1	Functions
----------	------------------

Functions

addLabelDefinitions

Add label definitions to labeled signal set

Syntax

```
addLabelDefinitions(lss,lbldefs)
addLabelDefinitions(lss,lbldefs,lblname)
```

Description

`addLabelDefinitions(lss,lbldefs)` adds the labels defined in the vector of signal label definitions `lbldefs` to the labeled signal set `lss`.

`addLabelDefinitions(lss,lbldefs,lblname)` adds the labels defined in `lbldefs` as sublabels of the label `lblname`.

Examples

Add Label Definition

Load a labeled signal set containing recordings of whale songs.

```
load whales
lss

lss =
    labeledSignalSet with properties:
        Source: {2x1 cell}
        NumMembers: 2
        TimeInformation: "sampleRate"
        SampleRate: 4000
        Labels: [2x3 table]
        Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

Create a label definition that specifies whether a signal corresponds to a calf or to an adult whale.

```
calf = signalLabelDefinition('Calf','LabelDataType','logical','DefaultValue',false, ...
    'Description','Is the specimen a calf, or an adult?')

calf =
    signalLabelDefinition with properties:
        Name: "Calf"
        LabelType: "attribute"
        LabelDataType: "logical"
        ValidationFunction: []
```

```

    DefaultValue: 0
    Sublabels: [0x0 signalLabelDefinition]
    Tag: ""
    Description: "Is the specimen a calf, or an adult?"

```

Use `labeledSignalSet` to create a labeled signal set.

Add the definition to the labeled signal set. Retrieve the names of the labels.

```
addLabelDefinitions(lss,calf)
```

```
getLabelNames(lss)
```

```
ans = 4x1 string
    "WhaleType"
    "MoanRegions"
    "TrillRegions"
    "Calf"
```

Create a label definition that specifies the sex of the whale. Add the label to the set as a sublabel of 'WhaleType'.

```

sx = signalLabelDefinition('Sex','LabelDataType','categorical', ...
    'Categories',["male" "female"]);
addLabelDefinitions(lss,sx,'WhaleType')

```

```
labelDefinitionsHierarchy(lss)
```

```

ans =
    'WhaleType
      Sublabels: Sex
    'MoanRegions
      Sublabels: []
    'TrillRegions
      Sublabels: TrillPeaks
    'Calf
      Sublabels: []

```

Input Arguments

lss — Labeled signal set

`labeledSignalSet` object

Labeled signal set, specified as a `labeledSignalSet` object.

Example: `labeledSignalSet({randn(100,1) randn(10,1)},signalLabelDefinition('female'))` specifies a two-member set of random signals containing the attribute 'female'.

lbldefs — Signal label definitions

`signalLabelDefinition` object | vector of `signalLabelDefinition` objects

Signal label definitions, specified as a `signalLabelDefinition` object or a vector of `signalLabelDefinition` objects.

Example:

```
signalLabelDefinition("Asleep", 'LabelType', 'roi', 'LabelDataType', 'logical')
```

can label a region of a signal in which a patient is asleep.

lblname — Label name

character vector | string scalar

Label name, specified as a character vector or a string scalar.

Example: `signalLabelDefinition("Asleep", 'LabelType', 'roi')` specifies a label of name "Asleep" for a region of a signal in which a patient is asleep during a clinical trial.

Introduced in R2018b

addlift

Add lifting steps to lifting scheme

Syntax

```
LSN = addlift(LS,ELS)
LSN = addlift(LS,ELS,'begin')
LSN = addlift(LS,ELS,'end')
addfilt(LS,ELS)
```

Description

$LSN = \text{addlift}(LS,ELS)$ returns the new lifting scheme LSN obtained by appending the elementary lifting step ELS to the lifting scheme LS .

$LSN = \text{addlift}(LS,ELS, 'begin')$ prepends the specified elementary lifting step.

ELS is either a cell array (see `lsinfo`)

```
{TYPEVAL, COEFS, MAX_DEG}
```

or a structure (see `liftfilt`)

```
struct('type',TYPEVAL,'value',LPVAL)
```

with

```
LPVAL = laurpoly(COEFS, MAX_DEG)
```

$LSN = \text{addlift}(LS,ELS, 'end')$ is equivalent to `addfilt(LS,ELS)`.

If ELS is a sequence of elementary lifting steps, stored in a cell array or an array of structures, then each of the elementary lifting steps is added to LS .

For more information about lifting schemes, see `lsinfo`.

Examples

Add Primal Lifting Step

This example shows how to start with the Haar lifting scheme and add a primal lifting step.

```
LSbegin = liftwave('haar');
```

Display the lifting scheme.

```
displs(LSbegin);
```

```
LSbegin = {...
'd'      [ -1.00000000] [0]
'p'      [  0.50000000] [0]
```

```
[ 1.41421356] [ 0.70710678] []  
};
```

Create a primal lifting step.

```
pstep = { 'p', [-1 2 -1]/4 , 1 };
```

Add the primal lifting step.

```
LSend = addlift(LSbegin,pstep);
```

Display the final lifting scheme.

```
displs(LSend);
```

```
LSend = {...  
'd'          [ -1.00000000]          [0]  
'p'          [  0.50000000]          [0]  
'p'          [ -0.25000000  0.50000000 -0.25000000] [1]  
[ 1.41421356] [ 0.70710678]          []  
};
```

liftfilt

Introduced before R2006a

addMembers

Add members to labeled signal set

Syntax

```
addMembers(lss,src)
addMembers(lss,src,tinfo)
addMembers(lss,src,tinfo,mnames)
```

Description

`addMembers(lss,src)` adds members to the labeled signal set `lss` from the input data source `src`.

`addMembers(lss,src,tinfo)` sets the time information for the new members to `tinfo`.

`addMembers(lss,src,tinfo,mnames)` sets the names of the new members to `mnames`. The length of `mnames` must be equal to the number of new members.

Examples

Add Member to Labeled Signal Set

Load a labeled signal set containing recordings of whale songs.

```
load whales
lss

lss =
  labeledSignalSet with properties:
        Source: {2x1 cell}
      NumMembers: 2
  TimeInformation: "sampleRate"
      SampleRate: 4000
        Labels: [2x3 table]
      Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

Retrieve the second member of the set and plot it.

```
[song,tinfo] = getSignal(lss,2);
t = (0:length(song)-1)/tinfo.SampleRate;
plot(t,song)
```

Remove the first and last seconds of the retrieved signal.

```
song2 = song(t>1 & t<t(end)-1);  
t2 = (0:length(song2)-1)/tinfo.SampleRate;  
  
plot(t2,song2)
```

Add the shorter signal as a new member of the labeled set.

```
addMembers(lss,song2)
lss
```

```
lss =
  labeledSignalSet with properties:
      Source: {3x1 cell}
      NumMembers: 3
      TimeInformation: "sampleRate"
      SampleRate: 4000
      Labels: [3x3 table]
      Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

Flip the shorter signal upside-down and add it as a new member of the labeled set. Specify that the new member is sampled at 1 kHz.

```
addMembers(lss,flipud(song2),1000)
lss.SampleRate
```

```
ans = 4x1
      4000
```

```
4000
4000
1000
```

Input Arguments

lss — Labeled signal set

labeledSignalSet object

Labeled signal set, specified as a `labeledSignalSet` object.

Example: `labeledSignalSet({randn(100,1), randn(10,1)}, signalLabelDefinition('female'))` specifies a two-member set of random signals containing the attribute 'female'.

src — Input data source

matrix | timetable | audio datastore

Input data source, specified as a matrix, a timetable, or an audio datastore. The particular form of `src` depends on the "Source" on page 1-0 property of `lss`.

- If "Source" on page 1-0 is a cell array of matrices:
 - Specify `src` as a matrix to add one member to the set.
 - Specify `src` as a cell array of matrices to add multiple members to the set.
- If "Source" on page 1-0 is a cell array containing cell arrays of vectors:
 - Specify `src` as a cell array of vectors to add one member to the set.
 - Specify `src` as a cell array containing cell arrays of vectors to add multiple members to the set.
- If "Source" on page 1-0 is a cell array of timetables:
 - Specify `src` as a timetable to add one member to the set.
 - Specify `src` as a cell array of timetables to add multiple members to the set.
- If "Source" on page 1-0 is an audio datastore, then add members by setting `src` as another audio datastore that points to new files.

Example: `{randn(10,3), randn(17,9)}` specifies two members. The first member contains three 10-sample signals. The second member contains nine 17-sample signals.

Example: `{{randn(10,1)}, {randn(17,1), randn(27,1)}}` specifies two members. The first member contains one 10-sample signal. The second member contains a 17-sample signal and a 27-sample signal.

Example:

`{{timetable(seconds(1:10)', randn(10,3)), timetable(seconds(1:7)', randn(7,2))}, {timetable(seconds(1:3)', randn(3,1))}}` specifies two members. The first member contains three signals sampled at 1 Hz for 10 seconds and two signals sampled at 1 Hz for 7 seconds. The second member contains one signal sampled at 1 Hz for 3 seconds.

tinfo — Time information for new members

scalar | vector | matrix | duration scalar | duration vector

Time information for new members, specified as a scalar, a vector, a matrix, a duration scalar, or a duration vector. This argument is valid only if the `"TimeInformation"` on page 1-0 property of `lss` is `'sampleRate'`, `'sampleTime'`, or `'timeValues'`.

- If `"TimeInformation"` on page 1-0 is `'sampleRate'`, then `tinfo` specifies sample rate values.
- If `"TimeInformation"` on page 1-0 is `'sampleTime'`, then `tinfo` specifies sample time values.
- If `"TimeInformation"` on page 1-0 is `'timeValues'`, then `tinfo` specifies time values.

If you add multiple members to a set, then specifying only one value of `tinfo` sets the same value for all members. If you want to specify a different value for each new member, then set `tinfo` to have multiple values.

When no source has been specified, or when the labeled signal set source is empty, you can change the `"TimeInformation"` on page 1-0 property to `'sampleRate'`, `'sampleTime'`, or `'timeValues'` to make `lss` interpret `tinfo` correctly.

Example: `addMembers(ks, {randn(10,5), randn(10,3)}, seconds([1 2]))` adds two new members with different time information to `ks = labeledSignalSet(randn(10,3), 'SampleTime', seconds(1))`.

Example: `addMembers(ks, {randn(10,5), randn(10,3)}, [1:10;2:2:20])` adds two new members with different time information to `ks = labeledSignalSet(randn(10,3), 'TimeValues', 1:10)`.

mnames — Member names

character vector | string scalar | cell array of character vectors | string array

Member names, specified as a character vector, a string scalar, a cell array of character vectors, or a string array.

Example: `labeledSignalSet({randn(100,1) randn(10,1)}, 'MemberNames', {'llama' 'alpaca'})` specifies a set of random signals with two members, `'llama'` and `'alpaca'`.

See Also

`labeledSignalSet` | `signalLabelDefinition`

Introduced in R2018b

allnodes

Tree nodes

Syntax

```
N = allnodes(T)
N = allnodes(T, 'deppos')
```

Description

`allnodes` is a tree management utility that returns one of two node descriptions: either indices, or depths and positions.

The nodes are numbered from left to right and from top to bottom. The root index is 0.

`N = allnodes(T)` returns the indices of all the nodes of the tree T in column vector N .

`N = allnodes(T, 'deppos')` returns the depths and positions of all the nodes in matrix N .

$N(i,1)$ is the depth and $N(i,2)$ the position of the node i .

Examples

Return Nodes of Wavelet Packet Tree

This example shows how to obtain the depth-position and linear indices of a wavelet packet tree.

Load the noisy Doppler signal and obtain the wavelet packet decomposition down to the level 4 using the 'db2' wavelet.

```
load noisdopp;
T = wpdec(noisdopp,4, 'db2');
```

Obtain the depth-position indices.

```
DepthPosition = allnodes(T, 'deppos');
```

Obtain the corresponding linear indices.

```
LinearIndices = allnodes(T);
```

Display the correspondence in a table.

```
table(DepthPosition, LinearIndices)
```

```
ans=31x2 table
   DepthPosition   LinearIndices
   _____   _____
         0         0
         1         0
```

appcoef

1-D approximation coefficients

Syntax

```
A = appcoef(C,L,wname)
A = appcoef(C,L,LoR,HiR)
A = appcoef( ____,N)
```

Description

`A = appcoef(C,L,wname)` returns the approximation coefficients at the coarsest scale using the wavelet decomposition structure `[C,L]` of a 1-D signal and the wavelet specified by `wname`. (See `wavedec` for more information.)

`A = appcoef(C,L,LoR,HiR)` uses the lowpass reconstruction filter `LoR` and highpass reconstruction filter `HiR`. (See `wfilters` for more information.)

`A = appcoef(____,N)` returns the approximation coefficients at level `N`. If `[C,L]` is the `M`-level wavelet decomposition structure of a 1-D signal, then $0 \leq N \leq M$.

Examples

Level 3 Approximation Coefficients

This example shows how to extract the level 3 approximation coefficients.

Load the signal consisting of electricity usage data.

```
load leleccum;
sig = leleccum(1:3920);
```

Obtain the DWT down to level 5 with the 'sym4' wavelet.

```
[C,L] = wavedec(sig,5,'sym4');
```

Extract the level-3 approximation coefficients. Plot the original signal and the approximation coefficients.

```
Lev = 3;
a3 = appcoef(C,L,'sym4',Lev);
subplot(2,1,1)
plot(sig); title('Original Signal');
subplot(2,1,2)
plot(a3); title('Level-3 Approximation Coefficients');
```

You can substitute any value from 1 to 5 for Lev to obtain the approximation coefficients for the corresponding level.

Input Arguments

C – Wavelet decomposition vector

real-valued vector

Wavelet decomposition vector of a 1-D signal, specified as a real-valued vector. C is the output of `wavedec`. The bookkeeping vector L is used to parse the coefficients in the wavelet decomposition vector by level.

Example: `[C,L] = wavedec(randn(1,256),4,'coif1')` returns the 4-level wavelet decomposition of a vector.

Data Types: double

L – Bookkeeping vector

vector of positive integers

Bookkeeping vector of the wavelet decomposition of a 1-D signal, specified as a vector of positive integers. The bookkeeping vector is used to parse the coefficients in the wavelet decomposition vector C by level.

Example: `[C,L] = wavedec(randn(1,256),4,'coif1')` returns the 4-level wavelet decomposition of a vector.

Data Types: `double`

wname — Wavelet

character vector | string scalar

Wavelet used to generate the wavelet decomposition of a 1-D signal, specified as a character vector or string scalar. The wavelet is from one of the following wavelet families: Daubechies, Coiflets, Symlets, Fejér-Korovkin, Discrete Meyer, Biorthogonal, and Reverse Biorthogonal. See `wavemngr` for the wavelets available in each family.

Example: `'db4'`

LoR — Wavelet lowpass reconstruction filter

even-length real-valued vector

Wavelet lowpass reconstruction filter, specified as an even-length real-valued vector. LoR must be the same length as HiR. LoR must be the lowpass reconstruction filter associated with the wavelet used to create the wavelet decomposition structure [C,L]. (See `wfilters` for more information.)

HiR — Wavelet highpass reconstruction filter

even-length real-valued vector

Wavelet highpass reconstruction filter, specified as an even-length real-valued vector. HiR must be the same length as LoR. HiR must be the highpass reconstruction filter associated with the wavelet used to create the wavelet decomposition structure [C,L]. (See `wfilters` for more information.)

N — Approximation coefficients level

positive integer

Approximation coefficients level, specified as a positive integer. If [C,L] is the M-level wavelet decomposition structure of a 1-D signal, then $0 \leq N \leq M$.

Output Arguments

A — Approximation coefficients

real-valued vector

Approximation coefficients at level N, returned as a real-valued vector.

Algorithms

The input vectors C and L contain all the information about the signal decomposition.

Let $N_{MAX} = \text{length}(L) - 2$; then $C = [A(N_{MAX}) \ D(N_{MAX}) \ \dots \ D(1)]$ where A and the D are vectors. If $N = N_{MAX}$, then a simple extraction is done; otherwise, `appcoef` computes iteratively the approximation coefficients using the inverse wavelet transform.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Variable-size data support must be enabled.
- The input `wname` must be constant.

See Also

`detcoef` | `wavedec`

Introduced before R2006a

appcoef2

2-D approximation coefficients

Syntax

```
A = appcoef2(C,S,wname)
A = appcoef2(C,S,LoR,HiR)
A = appcoef2( ____,N)
```

Description

`A = appcoef2(C,S,wname)` returns the approximation coefficients at the coarsest scale using the wavelet decomposition structure `[C,S]` of a 2-D signal and the wavelet specified by `wname`. (See `wavedec2` for more information.)

`A = appcoef2(C,S,LoR,HiR)` uses the lowpass reconstruction filter `LoR` and highpass reconstruction filter `HiR`. (See `wfilters` for more information.)

`A = appcoef2(____,N)` returns the approximation coefficients at level `N`. If `[C,S]` is the `M`-level wavelet decomposition structure of a 2-D signal, then $0 \leq N \leq M$.

Examples

Reconstruct Approximation Coefficients of an Image

This example shows how to reconstruct approximation coefficients from a multilevel wavelet decomposition of an image.

Set the DWT extension mode to zero-padding. Load and display an image.

```
dwtmode('zpd','nodisp')
load woman
image(X)
colormap(map)
title('Original')
```

```
size(X)
ans = 1×2
      256   256
```

Perform a three-level wavelet decomposition of the image using the `db1` wavelet. Display the number of elements in the coefficients array `cfs`, and the contents of the bookkeeping matrix `inds`. Note that `cfs` has the same number of elements as `X`.

```
wv = 'db1';
[cfs,inds] = wavedec2(X,3,wv);
numel(X)

ans = 65536

numel(cfs)

ans = 65536

inds

inds = 5×2
      32   32
      32   32
      64   64
     128  128
```

256 256

Extract and display the approximation coefficients at level 2.

```
cfs2 = appcoef2(cfs,inds,wv,2);  
figure;  
imagesc(cfs2)  
colormap('gray')  
title('Level 2 Approximation Coefficients')
```

```
size(cfs2)  
ans = 1×2  
64 64
```

Extract and display the approximation coefficients at level 3.

```
cfs3 = appcoef2(cfs,inds,wv,3);  
figure;  
imagesc(cfs3)  
colormap('gray')  
title('Level 3 Approximation Coefficients')
```

```
size(cfs3)
ans = 1x2
    32    32
```

Input Arguments

C — Wavelet decomposition vector

real-valued vector

Wavelet decomposition vector of a 2-D signal, specified as a real-valued vector. **C** is the output of `wavedec2`. The bookkeeping matrix **S** contains the dimensions of the coefficients by level.

Example: `[C,S] = wavedec2(randn(256,256),4,'db4')` returns the 4-level wavelet decomposition of a matrix.

Data Types: `double`

S — Bookkeeping matrix

matrix of positive integers

Bookkeeping matrix of the wavelet decomposition of a 2-D signal, specified as a matrix of positive integers. The bookkeeping matrix is used to parse the coefficients in the wavelet decomposition vector **C** by level.

Example: `[C,S] = wavedec2(randn(256,256),4,'db4')` returns the 4-level wavelet decomposition of a matrix.

Data Types: `double`

wname — Wavelet

character vector | string scalar

Wavelet used to generate the wavelet decomposition of a 2-D signal, specified as a character vector or string scalar. The wavelet is from one of the following wavelet families: Daubechies, Coiflets, Symlets, Fejér-Korovkin, Discrete Meyer, Biorthogonal, and Reverse Biorthogonal. See `wavemngr` for the wavelets available in each family.

Example: `'db4'`

LoR — Wavelet lowpass reconstruction filter

even-length real-valued vector

Wavelet lowpass reconstruction filter, specified as an even-length real-valued vector. LoR must be the same length as HiR. LoR must be the lowpass reconstruction filter associated with the wavelet used to create the wavelet decomposition structure [C,S]. (See `wfilters` for more information.)

HiR — Wavelet highpass reconstruction filter

even-length real-valued vector

Wavelet highpass reconstruction filter, specified as an even-length real-valued vector. HiR must be the same length as LoR. HiR must be the highpass reconstruction filter associated with the wavelet used to create the wavelet decomposition structure [C,S]. (See `wfilters` for more information.)

N — Approximation coefficients level

positive integer

Approximation coefficients level, specified as a positive integer. If [C,S] is the M-level wavelet decomposition structure of a 2-D signal, then $0 \leq N \leq M$.

Output Arguments

A — Approximation coefficients

real-valued matrix | real-valued 3-D array

Approximation coefficients at level N, returned as a real-valued matrix or 3-D real-valued array. If C and S are obtained from an indexed image analysis or a truecolor image analysis, A is an m-by-n matrix or an m-by-n-by-3 array, respectively.

For more information on image formats, see `image` and `imfinfo`.

Algorithms

The input vector C and bookkeeping matrix S contain all the information about the 2-D signal decomposition.

Let `NMAX = size(S,1)-2`; then `C = [A(NMAX) H(NMAX) V(NMAX) D(NMAX) ... H(1) V(1) D(1)]` where A, H, V, and D are vectors. If `N = NMAX`, then a simple extraction is done; otherwise, `appcoef2` computes iteratively the approximation coefficients using the inverse wavelet transform.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Variable-size data support must be enabled.
- The input `wname` must be constant.

bestlevt

Best level tree wavelet packet analysis

Syntax

```
T = bestlevt(T)
[T,E] = bestlevt(T)
```

Description

`bestlevt` is a one- or two-dimensional wavelet packet analysis function.

`bestlevt` computes the optimal complete subtree of an initial tree with respect to an entropy type criterion. The resulting complete tree may be of smaller depth than the initial one.

`T = bestlevt(T)` computes the modified wavelet packet tree T corresponding to the best level tree decomposition.

`[T,E] = bestlevt(T)` computes the best level tree T , and in addition, the best entropy value E .

The optimal entropy of the node, whose index is $j-1$, is $E(j)$.

Examples

```
% The current extension mode is zero-padding (see dwtmode).

% Load signal.
load noisdopp;
x = noisdopp;

% Decompose x at depth 3 with db1 wavelet, using default
% entropy (shannon).
wpt = wptdec(x,3,'db1');

% Decompose the packet [3 0].
wpt = wpsplt(wpt,[3 0]);

% Plot wavelet packet tree wpt.
plot(wpt)
```

```
% Compute best level tree.  
blt = bestlevt(wpt);  
  
% Plot best level tree blt.  
plot(blt)
```

Algorithms

See `besttree` algorithm section. The only difference is that the optimal tree is searched among the complete subtrees of the initial tree, instead of among all the binary subtrees.

besttree

Best tree wavelet packet analysis

Syntax

```
T = besttree(T)
[T,E] = besttree(T)
[T,E,N] = besttree(T)
```

Description

`besttree` is a one- or two-dimensional wavelet packet analysis function that computes the optimal subtree of an initial tree with respect to an entropy type criterion. The resulting tree may be much smaller than the initial one.

Following the organization of the wavelet packets library, it is natural to count the decompositions issued from a given orthogonal wavelet.

A signal of length $N = 2^L$ can be expanded in α different ways, where α is the number of binary subtrees of a complete binary tree of depth L .

As a result, we can conclude that $\alpha \geq 2^{N/2}$ (for more information, see the Mallat's book given in References at page 323).

This number may be very large, and since explicit enumeration is generally intractable, it is interesting to find an optimal decomposition with respect to a convenient criterion, computable by an efficient algorithm. We are looking for a minimum of the criterion.

`T = besttree(T)` computes the best tree T corresponding to the best entropy value.

`[T,E] = besttree(T)` computes the best tree T and, in addition, the best entropy value E .

The optimal entropy of the node, whose index is $j - 1$, is $E(j)$.

`[T,E,N] = besttree(T)` computes the best tree T , the best entropy value E and, in addition, the vector N containing the indices of the merged nodes.

Examples

Best Wavelet Packet Tree

This example shows to obtain the optimal wavelet packet tree based on an entropy criterion.

Load the noisy Doppler signal. Obtain the wavelet packet tree down to level 4 with the 'sym4' wavelet. Use the periodic extension mode.

```
dwtmode('per');
```

```
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
```

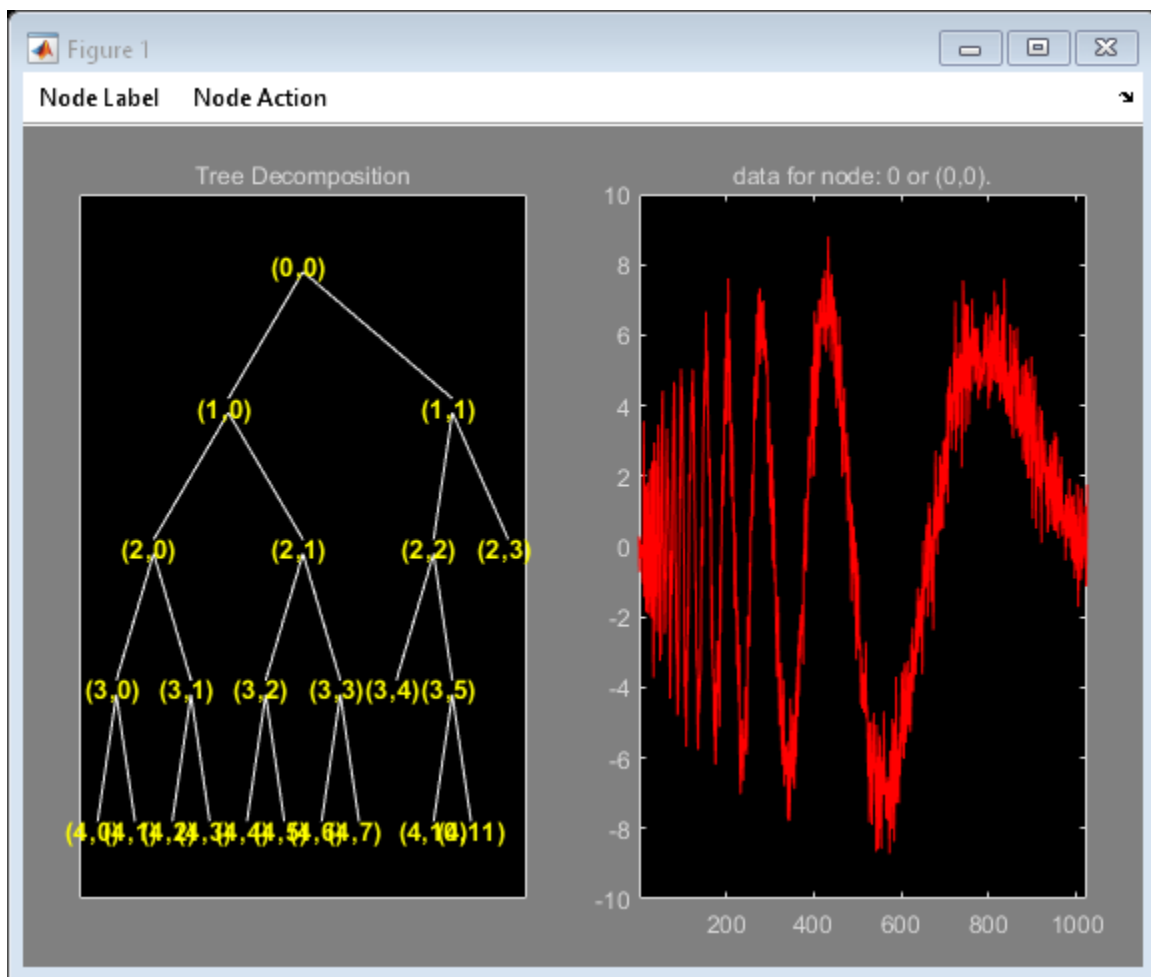

```
! WARNING: Change DWT Extension Mode !
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
```

```
*****
** DWT Extension Mode: Periodization **
*****
```

```
load noisdopp;
T = wpdec(noisdopp,4,'sym4');
```

Obtain the best wavelet packet tree and plot the result.

```
BstTree = besttree(T);
plot(BstTree)
```

Return the DWT extension mode to the default value.

```
dwtmode('sym');
```

```
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
! WARNING: Change DWT Extension Mode !
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
```

```
*****  
** DWT Extension Mode: Symmetrization (half-point) **  
*****
```

Algorithms

Consider the one-dimensional case. Starting with the root node, the best tree is calculated using the following scheme. A node N is split into two nodes $N1$ and $N2$ if and only if the sum of the entropy of $N1$ and $N2$ is lower than the entropy of N . This is a local criterion based only on the information available at the node N .

Several entropy type criteria can be used (see `wenergy` for more information). If the entropy function is an additive function along the wavelet packet coefficients, this algorithm leads to the best tree.

Starting from an initial tree T and using the merging side of this algorithm, we obtain the best tree among all the binary subtrees of T .

"Reconstructing a Signal Approximation from a Node"

Introduced before R2006a

biorfilt

Biorthogonal wavelet filter set

Syntax

```
[Lo_D,Hi_D,Lo_R,Hi_R] = biorfilt(DF,RF)
[Lo_D1,Hi_D1,Lo_R1,Hi_R1,Lo_D2,Hi_D2,Lo_R2,Hi_R2] = biorfilt(DF,RF,'8')
```

Description

The `biorfilt` command returns either four or eight filters associated with biorthogonal wavelets.

`[Lo_D,Hi_D,Lo_R,Hi_R] = biorfilt(DF,RF)` computes four filters associated with the biorthogonal wavelet specified by decomposition filter `DF` and reconstruction filter `RF`. These filters are

Lo_D	Decomposition low-pass filter
Hi_D	Decomposition high-pass filter
Lo_R	Reconstruction low-pass filter
Hi_R	Reconstruction high-pass filter

`[Lo_D1,Hi_D1,Lo_R1,Hi_R1,Lo_D2,Hi_D2,Lo_R2,Hi_R2] = biorfilt(DF,RF,'8')` returns eight filters, the first four associated with the decomposition wavelet, and the last four associated with the reconstruction wavelet.

It is well known in the subband filtering community that if the same FIR filters are used for reconstruction and decomposition, then symmetry and exact reconstruction are incompatible (except with the Haar wavelet). Therefore, with biorthogonal filters, two wavelets are introduced instead of just one:

One wavelet, $\tilde{\psi}$, is used in the analysis, and the coefficients of a signal s are

$$\tilde{c}_{j,k} = \int s(x) \tilde{\psi}_{j,k}(x) dx$$

The other wavelet, ψ , is used in the synthesis:

$$s = \sum_{j,k} \tilde{c}_{j,k} \psi_{j,k}$$

Furthermore, the two wavelets are related by duality in the following sense:

$$\int \tilde{\psi}_{j,k}(x) \psi_{j',k'}(x) dx = 0 \text{ as soon as } j \neq j' \text{ or } k \neq k' \text{ and}$$

$$\int \tilde{\phi}_{0,k}(x) \phi_{0,k'}(x) dx = 0 \text{ as soon as } k \neq k'.$$

It becomes apparent, as A. Cohen pointed out in his thesis (p. 110), that “the useful properties for analysis (e.g., oscillations, null moments) can be concentrated in the $\tilde{\psi}$ function; whereas, the interesting properties for synthesis (regularity) are assigned to the ψ function. The separation of these two tasks proves very useful.”

$\tilde{\psi}$ and ψ can have very different regularity properties, ψ being more regular than $\tilde{\psi}$.

The $\tilde{\psi}$, ψ , $\tilde{\phi}$ and ϕ functions are zero outside a segment.

Examples

Biorthogonal Filters and Transfer Functions

This example shows how to obtain the decomposition (analysis) and reconstruction (synthesis) filters for the 'bior3.5' wavelet.

Determine the two scaling and wavelet filters associated with the 'bior3.5' wavelet.

```
wv = 'bior3.5';  
[Rf,Df] = biorwavf(wv);  
[LoD,HiD,LoR,HiR] = biorfilt(Df,Rf);
```

Plot the filter impulse responses.

```
subplot(2,2,1)  
stem(LoD)  
title(['Dec. lowpass filter ',wv])  
subplot(2,2,2)  
stem(HiD)  
title(['Dec. highpass filter ',wv])  
subplot(2,2,3)  
stem(LoR)  
title(['Rec. lowpass filter ',wv])  
subplot(2,2,4)  
stem(HiR)  
title(['Rec. highpass filter ',wv])
```

Demonstrate that autocorrelations at even lags are only zero for dual pairs of filters. Examine the autocorrelation sequence for the lowpass decomposition filter.

```

npad = 2*length(LoD)-1;
LoDxcr = fftshift(iffshift(abs(fft(LoD,npad)).^2));
lags = -floor(npad/2):floor(npad/2);
figure
stem(lags,LoDxcr,'markerfacecolor',[0 0 1])
set(gca,'xtick',-10:2:10)
    
```

Examine the cross correlation sequence for the lowpass decomposition and synthesis filters. Compare the result with the preceding figure.

```
npad = 2*length(LoD)-1;  
xcr = fftshift(ifft(fft(LoD,npad).*conj(fft(LoR,npad))));  
lags = -floor(npad/2):floor(npad/2);  
stem(lags,xcr,'markerfacecolor',[0 0 1])  
set(gca,'xtick',-10:2:10)
```

Compare the transfer functions of the analysis and synthesis scaling and wavelet filters

```
dftLoD = fft(LoD,64);
dftLoD = dftLoD(1:length(dftLoD)/2+1);
dftHiD= fft(HiD,64);
dftHiD = dftHiD(1:length(dftHiD)/2+1);
dftLoR = fft(LoR,64);
dftLoR = dftLoR(1:length(dftLoR)/2+1);
dftHiR = fft(HiR,64);
dftHiR = dftHiR(1:length(dftHiR)/2+1);
df = (2*pi)/64;
freqvec = 0:df:pi;

subplot(2,1,1)
plot(freqvec,abs(dftLoD),freqvec,abs(dftHiD),'r')
axis tight
title('Transfer modulus for dec. filters')
subplot(2,1,2)
plot(freqvec,abs(dftLoR),freqvec,abs(dftHiR),'r')
axis tight
title('Transfer modulus for rec. filters')
```

`biorwavf` | `orthfilt`

Introduced before R2006a

biorwavf

Biorthogonal spline wavelet filter

Syntax

```
[RF,DF] = biorwavf(wname)
```

Description

`[RF,DF] = biorwavf(wname)` returns the reconstruction (synthesis) and decomposition (analysis) scaling filters, RF and DF, respectively, associated with the biorthogonal wavelet specified by `wname`.

Examples

Biorthogonal Spline Wavelet Filter

Return the biorthogonal spline wavelet scaling filters with two vanishing moments.

```
wname = 'bior2.2';
[RF,DF] = biorwavf(wname)
```

```
RF = 1×3
```

```
    0.2500    0.5000    0.2500
```

```
DF = 1×5
```

```
   -0.1250    0.2500    0.7500    0.2500   -0.1250
```

Input Arguments

wname — Name of biorthogonal wavelet

character vector | string scalar

Name of biorthogonal wavelet, specified as 'biorNr.Nd' where possible values for Nr and Nd are as follows:

Nr = 1	Nd = 1 , 3 or 5
Nr = 2	Nd = 2 , 4 , 6 or 8
Nr = 3	Nd = 1 , 3 , 5 , 7 or 9
Nr = 4	Nd = 4
Nr = 5	Nd = 5
Nr = 6	Nd = 8

N_r and N_d are the numbers of vanishing moments for the reconstruction and decomposition filters, respectively.

Example: 'biorwavf3.7'

Output Arguments

RF — Reconstruction filter

real-valued vector

Reconstruction filter associated with the biorthogonal wavelet `wname`, returned as a real-valued vector.

DF — Decomposition filter

real-valued vector

Decomposition filter associated with the biorthogonal wavelet `wname`, returned as a real-valued vector.

BPfrequencies

CWT filter bank bandpass center frequencies

Note BPfrequencies is not recommended and may be removed in a future release. Use centerFrequencies instead.

Syntax

```
bpcf = BPfrequencies(fb)
```

Description

bpcf = BPfrequencies(fb) returns the wavelet bandpass center frequencies bpcf for the CWT filter bank fb. Frequencies are ordered from high to low. Frequencies are in cycles/sample if a sampling frequency or sampling period is not specified. If a sampling frequency is specified, bpcf has units of hertz. If a sampling period is specified, bpcf has units cycles/unit time where the time unit is the same as the duration SamplingPeriod.

Examples

Wavelet Bandpass Center Frequencies

Create a CWT filter bank.

```
fb = cwtfilterbank;
```

Calculate the bandpass center frequencies.

```
bpcf = centerFrequencies(fb);
```

Plot the frequency responses of the filter bank and the bandpass center frequencies. The bandpass center frequencies correspond to the peaks of the frequency response of each wavelet in the filter bank.

```
freqz(fb)  
hold on  
plot(bpcf, 2*ones(size(bpcf)), 'rx')
```

Input Arguments

fb – Continuous wavelet transform filter bank

`cwtfilterbank` object

Continuous wavelet transform (CWT) filter bank, specified as a `cwtfilterbank` object.

Output Arguments

bpcf – Wavelet bandpass center frequencies

real-valued vector

Wavelet bandpass center frequencies, returned as a real-valued vector of length `Ns` where `Ns` is the number of scales in the filter bank. Frequencies are ordered from high to low. Frequencies are in cycles/sample if a sampling frequency or sampling period is not specified. If a sampling frequency is specified, `bpcf` has units of hertz. If a sampling period is specified, `bpcf` has units cycles/unit time where the time unit is the same as the duration `SamplingPeriod`.

Compatibility Considerations

BPfrequencies will be removed

Not recommended starting in R2018b

The BPfrequencies object function of cwtfilterbank has been renamed centerFrequencies. The functionality remains unchanged. BPfrequencies will be removed in a future release.

Functionality	What Happens When You Use This Functionality?	Use This Instead	Compatibility Considerations
BPfrequencies	Still runs	Use centerFrequencies	Replace all instances of BPfrequencies with centerFrequencies.

See Also

centerPeriods | cwtfilterbank | freqz | powerbw

Introduced in R2018a

BPperiods

CWT filter bank bandpass periods

Note BPperiods is not recommended and may be removed in a future release. Use centerPeriods instead.

Syntax

```
p = BPperiods(fb)
```

Description

`p = BPperiods(fb)` returns the wavelet bandpass periods, `p`, for the continuous wavelet transform (CWT) filter bank, `fb`.

Examples

Wavelet Filter Bank Bandpass Periods

Create two CWT filter banks. Set the sampling period of the first filter bank to 0.5 seconds, and the sampling frequency of the second filter bank to 2 Hz.

```
fb = cwtfilterbank('SamplingPeriod',seconds(0.5));  
fb2 = cwtfilterbank('SamplingFrequency',2);
```

Obtain the bandpass center periods of both filter banks. Confirm the center periods of both filter banks are equal.

```
bp = centerPeriods(fb);  
bp2 = centerPeriods(fb2);  
bp(1:5)
```

```
ans = 5x1 duration  
    1.1517 sec  
    1.2344 sec  
    1.323 sec  
    1.418 sec  
    1.5197 sec
```

```
bp2(1:5)
```

```
ans = 5x1  
  
    1.1517  
    1.2344  
    1.3230  
    1.4180  
    1.5197
```

Obtain the bandpass center frequencies of the second filter bank. Confirm the reciprocals of the center frequencies are equal to the center periods.

```
f2 = centerFrequencies(fb2);
1./f2(1:5)
```

```
ans = 5×1

    1.1517
    1.2344
    1.3230
    1.4180
    1.5197
```

Input Arguments

fb — Continuous wavelet transform filter bank

cwtfilterbank object

Continuous wavelet transform (CWT) filter bank, specified as a `cwtfilterbank` object.

Output Arguments

p — Wavelet bandpass filter periods

real-valued vector | duration array

Wavelet bandpass filter periods, returned as a real-valued vector of length N_s where N_s is the number of scales in the filter bank.

If `SamplingPeriod` is specified, `p` is a duration array with the same units and format as `SamplingPeriod`. If `SamplingFrequency` is specified, `p` is in seconds.

Compatibility Considerations

BPperiods will be removed

Not recommended starting in R2018b

The `BPperiods` object function of `cwtfilterbank` has been renamed `centerPeriods`. The functionality remains unchanged. `BPperiods` will be removed in a future release.

Functionality	What Happens When You Use This Functionality?	Use This Instead	Compatibility Considerations
BPperiods	Still runs	Use centerPeriods	Replace all instances of BPperiods with centerPeriods.

bswfun

Biorthogonal scaling and wavelet functions

Syntax

```
[PHIS,PSIS,PHIA,PSIA,XVAL] = bswfun(LoD,HiD,LoR,HiR)
bswfun(LoD,HiD,LoR,HiR,ITER)
bswfun(LoD,HiD,LoR,HiR,'plot')
bswfun(LoD,HiD,LoR,HiR,ITER,'plot')
bswfun(LoD,HiD,LoR,HiR,'plot',ITER)
```

Description

`[PHIS,PSIS,PHIA,PSIA,XVAL] = bswfun(LoD,HiD,LoR,HiR)` returns approximations on the grid `XVAL` of the two pairs of biorthogonal scaling and wavelet functions. `PHIS` and `PSIS` are the scaling and wavelet functions constructed from the decomposition filters, `LoD` and `HiD`. `PHIA` and `PSIA` are the scaling and wavelet functions constructed from the reconstruction filters, `LoR` and `HiR`.

`bswfun(LoD,HiD,LoR,HiR,ITER)` computes the two pairs of scaling and wavelet functions using `ITER` iterations.

`bswfun(LoD,HiD,LoR,HiR,'plot')` or `bswfun(LoD,HiD,LoR,HiR,ITER,'plot')` or `bswfun(LoD,HiD,LoR,HiR,'plot',ITER)` computes and plots the functions.

Examples

Biorthogonal Scaling and Wavelet from Lifting Scheme

This example shows how to obtain the biorthogonal scaling and wavelet functions corresponding to a lifting scheme. Obtain the lifting scheme for the CDF 3/1 wavelet.

```
lscdf = liftwave('cdf3.1');
```

Display the lifting scheme, which consists of two primal and one dual step.

```
Sc = displs(lscdf);
Sc
```

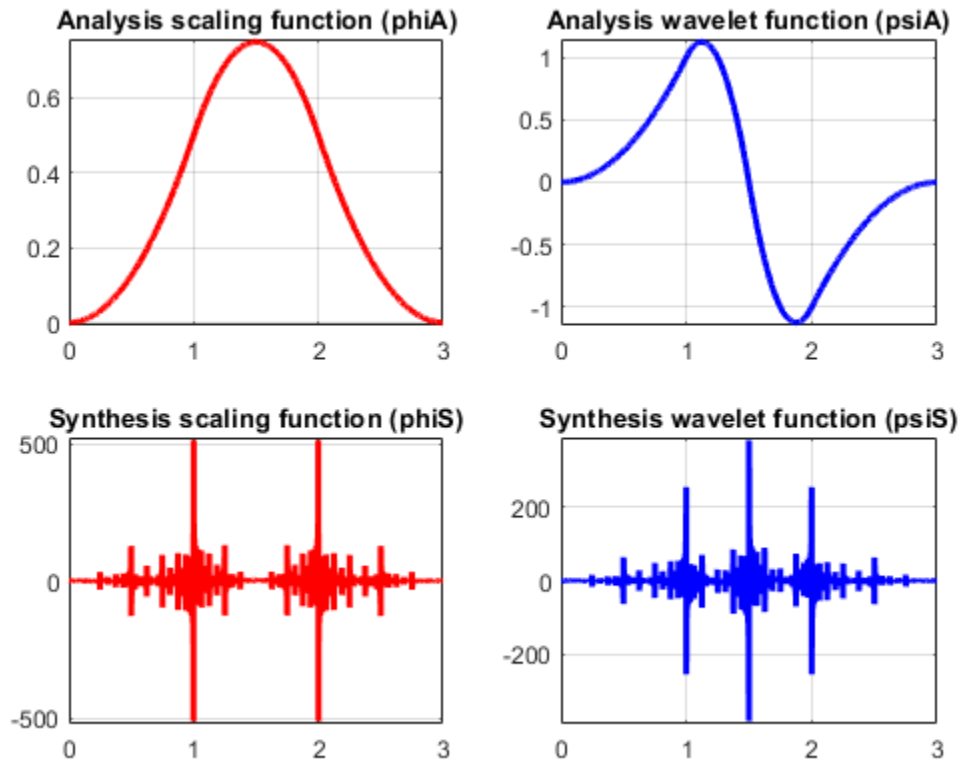

```
Sc = 6x50 char array
    'lscdf = {...'
    'p'          [ -0.333333333]      [-1]
    'd'          [ -0.375000000 -1.125000000] [1]
    'p'          [  0.444444444]      [0]
    '[ 2.12132034] [  0.47140452]      []
    '};
```

Obtain the decomposition and reconstruction filters from the lifting scheme.

```
[LoD,HiD,LoR,HiR] = ls2filt(lscdf);
```

Visualize the scaling and wavelet function and their duals.

```
bswfun(LoD,HiD,LoR,HiR,'plot');
```

Algorithms

This function uses the cascade algorithm.

centerFrequencies

CWT filter bank bandpass center frequencies

Syntax

```
bpcf = centerFrequencies(fb)
```

Description

`bpcf = centerFrequencies(fb)` returns the wavelet bandpass center frequencies `bpcf` for the CWT filter bank `fb`. Frequencies are ordered from high to low. Frequencies are in cycles/sample if a sampling frequency or sampling period is not specified. If a sampling frequency is specified, `bpcf` has units of hertz. If a sampling period is specified, `bpcf` has units of cycles/unit time, where the time unit is the same as the duration `SamplingPeriod`.

Examples

Wavelet Bandpass Center Frequencies

Create a CWT filter bank.

```
fb = cwtfilterbank;
```

Calculate the bandpass center frequencies.

```
bpcf = centerFrequencies(fb);
```

Plot the frequency responses of the filter bank and the bandpass center frequencies. The bandpass center frequencies correspond to the peaks of the frequency response of each wavelet in the filter bank.

```
freqz(fb)  
hold on  
plot(bpcf, 2*ones(size(bpcf)), 'rx')
```

Input Arguments

fb – Continuous wavelet transform filter bank

cwtfilterbank object

Continuous wavelet transform (CWT) filter bank, specified as a `cwtfilterbank` object.

Output Arguments

bpcf – Wavelet bandpass center frequencies

real-valued vector

Wavelet bandpass center frequencies, returned as a real-valued vector of length N_s , where N_s is the number of scales in the filter bank. Frequencies are ordered from high to low. Frequencies are in cycles/sample if a sampling frequency or sampling period is not specified. If a sampling frequency is specified, `bpcf` has units of hertz. If a sampling period is specified, `bpcf` has units of cycles/unit time, where the time unit is the same as the duration `SamplingPeriod`.

Introduced in R2018b

centerFrequencies

Wavelet scattering bandpass center frequencies

Syntax

```
F = centerFrequencies(sf)
F = centerFrequencies(sf,filterbanks)
```

Description

`F = centerFrequencies(sf)` returns the wavelet bandpass center frequencies for all filter banks of the scattering decomposition framework, `sf`. The output `F` is a cell array with `Nfb` elements, where `Nfb` is the number of scattering filter banks. Each element of `F` is a real-valued vector. If you specify a sampling frequency in `sf`, `F` is in hertz. If you do not specify a sampling frequency, `F` is in cycles/sample.

If there is only one filter bank in the scattering framework, `F` is a real-valued vector containing the wavelet bandpass center frequencies.

`F = centerFrequencies(sf,filterbanks)` returns the wavelet bandpass center frequencies for the specified `filterbanks`. The argument `filterbanks` is a scalar or vector with all the elements between 1 and `Nfb` inclusive, where `Nfb` is the number of scattering filter banks.

Examples

Wavelet Bandpass Center Frequencies

Create a scattering decomposition framework with a sampling frequency of 50 Hz.

```
sf = waveletScattering('SamplingFrequency',50)
```

```
sf =
    waveletScattering with properties:
```

```
    SignalLength: 1024
    InvarianceScale: 10.2400
    QualityFactors: [8 1]
        Boundary: "periodic"
    SamplingFrequency: 50
        Precision: "double"
    OversamplingFactor: 0
```

Plot the wavelet bandpass center frequencies for all the filter banks.

```
bpcf = centerFrequencies(sf);
plot(bpcf{1}, 'rx-')
hold on
plot(bpcf{2}, 'bo-')
grid on
```

```

title('Wavelet Bandpass Center Frequencies')
legend('Filter Bank 1','Filter Bank 2')
ylabel('Hz')

```

Plot the wavelets filters used in computing the second-order scattering coefficients.

```

orderCoef = 2;
[filters,f] = filterbank(sf);
figure
plot(f,filters{orderCoef+1}.psift)
grid on
title('Wavelet Filters with Q = 1')
xlabel('Hz')
ylabel('Magnitude')
hold on
pl = plot(bpcf{orderCoef},max(filters{orderCoef+1}.psift),'bo');
legend(pl,'Center Frequencies')

```

Input Arguments

sf – Scattering decomposition framework

waveletScattering object

Scattering decomposition framework, specified as a waveletScattering object.

filterbanks – Filter bank indices

positive integer | vector of integers

Filter bank indices, specified as a positive integer or vector of integers. Elements of `filterbanks` are integers between 1 and `Nfb` inclusive, where `Nfb` is the number of scattering filter banks.

Example: `F = centerFrequencies(sf, [1 2])` returns the wavelet bandpass center frequencies for the first two filter banks in `sf`.

Data Types: double

See Also

waveletScattering

Introduced in R2018b

centerPeriods

CWT filter bank bandpass center periods

Syntax

```
p = centerPeriods(fb)
```

Description

`p = centerPeriods(fb)` returns the wavelet bandpass center periods `p` for the continuous wavelet transform (CWT) filter bank `fb`.

Examples

Wavelet Filter Bank Bandpass Periods

Create two CWT filter banks. Set the sampling period of the first filter bank to 0.5 seconds, and the sampling frequency of the second filter bank to 2 Hz.

```
fb = cwtfilterbank('SamplingPeriod',seconds(0.5));
fb2 = cwtfilterbank('SamplingFrequency',2);
```

Obtain the bandpass center periods of both filter banks. Confirm the center periods of both filter banks are equal.

```
bp = centerPeriods(fb);
bp2 = centerPeriods(fb2);
bp(1:5)
```

```
ans = 5x1 duration
    1.1517 sec
    1.2344 sec
    1.323 sec
    1.418 sec
    1.5197 sec
```

```
bp2(1:5)
```

```
ans = 5x1
    1.1517
    1.2344
    1.3230
    1.4180
    1.5197
```

Obtain the bandpass center frequencies of the second filter bank. Confirm the reciprocals of the center frequencies are equal to the center periods.

```
f2 = centerFrequencies(fb2);  
1./f2(1:5)  
  
ans = 5×1  
  
    1.1517  
    1.2344  
    1.3230  
    1.4180  
    1.5197
```

Input Arguments

fb — Continuous wavelet transform filter bank

cwtfilterbank object

Continuous wavelet transform (CWT) filter bank, specified as a `cwtfilterbank` object.

Output Arguments

p — Wavelet bandpass center periods

real-valued vector | duration array

Wavelet bandpass center periods, returned as a real-valued vector of length N_s , where N_s is the number of scales in the filter bank.

If `SamplingPeriod` is specified, `p` is a duration array with the same units and format as `SamplingPeriod`. If `SamplingFrequency` is specified, `p` is in seconds.

Introduced in R2018b

centfrq

Wavelet center frequency

Syntax

```
FREQ = centfrq(wname)
FREQ = centfrq(wname,ITER)
[FREQ,XVAL,RECFREQ] = centfrq(wname,ITER,'plot')
```

Description

`FREQ = centfrq(wname)` returns the center frequency in hertz of the wavelet specified by `wname` (see `wavefun` for more information).

`FREQ = centfrq(wname,ITER)` uses `ITER` many iterations to generate the wavelet.

`[FREQ,XVAL,RECFREQ] = centfrq(wname,ITER,'plot')` returns the associated center frequency-based approximation `RECFREQ` on the 2^{ITER} points grid `XVAL` and plots the wavelet function and `RECFREQ`.

Examples

Determine Center Frequency

This example shows how to determine the center frequency in hertz for Daubechies' least-asymmetric wavelet with 4 vanishing moments.

```
cfreq = centfrq('sym4');
```

Obtain the wavelet and create a sine wave with a frequency equal to the center frequency, `cfreq`, of the wavelet. Use a starting phase of $-\pi$ for the sine wave to visualize how the oscillation in the sine wave matches the oscillation in the wavelet.

```
[~,psi,xval] = wavefun('sym4');
y = cos(2*pi*cfreq*xval-pi);
plot(xval,psi,'linewidth',2);
hold on;
plot(xval,y,'r');
```

Convert Scales to Frequencies

This example shows to convert scales to frequencies for the Morlet wavelet. There is an approximate inverse relationship between scale and frequency. Specifically, scale is inversely proportional to frequency with the constant of proportionality being the center frequency of the wavelet.

Construct a vector of scales with 32 voices per octave over 5 octaves for data sampled at 1 kHz.

```
Fs = 1000;
numvoices = 32;
a0 = 2^(1/numvoices);
numoctaves = 5;
scales = a0.^(0:numvoices*numoctaves-1).*1/Fs;
```

Convert the scales to approximate frequencies in hertz for the Morlet wavelet.

```
Frq = centfrq('morl')./scales;
```

You can also use `scal2frq` to convert scales to approximate frequencies in hertz.

Input Arguments

wname — Wavelet

character vector | string scalar

Wavelet, specified as a character vector or string scalar. See `wavefun` for more information.

ITER — Number of iterations

8 (default) | positive integer

Number of iterations, specified by a positive integer, used to generate the wavelet `wname`. Internally, `centfrq` uses `wavefun` to generate the wavelet.

Output Arguments

FREQ — Wavelet center frequency

scalar

Wavelet center frequency in hertz, returned as a scalar.

XVAL — Grid points

real-valued vector

Grid points where the center frequency-based approximation to the wavelet is evaluated, returned as a real-valued vector.

RECFREQ — Center frequency-based approximation

vector

Center frequency-based approximation to the wavelet, returned as a vector. Depending on the wavelet, `RECFREQ` is either a real- or complex-valued vector.

Introduced before R2006a

cfs2wpt

Wavelet packet tree construction from coefficients

Syntax

Description

`cfs2wpt` builds a wavelet packet tree (T) and the related analyzed signal or image (X) using the following input information:

WNAME: name of the wavelet used for the analysis

SIZE_OF_DATA: size of the analyzed signal or image

TN_OF_TREE: vector containing the terminal node indices of the tree

ORDER: 2 for a signal or 4 for an image

CFS: coefficients used to reconstruct the original signal or image. *CFS* is optional. When `cfs2wpt` is used without the *CFS* input parameter, the wavelet packet tree structure (T) is generated, but all the tree coefficients are null (including X).

Examples

Build Wavelet Packet Tree

This example shows how to build a wavelet packet tree in two ways: 1.) By filling the wavelet packet tree with coefficients, and 2.) By creating the wavelet packet tree and using `write`

Load an image and obtain the wavelet packet decomposition down to level 2 with the 'sym4' wavelet.

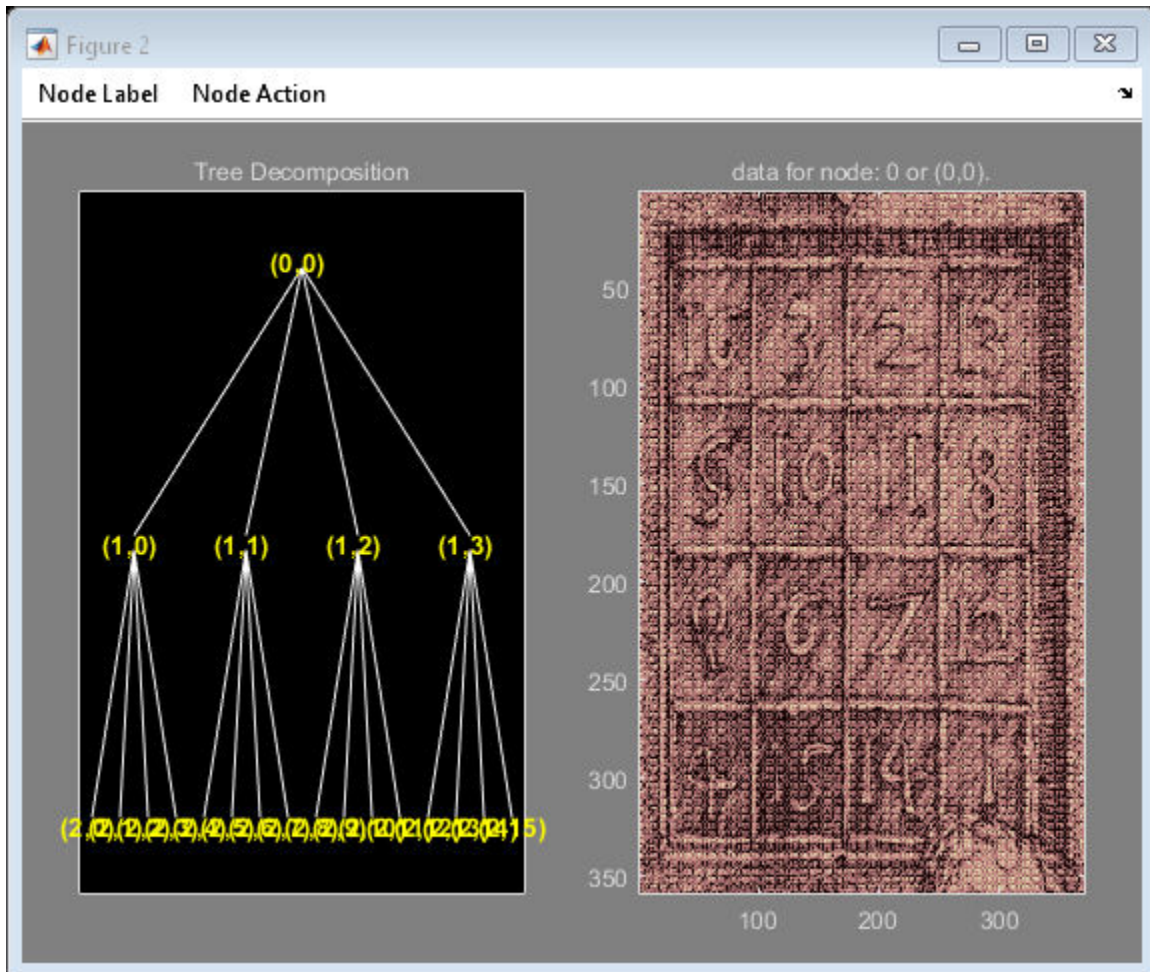

```
load detail;  
imagesc(X); colormap gray; title('Original Image');
```

```
Tr = wpdec2(X,2, 'sym4');
```

Read the coefficients from the wavelet packet tree. Add $N(0, 40^2)$ noise to the coefficients and plot the new wavelet packet tree.

```
cfs = read(Tr, 'allcfs');
noisyCfs = cfs + 40*rand(size(cfs));
noisyT = cfs2wpt('sym4', size(X), tnodes(Tr), 4, noisyCfs);
plot(noisyT)
```

To illustrate building a wavelet packet tree using `write`, construct an admissible binary wavelet packet tree with terminal nodes [2 3 9 10]. The analyzing wavelet is 'sym4' and the signal length is 1024.

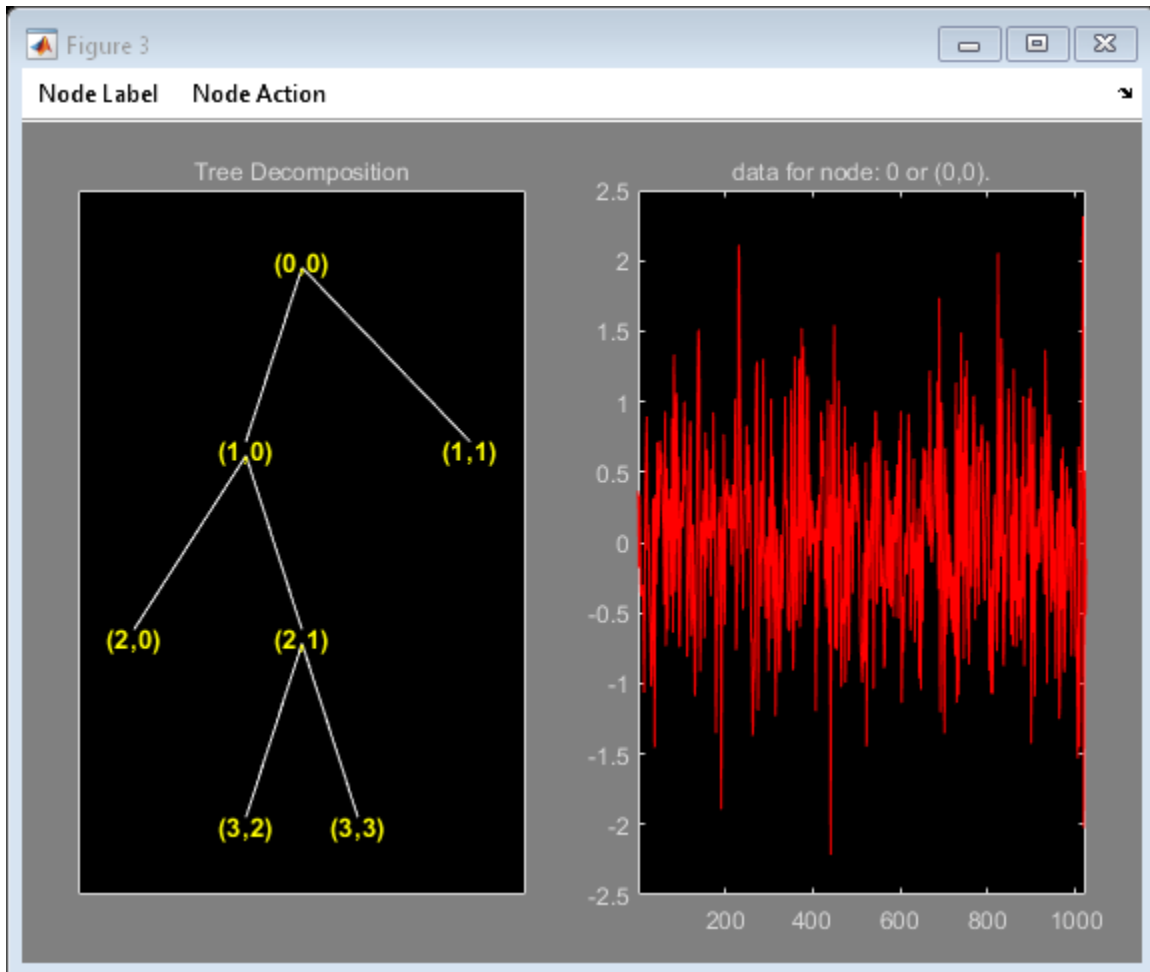

```
tr = cfs2wpt('sym4',[1 1024],[2 3 9 10]',2);
```

Fill terminal nodes [3 9] with $N(0, 1)$ coefficients.

```
sN = read(tr,'sizes',[3,9]);
sN3 = sN(1,:); sN9 = sN(2,:);
cfsN3 = randn(sN3);
cfsN9 = randn(sN9);
tr = write(tr,'cfs',3,cfsN3,'cfs',9,cfsN9);
```

Plot the resulting wavelet packet tree and synthesized signal.

```
plot(tr)
```

Introduced before R2006a

cgauwavf

Complex Gaussian wavelet

Syntax

```
[psi,x] = cgauwavf(lb,ub,n)
[psi,x] = cgauwavf(lb,ub,n,p)
[psi,x] = cgauwavf(lb,ub,n,wname)
```

Description

`[psi,x] = cgauwavf(lb,ub,n)` returns the 1st order derivative of the complex-valued Gaussian wavelet, `psi`, on an `n`-point regular grid, `x`, for the interval `[lb,ub]`. The effective support of the complex-valued Gaussian wavelets is `[-5, 5]`.

`[psi,x] = cgauwavf(lb,ub,n,p)` returns the `p`th derivative. `p` is an integer from 1 through 8.

The complex Gaussian function is defined as $C_p e^{-ix} e^{-x^2}$. C_p is such that the 2-norm of the `p`th derivative of `psi` is equal to 1.

`[psi,x] = cgauwavf(lb,ub,n,wname)` used the valid wavelet family short name `wname` plus the order of the derivative in a character vector or string scalar, such as `'cgau4'`. To see valid character vectors for complex-valued Gaussian wavelets, use `waveinfo('cgau')` or use `wavemngr('read',1)` and refer to the Complex Gaussian section.

Examples

Create Complex Gaussian Wavelet

This example shows how to create a complex-valued Gaussian wavelet of order 4. The wavelet has an effective support of `[-5,5]` and is constructed using 1,000 samples.

```
lb = -5;
ub = 5;
n = 1000;
order = 4;
[psi,x] = cgauwavf(lb,ub,n,order);
subplot(2,1,1)
plot(x,real(psi))
title('Real Part')
grid on
subplot(2,1,2)
plot(x,imag(psi))
title('Imaginary Part')
grid on
```

Input Arguments

lb – Left endpoint

real number

Left endpoint of the closed interval, specified as a real number. `lb` is strictly less than `ub`.

Data Types: `double`

ub – Right endpoint

real number

Right endpoint of the closed interval, specified as a real number. `ub` is strictly greater than `lb`.

Data Types: `double`

n – Number of regularly spaced points

positive integer

Number of regularly spaced points in the interval `[lb,ub]`, specified as a positive integer. The derivative of the complex-valued Gaussian wavelet is evaluated at these points.

Data Types: `double`

p – Derivative

positive integer

Positive integer defining the order of the derivative of the complex-valued Gaussian, specified as a positive integer. p is an integer from 1 through 8.

wname — Gaussian wavelet

character vector | string scalar

Gaussian wavelet to evaluate, specified as a character vector or string scalar. `wname` is of the form 'cgau N ' where N is an integer that denotes the order of the derivative of the complex-valued Gaussian. N is an integer from 1 through 8.

Example: 'cgau4' denotes the fourth derivative of the complex-valued Gaussian wavelet.

Output Arguments**psi — Derivative of complex-valued Gaussian wavelet**

complex-valued vector

Derivative of the complex-valued Gaussian wavelet, returned as a complex-valued 1-by- N vector.

x — Sample points

real-valued vector

Sample points where the derivative of the complex-valued Gaussian wavelet is evaluated, returned as a real-valued 1-by- N vector. The sample points are evenly distributed between `lb` and `ub`.

waveinfo | wavemngr

Introduced before R2006a

chgwdeccfs

Change multisignal 1-D decomposition coefficients

Syntax

```
DEC = chgwdeccfs(DEC, 'ca', COEFS)
DEC = chgwdeccfs(DEC, 'cd', COEFS, LEV)
DEC = chgwdeccfs(DEC, 'all', CA, CD)
DEC = chgwdeccfs(DEC, 'all', V)
DEC = chgwdeccfs(..., IDXSIG)
```

Description

`DEC = chgwdeccfs(DEC, 'ca', COEFS)` replaces the approximation coefficients at level `DEC.level` with those contained in the matrix `COEFS`. If `COEFS` is a single value V , all coefficients are replaced by V .

`DEC = chgwdeccfs(DEC, 'cd', COEFS, LEV)` replaces the detail coefficients at level `LEV` with those contained in the matrix `COEFS`. If `COEFS` is a single value V , then `LEV` can be a vector of levels and all the coefficients that belong to these levels are replaced by V . `LEV` must be such that $1 \leq LEV \leq DEC.level$

`DEC = chgwdeccfs(DEC, 'all', CA, CD)` replaces all the approximation and detail coefficients. `CA` must be a matrix and `CD` must be a cell array of length `DEC.level`.

If `COEFS` (or `CA` or `CD`) is a single number, then it replaces all the related coefficients. Otherwise, `COEFS` (or `CA`, or `CD`) must be a matrix of appropriate size.

For a real value V , `DEC = chgwdeccfs(DEC, 'all', V)` replaces all the coefficients by V .

`DEC = chgwdeccfs(..., IDXSIG)` replaces the coefficients for the signals whose indices are given by the vector `IDXSIG`. If the initial data are stored row-wise or column-wise in a matrix `X`, then `IDXSIG` contains the row or column indices, respectively, of the data.

Examples

Change Decomposition Coefficients

Load the 23 channel EEG data `Espiga3` [1]. The channels are arranged column-wise. The data is sampled at 200 Hz.

```
load Espiga3
```

Perform a decomposition at level 2 using the `db2` wavelet.

```
dec = mdwtdec('c', Espiga3, 2, 'db2')
```

```
dec = struct with fields:
    dirDec: 'c'
    level: 2
```

```
wname: 'db2'  
dwtFilters: [1x1 struct]  
dwtEXTM: 'sym'  
dwtShift: 0  
dataSize: [995 23]  
ca: [251x23 double]  
cd: {[499x23 double] [251x23 double]}
```

Change the coefficients of details at level 1. Replace all the values by 0.

```
decBis = chgwdccfs(dec, 'cd', 0, 1);
```

Change the coefficients of details at level 1 and level 2 for signals 11 to 15. Replace all values by 0.

```
decTer = chgwdccfs(dec, 'cd', 0, 1:2, 11:15);
```

Compare the original and new coefficients for details at level 1 for signals 11 to 15.

```
plot(dec.cd{1}(:, 11:15), 'b')  
hold on  
plot(decTer.cd{1}(:, 11:15), 'r')  
legend('Original', 'Changed')
```

cmddenoise

Interval-dependent denoising

Syntax

```
sigden = cmddenoise(sig,wname,level)
sigden = cmddenoise(sig,wname,level,sorh)
sigden = cmddenoise(sig,wname,level,sorh,nb_inter)
sigden = cmddenoise(sig,wname,level,sorh,nb_inter,thrParamsIn)
```

```
[sigden,coefs] = cmddenoise( ___ )
[sigden,coefs,thrParamsOut] = cmddenoise( ___ )
```

```
[sigden,coefs,thrParamsOut,int_DepThr_Cell] = cmddenoise(sig,wname,level,
sorh,nb_inter)
[sigden,coefs,thrParamsOut,int_DepThr_Cell,BestNbofInt] = cmddenoise(sig,
wname,level,sorh,nb_inter)
```

Description

`sigden = cmddenoise(sig,wname,level)` returns the denoised signal, `sigden`, obtained from an interval-dependent denoising of the signal, `sig`, using the orthogonal or biorthogonal wavelet and scaling filters, `wname`. `cmddenoise` thresholds the wavelet (detail) coefficients down to `level`, `level`, and reconstructs a signal approximation using the modified detail coefficients. `cmddenoise` partitions the signal into intervals based on variance change points in the first level detail coefficients and thresholds each interval separately. The location and number of variance change points are automatically selected using a penalized contrast function [2]. The minimum delay between change points is 10 samples. Thresholds are obtained using a minimax threshold rule and soft thresholding is used to modify the wavelet coefficients [1].

`sigden = cmddenoise(sig,wname,level,sorh)` returns the denoised signal, `sigden`, using the thresholding method, `sorh`, to modify the wavelet coefficients. Valid choices for `sorh` are 's' for soft thresholding or 'h' for hard thresholding.

`sigden = cmddenoise(sig,wname,level,sorh,nb_inter)` returns the denoised signal, `sigden`, with the number of denoising intervals as a positive integer between 1 and 6: $1 \leq \text{nb_inter} \leq 6$. For $\text{nb_inter} \geq 2$, `cmddenoise` estimates the location of the change points with a contrast function [2].

`sigden = cmddenoise(sig,wname,level,sorh,nb_inter,thrParamsIn)` returns the denoised signal, `sigden`, with the denoising intervals and corresponding thresholds specified as a cell array of matrices with length equal to `level`. Each element of the cell array contains the interval and threshold information for the corresponding level of the wavelet transform. The elements of `thrParamsIn` are N-by-3 matrices with N equal to the number of intervals. The 1st and 2nd columns contain the beginning and ending indices of the intervals and the 3rd column contains the corresponding threshold value. If you specify `thrParamsIn`, `cmddenoise` ignores the value of `nb_inter`.

`[sigden,coefs] = cmddenoise(___)` returns the approximation (scaling) and detail (wavelet) coefficients, `coefs`. The organization of `coefs` is identical to the structure returned by `wavedec`. This syntax can include any of the input arguments used in previous syntaxes.

`[sigden,coefs,thrParamsOut] = cmddenoise(___)` returns a cell array, `thrParamsOut`, with length equal to `level`. Each element of `thrParamsOut` is an N-by-3 matrix. The row dimension of the matrix elements is the number of intervals and is determined by the value of the input arguments. Each row of the matrix contains the beginning and end points (indices) of the thresholded interval and the corresponding threshold value.

`[sigden,coefs,thrParamsOut,int_DepThr_Cell] = cmddenoise(sig,wname,level,sorh,nb_inter)` returns a cell array, `int_DepThr_Cell`, with length equal to 6. `int_DepThr_Cell` contains interval and threshold information assuming the number of change points ranges from 0 to 5. The N-th element of `int_DepThr_Cell` is a N-by-3 matrix containing the interval information assuming N-1 change points. Each row of the matrix contains the beginning and end points (indices) of the thresholded interval and the corresponding threshold value. Attempting to output `int_DepThr_Cell` if you use the input argument, `thrParamsIn`, results in an error.

`[sigden,coefs,thrParamsOut,int_DepThr_Cell,BestNbofInt] = cmddenoise(sig,wname,level,sorh,nb_inter)` returns the optimal number of signal intervals based on the estimated variance change points in the level-1 detail coefficients. To estimate the number of change points, `cmddenoise` assumes the total number is less than or equal to 6 and uses a penalized contrast [2]. Attempting to output `BestNbofInt` if you use the input argument, `thrParamsIn`, results in an error.

Examples

Denoising Blocks Signal with Haar Wavelet

Load the noisy blocks signal, `nblocr1.mat`. The signal consists of a piecewise constant signal in additive white Gaussian noise. The variance of the additive noise differs in three disjoint intervals.

```
load nblocr1;
```

Apply interval-dependent denoising down to level 4 using the Haar wavelet. `cmddenoise` automatically determines the optimal number and locations of the variance change points. Plot the denoised and original signal for comparison.

```
sigden = cmddenoise(nblocr1,'db1',4);
plot(nblocr1);
hold on;
plot(sigden,'r','linewidth',2);
axis tight;
```

Denoising Blocks Signal with Hard Thresholding

Load the noisy blocks signal, `nblocr1.mat`. The signal consists of a piecewise constant signal in additive white Gaussian noise. The variance of the additive noise differs in three disjoint intervals.

```
load nblocr1;
```

Apply interval-dependent denoising down to level 4 using the Haar wavelet and a hard thresholding rule. `cmddenoise` automatically determines the optimal number and locations of the intervals. Plot the original and denoised signals.

```
sorh = 'h';  
sigden = cmddenoise(nblocr1,'db1',4,sorh);  
plot(nblocr1);  
hold on;  
plot(sigden,'r','linewidth',2);  
axis tight;  
legend('Original Signal','Denoised Signal','Location','NorthWest');
```

Specify the Number of Intervals

Create a signal sampled at 1 kHz. The signal consists of a series of bumps of various widths.

```
t = [0.1 0.13 0.15 0.23 0.25 0.40 0.44 0.65 0.76 0.78 0.81];
h = [4 -5 3 -4 5 -4.2 2.1 4.3 -3.1 5.1 -4.2];
h = abs(h);
len = 1000;
w = 0.01*[0.5 0.5 0.6 1 1 3 1 1 0.5 0.8 0.5];
tt = linspace(0,1,len);
x = zeros(1,len);
for j=1:11
    x = x + ( h(j) ./ (1+ ((tt-t(j))/w(j)).^4));
end
```

Add white Gaussian noise with different variances to two disjoint segments of the signal. Add zero-mean white Gaussian noise with variance equal to 2 to the signal segment from 0 to 0.3 seconds. Add zero-mean white Gaussian noise with unit variance to the signal segment from 0.3 seconds to 1 second. Set the random number generator to the default settings for reproducible results.

```
rng default;
nv1 = sqrt(2).*randn(size(tt)).*(tt<=0.3);
nv2 = randn(size(tt)).*(tt>0.3);
xx = x+nv1+nv2;
sigden = cmddenoise(xx,'sym5',5,'s',2);
```

Apply interval-dependent denoising using the Daubechies' least-asymmetric wavelet with 5 vanishing moments down to level 3. Set the number of intervals to 2. Plot the noisy signal, original signal, and denoised signal for comparison.

```
sigden = cmddenoise(xx,'sym5',3,'s',2);
subplot(211)
plot(tt,xx); title('Noisy Signal');
subplot(212)
plot(tt,x,'k-.','linewidth',2);
hold on;
plot(tt,sigden,'r','linewidth',2);
legend('Original Signal','Denoised Signal','Location','SouthEast');
```

Specify Intervals and Thresholds

Load the example signal `nbumpr1.mat`. The variance of the additive noise differs in three disjoint intervals.

```
load nbumpr1.mat;
```

Use a level-5 multiresolution analysis. Create a cell array of length 5 consisting of 3-by-3 matrices. The first two elements of each row contain the beginning and ending indices of the interval and the last element of each row is the corresponding threshold.

```

wname = 'sym4';
level = 5;
sorh = 's';
thrParamsIn = {...
    [...
    1    207    1.0482; ...
    207  613    2.5110; ...
    613 1024    1.0031; ...
    ]; ...
    [...
    1    207    1.04824; ...
    207  613    3.8718; ...
    613 1024    1.04824; ...
    ]; ...
    [...
    1    207    1.04824; ...
    207  613    1.99710; ...
    613 1024    1.65613; ...
    ]; ...
    [...
    1    207    1.04824; ...
    207  613    2.09117; ...
    613 1024    1.04824; ...
    ]; ...
    [...
    1    207    1.04824; ...
    207  613    1.78620; ...
    613 102    1.04824; ...
    ]; ...
    };

```

Denoise the signal using the threshold settings and the Daubechies' least-asymmetric wavelet with 4 vanishing moments. Use a soft thresholding rule. Plot the noisy and denoised signals for comparison.

```

wname = 'sym4';
level = 5;
sorh = 's'; sigden = cmdddenoise(nbump1,wname,level,sorh,...
    NaN,thrParamsIn);
plot(nbump1); hold on;
plot(sigden,'r','linewidth',2); axis tight;
legend('Noisy Signal','Denoised Signal','Location','NorthEast');

```

Return Denoised Wavelet Coefficients

Load the example signal `nblocr1.mat`. Use the Haar wavelet and decompose the signal down to level 2. Obtain the discrete wavelet transform and denoise the signal. Return the wavelet coefficients of the noisy and denoised signals.

```
load nblocr1.mat;
[sigden,coefs] = cmdenoise(nblocr1,'db1',2);
[C,L] = wavedec(nblocr1,2,'db1');
```

Plot reconstructions based on the level-2 approximation and level-2 and level-1 detail coefficients for the noisy signal.

```
app = wrcoef('a',C,L,'db1',2);
subplot(3,1,1);
plot(app); title('Approximation Coefficients');
for nn = 1:2
    det = wrcoef('d',C,L,'db1',nn);
    subplot(3,1,nn+1)
    plot(det); title(['Noisy Wavelet Coefficients - Level '...
        num2str(nn)]);
end
```

Plot reconstructions based on the approximation and detail coefficients for the denoised signal at the same levels.

```
figure;
app = wrcoef('a',coefs,L,'db1',2);
subplot(3,1,1);
plot(app); title('Approximation Coefficients');
for nn = 1:2
    det = wrcoef('d',coefs,L,'db1',nn);
    subplot(3,1,nn+1)
    plot(det);
    title(['Thresholded Wavelet Coefficients-Level '...
          num2str(nn)]);
end
```

The approximation coefficients are identical in the noisy and denoised signal, but most of the detail coefficients in the denoised signal are close to zero.

Output Intervals and Thresholds

Create a signal sampled at 1 kHz. The signal consists of a series of bumps of various widths.

```
t = [0.1 0.13 0.15 0.23 0.25 0.40 0.44 0.65 0.76 0.78 0.81];
h = [4 -5 3 -4 5 -4.2 2.1 4.3 -3.1 5.1 -4.2];
h = abs(h);
len = 1000;
w = 0.01*[0.5 0.5 0.6 1 1 3 1 1 0.5 0.8 0.5];
tt = linspace(0,1,len); x = zeros(1,len);
for j=1:11
    x = x + ( h(j) ./ (1+ ((tt-t(j))/w(j)).^4));
end
plot(tt,x);
title('Original Signal');
hold on;
```

Add white Gaussian noise with different variances to two disjoint segments of the signal. Add zero-mean white Gaussian noise with variance equal to 2 to the signal segment from 0 to 0.3 seconds. Add zero-mean white Gaussian noise with unit variance to the signal segment from 0.3 seconds to 1 second. Set the random number generator to the default settings for reproducible results.

```
rng default;  
nv1 = sqrt(2).*randn(size(tt)).*(tt<=0.3);  
nv2 = randn(size(tt)).*(tt>0.3);  
xx = x+nv1+nv2;  
plot(tt,xx);  
title('Noisy Signal');
```

Apply interval-dependent denoising using the Daubechies' least- asymmetric wavelet with 4 vanishing moments down to level 5. Automatically choose the number of intervals and output the result.

```
[sigden,coefs,thrParamsOut] = cmddenoise(xx,'sym4',5);
thrParamsOut{1}
```

```
ans = 2×3
103 ×
```

```
0.0010    0.2930    0.0036
0.2930    1.0000    0.0028
```

`cmdnoise` identifies one variance change point in the 1st level detail coefficients defining two intervals. The first interval contains samples 1 to 293. The second interval contains samples 293 to 1000. This is close to the true variance change point, which occurs at sample 299.

Partition Signal into Increasing Numbers of Intervals with Thresholds

Load the example signal, `nbump.r1.mat`. Partition the signal into 1 to 6 intervals assuming 0 to 5 change points. Compute the thresholds for each interval. Using the Daubechies' least-asymmetric wavelet with 4 vanishing moments return the intervals and corresponding thresholds. Display the results.

```

load nbump1.mat;
[sigden,~,~,int_DepThr_Cell] = cmddenoise(nbump1,'sym4',1);
format bank;
disp('          Begin          End          Threshold ');
          Begin          End          Threshold
cellfun(@disp,int_DepThr_Cell,'UniformOutput',false);
          1.00          1024.00          1.36
          1.00          613.00          1.73
        613.00          1024.00          1.00
          1.00          207.00          1.05
        207.00          613.00          2.51
        613.00          1024.00          1.00
          1.00          207.00          1.05
        207.00          597.00          2.52
        597.00          627.00          1.69
        627.00          1024.00          0.97
          1.00          207.00          1.05
        207.00          613.00          2.51
        613.00          695.00          1.20
        695.00          725.00          0.59
        725.00          1024.00          1.05
          1.00          207.00          1.05
        207.00          597.00          2.52
        597.00          627.00          1.69
        627.00          695.00          1.19
        695.00          725.00          0.59
        725.00          1024.00          1.05

```

Detect Number of Change Points

Load the example signal, `nbump1.mat`. The signal has two variance change points, which results in three intervals. Use `cmddenoise` to detect the number of change points.

```

load nbump1.mat;
[sigden,~,thrParamsOut,~,bestNbofInt] = ...
    cmddenoise(nbump1,'sym4',1);
fprintf('Found %d change points.\n',bestNbofInt-1);

```

Found 2 change points.

Input Arguments

sig — Signal for interval-dependent denoising

1-D row or column vector

Input signal, specified as a 1-D row or column vector. `sig` is the real-valued input signal for interval-dependent denoising. The elements of `sig` are assumed to be equally spaced in time or space. If `sig`

contains unequally-sampled data, `cmddenoise` is not appropriate. Use a lifting transform instead. See `lwt` for details.

Data Types: `double`

wname — Wavelet name

character vector | string scalar

Wavelet name, specified as a character vector or string scalar. `wname` is any valid orthogonal or biorthogonal wavelet. You can use the command: `wtype = wavemngr('fields',wname,'type','file');` to determine if the wavelet name is valid to use with `cmddenoise`. Valid wavelet names return a 1 or 2 for `wtype`.

Example: `'bior2.2', 'db4', 'sym4'`

Data Types: `char`

level — Level of the decimated wavelet transform (multiresolution analysis)

positive integer

Wavelet transform (multiresolution analysis) level, specified as a positive integer. `level` gives the level of the multiresolution decomposition of the input signal using the decimated 1-D discrete wavelet transform, `wavedec`.

Data Types: `double`

sorh — Threshold rule

's' (default) | 'h'

Thresholding rule, specified as a character array. `sorh` is the threshold rule used in the modification of the detail coefficients. Valid choices for `sorh` are 's' (default) and 'h' for soft and hard thresholding.

nb_inter — Number of intervals

positive integer in the set {1,2,3,4,5,6} | NaN

Number of intervals, specified as a positive integer less than 7. `cmddenoise` divides the input signal into `nb_inter` intervals. `cmddenoise` determines the location of the `nb_inter` change points using a contrast function [2]. If you enter NaN for `nb_inter`, `cmddenoise` ignores the input. If you use the input argument `thrParamsIn`, `cmddenoise` disregards any value you enter for `nb_inter`.

Data Types: `double`

thrParamsIn — Intervals and thresholds by level

cell array of matrices

Intervals and thresholds by level, specified as a cell array of matrices equal in length to `level`. Each element of `thrParamsIn` contains the interval and threshold information for the corresponding level of the multiresolution analysis. The elements of `thrParamsIn` are N-by-3 matrices with N equal to the number of intervals. The 1st and 2nd columns contain the beginning and ending indices of the intervals and the 3rd column contains the corresponding threshold value. If you specify `thrParamsIn`, you cannot specify the output arguments `int_DepThr_Cell` or `BestNbofInt`.

Data Types: `cell`

Output Arguments

sigden — Denoised signal

1-D row or column vector

`sigden` is the denoised version of the input `sig`. `sigden` is a 1-D row vector equal in length to `sig`.

coefs — Approximation coefficients and thresholded wavelet coefficients

1-D row vector of approximation coefficients and thresholded wavelet coefficients

`coefs` is a row vector of approximation (scaling) and thresholded detail (wavelet) coefficients. The ordering of the approximation and detail coefficients by level in `coefs` is the same as the output of `wavedec`. `cmddenoise` does not apply thresholding to the approximation coefficients.

Data Types: `double`

thrParamsOut — Intervals and thresholds by level

cell array of matrices

`thrParamsOut` is a cell array of matrices equal in length to `level`. Each element of the cell array contains the interval and threshold information for the corresponding level of the multiresolution analysis. The elements of `thrParamsOut` are N-by-3 matrices with N equal to the number of intervals. N is determined by the value of the input arguments. The 1st and 2nd columns contain the beginning and ending indices of the intervals and the 3rd column contains the corresponding threshold value.

Data Types: `cell`

int_DepThr_Cell — Intervals and thresholds assuming 0 to 5 change points

cell array of matrices

`int_DepThr_Cell` contains interval and threshold information assuming the number of change points ranges from 0 to 5. The N-th element of `int_DepThr_Cell` is a N-by-3 matrix containing the interval information assuming N-1 change points. Each row of the matrix contains the beginning and ending indices of the thresholded interval and the corresponding threshold value. Attempting to output `int_DepThr_Cell` if you input the number of intervals and thresholds, `thrParamsIn`, results in an error. `int_DepThr_Cell{BestNbofInt}` or `int_DepThr_Cell{nb_inter}` is equal to the matrix elements of `thrParamsOut`.

Data Types: `cell`

BestNbofInt — Optimal number of intervals

positive integer ≤ 6

`BestNbofInt` is the optimal number of intervals based on estimated change points in the variance of the level-1 detail coefficients. The number and location of the change points are estimated using a penalized contrast method [2]. Attempting to output `BestNbofInt` if you input the number of intervals and thresholds, `thrParamsIn`, results in an error.

Wavelet Signal Denoiser

Introduced in R2010a

cmorwavf

Complex Morlet wavelet

Syntax

```
[PSI,X] = cmorwavf(LB,UB,N)
[PSI,X] = cmorwavf(LB,UB,N,FB,FC)
```

Description

`[PSI,X] = cmorwavf(LB,UB,N)` returns the complex Morlet wavelet, `PSI`, with time-decay parameter, `FB`, and center frequency, `FC`, both equal to 1. The general expression for the complex Morlet wavelet is

$$\text{PSI}(X) = ((\pi \cdot \text{FB})^{-0.5}) \cdot \exp(2 \cdot \pi \cdot i \cdot \text{FC} \cdot X) \cdot \exp(-(X^2)/\text{FB})$$

`X` is evaluated on an N -point regular grid in the interval `[LB,UB]`.

`[PSI,X] = cmorwavf(LB,UB,N,FB,FC)` returns values of the complex Morlet wavelet defined by a positive time-decay parameter, `FB`, and positive center frequency, `FC`.

`FB` controls the decay in the time domain and the corresponding energy spread (bandwidth) in the frequency domain. `FB` is the inverse of the variance in the frequency domain. Increasing `FB` makes the wavelet energy more concentrated around the center frequency and results in slower decay of the wavelet in the time domain. Decreasing `FB` results in faster decay of the wavelet in the time domain and less energy spread in the frequency domain. The value of `FB` does not affect the center frequency. When converting from scale to frequency, only the center frequency affects the frequency values. The energy spread or bandwidth parameter affects how localized the wavelet is in the frequency domain.

Examples

Complex Morlet Wavelet

Construct a complex-valued Morlet wavelet with a bandwidth parameter of 1.5 and a center frequency of 1. Set the effective support to `[-8,8]` and the length of the wavelet to 1000.

```
N = 1000;
Lb = -8;
Ub = 8;
fb = 1.5;
fc = 1;
[psi,x] = cmorwavf(Lb,Ub,N,fb,fc);
```

Plot the real and imaginary parts of the wavelet.

```
subplot(2,1,1)
plot(x,real(psi)); title('Real Part');
subplot(2,1,2)
plot(x,imag(psi)); title('Imaginary Part');
```

Effect of Bandwidth Parameter on Morlet Wavelet Shape

This example shows how the complex Morlet wavelet shape in the frequency domain is affected by the value of the bandwidth parameter (Fb). Both wavelets have a center frequency of 1. One wavelet has an Fb value of 0.5 and the other wavelet has a value of 8.

```
f = -5:.01:5;
Fc = 1;
Fb1 = 0.5;
Fb2 = 8;
psihat1 = exp(-pi^2*Fb1*(f-Fc).^2);
psihat2 = exp(-pi^2*Fb2*(f-Fc).^2);
plot(f,psihat1)
hold on;
plot(f,psihat2,'r')
legend('Fb = 0.5','Fb = 8')
```

The F_b bandwidth parameter for the complex Morlet wavelet is the inverse of the variance in frequency. Therefore, increasing F_b results in a narrower concentration of energy around the center frequency.

coefficientSize

Size of image scattering coefficients

Syntax

```
sz = coefficientSize(sf)
```

Description

`sz = coefficientSize(sf)` returns the scattering coefficient sizes for the wavelet image scattering framework, `sf`. The output `sz` is a two-element row vector that gives the scattering coefficient output size in the row and column dimensions. For an RGB image, the actual output size is `[sz(1) sz(2) 3]`.

Examples

Scattering Coefficient Sizes for Image Scattering Framework

This example shows how to determine the scattering coefficient sizes of an image scattering framework.

Create a wavelet image scattering framework with an image size of 128-by-64. Obtain the coefficient sizes of the framework.

```
sf = waveletScattering2('ImageSize',[128 64]);  
sz = coefficientSize(sf)
```

```
sz = 1×2  
    16     8
```

Create a second wavelet image scattering framework with an image size of 128-by-64 and an oversampling factor equal to 1. Obtain the coefficient sizes of the framework. Since the oversampling factor is equal to 1, the scattering transform of the second framework returns 2-by-2-by- P as many coefficients for each scattering path with respect to the critically sampled number.

```
sf2 = waveletScattering2('ImageSize',[128 64],'OversamplingFactor',1);  
sz = coefficientSize(sf2)
```

```
sz = 1×2  
    32    16
```

Input Arguments

sf — Scattering decomposition framework
waveletScattering2 object

Scattering decomposition framework, specified as a `waveletScattering2` object.

Introduced in R2019a

coifwavf

Coiflet wavelet filter

Syntax

```
f = coifwavf(wname)
```

Description

`f = coifwavf(wname)` returns the scaling filter `f` associated with the Coiflet wavelet specified by `wname`. `f` is a real-valued vector.

Examples

Coiflet Wavelet Filter

Set the Coiflet wavelet name.

```
wname = 'coif2';
```

Compute and plot the scaling filter coefficients associated with the Coiflet.

```
f = coifwavf(wname);  
stem(f)  
grid on  
title('Coiflet Scaling Coefficients')
```

Input Arguments

wname — Name of Coiflet

character vector | string scalar

Name of Coiflet, specified as 'coifN' where N is an integer between 1 and 5.

Example: 'coif3'

concatenate

Concatenate two or more labeled signal sets

Syntax

```
lssnew = concatenate(lss1,...,lssN)
```

Description

`lssnew = concatenate(lss1,...,lssN)` concatenates N labeled signal set objects, `lss1,...,lssN`, and returns a labeled signal set `lssnew` containing all the members and label values of the input sets.

Examples

Concatenate Labeled Signal Sets

Load a labeled signal set containing recordings of whale songs.

```
load whales
lss

lss =
  labeledSignalSet with properties:
        Source: {2x1 cell}
      NumMembers: 2
  TimeInformation: "sampleRate"
      SampleRate: 4000
         Labels: [2x3 table]
  Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

Create a new signal set with the same data source, time information, and labels as `lss`.

```
newlss = copy(lss)

newlss =
  labeledSignalSet with properties:
        Source: {2x1 cell}
      NumMembers: 2
  TimeInformation: "sampleRate"
      SampleRate: 4000
         Labels: [2x3 table]
  Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.

Use `setLabelValue` to add data to the set.

Concatenate the two signal sets.

```
lssconcat = concatenate(lss,newlss)
```

```
lssconcat =
  labeledSignalSet with properties:
        Source: {4x1 cell}
    NumMembers: 4
  TimeInformation: "sampleRate"
    SampleRate: 4000
        Labels: [4x3 table]
    Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

Input Arguments

`lss1, ..., lssN` — Input labeled signal sets

`labeledSignalSet` objects

Input labeled signal sets, specified as `labeledSignalSet` objects. All input sets must have the same time information settings, label definitions, and data source type.

Output Arguments

`lssnew` — Concatenated labeled signal set

`labeledSignalSet` object

Concatenated labeled signal set, returned as a `labeledSignalSet` object. The set `lssnew` contains a signal source, label definitions, and label values that are independent of those in the input labeled signal sets. Changing any of the input labeled signal sets does not affect the concatenated labeled signal set. Changing the concatenated labeled signal set does not affect the input label signal sets.

`labeledSignalSet` | `signalLabelDefinition`

Introduced in R2018b

conofinf

Cone of influence

Syntax

```
cone = conofinf(wname,scales,LenSig,SigVal)
[cone,PL,PR] = conofinf(wname,scales,LenSig,SigVal)
[cone,PL,PR,PLmin,PRmax] = conofinf(wname,scales,LenSig,SigVal)
[PLmin,PRmax] = conofinf(wname,scales,LenSig)
[...] = conofinf(...,'plot')
```

Description

`cone = conofinf(wname,scales,LenSig,SigVal)` returns the cone of influence (COI) for the wavelet `wname` at the scales in `scales` and positions in `SigVal`. `LenSig` is the length of the input signal. If `SigVal` is a scalar, `cone` is a matrix with row dimension `length(scales)` and column dimension `LenSig`. If `SigVal` is a vector, `cone` is cell array of matrices.

`[cone,PL,PR] = conofinf(wname,scales,LenSig,SigVal)` returns the left and right boundaries of the cone of influence at scale 1 for the points in `SigVal`. `PL` and `PR` are `length(SigVal)`-by-2 matrices. The left boundaries are $(1-PL(:,2))./PL(:,1)$ and the right boundaries are $(1-PR(:,2))./PR(:,1)$.

`[cone,PL,PR,PLmin,PRmax] = conofinf(wname,scales,LenSig,SigVal)` returns the equations of the lines that define the minimal left and maximal right boundaries of the cone of influence. `PLmin` and `PRmax` are 1-by-2 row vectors where `PLmin(1)` and `PRmax(1)` are the slopes of the lines. `PLmin(2)` and `PRmax(2)` are the points where the lines intercept the scale axis.

`[PLmin,PRmax] = conofinf(wname,scales,LenSig)` returns the slope and intercept terms for the first-degree polynomials defining the minimal left and maximal right vertices of the cone of influence.

`[...] = conofinf(...,'plot')` plots the cone of influence.

Input Arguments

wname

`wname` is a character vector or string scalar corresponding to a valid wavelet. To verify that `wname` is a valid wavelet, `wavemngr('fields',wname)` must return a struct array with a `type` field of 1 or 2, or a nonempty bound field.

scales

`scales` is a vector of scales over which to compute the cone of influence. Larger scales correspond to stretched versions of the wavelet and larger boundary values for the cone of influence.

LenSig

`LenSig` is the signal length and must exceed the maximum of `SigVal`.

SigVal

SigVal is a vector of signal values at which to compute the cone of influence. The largest value of **SigVal** must be less than the signal length, **LenSig**. If **SigVal** is empty, **conofinf** returns the slope and intercept terms for the minimal left and maximal right vertices of the cone of influence.

Output Arguments

cone

cone is the cone of influence. If **SigVal** is a scalar, **cone** is a matrix. The row dimension is equal to the number of **scales** and column dimension equal to the signal length, **LenSig**. If **SigVal** is a vector, **cone** is a cell array of matrices. The elements of each row of the matrix are equal to 1 in the interval around **SigVal** corresponding to the cone of influence.

PL

PL is the minimum value of the cone of influence on the position (time) axis.

PR

PR is the maximum value of the cone of influence on the position (time) axis.

PLmin

PLmin is a 1-by-2 row vector containing the slope and scale axis intercept of the line defining the minimal left vertex of the cone of influence. **PLmin(1)** is the slope and **PLmin(2)** is the point where the line intercepts the scale axis.

PRmax

PRmax is a 1-by-2 row vector containing the slope and scale axis intercept of the line defining the maximal right vertex of the cone of influence. **PRmax(1)** is the slope and **PRmax(2)** is the point where the line intercepts the scale axis.

Examples

Cone of Influence for Mexican Hat or Ricker Wavelet

Load the data.

```
load cuspamax
signal = cuspamax;
```

Set up the wavelet.

```
wname = 'mexh';
scales = 1:64;
lenSIG = length(signal);
x = 500;
```

Plot the wavelet.

```
figure;  
cwt(signal,scales,wname,'plot');
```

Plot the cone of influence.

```
hold on  
[cone,PL,PR,Pmin,Pmax] = conofinf(wname,scales,lenSIG,x,'plot');  
set(gca,'Xlim',[1 lenSIG])
```

Cone of Influence Minimal and Maximal Vertices

Return the left minimal and right maximal vertices for the cone of influence (Morlet wavelet).

```
[PLmin,PRmax] = conofinf('morl',1:32,1024,[],'plot');
```

PLmin

PLmin = 1x2

-0.1245 32.0000

PRmax

PRmax = 1x2

0.1250 -96.0000

More About

Cone of Influence

Let $\psi(t)$ be an admissible wavelet. Assume that the effective support of $\psi(t)$ is $[-B,B]$. Letting u denote the translation parameter and s denote the scale parameter, the dilated and translated wavelet is:

$$\psi_{u,s}(t) = \frac{1}{\sqrt{s}} \psi\left(\frac{t-u}{s}\right)$$

and has effective support $[u-sB,u+sB]$. The cone of influence (COI) is the set of all t included in the effective support of the wavelet at a given position and scale. This set is equivalent to:

$$|t - u| \leq sB$$

At each scale, the COI determines the set of wavelet coefficients influenced by the value of the signal at a specified position.

Topics

“Continuous and Discrete Wavelet Transforms”

Introduced in R2010b

cqt

Constant-Q nonstationary Gabor transform

Syntax

```
cfs = cqt(x)
[cfs,f] = cqt(x)
[cfs,f,g,fshifts] = cqt(x)
[cfs,f,g,fshifts,fintervals] = cqt(x)
[cfs,f,g,fshifts,fintervals,bw] = cqt(x)
[___] = cqt( ___,Name,Value)
cqt( ___ )
```

Description

`cfs = cqt(x)` returns the constant-Q transform (CQT), `cfs`, of the input signal `x`. The input signal must have at least four samples.

- If `x` is a vector, then `cqt` returns a matrix corresponding to the CQT.
- If `x` is a matrix, then `cqt` obtains the CQT for each column (independent channel) of `x`. The function returns a multidimensional array corresponding to the maximally redundant version of the CQT.

`[cfs,f] = cqt(x)` returns the approximate bandpass center frequencies, `f`, corresponding to the rows of `cfs`. The frequencies are ordered from 0 to 1 and are in cycles/sample.

`[cfs,f,g,fshifts] = cqt(x)` returns the Gabor frames, `g`, used in the analysis of `x` and the frequency shifts, `fshifts`, in discrete Fourier transform (DFT) bins between the passbands in the rows of `cfs`.

`cfs`, `g`, and `fshifts` are required inputs for the inversion of the CQT with `icqt`.

`[cfs,f,g,fshifts,fintervals] = cqt(x)` returns the frequency intervals, `fintervals`, corresponding the rows of `cfs`. The k th element of `fshifts` is the frequency shift in DFT bins between the $((k-1) \bmod N)$ and $(k \bmod N)$ element of `fintervals` with $k = 0, 1, 2, \dots, N-1$ where N is the number of frequency shifts. Because MATLAB® indexes from 1, `fshifts(1)` contains the frequency shift between `fintervals{end}` and `fintervals{1}`, `fshifts(2)` contains the frequency shift between `fintervals{1}` and `fintervals{2}`, and so on.

`[cfs,f,g,fshifts,fintervals,bw] = cqt(x)` returns the bandwidth, `bw`, in DFT bins of the frequency intervals, `fintervals`.

`[___] = cqt(___,Name,Value)` returns the CQT with additional options specified by one or more `Name,Value` pair arguments, using any of the preceding syntaxes.

`cqt(___)` with no output arguments plots the CQT in the current figure. Plotting is supported for vector inputs only. If the input signal is real and `Fs` is the sampling frequency, the CQT is plotted over the range $[0, Fs/2]$. If the signal is complex, the CQT is plotted over the range $[0, Fs)$.

Note In order for visualize a sparse CQT, coefficients have to be interpolated. When interpolation occurs, the plot can have significant smearing and be difficult to interpret. If you want to plot the CQT, we recommend using the default `TransformType` value `'full'`.

Examples

Constant-Q Transform Using Default Values

Load a signal and obtain the constant-Q transform.

```
load noisdopp
cfs = cqt(noisdopp);
```

Center Frequencies of the Constant-Q Transform

Load a real-valued signal and obtain the constant-Q transform. Return the approximate bandpass center frequencies.

```
load handel
[cfs,f] = cqt(y);
```

Plot on a logarithmic scale the bandpass center frequencies through the Nyquist frequency.

```
lfreq = length(f);
nyquistBin = floor(lfreq/2)+1;
plot(f(1:nyquistBin))
title('Bandpass Center Frequencies')
grid on
set(gca,'yscale','log')
```

To confirm the ratios of consecutive pairs of frequencies are constant, plot the ratios. Since `cqt` uses 12 bins per octave by default, the ratio should equal $2^{1/12}$. Since the DC and Nyquist frequencies are not members of the geometric sequence of center frequencies but are included in the frequency vector, exclude them from the plot.

```
figure
plot(f(3:nyquistBin-1)./f(2:nyquistBin-2))
grid on
title(['Ratio: ', num2str(2^(1/12))])
```

Visualize and Apply Constant-Q Transform Gabor Frames

Obtain the minimally redundant constant-Q transform of an audio signal. Use the Blackman-Harris window as the prototype function for the Gabor frames.

```
load handel
df = Fs/numel(y);
[cfs,f,g,fshifts,fintervals,bw] = cqt(y,'SamplingFrequency',Fs,'TransformType',"sparse",'Window'
```

`cfs` is a cell array, where each element in the array corresponds to a bandpass center frequency and Gabor frame. Plot the Gabor frame associated with the Nyquist frequency.

```
lf = length(f);
ind = floor(lf/2)+1;
gFrame = fftshift(g{ind});
fvec = f(ind-1):df:f(ind+1)-df;
plot(fvec,gFrame)
xlabel('Frequency (Hz)')
grid on
title(['Gabor Frame - Freq: ',num2str(f(ind)),' Hz'];['Bandwidth ',num2str(bw(ind)*Fs/numel(y))
```

In the constant-Q transform, the Gabor frames are applied to the discrete Fourier transform of the input signal, and the inverse discrete Fourier transform is performed. The k -th Gabor frame is applied to the k -th frequency interval specified in `fintervals`. Take the discrete Fourier transform of the signal and plot its magnitude spectrum. Use `fintervals` to indicate over which Fourier coefficients the Gabor frame associated with the Nyquist frequency are applied.

```

yDFT = fft(y);
lyDFT = length(yDFT);
plot(Fs*(0:lyDFT-1)/lyDFT,abs(yDFT))
grid on
fIntervalGabor = fintervals{ind};
mx = max(abs(yDFT));
hold on
plot([df*fIntervalGabor(1) df*fIntervalGabor(1)],[0 mx],'r-','LineWidth',2)
plot([df*fIntervalGabor(end) df*fIntervalGabor(end)],[0 mx],'r-','LineWidth',2)
str = sprintf('Gabor Frame Interval (Hz): [%3.2f, %3.2f]',df*fIntervalGabor(1),df*fIntervalGabor(end))
title(str)

```

Window the Fourier coefficients in the interval with the Gabor frame, and take the inverse discrete Fourier transform. Normalize the result, and compare with computed constant-Q coefficients and confirm they are equal.

```
lGframe = length(gFrame);
indx = 1:lGframe;
indx = fftshift(indx);
winDFT(indx) = yDFT(fIntervalGabor).*fftshift(gFrame(indx));
cqCoefs = ifft(winDFT);
cqCoefs = (2*lGframe/length(y))*cqCoefs;
max(abs(cqCoefs(:)-cfs{ind}(:)))

ans = 0
```

Constant-Q Transform of Audio Signal

Load an audio signal. Plot the constant-Q transform (CQT) using the maximally redundant version of the transform and using 12 bins per octave.

```
load handel
cqt(y, 'SamplingFrequency', Fs)
```

Perform the CQT of the same signal using 48 bins per octave. Set the frequency range over which the CQT has a logarithmic frequency response to be the minimum allowable frequency to 2 kHz.

```
minFreq = Fs/length(y);  
maxFreq = 2000;  
figure  
cqt(y, 'SamplingFrequency', Fs, 'BinsPerOctave', 48, 'FrequencyLimits', [minFreq maxFreq])
```

Input Arguments

x — Input signal

vector | matrix

Input signal, specified as a real or complex vector or matrix. `x` must have at least four samples.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'SamplingFrequency',20,'BinsPerOctave',15`

SamplingFrequency — Sampling frequency

positive scalar

Sampling frequency, in Hz, specified as the comma-separated pair consisting of `'SamplingFrequency'` and a positive scalar.

BinsPerOctave — Number of bins per octave

12 (default) | positive integer from 1 to 96

Number of bins per octave to use in the CQT, specified as a positive integer from 1 to 96.

TransformType — Type of constant-Q transform

'full' (default) | 'sparse'

Type of constant-Q transform to perform, specified as the comma-separated pair consisting of 'TransformType' and 'full' or 'sparse'. The sparse transform is the minimally redundant version of the constant-Q transform.

FrequencyLimits — Frequency limits

two-element real vector

Frequency limits over which the CQT has a logarithmic frequency response with the specified number of frequency bins per octave, specified as the comma-separated pair 'FrequencyLimits' and a two-element real vector.

- The first element must be greater than or equal to F_s/N , where F_s is the sampling frequency and N is the length of the signal.
- The second element must be strictly less than the Nyquist frequency.

Window — Window to use as prototype function

'hann' (default) | 'hamming' | 'blackmanharris' | 'itersine' | 'bartlett'

Window to use as the prototype function for the nonstationary Gabor frames, specified as 'hann', 'hamming', 'blackmanharris', 'itersine', or 'bartlett'. These compactly support functions are defined in frequency. For normalized frequencies, they are defined on the interval $(-1/2, 1/2)$. If you specify a sampling frequency, F_s , they are defined on the interval $(-F_s/2, F_s/2)$.

Output Arguments

cfs — Constant-Q transform

matrix | multidimensional array | cell array | structure array

Constant-Q transform, returned as a matrix, multidimensional array, cell array, or structure array.

- If 'TransformType' is specified as 'full' without 'FrequencyLimits', cfs is a matrix or multidimensional array.
 - If x is a vector, then cqt returns a matrix corresponding to the CQT.
 - If x is a matrix, then cqt obtains the CQT for each column (independent channel) of x . The function returns a multidimensional array corresponding to the maximally redundant version of the CQT.

The array, cfs, corresponds to the maximally redundant version of the CQT. Each row of the pages of cfs corresponds to passbands with normalized center frequencies (cycles/sample) logarithmically spaced between 0 and 1. A normalized frequency of 1/2 corresponds to the Nyquist frequency. The number of columns, or hops, corresponds to the largest bandwidth center frequency, which usually occurs one frequency bin below or above the Nyquist bin.

- If 'TransformType' is specified as 'full' and you specify frequency limits, cfs is returned as a structure array with the following four fields.
 - **c** — Coefficient matrix of multidimensional array for the frequencies within the specified frequency limits. This includes both the positive and "negative" frequencies.

- **DCcfs** — Coefficient vector or matrix for the passband from 0 to the lower frequency limit.
- **Nyquistcfs** — Coefficient vector or matrix for the passband from the upper frequency limit to the Nyquist.
- **NyquistBin** — DFT bin corresponding to the Nyquist frequency. This field is used when inverting the CQT.
- If 'TransformType' is specified as 'sparse', **cfs** is a cell array with the number of elements equal to the number of bandpass frequencies. Each element of the cell array, **cfs**, is a vector or matrix with the number of rows equal to the value of the bandwidth in DFT bins, **bw**.

cfs, **g**, and **fshifts** are required inputs for the inversion of the CQT with **icqt**.

f — Approximate bandpass center frequencies

real-valued vector

Approximate bandpass center frequencies corresponding to the rows of **cfs**, returned as a real-valued vector. The frequencies are ordered from 0 to 1 and are in cycles/sample. If you specified 'SamplingFrequency', then **f** is in Hertz.

g — Gabor frames

cell array of real-valued vectors

Gabor frames used in the analysis of **x**, returned as a cell array of real-valued vectors. Each vector in **g** corresponds to a row of **cfs**.

cfs, **g**, and **fshifts** are required inputs for the inversion of the CQT with **icqt**.

fshifts — Frequency shifts

real-valued vector

Frequency shifts in discrete Fourier transform bins, returned as a real-valued vector. The shifts are between the passbands in the rows of **cfs**.

cfs, **g**, and **fshifts** are required inputs for the inversion of the CQT with **icqt**.

fintervals — Frequency intervals

cell array of real-valued vectors

Frequency intervals corresponding to the rows of **cfs**, returned as a cell array. Each element in **fintervals** is a real-valued vector. The *k*th element of **fshifts** is the frequency shift in DFT bins between the $((k-1) \bmod N)$ and $(k \bmod N)$ element of **fintervals** with $k = 0, 1, 2, \dots, N-1$ where *N* is the number of frequency shifts. Because MATLAB indexes from 1, **fshifts(1)** contains the frequency shift between **fintervals{end}** and **fintervals{1}**, **fshifts(2)** contains the frequency shift between **fintervals{1}** and **fintervals{2}**, and so on.

bw — Bandwidths

real-valued vector

Bandwidths in DFT bins of the frequency intervals, **fintervals**, returned as a real-valued vector.

Algorithms

Nonstationary Gabor Frames

The theory of nonstationary Gabor (NSG) frames for frequency-adaptive analysis and efficient algorithms for analysis and synthesis using NSG frames are due to Dörfler, Holighaus, Grill, and

Velasco [1],[2]. The algorithms used in CQT and ICQT were developed by Dörfler, Holighaus, Grill, and Velasco and are described in [1],[2]. In [3], Schörkhuber, Klapuri, Holighaus, and Dörfler develop and provide algorithms for a phase-corrected CQT transform which matches the CQT coefficients that would be obtained by naïve convolution. The Large Time-Frequency Analysis Toolbox (<https://github.com/ltfat>) provides an extensive suite of algorithms for nonstationary Gabor frames [4].

Perfect Reconstruction

To achieve the perfect reconstruction property of the constant-Q analysis with nonstationary Gabor frames, `cqt` internally prepends the zero frequency (DC) and appends the Nyquist frequency to the frequency interval. The negative frequencies are mirrored versions of the positive center frequencies and bandwidths

cwt

Continuous 1-D wavelet transform

Note See `cwt` for information on the older version of the `cwt`. The older version is no longer recommended.

Syntax

```
wt = cwt(x)
wt = cwt(x,wname)

[wt,f] = cwt( ____, fs)
[wt,period] = cwt( ____, ts)
[wt,f,coi] = cwt( ____, fs)
[wt,period,coi] = cwt( ____, ts)

[ __ ] = cwt( ____, Name, Value)
[ __, coi, fb] = cwt( ____)
[ __, fb, scalingcfs] = cwt( ____)

cwt( ____)
```

Description

`wt = cwt(x)` returns the continuous wavelet transform (CWT) of `x`. The input, `x`, is a real- or complex-valued vector, or a single-variable regularly sampled timetable, and must have at least four samples. The CWT is obtained using the analytic Morse wavelet with the symmetry parameter (γ) equal to 3 and the time-bandwidth product equal to 60. `cwt` uses 10 voices per octave. The minimum and maximum scales are determined automatically based on the energy spread of the wavelet in frequency and time. If `x` is real-valued, `wt` is a 2-D matrix where each row corresponds to one scale. The column size of `wt` is equal to the length of `x`. If `x` is complex-valued, `wt` is a 3-D matrix, where the first page is the CWT for the positive scales (analytic part or counterclockwise component) and the second page is the CWT for the negative scales (anti-analytic part or clockwise component).

The `cwt` function uses L1 normalization. With L1 normalization, if you have equal amplitude oscillatory components in your data at different scales, they will have equal magnitude in the CWT. Using L1 normalization shows a more accurate representation of the signal. See “L1 Norm for CWT” on page 1-137 and “Continuous Wavelet Transform of Two Complex Exponentials” on page 1-114.

`wt = cwt(x,wname)` uses the analytic wavelet specified by `wname` to compute the CWT. Valid options for `wname` are 'morse', 'amor', and 'bump', which specify the Morse, Morlet (Gabor), and bump wavelet, respectively. If you do not specify `wname`, `wname` defaults to 'morse'.

`[wt,f] = cwt(____, fs)` specifies the sampling frequency, `fs`, in Hz as a positive scalar. `cwt` uses `fs` to determine the scale-to-frequency conversions and returns the frequencies `f` in Hz. If you do not specify a sampling frequency, `cwt` returns `f` in cycles per sample. If the input `x` is complex, the scale-to-frequency conversions apply to both pages of `wt`. If `x` is a timetable, you cannot specify `fs`. `fs` is determined from the `RowTimes` of the timetable.

`[wt,period] = cwt(____, ts)` specifies the sampling period, `ts`, as a positive duration scalar. The duration can be in years, days, hours, minutes, or seconds. `cwt` uses `ts` to compute the scale-to-period conversion and returns the time periods in `period`. The array of durations in `period` has the same format property as `ts`. If the input `x` is complex, the scale-to-period conversions apply to both pages of `wt`. If `x` is a timetable, you cannot specify `ts`. `ts` is determined from the `RowTimes` of the timetable when you set the `'PeriodLimits'` name-value pair.

`[wt,f,coi] = cwt(____, fs)` returns the cone of influence, `coi`, which shows where edge effects of the CWT become significant. The cone of influence for the CWT is in Hz. If the input `x` is complex, the cone of influence applies to both pages of `wt`.

`[wt,period,coi] = cwt(____, ts)` returns the cone of influence, `coi`, which shows where edge effects of the CWT become significant. The cone of influence for the CWT is in periods. If the input `x` is complex, the cone of influence applies to both pages of `wt`.

`[____] = cwt(____, Name, Value)` returns the CWT with additional options specified by one or more `Name, Value` pair arguments.

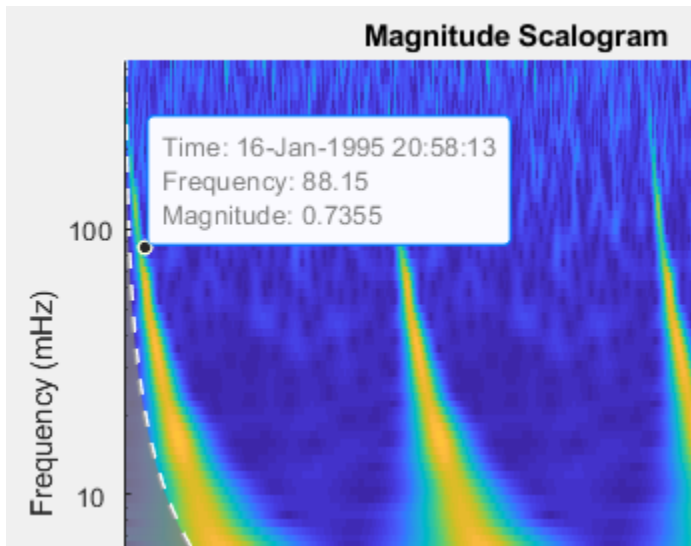

`[____, coi, fb] = cwt(____)` returns the filter bank used in the CWT. See `cwtfilterbank`.

`[____, fb, scalingcfs] = cwt(____)` returns the scaling coefficients if the analyzing wavelet is `'morse'` or `'amor'`. Scaling coefficients are not supported for the bump wavelet.

`cwt(____)` with no output arguments plots the CWT scalogram. The scalogram is the absolute value of the CWT plotted as a function of time and frequency. Frequency is plotted on a logarithmic scale. The cone of influence showing where edge effects become significant is also plotted. Gray regions outside the dashed white line delineate regions where edge effects are significant. If the input signal is complex-valued, the positive (counterclockwise) and negative (clockwise) components are plotted in separate scalograms.

If you do not specify a sampling frequency or sampling period, the frequencies are plotted in cycles per sample. If you specify a sampling frequency, the frequencies are in Hz. If you specify a sampling period, the scalogram is plotted as a function of time and periods. If the input signal is a timetable, the scalogram is plotted as a function of time and frequency in hertz and uses the `RowTimes` as the basis for the time axis.

To see the time, frequency, and magnitude of a scalogram point, enable data tips in the figure axes toolbar and click the desired point in the scalogram.

Note Before plotting, `cwt` clears (`clf`) the current figure. To plot the scalogram in a subplot, use a plotting function. See “Plot CWT Scalogram in Subplot” on page 1-129.

Examples

Continuous Wavelet Transform Using Default Values

Obtain the continuous wavelet transform of a speech sample using default values.

```
load mtlb;
w = cwt(mtlb);
```

Continuous Wavelet Transform Using Specified Wavelet

Obtain the continuous wavelet transform of a speech sample using the bump wavelet instead of the default Morse wavelet.

```
load mtlb
cwt(mtlb, 'bump', Fs)
```

Compare the result obtained from the CWT using the default Morse wavelet.

`cwt(mt1b,Fs)`

Continuous Wavelet Transform of Earthquake Data

Obtain the CWT of the Kobe earthquake data. The data are seismograph (vertical acceleration, nm/sq.sec) measurements recorded at Tasmania University, Hobart, Australia on 16 January 1995 beginning at 20:56:51 (GMT) and continuing for 51 minutes. The sampling frequency is 1 Hz.

```
load kobe
```

Plot the earthquake data.

```
plot((1:numel(kobe))./60,kobe)
xlabel('mins')
ylabel('nm/s^2')
grid on
title('Kobe Earthquake Data')
```

Obtain the CWT, frequencies, and cone of influence.

```
[wt,f,coi] = cwt(kobe,1);
```

Plot the data, including the cone of influence.

```
cwt(kobe,1)
```

Obtain the CWT, time periods, and cone of influence by specifying a sampling period instead of a sampling frequency.

```
[wt, periods, coi] = cwt(kobe, minutes(1/60));
```

View the same data by specifying a sampling period input instead of a frequency.

```
cwt(kobe, minutes(1/60))
```

Continuous Wavelet Transform of Two Complex Exponentials

Create two complex exponentials, of different amplitudes, with frequencies of 32 and 64 Hz. The data is sampled at 1000 Hz. The two complex exponentials have disjoint support in time.

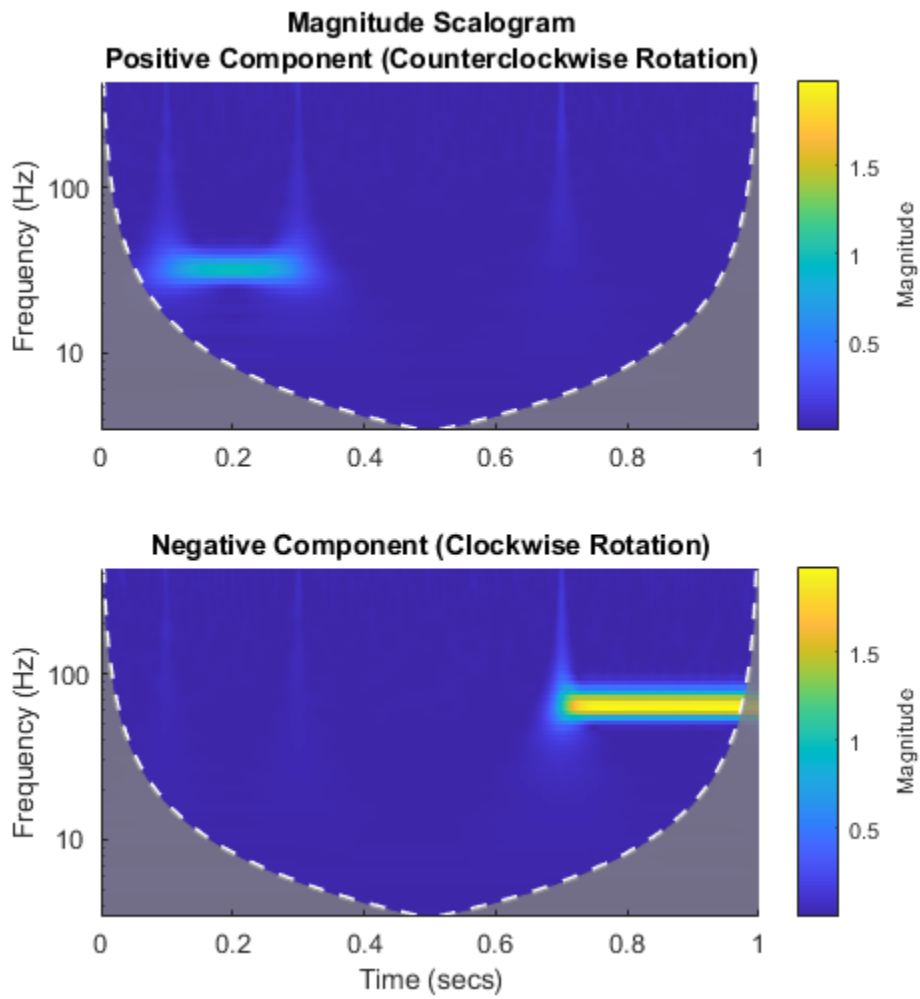

```
Fs = 1e3;
t = 0:1/Fs:1;
z = exp(1i*2*pi*32*t).*(t>=0.1 & t<0.3)+2*exp(-1i*2*pi*64*t).*(t>0.7);
```

Add complex white Gaussian noise with a standard deviation of 0.05.

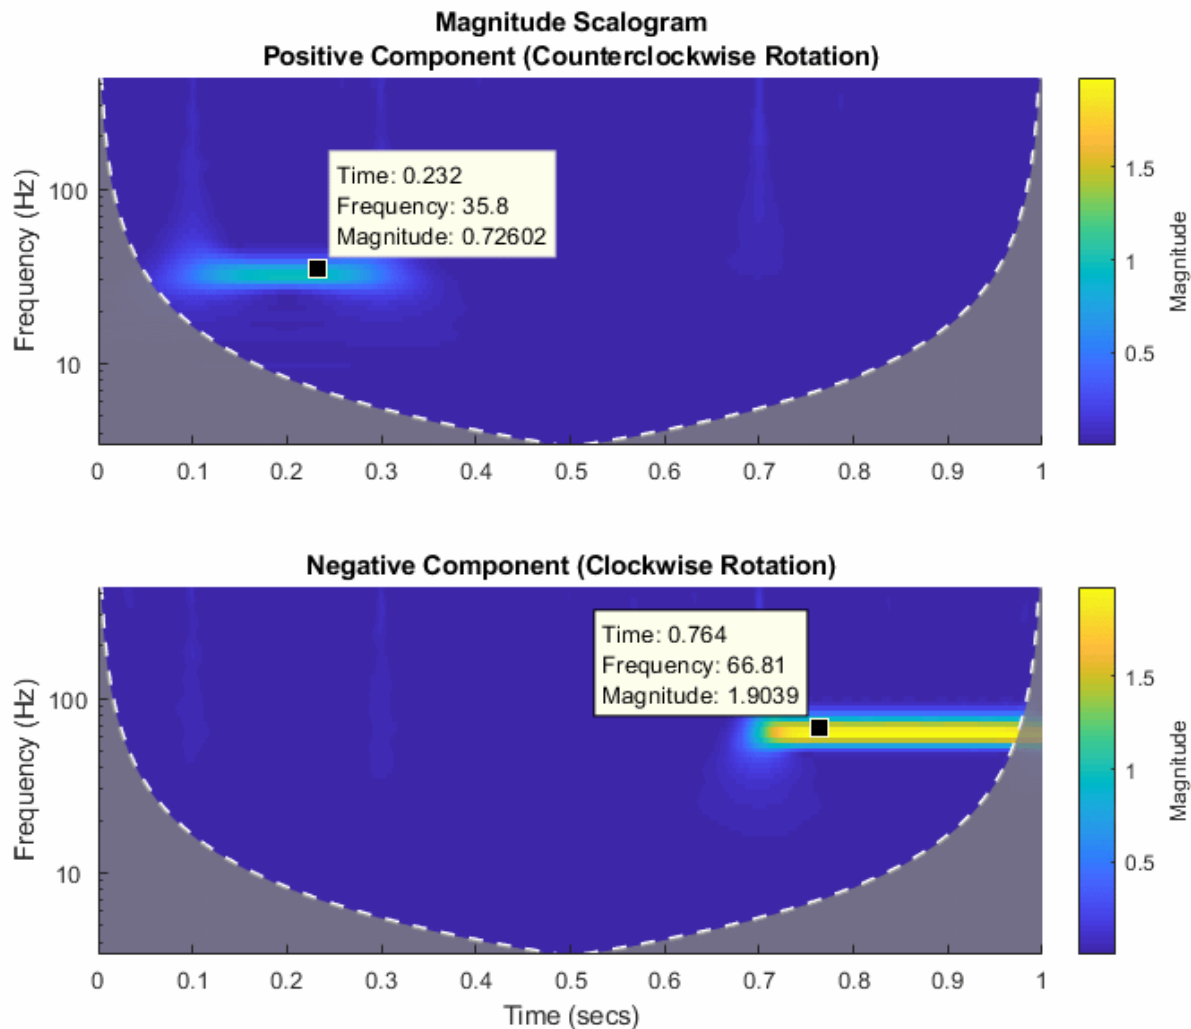

```
wgnNoise = 0.05/sqrt(2)*randn(size(t))+1i*0.05/sqrt(2)*randn(size(t));
z = z+wgnNoise;
```

Obtain and plot the cwt using a Morse wavelet.

```
cwt(z,Fs)
```

Note the magnitudes of the complex exponential components in the colorbar are essentially their amplitudes even though they are at different scales. This is a direct result of the L1 normalization. You can verify this by executing this script and exploring each subplot with a data cursor.

Sinusoid and Wavelet Coefficient Amplitudes

This example shows that the amplitudes of oscillatory components in a signal agree with the amplitudes of the corresponding wavelet coefficients.

Create a signal composed of two sinusoids with disjoint support in time. One sinusoid has a frequency of 32 Hz and amplitude equal to 1. The other sinusoid has a frequency of 64 Hz and amplitude equal to 2. The signal is sampled for one second at 1000 Hz. Plot the signal.

```

frq1 = 32;
amp1 = 1;
frq2 = 64;
amp2 = 2;

Fs = 1e3;
t = 0:1/Fs:1;

```

```

x = amp1*sin(2*pi*frq1*t).*(t>=0.1 & t<0.3)+amp2*sin(2*pi*frq2*t).*(t>0.6 & t<0.9);

plot(t,x)
grid on
xlabel('Time (sec)')
ylabel('Amplitude')
title('Signal')

```

Create a CWT filter bank that can be applied to the signal. Since the signal component frequencies are known, set the frequency limits of the filter bank to a narrow range that includes the known frequencies. To confirm the range, plot the magnitude frequency responses for the filter bank.

```

fb = cwtfilterbank('SignalLength',numel(x),'SamplingFrequency',Fs,...
    'FrequencyLimits',[20 100]);
figure
freqz(fb)

```

Use `cwt` and the filter bank to plot the scalogram of the signal.

```
figure  
cwt(x, 'FilterBank', fb)
```

Execute this script and use a data cursor to confirm that the amplitudes of the wavelet coefficients are essentially equal to the amplitudes of the sinusoidal components.

Using CWT Filter Bank on Multiple Time Series

This example shows how using a CWT filter bank improves computational efficiency when taking the CWT of multiple time series.

Load the seismograph data recorded during the 1995 Kobe earthquake. The data are seismograph (vertical acceleration, nm/sq.sec) measurements recorded at Tasmania University, Hobart, Australia on 16 January 1995 beginning at 20:56:51 (GMT) and continuing for 51 minutes at 1 second intervals. Create a CWT filter bank that can be applied to the data.

```
load kobe
fb = cwtfilterbank('SignalLength', numel(kobe), 'SamplingFrequency', 1);
```

Use the `cwt` function and take the CWT of the data 250 times. Display the elapsed time used.

```
num = 250;
tic;
for k=1:num
    cfs = cwt(kobe);
end
toc
```

Elapsed time is 6.551628 seconds.

Now use the `wt` object function of the filter bank to take the CWT of the data. Confirm using the filter bank is faster.

```
tic;
for k=1:num
    cfs = wt(fb,kobe);
end
toc
```

Elapsed time is 3.782376 seconds.

CUDA Code from CWT

This example shows how to generate a MEX file to perform the continuous wavelet transform (CWT) using generated CUDA code.

First, ensure that you have a CUDA-enabled GPU and the NVCC compiler. See “The GPU Environment Check and Setup App” (GPU Coder) to ensure you have the proper configuration.

Create a GPU coder configuration object.

```
cfg = coder.gpuConfig('mex');
```

Generate a signal of 100,000 samples at 1,000 Hz. The signal consists of two cosine waves with disjoint time supports.

```
t = 0:.001:(1e5*0.001)-0.001;
x = cos(2*pi*32*t).*(t > 10 & t<=50)+cos(2*pi*64*t).*(t >= 60 & t < 90)+ ...
    0.2*randn(size(t));
```

Cast the signal to use single precision. GPU calculations are often more efficiently done in single precision. You can however also generate code for double precision if your NVIDIA GPU supports it.

```
x = single(x);
```

Generate the GPU MEX file and a code generation report. To allow generation of the MEX file, you must specify the properties (class, size, and complexity) of the three input parameters:

- `coder.typeof(single(0), [1 1e5])` specifies a row vector of length 100,000 containing real single values.
- `coder.typeof('c', [1 inf])` specifies a character array of arbitrary length.
- `coder.typeof(0)` specifies a real double value.

```
codegen cwt -config cfg -args {coder.typeof(single(0),[1 1e5]),coder.typeof('c',[1 inf]),coder.t
```

Code generation successful: To view the report, open('codegen/mex/cwt/html/report.mldatx').

The `-report` flag is optional. Using `-report` generates a code generation report. In the **Summary** tab of the report, you can find a **GPU code metrics** link, which provides detailed information such as the number of CUDA kernels generated and how much memory was allocated.

Run the MEX file on the data and plot the scalogram. Confirm the plot is consistent with the two disjoint cosine waves.

```
[cfs,f] = cwt_mex(x, 'Morse', 1e3);
image('XData',t, 'YData',f, 'CData',abs(cfs), 'CDataMapping', 'scaled')
set(gca, 'YScale', 'log')
axis tight
xlabel('Seconds')
ylabel('Hz')
title('CWT of Two-Tone Signal')
```

Run the CWT command above without appending the `_mex`. Confirm the the MATLAB and the GPU MEX scalograms are identical.

```
[cfs2,f2] = cwt(x, 'Morse', 1e3);
max(abs(cfs2(:)-cfs(:)))
```

```
ans =
    single
    6.7237e-07
```

Change Default Frequency Axis Labels

This example shows how to change the default frequency axis labels for the CWT when you obtain a plot with no output arguments.

Create two sine waves with frequencies of 32 and 64 Hz. The data is sampled at 1000 Hz. The two sine waves have disjoint support in time. Add white Gaussian noise with a standard deviation of 0.05. Obtain and plot the CWT using the default Morse wavelet.

```

Fs = 1e3;
t = 0:1/Fs:1;
x = cos(2*pi*32*t).*(t>=0.1 & t<0.3)+sin(2*pi*64*t).*(t>0.7);
wgnNoise = 0.05*randn(size(t));
x = x+wgnNoise;
cwt(x,1000)

```

The plot uses a logarithmic frequency axis because frequencies in the CWT are logarithmic. In MATLAB, logarithmic axes are in powers of 10 (decades). You can use `cwtfreqbounds` to determine what the minimum and maximum wavelet bandpass frequencies are for a given signal length, sampling frequency, and wavelet.

```
[minf,maxf] = cwtfreqbounds(numel(x),1000);
```

You see that by default MATLAB has placed frequency ticks at 10 and 100 because those are the powers of 10 between the minimum and maximum frequencies. If you wish to add more frequency axis ticks, you can obtain a logarithmically spaced set of frequencies between the minimum and maximum frequencies using the following.

```

numfreq = 10;
freq = logspace(log10(minf),log10(maxf),numfreq);

```

Next, get the handle to the current axes and replace the frequency axis ticks and labels with the following.

```
AX = gca;  
AX.YTickLabelMode = 'auto';  
AX.YTick = freq;
```

In the CWT, frequencies are computed in powers of two. To create the frequency ticks and tick labels in powers of two, you can do the following.

```
newplot;  
cwt(x,1000);  
AX = gca;  
freq = 2.^(round(log2(minf)):round(log2(maxf)));  
AX.YTickLabelMode = 'auto';  
AX.YTick = freq;
```

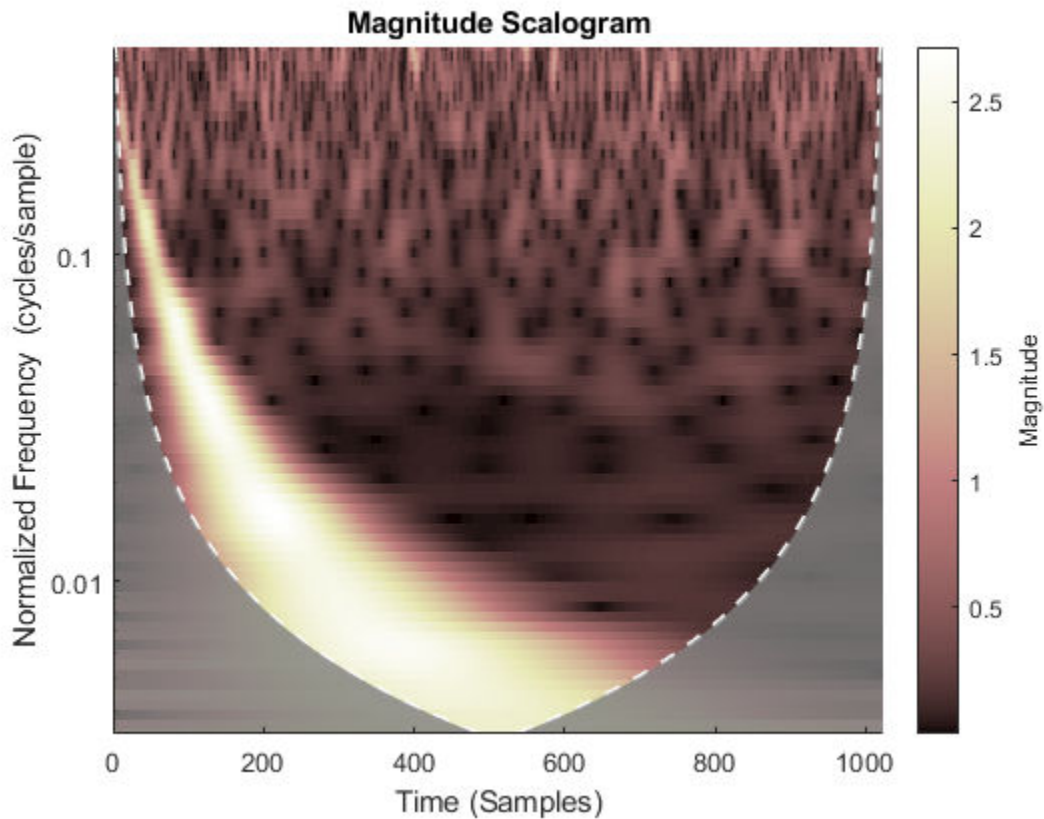

Change Scalogram Coloration

This example shows how to scale scalogram values by maximum absolute value at each level for plotting.

Load in a signal and display the default scalogram. Change the colormap to pink(240).

```
load noisdopp
cwt(noisdopp)
colormap(pink(240))
```

Take the CWT of the signal and obtain the wavelet coefficients and frequencies.

```
[cfs, frq] = cwt(noisdopp);
```

To efficiently find the maximum value of the coefficients at each frequency (level), first transpose the absolute value of the coefficients. Find the minimum value at every level. At each level, subtract the level's minimum value.

```
tmp1 = abs(cfs);
t1 = size(tmp1,2);
tmp1 = tmp1';
minv = min(tmp1);
tmp1 = (tmp1 - minv(ones(1,t1),:)));
```

Find the maximum value at every level of `tmp1`. For each level, divide every value by the maximum value at that level. Multiply the result by the number of colors in the colormap. Set equal to 1 all zero entries. Transpose the result.

```
maxv = max(tmp1);
maxvArray = maxv(ones(1,t1),:);
indx = maxvArray < eps;
tmp1 = 240*(tmp1./maxvArray);
tmp2 = 1+fix(tmp1);
tmp2(indx) = 1;
tmp2 = tmp2';
```

Display the result. The scalogram values are now scaled by the maximum absolute value at each level. Frequencies are displayed on a linear scale.

```

t = 0:length(noisdopp)-1;
pcolor(t, frq, tmp2);
shading interp
ylabel('Frequency')
title('Scalogram Scaled By Level')
colormap(pink(240))

```

Changing the Time-bandwidth Product

This example shows that increasing the time-bandwidth product P^2 of the Morse wavelet creates a wavelet with more oscillations under its envelope. Increasing P^2 narrows the wavelet in frequency.

Create two filter banks. One filter bank has the default `TimeBandwidth` value of 60. The second filter bank has a `TimeBandwidth` value of 10. The `SignalLength` for both filter banks is 4096 samples.

```

sigLen = 4096;
fb60 = cwtfilterbank('SignalLength',sigLen);
fb10 = cwtfilterbank('SignalLength',sigLen,'TimeBandwidth',10);

```

Obtain the time-domain wavelets for the filter banks.

```

[psi60,t] = wavelets(fb60);
[psi10,~] = wavelets(fb10);

```

Use the `scales` function to find the mother wavelet for each filter bank.

```

sca60 = scales(fb60);
sca10 = scales(fb10);
[~,idx60] = min(abs(sca60-1));
[~,idx10] = min(abs(sca10-1));
m60 = psi60(idx60,:);
m10 = psi10(idx10,:);

```

Since the time-bandwidth product is larger for the fb60 filter bank, verify the m60 wavelet has more oscillations under its envelope than the m10 wavelet.

```

subplot(2,1,1)
plot(t,abs(m60))
grid on
hold on
plot(t,real(m60))

```

Plot CWT Scalogram in Subplot

This example shows how to plot the CWT scalogram in a figure subplot.

Load the speech sample. The data is sampled at 7418 Hz. Plot the default CWT scalogram.

```
load mtlb
cwt(mtlb,Fs)
```

Obtain the continuous wavelet transform of the signal, and the frequencies of the CWT.

```
[cfs,frq] = cwt(mtlb,Fs);
```

The `cwt` function sets the time and frequency axes in the scalogram. Create a vector representing the sample times.

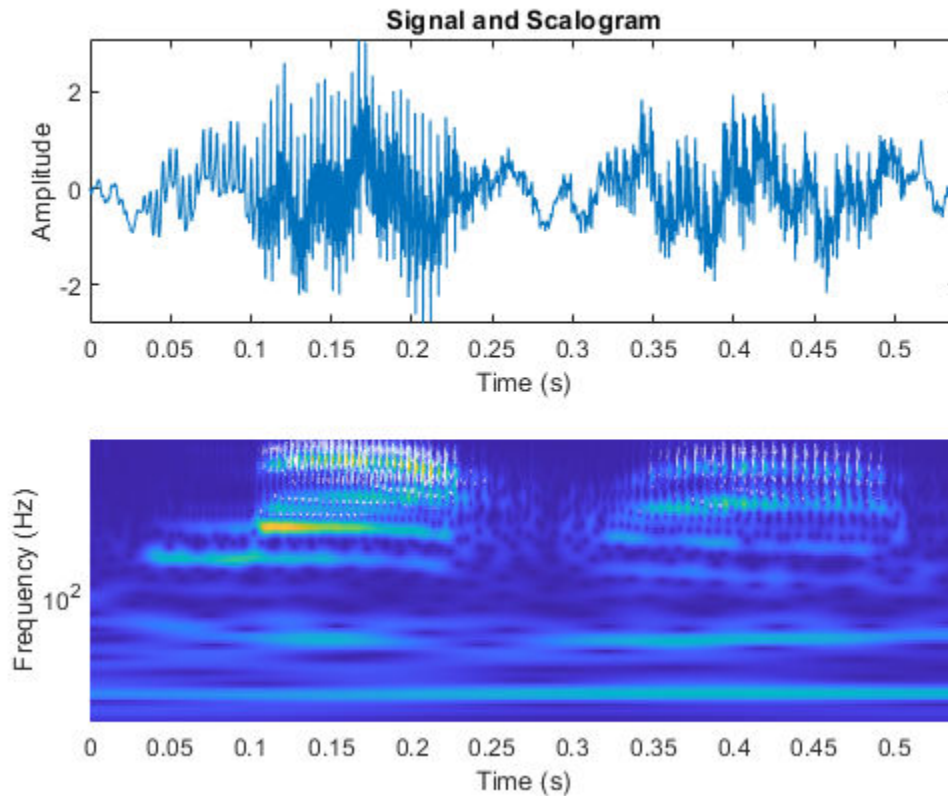

```
tms = (0:numel(mtlb)-1)/Fs;
```

In a new figure, plot the original signal in the upper subplot and the scalogram in the lower subplot. Plot the frequencies on a logarithmic scale.

```
figure
subplot(2,1,1)
plot(tms,mtlb)
axis tight
title('Signal and Scalogram')
xlabel('Time (s)')
ylabel('Amplitude')
subplot(2,1,2)
surface(tms,frq,abs(cfs))
axis tight
shading flat
xlabel('Time (s)')
```

```
ylabel('Frequency (Hz)')
set(gca,'yscale','log')
```

Input Arguments

x — Input signal

real- or complex-valued vector | timetable | gpuArray

Input signal, specified as a real- or complex-valued vector, single-variable regularly sampled timetable. The input `x` must have at least four samples.

The `cwt` function also accepts GPU array inputs. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Data Types: double | single

wname — Analytic wavelet

'morse' (default) | 'amor' | 'bump'

Analytic wavelet used to compute the CWT, specified as 'morse', 'amor', or 'bump'. These character vectors specify the analytic Morse, Morlet (Gabor), and bump wavelet, respectively.

The default Morse wavelet has symmetry parameter (γ) equal to 3 and time-bandwidth product equal to 60.

fs — Sampling frequency

positive scalar

Sampling frequency, in Hz, specified as a positive scalar. If you specify `fs`, then you cannot specify `ts`.

ts — Sampling period

scalar duration

Sampling period, also known as the time duration, specified as a scalar duration. Valid durations are years, days, hours, minutes, and seconds. You cannot use calendar durations. If you specify `ts`, then you cannot specify `fs`.

Example: `wt = cwt(x, hours(12))`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'ExtendSignal', false` indicates that the signal is not extended.

ExtendSignal — Extend input signal symmetrically`true (default) | false`

Option to extend the input signal symmetrically by reflection, specified as the comma-separated pair consisting of `'ExtendSignal'` and either `true` or `false`. Extending the signal symmetrically can mitigate boundary effects. If you specify `true`, then the signal is extended. If you specify `false`, then the signal is not extended.

FrequencyLimits — Frequency limits

two-element scalar vector

Frequency limits to use in the CWT, specified as a two-element vector with positive strictly increasing entries. The first element specifies the lowest peak passband frequency and must be greater than or equal to the product of the wavelet peak frequency in hertz and two time standard deviations divided by the signal length. The second element specifies the highest peak passband frequency and must be less than or equal to the Nyquist frequency. The base 2 logarithm of the ratio of the maximum frequency to the minimum frequency must be greater than or equal to $1/NV$ where NV is the number of voices per octave.

If you specify frequency limits outside the permissible range, `cwt` truncates the limits to the minimum and maximum valid values. Use `cwtfreqbounds` to determine frequency limits for different parameterizations of the CWT. For complex-valued signals, `(-1)*flimits` is used for the anti-analytic part, where `flimits` is the vector specified by `FrequencyLimits`.

Example: `'FrequencyLimits', [0.1 0.3]`

Data Types: `double`

PeriodLimits — Period limits

two-element duration array

Period limits to use in the CWT, specified as a two-element duration array with strictly increasing positive entries. The first element must be greater than or equal to $2*ts$ where `ts` is the sampling

period. The base 2 logarithm of the ratio of the minimum period to the maximum period must be less than or equal to $-1/NV$ where NV is the number of voices per octave. The maximum period cannot exceed the signal length divided by the product of two time standard deviations of the wavelet and the wavelet peak frequency.

If you specify period limits outside the permissible range, `cwt` truncates the limits to the minimum and maximum valid values. Use `cwtfreqbounds` to determine period limits for different parameterizations of the wavelet transform. For complex-valued signals, $(-1)*plimits$ is used for the anti-analytic part, where `plimits` is the vector specified by `PeriodLimits`.

Example: `'PeriodLimits',[seconds(0.2) seconds(1)]`

Data Types: `duration`

VoicesPerOctave — Number of voices per octave

10 (default) | even integer from 4 to 48

Number of voices per octave to use for the CWT, specified as the comma-separated pair consisting of `'VoicesPerOctave'` and an even integer from 4 to 48. The CWT scales are discretized using the specified number of voices per octave. The energy spread of the wavelet in frequency and time automatically determines the minimum and maximum scales.

TimeBandwidth — Time-bandwidth product of the Morse wavelet

60 (default) | scalar greater than 3 and less than or equal to 120

Time-bandwidth product of the Morse wavelet, specified as the comma-separated pair consisting of `'TimeBandwidth'` and a scalar greater than 3 and less than or equal to 120. The symmetry parameter, γ , is fixed at 3. Wavelets with larger time-bandwidth products have larger spreads in time and narrower spreads in frequency. The standard deviation of the Morse wavelet in time is approximately $\sqrt{\text{TimeBandwidth}/2}$. The standard deviation of the Morse wavelet in frequency is approximately $1/2*\sqrt{2/\text{TimeBandwidth}}$.

If you specify `'TimeBandwidth'`, you cannot specify `'WaveletParameters'`. To specify both the symmetry and time-bandwidth product, use `'WaveletParameters'` instead.

In the notation of “Morse Wavelets”, `TimeBandwidth` is P^2 .

WaveletParameters — Symmetry and time-bandwidth product of the Morse wavelet

(3,60) (default) | two-element vector of scalars

Symmetry and time-bandwidth product of the Morse wavelet, specified as the comma-separated pair consisting of `'WaveletParameters'` and a two-element vector of scalars. The first element is the symmetry, γ , which must be greater than or equal to 1. The second element is the time-bandwidth product, which must be strictly greater than γ . The ratio of the time-bandwidth product to γ cannot exceed 40.

When γ is equal to 3, the Morse wavelet is perfectly symmetric in the frequency domain and the skewness is 0. When γ is greater than 3, the skewness is positive. When γ is less than 3, the skewness is negative.

For more information, see “Morse Wavelets”.

If you specify `'WaveletParameters'`, you cannot specify `'TimeBandwidth'`.

NumOctaves — Number of octaves

positive integer

Number of octaves, specified as the comma-separated pair consisting of 'NumOctaves' and a positive integer. The number of octaves cannot exceed $\log_2(f_{\max}/f_{\min})$ where f_{\max} and f_{\min} are the maximum and minimum CWT frequencies (or periods) as determined by the signal length, sampling frequency, and wavelet. See `cwtfreqbounds` for details.

The 'NumOctaves' name-value pair is not recommended and will be removed in a future release. The recommended way to modify the frequency or period range of the CWT is with the 'FrequencyLimits' or 'PeriodLimits' name-value pairs. You cannot specify both the 'NumOctaves' and 'FrequencyLimits' or 'PeriodLimits' name-value pairs.

FilterBank – CWT filter bank

CWT filter bank object

CWT filter bank to use to compute the CWT, specified as a CWT filter bank object. If you use the 'FilterBank' name-value pair, you cannot specify any other options. All options for the computation of the CWT are defined as properties of `fb`.

If `x` is a timetable, the sampling frequency or sampling period in `fb` must agree with the sampling frequency or sampling period determined by the `RowTimes` of the timetable.

Example: `wt = cwt(x, 'FilterBank', fb)`

Output Arguments

wt – Continuous wavelet transform

matrix

Continuous wavelet transform, returned as a matrix of complex values. By default, `cwt` uses the analytic Morse (3,60) wavelet, where 3 is the symmetry and 60 is the time-bandwidth product. `cwt` uses 10 voices per octave. If `x` is real-valued, `wt` is an N_a -by- N matrix, where N_a is the number of scales, and N is the number of samples in `x`. If `x` is complex-valued, `wt` is a 3-D matrix, where the first page is the CWT for the positive scales (analytic part or counterclockwise component) and the second page is the CWT for the negative scales (anti-analytic part or clockwise component). The minimum and maximum scales are determined automatically based on the energy spread of the wavelet in frequency and time. See "Algorithms" on page 1-136 for information on how the scales are determined.

Data Types: `double`

f – Frequencies

vector

Frequencies of the CWT, returned as a vector. If you specify a sampling frequency, `fs`, then `f` is in Hz. If you do not specify `fs`, `cwt` returns `f` in cycles per sample.

period – Time periods

array

Time periods, returned as an array of durations. The durations are in the same format as `ts`. Each row corresponds to a period.

coi – Cone of influence

array of real numbers | array of durations

Cone of influence for the CWT, returned as either an array of real numbers or an array of durations. The cone of influence indicates where edge effects occur in the CWT. If you specify a sampling

frequency, `fs`, the cone of influence is in Hz. If you specify a scalar duration, `ts`, the cone of influence is in periods. Due to the edge effects, give less credence to areas that are outside or overlap the cone of influence.

For additional information, see “Boundary Effects and the Cone of Influence”.

fb — CWT filter bank

CWT filter bank object

CWT filter bank used in the CWT, returned as a CWT filter bank object. See `cwtfilterbank`.

scalingcfs — Scaling coefficients

real- or complex-valued vector

Scaling coefficients for the CWT if the analyzing wavelet is 'morse' or 'amor', returned as a real- or complex-valued vector. The length of `scalingcfs` is equal to the length of the input `x`.

Scaling coefficients are not supported for the bump wavelet.

More About

Analytic Wavelets

Analytic wavelets are complex-valued wavelets whose Fourier transform vanish for negative frequencies. Analytic wavelets are a good choice when doing time-frequency analysis with the CWT. Because the wavelet coefficients are complex-valued, the coefficients provide phase and amplitude information of the signal being analyzed. Analytic wavelets are well suited for studying how the frequency content in real world nonstationary signals evolves as a function of time.

Analytic wavelets are almost exclusively based on rapidly decreasing functions. If $\psi(t)$ is an analytic rapidly decreasing function in time, then its Fourier transform $\widehat{\psi}(\omega)$ is a rapidly decreasing function in frequency and is small outside of some interval $\alpha < \omega < \beta$ where $0 < \alpha < \beta$. Orthogonal and biorthogonal wavelets are typically designed to have compact support in time. Wavelets with compact support in time have relatively poorer energy concentration in frequency than wavelets which rapidly decrease in time. Most orthogonal and biorthogonal wavelets are not symmetric in the Fourier domain.

If your goal is to obtain a joint time-frequency representation of your signal, we recommend you use `cwt` or `cwtfilterbank`. Both functions support the following analytic wavelets:

- Morse Wavelet Family (default)
- Analytic Morlet (Gabor) Wavelet
- Bump

If you want to do time-frequency analysis using orthogonal or biorthogonal wavelets, we recommend `modwpt`.

When using wavelets for time-frequency analysis, you usually convert scales to frequencies or periods to interpret results. `cwt` and `cwtfilterbank` do the conversion. You can obtain the corresponding scales associated by using `scales` on the optional `cwt` output argument `fb`.

For more information regarding Morse wavelets, see “Morse Wavelets”. For guidance on how to choose the wavelet that is right for your application, see “Choose a Wavelet”.

Tips

- When performing multiple CWTs, for example inside a for-loop, the recommended workflow is to first create a `cwtfilterbank` object and then use the `wt` object function. This workflow minimizes overhead and maximizes performance. See “Using CWT Filter Bank on Multiple Time Series” on page 1-120.

Algorithms

Minimum Scale

To determine the minimum scale, find the peak frequency ω_x of the base wavelet. For Morse wavelets, dilate the wavelet so that the Fourier transform of the wavelet at π radians is equal to 10% of the peak frequency. The smallest scale occurs at the largest frequency:

$$s_0 = \frac{\omega'_x}{\pi}$$

As a result, the smallest scale is the minimum of $(2, s_0)$. For Morse wavelets, the smallest scale is usually s_0 . For the Morlet wavelet, the smallest scale is usually 2.

Maximum Scale

Both the minimum and maximum scales of the CWT are determined automatically based on the energy spread of the wavelet in frequency and time. To determine the maximum scale, CWT uses the following algorithm.

The standard deviation of the Morse wavelet in time, σ_t , is approximately $\sqrt{\frac{P^2}{2}}$, where P^2 is the time-bandwidth product. The standard deviation in frequency, σ_f , is approximately $\frac{1}{2}\sqrt{\frac{2}{P^2}}$. If you scale the wavelet by some $s > 1$, the time duration changes to $2s\sigma_t = N$, which is the wavelet stretched to equal the full length (N samples) of the input. You cannot translate this wavelet or stretch it further without causing it to wrap, so the largest scale is $\text{floor}\left(\frac{N}{2\sigma_t}\right)$.

Wavelet transform scales are powers of 2 and are denoted by $s_0\left(2^{\frac{1}{NV}}\right)^j$. NV is the number of voices per octave, and j ranges from 0 to the largest scale. For a specific small scale, s_0 :

$$s_0\left(2^{\frac{1}{NV}}\right)^j \leq \frac{N}{2\sigma_t}$$

Converting to \log_2 :

$$j\log_2\left(2^{\frac{1}{NV}}\right) \leq \log_2\left(\frac{N}{2\sigma_t s_0}\right)$$

$$j \leq NV\log_2\left(\frac{N}{2\sigma_t s_0}\right)$$

Therefore, the maximum scale is

$$s_0 \left(2^{\frac{1}{NV}} \right)^{\text{floor} \left(NV \log_2 \left(\frac{N}{2\sigma_t s_0} \right) \right)}$$

L1 Norm for CWT

In integral form, the CWT preserves energy. However, when you implement the CWT numerically, energy is not preserved. In this case, regardless of the normalization you use, the CWT is not an orthonormal transform. The `cwt` function uses L1 normalization.

Wavelet transforms commonly use L2 normalization of the wavelet. For the L2 norm, dilating a signal by $1/s$, where s is greater than 0, is defined as follows:

$$\left\| x\left(\frac{t}{s}\right) \right\|_2^2 = s \|x(t)\|_2^2$$

The energy is now s times the original energy. When included in the Fourier transform, multiplying by $1/\sqrt{s}$ produces different weights being applied to different scales, so that the peaks at higher frequencies are reduced more than the peaks at lower frequencies.

In many applications, L1 normalization is better. The L1 norm definition does not include squaring the value, so the preserving factor is $1/s$ instead of $1/\sqrt{s}$. Instead of high-frequency amplitudes being reduced as in the L2 norm, for L1 normalization, all frequency amplitudes are normalized to the same value. Therefore, using the L1 norm shows a more accurate representation of the signal. See example "Continuous Wavelet Transform of Two Complex Exponentials" on page 1-114.

Compatibility Considerations

'NumOctaves' name-value pair will be removed

Not recommended starting in R2018a

The 'NumOctaves' name-value pair argument will be removed in a future release. Use either:

- Name-value pair argument 'FrequencyLimits' to modify the frequency range of the CWT.
- Name-value pair argument 'PeriodLimits' to modify the period range of the CWT.

See `cwtfreqbounds` for additional information.

Extended Capabilities

GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- Single- and double-precision input signal are supported. The precision must be set at compile time.
- Timetable input signal is not supported.
- Only analytic Morse ('morse') and Morlet ('amor') wavelets are supported.
- The following input arguments are not supported: Sampling period (ts), PeriodLimits name-value pair, NumOctave name-value pair, and FilterBank name-value pair.
- Scaling coefficient output and filter bank output are not supported.
- Plotting is not supported.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see "Run MATLAB Functions on a GPU" (Parallel Computing Toolbox).

cwtfilterbank

Continuous wavelet transform filter bank

Description

Use `cwtfilterbank` to create a continuous wavelet transform (CWT) filter bank. The default wavelet used in the filter bank is the analytic Morse (3,60) wavelet. You can vary the time-bandwidth and symmetry parameters for the Morse wavelets, to tune the Morse wavelet for your needs. You can also use the analytic Morlet (Gabor) wavelet or bump wavelet. When analyzing multiple signals in time-frequency, for improved computational efficiency, you can precompute the filters once and then pass the filter bank as input to `cwt`. With the filter bank, you can visualize wavelets in time and frequency. You can also create filter banks with specific frequency or period ranges, and measure 3-dB bandwidths. You can determine the quality factor for the wavelets in the filter bank.

Creation

Syntax

```
fb = cwtfilterbank
fb = cwtfilterbank(Name,Value)
```

Description

`fb = cwtfilterbank` creates a continuous wavelet transform (CWT) filter bank `fb`. The filters are normalized so that the peak magnitudes for all passbands are approximately equal to 2. The default filter bank is designed for a signal with 1024 samples. The default filter bank uses the analytic Morse (3,60) wavelet. The filter bank uses the default scales: approximately 10 wavelet bandpass filters per octave (10 voices per octave). The highest-frequency passband is designed so that the magnitude falls to half the peak value at the Nyquist frequency.

As implemented, the CWT uses L1 normalization. With L1 normalization, equal amplitude oscillatory components at different scales have equal magnitude in the CWT. L1 normalization provides a more accurate representation of the signal. The amplitudes of the oscillatory components agree with the amplitudes of the corresponding wavelet coefficients. See “Sinusoid and Wavelet Coefficient Amplitudes” on page 1-148.

`fb` can be used as input for `cwt`.

`fb = cwtfilterbank(Name,Value)` creates a CWT filter bank `fb` with properties specified by one or more `Name,Value` pair arguments. Properties can be specified in any order as `Name1,Value1, . . . ,NameN,ValueN`. Enclose each property name in quotes.

Note You cannot change a property value of an existing filter bank. For example, if you have a filter bank `fb` with a `SignalLength` of 2000, you must create a second filter bank `fb2` to process a signal with 2001 samples. You cannot assign a different `SignalLength` to `fb`.

Properties

SignalLength — Length of the signal

1024 (default) | positive integer

Length of the signal, specified as a positive integer. The signal must have at least four samples.

Example: 'SignalLength', 1700

Data Types: double

Wavelet — Analysis wavelet

'Morse' (default) | 'amor' | 'bump'

Analysis wavelet used in the filter bank, specified as 'Morse', 'amor', or 'bump'. These strings specify the analytic Morse, Morlet (Gabor), and bump wavelet, respectively. The default wavelet is the analytic Morse (3,60) wavelet.

By default, for Morse wavelets, the frequency response decays to 50% of the peak magnitude at the Nyquist. For the Morlet and bump wavelets, the frequency response decays to 10% of the peak magnitude. You can change the decay percentage by setting the filter bank `FrequencyLimits` property. See `cwtfreqbounds`.

For Morse wavelets, you can also parameterize the wavelet using the `TimeBandwidth` or `WaveletParameters` properties.

Example: 'Wavelet', 'bump'

VoicesPerOctave — Number of voices per octave

10 (default) | even integer between 4 and 48

Number of voices per octave to use for the CWT, specified as an even integer from 4 to 48. The CWT scales are discretized using the specified number of voices per octave. The energy spread of the wavelet in frequency and time automatically determines the minimum and maximum scales.

You can use `cwtfreqbounds` to determine the frequency limits of the wavelet filter bank. The frequency limits depend on parameters such as the energy spread of the wavelet, number of voices per octave, signal length, and sampling frequency.

Example: 'VoicesPerOctave', 20

Data Types: single | double

SamplingFrequency — Sampling frequency in hertz

1 (default) | positive scalar

Sampling frequency in hertz, specified as a positive scalar. If unspecified, frequencies are in cycles/sample and the Nyquist frequency is $\frac{1}{2}$. To specify scales in periods, use the `SamplingPeriod` and `PeriodLimits` properties.

You cannot specify both the `SamplingFrequency` and `SamplingPeriod` properties.

Example: 'SamplingFrequency', 5

Data Types: single | double

FrequencyLimits — Frequency limits

two-element scalar vector

Frequency limits of the wavelet filter bank, specified as a two-element vector with positive strictly increasing entries. The first element specifies the lowest peak passband frequency. The frequency must be greater than or equal to the product of the wavelet peak frequency in hertz and two time standard deviations divided by the signal length. The base 2 logarithm of the ratio of maximum frequency to minimum frequency must be greater than or equal to $1/NV$, where NV is the number of voices per octave. The high frequency limit must be less than or equal to the Nyquist.

If you specify frequency limits outside the permissible range, `cwtfilterbank` truncates the limits to the minimum and maximum values. Use `cwtfreqbounds` to determine frequency limits for different parametrizations of the wavelet transform.

If using a sampling period in the filter bank, you cannot specify the `FrequencyLimits` property.

Example: `'SamplingFrequency',20,'FrequencyLimits',[1 5]`

Data Types: double

SamplingPeriod — Sampling period

duration scalar

Sampling period, specified as a scalar duration. You cannot specify both the `SamplingFrequency` and `SamplingPeriod` properties.

Example: `'SamplingPeriod',seconds(0.5)`

Data Types: duration

PeriodLimits — Period limits

two-element duration array

Period limits of the wavelet filter bank, specified as a two-element duration array with positive strictly increasing entries. The first element of `PeriodLimits` specifies the largest peak passband frequency and must be greater than or equal to twice the `SamplingPeriod`. The base 2 logarithm of the ratio of the minimum period to the maximum period must be less than or equal to $-1/NV$, where NV is the number of voices per octave. The maximum period cannot exceed the signal length divided by the product of two time standard deviations of the wavelet and the wavelet peak frequency.

If you specify period limits outside the permissible range, `cwtfilterbank` truncates the limits to the minimum and maximum values. Use `cwtfreqbounds` to determine period limits for different parametrizations of the wavelet transform.

If using a sampling frequency in the filter bank, you cannot specify the `PeriodLimits` property.

Example: `'SamplingPeriod',seconds(0.1),'PeriodLimits',[seconds(0.2) seconds(1)]`

Data Types: duration

TimeBandwidth — Time-bandwidth product for Morse wavelets

60 (default) | positive scalar

Time-bandwidth product for Morse wavelets, specified as a positive scalar. This property is only valid when the `Wavelet` property is `'morse'`. This property specifies the time-bandwidth product of the Morse wavelet with the symmetry parameter (γ) fixed at 3. `TimeBandwidth` is a positive number strictly greater than 3 and less than or equal to 120.

The larger the time-bandwidth product, the more spread out the wavelet is in time and narrower the wavelet is in frequency. The standard deviation of the Morse wavelet in time is approximately

$\text{sqrt}(\text{TimeBandwidth}/2)$. The standard deviation in frequency is approximately $1/2*\text{sqrt}(2/\text{TimeBandwidth})$. See “Generalized Morse and Analytic Morlet Wavelets” on page 1-152.

The `TimeBandwidth` and `WaveletParameters` properties cannot both be specified.

In the notation of “Morse Wavelets”, `TimeBandwidth` is P^2 .

Example: `'TimeBandwidth',20`

Data Types: double

WaveletParameters — Morse wavelet parameters

(3,60) (default) | two-element vector of scalars

Morse wavelet parameters, specified as a two-element vector. The first element is the symmetry parameter (γ), which must be greater than or equal to 1. The second element is the time-bandwidth product, which must be strictly greater than γ . The ratio of the time-bandwidth product to γ cannot exceed 40.

When γ is equal to 3, the Morse wavelet is perfectly symmetric in the frequency domain. The skewness is equal to 0. Values of γ greater than 3 result in positive skewness, while values of γ less than 3 result in negative skewness. `WaveletParameters` is only valid if the `Wavelet` property is set to `'Morse'`.

For more information, see “Morse Wavelets”.

The `WaveletParameters` and `TimeBandwidth` properties cannot both be specified.

Example: `'WaveletParameters',[4,20]`

Boundary — Boundary extension

'reflection' (default) | 'periodic'

Boundary extension of signal, specified as either `'reflection'` or `'periodic'`. Determines how the data is treated at the boundary.

Example: `'Boundary','periodic'`

Object Functions

<code>wt</code>	Continuous wavelet transform with filter bank

<code>centerPeriods</code>	CWT filter bank bandpass center periods

Examples

Continuous Wavelet Transform Filter Bank

Create a continuous wavelet transform filter bank.

```
fb = cwtfilterbank
```

```
fb =  
cwtfilterbank with properties:  
  
    VoicesPerOctave: 10  
        Wavelet: 'Morse'  
SamplingFrequency: 1  
    SamplingPeriod: []  
    PeriodLimits: []  
    SignalLength: 1024  
    FrequencyLimits: []  
    TimeBandwidth: 60  
WaveletParameters: []  
    Boundary: 'reflection'
```

Plot the magnitude frequency response.

```
freqz(fb)
```

Frequency Resolution of Continuous Wavelet Transform Filter Banks

Create two sine waves with frequencies of 16 and 64 Hz. The data is sampled at 1000 Hz. Plot the signal.

```
Fs = 1e3;  
t = 0:1/Fs:1-1/Fs;  
x = cos(2*pi*64*t).*(t>=0.1 & t<0.3)+sin(2*pi*16*t).*(t>=0.5 & t<0.9);  
plot(t,x)  
title('Signal')
```

Create a CWT filter bank for the signal. Plot the frequency responses of the wavelets in the filter bank.

```
fb = cwtfilterbank('SignalLength', numel(t), 'SamplingFrequency', Fs);  
freqz(fb)  
title('Frequency Responses – Morse (3,60) Wavelet')
```

The analytic Morse (3,60) wavelet is the default wavelet in the filter bank. The wavelet has a time-bandwidth product equal to 60. Create a second filter bank identical to the first filter bank but instead uses the analytic Morse (3,5) wavelet. Plot the frequency responses of the wavelets in the second filter bank.

```
fb3x5 = cwtfilterbank('SignalLength', numel(t), 'SamplingFrequency', Fs, ...
    'TimeBandwidth', 5);
figure
freqz(fb3x5)
title('Frequency Responses — Morse (3,5) Wavelet')
```

Observe that the frequency responses are wider than in the first filter bank. The Morse (3,60) wavelet is better localized in frequency than the Morse (3,5) wavelet. Apply each filter bank to the signal and plot the resulting scalograms. Observe that the Morse (3,60) wavelet has better frequency resolution than the Morse (3,5) wavelet.

```
figure
cwt(x, 'FilterBank', fb)
title('Magnitude Scalogram — Morse (3,60)')
```

```
figure  
cwt(x, 'FilterBank', fb3x5)  
title('Magnitude Scalogram - Morse (3,5)')
```

Sinusoid and Wavelet Coefficient Amplitudes

This example shows that the amplitudes of oscillatory components in a signal agree with the amplitudes of the corresponding wavelet coefficients.

Create a signal composed of two sinusoids with disjoint support in time. One sinusoid has a frequency of 32 Hz and amplitude equal to 1. The other sinusoid has a frequency of 64 Hz and amplitude equal to 2. The signal is sampled for one second at 1000 Hz. Plot the signal.

```

frq1 = 32;
amp1 = 1;
frq2 = 64;
amp2 = 2;

Fs = 1e3;
t = 0:1/Fs:1;
x = amp1*sin(2*pi*frq1*t).*(t>=0.1 & t<0.3)+amp2*sin(2*pi*frq2*t).*(t>0.6 & t<0.9);

plot(t,x)
grid on
xlabel('Time (sec)')
ylabel('Amplitude')
title('Signal')

```

Create a CWT filter bank that can be applied to the signal. Since the signal component frequencies are known, set the frequency limits of the filter bank to a narrow range that includes the known frequencies. To confirm the range, plot the magnitude frequency responses for the filter bank.

```
fb = cwtfilterbank('SignalLength', numel(x), 'SamplingFrequency', Fs, ...  
                  'FrequencyLimits', [20 100]);  
figure  
freqz(fb)
```

Use `cwt` and the filter bank to plot the scalogram of the signal.

```
figure  
cwt(x, 'FilterBank', fb)
```

Execute this script and use a data cursor to confirm that the amplitudes of the wavelet coefficients are essentially equal to the amplitudes of the sinusoidal components.

Generalized Morse and Analytic Morlet Wavelets

This example shows how to vary the time-bandwidth parameter of the generalized Morse wavelet to approximate the analytic Morlet wavelet.

Generalized Morse wavelets are a family of exactly analytic wavelets. Morse wavelets have two parameters, symmetry and time-bandwidth product. You can vary these parameters to obtain analytic wavelets with different properties and behaviors. For additional information, see “Morse Wavelets” and the references therein.

Load the seismograph data recorded during the 1995 Kobe earthquake. The data are seismograph (vertical acceleration, nm/sq.sec) measurements recorded at Tasmania University, Hobart, Australia on 16 January 1995 beginning at 20:56:51 (GMT) and continuing for 51 minutes at 1 second intervals. Create a CWT filter bank with default settings that can be applied to the data. Use the filter bank to generate the scalogram.

```
load kobe
fb = cwtfilterbank('SignalLength', numel(kobe), 'SamplingFrequency', 1);
cwt(kobe, 'FilterBank', fb)
```

The magnitude of the wavelet coefficients is large in the frequency range from 10 mHz to 100 mHz. Create a new filter bank with frequency limits set to these values. Generate the scalogram.

```
fb2 = cwtfilterbank('SignalLength', numel(kobe), 'SamplingFrequency', 1, ...
    'FrequencyLimits', [1e-2 1e-1]);
cwt(kobe, 'FilterBank', fb2)
title('Default (3,60) Morse')
```

By default, `cwtfilterbank` uses the (3,60) Morse wavelet. Create a filter bank using the analytic Morlet wavelet with the same frequency limits. Generate a scalogram and compare with the scalogram generated by the (3,60) Morse wavelet.

```
fbMorlet = cwtfilterbank('SignalLength', numel(kobe), 'SamplingFrequency', 1, ...
    'FrequencyLimits', [1e-2 1e-1], ...
    'Wavelet', 'amor');
cwt(kobe, 'FilterBank', fbMorlet)
title('Analytic Morlet')
```

The Morlet wavelet is not as well localized in frequency as the (3,60) Morse wavelet. However, by varying the time-bandwidth product, you can create a Morse wavelet with properties similar to the Morlet wavelet.

Create a filter bank using the Morse wavelet with a time-bandwidth value of 30 [2], with frequency limits as above. Generate the scalogram of the seismograph data. Note there is smearing in frequency nearly identical to the Morlet results.

```
fbMorse = cwtfilterbank('SignalLength', numel(kobe), 'SamplingFrequency', 1, ...
    'FrequencyLimits', [1e-2 1e-1], ...
    'TimeBandwidth', 30);
cwt(kobe, 'FilterBank', fbMorse)
title('(3,30) Morse')
```

Now examine the wavelets associated with the `fbMorlet` and `fbMorse` filter banks. From both filter banks, obtain the wavelet center frequencies, filter frequency responses, and time-domain wavelets. Confirm the center frequencies are nearly identical.

```
cfMorlet = centerFrequencies(fbMorlet);
[frMorlet,fMorlet] = freqz(fbMorlet);
[wvMorlet,tMorlet] = wavelets(fbMorlet);
cfMorse = centerFrequencies(fbMorse);
[frMorse,fMorse] = freqz(fbMorse);
[wvMorse,tMorse] = wavelets(fbMorse);

disp(['Number of Center Frequencies: ',num2str(length(cfMorlet))]);
Number of Center Frequencies: 34

disp(['Maximum difference: ',num2str(max(abs(cfMorlet-cfMorse)))]);
Maximum difference: 2.7756e-17
```

Each filter bank contains the same number of wavelets. Choose a center frequency, and plot the frequency response of the associated filter from each filter bank. Confirm the responses are nearly identical.

```
wv = 13;
figure
plot(fMorlet,frMorlet(wv,:));
hold on
plot(fMorse,frMorse(wv,:));
```

```

grid on
title('Frequency Response')
xlabel('Frequency')
ylabel('Amplitude')
legend('Morlet', '(3,30) Morse')

```

Plot the time-domain wavelets associated with the same center frequency. Confirm they are nearly identical.

```

figure
subplot(2,1,1)
plot(tMorlet,real(wvMorlet(wv,:)))
hold on
plot(tMorse,real(wvMorse(wv,:)))
grid on
title('Real')
legend('Morlet', '(3,30) Morse')
xlim([-100 100])
subplot(2,1,2)
plot(tMorlet,imag(wvMorlet(wv,:)))
hold on
plot(tMorse,imag(wvMorse(wv,:)))
grid on
title('Imaginary')
legend('Morlet', '(3,30) Morse')
xlim([-100 100])

```

Changing the Time-bandwidth Product

This example shows that increasing the time-bandwidth product P^2 of the Morse wavelet creates a wavelet with more oscillations under its envelope. Increasing P^2 narrows the wavelet in frequency.

Create two filter banks. One filter bank has the default `TimeBandwidth` value of 60. The second filter bank has a `TimeBandwidth` value of 10. The `SignalLength` for both filter banks is 4096 samples.

```
sigLen = 4096;
fb60 = cwtfilterbank('SignalLength',sigLen);
fb10 = cwtfilterbank('SignalLength',sigLen,'TimeBandwidth',10);
```

Obtain the time-domain wavelets for the filter banks.

```
[psi60,t] = wavelets(fb60);
[psi10,~] = wavelets(fb10);
```

Use the `scales` function to find the mother wavelet for each filter bank.

```
sca60 = scales(fb60);
sca10 = scales(fb10);
[~,idx60] = min(abs(sca60-1));
[~,idx10] = min(abs(sca10-1));
m60 = psi60(idx60,:);
m10 = psi10(idx10,:);
```

Since the time-bandwidth product is larger for the fb60 filter bank, verify the m60 wavelet has more oscillations under its envelope than the m10 wavelet.

```
subplot(2,1,1)
plot(t,abs(m60))
grid on
hold on
plot(t,real(m60))
plot(t,imag(m60))
xlim([-30 30])
legend('abs(m60)', 'real(m60)', 'imag(m60)')
title('TimeBandwidth = 60')
subplot(2,1,2)
plot(t,abs(m10))
grid on
hold on
plot(t,real(m10))
plot(t,imag(m10))
xlim([-30 30])
legend('abs(m10)', 'real(m10)', 'imag(m10)')
title('TimeBandwidth = 10')
```

Align the peaks of the m60 and m10 magnitude frequency responses. Verify the frequency response of the m60 wavelet is narrower than the frequency response for the m10 wavelet.

```
cf60 = centerFrequencies(fb60);
cf10 = centerFrequencies(fb10);
```

```

m60cFreq = cf60(idx60);
m10cFreq = cf10(idx10);

freqShift = 2*pi*(m60cFreq-m10cFreq);
x10 = m10.*exp(1j*freqShift*(-sigLen/2:sigLen/2-1));

figure
plot([abs(fft(m60)).' abs(fft(x10)).'])
grid on
legend('Time-bandwidth = 60','Time-bandwidth = 10')
title('Magnitude Frequency Responses')

```

Using CWT Filter Bank on Multiple Time Series

This example shows how using a CWT filter bank improves computational efficiency when taking the CWT of multiple time series.

Load the seismograph data recorded during the 1995 Kobe earthquake. The data are seismograph (vertical acceleration, nm/sq.sec) measurements recorded at Tasmania University, Hobart, Australia on 16 January 1995 beginning at 20:56:51 (GMT) and continuing for 51 minutes at 1 second intervals. Create a CWT filter bank that can be applied to the data.

```

load kobe
fb = cwtfilterbank('SignalLength', numel(kobe), 'SamplingFrequency', 1);

```

Use the `cwt` function and take the CWT of the data 250 times. Display the elapsed time used.

```
num = 250;
tic;
for k=1:num
    cfs = cwt(kobe);
end
toc
```

Elapsed time is 6.551628 seconds.

Now use the `wt` object function of the filter bank to take the CWT of the data. Confirm using the filter bank is faster.

```
tic;
for k=1:num
    cfs = wt(fb,kobe);
end
toc
```

Elapsed time is 3.782376 seconds.

Plot CWT Scalogram in Subplot

This example shows how to plot the CWT scalogram in a figure subplot.

Load the speech sample. The data is sampled at 7418 Hz. Plot the default CWT scalogram.

```
load mtlb
cwt(mtlb,Fs)
```

Obtain the continuous wavelet transform of the signal, and the frequencies of the CWT.

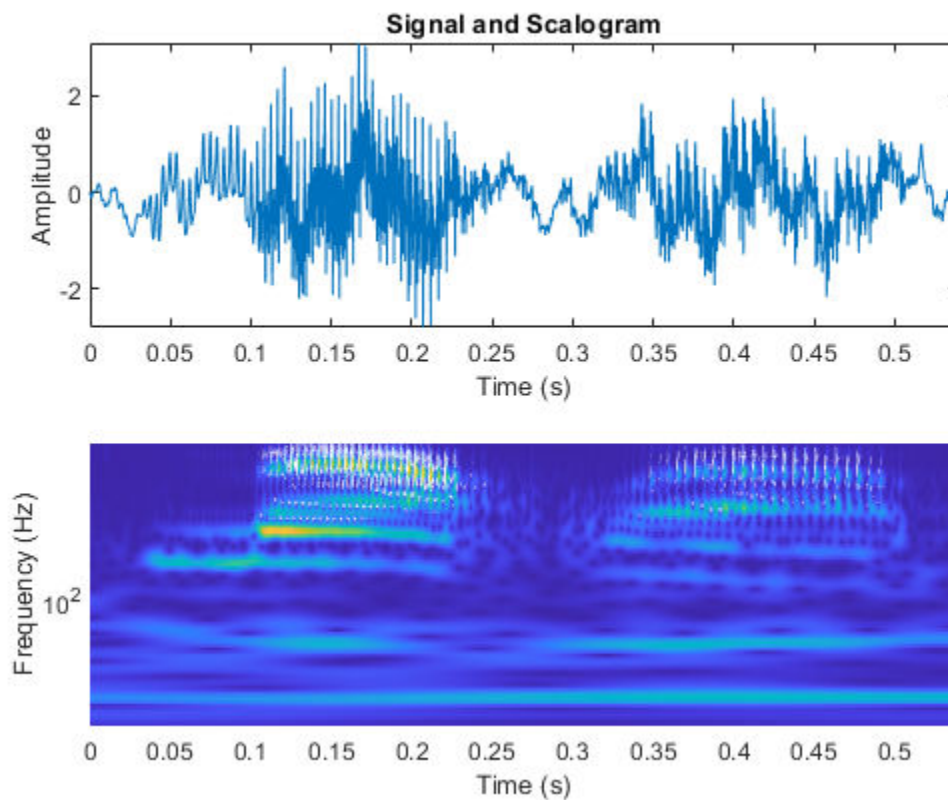

```
[cfs, frq] = cwt(mtlb, Fs);
```

The `cwt` function sets the time and frequency axes in the scalogram. Create a vector representing the sample times.

```
tms = (0:numel(mtlb)-1)/Fs;
```

In a new figure, plot the original signal in the upper subplot and the scalogram in the lower subplot. Plot the frequencies on a logarithmic scale.

```
figure
subplot(2,1,1)
plot(tms, mtlb)
axis tight
title('Signal and Scalogram')
xlabel('Time (s)')
ylabel('Amplitude')
subplot(2,1,2)
surface(tms, frq, abs(cfs))
axis tight
shading flat
xlabel('Time (s)')
ylabel('Frequency (Hz)')
set(gca, 'yscale', 'log')
```

Tips

- The first time you use a filter bank to take the CWT of a signal, the wavelet filters are constructed to have the same datatype as the signal. A warning message is generated when you apply the same filter bank to a signal with a different datatype. Changing datatypes comes with the cost of redesigning or changing the precision of the filter bank. For optimal performance, use a consistent datatype.
- When performing multiple CWTs, for example inside a for-loop, the recommended workflow is to first create a `cwtfilterbank` object and then use the `wt` object function. This workflow minimizes overhead and maximizes performance. See “Using CWT Filter Bank on Multiple Time Series” on page 1-160.

Compatibility Considerations

BPfrequencies and BPperiods will be removed

Not recommended starting in R2018b

The `BPfrequencies` and `BPperiods` object functions of `cwtfilterbank` have been renamed `centerFrequencies` and `centerPeriods`, respectively. The functionality remains unchanged. `BPfrequencies` and `BPperiods` will be removed in a future release.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The following properties are not supported: `SamplingPeriod`, `PeriodLimits`.
- The following object functions support C/C++ code generation:
 - `wt`
 - `wavelets`
 - `scales`
 - `qfactor`
 - `centerFrequencies`
- The object function `freqz` supports C/C++ code generation with the limitation that plotting is not supported.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see "Run MATLAB Functions on a GPU" (Parallel Computing Toolbox).

Introduced in R2018a

cwtfreqbounds

CWT maximum and minimum frequency or period

Syntax

```
[minfreq,maxfreq] = cwtfreqbounds(N)
[minfreq,maxfreq] = cwtfreqbounds(N,Fs)
[maxperiod,minperiod] = cwtfreqbounds(N,Ts)
[ ___ ] = cwtfreqbounds( ___ ,Name,Value)
```

Description

[minfreq,maxfreq] = cwtfreqbounds(N) returns the minimum and maximum wavelet bandpass frequencies in cycles/sample for a signal of length N. The minimum and maximum frequencies are determined for the default Morse (3,60) wavelet. The minimum frequency is determined so that two time standard deviations of the default wavelet span the N-point signal at the coarsest scale. The maximum frequency is such that the highest frequency wavelet bandpass filter drops to ½ of its peak magnitude at the Nyquist frequency.

[minfreq,maxfreq] = cwtfreqbounds(N,Fs) returns the bandpass frequencies in hertz for the sampling frequency Fs.

[maxperiod,minperiod] = cwtfreqbounds(N,Ts) returns the bandpass periods for the sampling period Ts. maxperiod and minperiod are scalar durations with the same format as Ts. If the number of standard deviations is set so that $\log_2(\text{maxperiod}/\text{minperiod}) < 1/NV$ where NV is the number of voices per octave, maxperiod is adjusted to $\text{minperiod} * 2^{(1/NV)}$.

[___] = cwtfreqbounds(___ ,Name,Value) returns the minimum and maximum wavelet bandpass frequencies or periods with additional options specified by one or more Name, Value pair arguments.

Examples

Wavelet Bandpass Frequencies Using Default Values

Obtain the minimum and maximum wavelet bandpass frequencies for a signal with 1000 samples using the default values.

```
[minfreq,maxfreq] = cwtfreqbounds(1000)

minfreq = 0.0033
maxfreq = 0.4341
```

Construct CWT Filter Bank With Peak Magnitude at Nyquist

Obtain the minimum and maximum wavelet bandpass frequencies for the default Morse wavelet for a signal of length 10,000 and a sampling frequency of 1kHz. Set the cutoff to 100% so that the highest frequency wavelet bandpass filter peaks at the Nyquist.

```
sigLength = 10000;
Fs = 1e3;
[minfreq,maxfreq] = cwtfreqbounds(sigLength,Fs,'cutoff',100);
```

Construct the filter bank using the values returned by `cwtfreqbounds`. Plot the frequency response. Note that the highest frequency wavelet bandpass filter peaks at the Nyquist frequency of 500 Hz.

```
fb = cwtfilterbank('SignalLength',sigLength,'SamplingFrequency',Fs,'FrequencyLimits',[minfreq maxfreq](fb))
```

Create a second frequency bank identical to the first, but instead use the default frequency limits. Plot the frequency response. In the case of the Morse wavelet, the CWT filter bank uses a default cutoff of 50% at the Nyquist.

```
fb2 = cwtfilterbank('SignalLength',sigLength,'SamplingFrequency',Fs);
figure
freqz(fb2)
```

Input Arguments

N — Signal length

positive integer

Signal length, specified as a positive integer greater than or equal to 4.

Fs — Sampling frequency

positive scalar

Sampling frequency in hertz, specified as a positive scalar.

Data Types: double

Ts — Sampling period

scalar duration

Sampling period, specified as a positive scalar duration.

Data Types: duration

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'Wavelet', "amor", 'CUTOFF', 75`

Wavelet — Analysis wavelet

`'Morse'` (default) | `'amor'` | `'bump'`

Analysis wavelet used to determine the minimum and maximum frequencies or periods, specified as `'Morse'`, `'amor'`, or `'bump'`. These strings specify the analytic Morse, Morlet, and bump wavelet, respectively. The default wavelet is the analytic Morse (3,60) wavelet.

For Morse wavelets, you can also parametrize the wavelet using the `TimeBandwidth` or `WaveletParameters` name-value pairs.

Example: `'Wavelet', 'bump'`

CUTOFF — Percentage of the peak magnitude

50 for the Morse wavelet | 10 for the analytic Morlet and bump wavelets

Percentage of the peak magnitude at the Nyquist, specified as a scalar between 0 and 100. Setting `CUTOFF` to 0 indicates that the wavelet frequency response decays to 0 at the Nyquist. Setting `CUTOFF` to 100 indicates that the value of the wavelet bandpass filters peaks at the Nyquist.

Data Types: `double`

StandardDeviations — Number of time standard deviations

2 (default)

Number of time standard deviations used to determine the minimum frequency (longest scale), specified as a positive integer greater than or equal to 2. For the Morse, analytic Morlet, and bump wavelets, four standard deviations generally ensures that the wavelet decays to zero at the ends of the signal support. Incrementing `'StandardDeviations'` by multiples of 4, for example `4*M`, ensures that `M` whole wavelets fit within the signal length. If unspecified, `'StandardDeviations'` defaults to 2. If the number of standard deviations is set so that $\log_2(\text{minfreq}/\text{maxfreq}) > -1/NV$ where `NV` is the number of voices per octave, `minfreq` is adjusted to $\text{maxfreq} * 2^{(-1/NV)}$.

Data Types: `double`

TimeBandwidth — Time-bandwidth for Morse wavelets

positive scalar

This property is read-only.

Time-bandwidth for Morse wavelets, specified as a positive scalar. This property is only valid when the `Wavelet` property is `'morse'`. This property specifies the time-bandwidth parameter of the Morse wavelet with the symmetry parameter (`gamma`) fixed at 3. `TimeBandwidth` is a positive number strictly greater than 3 and less than or equal to 120. The larger the time-bandwidth parameter, the more spread out the wavelet is in time and narrower the wavelet is in frequency. The standard deviation of the Morse wavelet in time is approximately $\text{sqrt}(\text{TimeBandwidth}/2)$. The standard deviation in frequency is approximately $1/2 * \text{sqrt}(2/\text{TimeBandwidth})$.

The `TimeBandwidth` and `WaveletParameters` properties cannot both be specified.

Example: `'TimeBandwidth', 4`

Data Types: `double`

WaveletParameters — Morse wavelet parameters

(3, 60) (default) | two-element vector of scalars

This property is read-only.

Morse wavelet parameters, specified as a two-element vector. The first element is the symmetry parameter (γ), which must be greater than or equal to 1. The second element is the time-bandwidth parameter, which must be strictly greater than γ . The ratio of the time-bandwidth parameter to γ cannot exceed 40. When γ is equal to 3, the Morse wavelet is perfectly symmetric in the frequency domain. The skewness is equal to 0. Values of γ greater than 3 result in positive skewness, while values of γ less than 3 result in negative skewness. `WaveletParameters` is only valid if the `Wavelet` property is set to 'Morse'.

The `WaveletParameters` and `TimeBandwidth` properties cannot both be specified.

Example: 'WaveletParameters', [4,20]

VoicesPerOctave — Number of voices per octave

10 (default) | even integer between 4 and 48

Number of voices per octave to use in determining the necessary separation between the minimum and maximum scales, specified as an even integer between 4 and 48. The minimum and maximum scales are equivalent to the minimum and maximum frequencies or maximum and minimum periods respectively.

Example: 'VoicesPerOctave', 20

Data Types: double

Output Arguments

minfreq — Minimum wavelet bandpass frequency

scalar

Minimum wavelet bandpass frequency, returned as a scalar. `minfreq` is in cycles/sample if `SamplingFrequency` is not specified. Otherwise, `minfreq` is in hertz.

maxfreq — Maximum wavelet bandpass frequency

scalar

Maximum wavelet bandpass frequency, returned as a scalar. `maxfreq` is in cycles/sample if `SamplingFrequency` is not specified. Otherwise, `maxfreq` is in hertz.

maxperiod — Maximum wavelet bandpass period

scalar duration

Maximum wavelet bandpass period, returned as a scalar duration with the same format as `Ts`.

If the number of standard deviations is set so that $\log_2(\text{maxperiod}/\text{minperiod}) < 1/NV$ where `NV` is the number of voices per octave, `maxperiod` is adjusted to $\text{minperiod} * 2^{(1/NV)}$.

minperiod — Minimum wavelet bandpass period

scalar duration

Minimum wavelet bandpass period, returned as a scalar duration with the same format as `Ts`.

If the number of standard deviations is set so that $\log_2(\text{maxperiod}/\text{minperiod}) < 1/NV$ where `NV` is the number of voices per octave, `maxperiod` is adjusted to $\text{minperiod} * 2^{(1/NV)}$.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

The `cwtfreqbounds` function supports C/C++ code generation. You must have MATLAB Coder™ to generate C/C++ code.

Usage notes and limitations:

- The sampling period (T_s) input argument is not supported.

See Also

`cwt` | `cwtfilterbank`

Introduced in R2018a

cwt

Continuous 1-D wavelet transform

Note This version of `cwt` is no longer recommended. Use the updated `cwt` instead.

Syntax

```

coefs = cwt(x,scales,'wname')
coefs = cwt(x,scales,'wname','plot')
coefs = cwt(x,scales,'wname','coloration')
coefs = cwt(x,scales,'wname','coloration',xlim)
[coefs,sgram] = cwt(x,scales,'wname','scal')
[coefs,sgram] = cwt(x,scales,'wname','scalCNT')
[coefs,frequencies] = cwt(x,scales,wname, samplingperiod)
[coefs,sgram,frequencies] = cwt(x,scales,wname, samplingperiod,'scal')

```

Description

`coefs = cwt(x,scales,'wname')` returns the continuous wavelet transform (CWT) of the real-valued signal `x`. The wavelet transform is computed for the specified scales using the analyzing wavelet `wname`. `scales` is a 1-D vector with positive elements. The character vector or string scalar `wname` denotes a wavelet recognized by `wavemngr`. `coefs` is a matrix with the number of rows equal to the length of `scales` and number of columns equal to the length of the input signal. The `k`-th row of `coefs` corresponds to the CWT coefficients for the `k`-th element in the `scales` vector.

`coefs = cwt(x,scales,'wname','plot')` plots the continuous wavelet transform coefficients, using default coloration `'absglb'`.

`coefs = cwt(x,scales,'wname','coloration')` uses the specified coloration. See “More About” on page 1-173 for coloration options.

`coefs = cwt(x,scales,'wname','coloration',xlim)` colors the coefficients using coloration and `xlim`, where `xlim` is a vector, `[x1 x2]`, with $1 \leq x1 < x2 \leq \text{length}(x)$.

`[coefs,sgram] = cwt(x,scales,'wname','scal')` returns and plots the scalogram. `'scal'` produces an image plot of the scalogram.

`[coefs,sgram] = cwt(x,scales,'wname','scalCNT')` displays a contour representation of the scalogram.

`[coefs,frequencies] = cwt(x,scales,wname, samplingperiod)` returns the frequencies in cycles per unit time corresponding to the scales and the analyzing wavelet `wname`. `samplingperiod` is a positive real-valued scalar. If the units of `samplingperiod` are seconds, the frequencies are in hertz.

`[coefs,sgram,frequencies] = cwt(x,scales,wname, samplingperiod,'scal')` returns the scalogram and the frequencies corresponding to the scales and the analyzing wavelet. If you have at least two elements in `scales`, you can also use the flag `'scalCNT'` to output the scalogram. The

samplingperiod is only used in the conversion of scales to frequencies. Specifying samplingperiod does not affect the appearance of plots generated by cwt.

Examples

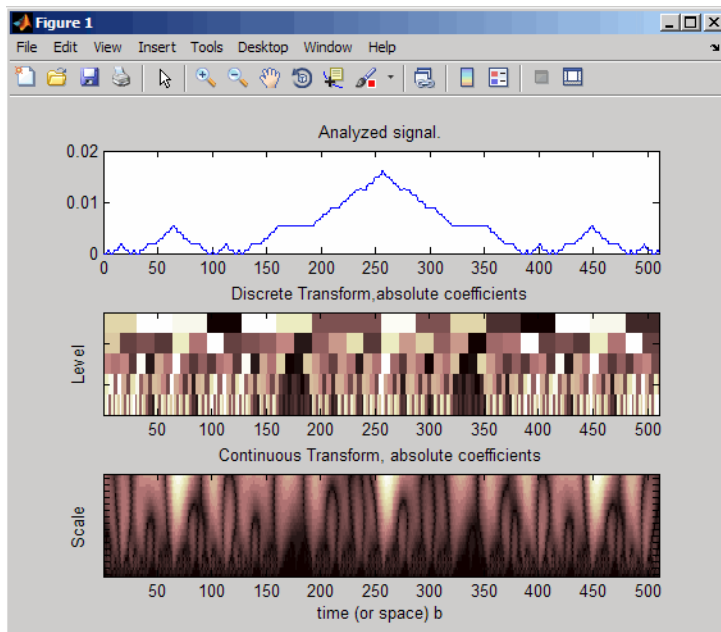

Plot the continuous wavelet transform and scalogram using sym2 wavelet at all integer scales from 1 to 32, using a fractal signal as input:

```
load vonkoch
vonkoch=vonkoch(1:510);
len = length(vonkoch);
cw1 = cwt(vonkoch,1:32,'sym2','plot');
title('Continuous Transform, absolute coefficients.')
ylabel('Scale')
[cw1,sc] = cwt(vonkoch,1:32,'sym2','scal');
title('Scalogram')
ylabel('Scale')
```

Compare discrete and continuous wavelet transforms, using a fractal signal as input:

```
load vonkoch
vonkoch=vonkoch(1:510);
len=length(vonkoch);
[c,l]=wavedec(vonkoch,5,'sym2');
% Compute and reshape DWT to compare with CWT.
cfd=zeros(5,len);
for k=1:5
    d=detcoef(c,l,k);
    d=d(ones(1,2^k),:);
    cfd(k,:)=wkeep(d(:)',len);
end
cfd=cfd(:);
I=find(abs(cfd) < sqrt(eps));
cfd(I)=zeros(size(I));
cfd=reshape(cfd,5,len);
% Plot DWT.
subplot(311); plot(vonkoch); title('Analyzed signal.');
```

```
set(gca,'xlim',[0 510]);
subplot(312);
image(flipud(wcodemat(cfd,255,'row')));
colormap(pink(255));
set(gca,'yticklabel',[]);
title('Discrete Transform,absolute coefficients');
ylabel('Level');
% Compute CWT and compare with DWT
subplot(313);
ccfs=cwt(vonkoch,1:32,'sym2','plot');
title('Continuous Transform, absolute coefficients');
set(gca,'yticklabel',[]);
ylabel('Scale');
```

More About

Scale Values

Scale values determine the degree to which the wavelet is compressed or stretched. Low scale values compress the wavelet and correlate better with high frequencies. The low scale CWT coefficients represent the fine-scale features in the input signal vector. High scale values stretch the wavelet and correlate better with the low frequency content of the signal. The high scale CWT coefficients represent the coarse-scale features in the input signal.

Coloration

Coloration is the method used to scale the coefficient values for plotting. Each coefficient is divided by the resulting coloration value.

- 'lvl' — uses maximum value in each scale
- 'glb' — uses maximum value in all scales
- 'abslvl' or 'lvlabs' — uses maximum absolute value in each scale
- 'absglb' or 'glbabs' — uses maximum absolute value in all scales
- 'scal' — produces a scaled image of the scalogram
- 'scalCNT' — produces a contour representation of the scalogram

For 3-D plots (surfaces), use the *coloration* parameter preceded by '3D', such as `coefs = cwt(..., '3Dplot')` or `coefs = cwt(..., '3Dlvl')` ...

Scalogram

Scalograms are plots that represent the percentage energy for each coefficient.

Topics

“New Wavelet for CWT”

Introduced before R2006a

cwtft

Continuous wavelet transform using FFT algorithm

Note This function is no longer recommended. Use `cwt` instead.

Syntax

```
cwtstruct = cwtft(sig)
cwtstruct = cwtft(sig,Name,Value)
cwtstruct = cwtft(...,'plot')
```

Description

`cwtstruct = cwtft(sig)` returns the continuous wavelet transform (CWT) of the 1-D input signal `sig`. `cwtft` uses an FFT algorithm to compute the CWT. `sig` can be a vector, a structure array, or a cell array. If the sampling interval of your signal is not equal to 1, you must input the sampling period with `sig` in a cell array or a structure array to obtain correct results. If `sig` is a cell array, `sig{1}` is equal to your signal and `sig{2}` is equal to the sampling interval. If `sig` is a structure array, the field `sig.val` contains your signal and `sig.period` contains the sampling interval.

By default, `cwtft` uses the analytic Morlet wavelet. See [More About](#) on page 1-180 for descriptions of valid analyzing wavelets.

For additional default values, see `scales` in “Name-Value Pair Arguments” on page 1-176.

`cwtstruct = cwtft(sig,Name,Value)` returns the continuous wavelet transform (CWT) of the 1-D input signal `sig` with additional options specified by one or more `Name, Value` pair arguments. See “Name-Value Pair Arguments” on page 1-176 for a comprehensive list.

`cwtstruct = cwtft(...,'plot')` plots the continuous wavelet transform. If the analyzing wavelet is real-valued, the original signal along with the CWT coefficient magnitudes and signed CWT coefficients are plotted. If the analyzing wavelet is complex-valued, the original signal is plotted along with the moduli, real parts, imaginary parts, and angles of the CWT coefficients. You can select the check box in the bottom left of the plot to superimpose the signal's reconstruction using `icwtft`.

Input Arguments

sig

The 1-D input signal. `sig` can be a vector, a structure array, or a cell array. If `sig` is a structure array, `sig` contains two fields: `val` and `period`. `sig.val` is the signal vector and `sig.period` is the sampling period. If `sig` is a cell array, `sig{1}` is the signal vector and `sig{2}` is the sampling period.

If `sig` is a vector, the sampling period defaults to 1.

Note If the sampling interval of your input signal is not 1, you must input the sampling interval with `sig` in a cell array or structure array to obtain correct results. If `sig` is a cell array, `sig{1}` is the 1-

D input signal and `sig{2}` is the sampling period. If `sig` is a structure array, the field `sig.val` is the 1-D input signal and `sig.period` is the sampling interval.

Name-Value Pair Arguments

scales

Scales over which to compute the CWT. The value of `scales` can be a vector, a structure array, or a cell array. If `scales` is a structure array, it contains at most five fields. The first three fields are mandatory. The last two fields are optional.

- 1 `s0` — The smallest scale. The default `s0` depends on the wavelet. See the More About on page 1-180 for descriptions of the default for each wavelet.
- 2 `nb` — Number of scales. The default `nb` depends on the wavelet. See the More About on page 1-180 for descriptions of the default for each wavelet.
- 3 `ds` — Spacing between scales. The default `ds` depends on the wavelet. See the More About on page 1-180 for descriptions of the default for each wavelet. You can construct a linear or logarithmic scale vector using `ds`. A logarithmic scale vector is constructed by default. Use the `type` field of `scales` to construct a linear scale vector.
- 4 `type` — Type of spacing between scales. `type` can be one of `'pow'` or `'lin'`. The default is `'pow'`. If `type` is equal to `'pow'`, the CWT scales are $s0 * pow.^{(0:nb-1)*ds}$. This results in a constant spacing of `ds` if you take the logarithm to the base power of the scales vector. If `type` is equal to `'lin'`, the CWT scales are linearly spaced by $s0 + (0:nb-1)*ds$.

Use the default power of two spacing to ensure an accurate approximation to the original signal based only on select scales. See the second example in “Examples” on page 1-177 for a signal approximation based on select scales.

- 5 `pow` — The base for `'pow'` spacing. The default is 2. This input is valid only if the `type` argument is `'pow'`.

If `scales` is a cell array, the first three elements of the cell array are identical to the first three elements of the structure array described in the preceding list. The last two elements of the cell array are optional and match the two optional inputs in the structure array described in the preceding list.

wavelet

Analyzing wavelet. To include a parameter for the wavelet, use a cell array. For example, to specify a fourth order derivative of a Gaussian wavelet, use `'wavelet',{'dog',4}` as in `cwtstruct = (sig,'wavelet',{'dog',4})`.

The supported analyzing wavelets are:

- `'dog'` — m -th order derivative of a Gaussian wavelet where m is a positive even integer. The default value of m is 2, which is the Mexican hat or Ricker wavelet..
- `'morl'` — Morlet wavelet. Results in an analytic Morlet wavelet. The Fourier transform of an analytic wavelet is zero for negative frequencies.
- `'morlex'` — non-analytic Morlet wavelet
- `'morl0'` — non-analytic Morlet wavelet with zero mean
- `'mexh'` — Mexican hat wavelet, which is also known as the Ricker wavelet. The Mexican hat wavelet is a special case of the m -th order derivative of a Gaussian wavelet with $m = 2$.

- 'paul' — Paul wavelet
- 'bump' — Bump wavelet

See the More About on page 1-180 for formal definitions of the supported analyzing wavelets and associated defaults.

Default: 'morl'

padmode

Signal extension mode. See `dwtmode` for supported extension modes. By default, `cwtft` does not extend the signal prior to computing the CWT. In a Fourier-transform-based CWT algorithm, extending a signal can mitigate wrap-around effects. The number of CWT coefficients in each row of the output matrix `cwtstruct.cfs` is truncated to match the length of the input signal.

Output Arguments

cwtstruct

A structure array with six fields. The fields of the structure array are:

- `cfs` — The CWT coefficient matrix. `cwtstruct.cfs` is an `nb`-by-`N` matrix where `nb` is the number of scales and `N` is the length of the input signal.
- `scales` — Vector of scales at which the CWT is computed. The length of `cwtstruct.scales` is equal to the row dimension of `cwtstruct.cfs`.
- `frequencies` — Frequencies in cycles per unit time (or space) corresponding to the scales. If the sampling period units are seconds, the frequencies are in hertz. The elements of `frequencies` are in decreasing order to correspond to the elements in the `scales` vector. Use this field to examine the CWT in the time-frequency plane.
- `omega` — Vector of angular frequencies used in the Fourier transform of the wavelet. This field is used in `icwtft` and `icwtlin` for the inversion of the CWT for all wavelets except the bump wavelet.
- `meanSIG` — Mean of the analyzed signal
- `dt` — The sampling interval of the 1-D input signal
- `wav` — Analyzing wavelet

Examples

Compute and display the CWT of sine waves with disjoint support. The sampling interval is 1/1023.

```
N = 1024;
% Sampling interval is 1/1023
t = linspace(0,1,N);
y = sin(2*pi*4*t).*(t<=0.5)+sin(2*pi*8*t).*(t>0.5);
% Because the sampling interval differs from the default
% you must input it along with the signal
% Using cell array input
sig = {y,1/1023};
cwtS1 = cwtft(sig,'plot');
```

You can display or hide the reconstructed signal using the check box at the bottom left of the figure. When you select the check box, the maximum and quadratic relative errors are computed and displayed along with the reconstructed signal.

Reconstruct an approximation to a sum of disjoint sine waves in noise using `cwtft` to decompose the signal and `icwtft` to reconstruct the approximation. Use the CWT coefficients to identify the scales isolating the sinusoidal components. Reconstruct an approximation to the signal based on those scales using the inverse CWT. To ensure an accurate approximation to the based on select scales, use the default power of two spacing in the CWT.

```
rng default % Reset random number generator for reproducible results
N = 1024;
% Sampling interval is 1/1023
t = linspace(0,1,N);
y = sin(2*pi*4*t).*(t<=0.5)+sin(2*pi*8*t).*(t>0.5);
ynoise = y+randn(size(t));
% Because the sampling interval differs from the default
% you must input it along with the signal
% Using structure array input
sig = struct('val',ynoise,'period',1/1023);
cwtS1 = cwtft(sig);
scales = cwtS1.scales;
MorletFourierFactor = 4*pi/(6+sqrt(2+6^2));
freq = 1./(scales.*MorletFourierFactor);
contour(t,freq,real(cwtS1.cfs));
```

```
xlabel('Seconds'); ylabel('Pseudo-frequency');
axis([0 t(end) 0 15]);
```

Extract the scales dominated by energy from the two sine waves and reconstruct a signal approximation using the inverse CWT.

```
cwtS2 = cwtS1;
cwtS2.cfs = zeros(size(cwtS1.cfs));
cwtS2.cfs(13:15,:) = cwtS1.cfs(13:15,:);
xrec = icwtft(cwtS2);
subplot(2,1,1);
plot(t,ynoise);
title('Sum of Disjoint Sinusoids in Noise');
subplot(2,1,2);
plot(t,xrec,'b'); hold on; axis([0 1 -4 4]);
plot(t,y,'r');
legend('Reconstructed Signal','Original Signal',...
'Location','NorthWest');
xlabel('Seconds'); ylabel('Amplitude');
```

More About

Morlet Wavelet

Both non-analytic and analytic Morlet wavelets are supported. The analytic Morlet wavelet, 'morl', is defined in the Fourier domain by:

$$\widehat{\Psi}(s\omega) = \pi^{-1/4} e^{-(s\omega - \omega_0)^2/2} U(s\omega)$$

where $U(\omega)$ is the Heaviside step function [5] on page 1-182.

The non-analytic Morlet wavelet, 'morlex', is defined in the Fourier domain by:

$$\widehat{\Psi}(s\omega) = \pi^{-1/4} e^{-(s\omega - \omega_0)^2/2}$$

'morl0' defines a non-analytic Morlet wavelet in the Fourier domain with exact zero mean:

$$\widehat{\Psi}(s\omega) = \pi^{-1/4} \left\{ e^{-(s\omega - \omega_0)^2/2} - e^{-\omega_0^2/2} \right\}$$

The default value of ω_0 is 6.

The default smallest scale for the Morlet wavelets is $s_0 = 2*dt$ where dt is the sampling period.

The default spacing between scales for the Morlet wavelets is $ds=0.4875$.

The default number of scales for the Morlet wavelets is $NbSc = \text{fix}(\log_2(\text{length}(\text{sig})*dt/s_0)/ds)$.

The default scales for the Morlet wavelet are $s_0*2.^{(0:NbSc-1)*ds}$.

m-th Order Derivative of Gaussian Wavelets

In the Fourier domain, the *m*-th order derivative of Gaussian wavelets, 'dog', are defined by:

$$\widehat{\Psi}(s\omega) = -\frac{1}{\sqrt{\Gamma(m+1/2)}} (js\omega)^m e^{-(s\omega)^2/2}$$

where $\Gamma(\cdot)$ denotes the gamma function [5] on page 1-182.

The derivative must be an even order. The default order of the derivative is 2, which is also known as the Mexican hat wavelet.

The default smallest scale for the DOG wavelet is $s_0 = 2*dt$ where dt is the sampling period.

The default spacing between scales for the DOG wavelet is $ds=0.4875$.

The default number of scales for the DOG wavelet is $NbSc = \text{fix}(\log_2(\text{length}(\text{sig})*dt/s_0)/ds)$.

The default scales for the DOG wavelet are $s_0*2.^{(0:NbSc-1)*ds}$.

Paul Wavelet

The Fourier transform of the analytic Paul wavelet, 'paul', of order *m* is:

$$\widehat{\Psi}(s\omega) = \frac{2^m}{\sqrt{m(2m-1)!}} (s\omega)^m e^{-s\omega} U(s\omega)$$

where $U(\omega)$ is the Heaviside step function [5] on page 1-182.

The default order of the Paul wavelet is 4.

The default smallest scale for the Paul wavelet is $s_0 = 2*dt$ where dt is the sampling period.

The default spacing between scales for the Paul wavelet is $ds=0.4875$.

The default number of scales for the Paul wavelet is $NbSc = \text{fix}(\log_2(\text{length}(\text{sig}) * dt / s_0) / ds)$.

The default scales for the Paul wavelet are $s_0 * 2.^{((0:NbSc-1)*ds)}$.

Bump wavelet

The Fourier transform of the analytic bump wavelet, 'bump', with parameters μ and σ is

$$\widehat{\psi}(s\omega) = e^{(1 - \frac{1}{1 - (s\omega - \mu)^2 / \sigma^2})} 1_{[(\mu - \sigma)/s, (\mu + \sigma)/s]}$$

where $1_{[(\mu - \sigma)/s, (\mu + \sigma)/s]}$ is the indicator function for the interval $(\mu - \sigma)/s \leq \omega \leq (\mu + \sigma)/s$.

Valid values for μ are [3,6]. Valid values for σ are [0.1, 1.2]. Smaller values of σ result in a wavelet with superior frequency localization but poorer time localization. Larger values of σ produce a wavelet with better time localization and poorer frequency localization.

The default values for μ and σ are 5 and 0.6 respectively.

The default smallest scale for the bump wavelet is $s_0 = 2*dt$ where dt is the sampling period.

The default spacing between scales for the bump wavelet is $ds=1/10$.

The default number of scales for the bump wavelet is $NbSc = \text{fix}(\log_2(\text{length}(\text{sig}) * dt / s_0) / ds)$.

The default scales for the bump wavelet are $s_0 * 2.^{((0:NbSc-1)*ds)}$.

Algorithms

cwtft implements the following algorithm:

- Obtain the discrete Fourier transform (DFT) of the signal using `fft`.
- Obtain the DFT of the analyzing wavelet at the appropriate angular frequencies. Scale the DFT of the analyzing wavelet at different scales to ensure different scales are directly comparable.
- Take the product of the signal DFT and the wavelet DFT over all the scales. Invert the DFT to obtain the CWT coefficients.

For a mathematical motivation for the FFT-based algorithm see "Continuous Wavelet Transform and Scale-Based Analysis".

Alternatives

- `cwt` — Computes the CWT using convolutions. `cwt` supports a wider choice of analyzing wavelets than `cwtft`, but may be more computationally expensive. The output of `cwt` is not compatible with the inverse CWT implemented with `icwtft`. To use `icwtft`, obtain the CWT with `cwtft`.

Valid analyzing wavelets for FFT-based CWT

Note This function is no longer recommended. Use `cwt` instead.

Syntax

`cwtftinfo`

Description

`cwtftinfo` displays expressions for the Fourier transforms of valid analyzing wavelets for use with `cwtft`.

Examples

Display a list of Fourier transforms for all valid analyzing wavelets.

`cwtftinfo`

More About

Morlet Wavelet

Both non-analytic and analytic Morlet wavelets are supported. The analytic Morlet wavelet, 'morl', is defined in the Fourier domain by:

$$\widehat{\Psi}(s\omega) = \pi^{-1/4} e^{-(s\omega - \omega_0)^2/2} U(s\omega)$$

where $U(\omega)$ is the Heaviside step function.

The non-analytic Morlet wavelet, 'morlex', is defined in the Fourier domain by:

$$\widehat{\Psi}(s\omega) = \pi^{-1/4} e^{-(s\omega - \omega_0)^2/2}$$

'morl0' defines a non-analytic Morlet wavelet in the Fourier domain with exact zero mean:

$$\widehat{\Psi}(s\omega) = \pi^{-1/4} \left\{ e^{-(s\omega - \omega_0)^2/2} - e^{-\omega_0^2/2} \right\}$$

The default value of ω_0 is 6.

m-th Order Derivative of Gaussian Wavelets

In the Fourier domain, the m -th order derivative of Gaussian wavelets, 'dog', is defined by:

$$\widehat{\Psi}(s\omega) = -\frac{1}{\sqrt{\Gamma(m + 1/2)}} (js\omega)^m e^{-(s\omega)^2/2}$$

The derivative must be an even order. The default order of the derivative is 2, which is also known as the *Mexican hat* or *Ricker* wavelet.

Because the unit imaginary, j , is always raised to an even power, the Fourier transform is real-valued.

Paul Wavelet

The Fourier transform of the Paul wavelet, 'paul', of order m is:

$$\widehat{\psi}(s\omega) = \frac{2^m}{\sqrt{m(2m-1)!}} (s\omega)^m e^{-s\omega} U(s\omega)$$

where $U(\omega)$ is the Heaviside step function. The Paul wavelet is analytic.

The default order of the Paul wavelet is 4.

Bump wavelet

The Fourier transform of the analytic bump wavelet, 'bump', with parameters μ and σ is

$$\widehat{\psi}(s\omega) = e^{(1 - \frac{1}{1 - (s\omega - \mu)^2/\sigma^2})} 1_{[(\mu - \sigma)/s, (\mu + \sigma)/s]}$$

where $1_{[(\mu - \sigma)/s, (\mu + \sigma)/s]}$ is the indicator function for the interval $(\mu - \sigma)/s \leq \omega \leq (\mu + \sigma)/s$.

Valid values for μ are [3,6]. Valid values for σ are [0.1, 1.2]. Smaller values of σ result in a wavelet with superior frequency localization but poorer time localization. Larger values of σ produce a wavelet with better time localization and poorer frequency localization.

The default values for μ and σ are 5 and 0.6 respectively.

cwtftinfo2

Supported 2-D CWT wavelets and Fourier transforms

Syntax

```
cwtftinfo2
cwtftinfo2(wname)
```

Description

`cwtftinfo2` lists the supported 2-D continuous wavelet transform (CWT) wavelets and corresponding parameters for use with `cwtft2`.

`cwtftinfo2(wname)` displays the equation for the 2-D Fourier transform of the wavelet, `wname`. The figure with the 2-D Fourier transform of the analyzing wavelet has a drop-down list from which you can select other wavelets.

Examples

Available Wavelets with Parameters

Introduced in R2013b

cwtft2

2-D continuous wavelet transform

Syntax

```
cwtstruct = cwtft2(x)
cwtstruct = cwtft2(x,'plot')
cwtstruct = cwtft2(x,Name,Value)
```

Description

`cwtstruct = cwtft2(x)` returns the 2-D continuous wavelet transform (CWT) of the 2-D matrix, `x`. `cwtft2` uses a Fourier transform-based algorithm in which the 2-D Fourier transforms of the input data and analyzing wavelet are multiplied together and inverted.

`cwtstruct = cwtft2(x,'plot')` plots the data and the 2-D CWT.

`cwtstruct = cwtft2(x,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

Examples

Compare Isotropic and Anisotropic Wavelets

Shows how an isotropic wavelet does not discern the orientation of features while an anisotropic wavelet does. The example uses the Mexican hat isotropic wavelet and the directional (anisotropic) Cauchy wavelet.

Load and view the hexagon image.

```
Im = imread('hexagon.jpg');
imagesc(Im); colormap(jet);
```

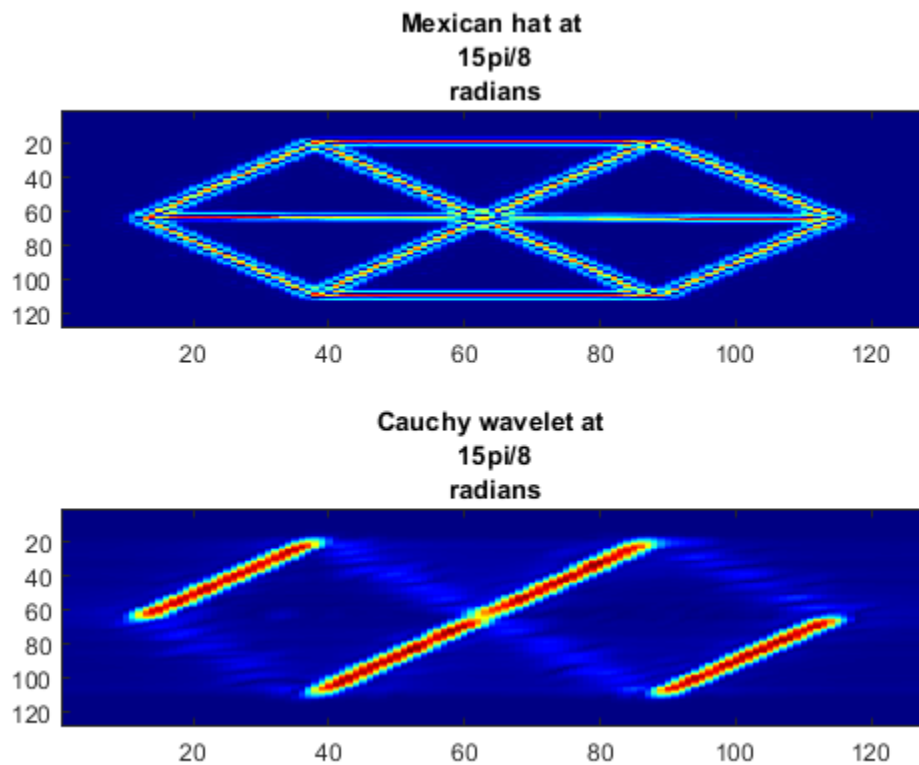

Obtain the scale-one 2-D CWT with both the Mexican hat and Cauchy wavelets. Specify a vector of angles going from 0 to $15\pi/8$ in $\pi/8$ increments.

```
cwtcauchy = cwtft2(Im, 'wavelet', 'cauchy', 'scales', 1, ...
    'angles', 0:pi/8:2*pi-pi/8);
cwtmexh = cwtft2(Im, 'wavelet', 'mexh', 'scales', 1, ...
    'angles', 0:pi/8:2*pi-pi/8);
```

Visualize the scale-one 2-D CWT coefficient magnitudes at each angle.

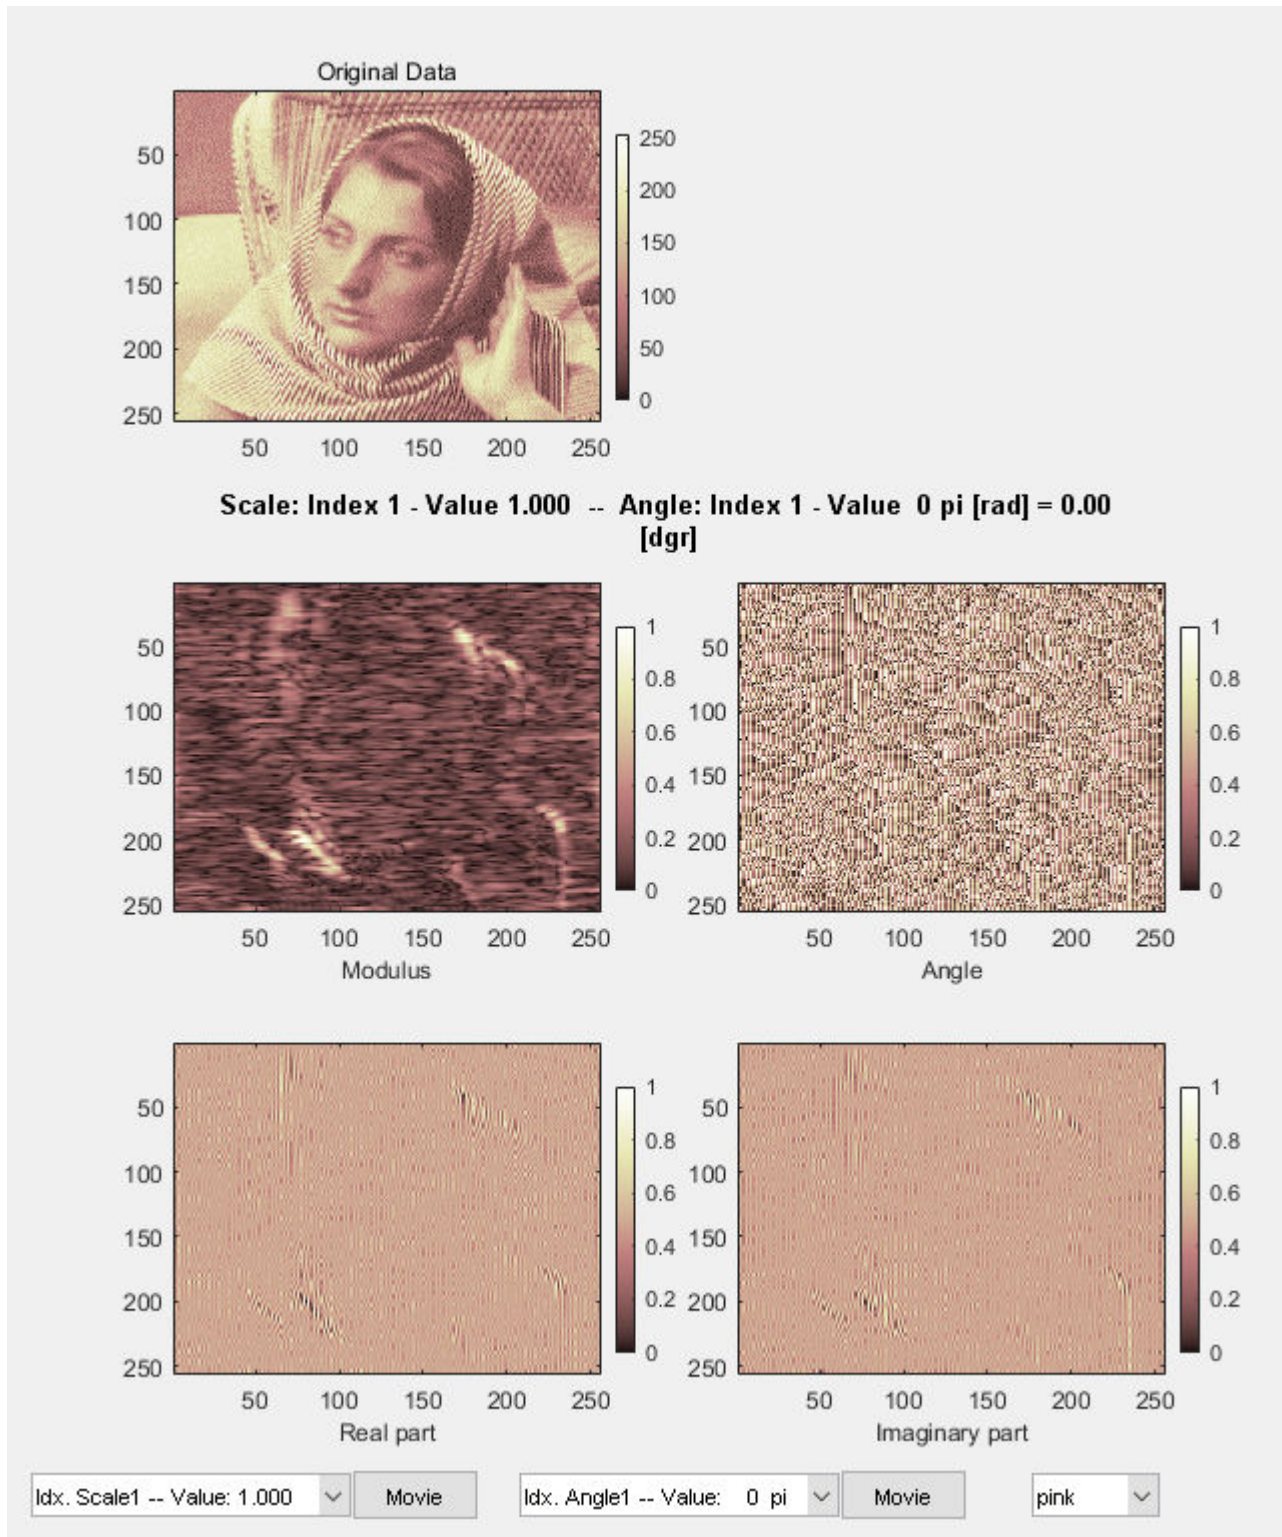

```
angz = {'0', 'pi/8', 'pi/4', '3pi/8', 'pi/2', '5pi/8', '3pi/4', ...
    '7pi/8', 'pi', '9pi/8', '5pi/4', '11pi/8', '3pi/2', ...
    '13pi/8', '7pi/4', '15pi/8'};
for angn = 1:length(angz)
    subplot(211)
    imagesc(abs(cwtmexh.cfs(:,:,1,1,angn)));
    title(['Mexican hat at ' angz(angn) 'radians']);
    subplot(212)
    imagesc(abs(cwtcauchy.cfs(:,:,1,1,angn)));
    title(['Cauchy wavelet at ' angz(angn) 'radians']);
    pause(1);
end
```

Plot 2-D CWT

Load an image of a woman, obtain the 2-D CWT using the Morlet wavelet, and plot the CWT coefficients.

```
load woman;  
cwtmorl = cwtft2(X, 'scales', 1:4, 'angles', 0:pi/2:3*pi/2, 'plot');
```

2-D CWT with Morlet Wavelet

Obtain the 2-D CWT of the star image using the default Morlet wavelet, scales $2^{(0:5)}$, and an angle of 0.

```
Im = imread('star.jpg');  
cwtout = cwtft2(Im);
```

Input Arguments

x — Input data

array

Input data, specified as a 2-D matrix or 3-D array. If the input data is a 3-D array, the input matrix is a truecolor image.

Example: `X = imread('stars.jpg');`

Data Types: `double` | `uint8`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'wavelet', 'paul', 'scales', 2^(0:5)` specifies to use the Paul wavelet and a vector of scales.

angles — Angles

0 (default) | scalar | vector

Angles in radians, specified as a comma-separated pair consisting of `'angles'` and either a scalar or a vector.

Example: `'angles', [0 pi/2 pi]`

norm — Normalization

'L2' (default) | 'L1' | 'L0'

Normalization used in the 2-D CWT, specified as a comma-separated pair consisting of `'norm'` and one of these character vectors:

- `'L2'` — The Fourier transform of the analyzing wavelet at a given scale is multiplied by the corresponding scale. `'L2'` is the default normalization.
- `'L1'` — The Fourier transform of the analyzing wavelet is multiplied by 1 at all scales.
- `'L0'` — The Fourier transform of the analyzing wavelet at a given scale is multiplied by the square of the corresponding scale.

Example: `'norm', 'L1'`

scales — Scales

$2^{(0:5)}$ (default) | scalar | vector

Scales, specified as a comma-separated pair consisting of 'scales' and either a positive real-valued scalar or a vector of positive real numbers.

Example: 'scales', 2^(1:6)

wavelet — Analyzing wavelet

'morl' (default) | character vector | string scalar | structure | cell array

Analyzing wavelet, specified as a comma-separated pair consisting of 'wavelet' and a character vector, a string scalar, a structure, or a cell array. `cwtftinfo2` provides a comprehensive list of supported wavelets and associated parameters.

If you specify 'wavelet' as a structure, the structure must contain two fields:

- `name` — the character vector or string scalar corresponding to a supported wavelet.
- `param` — a cell array with the parameters of the wavelet.

If you specify 'wavelet' as a cell array, `wav`, the cell array must contain two elements:

- `wav{1}` — the character vector or string scalar corresponding to a supported wavelet.
- `wav{2}` — a cell array with the parameters of the wavelet.

Example: 'wavelet', {'morl', {6,1,1}}

Example: 'wavelet', struct('name', 'paul', 'param', {'p', 2})

Output Arguments

cwtstruct — 2-D CWT

structure

The 2-D CWT, returned as a structure with the following fields:

wav — Analyzing wavelet and parameters

structure

Analyzing wavelet and parameters, returned as a structure with the following fields:

- `wname` — name
- `param` — parameters

wav_norm — Normalization constants

matrix

Normalization constants, returned as a M -by- N matrix where M is the number of scales and N is the number of angles.

cfs — CWT coefficients

array

CWT coefficients, returned as an N-D array. The row and column dimensions of the array equal the row and column dimensions of the input data. The third page of the array is equal to 1 or 3 depending on whether the input data is a grayscale or truecolor image. The fourth page of the array is equal to the number of scales and the fifth page of the array is equal to the number of angles.

scales — Scales

vector

Scales for the 2-D CWT, returned as a row vector.

angles — Angles

vector

Angles for the 2-D CWT, returned as a row vector.

meanSIG — Mean

scalar

Mean of the input data, returned as a scalar

dbaux

Daubechies wavelet filter computation

Syntax

```
W = dbaux(N)
W = dbaux(N, SUMW)
```

Description

The dbaux function generates the scaling filter coefficients for the "extremal phase" Daubechies wavelets.

$W = \text{dbaux}(N)$ is the order N Daubechies scaling filter such that $\text{sum}(W) = 1$.

Note

- Instability may occur when N is too large. Starting with values of N in the 30s range, function output will no longer accurately represent scaling filter coefficients.
 - For $N = 1, 2,$ and 3 , the order N Symlet filters and order N Daubechies filters are identical. See "Extremal Phase" on page 1-202.
-

$W = \text{dbaux}(N, \text{SUMW})$ is the order N Daubechies scaling filter such that $\text{sum}(W) = \text{SUMW}$.

$W = \text{dbaux}(N, 0)$ is equivalent to $W = \text{dbaux}(N, 1)$.

Examples

Daubechies Extremal Phase Scaling Filter with Specified Sum

This example shows how to determine the Daubechies extremal phase scaling filter with a specified sum. The two most common values for the sum are $\sqrt{2}$ and 1.

Construct two versions of the db4 scaling filter. One scaling filter sums to $\sqrt{2}$ and the other version sums to 1.

```
NumVanishingMoments = 4;
h = dbaux(NumVanishingMoments, sqrt(2));
m0 = dbaux(NumVanishingMoments, 1);
```

The filter with sum equal to $\sqrt{2}$ is the synthesis (reconstruction) filter returned by wfilters and used in the discrete wavelet transform.

```
[LoD, HiD, LoR, HiR] = wfilters('db4');
max(abs(LoR-h))
```

```
ans = 4.2590e-13
```

For orthogonal wavelets, the analysis (decomposition) filter is the time-reverse of the synthesis filter.

```
max(abs(LoD-flip1r(h)))
```

```
ans = 4.2590e-13
```

Symlet and Daubechies Scaling Filters

This example shows that symlet and Daubechies scaling filters of the same order are both solutions of the same polynomial equation.

Generate the order 4 Daubechies scaling filter and plot it.

```
wdb4 = dbaux(4)
```

```
wdb4 = 1×8
```

```
0.1629 0.5055 0.4461 -0.0198 -0.1323 0.0218 0.0233 -0.0075
```

```
stem(wdb4)
```

```
title('Order 4 Daubechies Scaling Filter')
```

wdb4 is a solution of the equation: $P = \text{conv}(\text{wrev}(w), w) * 2$, where P is the "Lagrange trous" filter for $N = 4$. Evaluate P and plot it. P is a symmetric filter and wdb4 is a minimum phase solution of the previous equation based on the roots of P.

```
P = conv(wrev(wdb4),wdb4)*2;
stem(P)
title('Lagrange trous' filter')
```

Generate wsym4, the order 4 symlet scaling filter and plot it. The Symlets are the "least asymmetric" Daubechies' wavelets obtained from another choice between the roots of P.

```
wsym4 = symaux(4)
```

```
wsym4 = 1×8
```

```
0.0228 -0.0089 -0.0702 0.2106 0.5683 0.3519 -0.0210 -0.0536
```

```
stem(wsym4)
title('Order 4 Symlet Scaling Filter')
```

Compute `conv(wrev(wsym4),wsym4)*2` and confirm that `wsym4` is another solution of the equation $P = \text{conv}(wrev(w),w)*2$.

```
P_sym = conv(wrev(wsym4),wsym4)*2;
err = norm(P_sym-P)
```

```
err = 1.8677e-15
```

Extremal Phase

This example demonstrates that for a given support, the cumulative sum of the squared coefficients of a scaling filter increase more rapidly for an extremal phase wavelet than other wavelets.

Generate the scaling filter coefficients for the `db15` and `sym15` wavelets. Both wavelets have support of width $2 \times 15 - 1 = 29$.

```
[~,~,LoR_db,~] = wfilters('db15');
[~,~,LoR_sym,~] = wfilters('sym15');
```

Next, generate the scaling filter coefficients for the `coif5` wavelet. This wavelet also has support of width $6 \times 5 - 1 = 29$.

```
[~,~,LoR_coif,~] = wfilters('coif5');
```

Confirm the sum of the coefficients for all three wavelets equals $\sqrt{2}$.

```
sqrt(2)-sum(LoR_db)
```

```
ans = 2.2204e-16
```

```
sqrt(2)-sum(LoR_sym)
```

```
ans = 0
```

```
sqrt(2)-sum(LoR_coif)
```

```
ans = 2.2204e-16
```

Plot the cumulative sums of the squared coefficients. Note how rapidly the Daubechies sum increases. This is because its energy is concentrated at small abscissas. Since the Daubechies wavelet has extremal phase, the cumulative sum of its squared coefficients increases more rapidly than the other two wavelets.

```
plot(cumsum(LoR_db.^2), 'rx-')
hold on
plot(cumsum(LoR_sym.^2), 'mo-')
plot(cumsum(LoR_coif.^2), 'b*-')
legend('Daubechies', 'Symlet', 'Coiflet')
title('Cumulative Sum')
```

Input Arguments

N — Order of Daubechies scaling filter

positive integer

Order of Daubechies scaling filter, specified as a positive integer.

Data Types: `single` | `double`

SUMW — Sum of coefficients

1 (default) | positive scalar

Sum of coefficients, specified as a positive scalar. Set to `sqrt(2)` to generate vector of coefficients whose norm is 1.

Data Types: `single` | `double`

Output Arguments

W — Scaling filter coefficients

vector

Scaling filter coefficients returned as a vector.

The scaling filter coefficients satisfy a number of properties. As the example “Daubechies Extremal Phase Scaling Filter with Specified Sum” on page 1-197 demonstrates, you can construct scaling filter coefficients with a specific sum. If $\{h_k\}$ denotes the set of order N Daubechies scaling filter

coefficients, where $n = 1, \dots, 2N$, then $\sum_{n=1}^{2N} h_n^2 = 1$. The coefficients also satisfy the relation

$\sum_n h(n)h(n - 2k) = \delta(k)$. You can use these properties to check your results.

Limitations

- The computation of the dbN Daubechies scaling filter requires the extraction of the roots of a polynomial of order 4N. Instability may occur beginning with values of N in the 30s.

More About

Extremal Phase

Constructing a compactly supported orthogonal wavelet basis involves choosing roots of a particular polynomial equation. Different choices of roots will result in wavelets whose phases are different. Choosing roots that lie within the unit circle in the complex plane results in a filter with highly nonlinear phase. Such a wavelet is said to have extremal phase, and has energy concentrated at small abscissas. Let $\{h_k\}$ denote the set of scaling coefficients associated with an extremal phase wavelet, where $k = 1, \dots, M$. Then for any other set of scaling coefficients $\{g_k\}$ resulting from a different choice of roots, the following inequality will hold for all $J = 1, \dots, M$:

$$\sum_{k=1}^J g_k^2 \leq \sum_{k=1}^J h_k^2$$

The $\{h_k\}$ are sometimes called a *minimal delay filter* [2].

The polynomial equation mentioned above depends on the number of vanishing moments N for the wavelet. To construct a wavelet basis involves choosing roots of the equation. In the case of least asymmetric wavelets and extremal phase wavelets for orders 1, 2, and 3, there are effectively no choices to make. For $N = 1, 2,$ and $3,$ the dbN and $symN$ filters are equal. The example "Symlet and Daubechies Scaling Filters" on page 1-198 shows that two different scaling filters can satisfy the same polynomial equation. For additional information, see Daubechies [1].

Algorithms

The algorithm used is based on a result obtained by Shensa [3], showing a correspondence between the "Lagrange à trous" filters and the convolutional squares of the Daubechies wavelet filters.

The computation of the order N Daubechies scaling filter w proceeds in two steps: compute a "Lagrange à trous" filter $P,$ and extract a square root. More precisely:

- P the associated "Lagrange à trous" filter is a symmetric filter of length $4N-1.$ P is defined by

$$P = [a(N) \ 0 \ a(N-1) \ 0 \ \dots \ 0 \ a(1) \ 1 \ a(1) \ 0 \ a(2) \ 0 \ \dots \ 0 \ a(N)]$$

- where

$$a(k) = \frac{\prod_{\substack{i = -N+1 \\ i \neq k}}^N \left(\frac{1}{2} - i\right)}{\prod_{\substack{i = -N+1 \\ i \neq k}}^N (k - i)} \quad \text{for } k = 1, \dots, N$$

- Then, if w denotes dbN Daubechies scaling filter of sum $\sqrt{2},$ w is a square root of $P:$

$$P = \text{conv}(w \text{rev}(w), w) \text{ where } w \text{ is a filter of length } 2N.$$

The corresponding polynomial has N zeros located at -1 and $N-1$ zeros less than 1 in modulus.

Note that other methods can be used; see various solutions of the spectral factorization problem in Strang-Nguyen [4] (p. 157).

Introduced before R2006a

dbwavf

Daubechies wavelet filter

Syntax

```
f = dbwavf(wname)
```

Description

`f = dbwavf(wname)` returns the scaling filter associated with the Daubechies wavelet specified by `wname`. `f` is a real-valued vector.

Examples

Scaling Filter Associated With Daubechies Wavelet

Specify the order 4 Daubechies wavelet.

```
wname = 'db4';
```

Compute the corresponding scaling filter.

```
f = dbwavf(wname);  
f'
```

```
ans = 8×1

ddencmp

Default values for denoising or compression

Syntax

```
[thr,sorh,keepapp] = ddencmp(in1,in2,x)
[ ___,crit] = ddencmp(in1,'wp',x)
```

Description

ddencmp returns default values for denoising or compression for the critically sampled discrete wavelet or wavelet packet transform.

[thr,sorh,keepapp] = ddencmp(in1,in2,x) returns default values for denoising or compression, using wavelets or wavelet packets, of the input data *x*. *x* is a real-valued vector or 2-D matrix. thr is the threshold, and sorh indicates soft or hard thresholding. keepapp can be used as a flag to set whether or not the approximation coefficients are thresholded.

- Set in1 to 'den' for denoising or 'cmp' for compression.
- Set in2 to 'wv' to use wavelets or 'wp' to use wavelet packets.

[___,crit] = ddencmp(in1,'wp',x) also returns the entropy type, crit. See wentropy for more information.

Examples

Default Global Threshold for Wavelet Denoising

Determine the default global denoising threshold for an $N(0,1)$ white noise input. Create an $N(0,1)$ white noise input. Change the DWT extension mode to periodic. Set the random number generator to the default initial settings for reproducible results.

```
dwtmode('per','nodisp');
rng default;
x = randn(512,1);
```

Use ddencmp to obtain the default global threshold for wavelet denoising. Demonstrate that the threshold is equal to the universal threshold of Donoho and Johnstone scaled by a robust estimate of the variance.

```
[thr,sorh,keepapp] = ddencmp('den','wv',x);
[A,D] = dwt(x,'db1');
noiselev = median(abs(D))/0.6745;
thresh = sqrt(2*log(length(x)))*noiselev;
```

Compare the value of the variable thr to the value of thresh.

```
thr
```

```
thr = 3.3639
```

```
thresh
```

```
thresh = 3.3639
```

Default Global Threshold for Wavelet Packet Compression

Determine the default global compression threshold for an $N(0,1)$ white noise input.

Create an $N(0,1)$ white noise input. Set the DWT extension mode to periodic. Set the random number generator to the default initial settings for reproducible results.

```
dwtmode('per','nodisp')
rng default
x = randn(512,1);
```

Use `ddencmp` with the `'cmp'` and `'wp'` input arguments to return the default global compression threshold for a wavelet packet transform.

```
[thr,sorh,keepapp,crit] = ddencmp('cmp','wp',x)
thr = 0.6424
```

```
sorh =
'h'
```

```
keepapp = 1
```

```
crit =
'threshold'
```

Compare with the default values returned for denoising.

```
[thr,sorh,keepapp,crit] = ddencmp('den','wp',x)
thr = 4.1074
```

```
sorh =
'h'
```

```
keepapp = 1
```

```
crit =
'sure'
```

Input Arguments

in1 — Purpose

```
'den' | 'cmp'
```

Purpose of `ddencmp` output, specified as:

- `'den'` — Denoising
- `'cmp'` — Compression

in2 — Transform type

'wv' | 'wp'

Transform type to be used for denoising or compression, specified as:

- 'wv' — Critically sampled discrete wavelet transform. This output can be used with `wdencomp`.
- 'wp' — Critically sampled wavelet packet transform. This output can be used with `wpdencmp`.

x — Input data

real-valued vector or matrix

Input data to be denoised or compressed, specified as a real-valued vector or 2-D matrix.

Data Types: `double`

Output Arguments**thr — Threshold**

real number

Threshold for denoising or compression, returned as a real number. Use this output with `wdencomp` or `wpdencmp`.

sorh — Thresholding type

character

Thresholding type for denoising or compression, returned as a character.

- 's' — Soft thresholding
- 'h' — Hard thresholding

Use this output with `wdencomp` or `wpdencmp`.

keepapp — Threshold approximation setting

1 (default)

Threshold approximation setting, returned as 1. Use this output with `wdencomp` or `wpdencmp`. If `keepapp = 1`, the approximation coefficients are not thresholded.

crit — Entropy type

character vector

Entropy type when denoising or compressing with wavelet packets, returned as a character vector. Use this output only with `wpdencmp`. See `wentropy` for more information.

Introduced before R2006a

dddtree

Dual-tree and double-density 1-D wavelet transform

Syntax

```
wt = dddtree(typetree,x,level,fdf,df)
wt = dddtree(typetree,x,level,fname)
wt = dddtree(typetree,x,level,fname1,fname2)
```

Description

`wt = dddtree(typetree,x,level,fdf,df)` returns the `typetree` discrete wavelet transform (DWT) of the 1-D input signal, `x`, down to level, `level`. The wavelet transform uses the decomposition (analysis) filters, `fdf`, for the first level and the analysis filters, `df`, for subsequent levels. Supported wavelet transforms are the critically sampled DWT, double-density, dual-tree complex, and dual-tree double-density complex wavelet transform. The critically sampled DWT is a filter bank decomposition in an orthogonal or biorthogonal basis (nonredundant). The other wavelet transforms are oversampled filter banks.

`wt = dddtree(typetree,x,level,fname)` uses the filters specified by `fname` to obtain the wavelet transform. Valid filter specifications depend on the type of wavelet transform. See `dtfilters` for details.

`wt = dddtree(typetree,x,level,fname1,fname2)` uses the filters specified in `fname1` for the first stage of the dual-tree wavelet transform and the filters specified in `fname2` for subsequent stages of the dual-tree wavelet transform. Specifying different filters for stage 1 is valid and necessary only when `typetree` is `'cplxdt'` or `'cplxddd'`.

Examples

Complex Dual-Tree Wavelet Transform

Obtain the complex dual-tree wavelet transform of the noisy Doppler signal. The FIR filters in the first and subsequent stages result in an approximately analytic wavelet as required.

Use `dtfilters` to create the first-stage Farras analysis filters and 6-tap Kingsbury Q-shift analysis filters for the subsequent stages of the multiresolution analysis.

```
df = dtfilters('dtf1');
```

The Farras and Kingsbury filters are in `df{1}` and `df{2}`, respectively. Load the noisy Doppler signal and obtain the complex dual-tree wavelet transform down to level 4.

```
load noisdopp;
wt = dddtree('cplxdt',noisdopp,4,df{1},df{2});
```

Plot an approximation based on the level-four approximation coefficients.

```
xapp = dddtreecfs('r',wt,'scale',{5});
plot(noisdopp)
```

```

hold on
plot(cell2mat(xapp), 'r', 'linewidth', 3)
axis tight

```

Using the output of `dtfilters`, or the filter name itself, in `dddtree` is preferable to manually entering truncated filter coefficients. To demonstrate the negative impact on signal reconstruction, create truncated versions of the Farras and Kingsbury analysis filters. Display the differences between the truncated and original filters.

max(max(abs(df{1}{1}-Faf{1})))
ans = 2.6792e-05

max(max(abs(df{1}{2}-Faf{2})))
ans = 2.6792e-05

max(max(abs(df{2}{1}-af{1})))
ans = 3.6160e-05

max(max(abs(df{2}{2}-af{2})))
ans = 3.6160e-05

```

Obtain the complex dual-tree wavelet transform down to level 4 using the truncated filters. Take the inverse transform and compare the reconstruction with the original signal.

```

wt = dddtree('cplxdt',noisdopp,4,Faf,af);
xrec = idddtree(wt);
max(abs(noisdopp-xrec))

ans = 0.0024

```

Do the same using the filter name. Confirm the difference is smaller.

```

wt = dddtree('cplxdt',noisdopp,4,'dtf1');
xrec = idddtree(wt);
max(abs(noisdopp-xrec))

ans = 2.1893e-07

```

Double-Density Wavelet Transform

Obtain the double-density wavelet transform of a signal with two discontinuities. Use the level-one detail coefficients to localize the discontinuities.

Create a signal consisting of a 2-Hz sine wave with a duration of 1 second. The sine wave has discontinuities at 0.3 and 0.72 seconds.

```
N = 1024;
t = linspace(0,1,1024);
x = 4*sin(4*pi*t);
x = x - sign(t - .3) - sign(.72 - t);
plot(t,x)
xlabel('Time (s)')
title('Original Signal')
grid on
```

Obtain the double-density wavelet transform of the signal. Reconstruct an approximation based on the level-one detail coefficients by first setting the lowpass (scaling) coefficients equal to 0. Plot the result. Observe features in the reconstruction align with the signal discontinuities.

```
wt = dddtree('ddt',x,1,'filters1');
wt.cfs{2} = zeros(1,512);
xrec = idddtree(wt);
plot(t,xrec,'linewidth',2)
set(gca,'xtick',[0 0.3 0.72 1])
set(gca,'xgrid','on')
```

First-Level Detail Coefficients Approximation — Complex Dual-Tree

Obtain the complex dual-tree wavelet transform of a signal with two discontinuities. Use the first-level detail coefficients to localize the discontinuities.

Create a signal consisting of a 2-Hz sine wave with a duration of 1 second. The sine wave has discontinuities at 0.3 and 0.72 seconds.

```
N = 1024;
t = linspace(0,1,1024);
x = 4*sin(4*pi*t);
x = x - sign(t - .3) - sign(.72 - t);
plot(t,x)
xlabel('Time (s)')
title('Original Signal')
grid on
```

Obtain the dual-tree wavelet transform of the signal, reconstruct an approximation based on the level-one detail coefficients, and plot the result.

```
wt = dddtree('cplxdt',x,1,'FSfarras','qshift06');  
wt.cfs{2} = zeros(1,512,2);  
xrec = idddtree(wt);  
plot(t,xrec,'linewidth',2)  
set(gca,'xtick',[0 0.3 0.72 1])  
set(gca,'xgrid','on')
```

Input Arguments

typetree — Type of wavelet decomposition

'dwt' | 'ddt' | 'cplxdt' | 'cplxdddtt'

Type of wavelet decomposition, specified as one of 'dwt', 'ddt', 'cplxdt', or 'cplxdddtt'. The type, 'dwt', gives a critically sampled (nonredundant) discrete wavelet transform. The other decomposition types produce oversampled wavelet transforms. 'ddt' produces a double-density wavelet transform. 'cplxdt' produces a dual-tree complex wavelet transform. 'cplxdddtt' produces a double-density dual-tree complex wavelet transform.

x — Input signal

vector

Input signal, specified as an even-length row or column vector. If L is the value of the `level` of the wavelet decomposition, 2^L must divide the length of x . Additionally, the length of the signal must be greater than or equal to the product of the maximum length of the decomposition (analysis) filters and $2^{(L-1)}$.

Data Types: double

level — Level of wavelet decomposition

positive integer

Level of the wavelet decomposition, specified as an integer. If L is the value of `level`, 2^L must divide the length of `x`. Additionally, the length of the signal must be greater than or equal to the product of the maximum length of the decomposition (analysis) filters and $2^{(L-1)}$.

Data Types: `double`

fdf — Level-one analysis filters

matrix | cell array

The level-one analysis filters, specified as a matrix or cell array of matrices. Specify `fdf` as a matrix when `typetree` is `'dwt'` or `'ddt'`. The size and structure of the matrix depend on the `typetree` input as follows:

- `'dwt'` — This is the critically sampled discrete wavelet transform. In this case, `fdf` is a two-column matrix with the lowpass (scaling) filter in the first column and the highpass (wavelet) filter in the second column.
- `'ddt'` — This is the double-density wavelet transform. The double-density DWT is a three-channel perfect reconstruction filter bank. `fdf` is a three-column matrix with the lowpass (scaling) filter in the first column and the two highpass (wavelet) filters in the second and third columns. In the double-density wavelet transform, the single lowpass and two highpass filters constitute a three-channel perfect reconstruction filter bank. This is equivalent to the three filters forming a tight frame. You cannot arbitrarily choose the two wavelet filters in the double-density DWT. The three filters together must form a tight frame.

Specify `fdf` as a 1-by-2 cell array of matrices when `typetree` is a dual-tree transform, `'cplxdt'` or `'cplxddd'`. The size and structure of the matrix elements depend on the `typetree` input as follows:

- For the dual-tree complex wavelet transform, `'cplxdt'`, `fdf{1}` is a two-column matrix containing the lowpass (scaling) filter and highpass (wavelet) filters for the first tree. The scaling filter is the first column and the wavelet filter is the second column. `fdf{2}` is a two-column matrix containing the lowpass (scaling) and highpass (wavelet) filters for the second tree. The scaling filter is the first column and the wavelet filter is the second column.
- For the double-density dual-tree complex wavelet transform, `'cplxddd'`, `fdf{1}` is a three-column matrix containing the lowpass (scaling) and two highpass (wavelet) filters for the first tree and `fdf{2}` is a three-column matrix containing the lowpass (scaling) and two highpass (wavelet) filters for the second tree.

Data Types: `double`

df — Analysis filters for levels > 1

matrix | cell array

Analysis filters for levels > 1, specified as a matrix or cell array of matrices. Specify `df` as a matrix when `typetree` is `'dwt'` or `'ddt'`. The size and structure of the matrix depend on the `typetree` input as follows:

- `'dwt'` — This is the critically sampled discrete wavelet transform. In this case, `df` is a two-column matrix with the lowpass (scaling) filter in the first column and the highpass (wavelet) filter in the second column. For the critically sampled orthogonal or biorthogonal DWT, the filters in `df` and `fdf` must be identical.
- `'ddt'` — This is the double-density wavelet transform. The double-density DWT is a three-channel perfect reconstruction filter bank. `df` is a three-column matrix with the lowpass (scaling) filter in the first column and the two highpass (wavelet) filters in the second and third columns. In the

double-density wavelet transform, the single lowpass and two highpass filters must constitute a three-channel perfect reconstruction filter bank. This is equivalent to the three filters forming a tight frame. For the double-density DWT, the filters in `df` and `fdf` must be identical.

Specify `df` as a 1-by-2 cell array of matrices when `typetree` is a dual-tree transform, `'cplxdt'` or `'cplxddd'`. For dual-tree transforms, the filters in `fdf` and `df` must be different. The size and structure of the matrix elements in the cell array depend on the `typetree` input as follows:

- For the dual-tree complex wavelet transform, `'cplxdt'`, `df{1}` is a two-column matrix containing the lowpass (scaling) and highpass (wavelet) filters for the first tree. The scaling filter is the first column and the wavelet filter is the second column. `df{2}` is a two-column matrix containing the lowpass (scaling) and highpass (wavelet) filters for the second tree. The scaling filter is the first column and the wavelet filter is the second column.
- For the double-density dual-tree complex wavelet transform, `'cplxddd'`, `df{1}` is a three-column matrix containing the lowpass (scaling) and two highpass (wavelet) filters for the first tree and `df{2}` is a three-column matrix containing the lowpass (scaling) and two highpass (wavelet) filters for the second tree.

Data Types: `double`

fname — Filter name

character vector | string scalar

Filter name, specified as a character vector or string scalar. For the critically sampled DWT, specify any valid orthogonal or biorthogonal wavelet filter. See `wfilters` for details. For the double-density wavelet transform, `'ddt'`, valid choices are `'filters1'` and `'filters2'`. For the complex dual-tree wavelet transform, valid choices are `'dtfP'` with $P = 1, 2, 3, 4$. For the double-density dual-tree wavelet transform, the only valid choice is `'dddtf1'`. See `dtfilters` for more details on valid filter names for the oversampled wavelet filter banks.

Data Types: `char`

fname1 — First-stage filter name

character vector | string scalar

First-stage filter name, specified as a character vector or string scalar. Specifying a different filter for the first stage is valid and necessary only in the dual-tree transforms, `'cplxdt'` and `'cplxddd'`. In the complex dual-tree wavelet transform, you can use any valid wavelet filter for the first stage. In the double-density dual-tree wavelet transform, the first-stage filters must form a three-channel perfect reconstruction filter bank.

Data Types: `char`

fname2 — Filter name for stages > 1

character vector | string scalar

Filter name for stages > 1, specified as a character vector or string scalar. You must specify a first-level filter that is different from the wavelet and scaling filters in subsequent levels when using the dual-tree wavelet transforms, `'cplxdt'` or `'cplxddd'`. See `dtfilters` for valid choices.

Data Types: `char`

Output Arguments

wt — Wavelet transform

structure

Wavelet transform, returned as a structure with these fields:

type — Type of wavelet decomposition (filter bank)

'dwt' | 'ddt' | 'cplxdt' | 'cplxdddtt'

Type of wavelet decomposition (filter bank) used in the analysis, returned as one of 'dwt', 'ddt', 'cplxdt', or 'cplxdddtt'. The type, 'dwt', gives a critically sampled discrete wavelet transform. The other types correspond to oversampled wavelet transforms. 'ddt' is a double-density wavelet transform, 'cplxdt' is a dual-tree complex wavelet transform, and 'cplxdddtt' is a double-density dual-tree complex wavelet transform.

level — Level of the wavelet decomposition

positive integer

Level of wavelet decomposition, returned as a positive integer.

filters — Decomposition (analysis) and reconstruction (synthesis) filters

structure

Decomposition (analysis) and reconstruction (synthesis) filters, returned as a structure with these fields:

Fdf — First-stage analysis filters

matrix | cell array

First-stage analysis filters, returned as an N -by-2 or N -by-3 matrix for single-tree wavelet transforms, or a cell array of two N -by-2 or N -by-3 matrices for dual-tree wavelet transforms. The matrices are N -by-3 for the double-density wavelet transforms. For an N -by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N -by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage analysis filters for the corresponding tree.

Df — Analysis filters for levels > 1

matrix | cell array

Analysis filters for levels > 1, returned as an N -by-2 or N -by-3 matrix for single-tree wavelet transforms, or a cell array of two N -by-2 or N -by-3 matrices for dual-tree wavelet transforms. The matrices are N -by-3 for the double-density wavelet transforms. For an N -by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N -by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the analysis filters for the corresponding tree.

Frf — First-level reconstruction filters

matrix | cell array

First-level reconstruction filters, returned as an N -by-2 or N -by-3 matrix for single-tree wavelet transforms, or a cell array of two N -by-2 or N -by-3 matrices for dual-tree wavelet transforms. The

matrices are N -by-3 for the double-density wavelet transforms. For an N -by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N -by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage synthesis filters for the corresponding tree.

Rf — Reconstruction filters for levels > 1

matrix | cell array

Reconstruction filters for levels > 1, returned as an N -by-2 or N -by-3 matrix for single-tree wavelet transforms, or a cell array of two N -by-2 or N -by-3 matrices for dual-tree wavelet transforms. The matrices are N -by-3 for the double-density wavelet transforms. For an N -by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N -by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the synthesis filters for the corresponding tree.

cfs — Wavelet transform coefficients

cell array of matrices

Wavelet transform coefficients, returned as a 1-by-(level+1) cell array of matrices. The size and structure of the matrix elements of the cell array depend on the type of wavelet transform, `typetree`, as follows:

- 'dwt' — `cfs{j}`
 - $j = 1, 2, \dots$ level is the level.
 - `cfs{level+1}` are the lowpass, or scaling, coefficients.
- 'ddt' — `cfs{j}(:, :, k)`
 - $j = 1, 2, \dots$ level is the level.
 - $k = 1, 2$ is the wavelet filter.
 - `cfs{level+1}(:, :, :)` are the lowpass, or scaling, coefficients.
- 'cplxdt' — `cfs{j}(:, :, m)`
 - $j = 1, 2, \dots$ level is the level.
 - $m = 1, 2$ are the real and imaginary parts.
 - `cfs{level+1}(:, :, m)` are the lowpass, or scaling, coefficients.
- 'cplxddt' — `cfs{j}(:, :, k, m)`
 - $j = 1, 2, \dots$ level is the level.
 - $k = 1, 2$ is the wavelet filter.
 - $m = 1, 2$ are the real and imaginary parts.
 - `cfs{level+1}(:, :, m)` are the lowpass, or scaling, coefficients.

Topics

"Dual-Tree Complex Wavelet Transforms"

“Analytic Wavelets Using the Dual-Tree Wavelet Transform”
“Critically Sampled and Oversampled Wavelet Filter Banks”

Introduced in R2013b

dddtrecfs

Extract dual-tree/double-density wavelet coefficients or projections

Syntax

```
out = dddtrecfs(outputtype,wt,outputspec,outputindices)
out = dddtrecfs(outputtype,wt,outputspec,outputindices,'plot')
```

Description

`out = dddtrecfs(outputtype,wt,outputspec,outputindices)` extracts the coefficients or subspace projections from the 1-D or 2-D wavelet decomposition, `wt`. If `outputtype` equals 'e', `out` contains wavelet or scaling coefficients. If `outputtype` equals 'r', `out` contains wavelet or scaling subspace projections (reconstructions).

`out = dddtrecfs(outputtype,wt,outputspec,outputindices,'plot')` plots the signal or image reconstruction or specified analysis coefficients. You can include the 'plot' option anywhere after the `wt` input.

Examples

Reconstruction from 1-D Complex Dual-Tree Wavelet Transform

Obtain the complex dual-tree wavelet transform of the 1-D noisy Doppler signal. Reconstruct an approximation based on the level-three detail coefficients in multiple ways.

Load the noisy Doppler signal. Obtain the complex dual-tree transform down to level 3.

```
load noisdopp;
wt = dddtree('cplxdt',noisdopp,3,'dtf1')
```

```
wt = struct with fields:
    type: 'cplxdt'
    level: 3
    filters: [1x1 struct]
    cfs: {1x4 cell}
```

Plot a reconstruction of the original signal based on the level-three detail coefficients with `outputspec` set to 'scale'.

```
xr = dddtrecfs('r',wt,'scale',{3},'plot');
```

The output `xr` is a 1-by-1 cell array. Generate the same reconstruction by using `'cumind'` and the level-three tree nodes. The first element of each vector in the cell array denotes the level, and the second element denotes the tree. Confirm the reconstructions are identical.

```
outputindices = {[3 1];[3 2]};
xr2 = dddtreecfs('r',wt,'cumind',outputindices);
max(abs(xr2-xr{1}))
```

```
ans = 0
```

The output `xr2` is the same datatype as the original signal.

Coefficients from 1-D Complex Dual-Tree Wavelet Transform

Load the noisy Doppler signal. Obtain the complex dual-tree transform down to level 3.

```
load noisdopp;
wt = dddtree('cplxdt',noisdopp,3,'dtf1')

wt = struct with fields:
    type: 'cplxdt'
    level: 3
    filters: [1x1 struct]
    cfs: {[1x512x2 double] [1x256x2 double] [1x128x2 double] [1x128x2 double]}
```

Create a cell array of vectors to obtain the second- and third-level detail coefficients from each of the wavelet filter bank trees.

```
outputindices = {[2 1]; [2 2]; [3 1]; [3 2]};
```

The first element of each vector in the cell array denotes the level, or stage. The second element denotes the tree.

Extract the detail coefficients.

```
detailCoeffs = dddtrecfs('e',wt,'ind',outputindices,'plot');
```

The output `detailCoeffs` is a 1-by-4 cell array. The cell array elements contain the wavelet coefficients corresponding to the elements in `outputindices`. For example, confirm `detailCoeffs{1}` contains the level-two detail coefficients from the first tree.

```
max(abs(wt.cfs{2}(1, :, 1) - detailCoeffs{1}))
```

```
ans = 0
```

1-D Complex Dual-Tree Wavelet Transform Structure

Load the noisy Doppler signal. Obtain the complex dual-tree transform down to level 3.

```
load noisdopp;  
wt = dddtree('cplxdt',noisdopp,3,'dtf1');
```

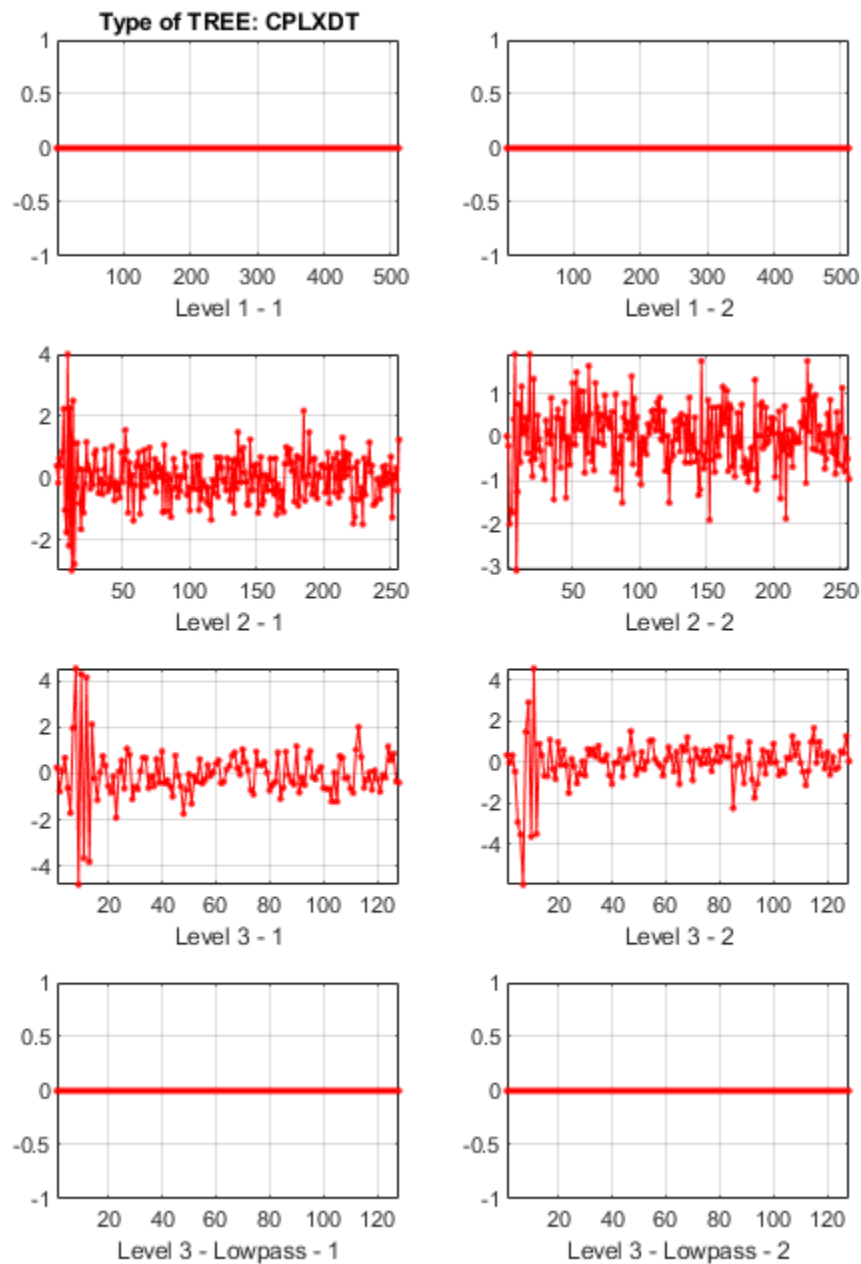

Create a cell array of vectors to obtain the second- and third-level detail coefficients from each of the wavelet filter bank trees.

```
outputindices = {[2 1]; [2 2]; [3 1];[3 2]};
```

The first element of each vector in the cell array denotes the level, or stage. The second element denotes the tree.

Create a structure array identical to the `wt` output of `dddtree` with all the coefficients equal to zero except the second- and third-level detail coefficients.

```
out = dddtreecfs('e',wt,'cumind',outputindices,'plot');
```

Generate a reconstruction based on the second- and third-level detail coefficients.

```
xr = idddtree(out);
```

Generate two reconstructions, based on the second- and third-level detail coefficients. Confirm the sum of the two reconstructions is identical to xr.

```

xr2 = dddtreecfs('r',wt,'scale',{2;3});
max(abs(xr-(xr2{1}+xr2{2})))

ans = 8.8818e-16

```

Extract Diagonal Features from Image

Use the complex dual-tree wavelet transform to isolate diagonal features in an image at +45 and -45 degrees.

Load and display the xbox image.

```

load xbox
imagesc(xbox)

```

Obtain the complex dual-tree wavelet transform down to level 3.

```

fdf = dtfilters('FSfarras');
df = dtfilters('qshift10');
wt = dddtree2('cplxdt',xbox,3,fdf,df);

```

Isolate the +45 and -45 diagonal image features in the level-one wavelet coefficients. Do this by creating a cell array of vectors specifying the tree nodes containing the diagonal details. The first element in the vector specifies the level. The three remaining elements specify the orientation, wavelet tree, and real and imaginary parts, respectively (see `dddtree2`).

```
outputindices = {[1 3 1 1];[1 3 1 2];[1 3 2 1];[1 3 2 2]};
out = dddtreecfs('e',wt,'ind',outputindices,'plot');
```

Distribution of Analysis Coefficients in Wavelet Tree Structure

This example shows how the analysis coefficients are distributed, depending on the transform, in the tree output of `dddtree` and `dddtree2`.

1-D Wavelet Transforms

Load in the noisy Doppler signal. Generate a four-level wavelet decomposition of the signal for each type of transform. Depending on the transform, different dimensions of the coefficient arrays correspond to orientation, wavelet tree, or real and imaginary parts.

Critically Sampled Discrete Wavelet Transform

```
load noisdopp
wt = dddtree('dwt',noisdopp,4,'sym4')

wt = struct with fields:
    type: 'dwt'
    level: 4
    filters: [1x1 struct]
    cfs: {1x5 cell}
```

This is the usual nonredundant discrete wavelet transform. The first four elements of `wt.cfs` are the wavelet coefficients. The fifth element are the scaling coefficients.

Double-Density Wavelet Transform

```
wt = dddtree('ddt',noisdopp,4,'filters1')

wt = struct with fields:
    type: 'ddt'
    level: 4
    filters: [1x1 struct]
    cfs: {1x5 cell}
```

The third dimension of the 3-D wavelet coefficient arrays corresponds to the tree. The fifth element are the scaling coefficients.

Dual-Tree Complex Wavelet Transform

```
wt = dddtree('cplxdt',noisdopp,4,'dtf1')

wt = struct with fields:
    type: 'cplxdt'
    level: 4
    filters: [1x1 struct]
    cfs: {1x5 cell}
```

The third dimension of all the 3-D arrays in `cfs` corresponds to the real and imaginary parts. The first four elements of `cfs` are the wavelet coefficients, and `cfs{5}` are the scaling coefficients.

Reconstruct signals from the coefficients at the tree nodes [1 1], [5 2], [3 1], and [4 2]. Plot the signals. The output is a cell array containing the reconstructions. The reconstructions are the same length as the original signal.

```
outputindices = {[1 1];[5 2];[3 1];[4 2]};
XR = dddtreecfs('r',wt,'plot','ind',outputindices);
```

Extract and plot the coefficients used to reconstruct the signals. The output is a cell array containing the coefficients of respective length: 512, 64, 128, and 64.

```
XR = dddtrecfs('e',wt,'plot','ind',outputindices);
```

Now use 'cumind' instead of 'ind'. The output XR is a signal of length 1024 in the first case, and a 'cplxdt' dual-tree in the second one.

```
XR = dddtreecfs('r',wt,'plot','cumind',outputindices);
```

```
XR = dddtrecfs('e',wt,'plot','cumind',outputindices);
```

Double-Density Dual-Tree Complex Wavelet Transform

```
wt = dddtree('cplxdddt',noisdopp,4,'dddtf1')
```

```
wt = struct with fields:
    type: 'cplxdddt'
    level: 4
```

```
filters: [1x1 struct]
cfs: {1x5 cell}
```

The third dimension of the 4-D wavelet coefficient arrays corresponds to the tree. The fourth dimension in the 4-D wavelet coefficient arrays and third dimension in the 3-D scaling coefficients array corresponds to the real and imaginary parts.

2-D Wavelet Transforms

Load in the 256-by-256 mask image. Generate a two-level wavelet decomposition of the image for each type of transform. Observe the dimensions of the output coefficients.

Critically Sampled Discrete Wavelet Transform

```
load mask
im = X;
wt = dddtree2('dwt',im,3,'sym4')

wt = struct with fields:
    type: 'dwt'
    level: 3
    filters: [1x1 struct]
    cfs: {1x4 cell}
    sizes: [10x2 double]
```

This is the usual nonredundant 2-D discrete wavelet transform. The third dimension in the 3-D wavelet coefficient arrays corresponds to the orientation. The scaling coefficients are the last element of cfs.

Real Oriented Dual-Tree Wavelet Transform

```
wt = dddtree2('realdt',im,3,'dtf1')

wt = struct with fields:
    type: 'realdt'
    level: 3
    filters: [1x1 struct]
    cfs: {1x4 cell}
    sizes: [11x2 double]
```

The fourth dimension in the 4-D wavelet coefficient arrays and third dimension in the 3-D scaling coefficients array correspond to the tree. The third dimension in the 4-D wavelet coefficient arrays corresponds to orientation.

Complex Oriented Dual-Tree Wavelet Transform

```
wt = dddtree2('cplxdt',im,3,'dtf1')

wt = struct with fields:
    type: 'cplxdt'
    level: 3
    filters: [1x1 struct]
    cfs: {[5-D double] [5-D double] [5-D double] [32x32x2x2 double]}
    sizes: [11x2 double]
```

```
[size(wt.cfs{1});size(wt.cfs{2});size(wt.cfs{3})]
```

```
ans = 3×5
```

```
128 128 3 2 2
 64 64 3 2 2
 32 32 3 2 2
```

The third dimension of the 5-D wavelet coefficient arrays represents the orientation. The fourth dimension in the 5-D arrays and third dimension in the 4-D scaling coefficients array represents the tree. The fifth dimension in the 5-D arrays and fourth dimension in the 4-D array represents the real and imaginary parts.

Double-Density Wavelet Transform

```
wt = dddtree2('ddt',im,3,'filters1')
```

```
wt = struct with fields:
    type: 'ddt'
    level: 3
    filters: [1x1 struct]
    cfs: {1x4 cell}
    sizes: [26x2 double]
```

The third dimension in the 3-D wavelet coefficient arrays represents the orientation.

Real Oriented Double-Density Wavelet Transform

```
wt = dddtree2('realdddt',im,3,'self1')
```

```
wt = struct with fields:
    type: 'realdddt'
    level: 3
    filters: [1x1 struct]
    cfs: {1x4 cell}
    sizes: [26x2 double]
```

The third dimension in the 4-D wavelet coefficient arrays represents the orientation. The fourth dimension in the 4-D arrays and third dimension in the 3-D scaling coefficients array represent the tree.

Complex Oriented Double-Density Wavelet Transform

```
wt = dddtree2('cplxdddt',im,3,'self1')
```

```
wt = struct with fields:
    type: 'cplxdddt'
    level: 3
    filters: [1x1 struct]
    cfs: {[5-D double] [5-D double] [5-D double] [32x32x2x2 double]}
    sizes: [26x2 double]
```

```
[size(wt.cfs{1}) ; size(wt.cfs{2}) ; size(wt.cfs{3})]
```

```
ans = 3×5
```

128	128	8	2	2
64	64	8	2	2
32	32	8	2	2

The third dimension of the 5-D wavelet coefficient arrays represents the orientation. The fourth dimension in the 5-D arrays and third dimension in the 4-D scaling coefficients array represents the tree. The fifth dimension in the 5-D arrays and fourth dimension in the 4-D array represents the real and imaginary parts.

Reconstruct and plot two images based on the second-level detail coefficients and scaling coefficients, respectively.

```
XR = dddtrecfs('r',wt,'plot','scale',{2;4});
```

The output XR is a cell array containing both 256-by-256 images.

Extract the coefficients used to produce the two images. The output is a cell array containing two dual-tree structures, one for each specified scale.

```
XR = ddtreecfs('e',wt,'scale',{2;4});
XR{1}

ans = struct with fields:
    type: 'cplxdddt'
    level: 3
    filters: [1x1 struct]
           cfs: {[5-D double] [5-D double] [5-D double] [32x32x2x2 double]}
           sizes: [26x2 double]
```

```
XR{2}

ans = struct with fields:
    type: 'cplxdddt'
    level: 3
    filters: [1x1 struct]
           cfs: {[5-D double] [5-D double] [5-D double] [32x32x2x2 double]}
           sizes: [26x2 double]
```

Confirm the only nonzero coefficients in each structure contained in XR are the level-two wavelet coefficients and scaling coefficients, respectively.

```
dtInd = 1;
[max(abs(XR{dtInd}.cfs{1}(:)));max(abs(XR{dtInd}.cfs{2}(:)));...
 max(abs(XR{dtInd}.cfs{3}(:)));max(abs(XR{dtInd}.cfs{4}(:)))]
```

```
ans = 4x1

     0
143.9924
     0
     0
```

```
dtInd = 2;
[max(abs(XR{dtInd}.cfs{1}(:)));max(abs(XR{dtInd}.cfs{2}(:)));...
 max(abs(XR{dtInd}.cfs{3}(:)));max(abs(XR{dtInd}.cfs{4}(:)))]
```

```
ans = 4x1
103 ×

     0
     0
     0
  1.0545
```

Use 'ind' to reconstruct and display the four images based on the four lowpass components, respectively.

```
outputindices = {[4 1 1];[4 2 1];[4 1 2];[4 2 2]};
XR = ddtreecfs('r',wt,'plot','ind',outputindices);
```

The output XR is a cell array containing the four images. Each image is 256-by-256. Display the coefficients used to reconstruct the images.

```
XR = dddtrecfs('e',wt,'plot','ind',outputindices);
```

The output XR is a cell array containing the four lowpass components. Each component is 32-by-32.

Input Arguments

outputtype — Output type

'e' | 'r'

Output type, specified as 'e' or 'r'. Use 'e' to obtain the scaling or wavelet coefficients. Use 'r' to obtain a projection, or reconstruction, onto the appropriate scaling or wavelet subspace.

wt — Wavelet transform

structure

Wavelet transform, specified as a structure. The structure array is the output of `dddtree` or `dddtree2`.

outputspec — Output specification

'lowpass' | 'scale' | 'ind' | 'cumind'

Output specification, specified as one of 'lowpass', 'scale', 'ind', or 'cumind'. The output specifications are defined as follows:

- 'lowpass' — Outputs the lowpass, or scaling, coefficients or a signal/image approximation based on the scaling coefficients. If you set the output specification to 'lowpass', do not specify `outputindices`. If the `outputtype` is 'e', `out` is a structure array with fields identical to the input structure array `wt` except that all wavelet (detail) coefficients are equal to zero. If the `outputtype` is 'r', `out` is a signal or image approximation based on the scaling coefficients. The signal or image approximation is equal in size to the original input to `dddtree` or `dddtree2`.
- 'scale' — Outputs the coefficients or a signal/image approximation based on the scales specified in `outputindices`. If the `outputtype` is 'e', `out` is a cell array of structure arrays. The fields of the structure arrays in `out` are identical to the fields of the input structure array `wt`. The coefficients in the `cfs` field are all equal to zero except the coefficients corresponding to the scales in `outputindices`. If the `outputtype` is 'r', `out` is a signal or image approximation based on the scales in `outputindices`. The signal or image approximation is equal in size to the original input to `dddtree` or `dddtree2`.
- 'ind' — Outputs the coefficients or a signal/image approximation based on the tree-position indices specified in `outputindices`. If the `outputtype` is 'e', `out` is a cell array of vectors or matrices containing the coefficients specified by the tree-position indices in `outputindices`. If the `outputtype` is 'r', `out` is a cell array of vectors or matrices containing signal or image approximations based on the corresponding tree-position indices in `outputindices`.
- 'cumind' — Outputs the coefficients or a signal/image approximation based on the tree-position indices specified in `outputindices`. If the `outputtype` is 'e', `out` is a structure array. The fields of the structure array are identical to the fields of the input structure array `wt`. The coefficients in the `cfs` field are all equal to zero except the coefficients corresponding to the tree positions in `outputindices`. If the `outputtype` is 'r', `out` is a signal or image approximation based on the coefficients corresponding to the tree-position indices in `outputindices`.

Example: 'ind', {[1 1]; [1 2]}

outputindices — Output indices

cell array

Output indices, specified as a cell array with scalar or vector elements. If `outputspec` equals 'scale', a scalar element selects the corresponding element in the `cfs` field of `wt`. If `outputspec` equals 'ind' or 'cumind', the elements of `outputspec` are row vectors. The first element of the row vector corresponds to the element in the `cfs` field of `wt`. Subsequent elements in the row vector correspond to the indices of the array contained in the cell array element. For a description of the subsequent elements, see “Distribution of Analysis Coefficients in Wavelet Tree Structure” on page 1-229. For more information, see `dddtree` and `dddtree2`.

Example: 'scale', {1;2;3}

Output Arguments

out — Signal or image reconstruction or coefficients

cell array | structure | vector | matrix

Signal or image reconstruction or coefficients, returned as a vector, matrix, structure array, cell array of vectors or matrices, or cell array of structure arrays. The form of `out` depends on the value of `outputspec` and `outputindices`.

Introduced in R2013b

dddtree2

Dual-tree and double-density 2-D wavelet transform

Syntax

```
wt = dddtree2(typetree,x,level,fdf,df)
wt = dddtree2(typetree,x,level,fname)
wt = dddtree2(typetree,x,level,fname1,fname2)
```

Description

`wt = dddtree2(typetree,x,level,fdf,df)` returns the `typetree` discrete wavelet transform of the 2-D input image, `x`, down to level, `level`. The wavelet transform uses the decomposition (analysis) filters, `fdf`, for the first level and the analysis filters, `df`, for subsequent levels. Supported wavelet transforms are the critically sampled DWT, double-density, real oriented dual-tree, complex oriented dual-tree, real oriented dual-tree double-density, and complex oriented dual-tree double-density wavelet transform. The critically sampled DWT is a filter bank decomposition in an orthogonal or biorthogonal basis (nonredundant). The other wavelet transforms are oversampled filter banks with differing degrees of directional selectivity.

`wt = dddtree2(typetree,x,level,fname)` uses the filters specified by `fname` to obtain the wavelet transform. Valid filter specifications depend on the type of wavelet transform. See `dtfilters` for details.

`wt = dddtree2(typetree,x,level,fname1,fname2)` uses the filters specified in `fname1` for the first stage of the dual-tree wavelet transform and the filters specified in `fname2` for subsequent stages of the dual-tree wavelet transform. Specifying different filters for stage 1 is valid and necessary only when `typetree` is `'realdt'`, `'cplxdt'`, `'realdtdt'`, or `'cplxdddtdt'`.

Examples

Real Oriented Dual-Tree Wavelets

Visualize the six directional wavelets of the real oriented dual-tree wavelet transform.

Create the first-stage Farras analysis filters for the two trees.

```
Faf{1} = [0      0

        -0.0883 -0.1143
           0  0
          0.0352  0];

```

To visualize the six directional wavelets, you will modify the wavelet coefficients of a four level real oriented dual-tree wavelet transform of an image of zeros. Create an image of zeros whose size satisfies the following constraints:

- The row and column dimensions are divisible by 2^4 .
- The minimum of the row and column size must be greater than or equal to the product of the maximum length of the analysis filters and 2^3 .

```

J = 4;
L = 3*2^(J+1);
N = L/2^J;
x = zeros(2*L,3*L);
[numrows,numcols] = size(x)

numrows = 192
numcols = 288

```

Obtain the real oriented dual-tree wavelet transform of the image of zeros down to level 4.

```

wt = dddtree2('realdt',x,J,Faf,af)

wt = struct with fields:
    type: 'realdt'

```

```

level: 4
filters: [1x1 struct]
  cfs: {1x5 cell}
  sizes: [14x2 double]

```

The fourth element in `wt.cfs` are the level 4 wavelet coefficients. Insert a 1 in one position of the six wavelet subbands (three orientations \times two trees) at the coarsest scale, and invert the wavelet transform.

```

wt.cfs{4}(N/2,N/2+0*N,1,1) = 1;
wt.cfs{4}(N/2,N/2+1*N,2,1) = 1;
wt.cfs{4}(N/2,N/2+2*N,3,1) = 1;
wt.cfs{4}(N/2+N,N/2+0*N,1,2) = 1;
wt.cfs{4}(N/2+N,N/2+1*N,2,2) = 1;
wt.cfs{4}(N/2+N,N/2+2*N,3,2) = 1;
xrec = iddttree2(wt);

```

Visualize the six directional wavelets.

```

imagesc(xrec);
colormap gray; axis off;
title('Real Oriented Dual-Tree Wavelets')

```

Real Oriented Dual-Tree Wavelets

Double-Density Wavelet Transform

Obtain the double-density wavelet transform of an image.

Load the image and obtain the double-density wavelet transform using 6-tap filters (see `dtfilters`).

```
load xbox
imagesc(xbox)
colormap gray
```

```
wt = dddtree2('ddt',xbox,1,'filters1')

wt = struct with fields:
    type: 'ddt'
    level: 1
    filters: [1x1 struct]
             cfs: {[64x64x8 double] [64x64 double]}
             sizes: [10x2 double]
```

In the critically sampled 2-D discrete wavelet transform, there is one highpass filter. Filtering the rows and columns of the image with the highpass filter corresponds to extracting details in the diagonal orientation. In the double-density wavelet transform, there are two highpass filters, H1 and H2. Diagonally oriented details are extracted by filtering the image rows and columns with four combinations of the highpass filters. Visualize the diagonal details in the four wavelet highpass-highpass subbands.

```

H1H1 = wt.cfs{1}(:,:,4);
H1H2 = wt.cfs{1}(:,:,5);
H2H1 = wt.cfs{1}(:,:,7);
H2H2 = wt.cfs{1}(:,:,8);
subplot(2,2,1)
imagesc(H1H1);
title('H1 H1')
colormap gray;
subplot(2,2,2);
imagesc(H1H2);
title('H1 H2')
subplot(2,2,3)
imagesc(H2H1)
title('H2 H1')
subplot(2,2,4)
imagesc(H2H2)
title('H2 H2')

```

Complex Dual-Tree Wavelet Transform

Obtain the complex dual-tree wavelet transform of an image. Show that the complex dual-tree wavelet transform can detect the two different diagonal directions.

Load the image and obtain the complex dual-tree wavelet transform.

```
load xbox
imagesc(xbox)
colormap gray
```

```
wt = dddtree2('cplxdt',xbox,1,'FSfarras','qshift10')
wt = struct with fields:
    type: 'cplxdt'
    level: 1
    filters: [1x1 struct]
    cfs: {[5-D double] [64x64x2x2 double]}
    sizes: [5x2 double]
```

Obtain and display the diagonally oriented details from the two trees.

```
waveletcfs = wt.cfs{1};
subplot(2,2,1)
imagesc(waveletcfs(:,:,3,1,1))
title('Diagonal - Tree 1 - Real')
colormap gray
subplot(2,2,2)
imagesc(waveletcfs(:,:,3,1,2))
title('Diagonal - Tree 1 - Imaginary')
subplot(2,2,3)
imagesc(waveletcfs(:,:,3,2,1))
title('Diagonal - Tree 2 - Real')
subplot(2,2,4)
```

```
imagesc(waveletcfs(:,:,3,2,2))
title('Diagonal - Tree 2 - Imaginary')
```

Input Arguments

typetree — Type of wavelet decomposition

'dwt' | 'ddt' | 'realdt' | 'cplxdt' | 'realdddt' | 'cplxdddtd'

Type of wavelet decomposition, specified as one of 'dwt', 'ddt', 'realdt', 'cplxdt', 'realdddt', or 'cplxdddtd'. The type, 'dwt', produces a critically sampled (nonredundant) discrete wavelet transform. The other decomposition types produce oversampled wavelet transforms. 'ddt' produces a double-density wavelet transform with one scaling and two wavelet filters for both row and column filtering. The double-density wavelet transform uses the same filters at all stages. 'realdt' and 'cplxdt' produce oriented dual-tree wavelet transforms consisting of two and four separable wavelet transforms. 'realdddt' and 'cplxdddtd' produce double-density dual-tree wavelet transforms. The dual-tree wavelet transforms use different filters for the first stage (level).

x — Input image

matrix

Input image, specified as a matrix with even-length row and column dimensions. Both the row and column dimensions must be divisible by 2^L , where L is the level of the wavelet transform. Additionally, the minimum of the row and column dimensions of the image must be greater than or equal to the product of the maximum length of the decomposition (analysis) filters and $2^{(L-1)}$.

Data Types: `double`

level — Level of wavelet decomposition

integer

Level of the wavelet decomposition, specified as a positive integer. If L is the value of `level`, 2^L must divide both the row and column dimensions of `x`. Additionally, the minimum of the row and column dimensions of the image must be greater than or equal to the product of the maximum length of the decomposition (analysis) filters and $2^{(L-1)}$.

fdf — Level-one analysis filters

matrix | cell array

The level-one analysis filters, specified as a matrix or cell array of matrices. Specify `fdf` as a matrix when `typetree` is `'dwt'` or `'ddt'`. The size and structure of the matrix depend on the `typetree` input as follows:

- `'dwt'` — This is the critically sampled discrete wavelet transform. In this case, `fdf` is a two-column matrix with the lowpass (scaling) filter in the first column and the highpass (wavelet) filter in the second column.
- `'ddt'` — This is the double-density wavelet transform. The double-density DWT is a three-channel perfect reconstruction filter bank. `fdf` is a three-column matrix with the lowpass (scaling) filter in the first column and the two highpass (wavelet) filters in the second and third columns. In the double-density wavelet transform, the single lowpass and two highpass filters constitute a three-channel perfect reconstruction filter bank. This is equivalent to the three filters forming a tight frame. You cannot arbitrarily choose the two wavelet filters in the double-density DWT. The three filters together must form a tight frame.

Specify `fdf` as a 1-by-2 cell array of matrices when `typetree` is a dual-tree transform, `'realdt'`, `'cplxdt'`, `'realdddt'`, or `'cplxdddt'`. The size and structure of the matrix elements in the cell array depend on the `typetree` input as follows:

- For the dual-tree complex wavelet transforms, `'realdt'` and `'cplxdt'`, `fdf{1}` is an N -by-2 matrix containing the lowpass (scaling) and highpass (wavelet) filters for the first tree and `fdf{2}` is an N -by-2 matrix containing the lowpass (scaling) and highpass (wavelet) filters for the second tree.
- For the double-density dual-tree complex wavelet transforms, `'realdddt'` and `'cplxdddt'`, `fdf{1}` is an N -by-3 matrix containing the lowpass (scaling) and two highpass (wavelet) filters for the first tree and `fdf{2}` is an N -by-3 matrix containing the lowpass (scaling) and two highpass (wavelet) filters for the second tree.

df — Analysis filters for levels > 1

matrix | cell array

Analysis filters for levels > 1, specified as a matrix or cell array of matrices. Specify `df` as a matrix when `typetree` is `'dwt'` or `'ddt'`. The size and structure of the matrix depend on the `typetree` input as follows:

- `'dwt'` — This is the critically sampled discrete wavelet transform. In this case, `df` is a two-column matrix with the lowpass (scaling) filter in the first column and the highpass (wavelet) filter in the second column. For the critically sampled orthogonal or biorthogonal DWT, the filters in `df` and `fdf` must be identical.
- `'ddt'` — This is the double-density wavelet transform. The double-density DWT is a three-channel perfect reconstruction filter bank. `df` is a three-column matrix with the lowpass (scaling) filter in

the first column and the two highpass (wavelet) filters in the second and third columns. In the double-density wavelet transform, the single lowpass and two highpass filters constitute a three-channel perfect reconstruction filter bank. This is equivalent to the three filters forming a tight frame. For the double-density DWT, the filters in `df` and `fdf` must be identical.

Specify `df` as a 1-by-2 cell array of matrices when `typetree` is a dual-tree transform, `'realdt'`, `'cplxdt'`, `'realdddt'`, or `'cplxdddt'`. For dual-tree transforms, the filters in `fdf` and `df` must be different. The size and structure of the matrix elements in the cell array depend on the `typetree` input as follows:

- For the dual-tree wavelet transforms, `'realdt'` and `'cplxdt'`, `df{1}` is an N -by-2 matrix containing the lowpass (scaling) and highpass (wavelet) filters for the first tree and `df{2}` is an N -by-2 matrix containing the lowpass (scaling) and highpass (wavelet) filters for the second tree.
- For the double-density dual-tree complex wavelet transforms, `'realdddt'` and `'cplxdddt'`, `df{1}` is an N -by-3 matrix containing the lowpass (scaling) and two highpass (wavelet) filters for the first tree and `df{2}` is an N -by-3 matrix containing the lowpass (scaling) and two highpass (wavelet) filters for the second tree.

fname — Filter name

character vector | string scalar

Filter name, specified as a character vector or string scalar. For the critically sampled DWT, specify any valid orthogonal or biorthogonal wavelet filter. See `wfilters` for details. For the redundant wavelet transforms, see `dtfilters` for valid filter names.

fname1 — First-stage filter name

character vector | string scalar

First-stage filter name, specified as a character vector or string scalar. Specifying a first-level filter that is different from the wavelet and scaling filters in subsequent levels is valid and necessary only with the dual-tree wavelet transforms, `'realdt'`, `'cplxdt'`, `'realdddt'`, and `'cplxdddt'`.

fname2 — Filter name for stages > 1

character vector | string scalar

Filter name for stages > 1, specified as a character vector or string scalar. Specifying a different filter for stages > 1 is valid and necessary only with the dual-tree wavelet transforms, `'realdt'`, `'cplxdt'`, `'realdddt'`, and `'cplxdddt'`.

Output Arguments

wt — Wavelet transform

structure

Wavelet transform, returned as a structure with these fields:

type — Type of wavelet decomposition (filter bank)

`'dwt'` | `'ddt'` | `'realdt'` | `'cplxdt'` | `'realdddt'` | `'cplxdddt'`

Type of wavelet decomposition used in the analysis returned as one of `'dwt'`, `'ddt'`, `'realdt'`, `'cplxdt'`, `'realdddt'`, or `'cplxdddt'`. `'dwt'` is the critically sampled DWT. `'ddt'` produces a double-density wavelet transform with one scaling and two wavelet filters for both row and column filtering. `'realdt'` and `'cplxdt'` produce oriented dual-tree wavelet transforms consisting of 2 and

4 separable wavelet transforms. 'realdddt' and 'cplxdddt' produce double-density dual-tree wavelet transforms consisting of two and four separable wavelet transforms.

Level — Level of wavelet decomposition

positive integer

Level of wavelet decomposition, returned as a positive integer.

filters — Decomposition (analysis) and reconstruction (synthesis) filters

structure

Decomposition (analysis) and reconstruction (synthesis) filters, returned as a structure with these fields:

Fdf — First-stage analysis filters

matrix | cell array

First-stage analysis filters, returned as an N -by-2 or N -by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two N -by-2 or N -by-3 matrices for dual-tree wavelet transforms. The matrices are N -by-3 for the double-density wavelet transforms. For an N -by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N -by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage analysis filters for the corresponding tree.

Df — Analysis filters for levels > 1

matrix | cell array

Analysis filters for levels > 1, returned as an N -by-2 or N -by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two N -by-2 or N -by-3 matrices for dual-tree wavelet transforms. The matrices are N -by-3 for the double-density wavelet transforms. For an N -by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N -by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the analysis filters for the corresponding tree.

Frf — First-level reconstruction filters

matrix | cell array

First-level reconstruction filters, returned as an N -by-2 or N -by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two N -by-2 or N -by-3 matrices for dual-tree wavelet transforms. The matrices are N -by-3 for the double-density wavelet transforms. For an N -by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N -by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage synthesis filters for the corresponding tree.

Rf — Reconstruction filters for levels > 1

matrix | cell array

Reconstruction filters for levels > 1, returned as an N -by-2 or N -by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two N -by-2 or N -by-3 matrices for dual-tree wavelet transforms. The matrices are N -by-3 for the double-density wavelet transforms. For an N -by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass)

filter. For an N-by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage analysis filters for the corresponding tree.

cfs – Wavelet transform coefficients

cell array of matrices

Wavelet transform coefficients, specified as a 1-by-(level+1) cell array of matrices. The size and structure of the matrix elements of the cell array depend on the type of wavelet transform, `typetree` as follows:

- 'dwt' – `cfs{j}(:, :, d)`
 - $j = 1, 2, \dots$ level is the level.
 - $d = 1, 2, 3$ is the orientation.
 - `cfs{level+1}(:, :)` are the lowpass, or scaling, coefficients.
- 'ddt' – `cfs{j}(:, :, d)`
 - $j = 1, 2, \dots$ level is the level.
 - $d = 1, 2, 3, 4, 5, 6, 7, 8$ is the orientation.
 - `cfs{level+1}(:, :)` are the lowpass, or scaling, coefficients.
- 'realdt' – `cfs{j}(:, :, d, k)`
 - $j = 1, 2, \dots$ level is the level.
 - $d = 1, 2, 3$ is the orientation.
 - $k = 1, 2$ is the wavelet transform tree.
 - `cfs{level+1}(:, :, k)` are the lowpass, or scaling, coefficients.
- 'cplxdt' – `cfs{j}(:, :, d, k, m)`
 - $j = 1, 2, \dots$ level is the level.
 - $d = 1, 2, 3$ is the orientation.
 - $k = 1, 2$ is the wavelet transform tree.
 - $m = 1, 2$ are the real and imaginary parts.
 - `cfs{level+1}(:, :, k, m)` are the lowpass, or scaling, coefficients.
- 'realdddt' – `cfs{j}(:, :, d, k)`
 - $j = 1, 2, \dots$ level is the level.
 - $d = 1, 2, 3, 4, 5, 6, 7, 8$ is the orientation.
 - $k = 1, 2$ is the wavelet transform tree.
 - `cfs{level+1}(:, :, k)` are the lowpass, or scaling, coefficients.
- 'cplxdddt' – `cfs{j}(:, :, d, k, m)`
 - $j = 1, 2, \dots$ level is the level.
 - $d = 1, 2, 3, 4, 5, 6, 7, 8$ is the orientation.
 - $k = 1, 2$ is the wavelet transform tree.
 - $m = 1, 2$ are the real and imaginary parts.

- `cfs{level+1}(:, :, k, m)` are the lowpass, or scaling, coefficients.

Each orientation corresponds to a particular subband. The double-density transforms 'ddt', 'realddt', and 'cplxddd' generate wavelet coefficients of eight orientations. The other transforms, 'dwt', 'realdt', and 'cplxdt' generate wavelet coefficients of three orientations. The correspondence to subbands is as follows.

typetree	Orientations
'dwt', 'realdt', 'cplxdt'	<p>'L' and 'H', denote the lowpass and highpass filters, respectively.</p> <ul style="list-style-type: none"> • d=1: 'LH' subband • d=2: 'HL' subband • d=3: 'HH' subband
'ddt', 'realddt', 'cplxddd'	<p>'Lo', 'H1', and 'H2' denote the lowpass and two highpass filters, respectively.</p> <ul style="list-style-type: none"> • d=1: 'Lo H1' subband • d=2: 'Lo H2' subband • d=3: 'H1 Lo' subband • d=4: 'H1 H1' subband • d=5: 'H1 H2' subband • d=6: 'H2 Lo' subband • d=7: 'H2 H1' subband • d=8: 'H2 H2' subband

sizes — Sizes of components

integer-valued matrix

Sizes of components in `cfs`, returned as an N-by-2 integer-valued matrix. The value of N depends on the level of wavelet decomposition and the type of wavelet decomposition: $N = 2 + \text{level} \times (\text{number of orientations})$.

- `cfs(1, :)` = dimensions of input image.
- `cfs(2+level, :)` = dimensions of scaling coefficients.
- `cfs(1+no*(i-1)+(1:no), :)` = dimensions of level *i* detail coefficients, where *no* is the number of orientations.

depo2ind

Node depth-position to node index

Syntax

```
N = depo2ind(ORD, [D P])
```

Description

depo2ind is a tree-management utility.

For a tree of order ORD , $N = \text{depo2ind}(ORD, [D P])$ computes the indices N of the nodes whose depths and positions are encoded within $[D, P]$.

The nodes are numbered from left to right and from top to bottom. The root index is 0.

D and P are column vectors. The values of depths D and positions P must be such that $D \geq 0$ and $0 \leq P \leq ORD^{D-1}$.

Output indices N are such that $0 \leq N < (ORD^{\max(D)} - 1) / (ORD - 1)$.

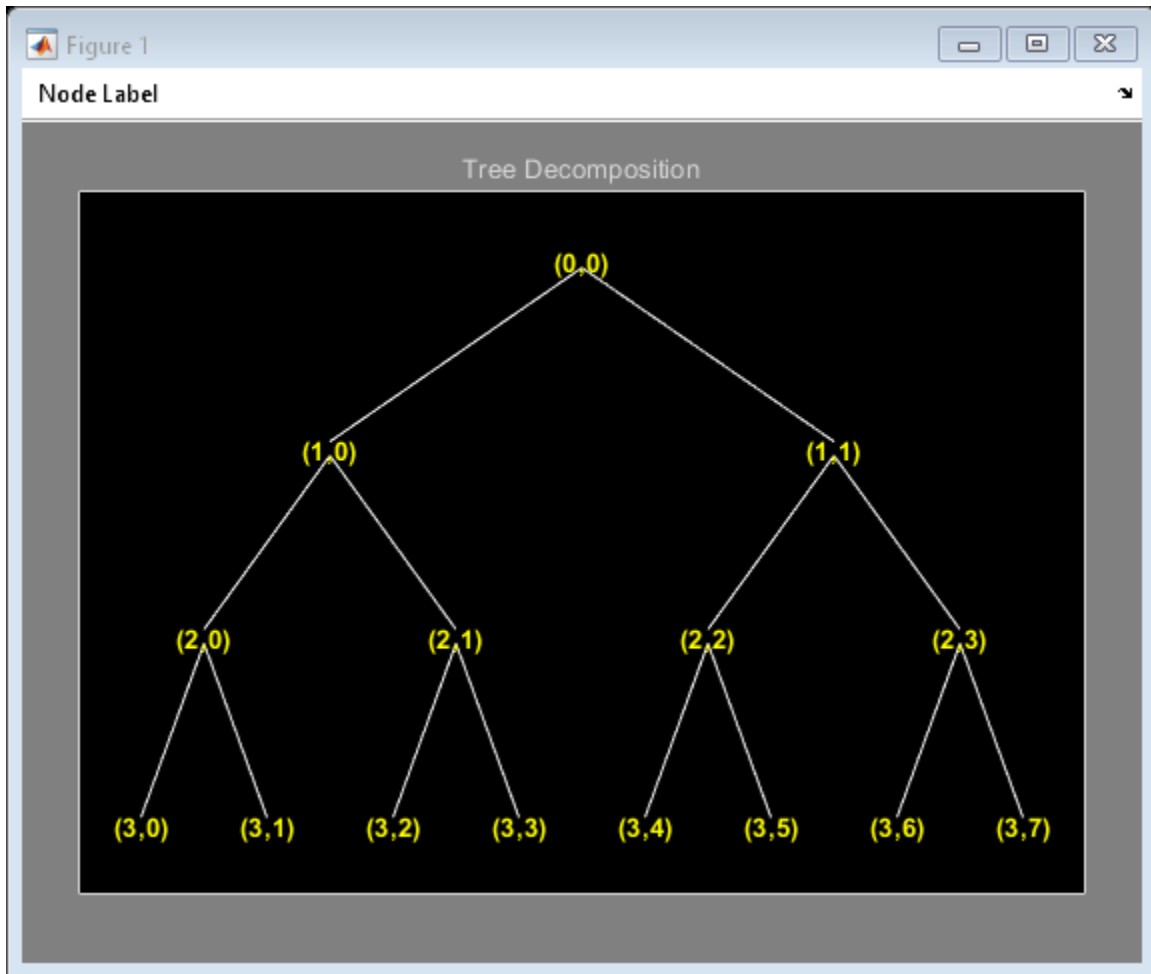

Note that for a column vector X , we have $\text{depo2ind}(0, X) = X$.

Examples

Convert Depth-Position to Node Index

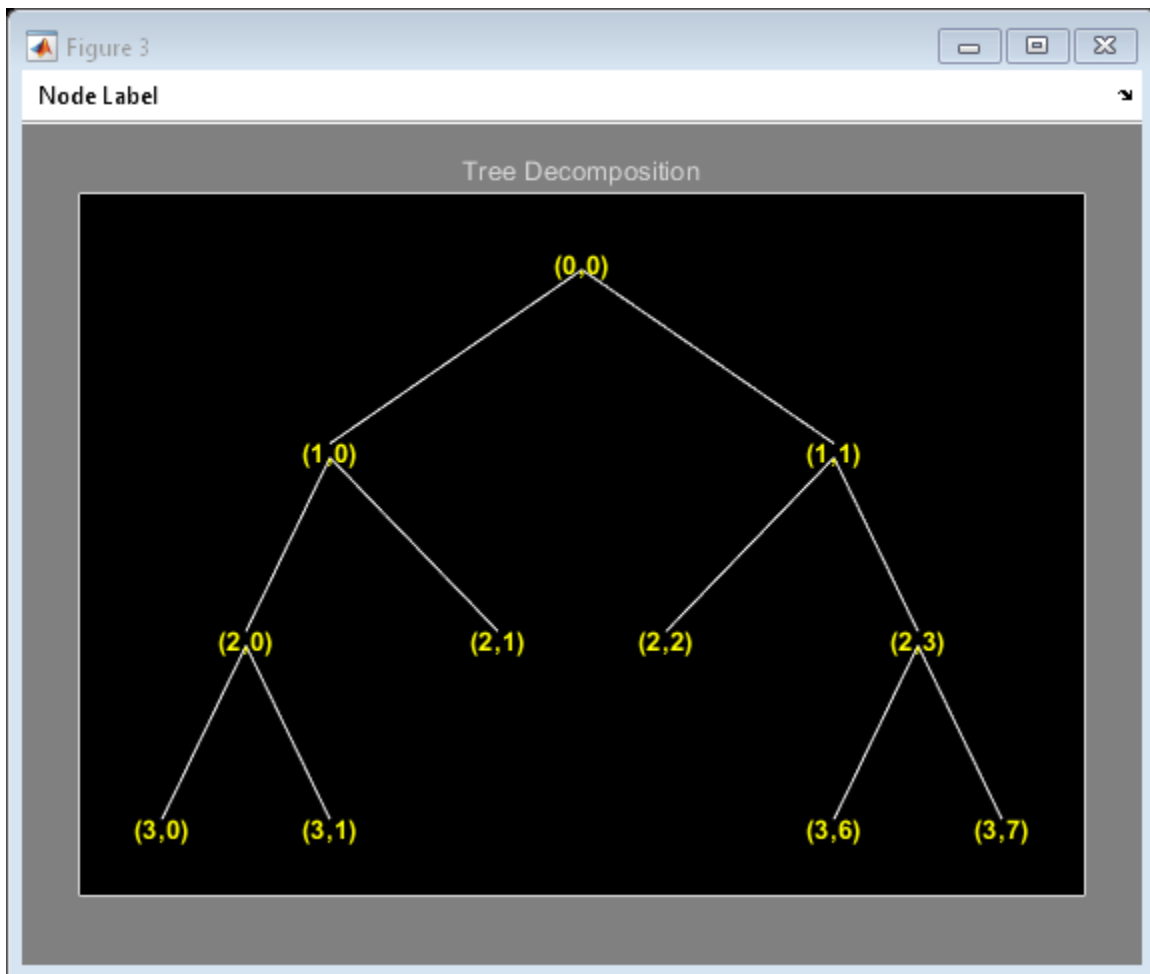

Create a binary tree of depth 3. Plot the tree.

```
ord = 2;  
t = ntree(ord,3);  
plot(t)
```

Merge the nodes of indices 4 and 5. Plot the new tree.

```
t = nodejoin(t,5);  
t = nodejoin(t,4);  
figure  
plot(t)
```

List the depth-position of the tree nodes.

```
aln_depo = allnodes(t, 'depos')
```

```
aln_depo = 11x2
```

```

detcoef

1-D detail coefficients

Syntax

```
D = detcoef(C,L)
D = detcoef(C,L,N)
D = detcoef(C,L,N,'cells')
```

```
[D1,...,Dp] = detcoef(C,L,N)
```

Description

`D = detcoef(C,L)` extracts the detail coefficients at the coarsest scale from the wavelet decomposition structure `[C, L]`. See `wavedec` for more information on `C` and `L`.

`D = detcoef(C,L,N)` extracts the detail coefficients at the level or levels specified by `N`.

`D = detcoef(C,L,N,'cells')` returns a cell array containing the detail coefficients. A minimum of two levels must be specified. The i^{th} element of `D` contains the detail coefficients at the i^{th} specified level.

- If `length(N)>1`, the `D = detcoef(C,L,N)` is equivalent to `D = detcoef(C,L,N,'cells')`.
- `D = detcoef(C,L,'cells')` is equivalent to `D = detcoef(C,L,[1:NMAX])`, where `NMAX = length(L)-2`.

`[D1,...,Dp] = detcoef(C,L,N)` extracts the detail coefficients at the levels specified by `N`. The length of `N` must equal the number of output arguments.

Examples

Detail Coefficients for 1-D Signal

This example shows how to obtain and plot the detail coefficients for an electrical current signal. This example uses zero-padding (see `dwtmode`).

Load the signal and select the first 3920 samples.

```
load leleccum;
s = leleccum(1:3920);
```

Perform the decomposition at level 3 using `db1`. Extract the detail coefficients at levels 1, 2, and 3 from the decomposition structure.

```
[c,l] = wavedec(s,3,'db1');
[cd1,cd2,cd3] = detcoef(c,l,[1 2 3]);
```

Plot the original signal.

```
plot(s)
title('Original signal')
ylim([0 1000])
```

Plot the level 3 detail coefficients.

```
plot(cd3)
title('Level 3 detail coefficients (cd3)')
ylim([-60 60])
```

Plot the level 2 detail coefficients.

```
plot (cd2)
title('Level 2 detail coefficients (cd2)')
ylim([-60 60])
```

Plot the level 1 detail coefficients.

```
plot (cd1)
title('Level 1 detail coefficients (cd1)')
ylim([-60 60])
```

Input Arguments

C – Wavelet decomposition vector

real-valued vector

Wavelet decomposition vector, specified as a real-valued vector. The vector **C** is the output of `wavedec`.

L – Bookkeeping vector

vector of positive integers

Bookkeeping vector, specified as a vector of positive integers. The bookkeeping vector **L** contains the number of coefficients by level. The bookkeeping vector is used to parse the coefficients in the wavelet decomposition vector **C**. The vectors **C** and **L** are the outputs of `wavedec`.

N – Detail level

positive integer | vector of positive integers

Detail level to extract from the wavelet decomposition, specified as a positive integer or a vector of positive integers.

- If **N** is an integer, then **N** must be an integer such that $1 \leq N \leq NMAX$, where $NMAX = \text{length}(L) - 2$.
- If **N** is a vector of integers, then $N(j)$ must be an integer such that $1 \leq N(j) \leq NMAX$, where $j = 1, \dots, \text{length}(N)$.

Output Arguments

D — Detail coefficients

real-valued vector | cell array

Detail coefficients, returned as a real-valued vector or a cell array. If D is a cell array, the i^{th} element of D are the detail coefficients at the level specified by the i^{th} element of N.

D1, ..., Dp — Detail coefficients

real-valued vectors

Detail coefficients, returned as set of real-valued vectors. The i^{th} output argument are the detail coefficients at the level specified by the corresponding element of N.

detcoef2

2-D detail coefficients

Syntax

`D = detcoef2(0,C,S,N)`

Description

`detcoef2` is a two-dimensional wavelet analysis function.

`D = detcoef2(0,C,S,N)` extracts from the wavelet decomposition structure `[C,S]` the horizontal, vertical, or diagonal detail coefficients for `0 = 'h'` (or `'v'` or `'d'`, respectively), at level `N`, where `N` must be an integer such that $1 \leq N \leq \text{size}(S,1) - 2$. See `wavedec2` for more information on `C` and `S`.

`[H,V,D] = detcoef2('all',C,S,N)` returns the horizontal `H`, vertical `V`, and diagonal `D` detail coefficients at level `N`.

`D = detcoef2('compact',C,S,N)` returns the detail coefficients at level `N`, stored row-wise.

`detcoef2('a',C,S,N)` is equivalent to `detcoef2('all',C,S,N)`.

`detcoef2('c',C,S,N)` is equivalent to `detcoef2('compact',C,S,N)`.

Examples

```
% The current extension mode is zero-padding (see dwtmode).
```

```
% Load original image.
load woman;
```

```
% X contains the loaded image.
```

```
% Perform decomposition at level 2
% of X using db1.
```

```
[c,s] = wavedec2(X,2,'db1');
```

```
sizec = size(X)
```

```
sizec =
    256    256
```

```
sizec = size(c)
```

```
sizec =
     1   65536
```

```
val_s = s
```

```
val_s =
    64    64
    64    64
   128   128
   256   256
```

```
% Extract details coefficients at level 2
% in each orientation, from wavelet decomposition
% structure [c,s].
[chd2,cvd2,cdd2] = detcoef2('all',c,s,2);
sized2 = size(chd2)
sized2 =
    64    64

% Extract details coefficients at level 1
% in each orientation, from wavelet decomposition
% structure [c,s].
[chd1,cvd1,cdd1] = detcoef2('all',c,s,1);
sized1 = size(chd1)
sized1 =
    128    128
```

Tips

If C and S are obtained from an indexed image analysis or a truecolor image analysis, D is an m-by-n matrix or an m-by-n-by-3 array, respectively.

For more information on image formats, see the `image` and `imfinfo` reference pages.

disp

WPTREE information

Syntax

`disp(T)`

Description

`disp(T)` displays the content of the WPTREE object *T*.

Examples

```
% Compute a wavelet packets tree
x = rand(1,1000);
t = wpdec(x,2,'db2');
disp(t)
```

```
Wavelet Packet Object Structure

displs

Display lifting scheme

Syntax

```
S = displs(LS,FRM)
```

Description

`S = displs(LS,FRM)` returns the character array describing the lifting scheme LS. The formatting operator FRM (see `sprintf`) builds S.

`displs(LS)` is equivalent to `displs(LS, '%12.8f')`.

Examples

Display Lifting Scheme

Start with the Haar wavelet and get the corresponding lifting scheme.

```
lshaar = liftwave('haar');
```

Visualized the lifting scheme.

```
displs(lshaar);
```

```
lshaar = {...  
'd'          [ -1.00000000] [0]  
'p'          [  0.50000000] [0]  
[ 1.41421356] [  0.70710678] []  
};
```

Add a primal elementary lifting step to the lifting scheme. Display the resulting scheme.

```
els = {'p',[-0.125 0.125],0};  
lsnew = addlift(lshaar,els);  
displs(lsnew);
```

```
lsnew = {...  
'd'          [ -1.00000000] [0]  
'p'          [  0.50000000] [0]  
'p'          [ -0.12500000  0.12500000] [0]  
[ 1.41421356] [  0.70710678] []  
};
```

Input Arguments

LS — Lifting scheme

lifting scheme

Lifting scheme associated with a wavelet. See `liftwave`.

Example: `LS = liftwave('db4')` returns the lifting scheme associated with the Daubechies wavelet db4.

FRM — Formatting operator

formatting operator

Formatting operator used to build LS. See `sprintf`.

Example: `'%12.3f'`

`liftwave` | `lsinfo`

Introduced before R2006a

drawtree

Draw wavelet packet decomposition tree (GUI)

Syntax

```
drawtree(T)
F = drawtree(T)
drawtree(T,F)
```

Description

`drawtree(T)` draws the wavelet packet tree T , and `F = drawtree(T)` also returns the figure's handle.

For an existing figure F produced by a previous call to the `drawtree` function, `drawtree(T,F)` draws the wavelet packet tree T in the figure whose handle is F .

Examples

```
x = sin(8*pi*[0:0.005:1]);
t = wpdec(x,3,'db2');
fig = drawtree(t);
```

```
%-----
% Use command line function to modify t.
%-----
t = wpjoin(t,2);
drawtree(t,fig);
```

See Also
readtree

Introduced before R2006a

dtfilters

Analysis and synthesis filters for oversampled wavelet filter banks

Syntax

```
df = dtfilters(name)
[df,rf] = dtfilters(name)
```

Description

`df = dtfilters(name)` returns the decomposition (analysis) filters corresponding to `name`. These filters are used most often as input arguments to `dddtree` and `dddtree2`.

`[df,rf] = dtfilters(name)` returns the reconstruction (synthesis) filters corresponding to `name`.

Examples

Filters for Complex Dual-Tree Wavelet Transform

Obtain valid filters for the complex dual-tree wavelet transform. The transform uses Farras nearly symmetric filters for the first stage and Kingsbury Q-shift filters with 10 taps for subsequent stages.

Load the noisy Doppler signal. Obtain the filters for the first and subsequent stages of the complex dual-tree wavelet transform. Demonstrate perfect reconstruction using the complex dual-tree wavelet transform.

```
load noisdopp;
df = dtfilters('dtf2');
dt = dddtree('cplxdt',noisdopp,5,df{1},df{2});
xrec = idddtree(dt);
max(abs(noisdopp-xrec))
```

```
ans = 1.3678e-13
```

Filters for Double-Density Wavelet Transform

Obtain valid filters for the double-density wavelet transform.

Load the noisy Doppler signal. Obtain the filters for the double-density wavelet transform. The double-density wavelet transform uses the same filters at all stages. Demonstrate perfect reconstruction using the double-density wavelet transform.

```
df = dtfilters('filters1');
load noisdopp;
dt = dddtree('ddt',noisdopp,5,df,df);
xrec = idddtree(dt);
max(abs(noisdopp-xrec))
```

ans = 2.3803e-13

Input Arguments

name — Filter name

'dtf1' | 'dddtf1' | 'self1' | 'self2' | ...

Filter name, specified as a character vector or string scalar. Valid entries for name are:

- Any valid orthogonal or biorthogonal wavelet name. See `wfilters` for details. An orthogonal or biorthogonal wavelet is only valid when the filter bank type is `'dwt'`, or when you use the filter as the first stage in a complex dual-tree transform, `'realdt'` or `'cplxdt'`. An orthogonal or biorthogonal wavelet filter is not a valid filter if you have a double-density, `'ddt'` or dual-tree double-density, `'realdddt'` or `'cplxdddt'`, filter bank. An orthogonal or biorthogonal wavelet filter is not a valid filter for complex dual-tree filter banks for stages greater than 1.
- `'dtfP'` — With P equal to 1, 2, 3, 4, or 5 returns the first-stage Farras filters (`'FSfarras'`) and Kingsbury Q-shift filters (`'qshiftN'`) for subsequent stages. This input is only valid for a dual-tree transform, `'realdt'` or `'cplxdt'`. Setting P = 1, 2, 3, 4, or 5 specifies the Kingsbury Q-shift filters with N = 6, 10, 14, 16, or 18 taps, respectively.
- `'dddtf1'` — Returns the filters for the first and subsequent stages of the double-density dual-tree transform. This input is only valid for the double-density dual-tree transforms, `'realdddt'` and `'cplxdddt'`.
- `'self1'` — Returns 10-tap filters for the double-density wavelet transform. This option is only valid for double-density wavelet transforms, `'ddt'`, `'realdddt'`, and `'cplxdddt'`.
- `'self2'` — Returns 16-tap filters for the double-density wavelet transform. This option is only valid for double-density wavelet transforms, `'ddt'`, `'realdddt'`, and `'cplxdddt'`.
- `'filters1'` — Returns 6-tap filters for the double-density wavelet transform, `'ddt'`.
- `'filters2'` — Returns 12-tap filters for the double-density wavelet transform, `'ddt'`.
- `'farras'` — Farras nearly symmetric filters for a two-channel perfect reconstruction filter bank. This option is meant to be used for one-tree transforms and is valid only for an orthogonal critically sampled wavelet transform, `'dwt'`. The output of `dtfilters` is a two-column matrix. The first column of the matrix is a scaling (lowpass) filter, and the second column is a wavelet (highpass) filter.
- `'FSfarras'` — Farras nearly symmetric first-stage filters intended for a dual-tree wavelet transform. With this option, the output of `dtfilters` is a cell array with two elements, one for each tree. Each element is a two-column matrix. The first column of the matrix is a scaling (lowpass) filter, and the second column is a wavelet (highpass) filter.
- `'qshiftN'` — Kingsbury Q-shift N-tap filters with N = 6, 10, 14, 16, or 18. The Kingsbury Q-shift filters are used most commonly in dual-tree wavelet transforms for stages greater than 1.
- `'doubledualfilt'` — Filters for one stage of the double-density dual-tree wavelet transforms, `'realdddt'` or `'cplxdddt'`.

Output Arguments

df — Decomposition (analysis) filters

matrix | cell array

Decomposition (analysis) filters, returned as a matrix or cell array of matrices.

rf – Reconstruction (synthesis) filters

matrix | cell array

Reconstruction (synthesis) filters, returned as a matrix or cell array of matrices.

See Also

dddtree | dddtree2

Introduced in R2013b

dtree

DTREE constructor

Syntax

```
T = dtree(ORD,D,X)
T = dtree(ORD,D,X,U)
[T,NB] = dtree(...)
[T,NB] = dtree('PropName1',PropValue1,'PropName2',PropValue2,...)
```

Description

$T = \text{dtree}(ORD, D, X)$ returns a complete data tree (DTREE) object of order ORD and depth D . The data associated with the tree T is X .

With $T = \text{dtree}(ORD, D, X, U)$ you can set a user data field.

$[T, NB] = \text{dtree}(\dots)$ returns also the number of terminal nodes (leaves) of T .

$[T, NB] = \text{dtree}('PropName1', PropValue1, 'PropName2', PropValue2, \dots)$ is the most general syntax to construct a DTREE object.

The valid choices for '*PropName*' are

'order'	Order of the tree
'depth'	Depth of the tree
'data'	Data associated to the tree
'spsch'	Split scheme for nodes
'ud'	User data field

The split scheme field is an order ORD by 1 logical array. The root of the tree can be split and it has ORD children. If $\text{spsch}(j) = 1$, you can split the j -th child. Each node that you can split has the same property as the root node.

For more information on object fields, type `help dtree/get`.

Class DTREE (Parent class: NTREE)

Fields

dtree	Parent object
allNI	All nodes information
terNI	Terminal nodes information

Examples

```
% Create a data tree.
x = [1:10];
```

```
t = dtree(3,2,x);  
t = nodejoin(t,2);
```

See Also

ntree | wtbo

Introduced before R2006a

dualtree

Kingsbury Q-shift 1-D dual-tree complex wavelet transform

Syntax

```
[A,D] = dualtree(X)
[ ___,Ascale] = dualtree(X)
[ ___ ] = dualtree(X,Name,Value)
```

Description

`[A,D] = dualtree(X)` returns the 1-D dual-tree complex wavelet transform (DTCWT) of X . The output A is the matrix of real-valued final-level scaling (lowpass) coefficients. The output D is an L -by-1 cell array of complex-valued wavelet coefficients, where L is the level of the transform.

The input X must have at least two samples. The DTCWT is obtained by default down to level $\text{floor}(\log_2 N)$, where N is the length of X if X is a vector and the row dimension of X if X is a matrix. If N is odd, X is extended by one sample by reflecting the last element of X .

By default, `dualtree` uses the near-symmetric biorthogonal filter pair with lengths 5 (scaling filter) and 7 (wavelet filter) for level 1 and the orthogonal Q-shift Hilbert wavelet filter pair of length 10 for levels greater than or equal to 2.

`[___,Ascale] = dualtree(X)` returns the scaling (lowpass) coefficients at each level.

`[___] = dualtree(X,Name,Value)` specifies additional options using name-value pair arguments. For example, `'Level',10` specifies a decomposition down to level 10.

Examples

Plot Dual-Tree Complex Wavelet Transform Coefficients

Load an ECG signal.

```
load wecg
plot(wecg)
axis tight
```

Obtain the 4-level dual-tree transform. Return the approximation (lowpass) coefficients at all levels.

```
[a,d,as] = dualtree(wecg, 'Level',4);
```

Plot the final-level wavelet coefficients from tree A and tree B.

```
figure
subplot(2,1,1)
plot(real(d{4}))
axis tight
title('Tree A')
subplot(2,1,2)
plot(imag(d{4}))
axis tight
title('Tree B')
```

Plot the lowpass coefficients at each level of the transform.

```
figure
for k=1:4
    subplot(2,2,k)
    plot(as{k})
    axis tight
    title(['Level: ', num2str(k)])
end
```

Distribution of Energy Across Scales

This example shows that small signal shifts do not significantly change the distribution of energy among the DTCWT coefficients at different scales.

Load an ECG signal. The signal has 2048 samples.

```
load wecg
len = numel(wecg);
plot(wecg)
axis tight
```

Create two 1-by-3000 zero vectors. Insert the ECG signal into different segments of each zero vector.

```
shift1 = 328;
shift2 = 368;
vec1 = zeros(1,3000);
vec2 = zeros(1,3000);
vec1(shift1+[1:len]) = wecg;
vec2(shift2+[1:len]) = wecg;
```

Obtain the dual-tree transform of both vectors. Use default settings.

```
[a1,d1] = dualtree(vec1);
[a2,d2] = dualtree(vec2);
```

Compute the energy at each scale for both decompositions. Note that the energy distribution of the shifted signals across all scales remains approximately the same.

```
energy1 = cell2mat(cellfun(@(x)(sum(abs(x).^2)),d1,'uni',0));
energy2 = cell2mat(cellfun(@(x)(sum(abs(x).^2)),d2,'uni',0));
levels =cell(numel(energy1),1);
for k=1:numel(energy1)
    levels{k} = sprintf('Level %d',k);
end
energies = table(levels,energy1,energy2)
```

```
energies=11x3 table
    levels      energy1      energy2
```

{'Level 9' }	23.006	22.56
{'Level 10' }	70.764	73.964
{'Level 11' }	64.097	59.022

Input Arguments

X — Input data

vector | matrix | timetable

Input data, specified as a real-valued vector, matrix, or timetable. The input X must have at least two samples. If X is a timetable, it can contain a single vector or matrix variable, or it can contain multiple variables, each containing a column vector. If X is a matrix, `dualtree` operates on the columns of X.

Data Types: double | single

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'LevelOneFilter', 'antonini', 'Level', 4

Level — Level of decomposition

positive integer

Level of decomposition, specified as a positive integer less than or equal to $\text{floor}(\log_2 N)$, where N is the length of X if X is a vector and the row dimension of X if X is a matrix. If unspecified, Level defaults to $\text{floor}(\log_2 N)$.

LevelOneFilter — Biorthogonal filter

'nearsym5_7' (default) | 'nearsym13_19' | 'antonini' | 'legall'

Biorthogonal filter to use in the first-level analysis, specified as:

- 'legall' — LeGall 5/3 filter [3]
- 'nearsym13_19' — (13,19)-tap near-orthogonal filter [2]
- 'nearsym5_7' — (5,7)-tap near-orthogonal filter [1]
- 'antonini' — (9,7)-tap Antonini filter [1]

By default, `dualtree` uses 'nearsym5_7', the near-symmetric biorthogonal filter pair with lengths 5 (scaling filter) and 7 (wavelet filter).

FilterLength — Orthogonal Hilbert Q-shift analysis filter pair length

10 (default) | 6 | 14 | 16 | 18

Orthogonal Hilbert Q-shift analysis filter pair length to use for levels 2 and higher, specified as one of the listed values [2]. By default, `dualtree` uses the orthogonal Q-shift Hilbert wavelet filter pair of length 10.

Output Arguments

A — Final-level approximation coefficients

real-valued vector | real-valued matrix

Final-level approximation coefficients, returned as a real-valued vector if X is a vector, or a matrix if X is a multisignal. The approximation coefficients are the final-level scaling (lowpass) coefficients. If X is a matrix, the column dimensions of X and A are equal.

D — Wavelet coefficients

cell array

Wavelet coefficients, returned as an L -by-1 cell array of complex-valued wavelet coefficients, where L is the level of the transform. The real parts of the coefficients are from tree A, and the imaginary parts are from tree B. If X is a matrix, each element of D is a matrix whose column dimension equals the column dimension of X .

Ascale — Approximation coefficients

cell array

Approximation coefficients at each level of the transform, returned as an L -by-1 cell array of real-valued scaling (lowpass) coefficients, where L is the level of the transform. If X is a matrix, each element of D is a matrix whose column dimension equals the column dimension of X .

Introduced in R2020a

dualtree2

Kingsbury Q-shift 2-D dual-tree complex wavelet transform

Syntax

```
[A,D] = dualtree2(X)
[ ___,Ascale] = dualtree2(X)
[ ___ ] = dualtree(X,Name,Value)
```

Description

`[A,D] = dualtree2(X)` returns the 2-D dual-tree complex wavelet transform (DTCWT) of `X` using Kingsbury Q-shift filters. The output `A` is the matrix of real-valued final-level scaling (lowpass) coefficients. The output `D` is a L -by-1 cell array of complex-valued wavelet coefficients, where L is the level of the transform. For each element of `D` there are six wavelet subbands.

The DTCWT is obtained by default down to level `floor(log2(min([H W])))`, where H and W refer to the height (row dimension) and width (column dimension) of `X`, respectively. If any of the row or column dimensions of `X` are odd, `X` is extended along that dimension by reflecting around the last row or column.

By default, `dualtree2` uses the near-symmetric biorthogonal wavelet filter pair with lengths 5 (scaling filter) and 7 (wavelet filter) for level 1 and the orthogonal Q-shift Hilbert wavelet filter pair of length 10 for levels greater than or equal to 2.

`[___,Ascale] = dualtree2(X)` returns the scaling (lowpass) coefficients at each level.

`[___] = dualtree(X,Name,Value)` specifies additional options using name-value pair arguments. For example, `'LevelOneFilter','antonini'` specifies the (9,7)-tap Antonini filter as the biorthogonal filter to use in the first-level analysis.

Examples

2-D Dual-Tree Complex Wavelet Transform

Load a grayscale image.

```
load mask
imagesc(X)
colormap gray
```

Obtain the dual-tree complex wavelet transform of the image down to four levels of resolution.

```
[a,d] = dualtree2(X, 'Level',4);
```

Display the final-level scaling (lowpass) coefficients.

```
imagesc(a)  
colormap gray
```

Display the tree B wavelet coefficients at the finest scale. Each subplot title denotes the particular subband ("H" for highpass, "L" for lowpass).

```
orientation = ["HL", "HH", "LH", "LH", "HH", "HL"];
for k=1:6
    subplot(3,2,k)
    imagesc(imag(d{1}(:,:,k)))
    title(['Orientation: ' orientation(k)])
    set(gca, 'xtick', [])
    set(gca, 'ytick', [])
end
colormap gray
set(gcf, 'Position', [0 0 560 800])
```

Input Arguments

X — Input data

real-valued matrix (default) | real-valued 3-D array | real-valued 4-D array

Input data, specified as a real-valued matrix, 3-D array, or 4-D array. X is a real-valued H -by- W -by- C -by- N array, where H is the height or row dimension, W is the width or column dimension, C is the number of channels, and N is the number of images. X must have at least two samples in each of the row and column dimensions.

Example: If X is a 256-by-256-by-3-by-2 array, X contains two 256-by-256 RGB images.

Data Types: double | single

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'LevelOneFilter', 'antonini', 'Level', 4

Level — Level of decomposition

positive integer

Level of decomposition, specified as a positive integer less than or equal to $\text{floor}(\log_2(\min([H W])))$, where H and W refer to the height (row dimension) and width (column dimension) of X, respectively. If unspecified, Level defaults to $\text{floor}(\log_2(\min([H W])))$.

LevelOneFilter — Biorthogonal filter

'nearsym5_7' (default) | 'nearsym13_19' | 'antonini' | 'legall'

Biorthogonal filter to use in the first-level analysis, specified as:

- 'legall' — LeGall 5/3 filter [3]
- 'nearsym13_19' — (13,19)-tap near-orthogonal filter [2]
- 'nearsym5_7' — (5,7)-tap near-orthogonal filter [1]
- 'antonini' — (9,7)-tap Antonini filter [1]

By default, dualtree2 uses 'nearsym5_7', the near-symmetric biorthogonal filter pair with lengths 5 (scaling filter) and 7 (wavelet filter).

FilterLength — Orthogonal Hilbert Q-shift analysis filter pair length

10 (default) | 6 | 14 | 16 | 18

Orthogonal Hilbert Q-shift analysis filter pair length to use for levels 2 and higher, specified as one of the listed values [2]. By default, dualtree2 uses the orthogonal Q-shift Hilbert wavelet filter pair of length 10.

Output Arguments

A — Final-level approximation coefficients

real-valued matrix

Final-level approximation coefficients, returned as a real-valued matrix.

D — Wavelet coefficients

cell array

Wavelet coefficients, returned as an L -by-1 cell array of complex-valued wavelet coefficients, where L is the level of the transform. The real parts of the coefficients are from tree A, and the imaginary parts are from tree B. For each element of D there are six wavelet subbands.

Ascale — Approximation coefficients

cell array

Approximation coefficients at each level of the transform, returned as an L -by-1 cell array of real-valued scaling (lowpass) coefficients, where L is the level of the transform. If X is a matrix, each element of D is a matrix whose column dimension equals the column dimension of X.

Topics

"Dual-Tree Complex Wavelet Transforms"

"Critically Sampled and Oversampled Wavelet Filter Banks"

"Analytic Wavelets Using the Dual-Tree Wavelet Transform"

Introduced in R2020a

dualtree3

3-D dual-tree complex wavelet transform

Syntax

```
[a,d] = dualtree3(x)
[a,d] = dualtree3(x,level)

[a,d] = dualtree3( ___,Name,Value)

[a,d] = dualtree3( ___, 'excludeL1')
```

Description

`[a,d] = dualtree3(x)` returns the 3-D dual-tree complex wavelet transform of `x` at the maximum level, `floor(log2(min(size(x))))`.

`[a,d] = dualtree3(x,level)` returns the 3-D dual-tree wavelet transform down to `level`.

`[a,d] = dualtree3(___,Name,Value)` specifies options using name-value pair arguments in addition to any of the input arguments in previous syntaxes.

`[a,d] = dualtree3(___, 'excludeL1')` excludes the first-level wavelet (detail) coefficients. Excluding the first-level wavelet coefficients can speed up the algorithm and saves memory. The first level does not exhibit the directional selectivity of levels 2 and higher. The perfect reconstruction property of the dual-tree wavelet transform holds only if the first-level wavelet coefficients are included. If you do not specify this option, or append `'includeL1'`, then the function includes the first-level coefficients.

Examples

Three-Dimensional Dual-Tree Transform of Volumetric Data

Generate a volumetric data set. Plot several cross-sections of the data seen from above. The data are not symmetric about the `x`-axis or the `y`-axis.

```
x1 = 64;
xx = linspace(-5,5,x1);
[x,y,z] = meshgrid(xx);
G = (x+3*y)./(1+exp((x.^2+2*y.^2+z.^2)-10));
for k = 1:16
    subplot(4,4,k)
    surf(xx,xx,G(:,:,4*k))
    view(2)
    shading interp
```

```

title(['z = ' num2str(xx(4*k),2)])
end

```

Compute the 3-D dual-tree transform of the data down to level 4. Specify a Hilbert Q-shift filter-pair length of 14.

```
[a,d] = dualtree3(G,4,'FilterLength',14);
```

Plot the real and imaginary parts of the first-level wavelet coefficients for selected subbands. The coefficients have the same directionality as the data. The imaginary parts are shifted versions of the real parts.

```
m = 1;
```

```

for k = 1:8
    subplot(4,4,2*k-1)
    surf(real(d{m}(:,:,3*k)))

    view(2)
    shading interp
    axis tight
    title(['Re d\{1\}, n = ' int2str(3*k)])

    subplot(4,4,2*k)
    surf(imag(d{m}(:,:,3*k)))

    view(2)
    shading interp

```

```

axis tight
title(['Im d\{1\}, n = ' int2str(3*k)])
end

```

Repeat the procedure for the second-level coefficients. When the level number increases by one, the array of wavelet coefficients decreases by half along the first two dimensions.

```

m = 2;
for k = 1:8
    subplot(4,4,2*k-1)
    surf(real(d{m}(:,:,3*k)))

    view(2)
    shading interp
    axis tight
    title(['Re d\{2\}, n = ' int2str(3*k)])

    subplot(4,4,2*k)
    surf(imag(d{m}(:,:,3*k)))

    view(2)
    shading interp
    axis tight
    title(['Im d\{2\}, n = ' int2str(3*k)])
end

```

Invert the transform, specifying the same filter-pair length. Check for perfect reconstruction.

```
xrec = idualtree3(a,d,'FilterLength',14);
max(abs(xrec(:)-G(:)))

ans = 1.4211e-14
```

3-D Dual-Tree Transform of MRI Data

Load a set of MRI measurements of a human head. Truncate the data so that it is even along the third dimension. Compute the 3-D dual-tree transform, excluding the first-level wavelet coefficients.

```
load wmri

[A,D] = dualtree3(X(:,:,1:26),2,'excludeL1');
```

Reconstruct the data by inverting the transform. Set the final-level scaling coefficients explicitly to 0. Display an evenly spaced selection of reconstructed images.

```
imrec = idualtree3(A*0,D);

colormap bone
for kj = 1:9
    subplot(3,3,kj)
    surf(imrec(:,:,3*kj-2))
```

```

shading interp
view(2)
axis tight off
end

```

Input Arguments

x — Input data

real 3-D array

Input data, specified as a real 3-D array. All three dimensions of **x** must be even and greater than or equal to 4.

Data Types: double | single

level — Transform level

$\text{floor}(\log_2(\min(\text{size}(x))))$ (default) | positive integer

Transform level, specified as a positive integer greater than or equal to 2 and less than or equal to $\text{floor}(\log_2(\min(\text{size}(x))))$.

Data Types: double | single

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'LevelOneFilter', 'legall', 'FilterLength', 6` computes a transform using LeGall analysis filters with scaling length 5 and wavelet length 3 at level 1, and length-6 Q-shift filters at levels 2 and greater.

FilterLength — Hilbert Q-shift filter-pair length

10 (default) | 6 | 14 | 16 | 18

Hilbert Q-shift filter-pair length, specified as the comma-separated pair consisting of `'FilterLength'` and one of 6, 10, 14, 16, or 18. `dualTree3` uses the orthogonal Hilbert Q-shift filter pair of length `'FilterLength'` for levels 2 and greater.

Data Types: `double` | `single`

LevelOneFilter — First-level biorthogonal analysis filter

'nearsym5_7' (default) | 'nearsym13_19' | 'antonini' | 'legall'

First-level biorthogonal analysis filter, specified as the comma-separated pair consisting of `'LevelOneFilter'` and a character vector or string. By default, `dualTree3` uses for level 1 the near-symmetric biorthogonal wavelet filter with lengths 5 (scaling filter) and 7 (wavelet filter).

Data Types: `char` | `string`

Output Arguments

a — Final-level scaling coefficients

real-valued matrix

Final-level scaling (lowpass) coefficients, returned as a real-valued matrix.

Data Types: `double`

d — Wavelet coefficients

1-by-level cell array

Wavelet coefficients, returned as a 1-by-level cell array. There are 28 wavelet subbands in the 3-D dual-tree transform at each level.

Data Types: `double`

dwpt

Multisignal 1-D wavelet packet transform

Syntax

```
wpt = dwpt(X)
wpt = dwpt(X,wname)
wpt = dwpt(X,LoD,HiD)
[wpt,l] = dwpt(____)
[wpt,l,packetlevels] = dwpt(____)
[wpt,l,packetlevels,f] = dwpt(____)
[wpt,l,packetlevels,f,re] = dwpt(____)
[____] = dwpt(____,Name,Value)
```

Description

`wpt = dwpt(X)` returns the terminal (final-level) nodes of the discrete wavelet packet transform (DWPT) of X . The input X is a real-valued vector, matrix, or timetable. By default, the `fk18` wavelet is used, and the decomposition level is `floor(log2(Ns))`, where Ns is the number of data samples. The wavelet packet transform `wpt` is a 1-by- N cell array, where $N = 2^{\text{floor}(\log_2(Ns))}$.

`wpt = dwpt(X,wname)` uses the wavelet specified by `wname` for the DWPT. `wname` must be recognized by `wavemngr`.

`wpt = dwpt(X,LoD,HiD)` uses the scaling (lowpass) filter, `LoD`, and wavelet (highpass) filter, `HiD`.

`[wpt,l] = dwpt(____)` also returns the bookkeeping vector using any of the previous syntaxes. The vector `l` contains the length of the input signal and the number of coefficients by level. The bookkeeping vector is required for perfect reconstruction.

`[wpt,l,packetlevels] = dwpt(____)` also returns the transform levels of the nodes of `wpt` using any of the previous syntaxes.

`[wpt,l,packetlevels,f] = dwpt(____)` also returns the center frequencies of the approximate passbands in cycles per sample using any of the previous syntaxes.

`[wpt,l,packetlevels,f,re] = dwpt(____)` also returns the relative energy for the wavelet packets in `wpt` using any of the previous syntaxes. The relative energy is the proportion of energy contained in each wavelet packet by level.

`[____] = dwpt(____,Name,Value)` specifies options using name-value pair arguments in addition to the input arguments in the previous syntaxes. For example, `'Level',4` specifies the decomposition level.

Examples

Multichannel Discrete Wavelet Packet Transform

Load the 23-channel EEG data `Espiga3` [3]. The data is sampled at 200 Hz.

```
load Espiga3
```

Compute the 1-D DWPT of the data using the `sym3` wavelet down to level 4. Obtain the terminal wavelet packet nodes, bookkeeping vector, and center frequencies of the approximate passbands.

```
[wpt,bk,~,f] = dwpt(Espiga3, 'sym3', 'Level', 4);
```

The output `wpt` is a $1\text{-by-}2^4$ cell array. Every element of `wpt` is a matrix. Choose any terminal node, and confirm the size of the matrix is $23\text{-by-}M$, where M is the last element of the bookkeeping vector `bk`.

```
nd = 13;
size(wpt{nd})
```

```
ans = 1x2
      23      66
```

```
bk(end)
```

```
ans = 66
```

Extract the final-level coefficients of the fifth channel.

```
p5 = cell2mat(cellfun(@(x) x(5,:).',wpt,'UniformOutput',false));
size(p5)
```

```
ans = 1x2
      66      16
```

The terminal nodes are sequency-ordered. Plot the center frequencies of the approximate passbands in hertz, and confirm they are in order of increasing frequency.

```
plot(200*f,'x')
title('Center Frequencies')
ylabel('Hz')
```

PR Biorthogonal Filters

This example shows how to take an expression of a biorthogonal filter pair and construct lowpass and highpass filters to produce a perfect reconstruction (PR) pair in Wavelet Toolbox™.

The LeGall 5/3 filter is the wavelet used in JPEG2000 for lossless image compression. The lowpass (scaling) filters for the LeGall 5/3 wavelet have five and three nonzero coefficients respectively. The expressions for these two filters are:

$$H_0(z) = 1/8(-z^2 + 2z + 6 + 2z^{-1} - z^{-2})$$

$$H_1(z) = 1/2(z + 2 + z^{-1})$$

Create these filters.

```
H0 = 1/8*[-1 2 6 2 -1];
H1 = 1/2*[1 2 1];
```

Many of the discrete wavelet and wavelet packet transforms in Wavelet Toolbox rely on the filters being both even-length and equal in length in order to produce the perfect reconstruction filter bank associated with these transforms. These transforms also require a specific normalization of the coefficients in the filters for the algorithms to produce a PR filter bank. Use the `biorfilt` function on the lowpass prototype functions to produce the PR wavelet filter bank.

```
[LoD,HiD,LoR,HiR] = biorfilt(H0,H1);
```

The sum of the lowpass analysis and synthesis filters is now equal to $\sqrt{2}$.

```
sum(LoD)
```

```
ans = 1.4142
```

```
sum(LoR)
```

```
ans = 1.4142
```

The wavelet filters sum, as required, to zero. The L2-norms of the lowpass analysis and highpass synthesis filters are equal. The same holds for the lowpass synthesis and highpass analysis filters.

Now you can use these filters in discrete wavelet and wavelet packet transforms and achieve a PR wavelet packet filter bank. To demonstrate this, load and plot an ECG signal.

```
load wecg
plot(wecg)
axis tight
grid on
```

Obtain the discrete wavelet packet transform of the ECG signal using the LeGall 5/3 filter set.

```
[wpt,L] = dwpt(wecg,LoD,HiD);
```

Now use the reconstruction (synthesis) filters to reconstruct the signal and demonstrate perfect reconstruction.

```
xrec = idwpt(wpt,L,LoR,HiR);  
plot([wecg xrec])  
axis tight, grid on;
```

```
norm(wecg-xrec, 'Inf')
```

```
ans = 3.1086e-15
```

You can also use this filter bank in the 1-D and 2-D discrete wavelet transforms. Read and plot an image.

```
im = imread('woodsculp256.jpg');  
image(im); axis off;
```

Obtain the 2-D wavelet transform using the LeGall 5/3 analysis filters.

```
[C,S] = wavedec2(im,3,LoD,HiD);
```

Reconstruct the image using the synthesis filters.

```
imrec = waverec2(C,S,LoR,HiR);  
image(uint8(imrec)); axis off;
```

The LeGall 5/3 filter is equivalent to the built-in 'bior2.2' wavelet in Wavelet Toolbox. Use the 'bior2.2' filters and compare with the LeGall 5/3 filters.

```
[LD,HD,LR,HR] = wfilters('bior2.2');
subplot(2,2,1)
hl = stem([LD' LoD']);
hl(1).MarkerFaceColor = [0 0 1];
hl(1).Marker = 'o';
hl(2).MarkerFaceColor = [1 0 0];
hl(2).Marker = '^';
grid on
title('Lowpass Analysis')
subplot(2,2,2)
hl = stem([HD' HiD']);
hl(1).MarkerFaceColor = [0 0 1];
hl(1).Marker = 'o';
hl(2).MarkerFaceColor = [1 0 0];
hl(2).Marker = '^';
grid on
title('Highpass Analysis')
subplot(2,2,3)
hl = stem([LR' LoR']);
hl(1).MarkerFaceColor = [0 0 1];
hl(1).Marker = 'o';
hl(2).MarkerFaceColor = [1 0 0];
hl(2).Marker = '^';
grid on
```

```

title('Lowpass Synthesis')
subplot(2,2,4)
hl = stem([HR' HiR']);
hl(1).MarkerFaceColor = [0 0 1];
hl(1).Marker = 'o';
hl(2).MarkerFaceColor = [1 0 0];
hl(2).Marker = '^';
grid on
title('Highpass Synthesis')

```

Input Arguments

X — Input data

real-valued vector | real-valued matrix | timetable

Input data, specified as a real-valued vector, matrix, or timetable. If X is a matrix, the transform is applied to each column of X . If X is a timetable, X must either contain a matrix in a single variable or column vectors in separate variables. X must be uniformly sampled.

Data Types: single | double

wname — Wavelet

'fk18' (default) | character vector | string scalar

Wavelet to use in the DWPT, specified as a character vector or string scalar. $wname$ must be recognized by `wavemngr`.

You cannot specify both `wname` and a filter pair, `LoD` and `HiD`.

Example: `wpt = dwpt(data, "sym4")` specifies the `sym4` wavelet.

LoD, HiD — Wavelet analysis filters

real-valued vectors

Wavelet analysis (decomposition) filters to use in the DWPT, specified as a pair of real-valued vectors. `LoD` is the scaling (lowpass) analysis filter, and `HiD` is the wavelet (highpass) analysis filter. You cannot specify both `wname` and a filter pair, `LoD` and `HiD`. See `wfilters` for additional information.

Note `dwpt` does not check that `LoD` and `HiD` satisfy the requirements for a perfect reconstruction wavelet packet filter bank. See “PR Biorthogonal Filters” on page 1-300 for an example of how to take a published biorthogonal filter and ensure that the analysis and synthesis filters produce a perfect reconstruction wavelet packet filter bank using `dwpt`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `wpt = dwpt(x, 'sym4', 'Level', 4)` specifies a level 4 decomposition using the `sym4` wavelet.

Level — Wavelet decomposition level

`floor(log2(Ns))` (default) | positive integer

Wavelet decomposition level, specified as a positive integer less than or equal to `floor(log2(Ns))`, where `Ns` is the number of samples in the data. If unspecified, `Level` defaults to `floor(log2(Ns))`.

FullTree — Wavelet packet tree handling

`false` or `0` (default) | `true` or `1`

Wavelet packet tree handling, specified as a numeric or logical `1` (`true`) or `0` (`false`). When set to `true`, `wpt` contains the full packet tree. When set to `false`, `wpt` contains only the terminal nodes. If unspecified, `FullTree` defaults to `false`.

Boundary — Wavelet packet transform boundary handling

'reflection' (default) | 'periodic'

Wavelet packet transform boundary handling, specified as 'reflection' or 'periodic'. Setting to 'reflection' or 'periodic', the wavelet packet coefficients are extended at each level based on the 'sym' or 'per' mode in `dwtmode`, respectively. If unspecified, `Boundary` defaults to 'reflection'.

Output Arguments

wpt — Wavelet packet transform

cell array

Wavelet packet transform, returned as a 1-by-*M* cell array. If taking the DWPT of one signal, each element of `wpt` is a vector. Otherwise, each element is a matrix. The coefficients in the *j*th row of the matrix correspond to the signal in the *j*th column of *X*. The packets are sequency-ordered.

If returning the terminal nodes of a level N decomposition, `wpt` is a 1-by- 2^N cell array. If returning the full wavelet packet tree, `wpt` is a 1-by- $(2^{N+1}-2)$ cell array.

l – Bookkeeping vector

vector of positive integers

Bookkeeping vector, returned as a vector of positive integers. The vector `l` contains the length of the input signal and the number of coefficients by level, and is required for perfect reconstruction.

packetlevels – Transform levels

vector of positive integers

Transform levels, returned as a vector of positive integers. The i th element of `packetlevels` corresponds to the i th element of `wpt`. If `wpt` contains only the terminal nodes, `packetlevels` is a vector with each element equal to the terminal level. If `wpt` contains the full wavelet packet tree, then `packetlevels` is a vector with 2^j elements for each level j .

f – Center frequencies

real-valued vector

Center frequencies of the approximate passbands in cycles per sample, returned as a real-valued vector. The j th element of `f` corresponds to the j th wavelet packet node of `wpt`. You can multiply the elements in `f` by a sampling frequency to convert to cycles per unit time.

re – Relative energy

cell array

Relative energy for the wavelet packets in `wpt`, returned as a cell array. The relative energy is the proportion of energy contained in each wavelet packet by level. The j th element of `re` corresponds to the j th wavelet packet node of `wpt`.

Each element of `re` is a scalar when taking the DWPT of one signal. Otherwise, when taking the DWPT of M signals, each element of `re` is a M -by-1 vector, where the i th element is the relative energy of the i th signal channel. For each channel, the sum of relative energies in the wavelet packets at a given level is equal to 1.

Algorithms

The `dwpt` function performs a discrete wavelet packet transform and produces a sequency-ordered wavelet packet tree. Compare the sequency-ordered and normal (Paley)-ordered trees. $\tilde{G}(f)$ is the scaling (lowpass) analysis filter, and $\tilde{H}(f)$ represents the wavelet (highpass) analysis filter. The labels at the bottom show the partition of the frequency axis $[0, \frac{1}{2}]$.

Sequency-Ordered Wavelet Packet Tree

Natural-Ordered Wavelet Packet Tree

Topics

“Wavelet Packets: Decomposing the Details”

Introduced in R2020a

dwt

Single-level 1-D discrete wavelet transform

Syntax

```
[cA,cD] = dwt(x,wname)
[cA,cD] = dwt(x,LoD,HiD)
[cA,cD] = dwt( ____, 'mode', extmode)
```

Description

`[cA,cD] = dwt(x,wname)` returns the single-level discrete wavelet transform (DWT) of the vector `x` using the wavelet specified by `wname`. The wavelet must be recognized by `wavemngr`. `dwt` returns the approximation coefficients vector `cA` and detail coefficients vector `cD` of the DWT.

Note If your application requires a multilevel wavelet decomposition, consider using `wavedec`.

`[cA,cD] = dwt(x,LoD,HiD)` returns the single-level DWT using the scaling (lowpass) filter `LoD` and wavelet (highpass) filter `HiD`. The filters must have the same length and an even number of samples.

`[cA,cD] = dwt(____, 'mode', extmode)` returns the single-level DWT with the specified extension mode `extmode`. For more information, see `dwtmode`.

Examples

DWT Using Wavelet Name

Obtain the single-level DWT of the noisy Doppler signal using a wavelet name.

```
load noisdopp;
[cA,cD] = dwt(noisdopp, 'sym4');
```

Reconstruct a smoothed version of the signal using the approximation coefficients. Plot and compare with the original signal.

```
xrec = idwt(cA,zeros(size(cA)), 'sym4');
plot(noisdopp)
hold on
grid on
plot(xrec)
legend('Original', 'Reconstruction')
```

DWT Using Wavelet and Scaling Filters

Obtain the single-level DWT of a noisy Doppler signal using the wavelet (highpass) and scaling (lowpass) filters.

```
load noisdopp;
[LoD,HiD] = wfilters('bior3.5','d');
[cA,cD] = dwt(noisdopp,LoD,HiD);
```

Create a DWT filter bank that can be applied to the noisy Doppler signal using the same wavelet. Obtain the highpass and lowpass filters from the filter bank.

```
len = length(noisdopp);
fb = dwtfilterbank('SignalLength',len,'Wavelet','bior3.5');
[lo,hi] = filters(fb);
```

For the `bior3.5` wavelet, `lo` and `hi` are 12-by-2 matrices. `lo` are the lowpass filters, and `hi` are the highpass filters. The first columns of `lo` and `hi` are used for analysis and the second columns are used for synthesis. Compare the first column of `lo` and `hi` with `LoD` and `HiD` respectively. Confirm they are equal.

```

Input Arguments

x — Input data

numeric vector

Input data, specified as a numeric vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

wname — Analyzing wavelet

character vector | string scalar

Analyzing wavelet used to compute the single-level DWT, specified as a character vector or string scalar. The wavelet must be recognized by `wavemngr`. The analyzing wavelet is from one of the following wavelet families: Daubechies, Coiflets, Symlets, Fejér-Korovkin, Discrete Meyer, Biorthogonal, and Reverse Biorthogonal. See `wfilters` for the wavelets available in each family.

Example: `'db4'`

LoD — Scaling filter

even-length real-valued vector

Scaling (lowpass) filter, specified as an even-length real-valued vector. `LoD` must be the same length as `HiD`. See `wfilters` for details.

Data Types: `double` | `single`

HiD — Wavelet filter

even-length real-valued vector

Wavelet (highpass) filter, specified as an even-length real-valued vector. `HiD` must be the same length as `LoD`. See `wfilters` for details.

Data Types: `double` | `single`

extmode — Extension mode

'zpd' | 'sp0' | 'spd' | ...

Extension mode used when performing the DWT, specified as one of the following:

mode	DWT Extension Mode
'zpd'	Zero extension
'sp0'	Smooth extension of order 0
'spd' (or 'sp1')	Smooth extension of order 1
'sym' or 'symh'	Symmetric extension (half point): boundary value symmetric replication
'symw'	Symmetric extension (whole point): boundary value symmetric replication
'asym' or 'asymh'	Antisymmetric extension (half point): boundary value antisymmetric replication
'asymw'	Antisymmetric extension (whole point): boundary value antisymmetric replication
'ppd'	Periodized extension (1)
'per'	Periodized extension (2) If the signal length is odd, <code>wextend</code> adds to the right an extra sample that is equal to the last value, and performs the extension using the 'ppd' mode. Otherwise, 'per' reduces to 'ppd'. This rule also applies to images.

The global variable managed by `dwtmode` specifies the default extension mode. See `dwtmode` for extension mode descriptions.

Example: `[cA,cD] = dwt(x,'db4','mode','symw')` returns the single-level DWT of `x` using the order 4 Daubechies extremal phase wavelet and whole point symmetric extension.

Output Arguments**cA — Approximation coefficients**

real-valued vector

Approximation coefficients obtained from the wavelet decomposition, returned as a vector. Convolution of the input signal `x` with the scaling filter `LoD`, followed by dyadic decimation, yields the approximation coefficients. Let `sx = size(x)` and `lf =` the length of the decomposition filters.

- If the DWT extension mode is set to periodization, `cA` is a vector of length `ceil(sx/2)`.
- For the other extension modes, `cA` is a vector of length `floor((sx+lf-1)/2)`.

Data Types: double | single

cd — Detail coefficients

real-valued vector

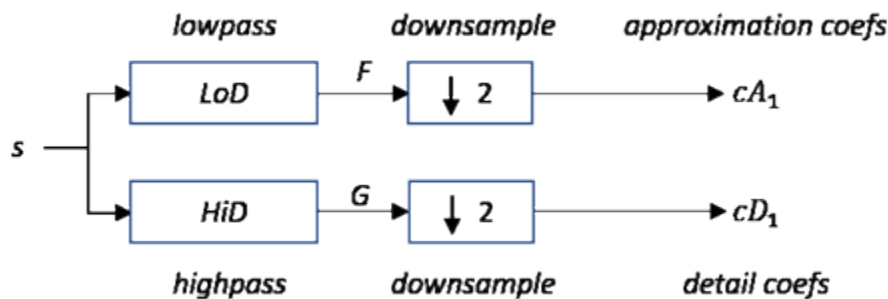

Detail coefficients obtained from the wavelet decomposition, returned as a vector. Convolution of the input signal x with the wavelet filter HiD , followed by dyadic decimation, yields the detail coefficients. Let $sx = \text{size}(x)$ and $lf =$ the length of the decomposition filters.

- If the DWT extension mode is set to periodization, cd is a vector of length $\text{ceil}(sx/2)$.
- For the other extension modes, cd is a vector of length $\text{floor}((sx+lf-1)/2)$.

Data Types: double | single

Algorithms

Starting from a signal s of length N , two sets of coefficients are computed: approximation coefficients cA_1 , and detail coefficients cD_1 . Convolution of s with the scaling filter LoD , followed by dyadic decimation, yields the approximation coefficients. Similarly, convolution of s with the wavelet filter HiD , followed by dyadic decimation, yields the detail coefficients.

where

- \boxed{X} — Convolve with filter X
- $\boxed{\downarrow 2}$ — Downsample (keep the even-indexed elements)

The length of each filter is equal to $2n$. If $N = \text{length}(s)$, the signals F and G are of length $N + 2n - 1$ and the coefficients cA_1 and cD_1 are of length $\text{floor}\left(\frac{N-1}{2}\right) + n$.

To deal with signal-end effects resulting from a convolution-based algorithm, a global variable managed by `dwtmode` defines the kind of signal extension mode used. The possible options include zero-padding and symmetric extension, which is the default mode.

Note For the same input, the `dwt` function and the DWT block in the DSP System Toolbox™ do not produce the same results. The DWT block is designed for real-time implementation while Wavelet Toolbox software is designed for analysis, so the products handle boundary conditions and filter states differently.

To make the `dwt` function output match the DWT block output, set the function boundary condition to zero-padding by typing `dwtmode('zpd')` at the MATLAB command prompt. To match the latency of the DWT block, which is implemented using FIR filters, add zeros to the input of the `dwt` function. The number of zeros you add must be equal to half the filter length.

dwt2

Single-level discrete 2-D wavelet transform

Syntax

```
[cA,cH,cV,cD] = dwt2(X,wname)
[cA,cH,cV,cD] = dwt2(X,LoD,HiD)
[cA,cH,cV,cD] = dwt2( ____, 'mode', extmode)
```

Description

`dwt2` computes the single-level 2-D wavelet decomposition. Compare `dwt2` with `wavedec2` which may be more useful for your application. The decomposition is done with respect to either a particular wavelet (see `wfilters` for more information) or particular wavelet decomposition filters.

`[cA,cH,cV,cD] = dwt2(X,wname)` computes the single-level 2-D discrete wavelet transform (DWT) of the input data `X` using the `wname` wavelet. `dwt2` returns the approximation coefficients matrix `cA` and detail coefficients matrices `cH`, `cV`, and `cD` (horizontal, vertical, and diagonal, respectively).

`[cA,cH,cV,cD] = dwt2(X,LoD,HiD)` computes the single-level 2-D DWT using the wavelet decomposition lowpass filter `LoD` and highpass filter `HiD`. The decomposition filters must have the same length and an even number of samples.

`[cA,cH,cV,cD] = dwt2(____, 'mode', extmode)` computes the single-level 2-D DWT with the extension mode `extmode`. Include this argument after all other arguments.

Examples

Single-Level 2-D Discrete Wavelet Transform of an Image

Load and display an image.

```
load woman
imagesc(X)
colormap(map)
```

Obtain the single-level 2-D discrete wavelet transform of the image using the order 4 symlet and periodic extension.

```
[cA,cH,cV,cD] = dwt2(X, 'sym4', 'mode', 'per');
```

Display the vertical detail coefficients and the approximation coefficients.

```
imagesc(cV)  
title('Vertical Detail Coefficients')
```

```

colormap gray
title('Diagonal')
```

Input Arguments

X — Input data

numeric array | logical array

Input data, specified as a numeric or logical array. **X** can be an *m*-by-*n* array representing an indexed image or an *m*-by-*n*-by-3 array representing a truecolor image. For more information on truecolor images, see “RGB (Truecolor) Images” (MATLAB).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

wname — Analyzing wavelet

character vector | string scalar

Analyzing wavelet used to compute the 2-D DWT, specified as a character vector or string scalar. The analyzing wavelet is from one of the following wavelet families: Daubechies, Coiflets, Symlets, Fejér-Korovkin, Discrete Meyer, Biorthogonal, and Reverse Biorthogonal. See `wfilters` for the wavelets available in each family.

LoD — Wavelet decomposition lowpass filter

even-length real-valued vector

Wavelet decomposition lowpass filter, specified as an even-length real-valued vector. **LoD** must be of the same length as **HiD**.

Data Types: double | single

HiD — Wavelet decomposition highpass filter

even-length real-valued vector

Wavelet decomposition highpass filter, specified as an even-length real-valued vector. HiD must be of the same length as LoD.

Data Types: double | single

extmode — Extension mode

'zpd' | 'sp0' | 'spd' | ...

Extension mode used when performing the DWT, specified as one of the following:

mode	DWT Extension Mode
'zpd'	Zero extension
'sp0'	Smooth extension of order 0
'spd' (or 'sp1')	Smooth extension of order 1
'sym' or 'symh'	Symmetric extension (half point): boundary value symmetric replication
'symw'	Symmetric extension (whole point): boundary value symmetric replication
'asym' or 'asymh'	Antisymmetric extension (half point): boundary value antisymmetric replication
'asymw'	Antisymmetric extension (whole point): boundary value antisymmetric replication
'ppd'	Periodized extension (1)
'per'	Periodized extension (2) If the signal length is odd, <code>wextend</code> adds to the right an extra sample that is equal to the last value, and performs the extension using the 'ppd' mode. Otherwise, 'per' reduces to 'ppd'. This rule also applies to images.

The global variable managed by `dwtmode` specifies the default extension mode.

Example: `[cA,cH,cV,cD] = dwt2(x,'db4','mode','symw');`

Output Arguments

cA — Approximation coefficients

array

Approximation coefficients, returned as an array whose size depends on X. Let `sx = size(X)` and `lf =` the length of the decomposition filters.

- If the DWT extension mode is set to periodization, then this output is of size `ceil(sx/2)`.
- For the other extension modes, this output is of size `floor((sx+lf-1)/2)`.

Data Types: double | single

cH — Horizontal detail coefficients

array

Horizontal detail coefficients, returned as an array whose size depends on X . Let $sx = \text{size}(X)$ and $lf =$ the length of the decomposition filters.

- If the DWT extension mode is set to periodization, then this output is of size $\text{ceil}(sx/2)$.
- For the other extension modes, this output is of size $\text{floor}((sx+lf-1)/2)$.

Data Types: double | single

cV — Vertical detail coefficients

array

Vertical detail coefficients, returned as an array whose size depends on X . Let $sx = \text{size}(X)$ and $lf =$ the length of the decomposition filters.

- If the DWT extension mode is set to periodization, then this output is of size $\text{ceil}(sx/2)$.
- For the other extension modes, this output is of size $\text{floor}((sx+lf-1)/2)$.

Data Types: double | single

cD — Diagonal detail coefficients

array

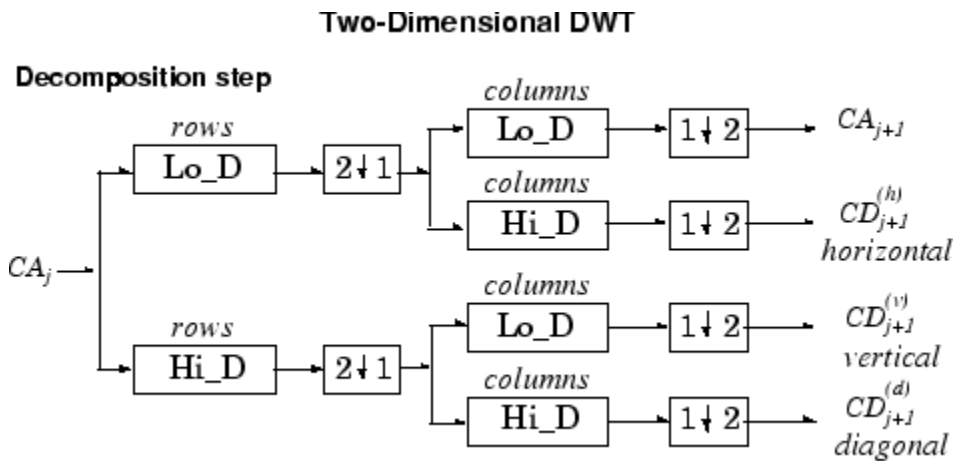

Diagonal detail coefficients, returned as an array whose size depends on X . Let $sx = \text{size}(X)$ and $lf =$ the length of the decomposition filters.

- If the DWT extension mode is set to periodization, then this output is of size $\text{ceil}(sx/2)$.
- For the other extension modes, this output is of size $\text{floor}((sx+lf-1)/2)$.

Data Types: double | single

Algorithms

The 2-D wavelet decomposition algorithm for images is similar to the one-dimensional case. The two-dimensional wavelet and scaling functions are obtained by taking the tensor products of the one-dimensional wavelet and scaling functions. This kind of two-dimensional DWT leads to a decomposition of approximation coefficients at level j in four components: the approximation at level $j + 1$, and the details in three orientations (horizontal, vertical, and diagonal). The following chart describes the basic decomposition steps for images.

- $\begin{bmatrix} 2 & \downarrow & 1 \end{bmatrix}$ — Downsample columns: keep the even indexed columns
- $\begin{bmatrix} 1 & \downarrow & 2 \end{bmatrix}$ — Downsample rows: keep the even indexed rows
- $\begin{matrix} \text{rows} \\ \boxed{X} \end{matrix}$ — Convolve with filter X the rows of the entry
- $\begin{matrix} \text{columns} \\ \boxed{X} \end{matrix}$ — Convolve with filter X the columns of the entry

The decomposition is initialized by setting the approximation coefficients equal to the image s : $CA_0 = s$.

Note To deal with signal-end effects introduced by a convolution-based algorithm, the 1-D and 2-D DWT use a global variable managed by `dwtmode`. This variable defines the kind of signal extension mode used. The possible options include zero-padding and symmetric extension, which is the default mode.

Introduced before R2006a

dwt3

Single-level discrete 3-D wavelet transform

Syntax

```
wt = dwt3(x,wname)
wt = dwt3(x,wname,'mode',extM)
wt = dwt3(x,w,___)
wt = dwt3(x,wf,___)
```

Description

`wt = dwt3(x,wname)` returns the single-level three-dimensional wavelet decomposition `wt` of the input data `x` using the `wname` wavelet. The default extension mode of the 3-D discrete wavelet transform (DWT) is 'sym' (see `dwtmode`).

`wt = dwt3(x,wname,'mode',extM)` uses the extension mode `extM` (see `dwtmode`).

`wt = dwt3(x,w,___)` specifies three wavelets, one for each direction. `w` is a cell array, string array, or structure, and can be followed by 'mode', `extM`.

`wt = dwt3(x,wf,___)` specifies four filters, two for decomposition and two for reconstruction, or 3×4 filters (one quadruplet by direction). `wf` is a cell array or structure, and can be followed by 'mode', `extM`.

Examples

Single-Level Three-Dimensional Wavelet Decomposition

Define the original 3-D data.

```
X = reshape(1:64,4,4,4)
```

```
X =
X(:,:,1) =
```

1	5	9	13
2	6	10	14
3	7	11	15
4	8	12	16

```
X(:,:,2) =
```

17	21	25	29
18	22	26	30
19	23	27	31
20	24	28	32

```
X(:,:,3) =
```

```
    33    37    41    45
    34    38    42    46
    35    39    43    47
    36    40    44    48
```

```
X(:,:,4) =
```

```
    49    53    57    61
    50    54    58    62
    51    55    59    63
    52    56    60    64
```

Perform single-level decomposition of X using 'db1'.

```
wt = dwt3(X, 'db1')
```

```
wt = struct with fields:
  sizeINI: [4 4 4]
  filters: [1x1 struct]
  mode: 'sym'
  dec: {2x2x2 cell}
```

Decompose X using 'db2'.

```
[LoD,HiD,LoR,HiR] = wfilters('db2');
wt = dwt3(X,{LoD,HiD,LoR,HiR})
```

```
wt = struct with fields:
  sizeINI: [4 4 4]
  filters: [1x1 struct]
  mode: 'sym'
  dec: {2x2x2 cell}
```

Decompose X using different wavelets, one for each orientation: 'db1', 'db2', and again 'db1'.

```
WS = struct('w1','db1','w2','db2','w3','db1');
wt = dwt3(X,WS, 'mode', 'per')
```

```
wt = struct with fields:
  sizeINI: [4 4 4]
  filters: [1x1 struct]
  mode: 'per'
  dec: {2x2x2 cell}
```

Decompose X using the filters given by WF and set the extension mode to symmetric.

```
WF = wt.filters;
wtBIS = dwt3(X,WF, 'mode', 'sym')
```

```
wtBIS = struct with fields:
  sizeINI: [4 4 4]
  filters: [1x1 struct]
```

```
mode: 'sym'
dec: {2x2x2 cell}
```

Input Arguments

x — Input data

3-D array

Input data, specified as a 3-D array.

Data Types: double

wname — Analyzing wavelet

character vector | string scalar

Analyzing wavelet used to compute the 2-D DWT, specified as a character vector or string scalar. The analyzing wavelet is from one of the following wavelet families: Daubechies, Coiflets, Symlets, Fejér-Korovkin, Discrete Meyer, Biorthogonal, and Reverse Biorthogonal. See `wfilters` for the wavelets available in each family.

w — Analyzing wavelets

cell array of character vectors | string array | structure

Analyzing wavelets to use in the 3-D wavelet decomposition, one for each direction, specified as a cell array of character vectors, a string array, or a structure. `w = {'wname1', 'wname2', 'wname3'}`, or `w = ["wname1", "wname2", "wname3"]`, or `w` is a structure with 3 fields 'w1', 'w2', 'w3' containing character vectors or string scalars that are the names of wavelets.

Example: `wt = dwt3(x, ["db2", "db4", "db6"]);`

wf — Wavelet filters

cell array | structure

Wavelet filters to use in the 3-D wavelet decomposition, specified as either a cell array or structure. `wf` specifies four filters, two for decomposition and two for reconstruction, or 3×4 filters (one quadruplet by direction). `wf` is either a cell array (1×4) or (3×4): `{LoD, HiD, LoR, HiR}` or a structure with the four fields 'LoD', 'HiD', 'LoR', 'HiR'.

extM — Extension mode

'zpd' | 'sp0' | 'spd' | ...

Extension mode used when performing the 3-D DWT, specified as one of the following:

mode	DWT Extension Mode
'zpd'	Zero extension
'sp0'	Smooth extension of order 0
'spd' (or 'sp1')	Smooth extension of order 1
'sym' or 'symh'	Symmetric extension (half point): boundary value symmetric replication

mode	DWT Extension Mode
'symw'	Symmetric extension (whole point): boundary value symmetric replication
'asym' or 'asymh'	Antisymmetric extension (half point): boundary value antisymmetric replication
'asymw'	Antisymmetric extension (whole point): boundary value antisymmetric replication
'ppd'	Periodized extension (1)
'per'	Periodized extension (2) If the signal length is odd, <code>wextend</code> adds to the right an extra sample that is equal to the last value, and performs the extension using the 'ppd' mode. Otherwise, 'per' reduces to 'ppd'. This rule also applies to images.

The global variable managed by `dwtmode` specifies the default extension mode.

Output Arguments

wt — Single-level 3-D wavelet decomposition

structure

Single-level 3-D wavelet decomposition, returned as a structure with the following fields:

<code>sizeINI</code>	Size of the three-dimensional array <code>X</code> .
<code>mode</code>	Name of the wavelet transform extension mode.
<code>filters</code>	Structure with four fields: <code>LoD</code> , <code>HiD</code> , <code>LoR</code> , <code>HiR</code> , which are the filters used for DWT.
<code>dec</code>	<p>$2 \times 2 \times 2$ cell array containing the coefficients of the decomposition.</p> <p><code>dec{i,j,k}</code>, $i,j,k = 1$ or 2 contains the coefficients obtained by lowpass filtering (for i or j or $k = 1$) or highpass filtering (for i or j or $k = 2$).</p> <p>The i element filters along the rows of <code>X</code>, the j element filters along the columns, and the k element filters along the third dimension. For example, <code>dec{1,2,1}</code> is obtained by filtering <code>X</code> along the rows with the lowpass (scaling) filter, along the columns with the highpass (wavelet) filter, and along the third dimension with the lowpass (scaling) filter.</p>

Introduced in R2010a

dwtfilterbank

Discrete wavelet transform filter bank

Description

Use `dwtfilterbank` to create a discrete wavelet transform (DWT) filter bank

- Visualize wavelets and scaling functions in time and frequency.
- Measure the 3-dB bandwidths of the wavelet and scaling functions. You can also measure energy concentration of the wavelet and scaling functions in the theoretical DWT passbands.
- Create a DWT filter bank using your own custom filters. You can determine whether the filter bank is orthogonal or biorthogonal.
- Determine the frame bounds of the filter bank.

Creation

Syntax

```
fb = dwtfilterbank  
fb = dwtfilterbank(Name,Value)
```

Description

`fb = dwtfilterbank` create a discrete wavelet transform (DWT) filter bank. The default filter bank is designed for a signal with 1024 samples. The default filter bank uses the analysis (decomposition) `sym4` wavelet and scaling filter with seven resolution levels.

`fb = dwtfilterbank(Name,Value)` creates a DWT filter bank `fb` with properties specified by one or more `Name,Value` pair arguments. Properties can be specified in any order as `Name1,Value1,...,NameN,ValueN`. Enclose each property name in quotes.

For example, `fb = dwtfilterbank('SignalLength',1000,'Wavelet','bior4.4')` creates a DWT filter bank for signals of length 1000 using the biorthogonal `bior4.4` wavelet.

Note You cannot change a property value of an existing filter bank. For example, if you have a filter bank `fb` for the `sym4` wavelet, you must create a second filter bank `fb2` for the `coif5` wavelet. You cannot assign a different `Wavelet` to `fb`.

Properties

SignalLength — Signal length

1024 (default) | positive integer greater than or equal to 2

Signal length, specified as a positive integer greater than or equal to 2.

Example: `'SignalLength',768`

Data Types: double

Wavelet — Name of wavelet

'sym4' (default) | 'Custom' | character vector | string scalar

Name of wavelet used to construct the filter bank, specified as a character vector or string scalar. **Wavelet** is an orthogonal or biorthogonal wavelet recognized by `wavemngr` or 'Custom'.

To use a wavelet filter not recognized by `wavemngr`, set the **Wavelet** property to 'Custom' and specify the “CustomWaveletFilter” on page 1-0 and “CustomScalingFilter” on page 1-0 properties.

Example: 'Wavelet', 'bior4.4'

Data Types: char | string

FilterType — Wavelet filter type

'Analysis' (default) | 'Synthesis'

Wavelet filter type, specified as one of 'Analysis' or 'Synthesis'. 'Analysis' uses the decomposition filters returned by `wfilters`. 'Synthesis' uses the reconstruction filters.

Level — Wavelet transform level

7 (default) | positive integer

Wavelet transform level, specified as a positive integer less than or equal to $\text{floor}(\log_2(\text{SignalLength}))$. For a signal of length 1024 and the `sym4` wavelet, the default level is 7.

By default the level is equal to $\text{floor}(\log_2(\text{SignalLength}/(L-1)))$ where L is the length of the wavelet filter associated with **Wavelet**. For wavelets recognized by `wavemngr`, the transform level is equal to `wmaxlev(SignalLength, Wavelet)`. If $\text{floor}(\log_2(\text{SignalLength}/(L-1)))$ is less than or equal to 0, **Level** defaults to $\text{floor}(\log_2(\text{SignalLength}))$.

SamplingFrequency — Sampling frequency in hertz

1 (default) | positive scalar

Sampling frequency in hertz, specified as a positive scalar. If unspecified, frequencies are in cycles/sample and the Nyquist frequency is $\frac{1}{2}$.

Example: 'SamplingFrequency', 5

Data Types: double

CustomWaveletFilter — Custom wavelet filter coefficients

even-length column vector | two-column matrix with even number of rows

Custom wavelet filter coefficients, specified as a real-valued column vector or matrix. **CustomWaveletFilter** must be an even-length column vector for an orthogonal wavelet or a two-column matrix with an even number of rows for a biorthogonal wavelet.

This property applies only when **Wavelet** is set to 'Custom'.

CustomScalingFilter — Custom scaling filter coefficients

even-length column vector | two-column matrix with even number of rows

Custom scaling filter coefficients, specified as a real-valued column vector or matrix. `CustomScalingFilter` must be an even-length column vector for an orthogonal wavelet or a two-column matrix with an even number of rows for a biorthogonal wavelet.

This property applies only when `Wavelet` is set to `'Custom'`.

Object Functions

<code>dwtpassbands</code>	DWT filter bank passbands
<code>filters</code>	DWT filter bank filters
<code>framebounds</code>	DWT filter bank frame bounds
<code>freqz</code>	DWT filter bank frequency responses
<code>isBiorthogonal</code>	Determine if DWT filter bank is biorthogonal
<code>isOrthogonal</code>	Determine if DWT filter bank is orthogonal
<code>powerbw</code>	DWT filter bank power bandwidth
<code>qfactor</code>	DWT filter bank quality factor
<code>scalingfunctions</code>	DWT filter bank time-domain scaling functions
<code>wavelets</code>	DWT filter bank time-domain wavelets
<code>waveletsupport</code>	DWT filter bank time supports

Examples

Discrete Wavelet Transform Filter Bank with Default Values

Create a DWT filter bank using default values.

```
fb = dwtfilterbank

fb =
    dwtfilterbank with properties:
        Wavelet: 'sym4'
        SignalLength: 1024
        Level: 7
        SamplingFrequency: 1
        FilterType: 'Analysis'
        CustomWaveletFilter: []
        CustomScalingFilter: []
```

Plot the magnitude frequency responses of the wavelets and coarsest-scale scaling function. Open the plot in a separate figure window. The plot legend in the window is interactive. To hide a particular frequency response, click on its name.

```
freqz(fb)
```

Obtain and plot the time-centered wavelets corresponding to the wavelet bandpass filters.

```
[psi,t] = wavelets(fb);  
plot(t,psi')  
grid on  
title('Time-Centered Wavelets')  
xlabel('Time')  
ylabel('Magnitude')
```

Create DWT Filter Bank Using Custom Filters

This example shows how to create a DWT filter bank using custom biorthogonal wavelet filters.

Two pairs of analysis (decomposition) and synthesis (reconstruction) filters are associated with a biorthogonal wavelet. Each pair consists of a lowpass and highpass filter. Specify the analysis and synthesis filters for the nearly-orthogonal biorthogonal wavelets based on the Laplacian pyramid scheme of Burt and Adelson (Table 8.4 on page 283 in [1]). Because the toolbox requires that all filters associated with a biorthogonal wavelet or an orthogonal wavelet have the same even length, the filters are prepended and appended with 0s.

```
Hd = [0 -1 5 12 5 -1 0 0]/20*sqrt(2);
Gd = [0 3 -15 -73 170 -73 -15 3]/280*sqrt(2);
Hr = [0 -3 -15 73 170 73 -15 -3]/280*sqrt(2);
Gr = [0 -1 -5 12 -5 -1 0 0]/20*sqrt(2);
```

Hd and Gd are the lowpass and highpass decomposition filters, respectively. Hr and Gr are the lowpass and highpass reconstruction filters, respectively.

Construct analysis and synthesis DWT filter banks using the biorthogonal filters. Confirm the filter banks are biorthogonal and not orthogonal.

```
fbAna = dwtfilterbank('Wavelet','Custom',...
    'CustomScalingFilter',[Hd' Hr'],'CustomWaveletFilter',[Gd' Gr]);
```

```

fbSyn = dwtfilterbank('Wavelet','Custom',...
    'CustomScalingFilter',[Hd' Hr'],'CustomWaveletFilter',[Gd' Gr'],...
    'FilterType','Synthesis');
fprintf('fbAna: isOrthogonal = %d\tisBiorthogonal = %d\n',...
    isOrthogonal(fbAna),isBiorthogonal(fbAna));

fbAna: isOrthogonal = 0    isBiorthogonal = 1

fprintf('fbSyn: isOrthogonal = %d\tisBiorthogonal = %d\n',...
    isOrthogonal(fbSyn),isBiorthogonal(fbSyn ));

fbSyn: isOrthogonal = 0    isBiorthogonal = 1

```

Obtain the wavelet and scaling functions of both filter banks. Plot the wavelet and scaling functions at the coarsest scales.

```

[fbAna_phi,t] = scalingfunctions(fbAna);
[fbAna_psi,~] = wavelets(fbAna);
[fbSyn_phi,~] = scalingfunctions(fbSyn);
[fbSyn_psi,~] = wavelets(fbSyn);
subplot(2,2,1)
plot(t,fbAna_phi(end,:))
grid on
title('Analysis - Scaling')
subplot(2,2,2)
plot(t,fbAna_psi(end,:))
grid on
title('Analysis - Wavelet')
subplot(2,2,3)
plot(t,fbSyn_phi(end,:))
grid on
title('Synthesis - Scaling')
subplot(2,2,4)
plot(t,fbSyn_psi(end,:))
grid on
title('Synthesis - Wavelet')

```

Compute the framebounds of the two filter banks. Since the filters are associated with biorthogonal wavelets, the framebounds will not equal 1.

```
[a1,a2] = framebounds(fbAna)
```

```
a1 = 0.9505
```

```
a2 = 1.0211
```

```
[b1,b2] = framebounds(fbSyn)
```

```
b1 = 0.9800
```

```
b2 = 1.0528
```

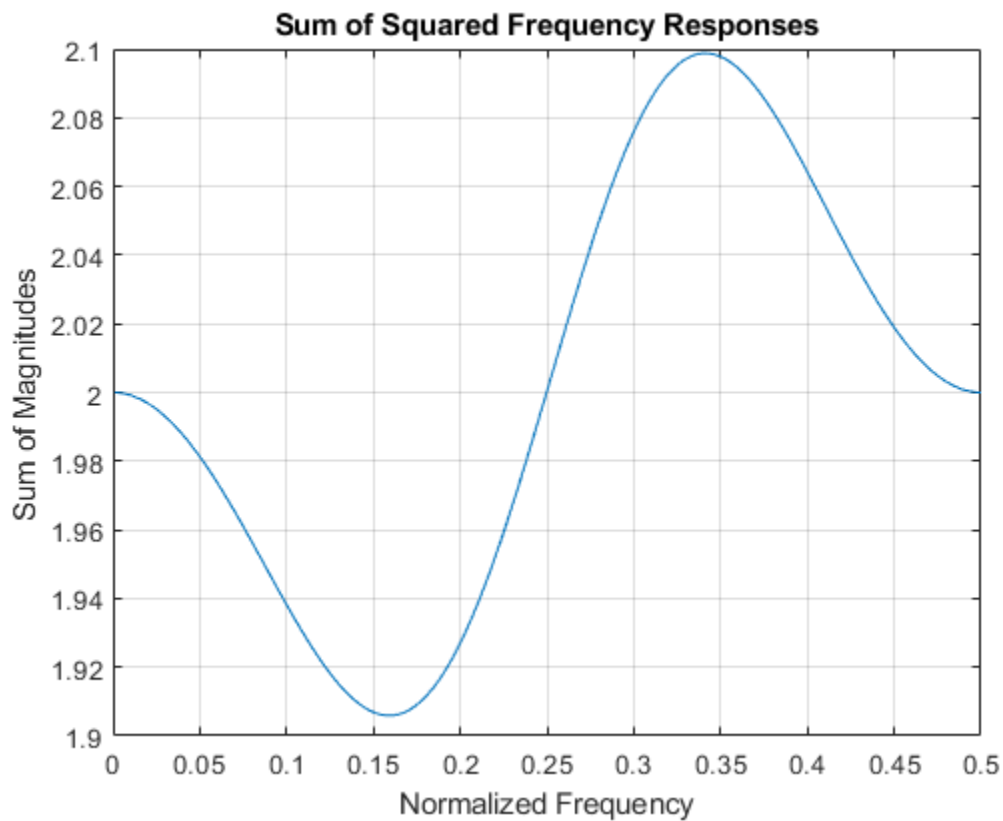

Obtain the frequency responses of the scaling and wavelets filters in the analysis filter bank. Plot up to Nyquist the magnitude frequency responses of the scaling and wavelet filters at the finest scale.

```
[psidft,f,phidft] = freqz(fbAna);
flen = length(f);
figure
plot(f(flen/2+1:end),abs(phidft(1,flen/2+1:end)))
hold on
plot(f(flen/2+1:end),abs(psidft(1,flen/2+1:end)))
grid on
legend('Scaling','Wavelet')
title('Frequency Responses')
xlabel('Normalized Frequency')
ylabel('Magnitude')
```

Zoom in and confirm the magnitude frequency responses at the point of intersection are not magnitude equal to 1. Plot the sum of the squared magnitudes of the frequency responses. Because the scaling (lowpass) and wavelet (highpass) filters do not form an orthogonal quadrature mirror filter pair, the sum does not equal to 2 at all frequencies.

```
figure
plot(f(flen/2+1:end),abs(phidft(1,flen/2+1:end)).^2 + abs(psidft(1,flen/2+1:end)).^2)
grid on
title('Sum of Squared Frequency Responses')
xlabel('Normalized Frequency')
ylabel('Sum of Magnitudes')
```

Topics

“Add Quadrature Mirror and Biorthogonal Wavelet Filters”

Introduced in R2018a

dwtleader

Multifractal 1-D wavelet leader estimates

Syntax

```
[dh,h] = dwtleader(x)
[dh,h,cp] = dwtleader(x)
[dh,h,cp,tauq] = dwtleader(x)
[dh,h,cp,tauq,leaders] = dwtleader( ___ )
[dh,h,cp,tauq,leaders,structfunc] = dwtleader( ___ )

[ ___ ] = dwtleader(x,wname)
[ ___ ] = dwtleader( ___ ,Name,Value)
```

Description

`[dh,h] = dwtleader(x)` returns the singularity spectrum, `dh`, and the Holder exponents, `h`, for the 1-D real-valued data, `x`. The singularity spectrum and Holder exponents are estimated for the linearly-spaced moments of the structure functions from -5 to +5.

`[dh,h,cp] = dwtleader(x)` also returns the first three log cumulants, `cp` of the scaling exponents.

`[dh,h,cp,tauq] = dwtleader(x)` also returns the scaling exponents for the linearly spaced moments from -5 to 5. Wavelet leaders are not defined for the finest scale.

`[dh,h,cp,tauq,leaders] = dwtleader(___)` also returns the wavelet leaders by scale.

`[dh,h,cp,tauq,leaders,structfunc] = dwtleader(___)` also returns the multiresolution structure functions.

`[___] = dwtleader(x,wname)` uses the orthogonal or biorthogonal wavelet specified by `wname` to compute the wavelet leaders and the fractal estimates.

`[___] = dwtleader(___ ,Name,Value)` returns the wavelet leaders and other specified outputs with additional options specified by one or more `Name,Value` pair arguments.

Examples

Multifractal Spectrum of Heart-Rate Variability

Compare the multifractal spectrum of heart-rate variability data before and after application of a drug that reduces heart dynamics.

```
load hrvDrug;
predrug = hrvDrug(1:4642);
postdrug = hrvDrug(4643:end);
[dhpre,hpre] = dwtleader(predrug);
[dhpost,hpost] = dwtleader(postdrug);
```

```

plot(hpre,dhpre,hpost,dhpost)
xlabel('h')
ylabel('D(h)')
grid on
legend('Predrug','Postdrug')

```

The spread of the Holder exponent values before drug administration (approximately 0.08 to 0.55) is much larger than the spread of the values afterward (approximately 0.08 to 0.31). This indicates that the heart rate has become more monofractal.

Brownian Noise Singularity Spectrum

Compute the singularity spectrum and cumulants for a Brownian noise process.

Create the Brownian noise signal.

```

rng(100);
x = cumsum(randn(2^15,1));

```

Obtain and plot the singularity spectrum.

```

[dh,h,cp] = dwtleader(x);
plot(h,dh,'o-','MarkerFaceColor','b')
grid on
title({'Singularity Spectrum'; ['First Cumulant ' num2str(cp(1))]}

```

The small spread in the Holder exponents (approximately 0.472 to 0.512) indicates that this Brownian noise signal can be characterized by a global Holder exponent of 0.49875. The theoretical Holder exponent for Brownian motion is 0.5.

Obtain the cumulants.

cp

cp = 1×3

```
0.4554   -0.0121   -0.0000
```

The first cumulant value is the slope of scaling exponents versus the moments. The second and third cumulants indicate the deviation from linearity. The first cumulant value and near-zero values of the second and third cumulants indicate that the scaling exponents are a linear function of the moments. Therefore, this Brownian motion signal is monofractal.

Multifractal Random Walk Cumulants

Compute the cumulants for a multifractal random walk. The multifractal random walk is a realization of a random process with a theoretical first cumulant of 0.75 and a second cumulant -0.05 . The second cumulant value of -0.05 indicates that the scaling exponents deviate from a linear function with slope 0.75.

Load a random walk signal.

```
load mrw07505
```

Obtain and display the first and second cumulants.

```
[~,~,cp,tauq] = dwtleader(mrw07505);  
cp([1 2])
```

```
ans = 1x2
```

```
0.7504 -0.0554
```

For monofractal processes, the scaling exponents are a linear function of the moments. Linearity is indicated by the second and third cumulants being close to zero. In this case, the nonzero second cumulant indicates that the process is multifractal.

Plot the scaling exponents for the q th moments.

```
plot(-5:5,tauq,'bo--')  
title('Estimated Scaling Exponents')  
grid on  
xlabel('qth Moments')  
ylabel('\tau(q)')
```

The scaling exponents are a nonlinear function of the moments.

Input Arguments

x — Input signal

vector of real values

Input signal, specified as a 1-D vector of real values. For the default wavelet and minimum regression level, the time series must have at least 248 samples. For nondefault values, the minimum-required data length depends on the wavelet filter and the levels used in the regression model. The wavelet leaders technique works best for data with 8000 or more samples.

wname — Wavelet name

'bior1.5' (default) | character vector | string scalar

Wavelet name, specified as a character vector or string scalar. `wname` is a wavelet family short name and filter number recognized by the wavelet manager, `wavemngr`.

To query valid wavelet family short names, use `wavemngr('read')`. To determine whether a particular wavelet is orthogonal or biorthogonal, use `waveinfo` with the wavelet family short name, for example, `waveinfo('db')`. Alternatively, use `wavemngr` with the 'type' option, for example, `wavemngr('type','fk4')`. A returned value of 1 indicates an orthogonal wavelet. A returned value of 2 indicates a biorthogonal wavelet.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'MinRegressionLevel',5` sets the minimum regression level to 5.

RegressionWeight — Weight option

'uniform' (default) | 'scale'

Weight option to use in the weighted least-squares regression model to determine the singularity spectrum, Holder exponents, cumulants, and scaling exponents, specified as the comma-separated pair consisting of 'RegressionWeight' and either 'uniform' or 'scale'. The 'uniform' option applies equal weight to each scale. The 'scale' option uses the number of wavelet leaders by scale as weights.

Note To duplicate the behavior of `dwtleader` found in releases prior to R2018a, update all instances of `dwtleader` to include the name-value pair argument 'RegressionWeight' set to 'scale'.

MinRegressionLevel — Minimum regression level

3 (default) | positive integer

Minimum regression level, *minlev*, specified as the comma-separated pair consisting of 'MinRegressionLevel' and a positive integer greater than or equal to 2. Only levels greater than or equal to the specified minimum level are used in the multifractal estimates. `dwtleader` requires at least 6 wavelet leaders at the maximum level and two levels to be used in the multifractal estimates. The scale in the discrete wavelet transform corresponding to the minimum level is 2^{minlev} . The smoother the data (that is, the closer the Holder exponents are to 1), the less likely that reducing the minimum regression level will degrade the results.

MaxRegressionLevel — Maximum regression level

positive integer

Maximum regression level, *maxlev*, specified as a positive integer greater than or equal to *minlev* + 1. The maximum level uses only levels less than or equal to *maxlev* in the multifractal estimates. The scale in the discrete wavelet transform corresponding to the maximum level is 2^{maxlev} . Specify a maximum regression level when you want to restrict the levels used in the regression to a value less than the default level. To determine the number of wavelet leaders by level, use the `leaders` output argument, or the `weights` field of the `structfunc` output argument. The default value is the largest level with at least six wavelet leaders

Output Arguments**dh** — Singularity spectrum

vector

Singularity spectrum, returned as a vector. The singularity spectrum is estimated using structure functions determined for the linearly-spaced moments from -5 to 5. The structure functions are computed based on the wavelet leaders obtained using the biorthogonal spline wavelet filter. The biorthogonal spline wavelet filter that is used has one vanishing moment in the synthesis wavelet and five vanishing moments in the analysis wavelet ('`bior1.5`'). By default, multifractal estimates are derived from wavelet leaders at a minimum level of 3 and maximum level where there are at least six wavelet leaders.

h — Holder exponent estimates

1-by-11 vector of real scalars

Holder exponent estimates, returned as a 1-by-11 vector of scalars. Holder exponents characterize signal regularity. The closer a Holder exponent is to 1, the closer the function is to differentiable. Conversely, the closer the Holder exponent is to zero, the closer the function is to discontinuous.

Data Types: `double`**cp** — Cumulants

vector

Cumulants, returned as a 1-by-3 vector of scalars. The vector contains the first three log cumulants of the scaling exponents. The first cumulant characterizes the linear behavior in the scaling exponents. The second and third cumulants characterize the departure from linearity.

Data Types: `double`**tauq** — Scaling exponents

column vector

Scaling exponents, returned as a column vector. The exponents are for the linearly-spaced moments from -5 to +5.

leaders — Wavelet leaders

cell array

`leaders` is a cell array with the *i*th element containing the wavelet leaders at level *i*+1, or scale 2^{i+1} . Wavelet leaders are not defined at level 1.

structfunc — Multiresolution structure functions

struct

Multiresolution structure functions for the global Holder exponent estimates, returned as a `struct`. The structure function for data x is defined as

$$S(q, a) = \frac{1}{n_a} \sum_{k=1}^{n_a} |T_x(a, k)|^q \approx a^{\zeta(q)},$$

where a is the scale, q is the moment, T_x are the wavelet leaders by scale, n_a is the number of wavelet leaders at each scale, and $\zeta(q)$ is the scaling exponent. Expanding $\zeta(q)$ to a polynomial produces

$$\zeta(q) = c_1 q + c_2 q^2/2 + c_3 q^3/6 + \dots$$

The scaling exponents can be estimated from the log-cumulants of the wavelet leader coefficients. When $\zeta(q)$ is a linear function, the signal is monofractal. When it deviates from linear, the signal is multifractal.

`structfunc` is a structure array containing the following fields:

- `Tq` — Measurements of the input, x , at various scales. `Tq` is a matrix of multiresolution quantities that depend jointly on time and scale. Scaling phenomena in x imply a power-law relationship between the moments of `Tq` and the scale. For `dwtleader`, the `Tq` field is an N_s -by-36 matrix, where N_s is the number of scales used in the multifractal estimates. The first 11 columns of `Tq` are the scaling exponent estimates by scale for each of the q th moments from -5 to 5. The next 11 columns contain the singularity spectrum estimates, `dh`, for each of the q th moments. Columns 23-33 contain the Holder exponent estimates, `h`. The last three columns contain the estimates for the first-order, second-order, and third-order cumulants, respectively.
- `weights` — Weights used in the regression. The weights are the number of wavelet leaders by scale. `weights` is an N_s -by-1 vector.
- `logscals` — Scales used as predictors in the regression. `logscals` is an N_s -by-1 vector with the base-2 logarithm of the scales.

Algorithms

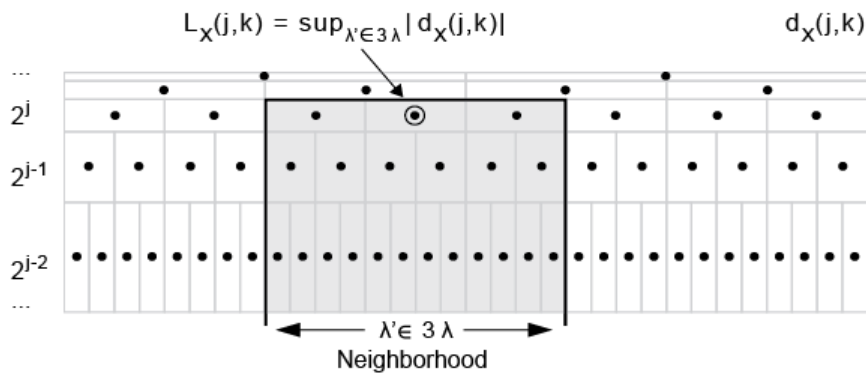

Wavelet leaders are derived from the critically sampled discrete wavelet transform (DWT) coefficients. Wavelet leaders offer significant theoretical advantages over wavelet coefficients in the multifractal formalism. Wavelet leaders are time- or space-localized suprema of the absolute value of the discrete wavelet coefficients. The time localization of the suprema requires that the wavelet coefficients are obtained using a compactly supported wavelet. The Holder exponents, which quantify the local regularity, are determined from these suprema. The singularity spectrum indicates the size of the set of Holder exponents in the data.

1-D wavelet leaders are defined as

$$L_x(j, k) = \sup_{\lambda' \subset 3\lambda_{j,k}} |d_x(j, k)|$$

where the scales are 2^j , translated to time positions $2^j k$. The time neighborhood is

$3\lambda_{j,k} = \lambda_{j,k-1} \cup \lambda_{j,k} \cup \lambda_{j,k+1}$, where $\lambda_{j,k} = [k2^j, (k+1)2^j]$. The time neighborhood is taken over the scale and all finer scales. $d_x(j, k)$ are the wavelet coefficients.

To calculate the wavelet leaders, $L_x(j,k)$:

- 1 Compute the wavelet coefficients, $d_x(j,k)$, using the discrete wavelet transform and save the absolute value of each coefficient for each scale. Each finer scale has twice the number of coefficients than the next coarser scale. Each dyadic interval at scale 2^j can be written as a union of two intervals at a finer scale.

$$[2^j k, 2^j(k+1)) = [2^{j-1}(2k), 2^{j-1}(2k+2))$$

$$[2^{j-1}(2k), 2^{j-1}(2k+2)) = [2^{j-1}(2k), 2^{j-1}(2k+1)) \cup [2^{j-1}(2k+1), 2^{j-1}(2k+2))$$

- 2 Start at the scale that is one level coarser than the finest obtained scale.
- 3 Compare the first value to all its finer dyadic intervals and obtain the maximum value.
- 4 Go to the next value and compare its value to all of its finer scale values.
- 5 Continue comparing the values with their nested values and obtaining the maxima.
- 6 From the maximum values obtained for that scale, examine the first three values and obtain the maximum of those neighbors. That maximum value is a leader for that scale.
- 7 Continue comparing the maximum values to obtain the other leaders for that scale.
- 8 Move to the next coarser scale and repeat the process.

For example, assume that you have these absolute values of the coefficients at these scales:

6		2		7		5	
4	3	5	2	1	0	4	3

Starting with the top row, which is the next coarsest level from the finest scale (bottom row), compare each value to its dyadic intervals and obtain the maxima.

6			2			7			5
4	3	5	2	1	0	4	3		
	6		5		7		5		

Then, look at the three neighboring values and obtain the maximum. Repeat for the next three neighbors. These maxima, 7 and 7, are the wavelet leaders for this level.

Introduced in R2016b

dwtmode

Discrete wavelet transform extension mode

Syntax

```
dwtmode(mode)
```

```
dwtmode  
dwtmode('status')  
st = dwtmode  
st = dwtmode('status')  
st = dwtmode('status','nodisp')
```

```
dwtmode('save',mode)  
dwtmode('save')  
dwtmode('save',CURRENTMODE)
```

Description

`dwtmode(mode)` sets the signal or image extension mode for both discrete wavelet and wavelet packet transforms to `mode`. All functions and Wavelet Analyzer app tools involving either the discrete wavelet transform (1-D and 2-D) or wavelet packet transform (1-D and 2-D), use the specified DWT extension mode.

The extension modes provide options for dealing with the problem of border distortion in signal or image analysis. For more information, see “Border Effects”.

`dwtmode` or `dwtmode('status')` display the current mode. If `DWTMODE.DEF` exists in the current path, the default mode is loaded from `DWTMODE.DEF` at the start of the MATLAB session. Otherwise, the file `DWTMODE.CFG` is used.

`st = dwtmode` or `st = dwtmode('status')` display and return the current mode in `st`.

`st = dwtmode('status','nodisp')` returns the current mode `st` and no status or warning text is displayed in the MATLAB command window.

`dwtmode('save',mode)` saves `mode` as the new default mode to the file `DWTMODE.DEF` in the current folder. If `DWTMODE.DEF` already exists in the current folder, the file is overwritten. The new default mode will be active as the default mode in the next MATLAB session.

Note To execute in parallel any functionality that depends on the extension mode, either save the extension mode using `dwtmode('save',mode)` before running your `parfor` loop, or call `dwtmode(mode)` inside your `parfor` loop.

Changing the extension mode in a MATLAB session does not have the desired effect if anything dependent on that mode is called in parallel. In a parallel environment, each worker has its own MATLAB execution engine, and each worker respects the `DWTMODE.CFG` file, but not an override in the current session. Therefore, to run in parallel, the extension mode must either be saved to the current folder, or the extension mode must be set for each worker.

Executing for-loop iterations in parallel requires Parallel Computing Toolbox™. For more information, see `parfor`.

`dwtmode('save')` is equivalent to `dwtmode('save', CURRENTMODE)`, where `CURRENTMODE` represents the current extension mode.

Examples

Display and Change Signal Extension Mode

Clear the DWT extension mode global variable, and display the current DWT signal extension mode. If the DWT extension mode global variable does not exist, the default is half-point symmetrization.

```
clear global
dwtmode
```

```
*****
** DWT Extension Mode: Symmetrization (half-point) **
*****
```

Change the extension mode to periodized extension.

```
dwtmode('per')
```

```
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
! WARNING: Change DWT Extension Mode !
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
```

```
*****
** DWT Extension Mode: Periodization **
*****
```

Display the current DWT signal extension mode.

```
dwtmode
```

```
*****
** DWT Extension Mode: Periodization **
*****
```

Input Arguments

mode — Discrete wavelet transform extension mode

'zpd' | 'sp0' | 'spd' | ...

DWT extension mode used to extend the input, specified as one of the following values.

mode	DWT Extension Mode
'zpd'	Zero extension
'sp0'	Smooth extension of order 0
'spd' (or 'sp1')	Smooth extension of order 1
'sym' or 'symh'	Symmetric extension (half point): boundary value symmetric replication
'symw'	Symmetric extension (whole point): boundary value symmetric replication
'asym' or 'asymh'	Antisymmetric extension (half point): boundary value antisymmetric replication
'asymw'	Antisymmetric extension (whole point): boundary value antisymmetric replication
'ppd', 'per'	Periodized extension If the signal length is odd and mode is 'per', an extra sample equal to the last value is added to the right and the extension is performed in 'ppd' mode. If the signal length is even, 'per' is equivalent to 'ppd'. This rule also applies to images.

The DWT associated with the symmetric, smooth, zero, and periodic extension modes are slightly redundant. But the inverse DWT ensures a perfect reconstruction for the extensions mentioned.

Note `dwtmode` updates a global variable. Only use `dwtmode` to change the extension mode. Avoid changing the global variable directly.

Output Arguments

st — DWT extension mode

character array

DWT extension mode, returned as a character array.

Tips

- For most wavelet applications, either a periodic extension or symmetric extension works fine.

dwtpassbands

DWT filter bank passbands

Syntax

```
dwtbands = dwtpassbands(fb)
```

Description

`dwtbands = dwtpassbands(fb)` returns the theoretical discrete wavelet transform (DWT) passbands for the DWT filter bank `fb`.

Examples

DWT Filter Bank Passbands

Obtain the theoretical DWT passbands for a four-level wavelet transform using the Daubechies `db6` wavelet with a sampling frequency of 1 kHz.

```
wv = 'db6';
Fs = 1e3;
fb = dwtfilterbank('Wavelet',wv,'Level',4,'SamplingFrequency',Fs);
dwtpassbands(fb)
```

```
ans = 5×2
```

```
250.0000 500.0000
125.0000 250.0000
 62.5000 125.0000
 31.2500  62.5000
         0  31.2500
```

Obtain the power bandwidths for the filter bank. Compare the theoretical passbands with the measured wavelet 3 dB bandwidths at all four levels.

```
ptable = powerbw(fb);
ptable(:,1:3)
```

```
ans=4×3 table
```

Level	DWTBand		Wavelet3dBBandwidth	
1	250	500	250	500
2	125	250	123.2	253.71
3	62.5	125	61.601	126.78
4	31.25	62.5	30.815	63.389

Input Arguments

fb — Discrete wavelet transform filter bank

`dwtfilterbank` object

Discrete wavelet transform (DWT) filter bank, specified as a `dwtfilterbank` object.

Output Arguments

dwtbands — Theoretical DWT passbands

real-valued matrix

Theoretical DWT passbands for the filter bank `fb`, returned as an $L+1$ -by-2 real-valued matrix, where L is the wavelet transform level of the filter bank.

- The first L rows of `dwtbands` contain the theoretical passband frequencies for the DWT listed in order of decreasing resolution (increasing scale).
- The final row of `dwtbands` contains the theoretical passband for the coarsest resolution scaling filter.
- The first column of `dwtbands` contains the lower frequency limit.
- The final row of `dwtbands` contains the theoretical passband for the coarsest resolution scaling filter.

Introduced in R2018a

dyaddown

Dyadic downsampling

Syntax

```
Y = dyaddown(X,EVENODD)
Y = dyaddown(X)
Y = dyaddown(X,EVENODD,'type')
Y = dyaddown(X,'type',EVENODD)
Y = dyaddown(X)
Y = dyaddown(X,'type')
Y = dyaddown(X,θ,'type')
Y = dyaddown(X,EVENODD)
Y = dyaddown(X,EVENODD,'c')
```

Description

$Y = \text{dyaddown}(X, \text{EVENODD})$ where X is a *vector*, returns a version of X that has been downsampled by 2. Whether Y contains the even- or odd-indexed samples of X depends on the value of positive integer EVENODD :

- If EVENODD is even, then $Y(k) = X(2k)$.
- If EVENODD is odd, then $Y(k) = X(2k+1)$.

$Y = \text{dyaddown}(X)$ is equivalent to $Y = \text{dyaddown}(X, \theta)$ (even-indexed samples).

$Y = \text{dyaddown}(X, \text{EVENODD}, 'type')$ or $Y = \text{dyaddown}(X, 'type', \text{EVENODD})$, where X is a *matrix*, returns a version of X obtained by suppressing one out of two:

Columns of X	If $'type' = 'c'$
Rows of X	If $'type' = 'r'$
Rows and columns of X	If $'type' = 'm'$

according to the parameter EVENODD , which is as above.

If you omit the EVENODD or $'type'$ arguments, dyaddown defaults to $\text{EVENODD} = \theta$ (even-indexed samples) and $'type' = 'c'$ (columns).

$Y = \text{dyaddown}(X)$ is equivalent to $Y = \text{dyaddown}(X, \theta, 'c')$.

$Y = \text{dyaddown}(X, 'type')$ is equivalent to $Y = \text{dyaddown}(X, \theta, 'type')$.

$Y = \text{dyaddown}(X, \text{EVENODD})$ is equivalent to $Y = \text{dyaddown}(X, \text{EVENODD}, 'c')$.

Examples

```
% For a vector.
s = 1:10
s =
     1     2     3     4     5     6     7     8     9    10
```

```

dse = dyaddown(s) % Downsample elements with even indices.
dse =
     2     4     6     8    10
% or equivalently
dse = dyaddown(s,0)
dse =
     2     4     6     8    10

dso = dyaddown(s,1) % Downsample elements with odd indices.
dso =
     1     3     5     7     9

% For a matrix.
s = (1:3)'.*(1:4)
s =
     1     2     3     4
     2     4     6     8
     3     6     9    12

dec = dyaddown(s,0,'c') % Downsample columns with even indices.
dec =
     2     4
     4     8
     6    12

der = dyaddown(s,1,'r') % Downsample rows with odd indices.
der =
     1     2     3     4
     3     6     9    12

dem = dyaddown(s,1,'m') % Downsample rows and columns
                        % with odd indices.
dem =
     1     3
     3     9

```

dyadup

Introduced before R2006a

dyadup

Dyadic upsampling

Syntax

```
Y = dyadup(X, EVENODD)
Y = dyadup(X)
Y = dyadup(X, EVENODD, 'type')
Y = dyadup(X, 'type', EVENODD)
Y = dyadup(X)
Y = dyadown(X, 1, 'c')
Y = dyadup(X, 'type')
Y = dyadup(X, 1, 'type')
Y = dyadup(X, EVENODD)
Y = dyadup(X, EVENODD, 'c')
```

Description

`dyadup` implements a simple zero-padding scheme very useful in the wavelet reconstruction algorithm.

$Y = \text{dyadup}(X, \text{EVENODD})$, where X is a *vector*, returns an extended copy of vector X obtained by inserting zeros. Whether the zeros are inserted as even- or odd-indexed elements of Y depends on the value of positive integer EVENODD :

- If EVENODD is even, then $Y(2k-1) = X(k)$, $Y(2k) = 0$.
- If EVENODD is odd, then $Y(2k-1) = 0$, $Y(2k) = X(k)$.

$Y = \text{dyadup}(X)$ is equivalent to $Y = \text{dyadup}(X, 1)$ (odd-indexed samples).

$Y = \text{dyadup}(X, \text{EVENODD}, \text{'type'})$ or $Y = \text{dyadup}(X, \text{'type'}, \text{EVENODD})$, where X is a *matrix*, returns extended copies of X obtained by inserting

Columns in X	If $\text{'type'} = \text{'c'}$
Rows in X	If $\text{'type'} = \text{'r'}$
Rows and columns in X	If $\text{'type'} = \text{'m'}$

according to the parameter EVENODD , which is as above.

If you omit the EVENODD or 'type' arguments, `dyadup` defaults to $\text{EVENODD} = 1$ (zeros in odd-indexed positions) and $\text{'type'} = \text{'c'}$ (insert columns).

$Y = \text{dyadup}(X)$ is equivalent to $Y = \text{dyadown}(X, 1, \text{'c'})$.

$Y = \text{dyadup}(X, \text{'type'})$ is equivalent to $Y = \text{dyadup}(X, 1, \text{'type'})$.

$Y = \text{dyadup}(X, \text{EVENODD})$ is equivalent to $Y = \text{dyadup}(X, \text{EVENODD}, \text{'c'})$.

Examples

```

% For a vector.
s = 1:5
s =
    1 2 3 4 5

dse = dyadup(s) % Upsample elements at odd indices.
dse =
    0 1 0 2 0 3 0 4 0 5 0

% or equivalently
dse = dyadup(s,1)
dse =
    0 1 0 2 0 3 0 4 0 5 0

dso = dyadup(s,0) % Upsample elements at even indices.
dso =
    1 0 2 0 3 0 4 0 5

% For a matrix.
s = (1:2)'+(1:3)
s =
    1 2 3
    2 4 6

der = dyadup(s,1,'r') % Upsample rows at even indices.
der =
    0 0 0
    1 2 3
    0 0 0
    2 4 6
    0 0 0

doc = dyadup(s,0,'c') % Upsample columns at odd indices.
doc =
    1 0 2 0 3
    2 0 4 0 6
dem = dyadup(s,1,'m') % Upsample rows and columns
                    % at even indices.
dem =
    0 0 0 0 0 0 0
    0 1 0 2 0 3 0
    0 0 0 0 0 0 0
    0 2 0 4 0 6 0
    0 0 0 0 0 0 0

% Using default values for dyadup and dyaddown, we have:
% dyaddown(dyadup(s)) = s.
s = 1:5
s =
    1 2 3 4 5

uds = dyaddown(dyadup(s))
uds =
    1 2 3 4 5

```

% In general reversed identity is false.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- If X is empty, generated code returns X and MATLAB returns `[]`.
- Suppose that all of the following conditions are true:
 - X is a variable-size array.
 - X is not a variable-length column vector (`:-by-1`).
 - X is a column vector at run time.
 - `'type'` is not supplied.

In generated code, the output for $y = \text{dyadup}(X, k)$, where k is optional, matches the output for $y = \text{dyadup}(X, k, 'c')$. In MATLAB, the output for $y = \text{dyadup}(X, k)$ matches the output for $y = \text{dyadup}(X, k, 'r')$.

For code generation, when you do not specify `'type'`, if you want `dyadup` to treat X as a column vector, X must be a variable-length vector (`:-by-1`).

`dyaddown`

Introduced before R2006a

editLabelDefinition

Edit label definition properties

Syntax

```
editLabelDefinition(lss, lblname, propname, val)
```

Description

`editLabelDefinition(lss, lblname, propname, val)` changes the `proppname` property of the label or sublabel definition `lblname` to `val`.

The function can edit only the “Name” on page 1-0 , “DefaultValue” on page 1-0 , “Tag” on page 1-0 , “Description” on page 1-0 , and “Categories” on page 1-0 properties. To change any other property of the label definition, remove the definition using `removeLabelDefinition` and add a definition with the desired property values using `addLabelDefinitions`.

- If you edit the “DefaultValue” on page 1-0 property, all existing label values remain unchanged. The new default value applies only to new members, new regions, or new points.
- You can edit the “Categories” on page 1-0 property only when the “LabelDataType” on page 1-0 of the target label or sublabel definition is 'Categorical'.

New specified categories do not replace any existing categories. They are appended to the existing values.

Examples

Edit Label Definition

Load a labeled signal set containing recordings of whale songs. Get the names of the labels.

```
load whales
lss

lss =
  labeledSignalSet with properties:
      Source: {2x1 cell}
      NumMembers: 2
      TimeInformation: "sampleRate"
      SampleRate: 4000
      Labels: [2x3 table]
      Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

```
getLabelNames(lss)
```

```
ans = 3x1 string
    "WhaleType"
    "MoanRegions"
    "TrillRegions"
```

The first label corresponds to the type of whale. Get the types available in the set.

```
lbldefs = getLabelDefinitions(lss);
types = lbldefs(1)

types =
    signalLabelDefinition with properties:
        Name: "WhaleType"
        LabelType: "attribute"
        LabelDataType: "categorical"
        Categories: [3x1 string]
        DefaultValue: []
        Sublabels: [0x0 signalLabelDefinition]
        Tag: ""
        Description: "Whale type"
```

Use `labeledSignalSet` to create a labeled signal set.

```
types = types.Categories
```

```
types = 3x1 string
    "blue"
    "humpback"
    "white"
```

Modify the label to incorporate sperm whales and killer whales. Verify that the labeled signal set includes the two new whale types.

```
editLabelDefinition(lss, 'WhaleType', ...
    'Categories', {'sperm', 'killer'})
```

```
lbldefs = getLabelDefinitions(lss);
types = lbldefs(1).Categories
```

```
types = 5x1 string
    "blue"
    "humpback"
    "white"
    "sperm"
    "killer"
```

The definition for trill regions has a sublabel that identifies peaks.

```
lbldefs(3).Sublabels
```

```
ans =
    signalLabelDefinition with properties:
        Name: "TrillPeaks"
        LabelType: "point"
```

```

        LabelDataType: "numeric"
        ValidationFunction: []
        PointLocationsDataType: "double"
        DefaultValue: []
        Sublabels: [0x0 signalLabelDefinition]
        Tag: ""
        Description: "Trill peaks"

```

Use `labeledSignalSet` to create a labeled signal set.

Change the description of the sublabel.

```
editLabelDefinition(lss, ["TrillRegions" "TrillPeaks"], 'Description', 'Peaks of trill regions')
```

```
lbldefs = getLabelDefinitions(lss);
lbldefs(3).Sublabels
```

```
ans =
    signalLabelDefinition with properties:
```

```

        Name: "TrillPeaks"
        LabelType: "point"
        LabelDataType: "numeric"
        ValidationFunction: []
        PointLocationsDataType: "double"
        DefaultValue: []
        Sublabels: [0x0 signalLabelDefinition]
        Tag: ""
        Description: "Peaks of trill regions"

```

Use `labeledSignalSet` to create a labeled signal set.

Input Arguments

lss — Labeled signal set

`labeledSignalSet` object

Labeled signal set, specified as a `labeledSignalSet` object.

Example: `labeledSignalSet({randn(100,1) randn(10,1)}, signalLabelDefinition('female'))` specifies a two-member set of random signals containing the attribute 'female'.

lblname — Label or sublabel name

character vector | string scalar | cell array of character vectors | string array

Label or sublabel name. To specify a label, use a character vector or a string scalar. To specify a sublabel, use a two-element cell array of character vectors or a two-element string array:

- The first element is the name of the parent label.
- The second element is the name of the sublabel.

Example: `signalLabelDefinition("Asleep", 'LabelType', 'roi')` specifies a label of name "Asleep" for a region of a signal in which a patient is asleep during a clinical trial.

Example: `{'Asleep' 'REM'}` or `["Asleep" "REM"]` specifies a region of a signal in which a patient undergoes REM sleep.

propname – Property name`'Name' | 'DefaultValue' | 'Tag' | 'Description' | 'Categories'`

Property name, specified as 'Name', 'DefaultValue', 'Tag', 'Description', or 'Categories'.

Data Types: `char` | `string`

val – Property value

numeric value | logical value | character vector | `string` | vector of strings | cell array of character vectors

Label values, specified as a numeric or logical value, a character vector or `string`, a vector of strings, or a cell array of character vectors. `val` must be of the data type specified for `propname`.

`labeledSignalSet` | `signalLabelDefinition`

Introduced in R2018b

emd

Empirical mode decomposition

Syntax

```
[imf,residual] = emd(X)
[imf,residual,info] = emd(X)
[ ___ ] = emd( ___,Name,Value)
```

```
emd( ___ )
```

Description

`[imf,residual] = emd(X)` returns intrinsic mode functions `imf` and residual signal `residual` corresponding to the empirical mode decomposition of `X`. Use `emd` to decompose and simplify complicated signals into a finite number of intrinsic mode functions required to perform Hilbert spectral analysis.

`[imf,residual,info] = emd(X)` returns additional information `info` on IMFs and residual signal for diagnostic purposes.

`[___] = emd(___,Name,Value)` performs the empirical mode decomposition with additional options specified by one or more `Name,Value` pair arguments.

`emd(___)` plots the original signal, IMFs, and residual signal as subplots in the same figure.

Examples

Perform Empirical Mode Decomposition and Visualize Hilbert Spectrum of Signal

Load and visualize a nonstationary continuous signal composed of sinusoidal waves with a distinct change in frequency. The vibration of a jackhammer and the sound of fireworks are examples of nonstationary continuous signals. The signal is sampled at a rate `fs`.

```
load('sinusoidalSignalExampleData.mat','X','fs')
t = (0:length(X)-1)/fs;
plot(t,X)
xlabel('Time(s)')
```

The mixed signal contains sinusoidal waves with different amplitude and frequency values.

To create the Hilbert spectrum plot, you need the intrinsic mode functions (IMFs) of the signal. Perform empirical mode decomposition to compute the IMFs and residuals of the signal. Since the signal is not smooth, specify 'pchip' as the interpolation method.

```
[imf,residual,info] = emd(X,'Interpolation','pchip');
```

The table generated in the command window indicates the number of sift iterations, the relative tolerance, and the sift stop criterion for each generated IMF. This information is also contained in `info`. You can hide the table by adding the `'Display',0` name value pair.

Create the Hilbert spectrum plot using the `imf` components obtained using empirical mode decomposition.

```
hht(imf,fs)
```

The frequency versus time plot is a sparse plot with a vertical color bar indicating the instantaneous energy at each point in the IMF. The plot represents the instantaneous frequency spectrum of each component decomposed from the original mixed signal. Three IMFs appear in the plot with a distinct change in frequency at 1 second.

Zero Crossings and Extrema in Intrinsic Mode Function of Sinusoid

This trigonometric identity presents two different views of the same physical signal:

$$\frac{5}{2}\cos 2\pi f_1 t + \frac{1}{4}(\cos 2\pi(f_1 + f_2)t + \cos 2\pi(f_1 - f_2)t) = (2 + \cos^2 \pi f_2 t)\cos 2\pi f_1 t.$$

Generate two sinusoids, s and z , such that s is the sum of three sine waves and z is a single sine wave with a modulated amplitude. Verify that the two signals are equal by calculating the infinity norm of their difference.

```
t = 0:1e-3:10;
omega1 = 2*pi*100;
omega2 = 2*pi*20;
s = 0.25*cos((omega1-omega2)*t) + 2.5*cos(omega1*t) + 0.25*cos((omega1+omega2)*t);
z = (2+cos(omega2/2*t).^2).*cos(omega1*t);
```

```
norm(s-z, Inf)
```

```
ans = 3.2729e-13
```

Plot the sinusoids and select a 1-second interval starting at 2 seconds.

```
plot(t,[s' z'])  
xlim([2 3])  
xlabel('Time (s)')  
ylabel('Signal')
```

Obtain the spectrogram of the signal. The spectrogram shows three distinct sinusoidal components. Fourier analysis sees the signals as a superposition of sine waves.

```
pspectrum(s,1000,'spectrogram','TimeResolution',4)
```

Use `emd` to compute the intrinsic mode functions (IMFs) of the signal and additional diagnostic information. The function by default outputs a table that indicates the number of sifting iterations, the relative tolerance, and the sifting stop criterion for each IMF. Empirical mode decomposition sees the signal as `z`.

```
[imf,~,info] = emd(s);
```

The number of zero crossings and local extrema differ by at most one. This satisfies the necessary condition for the signal to be an IMF.

```
info.NumZerocrossing - info.NumExtrema
```

```
ans = 1
```

Plot the IMF and select a 0.5-second interval starting at 2 seconds. The IMF is an AM signal because `emd` views the signal as amplitude modulated.

```
plot(t,imf)
xlim([2 2.5])
xlabel('Time (s)')
ylabel('IMF')
```

Compute Intrinsic Mode Functions of Vibration Signal

Simulate a vibration signal from a damaged bearing. Perform empirical mode decomposition to visualize the IMFs of the signal and look for defects.

A bearing with a pitch diameter of 12 cm has eight rolling elements. Each rolling element has a diameter of 2 cm. The outer race remains stationary as the inner race is driven at 25 cycles per second. An accelerometer samples the bearing vibrations at 10 kHz.

```
fs = 10000;  
f0 = 25;  
n = 8;  
d = 0.02;  
p = 0.12;
```

The vibration signal from the healthy bearing includes several orders of the driving frequency.

```
t = 0:1/fs:10-1/fs;
yHealthy = [1 0.5 0.2 0.1 0.05]*sin(2*pi*f0*[1 2 3 4 5]' .*t)/5;
```

A resonance is excited in the bearing vibration halfway through the measurement process.

```
yHealthy = (1+1./(1+linspace(-10,10,length(yHealthy)).^4)).*yHealthy;
```

The resonance introduces a defect in the outer race of the bearing that results in progressive wear. The defect causes a series of impacts that recur at the ball pass frequency outer race (BPFO) of the bearing:

$$\text{BPFO} = \frac{1}{2}nf_0\left[1 - \frac{d}{p}\cos\theta\right],$$

where f_0 is the driving rate, n is the number of rolling elements, d is the diameter of the rolling elements, p is the pitch diameter of the bearing, and θ is the bearing contact angle. Assume a contact angle of 15° and compute the BPFO.

```
ca = 15;
bpfo = n*f0/2*(1-d/p*cosd(ca));
```

Use the `pulstran` function to model the impacts as a periodic train of 5-millisecond sinusoids. Each 3 kHz sinusoid is windowed by a flat top window. Use a power law to introduce progressive wear in the bearing vibration signal.

```
fImpact = 3000;
tImpact = 0:1/fs:5e-3-1/fs;
```

```

wImpact = flattopwin(length(tImpact))'/10;
xImpact = sin(2*pi*fImpact*tImpact).*wImpact;

tx = 0:1/bpfo:t(end);
tx = [tx; 1.3.^tx-2];

nWear = 49000;
nSamples = 100000;
yImpact = pulstran(t,tx',xImpact,fs)/5;
yImpact = [zeros(1,nWear) yImpact(1,(nWear+1):nSamples)];

```

Generate the BPF0 vibration signal by adding the impacts to the healthy signal. Plot the signal and select a 0.3-second interval starting at 5.0 seconds.

```

yBPF0 = yImpact + yHealthy;

xLimLeft = 5.0;
xLimRight = 5.3;
yMin = -0.6;
yMax = 0.6;

plot(t,yBPF0)

hold on
[limLeft,limRight] = meshgrid([xLimLeft xLimRight],[yMin yMax]);
plot(limLeft,limRight,'--')
hold off

```

Zoom in on the selected interval to visualize the effect of the impacts.

```
xlim([xLimLeft xLimRight])
```

Add white Gaussian noise to the signals. Specify a noise variance of $1/150^2$.

```
rn = 150;  
yGood = yHealthy + randn(size(yHealthy))/rn;  
yBad = yBPF0 + randn(size(yHealthy))/rn;
```

```
plot(t,yGood,t,yBad)  
xlim([xLimLeft xLimRight])  
legend('Healthy','Damaged')
```

Use `emd` to perform an empirical mode decomposition of the healthy bearing signal. Compute the first five intrinsic mode functions (IMFs). Use the `'Display'` name-value pair to show a table with the number of sifting iterations, the relative tolerance, and the sifting stop criterion for each IMF.

```
imfGood = emd(yGood, 'MaxNumIMF', 5, 'Display', 1);
```

Current IMF	#Sift Iter	Relative Tol	Stop Criterion Hit
1	3	0.015551	SiftMaxRelativeTolerance
2	3	0.078816	SiftMaxRelativeTolerance
3	8	0.085954	SiftMaxRelativeTolerance
4	1	0.0043681	SiftMaxRelativeTolerance
5	2	0.010567	SiftMaxRelativeTolerance

The decomposition stopped because `'MaxNumIMF'` was reached.

Use `emd` without output arguments to visualize the first three modes and the residual.

```
emd(yGood, 'MaxNumIMF', 5)
```

Compute and visualize the IMFs of the defective bearing signal. The first empirical mode reveals the high-frequency impacts. This high-frequency mode increases in energy as the wear progresses. The third mode shows the resonance in the vibration signal.

```
imfBad = emd(yBad, 'MaxNumIMF', 5, 'Display', 1);
```

Current IMF	#Sift Iter	Relative Tol	Stop Criterion Hit
1	2	0.030781	SiftMaxRelativeTolerance
2	3	0.095804	SiftMaxRelativeTolerance
3	4	0.15371	SiftMaxRelativeTolerance
4	1	0.014778	SiftMaxRelativeTolerance
5	2	0.04312	SiftMaxRelativeTolerance

The decomposition stopped because 'MaxNumIMF' was reached.

```
emd(yBad, 'MaxNumIMF', 5)
```

The next step in the analysis is to compute the Hilbert spectrum of the extracted IMFs. For more details, see the “Compute Hilbert Spectrum of Vibration Signal” (Signal Processing Toolbox) example.

Visualize Residual and Intrinsic Mode Functions of Signal

Load and visualize a nonstationary continuous signal composed of sinusoidal waves with a distinct change in frequency. The vibration of a jackhammer and the sound of fireworks are examples of nonstationary continuous signals. The signal is sampled at a rate fs .

```
load('sinusoidalSignalExampleData.mat','X','fs')
t = (0:length(X)-1)/fs;
plot(t,X)
xlabel('Time(s)')
```

The mixed signal contains sinusoidal waves with different amplitude and frequency values.

Perform empirical mode decomposition to plot the intrinsic mode functions and residual of the signal. Since the signal is not smooth, specify 'pchip' as the interpolation method.

```
emd(X, 'Interpolation', 'pchip', 'Display', 1)
```

Current IMF	#Sift Iter	Relative Tol	Stop Criterion Hit
1	2	0.026352	SiftMaxRelativeTolerance
2	2	0.0039573	SiftMaxRelativeTolerance
3	1	0.024838	SiftMaxRelativeTolerance
4	2	0.05929	SiftMaxRelativeTolerance
5	2	0.11317	SiftMaxRelativeTolerance
6	2	0.12599	SiftMaxRelativeTolerance
7	2	0.13802	SiftMaxRelativeTolerance
8	3	0.15937	SiftMaxRelativeTolerance
9	2	0.15923	SiftMaxRelativeTolerance

The decomposition stopped because the number of extrema of the residual signal is less than 'MaxI'

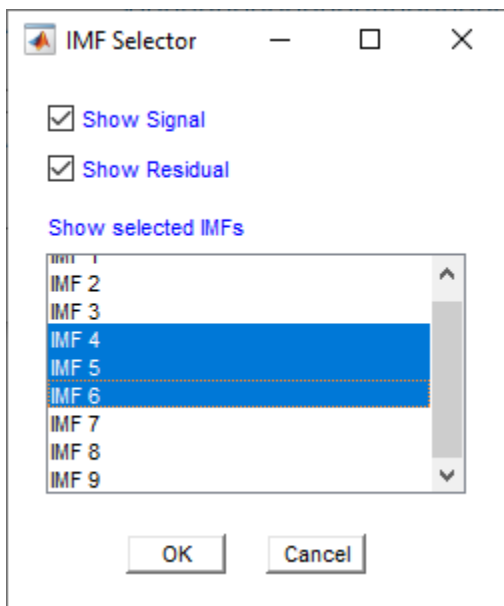

`emd` generates an interactive plot with the original signal, the first 3 IMFs, and the residual. The table generated in the command window indicates the number of sift iterations, the relative tolerance, and the sift stop criterion for each generated IMF. You can hide the table by removing the 'Display' name-value pair or specifying it as `0`.

Right-click on the white space in the plot to open the **IMF selector** window. Use **IMF selector** to selectively view the generated IMFs, the original signal, and the residual.

Select the IMFs to be displayed from the list. Choose whether to display the original signal and residual on the plot.

The selected IMFs are now displayed on the plot.

Use the plot to visualize individual components decomposed from the original signal along with the residual. Note that the residual is computed for the total number of IMFs, and does not change based on the IMFs selected in the **IMF selector** window.

Input Arguments

X — Time-domain signal

vector | timetable

Time-domain signal, specified as a real-valued vector, or a single-variable timetable with a single column. If X is a timetable, X must contain increasing, finite row times.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'MaxNumIMF', 5`

SiftRelativeTolerance — Cauchy-type convergence criterion

0.2 (default) | positive scalar

Cauchy-type convergence criterion, specified as the comma-separated pair consisting of `'SiftRelativeTolerance'` and a positive scalar. `SiftRelativeTolerance` is one of the sifting

stop criteria, that is, sifting stops when the current relative tolerance is less than `SiftRelativeTolerance`. For more information, see “Sift Relative Tolerance” on page 1-384.

SiftMaxIterations — Maximum number of sifting iterations

100 (default) | positive scalar integer

Maximum number of sifting iterations, specified as the comma-separated pair consisting of 'SiftMaxIterations' and a positive scalar integer. `SiftMaxIterations` is one of the sifting stop criteria, that is, sifting stops when the current number of iterations is larger than `SiftMaxIterations`.

`SiftMaxIterations` can be specified using only positive whole numbers.

MaxNumIMF — Maximum number of IMFs extracted

10 (default) | positive scalar integer

Maximum number of IMFs extracted, specified as the comma-separated pair consisting of 'MaxNumIMF' and a positive scalar integer. `MaxNumIMF` is one of the decomposition stop criteria, that is, decomposition stops when number of IMFs generated is equal to `MaxNumIMF`.

`MaxNumIMF` can be specified using only positive whole numbers.

MaxNumExtrema — Maximum number of extrema in the residual signal

1 (default) | positive scalar integer

Maximum number of extrema in the residual signal, specified as the comma-separated pair consisting of 'MaxNumExtrema' and a positive scalar integer. `MaxNumExtrema` is one of the decomposition stop criteria, that is, decomposition stops when number of extrema is less than `MaxNumExtrema`.

`MaxNumExtrema` can be specified using only positive whole numbers.

MaxEnergyRatio — Signal to residual energy ratio

20 (default) | scalar

Signal to residual energy ratio, specified as the comma-separated pair consisting of 'MaxEnergyRatio' and a scalar. `MaxEnergyRatio` is the ratio of the energy of the signal at the beginning of sifting and the average envelope energy. `MaxEnergyRatio` is one of the decomposition stop criteria, that is, decomposition stops when current energy ratio is larger than `MaxEnergyRatio`. For more information, see “Energy Ratio” on page 1-385.

Interpolation — Interpolation method for envelope construction

'spline' (default) | 'pchip'

Interpolation method for envelope construction, specified as the comma-separated pair consisting of 'Interpolation' and either 'spline' or 'pchip'.

Specify Interpolation as:

- 'spline', if X is a smooth signal
- 'pchip', if X is a nonsmooth signal

'spline' interpolation method uses cubic spline, while 'pchip' uses piecewise cubic Hermite interpolating polynomial method.

Display — Toggle information display in the command window

0 (default) | 1

Toggle information display in the command window, specified as the comma-separated pair consisting of 'Display' and either 0 or 1. The table generated in the command window indicates the number of sift iterations, the relative tolerance, and the sift stop criterion for each generated IMF. Specify Display as 1 to show the table or 0 to hide the table.

Output Arguments**imf — Intrinsic mode function**

matrix | timetable

Intrinsic mode function (IMF), returned as a matrix or timetable. Each IMF is an amplitude and frequency modulated signal with positive and slowly varying envelopes. To perform spectral analysis of a signal, you can apply the Hilbert-Huang transform to its IMFs. See `hht` and “Intrinsic Mode Functions” on page 1-384.

`imf` is returned as:

- A matrix whose each column is an `imf`, when `X` is a vector
- A timetable, when `X` is a single data column timetable

residual — Residual of the signal

column vector | single data column timetable

Residual of the signal, returned as a column vector or a single data column timetable. `residual` represents the portion of the original signal `X` not decomposed by `emd`.

`residual` is returned as:

- A column vector, when `X` is a vector.
- A single data column timetable, when `X` is a single data column timetable.

info — Additional information for diagnostics

structure

Additional information for diagnostics, returned as a structure with the following fields:

- `NumIMF` — Number of IMFs extracted

`NumIMF` is a vector from 1 to N , where N is the number of IMFs. If no IMFs are extracted, `NumIMF` is empty.

- `NumExtrema` — Number of extrema in each IMF

`NumExtrema` is a vector equal in length to the number of IMFs. The k th element of `NumExtrema` is the number of extrema found in the k th IMF. If no IMFs are extracted, `NumExtrema` is empty.

- `NumZerocrossing` — Number of zero crossings in each IMF

Number of zero crossings in each IMF. `NumZerocrossing` is a vector equal in length to the number of IMFs. The k th element of `NumZerocrossing` is the number of zero crossings in the k th IMF. If no IMFs are extracted, `NumZerocrossing` is empty.

- **NumSifting** — Number of sifting iterations used to extract each IMF

NumSifting is a vector equal in length to the number of IMFs. The k th element of **NumSifting** is the number of sifting iterations used in the extraction of the k th IMF. If no IMFs are extracted, **NumSifting** is empty.

- **MeanEnvelopeEnergy** — Energy of the mean of the upper and lower envelopes obtained for each IMF

If **UE** is the upper envelope and **LE** is the lower envelope, **MeanEnvelopeEnergy** is $\text{mean}((LE + UL)/2).^2$. **MeanEnvelopeEnergy** is a vector equal in length to the number of IMFs. The k th element of **MeanEnvelopeEnergy** is the mean envelope energy for the k th IMF. If no IMFs are extracted, **MeanEnvelopeEnergy** is empty.

- **RelativeTolerance** — Final relative tolerance of the residual for each IMF

The relative tolerance is defined as the ratio of the squared 2-norm of the difference between the residual from the previous sifting step and the residual from the current sifting step to the squared 2-norm of the residual from the i th sifting step. The sifting process stops when **RelativeTolerance** is less than **SiftRelativeTolerance**. For additional information, see “Sift Relative Tolerance” on page 1-384. **RelativeTolerance** is a vector equal in length to the number of IMFs. The k th element of **RelativeTolerance** is the final relative tolerance obtained for the k th IMF. If no IMFs are extracted, **RelativeTolerance** is empty.

More About

Empirical Mode Decomposition

The empirical mode decomposition (EMD) algorithm decomposes a signal $X(t)$ into intrinsic mode functions (IMFs) and a residual in an iterative process. The core component of the algorithm involves *sifting* a function $X(t)$ to obtain a new function $Y(t)$:

- First find the local minima and maxima of $X(t)$.
- Then use the local extrema to construct lower and upper envelopes $s_-(t)$ and $s_+(t)$, respectively, of $X(t)$. Form the mean of the envelopes, $m(t)$.
- Subtract the mean from $X(t)$ to obtain the residual: $Y(t) = X(t) - m(t)$.

An overview of the decomposition is as follows:

- 1 To begin, let $r_0(t) = X(t)$, where $X(t)$ is the initial signal, and let $i = 0$.
- 2 Before sifting, check $r_i(t)$:
 - a Find the total number (TN) of local extrema of $r_i(t)$.
 - b Find the energy ratio (ER) of $r_i(t)$ (see “Energy Ratio” on page 1-385).
- 3 If (ER > MaxEnergyRatio) or (TN < MaxNumExtrema) or (number of IMFs > MaxNumIMF) then stop the decomposition.
- 4 Let $r_{i,Prev}(t) = r_i(t)$.
- 5 Sift $r_{i,Prev}(t)$ to obtain $r_{i,Cur}(t)$.
- 6 Check $r_{i,Cur}(t)$
 - a Find the relative tolerance (RT) of $r_{i,Cur}(t)$ (see “Sift Relative Tolerance” on page 1-384).

- b** Get current sift iteration number (IN).
- 7** If ($RT < \text{SiftRelativeTolerance}$) or ($IN > \text{SiftMaxIterations}$) then stop sifting. An IMF has been found: $\text{IMF}_i(t) = r_{i,\text{Cur}}(t)$. Otherwise, let $r_{i,\text{Prev}}(t) = r_{i,\text{Cur}}(t)$ and go to Step 5.
- 8** Let $r_{i+1}(t) = r_i(t) - r_{i,\text{Cur}}(t)$.
- 9** Let $i = i + 1$. Return to Step 2.

For additional information, see [1] and [3].

Intrinsic Mode Functions

The EMD algorithm decomposes, via an iterative sifting process, a signal $X(t)$ into IMFs $\text{imf}_i(t)$ and a residual $r_N(t)$:

$$X(t) = \sum_{i=1}^N \text{IMF}_i(t) + r_N(t)$$

When first introduced by Huang et al. [1], an IMF was defined to be a function with two characteristics:

- The number of local extrema — the total number of local minima and local maxima — and the number of zero crossings differ by at most one.
- The mean value of the upper and lower envelopes constructed from the local extrema is zero.

However, as noted in [4], sifting until a strict IMF is obtained can result in IMFs that have no physical significance. Specifically, sifting until the number of zero crossings and local extrema differ by at most one can result in pure-tone like IMFs, in other words, functions very similar to what would be obtained by projection on the Fourier basis. This situation is precisely what EMD strives to avoid, preferring AM-FM modulated components for their physical significance.

Reference [4] proposes options to obtain physically meaningful results. The `emd` function relaxes the original IMF definition by using “Sift Relative Tolerance” on page 1-384, a Cauchy-type stop criterion. The `emd` function iterates to extract natural AM-FM modes. The IMFs generated may fail to satisfy the local extrema-zero crossings criteria. See “Zero Crossings and Extrema in Intrinsic Mode Function of Sinusoid” on page 1-367.

Sift Relative Tolerance

Sift Relative Tolerance is a Cauchy-type stop criterion proposed in [4]. Sifting stops when current relative tolerance is less than `SiftRelativeTolerance`. The current relative tolerance is defined as

$$\text{Relative Tolerance} \triangleq \frac{\|r_{\text{prev}}(t) - r_{\text{cur}}(t)\|_2^2}{\|r_{\text{prev}}(t)\|_2^2}.$$

Because the Cauchy criterion does not directly count the number of zero crossings and local extrema, it is possible that the IMFs returned by the decomposition do not satisfy the strict definition of an intrinsic mode function. In those cases, you can try reducing the value of the `SiftRelativeTolerance` from its default value. See [4] for a detailed discussion of stopping criteria. The reference also discusses the advantages and disadvantages of insisting on strictly defined IMFs in empirical mode decomposition.

Energy Ratio

Energy ratio is the ratio of the energy of the signal at the beginning of sifting and the average envelope energy [2]. Decomposition stops when current energy ratio is larger than `MaxEnergyRatio`. For the i th IMF, the energy ratio is defined as

$$\text{Energy Ratio} \triangleq 10\log_{10}\left(\frac{\|X(t)\|_2}{\|r_i(t)\|_2}\right).$$

entrupd

Entropy update (wavelet packet)

Syntax

```
T = entrupd(T,ENT)
T = entrupd(T,ENT,PAR)
```

Description

entrupd is a one- or two-dimensional wavelet packet utility.

`T = entrupd(T,ENT)` or `T = entrupd(T,ENT,PAR)` returns for a given wavelet packet tree *T*, the updated tree using the entropy function *ENT* with the optional parameter *PAR* (see `wenergy` for more information).

Examples

```
% The current extension mode is zero-padding (see dwtmode).

% Load signal.
load noisdopp; x = noisdopp;

% Decompose x at depth 2 with db1 wavelet packets
% using shannon entropy.
t = wpdec(x,2,'db1','shannon');

% Read entropy of all the nodes.
nodes = allnodes(t);
ent = read(t,'ent',nodes);
ent'
ent =
    1.0e+04 *
    -5.8615 -6.8204 -0.0350 -7.7901 -0.0497 -0.0205 -0.0138

% Update nodes entropy.
t = entrupd(t,'threshold',0.5);
nent = read(t,'ent');

featureMatrix

Scattering feature matrix

Syntax

```
smat = featureMatrix(sf,x)
smat = featureMatrix(sf,s)
smat = featureMatrix( ___,Name,Value)
```

Description

`smat = featureMatrix(sf,x)` returns the scattering features for the scattering decomposition framework `sf` and the input signal `x`. `x` is a real-valued vector or matrix. If `x` is a vector, `smat` is an M -by- N matrix, where M is the number of resolutions across all orders of the scattering transform, and N is the resolution of the scattering coefficients. If `x` is a matrix, `smat` is an M -by- N -by- P array, where P is the number of columns in `x`.

The precision of `smat` depends on the precision specified in the framework `sf`.

`smat = featureMatrix(sf,s)` returns the scattering feature matrix for the cell array of scattering coefficients `s`. `s` is the output of `scatteringTransform` applied to an input signal for the scattering decomposition framework `sf`.

`smat = featureMatrix(___,Name,Value)` returns the scattering feature matrix with additional options specified by one or more `Name,Value` pair arguments.

Examples

Obtain Scattering Feature Matrix

This example shows how to obtain the scattering feature matrix for a scattering decomposition framework and how to compare the matrix with scattering coefficients.

Load an ECG signal sampled at 180 Hz. Create a scattering decomposition framework that can be used with the signal.

```
load wecg
Fs = 180;
sf = waveletScattering('SignalLength',numel(wecg),...
    'SamplingFrequency',Fs);
```

Calculate the scattering feature matrix using the log transformation. Display the dimensions of the matrix.

```
smat = featureMatrix(sf,wecg,'Transform','Log');
size(smat)
```

```
ans = 1×2
```

154 8

Now calculate the scattering transform of the signal. Obtain the scattering coefficients. The output is a cell array with three elements. Each element is a table. Confirm the total number of rows in the tables is equal to the number of rows in the matrix.

```
S = scatteringTransform(sf,wecg);
t1rows = size(S{1},1);
t2rows = size(S{2},1);
t3rows = size(S{3},1);
disp(['Total Number of Rows: ',num2str(t1rows+t2rows+t3rows)])
```

```
Total Number of Rows: 154
```

Display the base-2 log resolution of the zeroth-order scattering coefficients.

```
disp(['Resolution: ',num2str(S{1}.resolution(1))])
```

```
Resolution: -8
```

Obtain the natural logarithm of the zeroth-order scattering coefficients. Compare the scattering coefficients with the first row in the feature matrix. The number of coefficients in each equals the absolute value of the base-2 log resolution.

```
logS = log(sf,S);
logScat = logS{1}.signals{1};
[smat(1,:) ' logScat]
```

```
ans = 8x2
```

```
-1.2914 -1.2914
-2.4682 -2.4682
-1.6368 -1.6368
-1.2716 -1.2716
-1.6818 -1.6818

-1.3199 -1.3199
-1.0542 -1.0542
```

Input Arguments

sf — Scattering decomposition framework

waveletScattering object

Scattering decomposition framework, specified as a waveletScattering object.

x — Input data

real-valued vector | real-valued matrix

Input data, specified as a real-valued vector or matrix. If **x** is a vector, the number of samples in **x** must equal the SignalLength value of **sf**. If **x** is a matrix, the number of rows in **x** must equal the SignalLength value of **sf**.

Data Types: double

s — Scattering coefficients

cell array

Scattering coefficients, specified as a cell array. `s` is obtained from the scattering transform of the scattering decomposition framework `sf`. For more information, see `scatteringTransform`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `smat = featureMatrix(sf,x,'Transform','log','Normalization','parent')`

Normalization — Type of normalization

'none' (default) | 'parent'

Type of normalization to apply to the scattering coefficients, specified as 'none' or 'parent'. If specified as 'parent', scattering coefficients of order greater than 0 are normalized by their parents along the scattering path.

Transform — Type of transformation

'none' (default) | 'log'

Type of transformation to apply to the scattering coefficients, specified as 'none' or 'log'.

Output Arguments**smat — Scattering features**

real-valued matrix | real-valued array

Scattering features for the scattering decomposition framework, `sf`, returned as a real-valued matrix or array. If `x` is a vector, `smat` is an M -by- N matrix, where M is the number of resolutions across all orders of the scattering transform and N is the resolution of the scattering coefficients. If `x` is a matrix, `smat` is an M -by- N -by- P array, where P is the number of columns in `x`.

The precision of `smat` depends on the precision specified in the framework `sf`.

Introduced in R2018b

featureMatrix

Image scattering feature matrix

Syntax

```
smat = featureMatrix(sf,im)
smat = featureMatrix(sf,sc)
smat = featureMatrix( ___, 'Transform', transformtype)
```

Description

`smat = featureMatrix(sf,im)` returns the scattering feature matrix for the image scattering decomposition framework, `sf`, and the input image, `im`. `im` is a real-valued 2-D (M -by- N) or 3-D matrix (M -by- N -by-3). If `im` is a 3-D matrix, the size of the third dimension must be 3. If `im` is a 2-D matrix, `smat` is N_p -by- M_s -by- N_s , where N_p is the number of scattering paths and M_s -by- N_s is the resolution of the scattering coefficients. If `im` is a 3-D matrix, `smat` is N_p -by- M_s -by- N_s -by-3.

`smat = featureMatrix(sf,sc)` returns the scattering feature matrix for the cell array of scattering coefficients, `sc`. `sc` is obtained from the `scatteringTransform` method of the image scattering decomposition framework.

`smat = featureMatrix(___, 'Transform', transformtype)` applies the transformation specified by `transformtype` to the scattering coefficients. Valid options for `transformtype` are 'log' and 'none'. If unspecified, `transformtype` defaults to 'none'. You can use this syntax with any of the previous syntaxes.

Examples

Obtain Feature Matrix for Wavelet Image Scattering Framework

This example shows how to obtain the feature matrix for a wavelet image scattering framework.

Load the `xbox` image. Create an image scattering framework suitable for the image.

```
load xbox
sf = waveletScattering2('ImageSize',size(xbox))

sf =
    waveletScattering2 with properties:

        ImageSize: [128 128]
        InvarianceScale: 64
        NumRotations: [6 6]
        QualityFactors: [1 1]
        Precision: "single"
        OversamplingFactor: 0
        OptimizePath: 1
```

Obtain the feature matrix.

```
smat = featureMatrix(sf,xbox);
```

Input Arguments

sf — Scattering decomposition framework

waveletScattering2 object

Scattering decomposition framework, specified as a waveletScattering2 object.

im — Input image

real-valued matrix

Input image, specified as real-valued 2-D matrix or 3-D matrix. If `im` is 3-D, `im` is assumed to be a color image in the RGB color space, and the size of the third dimension must equal 3. The row and column sizes of `im` must match the ImageSize property of `sf`.

sc — Scattering coefficients

cell array

Scattering coefficients, specified as a cell array. `sc` is obtained from the `scatteringTransform` method of the image scattering decomposition framework.

transformtype — Transformation

'none' (default) | 'log'

Transformation to apply to the scattering coefficients:

- 'none': No transformation is applied to the scattering coefficients.
- 'log': The natural logarithm is applied to the scattering coefficients.

Output Arguments

smat — Scattering feature matrix

real-valued array

Scattering feature matrix for the 2-D scattering decomposition framework `sf`, returned as a real-valued array. If `im` is a 2-D matrix, `smat` is N_p -by- M_s -by- N_s , where N_p is the number of scattering paths and M_s -by- N_s is the resolution of the scattering coefficients. If `im` is a 3-D matrix, `smat` is N_p - M_s -by- N_s -by-3.

Introduced in R2019a

fbspwavf

Complex frequency B-spline wavelet

Syntax

```
[PSI,X] = fbspwavf(LB,UB,N,M,FB,FC)
```

Description

[PSI,X] = fbspwavf(LB,UB,N,M,FB,FC) returns values of the complex frequency B-Spline wavelet defined by the order parameter M (M is an integer such that $1 \leq M$), a bandwidth parameter FB , and a wavelet center frequency FC .

The function PSI is computed using the explicit expression

$$\text{PSI}(X) = (FB^{\wedge}0.5) * ((\text{sinc}(FB*X/M).^M) .* \exp(2*i*pi*FC*X))$$

on an N point regular grid in the interval [LB,UB].

FB and FC must be such that $FC > 0$ and $FB > 0$.

Output arguments are the wavelet function PSI computed on the grid X .

Examples

```
% Set order, bandwidth and center frequency parameters.
m = 2; fb = 0.5; fc = 1;

% Set effective support and grid parameters.
lb = -20; ub = 20; n = 1000;

% Compute complex Frequency B-Spline wavelet fbsp2-0.5-1.
[psi,x] = fbspwavf(lb,ub,n,m,fb,fc);

% Plot complex Frequency B-Spline wavelet.
subplot(211)
plot(x,real(psi))
title('Complex Frequency B-Spline wavelet fbsp2-0.5-1')
xlabel('Real part'), grid
subplot(212)
plot(x,imag(psi))
xlabel('Imaginary part'), grid
```

fejerkorovkin

Fejér-Korovkin wavelet filters

Syntax

```
Lo = fejerkorovkin(wname)
```

Description

`Lo = fejerkorovkin(wname)` returns the Fejér-Korovkin scaling filter specified by `wname`. Valid entries for `wname` are 'fk4', 'fk6', 'fk8', 'fk14', 'fk18', and 'fk22'. For information on the Fejér-Korovkin filters, see Nielson[1].

Examples

Fejer-Korovkin Filters

Construct and plot the Fejer-Korovkin (14) scaling function and wavelet.

Obtain the Fejer-Korovkin scaling filter and display its 14 coefficients.

```
Lo = fejerkorovkin('fk14')
```

```
Lo = 1×14
```

```
    0.2604    0.6869    0.6116    0.0514   -0.2456   -0.0486    0.1243    0.0222   -0.0640   -0.0
```

Use the scaling filter to obtain the wavelet filter and display its wavelet filter coefficients.

```
Hi = qmf(Lo)
```

```
Hi = 1×14
```

```
    0.0035    0.0093   -0.0033   -0.0298   -0.0051    0.0640    0.0222   -0.1243   -0.0486    0.2
```

`wavefun` provides an efficient way to construct and plot the scaling function and wavelet.

```
[phi,psi,xval] = wavefun('fk14');  
subplot(2,1,1)  
plot(xval,phi)  
title('Scaling Function')  
subplot(2,1,2)  
plot(xval,psi)  
title('Wavelet')
```

Input Arguments

wname — Name

'fk4' | 'fk6' | 'fk8' | 'fk14' | 'fk18' | 'fk22'

Name of desired Fejér-Korovkin scaling filter. The numeric value in each name is the number of Fejér-Korovkin filter coefficients. For example, if wname is 'fk14', Lo has 14 coefficients.

Output Arguments

Lo — Scaling filter

vector

Scaling filter, returned as a vector.

filt2ls

Transform quadruplet of filters to lifting scheme

Syntax

```
LS = filt2ls(LoD,HiD,LoR,HiR)
```

Description

LS = filt2ls(LoD,HiD,LoR,HiR) returns the lifting scheme LS associated with the four input filters LoD, HiD, LoR, and HiR that verify the perfect reconstruction condition.

Examples

```
[LoD,HiD,LoR,HiR] = wfilters('db2')

LoD =
    -0.1294    0.2241    0.8365    0.4830

HiD =
    -0.4830    0.8365   -0.2241   -0.1294

LoR =
    0.4830    0.8365    0.2241   -0.1294

HiR =
    -0.1294   -0.2241    0.8365   -0.4830

LS = filt2ls(LoD,HiD,LoR,HiR);
displs(LS);

LS = {...
'd'          [ -1.73205081]          [0]
'p'          [ -0.06698730  0.43301270] [1]
'd'          [  1.00000000]          [-1]
[  1.93185165] [  0.51763809]          []
};

LSref = liftwave('db2');
displs(LSref);

LSref = {...
'd'          [ -1.73205081]          [0]
'p'          [ -0.06698730  0.43301270] [1]
'd'          [  1.00000000]          [-1]
[  1.93185165] [  0.51763809]          []
};
```

filterbank

Shearlet system filters

Syntax

```
psi = filterbank(sls)
[psi,scale] = filterbank(sls)
[psi,scale,shear] = filterbank(sls)
[psi,scale,shear,cone] = filterbank(sls)
```

Description

`psi = filterbank(sls)` returns the Fourier transforms of the shearlet filters defined by the shearlet system `sls` as a 3-D real-valued array. The array size is M -by- N -by- K , where M and N are the values of the two-element row vector "ImageSize" on page 1-0 of `sls`. K is the number of shearlets including the lowpass filter, $K = \text{numshears}(sls) + 1$.

`[psi,scale] = filterbank(sls)` returns the scale parameters of the shearlet filters as a K -by-1 integer vector. K is the number of shearlets including the lowpass filter, $K = \text{numshears}(sls) + 1$.

`[psi,scale,shear] = filterbank(sls)` returns the shearing parameters of the shearlet filters as a K -by-1 integer vector. K is the number of shearlets including the lowpass filter, $K = \text{numshears}(sls) + 1$.

`[psi,scale,shear,cone] = filterbank(sls)` returns the frequency cones of the shearlet filters as a K -by-1 cell array of characters. K is the number of shearlets including the lowpass filter, $K = \text{numshears}(sls) + 1$.

Examples

Obtain Shearlet Filters

Load an image. Create a shearlet system that can be used with the image.

```
load clown
sls = shearletSystem('ImageSize',size(X))

sls =
    shearletSystem with properties:
        ImageSize: [200 320]
        NumScales: 4
        PreserveEnergy: 0
        TransformType: 'real'
        FilterBoundary: 'periodic'
        Precision: 'double'
```

Obtain the shearlet filters defined by the shearlet system.

```
psi = filterbank(sls);
```

Obtain the shearlet transform of the image.

```
cfs = sheart2(sls,X);
```

Confirm that the size of the third dimension of `psi` is equal to the size of the third dimension of `cfs`.

```
[size(psi,3) size(cfs,3)]
```

```
ans = 1×2
```

```
41 41
```

Plot Shearlet Filters

Create a complex-valued shearlet system for 256-by-256 images with truncated boundaries and four scales.

```
sls = shearletSystem('TransformType','complex',...
    'ImageSize',[256 256],...
    'FilterBoundary','truncated',...
    'NumScales',4);
```

Obtain the shearlet filters and their geometric interpretations.

```
[psi,scale,shear,cone] = filterbank(sls);
```

Different scales can have a different number of shears. The scales in the shearlet system range from 0 to 3 inclusive. Find the range of shears per scale.

```
for k=0:3
    ind = find(scale==k);
    fprintf('scale: %d shear range: [%d:%d]\n',...
        k,min(shear(ind)),max(shear(ind)))
end
```

```
scale: 0 shear range: [-1:1]
scale: 1 shear range: [-2:2]
scale: 2 shear range: [-2:2]
scale: 3 shear range: [-3:3]
```

Display the unique frequency cone labels.

```
unique(cone)
```

```
ans = 5×1 cell
    {'B'}
    {'L'}
    {'R'}
    {'T'}
    {'X'}
```

Find the shearlet filter at scale 2 with shear parameter equal to 1 and whose support is in the 'R' frequency cone.

```

vScale = 2;
vShear = 1;
vCone = 'R';
ind = (scale==vScale)&(shear==vShear)&([cone{:}]==vCone);
shFilter = psi(:,:,ind);

```

Plot the shearlet filter.

```

omegax = -1/2:1/256:1/2-1/256;
omegay = omegax;
surf(omegax,flip(omegay),shFilter,'EdgeColor','none')
view(0,90)
xlabel('\omega_x')
ylabel('\omega_y')
str = sprintf('Shearlet Filter: Scale %d / Shear %d / Cone %c',...
    vScale,vShear,vCone);
title(str)
axis equal
axis tight

```

Plot the supports of all scale 2 shearlet filters with shear parameters equal to ± 2 . Areas where filter supports overlap have maximum brightness.

```

vScale = 2;
vShear = 2;
ind = find((scale==vScale).*(abs(shear)==vShear));
tmp = zeros(size(psi,1),size(psi,2));
for k=1:length(ind)

```

```

    tmp = tmp+(psi(:,:,ind(k))~=0);
end
surf(omegax,flip(omegay),double(tmp),'EdgeColor','none')
view(0,90)
xlabel('\omega_x')
ylabel('\omega_y')
str = sprintf('Filter Supports: Scale %d / Abs(Shear) %d',...
    vScale,vShear);
title(str)
axis equal
axis tight
colormap gray
colorbar

```

Input Arguments

sls — Shearlet system

shearletSystem object

Shearlet system, specified as a shearletSystem object.

Output Arguments

psi — Fourier transforms of shearlet filters

real-valued 3-D array

Fourier transforms of the shearlet filters defined by the shearlet system, returned as a 3-D real-valued array. The array size is M -by- N -by- K , where M and N are the first and second elements, respectively, of the ImageSize value of `sfs`. K is the number of shearlets including the lowpass filter, $K = \text{numshears}(sfs) + 1$. The first element in the third dimension of `psi` corresponds to the lowpass filter. The subsequent elements correspond to the shearlets.

The data type of `psi` matches the Precision value of the shearlet system.

Data Types: `single` | `double`

scale — Scale parameters

integer vector

Scale parameters of the shearlet filters defined by the shearlet system, returned as a K -by-1 integer vector. K is the number of shearlets including the lowpass filter, $K = \text{numshears}(sfs) + 1$. The first element of `scale`, -1 , corresponds to the lowpass filter. The remaining elements of `scale` correspond to the shearlet filters.

The data type of `scale` matches the Precision value of the shearlet system.

Data Types: `single` | `double`

shear — Shearing parameters

integer vector

Shearing parameters of the shearlet filters defined by the shearlet system, returned as a K -by-1 integer vector. K is the number of shearlets including the lowpass filter, $K = \text{numshears}(sfs) + 1$. The shear values at scale S range from $-\text{ceil}(2^{(S/2)})$ to $\text{ceil}(2^{(S/2)})$ inclusive. The first element of `shear`, 0 , corresponds to the lowpass filter. The remaining elements of `shear` denote the shears for the corresponding shearlet filters.

The data type of `shear` matches the Precision value of the shearlet system.

Data Types: `single` | `double`

cone — Frequency cones

cell array of characters

Frequency cones of the shearlet filters defined by the shearlet system, returned as a K -by-1 cell array of characters. K is the number of shearlets including the lowpass filter, $K = \text{numshears}(sfs) + 1$. The first element of `cone`, 'X', corresponds to the lowpass filter. The remaining elements of `cone` are the frequency cones in which the corresponding shearlet filters have their frequency support.

For complex-valued shearlets, the frequency plane is divided into four cones: 'R' (right), 'T' (top), 'L' (left), and 'B' (bottom). For real-valued shearlets, the frequency cones are 'H' (horizontal) and 'V' (vertical).

filterbank

Wavelet time scattering filter banks

Syntax

```
filters = filterbank(sf)
[filters,f] = filterbank(sf)
[filters,f,filterparams] = filterbank(sf)
[___] = filterbank(sf,order)
```

Description

`filters = filterbank(sf)` returns the filter banks used in the computation of the scattering coefficients. `filters` is a cell array of structure arrays with *norder* elements, where *norder* is the number of scattering orders. The first element of `filters` contains the scaling filter, `phift`, used in the computation of the 0th-order scattering coefficients. Subsequent elements of `filters` contain the wavelet filters, `psift`, and scaling filter, `phift`, for the corresponding filter banks of the scattering decomposition.

The precision of `phift` and `psift` depends on the precision specified in the framework `sf`.

`[filters,f] = filterbank(sf)` returns the frequencies corresponding to the DFT bins in the `psift` and `phift` fields of `filters`. If you specify a sampling frequency in the construction of `sf`, `f` is measured in hertz. Otherwise, `f` is measured in cycles/sample.

`[filters,f,filterparams] = filterbank(sf)` returns the filter parameters for each element of `filters`. `filterparams` is a cell array with *norder* elements. Each element of `filterparams` is a MATLAB table.

`[___] = filterbank(sf,order)` returns the filter banks used to compute the specified order scattering coefficients. `order` is an integer between 0 and *nfilters* inclusive, where *nfilters* is the number of filter banks in the scattering decomposition inclusive. These input arguments can be used with any of the output syntaxes shown previously.

Examples

Plot Scattering Framework Filter Banks

Create a scattering decomposition framework for a signal sampled at 25 Hz.

```
sf = waveletScattering('SamplingFrequency',25)
```

```
sf =
  waveletScattering with properties:
    SignalLength: 1024
    InvarianceScale: 20.4800
    QualityFactors: [8 1]
    Boundary: "periodic"
```

```

SamplingFrequency: 25
Precision: "double"
OversamplingFactor: 0

```

Obtain the filter banks, DFT frequency bins, and filter bank parameters.

```
[filters,f,fparams] = filterbank(sf);
```

Plot the wavelet filters used in computing the first-order coefficients. Plot the wavelet center frequencies as well.

```

coefOrder = 1;
wvFilters = filters{coefOrder+1}.psift;
wvcenFrq = fparams{coefOrder+1}.omegapsi;
plot(f,wvFilters)
hold on
cf = plot(wvcenFrq,max(wvFilters),'rx');
grid on
title('Wavelet Filters')
xlabel('Hz')
ylabel('Magnitude')
legend(cf,'Center Frequencies')

```

Input Arguments

sf — Scattering decomposition framework

waveletScattering object

Scattering decomposition framework, specified as a waveletScattering object.

order — Order of scattering coefficients

positive integer

Order of scattering coefficients, specified as a positive integer between 0 and *nfilters* inclusive, where *nfilters* is the number of filter banks in the scattering decomposition *sf*.

Data Types: double

Output Arguments

filters — Filter banks

cell array

Filter banks used in the computation of the scattering coefficients, returned as a cell array of structure arrays. *filters* has *norder* elements, where *norder* is the number of scattering orders. The first element of *filters* is a structure with the single field *phift*. *phift* contains the scaling filter used in the computation of the 0th-order scattering coefficients. Subsequent elements of *filters* contain the wavelet filters, *psift*, and the scaling filter, *phift*, used for the corresponding filter banks of the scattering decomposition in the structure fields.

The precision of *phift* and *psift* depends on the precision specified in the framework *sf*.

f — Frequencies

real-valued vector

Frequencies corresponding to the DFT bins in the *psift* and *phift* fields of *filters*. If you specify a sampling frequency in the construction of *sf*, *f* is measured in hertz. Otherwise, *f* is measured in cycles/sample.

Data Types: double

filterparams — Filter bank parameters

cell array

Filter bank parameters for each element of *filters*, returned as a cell array. *filterparams* has *norder* elements, where *norder* is the number of scattering orders.

The first element of *filterparams* is a MATLAB table with the following variables:

- **boundary** — The signal extension used in the filters, returned as either 'periodic' or 'reflection'.
- **precision** — The precision used in the filters, returned as 'double' or 'single'.
- **sigmaphi** — The time standard deviation of the scaling function, returned as a scalar. If you specify a sampling frequency, *sigmaphi* is in seconds. Otherwise, *sigmaphi* is in samples.
- **freqsigmaphi** — The frequency standard deviation of the scaling function, returned as a scalar. If you specify a sampling frequency, *freqsigmaphi* is in hertz. Otherwise, *freqsigmaphi* is in cycles/sample.

- `phifftsupport` — The frequency support of the scaling function, returned as a scalar. If you specify a sampling frequency, `phifftsupport` is in hertz. Otherwise, `phifftsupport` is in cycles/sample.
- `phi3dBbw` — The 3-dB bandwidth of the scaling function, returned as a scalar.

Subsequent elements of `filterparams` include additional variables for the wavelet parameters:

- `J` — The integer number of logarithmically spaced wavelet filters in the scattering filter bank.
- `omegapsi` — The center frequencies for the wavelet filters in descending order (highest to lowest), returned as a vector. The `omegapsi` variable includes the center frequencies for any linearly spaced filters.
- `freqsigmapsi` — The wavelet frequency standard deviations, returned as a vector.
- `timesigmapsi` — The wavelet time standard deviations, returned as a vector.
- `psi3dBbw` — The wavelet 3-dB bandwidths, returned as a vector.
- `psifftsupport` — The wavelet frequency supports, returned as a vector.

`littlewoodPaleySum` | `waveletScattering`

Introduced in R2018b

filterbank

Wavelet and scaling filters

Syntax

```
phif = filterbank(sf)
[phif,psifilters] = filterbank(sf)
[phif,psifilters,f] = filterbank(sf)
[phif,psifilters,f,filterparams] = filterbank(sf)
[___] = filterbank(sf,fb)
```

Description

`phif = filterbank(sf)` returns the Fourier transform of the scaling filter for the 2-D wavelet scattering framework, `sf`. `phif` is a single or double-precision matrix depending on the value of the `Precision` property of the scattering framework. `phif` has dimensions M -by- N , where M and N are the padded row and column sizes of the scattering framework.

`[phif,psifilters] = filterbank(sf)` returns the Fourier transforms for the wavelet filters in `psifilters`. `psifilters` is an Nfb -by-1 cell array, where Nfb is the number of filter banks in the scattering framework. Each element of `psifilters` is a 3-D array. The 3-D arrays are M -by- N -by- L , where M and N are the padded row and column sizes of the wavelet filters and L is the number of wavelet filters for each filter bank. The wavelet filters are ordered by increasing scale with `NumRotations` wavelet filters for each scale. Within a scale, the wavelet filters are ordered by rotation angle.

`[phif,psifilters,f] = filterbank(sf)` returns the center spatial frequencies for the wavelet filters in `psifilters`. `f` is an Nfb -by-1 cell array, where Nfb is the number of filter banks in `sf`. The j th element of `f` contains the center frequencies for the j th wavelet filter bank in `psifilters`. Each element of `f` is a L -by-2 matrix with each row containing the center frequencies of the corresponding L th wavelet.

`[phif,psifilters,f,filterparams] = filterbank(sf)` returns the filter parameters for the 2-D scattering framework. `filterparams` is an Nfb -by-1 cell array of MATLAB tables, where the j th element of `filterparams` is a MATLAB table containing the filter parameters for the j th filter bank

`[___] = filterbank(sf,fb)` returns the desired outputs for the filter banks specified in `fb`. `fb` is a scalar or vector of integers between 1 and `numfilterbanks(sf)` inclusive. If `fb` is a scalar, `psifilters` is an M -by- N -by- L matrix, and `filterparams` is a MATLAB table.

Examples

Plot Wavelet Center Frequencies

This example shows how to plot the scaling filter and the wavelet filter center frequencies for a two-filter bank wavelet image scattering framework.

Create a wavelet image scattering framework with two filter banks. The first filter bank has a quality factor of 2, and the second filter bank has a quality factor of 1.

```
sf = waveletScattering2('QualityFactors',[2 1])
```

```
sf =  
  waveletScattering2 with properties:
```

```
      ImageSize: [128 128]  
  InvarianceScale: 64  
      NumRotations: [6 6]  
    QualityFactors: [2 1]  
      Precision: "single"  
OversamplingFactor: 0  
      OptimizePath: 1
```

Obtain the scaling filter, wavelet filters, and wavelet center frequencies for the framework.

```
[phif,psifilters,f] = filterbank(sf);
```

Make a surface plot of the scaling filter.

```
Nx = size(phif,1);  
Ny = size(phif,2);  
fx = -1/2:1/Nx:1/2-1/Nx;  
fy = -1/2:1/Ny:1/2-1/Ny;  
surf(fx,fy,fftshift(phif))  
shading interp  
title('Scaling Filter')  
xlabel('f_x')  
ylabel('f_y')
```

Plot the wavelet center frequencies for the two filter banks.

```
figure
plot(f{1}(:,1),f{1}(:,2),'k*')
hold on
grid on
plot(f{2}(:,1),f{2}(:,2),'r^','MarkerFaceColor',[1 0 0])
axis equal
xlabel('f_x')
ylabel('f_y')
legend('First Filter Bank Q = 2','Second Filter Bank Q = 1')
```

Plot Specific Wavelet of Image Scattering Framework

This example shows how to obtain and plot a specific wavelet of a wavelet image scattering framework.

Create a wavelet image scattering framework with two filter banks. The first filter bank has a quality factor of 2 and seven rotations per wavelet. The second filter bank has a quality factor of 1 and five rotations per wavelet.

```
sf = waveletScattering2('QualityFactors',[2 1], 'NumRotations',[7 5])
```

```
sf =  
  waveletScattering2 with properties:
```

```
    ImageSize: [128 128]  
  InvarianceScale: 64  
    NumRotations: [7 5]  
  QualityFactors: [2 1]  
    Precision: "single"  
  OversamplingFactor: 0  
    OptimizePath: 1
```

Obtain the wavelet filters and center frequencies for the framework. Return the dimensions of the two cell arrays.

```
[~,psifilters,f] = filterbank(sf);
psifilters
```

```
psifilters=2x1 cell array
    {192x192x42 single}
    {192x192x20 single}
```

```
f
```

```
f=2x1 cell array
    {42x2 double}
    {20x2 double}
```

The first filter bank has 42 wavelet filters, and the second filter bank has 20 filters. The number of filters in each filter bank is a multiple of the corresponding value in `NumRotations`. Use the helper function `helperPlotWavelet` to plot a specific wavelet and mark its center frequency.

```
figure
whichFilterBank = 1;
whichWavelet = 13;
helperPlotWavelet(psifilters,f,whichFilterBank,whichWavelet)
```

Appendix

The following helper function is used in this example.

```

function helperPlotWavelet(psiFilters,psiFreq,filBank,wvFilter)
Nx = size(psiFilters{filBank},2);
Ny = size(psiFilters{filBank},1);
fx = -1/2:1/Nx:1/2-1/Nx;
fy = -1/2:1/Ny:1/2-1/Ny;
imagesc(fx,fy,fftshift(psiFilters{filBank}(:, :,wvFilter)))
axis xy
hold on
xlabel('f_x')
ylabel('f_y')
plot(psiFreq{filBank}(wvFilter,1),psiFreq{filBank}(wvFilter,2),...
     'k^','markerfacecolor',[0 0 0])
str = sprintf('Filter Bank: %d Wavelet: %d',filBank,wvFilter);
title(str)
end

```

Determine Wavelet Semi-Major Axis

This example shows how to determine the semi-major axis of a wavelet filter in a 2-D wavelet scattering framework.

Create a 2-D wavelet scattering framework. The framework has two filter banks with quality factors of 2 and 1, respectively. There are seven rotations per wavelet in the first filter bank and five rotations per wavelet in the second filter bank. Return the Fourier transforms of the wavelet filters and their center spatial frequencies, and the filter bank parameters.

```

sf = waveletScattering2('QualityFactors',[2 1],'NumRotations',[7 5]);
[~,psif,f,fparams] = filterbank(sf);

```

The wavelet filters in `psif` are ordered by increasing scale, with `NumRotations` wavelet filters for each scale. Within a scale, the wavelet filters are ordered by rotation.

Return the reported 3 dB bandwidths, rotation angles, and slant parameter of the first filter bank. Return the dimensions of the matrix containing the wavelet filters of the first filter bank. Confirm that (number of rotations) \times (number of bandwidths) equals the size of the third dimension of the matrix. The product is the number of wavelet filters in the filter bank. The row and column sizes are the dimensions of the padded wavelet filters. Note that the slant parameter is less than 1.

```
fparams{1}.psi3dBbw
```

```
ans = 1×6
```

```
    0.1464    0.1036    0.0732    0.0518    0.0366    0.0366
```

```
fparams{1}.rotations
```

```
ans = 1×7
```

```
    0    0.4488    0.8976    1.3464    1.7952    2.2440    2.6928
```

```
fparams{1}.slant
```

```
ans = 0.5817
```

```
size(psif{1})
```

```
ans = 1×3
    192    192    42
```

The vector `fparams{1}.psi3dBbw` has six elements. The number of elements is equal to the number of wavelet scales in the first filter bank.

From the first filter bank, obtain the unrotated wavelet filter from the second finest scale. Obtain the center spatial frequency of the wavelet. Use the helper function `helperPlotWaveletFT` to plot the wavelet and mark its center frequency. The code for `helperPlotWaveletFT` is shown at the end of this example.

```
whichFilterBank = 1;
whichScale = 2;
whichRotAngle = 1;
numRot = sf.NumRotations(whichFilterBank);

wvf = psif{whichFilterBank}(:, :, 1+(whichScale-1)*numRot+(whichRotAngle-1));
wvfCenFrq = f{whichFilterBank}(1+(whichScale-1)*numRot+(whichRotAngle-1), :);

helperPlotWaveletFT(wvf, wvfCenFrq)
```

Take the inverse Fourier transform of the wavelet filter. The filter is strictly real, and the inverse Fourier transform is complex-valued. Use the helper function `helperPlotWavelet` to plot the absolute value of the wavelet. The code for `helperPlotWavelet` is shown at the end of this example.

```
wvf_ifft = ifft2(wvf);  
figure  
helperPlotWavelet(wvf_ifft)
```

Note that the semi-major axis of the wavelet support is in the y -direction. This is consistent with a slant parameter whose value is less than 1. The vector $(0, 0.1)$ coincides with the semi-major axis. Plot the vector in the previous figure.

```
vec = [0 0.1];  
hold on  
plot([0 vec(1)], [0 vec(2)], 'wx-')  
xlim([-0.2 0.2])  
ylim([-0.2 0.2])
```

From the same filter bank and scale, choose a rotated wavelet filter. Plot the absolute value of the wavelet in the spatial domain. Use the associated rotation angle in `fparams{1}.rotations`, and rotate clockwise the vector $(0, 0.1)$ by that amount. Plot the rotated vector in the figure. Confirm that the vector is aligned with the semi-major axis of the rotated wavelet.

```
whichRotAngle = 3;
rotAngle = fparams{whichFilterBank}.rotations(whichRotAngle);
rmat = [cos(rotAngle) sin(rotAngle) ; -sin(rotAngle) cos(rotAngle)];

wvf = psif{whichFilterBank}(:, :, 1+(whichScale-1)*numRot+(whichRotAngle-1));
wvf_ifft = ifft2(wvf);

rvec = rmat*vec';

figure
helperPlotWavelet(wvf_ifft)
hold on
plot([0 rvec(1)], [0 rvec(2)], 'wx-')
xlim([-0.2 0.2])
ylim([-0.2 0.2])
```

Appendix

The following helper functions are used in this example.

helperPlotWaveletFT — Plot in the frequency domain

```
function helperPlotWaveletFT(wavelet,cenFreq)
Nx = size(wavelet,2);
Ny = size(wavelet,1);
fx = -1/2:1/Nx:1/2-1/Nx;
fy = -1/2:1/Ny:1/2-1/Ny;
imagesc(fx,fy,fftshift(wavelet))
colorbar
axis xy
hold on
xlabel('\omega_x','Interpreter','latex')
ylabel('\omega_y','Interpreter','latex')
axis equal
axis tight
plot(cenFreq(1),cenFreq(2),'k^','markerfacecolor',[0 0 0])
title('Wavelet Filter in Frequency Domain')
end
```

helperPlotWavelet — Plot in the spatial domain

```
function helperPlotWavelet(wavelet)
Nx = size(wavelet,2);
Ny = size(wavelet,1);
```

```

fx = -1/2:1/Nx:1/2-1/Nx;
fy = -1/2:1/Ny:1/2-1/Ny;
imagesc(fx,fy,abs(fftshift(wavelet)))
colorbar
axis xy
hold on
xlabel('x')
ylabel('y')
axis equal
axis tight
title('Wavelet Filter in Spatial Domain')
end

```

Input Arguments

sf — Scattering decomposition framework

waveletScattering2 object

Scattering decomposition framework, specified as a waveletScattering2 object.

fb — Filter banks

positive integer | vector of positive integers

Filter banks, specified as an integer or vector of integers between 1 and numfilterbanks(sf) inclusive. If fb is a scalar, psifilters is an M -by- N -by- L matrix and filterparams is a MATLAB table.

Output Arguments

phif — Fourier transform of scaling filter

real-valued matrix

Fourier transform of scaling filter, returned as a real-valued 2-D matrix. The precision of phif depends on the value of the Precision property of the scattering framework. phif has dimensions M -by- N , where M and N are the padded row and column sizes of the scattering framework.

psifilters — Fourier transforms of the wavelet filters

cell array

Fourier transforms of the wavelet filters, returned as an Nfb -by-1 cell array, where Nfb is the number of filter banks in the scattering framework. Each element of psifilters is a 3-D array. The 3-D arrays are M -by- N -by- L , where M and N are the padded row and column sizes of the wavelet filters and L is the number of wavelet filters for each filter bank. The wavelet filters are ordered by increasing scale with NumRotations wavelet filters for each scale.

Example: Note that `size(psifilters,3)` is equal to `size(f,1)`.

f — Center spatial frequencies

cell array

Center spatial frequencies of the wavelet filters, returned as a Nfb -by-1 cell array where Nfb is the number of filter banks in the scattering framework. The j th element of f contains the center frequencies for the j th wavelet filter bank in psifilters. Each element of f is an L -by-2 matrix with each row containing the center frequencies of the corresponding L th wavelet. The spatial frequencies are in cycles per pixel.

filterparams — Filter parameters

cell array

Filter parameters for the 2-D scattering framework, *sf*. `filterparams` is an *Nfb*-by-1 cell array of MATLAB tables, where the *j*th element of `filterparams` is a MATLAB table containing the filter parameters for the *j*th filter bank. Each table contains these variables:

- `Q` — The quality factor of the filter bank, returned as an integer.
- `J` — The highest factor used in the dilation of the Morlet wavelets, $2^{J/Q}$, returned as an integer.
- `precision` — The precision of the scattering framework, returned as 'single' or 'double'.
- `omegapsi` — The wavelet center frequencies in descending order (highest to lowest), returned as a vector.
- `freqsigmapsi` — The wavelet frequency standard deviations, returned as a vector.
- `slant` — The slant parameter for the spatial vertical semi-major axis of the wavelet, returned as a real number. The slant parameter, also known as the spatial aspect ratio, characterizes the shape of the support of the wavelet.
- `spatialsigmapsi` — The wavelet spatial standard deviations, returned as a vector.
- `spatialsigma phi` — The scaling filter spatial standard deviation, returned as a real number.
- `psi3dBbw` — The wavelet 3 dB bandwidths, returned as a vector.
- `psiftsupport` — The wavelet frequency support, returned as a vector.
- `phiftsupport` — The scaling filter frequency support, returned as a real number.
- `phi3dBbw` — The scaling filter 3 dB bandwidth, returned as a real number.
- `rotations` — The wavelet orientation angles in radians, returned as a vector. The length of `rotations` equals the `NumRotations` value associated with the filter bank.

The following vectors in the table have equal length: `omegapsi`, `freqsigmapsi`, `spatialsigmapsi`, `psi3dBbw`, and `psiftsupport`.

The total number of wavelet filters in a filter bank is `length(omegapsi) × length(rotations)`. See “Determine Wavelet Semi-Major Axis” on page 1-414.

More About**Slant Parameter**

The *slant parameter* or *spatial aspect ratio* controls the shape of the elliptical support of the Morlet wavelet.

The Morlet wavelet is of the form

$$\psi(x, y) = e^{-(x^2 + v^2 y^2)/2\sigma^2} e^{i\omega\lambda x}$$

where *v* is the *slant parameter*. Typically, $v < 1$, so that the ellipse $\frac{x^2}{\sigma^2} + \frac{y^2}{\sigma^2/v^2}$ is elongated spatially

in the *y*-direction. The wavelet is rotated in a clockwise direction: $\begin{pmatrix} x' \\ y' \end{pmatrix} = \begin{pmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix}$.

The rotated Morlet wavelet is of the form

$$\psi(x', y') = e^{-(x'^2 + v^2 y'^2)/2\sigma^2} e^{i\omega_\lambda x'}$$

If $g(x, y)$ and $G(\omega_x, \omega_y)$ form a Fourier pair: $g(x, y) \xleftrightarrow{FT} G(\omega_x, \omega_y)$, then so do their rotations:

$$g(x\cos\theta + y\sin\theta, -x\sin\theta + y\cos\theta) \xleftrightarrow{FT} G(\omega_x\cos\theta + \omega_y\sin\theta, -\omega_x\sin\theta + \omega_y\cos\theta)$$

The Fourier transform of the Morlet wavelet is

$$\widehat{\psi}(\omega_x, \omega_y) = \frac{2\pi\sigma^2}{v} e^{-\frac{\sigma^2}{v} \left((\omega_x - \omega_\lambda)^2 + \frac{\omega_y^2}{v^2} \right)}$$

A given wavelet $\psi(x, y)$ has a reported bandwidth bw . The reported bandwidth is dependent on the scale, but not the rotation angle. For a reported 3 dB bandwidth bw , the bandwidth along the semi-major spatial axis of the ellipse that describes the wavelet support is $bw \times \text{slant}$.

The semi-major spatial axis depends on the rotation angle. The semi-major spatial axis can be computed from the vector rotations in the output argument `filterparams`.

As ordered in the output arguments `f` and `psifilters`, the wavelet filter `psifilters(:, :, 1 + k \times \text{NumRotations})` for an integer k is the first, unrotated wavelet at a given scale. The wavelet has a center spatial frequency of `f(1 + k \times \text{NumRotations}, :)`, which is of the form (ω_x, θ) . See "Determine Wavelet Semi-Major Axis" on page 1-414.

filters

DWT filter bank filters

Syntax

```
[Lo,Hi] = filters(fb)
```

Description

`[Lo,Hi] = filters(fb)` returns the lowpass (scaling) and highpass (wavelet) filters, Lo and Hi, respectively, for the discrete wavelet transform (DWT) filter bank fb.

Examples

DWT Filter Bank Filters

Obtain the lowpass and highpass filters for the order-4 symlet.

```
fb = dwtfilterbank('Wavelet','sym4');  
[Lo,Hi] = filters(fb)
```

Lo = 8×2

```
-0.0758    0.0322  
-0.0296   -0.0126  
 0.4976   -0.0992  
 0.8037    0.2979  
 0.2979    0.8037  
-0.0992    0.4976  
-0.0126   -0.0296  
 0.0322   -0.0758
```

Hi = 8×2

```
-0.0322   -0.0758  
-0.0126    0.0296  
 0.0992    0.4976  
 0.2979   -0.8037  
-0.8037    0.2979  
 0.4976    0.0992  
 0.0296   -0.0126  
-0.0758   -0.0322
```

Confirm the filter bank is orthogonal.

```
isOrthogonal(fb)
```

```
ans = logical  
     1
```

Input Arguments

fb — Discrete wavelet transform filter bank

`dwtfilterbank` object

Discrete wavelet transform (DWT) filter bank, specified as a `dwtfilterbank` object.

Output Arguments

Lo — Lowpass (scaling) filters

real-valued matrix

Lowpass (scaling) filters for the DWT filter bank, returned as an L -by-2 matrix. L is an even positive integer. The first column of `Lo` is the analysis filter, and the second column is the synthesis filter.

For orthogonal wavelets, the lowpass synthesis and lowpass analysis filters are time-reversed versions of each other.

Hi — Highpass (wavelet) filters

real-valued matrix

Highpass (wavelet) filters for the DWT filter bank, returned as an L -by-2 matrix. L is an even positive integer. The first column of `Hi` is the analysis filter, and the second column is the synthesis filter.

For orthogonal wavelets, the highpass synthesis and highpass analysis filters are time-reversed versions of each other.

`dwtfilterbank` | `wfilters`

Introduced in R2018a

framebounds

DWT filter bank frame bounds

Syntax

```
[a,b] = framebounds(fb)
```

Description

`[a,b] = framebounds(fb)` returns the frame bounds for the discrete wavelet transform (DWT) filter bank `fb`. For an orthogonal wavelet filter bank, the theoretical frame bounds `a` and `b` are equal to 1.

Examples

DWT Filter Bank Frame Bounds

Obtain the frame bounds for the orthogonal Daubechies `db6` wavelet.

```
wv = 'db6';  
fb = dwtfilterbank('Wavelet',wv)  
  
fb =  
    dwtfilterbank with properties:  
  
        Wavelet: 'db6'  
    SignalLength: 1024  
        Level: 6  
    SamplingFrequency: 1  
        FilterType: 'Analysis'  
    CustomWaveletFilter: []  
    CustomScalingFilter: []
```

```
[a,b] = framebounds(fb)
```

```
a = 1.0000
```

```
b = 1.0000
```

The filter bank has the default filter type `Analysis`. Create a second filter bank using the same orthogonal wavelet but with the filter type `Synthesis`. Obtain the frame bounds of this filter bank, which are equal to the previous frame bounds.

```
fbSynthesis = dwtfilterbank('Wavelet',wv,'FilterType','Synthesis');  
[a2,b2] = framebounds(fbSynthesis)
```

```
a2 = 1.0000
```

```
b2 = 1.0000
```

Create a filter bank for the biorthogonal `bior3.9` wavelet. Obtain the frame bounds. The frame bounds are not equal to 1.

```
wv = 'bior3.9';  
fbA = dwtfilterbank('Wavelet',wv);  
[c,d] = framebounds(fbA)  
  
c = 0.6250  
d = 3.2982
```

Create a second filter bank using the same biorthogonal wavelet but with the filter type `Synthesis`. Obtain the frame bounds of this filter bank. Since the wavelet is biorthogonal, the frame bounds change.

```
fbASynthesis = dwtfilterbank('Wavelet',wv,'FilterType','Synthesis');  
[c2,d2] = framebounds(fbASynthesis)  
  
c2 = 0.5502  
d2 = 2.0015
```

Input Arguments

fb — Discrete wavelet transform filter bank

`dwtfilterbank` object

Discrete wavelet transform (DWT) filter bank, specified as a `dwtfilterbank` object.

Output Arguments

a — Lower frame bound

positive real number

Lower frame bound of the DWT filter bank `fb`, returned as a positive real number.

b — Upper frame bound

positive real number

Upper frame bound of the DWT filter bank `fb`, returned as a positive real number.

Introduced in R2018a

framebounds

Shearlet system frame bounds

Syntax

```
[a,b] = framebounds(sls)
```

Description

`[a,b] = framebounds(sls)` returns the lower and upper frame bounds for the shearlet system `sls`. The energy in the shearlet transform coefficients is bounded by the energy in the input image and the frame bounds. See “Frame Bounds” on page 1-427.

Examples

Shearlet System Frame Bounds

This example shows how the `PreserveEnergy` property affects the frame bounds of a shearlet system.

Load an image and calculate its energy.

```
load xbox  
energyIm = norm(xbox, 'fro')^2;
```

Create two shearlet systems that can be applied to the image. Set the value of `PreserveEnergy` in the first shearlet system to `true` and in the second shearlet system to `false`.

```
slsT = shearletSystem('ImageSize',size(xbox),'PreserveEnergy',true);  
slsF = shearletSystem('ImageSize',size(xbox),'PreserveEnergy',false);
```

Obtain the shearlet transform of the image using both shearlet systems.

```
cfsT = sheart2(slsT,xbox);  
cfsF = sheart2(slsF,xbox);
```

Calculate the frame bounds of `slsT`. Confirm that `slsT` is a Parseval frame.

```
[aT,bT] = framebounds(slsT)
```

```
aT = 1
```

```
bT = 1
```

Confirm that using `slsT` preserves energy.

```
energyCfsT = norm(cfsT(:))^2;  
abs(energyIm-energyCfsT)
```

```
ans = 6.9849e-10
```

Obtain the frame bounds of `slsF`. Confirm the lower and upper frame bounds are not both equal to 1.

```
[aF,bF] = framebounds(slsF)
```

```
aF = 1.0000
```

```
bF = 8.0000
```

Even though `slsF` is not normalized to be a Parseval frame, confirm the frame inequality is still satisfied.

```
energyCfsF = norm(cfsF(:))^2;
aF*energyIm <= norm(cfsF(:))^2 && norm(cfsF(:))^2 <= bF*energyIm
```

```
ans = logical
      1
```

Input Arguments

sls — Shearlet system

shearletSystem object

Shearlet system, specified as a `shearletSystem` object.

Output Arguments

a, b — Lower and upper frame bounds

positive real numbers

Lower and upper frame bounds of the shearlet system, returned as positive real numbers. If the `PreserveEnergy` value of `sls` is `true`, then `sls` is a Parseval frame, and both frame bounds are equal to 1. See “Frame Bounds” on page 1-427.

The data types of the frame bounds match the `Precision` value of the shearlet system.

Note For an image X , if `sls` is a Parseval frame and $C = \text{shearlet2}(\text{sls}, X)$, then the energy of X and the energy of C are equal within round-off error.

Data Types: `single` | `double`

More About

Frame Bounds

The energy in the shearlet transform of an image is bounded by the energy of the image and the lower and upper frame bounds a , b of the shearlet system. If X is an M -by- N image and C , the shearlet transform of X , is M -by- N -by- K , then the frame inequality holds:

$$a \sum_{i=1}^M \sum_{j=1}^N |x_{ij}|^2 \leq \sum_{i=1}^M \sum_{j=1}^N \sum_{k=1}^K |c_{ijk}|^2 \leq b \sum_{i=1}^M \sum_{j=1}^N |x_{ij}|^2.$$

In a Parseval frame, $a = b = 1$, and the shearlet transform preserves energy.

freqz

CWT filter bank frequency responses

Syntax

```
[psidft,f] = freqz(fb)
freqz(fb)
```

Description

`[psidft,f] = freqz(fb)` returns the frequency responses for the wavelet filters, `psidft`, and the frequency vector, `f`, for the continuous wavelet transform (CWT) filter bank, `fb`. Frequencies are in cycles/sample or Hz. If you specify a sampling period, the frequencies are in cycles/unit time where the time unit is the unit of the duration `SamplingPeriod`.

The frequency responses, `psidft`, are one-sided frequency responses for the positive frequencies. For the analytic wavelets supported by `cwtfilterbank`, the frequency responses are real-valued and are equivalent to the magnitude frequency response.

`freqz(fb)` with no output arguments plots the magnitude frequency responses for the CWT filter bank, `fb`.

Examples

Frequency Responses of a Continuous Wavelet Transform Filter Bank

Create a CWT filter bank. Set the voices per octave to 14, the sampling frequency to 1000 Hz, and frequency limits to range from 200 Hz to 300 Hz.

```
fb = cwtfilterbank('VoicesPerOctave',14,'SamplingFrequency',1000,'FrequencyLimits',[200 300])
```

```
fb =
  cwtfilterbank with properties:
    VoicesPerOctave: 14
    Wavelet: 'morse'
    SamplingFrequency: 1000
    SamplingPeriod: []
    PeriodLimits: []
    SignalLength: 1024
    FrequencyLimits: [200 300]
    TimeBandwidth: 60
    WaveletParameters: []
    Boundary: 'reflection'
```

Obtain the frequency responses for the filter bank. Plot the frequency responses.

```
[psidft,f] = freqz(fb);
plot(f,psidft)
```

```

grid on
title('Frequency Responses')
xlabel('Frequency (Hz)')
ylabel('Magnitude')

```

Input Arguments

fb — Continuous wavelet transform filter bank

cwtfilterbank object

Continuous wavelet transform (CWT) filter bank, specified as a `cwtfilterbank` object.

Output Arguments

psidft — Frequency responses

real-valued 2-D matrix

Frequency responses of a CWT filter bank, returned as a real-valued N_s -by- M matrix where N_s is the number of scales. If the filter bank `Boundary` is `'reflection'`, M is equal to $2 \cdot \text{floor}(\text{SignalLength}/2) + 1$. If the filter bank `Boundary` is `'periodic'`, M is equal to $\text{floor}(\text{SignalLength}/2) + 1$.

The frequency responses, `psidft`, are one-sided frequency responses for the positive frequencies. For the analytic wavelets supported by `cwtfilterbank`, the frequency responses are real-valued and are equivalent to the magnitude frequency response.

f – Frequencies

real-valued vector

Frequencies, in cycles/sample or Hz, returned as a real-valued vector. If the filter bank `Boundary` is `'reflection'`, `f` has length $2*\text{floor}(\text{SignalLength}/2)+1$. If the filter bank `Boundary` is `'periodic'`, `f` has length $\text{floor}(\text{SignalLength}/2)+1$.

If you specify a sampling period, the frequencies are in cycles/unit time where the time unit is the unit of the duration `SamplingPeriod`.

Data Types: `double`

freqz

DWT filter bank frequency responses

Syntax

```
[psidft,f] = freqz(fb)  
[psidft,f,phidft] = freqz(fb)  
freqz(fb)
```

Description

`[psidft,f] = freqz(fb)` returns the complex-valued frequency responses for the wavelet filters `psidft` and the frequency vector `f` for the discrete wavelet transform (DWT) filter bank `fb`. Frequencies are in cycles/sample or in Hz if a sampling frequency is defined in `fb`. The frequency responses are centered so that the zero frequency is in the middle.

`[psidft,f,phidft] = freqz(fb)` returns the complex-valued frequency responses for the scaling filters `phidft` for the DWT filter bank `fb` at all levels of the decomposition.

`freqz(fb)` plots the one-sided magnitude frequency responses for the wavelet filter bank, `fb`. Magnitude frequency responses are plotted for all wavelet bandpass filters and the coarsest resolution scaling filter. The legend is interactive. To toggle the visibility of the filter magnitude response, click the corresponding line in the legend.

Examples

DWT Filter Bank Frequency Responses

Create a DWT filter bank for a length 4096 signal and the Fejér-Korovkin `fk22` wavelet. Plot the magnitude frequency responses of the wavelet filters and final resolution scaling filter.

```
len = 4096;  
fb = dwtfilterbank('Wavelet','fk22','SignalLength',len);  
freqz(fb)
```

Obtain the frequency responses for the wavelet and scaling filters. Plot the magnitude frequency responses of the scaling filters at all levels of decomposition.

```
[psidft,f,phidft] = freqz(fb);
plot(f,abs(phidft))
grid on
xlabel('Normalized Frequency (cycles/sample)')
ylabel('Magnitude')
legend('A1','A2','A3','A4','A5','A6','A7')
```

Plot the one-sided magnitude frequency responses of the wavelet and scaling filters at the first two levels of decomposition. Note how the second level frequency responses overlap the magnitude response of the first level scaling filter.

```
plot(f(len/2:end),abs(psidft(1,len/2:end)))
hold on
plot(f(len/2:end),abs(phidft(1,len/2:end)))
plot(f(len/2:end),abs(psidft(2,len/2:end)))
plot(f(len/2:end),abs(phidft(2,len/2:end)))
grid on
xlabel('Normalized Frequency (cycles/sample)')
ylabel('Magnitude')
legend('Level 1 Wavelet','Level 1 Scaling','Level 2 Wavelet','Level 2 Scaling')
```

Input Arguments

fb — Discrete wavelet transform filter bank

`dwtfilterbank` object

Discrete wavelet transform (DWT) filter bank, specified as a `dwtfilterbank` object.

Output Arguments

psidft — Wavelet filter frequency responses

complex-valued matrix

Wavelet filter frequency responses for the DWT filter bank `fb`, returned as an L -by- N matrix, where L is the filter bank `Level` and N is the filter bank `SignalLength`. The frequency responses are centered so that the zero frequency is centered in the middle.

f — Frequencies

real-valued vector

Frequencies, in cycles/sample or Hz, returned as a real-valued vector of length N , where N is the filter bank `SignalLength`. If a sampling frequency is specified in `fb`, frequencies are in Hz.

Data Types: `double`

phidft — Scaling function frequency responses

complex-valued matrix

Scaling function frequency responses for the DWT filter bank `fb`, returned as an L -by- N matrix, where L is the filter bank `Level` and N is the filter bank `SignalLength`. The frequency responses are centered so that the zero frequency is centered in the middle.

See Also`dwtfilterbank` | `scalingfunctions` | `wavelets`**Introduced in R2018a**

gauswavf

Gaussian wavelet

Syntax

```
[psi,x] = gauwavf(lb,ub,n)
[psi,x] = gauwavf(lb,ub,n,p)
[psi,x] = gauwavf(lb,ub,n,wname)
```

Description

`[psi,x] = gauwavf(lb,ub,n)` returns the 1st order derivative of the Gaussian wavelet, `psi`, on an `n`-point regular grid, `x`, for the interval `[lb,ub]`. The effective support of the Gaussian wavelets is `[-5, 5]`.

`[psi,x] = gauwavf(lb,ub,n,p)` returns the p^{th} derivative. `p` is an integer from 1 through 8.

The Gaussian function is defined as $C_p e^{-x^2}$. C_p is such that the 2-norm of the p^{th} derivative of `psi` is equal to 1.

Note For visualizing the second or third order derivative of Gaussian wavelets, the convention is to use the negative of the normalized derivative. In the case of the second derivative, scaling by -1 produces a wavelet with its main lobe in the positive y direction. This scaling also makes the Gaussian wavelet resemble the Mexican hat, or Ricker, wavelet. The validity of the wavelet is not affected by the -1 scaling factor.

`[psi,x] = gauwavf(lb,ub,n,wname)` used the valid wavelet family short name `wname` plus the order of the derivative in a character vector or string scalar, such as `'gaus4'`. To see valid character vectors for Gaussian wavelets, use `waveinfo('gaus')` or use `wavemngr('read',1)` and refer to the Gaussian section.

Examples

Create Gaussian Wavelet

This example shows how to create and plot a Gaussian wavelet of order 8.

Set the initial effective support and grid parameters.

```
lb = -5;
ub = 5;
n = 1000;
```

Compute the Gaussian wavelet of order 8.

```
[psi,x] = gauswavf(lb,ub,n,8);
```

Now plot the wavelet.

```
plot(x,psi)
title('Order 8 Gaussian Wavelet')
grid on
```

Input Arguments

lb – Left endpoint

real number

Left endpoint of the closed interval, specified as a real number. lb is strictly less than ub .

Data Types: double

ub – Right endpoint

real number

Right endpoint of the closed interval, specified as a real number. ub is strictly greater than lb .

Data Types: double

n – Number of regularly spaced points

positive integer

Number of regularly spaced points in the interval $[lb,ub]$, specified as a positive integer. The derivative of the Gaussian is evaluated at these points.

Data Types: double

p — Derivative

positive integer

Positive integer defining the order of the derivative of the Gaussian wavelet, specified as a positive integer. `p` is an integer from 1 through 8.

wname — Gaussian wavelet

character vector | string scalar

Gaussian wavelet to evaluate, specified as a character vector or string scalar. `wname` is of the form 'cgau N ' where N is an integer that denotes the order of the derivative of the Gaussian wavelet. N is an integer from 1 through 8.

Example: 'gaus4' denotes the fourth derivative of the Gaussian wavelet.

Output Arguments**psi — Derivative of Gaussian wavelet**

real-valued vector

Derivative of the Gaussian wavelet, returned as a real-valued 1-by- N vector.

x — Sample points

real-valued vector

Sample points where the derivative of the Gaussian wavelet is evaluated, returned as a real-valued 1-by- N vector. The sample points are evenly distributed between `lb` and `ub`.

Introduced before R2006a

get

WPTREE contents

Syntax

```
[FieldValue1,FieldValue2, ...] = get(T,'FieldName1','FieldName2', ...)  
[FieldValue1,FieldValue2, ...] = get(T)
```

Description

[FieldValue1,FieldValue2, ...] = get(T,'FieldName1','FieldName2', ...) returns the content of the specified fields for the WPTREE object T.

For the fields that are objects or structures, you can get the subfield contents, giving the name of these subfields as '*FieldName*' values. (See "Examples" below.)

[FieldValue1,FieldValue2, ...] = get(T) returns all the field contents of the tree T.

The valid choices for '*FieldName*' are

'dtree'	DTREE parent object
'wavInfo'	Structure (wavelet information)

The fields of the wavelet information structure, 'wavInfo', are also valid for '*FieldName*':

'wavName'	Wavelet name
'Lo_D'	Low Decomposition filter
'Hi_D'	High Decomposition filter
'Lo_R'	Low Reconstruction filter
'Hi_R'	High Reconstruction filter

'entInfo'	Structure (entropy information)
-----------	---------------------------------

The fields of the entropy information structure, 'entInfo', are also valid for '*FieldName*':

'entName'	Entropy name
'entPar'	Entropy parameter

Or fields of DTREE parent object:

'ntree'	NTREE parent object
'allNI'	All nodes information
'terNI'	Terminal nodes information

Or fields of NTREE parent object:

'wtbo'	WTBO parent object
'order'	Order of the tree
'depth'	Depth of the tree
'spsch'	Split scheme for nodes
'tn'	Array of terminal nodes of the tree

Or fields of WTBO parent object:

'wtboInfo'	Object information
'ud'	Userdata field

Examples

```
% Compute a wavelet packets tree
x = rand(1,1000);
t = wpdec(x,2,'db2');
o = get(t,'order');
[o,tn] = get(t,'order','tn');
[o,allNI,tn] = get(t,'order','allNI','tn');
[o,wavInfo,allNI,tn] = get(t,'order','wavInfo','allNI','tn');
[o,tn,Lo_D,EntName] = get(t,'order','tn','Lo_D','EntName');
[wo,nt,dt] = get(t,'wtbo','ntree','dtree');
```

disp | read | set | write

Introduced before R2006a

getLabelDefinitions

Get label definitions in labeled signal set

Syntax

```
lbldefs = getLabelDefinitions(lss)
```

Description

`lbldefs = getLabelDefinitions(lss)` returns a vector of `signalLabelDefinition` objects with the labels of the labeled signal set `lss`.

Changing `lbldefs` does not affect the labeled set. To modify label definitions, use `editLabelDefinition`, `addLabelDefinitions`, and `removeLabelDefinition`.

Examples

Get Label Definitions

Load a labeled signal set containing recordings of whale songs.

```
load whales
lss

lss =
  labeledSignalSet with properties:
      Source: {2x1 cell}
      NumMembers: 2
      TimeInformation: "sampleRate"
      SampleRate: 4000
      Labels: [2x3 table]
      Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

Retrieve the definitions of the labels in the set.

```
dfs = getLabelDefinitions(lss);

for k = 1:length(dfs)
    dfs(k)
end

ans =
  signalLabelDefinition with properties:
      Name: "WhaleType"
      LabelType: "attribute"
```

```

LabelDataType: "categorical"
Categories: [3x1 string]
DefaultValue: []
Sublabels: [0x0 signalLabelDefinition]
Tag: ""
Description: "Whale type"

```

Use `labeledSignalSet` to create a labeled signal set.

```

ans =
  signalLabelDefinition with properties:
      Name: "MoanRegions"
      LabelType: "roi"
      LabelDataType: "logical"
      ValidationFunction: []
      ROILimitsDataType: "double"
      DefaultValue: []
      Sublabels: [0x0 signalLabelDefinition]
      Tag: ""
      Description: "Regions where moans occur"

```

Use `labeledSignalSet` to create a labeled signal set.

```

ans =
  signalLabelDefinition with properties:
      Name: "TrillRegions"
      LabelType: "roi"
      LabelDataType: "logical"
      ValidationFunction: []
      ROILimitsDataType: "double"
      DefaultValue: []
      Sublabels: [1x1 signalLabelDefinition]
      Tag: ""
      Description: "Regions where trills occur"

```

Use `labeledSignalSet` to create a labeled signal set.

Input Arguments

lss — Labeled signal set

`labeledSignalSet` object

Labeled signal set, specified as a `labeledSignalSet` object.

Example: `labeledSignalSet({randn(100,1)
randn(10,1)}, signalLabelDefinition('female'))` specifies a two-member set of random signals containing the attribute 'female'.

Output Arguments

lbldefs — Signal label definitions

`signalLabelDefinition` object

Signal label definitions, returned as a `signalLabelDefinition` object or a vector of such objects.

See Also

labeledSignalSet | signalLabelDefinition

Introduced in R2018b

getLabeledSignal

Get labeled signals from labeled signal set

Syntax

```
[t,info] = getLabeledSignal(lss)
[t,info] = getLabeledSignal(lss,midx)
```

Description

`[t,info] = getLabeledSignal(lss)` returns a table with all the signals and labeled data in the labeled signal set `lss`.

`[t,info] = getLabeledSignal(lss,midx)` returns a table with the signals specified in `midx`.

Examples

Get Labeled Signal

Load a labeled signal set containing recordings of whale songs.

```
load whales
lss
```

```
lss =
  labeledSignalSet with properties:
      Source: {2x1 cell}
    NumMembers: 2
  TimeInformation: "sampleRate"
    SampleRate: 4000
      Labels: [2x3 table]
  Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

Get a table with all the signals in `lss`.

```
t = getLabeledSignal(lss)
```

```
t=2x4 table
```

	Signal	WhaleType	MoanRegions	TrillRegions
Member{1}	{79572x1 double}	blue	{3x2 table}	{1x3 table}
Member{2}	{76579x1 double}	blue	{3x2 table}	{1x3 table}

Identify the sublabels of the trill regions.

```
d = getLabelNames(lss, 'TrillRegions')
```

```
d =
"TrillPeaks"
```

Get the labeled signal corresponding to the second member of the set.

```
[lbs,info] = getLabeledSignal(lss,2)
```

```
lbs=1x4 table
```

	Signal	WhaleType	MoanRegions	TrillRegions
Member{2}	{76579x1 double}	blue	{3x2 table}	{1x3 table}

```
info = struct with fields:
    TimeInformation: "sampleRate"
    SampleRate: 4000
```

Extract the signal. Determine its sample rate and use the sample rate to compute the time vector.

```
fs = info.SampleRate;
sg = getSignal(lss,2);
t = (0:length(sg)-1)/fs;
```

Identify the moan and trill regions of interest and the peaks of the trill region.

```
mvals = getLabelValues(lss,2, 'MoanRegions');
tvals = getLabelValues(lss,2, 'TrillRegions');

peaks = getLabelValues(lss,2, {'TrillRegions', 'TrillPeaks'});
```

Plot the signal. Highlight the regions of interest and the peaks.

```
plot(t,sg)

hold on
[X,Y] = meshgrid([mvals.ROIlimits;tvals.ROIlimits],ylim);
plot(X,Y,':k')
topts = {'HorizontalAlignment','center','FontWeight','bold', ...
        'FontSize',12,'Color',[139 69 19]/255};
text((X(1,1:4)+X(1,5:end))/2,Y(2,5:end)-0.1, ...
     ["moan" "moan" "moan" "trill"],topts{:})
hold off
```

Input Arguments

lss — Labeled signal set

labeledSignalSet object

Labeled signal set, specified as a labeledSignalSet object.

Example: `labeledSignalSet({randn(100,1),randn(10,1)},signalLabelDefinition('female'))` specifies a two-member set of random signals containing the attribute 'female'.

midx — Member row number

positive integer

Member row number, specified as a positive integer. `midx` specifies the member row number as it appears in the “Labels” on page 1-0 table of a labeled signal set.

Output Arguments

t — Labeled signal

table

Labeled signal, specified as a table.

info – Time information

structure

Time information, returned as a structure.

See Also

labeledSignalSet | signalLabelDefinition

Introduced in R2018b

getLabelNames

Get label names in labeled signal set

Syntax

```
lblnames = getLabelNames(lss)
sublblnames = getLabelNames(lss, lblname)
```

Description

`lblnames = getLabelNames(lss)` returns a string array containing the label names in the labeled signal set `lss`.

`sublblnames = getLabelNames(lss, lblname)` returns a string array containing the sublabel names for the label named `lblname` in the labeled signal set `lss`.

Examples

Get Label Names

Load a labeled signal set containing recordings of whale songs.

```
load whales
lss

lss =
    labeledSignalSet with properties:
        Source: {2x1 cell}
        NumMembers: 2
        TimeInformation: "sampleRate"
        SampleRate: 4000
        Labels: [2x3 table]
        Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

Get the names of the labels in the set.

```
str = getLabelNames(lss)

str = 3x1 string
    "WhaleType"
    "MoanRegions"
    "TrillRegions"
```

Verify that only the 'TrillRegions' label has sublabels.

```
for kj = 1:length(str)
    sbstr = str{kj};
    sbl = [sbstr getLabelNames(lss,sbstr)]
end

sbl =
'WhaleType'

sbl =
'MoanRegions'

sbl = 1x2 string
    "TrillRegions"    "TrillPeaks"
```

Input Arguments

lss — Labeled signal set

labeledSignalSet object

Labeled signal set, specified as a labeledSignalSet object.

Example: `labeledSignalSet({randn(100,1) randn(10,1)}, signalLabelDefinition('female'))` specifies a two-member set of random signals containing the attribute 'female'.

lblname — Label name

character vector | string scalar

Label name, specified as a character vector or a string scalar.

Example: `signalLabelDefinition("Asleep", 'LabelType', 'roi')` specifies a label of name "Asleep" for a region of a signal in which a patient is asleep during a clinical trial.

Output Arguments

lblnames — Label names

string array

Label names, returned as a string array.

sublblnames — Sublabel names

string array

Sublabel names, returned as a string array.

See Also

labeledSignalSet | signalLabelDefinition

Introduced in R2018b

getLabelValues

Get label values from labeled signal set

Syntax

```
val = getLabelValues(lss)
val = getLabelValues(lss,midx)

[val,sublbltbl] = getLabelValues(lss,midx,lblname)

[ ___ ] = getLabelValues( ___, 'LabelRowIndex', ridx)
[ ___ ] = getLabelValues( ___, 'SublabelRowIndex', sridx)
```

Description

`val = getLabelValues(lss)` returns a table containing the label values for all members of the labeled signal set `lss`.

`val = getLabelValues(lss,midx)` returns a table containing the label values for the member specified by `midx`.

`[val,sublbltbl] = getLabelValues(lss,midx,lblname)` returns the value of the label named `lblname`. If `lblname` has sublabels, then the table `sublbltbl` shows the structure of the label value and its sublabel variables.

`[___] = getLabelValues(___, 'LabelRowIndex', ridx)` specifies the row index, `ridx`, of an ROI or point label whose value you want to get.

`[___] = getLabelValues(___, 'SublabelRowIndex', sridx)` specifies the row index, `sridx`, of an ROI or point sublabel whose value you want to get.

Examples

Get Label Values

Load a labeled signal set containing recordings of whale songs.

```
load whales
lss

lss =
    labeledSignalSet with properties:

        Source: {2x1 cell}
        NumMembers: 2
        TimeInformation: "sampleRate"
        SampleRate: 4000
        Labels: [2x3 table]
        Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

Get the values of the labels.

```
lbls = getLabelValues(lss)
```

```
lbls=2×3 table
           WhaleType  MoanRegions  TrillRegions
Member{1}    blue    {3×2 table}  {1×3 table}
Member{2}    blue    {3×2 table}  {1×3 table}
```

Display the moan ROI limits for the second signal of the set.

```
lbb = getLabelValues(lss,2,'MoanRegions')
```

```
lbb=3×2 table
   ROIlimits  Value
   _____  _____
   2.5      3.5    {[1]}
   5.8      8      {[1]}
  15.4     16.7    {[1]}
```

Plot the trill region of the signal between the ROI limits. Display the labeled trill peaks.

```
tvals = getLabelValues(lss,2,'TrillRegions');
peaks = getLabelValues(lss,2,{'TrillRegions','TrillPeaks'});

sg = getSignal(lss,2);
plot((0:length(sg)-1)/lss.SampleRate,sg)
xlim(tvals.ROIlimits)
hold on
plot(peaks.Location,cell2mat(peaks.Value),'v')
hold off
```

Display the coordinates of the third trill peak.

```
pcoor = getLabelValues(lss,2,{'TrillRegions','TrillPeaks'}, ...
    'LabelRowIndex',1,'SubLabelRowIndex',3)
```

```
pcoor=1x2 table
  Location      Value
  _____  _____
      11.437    {[0.1500]}
```

Input Arguments

lss — Labeled signal set

labeledSignalSet object

Labeled signal set, specified as a labeledSignalSet object.

Example: `labeledSignalSet({randn(100,1) randn(10,1)},signalLabelDefinition('female'))` specifies a two-member set of random signals containing the attribute 'female'.

midx — Member row number

positive integer

Member row number, specified as a positive integer. `midx` specifies the member row number as it appears in the “Labels” on page 1-0 table of a labeled signal set.

lblname — Label or sublabel name

character vector | string scalar | cell array of character vectors | string array

Label or sublabel name. To specify a label, use a character vector or a string scalar. To specify a sublabel, use a two-element cell array of character vectors or a two-element string array:

- The first element is the name of the parent label.
- The second element is the name of the sublabel.

Example: `signalLabelDefinition("Asleep", 'LabelType', 'roi')` specifies a label of name "Asleep" for a region of a signal in which a patient is asleep during a clinical trial.

Example: `{'Asleep' 'REM'}` or `["Asleep" "REM"]` specifies a region of a signal in which a patient undergoes REM sleep.

ridx — Label row index

positive integer

Label row index, specified as a positive integer. This argument applies only for ROI and point labels.

sridx — Sublabel row index

positive integer

Sublabel row index, specified as a positive integer. This argument applies only when a label and sublabel pair has been specified in `lblname` and the sublabel is of type ROI or point.

Output Arguments

val — Label values

table

Label values, returned as a table.

sublbltbl — Sublabel values

table

Sublabel values, returned as a table showing the structure of the label value and its sublabel variables.

- If `lblname` has no sublabels, then `sublbltbl` is empty.
- If you specify `lblname` as a string or cell array, then `sublbltbl` is empty.

See Also

`labeledSignalSet` | `signalLabelDefinition`

Introduced in R2018b

getMemberNames

Get member names in labeled signal set

Syntax

```
mnames = getMemberNames(lss)
```

Description

`mnames = getMemberNames(lss)` returns a string array containing the member names in the order in which they are stored in the labeled signal set `lss`.

Examples

Get Member Names

Load a labeled signal set containing recordings of whale songs.

```
load whales
lss

lss =
  labeledSignalSet with properties:
      Source: {2x1 cell}
      NumMembers: 2
      TimeInformation: "sampleRate"
      SampleRate: 4000
      Labels: [2x3 table]
      Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

Return a string array with the names of the members.

```
getMemberNames(lss)
```

```
ans = 2x1 string
    "Member{1}"
    "Member{2}"
```

Set the names of the set members to the whales' nicknames.

```
setMemberNames(lss, {'Brutus' 'Lucy'})
```

Verify that the members have the nicknames as names.

```
getMemberNames(lss)
```

```
ans = 2x1 string  
    "Brutus"  
    "Lucy"
```

Input Arguments

lss — Labeled signal set

labeledSignalSet object

Labeled signal set, specified as a labeledSignalSet object.

Example: `labeledSignalSet({randn(100,1)
randn(10,1)}, signalLabelDefinition('female'))` specifies a two-member set of random signals containing the attribute 'female'.

Output Arguments

mnames — Member names

string array

Member names, returned as a string array.

See Also

labeledSignalSet | signalLabelDefinition

Introduced in R2018b

getSignal

Get signals from labeled signal set

Syntax

```
[s,info] = getSignal(lss,midx)
```

Description

`[s,info] = getSignal(lss,midx)` returns the values for the signals contained in member `midx` of the labeled signal set `lss`.

Examples

Get Signal

Load a labeled signal set containing recordings of whale songs.

```
load whales
lss

lss =
    labeledSignalSet with properties:
        Source: {2x1 cell}
        NumMembers: 2
        TimeInformation: "sampleRate"
        SampleRate: 4000
        Labels: [2x3 table]
        Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

Retrieve the second member of the set and plot it.

```
[song,tinfo] = getSignal(lss,2);
t = (0:length(song)-1)/tinfo.SampleRate;
plot(t,song)
```

Input Arguments

lss — Labeled signal set

labeledSignalSet object

Labeled signal set, specified as a labeledSignalSet object.

Example: `labeledSignalSet({randn(100,1)
randn(10,1)},signalLabelDefinition('female'))` specifies a two-member set of random signals containing the attribute 'female'.

midx — Member row number

positive integer

Member row number, specified as a positive integer. `midx` specifies the member row number as it appears in the “Labels” on page 1-0 table of a labeled signal set.

Output Arguments

s — Signal values

vector | matrix | timetable | cell array

Signal values, returned as vector, matrix, timetable, or cell array.

info – Time information

structure

Time information, returned as a structure.

See Also

labeledSignalSet | signalLabelDefinition

Introduced in R2018b

haart

Haar 1-D wavelet transform

Syntax

```
[a,d] = haart(x)
[a,d] = haart(x,level)
[a,d] = haart( ____,integerflag)
```

Description

`[a,d] = haart(x)` returns the approximation coefficients, `a`, and detail coefficients, `d`, of a 1-D Haar discrete wavelet transform. The input `x` can be univariate or multivariate data. The default `level` depends on the length of `x`.

`[a,d] = haart(x,level)` obtains the Haar transform down to the specified level.

`[a,d] = haart(____,integerflag)` specifies how the Haar transform handles integer-valued data, using any of the previous syntaxes.

Examples

Haar Transform of ECG Data

Obtain the Haar transform down to the default maximum level.

```
load wecg;
[a,d] = haart(wecg);
```

Haar Transform of Electricity Consumption Data Down to Specified Level

Obtain the Haar transform of a multivariate time series dataset of electricity consumption data down to level 4. The `signals` data is transposed so that each time series is in a column, rather than a row.

```
load elec35_nor;
signals = signals';
[a,d] = haart(signals,4);
```

Haar Transform of Integer Data Series

Obtain the Haar transform and inverse Haar transform of ECG heart rate data. The data is made up of integers only.

Load and plot the ECG data.

```
load BabyECGData;
plot(times,HR)
xlabel('Hours')
ylabel('Heart Rate')
title('ECG Data')
```

Obtain the Haar transform. Then, obtain the inverse Haar transform approximated at level 5. The scale for this level is 512 seconds, which is 2^5 times the sampling interval (16 seconds).

```
[a,d] = haart(HR,'integer');
HaarHR = ihaart(a,d,5,'integer');
```

Compare the reconstructed data to the original data.

```
figure;
plot(times,HaarHR)
xlabel('Hours')
ylabel('Heart Rate')
title('Haar Approximation of Heart Rate')
```

Input Arguments

x – Input signal

vector of real values | matrix of real values

Input signal, specified as vector or matrix of real values. If x is a vector, it must be even length. If x is a matrix, each column must be even length, and `haart` operates on each column of x .

Data Types: `double`

level – Maximum level

positive integer

Maximum level to which to perform the Haar transform, specified as a positive integer. The default value depends on the length of the input signal, x .

- If the length of x is a power of two, the Haar transform is obtained down to level $\log_2(\text{length}(x))$.
- If the length of x is even, but not a power of two, the Haar transform is obtained down to level $\text{floor}(\log_2(\text{length}(x)/2))$.

If `level` is 1, the detail coefficients, d , are returned as a vector or matrix, depending on whether the input is a vector or matrix, respectively.

integerflag — Integer-valued data handling

'noninteger' (default) | 'integer'

Integer-valued data handling, specified as either 'noninteger' or 'integer'. 'noninteger' does not preserve integer-valued data in the Haar transform, and 'integer' preserves it. The 'integer' option applies only if all elements of the input, x , are integers. For integer-valued input, haart returns integer-valued wavelet coefficients. For both 'noninteger' and 'integer', however, the Haar transform algorithm uses floating-point arithmetic. The data type of outputs a and d , is always double.

Output Arguments**a — Approximation coefficients**

scalar | vector | matrix

Approximation coefficients, returned as a scalar, vector, or matrix of coefficients, depending on the level to which the transform is calculated. Approximation, or scaling, coefficients are a lowpass representation of the input. At each level, the approximation coefficients are divided into coarser approximation and detail coefficients.

Data Types: double

d — Detail coefficients

scalar | vector | matrix | cell array

Detail coefficients, returned as a scalar, vector, matrix, or cell array. Detail coefficients are generally referred to as wavelet coefficients. The number of detail coefficients depends on the selected level and the length of the input. If d is a cell array, the elements of d are ordered from finest to coarsest resolution.

Note: Generated C and C++ code always returns the wavelet coefficients d in a cell array.

Data Types: double

Topics

“Haar Transforms for Time Series Data and Images”

Introduced in R2016b

haart2

2-D Haar wavelet transform

Syntax

```
[a,h,v,d] = haart2(x)
[a,h,v,d] = haart2(x,level)
[a,h,v,d] = haart2( ____,integerflag)
```

Description

`[a,h,v,d] = haart2(x)` performs the 2-D Haar discrete wavelet transform (DWT) of the matrix, `x`. `haart2` returns the approximation coefficients, `a`, at the coarsest level. `haart2` also returns cell arrays of matrices containing the horizontal, vertical, and diagonal detail coefficients by level. If the 2-D Haar transform is computed only at one level coarser in resolution, then `h`, `v`, and `d` are matrices. The default `level` depends on the number of rows of `x`.

`[a,h,v,d] = haart2(x,level)` performs the 2-D Haar transform down to the specified level.

`[a,h,v,d] = haart2(____,integerflag)` specifies how the 2-D Haar transform handles integer-valued data, using any of the previous syntaxes.

Examples

Haar Transform and First Level Details of 2-D Data

Obtain the 2-D Haar transform of 2-D data and plot its diagonal and horizontal level 1 details.

```
load xbox;
[a,h,v,d] = haart2(xbox);
imagesc(xbox)
title('Original Image')
```

```
figure
subplot(2,1,1)
imagesc(d{1})
title('Diagonal Level 1 Details')
subplot(2,1,2)
imagesc(h{1})
title('Horizontal Level 1 Details')
```

Haar Transform of Image Down to a Specified Level

Show the effect of limiting the maximum level of the 2-D Haar transform on an image.

Load and display the image of a cameraman.

```
im = imread('cameraman.tif');  
imagesc(im)
```

Obtain the 2-D Haar transform to level 2 and view the level 2 approximation.

```
[a2,h2,v2,d2] = haart2(im,2);  
imagesc(a2)
```

Haar Transform Using Integer Image Data

Compare 2-D Haar transform results using the default 'noninteger' flag and the 'integer' flag. The cameraman image is uint8 data, so its maximum value is 255.

Obtain the default Haar transform. The approximation detail coefficient is outside the range 0 to 255.

```
im = imread('cameraman.tif');  
[a,h,v,d] = haart2(im);  
a
```

```
a = 3.0393e+04
```

Obtain the Haar transform, limiting it to integer values. The approximation detail is an integer and is within the range of the original image data.

```
[a,h,v,d] = haart2(im,'integer');  
a
```

```
a = 119
```

Input Arguments

x — Input signal

matrix of real values

Input signal, specified as a 2-D or 3-D matrix of real values. If x is 3-D, the third dimension of x must equal 3. The row and column sizes of x must be even length.

Data Types: `double`

level — Maximum level

positive integer

Maximum level to which to perform the 2-D Haar transform, specified as a positive integer. The default value depends on the length of the input signal, x .

- If both the row and column sizes of x are powers of two, the 2-D Haar transform is obtained down to `level` $\log_2(\min(\text{size}(x)))$.
- If both the row and column sizes of x are even, but at least one is not a power of two, `level` is equal to `floor(log2(min(size(x)/2))`.

If `level` is greater than 1, then h , v , and d are cell arrays. If `level` is equal to 1, then h , v , and d are matrices.

integerflag — Integer-valued data handling

'noninteger' (default) | 'integer'

Integer-valued data handling, specified as either 'noninteger' or 'integer'. 'noninteger' does not preserve integer-valued data in the 2-D Haar transform, and 'integer' preserves it. The 'integer' option applies only if all elements of the input, x , are integers. For integer-valued input, `haart2` returns integer-valued wavelet coefficients. For both 'noninteger' and 'integer', however, the 2-D Haar transform algorithm uses floating-point arithmetic. The data type of outputs a , h , v , and d , is always `double`.

Output Arguments

a — Approximation coefficients

scalar | matrix

Approximation coefficients, returned as a scalar or matrix of coefficients, depending on the level to which the transform is calculated. Approximation, or scaling, coefficients are a lowpass representation of the input. At each level, the approximation coefficients are divided into coarser approximation and detail coefficients.

Data Types: `double`

h — Horizontal detail coefficients

matrix | cell array

Horizontal detail coefficients by level, returned as a matrix or cell array of matrices. If `level` is greater than 1, h is a cell array. If `level` is equal to 1, the 2-D Haar transform is computed at only one level coarser in resolution and h is a matrix.

Note: Generated C and C++ code always returns the horizontal detail coefficients h in a cell array.

Data Types: `double`

v – Vertical detail coefficients

`matrix` | `cell array`

Vertical detail coefficients by level, returned as a matrix or cell array of matrices. If `level` is greater than 1, `v` is a cell array. If `level` is equal to 1, the 2-D Haar transform is computed at only one level coarser in resolution and `v` is a matrix.

Note: Generated C and C++ code always returns the vertical detail coefficients `v` in a cell array.

Data Types: `double`

d – Diagonal detail coefficients

`matrix` | `cell array`

Diagonal detail coefficients by level, returned as a matrix or cell array of matrices. If `level` is greater than 1, `d` is a cell array. If `level` is equal to 1, the 2-D Haar transform is computed at only one level coarser in resolution and `d` is a matrix.

Note: Generated C and C++ code always returns the diagonal detail coefficients `d` in a cell array.

Data Types: `double`

“Haar Transforms for Time Series Data and Images”

Introduced in R2016b

head

Get top rows of labels table

Syntax

```
val = head(lss)
```

Description

`val = head(lss)` returns the top rows of the labels table of the labeled signal set `lss`.

Examples

Top Label Values

Load a labeled signal set containing recordings of whale songs.

```
load whales
lss
```

```
lss =
  labeledSignalSet with properties:
      Source: {2x1 cell}
      NumMembers: 2
      TimeInformation: "sampleRate"
      SampleRate: 4000
      Labels: [2x3 table]
      Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

Get the top rows of the labels table.

```
head(lss)
```

```
ans=2x3 table
```

	WhaleType	MoanRegions	TrillRegions
Member{1}	blue	{3x2 table}	{1x3 table}
Member{2}	blue	{3x2 table}	{1x3 table}

Input Arguments

lss — Labeled signal set
labeledSignalSet object

Labeled signal set, specified as a `labeledSignalSet` object.

Example: `labeledSignalSet({randn(100,1)
randn(10,1)}, signalLabelDefinition('female'))` specifies a two-member set of random signals containing the attribute 'female'.

Output Arguments

val — Top rows of labels

table

Top rows of labels, returned as a table.

`labeledSignalSet` | `signalLabelDefinition`

Introduced in R2018b

hht

Hilbert-Huang transform

Syntax

```

hs = hht(imf)
hs = hht(imf,fs)
[hs,f,t] = hht(____)
[hs,f,t,imfinsf,imfinse] = hht(____)
[____] = hht(____,Name,Value)

hht(____)
hht(____,freqlocation)

```

Description

`hs = hht(imf)` returns the Hilbert spectrum `hs` of the signal specified by intrinsic mode functions `imf`. `hs` is useful for analyzing signals that comprise a mixture of signals whose spectral content changes in time. Use `hht` to perform Hilbert spectral analysis on signals to identify localized features.

`hs = hht(imf, fs)` returns the Hilbert spectrum `hs` of a signal sampled at a rate `fs`.

`[hs,f,t] = hht(____)` returns frequency vector `f` and time vector `t` in addition to `hs`. These output arguments can be used with either of the previous input syntaxes.

`[hs,f,t,imfinsf,imfinse] = hht(____)` also returns the instantaneous frequencies `imfinsf` and the instantaneous energies `imfinse` of the intrinsic mode functions for signal diagnostics.

`[____] = hht(____,Name,Value)` estimates Hilbert spectrum parameters with additional options specified by one or more `Name,Value` pair arguments.

`hht(____)` with no output arguments plots the Hilbert spectrum in the current figure window. You can use this syntax with any of the input arguments in previous syntaxes.

`hht(____,freqlocation)` plots the Hilbert spectrum with the optional `freqlocation` argument to specify the location of the frequency axis. Frequency is represented on the *y*-axis by default.

Examples

Hilbert Spectrum of Quadratic Chirp

Generate a Gaussian-modulated quadratic chirp. Specify a sample rate of 2 kHz and a signal duration of 2 seconds.

```

fs = 2000;
t = 0:1/fs:2-1/fs;
q = chirp(t-2,4,1/2,6,'quadratic',100,'convex').*exp(-4*(t-1).^2);
plot(t,q)

```

Use `emd` to visualize the intrinsic mode functions (IMFs) and the residual.

```
emd(q)
```

Compute the IMFs of the signal. Use the 'Display' name-value pair to output a table showing the number of sifting iterations, the relative tolerance, and the sifting stop criterion for each IMF.

```
imf = emd(q, 'Display', 1);
```

Current IMF	#Sift Iter	Relative Tol	Stop Criterion Hit
1	2	0.0063952	SiftMaxRelativeTolerance
2	2	0.1007	SiftMaxRelativeTolerance
3	2	0.01189	SiftMaxRelativeTolerance
4	2	0.0075124	SiftMaxRelativeTolerance

The decomposition stopped because the number of extrema of the residual signal is less than 'Max'

Use the computed IMFs to plot the Hilbert spectrum of the quadratic chirp. Restrict the frequency range from 0 Hz to 20 Hz.

```
hht(imf, fs, 'FrequencyLimits', [0 20])
```

Perform Empirical Mode Decomposition and Visualize Hilbert Spectrum of Signal

Load and visualize a nonstationary continuous signal composed of sinusoidal waves with a distinct change in frequency. The vibration of a jackhammer and the sound of fireworks are examples of nonstationary continuous signals. The signal is sampled at a rate fs .

```
load('sinusoidalSignalExampleData.mat','X','fs')
t = (0:length(X)-1)/fs;
plot(t,X)
xlabel('Time(s)')
```

The mixed signal contains sinusoidal waves with different amplitude and frequency values.

To create the Hilbert spectrum plot, you need the intrinsic mode functions (IMFs) of the signal. Perform empirical mode decomposition to compute the IMFs and residuals of the signal. Since the signal is not smooth, specify 'pchip' as the interpolation method.

```
[imf,residual,info] = emd(X,'Interpolation','pchip');
```

The table generated in the command window indicates the number of sift iterations, the relative tolerance, and the sift stop criterion for each generated IMF. This information is also contained in `info`. You can hide the table by adding the `'Display',0` name value pair.

Create the Hilbert spectrum plot using the `imf` components obtained using empirical mode decomposition.

```
hht(imf,fs)
```

The frequency versus time plot is a sparse plot with a vertical color bar indicating the instantaneous energy at each point in the IMF. The plot represents the instantaneous frequency spectrum of each component decomposed from the original mixed signal. Three IMFs appear in the plot with a distinct change in frequency at 1 second.

Hilbert Spectrum of Whale Song

Load a file that contains audio data from a Pacific blue whale, sampled at 4 kHz. The file is from the library of animal vocalizations maintained by the Cornell University Bioacoustics Research Program. The time scale in the data is compressed by a factor of 10 to raise the pitch and make the calls more audible. Convert the signal to a MATLAB® timetable and plot it. Four features stand out from the noise in the signal. The first is known as a *trill*, and the other three are known as *moans*.

```
[w,fs] = audioread('bluewhale.wav');
whale = timetable(w,'SampleRate',fs);
stackedplot(whale);
```

Use `emd` to visualize the first three intrinsic mode functions (IMFs) and the residual.

```
emd(whale, 'MaxNumIMF', 3)
```

Compute the first three IMFs of the signal. Use the 'Display' name-value pair to output a table showing the number of sifting iterations, the relative tolerance, and the sifting stop criterion for each IMF.

```
imf = emd(whale, 'MaxNumIMF', 3, 'Display', 1);
```

Current IMF	#Sift Iter	Relative Tol	Stop Criterion Hit
1	1	0.13523	SiftMaxRelativeTolerance
2	2	0.030198	SiftMaxRelativeTolerance
3	2	0.01908	SiftMaxRelativeTolerance

The decomposition stopped because 'MaxNumIMF' was reached.

Use the computed IMFs to plot the Hilbert spectrum of the signal. Restrict the frequency range from 0 Hz to 1400 Hz.

```
hht(imf, 'FrequencyLimits', [0 1400])
```

Compute the Hilbert spectrum for the same range of frequencies. Visualize the Hilbert spectra of the trill and moans as a mesh plot.

```
[hs,f,t] = hht(imf,'FrequencyLimits',[0 1400]);
mesh(seconds(t),f,hs,'EdgeColor','none','FaceColor','interp')
xlabel('Time (s)')
ylabel('Frequency (Hz)')
zlabel('Instantaneous Energy')
```

Compute Hilbert Spectrum Parameters of Signal

Load and visualize a nonstationary continuous signal composed of sinusoidal waves with a distinct change in frequency. The vibration of a jackhammer and the sound of fireworks are examples of nonstationary continuous signals. The signal is sampled at a rate f_s .

```
load('sinusoidalSignalExampleData.mat','X','fs')
t = (0:length(X)-1)/fs;
plot(t,X)
xlabel('Time(s)')
```

The mixed signal contains sinusoidal waves with different amplitude and frequency values.

To compute the Hilbert spectrum parameters, you need the IMFs of the signal. Perform empirical mode decomposition to compute the intrinsic mode functions and residuals of the signal. Since the signal is not smooth, specify 'pchip' as the interpolation method.

```
[imf,residual,info] = emd(X,'Interpolation','pchip');
```

The table generated in the command window indicates the number of sift iterations, the relative tolerance, and the sift stop criterion for each generated IMF. This information is also contained in `info`. You can hide the table by specifying 'Display' as 0.

Compute the Hilbert spectrum parameters: Hilbert spectrum `hs`, frequency vector `f`, time vector `t`, instantaneous frequency `imfinsf`, and instantaneous energy `imfinse`.

```
[hs,f,t,imfinsf,imfinse] = hht(imf,fs);
```

Use the computed Hilbert spectrum parameters for time-frequency analysis and signal diagnostics.

VMD of Multicomponent Signal

Generate a multicomponent signal consisting of three sinusoids of frequencies 2 Hz, 10 Hz, and 30 Hz. The sinusoids are sampled at 1 kHz for 2 seconds. Embed the signal in white Gaussian noise of variance 0.01^2 .

```

fs = 1e3;
t = 1:1/fs:2-1/fs;
x = cos(2*pi*2*t) + 2*cos(2*pi*10*t) + 4*cos(2*pi*30*t) + 0.01*randn(1,length(t));

```

Compute the IMFs of the noisy signal and visualize them in a 3-D plot.

```

imf = vmd(x);
[p,q] = ndgrid(t,1:size(imf,2));
plot3(p,q,imf)
grid on
xlabel('Time Values')
ylabel('Mode Number')
zlabel('Mode Amplitude')

```

Use the computed IMFs to plot the Hilbert spectrum of the multicomponent signal. Restrict the frequency range to $[0, 40]$ Hz.

```

hht(imf, fs, 'FrequencyLimits', [0,40])

```

Compute Hilbert Spectrum of Vibration Signal

Simulate a vibration signal from a damaged bearing. Compute the Hilbert spectrum of this signal and look for defects.

A bearing with a pitch diameter of 12 cm has eight rolling elements. Each rolling element has a diameter of 2 cm. The outer race remains stationary as the inner race is driven at 25 cycles per second. An accelerometer samples the bearing vibrations at 10 kHz.

```
fs = 10000;  
f0 = 25;  
n = 8;  
d = 0.02;  
p = 0.12;
```

The vibration signal from the healthy bearing includes several orders of the driving frequency.

```
t = 0:1/fs:10-1/fs;
yHealthy = [1 0.5 0.2 0.1 0.05]*sin(2*pi*f0*[1 2 3 4 5]' .*t)/5;
```

A resonance is excited in the bearing vibration halfway through the measurement process.

```
yHealthy = (1+1./(1+linspace(-10,10,length(yHealthy)).^4)).*yHealthy;
```

The resonance introduces a defect in the outer race of the bearing that results in progressive wear. The defect causes a series of impacts that recur at the ball pass frequency outer race (BPFO) of the bearing:

$$\text{BPFO} = \frac{1}{2}nf_0\left[1 - \frac{d}{p}\cos\theta\right],$$

where f_0 is the driving rate, n is the number of rolling elements, d is the diameter of the rolling elements, p is the pitch diameter of the bearing, and θ is the bearing contact angle. Assume a contact angle of 15° and compute the BPFO.

```
ca = 15;
bpfo = n*f0/2*(1-d/p*cosd(ca));
```

Use the `pulstran` function to model the impacts as a periodic train of 5-millisecond sinusoids. Each 3 kHz sinusoid is windowed by a flat top window. Use a power law to introduce progressive wear in the bearing vibration signal.

```
fImpact = 3000;
tImpact = 0:1/fs:5e-3-1/fs;
```

```

wImpact = flattopwin(length(tImpact))'/10;
xImpact = sin(2*pi*fImpact*tImpact).*wImpact;

tx = 0:1/bpfo:t(end);
tx = [tx; 1.3.^tx-2];

nWear = 49000;
nSamples = 100000;
yImpact = pulstran(t,tx',xImpact,fs)/5;
yImpact = [zeros(1,nWear) yImpact(1,(nWear+1):nSamples)];

```

Generate the BPF0 vibration signal by adding the impacts to the healthy bearing signal. Plot the signal and select a 0.3-second interval starting at 5.0 seconds.

```

yBPF0 = yImpact + yHealthy;

xLimLeft = 5.0;
xLimRight = 5.3;
yMin = -0.6;
yMax = 0.6;

plot(t,yBPF0)

hold on
[limLeft,limRight] = meshgrid([xLimLeft xLimRight],[yMin yMax]);
plot(limLeft,limRight,'--')
hold off

```

Zoom in on the selected interval to visualize the effect of the impacts.

```
xlim([xLimLeft xLimRight])
```

Add white Gaussian noise to the signals. Specify a noise variance of $1/150^2$.

```
rn = 150;  
yGood = yHealthy + randn(size(yHealthy))/rn;  
yBad = yBPF0 + randn(size(yHealthy))/rn;
```

```
plot(t,yGood,t,yBad)  
xlim([xLimLeft xLimRight])  
legend('Healthy','Damaged')
```

Use `emd` to perform an empirical mode decomposition of the healthy bearing signal. Compute the first five intrinsic mode functions (IMFs). Use the `'Display'` name-value pair to output a table showing the number of sifting iterations, the relative tolerance, and the sifting stop criterion for each IMF.

```
imfGood = emd(yGood, 'MaxNumIMF', 5, 'Display', 1);
```

Current IMF	#Sift Iter	Relative Tol	Stop Criterion Hit
1	3	0.01727	SiftMaxRelativeTolerance
2	3	0.059819	SiftMaxRelativeTolerance
3	4	0.14846	SiftMaxRelativeTolerance
4	1	0.020337	SiftMaxRelativeTolerance
5	2	0.023529	SiftMaxRelativeTolerance

The decomposition stopped because `'MaxNumIMF'` was reached.

Use `emd` without output arguments to visualize the first three modes and the residual.

```
emd(yGood, 'MaxNumIMF', 5)
```

Compute and visualize the IMFs of the defective bearing signal. The first empirical mode reveals the high-frequency impacts. This high-frequency mode increases in energy as the wear progresses.

```
imfBad = emd(yBad, 'MaxNumIMF', 5, 'Display', 1);
```

Current IMF	#Sift Iter	Relative Tol	Stop Criterion Hit
1	2	0.038341	SiftMaxRelativeTolerance
2	3	0.085968	SiftMaxRelativeTolerance
3	6	0.17468	SiftMaxRelativeTolerance
4	1	0.01543	SiftMaxRelativeTolerance
5	2	0.025733	SiftMaxRelativeTolerance

The decomposition stopped because 'MaxNumIMF' was reached.

```
emd(yBad, 'MaxNumIMF', 5)
```

Plot the Hilbert spectrum of the first empirical mode of the defective bearing signal. The first mode captures the effect of high-frequency impacts. The energy of the impacts increases as the bearing wear progresses.

```
figure  
hht(imfBad(:,1),fs)
```

The Hilbert spectrum of the third mode shows the resonance in the vibration signal. Restrict the frequency range from 0 Hz to 100 Hz.

```
hht(imfBad(:,3),fs,'FrequencyLimits',[0 100])
```

For comparison, plot the Hilbert spectra of the first and third modes of the healthy bearing signal.

```
subplot(2,1,1)
hht(imfGood(:,1),fs)
subplot(2,1,2)
hht(imfGood(:,3),fs,'FrequencyLimits',[0 100])
```

Input Arguments

imf — Intrinsic mode function

matrix | timetable

Intrinsic mode function, specified as a matrix or timetable. **imf** is any signal whose envelope is symmetric with respect to zero and whose numbers of extrema and zero crossings differ by at most one. **emd** is used to decompose and simplify complicated signals into a finite number of intrinsic mode functions required to perform Hilbert spectral analysis.

hht treats each column in **imf** as an intrinsic mode function. For more information on computing **imf**, see **emd**.

fs — Sample Rate

2π (default) | positive scalar

Sample rate, specified as a positive scalar. If **fs** is not supplied, a normalized frequency of 2π is used to compute the Hilbert spectrum. If **imf** is specified as a timetable, the sample rate is inferred from it.

freqlocation — Location of frequency axis on plot

'yaxis' (default) | 'xaxis'

Location of frequency axis on the plot, specified as 'yaxis' or 'xaxis'. To display frequency data on the y-axis or x-axis of the plot, specify **freqlocation** as 'yaxis' or 'xaxis' respectively.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'FrequencyResolution', 1`

FrequencyLimits — Frequency limits to compute Hilbert spectrum

`[0, fs/2]` (default) | 1-by-2 integer-valued vector

Frequency limits to compute Hilbert spectrum, specified as the comma-separated pair consisting of `'FrequencyLimits'` and a 1-by-2 integer-valued vector. `FrequencyLimits` is specified in Hz.

FrequencyResolution — Frequency resolution to discretize frequency range

`(f_high-f_low)/100` (default) | positive scalar

Frequency resolution to discretize frequency limits, specified as the comma-separated pair consisting of `'FrequencyResolution'` and a positive scalar.

Specify `FrequencyResolution` in Hz. If `'FrequencyResolution'` is not specified, a value of $(f_{high} - f_{low})/100$ is inferred from `FrequencyLimits`. Here, f_{high} is the upper limit of `FrequencyLimits` and f_{low} is the lower limit.

MinThreshold — Minimum threshold value of Hilbert spectrum

`-inf` (default) | scalar

Minimum threshold value of Hilbert spectrum, specified as the comma-separated pair consisting of `'MinThreshold'` and a scalar.

`MinThreshold` sets elements of `hs` to 0 when the corresponding elements of $10\log_{10}(hs)$ are less than `MinThreshold`.

Output Arguments

hs — Hilbert spectrum of signal

sparse matrix

Hilbert spectrum of the signal, returned as a sparse matrix. Use `hs` for time-frequency analysis and to identify localized features in the signal.

f — Frequency values

vector

Frequency values of the signal, returned as a vector. `hht` uses the frequency vector `f` and the time vector `t` to create the Hilbert spectrum plot.

Mathematically, `f` is denoted as: $f = f_{low} : f_{res} : f_{high}$, where f_{res} is the frequency resolution.

t — Time values

vector | duration array

Time values of the signal, returned as a vector or a duration array. `hht` uses the time vector `t` and the frequency vector `f` to create the Hilbert spectrum plot.

`t` is returned as:

- An array, if `imf` is specified as an array.
- A duration array, if `imf` is specified as a uniformly sampled timetable.

imfinsf — Instantaneous frequency of each IMF

vector | matrix | timetable

Instantaneous frequency of each IMF, returned as a vector, a matrix, or a timetable.

`imfinsf` has the same number of columns as `imf` and is returned as:

- A vector, if `imf` is specified as a vector.
- A matrix, if `imf` is specified as a matrix.
- A timetable, if `imf` is specified as a uniformly sampled timetable.

imfinse — Instantaneous energy of each IMF

vector | matrix | timetable

Instantaneous energy of each IMF, returned as a vector, a matrix, or a timetable.

`imfinse` has the same number of columns as `imf` and is returned as:

- A vector, if `imf` is specified as a vector.
- A matrix, if `imf` is specified as a matrix.
- A timetable, if `imf` is specified as a uniformly sampled timetable.

Algorithms

The Hilbert-Huang transform is useful for performing time-frequency analysis of nonstationary and nonlinear data. The Hilbert-Huang procedure consists of the following steps:

- 1 `emd` decomposes the data set x into a finite number of intrinsic mode functions.
- 2 For each intrinsic mode function, x_i , the function `hht`:
 - a Uses `hilbert` to compute the analytic signal, $z_i(t) = x_i(t) + jH\{x_i(t)\}$, where $H\{x_i\}$ is the Hilbert transform of x_i .
 - b Expresses z_i as $z_i(t) = a_i(t) e^{j\theta_i(t)}$, where $a_i(t)$ is the instantaneous amplitude and $\theta_i(t)$ is the instantaneous phase.
 - c Computes the instantaneous energy, $|a_i(t)|^2$, and the instantaneous frequency, $\omega_i(t) \equiv d\theta_i(t)/dt$. If given a sample rate, `hht` converts $\omega_i(t)$ to a frequency in Hz.
 - d Outputs the instantaneous energy in `imfinse` and the instantaneous frequency in `imfinsf`.
- 3 When called with no output arguments, `hht` plots the energy of the signal as a function of time and frequency, with color proportional to amplitude.

Introduced in R2018a

icqt

Inverse constant-Q transform using nonstationary Gabor frames

Syntax

```
xrec = icqt(cfs,g,fshifts)
xrec = icqt( ___, 'SignalType', sigtype)
[xrec,gdual] = icqt( ___)
```

Description

`xrec = icqt(cfs,g,fshifts)` returns the inverse constant-Q transform, `xrec`, of the coefficients `cfs`. `cfs` is a matrix, cell array, or structure array. `g` is the cell array of nonstationary Gabor constant-Q analysis filters used to obtain the coefficients `cfs`. `fshifts` is a vector of frequency bin shifts for the constant-Q bandpass filters in `g`. `icqt` assumes by default that the original signal was real-valued. To indicate the original input signal was complex-valued, use the 'SignalType' name-value pair. If the input to `cqt` was a single signal, then `xrec` is a vector. If the input to `cqt` was a multichannel signal, then `xrec` is a matrix. `cfs`, `g`, and `fshifts` must be outputs of `cqt`.

`xrec = icqt(___, 'SignalType', sigtype)` designates whether the signal was real-valued or complex-valued. Valid options for `sigtype` are 'real' or 'complex'. If unspecified, `sigtype` defaults to 'real'.

`[xrec,gdual] = icqt(___)` returns the dual frames of `xrec` as a cell array the same size as `g`. The dual frames are the canonical dual frames derived from the analysis filters.

Examples

Perfect Reconstruction of Constant-Q Transform

Load and plot the Handel signal.

```
load handel
t = (0:length(y)-1)/Fs;
plot(t,y)
title('Handel')
xlabel('Time (s)')
```

Obtain the constant-Q transform of the signal using the `sparse` transform option. Because the transform will be inverted, you must also return the Gabor frames and frequency shifts used in the analysis.

```
[cfs,~,g,fshifts] = cqt(y,'SamplingFrequency',Fs,'TransformType','sparse');
```

Invert the constant-Q transform and demonstrate perfect reconstruction by showing the maximum absolute reconstruction error and the relative energy error in dB.

```
xrec = icqt(cfs,g,fshifts);
maxAbsError = max(abs(xrec-y))

maxAbsError = 7.6328e-16

relEnergyError = 20*log10(norm(xrec-y)/norm(y))

relEnergyError = -301.4461
```

Input Arguments

cfs — Constant-Q coefficients

matrix | cell array | structure array

Constant-Q coefficients of a signal or multichannel signal, specified as a matrix, cell array, or structure array. `cfs` must be the output of `cqt`.

g — Nonstationary Gabor constant-Q analysis filters

cell array

Nonstationary Gabor constant-Q analysis filters used to obtain the coefficients `cfs`, specified as a cell array. `cfs` must be the output of `cqt`.

fshifts — Frequency bin shifts

real-valued vector

Frequency bin shifts for the constant-Q bandpass filters in `g`, specified as a real-valued vector. `fshifts` must be the output of `cqt`.

sigtype — Signal type

'real' (default) | 'complex'

Signal type of the original signal, specified as 'real' or 'complex'. Use `sigtype` to designate whether the original signal was real-valued or complex-valued. If unspecified, `sigtype` defaults to 'real'.

Output Arguments**xrec — Inverse constant-Q transform**

vector | matrix

Inverse constant-Q transform, returned as a vector or matrix. If the input to `cqt` was a single signal, then `xrec` is a vector. If the input to `cqt` was a multichannel signal, then `xrec` is a matrix.

gdual — Dual frames

cell array

Dual frames used in the synthesis of `xrec`, returned as a cell array the same size as `g`. The dual frames are the canonical dual frames derived from the analysis filters.

Algorithms

The theory of nonstationary Gabor (NSG) frames for frequency-adaptive analysis and efficient algorithms for analysis and synthesis using NSG frames are due to Dörfler, Holighaus, Grill, and Velasco [1],[2]. The algorithms used in `cqt` and `icqt` were developed by Dörfler, Holighaus, Grill, and Velasco and are described in [1],[2]. In [3], Schörkhuber, Klapuri, Holighaus, and Dörfler develop and provide algorithms for a phase-corrected CQT transform which matches the CQT coefficients that would be obtained by naïve convolution. The Large Time-Frequency Analysis Toolbox (<https://github.com/ltfat>) provides an extensive suite of algorithms for nonstationary Gabor frames [4].

Introduced in R2018a

icwt

Inverse continuous 1-D wavelet transform

Syntax

```
xrec = icwt(wt)
xrec = icwt(wt,wname)
xrec = icwt(wt,f,freqrangle)
xrec = icwt(wt,period,periodrange)
xrec = icwt( ____,Name,Value)
```

Description

`xrec = icwt(wt)` inverts the continuous wavelet transform (CWT) coefficient matrix `wt` using default values. `icwt` assumes that you obtained the CWT using `cwt` with the default analytic Morse (3,60) wavelet. This wavelet has a symmetry of 3 and a time bandwidth of 60. `icwt` also assumes that the CWT uses default scales. If `wt` is a 2-D matrix, `icwt` assumes that the CWT was obtained from a real-valued signal. If `wt` is a 3-D matrix, `icwt` assumes that the CWT was obtained from a complex-valued signal. For a 3-D matrix, the first page of the `wt` is the CWT of the positive (counterclockwise) component and the second page of `wt` is the negative (clockwise) component. The pages represent the analytic and anti-analytic parts of the CWT, respectively.

`xrec = icwt(wt,wname)` uses the analytic wavelet `wname` to invert the CWT. The specified wavelet must be the same as the wavelet used in `cwt`. Valid options for `wname` are 'morse', 'amor', and 'bump', which specify the Morse, Morlet, and bump wavelet, respectively.

`xrec = icwt(wt,f,freqrangle)` inverts the CWT over the frequency range specified in `freqrangle`. `f` is the scale-to-frequency conversion obtained from `cwt`.

`xrec = icwt(wt,period,periodrange)` inverts the CWT over the range of periods specified in `periodrange`. `period` is an array of durations obtained from `cwt` with a duration input. The `period` is the `cwt` output obtained using a duration input. The period range must be increasing and contained in `period`.

`xrec = icwt(____,Name,Value)` returns the inverse CWT with additional options specified by one or more `Name,Value` pair arguments.

Examples

Inverse Continuous Wavelet Transform of Speech Signal

Obtain the CWT of a speech sample and invert the CWT using the default analytic Morse wavelet.

```
load mtlb;
wt = cwt(mtlb);
xrec = icwt(wt);
```

Inverse Continuous Wavelet Transform Using Specified Wavelet

Obtain the continuous wavelet transform of a speech sample and reconstruct the sample using the bump wavelet instead of the default Morse wavelet.

```
load mtlb
dt = 1/Fs;
t = 0:dt:numel(mtlb)*dt-dt;
```

Obtain the CWT.

```
bumpmtlb = cwt(mtlb,Fs,'bump');
```

Obtain the inverse CWT. Add the signal mean to the output.

```
xrec = icwt(bumpmtlb,'bump','SignalMean',mean(mtlb));
```

Plot the original and reconstructed signals.

```
plot(t,mtlb)
xlabel('Seconds')
ylabel('Amplitude')
hold on
plot(t,xrec,'r')
legend('Original','Reconstruction')
```

Play and compare the original and reconstructed signals.

```
p = audioplayer(mtlb,Fs);
play(p)
pause(2)
px = audioplayer(xrec,Fs);
play(px)
```

Reconstruct Frequency-Localized Data

Reconstruct a frequency-localized approximation to the Kobe earthquake data by extracting information from the CWT. The extracted information corresponds to frequencies in the range [0.030 0.070] Hz.

```
load kobe;
```

Obtain the CWT. Then, obtain the inverse CWT and add the signal mean back into the reconstructed data. The CWT does not preserve the signal mean.

```
[wt,f] = cwt(kobe,1);
xrec = icwt(wt,f,[0.030 0.070], 'SignalMean',mean(kobe));
```

Plot the original and reconstructed data.

```
subplot(211)
plot(kobe);
grid on
title('Original Data');
ylabel('Amplitude')

subplot(212)
plot(xrec);
grid on
title('Bandpass Filtered Reconstruction [0.030 0.070] Hz');
xlabel('Frequency');
ylabel('Amplitude');
```

Reconstruct Data from Specific Time Period

Use the inverse continuous wavelet transform to reconstruct an approximation to El Nino data based on 2 to 8 year periods.

Load the El Nino data and obtain its CWT. The data is sampled monthly. To obtain the periods in years, specify the sampling interval as 1/12 of a year.

```
load ninoairdata;
[cfs,period] = cwt(nino,years(1/12));
```

Obtain the inverse CWT for periods of 2 to 8 years.

```
xrec = icwt(cfs,period,[years(2) years(8)]);
```

Plot the CWT of the reconstructed data and compare it to the CWT of the original data.

```
cwt(nino,years(1/12)); title('Original Data');
```

```
figure;  
cwt(xrec,years(1/12)); title('Approximation Based on 2-8 Year Periods');
```

Compare the original data with the reconstructed data in time.

```
figure;
subplot(211)
plot(datayear,nino);
grid on;
ax = gca;
ax.XTickLabel = '';
axis tight;
title('Original Data');

subplot(212)
plot(datayear,xrec);
grid on;
axis tight;
xlabel('Year');
title('El Niño Data - 2-8 Year Periods');
```

Reconstruct Complex Data with Time-varying Trend

Add a trend to the continuous wavelet transform of a complex-valued dataset and reconstruct.

Obtain the CWT of the NPG2006 dataset.

```
load npg2006.mat
wt = cwt(npg2006.cx);
```

Create a time-varying trend derived from the data.

```
trend = smoothdata(npg2006.cx, 'movmean', 100);
```

Obtain the inverse CWT and add the trend. Plot the original data and the reconstructed data.

```
xrec = icwt(wt, 'SignalMean', trend);
plot([real(xrec)' real(npg2006.cx)])
grid on
legend('Trend', 'Original')
```

```
figure
plot([imag(xrec)' imag(npg2006.cx)])
grid on
legend('Trend','Original')
```

Input Arguments

wt — Continuous wavelet transform coefficients

matrix

Continuous wavelet transform coefficients, specified as a matrix of complex values. `wt` is the output from the `cwt` function.

Data Types: double

Complex Number Support: Yes

wname — Analytic wavelet

'morse' (default) | 'amor' | 'bump'

Analytic wavelet used to invert the CWT, specified as 'morse', 'amor', or 'bump'. These character vectors specify the analytic Morse, Morlet, and bump wavelet, respectively. The specified wavelet must be the same type of wavelet used to obtain the `cwt`.

The default Morse wavelet uses a default symmetry parameter, γ , that is 3 and has a default time bandwidth of 60.

f — CWT frequencies

vector

CWT frequencies, specified as a vector. The number of elements in the frequency vector must equal to the number of rows in the input CWT coefficient matrix, `wt`. If you specify `f`, you must also specify `freqrange`.

freqrange — Frequency range

two-element vector | 2-by-2 matrix

Frequency range for which to return inverse continuous wavelet transform values, specified as a two-element vector or 2-by-2 matrix. If `wt` is a 2-D matrix, `freqrange` must be a two-element vector. If `wt` is a 3-D matrix, `freqrange` can be a two-element vector or a 2-by-2 matrix. If `wt` is a 3-D matrix and `freqrange` is a vector, inversion is performed over the same frequency range in both the positive (analytic) and negative (anti-analytic) components of `wt`. If `freqrange` is a 2-by-2 matrix, the first row contains the frequency range for the positive part of `wt` (first page) and the second row contains the frequency range for the negative part of `wt` (second page). For a vector, the elements of `freqrange` must be strictly increasing and contained in the range of the frequency vector `f`. For a matrix, each row of `freqrange` must be strictly increasing and contained in the range of `f`. `f` is the scale-to-frequency conversion obtained in CWT. For the inversion of a complex-valued signal, you can specify one row of `freqrange` as a vector of zeros. If the first row of `freqrange` is a vector of zeros, only the negative (anti-analytic part) is used in the inversion. If you specify `freqrange`, you must also specify `f`.

For example `[0 0; 1/10 1/4]` inverts the negative (clockwise) component over the frequency range `[1/10 1/4]`. The positive (counterclockwise) component is first set to all zeros before performing the inversion. Similarly, `[1/10 1/4; 0 0]` inverts the CWT by selecting the frequency range `[1/10 1/4]` from the positive (counterclockwise) component and setting the negative component to all zeros.

period — Time periods

vector

Time periods corresponding to the rows of CWT coefficient matrix `wt`, specified as a vector. `period` is the output of `cwt`, when the CWT is obtained using a `duration` input.

periodrange — Period range

two-element vector | 2-by-2 matrix

Period range for which to return inverse continuous wavelet transform values, specified as a two-element vector or 2-by-2 matrix. If `wt` is a 2-D matrix, `periodrange` must be a two-element vector of durations. If `wt` is a 3-D matrix, `periodrange` can be a two-element vector of durations or 2-by-2 matrix of durations. If `periodrange` is a vector of durations and `wt` is a 3-D matrix, inversion is performed over the same frequency range in both the positive (analytic) and negative (anti-analytic) components of `wt`. If `periodrange` is a 2-by-2 matrix of durations, the first row contains the period range for the positive part of `wt` (first page) and the second row contains the period range for the negative part of `wt` (second page). For a vector, the elements of `periodrange` must be strictly increasing and contained in the range of the period vector `period`. The elements of `periodrange` and `period` must have the same units. For a matrix, each row of `periodrange` must be strictly increasing and contained in the range of the period vector `P`. For the inversion of a complex-valued signal, you can specify one row of `periodrange` as a vector of zero durations. If the first row of `periodrange` is a vector of zero durations, only the negative (anti-analytic part) is used in the inversion. If you specify `periodrange`, you must also specify `period`.

For example `[seconds(0) seconds(0); seconds(1/10) seconds(1/4)]` inverts the negative (clockwise) component over the period range `[seconds(1/10) seconds(1/4)]`. The positive (counterclockwise) component is first set to all zeros before performing the inversion.

Similarly, `[seconds(1/10) seconds(1/4); seconds(0) seconds(0)]` inverts the CWT by selecting the period range `[1/10 1/4]` from the positive (counterclockwise) component and setting the negative component to all zeros.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'TimeBandwidth', 45` sets the time bandwidth to 45.

TimeBandwidth — Time-bandwidth of Morse wavelet

60 (default) | scalar greater than 3 and less than or equal to 120

Time bandwidth of the Morse wavelet, specified as a comma-separated pair consisting of `'TimeBandwidth'` and a scalar greater than 3 and less than or equal to 120. The specified time bandwidth must be the same as the time bandwidth used in the `cwt`. The symmetry of the Morse wavelet is assumed to be 3.

You cannot specify both the `'TimeBandwidth'` and `'WaveletParameters'`. If you specify `'TimeBandwidth'`, you cannot specify `'WaveletParameters'`. To specify both the symmetry and time bandwidth, use `'WaveletParameters'` instead.

WaveletParameters — Symmetry and time bandwidth of Morse wavelet

(3, 60) (default) | two-element vector of scalars

Symmetry and time bandwidth of Morse wavelet, specified as the comma-separated pair consisting of `'WaveletParameters'` and a two-element vector of scalars. The first element of the vector is the symmetry, γ , and the second element is the time-bandwidth. The specified wavelet parameters must be the same as the parameters used in `cwt`.

You cannot specify both `'WaveletParameters'` and `'TimeBandwidth'`. If you specify `'WaveletParameters'`, you cannot specify `'TimeBandwidth'`. To specify the time bandwidth and use the default symmetry value of 3, use `'TimeBandwidth'` instead.

SignalMean — Signal mean

scalar | vector

Signal mean to add to the `icwt` output, specified as the comma-separated pair consisting of `'SignalMean'` and a scalar or vector. If signal mean is a vector, it must be the same length as the column size of the wavelet coefficient matrix. If `wt` is a 2-D matrix, the signal mean must be a real-valued scalar or vector. If `wt` is a 3-D matrix, the signal mean must be a complex-valued scalar or vector. Because `cwt` does not preserve the signal mean, `icwt` does not contain the signal mean by default. Adding a non-zero signal mean to a frequency- or period-limited reconstruction adds a zero-frequency component to the reconstruction.

ScalingCoefficients — Scaling coefficients

real- or complex-valued vector

Scaling coefficients to use in the inverse CWT, specified as a real- or complex-valued vector, obtained as an optional output of `cwt`.

The scaling coefficient output is only supported for Morse wavelets and the analytic Morlet wavelet. The length of `ScalingCoefficients` is equal to the column size of `wt`.

You cannot specify both the 'SignalMean' and 'ScalingCoefficients' name-value pairs.

VoicesPerOctave — Number of voices per octave

10 (default) | even integer from 4 to 48

Number of voices per octave, specified as the comma-separated pair consisting of 'VoicesPerOctave' and an even integer from 4 to 48. The CWT scales are discretized using the specified number of voices per octave. The number of voices per octave must be the same as the number of voices per octave used to obtain the CWT.

You cannot specify the number of voices per octave if you specify either the frequency, *f*, or duration, period.

Output Arguments

xrec — Inverse 1-D continuous wavelet transform

real- or complex-valued row vector

Inverse 1-D continuous wavelet transform, returned as a real- or complex-valued row vector.

Data Types: double

Introduced in R2016b

icwtft

Inverse CWT

Note This function is no longer recommended. Use `icwt` instead.

Syntax

```
xrec = icwtft(cwtstruct)
xrec = icwtft(cwtstruct,'plot')
xrec = icwtft(cwtstruct,'signal',SIG,'plot')
```

Description

`xrec = icwtft(cwtstruct)` returns the inverse continuous wavelet transform of the CWT coefficients contained in the `cfs` field of the structure array `cwtstruct`. Obtain the structure array `cwtstruct` as the output of `cwtft`.

`xrec = icwtft(cwtstruct,'plot')` plots the reconstructed signal.

`xrec = icwtft(cwtstruct,'signal',SIG,'plot')` places a check box in the bottom left corner of the plot. Enabling the check box superimposes the plot of the input signal `SIG` on the plot of the reconstructed signal. By default the check box is not enabled and only the reconstructed signal is plotted.

Input Arguments

`cwtstruct`

Structure array containing six fields.

- `cfs` — CWT coefficient matrix
- `scales` — Vector of scales
- `frequencies` — frequencies in cycles per unit time (or space) corresponding to the scales. If the sampling period units are seconds, the frequencies are in hertz. The elements of `frequencies` are in decreasing order to correspond to the elements in the `scales` vector.
- `omega` — Angular frequencies used in the Fourier transform
- `meanSig` — Mean of the analyzed signal
- `dt` — The sampling period
- `wav` — Analyzing wavelet used in the CWT with parameters specified

`cwtstruct` is the output of `cwtft`.

Output Arguments

xrec

Reconstructed signal

Examples

Compute the CWT and inverse CWT of two sinusoids with disjoint support.

```
N = 1024;
t = linspace(0,1,N);
y = sin(2*pi*8*t).*(t<=0.5)+sin(2*pi*16*t).*(t>0.5);
dt = 0.05;
s0 = 2*dt;
ds = 0.4875;
NbSc = 20;
wname = 'morl';
sig = {y,dt};
sca = {s0,ds,NbSc};
wave = {wname,[]};
cwtSig = cwtft(sig,'scales',sca,'wavelet',wave);

% Compute inverse CWT and plot reconstructed signal with original
sigrec = icwtft(cwtSig,'signal',sig,'plot');
```

Select the check box in the bottom left corner of the plot.

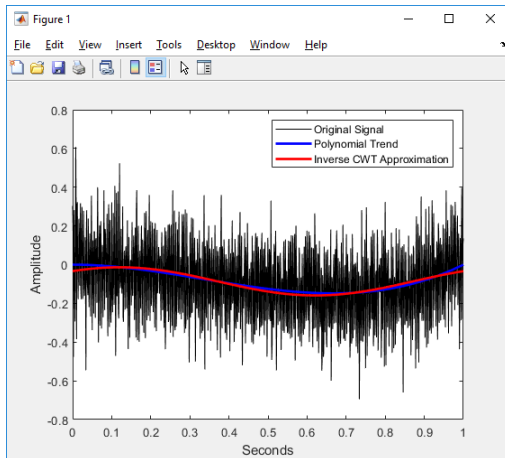

Use the inverse CWT to approximate a trend in a time series. Construct a time series consisting of a polynomial trend, a sinewave (oscillatory component), and additive white Gaussian noise. Obtain the CWT of the input signal and use the inverse CWT based on only the coarsest scales to reconstruct an approximation to the trend. To obtain an accurate approximation based on select scales use the default power of two spacing for the scales in the continuous wavelet transform. See `cwtft` for details.

```
t = linspace(0,1,1e3);
% Polynomial trend
x = t.^3-t.^2;
% Periodic term
x1 = 0.25*cos(2*pi*250*t);
% Reset random number generator for reproducible results
rng default
y = x+x1+0.1*randn(size(t));
% Obtain CWT of input time series
cwt_y = cwtft({y,0.001},'wavelet',{'bump',[4 0.7]});
% Zero out all but the nine coarsest scale CWT coefficients
cwt_y.cfs(1:80,:) = 0;
% Reconstruct a signal approximation based on the coarsest scales
xrec = icwtft(cwt_y);
plot(t,y,'k'); hold on;
xlabel('Seconds'); ylabel('Amplitude');
plot(t,x,'b','linewidth',2);
plot(t,xrec,'r','linewidth',2);
```

```

legend('Original Signal','Polynomial Trend',...
      'Inverse CWT Approximation');
figure
plot(t,x,'b'); hold on;
xlabel('Seconds'); ylabel('Amplitude');
plot(t,xrec,'r','linewidth',2);
legend('Polynomial Trend','Inverse CWT Approximation');

```

You can also use the following syntax to plot the approximation. Select the box to view the original polynomial trend superimposed on the wavelet approximation.

```

% Input the polynomial trend as the value of 'signal'
xrec = icwtft(cwty,'signal',x,'plot');

```

More About

Inverse CWT

`icwtft` computes the inverse CWT based on a discretized version of the single integral formula due to Morlet. The Wavelet Toolbox Getting Started Guide contains a brief description of the theoretical foundation for the single integral formula in “Inverse Continuous Wavelet Transform”. The discretized version of this integral is presented in [5]

“Inverse Continuous Wavelet Transform”

Introduced in R2011a

icwtlin

Inverse continuous wavelet transform (CWT) for linearly spaced scales

Note This function is no longer recommended. Use `icwt` instead.

Syntax

```
xrec = icwtlin(cwtstruct)
xrec = icwtlin(wav,meanSIG,cfs,scales,dt)
xrec = icwtin(...,'plot')
xrec = icwtlin (...,'signal',SIG,'plot')
xrec = icwtlin(...,Name,Value)
```

Description

`xrec = icwtlin(cwtstruct)` returns the inverse continuous wavelet transform (CWT) of the CWT coefficients obtained at linearly spaced scales.

Note To use `icwtlin` you must:

- Use linearly-spaced scales in the CWT. `icwtlin` does not verify that the scales are linearly-spaced.
 - Use one of the supported wavelets. See “Input Arguments” on page 1-521 for a list of supported wavelets.
-

`xrec = icwtlin(wav,meanSIG,cfs,scales,dt)` returns the inverse CWT of the coefficients in `cfs`. The inverse CWT is obtained using the wavelet `wav`, the linearly spaced scales `scales`, the sampling period `dt`, and the mean signal value `meanSig`.

`xrec = icwtin(...,'plot')` plots the reconstructed signal `xrec` along with the CWT coefficients and CWT moduli. If the analyzing wavelet is complex-valued, the plot includes the real and imaginary parts of the CWT coefficients.

`xrec = icwtlin (...,'signal',SIG,'plot')` places a check box in the bottom-left corner of the plot. Enabling the check box superimposes the plot of the input signal `SIG` on the plot of the reconstructed signal. `SIG` can be a structure array, a cell array, or a vector. If `SIG` is a structure array, there must be two fields: `val` and `period`. The `val` field contains the signal and the `period` field contains the sampling period. If `SIG` is a cell array, `SIG{1}` contains the signal and `SIG{2}` is the sampling period.

`xrec = icwtlin(...,Name,Value)` returns the inverse CWT transform with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

cwtstruct

A structure array that is the output of `cwtft` or constructed from the output of `cwt`. If you obtain `cwtstruct` from `cwtft`, the structure array contains seven fields:

- `cfs` — CWT coefficient matrix
- `scales` — Vector of linearly spaced scales. The scale vector must be linearly-spaced to ensure accurate reconstruction. `icwtlin` does not check that the spacing of your scale vector is linear.
- `frequencies` — frequencies in cycles per unit time (or space) corresponding to the scales. If the sampling period units are seconds, the frequencies are in hertz. The elements of `frequencies` are in decreasing order to correspond to the elements in the `scales` vector.
- `omega` — Angular frequencies used in the Fourier transform in radians/sample
- `MeanSIG` — Signal mean
- `dt` — Sampling period in seconds
- `wav` — Analyzing wavelet. `icwtlin` uses this wavelet as the reconstruction wavelet. The supported wavelets are:
 - `'dog'` — An m -th order derivative of Gaussian wavelet where m is a positive even integer. $m = 2$ is the Mexican-hat or Ricker wavelet.
 - `'morl'` — Analytic Morlet wavelet
 - `'morlex'` — Nonanalytic Morlet wavelet
 - `'morl0'` — Nonanalytic Morlet wavelet with exact zero mean
 - `'mexh'` — Mexican-hat wavelet. This argument represents a special case of the derivative of Gaussian wavelet with $m = 2$. This wavelet is also known as the Ricker wavelet.
 - `'paul'` — Paul wavelet
 - `'bump'` — Bump wavelet

If you create `cwtstruct` from the output of `cwt`, `cwtstruct` contains all of the preceding fields except `omega`.

Using `cwt` to obtain the CWT coefficients, the valid analyzing wavelets are:

- Coiflets — `'coif1'`, `'coif2'`, `'coif3'`, `'coif4'`, `'coif5'`
- Biorthogonal wavelets — `'bior2.2'`, `'bior2.4'`, `'bior2.6'`, `'bior2.8'`, `'bior4.4'`, `'bior5.5'`, `'bior6.8'`
- Reverse biorthogonal wavelets — `'rbio2.2'`, `'rbio2.4'`, `'rbio2.6'`, `'rbio2.8'`, `'rbio4.4'`, `'rbio5.5'`, `'rbio6.8'`
- Complex Gaussian wavelets — `'cgau2'`, `'cgau4'`, `'cgau6'`, `'cgau8'`

Name-Value Pair Arguments

IdxSc

Vector of scales to use in the signal reconstruction. Specifying a subset of scales results in a scale-localized approximation of the analyzed signal.

Output Arguments

xrec

Reconstructed signal. Signal approximation based on the input CWT coefficient matrix, analyzing wavelet, selected scales, and sampling period.

The purpose of the CWT inversion algorithm is not to produce a perfect reconstruction of the input signal. The inversion preserves time and scale-localized features in the reconstructed signal. The amplitude scaling in the reconstructed signal, however, can be significantly different. This difference in scaling can occur whether or not you use all the CWT coefficients in the inversion.

Examples

Compute the inverse CWT of a sum of sine waves with disjoint support.

```
% Define the signal
N = 100;
t = linspace(0,1,N);
Y = sin(8*pi*t).*(t<=0.5) + sin(16*pi*t).*(t>0.5) ;

% Define parameters before analysis
dt = 0.001;
maxsca = 1; s0 = 2*dt; ds = 2*dt;
scales = s0:ds:maxsca;
wname = 'morl';
SIG = {Y,dt};
WAV = {wname,[]};

% Compute the CWT using cwtft with linear scales
cwtS = cwtft(SIG,'scales',scales,'wavelet',WAV);
% Compute inverse CWT using linear scales
Yrec = icwtlin(cwtS,'Signal',Y,'plot');
```

Reconstruct an approximation to a noisy Doppler signal based on thresholded coefficients. Use the universal threshold. Assume the sampling period is 0.05 seconds.

```
load noisdopp;
Y = noisdopp;
N = length(Y);

% Define parameters before analysis
% Assume sampling period is 0.05
dt = 0.05;
maxsca = 100; s0 = 2*dt; ds = 4*dt;
scales = s0:ds:maxsca;
wname = 'morl';
SIG = {Y,dt};
WAV = {wname,[]};

% Compute CWT
cwtS = cwtft(SIG,'scales',scales,'wavelet',WAV);

% Select subset of coefficients
cwtS1 = cwtS;
Hfreq = cwtS.cfs(1:10,:);
% Set threshold
thr = sqrt(2*log(N))*median(abs(Hfreq(:)))/0.6745;
newCFS = cwtS.cfs;
% Set coefficients smaller than threshold in absolute value to 0
```

```
newCFS(abs(newCFS)<thr) = 0;
cwtS1.cfs = newCFS;
```

```
% Reconstruction from the modified structure
YRDen = icwtlin(cwtS1,'signal',Y,'plot');
```

Enable the **Reconstructed Signal On/Off** check box in the bottom-left corner.

Algorithms

See [4] for a description of the inverse CWT algorithm for linearly spaced scales. The `icwtlin` function uses heuristic scaling factors for the analyzing wavelets. These scaling factors can result in significant differences in the amplitude scaling of the reconstructed signal.

Alternatives

- `icwtft` — Computes the inverse for the CWT obtained using `cwtft` with logarithmically spaced scales. If you use linearly spaced scales in `cwtft`, or you obtain the CWT with `cwt`, use `icwtlin` to compute the inverse.

idddtree

Inverse dual-tree and double-density 1-D wavelet transform

Syntax

```
xrec = idddtree(wt)
```

Description

`xrec = idddtree(wt)` returns the inverse wavelet transform of the wavelet decomposition (analysis filter bank), `wt`. `wt` is the output of `dddtree`.

Examples

Perfect Reconstruction Using Dual-Tree Double-Density Wavelet Filter Bank

Demonstrate perfect reconstruction of a signal using a dual-tree double-density wavelet transform.

Load the noisy Doppler signal. Obtain the dual-tree double-density wavelet transform down to level 5. Invert the transform and demonstrate perfect reconstruction.

```
load noisdopp;  
wt = dddtree('cplxddd',noisdopp,5,'FSdoubledualfilt',...  
            'doubledualfilt');  
xrec = idddtree(wt);  
max(abs(noisdopp-xrec))  
  
ans = 1.9291e-12
```

Input Arguments

wt — Wavelet transform

structure

Wavelet transform, returned as a structure from `dddtree` with these fields:

type — Type of wavelet decomposition (filter bank)

'dwt' | 'ddt' | 'cplxdt' | 'cplxddd'

Type of wavelet decomposition (filter bank), specified as one of 'dwt', 'ddt', 'cplxdt', or 'cplxddd'. The type, 'dwt', gives a critically sampled discrete wavelet transform. The other types are oversampled wavelet transforms. 'ddt' is a double-density wavelet transform, 'cplxdt' is a dual-tree complex wavelet transform, and 'cplxddd' is a double-density dual-tree complex wavelet transform.

level — Level of wavelet decomposition

positive integer

Level of wavelet decomposition, specified as a positive integer.

filters — Decomposition (analysis) and reconstruction (synthesis) filters

structure

Decomposition (analysis) and reconstruction (synthesis) filters, specified as a structure with these fields:

Fdf — First-stage analysis filters

matrix | cell array

First-stage analysis filters, specified as an N -by-2 or N -by-3 matrix for single-tree wavelet transforms, or a cell array of two N -by-2 or N -by-3 matrices for dual-tree wavelet transforms. The matrices are N -by-3 for the double-density wavelet transforms. For an N -by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N -by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage analysis filters for the corresponding tree.

Df — Analysis filters for levels > 1

matrix | cell array

Analysis filters for levels > 1, specified as an N -by-2 or N -by-3 matrix for single-tree wavelet transforms, or a cell array of two N -by-2 or N -by-3 matrices for dual-tree wavelet transforms. The matrices are N -by-3 for the double-density wavelet transforms. For an N -by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N -by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the analysis filters for the corresponding tree.

Frf — First-level reconstruction filters

matrix | cell array

First-level reconstruction filters, specified as an N -by-2 or N -by-3 matrix for single-tree wavelet transforms, or a cell array of two N -by-2 or N -by-3 matrices for dual-tree wavelet transforms. The matrices are N -by-3 for the double-density wavelet transforms. For an N -by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N -by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage synthesis filters for the corresponding tree.

Rf — Reconstruction filters for levels > 1

matrix | cell array

Reconstruction filters for levels > 1, specified as an N -by-2 or N -by-3 matrix for single-tree wavelet transforms, or a cell array of two N -by-2 or N -by-3 matrices for dual-tree wavelet transforms. The matrices are N -by-3 for the double-density wavelet transforms. For an N -by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N -by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the synthesis filters for the corresponding tree.

cfs — Wavelet transform coefficients

cell array of matrices

Wavelet transform coefficients, specified as a 1-by-(level+1) cell array of matrices. The size and structure of the matrix elements of the cell array depend on the type of wavelet transform as follows:

- 'dwt' — `cfs{j}`
 - $j = 1, 2, \dots$ level is the level.
 - `cfs{level+1}` are the lowpass, or scaling, coefficients.
- 'ddt' — `cfs{j}(:, :, k)`
 - $j = 1, 2, \dots$ level is the level.
 - $k = 1, 2$ is the wavelet filter.
 - `cfs{level+1}(:, :, :)` are the lowpass, or scaling, coefficients.
- 'cplxdt' — `cfs{j}(:, :, m)`
 - $j = 1, 2, \dots$ level is the level.
 - $m = 1, 2$ are the real and imaginary parts.
 - `cfs{level+1}(:, :, :)` are the lowpass, or scaling, coefficients.
- 'cplxddt' — `cfs{j}(:, :, k, m)`
 - $j = 1, 2$ level is the level.
 - $k = 1, 2$ is the wavelet filter.
 - $m = 1, 2$ are the real and imaginary parts.
 - `cfs{level+1}(:, :, :)` are the lowpass, or scaling, coefficients.

Output Arguments

xrec — Synthesized 1-D signal

vector

Synthesized 1-D signal, returned as a vector. The row or column orientation of `xrec` depends on the row or column orientation of the 1-D signal input to `dddtree`.

Data Types: `double`

Introduced in R2013b

iddtree2

Inverse dual-tree and double-density 2-D wavelet transform

Syntax

```
xrec = idddtree2(wt)
```

Description

`xrec = idddtree2(wt)` returns the inverse wavelet transform of the 2-D decomposition (analysis filter bank), `wt`. `wt` is the output of `dddtree2`.

Examples

Perfect Reconstruction Using Complex Oriented Dual-Tree Wavelet Filter Bank

Demonstrate perfect reconstruction of an image using a complex oriented dual-tree wavelet transform.

Load the image and obtain the complex oriented dual-tree wavelet transform down to level 5 using `dddtree2`. Reconstruct the image using `iddtree2` and demonstrate perfect reconstruction.

```
load woman;
wt = dddtree2('cplxdt',X,5,'dtf2');
xrec = idddtree2(wt);
max(max(abs(X-xrec)))

ans = 7.3612e-12
```

Input Arguments

wt — Wavelet transform

structure

Wavelet transform, returned as a structure from `dddtree2` with these fields:

type — Type of wavelet decomposition (filter bank)

'dwt' | 'ddt' | 'realdt' | 'cplxdt' | 'realddd' | 'cplxddd'

Type of wavelet decomposition (filter bank), specified as one of 'dwt', 'ddt', 'realdt', 'cplxdt', 'realddd', or 'cplxddd'. 'dwt' is the critically sampled DWT. 'ddt' produces a double-density wavelet transform with one scaling and two wavelet filters for both row and column filtering. 'realdt' and 'cplxdt' produce oriented dual-tree wavelet transforms consisting of two and four separable wavelet transforms. 'realddd' and 'cplxddd' produce double-density dual-tree wavelet transforms consisting of two and four separable wavelet transforms.

level — Level of the wavelet decomposition

positive integer

Level of the wavelet decomposition, specified as a positive integer.

filters — Decomposition (analysis) and reconstruction (synthesis) filters

structure

Decomposition (analysis) and reconstruction (synthesis) filters, specified as a structure with these fields:

Fdf — First-stage analysis filters

matrix | cell array

First-stage analysis filters, specified as an N -by-2 or N -by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two N -by-2 or N -by-3 matrices for dual-tree wavelet transforms. The matrices are N -by-3 for the double-density wavelet transforms. For an N -by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N -by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage analysis filters for the corresponding tree.

Df — Analysis filters for levels > 1

matrix | cell array

Analysis filters for levels > 1, specified as an N -by-2 or N -by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two N -by-2 or N -by-3 matrices for dual-tree wavelet transforms. The matrices are N -by-3 for the double-density wavelet transforms. For an N -by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N -by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the analysis filters for the corresponding tree.

Frf — First-level reconstruction filters

matrix | cell array

First-level reconstruction filters, specified as an N -by-2 or N -by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two N -by-2 or N -by-3 matrices for dual-tree wavelet transforms. The matrices are N -by-3 for the double-density wavelet transforms. For an N -by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N -by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage synthesis filters for the corresponding tree.

Rf — Reconstruction filters for levels > 1

matrix | cell array

Reconstruction filters for levels > 1, specified as an N -by-2 or N -by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two N -by-2 or N -by-3 matrices for dual-tree wavelet transforms. The matrices are N -by-3 for the double-density wavelet transforms. For the dual-tree transforms, each element of the cell array contains the first-stage analysis filters for the corresponding tree.

cfs — Wavelet transform coefficients

cell array of matrices

Wavelet transform coefficients, specified as a 1-by-(level+1) cell array of matrices. The size and structure of the matrix elements of the cell array depend on the type of wavelet transform as follows:

- 'dwt' — $cfs\{j\}(:, :, d)$
 - $j = 1, 2, \dots$ level is the level.
 - $d = 1, 2, 3$ is the orientation.
 - $cfs\{level+1\}(:, :)$ are the lowpass, or scaling, coefficients.
- 'ddt' — $cfs\{j\}(:, :, d)$
 - $j = 1, 2, \dots$ level is the level.
 - $d = 1, 2, 3, 4, 5, 6, 7, 8$ is the orientation.
 - $cfs\{level+1\}(:, :)$ are the lowpass, or scaling, coefficients.
- 'realddt' — $cfs\{j\}(:, :, d, k)$
 - $j = 1, 2, \dots$ level is the level.
 - $d = 1, 2, 3$ is the orientation.
 - $k = 1, 2$ is the wavelet transform tree.
 - $cfs\{level+1\}(:, :)$ are the lowpass, or scaling, coefficients.
- 'cplxdt' — $cfs\{j\}(:, :, d, k, m)$
 - $j = 1, 2, \dots$ level is the level.
 - $d = 1, 2, 3$ is the orientation.
 - $k = 1, 2$ is the wavelet transform tree.
 - $m = 1, 2$ are the real and imaginary parts.
 - $cfs\{level+1\}(:, :)$ are the lowpass, or scaling, coefficients..
- 'realdddt' — $cfs\{j\}(:, :, d, k)$
 - $j = 1, 2, \dots$ level is the level.
 - $d = 1, 2, 3$ is the orientation.
 - $k = 1, 2$ is the wavelet transform tree.
 - $cfs\{level+1\}(:, :)$ are the lowpass, or scaling, coefficients.
- 'cplxdddt' — $cfs\{j\}(:, :, d, k, m)$
 - $j = 1, 2, \dots$ level is the level.
 - $d = 1, 2, 3$ is the orientation.
 - $k = 1, 2$ is the wavelet transform tree.
 - $m = 1, 2$ are the real and imaginary parts.
 - $cfs\{level+1\}(:, :)$ are the lowpass, or scaling, coefficients.

Output Arguments

xrec — Synthesized 2-D image

matrix

Synthesized image, returned as a matrix.

Data Types: double

Topics

“Analytic Wavelets Using the Dual-Tree Wavelet Transform”

“Critically Sampled and Oversampled Wavelet Filter Banks”

Introduced in R2013b

idualtree

Kingsbury Q-shift 1-D inverse dual-tree complex wavelet transform

Syntax

```
xrec = idualtree(A,D)
xrec = idualtree( ____,Name,Value)
```

Description

`xrec = idualtree(A,D)` returns the inverse 1-D complex dual-tree transform of the final-level approximation coefficients, `A`, and cell array of wavelet coefficients, `D`. `A` and `D` are outputs of `dualtree`. For the reconstruction, `idualtree` uses two sets of filters:

- Orthogonal Q-shift filter of length 10
- Near-symmetric biorthogonal filter pair with lengths 7 (scaling synthesis filter) and 5 (wavelet synthesis filter)

`xrec = idualtree(____,Name,Value)` specifies additional options using name-value pair arguments. For example, `'LowpassGain',0.1` applies a gain of 0.1 to the final-level approximation coefficients.

Examples

Inverse 1-D Dual-Tree Complex Wavelet Transform

Load a signal, and obtain its dual-tree transform.

```
load noisdopp
[a,d] = dualtree(noisdopp);
```

Reconstruct an approximation using all but the two finest-detail wavelet subbands.

```
dgain = ones(numel(d),1);
dgain(1:2) = 0;
xrec = idualtree(a,d,'DetailGain',dgain);
plot(noisdopp)
hold on
plot(xrec,'LineWidth',2);
legend('Original','Reconstruction')
```

Input Arguments

A — Final-level approximation coefficients

real-valued vector | real-valued matrix

Final-level approximation coefficients, specified as a real-valued vector or real-valued matrix. The approximation coefficients are the output of `dualtree`.

Data Types: `double` | `single`

D — Wavelet coefficients

cell array

Approximation coefficients, specified as a cell array. The wavelet coefficients are the output of `dualtree`.

Data Types: `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'LevelOneFilter','antonini','LowpassGain',0.5`

LevelOneFilter — Biorthogonal filter

'nearsym5_7' (default) | 'nearsym13_19' | 'antonini' | 'legall'

Biorthogonal filter to use in the first-level synthesis, specified by one of the values listed here. For perfect reconstruction, the first-level synthesis filters must match the first-level analysis filters used in `dualtree`.

- 'legall' — LeGall 5/3 filter
- 'nearsym13_19' — (13,19)-tap near-orthogonal filter
- 'nearsym5_7' — (5,7)-tap near-orthogonal filter
- 'antonini' — (9,7)-tap Antonini filter

FilterLength — Orthogonal Hilbert Q-shift synthesis filter pair length

10 (default) | 6 | 14 | 16 | 18

Orthogonal Hilbert Q-shift synthesis filter pair length to use for levels 2 and higher, specified as one of the listed values. For perfect reconstruction, the filter length must match the filter length used in `dualtree`.

DetailGain — Wavelet coefficients subband gains

real-valued vector

Wavelet coefficients subband gains, specified as a real-valued vector of length L , where L is the number of elements in `D`. The elements of `DetailGain` are real numbers in the interval $[0, 1]$. The k^{th} element of `DetailGain` is the gain (weighting) applied to the k^{th} wavelet subband. By default, `DetailGain` is a vector of L ones.

LowpassGain — Gain

1 (default) | real number

Gain to apply to final-level approximation (lowpass, scaling) coefficients, specified as a real number in the interval $[0, 1]$.

idualtree2

Kingsbury Q-shift 2-D inverse dual-tree complex wavelet transform

Syntax

```
imrec = idualtree2(A,D)
imrec = idualtree2( ____,Name,Value)
```

Description

`imrec = idualtree2(A,D)` returns the inverse 2-D complex dual-tree transform of the final-level approximation coefficients, `A`, and cell array of wavelet coefficients, `D`. `A` and `D` are outputs of `dualtree2`. For the reconstruction, `idualtree2` uses two sets of filters:

- Orthogonal Q-shift filter of length 10
- Near-symmetric biorthogonal filter pair with lengths 7 (scaling synthesis filter) and 5 (wavelet synthesis filter)

`imrec = idualtree2(____,Name,Value)` specifies additional options using name-value pair arguments. For example, `'LowpassGain',0.1` applies a gain of 0.1 to the final-level approximation coefficients.

Examples

Inverse 2-D Dual-Tree Wavelet Transform Using Specific Subbands

This example shows how to reconstruct an approximation based on a subset of the wavelet subbands.

Load a 128-by-128 grayscale image.

```
load xbox
imagesc(xbox)
colormap gray
```

Obtain the dual-tree wavelet transform of the image down to level 2

```
lev = 2;
[a,d] = dualtree2(xbox, 'Level', lev);
```

Since there are six wavelet subbands in each level of the decomposition, create a 2-by-6 matrix of zeros.

```
dgains = zeros(lev,6);
```

To reconstruct an approximation based on the 2nd and 5th wavelet subbands, set the second and fifth rows of `dgains` equal to 1. The 2nd and 5th wavelet subbands correspond to the highpass filtering of the rows and columns of the image.

```
dgains(:, [2 5]) = 1;
```

Obtain two reconstructions using the specified wavelet subbands. Include the scaling (lowpass) coefficients only in the first reconstruction.

```
imrec = idualtree2(a,d, 'DetailGain', dgains);
imrec2 = idualtree2(a,d, 'DetailGain', dgains, 'LowpassGain', 0);
figure
subplot(2,1,1)
imagesc(imrec)
title('With Lowpass Coefficients')
subplot(2,1,2)
imagesc(imrec2)
```

```
title('Without Lowpass Coefficients')
colormap gray
```

Input Arguments

A — Final-level approximation coefficients

real-valued array

Final-level approximation coefficients, specified as a real-valued array. The approximation coefficients are the output of `dualtree2`.

Data Types: `double` | `single`

D — Wavelet coefficients

cell array

Approximation coefficients, specified as a cell array. The wavelet coefficients are the output of `dualtree2`.

Data Types: `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: 'LevelOneFilter', 'antonini', 'LowpassGain', 0.5

LevelOneFilter — Biorthogonal filter

'nearsym5_7' (default) | 'nearsym13_19' | 'antonini' | 'legall'

Biorthogonal filter to use in the first-level synthesis, specified by one of the values listed here. For perfect reconstruction, the first-level synthesis filters must match the first-level analysis filters used in `dualtree2`.

- 'legall' — LeGall 5/3 filter
- 'nearsym13_19' — (13,19)-tap near-orthogonal filter
- 'nearsym5_7' — (5,7)-tap near-orthogonal filter
- 'antonini' — (9,7)-tap Antonini filter

FilterLength — Orthogonal Hilbert Q-shift synthesis filter pair length

10 (default) | 6 | 14 | 16 | 18

Orthogonal Hilbert Q-shift synthesis filter pair length to use for levels 2 and higher, specified as one of the listed values. For perfect reconstruction, the filter length must match the filter length used in `dualtree2`.

DetailGain — Wavelet coefficients subband gains

real-valued matrix

Wavelet coefficients subband gains, specified as a real-valued matrix with a row dimension of L , where L is the number of elements in `D`. There are six columns in `DetailGain` for each of the six wavelet subbands. The elements of `DetailGain` are real numbers in the interval $[0, 1]$. The k^{th} column elements of `DetailGain` are the gains (weightings) applied to the k^{th} wavelet subband. By default, `DetailGain` is a L -by-6 matrix of ones.

LowpassGain — Gain

1 (default) | real number

Gain to apply to final-level approximation (lowpass, scaling) coefficients, specified as a real number in the interval $[0, 1]$.

idualtree3

3-D dual-tree complex wavelet reconstruction

Syntax

```
xrec = idualtree3(a,d)  
xrec = idualtree3(a,d,Name,Value)
```

Description

`xrec = idualtree3(a,d)` returns the inverse 3-D dual-tree complex wavelet transform of the final-level approximation coefficients, `a`, and cell array of wavelet coefficients, `d`.

`xrec = idualtree3(a,d,Name,Value)` specifies options using name-value pair arguments.

Examples

Wavelet Coefficients

Generate all-zero sets of scaling and wavelet coefficients by computing the 3-D dual-tree complex wavelet transform of an array of zeros.

```
zr = zeros(64,64,64);
```

```
[a,d] = dualtree3(zr,4);
```

Find the real (4,5) wavelet coefficient of the 19th subband of the third level by assigning 1 to the corresponding array element and inverting the transform.

```
d{3}(4,5,19) = 1;
```

```
xr = idualtree3(a,d);
```

Find the corresponding imaginary coefficient assigning the imaginary unit to the array element and then inverting the transform.

```
[a,d] = dualtree3(zr,4);
```

```
d{3}(4,5,19) = 1j;
```

```
xi = idualtree3(a,d);
```

Display the 18th page of the real and imaginary reconstructions.

```
subplot(1,2,1)  
surf(xr(:,:,18))  
view(0,0)  
zlim([-0.02 0.02])  
shading interp
```

```
subplot(1,2,2)
```

```
surf(xi(:,:,18))
view(0,0)
zlim([-0.02 0.02])
shading interp
```

Input Arguments

a — Final-level scaling coefficients

real-valued matrix

Final-level scaling coefficients, specified as a real-valued matrix. **a** is an output of `dualtree3`.

Data Types: `single` | `double`

d — Wavelet coefficients

cell array

Wavelet coefficients, specified as a cell array. **d** is an output of `dualtree3`.

Data Types: `single` | `double`

Complex Number Support: Yes

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'LevelOneFilter', 'legall', 'FilterLength', 6` inverts a transform using LeGall synthesis filters with scaling length 3 and wavelet length 5 at level 1, and length-6 Q-shift filters at levels 2 and greater.

FilterLength — Hilbert Q-shift filter-pair length

10 (default) | 6 | 14 | 16 | 18

Hilbert Q-shift filter-pair length, specified as the comma-separated pair consisting of `'FilterLength'` and one of 6, 10, 14, 16, or 18. The synthesis filters used by `idualtree3` must match the analysis filters used by `dualtree3`.

Data Types: `double` | `single`

LevelOneFilter — First-level biorthogonal analysis filter

'nearsym5_7' (default) | 'nearsym13_19' | 'antonini' | 'legall'

First-level biorthogonal analysis filter, specified as the comma-separated pair consisting of `'LevelOneFilter'` and a character vector or string. By default, `idualtree3` uses the near-symmetric biorthogonal wavelet filter with lengths 7 (scaling synthesis filter) and 5 (wavelet synthesis filter) in the reconstruction.

Data Types: `char` | `string`

OriginalDataSize — Size of the original data

three-element vector of even integers

Size of the original data, specified as the comma-separated pair consisting of `'OriginalDataSize'` and a three-element vector of even integers. This vector must match the size of the original input to the 3-D dual-tree wavelet transform. When the first-level wavelet coefficients are not available, the reconstructed data size can differ from the original input data size. If you call `dualtree3` with the `'excludeL1'` option, then `'OriginalDataSize'` adjusts the size of `xrec` to match the size of the original input data. If you do not use the `'excludeL1'` option, then this argument is ignored.

Data Types: `double` | `single`

Output Arguments

xrec — Inverse 3-D dual-tree complex wavelet transform

3-D array

Inverse 3-D dual-tree complex wavelet transform, returned as a 3-D array.

idwpt

Multisignal 1-D inverse wavelet packet transform

Syntax

```
xrec = idwpt(wpt,l)
xrec = idwpt(wpt,l,wname)
xrec = idwpt(wpt,l,LoR,HiR)
xrec = idwpt( ____, 'Boundary',ExtensionMode)
```

Description

`xrec = idwpt(wpt,l)` inverts the discrete wavelet packet transform (DWPT) of the terminal node wavelet packet tree `wpt` using the bookkeeping vector `l`. The `idwpt` function assumes that you obtained `wpt` and `l` using `dwpt` with the `fk18` wavelet and default settings.

If the input to `dwpt` was one signal, `xrec` is a column vector. If the input was a multichannel signal, `xrec` is a matrix, where each matrix column corresponds to a channel.

`xrec = idwpt(wpt,l,wname)` uses the wavelet specified by `wname` to invert the DWPT. `wname` must be recognized by `wavemngr`. The specified wavelet must be the same wavelet used to obtain the DWPT.

`xrec = idwpt(wpt,l,LoR,HiR)` uses the scaling (lowpass) filter, `LoR`, and wavelet (highpass) filter, `HiR`. The synthesis filter pair `LoR` and `HiR` must be associated with the same wavelet used in the DWPT.

`xrec = idwpt(____, 'Boundary',ExtensionMode)` specifies the mode to extend the signal. `ExtensionMode` can be either `'reflection'` (default) and `'periodic'`. By setting `ExtensionMode` to `'periodic'` or `'reflection'`, the wavelet packet coefficients at each level are extended based on the modes `'per'` or `'sym'` in `dwtmode`, respectively. `ExtensionMode` must be the same mode used in the DWPT.

Examples

Inverse Wavelet Packet Transform

This example shows how to perform the inverse wavelet packet transform using synthesis filters.

Obtain the DWPT of an ECG signal using `dwpt` with default settings.

```
load wecg
[wpt,l] = dwpt(wecg);
```

By default, `dwpt` uses the `fk18` wavelet. Obtain the synthesis (reconstruction) filters associated with the wavelet.

```
[~,~,lor,hir] = wfilters('fk18');
```

Invert the DWPT using the synthesis filters and demonstrate perfect reconstruction.

```
xrec = idwpt(wpt,l,lor,hir);
norm(wecg-xrec, 'inf')
```

```
ans =
```

```
4.9236e-11
```

Change Boundary Extension Mode

Obtain the DWPT of an ECG signal using `dwpt` and periodic extension.

```
load wecg
[wpt,l] = dwpt(wecg, 'Boundary', 'periodic');
```

By default, `idwpt` uses symmetric extension. Invert the DWPT using periodic and symmetric extension modes.

```
xrecA = idwpt(wpt,l, 'Boundary', 'periodic');
xrecB = idwpt(wpt,l);
```

Demonstrate perfect reconstruction only when the extension modes of the forward and inverse DWPT agree.

```
fprintf('Periodic/Periodic : %f\n', norm(wecg-xrecA, 'inf'))
```

```
Periodic/Periodic : 0.000000
```

```
fprintf('Periodic/Symmetric: %f\n', norm(wecg-xrecB, 'inf'))
```

```
Periodic/Symmetric: 1.477907
```

PR Biorthogonal Filters

This example shows how to take an expression of a biorthogonal filter pair and construct lowpass and highpass filters to produce a perfect reconstruction (PR) pair in Wavelet Toolbox™.

The LeGall 5/3 filter is the wavelet used in JPEG2000 for lossless image compression. The lowpass (scaling) filters for the LeGall 5/3 wavelet have five and three nonzero coefficients respectively. The expressions for these two filters are:

$$H_0(z) = 1/8(-z^2 + 2z + 6 + 2z^{-1} - z^{-2})$$

$$H_1(z) = 1/2(z + 2 + z^{-1})$$

Create these filters.

```
H0 = 1/8*[-1 2 6 2 -1];
H1 = 1/2*[1 2 1];
```

Many of the discrete wavelet and wavelet packet transforms in Wavelet Toolbox rely on the filters being both even-length and equal in length in order to produce the perfect reconstruction filter bank

associated with these transforms. These transforms also require a specific normalization of the coefficients in the filters for the algorithms to produce a PR filter bank. Use the `biorfilt` function on the lowpass prototype functions to produce the PR wavelet filter bank.

```
[LoD,HiD,LoR,HiR] = biorfilt(H0,H1);
```

The sum of the lowpass analysis and synthesis filters is now equal to $\sqrt{2}$.

```
sum(LoD)
```

```
ans = 1.4142
```

```
sum(LoR)
```

```
ans = 1.4142
```

The wavelet filters sum, as required, to zero. The L2-norms of the lowpass analysis and highpass synthesis filters are equal. The same holds for the lowpass synthesis and highpass analysis filters.

Now you can use these filters in discrete wavelet and wavelet packet transforms and achieve a PR wavelet packet filter bank. To demonstrate this, load and plot an ECG signal.

```
load wecg
plot(wecg)
axis tight
grid on
```

Obtain the discrete wavelet packet transform of the ECG signal using the LeGall 5/3 filter set.

```
[wpt,L] = dwpt(wecg,LoD,HiD);
```

Now use the reconstruction (synthesis) filters to reconstruct the signal and demonstrate perfect reconstruction.

```
xrec = idwpt(wpt,L,LoR,HiR);  
plot([wecg xrec])  
axis tight, grid on;
```

```
norm(wecg-xrec, 'Inf')
```

```
ans = 3.1086e-15
```

You can also use this filter bank in the 1-D and 2-D discrete wavelet transforms. Read and plot an image.

```
im = imread('woodsculp256.jpg');  
image(im); axis off;
```

Obtain the 2-D wavelet transform using the LeGall 5/3 analysis filters.

```
[C,S] = wavedec2(im,3,LoD,HiD);
```

Reconstruct the image using the synthesis filters.

```
imrec = waverec2(C,S,LoR,HiR);  
image(uint8(imrec)); axis off;
```

The LeGall 5/3 filter is equivalent to the built-in 'bior2.2' wavelet in Wavelet Toolbox. Use the 'bior2.2' filters and compare with the LeGall 5/3 filters.

```
[LD,HD,LR,HR] = wfilters('bior2.2');
subplot(2,2,1)
hl = stem([LD' LoD']);
hl(1).MarkerFaceColor = [0 0 1];
hl(1).Marker = 'o';
hl(2).MarkerFaceColor = [1 0 0];
hl(2).Marker = '^';
grid on
title('Lowpass Analysis')
subplot(2,2,2)
hl = stem([HD' HiD']);
hl(1).MarkerFaceColor = [0 0 1];
hl(1).Marker = 'o';
hl(2).MarkerFaceColor = [1 0 0];
hl(2).Marker = '^';
grid on
title('Highpass Analysis')
subplot(2,2,3)
hl = stem([LR' LoR']);
hl(1).MarkerFaceColor = [0 0 1];
hl(1).Marker = 'o';
hl(2).MarkerFaceColor = [1 0 0];
hl(2).Marker = '^';
grid on
```

```

title('Lowpass Synthesis')
subplot(2,2,4)
hl = stem([HR' HiR']);
hl(1).MarkerFaceColor = [0 0 1];
hl(1).Marker = 'o';
hl(2).MarkerFaceColor = [1 0 0];
hl(2).Marker = '^';
grid on
title('Highpass Synthesis')

```

Input Arguments

wpt — Terminal node wavelet packet tree

cell array

Terminal node wavelet packet tree, specified as a cell array. `wpt` is the output of `dwpt` with the 'FullTree' value set to false.

Example: `[wpt,l] = dwpt(X,'Level',3,'FullTree',false)` returns the terminal node wavelet packet tree of the three-level wavelet packet decomposition of `X`.

Data Types: single | double

l — Bookkeeping vector

vector of positive integers

Bookkeeping vector, specified as a vector of positive integers. The vector `l` is the output of `dwpt`. The bookkeeping vector contains the length of the input signal and the number of coefficients by level, and is required for perfect reconstruction.

Data Types: `single` | `double`

wname — Wavelet

'fk18' (default) | character vector | string scalar

Wavelet to use in the inverse DWPT, specified as a character vector or string scalar. `wname` must be recognized by `wavemngr`. The specified wavelet must be the same wavelet used to obtain the DWPT.

You cannot specify both `wname` and a filter pair, `LoD` and `HiD`.

Example: `xrec = idwpt(wpt,l,"sym4")` specifies the `sym4` wavelet.

LoR, HiR — Wavelet synthesis filters

real-valued vectors

Wavelet synthesis (reconstruction) filters to use in the inverse DWPT, specified as a pair of real-valued vectors. `LoR` is the scaling (lowpass) synthesis filter, and `HiR` is the wavelet (highpass) synthesis filter. The synthesis filter pair must be associated with the same wavelet as used in the DWPT. You cannot specify both `wname` and a filter pair, `LoR` and `HiR`. See `wfilters` for additional information.

Note `idwpt` does not check that `LoR` and `HiR` satisfy the requirements for a perfect reconstruction wavelet packet filter bank. See “PR Biorthogonal Filters” on page 1-547 for an example of how to take a published biorthogonal filter and ensure that the analysis and synthesis filters produce a perfect reconstruction wavelet packet filter bank using `idwpt`.

ExtensionMode — Wavelet packet transform boundary handling

'reflection' (default) | 'periodic'

Wavelet packet transform boundary handling, specified as 'reflection' or 'periodic'. When set to 'reflection' or 'periodic', the wavelet packet coefficients are extended at each level based on the 'sym' or 'per' mode in `dwtmode`, respectively. `ExtensionMode` must be the same mode used in the DWPT. If unspecified, `ExtensionMode` defaults to 'reflection'.

idwt

Single-level inverse discrete 1-D wavelet transform

Syntax

```
X = idwt(cA,cD,'wname')
X = idwt(cA,cD,Lo_R,Hi_R)
X = idwt(cA,cD,'wname',L)
X = idwt(cA,cD,Lo_R,Hi_R,L)
idwt(cA,cD,'wname')
X = idwt(...,'mode',MODE)
X = idwt(cA,[],...)
X = idwt([],cD,...)
```

Description

The `idwt` command performs a single-level one-dimensional wavelet reconstruction with respect to either a particular wavelet (`'wname'`, see `wfilters` for more information) or particular wavelet reconstruction filters (`Lo_R` and `Hi_R`) that you specify.

`X = idwt(cA,cD,'wname')` returns the single-level reconstructed approximation coefficients vector `X` based on approximation and detail coefficients vectors `cA` and `cD`, and using the wavelet `'wname'`.

`X = idwt(cA,cD,Lo_R,Hi_R)` reconstructs as above using filters that you specify.

- `Lo_R` is the reconstruction low-pass filter.
- `Hi_R` is the reconstruction high-pass filter.

`Lo_R` and `Hi_R` must be the same length.

Let `la` be the length of `cA` (which also equals the length of `cD`) and `lf` the length of the filters `Lo_R` and `Hi_R`; then `length(X) = LX` where $LX = 2*la$ if the DWT extension mode is set to periodization. For the other extension modes $LX = 2*la - lf + 2$.

For more information about the different Discrete Wavelet Transform extension modes, see `dwtmode`.

`X = idwt(cA,cD,'wname',L)` or `X = idwt(cA,cD,Lo_R,Hi_R,L)` returns the length-`L` central portion of the result obtained using `idwt(cA,cD,'wname')`. `L` must be less than `LX`.

`X = idwt(...,'mode',MODE)` computes the wavelet reconstruction using the specified extension mode `MODE`.

`X = idwt(cA,[],...)` returns the single-level reconstructed approximation coefficients vector `X` based on approximation coefficients vector `cA`.

`X = idwt([],cD,...)` returns the single-level reconstructed detail coefficients vector `X` based on detail coefficients vector `cD`.

Examples

Inverse DWT Using Orthogonal Wavelet

Demonstrate perfect reconstruction using `dwt` and `idwt` with an orthonormal wavelet.

```
load noisdopp;
[A,D] = dwt(noisdopp, 'sym4');
x = idwt(A,D, 'sym4');
max(abs(noisdopp-x))
```

```
ans = 3.2156e-12
```

Inverse DWT Using Biorthogonal Wavelet

Demonstrate perfect reconstruction using `dwt` and `idwt` with a biorthogonal wavelet.

```
load noisdopp;
[Lo_D,Hi_D,Lo_R,Hi_R] = wfilters('bior3.5');
[A,D] = dwt(noisdopp,Lo_D,Hi_D);
x = idwt(A,D,Lo_R,Hi_R);
max(abs(noisdopp-x))
```

```
ans = 3.5527e-15
```

Algorithms

Starting from the approximation and detail coefficients at level j , cA_j and cD_j , the inverse discrete wavelet transform reconstructs cA_{j-1} , inverting the decomposition step by inserting zeros and convolving the results with the reconstruction filters.

`dwt` | `dwtmode` | `upwlev`

Introduced before R2006a

idwt2

Single-level inverse discrete 2-D wavelet transform

Syntax

```
X = idwt2(cA,cH,cV,cD,'wname')
X = idwt2(cA,cH,cV,cD,Lo_R,Hi_R)
X = idwt2(cA,cH,cV,cD,'wname',S)
X = idwt2(cA,cH,cV,cD,Lo_R,Hi_R,S)
idwt2(cA,cH,cV,cD,'wname')
X = idwt2(...,'mode',MODE)
X = idwt2(cA,[],[],[],...)
X = idwt2([],cH,[],[],...)
```

Description

The `idwt2` command performs a single-level two-dimensional wavelet reconstruction with respect to either a particular wavelet (`'wname'`, see `wfilters` for more information) or particular wavelet reconstruction filters (`Lo_R` and `Hi_R`) that you specify.

`X = idwt2(cA,cH,cV,cD,'wname')` uses the wavelet `'wname'` to compute the single-level reconstructed approximation coefficients matrix `X`, based on approximation matrix `cA` and details matrices `cH`, `cV`, and `cD` (horizontal, vertical, and diagonal, respectively).

`X = idwt2(cA,cH,cV,cD,Lo_R,Hi_R)` reconstructs as above, using filters that you specify.

- `Lo_R` is the reconstruction low-pass filter.
- `Hi_R` is the reconstruction high-pass filter.

`Lo_R` and `Hi_R` must be the same length.

Let `sa = size(cA) = size(cH) = size(cV) = size(cD)` and `lf` the length of the filters; then `size(X) = SX`, where `SX = 2 * SA`, if the DWT extension mode is set to periodization. For the other extension modes, `SX = 2 * size(cA) - lf + 2`.

For more information about the different Discrete Wavelet Transform extension modes, see `dwtmode`.

`X = idwt2(cA,cH,cV,cD,'wname',S)` and `X = idwt2(cA,cH,cV,cD,Lo_R,Hi_R,S)` return the size-`S` central portion of the result obtained using the syntax `idwt2(cA,cH,cV,cD,'wname')`. `S` must be less than `SX`.

`X = idwt2(...,'mode',MODE)` computes the wavelet reconstruction using the extension mode `MODE` that you specify.

`X = idwt2(cA,[],[],[],...)` returns the single-level reconstructed approximation coefficients matrix `X` based on approximation coefficients matrix `cA`.

`X = idwt2([],cH,[],[],...)` returns the single-level reconstructed detail coefficients matrix `X` based on horizontal detail coefficients matrix `cH`.

The same result holds for `X = idwt2([],[],cV,[],...)` and

`X = idwt2([], [], [], cD, ...)`, based on vertical and diagonal details.

More generally, `X = idwt2(AA, HH, VV, DD, ...)` returns the single-level reconstructed matrix `X`, where `AA` can be `cA` or `[]`, and so on.

`idwt2` is the inverse function of `dwt2` in the sense that the abstract statement `idwt2(dwt2(X, 'wname'), 'wname')` would give back `X`.

Examples

```
% The current extension mode is zero-padding (see dwtmode).
```

```
% Load original image.
load woman;
```

```
% X contains the loaded image.
sX = size(X);
```

```
% Perform single-level decomposition
% of X using db4.
[cA1, cH1, cV1, cD1] = dwt2(X, 'db4');
```

```
% Invert directly decomposition of X
% using coefficients at level 1.
A0 = idwt2(cA1, cH1, cV1, cD1, 'db4', sX);
```

```
% Check for perfect reconstruction.
max(max(abs(X-A0)))
ans =
    3.4176e-10
```

Tips

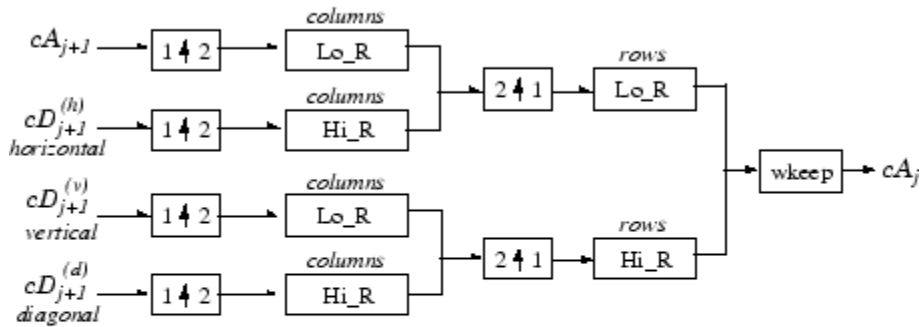

If `cA`, `cH`, `cV`, `cD` are obtained from an indexed image analysis or a truecolor image analysis, they are `m`-by-`n` matrices or `m`-by-`n`-by-3 arrays, respectively.

For more information on image formats, see the `image` and `imfinfo` reference pages.

Algorithms

dwt2 | dwtmode | upwlev2

Introduced before R2006a

idwt3

Single-level inverse discrete 3-D wavelet transform

Syntax

```
X = idwt3(WT)
C = idwt3(WT,TYPE)
```

Description

The `idwt3` command performs a single-level three-dimensional wavelet reconstruction starting from a single-level three-dimensional wavelet decomposition.

`X = idwt3(WT)` computes the single-level reconstructed 3-D array `X`, based on the three-dimensional wavelet decomposition stored in the `WT` structure. This structure contains the following fields.

<code>sizeINI</code>	Size of the three-dimensional array <code>X</code> .
<code>mode</code>	Name of the wavelet transform extension mode.
<code>filters</code>	Structure with 4 fields, <code>LoD</code> , <code>HiD</code> , <code>LoR</code> , <code>HiR</code> , which contain the filters used for DWT.
<code>dec</code>	2 x 2 x 2 cell array containing the coefficients of the decomposition. <code>dec{i,j,k}</code> , <code>i,j,k = 1</code> or <code>2</code> contains the coefficients obtained by low-pass filtering (for <code>i</code> or <code>j</code> or <code>k = 1</code>) or high-pass filtering (for <code>i</code> or <code>j</code> or <code>k = 2</code>).

`C = idwt3(WT,TYPE)` computes the single-level reconstructed component based on the three-dimensional wavelet decomposition. Valid values for `TYPE` are:

- A group of three characters `'xyz'`, one per direction, with `'x'`, `'y'` and `'z'` selected in the set `{'a','d','l','h'}` or in the corresponding uppercase set `{'A','D','L','H'}`, where `'A'` (or `'L'`) specifies low-pass filter and `'D'` (or `'H'`) specifies highpass filter.
- The char `'d'` (or `'h'` or `'D'` or `'H'`) which specifies the sum of all the components different from the lowpass component.

Examples

Single-Level Three-Dimensional Wavelet Reconstruction

Define the original 3-D data.

```
X = reshape(1:64,4,4,4)
```

```
X =
X(:,:,1) =
```

```
    1     5     9    13
    2     6    10    14
```

```

Introduced in R2010a

ihaart

Inverse 1-D Haar wavelet transform

Syntax

```
xrec = ihaart(a,d)
xrec = ihaart(a,d,level)
xrec = ihaart( ____,integerflag)
```

Description

`xrec = ihaart(a,d)` returns the inverse 1-D Haar transform, `xrec`, for the approximation coefficients, `a`, and the wavelet coefficients, `d`. Both `a` and `d` are obtained from `haart`.

`xrec = ihaart(a,d,level)` returns the inverse 1-D Haar transform at the specified level.

`xrec = ihaart(____,integerflag)` specifies how the inverse 1-D Haar transform handles integer-valued data, using any of the previous syntaxes.

Examples

Inverse Haar Transform of Noisy Data

Obtain the Haar and inverse Haar transforms of noisy data.

Load the noisy data signal

```
load noisdopp;
```

Obtain the Haar transform of the noisy signal.

```
[a,d] = haart(noisdopp);
```

Reconstruct the data by inverting the Haar transform.

```
xrec = ihaart(a,d);
```

Compare the original and reconstructed data by determining the maximum difference between them. The difference is essentially zero, which indicates a near-perfect reconstruction.

```
max(abs(xrec-noisdopp'))
```

```
ans = 4.4409e-15
```

Inverse Haar Transform of ECG Data

Obtain the Haar transform and inverse Haar transform of ECG heart rate data.

Load and plot the ECG data.

```
load BabyECGData;  
plot(times,HR)  
xlabel('Hours')  
ylabel('Heart Rate')  
title('ECG Data')
```

Obtain the Haar transform and inverse Haar transform. Compare the reconstructed data at level 4 to the original data.

```
[a,d] = haart(HR);  
HaarHR = ihaart(a,d,4);  
figure  
plot(times,HaarHR)  
xlabel('Hours')  
ylabel('Heart Rate')  
title('Haar Approximation of Heart Rate')
```

Inverse Haar Transform of Integer Data

Obtain the Haar and inverse Haar transforms for a series of random integers.

Create the series.

```
x = randi(10,100,1);
```

Obtain the Haar and inverse Haar transforms.

```
[a,d] = haart(x,'integer');
xrec = ihaart(a,d,'integer');
```

Plot and compare the original and reconstructed data.

```
subplot(2,1,1)
stem(x); title('Original Data')
subplot(2,1,2)
stem(xrec)
title('Reconstructed Integer-to-Integer Data')
```

Determine the maximum difference between the original data values and the reconstructed values. The difference is zero, which indicates perfect reconstruction.

```
max(abs(x(:)-xrec(:)))
```

```
ans = 0
```

Input Arguments

a – Approximation coefficients

scalar | vector | matrix

Approximation coefficients, specified as a scalar, vector, or matrix of coefficients, depending on the level to which the Haar transform was calculated. **a** is an output from the `haart` function.

Approximation, or scaling, coefficients are a lowpass representation of the input. At each level the approximation coefficients are divided into coarser approximation and detail coefficients.

Data Types: `double`

d – Detail coefficients

scalar | vector | matrix | cell array

Detail coefficients, specified as a scalar, vector, matrix, or cell array of wavelet coefficients. **d** is an output from the `haart` function. The number of detail coefficients depends on the selected level and

the length of the input. If `d` is a cell array, the elements of `d` are ordered from finest to coarsest resolution.

If `d` is a cell array, it can contain scalars, vectors, or matrices. The level of the Haar transform equals the number of elements in `d`.

If `d` is a vector or matrix, the Haar transform was computed only down to one level coarser in resolution.

If `a` and the elements of `d` are vectors, `xrec` is a vector. If `a` and the elements of `d` are matrices, `xrec` is a matrix, where each column is the inverse Haar transform of the corresponding columns in `a` and `d`.

Data Types: `double`

level — Maximum level

0 (default) | nonnegative integer

Maximum level to which to invert the Haar transform, specified as a nonnegative integer. If `d` is a cell array, `level` is less than or equal to `length(d) - 1`. If `d` is a vector or matrix, `level` must equal 0 or be unspecified. The level must be less than the level used to obtain `a` and `d` from `haart`.

integerflag — Integer-valued data handling

'noninteger' (default) | 'integer'

Integer-valued data handling, specified as either 'noninteger' or 'integer'. 'noninteger' does not preserve integer-valued data, and 'integer' preserves it. The 'integer' option applies only if all elements of `a` and `d` are integer-valued. You must have used 'integer' with `haart` to obtain integer-valued `a` and `d` inputs. The inverse 1-D Haar transform algorithm, however, uses floating-point arithmetic.

Output Arguments

xrec — Inverse 1-D Haar wavelet transform

vector | matrix

Inverse 1-D Haar wavelet transform, returned as a vector or matrix. If `a` and the elements of `d` are vectors, `xrec` is a vector. If `a` and the elements of `d` are matrices, `xrec` is a matrix, where each column is the inverse 1-D Haar transform of the corresponding columns in `a` and `d`.

Data Types: `double`

Topics

“Haar Transforms for Time Series Data and Images”

Introduced in R2016b

ihaart2

Inverse 2-D Haar wavelet transform

Syntax

```
xrec = ihaart2(a,h,v,d)
xrec = ihaart2(a,h,v,d,level)
xrec = ihaart2( ____,integerflag)
```

Description

`xrec = ihaart2(a,h,v,d)` returns the inverse 2-D Haar transform, `xrec`, for the approximation coefficients, `a`, and the horizontal, vertical, and diagonal detail coefficients, `h`, `v`, and `d`. All the inputs, `a`, `h`, `v`, and `d`, are outputs of `haart2`.

`xrec = ihaart2(a,h,v,d,level)` returns the inverse 2-D Haar transform at the specified level.

`xrec = ihaart2(____,integerflag)` specifies how the inverse 2-D Haar transform handles integer-valued data, using any of the previous syntaxes.

Examples

Inverse 2-D Haar Transform of an Image

Obtain the inverse 2-D Haar transform of image and view the reconstructed image.

Load the image and obtain its 2-D Haar transform.

```
im = imread('mandrill.png');
[a,h,v,d] = haart2(im);
```

Use the inverse 2-D Haar transform to reconstruct the image.

```
xrec = ihaart2(a,h,v,d);
```

Compare the original and reconstructed images.

```
imagesc(im)
title('Original RGB Image')
```

```
figure
imagesc(uint8(xrec))
title('Reconstructed RGB Image')
```

Inverse 2-D Haar Transform of Image Limited to Specified Level

Obtain the 2-D Haar transform of an image limiting the transform to 2 levels.

Load and view the image of a cameraman.

```
im = imread('cameraman.tif');  
imagesc(im)
```

Obtain the 2-D Haar transform using the default maximum number of levels.

```
[a,h,v,d] = haart2(im);
```

Reconstruct the image using the inverse 2-D Haar transform and view the image. Notice the near-perfect reconstruction.

```
xrec = ihaart2(a,h,v,d);  
imagesc(xrec)
```

Reconstruct and view the image using the inverse 2-D Haar transform, limited to level 2. Level 2 corresponds to the fourth scale because scale is defined as 2^j , where j is the level.

```
xrec1 = ihaart2(a,h,v,d,2);  
imagesc(xrec1)
```

Using fewer levels returns the average of the original image at level 2.

Inverse 2-D Haar Transform of Image Limited to Integer Data

Obtain the 2-D Haar transform of an image limiting the transform to integer data.

Load the image of a cameraman.

```
im = imread('cameraman.tif');
```

Obtain the 2-D Haar transform using the 'integer' flag.

```
[a,h,v,d]=haart2(im,'integer');
```

Reconstruct the image using the inverse 2-D Haar transform and view the image.

```
xrec = ihaart2(a,h,v,d,'integer');  
imagesc(xrec)
```

Use integer data when you need to reduce the amount of memory used compared to noninteger data.

Input Arguments

a — Approximation coefficients

scalar | matrix

Approximation coefficients, specified as a scalar or matrix of coefficients, depending on the level to which the 2-D Haar transform was calculated. **a** is an output from the `haart2` function. Approximation, or scaling, coefficients are a lowpass representation of the input. If **a** and the elements of **h**, **v**, and **d**, are vectors, **xrec** is a vector. If **a** and the elements of **h**, **v**, and **d** are matrices, **xrec** is a matrix, where each column is the inverse 2-D Haar transform of the corresponding columns in **a** and **h**, **v**, or **d**.

Data Types: double

h — Horizontal detail coefficients

matrix | cell array

Horizontal detail coefficients by level, specified as a matrix or cell array of matrices. **h** is an output from the `haart2` function. If **h** is a matrix, the 2-D Haar transform was computed only down to one level coarser in resolution.

Data Types: double

v — Vertical detail coefficients

matrix or | cell array

Vertical detail coefficients by level, specified as a matrix or cell array of matrices. `v` is an output from the `haart2` function. If `v` is a matrix, the 2-D Haar transform was computed only down to one level coarser in resolution.

Data Types: double

d — Diagonal detail coefficients

matrix or | cell array

Diagonal detail coefficients by level, specified as a matrix or cell array of matrices. `d` is an output from the `haart2` function. If `d` is a matrix, the 2-D Haar transform was computed only down to one level coarser in resolution.

Data Types: double

level — Maximum level

0 (default) | nonnegative integer

Maximum level to which to invert the Haar transform, specified as a nonnegative integer. If `h` is a cell array, `level` is less than or equal to `length(h) - 1`. If `h` is a vector or matrix, `level` must equal 0 or be unspecified.

integerflag — Integer-valued data handling

'noninteger' (default) | 'integer'

Integer-valued data handling, specified as either 'noninteger' or 'integer'. 'noninteger' does not preserve integer-valued data in the 2-D Haar transform, and 'integer' preserves it. The 'integer' option applies only if all elements of inputs, `a`, `h`, `v`, and `d`, are integer-valued. The inverse 2-D Haar transform algorithm, however, uses floating-point arithmetic.

Output Arguments**xrec — Inverse 2-D Haar wavelet transform**

matrix

2-D Haar wavelet transform, returned as a matrix.

Data Types: double

Topics

“Haar Transforms for Time Series Data and Images”

Introduced in R2016b

ilwt

Inverse 1-D lifting wavelet transform

Syntax

```
X = ilwt(AD_In_Place,W)
X = ilwt(CA,CD,W)
X = ilwt(AD_In_Place,W,LEVEL)
X = ILWT(CA,CD,W,LEVEL)
X = ilwt(AD_In_Place,W,LEVEL,'typeDEC',typeDEC)
X = ilwt(CA,CD,W,LEVEL,'typeDEC',typeDEC)
```

Description

`ilwt` performs a 1-D lifting wavelet reconstruction with respect to a particular lifted wavelet that you specify.

`X = ilwt(AD_In_Place,W)` computes the reconstructed vector `X` using the approximation and detail coefficients vector `AD_In_Place` obtained by a lifting wavelet reconstruction. `W` is a lifted wavelet name (see `liftwave`).

`X = ilwt(CA,CD,W)` computes the reconstructed vector `X` using the approximation coefficients vector `CA` and detail coefficients vector `CD` obtained by a lifting wavelet reconstruction.

`X = ilwt(AD_In_Place,W,LEVEL)` or `X = ILWT(CA,CD,W,LEVEL)` computes the lifting wavelet reconstruction, at level `LEVEL`.

`X = ilwt(AD_In_Place,W,LEVEL,'typeDEC',typeDEC)` or `X = ilwt(CA,CD,W,LEVEL,'typeDEC',typeDEC)` with `typeDEC = 'w'` or `'wp'` computes the wavelet or the wavelet packet decomposition using lifting, at level `LEVEL`.

Instead of a lifted wavelet name, you may use the associated lifting scheme `LS`: `X = ilwt(...,LS,...)` instead of `X = ILWT(...,W,...)`.

For more information about lifting schemes, see `lsinfo`.

Examples

```
% Start from the Haar wavelet and get the
% corresponding lifting scheme.
lshaar = liftwave('haar');

% Add a primal ELS to the lifting scheme.
els = {'p',[-0.125 0.125],0};
lsnew = addlift(lshaar,els);

% Perform LWT at level 1 of a simple signal.
x = 1:8;
[cA,cD] = lwt(x,lsnew);

% Perform integer LWT of the same signal.
```

```
lshaarInt = liftwave('haar','int2int');  
lsnewInt = addlift(lshaarInt,els);  
[cAint,cDint] = lwt(x,lsnewInt);
```

```
% Invert the two transforms.  
xRec = ilwt(cA,cD,lsnew);  
err = max(max(abs(x-xRec)))
```

```
err =
```

```
4.4409e-016
```

```
xRecInt = ilwt(cAint,cDint,lsnewInt);  
errInt = max(max(abs(x-xRecInt)))
```

```
errInt =
```

```
0
```

lwt

Introduced before R2006a

ilwt2

Inverse 2-D lifting wavelet transform

Syntax

```
X = ilwt2(AD_In_Place,W)
X = ilwt2(CA,CH,CV,CD,W)
X = ilwt2(AD_In_Place,W,LEVEL)
X = ILWT2(CA,CH,CV,CD,W,LEVEL)
X = ilwt2(AD_In_Place,W,LEVEL,'typeDEC',typeDEC)
X = ilwt2(CA,CH,CV,CD,W,LEVEL,'typeDEC',typeDEC)
```

Description

`ilwt2` performs a 2-D lifting wavelet reconstruction with respect to a particular lifted wavelet that you specify.

`X = ilwt2(AD_In_Place,W)` computes the reconstructed matrix `X` using the approximation and detail coefficients matrix `AD_In_Place`, obtained by a lifting wavelet decomposition. `W` is a lifted wavelet name (see `liftwave`).

`X = ilwt2(CA,CH,CV,CD,W)` computes the reconstructed matrix `X` using the approximation coefficients vector `CA` and detail coefficients vectors `CH`, `CV`, and `CD` obtained by a lifting wavelet decomposition.

`X = ilwt2(AD_In_Place,W,LEVEL)` or `X = ILWT2(CA,CH,CV,CD,W,LEVEL)` computes the lifting wavelet reconstruction, at level `LEVEL`.

`X = ilwt2(AD_In_Place,W,LEVEL,'typeDEC',typeDEC)` or `X = ilwt2(CA,CH,CV,CD,W,LEVEL,'typeDEC',typeDEC)` with `typeDEC = 'w'` or `'wp'` computes the wavelet or the wavelet packet decomposition using lifting, at level `LEVEL`.

Instead of a lifted wavelet name, you may use the associated lifting scheme `LS`: `X = ilwt2(...,LS,...)` instead of `X = ilwt2(...,W,...)`.

For more information about lifting schemes, see `lsinfo`.

Examples

```
% Start from the Haar wavelet and get the
% corresponding lifting scheme.
lshaar = liftwave('haar');

% Add a primal ELS to the lifting scheme.
els = {'p',[-0.125 0.125],0};
lsnew = addlift(lshaar,els);

% Perform LWT at level 1 of a simple image.
x = reshape(1:16,4,4);
[cA,cH,cV,cD] = lwt2(x,lsnew);
```

```
% Perform integer LWT of the same image.
lshaarInt = liftwave('haar','int2int');
lsnewInt = addlift(lshaarInt,els);
[cAint,cHint,cVint,cDint] = lwt2(x,lsnewInt);

% Invert the two transforms.
xRec = ilwt2(cA,cH,cV,cD,lsnew);
err = max(max(abs(x-xRec)))

err =

    0

xRecInt = ilwt2(cAint,cHint,cVint,cDint,lsnewInt);
errInt = max(max(abs(x-xRecInt)))

errInt =

    0
```

Tips

If `AD_In_Place` or `cA,cH,cV,cD` are obtained from an indexed image analysis or a truecolor image analysis, they are `m`-by-`n` matrices or `m`-by-`n`-by-3 arrays, respectively.

For more information on image formats, see the `image` and `imfinfo` reference pages.

imlpt

Inverse multiscale local 1-D polynomial transform

Syntax

```
y = imlpt(coefs,T,coefsPerLevel,scalingMoments)
y = imlpt( ____,Name,Value)
```

Description

`y = imlpt(coefs,T,coefsPerLevel,scalingMoments)` returns the inverse multiscale local polynomial 1-D transform (MLPT) of `coefs`. The inputs to `imlpt` must be the outputs of `mlpt`.

`y = imlpt(____,Name,Value)` specifies `mlpt` properties using one or more `Name, Value` pair arguments and the input arguments from the previous syntax.

Examples

Multiscale Local 1-D Polynomial Transform and Inverse Transform

Create a signal with nonuniform sampling and verify good reconstruction when performing the `mlpt` and `imlpt`.

Create and plot a sine wave with non-uniform sampling.

```
timeVector = 0:0.01:1;
sineWave = sin(2*pi*timeVector)';

samplesToErase = randi(100,100,1);
sineWave(samplesToErase) = [];
timeVector(samplesToErase) = [];

figure(1)
plot(timeVector,sineWave,'o')
hold on
```

Perform the multiscale local 1-D polynomial transform (mlpt) on the signal. Visualize the coefficients.

```
[coefs,T,coefsPerLevel,scalingMoments] = mlpt(sineWave,timeVector);
```

```
figure(2)  
stem(coefs)  
title('Wavelet Coefficients')
```

Perform the inverse multiscale local 1-D polynomial transform (`imlpt`) on the coefficients. Visualize the reconstructed signal.

```
y = imlpt(coefs,T,coefsPerLevel,scalingMoments);
```

```
figure(1)  
plot(T,y,'*')  
legend('Original Signal','Reconstructed Signal')  
hold off
```

Look at the total error to verify good reconstruction.

```
reconstructionError = sum(abs(y-sineWave))
```

```
reconstructionError = 1.7552e-15
```

Specify Nondefault Dual Moments

Specify nondefault dual moments by using the `m\lpt` function. Compare the results of analysis and synthesis using the default and nondefault dual moments.

Create an input signal and visualize it.

```
T = (1:16)';  
x = T.^2;  
plot(x)  
hold on
```

Perform the forward and inverse transform for the input signal using the default and nondefault dual moments.

```
[w2,t2,nj2,scalingmoments2] = mlpt(x,T);
y2 = imlpt(w2,t2,nj2,scalingmoments2);

[w3,t3,nj3,scalingmoments3] = mlpt(x,T,'dualmoments',3);
y3 = imlpt(w3,t3,nj3,scalingmoments3,'dualmoments',3);
```

Plot the reconstructed signal and verify perfect reconstruction using both the default and nondefault dual moments.

```
plot(y2,'o')
plot(y3,'*')
legend('Original Signal', ...
       'DualMoments = 3', ...
       'DualMoments = 2 (Default)');

fprintf('\nMean Reconstruction Error:\n');
Mean Reconstruction Error:
fprintf(' - Nondefault dual moments: %0.2f\n',mean(abs(y3-x)));
- Nondefault dual moments: 0.00
fprintf(' - Default dual moments: %0.2f\n\n',mean(abs(y2-x)));
- Default dual moments: 0.00
```

hold off

Input Arguments

coefs — MLPT coefficients

vector | matrix

MLPT coefficients, specified as a vector or matrix of MLPT coefficients returned by the `mlpt` function.

Data Types: double

T — Sampling instants corresponding to output

vector | duration array

Sampling instants corresponding to `y`, specified as a vector or duration array of increasing values returned by the `mlpt` function.

Data Types: double | duration

coefsPerLevel — Coefficients per resolution level

vector

Coefficients per resolution level, specified as a vector containing the number of coefficients at each resolution level in `coefs`. `coefsPerLevel` is an output argument of the `mlpt` function.

The elements of `coefsPerLevel` are organized as follows:

- `coefsPerLevel(1)` — Number of approximation coefficients at the coarsest resolution level.
- `coefsPerLevel(i)` — Number of detail coefficients at resolution level i , where $i = \text{numLevel} - i + 2$ for $i = 2, \dots, \text{numLevel} + 1$. `numLevel` is the number of resolution levels used to calculate the MLPT. `numLevel` is inferred from `coefsPerLevel`: `numLevel = length(coefsPerLevel) - 1`.

The smaller the index i , the lower the resolution. The MLPT is two times redundant in the number of detail coefficients, but not in the number of approximation coefficients.

Data Types: `double`

scalingMoments — Scaling function moments

matrix

Scaling function moments, specified as a `length(coefs)`-by- P matrix, where P is the number of primal moments specified by the MLPT.

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'DualMoments', 3` computes a transform using three dual vanishing moments.

DualMoments — Number of dual vanishing moments

2 (default) | 3 | 4

Number of dual vanishing moments in the lifting scheme, specified as the comma-separated pair consisting of `'DualMoments'` and 2, 3 or 4. The number of dual moments must match the number used by `mLpt`.

Data Types: `double`

Output Arguments

y — Reconstructed signal

vector | matrix

Reconstructed signal, returned as a vector or matrix, depending on the inputs to the `mLpt` function.

Data Types: `double`

Algorithms

Maarten Jansen developed the theoretical foundation of the multiscale local polynomial transform (MLPT) and algorithms for its efficient computation [1][2][3]. The MLPT uses a lifting scheme, wherein a kernel function smooths fine-scale coefficients with a given bandwidth to obtain the coarser resolution coefficients. The `mLpt` function uses only local polynomial interpolation, but the technique developed by Jansen is more general and admits many other kernel types with adjustable bandwidths [2].

Smoothing Nonuniformly Sampled Data

Introduced in R2017a

imodwpt

Inverse maximal overlap discrete wavelet packet transform

Syntax

```
xrec = imodwpt(coefs)
xrec = imodwpt(coefs,wname)
xrec = imodwpt(coefs,lo,hi)
```

Description

`xrec = imodwpt(coefs)` returns the inverse maximal overlap discrete wavelet packet transform (inverse MODWPT), in `xrec`. The inverse transform is for the terminal node coefficient matrix (`coefs`) obtained using `modwpt` with the default length 18 Fejér-Korovkin ('fk18') wavelet.

`xrec = imodwpt(coefs,wname)` returns the inverse MODWPT using the orthogonal filter specified by `wname`. This filter must be the same filter used in `modwpt`.

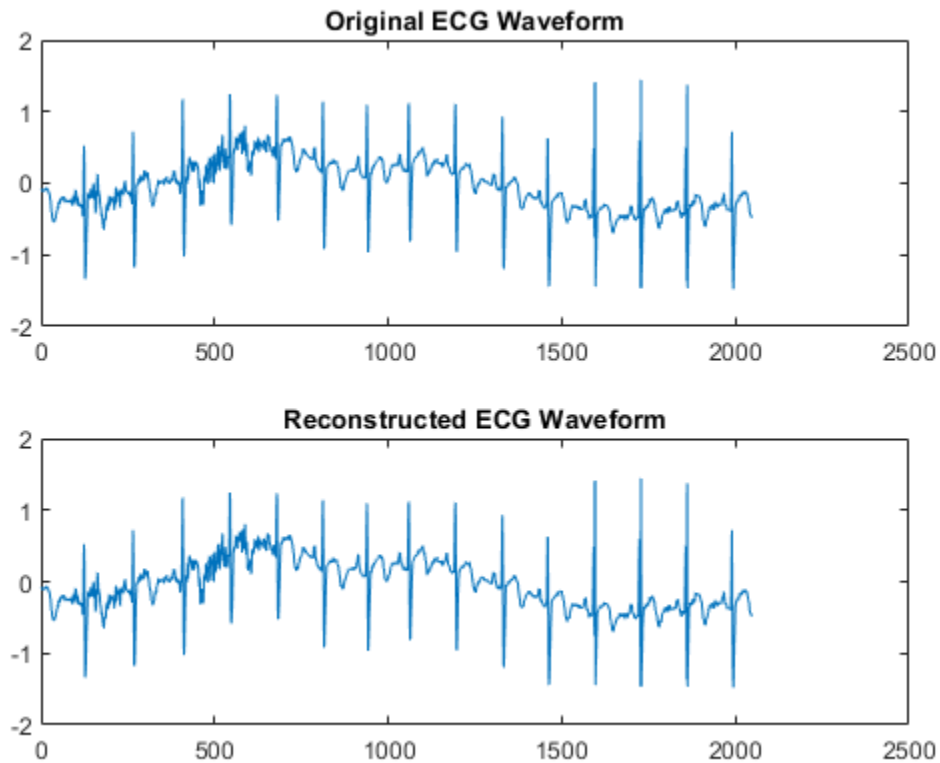

`xrec = imodwpt(coefs,lo,hi)` returns the inverse MODWPT using the orthogonal scaling filter, `lo`, and wavelet filter, `hi`.

Examples

Perfect Reconstruction with the Inverse MODWPT

Obtain the MODWPT of an ECG waveform and demonstrate perfect reconstruction using the inverse MODWPT.

```
load wecg;
wpt = modwpt(wecg);
xrec = imodwpt(wpt);
subplot(2,1,1)
plot(wecg);
title('Original ECG Waveform');
subplot(2,1,2)
plot(xrec);
title('Reconstructed ECG Waveform');
```

Find the largest absolute difference between the original signal and the reconstruction. The difference is on the order of 10^{-11} , which demonstrates perfect reconstruction.

```
max(abs(wecg-xrec'))
ans = 1.7902e-11
```

Inverse MODWPT Using Daubechies Extremal Phase Wavelet

Obtain the MODWPT of Southern Oscillation Index data using the Daubechies extremal phase wavelet with two vanishing moments ('db2'). Reconstruct the signal using the inverse MODWPT.

```
load soi;
wsoi = modwpt(soi,'db2');
xrec = imodwpt(wsoi,'db2');
```

Inverse MODWPT Using Scaling and Wavelet Filters

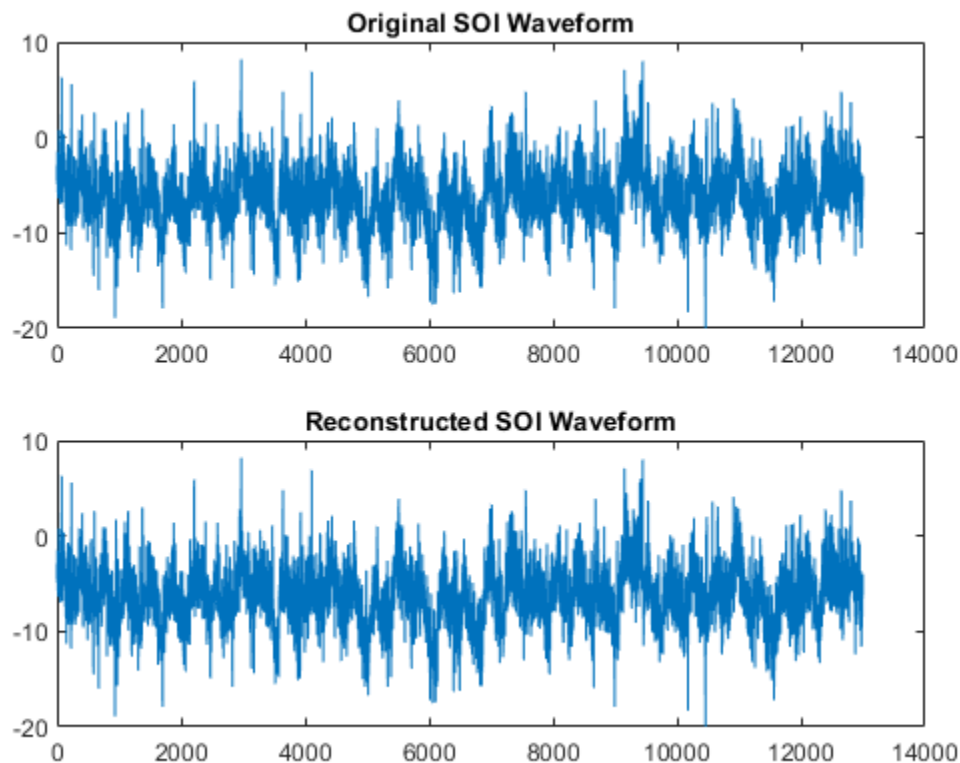

Obtain the MODWPT of Southern Oscillation Index data using specified scaling and wavelets filters with the Daubechies extremal phase wavelet with two vanishing moments ('db2').

```
load soi;
[lo,hi] = wfilters('db2');
```

```
wpt = modwpt(soi,lo,hi);
xrec = imodwpt(wpt,lo,hi);
```

Plot the original SOI waveform and the reconstructed waveform.

```
subplot(2,1,1)
plot(soi)
title('Original SOI Waveform');
subplot(2,1,2)
plot(xrec)
title('Reconstructed SOI Waveform')
```

Input Arguments

coefs — Terminal node coefficients

matrix

Terminal node coefficients of a wavelet packet tree, specified as a matrix. You must obtain the coefficient matrix from `modwpt` using the `'FullTree', false` option. `'FullTree', false` is the default value of `modwpt`.

Data Types: double

wname — Synthesizing wavelet filter

fk18 (default) | character vector | string scalar

Synthesizing wavelet filter used to invert the MODWPT, specified as a character vector or string scalar. The specified wavelet must be the same wavelet as used in the analysis with `modwpt`.

lo — Scaling filter

even-length real-valued vector

Scaling filter, specified as an even-length real-valued vector. `lo` must be the same scaling filter as used in the analysis with `modwpt`. You cannot specify both a scaling-wavelet filter pair and a `wname` filter.

hi — Wavelet filter

even-length real-valued vector

Wavelet filter, specified as an even-length real-valued vector. `hi` must be the same wavelet filter used in the analysis with `modwpt`. You cannot specify both a scaling-wavelet filter pair and a `wname` filter.

Output Arguments

xrec — Inverse maximal overlap discrete wavelet packet transform

row vector

Inverse maximal overlap discrete wavelet packet transform, returned as a row vector. The inverse transform is the reconstructed version of the original signal based on the MODWPT terminal node coefficients. `xrec` has the same number of columns as the input `coefs` matrix.

Introduced in R2016a

imodwt

Inverse maximal overlap discrete wavelet transform

Syntax

```
xrec = imodwt(w)
xrec = imodwt(w,wname)
xrec = imodwt(w,Lo,Hi)
xrec = imodwt( ____,lev)
xrec = imodwt( ____, 'reflection')
```

Description

`xrec = imodwt(w)` returns in `xrec` a reconstructed version of the signal. The reconstructed signal is based on `w`, the maximal overlap discrete wavelet transform (MODWT) coefficients and on the level of reconstruction, which defaults to zero.

`xrec = imodwt(w,wname)` reconstructs the signal using `wname`, the orthogonal wavelet. `wname` must be the same wavelet used to analyze the signal input to `modwt`. The reconstruction is up to level 0, which is a perfect reconstruction of the original signal.

`xrec = imodwt(w,Lo,Hi)` reconstructs the signal using the orthogonal scaling filter `Lo` and the wavelet filter `Hi`. The `Lo` and `Hi` filters must be the same filters used to analyze the signal input to `modwt`. The reconstruction is up to level 0, which is a perfect reconstruction of the original signal.

`xrec = imodwt(____,lev)` reconstructs the signal up to level `lev`. `xrec` is a projection onto the scaling space at level `lev`.

`xrec = imodwt(____, 'reflection')` uses the reflection boundary condition in the reconstruction. If you specify 'reflection', `imodwt` assumes that the length of the original signal length is one half the number of columns in the input coefficient matrix. By default, `imodwt` assumes periodic signal extension at the boundary.

Examples

Perfect Reconstruction with the Inverse MODWT

Obtain the MODWT of an ECG signal and demonstrate perfect reconstruction.

Load the ECG signal data and obtain the MODWT.

```
load wecg;
```

Obtain the MODWT and the Inverse MODWT.

```
w = modwt(wecg);
xrec = imodwt(w);
```

Use the L-infinity norm to show that the difference between the original signal and the reconstruction is extremely small. The largest absolute difference between the original signal and the reconstruction is on the order of 10^{-12} , which demonstrates perfect reconstruction.

```
norm(abs(xrec' -wecg), Inf)
ans = 2.3253e-12
```

Inverse MODWT with Specified Wavelet

Obtain the MODWT of Deutsche Mark-U.S. Dollar exchange rate data and demonstrate perfect reconstruction.

Load the Deutsche Mark-U.S. Dollar exchange rate data.

```
load DM_USD;
```

Obtain the MODWT and the Inverse MODWT using the 'db2' wavelet.

```
wdm = modwt(DM_USD, 'db2');
xrec = imodwt(wdm, 'db2');
```

Use the L-infinity norm to show that the difference between the original signal and the reconstruction is extremely small. The largest absolute difference between the original signal and the reconstruction is on the order of 10^{-13} , which demonstrates perfect reconstruction.

```
norm(abs(xrec' -DM_USD), Inf)
ans = 1.6362e-13
```

Inverse MODWT with Specified Filters

Obtain the MODWT of an ECG signal using the Fejer-Korovkin filters.

Load the ECG data.

```
load wecg;
```

Create the 8-coefficient Fejer-Korovkin filters.

```
[Lo,Hi] = wfilters('fk8');
```

Obtain the MODWT and Inverse MODWT.

```
wtecg = modwt(wecg,Lo,Hi);
xrec = imodwt(wtecg,Lo,Hi);
```

Plot the original data and the reconstruction.

```
subplot(2,1,1)
plot(wecg)
title('ECG Signal');
```

```
subplot(2,1,2)
plot(xrec)
title('Reconstruction')
```

Obtain Projection onto Scaling Space

Obtain the MODWT of an ECG signal down to the maximum level and obtain the projection of the ECG signal onto the scaling space at level 3.

Load the ECG data.

```
load wecg;
```

Obtain the MODWT.

```
wtecg = modwt(wecg);
```

Obtain the projection of the ECG signal onto V_3 , the scaling space at level three by using the `imodwt` function.

```
v3proj = imodwt(wtecg,3);
```

Plot the original signal and the projection.

```
subplot(2,1,1)
plot(wecg)
```

```
title('Original Signal')
subplot(2,1,2)
plot(v3proj)
title('Projection onto V3')
```

Note that the spikes characteristic of the R waves in the ECG are missing in the V_3 approximation. You can see the missing details by examining the wavelet coefficients at level three.

Plot the level-three wavelet coefficients.

```
figure
plot(wtecg(3,:))
title('Level-Three Wavelet Coefficients')
```

Inverse MODWT with Reflection Boundary

Obtain the inverse MODWT using reflection boundary handling for Southern Oscillation Index data. The sampling period is one day. `imodwt` with the `'reflection'` option assumes that the input matrix, which is the `modwt` output, is twice the length of the original signal length. `imodwt` reflection boundary handling reduces the number of wavelet and scaling coefficients at each scale by half.

```
load soi;
wsoi = modwt(soi,4,'reflection');
xrecsoi = imodwt(wsoi,'reflection');
```

Use the L-infinity norm to show that the difference between the original signal and the reconstruction is extremely small. The largest absolute difference between the original signal and the reconstruction is on the order of 10^{-11} , which demonstrates perfect reconstruction.

```
norm(abs(xrecsoi'-soi),Inf)
ans = 1.6433e-11
```

Input Arguments

w — MODWT transform matrix

MODWT transform, specified as a matrix of size $L+1$ -by- N . w is the output of `modwt`, which is the MODWT of an N -point input signal down to level L . By default, `imodwt` assumes that you obtained the MODWT using the 'sym4' wavelet with periodic boundary handling.

Data Types: `double`

wname — Synthesis wavelet

'sym4' (default) | 'dbN' | 'coifN' | 'haar' | 'fkN' | 'symN'

Synthesis wavelet, specified as one of the following:

- 'haar' — Haar wavelet
- 'dbN' — Extremal phase Daubechies wavelet with N vanishing moments, where N is a positive integer from 1 to 45.
- 'symN' — Symlets wavelet with N vanishing moments, where N is a positive integer from 2 to 45.
- 'coifN' — Coiflets wavelet with N vanishing moments, where N is a positive integer from 1 to 5.
- 'fkN' — Fejér-Korovkin wavelet with N coefficients, where $N = 4, 6, 8, 14, 18$ and 22 .

The synthesis wavelet must be the same wavelet used in the analysis with `modwt`.

Lo — Scaling filter

even-length real-valued vector

Scaling filter, specified as an even-length real-valued vector. You can specify `Lo` only if you do not specify `wname`. `Lo` must be the same scaling filter used in the analysis with `modwt`.

Hi — Wavelet filter

even-length real-valued vector

Wavelet filter, specified as an even-length real-valued vector. You can specify `Hi` only if you do not specify `wname`. `Hi` must be the same wavelet filter used in the analysis with `modwt`.

lev — Reconstruction level

0 (default) | nonnegative integer

Reconstruction level, specified as a nonnegative integer between 0 and `size(w,1)-2`. The level must be less than the level used to obtain w from `modwt`. If `lev` is 0 and you do not modify the coefficients, `imodwt` produces a perfect reconstruction of the signal.

Output Arguments**xrec — Reconstructed signal**

row vector

Reconstructed version of the original signal based on the MODWT and the level of reconstruction, returned as a row vector.

Introduced in R2015b

ind2depo

Node index to node depth-position

Syntax

```
[D,P] = ind2depo(ORD,[D P])
```

Description

ind2depo is a tree-management utility.

For a tree of order ORD , $[D,P] = \text{ind2depo}(ORD,N)$ computes the depths D and the positions P (at these depths D) for the nodes with indices N .

The nodes are numbered from left to right and from top to bottom. The root index is 0.

N must be a column vector of integers ($N \geq 0$).

Note that $[D,P] = \text{ind2depo}(ORD,[D P])$.

Examples

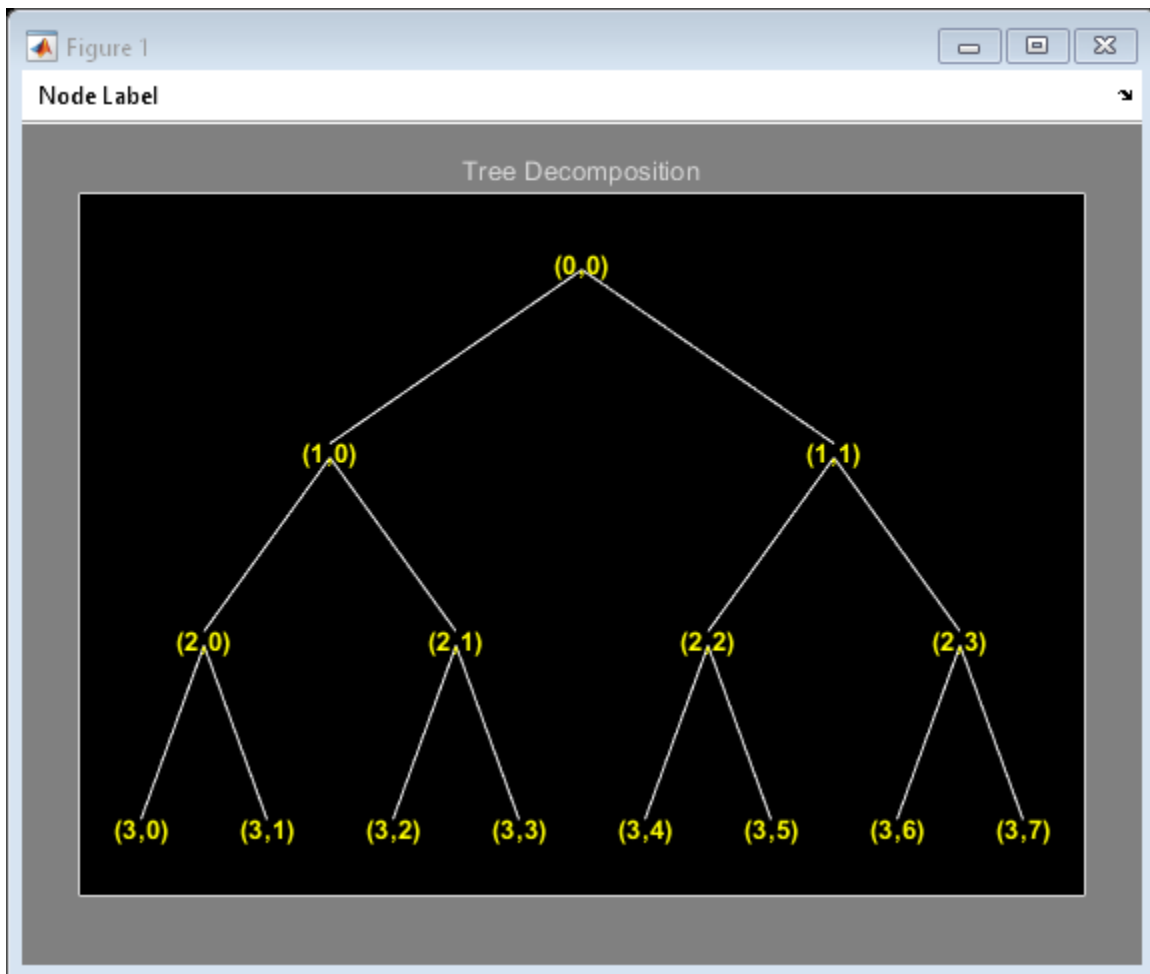

Depth and Position in Wavelet Packet Tree

Create a binary wavelet packet tree with three levels.

```
Ord = 2;  
Lev = 3;  
T = ntree(Ord,Lev);
```

Plot the binary wavelet packet tree.

```
plot(T)
```

Obtain the indices of the nodes in linear order.

```
idx = allnodes(T);
```

Convert the indices to depth-position format.

```
[depth,pos] = ind2depo(Ord,idx);
table(depth,pos)
```

```
ans=15x2 table
    depth    pos
    _____
    0         0
    1         0

intwave

Integrate wavelet function ψ (ψ)

Syntax

```
[INTEG,XVAL] = intwave('wname',PREC)
[INTDEC,XVAL,INTREC] = intwave('wname',PREC)
[INTEG,XVAL] = intwave('wname',PREC)
[INTEG,XVAL] = intwave('wname',PREC,0)
[INTEG,XVAL] = intwave('wname')
[INTEG,XVAL] = intwave('wname',8)
intwave('wname',IN2,IN3), PREC = max(IN2,IN3)
intwave('wname',0)
intwave('wname',8,IN3)
intwave('wname')
intwave('wname',8)
```

Description

[INTEG,XVAL] = intwave('wname',PREC) computes the integral, INTEG, of the wavelet function ψ (from $-\infty$ to XVAL values): $\int_{-\infty}^x \psi(y)dy$ for x in XVAL.

The function ψ is approximated on the 2^{PREC} points grid XVAL where *PREC* is a positive integer. 'wname' is a character vector containing the name of the wavelet ψ (see *wfilters* for more information).

Output argument *INTEG* is a real or complex vector depending on the wavelet type.

For biorthogonal wavelets,

[INTDEC,XVAL,INTREC] = intwave('wname',PREC) computes the integrals, INTDEC and INTREC, of the wavelet decomposition function ψ_{dec} and the wavelet reconstruction function ψ_{rec} .

[INTEG,XVAL] = intwave('wname',PREC) is equivalent to [INTEG,XVAL] = intwave('wname',PREC,0).

[INTEG,XVAL] = intwave('wname') is equivalent to [INTEG,XVAL] = intwave('wname',8).

When used with three arguments intwave('wname',IN2,IN3), $\text{PREC} = \max(\text{IN2}, \text{IN3})$ and plots are given.

When IN2 is equal to the special value 0, intwave('wname',0) is equivalent to intwave('wname',8,IN3).

intwave('wname') is equivalent to intwave('wname',8).

intwave is used only for continuous analysis (see *cwt* for more information).

Examples

```
% Set wavelet name.
wname = 'db4';

% Plot wavelet function.
[phi,psi,xval] = wavefun(wname,7);
subplot(211); plot(xval,psi); title('Wavelet');

% Compute and plot wavelet integrals approximations
% on a dyadic grid.
[integ,xval] = intwave(wname,7);
subplot(212); plot(xval,integ);
title(['Wavelet integrals over [-Inf x] ' ...
      'for each value of xval']);
```

Algorithms

First, the wavelet function is approximated on a grid of 2^{PREC} points using `wavefun`. A piecewise constant interpolation is used to compute the integrals using `cumsum`.

`wavefun`

Introduced before R2006a

isBiorthogonal

Determine if DWT filter bank is biorthogonal

Syntax

```
tf = isBiorthogonal(fb)
tf = isBiorthogonal(fb,tol)
```

Description

`tf = isBiorthogonal(fb)` returns `true` if the discrete wavelet transform (DWT) filter bank `fb` is a biorthogonal filter bank and `false` otherwise.

To determine if a DWT filter bank is orthogonal, use `isOrthogonal`.

`tf = isBiorthogonal(fb,tol)` uses the positive real-valued tolerance `tol` to determine the biorthogonality of the filter bank `fb`. `tol` is a small positive number in the interval $(0, 10^{-2}]$. If unspecified, `tol` defaults to 10^{-5} .

Examples

Biorthogonality Test of DWT Filter Bank

Check whether a filter bank is biorthogonal.

```
fb = dwtfilterbank('Wavelet','bior4.4');
isBiorthogonal(fb)
```

```
ans = logical
      1
```

Input Arguments

fb — Discrete wavelet transform filter bank

dwtfilterbank object

Discrete wavelet transform (DWT) filter bank, specified as a dwtfilterbank object.

tol — Tolerance

10^{-5} (default) | positive scalar

Tolerance to use to determine biorthogonality of the filter bank, specified as a positive scalar in the interval $(0, 10^{-2}]$. The sum of both scaling filters must be within `tol` of $\sqrt{2}$ and the sum of both wavelet filters must be less than `tol`.

See Also

dwtfilterbank | isOrthogonal

Introduced in R2018a

isheart2

Inverse shearlet transform

Syntax

```
imrec = isheart2(sls,cfs)
```

Description

`imrec = isheart2(sls,cfs)` returns the inverse shearlet transform or shearlet synthesis based on the shearlet system `sls` and the shearlet transform coefficients `cfs`. The `isheart2` function assumes `sls` is the same shearlet system used to obtain the transform coefficients `cfs`.

Examples

Perfect Reconstruction of Shearlet Transform

Load an image and create a shearlet system that can be applied to the image.

```
load shapes
[numRows,numCols] = size(shapes);
sls = shearletSystem('ImageSize',[numRows numCols],'NumScales',4)

sls =
    shearletSystem with properties:
```

```
    ImageSize: [512 512]
    NumScales: 4
    PreserveEnergy: 0
    TransformType: 'real'
    FilterBoundary: 'periodic'
    Precision: 'double'
```

Obtain the shearlet coefficients of the image.

```
cfs = sheart2(sls,shapes);
```

Take the inverse transform of the coefficients. Check for perfect reconstruction.

```
imrec = isheart2(sls,cfs);
norm(imrec-shapes,'fro')

ans = 8.2562e-14
```

Input Arguments

sls — Shearlet system
shearletSystem object

Shearlet system, specified as a `shearletSystem` object.

cfs — Shearlet transform coefficients

3-D array

Shearlet transform coefficients, specified as a real- or complex-valued 3-D array. The 3-D array `cfs` is an M -by- N -by- K matrix where M and N are equal to the row and column dimensions of the original image. The size of the third dimension, K , is equal to the number of shearlets including the lowpass filter, $K = \text{numshears}(sls) + 1$.

The `isheart2` function assumes `sls` is the same shearlet system used to obtain the transform coefficients `cfs`.

Data Types: `single` | `double`

Complex Number Support: Yes

Output Arguments

imrec — Inverse shearlet transform

real-valued matrix

Inverse shearlet transform or shearlet synthesis, based on the shearlet system `sls` and the shearlet transform coefficients `cfs`. The size of `imrec` is equal to the size of the original image. The data type of `imrec` matches the Precision value of the shearlet system.

Data Types: `single` | `double`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Introduced in R2019b

isnode

Existing node test

Syntax

```
R = isnode(T,N)
```

Description

isnode is a tree-management utility.

$R = \text{isnode}(T,N)$ returns 1's for nodes N , which exist in the tree T , and 0's for others.

N can be a column vector containing the indices of nodes or a matrix, that contains the depths and positions of nodes.

In the last case, $N(i,1)$ is the depth of the i -th node and $N(i,2)$ is the position of the i -th node.

The nodes are numbered from left to right and from top to bottom. The root index is 0.

Examples

```
% Create initial tree.
ord = 2;
t = ntree(ord,3);    % binary tree of depth 3.
t = nodejoin(t,5);
t = nodejoin(t,4);
plot(t)
```

```
% Change Node Label from Depth_Position to Index
% (see the plot function).
```

```
% Check node index.  
isnode(t,[1;3;25])
```

```
ans =  
    1  
    1  
    0
```

```
% Check node Depth_Position.  
isnode(t,[1 0;3 1;4 5])

isOrthogonal

Determine if DWT filter bank is orthogonal

Syntax

```
tf = isOrthogonal(fb)
tf = isOrthogonal(fb,tol)
```

Description

`tf = isOrthogonal(fb)` returns `true` if the discrete wavelet transform (DWT) filter bank `fb` is an orthogonal filter bank and `false` otherwise.

To determine if a DWT filter bank is biorthogonal, use `isBiorthogonal`.

`tf = isOrthogonal(fb,tol)` uses the positive real-valued tolerance `tol` to determine the orthogonality of the filter bank `fb`. `tol` is a small positive number in the interval $(0,10^{-2}]$. If unspecified, `tol` defaults to 10^{-5} .

Examples

Orthogonality Test of DWT Filter Bank

Create a DWT filter bank using the Daubechies `db6` wavelet. Confirm the filter bank is orthogonal.

```
fb = dwtfilterbank('Wavelet','db6');
isOrthogonal(fb)
```

```
ans = logical
     1
```

Plot the time-domain and centered scaling functions for each level in the filter bank.

```
[phi,t] = scalingfunctions(fb);
psi = wavelets(fb);
plot(t,phi')
grid on
xlim([-200 200])
title('Scaling Functions')
```

Confirm the scaling functions have norm square equal to 1.

```
sum(phi.^2,2)
```

```
ans = 6×1
```

```

1.0000  
1.0000  
1.0000  
1.0000  
1.0000
```

Plot the time-domain and centered wavelets corresponding to the wavelet passband filters.

```
plot(t,psi')  
grid on  
xlim([-200 200])  
title('Wavelets')
```

Confirm the wavelets have norm square equal to 1.

```
sum(psi.^2,2)
```

```
ans = 6×1
```

```
1.0000
1.0000
1.0000
1.0000
1.0000
1.0000
```

Input Arguments

fb — Discrete wavelet transform filter bank

dwtfilterbank object

Discrete wavelet transform (DWT) filter bank, specified as a dwtfilterbank object.

tol — Tolerance

10^{-5} (default) | positive scalar

Tolerance to use to determine orthogonality of the filter bank, specified as a positive scalar in the interval $(0,10^{-2}]$.

istnode

Terminal nodes indices test

Syntax

`R = istnode(T,N)`

Description

`istnode` is a tree-management utility.

`R = istnode(T,N)` returns ranks (in left to right terminal nodes ordering) for terminal nodes N belonging to the tree T , and 0's for others.

N can be a column vector containing the indices of nodes or a matrix that contains the depths and positions of nodes.

In the last case, $N(i, 1)$ is the depth of the i -th node and $N(i, 2)$ is the position of the i -th node.

The nodes are numbered from left to right and from top to bottom. The root index is 0.

Examples

```
% Create initial tree.
ord = 2;
t = ntree(ord,3); % binary tree of depth 3.
t = nodejoin(t,5);
t = nodejoin(t,4);
plot(t)
```

```
% Change Node Label from Depth_Position to Index
% (see the plot function)x.
```

```
% Find terminal nodes and return indices for terminal  
% nodes in the tree.
```

```
istnode(t,[14])
```

```
ans =  
    6
```

```

iswt

Inverse discrete stationary wavelet transform 1-D

Syntax

```
X = iswt(SWC, 'wname')
X = iswt(SWA, SWD, 'wname')
X = iswt(SWA(end, :), SWD, 'wname')
X = iswt(SWC, Lo_R, Hi_R)
X = iswt(SWA, SWD, Lo_R, Hi_R)
X = iswt(SWA(end, :), SWD, Lo_R, Hi_R)
```

Description

`iswt` performs a multilevel 1-D stationary wavelet reconstruction using either an orthogonal or a biorthogonal wavelet. Specify the wavelet using its name (`'wname'`, see `wfilters` for more information) or its reconstruction filters (`Lo_R` and `Hi_R`).

`X = iswt(SWC, 'wname')` or `X = iswt(SWA, SWD, 'wname')` or `X = iswt(SWA(end, :), SWD, 'wname')` reconstructs the signal `X` based on the multilevel stationary wavelet decomposition structure `SWC` or `[SWA, SWD]` (see `swt` for more information).

`X = iswt(SWC, Lo_R, Hi_R)` or `X = iswt(SWA, SWD, Lo_R, Hi_R)` or `X = iswt(SWA(end, :), SWD, Lo_R, Hi_R)` reconstruct as above, using filters that you specify.

- `Lo_R` is the reconstruction low-pass filter.
- `Hi_R` is the reconstruction high-pass filter.

`Lo_R` and `Hi_R` must be the same length.

Examples

Multilevel Stationary Wavelet Reconstruction

Demonstrate perfect reconstruction using `swt` and `iswt` with a biorthogonal wavelet.

```
load noisbloc
[Lo_D, Hi_D, Lo_R, Hi_R] = wfilters('bior3.5');
[swa, swd] = swt(noisbloc, 3, Lo_D, Hi_D);
recon = iswt(swa, swd, Lo_R, Hi_R);
norm(noisbloc-recon)

ans = 1.1386e-13
```

X = iswt2(A(:,:,1,:),H,V,D, 'wname')
```

Description

`iswt2` performs a multilevel 2-D stationary wavelet reconstruction using either an orthogonal or a biorthogonal wavelet. Specify the wavelet using its name (`'wname'`, see `wfilters` for more information) or its reconstruction filters (`Lo_R` and `Hi_R`).

`X = iswt2(SWC, 'wname')` or `X = iswt2(A,H,V,D,wname)` reconstructs the signal `X`, based on the multilevel stationary wavelet decomposition structure `SWC` or `[A,H,V,D]` (see `swt2`).

If multilevel stationary wavelet decomposition structure `SWC` or `[A,H,V,D]` was generated from a 2-D matrix, the syntax `X = iswt2(A(:,:,end),H,V,D, 'wname')` reconstructs the signal `X`.

If the stationary wavelet decomposition structure `SWC` or `[A,H,V,D]` was generated from a single level stationary wavelet decomposition of a 3-D matrix, `X = iswt2(A(:,:,1,:),H,V,D, 'wname')` reconstructs the signal `X`.

`X = iswt2(SWC,Lo_R,Hi_R)` or `X = iswt2(A,H,V,D,Lo_R,Hi_R)` or `X = iswt2(A(:,:,end),H,V,D,Lo_R,Hi_R)` or `X = iswt2(A(:,:,1,:),H,V,D, 'wname')` reconstructs as in the previous syntax, using filters that you specify:

- `Lo_R` is the reconstruction low-pass filter.
- `Hi_R` is the reconstruction high-pass filter.

`Lo_R` and `Hi_R` must be the same length.

Note

- `iswt2` synthesizes `X` from the coefficient arrays generated by `swt2`. `swt2` uses double-precision arithmetic internally and returns double-precision coefficient matrices. `swt2` warns if there is a loss of precision when converting to double.
- To distinguish a single-level decomposition of a truecolor image from a multilevel decomposition of an indexed image, the approximation and detail coefficient arrays of truecolor images are 4-D arrays. See “Distinguish Single-Level Truecolor Image from Multilevel Indexed Image Decompositions” on page 1-629. Also see examples “Stationary Wavelet Transform of an Image” on page 1-622 and “Inverse Stationary Wavelet Transform of an Image” on page 1-626.

If an K-level decomposition is performed, the dimensions of the A, H, V, and D coefficient arrays are m-by-n-by-3-by-K.

If a single-level decomposition is performed, the dimensions of the A, H, V, and D coefficient arrays are m-by-n-by-1-by-3. Since MATLAB removes singleton last dimensions by default, the third dimension of the coefficient arrays is singleton.

Examples

Multilevel Two-Dimensional Stationary Wavelet Reconstruction

Demonstrate perfect reconstruction using `swt2` and `iswt2` with an orthogonal wavelet.

```
load woman
[Lo_D,Hi_D,Lo_R,Hi_R] = wfilters('db6');
[ca,chd,cvd,cdd] = swt2(X,3,Lo_D,Hi_D);
recon = iswt2(ca,chd,cvd,cdd,Lo_R,Hi_R);
norm(X-recon)

ans = 1.0126e-08
```

Stationary Wavelet Transform of an Image

In this example you obtain single-level and multilevel stationary wavelet decompositions of a truecolor image. You view results of each decomposition.

Load in a truecolor image. The image is a 3-D array of type `uint8`. Since `swt2` requires the first and second dimensions both be divisible by a power of 2, extract a portion of the image and view it.

```
imdata = imread('ngc6543a.jpg');
x = imdata(1:512,1:512,:);
imagesc(x)
```

Obtain the 4-level stationary wavelet decomposition of the image using the db4 wavelet. Return the approximation coefficients and the horizontal, vertical, and detail coefficients as separate arrays. Note the dimensions of the output arrays.

```
[a,h,v,d] = swt2(x,4,'db4');
size(a)
```

```
ans = 1×4
```

```
512 512 3 4
```

```
size(h)
```

```
ans = 1×4
```

```
512 512 3 4
```

```
size(v)
```

```
ans = 1×4
```

```
512 512 3 4
```

```
size(d)
```

```
ans = 1×4
```

```
512 512 3 4
```

The output arrays are all of type `double`. View the level 2 approximation coefficients. Since the approximation coefficients are of type `double`, cast them as `uint8`, which is the datatype of the image.

```
figure
imagesc(uint8(a(:,:,2)))
title('Level 2 Approximation Coefficients')
```

Reconstruct the image by performing the inverse transform. Compute the difference between the original image and reconstruction. Since the reconstruction is of type `double`, cast the reconstruction as type `uint8` before computing the difference.

```
rec = iswt2(a,h,v,d,'db4');
maxdiff = max(abs(uint8(rec(:))-x(:)));
disp(['maximum difference = ' num2str(maxdiff)])
```

```
maximum difference = 0
```

Obtain the single-level stationary wavelet decomposition of the image using the `db4` wavelet. Return the approximation coefficients and horizontal, vertical, and detail coefficients in separate arrays. Note the dimensions of the output arrays.

```
[a,h,v,d] = swt2(x,1,'db4');
size(a)
```

```
ans = 1×4
    512    512     1     3
```

```
size(h)
```

```
ans = 1×4
    512    512     1     3
```

```
size(v)
```

```
ans = 1×4
    512    512     1     3
```

```
size(d)
```

```
ans = 1×4
    512    512     1     3
```

View the approximation coefficients. To prevent an error when using `imagesc`, squeeze the approximation coefficients array to remove the singleton dimension.

```
asqueeze = squeeze(a);
size(asqueeze)
```

```
ans = 1×3
    512    512     3
```

```
figure
imagesc(uint8(asqueeze))
title('Approximation Coefficients')
```

Reconstruct the image by performing the inverse transform. Compute the difference between the original image and reconstruction. Since the reconstruction is of type `double`, cast the reconstruction as type `uint8` before computing the difference.

```
rec = iswt2(a,h,v,d,'db4');
maxdiff = max(abs(uint8(rec(:))-x(:)));
disp(['maximum difference = ' num2str(maxdiff)])

maximum difference = 0
```

Inverse Stationary Wavelet Transform of an Image

This example shows how to reconstruct a truecolor image from a single-level stationary wavelet decomposition using 3-D approximation and detail coefficient arrays.

Load in a truecolor image. The image is a 3-D array of type `uint8`. Since `swt2` requires the first and second dimensions both be divisible by a power of 2, extract a portion of the image and view it.

```
imdata = imread('ngc6543a.jpg');
x = imdata(1:512,1:512,:);
imagesc(x)
```

Obtain the single-level stationary wavelet decomposition of the image using the db4 wavelet. Return the approximation coefficients and horizontal, vertical, and detail coefficients in separate arrays. Note the dimensions of the output arrays.

```
[a,h,v,d] = swt2(x,1,'db4');
size(a)
```

```
ans = 1×4
```

```
512 512 1 3
```

```
size(h)
```

```
ans = 1×4
```

```
512 512 1 3
```

```
size(v)
```

```
ans = 1×4
```

```
512 512 1 3
```

```
size(d)
```

```
ans = 1×4
```

```
512 512 1 3
```

Squeeze the coefficient arrays to remove their singleton dimensions. Note the dimensions of the squeezed arrays.

```
asq = squeeze(a);  
hsq = squeeze(h);  
vsq = squeeze(v);  
dsq = squeeze(d);  
size(asq)
```

```
ans = 1×3
```

```
512 512 3
```

```
size(hsq)
```

```
ans = 1×3
```

```
512 512 3
```

```
size(vsq)
```

```
ans = 1×3
```

```
512 512 3
```

```
size(dsq)
```

```
ans = 1×3
```

```
512 512 3
```

So that `iswt2` can properly reconstruct the true image from the new coefficient arrays, insert a singleton dimension by reshaping the squeezed arrays. Reconstruct the image with the reshaped coefficient arrays.

```
a2 = reshape(asq, [512,512,1,3]);  
h2 = reshape(hsq, [512,512,1,3]);  
v2 = reshape(vsq, [512,512,1,3]);  
d2 = reshape(dsq, [512,512,1,3]);  
rec = iswt2(a2,h2,v2,d2, 'db4');
```

Compute the difference between the original image and reconstruction. Since the reconstruction is of type `double`, cast the reconstruction as type `uint8` before computing the difference.

```
maxdiff = max(abs(uint8(rec(:))-x(:)));  
disp(['maximum difference = ' num2str(maxdiff)])
```

```
maximum difference = 0
```

Tips

If SWC or (cA,cH,cV,cD) are obtained from an indexed image analysis or a truecolor image analysis, then X is an m-by-n matrix or an m-by-n-by-3 array, respectively.

For more information on image formats, see the `image` and `imfinfo` reference pages.

Compatibility Considerations

Distinguish Single-Level Truecolor Image from Multilevel Indexed Image Decompositions *Behavior changed in R2017b*

To distinguish a single-level decomposition of a truecolor image from a multilevel decomposition of an indexed image, the approximation and detail coefficient arrays of truecolor images are 4-D arrays.

Migrate from Previous Releases to R2017b

Depending on the original input data type and level of wavelet decomposition, you might have to take different steps to make `swt2` coefficient arrays from previous releases compatible with R2017b coefficient arrays. The steps depend on whether you have a single coefficient array or separate approximation and detail coefficient arrays.

Single Coefficient Array	Multiple Coefficient Arrays
Input: Index image <ul style="list-style-type: none"> Single-level: No compatibility issues Multi-level: No compatibility issues 	Input: Index image <ul style="list-style-type: none"> Single-level: No compatibility issues Multi-level: No compatibility issues
Input: Truecolor image <ul style="list-style-type: none"> Single-level: If <code>swc</code> is the output of <code>swt2</code> from a previous release, execute: <pre>swc1 = double(swc);</pre> Multi-level: If <code>swc</code> is the output of <code>swt2</code> from a previous release, execute: <pre>swc1 = double(swc);</pre> 	Input: Truecolor image <ul style="list-style-type: none"> Single-level: If <code>ca</code>, <code>chd</code>, <code>cvd</code>, and <code>cdd</code> are outputs of <code>swt2</code> from a previous release, execute: <pre>ca1 = double(ca); chd1 = double(chd); cvd1 = double(cvd); cdd1 = double(cdd); ca2 = reshape(ca1,[m,n,1,3]); chd2 = reshape(chd1,[m,n,1,3]); cvd2 = reshape(cvd1,[m,n,1,3]); cdd2 = reshape(cdd1,[m,n,1,3]);</pre> Multi-level: If <code>ca</code>, <code>chd</code>, <code>cvd</code>, and <code>cdd</code> are outputs of <code>swt2</code> from a previous release, execute: <pre>ca1 = double(ca); chd1 = double(chd); cvd1 = double(cvd); cdd1 = double(cdd);</pre>

Migrate from R2017b to Previous Releases

Depending on the original input data type and level of wavelet decomposition, you might have to take different steps to make R2017b `swt2` coefficient arrays compatible with the coefficient arrays from previous releases. The steps depend on whether you have a single coefficient array or separate approximation and detail coefficient arrays.

Single Coefficient Array	Multiple Coefficient Arrays
Input: Index image <ul style="list-style-type: none"> • Single-level: No compatibility issues • Multi-level: No compatibility issues 	Input: Index image <ul style="list-style-type: none"> • Single-level: No compatibility issues • Multi-level: No compatibility issues
Input: Truecolor image <ul style="list-style-type: none"> • Single-level: No compatibility issues • Multi-level: No compatibility issues 	Input: Truecolor image <ul style="list-style-type: none"> • Single-level: If <code>ca</code>, <code>chd</code>, <code>cvd</code>, and <code>cdd</code> are outputs of <code>swt2</code> from R2017b, execute: <pre style="margin-left: 20px;"> ca1 = single(squeeze(ca)); chd1 = single(squeeze(chd)); cvd1 = single(squeeze(cvd)); cdd1 = single(squeeze(cdd)); </pre> • Multi-level: No compatibility issues

`idwt2` | `swt2` | `waverec2`

Introduced before R2006a

iwsst

Inverse wavelet synchrosqueezed transform

Syntax

```
xrec = iwsst(sst)
xrec = iwsst(sst,f,freqrange)
xrec = iwsst(sst,iridge)
xrec = iwsst( __ ,wav)
xrec = iwsst( __ ,iridge,'NumFrequencyBins',numBins)
```

Description

`xrec = iwsst(sst)` inverts the input synchrosqueezed transform, `sst`, and returns the inverse in vector `xrec`. To obtain the `sst` input, use the `wsst` function. The `iwsst` function assumes that you obtain `sst` using the analytic Morlet wavelet.

Note The wavelet transform does not preserve a nonzero mean. After inverting the synchrosqueezed transform, you must add back the original signal mean.

`xrec = iwsst(sst,f,freqrange)` inverts the synchrosqueezed transform for a specified range of frequencies, `freqrange`, contained in the frequency vector, `f`. The frequency vector, `f`, is the output of `wsst`.

`xrec = iwsst(sst,iridge)` inverts the synchrosqueezed transform along the time-frequency ridges specified by `iridge`, the index column vector. `iridge` is the output of `wsstridge`. The `xrec` output is the same size as `iridge`.

`xrec = iwsst(__ ,wav)` uses the analytic wavelet specified by `wav` to invert the synchrosqueezed transform. This wavelet must be the same wavelet as used in `wsst`. You can include any of the input arguments from previous syntaxes.

`xrec = iwsst(__ ,iridge,'NumFrequencyBins',numBins)` returns the inverse synchrosqueezed transform with `numBins`-many additional frequency bins included on either side of each `iridge` index bin.

Examples

Inverse Synchrosqueezed Transform of Chirp

Obtain the wavelet synchrosqueezed transform of a quadratic chirp using default values. Then reconstruct the signal using the inverse wavelet synchrosqueezed transform.

```
load quadchirp;
sst = wsst(quadchirp);
xrec = iwsst(sst);
```

Synchrosqueezed and Inverse Synchrosqueezed Transform of Chirp

Obtain the wavelet synchrosqueezed transform of a quadratic chirp sampled at 1000 Hz. Then reconstruct the chirp.

Load the chirp and obtain the synchrosqueezed transform.

```
load quadchirp;  
sstchirp = wsst(quadchirp, 'ExtendSignal', true);
```

Extract the maximum energy time-frequency ridge and reconstruct the signal mode along the ridge.

```
[~,iridge] = wsstridge(sstchirp);  
xrec = iwsst(sstchirp,iridge);
```

Plot and zoom in on the original and reconstructed signal.

```
plot(tquad,xrec, 'r');  
hold on;  
plot(tquad,quadchirp, 'b--');  
xlabel('Time'); ylabel('Amplitude');  
set(gca, 'ylim', [-1.5 1.5]);  
legend('Reconstruction', 'Original');  
grid on;  
title('Reconstruction of Chirp Along Maximum Time-Frequency Ridge');  
zoom xon  
zoom(50)
```

Inverse Synchrosqueezed Transform of Range of Frequencies

Obtain the inverse synchrosqueezed transform for a specified frequency range of a two-component signal. The input is a combination of an amplitude-modulated and a frequency-modulated signal.

Create the signal.

```
t = 0:0.001:0.1;
x1 = (2+0.5*cos(2*pi*10*t)).*cos(2*pi*200*t+10*sin(2*pi*5*t));
x2 = cos(2*pi*50*t);
sig = x1+x2;
```

Obtain the wavelet synchrosqueezed transform and plot the resulting two frequency components.

```
[sst,f] = wssst(sig,1000,'ExtendSignal',true);
contour(t,f,abs(sst));
grid on;
title('Wavelet Synchrosqueezed Transform');
ylabel('Frequency');
xlabel('Time');
hold on
plot(t,140*ones(size(t)),'r--');
plot(t,260*ones(size(t)),'r--');
```

Obtain the inverse synchrosqueezed transform for frequencies from 140 Hz to 260 Hz. Plot the result.

```

xrec = iwsst(sst,f,[140,260]);
subplot(2,1,1);
plot(t,x1);
title('Original Signal');
subplot(2,1,2);
plot(t,xrec,'r');
title('Reconstructed Signal');

```

Synchrosqueezed and Inverse Synchrosqueezed Transform of Speech Signal

Obtain the wavelet synchrosqueezed transform and inverse synchrosqueezed transform of a speech sample using the bump wavelet.

Load the speech signal and obtain the synchrosqueezed transform and inverse synchrosqueezed transform.

```

load mtlb
dt = 1/Fs;
t = 0:dt:numel(mtlb)*dt-dt;
Txmtlb = wssst(mtlb,'bump');
xrec = iwsst(Txmtlb,'bump');

```

Obtain the L-infinity norm of the difference between the original waveform and the reconstruction. Plot the results.

```

Linf = norm(abs(mtlb-xrec),Inf);
plot(t,mtlb)
hold on
xlabel('Seconds')
ylabel('Amplitude')
plot(t,xrec,'r')
title({'Reconstruction of Wavelet Synchrosqueezed Transform';...
      ['Largest Absolute Difference: ' num2str(Linf,'%1.2f')]])

```

Synchrosqueezed Transform Using Specified Number of Bins for Chirp

This example shows how to invert the wavelet synchrosqueezed transform using a specified number of frequency bins for a quadratic chirp. The chirp is sampled at 1000 Hz.

```

load quadchirp;
sstchirp = wssst(quadchirp,'ExtendSignal',true);

```

Extract the maximum energy time-frequency ridge using 10 bins on each side of the iridge index and reconstruct the signal mode along the ridge.

```

[~,iridge] = wsstridge(sstchirp);
xrec = iwsst(sstchirp,iridge,'NumFrequencyBins',10);

```

Plot the original and reconstructed signal.

```

plot(tquad,xrec,'r');
hold on;
plot(tquad,quadchirp,'b--');
xlabel('Time'); ylabel('Amplitude');
set(gca,'ylim',[-1.5 1.5]);
legend('Reconstruction','Original');
grid on;
title('Reconstruction of Chirp Along Maximum Time-Frequency Ridge');

```

Input Arguments

sst — Synchrosqueezed transform

matrix

Synchrosqueezed transform, specified as a matrix. `sst` is the output from the `wsst` function.

f — Synchrosqueezed transform frequencies

vector

Synchrosqueezed transform frequencies corresponding to the rows of the synchrosqueezed transform, specified as a vector. The number of elements in the frequency vector is equal to the number of rows in the `sst` input. If you specify `f`, you must also specify `freqrange`.

freqrange — Frequency range

two-element vector

Frequency range for which to return inverse synchrosqueezed transform values, specified as a two-element vector. The values of `freqrange` must be in the range of the values of the frequencies, `f`. The first and second elements of `freqrange` define the start and end of the frequency range, where the frequency values in that range must be positive and strictly increasing. If you specify `freqrange`, you must also specify `f`.

`iridge` — Time-frequency ridge row indices

vector or matrix

Time-frequency ridge row indices of the synchrosqueezed transform specified as a vector or matrix. `iridge` is the output of the `wsstridge` function. If `iridge` is a matrix, `iwsst` inverts the synchrosqueezed transform along the first column of `iridge`. Then, it iteratively reconstructs along subsequent columns of `iridge`. The sizes of `iridge` and the `xrec` output are the same.

`wav` — Analytic wavelet

'amor' (default) | 'bump'

Analytic wavelet used to compute the inverse synchrosqueezed transform, specified as one of the following:

- 'amor' — Analytic Morlet wavelet
- 'bump' — Bump wavelet

You must use the same wavelet in the reconstruction that you used to compute the synchrosqueezed transform, `sst`.

`numBins` — Number of additional frequency bins

16 (default) | positive integer

Number of additional frequency bins to include on either side of each `iridge` index bin, specified as a positive integer. If the number of additional bins exceeds the number of frequency bins available at a particular time step, `iwsst` truncates the reconstruction at the first or last frequency bin. The default, 16, is one half the default number of voices per octave.

To specify this argument, you also specify `iridge`, which is the output of `wsstridge`. You cannot include a frequency `f` and frequency range `freqrange`, if you include the number of frequency bins.

Output Arguments

`xrec` — Inverse synchrosqueezed transform

vector or matrix

Inverse synchrosqueezed transform, returned as a vector or matrix. If you do not specify an `iridge` input, `xrec` is a column vector with the same number of rows as `sst`. If you specify an `iridge` input, `xrec` is the same size as `iridge`.

labelDefinitionsHierarchy

Get hierarchical list of label and sublabel names

Syntax

```
str = labelDefinitionsHierarchy(lbldefs)
str = labelDefinitionsHierarchy(lss)
```

Description

`str = labelDefinitionsHierarchy(lbldefs)` returns a character array with a hierarchical list of label and sublabel names contained in `lbldefs`, a vector of `signalLabelDefinition` objects.

`str = labelDefinitionsHierarchy(lss)` returns a character array with a hierarchical list of label and sublabel names contained in the `labeledSignalSet` object `lss`.

Examples

Label Hierarchy

Load a labeled signal set containing recordings of whale songs.

```
load whales
lss

lss =
    labeledSignalSet with properties:

        Source: {2x1 cell}
        NumMembers: 2
        TimeInformation: "sampleRate"
        SampleRate: 4000
        Labels: [2x3 table]
        Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

Visualize the label hierarchy of the set.

```
labelDefinitionsHierarchy(lss)
```

```
ans =
    'WhaleType
      Sublabels: []
    MoanRegions
      Sublabels: []
    TrillRegions
      Sublabels: TrillPeaks
    ,
```

Input Arguments

lbldefs — Signal label definitions

signalLabelDefinition object | vector of signalLabelDefinition objects

Signal label definitions, specified as a signalLabelDefinition object or a vector of signalLabelDefinition objects.

Example:

```
signalLabelDefinition("Asleep", 'LabelType', 'roi', 'LabelDataType', 'logical')  
can label a region of a signal in which a patient is asleep.
```

lss — Labeled signal set

labeledSignalSet object

Labeled signal set, specified as a labeledSignalSet object.

Example: `labeledSignalSet({randn(100,1)
randn(10,1)}, signalLabelDefinition('female'))` specifies a two-member set of random signals containing the attribute 'female'.

Output Arguments

str — List of label and sublabel names

character array

List of label and sublabel names, returned as a character array.

See Also

labeledSignalSet | signalLabelDefinition

Introduced in R2018b

labelDefinitionsSummary

Get summary table of signal label definitions

Syntax

```
T = labelDefinitionsSummary(lbldefs)
T = labelDefinitionsSummary(lss)

T = labelDefinitionsSummary( ___, lblname)
T = labelDefinitionsSummary( ___, lblname, 'sublbls')
```

Description

`T = labelDefinitionsSummary(lbldefs)` returns a table, `T`, with the properties of the label definitions contained in `lbldefs`, a vector of `signalLabelDefinition` objects.

`T = labelDefinitionsSummary(lss)` returns a table, `T`, with the properties of the label definitions contained in the `labeledSignalSet` object `lss`.

`T = labelDefinitionsSummary(___, lblname)` returns a table with the properties of the label `lblname`.

`T = labelDefinitionsSummary(___, lblname, 'sublbls')` returns a table of the properties of the sublabels defined for `lblname`.

Examples

Label Properties

Load a labeled signal set containing recordings of whale songs.

```
load whales
lss

lss =
    labeledSignalSet with properties:
        Source: {2x1 cell}
        NumMembers: 2
        TimeInformation: "sampleRate"
        SampleRate: 4000
        Labels: [2x3 table]
        Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

Visualize the label properties of the set.

```

Input Arguments

lbldefs — Signal label definitions

signalLabelDefinition object | vector of signalLabelDefinition objects

Signal label definitions, specified as a signalLabelDefinition object or a vector of signalLabelDefinition objects.

Example:

```
signalLabelDefinition("Asleep",'LabelType','roi','LabelDataType','logical')
```

can label a region of a signal in which a patient is asleep.

lss — Labeled signal set

labeledSignalSet object

Labeled signal set, specified as a labeledSignalSet object.

Example: labeledSignalSet({randn(100,1)
randn(10,1)},signalLabelDefinition('female')) specifies a two-member set of random signals containing the attribute 'female'.

lblname — Label or sublabel name

character vector | string scalar | cell array of character vectors | string array

Label or sublabel name. To specify a label, use a character vector or a string scalar. To specify a sublabel, use a two-element cell array of character vectors or a two-element string array:

- The first element is the name of the parent label.
- The second element is the name of the sublabel.

Example: `signalLabelDefinition("Asleep", 'LabelType', 'roi')` specifies a label of name "Asleep" for a region of a signal in which a patient is asleep during a clinical trial.

Example: `{ 'Asleep' 'REM' }` or `["Asleep" "REM"]` specifies a region of a signal in which a patient undergoes REM sleep.

Output Arguments

T – Summary table

table

Summary table with the properties of a label.

See Also

`labeledSignalSet` | `signalLabelDefinition`

Introduced in R2018b

labeledSignalSet

Create labeled signal set

Description

Use `labeledSignalSet` to store labeled signals along with the label definitions. Create signal label definitions using `signalLabelDefinition`.

Creation

Syntax

```
lss = labeledSignalSet
```

```
lss = labeledSignalSet(src)
```

```
lss = labeledSignalSet(src,lbldefs)
```

```
lss = labeledSignalSet(src,lbldefs,'MemberNames',mnames)
```

```
lss = labeledSignalSet(src,lbldefs,Name,Value)
```

Description

`lss = labeledSignalSet` creates an empty labeled signal set. Use `addMembers` to add signals to the set. Use `addLabelDefinitions` to add label definitions to the set.

`lss = labeledSignalSet(src)` creates a labeled signal set for the input data source `src`. Use `addLabelDefinitions` to add label definitions to the set.

`lss = labeledSignalSet(src,lbldefs)` creates a labeled signal set for the input data source `src` using the signal label definitions `lbldefs`. Use `signalLabelDefinition` to create signal label definitions.

`lss = labeledSignalSet(src,lbldefs,'MemberNames',mnames)` creates a labeled signal set for the input data source `src` and specifies names for the members of the set. Use `setMemberNames` to modify the member names. `lbldefs` is optional.

`lss = labeledSignalSet(src,lbldefs,Name,Value)` sets “Properties” on page 1-645 using name-value pairs. You can specify multiple name-value pairs. Enclose each property name in quotes. `lbldefs` is optional.

Input Arguments

src — Input data source

matrix | cell array | timetable | audio datastore

Input data source, specified as a matrix, a timetable, a cell array, or an audio datastore. `src` specifies the number of members of the set, the number of signals in each member, and the data in each signal.

lbldefs — Label definitionsvector of `signalLabelDefinition` objectsLabel definitions, specified as a vector of `signalLabelDefinition` objects.**mnames — Member names**

character vector | string scalar | cell array of character vectors | string array

Member names, specified as a character vector, a string scalar, a cell array of character vectors, or a string array.

Example: `labeledSignalSet({randn(100,1) randn(10,1)}, 'MemberNames', {'llama' 'alpaca'})` specifies a set of random signals with two members, 'llama' and 'alpaca'.**Properties****Description — Labeled signal set description**

character vector | string scalar

Labeled signal set description, specified as a character vector or string scalar.

Example: 'Description', 'Sleep test patients by sex and age'

Data Types: `char` | `string`**SampleRate — Sample rate values**

positive scalar | vector

This property is read-only.

Sample rate values, specified as a positive scalar or a vector. This property is valid only when the data source does not contain inherent time information.

- Set `SampleRate` to a positive numeric scalar to specify the same sample rate for all signals in the labeled set.
- Set `SampleRate` to a vector to specify that each member of the labeled set has signals sampled at the same rate, but the sample rates differ from member to member. The vector must have a number of elements equal to the number of members of the set. If a member of a set has signals with different sample rates, then specify the sample rates using timetables.

Example: 'SampleRate', [1e2 1e3] specifies that the signals in the first member of a set are sampled at a rate of 100 Hz and the signals in the second member are sampled at 1 kHz.

SampleTime — Sample time values

positive scalar | vector | duration scalar | duration vector

This property is read-only.

Sample time values, specified as a positive scalar, a vector, a `duration` scalar, or a `duration` vector. This property is valid only when the data source does not contain inherent time information.

- Set `SampleTime` to a numeric or `duration` scalar to specify the same sample time for all signals in the labeled set.
- Set `SampleTime` to a numeric or `duration` vector to specify that each member of the labeled set has signals with the same time interval between samples, but the intervals differ from member to

member. The vector must have a number of elements equal to the number of members of the set. If a member of a set has signals with different sample times, then specify the sample times using timetables.

Example: `'SampleTime',seconds([1e-2 1e-3])` specifies that the signals in the first member of a set have 0.01 second between samples, and the signals in the second member have 1 millisecond between samples.

TimeValues — Time values

vector | duration vector | matrix | cell array

This property is read-only.

Time values, specified as a vector, a duration vector, a matrix, or a cell array. This property is valid only when the data source does not contain inherent time information. Time values must be unique and increasing.

- Set `TimeValues` to a numeric or duration vector to specify the same time values for all signals in the labeled set. The vector must have the same length as all the signals in the set.
- Set `TimeValues` to a numeric or duration matrix or cell array to specify that each member of the labeled set has signals with the same time values, but the time values differ from member to member.
 - If `TimeValues` is a matrix, then it must have a number of columns equal to the number of members of the set. All signals in the set must have a length equal to the number of rows of the matrix.
 - If `TimeValues` is a cell array, then it must contain a number of vectors equal to the number of members of the set. All signals in a member must have a length equal to the number of elements of the corresponding vector in the cell array.

If a member of a set has signals with different time values, then specify the time values using timetables.

Example: `'TimeValues',[1:1000;0:1/500:2-1/500]'` specifies that the signals in the first member of a set are sampled 1 Hz for 1000 seconds. The signals in the second member are sampled at 500 Hz for 2 seconds.

Example: `'TimeValues',seconds([1:1000;0:1/500:2-1/500])'` specifies that the signals in the first member of a set are sampled 1 Hz for 1000 seconds. The signals in the second member are sampled at 500 Hz for 2 seconds.

Example: `'TimeValues',{1:1000,0:1/500:2-1/500}` specifies that the signals in the first member of a set are sampled 1 Hz for 1000 seconds. The signals in the second member are sampled at 500 Hz for 2 seconds.

Example: `'TimeValues',{seconds(1:1000),seconds(0:1/500:2-1/500)}` specifies that the signals in the first member of a set are sampled 1 Hz for 1000 seconds. The signals in the second member are sampled at 500 Hz for 2 seconds.

NumMembers — Number of members in set

positive integer

This property is read-only.

Number of members in set, specified as a positive integer.

Labels — Labels table

table

This property is read-only.

Labels table, specified as a MATLAB table. Each variable of `Labels` corresponds to a label defined for the set. Each row of `Labels` corresponds to a member of the data source. The row names of `Labels` are the member names.

Data Types: table

TimeInformation — Time information of source

'none' | 'sampleRate' | 'sampleTime' | 'timeValues' | 'inherent'

Time information of source, specified as one of the following:

- 'none' — The signals in the source have no time information.
- 'sampleRate' — The signals in the source are sampled at a specified rate.
- 'sampleTime' — The signals in the source have a specified time interval between samples.
- 'timeValues' — The signals in the source have a time value corresponding to each sample.
- 'inherent' — The signals in the source contain inherent time information. MATLAB timetables are an example of such signals.

Data Types: char | string

Source — Data source of labeled signal set

matrix | cell array | timetable

This property is read-only.

Data source of labeled signal set, specified as a matrix, a timetable, a cell array, or an audio datastore.

- If `Source` is a numeric matrix, then the labeled signal set has one member that contains a number of signals equal to the number of matrix columns.

Example: `labeledSignalSet(randn(10,3))` has one member that contains three 10-sample signals.

- If `Source` is a cell array of matrices, then the labeled signal set has a number of members equal to the number of matrices in the cell array. Each member contains a number of signals equal to the number of columns of the corresponding matrix.

Example: `labeledSignalSet({randn(10,3),randn(17,9)})` has two members. The first member contains three 10-sample signals. The second member contains nine 17-sample signals.

- If `Source` is a cell array, and each element of the cell array is a cell array of numeric vectors, then the labeled signal set has a number of members equal to the number of cell array elements. Each signal within a member can have any length.

Example: `labeledSignalSet({{randn(10,1)},{randn(17,1),randn(27,1)}})` has two members. The first member contains one 10-sample signal. The second member contains a 17-sample signal and a 27-sample signal.

- If `Source` is a timetable with variables containing numeric values, then the labeled signal set has one member that contains a number of signals equal to the number of variables. The time values of the timetable must be of type `duration`, unique, and increasing.

Example: `labeledSignalSet(timetable(seconds(1:10)', randn(10,3)))` has one member that contains three signals sampled at 1 Hz for 10 seconds.

- If `Source` is a cell array of timetables, and each timetable has an arbitrary number of variables with numeric values, then the labeled signal set has a number of members equal to the number of timetables. Each member contains a number of signals equal to the number of variables in the corresponding timetable.

Example:

`labeledSignalSet({timetable(seconds(1:10)', randn(10,3)), timetable(seconds(1:5)', randn(5,13))})` has two members. The first member contains three signals sampled at 1 Hz for 10 seconds. The second member contains 13 signals sampled at 1 Hz for 5 seconds.

- If `Source` is a cell array, and each element of the cell array is a cell array of timetables, then the labeled signal set has a number of members equal to the number of cell array elements. Each member can have any number of timetables, and each timetable within a member can have any number of variables.

Example:

`labeledSignalSet({{timetable(seconds(1:10)', randn(10,3)), timetable(seconds(1:7)', randn(7,2))}, {timetable(seconds(1:3)', randn(3,1))})` has two members. The first member contains three signals sampled at 1 Hz for 10 seconds and two signals sampled at 1 Hz for 7 seconds. The second member contains one signal sampled at 1 Hz for 3 seconds.

- If the input data source, `src`, is an audio datastore, then the labeled signal set has a number of members equal to the number of files to which the datastore points. The `Source` property contains a cell array of character vectors with the file names. Each member contains all the signals returned by the read of the corresponding datastore file.

Object Functions

<code>addLabelDefinitions</code>	Add label definitions to labeled signal set
<code>addMembers</code>	Add members to labeled signal set
<code>editLabelDefinition</code>	Edit label definition properties
<code>getLabelDefinitions</code>	Get label definitions in labeled signal set
<code>getLabeledSignal</code>	Get labeled signals from labeled signal set
<code>getLabelNames</code>	Get label names in labeled signal set
<code>getLabelValues</code>	Get label values from labeled signal set
<code>getMemberNames</code>	Get member names in labeled signal set
<code>getSignal</code>	Get signals from labeled signal set
<code>head</code>	Get top rows of labels table
<code>labelDefinitionsHierarchy</code>	Get hierarchical list of label and sublabel names
<code>labelDefinitionsSummary</code>	Get summary table of signal label definitions
<code>merge</code>	Merge two or more labeled signal sets
<code>removeLabelDefinition</code>	Remove label definition from labeled signal set
<code>removeMembers</code>	Remove members from labeled signal set
<code>removePointValue</code>	Remove row from point label
<code>removeRegionValue</code>	Remove row from ROI label
<code>resetLabelValues</code>	Reset labels to default values
<code>setLabelValue</code>	Set label value in labeled signal set
<code>setMemberNames</code>	Set member names in labeled signal set

subset Get new labeled signal set with subset of members

Examples

Label Definitions for Whale Songs

Consider a set of whale sound recordings. The recorded whale sounds consist of trills and moans. You want to look at each signal and label it to identify the whale type, the trill regions, and the moan regions. For each trill region, you also want to label the signal peaks higher than a certain threshold.

Signal Label Definitions

Define an attribute label to store whale types. The possible categories are blue whale, humpback whale, and white whale.

```
dWhaleType = signalLabelDefinition('WhaleType',...
    'LabelType','attribute',...
    'LabelDataType','categorical',...
    'Categories', ["blue" "humpback" "white"],...
    'Description','Whale type');
```

Define a region-of-interest (ROI) label to capture moan regions. Define another ROI label to capture trill regions.

```
dMoans = signalLabelDefinition('MoanRegions',...
    'LabelType','roi',...
    'LabelDataType','logical',...
    'Description','Regions where moans occur');
```

```
dTrills = signalLabelDefinition('TrillRegions',...
    'LabelType','roi',...
    'LabelDataType','logical',...
    'Description','Regions where trills occur');
```

Finally, define a point label to capture the trill peaks. Set this label as a sublabel of the dTrills definition.

```
dTrillPeaks = signalLabelDefinition('TrillPeaks',...
    'LabelType','point',...
    'LabelDataType','numeric',...
    'Description','Trill peaks');
```

```
dTrills.Sublabels = dTrillPeaks;
```

Labeled Signal Set

Create a labeledSignalSet with the whale signals and the label definitions. Add label values to identify the whale type, the moan and trill regions, and the peaks of the trills.

```
load labelwhalesignals
lbldefs = [dWhaleType dMoans dTrills];

lss = labeledSignalSet({whale1 whale2},lbldefs,...
    'SampleRate',Fs,'Description','Characterize wave song regions');
```

Visualize the label hierarchy and label properties using `labelDefinitionsHierarchy` and `labelDefinitionsSummary`.

```
labelDefinitionsHierarchy(lss)
```

```
ans =
  WhaleType
    Sublabels: []
  MoanRegions
    Sublabels: []
  TrillRegions
    Sublabels: TrillPeaks
  ,
```

```
labelDefinitionsSummary(lss)
```

```
ans=3x9 table
  LabelName      LabelType      LabelDataType      Categories      ValidationFunction      Defa
_____
"WhaleType"     "attribute"    "categorical"     {3x1 string}    {"N/A"  }              {0x0
"MoanRegions"   "roi"         "logical"         {"N/A"  }        {0x0 double}          {0x0
"TrillRegions"  "roi"         "logical"         {"N/A"  }        {0x0 double}          {0x0
```

The signals in the loaded data correspond to songs of two blue whales. Set the 'WhaleType' values for both signals.

```
setLabelValue(lss,1,'WhaleType','blue');
setLabelValue(lss,2,'WhaleType','blue');
```

Visualize the 'Labels' property. The table has the newly added 'WhaleType' values for both signals.

```
lss.Labels
```

```
ans=2x3 table
           WhaleType      MoanRegions      TrillRegions
_____
Member{1}  blue          {0x2 table}    {0x3 table}
Member{2}  blue          {0x2 table}    {0x3 table}
```

Visualize Regions and Points

Visualize the whale songs to identify the trill and moan regions.

```
subplot(2,1,1)
plot((0:length(whale1)-1)/Fs,whale1)
ylabel('Whale 1')
hold on

subplot(2,1,2)
plot((0:length(whale2)-1)/Fs,whale2)
ylabel('Whale 2')
hold on
```

Add the moan and trill regions to the labeled set. For ROI labels, specify the ROI limits in seconds and the label values. Label the different regions in the plots using an auxiliary function.

```

moanRegionsWhale1 = [6.1 7.7; 11.4 13.1; 16.5 18.1];
setLabelValue(lss,1,'MoanRegions',moanRegionsWhale1,[true true true]);

trillRegionWhale1 = [1.4 3.1];
setLabelValue(lss,1,'TrillRegions',trillRegionWhale1,true);

subplot(2,1,1)
labelIntervals([moanRegionsWhale1;trillRegionWhale1])

moanRegionsWhale2 = [2.5 3.5; 5.8 8; 15.4 16.7];
setLabelValue(lss,2,'MoanRegions',moanRegionsWhale2,[true true true]);

trillRegionWhale2 = [11.1 13];
setLabelValue(lss,2,'TrillRegions',trillRegionWhale2,true);

subplot(2,1,2)
labelIntervals([moanRegionsWhale2;trillRegionWhale2])

```

Label three peaks for each trill region. For point labels, you specify the point locations and the label values. In this example, the point locations are in seconds.

```

peakLocsWhale1 = [1.553 1.626 1.7];
peakValsWhale1 = [0.211 0.254 0.211];

setLabelValue(lss,1,["TrillRegions" "TrillPeaks"],...
    peakLocsWhale1,peakValsWhale1,'LabelRowIndex',1);

subplot(2,1,1)
plot(peakLocsWhale1,peakValsWhale1,'v')
hold off

peakLocsWhale2 = [11.214 11.288 11.437];
peakValsWhale2 = [0.119 0.14 0.15];

setLabelValue(lss,2,["TrillRegions" "TrillPeaks"],...
    peakLocsWhale2,peakValsWhale2,'LabelRowIndex',1);

subplot(2,1,2)
plot(peakLocsWhale2,peakValsWhale2,'v')
hold off

```

Explore Label Values

Explore the label values using `getLabelValues`.

```
getLabelValues(lss)
```

ans=2x3 table

	WhaleType	MoanRegions	TrillRegions
Member{1}	blue	{3x2 table}	{1x3 table}
Member{2}	blue	{3x2 table}	{1x3 table}

Retrieve the moan regions for the first member of the labeled set.

```

signalLabelDefinition

Introduced in R2018b

laurmat

Laurent matrices constructor

Syntax

`M = laurmat(V)`

Description

`M = laurmat(V)` returns the Laurent matrix object `M` associated with `V` which can be a cell array (at most two dimensional) of Laurent polynomials (see `laurpoly`) or an ordinary matrix.

Examples

```
% Define Laurent matrices.
M1 = laurmat(eye(2,2))
```

$$M1 = \begin{vmatrix} 1 & 0 \\ 0 & 1 \end{vmatrix}$$

```
Z = laurpoly(1,1);
M2 = laurmat({1 Z;0 1})
```

$$M2 = \begin{vmatrix} 1 & z^{(+1)} \\ 0 & 1 \end{vmatrix}$$

```
% Calculus on Laurent polynomials.
P = M1 * M2
```

$$P = \begin{vmatrix} 1 & z^{(+1)} \\ 0 & 1 \end{vmatrix}$$

```
d = det(P)
```

```
d(z) = 1
```

laurpoly

Introduced before R2006a

laurpoly

Laurent polynomials constructor

Syntax

```
P = laurpoly(C,d)
P = laurpoly(C,'dmin',d)
P = laurpoly(C,'dmax',d)
P = laurpoly(C,d)
```

Description

$P = \text{laurpoly}(C, d)$ returns a Laurent polynomial object. C is a vector whose elements are the coefficients of the polynomial P and d is the highest degree of the monomials of P .

If m is the length of the vector C , P represents the following Laurent polynomial:

$$P(z) = C(1)*z^d + C(2)*z^{(d-1)} + \dots + C(m)*z^{(d-m+1)}$$

$P = \text{laurpoly}(C, 'dmin', d)$ specifies the lowest degree instead of the highest degree of monomials of P . The corresponding output P represents the following Laurent polynomial:

$$P(z) = C(1)*z^{(d+m-1)} + \dots + C(m-1)*z^{(d+1)} + C(m)*z^d$$

$P = \text{laurpoly}(C, 'dmax', d)$ is equivalent to $P = \text{laurpoly}(C, d)$.

Examples

```
% Define Laurent polynomials.
P = laurpoly([1:3],2);
P = laurpoly([1:3],'dmax',2)
```

$$P(z) = + z^{(+2)} + 2*z^{(+1)} + 3$$

```
P = laurpoly([1:3],'dmin',2)
```

$$P(z) = + z^{(+4)} + 2*z^{(+3)} + 3*z^{(+2)}$$

```
% Calculus on Laurent polynomials.
Z = laurpoly(1,1)
```

$$Z(z) = z^{(+1)}$$

$$Q = Z*P$$

$$Q(z) = + z^{(+5)} + 2*z^{(+4)} + 3*z^{(+3)}$$

$$R = Z^1 - Z^{-1}$$

$$R(z) = + z^{(+1)} - z^{(-1)}$$

laurmat

Introduced before R2006a

leaves

Determine terminal nodes

Syntax

```
N = leaves(T)
[N,K] = leaves(T,'sort')
N = leaves(T,'dp')
[N,K] = leaves(T,'sortdp')
[N,K] = leaves(T,'sdp')
```

Description

`N = leaves(T)` returns the indices of terminal nodes of the tree T where N is a column vector.

The nodes are ordered from left to right as in tree T .

`[N,K] = leaves(T,'s')` or `[N,K] = leaves(T,'sort')` returns sorted indices. $M = N(K)$ are the indices reordered as in tree T , from left to right.

`N = leaves(T,'dp')` returns a matrix N , which contains the depths and positions of terminal nodes.

$N(i,1)$ is the depth of the i -th terminal node, and $N(i,2)$ is the position of the i -th terminal node.

`[N,K] = leaves(T,'sortdp')` or `[N,K] = leaves(T,'sdp')` returns sorted nodes.

Examples

```
% Create initial tree.
ord = 2;
t = ntree(ord,3);           % binary tree of depth 3.
t=nodejoin(t,5);
t=nodejoin(t,4);
plot(t)
```

```
% List terminal nodes (index).
tnodes_ind = leaves(t)
tnodes_ind =

liftilt

Apply elementary lifting steps on quadruplet of filters

Syntax

```
[LoDN,HiDN,LoRN,HiRN] = liftilt(LoD,HiD,LoR,HiR,ELS)
liftilt(LoD,HiD,LoR,HiR,ELS,TYPE,VALUE)
```

Description

`[LoDN,HiDN,LoRN,HiRN] = liftilt(LoD,HiD,LoR,HiR,ELS)` returns the four filters LoDN, HiDN, LoRN, and HiRN obtained by an elementary lifting step (ELS) starting from the four filters LoD, HiD, LoR, and HiR. The four input filters verify the perfect reconstruction condition.

ELS is a structure such that

- `TYPE = ELS.type` contains the type of the elementary lifting step. The valid values for TYPE are 'p' (primal) or 'd' (dual).
- `VALUE = ELS.value` contains the Laurent polynomial T associated with the elementary lifting step (see `laurpoly`). If VALUE is a vector, the associated Laurent polynomial T is equal to `laurpoly(VALUE,0)`.

In addition, ELS may be a scaling step. In that case, TYPE is equal to 's' (scaling) and VALUE is a scalar different from zero.

`liftilt(LoD,HiD,LoR,HiR,ELS,TYPE,VALUE)` gives the same outputs.

Note If `TYPE = 'p'`, HiD and LoR are unchanged.
 If `TYPE = 'd'`, LoD and HiR are unchanged.
 If `TYPE = 's'`, the four filters are changed.
 If ELS is an array of elementary lifting steps, `liftilt(...,ELS)` performs each step successively.

`liftilt(...,FLAGPLOT)` plots the successive biorthogonal pairs—scaling function and wavelet.

Examples

```
% Get Haar filters.
[LoD,HiD,LoR,HiR] = wfilters('haar');

% Lift the Haar filters.
twoels(1) = struct('type','p','value',...
  laurpoly([0.125 -0.125],0));
twoels(2) = struct('type','p','value',...
  laurpoly([0.125 -0.125],1));
[LoDN,HiDN,LoRN,HiRN] = liftilt(LoD,HiD,LoR,HiR,twoels);

% The biorthogonal wavelet bior1.3 is obtained up to
% an insignificant sign.
[LoDB,HiDB,LoRB,HiRB] = wfilters('bior1.3');
```

```
samewavelet = ...  
isequal([LoDB,HiDB,LoRB,HiRB],[LoDN,-HiDN,LoRN,HiRN])
```

```
samewavelet =
```

```
1
```

Introduced before R2006a

liftwave

Lifting schemes

Syntax

```
LS = liftwave(WNAME)
LS = liftwave(WNAME, 'Int2Int')
```

Description

`LS = liftwave(WNAME)` returns the lifting scheme associated with the wavelet specified by `WNAME`. `LS` is a structure, not an integer, and used by `lwt`, `ilwt`, `lwt2`, etc.

`LS = liftwave(WNAME, 'Int2Int')` performs an integer to integer wavelet transform. Using `'Int2Int'` produces an `LS` such that when you use `[CA,CD] = lwt(X,LS)` or `Y = lwt(X,LS)` and `X` is a vector of integers, the resulting `CA`, `CD`, and `Y` are vectors of integers. If you omit `'Int2Int'` then `lwt` produces vectors of real numbers.

The valid values for `WNAME` are

WNAME Values
'lazy'
'haar'
'db1', 'db2', 'db3', 'db4', 'db5', 'db6', 'db7', 'db8'
'sym2', 'sym3', 'sym4', 'sym5', 'sym6', 'sym7', 'sym8'
Cohen-Daubechies-Feauveau wavelets
'cdf1.1', 'cdf1.3', 'cdf1.5'
'cdf3.1', 'cdf3.3', 'cdf3.5'
'cdf5.1', 'cdf5.3', 'cdf5.5'

laurpoly

Introduced before R2006a

littlewoodPaleySum

Littlewood-Paley sum

Syntax

```
lpsum = littlewoodPaleySum(sf)
lpsum = littlewoodPaleySum(sf,fb)
[lpsum,f] = littlewoodPaleySum( ___ )
```

Description

`lpsum = littlewoodPaleySum(sf)` returns the Littlewood-Paley sum for the scattering filter banks in `sf`, the scattering decomposition framework. `lpsum` is an M -by- L matrix, where M is the number of elements in the Fourier transform of the scattering filters, and L is the number of scattering filter banks. The columns of `lpsum` are ordered by the position of the filter bank in the scattering decomposition. For example, the first column of `lpsum` corresponds to the filter bank used for the first-order scattering coefficients.

Since the scattering transform is contractive, the Littlewood-Paley sums will not exceed one.

`lpsum = littlewoodPaleySum(sf,fb)` returns the Littlewood-Paley sum for the specified filter bank `fb` in `sf`. The argument `fb` is a positive integer between 1 and the number of filter banks in `sf` inclusive. The number of filter banks in `sf` is equal to the number of specified `QualityFactors` in `sf`.

`[lpsum,f] = littlewoodPaleySum(___)` returns the frequencies for the Littlewood-Paley sum. If you specify a sampling frequency in `sf`, `f` is in hertz. If you do not specify a sampling frequency, `f` is in cycles/sample. You can use these output arguments with any of the input syntaxes shown previously.

Examples

Plot Littlewood-Paley Sum

Create a scattering decomposition framework with three filter banks for data sampled at 25 Hz.

```
sf = waveletScattering('QualityFactors',[8 4 1],...
    'SamplingFrequency',25)
```

```
sf =
    waveletScattering with properties:
```

```
    SignalLength: 1024
    InvarianceScale: 20.4800
    QualityFactors: [8 4 1]
    Boundary: "periodic"
    SamplingFrequency: 25
    Precision: "double"
    OversamplingFactor: 0
```

Plot the Littlewood-Paley sums for the second and third filter banks. Note that the sums do not exceed 1. This shows the filters have been normalized so that the scattering transform is contractive.

```
[lpsum,f] = littlewoodPaleySum(sf);
plot(f,lpsum(:,2:3))
grid on
legend('Filter Bank 2','Filter Bank 3')
xlabel('Hz')
```

Input Arguments

sf – Scattering decomposition framework

waveletScattering object

Scattering decomposition framework, specified as a waveletScattering object.

fb – Filter bank index

positive integer

Filter bank index in the scattering decomposition framework, specified as a positive integer between 1 and the number of filter banks in `sf` inclusive. The number of filter banks in `sf` is equal to the number of specified QualityFactors in `sf`.

Data Types: double

Output Arguments

\mathcal{L} psum — Littlewood-Paley sum

real-valued matrix

Littlewood-Paley sum for the filter banks in the scattering decomposition framework `sf`, returned as a real-valued matrix. \mathcal{L} psum is an M -by- L matrix, where M is the number of elements in the Fourier transform of the scattering filters and L is the number of scattering filter banks. For example, the first column of \mathcal{L} psum corresponds to the filter bank used for the first-order scattering coefficients.

f — Frequencies

real-valued vector

Frequencies for the Littlewood-Paley sum, returned as a real-valued vector. If you specify a sampling frequency in `sf`, **f** is in hertz. If you do not specify a sampling frequency, **f** is in cycles/sample.

Data Types: `double`

See Also

`waveletScattering`

Introduced in R2018b

littlewoodPaleySum

Littlewood-Paley sum

Syntax

```
lpsum = littlewoodPaleySum(sf)
lpsum = littlewoodPaleySum(sf,fb)
[lpsum,f] = littlewoodPaleySum( ___ )
```

Description

`lpsum = littlewoodPaleySum(sf)` returns the Littlewood-Paley sum for the 2-D filter banks in the 2-D wavelet scattering decomposition `sf`. `lpsum` is an M -by- N -by- Nfb matrix, where M -by- N is the matrix size of the padded filters and Nfb is the number of filter banks.

Since the scattering transform is contractive, the Littlewood-Paley sums do not exceed 1.

`lpsum = littlewoodPaleySum(sf,fb)` returns the Littlewood-Paley sum for the specified filter banks `fb`. `fb` is a positive integer or vector of positive integers between 1 and `numfilterbanks(sf)` inclusive. `lpsum` is an M -by- N -by- L matrix, where L is the number of unique elements in `fb`.

`[lpsum,f] = littlewoodPaleySum(___)` returns the spatial frequencies for the Littlewood-Paley sum. `f` is a two-column matrix with the first column containing the spatial frequencies in the x -direction and the second column containing the spatial frequencies in the y -direction.

Examples

Littlewood-Paley Sum of Image Scattering Framework

This example shows how to obtain and display the Littlewood-Paley sum of an image scattering framework.

Create a scattering framework with two filter banks and quality factors of 2 and 1, respectively.

```
sf = waveletScattering2('QualityFactors',[2 1]);
```

Obtain the Littlewood-Paley sums and spatial frequencies of the two filter banks. Display the maximum value of the sums. Since the scattering transform is contractive, the sums do not exceed 1.

```
[lpsum,f] = littlewoodPaleySum(sf);
max(max(lpsum(:,:,1)))
```

```
ans = 1.0000
```

```
max(max(lpsum(:,:,2)))
```

```
ans = 1.0000
```

Display the Littlewood-Paley sum of the second filter bank with the zero frequency centered. Note the 2-D Morlet filter bank used in the scattering transform is not designed to capture the highest spatial frequencies jointly in the x- and y-directions.

```
f(f>1/2) = f(f>1/2)-1;
surf(fftshift(f(:,1)),fftshift(f(:,2)),fftshift(lpsum(:,:,2)))
shading interp
view(0,90)
xlabel('f_x')
ylabel('f_y')
colorbar
title('Q=1')
```

Input Arguments

sf – Scattering decomposition framework

waveletScattering2 object

Scattering decomposition framework, specified as a waveletScattering2 object.

fb – Filter bank index

positive integer | vector of positive integers

Filter bank index in the image scattering decomposition framework, specified as a positive integer or vector of positive integers between 1 and numfilterbanks(sf) inclusive. The number of filter banks in sf is equal to the number of specified QualityFactors in sf.

Output Arguments

lpsum — Littlewood-Paley sum

real-valued 3-D matrix

Littlewood-Paley sum for the filter banks in the image scattering decomposition framework `sf`, returned as a real-valued 3-D matrix. `lpsum` is an M -by- N -by- L matrix, where M -by- N is the matrix size of the padded filters and L does not exceed the number of filter banks in `sf`.

f — Frequencies

real-valued two-column matrix

Frequencies for the Littlewood-Paley sum, returned as a real-valued two-column matrix. Frequencies are in cycles per pixel. The first column of `f` contains the spatial frequencies in the x -direction, and the second column contains the spatial frequencies in the y -direction. In this convention, the Fourier transform is 1-periodic in both Fourier variables.

`waveletScattering2`

Introduced in R2019a

localmax

Identify and chain local maxima

Syntax

```
[lmaxima,indices] = localmax(inputmatrix)
[lmaxima,indices] = localmax(inputmatrix,initrow)
[lmaxima,indices] = localmax(inputmatrix,initrow,regflag)
```

Description

[lmaxima,indices] = localmax(inputmatrix) identifies and chains the local maxima in the rows of inputmatrix.

[lmaxima,indices] = localmax(inputmatrix,initrow) initializes the chaining of local maxima beginning with row initrow. If there are no local maxima in initrow, all rows in lmaxima with indices less than initrow consist of only zeros.

[lmaxima,indices] = localmax(inputmatrix,initrow,regflag) replaces initrow of inputmatrix with the level-5 approximation (scaling) coefficients obtained with the sym4 wavelet.

Input Arguments

inputmatrix

inputmatrix is a matrix of real or complex numbers. Most often, inputmatrix is a matrix of continuous wavelet transform (CWT) coefficients, and you use localmax to identify maxima lines. localmax operates on the absolute values of inputmatrix.

initrow

Initialization row for chaining local maxima. The chaining algorithm begins at initrow and decrements the row index by 1 until the first row of the matrix is reached. By specifying initrow, you can exclude rows from the chaining algorithm.

Default: size(inputmatrix,1)

regflag

Regularization flag. If you set regflag to true, the row of inputmatrix corresponding to initrow is replaced by the level-5 approximation (scaling) coefficients obtained with the sym4 wavelet.

Default: true

Output Arguments

`lmaxima`

Matrix with local maxima chains. `lmaxima` only has nonzero entries at the locations of local maxima in the absolute values of `inputmatrix`. Denote the row index of `lmaxima` by `R`. You can determine the value of `lmaxima` at a local maximum in row `R` as follows:

- If `R > initRow`, the value of `lmaxima` at a local maximum is 1.
- If `R = initRow`, the value of `lmaxima` at a local maximum is the column index in row `R`.
- If `R < initRow`, the value of `lmaxima` at a local maximum in row `R` is the column index of the nearest local maximum in row `R+1`.

To illustrate this, if `inputmatrix` is:

```
3   2   5   3
4   6   3   2
4   4   7   4
4   6   2   2
```

`lmaxima` with `initRow = 4` and `regflag = false` is:

```
0   0   2   0
0   3   0   0
0   0   2   0
0   2   0   0
```

`lmaxima` with `initRow = 3` and `regflag = false` is:

```
0   0   2   0
0   3   0   0
0   0   3   0
0   1   0   0
```

- If the local maximum in row `R` lies between two local maxima in row `R+1`, the value of the local maximum in row `R` is the higher column index in row `R+1`.

To illustrate this, if `inputmatrix` is:

```
0   0   1   0   0   0
0   1   0   1   0   0
```

`lmaxima` with `initRow = 2` and `regflag = false` is:

```
0   0   4   0   0   0
0   2   0   4   0   0
```

`lmaxima` with `initRow = 1` and `regflag = false` is:

```
0   0   3   0   0   0
0   1   0   1   0   0
```

indices

Linear indices of the nonzero values of `lmaxima`. Use `ind2sub` to convert the linear indices to matrix row and column indices.

Examples

Local Maxima of a Matrix

Construct a 4-by-4 matrix with local maxima at the following row-column indices: (4,2), (3,3), (2,2), and (1,3). Set `initrow` to 4 and `regflag` to `false`.

```
inputmatrix = ...
[3     2     5     3
 4     6     3     2
 4     4     7     4
 4     6     2     2];
[lmaxima,indices] = localmax(inputmatrix,4,false);
lmaxima
```

Because `localmax` operates on the absolute values of `inputmatrix`, setting `inputmatrix(4,2) = -inputmatrix(4,2)` produces an identical `lmaxima`.

```
inputmatrix(4,2) = -inputmatrix(4,2);
[lmaximal,indices1] = localmax(inputmatrix,4,false);
isequal(lmaxima,lmaximal)
```

CWT Coefficient Moduli and Maxima Lines

Determine the local maxima from the CWT of the `cuspsmax` signal using the default Morse wavelet. Plot the CWT coefficient moduli and maxima lines.

```
load cuspsmax;
```

Plot the `cuspsmax` signal and notice the shape of the signal near samples 300 and 700. The signal shows a cusp near sample 700.

```
plot(cuspsmax);
xlabel('Sample');
```

Plot the wavelet transform modulus maxima and note the local Holder exponent values at samples 308 and 717.

```
wttm(cuspamax, 'ScalingExponent', 'local');
```

Holder exponent values indicate the strength of the singularities in a signal. Signal locations where the local Holder exponent is 0 are discontinuous at that location. Locations with Holder exponents greater than or equal to 1 are differentiable. Holder exponent values less than but close to 1 indicate that the signal at the location is almost differentiable. The closer the Holder exponent value is to 0, the stronger the singularity.

The Holder exponent at sample 308 is 1.9 and at sample 717 is 0.39. The low Holder value at sample 717 confirms that the signal is not differentiable and has a fairly strong singularity at that point.

Introduced in R2008a

log

Natural logarithm of scattering transform

Syntax

```
slog = log(sf,s)
ulog = log(sf,u)
xlog = log(sf,x)
```

Description

`slog = log(sf,s)` returns the natural logarithm of the scattering coefficients in the cell array `s`. `s` is the output of `scatteringTransform` and is a cell array of structure arrays with a `signals` field.

The precision of `slog` depends on the precision specified in the framework `sf`.

`ulog = log(sf,u)` returns the natural logarithm of the scalogram coefficients in the cell array `u`. `u` is the output of `scatteringTransform` and is a cell array of structure arrays with a `coefficients` field.

The precision of `ulog` depends on the precision specified in the framework `sf`.

`xlog = log(sf,x)` returns the natural logarithm of the 2-D matrix or 3-D array `x`. `x` is the output of `featureMatrix`.

The precision of `xlog` depends on the precision specified in the framework `sf`.

Examples

Natural Logarithm of Scattering Coefficients

This example shows how to obtain the natural logarithm of scattering coefficients.

Load a noisy Doppler signal and create a scattering decomposition framework that can be used with the signal. Return the scattering coefficients.

```
load noisdopp
sf = waveletScattering('SignalLength',numel(noisdopp));
S = scatteringTransform(sf,noisdopp);
```

Calculate the natural logarithm of the scattering coefficients. Display the number of rows in the table containing the first-order scattering coefficients.

```
slog = log(sf,S);
coefOrder = 1;
display(['Number of rows: ',...
        num2str(size(S{coefOrder+1},1))])
```

```
Number of rows: 40
```

Choose a row from the first-order scattering coefficients table. Take the natural logarithm of the absolute value of the scattering coefficients in that row. Compare with the corresponding row in `slog` and confirm they are equal.

```
row = 23;
tmp1 = slog{coefOrder+1}.signals{row};
tmp2 = log(abs(S{coefOrder+1}.signals{row}));
disp(['Max Difference of Scattering Coefficients: ',...
      num2str(max(abs(tmp1(:)-tmp2(:)))])])
```

Max Difference of Scattering Coefficients: 0

Input Arguments

sf — Scattering decomposition framework

waveletScattering object

Scattering decomposition framework, specified as a `waveletScattering` object.

s — Scattering coefficients

cell array

Scattering coefficients, specified as a cell array of structure arrays. `s` is the output of `scatteringTransform` for the scattering decomposition framework `sf`.

u — Scalogram coefficients

cell array

Scalogram coefficients, specified as a cell array of structure arrays. `u` is the output of `scatteringTransform` for the scattering decomposition framework `sf`.

x — Scattering feature matrix

real-valued matrix | real-valued array

Scattering feature matrix, specified as a real-valued 2-D matrix or 3-D array. `x` is the output of `featureMatrix` for the scattering decomposition framework `sf`.

Output Arguments

slog — Natural logarithm of scattering coefficients

cell array

Natural logarithm of scattering coefficients, returned as a cell array. The dimensions of `slog` are equal to the dimensions of `s`.

The precision of `slog` depends on the precision specified in the framework `sf`.

ulog — Natural logarithm of scalogram coefficients

cell array

Natural logarithm of scalogram coefficients, returned as a cell array. The dimensions of `ulog are equal to the dimensions of u.`

The precision of `ulog depends on the precision specified in the framework sf.`

xlog — Natural logarithm of scattering feature matrix

real-valued matrix | real-valued array

Natural logarithm of scattering feature matrix, returned as a real-valued matrix or array. The dimensions of `xlog` are equal to the dimensions of `x`.

The precision of `xlog` depends on the precision specified in the framework `s f`.

Algorithms

`log` returns the natural logarithm of the absolute value of the input argument.

See Also

scatteringTransform | waveletScattering

Introduced in R2018b

log

Natural logarithm of 2-D scattering transform

Syntax

```
slog = log(sf,s)
ulog = log(sf,u)
xlog = log(sf,x)
```

Description

`slog = log(sf,s)` returns the natural logarithm of the scattering coefficients in the cell array `s`. `s` is the output of `scatteringTransform` and is a cell array of structure arrays with an `images` field.

The precision of `slog` depends on the precision specified in the framework `sf`.

`ulog = log(sf,u)` returns the natural logarithm of the scalogram coefficients in the cell array `u`. `u` is the output of `scatteringTransform` and is a cell array of structure arrays with a `coefficients` field.

The precision of `ulog` depends on the precision specified in the framework `sf`.

`xlog = log(sf,x)` returns the natural logarithm of the 3-D matrix or 4-D tensor `x`. `x` is the output of `featureMatrix`.

The precision of `xlog` depends on the precision specified in the framework `sf`.

Examples

Natural Logarithm of Scattering Coefficients

This example shows how to obtain the natural logarithm of scattering coefficients.

Load the `xbox` image. Create an image scattering framework that can be applied to the image.

```
load xbox
sf = waveletScattering2('ImageSize',size(xbox),...
    'InvarianceScale',min(size(xbox)))
```

```
sf =
    waveletScattering2 with properties:
```

```
    ImageSize: [128 128]
    InvarianceScale: 128
    NumRotations: [6 6]
    QualityFactors: [1 1]
    Precision: "single"
    OversamplingFactor: 0
    OptimizePath: 1
```

Obtain the scattering transform of the image and then the natural logarithm of the scattering coefficients. Display the number of rows in the table containing the first-order scattering coefficients.

```
S = scatteringTransform(sf,xbox);  
Slog = log(sf,S);  
coefOrder = 1;  
display(['Number of rows: ',num2str(size(S{coefOrder+1},1))])
```

```
Number of rows: 30
```

Choose a row from the first-order scattering coefficients table. Take the natural logarithm of the absolute value of the scattering coefficients in that row. Compare with the corresponding row in `Slog` and confirm they are equal.

```
row = 11;  
tmp1 = Slog{coefOrder+1}.images{row};  
tmp2 = log(abs(S{coefOrder+1}.images{row}));  
disp(['Max Difference of Scattering Coefficients: '...  
      num2str(max(abs(tmp1(:)-tmp2(:)))])])
```

```
Max Difference of Scattering Coefficients: 0
```

Input Arguments

sf — Scattering decomposition framework

waveletScattering2 object

Scattering decomposition framework, specified as a `waveletScattering2` object.

s — Scattering coefficients

cell array

Scattering coefficients, specified as a cell array of structure arrays. `s` is the output of `scatteringTransform` for the image scattering decomposition framework `sf`.

u — Scalogram coefficients

cell array

Scalogram coefficients, specified as a cell array of structure arrays. `u` is the output of `scatteringTransform` for the image scattering decomposition framework `sf`.

x — Scattering feature matrix

real-valued matrix | real-valued 4-D tensor

Scattering feature matrix, specified as a real-valued 3-D matrix or a real-valued 4-D tensor. `x` is the output of `featureMatrix` for the image scattering decomposition framework `sf`.

Output Arguments

slog — Natural logarithm of scattering coefficients

cell array

Natural logarithm of scattering coefficients, returned as a cell array. The dimensions of `slog` are equal to the dimensions of `s`.

The precision of `slog` depends on the precision specified in the framework `s f`.

u`log` – Natural logarithm of scalogram coefficients

cell array

Natural logarithm of scalogram coefficients, returned as a cell array. The dimensions of `ulog` are equal to the dimensions of `u`.

The precision of `ulog` depends on the precision specified in the framework `s f`.

x`log` – Natural logarithm of scattering feature matrix

real-valued 3-D matrix | real-valued 4-D tensor

Natural logarithm of scattering feature matrix, returned as a real-valued matrix or tensor. The dimensions of `xlog` are equal to the dimensions of `x`.

The precision of `xlog` depends on the precision specified in the framework `s f`.

Algorithms

`log` returns the natural logarithm of the absolute value of the input argument.

Introduced in R2019a

ls2filt

Transform lifting scheme to quadruplet of filters

Syntax

```
[LoD,HiD,LoR,HiR] = ls2filt(LS)
```

Description

[LoD,HiD,LoR,HiR] = ls2filt(LS) returns the four filters LoD, HiD, LoR, and HiR associated with the lifting scheme LS.

Examples

```
% Start from the db2 wavelet and get the
% corresponding lifting scheme.
LS = liftwave('db2')

LS =

    'd'      [ -1.7321]    [ 0]
    'p'      [1x2 double]  [ 1]
    'd'      [         1]  [-1]
    [1.9319] [ 0.5176]    []

% Visualize the obtained lifting scheme.
displs(LS);

LS = {...
    'd'      [ -1.73205081]    [0]
    'p'      [ -0.06698730  0.43301270] [1]
    'd'      [ 1.00000000]    [-1]
    [ 1.93185165] [ 0.51763809]    []
};

% Get the filters from the lifting scheme.
[LoD,HiD,LoR,HiR] = ls2filt(LS)

LoD =

    -0.1294    0.2241    0.8365    0.4830

HiD =

    -0.4830    0.8365   -0.2241   -0.1294

LoR =

    0.4830    0.8365    0.2241   -0.1294
```

```
HiR =  
    -0.1294   -0.2241    0.8365   -0.4830

linfo

Lifting schemes information

Syntax

`linfo`

Description

`linfo` displays the following information about lifting schemes. A lifting scheme LS is a $N \times 3$ cell array. The $N-1$ first rows of the array are elementary lifting steps (ELS). The last row gives the normalization of LS.

Each ELS has this format:

```
{type, coefficients, max_degree}
```

where `type` is 'p' (primal) or 'd' (dual), `coefficients` is a vector C of real numbers defining the coefficients of a Laurent polynomial P described below, and `max_degree` is the highest degree d of the monomials of P .

The Laurent polynomial P is of the form

$$P(z) = C(1)*z^d + C(2)*z^{(d-1)} + \dots + C(m)*z^{(d-m+1)}$$

The lifting scheme LS is such that for

$k = 1:N-1$, `LS{k, :}` is an ELS, where

`LS{k, 1}` is the lifting type 'p' (primal) or 'd' (dual).

`LS{k, 2}` is the corresponding lifting filter.

`LS{k, 3}` is the highest degree of the Laurent polynomial corresponding to the filter `LS{k, 2}`.

`LS{N, 1}` is the primal normalization (real number).

`LS{N, 2}` is the dual normalization (real number).

`LS{N, 3}` is not used.

Usually, the normalizations are such that `LS{N, 1}*LS{N, 2} = 1`.

For example, the lifting scheme associated with the wavelet db1 is

```
LS = { ...
      'd'          [ -1]    [0]
      'p'          [0.5000]  [0]
      [1.4142]     [0.7071]  []
    }
```

lwt

1-D lifting wavelet transform

Syntax

```
[CA,CD] = lwt(X,W)
X_InPlace = lwt(X,W)
lwt(X,W,LEVEL)
X_InPlace = lwt(X,W,LEVEL,'typeDEC',typeDEC)
[CA,CD] = lwt(X,W,LEVEL,'typeDEC',typeDEC)
```

Description

`lwt` performs a 1-D lifting wavelet decomposition with respect to a particular lifted wavelet that you specify.

`[CA,CD] = lwt(X,W)` computes the approximation coefficients vector `CA` and detail coefficients vector `CD`, obtained by a lifting wavelet decomposition, of the vector `X`. `W` is a lifted wavelet name (see `liftwave`).

`X_InPlace = lwt(X,W)` computes the approximation and detail coefficients. These coefficients are stored in place:

`CA = X_InPlace(1:2:end)` and `CD = X_InPlace(2:2:end)`

`lwt(X,W,LEVEL)` computes the lifting wavelet decomposition at level `LEVEL`.

`X_InPlace = lwt(X,W,LEVEL,'typeDEC',typeDEC)` or `[CA,CD] = lwt(X,W,LEVEL,'typeDEC',typeDEC)` with `typeDEC = 'w'` or `'wp'` computes the wavelet or the wavelet packet decomposition using lifting, at level `LEVEL`.

Instead of a lifted wavelet name, you may use the associated lifting scheme `LS`: `lwt(X,LS,...)` instead of `lwt(X,W,...)`.

For more information about lifting schemes, see `lsinfo`.

Examples

```
% Start from the Haar wavelet and get the
% corresponding lifting scheme.
lshaar = liftwave('haar');

% Add a primal ELS to the lifting scheme.
els = {'p',[-0.125 0.125],0};
lsnew = addlift(lshaar,els);

% Perform LWT at level 1 of a simple signal.
x = 1:8;
[CA,cD] = lwt(x,lsnew)

CA =
```

```

    1.9445    4.9497    7.7782   10.6066

cD =
    0.7071    0.7071    0.7071    0.7071

% Perform integer LWT of the same signal.
lshaarInt = liftwave('haar','int2int');
lsnewInt = addlift(lshaarInt,els);
[cAint,cDint] = lwt(x,lsnewInt)

cAint =
     1     3     5     7

cDint =
     1     1     1     1

```

Algorithms

This function uses the polyphase algorithm.

lwt reduces to dwt with zero-padding extension mode and without extra-coefficients.

lwt2

2-D lifting wavelet transform

Syntax

```
[CA,CH,CV,CD] = lwt2(X,W)
X_InPlace = lwt2(X,LS)
lwt2(X,W,LEVEL)
X_InPlace = lwt2(X,W,LEVEL,'typeDEC',typeDEC)
[CA,CH,CV,CD] = LWT2(X,W,LEVEL,'typeDEC',typeDEC)
```

Description

`lwt2` performs a 2-D lifting wavelet decomposition with respect to a particular lifted wavelet that you specify.

`[CA,CH,CV,CD] = lwt2(X,W)` computes the approximation coefficients matrix *CA* and detail coefficients matrices *CH*, *CV*, and *CD*, obtained by a lifting wavelet decomposition, of the matrix *X*. *W* is a lifted wavelet name (see `liftwave`).

`X_InPlace = lwt2(X,LS)` computes the approximation and detail coefficients. These coefficients are stored in place:

- `CA = X_InPlace(1:2:end,1:2:end)`
- `CH = X_InPlace(2:2:end,1:2:end)`
- `CV = X_InPlace(1:2:end,2:2:end)`
- `CD = X_InPlace(2:2:end,2:2:end)`

`lwt2(X,W,LEVEL)` computes the lifting wavelet decomposition at level `LEVEL`.

`X_InPlace = lwt2(X,W,LEVEL,'typeDEC',typeDEC)` or `[CA,CH,CV,CD] = LWT2(X,W,LEVEL,'typeDEC',typeDEC)` with `typeDEC = 'w'` or `'wp'` computes the wavelet or the wavelet packet decomposition using lifting, at level `LEVEL`.

Instead of a lifted wavelet name, you may use the associated lifting scheme `LS`: `lwt2(X,LS,...)` instead of `LWT2(X,W,...)`.

For more information about lifting schemes, see `lsinfo`.

Examples

```
% Start from the Haar wavelet and get the
% corresponding lifting scheme.
lshaar = liftwave('haar');

% Add a primal ELS to the lifting scheme.
els = {'p',[-0.125 0.125],0};
lsnew = addlift(lshaar,els);
```

```
% Perform LWT at level 1 of a simple image.
x = reshape(1:16,4,4);
[cA,cH,cV,cD] = lwt2(x,lsnew)

cA =

    5.7500    22.7500
   10.0000    27.0000

cH =

    1.0000    1.0000
    1.0000    1.0000

    4.0000    4.0000
    4.0000    4.0000

cD =

    0     0
    0     0

% Perform integer LWT of the same image.
lshaarInt = liftwave('haar','int2int');
lsnewInt = addlift(lshaarInt,els);
[cAint,cHint,cVint,cDint] = lwt2(x,lsnewInt)

cAint =

     3     11
     5     13

cHint =

     1     1
     1     1

cVint =

     4     4
     4     4

cDint =

     0     0
     0     0
```

Tips

When X represents an indexed image, X , as well as the output arrays cA, cH, cV, cD , or $X_InPlace$ are m -by- n matrices. When X represents a truecolor image, it is an m -by- n -by-3 array, where each m -by- n matrix represents a red, green, or blue color plane concatenated along the third dimension.

For more information on image formats, see the `image` and `imfinfo` reference pages .

Algorithms

This function implements the polyphase algorithm.

`lwt` reduces to `dwt` with zero-padding extension mode and without extra-coefficients.

lwtcoef

Extract or reconstruct 1-D LWT wavelet coefficients

Syntax

```
Y = lwtcoef(TYPE,XDEC,LS,LEVEL,LEVEXT)
```

```
Y = lwtcoef(TYPE,XDEC,W,LEVEL,LEVEXT)
```

Description

`Y = lwtcoef(TYPE,XDEC,LS,LEVEL,LEVEXT)` returns the coefficients or the reconstructed coefficients of level `LEVEXT`, extracted from `XDEC`, the LWT decomposition at level `LEVEL` obtained with the lifting scheme `LS`.

The valid values for `TYPE` are

TYPE Values	Description
'a'	Approximations
'd'	Details
'ca'	Coefficients of approximations
'cd'	Coefficients of details

`Y = lwtcoef(TYPE,XDEC,W,LEVEL,LEVEXT)` returns the same output using `W`, which is the name of a lifted wavelet.

Examples

```
% Start from the Haar wavelet and get the
% corresponding lifting scheme.
lshaar = liftwave('haar');
```

```
% Add a primal ELS to the lifting scheme.
els = {'p',[-0.125 0.125],0};

lwtcoef2

Extract or reconstruct 2-D LWT wavelet coefficients

Syntax

$Y = \text{lwtcoef2}(\text{TYPE}, \text{XDEC}, \text{LS}, \text{LEVEL}, \text{LEVEXT})$

$Y = \text{lwtcoef2}(\text{TYPE}, \text{XDEC}, \text{W}, \text{LEVEL}, \text{LEVEXT})$

Description

$Y = \text{lwtcoef2}(\text{TYPE}, \text{XDEC}, \text{LS}, \text{LEVEL}, \text{LEVEXT})$ returns the coefficients or the reconstructed coefficients of level LEVEXT, extracted from XDEC, the LWT decomposition at level LEVEL obtained with the lifting scheme LS.

The valid values for TYPE are listed in this table.

TYPE Values	Description
'a'	Approximations
'h'	Horizontal details
'v'	Vertical details
'd'	Diagonal details
'ca'	Coefficients of approximations
'ch'	Coefficients of horizontal details
'cv'	Coefficients of vertical details
'cd'	Coefficients of diagonal details

$Y = \text{lwtcoef2}(\text{TYPE}, \text{XDEC}, \text{W}, \text{LEVEL}, \text{LEVEXT})$ returns the same output using W, which is the name of a lifted wavelet.

Examples

```
% Start from the Haar wavelet and get the
% corresponding lifting scheme.
lshaar = liftwave('haar');

% Add a primal ELS to the lifting scheme.
els = {'p', [-0.125 0.125], 0};

`ilwt2` | `lwt2`

Introduced before R2006a

mdwtcluster

Multisignals 1-D clustering

Syntax

```
S = mdwtcluster(X)
S = mdwtcluster(X, 'PropName1', PropVal1, 'PropName2', PropVal2, ...)
```

Description

`S = mdwtcluster(X)` constructs clusters from a hierarchical cluster tree. The input matrix X is decomposed in row direction using the DWT function with the haar wavelet and the maximum allowed level.

`S = mdwtcluster(X, 'PropName1', PropVal1, 'PropName2', PropVal2, ...)` allows you to modify some properties. The valid choices for *PropName* are:

Note `mdwtcluster` requires the Statistics and Machine Learning Toolbox™

'dirDec'	'r' (row) or 'c' (column). Default value is 'r'.
'level'	Level of the DWT decomposition. Default value is: <code>level=fix(log2(size(X,d)))</code> where $d=1$ or $d=2$, depending on the <code>dirDec</code> value.
'wname'	Wavelet name used for DWT. Default value is 'haar'.
'dwtEXTM'	DWT extension mode (see <code>dwtmode</code>).
'pdist'	See Statistics and Machine Learning Toolbox <code>pdist</code> function. Default value is 'euclidean'.
'linkage'	See Statistics and Machine Learning Toolbox <code>linkage</code> function. Default value is 'ward'.
'maxclust'	Number of clusters. Default value is 6. The input variable can be a vector.
'lst2clu'	Cell array that contains the list of data to classify. If N is the level of decomposition, the allowed name values for the cells are: <ul style="list-style-type: none"> 's' — Signal 'aj' — Approximation at level j 'dj' — Detail at level j 'caj' — Coefficients of approximation at level j 'cdj' — Coefficients of detail at level j Default value is {'s'; 'ca1'; ...; 'caN'}.

The output structure `S` is such that for each partition `j`:

<code>S.Idx(:,j)</code>	Contains the cluster numbers obtained from the hierarchical cluster tree (see <code>cluster</code> in the Statistics and Machine Learning Toolbox software).
<code>S.Incons(:,j)</code>	Contains the inconsistent values of each non-leaf node in the hierarchical cluster tree (see Statistics and Machine Learning Toolbox software function <code>inconsistent</code>).
<code>S.Corr(j)</code>	Contains the cophenetic correlation coefficients of the partition (see Statistics and Machine Learning Toolbox software function <code>cophenet</code>).

Note If `maxClustVal` is a vector, then `IdxCLU` is a multidimensional array such that `IdxCLU(:,j,k)` contains the cluster numbers obtained from the hierarchical cluster tree for `k` clusters.

Examples

```
load elecsig10
lst2clu = {'s','ca1','ca3','ca6'};

% Compute the structure resulting from multisignal clustering
S = mdwtcluster(signals,'maxclust',4,'lst2clu',lst2clu)

S =

    IdxCLU: [70x4 double]
    Incons: [69x4 double]
    Corr: [0.7920 0.7926 0.7947 0.7631]

% Retrieve indices of clusters
IdxCLU = S.IdxCLU;

% Plot the first cluster
plot(signals(IdxCLU(:,1)==1,:),'r');
hold on;

% Plot the third clustering
plot(signals(IdxCLU(:,1)==3,:),'b')
```

```
% Check the equality of partitions  
equalPART = isequal(IdxCLU(:,1),IdxCLU(:,3))
```

```
equalPART =
```

```
1
```

```
% So we can see that we obtain the same partitions using  
% coefficients of approximation at level 3 instead of original  
% signals. Much less information is then used.
```

See Also

mdwtdec | wavedec

Introduced in R2008a

mdwtdec

Multisignal 1-D wavelet decomposition

Syntax

```
dec = mdwtdec(dirdec,x,lev,wname)
dec = mdwtdec(dirdec,x,lev,LoD,HiD,LoR,HiR)
dec = mdwtdec( ____, 'mode', extmode)
```

Description

`dec = mdwtdec(dirdec,x,lev,wname)` returns the 1-D discrete wavelet decomposition at level `lev` of each row or each column of the matrix `x`, using the wavelet `wname`.

`dec = mdwtdec(dirdec,x,lev,LoD,HiD,LoR,HiR)` uses the specified lowpass and highpass wavelet decomposition filters `LoD` and `HiD`, respectively, and the lowpass and highpass wavelet reconstruction filters `LoR` and `HiR`, respectively.

`dec = mdwtdec(____, 'mode', extmode)` uses the specified discrete wavelet transform (DWT) extension mode `extmode`. For more information, see `dwtmode`. This syntax can be used with any of the previous syntaxes.

Examples

Decompose Multisignals

This example shows how to return the wavelet decomposition of a multisignal using a wavelet name and wavelet filters.

Load the 23 channel EEG data `Espiga3` [4]. The channels are arranged column-wise. The data is sampled at 200 Hz.

```
load Espiga3
size(Espiga3)
```

```
ans = 1x2
      995    23
```

Perform a decomposition at level 2 using the `db2` wavelet.

```
dec = mdwtdec('c',Espiga3,2,'db2')
```

```
dec = struct with fields:
    dirDec: 'c'
    level: 2
    wname: 'db2'
    dwtFilters: [1x1 struct]
    dwtEXTM: 'sym'
```

```
dwtShift: 0
dataSize: [995 23]
         ca: [251x23 double]
         cd: {[499x23 double] [251x23 double]}
```

Compute the filters associated with the db2 wavelet.

```
[LoD,HiD,LoR,HiR] = wfilters('db2');
```

Perform a decomposition at level 2 using the filters.

```
decBIS = mdwtdec('c',Espiga3,2,LoD,HiD,LoR,HiR)
```

```
decBIS = struct with fields:
  dirDec: 'c'
  level: 2
  wname: ''
  dwtFilters: [1x1 struct]
  dwtEXTM: 'sym'
  dwtShift: 0
  dataSize: [995 23]
           ca: [251x23 double]
           cd: {[499x23 double] [251x23 double]}
```

Confirm the approximation and detail coefficients of both decompositions are identical.

```
max(abs(dec.ca(:)-decBIS.ca(:)))
```

```
ans = 0
```

```
max(abs(dec.cd{1}(:)-decBIS.cd{1}(:)))
```

```
ans = 0
```

```
max(abs(dec.cd{2}(:)-decBIS.cd{2}(:)))
```

```
ans = 0
```

Input Arguments

dirdec — Direction indicator

'r' | 'c'

Direction indicator of the wavelet decomposition, specified as:

- 'r': Take the 1-D wavelet decomposition of each row of x
- 'c': Take the 1-D wavelet decomposition of each column of x

x — Input data

real-valued matrix

Input data, specified as a real-valued matrix.

lev — Level of decomposition

positive integer

Level of decomposition, specified as a positive integer. `mdwtdec` does not enforce a maximum level restriction. Use `wmaxlev` to ensure that the wavelet coefficients are free from boundary effects. If boundary effects are not a concern, a good rule is to set `lev` less than or equal to `fix(log2(length(N)))`, where N is the number of samples in the 1-D data.

wname — Analyzing wavelet

character vector | string scalar

Analyzing wavelet, specified as a character vector or string scalar. The wavelet must be orthogonal or biorthogonal. Orthogonal and biorthogonal wavelets are designated as type 1 and type 2 wavelets respectively in the wavelet manager, `wavemngr`.

- Valid built-in orthogonal wavelet families begin with 'haar', 'dbN', 'fkN', 'coifN', or 'symN', where N is the number of vanishing moments for all families except `fk`. For `fk`, N is the number of filter coefficients.
- Valid biorthogonal wavelet families begin with 'biorNr.Nd' or 'rbioNd.Nr', where Nr and Nd are the number of vanishing moments in the reconstruction (synthesis) and decomposition (analysis) wavelet.

Determine valid values for the vanishing moments by using `waveinfo` with the wavelet family short name. For example, enter `waveinfo('db')` or `waveinfo('bior')`. Use `wavemngr('type', WNAME)` to determine if a wavelet is orthogonal (returns 1) or biorthogonal (returns 2).

LoD, HiD — Wavelet decomposition filters

even-length real-valued vectors

Wavelet decomposition filters, specified as a pair of even-length real-valued vectors. `LoD` is the lowpass decomposition filter, and `HiD` is the highpass decomposition filter. The lengths of `LoD` and `HiD` must be equal. See `wfilters` for additional information.

LoR, HiR — Wavelet reconstruction filters

even-length real-valued vectors

Wavelet reconstruction filters, specified as a pair of even-length real-valued vectors. `LoR` is the lowpass reconstruction filter, and `HiR` is the highpass reconstruction filter. The lengths of `LoR` and `HiR` must be equal. See `wfilters` for additional information.

extmode — Extension mode

'zpd' | 'sp0' | 'spd' | ...

Extension mode used when performing the wavelet decomposition, specified as:

mode	DWT Extension Mode
'zpd'	Zero extension
'sp0'	Smooth extension of order 0
'spd' (or 'sp1')	Smooth extension of order 1
'sym' or 'symh'	Symmetric extension (half point): boundary value symmetric replication
'symw'	Symmetric extension (whole point): boundary value symmetric replication

mode	DWT Extension Mode
'asym' or 'asymh'	Antisymmetric extension (half point): boundary value antisymmetric replication
'asymw'	Antisymmetric extension (whole point): boundary value antisymmetric replication
'ppd', 'per'	Periodized extension If the signal length is odd and mode is 'per', an extra sample equal to the last value is added to the right and the extension is performed in 'ppd' mode. If the signal length is even, 'per' is equivalent to 'ppd'. This rule also applies to images.

The global variable managed by `dwtmode` specifies the default extension mode. Use `dwtmode` to determine the extension modes.

Output Arguments

dec — Wavelet decomposition

structure

Wavelet decomposition of the multisignal `x`, returned as a structure with the following fields:

- `dirDec` — Direction indicator: 'r' (row) or 'c' (column)
- `level` — Level of wavelet decomposition
- `wname` — Wavelet name
- `dwtFilters` — Structure with four fields: `LoD`, `HiD`, `LoR`, and `HiR`
- `dwtEXTM` — DWT extension mode
- `dwtShift` — DWT shift parameter (0 or 1)
- `dataSize` — Size of `x`
- `ca` — Approximation coefficients at level `lev`
- `cd` — Cell array of detail coefficients, from level 1 to level `lev`

The coefficients `ca` and `cd{k}`, for `k` from 1 to `lev`, are matrices and are stored in rows if `dirdec = 'r'` or in columns if `dirdec = 'c'`.

`mdwtrec` | `wavedec`

Introduced in R2007a

mdwtrec

Multisignal 1-D wavelet reconstruction

Syntax

```
x = mdwtrec(dec)
x = mdwtrec(dec,idxsig)
y = mdwtrec(dec,type,lev)

a = mdwtrec(dec,'a')
d = mdwtrec(dec,'d')
ca = mdwtrec(dec,'ca')

cd = mdwtrec(dec,'cd',mode)
cfs = mdwtrec(dec,'cfs',mode)

y = mdwtrec( ____,idxsig)
```

Description

`x = mdwtrec(dec)` reconstructs the original matrix of signals from the wavelet decomposition structure `dec`.

`x = mdwtrec(dec,idxsig)` reconstructs the signals whose indices are specified in the vector `idxsig`.

`y = mdwtrec(dec,type,lev)` extracts or reconstructs the detail or approximation coefficients at level `lev` depending on the value of `type`.

`a = mdwtrec(dec,'a')` returns the reconstructed approximation coefficients.

`d = mdwtrec(dec,'d')` returns a matrix containing the sum of all the details, so that $x = a + d$.

`ca = mdwtrec(dec,'ca')` returns a matrix containing the extracted approximation coefficients.

`cd = mdwtrec(dec,'cd',mode)` returns a matrix containing all the detail coefficients concatenated in the order specified by `mode`.

`cfs = mdwtrec(dec,'cfs',mode)` returns a matrix containing all the coefficients in the order specified by `mode`.

`y = mdwtrec(____,idxsig)` extracts or reconstructs the coefficients whose indices are specified in the vector `idxsig`.

Examples

Reconstruct Multisignals

This example shows how to reconstruct a multisignal and a user-specified signal within the multisignal.

Load the 23 channel EEG data `Espiga3` [4]. The channels are arranged column-wise. The data is sampled at 200 Hz.

```
load Espiga3
size(Espiga3)
```

```
ans = 1×2
      995    23
```

Perform a decomposition at level 2 using the `db2` wavelet.

```
dec = mdwtdec('c',Espiga3,2,'db2');
```

Reconstruct the original matrix of signals using the decomposition structure `dec`.

```
XR = mdwtrec(dec);
```

Compute the reconstruction error.

```
errREC = max(abs(Espiga3(:)-XR(:)))
```

```
errREC = 3.5442e-10
```

Reconstruct the original signal at index 17, the corresponding approximation at level 2, and details at levels 1 and 2.

```
idx = 17;
Y = mdwtrec(dec,idx);
A2 = mdwtrec(dec,'a',2,idx);
D2 = mdwtrec(dec,'d',2,idx);
D1 = mdwtrec(dec,'d',1,idx);
```

Compute the reconstruction error for signal 17.

```
errREC = max(abs(Y-A2-D2-D1))
```

```
errREC = 1.3242e-17
```

Input Arguments

dec — Wavelet decomposition

structure

Wavelet decomposition of a multisignal, specified as a structure with the following fields:

- `dirDec` — Direction indicator: 'r' (row) or 'c' (column)
- `level` — Level of wavelet decomposition
- `wname` — Wavelet name
- `dwtFilters` — Structure with four fields: `LoD`, `HiD`, `LoR`, and `HiR`
- `dwtEXTM` — DWT extension mode
- `dwtShift` — DWT shift parameter (0 or 1)
- `dataSize` — Size of `x`

- `ca` — Approximation coefficients at level `lev`
- `cd` — Cell array of detail coefficients, from level 1 to level `lev`

The format of `dec` matches the output of `mdwtdec`.

idxsig — Indices

positive integer-valued vector

Indices of signals to reconstruct, specified as a positive integer-valued vector.

Example: If `S` is a matrix of 100 signals and `dec = mdwtdec('r', S, 3, 'db2')`, then `mdwtrec(dec, [1 20 98])` reconstructs the signals whose row indices are 1, 20, and 98.

lev — Level

nonnegative integer

Level of coefficients to extract or reconstruct, specified as a nonnegative integer.

- If `type` is `'a'` or `'ca'`, then `lev` must be an integer in the interval $[0, \text{levdec}]$, where `levdec = dec.level`.
- If `type` is `'d'` or `'cd'`, then `lev` must be an integer in the interval $[1, \text{levdec}]$, where `levdec = dec.level`.

type — Output type

`'cd' | 'ca' | 'd' | 'a'`

Output type, specified as one of the following:

- `'cd'` - detail coefficients of level `lev` are extracted
- `'d'` - detail coefficients of level `lev` are reconstructed
- `'ca'` - approximation coefficients of level `lev` are extracted
- `'a'` - approximation coefficients of level `lev` are reconstructed

mode — Order of concatenation

`'descend' (default) | 'ascend'`

Order of concatenation, specified as `'descend'` or `'ascend'`. For `mode = 'descend'`, the coefficients are concatenated from level `levdec` to level 1, where `levdec = dec.level`. If `mode = 'ascend'`, the coefficients are concatenated from level 1 to level `levdec`. The concatenation is made row-wise if `dec.dirDEC = 'r'` or column-wise if `dec.dirDEC = 'c'`.

Output Arguments**x — Reconstructed signals**

real-valued matrix

Reconstructed signals, returned as a real-valued matrix.

y — Decomposition coefficients

real-valued matrix

Decomposition coefficients, returned as a real-valued matrix, depending on `type`:

- 'cd' - extracted detail coefficients
- 'ca' - extracted approximation coefficients
- 'd' - reconstructed detail coefficients
- 'a' - reconstructed approximation coefficients

a – Reconstructed approximation coefficients

real-valued matrix

Reconstructed approximation coefficients, returned as a real-valued matrix.

d – Reconstructed detail coefficients

real-valued matrix

Reconstructed detail coefficients, returned as a real-valued matrix.

ca – Extracted approximation coefficients

real-valued matrix

Extracted approximation coefficients, returned as a real-valued matrix.

cd – Extracted detail coefficients

real-valued matrix

Extracted detail coefficients, returned as a real-valued matrix.

cfs – Extracted approximation and detail coefficients

real-valued matrix

Extracted approximation and detail coefficients, returned as a real-valued matrix.

mdwtdec | waverec

Introduced in R2007a

measerr

Quality metrics of signal or image approximation

Syntax

```
[PSNR,MSE,MAXERR,L2RAT] = measerr(X,XAPP)
[PSNR,MSE,MAXERR,L2RAT] = measerr(X,XAPP,BPS)
```

Description

`[PSNR,MSE,MAXERR,L2RAT] = measerr(X,XAPP)` returns the peak signal-to-noise ratio, PSNR, mean square error, MSE, maximum squared error, MAXERR, and ratio of squared norms, L2RAT, for an input signal or image, X, and its approximation, XAPP.

`[PSNR,MSE,MAXERR,L2RAT] = measerr(X,XAPP,BPS)` uses the bits per sample, BPS, to determine the peak signal-to-noise ratio.

Examples

Measure Approximation Quality in RGB Image

Approximate an RGB image and compute the quality metrics.

Load an RGB image. Return the image dimensions and minimum and maximum values.

```
X = imread('afrिकासculpt.jpg');
size(X)
```

```
ans = 1x3
```

```
    512    512     3
```

```
[min(X(:)) max(X(:))]
```

```
ans = 1x2 uint8 row vector
```

```
     0    236
```

Define the image approximation by setting equal to 1 all RGB values less than or equal to 100.

```
Xapp = X;
Xapp(X<=100) = 1;
```

Display the image and its approximation.

```
subplot(1,2,1)
image(X)
title('Original Image')
subplot(1,2,2)
```

```
image(Xapp)
title('Approximation')
```

Compute the quality metrics of the image approximation.

```
[psnr,mse,maxerr,L2rat] = measerr(X,Xapp)
psnr = 17.5287
mse = 1.1487e+03
maxerr = 99
L2rat = 0.9398
```

Measure Approximation Quality in Grayscale Image

Approximate a grayscale image and calculate approximation quality metrics.

Create a 256-by-256 grayscale image with intensities between 0 and $2^{16} - 1$.

```
val = 0:2^16-1;
X = reshape(val,256,256);
```

There are 16 bits per sample. Define the image approximation by setting equal to 1 all grayscale values less than or equal to 1000. Display the image and its approximation.

```

Xapp = X;
Xapp(X<=1000) = 1;
colormap(gray(2^16))
subplot(1,2,1)
image(X)
title('Original Image')
subplot(1,2,2)
image(Xapp)
title('Approximation')

```

There are 16 bits per sample. Compute the quality metrics of the grayscale approximation.

```

bps = 16;
[psnr,mse,maxerr,L2rat] = measerr(X,Xapp)

psnr = 11.0733
mse = 5.0786e+03
maxerr = 999
L2rat = 1.0000

```

Input Arguments

X — Input signal or image
real-valued array

Input signal or image, specified as a real-valued array.

XAPP — Approximation of signal or image

real-valued array

Approximation of signal or image X , specified as a real-valued array. $XAPP$ is the same size as X .

BPS — Bits per sample

8 (default) | positive integer

Bits per sample of the input data, specified as a positive integer. The default value is 8, so the maximum possible pixel value of an image ($MAXI$) is 255. More generally, when samples are represented using linear Pulse Code Modulation with B bits per sample, $MAXI$ is $2^B - 1$.

Output Arguments**PSNR — Peak signal-to-noise ratio**

positive real number

Peak signal-to-noise ratio (PSNR) in decibels, returned as a positive real number. The PSNR is only meaningful for data encoded in terms of bits per sample or bits per pixel. For example, an image with 8 bits per pixel contains integers from 0 to 255.

MSE — Mean square error

positive real number

Mean square error, returned as a positive real number. MSE is the squared norm of the difference between X and $XAPP$ divided by the number of elements.

MAXERR — Maximum absolute squared deviation

positive real number

Maximum absolute squared deviation of the data X from the approximation $XAPP$, returned as a positive real number.

L2RAT — Energy ratio

positive real number

Energy ratio between the approximation $XAPP$ and input data X , returned as a positive real number. $L2RAT$ is the ratio of the squared norm of $XAPP$ to X .

More About**Peak Signal to Noise Ratio**

The peak signal-to-noise ratio (PSNR) in decibels between a signal and its approximation is

$$20\log_{10}\left(\frac{2^B - 1}{\sqrt{MSE}}\right)$$

where MSE represents the mean square error, and B represents the bits per sample.

Mean Square Error

The mean square error (MSE) between a signal or image, X , and an approximation, Y , is

$$\frac{\|X - Y\|^2}{N}$$

where N is the number of elements in the signal.

Introduced in R2010b

merge

Merge two or more labeled signal sets

Syntax

```
lssnew = merge(lss1, ..., lssN)
```

Description

`lssnew = merge(lss1, ..., lssN)` merges N labeled signal set objects, `lss1, ..., lssN`, and returns a labeled signal set `lssnew` containing all the members and label values of the input sets.

Examples

Merge Labeled Signal Sets

Load a labeled signal set containing recordings of whale songs. Display the names of the set's members and a summary of its label definitions.

```
load whales
```

```
getMemberNames(lss)
```

```
ans = 2x1 string
    "Member{1}"
    "Member{2}"
```

```
labelDefinitionsSummary(lss)
```

```
ans=3x9 table
    LabelName      LabelType      LabelDataType      Categories      ValidationFunction      Defa
_____
    "WhaleType"    "attribute"    "categorical"      {3x1 string}    {"N/A"  }              {0x0
    "MoanRegions"  "roi"          "logical"          {"N/A"  }        {0x0 double}          {0x0
    "TrillRegions" "roi"          "logical"          {"N/A"  }        {0x0 double}          {0x0
```

Create a new signal set with the same data source, time information, and labels as `lss`. Remove the first member of the new set and change the name of the remaining one. Display the names of the new set's members.

```
newlss = copy(lss);
```

```
removeMembers(newlss, 1)
setMemberNames(newlss, "YoungOne")
```

```
getMemberNames(newlss)
```

```
ans =
    "YoungOne"
```

Create a label definition that specifies whether a signal corresponds to a calf or to an adult whale. Add the definition to the new labeled signal set and label the member. Remove the label that specifies the moan regions. Display a summary of the new member's label definitions

```
calf = signalLabelDefinition('Calf','LabelDataType','logical','DefaultValue',false, ...
    'Description','Is the specimen a calf, or an adult?');

addLabelDefinitions(newlss,calf)
setLabelValue(newlss,1,"Calf",true)

removeLabelDefinition(newlss,"MoanRegions")
labelDefinitionsSummary(newlss)
```

```

```

Input Arguments

lss1, ..., lssN — Input labeled signal sets
labeledSignalSet objects

Input labeled signal sets, specified as labeledSignalSet objects. All input sets must have the same time information settings and data source type.

Output Arguments

lssnew — Merged labeled signal set

labeledSignalSet object

Merged labeled signal set, returned as a `labeledSignalSet` object. The set `lssnew` contains a signal source, label definitions, and label values that are independent of those in the input labeled signal sets.

- Changing any of the input labeled signal sets does not affect the merged labeled signal set.
- Changing the merged labeled signal set does not affect any of the input labeled signal sets.

Introduced in R2020a

mexihat

Mexican hat (Ricker) wavelet

Syntax

```
[psi,x] = mexihat(lb,ub,n)
```

Description

`[psi,x] = mexihat(lb,ub,n)` returns the Mexican hat wavelet `psi` evaluated at `x`, an `n`-point regular grid in the interval `[lb, ub]`. The Mexican hat wavelet is also known as the Ricker wavelet.

The Mexican hat wavelet has the interval `[-5, 5]` as effective support. Nearly 100% of the wavelet's energy is in the interval. Although `[-5, 5]` is the correct theoretical effective support, a wider effective support, `[-8, 8]`, is used in the computation to provide more accurate results.

This function is proportional to the second derivative function of the Gaussian probability density function.

Note You can use `gauswavf` to obtain a second order derivative of a Gaussian wavelet. If you use the negative of this normalized derivative, the resulting wavelet resembles the Mexican hat wavelet.

Examples

Mexican Hat Wavelet

Create a Mexican hat wavelet with support on `[-5,5]`. Use 1,000 sample points. Plot the result.

```
lb = -5;  
ub = 5;  
N = 1000;  
[psi,xval] = mexihat(lb,ub,N);  
plot(xval,psi)  
title('Mexican Hat Wavelet')
```

Input Arguments

lb – Lower limit

real-valued scalar

Lower limit of interval, specified as a real-valued scalar.

ub – Upper limit

real-valued scalar

Upper limit of interval, specified as a real-valued scalar.

n – Number of sample points

positive integer

Number of sample points, specified as a positive integer.

Output Arguments

psi – Mexican hat wavelet

real-valued vector

Mexican hat wavelet, returned as a real-valued vector of length n.

x — Sampling instants

real-valued vector

Sampling instants, returned as a real-valued vector of length n .

gauswavf | waveinfo

Introduced before R2006a

meyer

Meyer wavelet

Syntax

```
[phi,psi,t] = meyer(lb,ub,n)
[phi,t] = meyer(lb,ub,n,'phi')
[psi,t] = meyer(lb,ub,n,'psi')
[phi,psi] = meyer(lb,ub,n,S)
```

Description

`[phi,psi,t] = meyer(lb,ub,n)` returns the Meyer scaling and wavelet functions, `phi` and `psi` respectively, evaluated at `t`, an `n`-point regular grid in the interval `[lb, ub]`. Both functions have the interval `[-8, 8]` as effective support.

Note `meyer` uses the auxiliary function `meyeraux`. If you change `meyeraux`, you get a family of different wavelets.

`[phi,t] = meyer(lb,ub,n,'phi')` returns only the Meyer scaling function.

`[psi,t] = meyer(lb,ub,n,'psi')` returns only the Meyer wavelet.

`[phi,psi] = meyer(lb,ub,n,S)` returns the Meyer scaling function and wavelet if `S` is not equal to `'phi'` or `'psi'`.

Examples

Plot Meyer Wavelet and Scaling Functions

Plot the Meyer wavelet and scaling functions.

```
lb = -8;
ub = 8;
n = 1024;
[phi,psi,x] = meyer(lb,ub,n);
subplot(2,1,1)
plot(x,phi)
grid on
title('Scaling Function')
subplot(2,1,2)
plot(x,psi)
grid on
title('Wavelet')
```

Input Arguments

lb – Lower limit

real-valued scalar

Lower limit of interval, specified as a real-valued scalar.

ub – Upper limit

real-valued scalar

Upper limit of interval, specified as a real-valued scalar.

n – Number of points

positive integer

Number of points, specified as a positive integer. n must be a power of 2.

Output Arguments

phi – Meyer scaling function

real-valued vector

Meyer scaling function, returned as a real-valued vector of length n .

psi — Meyer wavelet

real-valued vector

Meyer wavelet, returned as a real-valued vector of length n .

t — Sampling instants

real-valued vector

Sampling instants, returned as a real-valued vector of length n .

Algorithms

The Meyer wavelet and scaling functions are defined in the Fourier domain. Starting from an explicit form of the Fourier transform $\hat{\phi}$ of the scaling function ϕ , `meyer` computes the values of $\hat{\phi}$ on a regular grid. The values of ϕ are computed using an inverse Fourier transform.

The procedure for the wavelet ψ is identical to the procedure for the scaling function.

`meyeraux` | `wavefun` | `waveinfo`

Introduced before R2006a

meyeraux

Meyer wavelet auxiliary function

Syntax

`Y = meyeraux(X)`

Description

`Y = meyeraux(X)` returns values of the auxiliary function used for Meyer wavelet generation evaluated at the elements of `X`. The input `X` is a vector or matrix of real values. The function is

$$y = 35x^4 - 84x^5 + 70x^6 - 20x^7.$$

`X` and `Y` have the same dimensions. The range of `meyeraux` is the closed interval `[0, 1]`.

Examples

Plot Meyer Auxiliary Function

Plot the Meyer auxiliary function.

```
x = linspace(0,1,100);  
y = meyeraux(x);  
plot(x,y)  
grid on
```

Input Arguments

X — Sample points

real-valued vector | real-valued matrix

Sample points at which to evaluate the Meyer auxiliary function, specified as a vector or matrix of real values.

Data Types: `single` | `double`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

mlpt

Multiscale local 1-D polynomial transform

Syntax

```
[coefs,T,coefsPerLevel,scalingMoments] = mlpt(x,t)
[coefs,T,coefsPerLevel,scalingMoments] = mlpt(x,t,numLevel)
[coefs,T,coefsPerLevel,scalingMoments] = mlpt(x)
[coefs,T,coefsPerLevel,scalingMoments] = mlpt( ___,Name,Value)
```

Description

`[coefs,T,coefsPerLevel,scalingMoments] = mlpt(x,t)` returns the multiscale local polynomial 1-D transform (MLPT) of input signal `x` sampled at the sampling instants, `t`. If `x` or `t` contain NaNs, the union of the NaNs in `x` and `t` is removed before obtaining the `mlpt`.

`[coefs,T,coefsPerLevel,scalingMoments] = mlpt(x,t,numLevel)` returns the transform for `numLevel` resolution levels.

`[coefs,T,coefsPerLevel,scalingMoments] = mlpt(x)` uses uniform sampling instants for `x` as the time instants if `x` does not contain NaNs. If `x` contains NaNs, the NaNs are removed from `x` and the nonuniform sampling instants are obtained from the numeric elements of `x`.

`[coefs,T,coefsPerLevel,scalingMoments] = mlpt(___,Name,Value)` specifies `mlpt` properties using one or more `Name,Value` pair arguments and any of the previous input arguments.

Examples

Multiscale Local 1-D Polynomial Transform and Inverse Transform

Create a signal with nonuniform sampling and verify good reconstruction when performing the `mlpt` and `imlpt`.

Create and plot a sine wave with non-uniform sampling.

```
timeVector = 0:0.01:1;
sineWave = sin(2*pi*timeVector)';

samplesToErase = randi(100,100,1);
sineWave(samplesToErase) = [];
timeVector(samplesToErase) = [];

figure(1)
plot(timeVector,sineWave,'o')
hold on
```

Perform the multiscale local 1-D polynomial transform (mlpt) on the signal. Visualize the coefficients.

```
[coefs,T,coefsPerLevel,scalingMoments] = mlpt(sineWave,timeVector);
```

```
figure(2)  
stem(coefs)  
title('Wavelet Coefficients')
```

Perform the inverse multiscale local 1-D polynomial transform (`imlpt`) on the coefficients. Visualize the reconstructed signal.

```
y = imlpt(coefs,T,coefsPerLevel,scalingMoments);
```

```
figure(1)  
plot(T,y,'*')  
legend('Original Signal','Reconstructed Signal')  
hold off
```

Look at the total error to verify good reconstruction.

```
reconstructionError = sum(abs(y-sineWave))
```

```
reconstructionError = 1.7552e-15
```

Specify Nondefault Dual Moments

Specify nondefault dual moments by using the `m\lpt` function. Compare the results of analysis and synthesis using the default and nondefault dual moments.

Create an input signal and visualize it.

```
T = (1:16)';  
x = T.^2;  
plot(x)  
hold on
```

Perform the forward and inverse transform for the input signal using the default and nondefault dual moments.

```
[w2,t2,nj2,scalingmoments2] = mlpt(x,T);
y2 = imlpt(w2,t2,nj2,scalingmoments2);

[w3,t3,nj3,scalingmoments3] = mlpt(x,T,'dualmoments',3);
y3 = imlpt(w3,t3,nj3,scalingmoments3,'dualmoments',3);
```

Plot the reconstructed signal and verify perfect reconstruction using both the default and nondefault dual moments.

```
plot(y2,'o')
plot(y3,'*')
legend('Original Signal', ...
       'DualMoments = 3', ...
       'DualMoments = 2 (Default)');

fprintf('\nMean Reconstruction Error:\n');
Mean Reconstruction Error:
fprintf(' - Nondefault dual moments: %0.2f\n',mean(abs(y3-x)));
- Nondefault dual moments: 0.00
fprintf(' - Default dual moments: %0.2f\n\n',mean(abs(y2-x)));
- Default dual moments: 0.00
```

hold off

Specify Nondefault Resolution Levels

Resolution levels are the number of cascaded local polynomial smoothing operations. The details at each resolution level are obtained by predicting one half the samples based on a local polynomial interpolation of the other half. The difference between the predicted and actual values are the details at each resolution level. The scaling coefficients at each coarser resolution level are smoother versions of the higher resolution scaling coefficients. Only the final-level scaling coefficients are retained.

Increasing the number of resolution levels enables you to analyze narrowband coefficients for a computational and memory cost.

Create a dual-tone input signal, x , that contains high and low frequencies.

```
fs = 1000;
t = (0:1/fs:10)';
x = sin(499*pi.*t) + sin(2*pi.*t);
```

Use `mlpt` to obtain coefficients for minimum and maximum resolution levels. Print the computation time.

```
tic
[w1,~,nj1,m1] = mlpt(x,t,1);
computationTime1 = toc;
fprintf('Level one computation time: %0.2f\n',computationTime1)
```

Level one computation time: 5.94

```
tic
[w13,~,nj13,m13] = mlpt(x,t,13);
computationTime13 = toc;
fprintf('Level thirteen computation time: %0.2f\n',computationTime13)
```

Level thirteen computation time: 8.87

Use Default Time Instants

If your time instants are not known or specified, you can calculate the MLPT using default time instants.

Load a data signal corrupted with NaNs and with unknown time instants. Calculate the MLPT without specifying time instants. The resulting implied time instants is a vector of valid indices of the corrupted signal.

```
load('CorruptedData.mat');
```

```
[w,t,nj,scalingMoments] = mlpt(yCorrupt);
```

Calculate the inverse MLPT and visualize the results. Reinsert NaNs to visualize gaps in the signal.

```
z = imlpt(w,t,nj,scalingMoments);
```

```
zToPlot = NaN(numel(yCorrupt),1);
zToPlot(t) = z;
```

```
plot(yCorrupt,'k','LineWidth',2.5)
hold on
plot(zToPlot,'c','LineWidth',1)
hold off
legend('Original Signal','Reconstructed Signal')
xlabel('Time Instants')
```

Input Arguments

x — Input signal

vector | matrix

Input signal, specified as a vector or matrix.

- **matrix** — x must have at least two rows. `mlpt` operates independently on each column of x . The number of elements in t must equal the row dimension of x . Any NaNs in the columns of x must occur in the same rows.
- **vector** — x and t must have the same number of elements.

Data Types: double

t — Sampling instants

vector | duration array | datetime array

Sampling instants corresponding to the input signal, specified as a vector, duration array, or datetime array of monotonically increasing real values. The default value depends on the length of the input signal, x .

Data Types: double | duration | datetime

numLevel — Number of resolution levels

positive integer

Number of resolution levels, specified as a positive integer. The maximum value of `numLevel` depends on the shape of the input signal, `x`:

- matrix — `floor(log2(size(x,1)))`
- vector — `floor(log2(length(x)))`

If `numLevel` is not specified, `mlpt` uses the maximum value.

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'DualMoments', 3` computes a transform using three dual vanishing moments.

DualMoments — Number of dual vanishing moments

2 (default) | 3 | 4

Number of dual vanishing moments in the lifting scheme, specified as the comma-separated pair consisting of `'DualMoments'` and 2, 3 or 4.

Data Types: `double`

PrimalMoments — Number of primal vanishing moments

2 (default) | 3 | 4

Number of primal vanishing moments in the lifting scheme, specified as the comma-separated pair consisting of `'PrimalMoments'` and 2, 3, or 4.

Data Types: `double`

Prefilter — Prefilter before mlpt

'Haar' (default) | 'UnbalancedHaar' | 'None'

Prefilter before `mlpt` operation, specified as the comma-separated pair consisting of `'Prefilter'` and `'Haar'` [1], `'UnbalancedHaar'`, or `'None'`.

Data Types: `char` | `string`

Output Arguments

coefs — MLPT coefficients

vector | matrix

MLPT coefficients, returned as a vector or matrix of coefficients, depending on the level to which the transform is calculated. `coefs` contains the approximation and detail coefficients.

Data Types: `double`

T — Sampling instants corresponding to output

vector | duration array

Sampling instants corresponding to output, returned as a vector or duration array of sample times obtained from `x` and `t`. The `imlpt` function requires `T` as an input. If the input `t` is a `datetime` or

duration array, `t` is converted to units that allow for the stable computation of the `mlpt` and `imlpt`. Then `T` is returned as a duration array.

Data Types: `double` | `duration`

coefsPerLevel — Coefficients per resolution level

vector

Coefficients per resolution level, returned as a vector containing the number of coefficients at each resolution level in `coefs`. The elements of `coefsPerLevel` are organized as follows:

- `coefsPerLevel(1)` — Number of approximation coefficients at the coarsest resolution level.
- `coefsPerLevel(i)` — Number of detail coefficients at resolution level `i`, where `i = numLevel - i + 2` for `i = 2, ..., numLevel + 1`.

The smaller the index `i`, the lower the resolution. The MLPT is two times redundant in the number of detail coefficients, but not in the number of approximation coefficients.

Data Types: `double`

scalingMoments — Scaling function moments

matrix

Scaling function moments, returned as a `length(coefs)`-by-`P` matrix, where `P` is the number of primal moments specified by the `PrimalMoments` name-value pair.

Data Types: `double`

Algorithms

Maarten Jansen developed the theoretical foundation of the multiscale local polynomial transform (MLPT) and algorithms for its efficient computation [1][2][3]. The MLPT uses a lifting scheme, wherein a kernel function smooths fine-scale coefficients with a given bandwidth to obtain the coarser resolution coefficients. The `mlpt` function uses only local polynomial interpolation, but the technique developed by Jansen is more general and admits many other kernel types with adjustable bandwidths [2].

Topics

Smoothing Nonuniformly Sampled Data

Introduced in R2017a

mlptdenoise

Denoise signal using multiscale local 1-D polynomial transform

Syntax

```
y = mlptdenoise(x,t)
y = mlptdenoise(x,t,numLevel)
y = mlptdenoise(___,Name,Value)
[y,T] = mlptdenoise(___)
[y,T,thresholdedCoefs] = mlptdenoise(___)
[y,T,thresholdedCoefs,originalCoefs] = mlptdenoise(___)
```

Description

`y = mlptdenoise(x,t)` returns a denoised version of input signal `x` sampled at the sampling instants, `t`. If `x` or `t` contain NaNs, the union of the NaNs in `x` and `t` is removed before obtaining the `mlpt`.

`y = mlptdenoise(x,t,numLevel)` denoises `x` down to `numLevel`.

`y = mlptdenoise(___,Name,Value)` specifies `mlpt` properties using one or more `Name,Value` pair arguments, and any of the previous syntaxes

`[y,T] = mlptdenoise(___)` also returns the time instants for the denoised signal.

`[y,T,thresholdedCoefs] = mlptdenoise(___)` also returns the thresholded multiscale local 1-D polynomial transform coefficients.

`[y,T,thresholdedCoefs,originalCoefs] = mlptdenoise(___)` also returns the original multiscale local 1-D polynomial transform coefficients.

Examples

Specify Nondefault Denoising Method

Denoise a nonuniformly sampled spline signal with added noise using median smoothing and two primal vanishing moments. The nonuniformity of the signal is indicated by NaNs (missing data).

Load the data to your workspace and visualize it.

```
load nonuniformspline
plot(splinenoise)
grid on
title('Noisy Signal with Missing Data')
```

Denoise the data using the median denoising method.

```
xden = mlptdenoise(splinenoise,[],'DenoisingMethod','median');
```

Replace the original missing data in the correct position for plotting purposes. Visualize the original and denoised signals.

```
denoisedsig = NaN(size(splinenoise));
denoisedsig(~isnan(splinenoise)) = xden;
figure
plot([splinesig denoisedsig])
grid on
legend('Original Signal','Denoised Signal');
```

Denoise Using Multiscale Local Polynomial Transform

Reduce noise of signal using the multiscale local polynomial transform (MLPT).

Load a pure sine wave signal with uniform sampling, and a corrupted version of the signal.

```
load('InputSamples.mat')

plot(t,x)
hold on
plot(tCorrupt,xCorrupt)
legend('Original','Corrupted')
```

Use `mlptdenoise` to denoise the corrupted signal. Visually compare the corrupted and denoised signals against the original signal.

```
[xDenoised,tDenoised] = mlptdenoise(xCorrupt,tCorrupt);
```

```
plot(tDenoised,xDenoised,'b')  
hold off  
legend('Original','Corrupted','Denoised')
```

Compare the error signals associated with the corrupted signal and the denoised signal. Remove NaNs from the signals for visualization purposes.

```
x(samplesToErase) = [];  
xCorrupt(samplesToErase) = [];  
  
xCorruptError = abs(diff([x,xCorrupt],[],2));  
yError = abs(diff([x,xDenoised],[],2));  
  
plot(tDenoised,xCorruptError)  
hold on  
plot(tDenoised,yError)  
title('Error Signals')  
legend('Corrupted','Denoised')  
hold off
```

Specify Nondefault Denoising Level

By default, `mlptdenoise` denoises a signal based on the two highest-level detail coefficients. In this example, you denoise a signal to different levels and visualize the effect.

Create a multitone signal.

```
fs = 1000;
t = 0:1/fs:1;
x = sin(4*pi*t) + sin(120*pi*t) + sin(480*pi*t);
```

Denoise the signal to levels one, two, and five.

```
y1 = mlptdenoise(x,t,1);
y2 = mlptdenoise(x,t,2);
y5 = mlptdenoise(x,t,5);
```

Visualize the effect of level on the denoised signal.

```
subplot(4,1,1)
plot(t,x)
title('Original Signal')

subplot(4,1,2)
plot(t,y1)
```

```

title('Denoised Signal, Level = 1')

subplot(4,1,3)
plot(t,y2)
title('Denoised Signal, Level = 2')

subplot(4,1,4)
plot(t,y5)
title('Denoised Signal, Level = 5')

```

Compare Thresholded and Nonthresholded Coefficients

The `mlptdenoise` function performs the forward MLPT, thresholds the coefficients as specified by the 'DenoisingMethod' name-value pair. Then `mlptdenoise` performs the inverse MLPT to return a denoised signal in the domain of your original signal.

You can optionally return the thresholded and original coefficients for inspection and analysis.

Denoise a nonuniformly sampled signal using Stein's unbiased risk method. Return the denoised signal, the associated time instants, the thresholded MLPT coefficients, and the original MLPT coefficients. Plot the original and denoised signals.

```
load nonuniformheavisine;
```

```
[xDenoised,t,wThrolded,wOriginal] = mlptdenoise(x,t,3,'denoisingmethod','SURE');  
plot(t,[f,xDenoised])  
legend('Original signal','Denoised signal')
```

Plot the original MLPT coefficients and the thresholded MLPT coefficients for comparison.

```
plot([wOriginal,wThrolded])  
legend('Original coefficients','Thresholded coefficients')
```

Input Arguments

x — Input signal

vector | matrix

Input signal, specified as a vector or matrix.

- **matrix** — **x** must have at least two rows. `mlpt` operates independently on each column of **x**. The number of elements in **t** must equal the row dimension of **x**. Any NaNs in the columns of **x** must occur in the same rows.
- **vector** — **x** and **t** must have the same number of elements.

Data Types: double

t — Sampling instants

vector | duration array | datetime array

Sampling instants corresponding to the input signal, specified as a vector, duration array, or datetime array of monotonically increasing real values. The default value depends on the length of the input signal, **x**.

Data Types: double | duration | datetime

numLevel — Number of resolution levels

2 (default) | positive integer

Number of resolution levels, specified as a positive integer. The maximum value of `numLevel` depends on the shape of the input signal, `x`:

- matrix — `floor(log2(size(x,1)))`
- vector — `floor(log2(length(x)))`

`mlptdenoise` denoises `x` by thresholding all detail coefficients of an MLPT calculated for `numLevel` resolution levels.

Data Types: double

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'DualMoments', 3` computes a transform using three dual vanishing moments.

DualMoments — Number of dual vanishing moments

2 (default) | 3 | 4

Number of dual vanishing moments in the lifting scheme, specified as the comma-separated pair consisting of `'DualMoments'` and 2, 3 or 4.

Data Types: double

PrimalMoments — Number of primal vanishing moments

2 (default) | 3 | 4

Number of primal vanishing moments in the lifting scheme, specified as the comma-separated pair consisting of `'PrimalMoments'` and 2, 3, or 4.

Data Types: double

Prefilter — Prefilter before mlpt

'Haar' (default) | 'UnbalancedHaar'

Prefilter before `mlpt` operation, specified as the comma-separated pair consisting of `'Prefilter'` and `'Haar'` or `'UnbalancedHaar'`. If no prefilter is specified, `'Haar'` is used by default.

Data Types: char | string

DenoisingMethod — Denoising method applied to MLPT detail coefficients

'Bayesian' (default) | 'Median' | 'SURE' | 'FDR'

Denoising method applied to MLPT detail coefficients, specified as the comma-separated pair consisting of `'DenoisingMethod'` and `'Bayesian'`, `'Median'`, `'SURE'`, or `'FDR'`.

Note `'FDR'` has an optional argument for the Q-value. Q is the proportion of false positives and is specified as a real-valued scalar between zero and one. To specify `'FDR'` with a Q-value, use a cell array, where the second element is the Q-value, for example `'DenoisingMethod', {'FDR', 0.01}`. If unspecified, Q defaults to 0.05.

Data Types: char | string

Output Arguments

y — Denoised version of the input signal

vector | matrix

Denoised version of the input signal, returned as a vector or matrix. The size of `y` depends on the size of `x` and the union of NaNs in `x` and `t`.

By default, the `mlpt` is denoised based on the two highest resolution detail coefficients, unless `x` has fewer than four samples. If `x` has fewer than four samples, the `mlpt` is denoised based only on the highest resolution detail coefficients.

Data Types: double

T — Sampling instants corresponding to output

vector | duration array

Sampling instants corresponding to the output, returned as a vector or `duration` array obtained from `x` and the input `t`. If the input `t` is a `datetime` or `duration` array, `t` is converted to units that enable stable `mlpt` and `implt` computation. Then `T` is returned as a `duration` array.

Data Types: double | duration

thresholdedCoefs — Thresholded MLPT coefficients

vector | matrix

Thresholded MLPT coefficients, returned as a vector or matrix. The size of `thresholdedCoefs` depends on the size of `x` and the level to which the transform is calculated.

Data Types: double

originalCoefs — Original MLPT coefficients

vector | matrix

Original MLPT coefficients, returned as a vector or matrix. The size of `originalCoefs` depends on the size of `x` and the level to which the transform is calculated.

Data Types: double

Algorithms

Maarten Jansen developed the theoretical foundation of the multiscale local polynomial transform (MLPT) and algorithms for its efficient computation [1][2][3]. The MLPT uses a lifting scheme, wherein a kernel function smooths fine-scale coefficients with a given bandwidth to obtain the coarser resolution coefficients. The `mlpt` function uses only local polynomial interpolation, but the technique developed by Jansen is more general and admits many other kernel types with adjustable bandwidths [2].

Topics

Smoothing Nonuniformly Sampled Data

Introduced in R2017a

mlptrecon

Reconstruct signal using inverse multiscale local 1-D polynomial transform

Syntax

```
y = mlptrecon(type,coefs,T,coefsPerLevel,scalingMoments,reconstructionLevel)
y = mlptrecon( ___,Name,Value)
```

Description

`y = mlptrecon(type,coefs,T,coefsPerLevel,scalingMoments,reconstructionLevel)` returns an approximation to the inverse multiscale 1-D polynomial transform (MLPT) of `coefs`.

`y = mlptrecon(___,Name,Value)` specifies `mlptrecon` properties using one or more `Name,Value` pair arguments and the input arguments from the previous syntax.

Examples

Detect and Localize High-Frequency Content

Create a low-frequency signal with high-frequency blips.

```
t = (0:0.01:10)';
x = sin(2*pi.*t) + 0.5*sin(pi.*t+0.1);
bliptime = (0:0.01:0.5)';
blip = sin(50*pi.*bliptime).*triang(numel(bliptime));
for i = [200,700,900]
    x(i:i+numel(bliptime)-1) = x(i:i+numel(bliptime)-1)+blip;
end
```

Perform a multilevel polynomial transform. Perform the inverse multilevel polynomial transform using the detail coefficients.

```
[w,t,nj,scalingmoments] = mlpt(x,t);
yDetails = mlptrecon('d',w,t,nj,scalingmoments,1);
```

Plot the original signal and the processed signal.

```
subplot(2,1,1)
plot(t,x)
title('Original Signal')

subplot(2,1,2)
plot(t,yDetails)
title('Signal Details')
```

Approximate Data by Choosing Reconstruction Coefficients

Approximate data using multiscale local polynomial transform (MLPT) reconstruction. Use `mlptrecon` to approximate a corrupted and sparsely sampled pitch contour.

Load input data and visualize it.

```
load('CorruptedPitchData.mat');
plot(time,pitchContour,'k','linewidth',3)
hold on
xlabel('Time (s)')
ylabel('Pitch (Hz)')
```

Compute the MLPT of the pitch contour.

```
[w,t,nj,scalingMoments] = mlpt(pitchContour,time, ...
    'DualMoments',3, ...
    'PrimalMoments',4, ...
    'PreFilter','none');
```

Use `mlptrecon` to reconstruct the signal using the approximation coefficients at different levels.

```
y = zeros(numel(t),3);
for level = 1:3
    y(:,level) = mlptrecon('a',w,t,nj,scalingMoments,level,'DualMoments',3);
end
```

Plot the reconstructed signals. Level two obtains the best smoothed estimate.

```
plot(t,y(:,1),'c','linewidth',1)
plot(t,y(:,2),'linewidth',2)
plot(t,y(:,3),'linewidth',2)
legend('Original Data','Level = 1','Level = 2','Level = 3')
hold off
```

Input Arguments

type — Type of coefficients

'a' | 'd'

Type of coefficients used to reconstruct the signal, specified as 'a' or 'd'.

- 'a' — Approximation coefficients
- 'd' — Detail coefficients

Approximation coefficients are a lowpass representation of the input. At each level, the approximation coefficients are divided into coarser approximation and detail coefficients.

Data Types: char | string

coefs — MLPT coefficients

vector | matrix

MLPT coefficients, specified as a vector or matrix of MLPT coefficients returned by the `mlpt` function.

Data Types: double

T — Sampling instants corresponding to output

vector | duration array

Sampling instants corresponding to y , specified as a vector or duration array of increasing values returned by the `mlpt` function.

Data Types: `double` | `duration`

coefsPerLevel — Coefficients per resolution level

vector

Coefficients per resolution level, specified as a vector containing the number of coefficients at each resolution level in `coefs`. `coefsPerLevel` is an output argument of the `mlpt` function.

The elements of `coefsPerLevel` are organized as follows:

- `coefsPerLevel(1)` — Number of approximation coefficients at the coarsest resolution level.
- `coefsPerLevel(i)` — Number of detail coefficients at resolution level i , where $i = \text{numLevel} - i + 2$ for $i = 2, \dots, \text{numLevel} + 1$. `numLevel` is the number of resolution levels used to calculate the MLPT. `numLevel` is inferred from `coefsPerLevel`: `numLevel = length(coefsPerLevel - 1)`.

The smaller the index i , the lower the resolution. The MLPT is two times redundant in the number of detail coefficients, but not in the number of approximation coefficients.

Data Types: `double`

scalingMoments — Scaling function moments

matrix

Scaling function moments, specified as a `length(coefs)`-by- P matrix, where P is the number of primal moments specified by the MLPT.

Data Types: `double`

reconstructionLevel — Resolution level used for reconstruction

positive integer

Resolution level used for reconstruction, specified as a positive integer less than or equal to `length(coefsPerLevel - 1)`. `length(coefsPerLevel - 1)` is the number of resolution levels used to calculate the MLPT. Increasing the value of `reconstructionLevel` corresponds to reconstructing your signal with coarser resolution approximations.

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'DualMoments', 3` computes a transform using three dual vanishing moments.

DualMoments — Number of dual vanishing moments

2 (default) | 3 | 4

Number of dual vanishing moments in the lifting scheme, specified as the comma-separated pair consisting of `'DualMoments'` and 2, 3 or 4. The number of dual moments must match the number used by `mlpt`.

Data Types: double

Output Arguments

y — Reconstructed approximation or details of signal

vector | matrix

Reconstructed approximation or details of signal, returned as a vector or matrix, depending on the inputs to the `mlpt` function.

Data Types: double

Algorithms

Maarten Jansen developed the theoretical foundation of the multiscale local polynomial transform (MLPT) and algorithms for its efficient computation [1][2][3]. The MLPT uses a lifting scheme, wherein a kernel function smooths fine-scale coefficients with a given bandwidth to obtain the coarser resolution coefficients. The `mlpt` function uses only local polynomial interpolation, but the technique developed by Jansen is more general and admits many other kernel types with adjustable bandwidths [2].

modwpt

Maximal overlap discrete wavelet packet transform

Syntax

```
wpt = modwpt(x)
wpt = modwpt(x,wname)
wpt = modwpt(x,lo,hi)
wpt = modwpt( ____,lev)

[wpt,packetlevs] = modwpt( ____)
[wpt,packetlevs,cfreq] = modwpt( ____)
[wpt,packetlevs,cfreq,energy] = modwpt( ____)
[wpt,packetlevs,cfreq,energy,relenergy] = modwpt( ____)

[ ____ ] = modwpt( ____,Name,Value)
```

Description

`wpt = modwpt(x)` returns the terminal nodes for the maximal overlap discrete wavelet packet transform (MODWPT) for the 1-D real-valued signal, `x`.

Note The output of the MODWPT is time-delayed compared to the input signal. Most filters used to obtain the MODWPT have a nonlinear phase response, which makes compensating for the time delay difficult. This is true for all orthogonal scaling and wavelet filters, except the Haar wavelet. It is possible to time-align the coefficients with the signal features, but the result is an approximation, not an exact alignment with the original signal. The MODWPT partitions the energy among the wavelet packets at each level. The sum of the energy over all the packets equals the total energy of the input signal. The output of MODWPT is useful for applications where you want to analyze the energy levels in different packets.

The MODWPT details (`modwptdetails`) are the result of zero-phase filtering of the signal. The features in the MODWPT details align exactly with features in the input signal. For a given level, summing the details for each sample returns the exact original signal. The output of the MODWPT details is useful for applications that require time-alignment, such as nonparametric regression analysis.

`wpt = modwpt(x,wname)` returns the MODWPT using the orthogonal wavelet filter specified by the `wname`.

`wpt = modwpt(x,lo,hi)` returns the MODWPT using the orthogonal scaling filter, `lo`, and wavelet filter, `hi`.

`wpt = modwpt(____,lev)` returns the terminal nodes of the wavelet packet tree at positive integer level `lev`.

`[wpt,packetlevs] = modwpt(____)` returns a vector of transform levels corresponding to the rows of `wpt`.

`[wpt,packetlevs,cfreq] = modwpt(___)` returns the center frequencies of the approximate passbands corresponding to the rows of `wpt`.

`[wpt,packetlevs,cfreq,energy] = modwpt(___)` returns the energy (squared L2 norm) of the wavelet packet coefficients for the nodes in `wpt`.

`[wpt,packetlevs,cfreq,energy,relenergy] = modwpt(___)` returns the relative energy for the wavelet packets in `wpt`.

`[___] = modwpt(___ ,Name,Value)` returns the MODWPT with additional options specified by one or more `Name,Value` pair arguments.

Examples

MODWPT Using Default Wavelet

Obtain the MODWPT of an electrocardiogram (ECG) signal using the default length 18 Fejer-Korovkin ('fk18') wavelet.

```
load wecg;
wpt = modwpt(wecg);
```

`wpt` is a 16-by-2048 matrix containing the sequency-ordered wavelet packet coefficients for the wavelet packet transform nodes. In this case, the nodes are at level 4. Each node corresponds to an approximate passband filtering of $[nf_s/2^5, (n+1)f_s/2^5)$, where $n = 0, \dots, 15$, and f_s is the sampling frequency. Plot the wavelet packet coefficients at node (4,2), which is level 4, node 2.

```
plot(wpt(3,:))
title('Node 4 Wavelet Packet Coefficients')
```

MODWPT Using Daubechies Extremal Phase Wavelet with Two Vanishing Moments

Obtain the MODWPT of Southern Oscillation Index data with the Daubechies extremal phase wavelet with two vanishing moments ('db2').

```
load soi;
wsoi = modwpt(soi, 'db2');
```

Verify that the size of the resulting transform contains 16 nodes. Each node is in a separate row.

```
size(wsoi)
```

```
ans = 1×2
```

```
16      12998
```

MODWPT Using Scaling and Wavelet Filters

Obtain the MODWPT of an ECG waveform using the Fejer-Korovkin length 18 scaling and wavelet filters.

```
load wecg;
[lo,hi] = wfilters('fk18');
wpt = modwpt(wecg,lo,hi);
```

MODWPT Full Packet Tree and Passband Center Frequencies

Obtain the MODWPT and full wavelet packet tree of an ECG waveform using the default length 18 Fejer-Korovkin ('fk18') wavelet. Extract and plot the node coefficients at level 3, node 2.

```
load wecg;
[wpt,packetlevels,cfreq] = modwpt(wecg,'FullTree',true);
p3 = wpt(packetlevels==3,:);
plot(p3(3,:))
title('Level 3, Node 2 Wavelet Coefficients')
```

Display the center frequencies at level 3.

```
cfreq(packetlevels==3,:)
```

```
ans = 8×1
    0.0313
    0.0938
    0.1563
    0.2188
```

```
0.2813  
0.3438  
0.4063  
0.4688
```

MODWPT Energy and Relative Energy

Obtain and plot the MODWPT energy and relative energy of an ECG waveform.

```
load wecg  
[wpt,~,cfreq,energy,relenergy] = modwpt(wecg);
```

Show that the sum of the MODWPT energies is equal to the sum of the energy in the original signal. The difference between the total MODWPT energy and the signal energy is small enough to be considered insignificant.

```
disp(['Difference between MODWPT energy and signal energy: ',num2str(sum(energy)-sum(wecg.^2))])
```

```
Difference between MODWPT energy and signal energy: 3.612e-09
```

Plot the MODWPT energy by node.

```
figure  
bar(1:16,energy)  
xlabel('Node')  
ylabel('Energy')  
title('Energy by Node')
```

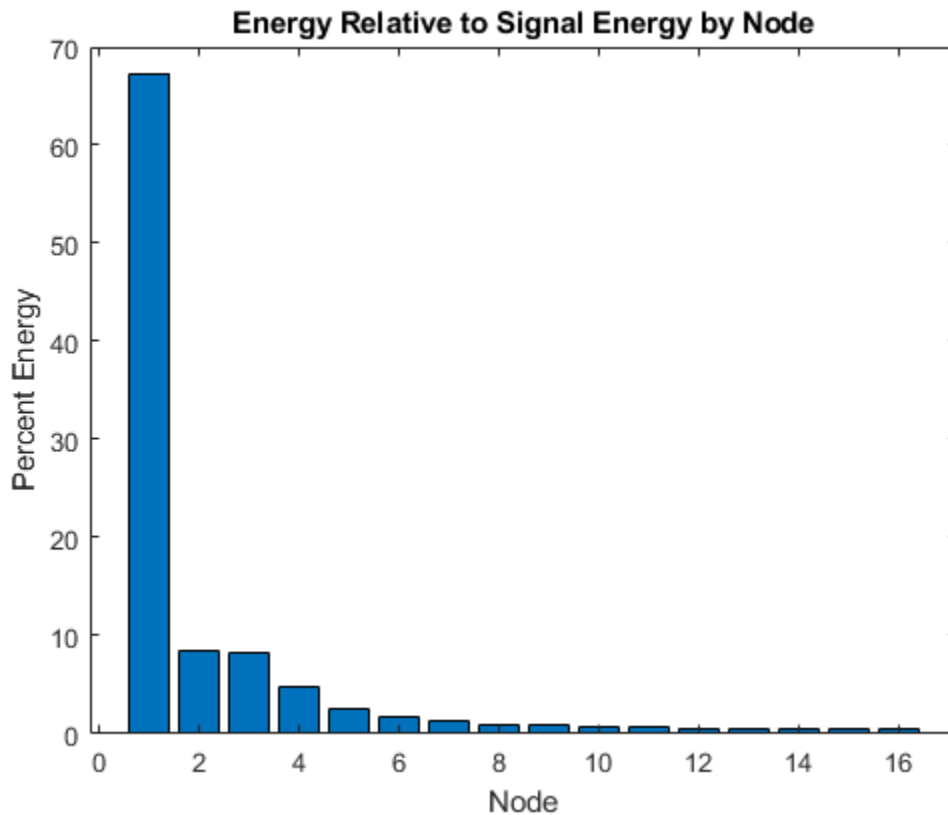

```
disp(['Total power in passband: ',num2str(energy(1))])
```

Total power in passband: 200.8446

Plot the relative energy and show the percentage of signal energy in the first passband [0,5.6250].

```
figure  
bar(1:16,relenergy*100)  
xlabel('Node')  
ylabel('Percent Energy')  
title('Energy Relative to Signal Energy by Node')
```

```
disp(['Percentage of signal power in passband: ', num2str(releenergy(1)*100)])
```

```
Percentage of signal power in passband: 67.3352
```

Time-Aligned MODWPT

Obtain the time-aligned MODWPT of two intermittent sine waves in noise. The sine wave frequencies are 150 Hz and 200 Hz. The data is sampled at 1000 Hz.

```
dt = 0.001;
t = 0:dt:1-dt;
x = cos(2*pi*150*t).*(t>=0.2 & t<0.4)+ sin(2*pi*200*t).*(t>0.6 & t<0.9);
y = x+0.05*randn(size(t));
[wpta,~,Falign] = modwpt(x, 'TimeAlign', true);
[wptn,~,Fnon] = modwpt(x);
```

Compare the nonaligned and time-aligned time-frequency plots.

```
subplot(2,1,1);
contour(t, Fnon.*(1/dt), abs(wptn).^2);
grid on;
ylabel('Hz');
title('Time-Frequency Plot (Nonaligned)');
subplot(2,1,2);
contour(t, Falign.*(1/dt), abs(wpta).^2);
```

```

grid on;
xlabel('Time');
ylabel('Hz');
title('Time-Frequency Plot (Aligned)');

```

Input Arguments

x — Input signal

real-valued vector

Input signal, specified as a real-valued row or column vector. **x** must have at least two elements.

Data Types: double

wname — Analyzing wavelet filter

'fk18' (default) | 'haar' | 'db2' | ...

Analyzing wavelet filter specified as a that corresponds to an orthogonal wavelet. If you specify the scaling (lo) and wavelet (hi) filters, `modwpt` ignores the `wname` input.

Valid orthogonal wavelet families begin with one of the following, followed by an integer, *N*, for example, `sym4`. Note, however, that 'haar' is not followed by an integer.

- 'haar' — Haar wavelet, which is the same as Daubechies wavelet with one vanishing moment, 'db1'.

- 'dbN' — Daubechies wavelet with N vanishing moments
- 'symN' — Symlets wavelet with N vanishing moments
- 'coifN' — Coiflets wavelet with N vanishing moments
- 'fkN' — Fejer-Korovkin wavelet with N coefficients

To check if your wavelet is orthogonal, use `wavemngr('type',wname)` and verify that it returns 1 as the wavelet type. To determine valid values for N , use `waveinfo`, for example, `waveinfo('fk')`.

lo — Scaling filter

even-length real-valued vector

Scaling filter, specified as an even-length real-valued vector. `lo` must satisfy the conditions necessary to generate an orthogonal scaling function. You cannot specify both the scaling-wavelet filters and the `wname` input.

hi — Wavelet filter

even-length real-valued vector

Wavelet filter, specified as an even-length real-valued vector. `hi` must satisfy the conditions necessary to generate an orthogonal wavelet. You cannot specify both the scaling-wavelet filters and the `wname` input.

lev — Transform level

positive integer

Transform level, specified as a positive integer less than or equal to `floor(log2(numel(x)))`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Fulltree', true` returns the full wavelet packet tree

FullTree — Full packet tree

false (default) | true

Option to return the full wavelet packet tree, specified as the comma-separated pair consisting of `'FullTree'` and either `false` or `true`. If you specify `false`, then `modwpt` returns only the terminal (final-level) wavelet packet nodes. If you specify `true`, then `modwpt` returns the full wavelet packet tree down to the specified level.

Example: `'Fulltree', true`

TimeAlign — Signal time alignment

false (default) | true

Option to time align wavelet packet coefficients with signal features, specified as the comma-separated pair consisting of `'TimeAlign'` and either `true` to time align or `false` to not align.

The scaling and wavelet filters have a time delay. Circularly shifting the wavelet packet coefficients in all nodes aligns the signal and wavelet coefficients in time. If you want to reconstruct the signal, such as by using `imodwpt`, do not shift the coefficients because time alignment is done during the inversion process.

Example: 'TimeAlign', true

Output Arguments

wpt — Wavelet packet transform

matrix

Wavelet packet tree, returned as a matrix with each row containing the sequency-ordered wavelet packet coefficients. By default, `wpt` contains only the terminal level for the MODWPT. The default terminal level is either level 4 or $\text{floor}(\log_2(\text{numel}(x)))$, whichever is smaller. At level 4, `wpt` is a 16-by- $\text{numel}(x)$ matrix. For the full tree, at level j , `wpt` is a 2^{j+2} -by- $\text{numel}(x)$ matrix, with each row containing the packet coefficients by level and index. The approximate passband for the n th row of `wpt` at level j is $\left[\frac{n-1}{2^{j+1}}, \frac{n}{2^{j+1}} \right)$ cycles/sample, where $n = 1, 2, \dots, 2^j$.

packetlevs — Transform levels

vector

Transform levels, returned as a vector. The levels correspond to the rows of `wpt`. If `wpt` contains only the terminal level coefficients, `packetlevs` is a vector of constants equal to the terminal level. If `wpt` contains the full wavelet packet table, `packetlevs` is a vector with 2^j elements for each level, j . To select all the wavelet packet nodes at a particular level, use `packetlevs` with logical indexing.

cfreq — Center frequencies of passbands

vector

Center frequencies of the approximate passbands in the `wpt` rows, returned as a vector. The center frequencies are in cycles/sample. To convert the units to cycles/unit time, multiply `cfreq` by the sampling frequency.

energy — Energy of the wavelet packet coefficients

vector

Energy of the wavelet packet coefficients for the `wpt` nodes, returned as a vector. The sum of the energies (squared L2 norms) for the wavelet packets at each level equals the energy in the signal.

relenergy — Relative energy

vector

Relative energy for each level, returned as a vector. The relative energy is the proportion of energy in each wavelet packet by level, relative to the total energy of that level. The sum of relative energies in all packets at each level equals 1.

Algorithms

The `modwpt` performs a discrete wavelet packet transform and produces a sequency-ordered wavelet packet tree. Compare the sequency-ordered and normal (Paley)-ordered trees.

`dwpt` | `imodwpt` | `modwptdetails`

Introduced in R2016a

modwptdetails

Maximal overlap discrete wavelet packet transform details

Syntax

```
w = modwptdetails(x)
w = modwptdetails(x,wname)
w = modwptdetails(x,lo,hi)
w = modwptdetails( ____,lev)

[w,packetlevs] = modwptdetails( ____)
[w,packetlevs,cfreq] = modwptdetails( ____)

[ ____ ] = modwptdetails( ____, 'FullTree', tf)
```

Description

`w = modwptdetails(x)` returns the maximal overlap discrete wavelet packet transform (MODWPT) details for the 1-D real-valued signal, `x`. The MODWPT details provide zero-phase filtering of the signal. By default, `modwptdetails` returns only the terminal nodes, which are at level 4 or at level `floor(log2(numel(x)))`, whichever is smaller.

Note To decide whether to use `modwptdetails` or `modwpt`, consider the type of data analysis you need to perform. For applications that require time alignment, such as nonparametric regression analysis, use `modwptdetails`. For applications where you want to analyze the energy levels in different packets, use `modwpt`. For more information, see “Algorithms” on page 1-775.

`w = modwptdetails(x,wname)` uses the orthogonal wavelet filter specified by `wname`.

`w = modwptdetails(x,lo,hi)` uses the orthogonal scaling filter, `lo`, and wavelet filter, `hi`.

`w = modwptdetails(____, lev)` returns the terminal nodes of the wavelet packet tree at positive integer level `lev`.

`[w,packetlevs] = modwptdetails(____)` returns a vector of transform levels corresponding to the rows of `w`.

`[w,packetlevs,cfreq] = modwptdetails(____)` returns `cfreq`, the center frequencies of the approximate passbands corresponding to the MODWPT details in `w`.

`[____] = modwptdetails(____, 'FullTree', tf)`, where `tf` is `false`, returns details about only the terminal (final-level) wavelet packet nodes. If you specify `true`, then `modwptdetails` returns details about the full wavelet packet tree down to the default or specified level. The default for `tf` is `false`.

Examples

MODWPT Details Using Default Wavelet

Obtain the MODWPT of an electrocardiogram (ECG) signal using the default length 18 Fejer-Korovkin ('fk18') wavelet and the default level, 4.

```
load wecg;  
wptdetails = modwptdetails(wecg);
```

Demonstrate that summing the MODWPT details over each sample reconstructs the signal. The largest absolute difference between the original signal and the reconstruction is on the order of 10^{-11} , which demonstrates perfect reconstruction.

```
xrec = sum(wptdetails);  
max(abs(wecg-xrec'))
```

```
ans = 1.7903e-11
```

MODWPT Details for Two Sine Waves

Obtain the MODWPT details for a signal containing 100 Hz and 450 Hz sine waves. Each row of the `modwptdetails` output corresponds to a separate frequency band.

```
dt = 0.001;  
fs = 1/dt;  
t = 0:dt:1;  
x = (sin(2*pi*100*t)+sin(2*pi*450*t));  
[lo,hi] = wfilters('fk22');  
wptdetails = modwptdetails(x,lo,hi);
```

Use `modwpt` to obtain the energy and center frequencies of the signal. Plot the energy in the wavelet packets. The fourth and fifteenth frequency bands contain most of the energy. Other frequency bands have significantly less energy. The frequency ranges of fourth and fifteenth bands are approximately 94-125 Hz and 438-469 Hz, respectively.

```
[wpt,~,cfreqs,energy] = modwpt(x,lo,hi);  
figure  
bar(1:16,energy);  
xlabel('Packet')  
ylabel('Packet Energy')  
title('Energy by Wavelet Packet')
```

Plot the power spectral density of the input signal.

```
pwelch(x,[],[],[],fs,'onesided');  
title('Power Spectral Density of Input Signal')
```

Show that the MODWPT details have zero-phase shift from the 100 Hz input sine.

```
p4 = wptdetails(4,:);  
plot(t,sin(2*pi*100*t).*(t>0.3 & t<0.7))  
hold on  
plot(t,p4.*(t>0.3 & t<0.7),'r')  
legend('Sine Wave','MODWPT Details')
```

MODWPT Details for Noisy Sine Wave

Obtain the MODWPT details for a 100 Hz time-localized sine wave in noise. The sampling rate is 1000 Hz. Obtain the MODWPT at level 4 using the length 22 Fejer-Korovkin ('fk22') wavelet.

```
dt = 0.001;
t = 0:dt:1;
x = cos(2*pi*100*t).*(t>0.3 & t<0.7)+0.25*randn(size(t));
wptdetails = modwptdetails(x,'fk22');
p4 = wptdetails(4,:);
```

Plot the MODWPT details for level 4, packet number 4. The MODWPT details represent zero-phase filtering of the input signal with an approximate passband of $[3F_s/2^5, 4F_s/2^5]$, where F_s is the sampling frequency.

```
plot(t,cos(2*pi*100*t).*(t>0.3 & t<0.7));
hold on
plot(t,p4,'r')
legend('Sine Wave','MODWPT Details')
```

MODWPT Details Using Scaling and Wavelet Filters

Obtain the MODWPT details of an ECG waveform using the length 18 Fejer-Korovkin scaling and wavelet filters.

```
load wecg;
[lo,hi] = wfilters('fk18');
wpt = modwptdetails(wecg,lo,hi);
```

MODWPT Details for Full Packet Tree

Obtain the MODWPT details for the full wavelet packet tree of an ECG waveform. Use the default length 18 Fejer-Korovkin ('fk18') wavelet. Extract and plot the node coefficients at level 3, node 2.

```
load wecg;
[w,packetlevels] = modwptdetails(wecg,'FullTree',true);
p3 = w(packetlevels==3,:);
plot(p3(3,:))
title('Level 3, Node 2 MODWPT Details')
```

Input Arguments

x — Input signal

real-valued vector

Input signal, specified as a real-valued row or column vector. `x` must have at least two elements.

Data Types: double

wname — Analyzing wavelet filter

'fk18' (default) | 'dbN' | 'coifN' | 'haar' | 'fkN' | 'symN'

Analyzing wavelet, specified as one of the following:

- 'haar' — Haar wavelet
- 'dbN' — Extremal phase Daubechies wavelet with N vanishing moments, where N is a positive integer from 1 to 45.
- 'symN' — Symlets wavelet with N vanishing moments, where N is a positive integer from 2 to 45.
- 'coifN' — Coiflets wavelet with N vanishing moments, where N is a positive integer from 1 to 5.
- 'fkN' — Fejér-Korovkin wavelet with N coefficients, where $N = 4, 6, 8, 14, 18$ and 22 .

lo — Scaling filter

even-length real-valued vector

Scaling filter, specified as an even-length real-valued vector. `lo` must satisfy the conditions necessary to generate an orthogonal scaling function. You can specify the `lo` and `hi` scaling-wavelet filter pair only if you do not specify `wname`.

hi — Wavelet filter

even-length real-valued vector

Wavelet filter, specified as an even-length real-valued vector. `hi` must satisfy the conditions necessary to generate an orthogonal wavelet. You can specify the `lo` and `hi` scaling-wavelet filter pair only if you do not specify `wname`.

lev — Transform level

positive integer

Transform level, specified as a positive integer less than or equal to `floor(log2(numel(x)))`.

tf — Return tree option

`false` (default) | `true`

Return tree option, specified as `false` or `true`. If `tf` is `false`, then `modwptdetails` returns details about only the terminal (final-level) wavelet packet nodes. If you specify `true`, then `modwptdetails` returns details about the full wavelet packet tree down to the default or specified level.

For the full wavelet packet tree, `w` is a 2^{j+1} -by-`numel(x)` matrix. Each level j has 2^j wavelet packet details.

Output Arguments

w — Wavelet packet tree details

matrix

Wavelet packet tree details, returned as a matrix with each row containing the sequency-ordered wavelet packet details for the terminal nodes. The terminal nodes are at level 4 or at level `floor(log2(numel(x)))`, whichever is smaller. The MODWPT details are zero-phase-filtered projections of the signal onto the subspaces corresponding to the wavelet packet nodes. The sum of the MODWPT details over each sample reconstructs the original signal.

For the default terminal nodes, `w` is a 2^j -by-`numel(x)` matrix. For the full packet table, at level j , `w` is a 2^{j+1} -by-`numel(x)` matrix of sequency-ordered wavelet packet coefficients by level and index. The approximate passband for the n th row of `w` at level j is $\left[\frac{n-1}{2^{(j+1)}}, \frac{n}{2^{(j+1)}} \right)$ cycles per sample, where $n = 1, 2, \dots, 2^j$.

packetlevs — Transform levels

vector

Transform levels, returned as a vector. The levels correspond to the rows of `w`. If `w` contains only the terminal level coefficients, `packetlevs` is a vector of constants equal to the terminal level. If `w` contains the full wavelet packet tree of details, `packetlevs` is a vector with 2^{j-1} elements for each level, j . To select all the MODWPT details at a particular level, use `packetlevs` with logical indexing.

cfreq — Center frequencies of passbands

vector

Center frequencies of the approximate passbands in the `w` rows, returned as a vector. The center frequencies are in cycles per sample. To convert the units to cycles per unit time, multiply `cfreq` by the sampling frequency.

Algorithms

The MODWPT details (`modwptdetails`) are the result of zero-phase filtering of the signal. The features in the MODWPT details align exactly with features in the input signal. For a given level, summing the details for each sample returns the exact original signal.

The output of the MODWPT (`modwpt`) is time delayed compared to the input signal. Most filters used to obtain the MODWPT have a nonlinear phase response, which makes compensating for the time delay difficult. All orthogonal scaling and wavelet filters have this response, except the Haar wavelet. It is possible to time align the coefficients with the signal features, but the result is an approximation, not an exact alignment with the original signal. The MODWPT partitions the energy among the wavelet packets at each level. The sum of the energy over all the packets equals the total energy of the input signal.

`imodwpt` | `modwpt` | `waveinfo` | `wavemngr`

Introduced in R2016a

modwt

Maximal overlap discrete wavelet transform

Syntax

```
w = modwt(x)
w = modwt(x,wname)
w = modwt(x,Lo,Hi)
w = modwt( ____,lev)
w = modwt( ____, 'reflection')
```

Description

`w = modwt(x)` returns the maximal overlap discrete wavelet transform (MODWT) of the 1-D real-valued signal, `x`.

`w = modwt(x,wname)` uses the orthogonal wavelet, `wname`, for the MODWT.

`w = modwt(x,Lo,Hi)` uses the scaling filter, `Lo`, and wavelet filter, `Hi`, to compute the MODWT. These filters must satisfy the conditions for an orthogonal wavelet. You cannot specify `Lo` and `Hi` if you specify `wname`.

`w = modwt(____,lev)` computes the MODWT down to the specified level, `lev`, using any of the arguments from previous syntaxes.

`w = modwt(____, 'reflection')` computes the MODWT using reflection boundary handling. Other inputs can be any of the arguments from previous syntaxes. Before computing the wavelet transform, `modwt` extends the signal symmetrically at the right boundary to twice the signal length, [`x flip(x)`]. The number of wavelet and scaling coefficients that `modwt` returns is equal to twice the length of the input signal. By default, the signal is extended periodically.

Examples

MODWT Using Default Wavelet

Obtain the MODWT of an electrocardiogram (ECG) signal using the default `sym4` wavelet down to the maximum level. The data are taken from Percival & Walden (2000), p.125 (data originally provided by William Constantine and Per Reinhall, University of Washington).

```
load wecg;
wtecg = modwt(wecg);
whos wtecg
```

Name	Size	Bytes	Class	Attributes
wtecg	12x2048	196608	double	

The first eleven rows of `wtecg` are the wavelet coefficients for scales 2^1 to 2^{11} . The final row contains the scaling coefficients at scale 2^{11} . Plot the detail (wavelet) coefficients for scale 2^3 .

```
plot(wtecg(3,:))
title('Level 3 Wavelet Coefficients')
```

MODWT Using Daubechies Extremal Phase Wavelet with Two Vanishing Moments

Obtain the MODWT of Southern Oscillation Index data with the db2 wavelet down to the maximum level.

```
load soi;
wsoi = modwt(soi, 'db2');
```

MODWT Using Scaling and Wavelet Filters

Obtain the MODWT of the Deutsche Mark - U.S. Dollar exchange rate data using the Fejer-Korovkin length 8 scaling and wavelet filters.

```
load DM_USD;
[Lo,Hi] = wfilters('fk8');
wdm = modwt(DM_USD,Lo,Hi);
```

MODWT to a Specified Level

Obtain the MODWT of an ECG signal down to scale 2^4 , which corresponds to level four. Use the default `sym4` wavelet. The data are taken from Percival & Walden (2000), p.125 (data originally provided by William Constantine and Per Reinhall, University of Washington).

```
load wecg;
wtecg = modwt(wecg,4);
whos wecg wtecg
```

Name	Size	Bytes	Class	Attributes
wecg	2048x1	16384	double	
wtecg	5x2048	81920	double	

The row size of `wtecg` is $L+1$, where, in this case, the level (L) is 4. The column size matches the number of input samples.

MODWT with Reflection Boundary

Obtain the MODWT of an ECG signal using reflection boundary handling. Use the default `sym4` wavelet and obtain the transform down to level 4. The data are taken from Percival & Walden (2000), p.125 (data originally provided by William Constantine and Per Reinhall, University of Washington).

```
load wecg;
wtecg = modwt(wecg,4,'reflection');
whos wecg wtecg
```

Name	Size	Bytes	Class	Attributes
wecg	2048x1	16384	double	
wtecg	5x4096	163840	double	

`wtecg` has 4096 columns, which is twice the length of the input signal, `wecg`.

Comparing MODWT and MODWTMRA

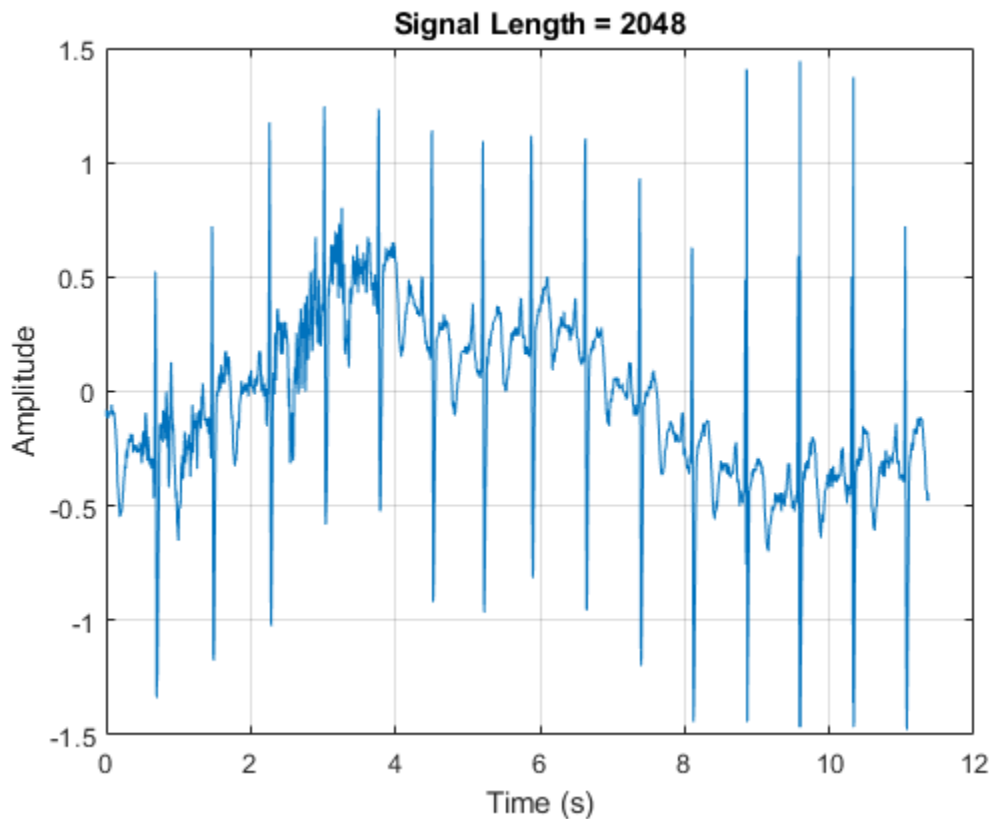

This example demonstrates the differences between the functions `MODWT` and `MODWTMRA`. The `MODWT` partitions a signal's energy across detail coefficients and scaling coefficients. The `MODWTMRA` projects a signal onto wavelet subspaces and a scaling subspace.

Choose the `sym6` wavelet. Load and plot an electrocardiogram (ECG) signal. The sampling frequency for the ECG signal is 180 hertz. The data are taken from Percival and Walden (2000), p.125 (data originally provided by William Constantine and Per Reinhall, University of Washington).

```
load wecg
t = (0:numel(wecg)-1)/180;
wv = 'sym6';
plot(t,wecg)
grid on
title(['Signal Length = ',num2str(numel(wecg))])
```

```
xlabel('Time (s)')
ylabel('Amplitude')
```

Take the MODWT of the signal.

```
wtecg = modwt(wecg,wv);
```

The input data are samples of a function $f(x)$ evaluated at N -many time points. The function can be expressed as a linear combination of the scaling function $\phi(x)$ and wavelet $\psi(x)$ at varying scales and

translations: $f(x) = \sum_{k=0}^{N-1} c_k 2^{-J_0/2} \phi(2^{-J_0}x - k) + \sum_{j=1}^{J_0} f_j(x)$ where $f_j(x) = \sum_{k=0}^{N-1} d_{j,k} 2^{-j/2} \psi(2^{-j}x - k)$

and J_0 is the number of levels of wavelet decomposition. The first sum is the coarse scale approximation of the signal, and the $f_j(x)$ are the details at successive scales. MODWT returns the N -many coefficients $\{c_k\}$ and the $(J_0 \times N)$ -many detail coefficients $\{d_{j,k}\}$ of the expansion. Each row in `wtecg` contains the coefficients at a different scale.

When taking the MODWT of a signal of length N , there are $\text{floor}(\log_2(N))$ -many levels of decomposition (by default). Detail coefficients are produced at each level. Scaling coefficients are returned only for the final level. In this example, since $N = 2048$, $J_0 = \text{floor}(\log_2(2048)) = 11$ and the number of rows in `wtecg` is $J_0 + 1 = 11 + 1 = 12$.

The MODWT partitions the energy across the various scales and scaling coefficients:

$\|X\|^2 = \sum_{j=1}^{J_0} \|W_j\|^2 + \|V_{J_0}\|^2$ where X is the input data, W_j are the detail coefficients at scale j , and V_{J_0} are the final-level scaling coefficients.

Compute the energy at each scale, and evaluate their sum.

```
energy_by_scales = sum(wtecg.^2,2);
Levels = {'D1';'D2';'D3';'D4';'D5';'D6';'D7';'D8';'D9';'D10';'D11';'A11'};
energy_table = table(Levels,energy_by_scales);
disp(energy_table)
```

Levels	energy_by_scales
{'D1' }	14.063
{'D2' }	20.612
{'D3' }	37.716
{'D4' }	25.123
{'D5' }	17.437
{'D6' }	8.9852
{'D7' }	1.2906
{'D8' }	4.7278
{'D9' }	12.205
{'D10' }	76.428
{'D11' }	76.268
{'A11' }	3.4192

```
energy_total = varfun(@sum,energy_table(:,2))
```

```
energy_total=table
sum_energy_by_scales
_____
298.28
```

Confirm the MODWT is energy-preserving by computing the energy of the signal and comparing it with the sum of the energies over all scales.

```
energy_ecg = sum(wecg.^2);
max(abs(energy_total.sum_energy_by_scales-energy_ecg))
ans = 7.4357e-10
```

Take the MODWTMRA of the signal.

```
mraecg = modwtmra(wtecg,wv);
```

MODWTMRA returns the projections of the function $f(x)$ onto the various wavelet subspaces and final

scaling space. That is, MODWTMRA returns $\sum_{k=0}^{N-1} c_k 2^{-J_0/2} \phi(2^{-J_0} x - k)$ and the J_0 -many $\{f_j(x)\}$

evaluated at N -many time points. Each row in `mraecg` is a projection of $f(x)$ onto a different subspace. This means the original signal can be recovered by adding all the projections. This is *not* true in the case of the MODWT. Adding the coefficients in `wtecg` will *not* recover the original signal.

Choose a time point, add the projections of $f(x)$ evaluated at that time point and compare with the original signal.

```
time_point = 1000;
abs(sum(mraecg(:,time_point))-wecg(time_point))

ans = 3.0849e-13
```

Confirm that, unlike MODWT, MODWTMRA is not an energy-preserving transform.

```
energy_ecg = sum(wecg.^2);
energy_mra_scales = sum(mraecg.^2,2);
energy_mra = sum(energy_mra_scales);
max(abs(energy_mra-energy_ecg))

ans = 115.7053
```

The MODWTMRA is a zero-phase filtering of the signal. Features will be time-aligned. Demonstrate this by plotting the original signal and one of its projections. To better illustrate the alignment, zoom in.

```
plot(t,wecg,'b')
hold on
plot(t,mraecg(4,:),'-')
hold off
grid on
xlim([4 8])
legend('Signal','Projection','Location','northwest')
xlabel('Time (s)')
ylabel('Amplitude')
```

Make a similar plot using the MODWT coefficients at the same scale. Note that features will not be time-aligned. The MODWT is *not* a zero-phase filtering of the input.

```
plot(t,wecg, 'b')
hold on
plot(t,wtecg(4,:), '-o')
hold off
grid on
xlim([4 8])
legend('Signal', 'Coefficients', 'Location', 'northwest')
xlabel('Time (s)')
ylabel('Amplitude')
```

Input Arguments

x — Input signal

real-valued vector

Input signal, specified as a row or column vector. `x` must have at least two elements.

By default, `modwt` computes the wavelet transform down to level `floor(log2(length(x)))` using the Daubechies least-asymmetric wavelet with four vanishing moments (`'sym4'`) and periodic boundary handling.

Data Types: `double`

wname — Analyzing wavelet

`'sym4'` (default) | `'haar'` | `'dbN'` | `'symN'` | `'coifN'` | `'fkN'`

Analyzing wavelet, specified as one of the following:

- `'haar'` — Haar wavelet
- `'dbN'` — Extremal phase Daubechies wavelet with `N` vanishing moments, where `N` is a positive integer from 1 to 45.
- `'symN'` — Symlets wavelet with `N` vanishing moments, where `N` is a positive integer from 2 to 45.
- `'coifN'` — Coiflets wavelet with `N` vanishing moments, where `N` is a positive integer from 1 to 5.

- 'fkN' — Fejér-Korovkin wavelet with N coefficients, where N = 4, 6, 8, 14, 18 and 22.

Lo — Scaling filter

even-length real-valued vector

Scaling filter, specified as an even-length real-valued vector. Lo must satisfy the conditions necessary to generate an orthogonal scaling function. You can specify Lo only if you do not specify wname.

Hi — Wavelet filter

even-length real-valued vector

Wavelet filter, specified as an even-length real-valued vector. Hi must satisfy the conditions necessary to generate an orthogonal wavelet. You can specify Hi only if you do not specify wname.

lev — Transform level

positive integer

Transform level, specified as a positive integer less than or equal to floor(log2(length(x))).

Output Arguments

w — Wavelet transform

matrix

Wavelet transform, returned as an L+1-by-N matrix containing wavelet coefficients and final-level scaling coefficients. L is the level of the MODWT. N is equal to the input signal length unless you specify 'reflection' boundary handling, in which case N is twice the length of the input signal. The kth row of w contains the wavelet coefficients for scale 2^k (wavelet scale 2^(k-1)). The final, (L+1)th, row of w contains the scaling coefficients for scale 2^L.

Algorithms

The standard algorithm for the MODWT implements the circular convolution directly in the time domain. This implementation of the MODWT performs the circular convolution in the Fourier domain. The wavelet and scaling filter coefficients at level j are computed by taking the inverse discrete Fourier transform (DFT) of a product of DFTs. The DFTs in the product are the signal's DFT and the DFT of the jth level wavelet or scaling filter.

Let H_k and G_k denote the length N DFTs of the MODWT wavelet and scaling filters, respectively. Let j denote the level and N denote the sample size.

The jth level wavelet filter is defined by

$$\frac{1}{N} \sum_{k=0}^{N-1} H_{j,k} e^{i2\pi nk/N}$$

where

$$H_{j,k} = H_{2^{j-1}k \bmod N} \prod_{m=0}^{j-2} G_{2^m k \bmod N}$$

The jth level scaling filter is

$$\frac{1}{N} \sum_{k=0}^{N-1} G_{j,k} e^{i2\pi mk/N}$$

where

$$G_{j,k} = \prod_{m=0}^{j-1} G_2^{m k \bmod N}$$

modwtcorr

Multiscale correlation using the maximal overlap discrete wavelet transform

Syntax

```
wcorr = modwtcorr(w1,w2)
wcrr = modwtcorr(w1,w2,wav)

[wcrr,wcrrci] = modwtcorr( ___ )
[wcrr,wcrrci] = modwtcorr( ___ ,conflvl)
[wcrr,wcrrci,pval] = modwtcorr( ___ )
[wcrr,wcrrci,pval,nj] = modwtcorr( ___ )

wcorrtable = modwtcorr( ___ , 'table' )

[ ___ ] = modwt( ___ , 'reflection' )

modwtcorr( ___ )
```

Description

`wcorr = modwtcorr(w1,w2)` returns the wavelet correlation by scale for the maximal overlap discrete wavelet transforms (MODWTs) specified in `w1` and `w2`. `wcorr` is an M -by-1 vector of correlation coefficients, where M is the number of levels with nonboundary wavelet coefficients. If the final level has enough nonboundary coefficients, `modwtcorr` returns the scaling correlation in the final row of `wcorr`.

`wcorr = modwtcorr(w1,w2,wav)` uses the wavelet `wav` to determine the number of boundary coefficients by level.

`[wcrr,wcrrci] = modwtcorr(___)` returns in `wcrrci` the lower and upper 95% confidence bounds for the correlation coefficients of `wcorr`, using any arguments from the previous syntaxes.

`[wcrr,wcrrci] = modwtcorr(___ ,conflvl)` uses `conflvl` for the coverage probability of the confidence interval. `conflvl` is a real scalar strictly greater than 0 and less than 1. If `conflvl` is unspecified or specified as empty, the coverage probability defaults to 0.95.

`[wcrr,wcrrci,pval] = modwtcorr(___)` returns the p-values for the null hypothesis test that the correlation coefficient in `wcorr` is equal to zero. `pval` is an M -by-2 matrix, where M is the number of levels with nonboundary wavelet coefficients. T

`[wcrr,wcrrci,pval,nj] = modwtcorr(___)` returns the number of nonboundary coefficients used in the computation of the correlation estimates by level, `nj`.

`wcorrtable = modwtcorr(___ , 'table')` returns an M -by-6 table with the correlation, confidence bounds, p-value, and adjusted p-value. The table also lists the number of nonboundary coefficients by level. The row names of the table `wcorrtable` designate the type and level of each estimate. For example, `D1` designates that the row corresponds to a wavelet or detail estimate at level 1 and `S6` designates that the row corresponds to the scaling estimate at level 6. The scaling correlation is only computed for the final level of the MODWT and only when there are nonboundary

scaling coefficients. You can specify the 'table' flag anywhere after the input transforms w1 and w2. You must enter the entire character vector 'table'. If you specify 'table', modwtcorr only outputs one argument.

[___] = modwt(___ , 'reflection') reduces the number of wavelet and scaling coefficients at each scale by half before computing the correlation. Use this option only when you obtain the MODWT of w1 and w2 were obtained using the 'reflection' boundary condition. You must enter the entire character vector 'reflection'. If you added a wavelet named 'reflection' using the wavelet manager, you must rename that wavelet prior to using this option.

modwtcorr supports only unbiased estimates of the wavelet correlation. For these estimates, the algorithm must remove the extra coefficients obtained using the 'reflection' boundary condition. Specifying the 'reflection' option in modwtcorr is identical to first obtaining the MODWT of w1 and w2 using the default 'periodic' boundary handling and then computing the wavelet correlation estimates.

modwtcorr(___) with no output arguments plots the wavelet correlations by scale with lower and upper confidence bounds. By default, the coverage probability is 0.95. Scales with NaNs for the confidence bounds and the scaling correlation are excluded.

Examples

Correlation by Scale

Find the correlation by scale for monthly DM-USD exchange rate returns from 1970 to 1998. The return data are log transformed. Use the Daubechies wavelet with two vanishing moments ('db2') to obtain the MODWT down to level 6. Then obtain the correlation data.

```
load DM_USD;
load JY_USD;
wdm = modwt(DM_USD, 'db2', 6);
wjy = modwt(JY_USD, 'db2', 6);
wcorr = modwtcorr(wdm, wjy, 'db2')
```

```
wcorr = 7×1

    0.5854
    0.5748
    0.6264
    0.4948
    0.3787
    0.9072
    0.7976
```

wcorr contains seven elements. The first six elements are the correlation coefficients for the wavelet (detail) levels one to six. The final element is the correlation for the scaling (lowpass) level six.

Multiscale Correlation

Obtain the MODWT of the Southern Oscillation Index and Truk Island daily pressure data sets. Tabulate the correlation between the two data sets by level.

```

load soi;
load truk;
wsoi = modwt(soi);
wtruk = modwt(truk);
wcorr = modwtcorr(wsoi,wtruk)

wcorr = 10×1

    0.1749
    0.2936
    0.0914
    0.0883
    0.2667
    0.0894
   -0.0415
    0.4825
    0.4394
    0.7433

```

Show that the number of nonboundary coefficients, in this case, is less than the maximal length of the input. The MODWT is computed down to level thirteen, which is the maximal level for the length of the input. Level thirteen contains thirteen wavelet coefficient vectors and one scaling coefficient vector.

```
size(wsoi,1)
```

```
ans = 14
```

The multiscale correlations are computed only down to level ten because the levels after than do not contain nonboundary coefficients. For unbiased estimates, you must use nonboundary coefficients only.

```
numel(wcorr)
```

```
ans = 10
```

Confidence Intervals for Correlation

Obtain the MODWT of the monthly US-DM and US-JPY exchange return data from 1970 to 1998. The return data are log transformed. Use the Daubechies wavelet with two vanishing moments ('db2') and obtain the MODWT of each series down to level six. Obtain the correlation estimates by scale and the 95% confidence intervals.

```

load DM_USD
load JY_USD
wdm = modwt(DM_USD, 'db2', 6);
wjy = modwt(JY_USD, 'db2', 6);
[wcorr,wcorrci] = modwtcorr(wdm,wjy, 'db2');
[wcorr wcorrci]

```

```
ans = 7×3
```

```

    0.5854    0.4780    0.6756
    0.5748    0.4133    0.7013

```

```

0.6264    0.4016    0.7800
0.4948    0.0803    0.7634
0.3787   -0.3295    0.8142
0.9072    0.1247    0.9939
0.7976   -0.2857    0.9860

```

The width of the confidence interval increases as you go down in level.

Confidence Intervals with 0.99 Coverage Probability

Specify the coverage probability for the confidence intervals. Obtain the 99% confidence intervals for the US-DM and US-JY exchange returns.

```

load DM_USD;
load JY_USD;
wdm = modwt(DM_USD, 'db2', 6);
wjy = modwt(JY_USD, 'db2', 6);
[wcorr, wcorrci] = modwtcorr(wdm, wjy, 'db2', 0.99);
[wcorr wcorrci]

```

ans = 7×3

```

0.5854    0.4407    0.7005

0.9072   -0.3006    0.9975
0.7976   -0.6227    0.9941

```

P-values for Correlation

Return p -values for the test of zero correlation by scale. Obtain the MODWT of the DM-USD and JY-USD exchange return data down to level six using the Daubechies wavelet with two vanishing moments ('db2') wavelet. Compute the correlation by scale and return the p -values.

```

load DM_USD;
load JY_USD;
wdm = modwt(DM_USD, 'db2', 6);
wjy = modwt(JY_USD, 'db2', 6);
[wcorr, wcorrci, pval] = modwtcorr(wdm, wjy, 'db2');
format longE

format

The first column contains the p -value and the second column contains the adjusted p -value based on the false discovery rate.

Multiscale Correlation in Tabular Form

Output results from `modwtcorr` in tabular form. Obtain the MODWT of the DM-USD and JY-USD exchange returns down to level six using the Daubechies wavelet with two vanishing moments ('db2'). Output the results in a table.

```

load DM_USD;
load JY_USD;
wdm = modwt(DM_USD, 'db2', 6);
wjy = modwt(JY_USD, 'db2', 6);
corrtable = modwtcorr(wdm, wjy, 'db2', 'table')

```

Plot Correlation with Confidence Intervals

Plot the multiscale correlation of the DM-USD and JY-USD exchange returns down to level six. Use `modwtcorr` with no output arguments.

```
load DM_USD;
load JY_USD;
wdm = modwt(DM_USD, 'db2', 6);
wjy = modwt(JY_USD, 'db2', 6);
modwtcorr(wdm, wjy, 'db2')
```

Input Arguments

w1 — MODWT transform of signal 1
matrix

MODWT transform of signal 1, specified as a matrix. `w1` is the output of `modwt`. `w1` and `w2` must be the same size and both must have been obtained using the same analyzing wavelet.

Data Types: `double`

w2 — MODWT transform of signal 2

matrix

MODWT transform of signal 2, specified as a matrix. `w2` is the output of `modwt`. `w1` and `w2` must be the same size and both must have been obtained using the same analyzing wavelet.

wav — Wavelet

'sym4' (default) | character vector | string scalar | positive even scalar

Wavelet, specified as a character vector or string scalar indicating a valid wavelet name, or as a positive even scalar indicating the length of the wavelet and scaling filters. `wav` must be the same wavelet and length used to obtain the MODWTs of `w1` and `w2`. For a list of valid wavelets, see `modwt`. If unspecified or specified as an empty, `[]`, `wav` defaults to the symlet wavelet with four vanishing moments, 'sym4'.

conflevel — Confidence level

0.95 (default) | positive scalar less than 1

Confidence level, specified as a positive scalar less than 1. `conflevel` determines the coverage probability of the confidence intervals in `wcorr` and in the table, if you specify 'table' as an input. If unspecified, or if specified as empty, `[]`, `conflevel` defaults to 0.95.

Output Arguments

wcorr — Correlation coefficients by scale

vector

Correlation coefficients by scale, returned as a vector. `wcorr` is an M -by-1 vector of correlation coefficients, where M is the number of levels with nonboundary wavelet coefficients. `modwtcorr` returns correlation estimates only where there are nonboundary coefficients. This condition is satisfied when the transform level is not greater than $\text{floor}(\log_2(N/(L-1)+1))$, where N is the length of the original signal and L is the filter length. If the final level has enough nonboundary coefficients, `modwtcorr` returns the scaling correlation in the final row of `wcorr`. By default, `modwtcorr` uses the symlet wavelet with four vanishing moments, 'sym4' to determine the boundary coefficients.

wcorrci — Confidence intervals by scale

matrix

Confidence intervals by scale, returned as a matrix. The matrix is of size M -by-2, where M is the number of levels with nonboundary wavelet coefficients. The first column contains the lower confidence bound and the second column contains the upper confidence bound. The `conflevel` determines the coverage probability.

Confidence bounds are computed using Fisher's Z-transformation. The standard error of Fisher's Z statistic is the square root of $(N - 3)$. In this case, N is the equivalent number of coefficients in the critically sampled discrete wavelet transform (DWT), $\text{floor}(\text{size}(w1, 2)/2^{\text{LEV}})$, where LEV is the level of the wavelet transform. `modwtcorr` returns NaNs for the confidence bounds when $(N - 3)$ is less than or equal to zero.

pval — P-values for null hypothesis test

matrix

P-values for null hypothesis test, returned as a matrix. `pval` is an M -by-2 matrix.

- The first column of `pval` is the p -value computed using the standard t -statistic test for a correlation coefficient of zero.
- The second column of `pval` contains the adjusted p -value using the false discovery procedure of Benjamini & Yekutieli under arbitrary dependence assumptions.

The degrees of freedom, $(N - 2)$, for the t -statistic are determined by the equivalent number of coefficients N in the critically sampled DWT, `floor(size(w1,2)/2^LEV)`, where LEV is the level of the wavelet transform. `modwtcorr` returns NaNs when $(N - 2)$ is less than or equal to zero.

nj — Number of nonboundary coefficients

vector

Number of nonboundary coefficients by scale, returned as a vector.

wcorrtable — Correlation table

table

Correlation table, returned as a MATLAB table. The table contains six variables:

- **NJ** — Number of nonboundary coefficients by level.
- **Lower** — Lower confidence bound for the coverage probability specified by `conflevel`.
- **Rho** — Correlation coefficient.
- **Upper** — Upper confidence bound for the coverage probability specified by `conflevel`.
- **Pvalue** — P-value for hypothesis test. The null hypothesis is that the correlation coefficient is equal to zero.
- **AdjustedPvalue** — P-value adjusted for multiple comparisons. The p -values are adjusted using false discovery rate under dependency assumptions.

modwtmra

Multiresolution analysis based on MODWT

Syntax

```
mra = modwtmra(w)
mra = modwtmra(w,wname)
mra = modwtmra(w,Lo,Hi)
mra = modwtmra( __ , 'reflection')
```

Description

`mra = modwtmra(w)` returns the multiresolution analysis (MRA) of the maximal overlap discrete wavelet transform (MODWT) matrix, `w`. The MODWT matrix, `w`, is the output of the `modwt` function.

`mra = modwtmra(w,wname)` constructs the MRA using the wavelet corresponding to `wname`. The `wname` wavelet must be the same wavelet used to obtain the MODWT.

`mra = modwtmra(w,Lo,Hi)` constructs the MRA using the scaling filter `Lo` and wavelet filter `Hi`. The `Lo` and `Hi` filters must be the same filters used to obtain the MODWT.

`mra = modwtmra(__ , 'reflection')` uses the reflection boundary condition in the construction of the MRA using any of the arguments from previous syntaxes. If you specify `'reflection'`, `modwtmra` assumes that the length of the original signal is one half the number of columns in the input coefficient matrix.

Examples

Perfect Reconstruction with the MODWTMRA

Obtain the MODWTMRA of a simple time-series signal and demonstrate perfect reconstruction.

Create a time-series signal

```
t = 1:10;
x = sin(2*pi*200*t);
```

Obtain the MODWT and the MODWTMRA and sum the MODWTMRA rows.

```
m = modwt(x);
mra = modwtmra(m);
xrec = sum(mra);
```

Use the maximum of the absolute values to show that the difference between the original signal and the reconstruction is extremely small. The largest absolute value is on the order of 10^{-25} , which demonstrates perfect reconstruction.

```
max(abs(x-xrec))
ans = 5.5738e-25
```

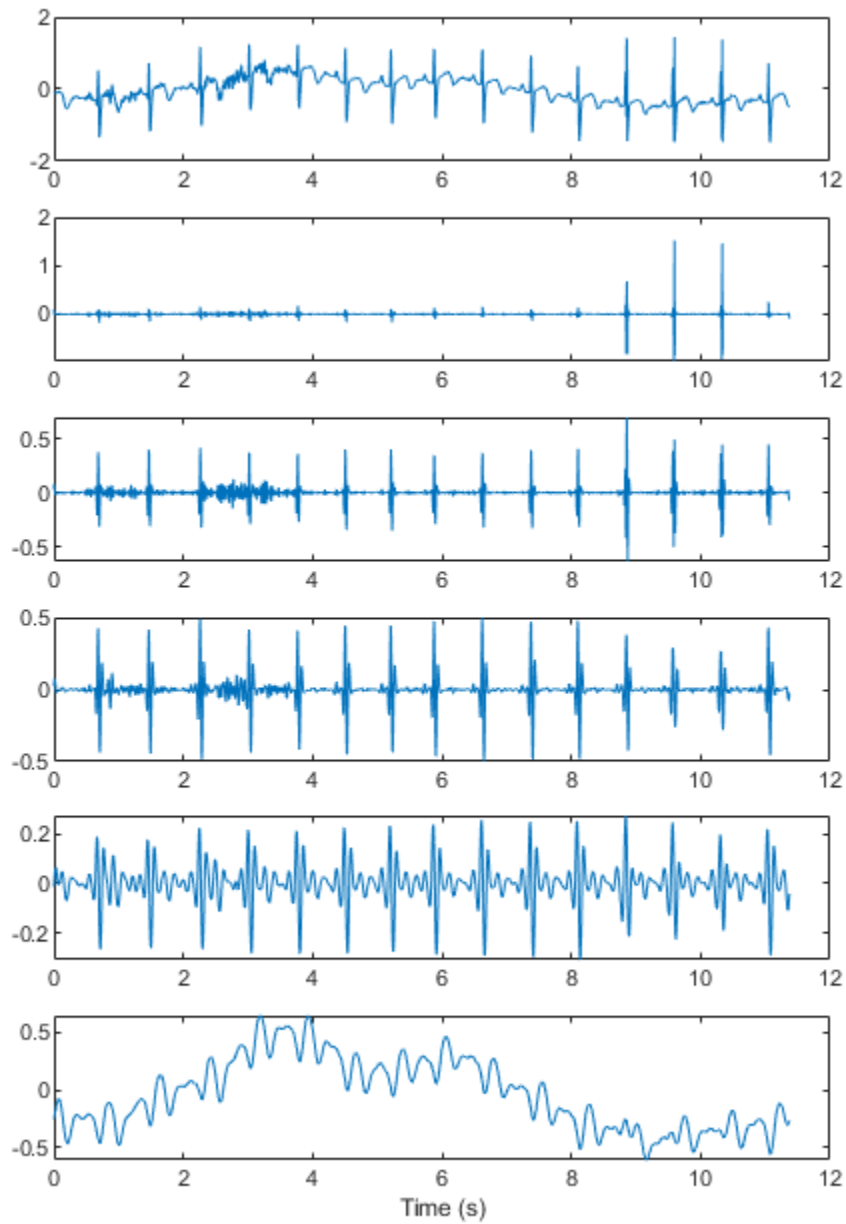

MRA Using Non-Default Wavelet

Construct an MRA of an ECG signal down to level four using the db2 wavelet. The data are taken from Percival & Walden (2000), p.125 (data originally provided by William Constantine and Per Reinhall, University of Washington). The sampling frequency for the ECG signal is 180 hertz.

```
load wecg;  
lev = 4;  
wtecg = modwt(wecg, 'db2', lev);  
mra = modwtmra(wtecg, 'db2');
```

Plot the ECG waveform and the MRA.

```
t = (0:numel(wecg)-1)/180;  
subplot(6,1,1)  
plot(t,wecg)  
for kk = 2:lev+2  
    subplot(6,1,kk)  
    plot(t,mra(kk-1,:))  
end  
xlabel('Time (s)')  
set(gcf, 'Position', [0 0 500 700])
```

MRA Using the Default Wavelet

Construct a multiresolution analysis for the Southern Oscillation Index data. The sampling period is one day. Plot the level eight details corresponding to a scale of 2^8 days. The details at this scale capture oscillations on a scale of approximately one year.

```
load soi
wtsoi = modwt(soi);
mrasoi = modwtmra(wtsoi);
plot(mrasoi(8,:))
title('Level 8 Details')
```

MRA Using Minimum Bandwidth Scaling and Wavelet Filters

Obtain the MRA for the Deutsch Mark - U.S. Dollar exchange rate data using the minimum bandwidth scaling and wavelet filters with four coefficients.

```
load DM_USD;
Lo = [0.4801755, 0.8372545, 0.2269312, -0.1301477];
Hi = qmf(Lo);
wdm = modwt(DM_USD,Lo,Hi);
mra = modwtmra(wdm,Lo,Hi);
```

MRA Using Reflection Boundary

Obtain the MRA for an ECG signal using 'reflection' boundary handling. The data are taken from Percival & Walden (2000), p.125 (data originally provided by William Constantine and Per Reinhall, University of Washington).

```
load wecg;
wtecg = modwt(wecg, 'reflection');
mra = modwtmra(wtecg, 'reflection');
```

Show that the number of columns in the MRA is equal to the number of elements in the original signal.

```
isequal(size(mra,2), numel(wecg))
```

```
ans = logical
      1
```

Comparing MODWT and MODWTMRA

This example demonstrates the differences between the functions MODWT and MODWTMRA. The MODWT partitions a signal's energy across detail coefficients and scaling coefficients. The MODWTMRA projects a signal onto wavelet subspaces and a scaling subspace.

Choose the sym6 wavelet. Load and plot an electrocardiogram (ECG) signal. The sampling frequency for the ECG signal is 180 hertz. The data are taken from Percival and Walden (2000), p.125 (data originally provided by William Constantine and Per Reinhall, University of Washington).

```
load wecg
t = (0:numel(wecg)-1)/180;
wv = 'sym6';
plot(t,wecg)
grid on
title(['Signal Length = ', num2str(numel(wecg))])
xlabel('Time (s)')
ylabel('Amplitude')
```

Take the MODWT of the signal.

```
wtecg = modwt(wecg,wv);
```

The input data are samples of a function $f(x)$ evaluated at N -many time points. The function can be expressed as a linear combination of the scaling function $\phi(x)$ and wavelet $\psi(x)$ at varying scales and

translations: $f(x) = \sum_{k=0}^{N-1} c_k 2^{-J_0/2} \phi(2^{-J_0} x - k) + \sum_{j=1}^{J_0} f_j(x)$ where $f_j(x) = \sum_{k=0}^{N-1} d_{j,k} 2^{-j/2} \psi(2^{-j} x - k)$

and J_0 is the number of levels of wavelet decomposition. The first sum is the coarse scale approximation of the signal, and the $f_j(x)$ are the details at successive scales. MODWT returns the N -many coefficients $\{c_k\}$ and the $(J_0 \times N)$ -many detail coefficients $\{d_{j,k}\}$ of the expansion. Each row in `wtecg` contains the coefficients at a different scale.

When taking the MODWT of a signal of length N , there are $\text{floor}(\log_2(N))$ -many levels of decomposition (by default). Detail coefficients are produced at each level. Scaling coefficients are returned only for the final level. In this example, since $N = 2048$, $J_0 = \text{floor}(\log_2(2048)) = 11$ and the number of rows in `wtecg` is $J_0 + 1 = 11 + 1 = 12$.

The MODWT partitions the energy across the various scales and scaling coefficients:

$\|X\|^2 = \sum_{j=1}^{J_0} \|W_j\|^2 + \|V_{J_0}\|^2$ where X is the input data, W_j are the detail coefficients at scale j , and V_{J_0} are the final-level scaling coefficients.

Compute the energy at each scale, and evaluate their sum.

```
energy_by_scales = sum(wtecg.^2,2);
Levels = {'D1';'D2';'D3';'D4';'D5';'D6';'D7';'D8';'D9';'D10';'D11';'A11'};
energy_table = table(Levels,energy_by_scales);
disp(energy_table)
```

Levels	energy_by_scales
{'D1' }	14.063
{'D2' }	20.612
{'D3' }	37.716
{'D4' }	25.123
{'D5' }	17.437
{'D6' }	8.9852
{'D7' }	1.2906
{'D8' }	4.7278
{'D9' }	12.205
{'D10' }	76.428
{'D11' }	76.268
{'A11' }	3.4192

```
energy_total = varfun(@sum,energy_table(:,2))
```

```
energy_total=table
sum_energy_by_scales
_____
298.28
```

Confirm the MODWT is energy-preserving by computing the energy of the signal and comparing it with the sum of the energies over all scales.

```
energy_ecg = sum(wecg.^2);
max(abs(energy_total.sum_energy_by_scales-energy_ecg))
ans = 7.4357e-10
```

Take the MODWTMRA of the signal.

```
mraecg = modwtmra(wtecg,wv);
```

MODWTMRA returns the projections of the function $f(x)$ onto the various wavelet subspaces and final

scaling space. That is, MODWTMRA returns $\sum_{k=0}^{N-1} c_k 2^{-J_0/2} \phi(2^{-J_0} x - k)$ and the J_0 -many $\{f_j(x)\}$

evaluated at N -many time points. Each row in `mraecg` is a projection of $f(x)$ onto a different subspace. This means the original signal can be recovered by adding all the projections. This is *not* true in the case of the MODWT. Adding the coefficients in `wtecg` will *not* recover the original signal.

Choose a time point, add the projections of $f(x)$ evaluated at that time point and compare with the original signal.

```
time_point = 1000;
abs(sum(mraecg(:,time_point))-wecg(time_point))
ans = 3.0849e-13
```

Confirm that, unlike MODWT, MODWTMRA is not an energy-preserving transform.

```
energy_ecg = sum(wecg.^2);
energy_mra_scales = sum(mraecg.^2,2);
energy_mra = sum(energy_mra_scales);
max(abs(energy_mra-energy_ecg))
```

```
ans = 115.7053
```

The MODWTMRA is a zero-phase filtering of the signal. Features will be time-aligned. Demonstrate this by plotting the original signal and one of its projections. To better illustrate the alignment, zoom in.

```
plot(t,wecg,'b')
hold on
plot(t,mraecg(4,:),'-')
hold off
grid on
xlim([4 8])
legend('Signal','Projection','Location','northwest')
xlabel('Time (s)')
ylabel('Amplitude')
```

Make a similar plot using the MODWT coefficients at the same scale. Note that features will not be time-aligned. The MODWT is *not* a zero-phase filtering of the input.

```
plot(t,wecg,'b')
hold on
```

```

plot(t,wtecg(4,:),'-')
hold off
grid on
xlim([4 8])
legend('Signal','Coefficients','Location','northwest')
xlabel('Time (s)')
ylabel('Amplitude')

```

Input Arguments

w — MODWT transform

matrix

Maximal overlap discrete wavelet transform, specified as a matrix. *w* is the output of `modwt`.

The input *w* is an $L+1$ -by- N matrix containing the MODWT of an N -point input signal down to level L . By default, `modwtmra` assumes that you obtained the MODWT using the `symlet` wavelet with four vanishing moments, `'sym4'`, and using periodic boundary handling.

Data Types: `double`

wname — Synthesis wavelet

`'sym4'` (default) | character vector | string scalar

Synthesis wavelet, specified as a character vector or string scalar. The synthesis wavelet must be the same wavelet used to obtain the MODWT with the `modwt` function.

Lo — Scaling filter

even-length real-valued vector

Scaling filter, specified as an even-length real-valued vector. You can specify `Lo` only if you do not specify `wname`. `Lo` must be the same scaling filter used to obtain the MODWT with the `modwt` function.

Hi — Wavelet filter

even-length real-valued vector

Wavelet filter, specified as an even-length real-valued vector. You can specify `Hi` only if you do not specify `wname`. `Hi` must be the same wavelet filter used to obtain the MODWT with the `modwt` function.

Output Arguments**mra — Multiresolution analysis**

matrix

Multiresolution analysis, returned as a matrix. By default, the `mra` is the same size as the input transform matrix `w`. If you specify reflection boundary handling, then `mra` has one half the number of columns as the input matrix `w`.

The output `mra` is an $L+1$ -by- N matrix. The k^{th} row of `mra` contains the details for the k^{th} level. The $(L+1)^{\text{th}}$ row of `mra` contains the L^{th} level smooth.

`imodwt` | `modwt`

Introduced in R2015b

modwtvar

Multiscale variance of maximal overlap discrete wavelet transform

Syntax

```
wvar = modwtvar(w)
wvar = modwtvar(w,wname)
[wvar,wvarci] = modwtvar( ___ )

[ ___ ] = modwtvar(w,wname, ___ ,conflvl)
[ ___ ] = modwtvar(w,wname, ___ ,Name,Value, )
[wvar,wvarci,nj] = modwtvar(w,wname, ___ )

wvartable = modwtvar(w,wname,'table')

modwtvar( ___ )
```

Description

`wvar = modwtvar(w)` returns unbiased estimates of the wavelet variance by scale for the maximal overlap discrete wavelet transform (MODWT). The default wavelet type is `sym4`.

`wvar = modwtvar(w,wname)` uses the wavelet `wname` to determine the number of boundary coefficients by level for unbiased estimates.

`[wvar,wvarci] = modwtvar(___)` returns the 95% confidence intervals for the variance estimates by scale.

`[___] = modwtvar(w,wname, ___ ,conflvl)` uses `conflvl` for the coverage probability of the confidence interval.

`[___] = modwtvar(w,wname, ___ ,Name,Value,)` returns wavelet variance with additional options specified by one or more `Name,Value` pair arguments.

`[wvar,wvarci,nj] = modwtvar(w,wname, ___)` returns the number of coefficients used to form the variance and confidence intervals by level.

`wvartable = modwtvar(w,wname,'table')`, where `'table'` returns a MATLAB table, `wvartable`, containing the number of MODWT coefficients by level, the confidence boundaries, and the variance estimates. You can place `'table'` anywhere after input `w`, except between the name and value of another `Name,Value` pair.

`modwtvar(___)` with no output arguments plots the wavelet variances by scale with lower and upper confidence bounds. The scaling variance is not included in the plot because the scaling variance can be much larger than the wavelet variances.

Examples

Wavelet Variance Using Default Wavelet

Obtain the MODWT of the Southern Oscillation Index data using the default symlets wavelet with 4 vanishing moments. Compute the unbiased estimates of the wavelet variance by scale.

```
load soi
wsoi = modwt(soi);
wvar = modwtvar(wsoi)
```

```
wvar = 10×1

    0.3568
    0.9026

    1.6672
    0.8048
    0.7555
    ⋮
```

Variance Estimates and Confidence Intervals Using MODWTVAR

Obtain the MODWT of the Nile River minimum level data using the Fejer- Korovkin wavelet with eight coefficients down to level five. Use `modwtvar` to obtain and plot the variance estimates and 95% confidence intervals.

```

load nileriverminima;
wtnile = modwt(nileriverminima,'fk8',5);
[wntilevar,wvarci] = modwtvar(wtnile,'fk8');

errlower = (wntilevar-wvarci(:,1));
errupper = (wvarci(:,2)-wntilevar);
errorbar(1:5,wntilevar(1:5),errlower(1:5),...
         errupper(1:5),'ko','markerfacecolor','k')
hold on
title('Wavelet Variance by Scale of Nile River Levels','fontsize',14);
ylabel('Variance');
xlabel('Time (in years)');
ax = gca;
ax.XTick = [1:5];
ax.XTickLabel = {'2','4','8','16','32'};
hold off

```

Wavelet Confidence Intervals

Show how different confidence level values affect the width of the confidence intervals. An increased confidence level value increases the confidence interval width.

Obtain the MODWT of the Southern Oscillation Index data using the Fejer-Korovkin wavelet with eight coefficients.

```
load soi;
wsoi = modwt(soi, 'fk8');
```

Obtain the width of the .90, .95, and .99 confidence intervals for each level.

```
[~,wvarci90] = modwtvar(wsoi, 'fk8', 0.90);
w90 = wvarci90(:,2)-wvarci90(:,1);
 [~,,wvarci95] = modwtvar(wsoi, 'fk8', 0.95);
w95 = wvarci95(:,2)-wvarci95(:,1);
[~,wvarci99] = modwtvar(wsoi, 'fk8', 0.99);
w99 = wvarci99(:,2)-wvarci99(:,1);
```

Compare the three columns. The first column shows the .90 confidence level values, the second the .95 values, and the third the .99 values. Each row is the width of the interval at each wavelet scale. You can see that the width of the confidence interval increases with larger confidence level values.

```
[w90,w95,w99]
```

```
ans = 10x3
```

Compare Chi2Eta2 and Gaussian Confidence Intervals

Specify non-default confidence methods using name-value pairs to compare the width of their confidence levels. Note that for Gaussian confidence level intervals, it is possible to obtain negative lower confidence bounds.

Obtain the MODWT of the Southern Oscillation Index data using the Fejer-Korovkin wavelet with eight coefficients.

```
load soi;
wsoi = modwt(soi, 'fk8');
```

Use the Chi2Eta and Gaussian confidence methods to obtain the variances and confidence interval bounds for each method.

```
[wvar_c,wvarci_c] = modwtvar(wsoi, 'fk8', [], 'ConfidenceMethod', 'chi2eta1');
[wvar_g,wvarci_g] = modwtvar(wsoi, 'fk8', [], 'ConfidenceMethod', 'gaussian');
```

Compute the upper and lower errors for each confidence interval and plot the results. Note that the Gaussian intervals are slightly shifted to enable better visualization.

```
errlower_c = wvar_c-wvarci_c(:,1);
errupper_c = wvarci_c(:,2)-wvar_c;
```

```

errlower_g = wvar_g(:,1)-wvarci_g(:,1);
errupper_g = wvarci_g(:,2)-wvar_g;

errorbar(1:10,wvar_c(1:10),errlower_c(1:10),...
         errupper_c(1:10),'ko','markerfacecolor','b')
hold on;
xoffset = (1.3:10.3);
errorbar(xoffset,wvar_g(1:10),errlower_g(1:10),...
         errupper_g(1:10),'ro','markerfacecolor','r')

title('Wavelet Chi2Eta2 vs. Gaussian Confidence Intervals','fontsize',14);

xlabel('Level')
ax = gca;
ax.XTick = [1:10];
legend('Chi2Eta','Gaussian','Location','northwest');
hold off

```

Compare Number of Coefficients for Unbiased and Biased Variance Estimates

Compare the number of coefficients for unbiased and biased wavelet variance estimates. For the unbiased (default) estimates, the number of nonboundary coefficients decreases by scale. For biased estimates, the number of coefficients matches the number of input rows and is constant for every scale.

Obtain the MODWT of the Southern Oscillation Index data using the Fejer-Korovkin wavelet with eight coefficients. Compute the unbiased and biased estimates of the wavelet variance down to level ten. The number of coefficients used in the unbiased estimates decrease by scale.

```
load soi
wsoi = modwt(soi, 'fk8');
[wvar_unb, wvarci_unb, nj_unb] = modwtvar(wsoi, 'fk8');
[wvar_b, wvarci_b, nj_b] = modwtvar(wsoi, 'fk8', [], 'EstimatorType', 'biased');
[nj_unb(1:10), nj_b(1:10)]
```

```
ans = 10×2

D10	5837	0.37485	0.84386	1.3129

The resulting table contains the number of nonboundary coefficients, the lower and upper confidence level bounds, and the variance estimate for each level.

Input Arguments

w — MODWT transform matrix

matrix

MODWT transform, specified as a matrix. `w` is the output of `modwt`.

Data Types: `double`

wname — Wavelet

'sym4' (default) | character vector | string scalar | positive even scalar

Wavelet, specified as a character vector or string scalar corresponding to a valid wavelet, or as a positive even scalar indicating the length of the wavelet and scaling filters. The wavelet filter length must match the length used in the MODWT of the input.

If you use `Name, Value` pairs arguments or the `'table'` syntax and you did not specify a `wname`, you must use `[]` as the second argument.

conflevel — Confidence level

0.95 (default) | real scalar greater than 0 and less than 1

Confidence level, specified as a real scalar value greater than 0 and less than 1. The confidence level determines the coverage probability of the confidence intervals. If you specify `'table'` as an input, the confidence levels are also shown in `wvartable`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'EstimatorType', 'biased'` specifies a biased estimator.

EstimatorType — Estimator

'unbiased' (default) | 'biased'

Type of estimator used for variance estimates and confidence bounds, specified as the comma-separated pair consisting of `'EstimatorType'` and one of these values.

- `'unbiased'` — Unbiased estimator, which identifies and removes boundary coefficients prior to computing the variance estimates and confidence bounds. Unbiased estimates are used more frequently for wavelet variance computations.
- `'biased'` — Biased estimator, which uses all coefficients to compute the variance estimates and confidence bounds.

ConfidenceMethod — Confidence method

'chi2eta3' (default) | 'chi2etal' | 'gaussian'

Confidence method used to compute the confidence intervals, specified as the comma-separated pair consisting of `'ConfidenceMethod'` and one of these values:

`'chi2eta3'` Chi-square probability density method three, which determines the degrees of freedom.[1].

'chi2etal'	Chi-square probability density method one, which determines the degrees of freedom [1].
'gaussian'	Gaussian method [1]. This method can result in negative lower bounds.

See “Algorithm” on page 1-813 for information on each of these confidence methods.

Boundary — Boundary condition

'periodic' (default) | 'reflection'

Boundary condition used to compute the variance estimates and confidence bounds, specified as the comma-separated pair consisting of 'Boundary' and one of these values:

'periodic'	Periodic boundary handling, which does not change the original signal before computing the MODWT. If <code>modwt</code> uses periodic boundary handling, you must specify 'Boundary', 'periodic' for <code>modwtvar</code> to obtain a correct estimate.
'reflection'	Reflection boundary handling. If the MODWT uses reflection boundary handling, you must also specify 'Boundary', 'reflection' for <code>modwtvar</code> to obtain a correct unbiased estimate. The MODWT, with reflection boundary handling, extends the original signal symmetrically at the right boundary to twice the signal length. The MODWTVAR algorithm has to know about this extended signal to calculate the correct unbiased estimate. For biased estimators, all the coefficients are used to form the variance estimates and confidence intervals regardless of the boundary handling.

Output Arguments

`wvar` — Wavelet variance estimates

matrix

Wavelet variance estimates, returned as vector. The number of elements in `wvar` depends on the number of scales in the input matrix and, for unbiased estimates, on the wavelet length. For the unbiased case, `modwtvar` returns estimates only where nonboundary coefficients exist. This condition is satisfied when the transform level is not greater than `floor(log2(N/(L-1)+1))`, where N is the input signal length and L is the length of the wavelet filter. The number of biased estimates equals the input signal length. If the final level has sufficient nonboundary coefficients, `modwtvar` returns the scaling variance in the final element of `wvar`.

`wvarci` — Confidence intervals for each variance estimate

matrix

Confidence bounds, expressed as upper and lower confidence bounds, for the variance estimates in `wvar`, returned as a matrix. The default is 95% confidence bounds, but you can use a different value

using the `conflevel` input argument. The confidence bounds matrix is M -by-2, where M is the number of levels. For unbiased estimates, the number of levels is limited by the number of nonboundary coefficients. For biased estimates, all levels are used. The first column of the confidence interval matrix contains the lower confidence bound and the second column contains the upper confidence bound. By default, `modwtvar` calculates the confidence intervals using the chi-square probability density, with the equivalent degrees of freedom estimated using the 'Chi2Eta3' confidence method.

nj — Number of coefficients by level

vector

Number of nonboundary coefficients by scale, returned as a vector. For unbiased estimates, `nj` is the number of nonboundary coefficients and decreases by level. For biased estimates, `nj` is a vector of constants equal to the number of columns in the input matrix.

wvartable — Variance table

table

Variance table, returned as a MATLAB table. The four variables in the table are:

- **NJ** — Number of MODWT coefficients by level. For biased estimates, `NJ` is the number of coefficients in the MODWT. For unbiased estimates, `NJ` is the number of nonboundary coefficients.
- **Lower** — Lower confidence bound for the variance estimate.
- **Variance** — Variance estimate by level.
- **Upper** — Upper confidence bound for the variance estimate.

The row names of `wvartable` indicate the type and level of each estimate. For example, `D1` indicates that the row corresponds to a wavelet or detail estimate at level 1. `S6` indicates that the row corresponds to the scaling estimate at level 6. The scaling variance is computed for the final level of the MODWT. For unbiased estimates, `modwtvar` computes the scaling variance only when nonboundary scaling coefficients exist.

Algorithms

The following expressions define the variance and confidence methods used in the MODWTVAR. The variables are

- N_j — Number of coefficients at level j
- v^2 — Variance
- j — Level
- $W_{j,t}$ — Wavelet coefficients

The variance estimate is

$$\hat{v}_j^2 = \frac{1}{N_j} \sum_{t=0}^{N_j-1} W_{j,t}^2$$

The degrees of freedom for the Chi2Eta1 (`chi2eta1`) method are defined as

$$\eta_1 = \frac{N_j \hat{v}_j^4}{\hat{A}_j}$$

where

$$\widehat{A}_j = \frac{1}{2} \int_{-1/2}^{1/2} \left[\widehat{S}_j^{(p)}(f) \right]^2 df.$$

In this equation, $\widehat{S}_j^{(p)}$ is the spectral density function estimate of the wavelet coefficients at level j .

The chi-square statistic is

$$\frac{\eta_1 N_j \widehat{v}_j^2}{v_j^2} \sim X_{\eta_1}^2$$

The degrees of freedom for the Chi2Eta3 (chi2eta3) method are defined as

$$\eta_3 = \max\left(\frac{N_j}{2^j}, 1\right)$$

The chi-square statistic is

$$\frac{\eta_3 N_j \widehat{v}_j^2}{v_j^2} \sim X_{\eta_3}^2$$

For the Gaussian method, the statistic

$$\frac{N_j^{1/2} (\widehat{v}_j^2 - v_j^2)}{(2\widehat{A}_j)^{1/2}}$$

is distributed as $N(0, 1)$. The variable \widehat{A}_j is as described for chi2eta1.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input `wname` must be constant.
- The input `confl` must be defined as a scalar.
- Plotting is not supported.

modwtxcorr

Wavelet cross-correlation sequence estimates using the maximal overlap discrete wavelet transform (MODWT)

Syntax

```
xcseq = modwtxcorr(w1,w2)
xcseq = modwtxcorr(w1,w2,wav)

[xcseq,xcseqci] = modwtxcorr(____)
[xcseq,xcseqci] = modwtxcorr(w1,w2,wav,confllevel)
[xcseq,xcseqci,lags] = modwtxcorr(____)

[____] = modwtxcorr(____,'reflection')
```

Description

`xcseq = modwtxcorr(w1,w2)` returns the wavelet cross-correlation sequence estimates for the maximal overlap discrete wavelet transform (MODWT) transforms specified in `w1` and `w2`. `xcseq` is a cell array of vectors where the elements in each cell correspond to cross-correlation sequence estimates. If there are enough nonboundary coefficients at the final level, `modwtxcorr` returns the scaling cross-correlation sequence estimate in the final cell of `xcseq`.

`xcseq = modwtxcorr(w1,w2,wav)` uses the wavelet `wav` to determine the number of boundary coefficients by level.

`[xcseq,xcseqci] = modwtxcorr(____)` returns in `xcseqci` the 95% confidence intervals for the cross-correlation sequence estimates in `xcseq`, using any arguments from the previous syntaxes.

`[xcseq,xcseqci] = modwtxcorr(w1,w2,wav,confllevel)` uses `confllevel` for the coverage probability of the confidence interval. `confllevel` is a real scalar strictly greater than 0 and less than 1. If `confllevel` is unspecified or specified as empty, the coverage probability defaults to 0.95.

`[xcseq,xcseqci,lags] = modwtxcorr(____)` returns the lags for the wavelet cross-correlation sequence estimates in a cell array of column vectors.

`[____] = modwtxcorr(____,'reflection')` reduces the number of wavelet and scaling coefficients at each scale by half before computing the cross-correlation sequences. Specifying the 'reflection' option in `modwtxcorr` is equivalent to first obtaining the MODWT of `w1 w2` with 'periodic' boundary handling and then computing the wavelet cross-correlation sequence estimates. Use this option only when you obtain the MODWT of `w1` and `w2` using the 'reflection' boundary condition. You must enter the entire character vector 'reflection'. If you added a wavelet named 'reflection' using the wavelet manager, you must rename that wavelet prior to using this option. 'reflection' may be placed in any position in the input argument list after the input transforms `w1 w2`.

Examples

Cross-Correlation Sequence

Obtain the MODWT of the Southern Oscillation Index and Truk Islands pressure data. The sampling period is one day.

```
load soi
load truk
wsoi = modwt(soi);
wtruk = modwt(truk);
```

Compute the wavelet cross-correlation sequences. Examine the level-five cross-correlation sequence corresponding to a scale of 32-64 days. Determine the index corresponding to a lag of zero and plot out to 240 lags.

```
xcseq = modwtxcorr(wsoi,wtruk);
zerolag = floor(numel(xcseq{5})/2)+1;
plot(xcseq{5}(zerolag:zerolag+240), 'linewidth',2)
set(gca,'xlim',[1 240]);
title({'Cross-Correlation Sequence Level 5'; 'Scale: 32-64 Days'});
hold off
```

Cross-Correlation Sequence with Fejér-Korovkin Wavelet

Obtain the MODWT of the Southern Oscillation Index and Truk Islands pressure data using the Fejér-Korovkin wavelet filter with 8 coefficients. The sampling period of the data is one day.

```
load soi
load truk
wsoi = modwt(soi, 'fk8');
wtruk = modwt(truk, 'fk8');
```

Compute the wavelet cross-correlation sequences. Examine the level-five cross-correlation sequence corresponding to a scale of 32-64 days. Determine the index corresponding to a lag of zero and plot out to 240 lags.

```
xcseq = modwtxcorr(wsoi,wtruk, 'fk8');
zerolag = floor(numel(xcseq{5})/2)+1;
plot(xcseq{5}(zerolag:zerolag+240), 'linewidth', 2)
set(gca, 'xlim', [1 240]);
title({'Cross-Correlation Sequence Level 5'; 'Scale: 32-64 Days'});
hold off
```

Cross-Correlation Confidence Intervals by Scale

Plot the wavelet cross-correlation with 95% confidence intervals at scale 4 for two 5-Hz sine wave signals with additive noise.

```
dt = 0.01;
t = 0:dt:6;
x = cos(2*pi*5*t)+1.5*randn(size(t));
y = cos(2*pi*5*t-pi)+2*randn(size(t));
```

```

wx = modwt(x, 'fk14', 5);
wy = modwt(y, 'fk14', 5);
modwtcorr(wx, wy, 'fk14')
j = 4;
[xcseq, xcseqci] = modwtcorr(wx, wy, 'fk14');
zerolag = floor(numel(xcseq{j})/2)+1;
lagidx = zerolag-30:zerolag+30;
plot(xcseq{j}(lagidx));
hold on;
grid
plot(xcseqci{j}(lagidx,:), 'r--');
xlabel('Samples');
title('Scale: 0.32-0.16 Seconds');

```

Cross-Correlation .90 and .95 Confidence Intervals Comparison

Compare the .90 and .95 (default) confidence intervals for the wavelet cross-correlation at level four.

Obtain the MODWT for two noisy sine waves using the Fejér-Korovkin with 14 coefficients, and specify the level to use.

```

dt = 0.01;
t = 0:dt:6;
x = cos(2*pi*5*t)+1.5*randn(size(t));
y = cos(2*pi*5*t-pi)+2*randn(size(t));
wx = modwt(x, 'fk14', 4);

```

```
wy = modwt(y, 'fk14', 4);  
lev = 4;  
  
[xcseq, xcseqci] = modwtcorr(wx, wy, 'fk14');  
[xcseq90, xcseqci90] = modwtcorr(wx, wy, 'fk14', 0.90);  
  
zerolag = floor(numel(xcseq{lev})/2)+1;  
zerolag90 = floor(numel(xcseq90{lev})/2)+1;  
  
lagidx = zerolag-30:zerolag+30;  
lagidx90 = zerolag90-30:zerolag90+30;  
  
plot(xcseqci{lev}(lagidx,:), '--r');  
hold on  
plot(xcseqci90{lev}(lagidx90,:), '--b');  
plot(xcseq{lev}(lagidx), '-k', 'LineWidth', 1);  
grid  
title('.90 and .95 Confidence Levels')
```

Notice that the .95 confidence interval width (in red) is larger than the .90 confidence interval width (in blue).

Plot Cross-Correlation Sequences by Lag

Plot the cross-correlation sequence estimate for the Southern Oscillation Index and Truk Island pressure data. Estimate 95% confidence intervals for scale of 2^5 days.

```
load soi
load truk
wsoi = modwt(soi);
wtruk = modwt(truk);
[xcseq,xcseqci,lags] = modwtcorr(wsoi,wtruk);
plot(lags{5},xcseq{5},'linewidth',2)
hold on
plot(lags{5},xcseqci{5},'r--')
set(gca,'xlim',[-120 120]);
xlabel('Lag (Days)');
grid
title({'Cross-Correlation Sequence Level 5'; 'Scale: 32-64 Days'});
hold off
```

Cross-Correlation with Reflection Boundary

Obtain the MODWT of 36 years of Southern Oscillation Index and Truk Islands pressure data with both periodic and reflection boundary conditions. The `modwt` function with the `'reflection'` option extends the input signal symmetrically at the right boundary. The input signal is then twice its

original length. MODWTXCORR with the reflection boundary handling reduces the number of wavelet and scaling coefficients at each half before computing the cross-correlation sequences. The size of the cross-correlation sequences is the same as acquiring the MODWT with the default periodic boundary condition.

```
load soi
load truk
```

Obtain the MODWT with the default periodic boundary condition.

```
wsoi_default = modwt(soi);
wtruk_default = modwt(truk);
```

Obtain the MODWT with the reflection boundary condition.

```
wsoi_reflect = modwt(soi,'reflection');
wtruk_reflect = modwt(truk,'reflection');
```

Obtain the cross-correlation sequences.

```
xcseq_default = modwtxcorr(wsoi_default,wtruk_default);
xcseq_reflect = modwtxcorr(wsoi_reflect,wtruk_reflect,'reflection');
```

Compare the number of elements in the cell array output for both boundary conditions.

```
cellfun(@numel,xcseq_reflect)
```

```
ans = 10×1
```

```

```

Input Arguments

w1 — MODWT transform of signal 1

matrix

MODWT transform of signal 1, specified as a matrix of doubles. The input w1 must be the same size as w2 and must have been obtained with the same wavelet. By default, `modwtcorr` assumes that you obtained the MODWT using the symlet wavelet with four vanishing moments, 'sym4'.

w2 — MODWT transform of signal 2

matrix

MODWT transform of signal 2, specified as a matrix of doubles. The input w2 must be the same size as w1 and must have been obtained with the same wavelet. By default, `modwtcorr` assumes that you obtained the MODWT using the symlet wavelet with four vanishing moments ('sym4').

wav — Wavelet

'sym4' (default) | character vector | string scalar | positive even integer

Wavelet, specified as a character vector or string scalar, indicating a valid wavelet, or as a positive even integer indicating the length of the wavelet and scaling filters. If wav is unspecified or specified as an empty, [], wav defaults to 'sym4'.

conflevel — Confidence level

0.95 (default) | positive scalar less than 1

Confidence level, specified as a positive scalar less than 1. `conflevel` determines the coverage probability of the confidence intervals in `xcseqci`. If unspecified, or specified as empty, [], `conflevel` defaults to 0.95.

Output Arguments

xcseq — Cross-correlation sequences by scale

cell array of vectors

Cross-correlation sequences by scale, returned as a cell array of vectors. The vectors are of size $2NJ-1$ by-1, where NJ is the number of nonboundary coefficients by level (scale). This level is the minimum of `size(w1,1)` and `floor(log2(N/(L-1)+1))` where N is the length of the data and L is the filter length. If there are enough nonboundary coefficients at the final level, `modwtcorr` returns the scaling cross-correlation sequence estimate in the final cell of `xcseq`.

xcseqci — Confidence intervals by scale

cell array of matrices

Confidence intervals by scale, returned as a cell array of matrices. The size of each matrix is $(2NJ-1)$ -by-2, where NJ is the number of nonboundary coefficients by level (scale).

- For the .95 default value, the first column of the i^{th} element of `xcseqci` contains the lower 95% confidence bound for the cross-correlation coefficient at each lag.
- For the .95 default value, the second column contains the upper 95% confidence bound.

Confidence bounds are computed using Fisher's Z-transformation. The standard error of Fisher's Z statistic is the square root of $N-3$. In this case, N is the equivalent number of coefficients in the

critically sampled discrete wavelet transform (DWT), `floor(size(w1,2)/2^LEV)`, where LEV is the level of the wavelet transform. `modwtcorr` returns NaNs for the confidence bounds when N^{-3} is less than or equal to zero.

lags — Lags for the cross-correlation sequences

cell array of vectors

Lags for the cross-correlation sequences, returned as a cell array of vectors. `lags` is a cell array of column vectors the same length as `xcseq`. The elements in each cell of `xcseq` correspond to the cross-correlation sequence estimates at lags from $-(NJ-1)$ to $(NJ-1)$, where NJ is the number of nonboundary coefficients at level J . The 0th lag element is located at the index `floor((2*NJ-1)/2)+1`.

Topics

"Wavelet Analysis of Financial Data"

Introduced in R2015b

morlet

Morlet wavelet

Syntax

```
[psi,x] = morlet(lb,ub,n)
```

Description

[psi,x] = morlet(lb,ub,n) returns the Morlet wavelet psi evaluated at x, an n-point regular grid in the interval [lb, ub]. The Morlet wavelet is defined as

$$\psi(x) = e^{-x^2/2} \cos(5x)$$

The Morlet wavelet has the interval [-4, 4] as effective support. Nearly 100% of the wavelet's energy is in the interval. Although [-4, 4] is the correct theoretical effective support, a wider effective support, [-8, 8], is used in the computation to provide more accurate results.

Examples

Morlet Wavelet

This example shows how to create a Morlet wavelet. The wavelet has an effective support of [-4, 4]. Use 1000 sample points.

```
lb = -4;  
ub = 4;  
n = 1000;  
[psi,xval] = morlet(lb,ub,n);  
plot(xval,psi)  
grid on  
title('Morlet Wavelet')
```

Compute the wavelet's energy in the interval. Normalize by the difference between sample points.

```
e1 = sum(psi.^2)*diff(xval(1:2));
fprintf('%.15f',e1)
```

```
0.886226920745596
```

Create a second Morlet wavelet with support on $[-8, 8]$ using 1000 sample points. Compute the second wavelet's energy, normalized by the difference between sample points. Return the ratio of the two energies.

```
[psi2,xval2] = morlet(-8,8,1000);
e2 = sum(psi2.^2)*diff(xval2(1:2));
fprintf('%.15f',e1/e2)
```

```
0.9999999994674671
```

Input Arguments

lb — Lower limit

real-valued scalar

Lower limit of interval, specified as a real-valued scalar.

ub — Upper limit

real-valued scalar

Upper limit of interval, specified as a real-valued scalar.

n — Number of points

positive integer

Number of sample points, specified as a positive integer.

Output Arguments

psi — Morlet wavelet

real-valued vector

Morlet wavelet, returned as a real-valued vector of length n.

x — Sampling instants

real-valued vector

Sampling instants, returned as a real-valued vector of length n.

Introduced before R2006a

mswcmp

Multisignal 1-D compression using wavelets

Syntax

```
[xc,deccmp,thresh] = mswcmp('cmp',dec,mthd)
[xc,deccmp,thresh] = mswcmp('cmp',dec,mthd,param)

[xc,thresh] = mswcmp('cmpsig',___)
[deccmp,thresh] = mswcmp('cmpdec',___)
thresh = mswcmp('thr',___)

[___] = mswcmp(option,dirdec,x,wname,lev,mthd)
[___] = mswcmp(option,dirdec,x,wname,lev,mthd,param)

[___] = mswcmp(___,s_or_h)
[___] = mswcmp(___,s_or_h,keepapp)
[___] = mswcmp(___,s_or_h,keepapp,idxsig)
```

Description

`mswcmp` computes thresholds and, depending on the selected option, performs compression of 1-D signals using wavelets.

`[xc,deccmp,thresh] = mswcmp('cmp',dec,mthd)` returns a compressed version `xc` of the original multisignal `x`, whose wavelet decomposition structure is `dec`. The compression method is specified by `mthd`. The output `xc` is obtained by thresholding the wavelet coefficients. The output `deccmp` is the wavelet decomposition associated with `xc`, and `thresh` is the matrix of threshold values.

`[xc,deccmp,thresh] = mswcmp('cmp',dec,mthd,param)` uses the parameter `param` associated with `mthd`, if required.

`[xc,thresh] = mswcmp('cmpsig',___)` returns the compressed multisignal and computed thresholds if `'cmp'` in the first or second syntaxes is replaced with `'cmpsig'`.

`[deccmp,thresh] = mswcmp('cmpdec',___)` returns the wavelet decomposition associated with the compressed multisignal and computed thresholds if `'cmp'` in the first or second syntaxes is replaced with `'cmpdec'`.

`thresh = mswcmp('thr',___)` returns the computed thresholds if `'cmp'` in the first or second syntaxes is replaced with `'thr'`.

`[___] = mswcmp(option,dirdec,x,wname,lev,mthd)` decomposes the multisignal `x` to level `lev` using the wavelet specified by `wname` in the direction `dirdec` before performing a compression or computing the thresholds.

`[___] = mswcmp(option,dirdec,x,wname,lev,mthd,param)` uses the parameter `param` associated with `mthd`, if required.

`[___] = mswcmp(___,s_or_h)` applies the threshold rule specified by `s_or_h`.

[___] = mswcmp(___ ,s_or_h,keepapp) either keeps the approximation coefficients (true) or does not (false).

[___] = mswcmp(___ ,s_or_h,keepapp,idxsig) is a vector, which contains the indices of the initial signals.

Examples

Compress Multisignal

Load the 23-channel EEG data `Espiga3` [8]. The channels are arranged column-wise. The data is sampled at 200 Hz.

```
load Espiga3
```

Perform a decomposition at level 2 using the `db2` wavelet.

```
dec = mdwtdec('c',Espiga3,2,'db2');
```

Compress the signals to obtain a percentage of zeros near 95% for the wavelet coefficients.

```
[xr,deccmp,thresh] = mswcmp('cmp',dec,'N0_perf',95);
```

Plot an original signal, and the corresponding compressed signal.

```
idx = 3;
plot(Espiga3(:,idx),'r')
hold on
plot(xr(:,idx),'b')
grid on
legend('Original','Compressed')
```

Input Arguments

dec — Wavelet decomposition

structure

Wavelet decomposition, specified as a structure. `dec` is the output of `mdwtdec`.

mthd — Compression method

'rem_n0' | 'bal_sn' | 'sqrtbal_sn' | 'scarce' | 'scarcehi' | 'scarceme' | 'scarcelo' | 'L2_perf' | 'N0_perf' | 'glb_thr' | 'man_thr'

Compression method, specified as one of the values listed here. For methods that use an associated parameter, the range of allowable `param` values is shown.

For methods listed in the following table, `param` is a sparsity parameter, and it should be specified such that $1 \leq \text{param} \leq 10$. For the 'scarce' method no control is done.

method	Description
'scarce'	Scarce, <code>param</code> (any number)
'scarcehi'	Scarce high, $2.5 \leq \text{param} \leq 10$
'scarceme'	Scarce medium, $1.5 \leq \text{param} \leq 2.5$
'scarcelo'	Scarce low, $1 \leq \text{param} \leq 2$

method	Description
'rem_n0'	Remove near 0
'bal_sn'	Balance sparsity-norm
'sqrtbal_sn'	Balance sparsity-norm (sqrt)

For methods listed in the following table, `param` is a real number, which represents the required performance: $0 \leq \text{param} \leq 100$.

method	Description
'L2_perf'	Energy ratio
'N0_perf'	Zero coefficients ratio

To apply a global threshold for compression, specify the method `'glb_thr'` and any positive real number `param`.

To apply a manual compression method, specify the method `'man_thr'`, and specify `param` as an *NbSig*-by-*NbLev* or an *NbSig*-by- $(\text{NbLev}+1)$ real-valued matrix, where *NbSig* is the number of signals, and *NbLev* the number of levels of decomposition.

- `param(i, j)` is the threshold for the detail coefficients of level *j* for the *i*th signal ($1 \leq j \leq \text{NbLev}$).
- `param(i, NbLev+1)` is the threshold for the approximation coefficients for the *i*th signal (if `keepapp` is 0).

param — Parameter

real number | matrix

Parameter associated with the compression method `mthd`, specified as a real number or a real-valued matrix. For additional information, see `mthd`.

option — Compression outputs option

'cmp' | 'cmpsig' | 'cmpdec' | 'thr'

Compression outputs option, specified as one of the values listed here.

option	Description
'cmp'	Return the compressed signal, the associated wavelet decomposition, and the thresholds.
'cmpsig'	Return the compressed signal, and the thresholds.
'cmpdec'	Return the wavelet decomposition associated with the compressed signal, and the thresholds.
'thr'	Return the thresholds.

dirdec — Direction indicator

'r' | 'c'

Direction indicator of the wavelet decomposition, specified as one of the following:

- 'r': Take the 1-D wavelet decomposition of each row of `x`
- 'c': Take the 1-D wavelet decomposition of each column of `x`

x — Multisignal

real-valued matrix

Multisignal, specified as a real-valued matrix.

Data Types: double

wname — Analyzing wavelet

character vector | string scalar

Analyzing wavelet, specified as a character vector or string scalar. The wavelet must be orthogonal or biorthogonal. Orthogonal and biorthogonal wavelets are designated as type 1 and type 2 wavelets, respectively, in the wavelet manager, `wavemngr`.

- Valid built-in orthogonal wavelet families begin with 'haar', 'dbN', 'fkN', 'coifN', or 'symN', where N is the number of vanishing moments for all families except `fk`. For `fk`, N is the number of filter coefficients.
- Valid biorthogonal wavelet families begin with 'biorNr.Nd' or 'rbioNd.Nr', where Nr and Nd are the number of vanishing moments in the reconstruction (synthesis) and decomposition (analysis) wavelet.

Determine valid values for the vanishing moments by using `waveinfo` with the wavelet family short name. For example, enter `waveinfo('db')` or `waveinfo('bior')`. Use `wavemngr('type',WNAME)` to determine if a wavelet is orthogonal (returns 1) or biorthogonal (returns 2).

lev — Level of decomposition

positive integer

Level of decomposition, specified as a positive integer. `mdwtdec` does not enforce a maximum level restriction. Use `wmaxlev` to ensure that the wavelet coefficients are free from boundary effects. If boundary effects are not a concern, a good rule is to set `lev` less than or equal to `fix(log2(length(N)))`, where N is the number of samples in the 1-D data.

s_or_h — Type of thresholding

'h' (default) | 's'

Type of thresholding to perform, specified as either of the following:

- 's' — Soft thresholding
- 'h' — Hard thresholding

keepapp — Threshold approximation

false or 0 (default) | true or 1

Threshold approximation setting:

- 0 — Approximation coefficients are thresholded
- 1 — Approximation coefficients are not thresholded

idxsig — Indices of initial signals

'all' (default) | vector of positive integers

Indices of initial signals, specified as a vector of positive integers, or 'all'.

Output Arguments

xc — Compressed multisignal

real-valued matrix

Compressed multisignal, returned as a real-valued matrix.

deccmp — Wavelet decomposition

structure

Wavelet decomposition of the compressed multisignal x , returned as a structure with the following fields:

- `dirDec` — Direction indicator: 'r' (row) or 'c' (column)
- `level` — Level of wavelet decomposition
- `wname` — Wavelet name
- `dwtFilters` — Structure with four fields: LoD, HiD, LoR, and HiR
- `dwtEXTM` — DWT extension mode
- `dwtShift` — DWT shift parameter (0 or 1)
- `dataSize` — Size of x
- `ca` — Approximation coefficients at level `lev`
- `cd` — Cell array of detail coefficients, from level 1 to level `lev`

The coefficients `ca` and `cd{k}`, for k from 1 to `lev`, are matrices and are stored in rows if `dirdec = 'r'` or in columns if `dirdec = 'c'`.

thresh — Threshold values

real-valued matrix

Threshold values used in the compression, returned as a real-valued matrix.

Introduced in R2007a

mswcmpscr

Multisignal 1-D wavelet compression scores

Syntax

```
[THR, L2SCR, N0SCR, IDXSORT] = mswcmpscr(DEC)
```

Description

`[THR, L2SCR, N0SCR, IDXSORT] = mswcmpscr(DEC)` computes four matrices: thresholds THR, compression scores L2SCR and N0SCR, and indices IDXSORT. The decomposition DEC corresponds to a matrix of wavelet coefficients CFS obtained by concatenation of detail and (optionally) approximation coefficients, where

$$\text{CFS} = [\text{cd}\{\text{DEC.level}\}, \dots, \text{cd}\{1\}] \text{ or } \text{CFS} = [\text{ca}, \text{cd}\{\text{DEC.level}\}, \dots, \text{cd}\{1\}]$$

The concatenation is made row-wise if `DEC.dirDec` is equal to 'r' or column-wise if `DEC.dirDec` is equal to 'c'.

If `NbSIG` is the number of original signals and `NbCFS` the number of coefficients for each signal (all or only the detail coefficients), then CFS is an `NbSIG`-by-`NbCFS` matrix. Therefore,

- THR, L2SCR, N0SCR are `NbSIG`-by-`(NbCFS+1)` matrices
- IDXSORT is an `NbSIG`-by-`NbCFS` matrix
- `THR(:, 2:end)` is equal to CFS sorted by row in ascending order with respect to the absolute value.
- For each row, IDXSORT contains the order of coefficients and `THR(:, 1)=0`.

For the *i*th signal:

- `L2SCR(i, j)` is the percentage of preserved energy (L2-norm), corresponding to a threshold equal to `CFS(i, j - 1)` ($2 \leq j \leq \text{NbCFS}$), and `L2SCR(:, 1)=100`.
- `N0SCR(i, j)` is the percentage of zeros corresponding to a threshold equal to `CFS(i, j - 1)` ($2 \leq j \leq \text{NbCFS}$), and `N0SCR(:, 1)=0`.

Three more optional inputs may be used:

```
[...] = mswcmpscr(..., S_OR_H, KEEPAPP, IDXSIG)
```

- `S_OR_H` ('s' or 'h') stands for soft or hard thresholding (see `mswthresh` for more details).
- `KEEPAPP` (true or false) indicates whether to keep approximation coefficients (true) or not (false).
- `IDXSIG` is a vector that contains the indices of the initial signals, or 'all'.

The defaults are, respectively, 'h', false and 'all'.

Examples

Multisignal Compression Scores

Load the 23 channel EEG data `Espiga3` [4]. The channels are arranged column-wise. The data is sampled at 200 Hz.

```
load Espiga3
```

Perform a decomposition at level 2 using the `db2` wavelet.

```
dec = mdwtdec('c',Espiga3,2,'db2')
```

```
dec = struct with fields:
    dirDec: 'c'
    level: 2
    wname: 'db2'
    dwtFilters: [1x1 struct]
    dwtEXTM: 'sym'
    dwtShift: 0
    dataSize: [995 23]
    ca: [251x23 double]
    cd: {[499x23 double] [251x23 double]}
```

Compute the compression performances for soft and hard thresholding.

```
[THR_S,L2SCR_S,N0SCR_S] = mswcmpscr(dec,'s');
[THR_H,L2SCR_H,N0SCR_H] = mswcmpscr(dec,'h');
```

mswcmptp

Multisignal 1-D compression thresholds and performances

Syntax

```
[THR_VAL,L2_Perf,N0_Perf] = mswcmptp(DEC,METH)
[THR_VAL,L2_Perf,N0_Perf] = mswcmptp(DEC,METH,PARAM)
```

Description

[THR_VAL,L2_Perf,N0_Perf] = mswcmptp(DEC,METH) or [THR_VAL,L2_Perf,N0_Perf] = mswcmptp(DEC,METH,PARAM) computes the vectors THR_VAL, L2_Perf and N0_Perf obtained after a compression using the METH method and, if required, the PARAM parameter (see mswcmp for more information on METH and PARAM).

For the *i*th signal:

- THR_VAL(*i*) is the threshold applied to the wavelet coefficients. For a level dependent method, THR_VAL(*i*, *j*) is the threshold applied to the detail coefficients at level *j*
- L2_Perf(*i*) is the percentage of energy (L2_norm) preserved after compression.
- N0_Perf(*i*) is the percentage of zeros obtained after compression.

You can use three more optional inputs:

```
[...] = mswcmptp(...,S_OR_H,KEEPAPP,IDXSIG)
```

- S_OR_H ('s' or 'h') stands for soft or hard thresholding (see mswthresh for more details).
- KEEPAPP (true or false) indicates whether to keep approximation coefficients (true) or not (false)
- IDXSIG is a vector which contains the indices of the initial signals, or 'all'.

The defaults are, respectively, 'h', false and 'all'.

Examples

Multisignal Compression Thresholds and Performance

Load the 23 channel EEG data Espiga3 [4]. The channels are arranged column-wise. The data is sampled at 200 Hz.

```
load Espiga3
```

Perform a decomposition at level 2 using the db2 wavelet.

```
dec = mdwtdec('c',Espiga3,2,'db2')
```

```
dec = struct with fields:
    dirDec: 'c'
    level: 2
```

```
wname: 'db2'  
dwtFilters: [1x1 struct]  
dwtEXTM: 'per'  
dwtShift: 0  
dataSize: [995 23]  
    ca: [249x23 double]  
    cd: {[498x23 double] [249x23 double]}
```

Compute compression thresholds and exact performances obtained after a compression using the method 'N0_perf' and requiring a percentage of zeros near 95% for the wavelet coefficients.

```
[THR_VAL,L2_Perf,N0_Perf] = mswcmptp(dec, 'N0_perf',95);
```

ddencmp | mdwtdec | mdwtrec | wdencmp

Introduced in R2007a

mswden

Multisignal 1-D denoising using wavelets

Note mswden is no longer recommended. Use wdenoise instead.

Syntax

```
[XD,DECDEN,THRESH] = mswden('den',...)
[XD,THRESH] = mswden('densig',...)
[DECDEN,THRESH] = mswden('dendec',...)
THRESH = mswden('thr',...)
[...] = mswden(OPTION,DIRDEC,X,WNAME,LEV,METH,PARAM)
[...] = mswden(...,S_OR_H)
[...] = mswden(...,S_OR_H,KEEPAPP)
[...] = mswden(...,S_OR_H,KEEPAPP,IDXSIG)
```

Description

mswden computes thresholds and, depending on the selected option, performs denoising of 1-D signals using wavelets.

[XD,DECDEN,THRESH] = mswden('den',...) returns a denoised version XD of the original multisignal matrix X, whose wavelet decomposition structure is DEC. The output XD is obtained by thresholding the wavelet coefficients, DECDEN is the wavelet decomposition associated to XD (see mdwtdec), and THRESH is the matrix of threshold values. The input METH is the name of the denoising method and PARAM is the associated parameter, if required.

Valid denoising methods METH and associated parameters PARAM are:

'rigrsure'	Principle of Stein's Unbiased Risk
'heursure'	Heuristic variant of the first option
'sqrtwolog'	Universal threshold $\sqrt{2 \cdot \log(\cdot)}$
'minimaxi'	Minimax thresholding (see thselect)

For these methods PARAM defines the multiplicative threshold rescaling:

'one'	No rescaling
'sln'	Rescaling using a single estimation of level noise based on first level coefficients
'mln'	Rescaling using a level dependent estimation of level noise

Penalization methods

'penal'	Penal
'penalhi'	Penal high, $2.5 \leq \text{PARAM} \leq 10$

'penalme'	Penal medium, $1.5 \leq \text{PARAM} \leq 2.5$
'penallo'	Penal low, $1 \leq \text{PARAM} \leq 2$

PARAM is a sparsity parameter, and it should be such that: $1 \leq \text{PARAM} \leq 10$. For penal method, no control is done.

Manual method

'man_thr'	Manual method
-----------	---------------

PARAM is an NbSIG-by-NbLEV matrix or NbSIG-by-(NbLEV+1) matrix such that:

- $\text{PARAM}(i, j)$ is the threshold for the detail coefficients of level j for the i th signal ($1 \leq j \leq \text{NbLEV}$).
- $\text{PARAM}(i, \text{NbLEV}+1)$ is the threshold for the approximation coefficients for the i th signal (if KEEPAPP is 0).

where NbSIG is the number of signals and NbLEV the number of levels of decomposition.

Instead of the 'den' input OPTION, you can use 'densig', 'dendec' or 'thr' OPTION to select output arguments:

`[XD, THRESH] = mswden('densig', ...)` or `[DECEN, THRESH] = mswden('dendec', ...)`

`THRESH = mswden('thr', ...)` returns the computed thresholds, but denoising is not performed.

The decomposition structure input argument DEC can be replaced by four arguments: DIRDEC, X, WNAME and LEV.

`[...] = mswden(OPTION, DIRDEC, X, WNAME, LEV, METH, PARAM)` before performing a denoising or computing thresholds, the multisignal matrix X is decomposed at level LEV using the wavelet WNAME, in the direction DIRDEC.

You can use three more optional inputs:

`[...] = mswden(..., S_OR_H)` or
`[...] = mswden(..., S_OR_H, KEEPAPP)` or
`[...] = mswden(..., S_OR_H, KEEPAPP, IDXSIG)`

- S_OR_H ('s' or 'h') stands for soft or hard thresholding (see mswthresh for more details).
- KEEPAPP (true or false) indicates whether to keep approximation coefficients (true) or not (false).
- IDXSIG is a vector that contains the indices of the initial signals, or 'all'.

The defaults are, respectively, 'h', false and 'all'.

Examples

Multisignal 1-D Wavelet Denoising

Load the 23 channel EEG data Espiga3 [8]. The channels are arranged column-wise. The data is sampled at 200 Hz.

```
load Espiga3
```

Perform a decomposition at level 2 using the db2 wavelet.

```
dec = mdwtdec('c',Espiga3,2,'db2')
```

```
dec = struct with fields:
    dirDec: 'c'
    level: 2
    wname: 'db2'
    dwtFilters: [1x1 struct]
    dwtEXTM: 'sym'
    dwtShift: 0
    dataSize: [995 23]
    ca: [251x23 double]
    cd: {[499x23 double] [251x23 double]}
```

Denoise the signals using the universal method of thresholding (`sqtwolog`) and the `'sln'` threshold rescaling (with a single estimation of level noise, based on the first level coefficients).

```
[xd,decden,thresh] = mswden('den',dec,'sqtwolog','sln');
```

Plot an original signal, and the corresponding denoised signal.

```
idxA = 3;
plot(Espiga3(:,idxA),'r')
hold on
plot(xd(:,idxA),'b')
grid on
legend('Original','Denoised')
```

Apps

Wavelet Signal Denoiser

Introduced in R2007a

msthresh

Perform multisignal 1-D thresholding

Syntax

```
Y = msthresh(X,sorh,T)
Y = msthresh(X,sorh,T,'c')
```

Description

`Y = msthresh(X,sorh,T)` returns the soft or hard T -thresholding of the matrix X . T can be a single value, a matrix the same size as X , or a vector. If T is a vector, thresholding is performed row-wise, and $LT = \text{length}(T)$ must be such that $\text{size}(X,1) \leq LT$. Only the first $\text{size}(X,1)$ values of T are used.

`Y = msthresh(X,sorh,T,'c')` performs thresholding column-wise, and $LT = \text{length}(T)$ must be such that $\text{size}(X,2) \leq LT$. Only the first $\text{size}(X,2)$ values of T are used.

Examples

Multisignal Thresholding

Create a 3-by-3 matrix and a 1-by-3 vector of threshold values.

```
mat = [1 1 3; 1 1 3; 2 2 3]
```

```
mat = 3×3
```

```
    1    1    3
    1    1    3
    2    2    3
```

```
thr = [1 2 3]
```

```
thr = 1×3
```

```
    1    2    3
```

Apply soft thresholding to the matrix row-wise. The k th threshold in `thr` is applied to the k th row of `mat`.

```
msthresh(mat,'s',thr)
```

```
ans = 3×3
```

```
    0    0    2
    0    0    1
    0    0    0
```

Apply soft thresholding to the matrix column-wise. The k th threshold in `thr` is applied to the k th column of `mat`.

```
mswthresh(mat, 's', thr, 'c')
```

```
ans = 3×3
```

```
    0    0    0
    0    0    0
    1    0    0
```

Apply hard thresholding to the matrix row-wise.

```
mswthresh(mat, 'h', thr)
```

```
ans = 3×3
```

```
    0    0    3
    0    0    3
    0    0    0
```

Apply hard thresholding to the matrix column-wise.

```
mswthresh(mat, 'h', thr, 'c')
```

```
ans = 3×3
```

```
    0    0    0
    0    0    0
    2    0    0
```

Input Arguments

X — Input data

real-valued matrix

Input data to threshold, specified as a real-valued matrix.

Data Types: `double`

sorh — Type of thresholding

's' | 'h'

Type of thresholding to perform, specified as:

- 's' — Soft thresholding
- 'h' — Hard thresholding

T — Threshold value

real-valued scalar or vector

Threshold value, specified as a real-valued scalar or vector.

Data Types: `double`

Output Arguments

Y — Thresholded data

real-valued matrix

Thresholded data, returned as a real-valued matrix. Y has the same dimensions as X.

Algorithms

- If `soth` is 's', Y is the soft thresholding of X: $Y = \text{sign}(X) \cdot (|X| - T)_+$ where

$$(x)_+ = \begin{cases} x & \text{if } x \geq 0 \\ 0 & \text{otherwise} \end{cases}$$

Soft thresholding is wavelet shrinkage.

- If `soth` is 'h', Y is the hard thresholding of X: $Y = X \cdot \mathbf{1}_{(|X| > T)}$ where

$$\mathbf{1}_{(|X| > T)} = \begin{cases} 1 & \text{if } |X| > T \\ 0 & \text{otherwise} \end{cases}$$

Hard thresholding is cruder than soft thresholding.

Introduced in R2007a

nodeasc

Node ascendants

Syntax

```
A = nodeasc(T,N)
```

Description

nodeasc is a tree-management utility.

$A = \text{nodeasc}(T, N)$ returns the indices of all the ascendants of the node N in the tree T where N can be the index node or the depth and position of the node. A is a column vector with $A(1) =$ index of node N .

$A = \text{nodeasc}(T, N, 'depos')$ is a matrix, which contains the depths and positions of all ascendants. $A(i, 1)$ is the depth of the i -th ascendant and $A(i, 2)$ is the position of the i -th ascendant.

The nodes are numbered from left to right and from top to bottom. The root index is 0.

Examples

```
% Create binary tree of depth 3.
t = ntree(2,3);
t = nodejoin(t,5);
t = nodejoin(t,4);
plot(t)
```

```
% Change Node Label from Depth_Position to Index
% (see the plot function).
```

```
nodeasc(t,[2 2])
ans =
     5
     2
     0
```

```
nodeasc(t,[2 2], 'depos')
ans =
     2     2

nodedesc

Node descendants

Syntax

```
D = nodedesc(T,N)
D = nodedesc(T,N,'deppos')
```

Description

nodedesc is a tree-management utility.

`D = nodedesc(T,N)` returns the indices of all the descendants of the node N in the tree T where N can be the index node or the depth and position of node. D is a column vector with $D(1)$ = index of node N .

`D = nodedesc(T,N,'deppos')` is a matrix that contains the depths and positions of all descendants. $D(i,1)$ is the depth of the i -th descendant and $D(i,2)$ is the position of the i -th descendant.

The nodes are numbered from left to right and from top to bottom. The root index is 0.

Examples

```
% Create binary tree of depth 3.
t = ntree(2,3);
t = nodejoin(t,5);
t = nodejoin(t,4);
plot(t)
```

```
% Change Node Label from Depth_Position to Index
% (see the plot function).
```

```
% Node descendants.

nodejoin

Recompose node

Syntax

```
T = nodejoin(T,N)
T = nodejoin(T)
T = nodejoin(T,0)
```

Description

nodejoin is a tree-management utility.

`T = nodejoin(T,N)` returns the modified tree T corresponding to a recomposition of the node N .

The nodes are numbered from left to right and from top to bottom. The root index is 0.

`T = nodejoin(T)` is equivalent to `T = nodejoin(T,0)`.

Examples

```
% Create binary tree of depth 3.
t = ntree(2,3);

% Plot tree t.
plot(t)

% Change Node Label from Depth_Position to Index
% (see the plot function).
```

```
% Merge nodes of indices 4 and 5.
t = nodejoin(t,5);
t = nodejoin(t,4);
% Plot new tree t.
plot(t)

% Change Node Label from Depth_Position to Index
% (see the plot function).
```

See Also

`nodesplt`

Introduced before R2006a

nodepar

Node parent

Syntax

```
F = nodepar(T,N)
F = nodepar(T,N, 'deppos')
```

Description

nodepar is a tree-management utility.

$F = \text{nodepar}(T, N)$ returns the indices of the "parent(s)" of the nodes N in the tree T where N can be a column vector containing the indices of nodes or a matrix that contains the depths and positions of nodes. In the last case, $N(i, 1)$ is the depth of the i -th node and $N(i, 2)$ is the position of the i -th node.

$F = \text{nodepar}(T, N, 'deppos')$ is a matrix that contains the depths and positions of returned nodes. $F(i, 1)$ is the depth of the i -th node and $F(i, 2)$ is the position of the i -th node.

$\text{nodepar}(T, \emptyset)$ or $\text{nodepar}(T, [\emptyset, \emptyset])$ returns -1.

$\text{nodepar}(T, \emptyset, 'deppos')$ or $\text{nodepar}(T, [\emptyset, \emptyset], 'deppos')$ returns $[-1, \emptyset]$.

The nodes are numbered from left to right and from top to bottom. The root index is 0.

Examples

```
% Create binary tree of depth 3.
t = ntree(2,3);
t = nodejoin(t,5);
t = nodejoin(t,4);
plot(t)
```

```
% Change Node Label from Depth_Position to Index
% (see the plot function).
```

```
% Nodes parent.  
nodepar(t,[2 2], 'deppos')
```

```
ans =

nodesplt

Split (decompose) node

Syntax

```
T = nodesplt(T,N)
```

Description

nodesplt is a tree-management utility.

`T = nodesplt(T,N)` returns the modified tree T corresponding to the decomposition of the node N .

The nodes are numbered from left to right and from top to bottom. The root index is 0.

Examples

```
% Create binary tree (tree of order 2) of depth 3.
t = ntree(2,3);
```

```
% Plot tree t.
plot(t)
```

```
% Change Node Label from Depth_Position to Index
% (see the plot function).

nodejoin

Introduced before R2006a

noleaves

Determine nonterminal nodes

Syntax

```
N = noleaves(T)
N = noleaves(T, 'dp')
```

Description

`N = noleaves(T)` returns the indices of nonterminal nodes of the tree T (i.e., nodes that are not leaves). N is a column vector.

The nodes are ordered from left to right as in tree T .

`N = noleaves(T, 'dp')` returns a matrix N , which contains the depths and positions of nonterminal nodes.

$N(i,1)$ is the depth of the i -th nonterminal node and
 $N(i,2)$ is the position of the i -th nonterminal node.

Examples

```
% Create initial tree.
ord = 2;
t = ntree(ord,3);           % binary tree of depth 3.
t=nodejoin(t,5);
t=nodejoin(t,4);
plot(t)

% Change Node Label from Depth_Position to Index
% (see the plot function).

ntree

NTREE constructor

Syntax

```
T = ntree(ORD,D)
T = ntree
T = ntree(2,0)
T = ntree(ORD)
T = ntree(ORD,0)
T = ntree(ORD,D,S)
T = ntree(ORD,D,S,U)
```

Description

`T = ntree(ORD,D)` returns an NTREE object, which is a complete tree of order `ORD` and depth `D`.

`T = ntree` is equivalent to `T = ntree(2,0)`.

`T = ntree(ORD)` is equivalent to `T = ntree(ORD,0)`.

With `T = ntree(ORD,D,S)` you can set a “split scheme” for nodes. The split scheme field `S` is a logical array of size `ORD` by 1.

The root of the tree can be split and it has `ORD` children. You can split the `j`-th child if `S(j) = 1`.

Each node that you can split has the same property as the root node.

With `T = ntree(ORD,D,S,U)` you can, in addition, set a userdata field.

Inputs can be given in another way:

`T = ntree('order',ORD,'depth',D,'spsch',S,'ud',U)`. For “missing” inputs the defaults are `ORD = 2` and `D = 0`, `S = ones([1:ORD])`, `U = {}`.

`[T,NB] = ntree(...)` returns also the number of terminal nodes (leaves) of `T`.

For more information on object fields, type `help ntree/get`.

Class NTREE (Parent class: WTBO)

Fields

wtbo	Parent object
order	Tree order
depth	Tree depth
spsch	Split scheme for nodes
tn	Column vector with terminal node indices

Examples

```
% Create binary tree (tree of order 2) of depth 3.
t2 = ntree(2,3);
```

```
% Plot tree t2.
plot(t2)
```

```
% Create a quadtree (tree of order 4) of depth 2.
t4 = ntree(4,2,[1 1 0 1]);
```

```
% Plot tree t4.
plot(t4)
```

```
% Split and merge some nodes using the gui
% generated by plot (see the plot function).
% The figure becomes:

wtbo

Introduced before R2006a

numCoefficients

Number of wavelet scattering coefficients

Syntax

```
ncf = numCoefficients(sf)
```

Description

`ncf = numCoefficients(sf)` returns the number of scattering coefficients for each scattering path in the scattering framework `sf`. The number of scattering coefficients depends on the values of the “SignalLength” on page 1-0 , “InvarianceScale” on page 1-0 , and “OversamplingFactor” on page 1-0 properties of `sf`.

Examples

Oversample 1-D Wavelet Scattering Transform

This example shows how to oversample a 1-D wavelet scattering transform.

Load an ECG signal sampled at 180 Hz, and create a wavelet scattering framework to process the signal. To perform a critically downsampled wavelet scattering transform, do not change the value of the `OversamplingFactor` property in `sf`. Return the number of scattering coefficients for the framework.

```
load wecg
Fs = 180;
sf = waveletScattering('SignalLength', numel(wecg), 'SamplingFrequency', Fs);
ncf = numCoefficients(sf)
```

```
ncf = 8
```

Return the 1-D wavelet scattering transform of `wecg`, and plot the zeroth-order scattering coefficients. Confirm the number of zeroth-order scattering coefficients is equal to `ncf`.

```
s = scatteringTransform(sf, wecg);
display(['Number of zeroth-order scattering coefficients: ', ...
        num2str(numel(s{1}.signals{1}))])
```

```
Number of zeroth-order scattering coefficients: 8
```

```
plot(s{1}.signals{1}, 'x-')
grid on
axis tight
title('Zeroth-Order Scattering Coefficients')
```

To oversample the scattering coefficients by a factor of 2, set the `OversamplingFactor` property of `sf` equal to 1 (because $\log_2 2 = 1$). Return the number of scattering coefficients for the edited framework. Confirm the number of scattering coefficients has doubled.

```
sf.OversamplingFactor = 1;  
ncf = numCoefficients(sf)
```

```
ncf = 16
```

Return the wavelet scattering transform of `wecg` using the edited framework, and plot the zeroth-order scattering coefficients. Since the number of coefficients in the critically sampled transform is equal to 8, confirm that the number of zeroth-order coefficients in the oversampled transform is equal to 16.

```
s = scatteringTransform(sf,wecg);  
figure  
plot(s{1}.signals{1},'x-')  
grid on  
axis tight  
title('Zeroth-Order Scattering Coefficients')
```

Input Arguments

sf — Scattering decomposition framework
waveletScattering object

Scattering decomposition framework, specified as a waveletScattering object.

See Also

waveletScattering

Introduced in R2019a

numfilterbanks

Number of scattering filter banks

Syntax

```
nfb = numfilterbanks(sf)
```

Description

`nfb = numfilterbanks(sf)` returns the number of filter banks in the scattering decomposition framework, `sf`. The number of filter banks in a scattering decomposition framework is equal to $ord - 1$ where ord is the number of scattering orders.

Examples

Number of Filter Banks in Scattering Decomposition Framework

Calculate the number of filter banks for the default scattering decomposition framework.

```
sf = waveletScattering

sf =
  waveletScattering with properties:
      SignalLength: 1024
      InvarianceScale: 512
      QualityFactors: [8 1]
      Boundary: 'periodic'
      SamplingFrequency: 1
      Precision: 'double'
      OversamplingFactor: 0
```

```
Nfb = numfilterbanks(sf)
```

```
Nfb = 2
```

Input Arguments

sf — Scattering decomposition framework

`waveletScattering` object | `waveletScattering2` object

Scattering decomposition framework, specified as a `waveletScattering` object or a `waveletScattering2` object.

See Also

`waveletScattering` | `waveletScattering2`

Introduced in R2018b

numorders

Number of scattering orders

Syntax

```
no = numorders(sf)
```

Description

`no = numorders(sf)` returns the number of orders for the scattering decomposition framework, `sf`. The number of orders is equal to $Nfb + 1$, where Nfb is the number of filter banks in `sf`.

Examples

Number of Orders in Scattering Decomposition Framework

Calculate the number of orders for the default scattering decomposition framework.

```
sf = waveletScattering
sf =
  waveletScattering with properties:
    SignalLength: 1024
    InvarianceScale: 512
    QualityFactors: [8 1]
    Boundary: 'periodic'
    SamplingFrequency: 1
    Precision: 'double'
    OversamplingFactor: 0

no = numorders(sf)

no = 3
```

Input Arguments

sf — Scattering decomposition framework

`waveletScattering` object | `waveletScattering2` object

Scattering decomposition framework, specified as a `waveletScattering` object or a `waveletScattering2` object.

See Also

`waveletScattering` | `waveletScattering2`

Introduced in R2018b

numshears

Number of shearlets

Syntax

```
NS = numshears(sls)
```

Description

`NS = numshears(sls)` returns the number of shearlets in the shearlet system `sls`. The number of shearlets does not include the lowpass filter, which is not sheared. The total filter size of the shearlet system is M -by- N -by- $NS+1$. M and N are the first and second elements, respectively, of the `ImageSize` value of `sls`.

The data type of `NS` matches the `Precision` value of the shearlet system.

Examples

Number of Shearlets in Shearlet System

Create a complex-valued shearlet system that can be applied to 256-by-256 images. The system has four scales.

```
sls = shearletSystem('ImageSize',[256 256],'TransformType','complex',...  
    'NumScales',4);
```

Obtain the number of shearlets in the shearlet system.

```
num = numshears(sls)
```

```
num = 80
```

Input Arguments

`sls` — Shearlet system

shearletSystem object

Shearlet system, specified as a shearletSystem object.

filterbank | shearletSystem

Introduced in R2019b

orthfilt

Orthogonal wavelet filter set

Syntax

```
[Lo_D,Hi_D,Lo_R,Hi_R] = orthfilt(W)
```

Description

`[Lo_D,Hi_D,Lo_R,Hi_R] = orthfilt(W)` computes the four filters associated with the scaling filter W corresponding to a wavelet:

Lo_D	Decomposition low-pass filter
Hi_D	Decomposition high-pass filter
Lo_R	Reconstruction low-pass filter
Hi_R	Reconstruction high-pass filter

For an orthogonal wavelet, in the multiresolution framework, we start with the scaling function ϕ and the wavelet function ψ . One of the fundamental relations is the twin-scale relation:

$$\frac{1}{2}\phi\left(\frac{x}{2}\right) = \sum_{n \in \mathbb{Z}} w_n \phi(x - n)$$

All the filters used in `dwt` and `idwt` are intimately related to the sequence $(w_n)_{n \in \mathbb{Z}}$. Clearly if ϕ is compactly supported, the sequence (w_n) is finite and can be viewed as a FIR filter. The scaling filter W is

- A low-pass FIR filter
- Of length $2N$
- Of sum 1
- Of norm $\frac{1}{\sqrt{2}}$

For example, for the `db3` scaling filter,

```
load db3
db3
db3 =
    0.2352  0.5706  0.3252 -0.0955 -0.0604  0.0249

sum(db3)
ans =
    1.000
norm(db3)
ans =
    0.7071
```

From filter W , we define four FIR filters, of length $2N$ and norm 1, organized as follows:

Filters	Low-Pass	High-Pass
Decomposition	Lo_D	Hi_D
Reconstruction	Lo_R	Hi_R

The four filters are computed using the following scheme:

where `qmf` is such that `Hi_R` and `Lo_R` are quadrature mirror filters (i.e., $\text{Hi_R}(k) = (-1)^k \text{Lo_R}(2N + 1 - k)$, for $k = 1, 2, \dots, 2N$), and where `wrev` flips the filter coefficients. So `Hi_D` and `Lo_D` are also quadrature mirror filters. The computation of these filters is performed using `orthfilt`.

Examples

```

% Load scaling filter.
load db8; w = db8;
subplot(421); stem(w);
title('Original scaling filter');

% Compute the four filters.
[Lo_D,Hi_D,Lo_R,Hi_R] = orthfilt(w);
subplot(423); stem(Lo_D);
title('Decomposition low-pass filter');
subplot(424); stem(Hi_D);
title('Decomposition high-pass filter');
subplot(425); stem(Lo_R);
title('Reconstruction low-pass filter');
subplot(426); stem(Hi_R);
title('Reconstruction high-pass filter');

% Check for orthonormality.
df = [Lo_D;Hi_D];
rf = [Lo_R;Hi_R];
id = df*df'

id =
    1.0000    0
         0    1.0000

id = rf*rf'

id =
    1.0000    0
         0    1.0000

% Check for orthogonality by dyadic translation, for example:

```

```
df = [Lo_D 0 0;Hi_D 0 0];
dft = [0 0 Lo_D; 0 0 Hi_D];
zer = df*dft'
```

```
zer =
```

```
1.0e-12 *
-0.1883 0.0000
-0.0000 -0.1883
```

```
% High- and low-frequency illustration.
fftlD = fft(Lo_D); ffthD = fft(Hi_D);
freq = [1:length(Lo_D)]/length(Lo_D);
subplot(427); plot(freq,abs(fftlD));
title('Transfer modulus: low-pass');
subplot(428); plot(freq,abs(ffthD));
title('Transfer modulus: high-pass')
% Editing some graphical properties,
% the following figure is generated.
```

otnodes

Order terminal nodes of binary wavelet packet tree

Syntax

```
[Tn_Pal,Tn_Seq] = otnodes(WPT)
[Tn_Pal,Tn_Seq,I,J] = otnodes(WPT)
[DP_Pal,DP_Seq] = otnodes(WPT,'dp')
```

Description

`[Tn_Pal,Tn_Seq] = otnodes(WPT)` returns the terminal nodes of the binary wavelet packet tree, `WPT`, in Paley (natural) ordering, `Tn_Pal`, and sequency (frequency) ordering, `Tn_Seq`. `Tn_Pal` and `Tn_Seq` are N -by-1 column vectors where N is the number of terminal nodes.

`[Tn_Pal,Tn_Seq,I,J] = otnodes(WPT)` returns the permutations of the terminal node indices such that `Tn_Seq = Tn_Pal(I)` and `Tn_Pal = Tn_Seq(J)`.

`[DP_Pal,DP_Seq] = otnodes(WPT,'dp')` returns the Paley and frequency-ordered terminal nodes in node depth-position format. `DP_Pal` and `DP_Seq` are N -by-2 matrices. The first column contains the depth index, and the second column contains the position index.

Input Arguments

WPT

Binary wavelet packet tree. You can use `treeord` to determine the order of your wavelet packet tree.

dp

Character vector indicating that the Paley-ordered or sequency-ordered nodes are returned in depth-position format.

Output Arguments

Tn_Pal

Terminal nodes in Paley (natural) ordering

Tn_Seq

Terminal nodes in sequency ordering

DP_Pal

Paley-ordered terminal nodes in depth-position format. This output argument only applies when you use the `'dp'` input argument.

DP_Seq

Sequency-ordered terminal nodes in depth-position format. This output argument only applies when you use the 'dp' input argument.

Examples

Order Terminal Nodes

Order terminal nodes with Paley and frequency ordering.

```
x = randn(8,1);
wpt = wptec(x,2, 'haar');
[Tn_Pal,Tn_Seq] = otnodes(wpt)
```

```
Tn_Pal = 4×1
```

```
3
4
5
6
```

```
Tn_Seq = 4×1
```

```
3
4
6
5
```

Return Permutations for Ordering

Return permutations for Paley and frequency ordering.

```
load noisdopp;
wpt = wptec(noisdopp,6, 'sym4');
[Tn_Pal,Tn_Seq,I,J] = otnodes(wpt);
isequal(Tn_Seq(J),Tn_Pal)
```

```
ans = logical
     1
```

```
isequal(Tn_Seq,Tn_Pal(I))
```

```
ans = logical
     1
```

Order Terminal Nodes by Depth and Position

Order terminal nodes by depth and position.

```
x = randn(8,1);  
wpt = wpdec(x,2, 'haar');  
[DP_Pal,DP_Seq] = otnodes(wpt, 'dp')
```

```
DP_Pal = 4x2
```

```
    2    0  
    2    1  
    2    2

More About

Paley (Natural) and Sequency (Frequency) Ordering

The discrete wavelet packet transform iterates on both approximation and detail coefficients at each level. In this transform, A denotes the lowpass (approximation) filter followed by downsampling. D denotes the highpass (detail) filter followed by downsampling. The following figure represents a wavelet packet transform in Paley ordering acting on a time series of length 8. The transform has a depth of two.

Because of aliasing introduced by downsampling, the frequency content extracted by the operator AD is higher than the frequency content extracted by the DD operator. Therefore, the terminal nodes in

frequency (sequency) order are: AA, DA, DD, AD . The terminal nodes in Paley order have the following indices: 3,4,5,6. The frequency order has the indices: 3,4,6,5.

Introduced in R2010b

pat2cwav

Build wavelet from pattern

Syntax

```
[psi,xval,nc] = pat2cwav(ypat,method,poldegree,regularity)
```

Description

`[psi,xval,nc] = pat2cwav(ypat,method,poldegree,regularity)` returns an admissible wavelet `psi` for the continuous wavelet transform (CWT) adapted to the pattern `ypat`. The wavelet `psi` is evaluated at `xval`, a regular grid in the interval $[0,1]$, and has L_2 -norm equal to 1.

The constant `nc` is such that `nc*psi` approximates `ypat` on the interval $[0,1]$ by least-squares fitting using the method specified by `method`, and a polynomial of degree `poldegree` with boundary constraints specified by `regularity`.

Examples

Create Wavelet for Continuous Wavelet Transform

This example illustrates how to generate a new wavelet starting from a pattern.

The principle for designing a new wavelet for CWT is to approximate a given pattern using least-squares optimization under constraints leading to an admissible wavelet well suited for the pattern detection using the continuous wavelet transform [1].

Load and plot a pattern.

```
load ptpssin1
plot(X,Y)
grid on
title('Original Pattern')
```

Integrate the pattern over the interval. The integral does not equal 0. However, the pattern is a good candidate since it oscillates like a wavelet.

```
dX = X(2)-X(1);
patternInt = dX*sum(Y);
disp(['Integral: ',num2str(patternInt)]);
```

```
Integral: 0.15915
```

To synthesize a new wavelet adapted to the given pattern, use a least-squares polynomial approximation of degree 6 with constraints of continuity at the beginning and the end of the pattern.

```
[psi,xval,nc] = pat2cwav(Y,'polynomial',6,'continuous');
```

Plot the new wavelet.

```
plot(X,Y,'-',xval,nc*psi,'-')
grid on
legend('Original Pattern','Adapted Wavelet','Location','NorthWest')
```

Check that ψ satisfies the definition of a wavelet by confirming that it integrates to zero and has L_2 norm is equal to 1.

```
dxval = xval(2)-xval(1);
psiIntegral = dxval*sum(psi);
disp(['Integral: ', num2str(psiIntegral)])
```

```
Integral: 1.9626e-05
```

```
psiSqN = dxval*sum(psi.^2);
disp(['L2-norm: ', num2str(psiSqN)])
```

```
L2-norm: 1
```

Input Arguments

ypat – Pattern

real-valued vector

Pattern to approximate, specified as a real-valued vector.

method – Least-squares fitting method

'polynomial' | 'orthconst'

Least-squares fitting method to use to approximate the pattern, specified as one of the following:

- 'polynomial' — Use a polynomial of degree poldegree
- 'orthconst' — Use a projection onto the space of functions orthogonal to constants

Note Specifying the 'orthconst' option does not produce an orthogonal wavelet. Any wavelet `psi` produced using `pat2cwav` is a type 4 wavelet (wavelet without a scaling function) in `wavemngr`.

poldegree — Degree of polynomial

integer

Degree of polynomial to use in least-squares fitting, specified as an integer.

regularity — Boundary constraints

'continuous' | 'differentiable' | 'none'

Boundary constraints at the points 0 and 1, specified as 'continuous', 'differentiable', or 'none'. When method is equal to 'polynomial':

- If regularity is equal to 'continuous', poldegree must be greater than or equal to 3.
- If regularity is equal to 'differentiable', poldegree must be greater than or equal to 5.

Output Arguments

psi — Admissible wavelet

real-valued vector

Admissible wavelet for CWT, returned as a real-valued vector. The length of `psi` equals the length of `ypat`. The wavelet `psi` integrates to zero and has L_2 -norm equal to 1.

xval — Sampling instants

real-valued vector

Sampling instants where `psi` is evaluated, returned as a real-valued vector. The sampling instants `xval` are a regular n -point grid spanning the interval $[0,1]$, where n is the length of `ypat`: `xval = linspace(0,1,length(ypat))`.

nc — Normalizing constant

scalar

Normalizing constant, returned as a scalar. The constant `nc` is such that `nc*psi` approximates `ypat` on the interval $[0,1]$ by least-squares fitting using the method specified by `method`.

wavemngr

Introduced before R2006a

paths

Scattering paths

Syntax

```
spaths = paths(sf)
[spath, npaths] = paths(sf)
```

Description

`spath = paths(sf)` returns the scattering paths for all orders of the scattering framework, `sf`. `spath` is a cell array of MATLAB tables with n elements, where n is the number of orders in the scattering framework.

`[spath, npaths] = paths(sf)` returns the number of paths in each order as n -by-1 column vector, where n is the number of orders in the scattering framework. The sum of the elements of `npaths` is the total number of scattering paths.

Examples

Scattering Paths of Wavelet Image Scattering Framework

This example compares the number of paths in a wavelet image scattering frameworks with three orders.

Create an image scattering framework with an image size of 256-by-256 and invariance scale equal to the minimum of the image size. The default `OptimizePath` value is 1 (true).

```
sf = waveletScattering2('ImageSize',[256 256], 'InvarianceScale',128)
```

```
sf =
    waveletScattering2 with properties:
```

```
    ImageSize: [256 256]
    InvarianceScale: 128
    NumRotations: [6 6]
    QualityFactors: [1 1]
    Precision: "single"
    OversamplingFactor: 0
    OptimizePath: 1
```

Obtain the number of scattering paths in each order. Display the total number of scattering paths.

```
[spath, npaths] = paths(sf);
sum(npaths)
```

```
ans = 391
```

Set the `OptimizePath` value of the framework to `false`. Display the total number of scattering paths. For this framework, the scattering transform does not reduce the number of paths to compute based on a bandwidth consideration.

```
sf.OptimizePath = false;
[spaths,npaths] = paths(sf);
sum(npaths)
```

```
ans = 571
```

Wavelets on Scattering Path

This example shows how the `OptimizePath` property can affect the scattering paths that include a specific wavelet.

Create the default wavelet image scattering framework. Obtain all the wavelet filters and center spatial frequencies for the framework. Obtain all the framework scattering paths. Display the total number of paths.

```
sf = waveletScattering2
[~,psifilters,f] = filterbank(sf);
[spaths,npaths] = paths(sf);
disp(['Total Number of Paths: ',num2str(sum(npaths))])
```

```
sf =
```

```
waveletScattering2 with properties:
```

```
    ImageSize: [128 128]
  InvarianceScale: 64
    NumRotations: [6 6]
  QualityFactors: [1 1]
    Precision: 'single'
  OversamplingFactor: 0
    OptimizePath: 1
```

```
Total Number of Paths: 241
```

Display the number of wavelet filters in each filter bank.

```
disp(['Filter Bank 1: ',num2str(size(psifilters{1},3))]);
disp(['Filter Bank 2: ',num2str(size(psifilters{2},3))]);
```

```
Filter Bank 1: 24
Filter Bank 2: 24
```

Choose a wavelet from the first filter bank and display its spatial center frequency. Use `spaths` to find all the three-element paths that include the chosen wavelet. Display the paths.

```
waveletA = 14;
disp(['Center Frequency: ',num2str(f{1}(waveletA,:))]);
ind = find(spaths{3}.path(:,2)==waveletA);
spaths{3}(ind,:)
```

```
Center Frequency: 0.08119    0.046875
```

```
ans =
```

```
6x1 table
```

path		
0	14	19
0	14	20
0	14	21
0	14	22
0	14	23
0	14	24

Plot the center frequencies of the wavelet filters on the paths.

```
plot(f{1}(waveletA,1),f{1}(waveletA,2),'k^');
xlabel('f_x')
ylabel('f_y')
hold on
waveletBs = spaths{3}.path(ind,3);
plot(f{2}(waveletBs,1),f{2}(waveletBs,2),'bx');
grid on
legend('First Filter Bank Wavelet','Second Filter Bank Wavelets',...
'Location','northeastoutside')
```

Now set the `OptimizePath` property of the scattering framework `sf` to `false`. Obtain the wavelet filters, center spatial frequencies, and scattering paths of the framework.

```
sf.OptimizePath = false
[~,psifilters2,f2] = filterbank(sf);
[spath2,npaths2] = paths(sf);
disp(['Total Number of Paths: ',num2str(sum(npaths2))])
```

```
sf =
```

```
  waveletScattering2 with properties:
```

```
      ImageSize: [128 128]
  InvarianceScale: 64
    NumRotations: [6 6]
  QualityFactors: [1 1]
    Precision: 'single'
  OversamplingFactor: 0
    OptimizePath: 0
```

```
Total Number of Paths: 385
```

Choose the same wavelet as above. To confirm it is the same wavelet, display its spatial center frequency. Use `spath2` to find all the three-element paths that include the wavelet. Because `OptimizePath` is set to `false`, the wavelet filter has more children.

```
waveletA = 14;
disp(['Center Frequency: ',num2str(f2{1}(waveletA,:))]);
ind = find(spath2{3}.path(:,2)==waveletA);
spath2{3}(ind,:)
```

```
Center Frequency: 0.08119    0.046875
```

```
ans =
```

```
12x1 table
```

	path	

0	14	13
0	14	14
0	14	15
0	14	16
0	14	17
0	14	18
0	14	19
0	14	20
0	14	21
0	14	22
0	14	23
0	14	24

Plot the center frequencies of the wavelet filters on the paths. Some of child filters have center frequencies higher than the chosen wavelet.

```

figure
plot(f2{1}(waveletA,1),f2{1}(waveletA,2),'k^');
xlabel('f_x')
ylabel('f_y')
hold on
waveletBs = spaths2{3}.path(ind,3);
plot(f2{2}(waveletBs,1),f2{2}(waveletBs,2),'bx');
grid on
legend('First Filter Bank Wavelet','Second Filter Bank Wavelets',...
       'Location','northeastoutside')

```

Input Arguments

sf — Scattering decomposition framework

waveletScattering2 object

Scattering decomposition framework, specified as a waveletScattering2 object.

Output Arguments

spaths — Scattering paths

cell array

Scattering paths of all orders of the scattering framework, returned as a cell array of MATLAB tables. `spaths` has n elements, where n is the number of orders in the scattering framework.

Each MATLAB table in `spaths` contains a single variable, `path`. The variable `path` is a row vector with one column for each element of the path. The scalar 0 denotes the original image. Positive integers in the L th column denote the corresponding wavelet filter in the $(L-1)$ th filter bank. Wavelet bandpass filters are ordered by decreasing center frequency. There are `NumRotations` wavelets per center frequency pair.

npaths — Number of scattering paths

column vector

Number of scattering paths in each order of the scattering framework. `npaths` is a no -by-1 column vector where no is the number of orders in the scattering framework. The sum of the elements of `npaths` is the total number of scattering paths.

plot

Plot tree GUI

Syntax

```
plot(T)
plot(T,FIG)
```

Description

`plot` is a graphical tree-management utility.

`plot(T)` plots the tree T .

The figure that contains the tree is a GUI tool. It lets you change the **Node Label** to **Depth_Position** or **Index**, and **Node Action** to **Split-Merge** or **Visualize**.

The default values are **Depth_Position** and **Visualize**.

You can click the nodes to execute the current **Node Action**.

`plot(T,FIG)` plots the tree T in the figure whose handle is `FIG`. This figure was already used to plot a tree, for example using the command

```
FIG = plot(T)
```

After some split or merge actions, you can get the new tree using its parent figure handle. The following syntax lets you perform this functionality:

```
NEWT = plot(T,'read',FIG)
```

In fact, the first argument is dummy. The most general syntax is

```
NEWT = plot(DUMMY,'read',FIG)
```

where `DUMMY` is any object parented by an `NTREE` object. More generally, `DUMMY` can be any object constructor name returning an `NTREE` parented object. For example:

```
NEWT = plot(ntree,'read',FIG)
NEWT = plot(dtree,'read',FIG)
NEWT = plot(wptree,'read',FIG)
```

Examples

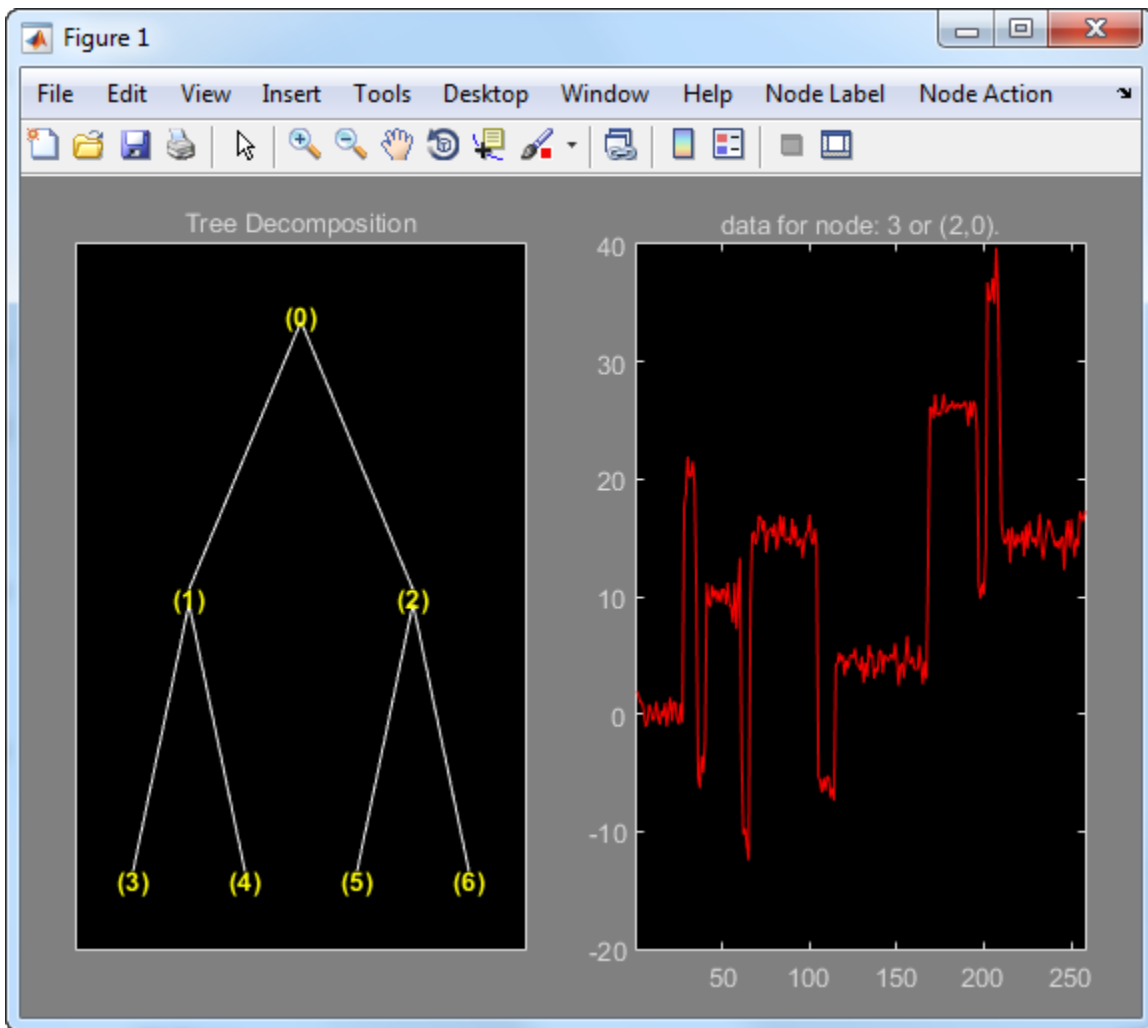

```
% Create a wavelet packets tree (1-D)
load noisbloc
x = noisbloc;
t = wpdec(x,2,'db2');

% Plot tree t.
plot(t)
```

```
% Change Node Label from Depth_Position to Index.
```

```
% Click the node (3). You get the following figure.
```

Now set the **Node Label** back to **Depth_Position**. Change **Node Action** to **Split-Merge**. Click on the (1,1) node.

The above figure now shows the discrete wavelet transform down to level 2.

```
% Create a wavelet packets tree (2-D)
load woman2
t = wpdec2(X,1,'sym4');
```

```
% Plot tree t.
plot(t)
```

```
% Change Node Label from Depth_Position to Index.
% Click the node (1). You get the following figure.
```

Introduced before R2006a

plotdt

Plot dual-tree or double-density wavelet transform

Syntax

```
plotdt(wt)
```

Description

`plotdt(wt)` plots the coefficients of the 1-D or 2-D wavelet filter bank decomposition, `wt`.

Examples

Plot Complex Dual-Tree Wavelet Transform of 1-D Signal

Plot the complex dual-tree wavelet transform of the noisy Doppler signal.

Load the noisy Doppler signal. Obtain the complex dual-tree wavelet transform down to level 4.

```
load noisdopp;  
wt = dddtree('cplxdt',noisdopp,4,'dtf1');
```

Plot the coefficients.

```
plotdt(wt)
```

Plot Complex Oriented Dual-Tree Wavelet Transform of 2-D Image

Plot the complex oriented dual-tree wavelet transform of an image.

Load the xbox image. Obtain the complex oriented dual-tree wavelet transform down to level 3.

```
load xbox;  
wt = ddtree2('cplxdt',xbox,3,'dtf1');
```

Plot the coefficients.

```
plotdt(wt)
```

Coefficients of level 3 - Lowpass

 C_{11}  C_{21}  C_{12}  C_{22} Level 3 - Lowpass

Select the desired level detail coefficients from the drop-down list.

Input Arguments

wt — Wavelet transform

structure

Wavelet transform, returned as a structure from `dddtree` or `dddtree2` with these fields:

type — Type of wavelet decomposition (filter bank)

'dwt' | 'ddt' | 'realdt' | 'cplxdt' | 'realdddt' | 'cplxdddtd'

Type of wavelet decomposition (filter bank), specified as one of 'dwt', 'ddt', 'realdt', 'cplxdt', 'realdddt', or 'cplxdddtd'. 'realdt' and 'realdddt' are only valid for the 2-D wavelet transform. The type, 'dwt', is a critically sampled (nonredundant) discrete wavelet transform for 1-D data or 2-D images. The other decomposition types are oversampled wavelet transforms. For details about transform types see `dddtree` for 1-D wavelet transforms and `dddtree2` for 2-D wavelet transforms.

level — Level of the wavelet decomposition

positive integer

Level of the wavelet decomposition, specified as a positive integer.

filters — Decomposition (analysis) and reconstruction (synthesis) filters

structure

Decomposition (analysis) and reconstruction (synthesis) filters, specified as a structure with these fields:

Fdf — First-stage analysis filters

matrix | cell array

First level decomposition filters specified as an N -by-2 or N -by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two N -by-2 or N -by-3 matrices for dual-tree wavelet transforms. The matrices are N -by-3 for the double-density wavelet transforms. For an N -by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N -by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage analysis filters for the corresponding tree.

Df — Analysis filters for levels > 1

matrix | cell array

Analysis filters for levels > 1, specified as an N -by-2 or N -by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two N -by-2 or N -by-3 matrices for dual-tree wavelet transforms. The matrices are N -by-3 for the double-density wavelet transforms. For an N -by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N -by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the analysis filters for the corresponding tree.

FrF — First-level reconstruction filters

matrix | cell array

First-level reconstruction filters, specified as an N -by-2 or N -by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two N -by-2 or N -by-3 matrices for dual-tree wavelet transforms.

The matrices are N -by-3 for the double-density wavelet transforms. For an N -by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N -by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage synthesis filters for the corresponding tree.

Rf — Reconstruction filters for levels > 1

matrix | cell array

Reconstruction filters for levels > 1, specified as an N -by-2 or N -by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two N -by-2 or N -by-3 matrices for dual-tree wavelet transforms. The matrices are N -by-3 for the double-density wavelet transforms. For an N -by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N -by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage synthesis filters for the corresponding tree.

cfs — Wavelet transform coefficients

cell array of matrices

Wavelet transform coefficients, specified as a 1-by-(level+1) cell array of matrices. The size and structure of the matrix elements of the cell array depend on the type of wavelet transform and whether the decomposition is 1-D or 2-D. For a 1-D wavelet transform, the coefficients are organized by transform type as follows:

- 'dwt' — cfs{j}

 - $j = 1, 2, \dots, \text{level}$ is the level.
 - cfs{level+1} are the lowpass, or scaling, coefficients.

- 'ddt' — cfs{j}(:, :, k)

 - $j = 1, 2, \dots, \text{level}$ is the level.
 - $k = 1, 2$ is the wavelet filter.
 - cfs{level+1}(:, :) are the lowpass, or scaling, coefficients.

- 'cplxdt' — cfs{j}(:, :, m)

 - $j = 1, 2, \dots, \text{level}$ is the level.
 - $m = 1, 2$ are the real and imaginary parts.
 - cfs{level+1}(:, :) are the lowpass, or scaling, coefficients.

- 'realdddt' — cfs{j}(:, :, d, k)

 - $j = 1, 2, \dots, \text{level}$ is the level.
 - $d = 1, 2, 3$ is the orientation.
 - $k = 1, 2$ is the wavelet transform tree.
 - cfs{level+1}(:, :) are the lowpass, or scaling, coefficients.

- 'cplxddd' — cfs{j}(:, :, d, k, m)

 - $j = 1, 2, \dots, \text{level}$ is the level.
 - $k = 1, 2$ is the wavelet transform tree.

- $m = 1,2$ are the real and imaginary parts.
- $cfs\{level+1\}(:, :)$ are the lowpass, or scaling, coefficients.

For a 2-D wavelet transform, the coefficients are organized by transform type as follows:

- 'dwt' — $cfs\{j\}(:, :, d)$
 - $j = 1,2,\dots$ level is the level.
 - $d = 1,2,3$ is the orientation.
 - $cfs\{level+1\}(:, :)$ are the lowpass, or scaling, coefficients.
- 'ddt' — $cfs\{j\}(:, :, d)$
 - $j = 1,2,\dots$ level is the level.
 - $d = 1,2,3,4,5,6,7,8$ is the orientation.
 - $cfs\{level+1\}(:, :)$ are the lowpass, or scaling, coefficients.
- 'realdwt' — $cfs\{j\}(:, :, d, k)$
 - $j = 1,2,\dots$ level is the level.
 - $d = 1,2,3$ is the orientation.
 - $k = 1,2$ is the wavelet transform tree.
 - $cfs\{level+1\}(:, :)$ are the lowpass, or scaling, coefficients.
- 'cplxdt' — $cfs\{j\}(:, :, d, k, m)$
 - $j = 1,2,\dots$ level is the level.
 - $d = 1,2,3$ is the orientation.
 - $k = 1,2$ is the wavelet transform tree.
 - $m = 1,2$ are the real and imaginary parts.
 - $cfs\{level+1\}(:, :)$ are the lowpass, or scaling, coefficients.
- 'realdwt' — $cfs\{j\}(:, :, d, k)$
 - $j = 1,2,\dots$ level is the level.
 - $d = 1,2,3$ is the orientation.
 - $k = 1,2$ is the wavelet transform tree.
 - $cfs\{level+1\}(:, :)$ are the lowpass, or scaling, coefficients.
- 'cplxddt' — $cfs\{j\}(:, :, d, k, m)$
 - $j = 1,2,\dots$ level is the level.
 - $d = 1,2,3$ is the orientation.
 - $k = 1,2$ is the wavelet transform tree.
 - $m = 1,2$ are the real and imaginary parts.
 - $cfs\{level+1\}(:, :)$ are the lowpass, or scaling, coefficients.

Topics

“Analytic Wavelets Using the Dual-Tree Wavelet Transform”

“Critically Sampled and Oversampled Wavelet Filter Banks”

Introduced in R2013b

powerbw

CWT filter bank 3 dB bandwidths

Syntax

```
bw = powerbw(fb)
```

Description

`bw = powerbw(fb)` returns 3 dB (half-power) bandwidths for the wavelet filters in the filter bank `fb`. `bw` is a N_s -by-4 MATLAB table, where N_s is the number of wavelet bandpass frequencies (equal to the number of scales). For every filter in `fb`, the table contains the corresponding bandpass frequency, the 3 dB bandwidth, and the lower frequency and upper frequency limits of the 3 dB bandwidth.

The 3 dB bandwidth limits mark where the filter power is half its peak value. The magnitude frequency response at the limits is equal to $1/\sqrt{2}$ times the peak magnitude. Since the passbands in `fb` are normalized with peak magnitudes approximately equal to 2, the magnitude frequency response at each limit is approximately equal to $2/\sqrt{2}$. The 3 dB bandwidth is also known as the half-power bandwidth because $20\log_{10}\frac{1}{\sqrt{2}} \approx -3$.

Examples

Half-Power Wavelet Bandwidths

Create a CWT filter bank.

```
fb = cwtfilterbank;
```

Obtain the 3 dB (half-power) bandwidths of the filter bank. Obtain the frequency responses of the wavelets.

```
bw = powerbw(fb);
[psidft,f] = freqz(fb);
```

Choose a wavelet bandpass filter from the filter bank. Extract from the table `bw` the 3 dB limits of the bandpass filter.

```
wv = 5;
frq = bw.Frequencies(wv);
lfb = bw.LowFrequencyBorder(wv);
hfb = bw.HighFrequencyBorder(wv);
```

Plot the frequency response and 3 dB limits. Since the frequency response is scaled to have a maximum value equal to 2, inspect the plot to confirm the lower and upper frequency borders intersect the frequency response at $\sqrt{2}$.

```
plot(f,psidft(wv,:))
grid on
```

```

hold on
plot([lfb lfb],[0 2],'r')
plot([hfb hfb],[0 2],'r')
xlabel('Normalized Frequency (cycles/sample)')
ylabel('Magnitude')
title(['Bandpass Frequency: ' num2str(frq) ' cycles/sample'])

```

Input Arguments

fb – Continuous wavelet transform filter bank

cwtfilterbank object

Continuous wavelet transform (CWT) filter bank, specified as a `cwtfilterbank` object.

Output Arguments

bw – 3 dB (half-power) bandwidths

table

3 dB (half-power) bandwidths, returned as an N_s -by-4 table, where N_s is the number of wavelet bandpass frequencies (equal to the number of scales). The table has four variables:

Frequencies – Bandpass frequency

positive scalar

Bandpass frequency, returned as a positive scalar (see `centerFrequencies`).

Data Types: `double`

HalfPowerBandwidth — Half-power bandwidth

positive scalar

Half-power bandwidth, returned as a positive scalar.

Data Types: `double`

LowFrequencyBorder — Lower frequency edge

positive scalar

Lower frequency edge of the 3 dB bandwidth, returned as a positive scalar.

Data Types: `double`

HighFrequencyBorder — High frequency edge

positive scalar

High frequency edge of the 3 dB bandwidth, returned as a positive scalar.

Data Types: `double`

Data Types: `table`

See Also

`centerFrequencies` | `cwtfilterbank` | `freqz`

Introduced in R2018a

powerbw

DWT filter bank power bandwidth

Syntax

```
bwtable = powerbw(fb)
```

Description

`bwtable = powerbw(fb)` returns a MATLAB table `bwtable` containing the theoretical and measured bandwidths of the discrete wavelet transform (DWT) filter bank `fb`. The table contains the following variables by level:

- DWT frequency bands
- Measured wavelet and scaling filter 3 dB bandwidths
- Proportions of the total energy in the reported bands

Examples

DWT Filter Bank Power Bandwidth

Obtain the 3 dB bandwidths of a level-4 discrete wavelet transform with the Fejér-Korovkin `fk18` wavelet. Obtain the frequency responses of the wavelets. Plot the one-sided frequency responses for the wavelet filters.

```
fb = dwtfilterbank('Wavelet','fk18','Level',4);  
bw = powerbw(fb);  
[psidft,f] = freqz(fb);  
freqz(fb)
```

Choose the wavelet bandpass filter whose peak magnitude is equal to 2. Obtain the lower and upper bounds of the 3 dB bandwidth of the filter.

```
wv = 2;
wvBw = bw.Wavelet3dBBandwidth(wv, :);
```

Plot the magnitude frequency response of the filter and the 3 dB limits. Since the frequency response has a maximum value equal to 2, confirm the lower and upper frequency bounds intersect the frequency response at $\sqrt{2}$.

```
fillLength = size(psidft,2);
plot(f(fillLength/2+1:end),abs(psidft(wv,fillLength/2+1:end)))
hold on
plot([wvBw(1) wvBw(1)],[0 2], 'r')
plot([wvBw(2) wvBw(2)],[0 2], 'r')
grid on
title(['Proportion of Wavelet Power in 3 dB Band: ',num2str(bw.WaveletPowerIn3dBBand(wv))])
xlabel('Normalized Frequency (cycles/sample)')
ylabel('Magnitude')
```

Input Arguments

fb – Discrete wavelet transform filter bank

`dwtfilterbank` object

Discrete wavelet transform (DWT) filter bank, specified as a `dwtfilterbank` object.

Output Arguments

bwtable – Theoretical and measured bandwidths

table

Theoretical and measured bandwidths of the DWT filter bank `fb`, returned as a MATLAB table. `bwtable` is L -by-8, where L is the wavelet transform level of the filter bank. Levels are ordered by decreasing resolution. `bwtable` has the following eight variables:

Level – Level of DWT decomposition

positive integer

Level of DWT decomposition, returned as a positive integer.

DWTBand – Theoretical DWT frequency bands

two-element real-valued vector

Theoretical DWT frequency bands by level, returned as a two-element real-valued vector.

Wavelet3dBBandwidth — Measured wavelet 3 dB bandwidths

two-element real-valued vector

Measured wavelet 3 dB bandwidths by level, returned as a two-element real-valued vector.

Scaling3dBBandwidth — Measured scaling filter 3 dB bandwidths

two-element real-valued vector

Measured scaling filter 3 dB bandwidths by level, returned as a two-element real-valued vector.

WaveletPowerIn3dBBand — Proportion of total wavelet power

positive scalar

Proportion of total wavelet power in the measured 3 dB band by level, returned as a positive scalar.

ScalingPowerIn3dBBand — Proportion of total scaling filter power

positive scalar

Proportion of total scaling filter power in the measured 3 dB band by level, returned as a positive scalar.

WaveletPowerInDWTBand — Proportion of total wavelet power

positive scalar

Proportion of total wavelet power in the theoretical DWT band by level, returned as a positive scalar.

ScalingPowerInDWTBand — Proportion of total scaling filter power

positive scalar

Proportion of total scaling filter power in the theoretical DWT band by level, returned as a positive scalar.

See Also

`dwtfilterbank` | `dwtpassbands`

Introduced in R2018a

qbiorthfilt

First-level dual-tree biorthogonal filters

Syntax

```
[LoD,HiD,LoR,HiR] = qbiorthfilt(name)
```

Description

[LoD,HiD,LoR,HiR] = qbiorthfilt(name) returns the first-level biorthogonal filters for Kingsbury's Q-shift complex dual-tree transform specified by name.

Examples

DTCWT First-Level Biorthogonal Filters

Obtain the decomposition and reconstruction filters associated with the biorthogonal wavelet `nearsym5_7`.

```
fname = 'nearsym5_7';
[LoD,HiD,LoR,HiR] = qbiorthfilt(fname);
```

Use the `dwtfilterbank` function to create a 7-level discrete wavelet transform filter bank with the biorthogonal filters. Specify the wavelet filter type as `analysis`. Because the filters are not of even lengths, extend the filters appropriately to match powers of their z -transforms.

```
scal(:,1) = [0 0 LoD' 0];
scal(:,2) = [0 LoR'];
wavf(:,1) = [0 HiD'];
wavf(:,2) = [0 0 HiR' 0];
fb = dwtfilterbank('Wavelet','Custom',...
    'CustomScalingFilter',scal,...
    'CustomWaveletFilter',wavf,...
    'Level',7,...
    'FilterType','analysis');
```

Obtain the time-domain wavelets corresponding to the wavelet passband filters. Plot the coarsest-scale wavelet.

```
[psi,t] = wavelets(fb);
plot(t,psi(end,:))
grid on
xlabel('Time')
ylabel('Amplitude')
```

Input Arguments

name — First-level biorthogonal filter

'nearsym5_7' | 'nearsym13_19' | 'antonini' | 'legall'

First-level biorthogonal filter used in Kingsbury's Q-shift complex dual-tree transform, specified by one of the values listed here.

- 'nearsym5_7' — (5,7)-tap near-orthogonal filter [1]
- 'nearsym13_19' — (13,19)-tap near-orthogonal filter [2]
- 'antonini' — (9,7)-tap Antonini filter [1]
- 'legall' — LeGall 5/3 filter [3]

Output Arguments

LoD — Lowpass analysis filter

real-valued vector

Lowpass (scaling) analysis filter associated with the biorthogonal filter name, returned as a real-valued vector. The length of LoD does not equal the length of HiD.

HiD — Highpass analysis filter

real-valued vector

Highpass (wavelet) analysis filter associated with the biorthogonal filter name, returned as a real-valued vector. The length of LoD does not equal the length of HiD.

LoR — Lowpass synthesis filter

real-valued vector

Lowpass (scaling) synthesis filter associated with the biorthogonal filter name, returned as a real-valued vector. The length of LoR does not equal the length of HiR.

HiR — Highpass synthesis filter

real-valued vector

Highpass (wavelet) synthesis filter associated with the biorthogonal filter name, returned as a real-valued vector. The length of LoR does not equal the length of HiR.

qfactor

CWT filter bank quality factor

Syntax

```
qf = qfactor(fb)
```

Description

`qf = qfactor(fb)` returns the quality factor for the wavelet bandpass filters in `fb`. The quality factor is the ratio of the 3-dB bandwidth to the center frequency, where the center frequency is the geometric mean of the bandwidth frequencies. The larger the quality factor, the more frequency localized the wavelet. For reference, a half-band filter has a quality factor of $\sqrt{2}$.

Examples

Quality Factor of CWT Filter Bank

Create a CWT filter bank using the default analytic Morse (3,60) wavelet.

```
fb = cwtfilterbank;
```

Compute the quality factor of the filter bank.

```
qf = qfactor(fb)
```

```
qf = 4.6296
```

Create a CWT filter bank using the analytic Morse (3,10) wavelet. Compute the quality factor of the filter bank. The analytic Morlet (3,10) wavelet is not localized in frequency as well as the Morse (3,60) wavelet. Confirm that the quality factor of the second filter bank is smaller than the first filter bank.

```
fb2 = cwtfilterbank('Timebandwidth',10);  
qf2 = qfactor(fb2)
```

```
qf2 = 1.8445
```

Input Arguments

fb — Continuous wavelet transform filter bank

`cwtfilterbank` object

Continuous wavelet transform (CWT) filter bank, specified as a `cwtfilterbank` object.

Output Arguments

qf — Quality factor

positive number

Quality factor, returned as a positive real number.

Data Types: `double`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

See Also

`cwtfilterbank` | `powerbw`

Introduced in R2018a

qfactor

DWT filter bank quality factor

Syntax

```
qf = qfactor(fb)
```

Description

`qf = qfactor(fb)` returns the quality factor for the discrete wavelet transform (DWT) filter bank `fb`.

The quality factor `qf` is defined to be the geometric mean frequency of the lower and upper 3 dB bandwidth frequencies divided by the 3 dB bandwidth. For orthogonal wavelets, the measured quality factor approximates the theoretical value of $\sqrt{2}$.

Examples

DWT Filter Bank Quality Factor

Obtain the quality factor for the Coiflet `coif4`. Since the wavelet is orthogonal, confirm the quality factor approximates the theoretical value of $\sqrt{2}$.

```
wvOrth = 'coif4';  
fb = dwtfilterbank('Wavelet',wvOrth);  
orthogAnalysis = qfactor(fb);  
abs(orthogAnalysis-sqrt(2))
```

```
ans = 5.7311e-11
```

Compare with the quality factor for the biorthogonal wavelet `bior6.8`. Since the wavelet is biorthogonal, confirm the quality factor does not approximate $\sqrt{2}$.

```
wvBior = 'bior6.8';  
fb2 = dwtfilterbank('Wavelet',wvBior);  
biorthogAnalysis = qfactor(fb2);  
abs(biorthogAnalysis-sqrt(2))
```

```
ans = 0.1339
```

By default, `fb` and `fb2` filter banks have the default filter type `Analysis`. Create two new filter banks of filter type `Synthesis` for the same wavelets. Compare the quality factors with the filter type `Analysis` filter banks. Confirm the quality factors using the orthogonal wavelet are equal.

```
fb3 = dwtfilterbank('Wavelet',wvOrth,'FilterType','Synthesis');  
fb4 = dwtfilterbank('Wavelet',wvBior,'FilterType','Synthesis');  
orthogSynthesis = qfactor(fb3);  
abs(orthogSynthesis-sqrt(2))
```

```
ans = 5.7311e-11
```

```
biorthogSynthesis = qfactor(fb4);  
abs(biorthogSynthesis-sqrt(2))
```

```
ans = 0.1141
```

Input Arguments

fb — Discrete wavelet transform filter bank

dwtfilterbank object

Discrete wavelet transform (DWT) filter bank, specified as a `dwtfilterbank` object.

See Also

`dwtfilterbank`

Introduced in R2018a

qmf

Scaling and Wavelet Filter

Syntax

```
Y = qmf(X,P)
Y = qmf(X)
Y = qmf(X,theta)
```

Description

$Y = \text{qmf}(X, P)$ changes the signs of the even index elements of the reversed vector filter coefficients X if P is 0. If P is 1, the signs of the odd index elements are reversed. Changing P changes the phase of the Fourier transform of the resulting wavelet filter by π radians.

$Y = \text{qmf}(X)$ is equivalent to $Y = \text{qmf}(X, 0)$.

Let x be a finite energy signal. Two filters F_0 and F_1 are quadrature mirror filters (QMF) if, for any x ,

$$\|y_0\|^2 + \|y_1\|^2 = \|x\|^2$$

where y_0 is a decimated version of the signal x filtered with F_0 so y_0 defined by $x_0 = F_0(x)$ and $y_0(n) = x_0(2n)$, and similarly, y_1 is defined by $x_1 = F_1(x)$ and $y_1(n) = x_1(2n)$. This property ensures a perfect reconstruction of the associated two-channel filter banks scheme (see Strang-Nguyen p. 103).

For example, if F_0 is a Daubechies scaling filter with norm equal to 1 and $F_1 = \text{qmf}(F_0)$, then the transfer functions $F_0(z)$ and $F_1(z)$ of the filters F_0 and F_1 satisfy the condition (see the example for db10):

$$|F_0(z)|^2 + |F_1(z)|^2 = 2.$$

Examples

Create a Quadrature Mirror Filter

This example shows how to create a quadrature mirror filter associated with the db10 wavelet.

Compute the scaling filter associated with the db10 wavelet.

```
sF = dbwavf('db10');
```

`dbwavf` normalizes the filter coefficients so that the norm is equal to $1/\sqrt{2}$. Normalize the coefficients so that the filter has norm equal to 1.

```
G = sqrt(2)*sF;
```

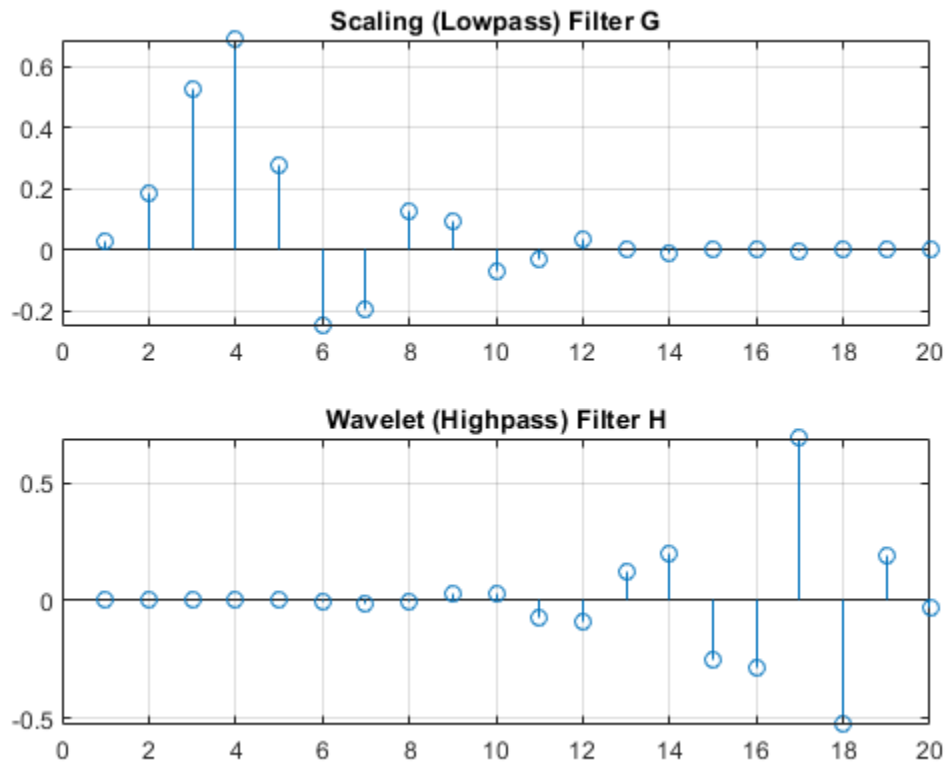

Obtain the wavelet filter coefficients by using `qmf`. Plot the filters.

```
H = qmf(G);
subplot(2,1,1)
```

```

stem(G)
title('Scaling (Lowpass) Filter G')
grid on
subplot(2,1,2)
stem(H)
title('Wavelet (Highpass) Filter H')
grid on

```

Set the DWT extension mode to Periodization. Generate a random signal of length 64. Perform a single-level wavelet decomposition of the signal using G and H.

```
dwtmode('per')
```

```

*****
** DWT Extension Mode: Periodization **
*****

```

```

n = 64;
rng 'default'
sig = randn(1,n);
[a,d] = dwt(sig,G,H);

```

The lengths of the approximation and detail coefficients are both 32. Confirm that the filters preserve energy.

```
[sum(sig.^2) sum(a.^2)+sum(d.^2)]
```

```
ans = 1x2
    92.6872    92.6872
```

Compute the frequency responses of G and H. Zero-pad the filters when taking the Fourier transform.

```
n = 128;
F = 0:1/n:1-1/n;
Gdft = fft(G,n);
Hdft = fft(H,n);
```

Plot the magnitude of each frequency response.

```
figure
plot(F(1:n/2+1),abs(Gdft(1:n/2+1)), 'r')
hold on
plot(F(1:n/2+1),abs(Hdft(1:n/2+1)), 'b')
grid on
title('Frequency Responses')
xlabel('Normalized Frequency')
ylabel('Magnitude')
legend('Lowpass Filter', 'Highpass Filter', 'Location', 'east')
```

Confirm the sum of the squared magnitudes of the frequency responses of G and H at each frequency is equal to 2.

```
sumMagnitudes = abs(Gdft).^2+abs(Hdft).^2;
[min(sumMagnitudes) max(sumMagnitudes)]
```

```
ans = 1×2
    2.0000    2.0000
```

Confirm that the filters are orthonormal.

```
df = [G;H];
id = df*df'
```

```
id = 2×2
    1.0000    0.0000
    0.0000    1.0000
```

Controlling the Phase of a Quadrature Mirror Filter

This example shows the effect of setting the phase parameter of the `qmf` function.

Obtain the decomposition low-pass filter associated with a Daubechies wavelet.

```
lowfilt = wfilters('db4');
```

Use the `qmf` function to obtain the decomposition low-pass filter for a wavelet. Then, compare the signs of the values when the `qmf` phase parameter is set to 0 or 1. The reversed signs indicates a phase shift of π radians, which is the same as multiplying the DFT by $e^{i\pi}$.

```
p0 = qmf(lowfilt,0)
```

```
p0 = 1×8
    0.2304   -0.7148    0.6309    0.0280   -0.1870   -0.0308    0.0329    0.0106
```

```
p1 = qmf(lowfilt,1)
```

```
p1 = 1×8
   -0.2304    0.7148   -0.6309   -0.0280    0.1870    0.0308   -0.0329   -0.0106
```

Compute the magnitudes and display the difference between them. Unlike the phase, the magnitude is not affected by the sign reversals.

```
abs(p0) - abs(p1)
```

```
ans = 1×8
    0     0     0     0     0     0     0     0
```

qorthwavf

Kingsbury Q-shift filters

Syntax

```
[LoDa,LoDb,HiDa,HiDb,LoRa,LoRb,HiRa,HiRb] = qorthwavf(num)
```

Description

[LoDa,LoDb,HiDa,HiDb,LoRa,LoRb,HiRa,HiRb] = qorthwavf(num) returns the Kingsbury Q-shift filters for the Q-shift complex dual-tree transform. The integer num refers to the number of nonzero coefficients (taps) in the filter. Valid options for num are 6, 10, 14, 16, and 18. All filters are of even lengths and the tree B filters are the time reverse of the tree A filters.

Examples

Kingsbury Q-shift Filters

Obtain the Q-shift filters for the case with 10 nonzero coefficients.

```
[LoDa,LoDb,HiDa,HiDb,LoRa,LoRb,HiRa,HiRb] = qorthwavf(10);
```

Use the `dwtfilterbank` function and create two discrete wavelet transform filter banks. Use the tree A analysis filters in the first filter bank, and the tree B analysis filters in the second filter bank.

```
fbTreeA = dwtfilterbank('Wavelet','Custom',...
    'CustomScalingFilter',LoDa,...
    'CustomWaveletFilter',HiDa);
fbTreeB = dwtfilterbank('Wavelet','Custom',...
    'CustomScalingFilter',LoDb,...
    'CustomWaveletFilter',HiDb);
```

Plot the coarsest-scale wavelets of each filter bank.

```
[psiA,t] = wavelets(fbTreeA);
[psiB,~] = wavelets(fbTreeB);
plot(t,psiA(end,:))
hold on
plot(t,psiB(end,:))
grid on
hold off
legend('Tree A','Tree B')
```

Confirm both filter banks are orthogonal.

```
isOrthogonal(fbTreeA)
```

```
ans = logical
      1
```

```
isOrthogonal(fbTreeB)
```

```
ans = logical
      1
```

Input Arguments

num — Number of nonzero coefficients

6 | 10 | 14 | 16 | 18

Number of nonzero coefficients in the Kingsbury Q-shift filters, specified as one of the listed values.

Output Arguments

LoDa — Tree A lowpass analysis filter

real-valued vector

Tree A lowpass (scaling) analysis filter associated with the Q-shift filter, returned as a real-valued vector.

LoDb — Tree B lowpass analysis filter

real-valued vector

Tree B lowpass (scaling) analysis filter associated with the Q-shift filter, returned as a real-valued vector.

HiDa — Tree A highpass analysis filter

real-valued vector

Tree A highpass (wavelet) analysis filter associated with the Q-shift filter, returned as a real-valued vector.

HiDb — Tree B highpass analysis filter

real-valued vector

Tree B highpass (wavelet) analysis filter associated with the Q-shift filter, returned as a real-valued vector.

LoRa — Tree A lowpass synthesis filter

real-valued vector

Tree A lowpass (scaling) synthesis filter associated with the Q-shift filter, returned as a real-valued vector.

LoRb — Tree B lowpass synthesis filter

real-valued vector

Tree B lowpass (scaling) synthesis filter associated with the Q-shift filter, returned as a real-valued vector.

HiRa — Tree A highpass synthesis filter

real-valued vector

Tree A highpass (wavelet) synthesis filter associated with the Q-shift filter, returned as a real-valued vector.

HiRb — Tree B highpass synthesis filter

real-valued vector

Tree B highpass (wavelet) synthesis filter associated with the Q-shift filter, returned as a real-valued vector.

rbiowavf

Reverse biorthogonal spline wavelet filters

Syntax

```
[RF,DF] = rbiowavf(wname)
```

Description

[RF,DF] = rbiowavf(wname) returns the reconstruction (synthesis) and decomposition (analysis) scaling filters, RF and DF, respectively, associated with the reverse biorthogonal wavelet specified by wname.

Examples

Reverse Biorthogonal Scaling Filter

Obtain the reverse biorthogonal reconstruction and decomposition scaling filters for the 'rbio3.1' wavelet. The 'rbio3.1' wavelet has three vanishing moments for the decomposition (analysis) wavelet and one vanishing moment for the reconstruction (synthesis) wavelet.

```
[RF,DF] = rbiowavf('rbio3.1');
```

The reconstruction scaling filter, RF, and the decomposition filter, DF, are equal to the filters returned by wfilters scaled by $\sqrt{2}$.

```
[LoD,HiD,LoR,HiR] = wfilters('rbio3.1');
max(abs(sqrt(2)*DF-LoD))
```

```
ans = 0
```

```
max(abs(sqrt(2)*RF-LoR))
```

```
ans = 0
```

Input Arguments

wname — Name of reverse biorthogonal wavelet

character vector | string scalar

Name of reverse biorthogonal wavelet, specified as 'rbioNd.Nr' where possible values for Nd and Nr are as follows:

Nd = 1	Nr = 1 , 3 or 5
Nd = 2	Nr = 2 , 4 , 6 or 8
Nd = 3	Nr = 1 , 3 , 5 , 7 or 9
Nd = 4	Nr = 4

Nd = 5	Nr = 5
Nd = 6	Nr = 8

Nd and Nr are the numbers of vanishing moments for the decomposition and reconstruction filters, respectively.

Example: 'rbiowavf3.7'

Output Arguments

RF — Reconstruction filter

real-valued vector

Reconstruction filter associated with the reverse biorthogonal wavelet `wname`, returned as a real-valued vector.

DF — Decomposition filter

real-valued vector

Decomposition filter associated with the reverse biorthogonal wavelet `wname`, returned as a real-valued vector.

`biorfilt` | `waveinfo`

Introduced before R2006a

read

Read values of WPTREE

Syntax

VARARGOUT = read(T,VARARGIN)

Description

VARARGOUT = read(T,VARARGIN) is the most general syntax to read one or more property values from the fields of a WPTREE object .

The different ways to call the read function are

PropValue = read(T,'PropName') or
PropValue = read(T,'PropName','PropParam')

or any combination of the previous syntaxes:

[PropValue1,PropValue2,] =
read(T,'PropName1','PropParam1','PropName2','PropParam2',)

where '*PropParam*' is optional.

The valid choices for '*PropName*' and '*PropParam*' are listed in this table.

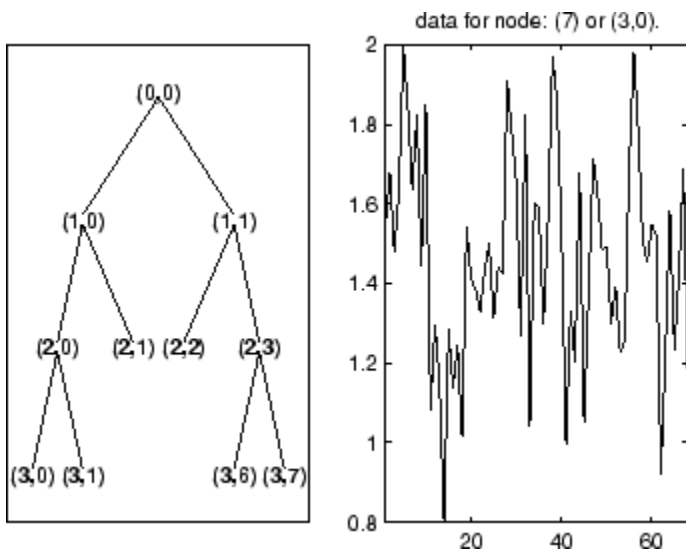

<i>PropName</i>	<i>PropParam</i>
'ent', 'ento' or 'sizes' (see wptree)	Without ' <i>PropParam</i> ' or with ' <i>PropParam</i> ' = Vector of node indices, PropValue contains the entropy (or optimal entropy, or size) of the tree nodes in ascending node index order.
'cfs'	With ' <i>PropParam</i> ' = One terminal node index. cfs = read(T,'cfs',NODE) is equivalent to cfs = read(T,'data',NODE) and returns the coefficients of the terminal node NODE.
'entName', 'entPar', 'wavName' (see wptree) or 'allcfs'	Without ' <i>PropParam</i> '. cfs = read(T,'allcfs') is equivalent to cfs = read(T,'data'). PropValue contains the desired information in ascending node index order of the tree nodes.
'wfilters' (see wfilters)	Without ' <i>PropParam</i> ' or with ' <i>PropParam</i> ' = 'd','r','l','h'.
'data'	Without ' <i>PropParam</i> ' or with ' <i>PropParam</i> ' = One terminal node index or ' <i>PropParam</i> ' = Column vector of terminal node indices. In this last case, PropValue is a cell array. Without ' <i>PropParam</i> ', PropValue contains the coefficients of the tree nodes in ascending node index order.

Examples

```
% Create a wavelet packet tree.
x = rand(1,512);
t = wpdec(x,3,'db3');
t = wpjoin(t,[4;5]);
plot(t);

% Click the node (3,0), (see the plot function).
l% Read values.

sAll = read(t,'sizes');
sNod = read(t,'sizes',[0,4,5]);
eAll = read(t,'ent');
eNod = read(t,'ent',[0,4,5]);
dAll = read(t,'data');
dNod = read(t,'data',[4;5]);
[lo_D,hi_D,lo_R,hi_R] = read(t,'wfilters');
[lo_D,lo_R,hi_D,hi_R] = read(t,'wfilters','l','wfilters','h');
[ent,ento,cfs4,cfs5] = read(t,'ent','ento','cfs',4,'cfs',5);
```

See Also

Introduced before R2006a

readtree

Read wavelet packet decomposition tree from figure

Syntax

```
T = readtree(F)
```

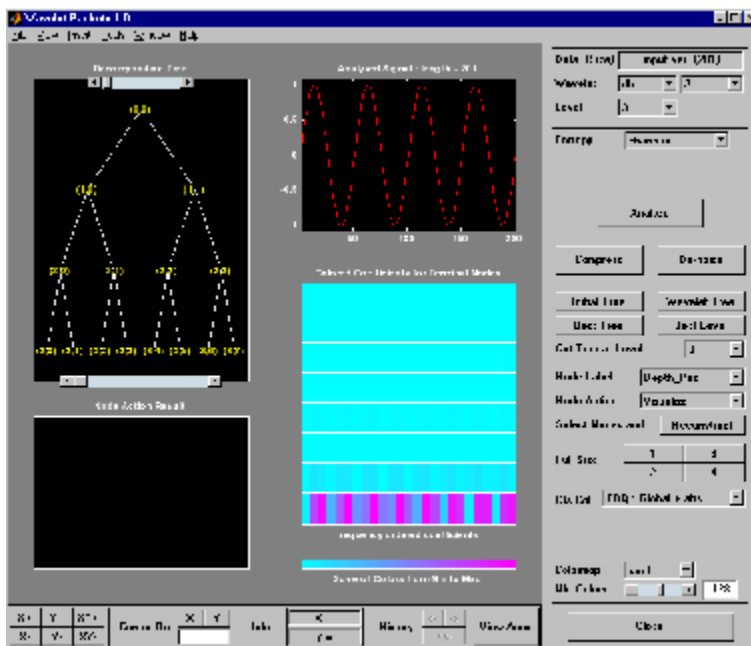

Description

T = readtree(F) reads the wavelet packet decomposition tree from the figure whose handle is F.

Examples

```
% Create a wavelet packet tree.
x = sin(8*pi*[0:0.005:1]);
t = wpdec(x,3,'db2');
```

```
% Display the generated tree in a Wavelet Packet 1-D GUI window.
fig = drawtree(t);
```

```
%-----
% Use the GUI to split or merge Nodes.
%-----
```

```
t = readtree(fig);
plot(t)

% Click the node (3,0), (see the plot function).
```

drawtree

Introduced before R2006a

removeLabelDefinition

Remove label definition from labeled signal set

Syntax

```
removeLabelDefinition(lss, lblname)
```

Description

`removeLabelDefinition(lss, lblname)` removes the label definition `lblname` from the labeled signal set `lss`. If you want to remove a sublabel, specify `lblname` as a two-element string array or two-element cell array of character vectors:

- The first element is the name of the parent label.
- The second element is the name of the sublabel.

Examples

Remove Label Definition

Load a labeled signal set containing recordings of whale songs.

```
load whales
lss

lss =
    labeledSignalSet with properties:
        Source: {2x1 cell}
        NumMembers: 2
        TimeInformation: "sampleRate"
        SampleRate: 4000
        Labels: [2x3 table]
        Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

Retrieve a hierarchical list of labels and sublabels.

```
labelDefinitionsHierarchy(lss)

ans =
    'WhaleType
      Sublabels: []
    MoanRegions
      Sublabels: []
    TrillRegions
      Sublabels: TrillPeaks
```

Remove the sublabel that labels peaks in the trill regions.

```
removeLabelDefinition(lss,{'TrillRegions' 'TrillPeaks'})  
  
labelDefinitionsHierarchy(lss)  
  
ans =  
    'WhaleType'  
      Sublabels: []  
    MoanRegions  
      Sublabels: []  
    TrillRegions  
      Sublabels: []  
,
```

Remove the label that specifies the whale type.

```
removeLabelDefinition(lss,"WhaleType")  
  
getLabelNames(lss)  
  
ans = 2x1 string  
    "MoanRegions"  
    "TrillRegions"
```

Input Arguments

lss — Labeled signal set

labeledSignalSet object

Labeled signal set, specified as a `labeledSignalSet` object.

Example: `labeledSignalSet({randn(100,1)
randn(10,1)},signalLabelDefinition('female'))` specifies a two-member set of random signals containing the attribute 'female'.

lblname — Label or sublabel name

character vector | string scalar | cell array of character vectors | string array

Label or sublabel name. To specify a label, use a character vector or a string scalar. To specify a sublabel, use a two-element cell array of character vectors or a two-element string array:

- The first element is the name of the parent label.
- The second element is the name of the sublabel.

Example: `signalLabelDefinition("Asleep", 'LabelType', 'roi')` specifies a label of name "Asleep" for a region of a signal in which a patient is asleep during a clinical trial.

Example: `{'Asleep' 'REM'}` or `["Asleep" "REM"]` specifies a region of a signal in which a patient undergoes REM sleep.

See Also

labeledSignalSet | signalLabelDefinition

Introduced in R2018b

removeMembers

Remove members from labeled signal set

Syntax

```
removeMembers(lss,midxvect)
```

Description

`removeMembers(lss,midxvect)` removes the members specified in `midxvect` from the labeled signal set `lss`.

Examples

Remove Member

Load a labeled signal set containing recordings of whale songs.

```
load whales
lss

lss =
  labeledSignalSet with properties:

        Source: {2x1 cell}
      NumMembers: 2
  TimeInformation: "sampleRate"
      SampleRate: 4000
         Labels: [2x3 table]
      Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

Remove the second member of the set.

```
removeMembers(lss,2)
lss

lss =
  labeledSignalSet with properties:

        Source: {[79572x1 double]}
      NumMembers: 1
  TimeInformation: "sampleRate"
      SampleRate: 4000
         Labels: [1x3 table]
      Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.

Use `setLabelValue` to add data to the set.

Input Arguments

lss — Labeled signal set

`labeledSignalSet` object

Labeled signal set, specified as a `labeledSignalSet` object.

Example: `labeledSignalSet({randn(100,1)
randn(10,1)}, signalLabelDefinition('female'))` specifies a two-member set of random signals containing the attribute 'female'.

midxvect — Subset member row numbers

vector of positive integers

Subset member row numbers, specified as a vector of positive integers. Each element of `midxvect` specifies a member row number as it appears in the “Labels” on page 1-0 table of the `labeledSignalSet` object `lss`.

Example: `[2 3 5 7 11 13 17]` chooses a subset of signals indexed by prime numbers.

`labeledSignalSet` | `signalLabelDefinition`

Introduced in R2018b

removePointValue

Remove row from point label

Syntax

```
removePointValue(lss,midx,lblname)
removePointValue(lss,midx,lblname,'LabelRowIndex',ridx)
removePointValue(lss,midx,lblname,'SublabelRowIndex',sridx)
removePointValue(lss,midx,lblname,'LabelRowIndex',ridx,'SublabelRowIndex',sridx)
```

Description

`removePointValue(lss,midx,lblname)` removes all rows of the point label `lblname` for the member specified by `midx`.

- If `lblname` is a character vector or a string scalar, the function targets a parent label.
- If `lblname` is a two-element string array or a two-element cell array of character vectors, the function:
 - Interprets the first element as the name of a parent label.
 - Interprets the second element as the sublabel name of a point label.
 - Removes all the points of the sublabel.

`removePointValue(lss,midx,lblname,'LabelRowIndex',ridx)` removes a row, specified by `ridx`, of the point label `lblname` for the member `midx`.

If `lblname` is a two-element string array or a two-element cell array of character vectors, the function:

- Interprets the first element as the name of a parent label.
- Interprets the second element as the sublabel name of a point label.
- Removes all the point of the sublabel contained in row `ridx`.

`removePointValue(lss,midx,lblname,'SublabelRowIndex',sridx)` removes the sublabel row specified by `sridx`. In this case, `lblname` must be a two-element string array or a two-element cell array of character vectors:

- The first element is the name of a parent attribute label.
- The second element is the sublabel name of a point label.

`removePointValue(lss,midx,lblname,'LabelRowIndex',ridx,'SublabelRowIndex',sridx)` removes the sublabel row specified by `sridx` of the ROI or point label row specified by `ridx`. In this case, `lblname` must be a two-element string array or a two-element cell array of character vectors:

- The first element is the name of a parent ROI or point label.
- The second element is the sublabel name of a point label.

Examples

Remove Point Value

Load a labeled signal set containing recordings of whale songs. Get the names of the labels and the number of members.

```
load whales
lss

lss =
  labeledSignalSet with properties:

        Source: {2x1 cell}
      NumMembers: 2
  TimeInformation: "sampleRate"
      SampleRate: 4000
        Labels: [2x3 table]
  Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

```
nm = lss.NumMembers;
```

Define a point label associated with the signal maximum.

```
themax = signalLabelDefinition('Maximum','LabelType','point', ...
    'LabelDataType','numeric')
```

```
themax =
  signalLabelDefinition with properties:

        Name: "Maximum"
      LabelType: "point"
  LabelDataType: "numeric"
  ValidationFunction: []
  PointLocationsDataType: "double"
      DefaultValue: []
      Sublabels: [0x0 signalLabelDefinition]
        Tag: ""
      Description: ""
```

Use `labeledSignalSet` to create a labeled signal set.

```
addLabelDefinitions(lss,themax)
```

Find the maxima of the signals and add their values to the labeled set.

```
figure
for idx = 1:nm
  sg = getSignal(lss,idx);
  [mx,idx] = max(sg);
  setLabelValue(lss,idx,'Maximum',ix,mx)

  subplot(nm,1,idx)
```

```
plot((0:length(sg)-1)/lss.SampleRate,sg,ix/lss.SampleRate,mx,'*')
end
```

Verify that the set includes the new point label.

```
getLabelValues(lss)
```

ans=2x4 table

	WhaleType	MoanRegions	TrillRegions	Maximum
Member{1}	blue	{3x2 table}	{1x3 table}	{1x2 table}
Member{2}	blue	{3x2 table}	{1x3 table}	{1x2 table}

Remove the 'Maximum' value for the first member of the set. Verify that the label is empty for the first member.

```
removePointValue(lss,1,'Maximum')
```

```
getLabelValues(lss,1)
```

ans=1x4 table

	WhaleType	MoanRegions	TrillRegions	Maximum
Member{1}	blue	{3x2 table}	{1x3 table}	{0x2 table}

Input Arguments

lss — Labeled signal set

labeledSignalSet object

Labeled signal set, specified as a labeledSignalSet object.

Example: `labeledSignalSet({randn(100,1)
randn(10,1)}, signalLabelDefinition('female'))` specifies a two-member set of random signals containing the attribute 'female'.

midx — Member row number

positive integer

Member row number, specified as a positive integer. `midx` specifies the member row number as it appears in the “Labels” on page 1-0 table of a labeled signal set.

lblname — Label or sublabel name

character vector | string scalar | cell array of character vectors | string array

Label or sublabel name. To specify a label, use a character vector or a string scalar. To specify a sublabel, use a two-element cell array of character vectors or a two-element string array:

- The first element is the name of the parent label.
- The second element is the name of the sublabel.

Example: `signalLabelDefinition("Asleep", 'LabelType', 'roi')` specifies a label of name "Asleep" for a region of a signal in which a patient is asleep during a clinical trial.

Example: `{'Asleep' 'REM'}` or `["Asleep" "REM"]` specifies a region of a signal in which a patient undergoes REM sleep.

ridx — Label row index

positive integer

Label row index, specified as a positive integer. This argument applies only for ROI and point labels.

sridx — Sublabel row index

positive integer

Sublabel row index, specified as a positive integer. This argument applies only when a label and sublabel pair has been specified in `lblname` and the sublabel is of type ROI or point.

See Also

labeledSignalSet | signalLabelDefinition

Introduced in R2018b

removeRegionValue

Remove row from ROI label

Syntax

```
removeRegionValue(lss,midx,lblname)
removeRegionValue(lss,midx,lblname,'LabelRowIndex',ridx)
removeRegionValue(lss,midx,lblname,'SublabelRowIndex',sridx)
removeRegionValue(lss,midx,lblname,'LabelRowIndex',ridx,'SublabelRowIndex',
sridx)
```

Description

`removeRegionValue(lss,midx,lblname)` removes all rows of the ROI label `lblname` for the member specified by `midx`.

- If `lblname` is a character vector or a string scalar, the function targets a parent label.
- If `lblname` is a two-element string array or a two-element cell array of character vectors, the function:
 - Interprets the first element as the name of a parent label.
 - Interprets the second element as the sublabel name of an ROI label.
 - Removes all the regions of the sublabel.

`removeRegionValue(lss,midx,lblname,'LabelRowIndex',ridx)` removes a row, specified by `ridx`, of the ROI label `lblname` for the member `midx`.

If `lblname` is a two-element string array or a two-element cell array of character vectors, the function:

- Interprets the first element as the name of a parent label.
- Interprets the second element as the sublabel name of an ROI label.
- Removes all the regions of the sublabel contained in row `ridx`.

`removeRegionValue(lss,midx,lblname,'SublabelRowIndex',sridx)` removes the sublabel row specified by `sridx`. In this case, `lblname` must be a two-element string array or a two-element cell array of character vectors:

- The first element is the name of a parent attribute label.
- The second element is the sublabel name of an ROI label.

`removeRegionValue(lss,midx,lblname,'LabelRowIndex',ridx,'SublabelRowIndex',sridx)` removes the sublabel row specified by `sridx` of the ROI or point label row specified by `ridx`. In this case, `lblname` must be a two-element string array or a two-element cell array of character vectors:

- The first element is the name of a parent ROI or point label.
- The second element is the sublabel name of an ROI label.

Examples

Remove Region Value

Load a labeled signal set containing recordings of whale songs.

```
load whales
lss
lss =
  labeledSignalSet with properties:
      Source: {2x1 cell}
      NumMembers: 2
      TimeInformation: "sampleRate"
      SampleRate: 4000
      Labels: [2x3 table]
      Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

Get the names and values of the labels in the set. For the following, concentrate on the second member of the set.

```
lbldefs = getLabelValues(lss)
lbldefs=2x3 table
      WhaleType      MoanRegions      TrillRegions
      _____      _____      _____
Member{1}      blue      {3x2 table}      {1x3 table}
Member{2}      blue      {3x2 table}      {1x3 table}
```

```
idx = 2;
```

Retrieve the signal and the time information. Plot the signal.

```
[lbs,info] = getLabeledSignal(lss,idx)
lbs=1x4 table
      Signal      WhaleType      MoanRegions      TrillRegions
      _____      _____      _____      _____
Member{2}      {76579x1 double}      blue      {3x2 table}      {1x3 table}
```

```
info = struct with fields:
  TimeInformation: "sampleRate"
  SampleRate: 4000
```

```
fs = info.SampleRate;
sg = getSignal(lss,idx);
t = (0:length(sg)-1)/fs;
```

```
plot(t,sg)
```

Highlight the moans and trills of the signal.

```
mvals = getLabelValues(lss,idx,'MoanRegions');
tvals = getLabelValues(lss,idx,'TrillRegions');

hold on
[X,Y] = meshgrid([mvals.ROIlimits;tvals.ROIlimits],ylim);
plot(X,Y,':k')
topts = {'HorizontalAlignment','center','FontWeight','bold', ...
         'FontSize',12,'Color',[139 69 19]/255};
text((X(1,1:4)+X(1,5:end))/2,Y(2,5:end)-0.1, ...
     ["moan" "moan" "moan" "trill"],topts{:})
hold off
```

Remove the second moan from the labels. Plot the signal again. Highlight the moans and trills.

```
removeRegionValue(lss,idx,'MoanRegions','LabelRowIndex',2)

plot(t,sg)
mvals = getLabelValues(lss,idx,'MoanRegions');

hold on
[X,Y] = meshgrid([mvals.ROIlimits;tvals.ROIlimits],ylim);
plot(X,Y,':k')
topts = {'HorizontalAlignment','center','FontWeight','bold', ...
```

```

    'FontSize',12, 'Color',[139 69 19]/255};
text((X(1,1:3)+X(1,4:end))/2,Y(2,4:end)-0.1, ...
    ["moan" "moan" "trill"],topts{:})
hold off

```

Input Arguments

lss — Labeled signal set

labeledSignalSet object

Labeled signal set, specified as a labeledSignalSet object.

Example: `labeledSignalSet({randn(100,1)
randn(10,1)},signalLabelDefinition('female'))` specifies a two-member set of random signals containing the attribute 'female'.

midx — Member row number

positive integer

Member row number, specified as a positive integer. `midx` specifies the member row number as it appears in the “Labels” on page 1-0 table of a labeled signal set.

lblname — Label or sublabel name

character vector | string scalar | cell array of character vectors | string array

Label or sublabel name. To specify a label, use a character vector or a string scalar. To specify a sublabel, use a two-element cell array of character vectors or a two-element string array:

- The first element is the name of the parent label.
- The second element is the name of the sublabel.

Example: `signalLabelDefinition("Asleep", 'LabelType', 'roi')` specifies a label of name "Asleep" for a region of a signal in which a patient is asleep during a clinical trial.

Example: `{'Asleep' 'REM'}` or `["Asleep" "REM"]` specifies a region of a signal in which a patient undergoes REM sleep.

ridx — Label row index

positive integer

Label row index, specified as a positive integer. This argument applies only for ROI and point labels.

sridx — Sublabel row index

positive integer

Sublabel row index, specified as a positive integer. This argument applies only when a label and sublabel pair has been specified in `lblname` and the sublabel is of type ROI or point.

`labeledSignalSet` | `signalLabelDefinition`

Introduced in R2018b

resetLabelValues

Reset labels to default values

Syntax

```
resetLabelValues(lss)
resetLabelValues(lss,midX)

resetLabelValues(lss,midX,lblname)
resetLabelValues( ____, 'LabelRowIndex', ridX)
```

Description

`resetLabelValues(lss)` resets all label values for all members of the labeled signal set `lss`.

`resetLabelValues(lss,midX)` resets all label values for the signals in the member specified by `midX`.

`resetLabelValues(lss,midX,lblname)` resets the values of label `lblname` for the signals in the member specified by `midX`. To reset a sublabel, make `lblname` a two-element string array or a two-element cell array of character vectors, with the first element containing the parent label name and the second element containing the sublabel name.

By default, the function resets all sublabels of a parent label. To target a sublabel of an ROI or point parent label, specify the parent label row index using `ridX`.

`resetLabelValues(____, 'LabelRowIndex', ridX)` specifies the row index of the ROI or point parent label for which you want to reset a sublabel value.

Examples

Reset Label Values

Load a labeled signal set containing recordings of whale songs. Get the names of the labels.

```
load whales
lss

lss =
  labeledSignalSet with properties:
      Source: {2x1 cell}
      NumMembers: 2
      TimeInformation: "sampleRate"
      SampleRate: 4000
      Labels: [2x3 table]
      Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

```
getLabelNames(lss)
```

```
ans = 3x1 string
    "WhaleType"
    "MoanRegions"
    "TrillRegions"
```

Get the label values corresponding to the trill regions for the second signal in the set.

```
idx = 2;
getLabelValues(lss,idx,'TrillRegions')
```

```
ans=1x2 table
    ROIlimits      Value
    _____    _____
    11.1          13      {[1]}
```

Reset the values. Verify that 'TrillRegions' becomes an empty array.

```
resetLabelValues(lss,idx,'TrillRegions')
```

```
getLabelValues(lss,idx,'TrillRegions')
```

```
ans =
```

```
0x2 empty table
```

```
getLabelValues(lss,idx)
```

```
ans=1x3 table
           WhaleType      MoanRegions      TrillRegions
           _____    _____    _____
Member{2}      blue      {3x2 table}      {0x3 table}
```

Input Arguments

lss — Labeled signal set

labeledSignalSet object

Labeled signal set, specified as a labeledSignalSet object.

Example: labeledSignalSet({randn(100,1)
randn(10,1)},signalLabelDefinition('female')) specifies a two-member set of random signals containing the attribute 'female'.

midx — Member row number

positive integer

Member row number, specified as a positive integer. midx specifies the member row number as it appears in the “Labels” on page 1-0 table of a labeled signal set.

lblname — Label or sublabel name

character vector | string scalar | cell array of character vectors | string array

Label or sublabel name. To specify a label, use a character vector or a string scalar. To specify a sublabel, use a two-element cell array of character vectors or a two-element string array:

- The first element is the name of the parent label.
- The second element is the name of the sublabel.

Example: `signalLabelDefinition("Asleep", 'LabelType', 'roi')` specifies a label of name "Asleep" for a region of a signal in which a patient is asleep during a clinical trial.

Example: `{'Asleep' 'REM'}` or `["Asleep" "REM"]` specifies a region of a signal in which a patient undergoes REM sleep.

ridx — Label row index

positive integer

Label row index, specified as a positive integer. This argument applies only for ROI and point labels.

See Also

labeledSignalSet | signalLabelDefinition

Introduced in R2018b

scal2frq

Scale to frequency

Syntax

```
frq = scal2frq(A,wname,delta)
frq = scal2frq(A,wname)
```

Description

`frq = scal2frq(A,wname,delta)` returns the pseudo-frequencies corresponding to the scales given by `A` and the wavelet specified by `wname` and the sampling period `delta`. The output `frq` is real-valued and has the same dimensions as `A`.

`frq = scal2frq(A,wname)` is equivalent to `frq = scal2frq(A,wname,1)`.

Examples

Scales and Pseudo-Frequencies

This example shows how the pseudo-frequency changes as you double the scale.

Construct a vector of scales with 10 voices per octave over five octaves.

```
vpo = 10;
no = 5;
a0 = 2^(1/vpo);
ind = 0:vpo*no;
sc = a0.^ind;
```

Verify that the range of scales covers five octaves.

```
log2(max(sc)/min(sc))
```

```
ans = 5.0000
```

If you plot the scales, you can use a data cursor to confirm that the scale at index $n + 10$ is twice the scale at index n . Set the y-ticks to mark each octave.

```
plot(ind,sc)
title('Scales')
xlabel('Index')
ylabel('Scale')
grid on
set(gca,'YTick',2.^(0:5))
```

Convert the scales to pseudo-frequencies for the real-valued Morlet wavelet. First, assume the sampling period is 1.

```
pf = scal2frq(sc,"morl");
T = [sc(:) pf(:)];
T = array2table(T,'VariableNames',{'Scale','Pseudo-Frequency'});
disp(T)
```

Scale	Pseudo-Frequency
1	0.8125
1.0718	0.75809
1.1487	0.70732
1.2311	0.65996

12.126	0.067006
12.996	0.062519
13.929	0.058332
14.929	0.054426
16	0.050781
17.148	0.047381
18.379	0.044208
19.698	0.041247
21.112	0.038485
22.627	0.035908
24.251	0.033503
25.992	0.03126
27.858	0.029166
29.857	0.027213
32	0.025391

Assume that data is sampled at 100 Hz. Construct a table with the scales, the corresponding pseudo-frequencies, and periods. Since there are 10 voices per octave, display every tenth row in the table. Observe that for each doubling of the scale, the pseudo-frequency is cut in half.

```

Fs = 100;
DT = 1/Fs;
pf = scal2frq(sc,"morl",DT);
T = [sc(:)/Fs pf(:) 1./pf(:)];
T = array2table(T,'VariableNames',{'Scale','Pseudo-Frequency','Period'});
T(1:vpo:end,:)

```

```

ans=6x3 table
    Scale    Pseudo-Frequency    Period
    _____    _____    _____
    0.01         81.25         0.012308
    0.02         40.625        0.024615
    0.04         20.313        0.049231
    0.08         10.156        0.098462
    0.16         5.0781        0.19692
    0.32         2.5391        0.39385

```

Note the presence of the $\Delta t = \frac{1}{F_s}$ factor in `scal2frq`. This is necessary in order to achieve the proper scale-to-frequency conversion. The Δt is needed to adjust the raw scales properly. For example, with:

```
f = scal2frq(1, 'morl', 0.01);
```

You are really asking what happens to the center frequency of the mother Morlet wavelet, if you dilate the wavelet by 0.01. In other words, what is the effect on the center frequency if instead of $\psi(t)$, you look at $\psi(t/0.01)$. The Δt provides the correct adjustment factor on the scales.

You could have obtained the same results by first converting the scales to their adjusted sizes and then using `scal2frq` without specifying Δt .

```
scadjusted = sc.*0.01;
pf2 = scal2frq(scadjusted, 'morl');
max(pf-pf2)
```

```
ans = 0
```

Plot CWT with Frequencies in a Contour Plot

The example shows how to create a contour plot of the CWT using approximate frequencies in Hz.

Create a signal consisting of two sine waves with disjoint support in additive noise. Assume the signal is sampled at 1 kHz.

```
Fs = 1000;
t = 0:1/Fs:1-1/Fs;
x = 1.5*cos(2*pi*100*t).*(t<0.25)+1.5*cos(2*pi*50*t).*(t>0.5 & t<=0.75);
x = x+0.05*randn(size(t));
```

Obtain the CWT of the input signal and plot the result.

```
[cfs,f] = cwt(x,Fs);
contour(t,f,abs(cfs).^2);
axis tight;
grid on;
xlabel('Time');
ylabel('Approximate Frequency (Hz)');
title('CWT with Time vs Frequency');
```

Input Arguments

A — Scales

positive real-valued vector

Scales, specified as a positive real-valued vector.

wname — Wavelet

character vector | string scalar

Wavelet, specified as a character vector or string scalar. See `wavefun` for more information.

delta — Sampling period

1 (default) | positive real-valued scalar

Sampling period, specified as a real-valued scalar.

Example: `pf = scal2frq([1:5], "db4", 0.01)`

More About

Pseudo-Frequencies

There is only an approximate answer for the relationship between scale and frequency.

In wavelet analysis, the way to relate scale to frequency is to determine the center frequency of the wavelet, F_c , and use the following relationship:

$$F_a = \frac{F_c}{a}$$

where

- a is a scale.
- F_c is the center frequency of the wavelet in Hz.
- F_a is the pseudo-frequency corresponding to the scale a , in Hz.

The idea is to associate with a given wavelet a purely periodic signal of frequency F_c . The frequency maximizing the Fourier transform of the wavelet modulus is F_c . The `centfrq` function computes the center frequency for a specified wavelet. From the above relationship, it can be seen that scale is inversely proportional to pseudo-frequency. For example, if the scale increases, the wavelet becomes more spread out, resulting in a lower pseudo-frequency.

Some examples of the correspondence between the center frequency and the wavelet are shown in the following figure.

As you can see, the center frequency-based approximation (red) captures the main wavelet oscillations (blue). The center frequency is a convenient and simple characterization of the dominant frequency of the wavelet.

Introduced before R2006a

scales

CWT filter bank scales

Syntax

```
rs = scales(fb)
[rs,cs] = scales(fb)
```

Description

`rs = scales(fb)` returns the raw (unitless) scales used in creating the wavelet bandpass filters. Scales are ordered from finest to coarsest.

`[rs,cs] = scales(fb)` returns the wavelet scales converted to units of the sampling frequency or sampling period.

Examples

CWT Filter Bank Scales

Create a CWT filter bank with sampling period equal to 0.001 seconds.

```
fb = cwtfilterbank('SamplingPeriod',seconds(0.001));
```

Obtain the raw and converted scales used in creating the wavelet bandpass filters.

```
[rs,cs] = scales(fb);
```

Obtain the filter bank bandpass center periods.

```
P = centerPeriods(fb);
```

Compare the finest converted scale with the smallest bandpass center period normalized by the sampling period.

```
min(cs)
```

```
ans = 2.3035
```

```
min(P)/seconds(0.001)
```

```
ans = 2.3035
```

The scales should increase by a factor of approximately $2^{1/|NV|}$, where NV is the number of voices per octave. The default value of NV is 10. Plot the ratios of successive scales and compare with $2^{1/10}$.

```
len = length(rs);
plot(rs(2:len)./rs(1:len-1),'rx-')
hold on
plot(1:len-1,2^(1/10)*ones(1,len-1),'b')
```

```
title('Successive Scale Ratios')
legend('Scale Ratio','Scale Factor')
```

Input Arguments

fb — Continuous wavelet transform filter bank

cwtfilterbank object

Continuous wavelet transform (CWT) filter bank, specified as a `cwtfilterbank` object.

Output Arguments

rs — Raw scales

real-valued vector

Raw scales used in creating the wavelet bandpass filters, returned as a real-valued vector of length N_s , where N_s is the number of wavelet bandpass frequencies (equal to the number of scales).

Data Types: double

cs — Converted scales

real-valued vector

Converted scales used in creating the wavelet bandpass filters, returned as a real-valued vector of length N_s , where N_s is the number of wavelet bandpass frequencies (equal to the number of scales). cs is in units of the sampling frequency or sampling period.

Data Types: `double`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Introduced in R2018a

scalingfunctions

DWT filter bank time-domain scaling functions

Syntax

```
phi = scalingfunctions(fb)
[phi,t] = scalingfunctions(fb)
```

Description

`phi = scalingfunctions(fb)` returns the time-centered scaling functions for each level of the discrete wavelet transform (DWT) filter bank `fb`.

`[phi,t] = scalingfunctions(fb)` returns the sampling instants, `t`.

Examples

DWT Filter Bank Scaling Functions

Create a seven-level DWT filter bank for a length 2048 signal, using the Daubechies db2 wavelet and a sampling frequency of 1 kHz.

```
wv = "db2";
len = 2048;
Fs = 1e3;
lev = 7;
fb = dwtfilterbank('SignalLength',len,'Wavelet',wv,'Level',lev,'SamplingFrequency',Fs);
```

Plot the scaling functions for each level of the filter bank.

```
[phi,t] = scalingfunctions(fb);
plot(t,phi')
grid on
xlim([-len/2*1e-3 len/2*1e-3])
title('Scaling Functions')
legend('A1','A2','A3','A4','A5','A6','A7')
```

Input Arguments

fb — Discrete wavelet transform filter bank

`dwtfilterbank` object

Discrete wavelet transform (DWT) filter bank, specified as a `dwtfilterbank` object.

Output Arguments

phi — Time-centered scaling functions

real-valued matrix

Time-centered scaling functions of the filter bank `fb`, returned as a real-valued L -by- N matrix, where L is the filter bank `Level` and N is the `SignalLength`. The scaling functions are ordered in `phi` from the finest scale resolution to the coarsest scale resolution.

t — Sampling instants

real-valued vector

Sampling instants, returned as a real-valued vector `t` of length N , where N is the filter bank `SignalLength`. Sampling instants lie in the interval $[-\frac{1}{2}NDT, \frac{1}{2}NDT)$, where DT is the filter bank sampling period (reciprocal of the filter bank sampling frequency).

scattergram

Visualize scattering or scalogram coefficients

Syntax

```
img = scattergram(sf,S)
img = scattergram(sf,U)
img = scattergram( ____,Name,Value)
scattergram( ____ )
```

Description

`img = scattergram(sf,S)` returns the scattergram as a matrix for the first-order scattering coefficients, `S`. The matrix `S` is the output of `scatteringTransform` computed using the scattering framework, `sf`.

`img = scattergram(sf,U)` returns the scattergram as a matrix for the first-order scalogram coefficients, `U`. The matrix `U` is the output of `scatteringTransform` computed using the scattering framework, `sf`.

`img = scattergram(____,Name,Value)` returns the scattergram with additional options specified by one or more `Name,Value` pair arguments. You can use this syntax with any of the input syntaxes shown previously.

`scattergram(____)` with no output arguments plots the scattergram in the current figure. You can use any of the input syntaxes shown previously.

Examples

Visualize Scattergram

Load an ECG signal sampled at 180 Hz. Create a scattering decomposition framework that can be used with the signal.

```
load wecg
Fs = 180;
sf = waveletScattering('SignalLength',numel(wecg),...
    'SamplingFrequency',Fs);
```

Calculate the scattering transform of the signal.

```
[S,U] = scatteringTransform(sf,wecg);
```

Visualize the scattergram for the first-order scattering and scalogram coefficients.

```
scattergram(sf,S,'FilterBank',1)
```

```
figure  
scattergram(sf,U,'FilterBank',1)
```

Input Arguments

sf – Scattering decomposition framework

waveletScattering object

Scattering decomposition framework, specified as a waveletScattering object.

S – Scattering coefficients

cell array

Scattering coefficients, specified as a cell array. **S** is the output of scatteringTransform computed using the scattering framework, **sf**. For more information, see scatteringTransform.

U – Scalogram coefficients

cell array

Scalogram coefficients, specified as a cell array. **U** is the output of scatteringTransform computed using the scattering framework, **sf**. For more information, see scatteringTransform.

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: 'FilterBank', 1 specifies the first filter bank.

FilterBank — Filter bank index

positive integer between 1 and the number of filter banks in `sf` inclusive

Filter bank index, specified as a positive number between 1 and the number of filter banks in `sf` inclusive. `scattergram` returns the scattergram for the specified filter bank in `sf`. The number of filter banks in `sf` is equal to the number of specified `QualityFactors` in `sf`.

If `FilterBank` is greater than 1, `scattergram` averages the scalogram or scattering coefficients over all paths terminating at each wavelet bandpass filter. To obtain paths with a common parent, use the 'Parent' name-value pair.

P — Path parent index

nonnegative integer

Path parent index, specified as a nonnegative integer. The scalar `P` is a nonnegative integer representing the `P`-th wavelet filter at the filter bank `FilterBank - 1`. `scattergram` returns the scattergram for the path at the specified filter bank with parent `P`. If `FilterBank` is equal to 1, the zeroth filter bank corresponds to the input signal in the case of the scalogram coefficients and the lowpass filtering of the input signal with the scaling function in the case of the scattering coefficients. Lower values of `P` correspond to wavelets with higher bandpass frequencies.

If you specify `P`, you must specify the `FilterBank` name-value pair.

If you specify a value for `P` which results in a single child, the output `img` is a vector. The scattergram of a single child is a line plot. If you specify a value for `P` that results in no children, `scattergram` returns the scattergram for the filter bank specified by `FilterBank`.

Output Arguments

img — Scattergram

real-valued matrix | real-valued vector

Scattergram, returned as a real-valued matrix or vector. If you use the `Parent` name-value pair and specify a value which results in a single child, `img` is a vector. If the parent has more than one child, `img` is a matrix.

`waveletScattering`

Introduced in R2018b

scatteringTransform

Wavelet 1-D scattering transform

Syntax

```
s = scatteringTransform(sf,x)
[s,u] = scatteringTransform(sf,x)
```

Description

`s = scatteringTransform(sf,x)` returns the wavelet 1-D scattering transform of `x` for the scattering decomposition framework, `sf`. `x` is a real-valued vector or matrix. If `x` is a matrix, `scatteringTransform` applies the scattering transform to each column of `x` separately. `s` is a cell array with $Nfb + 1$ elements, where Nfb is the number of filter banks in `sf`. The number of filter banks is also equal to the number of elements in the `QualityFactors` value of `sf`. Equivalently, the number of elements in `s` is equal to the number of orders in the scattering decomposition. Each element of `s` is a MATLAB table.

The precision of the scattering coefficients depends on the precision specified in the framework `sf`.

`[s,u] = scatteringTransform(sf,x)` returns `s`, the wavelet 1-D scattering transform, and `u`, the scalogram coefficients for each of the scattering orders. `u` is a cell array with $Nfb + 1$ elements, where Nfb is the number of filter banks in the scattering framework. The number of filter banks is also equal to the number of elements in the `QualityFactors` value of `sf`. Equivalently, the number of elements in `u` is equal to the number of orders in the scattering decomposition. Each element of `u` is a MATLAB table.

The precision of the scalogram coefficients depends on the precision specified in the framework `sf`.

Examples

Scattering Transform of ECG Signal

This example shows how to return the wavelet 1-D scattering transform of a real-valued signal.

Load an ECG signal sampled at 180 Hz.

```
load wecg
Fs = 180;
```

Create a scattering decomposition framework to apply to the signal. Compute the scattering transform of the signal.

```
sf = waveletScattering('SignalLength',numel(wecg),...
    'SamplingFrequency',Fs)
```

```
sf =
    waveletScattering with properties:
```

```
    SignalLength: 2048
```

```

InvarianceScale: 5.6889
QualityFactors: [8 1]
    Boundary: "periodic"
SamplingFrequency: 180
    Precision: "double"
OversamplingFactor: 0

```

```
[S,U] = scatteringTransform(sf,wecg);
```

Plot the signal and the zeroth-order scattering coefficients. Note that the invariance scale is one half the duration of the signal.

```

t = [0:length(wecg)-1]/Fs;
subplot(2,1,1)
plot(t,wecg)
grid on
axis tight
xlabel('Seconds')
title('ECG Signal')
subplot(2,1,2)
plot(S{1}.signals{1},'x-')
grid on
axis tight
title('Zeroth-Order Scattering Coefficients')

```

Visualize the scattergram for the first-order scalogram coefficients.

```
figure  
scattergram(sf,U,'FilterBank',1)
```

Input Arguments

sf – Scattering decomposition framework

waveletScattering object

Scattering decomposition framework, specified as a waveletScattering object.

x – Input data

real-valued vector | real-valued matrix

Input data, specified as a real-valued vector or matrix. If x is a vector, the number of samples in x must equal the SignalLength value of sf . If x is a matrix, the number of rows in x must equal the SignalLength value of sf .

Data Types: double | single

Output Arguments

s – Scattering coefficients

cell array

Scattering coefficients, returned as a cell array. s is a cell array with $Nfb+1$ elements where Nfb is the number of filter banks in the scattering decomposition framework. Nfb is equal to the number of

elements in the `QualityFactors` value of `sf`. Equivalently, the number of elements of `s` is equal to the number of orders in `sf`.

The precision of the scattering coefficients depends on the precision specified in the framework `sf`.

Each element of `s` is a MATLAB table with the following variables:

signals — Scattering coefficients

cell array

Scattering coefficients, returned as a cell array. If `x` is a vector, each element of `signals` is a column vector. If `x` has N columns, each element of `signals` is a M -by- N matrix, where M is the number of scattering coefficients.

Data Types: `double` | `single`

path — Scattering path

row vector

Scattering path used to obtain the scattering coefficients, returned as a row vector. Each column of `path` corresponds to one element of the path. The scalar 0 denotes the original signal. Positive integers in the L^{th} column denote the corresponding wavelet filter in the $(L-1)^{\text{th}}$ filter bank. Wavelet bandpass filters are ordered by decreasing center frequency.

Data Types: `double`

bandwidth — Bandwidth of scattering coefficients

scalar

Bandwidth of the scattering coefficients, returned as a scalar. If you specify a sampling frequency in the scattering framework, the bandwidth is in hertz. Otherwise, the bandwidth is in cycles/sample.

Data Types: `double`

resolution — Base-2 log resolution

scalar

Base-2 log resolution of the scattering coefficients, returned as a scalar.

Data Types: `double`

u — Scalogram coefficients

cell array

Scalogram coefficients, returned as a cell array. `u` is a cell array with $Nfb+1$ elements, where Nfb is the number of filter banks in the scattering decomposition framework. Nfb is equal to the number of elements in the `QualityFactors` value of `sf`. Equivalently, the number of elements of `u` is equal to the number of orders in `sf`.

The precision of the scalogram coefficients depends on the precision specified in the framework `sf`.

Each element of `u` is a MATLAB table with the following variables:

coefficients — Scalogram coefficients

cell array

Scalogram coefficients, returned as a cell array. If `x` is a vector, each element of `coefficients` is a column vector. If `x` has N columns, each element of `coefficients` is a M -by- N matrix, where M is the number of scalogram coefficients.

Data Types: `double` | `single`

path — Scattering path

row vector

Scattering path used to obtain the scalogram coefficients, returned as a row vector. Each column of `path` corresponds to one element of the path. The scalar 0 denotes the original signal. Positive integers in the L^{th} column denote the corresponding wavelet filter in the $(L-1)^{\text{th}}$ filter bank. Wavelet bandpass filters are ordered by decreasing center frequency.

Data Types: `double`

bandwidth — Bandwidth of scalogram coefficients

scalar

Bandwidth of the scalogram coefficients, returned as a scalar. If you specify a sampling frequency in the scattering decomposition framework, the bandwidth is in hertz. Otherwise, the bandwidth is in cycles/sample.

Data Types: `double`

resolution — Base-2 log resolution

scalar

Base-2 log resolution of the scalogram coefficients, returned as a scalar.

Data Types: `double`

`featureMatrix` | `waveletScattering`

Introduced in R2018b

scatteringTransform

Wavelet 2-D scattering transform

Syntax

```
s = scatteringTransform(sf,im)
[s,u] = scatteringTransform(sf,im)
```

Description

`s = scatteringTransform(sf,im)` returns the wavelet 2-D scattering transform of `im` for `sf`, the scattering decomposition framework. `im` is a real-valued 2-D matrix or 3-D matrix. If `im` is 3-D, the size of the third dimension must equal 3. The row and column sizes of `im` must match the `ImageSize` value of `sf`. The output `s` is a cell array with $Nfb+1$ elements, where Nfb is the number of filter banks in the scattering decomposition framework. Nfb is equal to the number of elements in the `QualityFactors` property of `sf`. Equivalently, the number of elements in `s` is equal to the number of orders in the scattering decomposition. Each element of `s` is a MATLAB table.

`[s,u] = scatteringTransform(sf,im)` also returns the wavelet scalogram coefficients for `im`. The output `u` is a cell array with $Nfb+1$ elements, where Nfb is the number of filter banks in the scattering decomposition framework. Nfb is equal to the number of elements in the `QualityFactors` property of `sf`. Equivalently, the number of elements in `u` is equal to the number of orders in the scattering decomposition. Each element of `u` is a MATLAB table.

Examples

Compare Scattering and Scalogram Coefficients

This example shows that scattering coefficients are lowpassed versions of scalogram coefficients.

Load an RGB image. Display the red channel.

```
im = imread('circle.jpg');
size(im)
```

```
ans = 1×3
```

```
    256    256     3
```

```
figure
imagesc(im(:,:,1))
colormap gray;
```

For RGB images, the size of the third dimension must be 3. You only have to specify the row and column sizes of the image when you create the scattering framework. Create a scattering framework to apply to the image and take the scattering transform.

```
sf = waveletScattering2('ImageSize',[256 256],'InvarianceScale',32,...
    'NumRotations',[8 8]);
[S,U] = scatteringTransform(sf,im);
```

The image and coefficient fields in S and U are M -by- N -by-3. The M -by- N dimensions are constant only in the scattering images because the scaling function has fixed bandwidth, while the wavelets have different bandwidths.

Use a for-loop and plot the red channel for the scalogram and scattering coefficients for the 8 rotation angles in the scattering transform. Note how the scattering coefficients are lowpass versions of the scalogram coefficients.

```
[~,~,~,filterparams] = sf.filterbank();
theta = filterparams{1}.rotations;
figure
for k = 1:numel(theta)
    subplot(2,1,1)
    imagesc(U{2}.coefficients{k}(:,:,1));
    axis xy
    title(['\Theta = ' num2str(theta(k))'],'Interpreter','Latex');
    subplot(2,1,2)
    imagesc(S{2}.images{k}(:,:,1));
    axis xy
```

```
pause(1)  
end
```

The above for-loop results in an animation identical to the one below.

Input Arguments

sf – Scattering decomposition framework

waveletScattering2 object

Scattering decomposition framework, specified as a waveletScattering2 object.

im – Input image

real-valued matrix

Input image, specified as a real-valued 2-D matrix or 3-D matrix. If `im` is 3-D, `im` is assumed to be a color image in the RGB color space, and the size of the third dimension must equal 3. The row and column sizes of `im` must match the ImageSize property of `sf`.

Output Arguments

s – Scattering coefficients

cell array

Scattering coefficients, returned as a cell array. `s` is a cell array with $Nfb+1$ elements where Nfb is the number of filter banks in the scattering decomposition framework. Nfb is equal to the number of elements in the QualityFactors property of `sf`. Equivalently, the number of elements in `s` is equal to the number of orders in the scattering decomposition. Each element of `s` is a MATLAB table with these variables:

images — Scattering coefficients

cell array

Scattering coefficients, returned as a cell array. Each element of `images` is an M -by- N or M -by- N -by-3 matrix.

path — Scattering path

row vector

Scattering path used to obtain the scattering coefficients, returned as a row vector. Each column of `path` corresponds to one element of the path. The scalar 0 denotes the original image. Positive integers in the L th column denote the corresponding wavelet filter in the $(L-1)$ th filter bank. Wavelet bandpass filters are ordered by decreasing center frequency.

There are `NumRotations` wavelets per center frequency pair.

bandwidth — Bandwidth of scattering coefficients

scalar

Bandwidth of scattering coefficients, returned as a scalar. The bandwidth is symmetric in the x and y directions.

resolution — Base-2 log resolution

scalar

Base-2 log resolution of the scattering coefficients, returned as a scalar.

u — Scalogram coefficients

cell array

Scalogram coefficients, returned as a cell array. `u` is a cell array with $Nfb+1$ elements, where Nfb is the number of filter banks in the scattering decomposition framework. Nfb is equal to the number of elements in the `QualityFactors` property of `sf`. Equivalently, the number of elements in `u` is equal to the number of orders in the scattering decomposition. Each element of `u` is a MATLAB table with these variables:

coefficients — Scalogram coefficients

cell array

Scalogram coefficients, returned as a cell array. Each element of `coefficients` is an M -by- N or M -by- N -by-3 matrix.

path — Scattering path

row vector

Scattering path used to obtain the scalogram coefficients, returned as a row vector. Each column of `path` corresponds to one element of the path. The scalar 0 denotes the original image. Positive integers in the L th column denote the corresponding wavelet filter in the $(L-1)$ th filter bank. Wavelet bandpass filters are ordered by decreasing center frequency.

There are `NumRotations` wavelets per center frequency pair.

bandwidth — Bandwidth of scalogram coefficients

scalar

Bandwidth of scalogram coefficients, returned as a scalar.

resolution — Base-2 log resolution

scalar

Base-2 log resolution of the scattering coefficients, returned as a scalar.

See Also

waveletScattering2

Introduced in R2019a

set

WPTREE field contents

Syntax

```
T = set(T,'FieldName1',FieldValue1,'FieldName2',FieldValue2, ...)
```

Description

`T = set(T,'FieldName1',FieldValue1,'FieldName2',FieldValue2, ...)` sets the content of the specified fields for the WPTREE object T.

For the fields that are objects or structures, you can set the subfield contents, giving the name of these subfields as '*FieldName*' values.

The valid choices for '*FieldName*' are

'dtree'	DTREE parent object
'wavInfo'	Structure (wavelet information)

The fields of the wavelet information structure, 'wavInfo', are also valid for '*FieldName*':

'wavName'	Wavelet name
'Lo_D'	Low Decomposition filter
'Hi_D'	High Decomposition filter
'Lo_R'	Low Reconstruction filter
'Hi_R'	High Reconstruction filter

'entInfo'	Structure (entropy information)
-----------	---------------------------------

The fields of the entropy information structure, 'entInfo', are also valid for '*FieldName*':

'entName'	Entropy name
'entPar'	Entropy parameter

Or fields of DTREE parent object:

'ntree'	NTREE parent object
'allNI'	All nodes information
'terNI'	Terminal nodes information

Or fields of NTREE parent object:

'wtbo'	WTBO parent object
'order'	Order of the tree

'depth'	Depth of the tree
'spsch'	Split scheme for nodes
'tn'	Array of terminal nodes of the tree

Or fields of WTBO parent object:

'wtboInfo'	Object information
'ud'	Userdata field

Caution The `set` function should only be used to set the field `'ud'`.

`disp` | `get` | `read` | `write`

Introduced before R2006a

setLabelValue

Set label value in labeled signal set

Syntax

```
setLabelValue(lss, midx, lblname, val)
setLabelValue(lss, midx, lblname, limits, val)
setLabelValue(lss, midx, lblname, locs, val)
setLabelValue( ____, 'LabelRowIndex', ridx)
setLabelValue( ____, 'SublabelRowIndex', sridx)
```

Description

`setLabelValue(lss, midx, lblname, val)` sets the attribute label `lblname` to value `val`, for the member of labeled signal set `lss` specified in `midx`. Omit `val` if `lblname` has a default value and you want to set the label to the default value.

`setLabelValue(lss, midx, lblname, limits, val)` adds regions delimited by `limits` to the ROI label named `lblname`. The number of rows of `limits` specifies the number of added regions.

`setLabelValue(lss, midx, lblname, locs, val)` adds points to the point label named `lblname`. `locs` specifies the number of added points and their locations.

`setLabelValue(____, 'LabelRowIndex', ridx)` specifies the row index, `ridx`, of an ROI or point label. The specified value replaces the current value of that row. If you omit this argument, the function appends ROI or point values to any existing label values.

`setLabelValue(____, 'SublabelRowIndex', sridx)` specifies the row index, `sridx`, of an ROI or point sublabel. The specified value replaces the current value of that sublabel row.

Examples

Set Label Value

Load a labeled signal set containing recordings of whale songs.

```
load whales
lss

lss =
    labeledSignalSet with properties:
        Source: {2x1 cell}
        NumMembers: 2
        TimeInformation: "sampleRate"
        SampleRate: 4000
        Labels: [2x3 table]
        Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.

Use `setLabelValue` to add data to the set.

Add a new label to the signal set, corresponding to the maximum value of each member.

```
theMax = signalLabelDefinition('Maximum', ...  
    'LabelDataType','numeric', ...  
    'Description','Maximum value of the signal');  
addLabelDefinitions(lss,theMax)
```

For each labeled signal, set the value of the new label to the signal maximum. Plot the signals and their maxima.

```
fs = lss.SampleRate;  
for k = 1:lss.NumMembers  
    sg = getSignal(lss,k);  
    [mx,ix] = max(sg);  
  
    setLabelValue(lss,k,'Maximum',mx)  
  
    subplot(2,1,k)  
    plot((0:length(sg)-1)/fs,sg,ix/fs,mx,'*')  
end
```

Display the names and values of the labels in the set.

```
lbldefs = getLabelValues(lss)
```

```
lbldefs=2x4 table
      WhaleType      MoanRegions      TrillRegions      Maximum
      -----      -
Member{1}      blue      {3x2 table}      {1x3 table}      {[0.2850]}
Member{2}      blue      {3x2 table}      {1x3 table}      {[0.3791]}
```

Decide that the signal maximum is better represented as a point label than as an attribute. Remove the numeric definition and redefine the maximum.

```
removeLabelDefinition(lss,'Maximum')
theMax = signalLabelDefinition('Maximum', ...
    'LabelType','point','LabelDataType','numeric', ...
    'Description','Maximum value of the signal');
addLabelDefinitions(lss,theMax)
```

For each labeled signal, set the value of the new label to the signal maximum.

```
for k = 1:lss.NumMembers
    sg = getSignal(lss,k);
    [mx,ix] = max(sg);
    setLabelValue(lss,k,'Maximum',ix/fs,mx)
end
```

Plot the signals and their maxima.

```
for k = 1:lss.NumMembers
    subplot(2,1,k)
    sg = getSignal(lss,k);
    peaks = getLabelValues(lss,k,'Maximum');
    plot((0:length(sg)-1)/fs,sg, ...
        peaks.Location,cell2mat(peaks.Value),'*')
end
```

Input Arguments

lss — Labeled signal set

labeledSignalSet object

Labeled signal set, specified as a `labeledSignalSet` object.

Example: `labeledSignalSet({randn(100,1)
randn(10,1)}, signalLabelDefinition('female'))` specifies a two-member set of random signals containing the attribute 'female'.

midx — Member row number

positive integer

Member row number, specified as a positive integer. `midx` specifies the member row number as it appears in the “Labels” on page 1-0 table of a labeled signal set.

lblname — Label or sublabel name

character vector | string scalar | cell array of character vectors | string array

Label name, specified as a character vector or string scalar.

Label or sublabel name. To specify a label, use a character vector or a string scalar. To specify a sublabel, use a two-element cell array of character vectors or a two-element string array:

- The first element is the name of the parent label.
- The second element is the name of the sublabel.

When targeting a sublabel of an ROI or point label, you must also specify the 'LabelRowIndex' of the parent label whose label you want to set. The row of the parent must already exist before you can set a sublabel value to it.

Example: `signalLabelDefinition("Asleep", 'LabelType', 'roi')` specifies a label of name "Asleep" for a region of a signal in which a patient is asleep during a clinical trial.

Example: `{'Asleep' 'REM'}` or `["Asleep" "REM"]` specifies a region of a signal in which a patient undergoes REM sleep.

val — Label values

numeric value or array | logical value or array | categorical value or array | character vector or cell array of character vectors | string or string array | table or table array | timetable or timetable array

Label values, specified as a numeric, logical, or categorical value, as a string, as a table, or as a timetable. `val` can also be an array of any of the previous types. `val` must be of the data type specified for `lblname`.

- If you specify `locs`, then `val` must have the same number of elements as `locs`.
- If you specify `limits`, then `val` must have a number of elements equal to the number of rows in `limits`.
 - If `limits` has more than one row, and `lblname` is of type 'numeric' or 'logical', then `val` must be a vector or a cell array.
 - If `limits` has more than one row, and `lblname` is of type 'string' or 'categorical', then `val` must be a string array or a cell array of character vectors.
 - If `limits` has more than one row, and `lblname` is of type 'table' or 'timetable', then `val` must be a cell array of tables or timetables.

limits — Region limits

two-column matrix

Region limits, specified as a two-column matrix.

- If `lss` does not have time information, then `limits` defines the minimum and maximum indices over which the regions are defined.
- If `lss` has time information, then `limits` defines the minimum and maximum instants over which the regions are defined.

`limits` must be of the data type specified by the "ROILimitsDataType" on page 1-0 property of the label definition for `lblname`.

Example: `seconds([0:3;1:4]')`

Example: `[0:3;1:4]'`

locs — Point locations

vector

Point locations, specified as a vector.

- If `lss` does not have time information, then `locs` defines the indices corresponding to the point locations.

- If `lss` has time information, then `locs` defines the instants corresponding to the point locations.

`locs` must be of the data type specified by the “PointLocationsDataType” on page 1-0 property of the label definition for `lblname`.

ridx – Label row index

positive integer

Label row index, specified as a positive integer. This argument applies only for ROI and point labels.

sridx – Sublabel row index

positive integer

Sublabel row index, specified as a positive integer. This argument applies only when a label and sublabel pair has been specified in `lblname` and the sublabel is of type ROI or point.

`labeledSignalSet` | `signalLabelDefinition`

Introduced in R2018b

setMemberNames

Set member names in labeled signal set

Syntax

```
setMemberNames(lss,mnames)
setMemberNames(lss,mnames,midx)
```

Description

`setMemberNames(lss,mnames)` sets the names of the members of the labeled signal set `lss` to `mnames`. The length of `mnames` must be equal to the number of members.

`setMemberNames(lss,mnames,midx)` sets the name of the member specified by `midx`.

Examples

Set Member Names

Load a labeled signal set containing recordings of whale songs.

```
load whales
lss

lss =
  labeledSignalSet with properties:
        Source: {2x1 cell}
      NumMembers: 2
  TimeInformation: "sampleRate"
      SampleRate: 4000
        Labels: [2x3 table]
      Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

Set the names of the set members to the whales' nicknames.

```
setMemberNames(lss,{'Brutus' 'Lucy'})
```

Return a string array with the names of the members.

```
getMemberNames(lss)

ans = 2x1 string
    "Brutus"
    "Lucy"
```

Input Arguments

lss — Labeled signal set

labeledSignalSet object

Labeled signal set, specified as a labeledSignalSet object.

Example: `labeledSignalSet({randn(100,1) randn(10,1)}, signalLabelDefinition('female'))` specifies a two-member set of random signals containing the attribute 'female'.

mnames — Member names

character vector | string scalar | cell array of character vectors | string array

Member names, specified as a character vector, a string scalar, a cell array of character vectors, or a string array.

Example: `labeledSignalSet({randn(100,1) randn(10,1)}, 'MemberNames', {'llama' 'alpaca'})` specifies a set of random signals with two members, 'llama' and 'alpaca'.

midx — Member row number

positive integer

Member row number, specified as a positive integer. `midx` specifies the member row number as it appears in the “Labels” on page 1-0 table of a labeled signal set.

labeledSignalSet | signalLabelDefinition

Introduced in R2019a

shanwavf

Complex Shannon wavelet

Syntax

```
[PSI,X] = shanwavf(LB,UB,N,FB,FC)
```

Description

[PSI,X] = shanwavf(LB,UB,N,FB,FC) returns values of the complex Shannon wavelet. The complex Shannon wavelet is defined by a bandwidth parameter FB, a wavelet center frequency FC, and the expression

$$\text{PSI}(X) = (\text{FB}^{\wedge}0.5) * (\text{sinc}(\text{FB}*X) .* \exp(2*i*pi*FC*X))$$

on an N point regular grid in the interval [LB,UB].

FB and FC must be such that $\text{FC} > 0$ and $\text{FB} > 0$.

Output arguments are the wavelet function PSI computed on the grid X.

Examples

Complex Shannon Wavelet

Obtain and plot a complex Shannon wavelet. Set the bandwidth and center frequency parameters.

```
fb = 1;
fc = 1.5;
```

Set the effective support and number of sample points.

```
lb = -20;
ub = 20;
n = 1000;
```

Obtain the complex-valued Shannon wavelet and plot the real and imaginary parts.

```
[psi,x] = shanwavf(lb,ub,n,fb,fc);
subplot(2,1,1)
plot(x,real(psi))
title('Complex Shannon Wavelet')
xlabel('Real Part')
grid on
subplot(2,1,2)
plot(x,imag(psi))
xlabel('Imaginary Part')
grid on
```

shearletSystem

Cone-adapted bandlimited shearlet system

Description

The `shearletSystem` object represents a cone-adapted bandlimited shearlet system. After you create the shearlet system, you can use `shearlet2` to obtain the shearlet transform of a real-valued 2-D image. You can also use `ishearlet2` to obtain the inverse transform. Additional “Object Functions” on page 1-994 are provided.

Creation

Syntax

```
sls = shearletSystem
sls = shearletSystem(Name,Value)
```

Description

`sls = shearletSystem` creates a cone-adapted real-valued bandlimited shearlet system for a real-valued image of size 128-by-128 with the number of scales equal to 4. The system `sls` is a nondecimated shearlet system. Shearlets extending beyond the 2-D frequency bounds are periodically extended. Using real-valued shearlets with periodic boundary conditions results in real-valued shearlet coefficients.

The implementation of `shearletSystem` follows the approach described in Häuser and Steidl [6]

`sls = shearletSystem(Name,Value)` creates a cone-adapted bandlimited shearlet system with “Properties” on page 1-993 specified by one or more `Name,Value` pairs. For example, `shearletSystem('ImageSize',[100 100])` creates a shearlet system for images of size 100-by-100. Properties can be specified in any order as `Name1,Value1,...,NameN,ValueN`. Enclose each property name in single quotes (' ') or double quotes (" ").

Note Property values of a shearlet system are fixed. For example, if the shearlet system `SLS` is created with an `ImageSize` of `[128 128]`, you cannot change that `ImageSize` to `[200 200]`.

Properties

ImageSize — Image size

`[128 128]` (default) | two-element integer-valued vector

Image size for the shearlet system, specified as a two-element integer-valued vector `[numrows numcolumns]`. Images must be at least 16-by-16.

Example: `sls = shearletSystem('ImageSize',[100 200])` creates a shearlet system for 100-by-200 images.

Data Types: `single` | `double`

NumScales — Number of scales

4 (default) | positive integer

Number of scales in the shearlet system, specified as a positive integer less than or equal to $\log_2(\min([M N]))-3$, where M and N are the row and column dimensions of the input image. For a 16-by-16 input image, $\log_2(\min([16 16]))-3 = 4-3 = 1$, so the smallest image compatible with `shearletSystem` has a minimum dimension of 16. For the default image size 128-by-128, the number of scales equals 4.

Example: `sls = shearletSystem('NumScale',1)` creates a shearlet system with `NumScales` equal to 1.

Data Types: `single` | `double`

TransformType — Shearlet system type

'real' (default) | 'complex'

Shearlet system type, specified as 'real' or 'complex'. Real-valued shearlets have two-sided 2-D frequency spectra, while complex-valued shearlets have one-sided 2-D spectra. If `FilterBoundary` is set to 'periodic', shearlets at the finest spatial scales have energy that wraps around in the 2-D frequency response. For both 'real' and 'complex' shearlet systems, the Fourier transforms of the shearlets are real valued.

FilterBoundary — Shearlet filter boundary handling

'periodic' (default) | 'truncated'

Shearlet filter boundary handling, specified as 'periodic' or 'truncated'. When set to 'periodic', shearlets extending beyond the 2-D frequency boundaries are periodically extended. When set to 'truncated', shearlets are truncated at the 2-D frequency boundaries.

PreserveEnergy — Shearlet system analysis normalization

false or 0 (default) | true or 1

Shearlet system analysis normalization, specified as a numeric or logical 1 (true) or 0 (false). When set to true, the shearlet system is normalized to be a Parseval frame, and the energy of the input image is preserved in the shearlet transform coefficients.

Example: `sls = shearletSystem('PreserveEnergy',true)`

Data Types: `logical`

Precision — Shearlet system precision

'double' (default) | 'single'

Shearlet system precision, specified as 'double' or 'single'. All computations are done using the specified precision.

Note To obtain the shearlet transform of an image, the precision of the image must match the precision of the shearlet system.

Object Functions

`shearlet2` Shearlet transform

isheart2	Inverse shearlet transform
framebounds	Shearlet system frame bounds
filterbank	Shearlet system filters
numshears	Number of shearlets

Examples

Create Energy-Preserving Shearlet System

Load an image. Create two real-valued shearlet systems that can be applied to the image. Normalize the first system so that energy is preserved in the shearlet transform coefficients. Leave the second shearlet system with the default (`false`) normalization.

```
load mask
[numRows,numCols] = size(X);
slsA = shearletSystem('ImageSize',[numRows numCols],'PreserveEnergy',true);
slsB = shearletSystem('ImageSize',[numRows numCols]);
```

Take the shearlet transform of the image using both shearlet systems.

```
cfA = sheart2(slsA,X);
cfB = sheart2(slsB,X);
```

Determine the energy of the input image and both sets of transform coefficients. Confirm that only the first shearlet system preserved energy.

```
energyA = sum(cfA(:).^2);
energyB = sum(cfB(:).^2);
energyImage = sum(X(:).^2)

energyImage = 2.4655e+09

diffSystemA = abs(energyImage-energyA)

diffSystemA = 3.8624e-05

diffSystemB = abs(energyImage-energyB)

diffSystemB = 1.4869e+07
```

Topics

"Shearlet Systems"

Introduced in R2019b

sheart2

Shearlet transform

Syntax

```
coefs = sheart2(sls,im)
```

Description

`coefs = sheart2(sls,im)` returns the shearlet transform or shearlet analysis of the real-valued 2-D image `im` for the shearlet system `sls`. If the shearlet system is real-valued with periodic boundary conditions, then `coefs` is real-valued. Otherwise, `coefs` is complex-valued. The size and class (data type) of `im` must match the `ImageSize` and `Precision` values, respectively, of `sls`.

Examples

Shearlet Transform of Circle

This example shows how to take the shearlet transform of an image and reconstruct the image using only coefficients corresponding to zero shearing.

Load and display an image of a circle.

```
load circleGS
imagesc(circleGS)
colormap gray
axis equal
axis tight
```

Create a shearlet system that can be used with the image. Obtain the shearlet filters defined by the system, as well as their geometric interpretations.

```
[numRows,numCols] = size(circleGS);
sls = shearletSystem('ImageSize',[numRows numCols],'FilterBoundary','truncated');
[psi,scale,shear,cone] = filterbank(sls);
```

Obtain the shearlet transform of the image.

```
cfs = sheart2(sls,circleGS);
```

Find the indices of the shearlet filters that correspond to zero shearing. Keep in mind that the lowpass filter also corresponds to zero shearing.

```
ind = find((shear==0).*(scale~-1))'
```

```
ind = 1×10
```

```
    3     6    10    15    20    25    31    38    46    55
```

Plot one of the shearlets in the frequency plane. Because the shearlet corresponds to zero shearing, confirm the frequency response is concentrated along either the horizontal or vertical axis.

```
sh = 31;
omegax = -1/2:1/numCols:1/2-1/numCols;
omegay = omegax;
figure
```

```

surf(omegax,flip(omegay),psi(:,:,sh),'EdgeColor','none')
view(0,90)
xlabel('\omega_x')
ylabel('\omega_y')
axis equal
axis tight
title(['Zero Shear Shearlet: Scale = ',num2str(scale(sh)),', Cone - ',cone{sh}])

```

Create an array that only contains the shearlet coefficients that correspond to the zero shearing filters.

```

cfsx = zeros(size(cfs));
for k=1:length(ind)
    cfsx(:,:,ind(k)) = cfs(:,:,ind(k));
end

```

Reconstruct the image using the new coefficients array. Because the only nonzero shearlet coefficients are those that correspond to zero shearing, the horizontal and vertical portions of the circle are emphasized in the reconstruction.

```

rec = isheart2(sls,cfsx);
imagesc(rec)
axis equal
axis tight
colormap gray
title('Reconstruction')

```

Input Arguments

sls — Shearlet system

shearletSystem object

Shearlet system, specified as a shearletSystem object.

im — Input image

real-valued matrix

Input image, specified a real-valued matrix. The size and data type of `im` must match the ImageSize and Precision values, respectively, of `sls`.

Data Types: `single` | `double`

Output Arguments

coefs — Shearlet coefficients

3-D array

Shearlet coefficients, returned as a 3-D array. The size of `coefs` is M -by- N -by- K , where M and N are the row and column dimensions of the input image, respectively. The size of the third dimension, K , equals the number of shearlets in `sls`, including the lowpass filter, $K = \text{numshears}(\text{sls}) + 1$.

For example, if `cfs = sheart2(sls,im)` and `psi = filterbank(sls)`, then the shearlet corresponding to `cfs(:, :, k)` is `psi(:, :, k)`. The data type of `coefs` matches the Precision value of the shearlet system.

Data Types: `single` | `double`

signalLabelDefinition

Create signal label definition

Description

Use `signalLabelDefinition` to create signal label definitions for data sets. The labels can correspond to attributes, regions, or points of interest. Use a vector of `signalLabelDefinition` objects to create a `labeledSignalSet`.

Creation

Syntax

```
sld = signalLabelDefinition(name)
sld = signalLabelDefinition(name,Name,Value)
```

Description

`sld = signalLabelDefinition(name)` creates a signal label definition object, `sld`, with the “Name” on page 1-0 property set to `name` and other properties set to default values.

`sld = signalLabelDefinition(name,Name,Value)` sets “Properties” on page 1-1002 using name-value pairs. You can specify multiple name-value pairs. Enclose each property name in quotes.

Input Arguments

name — Label name

character vector | string scalar

Label name, specified as a character vector or string scalar.

Data Types: `char` | `string`

Properties

Name — Name of label

character vector | string scalar

Name of label, specified as a character vector or string scalar.

Data Types: `char` | `string`

LabelType — Type of label

'attribute' (default) | 'roi' | 'point'

Type of label, specified as one of the following:

- 'attribute' — Define signal characteristics.

- 'roi' — Define signal characteristics over regions of interest.
- 'point' — Define signal characteristics over points of interest.

Data Types: char | string

LabelDataType — Data type of label

'logical' (default) | 'categorical' | 'numeric' | 'string' | 'table' | 'timetable'

Data type of label, specified as 'logical', 'categorical', 'numeric', 'string', 'table', or 'timetable'. Use the “Categories” on page 1-0 property to specify the array of categories when this property is set to 'categorical'.

Data Types: char | string

Categories — Label category names

string array | cell array of character vectors

Label category names, specified as a string array or a cell array of character vectors. The array must have unique elements. This property applies only when the “LabelDataType” on page 1-0 property is set to 'categorical'.

Example: 'LabelDataType', 'categorical', 'Categories', ["apple", "orange"]

Data Types: char | string

ROIlimitsDataType — Data type of ROI limits

'double' (default) | 'duration'

Data type of ROI limits, specified as either 'double' or 'duration'. This property applies only when “LabelType” on page 1-0 is set to 'roi'.

Data Types: char | string

PointLocationsDataType — Data type of point locations

'double' (default) | 'duration'

Data type of point locations, specified as either 'double' or 'duration'. This property applies only when “LabelType” on page 1-0 is set to 'point'.

Data Types: char | string

ValidationFunction — Validation function

function handle

Validation function, specified as a function handle and used when setting label values in a `labeledSignalSet` object. This property applies only when “LabelDataType” on page 1-0 is set to 'categorical', 'logical', 'numeric', 'table', or 'timetable'. If not specified, the function checks only that its input values are of the correct data type. If “LabelDataType” on page 1-0 is set to 'categorical', the function checks that the input is one of the values specified using “Categories” on page 1-0. The function takes an input value and returns `true` if the value is valid and `false` if the value is invalid.

Example:

'LabelDataType', 'numeric', 'DefaultValue', 1, 'ValidationFunction', @(x)x<2

Data Types: function_handle

DefaultValue — Default value of label

[] (default) | LabelDataType value

Default value of label, specified as a value of the type specified using “LabelDataType” on page 1-0 . If “LabelDataType” on page 1-0 is set to 'categorical', then “DefaultValue” on page 1-0 must be one of the values specified using “Categories” on page 1-0 .

Example: 'LabelDataType', 'categorical', 'Categories',
["apple", "orange"], 'DefaultValue', "apple"

Data Types: char | double | logical | string | table

Description — Label description

character vector | string scalar

Label description, specified as a character vector or string scalar.

Example: 'Description', 'Patient is asleep'

Data Types: char | string

Tag — Label tag identifier

character vector | string scalar

Label tag identifier, specified as a character vector or string scalar. Use this property to identify the same label in a larger labeling scheme or public labeling set.

Example: 'Tag', 'Peak1'

Data Types: char | string

Sublabels — Array of sublabels

signal label definition object

Array of sublabels, specified as a signal label definition object. To specify more than one sublabel, set this property to a vector of signal label definition objects. Use this property to create a relationship between a parent label and its children.

Note Sublabels cannot have sublabels.

Example: 'Sublabels',
[signalLabelDefinition("negative"), signalLabelDefinition("positive")]

Object Functions

labelDefinitionsHierarchy Get hierarchical list of label and sublabel names

labelDefinitionsSummary Get summary table of signal label definitions

Examples**Label Definitions for Whale Songs**

Consider a set of whale sound recordings. The recorded whale sounds consist of trills and moans. You want to look at each signal and label it to identify the whale type, the trill regions, and the moan regions. For each trill region, you also want to label the signal peaks higher than a certain threshold.

Signal Label Definitions

Define an attribute label to store whale types. The possible categories are blue whale, humpback whale, and white whale.

```
dWhaleType = signalLabelDefinition('WhaleType',...
  'LabelType','attribute',...
  'LabelDataType','categorical',...
  'Categories',["blue" "humpback" "white"],...
  'Description','Whale type');
```

Define a region-of-interest (ROI) label to capture moan regions. Define another ROI label to capture trill regions.

```
dMoans = signalLabelDefinition('MoanRegions',...
  'LabelType','roi',...
  'LabelDataType','logical',...
  'Description','Regions where moans occur');
```

```
dTrills = signalLabelDefinition('TrillRegions',...
  'LabelType','roi',...
  'LabelDataType','logical',...
  'Description','Regions where trills occur');
```

Finally, define a point label to capture the trill peaks. Set this label as a sublabel of the dTrills definition.

```
dTrillPeaks = signalLabelDefinition('TrillPeaks',...
  'LabelType','point',...
  'LabelDataType','numeric',...
  'Description','Trill peaks');
```

```
dTrills.Sublabels = dTrillPeaks;
```

Labeled Signal Set

Create a `labeledSignalSet` with the whale signals and the label definitions. Add label values to identify the whale type, the moan and trill regions, and the peaks of the trills.

```
load labelwhalesignals
lbldefs = [dWhaleType dMoans dTrills];

lss = labeledSignalSet({whale1 whale2},lbldefs,...
  'SampleRate',Fs,'Description','Characterize wave song regions');
```

Visualize the label hierarchy and label properties using `labelDefinitionsHierarchy` and `labelDefinitionsSummary`.

```
labelDefinitionsHierarchy(lss)
```

```
ans =
  'WhaleType
    Sublabels: []
  MoanRegions
    Sublabels: []
  TrillRegions
    Sublabels: TrillPeaks
  ,
```

```
labelDefinitionsSummary(lss)
```

```
ans=3x9 table
```

LabelName	LabelType	LabelDataType	Categories	ValidationFunction	Default
"WhaleType"	"attribute"	"categorical"	{3x1 string}	{["N/A"]}	{0x0 }
"MoanRegions"	"roi"	"logical"	{["N/A"]}	{0x0 double}	{0x0 }
"TrillRegions"	"roi"	"logical"	{["N/A"]}	{0x0 double}	{0x0 }

The signals in the loaded data correspond to songs of two blue whales. Set the 'WhaleType' values for both signals.

```
setLabelValue(lss,1,'WhaleType','blue');
setLabelValue(lss,2,'WhaleType','blue');
```

Visualize the 'Labels' property. The table has the newly added 'WhaleType' values for both signals.

```
lss.Labels
```

```
ans=2x3 table
```

	WhaleType	MoanRegions	TrillRegions
Member{1}	blue	{0x2 table}	{0x3 table}
Member{2}	blue	{0x2 table}	{0x3 table}

Visualize Regions and Points

Visualize the whale songs to identify the trill and moan regions.

```
subplot(2,1,1)
plot((0:length(whale1)-1)/Fs,whale1)
ylabel('Whale 1')
hold on

subplot(2,1,2)
plot((0:length(whale2)-1)/Fs,whale2)
ylabel('Whale 2')
hold on
```

Add the moan and trill regions to the labeled set. For ROI labels, specify the ROI limits in seconds and the label values. Label the different regions in the plots using an auxiliary function.

```

moanRegionsWhale1 = [6.1 7.7; 11.4 13.1; 16.5 18.1];
setLabelValue(lss,1,'MoanRegions',moanRegionsWhale1,[true true true]);

trillRegionWhale1 = [1.4 3.1];
setLabelValue(lss,1,'TrillRegions',trillRegionWhale1,true);

subplot(2,1,1)
labelIntervals([moanRegionsWhale1;trillRegionWhale1])

moanRegionsWhale2 = [2.5 3.5; 5.8 8; 15.4 16.7];
setLabelValue(lss,2,'MoanRegions',moanRegionsWhale2,[true true true]);

trillRegionWhale2 = [11.1 13];
setLabelValue(lss,2,'TrillRegions',trillRegionWhale2,true);

subplot(2,1,2)
labelIntervals([moanRegionsWhale2;trillRegionWhale2])

```

Label three peaks for each trill region. For point labels, you specify the point locations and the label values. In this example, the point locations are in seconds.

```

peakLocsWhale1 = [1.553 1.626 1.7];
peakValsWhale1 = [0.211 0.254 0.211];

setLabelValue(lss,1,["TrillRegions" "TrillPeaks"],...
    peakLocsWhale1,peakValsWhale1,'LabelRowIndex',1);

subplot(2,1,1)
plot(peakLocsWhale1,peakValsWhale1,'v')
hold off

peakLocsWhale2 = [11.214 11.288 11.437];
peakValsWhale2 = [0.119 0.14 0.15];

setLabelValue(lss,2,["TrillRegions" "TrillPeaks"],...
    peakLocsWhale2,peakValsWhale2,'LabelRowIndex',1);

subplot(2,1,2)
plot(peakLocsWhale2,peakValsWhale2,'v')
hold off

```

Explore Label Values

Explore the label values using `getLabelValues`.

```
getLabelValues(lss)
```

ans=2x3 table

	WhaleType	MoanRegions	TrillRegions
Member{1}	blue	{3x2 table}	{1x3 table}
Member{2}	blue	{3x2 table}	{1x3 table}

Retrieve the moan regions for the first member of the labeled set.

```
getLabelValues(lss,1,'MoanRegions')
```

ans=3x2 table

ROIlimits	Value
6.1 7.7	{[1]}
11.4 13.1	{[1]}
16.5 18.1	{[1]}

Use a second output argument to list the sublabels of a label.

```
[value,valueWithSublabel] = getLabelValues(lss,1,'TrillRegions')
```

```
value=1x2 table
  ROIlimits      Value
  _____      _____
  1.4      3.1      {[1]}
```

```

Signal Multiresolution Analyzer

Decompose signals into time-aligned components

Description

The **Signal Multiresolution Analyzer** app is an interactive tool for visualizing multilevel wavelet and empirical mode decompositions of real-valued 1-D signals and comparing results. With the app, you can:

- Access all the signals in the MATLAB workspace.
- Adjust default parameters and generate multiple decompositions using `modwt` and `modwtmra` (default) or `emd` methods.
- Choose decomposition levels to include in the signal reconstruction.
- Visualize and compare results.
- Obtain frequency ranges of the decomposition levels. (See `powerbw` for more information.)
- Determine the relative energy of the signal across levels.
- Export reconstructed signals and decompositions to your workspace.
- Recreate the decomposition in your workspace by generating a MATLAB script.

Open the Signal Multiresolution Analyzer App

- MATLAB Toolstrip: On the **Apps** tab, under **Signal Processing and Communications**, click

Signal Multiresolution Analyzer 

- MATLAB command prompt: Enter `signalMultiresolutionAnalyzer`.

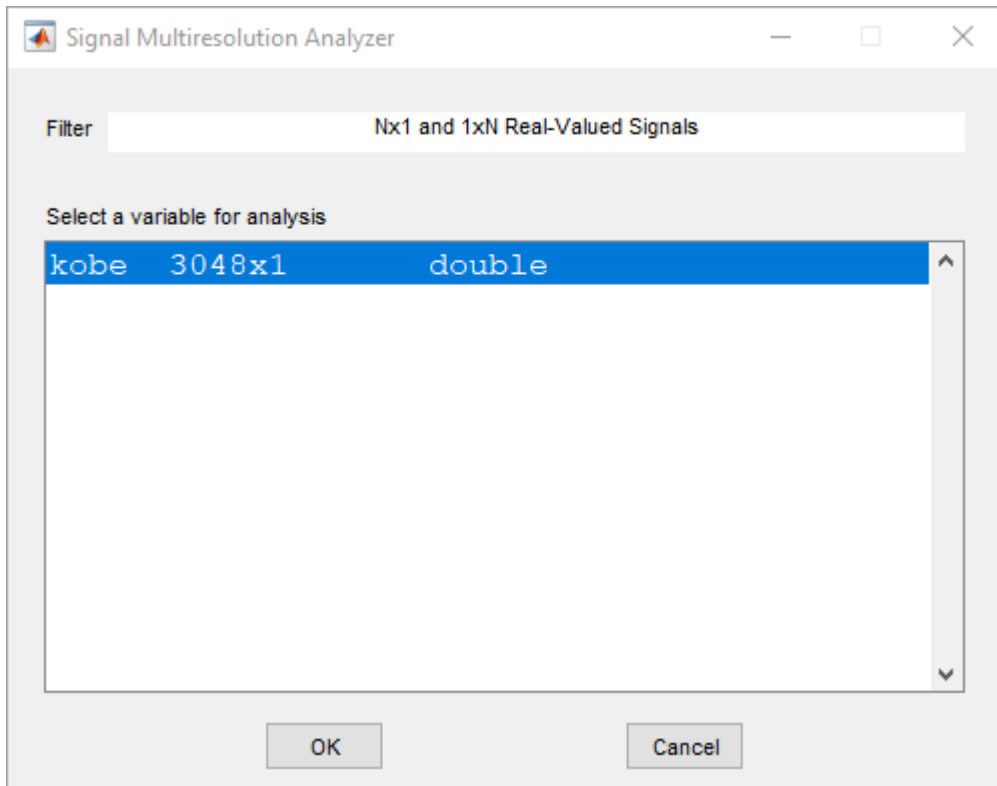

Examples

Visualize Time-Aligned Wavelet Decomposition

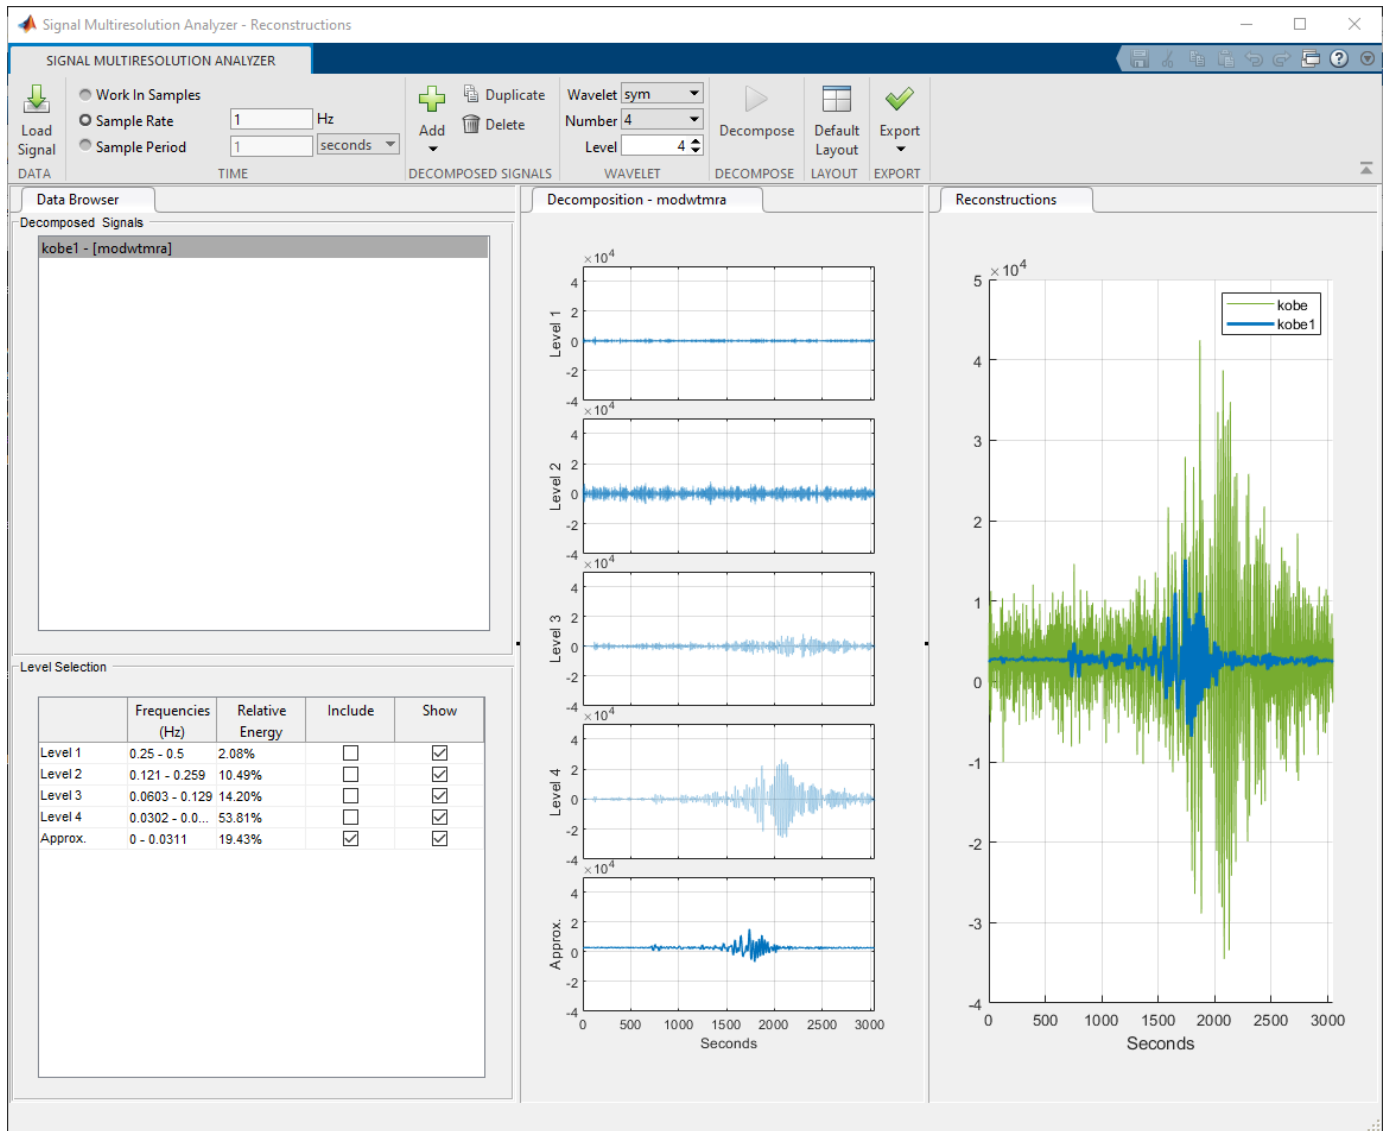

Load in the Kobe earthquake data. The data are seismograph measurements (vertical acceleration in nm/sec^2) recorded at Tasmania University, Hobart, Australia, on 16 January 1995, beginning at 20:56:51 (GMT) and continuing for 51 minutes at one second intervals.

```
load kobe
```

Open **Signal Multiresolution Analyzer** and click **Load Signal**. A window appears listing all the workspace variables the app can process.

Select the Kobe data from the dialog box and click **OK**. A four-level MODWTMRA decomposition of the signal appears. The decomposed signal is named `kobe1` in the **Decomposed Signals** pane. The suffix `[modwtmra]` identifies the decomposition as wavelet based. By default, plots are with respect to sample index and frequencies are in cycles per sample. Select the **Sample Rate** radio button. Because the data sample rate is 1 hertz, you do not have to change the default value. The plots and frequencies update to use the sample rate.

The plots in the middle **Decomposition** pane are the projections of the wavelet decompositions of the signal at each scale on the original signal subspace. The original signal, **kobe**, and the reconstruction, **kobe1**, are plotted in the **Reconstruction** pane. The **Level Selection** pane shows the relative energies of the signal across scales, as well as the frequency bands.

Level Selection				
	Frequencies (Hz)	Relative Energy	Include	Show
Level 1	0.25 - 0.5	2.08%	<input type="checkbox"/>	<input checked="" type="checkbox"/>
Level 2	0.121 - 0.259	10.49%	<input type="checkbox"/>	<input checked="" type="checkbox"/>
Level 3	0.0603 - 0.129	14.20%	<input type="checkbox"/>	<input checked="" type="checkbox"/>
Level 4	0.0302 - 0.0...	53.81%	<input type="checkbox"/>	<input checked="" type="checkbox"/>
Approx.	0 - 0.0311	19.43%	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>

A check box in the **Show** column controls whether or not that level is displayed in the **Decomposition** pane. A check box in the **Include** column controls whether or not to include that level of the wavelet decomposition in the reconstruction. Clicking a plot in the **Decomposition** pane is another way to include or exclude that level in the signal reconstruction. To generate a new wavelet decomposition, change one of the wavelet parameters in the toolstrip and click **Decompose**.

- **Wavelet** - Wavelet family
- **Number** - Wavelet filter number
- **Level** - Wavelet decomposition level

Changing any setting in the toolstrip will enable the **Decompose** button.

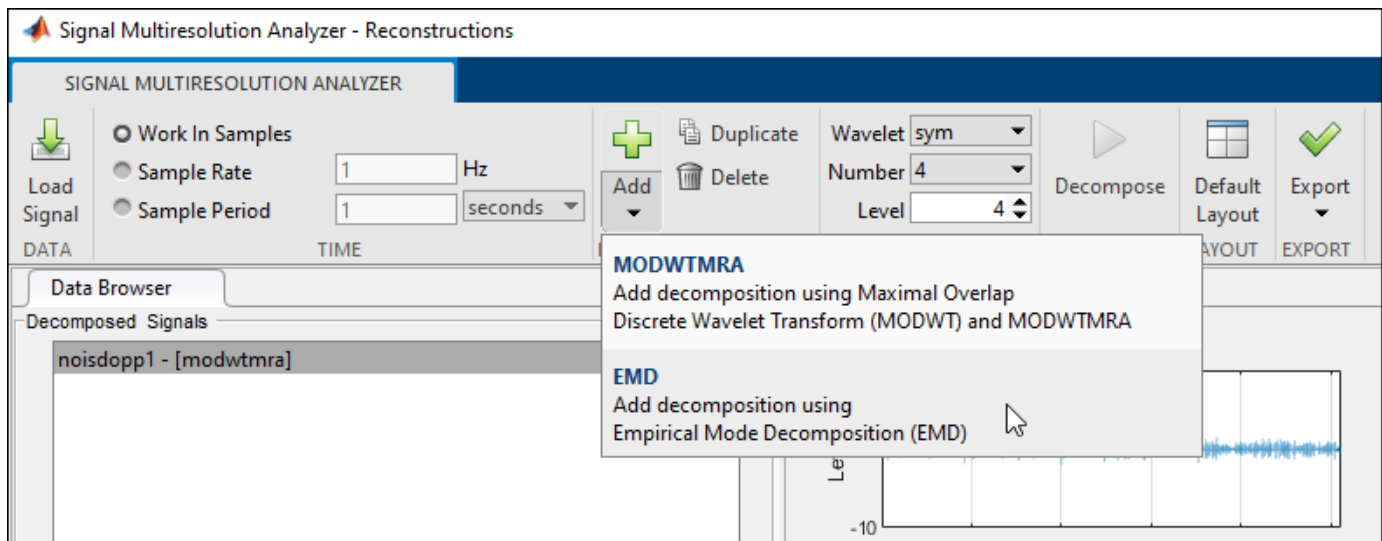

Compare MODWTMRA and EMD Decompositions

Load the noisy Doppler signal. The signal is a noisy version of the Doppler test signal of Donoho and Johnstone [1].

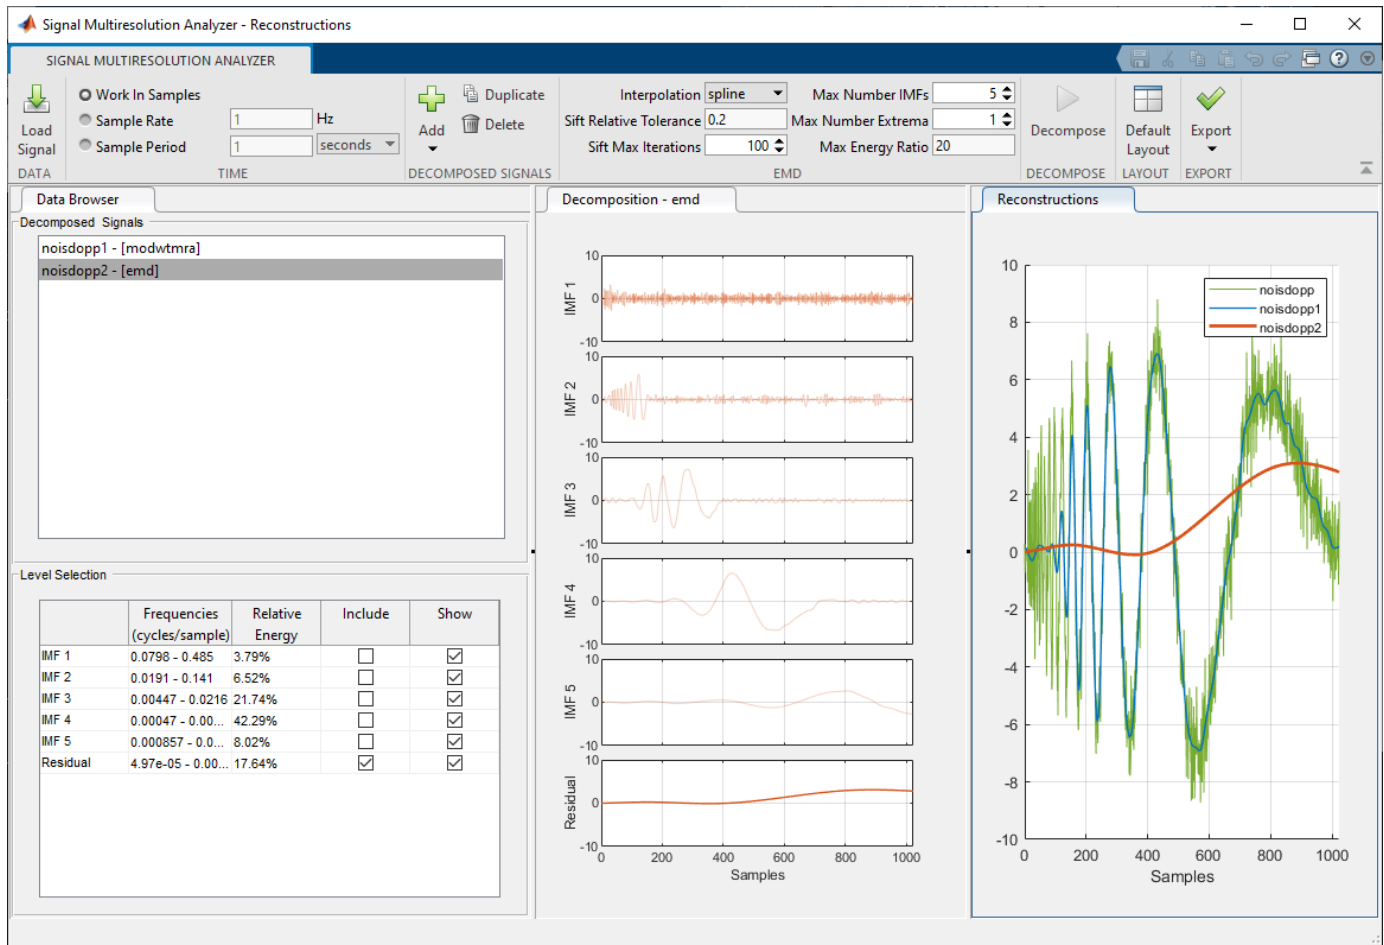

load `noisdopp`

Open **Signal Multiresolution Analyzer** and load the signal into the app. By default, the app creates a four-level MODWTMRA decomposition of the signal. In the **Decomposed Signals** pane, the wavelet decomposition is named `noisdopp1`. The **Reconstruction** pane shows the original and reconstructed signals plotted in two different colors.

To add the EMD decomposition, click **Add ▼** and select **EMD**.

After a few moments the EMD decomposition `noisdopp2` appears in the app. Because the EMD decomposition is selected in the **Decomposed Signals** pane, the toolstrip changes to show options related to EMD, and the residual is now the thickest plot in the **Reconstructions** pane.

To more easily see the differences between the two reconstructions, click `noisdopp` in the plot legend. The text fades, and the plot of the original signal is hidden. You can use the legend to hide any plot in the **Reconstruction** pane.

You can change the parameters in the toolstrip to generate a different EMD decomposition:

- **Interpolation** - Interpolation method for envelope construction
- **Sift Relative Tolerance** - Cauchy type convergence criterion
- **Sift Max Iterations** - Maximum number of sifting iterations
- **Max Number IMF** - Maximum number of IMFs extracted
- **Max Number Extrema** - Maximum number of extrema in the residual signal
- **Max Energy Ratio** - Signal to residual energy ratio

See [emd](#) for more information about the parameters.

Generate Decomposition Script

This example shows how to change the app default settings to duplicate a decomposition for modification, and then how to generate a script to recreate the decomposition in your workspace.

Load the Kobe earthquake data into your workspace. The data are seismograph measurements (vertical acceleration in nm/sec^2) recorded at Tasmania University, Hobart, Australia, on 16 January 1995, beginning at 20:56:51 (GMT) and continuing for 51 minutes at one second intervals.

load `kobe`

Open **Signal Multiresolution Analyzer** and load the earthquake data into the app. By default, the app creates a four-level MODWTMRA decomposition of the signal called `kobe1` using the order 4 Symlet `sym4`. Click the **Sample Rate** radio button so that plots are with respect to time.

Create a new six-level decomposition using the order 4 Coiflet. Click **Duplicate** in the toolbar. Since `kobe1` is the currently selected item in **Decomposed Signals**, a duplicate of the first decomposition is created. The duplicate is called `kobe1Copy`. The plots in **Reconstruction** are updated to include the new decomposition. Except for the color, the duplicate will be identical with the first decomposition. You can change the name of the duplicate by right-clicking on the name in **Decomposed Signals**.

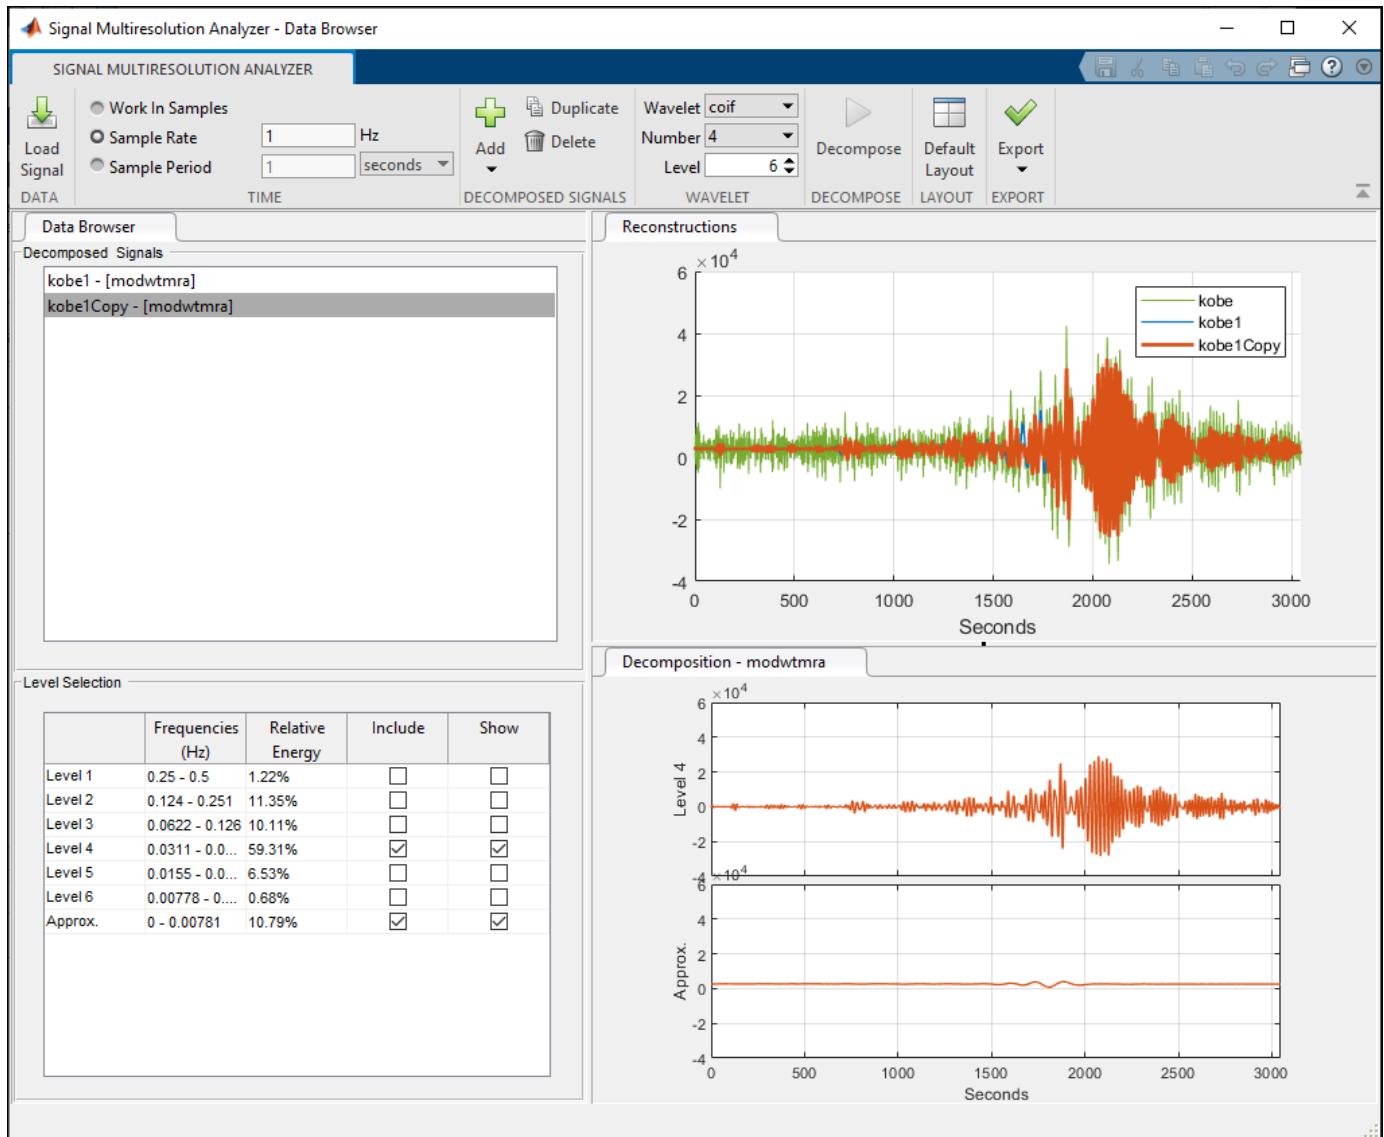

Change the settings in the toolbar to the following values and then click **Decompose**.

- **Wavelet:** `coif`
- **Number:** 4
- **Level:** 6

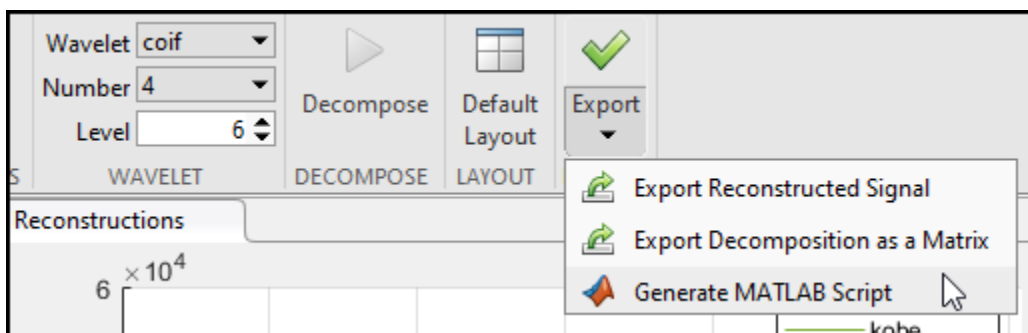

In **Level Selection**, note which components of the decomposition are included in the reconstruction: the approximation and the level 5 and level 6 details.

Level Selection				
	Frequencies (Hz)	Relative Energy	Include	Show
Level 1	0.25 - 0.5	1.22%	<input type="checkbox"/>	<input checked="" type="checkbox"/>
Level 2	0.124 - 0.251	11.35%	<input type="checkbox"/>	<input checked="" type="checkbox"/>
Level 3	0.0622 - 0.126	10.11%	<input type="checkbox"/>	<input checked="" type="checkbox"/>
Level 4	0.0311 - 0.0...	59.31%	<input type="checkbox"/>	<input checked="" type="checkbox"/>
Level 5	0.0155 - 0.0...	6.53%	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>
Level 6	0.00778 - 0....	0.68%	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>
Approx.	0 - 0.00781	10.79%	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>

Level 4 has approximately 60% of the total energy. Remove levels 5 and 6 from the reconstruction, and instead include level 4. Show only the approximation and level 4 details in the **Decomposition** pane. To approximately align the decomposition with the reconstruction, drag the **Decomposition** pane beneath the **Reconstructions** pane.

You have three export options. You can export the reconstruction or the entire decomposition to your workspace, or you can create a MATLAB™ script. To generate a script, click **Export > Generate MATLAB Script**.

An untitled script opens in your editor with the following executable code:

```
% Logical array for selecting reconstruction elements
levelForReconstruction = [false, false, false, true, false, false, true];
% Perform the decomposition using modwt
wt = modwt(kobe, 'coif4', 6);
% Construct MRA matrix using modwtmra
mra = modwtmra(wt, 'coif4');
% Sum along selected multiresolution signals
kobe1Copy = sum(mra(levelForReconstruction,:),1);
```

The true-false values in `levelForReconstruction` correspond to which Include boxes are checked in **Level Selection**. You can save the script as is, or modify it to apply the same decomposition settings to other signals. Run the script and plot the original signal and reconstruction. Except for possibly the colors, the plot will match the `kobe1Copy` reconstruction shown in the app.

```
t = 0:numel(kobe)-1;
plot(t,kobe)
grid on
hold on
plot(t,kobe1Copy,'LineWidth',2)
xlabel('Seconds')
title('Reconstruction')
legend('Original','Reconstruction','Location','northwest')
axis tight
```

Parameters

Wavelet — Orthogonal wavelet family

`sym` (default) | `coif` | `db` | `fk`

Orthogonal wavelet family to use to generate the multiresolution analysis (default), specified as:

- `sym` — Symlets
- `coif` — Coiflets
- `db` — Daubechies wavelets
- `fk` — Fejér-Korovkin wavelets

The `Wavelet` parameter is applicable only for generating a multiresolution analysis.

For more information about the wavelets, use the `waveinfo` function. For example, to learn more about Daubechies wavelets, enter `waveinfo('db')`.

Interpolation — Interpolation method

`spline` (default) | `pchip`

Interpolation method to use for envelope construction in empirical mode decomposition, specified as one of the following:

- `spline` — Cubic spline interpolation
- `pchip` — Piecewise cubic Hermite interpolating polynomial method

The `Interpolation` parameter is applicable only for generating an empirical mode decomposition. You can change other options with the app when creating empirical mode decompositions. For more information, see `emd`.

Programmatic Use

`signalMultiresolutionAnalyzer` opens the **Signal Multiresolution Analyzer** app. Once the app initializes, import a signal for analysis by clicking **Load Signal**.

`signalMultiresolutionAnalyzer(sig)` opens the **Signal Multiresolution Analyzer** app and imports, decomposes, and plots the multiresolution analysis of `sig` using `modwtmra` and `modwt` with the `sym4` wavelet and default settings. `sig` is a real-valued vector.

By default, the app plots the decomposition levels as functions of sample index. To plot with respect to time, you can set a sample rate or sample period using the app.

Tips

To decompose more than one signal simultaneously, you can run multiple instances of the **Signal Multiresolution Analyzer** app.

Algorithms

The **Signal Multiresolution Analyzer** uses `modwt` and `modwtmra` to generate the multiresolution analysis and `emd` to generate the empirical mode decompositions.

subset

Get new labeled signal set with subset of members

Syntax

```
lssnew = subset(lss,midxvect)
```

Description

`lssnew = subset(lss,midxvect)` returns a new labeled signal set containing the members specified in `midxvect`.

Examples

Labeled Subset

Load a labeled signal set of whale songs.

```
load whales  
lss
```

```
lss =  
  labeledSignalSet with properties:  
      Source: {2x1 cell}  
    NumMembers: 2  
  TimeInformation: "sampleRate"  
    SampleRate: 4000  
      Labels: [2x3 table]  
  Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

Create a new labeled signal set consisting of the second member of the original set.

```
lssnew = subset(lss,2)
```

```
lssnew =  
  labeledSignalSet with properties:  
      Source: {[76579x1 double]}  
    NumMembers: 1  
  TimeInformation: "sampleRate"  
    SampleRate: 4000  
      Labels: [1x3 table]  
  Description: "Characterize wave song regions"
```

Use `labelDefinitionsHierarchy` to see a list of labels and sublabels.
Use `setLabelValue` to add data to the set.

Input Arguments

lss — Labeled signal set

labeledSignalSet object

Labeled signal set, specified as a labeledSignalSet object.

Example: `labeledSignalSet({randn(100,1)
randn(10,1)}, signalLabelDefinition('female'))` specifies a two-member set of random signals containing the attribute 'female'.

midxvect — Subset member row numbers

vector of positive integers

Subset member row numbers, specified as a vector of positive integers. Each element of `midxvect` specifies a member row number as it appears in the “Labels” on page 1-0 table of the labeledSignalSet object `lss`.

Example: `[2 3 5 7 11 13 17]` chooses a subset of signals indexed by prime numbers.

Output Arguments

lssnew — New labeled signal set

labeledSignalSet object

New labeled signal set, returned as a labeledSignalSet object.

swt

Discrete stationary wavelet transform 1-D

Syntax

```
SWC = swt(X,N,'wname')  
SWC = swt(X,N,Lo_D,Hi_D)  
[SWA,SWD] = swt( ___ )
```

Description

swt performs a multilevel 1-D stationary wavelet decomposition using either an orthogonal or a biorthogonal wavelet. Specify the wavelet using its name (*'wname'*, see *wfilters* for more information) or its decomposition filters.

`SWC = swt(X,N,'wname')` computes the stationary wavelet decomposition of the signal *X* at level *N*, using *'wname'*.

N must be a strictly positive integer (see *wmaxlev* for more information) and `length(X)` must be a multiple of 2^N .

`SWC = swt(X,N,Lo_D,Hi_D)` computes the stationary wavelet decomposition as above, given these filters as input:

- *Lo_D* is the decomposition low-pass filter.
- *Hi_D* is the decomposition high-pass filter.

Lo_D and *Hi_D* must be the same length.

The output matrix *SWC* contains the vectors of coefficients stored row-wise:

For $1 \leq i \leq N$, the output matrix `SWC(i,:)` contains the detail coefficients of level *i* and `SWC(N+1,:)` contains the approximation coefficients of level *N*.

`[SWA,SWD] = swt(___)` computes approximations, *SWA*, and details, *SWD*, stationary wavelet coefficients.

The vectors of coefficients are stored row-wise:

For $1 \leq i \leq N$, the output matrix `SWA(i,:)` contains the approximation coefficients of level *i* and the output matrix `SWD(i,:)` contains the detail coefficients of level *i*.

Note swt is defined using periodic extension. The length of the approximation and detail coefficients computed at each level equals the length of the signal.

Examples

Multilevel Stationary Wavelet Decomposition

Perform a multilevel stationary wavelet decomposition of a signal.

Load a one-dimensional signal and acquire its length.

```
load noisbloc
s = noisbloc;
sLen = length(s);
```

Perform a stationary wavelet decomposition at level 3 of the signal using 'db1'. Extract the detail and approximation coefficients at level 3.

```
[swa,swd] = swt(s,3,'db1');
swd3 = swd(3,:);
swa3 = swa(3,:);
```

Plot the output of the decomposition.

```
plot(s)
xlim([0 sLen])
title('Original Signal')
```

Plot the level 3 approximation and detail coefficients.

```
subplot(2,1,1)
plot(swa3)
xlim([0 sLen])
```

```

title('Level 3 Approximation coefficients')
subplot(2,1,2)
plot(swd3)
xlim([0 sLen])
title('Level 3 Detail coefficients')

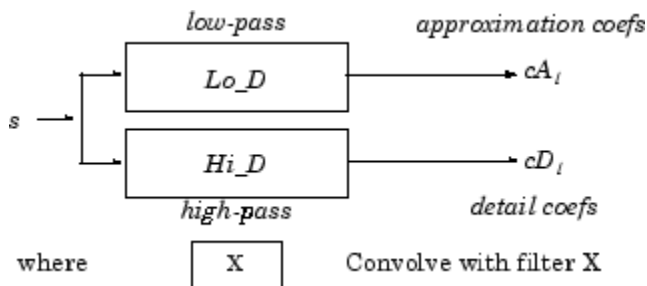

```

Algorithms

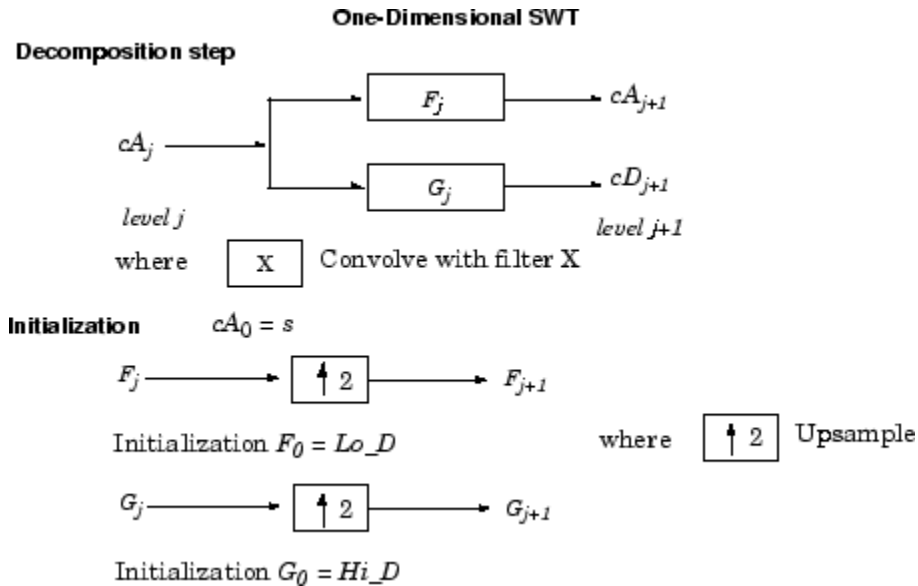

Given a signal s of length N , the first step of the SWT produces, starting from s , two sets of coefficients: approximation coefficients cA_1 and detail coefficients cD_1 . These vectors are obtained by convolving s with the low-pass filter Lo_D for approximation, and with the high-pass filter Hi_D for detail.

More precisely, the first step is

Note cA_1 and cD_1 are of length N instead of $N/2$ as in the DWT case.

The next step splits the approximation coefficients cA_1 in two parts using the same scheme, but with modified filters obtained by upsampling the filters used for the previous step and replacing s by cA_1 . Then, the SWT produces cA_2 and cD_2 . More generally,

dwt | iswt | modwt | wavedec

Introduced before R2006a

swt2

Discrete stationary wavelet transform 2-D

Syntax

```
SWC = swt2(X,N,'wname')
[A,H,V,D] = swt2(X,N,'wname')
SWC = swt2(X,N,Lo_D,Hi_D)
[A,H,V,D] = swt2(X,N,Lo_D,Hi_D)
```

Description

swt2 performs a multilevel 2-D stationary wavelet decomposition using either an orthogonal or a biorthogonal wavelet. Specify the wavelet using its name ('wname', see wfilters for more information) or its decomposition filters.

SWC = swt2(X,N,'wname') or [A,H,V,D] = swt2(X,N,'wname') compute the stationary wavelet decomposition of the real-valued 2-D or 3-D matrix X at level N, using 'wname'.

If X is a 3-D matrix, the third dimension of X must equal 3.

N must be a strictly positive integer (see wmaxlev for more information), and 2^N must divide size(X,1) and size(X,2).

The dimension of X and level N determine the dimensions of the outputs.

- If X is a 2-D matrix and N is greater than 1, the outputs [A,H,V,D] are 3-D arrays, which contain the coefficients:
 - For $1 \leq i \leq N$, the output matrix $A(:, :, i)$ contains the coefficients of approximation of level i.
 - The output matrices $H(:, :, i)$, $V(:, :, i)$ and $D(:, :, i)$ contain the coefficients of details of level i (horizontal, vertical, and diagonal):

$$SWC = [H(:, :, 1:N) ; V(:, :, 1:N) ; D(:, :, 1:N) ; A(:, :, N)]$$
- If X is a 2-D matrix and N is equal to 1, the outputs [A,H,V,D] are 2-D arrays where A contains the approximation coefficients, and H, V, and D contain the horizontal, vertical, and diagonal detail coefficients, respectively.
- If X is a 3-D matrix of dimension m-by-n-by-3, and N is greater than 1, the outputs [A,H,V,D] are 4-D arrays of dimension m-by-n-by-3-by-N, which contain the coefficients:
 - For $1 \leq i \leq N$ and $j = 1, 2, 3$, the output matrix $A(:, :, j, i)$ contains the coefficients of approximation of level i.
 - The output matrices $H(:, :, j, i)$, $V(:, :, j, i)$ and $D(:, :, j, i)$ contain the coefficients of details of level i (horizontal, vertical, and diagonal):

$$SWC = [H(:, :, 1:3, 1:N) ; V(:, :, 1:3, 1:N) ; D(:, :, 1:3, 1:N) ; A(:, :, 1:3, N)]$$
- If X is a 3-D matrix of dimension m-by-n-by-3, and N is equal to 1, the outputs [A,H,V,D] are 4-D arrays of dimension m-by-n-by-1-by-3, which contain the coefficients:

- For $j = 1, 2, 3$, the output matrix $A(:, :, 1, j)$ contains the approximation coefficients.
- The output matrices $H(:, :, 1, j)$, $V(:, :, 1, j)$ and $D(:, :, 1, j)$ contain the horizontal, vertical, and diagonal detail coefficients, respectively.

$$SWC = [H(:, :, 1, 1:3) ; V(:, :, 1, 1:3) ; D(:, :, 1, 1:3) ; A(:, :, 1, 1:3)]$$

Note

- `swt2` uses double-precision arithmetic internally and returns double-precision coefficient matrices. `swt2` warns if there is a loss of precision when converting to double.
- To distinguish a single-level decomposition of a truecolor image from a multilevel decomposition of an indexed image, the approximation and detail coefficient arrays of truecolor images are 4-D arrays. See “Distinguish Single-Level Truecolor Image from Multilevel Indexed Image Decompositions” on page 1-1040. Also see examples “Stationary Wavelet Transform of an Image” on page 1-1032 and “Inverse Stationary Wavelet Transform of an Image” on page 1-1036.

If an K -level decomposition is performed, the dimensions of the A , H , V , and D coefficient arrays are m -by- n -by-3-by- K .

If a single-level decomposition is performed, the dimensions of the A , H , V , and D coefficient arrays are m -by- n -by-1-by-3. Since MATLAB removes singleton last dimensions by default, the third dimension of the coefficient arrays is singleton.

`SWC = swt2(X,N,Lo_D,Hi_D)` or `[A,H,V,D] = swt2(X,N,Lo_D,Hi_D)`, computes the stationary wavelet decomposition as in the previous syntax, given these filters as input:

- `Lo_D` is the decomposition low-pass filter.
- `Hi_D` is the decomposition high-pass filter.

`Lo_D` and `Hi_D` must be the same length.

Note `swt2` is defined using periodic extension. The size of the approximation and details coefficients computed at each level equals the size of the input data.

Examples

Extract and Display Two-Dimensional Stationary Wavelet Decomposition

Extract and display images of the stationary wavelet decomposition level coefficients. First load and display the original image. Then perform the stationary wavelet decomposition of the image at level 2 using `db6`.

```
load woman
imagesc(X)
colormap(map)
title('Original')
```

```
[ca, chd, cvd, cdd] = swt2(X, 2, 'db6');
```

Extract the Level 1 and Level 2 approximation and detail coefficients from the decomposition.

```
A1 = wcodemat(ca(:, :, 1), 255);
H1 = wcodemat(chd(:, :, 1), 255);
V1 = wcodemat(cvd(:, :, 1), 255);
D1 = wcodemat(cdd(:, :, 1), 255);
```

```
A2 = wcodemat(ca(:, :, 2), 255);
H2 = wcodemat(chd(:, :, 2), 255);
V2 = wcodemat(cvd(:, :, 2), 255);
D2 = wcodemat(cdd(:, :, 2), 255);
```

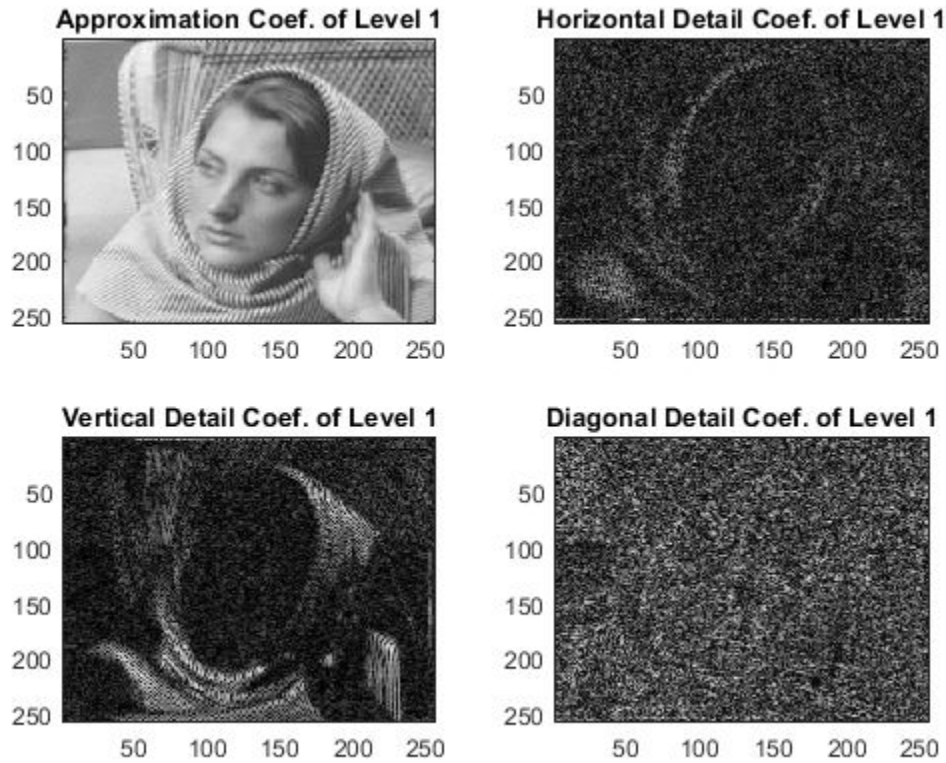

Display the approximation and detail coefficients from the two levels.

```
subplot(2,2,1)
imagesc(A1)
title('Approximation Coef. of Level 1')

subplot(2,2,2)
imagesc(H1)
title('Horizontal Detail Coef. of Level 1')

subplot(2,2,3)
imagesc(V1)
title('Vertical Detail Coef. of Level 1')
```

```
subplot(2,2,4)
imagesc(D1)
title('Diagonal Detail Coef. of Level 1')
```

```
subplot(2,2,1)
imagesc(A2)
title('Approximation Coef. of Level 2')
```

```
subplot(2,2,2)
imagesc(H2)
title('Horizontal Detail Coef. of Level 2')
```

```
subplot(2,2,3)
imagesc(V2)
title('Vertical Detail Coef. of Level 2')
```

```
subplot(2,2,4)
imagesc(D2)
title('Diagonal Detail Coef. of Level 2')
```

Stationary Wavelet Transform of an Image

In this example you obtain single-level and multilevel stationary wavelet decompositions of a truecolor image. You view results of each decomposition.

Load in a truecolor image. The image is a 3-D array of type `uint8`. Since `swt2` requires the first and second dimensions both be divisible by a power of 2, extract a portion of the image and view it.

```
imdata = imread('ngc6543a.jpg');  
x = imdata(1:512,1:512,:);  
imagesc(x)
```

Obtain the 4-level stationary wavelet decomposition of the image using the db4 wavelet. Return the approximation coefficients and the horizontal, vertical, and detail coefficients as separate arrays. Note the dimensions of the output arrays.

```
[a,h,v,d] = swt2(x,4,'db4');  
size(a)
```

```
ans = 1×4
```

```
512 512 3 4
```

```
size(h)
```

```
ans = 1×4
```

```
512 512 3 4
```

```
size(v)
```

```
ans = 1×4
```

```
512 512 3 4
```

```
size(d)
```

```
ans = 1×4
```

```
512 512 3 4
```

The output arrays are all of type `double`. View the level 2 approximation coefficients. Since the approximation coefficients are of type `double`, cast them as `uint8`, which is the datatype of the image.

```
figure
imagesc(uint8(a(:,:,2)))
title('Level 2 Approximation Coefficients')
```

Reconstruct the image by performing the inverse transform. Compute the difference between the original image and reconstruction. Since the reconstruction is of type `double`, cast the reconstruction as type `uint8` before computing the difference.

```
rec = iswt2(a,h,v,d,'db4');
maxdiff = max(abs(uint8(rec(:))-x(:)));
disp(['maximum difference = ' num2str(maxdiff)])
```

```
maximum difference = 0
```

Obtain the single-level stationary wavelet decomposition of the image using the `db4` wavelet. Return the approximation coefficients and horizontal, vertical, and detail coefficients in separate arrays. Note the dimensions of the output arrays.

```
[a,h,v,d] = swt2(x,1,'db4');
size(a)
```

```
ans = 1×4
    512    512     1     3
```

```
size(h)
```

```
ans = 1×4
    512    512     1     3
```

```
size(v)
```

```
ans = 1×4
    512    512     1     3
```

```
size(d)
```

```
ans = 1×4
    512    512     1     3
```

View the approximation coefficients. To prevent an error when using `imagesc`, squeeze the approximation coefficients array to remove the singleton dimension.

```
asqueeze = squeeze(a);
size(asqueeze)
```

```
ans = 1×3
    512    512     3
```

```
figure
imagesc(uint8(asqueeze))
title('Approximation Coefficients')
```

Reconstruct the image by performing the inverse transform. Compute the difference between the original image and reconstruction. Since the reconstruction is of type `double`, cast the reconstruction as type `uint8` before computing the difference.

```
rec = iswt2(a,h,v,d,'db4');
maxdiff = max(abs(uint8(rec(:))-x(:)));
disp(['maximum difference = ' num2str(maxdiff)])

maximum difference = 0
```

Inverse Stationary Wavelet Transform of an Image

This example shows how to reconstruct a truecolor image from a single-level stationary wavelet decomposition using 3-D approximation and detail coefficient arrays.

Load in a truecolor image. The image is a 3-D array of type `uint8`. Since `swt2` requires the first and second dimensions both be divisible by a power of 2, extract a portion of the image and view it.

```
imdata = imread('ngc6543a.jpg');
x = imdata(1:512,1:512,:);
imagesc(x)
```

Obtain the single-level stationary wavelet decomposition of the image using the db4 wavelet. Return the approximation coefficients and horizontal, vertical, and detail coefficients in separate arrays. Note the dimensions of the output arrays.

```
[a,h,v,d] = swt2(x,1,'db4');  
size(a)
```

```
ans = 1×4
```

```
512 512 1 3
```

```
size(h)
```

```
ans = 1×4
```

```
512 512 1 3
```

```
size(v)
```

```
ans = 1×4
```

```
512 512 1 3
```

```
size(d)
```

```
ans = 1×4
```

```
512 512 1 3
```

Squeeze the coefficient arrays to remove their singleton dimensions. Note the dimensions of the squeezed arrays.

```
asq = squeeze(a);  
hsq = squeeze(h);  
vsq = squeeze(v);  
dsq = squeeze(d);  
size(asq)
```

```
ans = 1×3
```

```
512 512 3
```

```
size(hsq)
```

```
ans = 1×3
```

```
512 512 3
```

```
size(vsq)
```

```
ans = 1×3
```

```
512 512 3
```

```
size(dsq)
```

```
ans = 1×3
```

```
512 512 3
```

So that `iswt2` can properly reconstruct the true image from the new coefficient arrays, insert a singleton dimension by reshaping the squeezed arrays. Reconstruct the image with the reshaped coefficient arrays.

```
a2 = reshape(asq, [512,512,1,3]);  
h2 = reshape(hsq, [512,512,1,3]);  
v2 = reshape(vsq, [512,512,1,3]);  
d2 = reshape(dsq, [512,512,1,3]);  
rec = iswt2(a2,h2,v2,d2, 'db4');
```

Compute the difference between the original image and reconstruction. Since the reconstruction is of type `double`, cast the reconstruction as type `uint8` before computing the difference.

```
maxdiff = max(abs(uint8(rec(:))-x(:)));  
disp(['maximum difference = ' num2str(maxdiff)])
```

```
maximum difference = 0
```

Tips

When X represents an indexed image, X is an m -by- n matrix. If the level of decomposition N is greater than 1, the output arrays SWC or cA , cH , cV , and cD are m -by- n -by- N arrays. If the level of decomposition N is equal to 1, the output arrays SWC or cA , cH , cV , and cD are m -by- n arrays.

When X represents a truecolor image, it becomes an m -by- n -by-3 array. This array is an m -by- n -by-3 array, where each m -by- n matrix represents a red, green, or blue color plane concatenated along the third dimension. If the level of decomposition N is greater than 1, the output arrays SWC or cA , cH , cV , and cD are m -by- n -by-3-by- N . If the level of decomposition N is equal to 1, the output arrays SWC or cA , cH , cV , and cD are m -by- n -by-1-by-3.

For more information on image formats, see the `image` and `imfinfo` reference pages.

Algorithms

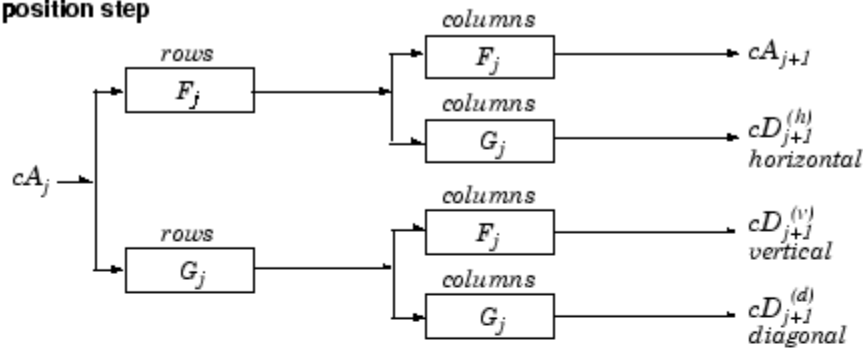

For images, an algorithm similar to the one-dimensional case is possible for two-dimensional wavelets and scaling functions obtained from one-dimensional ones by tensor product.

This kind of two-dimensional SWT leads to a decomposition of approximation coefficients at level j in four components: the approximation at level $j+1$, and the details in three orientations (horizontal, vertical, and diagonal).

The following chart describes the basic decomposition step for images:

Two-Dimensional SWT

Decomposition step

where

$\begin{matrix} \text{rows} \\ \boxed{X} \end{matrix}$ Convolve with filter X the rows of the entry

$\begin{matrix} \text{columns} \\ \boxed{X} \end{matrix}$ Convolve with filter X the columns of the entry

Initialization $cA_0 = s$ for the decomposition initialization

Initialization $F_0 = Lo_D$

where $\begin{matrix} \uparrow \\ \boxed{2} \end{matrix}$ Upsample

Initialization $G_0 = Hi_D$

Note $size(cA_j) = size(cD_j^{(h)}) = size(cD_j^{(v)}) = size(cD_j^{(d)}) = s$

where $s = size\ of\ the\ analyzed\ image$

Compatibility Considerations

Distinguish Single-Level Truecolor Image from Multilevel Indexed Image Decompositions

Behavior changed in R2017b

To distinguish a single-level decomposition of a truecolor image from a multilevel decomposition of an indexed image, the approximation and detail coefficient arrays of truecolor images are 4-D arrays.

Migrate from Previous Releases to R2017b

Depending on the original input data type and level of wavelet decomposition, you might have to take different steps to make swt2 coefficient arrays from previous releases compatible with R2017b coefficient arrays. The steps depend on whether you have a single coefficient array or separate approximation and detail coefficient arrays.

Single Coefficient Array	Multiple Coefficient Arrays
Input: Index image <ul style="list-style-type: none"> • Single-level: No compatibility issues • Multi-level: No compatibility issues 	Input: Index image <ul style="list-style-type: none"> • Single-level: No compatibility issues • Multi-level: No compatibility issues
Input: Truecolor image <ul style="list-style-type: none"> • Single-level: If swc is the output of swt2 from a previous release, execute: <code>swc1 = double(swc);</code> • Multi-level: If swc is the output of swt2 from a previous release, execute: <code>swc1 = double(swc);</code> 	Input: Truecolor image <ul style="list-style-type: none"> • Single-level: If ca, chd, cvd, and cdd are outputs of swt2 from a previous release, execute: <code>ca1 = double(ca);</code> <code>chd1 = double(chd);</code> <code>cvd1 = double(cvd);</code> <code>cdd1 = double(cdd);</code> <code>ca2 = reshape(ca1, [m,n,1,3]);</code> <code>chd2 = reshape(chd1, [m,n,1,3]);</code> <code>cvd2 = reshape(cvd1, [m,n,1,3]);</code> <code>cdd2 = reshape(cdd1, [m,n,1,3]);</code> • Multi-level: If ca, chd, cvd, and cdd are outputs of swt2 from a previous release, execute: <code>ca1 = double(ca);</code> <code>chd1 = double(chd);</code> <code>cvd1 = double(cvd);</code> <code>cdd1 = double(cdd);</code>

Migrate from R2017b to Previous Releases

Depending on the original input data type and level of wavelet decomposition, you might have to take different steps to make R2017b swt2 coefficient arrays compatible with the coefficient arrays from previous releases. The steps depend on whether you have a single coefficient array or separate approximation and detail coefficient arrays.

Single Coefficient Array	Multiple Coefficient Arrays

Introduced before R2006a

symaux

Symlet wavelet filter computation

Syntax

```
w = symaux(n)
w = symaux( ____, sumw)
```

Description

The `symaux` function generates the scaling filter coefficients for the "least asymmetric" Daubechies wavelets.

`w = symaux(n)` is the order n Symlet scaling filter such that $\text{sum}(w) = 1$.

Note

- Instability may occur when n is too large. Starting with values of n in the 30s range, function output will no longer accurately represent scaling filter coefficients.
 - As n increases, the time required to compute the filter coefficients rapidly grows.
 - For $n = 1, 2,$ and 3 , the order n Symlet filters and order n Daubechies filters are identical. See "Extremal Phase" on page 1-1055.
-

`w = symaux(____, sumw)` is the order n Symlet scaling filter such that $\text{sum}(w) = \text{sumw}$.

`w = symaux(n, 0)` is equivalent to `w = symaux(n, 1)`.

Examples

Unit Norm Scaling Filter Coefficients

In this example you will generate symlet scaling filter coefficients whose norm is equal to 1. You will also confirm the coefficients satisfy a necessary relation.

Compute the scaling filter coefficients of the order 10 symlet whose sum equals $\sqrt{2}$.

```
n = 10;
w = symaux(n, sqrt(2));
```

Confirm the sum of the coefficients is equal to $\sqrt{2}$ and the norm is equal to 1.

```
sqrt(2) - sum(w)
```

```
ans = 0
```

```
1 - sum(w.^2)
```

```
ans = 1.1324e-14
```

Since integer translations of the scaling function form an orthogonal basis, the coefficients satisfy the relation $\sum_n w(n)w(n-2k) = \delta(k)$. Confirm this by taking the autocorrelation of the coefficients and plotting the result.

```
corrw = xcorr(w,w);
stem(corrw)
grid on
title('Autocorrelation of scaling coefficients')
```

```
stem(corrw(2:2:end))
grid on
title('Even-indexed autocorrelation values')
```

Symlet and Daubechies Scaling Filters

This example shows that symlet and Daubechies scaling filters of the same order are both solutions of the same polynomial equation.

Generate the order 4 Daubechies scaling filter and plot it.

```
wdb4 = dbaux(4)
```

```
wdb4 = 1×8
```

```
0.1629    0.5055    0.4461   -0.0198   -0.1323    0.0218    0.0233   -0.0075
```

```
stem(wdb4)
```

```
title('Order 4 Daubechies Scaling Filter')
```

wdb4 is a solution of the equation: $P = \text{conv}(\text{wrev}(w), w) * 2$, where P is the "Lagrange trous" filter for $N = 4$. Evaluate P and plot it. P is a symmetric filter and wdb4 is a minimum phase solution of the previous equation based on the roots of P.

```
P = conv(wrev(wdb4), wdb4) * 2;  
stem(P)  
title('Lagrange trous' filter')
```

Generate `wsym4`, the order 4 symlet scaling filter and plot it. The Symlets are the "least asymmetric" Daubechies' wavelets obtained from another choice between the roots of P .

```
wsym4 = symaux(4)
```

```
wsym4 = 1×8
```

```
0.0228 -0.0089 -0.0702 0.2106 0.5683 0.3519 -0.0210 -0.0536
```

```
stem(wsym4)
```

```
title('Order 4 Symlet Scaling Filter')
```

Compute `conv(wrev(wsym4),wsym4)*2` and confirm that `wsym4` is another solution of the equation $P = \text{conv}(wrev(w),w)*2$.

```
P_sym = conv(wrev(wsym4),wsym4)*2;
err = norm(P_sym-P)
```

```
err = 1.8677e-15
```

Least Asymmetric Wavelet and Phase

For a given support, the orthogonal wavelet with a phase response that most closely resembles a linear phase filter is called least asymmetric. Symlets are examples of least asymmetric wavelets. They are modified versions of the classic Daubechies db wavelets. In this example you will show that the order 4 symlet has a nearly linear phase response, while the order 4 Daubechies wavelet does not.

First plot the order 4 symlet and order 4 Daubechies scaling functions. While neither is perfectly symmetric, note how much more symmetric the symlet is.

```
[phi_sym,~,xval_sym]=wavefun('sym4',10);
[phi_db,~,xval_db]=wavefun('db4',10);
subplot(2,1,1)
plot(xval_sym,phi_sym)
title('sym4 - Scaling Function')
```

```

grid on
subplot(2,1,2)
plot(xval_db,phi_db)
title('db4 - Scaling Function')
grid on

```

Generate the filters associated with the order 4 symlet and Daubechies wavelets.

```

scal_sym = symaux(4,sqrt(2));
scal_db = dbaux(4,sqrt(2));

```

Compute the frequency response of the scaling synthesis filters.

```

[h_sym,w_sym] = freqz(scal_sym);
[h_db,w_db] = freqz(scal_db);

```

To avoid visual discontinuities, unwrap the phase angles of the frequency responses and plot them. Note how well the phase angle of the symlet filter approximates a straight line.

```

h_sym_u = unwrap(angle(h_sym));
h_db_u = unwrap(angle(h_db));
figure
plot(w_sym/pi,h_sym_u, '.')
hold on
plot(w_sym([1 end])/pi,h_sym_u([1 end]), 'r')
grid on
xlabel('Normalized Frequency ( x \pi rad/sample)')
ylabel('Phase (radians)')

```

```

legend('Phase Angle of Frequency Response','Straight Line')
title('Symlet Order 4 - Phase Angle')

```

```

figure
plot(w_db/pi,h_db_u,'.')
hold on
plot(w_db([1 end])/pi,h_db_u([1 end]),'r')
grid on
xlabel('Normalized Frequency ( x \pi rad/sample)')
ylabel('Phase (radians)')
legend('Phase Angle of Frequency Response','Straight Line')
title('Daubechies Order 4 - Phase Angle')

```

The sym4 and db4 wavelets are not symmetric, but the biorthogonal wavelet is. Plot the scaling function associated with the bior3.5 wavelet. Compute the frequency response of the synthesis scaling filter for the wavelet and verify that it has linear phase.

```
[~,~,phi_bior_r,~,xval_bior]=wavefun('bior3.5',10);
figure
plot(xval_bior,phi_bior_r)
title('bior3.5 - Scaling Function')
grid on
```

```
[LoD_bior,HiD_bior,LoR_bior,HiR_bior] = wfilters('bior3.5');  
[h_bior,w_bior] = freqz(LoR_bior);  
h_bior_u = unwrap(angle(h_bior));  
figure  
plot(w_bior/pi,h_bior_u, '.')  
hold on  
plot(w_bior([1 end])/pi,h_bior_u([1 end]), 'r')  
grid on  
xlabel('Normalized Frequency ( x \pi rad/sample)')  
ylabel('Phase (radians)')  
legend('Phase Angle of Frequency Response','Straight Line')  
title('Biorthogonal 3.5 - Phase Angle')
```

Extremal Phase

This example demonstrates that for a given support, the cumulative sum of the squared coefficients of a scaling filter increase more rapidly for an extremal phase wavelet than other wavelets.

Generate the scaling filter coefficients for the db15 and sym15 wavelets. Both wavelets have support of width $2 \times 15 - 1 = 29$.

```
[~,~,LoR_db,~] = wfilters('db15');
[~,~,LoR_sym,~] = wfilters('sym15');
```

Next, generate the scaling filter coefficients for the coif5 wavelet. This wavelet also has support of width $6 \times 5 - 1 = 29$.

```
[~,~,LoR_coif,~] = wfilters('coif5');
```

Confirm the sum of the coefficients for all three wavelets equals $\sqrt{2}$.

```
sqrt(2) - sum(LoR_db)
```

```
ans = 2.2204e-16
```

```
sqrt(2) - sum(LoR_sym)
```

```
ans = 0
```

```
sqrt(2)-sum(LoR_coif)
```

```
ans = 2.2204e-16
```

Plot the cumulative sums of the squared coefficients. Note how rapidly the Daubechies sum increases. This is because its energy is concentrated at small abscissas. Since the Daubechies wavelet has extremal phase, the cumulative sum of its squared coefficients increases more rapidly than the other two wavelets.

```
plot(cumsum(LoR_db.^2), 'rx-')
hold on
plot(cumsum(LoR_sym.^2), 'mo-')
plot(cumsum(LoR_coif.^2), 'b*-')
legend('Daubechies', 'Symlet', 'Coiflet')
title('Cumulative Sum')
```

Input Arguments

n — Order of symlet

positive integer

Order of the symlet, specified as a positive integer.

sumw — Sum of coefficients

1 (default) | positive real number

Sum of the scaling filter coefficients, specified as a positive real number. Set to $\sqrt{2}$ to generate vector of coefficients whose norm is 1.

Output Arguments

w — Filter coefficients

row vector

Vector of scaling filter coefficients of the order n symlet.

The scaling filter coefficients satisfy a number of properties. You can use these properties to check your results. See “Unit Norm Scaling Filter Coefficients” on page 1-1043 for additional information.

More About

Least Asymmetric Wavelet

The Haar wavelet, also known as the Daubechies wavelet of order 1, **db1**, is the only compactly supported orthogonal wavelet that is symmetric, or equivalently has linear phase. No other compactly supported orthogonal wavelet can be symmetric. However, it is possible to derive wavelets which are minimally asymmetric, meaning that their phase will be very nearly linear. For a given support, the orthogonal wavelet with a phase response that most closely resembles a linear phase filter is called least asymmetric.

Extremal Phase

Constructing a compactly supported orthogonal wavelet basis involves choosing roots of a particular polynomial equation. Different choices of roots will result in wavelets whose phases are different. Choosing roots that lie within the unit circle in the complex plane results in a filter with highly nonlinear phase. Such a wavelet is said to have extremal phase, and has energy concentrated at small abscissas. Let $\{h_k\}$ denote the set of scaling coefficients associated with an extremal phase wavelet, where $k = 1, \dots, M$. Then for any other set of scaling coefficients $\{g_k\}$ resulting from a different choice of roots, the following inequality will hold for all $J = 1, \dots, M$:

$$\sum_{k=1}^J g_k^2 \leq \sum_{k=1}^J h_k^2$$

The $\{h_k\}$ are sometimes called a *minimal delay filter* [2].

The polynomial equation mentioned above depends on the desired number of vanishing moments N for the wavelet. To construct a wavelet basis involves choosing roots of the equation. In the case of least asymmetric wavelets and extremal phase wavelets for orders 1, 2, and 3, there are effectively no choices to make. For $N = 1, 2,$ and 3 , the **dbN** and **symN** filters are equal. The example “Symlet and Daubechies Scaling Filters” on page 1-1045 shows that two different scaling filters can satisfy the same polynomial equation. For additional information, see Daubechies [1].

`symaux` | `waveinfo`

Introduced before R2006a

thselect

Threshold selection for denoising

Syntax

```
THR = thselect(X,TPTR)
```

Description

`THR = thselect(X,TPTR)` returns the threshold value adapted to the 1-D signal `X` using the selection rule specified by `TPTR`. Available selection rules are:

- `'rigrsure'` — Adaptive threshold selection using the principle of Stein's Unbiased Risk Estimate (SURE).
- `'sqrtwolog'` — Fixed-form threshold is $\sqrt{2 \cdot \log(\text{length}(X))}$.
- `'heursure'` — Heuristic variant of `'rigrsure'` and `'sqrtwolog'`.
- `'minimaxi'` — Minimax thresholding.

Examples

Threshold Selection Rules

Generate a Gaussian white noise signal. For reproducibility, set the random seed to the default value.

```
rng default
x = randn(1,1000);
```

Find the threshold for each selection rule.

```
thrRig = thselect(x,'rigrsure');
disp(['SURE (''rigrsure'') threshold: ',num2str(thrRig)]);

SURE (''rigrsure'') threshold: 2.0518

thrSqt = thselect(x,'sqrtwolog');
disp(['Universal (''sqrtwolog'') threshold: ',num2str(thrSqt)]);

Universal (''sqrtwolog'') threshold: 3.7169

thrHeu = thselect(x,'heursure');
disp(['Heuristic variant (''heursure'') threshold: ',num2str(thrHeu)]);

Heuristic variant (''heursure'') threshold: 3.7169

thrMin = thselect(x,'minimaxi');
disp(['Minimax (''minimaxi'') threshold: ',num2str(thrMin)]);

Minimax (''minimaxi'') threshold: 2.2163
```

Minimax and SURE threshold selection rules are more conservative and would be more convenient when small details of the signal lie near the noise range.

Input Arguments

X — Input data

real-valued vector

Input data, specified as a real-valued vector.

Data Types: double

TPTR — Threshold selection rule

'rigrsure' | 'heursure' | 'sqtwo log' | 'minimaxi'

Threshold selection rule, specified:

- 'rigrsure' — A threshold selection rule based on SURE (a quadratic loss function) for the soft threshold estimator. Starting with an estimate of risk for a particular threshold value, t , the algorithm minimizes the risks in t to yield a threshold value.
- 'heursure' — A mixture of 'rigrsure' and 'sqtwo log'. If the signal-to-noise ratio is small, the SURE estimate is noisy. In that case, the fixed-form threshold is used.
- 'sqtwo log' — A fixed-form (universal) threshold yielding minimax performance multiplied by a small factor proportional to $\log(\text{length}(X))$.
- 'minimaxi' — A fixed threshold chosen to yield minimax performance for mean square error against an ideal procedure. The minimax principle is used in statistics to design estimators. The denoised signal can be assimilated to the estimator of the unknown regression function. Therefore, the minimax estimator realizes the minimum of the maximum mean square error obtained for the worst function in a given set.

Threshold selection rules are based on the underlying model $y = f(t) + e$, where e is an $N(0,1)$ white noise. Use level-dependent noise estimates for unscaled or nonwhite noise. (See `NoiseEstimate` parameter in `wdenoise` for more information.)

Output Arguments

THR — Threshold

positive real number

Threshold value adapted to X , returned as a positive real number.

N = tnodes(T, 'deppos')
[N,K] = tnodes(T)
[N,K] = tnodes(T, 'deppos'), M = N(K)
```

Description

tnodes is a tree-management utility.

$N = \text{tnodes}(T)$ returns the indices of terminal nodes of the tree T . N is a column vector.

The nodes are numbered from left to right and from top to bottom. The root index is 0.

$N = \text{tnodes}(T, 'deppos')$ returns a matrix N , which contains the depths and positions of terminal nodes.

$N(i, 1)$ is the depth of the i -th terminal node. $N(i, 2)$ is the position of the i -th terminal node.

For $[N,K] = \text{tnodes}(T)$ or $[N,K] = \text{tnodes}(T, 'deppos')$, $M = N(K)$ are the indices reordered as in tree T , from left to right.

Examples

```
% Create initial tree.
ord = 2;
t = ntree(ord,3);      % Binary tree of depth 3.
t = nodejoin(t,5);
t = nodejoin(t,4);
plot(t)
```

```
% Change Node Label from Depth_Position to Index
% (see the plot function).
```

```
% List terminal nodes (index).
tnodes(t)
```

```
ans =
  4
  5
  7
  8
 13
 14
```

```
% List terminal nodes (Depth_Position).
tnodes(t,'deppos')
```

```
ans =
  2  1
  2  2
  3  0
  3  1
  3  6
  3  7
```

treedpth

Tree depth

Syntax

```
D = treedpth(T)
```

Description

`treedpth` is a tree-management utility.

`D = treedpth(T)` returns the depth `D` of the tree `T`.

Examples

```
% Create binary tree (tree of order 2) of depth 3.  
t = ntree(2,3);
```

```
% Plot tree t.  
plot(t)
```

```
% Tree depth.  
treedpth(t)
```

```
ans =  
    3
```

treeord

Tree order

Syntax

```
ORD = treeord(T)
```

Description

treeord is a tree-management utility.

ORD = treeord(*T*) returns the order ORD of the tree *T*.

Examples

```
% Create binary tree (tree of order 2) of depth 3.
t = ntree(2,3);
```

```
% Plot tree t.
plot(t)
```

```
% Tree order.

upcoef

Direct reconstruction from 1-D wavelet coefficients

Syntax

```
Y = upcoef(0,X,wname,N)
Y = upcoef(0,X,wname,N,L)
Y = upcoef(0,X,Lo_R,Hi_R,N)
Y = upcoef(0,X,Lo_R,Hi_R,N,L)
Y = upcoef(0,X,wname)
Y = upcoef(0,X,wname,1)
Y = upcoef(0,X,Lo_R,Hi_R)
Y = upcoef(0,X,Lo_R,Hi_R,1)
```

Description

upcoef is a one-dimensional wavelet analysis function.

`Y = upcoef(0,X,wname,N)` computes the N-step reconstructed coefficients of vector X.

wname is a character vector or string scalar specifying the wavelet. See `wfilters` for more information.

N must be a strictly positive integer.

If `0 = 'a'`, approximation coefficients are reconstructed.

If `0 = 'd'`, detail coefficients are reconstructed.

`Y = upcoef(0,X,wname,N,L)` computes the N-step reconstructed coefficients of vector X and takes the length-L central portion of the result.

Instead of giving the wavelet name, you can give the filters.

For `Y = upcoef(0,X,Lo_R,Hi_R,N)` or `Y = upcoef(0,X,Lo_R,Hi_R,N,L)`, `Lo_R` is the reconstruction low-pass filter and `Hi_R` is the reconstruction high-pass filter.

`Y = upcoef(0,X,wname)` is equivalent to `Y = upcoef(0,X,wname,1)`.

`Y = upcoef(0,X,Lo_R,Hi_R)` is equivalent to `Y = upcoef(0,X,Lo_R,Hi_R,1)`.

Examples

```
% The current extension mode is zero-padding (see dwtmode).
```

```
% Approximation signals, obtained from a single coefficient
% at levels 1 to 6.
```

```
cfs = [1]; % Decomposition reduced a single coefficient.
essup = 10; % Essential support of the scaling filter db6.
figure(1)
for i=1:6
```

```

% Reconstruct at the top level an approximation
% which is equal to zero except at level i where only
% one coefficient is equal to 1.
rec = upcoef('a',cfs,'db6',i);

% essup is the essential support of the
% reconstructed signal.
% rec(j) is very small when j is  $\geq$  essup.
ax = subplot(6,1,i),h = plot(rec(1:essup));
set(ax,'xlim',[1 325]);
essup = essup*2;

end
subplot(6,1,1)
title(['Approximation signals, obtained from a single ' ...
      'coefficient at levels 1 to 6'])

% Editing some graphical properties,
% the following figure is generated.

```

Approximation signals, obtained from a single coefficient at levels 1 to 6

```

% The same can be done for details.
% Details signals, obtained from a single coefficient
% at levels 1 to 6.

```

```

cfs = [1];
mi = 12; ma = 30; % Essential support of
                  % the wavelet filter db6.
rec = upcoef('d',cfs,'db6',1);
figure(2)
subplot(6,1,1), plot(rec(3:12))
for i=2:6
    % Reconstruct at top level a single detail
    % coefficient at level i.
    rec = upcoef('d',cfs,'db6',i);
    subplot(6,1,i), plot(rec(mi*2^(i-2):ma*2^(i-2)))
end

```

```
subplot(611)
title(['Detail signals obtained from a single ' ...
      'coefficient at levels 1 to 6'])
% Editing some graphical properties,
% the following figure is generated.
```

Algorithms

upcoef is equivalent to an N time repeated use of the inverse wavelet transform.

upcoef2

Direct reconstruction from 2-D wavelet coefficients

Syntax

```
Y = upcoef2(0,X,wname,N,S)
Y = upcoef2(0,X,Lo_R,Hi_R,N,S)
Y = upcoef2(0,X,wname,N)
Y = upcoef2(0,X,Lo_R,Hi_R,N)
Y = upcoef2(0,X,wname)
Y = upcoef2(0,X,wname,1)
Y = upcoef2(0,X,Lo_R,Hi_R)
Y = upcoef2(0,X,Lo_R,Hi_R,1)
```

Description

upcoef2 is a two-dimensional wavelet analysis function.

`Y = upcoef2(0,X,wname,N,S)` computes the N-step reconstructed coefficients of matrix X and takes the central part of size S. wname is a character vector or string scalar specifying the wavelet. See `wfilters` for more information.

If `0 = 'a'`, approximation coefficients are reconstructed; otherwise if `0 = 'h'` ('v' or 'd', respectively), horizontal (vertical or diagonal, respectively) detail coefficients are reconstructed. N must be a strictly positive integer.

Instead of giving the wavelet name, you can give the filters.

For `Y = upcoef2(0,X,Lo_R,Hi_R,N,S)` is the reconstruction low-pass filter and `Hi_R` is the reconstruction high-pass filter.

`Y = upcoef2(0,X,wname,N)` or `Y = upcoef2(0,X,Lo_R,Hi_R,N)` returns the computed result without any truncation.

`Y = upcoef2(0,X,wname)` is equivalent to `Y = upcoef2(0,X,wname,1)`.

`Y = upcoef2(0,X,Lo_R,Hi_R)` is equivalent to `Y = upcoef2(0,X,Lo_R,Hi_R,1)`.

Examples

```
% The current extension mode is zero-padding (see dwtmode).

% Load original image.
load woman;
% X contains the loaded image.

% Perform decomposition at level 2
% of X using db4.
[c,s] = wavedec2(X,2,'db4');
```

```
% Reconstruct approximation and details
% at level 1, from coefficients.
% This can be done using wrcoef2, or
% equivalently using:
%
% Step 1: Extract coefficients from the
% decomposition structure [c,s].
%
% Step 2: Reconstruct using upcoef2.

siz = s(size(s,1),:);

ca1 = appcoef2(c,s,'db4',1);
a1 = upcoef2('a',ca1,'db4',1,siz);

chd1 = detcoef2('h',c,s,1);
hd1 = upcoef2('h',chd1,'db4',1,siz);

cvd1 = detcoef2('v',c,s,1);
vd1 = upcoef2('v',cvd1,'db4',1,siz);

cdd1 = detcoef2('d',c,s,1);
dd1 = upcoef2('d',cdd1,'db4',1,siz);
```

upwlev

Single-level reconstruction of 1-D wavelet decomposition

Syntax

```
[NC,NL,cA] = upwlev(C,L,wname)
[NC,NL,cA] = upwlev(C,L,Lo_R,Hi_R)
```

Description

upwlev is a one-dimensional wavelet analysis function.

[NC,NL,cA] = upwlev(C,L,wname) performs the single-level reconstruction of the wavelet decomposition structure [C,L] giving the new one [NC,NL], and extracts the last approximation coefficients vector cA.

[C,L] is a decomposition at level $n = \text{length}(L) - 2$, so [NC,NL] is the same decomposition at level $n-1$ and cA is the approximation coefficients vector at level n .

wname is a character vector or string scalar specifying the wavelet, C is the original wavelet decomposition vector, and L the corresponding bookkeeping vector (for detailed storage information, see wavedec).

Instead of giving the wavelet name, you can give the filters.

For [NC,NL,cA] = upwlev(C,L,Lo_R,Hi_R), Lo_R is the reconstruction low-pass filter and Hi_R is the reconstruction high-pass filter.

Examples

```
% The current extension mode is zero-padding (see dwtmode).
```

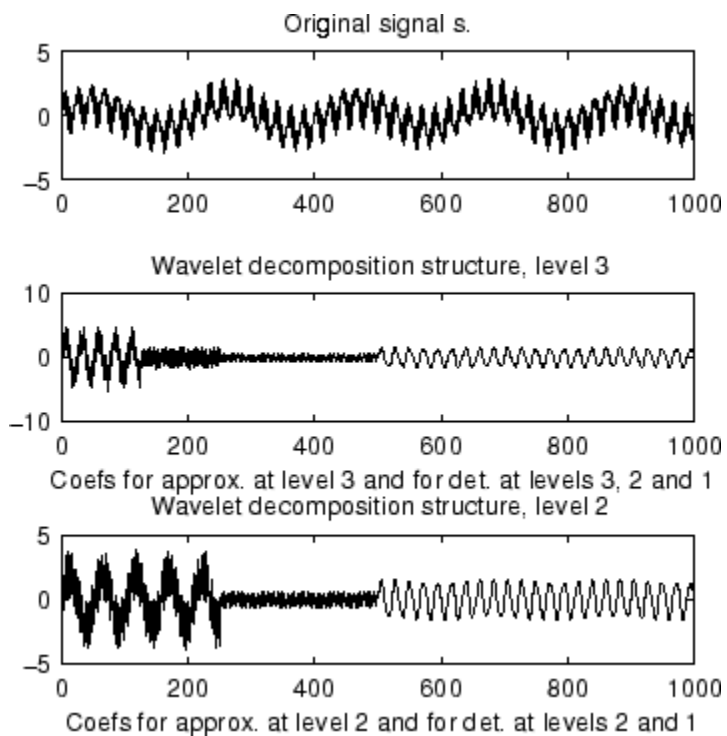

```
% Load original one-dimensional signal.
load sumsin; s = sumsin;
```

```
% Perform decomposition at level 3 of s using db1.
[c,l] = wavedec(s,3,'db1');
subplot(311); plot(s);
title('Original signal s. ');
subplot(312); plot(c);
title('Wavelet decomposition structure, level 3')
xlabel(['Coefs for approx. at level 3 ' ...
        'and for det. at levels 3, 2 and 1'])
```

```
% One step reconstruction of the wavelet decomposition
% structure at level 3 [c,l], so the new structure [nc,nl]
% is the wavelet decomposition structure at level 2.
[nc,nl] = upwlev(c,l,'db1');
subplot(313); plot(nc);
title('Wavelet decomposition structure, level 2')
xlabel(['Coefs for approx. at level 2 ' ...
```

```
'and for det. at levels 2 and 1'])

upwlev2

Single-level reconstruction of 2-D wavelet decomposition

Syntax

```
[NC,NS,cA] = upwlev2(C,S,wname)
[NC,NS,cA] = upwlev2(C,S,Lo_R,Hi_R)
```

Description

upwlev2 is a two-dimensional wavelet analysis function.

[NC,NS,cA] = upwlev2(C,S,wname) performs the single-level reconstruction of wavelet decomposition structure [C,S] giving the new one [NC,NS], and extracts the last approximation coefficients matrix cA.

[C,S] is a decomposition at level $n = \text{size}(S,1) - 2$, so [NC,NS] is the same decomposition at level $n-1$ and cA is the approximation matrix at level n .

wname is a character vector or string scalar specifying the wavelet, C is the original wavelet decomposition vector, and S the corresponding bookkeeping matrix (for detailed storage information, see wavedec2).

Instead of giving the wavelet name, you can give the filters.

For [NC,NS,cA] = upwlev2(C,S,Lo_R,Hi_R), Lo_R is the reconstruction low-pass filter and Hi_R is the reconstruction high-pass filter.

Examples

```
% The current extension mode is zero-padding (see dwtmode).
```

```
% Load original image.
load woman;
% X contains the loaded image.
```

```
% Perform decomposition at level 2
% of X using db1.

vmd

Variational mode decomposition

Syntax

```
imf = vmd(x)
[imf,residual] = vmd(x)
[imf,residual,info] = vmd(x)

[ ___ ] = vmd(x,Name,Value)

vmd( ___ )
```

Description

`imf = vmd(x)` returns the variational mode decomposition of `x`. Use `vmd` to decompose and simplify complicated signals into a finite number of intrinsic mode functions (IMFs) required to perform Hilbert spectral analysis.

`[imf,residual] = vmd(x)` also returns the residual signal `residual` corresponding to the variational mode decomposition of `x`.

`[imf,residual,info] = vmd(x)` returns additional information `info` on IMFs and the residual signal for diagnostic purposes.

`[___] = vmd(x,Name,Value)` performs the variational mode decomposition with additional options specified by one or more `Name,Value` pair arguments.

`vmd(___)` plots the original signal, IMFs, and the residual signal as subplots in the same figure.

Examples

Variational Mode Decomposition of Dial Tone Signal

Create a signal, sampled at 4 kHz, that resembles dialing all the keys of a digital telephone. Save the signal as a MATLAB® timetable.

```
fs = 4e3;
t = 0:1/fs:0.5-1/fs;

ver = [697 770 852 941];
hor = [1209 1336 1477];

tones = [];

for k = 1:length(ver)
    for l = 1:length(hor)
        tone = sum(sin(2*pi*[ver(k);hor(l)].*t))';
        tones = [tones;tone;zeros(size(tone))];
    end
end
```

end

```
% To hear, type soundsc(tones,fs)
```

```
S = timetable(seconds(0:length(tones)-1)/fs,tones);
```

Plot the variational mode decomposition of the timetable.

```
vmd(S)
```

VMD of Multicomponent Signal

Generate a multicomponent signal consisting of three sinusoids of frequencies 2 Hz, 10 Hz, and 30 Hz. The sinusoids are sampled at 1 kHz for 2 seconds. Embed the signal in white Gaussian noise of variance 0.01^2 .

```
fs = 1e3;  
t = 1:1/fs:2-1/fs;  
x = cos(2*pi*2*t) + 2*cos(2*pi*10*t) + 4*cos(2*pi*30*t) + 0.01*randn(1,length(t));
```

Compute the IMFs of the noisy signal and visualize them in a 3-D plot.

```
imf = vmd(x);  
[p,q] = ndgrid(t,1:size(imf,2));  
plot3(p,q,imf)
```

```
grid on
xlabel('Time Values')
ylabel('Mode Number')
zlabel('Mode Amplitude')
```

Use the computed IMFs to plot the Hilbert spectrum of the multicomponent signal. Restrict the frequency range to $[0, 40]$ Hz.

```
hht(imf, fs, 'FrequencyLimits', [0, 40])
```

VMD of Piecewise Signal

Generate a piecewise composite signal consisting of a quadratic trend, a chirp, and a cosine with a sharp transition between two constant frequencies at $t = 0.5$.

$$x(t) = 6t^2 + \cos(4\pi t + 10\pi t^2) + \begin{cases} \cos(60\pi t), & t \leq 0.5, \\ \cos(100\pi t - 10\pi), & t > 0.5. \end{cases}$$

The signal is sampled at 1 kHz for 1 second. Plot each individual component and the composite signal.

```
fs = 1e3;
t = 0:1/fs:1-1/fs;

x = 6*t.^2 + cos(4*pi*t+10*pi*t.^2) + ...
    [cos(60*pi*(t(t<=0.5))) cos(100*pi*(t(t>0.5))-10*pi)];

tiledlayout('flow')
nexttile
plot(t,[zeros(1,length(t)/2) cos(100*pi*(t(length(t)/2+1:end))-10*pi)])
xlabel('Time (s)')
ylabel('Cosine')

nexttile
```

```

plot(t,[cos(60*pi*(t(1:length(t)/2))) zeros(1,length(t)/2)])
xlabel('Time (s)')
ylabel('Cosine')

nexttile
plot(t,cos(4*pi*t+10*pi*t.^2))
xlabel('Time (s)')
ylabel('Chirp')

nexttile
plot(t,6*t.^2)
xlabel('Time (s)')
ylabel('Quadratic trend')

nexttile(5,[1 2])
plot(t,x)
xlabel('Time (s)')
ylabel('Signal')

```

Perform variational mode decomposition to compute four intrinsic mode functions. The four distinct components of the signal are recovered.

```

[imf,res] = vmd(x,'NumIMFs',4);

tiledlayout('flow')

for i = 1:4

```

```

nexttile
plot(t,imf(:,i))
txt = ['IMF',num2str(i)];
ylabel(txt)
xlabel('Time (s)')
grid on
end

```

Reconstruct the signal by adding the mode functions and the residual. Plot and compare the original and reconstructed signals.

```
sig = sum(imf,2) + res;
```

```
nexttile(5,[1 2])
plot(t,sig,'LineWidth',1.5)
```

```
hold on
```

```

plot(t,x,':','LineWidth',2)
xlabel('Time (s)')
ylabel('Signal')
hold off
legend('Reconstructed signal','Original signal', ...
       'Location','northwest')

```

Calculate the norm of the difference between the original and the reconstructed signals.

```
norm(x-sig',Inf)
```

```
ans = 0
```

Noise Removal from ECG Signal Using VMD

The signals labeled in this example are from the MIT-BIH Arrhythmia Database [3] (Signal Processing Toolbox). The signal in the database was sampled at 360 Hz.

Load the MIT database signals corresponding to record 200 and plot the signal.

```
load mit200
Fs = 360;
plot(tm,ecgsig)
ylabel('Time (s)')
xlabel('Signal')
```

The ECG signal contains spikes driven by the rhythm of the heartbeat and an oscillating low frequency pattern. The distinct spokes of the ECG create important higher order harmonics.

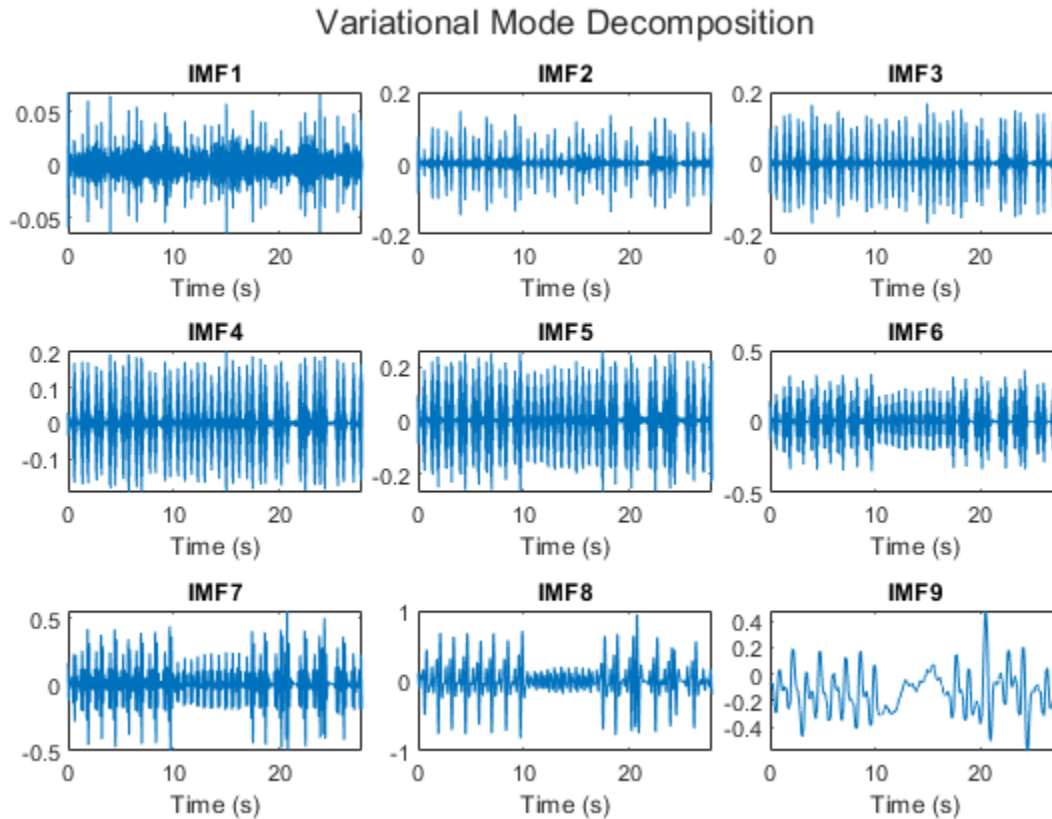

Calculate nine intrinsic mode functions of the windowed signal. Visualize the the IMFs.

```
[imf,residual] = vmd(ecgsig,'NumIMF',9);
t = tiledlayout(3,3,'TileSpacing','compact','Padding','compact');
for n = 1:9
    ax(n) = nexttile(t);
    plot(tm,imf(:,n)')
```

```

xlim([tm(1) tm(end)])
txt = ['IMF',num2str(n)];
title(txt)
xlabel('Time (s)')
end
title(t,'Variational Mode Decomposition')

```

The first mode contains the most noise, and the second mode oscillates at the frequency of the heartbeat. Construct a clean ECG signal by summing all but the first and last VMD modes, thus discarding the low frequency baseline oscillation and most of the high frequency noise.

```

cleanECG = sum(imf(:,2:8),2);
figure
plot(tm,ecgsig,tm,cleanECG)
legend('Original ECG','Clean ECG')
ylabel('Time (s)')
xlabel('Signal')

```

Input Arguments

x — Uniformly sampled time-domain signal

vector | timetable

Uniformly sampled time-domain signal, specified as either a vector or a timetable. If **x** is a timetable, then it must contain increasing finite row times. The timetable must contain only one numeric data vector with finite load values.

Note If a timetable has missing or duplicate time points, you can fix it using the tips in “Clean Timetable with Missing, Duplicate, or Nonuniform Times” (MATLAB).

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: 'NumIMF', 10

AbsoluteTolerance — Mode convergence absolute tolerance

5e-6 (default) | positive real scalar

Mode convergence absolute tolerance, specified as the comma-separated pair consisting of 'AbsoluteTolerance' and a positive real scalar. **AbsoluteTolerance** is one of the stopping criteria for optimization, that is, optimization stops when the average squared absolute improvement toward convergence of IMFs, in two consecutive iterations, is less than **AbsoluteTolerance**.

RelativeTolerance — Mode convergence relative tolerance

AbsoluteTolerance*1e3 (default) | positive real scalar

Mode convergence relative tolerance, specified as the comma-separated pair consisting of 'RelativeTolerance' and a positive real scalar. **RelativeTolerance** is one of the stopping criteria for optimization, that is, optimization stops when the average relative improvement toward convergence of IMFs, in two consecutive iterations, is less than **RelativeTolerance**.

Note The optimization process stops when 'AbsoluteTolerance' and 'RelativeTolerance' are jointly satisfied.

MaxIterations — Maximum number of optimization iterations

500 (default) | positive scalar integer

Maximum number of optimization iterations, specified as the comma-separated pair consisting of 'MaxIterations' and a positive scalar integer. **MaxIterations** is one of the stopping criteria for optimization, that is, optimization stops when the number of iterations is greater than **MaxIterations**.

MaxIterations can be specified using only positive whole numbers.

NumIMF — Number of IMFs extracted

5 (default) | positive scalar integer

Number of IMFs extracted, specified as the comma-separated pair consisting of 'NumIMF' and a positive scalar integer.

CentralFrequencies — Initial central IMF frequencies

vector

Initial central IMF frequencies, specified as the comma-separated pair consisting of 'CentralFrequencies' and a vector of length **NumIMFs**. Vector values must be within [0, 0.5] cycles/sample, which indicates that the true frequencies are within $[0, f_s/2]$, where f_s is the sample rate.

InitialIMFs — Initial IMFs

zero matrix (default) | real matrix

Initial IMFs, specified as the comma-separated pair consisting of 'InitialIMFs' and a real matrix. The rows correspond to time samples and columns correspond to modes.

PenaltyFactor — Penalty factor

1000 (default) | positive real scalar

Penalty factor, specified as the comma-separated pair consisting of 'PenaltyFactor' and a positive real scalar. This argument determines the reconstruction fidelity. Use smaller values of penalty factor to obtain stricter data fidelity.

InitialLM — Initial Lagrange multiplier

complex vector of zeros (default) | complex vector

Initial Lagrange multiplier, specified as the comma-separated pair consisting of 'InitialLM' and a complex vector. The range of the initial Lagrange multiplier in the frequency domain is $[0, 0.5]$ cycles/sample. The multiplier enforces the reconstruction constraint. The length of the multiplier depends on the input size.

LMUpdateRate — Update rate for Lagrange multiplier

0.01 (default) | real scalar

Update rate for the Lagrange multiplier in each iteration, specified as the comma-separated pair consisting of 'LMUpdateRate' and a positive real scalar. A higher rate results in faster convergence, but increases the chance of the optimization process getting stuck in a local optimum.

InitializeMethod — Method to initialize central frequencies

'peaks' (default) | 'random' | 'grid'

Method to initialize the central frequencies, specified as the comma-separated pair consisting of 'InitializeMethod' and either 'peaks', 'random', or 'grid'.

Specify InitializeMethod as:

- 'peaks' to initialize the central frequencies as the peak locations of the signal in the frequency domain (default).
- 'random' to initialize the central frequencies as random numbers distributed uniformly in the interval $[0, 0.5]$ cycles/sample.
- 'grid' to initialize the central frequencies as a uniformly sampled grid in the interval $[0, 0.5]$ cycles/sample.

Display — Toggle information display in command window

false or 0 (default) | true or 1

Toggle progress display in the command window, specified as the comma-separated pair consisting of 'Display' and either 'true' (or 1) or 'false' (or 0). If you specify 'true', the function displays the average absolute and relative improvement of modes and central frequencies every 20 iterations, and show the final stopping information.

Specify Display as 1 to show the table or 0 to hide the table.

Output Arguments**imf — Intrinsic mode function**

matrix | timetable

Intrinsic mode functions, returned as a matrix or timetable. Each imf is an amplitude and frequency modulated signal with positive and slowly varying envelopes. Each mode has an instantaneous frequency that is nondecreasing, varies slowly, and is concentrated around a central value. Use imf to apply Hilbert-Huang transform to perform spectral analysis on the signal.

imf is returned as:

- A matrix where each column is an imf, when x is a vector

- A timetable, when x is a single data column timetable

residual – Residual signal

column vector | single data column timetable

Residual signal, returned as a column vector or a single data column timetable. `residual` represents the portion of the original signal x not decomposed by `vmd`.

`residual` is returned as:

- A column vector, when x is a vector.
- A single data column timetable, when x is a single data column timetable.

info – Additional information for diagnostics

structure

Additional information for diagnostics, returned as a structure with these fields:

- `ExitFlag` - Termination flag. A value of 0 indicates the algorithm stopped when it reached the maximum number of iterations. A value of 1 indicates the algorithm stopped when it met the absolute and relative tolerances.
- `CentralFrequencies` - Central frequencies of the IMFs.
- `NumIterations` - Total number of iterations.
- `AbsoluteImprovement` - Average squared absolute improvement toward convergence of the IMFs between the final two iterations.
- `RelativeImprovement` - Average relative improvement toward convergence of the IMFs between the final two iterations.
- `LagrangeMultiplier` - Frequency-domain Lagrange multiplier at the last iteration.

More About

Intrinsic Mode Functions

The `vmd` function decomposes a signal $x(t)$ into a small number of K narrowband intrinsic mode functions (IMFs):

$$x(t) = \sum_{k=1}^K u_k(t).$$

The IMFs have these characteristics:

- 1 Each mode u_k is an amplitude and frequency modulated signal of the form

$$u_k(t) = A_k(t)\cos(\phi_k(t)),$$

where $\phi_k(t)$ is the phase of the mode and $A_k(t)$ is its envelope.

- 2 The modes have positive and slowly varying envelopes.
- 3 Each mode has an instantaneous frequency $\phi'_k(t)$ that is nondecreasing, varies slowly, and is concentrated around a central value f_k .

The variational mode decomposition method simultaneously calculates all the mode waveforms and their central frequencies. The process consists of finding a set of $u_k(t)$ and $f_k(t)$ that minimize the constrained variational problem.

Optimization

To calculate u_k and f_k , the procedure finds an optimum of the augmented Lagrangian

$$L(u_k(t), f_k, \lambda(t)) = \alpha \sum_{k=1}^K \underbrace{\left\| \frac{d}{dt} \left[\left(\delta(t) + \frac{j}{\pi t} \right) * u_k(t) \right] e^{-j2\pi f_k t} \right\|_2^2}_{(i)} + \underbrace{\left\| x(t) - \sum_{k=1}^K u_k(t) \right\|_2^2}_{(ii)} + \underbrace{\left\langle \lambda(t), x(t) - \sum_{k=1}^K u_k(t) \right\rangle}_{(iii)},$$

where the inner product $\langle p(t), q(t) \rangle = \int_{-\infty}^{\infty} p^*(t) q(t) dt$ and the 2-norm $\|p(t)\|_2^2 = \langle p(t), p(t) \rangle$. The regularization term (i) includes these steps:

- 1 Use the Hilbert transform to calculate the analytic signal associated with each mode, where $*$ denotes convolution. This results in each mode having a purely positive spectrum.
- 2 Demodulate the analytic signal to baseband by multiplying it with a complex exponential.
- 3 Estimate the bandwidth by calculating the squared 2-norm of the gradient of the demodulated analytic signal.

Terms (ii) and (iii) enforce the constraint $x(t) = \sum_{k=1}^K u_k(t)$ by imposing a quadratic penalty and incorporating a Lagrange multiplier. The `PenaltyFactor` α measures the relative importance of (i) compared to (ii) and (iii).

The algorithm solves the optimization problem using the alternating direction method of multipliers described in [1] (Signal Processing Toolbox).

Algorithms

The `vmd` function calculates the IMFs in the frequency domain, reconstructing $X(f) = \text{DFT}\{x(t)\}$ in terms of $U_k(f) = \text{DFT}\{u_k(t)\}$. To remove edge effects, the algorithm extends the signal by mirroring half its length on either side.

The Lagrange multiplier introduced in “Optimization” (Signal Processing Toolbox) has the Fourier transform $\Lambda(f)$. The length of the Lagrange multiplier vector is the length of the extended signal.

Unless otherwise specified in `'InitialIMFs'`, the IMFs are initialized at zero. Initialize `'CentralFrequencies'` using one of the methods specified in `'InitializeMethod'`. `vmd` iteratively updates the modes until one of these conditions is met:

- $\sum_k \|u_k^{n+1}(t) - u_k^n(t)\|_2^2 / \|u_k^n(t)\|_2^2 < \varepsilon_r$ and $\sum_k \|u_k^{n+1}(t) - u_k^n(t)\|_2^2 < \varepsilon_a$ are jointly satisfied, where ε_r and ε_a are specified using `'RelativeTolerance'` and `'AbsoluteTolerance'`, respectively.
- The algorithm exceeds the maximum number of iterations specified in `'MaxIterations'`.

For the $(n + 1)$ -th iteration, the algorithm performs these steps:

- 1 Iterate over the K modes of the signal (specified using `'NumIMF'`) to compute:

- a The frequency-domain waveforms for each mode using

$$U_k^{n+1}(f) = \frac{X(f) - \sum_{i < k} U_i^{n+1}(f) - \sum_{i > k} U_i^n(f) + \frac{\Lambda^n}{2}(f)}{1 + 2\alpha\{2\pi(f - f_k^n)\}^2},$$

where $U_k^{n+1}(f)$ is the Fourier transform of the k th mode calculated in the $(n + 1)$ -th iteration.

- b The k th central frequency f_k^{n+1} using

$$f_k^{n+1} = \frac{\int_{-\infty}^{\infty} |U_k^{n+1}(f)|^2 f df}{\int_{-\infty}^{\infty} |U_k^{n+1}(f)|^2 df} \approx \frac{\sum f |U_k^{n+1}(f)|^2}{\sum |U_k^{n+1}(f)|^2}.$$

- 2 Update the Lagrange multiplier using $\Lambda^{n+1}(f) = \Lambda^n(f) + \tau(X(f) - \sum_k U_k^{n+1}(f))$, where τ is the update rate of the Lagrange multiplier, specified using 'LMUpdateRate'.

wave2lp

Laurent polynomials associated with wavelet

Syntax

```
[Hs,Gs,Ha,Ga] = wave2lp(W)
```

Description

`[Hs,Gs,Ha,Ga] = wave2lp(W)` returns the four Laurent polynomials associated with the wavelet W (see `liftwave`).

The pairs (H_s, G_s) and (H_a, G_a) are the synthesis and the analysis pair respectively.

The H-polynomials (G-polynomials) are low-pass (high-pass) polynomials.

For an orthogonal wavelet, $H_s = H_a$ and $G_s = G_a$.

Examples

```
% Get Laurent polynomials associated to the "lazy" wavelet.
```

```
[Hs,Gs,Ha,Ga] = wave2lp('lazy')
```

```
Hs(z) = 1
```

```
Gs(z) = z^(-1)
```

```
Ha(z) = 1
```

```
Ga(z) = z^(-1)
```

```
% Get Laurent polynomials associated to the db1 wavelet.
```

```
[Hs,Gs,Ha,Ga] = wave2lp('db1')
```

```
Hs(z) = + 0.7071 + 0.7071*z^(-1)
```

```
Gs(z) = - 0.7071 + 0.7071*z^(-1)
```

```
Ha(z) = + 0.7071 + 0.7071*z^(-1)
```

```
Ga(z) = - 0.7071 + 0.7071*z^(-1)
```

```
% Get Laurent polynomials associated to the bior1.3 wavelet.
```

```
[Hs,Gs,Ha,Ga] = wave2lp('bior1.3')
```

```
Hs(z) = + 0.7071 + 0.7071*z^(-1)
```

```
Gs(z) = ...
      + 0.08839*z^(+2) + 0.08839*z^(+1) - 0.7071 + 0.7071*z^(-1) -
0.08839*z^(-2) ...
      - 0.08839*z^(-3)
```

$$\begin{aligned} \text{Ha}(z) = & \dots \\ & - 0.08839*z^{(+2)} + 0.08839*z^{(+1)} + 0.7071 + 0.7071*z^{(-1)} + \\ & 0.08839*z^{(-2)} \dots \\ & - 0.08839*z^{(-3)} \end{aligned}$$

$$\text{Ga}(z) = - 0.7071 + 0.7071*z^{(-1)}$$

wavedec

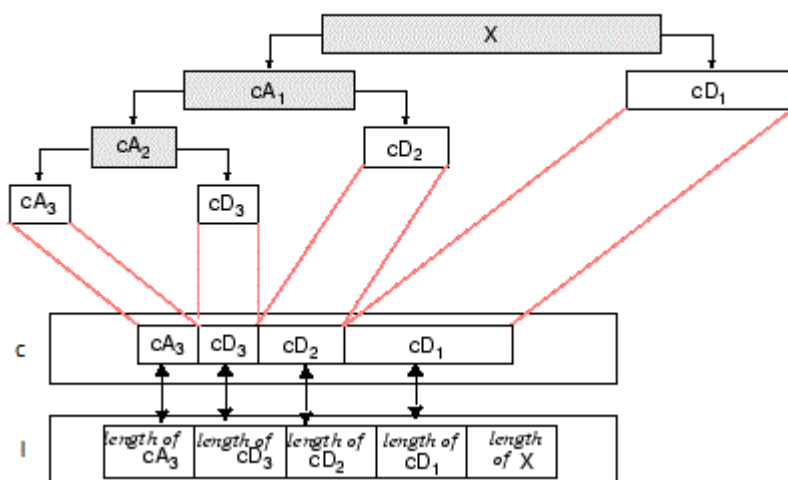

1-D wavelet decomposition

Syntax

```
[c, l] = wavedec(x, n, wname)
[c, l] = wavedec(x, n, LoD, HiD)
```

Description

`[c, l] = wavedec(x, n, wname)` returns the wavelet decomposition of the 1-D signal x at level n using the wavelet $wname$. The output decomposition structure consists of the wavelet decomposition vector c and the bookkeeping vector l , which contains the number of coefficients by level. The structure is organized as in this level-3 decomposition diagram.

`[c, l] = wavedec(x, n, LoD, HiD)` returns the wavelet decomposition using the specified lowpass and highpass wavelet decomposition filters LoD and HiD , respectively.

Examples

Multilevel One-Dimensional Wavelet Analysis

Load and plot a one-dimensional signal.

```
load sumsin
plot(sumsin)
title('Signal')
```

Perform a 3-level wavelet decomposition of the signal using the order 2 Daubechies wavelet. Extract the coarse scale approximation coefficients and the detail coefficients from the decomposition.

```
[c,l] = wavedec(sumsin,3,'db2');  
approx = appcoef(c,l,'db2');  
[cd1,cd2,cd3] = detcoef(c,l,[1 2 3]);
```

Plot the coefficients.

```
subplot(4,1,1)  
plot(approx)  
title('Approximation Coefficients')  
subplot(4,1,2)  
plot(cd3)  
title('Level 3 Detail Coefficients')  
subplot(4,1,3)  
plot(cd2)  
title('Level 2 Detail Coefficients')  
subplot(4,1,4)  
plot(cd1)  
title('Level 1 Detail Coefficients')
```

Input Arguments

x — Input signal

real-valued vector

Input signal, specified as a real-valued vector.

Data Types: double

n — Level of decomposition

positive integer

Level of decomposition, specified as a positive integer. `wavedec` does not enforce a maximum level restriction. Use `wmaxlev` to ensure that the wavelet coefficients are free from boundary effects. If boundary effects are not a concern in your application, a good rule is to set `n` less than or equal to `fix(log2(length(x)))`.

Data Types: double

wname — Analyzing wavelet

character vector | string scalar

Analyzing wavelet, specified as a character vector or string scalar.

Note `wavedec` supports only Type 1 (orthogonal) or Type 2 (biorthogonal) wavelets. See `wfilters` for a list of orthogonal and biorthogonal wavelets.

LoD, HiD — Wavelet decomposition filters

even-length real-valued vectors

Wavelet decomposition filters, specified as a pair of even-length real-valued vectors. LoD is the lowpass decomposition filter, and HiD is the highpass decomposition filter. The lengths of LoD and HiD must be equal. See `wfilters` for additional information.

Output Arguments

c — Wavelet decomposition vector

real-valued vector

Wavelet decomposition vector, returned as a real-valued vector. The bookkeeping vector `l` contains the number of coefficients by level.

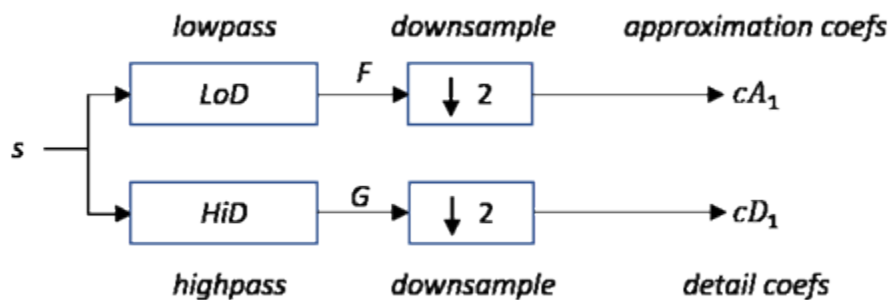

l — Bookkeeping vector

vector of positive integers

Bookkeeping vector, returned as a vector of positive integers. The bookkeeping vector is used to parse the coefficients in the wavelet decomposition vector `c` by level.

Algorithms

Given a signal s of length N , the DWT consists of at most $\log_2 N$ steps. Starting from s , the first step produces two sets of coefficients: approximation coefficients cA_1 and detail coefficients cD_1 . Convolution of s with the lowpass filter LoD and the highpass filter HiD, followed by dyadic decimation (downsampling), results in the approximation and detail coefficients respectively.

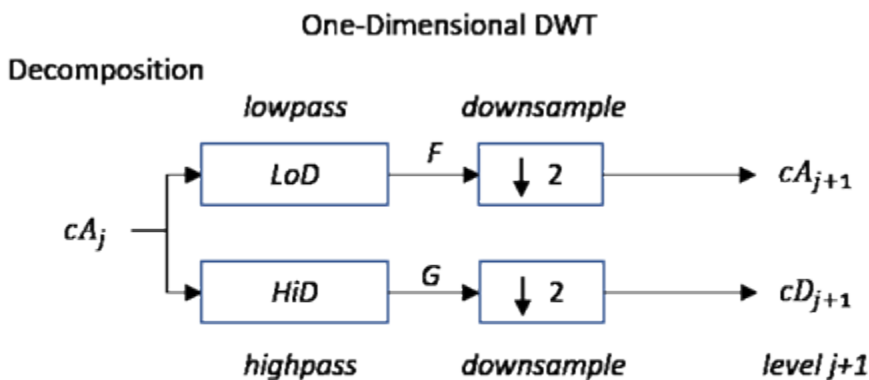

where

- \boxed{X} — Convolve with filter X
- $\boxed{\downarrow 2}$ — Downsample (keep the even-indexed elements)

The length of each filter is equal to $2n$. If $N = \text{length}(s)$, the signals F and G are of length $N + 2n - 1$ and the coefficients cA_1 and cD_1 are of length

$$\text{floor}\left(\frac{N-1}{2}\right) + n.$$

The next step splits the approximation coefficients cA_1 in two parts using the same scheme, replacing s by cA_1 , and producing cA_2 and cD_2 , and so on.

Initialization: $cA_0 = s$

The wavelet decomposition of the signal s analyzed at level j has the following structure: $[cA_j, cD_j, \dots, cD_1]$.

This structure contains, for $j = 3$, the terminal nodes of the following tree:

wavedec2

2-D wavelet decomposition

Syntax

```
[C,S] = wavedec2(X,N,wname)
[C,S] = wavedec2(X,N,Lod,Hid)
```

Description

`[C,S] = wavedec2(X,N,wname)` returns the wavelet decomposition of the matrix `X` at level `N` using the wavelet `wname`. The output decomposition structure consists of the wavelet decomposition vector `C` and the bookkeeping matrix `S`, which contains the number of coefficients by level and orientation.

`[C,S] = wavedec2(X,N,Lod,Hid)` returns the wavelet decomposition using the specified lowpass and highpass decomposition filters `Lod` and `Hid`, respectively. See `wfilters` for details.

Examples

Extract and Display Image Decomposition Level

This example shows how to extract and display images of wavelet decomposition level details.

Load an image. Perform a level 2 wavelet decomposition of the image using the haar wavelet.

```
load woman
[c,s]=wavedec2(X,2,'haar');
```

Extract the level 1 approximation and detail coefficients.

```
[H1,V1,D1] = detcoef2('all',c,s,1);
A1 = appcoef2(c,s,'haar',1);
```

Use `wcodemat` to rescale the coefficients based on their absolute values. Display the rescaled coefficients.

```
V1img = wcodemat(V1,255,'mat',1);
H1img = wcodemat(H1,255,'mat',1);
D1img = wcodemat(D1,255,'mat',1);
A1img = wcodemat(A1,255,'mat',1);

subplot(2,2,1)
imagesc(A1img)
colormap pink(255)
title('Approximation Coef. of Level 1')

subplot(2,2,2)
imagesc(H1img)
title('Horizontal Detail Coef. of Level 1')

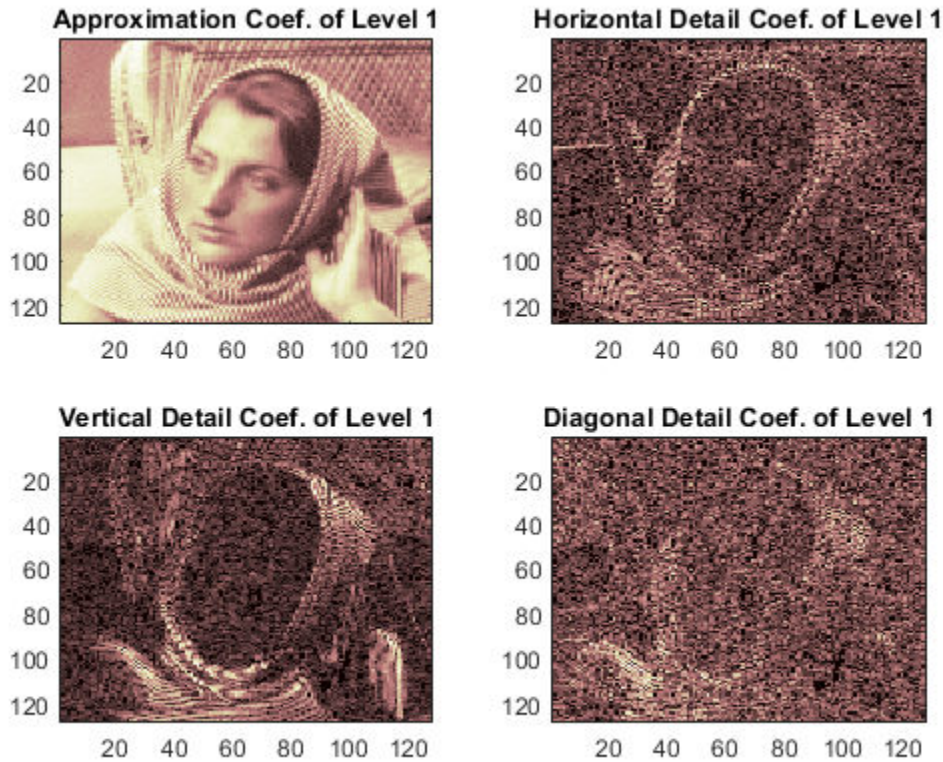

subplot(2,2,3)
```

```

imagesc(V1img)
title('Vertical Detail Coef. of Level 1')

subplot(2,2,4)
imagesc(D1img)
title('Diagonal Detail Coef. of Level 1')

```

Extract the level 2 approximation and detail coefficients.

```

[H2,V2,D2] = detcoef2('all',c,s,2);
A2 = appcoef2(c,s,'haar',2);

```

Use `wcodemat` to rescale the coefficients based on their absolute values. Display the rescaled coefficients.

```

V2img = wcodemat(V2,255,'mat',1);
H2img = wcodemat(H2,255,'mat',1);
D2img = wcodemat(D2,255,'mat',1);
A2img = wcodemat(A2,255,'mat',1);

```

```

figure
subplot(2,2,1)
imagesc(A2img)

2-D Wavelet Decomposition Structure

This example shows the structure of `wavedec2` output matrices.

Load and display an image.

```

load woman
imagesc(X)
colormap(map)

```

Save the current discrete wavelet transform extension mode.

```
origMode = dwtmode('status','nodisplay');
```

Change to periodic boundary handling. The `dwtmode` function displays a message indicating that the DWT extension mode is changing.

```
dwtmode('per');
```

```
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!  
! WARNING: Change DWT Extension Mode !  
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
```

```
*****  
** DWT Extension Mode: Periodization **  
*****
```

Perform a level 3 decomposition of the image using the `db1` (Haar) wavelet.

```
[c,s] = wavedec2(X,3,'db1');
```

Return the number of elements in the image `X` and coefficient vector `c`. Confirm the number of elements in each are equal.

```
numel(X)
```

```
ans = 65536
```

```
numel(c)
```

```
ans = 65536
```

Display the bookkeeping matrix `s`. The first row displays the dimensions of the coarse scale approximation of the image. The last row displays the dimensions of the original image. The intermediate rows display the dimensions of the detail coefficients at the three levels of the decomposition, proceeding from coarse to fine scale.

```
s
```

```
s = 5×2
```

```
    32    32
    32    32
    64    64
   128   128
   256   256
```

Reset discrete wavelet transform extension mode to its original mode. The `dwtmode` function displays a message indicating that the DWT extension mode is changing.

```
dwtmode(origMode);
```

```

```

Input Arguments

X — Input data

real-valued matrix | 3-D array of RGB triplets

Input data, specified as a real-valued M -by- N matrix representing an indexed image, or an M -by- N -by-3 array representing a truecolor image. For more information on truecolor images, see “RGB (Truecolor) Images” (MATLAB).

N — Decomposition level

positive integer

Decomposition level, specified as a positive integer. `wavedec2` does not enforce a maximum level restriction. Use `wmaxlev` to determine the maximum decomposition level possible of the matrix `X` using the wavelet `wname`. The maximum level is the last level for which at least one coefficient is correct.

wname — Analyzing wavelet

character vector | string scalar

Analyzing wavelet, specified as a character vector or string scalar.

Note `wavedec2` supports only Type 1 (orthogonal) or Type 2 (biorthogonal) wavelets. See `wfilters` for a list of orthogonal and biorthogonal wavelets.

Lod, Hid — Wavelet decomposition filters

even-length real-valued vectors

Wavelet decomposition filters associated with an orthogonal or biorthogonal wavelet, specified as even-length real-valued vectors. `Lod` is the lowpass decomposition filter, and `Hid` is the highpass decomposition filter. See `wfilters` for details.

Output Arguments

C — Wavelet decomposition vector

real-valued vector

Wavelet decomposition vector. The vector `C` contains the approximation and detail coefficients organized by level. The bookkeeping matrix `S` is used to parse `C`.

The vector `C` is organized as $A(N), H(N), V(N), D(N), H(N-1), V(N-1), D(N-1), \dots, H(1), V(1), D(1)$, where $A, H, V,$ and D are each a row vector. Each vector is the column-wise storage of a matrix.

- A contains the approximation coefficients.
- H contains the horizontal detail coefficients.
- V contains the vertical detail coefficients.
- D contains the diagonal detail coefficients.

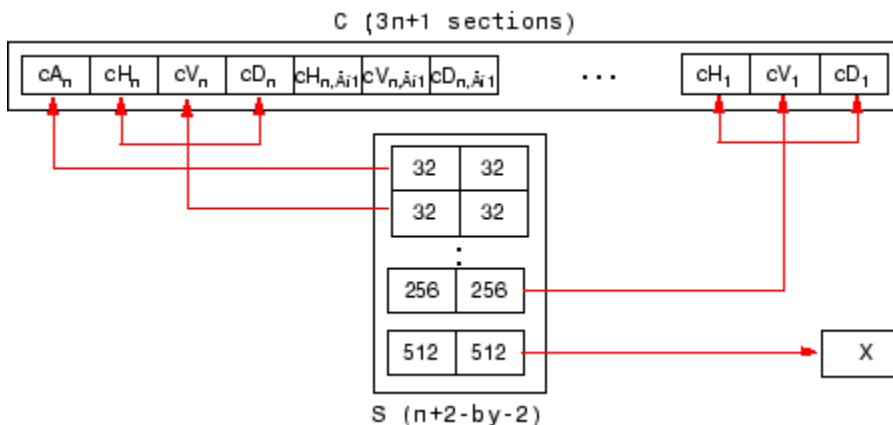

S — Bookkeeping matrix

integer-valued matrix

Bookkeeping matrix. The matrix `S` contains the dimensions of the wavelet coefficients by level and is used to parse the wavelet decomposition vector `C`.

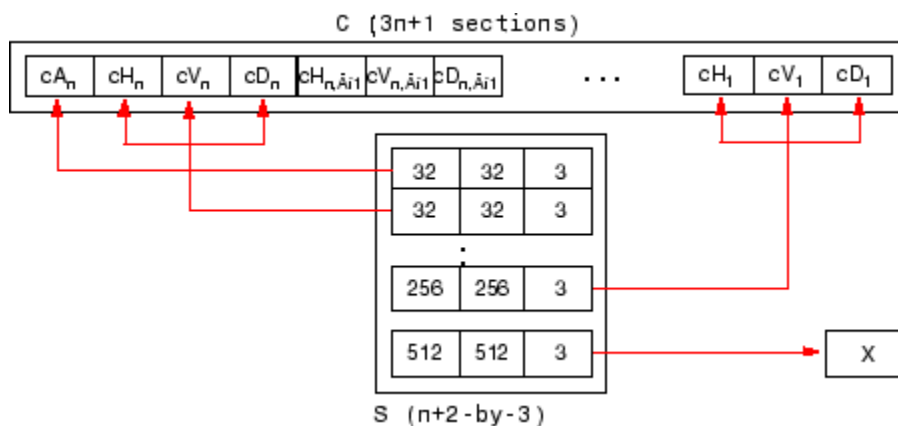

- $S(1, :) = \text{size of approximation coefficients}(N)$.
- $S(i, :) = \text{size of detail coefficients}(N - i + 2)$ for $i = 2, \dots, N + 1$ and $S(N + 2, :) = \text{size}(X)$.

The following diagram shows the relationship between `C` and `S` in the wavelet decomposition of a 512-by-512 matrix.

When X represents an indexed image, the output arrays cA , cH , cV , and cD are m -by- n matrices. When X represents a truecolor image, it is an m -by- n -by-3 array, where each m -by- n matrix represents a red, green, or blue color plane concatenated along the third dimension. The size of vector C and the size of matrix S depend on the type of analyzed image.

For a truecolor image, the decomposition vector C and the corresponding bookkeeping matrix S can be represented as shown.

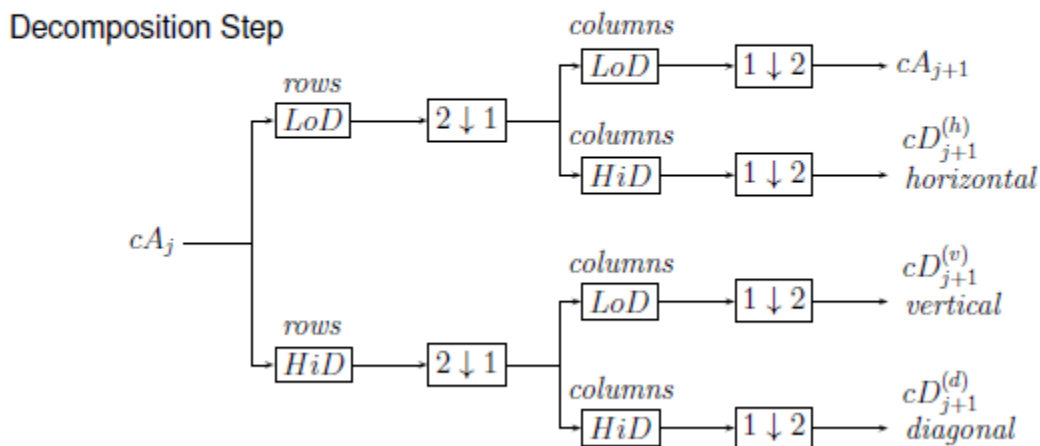

Algorithms

For images, an algorithm similar to the one-dimensional case is possible for two-dimensional wavelets and scaling functions obtained from one-dimensional vectors by tensor product. This kind of two-dimensional DWT leads to a decomposition of approximation coefficients at level j in four components: the approximation at level $j+1$ and the details in three orientations (horizontal, vertical, and diagonal).

The chart describes the basic decomposition step for images:

Two-Dimensional DWT

where

- $\boxed{2 \downarrow 1}$ — Downsample columns: keep the even-indexed columns.
- $\boxed{1 \downarrow 2}$ — Downsample rows: keep the even-indexed rows.
- $\overset{\text{rows}}{\boxed{X}}$ — Convolve with filter X the rows of the entry.
- $\overset{\text{columns}}{\boxed{X}}$ — Convolve with filter X the columns of the entry.

and

Initialization: $cA_0 = s$.

So, for $J = 2$, the two-dimensional wavelet tree has the form

wavedec3

3-D wavelet decomposition

Syntax

```
WDEC = wavedec3(X,N,wname)
WDEC = wavedec3(X,N,wname,'mode','ExtM')
WDEC = wavedec3(X,N,{LoD,HiD,LoR,HiR})
```

Description

wavedec3 is a three-dimensional wavelet analysis function.

`WDEC = wavedec3(X,N,wname)` returns the wavelet decomposition of the 3-D array `X` at level `N`, using the wavelet specified by the character vector or string scalar `wname` or the particular wavelet filters you specify. It uses the default extension mode `'sym'`. See `dwtmode`. `N` must be a positive integer.

`WDEC = wavedec3(X,N,wname,'mode','ExtM')` uses the specified DWT extension mode .

`WDEC = wavedec3(X,N,{LoD,HiD,LoR,HiR})` uses the decomposition and reconstruction filters you specify in a cell array.

`WDEC` is the output decomposition structure, with the following fields:

<code>sizeINI</code>	Size of the three-dimensional array <code>X</code>
<code>level</code>	Level of the decomposition
<code>mode</code>	Name of the wavelet transform extension mode
<code>filters</code>	Structure with 4 fields, <code>LoD</code> , <code>HiD</code> , <code>LoR</code> , <code>HiR</code> , which contain the filters used for the DWT.

dec	<p>$N \times 1$ cell array containing the coefficients of the decomposition. N is equal to $7 * \text{WDEC.level} + 1$.</p> <p><code>dec{1}</code> contains the lowpass component (approximation) at the level of the decomposition. The approximation is equivalent to the filtering operations 'LLL'.</p> <p><code>dec{k+2}, \dots, dec{k+8}</code> with $k = 0, 7, 14, \dots, 7 * (\text{WDEC.level} - 1)$ contain the 3-D wavelet coefficients for the multiresolution starting with the coarsest level when $k=0$.</p> <p>For example, if <code>WDEC.level=3</code>, <code>dec{2}, \dots, dec{8}</code> contain the wavelet coefficients for level 3 ($k=0$), <code>dec{9}, \dots, dec{15}</code> contain the wavelet coefficients for level 2 ($k=7$), and <code>dec{16}, \dots, dec{22}</code> contain the wavelet coefficients for level 1 ($k=7 * (\text{WDEC.level} - 1)$).</p> <p>At each level, the wavelet coefficients in <code>dec{k+2}, \dots, dec{k+8}</code> are in the following order: 'HLL', 'LHL', 'HHL', 'LLH', 'HLH', 'LHH', 'HHH'.</p> <p>The sequence of letters gives the order in which the separable filtering operations are applied from left to right. For example, 'LHH' means that the lowpass (scaling) filter with downsampling is applied to the rows of X, followed by the highpass (wavelet) filter with downsampling applied to the columns of X. Finally, the highpass filter with downsampling is applied to the 3rd dimension of X.</p>
sizes	Successive sizes of the decomposition components

Examples

3-D Wavelet Transform

Find the 3-D DWT of a volume. Construct 8-by-8-by-8 matrix of integers 1 to 64 and make the data 3-D.

```
M = magic(8);
X = repmat(M,[1 1 8]);
```

Obtain the 3-D discrete wavelet transform at level 1 using the Haar wavelet and the default whole-point symmetric extension mode.

```
wd1 = wavedec3(X,1,'db1');
```

3-D Wavelet Transform Using Specified Decomposition and Reconstruction Filters

Specify the decomposition and reconstruction filters as a cell array. Construct 8-by-8-by-8 matrix of integers 1 to 64 and make the data 3-D.

```
M = magic(8);
X = repmat(M,[1 1 8]);
```

Obtain the 3-D discrete wavelet transform down to level 2 using the Daubechies extremal phase wavelet with two vanishing moments. Input the decomposition and reconstruction filters as a cell array. Use the periodic extension mode.

```
[LoD,HiD,LoR,HiR] = wfilters('db2');  
wd2 = wavedec3(X,2,{LoD,HiD,LoR,HiR}, 'mode', 'per');
```

Coefficient Order in 3-D Wavelet Transform

Compare the output of `wavedec3` and `dwt3` to illustrate the ordering of the 3-D wavelet coefficients described in the `dec` field description.

```
X = reshape(1:512,8,8,8);  
dwtOut = dwt3(X, 'db1', 'mode', 'per');  
wdec = wavedec3(X,1, 'db1', 'mode', 'per');  
max(abs((wdec.dec{4}(:)-dwtOut.dec{2,2,1}(:))))  
  
ans = 0  
  
max(abs((wdec.dec{5}(:)-dwtOut.dec{1,1,2}(:))))  
  
ans = 0
```

Introduced in R2010a

wavefun

Wavelet and scaling functions

Syntax

```
[phi,psi,xval] = wavefun(wname,iter)
[phi1,psi1,phi2,psi2,xval] = wavefun(wname,iter)
[psi,xval] = wavefun(wname,iter)
```

```
[ ___ ] = wavefun(wname,A,B)
[ ___ ] = wavefun(wname,0)
[ ___ ] = wavefun(wname,8,0)
[ ___ ] = wavefun(wname)
[ ___ ] = wavefun(wname,8)
```

Description

`[phi,psi,xval] = wavefun(wname,iter)` returns `psi` and `phi`, approximations of the wavelet and scaling functions, respectively, associated with the orthogonal wavelet `wname`, or the Meyer wavelet. The approximations are evaluated on the grid points `xval`. The positive integer `iter` specifies the number of iterations computed.

`[phi1,psi1,phi2,psi2,xval] = wavefun(wname,iter)` returns approximations of the wavelet and scaling functions associated with the biorthogonal wavelet `wname`. The wavelet and scaling function approximations `psi1` and `phi1`, respectively, are for decomposition. The wavelet and scaling function approximations `psi2` and `phi2`, respectively, are for reconstruction.

`[psi,xval] = wavefun(wname,iter)` returns the wavelet approximation `psi` for those wavelets that do not have an associated scaling function, such as Morlet, Mexican Hat, Gaussian derivatives wavelets, or complex wavelets.

`[___] = wavefun(wname,A,B)` plots the wavelet and scaling function approximations generated using `max(A,B)` iterations. The output arguments are optional.

`[___] = wavefun(wname,0)` is equivalent to `[___] = wavefun(wname,8,0)`.

`[___] = wavefun(wname)` is equivalent to `[___] = wavefun(wname,8)`.

Examples

Wavelet Approximations

This example shows how the number of iterations affects the piecewise approximation of the specified wavelet.

Specify the number of iterations and the wavelet name.

```
wname = 'sym4';
itr = 10;
```

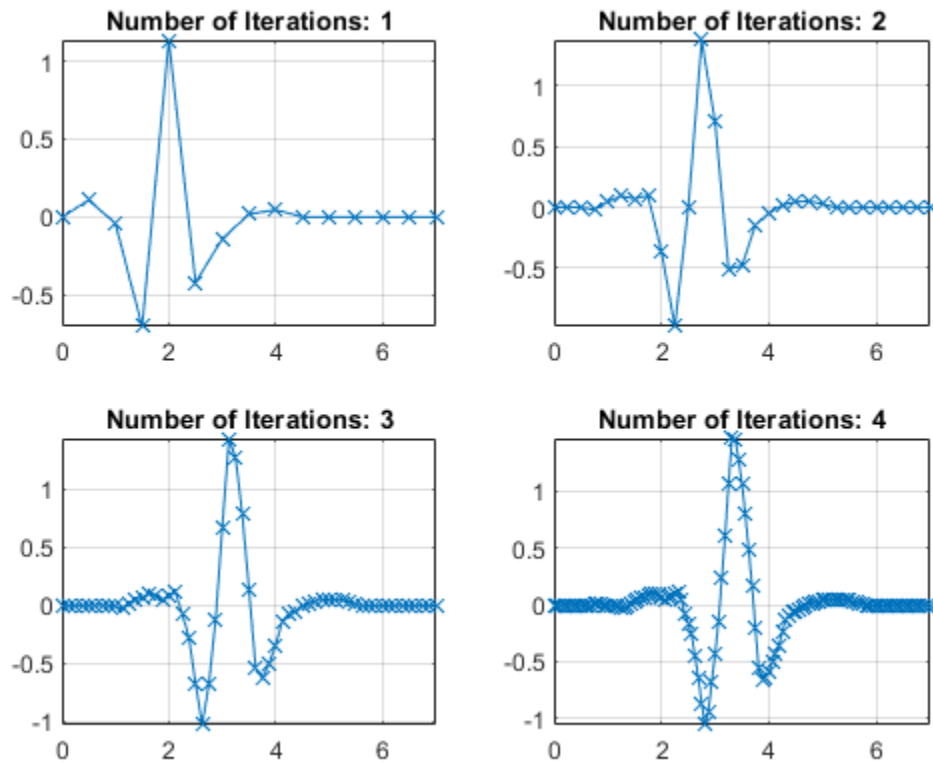

Plot the piecewise approximation of the wavelet generated after one iteration.

```
[~,psi,xval] = wavefun(wname,1);
plot(xval,psi,'x-')
grid on
title(['Approximation of ',wname,' Wavelet'])
```

Vary the number of iterations from one through four and plot the approximations. Observe that as the number of iterations grows, so do the number of sample points.

```
figure
for k=1:4
    [~,psi,xval] = wavefun(wname,k);
    subplot(2,2,k)
    plot(xval,psi,'x-')
    axis tight
    grid on
    title(['Number of Iterations: ',num2str(k)])
end
```

Now vary the number of iterations from one to the number specified by `itr`.

```
figure
for k=1:itr
    [~,psi,xval] = wavefun(wname,k);
    plot(xval,psi)
    hold on
end
grid on
title(['Approximations of ',wname,' for 1 to ',num2str(itr),' iterations'])
```

Approximations of Biorthogonal Wavelets

This example shows how to plot approximations of the scaling and wavelet functions associated with a biorthogonal wavelet.

Specify the name of a biorthogonal wavelet.

```
wname = 'bior3.7';
```

Plot approximations of the scaling and wavelet functions associated with the specified biorthogonal wavelet using the default number of iterations. Plot the approximations for both decomposition and reconstruction.

```
wavefun(wname,0);
```

Input Arguments

wname — Wavelet

character vector | string scalar

Wavelet, specified as a character vector or string scalar. See `waveinfo` for wavelets available.

iter — Number of iterations

8 (default) | positive integer

Number of iterations used to generate the wavelet and scaling function approximations, specified as a positive integer. Larger values of `iter` increase the refinement of the approximations.

A,B — Iteration

positive integers

Iteration, specified as a pair of positive integers. The number of iterations is equal to $\max(A, B)$.

Output Arguments

phi — Scaling function approximation

real-valued vector

Scaling function approximation, returned as a vector.

psi — Wavelet approximation

real-valued vector | complex-valued vector

Wavelet approximation, returned as a vector. Depending on `wname`, `psi` can be a real- or complex-valued vector.

phi1, psi1 — Approximations of decomposition scaling and wavelet functions

real-valued vectors

Approximations of decomposition scaling and wavelet functions, respectively, associated with the biorthogonal wavelet `wname`, returned as real-valued vectors.

phi2, psi2 — Approximations of reconstruction scaling and wavelet functions

real-valued vectors

Approximations of reconstruction scaling and wavelet functions, respectively, associated with the biorthogonal wavelet `wname`, returned as real-valued vectors.

xval — Grid points

real-valued vector

Grid points where the wavelet and scaling function approximations are evaluated, returned as a real-valued vector.

Algorithms

For compactly supported wavelets defined by filters, in general no closed form analytic formula exists.

The algorithm used is the cascade algorithm. It uses the single-level inverse wavelet transform repeatedly.

Let us begin with the scaling function ϕ .

Since ϕ is also equal to $\phi_{0,0}$, this function is characterized by the following coefficients in the orthogonal framework:

- $\langle \phi, \phi_{0,n} \rangle = 1$ only if $n = 0$ and equal to 0 otherwise
- $\langle \phi, \psi_{-j,k} \rangle = 0$ for positive j , and all k .

This expansion can be viewed as a wavelet decomposition structure. Detail coefficients are all zeros and approximation coefficients are all zeros except one equal to 1.

Then we use the reconstruction algorithm to approximate the function ϕ over a dyadic grid, according to the following result:

For any dyadic rational of the form $x = n2^{-j}$ in which the function is continuous and where j is sufficiently large, we have pointwise convergence and

$$\left| \phi(x) - 2^{\frac{j}{2}} \langle \phi, \phi_{-j, n 2^{j-j}} \rangle \right| \leq C \cdot 2^{-j\alpha}$$

where C is a constant, and α is a positive constant depending on the wavelet regularity.

Then using a good approximation of ϕ on dyadic rationals, we can use piecewise constant or piecewise linear interpolations η on dyadic intervals, for which uniform convergence occurs with similar exponential rate:

$$\|\phi - \eta\|_{\infty} \leq C \cdot 2^{-j\alpha}$$

So using a J -step reconstruction scheme, we obtain an approximation that converges exponentially towards ϕ when J goes to infinity.

Approximations are computed over a grid of dyadic rationals covering the support of the function to be approximated.

Since a scaled version of the wavelet function ψ can also be expanded on the $(\phi_{-1,n})_n$, the same scheme can be used, after a single-level reconstruction starting with the appropriate wavelet decomposition structure. Approximation coefficients are all zeros and detail coefficients are all zeros except one equal to 1.

For biorthogonal wavelets, the same ideas can be applied on each of the two multiresolution schemes in duality.

Note This algorithm may diverge if the function to be approximated is not continuous on dyadic rationals.

wavefun2

Wavelet and scaling functions 2-D

Syntax

```
[PHI,PSI,XVAL] = wavefun('wname',ITER)
[S,W1,W2,W3,XYVAL] = wavefun2('wname',ITER,'plot')
[S,W1,W2,W3,XYVAL] = wavefun2(wname,A,B)
[S,W1,W2,W3,XYVAL] = wavefun2('wname',max(A,B))
[S,W1,W2,W3,XYVAL] = wavefun2('wname',0)
[S,W1,W2,W3,XYVAL] = wavefun2('wname',4,0)
[S,W1,W2,W3,XYVAL] = wavefun2('wname')
[S,W1,W2,W3,XYVAL] = wavefun2('wname',4)
```

Description

For an orthogonal wavelet *wname*, `wavefun2` returns the scaling function and the three wavelet functions resulting from the tensor products of the one-dimensional scaling and wavelet functions.

If `[PHI,PSI,XVAL] = wavefun('wname',ITER)`, the scaling function *S* is the tensor product of *PHI* and *PSI*.

The wavelet functions *W1*, *W2*, and *W3* are the tensor products (*PHI,PSI*), (*PSI,PHI*), and (*PSI,PSI*), respectively.

The two-dimensional variable *XYVAL* is a $2^{\text{ITER}} \times 2^{\text{ITER}}$ points grid obtained from the tensor product (*XVAL,XVAL*).

The positive integer *ITER* determines the number of iterations computed and thus, the refinement of the approximations.

`[S,W1,W2,W3,XYVAL] = wavefun2('wname',ITER,'plot')` computes and also plots the functions.

`[S,W1,W2,W3,XYVAL] = wavefun2(wname,A,B)`, where *A* and *B* are positive integers, is equivalent to

`[S,W1,W2,W3,XYVAL] = wavefun2('wname',max(A,B))`. The resulting functions are plotted.

When *A* is set equal to the special value 0,

- `[S,W1,W2,W3,XYVAL] = wavefun2('wname',0)` is equivalent to `[S,W1,W2,W3,XYVAL] = wavefun2('wname',4,0)`.
- `[S,W1,W2,W3,XYVAL] = wavefun2('wname')` is equivalent to `[S,W1,W2,W3,XYVAL] = wavefun2('wname',4)`.

The output arguments are optional.

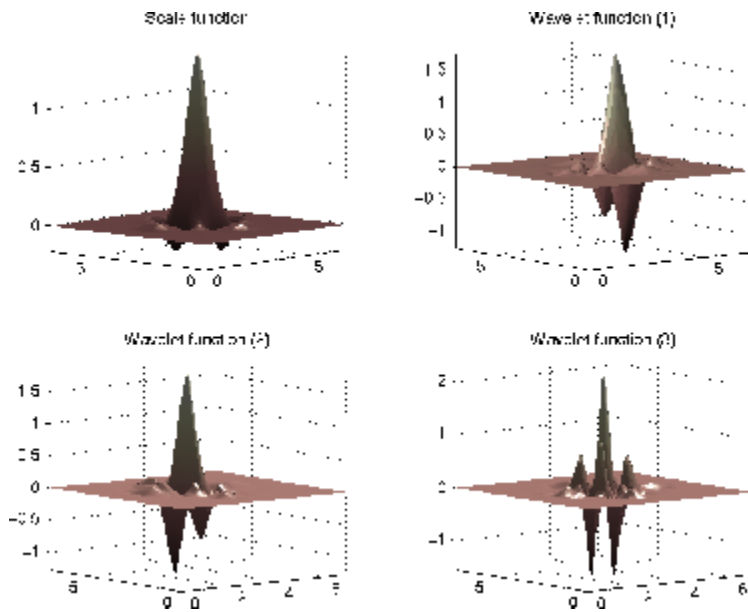

Note The `wavefun2` function can only be used with an orthogonal wavelet.

Examples

On the following graph, a linear approximation of the sym4 wavelet obtained using the cascade algorithm is shown.

```
% Set number of iterations and wavelet name.
iter = 4;
wav = 'sym4';
```

```
% Compute approximations of the wavelet and scale functions using
% the cascade algorithm and plot.
[s,w1,w2,w3,xyval] = wavefun2(wav,iter,0);
```

Algorithms

See `wavefun` for more information.

Input Arguments

wname — Wavelet family short name

character vector | string scalar | 'haar' | 'db' | 'sym' | 'coif' | ...

Wavelet family short name, specified as a character vector or string scalar. The wavelet family short name can be for a user-defined wavelet (see `wavemngr` for more information) or one of the values listed here.

Wavelet Family Short Name	Wavelet Family Name
'haar'	Haar wavelet
'db'	Daubechies wavelets
'sym'	Symlets
'coif'	Coiflets
'bior'	Biorthogonal wavelets
'fk'	Fejér-Korovkin filters
'rbio'	Reverse biorthogonal wavelets
'meyr'	Meyer wavelet
'dmey'	Discrete approximation of Meyer wavelet
'gaus'	Gaussian wavelets
'mexh'	Mexican hat wavelet (also known as Ricker wavelet)
'morl'	Morlet wavelet
'cgau'	Complex Gaussian wavelets
'shan'	Shannon wavelets
'fbsp'	Frequency B-Spline wavelets
'cmor'	Complex Morlet wavelets

Wavelet Analyzer

Analyze signals and images using wavelets

Note Some tools currently available in **waveletAnalyzer** will be removed in a future release. For a list of those tools and recommended alternatives, see “Compatibility Considerations”.

Description

The **Wavelet Analyzer** app is an interactive tool for using wavelets to visualize and analyze signals and images. With the app, you can:

- Perform wavelet and wavelet packet analysis
- Denoise and compress signals and images
- Estimate density and regression
- Perform matching pursuit analysis
- Perform image fusion

Open the Wavelet Analyzer App

- MATLAB Toolstrip: On the **Apps** tab, under **Signal Processing and Communications**, click the app icon.
- MATLAB command prompt: Enter `waveletAnalyzer`

Examples

- “Continuous Wavelet Analysis of Noisy Sinusoid Using the Wavelet Analyzer App”
- “Interactive 1-D Stationary Wavelet Transform Denoising”
- “Matching Pursuit Using Wavelet Analyzer App”

More About

Boundary Conditions

To change the way **Wavelet Analyzer** handles boundary conditions, use the `dwtmode` function.

Compatibility Considerations

Some tools in the Wavelet Analyzer app have been removed

The following tools in the **Wavelet Analyzer** app have been removed.

Tools	Replacement
Continuous Wavelet 1-D (Using FFT)	<ul style="list-style-type: none"> To take the CWT of a single time series, use <code>cwt</code>. To take the CWT of multiple time series, the recommended procedure is to precompute a CWT filter bank with <code>cwtfilterbank</code> and apply the filter bank to multiple time series. See “Using CWT Filter Bank on Multiple Time Series” on page 1-120. To visualize the scalogram, use <code>cwt</code>. To visualize wavelets in time and frequency, use <code>cwtfilterbank</code>.
New Wavelet for CWT	<ul style="list-style-type: none"> To tune the generalized Morse wavelet to your needs, vary the time-bandwidth and symmetry parameters of <code>cwtfilterbank</code> or <code>cwt</code>. To create a custom DWT filter bank, use <code>dwtfilterbank</code>. See “Add Quadrature Mirror and Biorthogonal Wavelet Filters”.
Fractional Brownian Generation 1-D	To synthesize fractional Brownian motion, use <code>wfbm</code> .
Wavelet Display, Wavelet Packet Display	<ul style="list-style-type: none"> To visualize the analytic Morse, Morlet, and bump wavelets in time and frequency, use <code>cwtfilterbank</code>. To visualize orthogonal and biorthogonal wavelets in time and frequency, use <code>dwtfilterbank</code>. To visualize in time other wavelets such as the Meyer, Morlet, Gaussian, Mexican hat, and Shannon wavelets, use <code>wavefun</code>. To display wavelet packets, use <code>wppfun</code>.
Signal Extension, Image Extension	To extend real-valued vectors or matrices, use <code>wextend</code> .

wavelets

CWT filter bank time-domain wavelets

Syntax

```
psi = wavelets(fb)  
[psi,t] = wavelets(fb)
```

Description

`psi = wavelets(fb)` returns the time-domain wavelets `psi` for the continuous wavelet transform (CWT) filter bank `fb`. The time-domain wavelets are centered at the origin.

`[psi,t] = wavelets(fb)` returns the sampling instants `t` for the wavelets.

Examples

Filter Bank Time Domain Wavelets

Create a continuous wavelet transform filter bank. Set the sampling frequency to 1000 Hz and the frequency limits to range from 50 Hz to 200 Hz. Plot the frequency response.

```
fb = cwtfilterbank('SamplingFrequency',1000,'FrequencyLimits',[50 200]);  
freqz(fb)
```

Obtain the filter bank time-domain wavelets. Plot the magnitudes of the first and last wavelets contained in the output. The first wavelet corresponds to the wavelet filter with center frequency equal to 200 Hz, and the last wavelet corresponds to the wavelet filter with center frequency equal to 50 Hz.

```
[psi,t] = wavelets(fb);  
figure  
plot(t,abs(psi(1,:)))  
hold on  
plot(t,abs(psi(end,:)))  
legend('Higher CF Wavelet','Lower CF Wavelet')  
grid on
```

Input Arguments

fb — Continuous wavelet transform filter bank

`cwtfilterbank` object

Continuous wavelet transform (CWT) filter bank, specified as a `cwtfilterbank` object.

Output Arguments

psi — Time-domain wavelets

complex-valued matrix

Time-domain wavelets, returned as a N_s -by- N complex-valued matrix, where N_s is the number of wavelet bandpass frequencies (equal to the number of scales) and N is the filter bank `SignalLength`. The wavelets are ordered in `psi` from the highest-frequency passband filter to the lowest-frequency passband filter.

t — Sampling instants

vector

Sampling instants of the time-domain wavelets, returned as a real-valued vector of length N , where N is the filter bank `SignalLength`. The data type of `t` is the same as the `SamplingPeriod`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

wavelets

DWT filter bank time-domain wavelets

Syntax

```
psi = wavelets(fb)  
[psi,t] = wavelets(fb)
```

Description

`psi = wavelets(fb)` returns the time-domain and centered wavelets corresponding to the wavelet passband filters in the discrete wavelet transform (DWT) filter bank `fb`.

`[psi,t] = wavelets(fb)` returns the sampling instants `t`.

Examples

DWT Filter Bank Wavelets

Create a seven-level DWT filter bank with a signal length of 1000 samples, using the Daubechies `db2` wavelet and a sampling frequency of 1 kHz.

```
wv = "db4";  
len = 1000;  
lev = 7;  
Fs = 1e3;  
fb = dwtfilterbank('Wavelet',wv,'SignalLength',len,'Level',lev,'SamplingFrequency',Fs);
```

Plot the time-domain and centered wavelets corresponding to the wavelet bandpass filters.

```
[psi,t] = wavelets(fb);  
plot(t,psi')  
grid on  
title('Time-domain Wavelets')
```

Plot the finest scale time-domain wavelet and the one-sided magnitude frequency response of the corresponding wavelet bandpass filter.

```

sc = 1;
[psidft,f] = freqz(fb);
subplot(2,1,1)
plot(t,psi(sc,:))
grid on
xlabel('Time (sec)')
ylabel('Magnitude')
title(['Level ',num2str(sc),'Time-Domain Wavelet'])
subplot(2,1,2)
plot(f(len/2:end),abs(psidft(sc,len/2:end)))
grid on
xlabel('Hz')
ylabel('Magnitude')
title('Magnitude Frequency Response')

```

Input Arguments

fb — Discrete wavelet transform filter bank

dwtfilterbank object

Discrete wavelet transform (DWT) filter bank, specified as a `dwtfilterbank` object.

Output Arguments

psi — Time-centered wavelets

real-valued matrix

Time-centered wavelets corresponding to the wavelet passband filters, returned as an L -by- N matrix, where L is the filter bank `Level` and N is the `SignalLength`. The wavelets are ordered in `psi` from the finest scale resolution to the coarsest scale resolution.

t — Sampling instants

real-valued vector

Sampling instants, returned as a real-valued vector `t` of length N , where N is the filter bank `SignalLength`. Sampling instants lie in the interval $[-\frac{1}{2}NDT, \frac{1}{2}NDT)$, where DT is the filter bank sampling period (reciprocal of the filter bank sampling frequency).

Introduced in R2018a

waveletScattering

Wavelet time scattering

Description

Use the `waveletScattering` object to create a framework for a wavelet time scattering decomposition using the Gabor (analytic Morlet) wavelet. The framework uses wavelets and a lowpass scaling function to generate low-variance representations of real-valued time series data. Wavelet time scattering yields representations insensitive to translations in the input signal without sacrificing class discriminability. You can use the representations as inputs to a classifier. You can specify the duration of translation invariance and the number of wavelet filters per octave.

Creation

Syntax

```
sf = waveletScattering
sf = waveletScattering(Name,Value)
```

Description

`sf = waveletScattering` creates a framework for a wavelet time scattering decomposition with two filter banks. The first filter bank has a quality factor of eight wavelets per octave. The second filter bank has a quality factor of one wavelet per octave. By default, `waveletScattering` assumes a signal input length of 1024 samples. The scale invariance length is 512 samples. By default, `waveletScattering` uses periodic boundary conditions.

`sf = waveletScattering(Name,Value)` creates a framework for wavelet scattering, `sf`, with properties specified by one or more `Name,Value` pair arguments. Properties can be specified in any order as `Name1,Value1,...,NameN,ValueN`. Enclose each property name in quotes.

Note With the exception of `OversamplingFactor`, after creation you cannot change a property value of an existing scattering framework. For example, if you have a framework `sf` with a `SignalLength` of 2000, you must create a second framework `sf2` for a signal with 2001 samples. You cannot assign a different `SignalLength` to `sf`.

Properties

SignalLength — Signal length

1024 (default) | positive integer ≥ 16

Signal length, specified as a positive integer ≥ 16 .

Data Types: `double`

SamplingFrequency — Sampling frequency

1 (default) | positive scalar

Sampling frequency in hertz, specified as a positive scalar. If unspecified, frequencies are in cycles/sample and the Nyquist frequency is $\frac{1}{2}$.

Data Types: double

InvarianceScale — Scattering transform invariance scale

one-half of `SignalLength` (default) | positive scalar

Scattering transform invariance scale, specified as a positive scalar. `InvarianceScale` specifies the translation invariance of the scattering transform. If you do not specify `SamplingFrequency`, `InvarianceScale` is measured in samples. If you specify `SamplingFrequency`, `InvarianceScale` is measured in seconds. By default, `InvarianceScale` is one-half the `SignalLength` in samples.

`InvarianceScale` cannot exceed `SignalLength` in samples.

Example: `sf =`

```
waveletScattering('SignalLength',1000,'SamplingFrequency',200,'InvarianceScale',5) has the largest possible InvarianceScale.
```

Data Types: double

QualityFactors — Scattering filter bank Q factors

[8 1] (default) | positive integer | vector of positive integers

Scattering filter bank Q factors, specified as a positive integer or a vector of positive integers. A filter bank Q factor is the number of wavelet filters per octave. Quality factors cannot exceed 32 and must be greater than or equal to 1.

If `QualityFactors` is specified as a vector, the elements of `QualityFactors` must be strictly decreasing.

Example: `sf = waveletScattering('QualityFactors',[8 2 1])` creates a wavelet scattering framework with three filter banks.

Data Types: double

Boundary — Signal extension method

'periodic' (default) | 'reflection'

Signal extension method to apply at the boundary:

- 'periodic' — Extend signal periodically to length $2^{\lceil \log_2(N) \rceil}$, where N is the signal length.
- 'reflection' — Extend signal by reflection to length $2^{\lceil \log_2(2N) \rceil}$, where N is the signal length.

The signal is extended to match the length of the wavelet filters. The length is always power of two.

The signal extension method is for internal operations. Results are downsampled back onto the scale of the original signal before being returned.

Precision — Precision of scattering decomposition

'double' (default) | 'single'

Precision of scattering decomposition:

- 'double' — Double precision
- 'single' — Single precision

Note

- All calculations involving the wavelet scattering framework are carried out in `Precision`. Wavelet scattering functions such as `featureMatrix` and `filterbank` return outputs such as filters in `Precision`.
 - The precision of the output of the `scatteringTransform` function does not exceed the precision of `sf`.
-

OversamplingFactor — Oversampling factor

0 (default) | nonnegative integer | Inf

Oversampling factor, specified as a nonnegative integer or `Inf`. The factor specifies how much the scattering coefficients are oversampled with respect to the critically downsampled values. The factor is on a \log_2 scale. By default, `OversamplingFactor` is set to 0, which corresponds to critically downsampling the coefficients. You can use `numCoefficients` to determine the number of coefficients obtained for a scattering framework. To obtain a fully undecimated scattering transform, set `OversamplingFactor` to `Inf`.

Setting `OversamplingFactor` to a value that would result in more coefficients than samples is equivalent to setting `OversamplingFactor` to `Inf`. Increasing the `OversamplingFactor` significantly increases the computational complexity and memory requirements of the scattering transform.

Example: If `sf = waveletScattering('OversamplingFactor',2)`, the scattering transform returns 2^2 times as many coefficients for each scattering path with respect to the critically sampled number.

Object Functions

<code>scatteringTransform</code>	Wavelet 1-D scattering transform
<code>featureMatrix</code>	Scattering feature matrix
<code>log</code>	Natural logarithm of scattering transform
<code>filterbank</code>	Wavelet time scattering filter banks
<code>littlewoodPaleySum</code>	Littlewood-Paley sum
<code>scattergram</code>	Visualize scattering or scalogram coefficients
<code>centerFrequencies</code>	Wavelet scattering bandpass center frequencies
<code>numorders</code>	Number of scattering orders
<code>numfilterbanks</code>	Number of scattering filter banks
<code>numCoefficients</code>	Number of wavelet scattering coefficients

Examples

Wavelet Time Scattering with Default Values

Create a scattering framework with default values.

```
sf = waveletScattering
```

```
sf =  
  waveletScattering with properties:  
      SignalLength: 1024  
      InvarianceScale: 512  
      QualityFactors: [8 1]  
      Boundary: 'periodic'  
      SamplingFrequency: 1  
      Precision: 'double'  
      OversamplingFactor: 0
```

Plot the wavelet filters used in the first and second filter banks.

```
[filters,f] = filterbank(sf);  
plot(f,filters{2}.psift)  
title('First Filter Bank')  
xlabel('Cycles/Sample')  
ylabel('Magnitude')  
grid on
```

```
figure  
plot(f,filters{3}.psift)  
title('Second Filter Bank')  
xlabel('Cycles/Sample')  
ylabel('Magnitude')  
grid on
```

Plot the Littlewood-Paley sums of the filter banks.

```
[lpsum,f] = littlewoodPaleySum(sf);  
figure  
plot(f,lpsum)  
legend('1st Filter Bank','2nd Filter Bank')  
xlabel('Cycles/Sample')  
grid on
```

Apply Scattering Decomposition Framework

This example shows how to create and apply a scattering framework with three filter banks to data.

Load in a data set. Create a framework with three filter banks that can be applied to the data.

```
load handel
disp(['Data Sampling Frequency: ',num2str(Fs),' Hz'])
```

```
Data Sampling Frequency: 8192 Hz
```

```
sf = waveletScattering('SignalLength',numel(y),...
    'SamplingFrequency',Fs,...
    'QualityFactors',[4 2 1])
```

```
sf =
    waveletScattering with properties:
```

```
    SignalLength: 73113
    InvarianceScale: 4.4625
    QualityFactors: [4 2 1]
    Boundary: "periodic"
    SamplingFrequency: 8192
    Precision: "double"
    OversamplingFactor: 0
```

Inspect the framework. Plot the wavelet filters used in the third filter bank.

```
[filters,f] = filterbank(sf);
plot(f,filters{4}.psift)
title('Third Filter Bank')
xlabel('Hertz')
ylabel('Magnitude')
grid on
```

Plot the Littlewood-Paley sums of the three filter banks.

```
[lpsum,f] = littlewoodPaleySum(sf);
figure
plot(f,lpsum)
xlabel('Hertz')
grid on
legend('1st Filter Bank','2nd Filter Bank','3rd Filter Bank')
```

Calculate the wavelet 1-D scattering transform of the data for `sf`. Visualize the scattergram of the scalogram coefficients for the first filter bank.

```
[S,U] = scatteringTransform(sf,y);  
figure  
scattergram(sf,U,'FilterBank',1)
```

Compatibility Considerations

waveletScattering property Decimate will be removed

Not recommended starting in R2019a

The waveletScattering property Decimate will be removed in a future release. Use the property OversamplingFactor instead.

Functionality	What Happens When You Use This Functionality?	Use This Instead	Compatibility Considerations
Decimate	Still runs	Use <code>OversamplingFactor</code>	<ul style="list-style-type: none"> • Replace all instances of <code>'Decimate', true</code> with <code>'OversamplingFactor', 0</code>. • Replace all instances of <code>'Decimate', false</code> with <code>'OversamplingFactor', Inf</code>.

waveletScattering2

Wavelet image scattering

Description

Use the `waveletScattering2` object to create a framework for a wavelet image scattering decomposition using complex-valued 2-D Morlet wavelets.

Creation

Syntax

```
sf = waveletScattering2
sf = waveletScattering2(Name,Value)
```

Description

`sf = waveletScattering2` creates a framework for a wavelet image scattering decomposition with two complex-valued 2-D Morlet filter banks and isotropic scale invariance. Both filter banks have quality factors of one wavelet per octave. There are six rotations linearly spaced between 0 and π radians for each wavelet filter. By default, `waveletScattering2` assumes an image input size of 128-by-128. The scale invariance is 64.

`sf = waveletScattering2(Name,Value)` creates a framework for wavelet image scattering with properties specified by one or more `Name,Value` pair arguments. Properties can be specified in any order as `Name1,Value1,...,NameN,ValueN`. Enclose each property name in single quotes (' ') or double quotes (" ").

Note With the exceptions of `OptimizePath` and `OversamplingFactor`, you cannot change a property value of an existing scattering framework. For example, if you create a framework `sf` with `ImageSize` set to `[256 256]`, you cannot assign a different `ImageSize` to `sf`.

Properties

ImageSize — Image size

`[128 128]` (default) | two-element integer-valued vector

Image size for wavelet image scattering framework, specified as a two-element integer-valued vector `[numrows numcolumns]`. Images must be at least 10-by-10.

If your input is an RGB image, you do not have to specify the third dimension. `waveletScattering2` only supports color images where the size of the third dimension is 3.

Example: `sf = waveletScattering2('ImageSize',[100 200])` creates a framework for 100-by-200 images and 100-by-200-by-3 color images.

InvarianceScale — Scattering transform invariance scale

64 (default) | positive scalar

Scattering transform invariance scale, specified as a positive scalar. `InvarianceScale` specifies the spatial support in the row and column dimensions of the scaling filter. `InvarianceScale` cannot exceed the minimum size of the row and column dimensions of the image.

By default, `InvarianceScale` is one-half the minimum of the row and column sizes of the image rounded to the nearest integer.

Example: `sf = waveletScattering2('ImageSize',[101 200])` creates a framework with `InvarianceScale` equal to 51.

NumRotations — Number of rotations per wavelet

[6 6] (default) | integer-valued vector

Number of rotations per wavelet per filter bank in the scattering framework, specified as an integer-valued vector. Specify one integer less than or equal to 12 for each filter bank in the scattering framework.

For each wavelet in each filter bank, there are `NumRotations` linearly spaced angles between 0 and π radians. The wavelet is rotated in a clockwise direction. The length of the vector specified in `NumRotations` must equal the length of the vector specified in `QualityFactors`.

Example: `sf = waveletScattering2('NumRotations',[7 5])` creates a framework with seven rotations per wavelet in the first filter bank and five rotations per wavelet in the second filter bank.

Note The 2-D wavelet scattering framework is constructed by rotating the 2-D Morlet wavelets in a clockwise direction. The opposite convention is used in the Image Processing Toolbox™. Creating a Gabor filter bank to apply to an image involves rotating the Gabor filter in a counter-clockwise direction. See “Slant Parameter” on page 1-420, and `gabor` in the Image Processing Toolbox.

QualityFactors — Scattering filter bank quality factors

[1 1] (default) | integer-valued vector

Scattering filter bank quality factors, specified as an integer-valued vector. The quality factor is the number of wavelet filters per octave. The number of wavelet filter banks in the scattering framework is equal to the number of elements in `QualityFactors`. Valid quality factors are integers less than or equal to 4. If `QualityFactors` is specified as a vector, the elements of `QualityFactors` must be nonincreasing.

The length of the vector specified in `QualityFactors` must equal the length of the vector specified in `NumRotations`.

Example: `sf = waveletScattering2('QualityFactors',[2 1])`

Precision — Precision of scattering coefficients and filters

'single' (default) | 'double'

Precision of scattering coefficients and filters:

- 'single' — Single precision
- 'double' — Double precision

Note

- All calculations involving the wavelet scattering framework are carried out in `Precision`.
 - The precision of the output of the `scatteringTransform` function does not exceed the precision of the `waveletScattering2` object.
-

OversamplingFactor — Oversampling factor

0 (default) | nonnegative integer | Inf

Oversampling factor, specified as a nonnegative integer or `Inf`. The factor specifies how much the image scattering coefficients are oversampled with respect to the critically downsampled values. The oversampling factor is on a \log_2 scale. For example, if `sf = waveletScattering2('OversamplingFactor', 1)`, the scattering transform returns 2^1 -by- 2^1 -by- P as many coefficients for each scattering path with respect to the critically sampled number. You can use `coefficientSize` to determine the number of coefficients obtained for a scattering framework. By default, `OversamplingFactor` is set to 0, which corresponds to critically downsampling the coefficients.

If you specify an oversampling factor that would result in an output image size larger than the input, the output size is truncated to the size of the input image. You can also specify the `OversamplingFactor` as `Inf`, which provides a fully undecimated scattering transform where each scattering path contains coefficient matrices equal in size to the input image.

Due to the computational complexity of the scattering transform, the recommended setting for the `OversamplingFactor` property is 0, 1, or 2. Values of 1 and 2 indicate a 2^1 -by- 2^1 -by- P and a 2^2 -by- 2^2 -by- P increase in the number of scattering coefficients per path, respectively.

Example: `sf.OversamplingFactor = 1` sets the `OversamplingFactor` property of an existing framework to 1.

OptimizePath — Optimize scattering transform logical

true (default) | false

Optimize scattering transform logical, which determines whether the scattering transform reduces the number of scattering paths to compute based on a bandwidth consideration.

When `OptimizePath` is set to `true`, a scattering path is computed only if the bandwidth of the parent node overlaps significantly with the bandwidth of the child node. 'Significant' in this context is defined as follows: for a quality factor of 1, 1/2 the 3 dB bandwidth of the child node is subtracted from the child node's wavelet center frequency. If that value is less than the 3 dB bandwidth of the parent, the scattering path is computed. For quality factors greater than 1, significant overlap is defined to be an overlap between the center frequency of the child minus the child's 3 dB bandwidth. If that overlaps with the 3 dB bandwidth of the parent, the scattering path is computed.

You can use `paths` to determine which and how many scattering paths are computed. `OptimizePath` generally results in computational savings in the second and subsequent filter banks only when the quality factors are equal in each filter bank.

Example: `sf.OptimizePath = false` sets the `OptimizePath` property of an existing framework to `false`.

Object Functions

scatteringTransform	Wavelet 2-D scattering transform
featureMatrix	Image scattering feature matrix
log	Natural logarithm of 2-D scattering transform
filterbank	Wavelet and scaling filters
littlewoodPaleySum	Littlewood-Paley sum
coefficientSize	Size of image scattering coefficients
numorders	Number of scattering orders
numfilterbanks	Number of scattering filter banks
paths	Scattering paths

Examples

Wavelet Image Scattering with Default Values

Create a wavelet image scattering framework with default settings. The default image size is 128-by-128, and the default invariance scale is 64.

```
sf = waveletScattering2

sf =
  waveletScattering2 with properties:

      ImageSize: [128 128]
  InvarianceScale: 64
      NumRotations: [6 6]
  QualityFactors: [1 1]
      Precision: 'single'
  OversamplingFactor: 0
      OptimizePath: 1
```

Use the `filterbank` function to obtain the Fourier transform of the scaling function, the wavelet filters, and the center spatial frequencies of the wavelet filters.

```
[phif,psif,f] = filterbank(sf);
```

The invariance scale gives the width in the x - and y -directions of the 2-D Gaussian scaling function. To confirm the scaling function has the expected spatial width, first take the inverse Fourier transform of `phif`. Use the helper function `helperPlotPhiSurface` to plot the scaling function with the extent of the invariance scale in both x and y designated. The source code for `helperPlotPhiSurface` is provided in the appendix at the end of this example.

```
phi = ifftshift(ifft2(phif));
figure
helperPlotPhiSurface(sf,phi)
```

The scaling function is larger than 128-by-128 because it has been padded to avoid edge effects.

Extract the Fourier transform of the coarsest scale wavelet in the second filter bank and take its inverse Fourier transform. Use `helperPlotPsiSurface` to plot the real and imaginary parts of the wavelet and confirm the spatial extent of the coarsest scale wavelet does not exceed the invariance scale. Similar to the scaling function, the wavelet has been padded to avoid edge effects. The source code for `helperPlotPsiSurface` is provided in the appendix at the end of this example.

```
psiF = psif{2}(:,:,end);
psiL = ifftshift(ifft2(psiF));
figure
helperPlotPsiSurface(sf,psiL)
```

Appendix

The following helper functions are used in this example.

helperPlotPhiSurface

```
function helperPlotPhiSurface(scatFrame,data)
halfscale = scatFrame.InvarianceScale/2;
surf(data)
shading interp
view(-20,35)
Ysize = size(data,1);
Xsize = size(data,2);
Ycenter = Ysize/2;
Xcenter = Xsize/2;
hold on
plot([Xcenter-halfscale Xcenter-halfscale],[0 Ysize],'r','LineWidth',2);
plot([Xcenter+halfscale Xcenter+halfscale],[0 Ysize],'r','LineWidth',2);
plot([0 Xsize],[Ycenter-halfscale Ycenter-halfscale],'r','LineWidth',2);
plot([0 Xsize],[Ycenter+halfscale Ycenter+halfscale],'r','LineWidth',2);
title('\phi(x,y)','FontSize',14,'Interpreter','Latex');
xlabel('$x$','FontSize',14,'Interpreter','Latex')
ylabel('$y$','FontSize',14,'Interpreter','Latex')
end
```

helperPlotPsiSurface

```

function helperPlotPsiSurface(scatFrame,data)
halfscale = scatFrame.InvarianceScale/2;
Ysize = size(data,1);
Xsize = size(data,2);
Ycenter = Ysize/2;
Xcenter = Xsize/2;
surf(real(data))
shading interp
view(-5,13)
hold on
surf(imag(data))
shading interp
plot([Xcenter-halfscale Xcenter+halfscale],[0 Ysize],'r','LineWidth',2);
plot([Xcenter+halfscale Xcenter+halfscale],[0 Ysize],'r','LineWidth',2);
plot([0 Xsize],[Ycenter-halfscale Ycenter-halfscale],'r','LineWidth',2);
plot([0 Xsize],[Ycenter+halfscale Ycenter+halfscale],'r','LineWidth',2);
title('$\frac{1}{2^{2J}}\psi(x/2^J,y/2^J)$','FontSize',14,...
      'Interpreter','Latex');
xlabel('$x$','FontSize',14,'Interpreter','Latex')
ylabel('$y$','FontSize',14,'Interpreter','Latex')
view(-10,51)
end

```

Wavelet Signal Denoiser

Visualize and denoise time series data

Description

The **Wavelet Signal Denoiser** app is an interactive tool for visualizing and denoising real-valued 1-D signals and comparing results. With the app, you can:

- Access all the signals in the MATLAB workspace.
- Easily adjust default parameters and apply different denoising techniques.
- Visualize and compare results.
- Export denoised signals to your workspace.
- Recreate the denoised signal in your workspace by generating a MATLAB script.

The **Wavelet Signal Denoiser** app provides a way to work with multiple versions of denoised data simultaneously.

A typical workflow for denoising a signal and comparing results using the app is:

- 1 Start the app and load a 1-D signal from the MATLAB workspace. The app provides an initial denoised version of your data using default parameters.
- 2 Adjust the denoising parameters and produce multiple versions of the denoised signal.
- 3 Compare results and export the desired denoised signal to your workspace.
- 4 To apply the same denoising parameters to other signals in your workspace, generate a MATLAB script and modify it as you see fit.

Open the Wavelet Signal Denoiser App

- MATLAB Toolstrip: On the **Apps** tab, under **Signal Processing and Communications**, click

Wavelet Signal Denoiser 

- MATLAB command prompt: Enter `waveletSignalDenoiser`.

Examples

Denoise Signal Using Default Settings

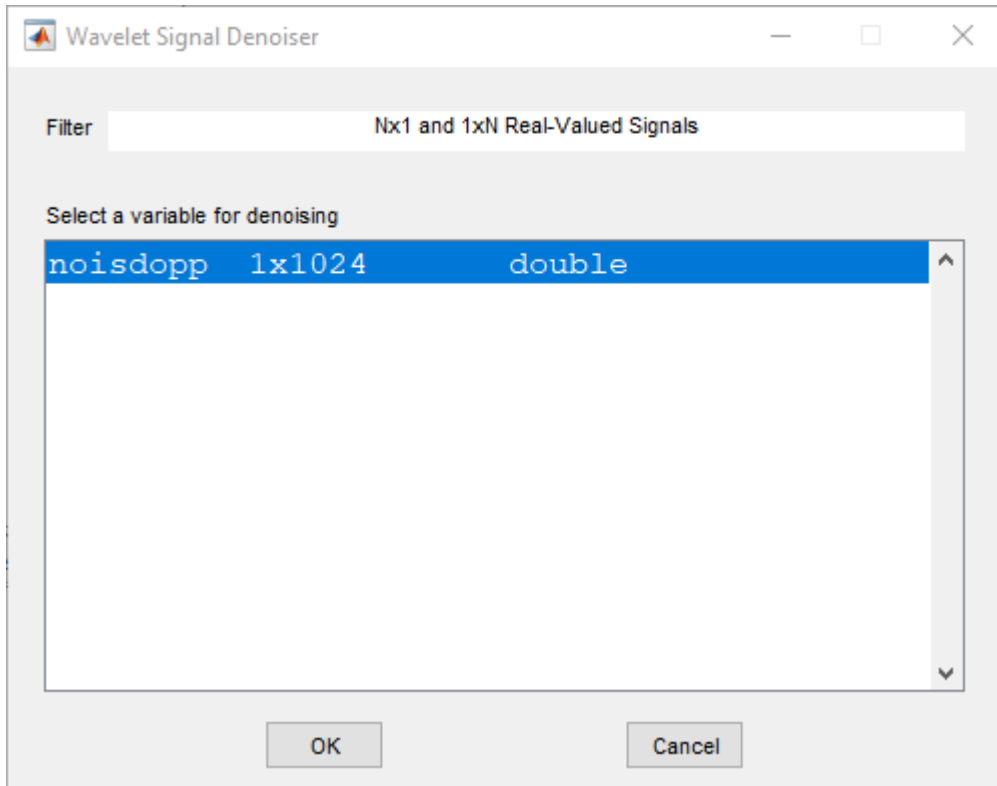

This example shows how to denoise a 1-D signal using the app default settings.

Load the noisy Doppler signal.

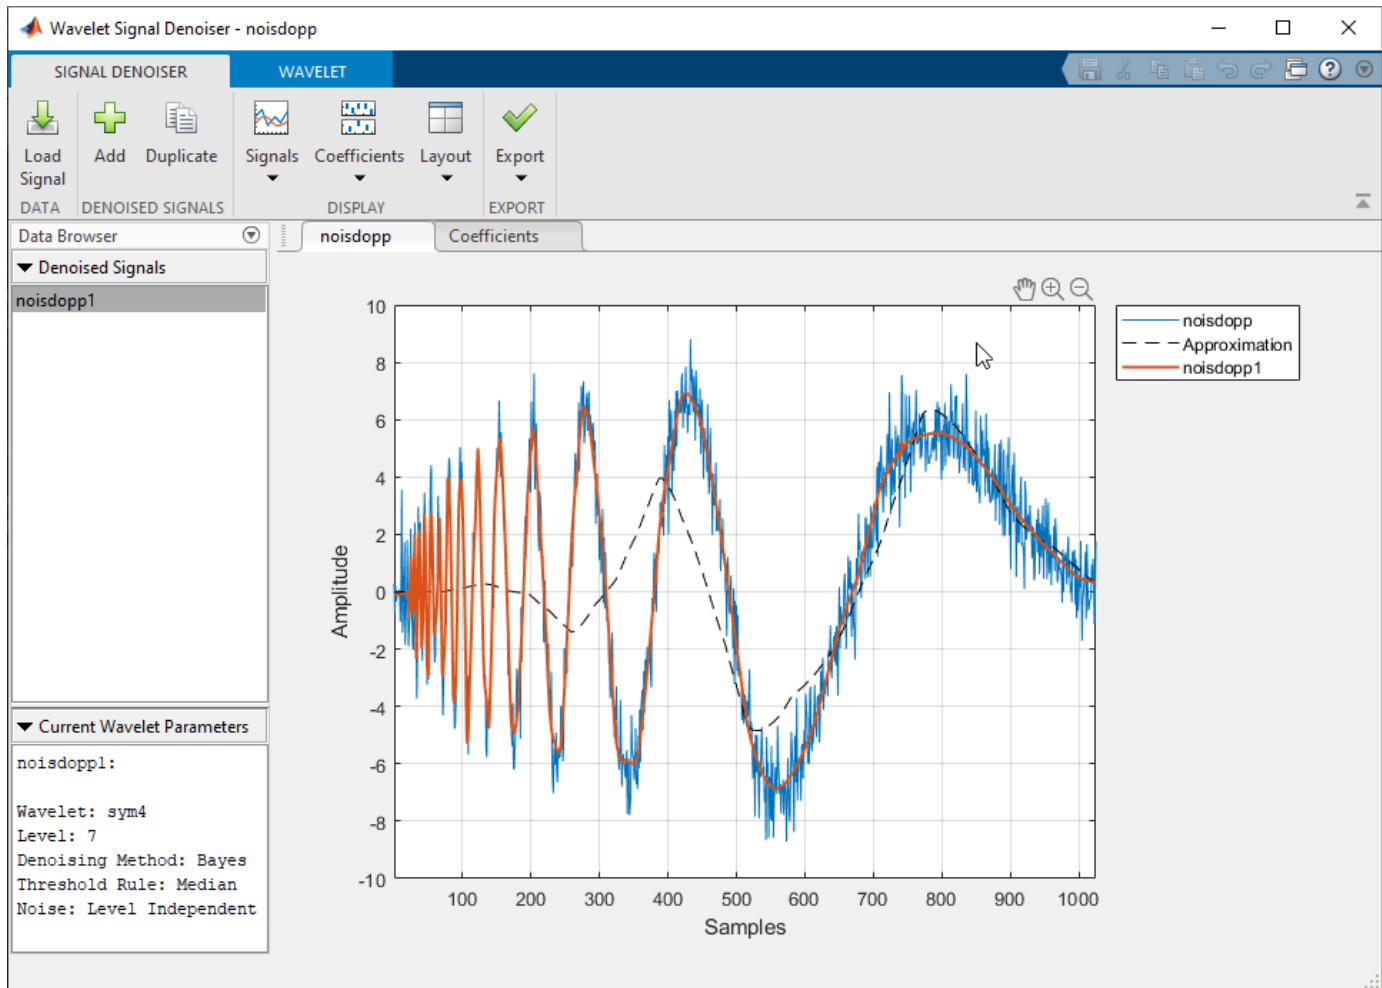

```
load noisdopp
```

Start the **Wavelet Signal Denoiser** app by choosing it from the **Apps** tab on the MATLAB® Toolstrip. You can also start the app by typing `waveletSignalDenoiser` at the MATLAB command prompt.

Load the noisy Doppler signal from the workspace into the app by clicking **Load Signal** in the toolstrip. From the list of workspace variables that can be loaded into the app, select `noisdopp` and click **OK**.

The app displays the original signal, `noisdopp`, the denoised signal, `noisdopp1`, and the coarse scale approximation, `Approximation`.

To toggle what plots are visible, you can:

- Click **Signals ▼** in the toolbar and use the drop-down menu to toggle the visibility of the original and approximation plots.
- Click individual signals in the plot legend.

Parameters

Wavelet — Wavelet family

sym (default) | bior | coif | db | fk

Wavelet family used to denoise the signal, specified as one of the following:

- sym — Symlets
- bior — Biorthogonal spline wavelets
- coif — Coiflets
- db — Daubechies wavelets

- `fk` — Fejér-Korovkin wavelets

For additional information, see `wdenoise`.

Method — Denoising method

`Bayes` (default) | `BlockJS` | `FDR` | `Minimax` | `SURE` | `UniversalThreshold`

Denoising method to apply, specified as one of the following:

- `Bayes` — Empirical Bayes
- `BlockJS` — Block James-Stein
- `FDR` — False Discovery Rate
- `Minimax` — Minimax Estimation
- `SURE` — Stein's Unbiased Risk Estimate
- `UniversalThreshold` — Universal Threshold

For additional information, see `wdenoise`.

Rule — Thresholding rule

`Median` (default) | `Mean` | `Soft` | `Hard` | `James-Stein`

Thresholding rule to use. Valid options depend on the denoising method.

- `Block James-Stein` — `James-Stein`
- `Empirical Bayes` — `Median`, `Mean`, `Soft`, `Hard`
- `False Discovery Rate` — `Hard`
- `Minimax Estimation` — `Soft`, `Hard`
- `Stein's Unbiased Risk Estimate` — `Soft`, `Hard`
- `Universal Threshold` — `Soft`, `Hard`

For additional information, see `wdenoise`.

Tips

To denoise more than one signal simultaneously, you can run multiple instances of the **Wavelet Signal Denoiser** app.

waveletsupport

CWT filter bank time supports

Syntax

```
spsi = waveletsupport(fb)
spsi = waveletsupport(fb,thresh)
```

Description

`spsi = waveletsupport(fb)` returns the wavelet time supports, defined as the time interval in which all of the wavelet's energy occurs. The default tolerance is 99.99% of the energy. The time supports are returned in the MATLAB table `spsi`. The wavelets are normalized to have unit energy.

`spsi = waveletsupport(fb,thresh)` specifies the threshold for the integrated energy. The time support of the wavelet is defined as the first instant the integrated energy exceeds `thresh` and the last instant the integrated energy is less than $1 - \text{thresh}$. If unspecified, `thresh` defaults to 10^{-4} .

Examples

Wavelet Filter Bank Time Supports

Create a continuous wavelet transform filter bank. Set the sampling frequency to 1000 Hz and the frequency limits to range from 100 Hz to 200 Hz. Obtain the time supports of the wavelets in the filter bank.

```
fb = cwtfilterbank('SamplingFrequency',1000,'FrequencyLimits',[100 200]);
spsi = waveletsupport(fb)
```

`spsi=11x5 table`

CF	IsAnalytic	TimeSupport	Begin	End
200	"Analytic"	0.032	-0.016	0.016
186.61	"Analytic"	0.034	-0.017	0.017
174.11	"Analytic"	0.038	-0.019	0.019
162.45	"Analytic"	0.04	-0.02	0.02
151.57	"Analytic"	0.042	-0.021	0.021
141.42	"Analytic"	0.046	-0.023	0.023
131.95	"Analytic"	0.048	-0.024	0.024
123.11	"Analytic"	0.052	-0.026	0.026
114.87	"Analytic"	0.056	-0.028	0.028
107.18	"Analytic"	0.06	-0.03	0.03
100	"Analytic"	0.064	-0.032	0.032

Obtain the time domain wavelets from the filter bank and plot their magnitudes. Use the table to set the minimum and maximum limits of the x-axis to the smallest `Begin` value and largest `End` value, respectively.

```
[psi,t] = wavelets(fb);
plot(t,abs(psi))
grid on
xlim([spsi.Begin(end) spsi.End(end)])
xlabel('Time (sec)')
ylabel('Magnitude')
title('Time Domain Wavelets')
```

Input Arguments

fb — Continuous wavelet transform filter bank

cwtfilterbank object

Continuous wavelet transform (CWT) filter bank, specified as a `cwtfilterbank` object.

thresh — Time support threshold

$10e-4$ (default) | positive real number

Time support threshold for the wavelet, specified as a positive real number between 0 and 0.05. The time support of the wavelet is defined as the first instant the integrated energy of the wavelet exceeds `thresh` and the last instant the integrated energy is less than $1 - \text{thresh}$.

Data Types: double

Output Arguments

spsi — Wavelet time supports

table

Wavelet time supports, returned as an N_s -by-5 MATLAB table, where N_s is the number of wavelet bandpass frequencies (equal to the number of scales). The table has five variables:

CF — Wavelet center frequency

positive real number

Wavelet center frequency, returned as a positive real number.

Data Types: double

IsAnalytic — Wavelet designation

"Analytic" | "Nonanalytic"

Wavelet designation, returned as a string. Wavelets that do not decay to 5% of their peak value at the Nyquist frequency are not considered analytic. The time support information for those wavelets are returned as NaNs.

Data Types: string

TimeSupport — Wavelet time support

positive integer | NaN

Wavelet time support, returned in samples, seconds, or MATLAB durations. The units of `TimeSupport` depend on whether you specify `SamplingFrequency` or `SamplingPeriod`. If you specify a `SamplingFrequency`, the units are seconds. If you specify a `SamplingPeriod`, the units are the same as the `SamplingPeriod`. If no `SamplingFrequency` or `SamplingPeriod` is specified, the units are samples.

Data Types: double

Begin — Beginning of wavelet time support

integer

Beginning of wavelet time support, returned as an integer. `Begin` is defined as the first instant the wavelet integrated energy exceeds the default threshold, 10^{-4} . `Begin` has the same units as `TimeSupport`.

Data Types: double

End — End of wavelet time support

integer

End of wavelet time support, returned as an integer. `End` is defined as the last instant the wavelet integrated energy is less than $1 - 10^{-4}$. `End` has the same units as `TimeSupport`.

Data Types: double

Data Types: table

Introduced in R2018a

waveletsupport

DWT filter bank time supports

Syntax

```
spsi = waveletsupport(fb)
spsi = waveletsupport(fb,thresh)
[spsi,sphi] = waveletsupport(fb)
[spsi,sphi,tlow,thigh] = waveletsupport(fb)
```

Description

`spsi = waveletsupport(fb)` returns the wavelet time supports of the discrete wavelet transform (DWT) filter bank `fb`. The time supports are defined as the time interval in which all the wavelet energy occurs (> 99.99% of the energy for the default threshold).

`spsi = waveletsupport(fb,thresh)` specifies the threshold for the integrated energy. `thresh` is a positive real number in the interval $0 < \text{thresh} \leq 0.05$.

`[spsi,sphi] = waveletsupport(fb)` returns the scaling function time supports at all levels. `sphi` is a real-valued L -by-1 vector, where L is the number of levels in the DWT filter bank `fb`.

`[spsi,sphi,tlow,thigh] = waveletsupport(fb)` returns the instants the integrated energy in the wavelets and scaling functions exceed `thresh` in `tlow` and the last instant the integrated energy is less than $1 - \text{thresh}$ in `thigh`.

Examples

DWT Filter Bank Wavelet Time Supports

Find the time supports for a Haar wavelet filter bank.

```
fb = dwtfilterbank('Wavelet','haar','Level',8);
Spsi = waveletsupport(fb)
```

```
Spsi = 8×1
```

```
    2
    4
    8
   16
   32
   64
  128
  256
```

Input Arguments

fb — Discrete wavelet transform filter bank

dwtfilterbank object

Discrete wavelet transform (DWT) filter bank, specified as a dwtfilterbank object.

thresh — Threshold for the integrated energy

1e-6 (default) | positive scalar

Threshold for the integrated energy, specified as a positive scalar in the interval $0 < \text{thresh} \leq 0.05$. If unspecified, thresh defaults to 10^{-6} .

The percent energy contained in the time support is $(1 - 2 \times \text{thresh}) \times 100$. The time support of the wavelet is defined as the first instant the integrated energy exceeds thresh and the last instant it is less than 1-thresh. The wavelets are normalized to have unit energy for the computation.

Output Arguments

spsi — Wavelet time supports

real-valued column vector

Wavelet time supports, returned as a real-valued column vector of length L , where L is the number of levels in the DWT filter bank.

sphi — Scaling function time supports

real-valued column vector

Scaling function time supports, returned as a real-valued column vector of length L , where L is the number of levels in the DWT filter bank.

tlow — First instants

real-valued matrix

First instants the integrated energy in the wavelet and scaling functions exceed thresh, returned as real-valued L -by-2 matrix, where L is the number of levels in the filter bank. The first column of tlow contains the times for the wavelets. The second column of tlow contains the times for the scaling functions.

The difference between the first column of thigh and the first column of tlow plus one sampling period equals spsi. The difference between the second column of thigh and the second column of tlow plus one sampling period equals sphi.

thigh — Last instants

real-valued matrix

Last instants the integrated energy in the wavelet and scaling functions is less than $1 - \text{thresh}$, returned as real-valued L -by-2 matrix, where L is the number of levels in the filter bank. The first column of thigh contains the times for the wavelets. The second column of thigh contains the times for the scaling functions.

The difference between the first column of thigh and the first column of tlow plus one sampling period equals spsi. The difference between the second column of thigh and the second column of tlow plus one sampling period equals sphi.

Introduced in R2018a

wavemngr

Wavelet manager

Syntax

```
wavemngr('add', FN, FSN, WT, NUMS, FILE)
wavemngr('add', FN, FSN, WT, {NUMS, TYPNUMS}, FILE)
wavemngr( ____, B)

wavemngr('del', WN)

wavemngr('restore')
wavemngr('restore', IN2)

out = wavemngr('read')
out = wavemngr('read', IN2)
out = wavemngr('read_asc')
```

Description

Use `wavemngr` to add, delete, restore, or read wavelets.

`wavemngr('add', FN, FSN, WT, NUMS, FILE)` adds a wavelet family to the toolbox. These parameters define the wavelet family:

- FN — Family name
- FSN — Family short name
- WT — Wavelet family type
- NUMS — Wavelet parameters
- FILE — Wavelet definition file

Note When you use `wavemngr` to add a wavelet family, three wavelet extension files are created in the current folder: the two ASCII files `wavelets.asc` and `wavelets.prv`, and the MAT-file `wavelets.inf`. If you add a new wavelet family, it is available in this folder only.

`wavemngr('add', FN, FSN, WT, {NUMS, TYPNUMS}, FILE)` adds a wavelet family with parameter NUMS with input format type TYPNUMS.

`wavemngr(____, B)` adds a wavelet family, where B specifies the effective support for the wavelets. The B input argument is valid only for wavelets of type WT = 3, 4, and 5. You can use this syntax with any of the previous syntaxes.

`wavemngr('del', WN)` deletes the wavelet family specified by WN.

`wavemngr('restore')` restores the previous `wavelets.asc` ASCII file

`wavemngr('restore', IN2)` restores the initial `wavelets.asc` ASCII file. Here IN2 is a dummy argument.

`out = wavemngr('read')` returns all wavelet family names in a character array.

`out = wavemngr('read',IN2)` returns all wavelet names in a character array. Here `IN2` is a dummy argument.

`out = wavemngr('read_asc')` reads the `wavelets.asc` ASCII file and returns all wavelet information.

Examples

Wavelet Names and Family Names

List the wavelet families available by default.

Add Wavelet Families

This example shows how to add new compactly supported orthogonal wavelets to the toolbox. These wavelets, which are a slight generalization of the Daubechies wavelets, are based on the use of Bernstein polynomials and are due to Kateb and Lemarié.

Add a new family of orthogonal wavelets. You must define:

- Family Name: Lemarie
- Family Short Name: lem
- Type of wavelet: 1 (orth)
- Wavelet numbers: 1 2 3 4 5
- File driver: lemwavf

The source code for `lemwavf.m` is provided at the end of the example. The input argument of `lemwavf` is a character vector of the form `lemN`, where $N = 1, 2, 3, 4, \text{ or } 5$.

```
wavemngr('add','Lemarie','lem',1,'1 2 3 4 5','lemwavf')
```

The ASCII file `wavelets.asc` is saved as `wavelets.prv`, then information defining the new family is added to `wavelets.asc`, and the MAT-file `wavelets.inf` is generated.

Note that `wavemngr` works on the current folder. If you add a new wavelet family, it is available in this folder only.

List the available wavelet families. Confirm the new wavelet family is added.

```
wavemngr('read')
```

```
ans = 19x35 char array
'=====
'Haar          ->->haar    |
'Daubechies    ->->db      |
'Symlets       ->->sym     |
'Coiflets      ->->coif    |
'BiorSplines   ->->bior    |
'ReverseBior   ->->rbio    |
'Meyer         ->->meyr    |
'DMeyer        ->->dmey    |
'Gaussian      ->->gaus    |
'Mexican_hat   ->->mexh    |
'Morlet        ->->morl    |
'Complex Gaussian ->->cgau  |
'Shannon       ->->shan    |
'Frequency B-Spline->->fbsp  |
'Complex Morlet ->->cmor    |
'Fejer-Korovkin ->->fk     |
'Lemarie       ->->lem     |
'=====
```

Remove the added family. Regenerate the list of wavelet families.

```
wavemngr('del','Lemarie')
wavemngr('read')
```

```
ans = 18x35 char array
'=====
'Haar          ->->haar      '
'Daubechies    ->->db        '
'Symlets       ->->sym       '
'Coiflets      ->->coif      '
'BiorSplines   ->->bior      '
'ReverseBior   ->->rbio      '
'Meyer         ->->meyr      '
'DMeyer        ->->dmey      '
'Gaussian      ->->gaus      '
'Mexican_hat   ->->mexh      '
'Morlet        ->->morl      '
'Complex Gaussian ->->cgau    '
'Shannon       ->->shan      '
'Frequency B-Spline->->fbsp  '
'Complex Morlet ->->cmor     '
'Fejer-Korovkin ->->fk      '
'=====
```

Restore the previous ASCII file `wavelets.prv`, then build the MAT-file `wavelets.inf`. List the restored wavelets. Because `wavemngr` reads the ASCII file in the current working directory, the new family appears in the list.

```
wavemngr('restore')
wavemngr('read',1)
```

```
ans = 76x44 char array

Add Biorthogonal Wavelet Filters

This example shows how to take analysis and synthesis filters associated with a biorthogonal wavelet and make them compatible with Wavelet Toolbox™. Wavelet Toolbox requires that analysis and synthesis lowpass and highpass filters have equal even length. This example uses the nearly orthogonal biorthogonal wavelets based on the Laplacian pyramid scheme of Burt and Adelson (Table

8.4 on page 283 in [1]). The example also demonstrates how to examine properties of the biorthogonal wavelets.

Define the analysis and synthesis filter coefficients of the biorthogonal wavelet.

```
Hd = [-1 5 12 5 -1]/20*sqrt(2);
Gd = [3 -15 -73 170 -73 -15 3]/280*sqrt(2);
Hr = [-3 -15 73 170 73 -15 -3]/280*sqrt(2);
Gr = [-1 -5 12 -5 -1]/20*sqrt(2);
```

Hd and Gd are the lowpass and highpass analysis filters, respectively. Hr and Gr are the lowpass and highpass synthesis filters. They are all finite impulse response (FIR) filters. Confirm the lowpass filter coefficients sum to $\sqrt{2}$ and the highpass filter coefficients sum to 0.

```
sum(Hd)/sqrt(2)
```

```
ans = 1.0000
```

```
sum(Hr)/sqrt(2)
```

```
ans = 1.0000
```

```
sum(Gd)
```

```
ans = -1.0061e-16
```

```
sum(Gr)
```

```
ans = -9.7145e-17
```

The z -transform of an FIR filter h is a Laurent polynomial $h(z)$ given by $h(z) = \sum_{k=k_b}^{k_e} h_k z^{-k}$. The degree $|h|$ of a Laurent polynomial is defined as $|h| = k_e - k_b$. Therefore, the length of the filter h is $1 + |h|$. Examine the Laurent expansion of the scaling and wavelet filters.

```
PHd = laurpoly(Hd, 'dmin', -2)
```

```
PHd(z) = - 0.07071*z^(+2) + 0.3536*z^(+1) + 0.8485 + 0.3536*z^(-1) - 0.07071*z^(-2)
```

```
PHr = laurpoly(Hr, 'dmin', -3)
```

```
PHr(z) = ...
- 0.01515*z^(+3) - 0.07576*z^(+2) + 0.3687*z^(+1) + 0.8586 + 0.3687*z^(-1) ...
- 0.07576*z^(-2) - 0.01515*z^(-3)
```

```
PGd = laurpoly(Gd, 'dmin', -3)
```

```
PGd(z) = ...
+ 0.01515*z^(+3) - 0.07576*z^(+2) - 0.3687*z^(+1) + 0.8586 - 0.3687*z^(-1) ...
- 0.07576*z^(-2) + 0.01515*z^(-3)
```

```
PGr = laurpoly(Gr, 'dmin', -2)
```

```
PGr(z) = - 0.07071*z^(+2) - 0.3536*z^(+1) + 0.8485 - 0.3536*z^(-1) - 0.07071*z^(-2)
```

Since the filters are associated with biorthogonal wavelet, confirm $PHd(z) PHr(z) + PG(z) PGr(z) = 2$.

```
PHd*PHr + PGd*PGr
```

```
ans(z) = 2
```

Wavelet Toolbox requires that filters associated with the wavelet have even equal length. To use the Laplacian wavelet filters in the toolbox, you must include the missing powers of the Laurent series as zeros.

The degrees of PHd and PHr are 4 and 6, respectively. The minimum even-length filter that can accommodate the four filters has length 8, which corresponds to a Laurent polynomial of degree 7. The strategy is to prepend and append 0s as evenly as possible so that all filters are of length 8. Prepend 0 to all the filters, and then append two 0s to Hd and Gr.

```
Hd = [0 Hd 0 0];
Gd = [0 Gd];
Hr = [0 Hr];
Gr = [0 Gr 0 0];
```

You can examine properties of the biorthogonal wavelets by creating DWT filter banks. Create two custom DWT filter banks using the filters, one for analysis and the other for synthesis. Confirm the filter banks are biorthogonal.

```
fb = dwtfilterbank('Wavelet','Custom',...
    'CustomScalingFilter',[Hd' Hr'],...
    'CustomWaveletFilter',[Gd' Gr']);

fb2 = dwtfilterbank('Wavelet','Custom',...
    'CustomScalingFilter',[Hd' Hr'],...
    'CustomWaveletFilter',[Gd' Gr'],...
    'FilterType','Synthesis');

fprintf('fb: isOrthogonal = %d\tisBiorthogonal = %d\n',...
    isOrthogonal(fb),isBiorthogonal(fb));

fb: isOrthogonal = 0    isBiorthogonal = 1

fprintf('fb2: isOrthogonal = %d\tisBiorthogonal = %d\n',...
    isOrthogonal(fb2),isBiorthogonal(fb2));

fb2: isOrthogonal = 0    isBiorthogonal = 1
```

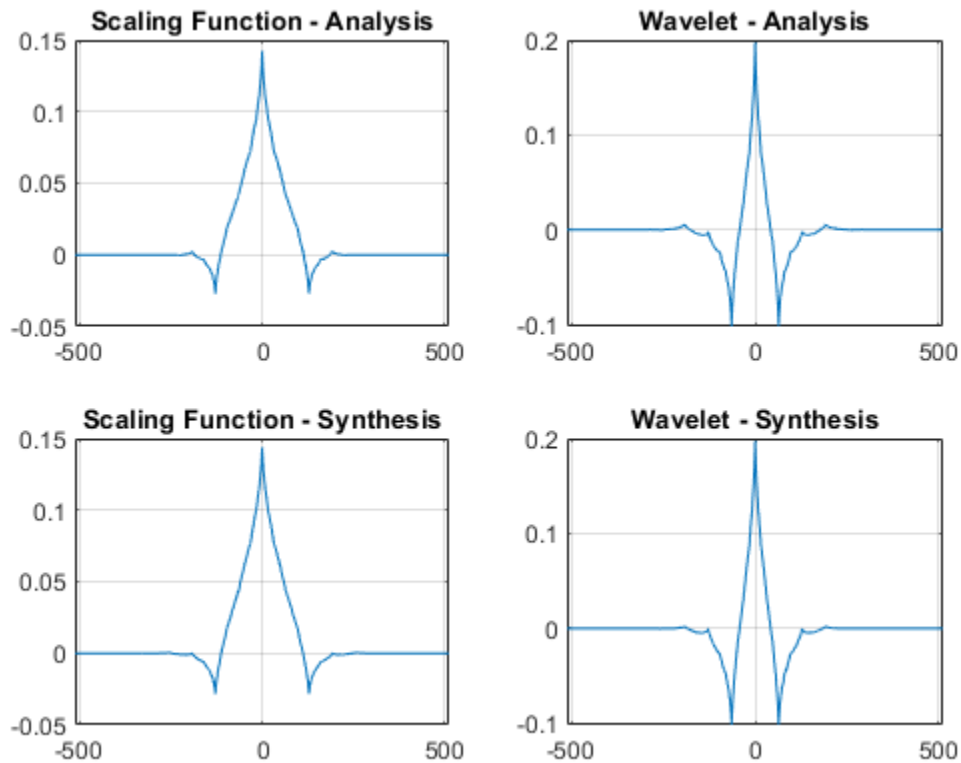

Plot the scaling and wavelet functions associated with the filter banks at the coarsest scale.

```
[phi,t] = scalingfunctions(fb);
[psi,~] = wavelets(fb);
[phi2,~] = scalingfunctions(fb2);
[psi2,~] = wavelets(fb2);
subplot(2,2,1)
plot(t,phi(end,:))
grid on
title('Scaling Function - Analysis')
subplot(2,2,2)
plot(t,psi(end,:))
grid on
```

```

title('Wavelet - Analysis')
subplot(2,2,3)
plot(t,phi2(end,:))
grid on
title('Scaling Function - Synthesis')
subplot(2,2,4)
plot(t,psi2(end,:))
grid on
title('Wavelet - Synthesis')

```

Compute the filter bank framebounds.

```

[analysisLowerBound,analysisUpperBound] = framebounds(fb)
analysisLowerBound = 0.9505
analysisUpperBound = 1.0211

[synthesisLowerBound,synthesisUpperBound] = framebounds(fb2)
synthesisLowerBound = 0.9800
synthesisUpperBound = 1.0528

```

Input Arguments

FN — Wavelet family name

character vector | string scalar

Wavelet family name, specified as a character vector or string scalar.

FSN — Wavelet family short name

character vector | string scalar

Wavelet family short name, specified as a character vector or string scalar. The number of characters in FSN must be less than or equal to 4.

WT — Wavelet family type

1 | 2 | 3 | 4 | 5

Wavelet family type, specified as one of the following:

- 1 - Orthogonal wavelets
- 2 - Biorthogonal wavelets
- 3 - Wavelet with a scaling function
- 4 - Wavelet without a scaling function
- 5 - Complex wavelet without a scaling function

NUMS — Wavelet parameters

' ' | character vector | string scalar

Wavelet parameters, specified as:

- If the family consists of a single wavelet, NUMS is the empty string ' '. For example, the mexh and morl families each contain a single wavelet.
- If the wavelet is member of a finite family of wavelets, NUMS contains a space-separated list of items representing wavelet parameters. For example, for the biorthogonal wavelet family bior, NUMS = '1.1 1.3 1.5 2.2 2.4 2.6 2.8 3.1 3.3 3.5 3.7 3.9 4.4 5.5 6.8'.
- If the wavelet is member of an infinite family of wavelets, NUMS contains a space-separated list of items representing wavelet parameters, terminated by the special sequence **. Two examples are listed in the following table.

Wavelet Family	NUMS
db	NUMS = '1 2 3 4 5 6 7 8 9 10 **'
shan	NUMS = '1-1.5 1-1 1-0.5 1-0.1 2-3 **'

TYPNUMS — Wavelet parameter input format

'integer' (default) | 'real' | 'charactervector'

Wavelet parameter input format, specified as:

- 'integer' — Use this option when the parameter is an integer. For example, the Daubechies wavelet family db uses an integer parameter.
- 'real' — Use this option when the parameter is real. For example, the biorthogonal wavelet family bior uses a real parameter.

- 'charactervector' — Use this option when the parameter is a character vector. For example, the Shannon wavelet family uses a character vector.

FILE — Wavelet definition file

character vector | string scalar

Wavelet definition file, specified as a character vector or string scalar. FILE is the name of a MAT-file or a code file name that defines the wavelet family.

B — Effective support

two-element real-valued vector

Effective support for wavelets with family type WT equal to 3, 4, or 5, specified as a two-element real-valued vector. If $B = [lb \ ub]$, then lb specifies the lower bound, and ub specifies the upper bound.

Data Types: double

WN — Wavelet family

character vector | string scalar

Wavelet family, specified by the character vector or string scalar WN. The value of WN is either the wavelet family name or wavelet family short name.

Example: `wavemngr('del','Lemarie')`**Limitations**

- `wavemngr` allows you to add a wavelet. You must verify that it is truly a wavelet. No check is performed to confirm the addition is a wavelet or to confirm the type of the new wavelet. You can use `dwtfilterbank` to verify if a wavelet is orthogonal or biorthogonal.

wavenames

Wavelet names for LWT

Syntax

`W = wavenames(T)`

Description

`W = wavenames(T)` returns a cell array that contains the name of all wavelets of type *T*. The valid values for *T* are

- 'all' — all wavelets
- 'lazy' — “lazy” wavelet
- 'orth' — orthogonal wavelets
- 'bior' — biorthogonal wavelets

`W = wavenames` is equivalent to `W = wavenames('all')`.

Introduced before R2006a

waverec

1-D wavelet reconstruction

Syntax

```
x = waverec(c,l,wname)
x = waverec(c,l,LoR,HiR)
```

Description

`x = waverec(c,l,wname)` reconstructs the 1-D signal `x` based on the multilevel wavelet decomposition structure `[c,l]` and the wavelet specified by `wname`. See `wavedec`.

Note `x = waverec(c,l,wname)` is equivalent to `x = appcoef(c,l,wname,0)`.

`x = waverec(c,l,LoR,HiR)` reconstructs the signal using the specified lowpass and highpass wavelet reconstruction filters `LoR` and `HiR`, respectively.

Examples

Multilevel 1-D Wavelet Reconstruction

Load a signal. Perform a level 3 wavelet decomposition of the signal using the `db6` wavelet.

```
load leleccum
wv = 'db6';
[c,l] = wavedec(leleccum,3,wv);
```

Reconstruct the signal using the wavelet decomposition structure.

```
x = waverec(c,l,wv);
```

Check for perfect reconstruction.

```
err = norm(leleccum-x)
err = 1.1134e-09
```

Input Arguments

c — Wavelet decomposition

vector

Wavelet decomposition, specified as a real-valued vector. The vector contains the wavelet coefficients. The bookkeeping vector `l` contains the number of coefficients by level. See `wavedec`.

l — Bookkeeping vector

vector

Bookkeeping vector, specified as a vector of positive integers. The bookkeeping vector is used to parse the coefficients in the wavelet decomposition `c` by level. See `wavedec`.

wname — Analyzing wavelet

character vector | string scalar

Analyzing wavelet, specified as a character vector or string scalar.

Note `waverec` supports only Type 1 (orthogonal) or Type 2 (biorthogonal) wavelets. See `wfilters` for a list of orthogonal and biorthogonal wavelets.

LoR, HiR — Wavelet reconstruction filters

even-length real-valued vectors

Wavelet reconstruction filters, specified as a pair of even-length real-valued vectors. `LoR` is the lowpass reconstruction filter, and `HiR` is the highpass reconstruction filter. The lengths of `LoR` and `HiR` must be equal. See `wfilters` for additional information.

Output Arguments

x — Reconstructed signal

vector

Reconstructed signal, returned as a real-valued vector.

`appcoef` | `idwt` | `wavedec`

Introduced before R2006a

waverec2

2-D wavelet reconstruction

Syntax

```
X = waverec2(C,S,wname)
X = waverec2(C,S,Lo_R,Hi_R)
X = waverec2(C,S,wname)
X = appcoef2(C,S,wname,0)
```

Description

`X = waverec2(C,S,wname)` performs a multilevel wavelet reconstruction of the matrix `X` based on the wavelet decomposition structure `[C,S]`. For detailed storage information, see `wavedec2`. `wname` is a character vector or string scalar specifying the wavelet. See `wfilters` for more information.

Instead of specifying the wavelet name, you can specify the filters.

- `X = waverec2(C,S,Lo_R,Hi_R)`, `Lo_R` is the reconstruction low-pass filter
- `Hi_R` is the reconstruction high-pass filter.

`waverec2` is the inverse function of `wavedec2` in the sense that the abstract statement `waverec2(wavedec2(X,N,wname),wname)` returns `X`.

`X = waverec2(C,S,wname)` is equivalent to `X = appcoef2(C,S,wname,0)`.

Examples

```
% The current extension mode is zero-padding (see dwtmode).
% Load original image.
load woman;
% X contains the loaded image.
% Perform decomposition at level 2
% of X using sym4.
[c,s] = wavedec2(X,2,'sym4');
% Reconstruct X from the wavelet
% decomposition structure [c,s].
a0 = waverec2(c,s,'sym4');
% Check for perfect reconstruction.
max(max(abs(X-a0)))
ans =
    2.5565e-10
```

Tips

If `C` and `S` are obtained from an indexed image analysis or a truecolor image analysis, `X` is an `m`-by-`n` matrix or an `m`-by-`n`-by-3 array, respectively.

For more information on image formats, see the `image` and `imfinfo` reference pages.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Variable-size data support must be enabled.
- The input `wname` must be constant.

`appcoef2` | `idwt2` | `wavedec2`

Introduced before R2006a

waverec3

3-D wavelet reconstruction

Syntax

```
X = waverec3(WDEC)
C = waverec3(WDEC,TYPE,N)
X = waverec3(WDEC,'a',0)
X = waverec3(WDEC,'ca',0)
C = waverec3(WDEC,TYPE)
C = waverec3(WDEC,TYPE,N)
```

Description

`waverec3` performs a multilevel 3-D wavelet reconstruction starting from a multilevel 3-D wavelet decomposition.

`X = waverec3(WDEC)` reconstructs the 3-D array `X` based on the multilevel wavelet decomposition structure `WDEC`. You can also use `waverec3` to extract coefficients from a 3-D wavelet decomposition.

`WDEC` is a structure with the fields shown in the table.

`C = waverec3(WDEC,TYPE,N)` reconstructs the multilevel components at level `N` of a 3-D wavelet decomposition. `N` must be a positive integer less than or equal to the level of the decomposition.

Valid values for `TYPE` are:

- A group of three characters 'xyz', one per direction, with 'x', 'y' and 'z' selected in the set {'a', 'd', 'l', 'h'} or in the corresponding uppercase set {'A', 'D', 'L', 'H'}), where 'A' (or 'L') is a low-pass filter and 'D' (or 'H') is a high-pass filter.
- The char 'd' (or 'h' or 'D' or 'H') gives the sum of all the components different from the low-pass.
- The char 'a' (or 'l' or 'A' or 'L') gives the low-pass component (the approximation at level `N`).

For extraction, the valid values for `TYPE` are the same but prefixed by 'c' or 'C'.

`X = waverec3(WDEC,'a',0)` or `X = waverec3(WDEC,'ca',0)` is equivalent to `X = waverec3(WDEC)`. `X` is a reconstruction of the coefficients in `WDEC` at level 0.

`C = waverec3(WDEC,TYPE)` is equivalent to `C = waverec3(WDEC,TYPE,N)` with `N` equal to the level of the decomposition.

<code>sizeINI</code>	Size of the three-dimensional array <code>X</code>
<code>level</code>	Level of the decomposition
<code>mode</code>	Name of the wavelet transform extension mode
<code>filters</code>	Structure with 4 fields, <code>LoD</code> , <code>HiD</code> , <code>LoR</code> , and <code>HiR</code> , which contain the filters used for DWT

dec	<p>$N \times 1$ cell array containing the coefficients of the decomposition. N is equal to $7 * WDEC.level + 1$.</p> <p>dec{1} contains the lowpass component (approximation) at the level of the decomposition. The approximation is equivalent to the filtering operations 'LLL'.</p> <p>dec{k+2}, ..., dec{k+8} with $k = 0, 7, 14, \dots, 7 * (WDEC.level - 1)$ contain the 3-D wavelet coefficients for the multiresolution starting with the coarsest level when $k=0$.</p> <p>For example, if $WDEC.level=3$, dec{2}, ..., dec{8} contain the wavelet coefficients for level 3 ($k=0$), dec{9}, ..., dec{15} contain the wavelet coefficients for level 2 ($k=7$), and dec{16}, ..., dec{22} contain the wavelet coefficients for level 1 ($k=7 * (WDEC.level - 1)$).</p> <p>At each level, the wavelet coefficients in dec{k+2}, ..., dec{k+8} are in the following order: 'HLL', 'LHL', 'HHL', 'LLH', 'HLH', 'LHH', 'HHH'.</p> <p>The sequence of letters gives the order in which the separable filtering operations are applied from left to right. For example, 'LHH' means that the lowpass (scaling) filter with downsampling is applied to the rows of X, followed by the highpass (wavelet) filter with downsampling applied to the columns of X. Finally, the highpass filter with downsampling is applied to the 3rd dimension of X.</p>
sizes	Successive sizes of the decomposition components

Examples

Perfect Reconstruction with 3-D Discrete Wavelet Transform

Construct a 3-D matrix, obtain the wavelet transform down to level 2 using the 'db2' wavelet, and reconstruct the matrix to verify perfect reconstruction.

Create 3-D matrix.

```
M = magic(8);
X = repmat(M,[1 1 8]);
```

Obtain the 3-D discrete wavelet transform of the matrix and reconstruct the input based on the 3-D approximation and detail coefficients.

```
wd = wavedec3(X,2,'db2');
XR = waverec3(wd);
```

Verify perfect reconstruction using the wavelet decomposition down to level 2.

```
err1 = max(abs(X(:)-XR(:)))
```

```
err1 = 8.6057e-11
```

Verify that the data matrix is the sum of the approximation and the details from levels 2 and 1.
Reconstruct the sum of components different from the lowpass component and check that $X = A + D$.

```
A = waverec3(wd, 'LLL');
D = waverec3(wd, 'd');
err2 = max(abs(X(:)-A(:)-D(:)))

err2 = 8.6054e-11
```

Compare waverec3 and idwt3

Compare level-1 reconstructions based on the filtering operations 'LLH' using `idwt3` and `waverec3`.

```
M = magic(8);
X = repmat(M,[1 1 8]);
wd = wavedec3(X,2,'db2','mode','per');
dwtOut = dwt3(X,'db2');
Xr = idwt3(dwtOut,'LLH');
Xrec = waverec3(wd,'LLH',1);
norm(Xr(:)-Xrec(:))

ans = 2.7511e-14
```

Introduced in R2010a

wavsupport

Wavelet support

Syntax

```
[LB,UB] = wavsupport(wname)
```

Description

`[LB,UB] = wavsupport(wname)` returns the lower bound, **LB**, and upper bound, **UB**, of the support for the wavelet specified by `wname`. `wname` is any valid wavelet. For real-valued wavelets with and without scaling functions and complex-valued wavelets without scaling functions (wavelets type 3,4, and 5), the bounds indicate the effective support of the wavelet. For orthogonal and biorthogonal wavelets (type 1 and type 2), the lower and upper bounds are $-0.5*(LF-1)$ and $0.5*(LF-1)$, where `LF` is the length of the wavelet filter.

Examples

Support of Haar Wavelet

Return the lower bound and upper bound of the support for the Haar wavelet.

```
[LB, UB] = wavsupport('haar')
```

```
LB = -0.5000
```

```
UB = 0.5000
```

Compare `LB` and `UB` to the lower and upper bounds for orthogonal and biorthogonal wavelets (type 1 and type 2).

```
LowerBound = -0.5*(2-1);
```

```
UpperBound = 0.5*(2-1);
```

Support of Complex-Valued Gaussian Wavelet

Return the lower bound and upper bound of the support for the complex-valued Gaussian wavelet.

```
[LB,UB] = wavsupport('cgau3')
```

```
LB = -5
```

```
UB = 5
```

wavemngr

Introduced in R2010b

wbmpen

Penalized threshold for wavelet 1-D or 2-D denoising

Syntax

```
THR = wbmpen(C,L,SIGMA,ALPHA)
wbmpen(C,L,SIGMA,ALPHA,ARG)
```

Description

`THR = wbmpen(C,L,SIGMA,ALPHA)` returns global threshold `THR` for denoising. `THR` is obtained by a wavelet coefficients selection rule using a penalization method provided by Birgé-Massart.

`[C,L]` is the wavelet decomposition structure of the signal or image to be denoised.

`SIGMA` is the standard deviation of the zero mean Gaussian white noise in denoising model (see `wnoisest` for more information).

`ALPHA` is a tuning parameter for the penalty term. It must be a real number greater than 1. The sparsity of the wavelet representation of the denoised signal or image grows with `ALPHA`. Typically `ALPHA = 2`.

`THR` minimizes the penalized criterion given by the following:

Let t^* be the minimizer of

$$\text{crit}(t) = -\sum(c(k)^2, k \leq t) + 2 \cdot \text{SIGMA}^2 \cdot t \cdot (\text{ALPHA} + \log(n/t))$$

where $c(k)$ are the wavelet coefficients sorted in decreasing order of their absolute value and n is the number of coefficients; then $\text{THR} = |c(t^*)|$.

`wbmpen(C,L,SIGMA,ALPHA,ARG)` computes the global threshold and, in addition, plots three curves:

- $2 \cdot \text{SIGMA}^2 \cdot t \cdot (\text{ALPHA} + \log(n/t))$
- $\sum(c(k)^2, k \leq t)$
- $\text{crit}(t)$

Examples

```
% Example 1: Signal denoising.
% Load noisy bumps signal.
load noisbump; x = noisbump;

% Perform a wavelet decomposition of the signal
% at level 5 using sym6.
wname = 'sym6'; lev = 5;
[c,l] = wavedec(x,lev,wname);
% Estimate the noise standard deviation from the
% detail coefficients at level 1, using wnoisest.
sigma = wnoisest(c,l,1);
```

```

% Use wbmpen for selecting global threshold
% for signal denoising, using the tuning parameter.
alpha = 2;
thr = wbmpen(c,l,sigma,alpha)
thr =

    2.7681

% Use wdencomp for denoising the signal using the above
% threshold with soft thresholding and approximation kept.
keepapp = 1;
xd = wdencomp('gbl',c,l,wname,lev,thr,'s',keepapp);

% Plot original and denoised signals.
figure(1)
subplot(211), plot(x), title('Original signal')
subplot(212), plot(xd), title('De-noised signal')

```

```

% Example 2: Image denoising.
% Load original image.
load noiswom;
nbc = size(map,1);

% Perform a wavelet decomposition of the image
% at level 3 using coif2.
wname = 'coif2'; lev = 3;
[c,s] = wavedec2(X,lev,wname);

% Estimate the noise standard deviation from the
% detail coefficients at level 1.
det1 = detcoef2('compact',c,s,1);
sigma = median(abs(det1))/0.6745;

% Use wbmpen for selecting global threshold
% for image denoising.
alpha = 1.2;
thr = wbmpen(c,l,sigma,alpha)

```

```
thr =  
  
    36.0621  
  
% Use wdencomp for denoising the image using the above  
% thresholds with soft thresholding and approximation kept.  
keepapp = 1;  
xd = wdencomp('gbl',c,s,wname,lev,thr,'s',keepapp);  
  
% Plot original and denoised images.  
figure(2)  
colormap(pink(nbc));  
subplot(221), image(wcodemat(X,nbc))  
title('Original image')  
subplot(222), image(wcodemat(xd,nbc))  
title('De-noised image')

Introduced before R2006a

wcodemat

Extended pseudocolor matrix scaling

Syntax

```
Y = wcodemat(X)
Y = wcodemat(X,NBCODES)
Y = wcodemat(X,NBCODES,OPT)
Y = wcodemat(X,NBCODES,OPT,ABSOL)
```

Description

`wcodemat` rescales an input matrix to a specified range for display. If the specified range is the full range of the current colormap, `wcodemat` is similar in behavior to `imagesc`.

`Y = wcodemat(X)` rescales the matrix `X` to integers in the range `[1,16]`.

`Y = wcodemat(X,NBCODES)` rescales the input `X` as integers in the range `[1,NBCODES]`. The default value of `NBCODES` is 16.

`Y = wcodemat(X,NBCODES,OPT)` rescales the matrix along the dimension specified by `OPT`. `OPT` can be one of: 'column' (or 'c'), 'row' (or 'r'), and 'mat' (or 'm'). 'rows' scales `X` row-wise, 'column' scales `X` column-wise, and 'mat' scales `X` globally. The default value of `OPT` is 'mat'.

`Y = wcodemat(X,NBCODES,OPT,ABSOL)` rescales the input matrix `X` based on the absolute values of the entries in `X` if `ABSOL` is nonzero, or based on the signed values of `X` if `ABSOL` is equal to zero. The default value of `ABSOL` is 1.

Examples

Extended Pseudocolor Matrix Scaling

Scale level-one approximation coefficients globally to the full range of the colormap.

Load an image.

```
load woman;
```

Get the range of the colormap.

```
NBCOL = size(map,1);
```

Obtain the 2D dwt using the Haar wavelet.

```
[cA1,cH1,cV1,cD1] = dwt2(X,'db1');
```

Display without scaling and with scaling.

```
image(cA1);
colormap(map);
title('Unscaled Image');
```

```
figure  
image(wcodemat(cA1,NBCOL));  
colormap(map);  
title('Scaled Image');
```

Scaled Image

Introduced before R2006a

wcoher

(Not recommended) Wavelet coherence

Note wcoher is not recommended. Use wcoherence instead.

Syntax

```
WCOH = wcoher(Sig1,Sig2,Scales,wname)
WCOH = wcoher(...,Name,Value)
[WCOH,WCS] = wcoher(...)
[WCOH,WCS,CWT_S1,CWT_S2] = wcoher(...)
[...] = wcoh(...,'plot')
```

Description

`WCOH = wcoher(Sig1,Sig2,Scales,wname)` returns the wavelet coherence for the input signals `Sig1` and `Sig2` using the wavelet specified in `wname` at the scales in `Scales`. The input signals must be real-valued and equal in length.

`WCOH = wcoher(...,Name,Value)` returns the wavelet coherence with additional options specified by one or more `Name,Value` pair arguments.

`[WCOH,WCS] = wcoher(...)` returns the wavelet cross spectrum.

`[WCOH,WCS,CWT_S1,CWT_S2] = wcoher(...)` returns the continuous wavelet transforms of `Sig1` and `Sig2`.

`[...] = wcoh(...,'plot')` displays the modulus and phase of the wavelet cross spectrum.

Input Arguments

Sig1

A real-valued one-dimensional input signal. `Sig1` is a row or column vector.

Sig2

A real-valued one-dimensional input signal. `Sig2` is a row or column vector.

Scales

`Scales` is a vector of real-valued, positive scales at which to compute the wavelet coherence.

wname

Wavelet used in the wavelet coherence. `wname` is any valid wavelet name.

Name-Value Pair Arguments

asc

Scale factor for arrows in quiver plot. `wcoher` represents the phase using `quiver`. `asc` corresponds to the `scale` input argument in `quiver`.

Default: 1

nas

Number of arrows in scale. Together with the number of scales, `nas` determines the spacing between the y coordinates in the input to `quiver`. The y input to `quiver` is `1:length(Scales)/(nas-1):Scales(end)`

Default: 20

nsw

Length of smoothing window in scale. `nsw` is a positive integer that specifies the length of a moving average filter in scale.

Default: 1

ntw

Length of smoothing window in time. `ntw` is a positive integer that specifies the length of a moving average filter in time.

Default: `min[20,0.05*length(Sig1)]`

plot

Type of plot. `plot` is one of the following:

- 'cwt'
Displays the continuous wavelet transforms of signals 1 and 2.
- 'wcs'
Displays the wavelet cross spectrum.
- 'wcoh'
Displays the phase of the wavelet cross spectrum.
- 'all'
Displays all plots in separate figures.

Output Arguments

WCOH

Wavelet coherence.

WCS

Wavelet cross spectrum.

CWT_S1

Continuous wavelet transform of signal 1.

CWT_S2

Continuous wavelet transform of signal 2.

Examples

Wavelet coherence of sine waves in noise with delay:

```
t = linspace(0,1,2048);
x = sin(16*pi*t)+0.5*randn(1,2048);
y = sin(16*pi*t+pi/4)+0.5*randn(1,2048);
wname = 'cgau3';
scales = 1:512;
ntw = 21; % smoothing parameter
% Display the modulus and phased of the wavelet cross spectrum.
wcoher(x,y,scales,wname,'ntw',ntw,'plot');
```

Sine wave and Doppler signal:

```
t = linspace(0,1,1024);
x = -sin(8*pi*t) + 0.4*randn(1,1024);
x = x/max(abs(x));
y = wnoise('doppler',10);
wname = 'cgau3';
scales = 1:512;
ntw = 21; % smoothing parameter
% Display of the CWT of the two signals.
wcoher(x,y,scales,wname,'ntw',ntw,'plot','cwt');
% Display of the wavelet cross spectrum.
wcoher(x,y,scales,wname,'ntw',ntw,'nsw',1,'plot','wcs');
% Display of the modulus and phased of the wavelet cross spectrum.
wcoher(x,y,scales,wname,'ntw',ntw,'plot');
```

More About

Wavelet Cross Spectrum

The wavelet cross spectrum of two time series, x and y is:

$$C_{xy}(a,b) = S(C_x^*(a,b)C_y(a,b))$$

where $C_x(a,b)$ and $C_y(a,b)$ denote the continuous wavelet transforms of x and y at scales a and positions b . The superscript $*$ is the complex conjugate and S is a smoothing operator in time and scale.

For real-valued time series, the wavelet cross spectrum is real-valued if you use a real-valued analyzing wavelet, and complex-valued if you use a complex-valued analyzing wavelet.

Wavelet Coherence

The wavelet coherence of two time series x and y is:

$$\frac{|S(C_x^*(a, b)C_y(a, b))|^2}{S(|C_x(a, b)|^2) \cdot S(|C_y(a, b)|^2)}$$

where $C_x(a, b)$ and $C_y(a, b)$ denote the continuous wavelet transforms of x and y at scales a and positions b . The superscript $*$ is the complex conjugate and S is a smoothing operator in time and scale.

For real-valued time series, the wavelet coherence is real-valued if you use a real-valued analyzing wavelet, and complex-valued if you use a complex-valued analyzing wavelet.

wcoherence

Wavelet coherence and cross-spectrum

Syntax

```
wcoh = wcoherence(x,y)
[wcoh,wcs] = wcoherence(x,y)
[wcoh,wcs,period] = wcoherence(x,y,ts)
[wcoh,wcs,f] = wcoherence(x,y,fs)
[wcoh,wcs,f,coi] = wcoherence(____)
[wcoh,wcs,period,coi] = wcoherence(____,ts)
[____,coi,wtx,wty] = wcoherence(____)
[____] = wcoherence(____,Name,Value)
wcoherence(____)
```

Description

`wcoh = wcoherence(x,y)` returns the magnitude-squared wavelet coherence, which is a measure of the correlation between signals `x` and `y` in the time-frequency plane. Wavelet coherence is useful for analyzing nonstationary signals. The inputs `x` and `y` must be equal length, 1-D, real-valued signals. The coherence is computed using the analytic Morlet wavelet.

`[wcoh,wcs] = wcoherence(x,y)` returns the wavelet cross-spectrum of `x` and `y`. You can use the phase of the wavelet cross-spectrum values to identify the relative lag between the input signals.

`[wcoh,wcs,period] = wcoherence(x,y,ts)` uses the positive duration `ts` as the sampling interval. The duration `ts` is used to compute the scale-to-period conversion, `period`. The duration array `period` has the same format as specified in `ts`.

`[wcoh,wcs,f] = wcoherence(x,y,fs)` uses the positive sampling frequency, `fs`, to compute the scale-to-frequency conversion, `f`. The sampling frequency `fs` is in Hz.

`[wcoh,wcs,f,coi] = wcoherence(____)` returns the cone of influence, `coi`, for the wavelet coherence in cycles per sample. If you specify the sampling frequency, `fs`, the cone of influence is in Hz.

`[wcoh,wcs,period,coi] = wcoherence(____,ts)` returns the cone of influence, `coi`, in cycles per unit time.

`[____,coi,wtx,wty] = wcoherence(____)` returns the continuous wavelet transforms (CWT) of `x` and `y` in `wtx`, `wty`, respectively. `wtx` and `wty` are used in the formation of the wavelet cross spectrum and coherence estimates.

`[____] = wcoherence(____,Name,Value)` specifies additional options using one or more name-value pair arguments. This syntax may be used in any of the previous syntaxes.

`wcoherence(____)` with no output arguments plots the wavelet coherence and cone of influence in the current figure. Due to the inverse relationship between frequency and period, a plot that uses the sampling interval is the inverse of a plot that uses the sampling frequency. For areas where the coherence exceeds 0.5, plots that use the sampling frequency display arrows to show the phase lag of

y with respect to x . The arrows are spaced in time and scale. The direction of the arrows corresponds to the phase lag on the unit circle. For example, a vertical arrow indicates a $\pi/2$ or quarter-cycle phase lag. The corresponding lag in time depends on the duration of the cycle.

Examples

Wavelet Coherence of Two Sine Waves

Use default `wcoherence` settings to obtain the wavelet coherence between a sine wave with random noise and a frequency-modulated signal with decreasing frequency over time.

```
t = linspace(0,1,1024);
x = -sin(8*pi*t) + 0.4*randn(1,1024);
x = x/max(abs(x));
y = wnoise('doppler',10);
wcoh = wcoherence(x,y);
```

The default coherence computation uses the analytic Morlet wavelet, 12 voices per octave and smooths 12 scales. The default number of octaves is equal to `floor(log2(numel(x))) - 1`, which in this case is 9.

Effect of Sampling Interval on Wavelet Coherence

Obtain the wavelet coherence data for two signals, specifying a sampling interval of 0.001 seconds. Both signals consist of two sine waves (10 Hz and 50 Hz) in white noise. The sine waves have different time supports.

Set the random number generator to its default settings for reproducibility. Then create the two signals.

```
rng default;
t = 0:0.001:2;
x = cos(2*pi*10*t).*(t>=0.5 & t<1.1)+ ...
cos(2*pi*50*t).*(t>= 0.2 & t< 1.4)+0.25*randn(size(t));
y = sin(2*pi*10*t).*(t>=0.6 & t<1.2)+...
sin(2*pi*50*t).*(t>= 0.4 & t<1.6)+ 0.35*randn(size(t));
subplot(2,1,1)
plot(t,x)
title('X')
subplot(2,1,2)
plot(t,y)
title('Y')
xlabel('Time (seconds)')
```

Obtain the coherence of the two signals.

```
[wcoh,~,period,coi] = wcoherence(x,y,seconds(0.001));
```

Use the `pcolor` command to plot the coherence and cone of influence.

```
figure
period = seconds(period);
coi = seconds(coi);
h = pcolor(t,log2(period),wcoh);
h.EdgeColor = 'none';
ax = gca;
ytick=round(pow2(ax.YTick),3);
ax.YTickLabel=ytick;
ax.XLabel.String='Time';
ax.YLabel.String='Period';
ax.Title.String = 'Wavelet Coherence';
hcol = colorbar;
hcol.Label.String = 'Magnitude-Squared Coherence';
hold on;
plot(ax,t,log2(coi),'w--','linewidth',2)
```

Use `wcoherence(x,y,seconds(0.001))` without any outputs arguments. This plot includes the phase arrows and the cone of influence.

```
wcoherence(x,y,seconds(0.001));
```

Effect of Sampling Frequency on Wavelet Coherence

Obtain the wavelet coherence for two signals, specifying a sampling frequency of 1000 Hz. Both signals consist of two sine waves (10 Hz and 50 Hz) in white noise. The sine waves have different time supports.

Set the random number generator to its default settings for reproducibility and create the two signals.

```
rng default
t = 0:0.001:2;
x = cos(2*pi*10*t).*(t>=0.5 & t<1.1)+...
    cos(2*pi*50*t).*(t>= 0.2 & t< 1.4)+0.25*randn(size(t));
y = sin(2*pi*10*t).*(t>=0.6 & t<1.2)+...
    sin(2*pi*50*t).*(t>= 0.4 & t<1.6)+ 0.35*randn(size(t));
```

Obtain the wavelet coherence. The coherence plot is flipped with respect to the plot in the previous example, which specifies a sampling interval instead of a sampling frequency.

```
wcoherence(x,y,1000)
```

Obtain the scale-to-frequency conversion output in `f`.

```
[wcoh,wcs,f] = wcoherence(x,y,1000);
```

Effect of Number of Smoothed Scales on Wavelet Coherence

Obtain the wavelet coherence for two signals. Both signals consist of two sine waves (10 Hz and 50 Hz) in white noise. Use the default number of scales to smooth. This value is equivalent to the number of voices per octave. Both values default to 12.

Set the random number generator to its default settings for reproducibility. Then, create the two signals and obtain the coherence.

```
rng default;
t = 0:0.001:2;
x = cos(2*pi*10*t).*(t>=0.5 & t<1.1)+ ...
cos(2*pi*50*t).*(t>= 0.2 & t< 1.4)+0.25*randn(size(t));
y = sin(2*pi*10*t).*(t>=0.6 & t<1.2)+...
sin(2*pi*50*t).*(t>= 0.4 & t<1.6)+ 0.35*randn(size(t));
wcoherence(x,y)
```

Set the number of scales to smooth to 18. The increased smoothing causes reduced low frequency resolution.

```
wcoherence(x,y,'NumScalesToSmooth',18)
```

Effect of Phase Display Threshold on Wavelet Coherence of Weather Data

Compare the effects of using different phase display thresholds on the wavelet coherence.

Plot the wavelet coherence between the El Nino time series and the All India Average Rainfall Index. The data are sampled monthly. Specify the sampling interval as 1/12 of a year to display the periods in years. Use the default phase display threshold of 0.5, which shows phase arrows only where the coherence is greater than or equal to 0.5.

```
load ninoairdata;
wcoherence(nino,air,years(1/12));
```

Set the phase display threshold to 0.7. The number of phase arrows decreases.

```
wcoherence(nino,air,years(1/12),'PhaseDisplayThreshold',0.7);
```

Input Arguments

x – Input signal

vector of real values

Input signal, specified as a vector of real values. x must be a 1-D, real-valued signal. The two input signals, x and y , must be the same length and must have at least four samples.

y – Input signal

vector of real values

Input signal, specified as vector of real values. y must be a 1-D, real-valued signal. The two input signals, x and y , must be the same length and must have at least four samples.

ts – Sampling interval

duration with positive scalar input

Sampling interval, also known as the sampling period, specified as a duration with positive scalar input. Valid durations are years, days, hours, seconds, and minutes. You can also use the `duration` function to specify ts . You cannot use calendar durations (`caldays`, `calweeks`, `calmonths`, `calquarters`, or `calyears`).

You cannot specify both a sampling frequency fs and a sampling period ts .

fs — Sampling frequency

positive scalar | []

Sampling frequency, specified as a positive scalar.

If you specify `fs` as empty, `wcoherence` uses normalized frequency in cycles/sample. The Nyquist frequency is $\frac{1}{2}$.

You cannot specify both a sampling frequency `fs` and a sampling period `ts`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'PhaseDisplayThreshold',0.7`; specifies the threshold for displaying phase vectors.

FrequencyLimits — Frequency limits

two-element scalar vector

Frequency limits to use in `wcoherence`, specified as a two-element vector with positive strictly increasing elements. The first element specifies the lowest peak passband frequency and must be greater than or equal to the product of the wavelet peak frequency in hertz and two time standard deviations divided by the signal length. The second element specifies the highest peak passband frequency and must be less than or equal to the Nyquist frequency. The base 2 logarithm of the ratio of the maximum frequency to the minimum frequency must be greater than or equal to $1/NV$ where NV is the number of voices per octave.

If you specify frequency limits outside the permissible range, `wcoherence` truncates the limits to the minimum and maximum valid values. Use `cwtfreqbounds` with the wavelet set to `'amor'` to determine frequency limits for different parameterizations of the wavelet coherence.

Example: `'FrequencyLimits',[0.1 0.3]`

PeriodLimits — Period limits

two-element duration array

Period limits to use in `wcoherence`, specified as a two-element duration array with strictly increasing positive elements. The first element must be greater than or equal to $2 \times ts$ where `ts` is the sampling period. The base 2 logarithm of the ratio of the minimum period to the maximum period must be less than or equal to $-1/NV$ where NV is the number of voices per octave. The maximum period cannot exceed the signal length divided by the product of two time standard deviations of the wavelet and the wavelet peak frequency.

If you specify period limits outside the permissible range, `wcoherence` truncates the limits to the minimum and maximum valid values. Use `cwtfreqbounds` with the wavelet set to `'amor'` to determine period limits for different parameterizations of the wavelet coherence.

Example: `'PeriodLimits',[seconds(0.2) seconds(1)]`

Data Types: duration

VoicesPerOctave — Number of voices per octave

12 (default) | even integer from 10 to 32

Number of voices per octave to use in the wavelet coherence, specified as an even integer from 10 to 32.

NumScalesToSmooth — Number of scales to smooth

positive integer

Number of scales to smooth in time and scale, specified as a positive integer less than or equal to one half N , where N is the number of scales in the wavelet transform. If unspecified, `NumScalesToSmooth` defaults to the minimum of $\text{floor}(N/2)$ and `VoicesPerOctave`. The function uses a moving average filter to smooth across scale. If your coherence is noisy, you can specify a larger `NumScalesToSmooth` value to smooth the coherence more.

NumOctaves — Number of octaves

positive integer

Number of octaves to use in the wavelet coherence, specified as a positive integer between 1 and $\text{floor}(\log_2(\text{numel}(x))) - 1$. If you do not need to examine lower frequency values, use a smaller `NumOctaves` value.

The `'NumOctaves'` name-value pair is not recommended and will be removed in a future release. The recommended way to modify the frequency or period range of wavelet coherence is with the `'FrequencyLimits'` or `'PeriodLimits'` name-value pairs. You cannot specify both the `'NumOctaves'` and `'FrequencyLimits'` or `'PeriodLimits'` name-value pairs. See `cwtfreqbounds`.

PhaseDisplayThreshold — Threshold for displaying phase vectors

0.5 (default) | real scalar between 0 and 1

Threshold for displaying phase vectors, specified as a real scalar between 0 and 1. This function displays phase vectors for regions with coherence greater than or equal to the specified threshold value. Lowering the threshold value displays more phase vectors. If you use `wcoherence` with any output arguments, the `PhaseDisplayThreshold` value is ignored.

Output Arguments

wcoh — Wavelet coherence

matrix

Wavelet coherence, returned as a matrix. The coherence is computed using the analytic Morlet wavelet over logarithmic scales, with a default value of 12 voices per octave. The default number of octaves is equal to $\text{floor}(\log_2(\text{numel}(x))) - 1$. If you do not specify a sampling interval, sampling frequency is assumed.

wcs — Wavelet cross spectrum

matrix of complex values

Wavelet cross-spectrum, returned as a matrix of complex values. You can use the phase of the wavelet cross-spectrum values to identify the relative lag between the input signals.

period — Scale-to-period conversion

array of durations

Scale-to-period conversion, returned as an array of durations. The conversion values are computed from the sampling period specified in `ts`. Each `period` element has the same format as `ts`.

f — Scale-to-frequency conversion

vector

Scale-to-frequency conversion, returned as a vector. The vector contains the peak frequency values for the wavelets used to compute the coherence. If you want to output **f**, but do not specify a sampling frequency input, **fs**, the returned wavelet coherence is in cycles per sample.

coi — Cone of influence

array of doubles | array of durations

Cone of influence for the wavelet coherence, returned as either an array of doubles or array of durations. The cone of influence indicates where edge effects occur in the coherence data. If you specify a sampling frequency, **fs**, the cone of influence is in Hz. If you specify a sampling interval or period, **ts**, the cone of influence is in periods. Due to the edge effects, give less credence to areas of apparent high coherence that are outside or overlap the cone of influence. The cone of influence is indicated by a dashed line.

For additional information, see “Boundary Effects and the Cone of Influence”.

wtx — Continuous wavelet transform of x

matrix

Continuous wavelet transform of **x**, returned as a matrix.

wty — Continuous wavelet transform of y

matrix

Continuous wavelet transform of **y**, returned as a matrix.

More About**Wavelet Cross Spectrum**

The wavelet cross-spectrum is a measure of the distribution of power of two signals.

The wavelet cross spectrum of two time series, **x** and **y**, is:

$$C_{xy}(a, b) = S(C_x^*(a, b)C_y(a, b))$$

$C_x(a, b)$ and $C_y(a, b)$ denote the continuous wavelet transforms of **x** and **y** at scales **a** and positions **b**. The superscript * is the complex conjugate, and **S** is a smoothing operator in time and scale.

For real-valued time series, the wavelet cross-spectrum is real-valued if you use a real-valued analyzing wavelet, and complex-valued if you use a complex-valued analyzing wavelet.

Wavelet Coherence

Wavelet coherence is a measure of the correlation between two signals.

The wavelet coherence of two time series **x** and **y** is:

$$\frac{|S(C_x^*(a, b)C_y(a, b))|^2}{S(|C_x(a, b)|^2) \cdot S(|C_y(a, b)|^2)}$$

$C_x(a,b)$ and $C_y(a,b)$ denote the continuous wavelet transforms of x and y at scales a and positions b . The superscript $*$ is the complex conjugate and S is a smoothing operator in time and scale.

For real-valued time series, the wavelet coherence is real-valued if you use a real-valued analyzing wavelet, and complex-valued if you use a complex-valued analyzing wavelet.

Compatibility Considerations

'NumOctaves' name-value pair will be removed

Not recommended starting in R2020a

The 'NumOctaves' name-value pair argument will be removed in a future release. Use either:

- Name-value pair argument 'FrequencyLimits' to modify the frequency range of wavelet coherence.
- Name-value pair argument 'PeriodLimits' to modify the period range of wavelet coherence.

See `cwtfreqbounds` for additional information.

`cwt` | `cwtfilterbank` | `cwtfreqbounds`

Introduced in R2016a

wcompress

True compression of images using wavelets

Syntax

```
wcompress('c',X,SAV_FILENAME,COMP_METHOD)
wcompress(...,'ParName1',ParVal1,'ParName2',ParVal2,...)
[COMPRAT,BPP] = wcompress('c',...)
XC = wcompress('u',SAV_FILENAME)
XC = wcompress('u',SAV_FILENAME,'plot')
XC = wcompress('u',SAV_FILENAME,'step')
```

Description

The `wcompress` command performs either compression or uncompression of grayscale or truecolor images.

More theoretical information on true compression is in “Wavelet Compression for Images” of the Wavelet Toolbox User's Guide.

Compression

`wcompress('c',X,SAV_FILENAME,COMP_METHOD)` compresses the image `X` using the compression method `COMP_METHOD`.

The compressed image is saved in the file `SAV_FILENAME`. You must have write permission in the current working directory or MATLAB will change directory to `tempdir` and write the `.wtc` file in that directory. `X` can be either a 2-D array containing an indexed image or a 3-D array of `uint8` containing a truecolor image. Both the row and column size of the image must be powers of two.

`wcompress('c',FILENAME,...)` loads the image `X` from the file `FILENAME` which is a MATLAB Supported Format (MSF) file: MAT-file or other image files (see `imread`).

`wcompress('c',I,...)` converts the indexed image `X = I{1}` to a truecolor image `Y` using the colormap `map = I{2}` and then compresses `Y`.

Note Data written to `.wtc` files uses `uint64` precision. In releases previous to R2016b, data was written using `uint32`. If your code is affected adversely by this change, use the `legacy` option to compress and uncompress your data using the previous behavior.

```
wcompress('c',X,SAV_FILENAME,COMP_METHOD,'legacy')
```

The valid compression methods are divided in three categories.

- 1 Progressive Coefficients Significance Methods (**PCSM**):

MATLAB Name	Compression Method Name
'ezw'	Embedded Zerotree Wavelet
'spiht'	Set Partitioning In Hierarchical Trees
'stw'	Spatial-orientation Tree Wavelet
'wdr'	Wavelet Difference Reduction
'aswdr'	Adaptively Scanned Wavelet Difference Reduction
'spiht_3d'	Set Partitioning In Hierarchical Trees 3D for truecolor images

For more details on these methods, see the references and especially Walker and also Said and Pearlman.

1 Coefficients Thresholding Methods (CTM-1):

MATLAB Name	Compression Method Name
'lvl_mmc'	Subband thresholding of coefficients and Huffman encoding

For more details on this method, see the Strang and Nguyen reference.

1 Coefficients Thresholding Methods (CTM-2):

MATLAB Name	Compression Method Name
'gbl_mmc_f'	Global thresholding of coefficients and fixed encoding
'gbl_mmc_h'	Global thresholding of coefficients and Huffman encoding

Note The Discrete Wavelet Transform uses the periodized extension mode.

All the compression methods use parameters which have default values. You can change these values using the following syntax:

```
wcompress(..., 'ParName1', ParVal1, 'ParName2', ParVal2, ...)
```

Some of the parameters are related to display or to data transform functionalities. The others are linked to the compression process itself.

Data transform parameters

- 'ParName' = 'wname' or 'WNAME' sets the wavelet name.

ParVal is a character vector or string scalar (see `waveletfamilies`). The default for is `bior4.4`

- 'ParName' = 'level' or 'LEVEL' sets the level of decomposition.

ParVal is an integer such that: $1 \leq \text{level} \leq \text{levmax}$ which is the maximum possible level (see `wmaxlev`).

The default level depends on the method:

- for **PCSM** methods level is equal to levmax.
- for **CTM** methods level is equal to `fix(levmax/2)`

- `ParName` = 'it' or 'IT' sets Image type Transform.

`ParVal` must be one of the following:

'n' : no transformation (default), image type (truecolor or grayscale) is automatically detected.

'g' : grayscale transformation type.

'c' : color transformation type (RGB uint8).

- `ParName` = 'cc' or 'CC' sets Color Conversion parameter if X is a truecolor image.

`ParVal` must be one of the following:

'rgb' or 'none' : No conversion (default).

'yuv' : YUV color space transform.

'klt' : Karhunen-Loeve transform.

'yiq' : YIQ color space transform.

'xyz' : CIEXYZ color space transform.

Parameter for Progressive Coefficients Significance Methods (PCSM)

- `ParName` = 'maxloop' or 'MAXLOOP' sets the maximum number of steps for the compression algorithm.

`ParVal` must be a positive integer or Inf (default is 10).

Parameters for Coefficients Thresholding Methods (CTM-1)

Either of the following parameters may be used:

- `ParName` = 'bpp' or 'BPP' sets the bit-per-pixel ratio.

`ParVal` must be such that $0 \leq \text{ParVal} \leq 8$ (grayscale) or 24 (truecolor).

- `ParName` = 'comprat' or 'COMPRAT' sets the compression ratio.

`ParVal` must be such that $0 \leq \text{ParVal} \leq 100$.

Parameters for Coefficients Thresholding Methods (CTM-2)

Two parameters may be used. The first is related to the threshold and the second is the number of classes for quantization.

The first one may be chosen among the five following parameters:

- `ParName` = 'threshold' or 'THRESHOLD' sets the threshold value for compression.

`ParVal` must be a positive (or zero) real number.

- `ParName` = 'nbcfs' or 'NBCFS' sets the number of preserved coefficients in the wavelet decomposition.

`ParVal` must be an integer such that: $0 \leq \text{ParVal} \leq$ total number of coefficients of wavelet decomposition.

- 'ParName' = 'percfs' or 'PERCFS' sets the percentage of preserved coefficients in the wavelet decomposition.

ParVal must be a real number such that: $0 \leq \text{ParVal} \leq 100$.

- 'ParName' = 'bpp' or 'BPP' sets the bit-per-pixel ratio.

ParVal must be such that: $0 \leq \text{ParVal} \leq 8$ (grayscale) or 24 (truecolor)

- 'ParName' = 'comprat' or 'COMPRAT' sets the compression ratio.

ParVal must be such that: $0 \leq \text{ParVal} \leq 100$.

The second parameter sets the number of classes for quantization:

- 'ParName' = 'nbclas' or 'NBCLAS' sets the number of classes.

ParVal must be a real number such that: $2 \leq \text{ParVal} \leq 200$.

Display parameter

- 'ParName' = 'plotpar' or 'PLOTPAR' sets the plot parameter.

ParVal must be one of the following:

'plot' or 0: plots only the compressed image.

'step' or 1: displays each step of the encoding process (only for **PCSM** methods).

[COMPRAT,BPP] = wcompress('c',...) returns the compression ratio COMPRAT and the bit_per_pixel ratio BPP.

Uncompression

XC = wcompress('u',SAV_FILENAME) uncompresses the file SAV_FILENAME, which contains the compressed image, and returns the image XC. Depending on the initial compressed image, XC can be a 2-D array containing either an indexed image or a 3-D array of uint8 containing a truecolor image.

XC = wcompress('u',SAV_FILENAME,'plot') plots the uncompressed image.

XC = wcompress('u',SAV_FILENAME,'step') shows the step-by-step uncompression, only for **PCSM** methods.

Examples

Image Compression Using Basic Parameters

This example shows how to compress and uncompress the jpeg image arms.jpg.

Use the spatial orientation tree wavelet ('stw') compression method and save the compressed image to a file.

```
wcompress('c','arms.jpg','comp_arms.wtc','stw');
```

Load the stored image and display the step-by-step uncompression to produce the uncompressed image.

```
wcompress('u','comp_arms.wtc','step');
```

Image Compression and Uncompression Using Advanced Parameters.

This example show how to compress a jpeg image using the adaptively scanned wavelet difference reduction compression method ('aswdr'). The conversion color ('cc') uses the Karhunen-Loeve transform ('klt'). The maximum number of loops ('maxloop') is set to 11 and the plot type ('plotpar') is set to step through the compression. Show the compression ratio (cratio) and the bit-per-pixel ratio (bpp), which indicate the quality of the compression.

```
[cratio,bpp] = wcompress('c','woodstatue.jpg','woodstatue.wtc', ...
    'aswdr','cc','klt','maxloop',11,'plotpar','step');
```

```
cratio
bpp
```

```
cratio =
    3.0792
```

```
bpp =
    0.7390
```

Load the compressed image and step through the uncompression process.

```
wcompress('u', 'woodstatue.wtc', 'step');
```

Compression and Uncompression of a Grayscale Image

This example shows how to compress a grayscale image using the set partitioning in hierarchical trees ('spih') compression method. It also computes the mean square error (MSE) and the peak signal to noise ratio (PSNR) error values. You use these two measures to quantify the error between two images. The PSNR is expressed in decibels.

Load the image and store it in a file.

```
load mask;  
[cr,bpp] = wcompress('c',X,'mask.wtc','spih','maxloop',12)  
  
cr = 2.8610  
  
bpp = 0.2289
```

Load the stored image from the file, uncompress it, and delete the file.

```
Xc = wcompress('u','mask.wtc');  
delete('mask.wtc')
```

Display the original and compressed images.

```
colormap(pink(255))  
subplot(1,2,1); image(X); title('Original image')  
axis square
```

```
subplot(1,2,2); image(Xc); title('Compressed image')
axis square
```

Compute the MSE and PSNR.

```
D = abs(X-Xc).^2;
mse = sum(D(:))/numel(X)

mse = 33.6564

psnr = 10*log10(255*255/mse)

psnr = 32.8601
```

Compression and Uncompression of a Truecolor Image

This example shows how to compress a truecolor image using the set partitioning in hierarchical trees - 3D ('spiht_3D') compression method.

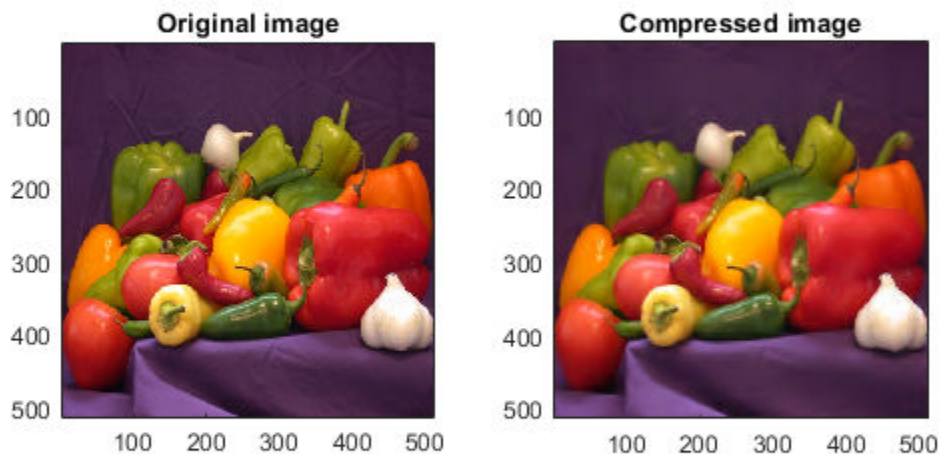

Load, compress, and store the image in a file. Plot the original and compressed images. Display the compression ratio ('cratio') and the bits-per-pixel ('bpp'), which indicate the quality of the compression.

```
load mask;
X = imread('wpeppers.jpg');
[cratio,bpp] = wcompress('c',X,'wpeppers.wtc','spiht','maxloop',12)
```

```
cratio = 1.6549  
bpp = 0.3972  
Xc = wcompress('u','wpeppers.wtc');  
delete('wpeppers.wtc')
```

Display the original and compressed images.

```
subplot(1,2,1)  
image(X)  
title('Original image')  
axis square  
subplot(1,2,2)  
image(Xc)  
title('Compressed image')  
axis square
```

Compute the mean square error (MSE) and the peak signal-to-noise ratio (PSNR) error values. You use these two measures to quantify the error between two images. The PSNR is expressed in decibels.

```
D = abs(double(X)-double(Xc)).^2;  
mse = sum(D(:))/numel(X)  
  
mse = 26.7808  
  
psnr = 10*log10(255*255/mse)
```

psnr = 33.8526

wdcbm

Thresholds for wavelet 1-D using Birgé-Massart strategy

Syntax

```
[THR,NKEEP] = wdcbm(C,L,ALPHA,M)
wdcbm(C,L,ALPHA)
wdcbm(C,L,ALPHA,L(1))
```

Description

[THR,NKEEP] = wdcbm(C,L,ALPHA,M) returns level-dependent thresholds THR and numbers of coefficients to be kept NKEEP, for denoising or compression. THR is obtained using a wavelet coefficients selection rule based on the Birgé-Massart strategy.

[C,L] is the wavelet decomposition structure of the signal to be denoised or compressed, at level $j = \text{length}(L) - 2$. ALPHA and M must be real numbers greater than 1.

THR is a vector of length j ; THR(i) contains the threshold for level i .

NKEEP is a vector of length j ; NKEEP(i) contains the number of coefficients to be kept at level i .

j , M and ALPHA define the strategy:

- At level $j+1$ (and coarser levels), everything is kept.
- For level i from 1 to j , the n_i largest coefficients are kept with $n_i = M / (j+2-i)^{\text{ALPHA}}$.

Typically ALPHA = 1.5 for compression and ALPHA = 3 for denoising.

A default value for M is $M = L(1)$, the number of the coarsest approximation coefficients, since the previous formula leads for $i = j+1$, to $n_{j+1} = M = L(1)$. Recommended values for M are from $L(1)$ to $2*L(1)$.

wdcbm(C,L,ALPHA) is equivalent to wdcbm(C,L,ALPHA,L(1)).

Examples

```
% Load electrical signal and select a part of it.
load leleccum; indx = 2600:3100;
x = leleccum(indx);

% Perform a wavelet decomposition of the signal
% at level 5 using db3.
wname = 'db3'; lev = 5;
[c,l] = wavedec(x,lev,wname);

% Use wdcbm for selecting level dependent thresholds
% for signal compression using the advised parameters.
alpha = 1.5; m = l(1);
[thr,nkeep] = wdcbm(c,l,alpha,m)
```

```

thr =
    19.5569    17.1415    20.2599    42.8959    15.0049

nkeep =
     1     2     3     4     7

% Use wdencmp for compressing the signal using the above
% thresholds with hard thresholding.
[xd, cxd, lxd, perf0, perf12] = ...
    wdencmp('lvd', c, l, wname, lev, thr, 'h');

% Plot original and compressed signals.
subplot(211), plot(indx, x), title('Original signal');
subplot(212), plot(indx, xd), title('Compressed signal');
xlab1 = ['2-norm rec.: ', num2str(perf12)];
xlab2 = ['% -- zero cfs: ', num2str(perf0), ' %'];
xlabel([xlab1 xlab2]);

```

wdcbm2

Thresholds for wavelet 2-D using Birgé-Massart strategy

Syntax

```
[THR,NKEEP] = wdcbm2(C,S,ALPHA,M)
wdcbm2(C,S,ALPHA)
wdcbm2(C,S,ALPHA,prod(S(1,:)))
```

Description

[THR,NKEEP] = wdcbm2(C,S,ALPHA,M) returns level-dependent thresholds THR and numbers of coefficients to be kept NKEEP, for de-noising or compression. THR is obtained using a wavelet coefficients selection rule based on the Birgé-Massart strategy.

[C,S] is the wavelet decomposition structure of the image to be de-noised or compressed, at level $j = \text{size}(S,1) - 2$.

ALPHA and M must be real numbers greater than 1.

THR is a matrix 3 by j ; THR(:,i) contains the level dependent thresholds in the three orientations: horizontal, diagonal, and vertical, for level i .

NKEEP is a vector of length j ; NKEEP(i) contains the number of coefficients to be kept at level i .

j , M and ALPHA define the strategy:

- At level $j+1$ (and coarser levels), everything is kept.
- For level i from 1 to j , the n_i largest coefficients are kept with $n_i = M / (j+2-i)^{\text{ALPHA}}$.

Typically ALPHA = 1.5 for compression and ALPHA = 3 for de-noising.

A default value for M is $M = \text{prod}(S(1,:))$, the length of the coarsest approximation coefficients, since the previous formula leads for $i = j+1$, to $n_{j+1} = M = \text{prod}(S(1,:))$.

Recommended values for M are from $\text{prod}(S(1,:))$ to $6 * \text{prod}(S(1,:))$.

wdcbm2(C,S,ALPHA) is equivalent to wdcbm2(C,S,ALPHA,prod(S(1,:))).

Examples

```
% Load original image.
load detfingr;
nbc = size(map,1);

% Perform a wavelet decomposition of the image
% at level 3 using sym4.
wname = 'sym4'; lev = 3;
[c,s] = wavedec2(X,lev,wname);

% Use wdcbm2 for selecting level dependent thresholds
```

```

% for image compression using the advised parameters.
alpha = 1.5; m = 2.7*prod(s(1,:));
[thr,nkeep] = wdcbm2(c,s,alpha,m)

thr =
    21.4814    46.8354    40.7907
    21.4814    46.8354    40.7907
    21.4814    46.8354    40.7907

nkeep =
         624         961        1765

% Use wdencomp for compressing the image using the above
% thresholds with hard thresholding.
[xd,cxd,sxd,perf0,perfl2] = ...
    wdencomp('lvd',c,s,wname,lev,thr,'h');

% Plot original and compressed images.
colormap(pink(nbc));
subplot(221), image(wcodemat(X,nbc)),
title('Original image')
subplot(222), image(wcodemat(xd,nbc)),
title('Compressed image')
xlabel = ['2-norm rec.: ',num2str(perfl2)];
xlab2 = [' % -- zero cfs: ',num2str(perf0), ' %'];
xlabel([xlabel xlab2]);

wdecenergy

Multisignal 1-D decomposition energy distribution

Syntax

```
[E,PEC,PECFS] = wdecenergy(DEC)
[E,PEC,PECFS,IDXSORT,LONGS] = wdecenergy(DEC,'sort')
[E,PEC,PECFS] = wdecenergy(DEC,OPTSORT,IDXSIG)
[E,PEC,PECFS,IDXSORT,LONGS] = wdecenergy(DEC,OPTSORT,IDXSIG)
```

Description

`[E,PEC,PECFS] = wdecenergy(DEC)` computes the vector `E` that contains the energy (L2-Norm) of each decomposed signal, the matrix `PEC` that contains the percentage of energy for each wavelet component (approximation and details) of each signal, and the matrix `PECFS` that contains the percentage of energy for each coefficient.

- `E(i)` is the energy (L2-norm) of the `i`th signal.
- `PEC(i,1)` is the percentage of energy for the approximation of level `MAXLEV = DEC.level` of the `i`th signal.
- `PEC(i,j)`, `j=2,...,MAXLEV+1` is the percentage of energy for the detail of level `(MAXLEV+1-j)` of the `i`th signal.
- `PECFS(i,j)`, is the percentage of energy for `j`th coefficients of the `i`th signal.

`[E,PEC,PECFS,IDXSORT,LONGS] = wdecenergy(DEC,'sort')` returns `PECFS` sorted (by row) in ascending order and an index vector `IDXSORT`.

- Replacing 'sort' by 'ascend' returns the same result.
- Replacing 'sort' by 'descend' returns `PECFS` sorted in descending order.

`LONGS` is a vector containing the lengths of each family of coefficients.

`[E,PEC,PECFS] = wdecenergy(DEC,OPTSORT,IDXSIG)` returns the values for the signals whose indices are given by the `IDXSIG` vector.

`[E,PEC,PECFS,IDXSORT,LONGS] = wdecenergy(DEC,OPTSORT,IDXSIG)` returns the values for the signals whose indices are given by the `IDXSIG` vector, the index vector `IDXSORT`, and `LONGS`, which is a vector containing the lengths of each family of coefficients. Valid values for `OPTSORT` are 'none', 'sort', 'ascend', 'descend'.

Examples

Multisignal 1-D Decomposition Energy Distribution

Load the 23 channel EEG data `Espiga3` [1]. The channels are arranged column-wise. The data is sampled at 200 Hz.

```
load Espiga3
```

Perform a decomposition at level 2 using the db2 wavelet.

```
dec = mdwtdec('c',Espiga3,2,'db2')

dec = struct with fields:
    dirDec: 'c'
    level: 2
    wname: 'db2'
    dwtFilters: [1x1 struct]
    dwtEXTM: 'per'
    dwtShift: 0
    dataSize: [995 23]
             ca: [249x23 double]
             cd: {[498x23 double] [249x23 double]}
```

Compute the energy distribution.

```
[e,pec,pecfs] = wdecenergy(dec);
```

Display the total energy and the distribution of energy for each wavelet component (A2, D2, D1) in the second channel.

```
idx = 2;
e(idx)

ans = 8.0445e+05

perA2D2D1 = pec(idx,:)

perA2D2D1 = 1×3

    99.0126    0.8986    0.0887
```

Compare the coefficient energy distribution for signal 1 and signal 10. Because most of the energy is in the approximation coefficients, zoom in the x-axis by the number of approximation coefficients.

```
sigA = 1;
sigB = 10;
pecfsA = pecfs(sigA,:);
pecfsB = pecfs(sigB,:);
plot(pecfsA,'r--')
hold on
plot(pecfsB,'b')
grid on
legend('pecfsA','pecfsB')
xlim([0 size(dec.ca,1)])
```

mdwtdec | mdwtrec

Introduced in R2012a

wden

Automatic 1-D denoising

Note wden is no longer recommended. Use wdenoise instead.

Syntax

```

XD = wden(X,TPTR,SORH,SCAL,N,wname)
XD = wden(C,L, ___)
XD = wden(W,'modwtsqtwo log',SORH,'mln',N,wname)
[XD,CXD] = wden( ___)
[XD,CXD,LXD] = wden( ___)
[XD,CXD,LXD,THR] = wden( ___)
[XD,CXD,THR] = wden( ___)

```

Description

`XD = wden(X,TPTR,SORH,SCAL,N,wname)` returns a denoised version `XD` of the signal `X`. The function uses an `N`-level wavelet decomposition of `X` using the specified orthogonal or biorthogonal wavelet `wname` to obtain the wavelet coefficients. The thresholding selection rule `TPTR` is applied to the wavelet decomposition. `SORH` and `SCAL` define how the rule is applied.

`XD = wden(C,L, ___)` returns a denoised version `XD` of the signal `X` using the same options as in the previous syntax, but obtained directly from the wavelet decomposition structure `[C,L]` of `X`. `[C,L]` is the output of `wavedec`.

`XD = wden(W,'modwtsqtwo log',SORH,'mln',N,wname)` returns the denoised signal `XD` obtained by operating on the maximal overlap discrete wavelet transform (MODWT) matrix `W`, where `W` is the output of `modwt`. You must use the same orthogonal wavelet in both `modwt` and `wden`.

`[XD,CXD] = wden(___)` returns the denoised wavelet coefficients. For discrete wavelet transform (DWT) denoising, `CXD` is a vector (see `wavedec`). For MODWT denoising, `CXD` is a matrix with `N+1` rows (see `modwt`). The number of columns of `CXD` is equal to the length of the input signal `X`.

`[XD,CXD,LXD] = wden(___)` returns the number of coefficients by level for DWT denoising. See `wavedec` for details. The `LXD` output is not supported for MODWT denoising. The additional output arguments `[CXD,LXD]` are the wavelet decomposition structure (see `wavedec` for more information) of the denoised signal `XD`.

`[XD,CXD,LXD,THR] = wden(___)` returns the denoising thresholds by level for DWT denoising.

`[XD,CXD,THR] = wden(___)` returns the denoising thresholds by level for MODWT denoising when you specify the `'modwtsqtwo log'` input argument.

Examples

Automatic 1-D Denoising Using Wavelets

This example shows how to apply three different denoising techniques to a noisy signal. It compares the results with plots and the threshold values produced by each technique.

First, to ensure reproducibility of results, set a seed that will be used to generate the random noise.

```
rng('default')
```

Create a signal consisting of a 2 Hz sine wave with transients at 0.3 and 0.72 seconds. Add randomly generated noise to the signal and plot the result.

```
N = 1000;  
t = linspace(0,1,N);  
x = 4*sin(4*pi*t);  
x = x - sign(t-0.3) - sign(0.72-t);  
sig = x + 0.5*randn(size(t));  
plot(t,sig)  
title('Signal')  
grid on
```

Using the `sym8` wavelet, perform a level 5 wavelet decomposition of the signal and denoise it by applying three different threshold selection rules to the wavelet coefficients: SURE, minimax, and Donoho and Johnstone's universal threshold with level-dependent estimation of the noise. In each case, apply hard thresholding.

```
lev = 5;  
wname = 'sym8';
```

```
[dnsig1,c1,l1,threshold_SURE] = wden(sig,'rigrsure','h','mln',lev,wname);
[dnsig2,c2,l2,threshold_Minimax] = wden(sig,'minimaxi','h','mln',lev,wname);
[dnsig3,c3,l3,threshold_DJ] = wden(sig,'sqtwolog','h','mln',lev,wname);
```

Plot and compare the three denoised signals.

```
subplot(3,1,1)
plot(t,dnsig1)
title('Denoised Signal - SURE')
grid on
subplot(3,1,2)
plot(t,dnsig2)
title('Denoised Signal - Minimax')
grid on
subplot(3,1,3)
plot(t,dnsig3)
title('Denoised Signal - Donoho-Johnstone')
grid on
```

Compare the thresholds applied at each detail level for the three denoising methods.

threshold_SURE

```
threshold_SURE = 1x5
```

```
    0.8079    1.1448    1.3915    0.9816    0.8667
```

threshold_Minimax

```
threshold_Minimax = 1x5
    1.0522    1.0881    1.2237    1.3366    1.1985

threshold_DJ
threshold_DJ = 1x5
    1.7644    1.8247    2.0520    2.2413    2.0097
```

Compare DWT and MODWT Denoising of a Sinusoid with Two Jumps

This example denoises a signal using the DWT and MODWT. It compares the results with plots and the threshold values produced by each technique.

First, to ensure reproducibility of results, set a seed that will be used to generate random noise.

```
rng('default')
```

Create a signal consisting of a 2 Hz sine wave with transients at 0.3 and 0.72 seconds. Add randomly generated noise to the signal and plot the result.

```
N = 1000;
t = linspace(0,1,N);
x = 4*sin(4*pi*t);
x = x - sign(t-0.3) - sign(0.72-t);
sig = x + 0.5*randn(size(t));
plot(t,sig)
title('Signal')
grid on
```

Using the db2 wavelet, perform a level 3 wavelet decomposition of the signal and denoise it using Donoho and Johnstone's universal threshold with level-dependent estimation of the noise. Obtain denoised versions using DWT and MODWT, both with soft thresholding.

```
wname = 'db2';
lev = 3;
[xdDWT,c1,l1,threshold_DWT] = wden(sig,'sqtwolog','s','mln',lev,wname);
[xdMODWT,c2,threshold_MODWT] = wden(sig,'modwtsqtwolog','s','mln',lev,wname);
```

Plot and compare the results.

```
subplot(2,1,1)
plot(t,xdDWT)
grid on
title('DWT Denoising')
subplot(2,1,2)
plot(t,xdMODWT)
grid on
title('MODWT Denoising')
```

Compare the thresholds applied in each case.

threshold_DWT

```
threshold_DWT = 1×3
```

```
    1.7783    1.6876    2.0434
```

threshold_MODWT

```
threshold_MODWT = 1×3
```

```
    1.2760    0.6405    0.3787
```

Compare DWT and MODWT Denoising of a Blocky Signal

This example denoises a blocky signal using the Haar wavelet with DWT and MODWT denoising. It compares the results with plots and metrics for the original and denoised versions.

First, to ensure reproducibility of results, set a seed that will be used to generate random noise.

```
rng('default')
```

Generate a signal and a noisy version with the square root of the signal-to-noise ratio equal to 3. Plot and compare each.

```
[osig,nsig] = wnoise('blocks',10,3);
plot(nsig,'r')
hold on
plot(osig,'b')
legend('Noisy Signal','Original Signal')
```

Using the Haar wavelet, perform a level 6 wavelet decomposition of the noisy signal and denoise it using Donoho and Johnstone's universal threshold with level-dependent estimation of the noise. Obtain denoised versions using DWT and MODWT, both with soft thresholding.

```
wname = 'haar';
lev = 6 ;
[xdDWT,c1,l1] = wden(nsig,'sqrtwolog','s','mln',lev,wname);
[xdMODWT,c2] = wden(nsig,'modwtsqrtwolog','s','mln',lev,wname);
```

Plot and compare the original, noise-free version of the signal with the two denoised versions.

```
figure
plot(osig,'b')
hold on
plot(xdDWT,'r--')
plot(xdMODWT,'k-.')
legend('Original','DWT','MODWT')
hold off
```

Calculate the L2 and L-infinity norms of the difference between the original signal and the two denoised versions.

```
L2norm_original_DWT = norm(abs(osig-xdDWT),2)
```

```
L2norm_original_DWT = 36.1194
```

```
L2norm_original_MODWT = norm(abs(osig-xdMODWT),2)
```

```
L2norm_original_MODWT = 14.5987
```

```
LInfinity_original_DWT = norm(abs(osig-xdDWT),Inf)
```

```
LInfinity_original_DWT = 4.7181
```

```
LInfinity_original_MODWT = norm(abs(osig-xdMODWT),Inf)
```

```
LInfinity_original_MODWT = 2.9655
```

Input Arguments

X — Input data

real-valued vector

Input data to denoise, specified as a real-valued vector.

Data Types: double

C — Wavelet expansion coefficients

real-valued vector

Wavelet expansion coefficients of the data to be denoised, specified as a real-valued vector. C is the output of `wavedec`.

Example: `[C,L] = wavedec(randn(1,1024),3,'db4')`

Data Types: `double`

L — Size of wavelet expansion coefficients

vector of positive integers

Size of wavelet expansion coefficients of the signal to be denoised, specified as a vector of positive integers. L is the output of `wavedec`.

Example: `[C,L] = wavedec(randn(1,1024),3,'db4')`

Data Types: `double`

W — Maximal overlap wavelet decomposition structure

real-valued matrix

Maximal overlap wavelet decomposition structure of the signal to denoise, specified as a real-valued matrix. W is the output of `modwt`. You must use the same orthogonal wavelet in both `modwt` and `wden`.

Data Types: `double`

TPTR — Threshold selection rule

character array

Threshold selection rule to apply to the wavelet decomposition structure of X:

- `'rigsure'` — Use the principle of Stein's Unbiased Risk.
- `'heursure'` — Use a heuristic variant of Stein's Unbiased Risk.
- `'sqrtwolog'` — Use the universal threshold $\sqrt{2\ln(\text{length}(x))}$.
- `'minimaxi'` — Use minimax thresholding. (See `thselect` for more information.)

SORH — Type of thresholding`'s' | 'h'`

Type of thresholding to perform:

- `'s'` — Soft thresholding
- `'h'` — Hard thresholding

SCAL — Multiplicative threshold rescaling`'one' | 'sln' | 'mln'`

Multiplicative threshold rescaling:

- `'one'` — No rescaling
- `'sln'` — Rescaling using a single estimation of level noise based on first-level coefficients
- `'mln'` — Rescaling using a level-dependent estimation of level noise

N — Level of wavelet decomposition

positive integer

Level of wavelet decomposition, specified as a positive integer. Use `wmaxlev` to ensure that the wavelet coefficients are free from boundary effects. If boundary effects are not a concern in your application, a good rule is to set `N` less than or equal to `fix(log2(length(X)))`.

wname — Name of wavelet

character array

Name of wavelet, specified as a character array, to use for denoising. For DWT denoising, the wavelet must be orthogonal or biorthogonal. For MODWT denoising, the wavelet must be orthogonal. Orthogonal and biorthogonal wavelets are designated as type 1 and type 2 wavelets, respectively, in the wavelet manager, `wavemngr`.

- Valid built-in orthogonal wavelet families begin with `haar`, `dbN`, `fkN`, `coifN`, or `symN`, where `N` is the number of vanishing moments for all families except `fk`. For `fk`, `N` is the number of filter coefficients.
- Valid biorthogonal wavelet families begin with `'biorNr.Nd'` or `'rbioNd.Nr'`, where `Nr` and `Nd` are the number of vanishing moments in the reconstruction (synthesis) and decomposition (analysis) wavelet.

Determine valid values for the vanishing moments by using `waveinfo` with the wavelet family short name. For example, enter `waveinfo('db')` or `waveinfo('bior')`. Use `wavemngr('type',wname)` to determine if a wavelet is orthogonal (returns 1) or biorthogonal (returns 2).

Output Arguments**XD — Denoised signal**

real-valued vector

Denoised data, returned as a real-valued vector.

Data Types: `double`**CXD — Denoised wavelet coefficients**

real-valued vector or matrix

Denoised wavelet coefficients, returned as a real-valued vector or matrix. For DWT denoising, `CXD` is a vector (see `wavedec`). For MODWT denoising, `CXD` is a matrix with `N+1` rows (see `modwt`). The number of columns is equal to the length of the input signal `X`.

Data Types: `double`**LXD — Size of denoised wavelet coefficients**

vector of positive integers

Size of denoised wavelet coefficients by level for DWT denoising, returned as a vector of positive integers (see `wavedec`). The `LXD` output is not supported for MODWT denoising. [`CXD`, `LXD`] is the wavelet decomposition structure of the denoised signal `XD`.

Data Types: `double`

THR — Denoising thresholds

real-valued vector

Denoising thresholds by level, returned as a length N real-valued vector.

Data Types: `double`

Algorithms

The most general model for the noisy signal has the following form:

$$s(n) = f(n) + \sigma e(n),$$

where time n is equally spaced. In the simplest model, suppose that $e(n)$ is a Gaussian white noise $N(0,1)$, and the noise level σ is equal to 1. The denoising objective is to suppress the noise part of the signal s and to recover f .

The denoising procedure has three steps:

- 1 Decomposition — Choose a wavelet, and choose a level N . Compute the wavelet decomposition of the signal s at level N .
- 2 Detail coefficients thresholding — For each level from 1 to N , select a threshold and apply soft thresholding to the detail coefficients.
- 3 Reconstruction — Compute wavelet reconstruction based on the original approximation coefficients of level N and the modified detail coefficients of levels from 1 to N .

More details about threshold selection rules are in “Wavelet Denoising and Nonparametric Function Estimation” and in the help of the `thselect` function. Note that:

- The detail coefficients vector is the superposition of the coefficients of f and the coefficients of e . The decomposition of e leads to detail coefficients that are standard Gaussian white noises.
- Minimax and SURE threshold selection rules are more conservative and more convenient when small details of function f lie in the noise range. The two other rules remove the noise more efficiently. The option `'heursure'` is a compromise.

In practice, the basic model cannot be used directly. To deal with model deviations, the remaining parameter `scal` must be specified. It corresponds to threshold rescaling methods.

- The option `scal = 'one'` corresponds to the basic model.
- The option `scal = 'sln'` handles threshold rescaling using a single estimation of level noise based on the first-level coefficients.

In general, you can ignore the noise level that must be estimated. The detail coefficients CD_1 (the finest scale) are essentially noise coefficients with standard deviation equal to σ . The median absolute deviation of the coefficients is a robust estimate of σ . The use of a robust estimate is crucial. If level 1 coefficients contain f details, these details are concentrated in a few coefficients to avoid signal end effects, which are pure artifacts due to computations on the edges.

- The option `scal = 'mln'` handles threshold rescaling using a level-dependent estimation of the level noise.

When you suspect a nonwhite noise e , thresholds must be rescaled by a level-dependent estimation of the level noise. The same kind of strategy is used by estimating σ_{lev} level by level.

This estimation is implemented in the file `wnoisest`, which handles the wavelet decomposition structure of the original signal `s` directly.

Wavelet Signal Denoiser

Introduced before R2006a

wdencmp

Denoising or compression

Syntax

```
[XC,CXC,LXC,PERF0,PERFL2] = wdencmp('gbl',X,wname,N,THR,SORH,KEEPAPP)
[___] = wdencmp('gbl',C,L,wname,N,THR,SORH,KEEPAPP)
[___] = wdencmp('lvl',X,wname,N,THR,SORH)
[___] = wdencmp('lvl',C,L,wname,N,THR,SORH)
```

Description

`[XC,CXC,LXC,PERF0,PERFL2] = wdencmp('gbl',X,wname,N,THR,SORH,KEEPAPP)` returns a denoised or compressed version `XC` of the input data `X` obtained by wavelet coefficients thresholding using the global positive threshold `THR`. `X` is a real-valued vector or matrix. `[CXC,LXC]` is the `N`-level wavelet decomposition structure of `XC` (see `wavedec` or `wavedec2` for more information). `PERFL2` and `PERF0` are the L^2 -norm recovery and compression scores in percentages, respectively. If `KEEPAPP = 1`, the approximation coefficients are kept. If `KEEPAPP = 0`, the approximation coefficients can be thresholded.

`[___] = wdencmp('gbl',C,L,wname,N,THR,SORH,KEEPAPP)` uses the wavelet decomposition structure `[C,L]` of the data to be denoised or compressed.

`[___] = wdencmp('lvl',X,wname,N,THR,SORH)` uses the level-dependent thresholds `THR`. The approximation coefficients are kept.

`[___] = wdencmp('lvl',C,L,wname,N,THR,SORH)` uses the wavelet decomposition structure `[C,L]`.

Examples

Denoise 1-D Signal Using Default Global Threshold

Denoise 1-D electricity consumption data using the Donoho-Johnstone global threshold.

Load the signal and select a segment for denoising.

```
load leleccum; indx = 2600:3100;
x = leleccum(indx);
```

Use `ddencmp` to determine the default global threshold and denoise the signal. Plot the original and denoised signals.

```
[thr,sorh,keepapp] = ddencmp('den','wv',x);
xd = wdencmp('gbl',x,'db3',2,thr,sorh,keepapp);
subplot(211)
plot(x); title('Original Signal');
subplot(212)
plot(xd); title('Denoised Signal');
```

Denoise Image Using Default Global Threshold

Denoise an image in additive white Gaussian noise using the Donoho-Johnstone universal threshold.

Load an image and add white Gaussian noise.

```
load sinsin
Y = X+18*randn(size(X));
```

Use `ddencmp` to obtain the threshold.

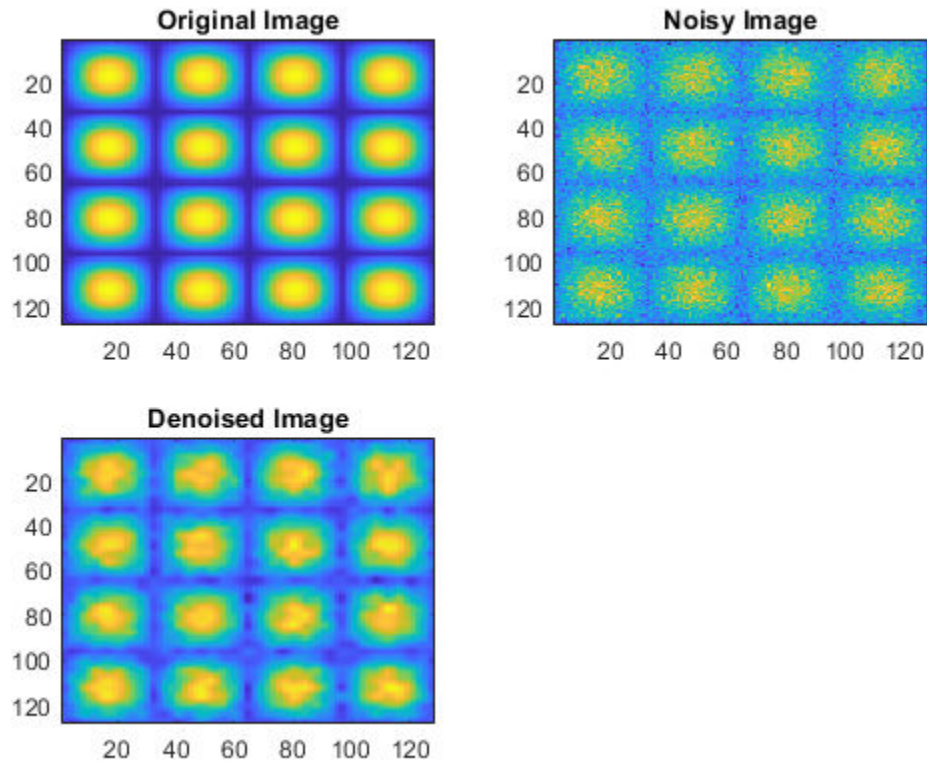

```
[thr,sorh,keepapp] = ddencmp('den','wv',Y);
```

Denoise the image. Use the order 4 Symlet and a two-level wavelet decomposition. Plot the original image, the noisy image, and the denoised result.

```
xd = wdencomp('gbl',Y,'sym4',2,thr,sorh,keepapp);
subplot(2,2,1)
imagesc(X)
title('Original Image')
subplot(2,2,2)
imagesc(Y)
title('Noisy Image')
subplot(2,2,3)
```

```
imagesc(xd)
title('Denoised Image')
```

Input Arguments

X — Input data

real-valued vector | real-valued matrix

Input data to denoise or compress, specified by a real-valued vector or matrix.

Data Types: double

C — Wavelet expansion coefficients

real-valued vector

Wavelet expansion coefficients of the data to be compressed or denoised, specified as a real-valued vector. If the data is one-dimensional, **C** is the output of `wavedec`. If the data is two-dimensional, **C** is the output of `wavedec2`.

Example: `[C,L] = wavedec(randn(1,1024),3,'db4')`

Data Types: double

L — Size of wavelet expansion coefficients

vector of positive integers | matrix of positive integers

Size of wavelet expansion coefficients of the signal or image to be compressed or denoised, specified as a vector or matrix of positive integers.

For signals, `L` is the output of `wavedec`. For images, `L` is the output of `wavedec2`.

Example: `[C,L] = wavedec(randn(1,1024),3,'db4')`

Data Types: `double`

wname — Name of wavelet

character vector | string scalar

Name of wavelet, specified as a character vector or string scalar, to use for denoising or compression. See `wavemngr` for more information. `wdencmp` uses `wname` to generate the `N`-level wavelet decomposition of `X`.

N — Level of wavelet decomposition

positive integer

Level of wavelet decomposition, specified as a positive integer.

THR — Threshold

scalar | real-valued vector | real-valued matrix

Threshold to apply to the wavelet coefficients, specified as a scalar, real-valued vector, or real-valued matrix.

- For the case `'gbl'`, `THR` is a scalar.
- For the one-dimensional case and `'lvd'` option, `THR` is a length `N` real-valued vector containing the level-dependent thresholds.
- For the two-dimensional case and `'lvd'` option, `THR` is a 3-by-`N` matrix containing the level-dependent thresholds in the three orientations: horizontal, diagonal, and vertical.

Data Types: `double`

SORH — Type of thresholding

`'s'` | `'h'`

Type of thresholding to perform:

- `'s'` — Soft thresholding
- `'h'` — Hard thresholding

See `wthresh` for more information.

KEEPAPP — Threshold approximation setting

`0` | `1`

Threshold approximation setting, specified as either `0` or `1`. If `KEEPAPP = 1`, the approximation coefficients cannot be thresholded. If `KEEPAPP = 0`, the approximation coefficients can be thresholded.

Data Types: `double`

Output Arguments

XC — Denoised or compressed data

real-valued vector | real-valued matrix

Denoised or compressed data, returned as a real-valued vector or matrix. XC and X have the same dimensions.

CXC — Wavelet expansion coefficients

real-valued vector

Wavelet expansion coefficients of the denoised or compressed data XC, returned as a real-valued vector. LXC contains the number of coefficients by level.

LXC — Size of wavelet expansion coefficients

vector of positive integers | matrix of positive integers

Size of wavelet expansion coefficients of the denoised or compressed data XC, specified as a vector or matrix of positive integers. If the data is one-dimensional, LXC is a vector of positive integers (see `wavedec` for more information). If the data is two-dimensional, LXC is a matrix of positive integers (see `wavedec2` for more information).

PERF0 — Compression score

scalar

Compression score, returned as a real number. PERF0 is the percentage of thresholded coefficients that are equal to 0.

PERFL2 — L^2 energy recovery

scalar

$PERFL2 = 100 * (\text{vector-norm of } CXC / \text{vector-norm of } C)^2$ if $[C, L]$ denotes the wavelet decomposition structure of X.

If X is a one-dimensional signal and 'wname' an orthogonal wavelet, PERFL2 is reduced to

$$\frac{100\|XC\|^2}{\|X\|^2}$$

Algorithms

The denoising and compression procedures contain three steps:

- 1 Decomposition.
- 2 Thresholding.
- 3 Reconstruction.

The two procedures differ in Step 2. In compression, for each level in the wavelet decomposition, a threshold is selected and hard thresholding is applied to the detail coefficients.

Apps

Wavelet Signal Denoiser

Introduced before R2006a

wdenoise

Wavelet signal denoising

Syntax

```
XDEN = wdenoise(X)
```

```
XDEN = wdenoise(X,LEVEL)
```

```
XDEN = wdenoise( ____,Name,Value)
```

```
[XDEN,DENOISEDDFS] = wdenoise( ____,Name,Value)
```

```
[XDEN,DENOISEDDFS,ORIGDFS] = wdenoise( ____,Name,Value)
```

Description

`XDEN = wdenoise(X)` denoises the data in `X` using an empirical Bayesian method with a Cauchy prior. By default, the `sym4` wavelet is used with a posterior median threshold rule. Denoising is down to the minimum of `floor(log2N)` and `wmaxlev(N, 'sym4')` where `N` is the number of samples in the data. (For more information, see `wmaxlev`.) `X` is a real-valued vector, matrix, or timetable.

- If `X` is a matrix, `wdenoise` denoises each column of `X`.
- If `X` is a timetable, `wdenoise` must contain real-valued vectors in separate variables, or one real-valued matrix of data.
- `X` is assumed to be uniformly sampled.
- If `X` is a timetable and the timestamps are not linearly spaced, `wdenoise` issues a warning.

`XDEN = wdenoise(X,LEVEL)` denoises `X` down to `LEVEL`. `LEVEL` is a positive integer less than or equal to `floor(log2N)` where `N` is the number of samples in the data. If unspecified, `LEVEL` defaults to the minimum of `floor(log2N)` and `wmaxlev(N, 'sym4')`.

`XDEN = wdenoise(____,Name,Value)` specifies options using name-value pair arguments in addition to any of the input arguments in previous syntaxes.

`[XDEN,DENOISEDDFS] = wdenoise(____,Name,Value)` returns the denoised wavelet and scaling coefficients in the cell array `DENOISEDDFS`. The elements of `DENOISEDDFS` are in order of decreasing resolution. The final element of `DENOISEDDFS` contains the approximation (scaling) coefficients.

`[XDEN,DENOISEDDFS,ORIGDFS] = wdenoise(____,Name,Value)` returns the original wavelet and scaling coefficients in the cell array `ORIGDFS`. The elements of `ORIGDFS` are in order of decreasing resolution. The final element of `ORIGDFS` contains the approximation (scaling) coefficients.

Examples

Denoise A Signal Using Default Values

Obtain the denoised version of a noisy signal using default values.

```
load noisdopp
xden = wdenoise(noisdopp);
```

Plot the original and denoised signals.

```
plot([noisdopp' xden'])  
legend('Original Signal','Denoised Signal')
```

Denoise a Timetable Using Block Thresholding

Denoise a timetable of noisy data down to level 5 using block thresholding.

Load a noisy dataset.

```
load wnoisydata
```

Denoise the data down to level 5 using block thresholding by setting the name-value pair 'DenoisingMethod', 'BlockJS'.

```
xden = wdenoise(wnoisydata,5,'DenoisingMethod','BlockJS');
```

Plot the original data and the denoised data.

```
h1 = plot(wnoisydata.t,[wnoisydata.noisydata(:,1) xden.noisydata(:,1)]);  
h1(2).LineWidth = 2;  
legend('Original','Denoised')
```

Compare Denoised Signals

Denoise a signal in different ways and compare results.

Load a datafile that contains clean and noisy versions of a signal. Plot the signals.

```
load fdata.mat
plot(fNoisy,'r-')
hold on
plot(fClean,'b-')
grid on
legend('Noisy','Clean');
```

Denoise the signal using the sym4 and db1 wavelets, with a nine-level wavelet decomposition. Plot the results.

```
cleansym = wdenoise(fNoisy,9,'Wavelet','sym4');
cleandb = wdenoise(fNoisy,9,'Wavelet','db1');
figure
plot(cleansym)
title('Denoised - sym')
grid on
```

```
figure
plot(cleandb)
title('Denoised - db')
grid on
```

Compute the SNR of each denoised signal. Confirm that using the `sym4` wavelet produces a better result.

```
snrsym = -20*log10(norm(abs(fClean-cleansym))/norm(fClean))
```

```
snrsym = 35.3294
```

```
snrdb = -20*log10(norm(abs(fClean-cleandb))/norm(fClean))
```

```
snrdb = 32.2672
```

Load in a file which contains noisy data of 100 time series. Every time series is a noisy version of `fClean`. Denoise the time series twice, estimating the noise variance differently in each case.

```
load fdataTS.mat
```

```
cleanTSld = wdenoise(fdataTS,9,'NoiseEstimate','LevelDependent');
```

```
cleanTSli = wdenoise(fdataTS,9,'NoiseEstimate','LevelIndependent');
```

Compare one of the noisy time series with its two denoised versions.

```
figure
plot(fdataTS.Time,fdataTS.fTS15)
title('Original')
grid on
```

```
figure
plot(cleanTSli.Time,cleanTSli.fTS15)
title('Level Independent')
grid on
```

```
figure  
plot(cleanTSld.Time,cleanTSld.fTS15)  
title('Level Dependent')  
grid on
```

Input Arguments

X — Input data

vector | matrix | timetable

Input data, specified as a matrix, vector, or timetable of real values. If X is a vector, it must have at least two samples. If X is a matrix or timetable, it must have at least two rows.

Data Types: double

LEVEL — Level of wavelet decomposition

positive integer

Level of wavelet decomposition, specified as a positive integer. LEVEL is a positive integer less than or equal to $\text{floor}(\log_2 N)$ where N is the number of samples in the data.

- If unspecified, LEVEL defaults to the minimum of $\text{floor}(\log_2 N)$ and $\text{wmaxlev}(N, 'sym4')$.
- For James-Stein block thresholding, 'BlockJS', there must be $\text{floor}(\log_2 N)$ coefficients at the coarsest resolution level, LEVEL.

Data Types: double

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Wavelet', 'db6', 'DenoisingMethod', 'Bayes'` denoises using the Daubechies db6 wavelet and the empirical Bayesian method.

Wavelet — Name of wavelet

`'sym4'` (default) | character array

Name of wavelet, specified as a character array, to use for denoising. The wavelet must be orthogonal or biorthogonal. Orthogonal and biorthogonal wavelets are designated as type 1 and type 2 wavelets respectively in the wavelet manager, `wavemngr`.

- Valid built-in orthogonal wavelet families begin with `haar`, `dbN`, `fkN`, `coifN`, or `symN` where `N` is the number of vanishing moments for all families except `fk`. For `fk`, `N` is the number of filter coefficients.
- Valid biorthogonal wavelet families begin with `'biorNr.Nd'` or `'rbioNd.Nr'`, where `Nr` and `Nd` are the number of vanishing moments in the reconstruction (synthesis) and decomposition (analysis) wavelet.

Determine valid values for the vanishing moments by using `waveinfo` with the wavelet family short name. For example, enter `waveinfo('db')` or `waveinfo('bior')`. Use `wavemngr('type', WNAME)` to determine if a wavelet is orthogonal (returns 1) or biorthogonal (returns 2).

DenoisingMethod — Denoising method

`'Bayes'` (default) | `'BlockJS'` | `'FDR'` | `'Minimax'` | `'SURE'` | `'UniversalThreshold'`

Denoising method used to determine the denoising thresholds for the data `X`.

- **Bayes** — Empirical Bayes

This method uses a threshold rule based on assuming measurements have independent prior distributions given by a mixture model. Because measurements are used to estimate the weight in the mixture model, the method tends to work better with more samples. By default, the posterior median rule is used to measure risk [8].

- **BlockJS** — Block James-Stein

This method is based on determining an `optimal block size and threshold. The resulting block thresholding estimator yields simultaneously optimal global and local adaptivity [3].

- **FDR** — False Discovery Rate

This method uses a threshold rule based on controlling the expected ratio of false positive detections to all positive detections. The FDR method works best with sparse data. Choosing a ratio, or *Q*-value, less than 1/2 yields an asymptotically minimax estimator [1].

- **Minimax** — Minimax Estimation

This method uses a fixed threshold chosen to yield minimax performance for mean square error against an ideal procedure. The minimax principle is used in statistics to design estimators. See `thselect` for more information.

- SURE — Stein's Unbiased Risk Estimate

This method uses a threshold selection rule based on Stein's Unbiased Estimate of Risk (quadratic loss function). One gets an estimate of the risk for a particular threshold value (t). Minimizing the risks in (t) gives a selection of the threshold value.

- UniversalThreshold - Universal Threshold $\sqrt{2\ln(\text{length}(x))}$.

This method uses a fixed-form threshold yielding minimax performance multiplied by a small factor proportional to $\log(\text{length}(X))$.

Note For 'FDR', there is an optional argument for the Q -value, which is the proportion of false positives. Q is a real-valued scalar between 0 and 1/2, $0 < Q \leq 1/2$. To specify 'FDR' with a Q -value, use a cell array where the second element is the Q -value. For example, 'DenoisingMethod', {'FDR', 0.01}. If unspecified, Q defaults to 0.05.

ThresholdRule — Threshold rule

character array

Threshold rule, specified as a character array, to use to shrink the wavelet coefficients.

'ThresholdRule' is valid for all denoising methods, but the valid options and defaults depend on the denoising method. Rules possible for different denoising methods are specified as follows:

- 'BlockJS' — The only supported option is 'James-Stein'. You do not need to specify ThresholdRule for 'BlockJS'.
- 'SURE', 'Minimax', 'UniversalThreshold' — Valid options are 'Soft' or 'Hard'. The default is 'Soft'.
- 'Bayes' — Valid options are 'Median', 'Mean', 'Soft', or 'Hard'. The default is 'Median'.
- 'FDR' — The only supported option is 'Hard'. You do not need to define ThresholdRule for 'FDR'.

NoiseEstimate — Method of estimating variance of noise

'LevelIndependent' (default) | 'LevelDependent'

Method of estimating variance of noise in the data.

- 'LevelIndependent' — Estimate the variance of the noise based on the finest-scale (highest-resolution) wavelet coefficients.
- 'LevelDependent' — Estimate the variance of the noise based on the wavelet coefficients at each resolution level.

Specifying NoiseEstimate with the 'BlockJS' denoising method has no effect. The block James-Stein estimator always uses a 'LevelIndependent' noise estimate.

Output Arguments

XDEN — Denoised data

vector | matrix | timetable

Denoised vector, matrix, or timetable version of X . For timetable input, XDEN has the same variable names and timestamps as the original timetable.

Data Types: `double`

DENOISEDCFS — Denoised wavelet and scaling coefficients

cell array

Denoised wavelet and scaling coefficients of the denoised data `XDEN`, returned in a cell array. The elements of `DENOISEDCFS` are in order of decreasing resolution. The final element of `DENOISEDCFS` contains the approximation (scaling) coefficients.

Data Types: `double`

ORIGCFS — Original wavelet and scaling coefficients

cell array

Original wavelet and scaling coefficients of the data `X`, returned in a cell array. The elements of `ORIGCFS` are in order of decreasing resolution. The final element of `ORIGCFS` contains the approximation (scaling) coefficients.

Data Types: `double`

Algorithms

The most general model for the noisy signal has the following form:

$$s(n) = f(n) + \sigma e(n),$$

where time n is equally spaced. In the simplest model, suppose that $e(n)$ is a Gaussian white noise $N(0,1)$, and the noise level σ is equal to 1. The denoising objective is to suppress the noise part of the signal s and to recover f .

The denoising procedure has three steps:

- 1** Decomposition — Choose a wavelet, and choose a level N . Compute the wavelet decomposition of the signal s at level N .
- 2** Detail coefficients thresholding — For each level from 1 to N , select a threshold and apply soft thresholding to the detail coefficients.
- 3** Reconstruction — Compute wavelet reconstruction based on the original approximation coefficients of level N and the modified detail coefficients of levels from 1 to N .

More details about threshold selection rules are in “Wavelet Denoising and Nonparametric Function Estimation” and in the help of the `thselect` function.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Timetable input data is not supported.
- The value of the 'Wavelet' name-value pair argument must be constant.
- The input LEVEL must be defined as a scalar during compilation.

Introduced in R2017b

wdenoise2

Wavelet image denoising

Syntax

```
IMDEN = wdenoise2(IM)
IMDEN = wdenoise2(IM,LEVEL)
[IMDEN,DENOISEDCFS] = wdenoise2( ___ )

[IMDEN,DENOISEDCFS,ORIGCFS] = wdenoise2( ___ )
[IMDEN,DENOISEDCFS,ORIGCFS,S] = wdenoise2( ___ )
[IMDEN,DENOISEDCFS,ORIGCFS,S,SHIFTS] = wdenoise2( ___ )

[ ___ ] = wdenoise2( ___ ,Name,Value)

wdenoise2( ___ )
```

Description

`IMDEN = wdenoise2(IM)` denoises the grayscale or RGB image `IM` using an empirical Bayesian method. The `bior4.4` wavelet is used with a posterior median threshold rule. Denoising is down to the minimum of `floor(log2([M N]))` and `wmaxlev([M N], 'bior4.4')` where `M` and `N` are the row and column sizes of the image. `IMDEN` is the denoised version of `IM`.

For RGB images, by default, `wdenoise2` projects the image onto its principle component analysis (PCA) color space before denoising. To denoise an RGB image in the original color space, use the `ColorSpace` name-value pair.

`IMDEN = wdenoise2(IM,LEVEL)` denoises the image `IM` down to resolution level `LEVEL`. `LEVEL` is a positive integer less than or equal to `floor(log2(min([M N])))` where `M` and `N` are the row and column sizes of the image. If unspecified, `LEVEL` defaults to the minimum `floor(log2(min([M N])))` and `wmaxlev([M N], wname)` where `wname` is the wavelet used (`'bior4.4'` by default).

`[IMDEN,DENOISEDCFS] = wdenoise2(___)` returns the scaling and denoised wavelet coefficients in `DENOISEDCFS` using any of the preceding syntaxes.

`[IMDEN,DENOISEDCFS,ORIGCFS] = wdenoise2(___)` returns the scaling and wavelet coefficients of the input image in `ORIGCFS` using any of the preceding syntaxes.

`[IMDEN,DENOISEDCFS,ORIGCFS,S] = wdenoise2(___)` returns the sizes of the approximation coefficients at the coarsest scale along with the sizes of the wavelet coefficients at all scales. `S` is a matrix with the same structure as the `S` output of `wavedec2`.

`[IMDEN,DENOISEDCFS,ORIGCFS,S,SHIFTS] = wdenoise2(___)` returns the shifts along the row and column dimensions for cycle spinning. `SHIFTS` is 2-by- $(\text{numshifts}+1)^2$ matrix where each column of `SHIFTS` contains the shifts along the row and column dimension used in cycle spinning and `numshifts` is the value of `CycleSpinning`.

`[___] = wdenoise2(___ ,Name,Value)` returns the denoised image with additional options specified by one or more `Name,Value` pair arguments, using any of the preceding syntaxes.

`wdenoise2(___)` with no output arguments plots the original image along with the denoised image in the current figure.

Examples

Denoise Grayscale Image Using Default Settings

Load the structure `flower`. The structure contains a grayscale image of a flower, and a noisy version of that image. Display the original and noisy images.

```
load flower
subplot(1,2,1)
imagesc(flower.Orig)
title('Original')
subplot(1,2,2)
imagesc(flower.Noisy)
title('Noisy')
colormap gray
```

Denoise the noisy image using the default `wdenoise2` settings. Compare with the original image.

```
imden = wdenoise2(flower.Noisy);
subplot(1,2,1)
imagesc(imden)
title('Denoised')
```

```
subplot(1,2,2)
imagesc(flower.Noisy)
title('Noisy')
colormap gray
```

Note the improvement in SNR before and after denoising.

```
beforeSNR = ...
    20*log10(norm(flower.Orig(:))/norm(flower.Orig(:)-flower.Noisy(:)))

beforeSNR = 14.1300

afterSNR = ...
    20*log10(norm(flower.Orig(:))/norm(flower.Orig(:)-imden(:)))

afterSNR = 20.1388
```

Denoise Color Image Using Cycle Spinning

This example shows how to denoise a color image using cycle spinning.

Load the structure `colorflower`. The structure contains the RGB image of a flower, and a noisy version of that image. Display the original and noisy images.

```
load colorflower
subplot(1,2,1)
```

```
imagesc(colorflower.Orig)
title('Original')
subplot(1,2,2)
imagesc(colorflower.Noisy)
title('Noisy')
```

Denoise the image down to level 2 using the default Bayesian method and cycle spinning with $(1 + 1)^2$ shifts. Display the noisy and denoised images.

```
imden = wdenoise2(colorflower.Noisy,2,'CycleSpinning',1);
figure
subplot(1,2,1)
imagesc(imden)
title('Denoised')
subplot(1,2,2)
imagesc(colorflower.Noisy)
title('Noisy')
```

Compute the SNR before and after denoising.

```
beforeSNR = ...
    20*log10(norm(colorflower.Orig(:))/norm(colorflower.Orig(:)-colorflower.Noisy(:)))

beforeSNR = 11.2217

afterSNR = ...
    20*log10(norm(colorflower.Orig(:))/norm(colorflower.Orig(:)-imden(:)))

afterSNR = 19.8813
```

Denoise Image Using Specific Subband

This example shows how to denoise an image using a specific subband to estimate the variance of the noise.

Load the structure `flower`. The structure contains the grayscale image of a flower, and a noisy version of that image. Display the original and noisy images.

```
load flower
subplot(1,2,1)
imagesc(flower.Orig)
title('Original')
subplot(1,2,2)
```

```

imagesc(flower.Noisy)
title('Noisy')
colormap gray

```

Denoise the image down to level 2 using the False Discovery Rate method with a Q-value of 0.01. Denoise only based on the diagonal wavelet coefficients. Display the denoised and noisy images.

```

imden = wdenoise2(flower.Noisy,2,...
    'DenoisingMethod',{'FDR',0.01},...
    'NoiseDirection',"d");
figure
subplot(1,2,1)
imagesc(imden)
title('Denoised')
subplot(1,2,2)
imagesc(flower.Noisy)
title('Noisy')
colormap gray

```

Compute the SNR before and after denoising.

```
beforeSNR = ...
    20*log10(norm(flower.Orig(:))/norm(flower.Orig(:)-flower.Noisy(:)))
beforeSNR = 14.1300
afterSNR = ...
    20*log10(norm(flower.Orig(:))/norm(flower.Orig(:)-imden(:)))
afterSNR = 19.9164
```

Input Arguments

IM — Input image

real-valued 2-D matrix | real-valued 3-D array

Input image to denoise, specified as a real-valued 2-D matrix or real-valued 3-D array. If IM is 3-D, IM is assumed to be a color image in the RGB color space and the third dimension of IM must be 3. For RGB images, `wdenoise2` by default projects the image onto its PCA color space before denoising. To denoise an RGB image in the original color space, use the `ColorSpace` name-value pair.

LEVEL — Wavelet decomposition level

positive integer

Wavelet decomposition level used for denoising, specified as a positive integer. LEVEL is a positive integer less than or equal to $\text{floor}(\log_2(\min([M \ N])))$ where M and N are the row and column

sizes of the image. If unspecified, LEVEL defaults to the minimum $\text{floor}(\log_2(\min([M \ N])))$ and $\text{wmaxlev}([M \ N], \text{wname})$ where *wname* is the wavelet used ('bior4.4' by default).

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'NoiseEstimate', 'LevelDependent', 'Wavelet', 'sym6'

Wavelet — Name of wavelet

'bior4.4' (default) | character vector | string scalar

Name of wavelet, specified as a character vector or string scalar, to use for denoising. The wavelet must be orthogonal or biorthogonal. Orthogonal and biorthogonal wavelets are designated as type 1 and type 2 wavelets respectively in the wavelet manager, `wavemngr`.

- Valid built-in orthogonal wavelet families begin with 'haar', 'dbN', 'fkN', 'coifN', or 'symN' where *N* is the number of vanishing moments for all families except 'fk'. For 'fk', *N* is the number of filter coefficients.
- Valid biorthogonal wavelet families begin with 'biorNr.Nd' or 'rbioNd.Nr', where *Nr* and *Nd* are the number of vanishing moments in the reconstruction (synthesis) and decomposition (analysis) wavelet.

Determine valid values for the vanishing moments by using `waveinfo` with the wavelet family short name. For example, enter `waveinfo('db')` or `waveinfo('bior')`. Use `wavemngr('type', WNAME)` to determine if a wavelet is orthogonal (returns 1) or biorthogonal (returns 2).

DenoisingMethod — Denoising method

'Bayes' (default) | 'FDR' | 'Minimax' | 'SURE' | 'UniversalThreshold'

Denoising method to use to determine the denoising thresholds for the image *IM*.

- Bayes - Empirical Bayes

This method uses a threshold rule based on assuming measurements have independent prior distributions given by a mixture model. Because measurements are used to estimate the weight in the mixture model, the method tends to work better with more samples. By default, the posterior median rule is used to measure risk [7].

- FDR - False Discovery Rate

This method uses a threshold rule based on controlling the expected ratio of false positive detections to all positive detections. The FDR method works best with sparse data. Choosing a ratio, or *Q*-value, less than 1/2 yields an asymptotically minimax estimator [1].

Note For 'FDR', there is an optional argument for the *Q*-value, which is the proportion of false positives. *Q* is a real-valued scalar between 0 and 1/2, $0 < Q \leq 1/2$. To specify 'FDR' with a *Q*-value, use a cell array where the second element is the *Q*-value. For example, 'DenoisingMethod', {'FDR', 0.01}. If unspecified, *Q* defaults to 0.05.

- Minimax - Minimax Estimation

This method uses a fixed threshold chosen to yield minimax performance for mean squared error against an ideal procedure. The minimax principle is used in statistics to design estimators. See `thselect` for more information.

- `SURE` - Stein's Unbiased Risk Estimate

This method uses a threshold selection rule based on Stein's Unbiased Estimate of Risk (quadratic loss function). One gets an estimate of the risk for a particular threshold value (t). Minimizing the risks in (t) gives a selection of the threshold value.

- `UniversalThreshold` - Universal Threshold $\sqrt{2\ln(\text{length}(x))}$.

This method uses a fixed-form threshold yielding minimax performance multiplied by a small factor proportional to $\log(\text{length}(X))$.

ThresholdRule — Threshold rule

'Hard' | 'Soft' | 'Mean' | 'Median'

Threshold rule to use to shrink the wavelet coefficients. 'ThresholdRule' is valid for all denoising methods, but the valid options and defaults depend on the denoising method. Rules possible for different denoising methods are specified as follows:

- 'SURE', 'Minimax', 'UniversalThreshold': Valid options are 'Soft' or 'Hard'. The default is 'Soft'.
- 'Bayes': Valid options are 'Median', 'Mean', 'Soft', or 'Hard'. The default is 'Median'.
- 'FDR': The only supported option is 'Hard'. You do not need to define 'ThresholdRule' for 'FDR'

NoiseEstimate — Method of estimating variance of noise

'LevelIndependent' (default) | 'LevelDependent'

Method of estimating variance of noise in the image. Valid options are 'LevelIndependent' and 'LevelDependent'.

- 'LevelIndependent' estimates the variance of the noise based on the finest-scale (highest-resolution) wavelet coefficients.
- 'LevelDependent' estimates the variance of the noise based on the wavelet coefficients at each resolution level.

There are three wavelet subbands: horizontal, vertical, and diagonal. The value of 'NoiseDirection' specifies which subbands to use in estimating the variance.

NoiseDirection — Wavelet subbands

["h", "v", "d"] (default) | string vector | scalar string

Wavelet subbands to use to estimate the variance of the noise, specified as a string vector or scalar string. Valid entries are "h", "v", or "d", for the horizontal, vertical, and diagonal subbands, respectively.

Example: 'NoiseDirection', ["h" "v"] specifies the horizontal and vertical subbands.

CycleSpinning — Number of circular shifts

0 (default) | nonnegative integer

Number of circular shifts in both the row and column directions to use for denoising IM with cycle spinning. In cycle spinning, circular shifts of the image along the row and column dimensions are denoised, shifted back, and averaged together to provide the final result.

Generally, SNR improvements are observed with cycle spinning up to 3-4 shifts and asymptote after that. Because of the asymptotic effect on SNR and the fact that $(\text{CycleSpinning}+1)^2$ images are being denoised, it is recommended to start with `CycleSpinning` equal to 0. Then gradually increase the number of shifts to determine if there is any improvement in SNR to justify the computational expense.

For example, specifying '`CycleSpinning`', 1 results in four copies of IM being denoised:

- The original image (unshifted)
- IM circularly shifted a single-element along the row dimension
- IM circularly shifted a single-element along the column dimension
- IM circularly shifted a single-element along both the row and column dimensions

The four denoised copies of IM are denoised, reconstructed, shifted back to their original positions, and averaged together. The value of `CycleSpinning` represents the maximum shift along both the row and column dimensions. For RGB images, there are no shifts applied along the color space dimension.

ColorSpace — Color space

'PCA' (default) | 'Original'

Color space used for denoising an RGB image. Valid options are 'PCA' and 'Original'.

- 'PCA': The RGB image is first projected onto its PCA color space, denoised in the PCA color space, and returned to the original color space after denoising.
- 'Original': Denoising is done in the same color space as the input image.

`ColorSpace` is valid only for RGB images.

Output Arguments

IMDEN — Denoised image

real-valued matrix

Denoised image, returned as a matrix. The dimensions of IM and IMDEN are equal.

DENOISED_CFS — Scaling and denoised wavelet coefficients

real-valued matrix

Scaling and denoised wavelet coefficients of the denoised image, returned as a real-valued matrix. `DENOISED_CFS` is a $(\text{numshifts}+1)^2$ -by-N matrix where N is the number of wavelet coefficients in the decomposition of IM and `numshifts` is the value of '`CycleSpinning`'. Each row of `DENOISED_CFS` contains the denoised wavelet coefficients for one of $(\text{numshifts}+1)^2$ shifted versions of IM. For RGB images, `DENOISED_CFS` are the denoised coefficients in the specified color space.

The i^{th} row of `DENOISED_CFS` contains the denoised wavelet coefficients of the image circularly shifted by the amount returned in the i^{th} column of `SHIFTS`. For example, if the second column of `SHIFTS` is `[1 ; 1]`, the second row of `DENOISED_CFS` contains the denoised coefficients of the image circularly shifted by a single element in the row direction and a single element in the column direction.

ORIGCFS — Scaling and wavelet coefficients

real-valued matrix

Scaling and wavelet coefficients of the input image, returned as a real-valued 2-D matrix. ORIGCFS is a $(\text{numshifts}+1)^2$ -by-N matrix where N is the number of wavelet coefficients in the decomposition of IM and numshifts is the value of the 'CycleSpinning'. Each row of ORIGCFS contains the wavelet coefficients for one of $(\text{numshifts}+1)^2$ shifted versions of IM. For RGB images, ORIGCFS are the original coefficients in the specified color space.

The i^{th} row of ORIGCFS contains the wavelet coefficients of the image circularly shifted by the amount returned in the i^{th} column of SHIFTS. For example, if the second column of SHIFTS is [1 ; 1], the second row of ORIGCFS contains the coefficients of the image circularly shifted by a single element in the row direction and a single element in the column direction.

S — Bookkeeping matrix

integer-valued matrix

Bookkeeping matrix. The matrix S contains the dimensions of the approximation coefficients at the coarsest scale, the sizes of the wavelet coefficients at all scales, and the size of the original input image. S is a matrix with the same structure as the S output of wavedec2.

SHIFTS — Image shifts

integer-valued matrix

Image shifts used in cycle spinning, returned as an integer-valued matrix. SHIFTS is 2-by- $(\text{numshifts}+1)^2$ matrix where each column of SHIFTS contains the shifts along the row and column dimension used in cycle spinning.

wavedec2 | wdenoise

Introduced in R2019a

wenergy

Energy for 1-D wavelet or wavelet packet decomposition

Syntax

```
[Ea,Ed] = wenergy(C,L)
E = wenergy(T)
```

Description

For a one-dimensional wavelet decomposition $[C,L]$ (see `wavedec` for details), $[Ea,Ed] = \text{wenergy}(C,L)$ returns Ea , which is the percentage of energy corresponding to the approximation and Ed , which is the vector containing the percentages of energy corresponding to the details.

For a wavelet packet tree T (see `wptree`, `wpdec`, `wpdec2`), $E = \text{wenergy}(T)$ returns a vector E , which contains the percentages of energy corresponding to the terminal nodes of the tree T . In this case, `wenergy` is a method of the `wptree` object T , which overloads the previous `wenergy` function.

Examples

```
% Example 1: 1-D wavelet decomposition
%-----
load noisbump
[C,L] = wavedec(noisbump,4,'sym4');
[Ea,Ed] = wenergy(C,L)

Ea =

    88.2860

Ed =

    2.1560    1.2286    1.4664    6.8630

% Example 2: 1-D wavelet packet decomposition
%-----
load noisbump
T = wpdec(noisbump,3,'sym4');
E = wenergy(T)

E =

    95.0329    1.4664    0.6100    0.6408    0.5935    0.5445    0.5154
    0.5965
```

Introduced before R2006a

wenergy2

Energy for 2-D wavelet decomposition

Syntax

```
[Ea,Eh,Ev,Ed] = wenergy2(C,S)
[Ea,EDetail] = wenergy2(C,S)
```

Description

For a two-dimensional wavelet decomposition $[C, S]$ (see `wavedec2` for details), $[Ea, Eh, Ev, Ed] = wenergy2(C, S)$ returns Ea , which is the percentage of energy corresponding to the approximation, and vectors Eh, Ev, Ed , which contain the percentages of energy corresponding to the horizontal, vertical, and diagonal details, respectively.

$[Ea, EDetail] = wenergy2(C, S)$ returns Ea , and $EDetail$, which is the sum of vectors Eh, Ev , and Ed .

Examples

```
load detail
[C,S] = wavedec2(X,2,'sym4');
[Ea,Eh,Ev,Ed] = wenergy2(C,S)
```

```
Ea =
    89.3520
```

```
Eh =
    1.8748    2.7360
```

```
Ev =
    1.5860    2.6042
```

```
Ed =
    0.7539    1.0932
```

```
[Ea,EDetails] = wenergy2(C,S)
```

```
Ea =
    89.3520
```

```
EDetails =
    4.2147    6.4334
```

Introduced before R2006a

wentropy

Entropy (wavelet packet)

Syntax

```
E = wentropy(X,T)
E = wentropy(X,T,P)
```

Description

`E = wentropy(X,T)` returns the entropy specified by `T` of the vector or matrix `X`.

`E = wentropy(X,T,P)` returns the entropy where `P` is a parameter depending on `T`.

`E = wentropy(X,T,θ)` is equivalent to `E = wentropy(X,T)`.

Examples

Signal Entropy

This example shows the different values of entropy of a random signal.

For purposes of reproducibility, reset the random seed and generate a random signal.

```
rng default
x = randn(1,200);
```

Compute the Shannon entropy of `x`.

```
e = wentropy(x, 'shannon')
e = -224.5551
```

Compute the log energy entropy of `x`.

```
e = wentropy(x, 'log energy')
e = -229.5183
```

Compute the threshold entropy of `x` with the threshold entropy equal to 0.2.

```
e = wentropy(x, 'threshold', 0.2)
e = 168
```

Compute the Sure entropy of `x` with the threshold equal to 3.

```
e = wentropy(x, 'sure', 3)
e = 35.7962
```

Compute the norm entropy of `x` with power equal to 1.1

```
e = wentropy(x, 'norm', 1.1)
```

```
e = 173.6578
```

You can use your own entropy function `ABC` with `wentropy`. Your function must be defined in a `.m` file, and the first line must be of the form:

```
function e = ABC(x)
```

where `x` is a vector and `e` is a real number. The new entropy can be used by typing

```
e = wentropy(x, 'user', 'ABC')
```

or more directly

```
e = wentropy(x, 'ABC')
```

The function file `myEntropy.m` returns the normalized Shannon entropy of a signal. Compute the normalized Shannon entropy of `x`.

```
w = wentropy(x, 'myEntropy')
```

```
w = -1.1228
```

Input Arguments

X — Input data

real-valued vector or matrix

Input data, specified as a real-valued vector or matrix.

T — Entropy type

'shannon' | 'log energy' | 'threshold' | 'sure' | 'norm' | 'user' | 'FunName'

Entropy type, specified as one of the following:

Entropy Type (T)	Threshold Parameter (P)	Comments
'shannon'		P is not used.
'log energy'		P is not used.
'threshold'	$0 \leq P$	P is the threshold.
'sure'	$0 \leq P$	P is the threshold.
'norm'	$1 \leq P$	P is the power.
'user'	Character vector	P is a character vector containing the file name of your own entropy function, with a single input <code>x</code> .

Entropy Type (T)	Threshold Parameter (P)	Comments
'FunName'	No constraints on P	FunName is any character vector other than the previous entropy types listed. FunName contains the file name of your own entropy function, with x as input and P as an additional parameter to your entropy function.

T and the threshold parameter P together define the entropy criterion.

Note The 'user' option is historical and still kept for compatibility, but it is obsoleted by the last option described in the table above. The *FunName* option do the same as the 'user' option and in addition gives the possibility to pass a parameter to your own entropy function.

P – Threshold parameter

real number | character vector | string scalar

Threshold parameter, specified by a real number, character vector, or string scalar. P and the entropy type T together define the entropy criterion.

Output Arguments

E – Entropy

real number

Entropy of X, returned as a real number.

More About

Entropy

Functionals verifying an additive-type property are well suited for efficient searching of binary-tree structures and the fundamental splitting property of the wavelet packets decomposition. Classical entropy-based criteria match these conditions and describe information-related properties for an accurate representation of a given signal. Entropy is a common concept in many fields, mainly in signal processing. The following example lists different entropy criteria. Many others are available and can be easily integrated. In the following expressions, s is the signal and $(s_i)_i$ the coefficients of s in an orthonormal basis.

The entropy E must be an additive cost function such that $E(0) = 0$ and

$$E(s) = \sum_i E(s_i)$$

- The (nonnormalized) Shannon entropy.

$$E1(s_i) = s_i^2 \log(s_i^2)$$

so,

$$E1(s) = -\sum_i s_i^2 \log(s_i^2)$$

with the convention $0\log(0) = 0$.

- The concentration in l^p norm entropy with $1 \leq p$.

$$E2(s_i) = |s_i|^p \text{ so } E2(s) = \sum_i |s_i|^p = \|s\|_p^p$$

- The “log energy” entropy.

$$E3(s_i) = \log(s_i^2)$$

so,

$$E3(s) = \sum_i \log(s_i^2)$$

with the convention $\log(0) = 0$.

- The threshold entropy.

$E4(s_i) = 1$ if $|s_i| > p$ and 0 elsewhere so $E4(s) = \#\{i \text{ such that } |s_i| > p\}$ is the number of time instants when the signal is greater than a threshold p .

- The “SURE” entropy.

$E5(s) = n - \#\{i \text{ such that}$

$$|s_i| \leq p\} + \sum_i \min(s_i^2, p^2)$$

For more information, see “Wavelet Packets for Compression and Denoising”.

Introduced before R2006a

wextend

Extend vector or matrix

Syntax

```
YEXT= wextend(TYPE,MODE,X,LEN)  
YEXT = wextend( ____,LOC)
```

Description

YEXT= wextend(TYPE,MODE,X,LEN) extends real-valued input vector or matrix X by length LEN, using the TYPE method and MODE extension. The TYPE specifies the dimension of the extension. The MODE specifies the rule to apply to fill in values in the extension.

YEXT = wextend(____,LOC) also specifies the location of the extension.

Examples

Extending Vectors and Matrices

Extend Vector

Extend a vector using a number of different methods.

Create a vector and set the extension length to 2.

```
len = 2;  
x = [1 2 3]
```

```
x = 1×3
```

```
    1    2    3
```

Perform a zero-pad extension. To verify that different forms of the input arguments are possible, perform this extension twice. The result is the same both times.

```
xextzpd1 = wextend('1','zpd',x,len)
```

```
xextzpd1 = 1×7
```

```
    0    0    1    2    3    0    0
```

```
xextzpd2 = wextend('1D','zpd',x,len,'b')
```

```
xextzpd2 = 1×7
```

```
    0    0    1    2    3    0    0
```

Perform a half-point symmetric extension.

```
xextsym = wextend('1D', 'sym', x, len)
xextsym = 1×7
    2    1    1    2    3    3    2
```

Perform a periodic extension. Since the input vector is of odd length, wextend appends an extra example to the end before extending using the 'ppd' mode. This sample is equal to the last value on the right.

```
xextper = wextend('1D', 'per', x, len)
xextper = 1×8
    3    3    1    2    3    3    1    2
```

Extend Matrix

Extend a small matrix using a number of different methods.

Create a matrix and set the extension length to 2.

```
len = 2;
X = [1 2 3; 4 5 6]
X = 2×3
    1    2    3
    4    5    6
```

Perform a zero-pad extension of the array.

```
Xextzpd = wextend(2, 'zpd', X, len)
Xextzpd = 6×7
    0    0    0    0    0    0    0
    0    0    0    0    0    0    0
    0    0    1    2    3    0    0
    0    0    4    5    6    0    0
    0    0    0    0    0    0    0
    0    0    0    0    0    0    0
```

Perform a half-point symmetric extension of the array.

```
Xextsym = wextend('2D', 'sym', X, len)
Xextsym = 6×7
    5    4    4    5    6    6    5
    2    1    1    2    3    3    2
    2    1    1    2    3    3    2
    5    4    4    5    6    6    5
    5    4    4    5    6    6    5
```

```
2 1 1 2 3 3 2
```

Extend uint8 Data Beyond Range Limits

Observe the effects of symmetric, antisymmetric, and smooth extensions on a `uint8` vector when values are at or near the limits of the data type's range.

Symmetric Extensions

The smallest `uint8` integer is 0, and the largest is 255. Create a vector of `uint8` integers that includes those limits.

```
dataVector = uint8([0 1 2 253 254 255])
```

```
dataVector = 1x6 uint8 row vector
```

```
0 1 2 253 254 255
```

Obtain whole-point and half-point symmetric extensions of the vector. Extend the vector by two values on the left and right.

```
wholePointSym = wextend('1','symw',dataVector,2)
```

```
wholePointSym = 1x10 uint8 row vector
```

```
2 1 0 1 2 253 254 255 254 253
```

```
halfPointSym = wextend('1','symh',dataVector,2)
```

```
halfPointSym = 1x10 uint8 row vector
```

```
1 0 0 1 2 253 254 255 255 254
```

Extending symmetrically never results in values outside the `uint8` range.

Antisymmetric Extensions

Create a type `double` copy of the vector, and then obtain a whole-point antisymmetric extension of the copy. The extension includes negative values and values greater than 255.

```
dataVectorDouble = double(dataVector);
```

```
wholePointAsymDouble = wextend('1','asymw',dataVectorDouble,2)
```

```
wholePointAsymDouble = 1x10
```

```
-2 -1 0 1 2 253 254 255 256 257
```

Obtain a whole-point antisymmetric extension of the original `uint8` vector. Values outside the `uint8` range are mapped to the closest `uint8` integer, which is 0 for negative values and 255 for values greater than 255.

```
wholePointAsym = wextend('1','asymw',dataVector,2)
```

```
wholePointAsym = 1x10 uint8 row vector
    0     0     0     1     2  253  254  255  255  255
```

Now obtain half-point antisymmetric extensions of the double copy and the original uint8 vector.

```
halfPointAsymDouble = wextend('1','asymh',dataVectorDouble,2)
halfPointAsymDouble = 1x10
   -1     0     0     1     2  253  254  255 -255 -254
```

```
halfPointAsym = wextend('1','asymh',dataVector,2)
halfPointAsym = 1x10 uint8 row vector
    0     0     0     1     2  253  254  255     0     0
```

As with the whole-point antisymmetric extension, negative values in the extended uint8 data are mapped to 0.

Smooth Extensions

Obtain order-0 smooth extensions of the double copy and the original uint8 vector.

```
smooth0Double = wextend('1','sp0',dataVectorDouble,2)
smooth0Double = 1x10
    0     0     0     1     2  253  254  255  255  255
```

```
smooth0 = wextend('1','sp0',dataVector,2)
smooth0 = 1x10 uint8 row vector
    0     0     0     1     2  253  254  255  255  255
```

Results are identical. Next, obtain an order-1 smooth extension of each vector.

```
smooth1Double = wextend('1','sp1',dataVectorDouble,2)
smooth1Double = 1x10
   -2   -1     0     1     2  253  254  255  256  257
```

```
smooth1 = wextend('1','sp1',dataVector,2)
smooth1 = 1x10 uint8 row vector
    0     0     0     1     2  253  254  255  255  255
```

The values in the `double` result that are outside the `uint8` range are mapped to the closest `uint8` values in the `uint8` extension.

Extend int8 Data Beyond Range Limits

Observe the effects of symmetric, antisymmetric, and smooth extensions of `int8` data when values are at or near the limits of the data type's range.

Symmetric Extensions

The smallest `int8` integer is -128 , and the largest is 127 . Create a vector of `int8` integers that includes those limits.

```
dataVector = int8([-128 -127 -126 125 126 127])
```

```
dataVector = 1x6 int8 row vector
```

```
-128 -127 -126 125 126 127
```

Obtain whole-point and half-point symmetric extensions of the data. Extend the vector by two values on the left and right.

```
wholePointSym = wextend('1','symw',dataVector,2)
```

```
wholePointSym = 1x10 int8 row vector
```

```
-126 -127 -128 -127 -126 125 126 127 126 125
```

```
halfPointSym = wextend('1','symh',dataVector,2)
```

```
halfPointSym = 1x10 int8 row vector
```

```
-127 -128 -128 -127 -126 125 126 127 127 126
```

Extending symmetrically never results in values outside the `int8` range.

Antisymmetric Extensions

Create a type `double` copy of the vector, and then obtain a whole-point antisymmetric extension of the copy. The extension includes negative values less than -128 and values greater than 127 .

```
dataVectorDouble = double(dataVector);
```

```
wholePointsAsymDouble = wextend('1','asymw',dataVectorDouble,2)
```

```
wholePointsAsymDouble = 1x10
```

```
-130 -129 -128 -127 -126 125 126 127 128 129
```

Obtain a whole-point antisymmetric extension of the original `int8` vector. Values outside the `int8` range are mapped to the closest `int8` integer, which is -128 for values less than -128 and 127 for values greater than 127 .

```
wholePointAsym = wextend('1','asymw',dataVector,2)
```

```
wholePointAsym = 1x10 int8 row vector
```

```
-128 -128 -128 -127 -126 125 126 127 127 127
```

Now obtain half-point antisymmetric extensions of the double copy and the original int8 vector.

```
halfPointAsymDouble = wextend('1','asymh',dataVectorDouble,2)
```

```
halfPointAsymDouble = 1x10
```

```
127 128 -128 -127 -126 125 126 127 -127 -126
```

```
halfPointAsym = wextend('1','asymh',dataVector,2)
```

```
halfPointAsym = 1x10 int8 row vector
```

```
127 127 -128 -127 -126 125 126 127 -127 -126
```

In the double result, the first value is 127, which can be represented as an int8 integer. The second value is 128, which cannot be represented as an int8 integer. Therefore, in the int8 result, it is being mapped to 127. The remaining values in the type double result can all be represented as int8 integers.

Smooth Extensions

Obtain order-0 smooth extensions of the double copy and the original int8 vector.

```
smooth0Double = wextend('1','sp0',dataVectorDouble,2)
```

```
smooth0Double = 1x10
```

```
-128 -128 -128 -127 -126 125 126 127 127 127
```

```
smooth0 = wextend('1','sp0',dataVector,2)
```

```
smooth0 = 1x10 int8 row vector
```

```
-128 -128 -128 -127 -126 125 126 127 127 127
```

The results are identical. Now obtain an order-1 smooth extension of each vector.

```
smooth1Double = wextend('1','sp1',dataVectorDouble,2)
```

```
smooth1Double = 1x10
```

```
-130 -129 -128 -127 -126 125 126 127 128 129
```

```
smooth1 = wextend('1','sp1',dataVector,2)
```

```
smooth1 = 1x10 int8 row vector
```

```
-128 -128 -128 -127 -126 125 126 127 127 127
```

The values in the `double` result outside the `int8` range are mapped to the closest `int8` values in the `int8` extension.

Input Arguments

TYPE — Extension method

1 | '1' | '1d' | '1D' | 2 | '2' | '2d' | '2D' | 'ar' | 'addrow' | 'ac' | 'addcol'

Extension method used on the input, specified as one of the values listed here.

TYPE	Description
1, '1', '1d', or '1D'	1-D extension
2, '2', '2d', or '2D'	2-D extension
'ar' or 'addrow'	Add rows
'ac' or 'addcol'	Add columns

Data Types: `double` | `char`

MODE — Specific extension

'zpd' | 'sp0' | 'spd' | 'sp1' | 'sym' | 'symh' | 'symw' | 'asym' | 'asymh' | 'asymw' | 'ppd' | 'per'

Specific extension method to use to extend the input, specified as one of the values listed here.

MODE	Description
'zpd'	Zero extension
'sp0'	Smooth extension of order 0
'spd' (or 'sp1')	Smooth extension of order 1
'sym' or 'symh'	Symmetric padding (half point): boundary value symmetric replication
'symw'	Symmetric padding (whole point): boundary value symmetric replication
'asym' or 'asymh'	Antisymmetric padding (half point): boundary value antisymmetric replication
'asymw'	Antisymmetric padding (whole point): boundary value antisymmetric replication
'ppd'	Periodized extension (1)
'per'	Periodized extension (2) If the signal length is odd, <code>wextend</code> appends on the right a copy of the last value, and performs the extension using the 'ppd' mode. Otherwise, 'per' reduces to 'ppd'. This rule also applies to images.

For more information on symmetric extension modes, see [1].

Note The extension modes 'sp0' and 'spd' (or 'sp1') cast the data internally to double precision before performing the extension. For integer data types, `wextend` warns if one of the following occurs.

- The conversion to double causes a loss of precision.
 - The requested extension results in integers beyond the range where double precision numbers can represent consecutive integers exactly.
-

Data Types: char

X — Input data

real-valued vector or matrix

Input data, specified as a real-valued vector or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

LEN — Length of extension

nonnegative integer | two-element vector of nonnegative integers

Length of extension, specified as a nonnegative integer or two-element vector of nonnegative integers. You can extend a matrix by expressing LEN as [LROW, LCOL], where LROW is the number of rows to add and LCOL is the number of columns to add. You can perform a 2-D extension of a matrix by the same amount in both directions by specifying LEN as single integer.

An extension of length 0 is equivalent to the null extension.

Example: `wextend('2D','sym',[1 2 3 4;5 6 7 8],[2 0])` extends only two rows up and two rows down.

LOC — Location of extension

'l' | 'u' | 'r' | 'd' | 'b' | 'n' | two-character array

Location of extension, specified as one or a pair of the following:

- 'l' — Extension left
- 'u' — Extension up
- 'r' — Extension right
- 'd' — Extension down
- 'b' — Extension on both sides
- 'n' — Null extension

The valid and default values for LOC, and the behavior of LEN, depend on the specified TYPE.

TYPE	LOC
1, 'l', 'ld' or 'lD'	'l', 'u', 'r', 'd', 'b', or 'n' Example: <code>wextend('lD','zpd',X,3,'r')</code> extends input vector X three elements to the right. Default: 'b' LEN is the length of the extension.

TYPE	LOC
2, '2', '2d' or '2D'	[LOCROW, LOCCOL], where LOCROW and LOCCOL are 1-D extension locations or 'n' (none). Example: <code>wextend('2D', 'zpd', X, [2 3], 'ub')</code> extends input vector or matrix X two rows up and three columns on both sides. Default: 'bb' LEN, specified as [LROW, LCOL], is the number of rows and columns to add.
'ar' or 'addrow'	'l', 'u', 'r', 'd', 'b', or 'n' Example: <code>wextend('addrow', 'zpd', X, 4, 'd')</code> extends input vector or matrix X four rows down. Default: 'b' LEN is the number of rows to add.
'ac' or 'addcol'	'l', 'u', 'r', 'd', 'b', or 'n' Example: <code>wextend('addcol', 'zpd', X, 1, 'l')</code> extends input vector or matrix X one column to the left. Default: 'b' LEN is the number of columns to add.

Tips

For most wavelet applications, either a periodic extension or symmetric extension works fine.

Algorithms

When a value is outside the input data type's range, `wextend` maps it to the closest value of the input data type. For examples of data being extended beyond a data type's range, see “Extend uint8 Data Beyond Range Limits” on page 1-1280 and “Extend int8 Data Beyond Range Limits” on page 1-1282.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The generated code can return a column vector when MATLAB returns a row vector if all of the following conditions are true:
 - TYPE specifies a 1-D extension.
 - Input X is a variable-size vector.
 - Input X is not a variable-length row vector (1-by-:).

Code generation does not produce a warning or error message about the shape mismatch. In the output vector that the generated code returns, the values match the values in the output vector that MATLAB returns.

In this case, to generate code that returns a row vector, pass `X(:)'` instead of `X`.

- Input `X` must be of type `double`.

`dwtmode`

Introduced before R2006a

wfbm

Fractional Brownian motion synthesis

Syntax

```
FBM = wfbm(H,L)
FBM = wfbm(H,L,'plot')
FBM = wfbm(H,L,NS,W)
FBM = wfbm(H,L,W,NS)
wfbm(H,L,'plot',NS)
wfbm(H,L,'plot',W)
wfbm(H,L,'plot',NS,W)
wfbm(H,L,'plot',W,NS)
```

Description

`FBM = wfbm(H,L)` returns a fractional Brownian motion signal FBM of the Hurst parameter H ($0 < H < 1$) and length L , following the algorithm proposed by Abry and Sellan.

`FBM = wfbm(H,L,'plot')` generates and plots the FBM signal.

`FBM = wfbm(H,L,NS,W)` or `FBM = wfbm(H,L,W,NS)` returns the FBM using NS reconstruction steps and the sufficiently regular orthogonal wavelet W .

`wfbm(H,L,'plot',NS)` or `wfbm(H,L,'plot',W)` or `wfbm(H,L,'plot',NS,W)` or `wfbm(H,L,'plot',W,NS)` generates and plots the FBM signal.

`wfbm(H,L)` is equivalent to `WFBM(H,L,6,'db10')`.

`wfbm(H,L,NS)` is equivalent to `WFBM(H,L,NS,'db10')`.

`wfbm(H,L,W)` is equivalent to `WFBM(H,L,W,6)`.

A fractional Brownian motion (fBm) is a continuous-time Gaussian process depending on the Hurst parameter $0 < H < 1$. It generalizes the ordinary Brownian motion corresponding to $H = 0.5$ and whose derivative is the white noise. The fBm is self-similar in distribution and the variance of the increments is given by

$$\text{Var}(fBm(t) - fBm(s)) = v |t-s|^{2H}$$

where v is a positive constant.

Examples

According to the value of H , the fBm exhibits for $H > 0.5$, long-range dependence and for $H < 0.5$, short or intermediate dependence. This example shows each situation using the `wfbm` file, which generates a sample path of this process.

```
% Generate fBm for H = 0.3 and H = 0.7
```

```

% Set the parameter H and the sample length
H = 0.3; lg = 1000;
% Generate and plot wavelet-based fBm for H = 0.3
fBm03 = wfbm(H,lg,'plot');

H = 0.7;
% Generate and plot wavelet-based fBm for H = 0.7
fBm07 = wfbm(H,lg,'plot');

% The last step is equivalent to
% Define wavelet and level of decomposition
% w = 'db10'; ns = 6;
% Generate
% fBm07 = wfbm(H,lg,'plot',w,ns);

```

fBm07 clearly exhibits a stronger low-frequency component and has, locally, less irregular behavior.

Algorithms

Starting from the expression of the fBm process as a fractional integral of the white noise process, the idea of the algorithm is to build a biorthogonal wavelet depending on a given orthogonal one and adapted to the parameter H.

Then the generated sample path is obtained by the reconstruction using the new wavelet starting from a wavelet decomposition at a given level designed as follows: details coefficients are independent random Gaussian realizations and approximation coefficients come from a fractional ARIMA process.

This method was first proposed by Meyer and Sellan and implementation issues were examined by Abry and Sellan.

Nevertheless, the samples generated following this original scheme exhibit too many high-frequency components. To circumvent this undesirable behavior Bardet et al. propose downsampling the obtained sample by a factor 10.

Two internal parameters `delta = 10` (the downsampling factor) and a threshold `prec = 1E-4`, to evaluate series by truncated sums, can be modified by the user for extreme values of H.

A complete overview of long-range dependence process generators is available in Bardet et al.

wfbmesti

Introduced before R2006a

wfbmesti

Parameter estimation of fractional Brownian motion

Syntax

`HEST = wfbmesti(X)`

Description

`HEST = wfbmesti(X)` returns a one-by-three vector `HEST` which contains three estimates of the fractal index H of the input signal X . The signal X is assumed to be a realization of fractional Brownian motion with Hurst index H .

The first two elements of the vector are estimates based on the second derivative with the second computed in the wavelet domain.

The third estimate is based on the linear regression in loglog plot, of the variance of detail versus level.

A fractional Brownian motion (fBm) is a continuous-time Gaussian process depending on the so-called Hurst parameter $0 < H < 1$. It generalizes the ordinary Brownian motion corresponding to $H = 0.5$ and whose derivative is the white noise. The fBm is self-similar in distribution and the variance of the increments is

$$\text{Var}(fBm(t) - fBm(s)) = \nu |t - s|^{2H}$$

where ν is a positive constant.

This special form of the variance of the increments suggests various ways to estimate the parameter H . One can find in Bardet et al. a survey of such methods. The `wfbmesti` file provides three different estimates. The first one, due to Istas and Lang, is based on the discrete second-order derivative. The second one is a wavelet-based adaptation and has similar properties. The third one, proposed by Flandrin, estimates H using the slope of the loglog plot of the detail variance versus the level. A more recent extension can be found in Abry et al.

Examples

Hurst Parameter Estimation

This example shows how to estimate the Hurst index of a fractional Brownian motion. The example simulates 1,000 realizations of fractional Brownian motion with $H=0.6$. Each realization consists of 10,000 samples. At the end of the simulation, the three estimates of the Hurst index are compared.

Initialize the random number generator for repeatable results. Set the Hurst index equal to 0.6 and the length of the realizations to be 10,000.

```
rng default;
H = 0.6;
len = 10000;
```

Generate 1,000 realizations of fractional Brownian motion and compute the estimates of the Hurst parameter.

```
n = 1000;
Hest = zeros(n,3);
for ii = 1:n
    fBm06 = wfbm(H,len);
    Hest(ii,:) = wfbmesti(fBm06);
end
```

Compare the estimates.

wfilters

Wavelet filters

Syntax

```
[LoD,HiD,LoR,HiR] = wfilters(wname)
[F1,F2] = wfilters(wname,type)
```

Description

[LoD,HiD,LoR,HiR] = wfilters(wname) returns the four lowpass and highpass, decomposition and reconstruction filters associated with the orthogonal or biorthogonal wavelet wname.

[F1,F2] = wfilters(wname,type) returns the pair of type filters associated with the orthogonal or biorthogonal wavelet wname. For example, wfilters('db6','h') returns the pair of highpass filters HiD and HiR associated with the db6 wavelet.

Examples

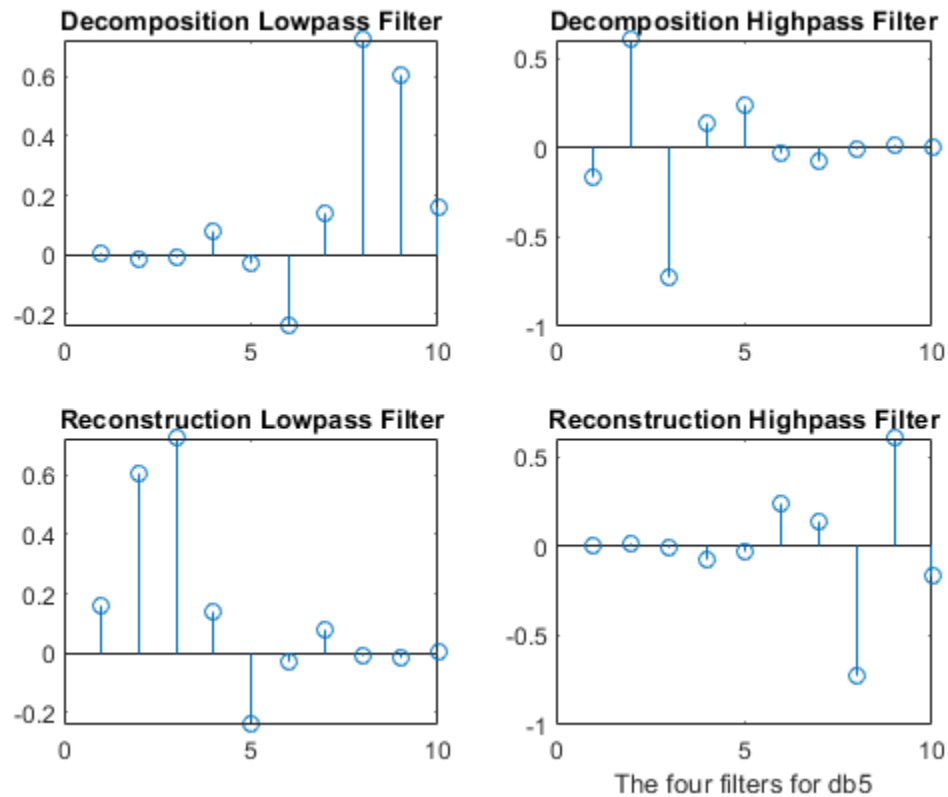

Compute Four Filters

Set the wavelet name.

```
wname = 'db5';
```

Compute the four filters associated with wavelet name specified by wname and plot the results.

```
[LoD,HiD,LoR,HiR] = wfilters(wname);
subplot(2,2,1)
stem(LoD)
title('Decomposition Lowpass Filter')
subplot(2,2,2)
stem(HiD)
title('Decomposition Highpass Filter')
subplot(2,2,3)
stem(LoR)
title('Reconstruction Lowpass Filter')
subplot(2,2,4)
stem(HiR)
title('Reconstruction Highpass Filter')
xlabel(['The four filters for ',wname])
```

Input Arguments

wname — Name of orthogonal or biorthogonal wavelet

'haar' | 'db1' | 'db2' | 'coif1' | 'coif2' | ...

Name of orthogonal or biorthogonal wavelet, specified as one of the values listed here.

Wavelet Families	Wavelets
Daubechies	'db1' or 'haar', 'db2', ..., 'db10', ..., 'db45'
Coiflets	'coif1', ..., 'coif5'
Symlets	'sym2', ..., 'sym8', ..., 'sym45'
Fejer-Korovkin filters	'fk4', 'fk6', 'fk8', 'fk14', 'fk22'
Discrete Meyer	'dmey'
Biorthogonal	'bior1.1', 'bior1.3', 'bior1.5' 'bior2.2', 'bior2.4', 'bior2.6', 'bior2.8' 'bior3.1', 'bior3.3', 'bior3.5', 'bior3.7' 'bior3.9', 'bior4.4', 'bior5.5', 'bior6.8'

Wavelet Families	Wavelets
Reverse Biorthogonal	'rbio1.1', 'rbio1.3', 'rbio1.5' 'rbio2.2', 'rbio2.4', 'rbio2.6', 'rbio2.8' 'rbio3.1', 'rbio3.3', 'rbio3.5', 'rbio3.7' 'rbio3.9', 'rbio4.4', 'rbio5.5', 'rbio6.8'

type — Type of filter pair

'd' | 'r' | 'l' | 'h'

Type of filter pair to return, specified as one of the values listed here.

type	Description
'd'	Decomposition filters (LoD and HiD)
'r'	Reconstruction filters (LoR and HiR)
'l'	Lowpass filters (LoD and LoR)
'h'	Highpass filters (HiD and HiR)

Output Arguments

LoD — Decomposition lowpass filter

real-valued vector

Decomposition lowpass filter, returned as a real-valued vector, associated with the wavelet wname.

HiD — Decomposition highpass filter

real-valued vector

Decomposition highpass filter, returned as a real-valued vector, associated with the wavelet wname.

LoR — Reconstruction lowpass filter

real-valued vector

Reconstruction lowpass filter, returned as a real-valued vector, associated with the wavelet wname.

HiR — Reconstruction highpass filter

real-valued vector

Reconstruction highpass filter, returned as a real-valued vector, associated with the wavelet wname.

F1, F2 — Filter pair

real-valued vectors

Filter pair of requested type, returned, specified as one of the pairs of filters listed here.

type	Description	Filter Pair
'd'	Decomposition filters	LoD and HiD
'r'	Reconstruction filters	LoR and HiR
'l'	Lowpass filters	LoD and LoR
'h'	Highpass filters	HiD and HiR

`biorfilt` | `orthfilt` | `waveinfo` | `wavemngr`

Introduced before R2006a

wfusing

Fusion of two images

Syntax

```
xfus = wfusing(x1,x2,wname,level,afusmeth,dfusmeth)
[xfus,txfus,tx1,tx2] = wfusing(x1,x2,wname,level,afusmeth,dfusmeth)

[ ___ ] = wfusing( ___ , 'plot')
```

Description

The principle of image fusion using wavelets is to merge the wavelet decompositions of the two original images using fusion methods applied to approximations coefficients and details coefficients.

`xfus = wfusing(x1,x2,wname,level,afusmeth,dfusmeth)` returns the fused image `xfus` obtained by fusion of the two original images `x1` and `x2`.

`[xfus,txfus,tx1,tx2] = wfusing(x1,x2,wname,level,afusmeth,dfusmeth)` also returns three wavelet decomposition tree objects associated with `xfus`, `x1`, and `x2`, respectively.

`[___] = wfusing(___ , 'plot')` plots the objects `txfus`, `tx1`, and `tx2`. This syntax can be used with any of the previous syntaxes.

Examples

Fuse Two Images

This example shows how to fuse two images to create a new image.

Load the mask and bust images.

```
load mask
x1 = X;
load bust
x2 = X;
```

Merge the two images from level 5 wavelet decompositions using the `db2` wavelet. Perform the fusion by taking the mean for both approximations and details.

```
wv = 'db2';
lv = 5;
xfusmean = wfusing(x1,x2,wv,lv,'mean','mean');
```

Merge the two images again, but this time perform the fusion by taking the maximum of the approximations and the minimum for the details.

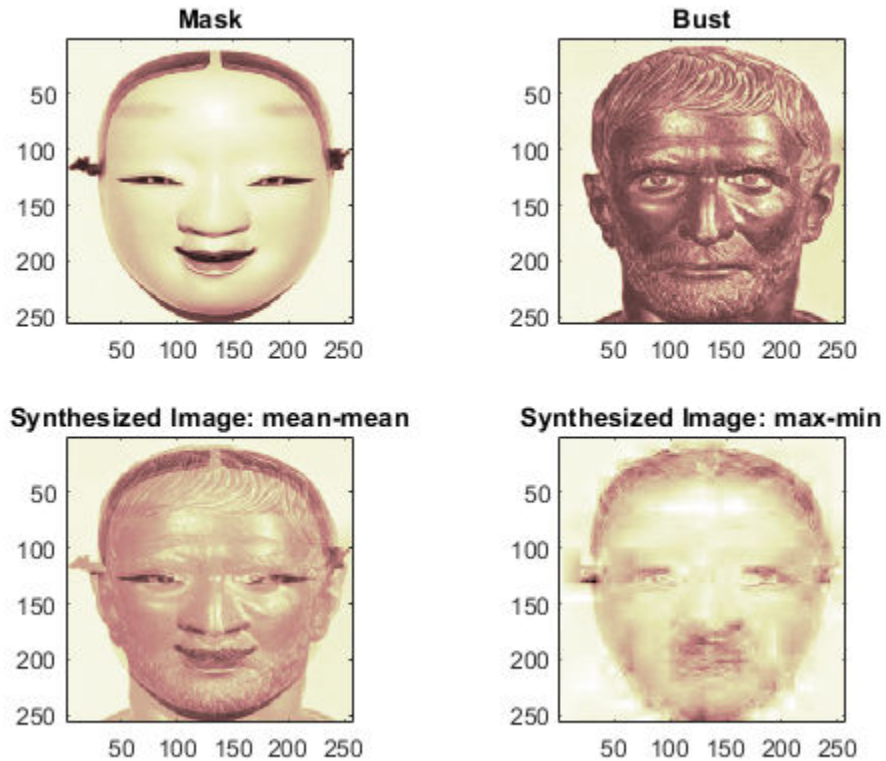

```
xfusmaxmin = wfusing(x1,x2,wv,lv,'max','min');
```

Plot the original and fused images.

```

subplot(2,2,1)
image(x1)
axis square
title('Mask')
subplot(2,2,2)
image(x2)
axis square
title('Bust')
subplot(2,2,3)
image(xfusmean)
axis square
title('Synthesized Image: mean-mean')
subplot(2,2,4)
image(xfusmaxmin)
axis square
title('Synthesized Image: max-min')
colormap(map)

```

Restore Image From Two Fuzzy Versions

This example shows how to restore an image from two fuzzy versions of an original image.

Load two fuzzy versions of an original image.

```
load cathe_1
x1 = X;
load cathe_2
x2 = X;
```

Merge the two images from level 5 wavelet decompositions using the sym4 wavelet. Perform the fusion by taking the maximum of the absolute value of the coefficients for both approximations and details.

```
wv = 'sym4';
lv = 5;
xfus = wffusimg(x1,x2,wv,lv,'max','max');
```

Plot the original and fused images.

```
subplot(2,2,1)
image(x1)
axis square
title('Catherine 1')
subplot(2,2,2)
image(x2)
axis square
title('Catherine 2')
subplot(2,2,3)
image(xfus)
axis square
title('Synthesized Image')
colormap(map)
```

Fuse Two Images With User-Defined Fusion Method

This example shows how to fuse two images using a user-defined fusion method.

Load two images of the same size.

```
load mask
a = X;
load bust
b = X;
```

Define the fusion method and call the fusion function `helperUserFusion`. The source code for `helperUserFusion` is listed in the appendix.

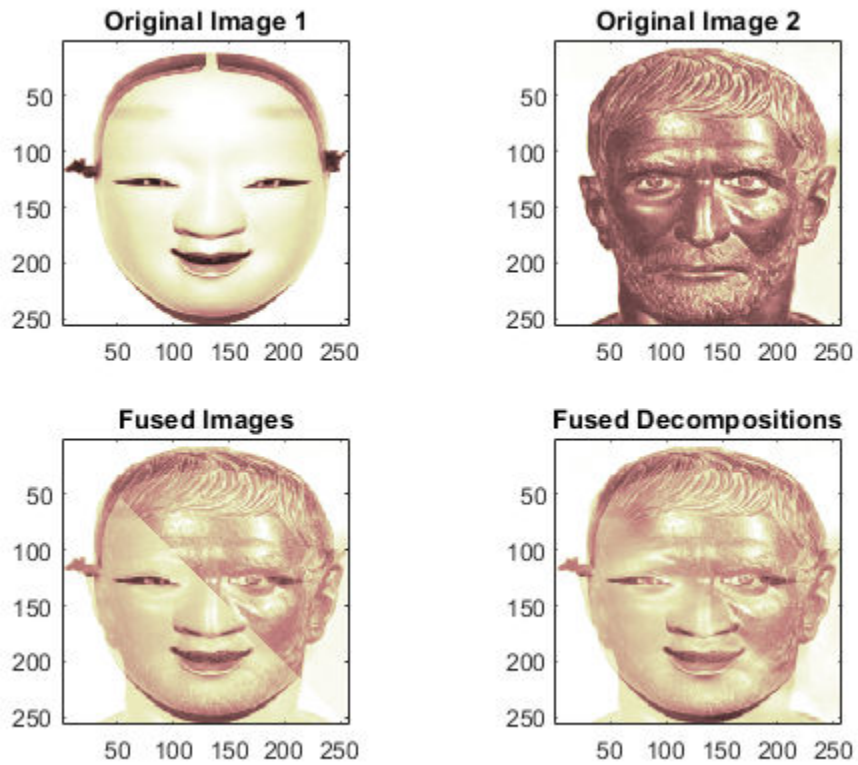

```
fus_method = struct('name','userDEF','param','helperUserFusion');
```

Merge the images twice with the user-defined method. First use `wfusmat`, which fuses the images themselves and not their wavelet decompositions. Then use `wfusing`, which fuses the wavelet decompositions.

```
c = wfusmat(a,b,fus_method);
d = wfusing(a,b,'db4',5,fus_method,fus_method);
```

Plot the original and fused images.

```
subplot(2,2,1)
image(a)
title('Original Image 1')
axis square
subplot(2,2,2)
image(b)
title('Original Image 2')
axis square
subplot(2,2,3)
image(c)
title('Fused Images')
axis square
subplot(2,2,4)
image(d)
title('Fused Decompositions')
axis square
colormap(pink(220))
```

Visualize the differences between the merged images.

```
figure  
image(c-d)  
axis square  
colormap(pink(220))
```

Appendix

helperUserFusion

If you want to try a different user-defined fusion method, edit the file `helperUserFusion.m`, which is located in the same folder as this example.

```
function c = helperUserFusion(A,B)
% This function is in support of the wavelet fusion examples only. It may
% change or be removed in a future release.

% create an upper triangular logical array the same size as A.
d = logical(triu(ones(size(A))));
% set a threshold
t = 0.3;

c = A;
% set the upper triangular portion of the output to a blend of A and B
c(d) = t*A(d)+(1-t)*B(d);
% set the lower triangular portion of the output to a different blend of A
% and B
```

```
c(~d) = t*B(~d)+(1-t)*A(~d);
end
```

Input Arguments

x1, x2 — Images to merge

real-valued 2-D matrix | real-valued 3-D array

Images to merge, specified as real-valued 2-D matrices or real-valued 3-D arrays. If specified as 3-D arrays, x1 and x2 are assumed to be color images in the RGB color space and the third dimension of the arrays must be 3.

The images x1 and x2 must be the same size. To resize the images, use `wextend` or `imresize`.

wname — Wavelet

character vector | string scalar

Wavelet used to create the wavelet decomposition, specified as a character vector or string scalar. The wavelet must be orthogonal or biorthogonal and recognized by `wfilters`.

level — Wavelet decomposition level

positive integer

Wavelet decomposition level, specified as a positive integer.

afusmeth, dfusmeth — Fusion methods for approximations and details

'max' | 'min' | 'mean' | 'img1' | 'img2' | 'rand' | structure array

Fusion methods for approximations and details, respectively, each specified either as a structure array or as one of the values listed here. The approximation and details are merged element-wise.

afusmeth	Description
'max'	Maximum
'min'	Minimum
'mean'	Mean
'img1'	First element
'img2'	Second element
'rand'	Random element

When specified as a structure array, the structure has the form `struct('name', nameMETH, 'param', paramMETH)` where `nameMETH` can be one of the values listed here.

nameMETH	Description
'linear'	
'UD_fusion'	Up-down fusion
'DU_fusion'	Down-up fusion
'RL_fusion'	Right-left fusion
'UserDEF'	User-defined fusion

For the description of these options and the `paramMETH` parameter, see `wfusmat`.

Example: `afusmeth = struct('name','linear','param',0.3)`

Data Types: `double` | `struct`

Output Arguments

xfus — Fused image

real-valued 2-D matrix | real-valued 3-D array

Fused image, returned as a real-valued 2-D matrix or a real-valued 3-D array. The fused image `xfus` has the same size as `x1` and `x2`.

txfus, tx1, tx2 — Wavelet decomposition trees

`wdectree` object

Wavelet decomposition trees associated with `xfus`, `x1`, and `x2`, respectively, returned as `wdectree` objects.

Example: `plot(txfus)` plots the object in a GUI tool that you can use to inspect the tree.

See Also

`wextend` | `wfusmat`

Introduced before R2006a

wfusmat

Fusion of two matrices or arrays

Syntax

```
C = wfusmat(A,B,METHOD)
```

Description

`C = wfusmat(A,B,METHOD)` returns the fused matrix `C` obtained from the matrices `A` and `B` using the fusion method defined by `METHOD`.

The matrices `A` and `B` must be of the same size. The output matrix `C` is of the same size as `A` and `B`.

Available fusion methods are

- Simple, where `METHOD` is
 - 'max' : $D = \text{abs}(A) \geq \text{abs}(B)$; $C = A(D) + B(\sim D)$
 - 'min' : $D = \text{abs}(A) \leq \text{abs}(B)$; $C = A(D) + B(\sim D)$
 - 'mean' : $C = (A+B) / 2$; $D = \text{ones}(\text{size}(A))$
 - 'rand' : $C = A(D) + B(\sim D)$; D is a Boolean random matrix
 - 'img1' : $C = A$
 - 'img2' : $C = B$
- Parameter-dependent, where `METHOD` is of the following form:

```
METHOD = struct('name',nameMETH,'param',paramMETH)
```

where `nameMETH` can be

- 'linear' : $C = A*\text{paramMETH} + B*(1-\text{paramMETH})$,

where $0 \leq \text{paramMETH} \leq 1$

- 'UD_fusion': Up-down fusion, with $\text{paramMETH} \geq 0$

```
x = linspace(0,1,size(A,1));
```

```
P = x.^paramMETH;
```

Then each row of `C` is computed with

```
C(i,:) = A(i,)*(1-P(i)) + B(i,)*P(i);
```

So $C(1,:) = A(1,:)$ and $C(\text{end},:) = B(\text{end},:)$

- 'DU_fusion': Down-up fusion
- 'LR_fusion': Left-right fusion (column-wise fusion)
- 'RL_fusion': Right-left fusion (column-wise fusion)
- 'UserDEF': User-defined fusion, `paramMETH` is a character vector or string scalar 'userFUNCTION' containing a function name such that $C = \text{userFUNCTION}(A,B)$.

In addition, `[C,D] = wfusmat(A,B,METHOD)` returns the Boolean matrix `D` when defined, or an empty matrix otherwise.

Introduced before R2006a

wkeep

Keep part of vector or matrix

Syntax

```
Y = wkeep(X,L,OPT)
Y = wkeep(X,L,FIRST)
Y = wkeep(X,L)
Y = wkeep(X,L,'c')
Y = wkeep(X,S,[FIRSTR FIRSTC])
```

Description

wkeep is a general utility.

For a vector, $Y = \text{wkeep}(X,L,OPT)$ extracts the vector Y from the vector X . The length of Y is L .

If OPT is equal to 'c', 'l', or 'r', Y is the central, left, or right part of X .

$Y = \text{wkeep}(X,L,FIRST)$ returns the vector $X(FIRST:FIRST+L-1)$.

$Y = \text{wkeep}(X,L)$ is equivalent to $Y = \text{wkeep}(X,L,'c')$.

For a matrix, $Y = \text{wkeep}(X,S)$ extracts the central part of the matrix X . The size of Y is S .

$Y = \text{wkeep}(X,S,[FIRSTR FIRSTC])$ extracts the submatrix of matrix X , of size S and starting from $X(FIRSTR,FIRSTC)$.

Examples

```
% For a vector.
x = 1:10;
y = wkeep(x,6,'c')
y =
     3     4     5     6     7     8

y = wkeep(x,6)
y =
     3     4     5     6     7     8

y = wkeep(x,7,'c')
y =
     2     3     4     5     6     7     8
y = wkeep(x,6,'l')
y =
     1     2     3     4     5     6

y = wkeep(x,6,'r')
y =
     5     6     7     8     9    10

% For a matrix.
```

```
x = magic(5)
x =
    17    24     1     8    15
    23     5     7    14    16
     4     6    13    20    22
    10    12    19    21     3
    11    18    25     2     9
```

```
y = wkeep(x,[3 2])
y =
     5     7
     6    13
    12    19
```

Introduced before R2006a

wmaxlev

Maximum wavelet decomposition level

Syntax

```
L = wmaxlev(S,wname)
```

Description

`L = wmaxlev(S,wname)` returns the maximum level `L` possible for a wavelet decomposition of a signal or image of size `S` using the wavelet specified by `wname` (see `wfilters` for more information). The maximum level is the last level for which at least one coefficient is correct.

`wmaxlev` returns the maximum allowed level decomposition, but in a general, a smaller value is taken.

Examples

Maximum Levels of Decomposition for a Signal and Image

Return the maximum level of decomposition of a 1-D signal with 1024 samples using the Haar wavelet.

```
s = 1024;  
wv = 'haar';  
l = wmaxlev(s,wv)
```

```
l = 10
```

Return the maximum level using the `db7` wavelet.

```
wv = 'db7';  
l = wmaxlev(s,wv)
```

```
l = 6
```

Return the maximum level of decomposition for a 2-D signal of dimension 512-by-128 using the Haar wavelet.

```
s = [512 128];  
wv = 'haar';  
l = wmaxlev(s,wv)
```

```
l = 7
```

Observe the maximum level is the same when taking the minimum of the two dimensions.

```
l = wmaxlev(min(s),wv)
```

```
l = 7
```

Return the maximum level using the `db7` wavelet.

```
wv = 'db7';  
l = wmaxlev(s,wv)  
  
l = 3
```

Input Arguments

S — Size of signal or image

positive integer | two-element vector of positive integers

Size of signal or image, specified as a positive integer for a signal, or two-element vector of positive integers for an image.

Data Types: `double`

wname — Wavelet

character vector | string scalar

Wavelet used to determine maximum level of wavelet decomposition. The wavelet is from one of the following wavelet families: Daubechies, Coiflets, Symlets, Fejér-Korovkin, Discrete Meyer, Biorthogonal, and Reverse Biorthogonal. See `wfilters` for the wavelets available in each family.

`wavedec` | `wavedec2` | `wpdec` | `wpdec2`

Introduced before R2006a

wmpalg

Matching pursuit

Syntax

```
YFIT = wmpalg(MPALG,Y,MPDICT)
[YFIT,R] = wmpalg(...)
[YFIT,R,COEFF] = wmpalg(...)
[YFIT,R,COEFF,IOPT] = wmpalg(...)
[YFIT,R,COEFF,IOPT,QUAL] = wmpalg(...)
[YFIT,R,COEFF,IOPT,QUAL,X] = wmpalg(...)
[YFIT,R,COEFF,IOPT,QUAL,X] = wmpalg(...,Name,Value)
```

Description

`YFIT = wmpalg(MPALG,Y,MPDICT)` returns an adaptive greedy approximation, `YFIT`, of the input signal, `Y`, in the dictionary, `MPDICT`. The adaptive greedy approximation uses the matching pursuit algorithm, `MPALG`. The dictionary, `MPDICT`, is typically an overcomplete set of vectors constructed using `wmpdictionary`.

`[YFIT,R] = wmpalg(...)` returns the residual, `R`, which is the difference vector between `Y` and `YFIT` at the termination of the matching pursuit.

`[YFIT,R,COEFF] = wmpalg(...)` returns the expansion coefficients, `COEFF`. The number of expansion coefficients depends on the number of iterations in the matching pursuit.

`[YFIT,R,COEFF,IOPT] = wmpalg(...)` returns the column indices of the retained atoms, `IOPT`. The length of `IOPT` equals the length of `COEFF` and is determined by the number of iterations in the matching pursuit.

`[YFIT,R,COEFF,IOPT,QUAL] = wmpalg(...)` returns the proportion of retained signal energy, `QUAL`, for each iteration of the matching pursuit. `QUAL` is the ratio of the ℓ^2 squared norm of the expansion coefficient vector, `COEFF`, to the ℓ^2 squared norm of the input signal, `Y`.

`[YFIT,R,COEFF,IOPT,QUAL,X] = wmpalg(...)` returns the normalized dictionary, `X`. `X` contains the unit vectors in the ℓ^2 norm corresponding to the columns of `MPDICT`.

`[YFIT,R,COEFF,IOPT,QUAL,X] = wmpalg(...,Name,Value)` returns an adaptive greedy approximation with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

MPALG

Matching pursuit algorithm as a character vector or string scalar. Valid entries are:

- 'BMP' — Basic matching pursuit
- 'OMP' — Orthogonal matching pursuit
- 'WMP' — Weak orthogonal matching pursuit

See “Matching Pursuit Algorithms”.

Default: 'BMP'

MPDICT

Matching pursuit dictionary. MPDICT is a N-by-P matrix where N is equal to the length of the input signal, Y. You can construct MPDICT using `wmpdictionary`. In matching pursuit, MPDICT is commonly a frame, or overcomplete set of vectors. You may use the Name-Value pair 'lstcpt' to specify a dictionary instead of using MPDICT. If you specify a value for 'lstcpt', `wmpalg` calls `wmpdictionary`.

Y

Signal for matching pursuit. Y is 1-D, real-valued row or column vector. The row dimension of MPDICT must match the length of Y.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

itermax

Positive integer fixing the maximum number of iterations of the matching pursuit algorithm. If you do not specify a 'maxerr' value, the number of expansion coefficients, COEFF, the number of dictionary vector indices, IOPT, and the length of the QUAL vector equal the value of 'itermax'.

Default: 25

lstcpt

A cell array of cell arrays with valid subdictionaries. This name-value pair is only valid if you do not input a dictionary in MPDICT. Each cell array describes one subdictionary. Valid subdictionaries are:

- A valid Wavelet Toolbox orthogonal or biorthogonal wavelet family short name with the number of vanishing moments and an optional decomposition level and extension mode. For example, {'sym4', 5} denotes the Daubechies least-asymmetric wavelet with 4 vanishing moments at level 5 and the default extension mode 'per'. If you do not specify the optional number level and extension mode, the decomposition level defaults to 5 and the extension mode to 'per'.
- A valid Wavelet Toolbox orthogonal or biorthogonal wavelet family short name preceded by `wp` with the number of vanishing moments and an optional decomposition level and extension mode. For example, {'wpsym4', 5} denotes the Daubechies least-asymmetric wavelet packet with 4 vanishing moments at level 5. If you do not specify the optional number level and extension mode, the decomposition level defaults to 5 and the extension mode to 'per'.
- 'dct' Discrete cosine transform-II basis. The DCT-II orthonormal basis is:

$$\phi_k(n) = \begin{cases} \frac{1}{\sqrt{N}} & k = 0 \\ \sqrt{\frac{2}{N}} \cos\left(\frac{\pi}{N}\left(n + \frac{1}{2}\right)k\right) & k = 1, 2, \dots, N - 1 \end{cases}$$

- 'sin' Sine subdictionary. The sine subdictionary is:

$$\phi_k(t) = \sin(2\pi kt) \quad k = 1, 2, \dots, \left\lfloor \frac{N}{2} \right\rfloor \quad 0 \leq t \leq 1$$

- 'cos' Cosine subdictionary. The cosine subdictionary is

$$\phi_k(t) = \cos(2\pi kt) \quad k = 1, 2, \dots, \left\lfloor \frac{N}{2} \right\rfloor \quad 0 \leq t \leq 1$$

- 'poly' Polynomial subdictionary. The polynomial subdictionary is:

$$p_n(t) = t^{n-1} \quad n = 1, 2, \dots, 20 \quad 0 \leq t \leq 1$$

- 'RnIdent' The shifted Kronecker delta subdictionary. The shifted Kronecker delta subdictionary is:

$$\phi_k(n) = \delta(n - k) \quad k = 0, 1, \dots, N$$

If you use the 'lstcpt' name-value pair to generate your dictionary, you can use the additional 'addbeg' and 'addend' name-value pairs to append and addend dictionary atoms. See `wmpdictionary` for details.

maxerr

Cell array containing the name of the norm and the maximum relative error in the norm expressed as a percentage. Valid norms are 'L1', 'L2', and 'Linf'. The relative error expressed as a percentage is

$$100 \frac{\|R\|}{\|Y\|}$$

where R is the residual at each iteration and Y is the input signal. For example, {'L1', 10} sets maximum acceptable ratio of the L1 norms of the residual to the input signal to 0.10.

If you specify 'maxerr', the matching pursuit terminates when the first of the following conditions is satisfied:

- The number of iterations reaches the minimum of the length of the input signal, Y , or 500: `min(length(Y), 500)`
- The relative error falls below the percentage you specify with the 'maxerr' name-value pair.

stepplot

Number of iterations between successive plots. 'stepplot' requires a positive integer. This name-value pair is only valid when 'typeplot' is 2 or 3 ('movie' or 'stepwise').

typeplot

Type of plot to produce during the progression of matching pursuit. Valid entries for 'typeplot' are: 0 or 'none', 1 or 'one', 2 or 'movie', 3 or 'stepwise'. When 'typeplot' is 'movie' or 'stepwise', the plot updates based on the value of 'stepplot'.

Default: 0 or 'none'

wmpcfs

Optimality factor for weak orthogonal matching pursuit. The optimality factor is a real number in the interval (0,1]. This name-value pair is only valid when MPALG is 'WMP'.

Default: 0.6

Output Arguments

YFIT

Adaptive greedy approximation of the input signal, Y, in the dictionary

R

Residual after matching pursuit terminates

COEFF

Expansion coefficients in the dictionary. The selected dictionary atoms weighted by the expansion coefficients yield the approximated signal, YFIT.

IOPT

Column indices of the selected dictionary atoms. Using the column indices in IOPT with the expansion coefficients in COEFF, you can form the approximated signal, YFIT.

QUAL

Proportion of retained signal energy for each iteration in the matching pursuit. QUAL is a vector with each element equal to

$$\frac{\|\alpha_k\|_2^2}{\|Y\|_2^2}$$

where α_k is the vector of expansion coefficients after the k -th iteration.

X

The normalized matching pursuit dictionary. X is an N-by-P matrix where N is the length of the input signal, Y. The columns of X have unit norm.

Examples

Adaptive Approximation using Orthogonal Matching Pursuit

Approximate the cuspamax signal with the dictionary using orthogonal matching pursuit.

Use a dictionary consisting of sym4 wavelet packets and the DCT-II basis.

```
load cuspamax;
mpdict = wmpdictionary(length(cuspamax),'LstCpt',...
    {'wpsym4',2},'dct');
yfit = wmpalg('OMP',cuspamax,mpdict);
plot(cuspamax,'k'); hold on;
plot(yfit,'linewidth',2); legend('Original Signal',...
    'Matching Pursuit');
```

Return Residual, Expansion Coefficients, Selected Atoms, and Approximation Quality

Obtain the expansion coefficients in the dictionary, the column indices of the selected dictionary atoms, and the proportion of retained signal energy.

Create a dictionary consisting of `sym4` wavelet packets and the DCT-II basis. Approximate the `cuspsmax` signal with the dictionary using orthogonal matching pursuit.

```
load cuspsmax;
mpdict = wmpdictionary(length(cuspsmax), 'LstCpt', ...
    {'wpsym4', 2}, 'dct');
[yfit, r, coeff, iopt, qual] = wmpalg('OMP', cuspsmax, mpdict);
```

Specify the Maximum Number of Iterations

This example shows how to set the maximum number of iterations of the orthogonal matching pursuit to 50.

```
load cuspsmax;
lstcpt = {'wpsym4', 1}, {'wpsym4', 2}, 'dct';
mpdict = wmpdictionary(length(cuspsmax), 'LstCpt', lstcpt);
```

```
[yfit,r,coeff,iopt,qual] = wmpalg('OMP',cuspamax,mpdict,...
    'itermax',50);
```

Stepwise Plot of Weak Orthogonal Matching Pursuit

This example shows how to allow for a suboptimal choice in the update of the orthogonal matching pursuit. Relax the requirement to be 0.8 times the optimal assignment. Plot the results stepwise and update the plot every 5 iterations.

```
load cuspamax;
lstcpt = {'wpsym4',1},{'wpsym4',2},'dct';
mpdict = wmpdictionary(length(cuspamax),'LstCpt',lstcpt);
[yfit,r,coeff,iopt,qual] = wmpalg('WMP',cuspamax,...
    mpdict,'wmpcfs',0.8, 'typeplot','stepwise','stepplot',3);
```

Matching Pursuit of Electricity Consumption Data

Obtain a matching pursuit of electricity consumption measured every minute over a 24-hour period.

Load and plot data. The data shows electricity consumption sampled every minute over a 24-hour period. Because the data is centered, the actual usage values are not interpretable.

```
load elec35_nor;
y = signals(32,:);
plot(y); xlabel('Minutes'); ylabel('Usage');
set(gca,'xlim',[1 1440]);
```

Construct a dictionary for matching pursuit consisting of the Daubechies' extremal-phase wavelet with 2 vanishing moments at level 2, the Daubechies' least-asymmetric wavelet with 4 vanishing moments at levels 1 and 4, the discrete cosine transform-II basis, and the sine basis.

```
dictionary = {'db4',2},{'dct','sin',{'sym4',1},{'sym4',4}};
[mpdict,nbvect] = wmpdictionary(length(y),'lstcpt',dictionary);
```

Implement orthogonal matching pursuit to obtain a signal approximation in the dictionary. Use 35 iterations. Plot the result.

```
[yfit,r,coef,iopt,qual] = wmpalg('OMP',y,mpdict,'itermax',35);
plot(y); hold on;
plot(yfit,'r'); xlabel('Minutes'); ylabel('Usage');
legend('Original Signal','OMP','Location','NorthEast');
set(gca,'xlim',[1 1440]);
```

Using the expansion coefficients in `coef` and the atom indices in `iopt`, construct the signal approximation, `yhat`, directly from the dictionary. Compare `yhat` with `yfit` returned by `wmpalg`.

```
[~,I] = sort(iopt);
X = mpdict(:,iopt(I));
yhat = X*coef(I);
max(abs(yfit-yhat))
```

```
ans = 2.2204e-15
```

Introduced in R2012a

wmpdictionary

Dictionary for matching pursuit

Syntax

```
MPDICT = wmpdictionary(N)
[MPDICT,NBVECT] = wmpdictionary(N)
[MPDICT,NBVECT]= wmpdictionary(N,Name,Value)
[MPDICT,NBVECT,LST] = wmpdictionary(N,Name,Value)
[MPDICT,NBVECT,LST,LONGS] = wmpdictionary(N,Name,Value)
```

Description

`MPDICT = wmpdictionary(N)` returns the N-by-P dictionary, `MPDICT`, for the default subdictionaries `{{'sym4',5},{'wpsym4',5},'dct','sin'}`. The column dimension of `MPDICT` depends on `N`.

`[MPDICT,NBVECT] = wmpdictionary(N)` returns the row vector, `NBVECT`, which contains the number of vectors in each subdictionary. The order of the elements in `NBVECT` corresponds to the order of the subdictionaries and any prepended or appended subdictionaries. The sum of the elements in `NBVECT` is the column dimension of `MPDICT`.

`[MPDICT,NBVECT]= wmpdictionary(N,Name,Value)` returns the dictionary, `MPDICT`, using additional options specified by one or more `Name,Value` pair arguments.

`[MPDICT,NBVECT,LST] = wmpdictionary(N,Name,Value)` returns the cell array, `LST`, with descriptions of the subdictionaries.

`[MPDICT,NBVECT,LST,LONGS] = wmpdictionary(N,Name,Value)` returns the cell array, `LONGS`, containing the number of vectors in each subdictionary. `LONGS` is only useful for wavelet subdictionaries. In wavelet subdictionaries, the corresponding element in `LONGS` gives the number of scaling functions at the coarsest level and wavelet functions by level. See “Visualize Haar Wavelet Dictionary” on page 1-1324 for an example using `LONGS`.

Input Arguments

N

A positive integer equal to the length of your input signal. The dictionary atoms are constructed to have `N` elements. `N` equals the row dimension of the dictionary, `MPDICT`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

addbeg

Prepended subdictionary. The prepended subdictionary is an N-by-M matrix where `N` is the length of the input signal. `wmpdictionary` does not check that the `M` column vectors of the prepended

dictionary form a basis. If you do not specify a value for `lstcpt`, the subdictionary is prepended to the default dictionary. The column vectors in the prepended subdictionary do not have to be unit-norm.

addend

Appended subdictionary. The appended subdictionary is a N-by-M matrix where N is the length of the input signal. `wmpdictionary` does not check that the M column vectors of the prepended dictionary form a basis. If you do not specify a value for `lstcpt`, the subdictionary is appended to the default dictionary. The column vectors in the appended subdictionary do not have to be unit-norm.

lstcpt

A cell array of cell arrays with valid subdictionaries. Each cell array describes one subdictionary. Valid subdictionaries are:

- A valid Wavelet Toolbox orthogonal or biorthogonal wavelet family short name with the number of vanishing moments and an optional decomposition level and extension mode. For example, { 'sym4', 5 } denotes the Daubechies least-asymmetric wavelet with 4 vanishing moments at level 5 and the default extension mode 'per'. If you do not specify the optional level and extension mode, the decomposition level defaults to 5 and the extension mode to 'per'.
- A valid Wavelet Toolbox orthogonal or biorthogonal wavelet family short name preceded by `wp` with the number of vanishing moments and an optional decomposition level and extension mode. For example, { 'wpsym4', 5 } denotes the Daubechies least-asymmetric wavelet packet with 4 vanishing moments at level 5. If you do not specify the optional level and extension mode, the decomposition level defaults to 5 and the extension mode to 'per'.
- 'dct' Discrete cosine transform-II basis. The DCT-II orthonormal basis is:

$$\phi_k(n) = \begin{cases} \frac{1}{\sqrt{N}} & k = 0 \\ \sqrt{\frac{2}{N}} \cos(\frac{\pi}{N}(n + \frac{1}{2})k) & k = 1, 2, \dots, N - 1 \end{cases}$$

- 'sin' Sine subdictionary. The sine subdictionary is

$$\phi_k(t) = \sin(2\pi kt) \quad k = 1, 2, \dots, \left\lfloor \frac{N}{2} \right\rfloor \quad 0 \leq t \leq 1$$

where t is a linearly-spaced N -point vector.

- 'cos' Cosine subdictionary. The cosine subdictionary is

$$\phi_k(t) = \cos(2\pi kt) \quad k = 1, 2, \dots, \left\lfloor \frac{N}{2} \right\rfloor \quad 0 \leq t \leq 1$$

where t is a linearly-spaced N -point vector.

- 'poly' Polynomial subdictionary. The polynomial subdictionary is:

$$p_n(t) = t^{n-1} \quad n = 1, 2, \dots, 20 \quad 0 \leq t \leq 1$$

where t is a linearly-spaced N -point vector.

- 'RnIdent' The shifted Kronecker delta subdictionary. The shifted Kronecker delta subdictionary is:

$$\phi_k(n) = \delta(n - k) \quad k = 0, 1, \dots, N$$

Default: `{{ 'sym4',5},{ 'wpsym4',5}, 'dct', 'sin' }`

Output Arguments

MPDICT

Matching pursuit dictionary. MPDICT is an N-by-P matrix with the row dimension, N, equal to the length of the input signal. The column dimension of the matrix depends on the size of the concatenated subdictionaries.

NBVECT

Number of vectors in subdictionaries. NBVECT is a row vector containing the number of elements in each subdictionary. The order of the elements in NBVECT corresponds to the order of the subdictionaries and any prepended or appended subdictionaries.

LST

Cell array describing the dictionary. LST is a 1-by-N cell array where N is the number of subdictionaries. Each element of the cell array contains a description of a subdictionary. If you specify a prepended or appended subdictionary, the first element of LST is 'AddBeg' or 'AddEnd'. If you specify a level for the wavelet or wavelet packet, the corresponding element of LST is a 1-by-2 cell array containing the wavelet or wavelet packet name in the first element and the level in the second element.

LONGS

Cell array containing the number of elements for each subdictionary. LONGS is useful only for wavelet subdictionaries. If you specify a wavelet subdictionary, the corresponding element of LONGS provides the number of scaling functions at the coarsest level and the number of wavelets at each level. See “Visualize Haar Wavelet Dictionary” on page 1-1324 for an example using LONGS.

Examples

Default Dictionary

Create the default dictionary to represent a signal of length 100.

```
mpdict = wmpdictionary(100);
```

Discrete Cosine Transform and Kronecker Delta Dictionary

Create a DCT and shifted Kronecker delta dictionary to represent a signal of length 100.

```
mpdict = wmpdictionary(100, 'lstcpt', {'dct', 'RnIdent'});
```

Haar Wavelet Packets and Discrete Cosine Transform Dictionary

Create a Haar wavelet packet (level 2) and DCT dictionary. Return the number of atoms in each subdictionary.

```
[mpdict,nbvect] = wmpdictionary(100,'lstcpt',{{'wphaar',2},'dct'});
```

Visualize Haar Wavelet Dictionary

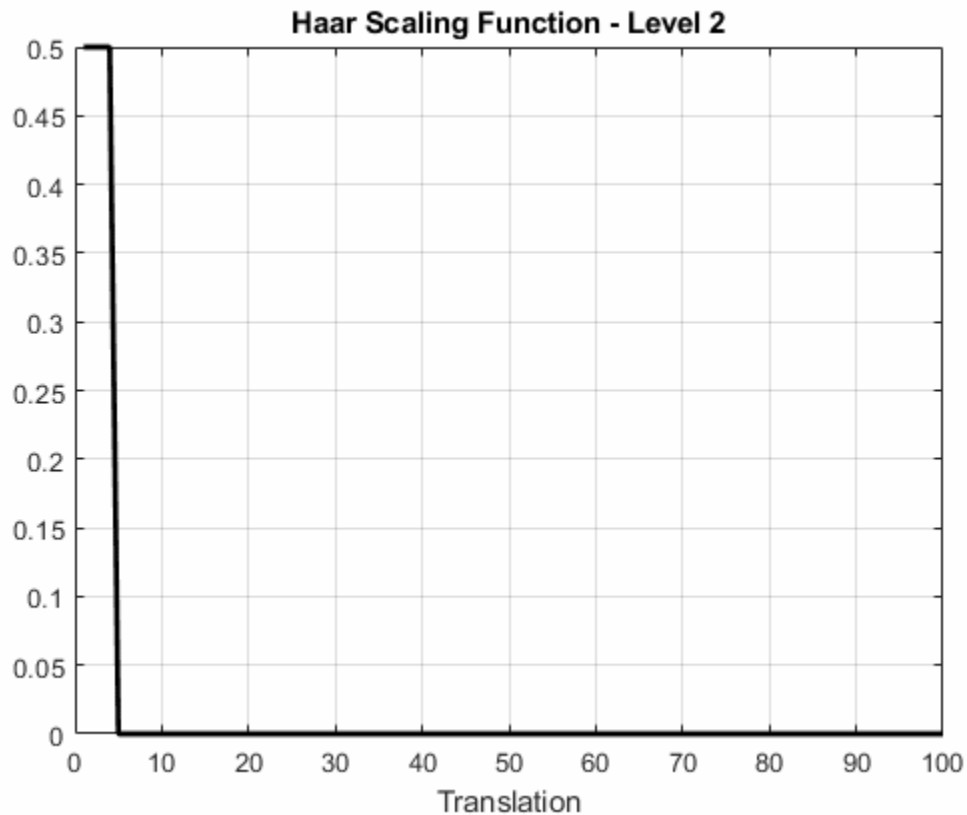

Use the `longs` output argument to visualize a dictionary. Create a Haar wavelet dictionary consisting of level-2 scaling functions, and level-1 and level-2 wavelet functions. Step through a plot of the translated scaling functions and wavelets by level.

```
[mpdict,~,~,longs] = wmpdictionary(100,'lstcpt',{{'haar',2}});
```

```
for nn = 1:size(mpdict,2)
    if (nn<=longs{1}(1))
        plot(mpdict(:,nn),'k','linewidth',2)
        grid on
        xlabel('Translation')
        title('Haar Scaling Function - Level 2')
    elseif (nn>longs{1}(1) && nn<=longs{1}(1)+longs{1}(2))
        plot(mpdict(:,nn),'r','linewidth',2)
        grid on
        xlabel('Translation')
        title('Haar Wavelet - Level 2')
    else
        plot(mpdict(:,nn),'b','linewidth',2)
        grid on
        xlabel('Translation')
        title('Haar Wavelet - Level 1')
    end
    pause(0.2)
end
```

This animation infinitely loops through all the plots generated.

More About

Matching Pursuit

Matching pursuit refers to a number of greedy or weak-greedy algorithms for computing an adaptive nonlinear expansion of a signal in a *dictionary*. In the majority of matching pursuit applications, a dictionary is an overcomplete set of vectors. The elements of the dictionary are referred to as *atoms* and are typically constructed to have certain time/frequency or time/scale properties. Matching pursuit takes the NP-hard problem of finding the best nonlinear expansion in a dictionary and implements it in an energy-preserving formulation that guarantees convergence. See “Matching Pursuit Algorithms” for more details.

Introduced in R2012a

wmspca

Multiscale Principal Component Analysis

Syntax

```
[X_SIM, QUAL, NPC, DEC_SIM, PCA_Params] = wmspca(X, LEVEL, WNAME, NPC)
[... ] = wmspca(X, LEVEL, WNAME, 'mode', EXTMODE, NPC)
[... ] = wmspca(DEC, NPC)
[... ] = wmspca(X, LEVEL, WNAME, 'mode', EXTMODE, NPC)
```

Description

[X_SIM, QUAL, NPC, DEC_SIM, PCA_Params] = wmspca(X, LEVEL, WNAME, NPC) or [...] = wmspca(X, LEVEL, WNAME, 'mode', EXTMODE, NPC) returns a simplified version X_SIM of the input matrix X obtained from the wavelet-based multiscale principal component analysis (PCA).

The input matrix X contains P signals of length N stored column-wise ($N > P$).

Wavelet Decomposition Parameters

The wavelet decomposition is performed using the decomposition level LEVEL and the wavelet WNAME.

EXTMODE is the extended mode for the DWT (See `dwtmode`).

If a decomposition DEC obtained using `mdwtdec` is available, you can use

```
[... ] = wmspca(DEC, NPC) instead of
```

```
[... ] = wmspca(X, LEVEL, WNAME, 'mode', EXTMODE, NPC).
```

Principal Components Parameter: NPC

If NPC is a vector, then it must be of length LEVEL+2. It contains the number of retained principal components for each PCA performed:

- NPC(d) is the number of retained noncentered principal components for details at level d, for $1 \leq d \leq \text{LEVEL}$.
- NPC(LEVEL+1) is the number of retained non-centered principal components for approximations at level LEVEL.
- NPC(LEVEL+2) is the number of retained principal components for final PCA after wavelet reconstruction.

NPC must be such that $0 \leq \text{NPC}(d) \leq P$ for $1 \leq d \leq \text{LEVEL}+2$.

If NPC = 'kais' (respectively, 'heur'), then the number of retained principal components is selected automatically using Kaiser's rule (or the heuristic rule).

- Kaiser's rule keeps the components associated with eigenvalues greater the mean of all eigenvalues.

- The heuristic rule keeps the components associated with eigenvalues greater than 0.05 times the sum of all eigenvalues.

If `NPC = 'nodet'`, then the details are “killed” and all the approximations are retained.

Output Parameters

`X_SIM` is a simplified version of the matrix `X`.

`QUAL` is a vector of length `P` containing the quality of column reconstructions given by the relative mean square errors in percent.

`NPC` is the vector of selected numbers of retained principal components.

`DEC_SIM` is the wavelet decomposition of `X_SIM`

`PCA_Params` is a structure array of length `LEVEL+2` such that:

- `PCA_Params(d).pc` is a `P`-by-`P` matrix of principal components.
The columns are stored in descending order of the variances.
- `PCA_Params(d).variances` is the principal component variances vector.
- `PCA_Params(d).npc = NPC`

Examples

Wavelet Principal Component Analysis of Noisy Multivariate Signal

Use wavelet multiscale principal component analysis to denoise a multivariate signal.

Load the dataset consisting of four signals of length 1024. Plot the original signals and the signals with additive noise.

```
load ex4mwden;
kp = 0;
for i = 1:4
    subplot(4,2,kp+1)
    plot(x_orig(:,i))
    axis tight
    title(['Original signal ',num2str(i)])
    subplot(4,2,kp+2)
    plot(x(:,i))
    axis tight
    title(['Noisy signal ',num2str(i)])
    kp = kp + 2;
end
```

Perform the first multiscale wavelet PCA using the Daubechies least-asymmetric wavelet with four vanishing moments, `sym4`. Obtain the multiresolution decomposition down to level 5. Use the heuristic rule to decide how many principal components to retain.

```
level = 5;
wname = 'sym4';
npc = 'heur';
[x_sim, qual, npc] = wmspca(x, level, wname, npc);
```

Plot the result and examine the quality of the approximation.

```
qual
```

```
qual = 1x4
```

```
    97.4064    94.6863    97.8333    99.5441
```

```
kp = 0;
for i = 1:4
    subplot(4,2,kp+1)
    plot(x(:,i))
    axis tight
    title(['Noisy signal ', num2str(i)])
    subplot(4,2,kp+2)
    plot(x_sim(:,i))
    axis tight
    title(['First PCA ', num2str(i)])
```

```

kp = kp+2;
end

```

The quality results are all close to 100%. The npc vector gives the number of principal components retained at each level.

Suppress the noise by removing the principal components at levels 1-3. Perform the multiscale PCA again.

```

npc(1:3) = zeros(1,3);
[x_sim, qual, npc] = wmspca(x,level,wname,npc);

```

Plot the result.

```

kp = 0;
for i = 1:4
    subplot(4,2,kp+1)
    plot(x(:,i))
    axis tight
    title(['Noisy signal ',num2str(i)])
    subplot(4,2,kp+2)
    plot(x_sim(:,i))
    axis tight
    title(['Second PCA ',num2str(i)])
    kp = kp+2;
end

```

Algorithms

The multiscale principal components generalizes the usual PCA of a multivariate signal seen as a matrix by performing simultaneously a PCA on the matrices of details of different levels. In addition, a PCA is performed also on the coarser approximation coefficients matrix in the wavelet domain as well as on the final reconstructed matrix. By selecting conveniently the numbers of retained principal components, interesting simplified signals can be reconstructed.

wmulden

Introduced in R2006b

wmulden

Wavelet multivariate denoising

Syntax

```
[X_DEN,NPC,NESTCOV,DEC_DEN,PCA_Params,DEN_Params] = ...
wmulden(X,LEVEL,WNAME,NPC_APP,NPC_FIN,TPTR,SORH)
[...] = wmulden(X,LEVEL,WNAME,'mode',EXTMODE,NPC_APP,...)
[...] = wmulden(DEC,NPC_APP)
[...] = wmulden(X,LEVEL,WNAME,'mode',EXTMODE,NPC_APP)
[DEC,PCA_Params] = wmulden('estimate',DEC,NPC_APP,NPC_FIN)
[X_DEN,NPC,DEC_DEN,PCA_Params] = wmulden('execute',DEC,PC_Params)
```

Description

```
[X_DEN,NPC,NESTCOV,DEC_DEN,PCA_Params,DEN_Params] = ...
wmulden(X,LEVEL,WNAME,NPC_APP,NPC_FIN,TPTR,SORH) or
[...] = wmulden(X,LEVEL,WNAME,'mode',EXTMODE,NPC_APP,...) returns a denoised version
X_DEN of the input matrix X. The strategy combines univariate wavelet denoising in the basis where
the estimated noise covariance matrix is diagonal with noncentered Principal Component Analysis
(PCA) on approximations in the wavelet domain or with final PCA.
```

The input matrix X contains P signals of length N stored column-wise where $N > P$.

Wavelet Decomposition Parameters

The wavelet decomposition is performed using the decomposition level LEVEL and the wavelet WNAME.

EXTMODE is the extended mode for the DWT (See `dwtmode`).

If a decomposition DEC obtained using `mdwtdec` is available, you can use

```
[...] = wmulden(DEC,NPC_APP) instead of
```

```
[...] = wmulden(X,LEVEL,WNAME,'mode',EXTMODE,NPC_APP).
```

Principal Components Parameters: NPC_APP and NPC_FIN

The input selection methods NPC_APP and NPC_FIN define the way to select principal components for approximations at level LEVEL in the wavelet domain and for final PCA after wavelet reconstruction, respectively.

If NPC_APP (or NPC_FIN) is an integer, it contains the number of retained principal components for approximations at level LEVEL (or for final PCA after wavelet reconstruction).

NPC_XXX must be such that $0 \leq \text{NPC_XXX} \leq P$

NPC_APP or NPC_FIN = 'kais' or 'heur' selects the number of retained principal components using Kaiser's rule or the heuristic rule automatically.

- Kaiser's rule keeps the components associated with eigenvalues greater than the mean of all eigenvalues.
- The heuristic rule keeps the components associated with eigenvalues greater than 0.05 times the sum of all eigenvalues.

`NPC_APP` or `NPC_FIN = 'none'` is equivalent to `NPC_APP` or `NPC_FIN = P`.

Denoising Parameters: TPTR and SORH

The default values for the denoising parameters TPTR and SORH are:

`TPTR = 'sqrtwolog'` and `SORH = 's'`

- Valid values for TPTR are
`'rigsure'`, `'heursure'`, `'sqrtwolog'`, `'minimaxi'`,
`'penalhi'`, `'penalme'`, `'penallo'`
- Valid values for SORH are:
`'s'` (soft) or `'h'` (hard)

For additional information, see `wden` and `wbmpen`.

Output Parameters

`X_DEN` is a denoised version of the input matrix `X`.

`NPC` is the vector of selected numbers of retained principal components.

`NESTCOV` is the estimated noise covariance matrix obtained using the minimum covariance determinant (MCD) estimator.

`DEC_DEN` is the wavelet decomposition of `X_DEN`.

`PCA_Params` is a structure such that:

```
PCA_Params.NEST = {pc_NEST, var_NEST, NESTCOV}
PCA_Params.APP = {pc_APP, var_APP, npc_APP}
PCA_Params.FIN = {pc_FIN, var_FIN, npc_FIN}
```

where:

- `pc_XXX` is a P-by-P matrix of principal components.
The columns are stored in descending order of the variances.
- `var_XXX` is the principal component variances vector.
- `NESTCOV` is the covariance matrix estimate for detail at level 1.

`DEN_Params` is a structure such that:

- `DEN_Params.thrVAL` is a vector of length LEVEL which contains the threshold values for each level.
- `DEN_Params.thrMETH` is a character vector containing the name of the denoising method (TPTR).
- `DEN_Params.thrTYPE` is a character variable containing the type of the thresholding (SORH).

Special Cases

`[DEC,PCA_Params] = wmulden('estimate',DEC,NPC_APP,NPC_FIN)` returns the wavelet decomposition DEC and the Principal Components Estimates PCA_Params.

`[X_DEN,NPC,DEC_DEN,PCA_Params] = wmulden('execute',DEC,PC_Params)` uses the principal components estimates PCA_Params previously computed.

The input value DEC can be replaced by X, LEVEL, and WNAME.

Examples

```
% Load a multivariate signal x together with
% the original signals (x_orig) and true noise
% covariance matrix (covar).

load ex4mwden

% Set the denoising method parameters.
level = 5;
wname = 'sym4';
tptr = 'sqtwoolog';
sorh = 's';

% Set the PCA parameters to select the number of
% retained principal components automatically by
% Kaiser's rule.

npc_app = 'kais';
npc_fin = 'kais';

% Perform multivariate denoising.
[x_den, npc, nestco] = wmulden(x, level, wname, npc_app, ...
                             npc_fin, tptr, sorh);

% Display the original and denoised signals.
kp = 0;
for i = 1:4
    subplot(4,3,kp+1), plot(x_orig(:,i));
    title(['Original signal ',num2str(i)])
    subplot(4,3,kp+2), plot(x(:,i));
    title(['Observed signal ',num2str(i)])
    subplot(4,3,kp+3), plot(x_den(:,i));
    title(['Denoised signal ',num2str(i)])
    kp = kp + 3;
end
```

```

Algorithms

The multivariate denoising procedure is a generalization of the one-dimensional strategy. It combines univariate wavelet denoising in the basis where the estimated noise covariance matrix is diagonal and non-centered Principal Component Analysis (PCA) on approximations in the wavelet domain or with final PCA.

The robust estimate of the noise covariance matrix given by the minimum covariance determinant estimator based on the matrix of finest details.

Wavelet Signal Denoiser

Introduced in R2006b

wnoise

Noisy wavelet test data

Syntax

```
x = wnoise(fun,n)
[x,xn] = wnoise(fun,n,sqrtsnr)
[x,xn] = wnoise( ____,init)
```

Description

`x = wnoise(fun,n)` returns values `x` of the test signal `fun` evaluated at 2^n linearly spaced points from 0 to 1.

`[x,xn] = wnoise(fun,n,sqrtsnr)` returns `x` rescaled such that the standard deviation of `x` is `sqrtsnr`. `xn` is `x` corrupted by additive Gaussian white noise $N(0,1)$ and has a signal-to-noise ratio (SNR) of `sqrtsnr`².

`[x,xn] = wnoise(____,init)` sets the generator seed to `init` before generating additive Gaussian white noise $N(0,1)$.

Examples

Plot Wavelet Test Signals

There are six test signals. Generate and plot 2^{10} samples of the third test signal, heavy sine.

```
loc = linspace(0,1,2^10);
x = wnoise(3,10);
plot(loc,x)
title('Heavy Sine')
```

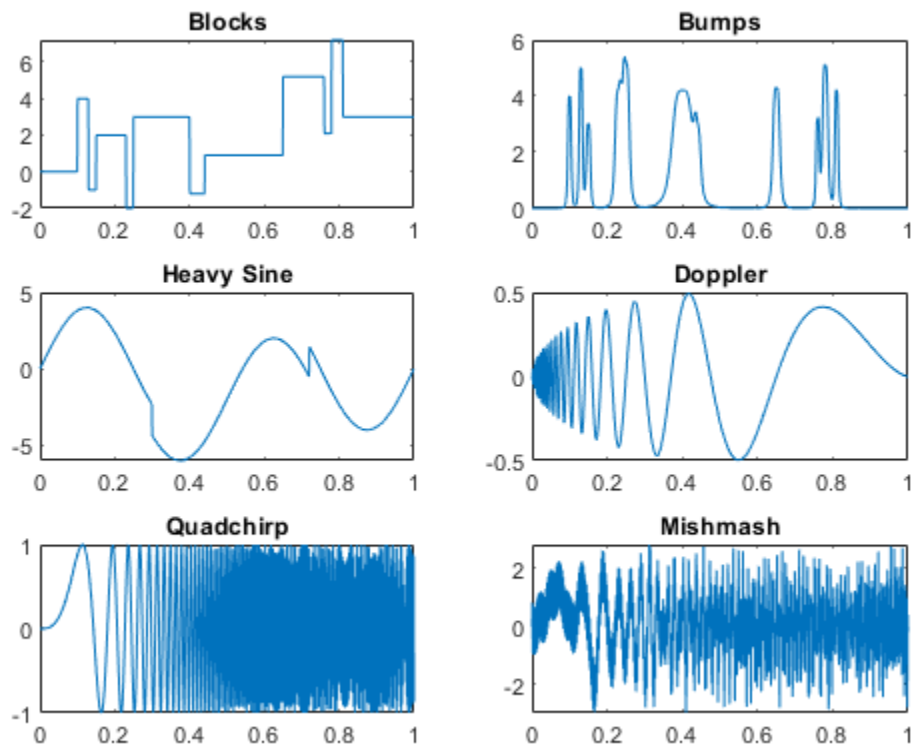

Generate and plot 2^{10} samples of the doppler test signal and a noisy version of doppler with a square root of the signal-to-noise ratio equal to 7.

```
[x,noisyx] = wnoise('doppler',10,7);
subplot(2,1,1)
plot(loc,x)
title('Clean Doppler')
ylim([-15 15])
subplot(2,1,2)
plot(loc,noisyx)
title('Noisy Doppler')
ylim([-15 15])
```

Plot all the test functions.

```
testFunctions = {'Blocks', 'Bumps', 'Heavy Sine', 'Doppler', 'Quadchirp', 'Mishmash'};
for i=1:6
    x = wnoise(lower(testFunctions{i}),10);
    subplot(3,2,i)
    plot(loc,x)
    title(testFunctions{i})
end
```

Input Arguments

fun — Wavelet test function

positive integer | character array

Wavelet test function, specified as one of the values listed here. The six test functions are due to Donoho and Johnstone [1], [2].

- 1 or 'blocks'
- 2 or 'bumps'
- 3 or 'heavy sine'
- 4 or 'doppler'
- 5 or 'quadchirp'
- 6 or 'mishmash'

n — Exponent

positive integer

Exponent used to determine the number of linearly spaced points from 0 to 1 to evaluate the test function, specified as a positive integer. The number of linearly spaced points is 2^n .

sqrtsnr — Square root of SNR

positive real number

Square root of SNR, specified by a positive real number. The test values x are rescaled such that the standard deviation of x is `sqrtsnr`. x_n is equal to x corrupted by additive Gaussian white noise $N(0,1)$ and has an SNR of `sqrtsnr`².

init – Seed

nonnegative integer

Seed used to initialize the random number generator, specified as a nonnegative integer. `init` is used to generate additive Gaussian white noise.

Example: `[a,b] = wnoise(4,10,7,2055415866)`; returns a noisy version of the fourth test signal using the seed `init = 2055415866`.

Output Arguments**x – Test signal**

real-valued vector

Test signal, returned as a real-valued vector of length 2^n . x are the values of the test function specified by `fun` evaluated at the 2^n evenly spaced points from 0 to 1. If `sqrtsnr` is set, the standard deviation of x is `sqrtsnr`.

xn – Noisy test signal

real-valued vector

Noisy test signal, returned as a real-valued vector of length 2^n . x_n is x corrupted by additive Gaussian white noise $N(0,1)$ and has an SNR of `sqrtsnr`².

`wden` | `wdenoise`

Introduced before R2006a

wnoisest

Estimate noise of 1-D wavelet coefficients

Syntax

```
STDC = wnoisest(C,L,S)
STDC = wnoisest(C)
STDC = wnoisest(C)
```

Description

`STDC = wnoisest(C,L,S)` returns estimates of the detail coefficients' standard deviation for levels contained in the input vector `S`. `[C,L]` is the input wavelet decomposition structure (see `wavedec` for more information).

If `C` is a one dimensional cell array, `STDC = wnoisest(C)` returns a vector such that `STDC(k)` is an estimate of the standard deviation of `C{k}`.

If `C` is a numeric array, `STDC = wnoisest(C)` returns a vector such that `STDC(k)` is an estimate of the standard deviation of `C(k,:)`.

The estimator used is Median Absolute Deviation / 0.6745, well suited for zero mean Gaussian white noise in the de-noising one-dimensional model (see `thselect` for more information).

Examples

Estimate Noise Standard Deviation in The Presence of Outliers

Estimate of the noise standard deviation in an $N(0,1)$ white Gaussian noise vector with outliers.

Create an $N(0,1)$ noise vector with 10 randomly-placed outliers.

```
rng default;
x = randn(1000,1);
P = randperm(length(x));
indices = P(1:10);
x(indices(1:5)) = 10;
x(indices(6:end)) = -10;
```

Obtain the discrete wavelet transform down to level 2 using the Daubechies' extremal phase wavelet with 3 vanishing moments.

```
[c,l] = wavedec(x,2,'db3');
stdc = wnoisest(c,l,1:2)
```

```
stdc = 1×2
```

```
    0.9559    1.0556
```

In spite of the outliers, `wnoisest` provides a robust estimate of the standard deviation.

Wavelet Signal Denoiser

Introduced before R2006a

wp2wtree

Extract wavelet tree from wavelet packet tree

Syntax

```
T = wp2wtree(T)
```

Description

wp2wtree is a one- or two-dimensional wavelet packet analysis function.

`T = wp2wtree(T)` computes the modified wavelet packet tree `T` corresponding to the wavelet decomposition tree.

Examples

```
% The current extension mode is zero-padding (see dwtmode).
```

```
% Load signal.
load noisdopp; x = noisdopp;
```

```
% Decompose x at depth 3 with db1 wavelet packets
% using shannon entropy.
wpt = wpdec(x,3,'db1');
```

```
% Plot wavelet packet tree wpt.

wpbmpen

Penalized threshold for wavelet packet denoising

Syntax

```
THR = wpbmpen(T, SIGMA, ALPHA)
wpbmpen(T, SIGMA, ALPHA, ARG)
```

Description

`THR = wpbmpen(T, SIGMA, ALPHA)` returns a global threshold `THR` for denoising. `THR` is obtained by a wavelet packet coefficients selection rule using a penalization method provided by Birgé-Massart.

`T` is a wavelet packet tree corresponding to the wavelet packet decomposition of the signal or image to be denoised.

`SIGMA` is the standard deviation of the zero mean Gaussian white noise in the denoising model (see `wnoisest` for more information).

`ALPHA` is a tuning parameter for the penalty term. It must be a real number greater than 1. The sparsity of the wavelet packet representation of the denoised signal or image grows with `ALPHA`. Typically `ALPHA = 2`.

`THR` minimizes the penalized criterion given by

let t^* be the minimizer of

$$\text{crit}(t) = -\sum(c(k)^2, k \leq t) + 2 \cdot \text{SIGMA}^2 \cdot t \cdot (\text{ALPHA} + \log(n/t))$$

where $c(k)$ are the wavelet packet coefficients sorted in decreasing order of their absolute value and n is the number of coefficients, then $\text{THR} = |c(t^*)|$.

`wpbmpen(T, SIGMA, ALPHA, ARG)` computes the global threshold and, in addition, plots three curves:

- $2 \cdot \text{SIGMA}^2 \cdot t \cdot (\text{ALPHA} + \log(n/t))$
- $\sum(c(k)^2, k \leq t)$
- $\text{crit}(t)$

Examples

```
% Example 1: Signal denoising.
% Load noisy chirp signal.
load noischir; x = noischir;

% Perform a wavelet packet decomposition of the signal
% at level 5 using sym6.
wname = 'sym6'; lev = 5;
tree = wpdec(x, lev, wname);

% Estimate the noise standard deviation from the
% detail coefficients at level 1,
```

```

% corresponding to the node index 2.
det1 = wpccoef(tree,2);
sigma = median(abs(det1))/0.6745;

% Use wpbmpen for selecting global threshold
% for signal denoising, using the recommended parameter.
alpha = 2;
thr = wpbmpen(tree,sigma,alpha)

thr =

    4.5740

% Use wpdencmp for denoising the signal using the above
% threshold with soft thresholding and keeping the
% approximation.
keepapp = 1;
xd = wpdencmp(tree,'s','nobest',thr,keepapp);

% Plot original and denoised signals.
figure(1)
subplot(211), plot(x),
title('Original signal')
subplot(212), plot(xd)
title('De-noised signal')

```

```

% Example 2: Image denoising.
% Load original image.
load noiswom;
nbc = size(map,1);

% Perform a wavelet packet decomposition of the image
% at level 3 using coif2.
wname = 'coif2'; lev = 3;
tree = wpdec2(X,lev,wname);

% Estimate the noise standard deviation from the

```

```

% detail coefficients at level 1.
det1 = [wpcoef(tree,2) wpcoef(tree,3) wpcoef(tree,4)];
sigma = median(abs(det1(:)))/0.6745;

% Use wpbmpen for selecting global threshold
% for image denoising.
alpha = 1.1;
thr = wpbmpen(tree,sigma,alpha)

thr =

    38.5125

% Use wpdncmp for denoising the image using the above
% thresholds with soft thresholding and keeping the
% approximation.
keepapp = 1;

wpcoef

Wavelet packet coefficients

Syntax

```
X = wpcoef(T,N)
X = wpcoef(T)
```

Description

wpcoef is a one- or two-dimensional wavelet packet analysis function.

$X = \text{wpcoef}(T, N)$ returns the coefficients associated with the node N of the wavelet packet tree T . If N doesn't exist, $X = []$;

$X = \text{wpcoef}(T)$ is equivalent to $X = \text{wpcoef}(T, 0)$.

Examples

```
% The current extension mode is zero-padding (see dwtmode).
```

```
% Load signal.
load noisdopp; x = noisdopp;
```

```
figure(1); subplot(211);
plot(x); title('Original signal');
```

```
% Decompose x at depth 3 with db1 wavelet packets
% using Shannon entropy.
wpt = wptdec(x,3,'db1');
```

```
% Plot wavelet packet tree wpt.
plot(wpt)
```

```
% Read packet (2,1) coefficients.
cfs = wpcoef(wpt,[2 1]);
```

```
figure(1); subplot(212);
plot(cfs); title('Packet (2,1) coefficients');
```

wpcutree

Cut wavelet packet tree

Syntax

```
T = wpcutree(T,L)
T
[T,RN] = wpcutree(T,L)
```

Description

wpcutree is a one- or two-dimensional wavelet packet analysis function.

`T = wpcutree(T,L)` cuts the tree `T` at level `L`.

`[T,RN] = wpcutree(T,L)` returns the same arguments as above and, in addition, the vector `RN` contains the indices of the reconstructed nodes.

Examples

```
% The current extension mode is zero-padding (see dwtmode).

% Load signal.
load noisdopp; x = noisdopp;

% Decompose x at depth 3 with db1 wavelet packets
% using Shannon entropy.
wpt = wpdec(x,3,'db1');

% Plot wavelet packet tree wpt.
plot(wpt)
```

```
% Cut wavelet packet tree at level 2.
nwpt = wpcutree(wpt,2);
```

```
% Plot new wavelet packet tree nwpt.
plot(nwpt)
```

wpdec | wpdec2

Introduced before R2006a

wpdec

Wavelet packet decomposition 1-D

Syntax

```
T = wpdec(X,N,wname,E,P)
T = wpdec(X,N,wname)
T = wpdec(X,N,wname,'shannon')
```

Description

wpdec is a one-dimensional wavelet packet analysis function.

$T = \text{wpdec}(X,N,wname,E,P)$ returns a wavelet packet tree T corresponding to the wavelet packet decomposition of the vector X at level N , using the wavelet specified by $wname$ (see `wfilters` for more information).

$T = \text{wpdec}(X,N,wname)$ is equivalent to $T = \text{wpdec}(X,N,wname,'shannon')$.

E is a character vector or string scalar containing the type of entropy and P is an optional parameter depending on the value of T (see `wentropy` for more information).

Entropy Type Name (E)	Parameter (P)	Comments
'shannon'		P is not used.
'log energy'		P is not used.
'threshold'	$0 \leq P$	P is the threshold.
'sure'	$0 \leq P$	P is the threshold.
'norm'	$1 \leq P$	P is the power.
'user'	character vector or string scalar	P is a character vector or string scalar containing the file name of your own entropy function, with a single input X .
FunName	No constraints on P	FunName is any other character vector or string scalar except those used for the previous Entropy Type Names listed above. FunName contains the file name of your own entropy function, with X as input and P as additional parameter to your entropy function.

Note The 'user' option is historical and still kept for compatibility, but it is obsoleted by the last option described in the table above. The FunName option do the same as the 'user' option and in addition gives the possibility to pass a parameter to your own entropy function.

The wavelet packet method is a generalization of wavelet decomposition that offers a richer signal analysis. Wavelet packet atoms are waveforms indexed by three naturally interpreted parameters: position and scale as in wavelet decomposition, and frequency.

For a given orthogonal wavelet function, a library of wavelet packets bases is generated. Each of these bases offers a particular way of coding signals, preserving global energy and reconstructing exact features. The wavelet packets can then be used for numerous expansions of a given signal.

Simple and efficient algorithms exist for both wavelet packets decomposition and optimal decomposition selection. Adaptive filtering algorithms with direct applications in optimal signal coding and data compression can then be produced.

In the orthogonal wavelet decomposition procedure, the generic step splits the approximation coefficients into two parts. After splitting we obtain a vector of approximation coefficients and a vector of detail coefficients, both at a coarser scale. The information lost between two successive approximations is captured in the detail coefficients. The next step consists in splitting the new approximation coefficient vector; successive details are never re-analyzed.

In the corresponding wavelet packets situation, each detail coefficient vector is also decomposed into two parts using the same approach as in approximation vector splitting. This offers the richest analysis: the complete binary tree is produced in the one-dimensional case or a quaternary tree in the two-dimensional case.

Examples

```
% The current extension mode is zero-padding (see dwtmode).

% Load signal.
load noisdopp; x = noisdopp;

% Decompose x at depth 3 with db1 wavelet packets
% using Shannon entropy.
wpt = wpdec(x,3,'db1','shannon');

% The result is the wavelet packet tree wpt.

% Plot wavelet packet tree (binary tree, or tree of order 2).
plot(wpt)
```

Algorithms

The algorithm used for the wavelet packets decomposition follows the same line as the wavelet decomposition process (see `dwt` and `wavedec` for more information).

wpdec2

Wavelet packet decomposition 2-D

Syntax

```
T = wpdec2(X,N,wname,E,P)
T = wpdec2(X,N,wname)
T = wpdec2(X,N,wname,'shannon')
```

Description

wpdec2 is a two-dimensional wavelet packet analysis function.

$T = \text{wpdec2}(X, N, \text{wname}, E, P)$ returns a wavelet packet tree T corresponding to the wavelet packet decomposition of the matrix X , at level N , with the specified wavelet wname (see `wfilters` for more information).

$T = \text{wpdec2}(X, N, \text{wname})$ is equivalent to $T = \text{wpdec2}(X, N, \text{wname}, 'shannon')$.

E is a character vector or string scalar containing the type of entropy and P is an optional parameter depending on the value of T (see `wentropy` for more information).

Entropy Type Name (E)	Parameter (P)	Comments
'shannon'		P is not used.
'log energy'		P is not used.
'threshold'	$0 \leq P$	P is the threshold.
'sure'	$0 \leq P$	P is the threshold.
'norm'	$1 \leq P$	P is the power.
'user'	Character vector or string scalar	P is a character vector or string scalar containing the file name of your own entropy function, with a single input X.
FunName	No constraints on P	FunName is any other character vector or string scalar except those used for the previous Entropy Type Names listed above. FunName contains the file name of your own entropy function, with X as input and P as additional parameter to your entropy function.

Note The 'user' option is historical and still kept for compatibility, but it is obsoleted by the last option described in the preceding table. The FunName option does the same as the 'user' option and in addition, allows you to pass a parameter to your own entropy function.

See `wpdec` for a more complete description of the wavelet packet decomposition.

Examples

```
% The current extension mode is zero-padding (see dwtmode).

% Load image.
load tire
% X contains the loaded image.

% For an image the decomposition is performed using:
t = wpdec2(X,2,'db1');
% The default entropy is shannon.

% Plot wavelet packet tree
% (quarternary tree, or tree of order 4).
plot(t)
```

Tips

When X represents an indexed image, X is an m -by- n matrix. When X represents a truecolor image, it is an m -by- n -by-3 array, where each m -by- n matrix represents a red, green, or blue color plane concatenated along the third dimension.

For more information on image formats, see the `image` and `imfinfo` reference pages.

Algorithms

The algorithm used for the wavelet packets decomposition follows the same line as the wavelet decomposition process (see `dwt2` and `wavedec2` for more information).

wpdencmp

Denoising or compression using wavelet packets

Syntax

```
[xd,treed,perf0,perf12] = wpdencmp(x,sorh,n,wname,crit,par,keepapp)
[ ___ ] = wpdencmp(tree,sorh,crit,par,keepapp)
```

Description

`wpdencmp` performs a denoising or compression process of a signal or image using wavelet packets. The ideas and procedures for denoising and compression using either wavelet or wavelet packet decompositions are the same. See `wdenoise` or `wdencmp` for more information.

`[xd,treed,perf0,perf12] = wpdencmp(x,sorh,n,wname,crit,par,keepapp)` returns a denoised or compressed version `xd` of the input data `x` obtained by wavelet packet coefficient thresholding. `wpdencmp` also returns the wavelet packet best tree decomposition `treed` of `xd` (see `besttree` for more information), and the L^2 energy recovery and compression scores in percentages as `perf12` and `perf0`, respectively.

`[___] = wpdencmp(tree,sorh,crit,par,keepapp)` uses the wavelet packet decomposition tree of the data to be denoised or compressed.

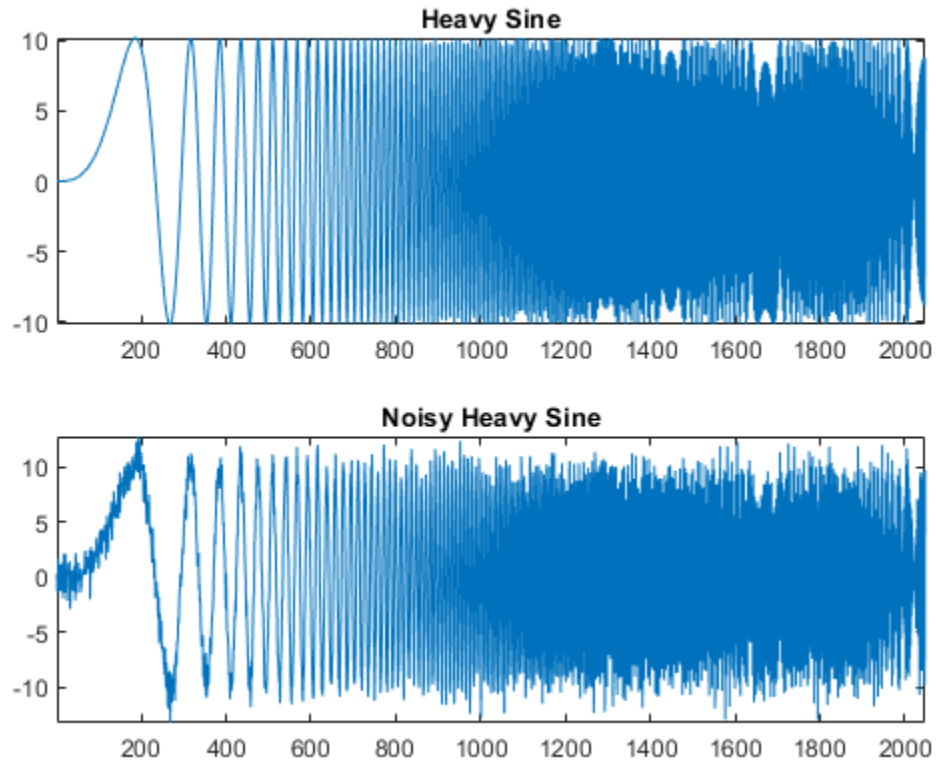

Examples

1-D Denoising Using Wavelet Packets

This example shows how to denoise using wavelet packets.

Use `wnoise` to generate the heavy sine signal and a noisy version.

```
init = 1000;
[xref,x] = wnoise(5,11,7,init);
figure
subplot(2,1,1)
plot(xref)
axis tight
title('Heavy Sine')
subplot(2,1,2)
plot(x)
axis tight
title('Noisy Heavy Sine')
```

Denoise the noisy signal using a four-level wavelet packet decomposition. Use the order 4 Daubechies least asymmetric wavelet.

```
n = length(x);
thr = sqrt(2*log(n*log(n)/log(2)));
xwpd = wpdencmp(x, 's', 4, 'sym4', 'sure', thr, 1);
```

Compare with a wavelet-based denoising result. Use `wdenoise` with comparable input arguments. Plot the differences between the two denoised signals and original signal.

```
xwd = wdenoise(x, 4, 'Wavelet', 'sym4', 'DenoisingMethod', 'UniversalThreshold', 'ThresholdRule', 'Hard');
figure
subplot(2,1,1)
plot(x-xwpd)
axis tight
ylim([-12 12])
title('Difference Between Wavelet Packet Denoised and Original')
subplot(2,1,2)
plot(x-xwd)
axis tight
ylim([-12 12])
title('Difference Between Wavelet Denoised and Original')
```

2-D Denoising Using Wavelet Packets

This example shows how to denoise an image using wavelet packets.

Load an image and generate a noisy copy. For reproducibility set the random seed.

```
rng default
load sinsin
x = X/18 + randn(size(X));
imagesc(X)
colormap(gray)
title('Original Image')
```

```
figure
imagesc(x)
colormap(gray)
title('Noisy Image')
```

Denoise the noisy image using wavelet packet decomposition. Use `ddencmp` to determine denoising parameters. Do a three-level decomposition with the order 4 Daubechies least asymmetric wavelet.

```
[thr,sorh,keepapp,crit] = ddencmp('den','wp',x);  
xd = wpdencmp(x,sorh,3,'sym4',crit,thr,keepapp);  
figure  
imagesc(xd)  
colormap(gray)  
title('Denoised Image')
```

1-D Compression Using Wavelet Packets

This example shows how to compress a 1-D signal using wavelet packets.

Load a signal. Use `ddencmp` to determine compression values for that signal.

```
load sumlichr
x = sumlichr;
[thr,sorh,keepapp,crit] = ddencmp('cmp','wp',x)

thr = 0.5193

sorh =
'h'

keepapp = 1

crit =
'threshold'
```

Compress the signal using global thresholding with threshold best basis. Use the order 4 Daubechies least asymmetric wavelet and do a three-level wavelet packet decomposition.

```
[xc,wpt,perf0,perf12] = wpdencmp(x,sorh,3,'sym4',crit,thr,keepapp);
```

Compare the original signal with the compressed version.

```

subplot(2,1,1)
plot(x)
title('Original Signal')
axis tight
subplot(2,1,2)
plot(xc)
xlabel(['L^2 rec.: ',num2str(perfl2),'% zero cfs.: ',num2str(perf0),'%'])
title('Compressed Signal Using Wavelet Packets')
axis tight

```

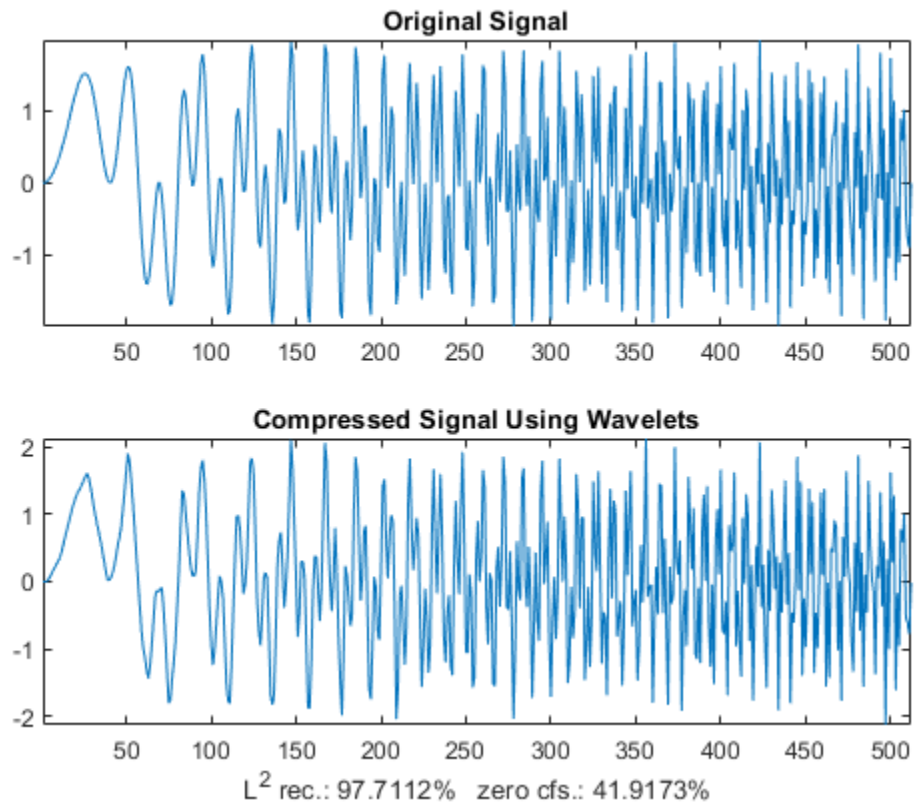

Compress the signal again, but this do a three-level wavelet decomposition. Keep all the other parameters the same.

```

[thr,sorh,keepapp] = ddencmp('cmp','wv',x);
[xcwv,~,~,perf0wv,perfl2wv] = wdencomp('gbl',x,'sym4',3,thr,sorh,keepapp);
figure
subplot(2,1,1)
plot(x)
title('Original Signal')
axis tight
subplot(2,1,2)
plot(xc)
xlabel(['L^2 rec.: ',num2str(perfl2wv),'% zero cfs.: ',num2str(perf0wv),'%'])
title('Compressed Signal Using Wavelets')
axis tight

```

A larger fraction of coefficients are set equal to 0 when compressing using a wavelet packet decomposition.

Input Arguments

x — Input data

real-valued vector or matrix

Input data to denoise or compress, specified by a real-valued vector or matrix.

Data Types: `double`

tree — Wavelet packet decomposition

wavelet packet decomposition

Wavelet packet decomposition of the data to be denoised or compressed, specified as a wavelet packet tree. See `wpdec` and `wpdec2` for more information.

sorh — Type of thresholding

's' | 'h'

Type of thresholding to perform:

- 's' — Soft thresholding

- 'h' — Hard thresholding

See `wthresh` for more information.

n — Wavelet packet decomposition level

positive integer

Wavelet packet decomposition level, specified as a positive integer.

wname — Name of wavelet

character vector | string scalar

Name of wavelet, specified as a character vector or string scalar, to use for denoising. See `wavemngr` for more information.

crit — Entropy type

'shannon' | 'log energy' | 'threshold' | 'sure' | 'norm' | 'user' | ...

Entropy type, specified as one of the following:

Entropy Type (crit)	Threshold Parameter (par)	Comments
'shannon'		par is not used.
'log energy'		par is not used.
'threshold'	$0 \leq \text{par}$	par is the threshold.
'sure'	$0 \leq \text{par}$	par is the threshold.
'norm'	$1 \leq \text{par}$	par is the power.
'user'	Character vector	par is a character vector containing the file name of your own entropy function, with a single input x.
'FunName'	No constraints on par	FunName is any character vector other than the previous entropy types listed. FunName contains the file name of your own entropy function, with x as input and par as an additional parameter to your entropy function.

`crit` and threshold parameter `par` together define the entropy criterion used to determine the best decomposition. See `wentropy` for more information.

If `crit = 'nobest'`, no optimization is done, and the current decomposition is thresholded.

par — Threshold parameter

real number | character vector | string scalar

Threshold parameter, specified by a real number, character vector, or string scalar. `par` and the entropy type `crit` together define the entropy criterion used to determine the best decomposition. See `wentropy` for more information.

Data Types: double

keepapp — Threshold approximation setting

0 | 1

Threshold approximation setting, specified as either 0 or 1. If `keepapp = 1`, the approximation coefficients cannot be thresholded. If `keepapp = 0`, the approximation coefficients can be thresholded.

Data Types: `double`

Output Arguments

xd — Denoised or compressed data

real-valued vector or matrix

Denoised or compressed data, returned as a real-valued vector or matrix. `xd` and `x` have the same dimensions.

treed — Wavelet packet best tree decomposition

wavelet packet tree

Wavelet packet best tree decomposition of `xd`, returned as a wavelet packet tree.

perf0 — Compression score

real number

Compression score, returned as a real number. `perf0` is the percentage of thresholded coefficients that are equal to 0.

perf12 — L^2 energy recovery

real number

L^2 energy recovery, returned as a real number. `perf12` is equal to

$100 \times \left(\frac{\text{vector-norm of wavelet packet coefficients of } xd}{\text{vector-norm of wavelet packet coefficients of } x} \right)^2$. If `x` is a one-dimensional signal and `wname` an orthogonal wavelet, `perf12` simplifies to $\frac{100 \|xd\|^2}{\|x\|^2}$.

Wavelet Signal Denoiser

Introduced before R2006a

wpfun

Wavelet packet functions

Syntax

```
[WPWS,X] = wpfun('wname',NUM,PREC)
[WPWS,X] = wpfun('wname',NUM)
[WPWS,X] = wpfun('wname',NUM,7)
```

Description

wpfun is a wavelet packet analysis function.

[WPWS,X] = wpfun('wname',NUM,PREC) computes the wavelet packets for a wavelet 'wname' (see wfilters for more information), on dyadic intervals of length $2^{-\text{PREC}}$.

PREC must be a positive integer. Output matrix WPWS contains the W functions of index from 0 to NUM, stored row-wise as $[W_0; W_1; \dots; W_{\text{NUM}}]$. Output vector X is the corresponding common X-grid vector.

[WPWS,X] = wpfun('wname',NUM) is equivalent to
[WPWS,X] = wpfun('wname',NUM,7).

The computation scheme for wavelet packets generation is easy when using an orthogonal wavelet. We start with the two filters of length $2N$, denoted $h(n)$ and $g(n)$, corresponding to the wavelet.

Now by induction let us define the following sequence of functions ($W_n(x)$, $n = 0,1,2,\dots$) by

$$W_{2n}(x) = \sqrt{2} \sum_{k=0, \dots, 2N-1} h(k)W_n(2x-k)$$

$$W_{2n+1}(x) = \sqrt{2} \sum_{k=0, \dots, 2N-1} g(k)W_n(2x-k)$$

where $W_0(x) = \phi(x)$ is the scaling function and $W_1(x) = \psi(x)$ is the wavelet function.

For example for the Haar wavelet we have

$$N = 1, h(0) = h(1) = \frac{1}{\sqrt{2}}$$

and

$$g(0) = -g(1) = \frac{1}{\sqrt{2}}$$

The equations become

$$W_{2n}(x) = W_n(2x) + W_n(2x-1)$$

and

$$(W_{2n+1}(x) = W_n(2x) - W_n(2x-1))$$

$W_0(x) = \phi(x)$ is the haar scaling function and $W_1(x) = \psi(x)$ is the haar wavelet, both supported in $[0,1]$.

Then we can obtain W_{2^n} by adding two $1/2$ -scaled versions of W_n with distinct supports $[0,1/2]$ and $[1/2,1]$, and obtain $W_{2^{n+1}}$ by subtracting the same versions of W_n .

Starting from more regular original wavelets, using a similar construction, we obtain smoothed versions of this system of W -functions, all with support in the interval $[0, 2N-1]$.

Examples

```
% Compute the db2 Wn functions for n = 0 to 7, generating
% the db2 wavelet packets.
[wp,x] = wpsfun('db2',7);

% Using some plotting commands,
% the following figure is generated.
```

wpjoin

Recompose wavelet packet

Syntax

```
T = wpjoin(T,N)
[T,X] = wpjoin(T,N)
T = wpjoin(T)
T = wpjoin(T,0)
[T,X] = wpjoin(T)
[T,X] = wpjoin(T,0)
```

Description

wpjoin is a one- or two-dimensional wavelet packet analysis function.

wpjoin updates the wavelet packet tree after the recomposition of a node.

The nodes are numbered from left to right and from top to bottom. The root index is 0.

$T = \text{wpjoin}(T,N)$ returns the modified wavelet packet tree T corresponding to a recomposition of the node N .

$[T,X] = \text{wpjoin}(T,N)$ also returns the coefficients of the node.

$T = \text{wpjoin}(T)$ is equivalent to $T = \text{wpjoin}(T,0)$.

$[T,X] = \text{wpjoin}(T)$ is equivalent to $[T,X] = \text{wpjoin}(T,0)$.

Examples

```
% The current extension mode is zero-padding (see dwtmode).

% Load signal.
load noisdopp; x = noisdopp;

% Decompose x at depth 3 with db1 wavelet packets.
wpt = wpdec(x,3,'db1');

% Plot wavelet packet tree wpt.
plot(wpt)
```

```
% Recompose packet (1,1) or 2
wpt = wpjoin(wpt,[1 1]);

% Plot wavelet packet tree wpt.
plot(wpt)
```

wprcoef

Reconstruct wavelet packet coefficients

Syntax

```
X = wprcoef(T,N)
X = wprcoef(T)
X = wprcoef(T,0)
```

Description

wprcoef is a one- or two-dimensional wavelet packet analysis function.

$X = \text{wprcoef}(T,N)$ computes reconstructed coefficients of the node N of the wavelet packet tree T .

$X = \text{wprcoef}(T)$ is equivalent to $X = \text{wprcoef}(T,0)$.

Examples

```
% The current extension mode is zero-padding (see dwtmode)

% Load signal.
load noisdopp; x = noisdopp;

figure(1); subplot(211);
plot(x); title('Original signal');

% Decompose x at depth 3 with db1 wavelet packets
% using Shannon entropy.
t = wpdec(x,3,'db1','shannon');

% Plot wavelet packet tree.
plot(t)
```

```
% Reconstruct packet (2,1).
rcfs = wprcoef(t,[2 1]);

figure(1); subplot(212);
plot(rcfs); title('Reconstructed packet (2,1)');
```

Topics

"Reconstructing a Signal Approximation from a Node"

Introduced before R2006a

wprec

Wavelet packet reconstruction 1-D

Syntax

```
X = wprec(T)  
wprec(wpdec(X, 'wname'))
```

Description

wprec is a one-dimensional wavelet packet analysis function.

$X = \text{wprec}(T)$ returns the reconstructed vector X corresponding to a wavelet packet tree T .

wprec is the inverse function of wpdec in the sense that the abstract statement $\text{wprec}(\text{wpdec}(X, 'wname'))$ would give back X .

dwpt | idwpt | wpdec | wpdec2 | wpjoin | wprec2 | wpsplt

Introduced before R2006a

wprec2

Wavelet packet reconstruction 2-D

Syntax

```
X = wprec2(T)
wprec2(wpdec2(X, 'wname'))
```

Description

wprec2 is a two-dimensional wavelet packet analysis function.

$X = \text{wprec2}(T)$ returns the reconstructed matrix X corresponding to a wavelet packet tree T .

wprec2 is the inverse function of wpdec2 in the sense that the abstract statement $\text{wprec2}(\text{wpdec2}(X, 'wname'))$ would give back X .

Tips

If T is obtained from an indexed image analysis or a truecolor image analysis, X is an m -by- n matrix or an m -by- n -by-3 array, respectively.

For more information on image formats, see the [image](#) and [imfinfo](#) reference pages.

wpspectrum

Wavelet packet spectrum

Syntax

```
[SPEC,TIMES,FREQ] = wpspectrum(WPT,Fs)
[...] = wpspectrum(WPT,Fs,'plot')
[... ,TNF0] = wpspectrum(...)
```

Description

`[SPEC,TIMES,FREQ] = wpspectrum(WPT,Fs)` returns a matrix of wavelet packet spectrum estimates, `SPEC`, for the binary wavelet packet tree object, `WPT`. `Fs` is the sampling frequency in Hertz. `SPEC` is a 2^J -by- N matrix where J is the level of the wavelet packet transform and N is the length of the time series. `TIMES` is a 1-by- N vector of times and `FREQ` is a 1-by- 2^J vector of frequencies.

`[...] = wpspectrum(WPT,Fs,'plot')` displays the wavelet packet spectrum.

`[... ,TNF0] = wpspectrum(...)` returns the terminal nodes of the wavelet packet tree in frequency order.

Input Arguments

WPT

WPT is a binary wavelet packet tree of class `wptree`.

Fs

Sampling frequency in Hertz as a scalar of class `double`.

Default: 1

plot

The character vector `'plot'` displays the wavelet packet spectrum. Enter `'plot'` after `Fs` to produce a plot of the wavelet packet spectrum.

Output Arguments

SPEC

Wavelet packet spectrum. `SPEC` is a 2^J -by- N matrix where J is the level of the wavelet packet transform and N is the length of node 0 in the wavelet packet tree object.

The frequency spacing between the rows of `SPEC` is $Fs/2^{J+1}$.

TIMES

Time vector. TIMES is a vector of times in seconds equal in length to node 0 of the wavelet packet tree object. The time spacing between elements is $1/Fs$.

FREQ

Frequency vector. FREQ is a vector of frequencies of length 2^J where J is the level of the wavelet packet tree object. The frequency spacing in FREQ is $Fs/2^{J+1}$.

TNFO

Terminal nodes. TNFO is a vector of the terminal nodes of the wavelet packet tree object in frequency order.

Examples**Wavelet Packet Spectrum for Sinusoids**

This example shows wavelet packet spectrum for signal consisting of two sinusoids with disjoint support.

Define wavelet.

```
fs = 500;  
t = 0:1/fs:4;  
y = sin(32*pi*t).*(t<2) + sin(128*pi*t).*(t>=2);  
plot(t,y);  
axis tight  
title('Analyzed Signal');
```

Define wavelet packet spectrum.

```
level = 6;  
wpt = wptdec(y,level,'sym6');  
figure;  
[S,T,F] = wpspectrum(wpt,fs,'plot');
```

Wavelet Packet Spectrum of Chirp Signal

Create the chirp signal.

```
fs = 1000;
t = 0:1/fs:2;
% create chirp signal
y = sin(256*pi*t.^2);
```

Plot the analyzed signal.

```
plot(t,y);
axis tight
title('Analyzed Signal');
```

Get the wavelet packet spectrum estimates.

```
level = 6;  
wpt = wptdec(y,level,'sym8');  
figure;  
[S,T,F] = wpspectrum(wpt,fs,'plot');
```

More About

Wavelet Packet Spectrum

The wavelet packet spectrum contains the absolute values of the coefficients from the frequency-ordered terminal nodes of the input binary wavelet packet tree. The terminal nodes provide the finest level of frequency resolution in the wavelet packet transform. If J denotes the level of the wavelet packet transform and F_s is the sampling frequency, the terminal nodes approximate bandpass filters of the form:

$$\left[\frac{nF_s}{2^{J+1}}, \frac{(n+1)F_s}{2^{J+1}} \right) \quad n = 0, 1, 2, 3, \dots, 2^J - 1$$

At the terminal level of the wavelet packet tree, the transform divides the interval from 0 to the Nyquist frequency into bands of approximate width $F_s/2^{J+1}$.

Algorithms

wpspectrum computes the wavelet packet spectrum as follows:

- Extract the wavelet packet coefficients corresponding to the terminal nodes. Take the absolute value of the coefficients.

- Order the wavelet packet coefficients by frequency ordering.
- Determine the time extent on the original time axis corresponding to each wavelet packet coefficient. Repeat each wavelet packet coefficient to fill in the time gaps between neighboring wavelet packet coefficients and create a vector equal in length to node 0 of the wavelet packet tree object.

wpsplt

Split (decompose) wavelet packet

Syntax

```
T = wpsplt(T,N)
[T,cA,cD] = wpsplt(T,N)
[T,cA,cH,cV,cD] = wpsplt(T,N)
```

Description

wpsplt is a one- or two-dimensional wavelet packet analysis function.

wpsplt updates the wavelet packet tree after the decomposition of a node.

$T = \text{wpsplt}(T,N)$ returns the modified wavelet packet tree T corresponding to the decomposition of the node N .

For a one-dimensional decomposition,

$[T, cA, cD] = \text{wpsplt}(T, N)$ with cA = approximation and cD = detail of node N .

For a two-dimensional decomposition,

$[T, cA, cH, cV, cD] = \text{wpsplt}(T, N)$ with cA = approximation and cH, cV, cD = horizontal, vertical, and diagonal details of node N .

Examples

```
% The current extension mode is zero-padding (see dwtmode).
```

```
% Load signal.
load noisdopp;
x = noisdopp;
```

```
% Decompose x at depth 3 with db1 wavelet packets.
wpt = wpdec(x,3,'db1');
```

```
% Plot wavelet packet tree wpt.
plot(wpt)
```

```
% Decompose packet (3,0).  
wpt = wpsplt(wpt,[3 0]);  
% or equivalently wpsplt(wpt,7).
```

```
% Plot wavelet packet tree wpt.  
plot(wpt)
```

Introduced before R2006a

wpthcoef

Wavelet packet coefficients thresholding

Syntax

`NT = wpthcoef(T,KEEPAPP,SORH,THR)`

Description

wpthcoef is a one- or two-dimensional de-noising and compression utility.

`NT = wpthcoef(T,KEEPAPP,SORH,THR)` returns a new wavelet packet tree NT obtained from the wavelet packet tree *T* by coefficients thresholding.

If `KEEPAPP = 1`, approximation coefficients are not thresholded; otherwise, they can be thresholded.

If `SORH = 's'`, soft thresholding is applied; if `SORH = 'h'`, hard thresholding is applied (see `wthresh` for more information).

`THR` is the threshold value.

Introduced before R2006a

wptree

WPTREE constructor

Syntax

```
T = wptree(ORDER,DEPTH,X,WNAME,ENT_TYPE,PARAMETER)
T = wptree(ORDER,DEPTH,X,WNAME)
T = wptree(ORDER,DEPTH,X,WNAME,'shannon')
T = wptree(ORDER,DEPTH,X,WNAME,ENT_TYPE,ENT_PAR,USERDATA)
```

Description

`T = wptree(ORDER,DEPTH,X,WNAME,ENT_TYPE,PARAMETER)` returns a complete wavelet packet tree `T`.

`ORDER` is an integer representing the order of the tree (the number of “children” of each non terminal node). `ORDER` must be equal to 2 or 4.

If `ORDER = 2`, `T` is a `WPTREE` object corresponding to a wavelet packet decomposition of the vector (signal) `X`, at level `DEPTH` with a particular wavelet `WNAME`.

If `ORDER = 4`, `T` is a `WPTREE` object corresponding to a wavelet packet decomposition of the matrix (image) `X`, at level `DEPTH` with a particular wavelet `WNAME`.

`ENT_TYPE` is a character vector or string scalar containing the entropy type and `ENT_PAR` is an optional parameter used for entropy computation (see `wentropy`, `wpdec`, or `wpdec2` for more information).

`T = wptree(ORDER,DEPTH,X,WNAME)` is equivalent to `T = wptree(ORDER,DEPTH,X,WNAME,'shannon')`

With `T = wptree(ORDER,DEPTH,X,WNAME,ENT_TYPE,ENT_PAR,USERDATA)` you may set a `userdata` field.

The function `wptree` returns a `WPTREE` object.

For more information on object fields, see the `get` function or type

`help wptree/get`

Class `WPTREE` (Parent class: `DTREE`)

Fields

'dtree'	DTREE parent object
'wavInfo'	Structure (wavelet information)
'entInfo'	Structure (entropy information)

The wavelet information structure, `'wavInfo'`, contains

'wavName'	Wavelet name
'Lo_D'	Low Decomposition filter
'Hi_D'	High Decomposition filter
'Lo_R'	Low Reconstruction filter
'Hi_R'	High Reconstruction filter

The entropy information structure, 'entInfo', contains

'entName'	Entropy name
'entPar'	Entropy parameter

Fields from the DTREE parent object:

'allNI'	All nodes information
---------	-----------------------

'allNI' is an array of size nbnod by 5, which contains

ind	Index
size	Size of data
ent	Entropy
ento	Optimal entropy

Each line is built based on the following scheme:

Examples

```
% Create a wavelet packet tree.
x = rand(1,512);
t = wptree(2,3,x,'db3');
t = wpjoin(t,[4;5]);

% Plot tree t4.
plot(t);

% Click the node (3,0), (see the plot function).
```

Introduced before R2006a

wpviewcf

Plot wavelet packets colored coefficients

Syntax

```
wpviewcf(T,CMODE)
wpviewcf(T,CMODE,NBCOL)
```

Description

`wpviewcf(T,CMODE)` plots the colored coefficients for the terminal nodes of the tree T .

T is a wavelet packet tree and $CMODE$ is an integer, which represents the color mode. The color modes are listed in the table below.

Color Mode	Description
1	Frequency order - Global coloration - Absolute values
2	Frequency order - By level - Absolute values
3	Frequency order - Global coloration - Values
4	Frequency order - By level coloration - Values
5	Natural order - Global coloration - Absolute values
6	Natural order - By level - Absolute values
7	Natural order - Global coloration - Values
8	Natural order - By level coloration - Values

`wpviewcf(T,CMODE,NBCOL)` uses $NBCOL$ colors.

Examples

```
% Create a wavelet packet tree.
x = sin(8*pi*[0:0.005:1]);
t = wpdec(x,3,'db1');

% Plot tree t.
% Click the node (3,0), (see the plot function)
plot(t);
```

```
% Plot the colored wavelet packet coefficients.
wpviewcf(t,1);
```

Introduced before R2006a

wrcoef

Reconstruct single branch from 1-D wavelet coefficients

Syntax

```
X = wrcoef('type',C,L,wname,N)
X = wrcoef('type',C,L,Lo_R,Hi_R,N)
X = wrcoef('type',C,L,wname)
X = wrcoef('type',C,L,Lo_R,Hi_R)
```

Description

wrcoef reconstructs the coefficients of a one-dimensional signal, given a wavelet decomposition structure (C and L) and either a specified wavelet (wname, see wfilters for more information) or specified reconstruction filters (Lo_R and Hi_R).

`X = wrcoef('type',C,L,wname,N)` computes the vector of reconstructed coefficients, based on the wavelet decomposition structure [C,L] (see wavedec for more information), at level N. wname is a character vector or string scalar containing the wavelet name.

Argument 'type' determines whether approximation ('type' = 'a') or detail ('type' = 'd') coefficients are reconstructed. When 'type' = 'a', N is allowed to be 0; otherwise, a strictly positive number N is required. Level N must be an integer such that $N \leq \text{length}(L) - 2$.

`X = wrcoef('type',C,L,Lo_R,Hi_R,N)` computes coefficients as above, given the reconstruction filters you specify.

`X = wrcoef('type',C,L,wname)` and `X = wrcoef('type',C,L,Lo_R,Hi_R)` reconstruct coefficients of maximum level $N = \text{length}(L) - 2$.

Examples

```
% The current extension mode is zero-padding (see dwtmode).
```

```
% Load a one-dimensional signal.
load sumsin; s = sumsin;
```

```
% Perform decomposition at level 5 of s using sym4.
[c,l] = wavedec(s,5,'sym4');
```

```
% Reconstruct approximation at level 5,
% from the wavelet decomposition structure [c,l].
a5 = wrcoef('a',c,l,'sym4',5);
```

```
% Using some plotting commands,
% the following figure is generated.
```

See Also

`appcoef` | `detcoef` | `wavedec`

Introduced before R2006a

wrcoef2

Reconstruct single branch from 2-D wavelet coefficients

Syntax

```
X = wrcoef2('type',C,S,wname,N)
X = wrcoef2('type',C,S,Lo_R,Hi_R,N)
X = wrcoef2('type',C,S,wname)
X = wrcoef2('type',C,S,Lo_R,Hi_R)
```

Description

wrcoef2 is a two-dimensional wavelet analysis function. wrcoef2 reconstructs the coefficients of an image.

$X = \text{wrcoef2}('type', C, S, wname, N)$ computes the matrix of reconstructed coefficients of level N , based on the wavelet decomposition structure $[C, S]$ (see `wavedec2` for more information).

`wname` is a character vector or string scalar containing the name of the wavelet (see `wfilters` for more information). If `'type' = 'a'`, approximation coefficients are reconstructed; otherwise if `'type' = 'h'` (`'v'` or `'d'`, respectively), horizontal (vertical or diagonal, respectively) detail coefficients are reconstructed.

Level N must be an integer such that $0 \leq N \leq \text{size}(S,1) - 2$ if `'type' = 'a'` and such that $1 \leq N \leq \text{size}(S,1) - 2$ if `'type' = 'h', 'v', or 'd'`.

Instead of giving the wavelet name, you can give the filters.

For $X = \text{wrcoef2}('type', C, S, Lo_R, Hi_R, N)$, `Lo_R` is the reconstruction low-pass filter and `Hi_R` is the reconstruction high-pass filter.

$X = \text{wrcoef2}('type', C, S, wname)$ or $X = \text{wrcoef2}('type', C, S, Lo_R, Hi_R)$ reconstruct coefficients of maximum level $N = \text{size}(S,1) - 2$.

Examples

```
% The current extension mode is zero-padding (see dwtmode).
```

```
% Load an image.
load woman;
% X contains the loaded image.
```

```
% Perform decomposition at level 2
% of X using sym5.
[c,s] = wavedec2(X,2,'sym5');
```

```
% Reconstruct approximations at
% levels 1 and 2, from the wavelet
% decomposition structure [c,s].
a1 = wrcoef2('a',c,s,'sym5',1);
a2 = wrcoef2('a',c,s,'sym5',2);
```

```
% Reconstruct details at level 2,  
% from the wavelet decomposition  
% structure [c,s].  
% 'h' is for horizontal,  
% 'v' is for vertical,  
% 'd' is for diagonal.  
hd2 = wrcoef2('h',c,s,'sym5',2);  
vd2 = wrcoef2('v',c,s,'sym5',2);  
dd2 = wrcoef2('d',c,s,'sym5',2);  
  
% All these images are of same size sX.  
sX = size(X)  
  
sX =  
    256 256  
  
sa1 = size(a1)  
  
sa1 =  
    256 256  
  
shd2 = size(hd2)  
  
shd2 =  
    256 256
```

Tips

If C and S are obtained from an indexed image analysis (respectively a truecolor image analysis) then X is an m-by-n matrix (respectively an m-by-n-by-3 array).

For more information on image formats, see the reference pages of `image` and `imfinfo` functions.

wrev

Flip vector

Syntax

```
Y = wrev(X)
```

Description

wrev is a general utility.

$Y = \text{wrev}(X)$ reverses the vector X .

Examples

```
v = [1 2 3];  
wrev(v)  
wrev(v')
```

fliplr | flipud

Introduced before R2006a

write

Write values in WPTREE fields

Syntax

```
T = write(T,'cfs',NODE,COEFS)
T = write(T,'cfs',N1,CFS1,'cfs',N2,CFS2, ...)
```

Description

`T = write(T,'cfs',NODE,COEFS)` writes coefficients for the terminal node `NODE`.

`T = write(T,'cfs',N1,CFS1,'cfs',N2,CFS2, ...)` writes coefficients `CFS1`, `CFS2`, ... for the terminal nodes `N1`, `N2`,

Caution The coefficients values must have the suitable size. You can use `S = read(T,'sizes',NODE)` or `S = read(T,'sizes',[N1;N2; ...])` in order to get those sizes.

Examples

```
% Create a wavelet packet tree.
load noisdopp; x = noisdopp;
t = wptec(x,3,'db3');
t = wpjoin(t,[4;5]);

% Plot tree t and click the node (0,0) (see the plot function).
plot(t);
```

```
% Write values.
sNod = read(t,'sizes',[4,5,7]);
cfs4 = zeros(sNod(1,:));
cfs5 = zeros(sNod(2,:));
cfs7 = zeros(sNod(3,:));
t = write(t,'cfs',4,cfs4,'cfs',5,cfs5,'cfs',7,cfs7);
```

```
% Plot tree t and click the node (0,0) (see the plot function).  
plot(t)
```

wscalogram

Scalogram for continuous wavelet transform

Note This function is no longer recommended. Use `cwt` instead.

Syntax

```
SC = wscalogram(TYPEPLOT,COEFS)
SC = wscalogram(TYPEPLOT,COEFS,'PropName1',PropVal1,...)
```

Description

`SC = wscalogram(TYPEPLOT,COEFS)` computes the scalogram `SC` which represents the percentage of energy for each coefficient. `COEFS` is the matrix of the continuous wavelet coefficients (see `cwt`).

The scalogram is obtained by computing:

```
S = abs(coefs.*coefs); SC = 100*S./sum(S(:))
```

When `TYPEPLOT` is equal to `'image'`, a scaled image of scalogram is displayed. When `TYPEPLOT` is equal to `'contour'`, a contour representation of scalogram is displayed. Otherwise, the scalogram is returned without plot representation.

`SC = wscalogram(TYPEPLOT,COEFS,'PropName1',PropVal1,...)` allows you to modify some properties. The valid choices for `PropName` are:

<code>'scales'</code>	Scales used for the CWT.
<code>'ydata'</code>	Signal used for the CWT.
<code>'xdata'</code>	x values corresponding to the signal values.
<code>'power'</code>	Positive real value. Default value is zero.

If `power > 0`, coefficients are first normalized

```
coefs(k,:) = coefs(k,)/(scales(k)^power)
```

and then the scalogram is computed as explained above.

Examples

```
% Compute signal s
t = linspace(-1,1,512);
s = 1-abs(t);
```

```
% Plot signal s
figure;
plot(s), axis tight
```

```
% Compute coefficients COEFS using cwt
COEFS = cwt(s,1:32,'cgau4');

% Compute and plot the scalogram (image option)
figure;
SC = wscalogram('image',COEFS);
```

```
% Compute and plot the scalogram (contour option)
figure;
SC = wscalogram('contour',COEFS);
```

cwt

Introduced in R2008a

wsst

Wavelet synchrosqueezed transform

Syntax

```
sst = wsst(x)
[sst,f] = wsst(x)
[ ___ ] = wsst(x,fs)
[ ___ ] = wsst(x,ts)
[ ___ ] = wsst( ___,wav)
wsst( ___ )
[ ___ ] = wsst( ___,Name,Value)
```

Description

`sst = wsst(x)` returns the wavelet synchrosqueezed transform, `sst`, which you use to examine data in the time-frequency plane. The synchrosqueezed transform has reduced energy smearing when compared to the continuous wavelet transform. The input, `x`, must be a 1-D real-valued signal with at least four samples. `wsst` computes the synchrosqueezed transform using the analytic Morlet wavelet.

`[sst,f] = wsst(x)` returns a vector of frequencies, `f`, in cycles per sample. The frequencies correspond to the rows of `sst`.

`[___] = wsst(x,fs)` computes the synchrosqueezed transform using the specified sampling frequency, `fs`, in Hz, to compute the synchrosqueezed transform. If you specify an `f` output, `wsst` returns the frequencies in Hz. You can use any previous combination of output values.

`[___] = wsst(x,ts)` uses a duration `ts` with a positive, scalar input, as the sampling interval. The duration can be in years, days, hours, minutes, or seconds. If you specify `ts` and the `f` output, `wsst` returns the frequencies in `f` in cycles per unit time, where the time unit is derived from specified duration.

`[___] = wsst(___,wav)` uses the analytic wavelet specified by `wav` to compute the synchrosqueezed transform. Valid values are 'amor' and 'bump', which specify the analytic Morlet and bump wavelet, respectively.

`wsst(___)` with no output arguments plots the synchrosqueezed transform as a function of time and frequency. If you do not specify a sampling frequency, `fs`, or interval, `ts`, the synchrosqueezed transform is plotted in cycles per sample. If you specify a sampling frequency, the synchrosqueezed transform is plotted in Hz. If you specify a sampling interval using a duration, the plot is in cycles per unit time. The time units are derived from the duration.

`[___] = wsst(___,Name,Value)` returns the synchrosqueezed transform with additional options specified by one or more `Name,Value` pair arguments.

Examples

Synchrosqueezed Transform of Speech Signal

Obtain the wavelet synchrosqueezed transform of a speech sample using default values.

```
load mtlb;  
sst = wsst(mtlb);
```

Synchrosqueezed Transform and Reconstruction of Speech Signal

Obtain the wavelet synchrosqueezed transform of a speech signal and compare the original and reconstructed signals.

Load the speech signal and obtain its synchrosqueezed transform.

```
load mtlb  
soundsc(mtlb,Fs)  
dt = 1/Fs;  
t = 0:dt: numel(mtlb)*dt-dt;  
[sst,f] = wsst(mtlb,Fs);
```

Plot the synchrosqueezed transform.

```
pcolor(t,f,abs(sst))  
shading interp  
xlabel('Seconds')  
ylabel('Frequency (Hz)')  
title('Synchrosqueezed Transform')
```

Obtain the inverse synchrosqueezed transform and play the reconstructed speech signal.

```
xrec = iwsst(sst);  
soundsc(xrec,Fs)
```

Synchrosqueezed Transform of Quadratic Chirp

Obtain and plot the wavelet synchrosqueezed transform of a quadratic chirp. The chirp is sampled at 1000 Hz.

```
load quadchirp;  
[sst,f] = wssst(quadchirp,1000);  
hp = pcolor(tquad,f,abs(sst));  
hp.EdgeColor = 'none';  
title('Wavelet Synchrosqueezed Transform');  
xlabel('Time'); ylabel('Hz');
```

Synchrosqueezed Transform of Sunspot Data

Obtain the wavelet synchrosqueezed transform of sunspot data using the default Morlet wavelet. Specify the sampling interval to be one year.

```
load sunspot.dat;  
wsst(sunspot(:,2),years(1))
```

Synchrosqueezed Transform of Sunspot Data Using Bump Wavelet

Obtain and plot the wavelet synchrosqueezed transform of sunspot data using the bump wavelet. Specify the sampling interval to be 1 for one sample per year.

```
load sunspot.dat  
wsst(sunspot(:,2),years(1),'bump')
```

Input Arguments

x – Input signal

row or column vector of real values

Input signal, specified as a row or column vector. `x` must be a 1-D, real-valued signal with at least four samples.

fs – Sampling frequency

positive scalar

Sampling frequency, specified as a positive scalar.

ts – Sampling interval

duration with positive scalar input

Sampling interval, also known as the sampling period, specified as a duration with positive scalar input. Valid durations are years, days, hours, seconds, and minutes. You cannot use calendar durations (caldays, calweeks, calmonths, calquarters, or calyears). You cannot specify both `ts` and `fs`.

Example: `sst = wsst(x, hours(12))`

wav – Analytic wavelet

'amor' (default) | 'bump'

Analytic wavelet used to compute the synchrosqueezed transform, specified as one of the following:

- 'amor' — Analytic Morlet wavelet
- 'bump' — Bump wavelet

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: 'VoicesPerOctave', 26

VoicesPerOctave — Number of voices per octave

32 (default) | even integer from 10 to 48

Number of voices per octave to use in the synchrosqueezed transform, specified as the comma-separated pair consisting of 'VoicesPerOctave' and an even integer from 10 to 48. The product of the number of voices per octave and the number of octaves is the number of scales. The number of octaves depends on the size of the input `x` and is $\text{floor}(\log_2(\text{numel}(x))) - 1$.

ExtendSignal — Extend input signal symmetrically

false (default) | true

Option to extend the input signal symmetrically, specified as the comma-separated pair consisting of 'ExtendSignal' and either `false` or `true`. Extending the signal symmetrically can mitigate boundary effects. If you specify `false`, then the signal is not extended. If you specify `true`, then the signal is extended.

Output Arguments

sst — Synchrosqueezed transform

matrix

Synchrosqueezed transform, returned as a matrix. By default, the synchrosqueezed transform uses $\text{floor}(\log_2(\text{numel}(x))) - 1$ octaves, 32 voices per octave, and the analytic Morlet wavelet. `sst` is an N_a -by- N matrix where N_a is the number of scales, and N is the number of samples in `x`. The default number of scales is $32 * (\text{floor}(\log_2(\text{numel}(x))) - 1)$.

f — Frequencies

vector

Frequencies of the synchrosqueezed transform, returned as a vector. The frequencies correspond to the rows of the `sst`. If you do not specify `fs` or `ts`, the frequencies are in cycles per sample. If you specify `fs`, the frequencies are in Hz. If you specify `ts`, the frequencies are in cycles per unit time. The length of the frequency vector is the same as the number of `sst` rows. If you specify `ts` as the sampling interval, `ts` is used to compute the scale-to-frequency conversion for `f`.

wsstridge

Time-frequency ridges from wavelet synchrosqueezing

Syntax

```
fridge = wsstridge(sst)
[fridge,iridge] = wsstridge(sst)
[ ___ ] = wsstridge(sst,penalty)
[ ___ ] = wsstridge( ___,f)
[ ___ ]= wsstridge( ___,Name,Value)
```

Description

`fridge = wsstridge(sst)` extracts the maximum energy time-frequency ridge in cycles per sample from the wavelet synchrosqueezed transform, `sst`. The `sst` input is the output of `wsst`. Each ridge is a separate signal mode.

`[fridge,iridge] = wsstridge(sst)` returns in `iridge` the row indices of `sst`. The row indices are the maximum time-frequency ridge at each sample. Use `iridge` to reconstruct the signal mode along a time-frequency ridge using `iwsst`.

`[___] = wsstridge(sst,penalty)` multiplies the squared distance between frequency bins by the `penalty` value. You can include any of the output arguments from previous syntaxes.

`[___] = wsstridge(___,f)` returns the maximum energy time-frequency ridge in cycles per unit time based on the `f` input frequency vector. `f` is the frequency output of `wsst`. The `f` input and `fridge` output have the same units.

`[___]= wsstridge(___,Name,Value)` returns the time-frequency ridge with additional options specified by one or more `Name,Value` pair arguments.

Examples

Extract Time-Frequency Ridge from Chirp Signal

Obtain the wavelet synchrosqueezed transform of a quadratic chirp and extract the maximum time-frequency ridge, in `fridge`, and the associated row indices, in `iridge`.

Load the chirp signal and obtain its synchrosqueezed transform.

```
load quadchirp;
[sst,f] = wsst(quadchirp);
```

Extract the maximum time-frequency ridge.

```
[fridge,iridge] = wsstridge(sst);
```

Plot the synchrosqueezed transform.

```
pcolor(tquad, f, abs(sst))  
shading interp  
title('Synchrosqueezed Transform')
```

Overlay the plot of the maximum energy frequency ridge.

```
hold on  
plot(tquad, fridge)  
title('Synchrosqueezed Transform with Overlaid Ridge')
```

Extract Time-Frequency Ridge from Multicomponent Signal

Extract the two highest energy modes from a multicomponent signal.

Obtain and plot the wavelet synchrosqueezed transform.

```
load multicompsig;  
sig = sig1+sig2;  
[sst,F] = wsst(sig,sampfreq);  
contour(t,F,abs(sst));  
xlabel('Time'); ylabel('Hz');  
grid on;  
title('Synchrosqueezed Transform of Two-Component Signal');
```

Using a penalty of 10, extract the two highest energy modes and plot the result.

```
[fridge,iridge] = wsstridge(sst,10,F,'NumRidges',2);  
hold on;  
plot(t,fridge,'k','linewidth',2);
```

Input Arguments

sst — Synchronsqueezed transform

matrix

Synchronsqueezed transform, specified as a matrix. `sst` is a time-frequency matrix and is the output of `wsst`.

penalty — Frequency bins scaling penalty

0 (default) | nonnegative scalar

Frequency bins scaling penalty, specified as a nonnegative scalar. This input penalizes changes in frequency by multiplying the penalty value by the squared distance between frequency bins. Use a penalty term when you extract multiple ridges, or when you have a single modulated component in additive noise. The penalty term prevents jumps in frequency that occur when the region of highest energy in the time-frequency plane changes abruptly.

f — Synchronsqueezed transform frequencies

vector

Synchronsqueezed transform frequencies corresponding to the rows of the synchronsqueezed transform, which is the vector output of `wsst`. The number of elements in the frequency vector is equal to the number of rows in the `sst` input.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'NumRidges', 3`

NumRidges — Number of highest energy time-frequency ridges

1 (default) | positive integer

Number of highest energy time-frequency ridges to extract, specified as the comma-separated pair consisting of `'NumRidges'` and a positive integer. If this integer is greater than 1, `wsstridge` iteratively determines the maximum energy time-frequency ridge by removing the previously computed ridges and the default or specified `'NumFrequencyBins'` on either side of each ridge bin.

NumFrequencyBins — Number of frequency bins to remove

4 (default) | positive integer

Number of frequency bins to remove from synchrosqueezed transform `sst` when extracting multiple ridges, specified as the comma-separated pair consisting of `'NumFrequencyBins'` and a positive integer. This integer must be less than or equal to $\text{round}(\text{size}(\text{sst}, 1)/4)$. You can specify the number of frequency bins to remove only if you extract more than one ridge. After extracting the highest energy time-frequency ridge, `wsstridge` removes the `sst` values corresponding to the `iridge` indices at each time step. The energy is removed along the time-frequency ridge extended on both sides of the `iridge` index by the specified number of frequency bins. If the index of the extended time-frequency ridge exceeds the number of frequency bins at any time step, `wsstridge` truncates the removal region at the first or last frequency bin. To specify `'NumFrequencyBins'`, you must specify `'NumRidges'`.

Output Arguments

fridge — Time-frequency ridge frequencies

vector or matrix

Time-frequency ridge frequencies, returned as a vector or matrix. The frequencies correspond to the time-frequency ridge at each time step. `fridge` is an N -by- nr matrix where N is the number of time samples (columns) in `sst` and nr is the number of ridges. The first column of the matrix contains the frequencies for the maximum energy time-frequency ridge in `sst`. Subsequent columns contain the frequencies for the time-frequency ridges in decreasing energy order. By default, `fridge` contains frequencies in cycles per sample.

iridge — Time-frequency ridge indices

vector or matrix

Time-frequency ridge row indices of `sst`, returned as a vector or matrix. The row indices in `iridge` correspond to the row index of the maximum time-frequency ridge for each `sst` column. `iridge` is an N -by- nr matrix where N is the number of time samples (columns) in `sst`, and nr is the number of ridges. The first column of the matrix contains the indices for the maximum energy time-frequency ridge in `sst`. Subsequent columns contain the indices for the time-frequency ridges in decreasing energy order.

Algorithms

The function uses a penalized forward-backward greedy algorithm to extract the maximum-energy ridges from a time-frequency matrix. The algorithm finds the maximum time-frequency ridge by minimizing $-\ln A$ at each time point, where A is the absolute value of the matrix. Minimizing $-\ln A$ is equivalent to maximizing the value of A . The algorithm optionally constrains jumps in frequency with a penalty that is proportional to the distance between frequency bins.

The following example illustrates the time-frequency ridge algorithm using a penalty that is two times the distance between frequency bins. Specifically, the distance between the elements (j, k) and (m, n) is defined as $(j - m)^2$. The time-frequency matrix has three frequency bins and three time steps. The matrix columns correspond to time steps, and the matrix rows correspond to frequency bins. The values in the second row represent a sine wave.

- 1 Suppose you have the matrix:

$$\begin{array}{ccc} 1 & 4 & 4 \\ 2 & 2 & 2 \\ 5 & 5 & 4 \end{array}$$

- 2 Update the value for the (1,2) element as follows.

- a Leave the values at the first time point unaltered. Begin the algorithm with the (1,2) element of the matrix, which presents the first frequency bin at the second time point. The bin value is 4. Penalize the values in the first column based on their distance from the (1,2) element. Applying the penalty to the first column produces

original value + penalty \times distance

$$\begin{array}{l} 1 + 2 \times 0 = 1 \\ 2 + 2 \times 1 = 4 \\ 5 + 2 \times 4 = 13 \end{array}$$

$$\begin{array}{cc} 1 & 4 \\ 4 & 2 \\ 13 & 5 \end{array}$$

The minimum value of the first column is 1, which is in bin 1.

- b Add the minimum value in column 1 to the current bin value, 4. The updated value for (1,2) becomes 5, which came from bin 1.
- 3 Update the values for the remaining elements in column 2 as follows.

Recompute the original column 1 values with the penalty factor using the same process as in Step 2a. Obtain the remaining second column values using the same process as in Step 2b. For example, when updating the (2,2) element, which has bin value 2, applying the penalty to the column yields

original value + penalty \times distance

$$\begin{array}{l} 1 + 2 \times 1 = 3 \\ 2 + 2 \times 0 = 2 \\ 5 + 2 \times 1 = 7 \end{array}$$

Add the minimum value, 2, to the current bin value. The updated value for (2,2) becomes 4. After updating the (3,2) element, the matrix is

$$\begin{array}{rcl} 1 & 5_{(1)} & 4 \\ 2 & 4_{(2)} & 2 \\ 5 & 9_{(2)} & 4 \end{array}$$

Only the second column has been updated. The subscripts indicate the index of the bin in the previous column from which a value came.

- 4 Repeat Step 2 for the third column. But now the penalty is applied to the updated second column. For example, when updating the (1,3) element, the penalty is

$$\begin{array}{l} 5 + 2 \times 0 = 5 \\ 4 + 2 \times 1 = 6 \\ 9 + 2 \times 4 = 17 \end{array}$$

The minimum value, 5, which is in the first bin, is added to the (1,3) bin value. After updating all the values in the third column, the final matrix is

$$\begin{array}{rcl} 1 & 5_{(1)} & 9_{(1)} \\ 2 & 4_{(2)} & 6_{(2)} \\ 5 & 9_{(2)} & 10_{(2)} \end{array}$$

- 5 Starting at the last column of the matrix, find the minimum value. Walk back in time through the matrix by going from the current bin to the origin of that bin at the previous time point. Keep track of the bin indices, which form the path composing the ridge. The algorithm smooths the transition by using the origin bin instead of the bin with the minimum value. For this example, the ridge indices are 2, 2, 2, which matches the energy path of the sine wave in row 2 of the matrix shown in Step 1.

If you are extracting multiple ridges, the algorithm removes the first ridge from the time-frequency matrix and repeats the process.

wt

Continuous wavelet transform with filter bank

Syntax

```
cfs = wt(fb,x)
[cfs,f] = wt(fb,x)
[cfs,f,coi] = wt(fb,x)
[cfs,f,coi,scalcf] = wt(fb,x)
[cfs,p] = wt(fb,x)
[cfs,p,coi] = wt(fb,x)
[cfs,p,coi,scalcf] = wt(fb,x)
```

Description

`cfs = wt(fb,x)` returns the continuous wavelet transform (CWT) coefficients of the signal `x`, using `fb`, a CWT filter bank. `x` is a real- or complex-valued vector. `x` must have at least 4 samples. If `x` is real-valued, `cfs` is a 2-D matrix, where each row corresponds to one scale. The column size of `cfs` is equal to the length of `x`. If `x` is complex-valued, `cfs` is a 3-D array, where the first page is the CWT for the positive scales (analytic part or counterclockwise component), and the second page is the cwt for the negative scales (anti-analytic part or clockwise component).

`[cfs,f] = wt(fb,x)` returns the frequencies `f` corresponding to the scales (rows) of `cfs` if the `SamplingPeriod` property is not specified in the CWT filter bank `fb`. If you do not specify a sampling frequency, `f` is in cycles/sample.

`[cfs,f,coi] = wt(fb,x)` returns the cone of influence `coi` for the CWT. `coi` is in the same units as `f`. If the input `x` is complex, the `coi` applies to both pages of `cfs`.

`[cfs,f,coi,scalcf] = wt(fb,x)` returns the scaling coefficients `scalcf` for the wavelet transform. Scaling coefficients are not supported for the bump wavelet.

`[cfs,p] = wt(fb,x)` returns the periods `p` corresponding to the scales (rows) of `cfs` if you specify a sampling period in the CWT filter bank. `p` has the same units and format as the duration scalar `SamplingPeriod`.

`[cfs,p,coi] = wt(fb,x)` returns the cone of influence `coi` in periods for the CWT. `coi` is an array of durations with the same format property as the sampling period. If the input `x` is complex, the `coi` applies to both pages of `cfs`.

`[cfs,p,coi,scalcf] = wt(fb,x)` returns the scaling coefficients `scalcf` for the wavelet transform. Scaling coefficients are not supported for the bump wavelet.

Examples

Continuous Wavelet Transform Using Filter Bank

Load the noisy Doppler signal. Create a CWT filter bank that can be applied to the signal.

```
load noisdopp
fb = cwtfilterbank('SignalLength', numel(noisdopp));
```

Use the filter bank to obtain the continuous wavelet transform of the signal.

```
[cfs,f,coi] = wt(fb,noisdopp);
```

Plot the CWT scalogram, including the cone of influence.

```
t = 0: numel(noisdopp)-1;
pcolor(t,f,abs(cfs))
shading flat
set(gca,'YScale','log')
hold on
plot(t,coi,'w-','LineWidth',3)
xlabel('Time (Samples)')
ylabel('Normalized Frequency (cycles/sample)')
title('Scalogram')
```

Inverse Continuous Wavelet Transform Using Scaling Coefficients

Create and plot a signal sampled at 1000 Hz. Create a CWT filter bank that can be used on the signal. Since the signal is periodic, set the boundary extension property of the filter bank to 'periodic'.

```
Fs = 1000;
t = 0:1/Fs:1-1/Fs;
```

```

sig = 3*sin(2*pi*20*t) + cos(2*pi*2*t);
fb = cwtfilterbank('SignalLength',length(sig),'SamplingFrequency',Fs,'Boundary','periodic');
plot(t,sig)
xlabel('Time (sec)')
title('Signal')

```

Take the CWT of the signal. Return the wavelet and scaling coefficients.

```
[cfs,~,~,scalcfs] = wt(fb,sig);
```

Reconstruct the signal two ways. First use the mean of the signal, then use the scaling coefficients. Plot the difference between the original signal and both reconstructions.

```

xrec0 = icwt(cfs,'SignalMean',mean(sig));
xrec1 = icwt(cfs,'ScalingCoefficients',scalcfs);
plot(t,sig-xrec0)
hold on
plot(t,sig-xrec1)
grid on
legend('Using mean(sig)','Using scalcfs')
title('Difference Between Reconstructions')

```

The scaling coefficients results in a significantly more accurate reconstruction. To investigate the source of the dramatic improvement, create a second signal consisting of the 2 Hz component of the original signal. Compare the scaling coefficients with the 2 Hz signal. The scaling coefficients and 2 Hz signal are virtually identical. Using the scaling coefficients helps with the reconstruction because the 2 Hz component is not representable by a wavelet with this sampling frequency and length.

```
figure
sig2hz = cos(2*pi*2*t);
plot(t,sig2hz)
hold on
plot(t,scalcfs)
grid on
title('Comparing Scaling Coefficients with 2 Hz Component')
xlabel('Time (sec)')
legend('2 Hz Component', 'Scaling Coefficients')
```

Using CWT Filter Bank on Multiple Time Series

This example shows how using a CWT filter bank improves computational efficiency when taking the CWT of multiple time series.

Load the seismograph data recorded during the 1995 Kobe earthquake. The data are seismograph (vertical acceleration, nm/sq.sec) measurements recorded at Tasmania University, Hobart, Australia on 16 January 1995 beginning at 20:56:51 (GMT) and continuing for 51 minutes at 1 second intervals. Create a CWT filter bank that can be applied to the data.

```
load kobe
fb = cwtfilterbank('SignalLength', numel(kobe), 'SamplingFrequency', 1);
```

Use the `cwt` function and take the CWT of the data 250 times. Display the elapsed time used.

```
num = 250;
tic;
for k=1:num
    cfs = cwt(kobe);
end
toc
```

Elapsed time is 6.551628 seconds.

Now use the `wt` object function of the filter bank to take the CWT of the data. Confirm using the filter bank is faster.

```
tic;
for k=1:num
    cfs = wt(fb,kobe);
end
toc
```

Elapsed time is 3.782376 seconds.

Input Arguments

fb — Continuous wavelet transform filter bank

`cwtfilterbank` object

Continuous wavelet transform (CWT) filter bank, specified as a `cwtfilterbank` object.

x — Input signal

real- or complex-valued vector | `gpuArray`

Input signal, specified as a real- or complex-valued vector. `x` must have at least four samples.

Data Types: `double` | `single`

Complex Number Support: Yes

Output Arguments

cfs — Continuous wavelet transform

matrix | 3-D array

Continuous wavelet transform, returned as a matrix or 3-D array of complex values. If `x` is real-valued, `cfs` is a 2-D matrix, where each row corresponds to one scale. The column size of `cfs` is equal to the length of `x`. If `x` is complex-valued, `cfs` is a 3-D array, where the first page is the CWT for the positive scales (analytic part or counterclockwise component), and the second page is the CWT for the negative scales (anti-analytic part or clockwise component).

f — Frequencies

vector

Frequencies, returned as a vector, corresponding to the scales (rows) of `cfs` if the `'SamplingPeriod'` is not specified in `fb`. If you specify a sampling frequency, `f` is in hertz. If you do not specify a frequency, `f` is in cycles/sample.

Data Types: `double`

p — Periods

array

Periods, returned as an array of durations, corresponding to the scales (rows) of `cfs` if `fb` has a specified sampling period. `p` has the same units and format as the duration scalar sampling period.

Data Types: `duration`

coi — Cone of influence

array of real numbers | array of durations

Cone of influence for the CWT, returned as either an array of real numbers or an array of durations. The cone of influence indicates where edge effects occur in the CWT. If you specify a sampling frequency, `coi` is an array of real numbers in the same units as `f`. If you specify a sampling period, `coi` is an array of durations with the same format property as the sampling period. Due to the edge effects, give less credence to areas that are outside or overlap the cone of influence.

For additional information, see “Boundary Effects and the Cone of Influence”.

Data Types: `double` | `duration`

scalcofs — Scaling coefficients

real- or complex-valued vector

Scaling coefficients for the wavelet transform, returned as a vector with the same length as `x`. If `x` is real-valued, `scalcofs` is real valued. If `x` is complex valued, `scalcofs` is complex valued.

Data Types: `double`

Tips

- The first time you use a filter bank to take the CWT of a signal, the wavelet filters are constructed to have the same datatype as the signal. A warning message is generated when you apply the same filter bank to a signal with a different datatype. Changing datatypes comes with the cost of redesigning or changing the precision of the filter bank. For optimal performance, use a consistent datatype.
- When performing multiple CWTs, for example inside a for-loop, the recommended workflow is to first create a `cwtfilterbank` object and then use the `wt` object function. This workflow minimizes overhead and maximizes performance. See “Using CWT Filter Bank on Multiple Time Series” on page 1-1426.

Extended Capabilities**C/C++ Code Generation**

Topics

“Boundary Effects and the Cone of Influence”

Introduced in R2018a

wtbo

WTBO constructor

Syntax

```
OBJ = wtbo  
OBJ = wtbo(USERDATA)
```

Description

OBJ = wtbo returns a WTBO object. Any object in the Wavelet Toolbox software is parented by a WTBO object.

With OBJ = wtbo(USERDATA) you can set a userdata field.

Class WTBO (Parent class: none)

Fields

wtboInfo	Object information (not used in the current version of the toolbox)
ud	Userdata field

Introduced before R2006a

wtbxmngr

Wavelet Toolbox manager

Syntax

```
wtbxmngr(OPTION)
V = wtbxmngr('version')
```

Description

`wtbxmngr` or `wtbxmngr('version')` displays the current version of Wavelet Toolbox software.

`wtbxmngr(OPTION)` sets a toolbox option. Available options are

Option	Description
'LargeFonts'	Sets the size of future-created figures to use large fonts.
'DefaultSize'	Restores the default figure size for future- created figures.
'FigRatio'	Returns the current figure ratio value.
'FigRatio', ratio	Changes the size of future-created figures by multiplying the default size by the specified ratio, where ratio must be between 0.75 and 1.25.

`V = wtbxmngr('version')` saves the current version of the toolbox to variable `V`.

Examples

```
wtbxmngr('version')
```

```
*****
** Wavelet Toolbox Version: V3.1 **
*****
```

```
wtbxmngr('FigRatio')      % Display the current figure ratio
wtbxmng('FigRatio',1.25) % Set the figure ratio to 1.25
wtbxmng('FigRatio')      % Display the current figure ratio
wtbxmng('DefaultSize')   % Return to the default figure ratio
```

Introduced before R2006a

wthcoef

1-D wavelet coefficient thresholding

Syntax

```
NC = wthcoef('d',C,L,N,P)
NC = wthcoef('d',C,L,N)
NC = wthcoef('a',C,L)
NC = wthcoef('t',C,L,N,T,SORH)
```

Description

wthcoef thresholds wavelet coefficients for the denoising or compression of a 1-D signal.

`NC = wthcoef('d',C,L,N,P)` returns coefficients obtained from the wavelet decomposition structure `[C,L]` (see `wavedec` for more information), by rate compression defined in vectors `N` and `P`. `N` contains the detail levels to be compressed and `P` the corresponding percentages of lower coefficients to be set to zero. `N` and `P` must be of same length. Vector `N` must be such that $1 \leq N(i) \leq \text{length}(L) - 2$.

`NC = wthcoef('d',C,L,N)` returns coefficients obtained from `[C,L]` by setting all the coefficients of detail levels defined in `N` to zero.

`NC = wthcoef('a',C,L)` returns coefficients obtained by setting approximation coefficients to zero.

`NC = wthcoef('t',C,L,N,T,SORH)` returns coefficients obtained from the wavelet decomposition structure `[C,L]` by soft (if `SORH = 's'`) or hard (if `SORH = 'h'`) thresholding (see `wthresh` for more information) defined in vectors `N` and `T`. `N` contains the detail levels to be thresholded and `T` the corresponding thresholds. `N` and `T` must be of the same length.

`[NC,L]` is the modified wavelet decomposition structure.

wavedec | wthresh

Introduced before R2006a

wthcoef2

Wavelet coefficient thresholding 2-D

Syntax

`NC = wthcoef2('type',C,S,N,T,SORH)`

`NC = wthcoef2('type',C,S,N)`

`NC = wthcoef2('a',C,S)`

`NC = wthcoef2('t',C,S,N,T,SORH)`

Description

`wthcoef2` is a two-dimensional de-noising and compression oriented function.

For `'type' = 'h'` (`'v'` or `'d'`), `NC = wthcoef2('type',C,S,N,T,SORH)` returns the horizontal (vertical or diagonal, respectively) coefficients obtained from the wavelet decomposition structure `[C,S]` (see `wavedec2` for more information), by soft (if `SORH = 's'`) or hard (if `SORH = 'h'`) thresholding defined in vectors `N` and `T`. `N` contains the detail levels to be thresholded and `T` the corresponding thresholds. `N` and `T` must be of the same length. The vector `N` must be such that $1 \leq N(i) \leq \text{size}(S,1)-2$.

For `'type' = 'h'` (`'v'` or `'d'`), `NC = wthcoef2('type',C,S,N)` returns the horizontal (vertical or diagonal, respectively) coefficients obtained from `[C,S]` by setting all the coefficients of detail levels defined in `N` to zero.

`NC = wthcoef2('a',C,S)` returns the coefficients obtained by setting approximation coefficients to zero.

`NC = wthcoef2('t',C,S,N,T,SORH)` returns the detail coefficients obtained from the wavelet decomposition structure `[C,S]` by soft (if `SORH = 's'`) or hard (if `SORH = 'h'`) thresholding (see `wthresh` for more information) defined in vectors `N` and `T`. `N` contains the detail levels to be thresholded and `T` the corresponding thresholds which are applied in the three detail orientations. `N` and `T` must be of the same length.

`[NC,S]` is the modified wavelet decomposition structure.

`wavedec2` | `wthresh`

Introduced before R2006a

wthresh

Soft or hard thresholding

Syntax

```
Y = wthresh(X, sorh, T)
```

Description

`Y = wthresh(X, sorh, T)` returns the soft or hard thresholding, indicated by `sorh`, of the vector or matrix `X`. `T` is the threshold value.

Examples

Hard and Soft Thresholding

Generate a signal and set a threshold.

```
y = linspace(-1,1,100);  
thr = 0.4;
```

Perform hard and soft thresholding.

```
ythard = wthresh(y, 'h', thr);  
ytsoft = wthresh(y, 's', thr);
```

Plot the results and compare with the original signal.

```
subplot(1,3,1)  
plot(y,y)  
ylim([-1 1])  
title('Original Signal')  
subplot(1,3,2)  
plot(y,ythard)  
ylim([-1 1])  
title('Hard Threshold')  
subplot(1,3,3)  
plot(y,ytsoft)  
ylim([-1 1])  
title('Soft Threshold')
```

Input Arguments

X — Input data

real-valued vector or matrix

Input data to threshold, specified as a real-valued vector or matrix.

Data Types: `double`

sorh — Type of thresholding

's' | 'h'

Type of thresholding to perform:

- 's' — Soft thresholding
- 'h' — Hard thresholding

T — Threshold value

positive real number

Threshold value, specified as a positive real number.

Output Arguments

Y — Thresholded data

real-valued vector or matrix

Thresholded data, returned as a real-valued vector or matrix. Y has the same dimensions as X.

Algorithms

If `sorh` is 's', Y is the soft thresholding of X: $Y = \text{sign}(X) \cdot (|X| - T)_+$ where

$$(x)_+ = \begin{cases} x & \text{if } x \geq 0 \\ 0 & \text{otherwise} \end{cases}$$

Soft thresholding is wavelet shrinkage.

If `sorh` is 'h', Y is the hard thresholding of X: $Y = X \cdot \mathbf{1}_{(|X| > T)}$ where

$$\mathbf{1}_{(|X| > T)} = \begin{cases} 1 & \text{if } |X| > T \\ 0 & \text{otherwise} \end{cases}$$

Hard thresholding is cruder than soft thresholding.

Apps

Wavelet Signal Denoiser

Introduced before R2006a

wthrmngr

Threshold settings manager

Syntax

```
thr = wthrmngr(opt,method,C,L)
thr = wthrmngr(opt,method,C,L,alpha)
thr = wthrmngr(opt,method,C,L,scale)

thr = wthrmngr(opt,method,swtdec,alpha)
thr = wthrmngr(opt,method,swtdec,scale)

thr = wthrmngr(opt,method,wpt)
thr = wthrmngr(opt,'rem_n0',X)
```

Description

`wthrmngr` returns a global threshold or level-dependent thresholds for wavelet-based denoising and compression. The function derives thresholds from the wavelet coefficients in a wavelet decomposition.

The thresholds are used by Wavelet Toolbox denoising and compression tools, such as command-line functions and the **Wavelet Analyzer** app.

`thr = wthrmngr(opt,method,C,L)` returns the threshold for the $[C,L]$ wavelet decomposition of the signal or image to compress or denoise. For signals, $[C,L]$ is the output of `wavedec`. For images, $[C,L]$ is the output of `wavedec2`.

`thr = wthrmngr(opt,method,C,L,alpha)` returns the $[C,L]$ wavelet decomposition threshold using the sparsity parameter `alpha`. For signals, $[C,L]$ is the output of `wavedec`. For images, $[C,L]$ is the output of `wavedec2`.

To learn more about `alpha`, see `wdcbm` or `wdcbm2` for compression, and `wbmpen` for denoising.

`thr = wthrmngr(opt,method,C,L,scale)` returns the $[C,L]$ wavelet decomposition threshold using the type of multiplicative threshold rescaling specified in `scale`. For signals, $[C,L]$ is the output of `wavedec`. For images, $[C,L]$ is the output of `wavedec2`.

The `'rigrsure'`, `'heursure'`, and `'minimaxi'` denoising methods are only applicable to signals.

To learn more about multiplicative threshold rescaling, see `wden`.

`thr = wthrmngr(opt,method,swtdec,alpha)` returns the level-dependent threshold for the stationary wavelet decomposition, `swtdec`, of the signal or image to denoise. `alpha` specifies the sparsity parameter (see `wbmpen`). For signals, `swtdec` is the output of `swt`. For images, `swtdec` is the output of `swt2`.

Thresholds are derived from a subset of the coefficients in the stationary wavelet decomposition. For more information, see “Coefficient Selection” on page 1-1457.

`thr = wthrmngr(opt,method,swtdec,scale)` returns the level-dependent threshold for the stationary wavelet decomposition using the type of multiplicative threshold rescaling specified in `scale`. For signals, `swtdec` is the output of `swt`. For images, `swtdec` is the output of `swt2`.

Thresholds are derived from a subset of the coefficients in the stationary wavelet decomposition. For more information, see “Coefficient Selection” on page 1-1457.

The `'rigrsure'`, `'heursure'`, and `'minimaxi'` denoising methods apply only to signals.

To learn more about multiplicative threshold rescaling, see `wden`.

`thr = wthrmngr(opt,method,wpt)` returns the global threshold for the wavelet packet decomposition, `wpt`, of the signal or image to compress or denoise.

`thr = wthrmngr(opt,'rem_n0',X)` returns the global threshold to compress the signal or image, `X`, using the specified wavelet option and method `'rem_n0'`.

If `opt` is `'dw1dcompGBL'` or `'dw2dcompGBL'`, thresholds are based on the finest-scale wavelet coefficients obtained using the Haar wavelet. If `opt` is `'wp1dcompGBL'` or `'wp2dcompGBL'`, thresholds are based on the finest-scale wavelet packet coefficients obtained using the Haar wavelet.

Examples

Global Threshold — Discrete Wavelet Decomposition

Load and plot a noisy signal.

```
load noisdopp
plot(noisdopp)
grid on
title('Noisy Signal')
```

Generate a level 5 wavelet decomposition of the noisy signal using the order 4 Daubechies wavelet. Plot the coefficients.

```
[c,l] = wavedec(noisdopp,5,'db4');  
plot(c)  
grid on  
title('Wavelet Coefficients')
```

Determine a global threshold for compressing the signal.

```
thr = wthrmngr('dwtlcompGBL','bal_sn',c,l);
```

The index of the first wavelet detail coefficient in c is $l(1)+1$. Apply the threshold to all the detail coefficients. Plot the thresholded coefficients. Observe that most of the coefficients have been set to 0.

```
c(l(1)+1:end) = c(l(1)+1:end).*(c(l(1)+1:end)>thr);  
plot(c)  
grid on  
title('Thresholded Coefficients')
```

Reconstruct the signal from the thresholded coefficients. Plot the reconstruction.

```
xrec = waverec(c,l,'db4');  
plot(xrec)  
grid on  
title('Compressed Signal')
```

Image Compression — Birgé-Massart Thresholds

Compress an image using the Birgé-Massart strategy.

Load an image and add white Gaussian noise. For purposes of reproducibility, set the random seed to the default value.

```
rng default
load sinsin
x = X+18*randn(size(X));
```

Obtain the 2-D discrete wavelet transform down to level 3 using the Daubechies least-asymmetric wavelet with 4 vanishing moments. Obtain the compression thresholds using the Birgé-Massart strategy with sparsity parameter, α , equal to 2.

```
[C,L] = wavedec2(x,3,'sym4');
alpha = 2;
THR = wthrmngr('dw2dcomplVL','scarcehi',C,L,alpha);
```

Compress the image and display the result.

```
xd = wdencomp('lvd',x,'sym4',3,THR,'s');
image(X)
title('Original Image')
```

```
figure  
image(x)  
title('Noisy Image')
```

```
figure  
image(xd)  
title('Compressed Image')
```

Level-Dependent Threshold – Stationary Wavelet Transform

This example uses a level-dependent threshold derived from the wavelet coefficients at each scale to implement hard thresholding with the stationary wavelet transform.

Load the noisy blocks signal. Obtain the stationary wavelet transform down to level 5 by using the Haar wavelet.

```
load noisbloc
L = 5;
swc = swt(noisbloc,L,'haar');
```

Make a copy of the wavelet transform coefficients. Determine the Donoho-Johnstone universal threshold based on the detail coefficients for each scale. Using the 'mln' option, wthrmngr returns a 1-by-L vector, with every element equal to the universal threshold for the corresponding scale.

```
swcnew = swc;
ThreshML = wthrmngr('swlddenoLVL','sqrtwolog',swc,'mln');
```

Use the universal thresholds to implement hard thresholding. The thresholds are applied in a scale-dependent manner.

```
for jj = 1:L
    swcnew(jj,:) = wthresh(swc(jj,:), 'h',ThreshML(jj));
end
```

Invert the stationary wavelet transform on the thresholded coefficients, `swcnew`. Plot the original signal and the denoised signal for comparison.

```
noisbloc_denoised = iswt(swcnew, 'haar');  
plot(noisbloc)  
hold on  
plot(noisbloc_denoised, 'r', 'linewidth', 2)  
legend('Original', 'Denoised')
```

Global Threshold — Wavelet Packet Decomposition

Denoise a noisy signal by applying a global threshold to a wavelet packet decomposition structure.

Load and plot a noisy signal.

```
load noisdopp  
plot(noisdopp)  
grid on  
title('Noisy Signal')
```

Generate a level 3 wavelet packet decomposition of the noisy signal using the order 4 Daubechies wavelet.

```
T = wpdec(noisdopp,3,'db4');
```

Determine a global threshold for denoising the signal.

```
thr = wthrmngr('wplddenoGBL','sqrtwologuwn',T);
```

Obtain the leaves from the wavelet packet decomposition tree T and apply the threshold to the leaves. Use hard thresholding.

```
T1 = T;
sorrh = 'h';
cfs = read(T,'data');
cfs = wthresh(cfs,sorrh,thr);
T1 = write(T1,'data',cfs);
```

Reconstruct the denoised signal from the thresholded coefficients. Plot the reconstruction.

```
xrec = wprec(T1);
plot(xrec)
grid on
title('Denoised Signal')
```

Level-Independent Threshold – Stationary Wavelet Transform

This example uses a level-independent threshold based on the finest-scale wavelet coefficients to implement hard thresholding with the stationary wavelet transform.

Load the noisy blocks signal. Obtain the stationary wavelet transform down to level 5 by using the Haar wavelet.

```
load noisbloc
L = 5;
swc = swt(noisbloc,L,'haar');
```

Make a copy of the wavelet transform coefficients. Determine the Donoho-Johnstone universal threshold based on the first-level detail coefficients. Using the 'sln' option, `wthrmngr` returns a 1-by-L vector, with every element equal to the same value. Take the mean of the vector to obtain a scalar threshold.

```
swcnew = swc;
ThreshSL = mean(wthrmngr('swlddenoLVL','sqrtwolog',swc,'sln'));
```

Use the universal threshold to implement hard thresholding. The same threshold is applied to the wavelet coefficients at every level.

```

for jj = 1:L
    swcnew(jj,:) = wthresh(swc(jj,:), 'h', ThreshSL);
end

```

Invert the stationary wavelet transform on the thresholded coefficients, `swcnew`. Plot the original signal and the denoised signal for comparison.

```

noisbloc_denoised = iswt(swcnew, 'haar');
plot(noisbloc)
hold on
plot(noisbloc_denoised, 'r', 'linewidth', 2)
legend('Original', 'Denoised')

```

Input Arguments

opt — Type and dimension of compression or denoising

'dw1dcompGBL' | 'dw1dcompLVL' | 'dw1ddenoLVL' | 'sw1ddenoLVL' | 'dw2dcompGBL' |
'dw2dcompLVL' | ...

Type and dimension of compression or denoising, specified as one of the values listed in the tables that follow. `wthrmngr` returns thresholds appropriate for the option you specify.

With a discrete wavelet or wavelet packet decomposition of the data, you can compress or denoise that data. With a stationary wavelet decomposition of the data, you can only denoise the data.

For an explanation of which coefficients are used to determine the thresholds, see “Coefficient Selection” on page 1-1457.

1-D Discrete Wavelet Decomposition Options

In these options, *X* is the signal, the wavelet coefficients are in the vector *C*, and the lengths of the coefficient vectors are in *L*. The argument *alpha* is the sparsity parameter, and *scale* defines the multiplicative threshold rescaling.

For additional information regarding the wavelet decomposition, see `wavedec`. To learn more about *alpha* and *scale*, see `wdcbm` and `wden` respectively.

opt	Description	Valid Syntaxes
'dw1dcompGB L'	1-D compression using a global threshold	<ul style="list-style-type: none"> • <code>thr = wthrmngr('dw1dcompGBL','rem_n0',X)</code> • <code>thr = wthrmngr('dw1dcompGBL','bal_sn',C,L)</code>
'dw1dcompLV L'	1-D compression using level-dependent thresholds	<ul style="list-style-type: none"> • <code>thr = wthrmngr('dw1dcompLVL','scarcehi',C,L,alpha)</code>, where $2.5 < \alpha < 10$ • <code>thr = wthrmngr('dw1dcompLVL','scarceme',C,L,alpha)</code>, where $1.5 < \alpha < 2.5$ • <code>thr = wthrmngr('dw1dcompLVL','scarcelo',C,L,alpha)</code>, where $1 < \alpha < 2$
'dw1ddenoLV L'	1-D denoising using level-dependent thresholds	<ul style="list-style-type: none"> • <code>thr = wthrmngr('dw1ddenoLVL','sqrtwolog',C,L,scale)</code> • <code>thr = wthrmngr('dw1ddenoLVL','rigrsure',C,L,scale)</code> • <code>thr = wthrmngr('dw1ddenoLVL','heursure',C,L,scale)</code> • <code>thr = wthrmngr('dw1ddenoLVL','minimaxi',C,L,scale)</code> • <code>thr = wthrmngr('dw1ddenoLVL','penalhi',C,L,alpha)</code>, where $2.5 < \alpha < 10$ • <code>thr = wthrmngr('dw1ddenoLVL','penalme',C,L,alpha)</code>, where $1.5 < \alpha < 2.5$ • <code>thr = wthrmngr('dw1ddenoLVL','penallo',C,L,alpha)</code>, where $1 < \alpha < 2$

2-D Discrete Wavelet Decomposition Options

In these options, X is the data, the wavelet coefficients are in the vector C , and the size of the coefficient matrices are in L . The argument α is the sparsity parameter, and $scale$ defines the multiplicative threshold rescaling.

For additional information regarding the wavelet decomposition, see `wavedec2`. To learn more about α and $scale$, see `wdcbm2` and `wden` respectively.

opt	Description	Valid Syntaxes

1-D Stationary Wavelet Decomposition Options

Denoising using level-dependent thresholds is the only option available for a 1-D stationary wavelet decomposition, `swtdec`. In this option, `alpha` is a sparsity parameter and `scale` defines the multiplicative threshold rescaling.

For more information regarding the stationary wavelet decomposition, see `swt`. To learn more about `alpha` and `scale`, see `wbmpen` and `wden` respectively.

opt	Valid Syntaxes
'sw1ddenoLVL'	<ul style="list-style-type: none"> • thr = wthrmngr('sw1ddenoLVL','sqrtwolog',swtdec,scale) • thr = wthrmngr('sw1ddenoLVL','rigrsure',swtdec,scale) • thr = wthrmngr('sw1ddenoLVL','heursure',swtdec,scale) • thr = wthrmngr('sw1ddenoLVL','minimaxi',swtdec,scale) • thr = wthrmngr('sw1ddenoLVL','penalhi',swtdec,alpha), where $2.5 < \alpha < 10$ • thr = wthrmngr('sw1ddenoLVL','penalme',swtdec,alpha), where $1.5 < \alpha < 2.6$ • thr = wthrmngr('sw1ddenoLVL','penallo',swtdec,alpha), where $1 < \alpha < 2$

Thresholds are based on a subset of the coefficients in the stationary wavelet decomposition. See “Coefficient Selection” on page 1-1457 for additional information.

2-D Stationary Wavelet Decomposition Options

Denosing using level-dependent thresholds is the only option available for a 2-D stationary wavelet decomposition, swtdec. In this option, alpha is a sparsity parameter and scale defines the multiplicative threshold rescaling.

For more information regarding the stationary wavelet decomposition, see swt2. To learn more about alpha and scale, see wbmpen and wden respectively.

opt	Valid Syntaxes
'sw2ddenoLVL'	<ul style="list-style-type: none"> • thr = wthrmngr('sw2ddenoLVL','sqrtbal_sn',swtdec) • thr = wthrmngr('sw2ddenoLVL','penalhi',swtdec,alpha) where $2.5 < \alpha < 10$ • thr = wthrmngr('sw2ddenoLVL','penalme',swtdec,alpha) where $1.5 < \alpha < 2.5$ • thr = wthrmngr('sw2ddenoLVL','penallo',swtdec,alpha) where $1 < \alpha < 2$ • thr = wthrmngr('sw2ddenoLVL','sqrtwolog',swtdec,scale)

Thresholds are based on a subset of the coefficients in the stationary wavelet decomposition. See “Coefficient Selection” on page 1-1457 for additional information.

method — Thresholding method

'scarcehi' | 'scarceme' | 'scarcelo' | 'sqtwolog' | 'sqtwologuwn' | 'sqtwologswn' | ...

Thresholding method, specified as one of the values listed here.

method	Description
'scarcehi'	Uses Birgé-Massart strategy on page 1-1457 for determining thresholds.
'scarceme'	Uses Birgé-Massart strategy for determining thresholds.
'scarcelo'	Uses Birgé-Massart strategy for determining thresholds.
'sqtwolog'	Uses fixed-form universal threshold. See 'sqtwolog' option in wden.
'sqtwologuwn'	Uses fixed-form universal threshold. See 'sqtwolog' option in wden when used with 'sln' option.
'sqtwologswn'	Uses fixed-form universal threshold. See 'sqtwolog' option in wden when used with 'mln' option.
'rigsure'	Uses soft threshold estimator rule based on Stein's Unbiased Estimate of Risk. See 'SURE' option in wdenoise.
'heursure'	Uses mixture of 'rigsure' and 'sqtwolog'. See 'heursure' option in wden.
'minimaxi'	Uses a fixed threshold chosen which yields minimax performance. See 'Minimax' option in wdenoise.
'penalhi'	Used to define Birgé-Massart strategy on page 1-1457 for determining thresholds.
'penalme'	Used to define Birgé-Massart strategy for determining thresholds.
'penallo'	Used to define Birgé-Massart strategy for determining thresholds.
'rem_n0'	Returns a threshold close to 0. A typical THR value is <code>median(abs(coefficients))</code> .
'bal_sn'	Returns a threshold such that the percentages of retained energy and number of zeros are the same.
'sqrtbal_sn'	Returns a threshold equal to the square root of the value such that the percentages of retained energy and number of zeros are the same.

Data Types: char

X — Input data

real-valued vector | real-valued matrix

Input data, specified as a real-valued vector or real-valued matrix.

Data Types: double

C — Wavelet expansion coefficients

real-valued vector

Wavelet expansion coefficients of the data to be compressed or denoised, specified as a real-valued vector. If the data is one-dimensional, C is the output of `wavedec`. If the data is two-dimensional, C is the output of `wavedec2`.

Example: `[C,L] = wavedec(randn(1,1024),3,'db4')`

Data Types: `double`

L — Size of wavelet expansion coefficients

vector of positive integers | matrix of positive integers

Size of wavelet expansion coefficients of the signal or image to be compressed or denoised, specified as a vector or matrix of positive integers.

For signals, L is the output of `wavedec`. For images, L is the output of `wavedec2`.

Example: `[C,L] = wavedec(randn(1,1024),3,'db4')`

Data Types: `double`

alpha — Sparsity parameter

positive scalar

Sparsity parameter used for compressing or denoising data, specified as a positive scalar greater than 1 and less than 10. See `wdcbm`, `wdcbm2`, and `wbopen` for additional information.

Data Types: `double`

scale — Multiplicative threshold rescaling

'one' | 'sln' | 'mln'

Multiplicative threshold rescaling, specified as one of the following:

- 'one' — No rescaling
- 'sln' — Rescaling using a single estimation of level noise based on first-level coefficients
- 'mln' — Rescaling using a level-dependent estimation of level noise

For more information, see `wden`.

swtdec — Stationary wavelet decomposition structure

real-valued matrix

Stationary wavelet decomposition structure of data to be compressed or denoised, specified as a real-valued matrix. If the data is one-dimensional, `swtdec` is the output of `swt`. If the data is two-dimensional, `swtdec` is the output of `swt2`.

Example: `swtdec = swt2(randn(256),3,'db1')`

Data Types: `double`

wpt — Wavelet packet decomposition structure

wavelet packet object structure

Wavelet packet decomposition structure of the data to be compressed or denoised. If the data is one-dimensional, `wpt` is the output of `wpdec`. If the data is two-dimensional, `wpt` is the output of `wpdec2`.

Example: `wpt = wpdec(randn(1,1024),5,'db1')`

Output Arguments

thr — Threshold

real-valued scalar | real-valued vector | real-valued matrix

Threshold, returned as a real-valued scalar for global thresholds, or a real-valued vector or matrix for level-dependent thresholds.

Data Types: `double`

Tips

- To denoise 1-D signals, consider using the **Wavelet Signal Denoiser**. The app visualizes and denoises real-valued 1-D signals using default parameters. You can also compare results. In addition, you can also recreate the denoised signal in your workspace by generating a MATLAB script, which uses the `wdenoise` function.

Algorithms

Coefficient Selection

A critically sampled wavelet or wavelet packet decomposition involves decimating coefficients by a factor of 2 at each stage of the decomposition. Decimation does not occur in the nondecimated stationary wavelet decomposition.

`wthrmngr` derives denoising and compression thresholds from the wavelet coefficients. For a critically sampled wavelet or wavelet packet decomposition, the option and method determine whether all wavelet coefficients or only the finest scale coefficients are used.

For the stationary wavelet decomposition, `wthrmngr` always uses a subset of the wavelet coefficients. When computing the denoising thresholds of an N -level stationary wavelet decomposition, the algorithm first subsamples the wavelet coefficients at level k by a factor of 2^k , for $k = 1, \dots, N$. The algorithm uses this subset of coefficients to determine the thresholds. Most of the coefficients in the stationary wavelet decomposition are not considered.

Birgé-Massart Strategy

The Birgé-Massart strategy for determining thresholds depends on several different parameters. You specify the wavelet decomposition and a thresholding method. You can also specify a sparsity parameter, `alpha`, or a specific multiplicative threshold rescaling, `scale`. Based on your inputs, `wthrmngr` derives the necessary Birgé-Massart parameters. The parameters depend on the dimension of the signal, and the total number, N , of coefficients at the coarsest scale of wavelet decomposition.

If the thresholding method is `'scarcehi'`, `'scarceme'`, or `'scarcelo'`, the `wthrmngr` executes either `wdcbm` or `wdcbm2`. If the thresholding method is `'penalhi'`, `'penalme'`, or `'penallo'`, then `wthrmngr` executes either `wbmpen` or `wpbmpen`.

Thresholding Method	Description
<code>'scarcehi'</code>	<ul style="list-style-type: none"> If the signal is 1-D, then <code>wdcbm</code> is used with input argument $M = N$. If the signal is 2-D, then <code>wdcbm2</code> is used with $M = 4*N$.

Thresholding Method	Description
'scarceme'	<ul style="list-style-type: none"> If the signal is 1-D, then <code>wdcbm</code> is used with input argument $M = 3*N/2$. If the signal is 2-D, then <code>wdcbm2</code> is used with input argument with $M = 16*N/3$.
'scarcelo'	<ul style="list-style-type: none"> If the signal is 1-D, then <code>wdcbm</code> is used with input argument $M = 2 N$. If the signal is 2-D, then <code>wdcbm2</code> is used with input argument $M = 32*N/3$.
'penalhi'	<ul style="list-style-type: none"> If the input is a wavelet decomposition, then <code>wbmpen</code> is used with $ALPHA = 5*(3*\alpha+1)/8$. If the input is a wavelet packet decomposition, then <code>wpbmpen</code> is used $ALPHA = 6.25$.
'penalme'	<ul style="list-style-type: none"> If the input is a wavelet decomposition, then <code>wbmpen</code> is used with $ALPHA = (\alpha+5)/8$. If the input is a wavelet packet decomposition, then <code>wpbmpen</code> is used $ALPHA = 2$.
'penallo'	<ul style="list-style-type: none"> If the input is a wavelet decomposition, then <code>wbmpen</code> is used with $ALPHA = (\alpha+3)/4$. If the input is a wavelet packet decomposition, then <code>wpbmpen</code> is used $ALPHA = 1.5$.

Wavelet Signal Denoiser

Functions

`wbmpen` | `wdcbm` | `wdcbm2` | `wdenoise` | `wpbmpen`

Introduced before R2006a

wtmm

Wavelet transform modulus maxima

Syntax

```
hexp = wtmm(x)
[hexp,tauq] = wtmm(x)
[ ___ ] = wtmm(x,'MinRegressionScale',scale)
[hexp,tauq,structfunc] = wtmm( ___ )

[localhexp,wt,wavscscales] = wtmm(x,'ScalingExponent','local')

wtmm( ___ , 'ScalingExponent', 'local')

[ ___ ] = wtmm( ___ ,Name,Value)
```

Description

`hexp = wtmm(x)` returns an estimate of the global Holder exponent, `hexp`, for the real-valued, 1-D input signal, `x`. The global and local Holder exponents are estimated for the linearly-spaced moments of the structure functions from -2 to +2 in 0.1 increments.

`[hexp,tauq] = wtmm(x)` also returns an estimate of the partition function scaling exponents, `tauq`.

`[___] = wtmm(x,'MinRegressionScale',scale)` uses only scales greater than or equal to `scale` to estimate the global Holder exponent. This syntax can include any of the output arguments used in previous syntaxes.

`[hexp,tauq,structfunc] = wtmm(___)` also returns the multiresolution structure functions, `structfunc`, for the global Holder exponent estimate. This syntax can include any of the input arguments used in previous syntaxes.

`[localhexp,wt,wavscscales] = wtmm(x,'ScalingExponent','local')` returns the local Holder exponent estimates, the continuous wavelet transform `wt`, and the scales, `wavscscales`, which are used to calculate the CWT used in the `wtmm` algorithm. The wavelet used in the CWT is the second derivative of a Gaussian.

`wtmm(___ , 'ScalingExponent', 'local')` with no output arguments plots the wavelet maxima lines in the current figure. Estimates of the local Holder exponents are displayed in a table to the right of the plot.

`[___] = wtmm(___ ,Name,Value)` returns the Holder exponent and other specified outputs with additional options specified by one or more `Name, Value` pair arguments.

Examples

Global Holder Exponent for Brownian Motion

Estimate the global Holder exponent for Brownian motion. This monofractal signal has a Holder exponent of approximately 0.5.

```
rng(100);  
x = cumsum(randn(2^15,1));  
hexp = wtmm(x)  
  
hexp = 0.5010
```

Linearity of Scaling Exponents for Monofractal Signal

Confirm that for a monofractal signal, the scaling exponents are a linear function of the moments. For multifractal signals, the exponents are a nonlinear function of the moments.

Load a signal that contains two time series, each with 8000 samples. Ts1 is a multifractal signal and Ts2 is a monofractal fractional Brownian signal. Obtain the exponents using wtmm.

```
load RWdata;  
[hexp1,tauq1] = wtmm(Ts1);  
[hexp2,tauq2] = wtmm(Ts2);
```

Plot the scaling exponents.

```
expplot = plot(-2:0.1:2,tauq2,'b-o',-2:0.1:2,tauq1,'r-^');  
grid on;  
expplot(1).MarkerFaceColor = 'b';  
expplot(2).MarkerFaceColor = 'r';  
legend('Ts2-Monofractal','Ts1-Multifractal','Location','SouthEast');  
title('Monofractal vs. Multifractal Scaling Exponents');  
xlabel('Qth Moment');  
ylabel('Scaling Exponents');
```

Ts2, which is the monofractal signal, is a linear function. Ts1, the multifractal signal, is not linear.

Structure Function of Wavelet Transform Modulus Maxima

Use the structure function output of wtmm to analyze a Brownian motion signal.

Create fractional Brownian motion with a Holder exponent of 0.6.

```
Brn = wfbm(0.6,2^15);
[hexp,tauq,structfunc] = wtmm(Brn);
```

Compare the calculated Holder exponent with the theoretical value of 0.6.

```
hexp
```

```
hexp = 0.6072
```

Use the data in the structfunc output and the lscov function to perform the regression on the data.

```
x = ones(length(structfunc.logscases),2);
x(:,2) = structfunc.logscases;
betahat = lscov(x,structfunc.Tq,structfunc.weights);
betahat = betahat(2,:);
```

Plot and compare the scaling exponents from the tauq output and from the regressed structure function output.

```
subplot(1,2,1)
plot(-2:.1:2,tauq)
grid on
title('From tauq Output')
xlabel('Qth Moment')
ylabel('Scaling Exponents')

subplot(1,2,2)
plot(-2:.1:2,betahat(1:41))
grid on
title('From structfunc Output')
xlabel('Qth Moment')
```

The plots are the same and show a linear relationship between the moments and the exponents. Therefore, the signal is monofractal. The Holder exponent returned in hexp is the slope of this line.

Local Holder Exponents for Cusp Signal and Delta Functions

Using a cusp signal and a signal containing delta functions, generate their local Holder exponents.

Cusp Signal

Load and plot a cusp signal. Note the difference between the two cusps.

```
load cusp;
plot(cusp)
grid on
xlabel('Sample')
ylabel('Amplitude')
```

The equation for this cusp signal specifies a Holder exponent of 0.5 at sample 241 and a Holder exponent of 0.3 at sample 803.

$$-0.2 * \text{abs}(x-241)^{0.5} - 0.5 * \text{abs}(x-803)^{0.3} + 0.00346 * x + 1.34$$

Obtain the local Holder exponents and plot the modulus maxima.

```
wtmm(cusp, 'ScalingExponent', 'local');
```

The Holder exponents at samples 241 and 803 are very close to the values specified in the cusp signal equation. The higher Holder value at sample 241 indicates that the signal at that point is closer to being differentiable than the signal at sample 803, which has a smaller Holder value.

Delta Functions

Create and plot two delta functions.

```
x = zeros(1e3,1);
x([200 500]) = 1;
plot(x)
grid on
xlabel('Sample')
ylabel('Amplitude')
```

Obtain the local Holder exponents using the default number of octaves, which in this case is 7. Plot the modulus maxima. A delta function has a Holder exponent of -1.

```
wtmm(x, 'ScalingExponent', 'local');
```

Obtain the local Holder exponents using 5 octaves and compare the modulus maxima plot to the plot using the default number of octaves.

```
wtmm(x, 'ScalingExponent', 'local', 'NumOctaves', 5);
```

Reducing the number of scales provides more separation in frequency and less overlap between the modulus maxima lines of the delta functions.

Input Arguments

x – Input signal

real-valued vector

Input signal, specified as a real-valued vector with a minimum of 128 samples. The wavelet transform modulus maxima technique works best for data with 8000 or more samples.

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: 'VoicesPerOctave', 18 estimates the global Holder estimate using 18 voices per octave.

MinRegressionScale — Minimum scale for regression

4 (default) | scalar greater than or equal to 4

Minimum scale for regression, specified as the comma-separated pair consisting of 'MinRegressionScale' and a scalar greater than or equal to 4. This scale is the smallest scale used by the regression. There must be at least two scales with more than 6 CWT maxima. 'MinRegressionScale' applies only to global Holder exponents.

VoicesPerOctave — Number of voices per octave

10 (default) | even integer from 8 to 32

Number of voices per octave, specified as the comma-separated pair consisting of 'VoicesPerOctave' and an even integer from 8 to 32. The number of voices per octave and the number of octaves determine the number of scales used in the CWT.

NumOctaves — Number of octavesminimum of 7 and $\text{floor}(\log_2(\text{numel}(x)/(3*\text{sqrt}(1.1666))))$ (default) | integer greater than or equal to 4

Number of octaves, specified as the comma-separated pair consisting of 'NumOctaves' and an integer. The number of octaves and the number of voices per octave determine the number of scales used in the CWT. The maximum number of octaves is less than or equal to $\text{floor}(\log_2(\text{numel}(x)/(3*\text{sqrt}(1.1666))))$. The $\text{sqrt}(1.1666)$ factor is the standard deviation of the second derivative of a Gaussian wavelet. If you specify the number of octaves as greater than the maximum number of octaves, `wttm` uses the maximum supported number of octaves.

ScalingExponent — Type of scaling exponents

'global' (default) | 'local'

Type of scaling exponents, specified as a comma-separated pair consisting of 'ScalingExponent' and either 'global' or 'local'. A global Holder exponent is used for monofractal signals, such as white noise, which are singular everywhere. Global holder exponents give a single estimate of degree of these singularities over the whole signal. Local Holder exponents are useful for signals with cusp singularities.

Output Arguments**hexp — Global Holder exponent**

real scalar

Global Holder exponent, returned as a real scalar. Holder exponents are useful for identifying singularities, which are locations where a signal is not differentiable. A global Holder exponent uses a single value to estimate the degree of differentiability of all of the singularities of a signal. Signals with a global Holder exponent are monofractal signals.

tauq — Scaling exponents

column vector

Scaling exponents, returned as a column vector. The exponents are estimated for the linearly-spaced moments of the structure functions from -2 to +2 in 0.1 increments.

structfunc — Multiresolution structure functions

struct

Multiresolution structure functions for the global Holder exponent estimates, returned as a `struct`. The structure function for data `x` is defined as

$$S(q, a) = \frac{1}{n_a} \sum_{k=1}^{n_a} |T_x(a, k)|^q \approx a^{\zeta(q)},$$

where a is the scale, q is the moment, T_x is the maxima at each scale, n_a is the number of maxima at each scale, and $\zeta(q)$ is the scaling exponent. `structfunc` is a structure array containing the following fields:

- `Tq` — Measurements of the input, `x`, at various scales. `Tq` is a matrix of multiresolution quantities that depend jointly on time and scale. Scaling phenomena in `x` imply a power-law relationship between the moments of `Tq` and the scale. `Tq` is an N_s -by-44 matrix, where N_s is the number of scales. The first 41 columns of `Tq` contain the scaling exponent estimates for each of the q th from -2:0.1:2, by scale. The last three columns correspond to the first-order, second-order, and third-order cumulants, respectively, by scale. For a monofractal signal, cumulants greater than the first cumulant are zero.
- `weights` — Weights used in the regression estimates. The weights correspond to the number of wavelet maxima at each scale. `weights` is an N_s -by-1 vector.
- `logscals` — Scales used as predictors in the regression. `logscals` is an N_s -by-1 vector with the base-2 logarithm of the scales.

localhexp — Local Holder exponent estimates

array of real values

Local Holder exponent estimates, returned as an M -by-2 array of real values, where M is the number of maxima. If no maxima lines converge to the finest scale in the wavelet transform, then `localhexp` is an empty array. The wavelet transform modulus maxima method (WTMM) identifies cusp-like singularities in a signal. To analyze multifractal signals, use `dwtleader`.

wt — Continuous wavelet transform

matrix

Continuous wavelet transform, returned as a matrix of real values. `wt` is a `numel(wavscals)`-by- N matrix where N is the length of the input signal `x`.

wavscals — Wavelet scales

column vector

Wavelet scales, returned as a column vector of real values. `wavscals` are the scales used to calculate the CWT.

Algorithms

The WTMM algorithm finds singularities in a signal by determining maxima. The algorithm first calculates the continuous wavelet transform using the second derivative of a Gaussian wavelet with 10 voices per octave. The wavelet that meets this criteria is the Mexican hat, or Ricker, wavelet. Then, the algorithm determines the modulus maxima for each scale. The WTMM is intended to be used with large data sets so that enough samples are available to determine maxima accurately.

The definition of the modulus maximum at point x_0 and scale s_0 is

$$|Wf(s_0, x)| < |Wf(s_0, x_0)|$$

where x is either in the right or left neighborhood of x_0 . When x is in the opposite neighborhood of x_0 , the definition is

$$|Wf(s_0, x)| \leq |Wf(s_0, x_0)|$$

. The algorithm for finding additional maxima repeats for values in that scale. Then, the algorithm continues up through finer scales, checking whether the maxima align between scales. If a maximum converges to the finest scale, it is a true maximum and indicates a singularity at that point.

When each singularity is determined, the algorithm then estimates its Holder exponent. Holder exponents indicate the degree of differentiability for each singularity, which classifies the singularity strength. A Holder exponent less than or equal to 0 indicates a discontinuity at that location. Holder exponents greater than or equal to 1 indicate that the signal is differentiable at that location. Holder values between 0 and 1 indicate continuous, but not differentiable locations. They indicate how close the signal at that sample is to being differentiable. Holder exponents close to 0 indicate signal locations that are less differentiable than locations with exponents closer to 1. The signal is smoother at locations with higher local Holder exponents.

For signals with a few cusp-like singularities and Holder exponents that have large variation, you set the algorithm to return local Holder exponents, which provide individual values for each singularity. For signals with numerous Holder exponents that have relatively small variations, you set the algorithm to return a global Holder exponent. A global Holder exponent applies to the whole signal. For signals with many singularities, you can reduce the number of maxima found by limiting the algorithm to start at or regress to a specific minimum or maximum scale, respectively. For detailed information about the WTMM, see [1] and [3].

Introduced in R2016b

wtreemgr

NTREE manager

Syntax

Description

wtreemgr is a tree management utility.

This function returns information on the tree T depending on the value of the OPT parameter.

Allowed values for OPT are listed in the table below.

'allnodes'	Tree nodes
'isnode'	True for existing node
'istnode'	True for terminal nodes
'nodeasc'	Node ascendants
'nodedesc'	Node descendants
'nodepar'	Node parent
'ntnode'	Number of terminal nodes
'tnodes'	Terminal nodes
'leaves'	Terminal nodes
'noleaves'	Not terminal nodes
'order'	Tree order
'depth'	Tree depth

Introduced before R2006a

wvarchg

Find variance change points

Syntax

```
[chgpts,kopt,est] = wvarchg(Y)
[ ___ ] = wvarchg(Y,K)
[ ___ ] = wvarchg(Y,K,D)
```

Description

`[chgpts,kopt,est] = wvarchg(Y)` computes estimated variation change points for the signal `Y` for six change points, where the minimum delay between two change points is 10.

`[___] = wvarchg(Y,K)` computes estimated variation change points for `j` change points, where `j = 0, 1, 2, ..., K`, and the minimum delay between two change points is 10.

`[___] = wvarchg(Y,K,D)` computes estimated variation change points where the minimum delay between two change points is `D`.

- `wvarchg(Y,6,10)` is equivalent to `wvarchg(Y)`.
- `wvarchg(Y,K,10)` is equivalent to `wvarchg(Y,K)`.

Examples

Detect Variance Change Points

For reproducibility, set the random seed to the default value. Load the `blocks` wavelet test signal. Add white noise with two variance change points located at indices 180 and 600. Plot the noise and the noisy signal.

```
rng default
x = wnoise(1,10);
cp1 = 180;
cp2 = 600;
bb = 1.5*randn(1,length(x));
seg1 = bb(1:cp1);
seg2 = bb(cp1+1:cp2)/4;
seg3 = bb(cp2+1:end);
wn = [seg1 seg2 seg3];
x = x+wn;
subplot(2,1,1)
plot(wn)
title('Noise')
subplot(2,1,2)
plot(x)
title('Noisy Signal')
```

Use the db3 wavelet and do a level-1 wavelet decomposition of the signal. Reconstruct the detail coefficients. Replace the top 2% of values with the mean value of the wavelet coefficients to remove most of the signal. Plot the values.

```
wname = 'db3';
lev = 1;
[c,l] = wavedec(x,lev,wname);
det = wrcoef('d',c,l,wname,1);
y = sort(abs(det));
v2p100 = y(fix(length(y)*0.98));
ind = find(abs(det)>v2p100);
det(ind) = mean(det);
figure
plot(det)
title('Reconstructed Details')
```

Estimate the variance change points using the wavelet coefficients.

```
[pts_opt,kopt,t_est] = wvarchg(det,5);  
fprintf('The estimated change points are %d and %d.',pts_opt)
```

The estimated change points are 181 and 601.

Input Arguments

Y — Input signal

real-valued vector

Input signal, specified as a real-valued vector. The input signal Y should have zero mean.

Data Types: double

K — Number of change points

6 (default) | positive integer

Number of change points, specified as an integer. K satisfies the inequalities $1 < K \ll \text{length}(Y)$.

Data Types: double

D — Minimum delay

10 (default) | positive integer

Number of change points, specified as an integer. D satisfies the inequalities $1 \leq D \ll \text{length}(Y)$.

Data Types: double

Output Arguments

chgpts — Estimated variance change points

vector

Estimated variance change points, returned as a vector. `chgpts` is the empty vector `[]` when no change points are found.

kopt — Proposed number of change points

nonnegative integer

Proposed number of change points, returned as a nonnegative integer in the interval $[0, k]$.

est — Instants of the variation change points

real-valued matrix

Instants of the variation change points, returned as a real-valued matrix. For $1 \leq k \leq K$, `est(k+1, 1:k)` contains the k instants of the variance change points. If `kopt > 0`, then `chgpts = est(kopt+1, 1:kopt)`, else `chgpts = []`.

wvd

Wigner-Ville distribution and smoothed pseudo Wigner-Ville distribution

Syntax

```
d = wvd(x)
d = wvd(x,fs)
d = wvd(x,ts)

d = wvd( ____, 'smoothedPseudo' )
d = wvd( ____, 'smoothedPseudo',twin,fwin)
d = wvd( ____, 'smoothedPseudo',Name,Value)

d = wvd( ____, 'MinThreshold',thresh)

[d,f,t] = wvd( ____)

wvd( ____)
```

Description

`d = wvd(x)` returns the Wigner-Ville distribution of `x`.

`d = wvd(x,fs)` returns the Wigner-Ville distribution when `x` is sampled at a rate `fs`.

`d = wvd(x,ts)` returns the Wigner-Ville distribution when `x` is sampled with a time interval `ts` between samples.

`d = wvd(____, 'smoothedPseudo')` returns the smoothed pseudo Wigner-Ville distribution of `x`. The function uses the length of the input signal to choose the lengths of the windows used for time and frequency smoothing. This syntax can include any combination of input arguments from previous syntaxes.

`d = wvd(____, 'smoothedPseudo',twin,fwin)` specifies the time window, `twin`, and the frequency window, `fwin`, used for smoothing. To use the default window for either time or frequency smoothing, specify the corresponding argument as empty, `[]`.

`d = wvd(____, 'smoothedPseudo',Name,Value)` specifies additional options for the smoothed pseudo Wigner-Ville distribution using name-value pair arguments. You can specify `twin` and `fwin` in this syntax, or you can omit them.

`d = wvd(____, 'MinThreshold',thresh)` sets to zero those elements of `d` whose amplitude is less than `thresh`. This syntax applies to both the Wigner-Ville distribution and the smoothed pseudo Wigner-Ville distribution.

`[d,f,t] = wvd(____)` also returns a vector of frequencies, `f`, and a vector of times, `t`, at which `d` is computed.

`wvd(____)` with no output arguments plots the Wigner-Ville or smoothed pseudo Wigner-Ville distribution in the current figure.

Examples

Wigner-Ville Distribution of Impulse and Tone

Generate a 1000-sample impulse and a 1000-sample tone with normalized frequency $\pi/2$. Compute the Wigner-Ville distribution of the sum of the two signals.

```
x = zeros(1001,1);  
x(500) = 10;  
  
y = sin(pi*(0:1000)/2)';  
  
[d,f,t] = wvd(x+y);
```

Plot the Wigner-Ville distribution.

```
imagesc(t,f,d)  
axis xy  
colorbar
```

Reproduce the result by calling `wvd` with no output arguments.

```
wvd(x+y)
```

Wigner-Ville Distribution of Sinusoids

Generate a signal consisting of a 200 Hz sinusoid sampled at 1 kHz for 1.5 seconds.

```
fs = 1000;  
t = (0:1/fs:1.5)';  
x = cos(2*pi*t*200);
```

Compute the Wigner-Ville distribution of the signal.

```
wvd(x, fs)
```

Add to the signal a chirp whose frequency varies sinusoidally between 250 Hz and 450 Hz. Convert the signal to a MATLAB® timetable. Compute the Wigner-Ville distribution.

```
x = x + vco(cos(2*pi*t),[250 450],fs);  
xt = timetable(seconds(t),x);
```

```
wvd(xt)
```

Set to zero the distribution elements with amplitude less than 0.

```
wvd(xt, 'MinThreshold', 0)
```

Wigner-Ville Distribution of Chirps

Generate a signal sampled at 1 kHz for 1 second. One component of the signal is a chirp that increases in frequency quadratically from 100 Hz to 400 Hz during the measurement. The other component of the signal is a chirp that decreases in frequency linearly from 350 Hz to 50 Hz in the same lapse.

Store the signal in a timetable.

```
fs = 1000;
t = 0:1/fs:1;
```

```
x = chirp(t,100,1,400,'quadratic') + chirp(t,350,1,50);
```

Compute the Wigner-Ville distribution of the signal.

```
wvd(x, fs)
```

Compute the smoothed pseudo Wigner-Ville distribution of the signal. Specify 501 frequency points and 502 time points.

```
wvd(x, fs, 'smoothedPseudo', 'NumFrequencyPoints', 501, 'NumTimePoints', 502)
```

Increase the number of time points so the quadratic chirp becomes visible.

```
wvd(x, fs, 'smoothedPseudo', 'NumFrequencyPoints', 501, 'NumTimePoints', 522)
```

Increase the frequency points and time points to get a sharper image.

```
wvd(x, fs, 'smoothedPseudo', 'NumFrequencyPoints', 1000, 'NumTimePoints', 1502)
```

Smoothed Pseudo Wigner-Ville Distribution of Complex Signal

Generate a two-component signal sampled at 3 kHz for 1 second. The first component is a quadratic chirp whose frequency increases from 300 Hz to 1300 Hz during the measurement. The second component is a chirp with sinusoidally varying frequency content. The signal is embedded in white Gaussian noise. Express the time between consecutive samples as a `duration` scalar.

```
fs = 3000;
t = 0:1/fs:1-1/fs;
dt = seconds(t(2)-t(1));

x1 = chirp(t,300,t(end),1300,'quadratic');
x2 = exp(2j*pi*100*cos(2*pi*2*t));

x = x1 + x2 + randn(size(t))/10;
```

Compute and plot the smoothed pseudo Wigner Ville of the signal. Window the distribution in time using a 601-sample Hamming window and in frequency using a 305-sample rectangular window. Use 600 frequency points for the display. Set to zero those components of the distribution with amplitude less than -50 .

```
wvd(x,dt,'smoothedPseudo',hamming(601),rectwin(305), ...
    'NumFrequencyPoints',600,'MinThreshold',-50)
```

Interference Terms

Generate a signal composed of four Gaussian atoms. Each atom consists of a sinusoid modulated by a Gaussian. The sinusoids have frequencies of 100 Hz and 400 Hz. The Gaussians are centered at 150 milliseconds and 350 milliseconds and have a variance of 0.01^2 . All atoms have unit amplitude. The signal is sampled at 1 kHz for half a second.

```
fs = 1000;
t = (0:1/fs:0.5)';

f1 = 100;
f2 = 400;

mu1 = 0.15;
mu2 = 0.35;

gaussFun = @(A,x,mu,f) exp(-(x-mu).^2/(2*0.01^2)).*sin(2*pi*f.*x)*A';
s = gaussFun([1 1 1 1],t,[mu1 mu1 mu2 mu2],[f1 f2 f1 f2]);

Compute and display the Wigner-Ville distribution of the signal. Interference terms, which can have negative values, appear halfway between each pair of auto-terms.

wvd(s,fs)
```

Compute and display the smoothed pseudo Wigner-Ville distribution of the signal. Smoothing in time and frequency attenuates the interference terms.

```
wvd(s, fs, 'SmoothedPseudo')
```

Input Arguments

x — Input signal

vector | timetable

Input signal, specified as a vector or a MATLAB timetable containing a single vector variable.

- If **x** is a timetable, then it must contain increasing finite row times.
- If a timetable has missing or duplicate time points, you can fix it using the tips in “Clean Timetable with Missing, Duplicate, or Nonuniform Times” (MATLAB).

If the input signal has odd length, the function appends a zero to make the length even.

Example: `cos(pi/8*(0:159))'+randn(160,1)/10` specifies a sinusoid embedded in white noise.

Example: `timetable(seconds(0:5)', rand(6,1))` specifies a random variable sampled at 1 Hz for 5 seconds.

Data Types: `single` | `double`

Complex Number Support: Yes

fs — Sample rate

2π (default) | positive numeric scalar

Sample rate, specified as a positive numeric scalar.

ts — Sample time

duration scalar

Sample time, specified as a duration scalar.

twin, fwin — Time and frequency windows

vectors of odd length

Time and frequency windows used for smoothing, specified as vectors of odd length. By default, `wvd` uses Kaiser windows with shape factor $\beta = 20$.

- The default length of `twin` is the smallest odd integer greater than or equal to `round(length(x)/10)`.
- The default length of `fwin` is the smallest odd integer greater than or equal to $nf/4$, where `nf` is specified using `NumFrequencyPoints`.

Each window must have a length smaller than or equal to `2*ceil(length(x)/2)`.

Example: `kaiser(65,0.5)` specifies a 65-sample Kaiser window with a shape factor of 0.5.

thresh — Minimum nonzero value

-Inf (default) | real scalar

Minimum nonzero value, specified as a real scalar. The function sets to zero those elements of `d` whose amplitudes are less than `thresh`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'NumFrequencyPoints', 201, 'NumTimePoints', 300` computes the Wigner-Ville distribution at 201 frequency points and 300 time points.

NumFrequencyPoints — Number of frequency points`2*ceil(length(x)/2)` (default) | integer

Number of frequency points, specified as the comma-separated pair consisting of `'NumFrequencyPoints'` and an integer. This argument controls the degree of oversampling in frequency. The number of frequency points must be at least $(\text{length}(\text{fwin})+1)/2$ and cannot be greater than the default.

NumTimePoints — Number of time points`4*ceil(length(x)/2)` (default) | even integer

Number of time points, specified as the comma-separated pair consisting of `'NumTimePoints'` and an even integer. This argument controls the degree of oversampling in time [3] (Signal Processing Toolbox). The number of time points must be at least $2*\text{length}(\text{twin})$ and cannot be greater than the default.

Tip If the input signal is large, reduce the number of time points to lower the memory requirements and speed up the computation.

Output Arguments

d — Wigner-Ville distribution

matrix

Wigner-Ville distribution, returned as a matrix. Time increases across the columns of **d**, and frequency increases down the rows. The matrix is of size $N_f \times N_t$, where N_f is the length of **f** and N_t is the length of **t**.

f — Frequencies

vector

Frequencies, returned as a vector.

- If the input has time information, then **f** contains frequencies expressed in Hz.
- If the input does not have time information, then **f** contains normalized frequencies expressed in rad/sample.

t — Time instants

vector

Time instants, returned as a vector.

- If the input has time information, then **t** contains time values expressed in seconds.
- If the input does not have time information, then **t** contains sample numbers.

More About

Wigner-Ville Distribution

The Wigner-Ville distribution provides a high-resolution time-frequency representation of a signal. The distribution has applications in signal visualization, detection, and estimation.

For a continuous signal $x(t)$, the Wigner-Ville distribution is defined as

$$\text{WVD}_x(t, f) = \int_{-\infty}^{\infty} x\left(t + \frac{\tau}{2}\right) x^*\left(t - \frac{\tau}{2}\right) e^{-j2\pi f \tau} d\tau.$$

For a discrete signal with N samples, the distribution becomes

$$\text{WVD}_x(n, k) = \sum_{m=-N}^N x(n + m/2) x^*(n - m/2) e^{-j2\pi km/N}.$$

For odd values of m , the definition requires evaluation of the signal at half-integer sample values. It therefore requires interpolation, which makes it necessary to zero-pad the discrete Fourier transform to avoid aliasing.

The Wigner-Ville distribution contains interference terms that often complicate its interpretation. To sharpen the distribution, one can filter the definition with lowpass windows. The smoothed pseudo Wigner-Ville distribution uses independent windows to smooth in time and frequency:

$$\text{SPWVD}_x^{g, H}(t, f) = \int_{-\infty}^{\infty} g(t) H(f) x\left(t + \frac{\tau}{2}\right) x^*\left(t - \frac{\tau}{2}\right) e^{-j2\pi f \tau} d\tau.$$

Functions

xwvd

Topics

"Time-Frequency Gallery"

Introduced in R2018b

xwvd

Cross Wigner-Ville distribution and cross smoothed pseudo Wigner-Ville distribution

Syntax

```
d = xwvd(x,y)
d = xwvd(x,y,fs)
d = xwvd(x,y,ts)

d = xwvd( ____, 'smoothedPseudo' )
d = xwvd( ____, 'smoothedPseudo', twin, fwin)
d = xwvd( ____, 'smoothedPseudo', 'NumFrequencyPoints', nf)

d = xwvd( ____, 'MinThreshold', thresh)

[d,f,t] = xwvd( ____ )

xwvd( ____ )
```

Description

`d = xwvd(x,y)` returns the cross Wigner-Ville distribution of `x` and `y`.

`d = xwvd(x,y,fs)` returns the cross Wigner-Ville distribution when `x` and `y` are sampled at a rate `fs`.

`d = xwvd(x,y,ts)` returns the cross Wigner-Ville distribution when `x` and `y` are sampled with a time interval `ts` between samples.

`d = xwvd(____, 'smoothedPseudo')` returns the cross smoothed pseudo Wigner-Ville distribution of `x` and `y`. The function uses the length of the input signals to choose the lengths of the windows used for time and frequency smoothing. This syntax can include any combination of input arguments from previous syntaxes.

`d = xwvd(____, 'smoothedPseudo', twin, fwin)` specifies the time window, `twin`, and the frequency window, `fwin`, used for smoothing. To use the default window for either time or frequency smoothing, specify the corresponding argument as empty, `[]`.

`d = xwvd(____, 'smoothedPseudo', 'NumFrequencyPoints', nf)` computes the cross smoothed pseudo Wigner-Ville distribution using `nf` frequency points. You can specify `twin` and `fwin` in this syntax, or you can omit them.

`d = xwvd(____, 'MinThreshold', thresh)` sets to zero those elements of `d` whose amplitude is less than `thresh`. This syntax applies to both the cross Wigner-Ville distribution and the cross smoothed pseudo Wigner-Ville distribution.

`[d,f,t] = xwvd(____)` also returns a vector of frequencies, `f`, and a vector of times, `t`, at which `d` is computed.

`xwvd(____)` with no output arguments plots the real part of the cross Wigner-Ville or cross smoothed pseudo Wigner-Ville distribution in the current figure.

Examples

Cross Wigner-Ville Distribution of Signals

Generate two signals sampled at 1 kHz for 1 second and embedded in white noise. One signal is a sinusoid of frequency 150 Hz. The other signal is a chirp whose frequency varies sinusoidally between 200 Hz and 400 Hz. The noise has a variance of 0.1^2 .

```
fs = 1000;
t = (0:1/fs:1)';
```

```
x = cos(2*pi*t*150) + 0.1*randn(size(t));
y = vco(cos(3*pi*t), [200 400], fs) + 0.1*randn(size(t));
```

Compute the Wigner-Ville distribution of the sum of the signals.

```
wvd(x+y, fs)
```

Compute and plot the cross Wigner-Ville distribution of the signals. The cross-distribution corresponds to the cross-terms of the Wigner-Ville distribution.

```
xwvd(x, y, fs)
```

Cross Wigner-Ville Distribution of Chirps

Generate a two-channel signal that consists of two chirps. The signal is sampled at 3 kHz for one second. The first chirp has an initial frequency of 400 Hz and reaches 800 Hz at the end of the sampling. The second chirp starts at 500 Hz and reaches 1000 Hz at the end. The second chirp has twice the amplitude of the first chirp.

```
fs = 3000;
t = (0:1/fs:1-1/fs)';

x1 = chirp(t,1400,t(end),800);
x2 = 2*chirp(t,200,t(end),1000);
```

Store the signal as a timetable. Compute and plot the cross Wigner-Ville distribution of the two channels.

```
xt = timetable(seconds(t),x1,x2);
xwvd(xt(:,1),xt(:,2))
```

Use Cross Wigner-Ville Distribution to Estimate Instantaneous Frequency

Compute the instantaneous frequency of a signal by using a known reference signal and the cross Wigner-Ville distribution.

Create a reference signal consisting of a Gaussian atom sampled at 1 kHz for 1 second. A Gaussian atom is a sinusoid modulated by a Gaussian. Specify a sinusoid frequency of 50 Hz. The Gaussian is centered at 64 milliseconds and has a variance of 0.01^2 .

```
fs = 1e3;
t = (0:1/fs:1-1/fs)';
```

```
mu = 0.064;
sigma = 0.01;
fsin = 50;
```

```
xr = exp(-(t-mu).^2/(2*sigma^2)).*sin(2*pi*fsin*t);
```

Create the "unknown" signal to analyze, consisting of a chirp. The signal starts suddenly at 0.4 second and ends suddenly half a second later. In that lapse, the frequency of the chirp decreases linearly from 400 Hz to 100 Hz.

```
f0 = 400;
f1 = 100;
```

```

xa = zeros(size(t));
xa(t>0.4 & t<=0.9) = chirp((0:1/fs:0.5-1/fs)',f0,0.5,f1);

```

Create a two-component signal consisting of the sum of the unknown and reference signals. The smoothed pseudo Wigner-Ville distribution of the result provides an "ideal" time-frequency representation.

Compute and display the smoothed pseudo Wigner-Ville distribution.

```

w = wvd(xa+xr,fs,'smoothedPseudo');
wvd(xa+xr,fs,'smoothedPseudo')

```

Compute the cross Wigner-Ville distribution of the unknown and reference signals. Take the absolute value of the distribution and set to zero the elements with amplitude less than 10. The cross Wigner-Ville distribution is equal to the cross-terms of the two-component signal.

Plot the real part of the cross Wigner-Ville distribution.

```

[c,fc,tc] = xwvd(xa,xr,fs);
c = abs(c);
c(c<10) = 0;

xwvd(xa,xr,fs)

```

Enhance the Wigner-Ville cross-terms by adding the ideal time-frequency representation to the cross Wigner-Ville distribution. The cross-terms of the Wigner-Ville distribution occur halfway between the reference signal and the unknown signal.

```
d = w + c;
```

```
d = abs(real(d));
```

```
imagesc(tc,fc,d)
```

```
axis xy
```

```
colorbar
```

Identify and plot the high-energy ridge corresponding to the cross-terms. To isolate the ridge, find the time values where the cross-distribution has nonzero energy.

```
ff = tfridge(c,fc);  
  
tv = sum(c)>0;  
  
ff = ff(tv);  
tc = tc(tv);  
  
hold on  
plot(tc,ff,'r--','linewidth',2)  
hold off
```

Reconstruct the instantaneous frequency of the unknown signal by using the ridge and the reference function. Plot the instantaneous frequency as a function of time.

```
tEst = 2*tc - mu;  
fEst = 2*ff - fsin;
```

```
plot(tEst, fEst)
```

Input Arguments

x, y — Input signals

vectors | timetables

Input signals, specified as vectors or MATLAB timetables each containing a single vector variable. *x* and *y* must both be vectors or both be timetables and must have the same length.

- If *x* and *y* are timetables, then they must contain increasing finite row times.
- If a timetable has missing or duplicate time points, you can fix it using the tips in “Clean Timetable with Missing, Duplicate, or Nonuniform Times” (MATLAB).

If the input signals have odd length, the function appends a zero to make the length even.

Example: `cos(pi/8*(0:159))'+randn(160,1)/10` specifies a sinusoid embedded in white noise.

Example: `timetable(seconds(0:5)',rand(6,1))` specifies a random variable sampled at 1 Hz for 4 seconds.

Data Types: `single` | `double`

Complex Number Support: Yes

fs — Sample rate

`2*pi` (default) | positive numeric scalar

Sample rate, specified as a positive numeric scalar.

ts — Sample time

duration scalar

Sample time, specified as a duration scalar.

twin, fwin — Time and frequency windows

vectors of odd length

Time and frequency windows used for smoothing, specified as vectors of odd length. By default, `xwvd` uses Kaiser windows with shape factor $\beta = 20$.

- The default length of `twin` is the smallest odd integer greater than or equal to `round(length(x)/10)`.
- The default length of `fwin` is the smallest odd integer greater than or equal to `nf/4`.

Each window must have a length smaller than or equal to `2*ceil(length(x)/2)`.

Example: `kaiser(65,0.5)` specifies a 65-sample Kaiser window with a shape factor of 0.5.

nf — Number of frequency points`2*ceil(length(x)/2)` (default) | integer

Number of frequency points, specified as an integer. This argument controls the degree of oversampling in frequency. The number of frequency points must be at least `(length(fwin)+1)/2` and cannot be greater than the default.

thresh — Minimum nonzero value

-Inf (default) | real scalar

Minimum nonzero value, specified as a real scalar. The function sets to zero those elements of `d` whose amplitudes are less than `thresh`.

Output Arguments**d — Cross Wigner-Ville distribution**

matrix

Cross Wigner-Ville distribution, returned as a matrix. Time increases across the columns of `d`, and frequency increases down the rows. The matrix is of size $N_f \times N_t$, where N_f is the length of `f` and N_t is the length of `t`.

f — Frequencies

vector

Frequencies, returned as a vector.

- If the input has time information, then `f` contains frequencies expressed in Hz.
- If the input does not have time information, then `f` contains normalized frequencies expressed in rad/sample.

t — Time instants

vector

Time instants, returned as a vector.

- If the input has time information, then `t` contains time values expressed in seconds.
- If the input does not have time information, then `t` contains sample numbers.

The number of time points is fixed as $4 \cdot \text{ceil}(\text{length}(x)/2)$.

More About

Cross Wigner-Ville Distribution

For continuous signals $x(t)$ and $y(t)$, the *cross Wigner-Ville distribution* is defined as

$$\text{XWVD}_{x,y}(t, f) = \int_{-\infty}^{\infty} x\left(t + \frac{\tau}{2}\right) y^*\left(t - \frac{\tau}{2}\right) e^{-j2\pi f \tau} d\tau.$$

For a discrete signal with N samples, the distribution becomes

$$\text{XWVD}_{x,y}(n, k) = \sum_{m=-N}^N x(n + m/2) y^*(n - m/2) e^{-j2\pi km/N}.$$

For odd values of m , the definition requires evaluation of the signal at half-integer sample values. It therefore requires interpolation, which makes it necessary to zero-pad the discrete Fourier transform to avoid aliasing.

The cross Wigner-Ville distribution contains interference terms that often complicate its interpretation. To sharpen the distribution, one can filter the definition with lowpass windows. The cross smoothed pseudo Wigner-Ville distribution uses independent windows to smooth in time and frequency:

$$\text{XSPWVD}_{x,y}^{g,H}(t, f) = \int_{-\infty}^{\infty} g(t) H(f) x\left(t + \frac{\tau}{2}\right) y^*\left(t - \frac{\tau}{2}\right) e^{-j2\pi f \tau} d\tau.$$

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Arguments specified using name value pairs must be compile time constants.
