse),...
    log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} MSE')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
hold off
```

Choose the index of the regularization strength that balances predictor variable sparsity and low MSE (for example, $\text{Lambda}(10)$).

```
idxFinal = 10;
```

Extract the model with corresponding to the minimal MSE.

```
MdlFinal = selectModels(Mdl,idxFinal)
```

```
MdlFinal =
    RegressionLinear
```

```
ResponseName: 'Y'  
ResponseTransform: 'none'  
Beta: [1000x1 double]  
Bias: -0.0050  
Lambda: 0.0037  
Learner: 'leastsquares'
```

Properties, Methods

```
idxNZCoeff = find(MdlFinal.Beta~=0)
```

```
idxNZCoeff = 2×1
```

```
100  
200
```

```
EstCoeff = Mdl.Beta(idxNZCoeff)
```

```
EstCoeff = 2×1
```

```
1.0051  
1.9965
```

`MdlFinal` is a `RegressionLinear` model with one regularization strength. The nonzero coefficients `EstCoeff` are close to the coefficients that simulated the data.

Introduced in R2016a

RegressionPartitionedModel

Package: `classreg.learning.partition`

Cross-validated regression model

Description

`RegressionPartitionedModel` is a set of regression models trained on cross-validated folds. Estimate the quality of regression by cross validation using one or more “kfold” methods: `kfoldPredict`, `kfoldLoss`, and `kfoldfun`. Every “kfold” method uses models trained on in-fold observations to predict response for out-of-fold observations. For example, suppose you cross validate using five folds. In this case, every training fold contains roughly 4/5 of the data and every test fold contains roughly 1/5 of the data. The first model stored in `Trained{1}` was trained on `X` and `Y` with the first 1/5 excluded, the second model stored in `Trained{2}` was trained on `X` and `Y` with the second 1/5 excluded, and so on. When you call `kfoldPredict`, it computes predictions for the first 1/5 of the data using the first model, for the second 1/5 of data using the second model and so on. In short, response for every observation is computed by `kfoldPredict` using the model trained without this observation.

Construction

`cvmodel = crossval(tree)` creates a cross-validated classification model from a regression tree. For syntax details, see the `crossval` method reference page.

`cvmodel = fitrtree(X,Y,Name,Value)` creates a cross-validated model when `name` is one of 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'. For syntax details, see the `fitrtree` function reference page.

Input Arguments

tree

A regression tree constructed with `fitrtree`.

Properties

BinEdges

Bin edges for numeric predictors, specified as a cell array of p numeric vectors, where p is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the 'NumBins' name-value pair argument as a positive integer scalar when training a model with tree learners. The `BinEdges` property is empty if the 'NumBins' value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the `BinEdges` property of the trained model `mdl`.

```

X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end

```

Xbinned contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. Xbinned values are 0 for categorical predictors. If X contains NaNs, then the corresponding Xbinned values are NaNs.

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. CategoricalPredictors contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

CrossValidatedModel

Name of the cross-validated model, a character vector.

Kfold

Number of folds used in a cross-validated tree, a positive integer.

ModelParameters

Object holding parameters of tree.

Partition

The partition of class cvpartition used in the cross-validated model.

PredictorNames

A cell array of names for the predictor variables, in the order in which they appear in X.

ResponseName

Name of the response variable Y, a character vector.

ResponseTransform

Function handle for transforming the raw response values (mean squared error). The function handle should accept a matrix of response values and return a matrix of the same size. The default character vector 'none' means $@(x)x$, or no transformation.

Add or change a ResponseTransform function using dot notation:

```
ctree.ResponseTransform = @function
```

Trained

The trained learners, a cell array of compact regression models.

W

The scaled weights, a vector with length n , the number of rows in X .

X

A matrix or table of predictor values. Each column of X represents one variable, and each row represents one observation.

Y

A numeric column vector with the same number of rows as X . Each entry in Y is the response to the data in the corresponding row of X .

Methods

kfoldfun	Cross validate function
kfoldLoss	Cross-validation loss of partitioned regression model
kfoldPredict	Predict response for observations not used for training

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Evaluate Cross-Validation Error

Load the sample data. Create a variable X containing the Horsepower and Weight data.

```
load carsmall
X = [Horsepower Weight];
```

Construct a regression tree using the sample data.

```
cvtree = fitrtree(X,MPG, 'crossval', 'on');
```

Evaluate the cross-validation error of the carsmall data using Horsepower and Weight as predictor variables for mileage (MPG).

```
L = kfoldLoss(cvtree)
```

```
L = 25.5338
```

RegressionPartitionedSVM

Package: `classreg.learning.partition`

Superclasses: `RegressionPartitionedModel`

Cross-validated support vector machine regression model

Description

`RegressionPartitionedSVM` is a set of support vector machine (SVM) regression models trained on cross-validated folds.

Construction

`CVMdl = crossval mdl` returns a cross-validated (partitioned) support vector machine regression model, `CVMdl`, from a trained SVM regression model, `mdl`.

`CVMdl = crossval(mdl, Name, Value)` returns a cross-validated model with additional options specified by one or more `Name, Value` pair arguments. `Name` can also be a property name on page 32-4648 and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Input Arguments

mdl — Full, trained SVM regression model

`RegressionSVM` model

Full, trained SVM regression model, specified as a `RegressionSVM` model returned by `fitrsvm`.

Properties

CategoricalPredictors — Indices of categorical predictors

vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

CrossValidatedModel — Name of the cross-validated model

character vector

Name of the cross-validated model, stored as a character vector.

Data Types: `char`

KFold — Number of cross-validation folds

positive integer value

Number of cross-validation folds, stored as a positive integer value.

Data Types: `single` | `double`

ModelParameters — Cross-validation parameters

object

Cross-validation parameters, stored as an object.

NumObservations — Number of observations

positive integer value

Number of observations in the training data, stored as a positive integer value.

Data Types: `single` | `double`

Partition — Data partition for cross-validation

cvpartition object

Data partition for cross-validation, stored as a cvpartition object.

PredictorNames — Predictor names

cell array of character vectors

Predictor names, stored as a cell array of character vectors containing the name of each predictor in the order in which they appear in X. PredictorNames has a length equal to the number of columns in X.

Data Types: `cell`

ResponseName — Response variable name

character vector

Response variable name, stored as a character vector.

Data Types: `char`

ResponseTransform — Response transformation function

'none' | function handle

Response transformation function, specified as 'none' or a function handle. ResponseTransform describes how the software transforms raw response values.

For a MATLAB function, or a function that you define, enter its function handle. For example, you can enter `Mdl.ResponseTransform = @function`, where *function* accepts a numeric vector of the original responses and returns a numeric vector of the same size containing the transformed responses.

Data Types: `char` | `function_handle`

Trained — Trained, compact regression models

cell array of CompactRegressionSVM models

Trained, compact regression models, stored as a cell array of CompactRegressionSVM models.

Data Types: `cell`

W — Observation weights

vector of numeric values

Observation weights used to train the model, stored as a numeric vector containing `NumObservation` number of elements. `fitrsvm` normalizes the weights used for training so that they sum to 1.

Data Types: `single` | `double`

X — Predictor values

matrix of numeric values | table of numeric values

Predictor values used to train the model, stored as a matrix of numeric values if the model is trained on a matrix, or a table if the model is trained on a table. `X` has size n -by- p , where n is the number of rows and p is the number of predictor variables or columns in the training data.

Data Types: `single` | `double` | `table`

Y — Observed responses

numeric vector

Observed responses used to cross-validate the model, specified as a numeric vector containing `NumObservations` elements.

Each row of `Y` represents the observed classification of the corresponding row of `X`.

Data Types: `single` | `double`

Methods

Inherited Methods

<code>kfoldfun</code>	Cross validate function
<code>kfoldLoss</code>	Cross-validation loss of partitioned regression model
<code>kfoldPredict</code>	Predict response for observations not used for training

Examples

Train Cross-Validated SVM Regression Model Using `crossval`

This example shows how to train a cross-validated SVM regression model using `crossval`.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current directory with the name `'abalone.data'`. Read the data into a table.

```
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);
rng default % for reproducibility
```

The sample data contains 4177 observations. All of the predictor variables are continuous except for `sex`, which is a categorical variable with possible values `'M'` (for males), `'F'` (for females), and `'I'` (for infants). The goal is to predict the number of rings on the abalone, and thereby determine its age, using physical measurements.

Train an SVM regression model, using a Gaussian kernel function with a kernel scale equal to 2.2. Standardize the data.

```
mdl = fitrsvm(tbl,'Var9','KernelFunction','gaussian','KernelScale',2.2,'Standardize',true);
```

`mdl` is a trained `RegressionSVM` regression model.

Cross validate the model using 10-fold cross validation.

```
CVMdl = crossval(mdl)
```

```
CVMdl =
```

```
classreg.learning.partition.RegressionPartitionedSVM
  CrossValidatedModel: 'SVM'
  PredictorNames: {1x8 cell}
  CategoricalPredictors: 1
  ResponseName: 'Var9'
  NumObservations: 4177
  KFold: 10
  Partition: [1x1 cvpartition]
  ResponseTransform: 'none'
```

Properties, Methods

`CVMdl` is a `RegressionPartitionedSVM` cross-validated regression model. The software:

1. Randomly partitions the data into ten equally-sized sets.
2. Trains an SVM regression model on nine of the ten sets.
3. Repeats steps 1 and 2 $k = 10$ times. It leaves out one of the partitions each time, and trains on the other nine partitions.
4. Combines generalization statistics for each fold.

Display the first of the 10 trained models.

```
FirstModel = CVMdl.Trained{1}
```

```
FirstModel =
```

```
classreg.learning.regr.CompactRegressionSVM
  PredictorNames: {1x8 cell}
  ResponseName: 'Var9'
  ResponseTransform: 'none'
  Alpha: [3553x1 double]
  Bias: 11.0623
  KernelParameters: [1x1 struct]
  Mu: [0 0 0 0.5242 0.4080 0.1393 0.8300 0.3599 0.1811 0.2392]
  Sigma: [1 1 1 0.1205 0.0995 0.0392 0.4907 0.2217 0.1103 0.1392]
  SupportVectors: [3553x10 double]
```

Properties, Methods

`FirstModel` is the first of the 10 trained `CompactRegressionSVM` models.

Specify Cross-Validation Holdout Proportion for SVM Regression

This example shows how to specify a holdout proportion for training a cross-validated SVM regression model.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current directory with the name 'abalone.data'. Read the data into a table.

```
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);
rng default % for reproducibility
```

The sample data contains 4177 observations. All of the predictor variables are continuous except for sex, which is a categorical variable with possible values 'M' (for males), 'F' (for females), and 'I' (for infants). The goal is to predict the number of rings on the abalone, and thereby determine its age, using physical measurements.

Train an SVM regression model, using a Gaussian kernel function with a kernel scale equal to 2.2. Standardize the data.

```
mdl = fitsvm(tbl,'Var9','KernelFunction','gaussian','KernelScale',2.2,'Standardize',true);
```

mdl is a trained RegressionSVM regression model.

Cross validate the regression model by specifying a 10% holdout sample.

```
CVMDL = crossval(mdl,'Holdout',0.1)
```

CVMDL =

```
classreg.learning.partition.RegistrationPartitionedSVM
  CrossValidatedModel: 'SVM'
  PredictorNames: {1x8 cell}
  CategoricalPredictors: 1
  ResponseName: 'Var9'
  NumObservations: 4177
  KFold: 1
  Partition: [1x1 cvpartition]
  ResponseTransform: 'none'
```

Properties, Methods

CVMDL is a RegressionPartitionedSVM model object.

Extract and display the trained, compact SVM regression model from CVMDL.

```
CVMDL.Trained{1}
```

TrainedModel =

```
classreg.learning.regr.CompactRegressionSVM
  PredictorNames: {1x8 cell}
  ResponseName: 'Var9'
  ResponseTransform: 'none'
  Alpha: [3530x1 double]
  Bias: 11.2646
  KernelParameters: [1x1 struct]
  Mu: [0 0 0 0.5244 0.4080 0.1393 0.8282 0.3595 0.1805 0.2386]
```

```
Sigma: [1 1 1 0.1198 0.0989 0.0388 0.4891 0.2218 0.1093 0.1390]  
SupportVectors: [3530x10 double]
```

Properties, Methods

`TrainedModel` is a `CompactRegressionSVM` regression model that was trained using 90% of the data.

Alternatives

You can create a `RegressionPartitionedSVM` model using the following techniques:

- Use the training function `fitrsvm` and specify one of the `'CrossVal'`, `'Holdout'`, `'KFold'`, or `'Leaveout'` name-value pairs.
- Train a model using `fitrsvm`, then cross validate the model using the `crossval` method.
- Create a cross validation partition using `cvpartition`, then pass the resulting partition object to `fitrsvm` during training using the `'CVPartition'` name-value pair.

`RegressionSVM` | `crossval` | `cvpartition` | `fitrsvm`

Introduced in R2015b

RegressionSVM class

Superclasses: CompactRegressionSVM

Support vector machine regression model

Description

RegressionSVM is a support vector machine (SVM) regression model. Train a RegressionSVM model using `fitrsvm` and the sample data.

RegressionSVM models store data, parameter values, support vectors, and algorithmic implementation information. You can use these models to:

- Estimate resubstitution predictions. For details, see `resubPredict`.
- Predict values for new data. For details, see `predict`.
- Compute resubstitution loss. For details, see `resubLoss`.
- Compute the mean square error or epsilon-insensitive loss. For details, see `loss`.

Construction

Create a RegressionSVM object by using `fitrsvm`.

Properties

Alpha — Dual problem coefficients

vector of numeric values

Dual problem coefficients, specified as a vector of numeric values. Alpha contains m elements, where m is the number of support vectors in the trained SVM regression model. The dual problem introduces two Lagrange multipliers for each support vector. The values of Alpha are the differences between the two estimated Lagrange multipliers for the support vectors. For more details, see “Understanding Support Vector Machine Regression” on page 25-2.

If you specified to remove duplicates using `RemoveDuplicates`, then, for a particular set of duplicate observations that are support vectors, Alpha contains one coefficient corresponding to the entire set. That is, MATLAB attributes a nonzero coefficient to one observation from the set of duplicates and a coefficient of 0 to all other duplicate observations in the set.

Data Types: `single` | `double`

Beta — Primal linear problem coefficients

vector of numeric values | '[]'

Primal linear problem coefficients, stored as a numeric vector of length p , where p is the number of predictors in the SVM regression model.

The values in Beta are the linear coefficients for the primal optimization problem.

If the model is obtained using a kernel function other than `'linear'`, this property is empty (`'[]'`).

The `predict` method computes predicted response values for the model as $YFIT = (X/S) \times \text{Beta} + \text{Bias}$, where S is the value of the kernel scale stored in the `KernelParameters.Scale` property.

Data Types: `single` | `double`

Bias – Bias term

scalar value

Bias term in the SVM regression model, stored as a scalar value.

Data Types: `single` | `double`

BoxConstraints – Box constraints for dual problem coefficients

vector of numeric values

Box constraints for dual problem alpha coefficients, stored as a numeric vector containing n elements, where n is the number of observations in X (`Mdl.NumObservations`).

The absolute value of the dual coefficient Alpha for observation i cannot exceed `BoxConstraints(i)`.

If you specify removing duplicates using `'RemoveDuplicates'`, then for a given set of duplicate observations, MATLAB sums the box constraints, and then attributes the sum to one observation and box constraints of 0 to all other observations in the set.

Data Types: `single` | `double`

CacheInfo – Caching information

structure

Caching information, stored as a structure with the following fields.

Field	Description
'Size'	Positive scalar value indicating the cache size (in MB) that the software reserves to store entries of the Gram matrix. Set the cache size by using the <code>'CacheSize'</code> name-value pair argument in <code>fitrsvm</code> .
'Algorithm'	Character vector containing the name of the algorithm used to remove entries from the cache when its capacity is exceeded. Currently, the only available caching algorithm is <code>'Queue'</code> . You cannot set the caching algorithm.

Data Types: `struct`

CategoricalPredictors – Indices of categorical predictors

vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

ConvergenceInfo – Convergence information

structure

Convergence information, stored as a structure with the following fields.

Field	Description
Converged	Logical flag indicating whether the algorithm converged. A value of 1 indicates convergence.
ReasonForConvergence	Character vector indicating the criterion the software used to detect convergence.
Gap	Scalar feasibility gap between the dual and primal objective functions.
GapTolerance	Scalar tolerance for the feasibility gap. You can set this tolerance using the 'GapTolerance' name-value pair argument in <code>fitrsvm</code> .
DeltaGradient	Scalar gradient difference between upper and lower violators.
DeltaGradientTolerance	Scalar tolerance for the gradient difference. You can set this tolerance using the <code>DeltaGradientTolerance</code> name-value pair argument in <code>fitrsvm</code> .
LargestKKTViolation	Maximal scalar Karush-Kuhn-Tucker (KKT) violation value.
KKTTolerance	Scalar tolerance for the largest KKT violation. You can set this tolerance using the 'KKTTolerance' name-value pair argument in <code>fitrsvm</code> .
History	Structure containing convergence information recorded at periodic intervals during the model training process. This structure contains the following fields: <ul style="list-style-type: none"> • <code>NumIterations</code> — Array of iteration indices at which the software recorded convergence criteria. • <code>Gap</code> — Gap values at these iterations. • <code>DeltaGradient</code> — <code>DeltaGradient</code> values at these iterations. • <code>LargestKKTViolation</code> — <code>LargestKKTViolation</code> values at these iterations. • <code>NumSupportVectors</code> — Number of support vectors at these iterations. • <code>Objective</code> — Objective values at these iterations.
Objective	Numeric value of the dual objective.

Data Types: `struct`

Epsilon — Half the width of the epsilon-insensitive band

nonnegative scalar value

Half the width of the epsilon-insensitive band, stored as a nonnegative scalar value.

Data Types: `single` | `double`

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

Data Types: `cell`

Gradient — Gradient values in training data

vector of numeric values

Gradient values in training data, stored as a numeric vector containing $2n$ elements, where n is the number of observations in the training data.

Element i of `Gradient` contains the gradient value for the Alpha coefficient that corresponds to the upper boundary of the epsilon-insensitive band at observation i at the end of the optimization.

Element $i + NumObservations$ of `Gradient` contains the gradient value for the Alpha coefficient that corresponds to the lower boundary of the epsilon-insensitive band at observation i at the end of the optimization.

Data Types: `single` | `double`

HyperparameterOptimizationResults — Description of cross-validation optimization of hyperparameters

`BayesianOptimization` object | table

Description of the cross-validation optimization of hyperparameters, specified as a `BayesianOptimization` object or a table of hyperparameters and associated values. This property is nonempty if the `'OptimizeHyperparameters'` name-value pair argument is nonempty when you create the model. The value of `HyperparameterOptimizationResults` depends on the setting of the `Optimizer` field in the `HyperparameterOptimizationOptions` structure when you create the model, as described in this table.

Value of Optimizer Field	Value of HyperparameterOptimizationResults
<code>'bayesopt'</code> (default)	Object of class <code>BayesianOptimization</code>
<code>'gridsearch'</code> or <code>'randomsearch'</code>	Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

IsSupportVector — Flag indicating whether observation is support vector

logical vector

Flag indicating whether an observation is a support vector, stored as an n -by-1 logical vector. n is the number of observations in X (see `NumObservations`). A value of 1 indicates that the corresponding observation in the training data is a support vector.

If you specify removing duplicates using `RemoveDuplicates`, then for a given set of duplicate observations that are support vectors, `IsSupportVector` flags only one as a support vector.

Data Types: `logical`**KernelParameters — Kernel function parameters**

structure

Kernel function parameters, stored as a structure with the following fields.

Field	Description
Function	Kernel function name (a character vector).
Scale	Numeric scale factor used to divide predictor values.

You can specify values for `KernelParameters.Function` and `KernelParameters.Scale` by using the `KernelFunction` and `KernelScale` name-value pair arguments in `fitrsvm`, respectively.

Data Types: `struct`**ModelParameters — Parameter values**

model parameter object

Parameter values used to train the SVM regression model, stored as a model parameter object. Access the properties of `ModelParameters` using dot notation. For example, access the value of `Epsilon` used to train the model as `Mdl.ModelParameters.Epsilon`.

Mu — Predictor means

vector of numeric values | ' [] '

Predictor means, stored as a vector of numeric values.

If the predictors are standardized, then `Mu` is a numeric vector of length p , where p is the number of predictors used to train the model. In this case, the `predict` method centers predictor matrix X by subtracting the corresponding element of `Mu` from each column.

If the predictors are not standardized, then `Mu` is empty (' [] ').

If the data contains categorical predictors, then `Mu` includes elements for the dummy variables for those predictors. The corresponding entries in `Mu` are 0 because dummy variables are not centered or scaled.

Data Types: `single` | `double`**NumIterations — Number of iterations required for convergence**

positive integer value

Number of iterations required for the optimization routine to reach convergence, stored as a positive integer value.

To set a limit on the number of iterations, use the 'IterationLimit' name-value pair argument of `fitrsvm`.

Data Types: `single` | `double`

NumObservations — Number of observations

positive integer value

Number of observations in the training data, stored as a positive integer value.

Data Types: `single` | `double`

PredictorNames — Predictor names

cell array of character vectors

Predictor names, stored as a cell array of character vectors containing the name of each predictor in the order they appear in X. `PredictorNames` has a length equal to the number of columns in X.

Data Types: `cell`

OutlierFraction — Expected fraction of outliers

scalar value in the range [0,1]

Expected fraction of outliers in the training set, stored as a scalar value in the range [0,1]. You can specify the expected fraction of outliers using the 'OutlierFraction' name-value pair argument in `fitrsvm`.

Data Types: `double`

ResponseName — Response variable name

character vector

Response variable name, stored as a character vector.

Data Types: `char`

ResponseTransform — Response transformation function

'none' | function handle

Response transformation function, specified as 'none' or a function handle. `ResponseTransform` describes how the software transforms raw response values.

For a MATLAB function, or a function that you define, enter its function handle. For example, you can enter `Mdl.ResponseTransform = @function`, where *function* accepts a numeric vector of the original responses and returns a numeric vector of the same size containing the transformed responses.

Data Types: `char` | `function_handle`

ShrinkagePeriod — Number of iterations between reductions of active set

nonnegative integer value

Number of iterations between reductions of the active set during optimization, stored as a nonnegative integer value.

You can set the shrinkage period by using the 'ShrinkagePeriod' name-value pair argument in `fitrsvm`.

Data Types: `single` | `double`

Sigma — Predictor standard deviations

vector of numeric values | ' [] '

Predictor standard deviations, stored as a vector of numeric values.

If the predictors are standardized, then `Sigma` is a numeric vector of length p , where p is the number of predictors used to train the model. In this case, the `predict` method scales the predictor matrix `X` by dividing each column by the corresponding element of `Sigma`, after centering each element using `Mu`.

If the predictors are not standardized, then `Sigma` is empty (' [] ').

If the data contains categorical predictors, `Sigma` includes elements for the dummy variables for those predictors. The corresponding entries in `Sigma` are 1, because dummy variables are not centered or scaled.

Data Types: `single` | `double`

Solver — Name of solver algorithm

character vector

Name of the solver algorithm used to solve the optimization problem, stored as a value in this table.

Value	Description
'SMO'	Sequential Minimal Optimization
'ISDA'	Iterative Single Data Algorithm
'L1QP'	L1 soft-margin minimization by quadratic programming (requires an Optimization Toolbox license).

SupportVectors — Support vectors

matrix of numeric values

Support vectors, stored as an m -by- p matrix of numeric values. m is the number of support vectors (`sum(Mdl.IsSupportVector)`), and p is the number of predictors in `X`.

If you specified to remove duplicates using `RemoveDuplicates`, then for a given set of duplicate observations that are support vectors, `SupportVectors` contains one unique support vector.

Data Types: `single` | `double`

W — Observation weights

vector of numeric values

Observation weights used to train the model, stored as a numeric vector containing `NumObservation` number of elements. `fitrsvm` normalizes the weights used for training so that they sum to 1.

Data Types: `single` | `double`

X — Predictor values

matrix of numeric values | table of numeric values

Predictor values used to train the model, stored as a matrix of numeric values if the model is trained on a matrix, or a table if the model is trained on a table. X has size n -by- p , where n is the number of rows and p is the number of predictor variables or columns in the training data.

Data Types: `single` | `double` | `table`

Y — Observed response values

vector of numeric values

Observed response values, stored as a numeric vector containing `NumObservations` number of elements.

Data Types: `single` | `double`

Methods

<code>compact</code>	Compact support vector machine regression model
<code>crossval</code>	Cross-validated support vector machine regression model
<code>resubLoss</code>	Resubstitution loss for support vector machine regression model
<code>resubPredict</code>	Predict resubstitution response of support vector machine regression model
<code>resume</code>	Resume training support vector machine regression model

Inherited Methods

<code>discardSupportVectors</code>	Discard support vectors
<code>loss</code>	Regression error for support vector machine regression model
<code>predict</code>	Predict responses using support vector machine regression model

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Train Linear Support Vector Machine Regression Model

This example shows how to train a linear support vector machine (SVM) regression model using sample data stored in matrices.

Load the `carsmall` data set.

```
load carsmall
rng default % for reproducibility
```

Specify `Horsepower` and `Weight` as the predictor variables (X) and `MPG` as the response variable (Y).

```
X = [Horsepower,Weight];
Y = MPG;
```

Train a linear SVM regression model.

```
Mdl = fitrsvm(X,Y)
```

```
Mdl =
  RegressionSVM
      ResponseName: 'Y'
  CategoricalPredictors: []
      ResponseTransform: 'none'
              Alpha: [76x1 double]
              Bias: 43.1920
  KernelParameters: [1x1 struct]
  NumObservations: 93
      BoxConstraints: [93x1 double]
  ConvergenceInfo: [1x1 struct]
  IsSupportVector: [93x1 logical]
      Solver: 'SM0'
```

Properties, Methods

The Command Window shows that `Mdl` is a trained `RegressionSVM` model and a list of its properties.

Check the model for convergence.

```
Mdl.ConvergenceInfo.Converged
```

```
ans = logical
      0
```

0 indicates that the model did not converge.

```
MdlStd = fitrsvm(X,Y,'Standardize',true)
```

```
MdlStd =
  RegressionSVM
      ResponseName: 'Y'
  CategoricalPredictors: []
      ResponseTransform: 'none'
              Alpha: [77x1 double]
              Bias: 22.9131
  KernelParameters: [1x1 struct]
              Mu: [109.3441 2.9625e+03]
              Sigma: [45.3545 805.9668]
  NumObservations: 93
      BoxConstraints: [93x1 double]
  ConvergenceInfo: [1x1 struct]
  IsSupportVector: [93x1 logical]
      Solver: 'SM0'
```

Properties, Methods

Check the model for convergence.

```
MdlStd.ConvergenceInfo.Converged
```

```
ans = logical
      1
```

1 indicates that the model did converge.

Compute the resubstitution mean squared error for the new model.

```
lStd = resubLoss(MdlStd)
lStd = 17.0256
```

Train Support Vector Machine Regression Model

Train a support vector machine regression model using the abalone data from the UCI Machine Learning Repository.

Download the data and save it in your current folder with the name 'abalone.csv'.

```
url = 'https://archive.ics.uci.edu/ml/machine-learning-databases/abalone/abalone.data';
websave('abalone.csv',url);
```

Read the data into a table. Specify the variable names.

```
varnames = {'Sex'; 'Length'; 'Diameter'; 'Height'; 'Whole_weight'; ...
            'Shucked_weight'; 'Viscera_weight'; 'Shell_weight'; 'Rings'};
Tbl = readtable('abalone.csv', 'Filetype', 'text', 'ReadVariableNames', false);
Tbl.Properties.VariableNames = varnames;
```

The sample data contains 4177 observations. All the predictor variables are continuous except for Sex, which is a categorical variable with possible values 'M' (for males), 'F' (for females), and 'I' (for infants). The goal is to predict the number of rings (stored in Rings) on the abalone and determine its age using physical measurements.

Train an SVM regression model, using a Gaussian kernel function with an automatic kernel scale. Standardize the data.

```
rng default % For reproducibility
Mdl = fitrsvm(Tbl, 'Rings', 'KernelFunction', 'gaussian', 'KernelScale', 'auto', ...
             'Standardize', true)
```

```
Mdl =
  RegressionSVM
    PredictorNames: {1x8 cell}
    ResponseName: 'Rings'
    CategoricalPredictors: 1
    ResponseTransform: 'none'
    Alpha: [3635x1 double]
    Bias: 10.8144
    KernelParameters: [1x1 struct]
    Mu: [1x10 double]
    Sigma: [1x10 double]
    NumObservations: 4177
```

```
BoxConstraints: [4177x1 double]
ConvergenceInfo: [1x1 struct]
IsSupportVector: [4177x1 logical]
Solver: 'SMO'
```

The Command Window shows that `Mdl` is a trained `RegressionSVM` model and displays a property list.

Display the properties of `Mdl` using dot notation. For example, check to confirm whether the model converged and how many iterations it completed.

```
conv = Mdl.ConvergenceInfo.Converged
iter = Mdl.NumIterations
```

```
conv =
    logical
     1

iter =
    2759
```

The returned results indicate that the model converged after 2759 iterations.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `update` functions support code generation.

- When you train an SVM regression model by using `fitrsvm`, the following restrictions apply.
 - Code generation does not support categorical predictors (`logical`, `categorical`, `char`, `string`, or `cell`). If you supply training data in a table, the predictors must be numeric (`double` or `single`). Also, you cannot use the `'CategoricalPredictors'` name-value pair argument. To include categorical predictors in a model, preprocess the categorical predictors by using `dummyvar` before fitting the model.
 - The value of the `'ResponseTransform'` name-value pair argument cannot be an anonymous function. For fixed-point code generation, the `'ResponseTransform'` value must be `'none'`.

For more information, see “Introduction to Code Generation” on page 31-2.

RegressionSVMCoderConfigurer

Coder configurer for support vector machine (SVM) regression model

Description

A `RegressionSVMCoderConfigurer` object is a coder configurer of an SVM regression model (`RegressionSVM` or `CompactRegressionSVM`).

A coder configurer offers convenient features to configure code generation options, generate C/C++ code, and update model parameters in the generated code.

- Configure code generation options and specify the coder attributes for SVM model parameters by using object properties.
- Generate C/C++ code for the `predict` and `update` functions of the SVM regression model by using `generateCode`. Generating C/C++ code requires MATLAB Coder.
- Update model parameters in the generated C/C++ code without having to regenerate the code. This feature reduces the effort required to regenerate, redeploy, and reverify C/C++ code when you retrain the SVM model with new data or settings. Before updating model parameters, use `validatedUpdateInputs` to validate and extract the model parameters to update.

This flow chart shows the code generation workflow using a coder configurer.

For the code generation usage notes and limitations of an SVM regression model, see the Code Generation sections of `CompactRegressionSVM`, `predict`, and `update`.

Creation

After training an SVM regression model by using `fitrsvm`, create a coder configurer for the model by using `learnerCoderConfigurer`. Use the properties of a coder configurer to specify the coder attributes of `predict` and `update` arguments. Then, use `generateCode` to generate C/C++ code based on the specified coder attributes.

Properties

`predict` Arguments

The properties listed in this section specify the coder attributes of the `predict` function arguments in the generated code.

X — Coder attributes of predictor data

LearnerCoderInput object

Coder attributes of predictor data to pass to the generated C/C++ code for the `predict` function of the SVM regression model, specified as a `LearnerCoderInput` on page 32-4677 object.

When you create a coder configurer by using the `learnerCoderConfigurer` function, the input argument `X` determines the default values of the `LearnerCoderInput` coder attributes:

- `SizeVector` — The default value is the array size of the input `X`.
- `VariableDimensions` — This value is `[0 0]`(default) or `[1 0]`.
 - `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
 - `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is `single` or `double`. The default data type depends on the data type of the input `X`.
- `Tunability` — This value must be `true`, meaning that `predict` in the generated C/C++ code always includes predictor data as an input.

You can modify the coder attributes by using dot notation. For example, to generate C/C++ code that accepts predictor data with 100 observations of three predictor variables, specify these coder attributes of `X` for the coder configurer `configurer`:

```
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [0 0];
```

`[0 0]` indicates that the first and second dimensions of `X` (number of observations and number of predictor variables, respectively) have fixed sizes.

To allow the generated C/C++ code to accept predictor data with up to 100 observations, specify these coder attributes of `X`:

```
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [1 0];
```

`[1 0]` indicates that the first dimension of `X` (number of observations) has a variable size and the second dimension of `X` (number of predictor variables) has a fixed size. The specified number of observations, 100 in this example, becomes the maximum allowed number of observations in the generated C/C++ code. To allow any number of observations, specify the bound as `Inf`.

NumOutputs — Number of outputs in predict

1 (default)

Number of output arguments to return from the generated C/C++ code for the `predict` function of the SVM regression model, specified as 1. `predict` returns `yfit` (predicted responses) in the generated C/C++ code.

The `NumOutputs` property is equivalent to the `'-nargout'` compiler option of `codegen`. This option specifies the number of output arguments in the entry-point function of code generation. The object function `generateCode` generates two entry-point functions—`predict.m` and `update.m` for the

`predict` and `update` functions of an SVM regression model, respectively—and generates C/C++ code for the two entry-point functions. The specified value for the `NumOutputs` property corresponds to the number of output arguments in the entry-point function `predict.m`.

Data Types: `single` | `double`

update Arguments

The properties listed in this section specify the coder attributes of the `update` function arguments in the generated code. The `update` function takes a trained model and new model parameters as input arguments, and returns an updated version of the model that contains the new parameters. To enable updating the parameters in the generated code, you need to specify the coder attributes of the parameters before generating code. Use a `LearnerCoderInput` on page 32-4677 object to specify the coder attributes of each parameter. The default attribute values are based on the model parameters in the input argument `Mdl` of `learnerCoderConfigurer`.

Alpha — Coder attributes of dual problem coefficients

`LearnerCoderInput` object

Coder attributes of the dual problem coefficients (Alpha of an SVM regression model), specified as a `LearnerCoderInput` on page 32-4677 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — The default value is `[s, 1]`, where `s` is the number of support vectors in `Mdl`.
- `VariableDimensions` — This value is `[0 0]`(default) or `[1 0]`.
 - `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
 - `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — If you train a model with a linear kernel function and discard support vectors by using `discardSupportVectors`, this value must be `false`. Otherwise, this value must be `true`.

Beta — Coder attributes of primal linear problem coefficients

`LearnerCoderInput` object

Coder attributes of the primal linear problem coefficients (Beta of an SVM regression model), specified as a `LearnerCoderInput` on page 32-4677 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — This value must be `[p 1]`, where `p` is the number of predictors in `Mdl`.
- `VariableDimensions` — This value must be `[0 0]`, indicating that the array size is fixed as specified in `SizeVector`.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — If you train a model with a linear kernel function and discard support vectors by using `discardSupportVectors`, this value must be `true`. Otherwise, this value must be `false`.

Bias — Coder attributes of bias term

LearnerCoderInput object

Coder attributes of the bias term (**Bias** of an SVM regression model), specified as a **LearnerCoderInput** on page 32-4677 object.

The default attribute values of the **LearnerCoderInput** object are based on the input argument **Mdl** of **learnerCoderConfigurer**:

- **SizeVector** — This value must be [1 1].
- **VariableDimensions** — This value must be [0 0], indicating that the array size is fixed as specified in **SizeVector**.
- **DataType** — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train **Mdl**.
- **Tunability** — This value must be true.

Mu — Coder attributes of predictor means

LearnerCoderInput object

Coder attributes of the predictor means (**Mu** of an SVM regression model), specified as a **LearnerCoderInput** on page 32-4677 object.

The default attribute values of the **LearnerCoderInput** object are based on the input argument **Mdl** of **learnerCoderConfigurer**:

- **SizeVector** — If you train **Mdl** using standardized predictor data by specifying 'Standardize', true, this value must be [1, p], where p is the number of predictors in **Mdl**. Otherwise, this value must be [0, 0].
- **VariableDimensions** — This value must be [0 0], indicating that the array size is fixed as specified in **SizeVector**.
- **DataType** — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train **Mdl**.
- **Tunability** — If you train **Mdl** using standardized predictor data by specifying 'Standardize', true, the default value is true. Otherwise, this value must be false.

Scale — Coder attributes of kernel scale parameter

LearnerCoderInput object

Coder attributes of the kernel scale parameter (**KernelParameters.Scale** of an SVM regression model), specified as a **LearnerCoderInput** on page 32-4677 object.

The default attribute values of the **LearnerCoderInput** object are based on the input argument **Mdl** of **learnerCoderConfigurer**:

- **SizeVector** — This value must be [1 1].
- **VariableDimensions** — This value must be [0 0], indicating that the array size is fixed as specified in **SizeVector**.
- **DataType** — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train **Mdl**.
- **Tunability** — The default value is true.

Sigma — Coder attributes of predictor standard deviations

LearnerCoderInput object

Coder attributes of the predictor standard deviations (Sigma of an SVM regression model), specified as a LearnerCoderInput on page 32-4677 object.

The default attribute values of the LearnerCoderInput object are based on the input argument Mdl of learnerCoderConfigurer:

- **SizeVector** — If you train Mdl using standardized predictor data by specifying 'Standardize', true, this value must be [1, p], where p is the number of predictors in Mdl. Otherwise, this value must be [0, 0].
- **VariableDimensions** — This value must be [0 0], indicating that the array size is fixed as specified in SizeVector.
- **DataType** — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train Mdl.
- **Tunability** — If you train Mdl using standardized predictor data by specifying 'Standardize', true, the default value is true. Otherwise, this value must be false.

SupportVectors — Coder attributes of support vectors

LearnerCoderInput object

Coder attributes of the support vectors (SupportVectors of an SVM regression model), specified as a LearnerCoderInput on page 32-4677 object.

The default attribute values of the LearnerCoderInput object are based on the input argument Mdl of learnerCoderConfigurer:

- **SizeVector** — The default value is [s, p], where s is the number of support vectors, and p is the number of predictors in Mdl.
- **VariableDimensions** — This value is [0 0](default) or [1 0].
 - [0 0] indicates that the array size is fixed as specified in SizeVector.
 - [1 0] indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of SizeVector is the upper bound for the number of rows, and the second value of SizeVector is the number of columns.
- **DataType** — This value is 'single' or 'double'. The default data type is consistent with the data type of the training data you use to train Mdl.
- **Tunability** — If you train a model with a linear kernel function and discard support vectors by using discardSupportVectors, this value must be false. Otherwise, this value must be true.

Other Configurer Options**OutputFileName — File name of generated C/C++ code**

'RegressionSVMModel' (default) | character vector

File name of the generated C/C++ code, specified as a character vector.

The object function generateCode of RegressionSVMCoderConfigurer generates C/C++ code using this file name.

The file name must not contain spaces because they can lead to code generation failures in certain operating system configurations. Also, the name must be a valid MATLAB function name.

After creating the coder configurer `configurer`, you can specify the file name by using dot notation.

```
configurer.OutputFileName = 'myModel';
```

Data Types: `char`

Verbose — Verbosity level

`true` (logical 1) (default) | `false` (logical 0)

Verbosity level, specified as `true` (logical 1) or `false` (logical 0). The verbosity level controls the display of notification messages at the command line.

Value	Description
<code>true</code> (logical 1)	The software displays notification messages when your changes to the coder attributes of a parameter result in changes for other dependent parameters.
<code>false</code> (logical 0)	The software does not display notification messages.

To enable updating machine learning model parameters in the generated code, you need to configure the coder attributes of the parameters before generating code. The coder attributes of parameters are dependent on each other, so the software stores the dependencies as configuration constraints. If you modify the coder attributes of a parameter by using a coder configurer, and the modification requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters. The verbosity level determines whether or not the software displays notification messages for these subsequent changes.

After creating the coder configurer `configurer`, you can modify the verbosity level by using dot notation.

```
configurer.Verbose = false;
```

Data Types: `logical`

Options for Code Generation Customization

To customize the code generation workflow, use the `generateFiles` function and the following three properties with `codegen`, instead of using the `generateCode` function.

After generating the two entry-point function files (`predict.m` and `update.m`) by using the `generateFiles` function, you can modify these files according to your code generation workflow. For example, you can modify the `predict.m` file to include data preprocessing, or you can add these entry-point functions to another code generation project. Then, you can generate C/C++ code by using the `codegen` function and the `codegen` arguments appropriate for the modified entry-point functions or code generation project. Use the three properties described in this section as a starting point to set the `codegen` arguments.

CodeGenerationArguments — codegen arguments

cell array

This property is read-only.

`codegen` arguments, specified as a cell array.

This property enables you to customize the code generation workflow. Use the `generateCode` function if you do not need to customize your workflow.

Instead of using `generateCode` with the coder configurer `configurer`, you can generate C/C++ code as follows:

```
generateFiles(configurer)
cgArgs = configurer.CodeGenerationArguments;
codegen(cgArgs{:})
```

If you customize the code generation workflow, modify `cgArgs` accordingly before calling `codegen`.

If you modify other properties of `configurer`, the software updates the `CodeGenerationArguments` property accordingly.

Data Types: `cell`

PredictInputs — Input argument of predict

cell array of a `coder.PrimitiveType` object

This property is read-only.

Input argument of the entry-point function `predict.m` for code generation, specified as a cell array of a `coder.PrimitiveType` object. The `coder.PrimitiveType` object includes the coder attributes of the predictor data stored in the `X` property.

If you modify the coder attributes of the predictor data, then the software updates the `coder.PrimitiveType` object accordingly.

The `coder.PrimitiveType` object in `PredictInputs` is equivalent to `configurer.CodeGenerationArguments{6}` for the coder configurer `configurer`.

Data Types: `cell`

UpdateInputs — List of tunable input arguments of update

cell array of a structure including `coder.PrimitiveType` objects

This property is read-only.

List of the tunable input arguments of the entry-point function `update.m` for code generation, specified as a cell array of a structure including `coder.PrimitiveType` objects. Each `coder.PrimitiveType` object includes the coder attributes of a tunable machine learning model parameter.

If you modify the coder attributes of a model parameter by using the coder configurer properties (update Arguments on page 32-4668 properties), then the software updates the corresponding `coder.PrimitiveType` object accordingly. If you specify the `Tunability` attribute of a machine learning model parameter as `false`, then the software removes the corresponding `coder.PrimitiveType` object from the `UpdateInputs` list.

The structure in `UpdateInputs` is equivalent to `configurer.CodeGenerationArguments{3}` for the coder configurer `configurer`.

Data Types: `cell`

Object Functions

<code>generateCode</code>	Generate C/C++ code using coder configurer
<code>generateFiles</code>	Generate MATLAB files for code generation using coder configurer

validatedUpdateInputs Validate and extract machine learning model parameters to update

Examples

Generate Code Using Coder Configurer

Train a machine learning model, and then generate code for the `predict` and `update` functions of the model by using a coder configurer.

Load the `carsmall` data set and train a support vector machine (SVM) regression model.

```
load carsmall
X = [Horsepower,Weight];
Y = MPG;
Mdl = fitrsvm(X,Y);
```

`Mdl` is a `RegressionSVM` object.

Create a coder configurer for the `RegressionSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input.

```
configurer = learnerCoderConfigurer(Mdl,X)

configurer =
  RegressionSVMCoderConfigurer with properties:

  Update Inputs:
    Alpha: [1x1 LearnerCoderInput]
    SupportVectors: [1x1 LearnerCoderInput]
    Scale: [1x1 LearnerCoderInput]
    Bias: [1x1 LearnerCoderInput]

  Predict Inputs:
    X: [1x1 LearnerCoderInput]

  Code Generation Parameters:
    NumOutputs: 1
    OutputFileName: 'RegressionSVMModel'
```

Properties, Methods

`configurer` is a `RegressionSVMCoderConfigurer` object, which is a coder configurer of a `RegressionSVM` object.

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the `predict` and `update` functions of the SVM regression model (`Mdl`) with default settings.

```
generateCode(configurer)
```

generateCode creates these files in output folder:
 'initialize.m', 'predict.m', 'update.m', 'RegressionSVMModel.mat'

The generateCode function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `RegressionSVMModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\RegressionSVMModel` folder.
- Copy the MEX function to the current folder.

Display the contents of the `predict.m`, `update.m`, and `initialize.m` files by using the `type` function.

`type predict.m`

```
function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:40:03
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end
```

`type update.m`

```
function update(varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:40:03
initialize('update',varargin{:});
end
```

`type initialize.m`

```
function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:40:03
coder.inline('always')
persistent model
if isempty(model)
    model = loadLearnerForCoder('RegressionSVMModel.mat');
end
switch(command)
    case 'update'
        % Update struct fields: Alpha
        %                               SupportVectors
        %                               Scale
        %                               Bias
        model = update(model,varargin{:});
    case 'predict'
        % Predict Inputs: X
        X = varargin{1};
        if nargin == 2
            [varargout{1:nargout}] = predict(model,X);
        else
            PVPairs = cell(1,nargin-2);
            for i = 1:nargin-2
                PVPairs{1,i} = varargin{i+1};
            end
            [varargout{1:nargout}] = predict(model,X,PVPairs{:});
        end
end
end
end
```

Update Parameters of SVM Regression Model in Generated Code

Train a support vector machine (SVM) model using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the SVM model parameters. Use the object function of the coder configurer to generate C code that predicts responses for new predictor data. Then retrain the model using the whole data set and update parameters in the generated code without regenerating the code.

Train Model

Load the `carsmall` data set and train an SVM regression model using the first 50 observations.

```
load carsmall
X = [Horsepower,Weight];
Y = MPG;
Mdl = fitrsvm(X(1:50,:),Y(1:50));
```

`Mdl` is a `RegressionSVM` object.

Create Coder Configurer

Create a coder configurer for the `RegressionSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input.

```
configurer = learnerCoderConfigurer(Mdl,X(1:50,:));
```

`configurer` is a `RegressionSVMCoderConfigurer` object, which is a coder configurer of a `RegressionSVM` object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the SVM regression model parameters so that you can update the parameters in the generated code after retraining the model. This example specifies the coder attributes of predictor data that you want to pass to the generated code and the coder attributes of the support vectors of the SVM regression model.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 2];
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. `X` contains two predictors, so the value of the `SizeVector` attribute must be two and the value of the `VariableDimensions` attribute must be `false`.

If you retrain the SVM model using new data or different settings, the number of support vectors can vary. Therefore, specify the coder attributes of `SupportVectors` so that you can update the support vectors in the generated code.

```
configurer.SupportVectors.SizeVector = [250 2];
```

`SizeVector` attribute for Alpha has been modified to satisfy configuration constraints.

```
configurer.SupportVectors.VariableDimensions = [true false];
```

`VariableDimensions` attribute for Alpha has been modified to satisfy configuration constraints.

If you modify the coder attributes of `SupportVectors`, then the software modifies the coder attributes of Alpha to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use `generateCode` to generate code for the `predict` and `update` functions of the SVM regression model (Mdl) with default settings.

```
generateCode(configurer)
```

`generateCode` creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionSVMModel.mat'

`generateCode` generates the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of Mdl, respectively. Then `generateCode` creates a MEX function named `RegressionSVMModel` for the two entry-point functions in the `codegen\mex\RegressionSVMModel` folder and copies the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of Mdl and the `predict` function in the MEX function return the same predicted responses. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
yfit = predict(Mdl,X);
yfit_mex = RegressionSVMModel('predict',X);
```

`yfit_mex` might include round-off differences compared with `yfit`. In this case, compare `yfit` and `yfit_mex`, allowing a small tolerance.

```
find(abs(yfit-yfit_mex) > 1e-6)
```

```
ans =
```

```
0x1 empty double column vector
```

The comparison confirms that `yfit` and `yfit_mex` are equal within the tolerance `1e-6`.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

```
retrainedMdl = fitrsvm(X,Y);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
RegressionSVMModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```
yfit = predict(retrainedMdl,X);
yfit_mex = RegressionSVMModel('predict',X);
find(abs(yfit-yfit_mex) > 1e-6)
```

```
ans =
```

```
0x1 empty double column vector
```

The comparison confirms that `yfit` and `yfit_mex` are equal within the tolerance `1e-6`.

More About

LearnerCoderInput Object

A coder configurer uses a `LearnerCoderInput` object to specify the coder attributes of `predict` and `update` input arguments.

A `LearnerCoderInput` object has the following attributes to specify the properties of an input argument array in the generated code.

Attribute Name	Description
SizeVector	Array size if the corresponding <code>VariableDimensions</code> value is false. Upper bound of the array size if the corresponding <code>VariableDimensions</code> value is true. To allow an unbounded array, specify the bound as <code>Inf</code> .

Attribute Name	Description
VariableDimensions	<p>Indicator specifying whether each dimension of the array has a variable size or fixed size, specified as <code>true</code> (logical 1) or <code>false</code> (logical 0):</p> <ul style="list-style-type: none"> • A value of <code>true</code> (logical 1) means that the corresponding dimension has a variable size. • A value of <code>false</code> (logical 0) means that the corresponding dimension has a fixed size.
DataType	Data type of the array
Tunability	<p>Indicator specifying whether or not <code>predict</code> or <code>update</code> includes the argument as an input in the generated code, specified as <code>true</code> (logical 1) or <code>false</code> (logical 0).</p> <p>If you specify other attribute values when <code>Tunability</code> is <code>false</code>, the software sets <code>Tunability</code> to <code>true</code>.</p>

After creating a coder configurer, you can modify the coder attributes by using dot notation. For example, specify the coder attributes of the coefficients `Alpha` of the coder configurer `configurer` as follows:

```
configurer.Alpha.SizeVector = [100 1];
configurer.Alpha.VariableDimensions = [1 0];
configurer.Alpha.DataType = 'double';
```

If you specify the verbosity level (`Verbose`) as `true` (default), then the software displays notification messages when you modify the coder attributes of a machine learning model parameter and the modification changes the coder attributes of other dependent parameters.

RegressionTree class

Superclasses: CompactRegressionTree

Regression tree

Description

A decision tree with binary splits for regression. An object of class `RegressionTree` can predict responses for new data with the `predict` method. The object contains the data used for training, so can compute resubstitution predictions.

Construction

Create a `RegressionTree` object by using `fitrtree`.

Properties

BinEdges

Bin edges for numeric predictors, specified as a cell array of p numeric vectors, where p is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the `'NumBins'` name-value pair argument as a positive integer scalar when training a model with tree learners. The `BinEdges` property is empty if the `'NumBins'` value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the `BinEdges` property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

`Xbinned` contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. `Xbinned` values are 0 for categorical predictors. If `X` contains NaNs, then the corresponding `Xbinned` values are NaNs.

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

CategoricalSplits

An n -by-2 cell array, where n is the number of categorical splits in `tree`. Each row in `CategoricalSplits` gives left and right values for a categorical split. For each branch node with categorical split j based on a categorical predictor variable z , the left child is chosen if z is in `CategoricalSplits(j,1)` and the right child is chosen if z is in `CategoricalSplits(j,2)`. The splits are in the same order as nodes of the tree. Nodes for these splits can be found by running `cuttype` and selecting 'categorical' cuts from top to bottom.

Children

An n -by-2 array containing the numbers of the child nodes for each node in `tree`, where n is the number of nodes. Leaf nodes have child node 0.

CutCategories

An n -by-2 cell array of the categories used at branches in `tree`, where n is the number of nodes. For each branch node i based on a categorical predictor variable x , the left child is chosen if x is among the categories listed in `CutCategories{i,1}`, and the right child is chosen if x is among those listed in `CutCategories{i,2}`. Both columns of `CutCategories` are empty for branch nodes based on continuous predictors and for leaf nodes.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

CutPoint

An n -element vector of the values used as cut points in `tree`, where n is the number of nodes. For each branch node i based on a continuous predictor variable x , the left child is chosen if $x < \text{CutPoint}(i)$ and the right child is chosen if $x \geq \text{CutPoint}(i)$. `CutPoint` is NaN for branch nodes based on categorical predictors and for leaf nodes.

CutType

An n -element cell array indicating the type of cut at each node in `tree`, where n is the number of nodes. For each node i , `CutType{i}` is:

- 'continuous' — If the cut is defined in the form $x < v$ for a variable x and cut point v .
- 'categorical' — If the cut is defined by whether a variable x takes a value in a set of categories.
- '' — If i is a leaf node.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

CutPredictor

An n -element cell array of the names of the variables used for branching in each node in `tree`, where n is the number of nodes. These variables are sometimes known as *cut variables*. For leaf nodes, `CutPredictor` contains an empty character vector.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

CutPredictorIndex

An n -element array of numeric indices for the variables used for branching in each node in `tree`, where n is the number of nodes. For more information, see `CutPredictor`.

ExpandedPredictorNames

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

HyperparameterOptimizationResults

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- 'bayesopt' (default) — Object of class `BayesianOptimization`
- 'gridsearch' or 'randomsearch' — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

IsBranchNode

An n -element logical vector `ib` that is `true` for each branch node and `false` for each leaf node of `tree`.

ModelParameters

Object holding parameters of `tree`.

NumObservations

Number of observations in the training data, a numeric scalar. `NumObservations` can be less than the number of rows of input data X when there are missing values in X or response Y .

NodeError

An n -element vector `e` of the errors of the nodes in `tree`, where n is the number of nodes. `e(i)` is the misclassification probability for node i .

NodeMean

An n -element numeric array with mean values in each node of `tree`, where n is the number of nodes in the tree. Every element in `NodeMean` is the average of the true Y values over all observations in the node.

NodeProbability

An n -element vector `p` of the probabilities of the nodes in `tree`, where n is the number of nodes. The probability of a node is computed as the proportion of observations from the original data that satisfy the conditions for the node. This proportion is adjusted for any prior probabilities assigned to each class.

NodeRisk

An n -element vector of the risk of the nodes in the tree, where n is the number of nodes. The risk for each node is the node error weighted by the node probability.

NodeSize

An n -element vector `sizes` of the sizes of the nodes in `tree`, where n is the number of nodes. The size of a node is defined as the number of observations from the data used to create the tree that satisfy the conditions for the node.

NumNodes

The number of nodes n in `tree`.

Parent

An n -element vector `p` containing the number of the parent node for each node in `tree`, where n is the number of nodes. The parent of the root node is 0.

PredictorNames

A cell array of names for the predictor variables, in the order in which they appear in X .

PruneAlpha

Numeric vector with one element per pruning level. If the pruning level ranges from 0 to M , then `PruneAlpha` has $M + 1$ elements sorted in ascending order. `PruneAlpha(1)` is for pruning level 0 (no pruning), `PruneAlpha(2)` is for pruning level 1, and so on.

PruneList

An n -element numeric vector with the pruning levels in each node of `tree`, where n is the number of nodes. The pruning levels range from 0 (no pruning) to M , where M is the distance between the deepest leaf and the root node.

ResponseName

A character vector that specifies the name of the response variable (Y).

ResponseTransform

Function handle for transforming the raw response values (mean squared error). The function handle must accept a matrix of response values and return a matrix of the same size. The default 'none' means $@(x)x$, or no transformation.

Add or change a ResponseTransform function using dot notation:

```
tree.ResponseTransform = @function
```

RowsUsed

An n -element logical vector indicating which rows of the original predictor data (X) were used in fitting. If the software uses all rows of X , then RowsUsed is an empty array (`[]`).

SurrogateCutCategories

An n -element cell array of the categories used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutCategories{k}` is a cell array. The length of `SurrogateCutCategories{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutCategories{k}` is either an empty character vector for a continuous surrogate predictor, or is a two-element cell array with categories for a categorical surrogate predictor. The first element of this two-element cell array lists categories assigned to the left child by this surrogate split, and the second element of this two-element cell array lists categories assigned to the right child by this surrogate split. The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutCategories` contains an empty cell.

SurrogateCutFlip

An n -element cell array of the numeric cut assignments used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutFlip{k}` is a numeric vector. The length of `SurrogateCutFlip{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutFlip{k}` is either zero for a categorical surrogate predictor, or a numeric cut assignment for a continuous surrogate predictor. The numeric cut assignment can be either -1 or $+1$. For every surrogate split with a numeric cut C based on a continuous predictor variable Z , the left child is chosen if $Z < C$ and the cut assignment for this surrogate split is $+1$, or if $Z \geq C$ and the cut assignment for this surrogate split is -1 . Similarly, the right child is chosen if $Z \geq C$ and the cut assignment for this surrogate split is $+1$, or if $Z < C$ and the cut assignment for this surrogate split is -1 . The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutFlip` contains an empty array.

SurrogateCutPoint

An n -element cell array of the numeric values used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutPoint{k}` is a numeric vector. The length of `SurrogateCutPoint{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutPoint{k}` is either NaN for a categorical surrogate predictor, or a numeric cut for a continuous surrogate predictor. For every surrogate split with a numeric cut C based on a continuous predictor variable Z , the left child is chosen if $Z < C$ and `SurrogateCutFlip` for this surrogate split is $+1$, or if $Z \geq C$ and `SurrogateCutFlip` for this surrogate split is -1 . Similarly, the right child is chosen if $Z \geq C$ and `SurrogateCutFlip` for this surrogate split is $+1$, or if $Z < C$ and

`SurrogateCutFlip` for this surrogate split is `-1`. The order of the surrogate split variables at each node is matched to the order of variables returned by `SurrCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutPoint` contains an empty cell.

SurrogateCutType
