Apps

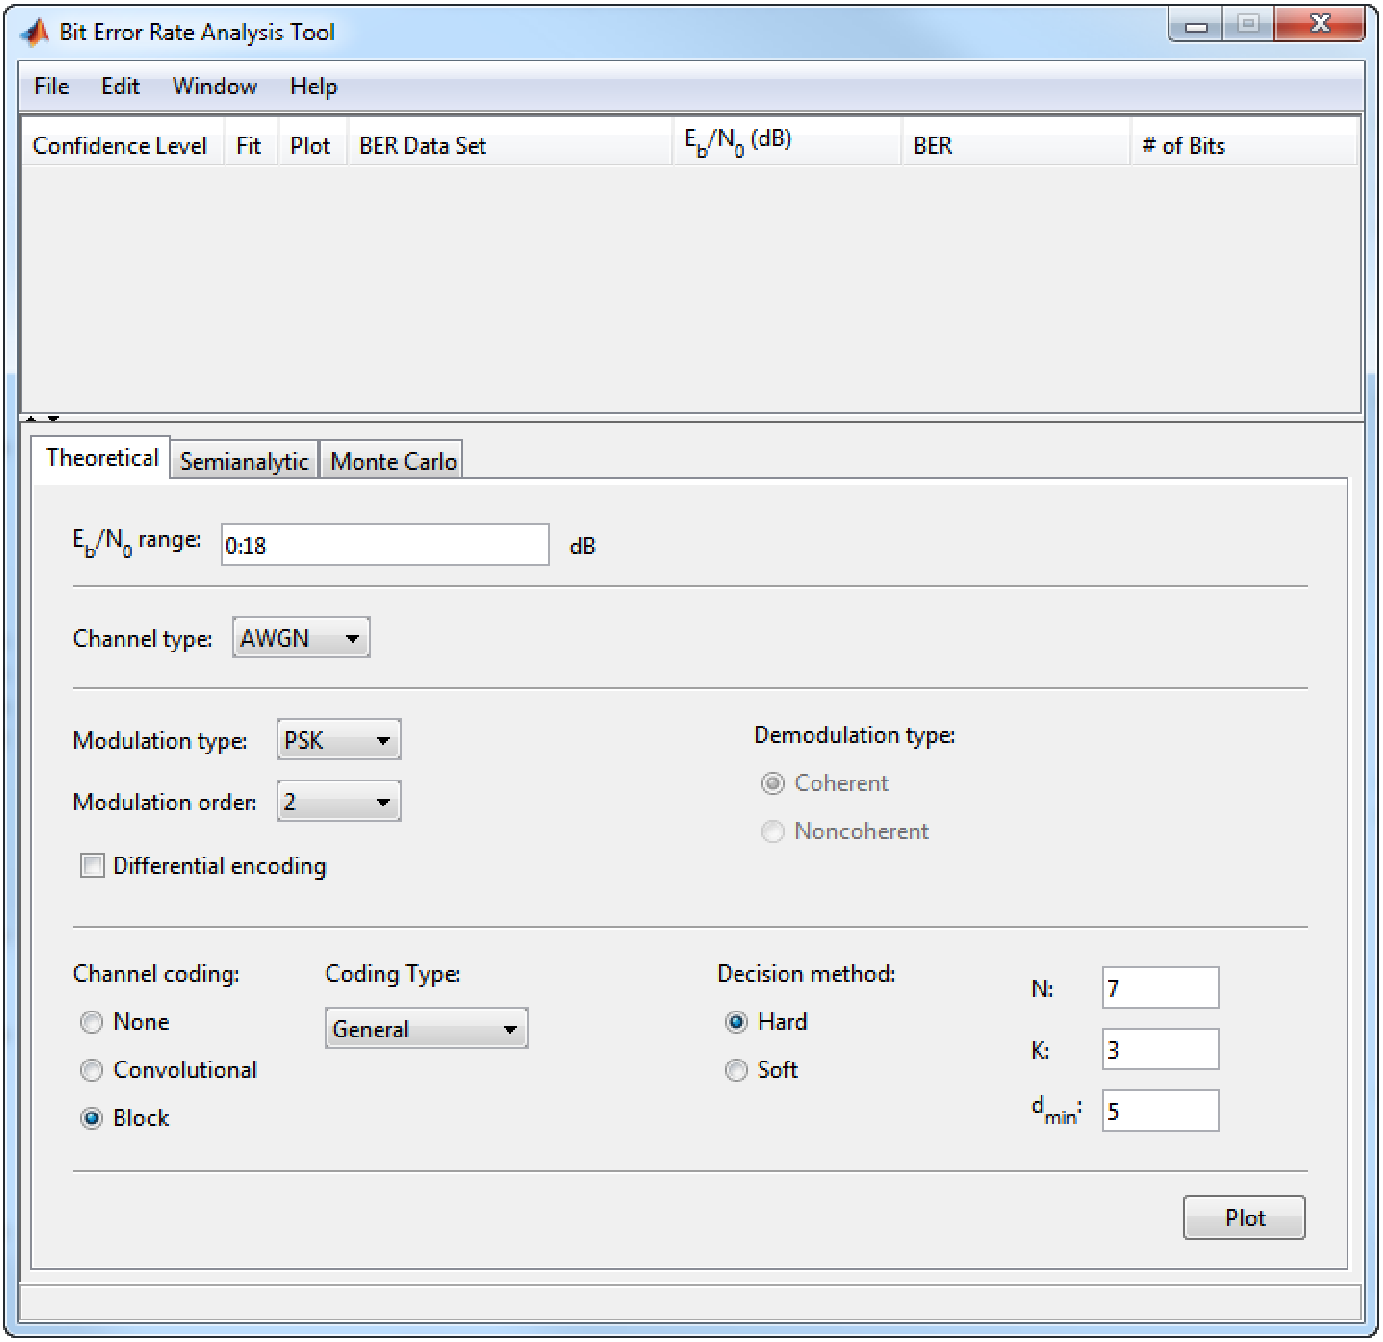
BER Analyzer

Analyze bit error rate (BER) performance of communications systems

Description

The **BER Analyzer** app calculates BER as a function of the energy per bit to noise power spectral density ratio (E_b/N_0). Using this app, you can:

- Plot theoretical BER vs. E_b/N_0 estimates and upper bounds.
- Plot BER vs. E_b/N_0 using the semianalytic technique. The semianalytic technique estimates BER performance by using a combination of simulation and analysis. Use this technique when the system error rate is small, for example, $< 10^{-6}$.
- Estimate BER performance by using MATLAB® functions or Simulink® models.



E_b/N_0 range: 0:18 dB

Channel type: AWGN

Modulation type: PSK

Modulation order: 2

□ Differential encoding

Demodulation type: ● Coherent ○ Noncoherent

Channel coding: ○ None ○ Convolutional ● Block

Coding Type: General

Decision method: ● Hard ○ Soft

N: 7

K: 3

d_{min}: 5

Open the BER Analyzer App

- MATLAB Toolstrip: On the **Apps** tab, under **Signal Processing and Communications**, click the app icon.
- MATLAB command prompt: Enter `bertool`.

Examples

Theoretical Plot

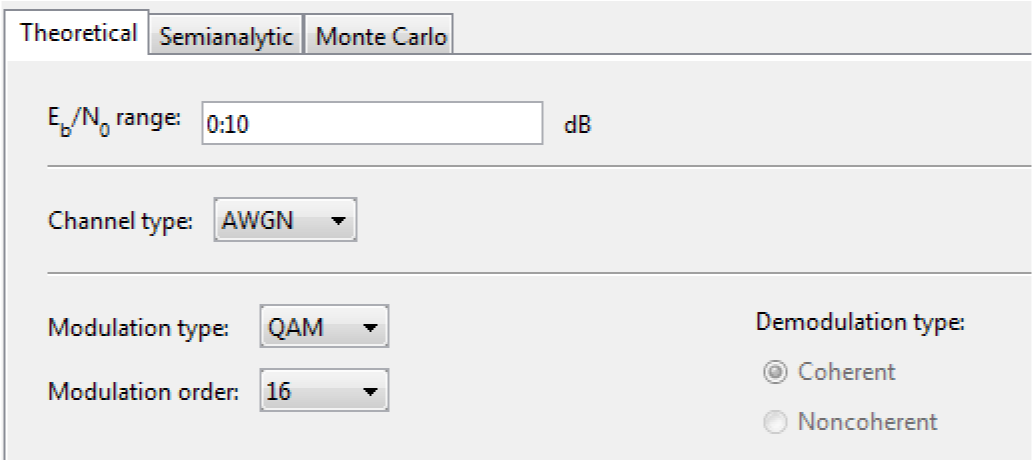
Generate a theoretical estimate of BER performance for a 16-QAM link in AWGN.

Open the **BER Analysis** app.

```
bertool
```

Specify the **E_b/N_0 range** as `0:10`.

Set **Modulation type** to `QAM` and **Modulation order** to `16`.



E_b/N_0 range: 0:10 dB

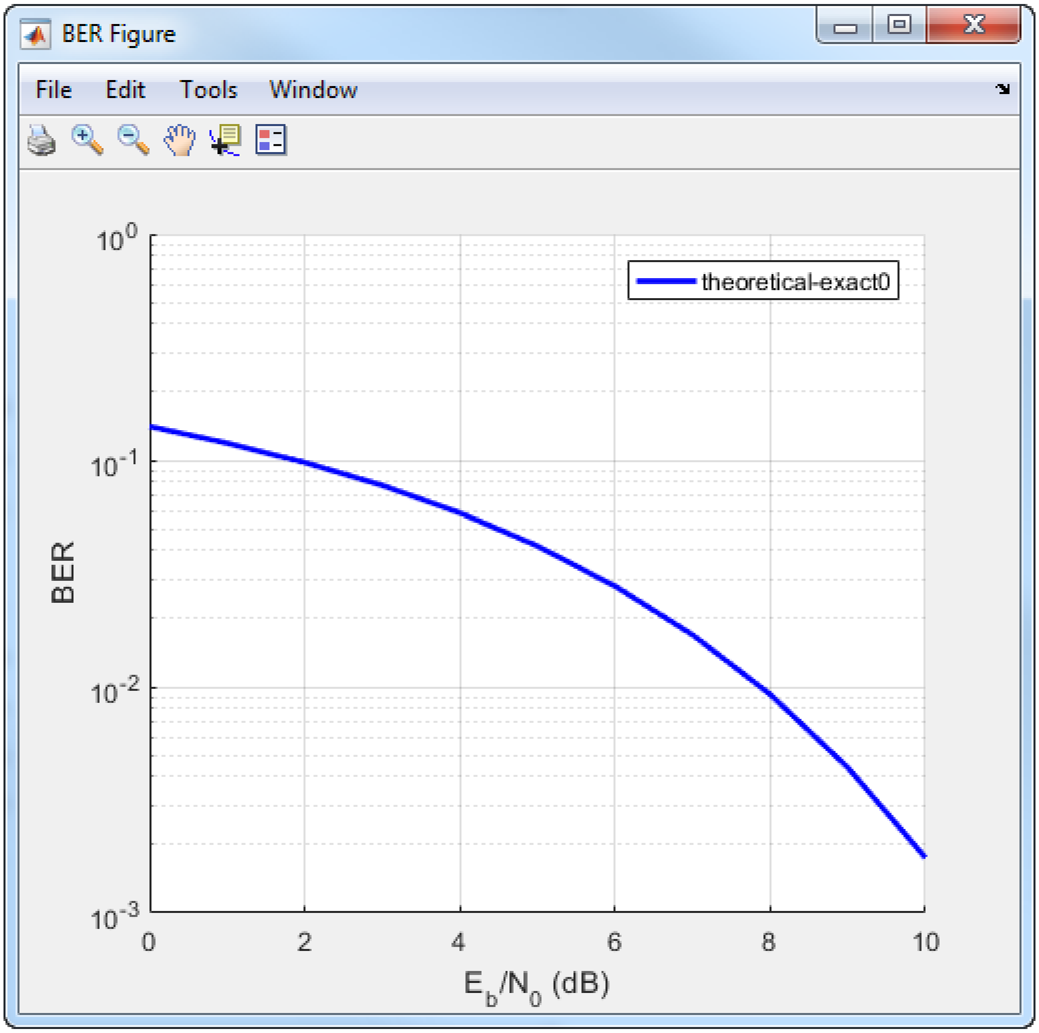
Channel type: AWGN

Modulation type: QAM

Modulation order: 16

Demodulation type:
● Coherent
○ Noncoherent

Plot the BER curve by clicking **Plot**.



Semianalytic Plot

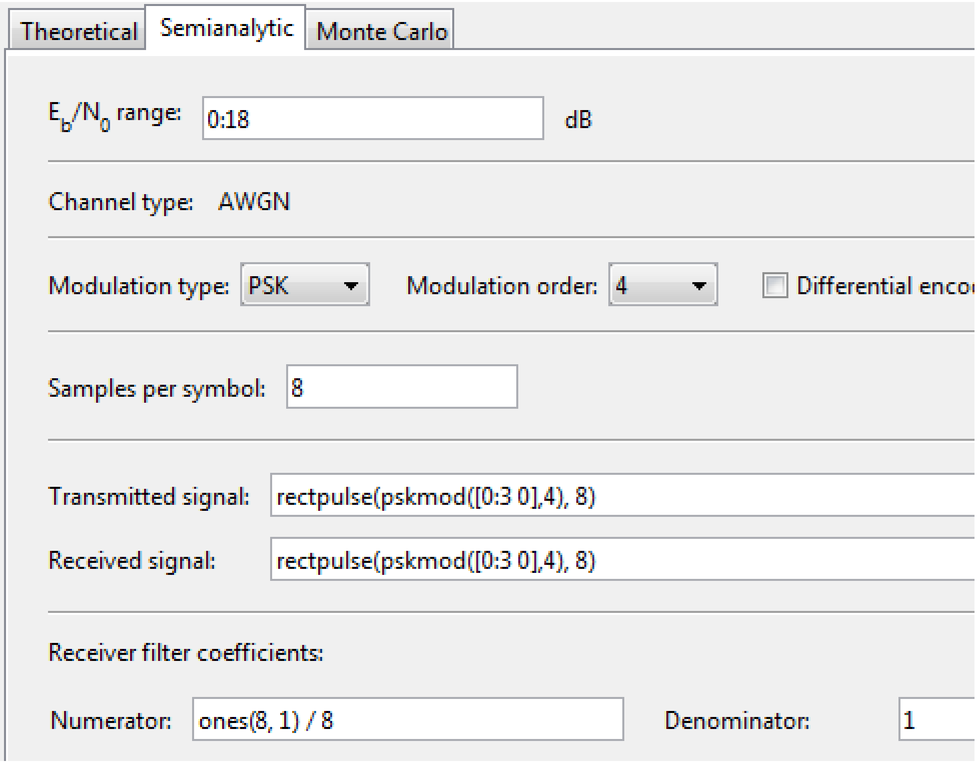
Use the semianalytic technique to plot the BER for a QPSK link having rectangular pulses.

Open the **BER Analysis** app.

```
bertool
```

On the **Semianalytic** tab, set these parameters:

- Set the **Modulation order** to `4`.
- Set the **Samples per symbol** parameter to `8`.
- Set the **Transmitted signal** and **Received signal** parameters to `rectpulse(pskmod([0:3 0],4),8)`. To use the semianalytic technique, the number of symbols must exceed M^L, where M is the modulation order and L is the impulse response length. The impulse response is 1, so a minimum of five symbols is required.
- Specify the **Numerator** as `ones(8,1)/8`. These coefficients specify an ideal integrator having eight samples per symbol.



E_b/N_0 range: 0:18 dB

Channel type: AWGN

Modulation type: PSK Modulation order: 4 □ Differential enco

Samples per symbol: 8

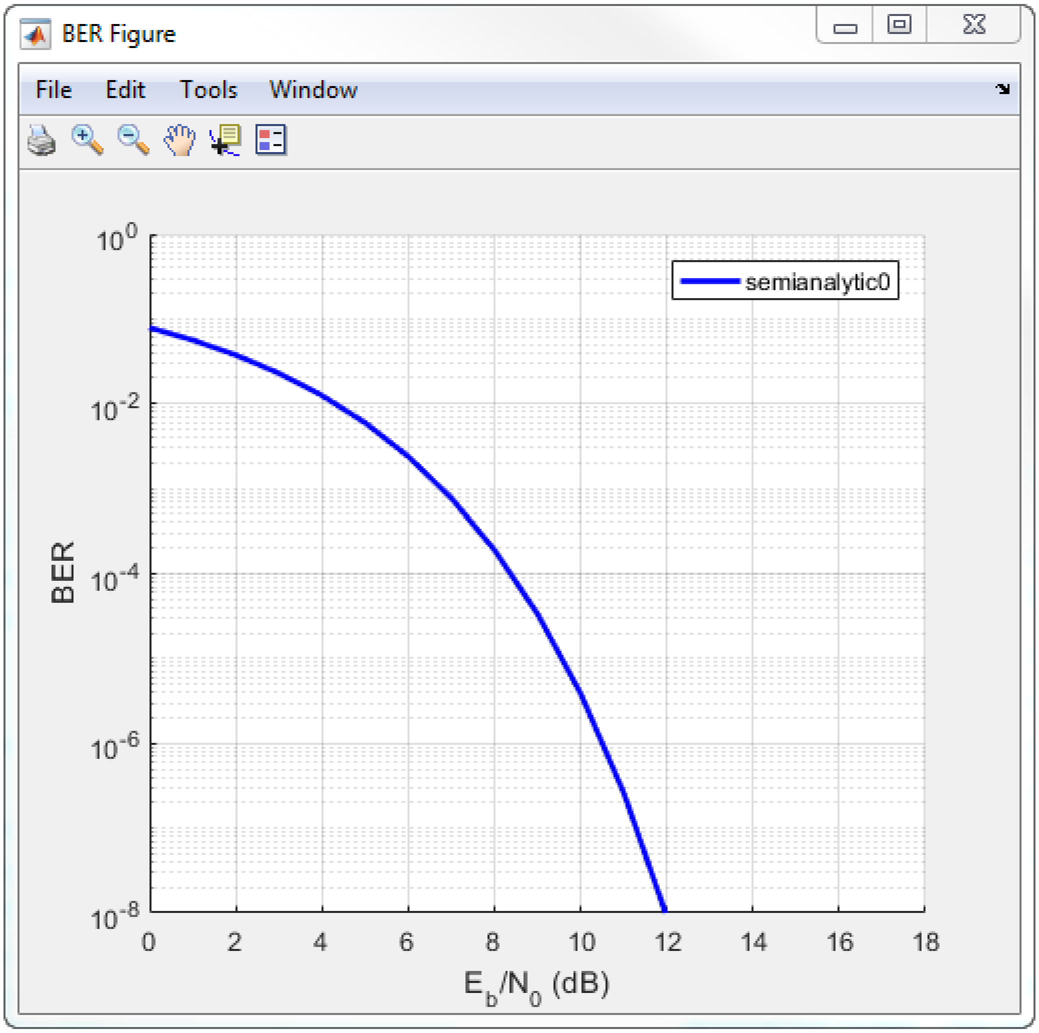
Transmitted signal: rectpulse(pskmod([0:3 0],4), 8)

Received signal: rectpulse(pskmod([0:3 0],4), 8)

Receiver filter coefficients:

Numerator: ones(8, 1) / 8 Denominator: 1

Plot the BER vs. E_b/N_0 curve by clicking **Plot**.



Monte Carlo Simulation

Simulate BER using a custom MATLAB function.

Open the **BER Analysis** app.

```
bertool
```

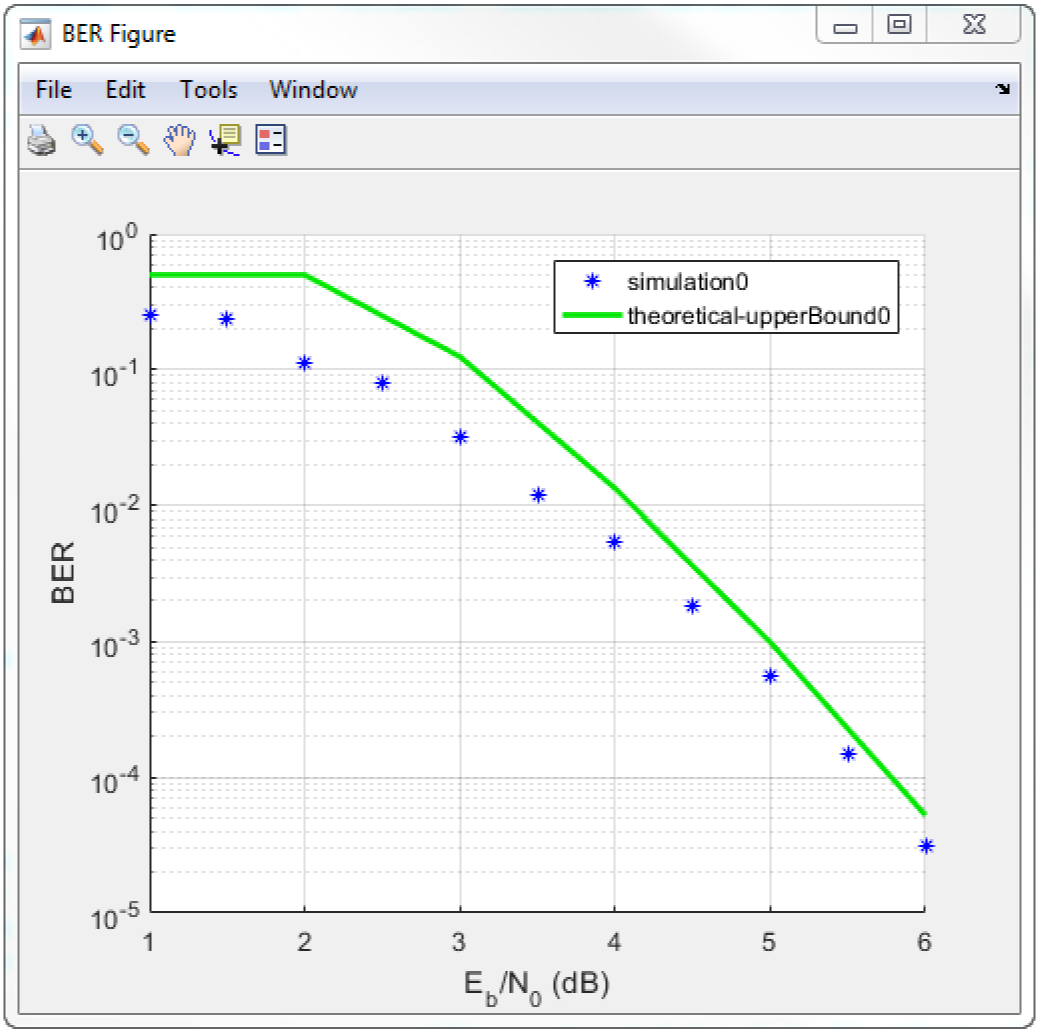
On the **Monte Carlo** tab, specify E_b/N_0 range as `1:.5:6`.

To plot estimated BER values, run the simulation by clicking **Run**.

On the **Theoretical** tab, specify E_b/N_0 range as `1:6` and set **Modulation order** to 4.

Enable convolutional coding by selecting the **Convolutional** check box.

Plot the upper bound of the BER curve by clicking **Plot**.



Parameters

Theoretical

E_b/N_0 range — Range of E_b/N_0 values over which the BER is evaluated
0:18 (default) | vector

Specifies the range of E_b/N_0 values, in dB, over which the BER is evaluated. The values in the range vector must be real.

Example: 5:10

Channel type — Type of channel over which the BER is evaluated
AWGN (default) | Rayleigh | Rician

Specifies the type of channel over which the BER is evaluated. The Rayleigh and Rician options correspond to flat fading channels.

Modulation type — Modulation type of the communication link
PSK (default) | DPSK | OQPSK | PAM | QAM | FSK | MSK | CPFSK

Specifies the modulation type of the communication link.

`Modulation order` — Modulation order of the communication link

2 (default) | 4 | 8 | 16 | 32 | 64

Specifies the modulation order of the communication link.

`Differential encoding` — Differential encoding of the input data

`Off` (default) | `On`

Specifies if the input data sequence is differentially encoded.

`Demodulation type` — Demodulation type

`Coherent` | `Noncoherent`

Specifies if `Coherent` or `Noncoherent` demodulation is used. This parameter is available only when the **Modulation type** is FSK or MSK.

`Channel coding` — Channel coding used in estimating the BER

`None` (default) | `Convolutional` | `Block`

Specifies the type of channel coding used to estimate the theoretical BER.

`Synchronization` — Synchronization error

`Perfect synchronization` (default) | `Normalized timing error` | `RMS phase noise level`

Specifies the synchronization error in the demodulation process. This parameter is available only when the **Modulation type** is PSK and the **Modulation order** is 2.

- When **Synchronization** is `Normalized timing error`, specify the normalized error as a real number from `0` to `0.5`.
- When **Synchronization** is `RMS phase noise level`, specify the RMS phase noise as a nonnegative real number.

`Decision method` — Decoding decision method

`Hard` (default) | `Soft`

Specify the method used to decode the received data. This parameter is available when either of these conditions exist:

- **Channel coding** is set to **Convolutional**
- **Channel coding** is set to **Block** and **Coding Type** is `General`

`Trellis` — Convolutional code trellis

`poly2trellis(7,[171 133])` (default) | structure

Specify the convolutional code trellis as a structure variable. You can generate this structure by using the `poly2trellis` function. The parameter is available only when the **Channel coding** parameter is `Convolutional`.

`Coding type` — Specify block coding type

`General` (default) | `Hamming` | `Golay` | `Reed-Solomon`

Specify the block code used in the BER evaluation.

`N` — Codeword length

positive integer

Specify the codeword length as a positive integer.

`K` — Message length

positive integer

Specify the message length as a positive integer such that **K** is less than **N**.

d_{min} — Minimum code distance

positive integer

Specify the minimum distance of the (N,K) block code as a positive integer. This parameter is available when the **Coding type** is `General`.

Semianalytic

`Samples per symbol` — Samples per symbol

`16` (default) | positive integer

Specify the number of samples per symbol as a positive integer.

`Transmitted signal` — Transmitted sample sequence

`rectpulse(step(comm.BPSKModulator, [0 1 1 0 0 1 1 1 1 0 1 1 0 0 0 0].'), 16)` (default) | vector

Specify the transmit sequence as a real or complex column vector.

Data Types: `double`

`Received signal` — Received sample sequence

`rectpulse(step(comm.BPSKModulator, [0 1 1 0 0 1 1 1 1 0 1 1 0 0 0 0].'), 16)` (default) | vector

Specify the received sequence as a real or complex column vector.

Data Types: `double`

`Numerator` — Numerator of the receive filter coefficients

`ones(16,1)/16` (default) | scalar | vector

Specify the numerator of the receive filter coefficients as a vector.

`Denominator` — Denominator of the receive filter coefficients

`1` (default) | scalar | vector

Specify the denominator of the receive filter coefficients as a vector.

Monte Carlo

`Simulation MATLAB file or Simulink model` — File name of the BER simulation

character vector

Specify the name of the MATLAB file or Simulink model containing the simulation code.

`BER variable name` — Name of the variable containing the BER simulation data
character vector

Specify the name of the MATLAB workspace variable that contains the BER simulation data.

`Number of errors` — Number of errors measured before simulation stop
`100` (default) | positive integer

Specify the number of errors that must be measured before the simulation stops. Typically, 100 measured errors are enough to produce an accurate BER estimate.

`Number of bits` — Number of bits processed before simulation stop
`1e8` (default) | positive integer

Specify the number of bits that must be processed before the simulation stops. This parameter is used to prevent the simulation from running too long.

Note The Monte Carlo simulation stops when either the number of errors or number of bits threshold is reached.

Eye Diagram Analyzer

(Removed) Visualize and measure effects of impairments

Note **eyescope** has been removed. Use `eyediagram` instead.

Description

The **Eye Diagram Analyzer** app displays and measures the effects of various impairments. Using this app, you can:

- Visualize eye diagrams.
- Measure these quantities:
  - Horizontal and vertical eye openings
  - Random, deterministic, total, RMS, and peak-to-peak jitter
  - Rise and fall times
  - Signal-to-noise ratio
- Import and compare measurement results for eye diagrams of multiple signals.

Open the Eye Diagram Analyzer App

- MATLAB Toolstrip: On the **Apps** tab, under **Signal Processing and Communications**, click the app icon.
- MATLAB command prompt: Enter `eyescope`.

Programmatic Use

`eyescope` calls an empty scope.

`eyescope(obj)` calls the eye scope and displays object `obj`.

Compatibility Considerations

eyescope has been removed
Errors starting in R2020a

Eye Diagram Analyzer has been removed. Use `eyediagram` instead.

Wireless Waveform Generator

Create, impair, visualize, and export modulated waveforms

Description

The **Wireless Waveform Generator** app enables you to create, impair, visualize, and export modulated waveforms.

Using the app, you can:

- Generate custom OFDM, QAM, and PSK modulated waveforms.
- Generate sine wave test waveforms.
- Generate NR test models (NR-TM) and NR uplink and downlink fixed reference channel (FRC) waveforms. This feature requires “5G Toolbox”.
- Generate LTE modulated waveforms. This feature requires the “LTE Toolbox”.
- Generate WLAN (802.11™) modulated waveforms. This feature requires the “WLAN Toolbox”.
- Generate Bluetooth modulated waveforms. This feature requires the Communications Toolbox Library for the Bluetooth® Protocol. To download this library, go to Get Add-Ons.
- Distort the waveform by adding RF impairments, such as AWGN, phase offset, frequency offset, DC offset, IQ imbalance, and memoryless cubic nonlinearity.
- Visualize the waveform in constellation diagram, spectrum analyzer, OFDM grid, and time scope plots.
- Export the waveform to your workspace as a structure, to a `.mat` or a `.bb` file, or to a runnable MATLAB script.

  Note You can use the MATLAB script to reproduce your waveform outside of the **Wireless Waveform Generator** app.
- Generate a waveform that you can transmit using a connected lab test instrument. The app can transmit a waveform by using instruments supported by the `rfsiggen` function. Use of the transmit feature in the app requires Instrument Control Toolbox™ software. For more information, see the documentation for “Instrument Control Toolbox”.

For more information, see “Using Wireless Waveform Generator App”.

App-Based 5G NR-TM and FRC Waveform Generation

This example shows how to use the **5G Waveform Generator** app to generate NR test models (NR-TM) and NR uplink and downlink fixed reference channel (FRC) waveforms.

Open 5G Waveform Generator App

On the **Apps** tab of the MATLAB® toolstrip, under **Signal Processing and Communications**, click the **5G Waveform Generator** app icon. This app opens the **Wireless Waveform Generator** app configured for 5G waveform generation.

Select 5G NR Waveform

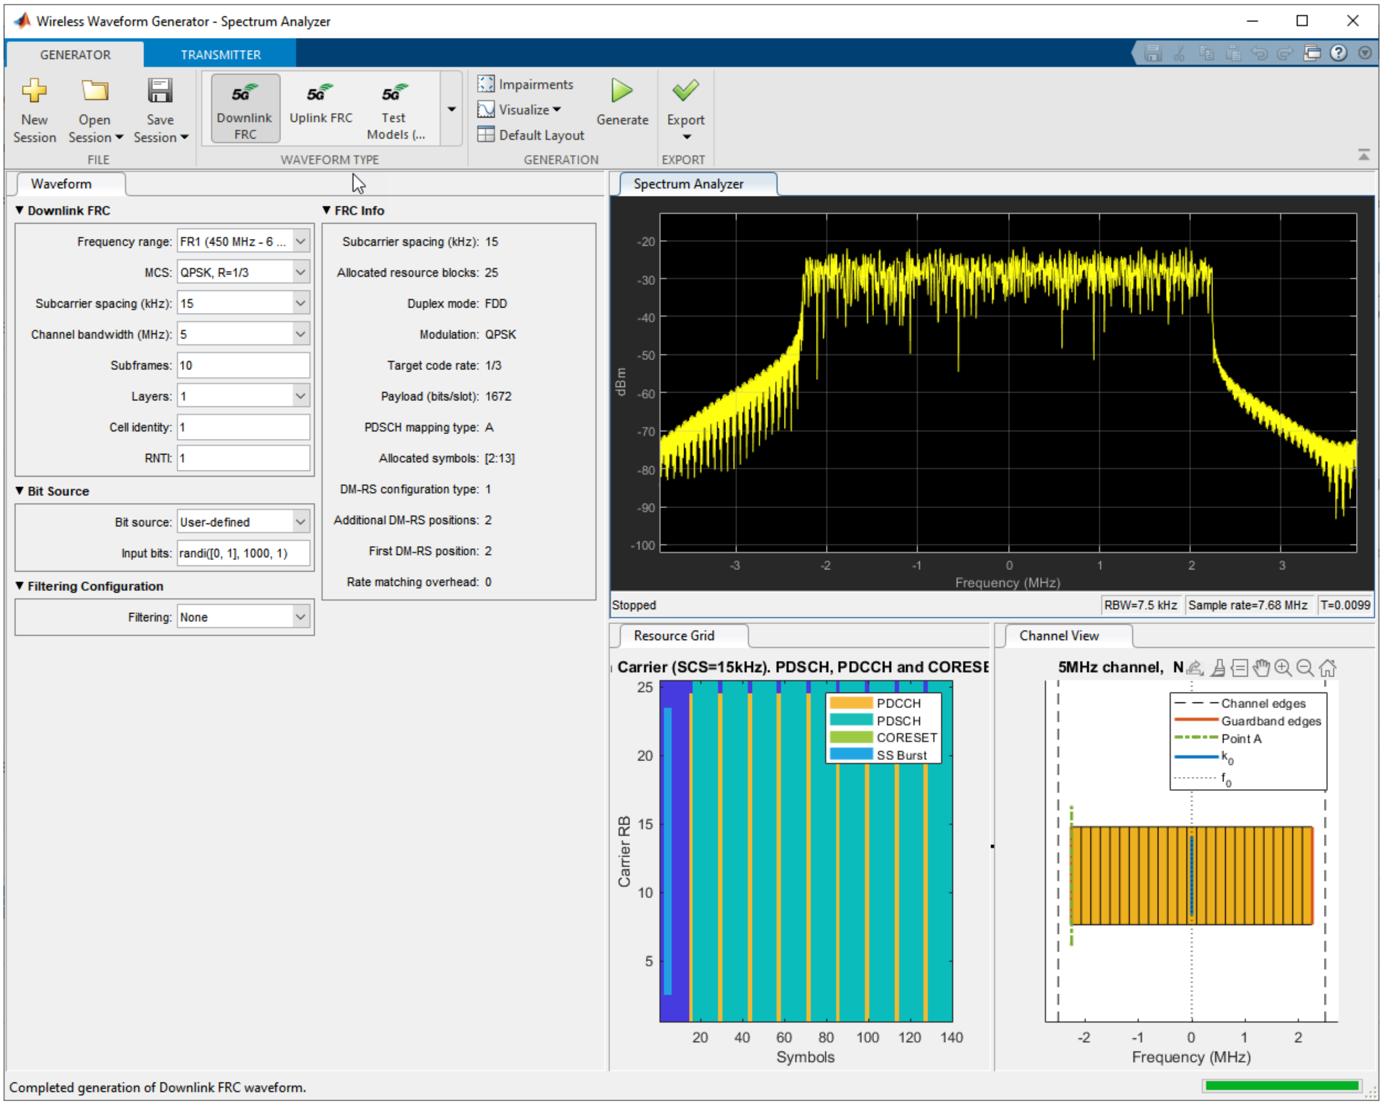
In the **Waveform Type** section on the app toolstrip, click the waveform you want to generate. You can select any of these waveforms.

- `5G Downlink FRC`
- `5G Uplink FRC`
- `5G Test Models`

Generate 5G NR Waveform

In the left pane of the app, on the **Waveform** tab, you can set the parameters of the selected waveform. On the app toolstrip, in the **Generation** section, you can add impairments and set visualization tools. To visualize the waveform, click **Generate**. You can export the generated waveform to the MATLAB workspace as a structure in a `.mat` or `.bb` file.

For example, this picture shows the visualization results of a downlink FRC waveform using default parameters.



▼ Downlink FRC

Frequency range:	FR1 (450 MHz - 6 ...
MCS:	QPSK, R=1/3
Subcarrier spacing (kHz):	15
Channel bandwidth (MHz):	5
Subframes:	10
Layers:	1
Cell identity:	1
RNTI:	1

▼ Bit Source

Bit source:	User-defined
Input bits:	randi([0, 1], 1000, 1)

▼ Filtering Configuration

Filtering:	None

▼ FRC Info

Subcarrier spacing (kHz):	15
Allocated resource blocks:	25
Duplex mode:	FDD
Modulation:	QPSK
Target code rate:	1/3
Payload (bits/slot):	1672
PDSCH mapping type:	A
Allocated symbols:	[2:13]
DM-RS configuration type:	1
Additional DM-RS positions:	2
First DM-RS position:	2
Rate matching overhead:	0

Stopped RBW=7.5 kHz Sample rate=7.68 MHz T=0.0099

Completed generation of Downlink FRC waveform.

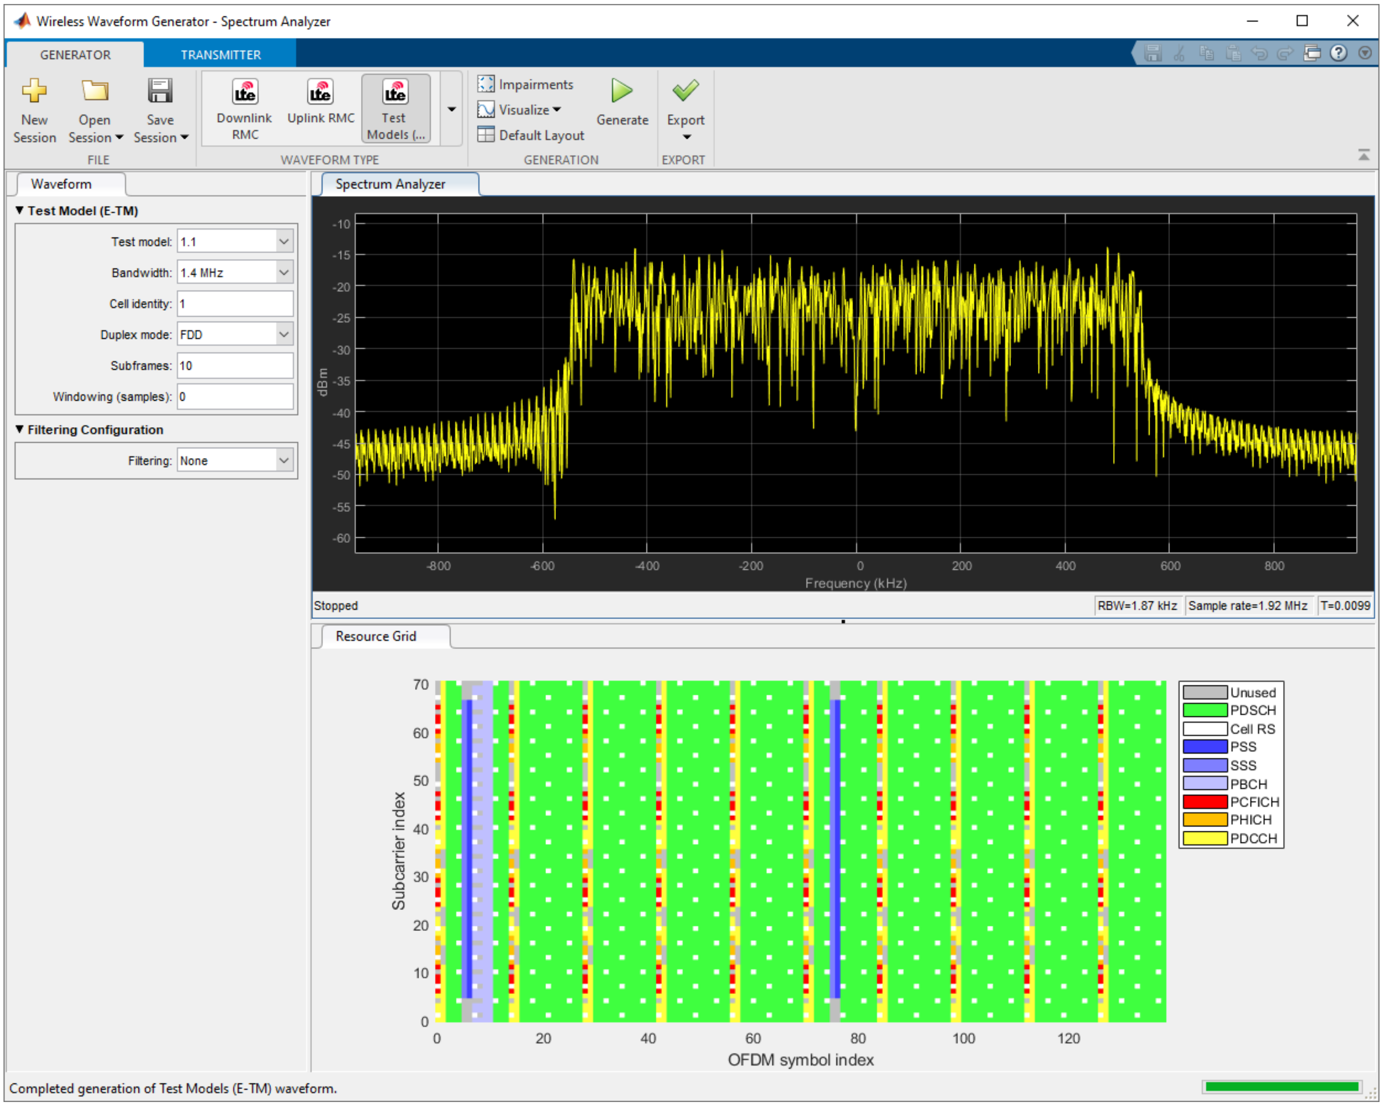
Transmit 5G NR Waveform

This feature requires “Instrument Control Toolbox”. To transmit the generated waveform, on the app toolstrip, click on the **Transmitter** tab and set up the instruments. You can use all the instruments supported by the `rfsiggen` (Instrument Control Toolbox) function.

Generate LTE E-TM Test Model Waveforms

Open the **Wireless Waveform Generator** app and configure to generate LTE E-TM Test Model waveforms. Using this feature of the app requires the LTE Toolbox™.

In the **Waveform Type** section, select `Test Model (E-TM) waveforms, specified in TS 36.141, Sec. 6`. To display an LTE E-TM Test Model 1.1 frame with a 1.4 MHz channel bandwidth, click **Generate**.



Wireless Waveform Generator - Spectrum Analyzer

Test Model (E-TM)

Test model: 1.1

Completed generation of Test Models (E-TM) waveform.

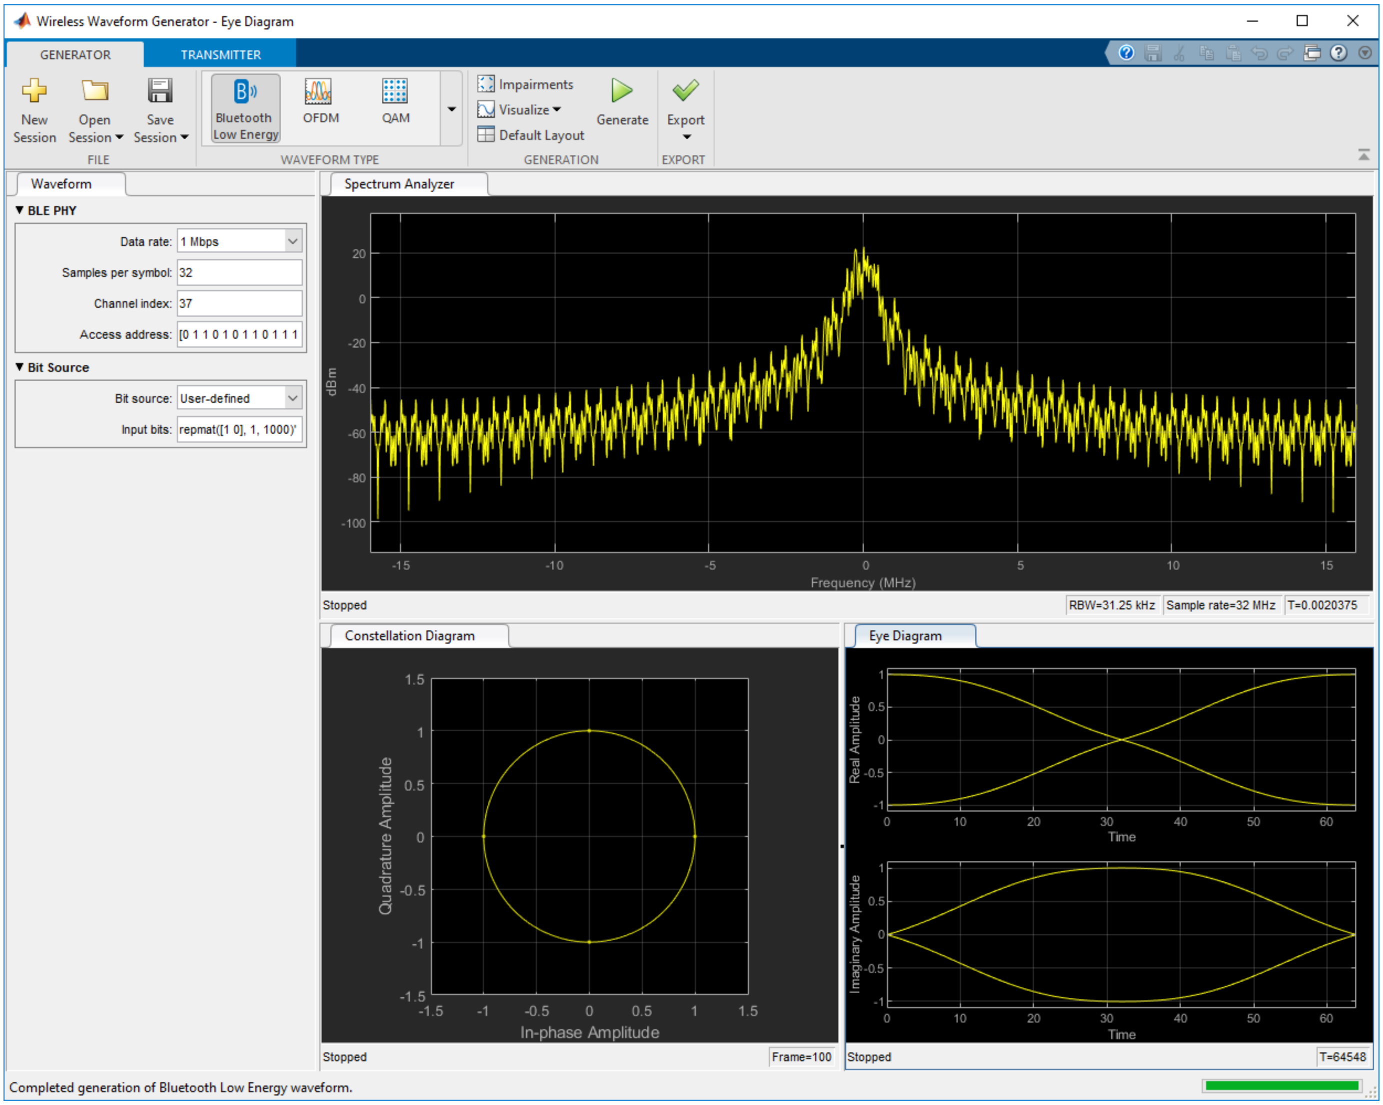
Generate BLE Waveform

Open the **Wireless Waveform Generator** app and configure a Bluetooth low energy (BLE) waveform. To use the BLE feature, the app requires Communications Toolbox Library for the Bluetooth Protocol . In the **Waveform Type** section, click `Bluetooth Low Energy`. Change the bit source to `User-defined` and enter the input bits. Specify the value of **Samples per symbol** as 32. Click **Generate** to generate the BLE waveform. The plotted waveform is a BLE waveform with GMSK-modulated samples. Change the visible plots by clicking **Visualize** and then selecting one or more options between `Constellation Diagram`, `Time Scope` and `Eye Diagram`.



▼ BLE PHY

Data rate: 1 Mbps

Stopped Frame=100

Stopped T=64548

Completed generation of Bluetooth Low Energy waveform.

Generate WLAN HE ER SU PPDU with Packet Extension

Open **Wireless Waveform Generator** and configure an HE extended-range (ER) SU PPDU. Using this feature of the app requires the WLAN Toolbox™.

In the **Waveform Type** section, select `802.11ax`. Configure the app to generate an HE ER SU PPDU with two packets, specifying a delay of 50 microseconds between packets. Specify two transmit antennas, and a nominal packet padding of eight microseconds. Click **Visualize** and configure to select `Time Scope` only. To generate the waveform, click **Generate**.

Functions

algdeintrlv

Restore ordering of symbols using algebraically derived permutation table

Syntax

```
deintrlvd = algdeintrlv(data,num,'takeshita-costello',k,h)
deintrlvd = algdeintrlv(data,num,'welch-costas',alph)
```

Description

`deintrlvd = algdeintrlv(data,num,'takeshita-costello',k,h)` restores the original ordering of the elements in `data` using a permutation table that is algebraically derived using the Takeshita-Costello method. `num` is the number of elements in `data` if `data` is a vector, or the number of rows of `data` if `data` is a matrix with multiple columns. In the Takeshita-Costello method, `num` must be a power of 2. The multiplicative factor, `k`, must be an odd integer less than `num`, and the cyclic shift, `h`, must be a nonnegative integer less than `num`. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

`deintrlvd = algdeintrlv(data,num,'welch-costas',alph)` uses the Welch-Costas method. In the Welch-Costas method, `num+1` must be a prime number. `alph` is an integer between 1 and `num` that represents a primitive element of the finite field GF(`num+1`).

To use this function as an inverse of the `algintrlv` function, use the same inputs in both functions, except for the `data` input. In that case, the two functions are inverses in the sense that applying `algintrlv` followed by `algdeintrlv` leaves data unchanged.

Examples

Interleave and Deinterleave Symbols

This example uses the Takeshita-Costello method of `algintrlv` and `algdeintrlv`.

Generate random data symbols to interleave. The number of rows of input data, `num`, must be a power of two.

```
num = 16;
ncols = 3;
data = rand(num,ncols)
```

```
data = 16×3

    0.8147    0.4218    0.2769
    0.9058    0.9157    0.0462
    0.1270    0.7922    0.0971
    0.9134    0.9595    0.8235

algintrlv

Reorder symbols using algebraically derived permutation table

Syntax

```
intrlvd = algintrlv(data,num,'takeshita-costello',k,h)
intrlvd = algintrlv(data,num,'welch-costas',alph)
```

Description

`intrlvd = algintrlv(data,num,'takeshita-costello',k,h)` rearranges the elements in `data` using a permutation table that is algebraically derived using the Takeshita-Costello method. `num` is the number of elements in `data` if `data` is a vector, or the number of rows of `data` if `data` is a matrix with multiple columns. In the Takeshita-Costello method, `num` must be a power of 2. The multiplicative factor, `k`, must be an odd integer less than `num`, and the cyclic shift, `h`, must be a nonnegative integer less than `num`. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

`intrlvd = algintrlv(data,num,'welch-costas',alph)` uses the Welch-Costas method. In the Welch-Costas method, `num+1` must be a prime number. `alph` is an integer between 1 and `num` that represents a primitive element of the finite field GF(`num+1`). This means that every nonzero element of GF(`num+1`) can be expressed as `alph` raised to some integer power.

Examples

Reorder Symbols Using Algebraically Derived Permutation Table

This example illustrates how to use the Welch-Costas method of algebraic interleaving.

Define `num` such that `num+1` is prime. Create data to interleave.

```
num = 10;
ncols = 3; % Number of columns of data to interleave
data = randi([0 num-1],num,ncols); % Random data to interleave
```

Find primitive polynomials of the finite field GF(num+1). The `gfprimfd` function represents each primitive polynomial as a row containing the coefficients in order of ascending powers.

```
pr = gfprimfd(1,'all',num+1)
```

```
pr = 4×2

     3     1
     4     1
     5     1
     9     1
```

Notice from the output that `pr` has two columns and that the second column consists solely of 1s. In other words, each primitive polynomial is a monic degree-one polynomial. This is because `num+1` is prime. As a result, to find the primitive element that is a root of each primitive polynomial, find a root of the polynomial by subtracting the first column of pr from num+1 .

```
primel = (num+1)-pr(:,1) % Primitive elements of GF(num+1)
```

```
primel = 4×1

     8
     7
     6
     2
```

Now define alph as one of the elements of primel and use algintrlv to interleave.

```
alph = primel(1);
intrlvd = algintrlv(data,num,'Welch-Costas',alph);
```

Algorithms

- A Takeshita-Costello interleaver uses a length-num cycle vector whose nth element is mod(k*(n-1)*n/2, num) for integers n between 1 and num. The function creates a permutation vector by listing, for each element of the cycle vector in ascending order, one plus the element's successor. The interleaver's actual permutation table is the result of shifting the elements of the permutation vector left by h. (The function performs all computations on numbers and indices modulo num.)
- A Welch-Costas interleaver uses a permutation that maps an integer K to mod(A^K,num+1)-1.

amdemod

Amplitude demodulation

Syntax

```
z = amdemod(y,Fc,Fs)
z = amdemod(y,Fc,Fs,ini_phase)
z = amdemod(y,Fc,Fs,ini_phase,carramp)
z = amdemod(y,Fc,Fs,ini_phase,carramp,num,den)
```

Description

`z = amdemod(y,Fc,Fs)` returns a demodulated signal `z`, given the input amplitude modulated (AM) signal `y`, where the carrier signal has frequency `Fc`. The carrier signal and `y` have sampling frequency `Fs`. The modulated signal `y` has zero initial phase and zero carrier amplitude, resulting from a suppressed-carrier modulation.

Note The value of `Fs` must satisfy `Fs` ≥ `2Fc`.

`z = amdemod(y,Fc,Fs,ini_phase)` specifies the initial phase of the modulated signal in radians.

`z = amdemod(y,Fc,Fs,ini_phase,carramp)` demodulates a signal created through transmitted-carrier modulation instead of suppressed-carrier modulation, where `carramp` is the carrier amplitude of the modulated signal.

`z = amdemod(y,Fc,Fs,ini_phase,carramp,num,den)` specifies the numerator and denominator of the lowpass Butterworth filter used in the demodulation. The numerator and denominator are generated by [num,den] = `butter(n,Fc*2/Fs)`, where `n` is the order of the lowpass filter.

Examples

Demodulate AM Signal

Set the carrier frequency to 10 kHz and sampling frequency to 80 kHz. Generate a time vector having a duration of 0.01 s.

```
fc = 10e3;
fs = 80e3;
t = (0:1/fs:0.01)';
```

Create a two-tone sinusoidal signal with frequencies 300 and 600 Hz.

```
s = sin(2*pi*300*t)+2*sin(2*pi*600*t);
```

Create a lowpass filter.

```
[num,den] = butter(10,fc*2/fs);
```

Amplitude modulate the signal s.

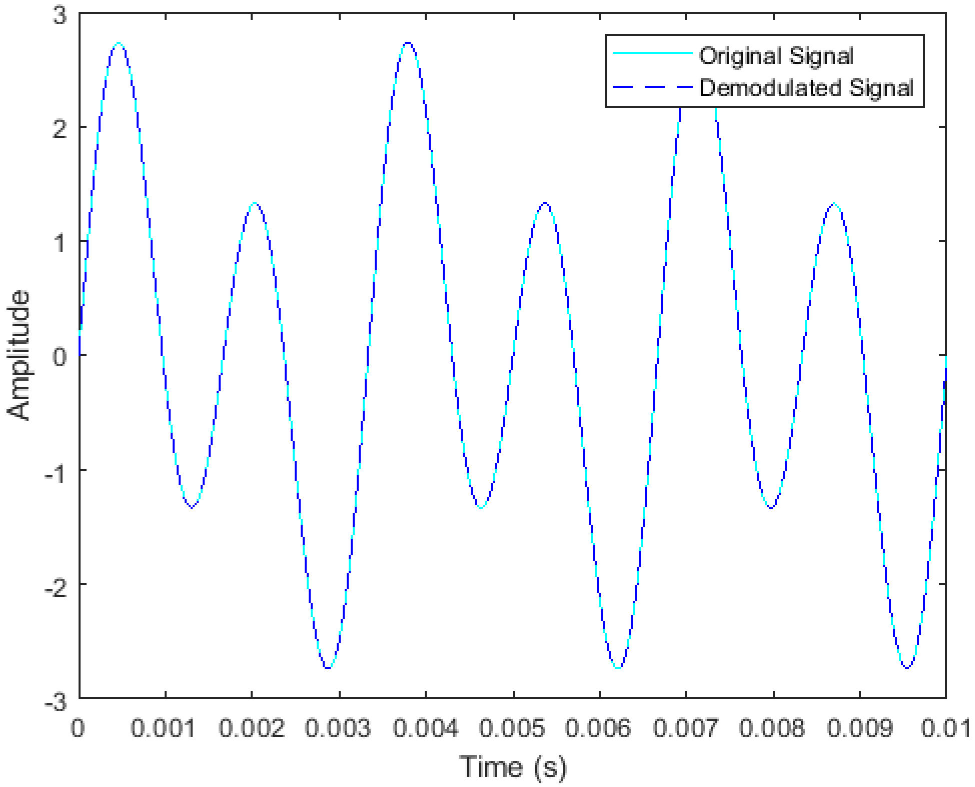
```
y = ammod(s,fc,fs);
```

Demodulate the received signal.

```
z = amdemod(y,fc,fs,0,0,num,den);
```

Plot the original and demodulated signals.

```
plot(t,s,'c',t,z,'b--')
legend('Original Signal','Demodulated Signal')
xlabel('Time (s)')
ylabel('Amplitude')
```



The demodulated signal is nearly identical to the original signal.

Input Arguments

y — Amplitude modulated input signal

scalar | vector | matrix | 3-D array

Amplitude modulated input signal, specified as a scalar, vector, matrix, or 3-D array. Each element of y must be real.

Data Types: double | single

`Fc` — Carrier signal frequency

positive scalar

Carrier signal frequency in hertz (Hz), specified as a positive scalar.

Data Types: `double`

`Fs` — Sampling frequency

positive scalar

Sampling frequency of the carrier signal and input message signal in hertz (Hz), specified as a positive scalar. To avoid aliasing, the value of `Fs` must satisfy `Fs` > 2(`Fc` + `BW`), where `BW` is the bandwidth of the original modulated signal.

Data Types: `double`

`ini_phase` — Initial phase

scalar

Initial phase of the modulated signal in radians, specified as a scalar.

Data Types: `double`

`carramp` — Carrier amplitude

scalar

Carrier amplitude of the modulated signal, specified as a scalar.

Data Types: `double`

`num` — Lowpass Butterworth filter numerator

scalar

Lowpass Butterworth filter numerator, specified as a scalar.

Data Types: `double`

`den` — Lowpass Butterworth filter denominator

scalar

Lowpass Butterworth filter denominator, specified as a scalar.

Data Types: `double`

Output Arguments

`z` — Amplitude demodulated output signal

scalar | vector | matrix | 3-D array

Amplitude demodulated output signal, returned as a scalar, vector, matrix, or 3-D array.

"Analog Passband Modulation"

Introduced before R2006a

ammod

Amplitude modulation

Syntax

```
y = ammod(x,Fc,Fs)
y = ammod(x,Fc,Fs,ini_phase)
y = ammod(x,Fc,Fs,ini_phase,carramp)
```

Description

`y = ammod(x,Fc,Fs)` returns an amplitude modulated (AM) signal `y`, given the input message signal `x`, where the carrier signal has frequency `Fc`. The carrier signal and `x` have a sampling frequency `Fs`. The modulated signal has zero initial phase and zero carrier amplitude, so the result is suppressed-carrier modulation.

Note The value of `Fs` must satisfy `Fs` ≥ 2`Fc`.

`y = ammod(x,Fc,Fs,ini_phase)` specifies the initial phase in the modulated signal `y` in radians.

`y = ammod(x,Fc,Fs,ini_phase,carramp)` performs transmitted-carrier modulation instead of suppressed-carrier modulation where `carramp` is the carrier amplitude of the modulated signal.

Examples

Compare Double-Sideband and Single-Sideband Amplitude Modulation

Set the sample rate to 100 Hz. Create a time vector 100 seconds long.

```
fs = 100;
t = (0:1/fs:100)';
```

Set the carrier frequency to 10 Hz. Generate a sinusoidal signal.

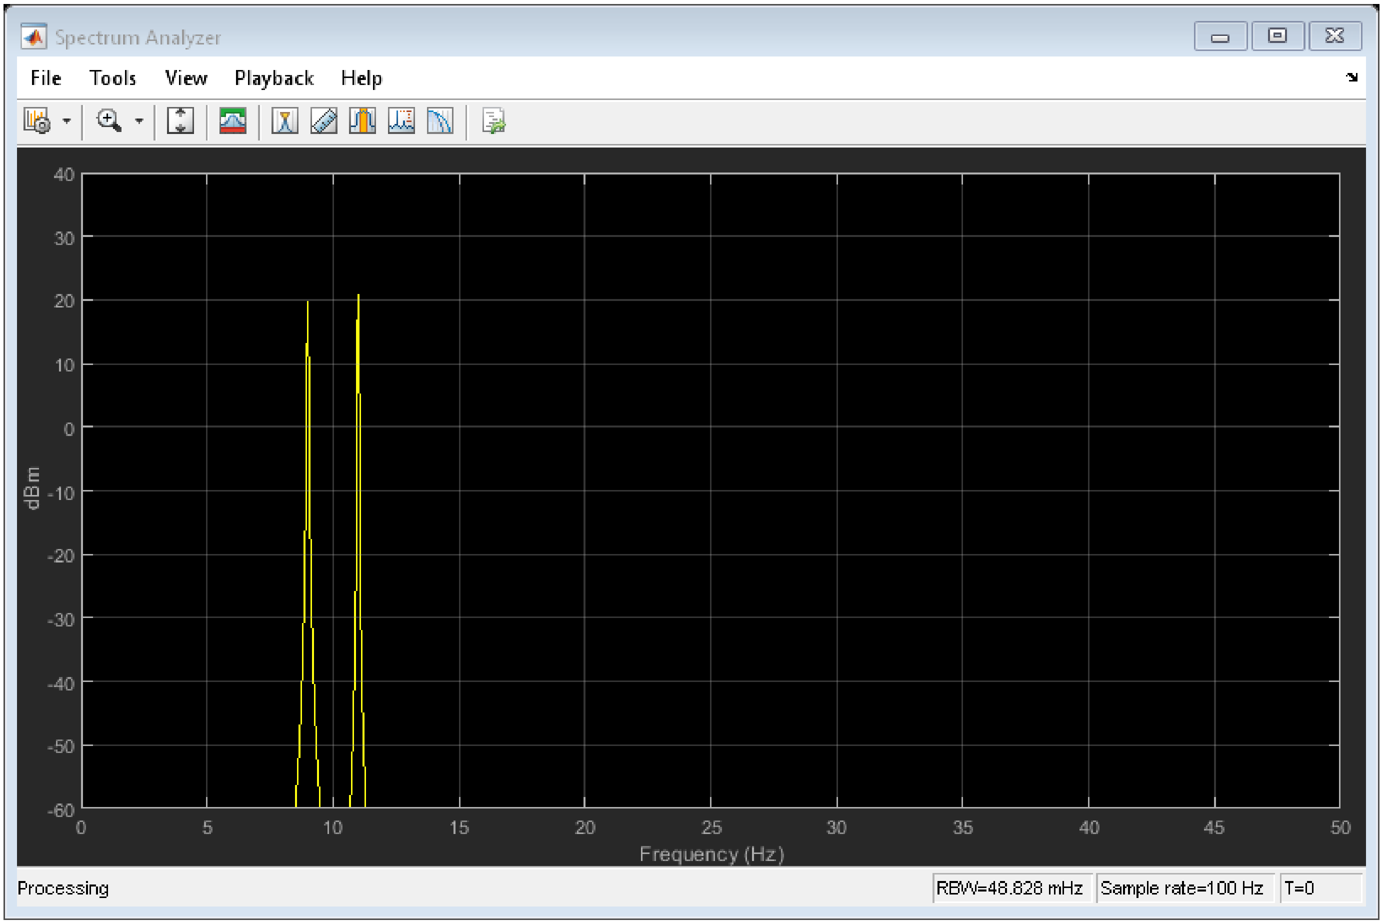
```
fc = 10;
x = sin(2*pi*t);
```

Modulate `x` using single- and double-sideband AM.

```
ydouble = ammod(x,fc,fs);
ysingle = ssbmod(x,fc,fs);
```

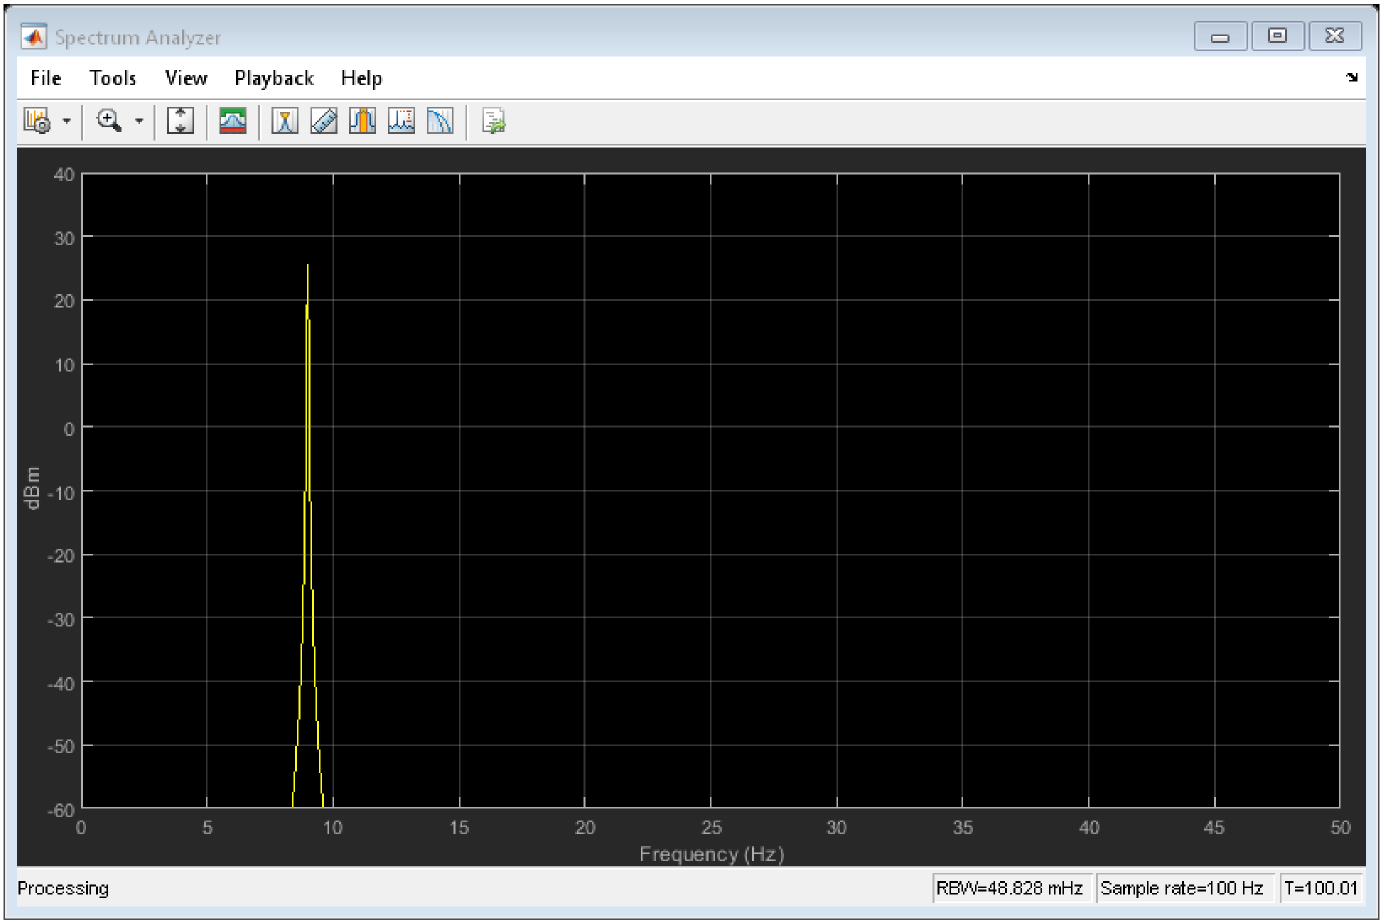
Create a spectrum analyzer object to plot the spectra of the two signals. Plot the spectrum of the double-sideband signal.

```
sa = dsp.SpectrumAnalyzer('SampleRate',fs, ...
    'PlotAsTwoSidedSpectrum',false, ...
    'YLimits',[-60 40]);
step(sa,ydouble)
```



Plot the single-sideband spectrum.

```
step(sa,ysingle)
```



Input Arguments

x — Input message signal

scalar | vector | matrix | 3-D array

Input message signal, specified as a scalar, vector, matrix, or a 3-D array. Each element of `x` must be real.

Data Types: `single` | `double`

Fc — Carrier signal frequency

positive real scalar

Carrier signal frequency in hertz (Hz), specified as a positive real scalar.

Data Types: `single` | `double`

Fs — Sampling frequency

positive real scalar

Sampling frequency of carrier signal and input message signal in hertz (Hz), specified as a positive real scalar. To avoid aliasing, the value of `Fs` must satisfy `Fs` > 2(`Fc` + `BW`), where `BW` is the bandwidth of `x`.

Data Types: `single` | `double`

`ini_phase` — Initial phase

real scalar

Initial phase of the modulated signal in radians, specified as a real scalar.

Data Types: `single` | `double`

`carramp` — Carrier amplitude

real scalar

Carrier amplitude of the modulated signal, specified as a real scalar.

Data Types: `single` | `double`

Output Arguments

y — Amplitude modulated output signal

scalar | vector | matrix | 3-D array

Amplitude modulated signal, returned as a scalar, vector, matrix, or 3-D array.

“Analog Passband Modulation”

Introduced before R2006a

apskdemod

Amplitude phase shift keying (APSK) demodulation

Syntax

```
z = apskdemod(y,M,radii)
z = apskdemod(y,M,radii,phaseoffset)
z = apskdemod( ___ ,Name,Value)
```

Description

`z = apskdemod(y,M,radii)` performs APSK demodulation of the input signal `y`, based on the specified number of constellation points per PSK ring, `M`, and the radius of each PSK ring, `radii`. For a description of APSK demodulation, see “APSK Hard Demodulation” on page 2-22 and “APSK Soft Demodulation” on page 2-23.

Note apskdemod specifically applies to multiple ring PSK constellations. For a single ring PSK constellation, use `pskdemod`.

`z = apskdemod(y,M,radii,phaseoffset)` specifies an initial phase offset for each PSK ring of the APSK modulated signal.

`z = apskdemod( ___ ,Name,Value)` specifies options using one or more name-value pair arguments using any of the previous syntaxes. For example, `'OutputDataType','double'` specifies the desired output data type as double. Specify name-value pair arguments after all other input arguments.

Examples

Demodulate 16-APSK Signal

Demodulate a 16-APSK signal that has an unequal number of constellation points on each circle. Plot the received constellation.

Define vectors for modulation order and PSK ring radii. Generate random 16-ary data symbols.

```
M = [4 12];
radii = [1 2];
modOrder = sum(M);

x = randi([0 modOrder-1],1000,1);
```

Apply APSK modulation to the data.

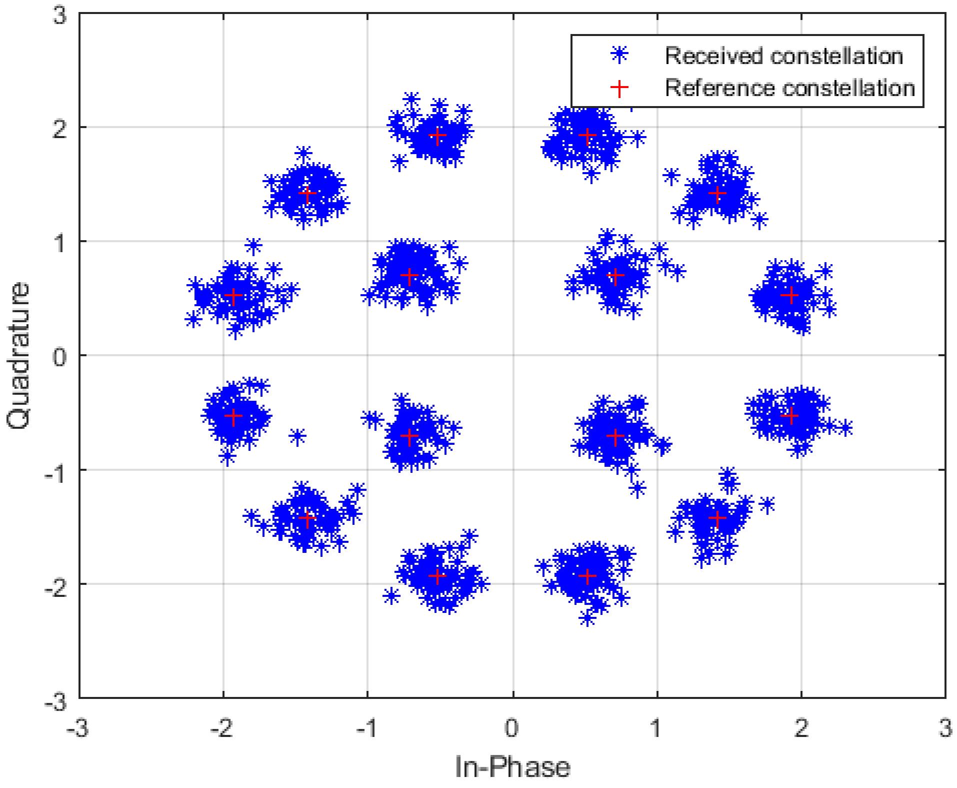
```
txSig = apskmod(x,M,radii);
```

Pass the modulated signal through a noisy channel.

```
snr = 20; % dB
rxSig = awgn(txSig,snr,'measured');
```

Plot the transmitted (reference) signal points and the noisy received signal points.

```
plot(rxSig,'b*')
hold on
grid
plot(txSig,'r+')
xlim([-3 3])
ylim([-3 3])
xlabel('In-Phase')
ylabel('Quadrature')
legend('Received constellation','Reference constellation')
```



Demodulate the received signal and compare to the input data.

```
z = apskdemod(rxSig,M,radii);
isequal(x,z)
```

```
ans = logical
   1
```

Demodulate 64-APSK Custom Symbol Mapped Signal

Demodulate a 64-APSK signal with custom symbol mapping. Compute hard decision bit output and verify that the input matches the output.

Define vectors for modulation order and PSK ring radii. Generate 100 symbols of random bit input.

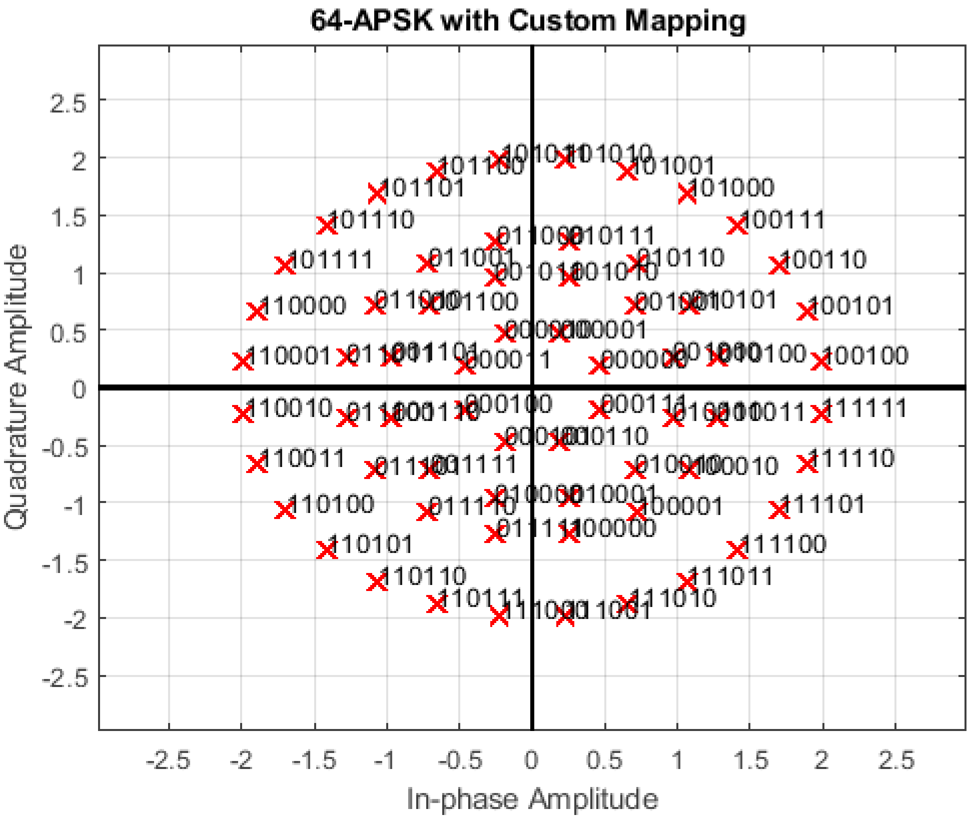
```
M = [8 12 16 28]; % 4-PSK circles
modOrder = sum(M);
radii = [0.5 1 1.3 2];
x = randi([0 1],100*log2(modOrder),1);
```

Create a custom symbol mapping vector of binary mapping.

```
cmap = 0:63;
```

Modulate the data and plot the constellation.

```
y = apskmod(x,M,radii,'SymbolMapping',cmap,'inputType','bit', ...
    'PlotConstellation',true);
```



Demodulate the received signal.

```
z = apskdemod(y,M,radii,'SymbolMapping',cmap,'OutputType','bit');
```

Verify that the demodulated signal is equal to the original data.

```
isequal(x,z)
```

```
ans = logical
   1
```

Soft Bit Demodulate 32-APSK Signal

Demodulate a 32-APSK signal and calculate soft bits.

Define vectors for modulation order and PSK ring radii. Generate 10000 symbols of random bit data.

```
M = [16 16];
modOrder = sum(M);
radii = [0.6 1.2];
numSym = 10000;
x = randi([0 1], numSym*log2(modOrder),1);
```

Generate a reference constellation. Create a constellation diagram object.

```
refAPSK = apskmod(0:modOrder-1,M,radii);
constDiagAPSK = comm.ConstellationDiagram('ReferenceConstellation',refAPSK, ...
  'Title','Received Symbols','XLimits',[-2 2],'YLimits',[-2 2]);
```

Modulate the data.

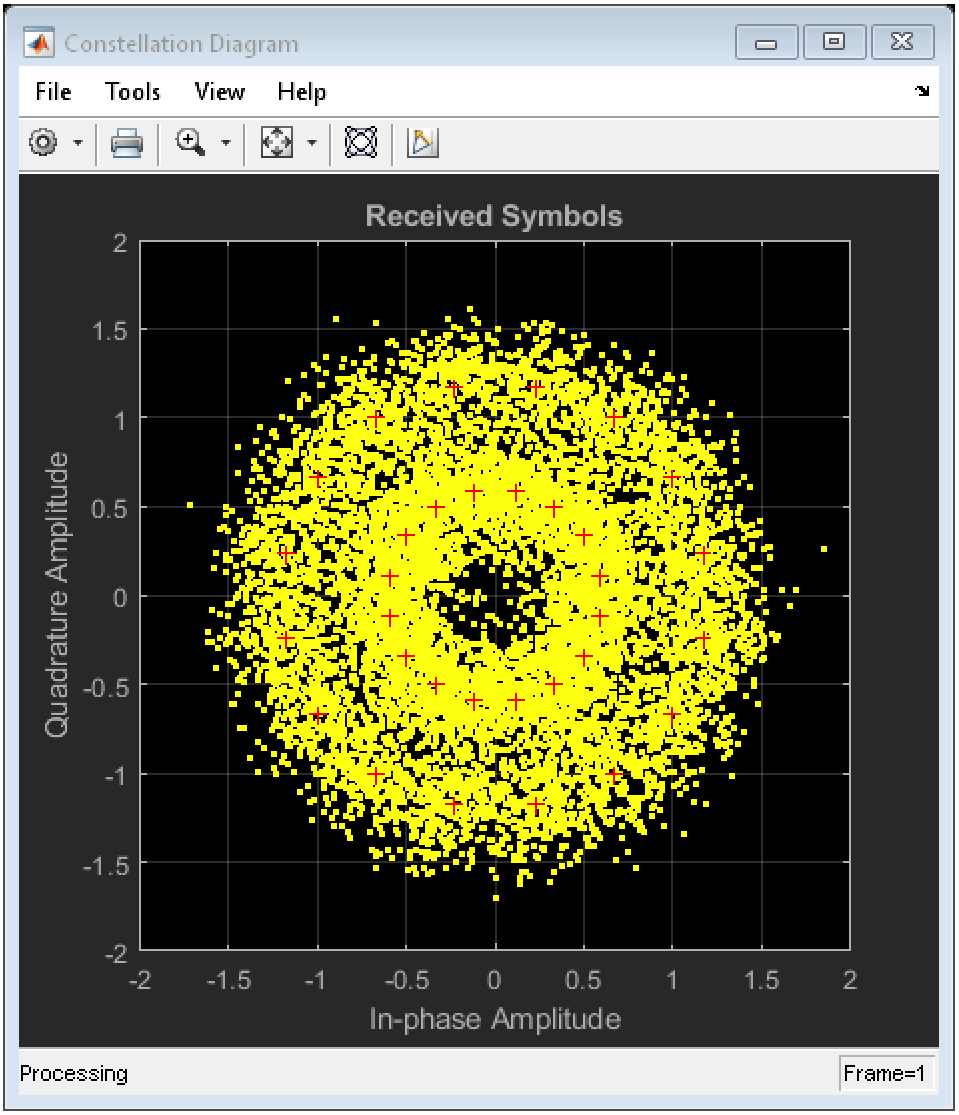
```
txSig = apskmod(x,M,radii,'InputType','bit');
sigPow = var(txSig);
```

Pass the signal through a noisy channel.

```
snr = 15;
rxSig = awgn(txSig,snr,sigPow,'linear');
```

Plot the reference and received constellation symbols.

```
constDiagAPSK(rxSig)
```



Demodulate the signal and compute soft bits.

```
z = apskdemod(rxSig,M,radii,'OutputType','approxllr', ...
    'NoiseVariance',sigPow/snr);
```

Input Arguments

y — APSK modulated signal

scalar | vector | matrix

APSK modulated signal, specified as a complex scalar, vector, or matrix. Each column is treated as an independent channel.

Data Types: double | single
Complex Number Support: Yes

M — Constellation points per PSK ring

vector

Constellation points per PSK ring, specified as a vector with more than one element. Vector elements indicate the number of constellation points in each PSK ring. The first element corresponds to the innermost circle, and so on, until the last element, that corresponds to the outermost circle. Element values must be multiples of four and `sum(M)` must be a power of two. The modulation order is the total number of points in the signal constellation and equals the sum of the vector elements, `sum(M)`.

Example: `[4 12 16]` specifies a three PSK ring constellation with a modulation order of `sum(M) = 32`.

Data Types: `double`

`radii` — PSK ring radii

vector

PSK ring radii, specified as a vector with the same length as `M`. The first element corresponds to the innermost circle, and so on, until the last element, that corresponds to the outermost circle. The elements must be positive and arranged in increasing order.

Example: `[0.5 1 2]` defines constellation PSK ring radii. The inner ring has a radius of 0.5, the second ring has a radius of 1.0, and the outer ring has a radius of 2.0.

Data Types: `double`

`phaseoffset` — PSK ring phase offsets

`[pi/M(1) pi/M(2) … pi/M(end)]` (default) | scalar | vector

Phase offset of each PSK ring in radians, specified as a scalar or vector with the same length as `M`. The first element corresponds to the innermost circle, and so on, until the last element, that corresponds to the outermost circle. The `phaseoffset` can be a scalar only if all the elements of `M` are the same value.

Example: `[pi/4 pi/12 pi/16]` defines three constellation PSK ring phase offsets. The inner ring has a phase offset of pi/4, the second ring has a phase offset of pi/12, and the outer ring has a phase offset of pi/16.

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `y = apskdemod(x,M,radii,'OutputType','bit','OutputDataType','single');`

`SymbolMapping` — Symbol mapping

`'gray'` | `'contourwise-gray'` | integer vector

Symbol mapping, specified as the comma-separated pair consisting of `SymbolMapping` and one of the following:

- `'contourwise-gray'` — Uses Gray mapping along the contour in phase dimension.
- `'gray'` — Uses Gray mapping along the contour in both the amplitude and phase dimensions. For Gray symbol mapping, all the values for `M` must be equal and all the values for `phaseoffset` must be equal. For a description of the Gray mapping used, see [2].
- integer vector — Use custom symbol mapping. Vector must consist of `sum(M)` unique elements with values from 0 to (`sum(M)-1`). The first element corresponds to the constellation point in the

first quadrant of the innermost circle, with subsequent elements positioned counterclockwise around the PSK rings.

The default symbol mapping depends on M and phaseOffset. When all the elements of M and phaseOffset are equal, the default is 'gray'. For all other cases, the default is 'contourwise-gray'.

Data Types: double | char | string

OutputType — Output type

'integer' (default) | 'bit' | 'llr' | 'approxllr'

Output type, specified as the comma-separated pair consisting of 'OutputType' and 'integer', 'bit', 'llr', or 'approxllr'. For a description of the returned output, see z.

Data Types: char | string

OutputDataType — Output data type

'double' (default) | ...

Output data type, specified as the comma-separated pair consisting of OutputDataType and one of the indicated data types. Acceptable values for OutputDataType depend on the OutputType value.

OutputType Value	Acceptable OutputDataType Values
'integer'	'double', 'single', 'int8', 'int16', 'int32', 'uint8', 'uint16', or 'uint32'
'bit'	'double', 'single', 'int8', 'int16', 'int32', 'uint8', 'uint16', 'uint32', or 'logical'

Dependencies

This name-value pair argument applies only when OutputType is set to 'integer' or 'bit'.

Data Types: char | string

NoiseVariance — Noise variance

1 (default) | positive scalar | vector of positive values

Noise variance, specified as the comma-separated pair consisting of NoiseVariance and a positive scalar or vector of positive values.

- When specified as a scalar, the same noise variance value is used on all input elements.
- When specified as a vector, the vector length must be equal to the number of columns in the input signal.

When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see “APSK Soft Demodulation” on page 2-23 for algorithm selection considerations.

Dependencies

This name-value pair argument applies only when OutputType is set to 'llr' or 'approxllr'.

Data Types: double

PlotConstellation — Option to plot constellation

false (default) | true

Option to plot constellation, specified as the comma-separated pair consisting of 'PlotConstellation' and a logical scalar. To plot the constellation, set PlotConstellation to true.

Data Types: logical

Output Arguments

z — Demodulated signal

scalar | vector | matrix

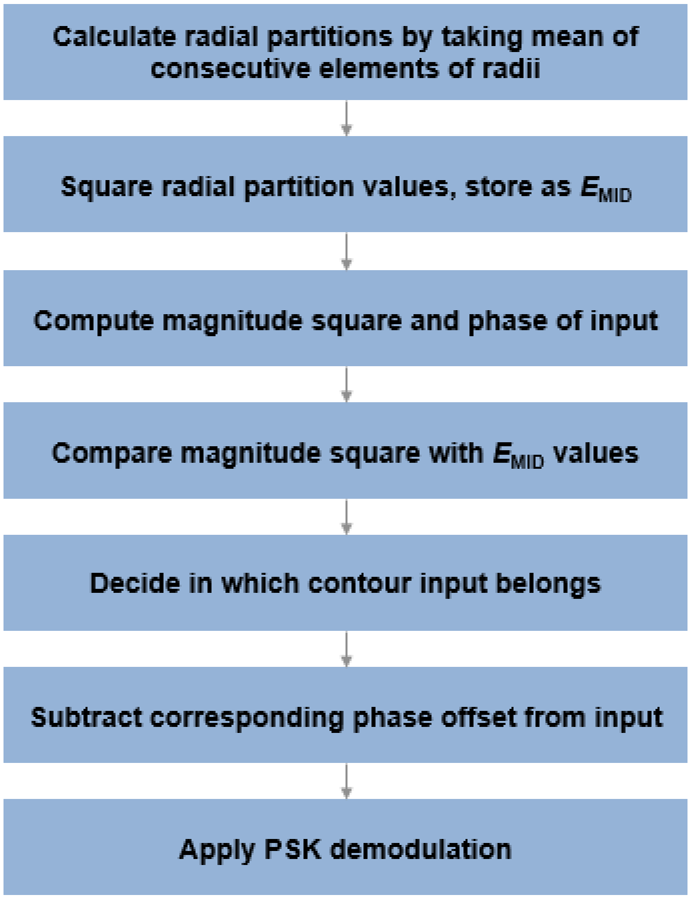
Demodulated signal, returned as a scalar, vector, or matrix. The dimensions of z depend on the specified OutputType value.

OutputType Value	Return Value of apskdemod	Dimensions of z
'integer'	Demodulated integer values from 0 to (sum(M) – 1)	z has the same dimensions as input y.
'bit'	Demodulated bits	The number of rows in z is $\log_2$(sum(M)) times the number of rows in y. Each demodulated symbol is mapped to a group of $\log_2$(sum(M)) elements in a column, where the first element represents the MSB and the last element represents the LSB.
'llr'	Log-likelihood ratio value for each bit	
'approxllr'	Approximate log-likelihood ratio value for each bit	

More About

APSK Hard Demodulation

The hard demodulation algorithm applies amplitude phase decoding as described in [1].



Calculate radial partitions by taking mean of consecutive elements of radii
Square radial partition values, store as E_{MID}
Compute magnitude square and phase of input
Compare magnitude square with E_{MID} values
Decide in which contour input belongs
Subtract corresponding phase offset from input
Apply PSK demodulation

APSK Soft Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. This table compares these algorithms.

Algorithm	Accuracy	Execution Speed
Exact LLR	more accurate	slower execution
Approximate LLR	less accurate	faster execution

For further description of these algorithms, see “Exact LLR Algorithm” and “Approximate LLR Algorithm”.

Note The exact LLR algorithm computes exponentials using finite precision arithmetic. Computation of exponentials with very large positive or negative magnitudes might yield:

- `Inf` or `-Inf` if the noise variance is a very large value
- `NaN` if both the noise variance and signal power are very small values

When the output returns any of these values, try using the approximate LLR algorithm because it does not compute exponentials.

apskmod

Amplitude phase shift keying (APSK) modulation

Syntax

```
y = apskmod(x,M,radii)
y = apskmod(x,M,radii,phaseoffset)
y = apskmod( ___ ,Name,Value)
```

Description

y = apskmod(x,M,radii) performs APSK modulation on the input data, x, based on the specified number of constellation points per PSK ring, M, and the radius of each PSK ring, radii. For a description of APSK modulation, see “Algorithms” on page 2-32.

Note apskmod specifically applies to multiple ring PSK constellations. For a single ring PSK constellation, use pskmod.

y = apskmod(x,M,radii,phaseoffset) specifies an initial phase offset for each PSK ring of the APSK modulated signal.

y = apskmod(___ ,Name,Value) specifies options using one or more name-value pair arguments using any of the previous syntaxes. For example, 'OutputDataType','double' specifies the desired output data type as double. Specify name-value pair arguments after all other input arguments.

Examples

Apply APSK Modulation

Modulate data using APSK with an unequal number of constellation points on each circle.

Define vectors for modulation order and PSK ring radii. Generate data for constellation points.

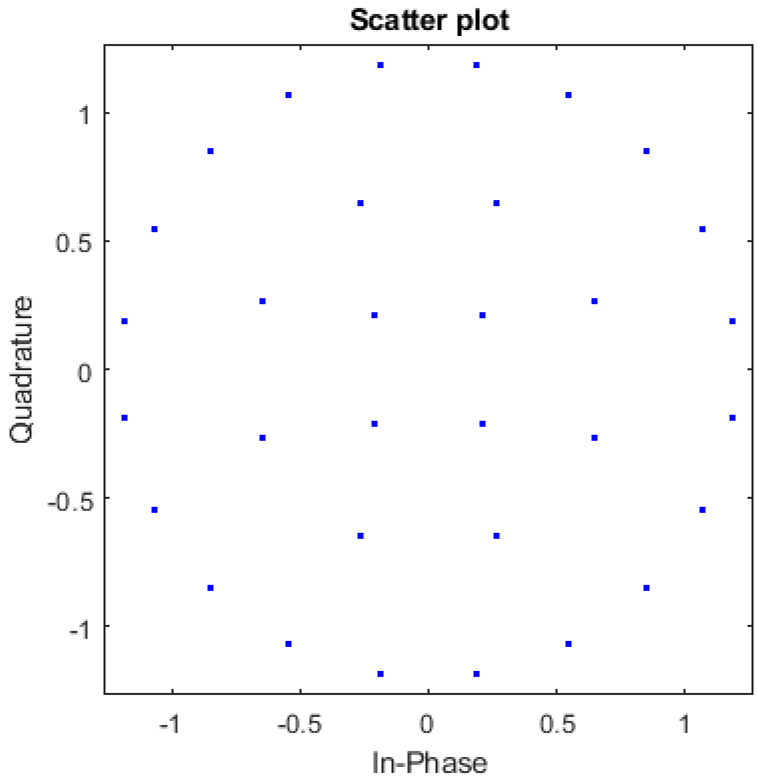
```
M = [4 8 20];
radii = [0.3 0.7 1.2];
modOrder = sum(M);
x = 0:modOrder-1;
```

Apply APSK modulation to the data.

```
y = apskmod(x,M,radii);
```

Plot the resulting constellation using a scatter plot.

```
scatterplot(y)
```



Apply APSK Modulation with Phase Offset

Modulate a random data sequence using APSK with zero phase offset for the inner circle and pi/6 phase offset for the outer circle.

Define vectors for modulation order, PSK ring radii, and PSK ring phase offset. Generate random data.

```
M = [8 8];
modOrder = sum(M);
radii = [0.5 1];
phOff = [0 pi/6];

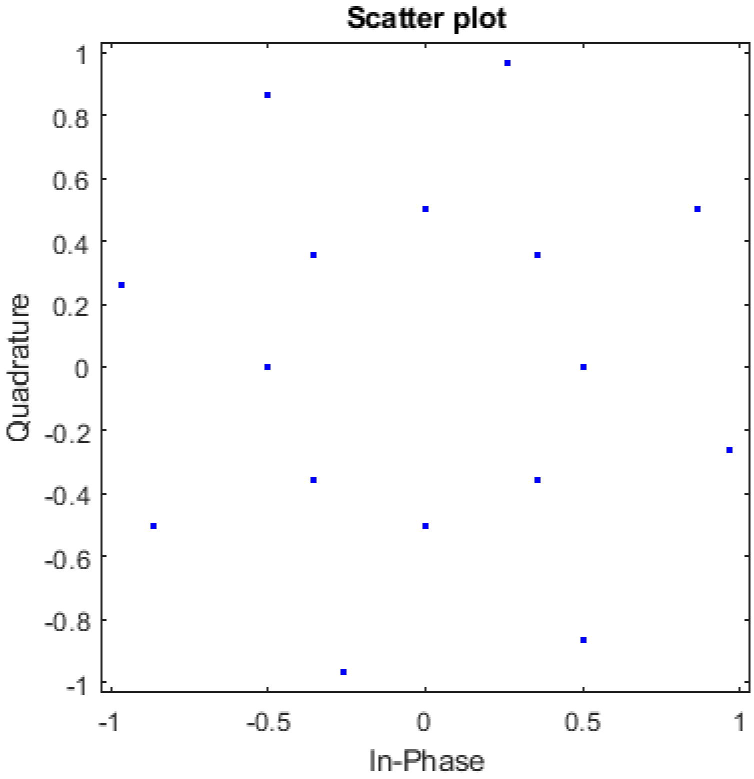
x = randi([0 modOrder-1],100,1);
```

Apply APSK modulation to the data.

```
y = apskmod(x,M,radii,phOff);
```

Plot the resulting constellation using a scatter plot and observe the phase offset between the constellation circles.

```
scatterplot(y)
```



Apply APSK Modulation Modifying Symbol Ordering

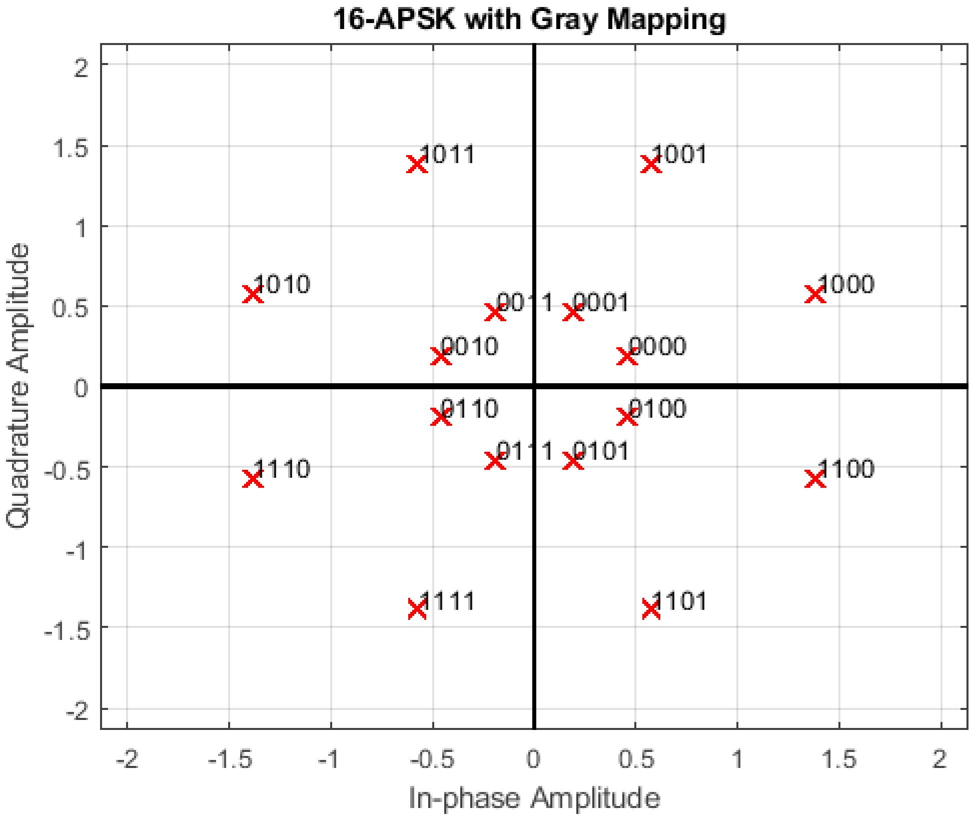
Plot APSK constellations for gray and custom symbol mappings.

Define vectors for modulation order and PSK ring radii. Generate bit data for constellation points.

```
M = [8 8];
modOrder = sum(M);
radii = [0.5 1.5];
x = 0:modOrder-1;
xBit = de2bi(x);
```

Apply APSK modulation to the data using the default phase offset. Since element values for `M` are equal and element values for phase offset are equal, the symbol mapping defaults to `'gray'`. Binary input is used to highlight the Gray nature of the constellation mapping. Plot the constellation.

```
y = apskmod(xBit,M,radii,'PlotConstellation',true,'InputType','bit');
```

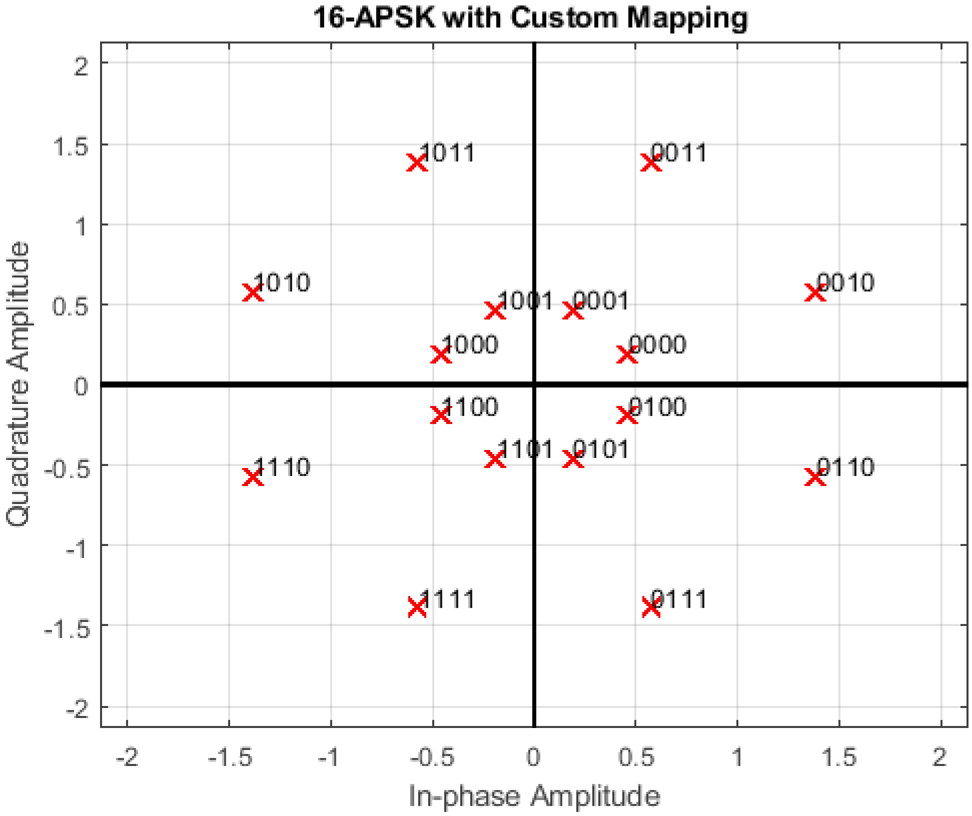


Create a custom symbol mapping vector. This custom mapping happens to be another Gray mapping.

```
cmap = [0;1;9;8;12;13;5;4;2;3;11;10;14;15;7;6];
```

Apply APSK modulation with a custom symbol mapping. Plot the constellation. Binary input is used to highlight that the custom mapping defines different Gray symbol mapping.

```
z = apskmod(xBit,M,radii,'SymbolMapping',cmap,'PlotConstellation',true,'InputType','bit');
```



Apply APSK Modulation to Input Bits

Modulate a random bit sequence using APSK and output data type `single`. Pass the signal through a noisy channel and display the constellation diagram.

Define vectors for modulation order and PSK ring radii. Generate random binary data.

```
M = [8 12 20 24];
radii = [0.8 1.2 2 2.5];
bitsPerSym = log2(sum(M));

x = randi([0 1],2000*bitsPerSym,1);
```

Apply APSK modulation to the data and use a name-value pair to output as data type `single`.

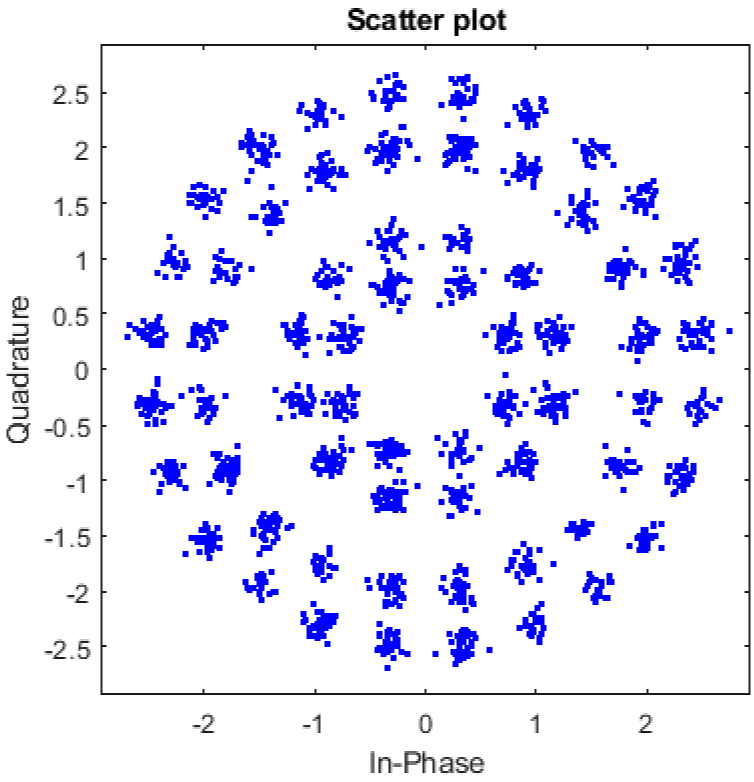
```
y = apskmod(x,M,radii,'InputType','bit','OutputDataType','single');
```

Pass through an AWGN channel with a 25 dB SNR.

```
yrec = awgn(y,25,'measured');
```

Plot the received constellation as a scatter plot.

```
scatterplot(yrec)
```



Input Arguments

x — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix. The elements of x must be binary values or integers in the range [0, (`sum(M)-1`)].

Note To process the input signal as binary elements, set the '`InputType`' name-value pair to `'bit'`. For binary inputs, the number of rows must be an integer multiple of $\log_2(\text{sum}(M))$. Groups of $\log_2(\text{sum}(M))$ bits in a column are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

`M` — Constellation points per PSK ring

vector

Constellation points per PSK ring, specified as a vector with more than one element. Each vector element indicates the number of constellation points in its corresponding PSK ring. The first element corresponds to the innermost circle, and so on, until the last element, which corresponds to the outermost circle. Element values must be multiples of four and `sum(M)` must be a power of two. The modulation order is the total number of points in the signal constellation and equals the sum of the vector elements, `sum(M)`.

Example: `[4 12 16]` specifies a three PSK ring constellation with a modulation order of `sum(M) =` 32.

Data Types: `double`

`radii` — Radius per PSK ring

vector

Radius per PSK ring, specified as a vector with the same length as `M`. The first element corresponds to the innermost circle, and so on, until the last element, which corresponds to the outermost circle. The elements must be positive and arranged in increasing order.

Example: `[0.5 1 2]` defines radii for three constellation PSK rings. The inner ring has a radius of 0.5, the second ring has a radius of 1.0, and the outer ring has a radius of 2.0.

Data Types: `double`

`phaseoffset` — Phase offset per PSK ring

`[pi/M(1) pi/M(2) … pi/M(end)]` (default) | scalar | vector

Phase offset per PSK ring in radians, specified as a scalar or vector with the same length as `M`. The first element corresponds to the innermost circle, and so on, until the last element, which corresponds to the outermost circle. The `phaseoffset` can be a scalar only if all the elements of `M` are the same value.

Example: `[pi/4 pi/12 pi/16]` defines three constellation PSK ring phase offsets. The inner ring has a phase offset of pi/4, the second ring has a phase offset of pi/12, and the outer ring has a phase offset of pi/16.

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `y = apskmod(x,M,radii,'InputType','bit','OutputDataType','single');`

`SymbolMapping` — Symbol mapping

`'gray'` | `'contourwise-gray'` | integer vector

Symbol mapping, specified as the comma-separated pair consisting of `'SymbolMapping'` and one of the following:

- `'contourwise-gray'` — Uses Gray mapping along the contour in the phase dimension for each PSK ring.
- `'gray'` — Uses Gray mapping along the contour in both the amplitude and phase dimensions. For Gray symbol mapping, all the values for `M` must be equal and all the values for `phaseoffset` must be equal. For a description of the Gray mapping used, see [2].
- integer vector — Use custom symbol mapping. Vector must consist of `sum(M)` unique elements with values in the range [0, (`sum(M)-1`]. The first element corresponds to the constellation point in the first quadrant of the innermost circle, with subsequent elements positioned counterclockwise around the PSK rings.

The default symbol mapping depends on M and phaseOffset. When all the elements of M are equal and all the elements of phaseOffset are equal, the default is 'gray'. For all other cases, the default is 'contourwise-gray'.

Data Types: double | char | string

InputType — Input type
'integer' (default) | 'bit'

Input type, specified as the comma-separated pair consisting of 'InputType' and either 'integer' or 'bit'. To use 'integer', the input signal must consist of integers in the range [0, (sum(*M*) – 1)]. To use 'bit', the input signal must contain binary values and the number of rows must be an integer multiple of $\log_2$(sum(M)).

Data Types: char | string

OutputDataType — Output data type
'double' (default) | 'single'

Output data type, specified as the comma-separated pair consisting of 'OutputDataType' and either 'double' or 'single'.

Data Types: char | string

PlotConstellation — Plot reference constellation
false (default) | true

Plot reference constellation, specified as the comma-separated pair consisting of 'PlotConstellation' and a logical scalar. To plot the reference constellation, set PlotConstellation to true.

Data Types: logical

Output Arguments

y — APSK modulated signal
scalar | vector | matrix

APSK modulated signal, returned as a complex scalar, vector, or matrix. The dimensions of y depend on the specified 'InputType' value.

InputType	Dimensions of y
'integer'	y has the same dimensions as input x.
'bit'	The number of rows in y equals the number of rows in x divided by $\log_2$(sum(M)).

Algorithms

The function implements a pure APSK constellation.

A pure M-APSK constellation is composed of N_C concentric rings or contours, each with uniformly spaced PSK points. The M-APSK constellation set is

$$\chi = \begin{cases} R_1 \exp\left(j\left(\frac{2\pi}{M_1} i + \theta_1\right)\right), & i = 0, \ldots, M_1 - 1, \\ R_2 \exp\left(j\left(\frac{2\pi}{M_2} i + \theta_2\right)\right), & i = 0, \ldots, M_2 - 1, \\ \vdots & \vdots \\ R_{N_C} \exp\left(j\left(\frac{2\pi}{M_{N_C}} i + \theta_{\mathrm{Nc}}\right)\right), & i = 0, \ldots, M_{N_C} - 1, \end{cases}$$

where

- The modulation order is equal to the sum of all M_l for l = 1, 2, ... , N_C.
- N_C is the number of concentric rings. $N_C \geq 2$.
- M_l is the number of constellation points in the lth ring.
- R_l is the radius of the lth ring.
- θ_l is the phase offset of the lth ring.
- $j = \sqrt{-1}$

arithdeco

Decode binary code by arithmetic decoding

Syntax

```
dseq = arithdeco(code,counts,len)
```

Description

`dseq = arithdeco(code,counts,len)` decodes the binary arithmetic code in `code` to recover the corresponding sequence of `len` symbols. The input `counts`specifies the statistics of the source by listing the number of times each symbol of the source alphabet occurs in a test data set. `code` must be an output of the `arithenco` function.

Examples

Decode Sequence Using Arithmetic Code

Using a source with a two-symbol alphabet, produce a test data set in which 99% of the symbols are 1s. Encode 1000 symbols from this source to produce a code vector with less than 1000 elements. The actual number of elements in the encoded sequence varies depending on the particular random sequence.

Specify for symbol 1 from the source alphabet to occur 99 times in the test data set.

```
counts = [99 1];
```

Generate a random sequence of length 1000.

```
len = 1000;
seq = randsrc(1,len,[1 2; .99 .01]);
```

Encode the random sequence. Then, decode the encoded sequence.

```
code = arithenco(seq,counts);
dseq = arithdeco(code,counts,length(seq));
```

Verify that the decoded sequence matches the original random sequence.

```
isequal(seq,dseq)
```

```
ans = logical
   1
```

Input Arguments

code — Binary arithmetic code
nonnegative binary row vector

Binary arithmetic code, specified as a nonnegative binary row vector. This value must be a binary arithmetic code produced by the `arithenco` function.

Data Types: `double`

`counts` — Statistics of symbols
positive numeric vector

Statistics of symbols, specified as a positive numeric vector. This input specifies the number of times each symbol of the source alphabet occurs in a test data set.

Data Types: `double`

`len` — Length of sequence
positive scalar

Length of the sequence to decode, specified as a positive scalar.

Data Types: `double`

Output Arguments

`dseq` — Decoded arithmetic code
positive numeric row vector

Decoded arithmetic code with a sequence of `len` source symbols, specified as a positive numeric row vector.

Algorithms

The `arithdeco` function uses the algorithm described in [1] .

arithenco

Encode sequence of symbols by arithmetic encoding

Syntax

```
code = arithenco(seq,counts)
```

Description

`code = arithenco(seq,counts)` generates the binary arithmetic code corresponding to the sequence of symbols specified in `seq`. The input `counts` specifies the statistics of the source by listing the number of times each symbol of the source alphabet occurs in a test data set.

Examples

Encode Data Sequence with Arithmetic Code

Using a source with a two-symbol alphabet, produce a test data set in which 99% of the symbols are 1s. Encode 1000 symbols from this source to produce a code vector with less than 1000 elements. The actual number of elements in the encoded sequence varies depending on the particular random sequence.

Specify for symbol 1 from the source alphabet to occur 99 times in the test data set.

```
counts = [99 1]
```

```
counts = 1×2

    99     1
```

Generate a random sequence of length 1000.

```
len = 1000;
seq = randsrc(1,len,[1 2; .99 .01]);
```

Encode the random sequence and display the encoded length.

```
code = arithenco(seq,counts);
s = size(code)
```

```
s = 1×2

     1    57
```

Input Arguments

seq — Sequence of symbols
positive numeric row vector

Sequence of symbols, specified as a positive numeric row vector. This input specifies the random sequence for the function to encode.

Data Types: `double`

`counts` — Statistics of symbols

positive numeric row vector

Statistics of symbols, specified as a positive numeric row vector. This input specifies the number of times each symbol of the source alphabet occurs in a test data set.

Data Types: `double`

Output Arguments

code — Generated binary arithmetic code

nonnegative binary row vector

Generated binary arithmetic code corresponding to the sequence of source symbols, returned as a nonnegative binary row vector.

Algorithms

The `arithenco` function uses the algorithm described in [1].

awgn

Add white Gaussian noise to signal

Syntax

```
out = awgn(in,snr)
out = awgn(in,snr,signalpower)

out = awgn(in,snr,signalpower,randobject)
out = awgn(in,snr,signalpower,seed)
out = awgn( ___ ,powertype)
```

Description

`out = awgn(in,snr)` adds white Gaussian noise to the vector signal `in`. This syntax assumes that the power of `in` is 0 dBW.

`out = awgn(in,snr,signalpower)` accepts an input signal power value in dBW. To have the function measure the power of `in` before adding noise, specify `signalpower` as `'measured'`.

`out = awgn(in,snr,signalpower,randobject)` accepts input combinations from prior syntaxes and a random number stream object to generate normal random noise samples. For information about producing repeatable noise samples, see “Tips” on page 2-43.

`out = awgn(in,snr,signalpower,seed)` specifies a seed value for initializing the normal random number generator that is used when adding white Gaussian noise to the input signal. For information about producing repeatable noise samples, see “Tips” on page 2-43.

`out = awgn( ___ ,powertype)` specifies the signal and noise power type as `'dB'` or `'linear'` in addition to the input arguments in any of the previous syntaxes.

For the relationships between SNR and other measures of the relative power of the noise, such as E_s/N_0, and E_b/N_0, see “AWGN Channel Noise Level”.

Examples

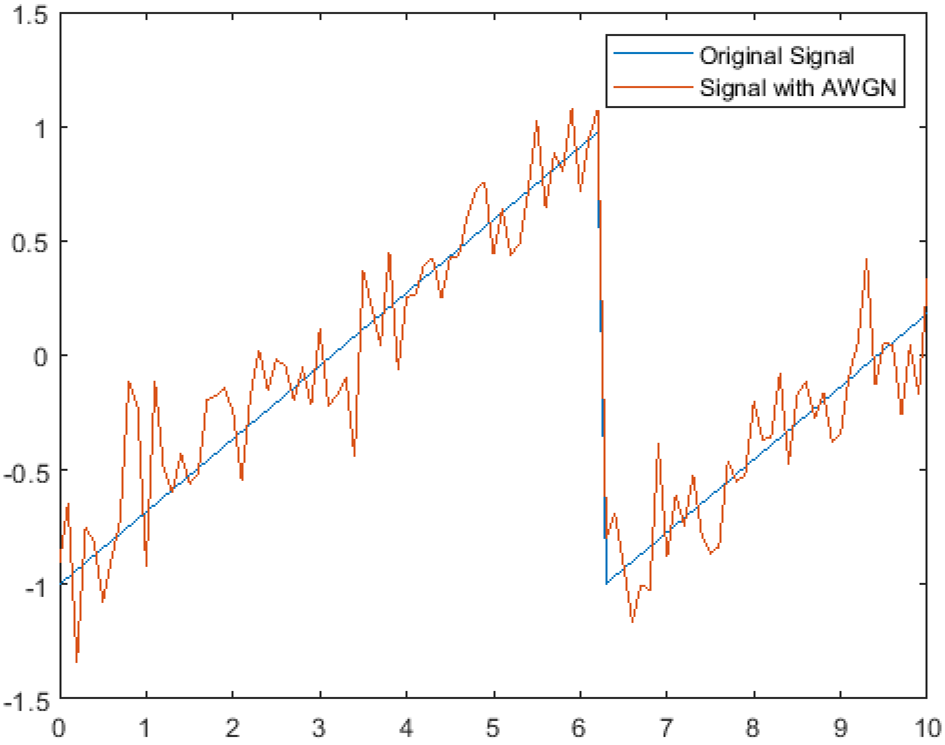
Add AWGN to Sawtooth Signal

Create a sawtooth wave.

```
t = (0:0.1:10)';
x = sawtooth(t);
```

Apply white Gaussian noise and plot the results.

```
y = awgn(x,10,'measured');
plot(t,[x y])
legend('Original Signal','Signal with AWGN')
```



General QAM Modulation in AWGN Channel

Transmit and receive data using a nonrectangular 16-ary constellation in the presence of Gaussian noise. Show the scatter plot of the noisy constellation and estimate the symbol error rate (SER) for two different signal-to-noise ratios.

Create a 16-QAM constellation based on the V.29 standard for telephone-line modems.

```
c = [-5 -5i 5 5i -3 -3-3i -3i 3-3i 3 3+3i 3i -3+3i -1 -1i 1 1i];
M = length(c);
```

Generate random symbols.

```
data = randi([0 M-1],2000,1);
```

Modulate the data by using the `genqammod` function. General QAM modulation is necessary because the custom constellation is not rectangular.

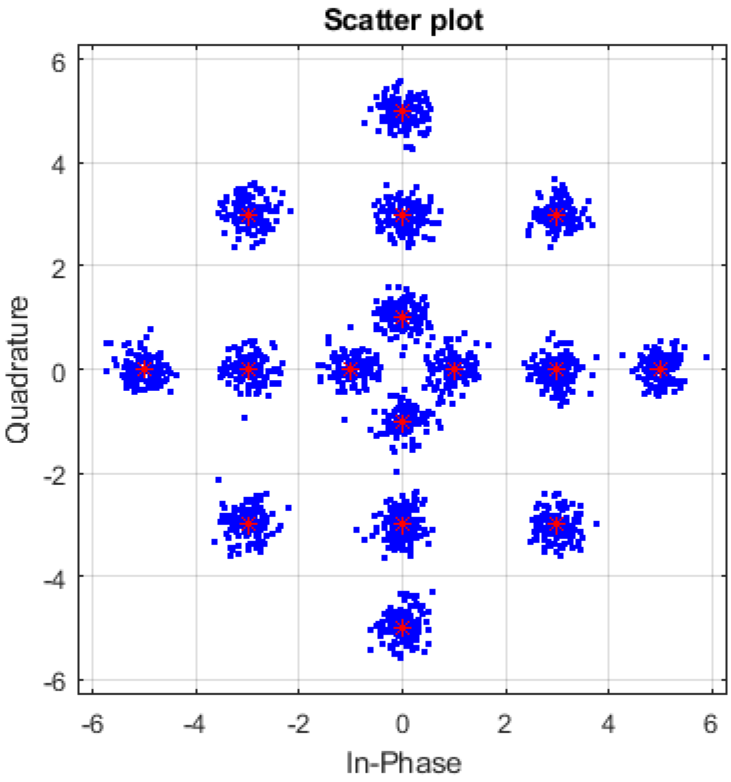
```
modData = genqammod(data,c);
```

Pass the signal through an AWGN channel having a 20 dB signal-to-noise ratio (SNR).

```
rxSig = awgn(modData,20,'measured');
```

Display a scatter plot of the received signal and the reference constellation, `c`.

```
h = scatterplot(rxSig);
hold on
scatterplot(c,[],[],'r*',h)
grid
hold off
```



Demodulate the received signal by using the `genqamdemod` function. Determine the number of symbol errors and the symbol error ratio.

```
demodData = genqamdemod(rxSig,c);
[numErrors,ser] = symerr(data,demodData)
```

```
numErrors = 1
```

```
ser = 5.0000e-04
```

Repeat the transmission and demodulation process with an AWGN channel having a 10 dB SNR. Determine the symbol error rate for the reduced SNR. As expected, the performance degrades when the SNR is decreased.

```
rxSig = awgn(modData,10,'measured');
demodData = genqamdemod(rxSig,c);
[numErrors,ser] = symerr(data,demodData)
```

```
numErrors = 462
```

```
ser = 0.2310
```

Repeatable AWGN with RandStream

Generate white Gaussian noise addition results using a `RandStream` object and the `reset` object function.

Specify the power of X to be `0` dBW, add noise to produce an SNR of `10` dB, and utilize a local random stream.

```
S = RandStream('mt19937ar','Seed',5489);
sigin = sqrt(2)*sin(0:pi/8:6*pi);
sigout1 = awgn(sigin,10,0,S);
```

Add AWGN to `sigin`. Use `isequal` to compare `sigout1` to `sigout2`. The outputs are not equal when the random stream was not reset.

```
sigout2 = awgn(sigin,10,0,S);
isequal(sigout1,sigout2)
```

```
ans = logical
   0
```

Reset the random stream object, returning the object to its state prior to adding AWGN to `sigout1`. Add AWGN to `sigin` and compare `sigout1` to `sigout3`. The outputs are equal after the random stream was reset.

```
reset(S);
sigout3 = awgn(sigin,10,0,S);
isequal(sigout1,sigout3)
```

```
ans = logical
   1
```

Input Arguments

in — Input signal

scalar | vector | array

Input signal, specified as a scalar, vector, or array. The power of the input signal is assumed to be 0 dBW.

Data Types: `double`
Complex Number Support: Yes

`snr` — Signal-to-noise ratio

scalar

Signal-to-noise ratio in dB, specified as a scalar.

Note When the noise is added, this function applies the same `snr` to all elements of the full input signal. Array input signals do not have a notion of independent channels. To consider multiple channels independently, see `comm.AWGNChannel`.

Data Types: `double`

`signalpower` — Signal power

scalar | `'measured'`

Signal power, specified as a scalar or `'measured'`.

- When `signalpower` is a scalar, the value is used as the signal level of `in` to determine the appropriate noise level based on the value of `snr`.
- When `signalpower` is `'measured'`, the signal level of `in` is computed to determine the appropriate noise level based on the value of `snr`.

> **Note** When you specify `'measured'`, this function computes the signal power using all elements of the full input signal. When the power is computed, array input signals do not have a notion of independent channels.

Data Types: `double`

`randobject` — Random number stream object

`RandStream` object

Random number stream object, specified as a `RandStream` object. The state of the random stream object determines the sequence of numbers produced by the `randn` function. Configure the random stream object using the `reset (RandStream)` function and its properties.

`wgn` generates normal random noise samples using `randn`. The `randn` function uses one or more uniform values from the `RandStream` object to generate each normal value.

For information about producing repeatable noise samples, see “Tips” on page 2-43.

`seed` — Random number generator seed

scalar

Random number generator seed value, specified as a scalar.

Data Types: `double`

`powertype` — Signal power unit

`'dB'` (default) | `'linear'`

Signal power unit, specified as `'dB'` or `'linear'`

- When `powertype` is `'dB'`, the `snr` is measured in dB and `signalpower` is measured in dBW.
- When `powertype` is `'linear'`, the `snr` is measured as a ratio and `signalpower` is measured in watts.

For the relationships between SNR and other measures of the relative power of the noise, such as E_s/N_0, and E_b/N_0, see “AWGN Channel Noise Level”.

Output Arguments

`out` — Output signal

scalar | vector | array

Output signal, returned as a scalar, vector, or array. The returned output signal is the input signal with white Gaussian noise added to it.

Tips

- To generate repeatable white Gaussian noise samples, use one of these tips:
  - Provide a static `seed` value as an input to `awgn`.
  - Use the `reset (RandStream)` function on the `randobject` before passing it as an input to `awgn`.
  - Provide `randobject` in a known state as an input to `awgn`. For more information, see `RandStream`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Code generation supported, except for syntaxes that include a `RandStream` object.

bchdec

BCH decoder

Syntax

```
decoded = bchdec(code,N,K)
decoded = bchdec(code,N,K,paritypos)
[decoded,cnumerr] = bchdec( ___ )
[decoded,cnumerr,ccode] = bchdec( ___ )
```

Description

`decoded = bchdec(code,N,K)` attempts to decode the received signal in `code` using an (`N`,`K`) BCH decoder with the narrow-sense generator polynomial. Parity symbols are at the end and the leftmost symbol is the most significant symbol.

In the `decoded` Galois field array, each row represents the attempt at decoding the corresponding row in `code`.

`decoded = bchdec(code,N,K,paritypos)` specifies in `paritypos` whether the parity symbols in `code` were appended or prepended to the message in the coding operation.

`[decoded,cnumerr] = bchdec( ___ )` returns a column vector, `cnumerr`, where each element is the number of corrected errors in the corresponding row of `code`. You can return `cnumerr` with either of the preceding syntaxes.

`[decoded,cnumerr,ccode] = bchdec( ___ )` returns `ccode`, the corrected version of `code`.

Examples

Results of Error Correction

BCH-decode an input that has more errors per codeword than the error correcting capability of the BCH decoder. Decode a BCH coded message with two errors per codeword using a single-error correcting BCH decoder. View the effects of the error mismatch on the output codeword.

Check the number of errors per codeword a [63,57] BCH decoder is capable of correcting.

```
n = 63;
k = 57;
t = bchnumerr(n,k)
```

```
t = 1
```

The [63,57] BCH decoder is capable of correcting one error per codeword.

Create a random stream and use it to generate a GF array. Encode the message.

```
s = RandStream('swb2712','Seed',9973);
msg = gf(randi(s,[0 1],1,k));
code = bchenc(msg,n,k);
```

Add two errors per codeword and decode the errored code.

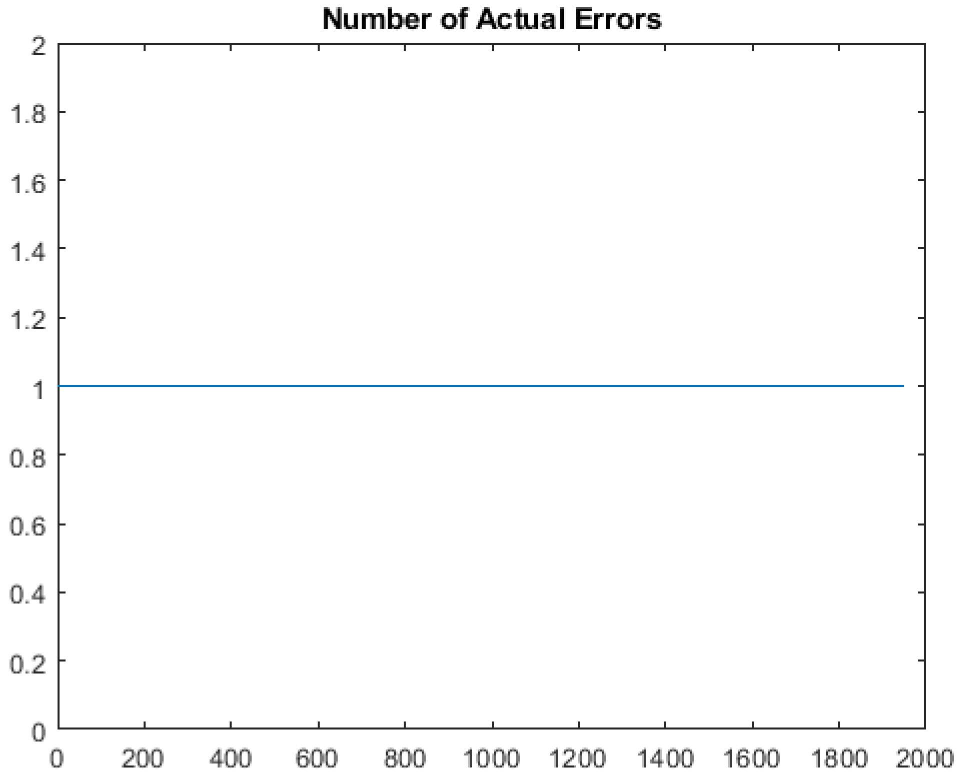
```
cnumerr2 = zeros(nchoosek(n,2),1);
nErrs = zeros(nchoosek(n,2),1);
cnumerrIdx = 1;
for idx1 = 1 : n-1
    %sprintf('idx1 for 2 errors = %d', idx1)
    for idx2 = idx1+1 : n
        errors = zeros(1,n);
        errors(idx1) = 1;
        errors(idx2) = 1;
        erroredCode = code + gf(errors);
        [decoded2, cnumerr2(cnumerrIdx)] ...
          = bchdec(erroredCode,n,k);
```

Encode the decoded message. Check that the re-encoded message differs from the errored message in only one bit.

```
        if cnumerr2(cnumerrIdx) == 1
            code2 = bchenc(decoded2,n,k);
            nErrs(cnumerrIdx) = biterr(double(erroredCode.x), ...
              double(code2.x));
        end
        cnumerrIdx = cnumerrIdx + 1;
    end
end
```

Plot the computed number of errors, based on the difference between the doubly-errored code and the re-encoded version of the initial decoding.

```
plot(nErrs)
title('Number of Actual Errors')
```



All inputs with two errors were decoded to a codeword that differs in exactly one bit from the re-encoded version.

Decode Received BCH Codeword in Noisy Channel

Set the BCH parameters for a Galois array of GF(2).

```
M = 4;
n = 2^M-1;   % Codeword length
k = 5;       % Message length
nwords = 10; % Number of words to encode
```

Create a message.

```
msgTx = gf(randi([0 1],nwords,k));
```

Find the error-correction capability.

```
t = bchnumerr(n,k)
```

```
t = 3
```

Encode the message.

```
enc = bchenc(msgTx,n,k);
```

Corrupt up to t bits in each codeword.

```
noisycode = enc + randerr(nwords,n,1:t);
```

Decode the noisy code.

```
msgRx = bchdec(noisycode,n,k);
```

Validate that the message was properly decoded.

```
isequal(msgTx,msgRx)
```

```
ans = logical
   1
```

Increase the number of possible errors, and generate another noisy codeword.

```
t2 = t + 1;
noisycode2 = enc + randerr(nwords,n,1:t2);
```

Decode the new received codeword.

```
[msgRx2,numerr] = bchdec(noisycode2,n,k);
```

Determine if the message was properly decoded by examining the number of corrected errors, `numerr`. Entries of `-1` correspond to decoding failures, which occur when the codeword has more errors than can be corrected for the specified `[n,k]` pair.

```
numerr
```

```
numerr = 10×1

     1
     2
    -1
     2
     3
     1
    -1
     4
     2
     3
```

Two of the ten transmitted codewords were not correctly received.

Input Arguments

code — Encoded message
Galois field array

Encoded message, specified as a Galois field array of symbols over GF(2). Each `N`-element row of `code` represents a corrupted systematic codeword.

For more information, see “Creating a Galois field array”.

N — Codeword length

integer

Codeword length, specified as an integer of the form N = 2^M–1, where M is an integer from 3 to 16. See “Tips” on page 2-49 for information about valid N values, valid (N,K) pairs, and error correcting capabilities for a given BCH code.

Example: 15 for *M*=4

K — Message length

integer

Message length, specified as an integer. N and K must produce a narrow-sense BCH code.

Example: 5 specifies a Galois field array with five elements.

paritypos — Parity position

'end' (default) | 'beginning'

Parity position, specified as 'end' or 'beginning'. Parity symbols are at the end or beginning of each word in the output Galois field array. If paritypos is 'beginning', then a decoding failure causes bchdec to remove N-K symbols from the beginning rather than the end of the row.

Output Arguments

decoded — Decoded message

Galois field array of symbols over GF(2)

Decoded message, returned as a Galois field array of symbols over GF(2). Each row represents the attempt at decoding the corresponding row in code. A decoding failure occurs if bchdec detects more than *T* errors in a row of code, where *T* is the number of errors per codeword that the decoder is capable of correcting. When a decoding failure occurs, bchdec forms the corresponding row of decoded by removing N-K symbols from the end of the row of code. For more information, see “Error Correcting Capability” on page 2-48.

cnumerr — Number of corrected errors

column vector

Number of corrected errors in the corresponding row of code, returned as a column vector. A value of –1 in cnumerr indicates a decoding failure in that row in code.

ccode — Corrected version of code

Galois field array

Corrected version of code, returned as a Galois field array. ccode has the same format as the input code. If a decoding failure occurs in a certain row of code, the corresponding row in ccode contains that row unchanged.

More About

Error Correcting Capability

BCH decoders correct up to a specified number of errors per codeword based on the (N,K) pair used to BCH encode that message. The error correcting capability, *T*, of a given (N,K) pair is returned by bchnumerr. See “Tips” on page 2-49 for information about valid N values, valid (N,K) pairs, and error correcting capabilities for a given BCH code.

If the coded message contains more errors per codeword than the decoder is capable of correcting, the decoder is unlikely to decode to the correct codeword. For example, when a single-error-correcting BCH decoder (*T*=1) is given an input with two errors per codeword, it decodes it to a valid codeword but not the correct codeword. When a double-error-correcting BCH decoder (*T*=2) is given an input with three errors per codeword, the decoder sometimes decodes to an invalid codeword. The cnumerr and ccode output provide feedback to analyze the correctness of the decoded message.

Tips

- To generate the list of valid (N,K) pairs along with the corresponding values of the error-correction capability, run bchnumerr(N).
- Valid values for N = 2^M–1, where *M* is an integer from 3 through 16. The maximum allowable value of N is 65,535.

Algorithms

bchdec uses the Berlekamp-Massey decoding algorithm. For information about this algorithm, see the works listed in “References” on page 2-49.

Topics
“Block Codes”

Introduced before R2006a

bchenc

BCH encoder

Syntax

```
code = bchenc(msg,N,K)
code = bchenc(msg,N,K,paritypos)
```

Description

`code = bchenc(msg,N,K)` encodes the input message using an (`N`,`K`) BCH encoder that uses a narrow-sense generator polynomial. For a description of Bose–Chaudhuri–Hocquenghem (BCH) coding, see [1].

`code = bchenc(msg,N,K,paritypos)` appends or prepends the parity symbols to the encoded input message to form the output.

Examples

Decode Received BCH Codeword in Noisy Channel

Set the BCH parameters for a Galois array of GF(2).

```
M = 4;
n = 2^M-1;   % Codeword length
k = 5;       % Message length
nwords = 10; % Number of words to encode
```

Create a message.

```
msgTx = gf(randi([0 1],nwords,k));
```

Find the error-correction capability.

```
t = bchnumerr(n,k)
```

```
t = 3
```

Encode the message.

```
enc = bchenc(msgTx,n,k);
```

Corrupt up to `t` bits in each codeword.

```
noisycode = enc + randerr(nwords,n,1:t);
```

Decode the noisy code.

```
msgRx = bchdec(noisycode,n,k);
```

Validate that the message was properly decoded.

```
isequal(msgTx,msgRx)
```

```
ans = logical
   1
```

Increase the number of possible errors, and generate another noisy codeword.

```
t2 = t + 1;
noisycode2 = enc + randerr(nwords,n,1:t2);
```

Decode the new received codeword.

```
[msgRx2,numerr] = bchdec(noisycode2,n,k);
```

Determine if the message was properly decoded by examining the number of corrected errors, numerr. Entries of -1 correspond to decoding failures, which occur when the codeword has more errors than can be corrected for the specified [n,k] pair.

```
numerr
```

```
numerr = 10×1

     1
     2
    -1
     2
     3
     1
    -1
     4
     2
     3
```

Two of the ten transmitted codewords were not correctly received.

Input Arguments

msg — Message to encode

Galois field array of symbols over GF(2)

Message to encode, specified as a Galois field array of symbols over GF(2). Each K-element row of msg represents a message word, where the leftmost symbol is the most significant symbol.

For more information, see “Creating a Galois field array”.

Example: msgTx = gf(randi([0 1],10,5)), where msgTx is a 10-by-5 gf array.

N — Codeword length

integer

Codeword length, specified as an integer of the form N = 2^M–1, where *M* is an integer from 3 through 16. For more information, see “Tips” on page 2-52.

Example: 15 for *M*=4

K — Message length

integer

Message length, specified as an integer. N and K must produce a narrow-sense BCH code.

Example: 5 specifies a Galois array with five elements

paritypos — Parity position

'end' (default) | 'beginning'

Parity position, specified as 'end' or 'beginning'. Parity symbols are at the end or beginning of each word in the output Galois array.

Output Arguments

code — Encoded message

Galois field array

Encoded message, returned as a Galois field array. Parity symbols are at the end or beginning of each word in the output Galois array. To specify the position of the parity symbols, use the paritypos argument.

Tips

- To generate the list of valid (N,K) pairs along with the corresponding values of the error-correction capability, run bchnumerr(N).
- Valid values for N = 2^M–1, where *M* is an integer from 3 through 16. The maximum allowable value of N is 65,535.

bchgenpoly

Generator polynomial of BCH code

Syntax

```
genpoly = bchgenpoly(n,k)
genpoly = bchgenpoly(n,k,prim_poly)
genpoly = bchgenpoly(n,k,prim_poly,outputFormat)
[genpoly,t] = bchgenpoly(...)
```

Description

`genpoly = bchgenpoly(n,k)` returns the narrow-sense generator polynomial of a BCH code with codeword length `n` and message length `k`. The codeword length `n` must have the form 2^m-1 for some integer m between 3 and 16. The output `genpoly` is a Galois row vector that represents the coefficients of the generator polynomial in order of descending powers. The narrow-sense generator polynomial is LCM[m_1(x), m_2(x), ..., m_2t(x)], where:

- LCM represents the least common multiple,
- m_i(x) represents the minimum polynomial corresponding to α^i, α is a root of the default primitive polynomial for the field GF(`n+1`),
- and t represents the error-correcting capability of the code.

Note Although the `bchgenpoly` function performs intermediate computations in GF(`n+1`), the final polynomial has binary coefficients. The output from `bchgenpoly` is a Galois vector in GF(2) rather than in GF(`n+1`).

`genpoly = bchgenpoly(n,k,prim_poly)` is the same as the syntax above, except that `prim_poly` specifies the primitive polynomial for GF(`n+1`) that has Alpha as a root. `prim_poly` is either a polynomial character vector or an integer whose binary representation indicates the coefficients of the primitive polynomial in order of descending powers. To use the default primitive polynomial for GF(`n+1`), set `prim_poly` to `[]`.

`genpoly = bchgenpoly(n,k,prim_poly,outputFormat)` is the same as the previous syntax, except that `outputFormat` specifies output data type. The value of `outputFormat` can be ‘`gf`' or '`double`' corresponding to Galois field and double data types respectively. The default value of `outputFormat` is '`gf`'.

`[genpoly,t] = bchgenpoly(...)` returns `t`, the error-correction capability of the code.

Examples

Create a BCH Generator Polynomial

Create two BCH generator polynomials based on different primitive polynomials.

Set the codeword and message lengths, `n` and `k`.

```
n = 15;
k = 11;
```

Create the generator polynomial and return the error correction capability, `t`.

```
[genpoly,t] = bchgenpoly(15,11)
```

```
genpoly = GF(2) array.

Array elements =

   1   0   0   1   1

t = 1
```

Create a generator polynomial for a (15,11) BCH code using a different primitive polynomial expressed as a character vector. Note that `genpoly2` differs from `genpoly`, which uses the default primitive.

```
genpoly2 = bchgenpoly(15,11,'D^4 + D^3 + 1')
```

```
genpoly2 = GF(2) array.

Array elements =

   1   1   0   0   1
```

Limitations

The maximum allowable value of `n` is 65535.

“Block Codes”

Introduced before R2006a

bchnumerr

Number of correctable errors for BCH code

Syntax

```
T = bchnumerr(N)
T = bchnumerr(N, K)
```

Description

`T = bchnumerr(N)` returns all the possible combinations of message length, `K`, and number of correctable errors, `T`, for a BCH code of codeword length, `N`.

`T = bchnumerr(N, K)` returns the number of correctable errors, `T`, for an `(N, K)` BCH code.

Examples

Determine Message Length Combinations for BCH Code

Calculate the possible message length combinations for a BCH code word length of `15`.

```
T = bchnumerr(15)
```

```
T = 3×3

    15    11     1
    15     7     2
    15     5     3
```

Compute the Correctable Errors for BCH Code

Calculate the number of correctable errors for BCH code `15,11`

```
T = bchnumerr(15,11)
```

```
T = 1
```

Input Arguments

N — Codeword length
integer scalar

Codeword length, specified as an integer scalar. `N` must have the form 2^m-1 for some integer, m, between 3 and 16.

Example: 15

Data Types: `double`

K — Message length

integer scalar

Message length, specified as an integer scalar. `N` and `K` must produce a narrow-sense BCH code.

Example: 11

Data Types: `double`

Output Arguments

T — Number of correctable errors

scalar or matrix

Number of correctable errors, returned as a scalar or matrix value.

`bchnumerr(N)` returns a matrix with three columns. The first column lists `N`, the second column lists `K`, and the third column lists `T`.

`bchnumerr(N,K)` returns a scalar, which represents the number of correctable errors for the BCH code.

berawgn

BER and SER for uncoded AWGN channels

Syntax

```
ber = berawgn(EbNo,modtype,M)

ber = berawgn(EbNo,'psk',M,dataenc)
ber = berawgn(EbNo,'oqpsk',dataenc)

ber = berawgn(EbNo,'fsk',M,coherence)
ber = berawgn(EbNo,'fsk',M,coherence,rho)

ber = berawgn(EbNo,'msk',precoding)
ber = berawgn(EbNo,'msk',precoding,coherence)

ber = berawgn(EbNo,'cpfsk',M,modindex,kmin)

[ber,ser] = berawgn( ___ )
```

Description

The berawgn function returns the bit error rate (BER) and symbol error rate (SER) in an additive white Gaussian noise (AWGN) channel for uncoded data using various modulation schemes. The first input argument, `EbNo`, is the ratio of bit energy to noise power spectral density (E_b/N_0) and its units are in dB. Values in the output `ber` and `ser` vectors correspond to the theoretical error rate at the specified E_b/N_0 levels for a Gray-coded signal constellation. For more information, see Analytical Expressions Used in berawgn.

`ber = berawgn(EbNo,modtype,M)` returns the BER at the specified E_b/N_0 levels for the modulation type and modulation order specified by `modtype` and `M`, respectively.

`ber = berawgn(EbNo,'psk',M,dataenc)` specifies the data encoding type as differential or nondifferential for PSK modulation.

`ber = berawgn(EbNo,'oqpsk',dataenc)` specifies the data encoding type as differential or nondifferential for OQPSK modulation.

`ber = berawgn(EbNo,'fsk',M,coherence)` specifies the receiver technique as coherent or noncoherent for FSK modulation.

`ber = berawgn(EbNo,'fsk',M,coherence,rho)` additionally specifies the complex correlation coefficient of the FSK-modulated signal.

`ber = berawgn(EbNo,'msk',precoding)` specifies whether precoding is applied for MSK modulation.

`ber = berawgn(EbNo,'msk',precoding,coherence)` additionally specifies the receiver technique as coherent or noncoherent for MSK modulation.

`ber = berawgn(EbNo,'cpfsk',M,modindex,kmin)` specifies the modulation index, `modindex`, and the number of paths having the minimum distance, `kmin`, for CPFSK modulation.

`[ber,ser] = berawgn( ___ )` returns the BER and symbol error rate (SER) using any input argument combination from previous syntaxes.

Examples

Return Theoretical BER Data for AWGN Channels

Return theoretical bit error rate data for several modulation schemes in an AWGN channel.

Create a vector of E_b/N_0 values and specify the modulation order.

```
EbNo = (0:10)';
M = 4; % Modulation order
```

Return theoretical BER data for QPSK modulation.

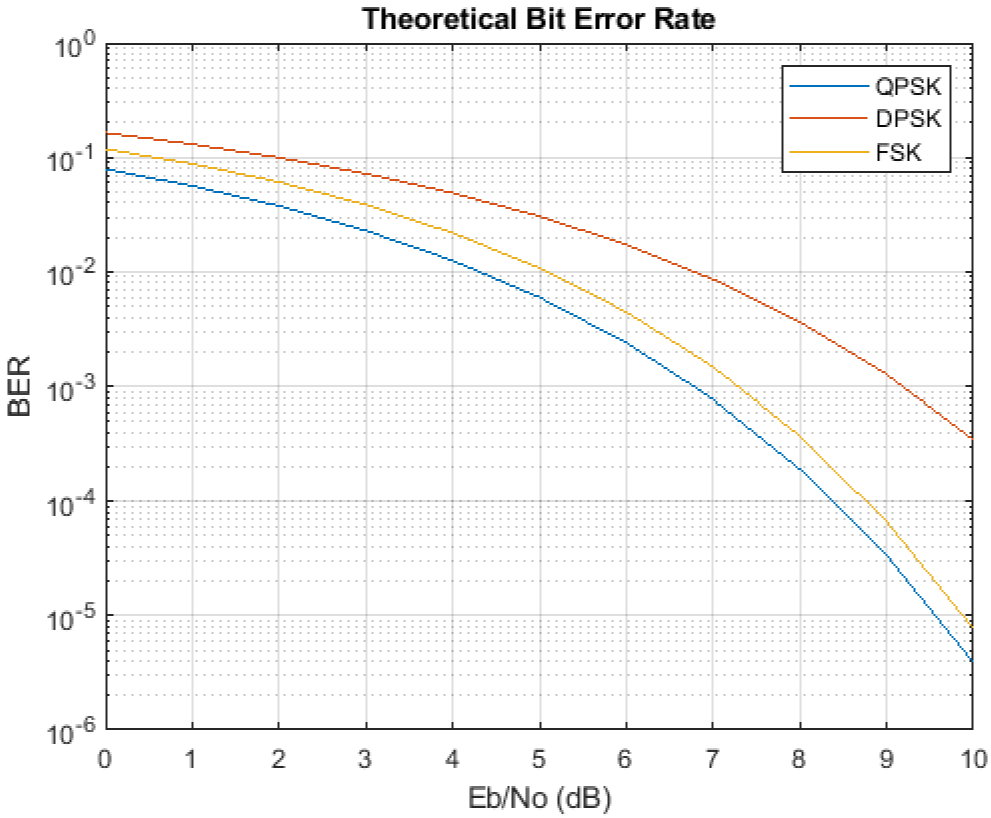
```
berQ = berawgn(EbNo,'psk',M,'nondiff');
```

Return equivalent data for DPSK and FSK modulations.

```
berD = berawgn(EbNo,'dpsk',M);
berF = berawgn(EbNo,'fsk',M,'coherent');
```

Plot the results.

```
semilogy(EbNo,[berQ berD berF])
xlabel('Eb/No (dB)')
ylabel('BER')
legend('QPSK','DPSK','FSK')
title("Theoretical Bit Error Rate")
grid
```



Input Arguments

EbNo — Energy per bit to noise power spectral density ratio

scalar | vector

Energy per bit to noise power spectral density ratio in dB, specified as a scalar or vector.

Data Types: `single` | `double`

`modtype` — Modulation type

`'psk'` | `'oqpsk'` | `'dpsk'` | ...

Modulation type, specified as one of these options.

`modtype` Value	Modulation Scheme	Dependencies
`'psk'`	Phase shift keying (PSK)	When you set the input `dataenc` to `'diff'`, modulation order `M` must be 2 or 4.
`'oqpsk'`	Offset quadrature phase shift keying (OQPSK)	None
`'dpsk'`	Differential phase shift keying (DPSK)	None

modtype Value	Modulation Scheme	Dependencies
'pam'	Pulse amplitude modulation (PAM)	None
'qam'	Quadrature amplitude modulation (QAM)	The modulation order M must be at least 4. • When $k = log_2$M is odd, the symbols lie in a rectangular constellation of size M = $I \times J$, where $I = 2^{\frac{k-1}{2}}$ and $J = 2^{\frac{k+1}{2}}$. • When k is even, the symbols lie in a square constellation of size$2^{\frac{k}{2}} \times 2^{\frac{k}{2}}$.
'fsk'	Frequency-shift keying (FSK)	When you set the input coherence to 'noncoherent', modulation order M must be in the range [2, 64].
'msk'	Minimum-shift keying (MSK)	None
'cpfsk'	Continuous-phase frequency-shift keying (CPFSK)	None

Data Types: char | string

M — Modulation order
2^k

Modulation order, specified as an integer equal to 2^k, where k is a positive integer.

Example: 4 or 2^2

Data Types: single | double

dataenc — Data encoding type
'diff' | 'nondiff'

Data encoding type, specified as one of these values.

- 'diff' — For differential data encoding
- 'nondiff' — For nondifferential data encoding

Dependencies

To enable this argument, set the modtype argument to 'psk' or 'oqpsk'.

Data Types: char | string

coherence — Coherent detection type
'conherent' | 'noncoherent'

Coherent detection type, specified as one of these values.

- 'conherent' — For coherent detection
- 'noncoherent' — For noncoherent detection

Dependencies

To enable this argument, set the modtype argument to 'fsk' or 'msk'.

Data Types: char | string

rho — Complex correlation coefficient

complex scalar

Complex correlation coefficient, specified as a complex scalar. For more information about the complex correlation coefficient and how to compute it for nonorthogonal binary frequency-shift keying (BFSK) modulation, see “Nonorthogonal 2-FSK with Coherent Detection”.

Dependencies

To enable this argument, set the modtype argument to 'fsk' and the M argument to 2.

Data Types: single | double
Complex Number Support: Yes

precoding — Enable precoding

'off' | 'on'

Enable precoding, specified as one of these values.

- 'off' — For conventional MSK
- 'on' — For precoded MSK

Dependencies

To enable this argument, set the modtype argument to 'msk'.

Data Types: char | string

modindex — Modulation index

positive integer

Modulation index, specified as a positive integer.

Dependencies

To enable this argument, set the modtype argument to 'cpfsk'.

Data Types: single | double

kmin — Number of paths having minimum distance

positive integer

Number of paths having the minimum distance, specified as a positive integer. If the number of paths is unknown, specify a value of 1.

Dependencies

To enable this argument, set the modtype argument to 'cpfsk'.

Data Types: `single` | `double`

Output Arguments

`ber` — Bit error rate

scalar | vector

Bit error rate (BER) for uncoded data over an AWGN channel, returned as a scalar or vector. The BER is computed for each E_b/N_0 setting specified by input `EbNo` according to the modulation type specified by input `modtype` and related dependencies.

Data Types: `double`

`ser` — Symbol error rate

scalar | vector

Symbol error rate (SER) for uncoded data over an AWGN channel, returned as a scalar or vector. The SER is computed for each E_b/N_0 setting specified by input `EbNo` according to the modulation type specified by input `modtype` and related dependencies.

Data Types: `double`

Limitations

The numerical accuracy of the output returned by this function is limited by approximations related to the numerical implementation of the expressions to roughly two significant digits.

Alternatives

As an alternative to the `berawgn` function, use the **BER Analyzer** app and configure settings in the **Theoretical** tab.

bercoding

Bit error rate (BER) for coded AWGN channels

Syntax

```
berub = bercoding(EbNo,'conv',decision,coderate,dspec)
berub = bercoding(EbNo,'block','hard',n,k,dmin)
berub = bercoding(EbNo,'block','soft',n,k,dmin)
berapprox = bercoding(EbNo,'Hamming','hard',n)
berub = bercoding(EbNo,'Golay','hard',24)
berapprox = bercoding(EbNo,'RS','hard',n,k)
berapprox = bercoding(...,modulation)
```

Description

`berub = bercoding(EbNo,'conv',`*`decision`*`,coderate,dspec)` returns an upper bound or approximation on the BER of a binary convolutional code with coherent phase shift keying (PSK) modulation over an additive white Gaussian noise (AWGN) channel. `EbNo` is the ratio of bit energy to noise power spectral density, in dB. If `EbNo` is a vector, `berub` is a vector of the same size, whose elements correspond to the different E_b/N_0 levels. To specify hard-decision decoding, set *`decision`* to `'hard'`; to specify soft-decision decoding, set *`decision`* to `'soft'`. The convolutional code has code rate equal to `coderate`. The `dspec` input is a structure that contains information about the code's distance spectrum:

- `dspec.dfree` is the minimum free distance of the code.
- `dspec.weight` is the weight spectrum of the code.

To find distance spectra for some sample codes, use the `distspec` function or see [5] and [3].

Note The results for binary PSK and quadrature PSK modulation are the same. This function does not support M-ary PSK when M is other than 2 or 4.

`berub = bercoding(EbNo,'block','hard',n,k,dmin)` returns an upper bound on the BER of an [`n`,`k`] binary block code with hard-decision decoding and coherent BPSK or QPSK modulation. `dmin` is the minimum distance of the code.

`berub = bercoding(EbNo,'block','soft',n,k,dmin)` returns an upper bound on the BER of an [`n`,`k`] binary block code with soft-decision decoding and coherent BPSK or QPSK modulation. `dmin` is the minimum distance of the code.

`berapprox = bercoding(EbNo,'Hamming','hard',n)` returns an approximation of the BER of a Hamming code using hard-decision decoding and coherent BPSK modulation. (For a Hamming code, if n is known, then k can be computed directly from n.)

`berub = bercoding(EbNo,'Golay','hard',24)` returns an upper bound of the BER of a Golay code using hard-decision decoding and coherent BPSK modulation. Support for Golay currently is only for n=24. In accordance with [3], the Golay coding upper bound assumes only the correction of

3-error patterns. Even though it is theoretically possible to correct approximately 19% of 4-error patterns, most decoders in practice do not have this capability.

`berapprox = bercoding(EbNo,'RS','hard',n,k)` returns an approximation of the BER of (n,k) Reed-Solomon code using hard-decision decoding and coherent BPSK modulation.

`berapprox = bercoding(...,`*`modulation`*`)` returns an approximation of the BER for coded AWGN channels when you specify a *`modulation`* type. See the `berawgn` function for a listing of the supported modulation types.

Examples

Upper Bound on Theoretical BER for a Block Code

Find an upper bound on the theoretical BER of a (23,12) block code.

Set the example parameters.

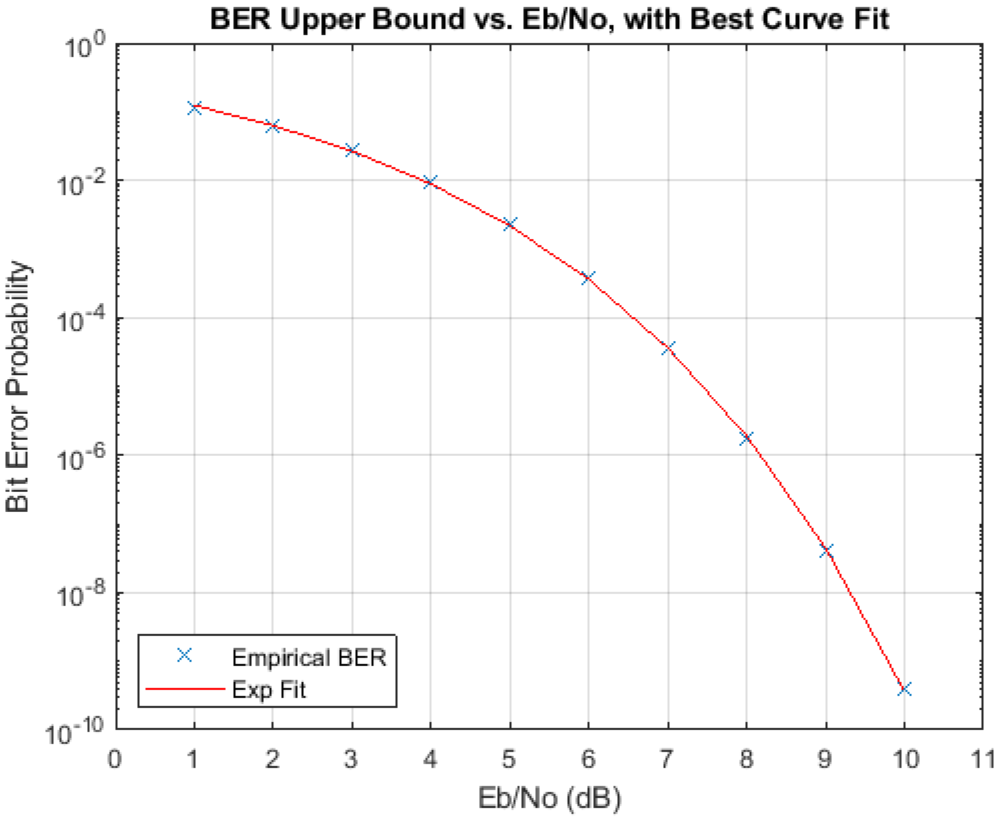
```
n = 23;             % Codeword length
k = 12;             % Message length
dmin = 7;           % Minimum distance
EbNo = 1:10;        % Eb/No range (dB)
```

Estimate the BER.

```
berBlk = bercoding(EbNo,'block','hard',n,k,dmin);
```

Plot the estimated BER.

```
berfit(EbNo,berBlk)
ylabel('Bit Error Probability')
title('BER Upper Bound vs. Eb/No, with Best Curve Fit')
```



Estimate Coded BER Performance of 16-QAM in AWGN

Estimate the performance of a 16-QAM channel in AWGN when encoded with a (15,11) Reed-Solomon code using hard-decision decoding.

Set the input Eb/No range and determine the uncoded BER for 16-QAM.

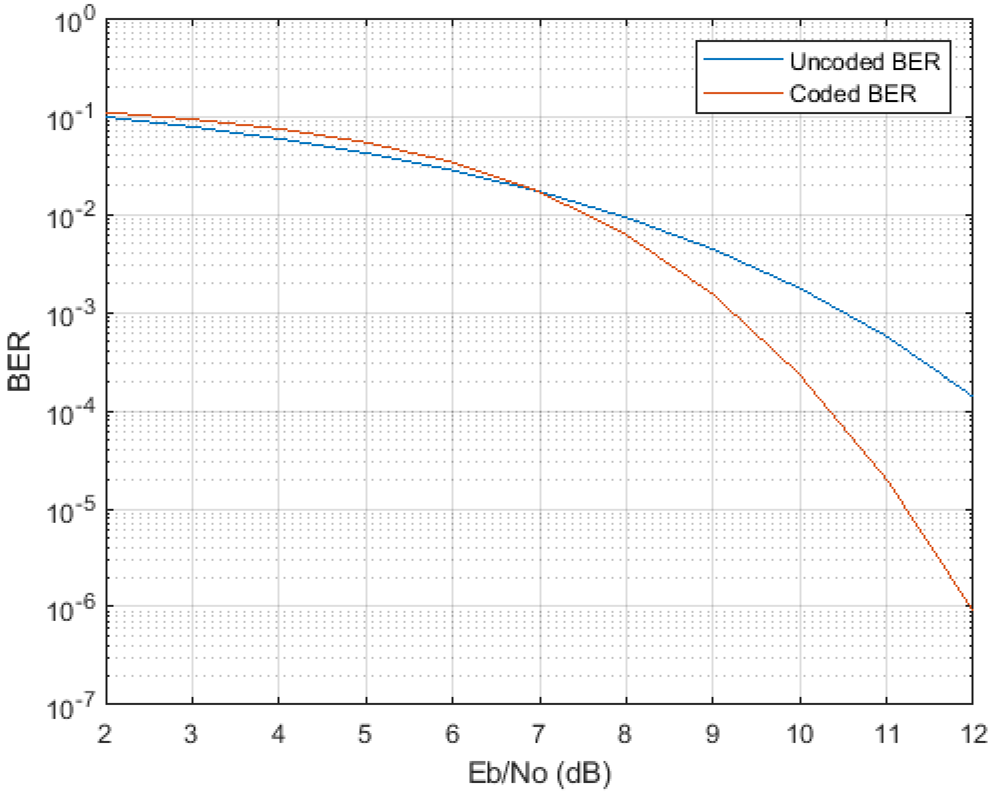
```
ebno = (2:12)';
uncodedBER = berawgn(ebno,'qam',16);
```

Estimate the coded BER for 16-QAM channel with a (15,11) Reed-Solomon code using hard decision decoding.

```
codedBER = bercoding(ebno,'RS','hard',15,11,'qam',16);
```

Plot the estimated BER curves.

```
semilogy(ebno,[uncodedBER codedBER])
grid
legend('Uncoded BER','Coded BER')
xlabel('Eb/No (dB)')
ylabel('BER')
```



Limitations

The numerical accuracy of this function's output is limited by

- Approximations in the analysis leading to the closed-form expressions that the function uses
- Approximations related to the numerical implementation of the expressions

You can generally rely on the first couple of significant digits of the function's output.

Alternatives

As an alternative to the `bercoding` function, invoke the BERTool GUI (`bertool`) and use the **Theoretical** tab.

berconfint

Bit error rate (BER) and confidence interval of Monte Carlo simulation

Syntax

```
[ber,interval] = berconfint(nerrs,ntrials)
[ber,interval] = berconfint(nerrs,ntrials,level)
```

Description

`[ber,interval] = berconfint(nerrs,ntrials)` returns the error probability estimate `ber` and the 95% confidence interval `interval` for a Monte Carlo simulation of `ntrials` trials with `nerrs` errors. `interval` is a two-element vector that lists the endpoints of the interval. If the errors and trials are measured in bits, the error probability is the bit error rate (BER); if the errors and trials are measured in symbols, the error probability is the symbol error rate (SER).

`[ber,interval] = berconfint(nerrs,ntrials,level)` specifies the confidence level as a real number between 0 and 1.

Examples

If a simulation of a communication system results in 100 bit errors in 10^6 trials, the BER (bit error rate) for that simulation is the quotient 10^{-4}. The command below finds the 95% confidence interval for the BER of the system.

```
nerrs = 100; % Number of bit errors in simulation
ntrials = 10^6; % Number of trials in simulation
level = 0.95; % Confidence level
[ber,interval] = berconfint(nerrs,ntrials,level)
```

The output below shows that, with 95% confidence, the BER for the system is between 0.0000814 and 0.0001216.

```
ber =

  1.0000e-004

interval =

  1.0e-003 *

    0.0814    0.1216
```

For an example that uses the output of `berconfint` to plot error bars on a BER plot, see “Curve Fitting An Error Rate Plot”

berfading

Bit error rate (BER) for Rayleigh and Rician fading channels

Syntax

```
ber = berfading(EbNo,'pam',M,divorder)
ber = berfading(EbNo,'qam',M,divorder)
ber = berfading(EbNo,'psk',M,divorder)
ber = berfading(EbNo,'depsk',M,divorder)
ber = berfading(EbNo,'oqpsk',divorder)
ber = berfading(EbNo,'dpsk',M,divorder)
ber = berfading(EbNo,'fsk',M,divorder,coherence)
ber = berfading(EbNo,'fsk',2,divorder,coherence,rho)
ber = berfading(EbNo,...,K)
ber = berfading(EbNo,'psk',2,1,K,phaserr)
[BER,SER] = berfading(EbNo, ...)
```

Description

For All Syntaxes

The first input argument, `EbNo`, is the ratio of bit energy to noise power spectral density, in dB. If `EbNo` is a vector, the output `ber` is a vector of the same size, whose elements correspond to the different E_b/N_0 levels.

Most syntaxes also have an `M` input that specifies the alphabet size for the modulation. `M` must have the form 2^k for some positive integer `k`.

`berfading` uses expressions that assume Gray coding. If you use binary coding, the results may differ.

For cases where diversity is used, the E_b/N_0 on each diversity branch is `EbNo/divorder`, where `divorder` is the diversity order (the number of diversity branches) and is a positive integer.

For Specific Syntaxes

`ber = berfading(EbNo,'pam',M,divorder)` returns the BER for PAM over an uncoded Rayleigh fading channel with coherent demodulation.

`ber = berfading(EbNo,'qam',M,divorder)` returns the BER for QAM over an uncoded Rayleigh fading channel with coherent demodulation. The alphabet size, `M`, must be at least 4. When $k = \log_2 M$ is odd, a rectangular constellation of size $M = I \times J$ is used, where $I = 2^{\frac{k-1}{2}}$ and $J = 2^{\frac{k+1}{2}}$.

`ber = berfading(EbNo,'psk',M,divorder)` returns the BER for coherently detected PSK over an uncoded Rayleigh fading channel.

`ber = berfading(EbNo,'depsk',M,divorder)` returns the BER for coherently detected PSK with differential data encoding over an uncoded Rayleigh fading channel. Only $M = 2$ is currently supported.

`ber = berfading(EbNo,'oqpsk',divorder)` returns the BER of coherently detected offset-QPSK over an uncoded Rayleigh fading channel.

`ber = berfading(EbNo,'dpsk',M,divorder)` returns the BER for DPSK over an uncoded Rayleigh fading channel. For DPSK, it is assumed that the fading is slow enough that two consecutive symbols are affected by the same fading coefficient.

`ber = berfading(EbNo,'fsk',M,divorder,coherence)` returns the BER for orthogonal FSK over an uncoded Rayleigh fading channel. `coherence` should be `'coherent'` for coherent detection, or `'noncoherent'` for noncoherent detection.

`ber = berfading(EbNo,'fsk',2,divorder,coherence,rho)` returns the BER for binary nonorthogonal FSK over an uncoded Rayleigh fading channel. `rho` is the complex correlation coefficient. See “Nonorthogonal 2-FSK with Coherent Detection” for the definition of the complex correlation coefficient and how to compute it for nonorthogonal BFSK.

`ber = berfading(EbNo,...,K)` returns the BER over an uncoded Rician fading channel, where `K` is the ratio of specular to diffuse energy in linear scale. For the case of `'fsk'`, `rho` must be specified before `K`.

`ber = berfading(EbNo,'psk',2,1,K,phaserr)` returns the BER of BPSK over an uncoded Rician fading channel with imperfect phase synchronization. `phaserr` is the standard deviation of the reference carrier phase error in radians.

`[BER,SER] = berfading(EbNo, ...)` returns both the BER and SER.

Examples

Estimate BER Performance of 16-QAM in Fading

Generate a vector of Eb/No values to evaluate.

```
EbNo = 8:2:20;
```

Initialize the BER results vector.

```
ber = zeros(length(EbNo),20);
```

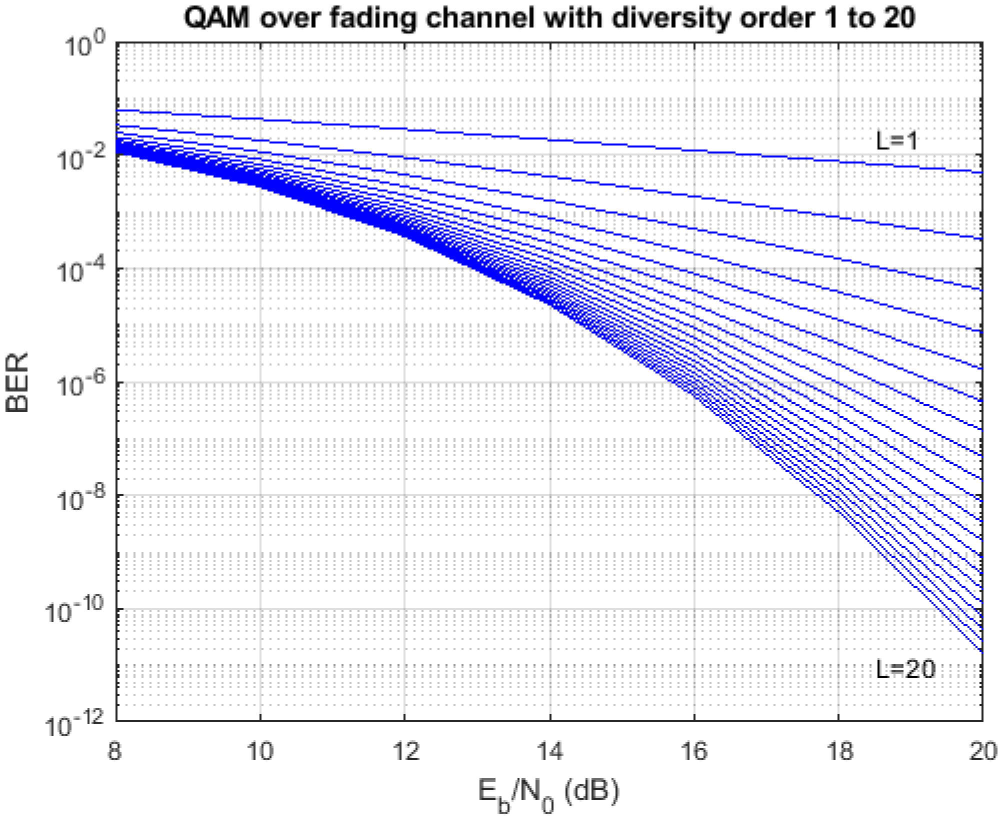
Generate BER vs. Eb/No curves for 16-QAM in a fading channel. Vary the diversity order from 1 to 20.

```
for L = 1:20
    ber(:,L) = berfading(EbNo,'qam',16,L);
end
```

Plot the results.

```
semilogy(EbNo,ber,'b')
text(18.5, 0.02, sprintf('L=%d',1))
text(18.5, 1e-11, sprintf('L=%d',20))
title('QAM over fading channel with diversity order 1 to 20')
xlabel('E_b/N_0 (dB)')
```

```
ylabel('BER')
grid on
```



Limitations

The numerical accuracy of this function's output is limited by approximations related to the numerical implementation of the expressions

You can generally rely on the first couple of significant digits of the function's output.

Alternatives

As an alternative to the `berfading` function, invoke the BERTool GUI (`bertool`), and use the **Theoretical** tab.

berfit

Fit curve to nonsmooth empirical bit error rate (BER) data

Syntax

```
fitber = berfit(empEbNo,empber)
fitber = berfit(empEbNo,empber,fitEbNo)
fitber = berfit(empEbNo,empber,fitEbNo,options)
fitber = berfit(empEbNo,empber,fitEbNo,options,fittype)
[fitber,fitprops] = berfit(...)
berfit(...)
berfit(empEbNo,empber,fitEbNo,options,'all')
```

Description

`fitber = berfit(empEbNo,empber)` fits a curve to the empirical BER data in the vector `empber` and returns a vector of fitted bit error rate (BER) points. The values in `empber` and `fitber` correspond to the E_b/N_0 values, in dB, given by `empEbNo`. The vector `empEbNo` must be in ascending order and must have at least four elements.

Note The `berfit` function is intended for curve fitting or interpolation, *not* extrapolation. Extrapolating BER data beyond an order of magnitude below the smallest empirical BER value is inherently unreliable.

`fitber = berfit(empEbNo,empber,fitEbNo)` fits a curve to the empirical BER data in the vector `empber` corresponding to the E_b/N_0 values, in dB, given by `empEbNo`. The function then evaluates the curve at the E_b/N_0 values, in dB, given by `fitEbNo` and returns the fitted BER points. The length of `fitEbNo` must equal or exceed that of `empEbNo`.

`fitber = berfit(empEbNo,empber,fitEbNo,options)` uses the structure `options` to override the default options used for optimization. These options are the ones used by the `fminsearch` function. You can create the `options` structure using the `optimset` function. Particularly relevant fields are described in the table below.

Field	Description
`options.Display`	Level of display: `'off'` (default) displays no output; `'iter'` displays output at each iteration; `'final'` displays only the final output; `'notify'` displays output only if the function does not converge.
`options.MaxFunEvals`	Maximum number of function evaluations before optimization ceases. The default is 10^4.
`options.MaxIter`	Maximum number of iterations before optimization ceases. The default is 10^4.

Field	Description
`options.TolFun`	Termination tolerance on the closed-form function used to generate the fit. The default is 10^{-4}.
`options.TolX`	Termination tolerance on the coefficient values of the closed-form function used to generate the fit. The default is 10^{-4}.

`fitber = berfit(empEbNo,empber,fitEbNo,options,`*`fittype`*`)` specifies which closed-form function `berfit` uses to fit the empirical data, from the possible fits listed in "Algorithms" on page 2-80 below. *`fittype`* can be `'exp'`, `'exp+const'`, `'polyRatio'`, or `'doubleExp+const'`. To avoid overriding default optimization options, use `options = []`.

`[fitber,fitprops] = berfit(...)` returns the MATLAB structure `fitprops`, which describes the results of the curve fit. Its fields are described in the table below.

Field	Description
`fitprops.fitType`	The closed-form function type used to generate the fit: `'exp'`, `'exp+const'`, `'polyRatio'`, or `'doubleExp+const'`.
`fitprops.coeffs`	The coefficients used to generate the fit. If the function cannot find a valid fit, `fitprops.coeffs` is an empty vector.
`fitprops.sumSqErr`	The sum squared error between the log of the fitted BER points and the log of the empirical BER points.
`fitprops.exitState`	The exit condition of `berfit`: `'The curve fit converged to a solution.'`, `'The maximum number of function evaluations was exceeded.'`, or `'No desirable fit was found'`.
`fitprops.funcCount`	The number of function evaluations used in minimizing the sum squared error function.
`fitprops.iterations`	The number of iterations taken in minimizing the sum squared error function. This is not necessarily equal to the number of function evaluations.

`berfit(...)` plots the empirical and fitted BER data.

`berfit(empEbNo,empber,fitEbNo,options,'all')` plots the empirical and fitted BER data from all the possible fits, listed in the "Algorithms" on page 2-80 below, that return a valid fit. To avoid overriding default options, use `options = []`.

Note A valid fit must be

- real-valued
- monotonically decreasing
- greater than or equal to 0 and less than or equal to 1

If a fit does not confirm to this criteria, it is rejected.

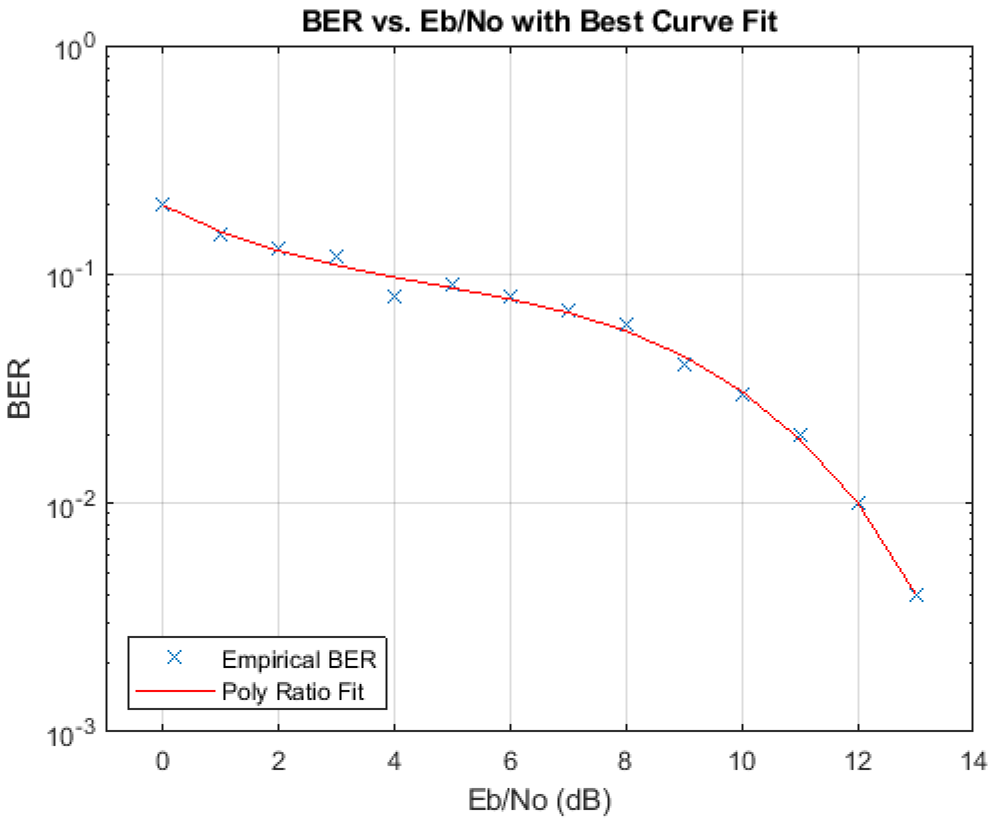
Examples

Bit Error Rate Curve Fitting

These examples illustrate the syntax of the `berfit` function, but they use hard-coded or theoretical BER data for simplicity. For an example that uses empirical BER data from a simulation, see “Curve Fitting An Error Rate Plot”.

Best fit for a sample set of data

```
EbN0 = 0:13;
berdata = [.2 .15 .13 .12 .08 .09 .08 .07 .06 .04 .03 .02 .01 .004];
berfit(EbN0,berdata);
```

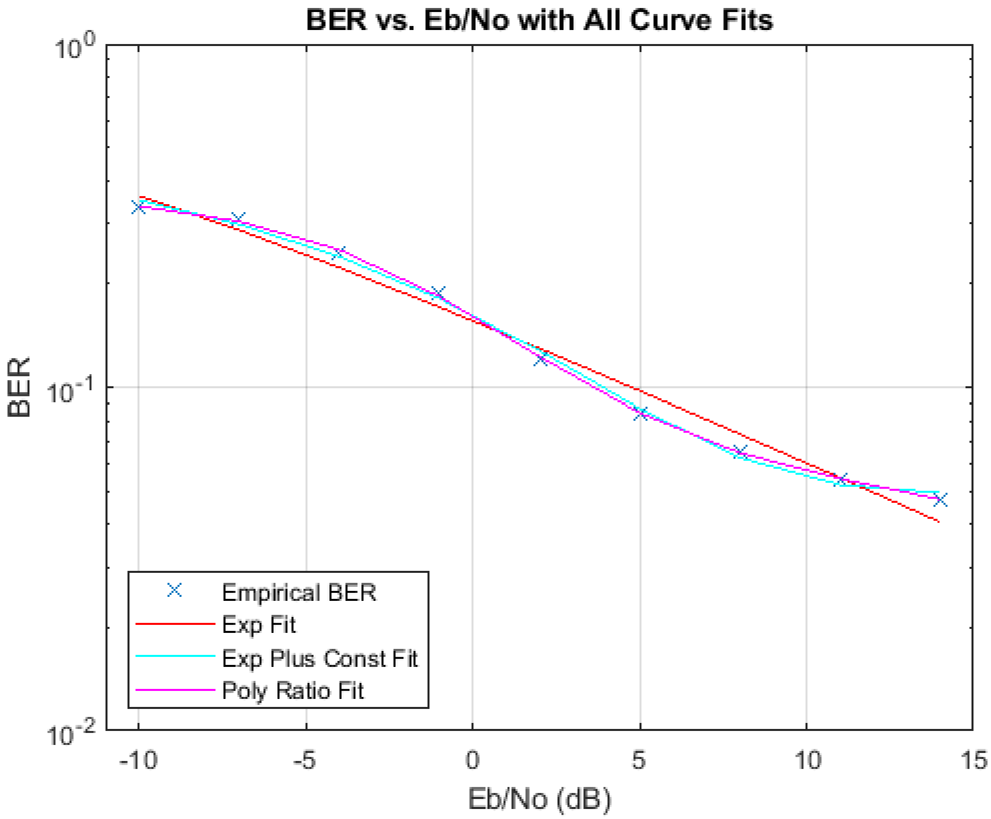


Plot the best fit. The curve connects the points created by evaluating the fit expression at the values in EbN0. To make the curve look smoother, use a syntax like `berfit(EbN0,berdata,[0:0.2:13])`. This alternative syntax uses more points when plotting the curve, but it does not change the fit expression.

Fit for a BER curve with an error floor

We generate the empirical BER array by simulating a channel with a null (ch = [0.5 0.47]) with BPSK modulation and linear MMSE equalizer at the receiver. We run the berfit with the 'all' option. The 'doubleExp+const' fit does not provide a valid fit, and the 'exp' fit type does not work well for this data. The 'exp+const' and 'polyRatio' fits closely match the simulated data.

```
EbN0 = -10:3:15;
empBER = [0.3361 0.3076 0.2470 0.1878 0.1212 0.0845 0.0650 0.0540 0.0474];
figure; berfit(EbN0, empBER, [], [], 'all');
```



Use of the options input structure as well as the fitprops output structure

The 'notify' value for the display level causes the function to produce output when one of the attempted fits does not converge. The exitState field of the output structure also indicates which fit converges and which fit does not.

```
M = 8; EbN0 = 3:10;
berdata = berfading(EbN0,'psk',M,2); % Compute theoretical BER.
noisydata = berdata.*[.93 .92 1 .59 .08 .15 .01 .01];
% Say when fit fails to converge.
options = optimset('display','notify');

disp('*** Trying exponential fit.') % Poor fit

*** Trying exponential fit.

[fitber1,fitprops1] = berfit(EbN0,noisydata,EbN0,...
   options,'exp')
```

```
Exiting: Maximum number of function evaluations has been exceeded
         - increase MaxFunEvals option.
         Current function value: 2.749919

fitber1 = 1×8

    0.1247    0.0727    0.0376    0.0168    0.0064    0.0020    0.0005    0.0001

fitprops1 = struct with fields:
       fitType: 'exp'
        coeffs: [4x1 double]
      sumSqErr: 2.7499
     exitState: 'The maximum number of function evaluations has been exceeded'
     funcCount: 10001
    iterations: 6193
```

```
disp('*** Trying polynomial ratio fit.') % Good fit
```

```
*** Trying polynomial ratio fit.
```

```
[fitber2,fitprops2] = berfit(EbN0,noisydata,EbN0,...
   options,'polyRatio')
```

```
fitber2 = 1×8

    0.1701    0.0874    0.0407    0.0169    0.0060    0.0016    0.0003    0.0001

     exitState: 'The curve fit converged to a solution'
     funcCount: 554
    iterations: 331
```

Algorithms

The `berfit` function fits the BER data using unconstrained nonlinear optimization via the `fminsearch` function. The closed-form functions that `berfit` considers are listed in the table below, where *x* is the E_b/N_0 in linear terms (*not* dB) and *f* is the estimated BER. These functions were empirically found to provide close fits in a wide variety of situations, including exponentially decaying BERs, linearly varying BERs, and BER curves with error rate floors.

Value of *fittype*	Functional Expression
'exp'	$f(x) = a_1 \exp\left[\frac{-(x - a_2)^{a_3}}{a_4}\right]$
'exp+const'	$f(x) = a_1 \exp\left[\frac{-(x - a_2)^{a_3}}{a_4}\right] + a_5$

Value of *fittype*	Functional Expression
'polyRatio'	$f(x) = \frac{a_1x^2 + a_2x + a_3}{x^3 + a_4x^2 + a_5x + a_6}$
'doubleExp+const'	$a_1\exp\left[\frac{-(x-a_2)^{a_3}}{a_4}\right] + a_5\exp\left[\frac{-(x-a_6)^{a_7}}{a_8}\right] + a_9$

The sum squared error function that `fminsearch` attempts to minimize is

$$F = \sum[\log(\text{empirical BER}) - \log(\text{fitted BER})]^2$$

where the fitted BER points are the values in `fitber` and the sum is over the E_b/N_0 points given in `empEbNo`. It is important to use the log of the BER values rather than the BER values themselves so that the high-BER regions do not dominate the objective function inappropriately.

bersync

Bit error rate (BER) for imperfect synchronization

Syntax

```
ber = bersync(EbNo,timerr,'timing')
ber = bersync(EbNo,phaserr,'carrier')
```

Description

`ber = bersync(EbNo,timerr,'timing')` returns the BER of uncoded coherent binary phase shift keying (BPSK) modulation over an additive white Gaussian noise (AWGN) channel with imperfect timing. The normalized timing error is assumed to have a Gaussian distribution. `EbNo` is the ratio of bit energy to noise power spectral density, in dB. If `EbNo` is a vector, the output `ber` is a vector of the same size, whose elements correspond to the different E_b/N_0 levels. `timerr` is the standard deviation of the timing error, normalized to the symbol interval. `timerr` must be between 0 and 0.5.

`ber = bersync(EbNo,phaserr,'carrier')` returns the BER of uncoded BPSK modulation over an AWGN channel with a noisy phase reference. The phase error is assumed to have a Gaussian distribution. `phaserr` is the standard deviation of the error in the reference carrier phase, in radians.

Examples

Calculate Bit Error Rate (BER) for Imperfect Synchronization

The code below computes the BER of coherent BPSK modulation over an AWGN channel with imperfect timing. The example varies both `EbNo` and `timerr`. (When `timerr` assumes the final value of zero, the `bersync` command produces the same result as `berawgn(EbNo,'psk',2)`.)

```
EbNo = [4 8 12];
timerr = [0.2 0.07 0];
ber = zeros(length(timerr),length(EbNo));
for ii = 1:length(timerr)
    ber(ii,:) = bersync(EbNo,timerr(ii),'timerr');
end
```

Display result using scientific notation.

```
format short e; ber
```

```
ber = 3×3

   5.2073e-02   2.0536e-02   1.1160e-02
   1.8948e-02   7.9757e-04   4.9008e-06
   1.2501e-02   1.9091e-04   9.0060e-09
```

Switch back to default notation format.

```
format;
```

Limitations

The numerical accuracy of this function's output is limited by

- Approximations in the analysis leading to the closed-form expressions that the function uses
- Approximations related to the numerical implementation of the expressions

You can generally rely on the first couple of significant digits of the function's output.

Limitations Related to Extreme Values of Input Arguments

Inherent limitations in numerical precision force the function to assume perfect synchronization if the value of `timerr` or `phaserr` is very small. The table below indicates how the function behaves under these conditions.

Condition	Behavior of Function
`timerr < eps`	`bersync(EbNo,timerr,'timing')` defined as `berawgn(EbNo,'psk',2)`
`phaserr < eps`	`bersync(EbNo,phaserr,'carrier')` defined as `berawgn(EbNo,'psk',2)`

Algorithms

This function uses formulas from [3].

When the last input is `'timing'`, the function computes

$$\frac{1}{4\pi\sigma}\int_{-\infty}^{\infty}\exp(-\frac{\xi^2}{2\sigma^2})\int_{\sqrt{2R}(1-2|\xi|)}^{\infty}\exp(-\frac{x^2}{2})dxd\xi+\frac{1}{2\sqrt{2\pi}}\int_{\sqrt{2R}}^{\infty}\exp(-\frac{x^2}{2})dx$$

where σ is the `timerr` input and R is the value of `EbNo` converted from dB to a linear scale.

When the last input is `'carrier'`, the function computes

$$\frac{1}{\pi\sigma}\int_{0}^{\infty}\exp(-\frac{\phi^2}{2\sigma^2})\int_{\sqrt{2R}\cos\phi}^{\infty}\exp(-\frac{y^2}{2})dyd\phi$$

where σ is the `phaserr` input and R is the value of `EbNo` converted from dB to a linear scale.

Alternatives

As an alternative to the `bersync` function, invoke the BERTool GUI (`bertool`) and use the **Theoretical** tab.

bertool

Open bit error rate analysis GUI (BERTool)

Syntax

```
bertool
```

Description

`bertool` launches the Bit Error Rate Analysis Tool (BERTool). The BERTool application enables you to analyze the bit error rate (BER) performance of communications systems. BERTool computes the BER as a function of signal-to-noise ratio. It analyzes performance either with Monte-Carlo simulations of MATLAB functions and Simulink models or with theoretical closed-form expressions for selected types of communication systems. See “BERTool” to learn more.

Introduced before R2006a

bi2de

Convert binary vectors to decimal numbers

Syntax

```
d = bi2de(b)
d = bi2de(b,flg)
d = bi2de(b,p)
d = bi2de(b,p,flg)
```

Description

`d = bi2de(b)` converts a binary row vector `b` to a decimal integer.

`d = bi2de(b,flg)` converts a binary row vector to a decimal integer, where `flg` determines the position of the most significant digit.

`d = bi2de(b,p)` converts a base-`p` row vector `b` to a decimal integer.

`d = bi2de(b,p,flg)` converts a base-`p` row vector to a decimal integer, where `flg` determines the position of the most significant digit.

Examples

Convert Binary Numbers to Decimals

Generate a matrix that contains binary representations of five random numbers between 0 and 15. Convert the binary numbers to decimal integers.

```
b = randi([0 1],5,4);
d = bi2de(b)
```

```
d = 5×1

     1
     5
    14
    11
    15
```

Convert Binary to Decimal

This example shows how to convert binary numbers to decimal integers. It highlights the difference between right- and left- most significant digit positioning.

```
b1 = [0 1 0 1 1];
b2 = [1 1 1 0];
```

Convert the two binary arrays to decimal by using the bi2de function. Assign the most significant digit is the leftmost element. The output of converting b1 corresponds to $0(2^4) + 1(2^3) + 0(2^2) + 1(2^1) + 1(2^0) = 11$, and b2 corresponds to $1(2^3) + 1(2^2) + 1(2^1) + 0(2^0) = 14$.

```
d1 = bi2de(b1,'left-msb')
```

```
d1 = 11
```

```
d2 = bi2de(b2,'left-msb')
```

```
d2 = 14
```

Assign the most significant digit is the rightmost element. The output of converting b1 corresponds to $0(2^0) + 1(2^1) + 0(2^2) + 1(2^3) + 1(2^4) = 26$, and b2 corresponds to $1(2^0) + 1(2^1) + 1(2^2) + 0(2^3) = 7$.

```
d1 = bi2de(b1,'right-msb')
```

```
d1 = 26
```

```
d2 = bi2de(b2,'right-msb')
```

```
d2 = 7
```

Convert Octal Number to Decimal

Convert an octal (base-8) number to its decimal equivalent.

Assign the most significant digit to the leftmost position. The output corresponds to $4(8^3) + 2(8^2) + 7(8^1) + 1(8^0) = 2233$.

```
d = bi2de([4 2 7 1],8,'left-msb')
```

```
d = 2233
```

Assign the most significant digit to the rightmost position. The output corresponds to $4(8^0) + 2(8^1) + 7(8^2) + 1(8^3) = 980$.

```
d = bi2de([4 2 7 1],8,'right-msb')
```

```
d = 980
```

Input Arguments

b — Binary input

row vector | matrix

Binary input, specified as a row vector or matrix of positive integer or logical values.

Note b must represent an integer less than or equal to 2^{52}.

Data Types: double | single | logical | integer | fi

`flg` — MSB flag

`'right-msb'` (default) | `'left-msb'`

MSB flag, specified as `'right-msb'` or `'left-msb'`.

- `'right-msb'` –– Indicates the right (or last) column of the binary input, b, as the most significant bit (or highest-order digit).
- `'left-msb'` –– Indicates the left (or first) column of the binary input, b, as the most significant bit (or highest-order digit).

Data Types: `char` | `string`

p — Base

2 (default) | positive integer scalar

Base of the input `b`, specified as an integer greater than or equal to `2`.

Data Types: `double` | `single`

Output Arguments

d — Decimal output

nonnegative integer | vector

Decimal output, returned as an nonnegative integer or row vector. If `b` is a matrix, each row represents a base-`p` number. In this case, the output `d` is a column vector in which each element is the decimal representation of the corresponding row of `b`.

If the input data type is

- An integer data type and the value of `d` can be contained in the same integer data type as the input, the output data type uses the same data type as the input. Otherwise, the output data type is chosen to be big enough to contain the decimal output.
- double or logical data type, the output data type is double.
- single data type, the output data type is single.

Introduced before R2006a

bin2gray

(To be removed) Convert positive integers into corresponding Gray-encoded integers

Note will be removed in a future release. Use the appropriate modulation object or function to remap constellation points instead. For more information, see “Compatibility Considerations”.

Syntax

```
y = bin2gray(x,modulation,M)
[y,map] = bin2gray(x,modulation,M)
```

Description

`y = bin2gray(x,modulation,M)` generates a Gray-encoded vector or matrix output `y` with the same dimensions as its input parameter `x`. `x` can be a scalar, vector, matrix, or 3-D array. `modulation` is the modulation type and must be `'qam'`, `'pam'`, `'fsk'`, `'dpsk'`, or `'psk'`. `M` is the modulation order and must be an integer power of 2.

Note If you are converting binary-coded data to Gray-coded data and modulating the result immediately afterwards, you should use the appropriate modulation object or function with the `'Gray'` option, instead of `bin2gray`.

`[y,map] = bin2gray(x,modulation,M)` generates a Gray-encoded output `y` with its respective Gray-encoded constellation map, `map`.

You can use map output to label a Gray-encoded constellation. The map output gives the Gray-encoded labels for the corresponding modulation.

Examples

Binary to Gray Symbol Mapping

This example shows how to use the `bin2gray` and `gray2bin` functions to map integer inputs from a natural binary order symbol mapping to a Gray-coded signal constellation and vice versa, assuming 16-QAM modulation. In addition, a visual representation of the difference between Gray-coded and binary-coded symbol mappings is shown.

Convert Binary to Gray

Create a complete vector of 16-QAM integers.

```
M = 16;
x = (0:M-1);
```

Convert the input vector from a natural binary order to a Gray-encoded vector using `bin2gray`.

```
[y,mapy] = bin2gray(x,'qam',M);
```

Convert Gray to Binary

Convert the Gray-encoded symbols, y, back to a binary ordering using gray2bin.

```
z = gray2bin(y,'qam',M);
```

Verify that the original data, x, and the final output vector, z, are identical.

```
isequal(x,z)
```

```
ans = logical
   1
```

Show Symbol Mappings

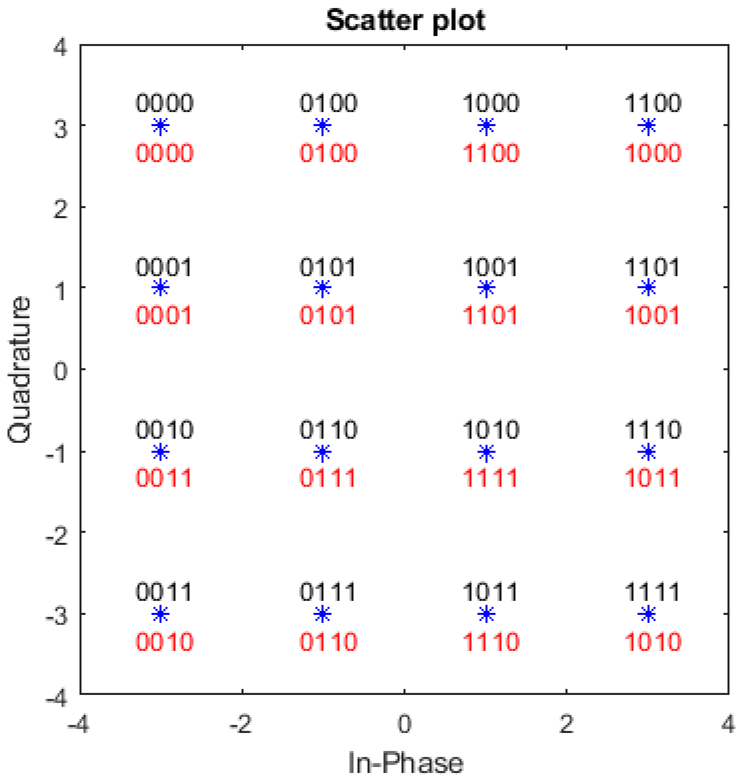
To create a constellation plot showing the different symbol mappings, use the qammod function to find the complex symbol values.

```
sym = qammod(x,M);
```

Plot the constellation symbols and label them using the Gray (y) and binary (z) output vectors. The binary representation of the Gray-coded symbols is shown in black while the binary representation of the naturally ordered symbols is shown in red. Set the axes scaling so that all points are displayed.

```
scatterplot(sym,1,0,'b*');
for k = 1:16
    text(real(sym(k))-0.3,imag(sym(k))+0.3,...
        dec2base(mapy(k),2,4));

    text(real(sym(k))-0.3,imag(sym(k))-0.3,...
        dec2base(z(k),2,4),'Color',[1 0 0]);
end
axis([-4 4 -4 4])
```



Input Arguments

x — Binary-encoded data

vector | matrix

Input binary-encoded data, specified as a vector or matrix.

Data Types: `double`

`modulation` — Modulation type

`'qam'` | `'pam'` | `'fsk'` | `'dpsk'` | `'psk'`

Modulation type, specified as, `'qam'`, `'pam'`, `'fsk'`, `'dpsk'`, or `'psk'`

`M` — Modulation order

scalar

Modulation order, specified as an integer power of 2.

Data Types: `double`

Output Arguments

y — Gray-encoded data

vector | matrix

Gray-encoded data with the same size and dimensions input x.

map — Map of labels
vector

Map output to label a Gray-encoded constellation, specified as a vector with a length the size of the modulation order, M. The map gives the Gray-encoded labels for the corresponding modulation.

Compatibility Considerations

bin2gray will be removed
Not recommended starting in R2020a

bin2gray will be removed in a future release. Use the appropriate modulation object or function instead. If your workflow uses bin2gray or gray2bin with any of the modulations schemes in this table, follow the appropriate example.

Modulation	Old Functionality	Use This Instead

QAM (qammod and qamdemod)	x = randi([0 63],1,100);
	y = bin2gray(x,'qam',64);
	z = qammod(y,64,'bin');
	
	x = 2*(randn(100,1)+1j*randn(100,1));
	y = qamdemod(x,64,'bin');
	z = gray2bin(y,'qam',64);
		x = randi([0 63],1,100);
		z = qammod(x,64,'gray');
		
		x = 2*(randn(100,1)+1j*randn(100,1));
		z = qamdemod(x,64,'gray')

PAM (pammod and pamdemod)	x = randi([0 63],1,100);
	y = gray2bin(x,'pam',64);
	z = pammod(y,64,pi/4,'bin');
	
	x = 2*(randn(100,1)+1j*randn(100,1));
	y = pamdemod(x,64,pi/4,'bin');
	z = bin2gray(y,'pam',64);
		x = randi([0 63],1,100);
		z = pammod(x,64,pi/4,'gray');
		
		x = 2*(randn(100,1)+1j*randn(100,1));
		z = pamdemod(x,64,pi/4,'gray')

FSK (fskmod and fskdemod)	x = randi([0 63],1,100);
	y = gray2bin(x,'fsk',64);
	z = fskmod(y,64,1,256,256,'cont','bin')
	
	x = 2*(randn(512,1)+1j*randn(512,1));
	y = fskdemod(x,64,1,256,256,'bin');
	z = bin2gray(y,'fsk',64)
		x = randi([0 63],1,100);
		z = fskmod(x,64,1,256,256,'cont','gray')
		x = 2*(randn(512,1)+1j*randn(512,1));
		z = fskdemod(x,64,1,256,256,'gray');

DPSK (dpskmod and dpskdemod)	x = randi([0 63],1,100);
	y = gray2bin(x,'dpsk',64);
	z = dpskmod(y,64,pi/4,'bin');
	
	x = 2*(randn(100,1)+1j*randn(100,1));
	y = dpskdemod(x,64,pi/4,'bin');
	z = bin2gray(y,'dpsk',64);
		x = randi([0 63],1,100);
		z = dpskmod(x,64,pi/4,'gray');
		
		x=2*(randn(100,1)+1j*randn(100,1));
		z = dpskdemod(x,64,pi/4,'gray');

PSK (pskmod and pskdemod)	x=randi([0 63],1,100);
	y=gray2bin(x,'psk',64);
	z=pskmod(y,64,0,'bin');
	
	x = 2*(randn(100,1)+1j*randn(100,1));
	y = pskdemod(x,64,0,'bin');
	z = bin2gray(y,'psk',64);
		x=randi([0 63],1,100);
		z=pskmod(x,64,0,'gray');
		
		x = 2*(randn(100,1)+1j*randn(100,1));
		z = pskdemod(x,64,0,'gray');

Gray Encoding a Modulated Signal

Introduced before R2006a

biterr

Number of bit errors and bit error rate (BER)

Syntax

```
[number,ratio] = biterr(x,y)
[number,ratio] = biterr(x,y,k)
[number,ratio] = biterr(x,y,k,flag)
[number,ratio,individual] = biterr( ___ )
```

Description

`[number,ratio] = biterr(x,y)` compares the unsigned binary representation of elements in `x` to those in `y`. The function returns `number`, the number of bits that differ in the comparison, and `ratio`, the ratio of `number` to the total number of bits. The function determines the order in which it compares `x` and `y` based on their sizes. For more details, see Algorithms on page 2-98 section.

`[number,ratio] = biterr(x,y,k)` also specifies `k`, the maximum number of bits for each element in `x` and `y`. If the unsigned binary representation of any element in `x` or `y` is more than `k` digits, the function errors.

`[number,ratio] = biterr(x,y,k,flag)` specifies a `flag` to override default settings for how the function compares the elements and computes the outputs. For more information, see Algorithms on page 2-99 section.

`[number,ratio,individual] = biterr( ___ )` returns the binary comparison result of `x` and `y` as matrix `individual`. You can specify any of the input argument combination from the previous syntaxes.

Examples

Bit Error Rate Computation

Create two binary matrices.

```
x = [0 0; 0 0; 0 0; 0 0]
```

```
x = 4×2

     0     0
     0     0
     0     0
     0     0
```

```
y = [0 0; 0 0; 0 0; 1 1]
```

```
y = 4×2

     0     0
     0     0
     0     0
     1     1
```

Determine the number of bit errors.

```
numerrs = biterr(x,y)
```

```
numerrs = 2
```

Compute the number of column-wise errors .

```
numerrs = biterr(x,y,[],'column-wise')
```

```
numerrs = 1×2

     1     1
```

Compute the number of row-wise errors.

```
numerrs = biterr(x,y,[],'row-wise')
```

```
numerrs = 4×1

     0
     0
     0
     2
```

Compute the number of overall errors. Behavior is the same as the default behaviour.

```
numerrs = biterr(x,y,[],'overall')
```

```
numerrs = 2
```

Estimate Bit Error Rate for 64-QAM in AWGN

Demodulate a noisy 64-QAM signal and estimate the bit error rate (BER) for a range of Eb/No values. Compare the BER estimate to theoretical values.

Set the simulation parameters.

```
M = 64;                 % Modulation order
k = log2(M);            % Bits per symbol
EbNoVec = (5:15)';      % Eb/No values (dB)
numSymPerFrame = 100;   % Number of QAM symbols per frame
```

Initialize the results vector.

```
berEst = zeros(size(EbNoVec));
```

The main processing loop executes these steps.

- Generate binary data and convert to 64-ary symbols.
- QAM-modulate the data symbols.
- Pass the modulated signal through an AWGN channel.
- Demodulate the received signal.
- Convert the demodulated symbols into binary data.
- Calculate the number of bit errors.

The `while` loop continues to process data until either 200 errors are encountered or 1e7 bits are transmitted.

```
for n = 1:length(EbNoVec)
    % Convert Eb/No to SNR
    snrdB = EbNoVec(n) + 10*log10(k);
    % Reset the error and bit counters
    numErrs = 0;
    numBits = 0;

    while numErrs < 200 && numBits < 1e7
        % Generate binary data and convert to symbols
        dataIn = randi([0 1],numSymPerFrame,k);
        dataSym = bi2de(dataIn);

        % QAM modulate using 'Gray' symbol mapping
        txSig = qammod(dataSym,M);

        % Pass through AWGN channel
        rxSig = awgn(txSig,snrdB,'measured');

        % Demodulate the noisy signal
        rxSym = qamdemod(rxSig,M);
        % Convert received symbols to bits
        dataOut = de2bi(rxSym,k);

        % Calculate the number of bit errors
        nErrors = biterr(dataIn,dataOut);

        % Increment the error and bit counters
        numErrs = numErrs + nErrors;
        numBits = numBits + numSymPerFrame*k;
    end

    % Estimate the BER
    berEst(n) = numErrs/numBits;
end
```

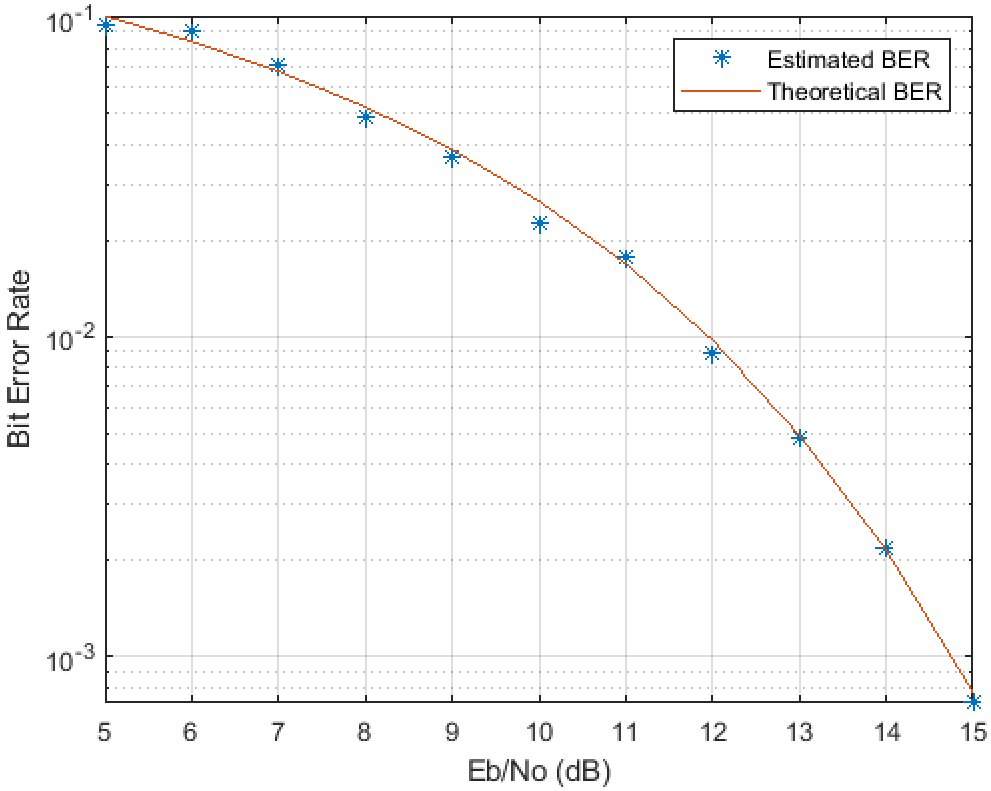
Determine the theoretical BER curve by using the `berawgn` function.

```
berTheory = berawgn(EbNoVec,'qam',M);
```

Plot the estimated and theoretical BER data. The estimated BER data points are well aligned with the theoretical curve.

```
semilogy(EbNoVec,berEst,'*')
hold on
semilogy(EbNoVec,berTheory)
grid
```

```
legend('Estimated BER','Theoretical BER')
xlabel('Eb/No (dB)')
ylabel('Bit Error Rate')
```



Input Arguments

x,y — Inputs to be compared (as separate arguments)

vector | matrix

Inputs to be compared, specified as separate arguments, as a vector or matrix of nonnegative integer elements. The function converts each element of x and y to its unsigned binary representation for comparison.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

k — Maximum number of bits for input elements

positive integer

Maximum number of bits for input elements of x and y, specified as a positive integer. If the number of bits required for binary representation of any element in x or y is greater than k, the function errors.

If you do not set k, the function sets it as the number of bits in the binary representation of the largest element in x and y.

Data Types: `single` | `double`

`flag` — Flag to override default settings
`'overall'` | `'row-wise'` | `'column-wise'`

Flag to override default settings of the function, specified as `'overall'`, `'row-wise'`, or `'column-wise'`. Flag specifies how the function compares elements in inputs `x,y` and computes the output. For more details, see the Algorithms on page 2-99 section.

Data Types: `string` | `char`

Output Arguments

`number` — Number of bit errors
nonnegative integer | integer vector

Number of bit errors, returned as a nonnegative integer or integer vector.

Data Types: `single` | `double`

`ratio` — Bit error rate
scalar

Bit error rate, returned as a scalar. `ratio` is the number of bit errors, `number`, to the total number of bits used in the binary representation. The total number of bits is `k` times the number of entries in the smaller of the inputs `x,y`.

`individual` — Binary comparison result of each input element
matrix

Binary comparison result of each input element in `x` and `y`, returned as a matrix whose dimensions are those of the larger of `x` and `y`. Each element specifies the number of bits by which the elements in the pair differ.

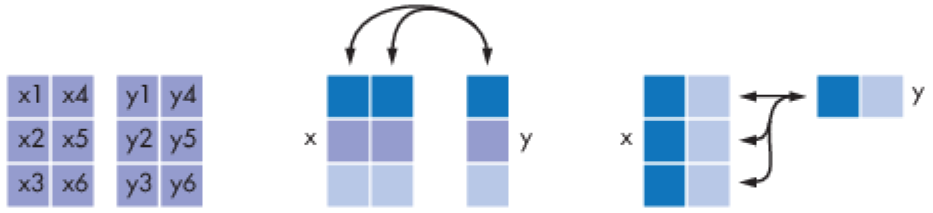
Data Types: `single` | `double`

Algorithms

Comparing Inputs Based on Sizes

The function uses the sizes of `x` and `y` to determine the order in which it compares their elements.

- If inputs are matrices of the same dimensions, then the function compares the inputs element by element. `number` is a nonnegative integer in this case. For example, see case (a) in the figure.
- If one input is a matrix and the other input is a column vector, then the function compares each column of the matrix element by element with the column vector. The number of rows in the matrix must be equal to the length of the column vector. In other words, if the matrix has dimensions *m*-by-*n*, then the column vector must have dimensions *m*-by-1. For example, see case (b) in the figure.
- If one input is a matrix and the other input is a row vector, then the function compares each row of the matrix element by element with the row vector. The number of columns in the matrix must be equal to the length of the row vector. In other words, if the matrix has dimensions *m*-by-*n*, then the row vector must have dimensions 1-by-*n*. For example, see case (c) in the figure.



(a) Compares x1 with y1, x2 with y2, and so on.

(b) Compares column vector y with each column of matrix x

(c) Compares row vector y with each row of matrix x

Comparing Inputs Based on Flag

This table describes how the output is computed based on the different values of `flag`. `x` is considered as a matrix in this table and the size of `y` is varied.

Size of `y`	`flag` Value	Type of Comparison	`number` Value	Total Number of Bits
Matrix	`'overall'` (default)	Element by element	Total number of bit errors	`k` times the number of elements in `y`
	`'row-wise'`	*m*th row of `x` to *m*th row of `y`	Column vector whose elements represent the bit errors in each row	`k` times the number of elements in `y`
	`'column-wise'`	*m*th column of `x` to *m*th column of `y`	Row vector whose elements represent the bit errors in each column	`k` times the number of elements in `y`
Row vector	`'overall'`	`y` to each row of `x`	Total number of bit errors	`k` times the number of elements of `x`
	`'row-wise'`(default)	`y` to each row of `x`	Column vector whose elements represent the bit errors in each row of `x`	`k` times the size of `y`
Column vector	`'overall'`	`y` to each column of `x`	Total number of bit errors	`k` times the number of elements of `x`
	`'column-wise'` (default)	`y` to each column of `x`	Row vector whose elements represent bit errors in each column of `x`	`k` times the size of `y`

Introduced before R2006a

bsc

Binary symmetric channel

Syntax

```
ndata = bsc(data,probability)
ndata = bsc(data,probability,streamhandle)
ndata = bsc(data,probability,seed)
[ndata,err] = bsc( ___ )
```

Description

`ndata = bsc(data,probability)` passes the binary input signal `data` through a binary symmetric channel having the specified error probability. The channel introduces a bit error and processes each element of the input `data` independently. `data` must be an array of binary numbers or a Galois array in GF(2). `probability` must be a scalar from 0 to 1.

`ndata = bsc(data,probability,streamhandle)` accepts a random stream handle to generate uniform noise samples by using `rand`. Providing a random stream handle or using the `reset (RandStream)` function on the default random stream object enables you to generate repeatable noise samples. For more information, see `RandStream`.

`ndata = bsc(data,probability,seed)` accepts a seed value, for initializing the uniform random number generator, `rand`. If you want to generate repeatable noise samples, then either reset the random stream input before calling `bsc` or use the same seed input.

`[ndata,err] = bsc( ___ )` returns an array containing the channel errors, using any of the preceding syntaxes.

Examples

Add Bit Errors to Bit Stream

Using the `bsc` function, introduce bit errors in the bits in a random matrix with probability 0.15.

```
z = randi([0 1],100,100); % Random matrix
nz = bsc(z,.15); % Binary symmetric channel
[numerrs, pcterrs] = biterr(z,nz) % Number and percentage of errors
```

```
numerrs = 1509

pcterrs = 0.1509
```

The output below is typical. For relatively small sets of data, the percentage of bit errors is not exactly 15% in most trials. If the size of the matrix `z` is large, the bit error percentage will be closer to the exact probability you specify.

Check for Errors After Decoding

Using the bsc function, introduce bit errors in the bits in a random matrix with probability 0.01. Use Viterbi decoder to decode message data.

Define trellis for Viterbi decoder. Generate and encode message data.

```
trel = poly2trellis([4 3],[4 5 17;7 4 2]);
msg = ones(10000,1);
```

Create objects for convolutional encoder, Viterbi decoder, and error rate calculator.

```
hEnc = comm.ConvolutionalEncoder(trel);
hVitDec = comm.ViterbiDecoder(trel, 'InputFormat','hard', 'TracebackDepth',...
    2, 'TerminationMethod', 'Truncated');
hErrorCalc = comm.ErrorRate;
```

Encode the message data. Introduce bit errors. Display the total number of errors.

```
code = hEnc(msg);
[ncode,err] = bsc(code,.01);
numchanerrs = sum(sum(err))
```

```
numchanerrs = 158
```

Decode the data and check the number of errors after decoding.

```
dcode = hVitDec(ncode);
berVec = hErrorCalc(msg, dcode);
ber = berVec(1)
```

```
ber = 0.0049
```

```
numsyserrs = berVec(2)
```

```
numsyserrs = 49
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Code generation supported, except for syntaxes that include a RandStream object.

Topics

“Design a Rate 2/3 Feedforward Encoder Using Simulink”

Introduced before R2006a

cdma2000ForwardReferenceChannels

Define cdma2000 forward reference channel

Syntax

```
cfg = cdma2000ForwardReferenceChannels(wv)
cfg = cdma2000ForwardReferenceChannels(wv,numchips)
cfg = cdma2000ForwardReferenceChannels(BSTM-RC,numchips,P,M)
cfg = cdma2000ForwardReferenceChannels(traffic,numchips,F-SCH-SPEC)
```

Description

`cfg = cdma2000ForwardReferenceChannels(wv)` returns a structure, `cfg`, that defines the cdma2000® forward link parameters given the input waveform identifier, `wv`. To generate a forward link reference channel waveform, pass this structure to the `cdma2000ForwardWaveformGenerator` function.

For all syntaxes, `cdma2000ForwardReferenceChannels` creates a configuration structure that is compliant with the cdma2000 physical layer specification [1].

`cfg = cdma2000ForwardReferenceChannels(wv,numchips)` specifies the number of chips to generate.

`cfg = cdma2000ForwardReferenceChannels(BSTM-RC,numchips,P,M)` returns the data structure for the `BSTM-RC` waveform identifiers, given the total traffic channel power, `P`, and the number of traffic channels, `M`. For more information on base station testing, see Table 6.5.2-1 of [2].

`cfg = cdma2000ForwardReferenceChannels(traffic,numchips,F-SCH-SPEC)` returns the data structure for the specified traffic channel, `traffic`, and the forward supplemental channel (F-SCH) and frame length combination, `F-SCH-SPEC`. If omitted, `F-SCH-SPEC` has a default value of the lowest F-SCH data rate allowable for a 20 ms frame length, given the radio configuration specified by `traffic`.

Examples

Generate Waveform for RC2 Forward Traffic Channels

Create a parameter structure, `config`, for all forward traffic channels (F-FCH and F-SCCH) that are supported by radio configuration 2.

```
config = cdma2000ForwardReferenceChannels('ALL-RC2')
```

```
config = struct with fields:
          SpreadingRate: 'SR1'
              Diversity: 'NTD'
                    QOF: 'QOF1'
               PNOffset: 0
          LongCodeState: 0
     PowerNormalization: 'Off'
```

```
      OversamplingRatio: 4
             FilterType: 'cdma2000Long'
                InvertQ: 'Off'
       EnableModulation: 'Off'
    ModulationFrequency: 0
               NumChips: 1000
                  FPICH: [1x1 struct]
                 FAPICH: [1x1 struct]
                FTDPICH: [1x1 struct]
               FATDPICH: [1x1 struct]
                   FPCH: [1x1 struct]
                  FSYNC: [1x1 struct]
                  FBCCH: [1x1 struct]
                  FCACH: [1x1 struct]
                  FCCCH: [1x1 struct]
                 FCPCCH: [1x1 struct]
                  FQPCH: [1x1 struct]
                   FFCH: [1x1 struct]
                  FOCNS: [1x1 struct]
                  FSCCH: [1x1 struct]
```

Examine the fields for the Forward Fundamental Channel (F-FCH). The data rate is 14,400 bps and the frame length is 20 ms.

```
config.FFCH
```

```
ans = struct with fields:
                Enable: 'On'
                 Power: 0
    RadioConfiguration: 'RC2'
              DataRate: 14400
           FrameLength: 20
          LongCodeMask: 0
          EnableCoding: 'On'
            DataSource: {'PN9'  [1]}
             WalshCode: 7
             EnableQOF: 'Off'
    PowerControlEnable: 'Off'
```

Generate the complex waveform using the corresponding waveform generator function.

```
waveform = cdma2000ForwardWaveformGenerator(config);
```

A waveform composed of the channels specified by each substructure of `config` is generated by `cdma2000ForwardWaveformGenerator`.

Generate CDMA200 Waveform Containing Sync Channel Message

Create a reference channel, specify the sync channel message as the data source, add the `SyncMessage` structure to the `FSYNC` substructure. Generate the waveform using this reference channel configuration.

Create a reference channel for testing a base station using radio configuration 3.

```
config = cdma2000ForwardReferenceChannels('BSTM-RC3');
```

Adjust the Forward Sync Channel (F-SYNC) settings. Set a relative channel power of 0.0 dB and specify the sync channel message as the data source.

```
config.FSYNC.Power = 0.0;
config.FSYNC.DataSource = 'SyncMessage';
```

Define the sync channel message structure (for P_REV = 6 (IS-2000-0)) and add it to the `config.FSYNC` substructure. Display the `FSYNC` structure.

```
sm = struct();
sm.P_REV = 6;                          % Protocol revision field
sm.MIN_P_REV = 6;                      % Minimum protocol revision field
sm.SID = hex2dec('14B');               % System identifier field
sm.NID = 1;                            % Network identification field
sm.PILOT_PN = 0;                       % Pilot PN offset field
sm.LC_STATE = hex2dec('20000000000');  % Long code state field
sm.SYS_TIME = hex2dec('36AE0924C');    % System time field
sm.LP_SEC = 0;                         % Leap second field
sm.LTM_OFF = 0;                        % Local time offset field
sm.DAYLT = 0;                          % Daylight saving time indicator field
sm.PRAT = 0;                           % Paging channel data rate field
sm.CDMA_FREQ = hex2dec('2F6');         % CDMA frequency field
sm.EXT_CDMA_FREQ = hex2dec('2F6');     % Extended CDMA frequency field

config.FSYNC.SyncMessage = sm;

config.FSYNC
```

```
ans = struct with fields:
          Enable: 'On'
           Power: 0
    EnableCoding: 'On'
      DataSource: 'SyncMessage'
     SyncMessage: [1x1 struct]
```

Generate the forward link waveform.

```
waveform = cdma2000ForwardWaveformGenerator(config);
```

Generate F-CCCH Waveform

Create a structure for a 2000-chip forward common control channel (F-CCCH). Specify a 38,400 bps data rate, a 5 ms frame length, and an accompanying broadcast control channel (F-BCCH) with a 9600 bps data rate.

```
config   = cdma2000ForwardReferenceChannels('CONTROL-38400-5-9600',2000)
```

```
config = struct with fields:
          SpreadingRate: 'SR1'
              Diversity: 'NTD'
                    QOF: 'QOF1'
               PNOffset: 0
          LongCodeState: 0
```

```
     PowerNormalization: 'Off'
      OversamplingRatio: 4
             FilterType: 'cdma2000Long'
                InvertQ: 'Off'
       EnableModulation: 'Off'
    ModulationFrequency: 0
               NumChips: 2000
                  FPICH: [1x1 struct]
                   FPCH: [1x1 struct]
                  FCCCH: [1x1 struct]
                  FBCCH: [1x1 struct]
```

Verify that the F-CCCH and F-BCCH data rates are 38,400 bps and 9600 bps, respectively.

```
config.FCCCH.DataRate
```

```
ans = 38400
```

```
config.FBCCH.DataRate
```

```
ans = 9600
```

Generate the forward link waveform.

```
waveform = cdma2000ForwardWaveformGenerator(config);
```

Generate Waveform for Base Station Testing

Create a reference channel for testing a base station using radio configuration 3. Specify the number of chips, the total power allocated to the individual channels, and the number of traffic channels. The FFCH substructure is a structure array whose dimensions are set by the number of traffic channels.

```
config = cdma2000ForwardReferenceChannels('BSTM-RC3',1000,-3,4)
```

```
config = struct with fields:
          SpreadingRate: 'SR1'
              Diversity: 'NTD'
                    QOF: 'QOF1'
               PNOffset: 0
          LongCodeState: 0
     PowerNormalization: 'Off'
      OversamplingRatio: 4
             FilterType: 'cdma2000Long'
                InvertQ: 'Off'
       EnableModulation: 'Off'
    ModulationFrequency: 0
               NumChips: 1000
                  FPICH: [1x1 struct]
                  FSYNC: [1x1 struct]
                   FPCH: [1x1 struct]
                   FFCH: [1x4 struct]
```

Verify that the length of the FFCH substructure corresponds to the number of specified traffic channels, 4.

```
length(config.FFCH)
```

```
ans = 4
```

Generate the forward link waveform.

```
waveform = cdma2000ForwardWaveformGenerator(config);
```

Generate F-SCH Waveform

Create a traffic channel using radio configuration 7 composed of a 614,400 bps forward supplemental channel (F-SCH) having a 20 ms frame length. Set the number of chips to 5000.

```
config = cdma2000ForwardReferenceChannels('TRAFFIC-RC7-4800', ...
    5000,'F-SCH-614400-20')
```

```
config = struct with fields:
          SpreadingRate: 'SR3'
              Diversity: 'NTD'
                    QOF: 'QOF1'
               PNOffset: 0
           LongCodeState: 0
      PowerNormalization: 'Off'
       OversamplingRatio: 4
             FilterType: 'cdma2000Long'
                InvertQ: 'Off'
        EnableModulation: 'Off'
     ModulationFrequency: 0
               NumChips: 5000
                  FPICH: [1x1 struct]
                   FFCH: [1x1 struct]
                   FSCH: [1x1 struct]
```

This channel uses spreading rate 3, `'SR3'`, which has a 3.75 MHz bandwidth.

Generate the forward link waveform.

```
waveform = cdma2000ForwardWaveformGenerator(config);
```

Input Arguments

wv — Waveform identification

character vector

Waveform identification of the reference channel, specified as a character vector. The input typically identifies the channel type, radio configuration, data rate, and frame length. To specify `wv`, connect the substrings with hyphens, for example, `'CONTROL-19200-10-4800'`.

Parameter Field	Values				Description
	Substring 1	Substring 2	Substring 3	Substring 4	
wv	'FPICH-ONLY'				Generates a waveform containing a pilot channel only.
	'CONTROL'	9600	20	4800 | 9600 | 19200	Character vector representing the forward common control channel (F-CCCH) data rate in bps, the frame length in ms, and the forward broadcast control channel (F-BCCH) data rate in bps. Specify `'CONTROL-9600-20-9600'` to create a structure variable, `wv`, with a 9600 bps F-CCCH data rate, a 20 ms frame length, and a 9600 bps F-BCCH data rate.
		19200	10 | 20		
		38400	5 | 10 | 20		
	'TRAFFIC'	RC1	1200 | 2400 | 4800 | 9600	N/A	Character vector representing the radio configuration and the forward fundamental channel (F-FCH) data rate in bps. Specify `'TRAFFIC-RC9-14400'` to create a channel with radio
		RC2 | RC5 | RC8 | RC9	1800 | 3600 | 7200 | 14400		

Parameter Field	Values				Description
	Substring 1	Substring 2	Substring 3	Substring 4	
		RC3 | RC4 | RC6 | RC7	1500 | 2700 | 4800 | 9600		configuration 9 having a 14400 bps F-FCH data rate.
	'BSTM'	RC1 | RC2 | RC3 | RC4 | RC5 | RC6 | RC7 | RC8 | RC9	N/A	N/A	Models for testing the base station transmitter. Specify 'BSTM-RC1' to create a structure for base station testing with radio configuration 1.
	'ALL'	RC1 | RC2 | RC3 | RC4 | RC5 | RC6 | RC7 | RC8 | RC9	N/A	N/A	Returns all channels that are supported for the specified radio configuration. Specify 'ALL-RC4' to create a structure containing all traffic channels for radio configuration 4.

Example: 'CONTROL-9600-20-9600'

Example: 'TRAFFIC-RC9-7200'

Example: 'ALL-RC5'

Data Types: char

numchips — Number of chips
1000 (default) | positive integer scalar

Number of chips, specified as a positive integer.

Example: 1024

Data Types: double

BSTM-RC — BSTM reference channel type
'BSTM-RC1' | 'BSTM-RC2' | 'BSTM-RC3' | 'BSTM-RC4' | 'BSTM-RC5' | 'BSTM-RC6' | 'BSTM-RC7' | 'BSTM-RC8' | 'BSTM-RC9'

BSTM reference channel type, specified as a character vector. For more information, see Table 6.5.2-1 of [2].

Example: 'BSTM-RC8'

Data Types: char

P — Power budget allocated to traffic channels

0 (default) | real scalar

Power budget allocated to all traffic channels, specified in decibels as a real scalar.

Example: 5

Data Types: double

M — Number of traffic channels

6 (default) | positive integer scalar

Number of traffic channels, specified as a positive integer.

Example: 8

Data Types: double

traffic — Traffic configuration

character vector

Traffic channel configuration, specified as a character vector. The table shows the supported traffic channel configurations.

Radio Configuration	Traffic Channel Configuration			
1	'TRAFFIC-RC1-1200'	'TRAFFIC-RC1-2400'	'TRAFFIC-RC1-4800'	'TRAFFIC-RC1-9600'
2	'TRAFFIC-RC2-1800'	'TRAFFIC-RC2-3600'	'TRAFFIC-RC2-7200'	'TRAFFIC-RC2-14400'
3	'TRAFFIC-RC3-1500'	'TRAFFIC-RC3-2700'	'TRAFFIC-RC3-4800'	'TRAFFIC-RC3-9600'
4	'TRAFFIC-RC4-1500'	'TRAFFIC-RC4-2700'	'TRAFFIC-RC4-4800'	'TRAFFIC-RC4-9600'
5	'TRAFFIC-RC5-1800'	'TRAFFIC-RC5-3600'	'TRAFFIC-RC5-7200'	'TRAFFIC-RC5-14400'
6	'TRAFFIC-RC6-1500'	'TRAFFIC-RC6-2700'	'TRAFFIC-RC6-4800'	'TRAFFIC-RC6-9600'
7	'TRAFFIC-RC7-1500'	'TRAFFIC-RC7-2700'	'TRAFFIC-RC7-4800'	'TRAFFIC-RC7-9600'
8	'TRAFFIC-RC8-1800'	'TRAFFIC-RC8-3600'	'TRAFFIC-RC8-7200'	'TRAFFIC-RC8-14400'
9	'TRAFFIC-RC9-1800'	'TRAFFIC-RC9-3600'	'TRAFFIC-RC9-7200'	'TRAFFIC-RC9-14400'

Example: 'TRAFFIC-RC6-4800' is a traffic channel that uses radio configuration 6 with a 4800 bps data rate.

Data Types: char

`F-SCH-SPEC` — Forward supplemental channel data rate and frame length

character vector

Forward supplemental channel data rate and frame length, specified as a character vector. The supported data rate and frame length combinations are summarized in the table.

Radio Configuration	Frame Length		
	20 ms	40 ms	80 ms
3 | **4** | **6** | **7**	'F-SCH-1500-20' | 'F-SCH-2700-20' | 'F-SCH-4800-20' | 'F-SCH-9600-20' | 'F-SCH-19200-20' | 'F-SCH-38400-20' | 'F-SCH-76800-20' | 'F-SCH-153600-20'	'F-SCH-1350-40' | 'F-SCH-2400-40' | 'F-SCH-4800-40' | 'F-SCH-9600-40' | 'F-SCH-19200-40' | 'F-SCH-38400-40' | 'F-SCH-76800-40'	'F-SCH-1200-80' | 'F-SCH-2400-80' | 'F-SCH-4800-80' | 'F-SCH-9600-80' | 'F-SCH-19200-80' | 'F-SCH-38400-80'
4 | **6** | **7**	'F-SCH-307200-20'	'F-SCH-153600-40'	'F-SCH-76800-80'
7	'F-SCH-614400-20'	'F-SCH-307200-40'	'F-SCH-153600-80'
5 | **8** | **9**	'F-SCH-1800-20' | 'F-SCH-3600-20' | 'F-SCH-7200-20' | 'F-SCH-14400-20' | 'F-SCH-28800-20' | 'F-SCH-57600-20' | 'F-SCH-115200-20' | 'F-SCH-230400-20'	'F-SCH-1800-40' | 'F-SCH-3600-40' | 'F-SCH-7200-40' | 'F-SCH-14400-40' | 'F-SCH-28800-40' | 'F-SCH-57600-40' | 'F-SCH-115200-40'	'F-SCH-1800-80' | 'F-SCH-3600-80' | 'F-SCH-7200-80' | 'F-SCH-14400-80' | 'F-SCH-28800-80' | 'F-SCH-57600-80'
8 | **9**	'F-SCH-460800-20'	'F-SCH-230400-40'	'F-SCH-115200-80'
9	'F-SCH-1036800-20'	'F-SCH-518400-40'	'F-SCH-259200-80'

For more data rate information for the cdma2000 forward links, see tables 3.1.3.1.3-2 and 3.1.3.1.3-4 of [1].

Example: `'F-SCH-460800-20'` is a supplemental channel with a 460,800 bps data rate and a 20 ms frame length.

Data Types: `char`

Output Arguments

`cfg` — Configuration of the parameters and channels used by the waveform generator

structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

Top-Level Parameters and Substructures

Parameter Field	Values	Description
SpreadingRate	'SR1' | 'SR3'	Spreading rate of the waveform. SR1 corresponds to a 1.2288 Mcps carrier. SR3 corresponds to a 3.6864 Mcps carrier. SR3 supports direct sequence spreading only.
Diversity	'NTD' | 'OTD' | 'STS'	Transmit diversity type (applicable only for SR1), where NTD is no transmit diversity, OTD is orthogonal transmit diversity, and STS is space time spreading
QOF	'QOF1' | 'QOF2' | 'QOF3'	Quasi-orthogonal function type
PNOffset	Nonnegative scalar integer	PN offset of the base station
LongCodeState	Positive scalar integer	Initial long code state
PowerNormalization	'Off' | 'NormalizeTo0dB' | 'NoiseFillTo0dB'	Power normalization of the waveform
NumChips	Positive scalar integer	Number of chips in the waveform
FilterType	'cdma2000Long' | 'cdma2000Short' | 'Off' | 'Custom'	Type of output filtering
CustomFilterCoefficients	Real vector	Custom filter coefficients, used only when the FilterType field is set to 'Custom'
OversamplingRatio	Positive scalar integer	Oversampling ratio at output
InvertQ	'Off' | 'On'	Negate the quadrature output
EnableModulation	'Off' | 'On'	Enable carrier modulation
ModulationFrequency	Nonnegative scalar integer	Carrier modulation frequency (applies when EnableModulation is 'On')
FPICH	Structure	See **FPICH Substructure**. Optional.
FAPICH	Structure	See **FAPICH Substructure**. Optional.
FTDPICH	Structure	See **FTDPICH Substructure**. Optional.
FATDPICH	Structure	See **FATDPICH Substructure**. Optional.
FSYNC	Structure	See **FSYNC Substructure**. Optional.
FPCH	Structure	See **FPCH Substructure**. Optional.
FCCCH	Structure	See **FCCCH Substructure**. Optional.
FCACH	Structure	See **FCACH Substructure**. Optional.
FQPCH	Structure	See **FQPCH Substructure**. Optional.
FCPCCH	Structure	See **FCPCCH Substructure**. Optional.
FBCCH	Structure	See **FBCCH Substructure**. Optional.
FFCH	Structure	See **FFCH Substructure**. Optional.
FDCCH	Structure	See **FDCCH Substructure**. Optional.
FSCCH	Structure	See **FSCCH Substructure**. Optional.

Parameter Field	Values	Description
FSCH	Structure	See **FSCH Substructure**. Optional.
FOCNS	Structure	See **FOCNS Substructure**. Optional.

FPICH Substructure

Include the FPICH substructure in the cfg structure to configure the forward pilot channel (F-PICH). The FPICH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)

FAPICH Substructure

Include the FAPICH substructure in the cfg structure to configure the forward auxiliary pilot channel (F-APICH). The FAPICH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
WalshLength	64 | 128 | 256 | 512	Walsh code length
WalshCode	Nonnegative integer scalar, such that 0 ≤ WalshCode ≤ WalshLength – 1	Walsh code number
LongCodeMask	Positive scalar integer	Long code identifier

FTDPICH Substructure

Include the FTDPICH substructure in the cfg structure to configure the forward transmit diversity pilot Channel (F-TDPICH). The FTDPICH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)

FATDPICH

Include the FATDPICH substructure in the cfg structure to configure the forward auxiliary transmit diversity pilot channel (F-ATDPICH). The FATDPICH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
WalshLength	64 | 128 | 256, 512	Walsh code length

Parameter Field	Values	Description
WalshCode	Nonnegative integer scalar, such that 0 ≤ WalshCode ≤ WalshLength – 1	Walsh code number
LongCodeMask	Positive scalar integer	Long code identifier

FSYNC Substructure

Include the FSYNC substructure in the cfg structure to configure the forward sync channel (F-SYNC). The FSYNC substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array: {'PN Type', RN Seed}, binary vector, or 'SyncMessage'. Standard PN types are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed, a binary vector, or a 'SyncMessage' character vector.
SyncMessage	Structure	See **SyncMessage Substructure**. Optional.

SyncMessage Substructure

If the DataSource field of the FSYNC substructure is set to 'SyncMessage', add the SyncMessage substructure to the cfg.FSYNC substructure to configure the sync channel message. The SyncMessage substructure contains these fields.

Parameter Field	Typical Value	Description
P_REV	6	Protocol revision
MIN_P_REV	6	Minimum protocol revision
SID	hex2dec('14B')	System identifier
NID	1	Network identification
PILOT_PN	0	Pilot PN offset
LC_STATE	hex2dec('20000000000')	Long code state
SYS_TIME	hex2dec('36AE0924C')	System time
LP_SEC	0	Leap second
LTM_OFF	0	Local time offset
DAYLT	0	Daylight saving time indicator
PRAT	0	Paging channel data rate
CDMA_FREQ	hex2dec('2F6')	CDMA frequency
EXT_CDMA_FREQ	hex2dec('2F6')	Extended CDMA frequency

FPCH Substructure

Include the FPCH substructure in the cfg substructure to configure the forward paging channel (F-PCH). The FPCH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
DataRate	4800 | 9600	Data rate (bps)
LongCodeMask	Positive scalar integer	Long code identifier
WalshCode	Nonnegative integer scalar, such that 0 ≤ WalshCode ≤ 7	Walsh code number
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array: {'PN Type', RN Seed}, binary vector, or a paging message character vector. Standard PN types are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'. Paging message options include 'PagingMessage1', 'PagingMessage2', and 'PagingMessage3'.	Data source. Specify a standard PN sequence with a random number seed, a binary vector, or one of three paging messages. For a description of paging message contents see footnote 1.

[1] When the DataSource enumeration specifies one of the paging message options, simulated paging message data is used as input to the F-PCH physical channel:

- 'PagingMessage1' — Streams a 7680 bit sequence (800 ms at fullrate) of paging message contents onto the channel that includes the General Page Message, the CDMA Channel List Message, the Extended System Parameter Message, the Extended Neighbor List Message, the System Parameter Message, and the Access Parameter Message. The paging message repeats these messages in a nonsequential pattern.
- 'PagingMessage2' — Streams a 2304 bit sequence (240 ms at fullrate) of paging message contents onto the channel that includes a truncated version of the full 'PagingMessage1' content.
- 'PagingMessage3' — Streams an 864 bit sequence (90 ms at fullrate) of paging message contents onto the channel that includes the Neighbor List Message, the CDMA Channel List Message, the General Page Message, the System Parameter Message, and the Access Parameter Message. The paging message repeats these messages in a sequential pattern.

For more information on the F-PCH contents, refer to 3GPP2 C.S0004, Table 3.1.2.3.1.1.2–1.

FCCCH Substructure

Include the FCCCH substructure in the cfg structure to configure the forward common control channel (F-CCCH). The FCCCH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On'|'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
DataRate	9600 | 19200 | 38400	Data rate (bps)
FrameLength	5 | 10 | 20	Frame length (ms)
CodingType	'conv' | 'turbo'	Type of error correction coding
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ 255	Walsh code number
LongCodeMask	Positive scalar integer	Long code identifier
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array: {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FCACH Substructure

Include the FCACH substructure in the cfg structure to configure the forward common assignment channel (F-CACH). The FCACH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
CodingType	'conv' | 'turbo'	Type of error correction coding
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ 255	Walsh code number
LongCodeMask	Positive scalar integer	Long code identifier
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array: {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FQPCH Substructure

Include the FQPCH substructure in the cfg structure to configure the forward quick paging channel (F-QPCH). The FQPCH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
DataRate	2400 | 4800	Data rate (bps)
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ 255	Walsh code number
LongCodeMask	Positive scalar integer	Long code identifier
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array: {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FCPCCH Substructure

Include the FCPCCH substructure in the cfg structure to configure the forward common power control channel (F-CPCCH). The FCPCCH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ 63	Walsh code number
LongCodeMask	Positive scalar integer	Long code identifier
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array: {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FBCCH Substructure

Include the FBCCH substructure in the cfg structure to configure the forward broadcast control channel (F-BCCH). The FBCCH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)

Parameter Field	Values	Description
DataRate	4800 | 9600 | 19200	Data rate (bps)
CodingType	'conv' | 'turbo'	Type of error correction coding
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ 127	Walsh code number
LongCodeMask	Positive scalar integer	Long code identifier
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array: {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FFCH Substructure

Include the FFCH substructure in the cfg structure to configure the forward fundamental traffic channel (F-FCH). The FFCH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
RadioConfiguration	'RC1' through 'RC9'	Radio configuration channel
DataRate	1200 | 1500 | 1800 | 2400 | 2700 | 3600 | 4800 | 7200 | 9600 | 14400	Data rate (bps)
FrameLength	5 | 10 | 20	Frame length (ms)
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ 255	Walsh code number
LongCodeMask	Positive scalar integer	Long code identifier
EnableQOF	'On' | 'Off'	Enable QOF spreading
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array: {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
PowerControlEnable	'On' | 'Off'	Enable or disable power control subchannel

Parameter Field	Values	Description
PowerControlPower	Real scalar	Power control subchannel power (relative to F-FCH)
PowerControlDataSource	Cell array: {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Power control subchannel data source

FDCCH Substructure

Include the FDCCH substructure in the cfg structure to configure the forward dedicated control channel (F-DCCH). The FDCCH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
RadioConfiguration	'RC3' through 'RC9'	Radio configuration channel
DataRate	9600 | 14400	Data rate (bps)
FrameLength	5 | 20	Frame length (ms)
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ 255	Walsh code number
LongCodeMask	Positive scalar integer	Long code identifier
EnableQOF	'On' | 'Off'	Enable QOF spreading
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array: {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FSCCH Substructure

Include the FSCCH substructure in the cfg structure to configure the forward supplemental code channel (F-SCCH). The FSCCH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
RadioConfiguration	'RC1' | 'RC2'	Radio configuration channel

Parameter Field	Values	Description
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 255	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FSCH Substructure

Include the `FSCH` substructure in the `cfg` structure to configure the forward supplemental channel (F-SCH). The `FSCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`RadioConfiguration`	`'RC3'` | `'RC4'` | `'RC5'` | `'RC6'` | `'RC7'` | `'RC8'` | `'RC9'`	Radio configuration channel
`DataRate`	`1200` | `1350` | `1500` | `1800` | `2400` | `2700` | `3600` | `4800` | `7200` | `9600` | `14400` | `19200` | `28800` | `38400` | `57600` | `76800` | `115200` | `153600` | `230400` | `307200`	Data rate (bps)
`FrameLength`	`20` | `40` | `80`	Frame length (ms)
`CodingType`	`'Conv'` | `'Turbo'`	Channel coding type, convolutional or turbo
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 255	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableQOF`	`'On'` | `'Off'`	Enable QOF spreading
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FOCNS Substructure

Include the FOCNS substructure in the cfg structure to configure orthogonal channel noise source information. The FOCNS substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
WalshLength	64 | 128 | 256	Walsh code length
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ WalshLength – 1	Walsh code number

Introduced in R2015b

cdma2000ForwardWaveformGenerator

Generate cdma2000 forward link waveform

Syntax

```
[waveform1,waveform2] = cdma2000ForwardWaveformGenerator(cfg)
```

Description

`[waveform1,waveform2] = cdma2000ForwardWaveformGenerator(cfg)` returns the cdma2000 forward link baseband primary waveform, `waveform1`, and the forward link diversity waveform, `waveform2`, as defined by the parameter definition structure, `cfg`.

The top-level parameters and lower-level substructures of `cfg` specify the waveform and channel properties the function uses to generate a cdma2000 waveform. You can generate `cfg` by using the `cdma2000ForwardReferenceChannels` function. The top-level parameters of `cfg` are `SpreadingRate`, `Diversity`, `QOF`, `PNOffset`, `LongCodeState`, `PowerNormalization`, `CustomFilterCoefficients`, `OversamplingRatio`, `FilterType`, `InvertQ`, `EnableModulation`, `ModulationFrequency`, and `NumChips`. To enable specific channels, add their associated substructures, for example, the forward paging channel, `FPCH`.

Note The tables herein list the allowable values for the top-level parameters and substructure fields. However, not all combinations of spreading rate, radio configuration, frame length, and data rate are supported. To ensure that the input argument is valid, use the `cdma2000ForwardReferenceChannels` function. If you input the structure fields manually, consult [1] to ensure that the input parameter combinations are permitted.

Examples

Generate Waveform for RC2 Forward Traffic Channels

Create a parameter structure, `config`, for all forward traffic channels (F-FCH and F-SCCH) that are supported by radio configuration 2.

```
config = cdma2000ForwardReferenceChannels('ALL-RC2')
```

```
config = struct with fields:
          SpreadingRate: 'SR1'
              Diversity: 'NTD'
                    QOF: 'QOF1'
               PNOffset: 0
          LongCodeState: 0
     PowerNormalization: 'Off'
      OversamplingRatio: 4
             FilterType: 'cdma2000Long'
                InvertQ: 'Off'
       EnableModulation: 'Off'
    ModulationFrequency: 0
```

```
               NumChips: 1000
                  FPICH: [1x1 struct]
                 FAPICH: [1x1 struct]
                FTDPICH: [1x1 struct]
               FATDPICH: [1x1 struct]
                   FPCH: [1x1 struct]
                  FSYNC: [1x1 struct]
                  FBCCH: [1x1 struct]
                  FCACH: [1x1 struct]
                  FCCCH: [1x1 struct]
                 FCPCCH: [1x1 struct]
                  FQPCH: [1x1 struct]
                   FFCH: [1x1 struct]
                  FOCNS: [1x1 struct]
                  FSCCH: [1x1 struct]
```

Examine the fields for the Forward Fundamental Channel (F-FCH). The data rate is 14,400 bps and the frame length is 20 ms.

```
config.FFCH
```

```
ans = struct with fields:
                Enable: 'On'
                 Power: 0
    RadioConfiguration: 'RC2'
              DataRate: 14400
           FrameLength: 20
          LongCodeMask: 0
          EnableCoding: 'On'
            DataSource: {'PN9'  [1]}
             WalshCode: 7
             EnableQOF: 'Off'
    PowerControlEnable: 'Off'
```

Generate the complex waveform using the corresponding waveform generator function.

```
waveform = cdma2000ForwardWaveformGenerator(config);
```

A waveform composed of the channels specified by each substructure of `config` is generated by `cdma2000ForwardWaveformGenerator`.

Generate Forward Traffic Channel for RC4

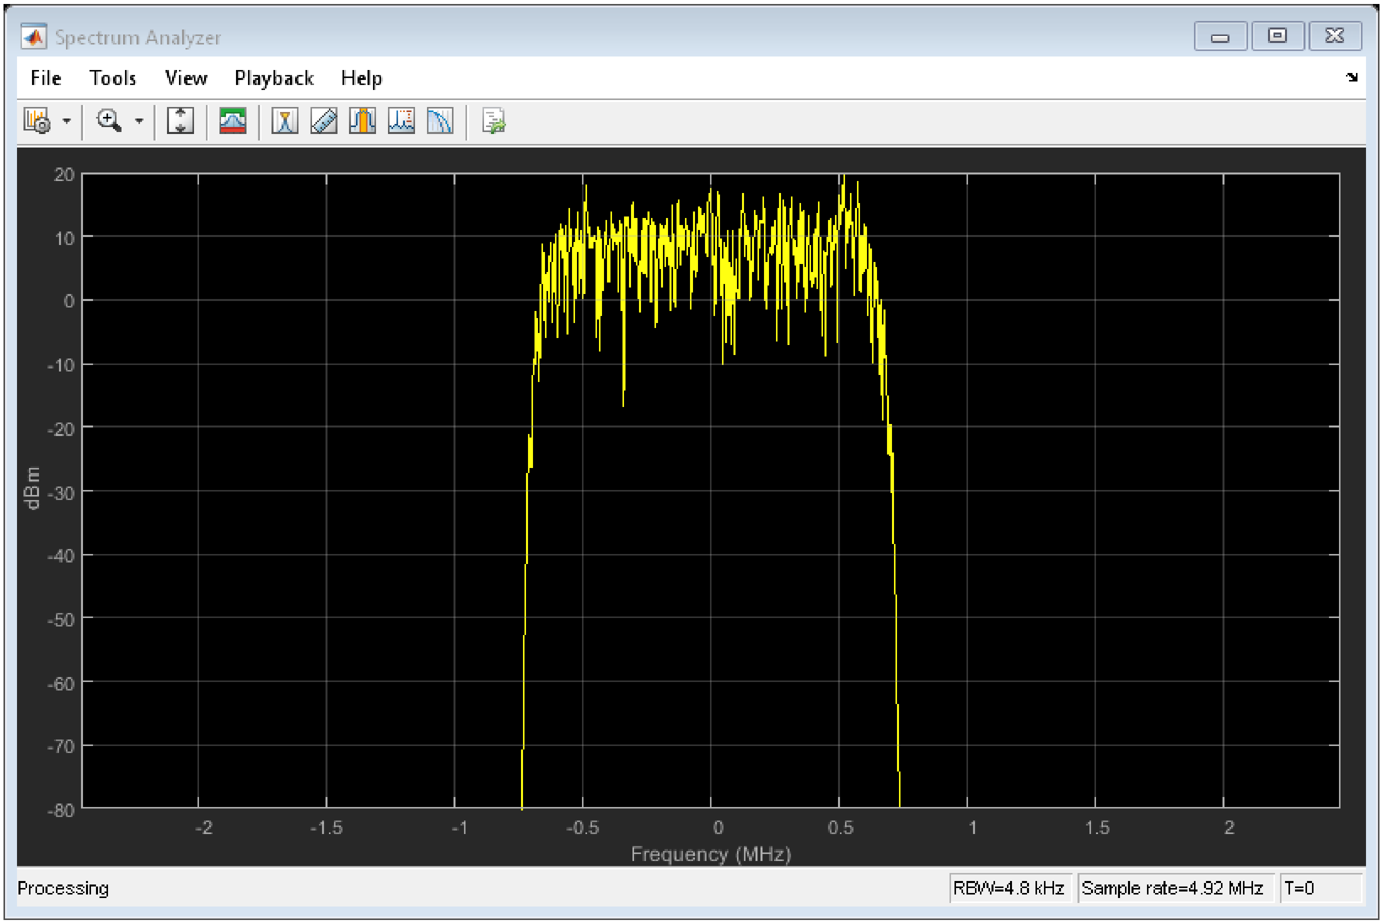
Configure a cdma2000 forward link supporting a 307.2 kbps forward supplemental channel (F-SCH) using radio configuration 4.

```
config = cdma2000ForwardReferenceChannels('TRAFFIC-RC4-4800',5000, ...
    'F-SCH-307200-20');
```

Generate the waveform and plot its spectrum. The sample rate is equal to the product of the chip rate and the oversampling ratio. RC4 uses spreading rate 1, which is equivalent to a 1.2288 Mcps chip rate.

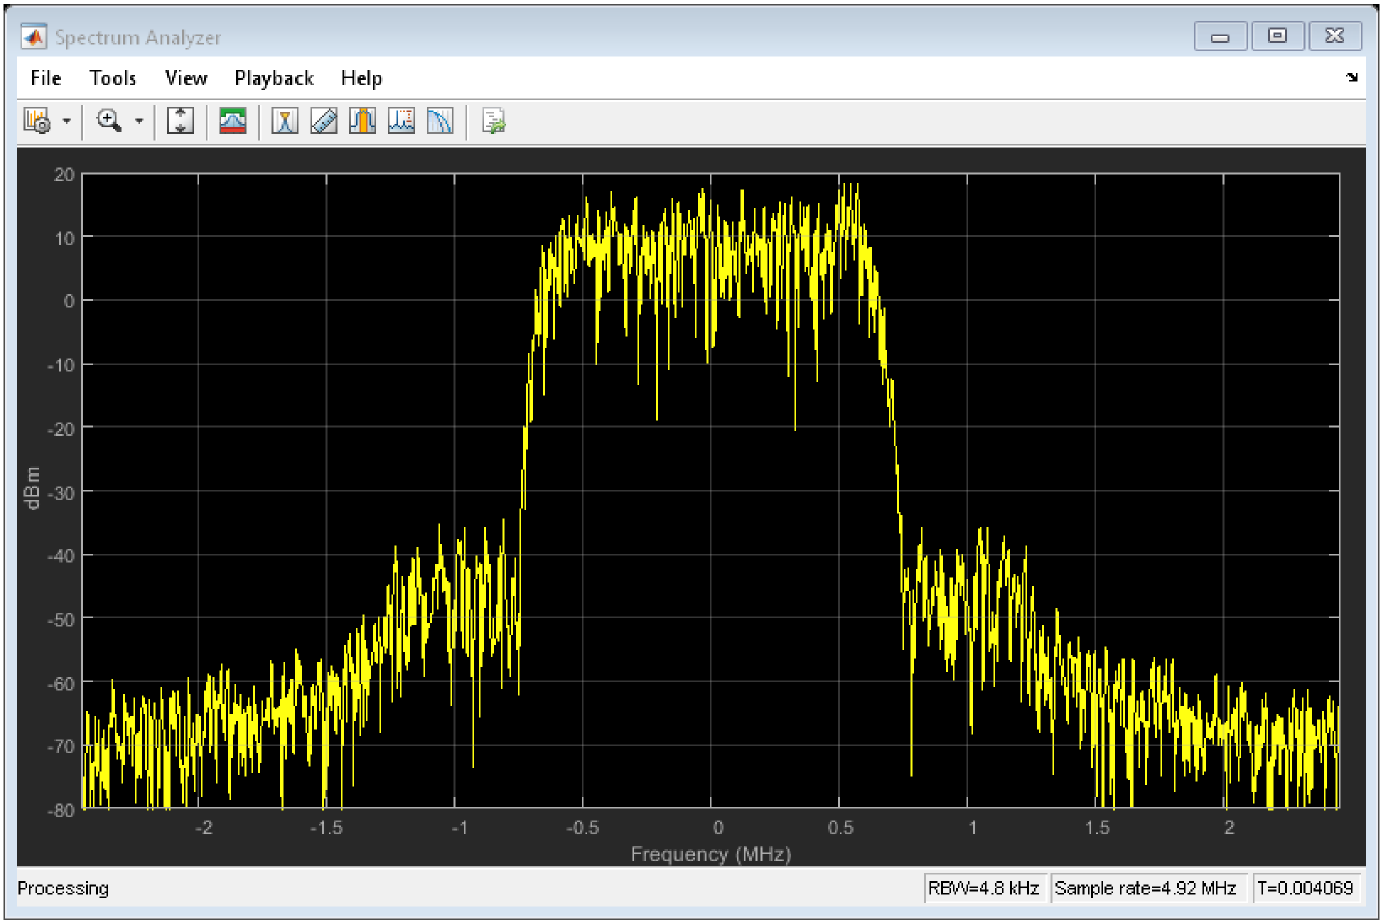
```
wv = cdma2000ForwardWaveformGenerator(config);
fs = 1.2288e6 * config.OversamplingRatio;

sa = dsp.SpectrumAnalyzer('SampleRate',fs);
step(sa,wv)
```



Change the filter type to `'cdma2000Short'` and plot the spectrum.

```
config.FilterType = 'cdma2000Short';
wv = cdma2000ForwardWaveformGenerator(config);
step(sa,wv)
```



The 'cdma2000Short' filter does not provide as much out-of-band attenuation as does the 'cdma2000Long' filter.

Generate cdma2000 Waveform with Two Forward Supplemental Channels

Create a parameter structure that specifies a forward traffic channel. Use it to generate a forward channel waveform.

Create a parameter structure specifying a traffic channel consisting of a 4800 bps fundamental channel, 5000 chips, and a 614.4 kbps supplemental channel (F-SCH) having a 20 ms frame duration.

```
cfg = cdma2000ForwardReferenceChannels('TRAFFIC-RC7-4800', ...
    5000,'F-SCH-614400-20');
```

Based on the first F-SCH, create a second F-SCH.

```
cfg(2).FSCH = cfg.FSCH;
```

Set the data rate of the second F-SCH to 38.4 kbps. Set the frame duration to 40 ms.

```
cfg(2).FSCH.DataRate = 38400;
cfg(2).FSCH.FrameLength = 40;
cfg.FSCH
```

```
ans = struct with fields:
                Enable: 'On'
                 Power: 0
    RadioConfiguration: 'RC7'
              DataRate: 614400
           FrameLength: 20
          LongCodeMask: 0
          EnableCoding: 'On'
            DataSource: {'PN9'  [1]}
             WalshCode: 2
             EnableQOF: 'Off'
            CodingType: 'conv'

ans = struct with fields:
                Enable: 'On'
                 Power: 0
    RadioConfiguration: 'RC7'
              DataRate: 38400
           FrameLength: 40
          LongCodeMask: 0
          EnableCoding: 'On'
            DataSource: {'PN9'  [1]}
             WalshCode: 2
             EnableQOF: 'Off'
            CodingType: 'conv'
```

Set the Walsh code of the second F-SCH so that it is not identical to the Walsh code of the first F-SCH.

```
cfg(2).FSCH.WalshCode = 3;
```

Generate the forward link waveform.

```
wv = cdma2000ForwardWaveformGenerator(cfg);
```

Input Arguments

`cfg` — Configuration of the parameters and channels used by the waveform generator

structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

Top-Level Parameters and Substructures

Parameter Field	Values	Description
`SpreadingRate`	`'SR1'` | `'SR3'`	Spreading rate of the waveform. `SR1` corresponds to a 1.2288 Mcps carrier. `SR3` corresponds to a 3.6864 Mcps carrier. SR3 supports direct sequence spreading only.

Parameter Field	Values	Description
Diversity	'NTD' | 'OTD' | 'STS'	Transmit diversity type (applicable only for SR1), where NTD is no transmit diversity, OTD is orthogonal transmit diversity, and STS is space time spreading
QOF	'QOF1' | 'QOF2' | 'QOF3'	Quasi-orthogonal function type
PNOffset	Nonnegative scalar integer	PN offset of the base station
LongCodeState	Positive scalar integer	Initial long code state
PowerNormalization	'Off' | 'NormalizeTo0dB' | 'NoiseFillTo0dB'	Power normalization of the waveform
NumChips	Positive scalar integer	Number of chips in the waveform
FilterType	'cdma2000Long' | 'cdma2000Short' | 'Off' | 'Custom'	Type of output filtering
CustomFilterCoefficients	Real vector	Custom filter coefficients, used only when the FilterType field is set to 'Custom'
OversamplingRatio	Positive scalar integer	Oversampling ratio at output
InvertQ	'Off' | 'On'	Negate the quadrature output
EnableModulation	'Off' | 'On'	Enable carrier modulation
ModulationFrequency	Nonnegative scalar integer	Carrier modulation frequency (applies when EnableModulation is 'On')
FPICH	Structure	See **FPICH Substructure**. Optional.
FAPICH	Structure	See **FAPICH Substructure**. Optional.
FTDPICH	Structure	See **FTDPICH Substructure**. Optional.
FATDPICH	Structure	See **FATDPICH Substructure**. Optional.
FSYNC	Structure	See **FSYNC Substructure**. Optional.
FPCH	Structure	See **FPCH Substructure**. Optional.
FCCCH	Structure	See **FCCCH Substructure**. Optional.
FCACH	Structure	See **FCACH Substructure**. Optional.
FQPCH	Structure	See **FQPCH Substructure**. Optional.
FCPCCH	Structure	See **FCPCCH Substructure**. Optional.
FBCCH	Structure	See **FBCCH Substructure**. Optional.
FFCH	Structure	See **FFCH Substructure**. Optional.
FDCCH	Structure	See **FDCCH Substructure**. Optional.
FSCCH	Structure	See **FSCCH Substructure**. Optional.
FSCH	Structure	See **FSCH Substructure**. Optional.
FOCNS	Structure	See **FOCNS Substructure**. Optional.

FPICH Substructure

Include the FPICH substructure in the cfg structure to configure the forward pilot channel (F-PICH). The FPICH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)

FAPICH Substructure

Include the FAPICH substructure in the cfg structure to configure the forward auxiliary pilot channel (F-APICH). The FAPICH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
WalshLength	64 | 128 | 256 | 512	Walsh code length
WalshCode	Nonnegative integer scalar, such that 0 ≤ WalshCode ≤ WalshLength – 1	Walsh code number
LongCodeMask	Positive scalar integer	Long code identifier

FTDPICH Substructure

Include the FTDPICH substructure in the cfg structure to configure the forward transmit diversity pilot Channel (F-TDPICH). The FTDPICH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)

FATDPICH

Include the FATDPICH substructure in the cfg structure to configure the forward auxiliary transmit diversity pilot channel (F-ATDPICH). The FATDPICH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
WalshLength	64 | 128 | 256, 512	Walsh code length
WalshCode	Nonnegative integer scalar, such that 0 ≤ WalshCode ≤ WalshLength – 1	Walsh code number
LongCodeMask	Positive scalar integer	Long code identifier

FSYNC Substructure

Include the FSYNC substructure in the cfg structure to configure the forward sync channel (F-SYNC). The FSYNC substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array: {'PN Type', RN Seed}, binary vector, or 'SyncMessage'. Standard PN types are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed, a binary vector, or a 'SyncMessage' character vector.
SyncMessage	Structure	See **SyncMessage Substructure**. Optional.

SyncMessage Substructure

If the DataSource field of the FSYNC substructure is set to 'SyncMessage', add the SyncMessage substructure to the cfg.FSYNC substructure to configure the sync channel message. The SyncMessage substructure contains these fields.

Parameter Field	Typical Value	Description
P_REV	6	Protocol revision
MIN_P_REV	6	Minimum protocol revision
SID	hex2dec('14B')	System identifier
NID	1	Network identification
PILOT_PN	0	Pilot PN offset
LC_STATE	hex2dec('20000000000')	Long code state
SYS_TIME	hex2dec('36AE0924C')	System time
LP_SEC	0	Leap second
LTM_OFF	0	Local time offset
DAYLT	0	Daylight saving time indicator
PRAT	0	Paging channel data rate
CDMA_FREQ	hex2dec('2F6')	CDMA frequency
EXT_CDMA_FREQ	hex2dec('2F6')	Extended CDMA frequency

FPCH Substructure

Include the FPCH substructure in the cfg substructure to configure the forward paging channel (F-PCH). The FPCH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
DataRate	4800 | 9600	Data rate (bps)
LongCodeMask	Positive scalar integer	Long code identifier

Parameter Field	Values	Description
`WalshCode`	Nonnegative integer scalar, such that 0 ≤ `WalshCode` ≤ 7	Walsh code number
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}`, binary vector, or a paging message character vector. Standard PN types are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`. Paging message options include `'PagingMessage1'`, `'PagingMessage2'`, and `'PagingMessage3'`.	Data source. Specify a standard PN sequence with a random number seed, a binary vector, or one of three paging messages. For a description of paging message contents see footnote 1.

[1] When the `DataSource` enumeration specifies one of the paging message options, simulated paging message data is used as input to the F-PCH physical channel:

- `'PagingMessage1'` — Streams a 7680 bit sequence (800 ms at fullrate) of paging message contents onto the channel that includes the General Page Message, the CDMA Channel List Message, the Extended System Parameter Message, the Extended Neighbor List Message, the System Parameter Message, and the Access Parameter Message. The paging message repeats these messages in a nonsequential pattern.
- `'PagingMessage2'` — Streams a 2304 bit sequence (240 ms at fullrate) of paging message contents onto the channel that includes a truncated version of the full `'PagingMessage1'` content.
- `'PagingMessage3'` — Streams an 864 bit sequence (90 ms at fullrate) of paging message contents onto the channel that includes the Neighbor List Message, the CDMA Channel List Message, the General Page Message, the System Parameter Message, and the Access Parameter Message. The paging message repeats these messages in a sequential pattern.

For more information on the F-PCH contents, refer to 3GPP2 C.S0004, Table 3.1.2.3.1.1.2–1.

FCCCH Substructure

Include the `FCCCH` substructure in the `cfg` structure to configure the forward common control channel (F-CCCH). The `FCCCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'`| `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`DataRate`	`9600` | `19200` | `38400`	Data rate (bps)
`FrameLength`	`5` | `10` | `20`	Frame length (ms)
`CodingType`	`'conv'` | `'turbo'`	Type of error correction coding

Parameter Field	Values	Description
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ 255	Walsh code number
LongCodeMask	Positive scalar integer	Long code identifier
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array: {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FCACH Substructure

Include the FCACH substructure in the cfg structure to configure the forward common assignment channel (F-CACH). The FCACH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
CodingType	'conv' | 'turbo'	Type of error correction coding
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ 255	Walsh code number
LongCodeMask	Positive scalar integer	Long code identifier
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array: {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FQPCH Substructure

Include the FQPCH substructure in the cfg structure to configure the forward quick paging channel (F-QPCH). The FQPCH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
DataRate	2400 | 4800	Data rate (bps)

Parameter Field	Values	Description
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 255	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FCPCCH Substructure

Include the `FCPCCH` substructure in the `cfg` structure to configure the forward common power control channel (F-CPCCH). The `FCPCCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 63	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FBCCH Substructure

Include the `FBCCH` substructure in the `cfg` structure to configure the forward broadcast control channel (F-BCCH). The `FBCCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`DataRate`	`4800` | `9600` | `19200`	Data rate (bps)
`CodingType`	`'conv'` | `'turbo'`	Type of error correction coding

Parameter Field	Values	Description
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 127	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FFCH Substructure

Include the `FFCH` substructure in the `cfg` structure to configure the forward fundamental traffic channel (F-FCH). The `FFCH` substructure contains these fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`RadioConfiguration`	`'RC1'` through `'RC9'`	Radio configuration channel
`DataRate`	`1200` | `1500` | `1800` | `2400` | `2700` | `3600` | `4800` | `7200` | `9600` | `14400`	Data rate (bps)
`FrameLength`	`5` | `10` | `20`	Frame length (ms)
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 255	Walsh code number
`LongCodeMask`	Positive scalar integer	Long code identifier
`EnableQOF`	`'On'` | `'Off'`	Enable QOF spreading
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array: `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
`PowerControlEnable`	`'On'` | `'Off'`	Enable or disable power control subchannel
`PowerControlPower`	Real scalar	Power control subchannel power (relative to F-FCH)

Parameter Field	Values	Description
PowerControlDataSource	Cell array: {'PN Type', RNSeed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Power control subchannel data source

FDCCH Substructure

Include the FDCCH substructure in the cfg structure to configure the forward dedicated control channel (F-DCCH). The FDCCH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
RadioConfiguration	'RC3' through 'RC9'	Radio configuration channel
DataRate	9600 | 14400	Data rate (bps)
FrameLength	5 | 20	Frame length (ms)
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ 255	Walsh code number
LongCodeMask	Positive scalar integer	Long code identifier
EnableQOF	'On' | 'Off'	Enable QOF spreading
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array: {'PN Type', RNSeed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FSCCH Substructure

Include the FSCCH substructure in the cfg structure to configure the forward supplemental code channel (F-SCCH). The FSCCH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
RadioConfiguration	'RC1' | 'RC2'	Radio configuration channel

Parameter Field	Values	Description
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ 255	Walsh code number
LongCodeMask	Positive scalar integer	Long code identifier
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array: {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FSCH Substructure

Include the FSCH substructure in the cfg structure to configure the forward supplemental channel (F-SCH). The FSCH substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
RadioConfiguration	'RC3' | 'RC4' | 'RC5' | 'RC6' | 'RC7' | 'RC8' | 'RC9'	Radio configuration channel
DataRate	1200 | 1350 | 1500 | 1800 | 2400 | 2700 | 3600 | 4800 | 7200 | 9600 | 14400 | 19200 | 28800 | 38400 | 57600 | 76800 | 115200 | 153600 | 230400 | 307200	Data rate (bps)
FrameLength	20 | 40 | 80	Frame length (ms)
CodingType	'Conv' | 'Turbo'	Channel coding type, convolutional or turbo
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ 255	Walsh code number
LongCodeMask	Positive scalar integer	Long code identifier
EnableQOF	'On' | 'Off'	Enable QOF spreading
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array: {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

FOCNS Substructure

Include the FOCNS substructure in the cfg structure to configure orthogonal channel noise source information. The FOCNS substructure contains these fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
WalshLength	64 | 128 | 256	Walsh code length
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ WalshLength – 1	Walsh code number

Output Arguments

waveform1 — Modulated baseband waveform comprising the primary physical channels
complex vector array

Modulated baseband waveform comprising the primary cdma2000 physical channels, returned as a complex vector array.

waveform2 — Modulated baseband waveform comprising the diversity physical channels
complex vector array

Modulated baseband waveform comprising the diversity cdma2000 physical channels, returned as a complex vector array.

cdma2000ForwardReferenceChannels | cdma2000ReverseWaveformGenerator

Introduced in R2015b

cdma2000ReverseReferenceChannels

Define cdma2000 reverse reference channel

Syntax

```
cfg = cdma2000ReverseReferenceChannels(wv)
cfg = cdma2000ReverseReferenceChannels(wv,numchips)
cfg = cdma2000ReverseReferenceChannels(traffic,numchips,R-SCH-SPEC)
```

Description

`cfg = cdma2000ReverseReferenceChannels(wv)` returns a structure, `cfg`, that defines the cdma2000 reverse link parameters given the input waveform identifier, `wv`. Pass the structure to the `cdma2000ReverseWaveformGenerator` function to generate a reverse link reference channel waveform.

For all syntaxes, `cdma2000ReverseReferenceChannels` creates a configuration structure that is compliant with the physical layer specification for cdma2000 systems described in [1].

`cfg = cdma2000ReverseReferenceChannels(wv,numchips)` specifies the number of chips to generate.

`cfg = cdma2000ReverseReferenceChannels(traffic,numchips,R-SCH-SPEC)` returns `cfg` for the specified traffic channel, `traffic`, and the reverse supplemental channel (R-SCH) and frame length combination, `R-SCH-SPEC`.

Examples

Generate Reverse Common Control Channel Waveform

Generate the structure corresponding to the reverse common control channel (R-CCCH) having a 19,200 bps data rate and 10 ms frames.

```
config = cdma2000ReverseReferenceChannels('R-CCCH-19200-10');
```

Verify that the R-CCCH substructure is configured for the correct data rate and frame duration.

```
config.RCCCH
```

```
ans = struct with fields:
          Enable: 'On'
           Power: 0
    LongCodeMask: 0
    EnableCoding: 'On'
      DataSource: {'PN9'  [1]}
        DataRate: 19200
     FrameLength: 10
       WalshCode: 1
```

Generate the reverse channel waveform using the corresponding waveform generator function, `cdma2000ReverseWaveformGenerator`.

```
wv = cdma2000ReverseWaveformGenerator(config);
```

Generate Reverse Channels for RC1 and RC6

Create a configuration structure to generate all possible channels associated with radio configuration 1 in which the number of chips is specified as 2500.

```
config = cdma2000ReverseReferenceChannels('ALL-RC1',2500)
```

```
config = struct with fields:
     RadioConfiguration: 'RC1'
     PowerNormalization: 'Off'
      OversamplingRatio: 4
             FilterType: 'cdma2000Long'
                InvertQ: 'Off'
       EnableModulation: 'Off'
    ModulationFrequency: 0
               NumChips: 2500
                   RFCH: [1x1 struct]
                   RACH: [1x1 struct]
                  RSCCH: [1x1 struct]
```

The structure contains substructures corresponding to the R-FCH, R-ACH, and R-SCCH channels.

Call the function again using radio configuration 6.

```
config = cdma2000ReverseReferenceChannels('ALL-RC6',2500)
```

```
config = struct with fields:
     RadioConfiguration: 'RC6'
     PowerNormalization: 'Off'
      OversamplingRatio: 4
             FilterType: 'cdma2000Long'
                InvertQ: 'Off'
       EnableModulation: 'Off'
    ModulationFrequency: 0
               NumChips: 2500
                   RFCH: [1x1 struct]
                  RPICH: [1x1 struct]
                  REACH: [1x1 struct]
                  RCCCH: [1x1 struct]
                  RDCCH: [1x1 struct]
                  RSCH1: [1x1 struct]
                  RSCH2: [1x1 struct]
```

The channels supported by RC6 differ from those supported by RC1. They include R-FCH, R-PICH, R-EACH, R-CCCH, R-DCCH, R-SCH1, and R-SCH2.

Create the waveform corresponding to the set of RC6 channels.

```
wv = cdma2000ReverseWaveformGenerator(config);
```

Generate Reverse Supplemental Channel

Create a configuration structure using radio configuration 3 with a reverse fundamental channel (R-FCH). Specify a 2700 bps data rate and a reverse supplemental channel (R-SCH) having a 76,800 bps data rate and an 80 ms frame length.

```
config = cdma2000ReverseReferenceChannels('TRAFFIC-RC3-2700',2000, ...
    'R-SCH-76800-80');
```

Verify that the R-FCH data rate is 2700 bps and the first R-SCH data rate is 76,800 bps with an 80 ms frame length.

```
config.RFCH.DataRate
```

```
ans = 2700
```

```
config.RSCH1.DataRate
```

```
ans = 76800
```

```
config.RSCH1.FrameLength
```

```
ans = 80
```

Generate the corresponding waveform.

```
wv = cdma2000ReverseWaveformGenerator(config);
```

Input Arguments

wv — Waveform identification

character vector

Waveform identification of the reference channel, specified as a character vector. The input typically identifies the channel type, radio configuration, data rate, and frame length. To specify wv, connect the substrings with hyphens, for example, 'TRAFFIC-RC2-3600'.

Parameter Field	Values			Description
	Substring 1	Substring 2	Substring 3	
wv	'R-PICH-ONLY'			Generates a waveform containing a pilot channel only.
	'R-CCCH'	9600	20	Character vector representing the Reverse Common Control Channel (R-CCCH) data rate in bps and the frame length in
		19200	10 | 20	

Parameter Field	Values			Description
	Substring 1	Substring 2	Substring 3	
		38400	5 | 10 | 20	ms. Specify 'R-CCCH-9600-20' to create a structure variable, wv, with a 9600 bps R-CCCH data rate and a 20 ms frame length.
	'TRAFFIC'	RC1	1200 | 2400 | 4800 | 9600	Character vector representing the radio configuration and the Reverse Fundamental Channel (R-FCH) data rate in bps. Specify 'TRAFFIC-RC6-14400', corresponds to radio configuration 6 with a 14400 bps R-FCH data rate.
		RC2 | RC4 | RC6	1800 | 3600 | 7200 | 14400	
		RC3 | RC5 | RC6	1500 | 2700 | 4800 | 9600	
	'R-EACH'	9600	20	Reverse Enhanced Access Channel waveforms. Specify 'R-EACH-38400-5' to create a structure corresponding to an R-EACH channel with a 38400 bps data rate and a 5 ms frame length.
		19200	10 | 20	
		38400	5 | 10 | 20	
	'R-PICH-R-FCH'			Specify tests for the mobile transmitter in accordance with [2].

Parameter Field	Values			Description
	Substring 1	Substring 2	Substring 3	
	`'ALL'`	RC1 | RC2 | RC3 | RC4 | RC5 | RC6	N/A	Returns all channels that are supported for the specified radio configuration. Specify `'ALL-RC4'` to create a structure containing all traffic channels for radio configuration 4.

Example: `'R-CCCH-9600-20'` is a R-CCH channel having a 9600 bps data rate and a 20 ms frame length.

Example: `'R-EACH-38400-5'` is a R-EACH channel having a 38,400 bps data rate and a 5 ms frame length.

Data Types: `char`

`numchips` — Number of chips

`1000` (default) | positive integer scalar

Number of chips, specified as a positive integer.

Example: `2048`

Data Types: `double`

`traffic` — Traffic configuration

character vector

Traffic channel configuration, specified as a character vector. The table shows the valid configurations.

Radio Configuration	Traffic Channel Configuration			
1	`'TRAFFIC-RC1-1200'`	`'TRAFFIC-RC1-2400'`	`'TRAFFIC-RC1-4800'`	`'TRAFFIC-RC1-9600'`
2	`'TRAFFIC-RC2-1800'`	`'TRAFFIC-RC2-3600'`	`'TRAFFIC-RC2-7200'`	`'TRAFFIC-RC2-14400'`
3	`'TRAFFIC-RC3-1500'`	`'TRAFFIC-RC3-2700'`	`'TRAFFIC-RC3-4800'`	`'TRAFFIC-RC3-9600'`
4	`'TRAFFIC-RC4-1800'`	`'TRAFFIC-RC4-3600'`	`'TRAFFIC-RC4-7200'`	`'TRAFFIC-RC4-14400'`
5	`'TRAFFIC-RC5-1500'`	`'TRAFFIC-RC5-2700'`	`'TRAFFIC-RC5-4800'`	`'TRAFFIC-RC5-9600'`

Radio Configuration	Traffic Channel Configuration			
6	'TRAFFIC-RC6-1800'	'TRAFFIC-RC6-3600'	'TRAFFIC-RC6-7200'	'TRAFFIC-RC6-14400'

Example: `'TRAFFIC-RC4-1800'` is a traffic channel using radio configuration 4 and having an R-FCH with an 1800 bps data rate .

Data Types: `char`

`R-SCH-SPEC` — Reverse Supplemental Channel data rate and frame length
character vector

Specify the R-SCH data rate and frame length as a character vector. If omitted, `R-SCH-SPEC` defaults to the lowest R-SCH data rate allowable for a 20 ms frame length given the radio configuration specified by `traffic`. The table summarizes the supported data rate and frame length combinations.

Radio Configuration	Frame Length		
	20 ms	40 ms	80 ms
3 | 5	'R-SCH-1500-20' | 'R-SCH-2700-20' | 'R-SCH-4800-20' | 'R-SCH-9600-20' | 'R-SCH-19200-20' | 'R-SCH-38400-20' | 'R-SCH-76800-20' | 'R-SCH-153600-20' | 'R-SCH-307200-20'	'R-SCH-1350-40' | 'R-SCH-2400-40' | 'R-SCH-4800-40' | 'R-SCH-9600-40' | 'R-SCH-19200-40' | 'R-SCH-38400-40' | 'R-SCH-76800-40'| 'R-SCH-153600-40'	'R-SCH-1350-80' | 'R-SCH-2400-80' | 'R-SCH-4800-80' | 'R-SCH-9600-80' | 'R-SCH-19200-80' | 'R-SCH-38400-80' | 'R-SCH-76800-80'
5	'R-SCH-614400-20'	'R-SCH-307200-40'	'R-SCH-153600-80'
4 | 6	'R-SCH-1800-20' | 'R-SCH-3600-20' | 'R-SCH-7200-20' | 'R-SCH-14400-20' | 'R-SCH-28800-20' | 'R-SCH-57600-20' | 'R-SCH-115200-20' | 'R-SCH-230400-20'	'R-SCH-1800-40' | 'R-SCH-3600-40' | 'R-SCH-7200-40' | 'R-SCH-14400-40' | 'R-SCH-28800-40' | 'R-SCH-57600-40' | 'R-SCH-115200-40'	'R-SCH-1800-80' | 'R-SCH-3600-80' | 'R-SCH-7200-80' | 'R-SCH-14400-80' | 'R-SCH-28800-80' | 'R-SCH-57600-80'
6	'R-SCH-460800-20' | 'R-SCH-1036800-20'	'R-SCH-230400-40' | 'R-SCH-518400-40'	'R-SCH-115200-80' | 'R-SCH-259200-80'

Additional data rate information for the cdma2000 reverse links is given in Tables 2.1.3.1.3-1 and 2.1.3.1.3-2 of [1].

Example: `'R-SCH-153600-20'` is an R-SCH having a 153,600 bps data rate and a 20 ms frame length.

Data Types: `char`

Output Arguments

`cfg` — Configuration of the parameters and channels used by the waveform generator
structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

Top-Level Parameters and Substructures

Parameter Field	Values	Description
RadioConfiguration	'RC1' | 'RC2' | 'RC3' | 'RC4' | 'RC5' | 'RC6'	Radio configuration of the reverse channel. The spreading rate of the waveform is derived from the radio configuration. Spreading rate 1, SR1, corresponds to a 1.2288 Mcps carrier and is associated with RC1 through RC4. Spreading rate 3, SR3, corresponds to a 3.6864 Mcps carrier and is associated with RC5 and RC6.
PowerNormalization	'Off' | 'NormalizeTo0dB'	Power normalization of the waveform
NumChips	Positive scalar integer	Number of chips in the waveform
OversamplingRatio	Positive scalar integer	Oversampling ratio at output
FilterType	'cdma2000Long' | 'cdma2000Short' | 'Off' | 'Custom'	Type of output filtering
CustomFilterCoefficients	Real vector	Custom filter coefficients used only when the FilterType field is set to 'Custom'
InvertQ	'Off' | 'On'	Negate the quadrature output
EnableModulation	'Off' | 'On'	Enable carrier modulation
ModulationFrequency	Nonnegative scalar integer	Carrier modulation frequency (applies when EnableModulation is 'On')
RPICH	Structure	See **RPICH Substructure**. Optional.
RACH	Structure	See **RACH Substructure**. Optional.
REACH	Structure	See **REACH Substructure**. Optional.
RCCCH	Structure	See **RCCCH Substructure**. Optional.
RDCCH	Structure	See **RDCCH Substructure**. Optional.
RFCH	Structure	See **RFCH Substructure**. Optional.
RSCCH	Structure	See **RSCCH Substructure**. Optional.
RSCH1	Structure	See **RSCH1 Substructure**. Optional.
RSCH2	Structure	See **RSCH2 Substructure**. Optional.

RPICH Substructure

Include the RPICH substructure in the cfg structure to configure the Reverse Pilot Channel (R-PICH). The RPICH substructure contains the following fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
LongCodeMask	42-bit binary number	Long code identifier

Parameter Field	Values	Description
PowerControlEnable	'On' | 'Off'	Enable or disable power control subchannel
PowerControlPower	Real scalar	Power control subchannel power (relative to R-PICH)
PowerControlDataSource	Cell array, {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Power control subchannel data source

RACH Substructure

Include the RACH substructure in the cfg structure to configure the Reverse Access Channel (R-ACH). The RACH substructure contains the following fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
LongCodeMask	42-bit binary number	Long code identifier
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array: {'PN Type', RN Seed} or a binary vector. Standard PN types are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a binary vector.

REACH Substructure

Include the REACH substructure in the cfg structure to configure the Reverse Enhanced Access Channel (R-EACH). The REACH substructure contains the following fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
DataRate	9600 | 19200 | 38400	Data rate (bps)
FrameLength	5 | 10 | 20	Frame length (ms)
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ 7	Walsh code number
LongCodeMask	42-bit binary number	Long code identifier
EnableCoding	'On' | 'Off'	Enable or disable channel coding

Parameter Field	Values	Description
DataSource	Cell array: {'PN Type', RN Seed} or a binary vector. Standard PN types are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a binary vector.

RCCCH Substructure

Include the RCCCH substructure in the cfg structure to configure the Reverse Common Control Channel (R-CCCH). The RCCCH substructure contains the following fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
DataRate	9600 | 19200 | 38400	Data rate (bps)
FrameLength	5 | 10 | 20	Frame length (ms)
CodingType	'conv' | 'turbo'	Type of error control coding
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ 7	Walsh code number
LongCodeMask	42-bit binary number	Long code identifier
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array: {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

RDCCH Substructure

Include the RDCCH substructure in the cfg structure to configure the Reverse Dedicated Control Channel (R-DCCH). The RDCCH substructure contains the following fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
FrameLength	5 | 20	Frame length (ms)
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ 15	Walsh code number
LongCodeMask	42-bit binary number	Long code identifier
EnableCoding	'On' | 'Off'	Enable or disable channel coding

Parameter Field	Values	Description
DataSource	Cell array, {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

RFCH Substructure

Include the RFCH substructure in the cfg structure to configure the Reverse Fundamental Traffic Channel (R-FCH). The RFCH substructure contains the following fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
DataRate	1200 | 1500 | 1800 | 2400 | 2700 | 3600 | 4800 | 7200 | 9600 | 14400	Data rate (bps)
FrameLength	5 | 10 | 20	Frame length (ms)
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ 15	Walsh code number
LongCodeMask	42-bit binary number	Long code identifier
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array, {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

RSCCH Substructure

Include the RSCCH substructure in the cfg structure to configure the Reverse Supplemental Code Channel (R-SCCH). The RSCCH substructure contains the following fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
LongCodeMask	42-bit binary number	Long code identifier
EnableCoding	'On' | 'Off'	Enable or disable channel coding

Parameter Field	Values	Description
DataSource	Cell array, {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

RSCH1 Substructure

Include the RSCH1 substructure in the cfg structure to configure the Reverse Supplemental Channel 1 (R-SCH 1). The RSCH1 substructure contains the following fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
DataRate	1200 | 1350 | 1500 | 1800 | 2400 | 2700 | 3600 | 4800 | 7200 | 9600 | 14400 | 19200 | 28800 | 38400 | 57600 | 76800 | 115200 | 153600 | 230400 | 259200 | 307200 | 460800 | 518400 | 614400 | 1036800	Data rate (bps)
FrameLength	20 | 40 | 80	Frame length (ms)
WalshLength	2 | 4	Walsh code length
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ WalshLength – 1	Walsh code number
LongCodeMask	42-bit binary number	Long code identifier
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array, {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

RSCH2 Substructure

Include the RSCH2 substructure in the cfg structure to configure the Reverse Supplemental Channel 2 (R-SCH 2). The RSCH2 substructure contains the following fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)

Parameter Field	Values	Description
DataRate	1200 | 1350 | 1500 | 1800 | 2400 | 2700 | 3600 | 4800 | 7200 | 9600 | 14400 | 19200 | 28800 | 38400 | 57600 | 76800 | 115200 | 153600 | 230400 | 259200 | 307200 | 460800 | 518400 | 614400 | 1036800	Data rate (bps)
FrameLength	20 | 40 | 80	Frame length (ms)
WalshLength	4 | 8	Walsh code length
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ WalshLength – 1	Walsh code number
LongCodeMask	42-bit binary number	Long code identifier
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array, {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

Data Types: struct

Introduced in R2015b

cdma2000ReverseWaveformGenerator

Generate cdma2000 reverse link waveform

Syntax

```
waveform = cdma2000ReverseWaveformGenerator(cfg)
```

Description

`waveform = cdma2000ReverseWaveformGenerator(cfg)` returns the cdma2000 reverse link baseband waveform, `waveform` as defined by the parameter configuration structure, `cfg`.

The top-level parameters and lower-level substructures of `cfg` specify the waveform and channel properties used by the function to generate a cdma2000 waveform. You can generate the input argument by using the `cdma2000ReverseReferenceChannels` function. The top-level parameters of `cfg` are `RadioConfiguration`, `LongCodeState`, `PowerNormalization`, `OversamplingRatio`, `FilterType`, `InvertQ`, `EnableModulation`, `ModulationFrequency`, and `NumChips`. To enable specific channels, add their associated substructures, for example, the reverse dedicated control channel, `RDCCH`.

Note The tables herein list the allowable values for the top-level parameters and substructure fields. However, not all combinations of spreading rate, radio configuration, frame length, and data rate are supported. To ensure that the input argument is valid, use the `cdma2000ReverseReferenceChannels` function. If you input the structure fields manually, consult [1] to ensure that the input parameter combinations are permitted.

Examples

Generate Reverse Common Control Channel Waveform

Generate the structure corresponding to the reverse common control channel (R-CCCH) having a 19,200 bps data rate and 10 ms frames.

```
config = cdma2000ReverseReferenceChannels('R-CCCH-19200-10');
```

Verify that the R-CCCH substructure is configured for the correct data rate and frame duration.

```
config.RCCCH
```

```
ans = struct with fields:
          Enable: 'On'
           Power: 0
     LongCodeMask: 0
     EnableCoding: 'On'
       DataSource: {'PN9'  [1]}
         DataRate: 19200
      FrameLength: 10
        WalshCode: 1
```

Generate the reverse channel waveform using the corresponding waveform generator function, `cdma2000ReverseWaveformGenerator`.

```
wv = cdma2000ReverseWaveformGenerator(config);
```

Generate R-SCH Channels for RC5

Create a configuration structure for a reverse channel having an R-FCH with a 4800 bps data rate and two R-SCHs. Specify that each R-SCH have a 153,600 bps data rate using RC5.

```
config = cdma2000ReverseReferenceChannels('TRAFFIC-RC5-4800',5000, ...
    'R-SCH-153600-40');
```

Determine the sample rate. Because RC5 corresponds to SR3, the chip rate is 3.6864 Mcps. Multiply by the oversampling ratio to obtain the sample rate.

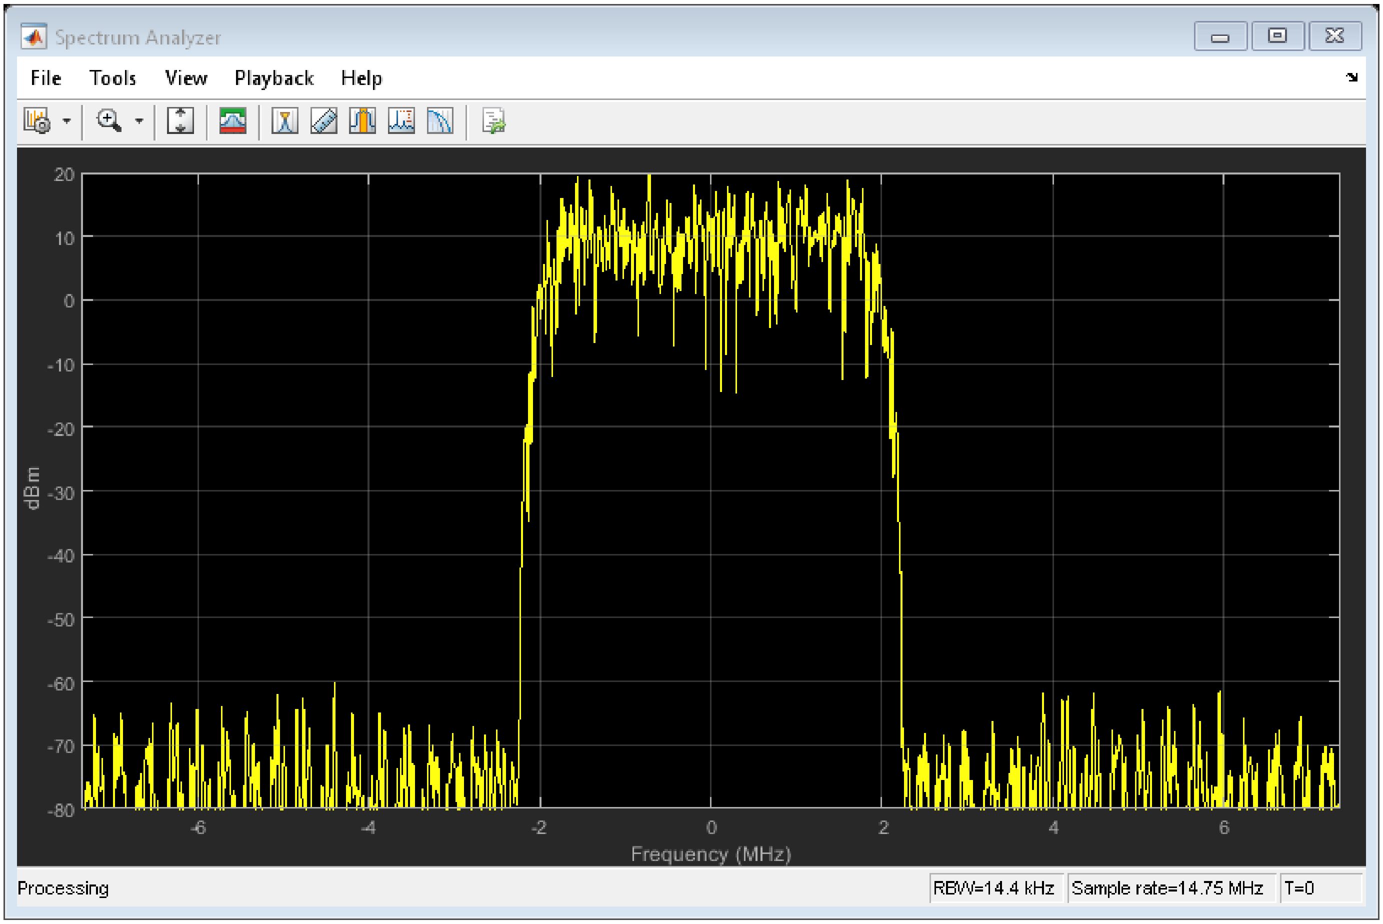
```
fs = 3.6864e6*config.OversamplingRatio;
```

Generate the reverse link waveform.

```
wv = cdma2000ReverseWaveformGenerator(config);
```

Plot the spectrum of the resultant waveform.

```
sa = dsp.SpectrumAnalyzer('SampleRate',fs);
step(sa,wv)
```



Generate cdma2000 Waveform with Two Reverse Supplemental Channels

Create a parameter structure specifying a reverse traffic channel containing a pair of supplemental channels and generate the corresponding waveform.

Create a parameter structure specifying a traffic channel consisting of a 14,400 bps fundamental channel, 2000 chips, and a 57,600 bps supplemental channel (R-SCH) pair having a 40 ms frame duration.

```
cfg = cdma2000ReverseReferenceChannels('TRAFFIC-RC4-14400',2000,'F-SCH-57600-40');
```

Create a second R-SCH pair by copying the R-SCH fields from the existing pair.

```
cfg(2).RSCH1 = cfg.RSCH1;
cfg(2).RSCH2 = cfg.RSCH2;
```

Set the data rate of the second R-SCH pair to 28,800 bps.

```
cfg(2).RSCH1.DataRate = 28800;
cfg(2).RSCH2.DataRate = 28800;
```

Set the Walsh codes of the second pair so that they differ from the first pair.

```
cfg(2).RSCH1.WalshCode = 4;
cfg(2).RSCH2.WalshCode = 5;
```

Verify that the data rates are set correctly and that no two supplemental channels share the same Walsh code.

```
cfg.RSCH1
```

```
ans = struct with fields:
          Enable: 'On'
           Power: 0
    LongCodeMask: 0
    EnableCoding: 'On'
      DataSource: {'PN9'  [1]}
        DataRate: 57600
     FrameLength: 40
     WalshLength: 2
       WalshCode: 0

ans = struct with fields:
          Enable: 'On'
           Power: 0
    LongCodeMask: 0
    EnableCoding: 'On'
      DataSource: {'PN9'  [1]}
        DataRate: 28800
     FrameLength: 40
     WalshLength: 2
       WalshCode: 4
```

```
cfg.RSCH2
```

```
ans = struct with fields:
          Enable: 'On'
           Power: 0
    LongCodeMask: 0
    EnableCoding: 'On'
      DataSource: {'PN9'  [1]}
        DataRate: 57600
     FrameLength: 40
     WalshLength: 2
       WalshCode: 1

ans = struct with fields:
          Enable: 'On'
           Power: 0
    LongCodeMask: 0
    EnableCoding: 'On'
      DataSource: {'PN9'  [1]}
        DataRate: 28800
     FrameLength: 40
     WalshLength: 2
       WalshCode: 5
```

Generate the reverse link waveform.

```
wv = cdma2000ReverseWaveformGenerator(cfg);
```

Input Arguments

`cfg` — Configuration of the parameters and channels used by the waveform generator

structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

Top-Level Parameters and Substructures

Parameter Field	Values	Description
`RadioConfiguration`	`'RC1'` | `'RC2'` | `'RC3'` | `'RC4'` | `'RC5'` | `'RC6'`	Radio configuration of the reverse channel. The spreading rate of the waveform is derived from the radio configuration. Spreading rate 1, SR1, corresponds to a 1.2288 Mcps carrier and is associated with RC1 through RC4. Spreading rate 3, SR3, corresponds to a 3.6864 Mcps carrier and is associated with RC5 and RC6.
`PowerNormalization`	`'Off'` | `'NormalizeTo0dB'`	Power normalization of the waveform
`NumChips`	Positive scalar integer	Number of chips in the waveform
`OversamplingRatio`	Positive scalar integer	Oversampling ratio at output
`FilterType`	`'cdma2000Long'` | `'cdma2000Short'` | `'Off'` | `'Custom'`	Type of output filtering
`CustomFilterCoefficients`	Real vector	Custom filter coefficients used only when the `FilterType` field is set to `'Custom'`
`InvertQ`	`'Off'` | `'On'`	Negate the quadrature output
`EnableModulation`	`'Off'` | `'On'`	Enable carrier modulation
`ModulationFrequency`	Nonnegative scalar integer	Carrier modulation frequency (applies when `EnableModulation` is `'On'`)
`RPICH`	Structure	See **RPICH Substructure**. Optional.
`RACH`	Structure	See **RACH Substructure**. Optional.
`REACH`	Structure	See **REACH Substructure**. Optional.
`RCCCH`	Structure	See **RCCCH Substructure**. Optional.
`RDCCH`	Structure	See **RDCCH Substructure**. Optional.
`RFCH`	Structure	See **RFCH Substructure**. Optional.
`RSCCH`	Structure	See **RSCCH Substructure**. Optional.
`RSCH1`	Structure	See **RSCH1 Substructure**. Optional.
`RSCH2`	Structure	See **RSCH2 Substructure**. Optional.

RPICH Substructure

Include the `RPICH` substructure in the `cfg` structure to configure the Reverse Pilot Channel (R-PICH). The `RPICH` substructure contains the following fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
LongCodeMask	42-bit binary number	Long code identifier
PowerControlEnable	'On' | 'Off'	Enable or disable power control subchannel
PowerControlPower	Real scalar	Power control subchannel power (relative to R-PICH)
PowerControlDataSource	Cell array, {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Power control subchannel data source

RACH Substructure

Include the RACH substructure in the cfg structure to configure the Reverse Access Channel (R-ACH). The RACH substructure contains the following fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
LongCodeMask	42-bit binary number	Long code identifier
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array: {'PN Type', RN Seed} or a binary vector. Standard PN types are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a binary vector.

REACH Substructure

Include the REACH substructure in the cfg structure to configure the Reverse Enhanced Access Channel (R-EACH). The REACH substructure contains the following fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
DataRate	9600 | 19200 | 38400	Data rate (bps)
FrameLength	5 | 10 | 20	Frame length (ms)
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ 7	Walsh code number

Parameter Field	Values	Description
LongCodeMask	42-bit binary number	Long code identifier
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array: {'PN Type', RN Seed} or a binary vector. Standard PN types are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a binary vector.

RCCCH Substructure

Include the RCCCH substructure in the cfg structure to configure the Reverse Common Control Channel (R-CCCH). The RCCCH substructure contains the following fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
DataRate	9600 | 19200 | 38400	Data rate (bps)
FrameLength	5 | 10 | 20	Frame length (ms)
CodingType	'conv' | 'turbo'	Type of error control coding
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ 7	Walsh code number
LongCodeMask	42-bit binary number	Long code identifier
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array: {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

RDCCH Substructure

Include the RDCCH substructure in the cfg structure to configure the Reverse Dedicated Control Channel (R-DCCH). The RDCCH substructure contains the following fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
FrameLength	5 | 20	Frame length (ms)
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ 15	Walsh code number

Parameter Field	Values	Description
`LongCodeMask`	42-bit binary number	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

RFCH Substructure

Include the `RFCH` substructure in the `cfg` structure to configure the Reverse Fundamental Traffic Channel (R-FCH). The `RFCH` substructure contains the following fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`DataRate`	`1200` | `1500` | `1800` | `2400` | `2700` | `3600` | `4800` | `7200` | `9600` | `14400`	Data rate (bps)
`FrameLength`	`5` | `10` | `20`	Frame length (ms)
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ 15	Walsh code number
`LongCodeMask`	42-bit binary number	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

RSCCH Substructure

Include the `RSCCH` substructure in the `cfg` structure to configure the Reverse Supplemental Code Channel (R-SCCH). The `RSCCH` substructure contains the following fields.

Parameter Field	Values	Description
`Enable`	`'On'` | `'Off'`	Enable or disable the channel
`Power`	Real scalar	Relative channel power (dB)
`LongCodeMask`	42-bit binary number	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding

Parameter Field	Values	Description
DataSource	Cell array, {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

RSCH1 Substructure

Include the RSCH1 substructure in the cfg structure to configure the Reverse Supplemental Channel 1 (R-SCH 1). The RSCH1 substructure contains the following fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)
DataRate	1200 | 1350 | 1500 | 1800 | 2400 | 2700 | 3600 | 4800 | 7200 | 9600 | 14400 | 19200 | 28800 | 38400 | 57600 | 76800 | 115200 | 153600 | 230400 | 259200 | 307200 | 460800 | 518400 | 614400 | 1036800	Data rate (bps)
FrameLength	20 | 40 | 80	Frame length (ms)
WalshLength	2 | 4	Walsh code length
WalshCode	Nonnegative integer scalar such that 0 ≤ WalshCode ≤ WalshLength – 1	Walsh code number
LongCodeMask	42-bit binary number	Long code identifier
EnableCoding	'On' | 'Off'	Enable or disable channel coding
DataSource	Cell array, {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

RSCH2 Substructure

Include the RSCH2 substructure in the cfg structure to configure the Reverse Supplemental Channel 2 (R-SCH 2). The RSCH2 substructure contains the following fields.

Parameter Field	Values	Description
Enable	'On' | 'Off'	Enable or disable the channel
Power	Real scalar	Relative channel power (dB)

Parameter Field	Values	Description
`DataRate`	`1200` | `1350` | `1500` | `1800` | `2400` | `2700` | `3600` | `4800` | `7200` | `9600` | `14400` | `19200` | `28800` | `38400` | `57600` | `76800` | `115200` | `153600` | `230400` | `259200` | `307200` | `460800` | `518400` | `614400` | `1036800`	Data rate (bps)
`FrameLength`	`20` | `40` | `80`	Frame length (ms)
`WalshLength`	`4` | `8`	Walsh code length
`WalshCode`	Nonnegative integer scalar such that 0 ≤ `WalshCode` ≤ `WalshLength` – 1	Walsh code number
`LongCodeMask`	42-bit binary number	Long code identifier
`EnableCoding`	`'On'` | `'Off'`	Enable or disable channel coding
`DataSource`	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

Output Arguments

`waveform` — Modulated baseband waveform comprising the physical channels

complex vector array

Modulated baseband waveform comprising the cdma2000 physical channels, returned as a complex vector array.

Introduced in R2015b

cma

(To be removed) Construct constant modulus algorithm (CMA) object

Note will be removed in a future release. Use `comm.LinearEqualizer` or `comm.DecisionFeedback` instead.

Syntax

```
alg = cma(stepsize)
alg = cma(stepsize,leakagefactor)
```

Description

The `cma` function creates an adaptive algorithm object that you can use with the `lineareq` function or `dfe` function to create an equalizer object. You can then use the equalizer object with the `equalize` function to equalize a signal. To learn more about the process for equalizing a signal, see “Equalization”.

Note After you use either `lineareq` or `dfe` to create a CMA equalizer object, you should initialize the equalizer object's `Weights` property with a nonzero vector. Typically, CMA is used with differential modulation; otherwise, the initial weights are very important. A typical vector of initial weights has a 1 corresponding to the center tap and 0s elsewhere.

`alg = cma(stepsize)` constructs an adaptive algorithm object based on the constant modulus algorithm (CMA) with a step size of `stepsize`.

`alg = cma(stepsize,leakagefactor)` sets the leakage factor of the CMA. `leakagefactor` must be between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, while a value of 0 corresponds to a memoryless update algorithm.

Properties

The table below describes the properties of the CMA adaptive algorithm object. To learn how to view or change the values of an adaptive algorithm object, see “Equalization”.

Property	Description
`AlgType`	Fixed value, `'Constant Modulus'`
`StepSize`	CMA step size parameter, a nonnegative real number
`LeakageFactor`	CMA leakage factor, a real number between 0 and 1

Examples

Configuring Linear Equalizers

This example configures the recommended `comm.LinearEqualizer` System object™ and the legacy `lineareq` feature with comparable settings.

Initialize Variables and Supporting Objects

```
d = randi([0 3],1000,1);
x = pskmod(d,4,pi/4);
r = awgn(x,25);
sps = 2; %samples per symbol for oversampled cases
nTaps = 6;
txFilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',nTaps, ...
    'OutputSamplesPerSymbol',4);
rxFilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',nTaps, ...
    'InputSamplesPerSymbol',4,'DecimationFactor',2);
x2 = txFilter(x);
r2 = rxFilter(awgn(x2,25,0.5));
filterDelay = txFilter.FilterSpanInSymbols/2 + ...
    rxFilter.FilterSpanInSymbols/2; % Total filter delay in symbols
```

To compare the equalized output, plot the constellations using code such as:

```
% plot(yNew,'*')
% hold on
% plot(yOld,'o')
% hold off; legend('New Eq','Old Eq'); grid on
```

Use CMA Algorithm with Linear Equalizer

Configure `lineareq` and `comm.LinearEqualizer` objects with comparable settings. The `LeakageFactor` property has been removed from CMA algorithm. The `comm.LinearEqualizer` System object™ assumes that leakage factor is always 1.

```
eqOld = lineareq(5,cma(0.05),pskmod(0:3,4,pi/4))
```

```
eqOld =
  EqType: 'Linear Equalizer'
  AlgType: 'Constant Modulus'
  nWeights: 5
  nSampPerSym: 1
  SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  StepSize: 0.0500
  LeakageFactor: 1
  Weights: [1 0 0 0 0]
  WeightInputs: [0 0 0 0 0]
  ResetBeforeFiltering: 1
  NumSamplesProcessed: 0
```

```
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','CMA','StepSize',0.05, ...
    'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'CMA'
  NumTaps: 5
  StepSize: 0.0500
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 1
  InputSamplesPerSymbol: 1
  AdaptWeightsSource: 'Property'
  AdaptWeights: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers.

```
yOld = equalize(eqOld,r);
yNew = eqNew(r);
```

Algorithms

Referring to the schematics in “Equalization”, define *w* as the vector of all weights w_i and define *u* as the vector of all inputs u_i. Based on the current set of weights, *w*, this adaptive algorithm creates the new set of weights given by

(`LeakageFactor`) w + (`StepSize`) u^*e

where the * operator denotes the complex conjugate.

Compatibility Considerations

`cma` will be removed
Warns starting in R2020a

- cma will be removed in a future release. Use `comm.LinearEqualizer` or `comm.DecisionFeedback` instead with the adaptive algorithm set to CMA.
- The `comm.LinearEqualizer` or `comm.DecisionFeedback` System objects do not have a leakage factor property. This is equivalent to setting `LeakageFactor` to `1` in the cma function.
- For examples comparing setup of `comm.LinearEqualizer` to `lineareq`, see “Configuring Linear Equalizers” on page 2-159.

comm_links

Library link information for Communications Toolbox blocks

Syntax

```
comm_links
comm_links(sys)
comm_links(sys,color)
```

Description

`comm_links` returns a structure with two elements. Each element contains a cell array of strings containing names of library blocks in the current system. The blocks are grouped into two categories: obsolete and current. Blocks at all levels of the model are analyzed.

`comm_links(sys)` works as above on the named system `sys`, instead of the current system.

`comm_links(sys,`*`color`*`)` additionally colors all obsolete blocks according to the specified *`color`*. *`color`* is one of the following strings: 'blue', 'green', 'red', 'cyan', 'magenta', 'yellow', or 'black'.

Obsolete blocks are blocks that are no longer supported. They might or might not work properly.

Current blocks are supported and represent the latest block functionality.

`dsplib`

Introduced before R2006a

commscope

(To be removed) Package of communications scope classes

Note `commscope.eyediagram` will be removed in a future release. Use `comm.ConstellationDiagram` and `eyediagram` instead.

Syntax

```
h = commscope.<type>(...)
```

Description

`h = commscope.<type>(...)` returns a communications scope object `h` of type `type`.

Type `help commscope` to get a complete list of available types.

Each `type` of communications scope object is equipped with functions for simulation and visualization. Type `help commscope.<type>` to get the complete help on a specific communications scope object, for example `help commscope.eyediagram`.

Compatibility Considerations

`commscope` will be removed
Warns starting in R2017b

`commscope.eyediagram` will be removed in a future release. Use `comm.ConstellationDiagram` and `eyediagram` instead.

Objects
`comm.ConstellationDiagram`

Functions
`eyediagram` | `scatterplot`

Introduced in R2007b

commscope.eyediagram

(Removed) Eye diagram analysis

Note `commscope.eyediagram` has been removed. Use `eyediagram` instead.

Syntax

```
h = commscope.eyediagram
h = commscope.eyediagram(property1,value1,...)
```

Description

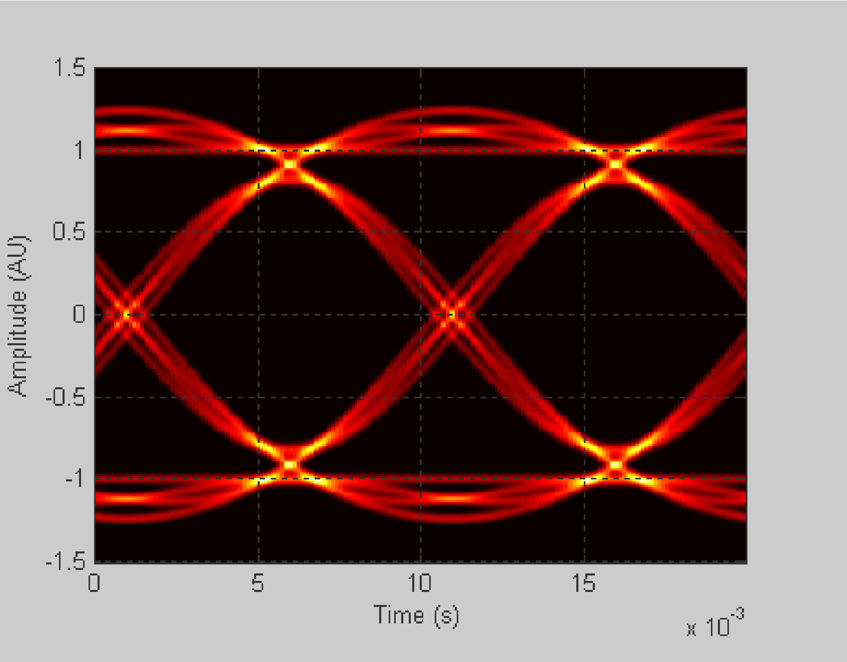
`h = commscope.eyediagram` constructs an eye diagram object, `h`, with default properties. This syntax is equivalent to:

```
H = commscope.eyediagram('SamplingFrequency', 10000, ...
                         'SamplesPerSymbol', 100, ...
                         'SymbolsPerTrace', 2, ...
                         'MinimumAmplitude', -1, ...
                         'MaximumAmplitude', 1, ...
                         'AmplitudeResolution', 0.0100, ...
                         'MeasurementDelay', 0, ...
                         'PlotType', '2D Color', ...
                         'PlotTimeOffset', 0, ...
                         'PlotPDFRange', [0 1], ...
                         'ColorScale', 'linear', ...
                         'RefreshPlot', 'on');
```

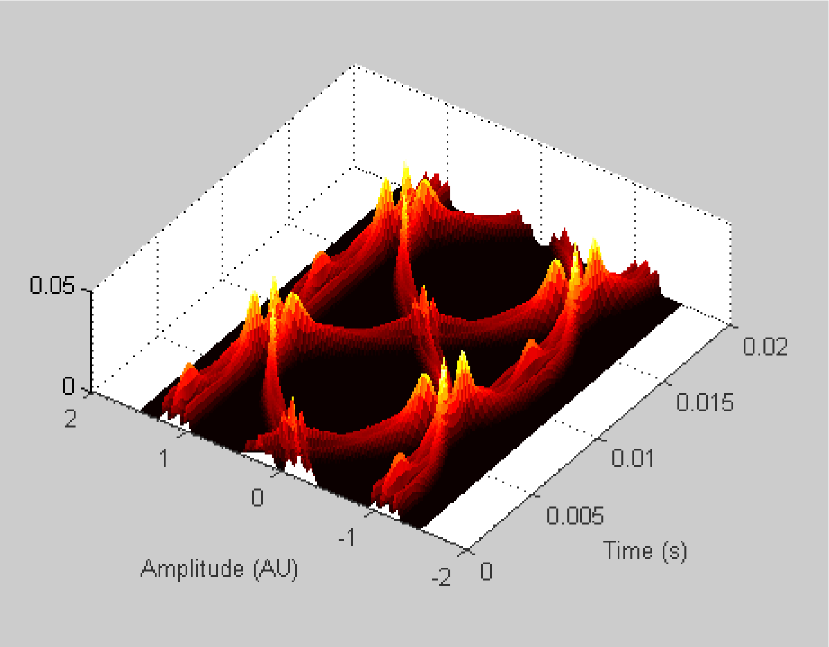
`h = commscope.eyediagram(property1,value1,...)` constructs an eye diagram object, `h`, with properties as specified by property/value pairs.

The eye diagram object creates a series of vertical histograms from zero to *T* seconds, at T_s second intervals, where *T* is a multiple of the symbol duration of the input signal and T_s is the sampling time. A vertical histogram is defined as the histogram of the amplitude of the input signal at a given time. The histogram information is used to obtain an approximation to the probability density function (PDF) of the input amplitude distribution. The histogram data is used to generate `'2D Color'` plots, where the color indicates the value of the PDF, and `'3D Color'` plots. The `'2D Line'` plot is obtained by constructing an eye diagram from the last *n* traces stored in the object, where a trace is defined as the segment of the input signal for a *T* second interval.

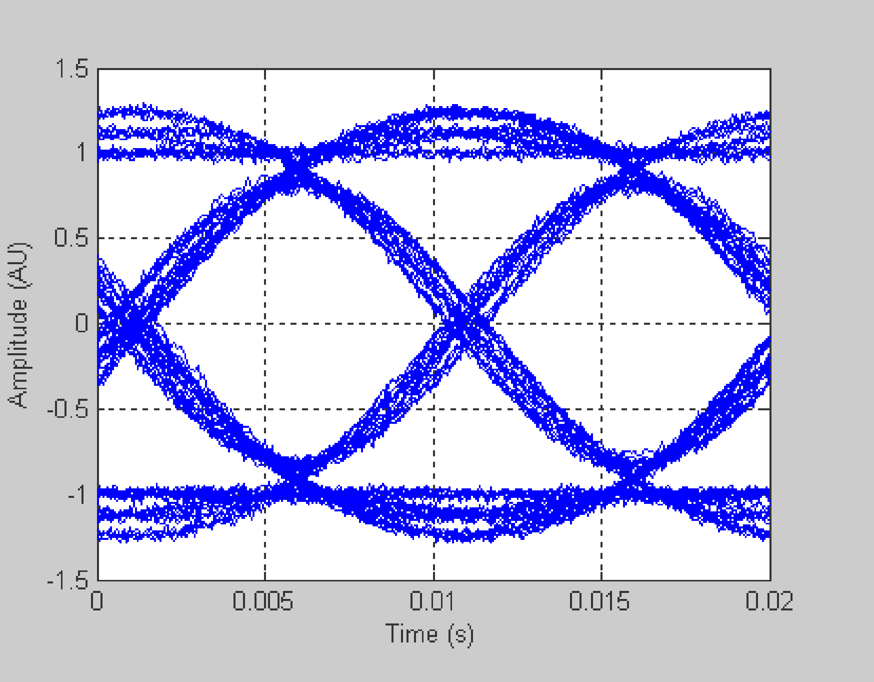
You can change the plot type by setting the `PlotType` property. The following plots are examples of each type.



2D-Color Eye Diagram



3D-Color Eye Diagram



2D-Line Eye Diagram

To see a detailed demonstration of this object's use, type `showdemo scattereyedemo;` at the command line.

Properties

An eye diagram scope object has the properties shown on the following table. All properties are writable except for the ones explicitly noted otherwise.

Property	Description
`Type`	Type of scope object (`'Eye Diagram'`). This property is not writable.
`SamplingFrequency`	Sampling frequency of the input signal in hertz.
`SamplesPerSymbol`	Number of samples used to represent a symbol. An increase in `SamplesPerSymbol` improves the resolution of an eye diagram.
`SymbolRate`	The symbol rate of the input signal. This property is not writable and is automatically computed based on `SamplingFrequency` and `SamplesPerSymbol`.
`SymbolsPerTrace`	The number of symbols spanned on the time axis of the eye diagram scope.
`MinimumAmplitude`	Minimum amplitude of the input signal. Signal values less than this value are ignored both for plotting and for measurement computation.

Property	Description
MaximumAmplitude	Maximum amplitude of the input signal. Signal values greater than this value are ignored both for plotting and for measurement computation.
AmplitudeResolution	The resolution of the amplitude axis. The amplitude axis is created from MinimumAmplitude to MaximumAmplitude with AmplitudeResolution steps.
MeasurementDelay	The time in seconds the scope waits before starting to collect data.
PlotType	Type of the eye diagram plot. The choices are '2D Color' (two dimensional eye diagram, where color intensity represents the probability density function values), '3D Color' (three dimensional eye diagram, where the z-axis represents the probability density function values), and '2D Line' (two dimensional eye diagram, where each trace is represented by a line).
NumberOfStoredTraces	The number of traces stored to display the eye diagram in '2D Line' mode.
PlotTimeOffset	The plot time offset input values must reside in the closed interval [-Tsym Tsym], where Tsym is the symbol duration. Since the eye diagram is periodic, if the value you enter is out of range, it wraps to a position on the eye diagram that is within range.
RefreshPlot	The switch that controls the plot refresh style. The choices are 'on' (the eye diagram plot is refreshed every time the update method is called) and 'off' (the eye diagram plot is not refreshed when the update method is called).
PlotPDFRange	The range of the PDF values that will be displayed in the '2D Color' mode. The PDF values outside the range are set to a constant mask color.
ColorScale	The scale used to represent the color, the z-axis, or both. The choices are 'linear' (linear scale) and 'log' (base ten logarithmic scale).
SamplesProcessed	The number of samples processed by the eye diagram object. This value does not include the discarded samples during the MeasurementDelay period. This property is not writable.
OperationMode	When the operation mode is complex signal, the eye diagram collects and plots data on both the in-phase component and the quadrature component. When the operation mode is real signal, the eye diagram collects and plots real signal data.
Measurements	An eye diagram can display various types of measurements. All measurements are done on both the in-phase and quadrature signal, unless otherwise stated. For more information, see the Measurements section.

The resolution of the eye diagram in '2D Color' and '3D Color' modes can be increased by increasing SamplingFrequency, decreasing AmplitudeResolution, or both.

Changing MinimumAmplitude, MaximumAmplitude, AmplitudeResolution, SamplesPerSymbol, SymbolsPerTrace, and MeasurementDelay resets the measurements and updates the eye diagram.

Methods

An eye diagram object is equipped with seven methods for inspection, object management, and visualization.

update

This method updates the eye diagram object data.

update(h,x) updates the collected data of the eye diagram object h with the input x.

If the RefreshPlot property is set to 'on', the update method also refreshes the eye diagram figure.

The following example shows this method's use:

```
% Create an eye diagram scope object
h = commscope.eyediagram('RefreshPlot', 'off')

% Prepare a noisy sinusoidal as input
hChan = comm.AWGNChannel('NoiseMethod', 'Signal to noise ratio (SNR)',...
  'SNR', 20);
x = step(hChan,0.5*sin(2*pi*(0:1/100:10))+j*cos(2*pi*(0:1/100:10)));
% update the eyediagram
update(h, x);
% Check the number of processed samples
h.SamplesProcessed
```

plot

This method displays the eye diagram figure.

The plot method has three usage cases:

plot(h) plots the eye diagram for the eye diagram object h with the current colormap or the default linespec.

plot(h,cmap), when used with the plottype set to '2D Color' or '3D Color', plots the eye diagram for the object h, and sets the colormap to cmap.

plot(h,linespec), when used with the plottype set to '2D Line', plots the eye diagram for the object h using linespec as the line specification. See the help for plot for valid linespecs.

The following example shows this method's use:

```
% Create an eye diagram scope object
h = commscope.eyediagram;
% Prepare a noisy sinusoid as input
hChan = comm.AWGNChannel('NoiseMethod', 'Signal to noise ratio (SNR)',...
  'SNR', 20);
x = step(hChan, 0.5*sin(2*pi*(0:1/100:10))+ j*0.5*cos(2*pi*(0:1/100:10)));
% Update the eye diagram
update(h, x);
% Display the eye diagram figure
plot(h)

% Display the eye diagram figure with jet colormap
plot(h, jet(64))

% Display 2D Line eye diagram with red dashed lines
h.PlotType = '2D Line';
plot(h, 'r--')
```

exportdata

This method exports the eye diagram data.

`[VERHIST EYEL HORHISTX HORHISTRF] = EXPORTDATA(H)` Exports the eye diagram data collected by the eyediagram object *H*.

`VERHIST` is a matrix that holds the vertical histogram, which is also used to plot '2D Color' and '3D Color' eye diagrams.

`EYEL` is a matrix that holds the data used to plot 2D Line eye diagram. Each row of the EYEC holds one trace of the input signal.

`HORHISTX` is a matrix that holds the crossing point histogram data collected for the values defined by the CrossingAmplitudes property of the MeasurementSetup object. HORHISTX(i, :) represents the histogram for CrossingAmplitudes(i).

`HORHISTRF` is a matrix that holds the crossing point histograms for rise and fall time levels. HORHISTRF(i,:) represents the histogram for AmplitudeThreshold(i).

The following example shows this method's use:

```
% Create an eye diagram scope object
h = commscope.eyediagram('RefreshPlot', 'off');
% Prepare a noisy sinusoidal as input
hChan = comm.AWGNChannel('NoiseMethod', 'Signal to noise ratio (SNR)',...
  'SNR', 20);
x = step(hChan, 0.5*sin(2*pi*(0:1/100:10))+ j*0.5*cos(2*pi*(0:1/100:10)));
% Update the eyediagram
update(h, x);
% Export the data
[eyec eyel horhistx horhistrf] = exportdata(h);
% Plot line data
t=0:1/h.SamplingFrequency:h.SymbolsPerTrace/h.SymbolRate;
plot(t, real(eyel)); xlabel('time (s)');...
          ylabel('Amplitude (AU)'); grid on;
% Plot 2D Color data
t=0:1/h.SamplingFrequency:h.SymbolsPerTrace/h.SymbolRate;
a=h.MinimumAmplitude:h.AmplitudeResolution:h.MaximumAmplitude;
imagesc(t,a,eyec); xlabel('time (s)'); ylabel('Amplitude (AU)');
```

reset

This method resets the eye diagram object.

reset(h) resets the eye diagram object h. Resetting h clears all the collected data.

The following example shows this method's use:

```
% Create an eye diagram scope object
h = commscope.eyediagram('RefreshPlot', 'off');
% Prepare a noisy sinusoidal as input
hChan = comm.AWGNChannel('NoiseMethod', 'Signal to noise ratio (SNR)',...
  'SNR', 20);
x = step(hChan, 0.5*sin(2*pi*(0:1/100:10))+ j*0.5*cos(2*pi*(0:1/100:10)));
update(h, x);             % update the eyediagram
h.SamplesProcessed        % Check the number of processed samples
reset(h);                 % reset the object
h.SamplesProcessed        % Check the number of processed samples
```

copy

This method copies the eye diagram object.

h = copy(ref_obj) creates a new eye diagram object h and copies the properties of object h from properties of ref_obj.

The following example shows this method's use:

```
% Create an eye diagram scope object
h = commscope.eyediagram('MinimumAmplitude', -3, ...
    'MaximumAmplitude', 3);
disp(h); % display object properties
h1 = copy(h)
```

disp

This method displays properties of the eye diagram object.

disp(h) displays relevant properties of eye diagram object h.

If a property is not relevant to the object's configuration, it is not displayed. For example, for a commscope.eyediagram object, the ColorScale property is not relevant when PlotType property is set to '2D Line'. In this case the ColorScale property is not displayed.

The following is an example of its use:

```
% Create an eye diagram scope object
h = commscope.eyediagram;
% Display object properties
disp(h);
h = commscope.eyediagram('PlotType', '2D Line')
```

close

This method closes the eye diagram object figure.

close(h) closes the figure of the eye diagram object h.

The following example shows this method's use:

```
% Create an eye diagram scope object
h = commscope.eyediagram;
```

```
% Call the plot method to display the scope
plot(h);
% Wait for 1 seconds
pause(1)
% Close the scope
close(h)
```

analyze

This methods executes eye diagram measurements. analyze(h) executes the eye diagram measurements on the collected data of the eye diagram scope object *h*. The results of the measurements are stored in the Measurements property of *h*. For more information, see “Eye Diagram Analysis”.

In some cases, the analyze method cannot determine a measurement value. If this problem occurs, verify that your settings for measurement setup values or the eye diagram are valid.

Measurement Setup Parameters

A number of set-up parameters control eye diagram measurements. This section describes these set-up parameters and the measurements they affect. For more information, see “Eye Diagram Analysis”.

Eye Level Boundaries

Eye Level Boundaries are defined as a percentage of the symbol duration. The analyze method calculates the eye levels by averaging the vertical histogram within a given time interval defined by the eye level boundaries. A common value you can use for NRZ signals is 40% to 60%. For RZ signals, a narrower band of 5% is more appropriate. The default setting for *Eye level Boundaries* is a 2-by-1 vector where the first element is the lower boundary and the second element is the upper boundary. When the eye level boundary changes, the object recalculates this value.

Reference Amplitude

Reference Amplitude is the boundary value at which point the signal crosses from one signal level to another. Reference amplitude represents the decision boundary of the modulation scheme. This value is used to perform jitter measurements. The default setting for *Reference Amplitude* is a 2-by-1 double vector where the first element is the lower boundary and the second element is the upper boundary. Setting the reference amplitude resets the eye diagram.

The crossing instants of the input signal are detected and recorded as crossing times. A common value you can use for NRZ signals is `0`. For RZ signals, you can use the mean value of `1` and `0` levels. Reference amplitude is stored in a 2-by-N matrix, where the first row is the in-phase values and second row is the quadrature values. See Eye Crossing Time for more information.

Crossing Bandwidth

Crossing Bandwidth is the amplitude band used to measure the crossing times of the eye diagram. *Crossing Bandwidth* represents a percentage of the amplitude span of the eye diagram, typically 5%. See Eye Crossing Time for more information. The default setting for *Crossing Bandwidth* is 0.0500.

Bit Error Rate Threshold

The eye opening measurements, random, and total jitter measurements are performed at a given BER value. This BER value defines the BER threshold. A typical value is 1e^{-12}. The default setting for *Bit*

Error Threshold is 1.0000e^{-12}. When the bit error rate threshold changes, the object recalculates this value.

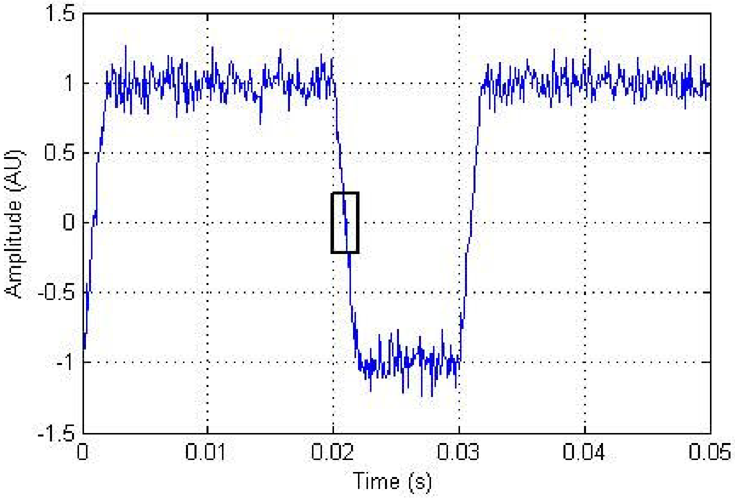
Amplitude Threshold

The rise time of the signal is defined as the time required for the signal to travel from the lower amplitude threshold to the upper amplitude threshold. The fall time, measured from the upper amplitude threshold to the lower amplitude threshold, is defined as a percentage of the eye amplitude. The default setting is 10% for the lower threshold and 90% for the upper threshold. Setting the amplitude threshold resets the eye diagram. See Eye Rise Time and Eye Fall Time for more information.

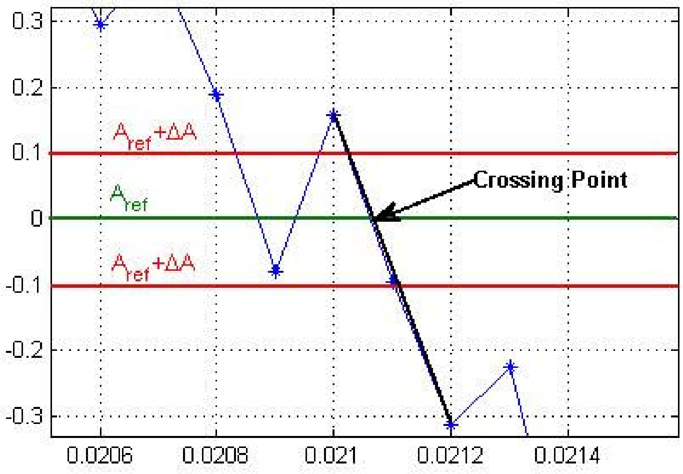
Jitter Hysteresis

You can use the *JitterHysteresis* property of the eye measurement setup object to remove the effect of noise from the horizontal histogram estimation. The default value for *Jitter Hysteresis* is zero. Setting the jitter hysteresis value resets the eye diagram.

If channel noise impairs the signal being tested, as shown in the following figure, the signal may seem like it crosses the reference amplitude level multiple times during a single 0-1 or 1-0 transition.



See the zoomed—in image for more detail.



To eliminate the effect of noise, define a hysteresis region between two threshold values: A_{ref} + ΔA and A_{ref} - ΔA, where A_{ref} is the reference amplitude value and ΔA is the jitter hysteresis value. If the signal crosses both threshold values, level crossing is declared. Then, linear interpolation calculates the crossing point in the horizontal histogram estimation.

Compatibility Considerations

`commscope.eyediagram` has been removed
Errors starting in R2020a

`commscope.eyediagram` has been removed. Use `eyediagram` instead.

Introduced in R2007b

commsrc.combinedjitter

Construct combined jitter generator object

Syntax

```
combJitt = commsrc.combinedjitter
combJitt = commsrc.combinedjitter(Name,Value)
```

Description

`combJitt = commsrc.combinedjitter` constructs a default combined jitter generator object, `combJitt`, with all jitter components disabled.

Use the object to generate jitter samples that include any combination of random, periodic, and Dirac components.

`combJitt = commsrc.combinedjitter(Name,Value)` creates a combined jitter generator object with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

A combined jitter generator object includes these properties. You can edit all properties, except those explicitly noted.

Property	Description
`Type`	Type of object, `Combined Jitter Generator`. This property is not writable.
`SamplingFrequency`	Sampling frequency of the input signal in hertz. Default value 1e4.
`RandomJitter`	Variable to enable the random jitter generator. Specify as either `'off'` (default) or `'on'`.
`RandomStd`	Standard deviation of the random jitter generator in seconds. Applies when `RandomJitter` is `'on'`. Default value 1e-4.
`PeriodicJitter`	Variable to enable the periodic jitter generator. Specify as either `'off'` (default) or `'on'`.
`PeriodicNumber`	Number of sinusoidal components. The `PeriodicNumber` must be a finite positive scalar integer. Applies when `PeriodicJitter` is `'on'`. Default value 1.
`PeriodicAmplitude`	Amplitude of each sinusoidal component of the periodic jitter in seconds. Applies when `PeriodicJitter` is `'on'`. Default value 5e-4.

Property	Description
PeriodicFrequencyHz	Frequency of each sinusoidal component of the periodic jitter measured in Hz. Applies when PeriodicJitter is 'on'. Default value is 200.
PeriodicPhase	Phase of each sinusoidal component of the periodic jitter in radians. Applies when PeriodicJitter is 'on'. Default value 0.
DiracJitter	Variable to enable the Dirac jitter generator. Specify as either 'off' (default) or 'on'.
DiracNumber	Number of Dirac components. The DiracNumber must be a finite positive scalar integer. Applies when DiracJitter is 'on'. Default value 2.
DiracDelta	Time delay of each Dirac component in seconds. Applies when DiracJitter is 'on'. Default value [-5.e-4 5.e-4].
DiracProbability	Probability of each Dirac component represented as a vector of length DiracNumber. The sum of the probabilities must equal one. Applies when DiracJitter is 'on'. Default value [0.5 0.5].

Object Functions

A combined jitter generator object has three object functions, as described in this section.

generate

This object function generates jitter samples based on the jitter generator object. It has one input argument, which is the number of samples in a frame. Its output is a single-column vector of length N. You can call this object function using this syntax:

```
x = generate(combJitt,N)
```

where combJitt is the generator object, N is the number of output samples, and x is a real single-column vector.

reset

This object function resets the internal states of the combined jitter generator. You can call this object function using this syntax:

```
reset(combJitt)
```

where combJitt is the generator object.

disp

Display the properties of the combined generator object, combJitt. You can call this object function using this syntax:

```
disp(combJitt)
```

where combJitt is the generator object.

Examples

Generate Combined Random and Periodic Jitter

Generate 500 jitter samples composed of random and periodic components.

Create a commsrc.combinedjitter object configured to apply a combination of random and periodic jitter components. Use name-value pairs to enable RandomJitter and PeriodicJitter, and to assign jitter settings. Set the standard deviation of the random jitter to 2e-4 seconds, the periodic jitter amplitude to 5e-4 seconds, and the periodic jitter frequency to 2 Hz.

```
numSamples = 500;
combJitt = commsrc.combinedjitter(...
    'RandomJitter','on', ...
    'RandomStd',2e-4, ...
    'PeriodicJitter','on', ...
    'PeriodicAmplitude',5e-4, ...
    'PeriodicFrequencyHz',200)
```

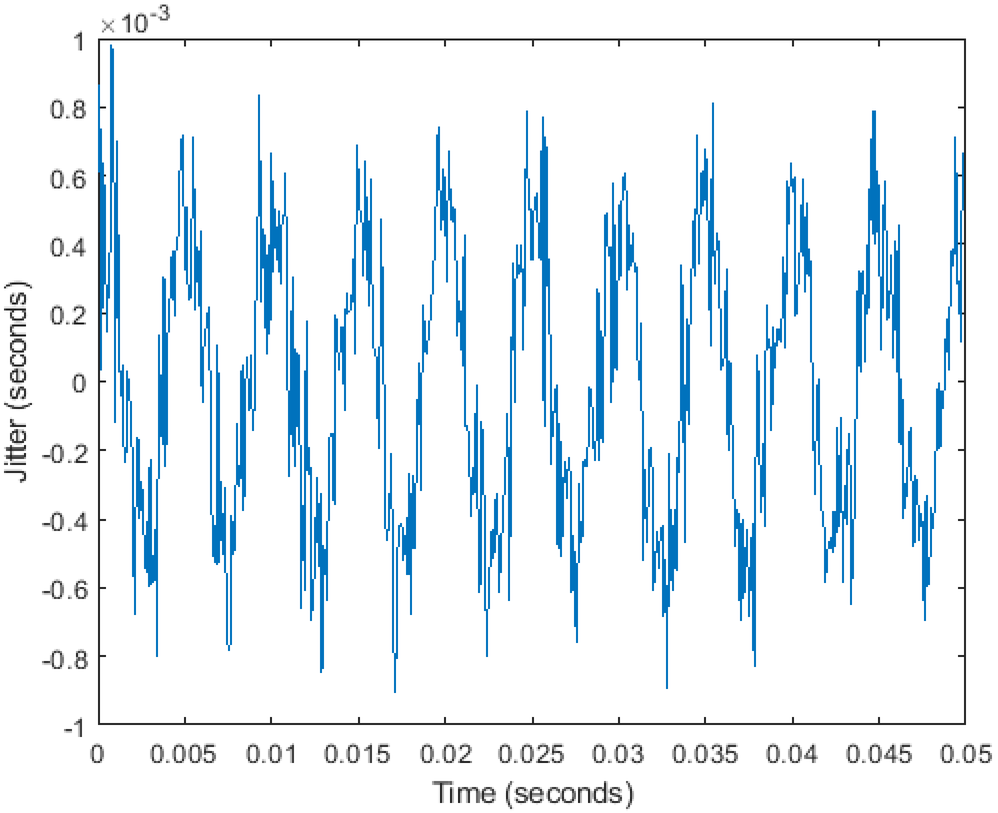
```
combJitt =
                   Type: 'Combined Jitter Generator'
      SamplingFrequency: 10000
           RandomJitter: 'on'
              RandomStd: 2.0000e-04
         PeriodicJitter: 'on'
         PeriodicNumber: 1
      PeriodicAmplitude: 5.0000e-04
    PeriodicFrequencyHz: 200
          PeriodicPhase: 0
            DiracJitter: 'off'
```

Use the generate method to create the combined jitter samples.

```
y = generate(combJitt,numSamples);
x = [0:numSamples-1];
```

Plot the jitter samples. You can see the Gaussian and periodic nature of the combined jitter.

```
plot(x/combJitt.SamplingFrequency,y)
xlabel('Time (seconds)')
ylabel('Jitter (seconds)')
```



Display commsrc.combinedjitter Object Settings

Create a `commsrc.combinedjitter` object. Display the default object property values.

```
combJitt = commsrc.combinedjitter;
disp(combJitt)
```

```
                 Type: 'Combined Jitter Generator'
    SamplingFrequency: 10000
         RandomJitter: 'off'
       PeriodicJitter: 'off'
          DiracJitter: 'off'
```

Create a `commsrc.combinedjitter` object with random, periodic, and Dirac jitters enabled. Display the object property values.

```
combJitt = commsrc.combinedjitter('RandomJitter','on', ...
    'PeriodicJitter','on','DiracJitter','on');
disp(combJitt)
```

```
                   Type: 'Combined Jitter Generator'
      SamplingFrequency: 10000
           RandomJitter: 'on'
              RandomStd: 1.0000e-04
         PeriodicJitter: 'on'
         PeriodicNumber: 1
      PeriodicAmplitude: 5.0000e-04
    PeriodicFrequencyHz: 200
          PeriodicPhase: 0
            DiracJitter: 'on'
            DiracNumber: 2
             DiracDelta: [-5.0000e-04 5.0000e-04]
       DiracProbability: [0.5000 0.5000]
```

Generate Non-return-to-zero Pattern Signal

Generate a binary non-return-to-zero (NRZ) signal utilizing the pattern generator object. View the NRZ signal with and without jitter applied to the signal.

Initialize system parameters.

```
Fs = 10000;            % Sample rate
Rs = 50;               % Symbol rate (Sps)
sps = Fs/Rs;           % Number of samples per symbol
Trise = 1/(5*Rs);      % Rise time of the NRZ signal
Tfall = 1/(5*Rs);      % Fall time of the NRZ signal
frameLen = 100;        % Number of symbols in a frame
spt = 200;               % Number of samples per trace on eye diagram
```

Create a pattern generator object with no jitter component assigned.

```
src = commsrc.pattern('SamplingFrequency', Fs, ...
                      'SamplesPerSymbol', sps, ...
                      'RiseTime', Trise, ...
                      'FallTime', Tfall)
```

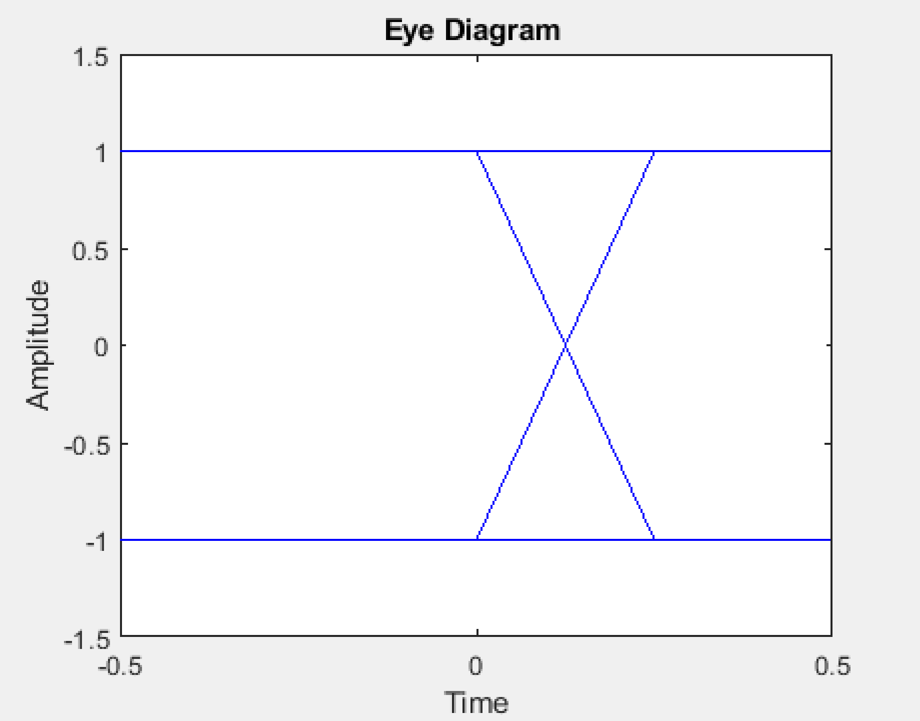
```
src =
                 Type: 'Pattern Generator'
    SamplingFrequency: 10000
     SamplesPerSymbol: 200
           SymbolRate: 50
            PulseType: 'NRZ'
         OutputLevels: [-1 1]
             RiseTime: 0.0040
             FallTime: 0.0040
          DataPattern: 'PRBS7'
               Jitter: [1x1 commsrc.combinedjitter]
```

```
src.Jitter
```

```
ans =
                 Type: 'Combined Jitter Generator'
    SamplingFrequency: 10000
         RandomJitter: 'off'
       PeriodicJitter: 'off'
          DiracJitter: 'off'
```

Generate an NRZ signal and view the eye diagram of the signal.

```
message = generate(src,frameLen);
eyediagram(message,spt)
```



Add inter-symbol-interference (ISI) to an NRZ signal. ISI is modeled by two equal amplitude Dirac functions. Create a combined jitter object with Dirac jitter and assign it to the pattern generator object.

```
jitterSrc = commsrc.combinedjitter('DiracJitter','on', ...
    'DiracDelta',0.05/Rs*[-1 1]);
src.Jitter = jitterSrc
```

```
src =
                 Type: 'Pattern Generator'
    SamplingFrequency: 10000
     SamplesPerSymbol: 200
           SymbolRate: 50
            PulseType: 'NRZ'
         OutputLevels: [-1 1]
             RiseTime: 0.0040
             FallTime: 0.0040
          DataPattern: 'PRBS7'
               Jitter: [1x1 commsrc.combinedjitter]
```

Generate an NRZ signal that has jitter added to it and view the eye diagram of the signal.

```
reset(src);
message = generate(src, frameLen);
eyediagram(message,spt)
```

Topics
"Eye Diagram Analysis"

Introduced in R2015a

commsrc.pattern

Construct pattern generator object

Syntax

```
h = commsrc.pattern
h = commsrc.pattern(Name,Value)
```

Description

`h = commsrc.pattern` constructs a pattern generator object, `h`.

The pattern generator object produces modulated data patterns. The object can be used to inject jitter into modulated signals.

`h = commsrc.pattern(Name,Value)` creates a combined jitter generator object with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

A pattern generator object includes these properties. You can edit all properties, except those explicitly noted.

Property	Description
`Type`	Type of pattern generator object (`'Pattern Generator'`). This property is not writable.
`SamplingFrequency`	Sampling frequency of the input signal in hertz.
`SymbolRate`	The symbol rate of the input signal. This property depends upon the `SamplingFequency` and `SamplesPerSymbol` properties. This property is not writable.
`SamplesPerSymbol`	The number of samples representing a symbol. `SamplesPerSymbol` must be an integer. This property affects `SymbolRate`.
`PulseType`	The type of pulse the object generates. Pulse types available: return-to-zero (`'RZ'`) and non-return-to-zero (`'NRZ'`). The initial condition for an `'NRZ'` pulse is `0`.
`OutputLevels`	Amplitude levels that correspond to the symbol indices. For an `'NRZ'` pulse, specify as a 1-by-2 vector. The first element of the 1-by-2 vector corresponds to the 0th symbol (data bit value 0). The second element corresponds to the 1st symbol (data bit value 1). For an `'RZ'` pulse, specify as a scalar and the value corresponds to the data bit value `1`.

Property	Description
`DutyCycle`	The duty cycle of the pulse the object generates. Displays calculated duty cycle based on pulse parameters. This property is not writable.
`RiseTime`	Specifies 10% to 90% rise time of the pulse in seconds.
`PulseDuration`	Pulse duration in seconds defined by IEEE STD 181 standard. See the Return-to-Zero (RZ) Signal Conversion: Ideal Pulse to STD–181 figure in the “Object Functions” on page 2-184. Applies when `PulseType` is `'RZ'`.
`FallTime`	Fall time of the pulse in seconds, specified as a percentage from 10 to 90.
`DataPattern`	The bit sequence the object uses, specified as `'PRBS5'`, `'PRBS6'`, ..., `'PRBS15'`, `'PRBS23'`, `'PRBS31'`, and`'User Defined'`.
`UserDataPattern`	User-defined bit pattern consisting of a vector of ones and zeroes. Applies when `DataPattern` is `'User Defined'`.
`Jitter`	Jitter characteristics, specified as a `commsrc.combinedjitter` object. Use this property to configure Random, Periodic and Dual Dirac Jitter.

Object Functions

A pattern generator object has five object functions, as described in this section.

generate

This object function outputs a frame worth of modulated and interpolated symbols. It has one input argument, which is the number of symbols in a frame. Its output is a column vector. You can call the object function using this syntax:

```
x = generate(h, N)
```

where `h` is the handle to the object, `N` is the number of output symbols, and `x` is a column vector whose length is `N` multiplied by `h.SamplesPerSymbol`.

reset

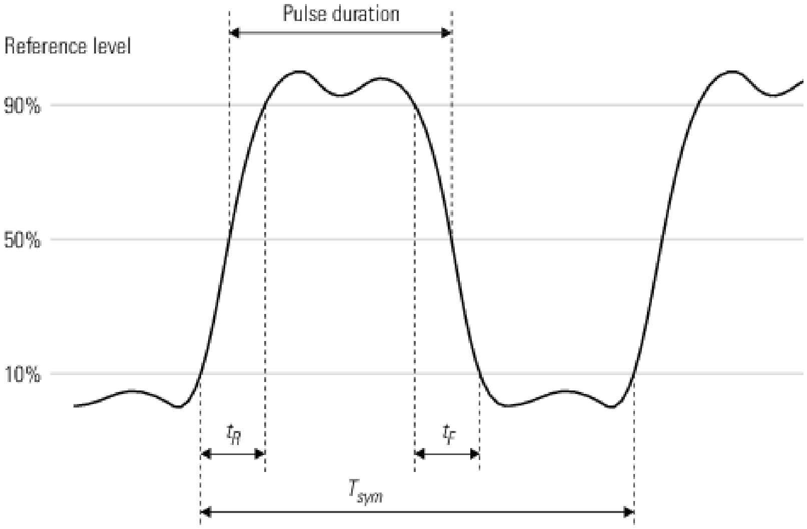
This object function resets the pattern generator to its default state. The property values do not reset unless they relate to the state of the object. This object function has no input arguments.

idealtostd181

This object function converts the ideal pulse specifications to IEEE STD-181 specifications. The ideal 0% to 100% span rise time (`tr`) and fall time (`tf`) are converted to 10% to 90% spans with a 50% pulse width duration (`pw`). Call the `idealtostd181` object function using this syntax:

```
h = idealtostd181(tr,tf,pw)
```

The object function sets the appropriate properties. The IEEE STD-181 Return-to-Zero (RZ) signal parameters are shown in this figure.

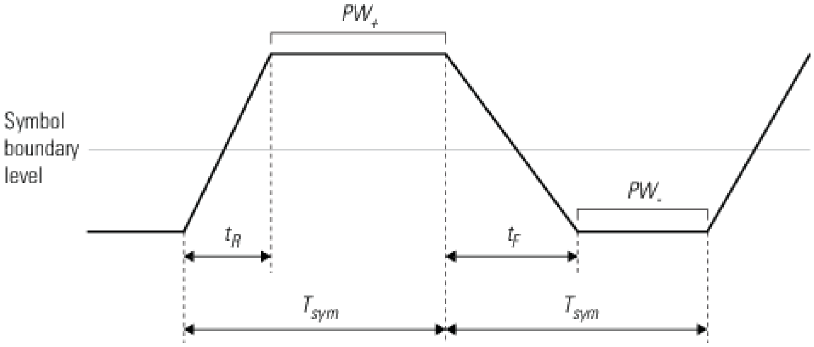


std181toideal

The `std181toideal` object function converts the IEEE STD-181 pulse specifications, stored in the pattern generator, to ideal pulse specifications. The function converts the rise and fall times from 10% – 90% span to 0% – 100% span, and converts the 50% pulse duration to pulse width. Call the `std181toideal` object function using this syntax:

```
[tr tf pw] = std181toideal(h)
```

where `h` is the pattern generator object handle, `tr` is the ideal 0% – 100% rise time, `tf` is the ideal 0% – 100% fall time, and `pw` is the ideal pulse width. The ideal pulse non-return-to-zero (NRZ) signal parameters are shown in this figure.



Use the property values for IEEE STD-181 specifications.

computedcd

The `computedcd` object function computes the duty cycle distortion, *DCD*, of the pulse defined by the pattern generator object *h*.

DCD represents the ratio of the pulse on duration to the pulse off duration. For an NRZ pulse, on duration is the duration the pulse spends above the symbol boundary level. Off duration is the duration the pulse spends below zero. Call the `computedcd` object function using this syntax:

```
dcd = computedcd(h)
```

The software calculates *DCD* given t_R, t_F, T_{sym}. This formula assumes that the symbol boundary level is zero.

$$T_h = (A_h\text{-}A_l) * \frac{t_R}{A_l} + (A_h\text{-}A_l) * \frac{t_F}{A_l} + PW_+$$

$$T_l = (A_h\text{-}A_l) * \frac{t_R}{A_l} + (A_h\text{-}A_l) * \frac{t_F}{A_l} + PW_-$$

$$DCD = \frac{T_h}{T_l}$$

Where T_h is the duration of the high signal, T_l is the duration of the low signal, and *DCD* represents the ratio of the duration of the high signal to the low signal.

Examples

Display commsrc.pattern Object Settings

Create a `commsrc.pattern` object. Display the default object property values.

```
h = commsrc.pattern;
disp(h)
```

```
                 Type: 'Pattern Generator'
    SamplingFrequency: 10000
     SamplesPerSymbol: 100
           SymbolRate: 100
            PulseType: 'NRZ'
         OutputLevels: [-1 1]
             RiseTime: 0
             FallTime: 0
          DataPattern: 'PRBS7'
               Jitter: [1x1 commsrc.combinedjitter]
```

Generate Non-return-to-zero Pattern Signal

Generate a binary non-return-to-zero (NRZ) signal utilizing the pattern generator object. View the NRZ signal with and without jitter applied to the signal.

Initialize system parameters.

```
Fs = 10000;            % Sample rate
Rs = 50;               % Symbol rate (Sps)
sps = Fs/Rs;           % Number of samples per symbol
Trise = 1/(5*Rs);      % Rise time of the NRZ signal
Tfall = 1/(5*Rs);      % Fall time of the NRZ signal
frameLen = 100;        % Number of symbols in a frame
spt = 200;               % Number of samples per trace on eye diagram
```

Create a pattern generator object with no jitter component assigned.

```
src = commsrc.pattern('SamplingFrequency', Fs, ...
                      'SamplesPerSymbol', sps, ...
                      'RiseTime', Trise, ...
                      'FallTime', Tfall)

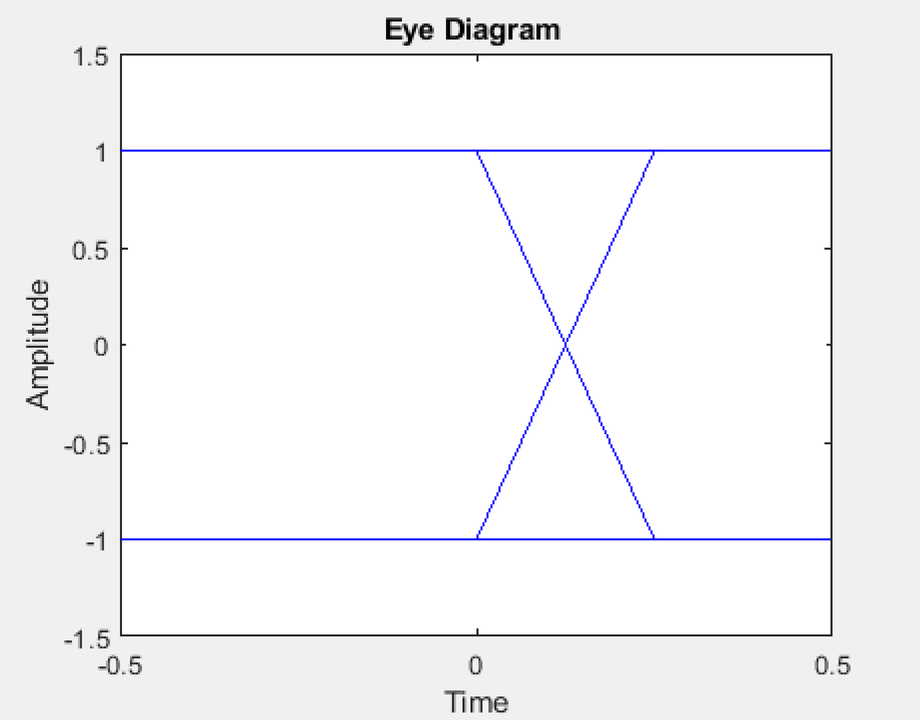
src =
                 Type: 'Pattern Generator'
    SamplingFrequency: 10000
     SamplesPerSymbol: 200
           SymbolRate: 50
            PulseType: 'NRZ'
         OutputLevels: [-1 1]
             RiseTime: 0.0040
             FallTime: 0.0040
          DataPattern: 'PRBS7'
               Jitter: [1x1 commsrc.combinedjitter]
```

```
src.Jitter

ans =
                 Type: 'Combined Jitter Generator'
    SamplingFrequency: 10000
         RandomJitter: 'off'
       PeriodicJitter: 'off'
          DiracJitter: 'off'
```

Generate an NRZ signal and view the eye diagram of the signal.

```
message = generate(src,frameLen);
eyediagram(message,spt)
```



Add inter-symbol-interference (ISI) to an NRZ signal. ISI is modeled by two equal amplitude Dirac functions. Create a combined jitter object with Dirac jitter and assign it to the pattern generator object.

```
jitterSrc = commsrc.combinedjitter('DiracJitter','on', ...
    'DiracDelta',0.05/Rs*[-1 1]);
src.Jitter = jitterSrc
```

```
src =
                 Type: 'Pattern Generator'
    SamplingFrequency: 10000
     SamplesPerSymbol: 200
           SymbolRate: 50
            PulseType: 'NRZ'
         OutputLevels: [-1 1]
             RiseTime: 0.0040
             FallTime: 0.0040
          DataPattern: 'PRBS7'
               Jitter: [1x1 commsrc.combinedjitter]
```

Generate an NRZ signal that has jitter added to it and view the eye diagram of the signal.

```
reset(src);
message = generate(src, frameLen);
eyediagram(message,spt)
```

Introduced in R2008b

commsrc.pn

(To be removed) Create PN sequence generator object

Compatibility

commsrc.pn will be removed in a future release. To generate a pseudo-noise (PN) sequence, use the `comm.PNSequence` System object instead. For more details on the recommended workflow, see "Compatibility Considerations" on page 2-195.

Syntax

```
h = commsrc.pn
h = commsrc.pn(property1,value1,...)
```

Description

`h = commsrc.pn` creates a default PN sequence generator object *h*, and is equivalent to the following:

```
H = commsrc.pn('GenPoly',       [1 0 0 0 0 1 1], ...
              'InitialStates', [0 0 0 0 0 1],   ...
              'CurrentStates', [0 0 0 0 0 1],   ...
              'Mask',          [0 0 0 0 0 1],   ...
              'NumBitsOut',    1)
```

or

```
H = commsrc.pn('GenPoly',       [1 0 0 0 0 1 1], ...
              'InitialStates', [0 0 0 0 0 1],   ...
              'CurrentStates', [0 0 0 0 0 1],   ...
              'Shift',         0,               ...
              'NumBitsOut',    1)
```

`h = commsrc.pn(property1,value1,...)` creates a PN sequence generator object, *h*, with properties you specify as property/value pairs.

Properties

A PN sequence generator has the properties shown on the following table. All properties are writable except for the ones explicitly noted otherwise.

Property	Description
GenPoly	Generator polynomial vector array of bits; must be descending order
InitialStates	Vector array (with length of the generator polynomial order) of initial shift register values (in bits)

Property	Description
CurrentStates	Vector array (with length of the generator polynomial order) of present shift register values (in bits)
NumBitsOut	Number of bits to output at each `generate` method invocation
`Mask` or `Shift`	A mask vector of binary 0 and 1 values is used to specify which shift register state bits are XORed to produce the resulting output bit value. Alternatively, a scalar shift value may be used to specify an equivalent shift (either a delay or advance) in the output sequence.

The `'GenPoly'` property values specify the shift register connections. Enter these values as either a binary vector or a vector of exponents of the nonzero terms of the generator polynomial in descending order of powers. For the binary vector representation, the first and last elements of the vector must be 1. For the descending-ordered polynomial representation, the last element of the vector must be 0. For more information and examples, see the LFSR SSRG Details section of this page.

Methods

A PN sequence generator is equipped with the following methods.

generate

Generate [NumBitsOut x 1] PN sequence generator values

reset

Set the `CurrentStates` values to the `InitialStates` values

getshift

Get the actual or equivalent `Shift` property value

getmask

Get the actual or equivalent `Mask` property value

copy

Make an independent copy of a `commsrc.pn` object

disp

Display PN sequence generator object properties

Side Effects of Setting Certain Properties

Setting the GenPoly Property

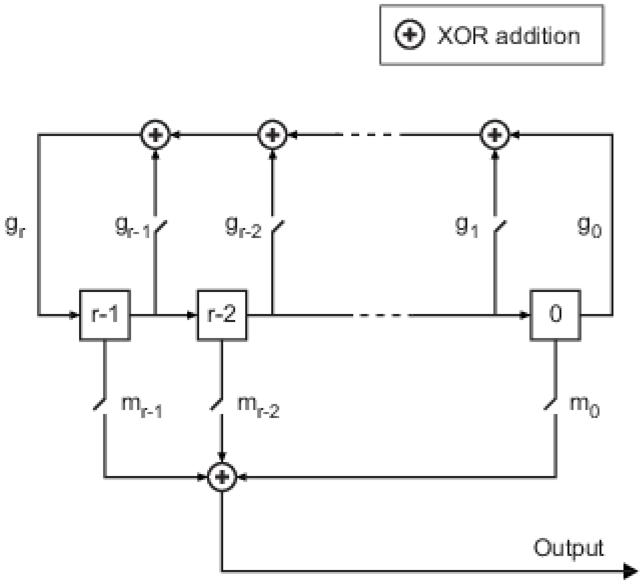
Every time this property is set, it will reset the entire object. In addition to changing the polynomial values, `'CurrentStates'`, `'InitialStates'`, and `'Mask'` will be set to their default values (`'NumBitsOut'` will remain the same), and no warnings will be issued.

Setting the InitialStates Property

Every time this property is set, it will also set `'CurrentStates'` to the new `'InitialStates'` setting.

LFSR SSRG Details

The `generate` method produces a pseudorandom noise (PN) sequence using a linear feedback shift register (LFSR). The LFSR is implemented using a simple shift register generator (SSRG, or Fibonacci) configuration, as shown below.



All *r* registers in the generator update their values at each time step according to the value of the incoming arrow to the shift register. The adders perform addition modulo 2. The shift register is described by the `'GenPoly'` property (generator polynomial), which is a primitive binary polynomial in *z*, $g_r z^r + g_{r-1} z^{r-1} + g_{r-2} z^{r-2} + ... + g_0$. The coefficient g_k is 1 if there is a connection from the kth register, as labeled in the preceding diagram, to the adder. The leading term g_r and the constant term g_0 of the `'GenPoly'` property must be 1 because the polynomial must be primitive.

You can specify the **Generator polynomial** parameter using either of these formats:

- A vector that lists the coefficients of the polynomial in descending order of powers. The first and last entries must be 1. Note that the length of this vector is one more than the degree of the generator polynomial.
- A vector containing the exponents of *z* for the nonzero terms of the polynomial in descending order of powers. The last entry must be `0`.

For example, `[1 0 0 0 0 0 1 0 1]` and `[8 2 0]` represent the same polynomial, p(z) = $z^8 + z^2 + 1$.

The **Initial states** parameter is a vector specifying the initial values of the registers. The **Initial states** parameter must satisfy these criteria:

- All elements of the **Initial states** vector must be binary numbers.
- The length of the **Initial states** vector must equal the degree of the generator polynomial.

Note At least one element of the **Initial states** vector must be nonzero in order for the block to generate a nonzero sequence. That is, the initial state of at least one of the registers must be nonzero.

For example, the following table indicates two sets of parameter values that correspond to a generator polynomial of p(z) = $z^8 + z^2 + 1$.

Quantity	Example 1	Example 2
Generator polynomial	`g1 = [1 0 0 0 0 0 1 0 1]`	`g2 = [8 2 0]`
Degree of generator polynomial	8, which is `length(g1)-1`	8
Initial states	`[1 0 0 0 0 0 1 0]`	`[1 0 0 0 0 0 1 0]`

Output mask vector (or scalar shift value) shifts the starting point of the output sequence. With the default setting for this parameter, the only connection is along the arrow labeled m_0, which corresponds to a shift of 0. The parameter is described in greater detail below.

You can shift the starting point of the PN sequence with **Output mask vector (or scalar shift value)**. You can specify the parameter in either of two ways:

- An integer representing the length of the shift
- A binary vector, called the *mask vector*, whose length is equal to the degree of the generator polynomial

The difference between the block's output when you set **Output mask vector (or scalar shift value)** to 0, versus a positive integer d, is shown in the following table.

	T = 0	T = 1	T = 2	...	T = d	T = d+1
Shift = 0	x_0	x_1	x_2	...	x_d	x_{d+1}
Shift = d	x_d	x_{d+1}	x_{d+2}	...	x_{2d}	x_{2d+1}

Alternatively, you can set **Output mask vector (or scalar shift value)** to a binary vector, corresponding to a polynomial in *z*, $m_{r-1}z^{r-1} + m_{r-2}z^{r-2} + \ldots + m_1z + m_0$, of degree at most r-1. The mask vector corresponding to a shift of d is the vector that represents m(z) = z^d modulo g(*z*), where g(*z*) is the generator polynomial. For example, if the degree of the generator polynomial is 4, then the mask vector corresponding to d = 2 is `[0 1 0 0]`, which represents the polynomial m(z) = z^2. The preceding schematic diagram shows how **Output mask vector (or scalar shift value)** is implemented when you specify it as a mask vector. The default setting for **Output mask vector (or scalar shift value)** is `0`. You can calculate the mask vector using the Communications Toolbox function `shift2mask`.

Sequences of Maximum Length

If you want to generate a sequence of the maximum possible length for a fixed degree, *r*, of the generator polynomial, you can set **Generator polynomial** to a value from the following table. See Proakis, John G., *Digital Communications*, Third edition, New York, McGraw Hill, 1995 for more information about the shift-register configurations that these polynomials represent.

r	Generator Polynomial	r	Generator Polynomial
2	[2 1 0]	21	[21 19 0]

46	[46 21 10 1 0]	53	[53 6 2 1 0]

Examples

Typically `commsrc.pn` is used to output pseudorandom data streams.

Construct a PN object.

```
h = commsrc.pn('Shift',0);
```

Output 10 PN bits.

```
set(h,'NumBitsOut',10);
generate(h)
```

```
ans = 10×1

     1
     0
     0
     0
     0
     0
     1
     0
     0
     0
```

Output 10 more PN bits.

```
generate(h)
```

```
ans = 10×1

     0
     1
     1
     0
     0
     0
     1
     0
     1
     0
```

Reset the object to the initial shift register state values.

```
reset(h);
```

Output 4 PN bits.

```
set(h,'NumBitsOut',4);
generate(h)
```

```
ans = 4×1

     1
     0
     0
     0
```

Compatibility Considerations

`commsrc.pn` will be removed in a future release.
Not recommended starting in R2020b

commsrc.pn will be removed in a future release. To generate a pseudo-noise (PN) sequence, use the `comm.PNSequence` System object instead.

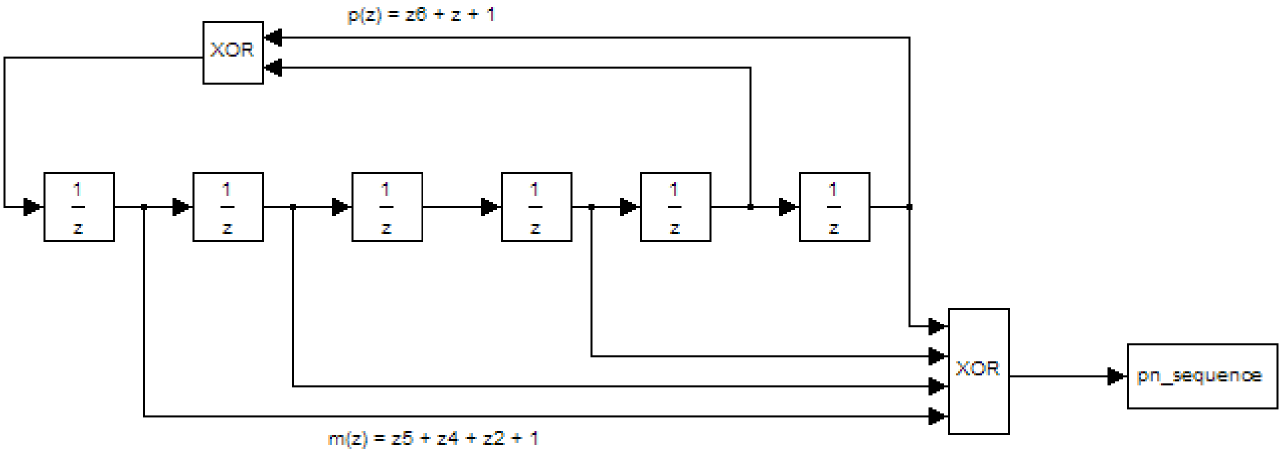
Replace instances of commsrc.pn with a `comm.PNSequence` System object. Note the mapping between commsrc.pn properties and `comm.PNSequence` properties:

commsrc.pn	**comm.PNSequence**
GenPoly	Polynomial
InitialStates	InitialConditions
Mask	Mask
NumBitsOut	SamplesPerFrame
CurrentStates	N/A

See the following table for an example of migrating the old workflow to the recommended workflow.

Set up a PN sequence generator. Define the polynomial in binary vector format or exponential vector format.

This figure defines a PN sequence generator with a generator polynomial p(z) = $z^6 + z + 1$.



See the following table for examples of migrating the old workflow to the recommended workflow.

Previous Workflow	**Recommended Workflow**

<table>
<tr>
<td>

Define this PN sequence generator as:

```
h1 = commsrc.pn('GenPoly', [1 0 0 0 0 1 1], 'Mask', [1 1 0 1 0 1]);
h2 = commsrc.pn('GenPoly', [1 0 0 0 0 1 1], 'Shift', 22);
mask2shift ([1 0 0 0 0 1 1],[1 1 0 1 0 1])
```

Alternatively, you can input `GenPoly` as the exponents of z for the nonzero terms of the polynomial in descending order of powers:

```
h = commsrc.pn('GenPoly', [6 1 0], 'Mask', [1 1 0 1 0 1])

h =
          GenPoly: [1 0 0 0 0 1 1]
    InitialStates: [0 0 0 0 0 1]
    CurrentStates: [0 0 0 0 0 1]
             Mask: [1 1 0 1 0 1]
       NumBitsOut: 1
```

</td>
<td>

Define this PN sequence generator as:

```
h1 = comm.PNSequence('Polynomial', [1 0 0 0 0 1 1],..
 'InitialConditions', [1 1 0 1 0 1]);
h2 = comm.PNSequence('Polynomial', [1 0 0 0 0 1 1],..
 'Mask', 22);
mask2shift ([1 0 0 0 0 1 1],[1 1 0 1 0 1])

ans = 22
```

Alternatively you can input the polynomial exponents of `z` for the nonzero terms of the polynomial in descending order of powers.

```
h = comm.PNSequence('Polynomial',...
 [6 1 0], 'InitialConditions', [1 1 0 1 0 1])

h =
  comm.PNSequence with properties:

               Polynomial: [6 1 0]
    InitialConditionsSource: 'Property'
        InitialConditions: [1 1 0 1 0 1]
               MaskSource: 'Property'
                     Mask: 0
       VariableSizeOutput: false
          SamplesPerFrame: 1
           ResetInputPort: false
          BitPackedOutput: false
           OutputDataType: 'double'
```

</td>

Introduced in R2009a

commtest.ErrorRate

(To be removed) Create error rate test console

Compatibility

commtest.ErrorRate will be removed in a future release. Use `comm.ErrorRate` or `bertool` instead. For more information, see "Compatibility Considerations" on page 2-215.

Syntax

```
h = commtest.ErrorRate
h = commtest.ErrorRate(sys)
h = commtest.ErrorRate(sys,'PropertyName',PropertyValue,...)
h = commtest.ErrorRate('PropertyName',PropertyValue,...)
```

Description

`h = commtest.ErrorRate` returns an error rate test console, h. The error rate test console runs simulations of a system under test to obtain error rates.

`h = commtest.ErrorRate(sys)` returns an error rate test console, error rate test console, h, with each specified property set to the h, with an attached system under test, SYS.

`h = commtest.ErrorRate(sys,'PropertyName',PropertyValue,...)` returns an error rate test console, h, with an attached system under test, sys. Each specified property, 'PropertyName', is set to the specified value, PropertyValue.

`h = commtest.ErrorRate('PropertyName',PropertyValue,...)` returns an error rate test console, h, with each specified property 'PropertyName', set to the specified value, PropertyValue.

Properties

The error rate test console object has the properties in the following table. Setting any property resets the object. A property that is irrelevant is one that you can set, but its value does not affect measurements. Similarly, you cannot display irrelevant properties using the `disp` method. You can write to all properties, except for the ones explicitly noted otherwise.

Property	Description
Description	'Error Rate Test Console'. Read-only.
SystemUnderTestName	System under test name. Read-only.

Property	Description
FrameLength	Specify the length of the transmission frame at each iteration. This property becomes relevant only when the system under test registers a valid test input. • If the system under test registers a `NumTransmissions` test input and calls its `getInput` method, the error rate test console returns the value stored in `FrameLength`. Using an internal data source, the system under test uses this value to generate a transmission frame of the specified length. • If the system under test registers a `DiscreteRandomSource` test input and calls its `getInput` method, the test console generates and returns a frame of symbols. The length of the frame of symbols matches the `FrameLength` property. This property defaults to 500.
IterationMode	Specify how the object determines simulation points. • If set to `Combinatorial`, the object performs simulations for all possible combinations of registered test parameter sweep values. • If set to `Indexed`, the object performs simulations for all indexed sweep value sets. The i^{th} sweep value set consists of the i^{th} element of every sweep value vector for each registered test parameter. All sweep value vectors must have equal length, except for values that are unit length. Note that for the following sweep parameter settings: • Parameter1 = [a_1 a_2] • Parameter2 = [b_1 b_2] • Parameter3 = [c_1] In Indexed Mode, the test console performs simulations for the following sweep parameter sets: (a_1, b_1, c_1) (a_2, b_2, c_1) In Combinatorial Mode, the test console performs simulations for the following sweep parameter sets: (a_1, b_1, c_1) (a_1, b_2, c_1) (a_2, b_1, c_1) (a_2, b_2, c_1)

Property	Description
SystemResetMode	Specify the stage of a simulation run at which the system resets. • Setting to `Reset at new simulation point` resets the system under test at the beginning of a new simulation point. • Setting to `Reset at every iteration` resets the system under test at every iteration.
SimulationLimitOption	Specify how to stop the simulation for each sweep parameter point. • If set to `Number of transmissions` the simulation for a sweep parameter point stops when the number of transmissions equals the value for `MaxNumTransmissions`. • Set `TransmissionCountTestPoint` to the name of the registered test point containing the transmission count you are comparing to `MaxNumTransmissions`. • If set to `Number of errors` the simulation for a sweep parameter point stops when the number of errors equals the value for `MinNumErrors`. • Set the `ErrorCountTestPoint` to the name of the registered test point containing the error count you are comparing to the `MinNumErrors`. • Setting to `Number of errors or transmissions` stops the simulation for a sweep parameter point when meeting one of two conditions. • The simulation stops when the number of transmissions equals the value for `MaxNumTransmissions`. • The simulation stops when obtaining the number of errors matching `NumErrors`. • Setting this property to `Number of errors and transmissions` stops the simulation for a sweep parameter point when meeting the following condition. • The simulation stops when the number of transmissions *and* the number errors have at least reached the values in `MinNumTransmissions` and `MinNumErrors`. Set `TransmissionCountTestPoint` to the name of the registered test point that contains the transmission count you are comparing to the `MaxNumTransmissions` property. To control the simulation length, set `ErrorCountTestPoint` to the name of the registered test point containing the error count you are comparing to `MinNumErrors`. Call the `info` method of the error rate test console to see the valid registered test point names.

Property	Description
MaxNumTransmissions	Specify the maximum number of transmissions the object counts before stopping the simulation for a sweep parameter point. This property becomes relevant only when `SimulationLimitOption` is `Number of transmissions` or `Number of errors or transmissions`. • When setting `SimulationLimitOption` to `Number of transmissions` the simulation for each sweep parameter point stops when reaching the number of transmissions `MaxNumTransmissions` specifies. • Setting `SimulationLimitOption` to `Number of errors or transmissions` stops the simulation for each sweep parameter point for one of two conditions. • The simulation stops when completing the number of transmissions `MaxNumTransmissions` specifies. • The simulation stops when obtaining the number of errors `MinNumErrors` specifies. The `TransmissionCountTestPoint` property supplies the name of a registered test point containing the count transmission type. Calling the `info` method of the error rate test console displays the valid registered test points. If this property contains registered test points, the test console runs iterations equal to the value for `MaxNumTransmissions` for each sweep parameter point. If this property has no registered test parameters, the test console runs the number of iterations equal to the value for `MaxNumTransmissions` and stops. The value defaults to 1000.
MinNumErrors	Specify the minimum number of errors the object counts before stopping the simulation for a sweep parameter point. This property becomes relevant only when setting the `SimulationLimitOption` to `Number of errors` or `Number of errors or transmissions`. • When setting `SimulationLimitOption` to `Number of errors` the simulation for each parameter point stops when reaching the number of errors you specify for the `MinNumErrors` property. • When setting the `SimulationLimitOption` property to `Number of errors or transmissions` the simulation for each sweep parameter point stops for one of two conditions. • The simulation stops when reaching the number of errors you specify for the `MaxNumTransmissions` property. • The simulation stops when reaching the number of errors you specify for the `MinNumErrors` property. Specify the type of errors the error count uses by setting the `ErrorCountTestPoint` property to the name of a registered test point containing the count. Call the `info` method of the error rate test console to see the valid registered test point names. This value defaults to 100.

Property	Description
TransmissionCountTestPoint	Specify and register a test point containing the transmission count that controls the test console simulation stop mechanism. This property becomes relevant only when setting `SimulationLimitOption` to `Number of transmissions`, `Number of errors or transmissions`, or `Number of errors and transmissions`. In this scenario, if you register a test point, and `TransmissionCountTestPoint` equals `Not set`, the value of this property automatically updates to that of the registered test point name. Call the `info` method to see the valid test point names.
ErrorCountTestPoint	Specify and register the name of a test point containing the error count that controls the simulation stop mechanism. This property is only relevant when setting the `SimulationLimitOption` property to `Number of errors`, `Number of errors or transmissions`, or `Number of errors and transmissions`. In this scenario, if you register a test point, and `ErrorCountTestPoint` equals `Not set`, the value of this property automatically updates to that of the registered test point name. Call the `info` method to see the valid test point names.

Methods

The error rate test console object has the following methods:

run

Runs a simulation.

Runs the number of error rate simulations you specify for a system under test with a specified set of parameter values. If a Parallel Computing Toolbox™ license is available and a parpool is open, then the object distributes the iterations among the number of workers available.

getResults

Returns the simulation results.

r = getResults(h) returns the simulation results, *r*, for the test console, *h*. *r* is an object of the type you specify using testconsole.Results. It contains the simulation data for all the registered test points and methods to parse the data and plot it.

info

Returns a report of the current test console settings.

info(h) displays the current test console settings, such as registered test parameters and registered test points.

reset

Resets the error rate test console.

reset(h) resets test parameters and test probes and then clears all simulation results of test console, *h*.

attachSystem

Attaches a system to test console.

attachSystem(ho,sys) attaches a valid user-defined system, sys, to the test console, h.

detachSystem

Detaches the system from the test console.

detachSystem(h) detaches a system from the test console, h. This method also clears the registered test inputs, test parameters, test probes, and test points.

setTestParameterSweepValues

Sets test parameter sweep values.

setTestParameterSweepValues(h,name,sweep) specifies a set of sweep values, 'sweep', for the registered test parameter, 'name', in the test console, h. You only specify sweep values for registered test parameters. sweep must have values within the specified range of the test parameter. It can be a row vector of numeric values, or a cell array of char values. Display the valid ranges using the getTestParameterValidRanges method.

setTestParameterSweepValues(h,name1,sweep1,name2,sweep2...) simultaneously specifies sweep values for multiple registered test parameters.

getTestParameterSweepValues

Returns test parameter sweep values.

getTestParameterSweepValues(h,name) gets the sweep values currently specified for the registered test parameter, name, in the test console, h.

getTestParameterValidRanges

Returns the test parameter valid ranges.

getTestParameterValidRanges(h,name) gets the valid ranges for a registered test parameter, name, in the test console, h.

registerTestPoint

Registers a test point.

registerTestPoint(h, name, actprobe,expprobe) registers a new test point object, name, to the error rate test console, h. The test point must contain a pair of registered test probes, actprobe, and expprobe. actprobe contains actual data, and expprobe contains expected data. The object compares the data from these probes and obtains error rate values. The error rate calculation uses a default error rate calculator function that simply performs one-to-one comparisons of the data vectors available in the probes.

registerTestPoint(h, name, actprobe,expprobe, handle) adds the handle, handle, to a user-defined error calculation function that compares the data in the probes and then obtains error rate results.

The user-defined error calculation function must comply with the following syntax: [ecnt tcnt] = functionName(act, exp, udata) where

- ecnt output corresponds to the error count
- tcnt output is the number of transmissions used to obtain the error count
- act and exp correspond to actual and expected data

The error rate test console sets the inputs to the data available in the pair of test point probes, actprobe, and expprobe.

udata is a data input that the system under test passes to the test console at run time, using the setUserData method. udata contains the data necessary to compute errors, such as delays and data buffers.

The error rate test console passes the data that the system under test logs to the error calculation functions for all the registered test points. Calling the info method returns the names of the registered test points and the error rate calculator functions associated with them. It also returns the names of the registered test probes.

unregisterTestPoint

Unregister a test point.

unregisterTestPoint(h,name) removes the test point, name, from the test console, h.

Examples

Error Rate Simulation Sweeps

The `commtest.ErrorRate` and `testconsole.Results` object packages will be removed in a future release. They can be used to perform parameter sweeps to analyze communication system performance. This example demonstrates a workflow that uses them and along with recommended alternate workflows.

Multiple Parameter Sweep and Parallel Run using commtest.ErrorRate

Obtain bit error rate and symbol error rate of an M-PSK system for different modulation orders and EbNo values. System under test is `commtest.MPSKSystem`.

```
% Create an M-ary PSK system
systemUnderTest = commtest.MPSKSystem;

% Instantiate an Error Rate Test Console and attach the system
errorRateTester = commtest.ErrorRate(systemUnderTest);
```

```
Warning: commtest.ErrorRate will be removed in the future. Use comm.ErrorRate or bertool instead
```

```
errorRateTester.SimulationLimitOption = 'Number of errors or transmissions';
errorRateTester.MaxNumTransmissions = 1e5;

% Set sweep values for simulation test parameters
setTestParameterSweepValues(errorRateTester,'M',2.^[1 2 3 4],'EbNo',(-5:10))

% Register a test point
registerTestPoint(errorRateTester,'MPSK_BER','TxInputBits','RxOutputBits')

% Get information about the simulation settings
info(errorRateTester)
```

```
Test console name:            commtest.ErrorRate
System under test name:       commtest.MPSKSystem
Available test inputs:        NumTransmissions, RandomIntegerSource
Registered test inputs:       NumTransmissions
Registered test parameters:   EbNo, M
Registered test probes:       RxOutputBits, RxOutputSymbols, TxInputBits, TxInputSymbols
Registered test points:       MPSK_BER
Metric calculator functions: @commtest.ErrorRate.defaultErrorCalculator
Test metrics:                 ErrorCount, TransmissionCount, ErrorRate

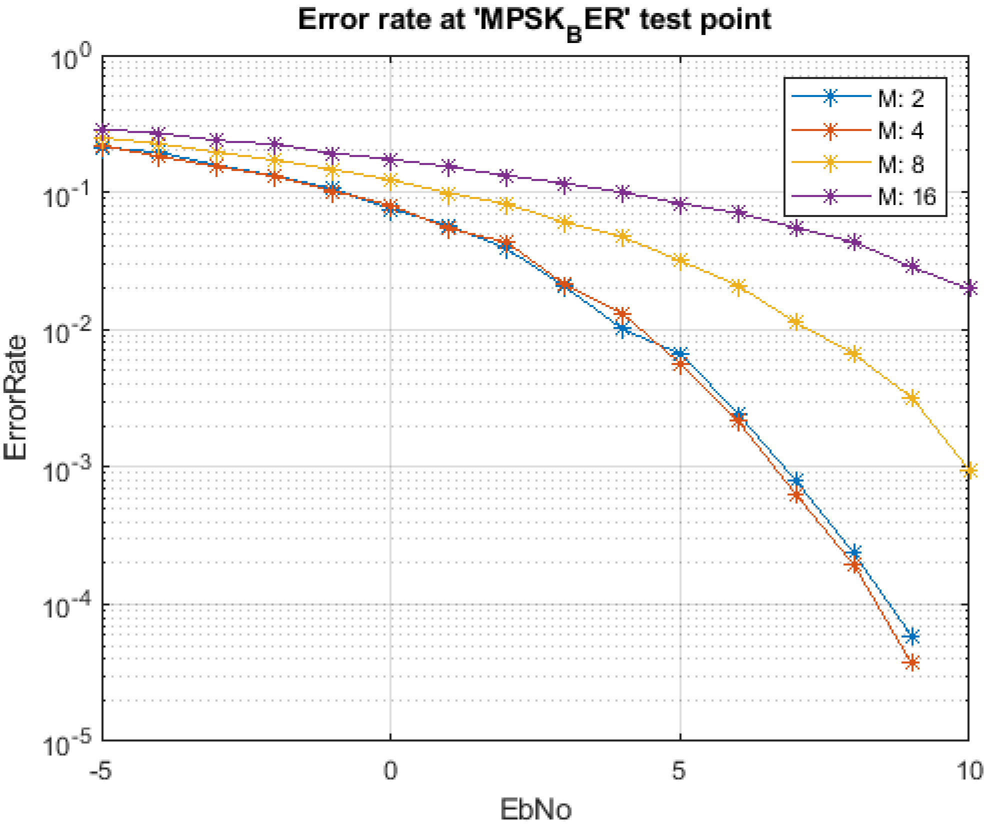
% Run the M-PSK simulations
run(errorRateTester)

Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 12).
12 workers available for parallel computing. Simulations will be distributed among these workers
Running simulations...

% Get the results
mpskResults = getResults(errorRateTester);

Warning: testconsole.Results will be removed in the future. See <a href="matlab:helpview(fullfile

% Get a semi-log scale plot of EbNo versus bit error rate for
% different values of modulation order M
mpskResults.TestParameter2 = 'M';
semilogy(mpskResults,'*-')
```



Multiple Parameter Sweep and Parallel Run using nested for loops and comm.ErrorRate

Run an error rate simulation over M=2.^(1:4) and EbNo=-5:10. Use `comm.ErrorRate` to collect both bit error rate (BER) and symbol error rate (SER) data. Run the simulations to collect a minimum of 100 symbol errors or for a maximum of 1e5 symbols.

```
% Set the M sweep values same as the commtest.ErrorRate object
getTestParameterSweepValues(errorRateTester,'M')
```

```
ans = 1×4

     2     4     8    16
```

```
MSweep = 2.^[1 2 3 4];

% Set EbNo sweep values same as the commtest.ErrorRate object
getTestParameterSweepValues(errorRateTester,'EbNo')
```

```
ans = 1×16

    -5    -4    -3    -2    -1     0     1     2     3     4     5     6     7     8     9    10
```

```
EbNoSweep = -5:10;

% Set minumum number of errors same as the commtest.ErrorRate object
errorRateTester.MinNumErrors
```

```
ans = 100
```

```
minNumErrors = 100;

% Set maximum number of transmissions same as the commtest.ErrorRate
% object. In this example a transmission is a symbol.
errorRateTester.MaxNumTransmissions
```

```
ans = 100000
```

```
MaxNumTransmissions = 1e5;

% Set frame length same as the commtest.ErrorRate object
errorRateTester.FrameLength
```

```
ans = 500
```

```
frameLength = 500;

% Find out if there is a parallel pool and how many workers are available
[licensePCT,~] = license('checkout','distrib_computing_toolbox');

```

Multiple Variable Sweeps using BERTool

`BERTool` computes the BER as a function of signal-to-noise ratio. It analyzes performance either with Monte-Carlo simulations of MATLAB® functions and Simulink® models or with theoretical closed-form expressions for selected types of communication systems. The `bertool` function opens the `BERTool`. Here `BERTool` is configured to call the simulation defined in the function `mpsksim` included below.

```
function [ber,numBits] = mpsksim(EbNo,minNumErrs,maxNumBits)
% Import the Java class for BERTool, so that you will be able to stop the simulation using the "S
import com.mathworks.toolbox.comm.BERTool;
```

```
frameLength = 500;

M = 16; % Can be 2, 4, 8, 16
bitsPerSymbol = log2(M);

maxNumSymbols = maxNumBits/bitsPerSymbol;

SNR = EbNo + 10*log10(bitsPerSymbol);

% Initialize variables related to exit criteria.
numBitErrors = 0;
numSymbols = 0;

while (numBitErrors < minNumErrs) || (numSymbols < maxNumSymbols)

  % Check if the user clicked the Stop button of BERTool.
  if (BERTool.getSimulationStop)
    break;
  end

  % Generate frameLength source outputs
  txMsg = randi([0 M-1],frameLength,1);
  numSymbols = numSymbols+frameLength;

  % Modulate the data
  txOutput = pskmod(txMsg,M,0,'gray');
  % Pass data through an AWGN channel with current SNR value
  chnlOutput  = awgn(txOutput,SNR,'measured',[],'dB');
  % Demodulate the data
  rxOutput = pskdemod(chnlOutput,M,0,'gray');

  % Convert symbol streams to bit streams
  bTx = de2bi(txMsg,bitsPerSymbol,'left-msb')';
  bTx = bTx(:);
  bRx = de2bi(rxOutput,bitsPerSymbol,'left-msb')';
  bRx = bRx(:);

  % Calculate number of bit errors
  numBitErrors = numBitErrors+sum(bTx~=bRx);
end

% Assign values to the output variables.
numBits = numSymbols*bitsPerSymbol;
ber = numBitErrors/numBits;
```

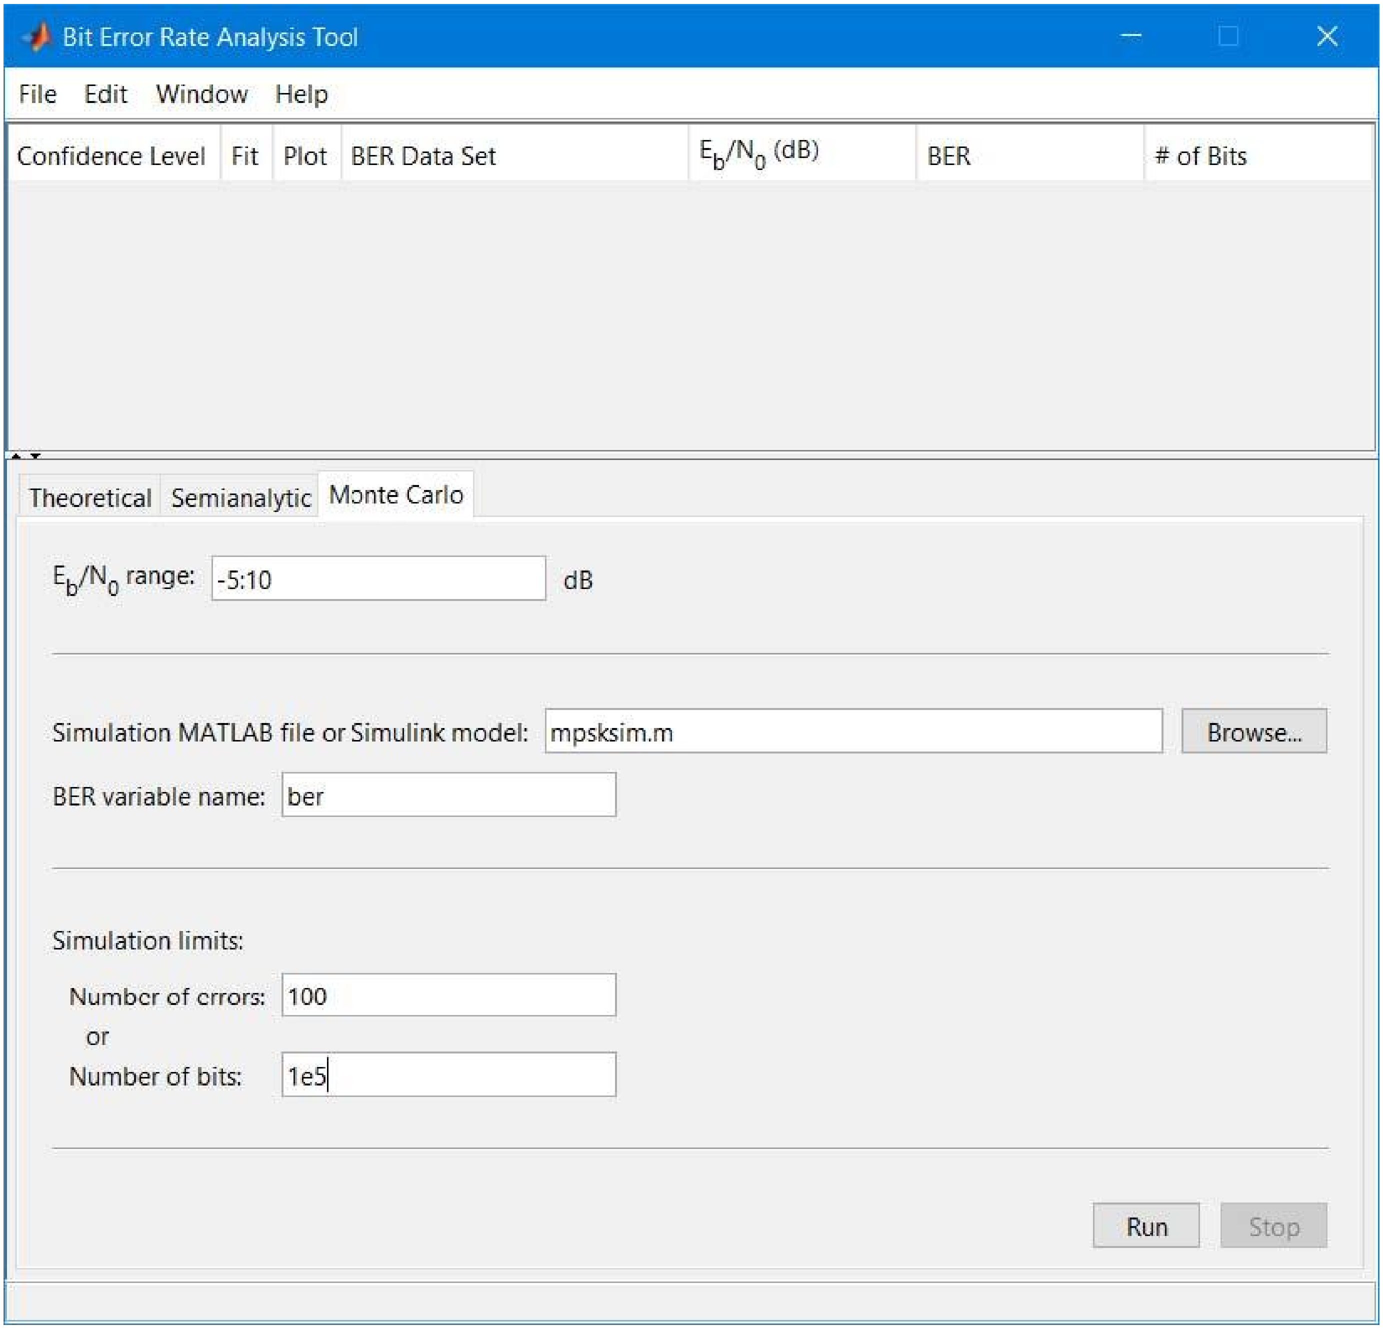
Configure `BERTool` as follows.



E_b/N_0 range: -5:10 dB

Simulation MATLAB file or Simulink model: mpsksim.m

BER variable name: ber

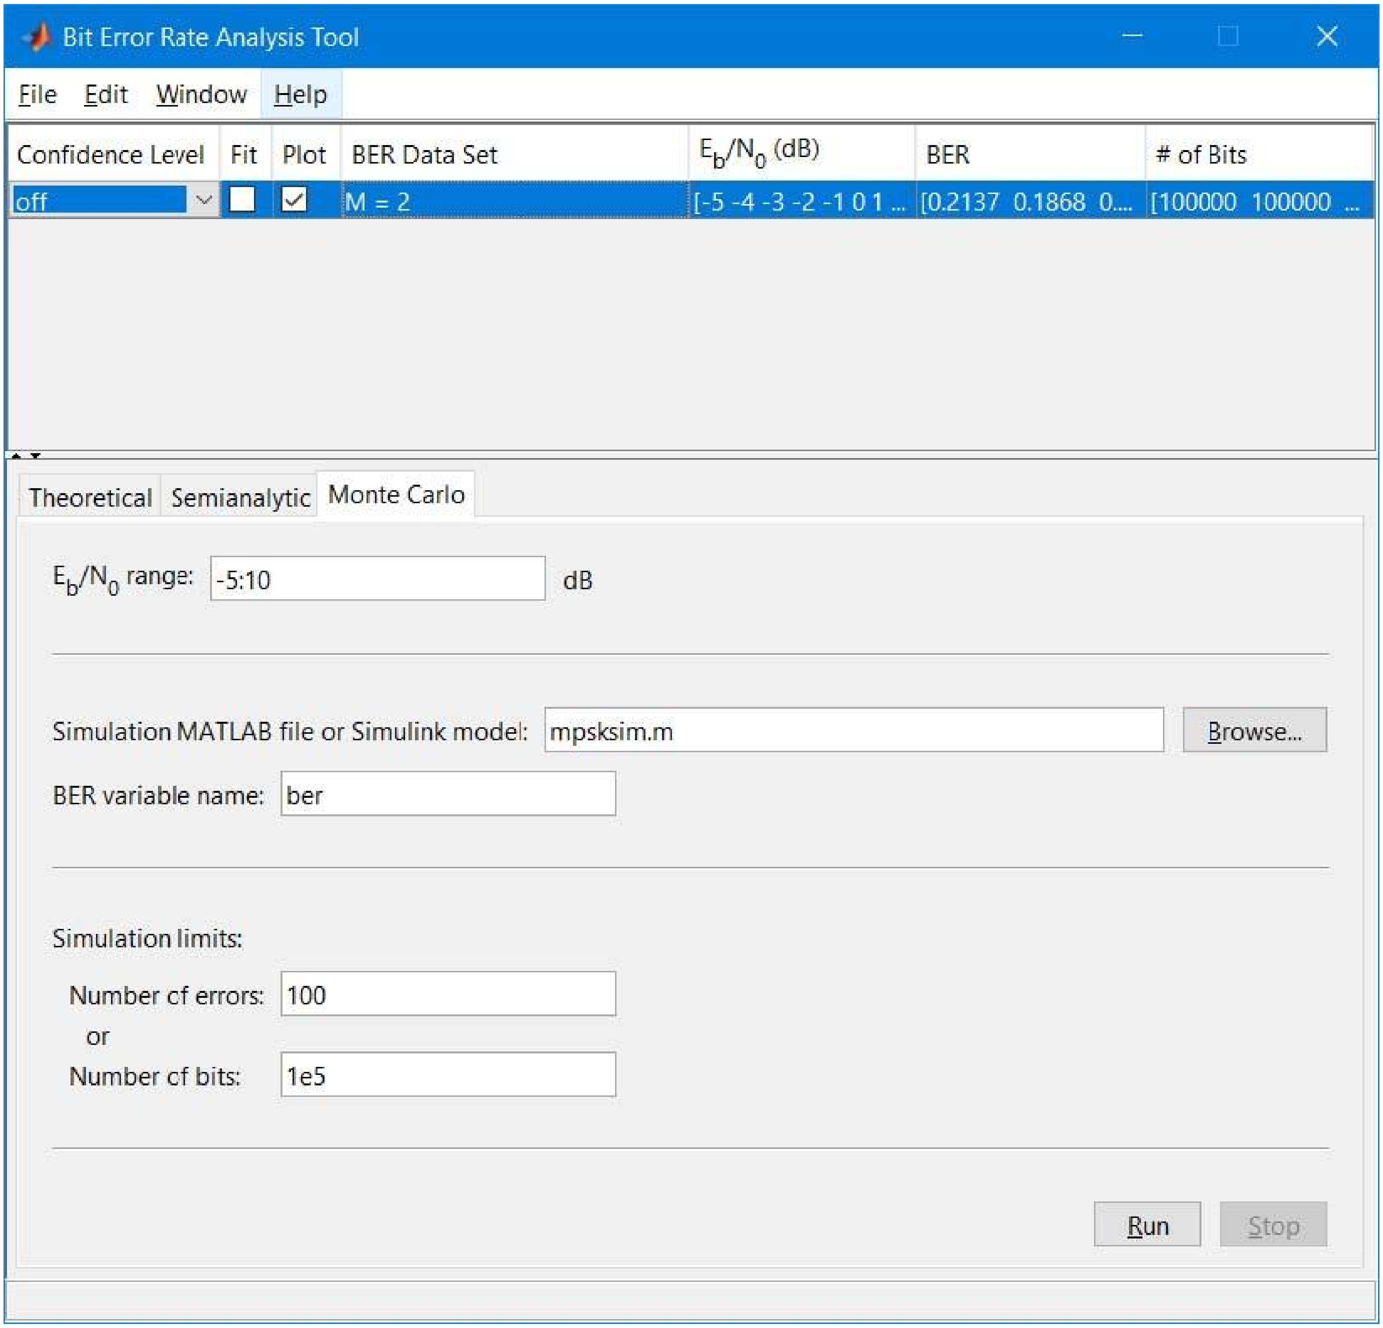
Simulation limits:

Number of errors: 100

or

Number of bits: 1e5

Set M=2 in the `mpsksim` function and click Run. Set the **BER Data Set** name to `'M=2'`.



Confidence Level	Fit	Plot	BER Data Set	E_b/N_0 (dB)	BER	# of Bits
off	□	☑	M = 2	[-5 -4 -3 -2 -1 0 1 ...	[0.2137 0.1868 0....	[100000 100000 ...

Simulation limits:

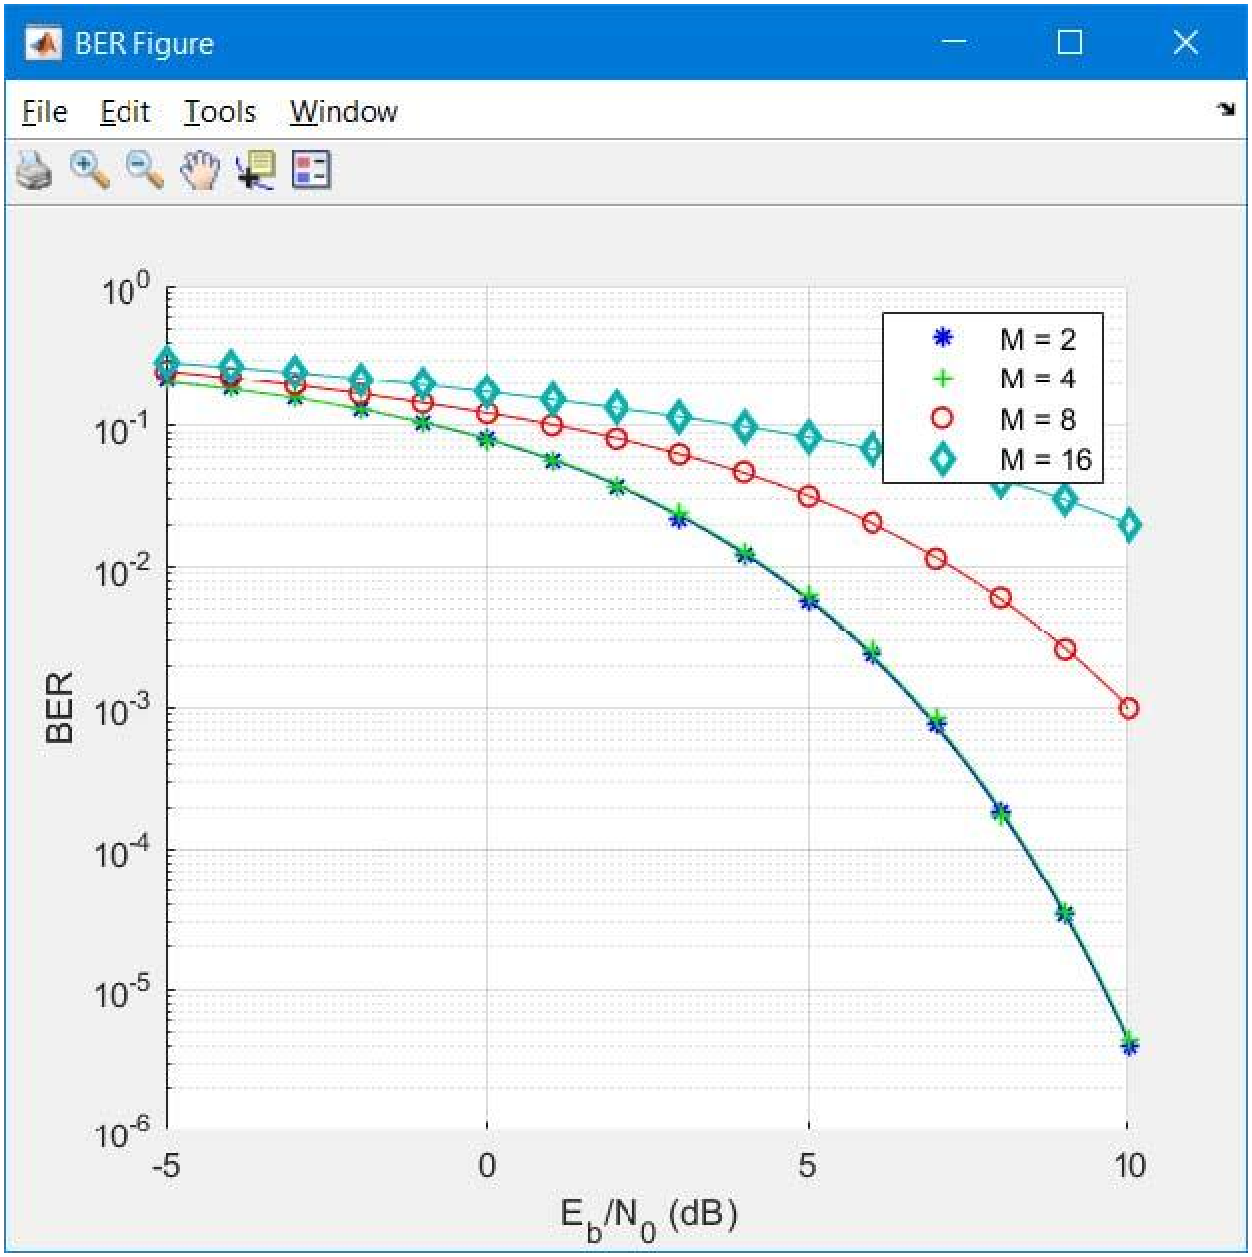
Number of errors: 100

or

Number of bits: 1e5



Parallel SNR Sweep using BERTool

Using `parfor`, run each simulation point in parallel by configuring your simulation function similar to the `mpsksim_parfor` function included below. Since `parfor` cannot work with the Java class for `BERTool`, you will not be able to stop the simulation using the **Stop** button.

```
function [ber,numBits] = mpsksim_parfor(EbNo,minNumErrs,maxNumBits)

% Find out if there is a parallel pool and how many workers are available
if license('test','Distrib_Computing_Toolbox')
  p = gcp;
  if isempty(p)
    numWorkers = 1;
  else
    numWorkers = p.NumWorkers;
  end
else
  numWorkers = 1;
end

M = 2;
bitsPerSymbol = log2(M);

maxNumSymbols = maxNumBits/bitsPerSymbol;

minNumErrorsPerWorker = minNumErrs/numWorkers;
maxNumSymbolsPerWorker = maxNumSymbols/numWorkers;
frameLength = 500;

SNR = EbNo + 10*log10(bitsPerSymbol);

% Initialize variables related to exit criteria.
numBitErrors = zeros(numWorkers,1);
numSymbols = zeros(numWorkers,1);

parfor worker = 1:numWorkers
  while (numBitErrors(worker) < minNumErrorsPerWorker) ...
      || (numSymbols(worker) < maxNumSymbolsPerWorker)

    % Generate frameLength source outputs
    txMsg = randi([0 M-1],frameLength,1);
    numSymbols(worker) = numSymbols(worker)+frameLength;

    % Modulate the data
    txOutput = pskmod(txMsg, M, 0, 'gray');
    % Pass data through an AWGN channel with current SNR value
    chnlOutput  = awgn(txOutput,SNR,'measured',[],'dB');
    % Demodulate the data
    rxOutput = pskdemod(chnlOutput,M,0,'gray');

    % Convert symbol streams to bit streams
    bTx = de2bi(txMsg,bitsPerSymbol,'left-msb')';
    bTx = bTx(:);
    bRx = de2bi(rxOutput,bitsPerSymbol,'left-msb')';
    bRx = bRx(:);

    % Calculate number of bit errors
    numBitErrors(worker) = numBitErrors(worker)+sum(bTx~=bRx);
  end
end

% Assign values to the output variables.
ber = sum(numBitErrors)/sum(numSymbols);
numBits = sum(numSymbols)*bitsPerSymbol;
```

Compatibility Considerations

`commtest.ErrorRate` will be removed

Warns starting in R2019b

commtest.ErrorRate will be removed in a future release. Use `comm.ErrorRate` or `bertool` instead. The “Error Rate Simulation Sweeps” on page 2-204 example demonstrates alternate workflows using `comm.ErrorRate` and `bertool`.

compand

Source coding mu-law or A-law compressor or expander

Syntax

```
out = compand(in,param,v)
out = compand(in,param,v,method)
```

Description

`out = compand(in,param,v)` performs mu-law compression on the input data sequence. The `param` input specifies the mu-law compression value and must be set to a mu value for mu-law compressor computation (a mu-law value of 255 is used in practice). `v` specifies the peak magnitude of the input data sequence.

`out = compand(in,param,v,method)` performs mu-law or A-law compression or expansion on the input data sequence. `param` specifies the mu-law compander or A-law compander value (a mu-law value of 255 and an A-law value of 87.6 are used in practice). `method` specifies the type of compressor or expander computation for the function to perform on the input data sequence.

Examples

Compress and Expand Data Sequence Using Mu-Law

Generate a data sequence.

```
data = 2:2:12
```

```
data = 1×6

     2     4     6     8    10    12
```

Compress the data sequence by using a mu-law compressor. Set the value for mu to 255. The compressed data sequence now ranges between 8.1 and 12.

```
compressed = compand(data,255,max(data),'mu/compressor')
```

```
compressed = 1×6

    8.1644    9.6394   10.5084   11.1268   11.6071   12.0000
```

Expand the compressed data sequence by using a mu-law expander. The expanded data sequence is nearly identical to the original data sequence.

```
expanded = compand(compressed,255,max(data),'mu/expander')
```

```
expanded = 1×6
```

```
    2.0000    4.0000    6.0000    8.0000   10.0000   12.0000
```

Calculate the difference between the original data sequence and the expanded sequence.

```
diffvalue = expanded - data
```

```
diffvalue = 1×6
10^-14 ×

   -0.0444    0.1776    0.0888    0.1776    0.1776   -0.3553
```

Compress and Expand Data Sequence Using A-Law

Generate a data sequence.

```
data = 1:5;
```

Compress the data sequence by using an A-law compressor. Set the value for A to 87.6. The compressed data sequence now ranges between 3.5 and 5.

```
compressed = compand(data,87.6,max(data),'A/compressor')
```

```
compressed = 1×5

    3.5296    4.1629    4.5333    4.7961    5.0000
```

Expand the compressed data sequence by using an A-law expander. The expanded data sequence is nearly identical to the original data sequence.

```
expanded = compand(compressed,87.6,max(data),'A/expander')
```

```
expanded = 1×5

    1.0000    2.0000    3.0000    4.0000    5.0000
```

Calculate the difference between the original data sequence and the expanded sequence.

```
diffvalue = expanded - data
```

```
diffvalue = 1×5
10^-14 ×

         0         0    0.1332    0.0888    0.0888
```

Quantize and Compand an Exponential Signal

Set the mu-law parameter.

```
mu = 255;
```

Create an exponential signal and calculate its maximum value.

```
sig = exp(-4:0.1:4);
V = max(sig);
```

Quantize the signal by using equal-length intervals. Set partition and codebook values, assuming 6-bit quantization. Calculate the mean square distortion.

```
partition = 0:2^6 - 1;
codebook = 0:2^6;
[~,~,distortion] = quantiz(sig,partition,codebook);
```

Compress the signal by using the `compand` function. Apply quantization and expand the quantized signal. Calculate the mean square distortion of the companded signal.

```
compsig = compand(sig,mu,V,'mu/compressor');
[~,quants] = quantiz(compsig,partition,codebook);
newsig = compand(quants,mu,max(quants),'mu/expander');
distortion2 = sum((newsig - sig).^2)/length(sig);
```

Compare the mean square distortions. The distortion is smaller when you perform companding. This difference is because equal-length intervals are well suited to the logarithm of the exponential signal but not well suited to exponential signal itself.

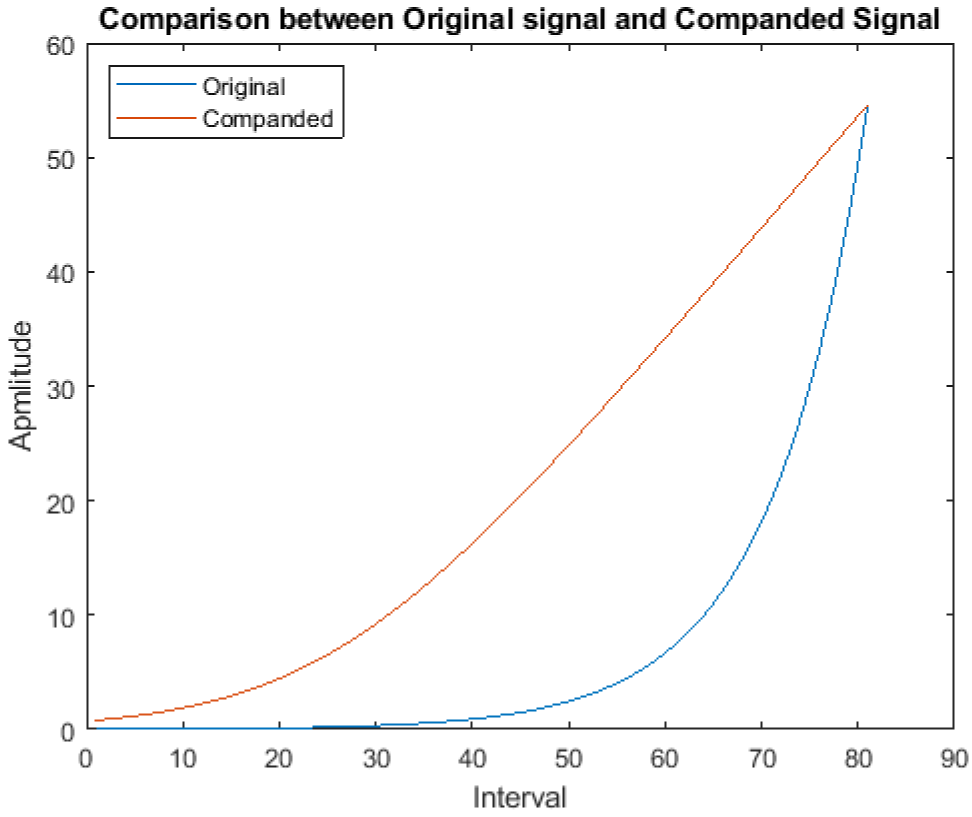
```
[distortion, distortion2]
```

```
ans = 1×2

    0.5348    0.0397
```

Plot the original exponential signal and the companded signal.

```
plot([sig' compsig']);
title('Comparison between Original signal and Companded Signal');
xlabel('Interval');
ylabel('Apmlitude');
legend('Original','Companded','location','nw');
```



Input Arguments

in — Input data sequence

row vector

Input data sequence, specified as a row vector. This input specifies the data sequence for the function to perform compression or expansion.

Data Types: `double`

param — mu or A value of compander

positive scalar | `255` | `87.6`

mu or A value of the compander, specified as a positive scalar. The prevailing values used in practice are µ = `255` and A = `87.6`.

Data Types: `double`

method — Type of compressor or expander computation

`mu/compressorr` | `mu/expander` | `A/compressor` | `A/expander`

Type of compressor or expander computation for the function to perform on the input data sequence, specified as one of these values.

- `mu/compressor`

- `mu/expander`
- `A/compressor`
- `A/expander`

Data Types: `char` | `string`

v — Peak magnitude of input data sequence
positive scalar

Peak magnitude of the input data sequence, specified as a positive scalar.

Data Types: `double`

Output Arguments

`out` — Compressed or expanded signal
positive row vector

Compressed or expanded signal, returned as a positive row vector. The size of `out` matches that of input argument `in`.

Algorithms

In certain applications, such as speech processing, using a logarithmic computation (called a compressor) before quantizing the input data is common. The inverse operation of a compressor is called an *expander*. The combination of a compressor and expander is called a *compander*.

For a given signal, x, the output of the (μ-law) compressor is

$$y = \frac{\log(1 + \mu|x|)}{\log(1 + \mu)}\mathrm{sgn}(x) .$$

μ is the µ-law parameter of the compander, `log` is the natural logarithm, and `sgn` is the signum function (`sign` in MATLAB).

µ-law expansion for input signal x is given by the inverse function y^{1},

$$y^{-1} = \mathrm{sgn}(y)\left(\frac{1}{\mu}\right)\left((1 + \mu)^{|y|} - 1\right) \qquad \text{for -1} \le y \le 1$$

For a given signal, x, the output of the (A-law) compressor is

$$y = \begin{cases} \dfrac{A|x|}{1 + \log A}\mathrm{sgn}(x) & \text{for } 0 \le |x| \le \dfrac{1}{A} \\ \dfrac{(1 + \log(A|x|))}{1 + \log A}\mathrm{sgn}(x) & \text{for } \dfrac{1}{A} < |x| \le 1 \end{cases}$$

A is the A-law parameter of the compander, `log` is the natural logarithm, and `sgn` is the signum function (`sign` in MATLAB).

A-law expansion for input signal x is given by the inverse function y^{1},

$$y^{-1} = \mathrm{sgn}(y)\begin{cases} \dfrac{|y|(1 + \log(A))}{A} & \text{for } 0 \le |y| < \dfrac{1}{1 + \log(A)} \\ \dfrac{\exp(|y|(1 + \log(A)) - 1)}{A} & \text{for } \dfrac{1}{1 + \log(A)} \le |y| < 1 \end{cases}$$

convdeintrlv

Restore ordering of symbols using shift registers

Syntax

```
deintrlved = convdeintrlv(data,nrows,slope)
[deintrlved,state] = convdeintrlv(data,nrows,slope)
[deintrlved,state] = convdeintrlv(data,nrows,slope,init_state)
```

Description

`deintrlved = convdeintrlv(data,nrows,slope)` restores the ordering of elements in `data` by using a set of `nrows` internal shift registers. The delay value of the kth shift register is `(nrows-k)*slope`, where k = 1, 2, 3,..., `nrows`. Before the function begins to process data, it initializes all shift registers with zeros. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

`[deintrlved,state] = convdeintrlv(data,nrows,slope)` returns a structure that holds the final state of the shift registers. `state.value` stores any unshifted symbols. `state.index` is the index of the next register to be shifted.

`[deintrlved,state] = convdeintrlv(data,nrows,slope,init_state)` initializes the shift registers with the symbols contained in `init_state.value` and directs the first input symbol to the shift register referenced by `init_state.index`. The structure `init_state` is typically the `state` output from a previous call to this same function, and is unrelated to the corresponding interleaver.

Using an Interleaver-Deinterleaver Pair

To use this function as an inverse of the `convintrlv` function, use the same `nrows` and `slope` inputs in both functions. In that case, the two functions are inverses in the sense that applying `convintrlv` followed by `convdeintrlv` leaves data unchanged, after you take their combined delay of `nrows*(nrows-1)*slope` into account. To learn more about delays of convolutional interleavers, see “Delays of Convolutional Interleavers”.

Examples

The example in “Effect of Delays on Recovery of Convolutionally Interleaved Data Using MATLAB” uses `convdeintrlv` and illustrates how you can handle the delay of the interleaver/deinterleaver pair when recovering data.

The example on the reference page for `muxdeintrlv` illustrates how to use the `state` output and `init_state` input with that function; the process is analogous for this function.

Introduced before R2006a

convenc

Convolutionally encode binary message

Syntax

```
codedout = convenc(msg,trellis)
codedout = convenc(msg,trellis,puncpat)
codedout = convenc( ___ ,istate)
[codedout,fstate] = convenc( ___ )
```

Description

`codedout = convenc(msg,trellis)` encodes the input binary message by using a convolutional encoder represented by a trellis structure. For details about trellis structures in MATLAB, see “Trellis Description of a Convolutional Code”. The input message contains one or more symbols, each of which consists of log2(`trellis`.`numInputSymbols`) bits. The coded output, `codedout`, contains one or more symbols, each of which consists of log2(`trellis`.`numOutputSymbols`) bits.

`codedout = convenc(msg,trellis,puncpat)`specifies a puncture pattern, `puncpat`, to enable higher rate encoding than unpunctured coding.

For some commonly used puncture patterns for specific rates and polynomials, see the last three references.

`codedout = convenc( ___ ,istate)` enables the encoder registers to start at a state specified by `istate`. Specify `istate` as the last input parameter preceded by any of the input argument combinations in the previous syntaxes.

`[codedout,fstate] = convenc( ___ )` also returns the final state of the encoder. When calling `convenc` iteratively, `fstate` is typically used to set `istate` for subsequent calls to the `convenc` function.

Examples

Create Convolutional Codes

Create convolutional codes by using a trellis structure. You can define the trellis by using the `poly2trellis` function or by manually specifying the trellis structure. The example shows both methods.

Define trellis by using `poly2trellis` function

Define the trellis structure to be used to configure the encoder by using the `poly2trellis` function.

```
trellis_a = poly2trellis([5 4],[23 35 0; 0 5 13])
```

```
trellis_a = struct with fields:
     numInputSymbols: 4
    numOutputSymbols: 8
```

```
           numStates: 128
          nextStates: [128x4 double]
             outputs: [128x4 double]
```

Use the trellis structure to configure the `convenc` function. Encode five two-bit symbols for a K/N rate 2/3 convolutional code by using the `convenc` function.

```
K = log2(trellis_a.numInputSymbols) % Number of input bit streams
```

```
K = 2
```

```
N = log2(trellis_a.numOutputSymbols) % Number of output bit streams
```

```
N = 3
```

```
numReg = log2(trellis_a.numStates) % Number of coder registers
```

```
numReg = 7
```

```
numSymPerFrame = 5; % Number of symbols per frame
data = randi([0 1],K*numSymPerFrame,1);
[code_a,fstate_a] = convenc(data,trellis_a);
```

Verify that the encoded output is 15 bits, which is 3/2 (N/K) times the length of the input sequence, `data`.

```
code_a'
```

```
ans = 1×15

     1     1     1     0     0     1     1     1     1     1     0     1     0     1     0
```

```
length(data)
```

```
ans = 10
```

```
length(code_a)
```

```
ans = 15
```

Define trellis manually

Manually define a trellis structure for a K/N rate 1/2 convolutional code.

```
trellis_b = struct('numInputSymbols',2,'numOutputSymbols',4, ...
'numStates',4,'nextStates',[0 2;0 2;1 3;1 3], ...
'outputs',[0 3;1 2;3 0;2 1])
```

```
trellis_b = struct with fields:
     numInputSymbols: 2
    numOutputSymbols: 4
           numStates: 4
          nextStates: [4x2 double]
             outputs: [4x2 double]
```

Use the trellis structure to configure the `convenc` function when encoding 10 one-bit symbols.

```
K = log2(trellis_b.numInputSymbols) % Number of input bit streams
```

```
K = 1
```

```
N = log2(trellis_b.numOutputSymbols) % Number of output bit streams
```

```
N = 2
```

```
numReg = log2(trellis_b.numStates) % Number of coder registers
```

```
numReg = 2
```

```
numSymPerFrame = 10; % Number of symbols per frame
data = randi([0 1],K*numSymPerFrame,1);
code_b = convenc(data,trellis_b);
```

Verify that the encoded output is 20 bits, which is 2/1 (N/K) times the length of the input sequence, `data`.

```
code_b'
```

```
ans = 1×20

     0     0     1     1     0     0     1     0     1     0     1     1     0     1     1     1
```

```
length(data)
```

```
ans = 10
```

```
length(code_b)
```

```
ans = 20
```

Adjust Convolutional Encoding Code Rate by Using Puncturing

Use puncturing to adjust the K/N code rate of the convolutional encoder from 1/2 to 3/4.

Initialize parameters for the encoding operation.

```
trellis = poly2trellis(7,[171 133])
```

```
trellis = struct with fields:
     numInputSymbols: 2
    numOutputSymbols: 4
           numStates: 64
          nextStates: [64x2 double]
             outputs: [64x2 double]
```

```
puncpat = [1;1;0];
```

Calculate the unpunctured and punctured code rates.

```
K = log2(trellis.numInputSymbols); % Number of input streams
N = log2(trellis.numOutputSymbols); % Number of output streams
unpunc_coderate = K/N; % Unpunctured code rate
punc_coderate = (K/N)*length(puncpat)/sum(puncpat); % Punctured code rate
fprintf('K is %d and N is %d. The unpunctured code rate is %3.2f and the punctured code rate is %
```

```
K is 1 and N is 2. The unpunctured code rate is 0.50 and the punctured code rate is 0.75.
```

Convolutionally encode an all 1s three-bit message without puncturing applied to the coded output. Then, convolutionally encode the same message with puncturing.

```
msg = ones(length(puncpat),1);
unpuncturedcode = convenc(msg,trellis);
puncturedcode = convenc(msg,trellis,puncpat);
```

Show the message, the unpunctured code, the punctured code, and the puncture pattern.

```
msg'
```

```
ans = 1×3

     1     1     1
```

```
unpuncturedcode'
```

```
ans = 1×6

     1     1     0     1     1     0
```

```
puncpat'
```

```
ans = 1×3

     1     1     0
```

```
puncturedcode'
```

```
ans = 1×4

     1     1     1     1
```

Without puncturing, the configured convolutional encoding inputs three message bits and outputs six coded bits. Confirm the resulting code rate matches the expected code rate of 1/2.

```
length(msg)/length(unpuncturedcode)
```

```
ans = 0.5000
```

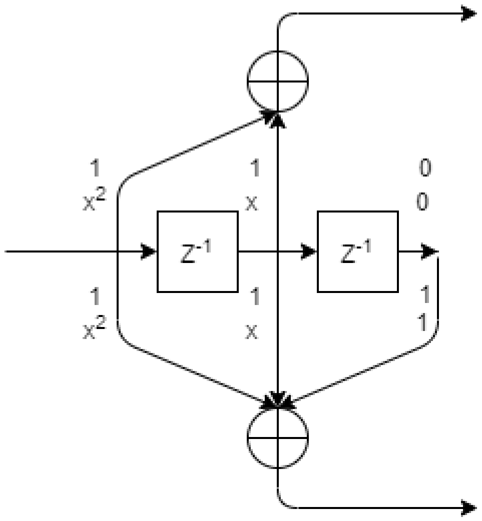
With puncturing, bits in positions 1 and 2 of the input message are transmitted, while the bit in position 3 is removed. For every three bits of input, the punctured code generates four bits of output. Confirm the resulting code rate matches the expected code rate of 3/4.

```
length(msg)/length(puncturedcode)
```

```
ans = 0.7500
```

Use Trellis Structure for Rate 1/2 Feedforward Convolutional Encoder

Use a trellis structure to configure the rate 1/2 feedforward convolutional code in this diagram.



Create a trellis structure, setting the constraint length to 3 and specifying the code generator as a vector of octal values. The diagram indicates the binary values and polynomial form, indicating the left-most bit is the most-significant-bit (MSB). The binary vector [1 1 0] represents octal 6 and corresponds to the upper row of binary digits in the diagram. The binary vector [1 1 1] represents octal 7 and corresponds to the lower row of binary digits in the diagram. These binary digits indicate connections from the outputs of the registers to the two adders in the diagram.

```
trellis = poly2trellis(3,[6 7])
```

```
trellis = struct with fields:
     numInputSymbols: 2
    numOutputSymbols: 4
           numStates: 4
          nextStates: [4x2 double]
             outputs: [4x2 double]
```

Generate random binary data. Convolutionally encode the data, by using the specified trellis structure. Decode the coded data by using the Viterbi algorithm with the specified trellis structure, 34 for its traceback depth, truncated operation mode, and hard decisions.

```
data = randi([0 1],70,1);
codedData = convenc(data,trellis);
tbdepth = 34;
decodedData = vitdec(codedData,trellis,tbdepth,'trunc','hard');
```

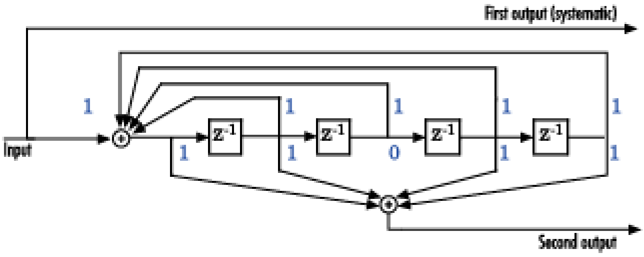
Verify the decoded data has zero bit errors.

```
biterr(data,decodedData)
```

```
ans = 0
```

Use Trellis Structure for Rate 1/2 Feedback Convolutional Encoder

Create a trellis structure to represent the rate 1/2 systematic convolutional encoder with feedback shown in this diagram.



This encoder has 5 for its constraint length, [37 33] as its generator polynomial matrix, and 37 for its feedback connection polynomial.

The first generator polynomial is octal 37. The second generator polynomial is octal 33. The feedback polynomial is octal 37. The first generator polynomial matches the feedback connection polynomial because the first output corresponds to the systematic bits.

The binary vector [1 1 1 1 1] represents octal 37 and corresponds to the upper row of binary digits in the diagram. The binary vector [1 1 0 1 1] represents octal 33 and corresponds to the lower row of binary digits in the diagram. These binary digits indicate connections from the outputs of the registers to the two adders in the diagram. The initial 1 corresponds to the input bit.

Convert the polynomial to a trellis structure by using the `poly2trellis` function. When used with a feedback polynomial, `poly2trellis` makes a feedback connection to the input of the trellis.

```
trellis = poly2trellis(5,[37 33],37)
```

```
trellis = struct with fields:
     numInputSymbols: 2
    numOutputSymbols: 4
           numStates: 16
          nextStates: [16x2 double]
             outputs: [16x2 double]
```

Generate random binary data. Convolutionally encode the data by using the specified trellis structure. Decode the coded data by using the Viterbi algorithm with the specified trellis structure, 34 for its traceback depth, truncated operation mode, and hard decisions.

```
data = randi([0 1],70,1);
codedData = convenc(data,trellis);
tbdepth = 34; % Traceback depth for Viterbi decoder
decodedData = vitdec(codedData,trellis,tbdepth,'trunc','hard');
```

Verify the decoded data has zero bit errors.

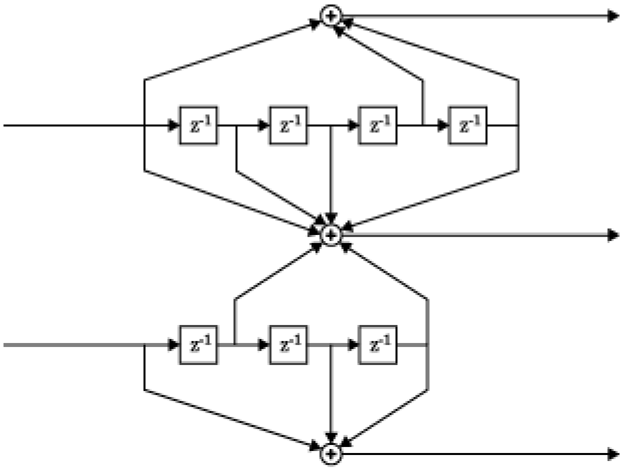
```
biterr(data,decodedData)
```

```
ans = 0
```

Compare Full Message to Piecewise Message Convolutional Encoding

Compare the convolutional encoding of a full message to the convolutional encoding of a message in two segments.

This diagram shows a rate 2/3 encoder with two input streams, three output streams, and seven shift registers.



Define the trellis structure in the diagram by using the `poly2trellis` function. Set the constraint length of the upper path to 5 and the constraint length of the lower path to 4. The octal representation of the code generator matrix corresponds to the taps from the upper and lower shift registers.

```
trellis = poly2trellis([5 4],[23 35 0; 0 5 13]);
```

Inspect the coder configuration.

```
K = log2(trellis.numInputSymbols) % Number of input bit streams
```

```
K = 2
```

```
N = log2(trellis.numOutputSymbols) % Number of output bit streams
```

```
N = 3
```

```
coderate = K/N
```

```
coderate = 0.6667
```

```
numReg = log2(trellis.numStates) % Number of coder registers
```

```
numReg = 7
```

Define a message with five two-bit input symbols.

```
numSymPerFrame = 5; % Number of symbols per frame
msg = randi([0 1],K*numSymPerFrame,1);
```

Encode the full message by using the trellis to configure the `convenc` function.

```
[code_a,fstate_a] = convenc(msg,trellis);
```

Apply piecewise message encoding by using the same trellis structure. Use the final and initial state arguments when using the `convenc` function. For piecewise message encoding, message segments must be a multiple of the number of bits in an input symbol.

Encode part of the message, recording the final state for later use.

```
[code_a1,fstate_a1] = convenc(msg(1:6),trellis);
```

Encode the rest of the message, using the final state, `fstate_a1`, as the initial state input argument.

```
[code_a2,fstate_a2] = convenc(msg(7:end),trellis,fstate_a1);
```

Verify that the full coded message, `code_a`, matches the concatenated piecewise coded message, `[code_a1; code_a2]`.

```
isequal(code_a,[code_a1; code_a2])
```

```
ans = logical
   1
```

Verify that the final state, `fstate_a`, of the encoder after the full message encoding matches the final state, `fstate_a2`, of the encoder after piecewise message encoding.

```
isequal(fstate_a,fstate_a2)
```

```
ans = logical
   1
```

Input Arguments

`msg` — Binary message

vector of binary values

Binary message, specified as a vector of binary values. `msg` must contain one or more symbols. Each symbol must consist of log2(`trellis`.`numInputSymbols`) bits.

Example: `[1 1 0 1 0 0 1 1]` specifies the message as a binary row vector with eight elements.

Data Types: `double` | `logical`

`trellis` — Trellis description

structure

Trellis description, specified as a MATLAB structure that contains the trellis description for a rate *K*/*N* code. *K* represents the number of input bit streams, and *N* represents the number of output bit streams.

The trellis structure contains these fields. You can either use the `poly2trellis` function to create the trellis structure or create it manually. For more about this structure, see “Trellis Description of a Convolutional Code” and the `istrellis` function.

`numInputSymbols` — Number of symbols input to encoder

2^K

Number of symbols input to the encoder, specified as an integer equal to 2^K, where K is the number of input bit streams.

Data Types: `double`

`numOutputSymbols` — Number of symbols output from encoder
2^N

Number of symbols output from the encoder, specified as an integer equal to 2^N, where N is the number of output bit streams.

Data Types: `double`

`numStates` — Number of states in encoder
power of 2

Number of states in the encoder, specified as a power of 2.

Data Types: `double`

`nextStates` — Next states
matrix of integers

Next states for all combinations of current states and current inputs, specified as a matrix of integers. The matrix size must be `numStates`-by-2^K.

Data Types: `double`

`outputs` — Outputs
matrix of octal numbers

Outputs for all combinations of current states and current inputs, specified as a matrix of octal numbers. The matrix size must be `numStates`-by-2^K.

Data Types: `double`

Data Types: `struct`

`puncpat` — Puncture pattern
vector of binary values

Puncture pattern, specified as a vector of binary values. Indicate punctured bits with `0`s and unpunctured bits with `1`s. The length of the `puncpat` vector must be an integer divisor of the input message vector length, `length(msg)`.

Data Types: `double`

`istate` — Initial state
integer scalar

Initial state used for the encoder registers, specified as an integer scalar in the range [0, (`trellis.numStates` – 1)].

Data Types: `double`

Output Arguments

`codedout` — Convolutionally encoded message

vector of binary values

Convolutionally encoded message, returned as a vector of binary values. This output vector has the same data type and orientation as input `msg`. Each symbol in `codedout` consists of log2(`trellis`.`numOutputSymbols`) bits.

Data Types: `double` | `logical`

`fstate` — Final state

integer scalar

Final state of the encoder registers, returned as an integer scalar. When calling `convenc` iteratively, such as in a loop, `fstate` is typically used to set `istate` for subsequent calls to the `convenc` function.

Data Types: `double`

More About

Convolutional Coding

Convolutional coding is an error-control coding that has memory. Specifically, the computations and coded output depend on the current set of input symbols and on a number of previous input symbols that varies depending on the trellis configuration. A convolutional encoder accepts a fixed number of message symbols and produces a fixed number of code symbols.

Using a trellis structure that defines a set of generator polynomials, you can model nonsystematic, systematic feedforward, or systematic feedback convolutional codes. Examples on this page demonstrate various convolutional code architectures. For more information, see “Convolutional Codes”.

To decode the convolutionally coded output, you can use:

- The `vitdec` function or `comm.ViterbiDecoder` System object™ — Uses the Viterbi algorithm with hard-decision and soft-decision decoding
- The `comm.APPDecoder` System object — Uses an *a posteriori* probability decoder for the soft output decoding of convolutional codes

convintrlv

Permute symbols using shift registers

Syntax

```
intrlved = convintrlv(data,nrows,slope)
[intrlved,state] = convintrlv(data,nrows,slope)
[intrlved,state] = convintrlv(data,nrows,slope,init_state)
```

Description

`intrlved = convintrlv(data,nrows,slope)` permutes the elements in `data` by using a set of `nrows` internal shift registers. The delay value of the kth shift register is `(k-1)*slope`, where k = 1, 2, 3,... `nrows`. Before the function begins to process data, it initializes all shift registers with zeros. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

`[intrlved,state] = convintrlv(data,nrows,slope)` returns a structure that holds the final state of the shift registers. `state.value` stores any unshifted symbols. `state.index` is the index of the next register to be shifted.

`[intrlved,state] = convintrlv(data,nrows,slope,init_state)` initializes the shift registers with the symbols contained in `init_state.value` and directs the first input symbol to the shift register referenced by `init_state.index`. The structure `init_state` is typically the `state` output from a previous call to this same function, and is unrelated to the corresponding deinterleaver.

Examples

The example below shows that `convintrlv` is a special case of the more general function `muxintrlv`. Both functions yield the same numerical results.

```
x = randi([0 1],100,1); % Original data
nrows = 5; % Use 5 shift registers
slope = 3; % Delays are 0, 3, 6, 9, and 12.
y = convintrlv(x,nrows,slope); % Interleaving using convintrlv.
delay = [0:3:12]; % Another way to express set of delays
y1 = muxintrlv(x,delay); % Interleave using muxintrlv.
isequal(y,y1)
```

The output below shows that `y`, obtained using `convintrlv`, and `y1`, obtained using `muxintrlv`, are the same.

```
ans =

     1
```

Another example using this function is in “Effect of Delays on Recovery of Convolutionally Interleaved Data Using MATLAB”.

The example on the `muxdeintrlv` reference page illustrates how to use the `state` output and `init_state` input with that function; the process is analogous for this function.

convmtx

Convolution matrix of Galois field vector

Syntax

```
A = convmtx(c,n)
```

Description

A *convolution matrix* is a matrix, formed from a vector, whose inner product with another vector is the convolution of the two vectors.

`A = convmtx(c,n)` returns a convolution matrix for the Galois vector `c`. The output `A` is a Galois array that represents convolution with `c` in the sense that `conv(c,x)` equals

- `A*x`, if `c` is a column vector and `x` is any Galois column vector of length `n`. In this case, `A` has `n` columns and `m+n-1` rows.
- `x*A`, if `c` is a row vector and `x` is any Galois row vector of length `n`. In this case, `A` has `n` rows and `m+n-1` columns.

Examples

The code below illustrates the equivalence between using the `conv` function and multiplying by the output of `convmtx`.

```
m = 4;
c = gf([1; 9; 3],m); % Column vector
n = 6;
x = gf(randi([0 2^m-1],n,1),m);
ck1 = isequal(conv(c,x), convmtx(c,n)*x) % True
ck2 = isequal(conv(c',x'),x'*convmtx(c',n)) % True
```

The output is

```
ck1 =

     1

ck2 =

     1
```

cosets

Produce cyclotomic cosets for Galois field

Syntax

```
cst = cosets(m)
```

Description

`cst = cosets(m)` produces cyclotomic cosets mod `2^m-1`. Each element of the cell array `cst` is a Galois array that represents one cyclotomic coset.

A cyclotomic coset is a set of elements that share the same minimal polynomial. Together, the cyclotomic cosets mod `2^m-1` form a partition of the group of nonzero elements of GF(`2^m`). For more details on cyclotomic cosets, see the works listed in “References” on page 2-241.

Examples

The commands below find and display the cyclotomic cosets for GF(8). As an example of interpreting the results, `c{2}` indicates that A, A^2, and $A^2 + A$ share the same minimal polynomial, where A is a primitive element for GF(8).

```
c = cosets(3);
c{1}'
c{2}'
c{3}'
```

The output is below.

```
ans = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)

Array elements =

     1

ans = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)

Array elements =

     2     4     6

ans = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)

Array elements =

     3     5     7
```

crc.detector

(To be removed) Construct CRC detector object

Note will be removed in a future release. To detect errors in input data using cyclic redundancy check (CRC), use the `comm.CRCDetector` System object instead. For more details on the recommended workflow, see “Compatibility Considerations”.

Syntax

```
h= crc.detector(polynomial)
```

```
h= crc.detector(generatorObj)
```

```
h= crc.detector(‘Polynomial’, polynomial, ‘param1’, val1, etc.)
```

```
h= crc.detector
```

Description

`h= crc.detector(polynomial)` constructs a CRC detector object H defined by the generator polynomial POLYNOMIAL

`h= crc.detector(generatorObj)` constructs a CRC detector object H defined by the parameters found in the CRC generator object GENERATOROBJ

`h= crc.detector('property1', val1, ...)` constructs a CRC detector object H with properties as specified by PROPERTY/VALUE pairs.

`h= crc.detector` constructs a CRC detector object H with default properties. It constructs a CRC-CCITT detector, and is equivalent to:

```
h=
crc.detector('Polynomial','0x1021','InitialState','0xFFFF','ReflectInput',fal
se,'ReflectRemainder',false,'FinalXOR','0x0000')
```

Properties

The following table describes the properties of a CRC detector object. All properties are writable, except `Type`.

Property	Description
Type	Specifies the object as a 'CRC Detector'.

Property	Description
`Polynomial`	The generator polynomial that defines connections for a linear feedback shift register. This property can be specified as a binary vector representing descending powers of the polynomial. In this case, the leading '1' of the polynomial must be included. It can also be specified as a string, prefaced by '0x', that is a hexadecimal representation of the descending powers of the polynomial. In this case, the leading '1' of the polynomial is omitted.
`InitialState`	The initial contents of the shift register. This property can be specified as a binary scalar, a binary vector, or as a string, prefaced by '0x', that is a hexadecimal representation of the binary vector. As a binary vector, its length must be one less than the length of the binary vector representation of the Polynomial.
`ReflectInput`	A Boolean quantity that specifies whether the input data should be flipped on a bytewise basis prior to entering the shift register.
`ReflectRemainder`	A Boolean quantity that specifies whether the binary output CRC checksum should be flipped around its center after the input data is completely through the shift register.
`FinalXOR`	The value with which the CRC checksum is to be XORed just prior to detecting the input data. This property can be specified as a binary scalar, a binary vector or as a string, prefaced by '0x', that is a hexadecimal representation of the binary vector. As a binary vector, its length must be one less than the length of the binary vector representation of the Polynomial.

A detect method is used with the object to detect errors in digital transmission.

CRC Generation Algorithm

For information pertaining to the CRC generation algorithm, see “Cyclic Redundancy Check Codes”.

Detector Method

`[OUTDATA ERROR] = DETECT(H, INDATA)` detects transmission errors in the encoded input message `INDATA` by regenerating a CRC checksum using the CRC detector object H. The detector then compares the regenerated checksum with the checksum appended to INDATA. The binary-valued INDATA can be either a column vector or a matrix. If it is a matrix, each column is considered to be a separate channel. OUTDATA is identical to the input message INDATA, except that it has the CRC checksum stripped off. ERROR is a 1xC logical vector indicating if the encoded message INDATA has errors, where C is the number of channels in INDATA. An ERROR value of 0 indicates no errors, and a value of 1 indicates errors.

Examples

Create a CRC-16 CRC generator, then use it to generate a checksum for the binary vector represented by the ASCII sequence '123456789'. Introduce an error, then detect it using a CRC-16 CRC detector.

```
gen = crc.generator('Polynomial', '0x8005', 'ReflectInput', ...
true, 'ReflectRemainder', true);
det = crc.detector('Polynomial', '0x8005', 'ReflectInput', ...
true, 'ReflectRemainder', true);
% The message below is an ASCII representation
% of the digits 1-9
msg = reshape(de2bi(49:57, 8, 'left-msb')', 72, 1);
encoded = generate(gen, msg);
encoded(1) = ~encoded(1);                % Introduce an error
[outdata error] = detect(det, encoded);  % Detect the error
noErrors = isequal(msg, outdata)         % Should be 0
error                                    % Should be 1
```

This example generates the following output:

```
noErrors = 0 error = 1
```

Compatibility Considerations

`crc.detector` will be removed in a future release.
Warns starting in R2020b

crc.detector will be removed in a future release. To detect errors in input data using cyclic redundancy check (CRC), use the `comm.CRCDetector` System object instead.

Replace instances of crc.detector with a `comm.CRCDetector` System object. Note the mapping between crc.detector properties and `comm.CRCDetector` properties:

crc.detector	comm.CRCDetector
Polynomial	Polynomial
InitialState	InitialConditions
ReflectInput	ReflectInputBytes
ReflectRemainder	ReflectChecksums
FinalXOR	FinalXOR

crc.generator

(To be removed) Construct CRC generator object

Note will be removed in a future release. To generate cyclic redundancy check (CRC) code bits, use the `comm.CRCGenerator` System object instead. For more details on the recommended workflow, see “Compatibility Considerations”.

Syntax

```
h = crc.generator(polynomial)
```

```
h = crc.generator(detectorObj)
```

```
h = crc.generator(‘Polynomial’, polynomial, ‘param1’, val1, etc.)
```

```
h = crc.generator
```

Description

`h = crc.generator(polynomial)` constructs a CRC generator object H defined by the generator polynomial POLYNOMIAL.

`h = crc.generator(detectorObj)` constructs a CRC generator object H defined by the parameters found in the CRC detector object DETECTOROBJ.

`h = crc.generator(‘property1', val1, ...)` constructs a CRC generator object H with properties as specified by the PROPERTY/VALUE pairs.

`h = crc.generator` constructs a CRC generator object H with default properties. It constructs a CRC-CCITT generator, and is equivalent to: h = crc.generator('Polynomial', '0x1021', 'InitialState', '0xFFFF', ...

'ReflectInput', false, 'ReflectRemainder', false, 'FinalXOR', '0x0000').

Properties

The following table describes the properties of a CRC generator object. All properties are writable, except `Polynomial`.

Property	Description
`Polynomial`	The generator polynomial that defines connections for a linear feedback shift register. This property can be specified as a binary vector representing descending powers of the polynomial. In this case, the leading '1' of the polynomial must be included. It can also be specified as a string, prefaced by '0x', that is a hexadecimal representation of the descending powers of the polynomial. In this case, the leading '1' of the polynomial is omitted.
`InitialState`	The initial contents of the shift register. This property can be specified as a binary scalar, a binary vector, or as a string, prefaced by '0x', that is a hexadecimal representation of the binary vector. As a binary vector, its length must be one less than the length of the binary vector representation of the Polynomial.
`ReflectInput`	A Boolean quantity that specifies whether the input data should be flipped on a bytewise basis prior to entering the shift register.
`ReflectRemainder`	A Boolean quantity that specifies whether the binary output CRC checksum should be flipped around its center after the input data is completely through the shift register.
`FinalXOR`	The value with which the CRC checksum is to be XORed just prior to being appended to the input data. This property can be specified as a binary scalar, a binary vector, or as a string, prefaced by '0x', that is a hexadecimal representation of the binary vector. As a binary vector, its length must be one less than the length of the binary vector representation of the Polynomial.

CRC Generation Algorithm

For information pertaining to the CRC generation algorithm, refer to the “CRC Non-Direct Algorithm” section of the Communications Toolbox User's Guide.

Generator Method

encoded = generate(h, msg) generates a CRC checksum for an input message using the CRC generator object H. It appends the checksum to the end of MSG. The binary-valued MSG can be either a column vector or a matrix. If it is a matrix, then each column is considered to be a separate channel.

Examples

Create a CRC-16 CRC generator, then use it to generate a checksum for the binary vector represented by the ASCII sequence '123456789'.

```
gen = crc.generator('Polynomial', '0x8005', ...
'ReflectInput', true, 'ReflectRemainder', true);
```

The message below is an ASCII representation of the digits 1-9.

```
msg = reshape(de2bi(49:57, 8, 'left-msb')', 72, 1);
encoded = generate(gen, msg);
```

```
h =

                Type: CRC Generator
          Polynomial: 0xF
        InitialState: 0xF
        ReflectInput: true
    ReflectRemainder: false
            FinalXOR: 0x0
```

Compatibility Considerations

General CRC Generator | General CRC Syndrome Detector

Introduced in R2008a

cyclgen

Produce parity-check and generator matrices for cyclic code

Syntax

```
h = cyclgen(n,pol)
h = cyclgen(n,pol,opt)
[h,g] = cyclgen(...)
[h,g,k] = cyclgen(...)
```

Description

For all syntaxes, the codeword length is `n` and the message length is `k`. A polynomial can generate a cyclic code with codeword length `n` and message length `k` if and only if the polynomial is a degree-(`n-k`) divisor of x^n-1. (Over the binary field GF(2), x^n-1 is the same as x^n+1.) This implies that `k` equals `n` minus the degree of the generator polynomial.

`h = cyclgen(n,pol)` produces an (`n-k`)-by-`n` parity-check matrix for a systematic binary cyclic code having codeword length `n`. The row vector `pol` gives the binary coefficients, in order of ascending powers, of the degree-(`n-k`) generator polynomial. Alternatively, you can specify `pol` as a polynomial character vector. For more information, see “Character Representation of Polynomials”.

`h = cyclgen(n,pol,opt)` is the same as the syntax above, except that the argument *`opt`* determines whether the matrix should be associated with a systematic or nonsystematic code. The values for *`opt`* are `'system'` and `'nonsys'`.

`[h,g] = cyclgen(...)` is the same as `h = cyclgen(...)`, except that it also produces the `k`-by-`n` generator matrix `g` that corresponds to the parity-check matrix `h`.

`[h,g,k] = cyclgen(...)` is the same as `[h,g] = cyclgen(...)`, except that it also returns the message length `k`.

Examples

Parity Check and Generator Matrices for Binary Cyclic Codes

Create parity check and generator matrices for a binary cyclic code having codeword length 7 and message length 4.

Create the generator polynomial using `cyclpoly`.

```
pol = cyclpoly(7,4);
```

Create the parity check and generator matrices. The parity check matrix `parmat` has a 3-by-3 identity matrix embedded in its leftmost columns.

```
[parmat,genmat,k] = cyclgen(7,pol)
```

```
parmat = 3×7
```

```
     1     0     0     1     1     1     0
     0     1     0     0     1     1     1
     0     0     1     1     1     0     1
```

```
genmat = 4×7

     1     0     1     1     0     0     0
     1     1     1     0     1     0     0
     1     1     0     0     0     1     0
     0     1     1     0     0     0     1
```

```
k = 4
```

Create a parity check matrix in which the code is not systematic. The matrix `parmatn` does not have an embedded 3-by-3 identity matrix.

```
parmatn = cyclgen(7,pol,'nonsys')
```

```
parmatn = 3×7

     1     1     1     0     1     0     0
     0     1     1     1     0     1     0
     0     0     1     1     1     0     1
```

Create the parity check and generator matrices for a (7,3) binary cyclic code. As this is a systematic code, there is a 4-by-4 identity matrix in the leftmost columns of `parmat2`.

```
parmat2 = cyclgen(7,'1 + x^2 + x^3 + x^4')
```

```
parmat2 = 4×7

     1     0     0     0     1     1     0
     0     1     0     0     0     1     1
     0     0     1     0     1     1     1
     0     0     0     1     1     0     1
```

Topics

“Block Codes”

Introduced before R2006a

cyclpoly

Produce generator polynomials for cyclic code

Syntax

```
pol = cyclpoly(n,k)
pol = cyclpoly(n,k,opt)
```

Description

For all syntaxes, a polynomial is represented as a row containing the coefficients in order of ascending powers.

`pol = cyclpoly(n,k)` returns the row vector representing one nontrivial generator polynomial for a cyclic code having codeword length `n` and message length `k`.

`pol = cyclpoly(n,k,opt)` searches for one or more nontrivial generator polynomials for cyclic codes having codeword length `n` and message length `k`. The output `pol` depends on the argument *`opt`* as shown in the table below.

opt	Significance of pol	Format of pol
`'min'`	One generator polynomial having the smallest possible weight	Row vector representing the polynomial
`'max'`	One generator polynomial having the greatest possible weight	Row vector representing the polynomial
`'all'`	All generator polynomials	Matrix, each row of which represents one such polynomial
a positive integer, *L*	All generator polynomials having weight *L*	Matrix, each row of which represents one such polynomial

The weight of a binary polynomial is the number of nonzero terms it has. If no generator polynomial satisfies the given conditions, the output `pol` is empty and a warning message is displayed.

Examples

Cyclic Code Generator Polynomials

Create [15,4] cyclic code generator polynomials.

Use the input `'all'` to show all possible generator polynomials for a [15,4] cyclic code. Use the input `'max'` to show that $1 + x + x^2 + x^3 + x^5 + x^7 + x^8 + x^{11}$ is one such polynomial that has the largest number of nonzero terms.

```
c1 = cyclpoly(15,4,'all')
```

```
c1 = 3×12
```

```
     1     1     0     0     0     1     1     0     0     0     1     1
     1     0     0     1     1     0     1     0     1     1     1     1
     1     1     1     1     0     1     0     1     1     0     0     1
```

```
c2 = cyclpoly(15,4,'max')
```

```
c2 = 1×12

     1     1     1     1     0     1     0     1     1     0     0     1
```

This command shows that no generator polynomial for a [15,4] cyclic code has exactly three nonzero terms.

```
c3 = cyclpoly(15,4,3)
```

```
Warning: No cyclic generator polynomial satisfies the given constraints.

Algorithms

If *opt* is `'min'`, `'max'`, or omitted, polynomials are constructed by converting decimal integers to base `p`. Based on the decimal ordering, `gfprimfd` returns the first polynomial it finds that satisfies the appropriate conditions. This algorithm is similar to the one used in `gfprimfd`.

“Block Codes”

Introduced before R2006a

de2bi

Convert decimal numbers to binary vectors

Syntax

```
b = de2bi(d)
b = de2bi(d,n)
b = de2bi(d,n,p)
b = de2bi(d,[],p)
b = de2bi(d,___,flg)
```

Description

`b = de2bi(d)` converts a nonnegative decimal integer `d` to a binary row vector. If `d` is a vector, the output `b` is a matrix in which each row is the binary form of the corresponding element in `d`.

`b = de2bi(d,n)` has an output with `n` columns.

`b = de2bi(d,n,p)` converts a nonnegative decimal integer `d` to a base-`p` row vector.

`b = de2bi(d,[],p)` specifies the base, `p` .

`b = de2bi(d,___,flg)` uses `flg` to determine whether the first column of `b` contains the lowest-order or highest-order digits.

Examples

Convert Decimals to Binary Numbers

Convert decimals 1 through 10 into their equivalent binary representations.

```
d = (1:10)';
b = de2bi(d);
[d b]
```

```
ans = 10×5

     1     1     0     0     0
     2     0     1     0     0
     3     1     1     0     0
     4     0     0     1     0
     5     1     0     1     0
     6     0     1     1     0
     7     1     1     1     0
     8     0     0     0     1
     9     1     0     0     1
    10     0     1     0     1
```

Convert 3 and 9 to binary numbers. Each value is represented by a four-element row.

```
b = de2bi([3 9])
```

```
b = 2×4

     1     1     0     0
     1     0     0     1
```

Repeat the conversion with the number of columns set to 5. The output is now padded with zeros in the fifth column.

```
bb = de2bi([3 9],5)
```

```
bb = 2×5

     1     1     0     0     0
     1     0     0     1     0
```

Convert Decimals to Base-3 Numbers

Convert the decimals 1 through 6 to their base-3 equivalents. Set the leftmost bit as the most significant digit.

```
d = (1:6)';
t = de2bi(d,[],3,'left-msb');
[d t]
```

```
ans = 6×3

     1     0     1
     2     0     2
     3     1     0
     4     1     1
     5     1     2
     6     2     0
```

Convert Decimal to Binary

This example shows how to convert decimals to binary numbers in their base-2 equivalents.

```
d_array = [1 2 3 4];
```

Convert the decimal array to binary by using the `de2bi` function. Specify that the most significant digit is the leftmost element and set the number of desired columns to 5. The output becomes a 4-by-5 matrix where each row corresponds to a decimal value from the input. Because the largest decimal value in `d_array` can be expressed in 3 columns, the `de2bi` pads the matrix with two extra zero columns at the specified most-significant bit side. If you specify too few columns, the conversion will fail.

```
b_array = de2bi(d_array,5,'left-msb')
b_array = 4×5

     0     0     0     0     1
     0     0     0     1     0
     0     0     0     1     1
     0     0     1     0     0
```

```
b_array = de2bi(d_array,5,'right-msb')
```

```
b_array = 4×5

     1     0     0     0     0
     0     1     0     0     0
     1     1     0     0     0
     0     0     1     0     0
```

If you do not specify a number of columns, the number of columns is exactly what is needed to express the largest decimal of the input.

```
b_array = de2bi(d_array,'left-msb')
```

```
b_array = 4×3

     0     0     1
     0     1     0
     0     1     1
     1     0     0
```

The output rows for specifying a leftmost-significant bit correspond to:

$$1 = 0(2^2) + 0(2^1) + 1(2^0)$$

$$2 = 0(2^2) + 1(2^1) + 0(2^0)$$

$$3 = 0(2^2) + 1(2^1) + 1(2^0)$$

$$4 = 1(2^2) + 0(2^1) + 0(2^0)$$

```
b_array = de2bi(d_array,'right-msb')
```

```
b_array = 4×3

     1     0     0
     0     1     0
     1     1     0
     0     0     1
```

The output rows for specifying a rightmost-significant bit correspond to:

$$1 = 1(2^0) + 0(2^1) + 0(2^2)$$

$$2 = 0(2^0) + 1(2^1) + 0(2^2)$$

$3 = 1(2^0) + 1(2^1) + 0(2^2)$

$4 = 0(2^0) + 0(2^1) + 1(2^2)$

Input Arguments

d — Decimal input
nonnegative integer | vector | matrix

Decimal input, specified as a nonnegative integer, vector, or matrix. If d is a matrix, it is treated like the column vector `d(:)`.

Note To ensure an accurate conversion, d must be less than or equal to 2^{52}.

Data Types: `double` | `single` | `integer` | `fi`

n — Number of output columns
positive integer scalar

The number of output columns specified as a positive scalar. If necessary, the binary representation of d is padded with extra zeros.

Data Types: `double` | `single`

p — Base
2 (default) | positive integer scalar

Base of the output b, specified as an integer greater than or equal to 2.

- If d is a vector, the output b is a matrix in which each row is the base-p form of the corresponding element in d.
- If d is a matrix, `de2bi` treats it like the vector `d(:)`.

Data Types: `double` | `single`

`flg` — MSB flag
`'right-msb'` (default) | `'left-msb'`

MSB flag, specified as `'right-msb'` or `'left-msb'`.

- `'right-msb'` –- Indicates the right (or last) column of the binary output, b, as the most significant bit (or highest-order digit).
- `'left-msb'` –- Indicates the left (or first) column of the binary output, b, as the most significant bit (or highest-order digit).

Data Types: `char` | `string`

Output Arguments

b — Binary output
vector | matrix

Binary representation of d, returned as a row vector or matrix. The output is of the same data type as the input.

decode

Block decoder

Syntax

```
msg = decode(code,n,k,'hamming/fmt',prim_poly)
msg = decode(code,n,k,'linear/fmt',genmat,trt)
msg = decode(code,n,k,'cyclic/fmt',genpoly,trt)
msg = decode(code,n,k)
[msg,err] = decode(...)
[msg,err,ccode] = decode(...)
[msg,err,ccode,cerr] = decode(...)
```

Optional Inputs

Input	Default Value
fmt	binary
prim_poly	gfprimdf(m) where n = 2^m-1
genpoly	cyclpoly(n,k)
trt	Uses syndtable to create the syndrome decoding table associated with the method's parity-check matrix

Description

For All Syntaxes

The decode function aims to recover messages that were encoded using an error-correction coding technique. The technique and the defining parameters must match those that were used to encode the original signal.

The encode reference page explains the meanings of n and k, the possible values of *fmt*, and the possible formats for code and msg. You should be familiar with the conventions described there before reading the rest of this section. Using the decode function with an input argument code that was *not* created by the encode function might cause errors.

For Specific Syntaxes

msg = decode(code,n,k,'hamming/*fmt*',prim_poly) decodes code using the Hamming method. For this syntax, n must have the form 2^m-1 for some integer m greater than or equal to 3, and k must equal n-m. prim_poly is a polynomial character vector or a row vector that gives the binary coefficients, in order of ascending powers, of the primitive polynomial for GF(2^m) that is used in the encoding process. The default value of prim_poly is gfprimdf(m). The decoding table that the function uses to correct a single error in each codeword is syndtable(hammgen(m)).

msg = decode(code,n,k,'linear/*fmt*',genmat,trt) decodes code, which is a linear block code determined by the k-by-n generator matrix genmat. genmat is required as input. decode tries to correct errors using the decoding table trt, where trt is a 2^(n-k)-by-n matrix.

`msg = decode(code,n,k,'cyclic/fmt',genpoly,trt)` decodes the cyclic code `code` and tries to correct errors using the decoding table `trt`, where `trt` is a `2^(n-k)`-by-`n` matrix. `genpoly` is a polynomial character vector or a row vector that gives the coefficients, in order of ascending powers, of the binary generator polynomial of the code. The default value of `genpoly` is `cyclpoly(n,k)`. By definition, the generator polynomial for an [`n`, `k`] cyclic code must have degree `n-k` and must divide x^n`-1`.

`msg = decode(code,n,k)` is the same as `msg = decode(code,n,k,'hamming/binary')`.

`[msg,err] = decode(...)` returns a column vector `err` that gives information about error correction. If the code is a convolutional code, `err` contains the metric calculations used in the decoding decision process. For other types of codes, a nonnegative integer in the rth row of `err` indicates the number of errors corrected in the rth *message* word; a negative integer indicates that there are more errors in the rth word than can be corrected.

`[msg,err,ccode] = decode(...)` returns the corrected code in `ccode`.

`[msg,err,ccode,cerr] = decode(...)` returns a column vector `cerr` whose meaning depends on the format of `code`:

- If `code` is a binary vector, a nonnegative integer in the rth row of `vec2matcerr` indicates the number of errors corrected in the rth *codeword*; a negative integer indicates that there are more errors in the rth codeword than can be corrected.
- If `code` is not a binary vector, `cerr = err`.

Examples

Encode and Decode Message with Hamming Code

Set the values of the codeword length and message length.

```
n = 15; % Codeword length
k = 11; % Message length
```

Create a random binary message with length equal to the message length.

```
data = randi([0 1],k,1);
```

Encode the message.

```
encData = encode(data,n,k,'hamming/binary');
```

Corrupt the encoded message sequence by introducing an error in the fourth bit.

```
encData(4) = ~encData(4);
```

Decode the corrupted sequence. Observe that the decoder has correctly recovered the message.

```
decData = decode(encData,n,k,'hamming/binary');
numerr = biterr(data,decData)
```

```
numerr = 0
```

Algorithms

Depending on the decoding method, decode relies on such lower-level functions as hammgen, syndtable, and cyclgen.

deintrlv

Restore ordering of symbols

Syntax

```
deintrlvd = deintrlv(data,elements)
```

Description

`deintrlvd = deintrlv(data,elements)` restores the original ordering of the elements of `data` by acting as an inverse of `intrlv`. If `data` is a length-N vector or an N-row matrix, `elements` is a length-N vector that permutes the integers from 1 to N. To use this function as an inverse of the `intrlv` function, use the same `elements` input in both functions. In that case, the two functions are inverses in the sense that applying `intrlv` followed by `deintrlv` leaves data unchanged.

Examples

The code below illustrates the inverse relationship between `intrlv` and `deintrlv`.

```
p = randperm(10); % Permutation vector
a = intrlv(10:10:100,p); % Rearrange [10 20 30 ... 100].
b = deintrlv(a,p) % Deinterleave a to restore ordering.
```

The output is

```
b =

    10    20    30    40    50    60    70    80    90   100
```

“Interleaving”

Introduced before R2006a

dfe

(To be removed) Construct decision-feedback equalizer object

Note will be removed in a future release. Use `comm.DecisionFeedback` instead.

Syntax

```
eqobj = dfe(nfwdweights,nfbkweights,alg)
eqobj = dfe(nfwdweights,nfbkweights,alg,sigconst)
eqobj = dfe(nfwdweights,nfbkweights,alg,sigconst,nsamp)
```

Description

The `dfe` function creates an equalizer object that you can use with the `equalize` function to equalize a signal. To learn more about the process for equalizing a signal, see “Equalization”.

`eqobj = dfe(nfwdweights,nfbkweights,alg)` constructs a decision feedback equalizer object. The equalizer's feedforward and feedback filters have `nfwdweights` and `nfbkweights` symbol-spaced complex weights, respectively, which are initially all zeros. `alg` describes the adaptive algorithm that the equalizer uses; you should create `alg` using any of these functions: `lms`, `signlms`, `normlms`, `varlms`, `rls`, or `cma`. The signal constellation of the desired output is `[-1 1]`, which corresponds to binary phase shift keying (BPSK).

`eqobj = dfe(nfwdweights,nfbkweights,alg,sigconst)` specifies the signal constellation vector of the desired output.

`eqobj = dfe(nfwdweights,nfbkweights,alg,sigconst,nsamp)` constructs a DFE with a fractionally spaced forward filter. The forward filter has `nfwdweights` complex weights spaced at `T/nsamp`, where `T` is the symbol period and `nsamp` is a positive integer. `nsamp = 1` corresponds to a symbol-spaced forward filter.

Properties

The table below describes the properties of the decision feedback equalizer object. To learn how to view or change the values of a decision feedback equalizer object, see “Equalization”.

Note To initialize or reset the equalizer object `eqobj`, enter `reset(eqobj)`.

Property	Description
`EqType`	Fixed value, `'Decision Feedback Equalizer'`
`AlgType`	Name of the adaptive algorithm represented by `alg`

Property	Description
nWeights	Number of weights in the forward filter and the feedback filter, in the format [nfwdweights, nfbkweights]. The number of weights in the forward filter must be at least 1.
nSampPerSym	Number of input samples per symbol (equivalent to nsamp input argument). This value relates to both the equalizer structure (see the use of K in “Equalization”) and an assumption about the signal to be equalized.
RefTap (except for CMA equalizers)	Reference tap index, between 1 and nfwdweights. Setting this to a value greater than 1 effectively delays the reference signal with respect to the equalizer's input signal.
SigConst	Signal constellation, a vector whose length is typically a power of 2.
Weights	Vector that concatenates the complex coefficients from the forward filter and the feedback filter. This is the set of w_i values in the schematic in “Equalization”.
WeightInputs	Vector that concatenates the tap weight inputs for the forward filter and the feedback filter. This is the set of u_i values in the schematic in “Equalization”.
ResetBeforeFiltering	If 1, each call to equalize resets the state of eqobj before equalizing. If 0, the equalization process maintains continuity from one call to the next.
NumSamplesProcessed	Number of samples the equalizer processed since the last reset. When you create or reset eqobj, this property value is 0.
Properties specific to the adaptive algorithm represented by alg	See reference page for the adaptive algorithm function that created alg: lms, signlms, normlms, varlms, rls, or cma.

Relationships Among Properties

If you change nWeights, MATLAB maintains consistency in the equalizer object by adjusting the values of the properties listed below.

Property	Adjusted Value
Weights	zeros(1,sum(nWeights))
WeightInputs	zeros(1,sum(nWeights))
StepSize (Variable-step-size LMS equalizers)	InitStep*ones(1,sum(nWeights))
InvCorrMatrix (RLS equalizers)	InvCorrInit*eye(sum(nWeights))

Examples

Configuring Decision Feedback Equalizers

This example configures the recommended `comm.DecisionFeedback` System object™ and the legacy `dfe` feature with comparable settings.

Initialize Variables and Supporting Objects

```
d = randi([0 3],1000,1);
x = pskmod(d,4,pi/4);
r = awgn(x,25);
sps = 2; %samples per symbol for oversampled cases
nTaps = 6;
txFilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',nTaps, ...
    'OutputSamplesPerSymbol',4);
rxFilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',nTaps, ...
    'InputSamplesPerSymbol',4,'DecimationFactor',2);
x2 = txFilter(x);
r2 = rxFilter(awgn(x2,25,0.5));
filterDelay = txFilter.FilterSpanInSymbols/2 + ...
    rxFilter.FilterSpanInSymbols/2; % Total filter delay in symbols
```

To compare the equalized output, plot the constellations using code such as:

```
% plot(yNew,'*')
% hold on
% plot(yOld,'o')
% hold off; legend('New Eq','Old Eq'); grid on
```

Use LMS Algorithm with Decision Feedback Equalizer

Configure `dfe` and `comm.DecisionFeedback` objects with comparable settings. The `LeakageFactor` property has been removed from LMS algorithm. The `comm.DecisionFeedback` System object™ assumes that leakage factor is always 1.

```
eqOld = dfe(5,3,lms(0.05),pskmod(0:3,4,pi/4))
```

```
eqOld =
  EqType: 'Decision Feedback Equalizer'
  AlgType: 'LMS'
  nWeights: [5 3]
  nSampPerSym: 1
  RefTap: 1
  SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  StepSize: 0.0500
  LeakageFactor: 1
  Weights: [0 0 0 0 0 0 0 0]
  WeightInputs: [0 0 0 0 0 0 0 0]
  ResetBeforeFiltering: 1
  NumSamplesProcessed: 0
```

```
eqNew = comm.DecisionFeedback('NumForwardTaps',5,'NumFeedbackTaps',3, ...
    'Algorithm','LMS','StepSize',0.05, ...
    'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
```

```
eqNew = comm.DecisionFeedback with properties:
  Algorithm: 'LMS'
  NumForwardTaps: 5
  NumFeedbackTaps: 3
  StepSize: 0.0500
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 1
  InputDelay: 0
  InputSamplesPerSymbol: 1
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers.

```
yOld = equalize(eqOld,r,x(1:100));
yNew = eqNew(r,x(1:100));
```

Use RLS Algorithm with Decision Feedback Equalizer

Configure `dfe` and `comm.DecisionFeedback` objects with comparable settings.

```
eqOld = dfe(5,3,rls(0.95),pskmod(0:3,4,pi/4))
```

```
eqOld =
  EqType: 'Decision Feedback  Equalizer'
  AlgType: 'RLS'
  nWeights: [5 3]
  nSampPerSym: 1
  RefTap: 1
  SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  Forget Factor: 0.9500
  InvCorrInit: 0.1000
  InvCorrMatrix: [8×8 double]
  Weights: [0 0 0 0 0 0 0 0]
  WeightInputs: [0 0 0 0 0 0 0 0]
  ResetBeforeFiltering: 1
  NumSamplesProcessed: 0
```

```
eqNew = comm.DecisionFeedback('NumForwardTaps',5,'NumFeedbackTaps',3,'Algorithm','RLS', ...
    'ForgettingFactor',0.95,'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
```

```
eqNew = comm.DecisionFeedback with properties:
  Algorithm: 'RLS'
  NumForwardTaps: 5
  NumFeedbackTaps: 3
  ForgettingFactor: 0.9500
  InitialInverseCorrelationMatrix: 0.1000
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 1
  InputDelay: 0
  InputSamplesPerSymbol: 1
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers. When `ResetBeforeFiltering` is set to `true`, each call of the `equalize` object resets the equalizer. To get the equivalent behavior call `reset` after each call of the `comm.DecisionFeedback` object.

```
yOld1 = equalize(eqOld,r,x(1:100));
yOld2 = equalize(eqOld,r,x(1:100));

yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

Configure `dfe` and `comm.DecisionFeedback` objects with comparable settings. For the `comm.DecisionFeedback` object, set the initial inverse correlation matrix to `eye(5)*0.2`.

```
eqOld = dfe(5,3,rls(0.95),pskmod(0:3,4,pi/4))
```

```
eqOld =
  EqType: 'Decision Feedback Equalizer'
  AlgType: 'RLS'
  nWeights: [5 3]
  nSampPerSym: 1
  RefTap: 1
  SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ForgetFactor: 0.9500
  InvCorrInit: 0.1000
  InvCorrMatrix: [8×8 double]
  Weights: [0 0 0 0 0 0 0 0]
  WeightInputs: [0 0 0 0 0 0 0 0]
  ResetBeforeFiltering: 1
  NumSamplesProcessed: 0
```

```
eqNew = comm.DecisionFeedback('NumForwardTaps',5,'NumFeedbackTaps',3,'Algorithm','RLS', ...
    'ForgettingFactor',0.95,'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1, ...
    'InitialInverseCorrelationMatrix',eye(5)*0.2)
```

```
eqNew = comm.DecisionFeedback with properties:
  Algorithm: 'RLS'
  NumForwardTaps: 5
  NumFeedbackTaps: 3
  ForgettingFactor: 0.9500
  InitialInverseCorrelationMatrix: [8×8 double]
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 1
  InputDelay: 0
  InputSamplesPerSymbol: 1
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers. When `ResetBeforeFiltering` is set to `true`, each call of the `equalize` object resets the equalizer. To get the equivalent behavior call `reset` after each call of the `comm.DecisionFeedback` object.

```
yOld1 = equalize(eqOld,r,x(1:100));
yOld2 = equalize(eqOld,r,x(1:100));

yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

Use Decision Feedback Equalizers Considering Signal Delays

Configure `dfe` and `comm.DecisionFeedback` objects with comparable settings. The transmit and receive filters result in a signal delay between the transit and receive signals. Account for this delay by setting the `RefTap` property of the `dfe` to a value close to the delay value in samples. Additionally, `nWeights` must be set to a value greater than `RefTap`.

```
eqOld = dfe(filterDelay*sps+4,6,lms(0.01),pskmod(0:3,4,pi/4),sps);
eqOld.RefTap = filterDelay*sps+1 % Adjust to synchronize with delayed signal
```

```
eqOld =
  EqType: 'Decision Feedback Equalizer'
  AlgType: 'LMS'
  nWeights: [16 6]
  nSampPerSym: 2
  RefTap: 13

```

```
eqNew = comm.DecisionFeedback('NumForwardTaps',filterDelay*sps+4, ...
    'NumFeedbackTaps',6,'Algorithm','LMS','StepSize',0.01, ...
    'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    'ReferenceTap',filterDelay*sps+1,'InputDelay',0)
```

```
eqNew = comm.DecisionFeedback with properties:
  Algorithm: 'LMS'
  NumForwardTaps: 16
  NumFeedbackTaps: 6
  StepSize: 0.0100
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 13
  InputDelay: 0
  InputSamplesPerSymbol: 2
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers. When `ResetBeforeFiltering` is set to `true`, each call of the `equalize` object resets the equalizer. To get the equivalent behavior call `reset` after each call of the `comm.DecisionFeedback` object.

```
yOld1 = equalize(eqOld,r,x(1:100));
yOld2 = equalize(eqOld,r,x(1:100));

yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

In the `comm.DecisionFeedback` object, `InputDelay` is used to synchronize with the delayed signal. `NumForwardTaps`, `NumFeedbackTaps`, and `ReferenceTap` are independent of delay value. We can reduce the number of taps by utilizing the `InputDelay` to synchronize instead of reference tap. Reducing the number of taps also reduces equalizer self noise.

```
eqNew = comm.DecisionFeedback('NumForwardTaps',11,'NumFeedbackTaps',4, ...
    'Algorithm','LMS','StepSize',0.01, ...
    'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    'ReferenceTap',6,'InputDelay',filterDelay*sps)
```

```
eqNew = comm.DecisionFeedback with properties:
  Algorithm: 'LMS'
  NumForwardTaps: 11
  NumFeedbackTaps: 4
  StepSize: 0.0100
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 6
  InputDelay: 12
  InputSamplesPerSymbol: 2
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

```
yNew1 = eqNew(r2,x(1:100));
reset(eqNew)
yNew2 = eqNew(r2,x(1:100));
```

Compatibility Considerations

`dfe` will be removed

Warns starting in R2020a

dfe will be removed in a future release. Use `comm.DecisionFeedback` instead. For examples comparing setup of `comm.DecisionFeedback` to `dfe`, see “Configuring Decision Feedback Equalizers” on page 2-266.

dftmtx

Discrete Fourier transform matrix in Galois field

Syntax

```
dm = dftmtx(alph)
```

Description

`dm = dftmtx(alph)` returns a Galois array that represents the discrete Fourier transform operation on a Galois vector, with respect to the Galois scalar `alph`. The element `alph` is a primitive nth root of unity in the Galois field GF(2^m) = GF(n+1); that is, n must be the smallest positive value of `k` for which `alph^k` equals 1. The discrete Fourier transform has size n and `dm` is an n-by-n array. The array `dm` represents the transform in the sense that `dm` times any length-n Galois column vector yields the transform of that vector.

Note The inverse discrete Fourier transform matrix is `dftmtx(1/alph)`.

Examples

The example below illustrates the discrete Fourier transform and its inverse, with respect to the element `gf(3,4)`. The example examines the first n powers of that element to make sure that only the nth power equals one. Afterward, the example transforms a random Galois vector, undoes the transform, and checks the result.

```
m = 4;
n = 2^m-1;
a = 3;
alph = gf(a,m);
mp = minpol(alph);
if (mp(1)==1 && isprimitive(mp)) % Check that alph has order n.
    disp('alph is a primitive nth root of unity.')
    dm = dftmtx(alph);
    idm = dftmtx(1/alph);
    x = gf(randi([0 2^m-1],n,1),m);
    y = dm*x; % Transform x.
    z = idm*y; % Recover x.
    ck = isequal(x,z)
end
```

The output is

```
alph is a primitive nth root of unity.

ck =

     1
```

Limitations

The Galois field over which this function works must have 256 or fewer elements. In other words, `alph` must be a primitive nth root of unity in the Galois field GF(2^m), where m is an integer between 1 and 8.

Algorithms

The element `dm(a,b)` equals `alph^((a-1)*(b-1))`.

distspec

Compute distance spectrum of convolutional code

Syntax

```
spect = distspec(trellis,n)
spect = distspec(trellis)
```

Description

`spect = distspec(trellis,n)` computes the free distance and the first `n` components of the weight and distance spectra of a linear convolutional code. Because convolutional codes do not have block boundaries, the weight spectrum and distance spectrum are semi-infinite and are most often approximated by the first few components. The input `trellis` is a valid MATLAB trellis structure, as described in “Trellis Description of a Convolutional Code”. The output, `spect`, is a structure with these fields:

Field	Meaning
`spect.dfree`	Free distance of the code. This is the minimum number of errors in the encoded sequence required to create an error event.
`spect.weight`	A length-`n` vector that lists the total number of information bit errors in the error events enumerated in `spect.event`.
`spect.event`	A length-`n` vector that lists the number of error events for each distance between `spect.dfree` and `spect.dfree+n-1`. The vector represents the first `n` components of the distance spectrum.

`spect = distspec(trellis)` is the same as `spect = distspec(trellis,1)`.

Examples

The example below performs these tasks:

- Computes the distance spectrum for the rate 2/3 convolutional code that is depicted on the reference page for the `poly2trellis` function
- Uses the output of `distspec` as an input to the `bercoding` function, to find a theoretical upper bound on the bit error rate for a system that uses this code with coherent BPSK modulation
- Plots the upper bound using the `berfit` function

```
trellis = poly2trellis([5 4],[23 35 0; 0 5 13])
spect = distspec(trellis,4)
berub = bercoding(1:10,'conv','hard',2/3,spect); % BER bound
berfit(1:10,berub); ylabel('Upper Bound on BER'); % Plot.
```

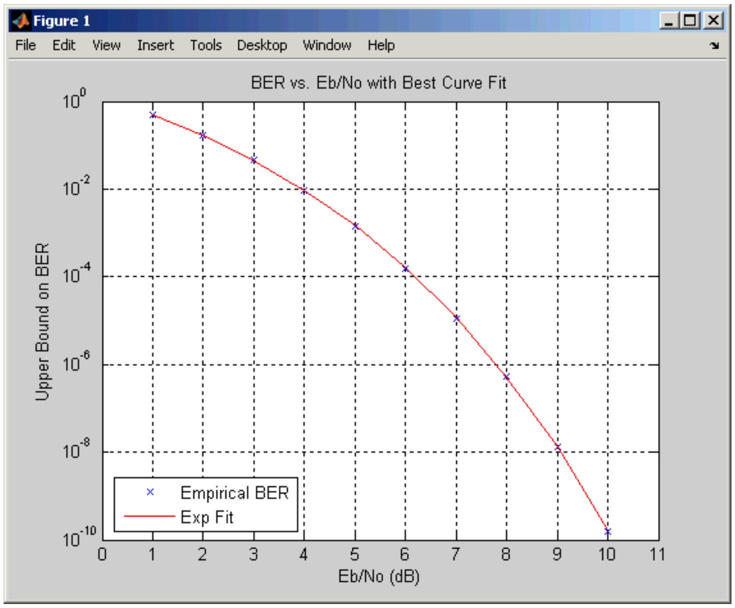
The output and plot are below.

```
trellis =

     numInputSymbols: 4
    numOutputSymbols: 8
           numStates: 128
          nextStates: [128x4 double]
             outputs: [128x4 double]

spect =

     dfree: 5
    weight: [1 6 28 142]
     event: [1 2 8 25]
```



Algorithms

The function uses a tree search algorithm implemented with a stack, as described in [2].

doppler

Construct Doppler spectrum structure

Syntax

```
s = doppler(specType)
s = doppler(specType, fieldValue)
s = doppler('BiGaussian', Name,Value)
```

Description

`s = doppler(specType)` constructs a Doppler spectrum structure of type `specType` for use with a fading channel System object. The returned structure, `s`, has default values for its dependent fields.

`s = doppler(specType, fieldValue)` constructs a Doppler spectrum structure of type `specType` for use with a fading channel System object. The returned structure, `s`, has its dependent field specified to `fieldValue`.

`s = doppler('BiGaussian', Name,Value)` constructs a BiGaussian Doppler spectrum structure for use with a fading channel System object. The returned structure, `s`, has dependent fields specified by `Name,Value` pair arguments.

Examples

Construct a Flat Doppler Spectrum Structure

Construct a flat Doppler structure variable for use with channel objects such as `comm.RayleighChannel`.

Invoke the `doppler` function to create a flat Doppler structure variable.

```
s = doppler('Flat')
```

```
s = struct with fields:
    SpectrumType: 'Flat'
```

Create a Bell Doppler Structure Variable

Use the `doppler` function to create a Doppler structure variable having the Bell spectrum.

```
s = doppler('Bell')
```

```
s = struct with fields:
    SpectrumType: 'Bell'
     Coefficient: 9
```

Construct a Rounded Doppler Spectrum Structure with Specified Polynomial

Specify the coefficients of the Doppler spectrum structure variable.

Construct a Rounded Doppler spectrum structure with coefficients `a0`, `a2`, and `a4` set to `2`, `6`, and `1`, respectively.

```
s = doppler('Rounded', [2, 6, 1])
```

```
s = struct with fields:
    SpectrumType: 'Rounded'
      Polynomial: [2 6 1]
```

Construct a BiGaussian Doppler Spectrum Structure with Specified Field Values

Use the `doppler` function to create a Doppler spectrum structure with the parameters specified for a BiGaussian spectrum.

```
s = doppler('BiGaussian','NormalizedCenterFrequencies', ...
    [.1 .85],'PowerGains',[1 2])
```

```
s = struct with fields:
                    SpectrumType: 'BiGaussian'
    NormalizedStandardDeviations: [0.7071 0.7071]
     NormalizedCenterFrequencies: [0.1000 0.8500]
                      PowerGains: [1 2]
```

The `NormalizedStandardDeviations` field is set to the default value. The `NormalizedCenterFrequencies`, and `PowerGains` fields are set to the values specified from the input arguments.

Input Arguments

`specType` — Spectrum type of Doppler spectrum structure for use with fading channel System object

`'Jakes'` | `'Flat'` | `'Rounded'` | `'Bell'` | `'Asymmetric Jakes'` | `'Restricted Jakes'` | `'Gaussian'` | `'BiGaussian'`

The spectrum type of a Doppler spectrum structure for use with a fading channel System object. Specify this value as a character vector.

The analytical expression for each Doppler spectrum type is described in the “Algorithms” on page 2-278 section.

Data Types: `char`

`fieldValue` — Value of dependent field of Doppler spectrum structure

scalar | vector

The value of the dependent field of the Doppler spectrum structure, specified as a scalar or vector of built-in data type. If you do not specify `fieldValue` , the dependent fields of the spectrum type use the default values.

Spectrum Type	Dependent Field	Description	Default Value
“Jakes” on page 2-279	—	—	—
“Flat” on page 2-279	—	—	—
“Rounded” on page 2-279	`Polynomial`	1-by-3 vector of real finite values, representing the polynomial coefficients, `a0, a2` and `a4`	`[1 -1.72 0.785]`
“Bell” on page 2-279	`Coefficient`	Nonnegative, finite, real scalar representing the Bell spectrum coefficient	`9`
“Asymmetric Jakes” on page 2-279	`NormalizedFrequencyInterval`	1-by-2 vector of real values between –1 and 1, inclusive, representing the minimum and maximum normalized Doppler shifts	`[0 1]`
“Restricted Jakes” on page 2-280	`NormalizedFrequencyInterval`	1-by-2 vector of real values between 0 and 1, inclusive, representing the minimum and maximum normalized Doppler shifts	`[0 1]`
“Gaussian” on page 2-280	`NormalizedStandardDeviation`	Normalized standard deviation of the Gaussian Doppler spectrum, specified as a positive, finite, real scalar	`0.7071`
“BiGaussian” on page 2-280	`NormalizedStandardDeviations`	Normalized standard deviations of the BiGaussian Doppler spectrum, specified as a positive, finite, real 1-by-2 vector	`[0.7071 0.7071]`
	`NormalizedCenterFreqencies`	Normalized center frequencies of the BiGaussian Doppler spectrum specified as a real 1-by-2 vector whose elements fall between –1 and 1	`[0 0]`

Spectrum Type	Dependent Field	Description	Default Value
	`PowerGains`	Linear power gains of the BiGaussian Doppler spectrum specified as a real nonnegative 1-by-2 vector	`[0.5 0.5]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `s=doppler('BiGaussian', 'NormalizedStandardDeviations', [.8 .75], 'NormalizedCenterFrequencies', [-.8 0], 'PowerGains', [.6 .6])`

`NormalizedStandardDeviations` — Normalized standard deviations of first and second Gaussian functions
`[1/sqrt(2) 1/sqrt(2)]` (default) | 1-by-2 positive numeric vector

The normalized standard deviation of the first and second Gaussian functions. You can specify this value as a 1-by-2 positive numeric vector, of built-in data types.

When you do not specify this dependent field, the default value is `[1/sqrt(2) 1/sqrt(2)]`.

Data Types: `double`

`NormalizedCenterFrequencies` — Normalized center frequencies of first and second Gaussian functions
`[0 0]` (default) | 1-by-2 numeric vector

The normalized center frequencies of the first and second Gaussian functions. You can specify this value as a 1-by-2 numeric vector of real values between –1 and 1, of built-in data types.

When you do not specify this dependent field, the default value is `[0 0]`.

Data Types: `double`

`PowerGains` — Power gains of first and second Gaussian functions
`[0.5 0.5]` (default) | 1-by-2 numeric vector

The power gains of the first and second Gaussian functions. You can specify this value as a 1-by-2 nonnegative numeric vector of built-in data types.

When you do not specify this dependent field, the default value is `[0.5 0.5]`.

Data Types: `double`

Algorithms

The following algorithms represent the analytical expressions for each Doppler spectrum type. In each case, f_d denotes the maximum Doppler shift (`MaximumDopplerShift` property) of the associated fading channel System object.

Jakes

The theoretical `Jakes` Doppler spectrum, *S(f)* has the analytic formula

$$S(f) = \frac{1}{\pi f_d \sqrt{1 - (f/f_d)^2}}, \ |f| \le f_d$$

Flat

The theoretical `Flat` Doppler spectrum, *S(f)* has the analytic formula

$$S(f) = \frac{1}{2f_d}, |f| \le f_d$$

Rounded

The theoretical `Rounded` Doppler spectrum, *S(f)* has the analytic formula

$$S(f) = C_r \left[a_0 + a_2 \left(\frac{f}{f_d} \right)^2 + a_4 \left(\frac{f}{f_d} \right)^4 \right], |f| \le f_d$$

where

$$C_r = \frac{1}{2f_d \left[a_0 + \frac{a_2}{3} + \frac{a_4}{5} \right]}$$

and you can specify $[a_0, \ a_2, \ a_4]$ in the dependent field, `polynomial`.

Bell

The theoretical `Bell` Doppler spectrum, *S(f)* has the analytic formula

$$S(f) = \frac{C_b}{1 + A \left(\frac{f}{f_d} \right)^2}$$

$$|f| \le f_d$$

where

$$C_b = \frac{\sqrt{A}}{\pi f_d}$$

You can specify *A* in the dependent field, `coefficient`.

Asymmetric Jakes

The theoretical `Asymmetric Jakes` Doppler spectrum, *S(f)* has the analytic formula

$$S(f) = \frac{A_a}{\pi f_d \sqrt{1 - (f/f_d)^2}}, \quad -f_d \le f_{\min} \le f \le f_{\max} \le f_d$$

$$A_a = \frac{1}{\frac{1}{\pi} \left[\sin^{-1} \left(\frac{f_{\max}}{f_d} \right) - \sin^{-1} \left(\frac{f_{\min}}{f_d} \right) \right]}$$

where you can specify $f_{\min}/\ f_d$ and$f_{\max}\ /f_d$ in the dependent field, `NormalizedFrequencyInterval`.

Restricted Jakes

The theoretical `Restricted Jakes` Doppler spectrum, *S(f)* has the analytic formula

$$S(f) = \frac{A_r}{\pi f_d \sqrt{1 - (f/f_d)^2}},\ 0 \le f_{\min} \le |f| \le f_{\max} \le f_d$$

where

$$A_r = \frac{1}{\frac{2}{\pi}\left[\sin^{-1}\left(\frac{f_{\max}}{f_d}\right) - \sin^{-1}\left(\frac{f_{\min}}{f_d}\right)\right]}$$

where you can specify $f_{\min}/\ f_d$ and$f_{\max}\ /f_d$ in the dependent field, `NormalizedFrequencyInterval`.

Gaussian

The theoretical `Gaussian` Doppler spectrum, *S(f)* has the analytic formula

$$S_G(f) = \frac{1}{\sqrt{2\pi\sigma_G^2}}\exp\left(-\frac{f^2}{2\sigma_G^2}\right)$$

You can specify σ_G/f_d in the dependent field, `NormalizedStandardDeviation`.

BiGaussian

The theoretical `BiGaussian` Doppler spectrum, *S(f)* has the analytic formula

$$S_G(f) = A_G\left[\frac{C_{G1}}{\sqrt{2\pi\sigma_{G1}^2}}\exp\left(-\frac{(f - f_{G1})^2}{2\sigma_{G1}^2}\right) + \frac{C_{G2}}{\sqrt{2\pi\sigma_{G2}^2}}\exp\left(-\frac{(f - f_{G2})^2}{2\sigma_{G2}^2}\right)\right]$$

where $A_G = \dfrac{1}{C_{G1} + C_{G2}}$ is a normalization coefficient.

You can specify σ_{G1}/f_d and σ_{G2}/f_d in the `NormalizedStandardDeviations` dependent field.

You can specify f_{G1}/f_d and f_{G2}/f_d in the `NormalizedCenterFrequencies` dependent field.

C_{G1} and C_{G2} are power gains that you can specify in the `PowerGains` dependent field.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

MIMO Channel | `comm.MIMOChannel` | `comm.RayleighChannel` | `comm.RicianChannel`

Introduced in R2007a

doppler.ajakes

(Removed) Construct asymmetrical Doppler spectrum object

Note `doppler.ajakes` has been removed. Use `doppler('Asymmetric Jakes',...)` instead.

Syntax

```
dop = doppler.ajakes(freqminmaxajakes)
dop = doppler.ajakes
```

Description

The `doppler.ajakes` function creates an asymmetrical Jakes (AJakes) Doppler spectrum object. This object is to be used for the `DopplerSpectrum` property of a channel object created with the `rayleighchan` or the `ricianchan` functions.

`dop = doppler.ajakes(freqminmaxajakes)`, where `freqminmaxajakes` is a row vector of two finite real numbers between -1 and 1, creates a Jakes Doppler spectrum that is nonzero only for normalized (by the maximum Doppler shift f_d, in Hz) frequencies f_{norm} such that $-1 \leq f_{\min,\, norm} \leq f_{norm} \leq f_{\max,\, norm} \leq 1$, where $f_{\min,\, norm}$ is given by `freqminmaxajakes(1)` and $f_{\max,\, norm}$ is given by `freqminmaxajakes(2)`. The maximum Doppler shift f_d is specified by the `MaxDopplerShift` property of the channel object. Analytically: $f_{\min,\, norm} = f_{\min}/f_d$ and $f_{\max,\, norm} = f_{\max}/f_d$, where $f_{\min}$ is the minimum Doppler shift (in hertz) and $f_{\max}$ is the maximum Doppler shift (in hertz).

When `dop` is used as the `DopplerSpectrum` property of a channel object, space `freqminmaxajakes(1)` and `freqminmaxajakes(2)` by more than 1/50. Assigning a smaller spacing results in `freqminmaxarjakes` being reset to the default value of `[0 1]`.

`dop = doppler.ajakes` creates an asymmetrical Doppler spectrum object with a default `freqminmaxajakes = [0 1]`. This syntax is equivalent to constructing a Jakes Doppler spectrum that is nonzero only for positive frequencies.

Properties

The AJakes Doppler spectrum object contains the following properties.

Property	Description
`SpectrumType`	Fixed value, `'AJakes'`
`FreqMinMaxAJakes`	Vector of minimum and maximum normalized Doppler shifts, two real finite numbers between -1 and 1

Theory and Applications

The Jakes power spectrum is based on the assumption that the angles of arrival at the mobile receiver are uniformly distributed [1]: the spectrum then covers the frequency range from $-f_d$ to f_d, f_d being the maximum Doppler shift. When the angles of arrival are not uniformly distributed, then the Jakes power spectrum does not cover the full Doppler bandwidth from $-f_d$ to f_d. The AJakes Doppler spectrum object covers the case of a power spectrum that is nonzero only for frequencies f such that $-f_d \leq f_{\min} \leq f \leq f_{\max} \leq f_d$. It is an asymmetrical spectrum in the general case, but becomes a symmetrical spectrum if $f_{\min} = -f_{\max}$.

The normalized AJakes Doppler power spectrum is given analytically by:

$$S(f) = \frac{A_a}{\pi f_d \sqrt{1-(f/f_d)^2}}, \quad -f_d \leq f_{\min} \leq f \leq f_{\max} \leq f_d$$

$$A_a = \frac{1}{\frac{1}{\pi}\left[\sin^{-1}\left(\frac{f_{\max}}{f_d}\right) - \sin^{-1}\left(\frac{f_{\min}}{f_d}\right)\right]}$$

where $f_{\min}$ and $f_{\max}$ denote the minimum and maximum frequencies where the spectrum is nonzero. You can determine these values from the probability density function of the angles of arrival.

Examples

The following MATLAB code first creates a Rayleigh channel object with a maximum Doppler shift of $f_d = 10$ Hz. It then creates an AJakes Doppler object with minimum normalized Doppler shift $f_{\min,\,norm} = -0.2$ and maximum normalized Doppler shift $f_{\max,\,norm} = 0.05$. The Doppler object is then assigned to the `DopplerSpectrum` property of the channel object. The channel then has a Doppler spectrum that is nonzero for frequencies f such that $-f_d \leq f_{\min} \leq f \leq f_{\max} \leq f_d$, where $f_{\min} = f_{\min,\,norm} \times f_d = -2$ Hz and $f_{\max} = f_{\max,\,norm} \times f_d = 0.5$ Hz.

```
chan = rayleighchan(1/1000, 10);
dop_ajakes = doppler.ajakes([-0.2 0.05]);
chan.DopplerSpectrum = dop_ajakes;
chan.DopplerSpectrum
```

This code returns:

```
        SpectrumType: 'AJakes'
    FreqMinMaxAJakes: [-0.2000 0.0500]
```

Compatibility Considerations

`doppler.ajakes` has been removed

Errors starting in R2020b

doppler.ajakes has been removed. Use `doppler('Asymmetric Jakes',...)` instead.

Topics

"Fading Channels"

Introduced in R2007b

doppler.bell

(Removed) Construct bell-shaped Doppler spectrum object

Note `doppler.ajakes` has been removed. Use `doppler('Bell',...)` instead.

Syntax

```
doppler.bell
doppler.bell(coeffbell)
```

Description

doppler.bell creates a bell Doppler spectrum object. You can use this object with the `DopplerSpectrum` property of any channel object created with either the `rayleighchan` function, the `ricianchan` function, or `comm.MIMOChannel` System object.

dop = `doppler.bell` creates a bell Doppler spectrum object with default coefficient.

dop = `doppler.bell(coeffbell)` creates a bell Doppler spectrum object with coefficient given by `coeffbell`, where `coeffbell` is a positive, finite, real scalar.

Properties

The bell Doppler spectrum object has the following properties.

Property	Description
SpectrumType	Fixed value, 'Bell'
CoeffBell	Bell spectrum coefficient, positive real finite scalar.

Theory and Applications

A bell spectrum was proposed in [1] for the Doppler spectrum of indoor MIMO channels, for 802.11n channel modeling.

The normalized bell Doppler spectrum is given analytically by:

$$S(f) = \frac{C_b}{1 + A\left(\frac{f}{f_d}\right)^2}$$

where

$$|f| \leq f_d$$

and

$$C_b = \frac{\sqrt{A}}{\pi f_d}$$

f_d represents the maximum Doppler shift specified for the channel object, and A represents a positive real finite scalar (`CoeffBell`). The indoor MIMO channel model of IEEE 802.11n [1] uses the following parameter: $A = 9$. Since the channel is modeled as Rician fading with a fixed line-of-sight (LOS) component, a Dirac delta is also present in the Doppler spectrum at $f = 0$.

Examples

Construct a bell Doppler spectrum object with a coefficient of 8.5. Assign it to a Rayleigh channel object with one path.

```
dop = doppler.bell(8.5);
chan = rayleighchan(1e-5, 10);
chan.DopplerSpectrum = dop;
```

Compatibility Considerations

`doppler.bell` has been removed

Errors starting in R2020b

doppler.bell has been removed. Use `doppler('Bell',...)` instead.

Introduced in R2009a

doppler.bigaussian

(Removed) Construct bi-Gaussian Doppler spectrum object

Note `doppler.bigaussian` has been removed. Use `doppler('BiGaussian',...)` instead.

Syntax

```
dop = doppler.bigaussian(property1,value1,...)
dop = doppler.bigaussian
```

Description

The `doppler.bigaussian` function creates a bi-Gaussian Doppler spectrum object to be used for the `DopplerSpectrum` property of a channel object (created with either the `rayleighchan` function or the `ricianchan` function).

`dop = doppler.bigaussian(property1,value1,...)` creates a bi-Gaussian Doppler spectrum object with properties as specified by the property/value pairs. If you do not specify a value for a property, the property is assigned a default value.

`dop = doppler.bigaussian` creates a bi-Gaussian Doppler spectrum object with default properties. The constructed Doppler spectrum object is equivalent to a single Gaussian Doppler spectrum centered at zero frequency. The equivalent command with property/value pairs is:

```
dop = doppler.bigaussian('SigmaGaussian1', 1/sqrt(2), ...
            'SigmaGaussian2', 1/sqrt(2), ...
            'CenterFreqGaussian1', 0, ...
            'CenterFreqGaussian2', 0, ...
            'GainGaussian1', 0.5, ...
            'GainGaussian2', 0.5)
```

Properties

The bi-Gaussian Doppler spectrum object contains the following properties.

Property	Description
`SpectrumType`	Fixed value, `'BiGaussian'`
`SigmaGaussian1`	Normalized standard deviation of first Gaussian function (real positive finite scalar value)
`SigmaGaussian2`	Normalized standard deviation of second Gaussian function (real positive finite scalar value)
`CenterFreqGaussian1`	Normalized center frequency of first Gaussian function (real scalar value between -1 and 1)
`CenterFreqGaussian2`	Normalized center frequency of second Gaussian function (real scalar value between -1 and 1)

Property	Description
GainGaussian1	Power gain of first Gaussian function (linear scale, real nonnegative finite scalar value)
GainGaussian2	Power gain of second Gaussian function (linear scale, real nonnegative finite scalar value)

All properties are writable except for the SpectrumType property.

The properties SigmaGaussian1, SigmaGaussian2, GainGaussian1, and GainGaussian2 are normalized by the MaxDopplerShift property of the associated channel object.

Analytically, the normalized standard deviations of the first and second Gaussian functions are determined as $\sigma_{G1,\,norm} = \sigma_{G1}/f_d$ and $\sigma_{G2,\,norm} = \sigma_{G2}/f_d$, respectively, where σ_{G1} and σ_{G2} are the standard deviations of the first and second Gaussian functions, and f_d is the maximum Doppler shift, in hertz. Similarly, the normalized center frequencies of the first and second Gaussian functions are determined as $f_{G1,\,norm} = f_{G1}/f_d$ and $f_{G2,\,norm} = f_{G2}/f_d$, respectively, where f_{G1} and f_{G2} are the center frequencies of the first and second Gaussian functions. The properties GainGaussian1 and GainGaussian2 correspond to the power gains C_{G1} and C_{G2}, respectively, of the two Gaussian functions.

Theory and Applications

The bi-Gaussian power spectrum consists of two frequency-shifted Gaussian spectra. The COST207 channel models ([1], [2], [3]) specify two distinct bi-Gaussian Doppler spectra, GAUS1 and GAUS2, to be used in modeling long echos for urban and hilly terrain profiles.

The normalized bi-Gaussian Doppler spectrum is given analytically by:

$$S_G(f) = A_G\left[\frac{C_{G1}}{\sqrt{2\pi\sigma_{G1}^2}}\exp\left(-\frac{(f-f_{G1})^2}{2\sigma_{G1}^2}\right) + \frac{C_{G2}}{\sqrt{2\pi\sigma_{G2}^2}}\exp\left(-\frac{(f-f_{G2})^2}{2\sigma_{G2}^2}\right)\right]$$

where σ_{G1} and σ_{G2} are standard deviations, f_{G1} and f_{G2} are center frequencies, C_{G1} and C_{G2} are power gains, and $A_G = \dfrac{1}{C_{G1} + C_{G2}}$ is a normalization coefficient.

If either $f_{G1} = 0$ or $f_{G2} = 0$, a frequency-shifted Gaussian Doppler spectrum is obtained.

Examples

The following MATLAB code first creates a bi-Gaussian Doppler spectrum object with the same parameters as that of a COST 207 GAUS2 Doppler spectrum. It then creates a Rayleigh channel object with a maximum Doppler shift of $f_d = 30$ and assigns the constructed Doppler spectrum object to its DopplerSpectrum property.

```
dop_bigaussian = doppler.bigaussian(‘SigmaGaussian1’, 0.1, ...
   ‘SigmaGaussian2’, 0.15, ‘CenterFreqGaussian1’, 0.7, ...
   ‘CenterFreqGaussian2’, -0.4, ‘GainGaussian1’, 1, ...
   ‘GainGaussian2’, 1/10^1.5)
chan = rayleighchan(1e-3, 30);
chan.DopplerSpectrum = dop_bigaussian;
```

Compatibility Considerations

`doppler.bigaussian` has been removed
Errors starting in R2020b

doppler.bigaussian has been removed. Use `doppler('BiGaussian',...)` instead.

doppler.flat

(Removed) Construct flat Doppler spectrum object

Note `doppler.flat` has been removed. Use `doppler('Flat')` instead.

Syntax

```
dop = doppler.flat
```

Description

`dop = doppler.flat` creates a flat Doppler spectrum object that is to be used for the `DopplerSpectrum` property of a channel object (created with either the `rayleighchan` or the `ricianchan` function). The maximum Doppler shift of the flat Doppler spectrum object is specified by the `MaxDopplerShift` property of the channel object.

Properties

The flat Doppler spectrum object contains only one property, `SpectrumType`, which is read-only and has a fixed value of `'Flat'`.

Theory and Applications

In a 3-D isotropic scattering environment, where the angles of arrival are uniformly distributed in the azimuth and elevation planes, the Doppler spectrum is found theoretically to be flat [2]. A flat Doppler spectrum is also specified in some cases of the ANSI J-STD-008 reference channel models for PCS, for both outdoor (pedestrian) and indoor (commercial) [1] applications.

The normalized flat Doppler power spectrum is given analytically by:

$$S(f) = \frac{1}{2f_d}, \ |f| \leq f_d$$

where f_d is the maximum Doppler frequency.

Examples

```
%% Create a Rayleigh Channel with Flat Doppler Spectrum
% This example shows how to create a Rayleigh channel
% object with a flat Doppler spectrum.
%%
% Set the sample time and maximum Doppler shift.
ts = 1e-6; % sec
fd = 50; % Hz
% Create the Rayleigh channel object.
chan = rayleighchan(ts,fd);
% Observe that the default Doppler spectrum
% property, SpectrumType, is 'Jakes'.
chan.DopplerSpectrum

ans =

    SpectrumType: 'Jakes'

% Change the Doppler spectrum property of the
% channel by using doppler.flat.
chan.DopplerSpectrum = doppler.flat
chan =

             ChannelType: 'Rayleigh'
       InputSamplePeriod: 1.0000e-06
         DopplerSpectrum: [1x1 doppler.flat]
         MaxDopplerShift: 50

doppler.gaussian

(Removed) Construct Gaussian Doppler spectrum object

Note `doppler.gaussian` has been removed in a future release. Use `doppler ('Gaussian',...)` instead.

Syntax

```
dop = doppler.gaussian
dop = doppler.gaussian(sigmagaussian)
```

Description

The `doppler.gaussian` function creates a Gaussian Doppler spectrum object that is to be used for the `DopplerSpectrum` property of a channel object (created with either the `rayleighchan` or the `ricianchan` function).

`dop = doppler.gaussian` creates a Gaussian Doppler spectrum object with a default standard deviation (normalized by the maximum Doppler shift f_d, in Hz) $\sigma_{G,\,norm} = 1/\sqrt{2}$. The maximum Doppler shift f_d is specified by the `MaxDopplerShift` property of the channel object. Analytically, $\sigma_{G,\,norm} = \sigma_G/f_d = 1/\sqrt{2}$, where σ_G is the standard deviation of the Gaussian Doppler spectrum.

`dop = doppler.gaussian(sigmagaussian)` creates a Gaussian Doppler spectrum object with a normalized f_d (by the maximum Doppler shift f_d, in Hz) $\sigma_{G,\,norm}$ of value `sigmagaussian`.

Properties

The Gaussian Doppler spectrum object contains the following properties.

Property	Description
`SpectrumType`	Fixed value, `'Gaussian'`
`SigmaGaussian`	Normalized standard deviation of the Gaussian Doppler spectrum (a real positive number)

Theory and Applications

The Gaussian power spectrum is considered to be a good model for multipath components with long delays in UHF communications [3]. It is also proposed as a model for the aeronautical channel [2]. A Gaussian Doppler spectrum is also specified in some cases of the ANSI J-STD-008 reference channel models for PCS applications, for both outdoor (wireless loop) and indoor (residential, office) [1]. The normalized Gaussian Doppler power spectrum is given analytically by:

$$S_G(f) = \frac{1}{\sqrt{2\pi\sigma_G^2}}\exp\left(-\frac{f^2}{2\sigma_G^2}\right)$$

An alternate representation is [4]:

$$S_G(f) = \frac{1}{f_c}\sqrt{\frac{\ln 2}{\pi}}\exp\left(-(\ln 2)\left(\frac{f}{f_c}\right)^2\right)$$

where $f_c = \sigma_G\sqrt{2\ln 2}$ is the 3 dB cutoff frequency. If you set $f_c = f_d\sqrt{\ln 2}$, where f_d is the maximum Doppler shift, or equivalently $\sigma_G = f_d/\sqrt{2}$, the Doppler spread of the Gaussian power spectrum becomes equal to the Doppler spread of the Jakes power spectrum, where Doppler spread is defined as:

$$\sigma_D = \sqrt{\frac{\int_{-\infty}^{\infty} f^2 S(f)df}{\int_{-\infty}^{\infty} S(f)df}}$$

Examples

The following code creates a Rayleigh channel object with a maximum Doppler shift of $f_d = 10$. It then creates a Gaussian Doppler spectrum object with a normalized standard deviation of $\sigma_{G,\mathrm{norm}} = 0.5$, and assigns it to the `DopplerSpectrum` property of the channel object.

```
chan = rayleighchan(1/1000,10);
dop_gaussian = doppler.gaussian(0.5);
chan.DopplerSpectrum = dop_gaussian;
```

Compatibility Considerations

`doppler.gaussian` has been removed

Errors starting in R2020b

doppler.gaussian has been removed. Use `doppler('Gaussian',...)` instead.

doppler.jakes

(Removed) Construct Jakes Doppler spectrum object

Note `doppler.jakes` has been removed. Use `doppler('Jakes')` instead.

Syntax

Description

`dop = doppler.jakes` creates a Jakes Doppler spectrum object that is to be used for the `DopplerSpectrum` property of a channel object (created with either the `rayleighchan` or the `ricianchan` function). The maximum Doppler shift of the Jakes Doppler spectrum object is specified by the `MaxDopplerShift` property of the channel object. By default, channel objects are created with a Jakes Doppler spectrum.

Properties

The Jakes Doppler spectrum object contains only one property, `SpectrumType`, which is read-only and has a fixed value of `'Jakes'`.

Theory and Applications

The Jakes Doppler power spectrum model is actually due to Gans [2], who analyzed the Clarke-Gilbert model ([1], [3], and [5]). The Clarke-Gilbert model is also called the *classical model*.

The Jakes Doppler power spectrum applies to a mobile receiver. It derives from the following assumptions [6]:

- The radio waves propagate horizontally.
- At the mobile receiver, the angles of arrival of the radio waves are uniformly distributed over $[-\pi, \pi]$.
- At the mobile receiver, the antenna is omnidirectional (i.e., the antenna pattern is circular-symmetrical).

The normalized Jakes Doppler power spectrum is given analytically by:

$$S(f) = \frac{1}{\pi f_d \sqrt{1 - (f/f_d)^2}}, \ |f| \le f_d$$

where f_d is the maximum Doppler frequency.

Examples

Create a Rayleigh channel object with a maximum Doppler shift of fd=10 Hertz. Then, create a Jakes Doppler spectrum object and assigns it to the `DopplerSpectrum` property of the channel object.

```
chan = rayleighchan(1/1000,10);
dop_gaussian = doppler.jakes;
chan.DopplerSpectrum = dop_gaussian
```

Compatibility Considerations

`doppler.jakes` has been removed

Errors starting in R2020b

doppler.jakes has been removed. Use `doppler('Jakes')` instead.

“Fading Channels”

Introduced in R2007a

doppler.rjakes

(Removed) Construct restricted Jakes Doppler spectrum object

Note `doppler.rjakes` has been removed. Use `doppler('Restricted Jakes',...)` instead.

Syntax

```
dop = doppler.rjakes
dop = doppler.rjakes(freqminmaxrjakes)
```

Description

The `doppler.rjakes` function creates a restricted Jakes (RJakes) Doppler spectrum object that is used for the `DopplerSpectrum` property of a channel object (created with either the `rayleighchan` or the `ricianchan` function).

`dop = doppler.rjakes` creates a Doppler spectrum object equivalent to the Jakes Doppler spectrum. The maximum Doppler shift of the RJakes Doppler spectrum object is specified by the `MaxDopplerShift` property of the channel object.

`dop = doppler.rjakes(freqminmaxrjakes)`, where `freqminmaxrjakes` is a row vector of two finite real numbers between 0 and 1, creates a Jakes Doppler spectrum. This spectrum is nonzero only for normalized frequencies (by the maximum Doppler shift, f_d, in Hertz), f_{norm}, such that $0 \le f_{\min,\,norm} \le |f_{norm}| \le f_{\max,\,norm} \le 1$, where $f_{\min,\,norm}$ is given by `freqminmaxrjakes(1)` and $f_{\max,\,norm}$ is given by `freqminmaxrjakes(2)`. The maximum Doppler shift f_d is specified by the `MaxDopplerShift` property of the channel object. Analytically, $f_{\min,\,norm} = f_{\min}/f_d$ and $f_{\max,\,norm} = f_{\max}/f_d$, where $f_{\min}$ is the minimum Doppler shift (in Hertz) and $f_{\max}$ is the maximum Doppler shift (in Hertz).

When `dop` is used as the `DopplerSpectrum` property of a channel object, `freqminmaxrjakes(1)` and `freqminmaxrjakes(2)` should be spaced by more than 1/50. Assigning a smaller spacing results in `freqminmaxrjakes` being reset to the default value of `[0 1]`.

Properties

The RJakes Doppler spectrum object contains the following properties.

Property	Description
`SpectrumType`	Fixed value, `'RJakes'`
`FreqMinMaxRJakes`	Vector of minimum and maximum normalized Doppler shifts (two real finite numbers between 0 and 1)

Theory and Applications

The Jakes power spectrum is based on the assumption that the angles of arrival at the mobile receiver are uniformly distributed [1], where the spectrum covers the frequency range from $-f_d$ to f_d, f_d

being the maximum Doppler shift. When the angles of arrival are not uniformly distributed, the Jakes power spectrum does not cover the full Doppler bandwidth from $-f_d$ to f_d. This exception also applies to the case where the antenna pattern is directional. This type of spectrum is known as *restricted Jakes* [3]. The RJakes Doppler spectrum object covers only the case of a symmetrical power spectrum, which is nonzero only for frequencies f such that $0 \leq f_{\min} \leq |f| \leq f_{\max} \leq f_d$.

The normalized RJakes Doppler power spectrum is given analytically by:

$$S(f) = \frac{A_r}{\pi f_d \sqrt{1 - (f/f_d)^2}},\ 0 \leq f_{\min} \leq |f| \leq f_{\max} \leq f_d$$

where

$$A_r = \frac{1}{\frac{2}{\pi}\left[\sin^{-1}\left(\frac{f_{\max}}{f_d}\right) - \sin^{-1}\left(\frac{f_{\min}}{f_d}\right)\right]}$$

$f_{\min}$ and $f_{\max}$ denote the minimum and maximum frequencies where the spectrum is nonzero. They can be determined from the probability density function of the angles of arrival.

Examples

The following code first creates a Rayleigh channel object with a maximum Doppler shift of $f_d = 10$. It then creates an RJakes Doppler object with minimum normalized Doppler shift $f_{\min,\,norm} = 0.14$ and maximum normalized Doppler shift $f_{\max,\,norm} = 0.9$.

The Doppler object is assigned to the `DopplerSpectrum` property of the channel object. The channel then has a Doppler spectrum that is nonzero for frequencies f such that $0 \leq f_{\min} \leq |f| \leq f_{\max} \leq f_d$, where $f_{\min} = f_{\min,\,norm} \times f_d = 1.4$ Hz and $f_{\max} = f_{\max,\,norm} \times f_d = 9$ Hz.

```
chan = rayleighchan(1/1000, 10);
dop_rjakes = doppler.rjakes([0.14 0.9]);
chan.DopplerSpectrum = dop_rjakes;
chan.DopplerSpectrum
```

The output is:

```
             SpectrumType: 'RJakes'
    FreqMinMaxRJakes: [0.1400 0.9000]
```

Compatibility Considerations

`doppler.rjakes` has been removed

Errors starting in R2020b

doppler.rjakes has been removed. Use `doppler('Restricted Jakes',...)` instead.

"Fading Channels"

Introduced in R2007a

doppler.rounded

(Removed) Construct rounded Doppler spectrum object

Note `doppler.rounded` has been removed. Use `doppler('Rounded',...)` instead.

Syntax

```
dop = doppler.rounded
dop = doppler.rounded(coeffrounded)
```

Description

The `doppler.rounded` function creates a rounded Doppler spectrum object that is used for the `DopplerSpectrum` property of a channel object (created with either the `rayleighchan` or the `ricianchan` function).

`dop = doppler.rounded` creates a rounded Doppler spectrum object with default polynomial coefficients $a_0 = 1$, $a_2 = -1.72$, $a_4 = 0.785$ (see “Theory and Applications” on page 2-300 for the meaning of these coefficients). The maximum Doppler shift f_d (in Hertz) is specified by the `MaxDopplerShift` property of the channel object.

`dop = doppler.rounded(coeffrounded)`, where `coeffrounded` is a row vector of three finite real numbers, creates a rounded Doppler spectrum object with polynomial coefficients, a_0, a_2, a_4, given by `coeffrounded(1)`, `coeffrounded(2)`, and `coeffrounded(3)`, respectively.

Properties

The rounded Doppler spectrum object contains the following properties.

Property	Description
`SpectrumType`	Fixed value, `'Rounded'`
`CoeffRounded`	Vector of three polynomial coefficients (real finite numbers)

Theory and Applications

A rounded spectrum is proposed as an approximation to the measured Doppler spectrum of the scatter component of fixed wireless channels at 2.5 GHz [1]. However, the shape of the spectrum is influenced by the center carrier frequency.

The normalized rounded Doppler spectrum is given analytically by a polynomial in f of order four, where only the even powers of f are retained:

$$S(f) = C_r\left[a_0 + a_2\left(\frac{f}{f_d}\right)^2 + a_4\left(\frac{f}{f_d}\right)^4\right],\ |f| \le f_d$$

where

$$C_r = \frac{1}{2f_d\left[a_0 + \frac{a_2}{3} + \frac{a_4}{5}\right]}$$

f_d is the maximum Doppler shift, and a_0, a_2, a_4 are real finite coefficients. The fixed wireless channel model of IEEE 802.16 [1] uses the following parameters: $a_0 = 1$, $a_2 = -1.72$, and $a_4 = 0.785$. Because the channel is modeled as Rician fading with a fixed line-of-sight (LOS) component, a Dirac delta is also present in the Doppler spectrum at $f = 0$.

Examples

The following code creates a Rician channel object with a maximum Doppler shift of $f_d = 10$. It then creates a rounded Doppler spectrum object with polynomial coefficients $a_0 = 1.0$, $a_2 = -0.5$, $a_4 = 1.5$, and assigns it to the `DopplerSpectrum` property of the channel object.

```
chan = ricianchan(1/1000,10,1);
dop_rounded = doppler.rounded([1.0 -0.5 1.5]);
chan.DopplerSpectrum = dop_rounded;
```

Compatibility Considerations

`doppler.rounded` has been removed

Errors starting in R2020b

doppler.rounded has been removed. Use `doppler('Rounded',...)` instead.

dpcmdeco

Decode using differential pulse code modulation

Syntax

```
sig = dpcmdeco(indx,codebook,predictor)
[sig,quanterror] = dpcmdeco(indx,codebook,predictor)
```

Description

`sig = dpcmdeco(indx,codebook,predictor)` implements differential pulse code demodulation to decode the vector `indx`. The vector `codebook` represents the predictive-error quantization codebook. The vector `predictor` specifies the predictive transfer function. If the transfer function has predictive order M, `predictor` has length M+1 and an initial entry of 0. To decode correctly, use the same codebook and predictor in `dpcmenco` and `dpcmdeco`.

See “Represent Partitions”, “Represent Codebooks”, or the `quantiz` reference page, for a description of the formats of `partition` and `codebook`.

`[sig,quanterror] = dpcmdeco(indx,codebook,predictor)` is the same as the syntax above, except that the vector `quanterror` is the quantization of the predictive error based on the quantization parameters. `quanterror` is the same size as `sig`.

Note You can estimate the input parameters `codebook`, `partition`, and `predictor` using the function `dpcmopt`.

Examples

See “Example: DPCM Encoding and Decoding” and “Example: Comparing Optimized and Nonoptimized DPCM Parameters” for examples that use `dpcmdeco`.

References

dpcmenco

Encode using differential pulse code modulation

Syntax

```
indx = dpcmenco(sig,codebook,partition,predictor)
[indx,quants] = dpcmenco(sig,codebook,partition,predictor)
```

Description

`indx = dpcmenco(sig,codebook,partition,predictor)` implements differential pulse code modulation to encode the vector `sig`. `partition` is a vector whose entries give the endpoints of the partition intervals. `codebook`, a vector whose length exceeds the length of `partition` by one, prescribes a value for each partition in the quantization. `predictor` specifies the predictive transfer function. If the transfer function has predictive order M, `predictor` has length M+1 and an initial entry of 0. The output vector `indx` is the quantization index.

See “Differential Pulse Code Modulation” for more about the format of `predictor`. See “Represent Partitions”, “Represent Partitions”, or the reference page for `quantiz` in this chapter, for a description of the formats of `partition` and `codebook`.

`[indx,quants] = dpcmenco(sig,codebook,partition,predictor)` is the same as the syntax above, except that `quants` contains the quantization of `sig` based on the quantization parameters. `quants` is a vector of the same size as `sig`.

Note If `predictor` is an order-one transfer function, the modulation is called a *delta modulation*.

Examples

See “Example: DPCM Encoding and Decoding” and “Example: Comparing Optimized and Nonoptimized DPCM Parameters” for examples that use `dpcmenco`.

References

[1] Kondoz, A. M., *Digital Speech*, Chichester, England, John Wiley & Sons, 1994.

Topics

“Differential Pulse Code Modulation”

Introduced before R2006a

dpcmopt

Optimize differential pulse code modulation parameters

Syntax

```
predictor = dpcmopt(training_set,ord)
[predictor,codebook,partition] = dpcmopt(training_set,ord,len)
[predictor,codebook,partition] = dpcmopt(training_set,ord,ini_cb)
```

Description

`predictor = dpcmopt(training_set,ord)` returns a vector representing a predictive transfer function of order `ord` that is appropriate for the training data in the vector `training_set`. `predictor` is a row vector of length `ord+1`. See "Represent Predictors" for more about its format.

Note `dpcmopt` optimizes for the data in `training_set`. For best results, `training_set` should be similar to the data that you plan to quantize.

`[predictor,codebook,partition] = dpcmopt(training_set,ord,len)` is the same as the syntax above, except that it also returns corresponding optimized codebook and partition vectors `codebook` and `partition`. `len` is an integer that prescribes the length of `codebook`. `partition` is a vector of length `len`-1. See "Represent Partitions", "Represent Codebooks", or the reference page for `quantiz` in this chapter, for a description of the formats of `partition` and `codebook`.

`[predictor,codebook,partition] = dpcmopt(training_set,ord,ini_cb)` is the same as the first syntax, except that it also returns corresponding optimized codebook and partition vectors `codebook` and `partition`. `ini_cb`, a vector of length at least 2, is the initial guess of the codebook values. The output `codebook` is a vector of the same length as `ini_cb`. The output `partition` is a vector whose length is one less than the length of `codebook`.

Examples

See "Example: Comparing Optimized and Nonoptimized DPCM Parameters" for an example that uses `dpcmopt`.

Topics

"Differential Pulse Code Modulation"

Introduced before R2006a

dpskdemod

Differential phase shift keying demodulation

Syntax

```
z = dpskdemod(y,M)
z = dpskdemod(y,M,phaserot)
z = dpskdemod(y,M,phaserot,symorder)
```

Description

`z = dpskdemod(y,M)` demodulates the complex envelope, `y`, of a DPSK-modulated signal having modulation order `M`.

`z = dpskdemod(y,M,phaserot)` specifies the phase rotation of the DPSK modulation.

`z = dpskdemod(y,M,phaserot,symorder)` also specifies the symbol order.

Examples

DPSK Demodulation

Demodulate DPSK data in a communication channel in which a phase shift is introduced.

Generate a 4-ary data vector and modulate it using DPSK.

```
M = 4;                         % Alphabet size
dataIn = randi([0 M-1],1000,1); % Random message
txSig = dpskmod(dataIn,M);      % Modulate
```

Apply the random phase shift resulting from the transmission process.

```
rxSig = txSig*exp(2i*pi*rand());
```

Demodulate the received signal.

```
dataOut = dpskdemod(rxSig,M);
```

The modulator and demodulator have the same initial condition. However, only the received signal experiences a phase shift. As a result, the first demodulated symbol is likely to be in error. Therefore, you should always discard the first symbol when using DPSK.

Find the number of symbol errors.

```
errs = symerr(dataIn,dataOut)
```

```
errs = 1
```

One symbol is in error. Repeat the error calculation after discarding the first symbol.

```
errs = symerr(dataIn(2:end),dataIn(2:end))
errs = 0
```

Input Arguments

y — DPSK-modulated input signal

vector | matrix

DPSK-modulated input signal, specified as a real or complex vector or matrix. If `y` is a matrix, the function processes the columns independently.

Data Types: `double`
Complex Number Support: Yes

`M` — Modulation order

integer power of two

Modulation order, specified as an integer power of two.

Example: `2` | `4` | `16`

Data Types: `double`

`phaserot` — Phase rotation

0 (default) | scalar | `[]`

Phase rotation of the DPSK modulation, specified in radians as a real scalar. The total phase shift per symbol is the sum of `phaserot` and the phase generated by the differential modulation.

If you specify `phaserot` as empty, then `dspkdemod` uses a phase rotation of 0 degrees.

Example: `pi/4`

Data Types: `double`

`symorder` — Symbol order

`'bin'` (default) | `'gray'`

Symbol order, specified as `'bin'` or `'gray'`. This argument specifies how the function assigns binary vectors to corresponding integers.

- If `symorder` is `'bin'`, the function uses a natural binary-coded ordering.
- If `symorder` is `'gray'`, the function uses a Gray-coded ordering.

Data Types: `char`

Output Arguments

z — DPSK-demodulated output signal

vector | matrix

DPSK-demodulated output signal, returned as a vector or matrix having the same number of columns as input signal `y`.

Note The differential algorithm used in this function compares two successive elements of a modulated signal. To determine the first element of vector `z`, or the first row of matrix `z`, the function uses an initial phase rotation of `0`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Topics

"Phase Modulation"

Introduced before R2006a

dpskmod

Differential phase shift keying modulation

Syntax

```
y = dpskmod(x,M)
y = dpskmod(x,M,phaserot)
y = dpskmod(x,M,phaserot,symorder)
```

Description

`y = dpskmod(x,M)` modulates the input signal using differential phase shift keying (DPSK) with modulation order `M`.

`y = dpskmod(x,M,phaserot)` specifies the phase rotation of the DPSK modulation.

`y = dpskmod(x,M,phaserot,symorder)` also specifies the symbol order.

Examples

View Signal Trajectory of DPSK-Modulated Signal

Plot the output of the `dspkmod` function to view the possible transitions between DPSK symbols.

Set the modulation order to 4 to model DQPSK modulation.

```
M = 4;
```

Generate a sequence of 4-ary random symbols.

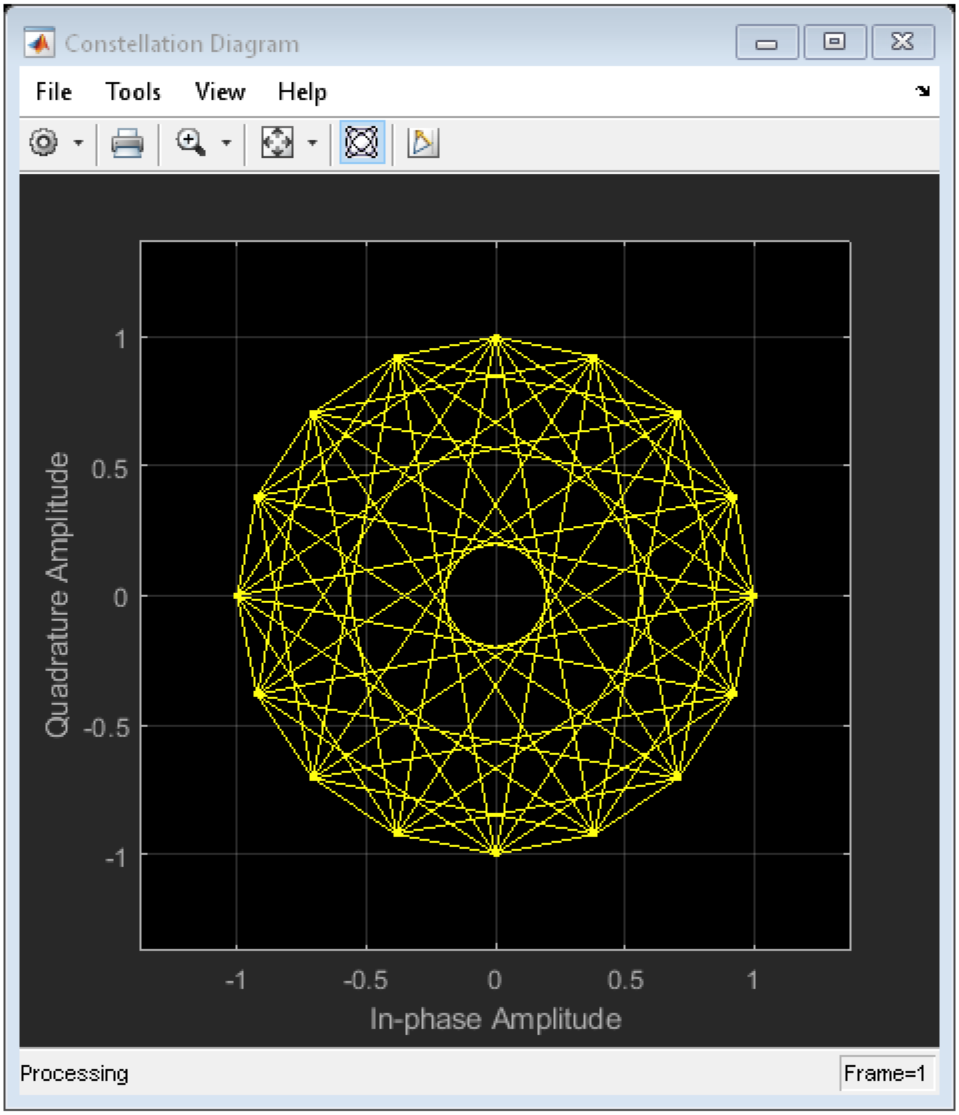
```
x = randi([0 M-1],500,1);
```

Apply DQPSK modulation to the input symbols.

```
y = dpskmod(x,M,pi/8);
```

Specify a constellation diagram object to display a signal trajectory diagram and without displaying the corresponding reference constellation. Display the trajectory.

```
cd = comm.ConstellationDiagram('ShowTrajectory',true,'ShowReferenceConstellation',false);
cd(y)
```



Input Arguments

x — Input signal

vector | matrix

Input signal, specified as a vector or matrix of positive integers. The elements of x must have values in the range of [0, M – 1].

Data Types: double

M — Modulation order

integer power of two

Modulation order, specified as an integer power of two.

Example: 2 | 4 | 16

Data Types: double

phaserot — Phase rotation

0 (default) | scalar | [ ]

Phase rotation of the DPSK modulation, specified in radians as a real scalar. The total phase shift per symbol is the sum of phaserot and the phase generated by the differential modulation.

If you specify phaserot as empty, then dpskmod uses a phase rotation of 0 degrees.

Example: pi/4

Data Types: double

symorder — Symbol order

'bin' (default) | 'gray'

Symbol order, specified as 'bin' or 'gray'. This argument specifies how the function assigns binary vectors to corresponding integers.

- If symorder is 'bin', the function uses a natural binary-coded ordering.
- If symorder is 'gray', the function uses a Gray-coded ordering.

Data Types: char

Output Arguments

y — DPSK-modulated output signal

vector | matrix

Complex baseband representation of a DPSK-modulated output signal, returned as vector or matrix of complex values. The columns represent independent channels.

Note An initial phase rotation of 0 is used in determining the first element of the output y (or the first row of y if it is a matrix with multiple rows), because two successive elements are required for a differential algorithm.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Topics

“Phase Modulation”

Introduced before R2006a

dvbs2ldpc

Low-density parity-check (LDPC) codes from DVB-S.2 standard

Syntax

```
H = dvbs2ldpc(r)
H = dvbs2ldpc(r,outputFormat)
```

Description

`H = dvbs2ldpc(r)` returns the parity-check matrix `H` of the LDPC code with code rate `r` from the Digital Video Broadcasting standard DVB-S.2. The block length of the code is 64,800.

`H = dvbs2ldpc(r,outputFormat)` specifies the format for the output parity-check matrix.

Examples

Create LDPC Code Parity-Check Matrix from DVB-S.2 Standard

Create an LDPC parity check matrix for a code rate of 3/5 from the DVB-S.2 standard.

```
p = dvbs2ldpc(3/5);
```

Create an LDPC encoder object from the parity-check matrix `p`.

```
enc = comm.LDPCEncoder(p);
```

The parity-check matrix has dimensions of (*N*-*K*)-by-*N*. Calculate the length of the input message.

```
msgLength = size(p,2) - size(p,1)
```

```
msgLength = 38880
```

Input Arguments

`r` — Code rate
1/4 | 1/3 | 2/5 | 1/2 | ...

Code rate, specified as `1/4`, `1/3`, `2/5`, `1/2`, `3/5`, `2/3`, `3/4`, `4/5`, `5/6`, `8/9`, or `9/10`.

Data Types: `double`

`outputFormat` — Output format
`'sparse'` | `'indices'`

Output format for parity-check matrix `H`, specified as `'sparse'` or `'indices'`.

If you set this value to `'sparse'`, `H` is a sparse logical matrix. If you set this value to `'indices'`, `H` is a two-column matrix that defines the row and column indices of the 1s in `H`.

Data Types: `char` | `string`

Output Arguments

`H` — Parity-check matrix

matrix

Parity-check matrix, returned as a matrix.

The default parity-check matrix of size 32,400-by-64,800 corresponds to an irregular LDPC code with the structure shown in this table.

Row	Number of 1s per Row
1	6
2 to 32400	7

Column	Number of 1s per Column
1 to 12960	8
12961–32400	3

Columns from 32,401 to 64,800 form a lower triangular matrix. Only the elements on the main diagonal of the matrix and the subdiagonal immediately below the main diagonal are 1s. This LDPC code is used in conjunction with a BCH code in the DVB-S.2 standard to achieve a packet error rate below 10^{-7} at about 0.7 dB to 1 dB from the Shannon limit.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

All inputs must be constants. Expressions or variables are allowed if their values do not change.

`comm.LDPCDecoder` | `comm.LDPCEncoder`

Introduced in R2007a

dvbsapskdemod

DVB-S2/S2X/SH standard-specific amplitude phase shift keying (APSK) demodulation

Syntax

```
z = dvbsapskdemod(y,M,stdSuffix)
z = dvbsapskdemod(y,M,stdSuffix,codeIDF)
z = dvbsapskdemod(y,M,stdSuffix,codeIDF,frameLength)
z = dvbsapskdemod( ___ ,Name,Value)
```

Description

`z = dvbsapskdemod(y,M,stdSuffix)` demodulates an APSK input signal, `y`, that was modulated in accordance with the digital video broadcast (DVB) standard identified by `stdSuffix` and the modulation order, `M`. For a description of DVB-compliant APSK demodulation, see “DVB Compliant APSK Hard Demodulation” on page 2-319 and “DVB Compliant APSK Soft Demodulation” on page 2-319.

`z = dvbsapskdemod(y,M,stdSuffix,codeIDF)` specifies code identifier `codeIDF`, to use when selecting the demodulation parameters.

`z = dvbsapskdemod(y,M,stdSuffix,codeIDF,frameLength)` specifies `codeIDF` and `frameLength` to use when selecting the demodulation parameters.

`z = dvbsapskdemod( ___ ,Name,Value)` specifies options using one or more name-value pair arguments using any of the previous syntaxes. For example, `'OutputDataType','double'` specifies the desired output data type. Specify name-value pair arguments after all other input arguments.

Examples

Demodulate DVB-S2X Specific 64-APSK Signal

Demodulate a 64-APSK signal that was modulated as specified in DVB-S2X. Compute hard decision integer output and verify that the output matches the input.

Set the modulation order and standard suffix. Generate random data.

```
M = 64;
std = 's2x';
x = randi([0 M-1],1000,1);
```

Modulate the data.

```
y = dvbsapskmod(x,M,std);
```

Demodulate the received signal. Compare the demodulated data to the original data.

```
z = dvbsapskdemod(y,M,std);
isequal(z,x)
```

```
ans = logical
   1
```

Demodulate DVB-S2 Specific 32-APSK Signal

Demodulate a 32-APSK signal that was modulated as specified in DVB-S2. Compute hard decision bit output and verify that the output matches the input.

Set the modulation order, standard suffix, and code identifier. Generate random bit data.

```
M = 32;
std = 's2';
codeIDF = '4/5';
numBitsPerSym = log2(M);
x = randi([0 1],100*numBitsPerSym,1,'uint32');
```

Modulate the data. Use a name-value pair to specify bit input data.

```
y = dvbsapskmod(x,M,std,codeIDF,'InputType','bit');
```

Demodulate the received signal. Compare the demodulated data to the original data.

```
z = dvbsapskdemod(y,M,std,'4/5','OutputType','bit', ...
    'OutputDataType','uint32');
isequal(z,x)
```

```
ans = logical
   1
```

Soft Bit Demodulate DVB-SH Specific 16-APSK Signal

Demodulate a DVB-SH compliant 16-APSK signal and calculate soft bits.

Set the modulation order and generate a random bit sequence.

```
M = 16;
std = 'sh';
numSym = 20000;
numBitsPerSym = log2(M);
x = randi([0 1],numSym*numBitsPerSym,1);
```

Modulate the data. Use a name-value pair to specify bit input data.

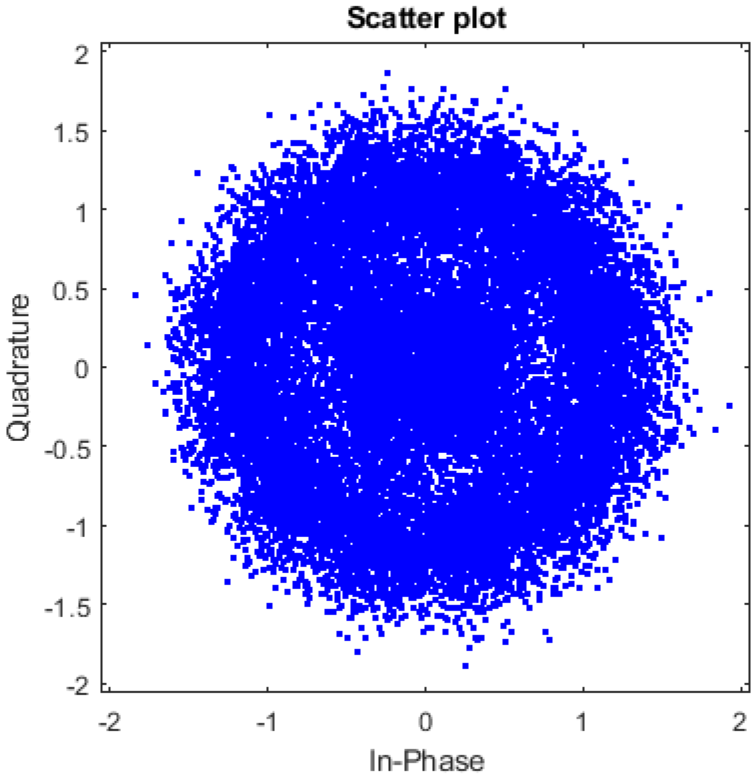
```
txSig = dvbsapskmod(x,M,std,'InputType','bit');
```

Pass the modulated signal through a noisy channel.

```
rxSig = awgn(txSig,10,'measured');
```

View the constellation of the received signal using a scatter plot.

```
scatterplot(rxSig)
```



DVB-SH compliant constellations have unit average power. Demodulate the signal, computing soft bits using the approximate LLR algorithm.

```
z = dvbsapskdemod(rxSig,M,std,'OutputType','approxllr', ...
     'NoiseVariance',0.1);
```

Input Arguments

y — APSK modulated signal

scalar | vector | matrix

APSK modulated signal, specified as a complex scalar, vector, or matrix. When y is a matrix, each column is treated as an independent channel.

y must be modulated in accordance with Digital Video Broadcasting (DVB) - Satellite Communications standard DVB-S2, DVB-S2X or DVB-SH. For more information, see [1], [2], and [3].

Data Types: single | double
Complex Number Support: Yes

M — Modulation order

integer

Modulation order, specified as a power of two. The modulation order specifies the total number of points in the signal constellation.

Data Types: double

stdSuffix — Standard suffix

's2' | 's2x' | 's2h'

Standard suffix for DVBS modulation variant, specified as 's2', 's2x', or 's2h'.

Data Types: char | string

codeIDF — Code identifier

char | string

Code identifier, specified as a character vector or string. This table lists the acceptable codeIDF values.

Constellation Order (M)	Applicable Standard (stdSuffix)	Acceptable Code Identifier (CodeIDF) Values
16	's2' or 's2x'	'2/3', '3/4', '4/5', '5/6', '8/9', '9/10'
16	's2x'	'26/45', '3/5', '28/45', '23/36', '25/36', '13/18', '7/9', '77/90', '100/180', '96/180', '90/180', '18/30', '20/30'
32	's2' or 's2x'	'3/4', '4/5', '5/6', '8/9', '9/10'
32	's2x'	'32/45', '11/15', '7/9', '2/3'
64	's2x'	'11/15', '7/9', '4/5', '5/6', '128/180'
128	's2x'	'3/4', '7/9'
256	's2x'	'32/45', '3/4', '116/180', '20/30', '124/180', '22/30'

For more information, refer to Tables 9 and 10 in the DVB-S2 standard [1] and Table 17a in the DVB-S2X standard [2].

Dependencies

This input argument applies only when stdSuffix is set to 's2' or 's2x'.

Data Types: char | string

frameLength — Frame length

'normal' (default) | 'short'

Frame length, specified as 'normal' or 'short'. The function usesframeLength and codeIDF to select the modulation parameters.

Dependencies

This input argument applies only when stdSuffix is set to 's2' or 's2x'.

Data Types: char | string

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `y = dvbsapskdemod(x,M,stdSuffix,'InputType','bit','OutputDataType','single');`

`OutputType` — Output type

`'integer'` (default) | `'bit'` | `'llr'` | `'approxllr'`

Output type, specified as the comma-separated pair consisting of `OutputType` and `'integer'`, `'bit'`, `'llr'`, or `'approxllr'`. For a description of returned output, see `z`.

Data Types: `char` | `string`

`OutputDataType` — Output data type

`'double'` (default) | `...`

Output data type, specified as the comma-separated pair consisting of `OutputDataType` and one of the indicated data types. Acceptable values for `OutputDataType` depend on the `OutputType` value.

`OutputType` Value	Acceptable `OutputDataType` Values
`'integer'`	`'double'`, `'single'`, `'int8'`, `'int16'`, `'int32'`, `'uint8'`, `'uint16'`, or `'uint32'`
`'bit'`	`'double'`, `'single'`, `'int8'`, `'int16'`, `'int32'`, `'uint8'`, `'uint16'`, `'uint32'`, or `'logical'`

Dependencies

This name-value pair argument applies only when `OutputType` is set to `'integer'` or `'bit'`.

Data Types: `char` | `string`

`UnitAveragePower` — Unit average power flag

`false` (default) | `true`

Unit average power flag, specified as the comma-separated pair consisting of `UnitAveragePower` and a logical scalar. When this flag is `true`, the function scales the constellation to an average power of 1 watt referenced to 1 ohm. When this flag is `false`, the function scales the constellation based on specifications in the relevant standard, as described in [1] and [2].

Note When `stdSuffix` is set to `'sh'`, the constellation always has unit average power.

Dependencies

This name-value pair argument applies only when `stdSuffix` is set to `'s2'` or `'s2x'`.

Data Types: `logical`

`NoiseVariance` — Noise variance

`1` (default) | positive scalar | vector of positive values

Noise variance, specified as the comma-separated pair consisting of NoiseVariance and a positive scalar or vector of positive values.

- When specified as a scalar, the same noise variance value is used on all input elements.
- When specified as a vector, the vector length must be equal to the number of columns in the input signal.

When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see “DVB Compliant APSK Soft Demodulation” on page 2-319 for algorithm selection considerations.

Dependencies

This name-value pair argument applies only when OutputType is set to 'llr' or 'approxllr'.

Data Types: double

PlotConstellation — Option to plot constellation

false (default) | true

Option to plot constellation, specified as the comma-separated pair consisting of 'PlotConstellation' and a logical scalar. To plot the constellation, set PlotConstellation to true.

Data Types: logical

Output Arguments

z — Demodulated signal

scalar | vector | matrix

Demodulated signal, returned as a scalar, vector, or matrix. The dimensions of the output vary depending on the specified OutputType value.

OutputType Value	Return Value of dvbsapskdemod	Dimensions of z
'integer'	Demodulated integer values from 0 to (M – 1)	z has the same dimensions as input y.
'bit'	Demodulated bits	The number of rows in z is $\log_2$(sum(M)) times the number of rows in y. Each demodulated symbol is mapped to a group of $\log_2$(sum(M)) elements in a column, where the first element represents the MSB and the last element represents the LSB.
'llr'	Log-likelihood ratio value for each bit	
'approxllr'	Approximate log-likelihood ratio value for each bit	

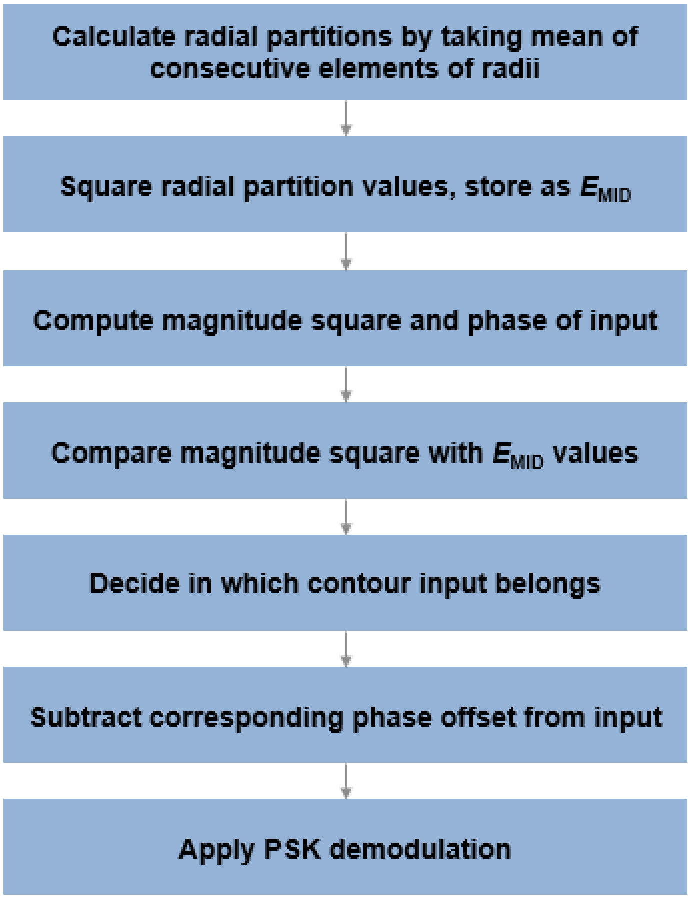
More About

DVB-S2/S2X/SH

Digital video broadcasting (DVB) standards specify S2, S2X, and SH standard-specific amplitude phase shift keying (APSK) modulation. For further information on the DVB-S2/S2X/SH standards, see specified in [1], [2], and [3], respectively.

DVB Compliant APSK Hard Demodulation

The hard demodulation algorithm applies amplitude phase decoding as described in [4].



Calculate radial partitions by taking mean of consecutive elements of radii
Square radial partition values, store as E_{MID}
Compute magnitude square and phase of input
Compare magnitude square with E_{MID} values
Decide in which contour input belongs
Subtract corresponding phase offset from input
Apply PSK demodulation

DVB Compliant APSK Soft Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. This table compares these algorithms.

Algorithm	Accuracy	Execution Speed
Exact LLR	more accurate	slower execution
Approximate LLR	less accurate	faster execution

For further description of these algorithms, see “Exact LLR Algorithm” and “Approximate LLR Algorithm”.

Note The exact LLR algorithm computes exponentials using finite precision arithmetic. Computation of exponentials with very large positive or negative magnitudes might yield:

- `Inf` or `-Inf` if the noise variance is a very large value

- `NaN` if both the noise variance and signal power are very small values

When the output returns any of these values, try using the approximate LLR algorithm because it does not compute exponentials.

dvbsapskmod

DVB-S2/S2X/SH standard-specific amplitude phase shift keying (APSK) modulation

Syntax

```
y = dvbsapskmod(x,M,stdSuffix)
y = dvbsapskmod(x,M,stdSuffix,codeIDF)
y = dvbsapskmod(x,M,stdSuffix,codeIDF,frameLength)
y = dvbsapskmod(___,Name,Value)
```

Description

`y = dvbsapskmod(x,M,stdSuffix)` performs APSK modulation on the input signal, `x`, in accordance with the digital video broadcast (DVB) standard identified by `stdSuffix` and the modulation order, `M`.

`y = dvbsapskmod(x,M,stdSuffix,codeIDF)` specifies the code identifier, `codeIDF`, to use when selecting the modulation parameters.

`y = dvbsapskmod(x,M,stdSuffix,codeIDF,frameLength)` specifies `codeIDF` and `frameLength` to use when selecting the modulation parameters.

`y = dvbsapskmod(___,Name,Value)` specifies options using one or more name-value pair arguments using any of the previous syntaxes. For example, `'OutputDataType','double'` specifies the desired output data type as double. Specify name-value pair arguments after all other input arguments.

Examples

Apply DVB-S2X 32-APSK Modulation to Data

Modulate data using the DVB-S2X standard specified 32-APSK modulation scheme. Display the result in a scatter plot.

Set the modulation order and the suffix identifying the DVB-S2X standard. Create a data vector with all possible symbols.

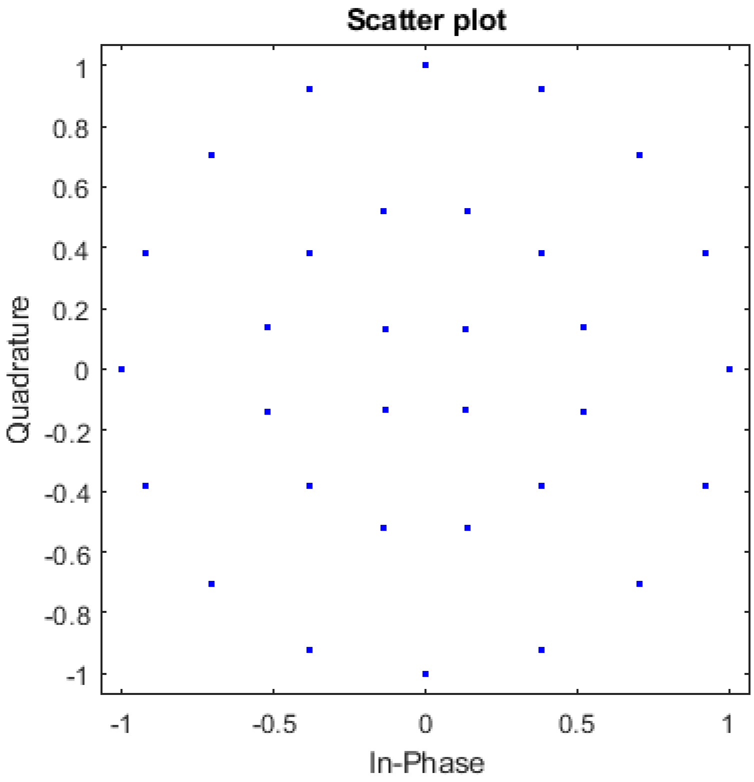
```
M = 32;
stdSuffix = 's2x';
x = (0:M-1);
```

Modulate the data.

```
y = dvbsapskmod(x,M,stdSuffix);
```

Display the constellation using a scatter plot.

```
scatterplot(y)
```



Apply DVB-S2X 64-APSK Modulation Specifying Code Identifier

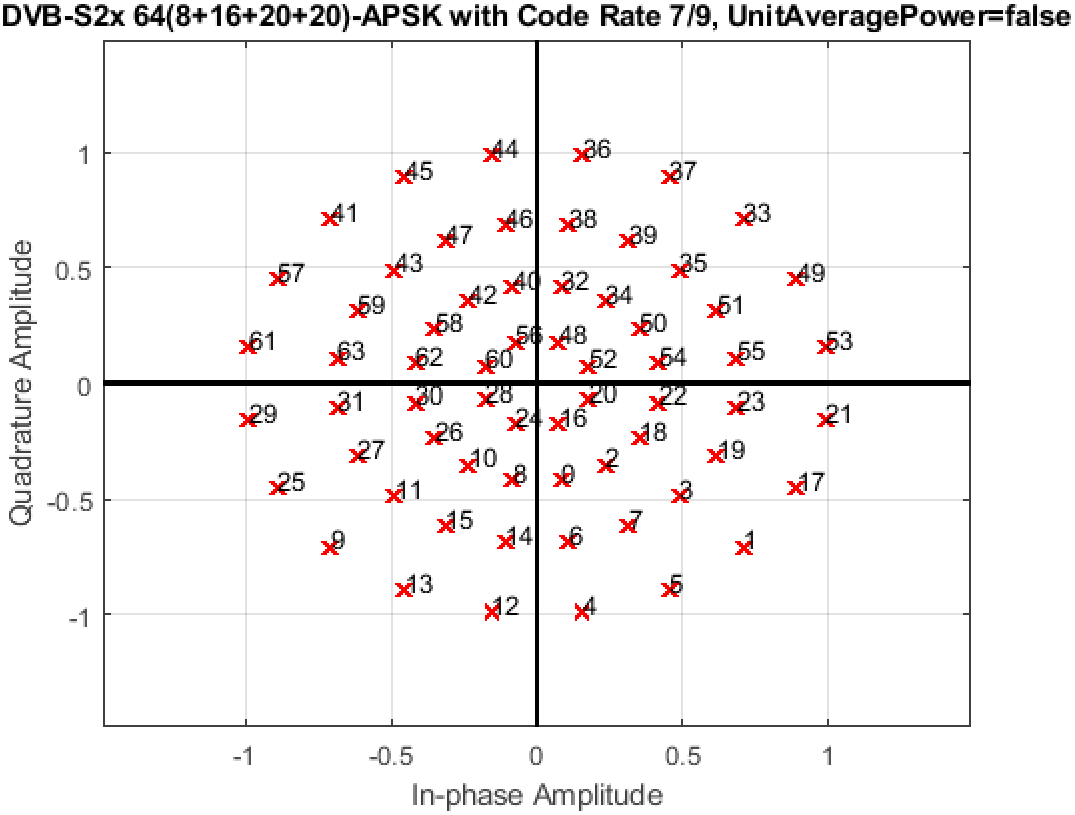
Modulate data using 64-APSK as specified in DVB-S2X standard. Plot constellation for different code identifiers.

Set the modulation order and standard suffix. Generate 1000 symbols of random data in one channel.

```
M = 64;
std = 's2x';
x = randi([0 M-1],1000,1);
```

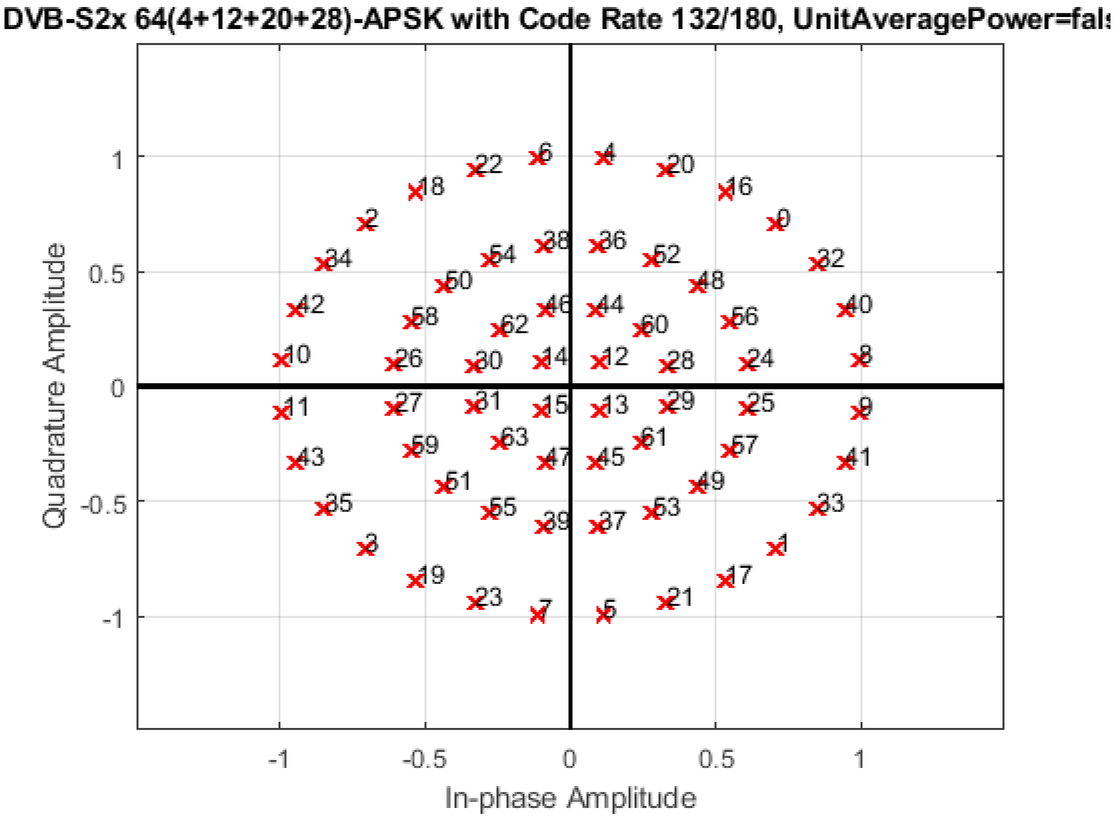
Modulate the data according to the 64-APSK constellation for the code identifier 7/9 and plot the reference constellation.

```
y1 = dvbsapskmod(x,M,std,'7/9','PlotConstellation',true);
```



Modulate setting the code identifier to 132/180 and observe the constellation structure differences.

```
y2 = dvbsapskmod(x,M,std,'132/180','PlotConstellation',true);
```



Apply DVB-S2 16-APSK Modulation Change Frame Length

Modulate data using 16-APSK as specified in DVB-S2 standard for normal and short frame lengths. Compute the output signal power.

Set the modulation order and the standard suffix. Generate random bit data for 1000 symbols in one channel.

```
M = 16;
std = 's2';
x = randi([0 1],1000*log2(M),1);
```

Set the input type to bit and modulate the data according to the 16-APSK constellation for code identifier 2/3. Use the default normal frame length.

```
y1 = dvbsapskmod(x,M,std,'2/3','InputType','bit');
```

Modulate the data using different settings, set the code-identifier to 8/9 and use a short frame length.

```
y2 = dvbsapskmod(x,M,std,'8/9','short','InputType','bit');
```

The average power of the modulated signal changes based on the code identifier. Compute the average power of the modulated signals.

```
y1avgPow = mean(abs(y1).^2)
```

```
y1avgPow = 0.7590
```

```
y2avgPow = mean(abs(y2).^2)
```

```
y2avgPow = 0.7716
```

Normalize 16-APSK Modulated DVB Signals by Average Power

Modulate data applying 16-APSK as specified in the DVB-SH and DVB-S2 standards. Normalize the modulator output so that it has an average signal power of 1 W.

Set the modulation order and generate all possible symbols.

```
M = 16;
x =  0:M-1;
```

Modulate the data applying 16-APSK as specified in DVB-SH. Use a name-value pair to specify single data type output.

```
y1 = dvbsapskmod(x,M,'sh','OutputDataType','single');
```

Modulate the data applying 16-APSK as specified in DVB-S2. Use a name-value pair to specify single data type output.

```
y2 = dvbsapskmod(x,M,'s2','OutputDataType','single');
```

Modulate the data applying 16-APSK as specified in DVB-S2. Use name-value pairs to set unit average power to true and to specify single data type output.

```
y3 = dvbsapskmod(x,M,'s2','UnitAveragePower',true,'OutputDataType','single');
```

Check which signals have unit average power.

```
y1avgPow = mean(abs(y1).^2)
```

```
y1avgPow = single
    1
```

```
y2avgPow = mean(abs(y2).^2)
```

```
y2avgPow = single
    0.7752
```

```
y3avgPow = mean(abs(y3).^2)
```

```
y3avgPow = single
    1.0000
```

Input Arguments

x — Input signal
scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix. The elements of x must be binary values or integers that range from 0 to (M – 1), where M is the modulation order.

Note To process the input signal as binary elements, set 'InputType' value to 'bit'. For binary inputs, the number of rows must be an integer multiple of $\log_2$(M). A group of $\log_2$(M) bits in a column are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

Data Types: double | single | int8 | int16 | int32 | uint8 | uint16 | uint32 | logical

M — Modulation order
integer

Modulation order, specified as a power of two. The modulation order specifies the total number of points in the signal constellation.

Data Types: double

stdSuffix — Standard suffix
's2' | 's2x' | 'sh'

Standard suffix for DVBS modulation variant, specified as 's2', 's2x', or 'sh'.

Data Types: char | string

codeIDF — Code identifier
char | string

Code identifier, specified as a character vector or string. This table lists the acceptable codeIDF values.

Constellation Order (M)	Applicable Standard (stdSuffix)	Acceptable Code Identifier (CodeIDF) Values
16	's2' or 's2x'	'2/3', '3/4', '4/5', '5/6', '8/9', '9/10'
16	's2x'	'26/45', '3/5', '28/45', '23/36', '25/36', '13/18', '7/9', '77/90', '100/180', '96/180', '90/180', '18/30', '20/30'
32	's2' or 's2x'	'3/4', '4/5', '5/6', '8/9', '9/10'
32	's2x'	'32/45', '11/15', '7/9', '2/3'
64	's2x'	'11/15', '7/9', '4/5', '5/6', '128/180'
128	's2x'	'3/4', '7/9'
256	's2x'	'32/45', '3/4', '116/180', '20/30', '124/180', '22/30'

For more information, refer to Tables 9 and 10 in the DVB-S2 standard, [1], and Table 17a in the DVB-S2X standard, [2].

Dependencies

This input argument applies only when `stdSuffix` is set to `'s2'` or `'s2x'`.

Data Types: `char` | `string`

`frameLength` — Frame length

`'normal'` (default) | `'short'`

Frame length, specified as `'normal'` or `'short'`. `frameLength` and `codeIDF` are used to determine the modulation parameters.

Dependencies

This input argument applies only when `stdSuffix` is set to `'s2'` or `'s2x'`.

Data Types: `char` | `string`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `y = dvbsapskmod(x,M,std,'InputType','bit','OutputDataType','single');`

`InputType` — Input type

`'integer'` (default) | `'bit'`

Input type, specified as the comma-separated pair consisting of `'InputType'` and either `'integer'` or `'bit'`. To use `'integer'`, the input signal must consist of integer values from `0` to (`M` – 1). To use `'bit'`, the input signal must contain binary values and the number of rows must be an integer multiple of $\log_2(M)$.

Data Types: `char` | `string`

`UnitAveragePower` — Unit average power flag

`false` (default) | `true`

Unit average power flag, specified as the comma-separated pair consisting of `'UnitAveragePower'` and a logical scalar. When this flag is `true`, the function scales the constellation to an average power of 1 watt referenced to 1 ohm. When this flag is `false`, the function scales the constellation based on specifications in the relevant standard, as described in [1] and [2].

Note When `stdSuffix` is set to `'sh'`, the constellation always has unit average power.

Dependencies

This name-value pair argument applies only when `stdSuffix` is set to `'s2'` or `'s2x'`.

Data Types: `logical`

`OutputDataType` — Output data type

`'double'` (default) | `'single'`

Output data type, specified as the comma-separated pair consisting of `'OutputDataType'` and either `'double'` or `'single'`.

Data Types: `char` | `string`

`PlotConstellation` — Option to plot constellation
`false` (default) | `true`

Option to plot constellation, specified as the comma-separated pair consisting of `'PlotConstellation'` and a logical scalar. To plot the constellation, set `PlotConstellation` to `true`.

Data Types: `logical`

Output Arguments

y — Modulated signal
scalar | vector | matrix

Modulated signal, returned as a complex scalar, vector, or matrix. The dimensions of `y` depend on the specified `'InputType'` value.

`'InputType'` Value	Dimensions of `y`
`'integer'`	`y` has the same dimensions as input `x`.
`'bit'`	The number of rows in `y` equals the number of rows in `x` divided by $\log_2$(`M`).

Data Types: `double` | `single`

More About

DVB-S2/S2X/SH

Digital video broadcasting (DVB) standards specify S2, S2X, and SH standard-specific amplitude phase shift keying (APSK) modulation. For further information on the DVB-S2/S2X/SH standards, see specified in [1], [2], and [3], respectively.

Introduced in R2018a

encode

Block encoder

Syntax

```
code = encode(msg,n,k)
code = encode(msg,n,k,codingMethod,prim_poly)
code = encode(msg,n,k,codingMethod,genmat)
code = encode(msg,n,k,codingMethod,genpoly)
[code,added] = encode( ___ )
```

Description

`code = encode(msg,n,k)` encodes message, `msg`, using the Hamming encoding method with codeword length, `n`, and message length, `k`. The value of `n` must be calculated for an integer, *m*, such that $m \geq 2$. The values of `n` and `k` are calculated as 2^m–1 and `n`–*m*, respectively.

`code = encode(msg,n,k,codingMethod,prim_poly)` encodes `msg` using `codingMethod` as the Hamming encoding method, and `prim_poly` as the primitive polynomial. The value of `n` must be calculated for an integer, m≥2.

`code = encode(msg,n,k,codingMethod,genmat)` encodes `msg` using `codingMethod` as the linear block encoding method and `genmat` as the generator matrix. The value of `n` must be calculated for an integer, m≥2.

`code = encode(msg,n,k,codingMethod,genpoly)` encodes `msg` using `codingMethod` as the systematic cyclic code and `genpoly`, as the generator polynomial. The value of `n` must be calculated for an integer, m≥2.

`[code,added] = encode( ___ )` returns the additional variable `added`. `added` denotes the number of zeros appended at the end of the message matrix before encoding. You can specify any of the input argument combinations from the previous syntaxes.

Examples

Encode and Decode Message with Hamming Code

Set the values of the codeword length and message length.

```
n = 15; % Codeword length
k = 11; % Message length
```

Create a random binary message with length equal to the message length.

```
data = randi([0 1],k,1);
```

Encode the message.

```
encData = encode(data,n,k,'hamming/binary');
```

Corrupt the encoded message sequence by introducing an error in the fourth bit.

```
encData(4) = ~encData(4);
```

Decode the corrupted sequence. Observe that the decoder has correctly recovered the message.

```
decData = decode(encData,n,k,'hamming/binary');
numerr = biterr(data,decData)
```

```
numerr = 0
```

Encode and Decode Message with Linear Block Code

Set the values of codeword length and message length.

```
n = 7; % Codeword length
k = 3; % Message length
```

Create a random binary message with length equal to the message length.

```
data = randi([0 1],k,1);
```

Create a cyclic generator polynomial. Then, create a parity-check matrix and convert it into a generator matrix.

```
pol = cyclpoly(n,k);
parmat = cyclgen(n,pol);
genmat = gen2par(parmat);
```

Encode the message sequence by using the generator matrix.

```
encData = encode(data,n,k,'linear/binary',genmat);
```

Corrupt the encoded message sequence by introducing an error in the third bit.

```
encData(3) = ~encData(3);
```

Decode the corrupted sequence. Observe that the decoder has correctly recovered the message.

```
decData = decode(encData,n,k,'linear/binary',genmat);
```

```
Single-error patterns loaded in decoding table.  8 rows remaining.
2-error patterns loaded.  1 rows remaining.
3-error patterns loaded.  0 rows remaining.
```

```
numerr = biterr(data,decData)
```

```
numerr = 0
```

Encode and Decode Message with Cyclic Block Code

Set the values of the codeword length and message length.

```
n = 15; % Codeword length
k = 5; % Message length
```

Create a random binary message with length equal to the message length.

```
data = randi([0 1],k,1);
```

Create a generator polynomial for a cyclic code. Create a parity-check matrix by using the generator polynomial.

```
genpoly = cyclpoly(n,k);
parmat = cyclgen(n,genpoly);
```

Create a syndrome decoding table by using the parity-check matrix.

```
trt = syndtable(parmat);
```

```
Single-error patterns loaded in decoding table.  1008 rows remaining.
2-error patterns loaded.  918 rows remaining.
3-error patterns loaded.  648 rows remaining.
4-error patterns loaded.  243 rows remaining.
5-error patterns loaded.  0 rows remaining.
```

Encode the data by using the generator polynomial.

```
encData = encode(data,n,k,'cyclic/binary',genpoly);
```

Corrupt the encoded message sequence by introducing errors in the first, second, fourth and seventh bits.

```
encData(1) = ~encData(1);
encData(2) = ~encData(2);
encData(4) = ~encData(4);
```

Decode the corrupted sequence. Observe that the decoder has correctly recovered the message.

```
decData = decode(encData,n,k,'cyclic/binary',genpoly,trt);
numerr = biterr(data,decData)
```

```
numerr = 0
```

Input Arguments

`msg` — Input messages

binary column or row vector | binary matrix with k columns | column or row vector of integers in the range [0, 2^{k}–1]

Input messages, specified as one of these options:

- Binary column or row vector with k columns
- Binary matrix with k columns
- Column or row vector of k columns and having integers in the range [0, 2^{k}–1]

Example: `msg = [0 1 1 0, 0 1 0 1, 1 0 0 1]` specifies a binary row vector for k=4.

Example: `msg = [0 1 1 0; 0 1 0 1; 1 0 0 1]` specifies a binary matrix for k=4.

Example: `msg = [6, 10, 9]` specifies a row vector of integers for k=4.

Data Types: `double`

n — Codeword length

positive integer

Codeword length, specified as a positive integer. The function calculates this value as 2^*m*–1, where *m* must be greater than or equal to 2.

Data Types: double

k — Message length

positive integer

Message length, specified as a positive integer. The function calculates this value as n–*m*, where *m* must be greater than or equal to 2.

Data Types: double

codingMethod — Error coding method and format

'hamming/binary' (default) | 'hamming/decimal' | 'linear/binary' | ...

Error coding method and format, specified as one of these:

- 'hamming/binary'
- 'hamming/decimal'
- 'linear/binary'
- 'linear/decimal'
- 'cyclic/binary'
- 'cyclic/decimal'

Data Types: char | string

prim_poly — Primitive polynomial

gfprimdf(n-k) (default) | binary row vector | character vector | string scalar | positive integer

Primitive polynomial, specified as one of these options:

- Binary row vector — This vector gives coefficients of prim_poly in the order of ascending powers.
- Character vector or a string scalar — This value defines prim_poly in textual representation. For more information, see polynomial character vector.
- Positive integer — This value defines prim_poly in the range [$2^m + 1$, $2^{m+1} - 1$].

For more information about default primitive polynomials, see “Default Primitive Polynomials” on page 2-400. For more information about the representation of primitive polynomials, see “Primitive Polynomials and Element Representations”.

Data Types: double | char | string

genmat — Generator matrix

k-by-n numeric matrix

Generator matrix, specified as a k-by-n numeric matrix.

Data Types: double

genpoly — Generator polynomial
cyclpoly(n-k) (default) | binary row vector | character vector | string scalar

Generator polynomial, specified as a polynomial character vector or a row vector that gives the coefficients in order of ascending powers of the binary generator polynomial. The value of genpoly for an [n, k] cyclic code must have degree n–k and divide x^n-1, where x is an identifier.

Data Types: char | string

Output Arguments

code — Output code
binary column or row vector | binary matrix with n columns | column or row vector of integers in the range [0, 2^n–1].

Output code, returned as one of the options in this table. The value and dimension of code depends on the value and dimension of the “msg” on page 2-0 and the input message format according to this table:

msg Value	Input Message Format	code Value
Binary column or row vector	binary	Binary column or row vector
Binary matrix with k columns	binary	Binary matrix with n columns
Column or row vector of integers in the range [0, 2^k–1]	decimal	Column or row vector of integers in the range [0, 2^n–1]

added — Additional variable
nonnegative integer

Additional variable, returned as the number of zeros that were appended at the end of the message matrix before encoding for the matrix to have the appropriate size. The size of the message matrix depends on the n, k, and msg and the encoding method.

Algorithms

Depending on the error-correction coding method, the encode function relies on lower-level functions such as hammgen and cyclgen.

Introduced before R2006a

equalize

(To be removed) Equalize signal using equalizer object

Note will be removed in a future release. Use comm.LinearEqualizer or comm.DecisionFeedback instead.

Syntax

```
y = equalize(eqobj,x)
y = equalize(eqobj,x,trainsig)
[y,yd] = equalize(...)
[y,yd,e] = equalize(...)
```

Description

y = equalize(eqobj,x) processes the baseband signal vector x with equalizer object eqobj and returns the equalized signal vector y. At the end of the process, eqobj contains updated state information such as equalizer weight values and input buffer values. To construct eqobj, use the lineareq or dfe function. The equalize function assumes that the signal x is sampled at nsamp samples per symbol, where nsamp is the value of the nSampPerSym property of eqobj. For adaptive algorithms other than CMA, the equalizer adapts in decision-directed mode using a detector specified by the SigConst property of eqobj. The delay of the equalizer is (eqobj.RefTap-1)/eqobj.nSampPerSym.

Note that (eqobj.RefTap-1) must be an integer multiple of nSampPerSym. For a fractionally-spaced equalizer, the taps are spaced at fractions of a symbol period. The reference tap pertains to training symbols, and thus, must coincide with a whole number of symbols (i.e., an integer number of samples per symbol). eqobj.RefTap=1 corresponds to the first symbol, eqobj.RefTap=nSampPerSym+1 to the second, and so on. Therefore (eqobj.RefTap-1) must be an integer multiple of nSampPerSym.

If eqobj.ResetBeforeFiltering is 0, equalize uses the existing state information in eqobj when starting the equalization operation. As a result, equalize(eqobj,[x1 x2]) is equivalent to [equalize(eqobj,x1) equalize(eqobj,x2)]. To reset eqobj manually, apply the reset function to eqobj.

If eqobj.ResetBeforeFiltering is 1, equalize resets eqobj before starting the equalization operation, overwriting any previous state information in eqobj.

y = equalize(eqobj,x,trainsig) initially uses a training sequence to adapt the equalizer. After processing the training sequence, the equalizer adapts in decision-directed mode. The vector length of trainsig must be less than or equal to length(x)-(eqobj.RefTap-1)/eqobj.nSampPerSym.

[y,yd] = equalize(...) returns the vector yd of detected data symbols.

[y,yd,e] = equalize(...) returns the result of the error calculation. For adaptive algorithms other than CMA, e is the vector of errors between y and the reference signal, where the reference signal consists of the training sequence or detected symbols.

Examples

Configuring Linear Equalizers

This example configures the recommended `comm.LinearEqualizer` System object™ and the legacy `lineareq` feature with comparable settings.

Initialize Variables and Supporting Objects

```
d = randi([0 3],1000,1);
x = pskmod(d,4,pi/4);
r = awgn(x,25);
sps = 2; %samples per symbol for oversampled cases
nTaps = 6;
txFilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',nTaps, ...
    'OutputSamplesPerSymbol',4);
rxFilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',nTaps, ...
    'InputSamplesPerSymbol',4,'DecimationFactor',2);
x2 = txFilter(x);
r2 = rxFilter(awgn(x2,25,0.5));
filterDelay = txFilter.FilterSpanInSymbols/2 + ...
    rxFilter.FilterSpanInSymbols/2; % Total filter delay in symbols
```

To compare the equalized output, plot the constellations using code such as:

```
% plot(yNew,'*')
% hold on
% plot(yOld,'o')
% hold off; legend('New Eq','Old Eq'); grid on
```

Use LMS Algorithm with Linear Equalizer

Configure `lineareq` and `comm.LinearEqualizer` objects with comparable settings. The `LeakageFactor` property has been removed from LMS algorithm. The `comm.LinearEqualizer` System object™ assumes that leakage factor is always 1.

```
eqOld = lineareq(5,lms(0.05),pskmod(0:3,4,pi/4))
```

```
eqOld =
  EqType: 'Linear Equalizer'
  AlgType: 'LMS'
  nWeights: 5
  nSampPerSym: 1
  RefTap: 1
  SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  StepSize: 0.0500
  LeakageFactor: 1
  Weights: [0 0 0 0 0]
  WeightInputs: [0 0 0 0 0]
  ResetBeforeFiltering: 1
  NumSamplesProcessed: 0
```

```
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','LMS','StepSize',0.05, ...
    'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'LMS'
  NumTaps: 5
  StepSize: 0.0500
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 1
  InputDelay: 0
  InputSamplesPerSymbol: 1
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers.

```
yOld = equalize(eqOld,r,x(1:100));
yNew = eqNew(r,x(1:100));
```

Use RLS Algorithm with Linear Equalizer

Configure `lineareq` and `comm.LinearEqualizer` objects with comparable settings.

```
eqOld = lineareq(5,rls(0.95),pskmod(0:3,4,pi/4))
```

```
eqOld =
  EqType: 'Linear Equalizer'
  AlgType: 'RLS'
  nWeights: 5
  nSampPerSym: 1
  RefTap: 1
  SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  InvCorrInit: 0.1000
  InvCorrMatrix: [5×5 double]
  Weights: [0 0 0 0 0]
  WeightInputs: [0 0 0 0 0]
  ResetBeforeFiltering: 1
  NumSamplesProcessed: 0
```

```
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','RLS', ...
    'ForgettingFactor',0.95,'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'RLS'
  NumTaps: 5
  ForgettingFactor: 0.9500
  InitialInverseCorrelationMatrix: 0.1000
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 1
  InputDelay: 0
  InputSamplesPerSymbol: 1
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers. When `ResetBeforeFiltering` is set to `true`, each call of the `equalize` object resets the equalizer. To get the equivalent behavior call `reset` after each call of the `comm.LinearEqualizer` object.

```
yOld1 = equalize(eqOld,r,x(1:100));
yOld2 = equalize(eqOld,r,x(1:100));

yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

Configure `lineareq` and `comm.LinearEqualizer` objects with comparable settings. For the `comm.LinearEqualizer` object, set the initial inverse correlation matrix to `eye(5)*0.2`.

```
eqOld = lineareq(5,rls(0.95),pskmod(0:3,4,pi/4))
```

```
eqOld =
  EqType: 'Linear Equalizer'
  AlgType: 'RLS'
  nWeights: 5
  nSampPerSym: 1
  RefTap: 1
  SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  InvCorrInit: 0.1000
  InvCorrMatrix: [5×5 double]
  Weights: [0 0 0 0 0]
  WeightInputs: [0 0 0 0 0]
  ResetBeforeFiltering: 1
  NumSamplesProcessed: 0
```

```
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','RLS', ...
    'ForgettingFactor',0.95,'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1, ...
    'InitialInverseCorrelationMatrix',eye(5)*0.2)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'RLS'
  NumTaps: 5
  ForgettingFactor: 0.9500
  InitialInverseCorrelationMatrix: [5×5 double]
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 1
  InputDelay: 0
  InputSamplesPerSymbol: 1
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers. When `ResetBeforeFiltering` is set to `true`, each call of the `equalize` object resets the equalizer. To get the equivalent behavior call `reset` after each call of the `comm.LinearEqualizer` object.

```
yOld1 = equalize(eqOld,r,x(1:100));
yOld2 = equalize(eqOld,r,x(1:100));

yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

Use CMA Algorithm with Linear Equalizer

Configure `lineareq` and `comm.LinearEqualizer` objects with comparable settings. The `LeakageFactor` property has been removed from LMS algorithm. The `comm.LinearEqualizer` System object™ assumes that leakage factor is always 1.

```
eqOld = lineareq(5,cma(0.05),pskmod(0:3,4,pi/4))
```

```
eqOld =
  EqType: 'Linear Equalizer'
  AlgType: 'Constant Modulus'
  nWeights: 5
  nSampPerSym: 1
  SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  StepSize: 0.0500
  LeakageFactor: 1
  Weights: [1 0 0 0 0]
  WeightInputs: [0 0 0 0 0]
  ResetBeforeFiltering: 1
  NumSamplesProcessed: 0
```

```
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','CMA','StepSize',0.05, ...
    'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'CMA'
  NumTaps: 5
  StepSize: 0.0500
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 1
  InputSamplesPerSymbol: 1
  AdaptWeightsSource: 'Property'
  AdaptWeights: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers.

```
yOld = equalize(eqOld,r);
yNew = eqNew(r);
```

Use Linear Equalizers Considering Signal Delays

Configure `lineareq` and `comm.LinearEqualizer` objects with comparable settings. The transmit and receive filters result in a signal delay between the transit and receive signals. Account for this delay by setting the `RefTap` property of the `lineareq` to a value close to the delay value in samples. Additionally, `nWeights` must be set to a value greater than `RefTap`.

```
eqOld = lineareq(filterDelay*sps+4,lms(0.01),pskmod(0:3,4,pi/4),sps);
eqOld.RefTap = filterDelay*sps+1 % Adjust to synchronize with delayed signal
```

```
eqOld =
  EqType: 'Linear Equalizer'
  AlgType: 'LMS'
  nWeights: 16
  nSampPerSym: 2
  RefTap: 13
  SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  StepSize: 0.0100
  LeakageFactor: 1
  Weights: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
  WeightInputs: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
  ResetBeforeFiltering: 1
  NumSamplesProcessed: 0
```

```
eqNew = comm.LinearEqualizer('NumTaps',16,'Algorithm','LMS','StepSize',0.01, ...
    'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    'ReferenceTap',filterDelay*sps+1,'InputDelay',0)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'LMS'
  NumTaps: 16
  StepSize: 0.0100
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 13
  InputDelay: 0
  InputSamplesPerSymbol: 2
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers. When `ResetBeforeFiltering` is set to `true`, each call of the `equalize` object resets the equalizer. To get the equivalent behavior call `reset` after each call of the `comm.LinearEqualizer` object.

```
yOld1 = equalize(eqOld,r,x(1:100));
yOld2 = equalize(eqOld,r,x(1:100));

yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

In the `comm.LinearEqualizer` object, `InputDelay` is used to synchronize with the delayed signal. `NumTaps` and `ReferenceTap` are independent of delay value. We can reduce the number of taps by utilizing the `InputDelay` to synchronize instead of reference tap. Reducing the number of taps also reduces equalizer self noise.

```
eqNew = comm.LinearEqualizer('NumTaps',11,'Algorithm','LMS','StepSize',0.01, ...
    'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    'ReferenceTap',6,'InputDelay',filterDelay*sps)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'LMS'
  NumTaps: 11
  StepSize: 0.0100
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 6
  InputDelay: 12
  InputSamplesPerSymbol: 2
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

```
yNew1 = eqNew(r2,x(1:100));
reset(eqNew)
yNew2 = eqNew(r2,x(1:100));
```

Compatibility Considerations

`equalize` will be removed

Warns starting in R2020a

equalize will be removed in a future release. Use `comm.LinearEqualizer` or `comm.DecisionFeedback` instead. For examples comparing setup of `comm.LinearEqualizer` to `lineareq`, see “Configuring Linear Equalizers” on page 2-336.

evdoForwardReferenceChannels

Define 1xEV-DO forward reference channel

Syntax

```
cfg = evdoForwardReferenceChannels(wv)
cfg = evdoForwardReferenceChannels(wv,numpackets)
```

Description

`cfg = evdoForwardReferenceChannels(wv)` returns a structure, `cfg`, that defines 1xEV-DO forward link parameters given the input waveform identifier, `wv`. Pass this structure to the `evdoForwardWaveformGenerator` function to generate a forward link reference channel waveform.

For all syntaxes, `evdoForwardReferenceChannels` creates a configuration structure that is compliant with the cdma2000 high data rate packet specification, [1].

`cfg = evdoForwardReferenceChannels(wv,numpackets)` specifies the number of packets to be generated.

Examples

Generate 1xEV-DO Release 0 Forward Link Waveform

Create a configuration structure for a Release 0 channel having a 921.6 kbps data rate and transmitted over two slots.

```
config = evdoForwardReferenceChannels('Rel0-921600-2');
```

Display the number of slots and the data rate.

```
config.PacketSequence
```

```
ans = struct with fields:
    MACIndex: 0
    DataRate: 921600
    NumSlots: 2
```

Generate the complex waveform using the associated waveform generator function, `evdoForwardWaveformGenerator`.

```
wv = evdoForwardWaveformGenerator(config);
```

Generate 1xEV-DO Revision A Forward Link Waveform

Create a structure to transmit a Revision A 1xEV-DO channel consisting of three 1024-bit packets transmitted over 2 slots with a 64-bit preamble length.

```
config = evdoForwardReferenceChannels('RevA-1024-2-64',3);
```

Verify that the function created a 1-by-3 structure array. Each element in the structure array corresponds to a data packet.

```
config.PacketSequence
```

```
ans=1×3 struct array with fields:
    MACIndex
    PacketSize
    NumSlots
    PreambleLength
```

Examine the first structure element to verify the packet size, number of slots, and preamble length match what you specified in the function call.

```
config.PacketSequence(1)
```

```
ans = struct with fields:
          MACIndex: 0
        PacketSize: 1024
          NumSlots: 2
    PreambleLength: 64
```

Generate the waveform.

```
wv = evdoForwardWaveformGenerator(config);
```

Input Arguments

wv — Waveform identification

character vector

Waveform identification of the reference channel, specified as a character vector.

Parameter Field	Values	Description
wv	'Rel0-38400-16' | 'Rel0-76800-8' | 'Rel0-153600-4' | 'Rel0-307200-2' | 'Rel0-307200-4' | 'Rel0-614400-1' | 'Rel0-614400-2' | 'Rel0-921600-2' | 'Rel0-1228800-1' | 'Rel0-1228800-2' | 'Rel0-1843200-1' | 'Rel0-2457600-1'	Character vector representing the 1xEV-DO Release 0 reference channel with data rate in bps and number of slots. For example, you can specify 'Rel0-153600-4' to create a structure that represents a reference channel with a 153,600 bps data rate and uses four slots.

Parameter Field	Values	Description
	`'RevA-128-1-64'` | `'RevA-128-2-128'` | `'RevA-128-4-256'` | `'RevA-128-4-1024'` | `'RevA-128-8-512'` | `'RevA-256-1-64'` | `'RevA-256-2-128'` | `'RevA-256-4-256'` | `'RevA-256-4-1024'` | `'RevA-256-8-512'` | `'RevA-256-16-1024'` | `'RevA-512-1-64'` | `'RevA-512-2-64'` | `'RevA-512-2-128'` | `'RevA-512-4-128'` | `'RevA-512-4-256'` | `'RevA-512-4-1024'` | `'RevA-512-8-512'` | `'RevA-512-16-1024'` | `'RevA-1024-1-64'` | `'RevA-1024-2-64'` | `'RevA-1024-2-128'` | `'RevA-1024-4-128'` | `'RevA-1024-4-256'` | `'RevA-1024-8-512'` | `'RevA-1024-16-1024'` | `'RevA-2048-1-64'` | `'RevA-2048-2-64'` | `'RevA-2048-4-128'` | `'RevA-3072-1-64'` | `'RevA-3072-2-64'` `'RevA-4096-1-64'` | `'RevA-4096-2-64'` | `'RevA-5120-1-64'` | `'RevA-5120-2-64'`	Character vector representing the 1xEV-DO Revision A reference channel with the packet size in bits, the number of slots, and the preamble length in chips. For example, you can specify `'RevA-256-1-64'` to create a reference channel having a 256-bit packet, transmitted in one slot, with a 64-bit preamble length.

Example: `'Rel0-614400-2'`

Example: `'RevA-4096-2-64'`

Data Types: `char`

`numpackets` — Number of packets
`1` (default) | positive integer scalar

Number of packets, specified as a positive integer.

Example: 4

Data Types: `double`

Output Arguments

`cfg` — Configuration of the parameters and channels used by the waveform generator
structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

Top-Level Parameters and Substructures

Parameter Field	Values	Description
Release	'Release0' | 'RevisionA'	1xEV-DO
PNOffset	Nonnegative scalar integer [0, 511]	PN offset of the base station
IdleSlotsWithControl	'Off' | 'On'	Include idle slots with control channels
EnableControl	'Off' | 'On'	Enable control signaling
NumChips	Positive scalar integer	Number of chips in the waveform
OversamplingRatio	Positive scalar integer [1, 8]	Oversampling ratio at output
FilterType	'cdma2000Long' | 'cdma2000short' | 'Custom' | 'Off'	Select filter type or disable filtering
CustomFilterCoefficients	Real vector	Custom filter coefficients (applies when the FilterType field is set to 'Custom')
InvertQ	'Off' | 'On'	Negate the quadrature output
EnableModulation	'Off' | 'On'	Enable carrier modulation
ModulationFrequency	Nonnegative scalar integer	Carrier modulation frequency (applies when EnableModulation is 'On')
PacketSequence	Structure	See **PacketSequence substructure**.
PacketDataSources	Structure	See **PacketDataSources substructure**.

PacketSequence Substructure

Include the PacketSequence substructure in the cfg structure to define a sequence of data packets for consecutive transmission. The PacketSequence substructure contains these fields.

Parameter Field	Values	Description
MACIndex	Positive scalar integer	MAC index associated with the packet
	Release 0	
DataRate	38400 | 76800 | 153600 | 307200 | 614400 | 921600 | 1228800 | 1843200 | 2457600	Data rate (bps)
NumSlots	Positive scalar integer	Number of slots
	Revision A	
PacketSize	128 | 256 | 512 | 1024 | 2048 | 3072 | 4096 | 5120	Packet size (bits)
NumSlots	1 | 2 | 4 | 8 | 16	Number of slots
PreambleLength	64 | 128 | 256 | 512 | 1024	Preamble length (chips)

PacketDataSources Substructure

Include a `PacketDataSources` substructure in the `cfg` structure to define a set of matching data sources for each MAC index. The `PacketDataSources` substructure contains these fields.

Parameter Field	Values	Description
`MACIndex`	Positive scalar integer	MAC index associated with the packet
`DataSource`	Cell array, `{'PN Type', RN Seed}` or binary vector. Standard PN sequence options are `'PN9'`, `'PN15'`, `'PN23'`, `'PN9-ITU'`, and `'PN11'`.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
`EnableCoding`	`'Off'` | `'On'`	Enable error correction coding

`evdoForwardWaveformGenerator` | `evdoReverseReferenceChannels`

Introduced in R2015b

evdoForwardWaveformGenerator

Generate 1xEV-DO forward link waveform

Syntax

```
waveform = evdoForwardWaveformGenerator(cfg)
```

Description

`waveform = evdoForwardWaveformGenerator(cfg)` returns the 1xEV-DO forward link `waveform` as defined by the parameter configuration structure, `cfg`.

The top-level parameters and lower-level substructures of `cfg` specify the waveform and channel properties the function uses to generate a 1xEV-DO waveform. You can generate `cfg` by using the `evdoForwardReferenceChannels` function.

Note The tables herein list the allowable values for the top-level parameters and substructure fields. However, not all parameter combinations are supported. To ensure that the input argument is valid, use the `evdoForwardReferenceChannels` function. If you input the structure fields manually, consult [1] to ensure that the input parameter combinations are permitted.

Examples

Generate 1xEV-DO Revision A Forward Link Waveform

Create a structure to transmit a Revision A 1xEV-DO channel consisting of three 1024-bit packets transmitted over 2 slots with a 64-bit preamble length.

```
config = evdoForwardReferenceChannels('RevA-1024-2-64',3);
```

Verify that the function created a 1-by-3 structure array. Each element in the structure array corresponds to a data packet.

```
config.PacketSequence
```

```
ans=1×3 struct array with fields:
    MACIndex
    PacketSize
    NumSlots
    PreambleLength
```

Examine the first structure element to verify the packet size, number of slots, and preamble length match what you specified in the function call.

```
config.PacketSequence(1)
```

```
ans = struct with fields:
          MACIndex: 0
```

```
        PacketSize: 1024
          NumSlots: 2
    PreambleLength: 64
```

Generate the waveform.

```
wv = evdoForwardWaveformGenerator(config);
```

Generate 1xEV-DO Forward Link Waveform with Custom Filter

Create a structure to generate two packets of a 1.8 Mbps Release 0 channel.

```
config = evdoForwardReferenceChannels('Rel0-1843200-1',2);
```

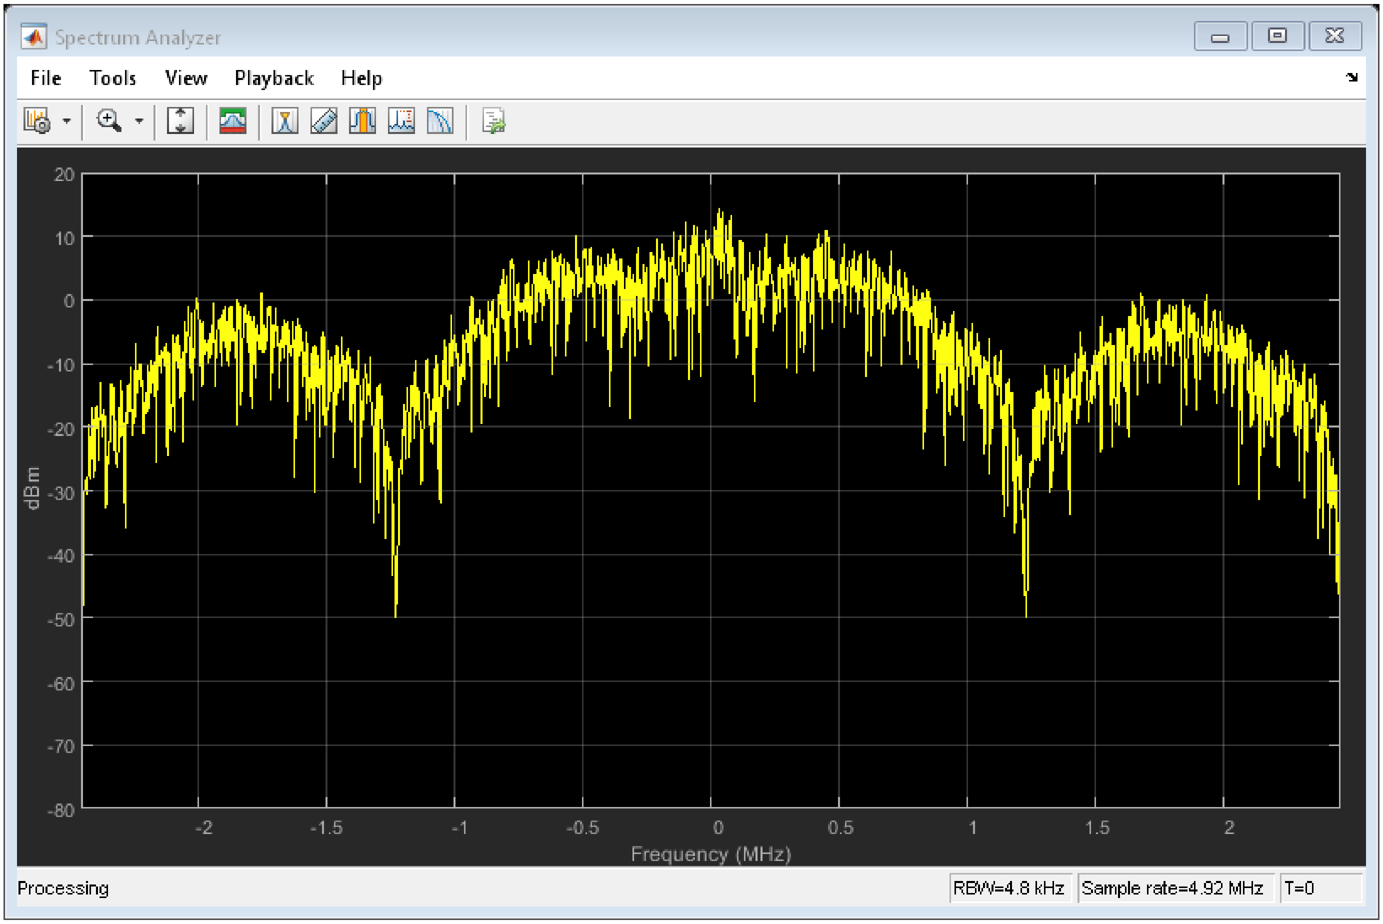
Calculate the sample rate of the waveform.

```
fs = 1.2288e6 * config.OversamplingRatio;
```

Disable the internal filter of the `evdoForwardWaveformGenerator` function. Generate the 1xEV-DO waveform. Plot the spectrum of the waveform.

```
config.FilterType = 'off';
wv = evdoForwardWaveformGenerator(config);

sa = dsp.SpectrumAnalyzer('SampleRate',fs);
step(sa,wv)
```



Create a lowpass FIR filter with a 500 kHz passband, a 750 kHz stopband, and a stopband attenuation of 60 dB.

```
d = designfilt('lowpassfir', ...
    'PassbandFrequency',500e3, ...
    'StopbandFrequency',750e3, ...
    'StopbandAttenuation',60, ...
    'SampleRate',fs);
```

Change the filter type to `'Custom'` and specify the coefficients from the digital filter, `d`.

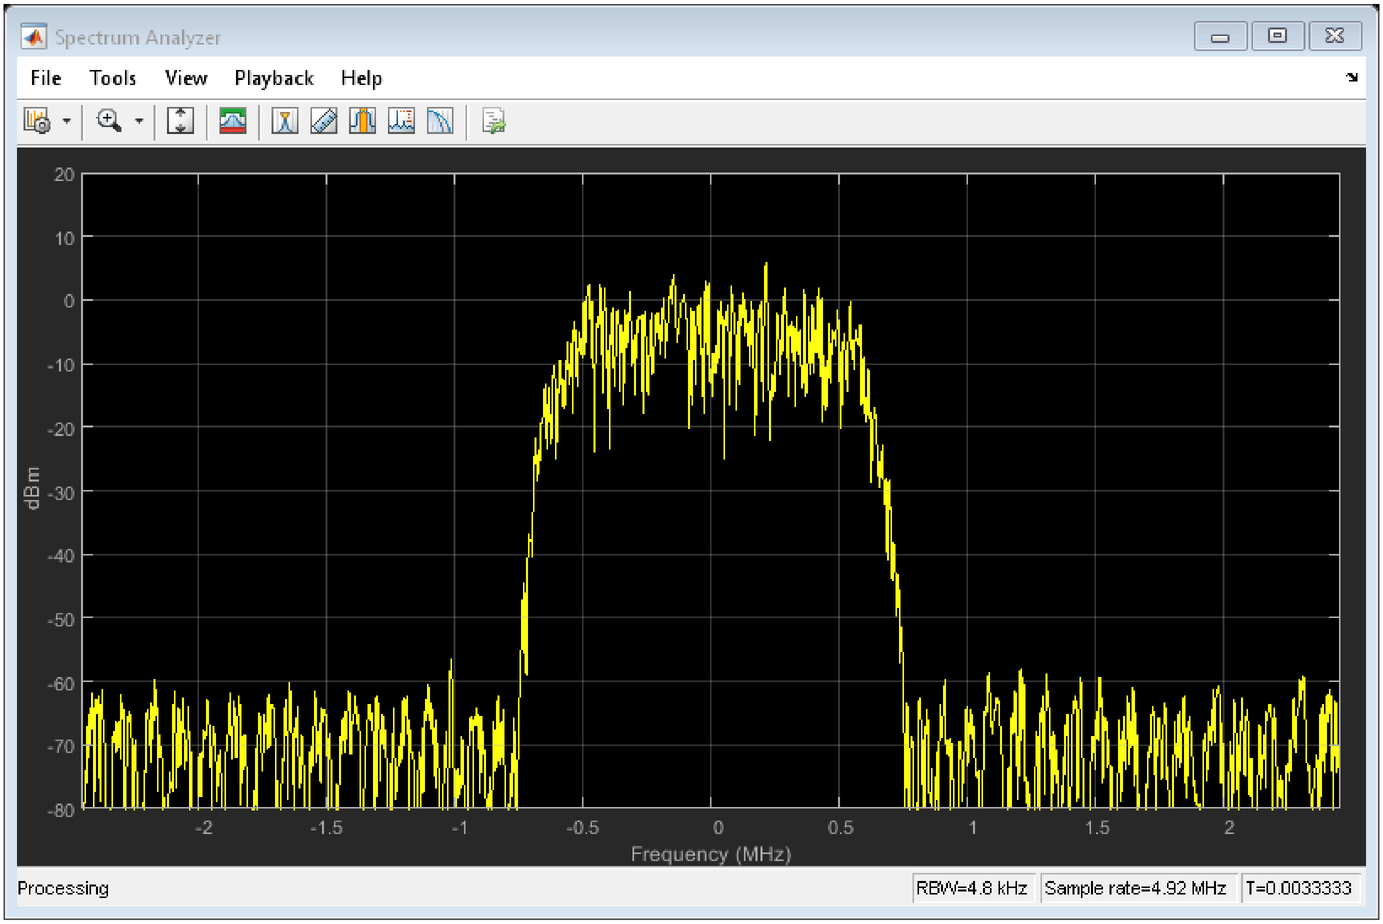
```
config.FilterType = 'Custom';
config.CustomFilterCoefficients = d.Coefficients;
```

Generate the waveform using the custom filter coefficients.

```
wv = evdoForwardWaveformGenerator(config);
```

Plot the spectrum of the filtered 1xEV-DO waveform.

```
step(sa,wv)
```



The filter attenuates the waveform by 60 dB for frequencies outside of ± 750 kHz.

Input Arguments

`cfg` — Configuration of the parameters and channels used by the waveform generator

structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

Top-Level Parameters and Substructures

Parameter Field	Values	Description
`Release`	`'Release0'` | `'RevisionA'`	1xEV-DO
`PNOffset`	Nonnegative scalar integer [0, 511]	PN offset of the base station
`IdleSlotsWithControl`	`'Off'` | `'On'`	Include idle slots with control channels
`EnableControl`	`'Off'` | `'On'`	Enable control signaling
`NumChips`	Positive scalar integer	Number of chips in the waveform
`OversamplingRatio`	Positive scalar integer [1, 8]	Oversampling ratio at output

Parameter Field	Values	Description
FilterType	'cdma2000Long' | 'cdma2000short' | 'Custom' | 'Off'	Select filter type or disable filtering
CustomFilterCoefficients	Real vector	Custom filter coefficients (applies when the FilterType field is set to 'Custom')
InvertQ	'Off' | 'On'	Negate the quadrature output
EnableModulation	'Off' | 'On'	Enable carrier modulation
ModulationFrequency	Nonnegative scalar integer	Carrier modulation frequency (applies when EnableModulation is 'On')
PacketSequence	Structure	See **PacketSequence substructure**.
PacketDataSources	Structure	See **PacketDataSources substructure**.

PacketSequence Substructure

Include the PacketSequence substructure in the cfg structure to define a sequence of data packets for consecutive transmission. The PacketSequence substructure contains these fields.

Parameter Field	Values	Description
MACIndex	Positive scalar integer	MAC index associated with the packet
	Release 0	
DataRate	38400 | 76800 | 153600 | 307200 | 614400 | 921600 | 1228800 | 1843200 | 2457600	Data rate (bps)
NumSlots	Positive scalar integer	Number of slots
	Revision A	
PacketSize	128 | 256 | 512 | 1024 | 2048 | 3072 | 4096 | 5120	Packet size (bits)
NumSlots	1 | 2 | 4 | 8 | 16	Number of slots
PreambleLength	64 | 128 | 256 | 512 | 1024	Preamble length (chips)

PacketDataSources Substructure

Include a PacketDataSources substructure in the cfg structure to define a set of matching data sources for each MAC index. The PacketDataSources substructure contains these fields.

Parameter Field	Values	Description
MACIndex	Positive scalar integer	MAC index associated with the packet
DataSource	Cell array, {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

Parameter Field	Values	Description
EnableCoding	'Off' | 'On'	Enable error correction coding

Output Arguments

waveform — Modulated baseband waveform comprising the primary physical channels
complex vector array

Modulated baseband waveform comprising the primary cdma2000 physical channels, returned as a complex vector array.

cdma2000ForwardReferenceChannels | cdma2000ReverseWaveformGenerator

Introduced in R2015b

evdoReverseReferenceChannels

Define 1xEV-DO reverse reference channel

Syntax

```
cfg = evdoReverseReferenceChannels(wv)
cfg = evdoReverseReferenceChannels(wv,numpackets)
```

Description

`cfg = evdoReverseReferenceChannels(wv)` returns a structure, `cfg`, that defines 1xEV-DO reverse link parameters given the input waveform identifier, `wv`. Pass this structure to the `evdoReverseWaveformGenerator` function to generate a reverse link reference channel waveform.

For all syntaxes, `evdoReverseReferenceChannels` creates a structure that is compliant with the cdma2000 high data rate packet specification,[1].

`cfg = evdoReverseReferenceChannels(wv,numpackets)` specifies the number of packets to be generated.

Examples

Generate 1xEV-DO Reverse Channel Waveform

Create a structure to generate a Release 0, 1xEV-DO waveform having a 19.2 kbps data rate.

```
config = evdoReverseReferenceChannels('Rel0-19200');
```

Verify that the packet has a data rate of 19.2 kbps.

```
config.PacketSequence.DataRate
```

```
ans = 19200
```

Generate the complex waveform.

```
wv = evdoReverseWaveformGenerator(config);
```

Generate 1xEV-DO Revision A Reverse Link Waveform

Create a structure for a Revision A 1xEV-DO channel having 2048-bit packets, transmitted in 12 slots. Specify that five packets are transmitted.

```
config = evdoReverseReferenceChannels('RevA-2048-12',5);
```

Verify that a 1-by-5 structure array is created. Each element in the structure array corresponds to a data packet.

```
config.PacketSequence
```

```
ans=1×5 struct array with fields:
    Power
    DataSource
    EnableCoding
    PayloadSize
    NumSlots
    DataRate
```

Examine the first structure element to verify the packet size and the number of slots are as specified in the function call.

```
config.PacketSequence(1)
```

```
ans = struct with fields:
           Power: 0
      DataSource: {'PN9'  [1]}
    EnableCoding: 'On'
     PayloadSize: 2048
        NumSlots: 12
        DataRate: 102400
```

Generate the waveform.

```
wv = evdoReverseWaveformGenerator(config);
```

Input Arguments

wv — Waveform identification

character vector

Waveform identification of the reference channel, specified as a character vector.

Parameter Field	Values	Description
wv	'Rel0-9600' | 'Rel0-19200' | 'Rel0-38400' | 'Rel0-76800' | 'Rel0-153600'	Character vector representing the 1xEV-DO Release 0 data rate in bps. For example, you can specify 'Rel0-153600' to create a structure corresponding to a Release 0 reference channel having a 153,600 bps data rate.

Parameter Field	Values	Description
	'RevA-128-4' | 'RevA-128-8' | 'RevA-128-12' | 'RevA-128-16' | 'RevA-256-4' | 'RevA-256-8' | 'RevA-256-12' | 'RevA-256-16' | 'RevA-512-4' | 'RevA-512-8' | 'RevA-512-12' | 'RevA-512-16' | 'RevA-768-4' | 'RevA-768-8' | 'RevA-768-12' | 'RevA-768-16' | 'RevA-1024-4' | 'RevA-1024-8' | 'RevA-1024-12' | 'RevA-1024-16' | 'RevA-1536-4' | 'RevA-1536-8' | 'RevA-1536-12' | 'RevA-1536-16' | 'RevA-2048-4' | 'RevA-2048-8' | 'RevA-2048-12' | 'RevA-2048-16' | 'RevA-3072-4' | 'RevA-3072-8' | 'RevA-3072-12' | 'RevA-3072-16' | 'RevA-4096-4' | 'RevA-4096-8' | 'RevA-4096-12' | 'RevA-4096-16' | 'RevA-6144-4' | 'RevA-6144-8' | 'RevA-6144-12' | 'RevA-6144-16' | 'RevA-8192-4' | 'RevA-8192-8' | 'RevA-8192-12' | 'RevA-8192-16' | 'RevA-12288-4' | 'RevA-12288-8' | 'RevA-12288-12' | 'RevA-12288-16'	Character vector representing the 1xEV-DO Revision A packet size in bits and the number of slots. For example, you can specify 'RevA-256-4' to create a structure corresponding to a Revision A reference channel having 256-bit packets and transmitted in four slots.

Example: 'Rel0-38400'

Example: 'RevA-3072-12'

Data Types: char

numpackets — Number of packets

1 (default) | positive integer scalar

Number of packets, specified as a positive integer.

Example: 2

Data Types: double

Output Arguments

cfg — Configuration of the parameters and channels used by the waveform generator

structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

Top-Level Parameters and Substructures

Parameter Field	Values	Description
Release	'Release0' | 'RevisionA'	1xEV-DO applicable standard
LongCodeMaskI	42-bit binary number	Long code identifier for in-phase channel
LongCodeMaskQ	42-bit binary number	Long code identifier for quadrature channel
NumChips	Positive scalar integer	Number of chips in the waveform
OversamplingRatio	Positive scalar integer	Oversampling ratio at output
FilterType	'cdma2000Long' | 'cdma2000Short' | 'Custom' | 'Off'	Specify the filter type or disable filtering
CustomFilterCoefficients	Real vector	Custom filter coefficients (applies when FilterType is set to 'Custom')
InvertQ	'Off' | 'On'	Negate the quadrature output
EnableModulation	'Off' | 'On'	Enable carrier modulation
ModulationFrequency	Nonnegative scalar integer	Carrier modulation frequency (applies when EnableModulation is 'On')
ACKChannel	Structure	See **ACKChannel substructure**.
PilotChannel	Structure	See **PilotChannel substructure**.
AuxPilotChannel	Not present or structure	See **AuxPilotChannel substructure**.
PacketSequence	Structure	See **PacketSequence substructure**.

ACKChannel Substructure

Include the ACKChannel substructure in the cfg structure to specify the acknowledgment channel. The ACKChannel substructure contains these fields.

Parameter Fields	Values	Description
Enable	'On' | 'Off'	Character vector to enable or disable the channel
Power	Real scalar	Channel power (dBW)
DataSource	Cell array, {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

PilotChannel Substructure

Include the PilotChannel substructure in the cfg structure to specify the pilot channel. The PilotChannel substructure contains these fields.

Parameter Fields	Values	Description
Enable	'On' | 'Off'	Character vector to enable or disable the channel
Power	Real scalar	Channel power (dBW)
DataSource	Cell array, {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
EnableCoding	'On' | 'Off'	Enable channel coding

AuxPilotChannel Substructure

Include the AuxPilotChannel substructure in the cfg structure to specify the auxiliary pilot channel, which is available only for Revision A. The AuxPilotChannel substructure contains these fields.

Parameter Fields	Values	Description
Enable	'On' | 'Off'	Character vector to enable or disable the channel
Power	Real scalar	Channel power (dBW)
DataSource	Cell array, {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
EnableCoding	'On' | 'Off'	Enable channel coding

PacketSequence Substructure

Include the PacketSequence substructure in the cfg structure to define a sequence of data packets for consecutive transmission. The PacketSequence substructure contains these fields.

Parameter Field	Values	Description
Power	Real scalar	MAC index associated with the packet
EnableCoding	'Off' | 'On'	Enable error correction coding
DataSource	Cell array, {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
Release 0		
DataRate	9600 | 19200 | 38400 | 76800 | 153600	Data rate (bps)
Revision A		
PacketSize	128 | 256 | 512 | 768 | 1024 | 1536 | 2048 | 3072 | 4096 | 6144 | 8192 | 12288	Packet size (bits)
NumSlots	4 | 8 | 12 | 16	Number of slots

evdoForwardReferenceChannels | evdoReverseWaveformGenerator

Introduced in R2015b

evdoReverseWaveformGenerator

Generate 1xEV-DO reverse link waveform

Syntax

```
waveform = evdoReverseWaveformGenerator(cfg)
```

Description

`waveform = evdoReverseWaveformGenerator(cfg)` returns the 1xEV-DO reverse link `waveform` as defined by the parameter configuration structure, `cfg`.

The top-level parameters and lower-level substructures of `cfg` specify the waveform and channel properties used by the function to generate a 1xEV-DO waveform. You can generate `cfg` by using the `evdoReverseReferenceChannels` function.

Note The tables herein list the allowable values for the top-level parameters and substructure fields. However, not all parameter combinations are supported. To ensure that the input argument is valid, use the `evdoReverseReferenceChannels` function. If you input the structure fields manually, consult [1] to ensure that the input parameter combinations are permitted.

Examples

Generate 1xEV-DO Reverse Channel Waveform

Create a structure to generate a Release 0, 1xEV-DO waveform having a 19.2 kbps data rate.

```
config = evdoReverseReferenceChannels('Rel0-19200');
```

Verify that the packet has a data rate of 19.2 kbps.

```
config.PacketSequence.DataRate
```

```
ans = 19200
```

Generate the complex waveform.

```
wv = evdoReverseWaveformGenerator(config);
```

Generate 1xEV-DO Reverse Link Waveform with Custom Filter

Create a structure to generate four packets of a Revision A channel having 768-bit packets transmitted over eight slots.

```
config = evdoReverseReferenceChannels('RevA-768-8',4);
```

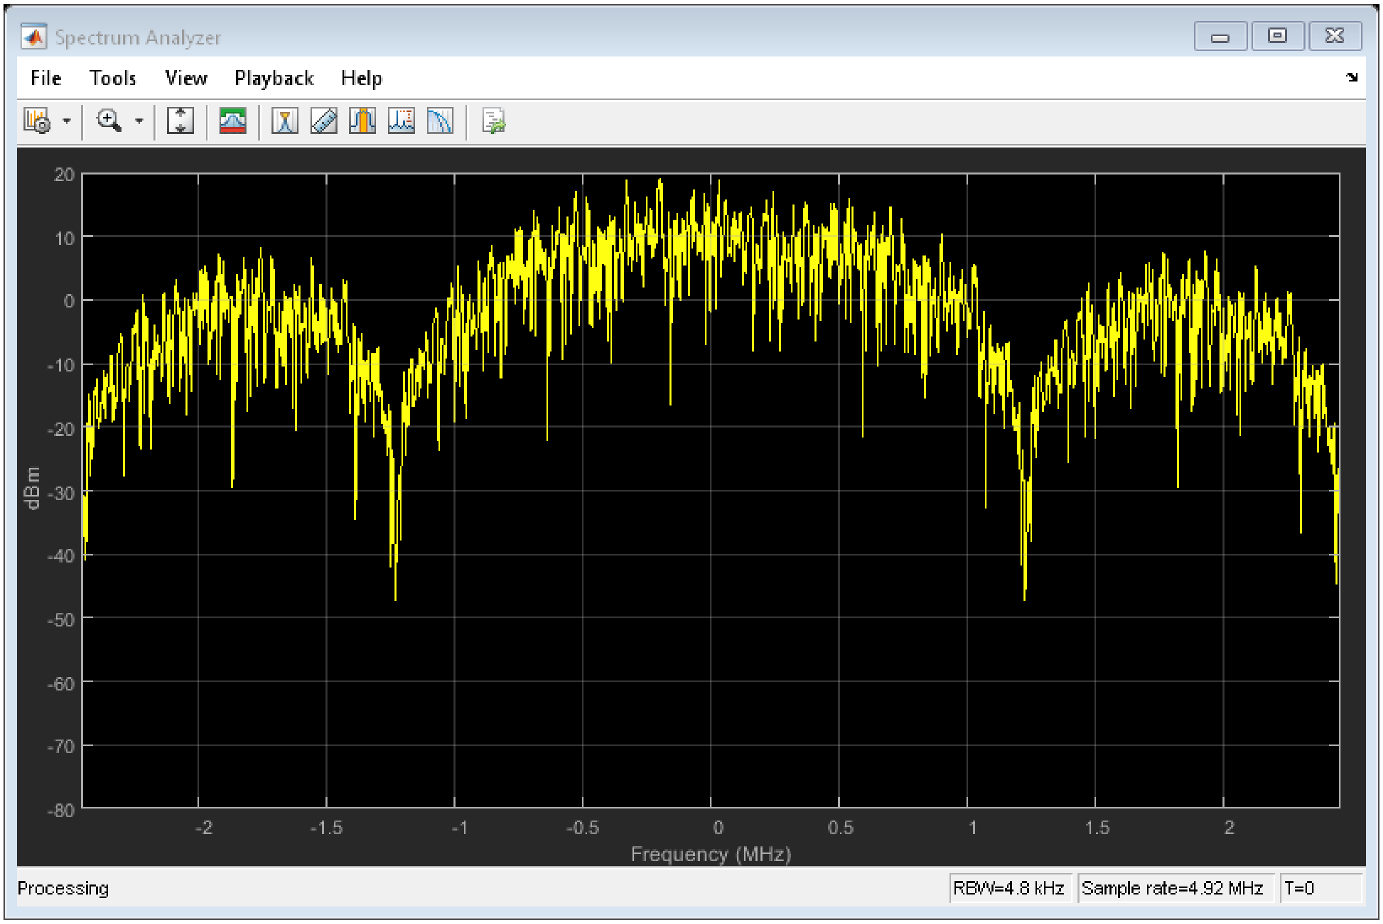
Calculate the sample rate of the waveform.

```
fs = 1.2288e6 * config.OversamplingRatio;
```

Disable the internal filter of the `evdoReverseWaveformGenerator`. Generate the 1xEV-DO waveform. Plot the spectrum of the waveform.

```
config.FilterType = 'off';
wv = evdoReverseWaveformGenerator(config);

sa = dsp.SpectrumAnalyzer('SampleRate',fs);
step(sa,wv)
```



Create a lowpass FIR filter with a 500 kHz passband, a 750 kHz stopband, and a stopband attenuation of 60 dB.

```
d = designfilt('lowpassfir', ...
    'PassbandFrequency',500e3, ...
    'StopbandFrequency',750e3, ...
    'StopbandAttenuation',60, ...
    'SampleRate',fs);
```

Change the filter type to `'Custom'` and specify the coefficients from the digital filter, `d`.

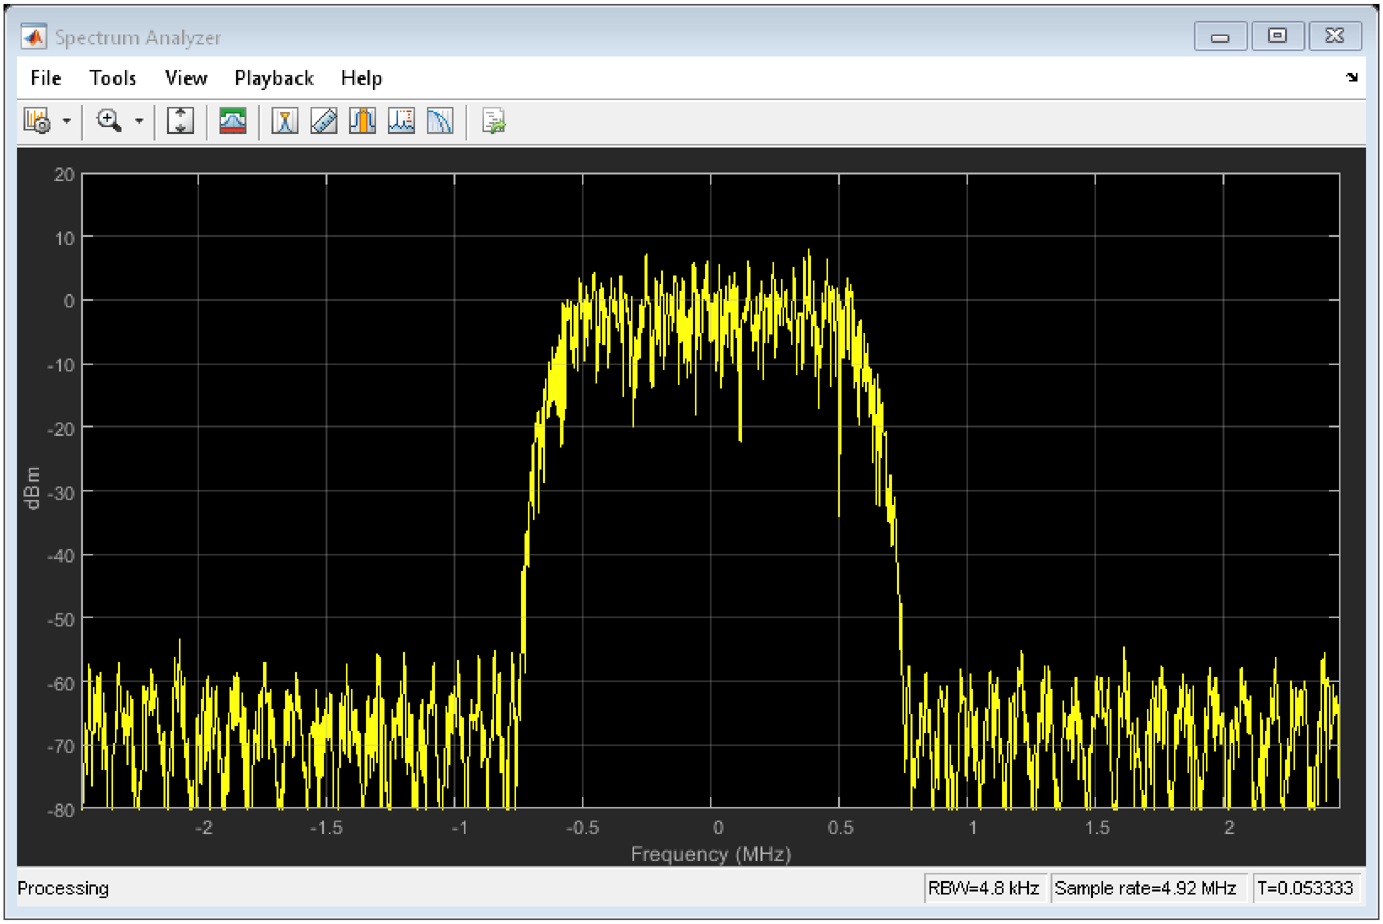
```
config.FilterType = 'Custom';
config.CustomFilterCoefficients = d.Coefficients;
```

Generate the waveform using the custom filter coefficients.

```
wv = evdoReverseWaveformGenerator(config);
```

Plot the spectrum of the filtered 1xEV-DO waveform.

```
step(sa,wv)
```



The filter attenuates the waveform by 60 dB for frequencies outside of ± 750 kHz.

Input Arguments

cfg — Configuration of the parameters and channels used by the waveform generator
structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

Top-Level Parameters and Substructures

Parameter Field	Values	Description
Release	'Release0' | 'RevisionA'	1xEV-DO applicable standard
LongCodeMaskI	42-bit binary number	Long code identifier for in-phase channel
LongCodeMaskQ	42-bit binary number	Long code identifier for quadrature channel

Parameter Field	Values	Description
NumChips	Positive scalar integer	Number of chips in the waveform
OversamplingRatio	Positive scalar integer	Oversampling ratio at output
FilterType	'cdma2000Long' | 'cdma2000Short' | 'Custom' | 'Off'	Specify the filter type or disable filtering
CustomFilterCoefficients	Real vector	Custom filter coefficients (applies when FilterType is set to 'Custom')
InvertQ	'Off' | 'On'	Negate the quadrature output
EnableModulation	'Off' | 'On'	Enable carrier modulation
ModulationFrequency	Nonnegative scalar integer	Carrier modulation frequency (applies when EnableModulation is 'On')
ACKChannel	Structure	See **ACKChannel substructure**.
PilotChannel	Structure	See **PilotChannel substructure**.
AuxPilotChannel	Not present or structure	See **AuxPilotChannel substructure**.
PacketSequence	Structure	See **PacketSequence substructure**.

ACKChannel Substructure

Include the ACKChannel substructure in the cfg structure to specify the acknowledgment channel. The ACKChannel substructure contains these fields.

Parameter Fields	Values	Description
Enable	'On' | 'Off'	Character vector to enable or disable the channel
Power	Real scalar	Channel power (dBW)
DataSource	Cell array, {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.

PilotChannel Substructure

Include the PilotChannel substructure in the cfg structure to specify the pilot channel. The PilotChannel substructure contains these fields.

Parameter Fields	Values	Description
Enable	'On' | 'Off'	Character vector to enable or disable the channel
Power	Real scalar	Channel power (dBW)

Parameter Fields	Values	Description
DataSource	Cell array, {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
EnableCoding	'On' | 'Off'	Enable channel coding

AuxPilotChannel Substructure

Include the AuxPilotChannel substructure in the cfg structure to specify the auxiliary pilot channel, which is available only for Revision A. The AuxPilotChannel substructure contains these fields.

Parameter Fields	Values	Description
Enable	'On' | 'Off'	Character vector to enable or disable the channel
Power	Real scalar	Channel power (dBW)
DataSource	Cell array, {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
EnableCoding	'On' | 'Off'	Enable channel coding

PacketSequence Substructure

Include the PacketSequence substructure in the cfg structure to define a sequence of data packets for consecutive transmission. The PacketSequence substructure contains these fields.

Parameter Field	Values	Description
Power	Real scalar	MAC index associated with the packet
EnableCoding	'Off' | 'On'	Enable error correction coding
DataSource	Cell array, {'PN Type', RN Seed} or binary vector. Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.	Data source. Specify a standard PN sequence with a random number seed or a custom vector.
Release 0		
DataRate	9600 | 19200 | 38400 | 76800 | 153600	Data rate (bps)
Revision A		

Parameter Field	Values	Description
`PacketSize`	`128` | `256` | `512` | `768` | `1024` | `1536` | `2048` | `3072` | `4096` | `6144` | `8192` | `12288`	Packet size (bits)
`NumSlots`	`4` | `8` | `12` | `16`	Number of slots

Output Arguments

`waveform` — Modulated baseband waveform comprising the physical channels
complex vector array

Modulated baseband waveform comprising the 1xEV-DO physical channels, returned as a complex vector array.

`evdoForwardWaveformGenerator` | `evdoReverseReferenceChannels`

Introduced in R2015b

eyediagram

Generate eye diagram

Syntax

```
eyediagram(x,n)
eyediagram(x,n,period)
eyediagram(x,n,period,offset)
eyediagram(x,n,period,offset,plotstring)
eyediagram(x,n,period,offset,plotstring,h)
h = eyediagram( ___ )
```

Description

`eyediagram(x,n)` generates an eye diagram for signal `x`, plotting `n` samples in each trace. The labels on the horizontal axis of the diagram range between –1/2 and 1/2. The function assumes that the first value of the signal and every `n`th value thereafter, occur at integer times.

`eyediagram(x,n,period)` sets the labels on the horizontal axis to the range between –`period`/2 to `period`/2.

`eyediagram(x,n,period,offset)` specifies the offset for the eye diagram. The function assumes that the (`offset` + 1)th value of the signal and every `n`th value thereafter, occur at times that are integer multiples of `period`.

`eyediagram(x,n,period,offset,plotstring)` specifies plot attributes for the eye diagram.

`eyediagram(x,n,period,offset,plotstring,h)` generates the eye diagram in an existing figure whose handle is `h`.

Note Use of `hold on` to plot multiple signals in the same figure is not supported.

`h = eyediagram( ___ )` returns the handle to the figure that contains the eye diagram. You can specify any of the input argument combinations from the previous syntaxes.

Examples

Generate Eye Diagram of Filtered QPSK Signal

Generate an eyediagram of a filtered QPSK signal.

Generate random symbols. Apply QPSK modulation to get a modulated signal.

```
data = randi([0 3],1000,1);
modSig = pskmod(data,4,pi/4);
```

Specify the number of output samples per symbol parameter. Create a transmit filter object, `txfilter`.

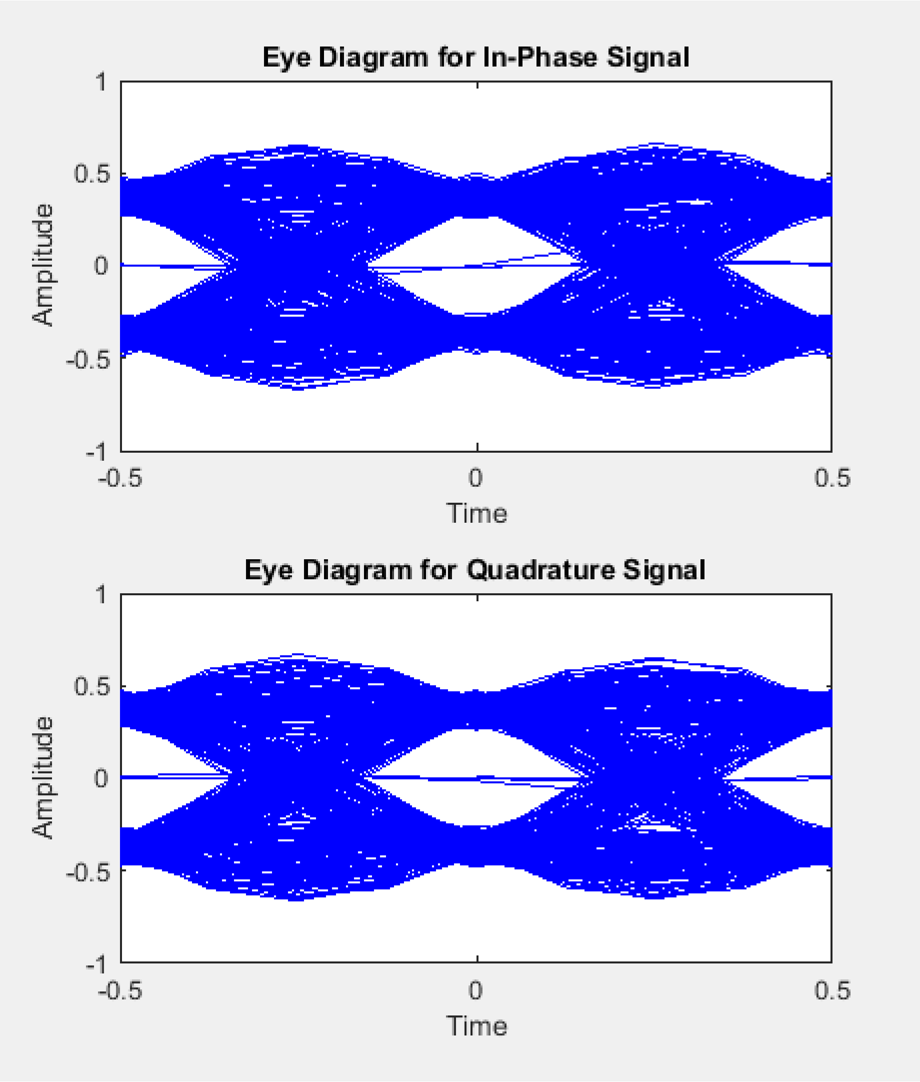
```
sps=4;
txfilter = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',sps);
```

Filter the modulated signal `modSig`.

```
txSig = txfilter(modSig);
```

Display the eye diagram.

```
eyediagram(txSig,2*sps)
```



Input Arguments

x — Input signal

vector | matrix

Input signal, specified as a vector or matrix.

The interpretation of x and the number of plots depend on the shape and complexity of x.

- If x is a real-valued two-column matrix, the function interprets the first column as in-phase components and the second column as quadrature components. The two components appear in different subplots of a single figure window.
- If x is a complex-valued vector, the function interprets the real part as in-phase components and the imaginary part as quadrature components. The two components appear in different subplots of a single figure window.
- If x is a real-valued vector, the function interprets the vector as a real signal. The figure window contains a single plot.

Data Types: double
Complex Number Support: Yes

n — Number of samples per trace
integer greater than 1

Number of samples per trace, specified as a integer greater than 1.

Data Types: double

period — Trace period
1 (default) | positive scalar

Trace period, specified as a positive scalar. The labels on the horizontal axis of the eye diagram range between -period/2 to period/2.

Data Types: double

offset — Offset value
0 (default) | integer in the range from 0 to (n–1)

Offset value, specified as an integer in the range 0 to (n–1). The function assumes that the (offset + 1)th value of the signal and every nth value thereafter, occur at times that are integer multiples of the input period.

Data Types: double

plotstring — Plot attributes
'b-' (default) | character vector | string scalar

Plot attributes, specified as a character vector or string scalar containing symbols.

This argument sets the plotting symbol, line type, and color for the eye diagram. The format and meaning of the symbols are the same as in the plot function. For example, the default value 'b-' produces a solid blue line.

Data Types: char | string

h — Figure handle
Figure object

Figure handle to an existing figure that contains an eye diagram, specified as a Figure object. h must be a handle to a figure that the eyediagram function previously generated.

Output Arguments

h — Figure handle
`Figure` object

Figure handle, returned as a `Figure` object. To modify properties of this object, see `Figure Properties`.

"Eye Diagram Analysis"

Introduced before R2006a

EyeScope

(Removed) Launch eye diagram scope for eye diagram object H

Note `eyescope` has been removed. Use `eyediagram` instead.

Syntax

```
eyescope
eyescope(h)
```

Description

Eye Diagram Scope is a graphical user interface (GUI) that enables you to visualize and measure the effects that various impairments, such as noise, jitter, and filtering, have on a modulated signal. The scope performs a probability density function (pdf) analysis on the signal to illustrate its trajectory in time, and to calculate such quantities as eye SNR, RMS jitter, rise time, and fall time. The scope also enables you to import and compare measurement results for eye diagrams of multiple signals.

There are two ways to call EyeScope:

- `eyescope` calls an empty scope
- `eyescope(h)` calls the scope and displays object `h`

Note You can call EyeScope with an eye diagram object as the input argument. EyeScope uses the `inputname` function to resolve the caller’s work space name for the argument. If the `inputname` function cannot resolve the caller’s work space name, then EyeScope uses a default name. To learn about the cases when EyeScope cannot determine the work space name, type `help inputname` at the MATLAB command line.

Compatibility Considerations

EyeScope has been removed
Errors starting in R2020a

`EyeScope` has been removed. Use `eyediagram` instead.

Functions
`eyediagram`

Introduced in R2008b

fft

Discrete Fourier transform

Syntax

```
fft(x)
```

Description

`fft(x)` is the discrete Fourier transform (DFT) of the Galois vector `x`. If `x` is in the Galois field GF(2^m), the length of `x` must be 2^m-1.

Examples

Discrete Fourier Transform of Galois Vector

Set the order of the Galois field. Because `x` is in the Galois field (2^4), the length of `x` must be $2^m - 1$.

```
m = 4;
n = 2^m-1;
```

Generate a random GF vector.

```
x = gf(randi([0 2^m-1],n,1),m);
```

Perform the Fourier transform.

```
y = fft(x);
```

Invert the transform.

```
z = ifft(y);
```

Confirm that the inverse transform `z` = `x`.

```
isequal(z,x)
```

```
ans = logical
   1
```

Limitations

The Galois field over which this function works must have 256 or fewer elements. In other words, `x` must be in the Galois field GF(2^m), where `m` is an integer between 1 and 8.

Algorithms

If x is a column vector, fft applies dftmtx to the primitive element of the Galois field and multiplies the resulting matrix by x.

Introduced before R2006a

filter (channel)

(To be removed) Filter signal with channel object

Note `filter` has been removed. Use function associated with `comm.RicianChannel` or `comm.RayleighChannel` instead.

Syntax

```
y = filter(chan,x)
```

Description

`y = filter(chan,x)` processes the baseband signal vector `x` with the channel object `chan`. The result is the signal vector `y`. The final state of the channel is stored in `chan`. You can construct `chan` using either `rayleighchan` or `ricianchan`. The `filter` function assumes `x` is sampled at frequency `1/ts`, where `ts` equals the `InputSamplePeriod` property of `chan`.

If `chan.ResetBeforeFiltering` is `0`, `filter` uses the existing state information in `chan` when starting the filtering operation. As a result, `filter(chan,[x1 x2])` is equivalent to `[filter(chan,x1) filter(chan,x2)]`. To reset `chan` manually, apply the `reset` function to `chan`.

If `chan.ResetBeforeFiltering` is `1`, `filter` resets `chan` before starting the filtering operation, overwriting any previous state information in `chan`.

Compatibility Considerations

`filter` has been removed

Errors starting in R2020b

filter (channel) has been removed. Use `comm.RicianChannel` instead.

Introduced in R2007a

filter (Galois field)

1-D digital filter over Galois field

Syntax

```
y = filter(b,a,x)
[y,zf] = filter(b,a,x)
```

Description

`y = filter(b,a,x)` filters the data in the vector `x` with the filter described by numerator coefficient vector `b` and denominator coefficient vector `a`. The vectors `b`, `a`, and `x` must be Galois vectors in the same field. If `a(1)` is not equal to `1`, then `filter` normalizes the filter coefficients by `a(1)`. As a result, `a(1)` must be nonzero.

The filter is a *Direct Form II Transposed* implementation of the standard difference equation shown here:

```
a(1)*y(n) = b(1)*x(n) + b(2)*x(n-1) + ... + b(nb+1)*x(n-nb) ...
                      - a(2)*y(n-1) - ... - a(na+1)*y(n-na)
```

`[y,zf] = filter(b,a,x)` returns the final conditions of the filter delays in the Galois vector `zf`. The length of the vector `zf` is `max(size(a),size(b))-1`.

Examples

Filter a Galois Field

When using the Galois 1-D digital filter function, the data is normalized by the first element of the denominator coefficient vector.

```
a = gf([2 3 5 7],3);
b = gf([1 3],3);
x = gf(randi([0,7],10,1),3);
filt_x = filter(b,a,x)
```

```
filt_x = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)

Array elements =

   6
   6
   3
   4
   7
   4
   2
   2
   0
   5
```

The first coefficient of the denominator coefficient vector, a(1) = 2. To confirm the function normalizes the data, manually normalize the filtered data. Use `isequal` to compare the outputs, we see they are equal.

```
filt_x2 = a(1) * filter(b/a(1),a,x)
```

```
filt_x2 = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)

Array elements =

   6
   6
   3
   4
   7
   4
   2
   2
   0
   5
```

```
isequal(filt_x,filt_x2)
```

```
ans = logical
   1
```

`gf`

Introduced before R2006a

fmdemod

Frequency demodulation

Syntax

```
z = fmdemod(y,Fc,Fs,freqdev)
z = fmdemod(y,Fc,Fs,freqdev,ini_phase)
```

Description

`z = fmdemod(y,Fc,Fs,freqdev)` returns a demodulated signal `z`, given the input frequency modulated (FM) signal `y`, where the carrier signal has frequency `Fc` and sampling rate `Fs`. `freqdev` is the frequency deviation of the modulated signal.

Note

- The value of `Fs` must satisfy `Fs` ≥ 2`Fc`.
- The value of `freqdev` must satisfy `freqdev` < `Fc`.

`z = fmdemod(y,Fc,Fs,freqdev,ini_phase)` specifies the initial phase of the modulated signal in radians.

Examples

FM Modulate and Demodulate Sinusoidal Signal

Set the sampling frequency to 1kHz and carrier frequency to 200 Hz. Generate a time vector having a duration of 0.2 s.

```
fs = 1000;
fc = 200;
t = (0:1/fs:0.2)';
```

Create two-tone sinusoidal signal with frequencies 30 and 60 Hz.

```
x = sin(2*pi*30*t)+2*sin(2*pi*60*t);
```

Set the frequency deviation to 50 Hz.

```
fDev = 50;
```

Frequency modulate `x`.

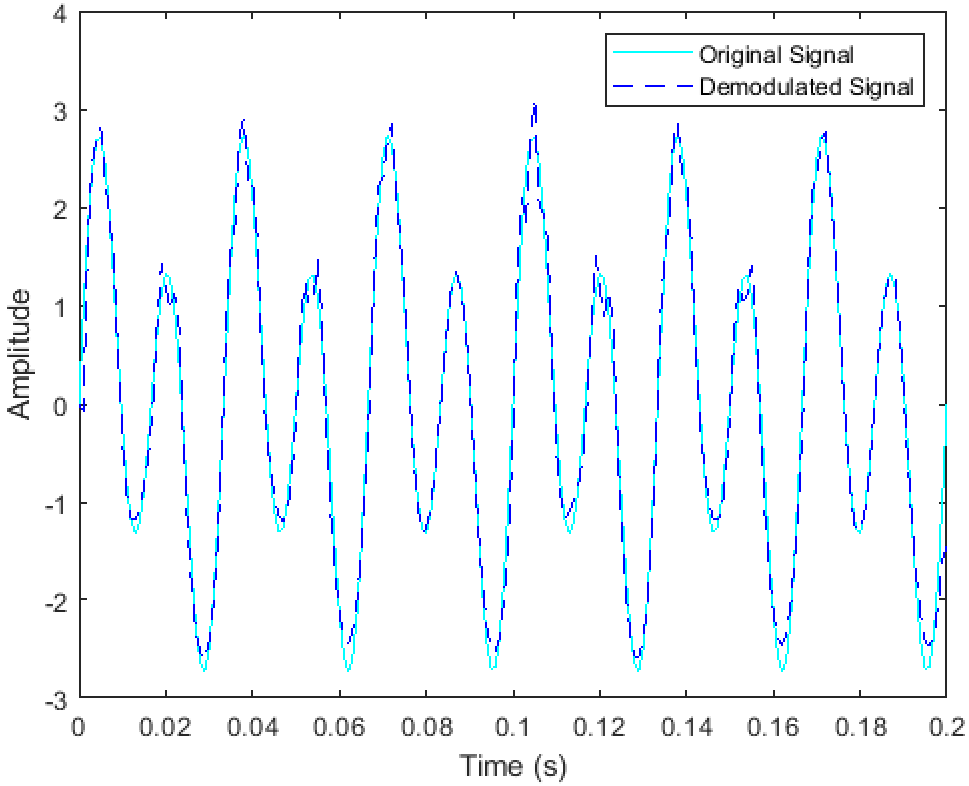
```
y = fmmod(x,fc,fs,fDev);
```

Demodulate z.

```
z = fmdemod(y,fc,fs,fDev);
```

Plot the original and demodulated signals.

```
plot(t,x,'c',t,z,'b--');
xlabel('Time (s)')
ylabel('Amplitude')
legend('Original Signal','Demodulated Signal')
```



The demodulated signal closely approximates the original.

Input Arguments

y — Frequency modulated input signal

scalar | vector | matrix | 3-D array

Frequency modulated input signal, specified as a scalar, vector, matrix, or 3-D array. Each element of y must be real.

Data Types: double | single

Fc — Carrier frequency

positive real scalar

Carrier frequency in hertz (Hz), specified as a positive real scalar.

Data Types: double

`Fs` — Sampling rate
positive scalar

Sampling rate in hertz (Hz), specified as a positive scalar.

Data Types: `double`

`freqdev` — Frequency deviation
positive scalar

Frequency deviation of the modulated signal in hertz (Hz), specified as a positive scalar.

Data Types: `double`

`ini_phase` — Initial phase
scalar

Initial phase of the modulated signal in radians, specified as a scalar.

Data Types: `double`

Output Arguments

`z` — Frequency demodulated output signal
scalar | vector | matrix | 3-D array

Frequency demodulated signal, returned as a scalar, vector, matrix, or 3-D array.

fmmod

Frequency modulation

Syntax

```
y = fmmod(x,Fc,Fs,freqdev)
y = fmmod(x,Fc,Fs,freqdev,ini_phase)
```

Description

`y = fmmod(x,Fc,Fs,freqdev)` returns a frequency modulated (FM) signal `y`, given the input message signal `x`, where the carrier signal has frequency `Fc` and sampling rate `Fs`. `freqdev` is the frequency deviation of the modulated signal.

Note

- The value of `Fs` must satisfy `Fs` ≥ 2`Fc`.
- The value of `freqdev` must satisfy `freqdev` < `Fc`.

`y = fmmod(x,Fc,Fs,freqdev,ini_phase)` specifies the initial phase of the modulated signal.

Examples

FM Modulate a Sinusoidal Signal

Set the sampling frequency to 1kHz and carrier frequency to 200 Hz. Generate a time vector having a duration of 0.2 s.

```
fs = 1000;
fc = 200;
t = (0:1/fs:0.2)';
```

Create two tone sinusoidal signal with frequencies 30 and 60 Hz.

```
x = sin(2*pi*30*t)+2*sin(2*pi*60*t);
```

Set the frequency deviation to 50 Hz.

```
fDev = 50;
```

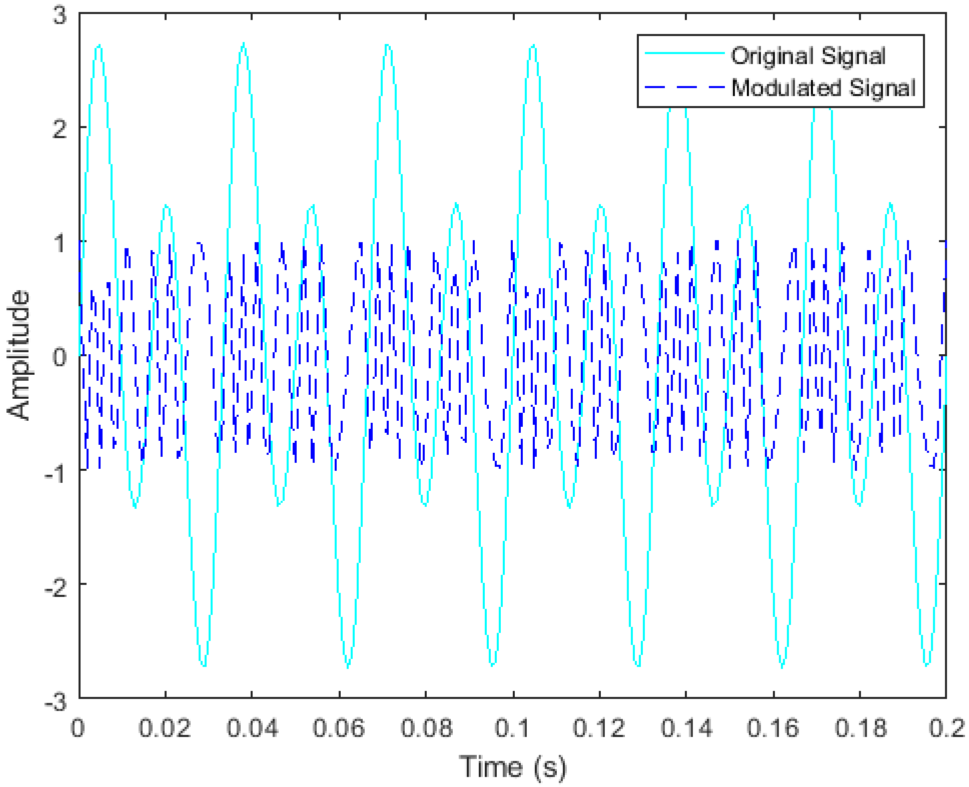
Frequency modulate `x`.

```
y = fmmod(x,fc,fs,fDev);
```

Plot the original and modulated signals.

```
plot(t,x,'c',t,y,'b--')
xlabel('Time (s)')
```

```
ylabel('Amplitude')
legend('Original Signal','Modulated Signal')
```



Input Arguments

x — Input message signal

scalar | vector | matrix | 3-D array

Input message signal, specified as a scalar, vector, matrix, or a 3-D array. Each element of x must be real.

Data Types: single | double

Fc — Carrier frequency

positive real scalar

Carrier frequency in hertz (Hz), specified as a positive real scalar.

Data Types: single | double

Fs — Sampling rate

positive real scalar

Sampling rate in hertz (Hz), specified as a positive real scalar.

Data Types: single | double

`freqdev` — Frequency deviation

positive real scalar

Frequency deviation of the modulated signal in hertz (Hz), specified as a positive real scalar.

Data Types: `single` | `double`

`ini_phase` — Initial phase

real scalar

Initial phase of the modulated signal in radians, specified as a real scalar.

Data Types: `single` | `double`

Output Arguments

y — Frequency modulated output signal

scalar | vector | matrix | 3-D array

Frequency modulated signal, returned as a scalar, vector, matrix, or 3-D array.

fskdemod

Frequency shift keying demodulation

Syntax

```
z = fskdemod(y,M,freq_sep,nsamp)
z = fskdemod(y,M,freq_sep,nsamp,Fs)
z = fskdemod(y,M,freq_sep,nsamp,Fs,symorder)
```

Description

`z = fskdemod(y,M,freq_sep,nsamp)` noncoherently demodulates the complex envelope `y` of a signal using the frequency shift key method.

`z = fskdemod(y,M,freq_sep,nsamp,Fs)` specifies the sampling frequency in Hz.

`z = fskdemod(y,M,freq_sep,nsamp,Fs,symorder)` specifies how the function assigns binary words to corresponding integers.

Examples

Modulation and Demodulation of an FSK Signal in AWGN

Pass an FSK signal through an AWGN channel and estimate the resulting bit error rate (BER). Compare the estimated BER to the theoretical value.

Set the simulation parameters.

```
M = 2;          % Modulation order
k = log2(M);    % Bits per symbol
EbNo = 5;       % Eb/No (dB)
Fs = 16;        % Sample rate (Hz)
nsamp = 8;      % Number of samples per symbol
freqsep = 10;   % Frequency separation (Hz)
```

Generate random data symbols.

```
data = randi([0 M-1],5000,1);
```

Apply FSK modulation.

```
txsig = fskmod(data,M,freqsep,nsamp,Fs);
```

Pass the signal through an AWGN channel

```
rxSig  = awgn(txsig,EbNo+10*log10(k)-10*log10(nsamp),...
    'measured',[],'dB');
```

Demodulate the received signal.

```
dataOut = fskdemod(rxSig,M,freqsep,nsamp,Fs);
```

Calculate the bit error rate.

```
[num,BER] = biterr(data,dataOut);
```

Determine the theoretical BER and compare it to the estimated BER. Your BER value might vary because the example uses random numbers.

```
BER_theory = berawgn(EbNo,'fsk',M,'noncoherent');
[BER BER_theory]
```

```
ans = 1×2

    0.0958    0.1029
```

Input Arguments

y — FSK-modulated output signal

vector | matrix

Complex baseband representation of a FSK-modulated signal, specfied as vector or matrix of complex values. If `y` is a matrix with multiple rows and columns, fskdemod processes the columns independently.

Data Types: `double` | `single`

`M` — Modulation order

integer power of two

Modulation order, specified as an integer power of two.

Example: 2 | 4 | 16

Data Types: `double`

`symorder` — Symbol order

`'bin'` (default) | `'gray'`

Symbol order, specified as `'bin'` or `'gray'`. This argument specifies how the function assigns binary vectors to corresponding integers.

- If `symorder` is `'bin'`, the function uses a natural binary-coded ordering.
- If `symorder` is `'gray'`, the function uses a Gray-coded ordering.

Data Types: `char`

`freq_sep` — Desired separation between frequencies

positive scalar

Desired separation between frequencies, specified in Hz. By the Nyquist sampling theorem, `freq_sep` and `M` must satisfy (`M`-1)*`freq_sep` <= 1.

Data Types: `double`

`nsamp` — Number of samples per output symbol

positive scalar greater than 1

Number of samples per output symbol, specified as a positive scalar greater than 1.

Data Types: `double`

`Fs` — Sample rate
1 Hz (default) | positive scalar

Sample rate, specified as a positive scalar.

Data Types: `double`

Output Arguments

`z` — Output signal
vector | matrix

Output signal, returned as a vector or matrix of positive integers. The elements of `z` have values in the range of [0, `M` – 1].

Example: `randi([0 3],100,1)`

Data Types: `double`

fskmod

Frequency shift keying modulation

Syntax

```
y = fskmod(x,M,freq_sep,nsamp)
y = fskmod(x,M,freq_sep,nsamp,Fs)
y = fskmod(x,M,freq_sep,nsamp,Fs,phase_cont)
y = fskmod(x,M,freq_sep,nsamp,Fs,phase_cont,symorder)
```

Description

`y = fskmod(x,M,freq_sep,nsamp)` outputs the complex envelope `y` of the modulation of the message signal `x` using frequency shift keying modulation.

`y = fskmod(x,M,freq_sep,nsamp,Fs)` specifies the sampling rate of `y`.

`y = fskmod(x,M,freq_sep,nsamp,Fs,phase_cont)` specifies the phase continuity.

`y = fskmod(x,M,freq_sep,nsamp,Fs,phase_cont,symorder)` specifies how the function assigns binary words to corresponding integers.

Examples

FSK Signal Spectrum Plot

Generate an FSK modulated signal and display its spectral characteristics.

Set the function parameters.

```
M = 4;          % Modulation order
freqsep = 8;    % Frequency separation (Hz)
nsamp = 8;      % Number of samples per symbol
Fs = 32;        % Sample rate (Hz)
```

Generate random M-ary symbols.

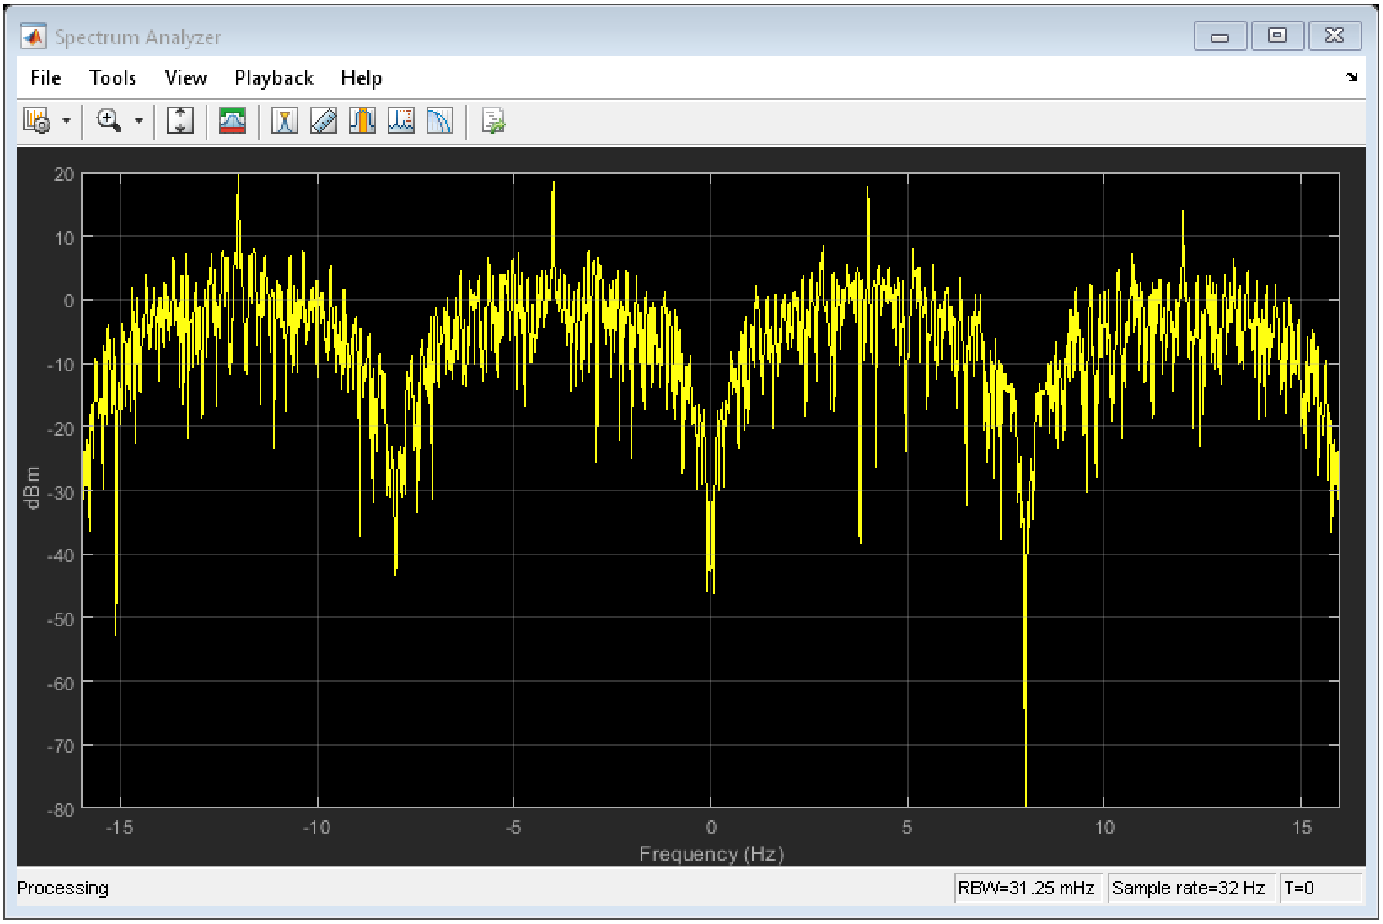
```
x = randi([0 M-1],1000,1);
```

Apply FSK modulation.

```
y = fskmod(x,M,freqsep,nsamp,Fs);
```

Create a spectrum analyzer System object? and use its `step` method to display a plot of the signal spectrum.

```
h = dsp.SpectrumAnalyzer('SampleRate',Fs);
step(h,y)
```



Input Arguments

x — Input signal

vector | matrix

Input signal, specified as a vector or matrix of positive integers. The elements of x must have values in the range of [0, M – 1]. If x is a matrix, fskmod processes the columns independently.

Example: randi([0 3],100,1)

Data Types: double

M — Modulation order

integer power of two

Modulation order, specified as an integer power of two.

Example: 2 | 4 | 16

Data Types: double

symorder — Symbol order

'bin' (default) | 'gray'

Symbol order, specified as 'bin' or 'gray'. This argument specifies how the function assigns binary vectors to corresponding integers.

- If symorder is 'bin', the function uses a natural binary-coded ordering.
- If symorder is 'gray', the function uses a Gray-coded ordering.

Data Types: char

freq_sep — Desired separation between frequencies

positive scalar

Desired separation between frequencies, specified in Hz. By the Nyquist sampling theorem, freq_sep and M must satisfy (M-1)*freq_sep <= 1.

Data Types: double

nsamp — Number of samples per output symbol

positive scalar greater than 1

Number of samples per output symbol, specified as a positive scalar greater than 1.

Data Types: double

Fs — Sample rate

1 Hz (default) | positive scalar

Sample rate, specified as a positive scalar.

Data Types: double

phase_cont — Phase continuity

'cont' (default) | 'discont'

Phase continuity, specified as either 'cont' or 'discont'. Set phase_cont to 'cont' to force phase continuity across symbol boundaries in y, or 'discont' to avoid forcing phase continuity.

Data Types: char

Output Arguments

y — FSK-modulated output signal

vector | matrix

Complex baseband representation of a FSK-modulated signal, returned as vector or matrix of complex values. The columns of y represent independent channels.

Data Types: double | single

gen2par

Convert between parity-check and generator matrices

Syntax

```
parmat = gen2par(genmat)
genmat = gen2par(parmat)
```

Description

`parmat = gen2par(genmat)` converts the standard-form binary generator matrix `genmat` into the corresponding parity-check matrix `parmat`.

`genmat = gen2par(parmat)` converts the standard-form binary parity-check matrix `parmat` into the corresponding generator matrix `genmat`.

The standard forms of the generator and parity-check matrices for an [n,k] binary linear block code are shown in the table below

Type of Matrix	Standard Form	Dimensions
Generator	[I_k P] or [P I_k]	k-by-n
Parity-check	[-P' I_{n-k}] or [I_{n-k} -P']	(n-k)-by-n

.

where I_k is the identity matrix of size k and the ' symbol indicates matrix transpose. Two standard forms are listed for each type, because different authors use different conventions. For *binary* codes, the minus signs in the parity-check form listed above are irrelevant; that is, -1 = 1 in the binary field.

Examples

Convert Parity-Check Matrix for a Hamming Code to Generator Matrix

Convert the parity-check matrix for a Hamming code into the corresponding generator matrix and back again.

Create the parity-check matrix.

```
parmat = hammgen(3)
```

```
parmat = 3×7

     1     0     0     1     0     1     1
     0     1     0     1     1     1     0
     0     0     1     0     1     1     1
```

Convert the parity-check matrix into the corresponding generator matrix.

```
genmat = gen2par(parmat)
genmat = 4×7

     1     1     0     1     0     0     0
     0     1     1     0     1     0     0
     1     1     1     0     0     1     0
     1     0     1     0     0     0     1
```

Convert the generator matrix back again. The output, `parmat2`, should be the same as the original matrix, `parmat`.

```
parmat2 = gen2par(genmat)
```

```
parmat2 = 3×7

     1     0     0     1     0     1     1
     0     1     0     1     1     1     0
     0     0     1     0     1     1     1
```

genqamdemod

General quadrature amplitude demodulation

Syntax

```
z = genqamdemod(y,const)
```

Description

`z = genqamdemod(y,const)` demodulates the complex envelope, `y`, of a quadrature amplitude modulated signal using the signal mapping specified in `const`.

Examples

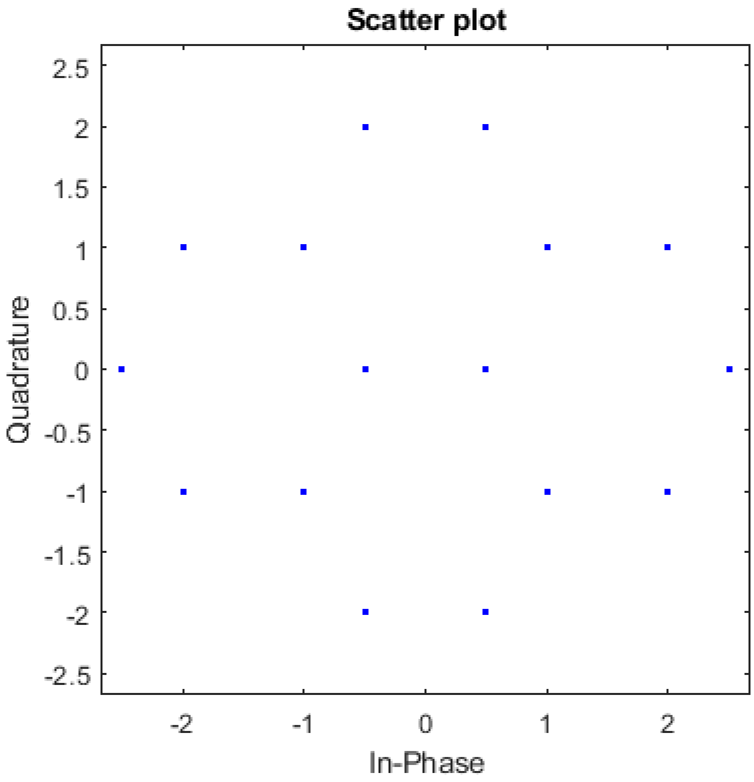
General QAM Modulation and Demodulation

Create the points that describe a hexagonal constellation.

```
inphase = [1/2 1 1 1/2 1/2 2 2 5/2];
quadr = [0 1 -1 2 -2 1 -1 0];
inphase = [inphase;-inphase]; inphase = inphase(:);
quadr = [quadr;quadr]; quadr = quadr(:);
const = inphase + 1i*quadr;
```

Plot the constellation.

```
h = scatterplot(const);
```



Generate input data symbols. Modulate the symbols using this constellation.

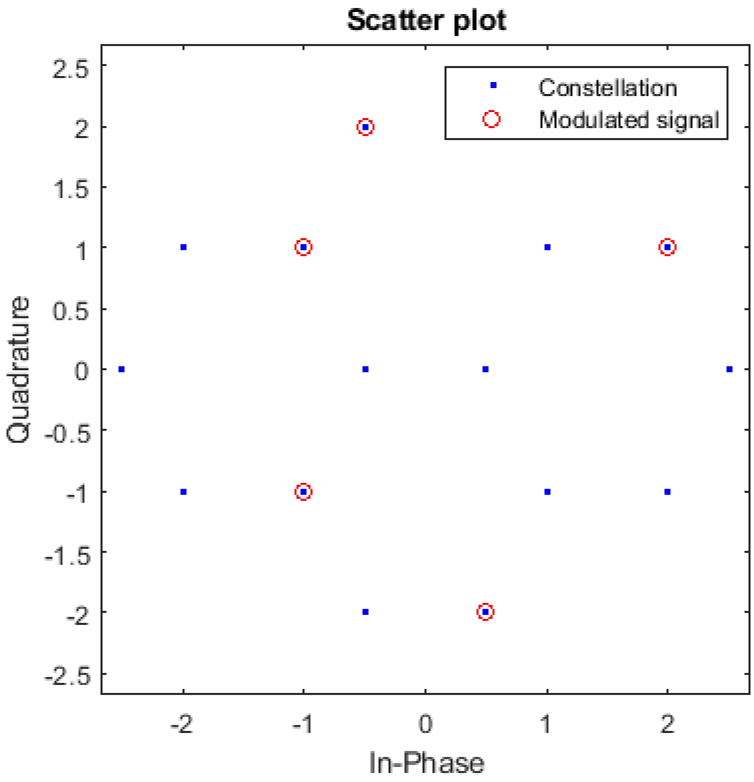
```
x = [3 8 5 10 7];
y = genqammod(x,const);
```

Demodulate the modulated signal, y.

```
z = genqamdemod(y,const);
```

Plot the modulated signal in same figure.

```
hold on;
scatterplot(y,1,0,'ro',h);
legend('Constellation','Modulated signal');
```



Determine the number of symbol errors between the demodulated data to the original sequence.

```
numErrs = symerr(x,z)
```

```
numErrs = 0
```

Input Arguments

y — Complex envelope

scalar | vector | matrix | 3-D array

Complex envelope, specified as a scalar, vector, matrix, or 3-D array of numeric values. If `y` is a matrix with multiple rows, the function processes the rows independently.

`const` — Signal mapping

complex vector

Signal mapping, specified as a complex vector.

Data Types: `double` | `single`

Output Arguments

z — Message signal

scalar | vector | matrix | 3-D array

Message signal, returned as a scalar, vector, matrix, or 3-D array of numeric values. The message signal consists of integers between 0 and `length(const)`–1. The datatype of `z` is the same as the data type of input `x`.

Data Types: `double` | `single`

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

genqammod

General quadrature amplitude modulation (QAM)

Syntax

```
y = genqammod(x,const)
```

Description

`y = genqammod(x,const)` returns the complex envelop of the QAM for message signal `x`. Input `const` specifies the signal mapping for the modulation.

Examples

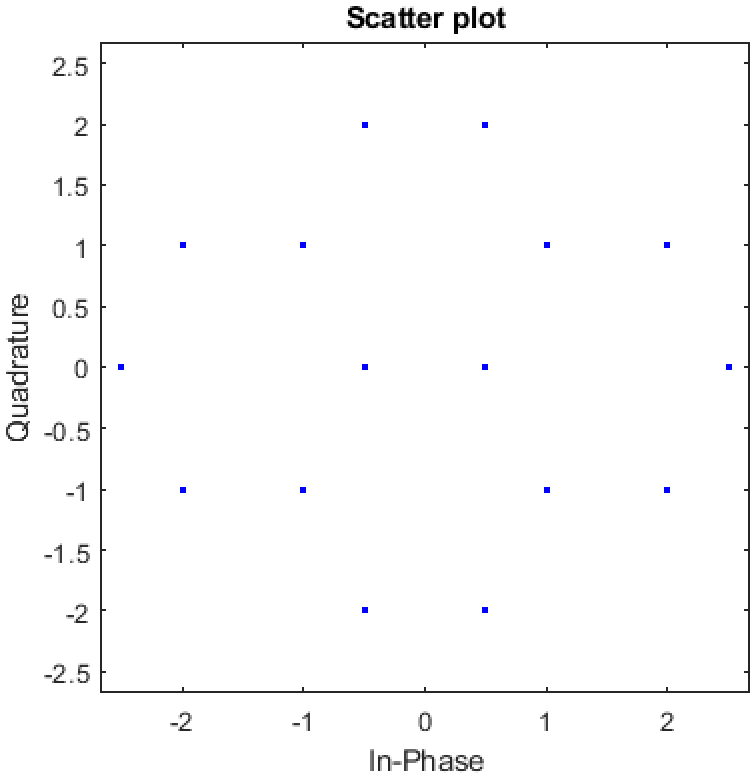
General QAM Modulation and Demodulation

Create the points that describe a hexagonal constellation.

```
inphase = [1/2 1 1 1/2 1/2 2 2 5/2];
quadr = [0 1 -1 2 -2 1 -1 0];
inphase = [inphase;-inphase]; inphase = inphase(:);
quadr = [quadr;quadr]; quadr = quadr(:);
const = inphase + 1i*quadr;
```

Plot the constellation.

```
h = scatterplot(const);
```



Generate input data symbols. Modulate the symbols using this constellation.

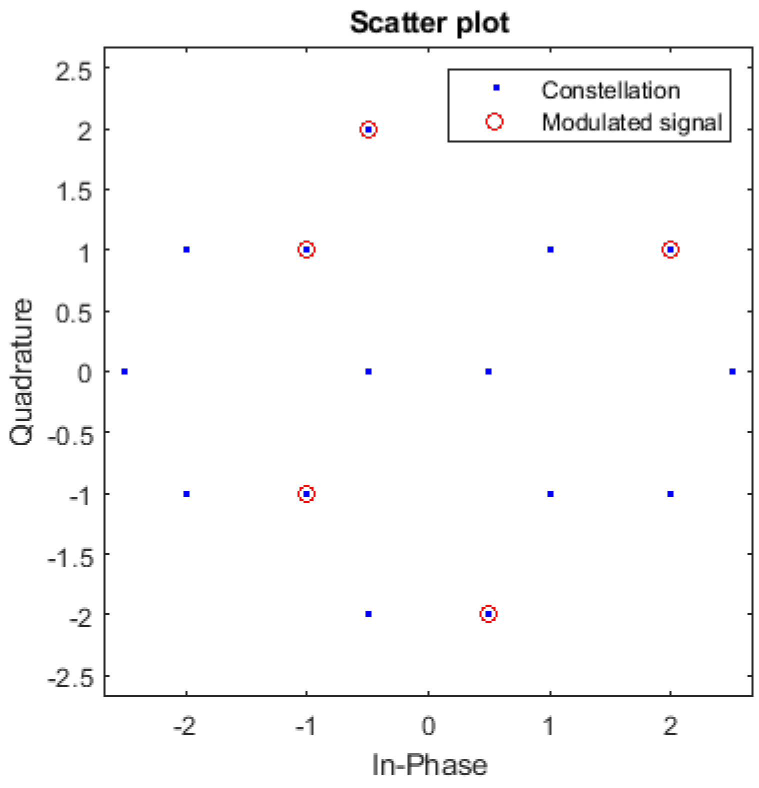
```
x = [3 8 5 10 7];
y = genqammod(x,const);
```

Demodulate the modulated signal, y.

```
z = genqamdemod(y,const);
```

Plot the modulated signal in same figure.

```
hold on;
scatterplot(y,1,0,'ro',h);
legend('Constellation','Modulated signal');
```



Determine the number of symbol errors between the demodulated data to the original sequence.

```
numErrs = symerr(x,z)
```

```
numErrs = 0
```

Input Arguments

x — Message signal

scalar | vector | matrix | 3-D array

Message signal, specified as a scalar, vector, matrix, or 3-D array of numeric values. The message signal must consist of integers from 0 and `length(const)`–1. If `x` is a matrix with multiple rows, the function processes the columns independently.

Data Types: `double` | `single` | `fi` | `int8` | `int16` | `uint8` | `uint16`

`const` — Signal mapping

complex vector

Signal mapping, specified as a complex vector.

Data Types: `double` | `single` | `fi` | `int8` | `int16` | `uint8` | `uint16`

Output Arguments

y — Complex envelope
scalar | vector | matrix | 3-D array

Complex envelope, returned as a scalar, vector, matrix, or 3-D array of numeric values. The length of `y` is the same as the length of input `x`.

Data Types: `double` | `single` | `fi` | `int8` | `int16` | `uint8` | `uint16`

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

gf

Galois field array

Syntax

```
x_gf = gf(x)
x_gf = gf(x,m)
x_gf = gf(x,m,prim_poly)
```

Description

`x_gf = gf(x)` creates a Galois field (GF) array, GF(2), from matrix `x`.

`x_gf = gf(x,m)` creates a Galois field array from matrix `x`. The Galois field has 2^m elements, where `m` is an integer from 1 through 16.

`x_gf = gf(x,m,prim_poly)` creates a Galois field array from matrix `x` by using the primitive polynomial `prim_poly`.

Examples

Create GF(2) Array from Specified Matrix

Specify a matrix of `0`s and `1`s.

```
x = [0 1 1; 0 1 0; 1 1 1];
```

Create a GF(2) array from `x`.

```
x_gf = gf(x)
```

```
x_gf = GF(2) array.

Array elements =

   0   1   1
   0   1   0
   1   1   1
```

Create Sequence of GF(16) Elements

Set the order of the Galois field to 16, where the order equals 2^m. Specify a matrix of elements that range from 0 to $2^m - 1$. Create the Galois field array.

```
m = 4;
x = [3 2 9; 1 2 1];
y = gf(x,m)
```

```
y = GF(2^4) array. Primitive polynomial = D^4+D+1 (19 decimal)

Array elements = 

   3   2   9
   1   2   1
```

Create GF Sequence with Specified Primitive Polynomial

Create a sequence of integers. Create a Galois field array in GF(2^5).

```
x = [17 8 11 27];
y = gf(x,5)
```

```
y = GF(2^5) array. Primitive polynomial = D^5+D^2+1 (37 decimal)

Array elements = 

   17    8   11   27
```

Determine all possible primitive polynomials for GF(2^5).

```
pp = primpoly(5,'all')
```

```
Primitive polynomial(s) = 

D^5+D^2+1
D^5+D^3+1
D^5+D^3+D^2+D^1+1
D^5+D^4+D^2+D^1+1
D^5+D^4+D^3+D^1+1
D^5+D^4+D^3+D^2+1

pp = 6×1

    37
    41
    47
    55
    59
    61
```

Create a Galois field array using the primitive polynomial that has a decimal equivalent of 59.

```
z = gf(x,5,'D5+D4+D3+D+1')
```

```
z = GF(2^5) array. Primitive polynomial = D^5+D^4+D^3+D+1 (59 decimal)

Array elements = 

   17    8   11   27
```

Input Arguments

x — Input matrix

matrix with all values greater than or equal to zero

Input matrix, specified as a matrix with values greater than or equal to zero. The function uses this value to create a GF array.

- If you do not specify the `prim_poly` input argument, each element of `x` must be an integer in the range [0, 2^m–1].
- If you specify `prim_poly` input argument, each element of `x` must be `0` or `1`.

Data Types: `double`

m — Order of primitive polynomial

positive integer

Order of primitive polynomial, specified as a positive integer from 1 through 16. The function uses this value to calculate the distinct number of elements in the GF.

Data Types: `double`

prim_poly — Primitive polynomial

primitive polynomial in GF(2^m) (default) | binary row vector | character vector | string scalar | positive integer

Primitive polynomial, specified as one of these options:

- Binary row vector — This vector specifies coefficients of `prim_poly` in the order of ascending powers.
- Character vector or a string scalar — This value defines `prim_poly` in a textual representation. For more details, refer to polynomial character vector.
- Positive integer — This value defines `prim_poly` in the range [(2^m + 1), (2^{m+1} – 1)].

If `prim_poly` is not specified, see “Default Primitive Polynomials” on page 2-400 for the list of default primitive polynomial used for each Galois field array GF(2^m).

Data Types: `double` | `char` | `string`

Output Arguments

x_gf — Galois field array

variable that MATLAB recognizes as a Galois field array

Galois field array, returned as a variable that MATLAB recognizes as a Galois field array, rather than an array of integers. As a result, when you manipulate the variable, MATLAB works within the Galois field the variable specifies. For example, if you apply the `log` function to a Galois array, MATLAB computes the logarithm in the Galois field for that Galois array and not in the field of real or complex numbers.

More About

Default Primitive Polynomials

This table lists the default primitive polynomial used for each Galois field array GF(2^m). To use a different primitive polynomial, specify `prim_poly` as an input argument. `prim_poly` must be in the range [(2^m + 1), (2^{m+1} – 1)] and must indicate an irreducible polynomial. For more information, see “Primitive Polynomials and Element Representations”.

Value of m	Default Primitive Polynomial	Integer Representation
1	$D + 1$	3
2	$D^2 + D + 1$	7
3	$D^3 + D + 1$	11
4	$D^4 + D + 1$	19
5	$D^5 + D^2 + 1$	37
6	$D^6 + D + 1$	67
7	$D^7 + D^3 + 1$	137
8	$D^8 + D^4 + D^3 + D^2 + 1$	285
9	$D^9 + D^4 + 1$	529
10	$D^{10} + D^3 + 1$	1033
11	$D^{11} + D^2 + 1$	2053
12	$D^{12} + D^6 + D^4 + D + 1$	4179
13	$D^{13} + D^4 + D^3 + D + 1$	8219
14	$D^{14} + D^{10} + D^6 + D + 1$	17475
15	$D^{15} + D + 1$	32771
16	$D^{16} + D^{12} + D^3 + D + 1$	69643

Galois Computations

This table lists the operations supported for Galois field arrays.

Operation	Description
+ -	Addition and subtraction of Galois arrays
* / \	Matrix multiplication and division of Galois arrays
.* ./ .\	Elementwise multiplication and division of Galois arrays
^	Matrix exponentiation of Galois array
.^	Elementwise exponentiation of Galois array
' .'	Transpose of Galois array
==, ~=	Relational operators for Galois arrays
all	True if all elements of a Galois vector are nonzero
any	True if any element of a Galois vector is nonzero

Operation	Description
conv	Convolution of Galois vectors
convmtx	Convolution matrix of Galois field vector
deconv	Deconvolution and polynomial division
det	Determinant of square Galois matrix
dftmtx	Discrete Fourier transform matrix in a Galois field
diag	Diagonal Galois matrices and diagonals of a Galois matrix
fft	Discrete Fourier transform
filter (gf)	One-dimensional digital filter over a Galois field
ifft	Inverse discrete Fourier transform
inv	Inverse of Galois matrix
length	Length of Galois vector
log	Logarithm in a Galois field
lu	Lower-Upper triangular factorization of Galois array
minpol	Find the minimal polynomial for a Galois element
mldivide	Matrix left division \ of Galois arrays
polyval	Evaluate polynomial in Galois field
rank	Rank of a Galois array
reshape	Reshape Galois array
roots	Find polynomial roots across a Galois field
size	Size of Galois array
tril	Extract lower triangular part of Galois array
triu	Extract upper triangular part of Galois array

Introduced before R2006a

gfadd

Add polynomials over Galois field

Syntax

```
c = gfadd(a,b)
c = gfadd(a,b,p)
c = gfadd(a,b,p,len)
c = gfadd(a,b,field)
```

Description

Note This function performs computations in GF(p^m) where p is prime. To work in GF(2^m), apply the + operator to Galois arrays of equal size. For details, see “Example: Addition and Subtraction”.

`c = gfadd(a,b)` adds two GF(2) polynomials, `a` and `b`, which can be either polynomial character vectors or numeric vectors. If `a` and `b` are vectors of the same orientation but different lengths, then the shorter vector is zero-padded. If `a` and `b` are matrices they must be of the same size.

`c = gfadd(a,b,p)` adds two GF(`p`) polynomials, where `p` is a prime number. `a`, `b`, and `c` are row vectors that give the coefficients of the corresponding polynomials in order of ascending powers. Each coefficient is between 0 and `p`-1. If `a` and `b` are matrices of the same size, the function treats each row independently.

`c = gfadd(a,b,p,len)` adds row vectors `a` and `b` as in the previous syntax, except that it returns a row vector of length `len`. The output `c` is a truncated or extended representation of the sum. If the row vector corresponding to the sum has fewer than `len` entries (including zeros), extra zeros are added at the end; if it has more than `len` entries, entries from the end are removed.

`c = gfadd(a,b,field)` adds two GF(p^m) elements, where m is a positive integer. `a` and `b` are the exponential format of the two elements, relative to some primitive element of GF(p^m). `field` is the matrix listing all elements of GF(p^m), arranged relative to the same primitive element. `c` is the exponential format of the sum, relative to the same primitive element. See “Representing Elements of Galois Fields” for an explanation of these formats. If `a` and `b` are matrices of the same size, the function treats each element independently.

Examples

Add Two GF Arrays

Sum $2 + 3x + x^2$ and $4 + 2x + 3x^2$ over GF(5).

```
x = gfadd([2 3 1],[4 2 3],5)
```

```
x = 1×3

     1     0     4
```

Add the two polynomials and display the first two elements.

```
y = gfadd([2 3 1],[4 2 3],5,2)
```

```
y = 1×2

     1     0
```

For prime number p and exponent m, create a matrix listing all elements of GF(p^m) given primitive polynomial $2 + 2x + x^2$.

```
p = 3;
m = 2;
primpoly = [2 2 1];
field = gftuple((-1:p^m-2)',primpoly,p);
```

Sum A^2 and A^4. The result is A.

```
g = gfadd(2,4,field)
```

```
g = 1
```

Topics

"Arithmetic in Galois Fields"

Introduced before R2006a

gfconv

Multiply polynomials over Galois field

Syntax

```
c = gfconv(a,b)
c = gfconv(a,b,p)
c = gfconv(a,b,field)
```

```
c = gfconv(polys)
c = gfconv(polys,p)
c = gfconv(polys,field)
```

Description

`c = gfconv(a,b)` returns a row vector that specifies the GF(2) polynomial coefficients in order of ascending powers. The returned vector results from the multiplication of GF(2) polynomials `a` and `b`. The polynomial degree of the resulting GF(2) polynomial `c` equals the degree of `a` plus the degree of `b`.

For additional information, see “Tips” on page 2-408.

`c = gfconv(a,b,p)` multiplies two GF(`p`) polynomials, where `p` is a prime number. `a`, `b`, and `c` are in the same Galois field. `a`, `b`, and `c` are polynomials with coefficients in order of ascending powers. Each coefficient is in the range [0, `p`–1].

`c = gfconv(a,b,field)` multiplies two GF(p^m) polynomials, where `field` is a matrix containing the *m*-tuple of all elements in GF(p^m). *p* is a prime number, and m is a positive integer. `a`, `b`, and `c` are in the same Galois field.

In this syntax, each coefficient is specified in exponential format, specifically [-Inf, 0, 1, 2, ...]. The elements in exponential format represent the `field` elements [0, 1, α, α^2, ...] relative to some primitive element α of GF(p^m).

`c = gfconv(polys)` returns a row vector that specifies the GF(2) polynomial coefficients in order of ascending powers. The returned vector results from the multiplication of the GF(2) polynomials specified in `polys`. The polynomial degree of the resulting GF(2) polynomial `c` equals the sum of the degrees of the polynomials contained in `polys`. Use this syntax when `polys` specifies polynomials as a cell array of character vectors or as a string array.

`c = gfconv(polys,p)` multiplies the GF(`p`) polynomials specified in `polys`, where `p` is a prime number. `polys` and `c` are polynomials with coefficients in order of ascending powers. Each coefficient is in the range [0, `p`–1]. `a`, `b`, and `c` are in the same Galois field.

`c = gfconv(polys,field)` multiplies the GF(p^m) polynomials in `polys`, where `field` is a matrix containing the *m*-tuple of all elements in GF(p^m). *p* is a prime number, and *m* is a positive integer. `a`, `b`, and `c` are in the same Galois field.

In this syntax, each coefficient is specified in exponential format, specifically [-Inf, 0, 1, 2, ...]. The elements in exponential format represent the `field` elements [0, 1, α, α^2, ...] relative to some primitive element α of GF(p^m).

Examples

Multiply GF(2) Polynomials

Multiply $1 + 2x + 3x^2 + 4x^3$ and $1 + x$ three times. Represent the polynomials as row vectors, character vectors, and strings.

```
c_rv = gfconv([1 1 0 1],[1 1])
```

```
c_rv = 1×5

     1     0     1     1     1
```

```
c_cv = gfconv('1 + x + x^3','1 + x')
```

```
c_cv = 1×5

     1     0     1     1     1
```

```
c_s = gfconv("1 + x + x^3","1 + x")
```

```
c_s = 1×5

     1     0     1     1     1
```

The results corresponds to $1 + x^2 + x^3 + x^4$.

Multiply Polynomials Over GF(3)

Multiply $1 + x + x^4$ and $x + x^2$ over the Galois field GF(3).

```
gfc = gfconv([1 1 0 0 1],[0 1 1],3)
```

```
gfc = 1×7

     0     1     2     1     0     1     1
```

The result corresponds to $x + 2x^2 + x^3 + x^5 + x^6$.

Multiply Polynomials Over GF(2^4) Using Field Input

Multiply $1 + 2x + 3x^2 + 4x^3 + 5x^4$ and $1 + x$ in the Galois field GF(2^4).

```
field = gftuple([-1:2^4-2]',4,2);
c = gfconv('1 + 2x + 3x^2 + 4x^3 + 5x^4','1 + x',field)
```

```
c = 1×6
```

```
     2     6     7     8     9     6
```

Use the `gfpretty` function to display the result in polynomial form.

```
gfpretty(c)
```

```
                                     2       3       4       5
                      2 + 6 X + 7 X  + 8 X  + 9 X  + 6 X
```

Multiply GF(2) Polynomials Specified As Cell Array

Create a cell array containing three polynomials that result in the DVB-S2 generator polynomial for *t* = 3 when multiplied together.

```
polyCell = {'1 + x + x3 + x5 + x14', ...
    '1 + x6 + x8 + x11 + x14','1 + x + x2 + x6 + x9 + x10 + x14'};
gp = gfconv(polyCell); % DVB-S2 for t=3
```

Use the `gfpretty` function to display the result in polynomial form.

```
gfpretty(gp)
```

```
     4    6    8    10    11    13    16    17    20    24    25    26    27
1 + X  + X  + X  + X   + X   + X   + X   + X   + X   + X   + X   + X   + X

              30    31    32    33    34    35    36    37    38    39    42
           + X   + X   + X   + X   + X   + X   + X   + X   + X   + X   + X
```

Multiply Polynomials Expressed As Strings in GF(2^4) Using Field Input

Multiply $1 + 2x + 3x^2 + 4x^3 + 5x^4$, $1 + x$, and $1 + x^3$ in the Galois field GF(2^4).

```
field = gftuple((-1:2^4-2)', 4, 2);
c = gfconv(["1 + 2x + 3x^2 + 4x^3 + 5x^4","1 + x","1 + x3"],field)
```

```
c = 1×9

     4    13    14     9     2     1     7     8     8
```

Use the `gfpretty` function to display the result in polynomial form.

```
gfpretty(c)
```

```
                          2      3      4    5      6      7      8
           4 + 13 X + 14 X  + 9 X  + 2 X  + X  + 7 X  + 8 X  + 8 X
```

Input Arguments

a — Galois field polynomial

row vector | character vector | string

Galois field polynomial, specified as a row vector, character vector, or string. a can be either a "Character Representation of Polynomials" or numeric vector.

a and b must both be GF(*p*) polynomials or GF(p^m) polynomials, where *p* is prime. The value of *p* is as specified when included, 2 when omitted, or implied when `field` is specified.

Example: `[1 2 3 4]` is the polynomial $1+2x+3x^2+4x^3$ in GF(5) expressed as a row vector.

Data Types: `double` | `char` | `string`

b — Galois field polynomial

row vector | character vector | string

Galois field polynomial, specified as a row vector, character vector, or string. b can be either a "Character Representation of Polynomials" or numeric vector.

a and b must both be GF(*p*) polynomials or GF(p^m) polynomials, where *p* is prime. The value of *p* is as specified when included, 2 when omitted, or implied when `field` is specified.

Example: `'1 + x'` is a polynomial in GF(2^4) expressed as a character vector.

Data Types: `double` | `char` | `string`

p — Prime number

2 (default) | prime number

Prime number, specified as a prime number.

Data Types: `double`

`field` — *m*-tuple of all elements in GF(p^m)

matrix

m-tuple of all elements in GF(p^m), specified as a matrix. `field` is the matrix listing all elements of GF(p^m), arranged relative to the same primitive element. To generate the *m*-tuple of all elements in GF(p^m), use

```
field =gftuple([-1:p^m-2]',m,p)
```

The coefficients, specified in exponential format, represent the field elements in GF(p^m). For an explanation of these formats, see "Representing Elements of Galois Fields".

Data Types: `double`

`polys` — Galois field polynomial list

cell array of character vectors | string array

Galois field polynomial list, specified as a cell array of character vectors or a string array.

Example: `["1+x+x3+x5+x14","1+x6+x8+x11+x14"]` is a string array of polynomials.

Data Types: `cell` | `string`

Output Arguments

c — Galois field polynomial

row vector

Galois field polynomial, returned as a row vector of the polynomial coefficients in order of ascending powers. The polynomial degree of the resulting GF(p^m) polynomial `c` equals the sum of the degrees of the input polynomials. `c` is in the same Galois field as the input polynomials.

Tips

- The gfconv function performs computations in GF(p^m), where p is prime, and m is a positive integer. It multiplies polynomials over a Galois field. To work in GF(2^m), you can also use the `conv` function of the `gf` object with Galois arrays. For details, see “Multiplication and Division of Polynomials”.
- To multiply elements of a Galois field, use `gfmul` instead of `gfconv`. Algebraically, multiplying polynomials over a Galois field is equivalent to convolving vectors containing the coefficients of the polynomials. This convolution operation uses arithmetic over the same Galois field.

gfcosets

Produce cyclotomic cosets for Galois field

Syntax

```
c = gfcosets(m)
c = gfcosets(m,p)
```

Description

Note This function performs computations in GF(p^m), where p is prime. To work in GF(2^m), use the `cosets` function.

`c = gfcosets(m)` produces cyclotomic cosets mod(2^m - 1). Each row of the output GFCS contains one cyclotomic coset.

`c = gfcosets(m,p)` produces the cyclotomic cosets for GF(`p^m`), where `m` is a positive integer and `p` is a prime number.

The output matrix `c` is structured so that each row represents one coset. The row represents the coset by giving the exponential format of the elements of the coset, relative to the default primitive polynomial for the field. For a description of exponential formats, see “Representing Elements of Galois Fields”.

The first column contains the coset leaders. Because the lengths of cosets might vary, entries of `NaN` are used to fill the extra spaces when necessary to make `c` rectangular.

A cyclotomic coset is a set of elements that all satisfy the same minimal polynomial. For more details on cyclotomic cosets, see the works listed in “References” on page 2-410.

Examples

The command below finds the cyclotomic cosets for GF(9).

```
c = gfcosets(2,3)
```

The output is

```
c =

     0   NaN
     1     3
     2     6
     4   NaN
     5     7
```

The `gfminpol` function can check that the elements of, for example, the third row of `c` indeed belong in the same coset.

```
m = [gfminpol(2,2,3); gfminpol(6,2,3)] % Rows are identical.
```

The output is

```
m =

     1     0     1
     1     0     1
```

gfdeconv

Divide polynomials over Galois field

Syntax

```
[q,r] = gfdeconv(b,a)
[q,r] = gfdeconv(b,a,p)
[q,r] = gfdeconv(b,a,field)
```

Description

`[q,r] = gfdeconv(b,a)` returns the quotient `q` and remainder `r` as row vectors that specify GF(2) polynomial coefficients in order of ascending powers. The returned vectors result from the division `b` by `a`. `a`, `b`, and `q` are in GF(2).

For additional information, see “Tips” on page 2-414.

`[q,r] = gfdeconv(b,a,p)` divides two GF(`p`) polynomials, where `p` is a prime number. `b`, `a`, and `q` are in the same Galois field. `b`, `a`, `q`, and `r` are polynomials with coefficients in order of ascending powers. Each coefficient is in the range [0, `p`–1].

`[q,r] = gfdeconv(b,a,field)` divides two GF(p^m) polynomials, where `field` is a matrix containing the *m*-tuple of all elements in GF(p^m). *p* is a prime number, and *m* is a positive integer. `b`, `a`, and `q` are in the same Galois field.

In this syntax, each coefficient is specified in exponential format, specifically [-Inf, 0, 1, 2, ...]. The elements in exponential format represent the `field` elements [0, 1, α, α^2, ...] relative to some primitive element α of GF(p^m).

Examples

Divide Polynomials in GF(3)

Divide $x + x^3 + x^4$ by $1 + x$ in the Galois field GF(3) three times. Represent the polynomials as row vectors, character vectors, and strings.

```
p = 3;
```

Represent the polynomials using row vectors and divide them in GF(3).

```
b = [0 1 0 1 1];
a = [1 1];
[q_rv,r_rv] = gfdeconv(b,a,p)
```

```
q_rv = 1×4

     1     0     0     1

r_rv = 2
```

To confirm the output, compare the original Galois field polynomials to the result of adding the remainder to the product of the quotient and the divisor.

```
bnew = gfadd(gfconv(q_rv,a,p),r_rv,p);
isequal(b,bnew)
```

```
ans = logical
   1
```

Represent the polynomials using character vectors and divide them in GF(3).

```
b = 'x + x^3 + x^4';
a = '1 + x';
[q_cv,r_cv] = gfdeconv(b,a,p)
```

```
q_cv = 1×4

     1     0     0     1

r_cv = 2
```

Represent the polynomials using strings and divide them in GF(3) .

```
b = "x + x^3 + x^4";
a = "1 + x";
[q_s,r_s] = gfdeconv(b,a,p)
```

```
q_s = 1×4

     1     0     0     1

r_s = 2
```

Use the `gfpretty` function to display the result without the remainder in polynomial form.

```
gfpretty(q_s)
```

```
                                     3
                                1 + X
```

Check for Irreducibility and Primitiveness Over GF(3^k)

In the Galois field GF(3), output polynomials of the form $x^k - 1$ for k in the range [2, 8] that are evenly divisible by $1 + x^2$. An irreducible polynomial over GF(p) of degree at least 2 is primitive if and only if it does not divide $-1 + x^k$ evenly for any positive integer k less than $p^m - 1$. For more information, see the `gfprimck` function.

The irreducibility of $1 + x^2$ over GF(3), along with the polynomials that are output, indicates that $1 + x^2$ is not primitive for GF(3^2).

```
p = 3; m = 2;
a = [1 0 1]; % 1+x^2
```

```
for ii = 2:p^m-1
   b = gfrepcov(ii); % x^ii
   b(1) = p-1; % -1+x^ii
   [quot,remd] = gfdeconv(b,a,p);
   % Display -1+x^ii if a divides it evenly.
   if remd==0
      multiple{ii}=b;
      gfpretty(b)
   end
end
```

```
     4
2 + X

     8
2 + X
```

Input Arguments

b — Galois field polynomial

row vector | character vector | string

Galois field polynomial, specified as a row vector, character vector, or string. b can be either a “Character Representation of Polynomials” or numeric vector.

a and b must both be GF(p) polynomials or GF(p^m) polynomials, where p is prime. The value of p is as specified when included, 2 when omitted, or implied when field is specified.

Example: '1 + x' is a polynomial in GF(2^4) expressed as a character vector.

Data Types: double | char | string

a — Galois field polynomial

row vector | character vector | string

Galois field polynomial, specified as a row vector, character vector, or string. a can be either a “Character Representation of Polynomials” or numeric vector.

a and b must both be GF(p) polynomials or GF(p^m) polynomials, where p is prime. The value of p is as specified when included, 2 when omitted, or implied when field is specified.

Example: [1 2 3 4] is the polynomial $1+2x+3x^2+4x^3$ in GF(5) expressed as a row vector.

Data Types: double | char | string

p — Prime number

2 (default) | prime number

Prime number, specified as a prime number.

Data Types: double

field — *m*-tuple of all elements in GF(p^m)

matrix

m-tuple of all elements in GF(p^m), specified as a matrix. `field` is the matrix listing all elements of GF(p^m), arranged relative to the same primitive element. To generate the *m*-tuple of all elements in GF(p^m), use

```
field =gftuple([-1:p^m-2]',m,p)
```

The coefficients, specified in exponential format, represent the field elements in GF(p^m). For an explanation of these formats, see “Representing Elements of Galois Fields”.

Data Types: `double`

Output Arguments

q — Galois field polynomial
row vector

Galois field polynomial, returned as a row vector of the polynomial coefficients in order of ascending powers. `q` is the quotient from the division of `b` by `a` and is in the same Galois field as the input polynomials.

r — Division remainder
scalar | row vector

Division remainder, returned as a scalar or a row vector of the polynomial coefficients in order of ascending powers. `r` is the remainder resulting from the division of `b` by `a`.

Tips

- The gfdeconv function performs computations in GF(p^m), where *p* is prime, and *m* is a positive integer. It divides polynomials over a Galois field. To work in GF(2^m), use the `deconv` function of the `gf` object with Galois arrays. For details, see “Multiplication and Division of Polynomials”.
- To divide elements of a Galois field, you can also use `gfdiv` instead of `gfdeconv`. Algebraically, dividing polynomials over a Galois field is equivalent to deconvolving vectors containing the coefficients of the polynomials. This deconvolution operation uses arithmetic over the same Galois field.

gfdiv

Divide elements of Galois field

Syntax

```
quot = gfdiv(b,a)
quot = gfdiv(b,a,p)
quot = gfdiv(b,a,field)
```

Description

Note This function performs computations in GF(p^m), where p is prime. To work in GF(2^m), apply the `./` operator to Galois arrays. For details, see “Example: Division”.

The `gfdiv` function divides elements of a Galois field. (To divide polynomials over a Galois field, use `gfdeconv` instead.)

`quot = gfdiv(b,a)` divides `b` by `a` in GF(2) element-by-element. `a` and `b` are scalars, vectors or matrices of the same size. Each entry in `a` and `b` represents an element of GF(2). The entries of `a` and `b` are either 0 or 1.

`quot = gfdiv(b,a,p)` divides b by a in GF(`p`) and returns the quotient. `p` is a prime number. If `a` and `b` are matrices of the same size, the function treats each element independently. All entries of `b`, `a`, and `quot` are between 0 and `p`-1.

`quot = gfdiv(b,a,field)` divides `b` by `a` in GF(p^m) and returns the quotient. p is a prime number and m is a positive integer. If `a` and `b` are matrices of the same size, then the function treats each element independently. All entries of `b`, `a`, and `quot` are the exponential formats of elements of GF(p^m) relative to some primitive element of GF(p^m). `field` is the matrix listing all elements of GF(p^m), arranged relative to the same primitive element. See “Representing Elements of Galois Fields” for an explanation of these formats.

In all cases, an attempt to divide by the zero element of the field results in a “quotient” of `NaN`.

Examples

The code below displays lists of multiplicative inverses in GF(5) and GF(25). It uses column vectors as inputs to `gfdiv`.

```
% Find inverses of nonzero elements of GF(5).
p = 5;
b = ones(p-1,1);
a = [1:p-1]';
quot1 = gfdiv(b,a,p);
disp('Inverses in GF(5):')
disp('element  inverse')
disp([a, quot1])

% Find inverses of nonzero elements of GF(25).
```

```
m = 2;
field = gftuple([-1:p^m-2]',m,p);
b = zeros(p^m-1,1); % Numerator is zero since 1 = alpha^0.
a = [0:p^m-2]';
quot2 = gfdiv(b,a,field);
disp('Inverses in GF(25), expressed in EXPONENTIAL FORMAT with')
disp('respect to a root of the default primitive polynomial:')
disp('element  inverse')
disp([a, quot2])
```

gfconv | gfdeconv | gfmul | gftuple

Introduced before R2006a

gffilter (prime Galois field)

Filter data using polynomials over prime Galois field

Syntax

```
y = gffilter(b,a,x)
y = gffilter(b,a,x,p)
```

Description

Note This function performs computations in GF(p^m), where p is prime. To work in GF(2^m), use the `filter` function with Galois arrays. For details, see “Filtering”.

`y = gffilter(b,a,x)` filters the data in vector `x` with the filter described by vectors `b` and `a`. The vectors `b`, `a` and `x` must be in GF(2), that is, be binary and `y` is also in GF(2).

`y = gffilter(b,a,x,p)` filters the data `x` using the filter described by vectors `a` and `b`. `y` is the filtered data in GF(`p`). `p` is a prime number, and all entries of `a` and `b` are between 0 and `p`-1.

By definition of the filter, `y` solves the difference equation

```
a(1)y(n) = b(1)x(n)+b(2)x(n-1)+b(3)x(n-2)+...+b(B+1)x(n-B)
                    -a(2)y(n-1)-a(3)y(n-2)-...-a(A+1)y(n-A)
```

where

- `A+1` is the length of the vector `a`
- `B+1` is the length of the vector `b`
- `n` varies between 1 and the length of the vector `x`.

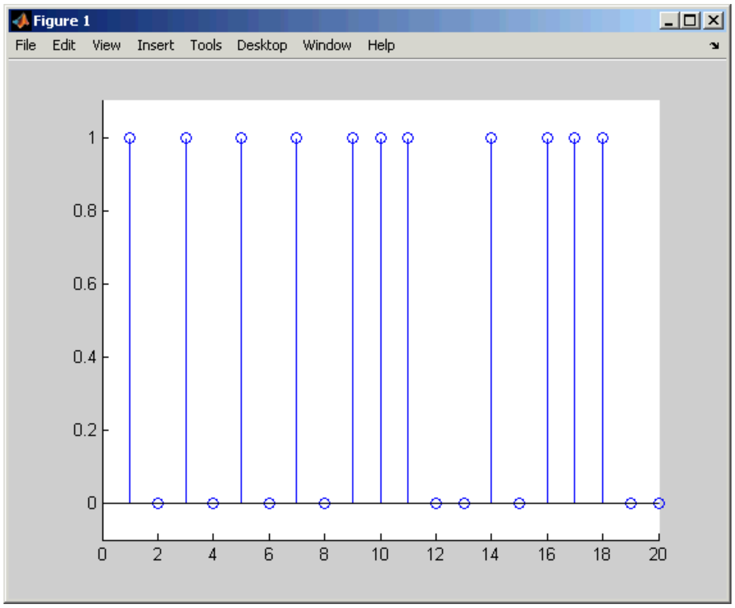
The vector `a` represents the degree-n_a polynomial

```
a(1)+a(2)x+a(3)x^2+...+a(A+1)x^A
```

Examples

The impulse response of a particular filter is given in the code and diagram below.

```
b = [1 0 0 1 0 1 0 1];
a = [1 0 1 1];
y = gffilter(b,a,[1,zeros(1,19)]);
stem(y);
axis([0 20 -.1 1.1])
```



See Also

`filter` | `gfadd` | `gfconv`

Introduced before R2006a

gflineq

Find particular solution of Ax = b over prime Galois field

Syntax

```
x = gflineq(A,b)
x = gflineq(A,b,p)
[x,vld] = gflineq(...)
```

Description

Note This function performs computations in GF(p), where p is prime. To work in GF(2^m), apply the \ or / operator to Galois arrays. For details, see “Solving Linear Equations”.

x = gflineq(A,b) outputs a particular solution of the linear equation A x = b in GF(2). The elements in a, b and x are either 0 or 1. If the equation has no solution, then x is empty.

x = gflineq(A,b,p) returns a particular solution of the linear equation A x = b over GF(p), where p is a prime number. If A is a k-by-n matrix and b is a vector of length k, x is a vector of length n. Each entry of A, x, and b is an integer between 0 and p-1. If no solution exists, x is empty.

[x,vld] = gflineq(...) returns a flag vld that indicates the existence of a solution. If vld = 1, the solution x exists and is valid; if vld = 0, no solution exists.

Examples

The code below produces some valid solutions of a linear equation over GF(3).

```
A = [2 0 1;
     1 1 0;
     1 1 2];
% An example in which the solutions are valid
[x,vld] = gflineq(A,[1;0;0],3)
```

The output is below.

```
x =

     2
     1
     0

vld =

     1
```

By contrast, the command below finds that the linear equation has *no* solutions.

```
[x2,vld2] = gflineq(zeros(3,3),[2;0;0],3)
```

The output is below.

```
This linear equation has no solution.

x2 =

     []

vld2 =

     0
```

Algorithms

`gflineq` uses Gaussian elimination.

See Also

`conv` | `gfadd` | `gfconv` | `gfdiv` | `gfrank` | `gfroots`

Introduced before R2006a

gfminpol

Find minimal polynomial of Galois field element

Syntax

```
pol = gfminpol(k,m)
pol = gfminpol(k,m,p)
pol = gfminpol(k,prim_poly,p)
```

Description

Note This function performs computations in GF(p^m), where p is prime. To work in GF(2^m), use the `minpol` function with Galois arrays. For details, see "Minimal Polynomials".

`pol = gfminpol(k,m)` produces a minimal polynomial for each entry in `k`. `k` must be either a scalar or a column vector. Each entry in `k` represents an element of GF(2^m) in exponential format. That is, `k` represents alpha`^k`, where alpha is a primitive element in GF(2^m). The *i*th row of `pol` represents the minimal polynomial of `k`(*i*). The coefficients of the minimal polynomial are in the base field GF(2) and listed in order of ascending exponents.

`pol = gfminpol(k,m,p)` finds the minimal polynomial of A^k over GF(`p`), where `p` is a prime number, `m` is an integer greater than 1, and A is a root of the default primitive polynomial for GF(`p^m`). The format of the output is as follows:

- If `k` is a nonnegative integer, `pol` is a row vector that gives the coefficients of the minimal polynomial in order of ascending powers.
- If `k` is a vector of length *len* all of whose entries are nonnegative integers, `pol` is a matrix having *len* rows; the rth row of `pol` gives the coefficients of the minimal polynomial of $A^{k(r)}$ in order of ascending powers.

`pol = gfminpol(k,prim_poly,p)` is the same as the first syntax listed, except that A is a root of the primitive polynomial for GF(p^m) specified by `prim_poly`. `prim_poly` is a polynomial character vector or a row vector that gives the coefficients of the degree-m primitive polynomial in order of ascending powers.

Examples

The syntax `gfminpol(k,m,p)` is used in the sample code in "Characterization of Polynomials".

gfmul

Multiply elements of Galois field

Syntax

```
c = gfmul(a,b,p)
c = gfmul(a,b,field)
```

Description

Note This function performs computations in GF(p^m) where p is prime. To work in GF(2^m), apply the `.*` operator to Galois arrays. For details, see “Example: Multiplication”.

The `gfmul` function multiplies elements of a Galois field. (To multiply polynomials over a Galois field, use `gfconv` instead.)

`c = gfmul(a,b,p)` multiplies `a` and `b` in GF(`p`). Each entry of `a` and `b` is between 0 and `p`-1. `p` is a prime number. If `a` and `b` are matrices of the same size, the function treats each element independently.

`c = gfmul(a,b,field)` multiplies `a` and `b` in GF(p^m), where p is a prime number and m is a positive integer. `a` and `b` represent elements of GF(p^m) in exponential format relative to some primitive element of GF(p^m). `field` is the matrix listing all elements of GF(p^m), arranged relative to the same primitive element. `c` is the exponential format of the product, relative to the same primitive element. See “Representing Elements of Galois Fields” for an explanation of these formats. If `a` and `b` are matrices of the same size, the function treats each element independently.

Examples

“Arithmetic in Galois Fields” contains examples. Also, the code below shows that

$$A^2 \cdot A^4 = A^6$$

where A is a root of the primitive polynomial $2 + 2x + x^2$ for GF(9).

```
p = 3; m = 2;
prim_poly = [2 2 1];
field = gftuple([-1:p^m-2]',prim_poly,p);
a = gfmul(2,4,field)
```

The output is

```
a =

     6
```

See Also

`gfadd` | `gfdeconv` | `gfdiv` | `gfsub` | `gftuple`

Introduced before R2006a

gfpretty

Polynomial in traditional format

Syntax

```
gfpretty(a)
gfpretty(a,st)
gfpretty(a,st,n)
```

Description

`gfpretty(a)` displays a polynomial in a traditional format, using `X` as the variable and the entries of the row vector `a` as the coefficients in order of ascending powers. The polynomial is displayed in order of ascending powers. Terms having a zero coefficient are not displayed.

`gfpretty(a,st)` is the same as the first syntax listed, except that the content of `st` is used as the variable instead of `X`.

`gfpretty(a,st,n)` is the same as the first syntax listed, except that the content of `st` is used as the variable instead of `X`, and each line of the display has width `n` instead of the default value of 79.

Note For all syntaxes: If you do not use a fixed-width font, the spacing in the display might not look correct.

Examples

Display statements about the elements of GF(81).

```
p = 3; m = 4;
ii = randi([1,p^m-2],1,1); % Random exponent for prim element
primpolys = gfprimfd(m,'all',p);
[rows, cols] = size(primpolys);
jj = randi([1,rows],1,1); % Random primitive polynomial

disp('If A is a root of the primitive polynomial')
gfpretty(primpolys(jj,:)) % Polynomial in X
disp('then the element')
gfpretty([zeros(1,ii),1],'A') % The polynomial A^ii
disp('can also be expressed as')
gfpretty(gftuple(ii,m,p),'A') % Polynomial in A
```

Below is a sample of the output.

```
If A is a root of the primitive polynomial

                                         3    4
                                2 + 2 X  + X
then the element

                                       22
```

```
                                      A
can also be expressed as

                                       2    3
                                  2 + A  + A
```

See Also

gfprimdf | gftuple

Introduced before R2006a

gfprimck

Check whether polynomial over Galois field is primitive

Syntax

```
ck = gfprimck(a)
ck = gfprimck(a,p)
```

Description

Note This function performs computations in GF(p^m), where p is prime. If you are working in GF(2^m), use the `isprimitive` function. For details, see *Finding Primitive Polynomials* in “Primitive Polynomials and Element Representations”.

`ck = gfprimck(a)` checks whether the degree-m GF(2) polynomial `a` is a primitive polynomial for GF(2^m), where m = length(`a`) - 1. The output `ck` is as follows:

- -1 if `a` is not an irreducible polynomial
- 0 if `a` is irreducible but not a primitive polynomial for GF(p^m)
- 1 if `a` is a primitive polynomial for GF(p^m)

`ck = gfprimck(a,p)` checks whether the degree-m GF(P) polynomial `a` is a primitive polynomial for GF(p^m). p is a prime number.

`a` is either a polynomial character vector or a row vector representing the polynomial by listing its coefficients in ascending order. For example, in GF(5), `'4 + 3x + 2x^3'` and `[4 3 0 2]` are equivalent.

This function considers the zero polynomial to be “not irreducible” and considers all polynomials of degree zero or one to be primitive.

Examples

“Characterization of Polynomials” contains examples.

Algorithms

An irreducible polynomial over GF(p) of degree at least 2 is primitive if and only if it does not divide $-1 + x^k$ for any positive integer k smaller than p^m-1.

gfprimdf

Provide default primitive polynomials for Galois field

Syntax

```
pol = gfprimdf(m)
pol = gfprimdf(m,p)
```

Description

Note This function performs computations in GF(p^m), where p is prime. To work in GF(2^m), use the `primpoly` function. For details, see *Finding Primitive Polynomials* in “Primitive Polynomials and Element Representations”.

`pol = gfprimdf(m)` outputs the default primitive polynomial `pol` in GF(2^m).

`pol = gfprimdf(m,p)` returns the row vector that gives the coefficients, in order of ascending powers, of the default primitive polynomial for GF(p^m). `m` is a positive integer and `p` is a prime number.

Examples

Find Default Primitive Polynomial for GF(52)

Find the default primitive polynomial for GF(52) by using the `gfprimdf` function. Then use the `gfpretty` function to display it in polynomial format.

```
pol = gfprimdf(2,5)
```

```
pol = 1×3

     2     1     1
```

```
gfpretty(pol)
```

```
                                   2
                       2 + X + X
```

Find Default Primitive Polynomials for Range of Galois Fields

Find the default primitive polynomials for a range of Galois fields by using the `gfprimdf` function.

Use the `gfpretty` function to display the default primitive polynomial for each of the fields GF(3*m*), where the range for *m* is [3, 5].

```
for m = 3:5
   gfpretty(gfprimdf(m,3))
end
```

```
                                            3
                                 1 + 2 X + X

                                           4
                                  2 + X + X

                                            5
                                 1 + 2 X + X
```

gfminpol | gfprimck | gfprimfd | gftuple

Introduced before R2006a

gfprimfd

Find primitive polynomials for Galois field

Syntax

```
pol = gfprimfd(m,opt,p)
```

Description

Note This function performs computations in GF(p^m), where p is prime. To work in GF(2^m), use the `primpoly` function. For details, see *Finding Primitive Polynomials* in “Primitive Polynomials and Element Representations”.

- If `m` = 1, `pol` = [1 1].
- A polynomial is represented as a row containing the coefficients in order of ascending powers.

`pol = gfprimfd(m,opt,p)` searches for one or more primitive polynomials for GF(`p^m`), where `p` is a prime number and `m` is a positive integer. If `m` = 1, `pol` = [1 1]. If `m` > 1, the output `pol` depends on the argument *`opt`* as shown in the table below. Each polynomial is represented in `pol` as a row containing the coefficients in order of ascending powers.

opt	Significance of pol	Format of pol
`'min'`	One primitive polynomial for GF(`p^m`) having the smallest possible number of nonzero terms	The row vector representing the polynomial
`'max'`	One primitive polynomial for GF(`p^m`) having the greatest possible number of nonzero terms	The row vector representing the polynomial
`'all'`	All primitive polynomials for GF(`p^m`)	A matrix, each row of which represents one such polynomial
A positive integer	All primitive polynomials for GF(`p^m`) that have *`opt`* nonzero terms	A matrix, each row of which represents one such polynomial

Examples

The code below seeks primitive polynomials for GF(81) having various other properties. Notice that `fourterms` is empty because no primitive polynomial for GF(81) has exactly four nonzero terms. Also notice that `fewterms` represents a *single* polynomial having three terms, while `threeterms` represents *all* of the three-term primitive polynomials for GF(81).

```
p = 3; m = 4; % Work in GF(81).
fewterms = gfprimfd(m,'min',p)
```

```
threeterms = gfprimfd(m,3,p)
fourterms = gfprimfd(m,4,p)
```

The output is below.

```
fewterms =

     2     1     0     0     1

threeterms =

     2     1     0     0     1
     2     2     0     0     1
     2     0     0     1     1
     2     0     0     2     1

No primitive polynomial satisfies the given constraints.

fourterms =

     []
```

Algorithms

`gfprimfd` tests for primitivity using `gfprimck`. If *`opt`* is `'min'`, `'max'`, or omitted, polynomials are constructed by converting decimal integers to base `p`. Based on the decimal ordering, `gfprimfd` returns the first polynomial it finds that satisfies the appropriate conditions.

gfrank

Compute rank of matrix over Galois field

Syntax

```
rk = gfrank(A,p)
```

Description

Note This function performs computations in GF(p) where p is prime. If you are working in GF(2^m), use the `rank` function with Galois arrays. For details, see “Computing Ranks”.

`rk = gfrank(A,p)` calculates the rank of the matrix `A` in GF(`p`), where `p` is a prime number.

Examples

In the code below, `gfrank` says that the matrix `A` has less than full rank. This conclusion makes sense because the determinant of `A` is zero mod `p`.

```
A = [1 0 1;
   2 1 0;
   0 1 1];
p = 3;
det_a = det(A); % Ordinary determinant of A
detmodp = rem(det(A),p); % Determinant mod p
rankp = gfrank(A,p);
disp(['Determinant = ',num2str(det_a)])
disp(['Determinant mod p is ',num2str(detmodp)])
disp(['Rank over GF(p) is ',num2str(rankp)])
```

The output is below.

```
Determinant = 3
Determinant mod p is 0
Rank over GF(p) is 2
```

Algorithms

`gfrank` uses an algorithm similar to Gaussian elimination.

Introduced before R2006a

gfrepcov

Convert one binary polynomial representation to another

Syntax

```
polystandard = gfrepcov(poly2)
```

Description

Two logical ways to represent polynomials over GF(2) are listed below.

1. `[A_0 A_1 A_2 ... A_(m-1)]` represents the polynomial

   $$\mathrm{A\_0} + \mathrm{A\_1}x + \mathrm{A\_2}x^2 + \cdots + \mathrm{A\_(m\text{-}1)}x^{m-1}$$

   Each entry `A_k` is either one or zero.
2. [A_0 A_1 A_2 ... A_(m-1)] represents the polynomial

   $$x^{\mathrm{A\_0}} + x^{\mathrm{A\_1}} + x^{\mathrm{A\_2}} + \cdots + x^{\mathrm{A\_(m\text{-}1)}}$$

   Each entry `A_k` is a nonnegative integer. All entries must be distinct.

Format **1** is the standard form used by the Galois field functions in this toolbox, but there are some cases in which format **2** is more convenient.

`polystandard = gfrepcov(poly2)` converts from the second format to the first, for polynomials of degree *at least* 2. `poly2` and `polystandard` are row vectors. The entries of `poly2` are distinct integers, and at least one entry must exceed 1. Each entry of `polystandard` is either 0 or 1.

Examples

The command below converts the representation format of the polynomial 1 + x^2 + x^5.

```
polystandard = gfrepcov([0 2 5])

polystandard =

     1     0     1     0     0     1
```

gfroots

Find roots of polynomial over prime Galois field

Syntax

```
rt = gfroots(f,m,p)
rt = gfroots(f,prim_poly,p)
[rt,rt_tuple] = gfroots(...)
[rt,rt_tuple,field] = gfroots(...)
```

Description

Note This function performs computations in GF(p^m), where p is prime. To work in GF(2^m), use the `roots` function with Galois arrays. For details, see “Roots of Polynomials”.

For all syntaxes, `f` is a polynomial character vector or a row vector that gives the coefficients, in order of ascending powers, of a degree-d polynomial.

Note `gfroots` lists each root exactly once, ignoring multiplicities of roots.

`rt = gfroots(f,m,p)` finds roots in GF(`p^m`) of the polynomial that `f` represents. `rt` is a column vector each of whose entries is the exponential format of a root. The exponential format is relative to a root of the default primitive polynomial for GF(`p^m`).

`rt = gfroots(f,prim_poly,p)` finds roots in GF(p^m) of the polynomial that `f` represents. `rt` is a column vector each of whose entries is the exponential format of a root. The exponential format is relative to a root of the degree-m primitive polynomial for GF(p^m) that `prim_poly` represents.

`[rt,rt_tuple] = gfroots(...)` returns an additional matrix `rt_tuple`, whose kth row is the polynomial format of the root `rt(k)`. The polynomial and exponential formats are both relative to the same primitive element.

`[rt,rt_tuple,field] = gfroots(...)` returns additional matrices `rt_tuple` and `field`. `rt_tuple` is described in the preceding paragraph. `field` gives the list of elements of the extension field. The list of elements, the polynomial format, and the exponential format are all relative to the same primitive element.

Note For a description of the various formats that `gfroots` uses, see “Representing Elements of Galois Fields”.

Examples

“Roots of Polynomials” contains a description and example of the use of `gfroots`.

The code below finds the polynomial format of the roots of the primitive polynomial $2 + x^3 + x^4$ for GF(81). It then displays the roots in traditional form as polynomials in `alph`. (The output is omitted here.) Because prim_poly is both the primitive polynomial and the polynomial whose roots are sought, alph itself is a root.

```
p = 3; m = 4;
prim_poly = [2 0 0 1 1]; % A primitive polynomial for GF(81)
f = prim_poly; % Find roots of the primitive polynomial.
[rt,rt_tuple] = gfroots(f,prim_poly,p);
% Display roots as polynomials in alpha.
for ii = 1:length(rt_tuple)
  gfpretty(rt_tuple(ii,:),'alpha')
end
```

See Also

gfprimdf

Introduced before R2006a

gfsub

Subtract polynomials over Galois field

Syntax

```
c = gfsub(a,b,p)
c = gfsub(a,b,p,len)
c = gfsub(a,b,field)
```

Description

Note This function performs computations in GF(p^m), where p is prime. To work in GF(2^m), apply the - operator to Galois arrays of equal size. For details, see "Example: Addition and Subtraction".

`c = gfsub(a,b,p)` calculates `a` minus `b`, where `a` and `b` represent polynomials over GF(`p`) and `p` is a prime number. `a`, `b`, and `c` are row vectors that give the coefficients of the corresponding polynomials in order of ascending powers. Each coefficient is between 0 and `p-1`. If `a` and `b` are matrices of the same size, the function treats each row independently. Alternatively, `a` and `b` can be represented as polynomial character vectors.

`c = gfsub(a,b,p,len)` subtracts row vectors as in the syntax above, except that it returns a row vector of length `len`. The output `c` is a truncated or extended representation of the answer. If the row vector corresponding to the answer has fewer than `len` entries (including zeros), extra zeros are added at the end; if it has more than `len` entries, entries from the end are removed.

`c = gfsub(a,b,field)` calculates `a` minus `b`, where `a` and `b` are the exponential format of two elements of GF(p^m), relative to some primitive element of GF(p^m). p is a prime number and m is a positive integer. `field` is the matrix listing all elements of GF(p^m), arranged relative to the same primitive element. `c` is the exponential format of the answer, relative to the same primitive element. See "Representing Elements of Galois Fields" for an explanation of these formats. If `a` and `b` are matrices of the same size, the function treats each element independently.

Examples

Subtract Two GF Arrays

Calculate $(2 + 3x + x^2) - (4 + 2x + 3x^2)$ over GF(5).

```
x = gfsub([2 3 1],[4 2 3],5)
```

```
x = 1×3

     3     1     3
```

Subtract the two polynomials and display the first two elements.

```
y = gfsub([2 3 1],[4 2 3],5,2)
```

```
y = 1×2

     3     1
```

For prime number p and exponent m, create a matrix listing all elements of GF(p^m) given primitive polynomial $2 + 2x + x^2$.

```
p = 3;
m = 2;
primpoly = [2 2 1];
field = gftuple((-1:p^m-2)',primpoly,p);
```

Subtract A^4 from A^2. The result is A^7.

```
g = gfsub(2,4,field)
```

```
g = 7
```

gfadd | gfconv | gfdeconv | gfdiv | gfmul | gftuple

Introduced before R2006a

gftable

Generate file to accelerate Galois field computations

Syntax

```
gftable(m,prim_poly);
```

Description

gftable(m,prim_poly) generates a file that can help accelerate computations in the field GF(2^m) as described by the *nondefault* primitive polynomial prim_poly, which can be either a polynomial character vector or an integer. prim_poly represents a primitive polynomial for GF(2^m), where 1 < *m* < 16, using the format described in “Primitive Polynomials and Element Representations”. The function places the file, called userGftable.mat, in your current working folder. If necessary, the function overwrites any writable existing version of the file.

Note If prim_poly is the default primitive polynomial for GF(2^m) listed in the table on the gf reference page, this function has no effect. A MAT-file in your MATLAB installation already includes information that facilitates computations with respect to the default primitive polynomial.

Examples

In the example below, you expect t3 to be similar to t1 and to be significantly smaller than t2, assuming that you do not already have a userGftable.mat file that includes the (m, prim_poly) pair (8, 501). Notice that before executing the gftable command, MATLAB displays a warning and that after executing gftable, there is no warning. By executing the gftable command you save the GF table for faster calculations.

```
% Sample code to check how much gftable improves speed.
tic; a = gf(repmat([0:2^8-1],1000,1),8); b = a.^100; t1 = toc;
tic; a = gf(repmat([0:2^8-1],1000,1),8,501); b = a.^100; t2 = toc;
gftable(8,501); % Include this primitive polynomial in the file.
tic; a = gf(repmat([0:2^8-1],1000,1),8,501); b = a.^100; t3 = toc;
```

gftrunc

Minimize length of polynomial representation

Syntax

```
c = gftrunc(a)
```

Description

`c = gftrunc(a)` truncates a row vector, `a`, that gives the coefficients of a GF(p) polynomial in order of ascending powers. If `a`(k) = 0 whenever k > d + 1, the polynomial has degree d. The row vector `c` omits these high-order zeros and thus has length d + 1.

Examples

Truncate Row-Vector Representation of Galois Field Polynomial

Use `gftrunc` to truncate the row-vector representation of $x^2 + 2x^3 + 3x^4 + 4x^7 + 5x^8$, removing nonsignificant zero-valued elements.

```
vec = [0 0 1 2 3 0 0 4 5 0 0]
```

```
vec = 1×11

     0     0     1     2     3     0     0     4     5     0     0
```

```
gfpretty([vec])
```

```
                         2      3      4      7      8
                        X  + 2 X  + 3 X  + 4 X  + 5 X
```

Zeros are removed from the end of the row-vector representation, but not from the beginning or middle of the row vector.

```
c = gftrunc([0 0 1 2 3 0 0 4 5 0 0])
```

```
c = 1×9

     0     0     1     2     3     0     0     4     5
```

```
gfpretty(c)
```

```
                         2      3      4      7      8
                        X  + 2 X  + 3 X  + 4 X  + 5 X
```

Introduced before R2006a

gftuple

Simplify or convert Galois field element formatting

Syntax

```
tp = gftuple(a,m)
tp = gftuple(a,prim_poly)
tp = gftuple(a,m,p)
tp = gftuple(a,prim_poly,p)
tp = gftuple(a,prim_poly,p,prim_ck)
[tp,expform] = gftuple(...)
```

Description

Note This function performs computations in GF(p^m), where p is prime. To perform equivalent computations in GF(2^m), apply the `.^` operator and the `log` function to Galois arrays. For more information, see “Example: Exponentiation” and “Example: Elementwise Logarithm”.

For All Syntaxes

`gftuple` serves to simplify the polynomial or exponential format of Galois field elements, or to convert from one format to another. For an explanation of the formats that `gftuple` uses, see “Representing Elements of Galois Fields”.

In this discussion, the format of an element of GF(p^m) is called “simplest” if all exponents of the primitive element are

- Between 0 and m-1 for the polynomial format
- Either `-Inf`, or between 0 and p^{m-2}, for the exponential format

For all syntaxes, `a` is a matrix, each row of which represents an element of a Galois field. The format of `a` determines how MATLAB interprets it:

- If `a` is a column of integers, MATLAB interprets each row as an *exponential* format of an element. Negative integers are equivalent to `-Inf` in that they all represent the zero element of the field.
- If `a` has more than one column, MATLAB interprets each row as a *polynomial* format of an element. (Each entry of `a` must be an integer between 0 and `p`-1.)

The exponential or polynomial formats mentioned above are all relative to a primitive element specified by the *second* input argument. The second argument is described below.

For Specific Syntaxes

`tp = gftuple(a,m)` returns the simplest polynomial format of the elements that `a` represents, where the kth row of `tp` corresponds to the kth row of `a`. The formats are relative to a root of the default primitive polynomial for GF(`2^m`), where `m` is a positive integer.

tp = gftuple(a,prim_poly) is the same as the syntax above, except that prim_poly is a polynomial character vector or a row vector that lists the coefficients of a degree m primitive polynomial for GF(2^m) in order of ascending exponents.

tp = gftuple(a,m,p) is the same as tp = gftuple(a,m) except that 2 is replaced by a prime number p.

tp = gftuple(a,prim_poly,p) is the same as tp = gftuple(a,prim_poly) except that 2 is replaced by a prime number p.

tp = gftuple(a,prim_poly,p,prim_ck) is the same as tp = gftuple(a,prim_poly,p) except that gftuple checks whether prim_poly represents a polynomial that is indeed primitive. If not, then gftuple generates an error and tp is not returned. The input argument prim_ck can be any number or character vector; only its existence matters.

[tp,expform] = gftuple(...) returns the additional matrix expform. The kth row of expform is the simplest exponential format of the element that the kth row of a represents. All other features are as described in earlier parts of this “Description” section, depending on the input arguments.

Examples

- “List of All Elements of a Galois Field” (end of section)
- “Converting to Simplest Polynomial Format”

As another example, the gftuple command below generates a list of elements of GF(p^m), arranged relative to a root of the default primitive polynomial. Some functions in this toolbox use such a list as an input argument.

```
p = 5; % Or any prime number
m = 4; % Or any positive integer
field = gftuple([-1:p^m-2]',m,p);
```

Finally, the two commands below illustrate the influence of the *shape* of the input matrix. In the first command, a column vector is treated as a sequence of elements expressed in exponential format. In the second command, a row vector is treated as a single element expressed in polynomial format.

```
tp1 = gftuple([0; 1],3,3)
tp2 = gftuple([0, 0, 0, 1],3,3)
```

The output is below.

```
tp1 =

     1     0     0
     0     1     0

tp2 =

     2     1     0
```

The outputs reflect that, according to the default primitive polynomial for GF(3^3), the relations below are true.

$\alpha^0 = 1 + 0\alpha + 0\alpha^2$

$\alpha^1 = 0 + 1\alpha + 0\alpha^2$

$0 + 0\alpha + 0\alpha^2 + \alpha^3 = 2 + \alpha + 0\alpha^2$

Algorithms

`gftuple` uses recursive callbacks to determine the exponential format.

gfweight

Calculate minimum distance of linear block code

Syntax

```
wt = gfweight(genmat)
wt = gfweight(genmat,'gen')
wt = gfweight(parmat,'par')
wt = gfweight(genpoly,n)
```

Description

The minimum distance, or minimum weight, of a linear block code is defined as the smallest positive number of nonzero entries in any n-tuple that is a codeword.

`wt = gfweight(genmat)` returns the minimum distance of the linear block code whose generator matrix is `genmat`.

`wt = gfweight(genmat,'gen')` returns the minimum distance of the linear block code whose generator matrix is `genmat`.

`wt = gfweight(parmat,'par')` returns the minimum distance of the linear block code whose parity-check matrix is `parmat`.

`wt = gfweight(genpoly,n)` returns the minimum distance of the *cyclic* code whose codeword length is `n` and whose generator polynomial is represented by `genpoly`. `genpoly` is a polynomial character vector or a row vector that gives the coefficients of the generator polynomial in order of ascending powers.

Examples

Calculate Minimum Distance of Linear Block Code

Calculate the minimum distance of a cyclic code using several methods.

Create the generate polynomial for a (7,4) cyclic code.

```
n = 7;
genpoly = cyclpoly(n,4);
```

Calculate the minimum distance for the cyclic code using:

1. Generator polynomial `genmat`
2. Parity check matrix `parmat`
3. Generator polynomial `genpoly`
4. Generator polynomial specified as a character vector

```
[parmat, genmat] = cyclgen(n,genpoly);
wts = [gfweight(genmat,'gen') gfweight(parmat,'par'),...
    gfweight(genpoly,n) gfweight('1+x2+x3',n)]
```

```
wts = 1×4

     3     3     3     3
```

“Block Codes”

Introduced before R2006a

gray2bin

(To be removed) Convert Gray-encoded positive integers to corresponding Gray-decoded integers

Note will be removed in a future release. Use the appropriate modulation object or function to remap constellation points instead. For more information, see “Compatibility Considerations”.

Syntax

```
y = gray2bin(x,modulation,M)
[y,map] = gray2bin(x,modulation,M)
```

Description

`y = gray2bin(x,modulation,M)` generates a Gray-decoded output vector or matrix `y` with the same dimensions as its input parameter `x`. `x` can be a scalar, vector, matrix, or 3-D array. `modulation` is the modulation type and must be `'qam'`, `'pam'`, `'fsk'`, `'dpsk'`, or `'psk'`. `M` is the modulation order and must be an integer power of 2.

`[y,map] = gray2bin(x,modulation,M)` generates a Gray-decoded output `y` with its respective Gray-encoded constellation map, `map`.

You can use map output to label a Gray-encoded constellation. The map output gives the Gray-encoded labels for the corresponding modulation. See “Binary to Gray Symbol Mapping” on page 2-446 example.

Note If you are converting binary coded data to Gray-coded data and modulating the result immediately afterwards, you should use the appropriate modulation object or function with the `'Gray'` symbol ordering option, instead of `gray2bin`.

Examples

Binary to Gray Symbol Mapping

This example shows how to use the `bin2gray` and `gray2bin` functions to map integer inputs from a natural binary order symbol mapping to a Gray-coded signal constellation and vice versa, assuming 16-QAM modulation. In addition, a visual representation of the difference between Gray-coded and binary-coded symbol mappings is shown.

Convert Binary to Gray

Create a complete vector of 16-QAM integers.

```
M = 16;
x = (0:M-1);
```

Convert the input vector from a natural binary order to a Gray-encoded vector using `bin2gray`.

```
[y,mapy] = bin2gray(x,'qam',M);
```

Convert Gray to Binary

Convert the Gray-encoded symbols, `y`, back to a binary ordering using `gray2bin`.

```
z = gray2bin(y,'qam',M);
```

Verify that the original data, `x`, and the final output vector, `z`, are identical.

```
isequal(x,z)
```

```
ans = logical
   1
```

Show Symbol Mappings

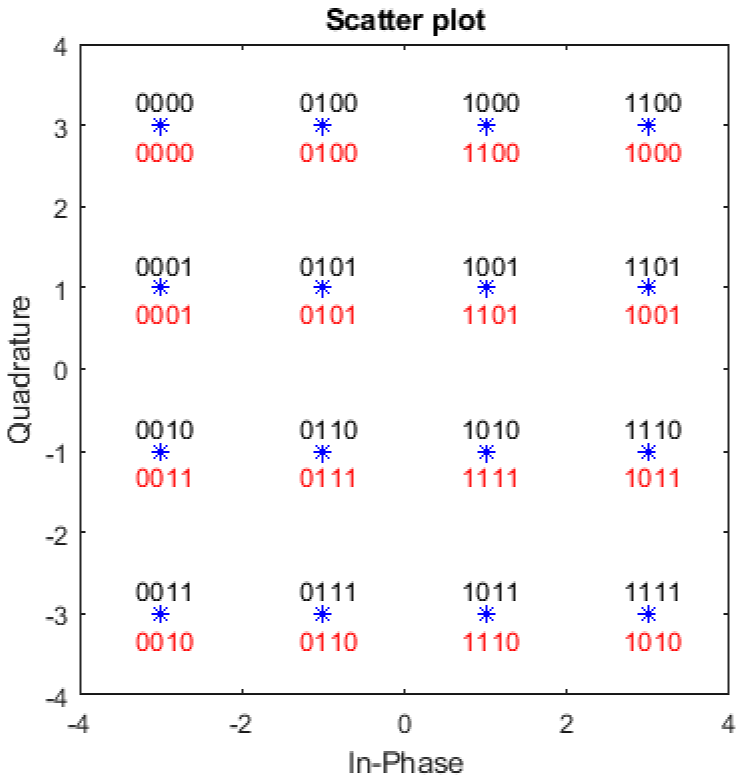
To create a constellation plot showing the different symbol mappings, use the `qammod` function to find the complex symbol values.

```
sym = qammod(x,M);
```

Plot the constellation symbols and label them using the Gray (`y`) and binary (`z`) output vectors. The binary representation of the Gray-coded symbols is shown in black while the binary representation of the naturally ordered symbols is shown in red. Set the axes scaling so that all points are displayed.

```
scatterplot(sym,1,0,'b*');
for k = 1:16
    text(real(sym(k))-0.3,imag(sym(k))+0.3,...
        dec2base(mapy(k),2,4));

    text(real(sym(k))-0.3,imag(sym(k))-0.3,...
        dec2base(z(k),2,4),'Color',[1 0 0]);
end
axis([-4 4 -4 4])
```



Input Arguments

x — Gray-encoded data

vector | matrix

Gray-encoded input data, specified as a vector or matrix.

Data Types: `double`

`modulation` — Modulation type

`'qam'` | `'pam'` | `'fsk'` | `'dpsk'` | `'psk'`

Modulation type, specified as, `'qam'`, `'pam'`, `'fsk'`, `'dpsk'`, or `'psk'`

`M` — Modulation order

scalar

Modulation order, specified as an integer power of 2.

Data Types: `double`

Output Arguments

y — Gray-decoded data

vector | matrix

Gray-decoded data with the same size and dimensions input `x`.

`map` — Map of labels
vector

Map output to label a Gray-encoded constellation, specified as a vector with a length the size of the modulation order, `M`. The map gives the Gray-encoded labels for the corresponding modulation.

Compatibility Considerations

`gray2bin` will be removed
Not recommended starting in R2020a

`gray2bin` will be removed in a future release. Use the appropriate modulation object or function instead. If your workflow uses `bin2gray` or `gray2bin` with any of the modulations schemes in this table, follow the appropriate example.

Modulation	Old Functionality	Use This Instead

QAM (`qammod` and `qamdemod`)	`x = randi([0 63],1,100);`
	`y = bin2gray(x,'qam',64);`
	`z = qammod(y,64,'bin');`
	
	`x = 2*(randn(100,1)+1j*randn(100,1));`
	`y = qamdemod(x,64,'bin');`
	`z = gray2bin(y,'qam',64);`
		`x = randi([0 63],1,100);`
		`z = qammod(x,64,'gray');`
		
		`x = 2*(randn(100,1)+1j*randn(100,1));`
		`z = qamdemod(x,64,'gray')`

PAM (`pammod` and `pamdemod`)	`x = randi([0 63],1,100);`
	`y = gray2bin(x,'pam',64);`
	`z = pammod(y,64,pi/4,'bin');`
	
	`x = 2*(randn(100,1)+1j*randn(100,1));`
	`y = pamdemod(x,64,pi/4,'bin');`
	`z = bin2gray(y,'pam',64);`
		`x = randi([0 63],1,100);`
		`z = pammod(x,64,pi/4,'gray');`
		
		`x = 2*(randn(100,1)+1j*randn(100,1));`
		`z = pamdemod(x,64,pi/4,'gray')`

FSK (`fskmod` and `fskdemod`)	`x = randi([0 63],1,100);`
	`y = gray2bin(x,'fsk',64);`
	`z = fskmod(y,64,1,256,256,'cont','bin')`
	
	`x = 2*(randn(512,1)+1j*randn(512,1));`
	`y = fskdemod(x,64,1,256,256,'bin');`
	`z = bin2gray(y,'fsk',64)`
		`x = randi([0 63],1,100);`
		`z = fskmod(x,64,1,256,256,'cont','gray')`
		`x = 2*(randn(512,1)+1j*randn(512,1));`
		`z = fskdemod(x,64,1,256,256,'gray');`

DPSK (`dpskmod` and `dpskdemod`)	`x = randi([0 63],1,100);`
	`y = gray2bin(x,'dpsk',64);`
	`z = dpskmod(y,64,pi/4,'bin');`
	
	`x = 2*(randn(100,1)+1j*randn(100,1));`
	`y = dpskdemod(x,64,pi/4,'bin');`
	`z = bin2gray(y,'dpsk',64);`
		`x = randi([0 63],1,100);`
		`z = dpskmod(x,64,pi/4,'gray');`
		
		`x=2*(randn(100,1)+1j*randn(100,1));`
		`z = dpskdemod(x,64,pi/4,'gray');`

PSK (`pskmod` and `pskdemod`)	`x=randi([0 63],1,100);`
	`y=gray2bin(x,'psk',64);`
	`z=pskmod(y,64,0,'bin');`
	
	`x = 2*(randn(100,1)+1j*randn(100,1));`
	`y = pskdemod(x,64,0,'bin');`
	`z = bin2gray(y,'psk',64);`
		`x=randi([0 63],1,100);`
		`z=pskmod(x,64,0,'gray');`
		
		`x = 2*(randn(100,1)+1j*randn(100,1));`
		`z = pskdemod(x,64,0,'gray');`

Gray Encoding a Modulated Signal

Introduced before R2006a

gsmCheckTimeMask

Inspect GSM burst against time mask

Syntax

```
gsmCheckTimeMask(gsmCfg)
gsmCheckTimeMask(gsmCfg,tn)

pf = gsmCheckTimeMask(gsmCfg)
pf = gsmCheckTimeMask(gsmCfg,tn)
```

Description

`gsmCheckTimeMask(gsmCfg)` plots the burst for the first time slot and the upper and lower time masks for the input GSM configuration object. The `RiseTime`, `RiseDelay`, `FallTime`, and `FallDelay` properties of the configuration object define the power level versus time characteristics. For more information, see “Time Mask” on page 2-465.

`gsmCheckTimeMask(gsmCfg,tn)` plots the burst for the specified time slot, `tn`.

`pf = gsmCheckTimeMask(gsmCfg)` returns a pass or fail result for the specified configuration object indicating compliance of the burst in the first time slot with the time mask defined in the GSM standard. For more information, see “Time Mask” on page 2-465.

`pf = gsmCheckTimeMask(gsmCfg,tn)` returns a pass or fail result indicating compliance of the burst in the specified time slot, `tn`.

Examples

Check GSM Burst Against Time Mask

Create a GSM uplink TDMA frame configuration object with default settings. The GSM TDMA frame has eight time slots. Check the burst in the first time slot against the time mask specified by the GSM standard.

Create a GSM uplink TDMA frame configuration object with default settings.

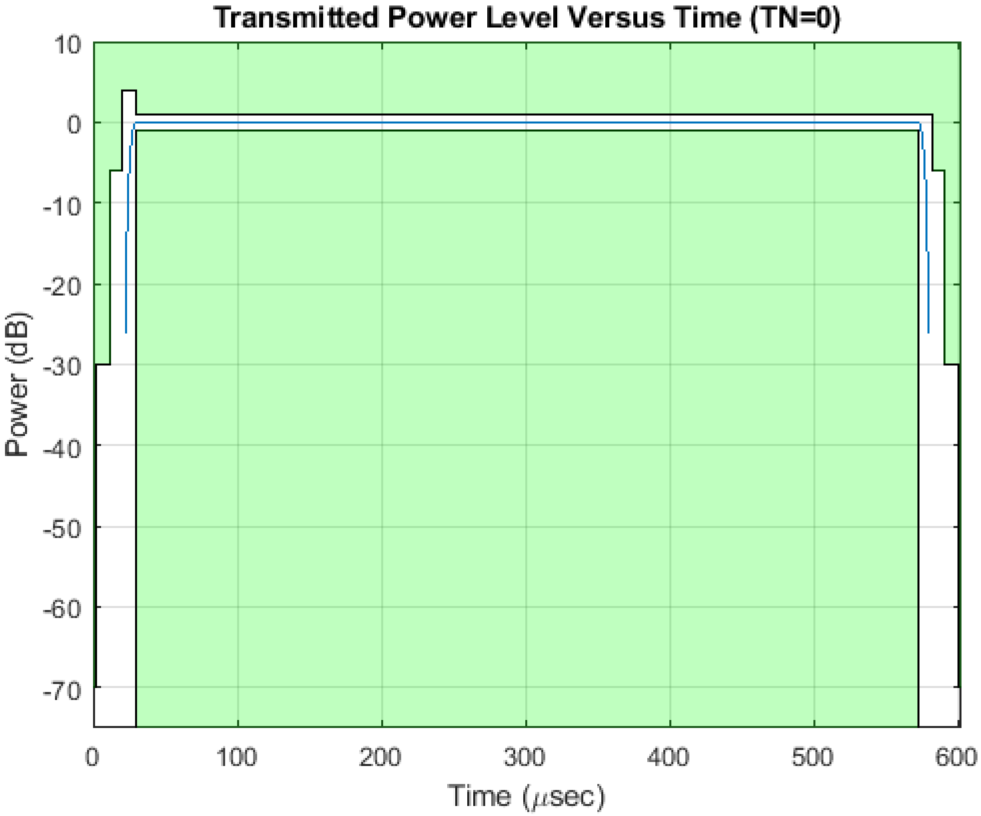
```
cfggsmul = gsmUplinkConfig;
```

Use the `gsmCheckTimeMask` function to view the time mask and verify that the configured rise and fall characteristics of the burst comply with the time mask specified in the GSM standard. Plot the GSM burst and time mask. When no time slot number is provided, the `gsmCheckTimeMask` function shows the first time slot, `TN=0`.

```
pf = gsmCheckTimeMask(cfggsmul);
if pf
    disp('Time mask test passed.')
else
    disp('Time mask test failed.')
end
```

```
Time mask test passed.
```

```
gsmCheckTimeMask(cfggsmul);
```



Adjust the rise time of the GSM uplink TDMA frame configuration object, specifying a value that causes a time mask failure.

```
cfggsmul.RiseTime = 5
```

```
cfggsmul = 
  gsmUplinkConfig with properties:

           BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 5
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

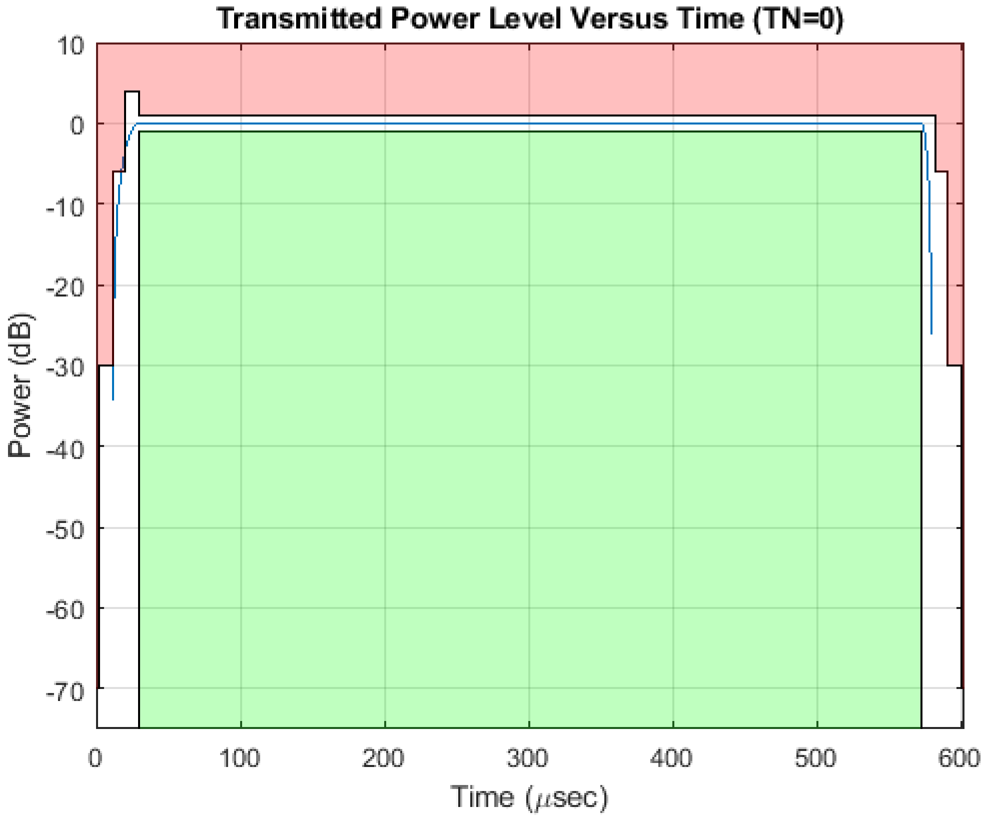
Use the gsmCheckTimeMask function to inspect the time mask of cfggsmul. The pass or fail result shows that the cfggsmul configuration now fails the time mask and the plot shows the upper time mask fails.

```
pf = gsmCheckTimeMask(cfggsmul);
if pf
```

```
    disp('Time mask test passed.')
else
    disp('Time mask test failed.')
end
```

```
Time mask test failed.
```

```
gsmCheckTimeMask(cfggsmul);
```



Check GSM Burst in Specified Time Slot Against Time Mask

Create a GSM uplink TDMA frame configuration object with default settings. The GSM TDMA frame has eight time slots. Check the burst in the specified time slot against the time mask specified by the GSM standard.

Create a GSM downlink TDMA frame configuration object with default settings.

```
cfggsmul = gsmDownlinkConfig;
```

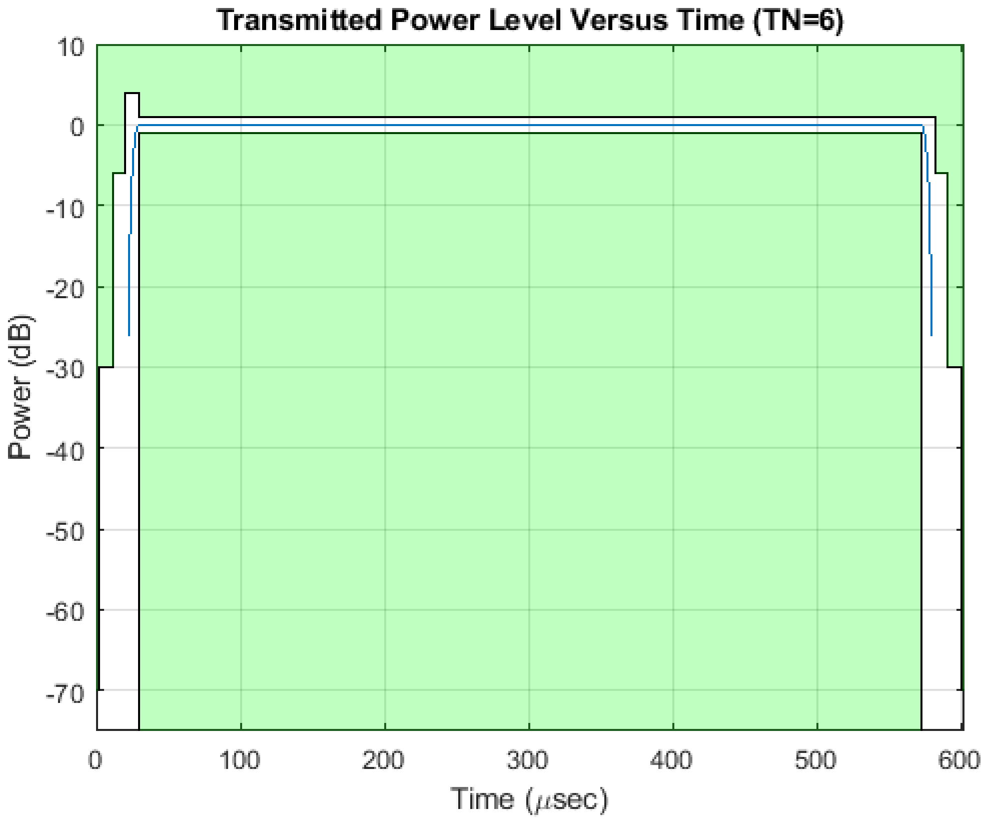
Use the `gsmCheckTimeMask` function to view the time mask and verify that the configured rise and fall characteristics of the burst in the specified time slot comply with the time mask specified by the GSM standard. Plot the GSM burst and time mask.

```
tn = 6; % Time slot number 6
pf = gsmCheckTimeMask(cfggsmul,tn);
```

```
if pf
    disp('Time mask test passed.')
else
    disp('Time mask test failed.')
end
```

```
Time mask test passed.
```

```
gsmCheckTimeMask(cfggsmul,tn);
```



Adjust the fall delay of the GSM downlink TDMA frame configuration object, specifying a value that causes a time mask failure.

```
cfggsmul.FallDelay = 4
```

```
cfggsmul = 
  gsmDownlinkConfig with properties:

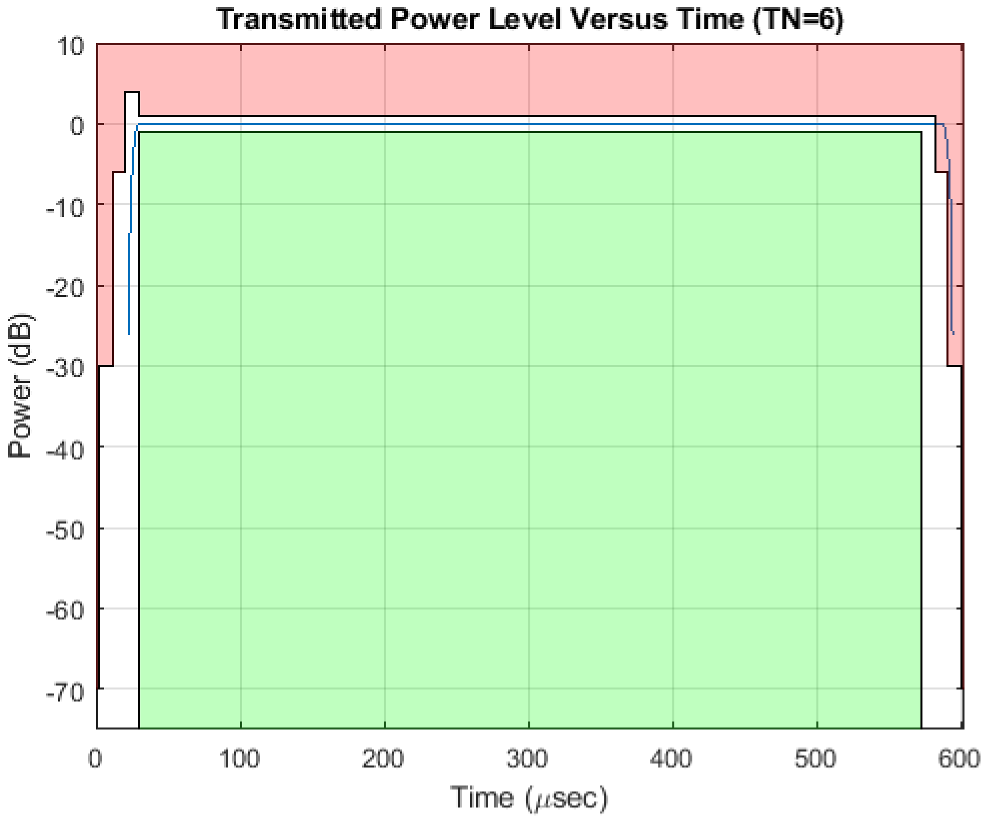
           BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 4
```

Use the `gsmCheckTimeMask` function to inspect the time mask of `cfggsmul`. The pass or fail result shows that the `cfggsmul` configuration now fails the time mask and the plot shows the upper time mask fails.

```
pf = gsmCheckTimeMask(cfggsmul,tn);
if pf
    disp('Time mask test passed.')
else
    disp('Time mask test failed.')
end
```

```
Time mask test failed.
```

```
gsmCheckTimeMask(cfggsmul,tn);
```



Check Time Mask for GSM Bursts

Create GSM downlink and uplink TDMA frame configuration objects that use the various burst types available.

- Normal bursts and bursts with no data are valid for downlink and uplink frames.
- Frequency correction, synchronization, and dummy bursts are valid in downlink frames only.
- Access bursts are valid in uplink frames only.

View time masks for the different burst types against the time mask specified by the GSM standard for the downlink and uplink frames.

Create a GSM downlink TDMA frame configuration object that configures the times slot bursts as [NB FB SB Dummy Off Off Off Off].

```
cfggsmdl = gsmDownlinkConfig('BurstType',["NB" "FB" "SB" "Dummy" "Off" "Off" "Off" "Off"])
```

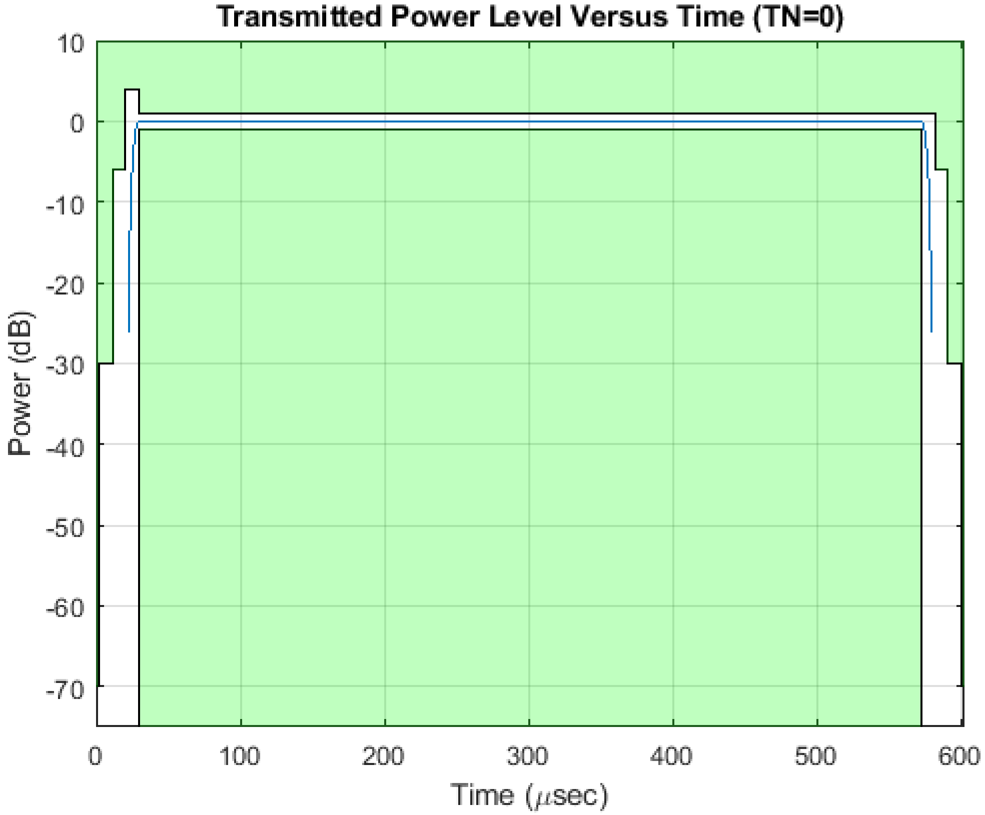
```
cfggsmdl = 
  gsmDownlinkConfig with properties:

           BurstType: [NB    FB    SB    Dummy    Off    Off    Off    Off]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

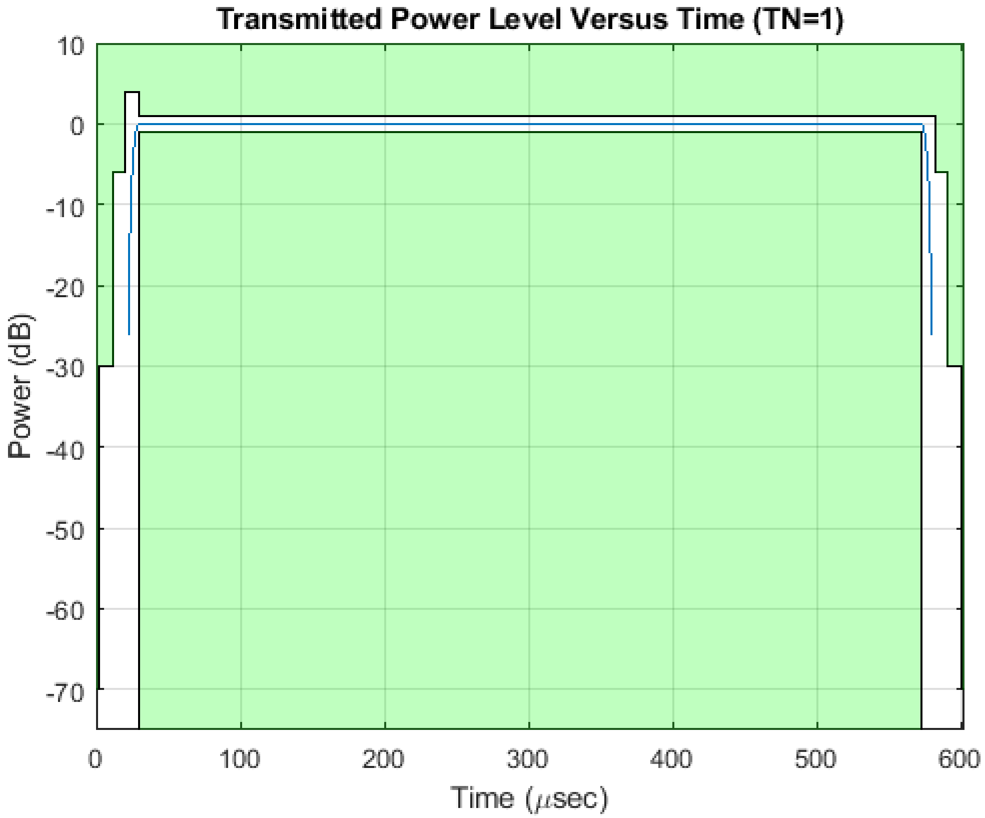
Use the gsmCheckTimeMask function to view the time mask for the different time slot burst types. For downlink GSM TDMA frames the same time mask limits applies for all burst types.

```
for tn = 0:4
    [dlbt,dlbtVal] = enumeration(cfggsmdl.BurstType);
    dlBurstInfo = ['Downlink (TN=',num2str(tn),'), BurstType: ',dlbtVal{tn+1}];
    disp(dlBurstInfo)
    gsmCheckTimeMask(cfggsmdl,tn);
end
```

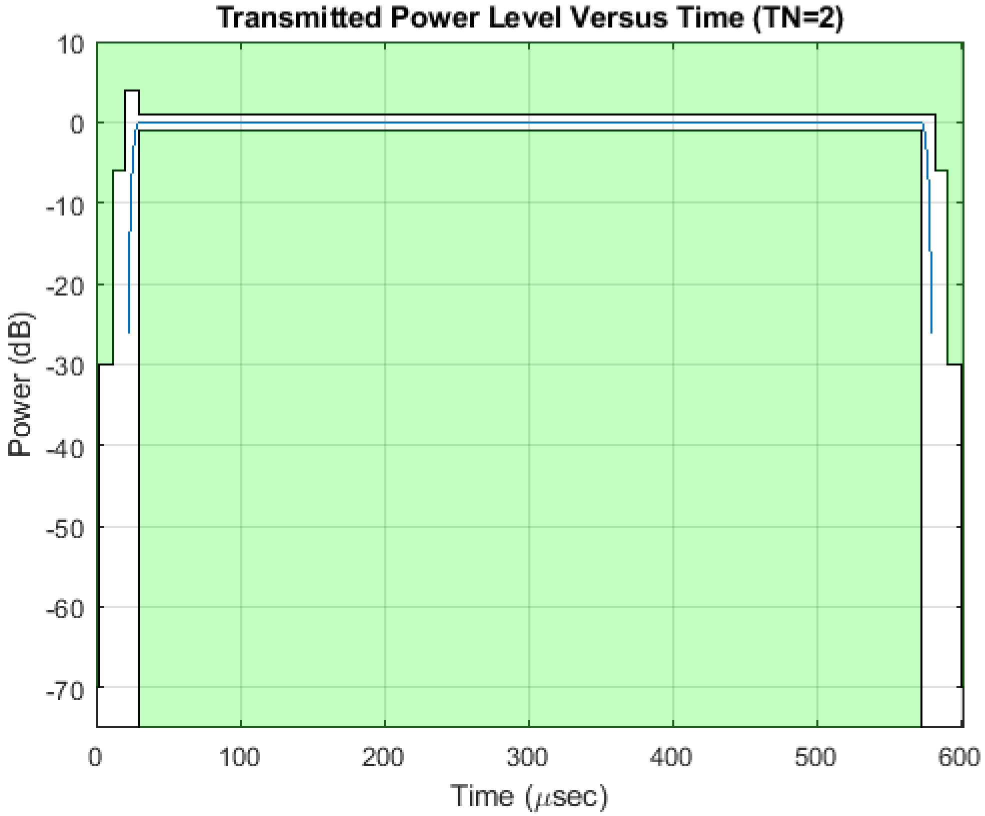
```
Downlink (TN=0), BurstType: NB
```



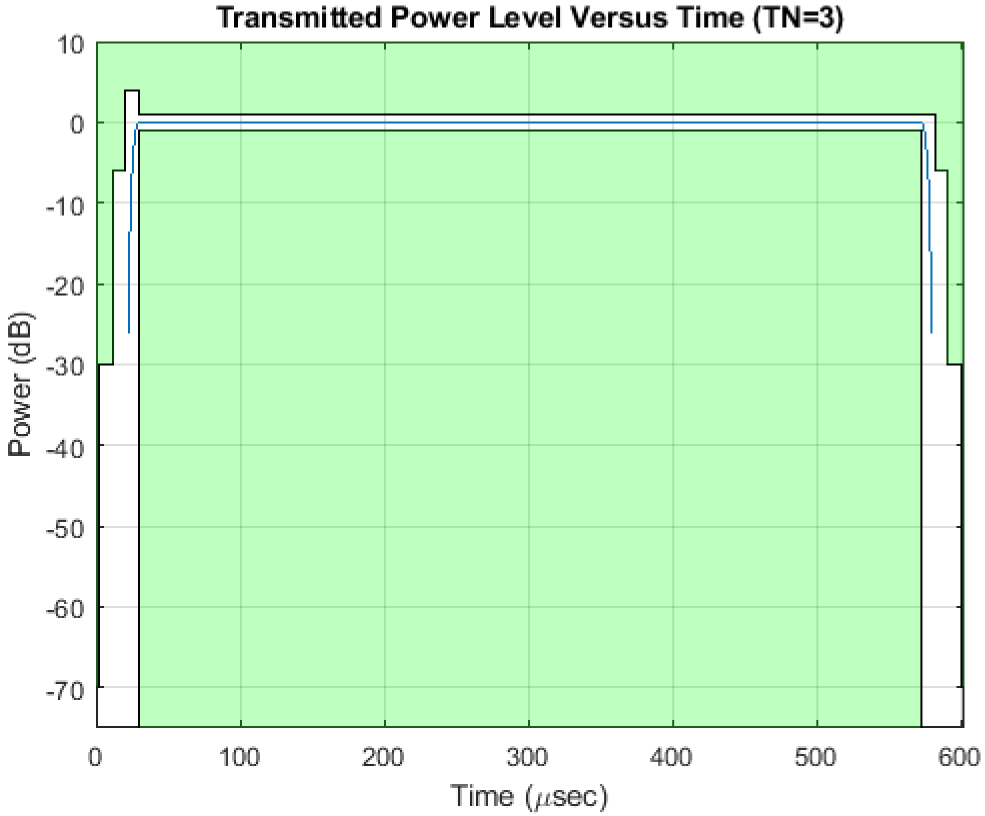
```
Downlink (TN=1), BurstType: FB
```



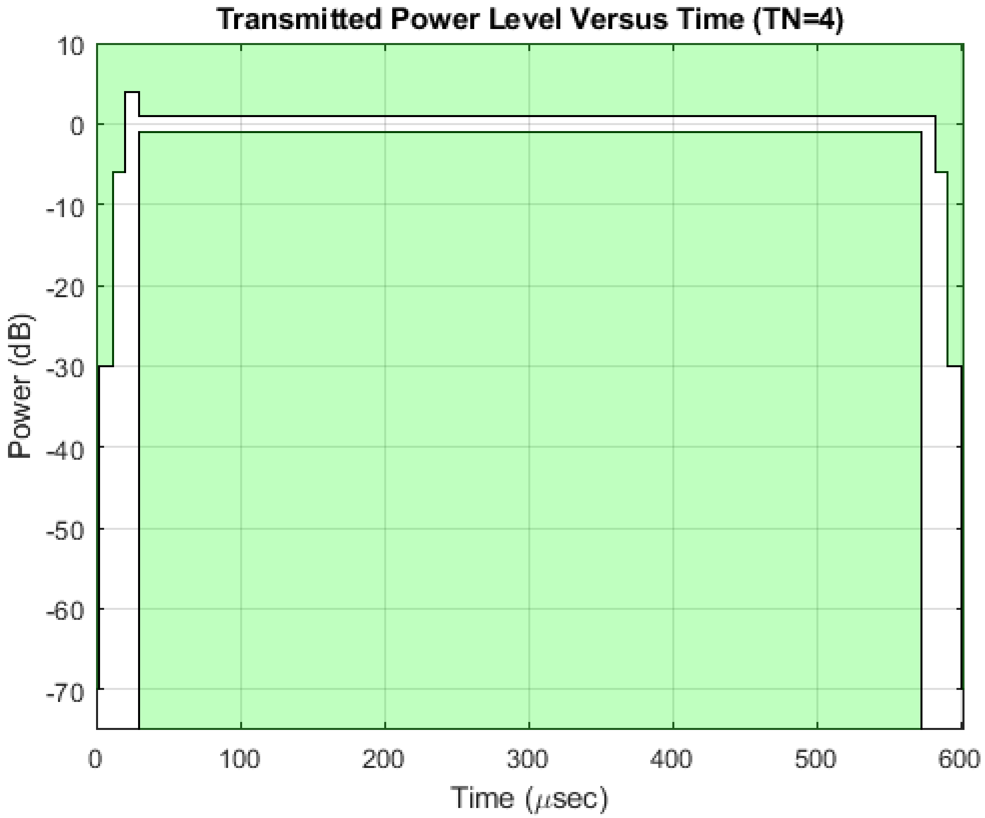
```
Downlink (TN=2), BurstType: SB
```



```
Downlink (TN=3), BurstType: Dummy
```



```
Downlink (TN=4), BurstType: Off
```



Create a GSM uplink TDMA frame configuration object that configures the times slot bursts as [NB AB Off Off Off Off Off Off].

```
cfggsmul = gsmUplinkConfig('BurstType',["NB" "AB" "Off" "Off" "Off" "Off" "Off" "Off"])
```

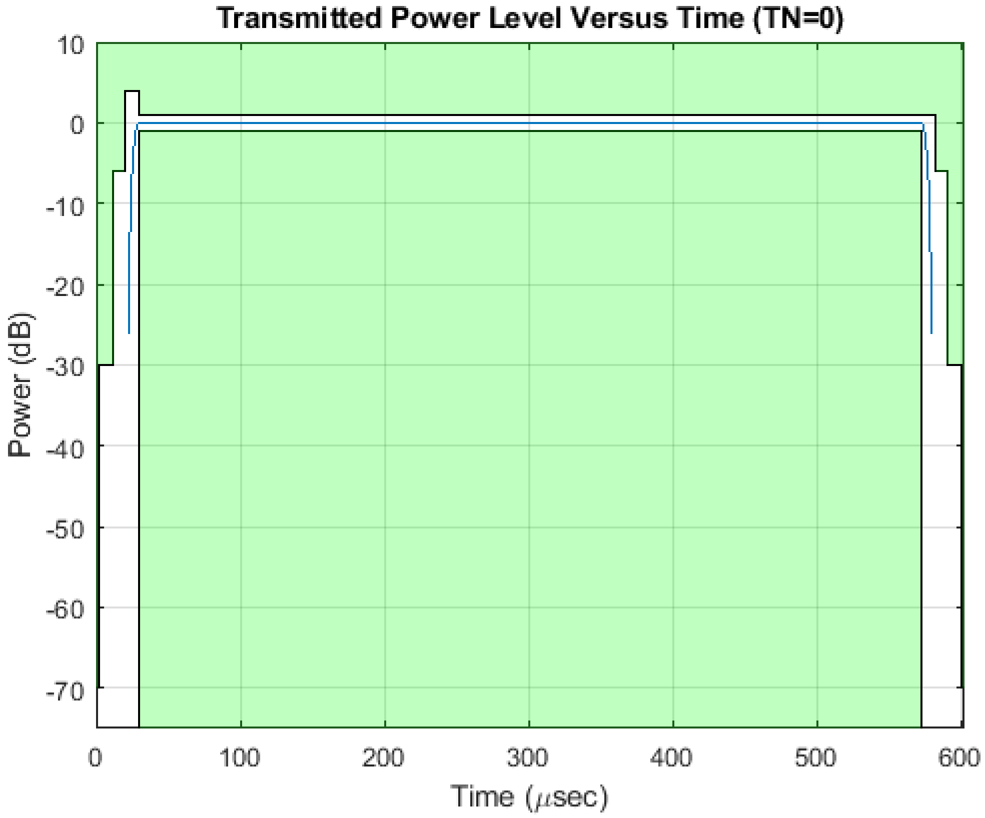
```
cfggsmul = 
  gsmUplinkConfig with properties:

          BurstType: [NB    AB    Off    Off    Off    Off    Off    Off]
    SamplesPerSymbol: 16
                TSC: [0 1 2 3 4 5 6 7]
        Attenuation: [0 0 0 0 0 0 0 0]
           RiseTime: 2
          RiseDelay: 0
           FallTime: 2
          FallDelay: 0
```

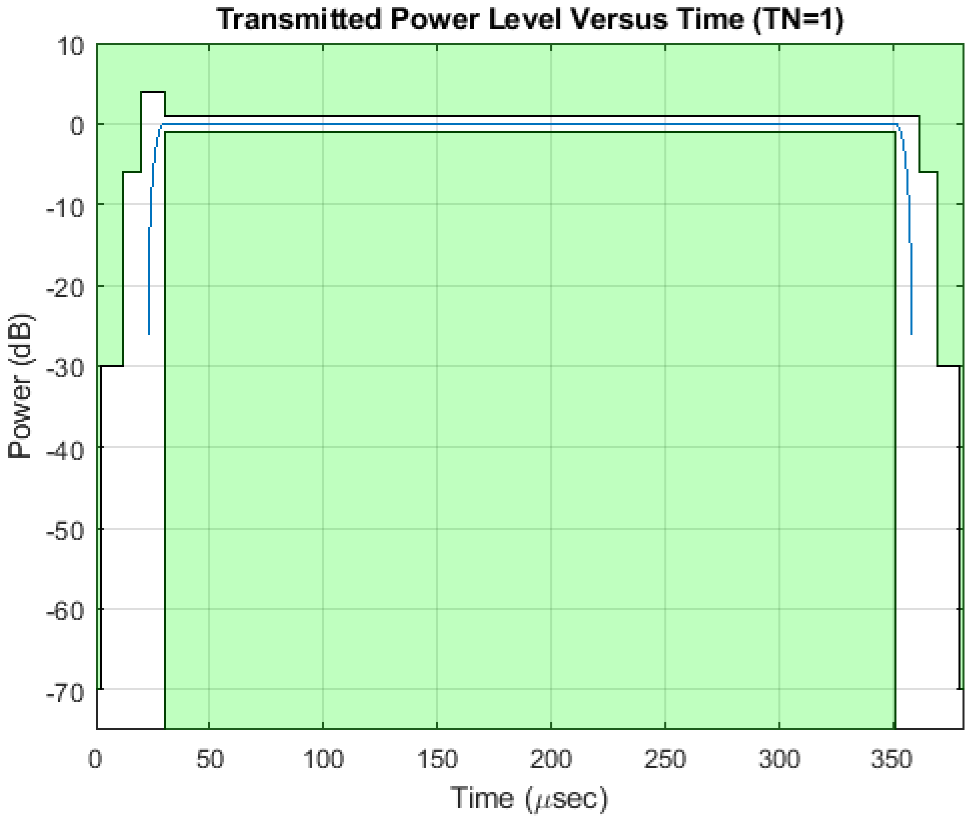
Use the `gsmCheckTimeMask` function to view the time masks for the different time slot burst types. For uplink GSM TDMA frames the access burst has a shorter time mask than the normal burst or no data burst.

```
for tn = 0:2
    [ulbt,ulbtVal] = enumeration(cfggsmul.BurstType);
    ulBurstInfo = ['Uplink (TN=',num2str(tn),'), BurstType: ',ulbtVal{tn+1}];
    disp(ulBurstInfo)
    gsmCheckTimeMask(cfggsmul,tn);
end
```

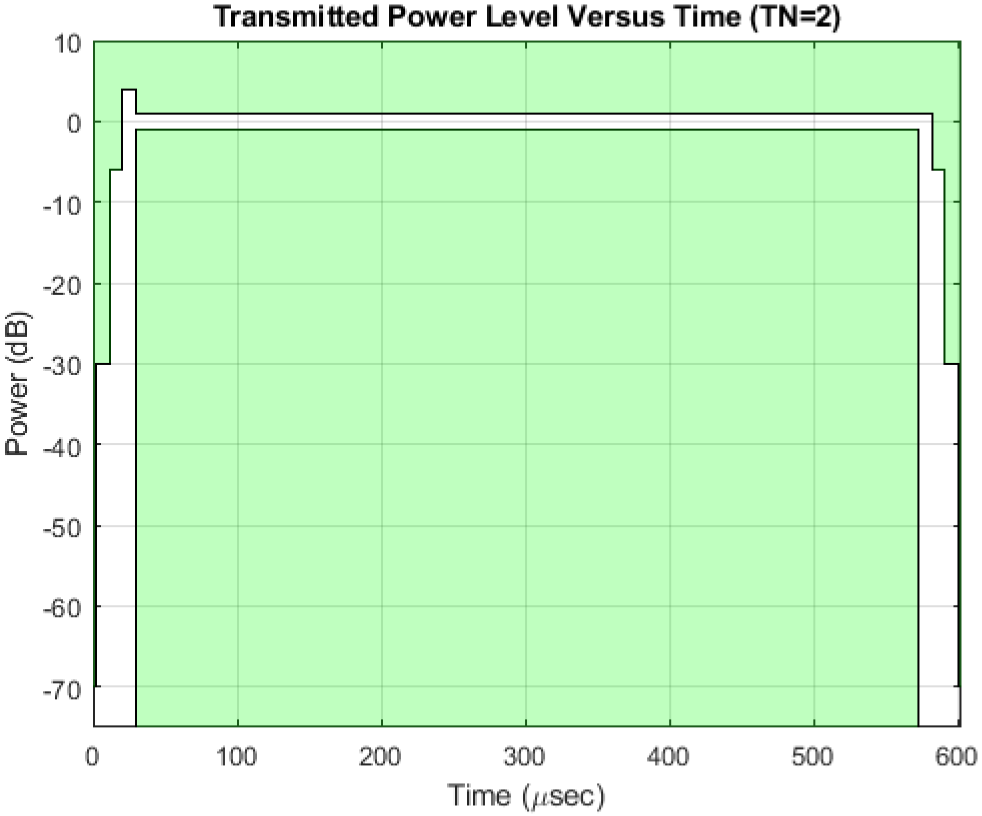
```
Uplink (TN=0), BurstType: NB
```



```
Uplink (TN=1), BurstType: AB
```



```
Uplink (TN=2), BurstType: Off
```



Input Arguments

gsmCfg — GSM configuration

gsmUplinkConfig object | gsmDownlinkConfig object

GSM configuration, specified as a gsmUplinkConfig or gsmDownlinkConfig object.

tn — Time slot number

0 (default) | integer in the range [0, 7]

Time slot number, specified as an integer in the range [0, 7].

Data Types: double

Output Arguments

pf — Pass or fail result

0 | 1

Pass or fail result, returned as:

- 1 if the time mask passes
- 0 if the time mask fails

For more information, see “Time Mask” on page 2-465.

More About

Time Mask

The time mask defines the allowable transmitted power level versus time for time slot bursts in a GSM TDMA frame. This figure, from Annex B of TS 45.005, shows the upper and lower power limits for the time mask of a burst.

Topics

"GSM TDMA Frame Parameterization for Waveform Generation"

Introduced in R2019b

gsmFrame

Create GSM waveform

Syntax

```
gsmWaveform = gsmFrame(gsmCfg)
gsmWaveform = gsmFrame(gsmCfg,numFrames)
```

Description

`gsmWaveform = gsmFrame(gsmCfg)` creates a GSM waveform with one TDMA frame based on the input GSM configuration object. The encrypted bit field of the transmission data bursts is filled with random data. For more information, see “GSM Frames, Time Slots, and Bursts” on page 2-473.

`gsmWaveform = gsmFrame(gsmCfg,numFrames)` creates a GSM waveform, with `numFrames` identically configured TDMA frames. In each frame, the encrypted bit field of the transmission data bursts is filled with random data. For more information, see “GSM Frames, Time Slots, and Bursts” on page 2-473.

Examples

Create GSM Uplink Waveform

Create a GSM uplink TDMA frame configuration object with default settings, and then create a GSM waveform containing one TDMA frame. GSM TDMA frames have eight time slots, each separated by a guard period of 8.25 symbols or about 30.46x10e-3 ms. Plot the GSM waveform.

Create a GSM uplink TDMA frame configuration object with default settings.

```
cfggsmul = gsmUplinkConfig
```

```
cfggsmul = 
  gsmUplinkConfig with properties:

           BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

Display information about the configured `gsmUplinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)
```

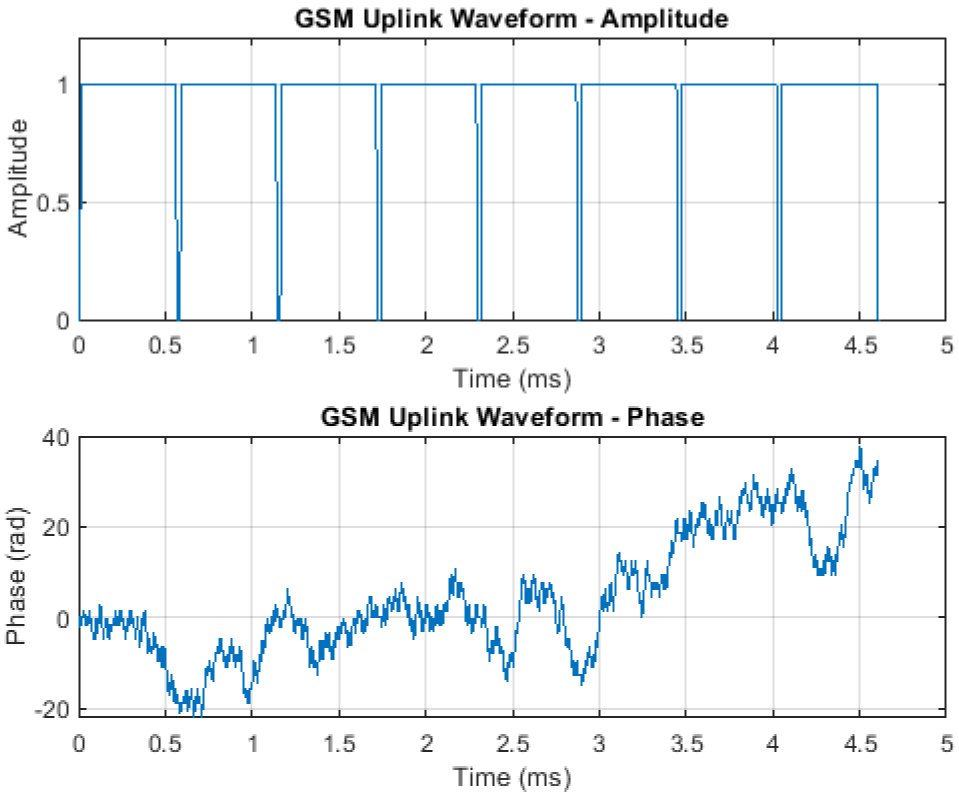
```
wfInfo = struct with fields:
              SymbolRate: 2.7083e+05
              SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
       NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmul);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```



Create GSM Uplink Waveform Containing Five TDMA Frames

Create a GSM downlink TDMA frame configuration object with default settings, and then create a GSM waveform containing five TDMA frames. GSM TDMA frames have eight time slots, each separated by a guard period of 8.25 symbols or about 30.46x10e-3 ms. Plot the GSM waveform.

Create a GSM uplink TDMA frame configuration object, specifying 3 dB of attenuation in the last time slot to help identify the end of each frame.

```
cfggsmul = gsmUplinkConfig('Attenuation',[0 0 0 0 0 0 0 3])
```

```
cfggsmul = 
  gsmUplinkConfig with properties:

           BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [0 0 0 0 0 0 0 3]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

Display information about the configured `gsmUplinkConfig` object by using the `gsmInfo` function. Assign the frame length in samples to a variable, `spf`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)
```

```
wfInfo = struct with fields:
              SymbolRate: 2.7083e+05
              SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
       NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

```
spf = wfInfo.FrameLengthInSamples;
```

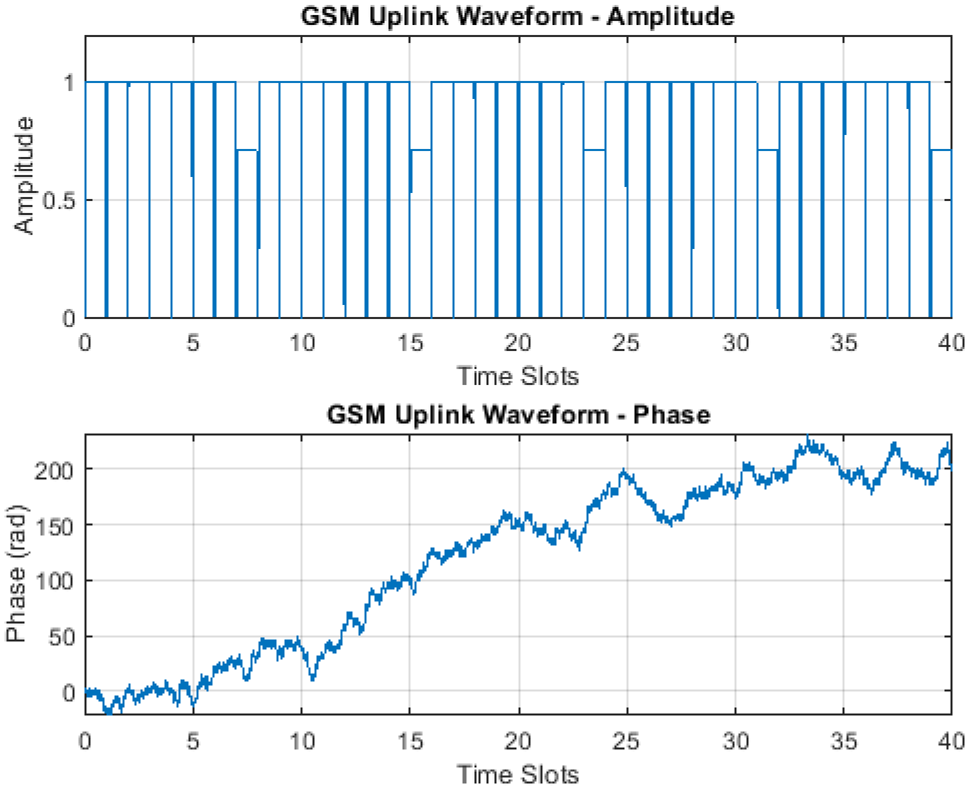
Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform. The last time slot of each frame is 3 dB less than the other time slots in that frame.

```
numFrames = 5;
waveform = gsmFrame(cfggsmul,numFrames);

t = 8*(0:length(waveform)-1)/spf;

numTS = 8*numFrames;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 numTS 0 1.2])
title('GSM Uplink Waveform - Amplitude')
```

```
xlabel('Time Slots')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time Slots')
ylabel('Phase (rad)')
```



Create GSM Downlink Waveform

Create a GSM downlink TDMA frame configuration object with default settings, and then create a GSM waveform containing one TDMA frame. The GSM TDMA frame has eight time slots, each separated by a guard period of 8.25 symbols or about 30.46x10e-3 ms. Plot the GSM waveform.

Create a GSM downlink TDMA frame configuration object with default settings.

```
cfggsmdl = gsmDownlinkConfig
```

```
cfggsmdl = 
  gsmDownlinkConfig with properties:

          BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
```

```
         Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

Display information about the configured `gsmDownlinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmdl)
```

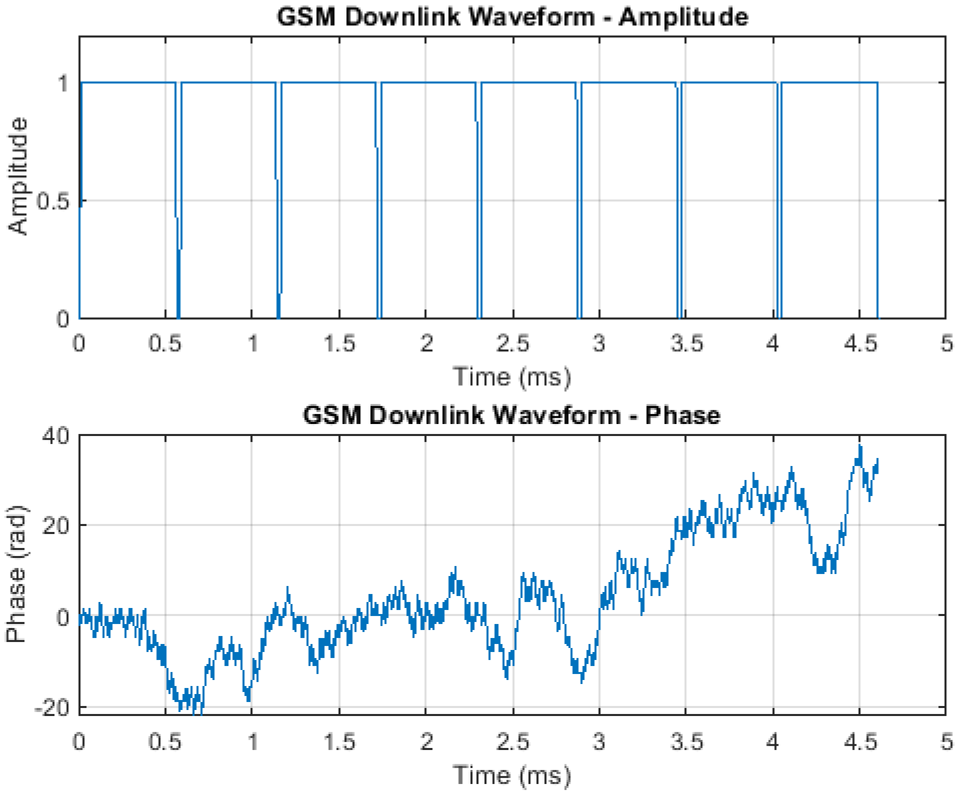
```
wfInfo = struct with fields:
              SymbolRate: 2.7083e+05
              SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
       NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmdl);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Downlink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Downlink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```



Input Arguments

`gsmCfg` — GSM configuration

`gsmUplinkConfig` object | `gsmDownlinkConfig` object

GSM configuration, specified as a `gsmUplinkConfig` or `gsmDownlinkConfig` object.

`numFrames` — Number of TDMA frames

`16` (default) | positive integer

Number of TDMA frames in the waveform, specified as a positive integer.

Data Types: `double`

Output Arguments

`gsmWaveform` — Output time-domain waveform

complex-valued column vector

Output time-domain waveform, returned as a complex-valued column vector of length N_s, where N_s represents the number of time-domain samples. The function generates this waveform in the form of complex in-phase quadrature (IQ) samples.

More About

GSM Frames, Time Slots, and Bursts

In GSM, transmissions consist of TDMA frames. Each GSM TDMA frame consists of eight time slots. The transmission data content of a time slot is called a burst. As described in Section 5.2 of 3GPP TS 45.011, a GSM time slot has a 156.25-symbol duration when using the normal symbol period, which is a time interval of 15/26 ms or about 576.9 microseconds. A guard period of 8.25 symbols or about 30.46 microseconds separates each time slot. The GSM standards describes a symbol as one bit period. Since GSM uses GMSK modulation, there is one bit per bit period. The transmission timing of a burst within a time slot is defined in terms of the bit number (BN). The BN refers to a particular bit period within a time slot. The bit with the lowest BN is transmitted first. BN0 is the first bit period, and BN156 is the last quarter-bit period.

This image from 3GPP TS 45.011 shows the relationship between different frame types and the relationship between different burst types.

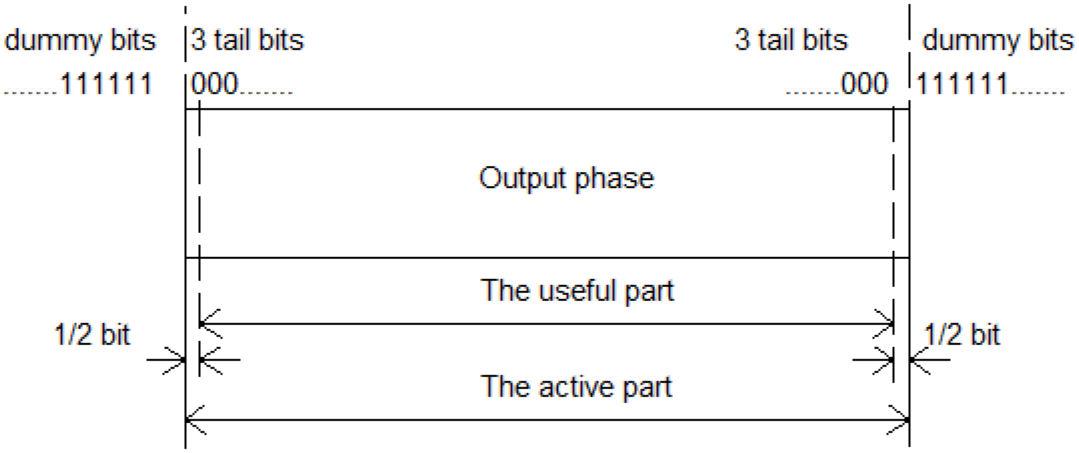
This table shows the supported burst types and their characteristics.

Burst Type	Description	Link Direction	Useful Duration
NB	Normal burst	Uplink/Downlink	147
FB	Frequency correction burst	Downlink	147
SB	Synchronization burst	Downlink	147
Dummy	Dummy burst	Downlink	147
AB	Access burst	Uplink	87
Off	No burst sent	Uplink/Downlink	0

Useful duration, described in Section 5.2.2 of 3GPP TS 45.002, is a characteristic of GSM bursts. The useful duration, or useful part, of a burst is defined as beginning halfway through BN0 and ending half a bit period before the start of the guard period. The guard period is the period between bursts in successive time slots. This figure, from Section 2.2 of 3GPP TS 45.004, shows the leading and trailing ½ bit difference between the useful and active parts of the burst.



For more information, see "GSM TDMA Frame Parameterization for Waveform Generation".

Training Sequence Code (TSC)

Normal bursts include a training sequence bits field assigned a bit pattern based on the specified TSC. For GSM, you can select one of these eight training sequences for normal burst type time slots.

Training Sequence Code (TSC)	Training Sequence Bits (BN61, BN62, …, BN86)
0	(0,0,1,0,0,1,0,1,1,1,0,0,0,0,1,0,0,0,1,0,0,1,0,1,1,1)

gsmInfo

View GSM waveform information

Syntax

```
infostruct= gsmInfo(gsmCfg)
```

Description

`infostruct= gsmInfo(gsmCfg)` returns a structure containing characteristic waveform information for the input GSM configuration object.

Examples

View GSM Configuration Object Information

View information from downlink and uplink GSM configuration objects.

Create a GSM downlink configuration object with default settings and use `gsmInfo` to view the waveform information structure.

```
cfgDL = gsmDownlinkConfig;
infostructDL = gsmInfo(cfgDL)
```

```
infostructDL = struct with fields:
              SymbolRate: 2.7083e+05
              SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
       NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

Create a GSM uplink configuration object with default settings and use `gsmInfo` to view the waveform information structure.

```
cfgUL = gsmUplinkConfig;
infostructUL = gsmInfo(cfgUL)
```

```
infostructUL = struct with fields:
              SymbolRate: 2.7083e+05
              SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
       NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

Create GSM Uplink Waveform Containing Five TDMA Frames

Create a GSM downlink TDMA frame configuration object with default settings, and then create a GSM waveform containing five TDMA frames. GSM TDMA frames have eight time slots, each separated by a guard period of 8.25 symbols or about 30.46x10e-3 ms. Plot the GSM waveform.

Create a GSM uplink TDMA frame configuration object, specifying 3 dB of attenuation in the last time slot to help identify the end of each frame.

```
cfggsmul = gsmUplinkConfig('Attenuation',[0 0 0 0 0 0 0 3])
```

```
cfggsmul = 
  gsmUplinkConfig with properties:

           BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [0 0 0 0 0 0 0 3]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

Display information about the configured `gsmUplinkConfig` object by using the `gsmInfo` function. Assign the frame length in samples to a variable, `spf`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)
```

```
wfInfo = struct with fields:
              SymbolRate: 2.7083e+05
              SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
       NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

```
spf = wfInfo.FrameLengthInSamples;
```

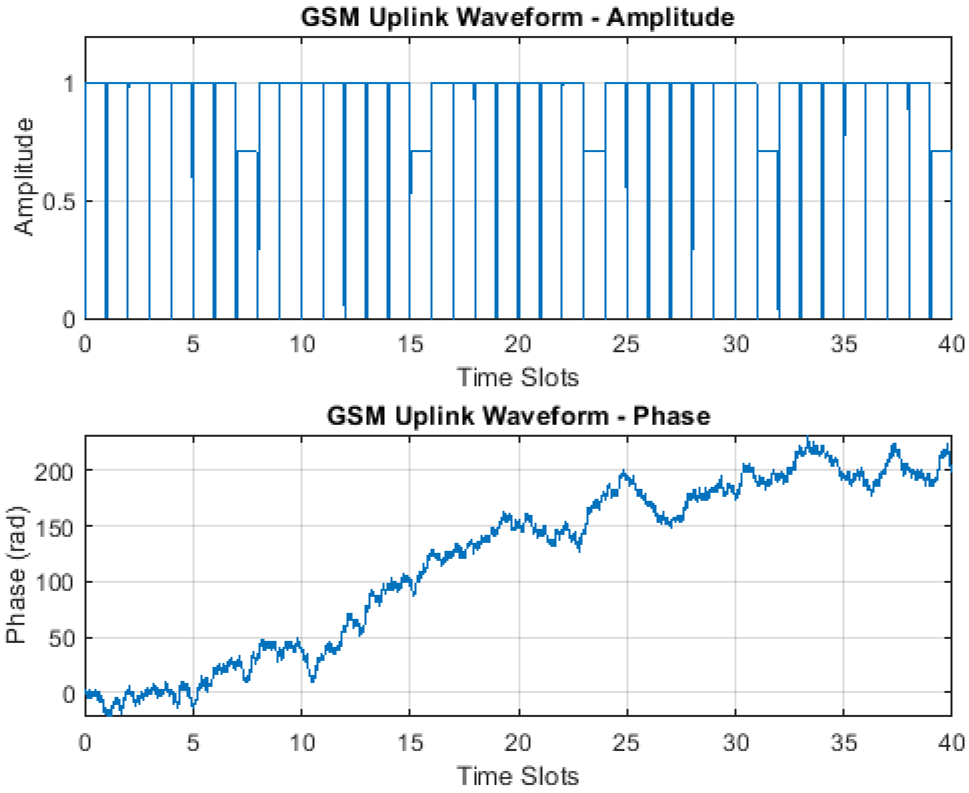
Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform. The last time slot of each frame is 3 dB less than the other time slots in that frame.

```
numFrames = 5;
waveform = gsmFrame(cfggsmul,numFrames);

t = 8*(0:length(waveform)-1)/spf;

numTS = 8*numFrames;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 numTS 0 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time Slots')
ylabel('Amplitude')
subplot(2,1,2)
```

```
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time Slots')
ylabel('Phase (rad)')
```



Input Arguments

gsmCfg — GSM configuration

gsmUplinkConfig object | gsmDownlinkConfig object

GSM configuration, specified as a gsmUplinkConfig or gsmDownlinkConfig object.

Output Arguments

infostruct — Structure containing object information

struct

Structure containing these fields with information about the characteristic GSM waveform based on the input configuration object.

SymbolRate — GSM symbol rate

positive integer

GSM symbol rate in symbols per second, returned as a positive integer.

`SampleRate` — GSM sample rate
positive integer

GSM sample rate in samples per second, returned as a positive integer.

`BandwidthTimeProduct` — Product of bandwidth and symbol time of Gaussian pulse
positive integer

Product of bandwidth and symbol time of Gaussian pulse for the GMSK modulator, returned as a positive integer.

`BurstLengthInSymbols` — GSM burst length
positive scalar

GSM burst length in symbols, returned as a positive scalar.

`NumBurstsPerFrame` — Number of bursts in GSM TDMA frame
positive integer

Number of bursts in a GSM TDMA frame, returned as a positive integer.

`BurstLengthInSamples` — GSM burst length
positive integer

GSM burst length in samples, returned as a positive integer.

`FrameLengthInSamples` — GSM frame length
positive integer

GSM frame length in samples, returned as a positive integer.

hammgen

Parity-check and generator matrices for Hamming code

Syntax

```
h = hammgen(m)
h = hammgen(m,poly)
[h,g] = hammgen( ___ )
[h,g,n,k] = hammgen( ___ )
```

Description

`h = hammgen(m)` returns an `m`-by-*n* parity-check matrix, `h`, for a Hamming code of codeword length *n* = 2^m–1. The message length of the Hamming code is *n* – `m`. The binary primitive polynomial that the function uses to create the Hamming code is the default primitive polynomial in GF(`2^m`). For more details of this default polynomial, see the `gfprimdf` function.

`h = hammgen(m,poly)` specifies `poly`, a binary primitive polynomial for GF(2^m). The function uses `poly` to create the Hamming code.

`[h,g] = hammgen( ___ )` additionally returns a *k*-by-*n* generator matrix, `g`, that corresponds to the parity-check matrix `h`. Specify any of the input argument combinations from the previous syntaxes.

`[h,g,n,k] = hammgen( ___ )` also returns `n`, the codeword length and `k`, the message length, for the Hamming code.

Examples

Generate Hamming Code Parity-Check Matrix Using Default Primitive Polynomial

Generate a parity-check matrix, `h`, for a Hamming code of codeword length 7. The function uses the default primitive polynomial in GF(8) to create the Hamming code.

```
h = hammgen(3)
```

```
h = 3×7

     1     0     0     1     0     1     1
     0     1     0     1     1     1     0
     0     0     1     0     1     1     1
```

Generate Hamming Code Parity-Check Matrix from Primitive Polynomials

Generate the parity-check matrices for the Hamming code of codeword length 15, specifying the primitive polynomials $1 + D + D^4$ and $1 + D^3 + D^4$ in GF(16).

```
h1 = hammgen(4,'1+D+D^4')
```

```
h1 = 4×15

     1     0     0     0     1     0     0     1     1     0     1     0     1     1     1
     0     1     0     0     1     1     0     1     0     1     1     1     1     0     0
     0     0     1     0     0     1     1     0     1     0     1     1     1     1     0
     0     0     0     1     0     0     1     1     0     1     0     1     1     1     1
```

```
h2 = hammgen(4,'1+D^3+D^4')
```

```
h2 = 4×15

     1     0     0     0     1     1     1     1     0     1     0     1     1     0     0
     0     1     0     0     0     1     1     1     1     0     1     0     1     1     0
     0     0     1     0     0     0     1     1     1     1     0     1     0     1     1
     0     0     0     1     1     1     1     0     1     0     1     1     0     0     1
```

Remove the embedded 4-by-4 identity matrices that is, the leftmost four columns in each parity-check matrix.

```
h1 = h1(:,5:end)
```

```
h1 = 4×11

     1     0     0     1     1     0     1     0     1     1     1
     1     1     0     1     0     1     1     1     1     0     0
     0     1     1     0     1     0     1     1     1     1     0
     0     0     1     1     0     1     0     1     1     1     1
```

```
h2 = h2(:,5:end)
```

```
h2 = 4×11

     1     1     1     1     0     1     0     1     1     0     0
     0     1     1     1     1     0     1     0     1     1     0
     0     0     1     1     1     1     0     1     0     1     1
     1     1     1     0     1     0     1     1     0     0     1
```

Verify that the two resulting matrices differ.

```
isequal(h1,h2)
```

```
ans = logical
   0
```

Generate Hamming Code Parity-Check and Generator Matrices

Generate the parity-check matrix, `h` and the generator matrix, `g` for the Hamming code of codeword length 7. Also return the codeword length, `n`, and the message length, `k` for the Hamming code. The function uses the default primitive polynomial in GF(8) to create the Hamming code.

```
[h,g,n,k] = hammgen(3)

h = 3×7

     1     0     0     1     0     1     1
     0     1     0     1     1     1     0
     0     0     1     0     1     1     1

g = 4×7

     1     1     0     1     0     0     0
     0     1     1     0     1     0     0
     1     1     1     0     0     1     0
     1     0     1     0     0     0     1

n = 7

k = 4
```

Input Arguments

`m` — Number of rows in parity-check matrix

integer greater than or equal to two

Number of rows in parity-check matrix, specified as an integer greater than or equal to two. The function uses this value to calculate the codeword length and the message length of the Hamming code.

Data Types: `double`

`poly` — Binary primitive polynomial in GF(2^m)

binary row vector | character vector | string scalar

Binary primitive polynomial in GF(2^m), specified as one of these values:

- Binary row vector of the polynomial coefficients in order of ascending powers
- Character vector
- String scalar

If `poly` is specified as a non-primitive polynomial, then the function `hammgen` displays an error.

Data Types: `double` | `char` | `string`

Output Arguments

`h` — Parity-check matrix for Hamming code

`m`-by-`n` matrix of binary values

Parity-check matrix for Hamming code, returned as an `m`-by-`n` matrix of binary values for the Hamming code.

Data Types: `single` | `double`

g — Generator matrix for Hamming code
k-by-n matrix of binary values

Generator matrix for Hamming code, returned as a k-by-n matrix of binary values corresponding to the parity-check matrix h.

Data Types: `single` | `double`

n — Codeword length of Hamming code
positive integer

Codeword length of Hamming code, returned as a positive integer. This value is calculated as 2^m–1.

Data Types: `single` | `double`

k — Message length of Hamming code
positive integer

Message length of Hamming code, returned as a positive integer. This value is calculated as n–m.

Data Types: `single` | `double`

Algorithms

`hammgen` uses the function `gftuple` to create the parity-check matrix by converting each element in the Galois field (GF) to its polynomial representation. Unlike `gftuple`, which performs computations in GF(2^m) and processes one m-tuple at a time, the `hammgen` function generates the entire sequence from 0 to 2^m–1. The computation algorithm uses all previously computed values to generate the computation result. If the value of m is less than 25 and the primitive polynomial is the default primitive polynomial for GF(2^m), the syntax `hammgen(m)` might be faster than the syntax `hammgen(m,poly)`.

hank2sys

(To be removed) Convert Hankel matrix to linear system model

Compatibility

hank2sys will be removed in a future release.

Syntax

```
[num,den] = hank2sys(h,ini,tol)
[num,den,sv] = hank2sys(h,ini,tol)
[a,b,c,d] = hank2sys(h,ini,tol)
[a,b,c,d,sv] = hank2sys(h,ini,tol)
```

Description

`[num,den] = hank2sys(h,ini,tol)` converts a Hankel matrix `h` to a linear system transfer function with numerator `num` and denominator `den`. The vectors `num` and `den` list the coefficients of their respective polynomials in ascending order of powers of z^{-1}. The argument `ini` is the system impulse at time zero. If `tol` > 1, `tol` is the order of the conversion. If `tol` < 1, `tol` is the tolerance in selecting the conversion order based on the singular values. If you omit `tol`, its default value is 0.01. This conversion uses the singular value decomposition method.

`[num,den,sv] = hank2sys(h,ini,tol)` returns a vector `sv` that lists the singular values of `h`.

`[a,b,c,d] = hank2sys(h,ini,tol)` converts a Hankel matrix `h` to a corresponding linear system state-space model. `a`, `b`, `c`, and `d` are matrices. The input parameters are the same as in the first syntax above.

`[a,b,c,d,sv] = hank2sys(h,ini,tol)` is the same as the syntax above, except that `sv` is a vector that lists the singular values of `h`.

Examples

```
h = hankel([1 0 1]);
[num,den,sv] = hank2sys(h,0,.01)
```

The output is

```
num =

         0    1.0000    0.0000    1.0000

den =

    1.0000    0.0000    0.0000    0.0000

sv =
    1.6180
    1.0000
    0.6180
```

Compatibility Considerations

hank2sys will be removed in a future release.
Not recommended starting in R2020b

hank2sys will be removed in a future release.

heldeintrlv

Restore ordering of symbols permuted using `helintrlv`

Syntax

```
[deintrlved,state] = heldeintrlv(data,col,ngrp,stp)
[deintrlved,state] = heldeintrlv(data,col,ngrp,stp,init_state)
deintrlved = heldeintrlv(data,col,ngrp,stp,init_state)
```

Description

`[deintrlved,state] = heldeintrlv(data,col,ngrp,stp)` restores the ordering of symbols in `data` by placing them in an array row by row and then selecting groups in a helical fashion to place in the output, `deintrlved`. `data` must have `col*ngrp` elements. If `data` is a matrix with multiple rows and columns, it must have `col*ngrp` rows, and the function processes the columns independently. `state` is a structure that holds the final state of the array. `state.value` stores input symbols that remain in the `col` columns of the array and do not appear in the output.

The function uses the array internally for its computations. The array has unlimited rows indexed by 1, 2, 3,..., and `col` columns. The function initializes the top of the array with zeros. It then places `col*ngrp` symbols from the input into the next `ngrp` rows of the array. The function places symbols from the array in the output, `intrlved`, placing `ngrp` symbols at a time; the kth group of `ngrp` symbols comes from the kth column of the array, starting from row 1+(k-1)*`stp`. Some output symbols are default values of 0 rather than input symbols; similarly, some input symbols are left in the array and do not appear in the output.

`[deintrlved,state] = heldeintrlv(data,col,ngrp,stp,init_state)` initializes the array with the symbols contained in `init_state.value` instead of zeros. The structure `init_state` is typically the `state` output from a previous call to this same function, and is unrelated to the corresponding interleaver. In this syntax, some output symbols are default values of 0, some are input symbols from `data`, and some are initialization values from `init_state.value`.

`deintrlved = heldeintrlv(data,col,ngrp,stp,init_state)` is the same as the syntax above, except that it does not record the deinterleaver's final state. This syntax is appropriate for the last in a series of calls to this function. However, if you plan to call this function again to continue the deinterleaving process, the syntax above is more appropriate.

Using an Interleaver-Deinterleaver Pair

To use this function as an inverse of the `helintrlv` function, use the same `col`, `ngrp`, and `stp` inputs in both functions. In that case, the two functions are inverses in the sense that applying `helintrlv` followed by `heldeintrlv` leaves data unchanged, after you take their combined delay of `col*ngrp*ceil(stp*(col-1)/ngrp)` into account. To learn more about delays of convolutional interleavers, see “Delays of Convolutional Interleavers”.

Note Because the delay is an integer multiple of the number of symbols in `data`, you must use `heldeintrlv` at least *twice* (possibly more times, depending on the actual delay value) before the function returns results that represent more than just the delay.

Examples

Recover interleaved data, taking into account the delay of the interleaver-deinterleaver pair.

```
col = 4; ngrp = 3; stp = 2; % Helical interleaver parameters
% Compute the delay of interleaver-deinterleaver pair.
delayval = col * ngrp * ceil(stp * (col-1)/ngrp);

len = col*ngrp; % Process this many symbols at one time.
data = randi([0 9],len,1); % Random symbols
data_padded = [data; zeros(delayval,1)]; % Pad with zeros.

% Interleave zero-padded data.
[i1,istate] = helintrlv(data_padded(1:len),col,ngrp,stp);
[i2,istate] = helintrlv(data_padded(len+1:2*len),col,ngrp, ...
              stp,istate);
i3 = helintrlv(data_padded(2*len+1:end),col,ngrp,stp,istate);

% Deinterleave.
[d1,dstate] = heldeintrlv(i1,col,ngrp,stp);
[d2,dstate] = heldeintrlv(i2,col,ngrp,stp,dstate);
d3 = heldeintrlv(i3,col,ngrp,stp,dstate);

% Check the results.
d0 = [d1; d2; d3]; % All the deinterleaved data
d0_trunc = d0(delayval+1:end); % Remove the delay.
ser = symerr(data,d0_trunc)
```

The output below shows that no symbol errors occurred.

```
ser =

     0
```

helintrlv

Permute symbols using helical array

Syntax

```
intrlved = helintrlv(data,col,ngrp,stp)
[intrlved,state] = helintrlv(data,col,ngrp,stp)
[intrlved,state] = helintrlv(data,col,ngrp,stp,init_state)
```

Description

intrlved = helintrlv(data,col,ngrp,stp) permutes the symbols in data by placing them in an unlimited-row array in helical fashion and then placing rows of the array in the output, intrlved. data must have col*ngrp elements. If data is a matrix with multiple rows and columns, it must have col*ngrp rows, and the function processes the columns independently.

The function uses the array internally for its computations. The array has unlimited rows indexed by 1, 2, 3,..., and col columns. The function partitions col*ngrp symbols from the input into consecutive groups of ngrp symbols. The function places the kth group in the array along column k, starting from row 1+(k-1)*stp. Positions in the array that do not contain input symbols have default values of 0. The function places col*ngrp symbols from the array in the output, intrlved, by reading the first ngrp rows sequentially. Some output symbols are default values of 0 rather than input symbols; similarly, some input symbols are left in the array and do not appear in the output.

[intrlved,state] = helintrlv(data,col,ngrp,stp) returns a structure that holds the final state of the array. state.value stores input symbols that remain in the col columns of the array and do not appear in the output.

[intrlved,state] = helintrlv(data,col,ngrp,stp,init_state) initializes the array with the symbols contained in init_state.value. The structure init_state is typically the state output from a previous call to this same function, and is unrelated to the corresponding deinterleaver. In this syntax, some output symbols are default values of 0, some are input symbols from data, and some are initialization values from init_state.value.

Examples

The example below rearranges the integers from 1 to 24.

```
% Interleave some symbols. Record final state of array.
[i1,state] = helintrlv([1:12]',3,4,1);
% Interleave more symbols, remembering the symbols that
% were left in the array from the earlier command.
i2 = helintrlv([13:24]',3,4,1,state);

disp('Interleaved data:')
disp([i1,i2]')
disp('Values left in array after first interleaving operation:')
state.value{:}
```

During the successive calls to helintrlv, it internally creates the three-column arrays

```
[1  0  0;
 2  5  0;
 3  6  9;
 4  7 10;
 0  8 11;
 0  0 12]
```

and

```
[13  8 11;
 14 17 12;
 15 18 21;
 16 19 22;
  0 20 23;
  0  0 24]
```

In the second array shown above, the 8, 11, and 12 are values left in the array from the previous call to the function. Specifying the `init_state` input in the second call to the function causes it to use those values rather than the default values of 0.

The output from this example is below. (The matrix has been transposed for display purposes.) The interleaved data comes from the top four rows of the three-column arrays shown above. Notice that some of the symbols in the first half of the interleaved data are default values of 0, some of the symbols in the second half of the interleaved data were left in the array from the first call to `helintrlv`, and some of the input symbols (20, 23, and 24) do not appear in the interleaved data at all.

```
Interleaved data:
  Columns 1 through 10

     1     0     0     2     5     0     3     6     9     4
    13     8    11    14    17    12    15    18    21    16

  Columns 11 through 12

     7    10
    19    22

Values left in array after first interleaving operation:

ans =

     []

ans =

     8

ans =

    11    12
```

The example on the reference page for `heldeintrlv` also uses this function.

"Interleaving"

Introduced before R2006a

helscandeintrlv

Restore ordering of symbols in helical pattern

Syntax

```
deintrlvd = helscandeintrlv(data,Nrows,Ncols,hstep)
```

Description

`deintrlvd = helscandeintrlv(data,Nrows,Ncols,hstep)` rearranges the elements in `data` by filling a temporary matrix with the elements in a helical fashion and then sending the matrix contents to the output row by row. `Nrows` and `Ncols` are the dimensions of the temporary matrix. `hstep` is the slope of the diagonal, that is, the amount by which the row index increases as the column index increases by one. `hstep` must be a nonnegative integer less than `Nrows`.

Helical fashion means that the function places input elements along diagonals of the temporary matrix. The number of elements in each diagonal is exactly `Ncols`, after the function wraps past the edges of the matrix when necessary. The function traverses diagonals so that the row index and column index both increase. Each diagonal after the first one begins one row below the first element of the previous diagonal.

If `data` is a vector, it must have `Nrows*Ncols` elements. If `data` is a matrix with multiple rows and columns, `data` must have `Nrows*Ncols` rows and the function processes the columns independently.

To use this function as an inverse of the `helscanintrlv` function, use the same `Nrows`, `Ncols`, and `hstep` inputs in both functions. In that case, the two functions are inverses in the sense that applying `helscanintrlv` followed by `helscandeintrlv` leaves data unchanged.

Examples

Apply Helical Deinterleaving to Integer Row Vector

Apply helical scan deinterleaving to the vector [1:12], rearranging the vector using a 3-by-4 temporary matrix and diagonals of slope 1.

Internally, the `helscandeintrlv` function creates the 3-by-4 temporary matrix using length-four diagonals. As represented here.

```
[1 10  7  4;
 5  2 11  8;
 9  6  3 12]
```

```
ans = 3×4

     1    10     7     4
     5     2    11     8
     9     6     3    12
```

The function then sends the elements, row by row, to the output `d`.

```
d = helscandeintrlv(1:12,3,4,1)
```

```
d = 1×12

     1    10     7     4     5     2    11     8     9     6     3    12
```

"Interleaving"

Introduced before R2006a

helscanintrlv

Reorder symbols in helical pattern

Syntax

```
intrlvd = helscanintrlv(data,Nrows,Ncols,hstep)
```

Description

`intrlvd = helscanintrlv(data,Nrows,Ncols,hstep)` rearranges the elements in `data` by filling a temporary matrix with the elements row by row and then sending the matrix contents to the output in a helical fashion. `Nrows` and `Ncols` are the dimensions of the temporary matrix. `hstep` is the slope of the diagonal, that is, the amount by which the row index increases as the column index increases by one. `hstep` must be a nonnegative integer less than `Nrows`.

Helical fashion means that the function selects elements along diagonals of the temporary matrix. The number of elements in each diagonal is exactly `Ncols`, after the function wraps past the edges of the matrix when necessary. The function traverses diagonals so that the row index and column index both increase. Each diagonal after the first one begins one row below the first element of the previous diagonal.

If `data` is a vector, it must have `Nrows*Ncols` elements. If `data` is a matrix with multiple rows and columns, `data` must have `Nrows*Ncols` rows and the function processes the columns independently.

Examples

The command below rearranges a vector using diagonals of two different slopes.

```
i1 = helscanintrlv(1:12,3,4,1) % Slope of diagonal is 1.
i2 = helscanintrlv(1:12,3,4,2) % Slope of diagonal is 2.
```

The output is below.

```
i1 =

  Columns 1 through 10

     1     6    11     4     5    10     3     8     9     2

  Columns 11 through 12

     7    12

i2 =

  Columns 1 through 10

     1    10     7     4     5     2    11     8     9     6

  Columns 11 through 12
```

```
     3     12
```

In each case, the function internally creates the temporary 3-by-4 matrix

```
[1  2  3  4;
 5  6  7  8;
 9 10 11 12]
```

To form i1, the function forms each slope-one diagonal by moving one row down and one column to the right. The first diagonal contains 1, 6, 11, and 4, while the second diagonal starts with 5 because that is beneath 1 in the temporary matrix.

To form i2, the function forms each slope-two diagonal by moving two rows down and one column to the right. The first diagonal contains 1, 10, 7, and 4, while the second diagonal starts with 5 because that is beneath 1 in the temporary matrix.

hex2poly

Convert hexadecimal character vector to binary coefficients

Syntax

```
b = hex2poly(hex)
b = hex2poly(hex,ord)
```

Description

`b = hex2poly(hex)` converts a hexadecimal character vector, `hex`, to a vector of binary coefficients, `b`.

`b = hex2poly(hex,ord)` specifies the power order, `ord`, of the coefficients that comprise the output. If omitted, `ord` is `'descending'`.

Examples

Convert Hexadecimal Polynomial to Binary Vector

Convert the hexadecimal polynomial `'1AF'` to a vector of binary coefficients. The coefficients represent the polynomial $x^8 + x^7 + x^5 + x^3 + x^2 + x + 1$.

```
b = hex2poly('1AF')
```

```
b = 1×9

     1     1     0     1     0     1     1     1     1
```

Convert Hexadecimal into Ascending Order Binary Vector

Convert hexadecimal `'0x82608EDB'` to a vector of binary coefficients. Specify that the binary coefficients are in ascending order.

```
b = hex2poly('0x82608EDB','ascending')
```

```
b = 1×32

     1     1     0     1     1     0     1     1     0     1     1     1     0     0     0     1
```

The binary representation corresponds to a polynomial of $x^{31} + x^{25} + x^{22} + x^{21} + x^{15} + x^{11} + x^{10} + x^9 + x^7 + x^6 + x^4 + x^3 + x + 1$.

Input Arguments

`hex` — Hexadecimal number

character vector

Hexadecimal number, specified as a character vector.

Example: `'FF'`

Example: `'0x3FA'`

Data Types: `char`

`ord` — Power order

`'descending'` (default) | `'ascending'`

Power order of the vector of binary coefficients, specified as a character vector having a value of `'ascending'` or `'descending'`.

Data Types: `char`

Output Arguments

`b` — Binary coefficients

vector

Binary coefficients representing a polynomial, returned as a row vector having length equal to $p + 1$, where p is the order of hexadecimal input.

`dec2hex` | `oct2poly`

Introduced in R2015b

hilbiir

(To be removed) Design Hilbert transform IIR filter

Compatibility

hilbiir will be removed in a future release. To design a Hilbert transform filter, use the `fdesign.hilbert` object.

Syntax

```
hilbiir
hilbiir(ts)
hilbiir(ts,dly)
hilbiir(ts,dly,bandwidth)
hilbiir(ts,dly,bandwidth,tol)
[num,den] = hilbiir(...)
[num,den,sv] = hilbiir(...)
[a,b,c,d] = hilbiir(...)
[a,b,c,d,sv] = hilbiir(...)
```

Description

The function `hilbiir` designs a Hilbert transform filter. The output is either

- A plot of the filter's impulse response, or
- A quantitative characterization of the filter, using either a transfer function model or a state-space model

Background Information

An ideal Hilbert transform filter has the transfer function `H(s) = -jsgn(s)`, where `sgn(.)` is the signum function (`sign` in MATLAB). The impulse response of the Hilbert transform filter is

$$h(t) = \frac{1}{\pi t}$$

Because the Hilbert transform filter is a noncausal filter, the `hilbiir` function introduces a group delay, `dly`. A Hilbert transform filter with this delay has the impulse response

$$h(t) = \frac{1}{\pi(t - \mathrm{dly})}$$

Choosing a Group Delay Parameter

The filter design is an approximation. If you provide the filter's group delay as an input argument, these two suggestions can help improve the accuracy of the results:

- Choose the sample time `ts` and the filter's group delay `dly` so that `dly` is at least a few times larger than `ts` and `rem(dly,ts) = ts/2`. For example, you can set `ts` to 2*`dly/N`, where `N` is a positive integer.

- At the point t = `dly`, the impulse response of the Hilbert transform filter can be interpreted as `0`, `-Inf`, or `Inf`. If `hilbiir` encounters this point, it sets the impulse response there to zero. To improve accuracy, avoid the point t = `dly`.

Syntaxes for Plots

Each of these syntaxes produces a plot of the impulse response of the filter that the `hilbiir` function designs, as well as the impulse response of a corresponding ideal Hilbert transform filter.

`hilbiir` plots the impulse response of a fourth-order digital Hilbert transform filter with a one-second group delay. The sample time is 2/7 seconds. In this particular design, the tolerance index is 0.05. The plot also displays the impulse response of the ideal Hilbert transform filter with a one-second group delay.

`hilbiir(ts)` plots the impulse response of a fourth-order Hilbert transform filter with a sample time of `ts` seconds and a group delay of `ts*7/2` seconds. The tolerance index is 0.05. The plot also displays the impulse response of the ideal Hilbert transform filter having a sample time of `ts` seconds and a group delay of `ts*7/2` seconds.

`hilbiir(ts,dly)` is the same as the syntax above, except that the filter's group delay is `dly` for both the ideal filter and the filter that `hilbiir` designs. See “Choosing a Group Delay Parameter” on page 2-497 above for guidelines on choosing `dly`.

`hilbiir(ts,dly,bandwidth)` is the same as the syntax above, except that `bandwidth` specifies the assumed bandwidth of the input signal and that the filter design might use a compensator for the input signal. If `bandwidth` = 0 or `bandwidth` > 1/(2*`ts`), `hilbiir` does not use a compensator.

`hilbiir(ts,dly,bandwidth,tol)` is the same as the syntax above, except that `tol` is the tolerance index. If `tol` < 1, the order of the filter is determined by

$$\frac{\text{truncated-singular-value}}{\text{maximum-singular-value}} < \text{tol}$$

If `tol` > 1, the order of the filter is `tol`.

Syntaxes for Transfer Function and State-Space Quantities

Each of these syntaxes produces quantitative information about the filter that `hilbiir` designs, but does *not* produce a plot. The input arguments for these syntaxes (if you provide any) are the same as those described in “Syntaxes for Plots” on page 2-498.

`[num,den] = hilbiir(...)` outputs the numerator and denominator of the IIR filter's transfer function.

`[num,den,sv] = hilbiir(...)` outputs the numerator and denominator of the IIR filter's transfer function, and the singular values of the Hankel matrix that `hilbiir` uses in the computation.

`[a,b,c,d] = hilbiir(...)` outputs the discrete-time state-space model of the designed Hilbert transform filter. `a`, `b`, `c`, and `d` are matrices.

`[a,b,c,d,sv] = hilbiir(...)` outputs the discrete-time state-space model of the designed Hilbert transform filter, and the singular values of the Hankel matrix that `hilbiir` uses in the computation.

Examples

For an example using the function's default values, type one of the following commands at the MATLAB prompt.

```
hilbiir
[num,den] = hilbiir
```

Algorithms

The `hilbiir` function calculates the impulse response of the ideal Hilbert transform filter response with a group delay. It fits the response curve using a singular-value decomposition method. See the book by Kailath [1].

Compatibility Considerations

`hilbiir` will be removed in a future release.

Not recommended starting in R2020b

hilbiir will be removed in a future release. To design Hilbert transform IIR filter, use the `fdesign.hilbert` object.

huffmandeco

Decode binary code by Huffman decoding

Syntax

```
sig = huffmandeco(code,dict)
```

Description

`sig = huffmandeco(code,dict)` decodes the numeric Huffman code vector, `code`, by using the Huffman codes described by input code dictionary `dict`. Input `dict` is an *N*-by-2 cell array, where *N* is the number of distinct possible symbols in the original signal that encodes `code`. The first column of `dict` represents the distinct symbols, and the second column represents the corresponding codewords. Each codeword is represented as a numeric row vector, and no codeword in `dict` can be the prefix of any other codeword in `dict`. You can generate `dict` by using the `huffmandict` function and `code` by using the `huffmanenco` function. If all symbols in `dict` are numeric, output `sig` is a vector. If any symbol in `dict` is alphabetic, `sig` is a one-dimensional cell array.

Examples

Huffman Encoding and Decoding

Create unique symbols, and assign probabilities of occurrence to them.

```
symbols = 1:6;
p = [.5 .125 .125 .125 .0625 .0625];
```

Create a Huffman dictionary based on the symbols and their probabilities.

```
dict = huffmandict(symbols,p);
```

Generate a vector of random symbols.

```
inputSig = randsrc(100,1,[symbols;p]);
```

Encode the random symbols.

```
code = huffmanenco(inputSig,dict);
```

Decode the data. Verify that the decoded symbols match the original symbols.

```
sig = huffmandeco(code,dict);
isequal(inputSig,sig)
```

```
ans = logical
   1
```

Convert the original signal to a binary, and determine the length of the binary symbols.

```
binarySig = de2bi(inputSig);
seqLen = numel(binarySig)
seqLen = 300
```

Convert the Huffman-encoded symbols to binary, and determine the length of the encoded binary symbols.

```
binaryComp = de2bi(code);
encodedLen = numel(binaryComp)
```

```
encodedLen = 224
```

Huffman Encoding and Decoding with Alphanumeric Signal

Define the alphanumeric symbols in cell array form.

```
inputSig = {'a2',44,'a3',55,'a1'}
```

```
inputSig=1×5 cell array
    {'a2'}    {[44]}    {'a3'}    {[55]}    {'a1'}
```

Define a Huffman dictionary. Codes for signal letters must be numeric.

```
dict = {'a1',0; 'a2',[1,0]; 'a3',[1,1,0]; 44,[1,1,1,0]; 55,[1,1,1,1]}
```

```
dict=5×2 cell array
    {'a1'}    {[       0]}
    {'a2'}    {1x2 double}
    {'a3'}    {1x3 double}
    {[44]}    {1x4 double}
    {[55]}    {1x4 double}
```

Encode the alphanumeric symbols.

```
enco = huffmanenco(inputSig,dict);
```

Decode the data. Verify that the decoded symbols match the original symbols.

```
sig = huffmandeco(enco,dict)
```

```
sig=1×5 cell array
    {'a2'}    {[44]}    {'a3'}    {[55]}    {'a1'}
```

```
isequal(inputSig,sig)
```

```
ans = logical
   1
```

Input Arguments

code — Huffman code
numeric vector

Huffman code, specified as a numeric vector. This value must be a Huffman code encoded using a code dictionary produced by the `huffmandict` function.

Data Types: `double`

`dict` — Huffman code dictionary
N-by-2 cell array

Huffman code dictionary, specified as an *N*-by-2 cell array. *N* is the number of distinct possible symbols for the function to encode. The first column of `dict` represents the distinct symbols, and the second column represents the corresponding codewords. Each codeword is represented as a numeric row vector, and no codeword in `dict` can be the prefix of any other codeword in `dict`. You can generate `dict` by using the `huffmandict` function.

Data Types: `double` | `cell`

Output Arguments

`sig` — Decoded signal
numeric vector | numeric cell array | alphanumeric cell array

Decoded signal, returned as a numeric vector, numeric cell array, or alphanumeric cell array.

- If all symbols in input code dictionary `dict` are numeric, `sig` is a vector.
- If any symbol in input code dictionary `dict` is alphabetic, `sig` is a one-dimensional cell array.

huffmandict

Generate Huffman code dictionary for source with known probability model

Syntax

```
[dict,avglen] = huffmandict(symbols,prob)
[dict,avglen] = huffmandict(symbols,prob,N)
[dict,avglen] = huffmandict(symbols,prob,N,variance)
```

Description

`[dict,avglen] = huffmandict(symbols,prob)` generates a binary Huffman code dictionary, `dict`, for the source symbols, `symbols`, by using the maximum variance algorithm. The input `prob` specifies the probability of occurrence for each of the input symbols. The length of `prob` must equal the length of `symbols`. The function also returns average codeword length `avglen` of the dictionary, weighted according to the probabilities in the input `prob`.

`[dict,avglen] = huffmandict(symbols,prob,N)` generates an `N`-ary Huffman code dictionary using maximum variance algorithm. `N` must not exceed the number of source symbols.

`[dict,avglen] = huffmandict(symbols,prob,N,variance)` generates an `N`-ary Huffman code dictionary with the specified variance.

Examples

Generate Huffman Code and View Results

Generate a binary Huffman code dictionary, additionally returning the average code length.

Specify a symbol alphabet vector and a symbol probability vector.

```
symbols = (1:5); % Alphabet vector
prob = [.3 .3 .2 .1 .1]; % Symbol probability vector
```

Generate a binary Huffman code, displaying the average code length and the cell array containing the codeword dictionary.

```
[dict,avglen] = huffmandict(symbols,prob)
```

```
dict=5×2 cell array
    {[1]}    {1x2 double}
    {[2]}    {1x2 double}
    {[3]}    {1x2 double}
    {[4]}    {1x3 double}
    {[5]}    {1x3 double}

avglen = 2.2000
```

Display the fifth codeword from the dictionary.

```
samplecode = dict{5,2} % Codeword for fifth signal value
```

```
samplecode = 1×3

     1     1     0
```

Generate Ternary Huffman Codes

Use the code dictionary generator for Huffman coder function to generate binary and ternary Huffman codes.

Specify a symbol alphabet vector and a symbol probability vector.

```
symbols = (1:5); % Alphabet vector
prob = [.3 .3 .2 .1 .1]; % Symbol probability vector
```

Generate a binary Huffman code, displaying the cell array containing the codeword dictionary.

```
[dict,avglen] = huffmandict(symbols,prob);
dict(:,2) = cellfun(@num2str,dict(:,2),'UniformOutput',false)
```

```
dict=5×2 cell array
    {[1]}    {'0  1'   }
    {[2]}    {'0  0'   }
    {[3]}    {'1  0'   }
    {[4]}    {'1  1  1'}
    {[5]}    {'1  1  0'}
```

Generate a ternary Huffman code with minimum variance.

```
[dict,avglen] = huffmandict(symbols,prob,3,'min');
dict(:,2) = cellfun(@num2str,dict(:,2),'UniformOutput',false)
```

```
dict=5×2 cell array
    {[1]}    {'2'   }
    {[2]}    {'1'   }
    {[3]}    {'0  0'}
    {[4]}    {'0  2'}
    {[5]}    {'0  1'}
```

Input Arguments

`symbols` — Source symbols

vector | cell array | alphanumeric cell array

Source symbols, specified as a vector, cell array, or an alphanumeric cell array. `symbols` lists the distinct signal values that the source produces. If `symbols` is a cell array, it must be a 1-by-*S* or *S*-by-1 cell array, where *S* is the number of symbols.

Data Types: `double` | `cell`

`prob` — Probability of occurrence

vector in the range [0, 1]

Probability of occurrence for each symbol, specified as a vector in the range [0, 1]. The elements of this vector must sum to 1. The length this vector must equal the length of input `symbols`.

Data Types: `double`

`N` — N-ary Huffman code dictionary

scalar in the range [2, 10]

N-ary Huffman code dictionary, specified as a scalar in the range [2, 10]. This value must be less than or equal to the length of input `symbols`.

Data Types: `double`

`variance` — Variance for Huffman code

`'min'` | `'max'`

Variance for Huffman code, specified as one of these values.

- `'min'` — This function generates `N`-ary Huffman code dictionary with the minimum variance. If you do not specify the variance input argument, the function uses this case.
- `'max'` — This function generates `N`-ary Huffman code dictionary with the maximum variance.

Data Types: `char`

Output Arguments

`dict` — Huffman code dictionary

two-column cell array

Huffman code dictionary, returned as a two-column cell array. The first column lists the distinct signal values from input `symbols`. The second column corresponds to Huffman codewords, where each Huffman codeword is represented as a row vector. If you specify the input argument `N`, the function returns dict as an `N`-ary Huffman code dictionary.

Data Types: `double` | `cell`

`avglen` — Average codeword length

positive scalar

Average codeword length, weighted according to the probabilities in the input `prob`, returned as a positive scalar.

Data Types: `double`

Topics
“Huffman Coding”

Introduced before R2006a

huffmanenco

Encode sequence of symbols by Huffman encoding

Syntax

```
code = huffmanenco(sig,dict)
```

Description

`code = huffmanenco(sig,dict)` encodes input signal `sig` using the Huffman codes described by input code dictionary `dict`. `sig` can have the form of a vector, cell array, or alphanumeric cell array. If `sig` is a cell array, it must be either a row or a column. `dict` is an N-by-2 cell array, where *N* is the number of distinct possible symbols to encode. The first column of `dict` represents the distinct symbols and the second column represents the corresponding codewords. Each codeword is represented as a row vector, and no codeword in `dict` can be the prefix of any other codeword in `dict`. You can generate `dict` using the `huffmandict` function.

Examples

Huffman Encoding and Decoding

Create unique symbols, and assign probabilities of occurrence to them.

```
symbols = 1:6;
p = [.5 .125 .125 .125 .0625 .0625];
```

Create a Huffman dictionary based on the symbols and their probabilities.

```
dict = huffmandict(symbols,p);
```

Generate a vector of random symbols.

```
inputSig = randsrc(100,1,[symbols;p]);
```

Encode the random symbols.

```
code = huffmanenco(inputSig,dict);
```

Decode the data. Verify that the decoded symbols match the original symbols.

```
sig = huffmandeco(code,dict);
isequal(inputSig,sig)
```

```
ans = logical
   1
```

Convert the original signal to a binary, and determine the length of the binary symbols.

```
binarySig = de2bi(inputSig);
seqLen = numel(binarySig)
seqLen = 300
```

Convert the Huffman-encoded symbols to binary, and determine the length of the encoded binary symbols.

```
binaryComp = de2bi(code);
encodedLen = numel(binaryComp)
```

```
encodedLen = 224
```

Huffman Encoding and Decoding with Alphanumeric Signal

Define the alphanumeric symbols in cell array form.

```
inputSig = {'a2',44,'a3',55,'a1'}
```

```
inputSig=1×5 cell array
    {'a2'}    {[44]}    {'a3'}    {[55]}    {'a1'}
```

Define a Huffman dictionary. Codes for signal letters must be numeric.

```
dict = {'a1',0; 'a2',[1,0]; 'a3',[1,1,0]; 44,[1,1,1,0]; 55,[1,1,1,1]}
```

```
dict=5×2 cell array
    {'a1'}    {[       0]}
    {'a2'}    {1x2 double}
    {'a3'}    {1x3 double}
    {[44]}    {1x4 double}
    {[55]}    {1x4 double}
```

Encode the alphanumeric symbols.

```
enco = huffmanenco(inputSig,dict);
```

Decode the data. Verify that the decoded symbols match the original symbols.

```
sig = huffmandeco(enco,dict)
```

```
sig=1×5 cell array
    {'a2'}    {[44]}    {'a3'}    {[55]}    {'a1'}
```

```
isequal(inputSig,sig)
```

```
ans = logical
   1
```

Input Arguments

sig — Input signal
vector | cell array | alphanumeric cell array

Input signal for the compression, specified as a vector, cell array, or an alphanumeric cell array. `sig` can have the form of a vector, cell array, or alphanumeric cell array. If `sig` is a cell array, it must be a 1-by-*S* or *S*-by-1 cell array, where *S* is the number of symbols.

Data Types: `double` | `cell`

`dict` — Huffman code dictionary
N-by-2 cell array

Huffman code dictionary, specified as an *N*-by-2 cell array. *N* is the number of distinct possible symbols for the function to encode. The first column of dict represents the distinct symbols and the second column represents the corresponding codewords. Each codeword is represented as a row vector, and no codeword in dict can be the prefix of any other codeword in dict. You can generate dict by using the `huffmandict` function.

Data Types: `double` | `cell`

Output Arguments

`code` — Encoded signal
vector

Encoded signal for the input Huffman code dictionary `dict`, returned as a vector.

Functions
`huffmandeco` | `huffmandict`

Topics
“Huffman Coding”

Introduced before R2006a

ifft

Inverse discrete Fourier transform

Syntax

```
ifft(x)
```

Description

`ifft(x)` is the inverse discrete Fourier transform (DFT) of the Galois vector `x`. If `x` is in the Galois field GF(2^m), the length of `x` must be 2^m-1.

Examples

For an example using `ifft`, see the reference page for `fft`.

Limitations

The Galois field over which this function works must have 256 or fewer elements. In other words, `x` must be in the Galois field GF(2^m), where m is an integer between 1 and 8.

Algorithms

If `x` is a column vector, `ifft` applies `dftmtx` to the multiplicative inverse of the primitive element of the Galois field and multiplies the resulting matrix by `x`.

`dftmtx` | `fft` | `gf`

Topics

"Signal Processing Operations in Galois Fields"

Introduced before R2006a

intdump

Integrate and dump

Syntax

```
y = intdump(x,nsamp)
```

Description

`y = intdump(x,nsamp)` integrates the signal `x` for one symbol period, then outputs the averaged one value into `Y`. `nsamp` is the number of samples per symbol. For two-dimensional signals, the function treats each column as one channel.

Examples

An example in “Combine Pulse Shaping and Filtering with Modulation” uses this function in conjunction with modulation.

Processes two independent channels, each of which contain three symbols of data made up of four samples.

```
s = rng;
rng(68521);
nsamp = 4; % Number of samples per symbol
ch1 = randi([0 1],3*nsamp,1); % Random binary channel
ch2 = rectpulse([1 2 3]',nsamp); % Rectangular pulses
x = [ch1 ch2]; % Two-channel signal
y = intdump(x,nsamp)
rng(s);
```

The output is below. Each column corresponds to one channel, and each row corresponds to one symbol.

```
y =

    0.5000    1.0000
    0.5000    2.0000
    1.0000    3.0000
```

See Also

`rectpulse`

Introduced before R2006a

intrlv

Reorder sequence of symbols

Syntax

```
intrlvd = intrlv(data,elements)
```

Description

`intrlvd = intrlv(data,elements)` rearranges the elements of `data` without repeating or omitting any elements. If `data` is a length-N vector or an N-row matrix, `elements` is a length-N vector that permutes the integers from 1 to N. The sequence in `elements` is the sequence in which elements from `data` or its columns appear in `intrlvd`. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

Examples

Apply Interleaving to Reorder Input Vector

Use the `intrlv` function to rearrange the elements of a vector to a random permutation determined by the `randperm` function.

```
p = randperm(10); % Permutation vector
a = intrlv(10:10:100,p)
```

```
a = 1×10

    60    30    70    80    50    10    20    40    90   100
```

The command below rearranges each of two columns of a matrix.

```
b = intrlv([.1 .2 .3 .4 .5; .2 .4 .6 .8 1]',[2 4 3 5 1])
```

```
b = 5×2

    0.2000    0.4000
    0.4000    0.8000
    0.3000    0.6000
    0.5000    1.0000
    0.1000    0.2000
```

Apply Interleaving to Reorder Input Matrix

Use the `intrlv` function to rearrange the elements of a matrix to a specified order.

Each column of the matrix applies the same reordering.

```
b = intrlv([.1 .2 .3 .4 .5; .2 .4 .6 .8 1]',[2 4 3 5 1])
```

```
b = 5×2

    0.2000    0.4000
    0.4000    0.8000
    0.3000    0.6000
    0.5000    1.0000
    0.1000    0.2000
```

Extended Capabilities

Topics

"Interleaving"

Introduced before R2006a

iqcoef2imbal

Convert compensator coefficient to amplitude and phase imbalance

Syntax

```
[A,P] = iqcoef2imbal(C)
```

Description

`[A,P] = iqcoef2imbal(C)` converts compensator coefficient `C` to its equivalent amplitude and phase imbalance.

Examples

Estimate I/Q Imbalance from Compensator Coefficient

Use `iqcoef2imbal` to estimate the amplitude and phase imbalance for a given complex coefficient. The coefficients are an output from the `step` function of the `IQImbalanceCompensator`.

Create a raised cosine transmit filter to generate a 64-QAM signal.

```
M = 64;
txFilt = comm.RaisedCosineTransmitFilter;
```

Modulate and filter random 64-ary symbols.

```
data = randi([0 M-1],100000,1);
dataMod = qammod(data,M);
txSig = step(txFilt,dataMod);
```

Specify amplitude and phase imbalance.

```
ampImb = 2; % dB
phImb = 15; % degrees
```

Apply the specified I/Q imbalance.

```
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(txSig)*gainI*exp(-0.5i*phImb*pi/180);
imbQ = imag(txSig)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));
rxSig = imbI + imbQ;
```

Normalize the power of the received signal

```
rxSig = rxSig/std(rxSig);
```

Remove the I/Q imbalance using the `comm.IQImbalanceCompensator` System object. Set the compensator object such that the complex coefficients are made available as an output argument.

```
hIQComp = comm.IQImbalanceCompensator('CoefficientOutputPort',true);
[compSig,coef] = step(hIQComp,rxSig);
```

Estimate the imbalance from the last value of the compensator coefficient.

```
[ampImbEst,phImbEst] = iqcoef2imbal(coef(end));
```

Compare the estimated imbalance values with the specified ones. Notice that there is good agreement.

```
[ampImb phImb; ampImbEst phImbEst]
```

```
ans = 2×2

    2.0000   15.0000
    2.0178   14.5740
```

Input Arguments

C — Compensator coefficient

complex-valued scalar or vector

Coefficient used to compensate for an I/Q imbalance, specified as a complex-valued vector.

Example: `0.4+0.6i`

Example: `[0.1+0.2i; 0.3+0.5i]`

Data Types: `single` | `double`

Output Arguments

A — Amplitude imbalance

real-valued vector

Amplitude imbalance in dB, returned as a real-valued vector with the same dimensions as `C`.

P — Phase imbalance

real-valued vector

Phase imbalance in degrees, returned as a real-valued vector with the same dimensions as `C`.

More About

I/Q Imbalance Compensation

The function `iqcoef2imbal` is a supporting function for the `comm.IQImbalanceCompensator` System object.

Given a scaling and rotation factor, *G*, compensator coefficient, *C*, and received signal, *x*, the compensated signal, *y*, has the form

$$y = G[x + C\mathrm{conj}(x)]\ .$$

In matrix form, this can be rewritten as

$$\mathbf{Y} = \mathbf{R}\mathbf{X}\,,$$

where **X** is a 2-by-1 vector representing the imbalanced signal [X_I, X_Q] and **Y** is a 2-by-1 vector representing the compensator output [Y_I, Y_Q].

The matrix **R** is expressed as

$$\mathbf{R} = \begin{bmatrix} 1+\mathrm{Re}\{C\} & \mathrm{Im}\{C\} \\ \mathrm{Im}\{C\} & 1-\mathrm{Re}\{C\} \end{bmatrix}$$

For the compensator to perfectly remove the I/Q imbalance, **R** = **K**$^{-1}$ because **X = K S**, where **K** is a 2-by-2 matrix whose values are determined by the amplitude and phase imbalance and **S** is the ideal signal. Define a matrix **M** with the form

$$\mathbf{M} = \begin{bmatrix} 1 & -\alpha \\ \alpha & 1 \end{bmatrix}$$

Both **M** and **M**$^{-1}$ can be thought of as scaling and rotation matrices that correspond to the factor *G*. Because **K** = **R**$^{-1}$, the product **M**$^{-1}$ **R K M** is the identity matrix, where **M**$^{-1}$ **R** represents the compensator output and **K M** represents the I/Q imbalance. The coefficient α is chosen such that

$$\mathbf{KM} = L\begin{bmatrix} I_{gain}\cos(\theta_I) & Q_{gain}\cos(\theta_Q) \\ I_{gain}\sin(\theta_I) & Q_{gain}\sin(\theta_Q) \end{bmatrix}$$

where *L* is a constant. From this form, we can obtain I_{gain}, Q_{gain}, θ_I, and θ_Q. For a given phase imbalance, Φ_{Imb}, the in-phase and quadrature angles can be expressed as

$$\theta_I = -(\pi/2)(\Phi_{Imb}/180)$$
$$\theta_Q = \pi/2 + (\pi/2)(\Phi_{Imb}/180)$$

Hence, $\cos(\theta_Q) = \sin(\theta_I)$ and $\sin(\theta_Q) = \cos(\theta_I)$ so that

$$L\begin{bmatrix} I_{gain}\cos(\theta_I) & Q_{gain}\cos(\theta_Q) \\ I_{gain}\sin(\theta_I) & Q_{gain}\sin(\theta_Q) \end{bmatrix} = L\begin{bmatrix} I_{gain}\cos(\theta_I) & Q_{gain}\sin(\theta_I) \\ I_{gain}\sin(\theta_I) & Q_{gain}\cos(\theta_I) \end{bmatrix}$$

The I/Q imbalance can be expressed as

$$\mathbf{KM} = \begin{bmatrix} K_{11}+\alpha K_{12} & -\alpha K_{11}+K_{12} \\ K_{21}+\alpha K_{22} & -\alpha K_{21}+K_{22} \end{bmatrix}$$
$$= L\begin{bmatrix} I_{gain}\cos(\theta_I) & Q_{gain}\sin(\theta_I) \\ I_{gain}\sin(\theta_I) & Q_{gain}\cos(\theta_I) \end{bmatrix}$$

Therefore,

$$(K_{21}+\alpha K_{22})/(K_{11}+\alpha K_{12}) = (-\alpha K_{11}+K_{12})/(-\alpha K_{21}+K_{22}) = \sin(\theta_I)/\cos(\theta_I)$$

The equation can be written as a quadratic equation to solve for the variable α, that is $D_1\alpha^2 + D_2\alpha + D_3 = 0$, where

$$D_1 = -K_{11}K_{12} + K_{22}K_{21}$$
$$D_2 = K_{12}^2 + K_{21}^2 - K_{11}^2 - K_{22}^2$$
$$D_3 = K_{11}K_{12} - K_{21}K_{22}$$

When $|C| \leq 1$, the quadratic equation has the following solution:

$$\alpha = \frac{-D_2 - \sqrt{D^2 - 4D_1D_3}}{2D_1}$$

Otherwise, when $|C| > 1$, the solution has the following form:

$$\alpha = \frac{-D_2 + \sqrt{D^2 - 4D_1D_3}}{2D_1}$$

Finally, the amplitude imbalance, A_{Imb}, and the phase imbalance, Φ_{Imb}, are obtained.

$$\mathbf{K}' = \mathbf{K}\begin{bmatrix} 1 & -\alpha \\ \alpha & 1 \end{bmatrix}$$

$$A_{Imb} = 20\log_{10}(K'_{11}/K'_{22})$$

$$\Phi_{Imb} = -2\tan^{-1}(K'_{21}/K'_{11})(180/\pi)$$

Note

- If C is real and $|C| \leq 1$, the phase imbalance is 0 and the amplitude imbalance is $20\log_{10}((1–C)/(1+C))$
- If C is real and $|C| > 1$, the phase imbalance is 180° and the amplitude imbalance is $20\log_{10}((C+1)/(C-1))$.
- If C is imaginary, $A_{Imb} = 0$.

Functions

`iqimbal` | `iqimbal2coef`

Objects

`comm.IQImbalanceCompensator`

Introduced in R2014b

iqimbal2coef

Convert I/Q imbalance to compensator coefficient

Syntax

```
C = iqimbal2coef(A,P)
```

Description

`C = iqimbal2coef(A,P)` converts an I/Q amplitude and phase imbalance to its equivalent compensator coefficient.

Examples

Generate Coefficients for I/Q Imbalance Compensation

Generate coefficients for the I/Q imbalance compensator System object™ using `iqimbal2coef`. The compensator corrects for an I/Q imbalance using the generated coefficients.

Create a raised cosine transmit filter System object.

```
txRCosFilt = comm.RaisedCosineTransmitFilter;
```

Modulate and filter random 64-ary symbols.

```
M= 64;
data = randi([0 M-1],100000,1);
dataMod = qammod(data,M);
txSig = txRCosFilt(dataMod);
```

Specify amplitude and phase imbalance.

```
ampImb = 2; % dB
phImb = 15; % degrees
```

Apply the specified I/Q imbalance.

```
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(txSig)*gainI*exp(-0.5i*phImb*pi/180);
imbQ = imag(txSig)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));
rxSig = imbI + imbQ;
```

Normalize the power of the received signal.

```
rxSig = rxSig/std(rxSig);
```

Remove the I/Q imbalance by creating and applying a `comm.IQImbalanceCompensator` object. Set the compensator such that the complex coefficients are made available as an output argument.

```
iqComp = comm.IQImbalanceCompensator('CoefficientOutputPort',true);
[compSig,coef] = iqComp(rxSig);
```

Compare the final compensator coefficient to the coefficient generated by the `iqimbal2coef` function. Observe that there is good agreement.

```
idealcoef = iqimbal2coef(ampImb,phImb);
[coef(end); idealcoef]
```

```
ans = 2×1 complex

  -0.1137 + 0.1296i
  -0.1126 + 0.1334i
```

Input Arguments

`A` — Amplitude imbalance

real-valued scalar or vector

Amplitude imbalance in dB, specified as a real-valued row or column vector.

Example: `3`

Example: `[0; 5]`

Data Types: `double`

`P` — Phase imbalance

real-valued scalar or vector

Phase imbalance in degrees, specified as a real-valued row or column vector.

Example: `10`

Example: `[15; 45]`

Data Types: `double`

Output Arguments

`C` — Compensator coefficient

complex-valued vector

Coefficient that perfectly compensates for the I/Q imbalance, returned as a complex-valued vector having the same dimensions as `A` and `P`.

More About

I/Q Imbalance Compensation

The function `iqimbal2coef` is a supporting function for the `comm.IQImbalanceCompensator` System object.

Define **S** and **X** as 2-by-1 vectors representing the I and Q components of the ideal and I/Q imbalanced signals, respectively.

$$\mathbf{X} = \mathbf{K} \cdot \mathbf{S}$$

where **K** is a 2-by-2 matrix whose values are determined by the amplitude imbalance, *A*, and phase imbalance, *P*. *A* is expressed in dB and *P* is expressed in degrees.

The imbalance can be expressed as:

$$I_{gain} = 10^{0.5A/20}$$

$$Q_{gain} = 10^{-0.5A/20}$$

$$\theta_i = -\left(\frac{P}{2}\right)\left(\frac{\pi}{180}\right)$$

$$\theta_q = \frac{\pi}{2} + \left(\frac{P}{2}\right)\left(\frac{\pi}{180}\right)$$

Then **K** has the form:

$$\mathbf{K} = \begin{bmatrix} I_{gain}\cos(\theta_i) & Q_{gain}\cos(\theta_q) \\ I_{gain}\sin(\theta_i) & Q_{gain}\sin(\theta_q) \end{bmatrix}$$

The vector **Y** is defined as the I/Q imbalance compensator output.

$$\mathbf{Y} = \mathbf{R} \cdot \mathbf{X}$$

For the compensator to perfectly remove the I/Q imbalance, **R** must be the matrix inversion of **K**, namely:

$$\mathbf{R} = \mathbf{K}^{-1}$$

Using complex notation, the vector **Y** can be rewritten as:

$$\begin{aligned} y &= w_1 x + w_2 \text{conj}(x) \\ &= w_1\left(x + \left({}^{w_2}\!/\!{}_{w_1}\right)\text{conj}(x)\right) \end{aligned}$$

where,

$$\text{Re}\{w_1\} = (R_{11} + R_{22})/2$$

$$\text{Im}\{w_1\} = (R_{21} - R_{12})/2$$

$$\text{Re}\{w_2\} = (R_{11} - R_{22})/2$$

$$\text{Im}\{w_2\} = (R_{21} + R_{12})/2$$

The output of the function is w_2/w_1. To exactly obtain the original signal, the compensator output needs to be scaled and rotated by the complex number w_1.

Note There are cases for which the output of `iqimbal2coef` is unreliable.

- If the phase imbalance is ±90°, the in-phase and quadrature components will become co-linear; consequently, the I/Q imbalance cannot be compensated.
- If the amplitude imbalance is 0 dB and the phase imbalance is 180°, $w_1 = 0$ and $w_2 = 1i$; therefore, the compensator takes the form of $y = 1i{*}\text{conj}(x)$.

Functions

`iqcoef2imbal` | `iqimbal`

Objects

`comm.IQImbalanceCompensator`

Introduced in R2014b

iqimbal

Apply I/Q imbalance to input signal

Syntax

```
y = iqimbal(x,A)
y = iqimbal(x,A,P)
```

Description

`y = iqimbal(x,A)` applies I/Q amplitude imbalance `A` to input signal `x`.

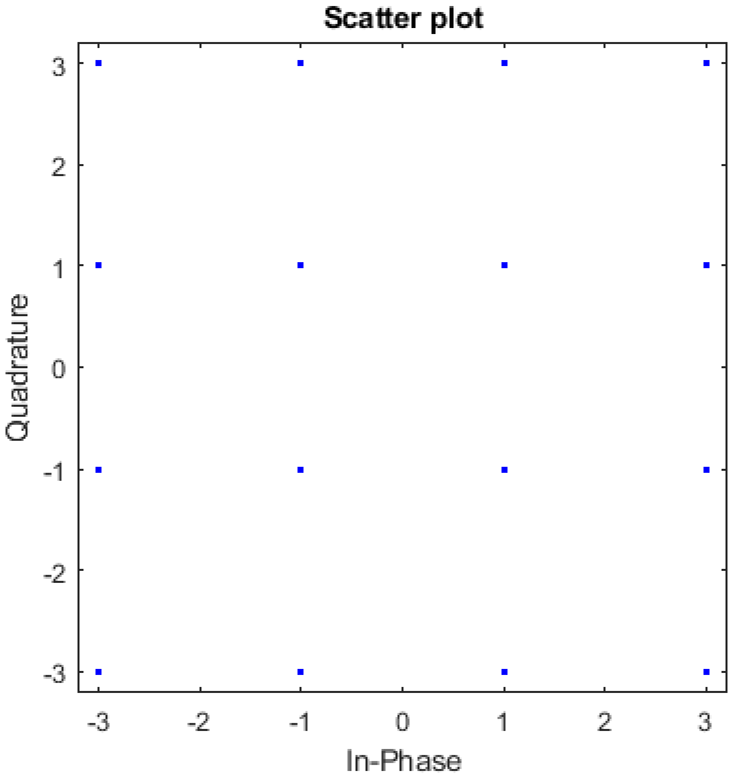
`y = iqimbal(x,A,P)` applies I/Q amplitude imbalance `A` and phase imbalance `P` to input signal `x`.

Examples

Apply Amplitude Imbalance to 16-QAM

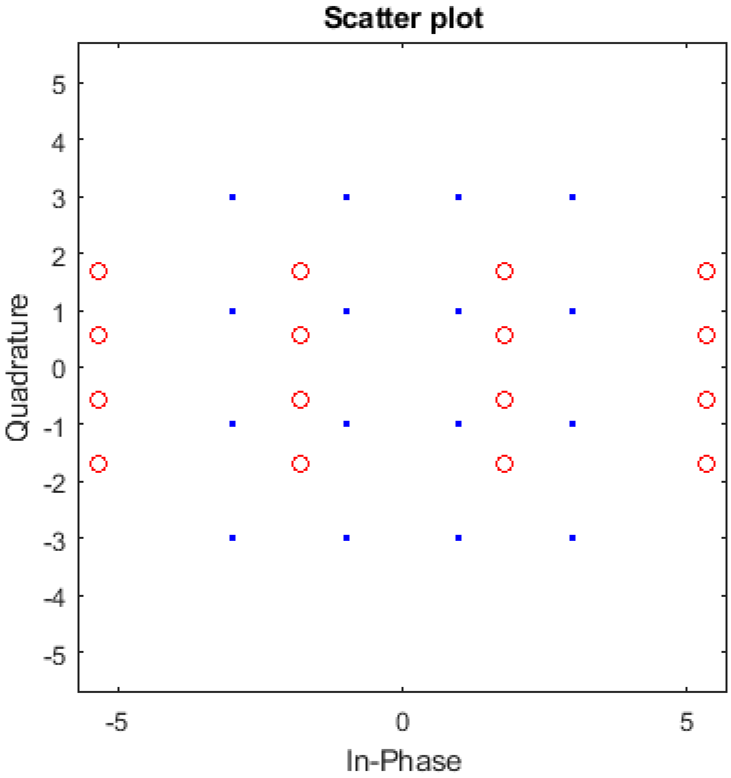
Generate a 16-QAM signal. Display the scatter plot.

```
x = qammod(randi([0 15],1000,1),16);
h = scatterplot(x);
hold on
```



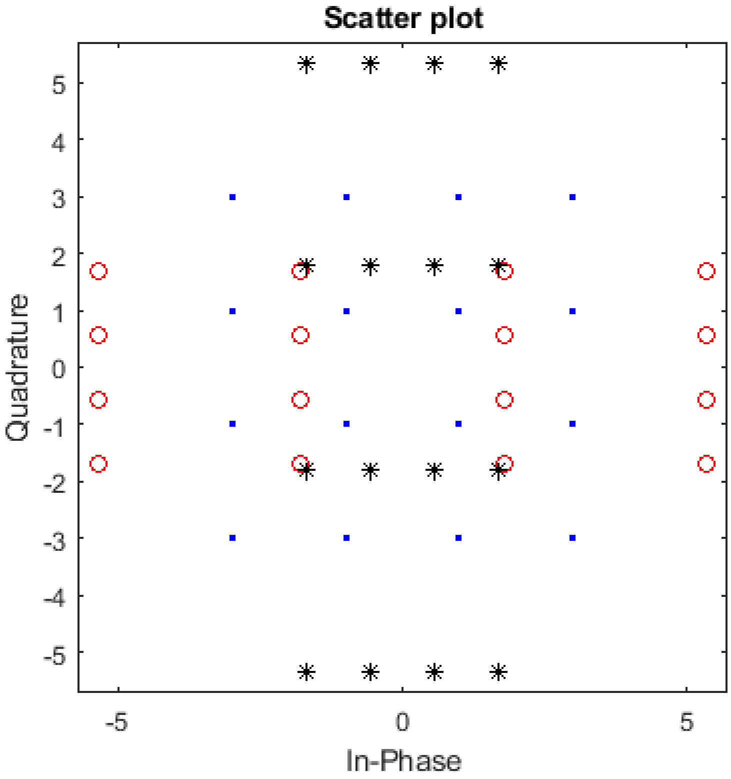
Apply a 10 dB amplitude imbalance. A positive amplitude imbalance causes horizontal stretching of the constellation.

```
y = iqimbal(x,10);
scatterplot(y,1,0,'ro',h)
```



Apply a -10 dB amplitude imbalance. A negative amplitude imbalance causes vertical stretching of the constellation.

```
z = iqimbal(x,-10);
scatterplot(z,1,0,'k*',h)
hold off
```



Apply Phase and Amplitude Imbalance to 16-QAM Signal

Generate a 16-QAM signal having two channels.

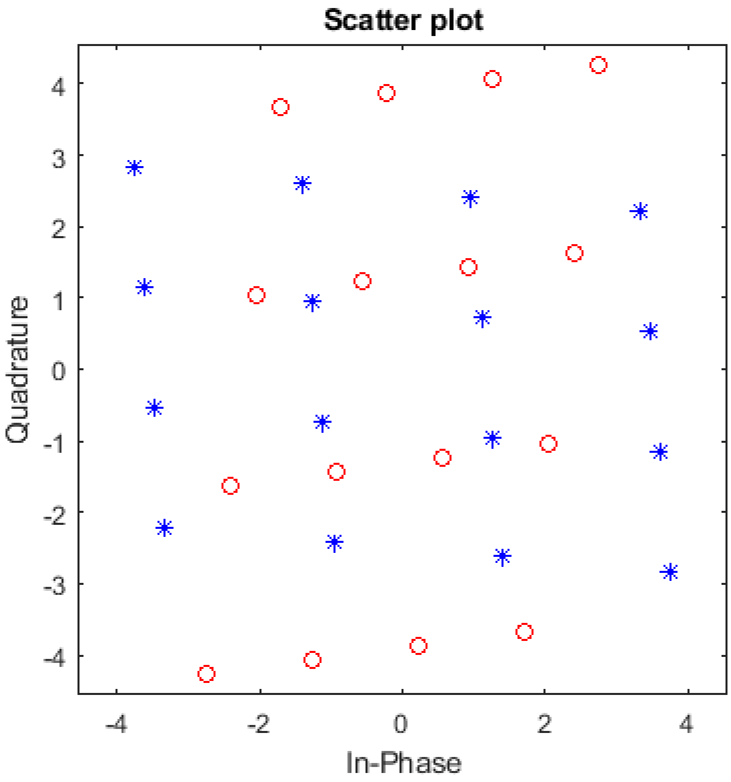
```
x = qammod(randi([0 15],1000,2),16);
```

Apply a 3 dB amplitude imbalance and a 10 degree phase imbalance to the first channel. Apply a –5 dB amplitude imbalance and a –15 degree phase imbalance to the second channel.

```
y = iqimbal(x,[3 -5],[10 -15]);
```

Plot the constellation diagram of both channels of the impaired signal.

```
h = scatterplot(y(:,1),1,0,'b*');
hold on
scatterplot(y(:,2),1,0,'ro',h)
hold off
```



The first channel is stretched horizontally, and the second channel is stretched vertically.

Apply I/Q Imbalance and DC Offset to QPSK

Apply a 1 dB, 5 degree I/Q imbalance to a QPSK signal. Then apply a DC offset. Visualize the offset using a spectrum analyzer.

Generate a QPSK sequence.

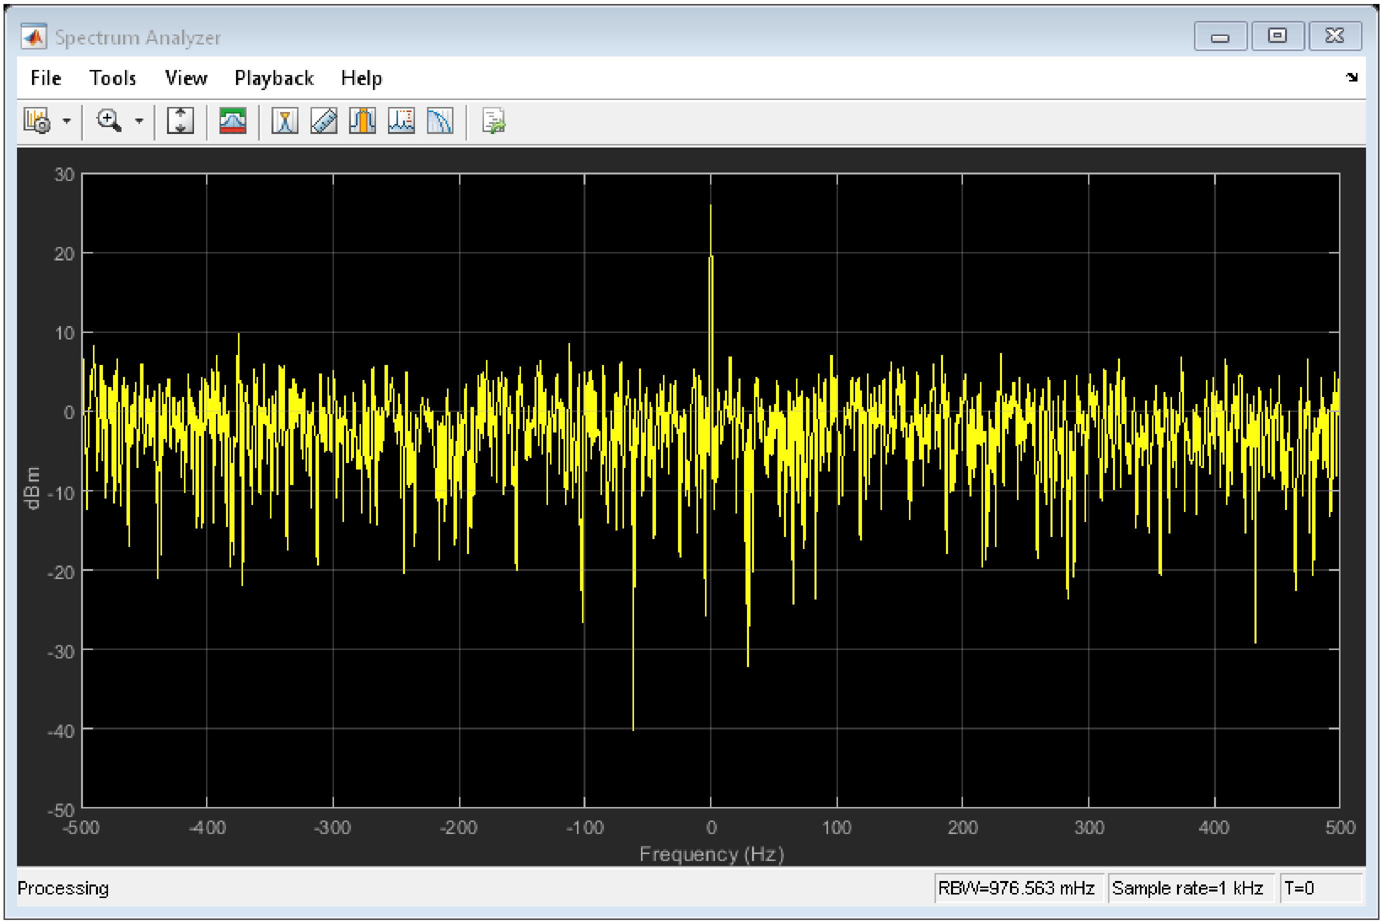
```
x = pskmod(randi([0 3],1e4,1),4,pi/4);
```

Apply a 1 dB amplitude imbalance and 5 degree phase imbalance to a QPSK signal. Apply a 0.5 + 0.3i DC offset.

```
y = iqimbal(x,1,5);
z = y + complex(0.5,0.3);
```

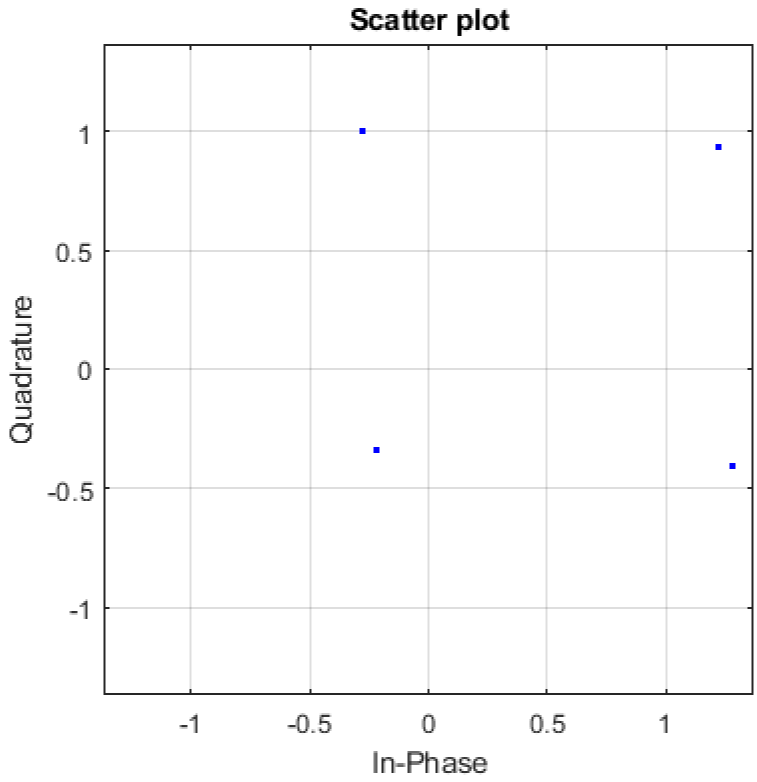
Plot the spectrum of the impaired signal.

```
sa = dsp.SpectrumAnalyzer('SampleRate',1000,'YLimits',[-50 30]);
sa(z)
```



Display the corresponding scatter plot.

```
scatterplot(z)
grid
```



The effect of the I/Q imbalance and the DC offset is observable.

Correct I/Q Imbalance on Noisy 8-PSK Signal

Generate random data and apply 8-PSK modulation.

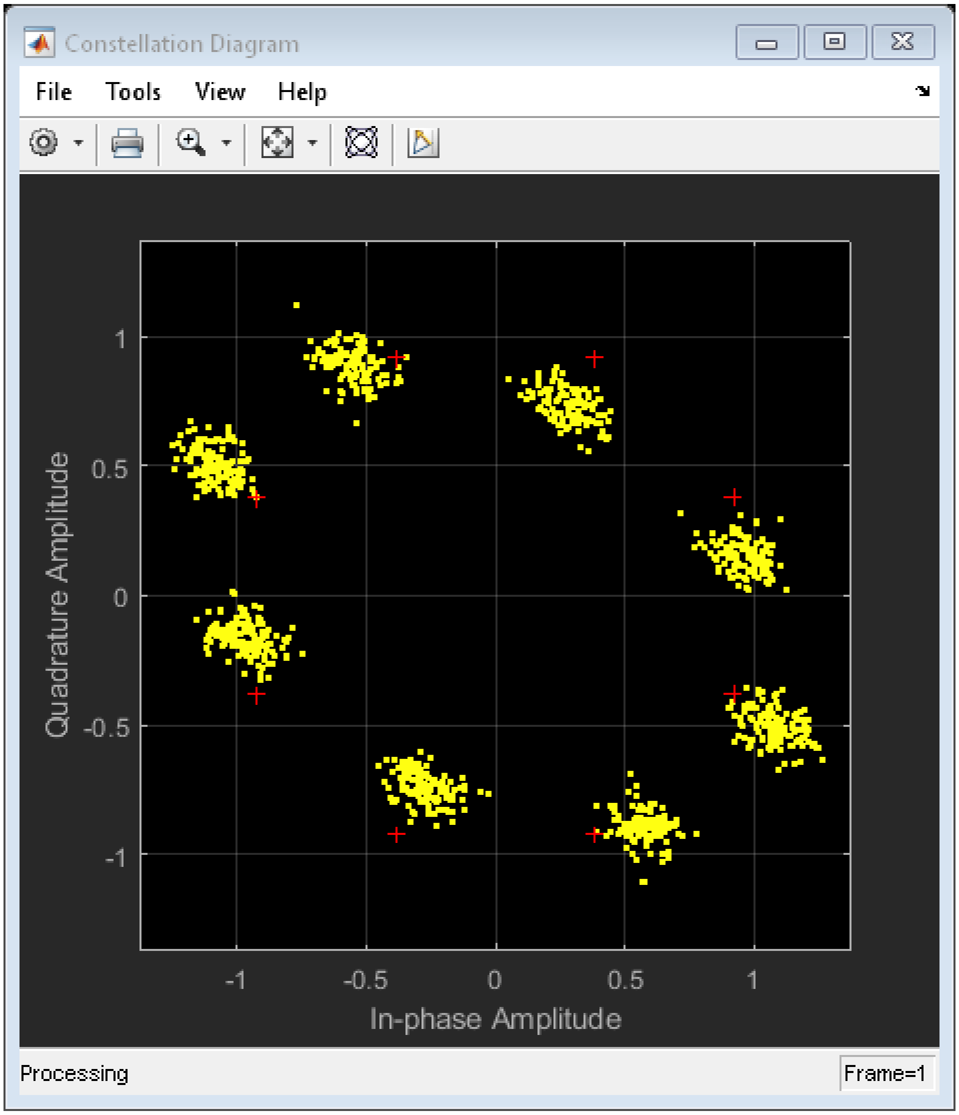
```
data = randi([0 7],2000,1);
txSig = pskmod(data,8,pi/8);
```

Pass the transmitted signal through an AWGN channel. Apply an I/Q imbalance.

```
noisySig = awgn(txSig,20);
rxSig = iqimbal(noisySig,2,20);
```

Create a constellation diagram object that displays only the last 1000 symbols. Plot the constellation diagram of the impaired signal.

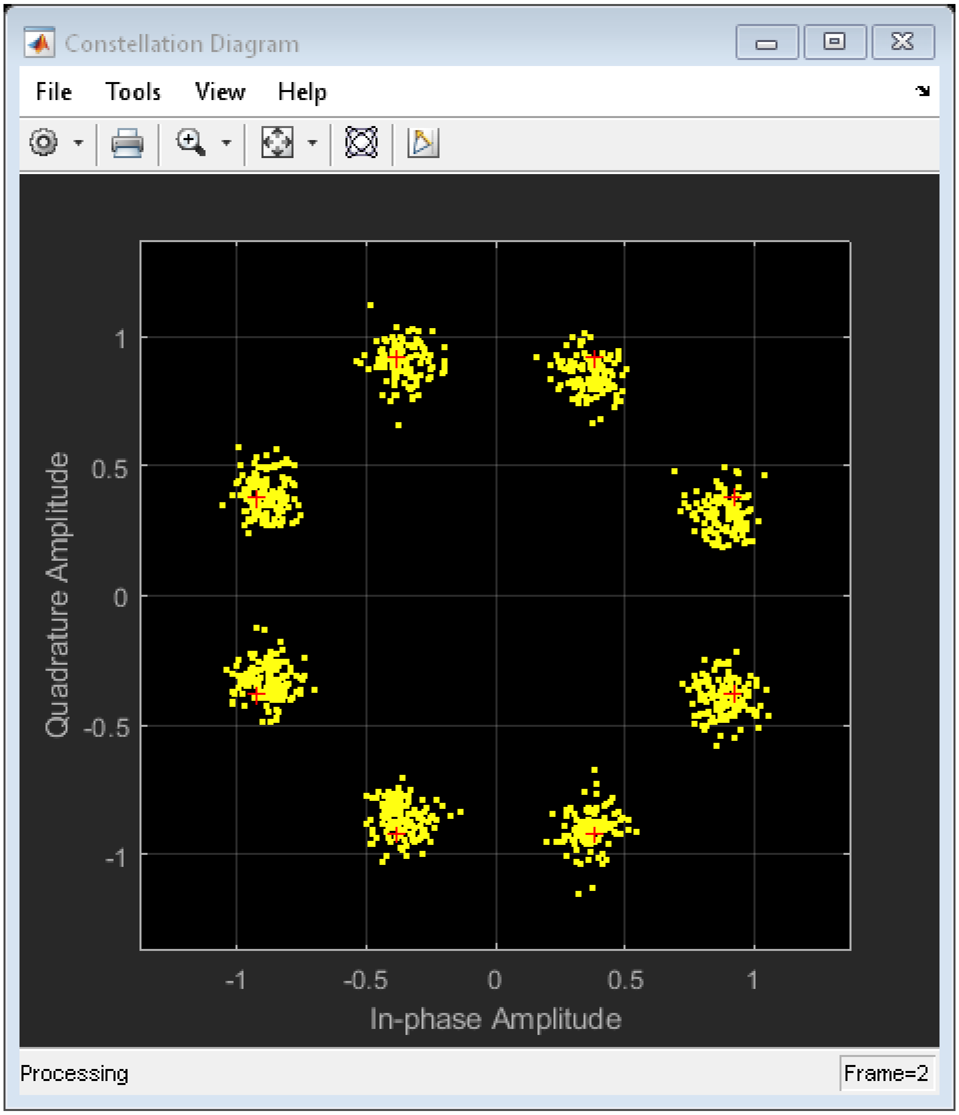
```
cd = comm.ConstellationDiagram('ReferenceConstellation',pskmod(0:7,8,pi/8), ...
    'SymbolsToDisplaySource','Property','SymbolsToDisplay',1000);
cd(rxSig)
```



Correct for the I/Q imbalance by using a `comm.IQImbalanceCompensator` object. Plot the constellation diagram of the signal after compensation.

```
iqComp = comm.IQImbalanceCompensator('StepSize',1e-3);
compSig = iqComp(rxSig);

cd(compSig)
```



The compensator removes the I/Q imbalance.

Input Arguments

x — Input signal

column vector | matrix

Input signal, specified as a column vector or matrix. The function supports multichannel operations, where the number of columns corresponds to the number of channels.

Example: `pskmod(randi([0 3],100,1),4,pi/4)`

Data Types: `single` | `double`

A — Amplitude imbalance

real scalar | row vector

Amplitude imbalance in dB, specified as a real scalar or row vector.

- If A is a scalar, the function applies the same amplitude imbalance to each channel.
- If A is a vector, then each element specifies the amplitude imbalance that is applied to the corresponding column (channel) of the input signal. The number of elements in A must equal the number of columns in x.

Example: 3

Example: [0 5]

Data Types: single | double

P — Phase imbalance
0 (default) | real scalar | row vector

Phase imbalance in degrees, specified as a real scalar or row vector.

- If P is omitted, a phase imbalance of zero degrees is used.
- If P is a scalar, the function applies the same phase imbalance to each channel.
- If P is a vector, then each element specifies the phase imbalance that is applied to the corresponding column (channel) of the input signal. The number of elements in P must equal the number of columns in x.

Example: 10

Example: [2.5 7]

Data Types: single | double

Output Arguments

y — Output signal
vector | matrix

Output signal, returned as a vector or matrix having the same dimensions as x. The number of columns in y corresponds to the number of channels.

Data Types: single | double

Algorithms

The iqimbal function applies an I/Q amplitude and phase imbalance to an input signal.

Given amplitude imbalance I_a in dB, the gain, g, resulting from the imbalance is defined as

$$g \triangleq g_r + ig_i = \left[10^{0.5\frac{I_a}{20}}\right] + i\left[10^{-0.5\frac{I_a}{20}}\right].$$

Applying the I/Q imbalance to input signal x results in output signal y such that

$$y = \mathrm{Re}(x) \cdot g_r e^{-i0.5 I_p(\pi/180)} + i\mathrm{Im}(x) \cdot g_i e^{i0.5 I_p(\pi/180)},$$

where g is the imbalance gain and I_p is the phase imbalance in degrees.

Introduced in R2016b

iscatastrophic

True for trellis corresponding to catastrophic convolutional code

Syntax

```
iscatastrophic(s)
```

Description

`iscatastrophic(s)` returns `true` if the trellis `s` corresponds to a convolutional code that causes catastrophic error propagation. Otherwise, it returns `false`.

Examples

Determine if a Convolutional Code is Catastrophic

Determine if a convolutional code causes catastrophic error propagation.

Create the trellis for the standard, rate 1/2, constraint length 7 convolutional code.

```
t = poly2trellis(7,[171 133]);
```

Verify that the code is not catastrophic.

```
iscatastrophic(t)
```

```
ans = logical
   0
```

Create a trellis for a different convolutional code using the `poly2trellis` function.

```
u = poly2trellis(7,[161 143]);
```

Verify that the code is catastrophic.

```
iscatastrophic(u)
```

```
ans = logical
   1
```

isprimitive

True for primitive polynomial for Galois field

Syntax

```
isprimitive(a)
```

Description

`isprimitive(a)` returns `1` if the polynomial that `a` represents is primitive for the Galois field GF(2^m), and `0` otherwise. The input `a` can represent the polynomial using one of these formats:

- A nonnegative integer less than 2^{17}. The binary representation of this integer indicates the coefficients of the polynomial. In this case, m is `floor(log2(a))`.
- A Galois row vector in GF(2), listing the coefficients of the polynomial in order of descending powers. In this case, m is the order of the polynomial represented by `a`.

Examples

The example below finds all primitive polynomials for GF(8) and then checks using `isprimitive` whether specific polynomials are primitive.

```
a = primpoly(3,'all','nodisplay'); % All primitive polys for GF(8)

isp1 = isprimitive(13) % 13 represents a primitive polynomial.

isp2 = isprimitive(14) % 14 represents a nonprimitive polynomial.
```

The output is below. If you examine the vector `a`, notice that `isp1` is true because `13` is an element in `a`, while `isp2` is false because `14` is not an element in `a`.

```
isp1 =

     1

isp2 =

     0
```

"Galois Field Computations"

Introduced before R2006a

istrellis

True for valid trellis structure

Syntax

```
[isok,status] = istrellis(s)
```

Description

`[isok,status] = istrellis(s)` checks if the input `s` is a valid trellis structure. If the input is a valid trellis structure, `isok` is 1 and `status` is an empty character vector. Otherwise, `isok` is 0 and `status` indicates why `s` is not a valid trellis structure.

A valid trellis structure is a MATLAB structure whose fields are as in the table below.

Fields of a Valid Trellis Structure for a Rate k/n Code

Field in Trellis Structure	Dimensions	Meaning
`numInputSymbols`	Scalar	Number of input symbols to the encoder: 2^k
`numOutputSymbols`	Scalar	Number of output symbols from the encoder: 2^n
`numStates`	Scalar	Number of states in the encoder
`nextStates`	`numStates`-by-2^k matrix	Next states for all combinations of current state and current input
`outputs`	`numStates`-by-2^k matrix	Outputs (in octal) for all combinations of current state and current input

In the `nextStates` matrix, each entry is an integer between 0 and `numStates`-1. The element in the sth row and uth column denotes the next state when the starting state is s-1 and the input bits have decimal representation u-1. To convert the input bits to a decimal value, use the first input bit as the most significant bit (MSB). For example, the second column of the `nextStates` matrix stores the next states when the current set of input values is {0,...,0,1}.

To convert the state to a decimal value, use this rule: If k exceeds 1, the shift register that receives the first input stream in the encoder provides the least significant bits in the state number, and the shift register that receives the last input stream in the encoder provides the most significant bits in the state number.

In the `outputs` matrix, the element in the sth row and uth column denotes the encoder's output when the starting state is s-1 and the input bits have decimal representation u-1. To convert to decimal value, use the first output bit as the MSB.

Examples

These commands assemble the fields into a very simple trellis structure, and then verify the validity of the trellis structure.

```
trellis.numInputSymbols = 2;
trellis.numOutputSymbols = 2;
trellis.numStates = 2;
trellis.nextStates = [0 1;0 1];
trellis.outputs = [0 0;1 1];
[isok,status] = istrellis(trellis)
```

The output is below.

```
isok =

     1

status =

     ''
```

Another example of a trellis is in “Trellis Description of a Convolutional Code”.

Introduced before R2006a

legacychannelsim

(Removed) Toggles random number generation mode for channel objects

Note `legacychannelsim` has been removed. Use `comm.RayleighChannel` or `comm.RicianChannel` instead.

Syntax

```
b = legacychannelsim
legacychannelsim(true)
legacychannelsim(false)
oldmode = legacychannelsim(newmode)
```

Description

`b = legacychannelsim` returns `false` if the code you are running uses the R2009b (or later) version of the random number generator for `rayleighchan` or `ricianchan`. (By default, these use the 2009b random number generator.) It returns `true` if pre-R2009b versions are used. See Version 4.4. (R2009b) Communications Toolbox Release Notes for more information.

`legacychannelsim(true)` reverts the random number generation mode for channel objects to pre-2009b version.

Note `legacychannelsim(true)` will support the `reset(chan,randstate)` functionality.

`legacychannelsim(false)` sets the random number generation mode for channel objects to 2009b and later versions.

`oldmode = legacychannelsim(newmode)` sets the random number generation mode for channel objects to `newmode` and returns the previous mode, `oldmode`.

Compatibility Considerations

`legacychannelsim` has been removed

Errors starting in R2020b

legacychannelsim has been removed. Use `comm.RayleighChannel` or `comm.RicianChannel` instead.

Introduced in R2009b

lineareq

(To be removed) Construct linear equalizer object

Note will be removed in a future release. Use `comm.LinearEqualizer` instead.

Syntax

```
eqobj = lineareq(nweights,alg)
eqobj = lineareq(nweights,alg,sigconst)
eqobj = lineareq(nweights,alg,sigconst,nsamp)
```

Description

The `lineareq` function creates an equalizer object that you can use with the `equalize` function to equalize a signal. To learn more about the process for equalizing a signal, see “Equalization”.

`eqobj = lineareq(nweights,alg)` constructs a symbol-spaced linear equalizer object. The equalizer has `nweights` complex weights, which are initially all zeros. `alg` describes the adaptive algorithm that the equalizer uses; you should create `alg` using any of these functions: `lms`, `signlms`, `normlms`, `varlms`, `rls`, or `cma`. The signal constellation of the desired output is `[-1 1]`, which corresponds to binary phase shift keying (BPSK).

`eqobj = lineareq(nweights,alg,sigconst)` specifies the signal constellation vector of the desired output.

`eqobj = lineareq(nweights,alg,sigconst,nsamp)` constructs a fractionally spaced linear equalizer object. The equalizer has `nweights` complex weights spaced at `T/nsamp`, where `T` is the symbol period and `nsamp` is a positive integer. `nsamp = 1` corresponds to a symbol-spaced equalizer.

Properties

The table below describes the properties of the linear equalizer object. To learn how to view or change the values of a linear equalizer object, see “Equalization”.

Tip To initialize or reset the equalizer object `eqobj`, enter `reset(eqobj)`.

Property	Description
`EqType`	Fixed value, `'Linear Equalizer'`
`AlgType`	Name of the adaptive algorithm represented by `alg`
`nWeights`	Number of weights

Property	Description
nSampPerSym	Number of input samples per symbol (equivalent to nsamp input argument). This value relates to both the equalizer structure (see the use of K in "Equalization") and an assumption about the signal to be equalized.
RefTap (except for CMA equalizers)	Reference tap index, between 1 and nWeights. Setting this to a value greater than 1 effectively delays the reference signal and the output signal by RefTap-1 with respect to the equalizer's input signal.
SigConst	Signal constellation, a vector whose length is typically a power of 2
Weights	Vector of complex coefficients. This is the set of w_i values in the schematic in "Equalization".
WeightInputs	Vector of tap weight inputs. This is the set of u_i values in the schematic in "Equalization".
ResetBeforeFiltering	If 1, each call to equalize resets the state of eqobj before equalizing. If 0, the equalization process maintains continuity from one call to the next.
NumSamplesProcessed	Number of samples the equalizer processed since the last reset. When you create or reset eqobj, this property value is 0.
Properties specific to the adaptive algorithm represented by alg	See reference page for the adaptive algorithm function that created alg: lms, signlms, normlms, varlms, rls, or cma.

Relationships Among Properties

If you change nWeights, MATLAB maintains consistency in the equalizer object by adjusting the values of the properties listed below.

Property	Adjusted Value
Weights	zeros(1,nWeights)
WeightInputs	zeros(1,nWeights)
StepSize (Variable-step-size LMS equalizers)	InitStep*ones(1,nWeights)
InvCorrMatrix (RLS equalizers)	InvCorrInit*eye(nWeights)

Examples

Configuring Linear Equalizers

This example configures the recommended comm.LinearEqualizer System object™ and the legacy lineareq feature with comparable settings.

Initialize Variables and Supporting Objects

```
d = randi([0 3],1000,1);
x = pskmod(d,4,pi/4);
r = awgn(x,25);
sps = 2; %samples per symbol for oversampled cases
nTaps = 6;
txFilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',nTaps, ...
    'OutputSamplesPerSymbol',4);
rxFilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',nTaps, ...
    'InputSamplesPerSymbol',4,'DecimationFactor',2);
x2 = txFilter(x);
r2 = rxFilter(awgn(x2,25,0.5));
filterDelay = txFilter.FilterSpanInSymbols/2 + ...
    rxFilter.FilterSpanInSymbols/2; % Total filter delay in symbols
```

To compare the equalized output, plot the constellations using code such as:

```
% plot(yNew,'*')
% hold on
% plot(yOld,'o')
% hold off; legend('New Eq','Old Eq'); grid on
```

Use LMS Algorithm with Linear Equalizer

Configure `lineareq` and `comm.LinearEqualizer` objects with comparable settings. The `LeakageFactor` property has been removed from LMS algorithm. The `comm.LinearEqualizer` System object™ assumes that leakage factor is always 1.

```
eqOld = lineareq(5,lms(0.05),pskmod(0:3,4,pi/4))
```

```
eqOld =
  EqType: 'Linear Equalizer'
  AlgType: 'LMS'
  nWeights: 5
  nSampPerSym: 1
  RefTap: 1
  SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  StepSize: 0.0500
  LeakageFactor: 1
  Weights: [0 0 0 0 0]
  WeightInputs: [0 0 0 0 0]
  ResetBeforeFiltering: 1
  NumSamplesProcessed: 0
```

```
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','LMS','StepSize',0.05, ...
    'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'LMS'
  NumTaps: 5
  StepSize: 0.0500
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 1
  InputDelay: 0
  InputSamplesPerSymbol: 1
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers.

```
yOld = equalize(eqOld,r,x(1:100));
yNew = eqNew(r,x(1:100));
```

Use RLS Algorithm with Linear Equalizer

Configure `lineareq` and `comm.LinearEqualizer` objects with comparable settings.

```
eqOld = lineareq(5,rls(0.95),pskmod(0:3,4,pi/4))
eqOld =
  EqType: 'Linear Equalizer'
  AlgType: 'RLS'
  nWeights: 5
  nSampPerSym: 1
  RefTap: 1
  SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  InvCorrInit: 0.1000
  InvCorrMatrix: [5×5 double]
  Weights: [0 0 0 0 0]
  WeightInputs: [0 0 0 0 0]
  ResetBeforeFiltering: 1
  NumSamplesProcessed: 0
```

```
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','RLS', ...
    'ForgettingFactor',0.95,'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'RLS'
  NumTaps: 5
  ForgettingFactor: 0.9500
  InitialInverseCorrelationMatrix: 0.1000
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 1
  InputDelay: 0
  InputSamplesPerSymbol: 1
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers. When `ResetBeforeFiltering` is set to `true`, each call of the `equalize` object resets the equalizer. To get the equivalent behavior call `reset` after each call of the `comm.LinearEqualizer` object.

```
yOld1 = equalize(eqOld,r,x(1:100));
yOld2 = equalize(eqOld,r,x(1:100));

yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

Configure `lineareq` and `comm.LinearEqualizer` objects with comparable settings. For the `comm.LinearEqualizer` object, set the initial inverse correlation matrix to `eye(5)*0.2`.

```
eqOld = lineareq(5,rls(0.95),pskmod(0:3,4,pi/4))
```

```
eqOld =
  EqType: 'Linear Equalizer'
  AlgType: 'RLS'
  nWeights: 5
  nSampPerSym: 1
  RefTap: 1
  SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ForgetFactor: 0.9500
  InvCorrInit: 0.1000
  InvCorrMatrix: [5×5 double]
  Weights: [0 0 0 0 0]
  WeightInputs: [0 0 0 0 0]
  ResetBeforeFiltering: 1
  NumSamplesProcessed: 0
```

```
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','RLS', ...
    'ForgettingFactor',0.95,'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1, ...
    'InitialInverseCorrelationMatrix',eye(5)*0.2)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'RLS'
  NumTaps: 5
  ForgettingFactor: 0.9500
  InitialInverseCorrelationMatrix: [5×5 double]
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 1
  InputDelay: 0
  InputSamplesPerSymbol: 1
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers. When `ResetBeforeFiltering` is set to `true`, each call of the `equalize` object resets the equalizer. To get the equivalent behavior call `reset` after each call of the `comm.LinearEqualizer` object.

```
yOld1 = equalize(eqOld,r,x(1:100));
yOld2 = equalize(eqOld,r,x(1:100));

yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

Use CMA Algorithm with Linear Equalizer

Configure `lineareq` and `comm.LinearEqualizer` objects with comparable settings. The `LeakageFactor` property has been removed from CMA algorithm. The `comm.LinearEqualizer` System object™ assumes that leakage factor is always 1.

```
eqOld = lineareq(5,cma(0.05),pskmod(0:3,4,pi/4))
```

```
eqOld =
  EqType: 'Linear Equalizer'
  AlgType: 'Constant Modulus'
  nWeights: 5
  nSampPerSym: 1
  SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  StepSize: 0.0500
  LeakageFactor: 1
  Weights: [1 0 0 0 0]
  WeightInputs: [0 0 0 0 0]
  ResetBeforeFiltering: 1
  NumSamplesProcessed: 0
```

```
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','CMA','StepSize',0.05, ...
    'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'CMA'
  NumTaps: 5
  StepSize: 0.0500
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 1
  InputSamplesPerSymbol: 1
  AdaptWeightsSource: 'Property'
  AdaptWeights: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers.

```
yOld = equalize(eqOld,r);
yNew = eqNew(r);
```

Use Linear Equalizers Considering Signal Delays

Configure `lineareq` and `comm.LinearEqualizer` objects with comparable settings. The transmit and receive filters result in a signal delay between the transit and receive signals. Account for this delay by setting the `RefTap` property of the `lineareq` to a value close to the delay value in samples. Additionally, `nWeights` must be set to a value greater than `RefTap`.

```
eqOld = lineareq(filterDelay*sps+4,lms(0.01),pskmod(0:3,4,pi/4),sps);
eqOld.RefTap = filterDelay*sps+1 % Adjust to synchronize with delayed signal
```

```
eqOld =
  EqType: 'Linear Equalizer'
  AlgType: 'LMS'
  nWeights: 16
  nSampPerSym: 2
  RefTap: 13
  SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  StepSize: 0.0100
  LeakageFactor: 1
  Weights: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
  WeightInputs: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
  ResetBeforeFiltering: 1
  NumSamplesProcessed: 0
```

```
eqNew = comm.LinearEqualizer('NumTaps',16,'Algorithm','LMS','StepSize',0.01, ...
    'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    'ReferenceTap',filterDelay*sps+1,'InputDelay',0)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'LMS'
  NumTaps: 16
  StepSize: 0.0100
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 13
  InputDelay: 0
  InputSamplesPerSymbol: 2
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers. When `ResetBeforeFiltering` is set to `true`, each call of the `equalize` object resets the equalizer. To get the equivalent behavior call `reset` after each call of the `comm.LinearEqualizer` object.

```
yOld1 = equalize(eqOld,r,x(1:100));
yOld2 = equalize(eqOld,r,x(1:100));

yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

In the `comm.LinearEqualizer` object, `InputDelay` is used to synchronize with the delayed signal. `NumTaps` and `ReferenceTap` are independent of delay value. We can reduce the number of taps by utilizing the `InputDelay` to synchronize instead of reference tap. Reducing the number of taps also reduces equalizer self noise.

```
eqNew = comm.LinearEqualizer('NumTaps',11,'Algorithm','LMS','StepSize',0.01, ...
    'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    'ReferenceTap',6,'InputDelay',filterDelay*sps)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'LMS'
  NumTaps: 11
  StepSize: 0.0100
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 6
  InputDelay: 12
  InputSamplesPerSymbol: 2
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

```
yNew1 = eqNew(r2,x(1:100));
reset(eqNew)
yNew2 = eqNew(r2,x(1:100));
```

Compatibility Considerations

`lineareq` will be removed

Warns starting in R2020a

lineareq will be removed in a future release. Use `comm.LinearEqualizer` instead. For examples comparing setup of `comm.LinearEqualizer` to `lineareq`, see “Configuring Linear Equalizers” on page 2-540.

lloyds

Optimize quantization parameters using Lloyd algorithm

Syntax

```
[partition,codebook] = lloyds(training_set,initcodebook)
[partition,codebook] = lloyds(training_set,len)
[partition,codebook] = lloyds(training_set,...,tol)
[partition,codebook,distor] = lloyds(...)
[partition,codebook,distor,reldistor] = lloyds(...)
```

Description

`[partition,codebook] = lloyds(training_set,initcodebook)` optimizes the scalar quantization parameters `partition` and `codebook` for the training data in the vector `training_set`. `initcodebook`, a vector of length at least 2, is the initial guess of the codebook values. The output `codebook` is a vector of the same length as `initcodebook`. The output `partition` is a vector whose length is one less than the length of `codebook`.

See “Represent Partitions”, “Represent Codebooks”, or the reference page for `quantiz` in this chapter, for a description of the formats of `partition` and `codebook`.

Note `lloyds` optimizes for the data in `training_set`. For best results, `training_set` should be similar to the data that you plan to quantize.

`[partition,codebook] = lloyds(training_set,len)` is the same as the first syntax, except that the scalar argument `len` indicates the size of the vector `codebook`. This syntax does not include an initial codebook guess.

`[partition,codebook] = lloyds(training_set,...,tol)` is the same as the two syntaxes above, except that `tol` replaces 10^{-7} in condition 1 of the algorithm description below.

`[partition,codebook,distor] = lloyds(...)` returns the final mean square distortion in the variable `distor`.

`[partition,codebook,distor,reldistor] = lloyds(...)` returns a value `reldistor` that is related to the algorithm's termination. In condition 1 of the algorithm below, `reldistor` is the relative change in distortion between the last two iterations. In condition 2, `reldistor` is the same as `distor`.

Examples

The code below optimizes the quantization parameters for a sinusoidal transmission via a three-bit channel. Because the typical data is sinusoidal, `training_set` is a sampled sine wave. Because the channel can transmit three bits at a time, `lloyds` prepares a codebook of length 2^3.

```
% Generate a complete period of a sinusoidal signal.
x = sin([0:1000]*pi/500);
[partition,codebook] = lloyds(x,2^3)
```

The output is below.

```
partition =

  Columns 1 through 6

   -0.8540   -0.5973   -0.3017    0.0031    0.3077    0.6023

  Column 7

    0.8572

codebook =

  Columns 1 through 6

   -0.9504   -0.7330   -0.4519   -0.1481    0.1558    0.4575

  Columns 7 through 8

    0.7372    0.9515
```

Algorithms

lloyds uses an iterative process to try to minimize the mean square distortion. The optimization processing ends when either

- The relative change in distortion between iterations is less than 10^{-7}.
- The distortion is less than eps*max(training_set), where eps is the MATLAB floating-point relative accuracy.

lms

(To be removed) Construct least mean square (LMS) adaptive algorithm object

Note will be removed in a future release. Use `comm.LinearEqualizer` or `comm.DecisionFeedbackEqualizer` instead.

Syntax

```
alg = lms(stepsize)
alg = lms(stepsize,leakagefactor)
```

Description

The `lms` function creates an adaptive algorithm object that you can use with the `lineareq` function or `dfe` function to create an equalizer object. You can then use the equalizer object with the `equalize` function to equalize a signal. To learn more about the process for equalizing a signal, see “Equalization”.

`alg = lms(stepsize)` constructs an adaptive algorithm object based on the least mean square (LMS) algorithm with a step size of `stepsize`.

`alg = lms(stepsize,leakagefactor)` sets the leakage factor of the LMS algorithm. `leakagefactor` must be between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, and a value of 0 corresponds to a memoryless update algorithm.

Properties

The table below describes the properties of the LMS adaptive algorithm object. To learn how to view or change the values of an adaptive algorithm object, see “Equalization”.

Property	Description
`AlgType`	Fixed value, `'LMS'`
`StepSize`	LMS step size parameter, a nonnegative real number
`LeakageFactor`	LMS leakage factor, a real number between 0 and 1

Examples

Configuring Linear Equalizers

This example configures the recommended `comm.LinearEqualizer` System object™ and the legacy `lineareq` feature with comparable settings.

Initialize Variables and Supporting Objects

```
d = randi([0 3],1000,1);
x = pskmod(d,4,pi/4);
r = awgn(x,25);
sps = 2; %samples per symbol for oversampled cases
nTaps = 6;
txFilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',nTaps, ...
    'OutputSamplesPerSymbol',4);
rxFilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',nTaps, ...
    'InputSamplesPerSymbol',4,'DecimationFactor',2);
x2 = txFilter(x);
r2 = rxFilter(awgn(x2,25,0.5));
filterDelay = txFilter.FilterSpanInSymbols/2 + ...
    rxFilter.FilterSpanInSymbols/2; % Total filter delay in symbols
```

To compare the equalized output, plot the constellations using code such as:

```
% plot(yNew,'*')
% hold on
% plot(yOld,'o')
% hold off; legend('New Eq','Old Eq'); grid on
```

Use LMS Algorithm with Linear Equalizer

Configure `lineareq` and `comm.LinearEqualizer` objects with comparable settings. The `LeakageFactor` property has been removed from LMS algorithm. The `comm.LinearEqualizer` System object™ assumes that leakage factor is always 1.

```
eqOld = lineareq(5,lms(0.05),pskmod(0:3,4,pi/4))
```

```
eqOld =
  EqType: 'Linear Equalizer'
  AlgType: 'LMS'
  nWeights: 5
  nSampPerSym: 1
  RefTap: 1
  SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  StepSize: 0.0500
  LeakageFactor: 1
  Weights: [0 0 0 0 0]
  WeightInputs: [0 0 0 0 0]
  ResetBeforeFiltering: 1
  NumSamplesProcessed: 0
```

```
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','LMS','StepSize',0.05, ...
    'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'LMS'
  NumTaps: 5
  StepSize: 0.0500
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 1
  InputDelay: 0
  InputSamplesPerSymbol: 1
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers.

```
yOld = equalize(eqOld,r);
yNew = eqNew(r);
```

Use Linear Equalizers Considering Signal Delays

Configure `lineareq` and `comm.LinearEqualizer` objects with comparable settings. The transmit and receive filters result in a signal delay between the transit and receive signals. Account for this delay by setting the `RefTap` property of the `lineareq` to a value close to the delay value in samples. Additionally, `nWeights` must be set to a value greater than `RefTap`.

```
eqOld = lineareq(filterDelay*sps+4,lms(0.01),pskmod(0:3,4,pi/4),sps);
eqOld.RefTap = filterDelay*sps+1 % Adjust to synchronize with delayed signal
```

```
eqOld =
  EqType: 'Linear Equalizer'
  AlgType: 'LMS'
  nWeights: 16
  nSampPerSym: 2
  RefTap: 13
  SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  StepSize: 0.0100
  LeakageFactor: 1
  Weights: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
  WeightInputs: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
  ResetBeforeFiltering: 1
  NumSamplesProcessed: 0
```

```
eqNew = comm.LinearEqualizer('NumTaps',16,'Algorithm','LMS','StepSize',0.01, ...
    'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    'ReferenceTap',filterDelay*sps+1,'InputDelay',0)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'LMS'
  NumTaps: 16
  StepSize: 0.0100
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 13
  InputDelay: 0
  InputSamplesPerSymbol: 2
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers. When `ResetBeforeFiltering` is set to `true`, each call of the `equalize` object resets the equalizer. To get the equivalent behavior call `reset` after each call of the `comm.LinearEqualizer` object.

```
yOld1 = equalize(eqOld,r,x(1:100));
yOld2 = equalize(eqOld,r,x(1:100));

yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

In the `comm.LinearEqualizer` object, `InputDelay` is used to synchronize with the delayed signal. `NumTaps` and `ReferenceTap` are independent of delay value. We can reduce the number of taps by utilizing the `InputDelay` to synchronize instead of reference tap. Reducing the number of taps also reduces equalizer self noise.

```
eqNew = comm.LinearEqualizer('NumTaps',11,'Algorithm','LMS','StepSize',0.01, ...
    'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    'ReferenceTap',6,'InputDelay',filterDelay*sps)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'LMS'
  NumTaps: 11
  StepSize: 0.0100
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 6
  InputDelay: 12
  InputSamplesPerSymbol: 2
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

```
yNew1 = eqNew(r2,x(1:100));
reset(eqNew)
yNew2 = eqNew(r2,x(1:100));
```

Algorithms

Referring to the schematics presented in “Equalization”, define w as the vector of all weights w_i and define u as the vector of all inputs u_i. Based on the current set of weights, w, this adaptive algorithm creates the new set of weights given by

(`LeakageFactor`) w + (`StepSize`) u^*e

where the * operator denotes the complex conjugate.

Compatibility Considerations

`lms` will be removed

Warns starting in R2020a

- lms will be removed in a future release. Use `comm.LinearEqualizer` or `comm.DecisionFeedback` instead with the adaptive algorithm set to LMS.
- The `comm.LinearEqualizer` or `comm.DecisionFeedback` System objects do not have a leakage factor property. This is equivalent to setting `LeakageFactor` to `1` in the lms function.
- For examples comparing setup of `comm.LinearEqualizer` to `lineareq`, see “Configuring Linear Equalizers” on page 2-548.

log

Logarithm in Galois field

Syntax

```
y = log(x)
```

Description

`y = log(x)` computes the logarithm of each element in the Galois array `x`. `y` is an integer array that solves the equation `A.^y = x`, where `A` is the primitive element used to represent elements in `x`. More explicitly, the base `A` of the logarithm is `gf(2,x.m)` or `gf(2,x.m,x.prim_poly)`. All elements in `x` must be nonzero because the logarithm of zero is undefined.

Examples

The code below illustrates how the logarithm operation inverts exponentiation.

```
m = 4; x = gf([8 1 6; 3 5 7; 4 9 2],m);
y = log(x);
primel = gf(2,m); % Primitive element in the field
z = primel .^ y; % This is now the same as x.
ck = isequal(x,z)
```

The output is

```
ck =

     1
```

The code below shows that the logarithm of `1` is `0` and that the logarithm of the base (`primel`) is `1`.

```
m = 4; primel = gf(2,m);
yy = log([1, primel])
```

The output is

```
yy =

     0     1
```

`gf`

Introduced before R2006a

marcumq

Generalized Marcum Q function

Syntax

```
Q = marcumq(a,b)
Q = marcumq(a,b,m)
```

Description

`Q = marcumq(a,b)` computes the Marcum Q function of `a` and `b`, defined by

$$Q(a,b) = \int_b^\infty x\mathrm{exp}\left(-\frac{x^2+a^2}{2}\right)I_0(ax)dx$$

where `a` and `b` are nonnegative real numbers. In this expression, I_0 is the modified Bessel function of the first kind of zero order.

`Q = marcumq(a,b,m)` computes the generalized Marcum Q, defined by

$$Q(a,b) = \frac{1}{a^{m-1}}\int_b^\infty x^m\mathrm{exp}\left(-\frac{x^2+a^2}{2}\right)I_{m-1}(ax)dx$$

where `a` and `b` are nonnegative real numbers, and `m` is a positive integer. In this expression, $I_{\mathrm{m-1}}$ is the modified Bessel function of the first kind of order *m*-1.

If any of the inputs is a scalar, it is expanded to the size of the other inputs.

Examples

Generate and Plot Marcum Q Function Data

This example shows how to use the `marcumq` function.

Create an input vector, `x`.

```
x = (0:0.1:10)';
```

Generate two output vectors for a=0 and a=2.

```
Q1 = marcumq(0,x);
Q2 = marcumq(2,x);
```

Plot the resultant Marcum Q functions.

```
plot(x,[Q1 Q2])
```

`besseli`

Introduced before R2006a

mask2shift

Convert mask vector to shift for shift register configuration

Syntax

```
shift = mask2shift(prpoly,mask)
```

Description

`shift = mask2shift(prpoly,mask)` returns the shift that is equivalent to a mask, for a linear feedback shift register whose connections are specified by the primitive polynomial `prpoly`. The `prpoly` input can have one of these formats:

- A polynomial character vector
- A binary vector that lists the coefficients of the primitive polynomial in order of descending powers
- An integer scalar whose binary representation gives the coefficients of the primitive polynomial, where the least significant bit is the constant term

The `mask` input is a binary vector whose length is the degree of the primitive polynomial.

Note To save time, `mask2shift` does not check that `prpoly` is primitive. If it is not primitive, the output is not meaningful. To find primitive polynomials, use `primpoly` or see [2].

For more information about how masks and shifts are related to pseudonoise sequence generators, see `shift2mask`.

Definition of Equivalent Shift

If A is a root of the primitive polynomial and m(A) is the mask polynomial evaluated at A, the equivalent shift s solves the equation $A^s = m(A)$. To interpret the vector `mask` as a polynomial, treat `mask` as a list of coefficients in order of descending powers.

Examples

Convert Mask to Shift

Convert masks into shifts for a linear feedback shift register.

Convert a mask of $x^3 + 1$ into an equivalent shift for the linear feedback shift register whose connections are specified by the primitive polynomial $x^4 + x^3 + 1$.

```
s1 = mask2shift([1 1 0 0 1],[1 0 0 1])
```

```
s1 = 4
```

Convert a mask of `1` to a shift. The mask is equivalent to a shift of `0`.

```
s2 = mask2shift([1 1 0 0 1],[0 0 0 1])
```

```
s2 = 0
```

Convert a mask of x^2 into an equivalent shift for the primitive polynomial $x^3 + x + 1$.

```
s3 = mask2shift('x3+x+1','x2')
```

```
s3 = 2
```

matdeintrlv

Restore ordering of symbols by filling matrix by columns and emptying it by rows

Syntax

```
deintrlvd = matdeintrlv(data,Nrows,Ncols)
```

Description

deintrlvd = matdeintrlv(data,Nrows,Ncols) rearranges the elements in data by filling a temporary matrix with the elements column by column and then sending the matrix contents, row by row, to the output. Nrows and Ncols are the dimensions of the temporary matrix. If data is a vector, it must have Nrows*Ncols elements. If data is a matrix with multiple rows and columns, data must have Nrows*Ncols rows and the function processes the columns independently.

To use this function as an inverse of the matintrlv function, use the same Nrows and Ncols inputs in both functions. In that case, the two functions are inverses in the sense that applying matintrlv followed by matdeintrlv leaves data unchanged.

Examples

The code below illustrates the inverse relationship between matintrlv and matdeintrlv.

```
Nrows = 2; Ncols = 3;
data = [1 2 3 4 5 6; 2 4 6 8 10 12]';
a = matintrlv(data,Nrows,Ncols); % Interleave.
b = matdeintrlv(a,Nrows,Ncols) % Deinterleave.
```

The output below shows that b is the same as data.

```
b =

     1     2
     2     4
     3     6
     4     8
     5    10
     6    12
```

matintrlv

Reorder symbols by filling matrix by rows and emptying it by columns

Syntax

```
intrlvd = matintrlv(data,Nrows,Ncols)
```

Description

`intrlvd = matintrlv(data,Nrows,Ncols)` rearranges the elements in `data` by filling a temporary matrix with the elements row by row and then sending the matrix contents, column by column, to the output. `Nrows` and `Ncols` are the dimensions of the temporary matrix. If `data` is a vector, it must have `Nrows*Ncols` elements. If `data` is a matrix with multiple rows and columns, `data` must have `Nrows*Ncols` rows and the function processes the columns independently.

Examples

Apply Matrix Interleaving to Reorder Input Matrix

Use the `matintrlv` function to reorder the elements filling matrix by rows and emptying it by columns.

To form the first column of the output, the function creates the temporary 2-by-3 matrix [1 2 3; 4 5 6]. Then the function reads down each column of the temporary matrix to get [1 4 2 5 3 6].

```
b = matintrlv([1 2 3 4 5 6; 2 4 6 8 10 12]',2,3)
```

```
b = 6×2

     1     2
     4     8
     2     4
     5    10
     3     6
     6    12
```

To form the first column of the output, the function creates the temporary 3-by-2 matrix [1 2; 3 4; 5 6]. Then the function reads down each column of the temporary matrix to get [1 3 5 2 4 6].

```
b = matintrlv([1 2 3 4 5 6; 2 4 6 8 10 12]',3,2)
```

```
b = 6×2

     1     2
     3     6
     5    10
     2     4
     4     8
     6    12
```

mil188qamdemod

MIL-STD-188-110 B/C standard-specific quadrature amplitude demodulation

Syntax

```
z = mil188qamdemod(y,M)
z = mil188qamdemod(y,M,Name,Value)
```

Description

`z = mil188qamdemod(y,M)` performs QAM demodulation on an input signal, `y`, that was modulated in accordance with MIL-STD-188-110 and the modulation order, `M`. For a description of MIL-STD-188-110 QAM demodulation, see “MIL-STD-188-110 QAM Hard Demodulation” on page 2-567 and “MIL-STD-188-110 QAM Soft Demodulation” on page 2-568.

`z = mil188qamdemod(y,M,Name,Value)` specifies options using one or more name-value pair arguments. For example, `'OutputDataType','double'` specifies the desired output data type as double. Specify name-value pair arguments after all other input arguments.

Examples

Demodulate MIL-STD-188-110B Specific 16-QAM Signal

Demodulate a 16-QAM signal that was modulated as specified in MIL-STD-188-110B. Plot the received constellation and verify that the output matches the input.

Set the modulation order and generate random data.

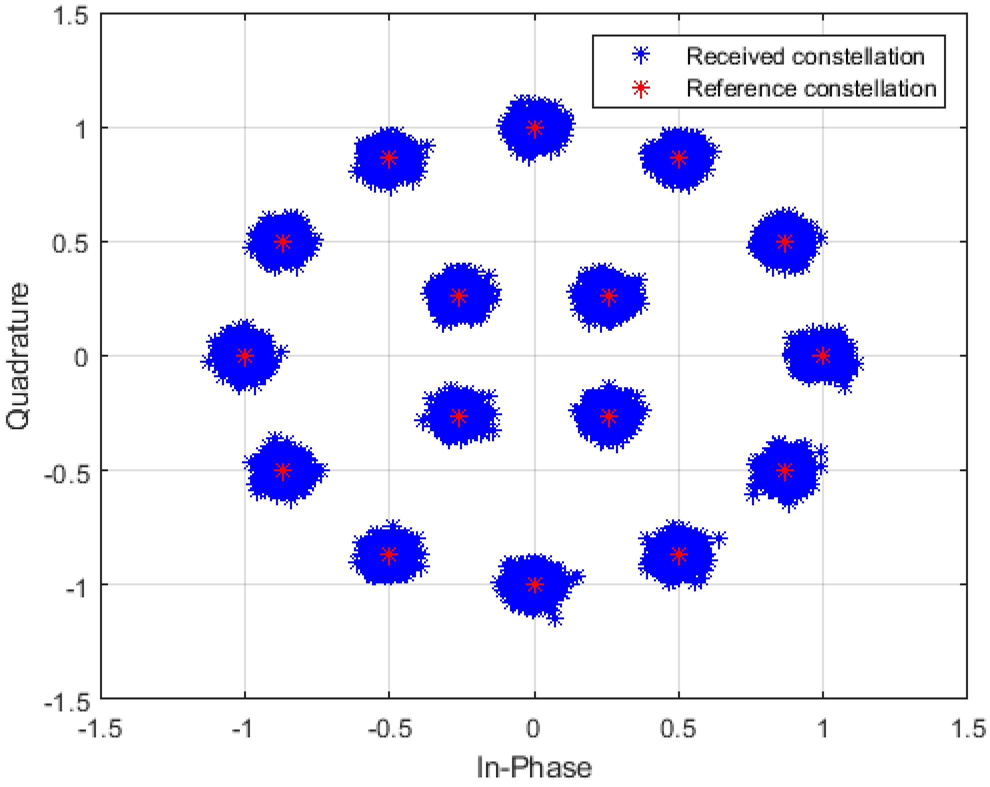
```
M = 16;
numSym = 20000;
x = randi([0 M-1],numSym,1);
```

Modulate the data and pass through a noisy channel.

```
txSig = mil188qammod(x,M);
rxSig = awgn(txSig,25,'measured');
```

Plot the transmitted and received signal.

```
plot(rxSig,'b*')
hold on; grid
plot(txSig,'r*')
xlim([-1.5 1.5]);
ylim([-1.5 1.5])
xlabel('In-Phase')
ylabel('Quadrature')
legend('Received constellation','Reference constellation')
```



Demodulate the received signal. Compare the demodulated data to the original data.

```
z = mil188qamdemod(rxSig,M);
isequal(x,z)
```

```
ans = logical
   1
```

Demodulate MIL-STD-188-110C Specific 64-QAM Signal

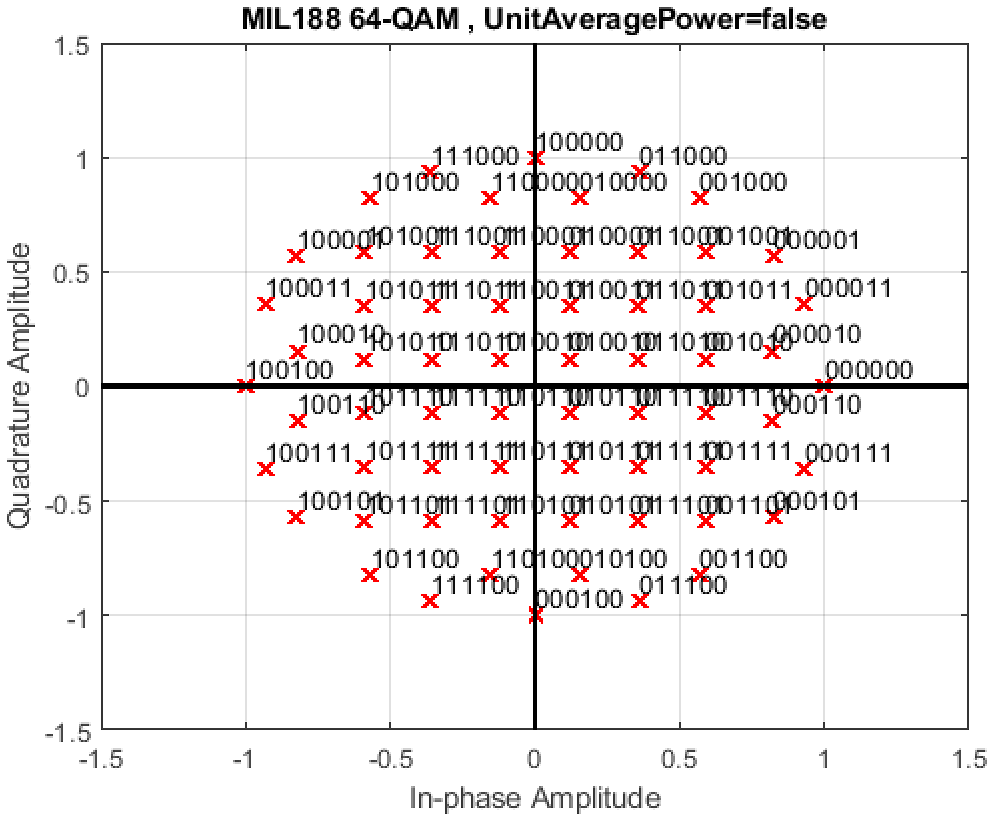
Demodulate a 64-QAM signal that was modulated as specified in MIL-STD-188-110C. Compute hard decision bit output and that verify the output matches the input.

Set the modulation order and generate random bit data.

```
M = 64;
numBitsPerSym = log2(M);
x = randi([0 1],1000*numBitsPerSym,1);
```

Modulate the data. Use name-value pairs to specify bit input data and to plot the constellation.

```
txSig = mil188qammod(x,M,'InputType','bit','PlotConstellation',true);
```



Demodulate the received signal. Compare the demodulated data to the original data.

```
z = mil188qamdemod(txSig,M,'OutputType','bit');
isequal(z,x)
```

```
ans = logical
   1
```

Soft Bit Demodulate MIL-STD-188-110 Specific 32-QAM Signal

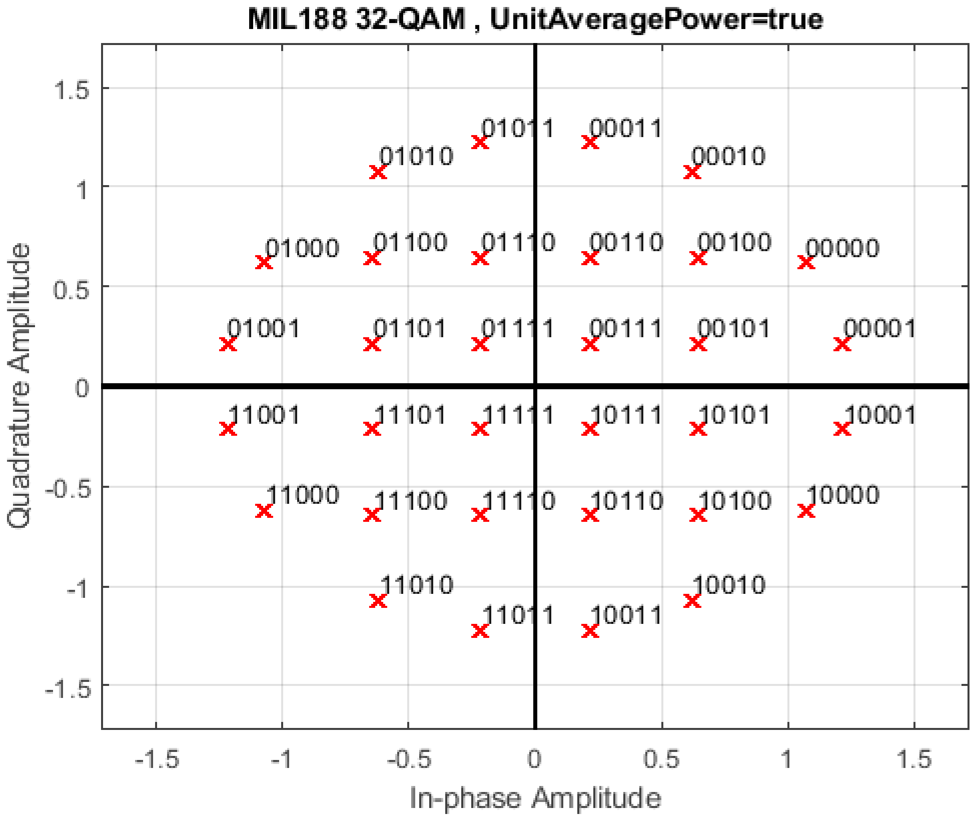
Demodulate a 32-QAM signal and calculate soft bits.

Set the modulation order and generate a random bit sequence.

```
M = 32;
numSym = 20000;
numBitsPerSym = log2(M);
x = randi([0 1], numSym*numBitsPerSym,1);
```

Modulate the data. Use name-value pairs to specify bit input data and unit average power, and to plot the constellation.

```
txSig = mil188qammod(x,M,'InputType','bit','UnitAveragePower',true, ...
    'PlotConstellation',true);
```

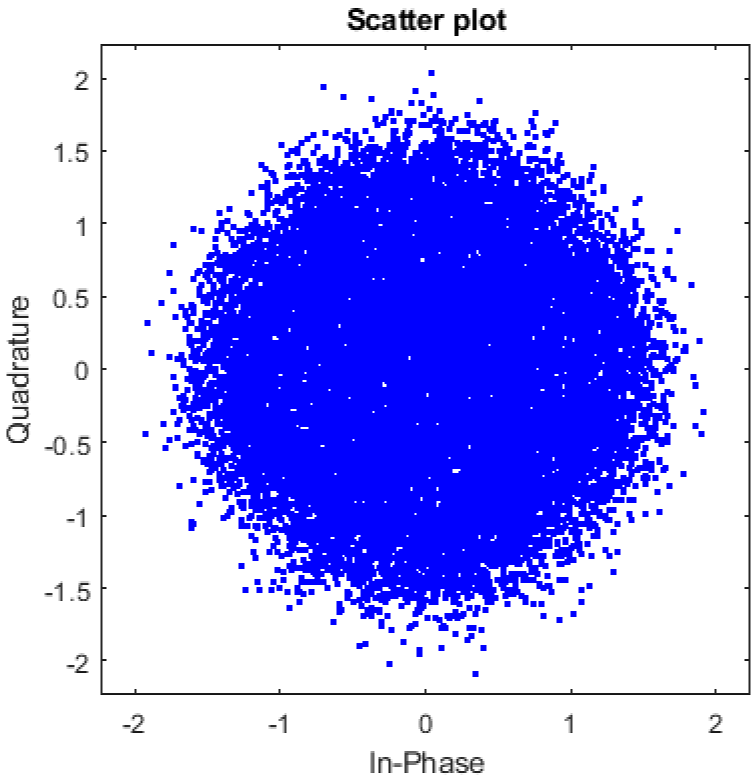


Pass the transmitted data through white Gaussian noise.

```
rxSig = awgn(txSig,10,'measured');
```

View the constellation using a scatter plot.

```
scatterplot(rxSig)
```



Demodulate the signal, computing soft bits using the approximate LLR algorithm.

```
z = mil188qamdemod(rxSig,M,'OutputType','approxllr', ...
    'NoiseVariance',10^(-1));
```

Input Arguments

y — Modulated signal

scalar | vector | matrix

Modulated signal, specified as a complex scalar, vector, or matrix. When y is a matrix, each column is treated as an independent channel.

y must be modulated in accordance with MIL-STD-188-110 [1].

Data Types: single | double
Complex Number Support: Yes

M — Modulation order

integer

Modulation order, specified as a power of two. The modulation order specifies the total number of points in the signal constellation.

Example: 16

Data Types: double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: y = mil188qamdemod(x,M,'OutputType','bit','OutputDataType','single');

OutputType — Output type
'integer' (default) | 'bit' | 'llr' | 'approxllr'

Output type, specified as the comma-separated pair consisting of OutputType and 'integer', 'bit', 'llr', or 'approxllr'.

Data Types: char | string

OutputDataType — Output data type
'double' (default) | ...

Output data type, specified as the comma-separated pair consisting of OutputDataType and one of the indicated data types. Acceptable values for OutputDataType depend on the OutputType value.

OutputType Value	Acceptable OutputDataType Values
'integer'	'double', 'single', 'int8', 'int16', 'int32', 'uint8', 'uint16', or 'uint32'
'bit'	'double', 'single', 'int8', 'int16', 'int32', 'uint8', 'uint16', 'uint32', or 'logical'

Dependencies

This name-value pair argument applies only when OutputType is set to 'integer' or 'bit'.

Data Types: char | string

UnitAveragePower — Unit average power flag
false (default) | true

Unit average power flag, specified as the comma-separated pair consisting of UnitAveragePower and a logical scalar. When this flag is true, the function scales the constellation to an average power of 1 watt referenced to 1 ohm. When this flag is false, the function scales the constellation based on specifications in the relevant standard, as described in [1].

Data Types: logical

NoiseVariance — Noise variance
1 (default) | positive scalar | vector of positive values

Noise variance, specified as the comma-separated pair consisting of NoiseVariance and a positive scalar or vector of positive values.

- When specified as a scalar, the same noise variance value is used on all input elements.
- When specified as a vector, the vector length must be equal to the number of columns in the input signal.

When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see “MIL-STD-188-110 QAM Soft Demodulation” on page 2-568 for algorithm selection considerations.

Dependencies

This name-value pair argument applies only when `OutputType` is set to `'llr'` or `'approxllr'`.

Data Types: `double`

`PlotConstellation` — Option to plot constellation

`false` (default) | `true`

Option to plot constellation, specified as the comma-separated pair consisting of `'PlotConstellation'` and a logical scalar. To plot the constellation, set `PlotConstellation` to `true`.

Data Types: `logical`

Output Arguments

z — Demodulated signal

scalar | vector | matrix

Demodulated signal, returned as a scalar, vector, or matrix. The dimensions of `z` depend on the specified `OutputType` value.

`OutputType` Value	Return Value of `mil188qamdemod`	Dimensions of `z`
`'integer'`	Demodulated integer values from 0 to (`M` – 1)	`z` has the same dimensions as input `y`.
`'bit'`	Demodulated bits	The number of rows in `z` is $\log_2$(sum(`M`)) times the number of rows in `y`. Each demodulated symbol is mapped to a group of $\log_2$(sum(`M`)) elements in a column, where the first element represents the MSB and the last element represents the LSB.
`'llr'`	Log-likelihood ratio value for each bit	
`'approxllr'`	Approximate log-likelihood ratio value for each bit	

More About

MIL-STD-188-110 QAM Hard Demodulation

The hard demodulation algorithm uses optimum decision region-based demodulation. Since all the constellation points are equally probable, maximum a posteriori probability (MAP) detection reduces to a maximum likelihood (ML) detection. The ML detection rule is equivalent to choosing the closest constellation point to the received symbol. The decision region for each constellation point is designed by drawing perpendicular bisectors between adjacent points. A received symbol is mapped to the proper constellation point based on which decision region it lies in.

Since all MIL-STD constellations are quadrant-based symmetric, for each symbol the optimum decision region-based demodulation:

- Maps the received symbol into the first quadrant

- Chooses the decision region for the symbol
- Maps the constellation point back to its original quadrant using the sign of real and imaginary parts of the received symbol

MIL-STD-188-110 QAM Soft Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. This table compares these algorithms.

Algorithm	Accuracy	Execution Speed
Exact LLR	more accurate	slower execution
Approximate LLR	less accurate	faster execution

For further description of these algorithms, see “Exact LLR Algorithm” and “Approximate LLR Algorithm”.

Note The exact LLR algorithm computes exponentials using finite precision arithmetic. Computation of exponentials with very large positive or negative magnitudes might yield:

- `Inf` or `-Inf` if the noise variance is a very large value
- `NaN` if both the noise variance and signal power are very small values

When the output returns any of these values, try using the approximate LLR algorithm because it does not compute exponentials.

mil188qammod

MIL-STD-188-110 B/C standard-specific quadrature amplitude modulation (QAM)

Syntax

```
y = mil188qammod(x,M)
y = mil188qammod(x,M,Name,Value)
```

Description

`y = mil188qammod(x,M)` performs QAM modulation on the input signal, `x`, in accordance with MIL-STD-188-110 and the modulation order, `M`. For more information, see “MIL-STD-188-110” on page 2-574.

`y = mil188qammod(x,M,Name,Value)` specifies options using one or more name-value pair arguments. For example, `'OutputDataType','double'` specifies the desired output data type as double. Specify name-value pair arguments after all other input arguments.

Examples

Apply 32-QAM to Data Per MIL-STD-188-110C

Modulate data using 32-QAM as specified in the MIL-188-110C standard. Display the result using a scatter plot.

Set M to 32 and create a data vector containing all possible symbols.

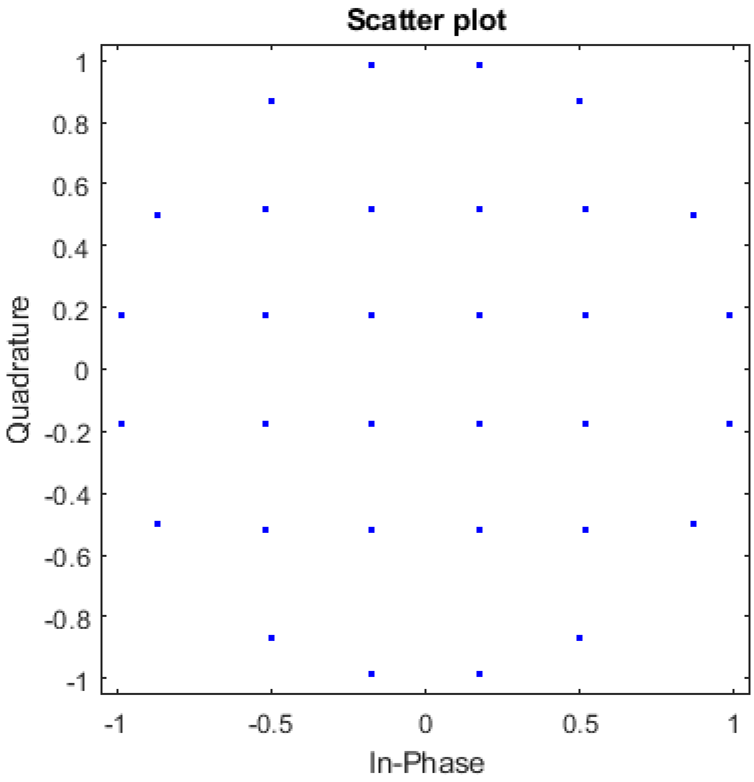
```
M = 32;
x = (0:M-1);
```

Modulate the data using QAM as specified in MIL-STD-188-110C.

```
y = mil188qammod(x,M);
```

Display the constellation as a scatter plot.

```
scatterplot(y)
```



Normalize 16-QAM Modulated MIL-STD-188-110B Signal by Average Power

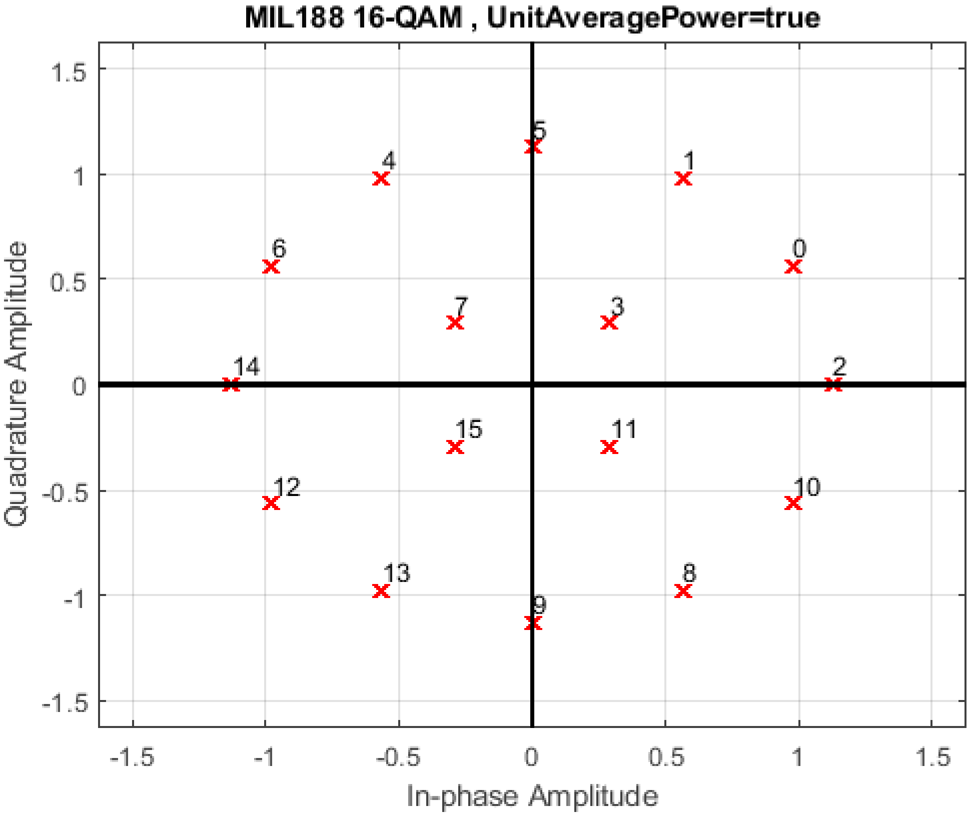
Modulate data using 16-QAM as specified in the MIL-STD-188-110B standard. Normalize the modulator output so that it has an average signal power of 1 W.

Set M and generate random data.

```
M = 16;
x = randi([0 M-1],1e5,1);
```

Modulate the data applying 16-QAM as specified in MIL-STD-188-110B. Using name-value pairs, set the unit average power to `true` and enable the constellation plot.

```
y = mil188qammod(x,M,'UnitAveragePower',true,'PlotConstellation',true);
```



Verify that the signal has approximately unit average power.

```
avgPow = mean(abs(y).^2)
```

```
avgPow = 1.0012
```

Apply 64-QAM MIL-STD-188-110B Modulation to Bit Data

Modulate a sequence of bits using 64-QAM as specified by MIL-STD188-110B. Display the constellation.

Set the modulation order and generate a sequence of random bits.

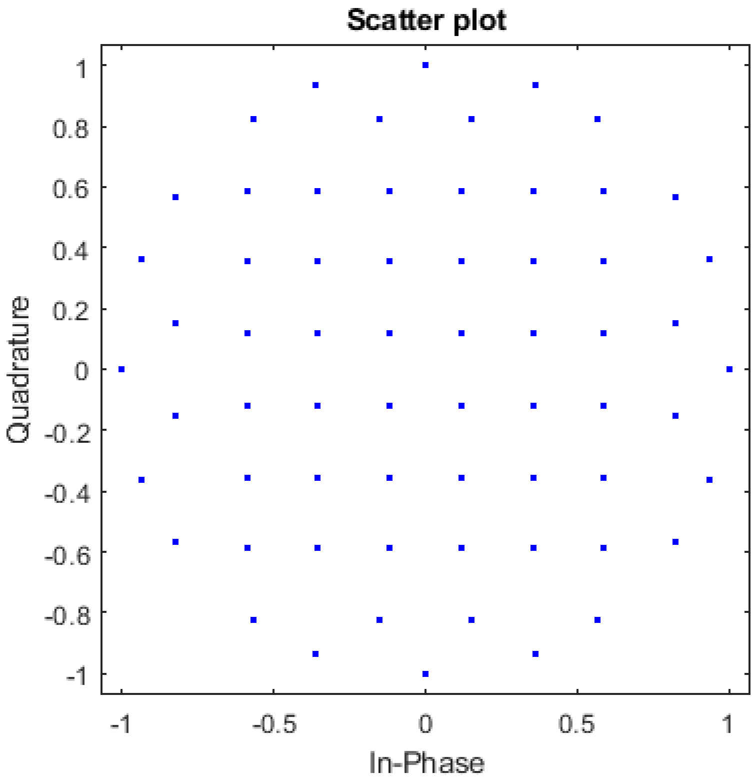
```
M = 64;
numBitsPerSym = log2(M);
data = randi([0 1],1000*numBitsPerSym,1);
```

Modulate the data applying 64-QAM as specified by MIL-STD-188-110B, and output constellation symbols of single data type.

```
y = mil188qammod(data,M,'InputType','bit','OutputDataType','single');
```

Plot the result constellation using a scatter plot.

```
scatterplot(y)
```



Input Arguments

x — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix. The elements of x must be binary values or integers that range from 0 to (`M` – 1), where `M` is the modulation order.

Note To process input signal as binary elements, set the `'InputType'` value to `'bit'`. For binary inputs, the number of rows must be an integer multiple of log$_2$(`M`). Groups of log$_2$(`M`) bits in a column are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

`M` — Modulation order

integer

Modulation order, specified as a power of two. The modulation order specifies the total number of points in the signal constellation.

Example: 16

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: y = mil188qammod(data,M,'InputType','bit','OutputDataType','single');

`InputType` — Input type

`'integer'` (default) | `'bit'`

Input type, specified as the comma-separated pair consisting of `'InputType'` and either `'integer'` or `'bit'`. If you specify `'integer'`, the input signal must consist of integers from 0 to `M` – 1. If you specify `'bit'`, the input signal must contain binary values, and the number of rows must be an integer multiple of $\log_2$(`M`).

Data Types: `char` | `string`

`OutputDataType` — Output data type

`'double'` (default) | `'single'`

Output data type, specified as the comma-separated pair consisting of `OutputDataType` and `'double'` or `'single'`.

Data Types: `char` | `string`

`UnitAveragePower` — Unit average power flag

`false` (default) | `true`

Unit average power flag, specified as the comma-separated pair consisting of `'UnitAveragePower'` and a logical scalar. When this flag is `true`, the function scales the constellation to an average power of 1 watt referenced to 1 ohm. When this flag is `false`, the function scales the constellation based on specifications in the relevant standard, as described in [1].

Data Types: `logical`

`PlotConstellation` — Option to plot constellation

`false` (default) | `true`

Option to plot constellation, specified as the comma-separated pair consisting of `'PlotConstellation'` and a logical scalar. To plot the constellation, set `PlotConstellation` to `true`.

Data Types: `logical`

Output Arguments

y — Modulated signal

scalar | vector | matrix

Modulated signal, returned as a complex scalar, vector, or matrix. The dimension of the output depends on the specified `InputType` value.

InputType	Dimensions of Output
`'integer'`	`y` has the same dimensions as input `x`.

InputType	Dimensions of Output
'bit'	The number of rows in y equals the number of rows in x divided by $\log_2$(M).

Data Types: double | single

More About

MIL-STD-188-110

MIL-STD-188-110 is a US Department of Defense standard for HF communications using serial PSK mode of both data and voice signals.

The standard specifies physical layer modulation schemes for tactical and long-haul communications. The modulation scheme specified by the standard is a mix of QAM and APSK. For a detailed description of the modulation scheme, see [1].

minpol

Find minimal polynomial of Galois field element

Syntax

```
pl = minpol(x)
```

Description

`pl = minpol(x)` finds the minimal polynomial of each element in the Galois column vector, `x`. The output `pl` is an array in GF(2). The kth row of `pl` lists the coefficients, in order of descending powers, of the minimal polynomial of the kth element of `x`.

Note The output is in GF(2) even if the input is in a different Galois field.

Examples

The code below uses `m = 4` and finds that the minimal polynomial of `gf(2,m)` is just the primitive polynomial used for the field GF(2^`m`). This is true for any value of `m`, not just the value used in the example.

```
m = 4;
A = gf(2,m)
pl = minpol(A)
```

The output is below. Notice that the row vector `[1 0 0 1 1]` represents the polynomial `D^4 + D + 1`.

```
A = GF(2^4) array. Primitive polynomial = D^4+D+1 (19 decimal)

Array elements =

     2

pl = GF(2) array.

Array elements =

     1     0     0     1     1
```

Another example is in “Minimal Polynomials”.

`cosets` | `gf`

Topics

“Polynomials over Galois Fields”

Introduced before R2006a

mldivide

Matrix left division \ of Galois arrays

Syntax

```
x = A\B
```

Description

`x = A\B` divides the Galois array `A` into `B` to produce a particular solution of the linear equation `A*x = B`. In the special case when `A` is a nonsingular square matrix, `x` is the unique solution, `inv(A)*B`, to the equation.

Examples

The code below shows that `A \ eye(size(A))` is the inverse of the nonsingular square matrix `A`.

```
m = 4; A = gf([8 1 6; 3 5 7; 4 9 2],m);
Id = gf(eye(size(A)),m);
X = A \ Id;
ck1 = isequal(X*A, Id)
ck2 = isequal(A*X, Id)
```

The output is below.

```
ck1 =

     1

ck2 =

     1
```

Other examples are in “Solving Linear Equations”.

Limitations

The matrix `A` must be one of these types:

- A nonsingular square matrix
- A matrix, in which there are more rows than columns, such that `A'*A` is nonsingular
- A matrix, in which there are more columns than rows, such that `A*A'` is nonsingular

Algorithms

If `A` is an M-by-N matrix where M > N, `A \ B` is the same as `(A'*A) \ (A'*B)`.

If `A` is an M-by-N matrix where M < N, `A \ B` is the same as `A' * ((A*A') \ B)`. This solution is not unique.

Introduced before R2006a

mlseeq

Equalize linearly modulated signal using MLSE

Syntax

```
y = mlseeq(x,chcffs,const,tblen,opmode)
y = mlseeq( ___ ,nsamp)

y = mlseeq( ___ ,nsamp,preamble,postamble)

y = mlseeq( ___ ,nsamp,init_metric,init_states,init_inputs)
[y,final_metric,final_states,final_inputs] = mlseeq( ___ )
```

Description

`y = mlseeq(x,chcffs,const,tblen,opmode)` equalizes the baseband signal vector `x` using the maximum likelihood sequence estimation (MLSE). `chcffs` provides estimated channel coefficients. `const` provides the ideal signal constellation points. `tblen` specifies the traceback depth. `opmode` specifies the operation mode of the equalizer. MLSE is implemented using the “Viterbi Algorithm” on page 2-586.

`y = mlseeq( ___ ,nsamp)` specifies the number of samples per symbol in `x`, in addition to arguments in the previous syntax.

`y = mlseeq( ___ ,nsamp,preamble,postamble)` specifies the number of samples per symbol in `x`, preamble, and postamble, in addition to arguments in the first syntax. This syntax applies when `opmode` is `'rst'` only. For more information, see “Preamble and Postamble in Reset Operation Mode” on page 2-586.

`y = mlseeq( ___ ,nsamp,init_metric,init_states,init_inputs)`specifies the number of samples per symbol in `x`, initial likelihood state metrics, initial traceback states, and initial traceback inputs for the equalizer, in addition to arguments in the first syntax. These three inputs are typically the `final_metric`, `final_states`, and `final_inputs` outputs from a previous call to this function. This syntax applies when `opmode` is `'cont'` only. For more information, see “Initialization in Continuous Operation Mode” on page 2-586.

`[y,final_metric,final_states,final_inputs] = mlseeq( ___ )` returns the normalized final likelihood state metrics, final traceback states, and final traceback inputs at the end of the traceback decoding process, using any of the previous input argument syntaxes. This syntax applies when `opmode` is `'cont'` only. For more information, see “Initialization in Continuous Operation Mode” on page 2-586.

Examples

Using MLSE Equalizer Reset Operating Mode

Use the reset operating mode of the `mlseeq` equalizer. Demodulate the signal and check the bit error rate.

Specify the modulation order, equalizer traceback depth, number of samples per symbol, and message length.

```
M = 2;
tblen =  10;
nsamp = 2;
msgLen = 1000;
```

Generate the reference constellation.

```
const = pammod([0:M-1],M);
```

Generate a message with random data. Modulate and upsample the signal.

```
msgData = randi([0 M-1],msgLen,1);
msgSym = pammod(msgData,M);
msgSymUp = upsample(msgSym,nsamp);
```

Filter the data through a distortion channel and add Gaussian noise to the signal.

```
chanest = [0.986; 0.845; 0.237; 0.12345+0.31i];
msgFilt = filter(chanest,1,msgSymUp);
msgRx = awgn(msgFilt,5,'measured');
```

Equalize and then demodulate the signal to recover the message. To initialize the equalizer, provide the channel estimate, reference constellation, equalizer traceback depth, number of samples per symbol, and set the operating mode to reset. Check the message bit error rate. Your results might vary because this example uses random numbers.

```
eqSym = mlseeq(msgRx,chanest,const,tblen,'rst',nsamp);
eqMsg = pamdemod(eqSym,M);
```

```
[nerrs ber] = biterr(msgData, eqMsg)
```

```
nerrs = 1
```

```
ber = 1.0000e-03
```

Recover Message Containing Preamble

Recover a message that includes a preamble, equalize the signal, and check the symbol error rate.

Specify the modulation order, equalizer traceback depth, number of samples per symbol, preamble, and message length.

```
M = 4;
tblen = 16;
nsamp = 1;
preamble = [3;1];
msgLen = 500;
```

Generate the reference constellation.

```
const = pskmod(0:3,4);
```

Generate a message by using random data and prepend the preamble to the message. Modulate the random data.

```
msgData = randi([0 M-1],msgLen,1);
msgData = [preamble; msgData];
msgSym = pskmod(msgData,M);
```

Filter the data through a distortion channel and add Gaussian noise to the signal.

```
chcoeffs = [0.623; 0.489+0.234i; 0.398i; 0.21];
chanest = chcoeffs;
msgFilt = filter(chcoeffs,1,msgSym);
msgRx = awgn(msgFilt,9,'measured');
```

Equalize the received signal. To configure the equalizer, provide the channel estimate, reference constellation, equalizer traceback depth, operating mode, number of samples per symbol, and preamble. The same preamble symbols appear at the beginning of the message vector and in the syntax for `mlseeq`. Because the system does not use a postamble, an empty vector is specified as the last input argument in this `mlseeq` syntax.

Check the symbol error rate of the equalized signal. Run-to-run results vary due to use of random numbers.

```
eqSym = mlseeq(msgRx,chanest,const,tblen,'rst',nsamp,preamble,[]);
[nsymerrs,ser] = symerr(msgSym,eqSym)
```

```
nsymerrs = 8
```

```
ser = 0.0159
```

Using MLSE Equalizer Continuous Operating Mode

Use the continuous operating mode of the `mlseeq` equalizer. Demodulate received signal packets and check the symbol error statistics.

Specify the modulation order, equalizer traceback depth, number of samples per symbol, message length, and number of packets to process.

```
M = 4;
tblen =  10;
nsamp = 1;
msgLen = 1000;
numPkts = 25;
```

Generate the reference constellation.

```
const = pskmod(0:M-1,M);
```

Set the initial input parameters for the metric, states, and inputs of the equalizer to empty vectors. These initial assignments represent the parameters for the first packet transmitted.

```
eq_metric = [];
eq_states = [];
eq_inputs = [];
```

Assign variables for symbol error statistics.

```
ttlSymbErrs = 0;
aggrPktSER = 0;
```

Send and receive multiple message packets in a simulation loop. Between the packet transmission and reception filter each packet through a distortion channel and add Gaussian noise.

```
for jj = 1:numPkts
```

Generate a message with random data. Modulate the signal.

```
    msgData = randi([0 M-1],msgLen,1);
    msgMod = pskmod(msgData,M);
```

Filter the data through a distortion channel and add Gaussian noise to the signal.

```
    chanest = [.986; .845; .237; .12345+.31i];
    msgFilt = filter(chanest,1,msgMod);
    msgRx = awgn(msgFilt,10,'measured');
```

Equalize the received symbols. To configure the equalizer, provide the channel estimate, reference constellation, equalizer traceback depth, operating mode, number of samples per symbol, and the equalizer initialization information. Continuous operating mode is specified for the equalizer. In continuous operating mode, the equalizer initialization information (metric, states, and inputs) are returned and used as inputs in the next iteration of the `for` loop.

```
    [eqSym,eq_metric,eq_states,eq_inputs] = ...
        mlseeq(msgRx,chanest,const,tblen,'cont',nsamp, ...
        eq_metric,eq_states,eq_inputs);
```

Save the symbol error statistics. Update the symbol error statistics with the aggregate results. Display the total number of errors. Your results might vary because this example uses random numbers.

```
    [nsymerrs,ser] = symerr(msgMod(1:end-tblen),eqSym(tblen+1:end));
    ttlSymbErrs = ttlSymbErrs + nsymerrs;
    aggrPktSER = aggrPktSER + ser;
end
printTtlErr = 'A total of %d symbol errors over the %d packets received.\n';
fprintf(printTtlErr,ttlSymbErrs,numPkts);
```

```
A total of 155 symbol errors over the 25 packets received.
```

Display the aggregate symbol error rate.

```
printAggrSER = 'The aggregate symbol error rate was %6.5d.\n';
fprintf(printAggrSER,aggrPktSER/numPkts);
```

```
The aggregate symbol error rate was 6.26263e-03.
```

Input Arguments

x — Input signal

vector

Input signal, specified as a vector of modulated symbols. The vector length of `x` must be an integer multiple of `nsamp`.

Data Types: `double`
Complex Number Support: Yes

`chcffs` — Channel coefficients

vector

Channel coefficients, specified as a vector. The channel coefficients provide an estimate of the channel response. When `nsamp` > 1, the `chcffs` input specifies the oversampled channel coefficients.

Data Types: `double`
Complex Number Support: Yes

`const` — Reference constellation

vector

Reference constellation, specified as a vector with *M* elements. *M* is the modulation order. `const` lists the ideal signal constellation points in the sequence used by the modulator.

Data Types: `double`
Complex Number Support: Yes

`tblen` — Traceback depth

positive integer

Traceback depth, specified as a positive integer. The equalizer traces back from the likelihood state with the maximum metric.

Data Types: `double`

`opmode` — Operation mode

`'rst'` | `'cont'`

Operation mode, specified as `'rst'` or `'cont'`.

Value	Usage
`'rst'`	Run equalizer using reset operating mode. Enables you to specify a `preamble` and `postamble` that accompany the input signal. The function processes the input signal, `x`, independently of the input signal from any other invocations of this function. This operating mode does not incur an output delay. For more information, see “Preamble and Postamble in Reset Operation Mode” on page 2-586.
`'cont'`	Run equalizer using continuous operating mode. Enables you to save the internal state information of the equalizer for use in a subsequent invocation of this function. Continuous operating mode is useful if the input signal is partitioned into a stream of packets processed within a loop. This operating mode incurs an output delay of `tblen` symbols. For more information, see “Initialization in Continuous Operation Mode” on page 2-586.

Data Types: `char`

`nsamp` — Number of samples per symbol

`1` (default) | positive integer

Number of samples per symbol, specified as a positive integer. `nsamp` is the oversampling factor.

Dependencies

The input signal, `x`, must be an integer multiple of `nsamp`.

Data Types: `double`

`preamble` — Input signal preamble

vector of integers

Input signal preamble, specified as a vector of integers between 0 and *M*–1, where *M* is the modulation order. To omit a preamble, specify `[]`.

For more information, see "Preamble and Postamble in Reset Operation Mode" on page 2-586.

Dependencies

This input argument applies only when `opmode` is set to `'rst'`.

Data Types: `double`

`postamble` — Input signal postamble

vector of integers

Input signal postamble, specified as a vector of integers between 0 and *M*–1, where *M* is the modulation order. To omit a postamble, specify `[]`.

For more information, see "Preamble and Postamble in Reset Operation Mode" on page 2-586.

Dependencies

This input argument applies only when `opmode` is set to `'rst'`.

Data Types: `double`

`init_metric` — Initial state metrics

[ ] (default) | column vector

Initial state metrics, specified as a column vector with N_{states} elements. For the description of N_{states}, see "Number of Likelihood States" on page 2-587.

For more information, see "Initialization in Continuous Operation Mode" on page 2-586.

Dependencies

This input argument applies only when `opmode` is set to `'cont'`. If specifying `[]` for `init_metric`, you must also specify `[]` for `init_states` and `init_inputs`.

Data Types: `double`

`init_states` — Initial traceback states

[ ] (default) | matrix of integers

Initial traceback states, specified as an N_{states}-by-`tblen` matrix of integers with values between 0 and N_{states}–1. For the description of N_{states}, see "Number of Likelihood States" on page 2-587.

For more information, see "Initialization in Continuous Operation Mode" on page 2-586.

Dependencies

This input argument applies only when `opmode` is set to `'cont'`. If specifying `[]` for `init_states`, you must also specify `[]` for `init_metric` and `init_inputs`.

Data Types: `double`

`init_inputs` — Initial traceback inputs

`[]` (default) | matrix of integers

Initial traceback inputs, specified as an N_{states}-by-`tblen` matrix of integers with values between 0 and M–1. For the description of N_{states}, see “Number of Likelihood States” on page 2-587.

For more information, see “Initialization in Continuous Operation Mode” on page 2-586.

Dependencies

This input argument applies only when `opmode` is set to `'cont'`. If specifying `[]` for `init_inputs`, you must also specify `[]` for `init_metric` and `init_states`.

Data Types: `double`

Output Arguments

y — Output signal

vector

Output signal, returned as a vector of modulated symbols.

`final_metric` — Final normalized state metrics

vector

Final normalized state metrics, returned as a vector with N_{states} elements. `final_metric` corresponds to the final state metrics at the end of the traceback decoding process. For the description of N_{states}, see “Number of Likelihood States” on page 2-587.

For more information, see “Initialization in Continuous Operation Mode” on page 2-586.

`final_states` — Final traceback states

vector

Final traceback states, returned as a N_{states}-by-`tblen` matrix of integers with values between 0 and N_{states}–1. `final_states` corresponds to the final traceback states at the end of the traceback decoding process. For the description of N_{states}, see “Number of Likelihood States” on page 2-587.

For more information, see “Initialization in Continuous Operation Mode” on page 2-586.

`final_inputs` — Final traceback inputs

vector

Final traceback inputs, returned as an N_{states}-by-`tblen` matrix of integers with values between 0 and M–1. `final_inputs` corresponds to the final traceback inputs at the end of the traceback decoding process. M is the order of the modulation. For the description of N_{states}, see “Number of Likelihood States” on page 2-587.

For more information, see “Initialization in Continuous Operation Mode” on page 2-586.

More About

Viterbi Algorithm

The Viterbi algorithm is a sequential trellis search algorithm used to perform maximum likelihood sequence detection.

The MLSE equalizer uses the Viterbi algorithm to recursively search for the sequences that maximize the likelihood function. Using the Viterbi algorithm reduces the number of sequences in the trellis search by eliminating sequences as new data is received. The metric used to determine the maximum likelihood sequence is the correlation between the received signal and an estimated signal for each received symbol over the “Number of Likelihood States” on page 2-587.

For more information, see [1] and [2].

Preamble and Postamble in Reset Operation Mode

When operating the MLSE equalizer in reset mode, you can specify a preamble and postamble as input arguments. Specify `preamble` and `postamble` as vectors equal to the preamble and postamble that are prepended and appended, respectively, to the input signal. The `preamble` and `postamble` vectors consist of integers between 0 and *M*-1, where *M* is the number of elements in `const`. To omit the `preamble` or `postamble` input argument, specify `[]`.

When the function applies the Viterbi algorithm, it initializes state metrics in a way that depends on whether you specify a preamble, a postamble, or both:

- If `preamble` is nonempty, the function decodes the preamble and assigns a metric of 0 to the decoded state. If the preamble does not decode to a unique state (that is, if the length of the preamble is less than the channel memory), the decoder assigns a metric of 0 to all states that are represented by the preamble. The traceback path ends at one of the states represented by the preamble.
- If `preamble` is `[]`, the decoder initializes the metrics of all states to 0.
- If `postamble` is nonempty, the traceback path begins at the smallest of all possible decoded states that are represented by the postamble.
- If `postamble` is `[]`, the traceback path starts at the state with the smallest metric.

Initialization in Continuous Operation Mode

When operating the MLSE equalizer in continuous mode, you can initialize the equalization based on values returned in the previous call of the function.

At the end of the traceback decoding process, the function returns `final_metric`, `final_states`, and `final_inputs`. When `opmode` is `'cont'`, assign these outputs to `init_metric`, `init_states`, and `init_inputs`, respectively for the next call of the function. These assignments initialize the equalizer to start with the final state metrics, final traceback states, and final traceback inputs from the previous call of the function.

Each real number in `init_metric` represents the starting state metric of the corresponding state. `init_states` and `init_inputs` jointly specify the initial traceback memory of the equalizer.

Output Argument	Input Argument	Meaning	Matrix Size	Range of Values
`final_metric`	`init_metric`	State metrics	1-by-N_{states}	Real numbers
`final_states`	`init_states`	Traceback states	N_{states}-by-`tblen`	Integers between 0 and N_{states}–1
`fianl_inputs`	`init_inputs`	Traceback inputs	N_{states}-by-`tblen`	Integers between 0 and M–1

To use default values for `init_metric`, `init_states`, and `init_inputs`, specify each as `[]`. For the description of N_{states}, see “Number of Likelihood States” on page 2-587.

Number of Likelihood States

The number of likelihood states, N_{states}, is the number of correlative phase states in the trellis. N_{states} is equal to $M^{L\text{-}1}$, where M is the number of elements in `const` and L is the number of symbols in the nonoversampled impulse response of the channel.

modnorm

Scaling factor for normalizing modulation output

Syntax

```
normfactor = modnorm(refconst,type,power)
```

Description

`normfactor = modnorm(refconst,type,power)` returns a scale factor for normalizing a PAM or QAM modulator output using the specified reference constellation, normalization type, and output power.

Examples

Normalize Power of QAM Signal

Generate a 16-QAM reference constellation.

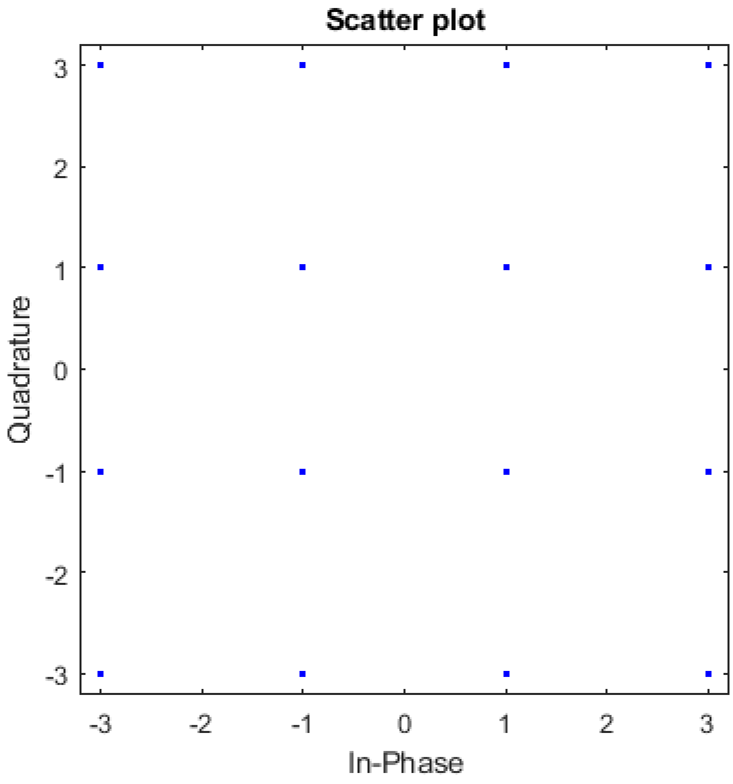
```
refconst = qammod(0:15,16);
```

Generate random symbols and apply 16-QAM modulation.

```
x = randi([0 15],1000,1);
y = qammod(x,16);
```

Plot the constellation.

```
h = scatterplot(y);
```



Compute the normalization factor so that the output signal has a peak power of 1 W.

```
nf = modnorm(refconst,'peakpow',1);
z = nf*y;
```

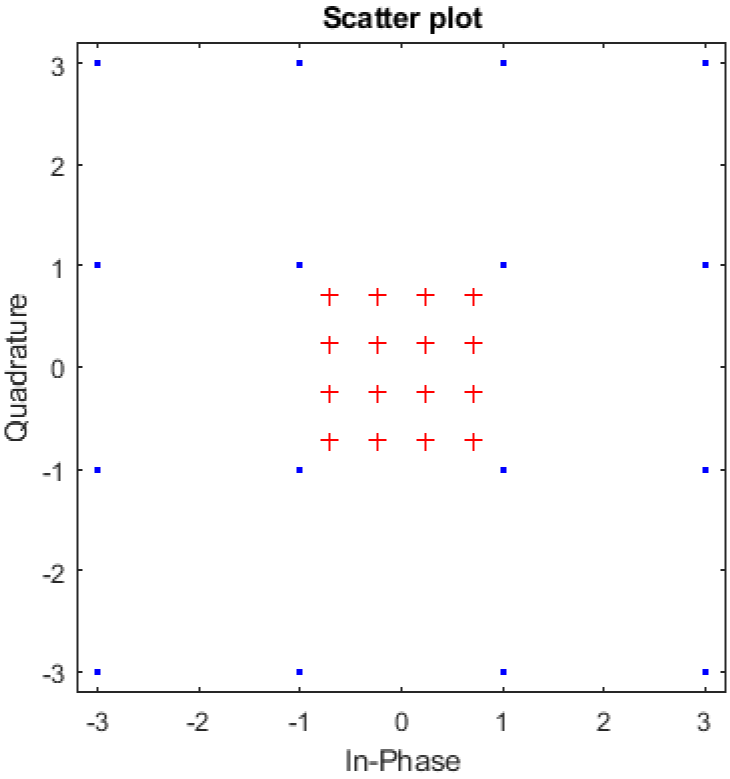
Confirm that no element of the normalized signal has a power greater than 1 W.

```
max(z.*conj(z))
```

```
ans = 1.0000
```

Plot the scatter plot of the normalized constellation.

```
hold on
scatterplot(z,1,0,'r+',h)
hold off
```



Input Arguments

`refconst` — Reference constellation

vector

Reference constellation, specified as a vector of complex elements that comprise the reference constellation points.

Example: `qammod(0:15,16)`

Data Types: `double`
Complex Number Support: Yes

`type` — Normalization type

`'avpow'` | `'peakpow'`

Normalization type, specified as either `'avpow'` or `'peakpow'`.

- If `type` is `'avpow'`, the normalization factor is calculated based on average power.
- If `type` is `'peakpow'`, the normalization factor is calculated based on peak power.

Data Types: `char`

`power` — Target power

scalar

Target power, specified as a real scalar. The target power is the intended power of the modulated signal multiplied by `normfactor`.

Data Types: `double`

Output Arguments

`normfactor` — Normalization factor

scalar

Normalization factor, returned as a real scalar. When a modulated signal is multiplied by the normalization factor, its average or peak power matches the target power. The function assumes that the signal you want to normalize has a minimum distance of 2.

`pamdemod` | `pammod` | `qamdemod` | `qammod`

Introduced before R2006a

mskdemod

Minimum shift keying demodulation

Syntax

```
z = mskdemod(y,nsamp)
z = mskdemod(y,nsamp,dataenc)
z = mskdemod(y,nsamp,dataenc,ini_phase)
z = mskdemod(y,nsamp,dataenc,ini_phase,ini_state)
[z,phaseout] = mskdemod(...)
[z,phaseout,stateout] = mskdemod(...)
```

Description

`z = mskdemod(y,nsamp)` demodulates the complex envelope `y` of a signal using the differentially encoded minimum shift keying (MSK) method. `nsamp` denotes the number of samples per symbol and must be a positive integer. The initial phase of the demodulator is 0. If `y` is a matrix with multiple rows and columns, the function treats the columns as independent channels and processes them independently.

`z = mskdemod(y,nsamp,`*`dataenc`*`)` specifies the method of encoding data for MSK. *`dataenc`* can be either `'diff'` for differentially encoded MSK or `'nondiff'` for nondifferentially encoded MSK.

`z = mskdemod(y,nsamp,`*`dataenc`*`,ini_phase)` specifies the initial phase of the demodulator. `ini_phase` is a row vector whose length is the number of channels in `y` and whose values are integer multiples of `pi/2`. To avoid overriding the default value of *`dataenc`*, set *`dataenc`* to `[]`.

`z = mskdemod(y,nsamp,`*`dataenc`*`,ini_phase,ini_state)` specifies the initial state of the demodulator. `ini_state` contains the last half symbol of the previously received signal. `ini_state` is an `nsamp`-by-C matrix, where C is the number of channels in `y`.

`[z,phaseout] = mskdemod(...)` returns the final phase of `y`, which is important for demodulating a future signal. The output `phaseout` has the same dimensions as the `ini_phase` input, and assumes the values `0`, `pi/2`, `pi`, and `3*pi/2`.

`[z,phaseout,stateout] = mskdemod(...)` returns the final `nsamp` values of `y`, which is useful for demodulating the first symbol of a future signal. `stateout` has the same dimensions as the `ini_state` input.

Examples

MSK Demodulation

Modulate and demodulate a noisy MSK signal. Display the number of received errors.

Define the number of samples per symbol for the MSK signal.

```
nsamp = 16;
```

Initialize the simulation parameters.

```
numerrs = 0;
modPhase = zeros(1,2);
demodPhase = zeros(1,2);
demodState = complex(zeros(nsamp,2));
```

The main processing loop includes these steps:

- Generate binary data.
- MSK modulate the data.
- Pass the signal through an AWGN channel.
- Demodulate the MSK signal.
- Determine the number of bit errors.

```
for iRuns = 1:20
    txData = randi([0 1],100,2);
    [modSig,modPhase] = mskmod(txData,nsamp,[],modPhase);
    rxSig = awgn(modSig,20,'measured');
    [rxData,demodPhase,demodState] = mskdemod(rxSig,nsamp,[],demodPhase,demodState);
    numerrs = numerrs + biterr(txData,rxData);
end
```

Display the number of bit errors.

```
numerrs
```

```
numerrs = 0
```

mskmod

Minimum shift keying modulation

Syntax

```
y = mskmod(x,nsamp)
y = mskmod(x,nsamp,dataenc)
y = mskmod(x,nsamp,dataenc,ini_phase)
[y,phaseout] = mskmod(...)
```

Description

`y = mskmod(x,nsamp)` outputs the complex envelope `y` of the modulation of the message signal `x` using differentially encoded minimum shift keying (MSK) modulation. The elements of `x` must be 0 or 1. `nsamp` denotes the number of samples per symbol in `y` and must be a positive integer. The initial phase of the MSK modulator is 0. If `x` is a matrix with multiple rows and columns, the function treats the columns as independent channels and processes them independently.

`y = mskmod(x,nsamp,`*`dataenc`*`)` specifies the method of encoding data for MSK. *`dataenc`* can be either `'diff'` for differentially encoded MSK or `'nondiff'` for nondifferentially encoded MSK.

`y = mskmod(x,nsamp,`*`dataenc`*`,ini_phase)` specifies the initial phase of the MSK modulator. `ini_phase` is a row vector whose length is the number of channels in `y` and whose values are integer multiples of `pi/2`. To avoid overriding the default value of *`dataenc`*, set *`dataenc`* to `[]`.

`[y,phaseout] = mskmod(...)` returns the final phase of `y`. This is useful for maintaining phase continuity when you are modulating a future bit stream with differentially encoded MSK. `phaseout` has the same dimensions as the `ini_phase` input, and assumes the values `0`, `pi/2`, `pi`, and `3*pi/2`.

Examples

Eye Diagram of MSK Signal

Generate a random binary signal.

```
x = randi([0 1],100,1);
```

MSK modulate the data.

```
y = mskmod(x,8,[],pi/2);
```

Pass the signal through an AWGN channel. Display the eye diagram.

```
z = awgn(y,30,'measured');
eyediagram(z,16);
```

Introduced before R2006a

muxdeintrlv

Restore ordering of symbols using specified shift registers

Syntax

```
deintrlved = muxdeintrlv(data,delay)
[deintrlved,state] = muxdeintrlv(data,delay)
[deintrlved,state] = muxdeintrlv(data,delay,init_state)
```

Description

`deintrlved = muxdeintrlv(data,delay)` restores the ordering of elements in `data` by using a set of internal shift registers, each with its own delay value. `delay` is a vector whose entries indicate how many symbols each shift register can hold. The length of `delay` is the number of shift registers. Before the function begins to process data, it initializes all shift registers with zeros. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

`[deintrlved,state] = muxdeintrlv(data,delay)` returns a structure that holds the final state of the shift registers. `state.value` stores any unshifted symbols. `state.index` is the index of the next register to be shifted.

`[deintrlved,state] = muxdeintrlv(data,delay,init_state)` initializes the shift registers with the symbols contained in `init_state.value` and directs the first input symbol to the shift register referenced by `init_state.index`. The structure `init_state` is typically the `state` output from a previous call to this same function, and is unrelated to the corresponding interleaver.

Using an Interleaver-Deinterleaver Pair

To use this function as an inverse of the `muxintrlv` function, use the same `delay` input in both functions. In that case, the two functions are inverses in the sense that applying `muxintrlv` followed by `muxdeintrlv` leaves data unchanged, after you take their combined delay of `length(delay)*max(delay)` into account. To learn more about delays of convolutional interleavers, see “Delays of Convolutional Interleavers”.

Examples

The example below illustrates how to use the state input and output when invoking `muxdeintrlv` repeatedly. Notice that `[deintrlved1; deintrlved2]` is the same as `deintrlved`.

```
delay = [0 4 8 12]; % Delays in shift registers
symbols = 100; % Number of symbols to process
% Interleave random data.
intrlved = muxintrlv(randi([0 1],symbols,1),delay);

% Deinterleave some of the data, recording state for later use.
[deintrlved1,state] = muxdeintrlv(intrlved(1:symbols/2),delay);
% Deinterleave the rest of the data, using state as an input argument.
deintrlved2 = muxdeintrlv(intrlved(symbols/2+1:symbols),delay,state);

% Deinterleave all data in one step.
deintrlved = muxdeintrlv(intrlved,delay);

isequal(deintrlved,[deintrlved1; deintrlved2])
```

The output is below.

```
ans =

     1
```

Another example using this function is in “Convolutional Interleaving and Deinterleaving Using a Sequence of Consecutive Integers in MATLAB”.

Introduced before R2006a

muxintrlv

Permute symbols using shift registers with specified delays

Syntax

```
intrlved = muxintrlv(data,delay)
[intrlved,state] = muxintrlv(data,delay)
[intrlved,state] = muxintrlv(data,delay,init_state)
```

Description

`intrlved = muxintrlv(data,delay)` permutes the elements in `data` by using internal shift registers, each with its own delay value. `delay` is a vector whose entries indicate how many symbols each shift register can hold. The length of `delay` is the number of shift registers. Before the function begins to process data, it initializes all shift registers with zeros. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

`[intrlved,state] = muxintrlv(data,delay)` returns a structure that holds the final state of the shift registers. `state.value` stores any unshifted symbols. `state.index` is the index of the next register to be shifted.

`[intrlved,state] = muxintrlv(data,delay,init_state)` initializes the shift registers with the symbols contained in `init_state.value` and directs the first input symbol to the shift register referenced by `init_state.index`. The structure `init_state` is typically the `state` output from a previous call to this same function, and is unrelated to the corresponding deinterleaver.

Examples

The examples in “Convolutional Interleaving and Deinterleaving Using a Sequence of Consecutive Integers in MATLAB” and on the reference page for the `convintrlv` function use `muxintrlv`.

The example on the reference page for `muxdeintrlv` illustrates how to use the `state` output and `init_state` input with that function; the process is analogous for this function.

noisebw

Equivalent noise bandwidth of filter

Syntax

```
bw = noisebw(num, den, numsamp, Fs)
```

Description

`bw = noisebw(num, den, numsamp, Fs)` returns the two-sided equivalent noise bandwidth, in Hz, of a digital lowpass filter given in descending powers of z by numerator vector `num` and denominator vector `den`. The bandwidth is calculated over `numsamp` samples of the impulse response. `Fs` is the sampling rate of the signal that the filter would process; this is used as a scaling factor to convert a normalized unitless quantity into a bandwidth in Hz.

Examples

Noise Equivalent Bandwidth of Butterworth Filter

Computes the equivalent noise bandwidth of a Butterworth filter over 100 samples of the impulse response.

Set the sampling rate, Nyquist frequency, and carrier frequency.

```
fs = 16;
fNyq = fs/2;
fc = 0.5;
```

Generate the Butterworth filter.

```
[num,den] = butter(2,fc/fNyq);
```

Determine the noise bandwidth.

```
bw = noisebw(num,den,100,fs)
```

```
bw = 1.1049
```

Algorithms

The two-sided equivalent noise bandwidth is

$$\frac{\mathrm{Fs}\sum_{i=1}^{N}|h(i)|^2}{\left|\sum_{i=1}^{N}h(i)\right|^2}$$

where h is the impulse response of the filter described by `num` and `den`, and N is `numsamp`.

Introduced before R2006a

normlms

(To be removed) Construct normalized least mean square (LMS) adaptive algorithm object

Note will be removed in a future release. Consider using `comm.LinearEqualizer` or `comm.DecisionFeedback` instead.

Syntax

```
alg = normlms(stepsize)
alg = normlms(stepsize,bias)
```

Description

The `normlms` function creates an adaptive algorithm object that you can use with the `lineareq` function or `dfe` function to create an equalizer object. You can then use the equalizer object with the `equalize` function to equalize a signal. To learn more about the process for equalizing a signal, see “Equalization”.

`alg = normlms(stepsize)` constructs an adaptive algorithm object based on the normalized least mean square (LMS) algorithm with a step size of `stepsize` and a bias parameter of zero.

`alg = normlms(stepsize,bias)` sets the bias parameter of the normalized LMS algorithm. `bias` must be between 0 and 1. The algorithm uses the bias parameter to overcome difficulties when the algorithm's input signal is small.

Properties

The table below describes the properties of the normalized LMS adaptive algorithm object. To learn how to view or change the values of an adaptive algorithm object, see “Equalization”.

Property	Description
`AlgType`	Fixed value, `'Normalized LMS'`
`StepSize`	LMS step size parameter, a nonnegative real number
`LeakageFactor`	LMS leakage factor, a real number between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, while a value of 0 corresponds to a memoryless update algorithm.
`Bias`	Normalized LMS bias parameter, a nonnegative real number

Examples

Configuring Linear Equalizers

This example configures the recommended `comm.LinearEqualizer` System object™ and the legacy `lineareq` feature with comparable settings.

Initialize Variables and Supporting Objects

```
d = randi([0 3],1000,1);
x = pskmod(d,4,pi/4);
r = awgn(x,25);
sps = 2; %samples per symbol for oversampled cases
nTaps = 6;
txFilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',nTaps, ...
    'OutputSamplesPerSymbol',4);
rxFilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',nTaps, ...
    'InputSamplesPerSymbol',4,'DecimationFactor',2);
x2 = txFilter(x);
r2 = rxFilter(awgn(x2,25,0.5));
filterDelay = txFilter.FilterSpanInSymbols/2 + ...
    rxFilter.FilterSpanInSymbols/2; % Total filter delay in symbols
```

To compare the equalized output, plot the constellations using code such as:

```
% plot(yNew,'*')
% hold on
% plot(yOld,'o')
% hold off; legend('New Eq','Old Eq'); grid on
```

Use LMS Algorithm with Linear Equalizer

Configure `lineareq` and `comm.LinearEqualizer` objects with comparable settings. The `LeakageFactor` property has been removed from LMS algorithm. The `comm.LinearEqualizer` System object™ assumes that leakage factor is always 1.

```
eqOld = lineareq(5,lms(0.05),pskmod(0:3,4,pi/4))
```

```
eqOld =

```

Call the equalizers.

```
yOld = equalize(eqOld,r);
yNew = eqNew(r);
```

Use Linear Equalizers Considering Signal Delays

Configure `lineareq` and `comm.LinearEqualizer` objects with comparable settings. The transmit and receive filters result in a signal delay between the transit and receive signals. Account for this delay by setting the `RefTap` property of the `lineareq` to a value close to the delay value in samples. Additionally, `nWeights` must be set to a value greater than `RefTap`.

```
eqOld = lineareq(filterDelay*sps+4,lms(0.01),pskmod(0:3,4,pi/4),sps);
eqOld.RefTap = filterDelay*sps+1 % Adjust to synchronize with delayed signal
```

```
eqOld =
  EqType: 'Linear Equalizer'
  AlgType: 'LMS'
  nWeights: 16
  nSampPerSym: 2
  RefTap: 13
  SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  StepSize: 0.0100
  LeakageFactor: 1
  Weights: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
  WeightInputs: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
  ResetBeforeFiltering: 1
  NumSamplesProcessed: 0
```

```
eqNew = comm.LinearEqualizer('NumTaps',16,'Algorithm','LMS','StepSize',0.01, ...
    'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    'ReferenceTap',filterDelay*sps+1,'InputDelay',0)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'LMS'
  NumTaps: 16
  StepSize: 0.0100
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 13
  InputDelay: 0
  InputSamplesPerSymbol: 2
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers. When `ResetBeforeFiltering` is set to `true`, each call of the `equalize` object resets the equalizer. To get the equivalent behavior call `reset` after each call of the `comm.LinearEqualizer` object.

```
yOld1 = equalize(eqOld,r,x(1:100));
yOld2 = equalize(eqOld,r,x(1:100));

yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

In the `comm.LinearEqualizer` object, `InputDelay` is used to synchronize with the delayed signal. `NumTaps` and `ReferenceTap` are independent of delay value. We can reduce the number of taps by utilizing the `InputDelay` to synchronize instead of reference tap. Reducing the number of taps also reduces equalizer self noise.

```
eqNew = comm.LinearEqualizer('NumTaps',11,'Algorithm','LMS','StepSize',0.01, ...
    'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    'ReferenceTap',6,'InputDelay',filterDelay*sps)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'LMS'
  NumTaps: 11
  StepSize: 0.0100
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 6
  InputDelay: 12
  InputSamplesPerSymbol: 2
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

```
yNew1 = eqNew(r2,x(1:100));
reset(eqNew)
yNew2 = eqNew(r2,x(1:100));
```

Algorithms

Referring to the schematics presented in “Equalization”, define *w* as the vector of all weights w_i and define *u* as the vector of all inputs u_i. Based on the current set of weights, *w*, this adaptive algorithm creates the new set of weights given by

$$(\text{LeakageFactor})w + \frac{(\text{StepSize})u^*e}{u^Hu + \text{Bias}}$$

where the * operator denotes the complex conjugate and *H* denotes the Hermitian transpose.

Compatibility Considerations

`normlms` will be removed

Warns starting in R2020a

- normlms will be removed in a future release. Consider using `comm.LinearEqualizer` or `comm.DecisionFeedback` instead with the adaptive algorithm set to LMS.
- The `comm.LinearEqualizer` or `comm.DecisionFeedback` System objects do not have a leakage factor property. This is equivalent to setting `LeakageFactor` to `1` in the normlms function.
- For examples comparing setup of `comm.LinearEqualizer` to `lineareq`, see “Configuring Linear Equalizers” on page 2-601.

Topics
“Equalization”

Introduced before R2006a

oct2dec

Convert octal to decimal numbers

Syntax

```
d = oct2dec(c)
```

Description

`d = oct2dec(c)` converts an octal matrix `c` to a decimal matrix `d`, element by element. In both octal and decimal representations, the rightmost digit is the least significant.

Examples

Convert Octal Matrix to Decimal Equivalent

Convert a 2-by-2 octal matrix its decimal equivalent.

```
d = oct2dec([12 144;0 25])
```

```
d = 2×2

    10   100
     0    21
```

The octal number 144 is equivalent to 100 because 144 = $1(8^2) + 4(8^1) + 4(8^0)$ = 100.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

`bi2de`

Introduced before R2006a

oct2poly

Convert octal number to binary coefficients

Syntax

```
b = oct2poly(oct)
b = oct2poly(oct,ord)
```

Description

`b = oct2poly(oct)` converts an octal number, `oct`, to a vector of binary coefficients, `b`.

`b = oct2poly(oct,ord)` specifies the power order, `ord`, of the coefficients that comprise the output. If omitted, `ord` is `'descending'`.

Examples

Convert Octal Number to Binary Vector

Convert the octal number `11` to a binary vector.

```
b = oct2poly(11)
```

```
b = 1×4

     1     0     0     1
```

The binary vector corresponds to the polynomial $x^3 + 1$.

Convert Octal Number to Ascending Order Binary Vector

Convert the octal number `65` to an ascending order binary vector.

```
b = oct2poly(65,'ascending')
```

```
b = 1×6

     1     0     1     0     1     1
```

Sixty-five octal is the generator polynomial of a (15,10) Hamming code in the Bluetooth v4.0 standard. The binary representation of 65 octal is 110101 and the GF(2) polynomial is $1 + x^2 + x^4 + x^5$ or [1 0 1 0 1 1] in ascending powers.

Input Arguments

`oct` — Octal number

scalar

Octal number, specified as a positive integer scalar.

Example: `15`

Example: `3177`

Data Types: `double`

`ord` — Power order

`'descending'` (default) | `'ascending'`

Power order of the binary coefficients vector, specified as a character vector having a value of `'ascending'` or `'descending'`.

Data Types: `char`

Output Arguments

`b` — Binary coefficients

vector

Binary coefficients representing a polynomial, returned as a row vector having length equal to $p + 1$, where p is the order of octal input.

ofdmdemod

Demodulate time-domain signal using orthogonal frequency division multiplexing (OFDM)

Syntax

```
outSym = ofdmdemod(ofdmSig,nfft,cplen)
outSym = ofdmdemod(ofdmSig,nfft,cplen,symOffset)
outSym = ofdmdemod(ofdmSig,nfft,cplen,symOffset,nullidx)
[outSym,pilots] = ofdmdemod(ofdmSig,nfft,cplen,symOffset,nullidx,pilotidx)
```

Description

`outSym = ofdmdemod(ofdmSig,nfft,cplen)` performs OFDM demodulation on the input time domain signal specified in `ofdmSig`, using an FFT size specified by `nfft` and cyclic prefix length specified by `cplen`. For information, see “OFDM Demodulation” on page 2-613.

`outSym = ofdmdemod(ofdmSig,nfft,cplen,symOffset)` applies the symbol sampling offset, `symOffset`, for each OFDM symbol before demodulation of the input.

`outSym = ofdmdemod(ofdmSig,nfft,cplen,symOffset,nullidx)` removes null subcarriers from the locations specified in `nullidx`. For this syntax, the symbol sampling offset is applied to each OFDM symbol and the number of rows in the output is `nfft – length(nullidx)`, which accounts for the removal of null subcarriers. Use null subcarriers to account for guard bands and DC subcarriers. For information, see “Subcarrier Allocation and Guard Bands” on page 2-614.

`[outSym,pilots] = ofdmdemod(ofdmSig,nfft,cplen,symOffset,nullidx,pilotidx)` returns pilot subcarriers for the pilot indices specified in `pilotidx`. For this syntax, the symbol sampling offset is applied to each OFDM symbol and number of rows in the output is `nfft – length(nullidx) – length(pilotidx)`, which accounts for the removal of null and pilot subcarriers. The function assumes that pilot subcarrier locations are the same across each OFDM symbol and transmit antenna.

Examples

OFDM Demodulation with Different CP Lengths

OFDM-demodulate a signal with different CP lengths for different symbols.

Initialize input parameters defining locations for null and pilot subcarriers. Generate random data and perform OFDM modulation.

```
nfft = 64;
cplen = [16 32];
nSym = 2;
dataIn = complex(randn(nfft,nSym),randn(nfft,nSym));
y1 = ofdmmod(dataIn,nfft,cplen);
```

Demodulate the OFDM symbols. Compare the results to the original input data. The difference between the signals is negligible.

```
x1 = ofdmdemod(y1,nfft,cplen);
max(x1-dataIn)
```

```
ans = 1×2 complex
10^-15 ×

   0.2220 - 0.7772i   0.2498 - 0.8882i
```

OFDM Mod-Demod SISO link

Apply OFDM multiplexing to a 16-QAM signal SISO link with Rayleigh fading.

```
s1 = RandStream('mt19937ar','Seed',12345);
nFFT = 64;
cpLen = 16;
nullIdx = [1:6 33 64-4:64].';
numTones = nFFT-length(nullIdx);

k = 4; % bits per symbol
M = 2^k;
constSym = qammod((0:M-1),M,'UnitAveragePower',true);

maxDopp = 1;
pathDelays = [0 4e-3 8e-3];
pathGains = [0 -2 -3];
sRate = 1000;
sampIdx = round(pathDelays/(1/sRate)) + 1;

chan = comm.RayleighChannel('PathGainsOutputPort',true, ...
    'MaximumDopplerShift',maxDopp,'PathDelays',pathDelays, ...
    'AveragePathGains',pathGains,'SampleRate',sRate, ...
    'RandomStream','mt19937ar with seed');

data = randi(s1,[0 M-1],numTones,1);

modOut = qammod(data,M,'UnitAveragePower',true);
```

Apply OFDM modulation and pass the signal through the channel.

```
y = ofdmmod(modOut,nFFT,cpLen,nullIdx);
[fadSig,pg] = chan(y);
```

Determine symbol sampling offset.

```
symOffset = min(max(sampIdx),cpLen)
```

```
symOffset = 9
```

OFDM demodulate the received signal.

```
x = ofdmdemod(fadSig,nFFT,cpLen,symOffset,nullIdx); % with a time shift
```

Convert path gains, `pg`, to scalar taps gains. Use the tap gains for equalization during signal recovery.

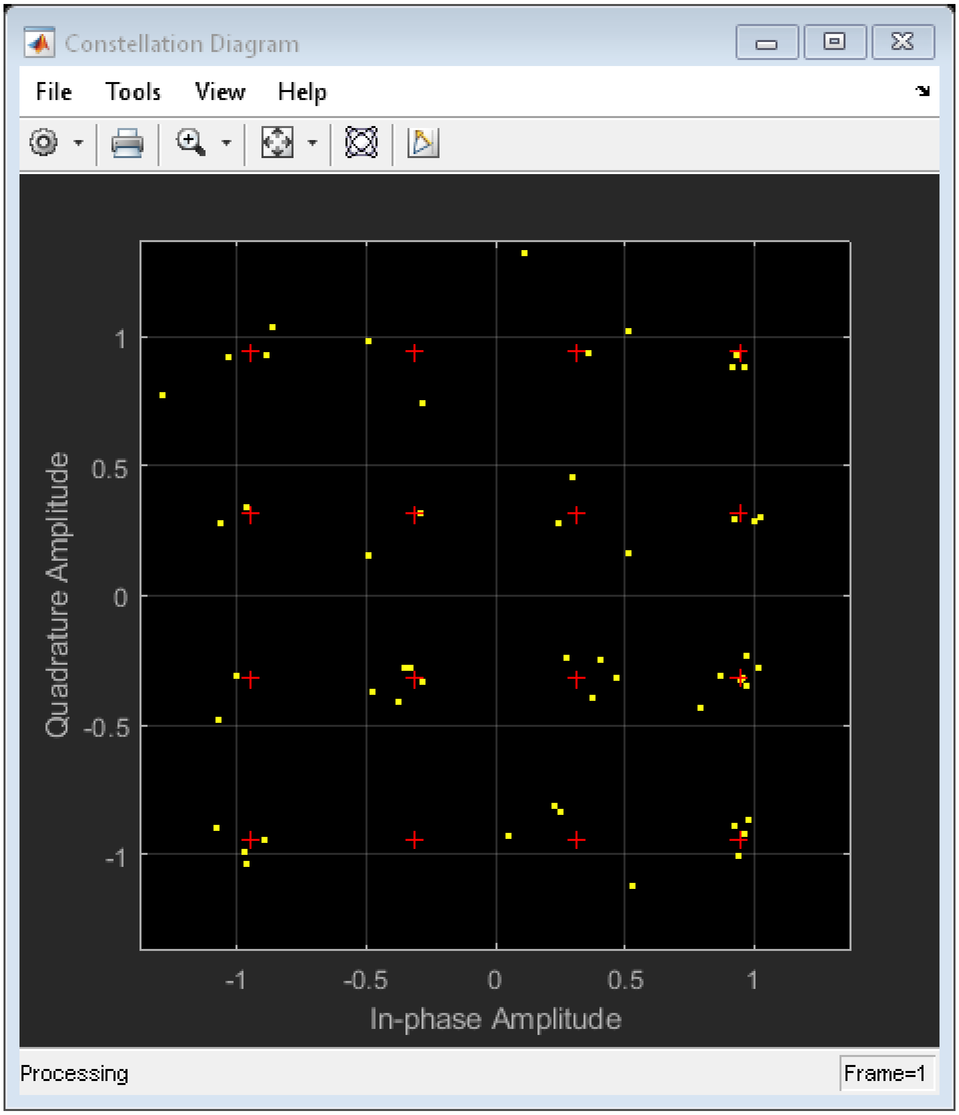
```
hImp = complex(zeros(1,nFFT));
hImp(:,sampIdx) = mean(pg,1);
```

```
hall = fftshift(fft(hImp.'),1);
dataIdx = double(setdiff((1:nFFT)',nullIdx));
h = hall(dataIdx);
```

Equalize the signal.

```
eqH = conj(h)./(conj(h).*h);
eqSig = eqH.*x;

cdScope = comm.ConstellationDiagram('ShowReferenceConstellation',true, ...
    'ReferenceConstellation',constSym);
cdScope(eqSig);
```



Demodulate the 16-QAM symbols to recover the signal. Compute the bit error rate.

```
rxSym = qamdemod(eqSig,M,'UnitAveragePower',true);

numErr = symerr(data,rxSym);
disp(['Number of symbol errors: ' num2str(numErr) ' out of ' num2str(length(data)) ' symbols.'])
```

```
Number of symbol errors: 2 out of 52 symbols.
```

OFDM Demodulation with Null and Pilot Packing

OFDM-demodulate data input that includes null and pilot packing.

Initialize input parameters, defining locations for null and pilot subcarriers. Generate random data and perform OFDM modulation.

```
nfft     = 64;
cplen    = 16;
nSym     = 10;
nullIdx  = [1:6 33 64-4:64]';
pilotIdx = [12 26 40 54]';
numDataCarrs = nfft-length(nullIdx)-length(pilotIdx);
dataIn = complex(randn(numDataCarrs,nSym),randn(numDataCarrs,nSym));
pilots = repmat(pskmod((0:3).',4),1,nSym);
y2 = ofdmmod(dataIn,nfft,cplen,nullIdx,pilotIdx,pilots);
```

Demodulate the OFDM symbols. Compare the results to the original input data to show that there is negligible difference between the demodulated signal and the original data and pilot signals.

```
symOffset = cplen;
[x2,rxPilots] = ofdmdemod(y2,nfft,cplen,symOffset,nullIdx,pilotIdx);
max(x2-dataIn)
```

```
ans = 1×10 complex
10^-15 ×

   0.5551 + 0.2220i   0.2220 + 0.4441i   0.4441 - 0.2220i   0.4718 - 0.3331i  -0.1665 - 0.4441i
```

```
max(rxPilots-pilots)
```

```
ans = 1×10 complex
10^-15 ×

   0.0000 + 0.3331i   0.1837 - 0.2220i  -0.4441 - 0.2776i   0.2220 + 0.2220i   0.2220 - 0.1665i
```

Input Arguments

ofdmSig — Modulated OFDM symbols
2-D array of complex symbols

Modulated OFDM symbols, specified as a 2-D array of complex symbols.

- If cplen is a scalar, the array size is ((nfft + cplen) × N_{Sym})-by-N_{R}.
- If cplen is a row vector, the array size is ((nfft × N_{Sym}) + sum(cplen))-by-N_{R}.

  N_{Sym} is the number of symbols per antenna and N_{R} is the number of receive antennas.

Data Types: double | single

Complex Number Support: Yes

nfft — FFT length
integer greater than or equal to 8

FFT length, specified as an integer greater than or equal to 8. `nfft` is equivalent to the number of subcarriers used in the demodulation process.

Data Types: `double`

cplen — Cyclic prefix length
scalar | row vector of length N_{Sym}

Cyclic prefix length, specified as a scalar or as a row vector of length N_{Sym}.

- When you specify `cplen` as a scalar, the cyclic prefix length is the same for all symbols through all antennas.
- When you specify `cplen` as a row vector of length N_{Sym}, the cyclic prefix length can vary across symbols but remains the same length through all antennas.

Data Types: `double`

symOffset — Symbol sampling offset
`cplen` (default) | scalar | row vector

Symbol sampling offset, specified as values from 0 to `cplen`.

- If you do not specify `symOffset`, the default value is an offset equal to `cplen`.
- If you specify `symOffset` as a scalar, the same offset is used for all symbols.
- If you specify `symOffset` as a row vector, the offset value can be different for each symbol.

For information, see “Windowing and Symbol Offset” on page 2-615.

Data Types: `double`

nullidx — Indices of null subcarrier locations
column vector

Indices of null subcarrier locations, specified as a column vector with element values from 1 to `nfft`. If you specify `nullidx`, the number of rows in `outSym` is `(nfft-length(nullidx))`. For information, see “Subcarrier Allocation and Guard Bands” on page 2-614.

Data Types: `double`

pilotidx — Indices of pilot subcarrier locations
column vector

Indices of pilot subcarrier locations, specified as a column vector with element values from 1 to `nfft`. If you specify `pilotidx`, the number of rows in `outSym` is `(nfft-length(nullidx)-length(pilotidx))`.For information, see “Subcarrier Allocation and Guard Bands” on page 2-614.

Data Types: `double`

Output Arguments

`outSym` — Output demodulated symbols

3-D array

Output demodulated symbols, returned as an N_D-by-N_{Sym}-by-N_R array of symbols. N_D must equal `nfft – length(nullidx) – length(pilotidx)`. N_{Sym} is the number of OFDM symbols per antenna. N_R is the number of receive antennas. For information, see “OFDM Demodulation” on page 2-613.

`pilots` — Pilot subcarriers

3-D array

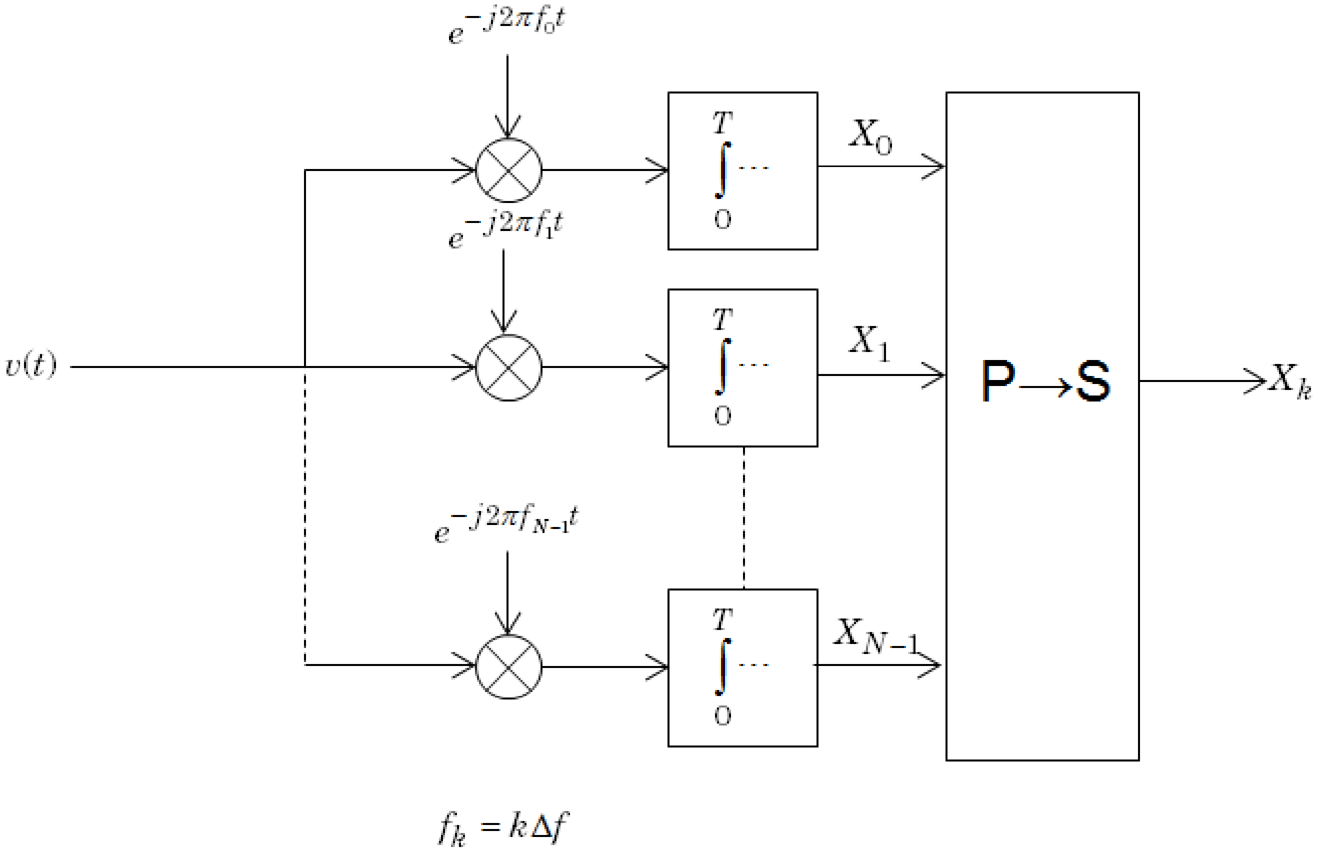
Pilot subcarriers, returned as an N_{Pilot}-by-N_{Sym}-by-N_R array of symbols. N_{Pilot} must equal the length of `pilotidx`. N_{Sym} is the number of OFDM symbols per antenna. N_R is the number of receive antennas. The function assumes that the pilot subcarrier locations are the same across each OFDM symbol and transmit antenna. Use the `comm.OFDMDemodulator` to vary pilot subcarrier locations across OFDM symbols or antennas.

More About

OFDM Demodulation

An OFDM demodulator demultiplexes a multi-subcarrier time-domain signal using orthogonal frequency division modulation.

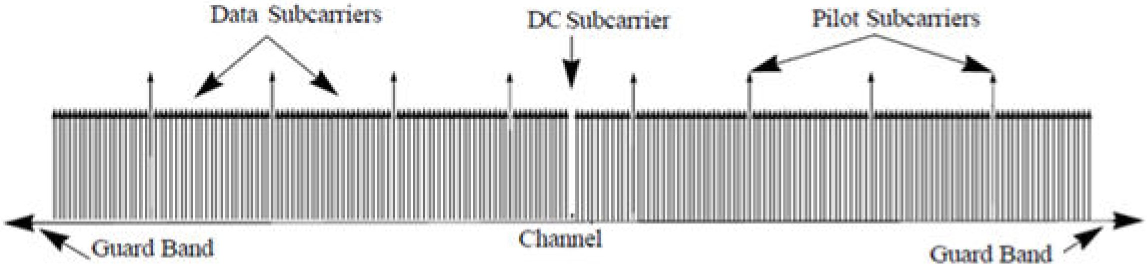
The OFDM demodulation uses an FFT operation that results in N parallel data streams. An OFDM demodulator consists of a bank of N correlators, with one correlator assigned to each OFDM subcarrier, followed by a parallel-to-serial conversion.



Subcarrier Allocation and Guard Bands

Individual OFDM subcarriers are allocated as data, pilot, or null subcarriers.

As shown here, subcarriers are designated as data, DC, pilot, or guard band subcarriers.



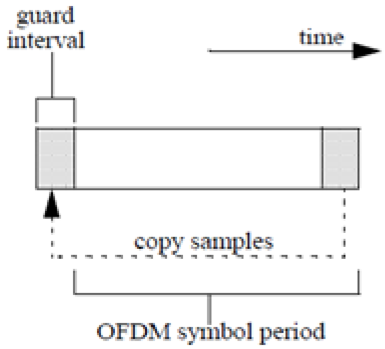
- Data subcarriers transmit user data.
- Pilot subcarriers are used for channel estimation.
- Null subcarriers transmit no data. Subcarriers with no data are used to provide a DC null and serve as buffers between OFDM resource blocks.

- The null DC subcarrier is the center of the frequency band with an index value of (`nfft`/2 + 1) if `nfft` is even, or ((`nfft` + 1) / 2) if `nfft` is odd.
- The guard bands provide buffers between consecutive OFDM symbols to protect the integrity of transmitted signals by reducing intersymbol interference.

Null subcarriers enable you to model guard bands and DC subcarrier locations for specific standards, such as the various 802.11 formats, LTE, WiMAX, or for custom allocations. You can allocate the location of nulls by assigning a vector of null subcarrier indices.

Similar to guard bands, guard intervals are used in OFDM to protect the integrity of transmitted signals by reducing intersymbol interference.

Assignment of guard intervals is analogous to the assignment of guard bands. You can model guard intervals to provide temporal separation between OFDM symbols. The guard intervals help preserve intersymbol orthogonality after the signal passes through time-dispersive channels. Guard intervals are created by using cyclic prefixes. Cyclic prefix insertion copies the last part of an OFDM symbol as the first part of the OFDM symbol.



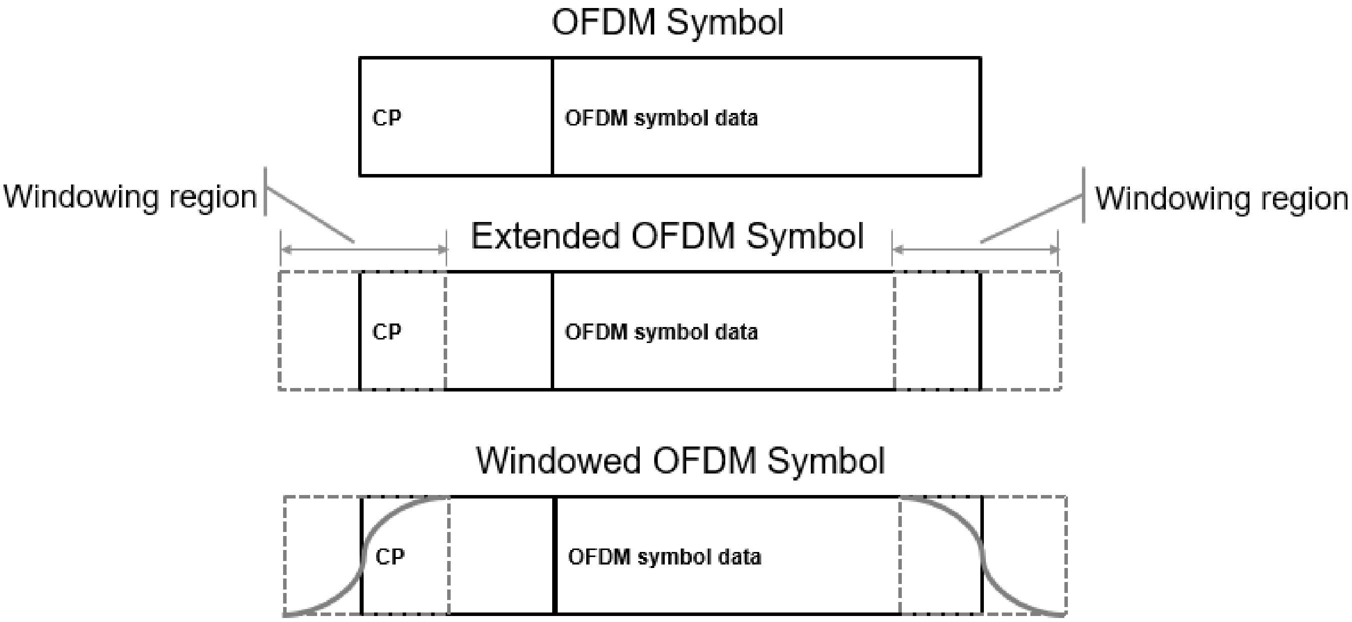
As long as the span of the time dispersion does not exceed the duration of the cyclic prefix, the benefit of cyclic prefix insertion is maintained.

Inserting a cyclic prefix results in a fractional reduction of user data throughput because the cyclic prefix occupies bandwidth that could be used for data transmission.

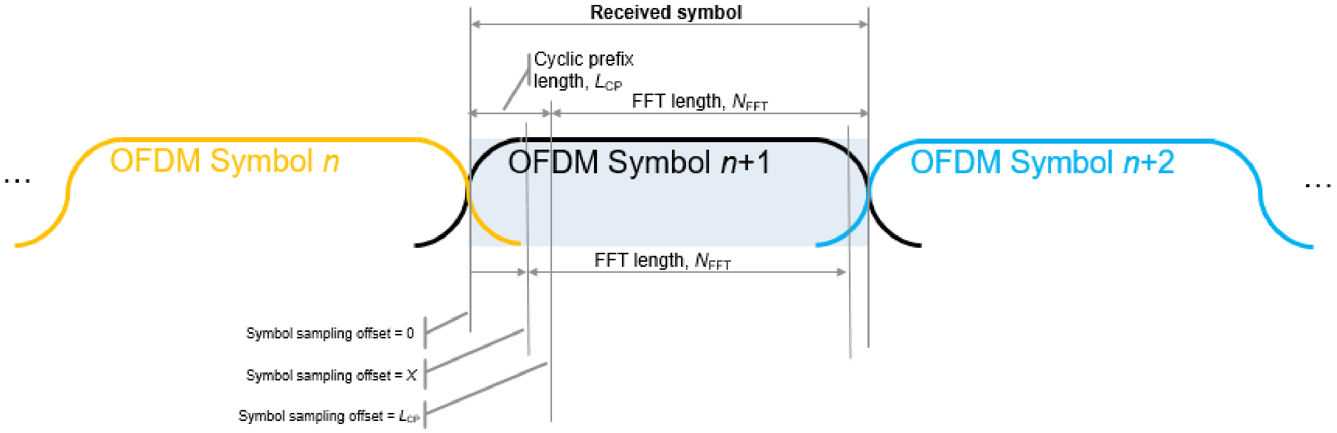
Windowing and Symbol Offset

To reduce intersymbol interference (ISI) introduced by signal windowing applied at the transmitter, the function applies a fractional symbol offset before demodulation of each OFDM symbol. Signal windowing is often applied to transmitted OFDM symbols to smooth the discontinuity between consecutive OFDM symbols. Windowing reduces intersymbol out-of-band emissions but increases ISI.

The windowed OFDM symbol consists of the cyclic prefix (CP), ODFM symbol data, plus windowing regions at the beginning and end of the symbol. The leading and trailing windowing shoulders have tails as shown in the figure.



To reduce ISI, you can align signal sample timing by specifying a symbol sampling offset that gets applied before OFDM symbol demodulation.



Received symbol
Cyclic prefix length, L_{CP}
FFT length, N_{FFT}
...
OFDM Symbol n
OFDM Symbol n+1
OFDM Symbol n+2
...
FFT length, N_{FFT}
Symbol sampling offset = 0
Symbol sampling offset = X
Symbol sampling offset = L_{CP}

Specify the symbol sampling offset as a value from 0 to L_{CP}.

- When the symbol sampling offset is a scalar from 0 to L_{CP}, the FFT window begins at the X+1 sample of the CP length.
- When the symbol sampling offset is zero, no offset is applied and the FFT window starts at the first sample of the symbol.
- When the symbol sampling offset is the cyclic prefix length, L_{CP}, the FFT window begins after the last CP sample. This offset is the default setting if symbol sampling offset is not specified.

Introduced in R2018a

ofdmmod

Modulate frequency-domain signal using orthogonal frequency division multiplexing (OFDM)

Syntax

```
ofdmSig = ofdmmod(inSym,nfft,cplen)
ofdmSig = ofdmmod(inSym,nfft,cplen,nullidx)
ofdmSig = ofdmmod(inSym,nfft,cplen,nullidx,pilotidx,pilots)
```

Description

`ofdmSig = ofdmmod(inSym,nfft,cplen)` performs OFDM modulation on the frequency-domain input data subcarriers, `inSym`, using an FFT size specified by `nfft` and cyclic prefix length specified by `cplen`. For information, see "OFDM Modulation" on page 2-622.

`ofdmSig = ofdmmod(inSym,nfft,cplen,nullidx)` inserts null subcarriers into the frequency domain input data signal prior to performing OFDM modulation. The null subcarriers are inserted at index locations from 1 to `nfft`, as specified by `nullidx`. For this syntax, the number of rows in the input `inSym` must be `nfft` – `length(nullidx)`. Use null carriers to account for guard bands and DC subcarriers. For information, see "Subcarrier Allocation, Guard Bands and Guard Intervals" on page 2-623.

`ofdmSig = ofdmmod(inSym,nfft,cplen,nullidx,pilotidx,pilots)` inserts null and pilot subcarriers into the frequency domain input data symbols prior to performing OFDM modulation. The null subcarriers are inserted at the index locations specified by `nullidx`. The pilot subcarriers, `pilots`, are inserted at the index locations specified by `pilotidx`. For this syntax, the number of rows in the input `inSym` must be `nfft` – `length(nullidx)` – `length(pilotidx)`. The function assumes pilot subcarrier locations are the same across each OFDM symbol and transmit antenna.

Examples

OFDM Modulation Over Two Antennas

OFDM-modulate a fully packed input over two transmit antennas.

Initialize input parameters, generate random data, and perform OFDM modulation.

```
nfft  = 128;
cplen = 16;
nSym  = 5;
nt    = 2;
dataIn = complex(randn(nfft,nSym,nt),randn(nfft,nSym,nt));

y1 = ofdmmod(dataIn,nfft,cplen);
```

Apply OFDM Assigning Null Subcarriers

Apply OFDM modulation assigning null subcarriers.

Initialize input parameters and generate random data.

```
M = 16; % Modulation order for 16QAM
nfft  = 64;
cplen = 16;
nSym  = 10;
nullIdx  = [1:6 33 64-4:64]';
numDataCarrs = nfft-length(nullIdx);
inSig = randi([0 M-1],numDataCarrs,nSym);
```

QAM modulate data. Perform OFDM modulation.

```
qamSym = qammod(inSig,M,'UnitAveragePower',true);
outSig = ofdmmod(qamSym,nfft,cplen,nullIdx);
```

Perform OFDM Modulation Varying Cyclic Prefix per Symbol

Perform OFDM modulation to input frequency domain data signal varying cyclic prefix length applied to each symbol.

Initialize input parameters and generate random data.

```
M = 16; % Modulation order for 16QAM
nfft  = 64;
cplen = [4 8 10 7 2 2 4 11 16 3];
nSym  = 10;
nullIdx  = [1:6 33 64-4:64]';
numDataCarrs = nfft-length(nullIdx);
inSig = randi([0 M-1],numDataCarrs,nSym);
```

QAM modulate data. Perform OFDM modulation.

```
qamSym = qammod(inSig,M,'UnitAveragePower',true);
outSig = ofdmmod(qamSym,nfft,cplen,nullIdx);
```

Apply OFDM to QPSK Signal Spatially Multiplexed Over Two Antennas

Apply OFDM modulation to a QPSK signal that is spatially multiplexed over two transmit antennas.

Initialize input parameters and generate random data for each antenna.

```
M = 4; % Modulation order for QPSK
nfft  = 64;
cplen = 16;
nSym  = 5;
nt    = 2;
nullIdx  = [1:6 33 64-4:64]';
pilotIdx = [12 26 40 54]';
numDataCarrs = nfft-length(nullIdx)-length(pilotIdx);
```

```
pilots = repmat(pskmod((0:M-1).',M),1,nSym,2);

ant1 = randi([0 M-1],numDataCarrs,nSym);
ant2 = randi([0 M-1],numDataCarrs,nSym);
```

QPSK modulate data individually for each antenna. Perform OFDM modulation.

```
qpskSym(:,:,1) = pskmod(ant1,M);
qpskSym(:,:,2) = pskmod(ant2,M);
y1 = ofdmmod(qpskSym,nfft,cplen,nullIdx,pilotIdx,pilots);
```

OFDM Modulation with Null and Pilot Packing

OFDM-modulate data input, specifying null and pilot packing.

Initialize input parameters, defining locations for null and pilot subcarriers. Generate random data and perform OFDM modulation.

```
nfft     = 64;
cplen    = 16;
nSym     = 10;

nullIdx  = [1:6 33 64-4:64]';
pilotIdx = [12 26 40 54]';

numDataCarrs = nfft-length(nullIdx)-length(pilotIdx);
dataIn = complex(randn(numDataCarrs,nSym),randn(numDataCarrs,nSym));
pilots = repmat(pskmod((0:3).',4),1,nSym);

y2 = ofdmmod(dataIn,nfft,cplen,nullIdx,pilotIdx,pilots);
```

Input Arguments

`inSym` — Input data subcarriers

3-D array

Input data subcarriers, specified as an N_D-by-N_{Sym}-by-N_T array of symbols. The number of data subcarriers, N_D, must equal `nfft – length(nullidx) – length(pilotidx)`. N_{Sym} is the number of OFDM symbols per transmit antenna, N_T is the number of transmit antennas.

Input data symbols to an OFDM modulator are typically created with a baseband digital modulator, such as `qammod`.

Data Types: `double` | `single`
Complex Number Support: Yes

`nfft` — FFT length

integer greater than or equal to 8

FFT length, specified as an integer greater than or equal to 8. `nfft` is equivalent to the number of subcarriers used in the modulation process.

Data Types: `double`

cplen — Cyclic prefix length

scalar | row vector of length N_{Sym}

Cyclic prefix length, specified as a scalar or as a row vector of length N_{Sym}.

- When you specify `cplen` as a scalar, the cyclic prefix length is the same for all symbols through all antennas.
- When you specify `cplen` as a row vector of length N_{Sym}, the cyclic prefix length can vary across symbols but remains the same length through all antennas.

For more information, see “Subcarrier Allocation, Guard Bands and Guard Intervals” on page 2-623.

Data Types: `double`

nullidx — Indices of null subcarrier locations

column vector

Indices of null subcarrier locations, specified as a column vector with element values from 1 to `nfft`.

Data Types: `double`

pilotidx — Indices of pilot subcarrier locations

column vector

Indices of pilot subcarrier locations, specified as a column vector with element values from 1 to `nfft`.

Data Types: `double`

pilots — Pilot subcarriers

3-D array

Pilot subcarriers, specified as an N_{Pilot}-by-N_{Sym}-by-N_{T} array of symbols. N_{Pilot} must equal the length of `pilotidx`. N_{Sym} is the number of OFDM symbols per transmit antenna. N_{T} is the number of transmit antennas. The function assumes pilot subcarrier locations are the same across each OFDM symbol and transmit antenna. Use the `comm.OFDMModulator` to vary pilot subcarrier locations across OFDM symbols or antennas.

Data Types: `double` | `single`

Output Arguments

ofdmSig — Modulated OFDM symbols

2-D array of complex symbols

Modulated OFDM symbols, returned as a 2-D array of complex symbols.

- If `cplen` is a scalar, the array size is ((`nfft` + `cplen`) × N_{Sym})-by-N_{T}.
- If `cplen` is a row vector, the array size is ((`nfft` × N_{Sym}) + `sum(cplen)`)-by-N_{T}.

  N_{Sym} is the number of symbols per transmit antenna and N_{T} is the number of transmit antennas.

Data Types: `double` | `single`

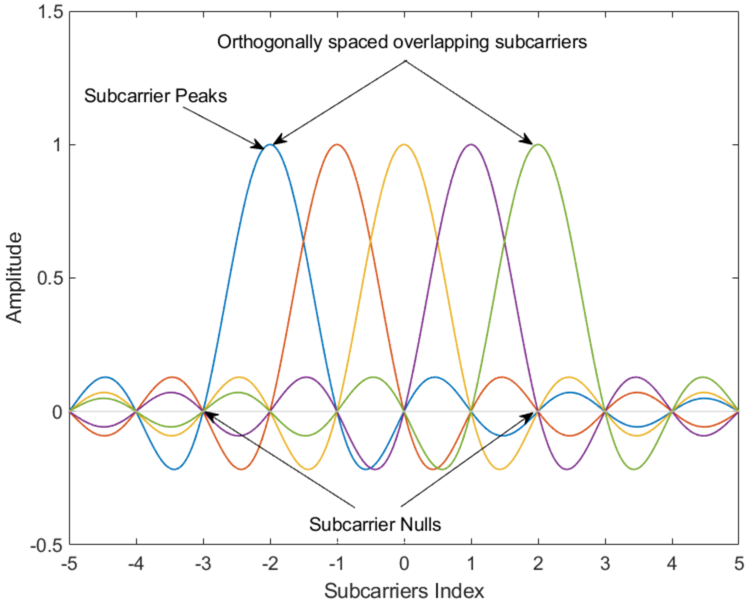
More About

OFDM Modulation

OFDM belongs to the class of multicarrier modulation schemes. Since the multiple data streams can be transmitted simultaneously with multiple carriers, OFDM is not influenced by noise to the same degree as single-carrier modulation.

OFDM operation divides a high-rate data stream into lower data rate substreams by decomposing the transmission frequency band into N contiguous individually modulated subcarriers. Multiple parallel and orthogonal subcarriers carry the samples with almost the same bandwidth as a wideband channel. By using narrow orthogonal subcarriers, the OFDM signal gains robustness over a frequency-selective fading channel and eliminates adjacent subcarrier interference. Intersymbol interference (ISI) is reduced because the lower data rate substreams have symbol durations larger than the channel delay spread.

The Frequency domain representation of orthogonal subcarriers in an OFDM waveform looks as follows:



The transmitter applies inverse fast Fourier transform (IFFT) to N symbols at a time. The output of the IFFT is the sum of the N orthogonal sinusoids:

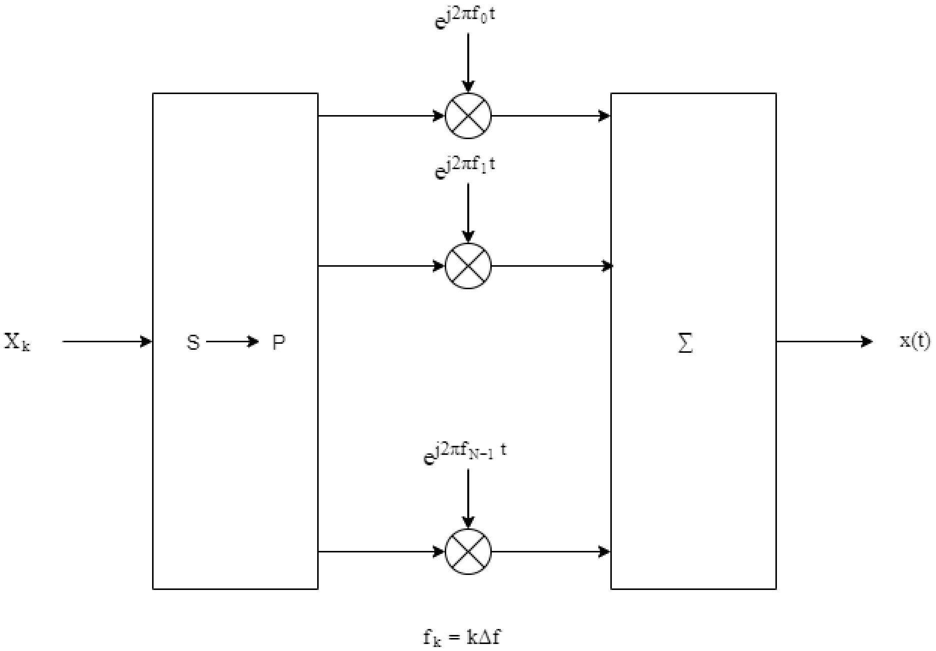
$$x(t) = \sum_{k=0}^{N-1} X_k e^{j2\pi k\Delta f t}, \quad 0 \le t \le T,$$

where $\{X_k\}$ are data symbols, and T is the OFDM symbol time. The data symbols X_k are typically complex and can be from any digital modulation alphabet (for example, QPSK, 16-QAM, 64-QAM).

The subcarrier spacing is $\Delta f = 1/T$; ensuring that the subcarriers are orthogonal over each symbol period, as shown below:

$$\frac{1}{T}\int_0^T \left(e^{j2\pi m\Delta ft}\right)^* \left(e^{j2\pi n\Delta ft}\right) dt = \frac{1}{T}\int_0^T e^{j2\pi(m-n)\Delta ft} dt = 0 \quad \text{for } m \neq n\,.$$

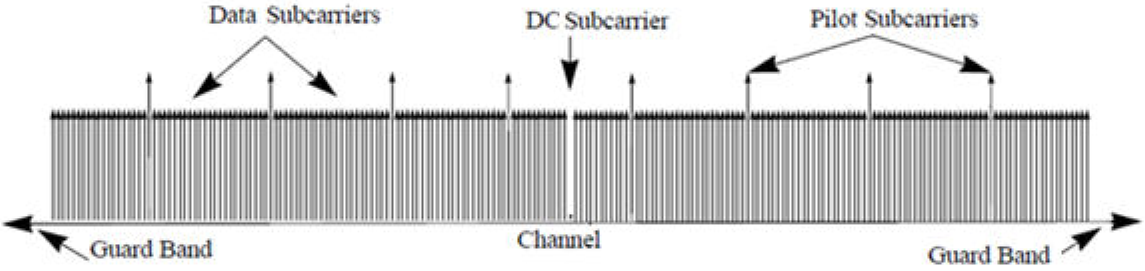
An OFDM modulator consists of a serial-to-parallel conversion followed by a bank of *N* complex modulators, individually corresponding to each OFDM subcarrier.



Subcarrier Allocation, Guard Bands and Guard Intervals

Individual OFDM subcarriers are allocated as data, pilot, or null subcarriers.

As shown here, subcarriers are designated as data, DC, pilot, or guard band subcarriers.



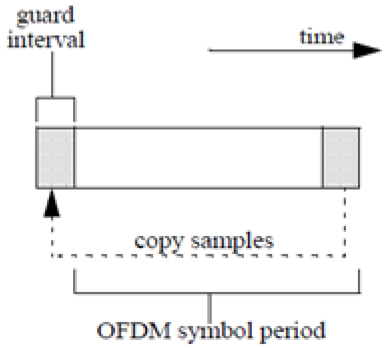
- Data subcarriers transmit user data.
- Pilot subcarriers are used for channel estimation.
- Null subcarriers transmit no data. Subcarriers with no data are used to provide a DC null and serve as buffers between OFDM resource blocks.

- The null DC subcarrier is the center of the frequency band with an index value of (`nfft`/2 + 1) if `nfft` is even, or ((`nfft` + 1) / 2) if `nfft` is odd.
- The guard bands provide buffers between consecutive OFDM symbols to protect the integrity of transmitted signals by reducing intersymbol interference.

Null subcarriers enable you to model guard bands and DC subcarrier locations for specific standards, such as the various 802.11 formats, LTE, WiMAX, or for custom allocations. You can allocate the location of nulls by assigning a vector of null subcarrier indices.

Similar to guard bands, guard intervals are used in OFDM to protect the integrity of transmitted signals by reducing intersymbol interference.

Assignment of guard intervals is analogous to the assignment of guard bands. You can model guard intervals to provide temporal separation between OFDM symbols. The guard intervals help preserve intersymbol orthogonality after the signal passes through time-dispersive channels. Guard intervals are created by using cyclic prefixes. Cyclic prefix insertion copies the last part of an OFDM symbol as the first part of the OFDM symbol.



As long as the span of the time dispersion does not exceed the duration of the cyclic prefix, the benefit of cyclic prefix insertion is maintained.

Inserting a cyclic prefix results in a fractional reduction of user data throughput because the cyclic prefix occupies bandwidth that could be used for data transmission.

Objects
`comm.OFDMDemodulator` | `comm.OFDMModulator`

Introduced in R2018a

pamdemod

Pulse amplitude demodulation

Syntax

```
z = pamdemod(y,M)
z = pamdemod(y,M,ini_phase)
z = pamdemod(y,M,ini_phase,symbol_order)
```

Description

`z = pamdemod(y,M)` demodulates the complex envelope `y` of a pulse amplitude modulated signal. `M` is the alphabet size. The ideal modulated signal should have a minimum Euclidean distance of 2.

`z = pamdemod(y,M,ini_phase)` specifies the initial phase of the modulated signal in radians.

`z = pamdemod(y,M,ini_phase,symbol_order)` specifies how the function assigns binary words to corresponding integers. If `symbol_order` is set to `'bin'` (default), the function uses a natural binary-coded ordering. If `symbol_order` is set to `'gray'`, it uses a Gray-coded ordering.

Examples

Demodulate PAM Signal

Modulate and demodulate random integers using pulse amplitude modulation. Verify that the output data matches the original data.

Set the modulation order and generate 100 M-ary data symbols.

```
M = 12;
dataIn = randi([0 M-1],100,1);
```

Perform modulation and demodulation operations.

```
modData = pammod(dataIn,M);
dataOut = pamdemod(modData,M);
```

Compare the first five symbols.

```
[dataIn(1:5) dataOut(1:5)]
```

```
ans = 5×2

     9     9
    10    10
     1     1
    10    10
     7     7
```

Verify that there are no symbol errors in the entire sequence.

```
symErrors = symerr(dataIn,dataOut)

symErrors = 0
```

Extended Capabilities

pammod

Pulse amplitude modulation (PAM)

Syntax

```
y = pammod(x,M)
y = pammod(x,M,initphase)
y = pammod(x,M,initphase,symorder)
```

Description

`y = pammod(x,M)` returns the complex envelope of the modulation of the input message signal, `x`, using PAM and the alphabet size, `M`.

`y = pammod(x,M,initphase)` specifies the initial phase of the modulated signal.

`y = pammod(x,M,initphase,symorder)` specifies the symbol order modulation, which defines how the function assigns binary words to corresponding integers.

Examples

Modulate Data Symbols with PAM

Generate random data symbols and apply pulse amplitude modulation.

Set the modulation order.

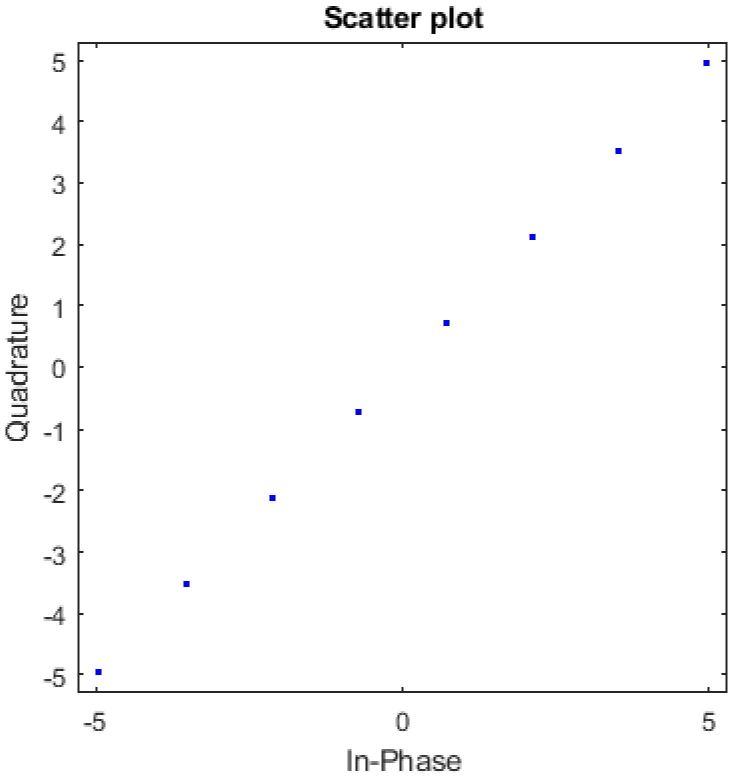
```
M = 8;
```

Generate random integers and apply PAM modulation having an initial phase of $\pi/4$.

```
data = randi([0 M-1],100,1);
modData = pammod(data,M,pi/4);
```

Display the PAM constellation diagram.

```
scatterplot(modData)
```



PAM Symbol Mapping

Plot PAM symbol mapping for Gray and natural binary encoded data.

Set the modulation order, and then create a data sequence containing a complete set of constellation points.

```
M = 8;
data = [0:M-1];
```

Modulate and demodulate Gray and natural binary encoded data.

```
symgray = pammod(data,M,0,'gray');
mapgray = pamdemod(symgray,M,0,'gray');

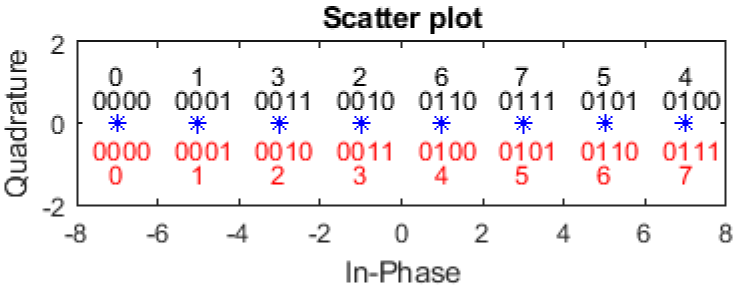
symbin = pammod(data,M,0,'bin');
mapbin = pamdemod(symbin,M,0,'bin');
```

Plot the constellation points using one of the symbol sets. For each constellation point, assign a label indicating the Gray and natural binary values for each symbol.

- For Gray binary symbol mapping, adjacent constellation points differ by a single binary bit and are not numerically sequential.
- For natural binary symbol mapping, adjacent constellation points follow the natural binary encoding and are sequential.

```
scatterplot(symgray,1,0,'b*');
for k = 1:M
    text(real(symgray(k))-0.6,imag(symgray(k))+0.6,...
        dec2base(mapgray(k),2,4));
    text(real(symgray(k))-0.2,imag(symgray(k))+1.2,...
        num2str(mapgray(k)));

    text(real(symbin(k))-0.6,imag(symbin(k))-0.6,...
        dec2base(mapbin(k),2,4),'Color',[1 0 0]);
    text(real(symbin(k))-0.2,imag(symbin(k))-1.2,...
        num2str(mapbin(k)),'Color',[1 0 0]);
end
axis([-M M -2 2])
```



Input Arguments

x — Input signal

vector | matrix

Input signal, specified as a vector or matrix of integers in the range of [0, M – 1].

Example: randi([0 3],100,1)

Data Types: double

M — Modulation order

power of two

Modulation order, specified as a power of two.

Example: 4

Data Types: double

initphase — Initial phase

0 (default) | real-valued scalar | []

Initial phase of the modulated signal (in radians), specified as a real scalar.

Example: pi/4

Data Types: double

symorder — Symbol order binary vectors

'bin' (default) | 'gray'

Symbol order of binary vectors, specified as 'bin' or 'gray'. This argument specifies how the function assigns binary vectors to corresponding integers.

- If symorder is 'bin', the function uses a natural binary-coded ordering.
- If symorder is 'gray', the function uses a Gray-coded ordering.

Data Types: char | string

Output Arguments

y — Complex baseband representation of PAM-modulated signal

vector | matrix

Complex baseband representation of a PAM-modulated signal, returned as vector or matrix of complex values. The modulated signal has a minimum Euclidean distance of 2. The columns of y represent independent channels.

Data Types: double | single

Extended Capabilities

channelDelay

Channel timing delay

Syntax

```
[delay,mag] = channelDelay(pathGains,pathFilters)
```

Description

`[delay,mag] = channelDelay(pathGains,pathFilters)` computes the channel timing delay by finding the peak of the channel impulse response. The function reconstructs the impulse response from a channel path gains array and a path filter impulse response matrix. The function returns the channel timing delay in samples, and the channel impulse response magnitude. For more information, see "Channel Delay and Magnitude Computation" on page 2-635.

Examples

Compute Timing Delay for 2-by-2 MIMO Channel

Configure a 2-by-2 MIMO channel. Use the `info` object function to retrieve the path filters.

```
chan = comm.MIMOChannel('SampleRate',1000,'PathDelays',[0 1.5e-3], ...
    'AveragePathGains',[1 0.8],'RandomStream','mt19937ar with seed', ...
    'Seed',10,'PathGainsOutputPort',true);
chanInfo = info(chan);
pathFilters = chanInfo.ChannelFilterCoefficients;
```

Compute the path gains by passing an impulse through the channel.

```
[~,pathGains] = chan(ones(1,2));
```

Compute the channel timing delay, specifying the retrieved path filters and computed path gains.

```
delay = channelDelay(pathGains,pathFilters)
```

```
delay = 6
```

Show Relative Timing Delay For Rayleigh Channel

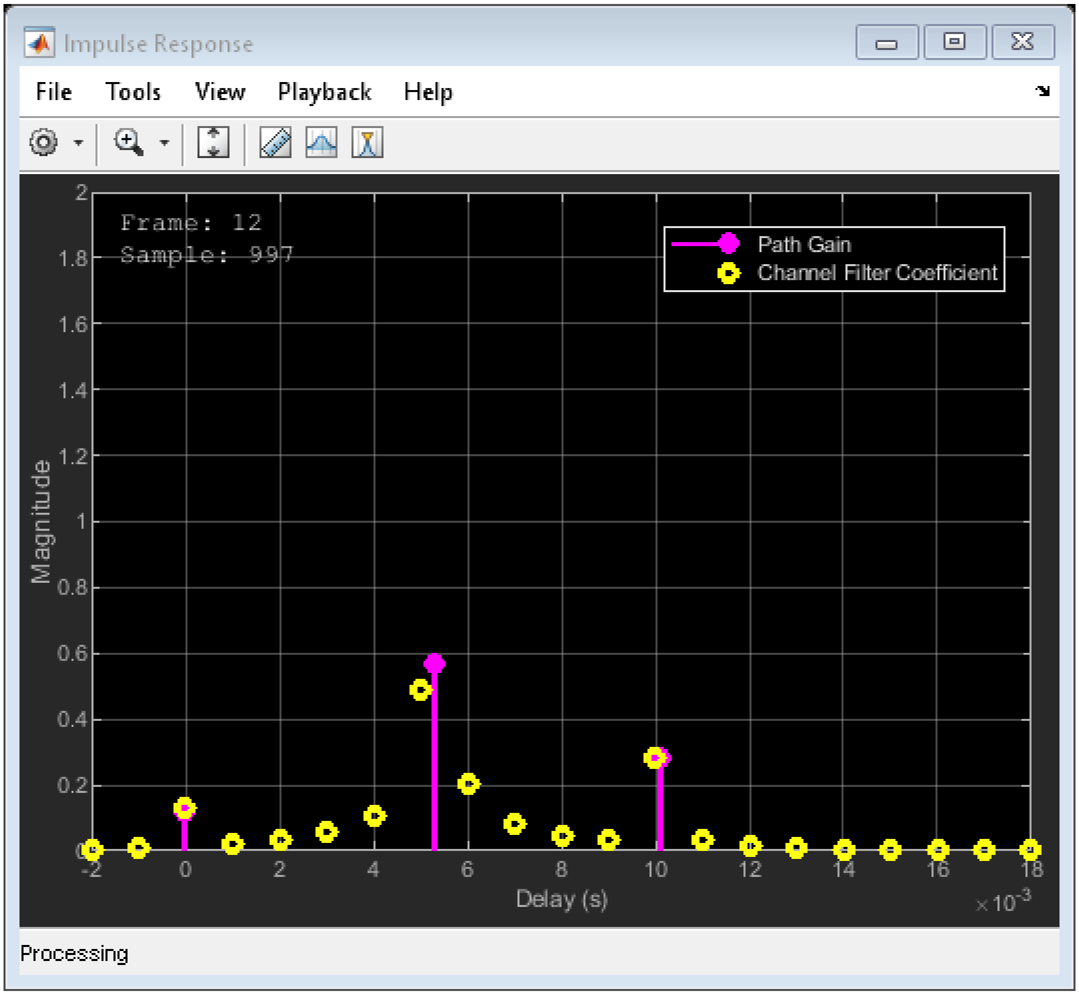
Compute and show the relative timing delay for a Rayleigh channel over time.

Create a `comm.RayleighChannel` System object configured with three paths and impulse response visualization enabled.

```
chan = comm.RayleighChannel;
chan.SampleRate = 1e3;
chan.PathDelays = [0 5.3e-3 10.1e-3];
chan.AveragePathGains = [0.1 1 0.5];
chan.PathGainsOutputPort = true;
chan.RandomStream = 'mt19937ar with seed';
chan.Seed = 1;
chan.Visualization = 'Impulse response';
chan.MaximumDopplerShift = 1;
```

Use the `info` object function to retrieve the Rayleigh channel path filters. In a loop, pass a static signal of all ones through the Rayleigh channel. The `channelDelay` function uses the channel path gains array from each pass through the channel and the path filter coefficients, `chanInfo.ChannelFilterCoefficients` (returned by the `info` function) to compute the relative channel timing delay. The impulse response varies for each iteration. The impulse response for the last iteration is shown here. The `delay` vector shows the relative channel timing delay computed for each iteration.

```
chanInfo = info(chan);
numIter = 12;
delay = zeros(1,numIter);
for p=1:numIter
    [~,pg] = chan(ones(1e3,1));
    delay(p) = channelDelay(pg,chanInfo.ChannelFilterCoefficients);
end
```



```
delay
```

```
delay = 1×12

    12     7    12     2    12     7    12     7     7     7     2     2
```

Input Arguments

`pathGains` — Channel path gains

4-D array

Channel path gains, specified as an N_{cs}-by-N_p-by-N_t-by-N_r array, where:

- N_{cs} is the number of channel snapshots.
- N_p is the number of paths.
- N_t is the number of transmit antennas.
- N_r is the number of receive antennas.

If any element in `pathGains` is `NaN`, the function assumes that no path exists between the transmitter and the receiver.

Data Types: `double` | `single`
Complex Number Support: Yes

`pathFilters` — Path filter impulse response

matrix

Path filter impulse response, specified as an N_p-by-N_h matrix. N_p is the number of paths, and N_h is the number of impulse response samples.

Data Types: `double` | `single`
Complex Number Support: Yes

Output Arguments

`delay` — Channel timing delay

integer

Channel timing delay in samples, returned as an integer. This value represents the number of samples of delay relative to the first sample of the channel impulse response reconstructed from the `pathGains` and `pathFilters` inputs. The function computes the channel timing delay by finding the peak of the composite channel impulse response. For more information, see “Channel Delay and Magnitude Computation” on page 2-635.

`mag` — Channel impulse response magnitude

matrix

Channel impulse response magnitude for each receive antenna, returned as an N_h-by-N_r matrix. N_h is the number of impulse response samples, and N_r is the number of receive antennas. For more information, see “Channel Delay and Magnitude Computation” on page 2-635.

More About

Channel Delay and Magnitude Computation

The computation of the channel delay and impulse response magnitudes uses the composite channel impulse response.

The composite channel impulse response results from averaging the impulse response across all channel snapshots as represented in the path gains array. The input path gains array must be of the format N_{cs}-by-N_{p}-by-N_{t}-by-N_{r} , where:

- N_{cs} is the number of channel snapshots.
- N_{p} is the number of paths.
- N_{t} is the number of transmit antennas.
- N_{r} is the number of receive antennas.

The channel timing delay, output as a single value, is relative to the first sample of the channel impulse response. The function computes this value by finding the peak of the composite channel impulse response. The composite channel impulse response is the summation of the impulse responses across all transmit and receive antennas.

The receive impulse response magnitudes are output as an N_{h}-by-N_{r} matrix. N_{h} is the number of impulse response samples, and N_{r} is the number of receive antennas. To compute the receive impulse response magnitudes,

1. Path gains are summed across all channel snapshots.
2. The contribution from each path is added to the channel impulse response across all transmit and receive antennas.
3. The transmit antenna paths are combined in the channel impulse response array, leaving a matrix of impulse response samples versus receive antennas.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

`comm.MIMOChannel` | `comm.RayleighChannel` | `comm.RicianChannel`

Introduced in R2020a

plot (channel)

(To be removed) Plot channel characteristics with channel visualization tool

Note This function will be removed in a future release. Use function associated with `comm.RicianChannel` or `comm.RayleighChannel` instead.

Syntax

```
plot(h)
```

Description

`plot(h)`, where `h` is a channel object, launches the channel visualization tool. This GUI tool allows you to plot channel characteristics in various ways. See Channel Visualization for details.

ExamplesVisualize RF Impairments

Apply various RF impairments to a QAM signal. Observe the effects by using constellation diagrams, time-varying error vector magnitude (EVM) plots, and spectrum plots. Estimate the equivalent signal-to-noise ratio (SNR).

Initialization

Set the sample rate, modulation order, and SNR. Calculate the reference constellation points.

```
fs = 1000;
M = 16;
snrdB = 30;
refConst = qammod(0:M-1,M,'UnitAveragePower',true);
```

Create constellation diagram and time scope objects to visualize the impairment effects.

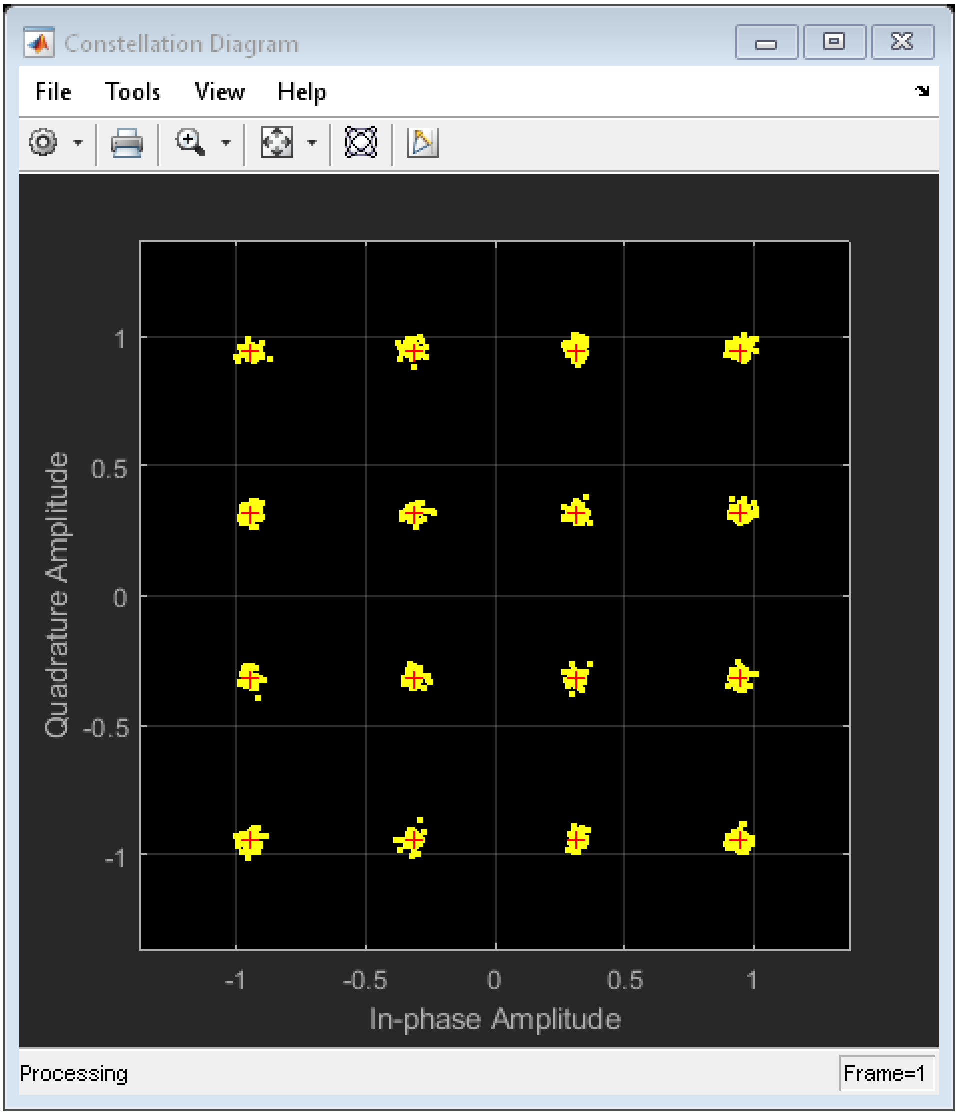
```
constDiagram = comm.ConstellationDiagram('ReferenceConstellation',refConst);
timeScope = timescope('YLimits',[0 40],'SampleRate',fs,'TimeSpanSource','property','TimeSpan',1,
    'ShowGrid',true,'YLabel','EVM (%)');
```

White Noise

Generate a 16-QAM signal, and pass it through an AWGN channel. Plot its constellation.

```
data = randi([0 M-1],1000,1);
modSig = qammod(data,M,'UnitAveragePower',true);
noisySig = awgn(modSig,snrdB);

constDiagram(noisySig)
```



Estimate the EVM of the noisy signal from the reference constellation points.

```
evm = comm.EVM('ReferenceSignalSource','Estimated from reference constellation', ...
    'ReferenceConstellation',refConst, ...
    'Normalization','Average constellation power');

rmsEVM = evm(noisySig)

rmsEVM = 3.1761
```

The modulation error rate (MER) closely corresponds to the SNR. Create an MER object, and estimate the SNR.

```
mer = comm.MER('ReferenceSignalSource','Estimated from reference constellation', ...
    'ReferenceConstellation',refConst);
snrEst = mer(noisySig)

snrEst = 30.1057
```

The estimate is quite close to the specified SNR of 30 dB.

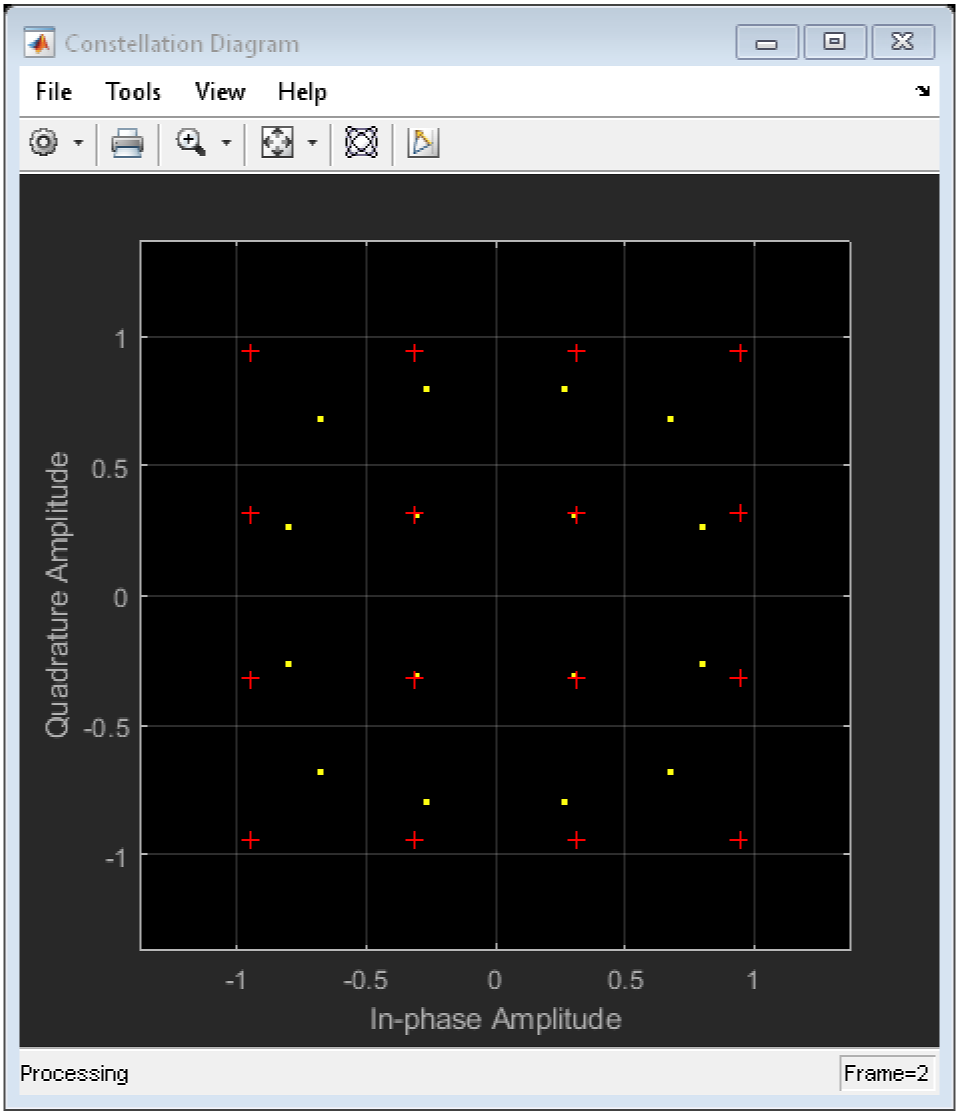
Amplifier Distortion

Create an amplifier using the memoryless nonlinearity object.

```
amp = comm.MemorylessNonlinearity('IIP3',38,'AMPMConversion',0);
```

Pass the modulated signal through the nonlinear amplifier and plot its constellation diagram.

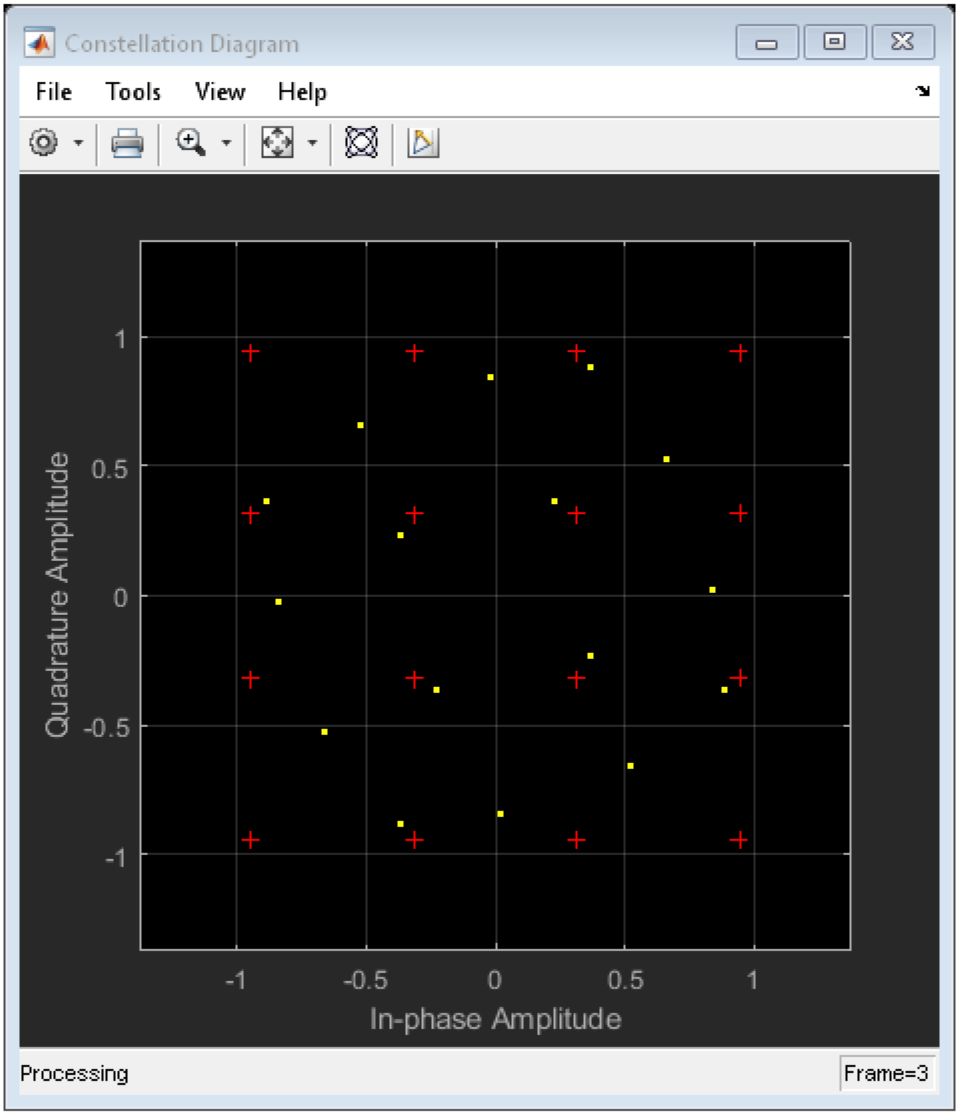
```
txSig = amp(modSig);
constDiagram(txSig)
```



The corner points of the constellation have moved toward the origin due to amplifier gain compression.

Introduce a small AM/PM conversion, and display the received signal constellation.

```
amp.AMPMConversion = 1;
txSig = amp(modSig);
constDiagram(txSig)
```

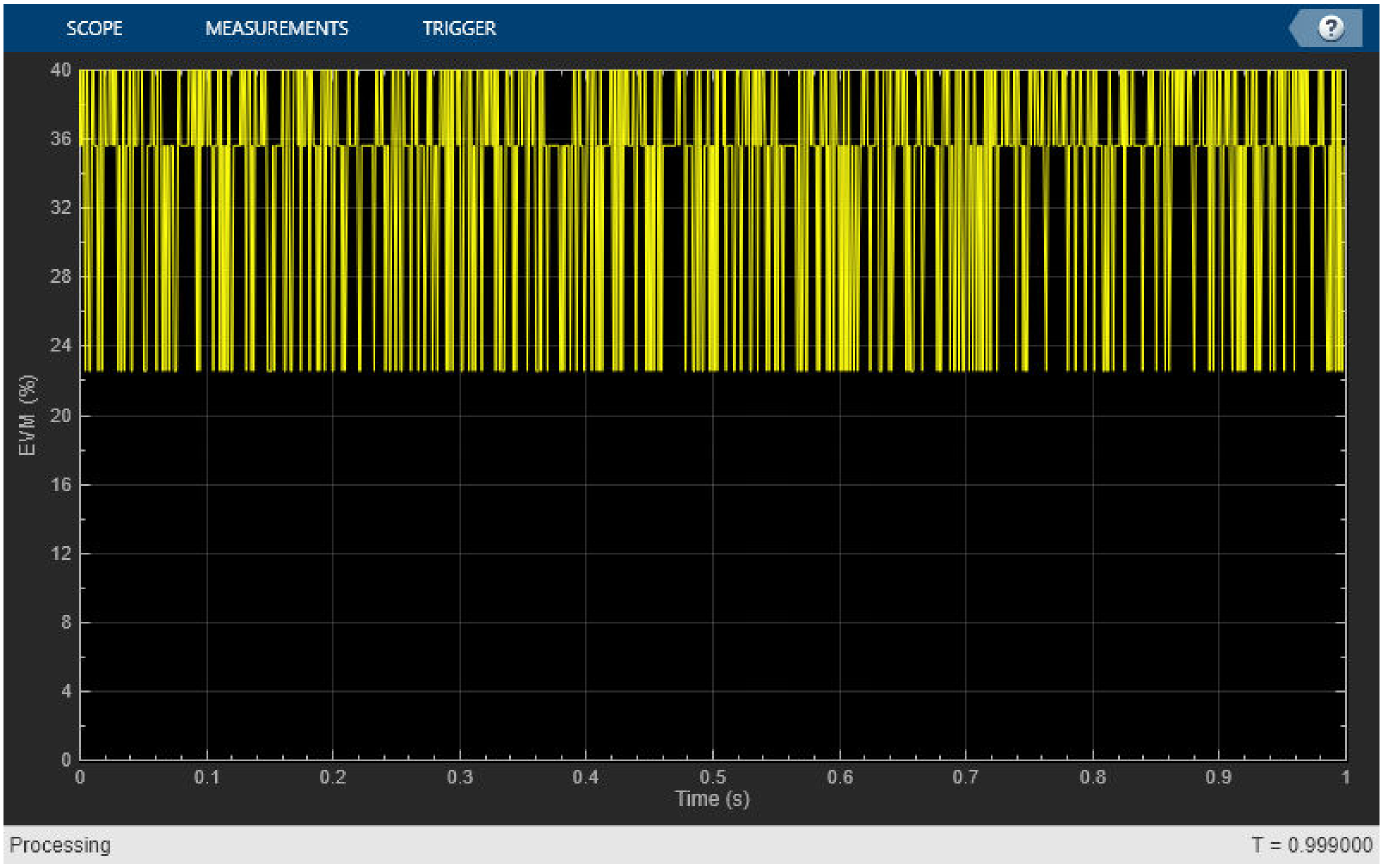


The constellation has rotated due to the AM/PM conversion. To compute the time-varying EVM, release the EVM object and set the `AveragingDimensions` property to 2. To estimate the EVM against an input signal, omit the `ReferenceSignalSource` property definition. This method produces more accurate results.

```
evm = comm.EVM('AveragingDimensions',2);
evmTime = evm(modSig,txSig);
```

Plot the time-varying EVM of the distorted signal.

```
timeScope(evmTime)
```



Compute the RMS EVM.

```
evmRMS = sqrt(mean(evmTime.^2))
```

```
evmRMS = 35.5812
```

Compute the MER.

```
mer = comm.MER;
snrEst = mer(modSig,txSig)
```

```
snrEst = 8.1390
```

The SNR (≈8 dB) is reduced from its initial value (∞) due to amplifier distortion.

Specify input power levels ranging from 0 to 40 dBm. Convert those levels to their linear equivalent in W. Initialize the output power vector.

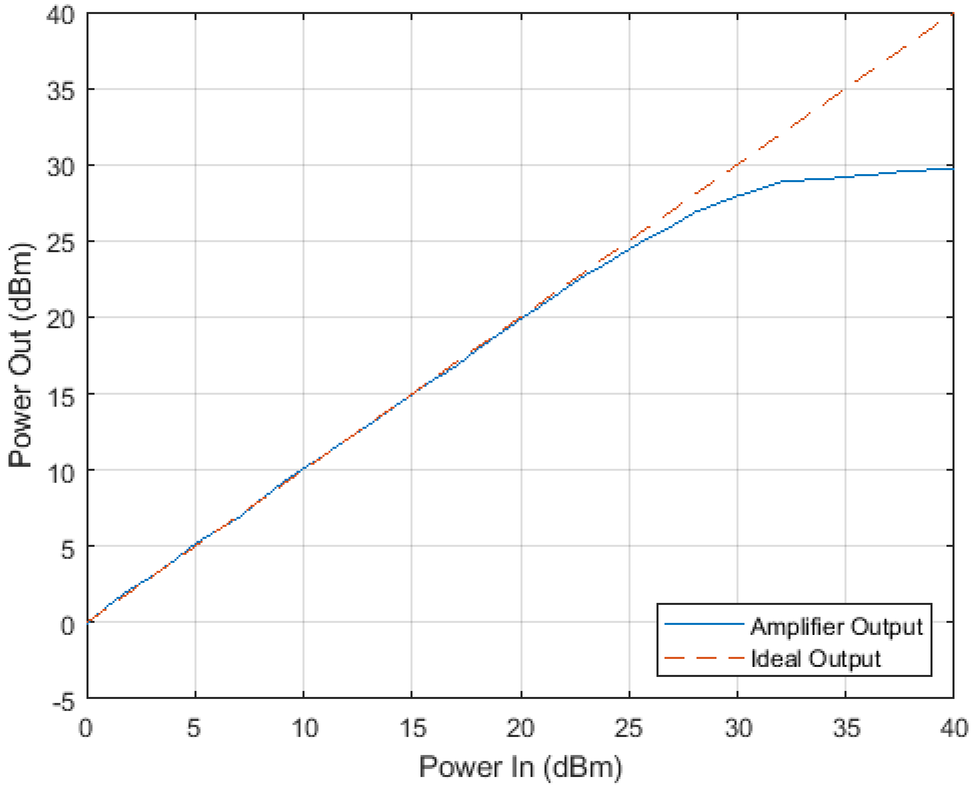
```
powerIn = 0:40;
pin = 10.^((powerIn-30)/10);
powerOut = zeros(length(powerIn),1);
```

Measure the amplifier output power for the range of input power levels.

```
for k = 1:length(powerIn)
    data = randi([0 15],1000,1);
    txSig = qammod(data,16,'UnitAveragePower',true)*sqrt(pin(k));
    ampSig = amp(txSig);
    powerOut(k) = 10*log10(var(ampSig))+30;
end
```

Plot the power output versus power input curve.

```
figure
plot(powerIn,powerOut,powerIn,powerIn,'--')
legend('Amplifier Output','Ideal Output','location','se')
xlabel('Power In (dBm)')
ylabel('Power Out (dBm)')
grid
```



The output power levels off at 30 dBm. The amplifier exhibits nonlinear behavior for input power levels greater than 25 dBm.

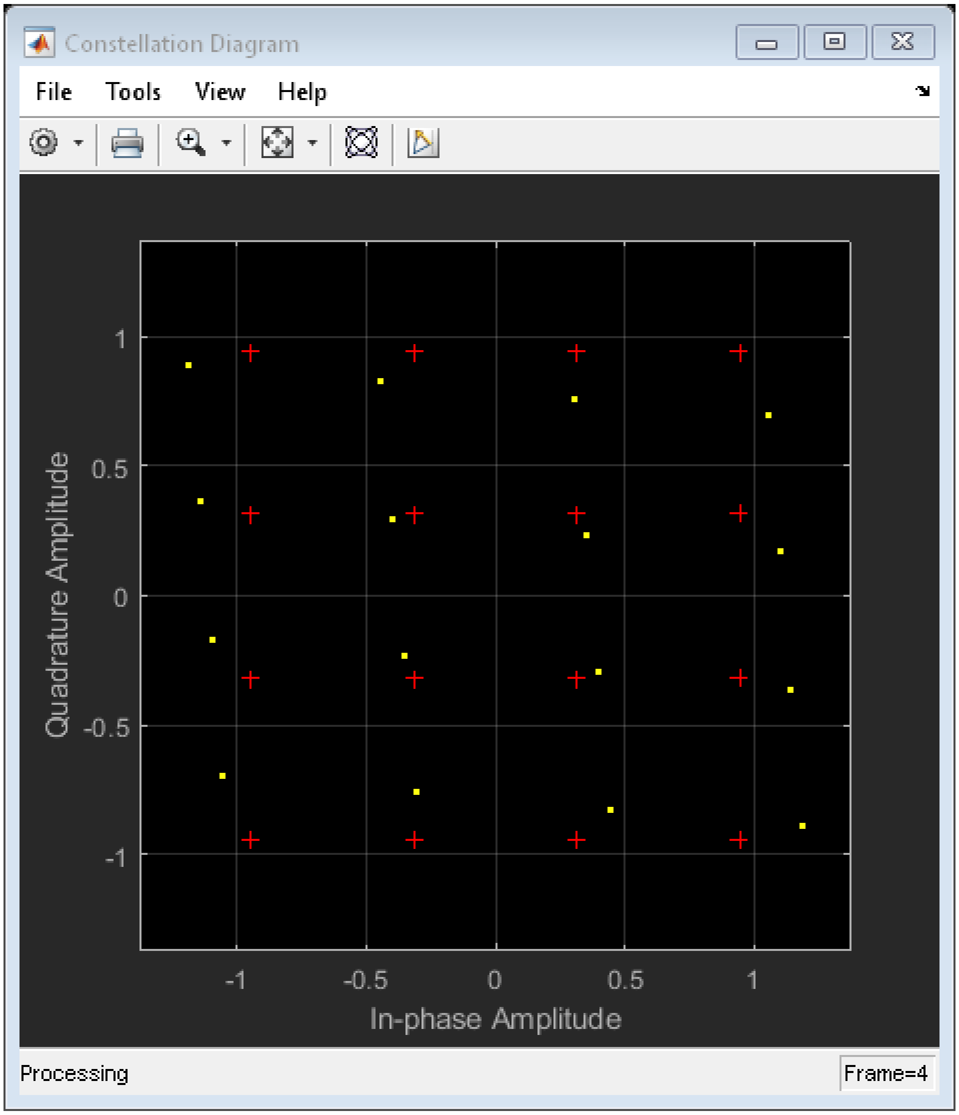
I/Q Imbalance

Apply an amplitude and phase imbalance to the modulated signal using the `iqimbal` function.

```
ampImb = 3;
phImb = 10;
rxSig = iqimbal(modSig,ampImb,phImb);
```

Plot the received constellation.

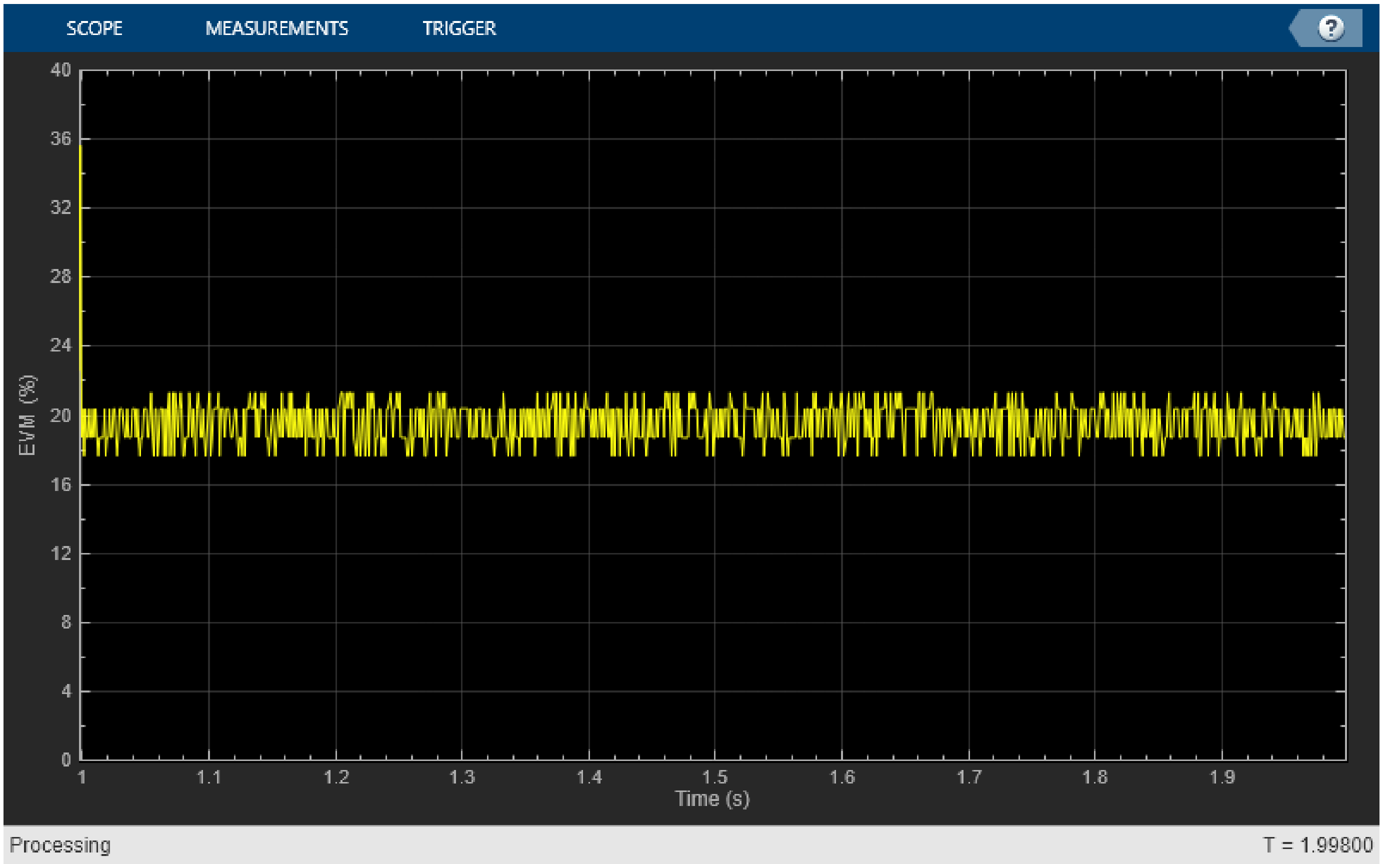
```
constDiagram(rxSig)
```



The magnitude and phase of the constellation has changed as a result of the I/Q imbalance.

Calculate and plot the time-varying EVM.

```
evmTime = evm(modSig,rxSig);
timeScope(evmTime)
```



The EVM exhibits a behavior that is similar to that experienced with a nonlinear amplifier though the variance is smaller.

Create a 100 Hz sine wave having a 1000 Hz sample rate.

```
sinewave = dsp.SineWave('Frequency',100,'SampleRate',1000, ...
    'SamplesPerFrame',1e4,'ComplexOutput',true);

x = sinewave();
```

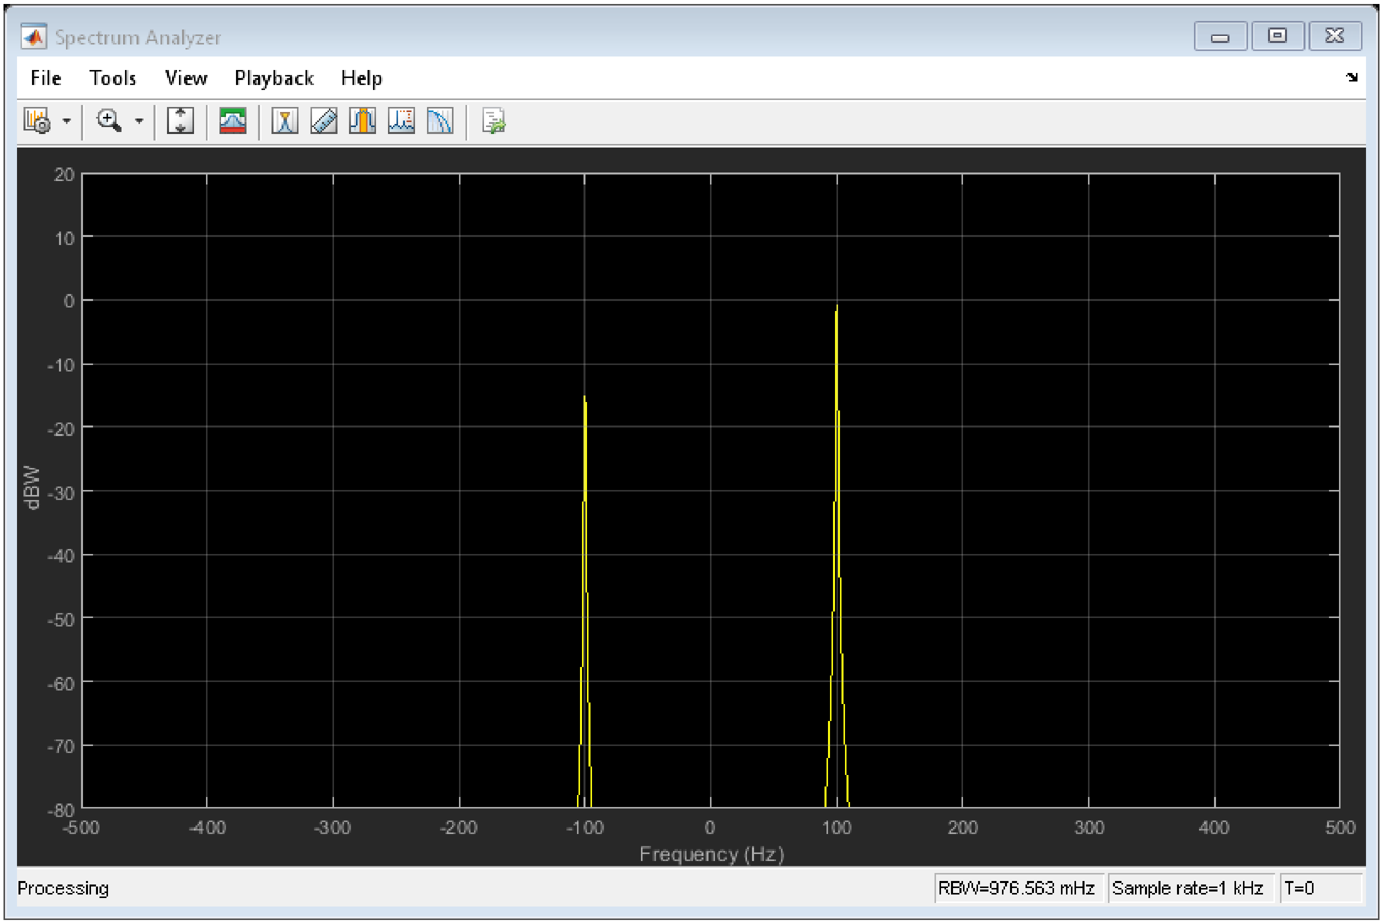
Apply the same 3 dB and 10 degree I/Q imbalance.

```
ampImb = 3;
phImb = 10;
y = iqimbal(x,ampImb,phImb);
```

Plot the spectrum of the imbalanced signal.

```
spectrum = dsp.SpectrumAnalyzer('SampleRate',1000,'PowerUnits','dBW');

spectrum(y)
```

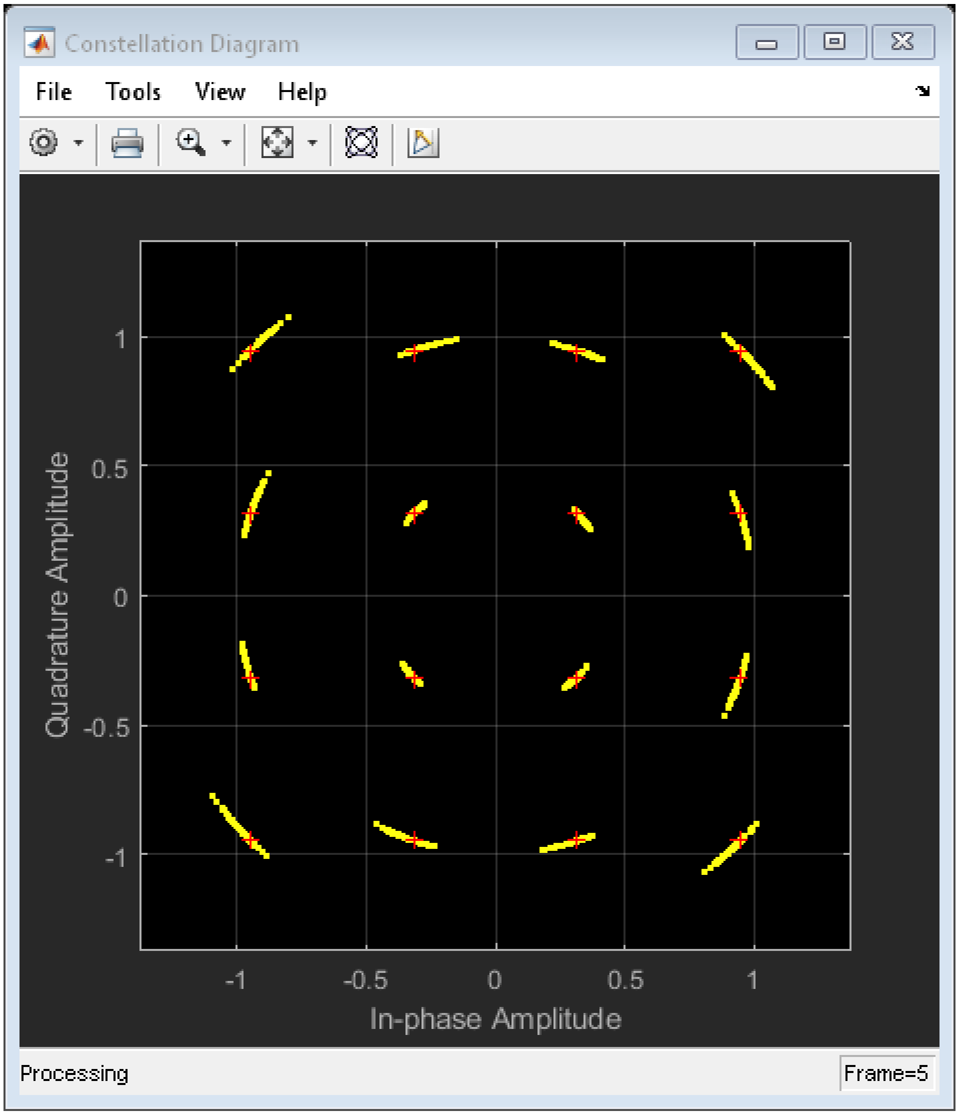


The I/Q imbalance introduces a second tone at -100 Hz, which is the inverse of the input tone.

Phase Noise

Apply phase noise to the transmitted signal. Plot the resulting constellation diagram.

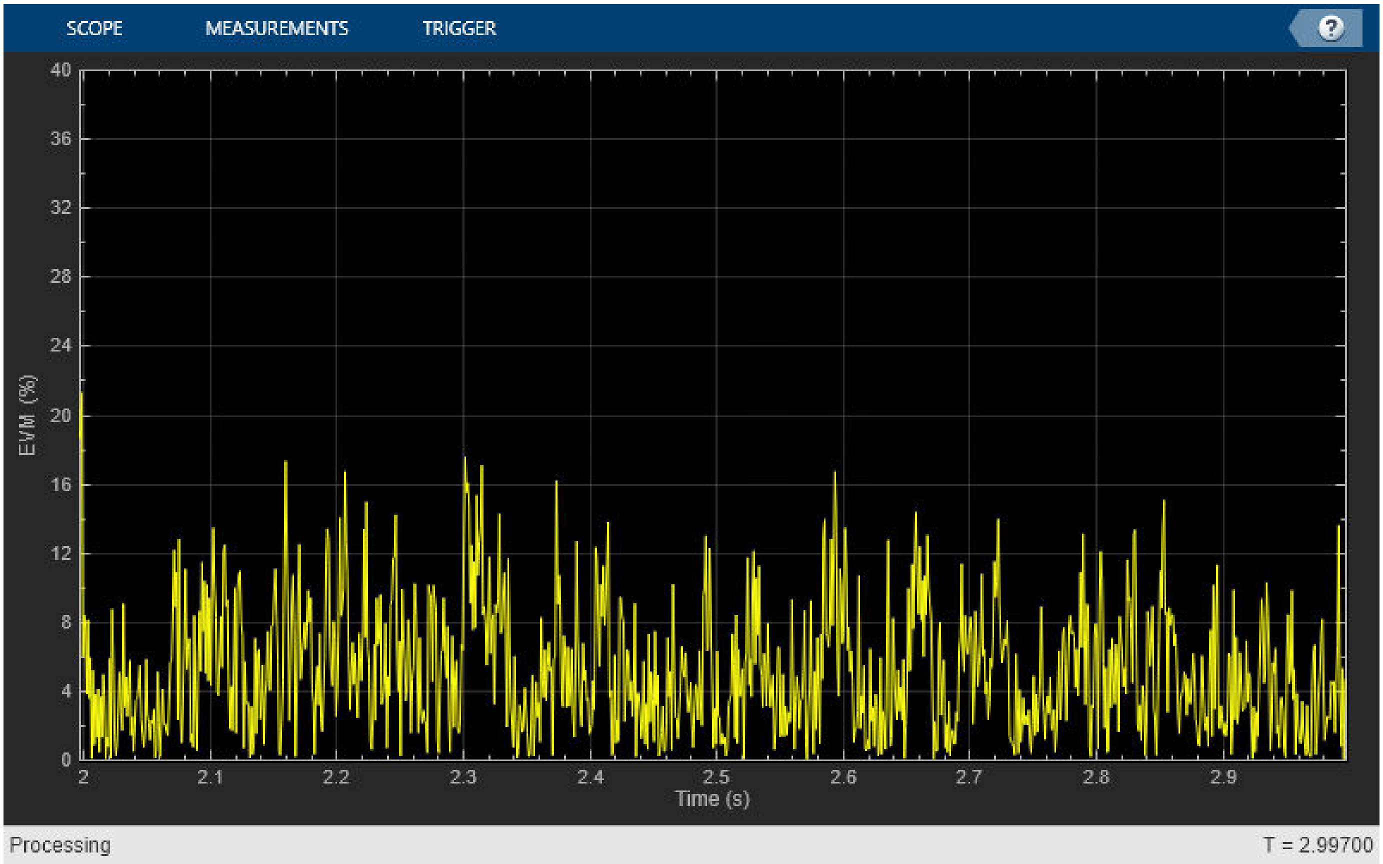
```
pnoise = comm.PhaseNoise('Level',-50,'FrequencyOffset',20,'SampleRate',fs);
pnoiseSig = pnoise(modSig);
constDiagram(pnoiseSig)
```



The phase noise introduces a rotational jitter.

Compute and plot the EVM of the received signal.

```
evmTime = evm(modSig,pnoiseSig);
timeScope(evmTime)
```



Determine the RMS EVM.

```
evmRMS = sqrt(mean(evmTime.^2))
```

```
evmRMS = 6.2675
```

Filter Effects

Specify the samples per symbol parameter. Create a pair of raised cosine matched filters.

```
sps = 4;
txfilter = comm.RaisedCosineTransmitFilter('RolloffFactor',0.2,'FilterSpanInSymbols',8, ...
    'OutputSamplesPerSymbol',sps,'Gain',sqrt(sps));

rxfilter = comm.RaisedCosineReceiveFilter('RolloffFactor',0.2,'FilterSpanInSymbols',8, ...
    'InputSamplesPerSymbol',sps,'Gain',1/sqrt(sps), ...
    'DecimationFactor',sps);
```

Determine the delay through the matched filters.

```
fltDelay = 0.5*(txfilter.FilterSpanInSymbols + rxfilter.FilterSpanInSymbols);
```

Pass the modulated signal through the matched filters.

```
filtSig = txfilter(modSig);
rxSig = rxfilter(filtSig);
```

To account for the delay through the filters, discard the first `fltDelay` samples.

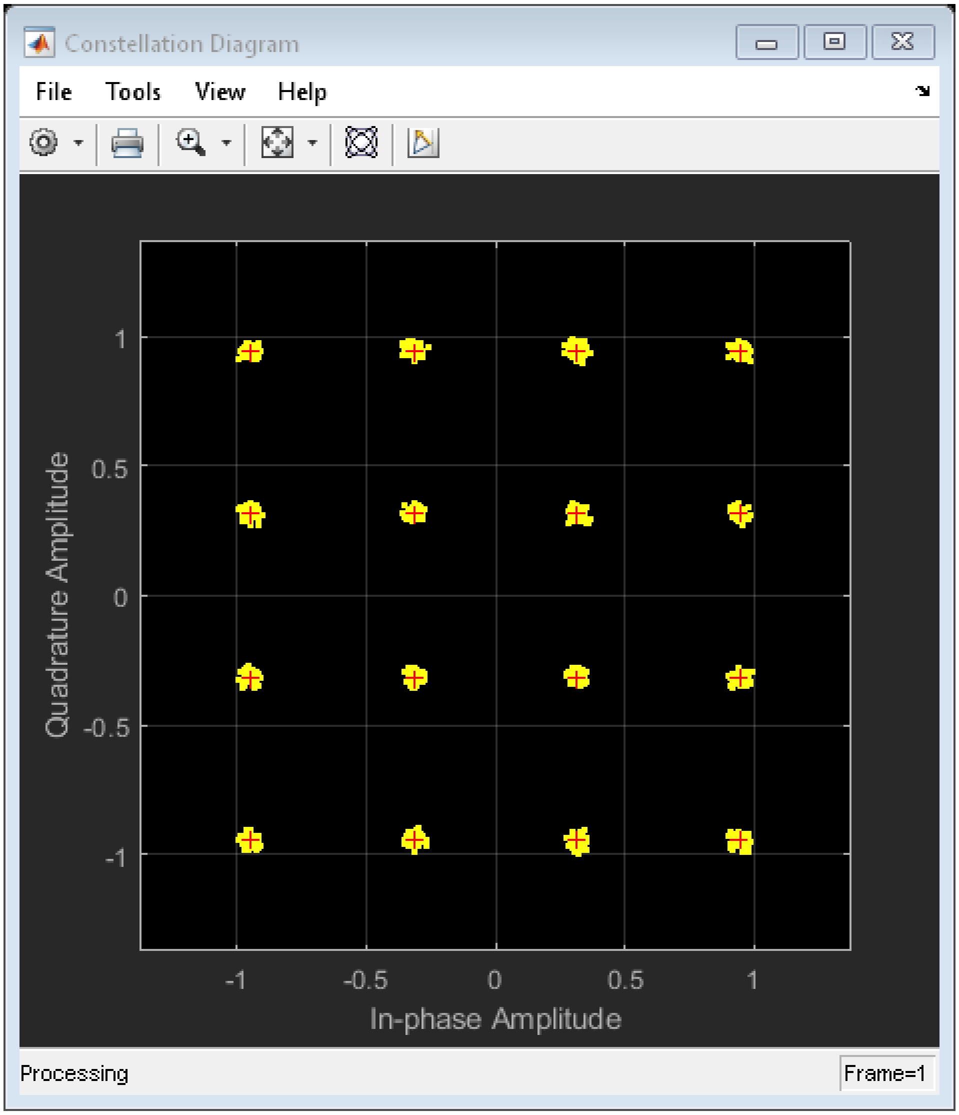
```
rxSig = rxSig(fltDelay+1:end);
```

To accommodate the change in the number of received signal samples, create new constellation diagram and time scope objects.

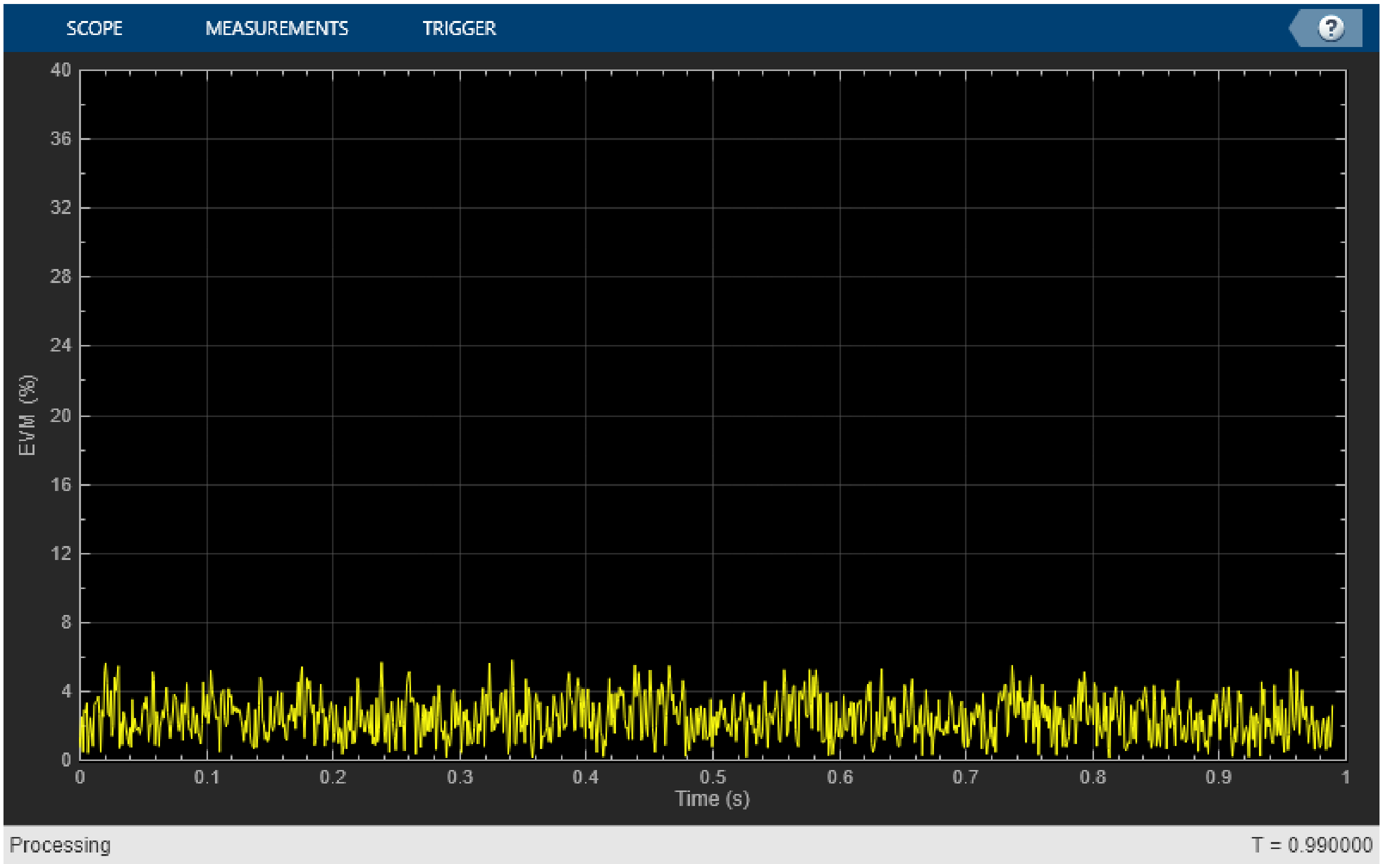
```
constDiagram = comm.ConstellationDiagram('ReferenceConstellation',refConst);
timeScope = timescope('YLimits',[0 40],'SampleRate',fs,'TimeSpanSource','property','TimeSpan',1,
    'ShowGrid',true,'YLabel','EVM (%)');
```

Estimate EVM. Plot the received signal constellation diagram and the time-varying EVM.

```
evm = comm.EVM('ReferenceSignalSource','Estimated from reference constellation', ...
    'ReferenceConstellation',refConst, ...
    'Normalization','Average constellation power','AveragingDimensions',2);
evmTime = evm(rxSig);
constDiagram(rxSig)
```



```
timeScope(evmTime)
```



Determine the RMS EVM.

```
evmRMS = sqrt(mean(evmTime.^2))
```

```
evmRMS = 2.7174
```

Determine the equivalent SNR.

```
mer = comm.MER;
snrEst = mer(modSig(1:end-fltDelay),rxSig)
```

```
snrEst = 31.4719
```

Combined Effects

Combine the effects of the filters, nonlinear amplifier, AWGN, and phase noise. Display the constellation and EVM diagrams.

Create EVM, time scope and constellation diagram objects.

```
evm = comm.EVM('ReferenceSignalSource','Estimated from reference constellation', ...
    'ReferenceConstellation',refConst, ...
    'Normalization','Average constellation power','AveragingDimensions',2);
timeScope = timescope('YLimits',[0 40],'SampleRate',fs,'TimeSpanSource','property','TimeSpan',1,
    'ShowGrid',true,'YLabel','EVM (%)');
constDiagram = comm.ConstellationDiagram('ReferenceConstellation',refConst);
```

Specify the nonlinear amplifier and phase noise objects.

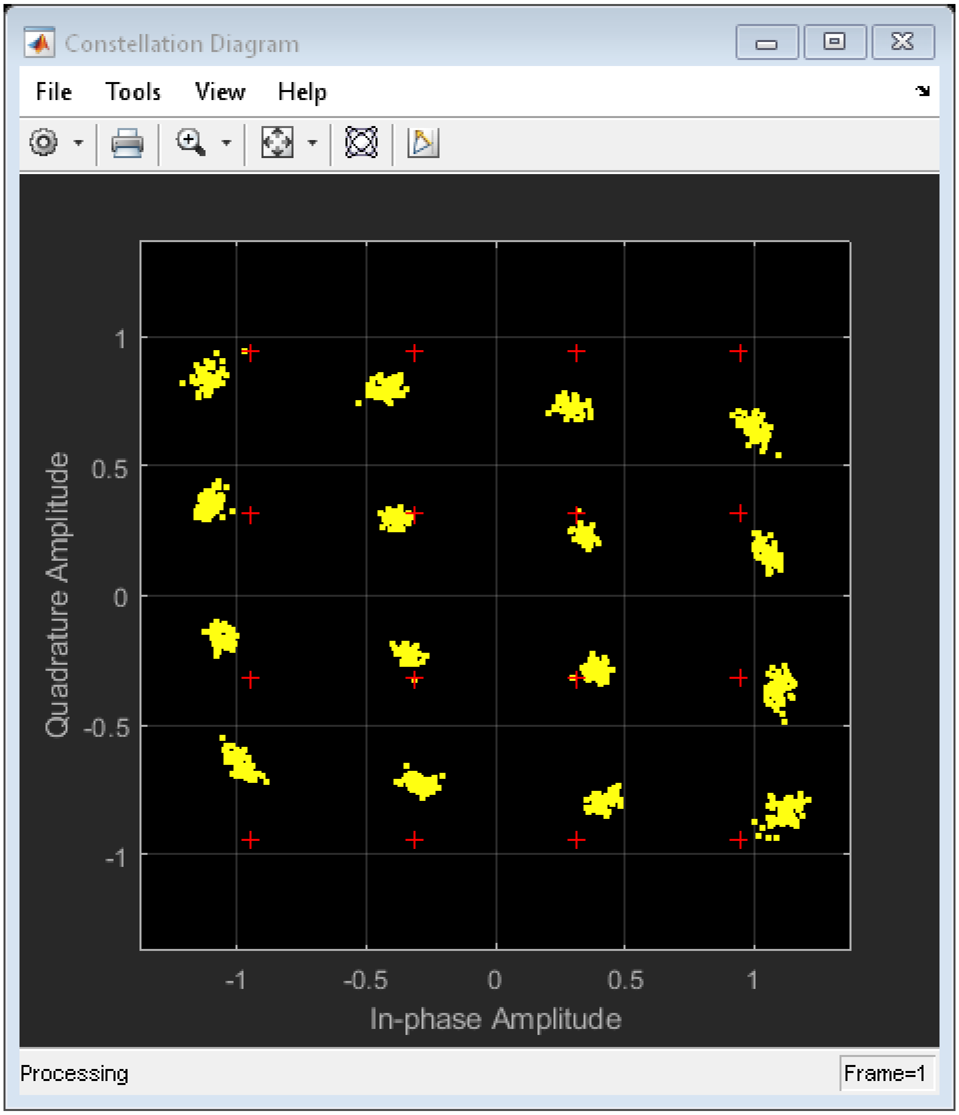
```
amp = comm.MemorylessNonlinearity('IIP3',45,'AMPMConversion',0);
pnoise = comm.PhaseNoise('Level',-55,'FrequencyOffset',20,'SampleRate',fs);
```

Filter and then amplify the modulated signal.

```
txfiltOut = txfilter(modSig);
txSig = amp(txfiltOut);
```

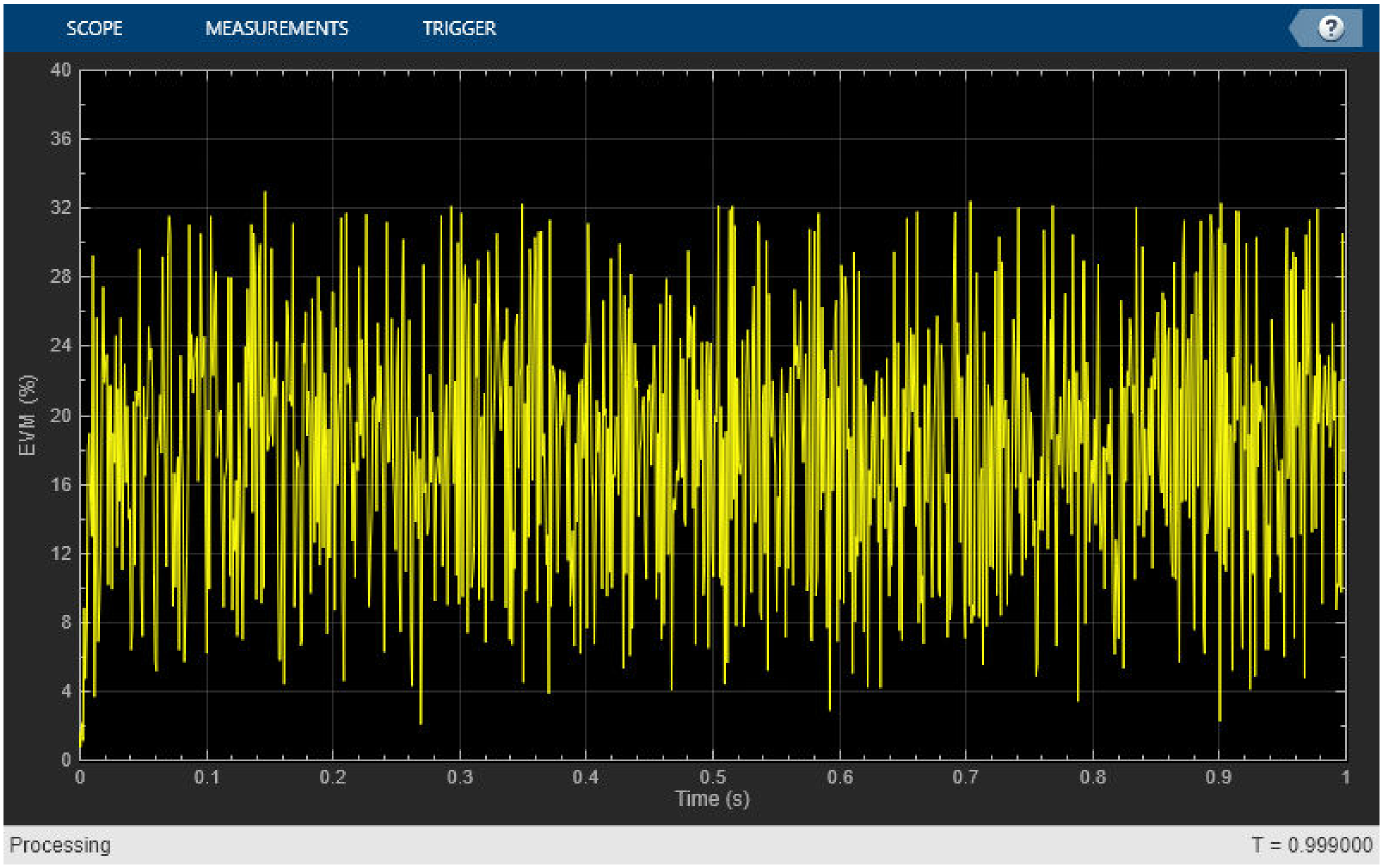
Add phase noise. Pass the impaired signal through the AWGN channel. Plot the constellation diagram.

```
rxSig = awgn(txSig,snrdB);
iqImbalSig = iqimbal(rxSig,ampImb,phImb);
pnoiseSig = pnoise(iqImbalSig);
rxfiltOut = rxfilter(pnoiseSig);
constDiagram(rxfiltOut)
```



Calculate the time-varying EVM. Plot the result.

```
evmTime = evm(rxfiltOut);
timeScope(evmTime)
```



Determine the RMS EVM.

```
evmRMS = sqrt(mean(evmTime.^2))
```

```
evmRMS = 19.4977
```

Estimate the SNR.

```
mer = comm.MER('ReferenceSignalSource','Estimated from reference constellation', ...
    'ReferenceConstellation',refConst);
snrEst = mer(rxfiltOut)
```

```
snrEst = 14.1829
```

This value is approximately 6 dB worse than the specified value of 30 dB, which means that the effects of the other impairments are significant and will degrade the bit error rate performance.

More About

Use the Channel Visualization Tool

You can use a graphical plotting function that helps you visualize the characteristics of a fading channel. For example, the following code opens the channel visualization tool showing a three-path Rayleigh channel through which a random signal is passed:

```
% Three-Path Rayleigh channel
h = rayleighchan(1/100000, 130, [0 1.5e-5 3.2e-5], [0, -3, -3]);
tx = randi([0 1],500,1);          % Random bit stream
hmod = comm.DBPSKModulator;       % Create DBPSKModulator
dpskSig = step(hmod,tx);          % DPSK signal
h.StoreHistory = true;            % Allow states to be stored
y = filter(h, dpskSig);           % Run signal through channel
plot(h);                          % Call Channel Visualization Tool
```

See “Fading Channels” for a description of fading channels and objects.

Compatibility Considerations

plot has been removed

Errors starting in R2020b

plot (channel) has been removed. Use comm.RicianChannel instead.

plotPhaseNoiseFilter

Plot response of phase noise filter block

Syntax

```
plotPhaseNoiseFilter(blockname)
```

Description

`plotPhaseNoiseFilter(blockname)` plots the response of the phase noise filter associated with the Phase Noise block specified by the variable `blockname`.

Examples

View Filter Response of Phase Noise Block

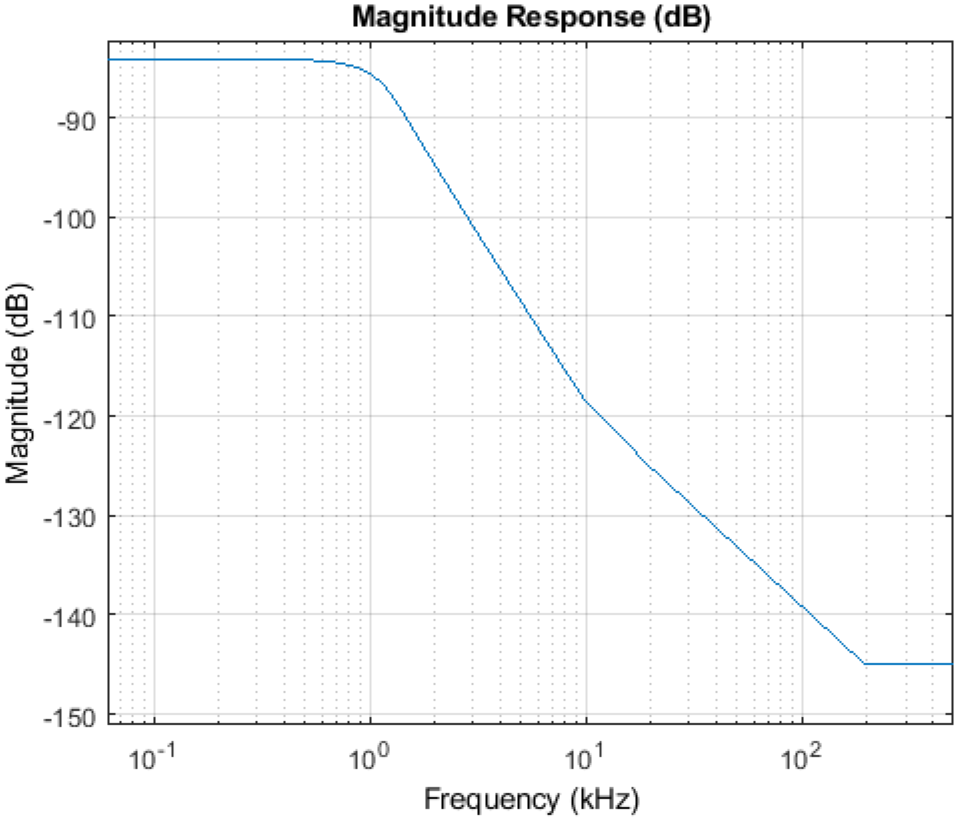
This example shows how to use the `plotPhaseNoiseFilter` function to view the filter response of a Phase Noise block in a Simulink model.

Load a Simulink model that contains a Phase Noise block. The `load_system` (Simulink) command loads a model into memory without making its model window visible. The function will also work with models whose window is visible. The example, `slex_phasenoise`, contains a `Phase Noise` block.

```
load_system('slex_phasenoise')
```

Run the `plotPhaseNoiseFilter` function to view the filter response of the block Phase Noise.

```
plotPhaseNoiseFilter('slex_phasenoise/Phase Noise')
```



Input Arguments

`blockname` — Phase noise block name
character vector

The name of a Phase Noise block in a Simulink model

Example: `plotPhaseNoiseFilter('Model Name/Phase Noise')`

Data Types: `char`

Phase Noise

Introduced in R2014b

pmdemod

Phase demodulation

Syntax

```
z = pmdemod(y,Fc,Fs,phasedev)
z = pmdemod(y,Fc,Fs,phasedev,ini_phase)
```

Description

`z = pmdemod(y,Fc,Fs,phasedev)` demodulates the phase-modulated signal `y` at the carrier frequency `Fc` (hertz). `z` and the carrier signal have sampling rate `Fs` (hertz), where `Fs` must be at least `2*Fc`. The `phasedev` argument is the phase deviation of the modulated signal, in radians.

`z = pmdemod(y,Fc,Fs,phasedev,ini_phase)` specifies the initial phase of the modulated signal, in radians.

Examples

Recover Phase Modulated Signal from AWGN Channel

Set the sample rate. To plot the signals, create a time vector.

```
fs = 50;
t = (0:2*fs+1)'/fs;
```

Create a sinusoidal input signal.

```
x = sin(2*pi*t) + sin(4*pi*t);
```

Set the carrier frequency and phase deviation.

```
fc = 10;
phasedev = pi/2;
```

Modulate the input signal.

```
tx = pmmod(x,fc,fs,phasedev);
```

Pass the signal through an AWGN channel.

```
rx = awgn(tx,10,'measured');
```

Demodulate the noisy signal.

```
y = pmdemod(rx,fc,fs,phasedev);
```

Plot the original and recovered signals.

```
figure; plot(t,[x y]);
legend('Original signal','Recovered signal');
```

```
xlabel('Time (s)')
ylabel('Amplitude (V)')
```

pmmod

Phase modulation

Syntax

```
y = pmmod(x,Fc,Fs,phasedev)
y = pmmod(x,Fc,Fs,phasedev,ini_phase)
```

Description

`y = pmmod(x,Fc,Fs,phasedev)` modulates the message signal `x` using phase modulation.

`y = pmmod(x,Fc,Fs,phasedev,ini_phase)` specifies the initial phase of the modulated signal in radians.

Examples

Recover Phase Modulated Signal from AWGN Channel

Set the sample rate. To plot the signals, create a time vector.

```
fs = 50;
t = (0:2*fs+1)'/fs;
```

Create a sinusoidal input signal.

```
x = sin(2*pi*t) + sin(4*pi*t);
```

Set the carrier frequency and phase deviation.

```
fc = 10;
phasedev = pi/2;
```

Modulate the input signal.

```
tx = pmmod(x,fc,fs,phasedev);
```

Pass the signal through an AWGN channel.

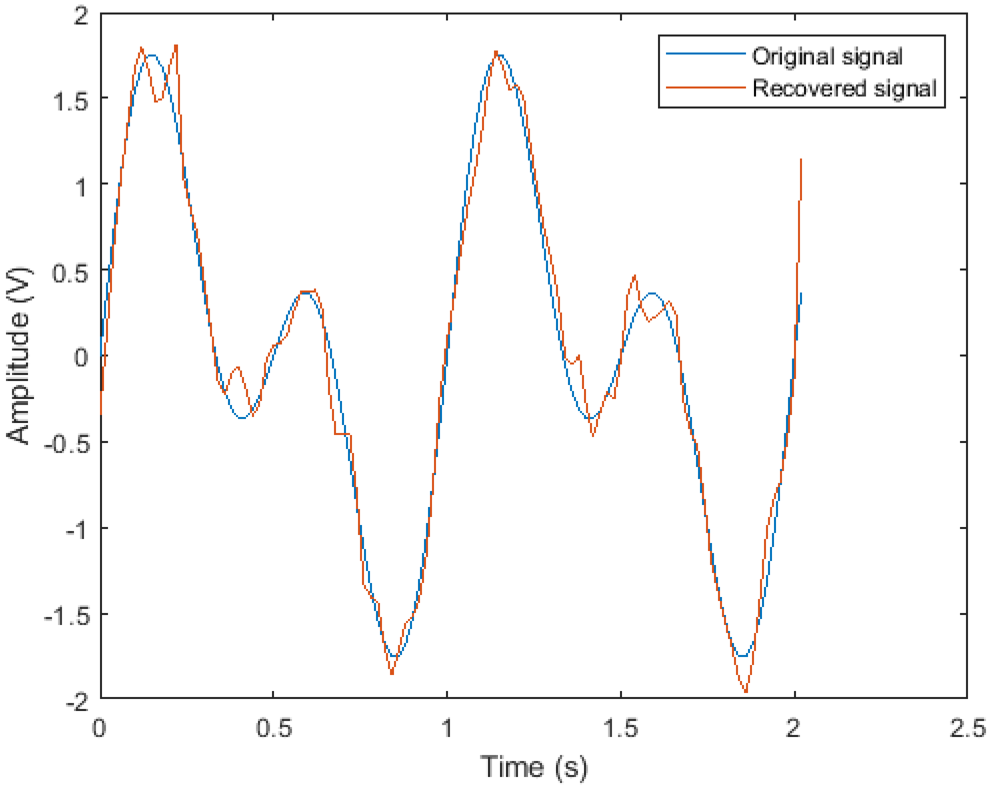
```
rx = awgn(tx,10,'measured');
```

Demodulate the noisy signal.

```
y = pmdemod(rx,fc,fs,phasedev);
```

Plot the original and recovered signals.

```
figure; plot(t,[x y]);
legend('Original signal','Recovered signal');
xlabel('Time (s)')
ylabel('Amplitude (V)')
```



Input Arguments

x — Input signal

vector | matrix

Input signal, specified as a vector or matrix of positive integers. If `x` is a matrix, `pmmod` processes the columns independently.

Example: `sin(2*pi*t) + sin(6*pi*t)`

Data Types: `double`

Fc — Carrier frequency

positive scalar

Carrier frequency, specified as a positive scalar.

Data Types: `double`

Fs — Sample rate

positive scalar

Sample rate, specified as a positive scalar. `Fs` must be at least 2*`Fc`.

Data Types: `double`

ini_phase — Initial phase

0 (default) | scalar | [ ]

Initial phase of the modulated signal (in radians), specified as a real scalar.

Example: pi/4

Data Types: double

phasedev — Phase deviation

positive scalar

Phase deviation, specified as a positive scalar in radians.

Data Types: double

Output Arguments

y — PM-modulated output signal

vector | matrix

Complex baseband representation of a PM-modulated signal, returned as vector or matrix of complex values. The columns of y represent independent channels.

Data Types: double | single

poly2trellis

Convert convolutional code polynomials to trellis description

Syntax

```
trellis = poly2trellis(ConstraintLength,CodeGenerator)
trellis = poly2trellis(ConstraintLength,CodeGenerator,FeedbackConnection)
```

Description

`trellis = poly2trellis(ConstraintLength,CodeGenerator)` returns the trellis structure description corresponding to the conversion for a rate *K* / *N* feedforward encoder. *K* is the number of input bit streams to the encoder, and *N* is the number of output connections. `ConstraintLength` specifies the delay for the input bit streams to the encoder. `CodeGenerator` specifies the output connections for the input bit streams to the encoder.

The poly2trellis function accepts a polynomial description of a convolutional encoder and returns the corresponding trellis structure description. This output can be used as an input to the `convenc` and `vitdec` functions. It can also be used as a mask parameter value for the Convolutional Encoder, Viterbi Decoder, and APP Decoder blocks.

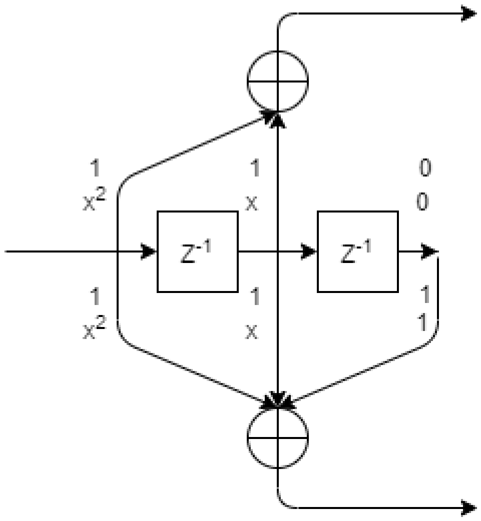
Note When used with a feedback polynomial, poly2trellis makes a feedback connection to the input of the trellis.

`trellis = poly2trellis(ConstraintLength,CodeGenerator,FeedbackConnection)` returns the trellis structure description corresponding to the conversion for a rate *K* / *N* feedback encoder. *K* is the number of input bit streams to the encoder, and *N* is the number of output connections. `ConstraintLength` specifies the delay for the input bit streams to the encoder. `CodeGenerator` specifies the output connections for the input bit streams to the encoder. `FeedbackConnection` specifies the feedback connection for each of the *K* input bit streams to the encoder.

Examples

Use Trellis Structure for Rate 1/2 Feedforward Convolutional Encoder

Use a trellis structure to configure the rate 1/2 feedforward convolutional code in this diagram.



Create a trellis structure, setting the constraint length to 3 and specifying the code generator as a vector of octal values. The diagram indicates the binary values and polynomial form, indicating the left-most bit is the most-significant-bit (MSB). The binary vector [1 1 0] represents octal 6 and corresponds to the upper row of binary digits in the diagram. The binary vector [1 1 1] represents octal 7 and corresponds to the lower row of binary digits in the diagram. These binary digits indicate connections from the outputs of the registers to the two adders in the diagram.

```
trellis = poly2trellis(3,[6 7])
```

```
trellis = struct with fields:
     numInputSymbols: 2
    numOutputSymbols: 4
           numStates: 4
          nextStates: [4x2 double]
             outputs: [4x2 double]
```

Generate random binary data. Convolutionally encode the data, by using the specified trellis structure. Decode the coded data by using the Viterbi algorithm with the specified trellis structure, 34 for its traceback depth, truncated operation mode, and hard decisions.

```
data = randi([0 1],70,1);
codedData = convenc(data,trellis);
tbdepth = 34;
decodedData = vitdec(codedData,trellis,tbdepth,'trunc','hard');
```

Verify the decoded data has zero bit errors.

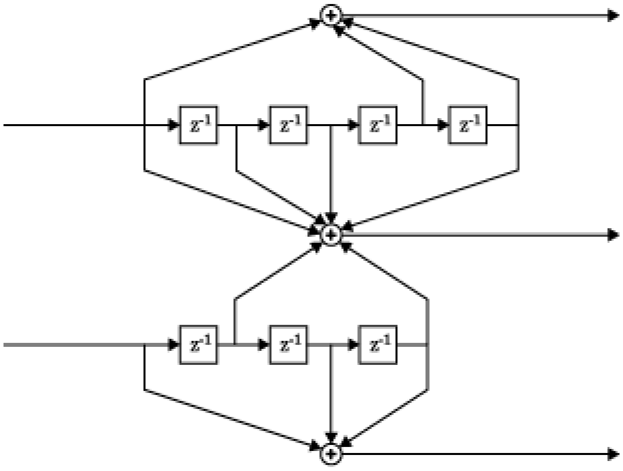
```
biterr(data,decodedData)
```

```
ans = 0
```

Trellis Structure for 2/3 Feedforward Convolutional Encoder

Create a trellis structure for a rate 2/3 feedforward convolutional code and display a portion of the next states of the trellis. See `convenc` for an example using this encoder.

The diagram shows a rate 2/3 encoder with two input streams, three output streams, and seven shift registers.



Create a trellis structure. Set the constraint length of the upper path to 5 and the constraint length of the lower path to 4. The octal representation of the code generator matrix corresponds to the taps from the upper and lower shift registers.

```
trellis = poly2trellis([5 4],[23 35 0; 0 5 13])
```

```
trellis = struct with fields:
     numInputSymbols: 4
    numOutputSymbols: 8
           numStates: 128
          nextStates: [128x4 double]
             outputs: [128x4 double]
```

The structure field `numInputSymbols` equals 4 because two bit streams can produce four different input symbols. The structure field `numOutputSymbols` equals 8 because three bit streams produce eight different output symbols. Because the encoder has seven total shift registers, the number of possible states is 2^7 = 128, as shown by the `nextStates` field.

Display the first five rows of the 128-by-4 `trellis.nextStates` matrix.

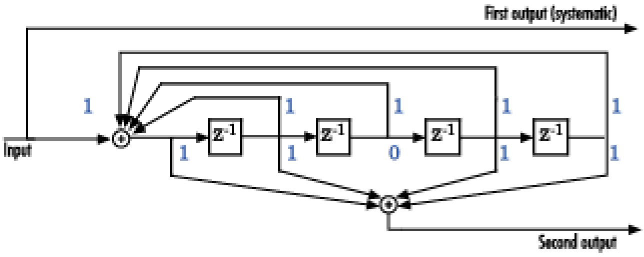
```
trellis.nextStates(1:5,:)
```

```
ans = 5×4

     0    64     8    72
     0    64     8    72
     1    65     9    73
     1    65     9    73
     2    66    10    74
```

Use Trellis Structure for Rate 1/2 Feedback Convolutional Encoder

Create a trellis structure to represent the rate 1/2 systematic convolutional encoder with feedback shown in this diagram.



This encoder has 5 for its constraint length, [37 33] as its generator polynomial matrix, and 37 for its feedback connection polynomial.

The first generator polynomial is octal 37. The second generator polynomial is octal 33. The feedback polynomial is octal 37. The first generator polynomial matches the feedback connection polynomial because the first output corresponds to the systematic bits.

The binary vector [1 1 1 1 1] represents octal 37 and corresponds to the upper row of binary digits in the diagram. The binary vector [1 1 0 1 1] represents octal 33 and corresponds to the lower row of binary digits in the diagram. These binary digits indicate connections from the outputs of the registers to the two adders in the diagram. The initial 1 corresponds to the input bit.

Convert the polynomial to a trellis structure by using the `poly2trellis` function. When used with a feedback polynomial, `poly2trellis` makes a feedback connection to the input of the trellis.

```
trellis = poly2trellis(5,[37 33],37)
```

```
trellis = struct with fields:
     numInputSymbols: 2
    numOutputSymbols: 4
           numStates: 16
          nextStates: [16x2 double]
             outputs: [16x2 double]
```

Generate random binary data. Convolutionally encode the data by using the specified trellis structure. Decode the coded data by using the Viterbi algorithm with the specified trellis structure, 34 for its traceback depth, truncated operation mode, and hard decisions.

```
data = randi([0 1],70,1);
codedData = convenc(data,trellis);
tbdepth = 34; % Traceback depth for Viterbi decoder
decodedData = vitdec(codedData,trellis,tbdepth,'trunc','hard');
```

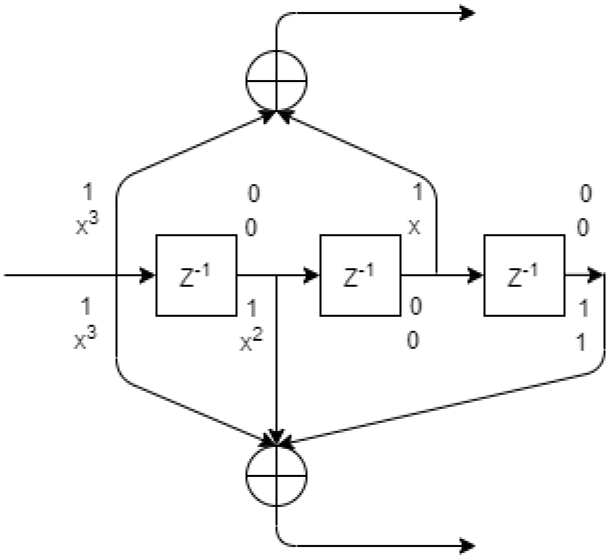
Verify the decoded data has zero bit errors.

```
biterr(data,decodedData)
```

```
ans = 0
```

Specifying Code Generators in Polynomial Form

Demonstrate alternative forms of specifying code generators for a trellis structure are equivalent.



Use a trellis structure to configure the rate 1/2 feedforward convolutional code in this diagram. The diagram indicates the binary values and polynomial form, indicating the left-most bit is the most-significant-bit (MSB).

Set the constraint length to 4. Use a cell array of polynomial character vectors to specify code generators. For more information, see “Character Representation of Polynomials”. When using character representation to specify the code generator, you can specify the polynomial in ascending or descending order, but the `poly2trellis` function always assigns registers in descending order with the left-most register for the MSB.

```
trellis_poly = poly2trellis(4,{'x3 + x','x3 + x2 + 1'})
```

```
trellis_poly = struct with fields:
     numInputSymbols: 2
    numOutputSymbols: 4
           numStates: 8
          nextStates: [8x2 double]
             outputs: [8x2 double]
```

The binary vector [1 0 1 0] represents octal 12 and corresponds to the upper row of binary digits in the diagram. The binary vector [1 1 0 1] represents octal 15 and corresponds to the lower row of binary digits in the diagram. Use octal representation to specify the code generators for an equivalent trellis structure.

```
trellis = poly2trellis(4,[12 15])
```

```
trellis = struct with fields:
     numInputSymbols: 2
    numOutputSymbols: 4
           numStates: 8
          nextStates: [8x2 double]
```

```
            outputs: [8x2 double]
```

Use `isequal` to confirm the two trellises are equal.

```
isequal(trellis,trellis_poly)
```

```
ans = logical
   1
```

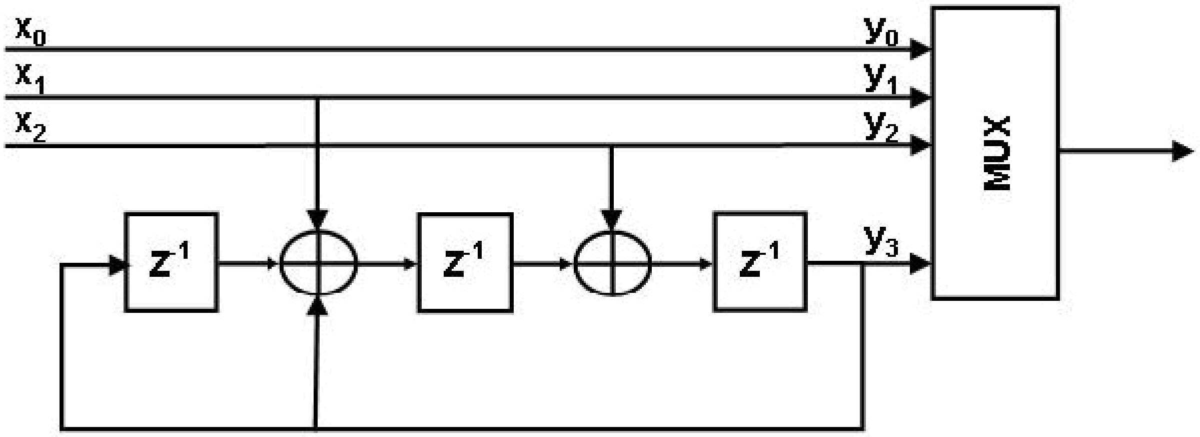
Create User Defined Trellis Structure

This example demonstrates creation of a nonstandard trellis structure for a convolutional encoder with uncoded bits and feedback. The encoder cannot be created using `poly2trellis` because the peculiar specifications for the encoder do not match the input requirements of `poly2trellis`.

You can manually create the trellis structure, and then use it as the input trellis structure for an encoder and decoder. The Convolutional Encoder and Viterbi Decoder blocks used in the "Convolutional Encoder with Uncoded Bits and Feedback" model load the trellis structure created here using a `PreLoadFcn` callback.

Convolutional Encoder

Create a rate 3/4 convolutional encoder with feedback connection whose MSB bit remains uncoded.



Declare variables according to the specifications.

```
K = 3;
N = 4;
constraintLength = 4;
```

Create trellis structure

A trellis is represented by a structure with the following fields:

- `numInputSymbols` – Number of input symbols

- `numOutputSymbols` – Number of output symbols
- `numStates` – Number of states
- `nextStates` – Next state matrix
- `outputs` – Output matrix

For more information about these structure fields, see `istrellis`.

Reset any previous occurrence of `myTrellis` structure.

```
clear myTrellis;
```

Define the trellis structure fields.

```
myTrellis.numInputSymbols = 2^K;
myTrellis.numOutputSymbols = 2^N;
myTrellis.numStates  = 2^(constraintLength-1);
```

Create nextStates Matrix

The `nextStates` matrix is a [`numStates` x `numInputSymbols`] matrix. The (*i*,*j*) element of the next state matrix is the resulting final state index that corresponds to a transition from the initial state *i* for an input equal to *j*.

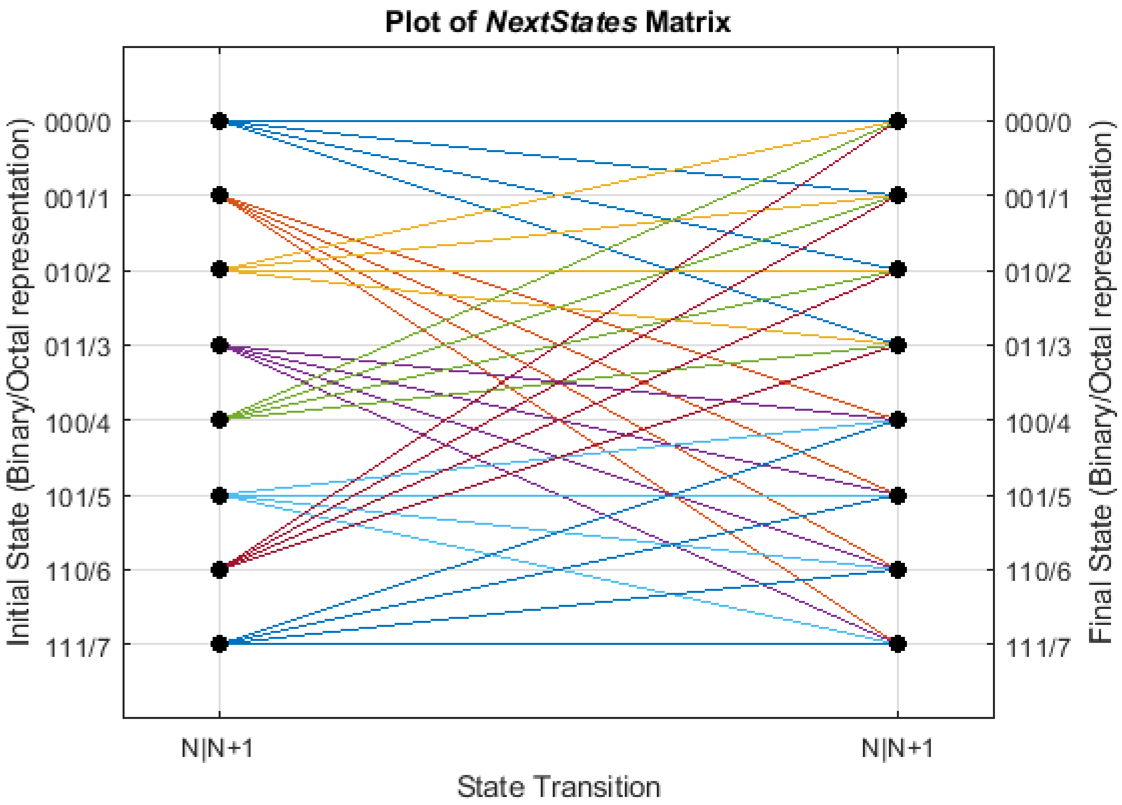
```
myTrellis.nextStates = [0  1  2  3  0  1  2  3; ...
                        6  7  4  5  6  7  4  5; ...
                        1  0  3  2  1  0  3  2; ...
                        7  6  5  4  7  6  5  4; ...
                        2  3  0  1  2  3  0  1; ...
                        4  5  6  7  4  5  6  7; ...
                        3  2  1  0  3  2  1  0; ...
                        5  4  7  6  5  4  7  6]
```

```
myTrellis = struct with fields:
     numInputSymbols: 8
    numOutputSymbols: 16
           numStates: 8
          nextStates: [8x8 double]
```

Plot nextStates Matrix

Use the `commcnv_plotnextstates` helper function to plot the `nextStates` matrix to illustrate the branch transitions between different states for a given input.

```
commcnv_plotnextstates(myTrellis.nextStates);
```



Create `outputs` Matrix

The `outputs` matrix is a [`numStates` x `numInputSymbols`] matrix. The (*i*,*j*) element of the output matrix is the output symbol in octal format given a current state *i* for an input equal to *j*.

```
outputs =  [0  2  4  6  10  12  14  16; ...
            1  3  5  7  11  13  15  17; ...
            0  2  4  6  10  12  14  16; ...
            1  3  5  7  11  13  15  17; ...
            0  2  4  6  10  12  14  16; ...
            1  3  5  7  11  13  15  17; ...
            0  2  4  6  10  12  14  16; ...
            1  3  5  7  11  13  15  17]
```

```
outputs = 8×8

     0     2     4     6    10    12    14    16
     1     3     5     7    11    13    15    17
     0     2     4     6    10    12    14    16
     1     3     5     7    11    13    15    17
     0     2     4     6    10    12    14    16
     1     3     5     7    11    13    15    17
     0     2     4     6    10    12    14    16
     1     3     5     7    11    13    15    17
```

Use `oct2dec` to display these values in decimal format.

```
outputs_dec = oct2dec(outputs)
```

```
outputs_dec = 8×8

     0     2     4     6     8    10    12    14
     1     3     5     7     9    11    13    15
     0     2     4     6     8    10    12    14
     1     3     5     7     9    11    13    15
     0     2     4     6     8    10    12    14
     1     3     5     7     9    11    13    15
     0     2     4     6     8    10    12    14
     1     3     5     7     9    11    13    15
```

Copy outputs matrix into the `myTrellis` structure.

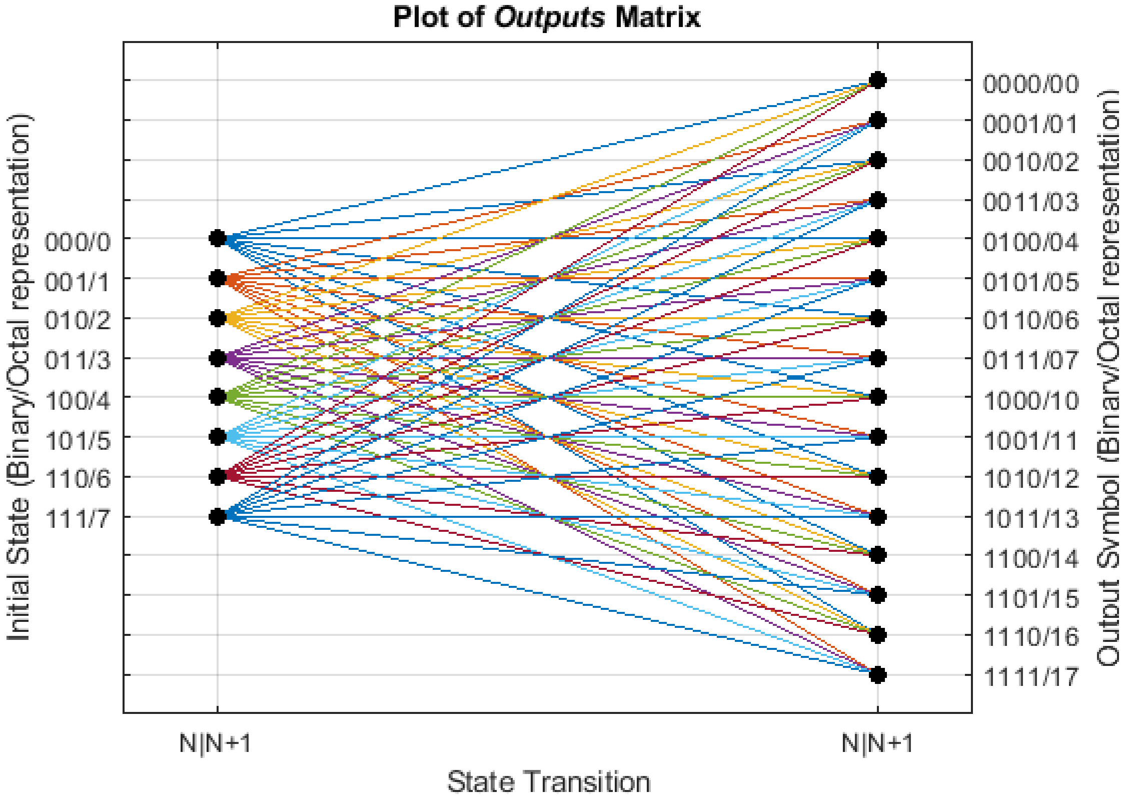
```
myTrellis.outputs = outputs
```

```
myTrellis = struct with fields:
     numInputSymbols: 8
    numOutputSymbols: 16
           numStates: 8
          nextStates: [8x8 double]
             outputs: [8x8 double]
```

Plot `outputs` Matrix

Use the `commcnv_plotoutputs` helper function to plot the `outputs` matrix to illustrate the possible output symbols for a given state depending on the input symbol.

```
commcnv_plotoutputs(myTrellis.outputs, myTrellis.numOutputSymbols);
```



Check Resulting Trellis Structure

```
istrellis(myTrellis)
```

```
ans = logical
   1
```

A return value of 1 confirms the trellis structure is valid.

Implement Soft-Decision Decoding

Decode with 3-bit soft decisions partitioned so that values near 0 map to 0, and values near 1 map to 7. If your application requires better decoding performance, refine the partition to obtain finer quantization.

The example decodes the code and computes the bit error rate. When comparing the decoded data with the original message, the example must take the decoding delay into account. The continuous operation mode of the Viterbi decoder causes a delay equal to the traceback length, so `msg(1)` corresponds to `decoded(tblen+1)` rather than to `decoded(1)`.

System Setup

Initialize runtime variables for the message data, trellis, bit error rate computations, and traceback length.

```
stream = RandStream.create('mt19937ar', 'seed',94384);
prevStream = RandStream.setGlobalStream(stream);
msg = randi([0 1],4000,1); % Random data

trellis = poly2trellis(7,[171 133]); % Define trellis

ber = zeros(3,1); % Store BER values
tblen = 48; % Traceback length
```

Create an AWGN channel System object, a Viterbi decoder System object, and an error rate calculator System object. Account for the receive delay caused by the traceback length of the Viterbi decoder.

```
awgnChan = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (SNR)','SNR',6);
vitDec = comm.ViterbiDecoder(trellis,'InputFormat','Soft', ...
    'SoftInputWordLength',3,'TracebackDepth',tblen,'TerminationMethod','Continuous');
errorCalc = comm.ErrorRate('ReceiveDelay', tblen);
```

Run Coding and Decoding

Convolutionally code the message, pass in through an AWGN filter, quantize the noisy message for soft-decision decoding. Perform Viterbi decoding using the trellis generated using `poly2trellis`.

```
code = convenc(msg,trellis);
awgnChan.SignalPower = (code'*code)/length(code);
ncode = awgnChan(code);
```

Use `quantiz` to map the noisy data values to appropriate decision-value integers between 0 and 7. The second argument in `quantiz` is a partition vector that determines which data values map to 0, 1, 2, etc.

```
qcode = quantiz(ncode,[0.001,0.1,0.3,0.5,0.7,0.9,0.999]);
decoded = vitDec(qcode);
```

Compute bit error rate.

```
ber = errorCalc(msg,decoded);
ratio = ber(1)
```

```
ratio = 0.0013
```

```
number = ber(2)
```

```
number = 5
```

```
RandStream.setGlobalStream(prevStream);
```

Input Arguments

`ConstraintLength` — Constraint length

row vector

Constraint length, specified as a 1-by-*K* row vector defining the delay for each of the *K* input bit streams to the encoder.

Data Types: `double`

`CodeGenerator` — Code generator

matrix | cell array of character vector | string array

Code generator, specified as a *K*-by-*N* matrix of octal numbers, a *K*-by-*N* cell array of polynomial character vectors, or a *K*-by-*N* string array. `CodeGenerator` specifies the *N* output connections for each of the *K* input bit streams to the encoder.

When using character representation to specify the code generator, you can specify the polynomial in ascending or descending order, but the `poly2trellis` function always assigns registers in descending order with the left-most register for the most-significant-bit (MSB). For more information, see “Specifying Code Generators in Polynomial Form” on page 2-662.

Data Types: `double` | `char` | `string`

`FeedbackConnection` — Feedback connection

row vector

Feedback connection, specified as a 1-by-*K* row vector of octal numbers defining the feedback connection for each of the *K* input bit streams to the encoder.

Data Types: `double`

Output Arguments

`trellis` — Trellis description

structure

Trellis description, returned as a structure with these fields. For more about this structure, see the `istrellis` function.

Trellis Structure Fields for Rate K/N Code

`numInputSymbols` — Number of input symbols

scalar

Number of input symbols, returned as a scalar with a value of 2^K. This value represents the number of input symbols to the encoder and *K* represents the number of input bit streams.

`numOutputSymbols` — Number of output symbols

scalar

Number of output symbols, returned as a scalar with a value of 2^N. This value represents the number of output symbols from the encoder and *N* represents the number of output bit streams.

`numStates` — Number of states

scalar

Number of states in the encoder, returned as a scalar.

`nextStates` — Next states

matrix

Next states for all combinations of current states and current inputs, returned as a `numStates`-by-2^K matrix, where *K* represents the number of input bit streams.

`outputs` — Outputs

matrix

Outputs for all combinations of current states and current inputs, returned as a `numStates`-by-2^K matrix, K represents the number of input bit streams. The elements of this matrix are octal numbers.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Inputs must be constants, of which there can be at most 3 (`ConstraintLength`, `CodeGenerator`, `FeedbackConnection`).

Topics

"Convolutional Codes"
"Character Representation of Polynomials"

Introduced before R2006a

primpoly

Find primitive polynomials for Galois field

Syntax

```
pr = primpoly(m)
pr = primpoly(m,opt)
pr = primpoly(m...,'nodisplay')
```

Description

`pr = primpoly(m)` returns the primitive polynomial for GF(`2^m`), where `m` is an integer between `2` and `16`. The Command Window displays the polynomial using "`D`" as an indeterminate quantity. The output argument `pr` is an integer whose binary representation indicates the coefficients of the polynomial.

`pr = primpoly(m,`*`opt`*`)` returns one or more primitive polynomials for GF(`2^m`). The output `pol` depends on the argument *`opt`* as shown in the table below. Each element of the output argument `pr` is an integer whose binary representation indicates the coefficients of the corresponding polynomial. If no primitive polynomial satisfies the constraints, `pr` is empty.

opt	Meaning of pr
`'min'`	One primitive polynomial for GF(`2^m`) having the smallest possible number of nonzero terms
`'max'`	One primitive polynomial for GF(`2^m`) having the greatest possible number of nonzero terms
`'all'`	All primitive polynomials for GF(`2^m`)
Positive integer k	All primitive polynomials for GF(`2^m`) that have k nonzero terms

`pr = primpoly(m...,'nodisplay')` prevents the function from displaying the result as polynomials in "`D`" in the Command Window. The output argument `pr` is unaffected by the `'nodisplay'` option.

Examples

The first example below illustrates the formats that `primpoly` uses in the Command Window and in the output argument `pr`. The subsequent examples illustrate the display options and the use of the *`opt`* argument.

```
pr = primpoly(4)

pr1 = primpoly(5,'max','nodisplay')

pr2 = primpoly(5,'min')

pr3 = primpoly(5,2)

pr4 = primpoly(5,3);
```

The output is below.

```
Primitive polynomial(s) =

D^4+D^1+1

pr =

    19

pr1 =

    61

Primitive polynomial(s) =

D^5+D^2+1

pr2 =

    37

No primitive polynomial satisfies the given constraints.

pr3 =

     []

Primitive polynomial(s) =

D^5+D^2+1
D^5+D^3+1
```

pskdemod

Phase shift keying demodulation

Syntax

```
z = pskdemod(y,M)
z = pskdemod(y,M,ini_phase)
z = pskdemod(y,M,ini_phase,symorder)
```

Description

`z = pskdemod(y,M)` demodulates the complex envelope, `y`, of a PSK-modulated signal having modulation order `M`.

`z = pskdemod(y,M,ini_phase)` specifies the initial phase of the PSK-modulated signal.

`z = pskdemod(y,M,ini_phase,symorder)` specifies the symbol order of the PSK-modulated signal.

Examples

Compare Phase Noise Effects on PSK and PAM Signals

Compare PSK and PAM modulation schemes to demonstrate that PSK is more sensitive to phase noise. This is the expected result because the PSK constellation is circular while the PAM constellation is linear.

Specify the number of symbols and the modulation order parameters. Generate random data symbols.

```
len = 10000;
M = 16;
msg = randi([0 M-1],len,1);
```

Modulate `msg` using both PSK and PAM to compare the two methods.

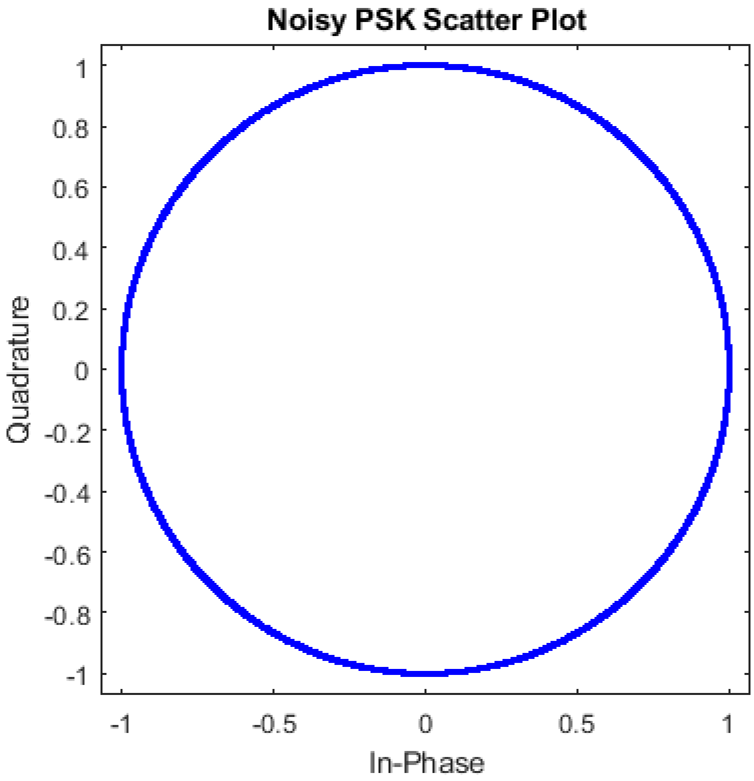
```
txpsk = pskmod(msg,M);
txpam = pammod(msg,M);
```

Perturb the phase of the modulated signals by applying a random phase rotation.

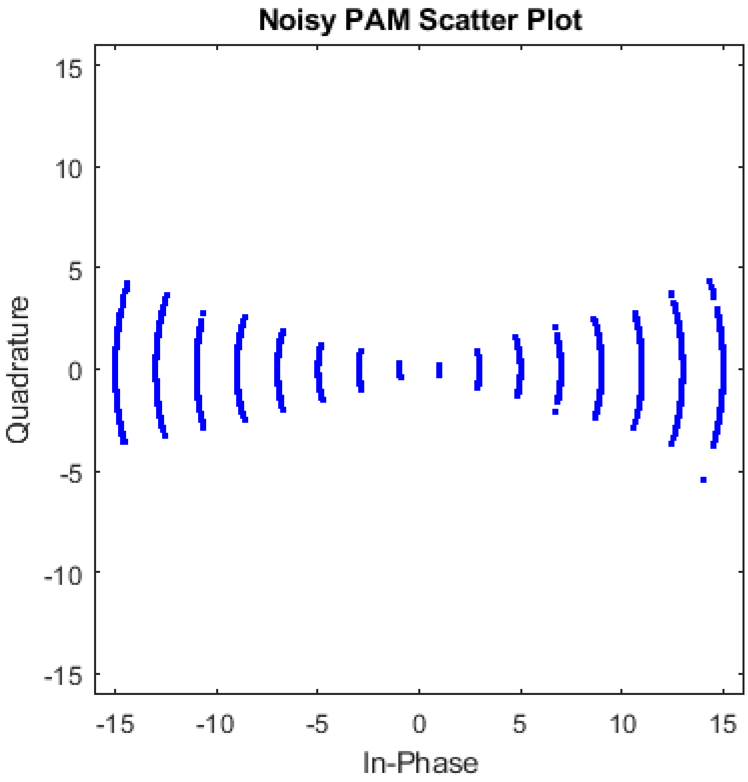
```
phasenoise = randn(len,1)*.015;
rxpsk = txpsk.*exp(2i*pi*phasenoise);
rxpam = txpam.*exp(2i*pi*phasenoise);
```

Create scatter plots of the received signals.

```
scatterplot(rxpsk);
title('Noisy PSK Scatter Plot')
```



```
scatterplot(rxpam);
title('Noisy PAM Scatter Plot')
```



Demodulate the received signals.

```
recovpsk = pskdemod(rxpsk,M);
recovpam = pamdemod(rxpam,M);
```

Compute the number of symbol errors for each modulation scheme. The PSK signal experiences a much greater number of symbol errors.

```
numerrs_psk = symerr(msg,recovpsk);
numerrs_pam = symerr(msg,recovpam);
[numerrs_psk numerrs_pam]
```

```
ans = 1×2

   343      1
```

Modulate and Demodulate QPSK Signal in AWGN

Generate random symbols.

```
dataIn = randi([0 3],1000,1);
```

QPSK modulate the data.

```
txSig = pskmod(dataIn,4,pi/4);
```

Pass the signal through an AWGN channel.

```
rxSig = awgn(txSig,10);
```

Demodulate the received signal and compute the number of symbol errors.

```
dataOut = pskdemod(rxSig,4,pi/4);
numErrs = symerr(dataIn,dataOut)
```

```
numErrs = 2
```

PSK Symbol Mapping

Plot PSK symbol mapping for Gray and natural binary encoded data.

Set the modulation order, and then create a data sequence containing a complete set of constellation points.

```
M = 8;
data = (0:M-1);
phz = 0;
```

Modulate and demodulate the data using Gray and natural binary encoded data.

```
symgray = pskmod(data,M,phz,'gray');
mapgray = pskdemod(symgray,M,phz,'gray');

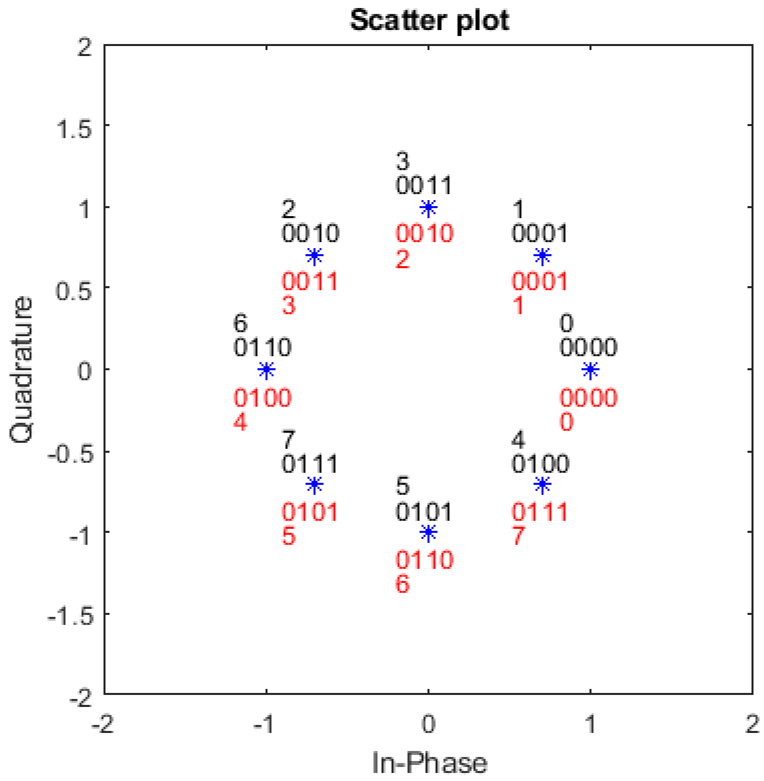
symbin = pskmod(data,M,phz,'bin');
mapbin = pskdemod(symbin,M,phz,'bin');
```

Plot the constellation points using one of the symbol sets. For each constellation point, assign a label indicating the Gray and natural binary values for each symbol.

- For Gray binary symbol mapping, adjacent constellation points differ by a single binary bit and are not numerically sequential.
- For natural binary symbol mapping, adjacent constellation points follow the natural binary encoding and are sequential.

```
scatterplot(symgray,1,0,'b*');
for k = 1:M
    text(real(symgray(k))-0.2,imag(symgray(k))+.15,...
        dec2base(mapgray(k),2,4));
     text(real(symgray(k))-0.2,imag(symgray(k))+.3,...
         num2str(mapgray(k)));

    text(real(symbin(k))-0.2,imag(symbin(k))-.15,...
        dec2base(mapbin(k),2,4),'Color',[1 0 0]);
    text(real(symbin(k))-0.2,imag(symbin(k))-.3,...
        num2str(mapbin(k)),'Color',[1 0 0]);
end
axis([-2 2 -2 2])
```



Input Arguments

y — PSK-modulated input signal

vector | matrix

PSK-modulated input signal, specified as a real or complex vector or matrix. If y is a matrix, the function processes the columns independently.

Data Types: double
Complex Number Support: Yes

M — Modulation order

integer power of two

Modulation order, specified as an integer power of two.

Example: 2 | 4 | 16

Data Types: double

ini_phase — Initial phase

0 (default) | scalar | [ ]

Initial phase of the PSK modulation, specified in radians as a real scalar.

If ini_phase is empty, then pskdemod uses an initial phase of 0.

Example: `pi/4`

Data Types: `double`

`symorder` — Symbol order

`'bin'` (default) | `'gray'`

Symbol order, specified as `'bin'` or `'gray'`. This argument specifies how the function assigns binary vectors to corresponding integers.

- If `symorder` is `'bin'`, the function uses a natural binary-coded ordering.
- If `symorder` is `'gray'`, the function uses a Gray-coded ordering.

Data Types: `char`

Output Arguments

`z` — PSK-demodulated output signal

vector | matrix

PSK-demodulated output signal, returned as a vector or matrix having the same number of columns as input signal `y`.

See Also

`comm.PSKDemodulator` | `modnorm` | `pskmod`

Topics

"Phase Modulation"

Introduced before R2006a

pskmod

Phase shift keying modulation

Syntax

```
y = pskmod(x,M)
y = pskmod(x,M,ini_phase)
y = pskmod(x,M,ini_phase,symorder)
```

Description

`y = pskmod(x,M)` modulates the input signal, `x`, using phase shift keying (PSK) with modulation order `M`.

`y = pskmod(x,M,ini_phase)` specifies the initial phase of the PSK-modulated signal.

`y = pskmod(x,M,ini_phase,symorder)` specifies the symbol order of the PSK-modulated signal.

Examples

Modulate PSK Signal

Modulate and plot the constellations of QPSK and 16-PSK signals.

QPSK

Set the modulation order to 4.

```
M = 4;
```

Generate random data symbols.

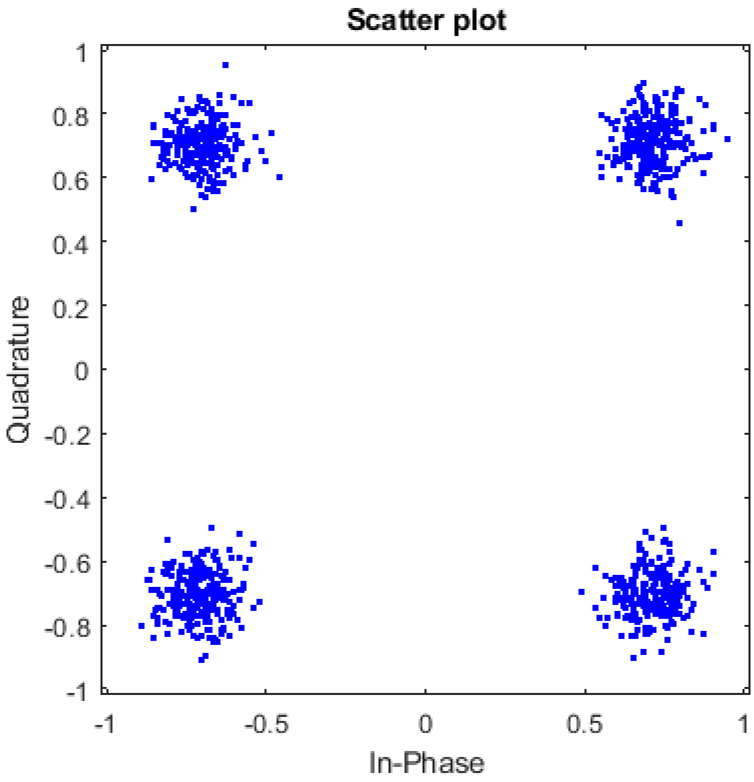
```
data = randi([0 M-1],1000,1);
```

Modulate the data symbols.

```
txSig = pskmod(data,M,pi/M);
```

Pass the signal through white noise and plot its constellation.

```
rxSig = awgn(txSig,20);
scatterplot(rxSig)
```



16-PSK

Change the modulation order from 4 to 16.

```
M = 16;
```

Generate random data symbols.

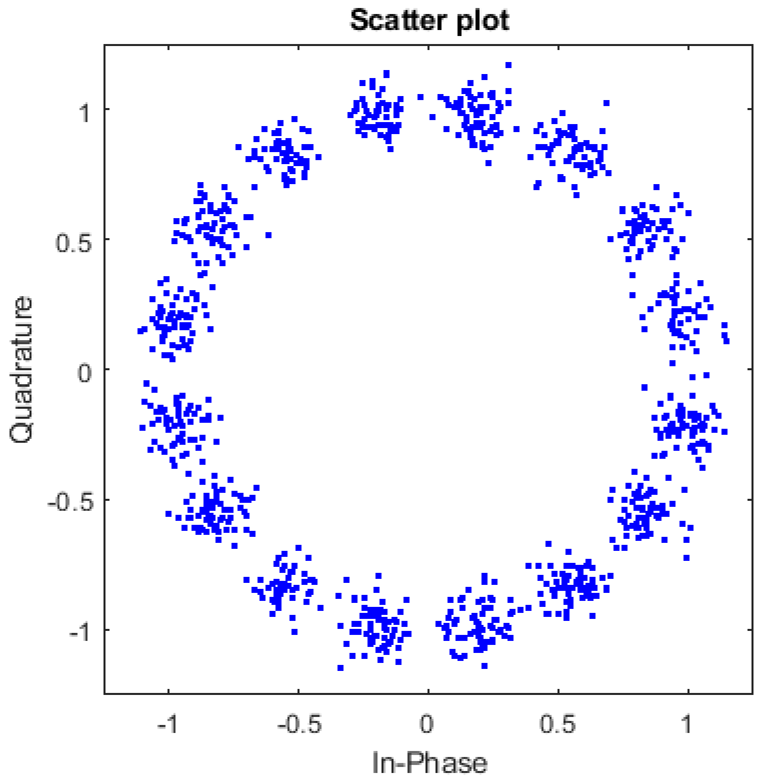
```
data = randi([0 M-1],1000,1);
```

Modulate the data symbols.

```
txSig = pskmod(data,M,pi/M);
```

Pass the signal through white noise and plot its constellation.

```
rxSig = awgn(txSig,20);
scatterplot(rxSig)
```



Modulate and Demodulate QPSK Signal in AWGN

Generate random symbols.

```
dataIn = randi([0 3],1000,1);
```

QPSK modulate the data.

```
txSig = pskmod(dataIn,4,pi/4);
```

Pass the signal through an AWGN channel.

```
rxSig = awgn(txSig,10);
```

Demodulate the received signal and compute the number of symbol errors.

```
dataOut = pskdemod(rxSig,4,pi/4);
numErrs = symerr(dataIn,dataOut)
```

```
numErrs = 2
```

PSK Symbol Mapping

Plot PSK symbol mapping for Gray and natural binary encoded data.

Set the modulation order, and then create a data sequence containing a complete set of constellation points.

```
M = 8;
data = (0:M-1);
phz = 0;
```

Modulate and demodulate the data using Gray and natural binary encoded data.

```
symgray = pskmod(data,M,phz,'gray');
mapgray = pskdemod(symgray,M,phz,'gray');

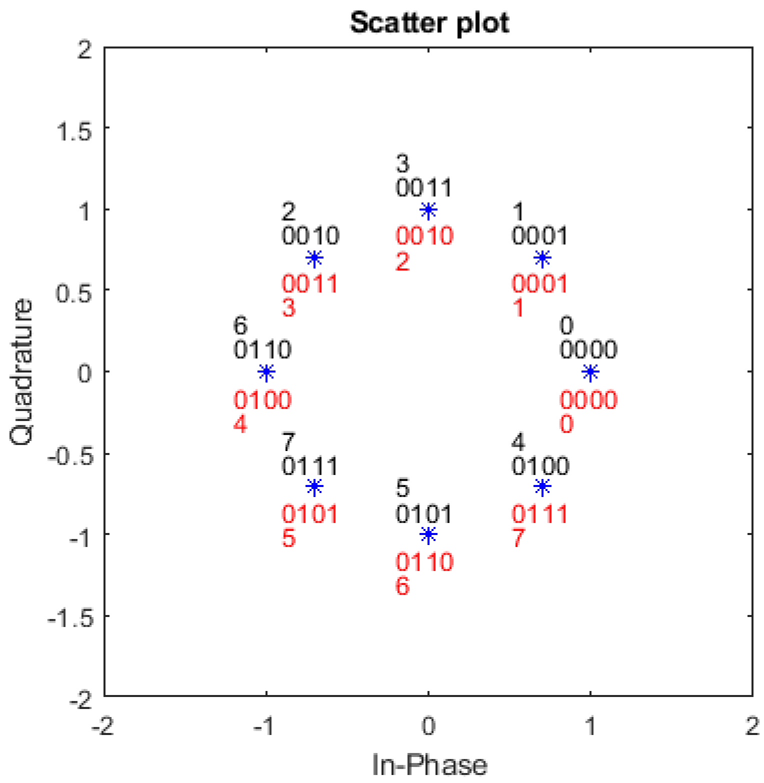
symbin = pskmod(data,M,phz,'bin');
mapbin = pskdemod(symbin,M,phz,'bin');
```

Plot the constellation points using one of the symbol sets. For each constellation point, assign a label indicating the Gray and natural binary values for each symbol.

- For Gray binary symbol mapping, adjacent constellation points differ by a single binary bit and are not numerically sequential.
- For natural binary symbol mapping, adjacent constellation points follow the natural binary encoding and are sequential.

```
scatterplot(symgray,1,0,'b*');
for k = 1:M
    text(real(symgray(k))-0.2,imag(symgray(k))+.15,...
        dec2base(mapgray(k),2,4));
     text(real(symgray(k))-0.2,imag(symgray(k))+.3,...
         num2str(mapgray(k)));

    text(real(symbin(k))-0.2,imag(symbin(k))-.15,...
        dec2base(mapbin(k),2,4),'Color',[1 0 0]);
    text(real(symbin(k))-0.2,imag(symbin(k))-.3,...
        num2str(mapbin(k)),'Color',[1 0 0]);
end
axis([-2 2 -2 2])
```



Input Arguments

x — Input signal

vector | matrix

Input signal, specified as a vector or matrix of positive integers. The elements of x must have values in the range of [0, M – 1].

Example: randi([0 3],100,1)

Data Types: double

M — Modulation order

integer power of two

Modulation order, specified as an integer power of two.

Example: 2 | 4 | 16

Data Types: double

ini_phase — Initial phase

0 (default) | scalar | [ ]

Initial phase of the PSK modulation, specified in radians as a real scalar.

If you specify ini_phase as empty, then pskmod uses an initial phase of 0.

Example: `pi/4`

Data Types: `double`

`symorder` — Symbol order

`'bin'` (default) | `'gray'`

Symbol order, specified as `'bin'` or `'gray'`. This argument specifies how the function assigns binary vectors to corresponding integers.

- If `symorder` is `'bin'`, the function uses a natural binary-coded ordering.
- If `symorder` is `'gray'`, the function uses a Gray-coded ordering.

Data Types: `char`

Output Arguments

y — PSK-modulated output signal

vector | matrix

Complex baseband representation of a PSK-modulated signal, returned as vector or matrix of complex values. The columns of `y` represent independent channels.

Topics

“Phase Modulation”

Introduced before R2006a

qamdemod

Quadrature amplitude demodulation

Syntax

```
z = qamdemod(y,M)
z = qamdemod(y,M,symOrder)
z = qamdemod( ___ ,Name,Value)
```

Description

`z = qamdemod(y,M)` returns a demodulated signal, `z`, given quadrature amplitude modulation (QAM) signal `y` of modulation order `M`.

`z = qamdemod(y,M,symOrder)` returns a demodulated signal, `z`, and specifies the symbol order for the demodulation.

`z = qamdemod( ___ ,Name,Value)` specifies options using one or more name-value pair arguments. For example, `'OutputType','bit'` sets the type of output signal to bits.

Examples

Demodulate 8-QAM Signal

Demodulate an 8-QAM signal and plot the points corresponding to symbols 0 and 3.

Generate random 8-ary data symbols.

```
data = randi([0 7],1000,1);
```

Modulate `data` by applying 8-QAM.

```
txSig = qammod(data,8);
```

Pass the modulated signal through an AWGN channel.

```
rxSig = awgn(txSig,18,'measured');
```

Demodulate the received signal using an initial phase of $\pi/8$.

```
rxData = qamdemod(rxSig.*exp(-1i*pi/8),8);
```

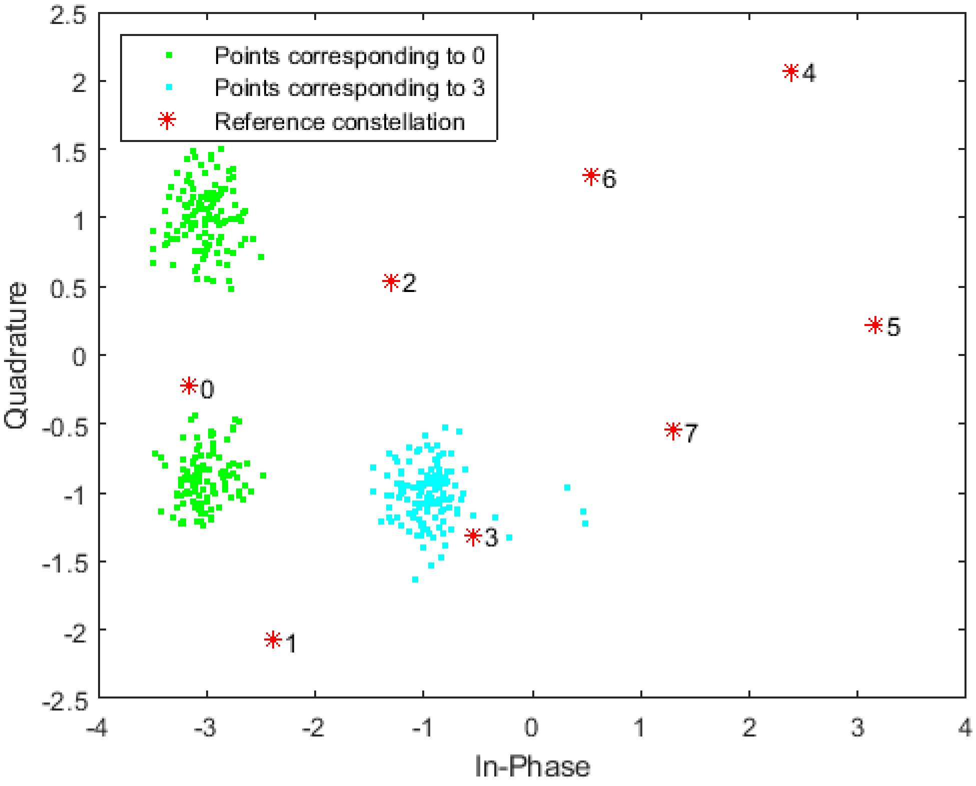
Generate the reference constellation points.

```
refpts = qammod((0:7)',8) .* exp(1i*pi/8);
```

Plot the received signal points corresponding to symbols 0 and 3 and overlay the reference constellation. The received data corresponding to those symbols is displayed.

```
plot(rxSig(rxData==0),'g.');
hold on
```

```
plot(rxSig(rxData==3),'c.');
plot(refpts,'r*')
text(real(refpts)+0.1,imag(refpts),num2str((0:7)'))
xlabel('In-Phase')
ylabel('Quadrature')
legend('Points corresponding to 0','Points corresponding to 3', ...
    'Reference constellation','location','nw');
```



QAM Demodulation with WLAN Symbol Mapping

Modulate and demodulate random data by using 16-QAM with WLAN symbol mapping. Verify that the input data symbols match the demodulated symbols.

Generate a 3-D array of random symbols.

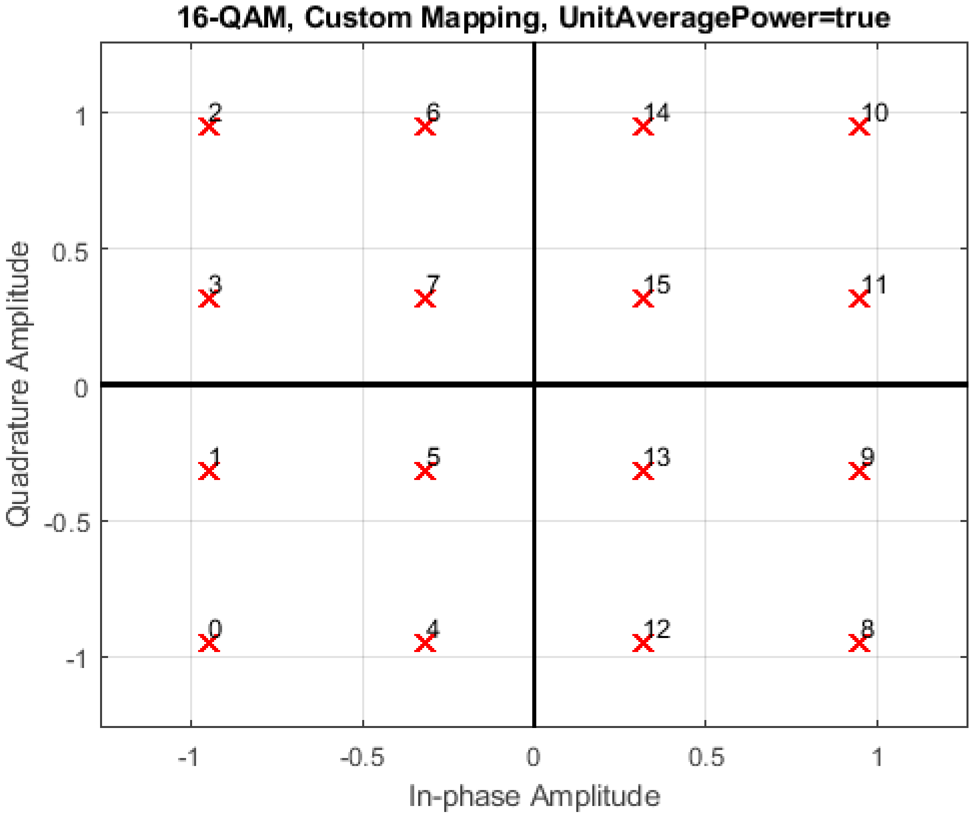
```
x = randi([0,15],20,4,2);
```

Create a custom symbol mapping for the 16-QAM constellation based on WLAN standards.

```
wlanSymMap = [2 3 1 0 6 7 5 4 14 15 13 12 10 11 9 8];
```

Modulate the data, and set the constellation to have unit average signal power. Plot the constellation.

```
y = qammod(x,16,wlanSymMap,'UnitAveragePower', true,'PlotConstellation',true);
```



Demodulate the received signal.

```
z = qamdemod(y,16,wlanSymMap,'UnitAveragePower',true);
```

Verify that the demodulated signal is equal to the original data.

```
isequal(x,z)
```

```
ans = logical
   1
```

Demodulate QAM Fixed-Point Signal

Demodulate a fixed-point QAM signal and verify that the data is recovered correctly.

Set the modulation order as 64, and determine the number of bits per symbol.

```
M = 64;
bitsPerSym = log2(M);
```

Generate random bits. When operating in bit mode, the length of the input data must be an integer multiple of the number of bits per symbol.

```
x = randi([0 1],10*bitsPerSym,1);
```

Modulate the input data using a binary symbol mapping. Set the modulator to output fixed-point data. The numeric data type is signed with a 16-bit word length and a 10-bit fraction length.

```
y = qammod(x,M,'bin','InputType','bit','OutputDataType', ...
    numerictype(1,16,10));
```

Demodulate the 64-QAM signal. Verify that the demodulated data matches the input data.

```
z = qamdemod(y,M,'bin','OutputType','bit');
s = isequal(x,double(z))
```

```
s = logical
   1
```

Estimate BER for Hard and Soft Decision Viterbi Decoding

Estimate bit error rate (BER) performance for hard-decision and soft-decision Viterbi decoders in AWGN. Compare the performance to that of an uncoded 64-QAM link.

Set the simulation parameters.

```
clear; close all
rng default
M = 64;                 % Modulation order
k = log2(M);            % Bits per symbol
EbNoVec = (4:10)';      % Eb/No values (dB)
numSymPerFrame = 1000;  % Number of QAM symbols per frame
```

Initialize the BER results vectors.

```
berEstSoft = zeros(size(EbNoVec));
berEstHard = zeros(size(EbNoVec));
```

Set the trellis structure and traceback depth for a rate `1/2`, constraint length `7`, convolutional code.

```
trellis = poly2trellis(7,[171 133]);
tbl = 32;
rate = 1/2;
```

The main processing loops performs these steps:

- Generate binary data
- Convolutionally encode the data
- Apply QAM modulation to the data symbols. Specify unit average power for the transmitted signal
- Pass the modulated signal through an AWGN channel
- Demodulate the received signal using hard decision and approximate LLR methods. Specify unit average power for the received signal
- Viterbi decode the signals using hard and unquantized methods
- Calculate the number of bit errors

The `while` loop continues to process data until either 100 errors are encountered or 10^7 bits are transmitted.

```
for n = 1:length(EbNoVec)
    % Convert Eb/No to SNR
    snrdB = EbNoVec(n) + 10*log10(k*rate);
    % Noise variance calculation for unity average signal power.
    noiseVar = 10.^(-snrdB/10);
    % Reset the error and bit counters
    [numErrsSoft,numErrsHard,numBits] = deal(0);

    while numErrsSoft < 100 && numBits < 1e7
        % Generate binary data and convert to symbols
        dataIn = randi([0 1],numSymPerFrame*k,1);

        % Convolutionally encode the data
        dataEnc = convenc(dataIn,trellis);

        % QAM modulate
        txSig = qammod(dataEnc,M,'InputType','bit','UnitAveragePower',true);

        % Pass through AWGN channel
        rxSig = awgn(txSig,snrdB,'measured');

        % Demodulate the noisy signal using hard decision (bit) and
        % soft decision (approximate LLR) approaches.
        rxDataHard = qamdemod(rxSig,M,'OutputType','bit','UnitAveragePower',true);
        rxDataSoft = qamdemod(rxSig,M,'OutputType','approxllr', ...
            'UnitAveragePower',true,'NoiseVariance',noiseVar);

        % Viterbi decode the demodulated data
        dataHard = vitdec(rxDataHard,trellis,tbl,'cont','hard');
        dataSoft = vitdec(rxDataSoft,trellis,tbl,'cont','unquant');

        % Calculate the number of bit errors in the frame. Adjust for the
        % decoding delay, which is equal to the traceback depth.
        numErrsInFrameHard = biterr(dataIn(1:end-tbl),dataHard(tbl+1:end));
        numErrsInFrameSoft = biterr(dataIn(1:end-tbl),dataSoft(tbl+1:end));

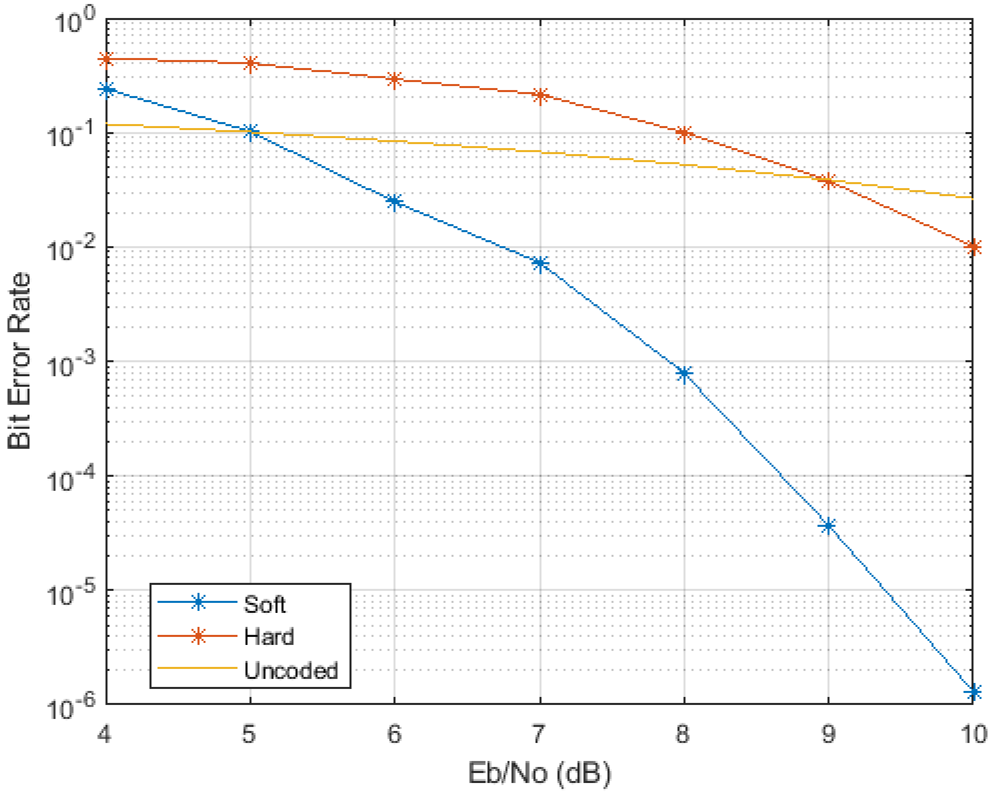
        % Increment the error and bit counters
        numErrsHard = numErrsHard + numErrsInFrameHard;
        numErrsSoft = numErrsSoft + numErrsInFrameSoft;
        numBits = numBits + numSymPerFrame*k;

    end

    % Estimate the BER for both methods
    berEstSoft(n) = numErrsSoft/numBits;
    berEstHard(n) = numErrsHard/numBits;
end
```

Plot the estimated hard and soft BER data. Plot the theoretical performance for an uncoded 64-QAM channel.

```
semilogy(EbNoVec,[berEstSoft berEstHard],'-*')
hold on
semilogy(EbNoVec,berawgn(EbNoVec,'qam',M))
legend('Soft','Hard','Uncoded','location','best')
grid
xlabel('Eb/No (dB)')
ylabel('Bit Error Rate')
```



As expected, the soft decision decoding produces the best results.

Soft-Decision OQPSK Modulation-Demodulation

Use the `qamdemod` function to simulate soft decision output for OQPSK-modulated signals.

Generate an OQPSK modulated signal.

```
sps = 4;
msg = randi([0 1],1000,1);
oqpskMod = comm.OQPSKModulator('SamplesPerSymbol',sps,'BitInput',true);
oqpskSig = oqpskMod(msg);
```

Add noise to the generated signal.

```
impairedSig = awgn(oqpskSig,15);
```

Perform Soft-Decision Demodulation

Create QPSK equivalent signal to align in-phase and quadrature.

```
impairedQPSK = complex(real(impairedSig(1+sps/2:end-sps/2)), imag(impairedSig(sps+1:end)));
```

Apply matched filtering to the received OQPSK signal.

```
halfSinePulse = sin(0:pi/sps:(sps)*pi/sps);
matchedFilter = dsp.FIRDecimator(sps,halfSinePulse,'DecimationOffset',sps/2);
filteredQPSK = matchedFilter(impairedQPSK);
```

To perform soft demodulation of the filtered OQPSK signal use the `qamdemod` function. Align symbol mapping of `qamdemod` with the symbol mapping used by the `comm.OQPSKModulator`, then demodulate the signal.

```
oqpskModSymbolMapping = [1 3 0 2];
demodulated = qamdemod(filteredQPSK,4,oqpskModSymbolMapping,'OutputType','llr');
```

Input Arguments

y — Input signal

scalar | vector | matrix | 3-D array

Input signal that resulted QAM, specified as a scalar, vector, matrix, or 3-D array of complex values. Each column in the matrix and 3-D array is considered as an independent channel.

Data Types: `single` | `double` | `fi`
Complex Number Support: Yes

`M` — Modulation order

scalar integer

Modulation order, specified as a power-of-two scalar integer. The modulation order specifies the number of points in the signal constellation.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`symOrder` — Symbol order

`'gray'` (default) | `'bin'` | vector

Symbol order, specified as one of these options:

- `'gray'` — Use “Gray Code” on page 2-694 ordering.
- `'bin'` — Use natural binary-coded ordering.
- Vector — Use custom symbol ordering. The vector must be of length `M`. Vectors must use unique elements whose values range from 0 to `M` – 1. The first element corresponds to the upper left point of the constellation, with subsequent elements running down column-wise from left to right.

Data Types: `char` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `z = qamdemod(y,M,symOrder,'OutputType','bit')`

`UnitAveragePower` — Unit average power flag

`false` or `0` (default) | `true` or `1`

Unit average power flag, specified as the comma-separated pair consisting of `'UnitAveragePower'` and a numeric or logical `0` (`false`) or `1` (`true`). When this flag is `1` (`true`), the function scales the constellation to the average power of one watt referenced to 1 ohm. When this flag is 0 (false), the function scales the constellation so that the QAM constellation points are separated by a minimum distance of two.

OutputType — Type of output

'integer' (default) | 'bit' | 'llr' | 'approxllr'

Type of output, specified as the comma-separated pair consisting of 'OutputType' and 'integer', 'bit', 'llr', or 'approxllr'.

Data Types: char

NoiseVariance — Noise variance

1 (default) | positive scalar | vector of positive values

Noise variance, specified as the comma-separated pair consisting of 'NoiseVariance' and one of these options:

- Positive scalar — The same noise variance value is used on all input elements.
- Vector of positive values — The vector length must be equal to the number of elements in the last dimension of the input signal. Each element of the vector specifies the noise variance for all the elements of the input along the corresponding last dimension.

Tip When 'OutputType' is ‘llr’, if the demodulation computation outputs Inf or -Inf value, it is likely because the specified noise variance values are smaller than the signal-to-noise ratio (SNR). Because the Log-Likelihood algorithm computes exponentials using finite precision arithmetic, the computation of exponentials with large or small numbers can yield positive or negative infinity. For more details, see “Exact LLR Algorithm”.

To avoid this issue, set 'OutputType' to ‘approxllr’ instead. The approximate LLR algorithm does not compute exponentials.

Dependencies

To enable this name-value pair argument, set 'OutputType' is 'llr' or 'approxllr'.

Data Types: double

PlotConstellation — Option to plot constellation

false or 0 (default) | true or 1

Option to plot constellation, specified as the comma-separated pair consisting of 'PlotConstellation' and a numeric or logical 0 (false) or 1 (true) To plot the QAM constellation, set 'PlotConstellation' to true.

Output Arguments

z — Demodulated output signal

scalar | vector | matrix | 3-D array

Demodulated output signal, returned as a scalar, vector, matrix, or 3-D array. The data type is the same as that of the input signal, y. The value and dimension of this output vary depending on the specified 'OutputType' value, as shown in this table.

'OutputType'	Return Value of qamdemod	Dimensions of Output
'integer'	Demodulated integer values from 0 to (M – 1)	z has the same dimensions as input y.
'bit'	Demodulated bits	The number of rows in z is $\log_2$(M) times the number of rows in y. Each demodulated symbol is mapped to a group of $\log_2$(M) bits, where the first bit represents the most significant bit (MSB) and the last bit represents the least significant bit (LSB).
'llr'	Log-likelihood ratio value for each bit calculated using the Exact Log Likelihood algorithm. For more details, see “Exact LLR Algorithm”.	
'approxllr'	Approximate log-likelihood ratio value for each bit. The values are calculated using the Approximate Log Likelihood algorithm. For more details, see “Approximate LLR Algorithm”.	

More About

Gray Code

A Gray code, also known as a reflected binary code, is a system where the bit patterns in adjacent constellation points differ by only one bit.

Compatibility Considerations

Initial Phase Input Removed

Errors starting in R2018b

Starting in R2018b, you can no longer offset the initial phase for the QAM constellation using the qamdemod function.

Instead, use the genqamdemod function to offset the initial phase of the QAM signal being demodulated. Alternatively, you can multiply the modulated input of qamdemod by the desired initial phase, as shown in this code

```
z = qamdemod(y.*exp(-1i*initPhase,M))
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Introduced before R2006a

qammod

Quadrature amplitude modulation (QAM)

Syntax

```
y = qammod(x,M)
y = qammod(x,M,symOrder)
y = qammod( ___ ,Name,Value)
```

Description

`y = qammod(x,M)` modulates input signal `x` by using QAM with the specified modulation order `M`. Output `y` is the modulated signal.

`y = qammod(x,M,symOrder)` specifies the symbol order.

`y = qammod( ___ ,Name,Value)` specifies options using name-value pair arguments in addition to any of the input argument combinations from previous syntaxes.

Examples

Modulate Data Using QAM

Modulate data using QAM and display the result in a scatter plot.

Set the modulation order to 16 and create a data vector containing each of the possible symbols.

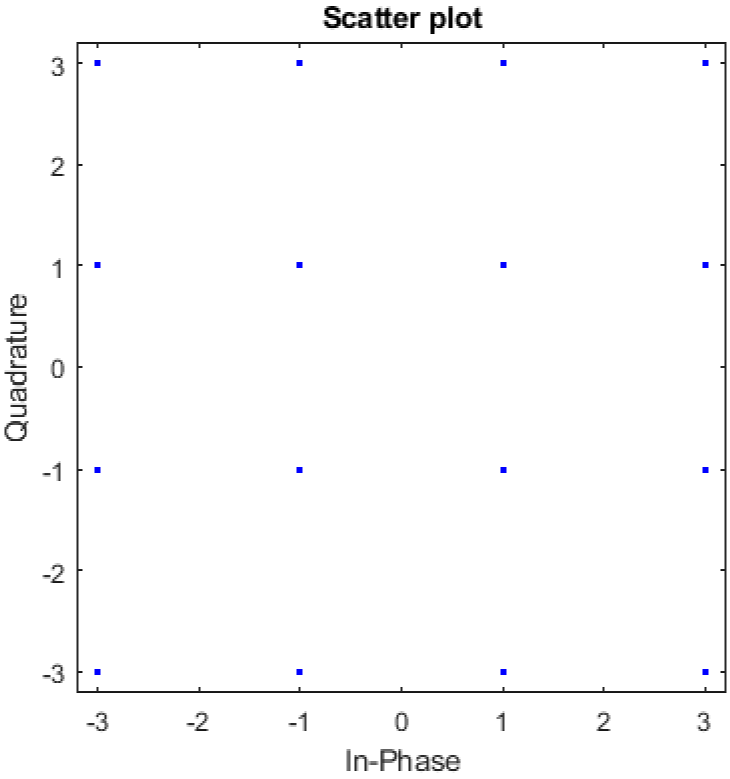
```
M = 16;
x = (0:M-1)';
```

Modulate the data using the `qammod` function.

```
y = qammod(x,M);
```

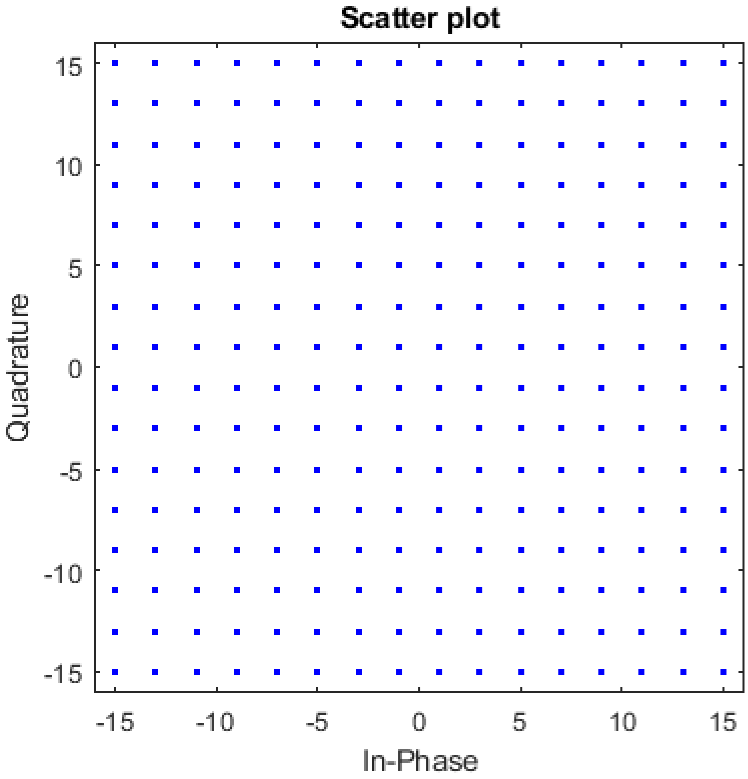
Display the modulated signal constellation using the `scatterplot` function.

```
scatterplot(y)
```



Set the modulation order to 256, and display the scatter plot of the modulated signal.

```
M = 256;
x = (0:M-1)';
y = qammod(x,M);
scatterplot(y)
```



Normalize QAM Signal by Average Power

Modulate random data symbols using QAM. Normalize the modulator output so that it has an average signal power of 1 W.

Set the modulation order and generate random data.

```
M = 64;
x = randi([0 M-1],1000,1);
```

Modulate the data. Use the `'UnitAveragePower'` name-value pair to set the output signal to have an average power of 1 W.

```
y = qammod(x,M,'UnitAveragePower',true);
```

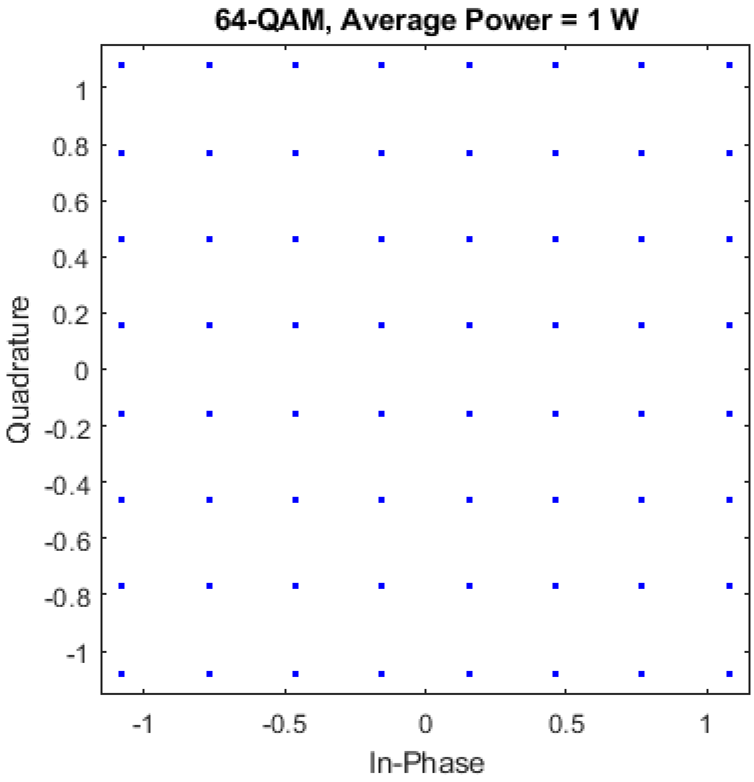
Confirm that the signal has unit average power.

```
avgPower = mean(abs(y).^2)
```

```
avgPower = 1.0070
```

Plot the resulting constellation.

```
scatterplot(y)
title('64-QAM, Average Power = 1 W')
```



QAM Symbol Ordering

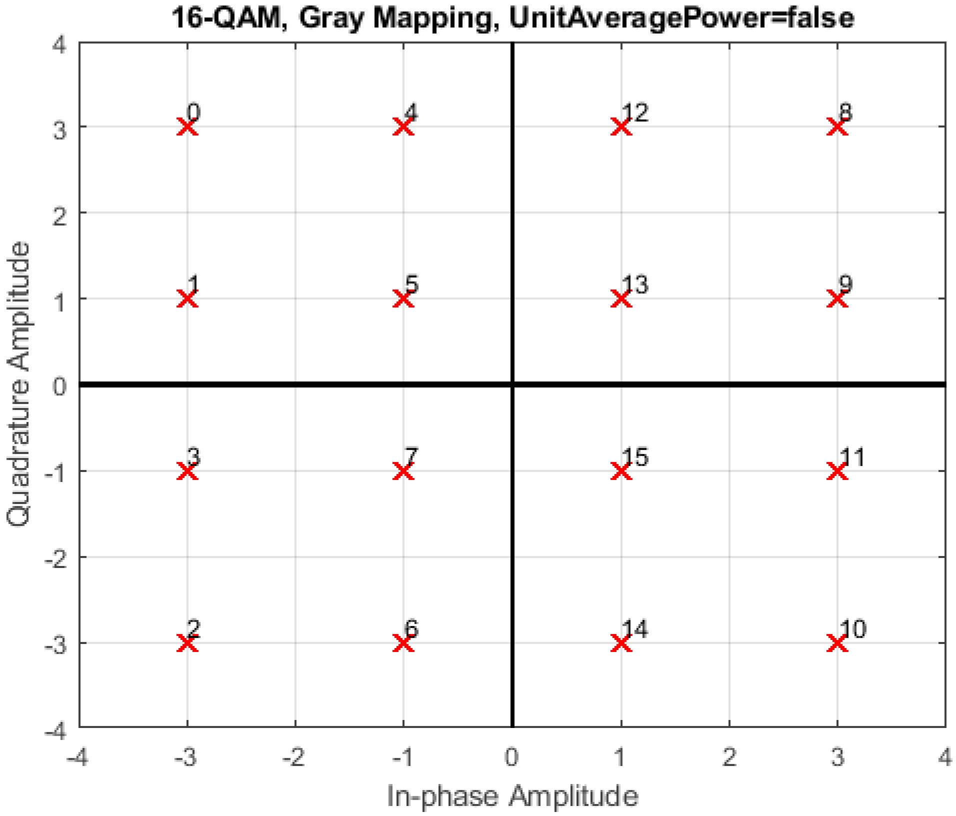
Plot QAM constellations for Gray, binary, and custom symbol mappings.

Set the modulation order, and create a data sequence that includes a complete set of symbols for the modulation scheme.

```
M = 16;
d = [0:M-1];
```

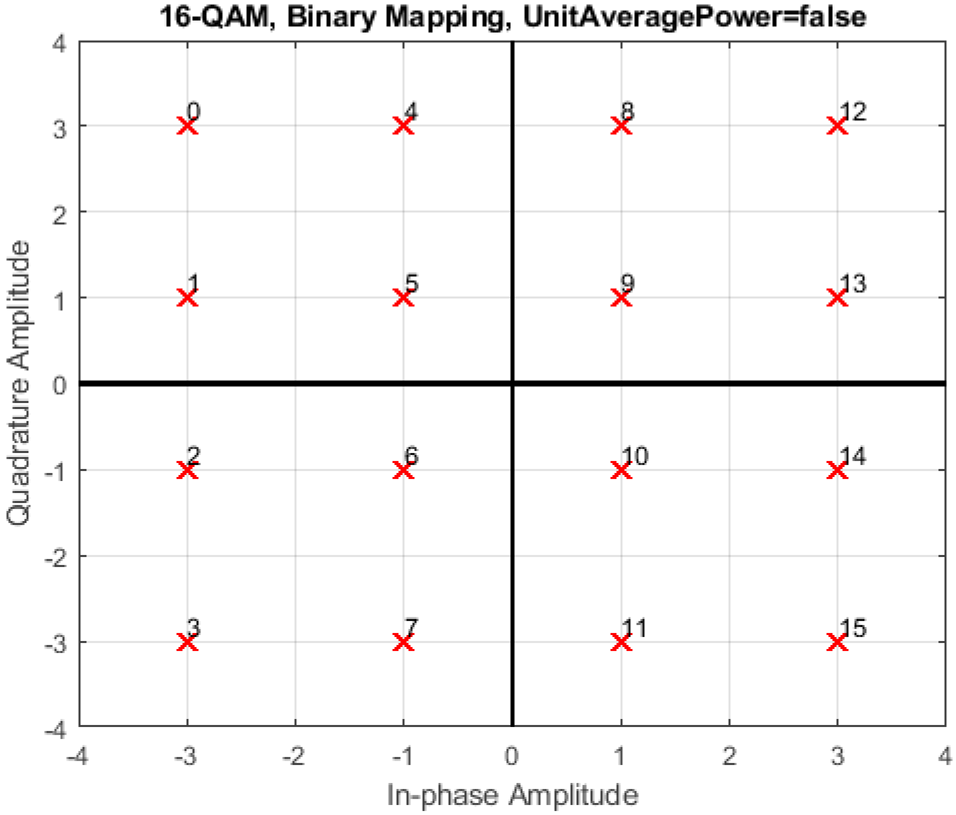
Modulate the data, and plot its constellation. The default symbol mapping uses Gray ordering. The ordering of the points is not sequential.

```
y = qammod(d,M,'PlotConstellation',true);
```



Repeat the modulation process with binary symbol mapping. The symbol mapping follows a natural binary order and is sequential.

```
z = qammod(d,M,'bin','PlotConstellation',true);
```

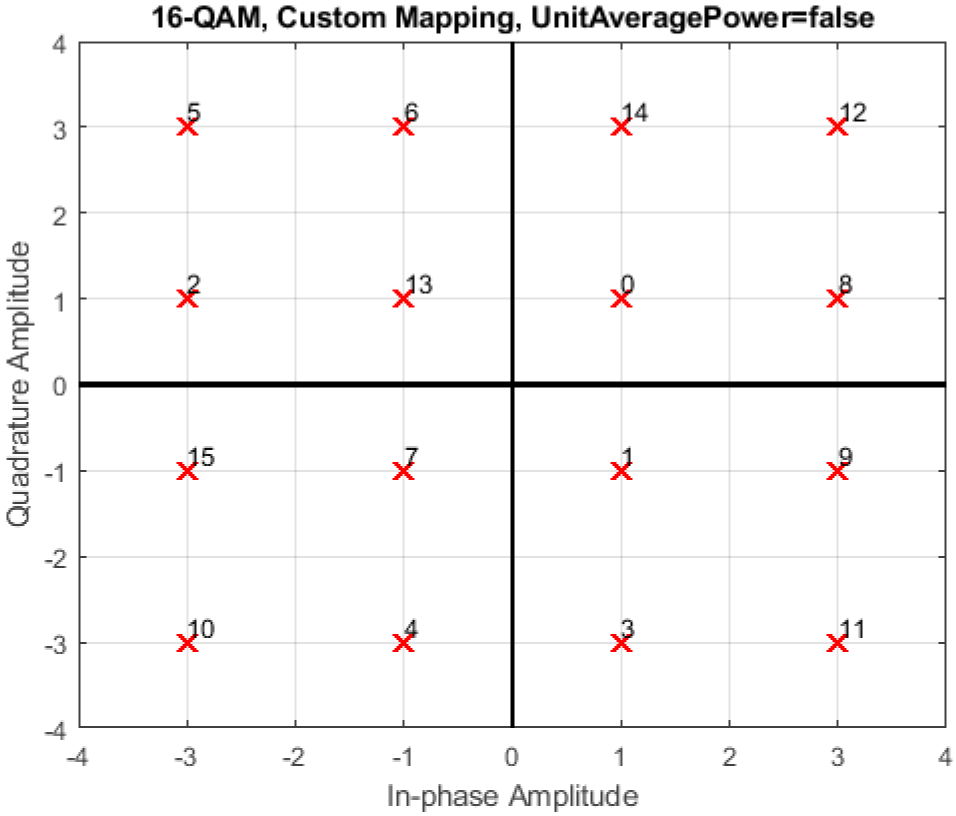


Create a custom symbol mapping.

```
smap = randperm(M)-1;
```

Modulate and plot the constellation.

```
w = qammod(d,M,smap,'PlotConstellation',true);
```



Quadrature Amplitude Modulation with Bit Inputs

Modulate a sequence of bits using 64-QAM. Pass the signal through a noisy channel. Display the resultant constellation diagram.

Set the modulation order, and determine the number of bits per symbol.

```
M = 64;
k = log2(M);
```

Create a binary data sequence. When using binary inputs, the number of rows in the input must be an integer multiple of the number of bits per symbol.

```
data = randi([0 1],1000*k,1);
```

Modulate the signal using bit inputs, and set it to have unit average power.

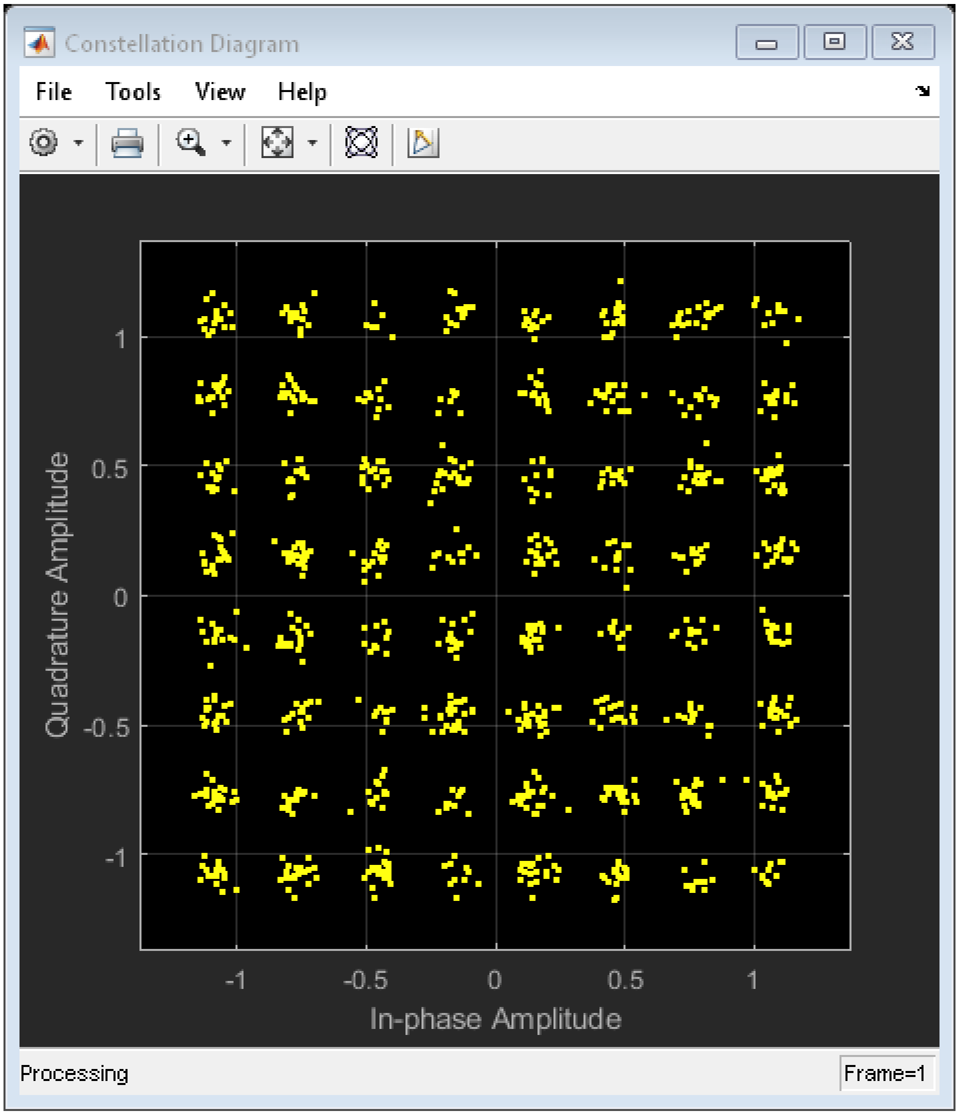
```
txSig = qammod(data,M,'InputType','bit','UnitAveragePower',true);
```

Pass the signal through a noisy channel.

```
rxSig = awgn(txSig,25);
```

Plot the constellation diagram.

```
cd = comm.ConstellationDiagram('ShowReferenceConstellation',false);
step(cd,rxSig)
```



Demodulate QAM Fixed-Point Signal

Demodulate a fixed-point QAM signal and verify that the data is recovered correctly.

Set the modulation order as 64, and determine the number of bits per symbol.

```
M = 64;
bitsPerSym = log2(M);
```

Generate random bits. When operating in bit mode, the length of the input data must be an integer multiple of the number of bits per symbol.

```
x = randi([0 1],10*bitsPerSym,1);
```

Modulate the input data using a binary symbol mapping. Set the modulator to output fixed-point data. The numeric data type is signed with a 16-bit word length and a 10-bit fraction length.

```
y = qammod(x,M,'bin','InputType','bit','OutputDataType', ...
    numerictype(1,16,10));
```

Demodulate the 64-QAM signal. Verify that the demodulated data matches the input data.

```
z = qamdemod(y,M,'bin','OutputType','bit');
s = isequal(x,double(z))
```

```
s = logical
   1
```

Input Arguments

x — Input signal

scalar | vector | matrix | 3-D array

Input signal, specified as a scalar, vector, matrix, or 3-D array. The elements of x must be binary values or integers that range from 0 to (M – 1), where M is the modulation order.

Note To process input signal as binary elements, set the 'InputType' name-value pair to 'bit'. For binary inputs, the number of rows must be an integer multiple of $\log_2$(M). Groups of $\log_2$(M) bits are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

Data Types: double | single | fi | int8 | int16 | uint8 | uint16

M — Modulation order

scalar integer

Modulation order, specified as a power-of-two scalar integer. The modulation order specifies the number of points in the signal constellation.

Example: 16

Data Types: double

symOrder — Symbol order

'gray' (default) | 'bin' | vector

Symbol order, specified as 'gray', 'bin', or a vector.

- 'gray' — Use “Gray Code” on page 2-706 ordering
- 'bin' — Use natural binary-coded ordering
- Vector — Use custom symbol ordering

Vectors must use unique elements whose values range from 0 to M – 1. The first element corresponds to the upper-left point of the constellation, with subsequent elements running down column-wise from left to right.

Example: [0 3 1 2]

Data Types: char | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `y = qammod(x,M,symOrder,'InputType','bit')`

InputType — Input type

'integer' (default) | 'bit'

Input type, specified as the comma-separated pair consisting of `'InputType'` and either `'integer'` or `'bit'`. If you specify `'integer'`, the input signal must consist of integers from 0 to `M` – 1. If you specify `'bit'`, the input signal must contain binary values, and the number of rows must be an integer multiple of $\log_2(M)$.

Data Types: char

UnitAveragePower — Unit average power flag

false or 0 (default) | true or 1

Unit average power flag, specified as the comma-separated pair consisting of `'UnitAveragePower'` and a numeric or logical `0` (`false`) or `1` (`true`). When this flag is `1` (`true`), the function scales the constellation to the average power of one watt referenced to 1 ohm. When this flag is `0` (`false`), the function scales the constellation so that the QAM constellation points are separated by a minimum distance of two.

OutputDataType — Output data type

numerictype object

Output data type, specified as the comma-separated pair consisting of `'OutputDataType'` and a `numerictype` object.

For more information on constructing these objects, see `numerictype`. If you do not specify `'OutputDataType'`, data type is `double` if the input is of data type `double` or built-in integer and `single` if the input is of data type `single`.

PlotConstellation — Option to plot constellation

false or 0 (default) | true or 1

Option to plot constellation, specified as the comma-separated pair consisting of `'PlotConstellation'` and a numeric or logical `0` (`false`) or `1` (`true`) To plot the QAM constellation, set `'PlotConstellation'` to `true`.

Output Arguments

y — Modulated signal

scalar | vector | matrix | 3-D array

Modulated signal, returned as a complex scalar, vector, matrix, or 3-D array of numeric values. For integer inputs, output `y` has the same dimensions as input signal `x`. For bit inputs, the number of rows in `y` is the number of rows in `x` divided by $\log_2(M)$.

Data Types: double | single

More About

Gray Code

A Gray code, also known as a reflected binary code, is a system where the bit patterns in adjacent constellation points differ by only one bit.

Compatibility Considerations

Initial Phase Input Removed

Errors starting in R2018b

Starting in R2018b, you can no longer offset the initial phase for the QAM constellation using the `qammod` function.

Instead use `genqammod` to offset the initial phase of the data being modulated, or you can multiply the `qammod` output by the desired initial phase:

```
y = qammod(x,M) .* exp(1i*initPhase)
```

to adjust the initial phase of the QAM data.

qfunc

Q function

Syntax

```
y = qfunc(x)
```

Description

`y = qfunc(x)` returns the output of the Q function for each element of the real-valued input. The Q function is (1 – *f*), where *f* is the result of the cumulative distribution function of the standardized normal random variable. For more information, see “Algorithms” on page 2-709.

Examples

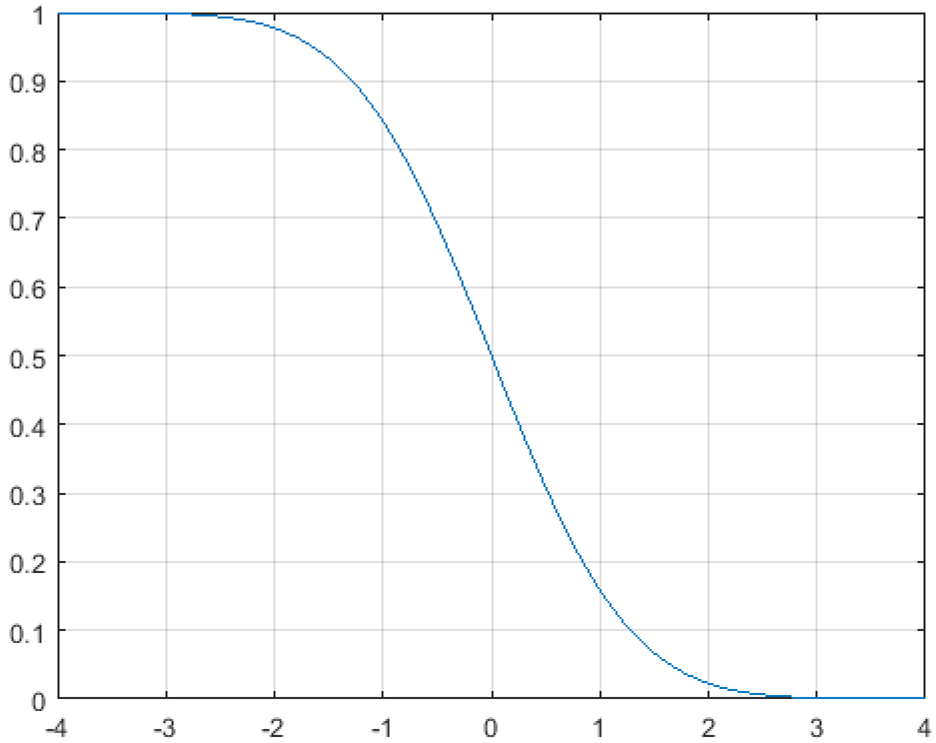
Calculate Q Function Value and Plot Results

Calculate the Q function values for a real-valued input vector.

```
x = -4:0.1:4;
y = qfunc(x);
```

Plot the results.

```
plot(x,y)
grid
```



Calculate QPSK Error Probability Using Q Function

Calculate the QPSK error probability at an E_b/N_0 setting of 7 dB by using the Q function.

Convert the E_b/N_0 in dB to its linear equivalent.

```
ebnodB = 7;
ebno = 10^(ebnodB/10);
```

Using the Q function, calculate the QPSK error probability, $P_b = Q\left(\sqrt{2\frac{E_\mathrm{b}}{N_0}}\right)$.

```
Pb = qfunc(sqrt(2*ebno))
```

```
Pb = 7.7267e-04
```

Input Arguments

x — Input
scalar | vector | matrix | array

Input, specified as a real-valued scalar, matrix, or array.

Data Types: `double`

Output Arguments

y — Q function output

scalar | vector | matrix | array

Q function output, returned as a scalar, matrix, or array. `y` has the same dimensions as input `x`. Output values are in the range [0, 1].

Algorithms

For a scalar *x*, the Q function is (1 – *f*), where *f* is the result of the cumulative distribution function of the standardized normal random variable. The Q function is defined as

$$Q(x) = \frac{1}{\sqrt{2\pi}}\int_{x}^{\infty} \exp(-t^2/2)dt$$

The Q function is related to the complementary error function, erfc, according to

$$Q(x) = \frac{1}{2}\mathrm{erfc}\left(\frac{x}{\sqrt{2}}\right)$$

qfuncinv

Inverse Q function

Syntax

```
z = qfuncinv(y)
```

Description

`z = qfuncinv(y)` returns the input argument of the Q function for which the output value of the Q function is `y`. For more information, see “Algorithms” on page 2-711.

Examples

Recover Argument of Q Function

Recover the Q function input argument by using the inverse Q function. Show the inverse relationship between Q function and its inverse.

Calculate the Q function values for a real-valued input.

```
x1 = [0 1 2; 3 4 5];
y1 = qfunc(x1)
```

```
y1 = 2×3

    0.5000    0.1587    0.0228
    0.0013    0.0000    0.0000
```

Recover the Q function input argument by calculating the inverse Q function values for `y1`.

```
x1_recovered = qfuncinv(y1)
```

```
x1_recovered = 2×3

     0     1     2
     3     4     5
```

Confirm the original and recovered Q functions arguments are the same.

```
isequal (x1,x1_recovered)
```

```
ans = logical
   1
```

Calculate the inverse of values representing Q function output values.

```
y2 = 0:0.2:1;
x2 = qfuncinv(y2)
```

```
x2 = 1×6

       Inf    0.8416    0.2533   -0.2533   -0.8416      -Inf
```

Recover the Q function output argument by calculating the Q function values for `x2`.

```
y2_recovered = qfunc(x2)
```

```
y2_recovered = 1×6

         0    0.2000    0.4000    0.6000    0.8000    1.0000
```

Confirm the original values and recovered inverse Q functions arguments are the same.

```
isequal (y2,y2_recovered)
```

```
ans = logical
   1
```

Input Arguments

y — Q function output
scalar | vector | matrix | array

Q function output, specified as a scalar, matrix, or array. Input values must be in the range [0, 1].

Data Types: `double`

Output Arguments

z — Q function input argument
scalar | vector | matrix | N-D array

Q function input argument, returned as a real-valued scalar, matrix, or array. `z` has the same dimensions as input `y`.

Algorithms

For a scalar *x*, the Q function is (1 – *f*), where *f* is the result of the cumulative distribution function of the standardized normal random variable. The Q function is defined as

$$Q(x) = \frac{1}{\sqrt{2\pi}}\int_{x}^{\infty}\exp(-t^2/2)dt$$

The Q function is related to the complementary error function, erfc, according to

$$Q(x) = \frac{1}{2}\text{erfc}\left(\frac{x}{\sqrt{2}}\right)$$

Introduced before R2006a

quantiz

Produce quantization index and quantized output value

Syntax

```
index = quantiz(sig,partition)
[index,quants] = quantiz(sig,partition,codebook)
[index,quants,distor] = quantiz(sig,partition,codebook)
```

Description

`index = quantiz(sig,partition)` returns the quantization levels of input signal `sig` by using the scalar quantization partition specified in input `partition`.

`[index,quants] = quantiz(sig,partition,codebook)` specifies `codebook`, which prescribes a value for each partition in the scalar quantization. `codebook` is a vector whose length must exceed the length of `partition` by one. The function also returns `quants`, which contains the scalar quantization of `sig` and depends on the quantization levels and prescribed values in the codebook.

`[index,quants,distor] = quantiz(sig,partition,codebook)` returns an estimate of the mean square distortion of the quantization data.

Examples

Produce Quantization Index and Quantized Output Value

Generate sample data.

```
samp = [-2.4, -1, -0.2, 0, 0.2, 1, 1.2, 2, 2.9, 3, 3.5, 5]
```

```
samp = 1×12

   -2.4000   -1.0000   -0.2000         0    0.2000    1.0000    1.2000    2.0000    2.9000    3.0
```

Create the quantization partition. To specify a partition, list the distinct endpoints of the different ranges of values.

```
partition = [0, 1, 3];
```

Specify the codebook values.

```
codebook = [-1, 0.5, 2, 3]; % Codebook length must be equal to the number of partition intervals
```

Perform quantization on the sampled data. Display the quantization index and the corresponding quantized output value of the input data.

```
[index,quantized] = quantiz(samp,partition,codebook)
```

```
index = 1×12
```

```
     0     0     0     0     1     1     2     2     2     2     3     3

quantized = 1×12

   -1.0000   -1.0000   -1.0000   -1.0000    0.5000    0.5000    2.0000    2.0000    2.0000    2.0
```

Quantize Sampled Sine Wave

Generate a sampled sine wave.

```
t = [0:.1:2*pi];
sig = sin(t);
```

Create the quantization partition. To specify a partition, list the distinct endpoints of the different ranges of values.

```
partition = [-1:.2:1];
```

Specify the codebook values.

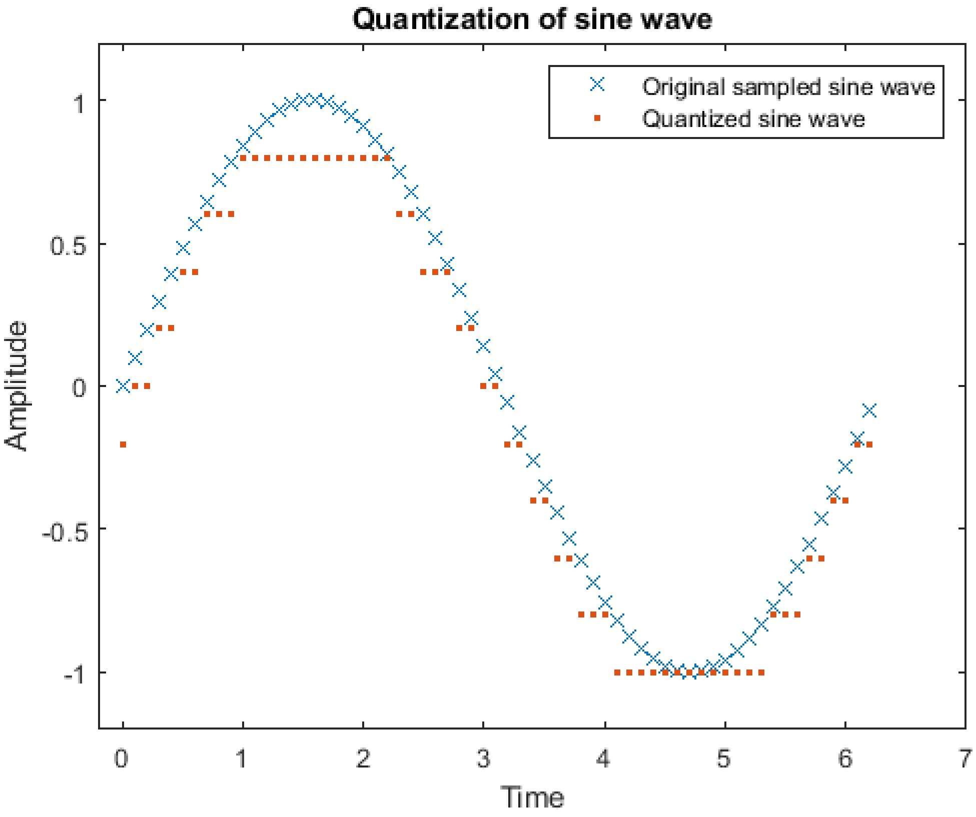
```
codebook = [-1.2:.2:1]; % Codebook length must be equal to the number of partition intervals
```

Perform quantization on the sampled sine wave.

```
[index,quants] = quantiz(sig,partition,codebook);
```

Plot the quantized sine wave and the sampled sine wave.

```
plot(t,sig,'x',t,quants,'.')
title('Quantization of sine wave')
xlabel('Time')
ylabel('Amplitude')
legend('Original sampled sine wave','Quantized sine wave');
axis([-.2 7 -1.2 1.2])
```



Input Arguments

`sig` — Input signal

vector

Input signal, specified as a vector. This input specifies the sampled signal for this function to perform quantization.

Data Types: `double`

`partition` — Distinct endpoints of different ranges

row vector

Distinct endpoints of different ranges, specified as a row vector. This input defines several contiguous, nonoverlapping ranges of values within the set of real numbers. The values present in this input must be strictly in ascending order. The length of this vector must be one less than the number of partition intervals.

Example: [`0`, `1`, `3`] partitions the input row vector into the four sets {*X*: *X* ≤ `0`}, {*X*: `0` < *X* ≤ `1`}, {*X*: `1` < *X* ≤ `3`}, and {*X*: *3* < *X*}.

Data Types: `double`

codebook — Quantization value for each partition

row vector

Quantization value for each partition, specified as a row vector. This input prescribes a common value for each partition in the scalar quantization. The length of this vector must equal the number of partition intervals, that is, the length of this vector must exceed the length of the `partition` input by one.

Data Types: `double`

Output Arguments

`index` — Quantization index

nonnegative row vector

Quantization index of the input signal, returned as a nonnegative row vector. This output determines on which partition interval, each input value is mapped. Each element in `index` is one of the *N* integers in the range [0, *N*–1].

If the `partition` input has length *N*, `index` is a vector whose *K*th entry is:

- `0` if `sig`(*K*) ≤ `partition`(`1`)
- *M* if `partition`(*M*) < `sig`(*K*) ≤ `partition`(*M+1*)
- *N* if `partition`(*N*) ≤ `sig`(K)

`quants` — Output of quantizer

row vector

Output of the quantizer, which contains the quantization values of the input signal, returned as a row vector. The size of `quants` matches that of input argument `sig`. When `codebook` is not specified as an input argument, you can define the codebook values as a vector whose length must exceed the length of the `partition` by one.

`quants` is calculated based on the `codebook` and `index` inputs and is given by `quants`(*i*) = `codebook`(`index`(*i*) + 1), where *i* is an integer between 1 and the length of `sig`.

`distor` — Mean square distortion

positive scalar

Mean square distortion of the quantized signal, returned as a positive scalar. You can reduce this distortion by choosing appropriate partition and codebook values. For more information on optimizing partition and codebook values, see the `lloyds` function.

Introduced before R2006a

randdeintrlv

Restore ordering of symbols using random permutation

Syntax

```
deintrlvd = randdeintrlv(data,state)
```

Description

`deintrlvd = randdeintrlv(data,state)` restores the original ordering of the elements in `data` by inverting a random permutation. The `state` parameter initializes the random number generator that the function uses to determine the permutation. `state` is either a scalar or a 35x1 vector, and is described in the `rand` function, which is used in `randintrlv`. The function is predictable for a given state, but different states produce different permutations. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

To use this function as an inverse of the `randintrlv` function, use the same `state` input in both functions. In that case, the two functions are inverses in the sense that applying `randintrlv` followed by `randdeintrlv` leaves data unchanged.

This function uses, by default, the Mersenne Twister algorithm by Nishimura and Matsumoto.

Note Using the `state` parameter causes this function to switch random generators to use the `'state'` algorithm of the `rand` function.

See `rand` for details on the generator algorithm.

Examples

For an example using random interleaving and deinterleaving, see "Improve Error Rate Using Block Interleaving in MATLAB".

randerr

Generate bit error patterns

Syntax

```
out = randerr(m)
out = randerr(m,n)
out = randerr(m,n,errors)
out = randerr(m,n,errors,seed)
out = randerr(m,n,errors,randstream)
```

Description

Use the `randerr` function to generate bit error patterns. For all syntaxes, `randerr` treats each row of the output independently.

`out = randerr(m)` generates an `m`-by-`m` binary matrix, where each row has exactly one nonzero entry in a random position. Each permutation has an equal probability.

`out = randerr(m,n)` generates an `m`-by-`n` binary matrix, where each row has exactly one nonzero entry in a random position. Each permutation has an equal probability.

`out = randerr(m,n,errors)` uses the `errors` input to determine the number of nonzero entries in each row of the output `m`-by-`n` binary matrix.

`out = randerr(m,n,errors,seed)` specifies a seed value for initializing the uniform random number generator of the `rand` function.

`out = randerr(m,n,errors,randstream)` specifies a random stream object to generate uniform random noise samples by using the `rand` function. Providing a random stream object or using the `reset (RandStream)` function on the default random stream object enables you to generate repeatable noise samples.

Note To generate repeatable noise samples, use the same seed input value for each call of `randerr` or reset the random stream input before calling `randerr`. For more information on resetting the random stream, see the `RandStream` object.

Examples

Generate Random Error Matrix

Generate an 8-by-7 binary matrix in which each row is equally likely to have either zero or two nonzero elements.

```
out = randerr(8,7,[0 2])
```

```
out = 8×7
```

```
     0     1     0     0     0     1     0
     0     1     0     0     0     1     0
     0     0     0     0     0     0     0
     0     0     0     0     0     1     1
     0     0     0     0     0     0     0
     0     0     0     0     0     0     0
     0     0     1     0     0     0     1
     0     0     1     0     1     0     0
```

Generate a matrix in which each row is three times more likely to have two nonzero elements rather than zero nonzero elements.

```
out = randerr(8,7,[0 2; 0.25 0.75])
```

```
out = 8×7

     0     0     0     0     1     0     1
     0     1     0     0     0     0     1
     0     0     1     0     0     1     0
     0     1     0     0     1     0     0
     1     0     0     0     1     0     0
     0     0     0     0     0     0     0
     0     0     0     0     0     0     0
     0     0     0     0     0     0     0
```

Generate Repeatable Random Error Matrix

Demonstrate generation of a random error matrix without a seed input value for a nonrepeatable output and with the seed input value for a repeatable output.

Specify input parameters for the output matrix dimensions, the number of errors, and a seed value.

```
m = 2;
n = 8;
errors = 2;
seed = 1234;
```

Use the `randerr` function to generate a random error binary matrix twice with the same command. The output binary matrix values are the same for each execution of the `randerr` function.

```
out = randerr(m,n,errors,seed)
```

```
out = 2×8

     0     0     1     1     0     0     0     0
     0     1     0     1     0     0     0     0
```

```
out = randerr(m,n,errors,seed)
```

```
out = 2×8

     0     0     1     1     0     0     0     0
     0     1     0     1     0     0     0     0
```

Change the seed value and call the `randerr` function twice. The binary matrix output values are the same for each execution of the `randerr` function, but they differ from the binary matrix values output using the previous seed value.

```
seed = 345;
out = randerr(m,n,errors,seed)
```

```
out = 2×8

     0     0     0     0     1     0     1     0
     1     0     0     0     1     0     0     0
```

```
out = randerr(m,n,errors,seed)
```

```
out = 2×8

     0     0     0     0     1     0     1     0
     1     0     0     0     1     0     0     0
```

Use the `randerr` function to generate a random error binary matrix twice with the same command, not specifying a seed input value. The output matrix values change for each execution of the `randerr` function.

```
out = randerr(m,n,errors)
```

```
out = 2×8

     0     1     0     0     0     1     0     0
     0     1     0     0     0     0     0     1
```

```
out = randerr(m,n,errors)
```

```
out = 2×8

     0     1     0     0     0     0     0     1
     0     0     0     1     0     1     0     0
```

Input Arguments

`m` — Size of random binary matrix

positive integer

Size of the random binary matrix, specified as a positive integer.

- When you specify only the input `m`, the random binary matrix output is of size `m`-by-`m`.
- When you specify the inputs `m` and `n`, the random binary matrix output is of size `m`-by-`n`.

Data Types: `double`

n — Column size of random binary matrix

1 (default) | positive integer

Column size of the random binary matrix, specified as a positive integer.

Data Types: double

errors — Number of nonzero entries

1 (default) | nonnegative integer | nonnegative integer row vector | nonnegative two-row matrix

Number of nonzero entries, specified as one of these forms.

- If specified as a integer, errors defines the number of 1s in each row.
- If specified as a integer row vector, errors defines the number of 1s possible in each row. Every number of 1s included in this vector occurs with equal probability.
- If specified as a two-row matrix, the first row of errors defines the integer number of 1s possible in any given row of the output matrix. The second row specifies the probabilities of each corresponding number of ones. The elements in the second row of errors must sum to 1.

Data Types: double

seed — Seed value

nonnegative integer value less than 2^{32}

Seed value for initializing the uniform random number generator used in the rand function, specified as nonnegative integer value less than 2^{32}.

Data Types: double

randstream — Random stream object

RandStream object

Random stream object to generate uniform random noise samples by using the rand function, specified as a RandStream object. Providing a random stream object or using the reset (RandStream) function on the default random stream object enables you to generate repeatable noise samples.

Output Arguments

out — Random binary matrix output

matrix

Random binary matrix output, returned as a matrix of binary values.

- When you specify only the input m, this output is of size m-by-m.
- When you specify the inputs m and n, this output is of size m-by-n.

Data Types: double

Objects
`RandStream`

Topics
"Sources and Sinks"

Introduced before R2006a

randintrlv

Reorder symbols using random permutation

Syntax

```
intrlvd = randintrlv(data,state)
```

Description

`intrlvd = randintrlv(data,state)` rearranges the elements in `data` using a random permutation. The `state` parameter initializes the random number generator that the function uses to determine the permutation. `state` is either a scalar or a 35x1 vector, and is described in the `rand` function, which is used in `randintrlv`. The function is predictable and invertible for a given state, but different states produce different permutations. If `data` is a matrix with multiple rows and columns, the function processes the columns independently.

This function uses, by default, the Mersenne Twister algorithm by Nishimura and Matsumoto.

Note Using the `state` parameter causes this function to switch random generators to use the `'state'` algorithm of the`rand` function.

See `rand` for details on the generator algorithm.

Examples

For an example using random interleaving and deinterleaving, see “Improve Error Rate Using Block Interleaving in MATLAB”.

Topics

“Interleaving”

Introduced before R2006a

randseed

(To be removed) Generate prime numbers for use as random number seeds

Compatibility

randseed will be removed in a future release. Use `rng(N)` or `rng('shuffle')` instead. For more information, see “Compatibility Considerations” on page 2-725.

Syntax

```
out = randseed
out = randseed(state)
out = randseed(state,m)
out = randseed(state,m,n)
out = randseed(state,m,n,rmin)
out = randseed(state,m,n,rmin,rmax)
```

Description

The `randseed` function produces random prime numbers that work well as seeds for random source blocks or noisy channel blocks in Communications Toolbox software.

Note The `randseed` function uses a local stream of numbers that is independent from the global stream of numbers in the MATLAB software. Use of this function does not affect the state of the global random number stream.

`out = randseed` generates a random prime number between 31 and 2^{17}-1, using the MATLAB function `rand`.

`out = randseed(state)` generates a random prime number after setting the state of `rand` to the positive integer `state`. This syntax produces the same output for a particular value of `state`.

`out = randseed(state,m)` generates a column vector of `m` random primes.

`out = randseed(state,m,n)` generates an `m`-by-`n` matrix of random primes.

`out = randseed(state,m,n,rmin)` generates an `m`-by-`n` matrix of random primes between `rmin` and 2^{17}-1.

`out = randseed(state,m,n,rmin,rmax)` generates an `m`-by-`n` matrix of random primes between `rmin` and `rmax`.

Examples

To generate a two-element sample-based row vector of random bits using the Bernoulli Random Binary Generator block, you can set **Probability of a zero** to `[0.1 0.5]` and set **Initial seed** to `randseed(391,1,2)`.

To generate three streams of random data from three different blocks in a single model, you can define `out = randseed(93,3)` in the MATLAB workspace and then set the three blocks' **Initial seed** parameters to `out(1)`, `out(2)`, and `out(3)`, respectively.

Compatibility Considerations

`randseed` will be removed

Warns starting in R2019a

The functionality provided by `randseed` is no longer necessary for controlling random number generation. Instead, use `rng`(`seed`), where `seed` specifies a nonnegative integer seed for the random number generator, or use `rng`(`‘shuffle’`) to seed the random number generator based on the current time.

See Also

`primes` | `rand` | `rng`

Introduced before R2006a

randsrc

Generate random matrix using prescribed alphabet

Syntax

```
out = randsrc
out = randsrc(m)
out = randsrc(m,n)
out = randsrc(m,n,alphabet)
out = randsrc(m,n,[alphabet; prob])
out = randsrc(m,n,___,seed)
out = randsrc(m,n,___,streamhandle)
```

Description

`out = randsrc` generates a random scalar that is either `-1` or `1`, with equal probability.

`out = randsrc(m)` generates an `m`-by-`m` random bipolar matrix. Each entry independently takes the value `-1` or `1` with equal probability.

`out = randsrc(m,n)` generates an `m`-by-`n` random bipolar matrix. Each entry independently takes the value `-1` or `1` with equal probability.

`out = randsrc(m,n,alphabet)` generates an `m`-by-`n` matrix, with each entry independently chosen from the entries in the row vector `alphabet`. Each entry in `alphabet` occurs in `out` with equal probability. Duplicate values in `alphabet` are ignored.

`out = randsrc(m,n,[alphabet; prob])` generates an `m`-by-`n` matrix, with each entry independently chosen from the entries in the row vector `alphabet`. Duplicate values in `alphabet` are ignored. The row vector `prob` lists corresponding probabilities, so that the symbol `alphabet(k)` occurs with probability `prob(k)`, where `k` is any integer between one and the number of columns of `alphabet`. The elements of `prob` must add up to 1.

`out = randsrc(m,n,___,seed)` accepts input combinations from prior syntaxes and a seed value, for initializing the uniform random number generator, `rand`.

`out = randsrc(m,n,___,streamhandle)` accepts input combinations from prior syntaxes and a random stream handle to generate uniform random noise samples by using `rand`. Providing a random stream handle or using the `reset (RandStream)` function on the default random stream object enables you to generate repeatable noise samples. If you want to generate repeatable noise samples, then either reset the random stream input before calling `randsrc` or use the same seed input. For more information, see `RandStream`.

Examples

Generate Random Matrix from Prescribed Alphabet

Generate a 10-by-10 matrix from the set of {-3,-1,1,3}.

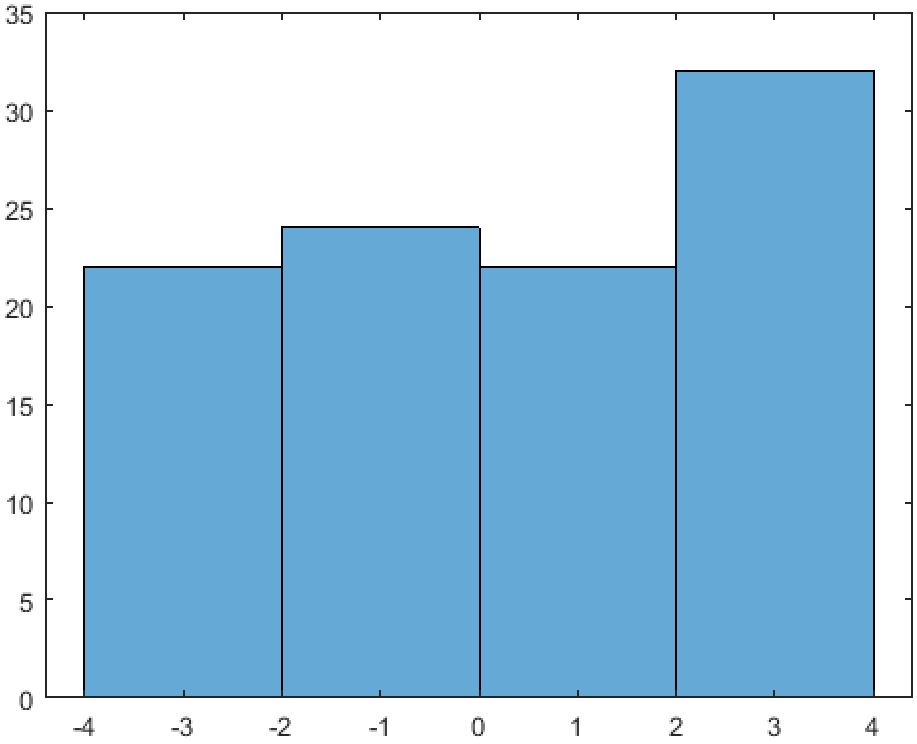
```
out = randsrc(10,10,[-3 -1 1 3])
```

```
out = 10×10

     3    -3     1     1    -1    -1     3     3    -1    -3
     3     3    -3    -3    -1     1    -1    -1     3    -3
    -3     3     3    -1     3     1     1     3     1     1
     3    -1     3    -3     3    -3     1    -3     1     3
     1     3     1    -3    -3    -3     3     3     3     3
    -3    -3     3     3    -1    -1     3    -1    -1    -3
    -1    -1     1     1    -1     3     1    -3     3     1
     1     3    -1    -1     1    -1    -3    -1     3    -1
     3     3     1     3     1     1    -3     1    -1    -3
     3     3    -3    -3     3    -3    -1    -1     1    -1
```

Plot the histogram. Each of the four possible element values occur with equal probability. Your values might differ.

```
histogram(out,[-4 -2 0 2 4])
```



Generate a matrix in which the likelihood of a -1 or 1 is four times higher than the likelihood of a -3 or 3.

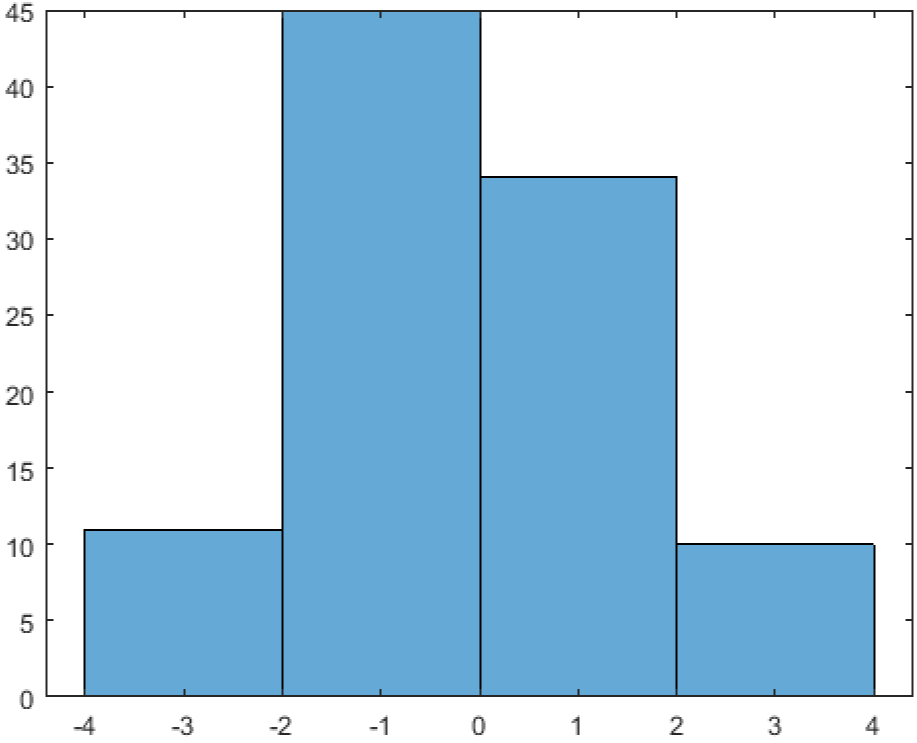
```
out = randsrc(10,10,[-3 -1 1 3; 0.1 0.4 0.4 0.1])
```

```
out = 10×10
```

```
    -1    -1    -1    -1     1    -1     1    -1     1     3
     1    -3     3     3     1    -3    -1    -1    -1     1
    -1    -1    -3    -1    -1     3    -1     1     1    -1
     1     3     1    -1     1     3    -1    -3    -1    -1
    -1    -1     1    -1    -1    -1    -3    -3     1    -1
     1     1     1    -1    -3    -1    -1    -1    -1    -1
    -1     1    -3     1    -1    -1     3     1    -1     1
     1     3    -1     1    -1     3     3     1     1     1
     1    -3    -1     1    -1    -1     1     1     1     1
     1    -1     1    -1    -1    -1    -3    -1    -3     1
```

Plot the histogram. Values of -1 and 1 are more likely.

```
histogram(out,[-4 -2 0 2 4])
```



Input Arguments

`m` — Bipolar matrix size

1 (default) | scalar

Size of random bipolar matrix, specified as a scalar. If `n` is specified, then `m` is the row size of the random bipolar matrix.

Data Types: `double`

n — Bipolar matrix column size

1 (default) | scalar

Column size of random binary matrix, specified as a scalar.

Data Types: double

alphabet — Possible element values

[-1 1] (default) | vector | matrix

Possible elements of output vector or matrix. If alphabet is a row vector, the contents of alphabet define which possible elements randsrc output. If alphabet is a two-row matrix, then the first row is defines the possible elements, and the second row defines the probabilities for each corresponding element in the first row. The elements of the second row must sum to one. If all entries of alphabet are distinct, then the probability distribution is uniform.

Data Types: double

prob — Element probabilities

[0.5 0.5] (default) | vector

Row vector of probabilities that correspond to elements of the corresponding alphabet vector.

Data Types: double

seed — Seed value

scalar

Seed value for initializing the uniform random number generator, rand.

Data Types: double

streamhandle — Random stream handle

RandStream Object

Random stream handle to generate uniform random noise samples by using rand. Providing a random stream handle or using the reset (RandStream) function on the default random stream object enables you to generate repeatable noise samples. If you want to generate repeatable noise samples, then either reset the random stream input before calling randsrc or use the same seed input. For more information, see RandStream.

Data Types: double

Output Arguments

out — Random matrix output

scalar | vector | matrix

Random output, returned as a scalar, vector, or matrix. The dimensions of the output are specified by arguments m and n, otherwise it is a 1-by-1 scalar. The possible elements of the output and their probabilities are specified by alphabet, prob respectively, otherwise the elements of the output are -1 and 1, with equal distribution.

Data Types: double

Functions

`RandStream` | `rand` | `randerr` | `randi`

Introduced before R2006a

rayleighchan

(Removed) Construct Rayleigh fading channel object

Note `rayleighchan` has been removed. Use `comm.RayleighChannel` instead.

Syntax

```
chan = rayleighchan(ts,fd)
chan = rayleighchan(ts,fd,tau,pdb)
chan = rayleighchan
```

Description

`chan = rayleighchan(ts,fd)` constructs a frequency-flat ("single path") Rayleigh fading channel object. `ts` is the sample time of the input signal, in seconds. `fd` is the maximum Doppler shift, in hertz. You can model the effect of the channel on a signal `x` by using the syntax `y = filter(chan,x)`.

`chan = rayleighchan(ts,fd,tau,pdb)` constructs a frequency-selective ("multiple path") fading channel object that models each discrete path as an independent Rayleigh fading process. `tau` is a vector of path delays, each specified in seconds. `pdb` is a vector of average path gains, each specified in dB.

With the above two syntaxes, a smaller `fd` (a few hertz to a fraction of a hertz) leads to slower variations, and a larger `fd` (a couple hundred hertz) to faster variations.

`chan = rayleighchan` constructs a frequency-flat Rayleigh channel object with no Doppler shift. This is a static channel. The sample time of the input signal is irrelevant for frequency-flat static channels.

Properties

The tables below describe the properties of the channel object, `chan`, that you can set and that MATLAB technical computing software sets automatically. To learn how to view or change the values of a channel object, see “Displaying and Changing Object Properties”.

Writeable Properties

Property	Description
InputSamplePeriod	Sample period of the signal on which the channel acts, measured in seconds.
DopplerSpectrum	Doppler spectrum object(s). The default is a Jakes Doppler object.
MaxDopplerShift	Maximum Doppler shift of the channel, in hertz (applies to all paths of a channel).
PathDelays	Vector listing the delays of the discrete paths, in seconds.
AvgPathGaindB	Vector listing the average gain of the discrete paths, in decibels.
NormalizePathGains	If 1, the Rayleigh fading process is normalized such that the expected value of the path gains' total power is 1.
StoreHistory	If this value is 1, channel state information needed by the channel visualization tool is stored as the channel filter function processes the signal. The default value is 0.
StorePathGains	If set to 1, the complex path gain vector is stored as the channel filter function processes the signal. The default value is 0.
ResetBeforeFiltering	If 1, each call to filter resets the state of chan before filtering. If 0, the fading process maintains continuity from one call to the next.

Read-Only Properties

Property	Description	When MATLAB Sets or Updates Value
ChannelType	Fixed value, 'Rayleigh'	When you create object
PathGains	Complex vector listing the current gains of the discrete paths. When you create or reset chan, PathGains is a random vector influenced by AvgPathGaindB and NormalizePathGains.	When you create object, reset object, or use it to filter a signal
ChannelFilterDelay	Delay of the channel filter, measured in samples. The ChannelFilterDelay property returns a delay value that is valid only if the first value of the PathGain is the biggest path gain. In other words, main channel energy is in the first path.	When you create object or change ratio of InputSamplePeriod to PathDelays
NumSamplesProcessed	Number of samples the channel processed since the last reset. When you create or reset chan, this property value is 0.	When you create object, reset object, or use it to filter a signal

Relationships Among Properties

The PathDelays and AvgPathGaindB properties of the channel object must always have the same vector length, because this length equals the number of discrete paths of the channel. The DopplerSpectrum property must either be a single Doppler object or a vector of Doppler objects with the same length as PathDelays.

If you change the length of PathDelays, MATLAB truncates or zero-pads the value of AvgPathGaindB if necessary to adjust its vector length (MATLAB may also change the values of read-only properties such as PathGains and ChannelFilterDelay). If DopplerSpectrum is a vector of Doppler objects, and you increase or decrease the length of PathDelays, MATLAB will add Jakes Doppler objects or remove elements from DopplerSpectrum, respectively, to make it the same length as PathDelays.

If StoreHistory is set to 1 (the default is 0), the object stores channel state information as the channel filter function processes the signal. You can then visualize this state information through a GUI using the plot (channel) method.

Note Setting StoreHistory to 1 will result in a slower simulation. If you do not want to visualize channel state information using plot (channel), but want to access the complex path gains, then set StorePathGains to 1, while keeping StoreHistory as 0.

Visualization of Channel

The characteristics of a channel can be plotted using the channel visualization tool, plot (channel). You can use the channel visualization tool in Normal mode and Accelerator mode.

Examples

The example below illustrates that when you change the value of `PathDelays`, MATLAB automatically changes the values of other properties to make their vector lengths consistent with that of the new value of `PathDelays`.

```
c1 = rayleighchan(1e-5,130) % Create object.
c1.PathDelays = [0 1e-6] % Change the number of delays.
```

MATLAB automatically changes the size of `c1.AvgPathGaindB`, `c1.PathGains`, and `c1.ChannelFilterDelay`. The output below displays all the properties of the channel object before and after the change in the value of the `PathDelays` property. In the second listing of properties, the `AvgPathGaindB`, `PathGains`, and `ChannelFilterDelay` properties all have different values compared to the first listing of properties.

```
c1 =

             ChannelType: 'Rayleigh'
       InputSamplePeriod: 1.0000e-005
         DopplerSpectrum: [1x1 doppler.jakes]
         MaxDopplerShift: 130
              PathDelays: 0
           AvgPathGaindB: 0
      NormalizePathGains: 1
            StoreHistory: 0
               PathGains: 0.2035 + 0.1014i
      ChannelFilterDelay: 0
    ResetBeforeFiltering: 1
     NumSamplesProcessed: 0

c1 =

             ChannelType: 'Rayleigh'
       InputSamplePeriod: 1.0000e-005
         DopplerSpectrum: [1x1 doppler.jakes]
         MaxDopplerShift: 130
              PathDelays: [0 1.0000e-006]
           AvgPathGaindB: [0 0]
      NormalizePathGains: 1
            StoreHistory: 0
               PathGains: [0.6108 - 0.4688i 0.1639 - 0.0027i]
      ChannelFilterDelay: 4
    ResetBeforeFiltering: 1
     NumSamplesProcessed: 0
```

Algorithms

The methodology used to simulate fading channels is described in “Methodology for Simulating Multipath Fading Channels”. The properties of the channel object are related to the quantities of the latter section as follows:

- The `InputSamplePeriod` property contains the value of T_s.
- The `PathDelays` vector property contains the values of $\{\tau_k\}$, where $1 \le k \le K$.

- The `PathGains` read-only property contains the values of $\{a_k\}$, where $1 \le k \le K$.
- The `AvgPathGaindB` vector property contains the values of $10\log_{10}\left\{E\left[|a_k|^2\right]\right\}$, where $1 \le k \le K$, and $E[\,\cdot\,]$ denotes statistical expectation.
- The `ChannelFilterDelay` read-only property contains the value of N_1.

Compatibility Considerations

`rayleighchan` has been removed
Errors starting in R2020b

rayleighchan has been removed. Use `comm.RayleighChannel` instead.

Introduced before R2006a

rectpulse

Rectangular pulse shaping

Syntax

```
y = rectpulse(x,nsamp)
```

Description

`y = rectpulse(x,nsamp)` applies rectangular pulse shaping to `x` to produce an output signal having `nsamp` samples per symbol. Rectangular pulse shaping means that each symbol from `x` is repeated `nsamp` times to form the output `y`. If `x` is a matrix with multiple rows, the function treats each column as a channel and processes the columns independently.

Note To insert zeros between successive samples of `x` instead of repeating the samples of `x`, use the `upsample` function instead.

Examples

An example in “Combine Pulse Shaping and Filtering with Modulation” uses this function in conjunction with modulation.

The code below processes two independent channels, each containing three symbols of data. In the pulse-shaped matrix `y`, each symbol contains four samples.

```
nsamp = 4; % Number of samples per symbol
nsymb = 3; % Number of symbols
s = RandStream('mt19937ar', 'Seed', 0);
ch1 = randi(s, [0 1], nsymb, 1); % Random binary channel
ch2 = [1:nsymb]';
x = [ch1 ch2] % Two-channel signal
y = rectpulse(x,nsamp)
```

The output is below. In `y`, each column corresponds to one channel and each row corresponds to one sample. Also, the first four rows of `y` correspond to the first symbol, the next four rows of `y` correspond to the second symbol, and the last four rows of `y` correspond to the last symbol.

```
x =

     1     1
     1     2
     0     3

y =

     1     1
     1     1
     1     1
     1     1
     1     2
     1     2
     1     2
     1     2
     0     3
     0     3
     0     3
     0     3
```

Introduced before R2006a

reset (channel)

(To be removed) Reset channel object

Note This function will be removed in a future release. Use function associated with `comm.RicianChannel` or `comm.RayleighChannel` instead.

Syntax

```
reset(chan)
reset(chan,randstate)
```

Description

`reset(chan)` resets the channel object `chan`, initializing the `PathGains` and `NumSamplesProcessed` properties as well as internal filter states. This syntax is useful when you want the effect of creating a new channel.

`reset(chan,randstate)` resets the channel object `chan` and initializes the state of the random number generator that the channel uses. `randstate` is a two-element column vector. This syntax is useful when you want to repeat previous numerical results that started from a particular state.

Note `reset(chan,randstate)` will not support `randstate` in a future release. See the `legacychannelsim` function for more information.

Examples

The example below shows how to obtain repeatable results. The example chooses a state for the random number generator immediately after defining the channel object and later resets the random number generator to that state.

```
%% Set up channel.
% Assume you want to maintain continuity
% from one filtering operation to the next, except
% when you explicitly reset the channel.
c = rayleighchan(1e-4,100);
c.ResetBeforeFiltering = 0;

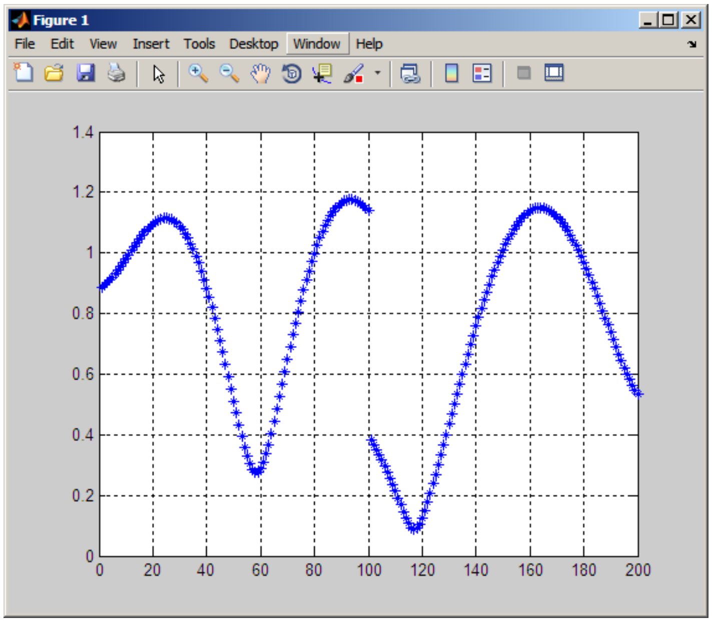
% Filter all ones.
sig = ones(100,1);
y1 = [filter(c,sig(1:50)); filter(c,sig(51:end))];

% Reset the channel and filter all ones.
reset(c);
% Generate an independent channel
y2 = [filter(c,sig(1:50)); filter(c,sig(51:end))];

% Plot the magnitude of the channel output
```

```
plot(abs([y1; y2]),'*')
grid on
```

This example generates a plot similar to this figure.



Compatibility Considerations

reset has been removed

Errors starting in R2020b

reset (channel) has been removed. Use `comm.RicianChannel` instead.

“Fading Channels”

Introduced in R2007a

reset (equalizer)

Reset equalizer object

Syntax

```
reset(eqobj)
```

Description

`reset(eqobj)` resets the equalizer object `eqobj`, initializing the `Weights`, `WeightInputs`, and `NumSamplesProcessed` properties and the adaptive algorithm states. If `eqobj` is a CMA equalizer, `reset` does not change the `Weights` property.

`dfe` | `equalize` | `lineareq`

Topics

"Equalization"

Introduced before R2006a

ricianchan

(Removed) Construct Rician fading channel object

Note `ricianchan` has been removed. Use `comm.RicianChannel` instead.

Syntax

```
chan = ricianchan(ts,fd,k)
chan = ricianchan(ts,fd,k,tau,pdb)
chan = ricianchan(ts,fd,k,tau,pdb,fdlos)
chan = ricianchan
```

Description

`chan = ricianchan(ts,fd,k)` constructs a frequency-flat (single path) Rician fading-channel object. `ts` is the sample time of the input signal, in seconds. `fd` is the maximum Doppler shift, in hertz. `k` is the Rician K-factor in linear scale. You can model the effect of the channel `chan` on a signal `x` by using the syntax `y = filter(chan,x)`.

`chan = ricianchan(ts,fd,k,tau,pdb)` constructs a frequency-selective (multiple paths) fading-channel object. If `k` is a scalar, then the first discrete path is a Rician fading process (it contains a line-of-sight component) with a K-factor of `k`, while the remaining discrete paths are independent Rayleigh fading processes (no line-of-sight component). If `k` is a vector of the same size as `tau`, then each discrete path is a Rician fading process with a K-factor given by the corresponding element of the vector `k`. `tau` is a vector of path delays, each specified in seconds. `pdb` is a vector of average path gains, each specified in dB.

`chan = ricianchan(ts,fd,k,tau,pdb,fdlos)` specifies `fdlos` as the Doppler shift(s) of the line-of-sight component(s) of the discrete path(s), in hertz. `fdlos` must be the same size as `k`. If `k` and `fdlos` are scalars, the line-of-sight component of the first discrete path has a Doppler shift of `fdlos`, while the remaining discrete paths are independent Rayleigh fading processes. If `fdlos` is a vector of the same size as `k`, the line-of-sight component of each discrete path has a Doppler shift given by the corresponding element of the vector `fdlos`. By default, `fdlos` is `0`. The initial phase(s) of the line-of-sight component(s) can be set through the property `DirectPathInitPhase`.

`chan = ricianchan` sets the maximum Doppler shift to `0`, the Rician K-factor to `1`, and the Doppler shift and initial phase of the line-of-sight component to `0`. This syntax models a static frequency-flat channel, and, in this trivial case, the sample time of the signal is unimportant.

Properties

The following tables describe the properties of the channel object, `chan`, that you can set and that MATLAB technical computing software sets automatically. To learn how to view or change the values of a channel object, see “Displaying and Changing Object Properties”.

Writeable Properties

Property	Description
`InputSamplePeriod`	Sample period of the signal on which the channel acts, measured in seconds.
`DopplerSpectrum`	Doppler spectrum object(s). The default is a Jakes doppler object.
`MaxDopplerShift`	Maximum Doppler shift of the channel, in hertz (applies to all paths of a channel).
`KFactor`	Rician K-factor (scalar or vector). The default value is 1 (line-of-sight component on the first path only).
`PathDelays`	Vector listing the delays of the discrete paths, in seconds.
`AvgPathGaindB`	Vector listing the average gain of the discrete paths, in decibels.
`DirectPathDopplerShift`	Doppler shift(s) of the line-of-sight component(s) in hertz. The default value is 0.
`DirectPathInitPhase`	Initial phase(s) of line-of-sight component(s) in radians. The default value is 0.
`NormalizePathGains`	If this value is `1`, the Rayleigh fading process is normalized such that the expected value of the path gains' total power is 1.
`StoreHistory`	If this value is `1`, channel state information needed by the channel visualization tool is stored as the channel filter function processes the signal. The default value is `0`.
`StorePathGains`	If this value is `1`, the complex path gain vector is stored as the channel filter function processes the signal. The default value is `0`.
`ResetBeforeFiltering`	If this value is `1`, each call to `filter` resets the state of `chan` before filtering. If it is `0`, the fading process maintains continuity from one call to the next.

Read-Only Properties

Property	Description	When MATLAB Sets or Updates Value
ChannelType	Fixed value, 'Rician'.	When you create object.
PathGains	Complex vector listing the current gains of the discrete paths. When you create or reset chan, PathGains is a random vector influenced by AvgPathGaindB and NormalizePathGains.	When you create object, reset object, or use it to filter a signal.
ChannelFilterDelay	Delay of the channel filter, measured in samples. The ChannelFilterDelay property returns a delay value that is valid only if the first value of the PathGain is the biggest path gain. In other words, main channel energy is in the first path.	When you create object or change ratio of InputSamplePeriod to PathDelays.
NumSamplesProcessed	Number of samples the channel processed since the last reset. When you create or reset chan, this property value is 0.	When you create object, reset object, or use it to filter a signal.

Relationships Among Properties

Changing the length of PathDelays also changes the length of AvgPathGaindB, the length of KFactor if KFactor is a vector (no change if it is a scalar), and the length of DopplerSpectrum if DopplerSpectrum is a vector (no change if it is a single object).

DirectPathDopplerShift and DirectPathInitPhase both follow changes in KFactor.

The PathDelays and AvgPathGaindB properties of the channel object must always have the same vector length, because this length equals the number of discrete paths of the channel. The DopplerSpectrum property must either be a single Doppler object or a vector of Doppler objects with the same length as PathDelays.

If you change the length of PathDelays, MATLAB truncates or zero-pads the value of AvgPathGaindB if necessary to adjust its vector length (MATLAB may also change the values of read-only properties such as PathGains and ChannelFilterDelay). If DopplerSpectrum is a vector of Doppler objects, and you increase or decrease the length of PathDelays, MATLAB will add Jakes Doppler objects or remove elements from DopplerSpectrum, respectively, to make it the same length as PathDelays.

If StoreHistory is set to 1 (the default is 0), the object stores channel state information as the channel filter function processes the signal. You can then visualize this state information through a GUI using the plot (channel) method.

Note Setting StoreHistory to 1 will result in a slower simulation. If you do not want to visualize channel state information using plot (channel), but want to access the complex path gains, then set StorePathGains to 1, while keeping StoreHistory as 0.

Reset Method

If `MaxDopplerShift` is set to `0` (the default), the channel object, `chan`, models a static channel.

Use the syntax `reset(chan)` to generate a new channel realization.

Algorithm

The methodology used to simulate fading channels is described in “Methodology for Simulating Multipath Fading Channels”, where the properties specific to the Rician channel object are related to the quantities of this section as follows:

- The `Kfactor` property contains the value of K_r (if it’s a scalar) or $\{K_{r,k}\}$, $1 \le k \le K$ (if it’s a vector).
- The `DirectPathDopplerShift` property contains the value of $f_{d,LOS}$ (if it’s a scalar) or $\{f_{d,LOS,k}\}$, $1 \le k \le K$ (if it’s a vector).
- The `DirectPathInitPhase` property contains the value of θ_{LOS} (if it’s a scalar) or $\{\theta_{LOS,k}\}$, $1 \le k \le K$ (if it’s a vector).

The `rayleighchan` reference page includes descriptions for properties common to both Rayleigh and Rician channel objects.

Channel Visualization

The characteristics of a channel can be plotted using the channel visualization tool, `plot (channel)`. You can use the channel visualization tool in Normal mode and Accelerator mode.

Compatibility Considerations

`ricianchan` has been removed

Errors starting in R2020b

ricianchan has been removed. Use `comm.RicianChannel` instead.

“Fading Channels”

Introduced before R2006a

rls

(To be removed) Construct recursive least squares (RLS) adaptive algorithm object

Note will be removed in a future release. Use `comm.LinearEqualizer` or `comm.DecisionFeedback` instead.

Syntax

```
alg = rls(forgetfactor)
alg = rls(forgetfactor,invcorr0)
```

Description

The `rls` function creates an adaptive algorithm object that you can use with the `lineareq` function or `dfe` function to create an equalizer object. You can then use the equalizer object with the `equalize` function to equalize a signal. To learn more about the process for equalizing a signal, see “Equalization”.

`alg = rls(forgetfactor)` constructs an adaptive algorithm object based on the recursive least squares (RLS) algorithm. The forgetting factor is `forgetfactor`, a real number between 0 and 1. The inverse correlation matrix is initialized to a scalar value.

`alg = rls(forgetfactor,invcorr0)` sets the initialization parameter for the inverse correlation matrix. This scalar value is used to initialize or reset the diagonal elements of the inverse correlation matrix.

Properties

The table below describes the properties of the RLS adaptive algorithm object. To learn how to view or change the values of an adaptive algorithm object, see “Equalization”.

Property	Description
`AlgType`	Fixed value, `'RLS'`
`ForgetFactor`	Forgetting factor
`InvCorrInit`	Scalar value used to initialize or reset the diagonal elements of the inverse correlation matrix

Also, when you use this adaptive algorithm object to create an equalizer object (via the `lineareq` function or `dfe` function), the equalizer object has an `InvCorrMatrix` property that represents the inverse correlation matrix for the RLS algorithm. The initial value of `InvCorrMatrix` is `InvCorrInit*eye(N)`, where `N` is the total number of equalizer weights.

Examples

Configuring Linear Equalizers

This example configures the recommended comm.LinearEqualizer System object™ and the legacy lineareq feature with comparable settings.

Initialize Variables and Supporting Objects

```
d = randi([0 3],1000,1);
x = pskmod(d,4,pi/4);
r = awgn(x,25);
sps = 2; %samples per symbol for oversampled cases
nTaps = 6;
txFilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',nTaps, ...
    'OutputSamplesPerSymbol',4);
rxFilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',nTaps, ...
    'InputSamplesPerSymbol',4,'DecimationFactor',2);
x2 = txFilter(x);
r2 = rxFilter(awgn(x2,25,0.5));
filterDelay = txFilter.FilterSpanInSymbols/2 + ...
    rxFilter.FilterSpanInSymbols/2; % Total filter delay in symbols
```

To compare the equalized output, plot the constellations using code such as:

```
% plot(yNew,'*')
% hold on
% plot(yOld,'o')
% hold off; legend('New Eq','Old Eq'); grid on
```

Use RLS Algorithm with Linear Equalizer

Configure lineareq and comm.LinearEqualizer objects with comparable settings.

```
eqOld = lineareq(5,rls(0.95),pskmod(0:3,4,pi/4))
```

```
eqOld =
  EqType: 'Linear Equalizer'
  AlgType: 'RLS'
  nWeights: 5
  nSampPerSym: 1
  RefTap: 1
  SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  InvCorrInit: 0.1000
  InvCorrMatrix: [5×5 double]
  Weights: [0 0 0 0 0]
  WeightInputs: [0 0 0 0 0]
  ResetBeforeFiltering: 1
  NumSamplesProcessed: 0
```

```
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','RLS', ...
    'ForgettingFactor',0.95,'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'RLS'
  NumTaps: 5
  ForgettingFactor: 0.9500
  InitialInverseCorrelationMatrix: 0.1000
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 1
  InputDelay: 0
  InputSamplesPerSymbol: 1
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers. When ResetBeforeFiltering is set to true, each call of the equalize object resets the equalizer. To get the equivalent behavior call reset after each call of the comm.LinearEqualizer object.

```
yOld1 = equalize(eqOld,r,x(1:100));
yOld2 = equalize(eqOld,r,x(1:100));
```

```
yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

Configure `lineareq` and `comm.LinearEqualizer` objects with comparable settings. For the `comm.LinearEqualizer` object, set the initial inverse correlation matrix to `eye(5)*0.2`.

```
eqOld = lineareq(5,rls(0.95),pskmod(0:3,4,pi/4))
```

```
eqOld =
  EqType: 'Linear Equalizer'
  AlgType: 'RLS'
  nWeights: 5
  nSampPerSym: 1
  RefTap: 1
  SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ForgetFactor: 0.9500
  InvCorrInit: 0.1000
  InvCorrMatrix: [5×5 double]
  Weights: [0 0 0 0 0]
  WeightInputs: [0 0 0 0 0]
  ResetBeforeFiltering: 1
  NumSamplesProcessed: 0
```

```
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','RLS', ...
    'ForgettingFactor',0.95,'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1, ...
    'InitialInverseCorrelationMatrix',eye(5)*0.2)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'RLS'
  NumTaps: 5
  ForgettingFactor: 0.9500
  InitialInverseCorrelationMatrix: [5×5 double]
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 1
  InputDelay: 0
  InputSamplesPerSymbol: 1
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers. When `ResetBeforeFiltering` is set to `true`, each call of the `equalize` object resets the equalizer. To get the equivalent behavior call `reset` after each call of the `comm.LinearEqualizer` object.

```
yOld1 = equalize(eqOld,r,x(1:100));
yOld2 = equalize(eqOld,r,x(1:100));

yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

Algorithms

Referring to the schematics presented in “Equalization”, define w as the vector of all weights w_i and define u as the vector of all inputs u_i. Based on the current set of inputs, u, and the current inverse correlation matrix, P, this adaptive algorithm first computes the Kalman gain vector, K

$$K = \frac{Pu}{(ForgettingFactor) + u^H Pu}\,.$$

where H denotes the Hermitian transpose.

Then the new inverse correlation matrix is given by

$(\texttt{ForgetFactor})^{-1}(P - Ku^{H}P)$

and the new set of weights is given by

$w + K^{*}e$

where the * operator denotes the complex conjugate.

Compatibility Considerations

`rls` will be removed

Warns starting in R2020a

rls will be removed in a future release. Use `comm.LinearEqualizer` or `comm.DecisionFeedback` instead with the adaptive algorithm set to RLS. For examples comparing setup of `comm.LinearEqualizer` to `lineareq`, see “Configuring Linear Equalizers” on page 2-745.

Introduced before R2006a

rsdec

Reed-Solomon decoder

Syntax

```
decoded = rsdec(code,n,k)
decoded = rsdec(code,n,k,genpoly)
decoded = rsdec(...,paritypos)
[decoded,cnumerr] = rsdec(...)
[decoded,cnumerr,ccode] = rsdec(...)
```

Description

`decoded = rsdec(code,n,k)` attempts to decode the received signal in `code` using an [`n`,`k`] Reed-Solomon decoding process with the narrow-sense generator polynomial. `code` is a Galois array of symbols having m bits each. Each `n`-element row of `code` represents a corrupted systematic codeword, where the parity symbols are at the end and the leftmost symbol is the most significant symbol. `n` is at most 2^m-1. If `n` is not exactly 2^m-1, `rsdec` assumes that `code` is a corrupted version of a shortened code.

In the Galois array `decoded`, each row represents the attempt at decoding the corresponding row in `code`. A *decoding failure* occurs if `rsdec` detects more than `(n-k)/2` errors in a row of `code`. In this case, `rsdec` forms the corresponding row of `decoded` by merely removing `n-k` symbols from the end of the row of `code`.

`decoded = rsdec(code,n,k,genpoly)` is the same as the syntax above, except that a nonempty value of `genpoly` specifies the generator polynomial for the code. In this case, `genpoly` is a Galois row vector that lists the coefficients, in order of descending powers, of the generator polynomial. The generator polynomial must have degree `n-k`. To use the default narrow-sense generator polynomial, set `genpoly` to `[]`.

`decoded = rsdec(...,`*`paritypos`*`)` specifies whether the parity symbols in `code` were appended or prepended to the message in the coding operation. *`paritypos`* can be either `'end'` or `'beginning'`. The default is `'end'`. If *`paritypos`* is `'beginning'`, a decoding failure causes `rsdec` to remove `n-k` symbols from the beginning rather than the end of the row.

`[decoded,cnumerr] = rsdec(...)` returns a column vector `cnumerr`, each element of which is the number of corrected errors in the corresponding row of `code`. A value of `-1` in `cnumerr` indicates a decoding failure in that row in `code`.

`[decoded,cnumerr,ccode] = rsdec(...)` returns `ccode`, the corrected version of `code`. The Galois array `ccode` has the same format as `code`. If a decoding failure occurs in a certain row of `code`, the corresponding row in `ccode` contains that row unchanged.

Examples

Reed-Solomon Decoding

Set the RS code parameters.

```
m = 3;                     % Number of bits per symbol
n = 2^m-1;                 % Codeword length
k = 3;                     % Message length
```

Generate three codewords composed of 3-bit symbols. Encode the message with a (7,3) RS code.

```
msg = gf([2 7 3; 4 0 6; 5 1 1],m);
code = rsenc(msg,n,k);
```

Introduce one error on the first codeword, two errors on the second codeword, and three errors on the third codeword.

```
errors = gf([2 0 0 0 0 0 0; 3 4 0 0 0 0 0; 5 6 7 0 0 0 0],m);
noisycode = code + errors;
```

Decode the corrupted codeword.

```
[rxcode,cnumerr] = rsdec(noisycode,n,k);
```

Observe that the number of corrected errors matches the introduced errors for the first two rows. In row three, the number of corrected errors is -1 because a (7,3) RS code cannot correct more than two errors.

```
cnumerr
```

```
cnumerr = 3×1

     1
     2
    -1
```

Limitations

n and k must differ by an even integer. n must be between 3 and 65535.

Algorithms

rsdec uses the Berlekamp-Massey decoding algorithm. For information about this algorithm, see the works listed in “References” on page 2-750 below.

rsenc

Reed-Solomon encoder

Syntax

```
code = rsenc(msg,n,k)
code = rsenc(msg,n,k,genpoly)
code = rsenc(...,paritypos)
```

Description

`code = rsenc(msg,n,k)` encodes the message in `msg` using an [`n`,`k`] Reed-Solomon code with the narrow-sense generator polynomial. `msg` is a Galois array of symbols having m bits each. Each `k`-element row of `msg` represents a message word, where the leftmost symbol is the most significant symbol. `n` is at most 2^m-1. If `n` is not exactly 2^m-1, `rsenc` uses a shortened Reed-Solomon code. Parity symbols are at the end of each word in the output Galois array `code`.

`code = rsenc(msg,n,k,genpoly)` is the same as the syntax above, except that a nonempty value of `genpoly` specifies the generator polynomial for the code. In this case, `genpoly` is a Galois row vector that lists the coefficients, in order of descending powers, of the generator polynomial. The generator polynomial must have degree `n-k`. To use the default narrow-sense generator polynomial, set `genpoly` to `[]`.

`code = rsenc(...,`*`paritypos`*`)` specifies whether `rsenc` appends or prepends the parity symbols to the input message to form `code`. *`paritypos`* can be either `'end'` or `'beginning'`. The default is `'end'`.

Examples

Reed-Solomon Code Generation

Set the code parameters.

```
m = 3;           % Number of bits per symbol
n = 2^m - 1;     % Codeword length
k = 3;           % Message length
```

Create two messages based on GF(8).

```
msg = gf([2 7 3; 4 0 6],m)
```

```
msg = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)

Array elements =

   2   7   3
   4   0   6
```

Generate RS (7,3) codewords.

```
code = rsenc(msg,n,k)
```

```
code = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)

Array elements =

   2   7   3   3   6   7   6
   4   0   6   4   2   2   0
```

The codes are systematic so the first three symbols of each row match the rows of `msg`.

Limitations

`n` and `k` must differ by an integer. `n` between 7 and 65535.

rsgenpoly

Generator polynomial of Reed-Solomon code

Syntax

```
genpoly = rsgenpoly(N,K)
genpoly = rsgenpoly(N,K,prim_poly)
genpoly = rsgenpoly(N,K,prim_poly,B)
genpoly = rsgenpoly(N,K,prim_poly,B,outputFormat)
[genpoly,T] = rsgenpoly( ___ )
```

Description

`genpoly = rsgenpoly(N,K)` returns the narrow-sense generator polynomial of an [N,K] Reed-Solomon code. The output `genpoly` is a Galois field array that represents the coefficients of the generator polynomial in order of descending powers. A narrow-sense BCH code is a BCH code with `B` = 1. Here, the narrow-sense generator polynomial is $(X - \alpha^1)(X - \alpha^2)\ldots(X - \alpha^{N-K})$, where α is a root of the default primitive polynomial for the field GF(`N+1`). For additional information, see Narrow-Sense BCH Codes and “Reed-Solomon Codes”.

`genpoly = rsgenpoly(N,K,prim_poly)` also specifies the primitive polynomial, `prim_poly`, for GF(`N+1`) that has α as a root.

`genpoly = rsgenpoly(N,K,prim_poly,B)` returns the generator polynomial, $(X - \alpha^{B})(X - \alpha^{B+1})\ldots(X - \alpha^{B+N-K-1})$, where `B` is an integer.

`genpoly = rsgenpoly(N,K,prim_poly,B,outputFormat)` specifies the output format of `genpoly` as a Galois field array or double-precision array.

`[genpoly,T] = rsgenpoly( ___ )` also returns the error-correction capability of the [N,K] Reed-Solomon code, `T`, using any of the preceding input argument syntaxes.

Examples

Create Narrow-Sense Generator Polynomial

Specify the codeword length, `n`, and message length, `k`.

```
n = 7;
k = 3;
```

Create the narrow-sense generator polynomial for the [n,k] Reed-Solomon code. `genpoly` is a Galois field array, by default, that represents the coefficients of this generator polynomial in order of descending powers.

```
genpoly = rsgenpoly(n,k)
```

```
genpoly = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)
```

```
Array elements = 

   1   3   1   2   3
```

Create Narrow-Sense Generator Polynomial Specifying Primitive Polynomial

Create the narrow-sense generator polynomial of a Reed-Solomon code with respect to the primitive polynomial $D^3 + D^2 + 1$.

Specify the codeword length, n, message length, k, and primitive polynomial $D^3 + D^2 + 1$ represented in decimal form.

```
n = 7;
k = 3;
prim_poly = 13;
```

Create the narrow-sense generator polynomial for the [n,k] Reed-Solomon code with respect to primitive polynomial $D^3 + D^2 + 1$ for GF(8). genpoly is a Galois field array, by default, that represent the coefficients of this generator polynomial in order of descending powers.

```
genpoly = rsgenpoly(n,k,prim_poly)
```

```
genpoly = GF(2^3) array. Primitive polynomial = D^3+D^2+1 (13 decimal)

Array elements = 

   1   4   5   1   5
```

Create Generator Polynomial for Specified B

Create the generator polynomial of a Reed-Solomon code with respect to the default primitive polynomial.

Specify the codeword length, n, message length, k, and exponent of α, b.

```
n = 7;
k = 3;
b = 4;
```

Create the generator polynomial $\left(X - \alpha^4\right)\left(X - \alpha^5\right)\left(X - \alpha^6\right)\left(X - \alpha^7\right)$, with respect to the default primitive polynomial. genpoly is a Galois field array that represents the coefficients of this generator polynomial in order of descending powers. Display the error-correcting capability of the code.

```
[genpoly,t] = rsgenpoly(n,k,[],b)
```

```
genpoly = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)

Array elements = 
     1     5     5     3     2

t = 2
```

Create Generator Polynomial for DVB-S and WiMAX

Create the generator polynomial of a Reed-Solomon code with respect to the primitive polynomial $D^8 + D^4 + D^3 + D^2 + 1$.

Specify the codeword length, n, message length, k, the primitive polynomial represented in decimal form, and the exponent of α, b.

```
n = 255;
k = 239;
prim_poly = 285;
b = 0;
```

Create the generator polynomial for the [n,k] Reed-Solomon code. genpoly is a Galois field array that represents a generator polynomial and is compliant with DVB-S and WiMAX.

```
genpoly = rsgenpoly(n,k,prim_poly,b)
```

```
genpoly = GF(2^8) array. Primitive polynomial = D^8+D^4+D^3+D^2+1 (285 decimal)

Array elements = 

  Columns 1 through 13

     1    59    13   104   189    68   209    30     8   163    65    41   229

  Columns 14 through 17

    98    50    36    59
```

Create Narrow-Sense Generator Polynomial with Output Format Double

Create the narrow-sense generator polynomial of a Reed-Solomon code. Specify the output data type as a double-precision array.

Specify the codeword length, n, and message length, k.

```
n = 7;
k = 3;
```

Create the narrow-sense generator polynomial for the [n,k] Reed-Solomon code. genpoly is a double-precision array, that represents the coefficients of this generator polynomial in order of descending powers. Specify defaults values for the primitive polynomial and exponent of α inputs by assigning [ ] for them.

```
genpoly = rsgenpoly(n,k,[],[],'double')
genpoly = 1×5

     1     3     1     2     3
```

Input Arguments

N — Codeword length

positive odd integer

Codeword length, specified as an integer of the form `N` = 2^M – 1, where M is in the range [3,16]. For more information, see “Limitations” on page 2-758.

Example: Set `N` to `15` for M=4.

K — Message length

positive integer

Message length, specified as a positive integer. For more information, see “Limitations” on page 2-758.

prim_poly — Primitive polynomial

GF(`N`+1) (default) | positive integer

Primitive polynomial, specified as a positive integer. `prim_poly` is an integer whose binary representation indicates the coefficients of the primitive polynomial. To use the default primitive polynomial GF(`N+1`), set `prim_poly` to `[]`. For more information, see “Default Primitive Polynomials” on page 2-758.

Example: `19` specifies the primitive polynomial D^4+D+1 because its binary representation is 10011.

B — Exponent of *α*

`1` (default) | positive integer

Exponent of α, specified as a positive integer. α is a root of `prim_poly`.

outputFormat — Output format

`'gf'` (default) | `'double'`

Output format of `genpoly`, specified as:

- `'gf'` — to output a Galois field array.
- `'double'` — to output a double-precision array of the Galois field values.

For more information, see “Working with Galois Fields”.

Output Arguments

genpoly — Generator polynomial coefficients

Galois field array | double-precision array

Generator polynomial coefficients in descending order, returned as a Galois field array or double-precision array. `genpoly` is a row vector that represents the coefficients of the narrow-sense generator polynomial of an [`N`,`K`] Reed-Solomon code in order of descending powers.

T — Error-correction capability
positive integer

Error-correction capability of the code, returned as a positive integer equal to $\lfloor(N – K)/2\rfloor$.

Limitations

- Valid values for N = 2^M – 1, where M is an integer in the range [3,16]. The maximum allowable value of N = 2^{16} – 1 = 65,535.
- Valid values for K = [1,N – 1].

More About

Default Primitive Polynomials

This table lists the default primitive polynomial used for each Galois field array GF(2^m). To use a different primitive polynomial, specify `prim_poly` as an input argument. `prim_poly` must be in the range [(2^m + 1), (2^{m+1} – 1)] and must indicate an irreducible polynomial. For more information, see “Primitive Polynomials and Element Representations”.

Value of m	Default Primitive Polynomial	Integer Representation
1	$D + 1$	3
2	$D^2 + D + 1$	7
3	$D^3 + D + 1$	11
4	$D^4 + D + 1$	19
5	$D^5 + D^2 + 1$	37
6	$D^6 + D + 1$	67
7	$D^7 + D^3 + 1$	137
8	$D^8 + D^4 + D^3 + D^2 + 1$	285
9	$D^9 + D^4 + 1$	529
10	$D^{10} + D^3 + 1$	1033
11	$D^{11} + D^2 + 1$	2053
12	$D^{12} + D^6 + D^4 + D + 1$	4179
13	$D^{13} + D^4 + D^3 + D + 1$	8219
14	$D^{14} + D^{10} + D^6 + D + 1$	17475
15	$D^{15} + D + 1$	32771
16	$D^{16} + D^{12} + D^3 + D + 1$	69643

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

All inputs must be constants. Expressions or variables are allowed if their values do not change.

rsgenpolycoeffs

Generator polynomial coefficients of Reed-Solomon code

Syntax

```
x = rsgenpolycoeffs(...)
[x,t] = rsgenpolycoeffs(...)
```

Description

`x = rsgenpolycoeffs(...)` returns the coefficients for the generator polynomial of the Reed-Solomon code. The output is identical to genpoly = rsgenpoly(...); x = genpoly.x.

`[x,t] = rsgenpolycoeffs(...)` returns *t*, the error-correction capability of the code.

Examples

Generate Polynomial Coefficients for a Reed-Solomon Code

This example shows how to generate polynomial coefficients for a (15,11) Reed-Solomon code.

Generate the coefficients using `rsgenpolycoeffs`.

```
genpoly = rsgenpolycoeffs(15,11)
```

```
genpoly = 1x5 uint32 row vector

    1    13    12     8     7
```

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

For C/C++ code generation, these usage notes and limitations apply:

All inputs must be constants. Expressions or variables are allowed if their values do not change.

Introduced in R2010b

scatterplot

Generate scatter plot

Syntax

```
scatterplot(x)
scatterplot(x,n)
scatterplot(x,n,offset)
scatterplot(x,n,offset,plotstring)
scatterplot(x,n,offset,plotstring,scatfig)
scatfig = scatterplot( ___ )
```

Description

`scatterplot(x)` creates a scatter plot for signal `x`.

`scatterplot(x,n)` specifies decimation factor `n`. The function plot every `n`th value of `x`, starting from its first value.

`scatterplot(x,n,offset)` specifies the offset value. The function plots every `n`th value of `x`, starting from its (`offset` + 1)th value.

`scatterplot(x,n,offset,plotstring)` specifies plot attributes for the scatter plot.

`scatterplot(x,n,offset,plotstring,scatfig)` generates the scatter plot in the existing `Figure` object, `scatfig`. To plot multiple signals in the same figure, use `hold on`.

`scatfig = scatterplot( ___ )` returns the `Figure` object of the scatter plot. Use `scatfig` to query or modify properties of the figure after it is created. You can specify any of the input argument combinations from the previous syntaxes.

Examples

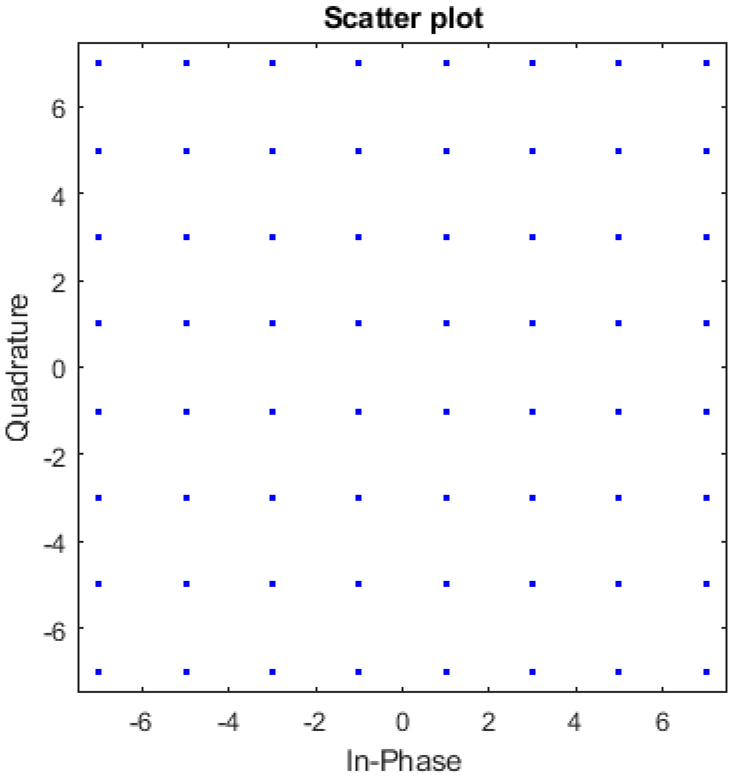
Generate Scatter Plot of 64-QAM Signal

Create a 64-QAM signal in which each constellation point is used.

```
d = (0:63)';
s = qammod(d,64);
```

Display the scatter plot of the constellation.

```
scatterplot(s)
```



Input Arguments

x — Input signal
vector | matrix

Input signal, specified as a vector or matrix.

The interpretation of x depends on its shape and complexity.

- If x is a real-valued two-column matrix, the function interprets the first column as in-phase components and the second column as quadrature components.
- If x is a complex-valued vector, the function interprets the real part as in-phase components and the imaginary part as quadrature components.
- If x is a real-valued vector, the function interprets it as a real signal.

Data Types: double | single
Complex Number Support: Yes

n — Decimation factor
1 (default) | positive integer

Decimation factor, specified as a positive integer. The function plots every nth value of input signal x, starting from its first value.

Data Types: double

`offset` — Offset value

`0` (default) | nonnegative integer

Offset value, specified as a nonnegative integer. This offset value specifies the number of samples at the beginning of input `x` that the function skips before generating the scatter plot.

Data Types: `double`

`plotstring` — Plot attributes

`'b.'` (default) | character vector | string scalar

Plot attributes, specified as a character vector or string scalar containing symbols.

This argument sets the plotting symbol, line type, and color for the scatter plot. The format and meaning of the symbols are the same as in the `plot` function. For example, the default value `'b.'` produces blue dots.

Data Types: `char` | `string`

`scatfig` — Target scatterplot

`Figure` object

Target scatterplot, specified as a `Figure` object for a previously generated `scatterplot`.

Output Arguments

`scatfig` — Target scatterplot

`Figure` object

Target scatterplot, returned as a `Figure` object. To modify properties of this object, see `Figure Properties`.

Introduced before R2006a

semianalytic

Calculate bit error rate (BER) using semianalytic technique

Syntax

```
ber = semianalytic(txsig,rxsig,modtype,M,Nsamp)
ber = semianalytic(txsig,rxsig,modtype,M,Nsamp,num,den)
ber = semianalytic(txsig,rxsig,modtype,M,Nsamp,EbNo)
ber = semianalytic(txsig,rxsig,modtype,M,Nsamp,num,den,EbNo)
[ber,avgampl,avgpower] = semianalytic(...)
```

Description

`ber = semianalytic(txsig,rxsig,`*`modtype`*`,`*`M`*`,Nsamp)` returns the bit error rate (BER) of a system that transmits the complex baseband vector signal `txsig` and receives the noiseless complex baseband vector signal `rxsig`. Each of these signals has `Nsamp` samples per symbol. `Nsamp` is also the sampling rate of `txsig` and `rxsig`, in Hz. The function assumes that `rxsig` is the input to the receiver filter, and the function filters `rxsig` with an ideal integrator. `modtype` is the modulation type of the signal and *`M`* is the alphabet size. The table below lists the valid values for *`modtype`* and *`M`*.

Modulation Scheme	Value of *modtype*	Valid Values of *M*
Differential phase shift keying (DPSK)	`'dpsk'`	2, 4
Minimum shift keying (MSK) with differential encoding	`'msk/diff'`	2
Minimum shift keying (MSK) with nondifferential encoding	`'msk/nondiff'`	2
Phase shift keying (PSK) with differential encoding, where the phase offset of the constellation is 0	`'psk/diff'`	2, 4
Phase shift keying (PSK) with nondifferential encoding, where the phase offset of the constellation is 0	`'psk/nondiff'`	2, 4, 8, 16, 32, or 64
Offset quadrature phase shift keying (OQPSK)	`'oqpsk'`	4
Quadrature amplitude modulation (QAM)	`'qam'`	4, 8, 16, 32, 64, 128, 256, 512, 1024

`'msk/diff'` is equivalent to conventional MSK (setting the `'Precoding'` property of the MSK object to `'off'`), while `'msk/nondiff'` is equivalent to precoded MSK (setting the `'Precoding'` property of the MSK object to `'on'`).

Note The output `ber` is an *upper bound* on the BER in these cases:

- DQPSK (*modtype* = `'dpsk'`, `M` = 4)
- Cross QAM (*modtype* = `'qam'`, `M` not a perfect square). In this case, note that the upper bound used here is slightly tighter than the upper bound used for cross QAM in the `berawgn` function.

When the function computes the BER, it assumes that symbols are Gray-coded. The function calculates the BER for values of E_b/N_0 in the range of [0:20] dB and returns a vector of length 21 whose elements correspond to the different E_b/N_0 levels.

Note You must use a sufficiently long vector `txsig`, or else the calculated BER will be inaccurate. If the system's impulse response is L symbols long, the length of `txsig` should be at least $\mathtt{M}^L$. A common approach is to start with an augmented binary pseudonoise (PN) sequence of total length $(\mathtt{log_2M})\mathtt{M}^L$. An *augmented* PN sequence is a PN sequence with an extra zero appended, which makes the distribution of ones and zeros equal.

`ber = semianalytic(txsig,rxsig,`*`modtype`*`,`*`M`*`,Nsamp,num,den)` is the same as the previous syntax, except that the function filters `rxsig` with a receiver filter instead of an ideal integrator. The transfer function of the receiver filter is given in descending powers of z by the vectors `num` and `den`.

`ber = semianalytic(txsig,rxsig,`*`modtype`*`,`*`M`*`,Nsamp,EbNo)` is the same as the first syntax, except that `EbNo` represents E_b/N_0, the ratio of bit energy to noise power spectral density, in dB. If `EbNo` is a vector, then the output `ber` is a vector of the same size, whose elements correspond to the different E_b/N_0 levels.

`ber = semianalytic(txsig,rxsig,`*`modtype`*`,`*`M`*`,Nsamp,num,den,EbNo)` combines the functionality of the previous two syntaxes.

`[ber,avgampl,avgpower] = semianalytic(...)` returns the mean complex signal amplitude and the mean power of `rxsig` after filtering it by the receiver filter and sampling it at the symbol rate.

Examples

A typical procedure for implementing the semianalytic technique is in “Procedure for the Semianalytic Technique”. Sample code is in “Using Semianalytic Technique”.

Limitations

The function makes several important assumptions about the communication system. See “When to Use the Semianalytic Technique” to find out whether your communication system is suitable for the semianalytic technique and the `semianalytic` function.

Alternatives

As an alternative to the `semianalytic` function, invoke the BERTool GUI (`bertool`) and use the **Semianalytic** tab.

Introduced before R2006a

shift2mask

Convert shift to mask vector for shift register configuration

Syntax

```
mask = shift2mask(prpoly,shift)
```

Description

`mask = shift2mask(prpoly,shift)` returns the mask that is equivalent to the shift (or offset) specified by `shift`, for a linear feedback shift register whose connections are specified by the primitive polynomial `prpoly`. The `prpoly` input can have one of these formats:

- A polynomial character vector
- A binary vector that lists the coefficients of the primitive polynomial in order of descending powers
- An integer scalar whose binary representation gives the coefficients of the primitive polynomial, where the least significant bit is the constant term

The `shift` input is an integer scalar.

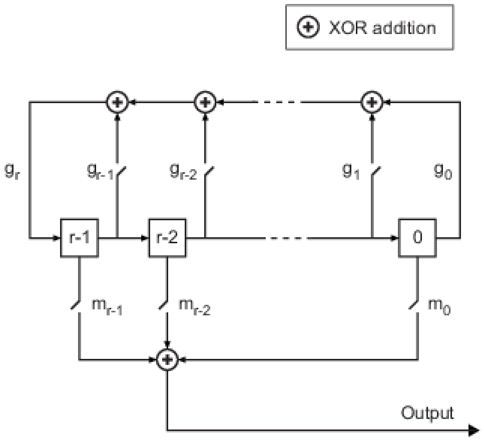
Note To save time, `shift2mask` does not check that `prpoly` is primitive. If it is not primitive, the output is not meaningful. To find primitive polynomials, use `primpoly` or see [2].

Definition of Equivalent Mask

The equivalent mask for the shift s is the remainder after dividing the polynomial x^s by the primitive polynomial. The vector `mask` represents the remainder polynomial by listing the coefficients in order of descending powers.

Shifts, Masks, and Pseudonoise Sequence Generators

Linear feedback shift registers are part of an implementation of a pseudonoise sequence generator. Below is a schematic diagram of a pseudonoise sequence generator. All adders perform addition modulo 2.



The primitive polynomial determines the state of each switch labeled g_k, and the mask determines the state of each switch labeled m_k. The lower half of the diagram shows the implementation of the shift, which delays the starting point of the output sequence. If the shift is zero, the m_0 switch is closed while all other m_k switches are open. The table below indicates how the shift affects the shift register's output.

	T = 0	**T = 1**	**T = 2**	**...**	**T = s**	**T = s+1**
Shift = 0	x_0	x_1	x_2	...	x_s	x_{s+1}
Shift = s > 0	x_s	x_{s+1}	x_{s+2}	...	x_{2s}	x_{2s+1}

If you have Communications Toolbox software and want to generate a pseudonoise sequence in a Simulink model, see the PN Sequence Generator block reference page.

Examples

Convert Shift to Mask

Convert a shift in a linear feedback shift register into an equivalent mask.

Convert a shift of 5 into the equivalent mask $x^3 + x + 1$ for the linear feedback shift register whose connections are specified by the primitive polynomial $x^4 + x^3 + 1$. The length of the mask is equal to the degree of the primitive polynomial, 4.

```
mk = shift2mask([1 1 0 0 1],5)
```

```
mk = 1×4

     1     0     1     1
```

Convert a shift of 7 to a mask of $x^4 + x^2$ for the primitive polynomial $x^5 + x^2 + 1$.

```
mk2 = shift2mask('x5+x2+1',7)
```

```
mk2 = 1×5

     1     0     1     0     0
```

showcommblockdatatypetable

Communications Toolbox block characteristics

Syntax

```
showcommblockdatatypetable
```

Description

`showcommblockdatatypetable` shows a table of characteristics for the Communications Toolbox blocks. The table lists capabilities and limitations about code generation, variable size, and supported data types for each block. If a cell includes an "X", the corresponding block supports the capability indicated by the column heading. Descriptions for numbered footnotes, "(#)", follow the table.

Examples

Show Communications Toolbox Block Characteristics

Show a table of Communications Toolbox block characteristics. The table opens in a separate window.

signlms

(To be removed) Construct signed least mean square (LMS) adaptive algorithm object

Note will be removed in a future release. Consider using `comm.LinearEqualizer` or `comm.DecisionFeedback` instead.

Syntax

```
alg = signlms(stepsize)
alg = signlms(stepsize,algtype)
```

Description

The `signlms` function creates an adaptive algorithm object that you can use with the `lineareq` function or `dfe` function to create an equalizer object. You can then use the equalizer object with the `equalize` function to equalize a signal. To learn more about the process for equalizing a signal, see “Equalization”.

`alg = signlms(stepsize)` constructs an adaptive algorithm object based on the signed least mean square (LMS) algorithm with a step size of `stepsize`.

`alg = signlms(stepsize,`*`algtype`*`)` constructs an adaptive algorithm object of type *`algtype`* from the family of signed LMS algorithms. The table below lists the possible values of *`algtype`*.

Value of *algtype*	Type of Signed LMS Algorithm
`'Sign LMS'`	Sign LMS (default)
`'Signed Regressor LMS'`	Signed regressor LMS
`'Sign Sign LMS'`	Sign-sign LMS

Properties

The table below describes the properties of the signed LMS adaptive algorithm object. To learn how to view or change the values of an adaptive algorithm object, see “Equalization”.

Property	Description
`AlgType`	Type of signed LMS algorithm, corresponding to the *`algtype`* input argument. You cannot change the value of this property after creating the object.
`StepSize`	LMS step size parameter, a nonnegative real number
`LeakageFactor`	LMS leakage factor, a real number between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, while a value of 0 corresponds to a memoryless update algorithm.

Examples

Configuring Linear Equalizers

This example configures the recommended `comm.LinearEqualizer` System object™ and the legacy `lineareq` feature with comparable settings.

Initialize Variables and Supporting Objects

```
d = randi([0 3],1000,1);
x = pskmod(d,4,pi/4);
r = awgn(x,25);
sps = 2; %samples per symbol for oversampled cases
nTaps = 6;
txFilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',nTaps, ...
    'OutputSamplesPerSymbol',4);
rxFilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',nTaps, ...
    'InputSamplesPerSymbol',4,'DecimationFactor',2);
x2 = txFilter(x);
r2 = rxFilter(awgn(x2,25,0.5));
filterDelay = txFilter.FilterSpanInSymbols/2 + ...
    rxFilter.FilterSpanInSymbols/2; % Total filter delay in symbols
```

To compare the equalized output, plot the constellations using code such as:

```
% plot(yNew,'*')
% hold on
% plot(yOld,'o')
% hold off; legend('New Eq','Old Eq'); grid on
```

Use LMS Algorithm with Linear Equalizer

Configure `lineareq` and `comm.LinearEqualizer` objects with comparable settings. The `LeakageFactor` property has been removed from LMS algorithm. The `comm.LinearEqualizer` System object™ assumes that leakage factor is always 1.

```
eqOld = lineareq(5,lms(0.05),pskmod(0:3,4,pi/4))
```

```

  InputDelay: 0
  InputSamplesPerSymbol: 1
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers.

```
yOld = equalize(eqOld,r);
yNew = eqNew(r);
```

Use Linear Equalizers Considering Signal Delays

Configure `lineareq` and `comm.LinearEqualizer` objects with comparable settings. The transmit and receive filters result in a signal delay between the transit and receive signals. Account for this delay by setting the `RefTap` property of the `lineareq` to a value close to the delay value in samples. Additionally, `nWeights` must be set to a value greater than `RefTap`.

```
eqOld = lineareq(filterDelay*sps+4,lms(0.01),pskmod(0:3,4,pi/4),sps);
eqOld.RefTap = filterDelay*sps+1 % Adjust to synchronize with delayed signal
```

```
eqOld =
  EqType: 'Linear Equalizer'
  AlgType: 'LMS'
  nWeights: 16
  nSampPerSym: 2
  RefTap: 13
  SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  StepSize: 0.0100
  LeakageFactor: 1
  Weights: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
  WeightInputs: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
  ResetBeforeFiltering: 1
  NumSamplesProcessed: 0
```

```
eqNew = comm.LinearEqualizer('NumTaps',16,'Algorithm','LMS','StepSize',0.01, ...
    'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    'ReferenceTap',filterDelay*sps+1,'InputDelay',0)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'LMS'
  NumTaps: 16
  StepSize: 0.0100
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 13
  InputDelay: 0
  InputSamplesPerSymbol: 2
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers. When `ResetBeforeFiltering` is set to `true`, each call of the `equalize` object resets the equalizer. To get the equivalent behavior call `reset` after each call of the `comm.LinearEqualizer` object.

```
yOld1 = equalize(eqOld,r,x(1:100));
yOld2 = equalize(eqOld,r,x(1:100));

yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

In the `comm.LinearEqualizer` object, `InputDelay` is used to synchronize with the delayed signal. `NumTaps` and `ReferenceTap` are independent of delay value. We can reduce the number of taps by utilizing the `InputDelay` to synchronize instead of reference tap. Reducing the number of taps also reduces equalizer self noise.

```
eqNew = comm.LinearEqualizer('NumTaps',11,'Algorithm','LMS','StepSize',0.01, ...
    'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    'ReferenceTap',6,'InputDelay',filterDelay*sps)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'LMS'
  NumTaps: 11
  StepSize: 0.0100
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 6
  InputDelay: 12
  InputSamplesPerSymbol: 2
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

```
yNew1 = eqNew(r2,x(1:100));
reset(eqNew)
yNew2 = eqNew(r2,x(1:100));
```

Algorithms

Referring to the schematics presented in “Equalization”, define *w* as the vector of all weights w_i and define *u* as the vector of all inputs u_i. Based on the current set of weights, *w*, this adaptive algorithm creates the new set of weights given by

- `(LeakageFactor) w + (StepSize) u`*`sgn(Re(e))`, for sign LMS
- `(LeakageFactor) w + (StepSize) sgn(Re(u)) Re(e)`, for signed regressor LMS
- `(LeakageFactor) w + (StepSize) sgn(Re(u)) sgn(Re(e))`, for sign-sign LMS

where the * operator denotes the complex conjugate and `sgn` denotes the signum function (`sign` in MATLAB technical computing software).

Compatibility Considerations

`signlms` will be removed

Warns starting in R2020a

- signlms will be removed in a future release. Consider using `comm.LinearEqualizer` or `comm.DecisionFeedback` instead with the adaptive algorithm set to LMS.
- The `comm.LinearEqualizer` or `comm.DecisionFeedback` System objects do not have a leakage factor property. This is equivalent to setting `LeakageFactor` to `1` in the signlms function.
- For examples comparing setup of `comm.LinearEqualizer` to `lineareq`, see “Configuring Linear Equalizers” on page 2-772.

ssbdemod

Single sideband amplitude demodulation

Syntax

```
z = ssbdemod(y,Fc,Fs)
z = ssbdemod(y,Fc,Fs,ini_phase)
z = ssbdemod(y,Fc,Fs,ini_phase,num,den)
```

Description

For All Syntaxes

`z = ssbdemod(y,Fc,Fs)` demodulates the single sideband amplitude modulated signal `y` from the carrier signal having frequency `Fc` (Hz). The carrier signal and `y` have sampling rate `Fs` (Hz). The modulated signal has zero initial phase, and can be an upper- or lower-sideband signal. The demodulation process uses the lowpass filter specified by `[num,den] = butter(5,Fc*2/Fs)`.

Note The `Fc` and `Fs` arguments must satisfy `Fs` > 2(`Fc` + `BW`), where `BW` is the bandwidth of the original signal that was modulated.

`z = ssbdemod(y,Fc,Fs,ini_phase)` specifies the initial phase of the modulated signal in radians.

`z = ssbdemod(y,Fc,Fs,ini_phase,num,den)` specifies the numerator and denominator of the lowpass filter used in the demodulation.

Examples

Demodulate Sideband Signal

Define the sampling frequency and original signal.

```
fs = 270000;
t = (0:1/fs:0.01)';
signal = sin(2*pi*300.*t)+2*sin(2*pi*600.*t);
```

Convert the original signal to upper-sideband and lower-sideband modulated signals using `ssbmod`. Use a cutoff frequency of `12000` and an initial phase of `0`.

```
fc = 12000;
initialPhase = 0;
lowerSidebandSignal = ssbmod(signal,fc,fs,initialPhase);
upperSidebandSignal = ssbmod(signal,fc,fs,initialPhase,'upper');
```

Demodulate the lower and upper sideband signals.

```
s1 = ssbdemod(lowerSidebandSignal,fc,fs);
s2 = ssbdemod(upperSidebandSignal,fc,fs);
```

Compare processed signals with original and verify reconstruction.

```
plot(t,signal,'k',t,s1,'r:',t,s2,'g-.');
legend('Original Signal','Demodulation of Lower Sideband','Demodulation of Upper Sideband');
```

ssbmod

Single sideband amplitude modulation

Syntax

```
y = ssbmod(x,Fc,Fs)
y = ssbmod(x,Fc,Fs,ini_phase)
y = ssbmod(x,fc,fs,ini_phase,'upper')
```

Description

`y = ssbmod(x,Fc,Fs)` uses the message signal `x` to modulate a carrier signal with frequency `Fc` (Hz) using single sideband amplitude modulation in which the lower sideband is the desired sideband. The generated output `y` is a single side band signal with a suppressed carrier. The carrier signal and `x` have sample frequency `Fs` (Hz). The modulated signal has zero initial phase.

`y = ssbmod(x,Fc,Fs,ini_phase)` specifies the initial phase of the modulated signal in radians.

`y = ssbmod(x,fc,fs,ini_phase,'upper')` uses the upper sideband as the desired sideband.

Examples

Compare Double-Sideband and Single-Sideband Amplitude Modulation

Set the sample rate to 100 Hz. Create a time vector 100 seconds long.

```
fs = 100;
t = (0:1/fs:100)';
```

Set the carrier frequency to 10 Hz. Generate a sinusoidal signal.

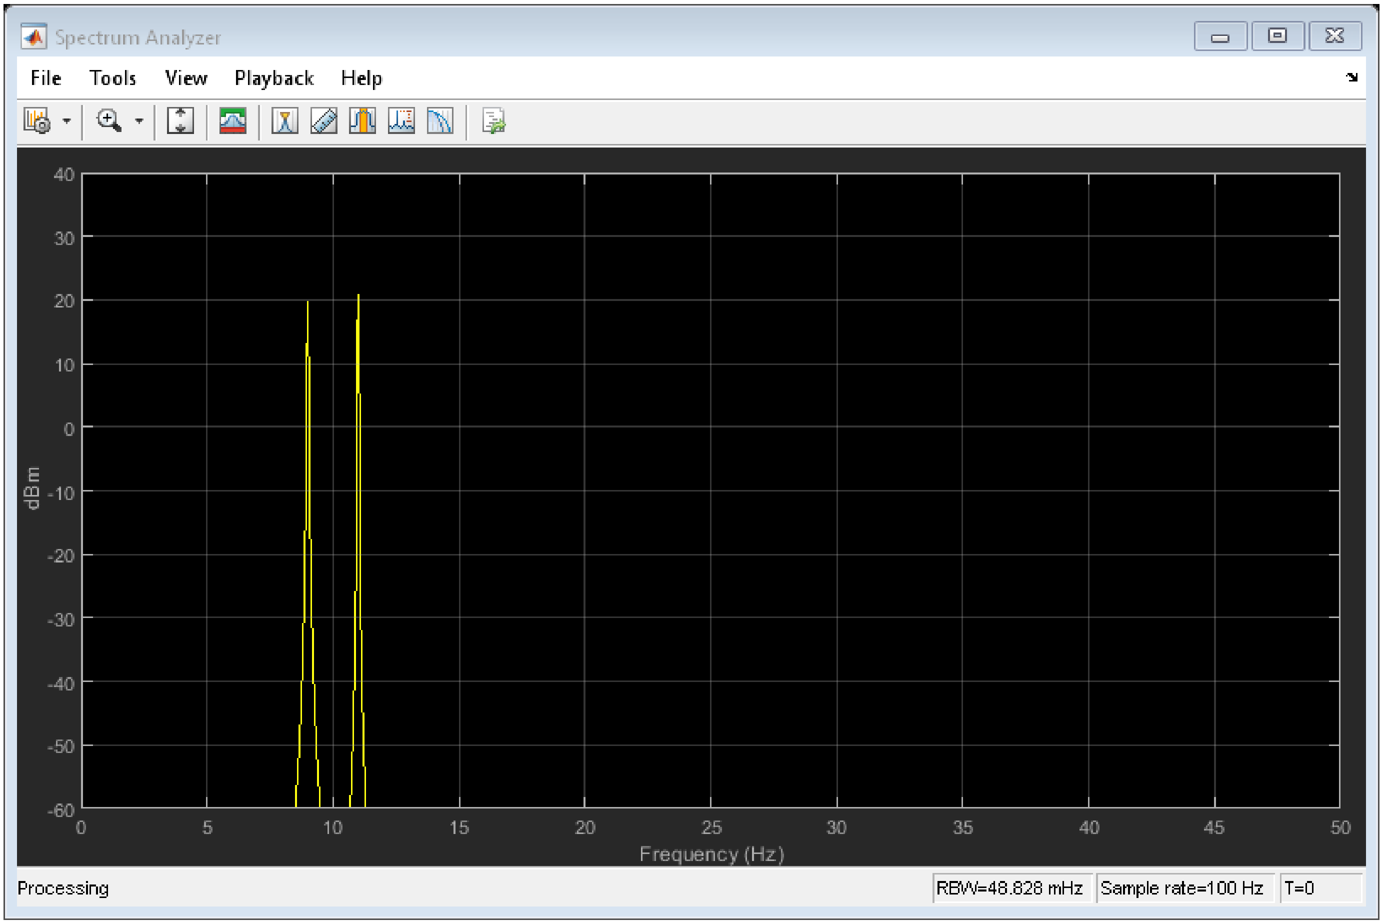
```
fc = 10;
x = sin(2*pi*t);
```

Modulate `x` using single- and double-sideband AM.

```
ydouble = ammod(x,fc,fs);
ysingle = ssbmod(x,fc,fs);
```

Create a spectrum analyzer object to plot the spectra of the two signals. Plot the spectrum of the double-sideband signal.

```
sa = dsp.SpectrumAnalyzer('SampleRate',fs, ...
    'PlotAsTwoSidedSpectrum',false, ...
    'YLimits',[-60 40]);
step(sa,ydouble)
```



Plot the single-sideband spectrum.

```
step(sa,ysingle)
```

stdchan

Construct channel System object from set of standardized channel models

Syntax

```
chan = stdchan(chantype,rs,fd)
```

Description

`chan = stdchan(chantype,rs,fd)` constructs a fading channel object `chan` according to the specified `chantype`. `chantype` is chosen from the channel models listed in “Supported Standards” on page 2-789. `rs` is the sampling rate of the input signal and `fd` is the maximum Doppler shift.

Examples

Filter Signal Through CDMA Channel

Set the sample rate and the maximum Doppler shift.

```
rs = 20e6;
fd = 3;
```

Create a CDMA Typical Urban channel model (TUx) channel object and turn on frequency response visualization.

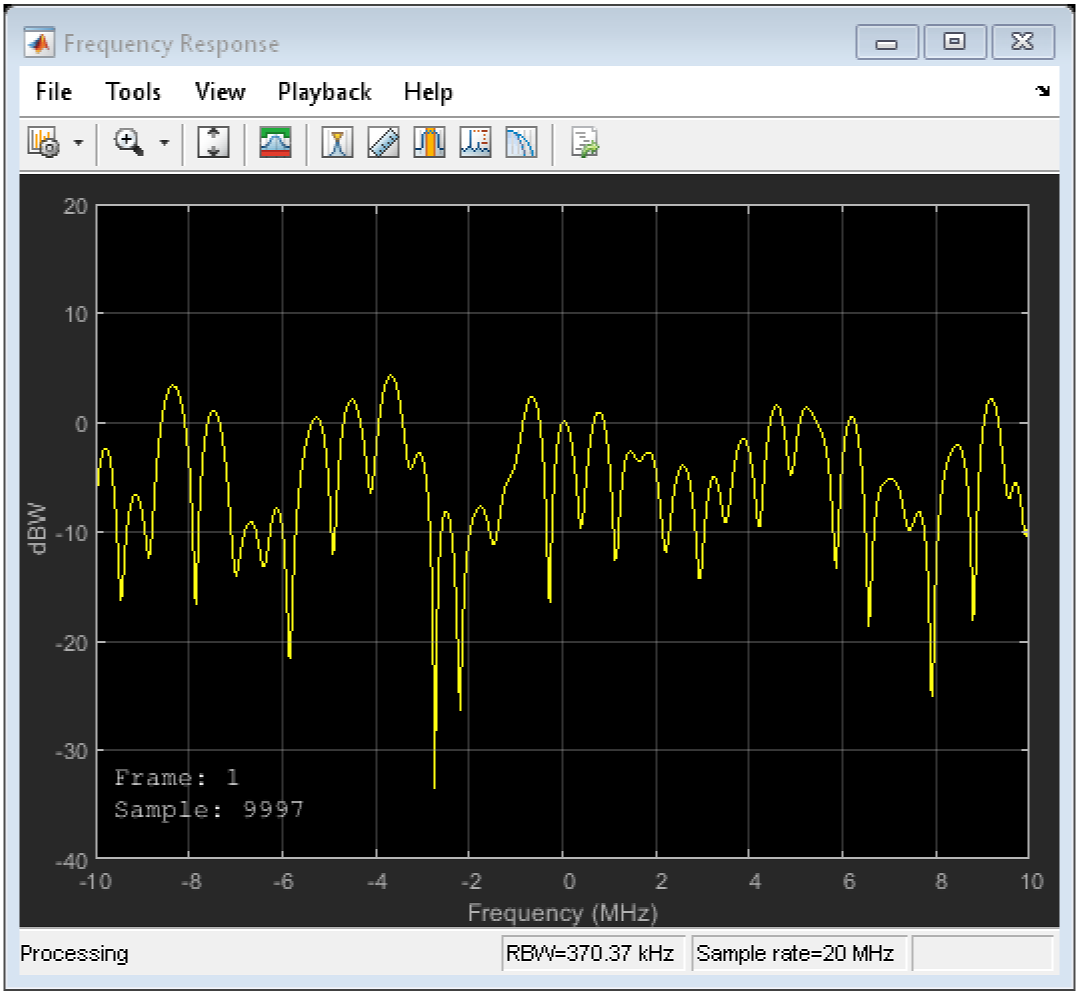
```
chan = stdchan('cdmaTUx',rs,fd);
chan.Visualization = 'Frequency response';
```

Generate random data and apply QPSK modulation.

```
data = randi([0 3],10000,1);
txSig = pskmod(data,4,pi/4);
```

Filter the QPSK signal through the CDMA channel.

```
y = chan(txSig);
```



GSM and EDGE Channel Model

Create a channel model useful for GSM and EDGE simulations. Experiment with low speed and high speed conditions.

Configure parameters and System objects

Frame configuration.

```
M = 8; % Modulation order, 8-PSK
Rbit = 9600; % Input bit rate
Rs = Rbit / log2(M); % Symbol rate
Nsamples = 5e2; % Number of samples per frame
Nframes = 10; % Number of frames
```

Speed and channel configuration.

```
v = 10 * 1e3/3600; % Mobile speed (m/s)
fc = 1800e6; % Carrier frequency
c = physconst('LightSpeed'); % Speed of light in free space
fd = v*fc/c; % Maximum Doppler shift of diffuse component
```

Create System objects for modulator and channel.

```
modulator  = comm.PSKModulator(M,'PhaseOffset',0);

channel = stdchan('gsmeqx6',Rs,fd);
channel.RandomStream = 'mt19937ar with seed'; % set for reproducibility
channel.Visualization = 'Impulse and frequency responses';
channel.SamplesToDisplay = '100%';

refC = constellation(modulator);
constDiagram = comm.ConstellationDiagram( ...
    'ReferenceConstellation',refC, ...
    'XLimits',[-3 3],'YLimits',[-3 3]);
```

Simulate at low speed

```
for iFrames = 1:Nframes
    msg = randi([0 M-1], Nsamples, 1);
    modSignal = modulator(msg);
    chanOut = channel(modSignal);
    constDiagram(chanOut);
end
```

Input Arguments

chantype — Channel type

string | character vector

Channel type, specified as a string or character vector. Valid options are listed in “Supported Standards” on page 2-789.

Example: `stdchan('gsmRAx6c1',rs,fd)`, configures a channel model for the GSM typical case for rural area (RAx), 6 taps, case 1, with a sample rate `rs`, and maximum Doppler shift `fd`

Data Types: `char` | `string`

rs — Sample rate

scalar

Sample rate in Hertz, specified as a scalar.

Data Types: `double`

fd — Maximum Doppler shift
scalar

Maximum Doppler shift in Hertz, specified as a scalar.

Data Types: `double`

Output Arguments

chan — Channel object
System object

Channel object, returned as a `comm.RayleighChannel` or `comm.RicianChannel` System object.

More About

Supported Standards

For GSM, CDMA, and ITU-R HF standards, call `stdchan` to return a `comm.RayleighChannel` or `comm.RicianChannel` System object modeling one of these profiles.

GSM/EDGE channel models (3GPP TS 45.005 V7.9.0 (2007-2), 3GPP TS 05.05 V8.20.0 (2005-11)):

Channel model	Profile
`gsmRAx6c1`	Typical case for rural area (RAx), 6 taps, case 1
`gsmRAx4c2`	Typical case for rural area (RAx), 4 taps, case 2
`gsmHTx12c1`	Typical case for hilly terrain (HTx), 12 taps, case 1
`gsmHTx12c2`	Typical case for hilly terrain (HTx), 12 taps, case 2
`gsmHTx6c1`	Typical case for hilly terrain (HTx), 6 taps, case 1
`gsmHTx6c2`	Typical case for hilly terrain (HTx), 6 taps, case 2
`gsmTUx12c1`	Typical case for urban area (TUx), 12 taps, case 1
`gsmTUx12c1`	Typical case for urban area (TUx), 12 taps, case 2
`gsmTUx6c1`	Typical case for urban area (TUx), 6 taps, case 1
`gsmTUx6c2`	Typical case for urban area (TUx), 6 taps, case 2
`gsmEQx6`	Profile for equalization test (EQx), 6 taps
`gsmTIx2`	Typical case for very small cells (TIx), 2 taps

CDMA channel models for deployment evaluation (3GPP TR 25.943 V6.0.0 (2004-12)):

Channel model	Profile
`cdmaTUx`	Typical Urban channel model (TUx)
`cdmaRAx`	Rural Area channel model (RAx)

Channel model	Profile
`cdmaHTx`	Hilly Terrain channel model (HTx)

ITU-R HF channel models (ITU-R F.1487 (2000)) (FD must be 1 to obtain the correct frequency spreads for these models.):

Channel model	Profile
`iturHFLQ`	Low latitudes, Quiet conditions
`iturHFLM`	Low latitudes, Moderate conditions
`iturHFLD`	Low latitudes, Disturbed conditions
`iturHFMQ`	Medium latitudes, Quiet conditions
`iturHFMM`	Medium latitudes, Moderate conditions
`iturHFMD`	Medium latitudes, Disturbed conditions
`iturHFMDV`	Medium latitudes, Disturbed conditions near vertical incidence
`iturHFHQ`	High latitudes, Quiet conditions
`iturHFHM`	High latitudes, Moderate conditions
`iturHFHD`	High latitudes, Disturbed conditions

Compatibility Considerations

`stdchan(ts,fd,channType)` syntax has been removed

stdchan`(ts,fd,channType)` syntax has been removed.

Compatibility considerations for the `stdchan` function includes addition of a function syntax, removal of a function syntax, and removal of configuration support for several channel models.

- The syntax `chan = stdchan(ts,fd,chantype)` has been removed. A System object is returned using the new syntax.
- `stdchan` has removed support for configuration of several channel models by supported standards and associated syntax, compatibility considerations are indicated here:

Standard	Previous Syntax	New Syntax to Return System Object	Notes
3GPP, CDMA	`stdchan(ts,fd,'3gppXXX')`	`stdchan('cdmaXXX',rs,fd)`	Prefix changed from '`3gpp`' to '`cdma`'. `ts` and `rs` are reciprocal values.
GSM	`stdchan(ts,fd,'gsmXXX')`	`stdchan('gsmXXX',rs,fd)`	`ts` and `rs` are reciprocal values.
ITU-R HF	`stdchan(ts,fd,'iturHFXXX')`	`stdchan('iturHFXXX',rs,fd)`	`ts` and `rs` are reciprocal values.

COST207	`stdchan(ts,fd,'cost207XXX')`	N/A	In the future `stdchan` will not configure these channels. Use `comm.RayleighChannel` or `comm.RicianChannel` to configure the channel models for COST207, ITU-R 3G, JTC, HIPERLAN/2, and 802.11a/b/g standards. For guidance mapping parameters, see “Rayleigh Channel Compatibility Considerations” and “Rician Channel Compatibility Considerations”.
ITU-R 3G	`stdchan(ts,fd,'itur3GXXX')`	N/A	
JTC	`stdchan(ts,fd,'jtcXXX')`	N/A	
HIPERLAN/2	`stdchan(ts,fd,'hiperlan2XXX')`	N/A	
802.11a/b/g	`stdchan(ts,fd,'802.11X')`	N/A

Introduced in R2007b

symerr

Compute number of symbol errors and symbol error rate

Syntax

```
[number,ratio] = symerr(x,y)
[number,ratio] = symerr(x,y,flg)
[number,ratio,loc] = symerr(...)
```

Description

`[number,ratio] = symerr(x,y)` compares the elements in `x` and `y`. The sizes of `x` and `y` determine which elements are compared. The output `number` is a scalar or vector that indicates the number of elements that differ. The output `ratio` equals `number` divided by the total number of elements in the *smaller* input.

`[number,ratio] = symerr(x,y,flg)` compares the elements in `x` and `y`. Optional input *`flg`* and the size of x, and y, determine the size of `number`.

`[number,ratio,loc] = symerr(...)` returns a binary matrix `loc` that indicates which elements of `x` and `y` differ. An element of `loc` is zero if the corresponding comparison yields no discrepancy, and one otherwise.

Examples

Compare Elements of Matrix

Compare Elements of Matrix with Another Matrix

```
x = [1,1,3,1;3,2,2,2;3,3,8,3]
```

```
x = 3×4

     1     1     3     1
     3     2     2     2
     3     3     8     3
```

```
aMatrix = [1,1,1,1;2,2,2,2;3,3,3,3]
```

```
aMatrix = 3×4

     1     1     1     1
     2     2     2     2
     3     3     3     3
```

```
[number1,ratio1] = symerr(x,aMatrix)
```

```
number1 = 3
```

```
ratio1 = 0.2500
```

Compare Elements of Matrix with Row Vector

```
x = [1,1,3,1;3,2,2,2;3,3,8,3]
```

```
x = 3×4

     1     1     3     1
     3     2     2     2
     3     3     8     3
```

```
aRowVector = [1,2,3,1]
```

```
aRowVector = 1×4

     1     2     3     1
```

```
[number2,ratio2] = symerr(x,aRowVector)
```

```
number2 = 3×1

     1
     3
     4
```

```
ratio2 = 3×1

    0.2500
    0.7500
    1.0000
```

Compare Elements of Matrix with Column Vector

```
x = [1,1,3,1;3,2,2,2;3,3,8,3]
```

```
x = 3×4

     1     1     3     1
     3     2     2     2
     3     3     8     3
```

```
aColumnVector = [1;2;3]
```

```
aColumnVector = 3×1

     1
     2
     3
```

```
[number3,ratio3] = symerr(x,aColumnVector)
```

```
number3 = 1×4

     1     0     2     0

ratio3 = 1×4

    0.3333         0    0.6667         0
```

Use Alternative Type of Comparison

You can specify alternative comparison methods used by `symerr`. In this example, you use a flag to override the default row-by-row comparison. Notice that number and ratio are scalars.

```
format rat;
[number,ratio,loc] = symerr([1 2; 3 4],[1 3],'overall')
```

```
number =
       3

ratio =
       3/4

loc =
       0              1
       1              1
```

Input Arguments

x — First input to compare

scalar | vector | matrix

First input to compare, specified as a vector, or a matrix.

Data Types: `double`

y — Second input to compare

scalar | vector | matrix

Second input to compare, specified as a vector, or a matrix.

Data Types: `double`

`flg` — Element comparison type

`'overall'` | `'column-wise'` | `'row-wise'`

Optional argument to override the defaults that govern which elements `symerr` compares and how `symerr` computes the outputs.

- `'overall'` -- `x` and `y` are compared element by element.

- `'column-wise'` -- m^{th} row of `x` vs. m^{th} row of `y`.
- `'row-wise'` -- m^{th} column of `x` vs. m^{th} column of `y`.

See “Specifying Element Comparison” on page 2-796 for more information

Output Arguments

`number` — Number of differing elements

scalar | vector

Number of elements that differ between `x` and `y`, returned as a scalar or vector. The size of `number` is determined by the optional input *`flg`* and by the dimensions of `x` and `y`. See “Default Element Comparison” on page 2-795 and “Specifying Element Comparison” on page 2-796 for more information.

`ratio` — Ratio of differing elements

scalar

The ratio of the number of differing elements, `number`, and the total number of elements of the *smaller* input, returned as a scalar.

`loc` — Location of errors

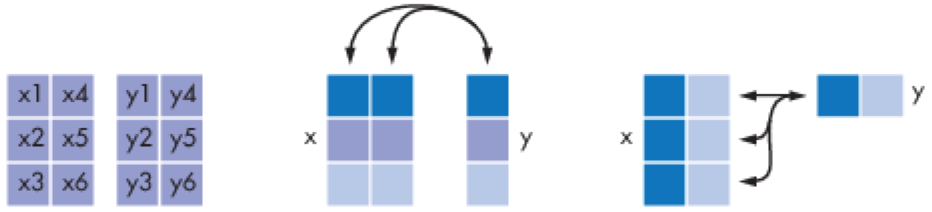
scalar | vector | matrix

Logical array of same size and dimensions as `x`, and `y`, with corresponding locations of errors between inputs `x` and `y`. An element of `loc` is zero if the corresponding comparison yields no discrepancy, and one otherwise.

More About

Default Element Comparison

The `symerr` function compares binary representations of elements in `x` with those in `y`. When optional argument *`flg`* is not specified, `symerr` uses the shape of the inputs `x` and `y` to determine the element comparison method. The schematics below illustrate how the shapes of `x` and `y` determine which elements `symerr` compares:



(a) Compares x1 with y1, x2 with y2, and so on.

(b) Compares column vector y with each column of matrix x

(c) Compares row vector y with each row of matrix x

- If `x` and `y` are matrices of the same dimensions, then `symerr` compares `x` and `y` element by element. `number` is a scalar. See schematic (a) in the figure.
- If one is a row (respectively, column) vector and the other is a two-dimensional matrix, then `symerr` compares the vector element by element with *each row (resp., column)* of the matrix. The length of the vector must equal the number of columns (resp., rows) in the matrix. `number` is a

column (resp., row) vector whose mth entry indicates the number of elements that differ when comparing the vector with the mth row (resp., column) of the matrix. See schematics (b) and (c) in the figure.

Specifying Element Comparison

Use *flg* to override the defaults that govern which elements `symerr` compares and how `symerr` computes the outputs. The values of *flg* are `'overall'`, `'column-wise'`, and `'row-wise'`. The table below describes the differences that result from various combinations of inputs. In all cases, `ratio` is `number` divided by the total number of elements in `y`.

Comparing a Two-Dimensional Matrix x with Another Input y

Shape of y	*flg*	Type of Comparison	number
Two-dim. matrix	`'overall'` (default)	Element by element	Total number of symbol errors
	`'column-wise'`	m^{th} column of `x` vs. m^{th} column of `y`	Row vector whose entries count symbol errors in each column
	`'row-wise'`	m^{th} row of `x` vs. m^{th} row of `y`	Column vector whose entries count symbol errors in each row
Column vector	`'overall'`	`y` vs. each column of `x`	Total number of symbol errors
	`'column-wise'` (default)	`y` vs. each column of `x`	Row vector whose entries count symbol errors in each column of `x`
Row vector	`'overall'`	`y` vs. each row of `x`	Total number of symbol errors
	`'row-wise'` (default)	`y` vs. each row of `x`	Column vector whose entries count symbol errors in each row of `x`

syndtable

Produce syndrome decoding table

Syntax

```
t = syndtable(h)
```

Description

`t = syndtable(h)` returns a decoding table for an error-correcting binary code having codeword length n and message length k. `h` is an (n-k)-by-n parity-check matrix for the code. `t` is a 2^{n-k}-by-n binary matrix. The rth row of `t` is an error pattern for a received binary codeword whose syndrome has decimal integer value r-1. (The syndrome of a received codeword is its product with the transpose of the parity-check matrix.) In other words, the rows of `t` represent the coset leaders from the code's standard array.

When converting between binary and decimal values, the leftmost column is interpreted as the *most* significant digit. This differs from the default convention in the `bi2de` and `de2bi` commands.

Examples

An example is in “Decoding Table”.

testconsole.Results

(To be removed) Gets results from test console simulations

Compatibility

testconsole.Results will be removed in a future release. Use `comm.ErrorRate` or `bertool` instead. For more information, see “Compatibility Considerations” on page 2-812.

Description

The getResults method of the Error Rate Test Console returns an instance of a testconsole.Results object containing simulation results data. You use methods of the results object to retrieve and plot simulations results data.

Properties

A testconsole.Results object has the properties shown in the following table. All properties are writable except for the ones explicitly noted otherwise.

Property	Description
TestConsoleName	Error Rate Test Console. This property is not writable.
System Under Test Name	Name of the system under test for which the Error Rate Test Console obtained results. This property is not writable.
IterationMode	Iteration mode the Error Rate Test Console used for obtaining results. This property is not writable.
TestPoint	Specify the name of the registered test point for which the results object parses results. The getData, plot, and semilogy methods of the Results object return data or create a plot for the test point that the TestPoint property specifies.
Metric	Specify the name of the test metric for which the results object parses results. The getData, plot, and semilogy methods of the Results object returns data or creates a plot for the metric that the Metric property specifies.
TestParameter1	Specifies the name of the first independent variable for which the results object parses results.
TestParameter2	Specifies the name of the second independent variable for which the results object parses results.

Methods

A testconsole.Results object has the following methods.

getData

`d = getData(r)` returns results data matrix, *d*, available in the results object *r*. The returned results correspond to the test point currently specified in the `TestPoint` property of *r*, and to the test metric currently specified in the `Metric` property of *r*.

If `IterationMode` is 'Combinatorial' then *d* is a matrix containing results for all the sweep values available in the test parameters specified in the `TestParameter1` and `TestParameter2` properties. The rows of the matrix correspond to results for all the sweep values available in `TestParameter1`. The columns of the matrix correspond to results for all sweep values available in `TestParameter2`. If more than two test parameters are registered to the Error Rate Test Console, *d* contains results corresponding to the first value in the sweep vector of all parameters that are not `TestParameter1` or `TestParameter2`.

If `IterationMode` is 'Indexed', then *d* is a vector of results corresponding to each indexed combination of all the test parameter values registered to the Error Rate Test Console.

plot

`plot(r)` creates a plot for the results available in the results object r. The plot corresponds to the test point and test metric, specified by the `TestPoint` and `Metric` properties of *r*

If `IterationMode` is 'Combinatorial' then the plot contains a set of curves. The sweep values in TestParameter1 control the x-axis and the number of sweep values for TestParameter2 specifies how many curves the plot contains. If more than two test parameters are registered to the Error Rate Test Console, the curves correspond to results obtained with the first value in the sweep vector of all parameters that are not TestParameter1, or TestParameter2.

No plots are available when 'IterationMode' is 'Indexed'.

semilogy

`semilogy(...)` is the same as `plot(...)`, except that the Y-Axis uses a logarithmic (base 10) scale.

surf

surf(r) creates a 3-D, color, surface plot for the results available in the `results` object, r. The surface plot corresponds to following items:

- The test point you specify using the `TestPoint` property of the `results` object
- The test metric currently you specify in the `Metric` property of the `results` object

You can specify parameter/value pairs for the `results` object, which establishes additional properties of the surface plot.

When you select 'Combinatorial' for the IterationMode, the sweep values available in the test parameter you specify for the TestParameter1 property control the x-axis of the surface plot. The sweep values available in the test parameter you specify for the TestParameter2 property control the y-axis.

If more than two test parameters are registered to the test console, the surface plot corresponds to the results obtained with the parameter sweep values previously specified with the setParsingValues method of the results object.

You display the current parsing values by calling the getParsingValues method of the results object. The parsing values default to the first value in the sweep vector of each test parameter. By default, the surf method ignores the parsing values for any parameters currently set as TestParameter1 or TestParameter2.

No surface plots are available if the IterationMode is 'Indexed', when less than two registered test parameters exist, or TestParameter2 is set to 'None'.

setParsingValues

`setParsingValues(R,'ParameterName1', 'Value1', ... 'ParameterName2', 'Value2', ...)` sets the parsing values to the values you specify using the parameter-value pairs. Parameter name inputs must correspond to names of registered test parameters, and value inputs must correspond to a valid test parameter sweep value.

You use this method for specifying single sweep values for test parameters that differ from the values for TestParameter1 and TestParameter2. When you define this method, the `results` object returns the data values or plots corresponding to the sweep values you set for the setParsingValues method. The parsing values default to the first value in the sweep vector of each test parameter.

You display the current parsing values by calling the `getParsingValues` method of the results object. You may set parsing values for parameters in TestParameter1 and TestParameter2, but the results object ignores the values when getting data or returning plots.

Parsing values are irrelevant when `IterationMode` is 'Indexed'.

getParsingValues

`getParsingValues` displays the current parsing values for the Error Rate Test Console.

`s = getParsingValues(r)` returns a structure, s, with field names equal to the registered test parameter names and with values corresponding to the current parsing values.

Parsing values are irrelevant when IterationMode is 'Indexed'.

Examples

Error Rate Simulation Sweeps

The `commtest.ErrorRate` and `testconsole.Results` object packages will be removed in a future release. They can be used to perform parameter sweeps to analyze communication system performance. This example demonstrates a workflow that uses them and along with recommended alternate workflows.

Multiple Parameter Sweep and Parallel Run using commtest.ErrorRate

Obtain bit error rate and symbol error rate of an M-PSK system for different modulation orders and EbNo values. System under test is `commtest.MPSKSystem`.

```
% Create an M-ary PSK system
systemUnderTest = commtest.MPSKSystem;

% Instantiate an Error Rate Test Console and attach the system
errorRateTester = commtest.ErrorRate(systemUnderTest);
```

```
Warning: commtest.ErrorRate will be removed in the future. Use comm.ErrorRate or bertool instead
```

```
errorRateTester.SimulationLimitOption = 'Number of errors or transmissions';
errorRateTester.MaxNumTransmissions = 1e5;

% Set sweep values for simulation test parameters
setTestParameterSweepValues(errorRateTester,'M',2.^[1 2 3 4],'EbNo',(-5:10))

% Register a test point
registerTestPoint(errorRateTester,'MPSK_BER','TxInputBits','RxOutputBits')

% Get information about the simulation settings
info(errorRateTester)
```

```
Test console name:           commtest.ErrorRate
System under test name:      commtest.MPSKSystem
Available test inputs:       NumTransmissions, RandomIntegerSource
Registered test inputs:      NumTransmissions
Registered test parameters:  EbNo, M
Registered test probes:      RxOutputBits, RxOutputSymbols, TxInputBits, TxInputSymbols
Registered test points:      MPSK_BER
Metric calculator functions: @commtest.ErrorRate.defaultErrorCalculator
Test metrics:                ErrorCount, TransmissionCount, ErrorRate
```

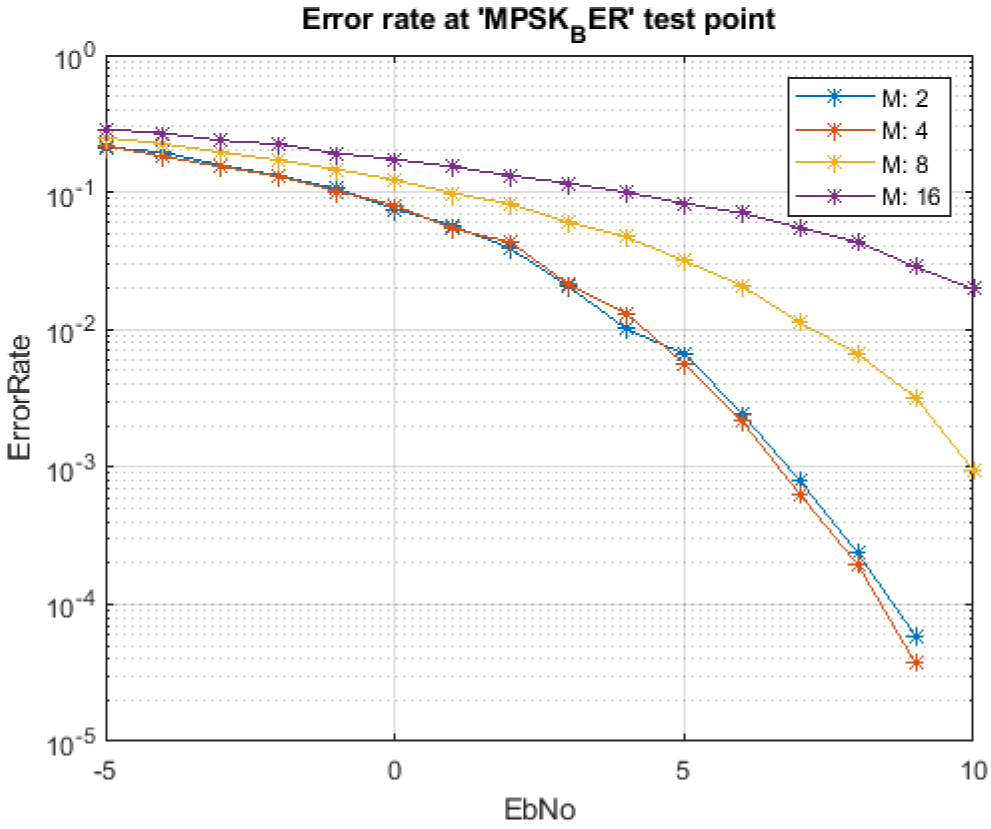
```
% Run the M-PSK simulations
run(errorRateTester)
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 12).
12 workers available for parallel computing. Simulations will be distributed among these workers
Running simulations...
```

```
% Get the results
mpskResults = getResults(errorRateTester);
```

```
Warning: testconsole.Results will be removed in the future. See <a href="matlab:helpview(fullfile
```

```
% Get a semi-log scale plot of EbNo versus bit error rate for
% different values of modulation order M
mpskResults.TestParameter2 = 'M';
semilogy(mpskResults,'*-')
```



Multiple Parameter Sweep and Parallel Run using nested for loops and comm.ErrorRate

Run an error rate simulation over M=2.^(1:4) and EbNo=-5:10. Use `comm.ErrorRate` to collect both bit error rate (BER) and symbol error rate (SER) data. Run the simulations to collect a minimum of 100 symbol errors or for a maximum of 1e5 symbols.

```
% Set the M sweep values same as the commtest.ErrorRate object
getTestParameterSweepValues(errorRateTester,'M')
```

```
ans = 1×4

     2     4     8    16
```

```
MSweep = 2.^[1 2 3 4];

% Set EbNo sweep values same as the commtest.ErrorRate object
getTestParameterSweepValues(errorRateTester,'EbNo')
```

```
ans = 1×16

    -5    -4    -3    -2    -1     0     1     2     3     4     5     6     7     8     9    10
```

```
EbNoSweep = -5:10;

% Set minumum number of errors same as the commtest.ErrorRate object
errorRateTester.MinNumErrors
```

```
ans = 100
```

```
minNumErrors = 100;

% Set maximum number of transmissions same as the commtest.ErrorRate
% object. In this example a transmission is a symbol.
errorRateTester.MaxNumTransmissions
```

```
ans = 100000
```

```
MaxNumTransmissions = 1e5;

% Set frame length same as the commtest.ErrorRate object
errorRateTester.FrameLength
```

```
ans = 500
```

```
frameLength = 500;

% Find out if there is a parallel pool and how many workers are available
[licensePCT,~] = license('checkout','distrib_computing_toolbox');
if (licensePCT && ~isempty(ver('parallel')))
    p = gcp;
    if isempty(p)
        numWorkers = 1;
    else
        numWorkers = p.NumWorkers
    end
else

end
legend(legendText)
```

Multiple Variable Sweeps using BERTool

`BERTool` computes the BER as a function of signal-to-noise ratio. It analyzes performance either with Monte-Carlo simulations of MATLAB® functions and Simulink® models or with theoretical closed-form expressions for selected types of communication systems. The `bertool` function opens the `BERTool`. Here `BERTool` is configured to call the simulation defined in the function `mpsksim` included below.

```
function [ber,numBits] = mpsksim(EbNo,minNumErrs,maxNumBits)
% Import the Java class for BERTool, so that you will be able to stop the simulation using the "S
import com.mathworks.toolbox.comm.BERTool;

frameLength = 500;

M = 16; % Can be 2, 4, 8, 16
bitsPerSymbol = log2(M);

maxNumSymbols = maxNumBits/bitsPerSymbol;

SNR = EbNo + 10*log10(bitsPerSymbol);

% Initialize variables related to exit criteria.
numBitErrors = 0;
numSymbols = 0;

while (numBitErrors < minNumErrs) || (numSymbols < maxNumSymbols)
```

```
  % Check if the user clicked the Stop button of BERTool.
  if (BERTool.getSimulationStop)
    break;
  end

  % Generate frameLength source outputs
  txMsg = randi([0 M-1],frameLength,1);
  numSymbols = numSymbols+frameLength;

  % Modulate the data
  txOutput = pskmod(txMsg,M,0,'gray');
  % Pass data through an AWGN channel with current SNR value
  chnlOutput  = awgn(txOutput,SNR,'measured',[],'dB');
  % Demodulate the data
  rxOutput = pskdemod(chnlOutput,M,0,'gray');

  % Convert symbol streams to bit streams
  bTx = de2bi(txMsg,bitsPerSymbol,'left-msb')';
  bTx = bTx(:);
  bRx = de2bi(rxOutput,bitsPerSymbol,'left-msb')';
  bRx = bRx(:);

  % Calculate number of bit errors
  numBitErrors = numBitErrors+sum(bTx~=bRx);
end

% Assign values to the output variables.
numBits = numSymbols*bitsPerSymbol;
ber = numBitErrors/numBits;
```

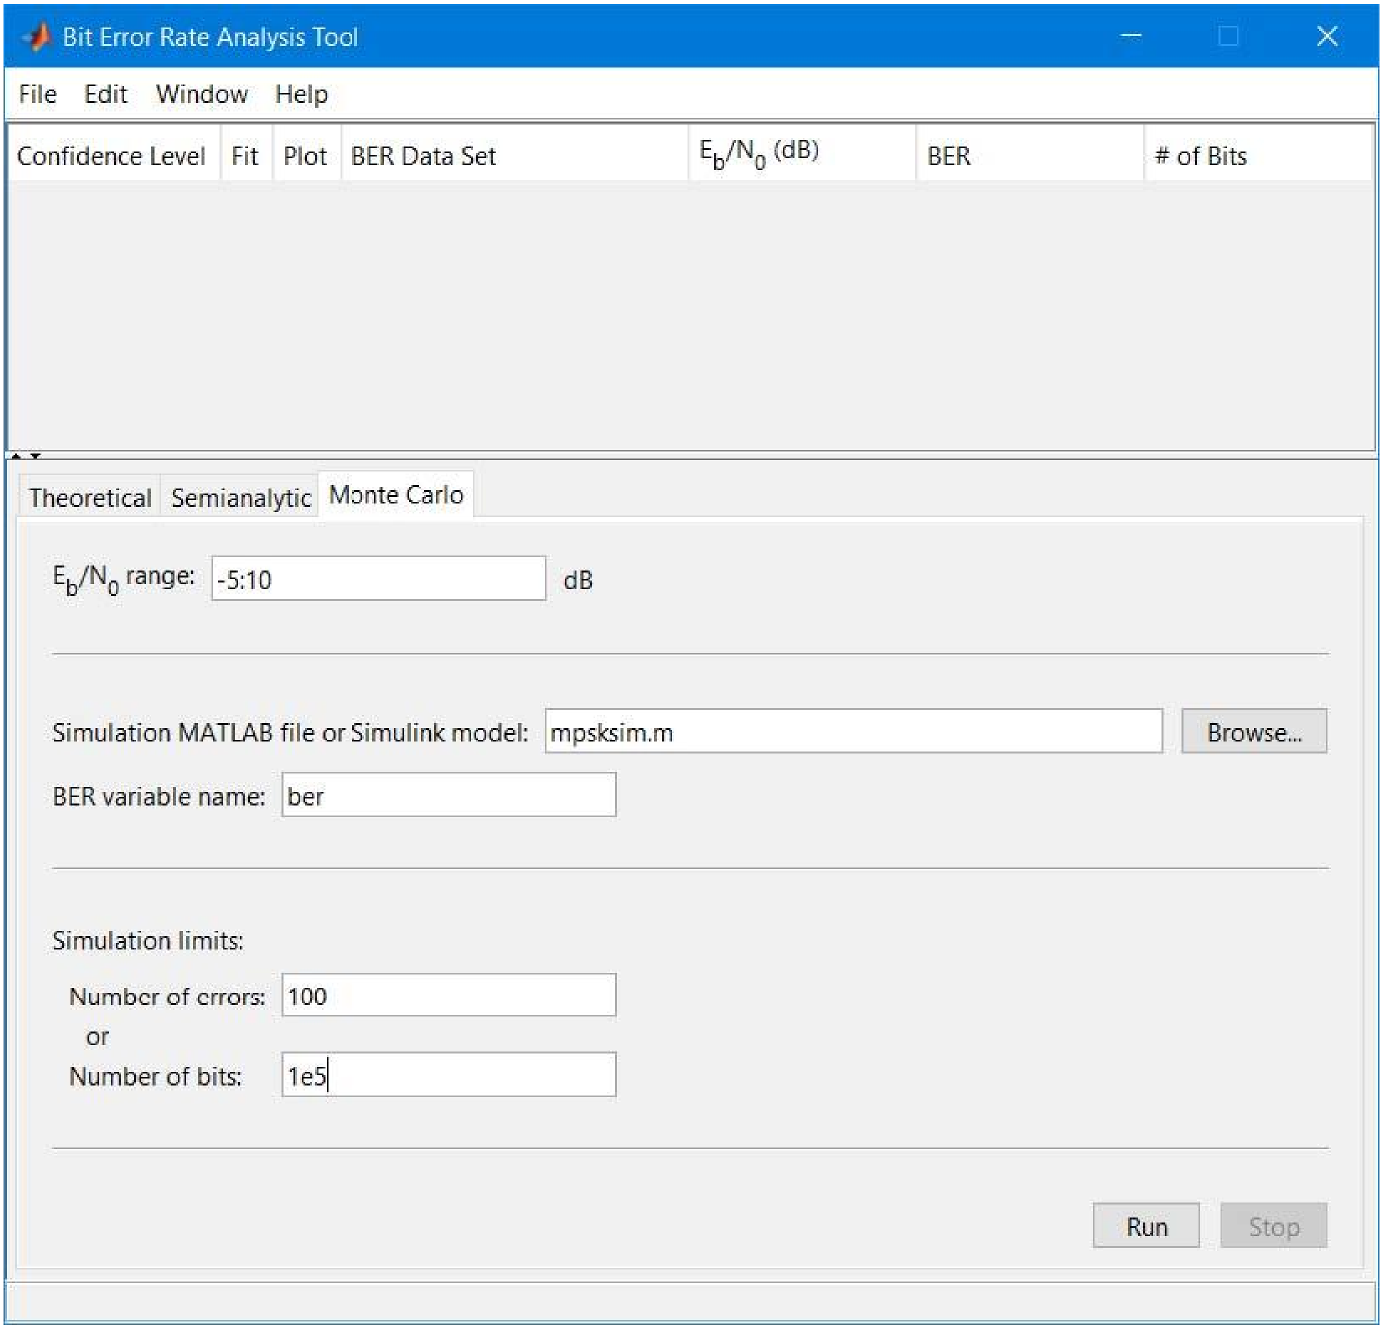
Configure `BERTool` as follows.



Bit Error Rate Analysis Tool

E_b/N_0 range: -5:10 dB

Simulation MATLAB file or Simulink model: mpsksim.m

BER variable name: ber

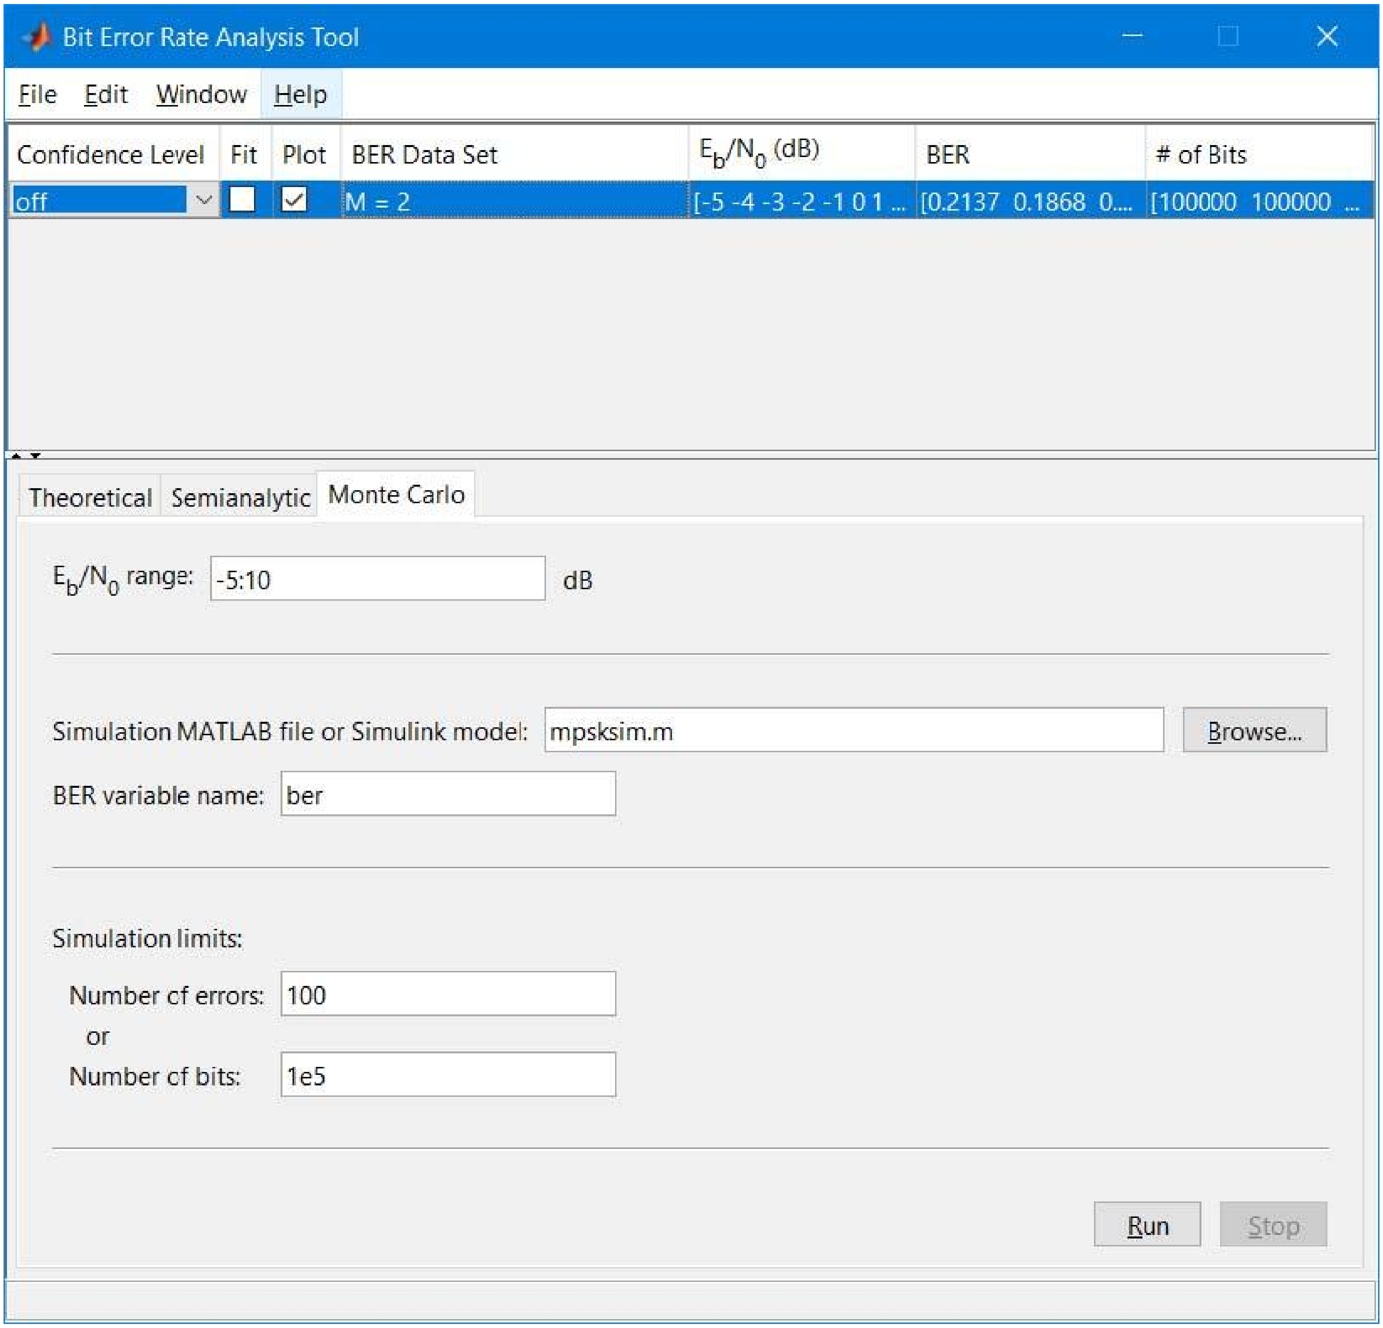
Simulation limits:

Number of errors: 100

or

Number of bits: 1e5

Set M=2 in the `mpsksim` function and click Run. Set the **BER Data Set** name to `'M=2'`.



Confidence Level	Fit	Plot	BER Data Set	E_b/N_0 (dB)	BER	# of Bits
off	□	☑	M = 2	[-5 -4 -3 -2 -1 0 1 ...	[0.2137 0.1868 0....	[100000 100000 ...

E_b/N_0 range: -5:10 dB

Simulation MATLAB file or Simulink model: mpsksim.m

BER variable name: ber

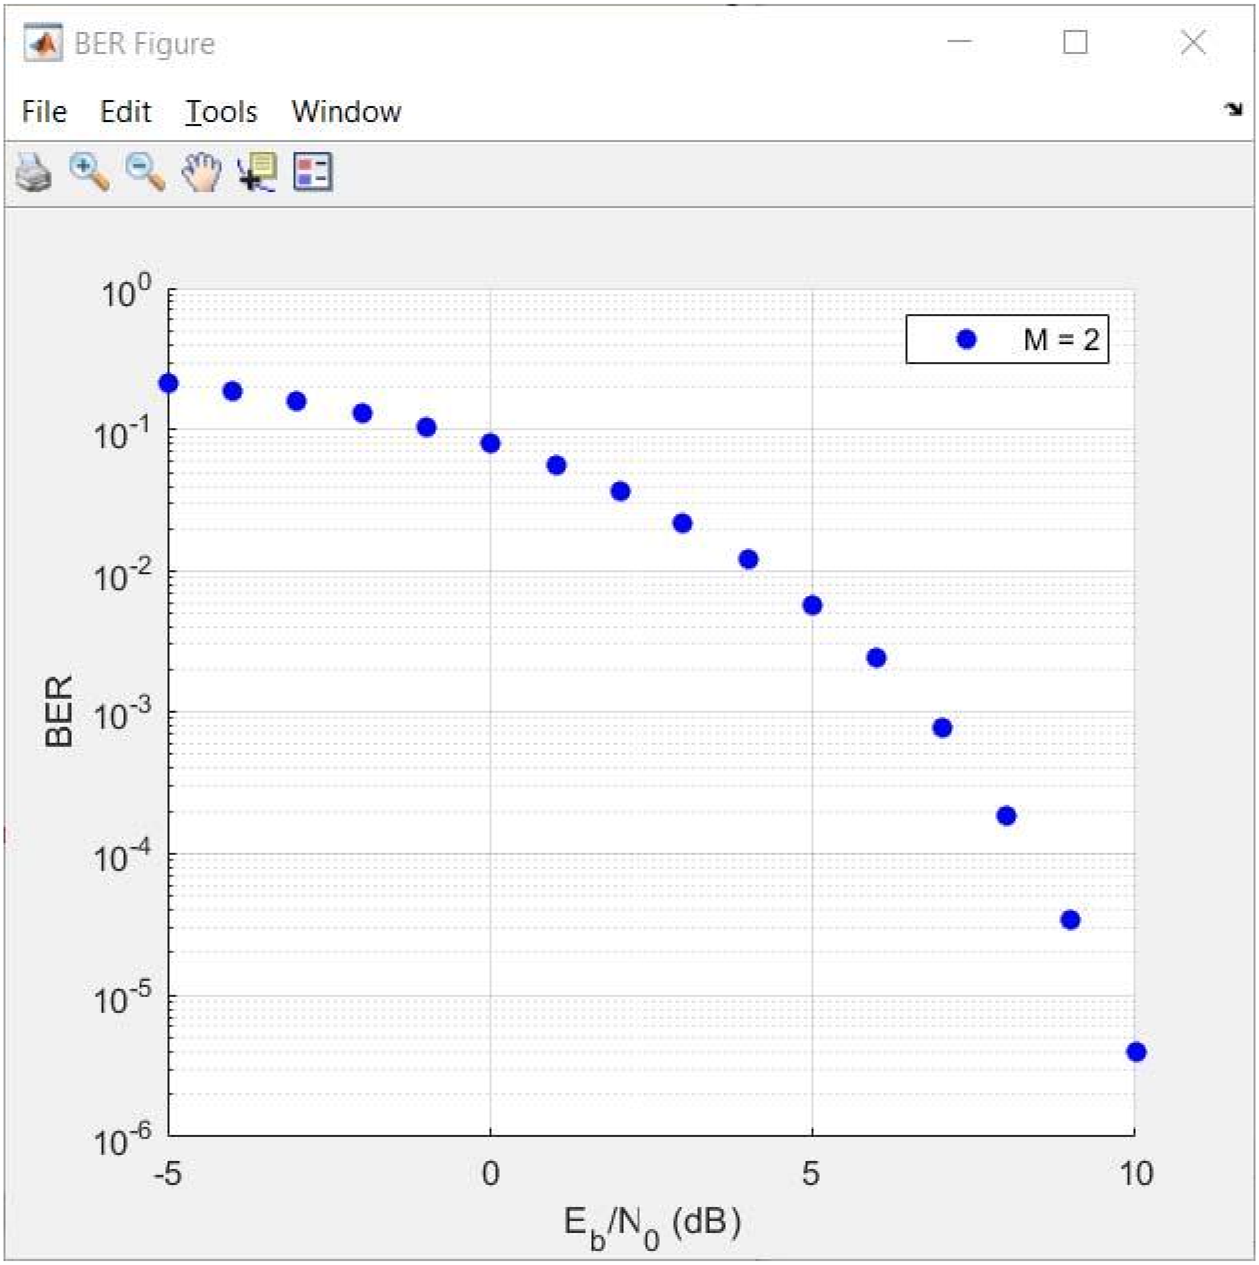
Simulation limits:

Number of errors: 100

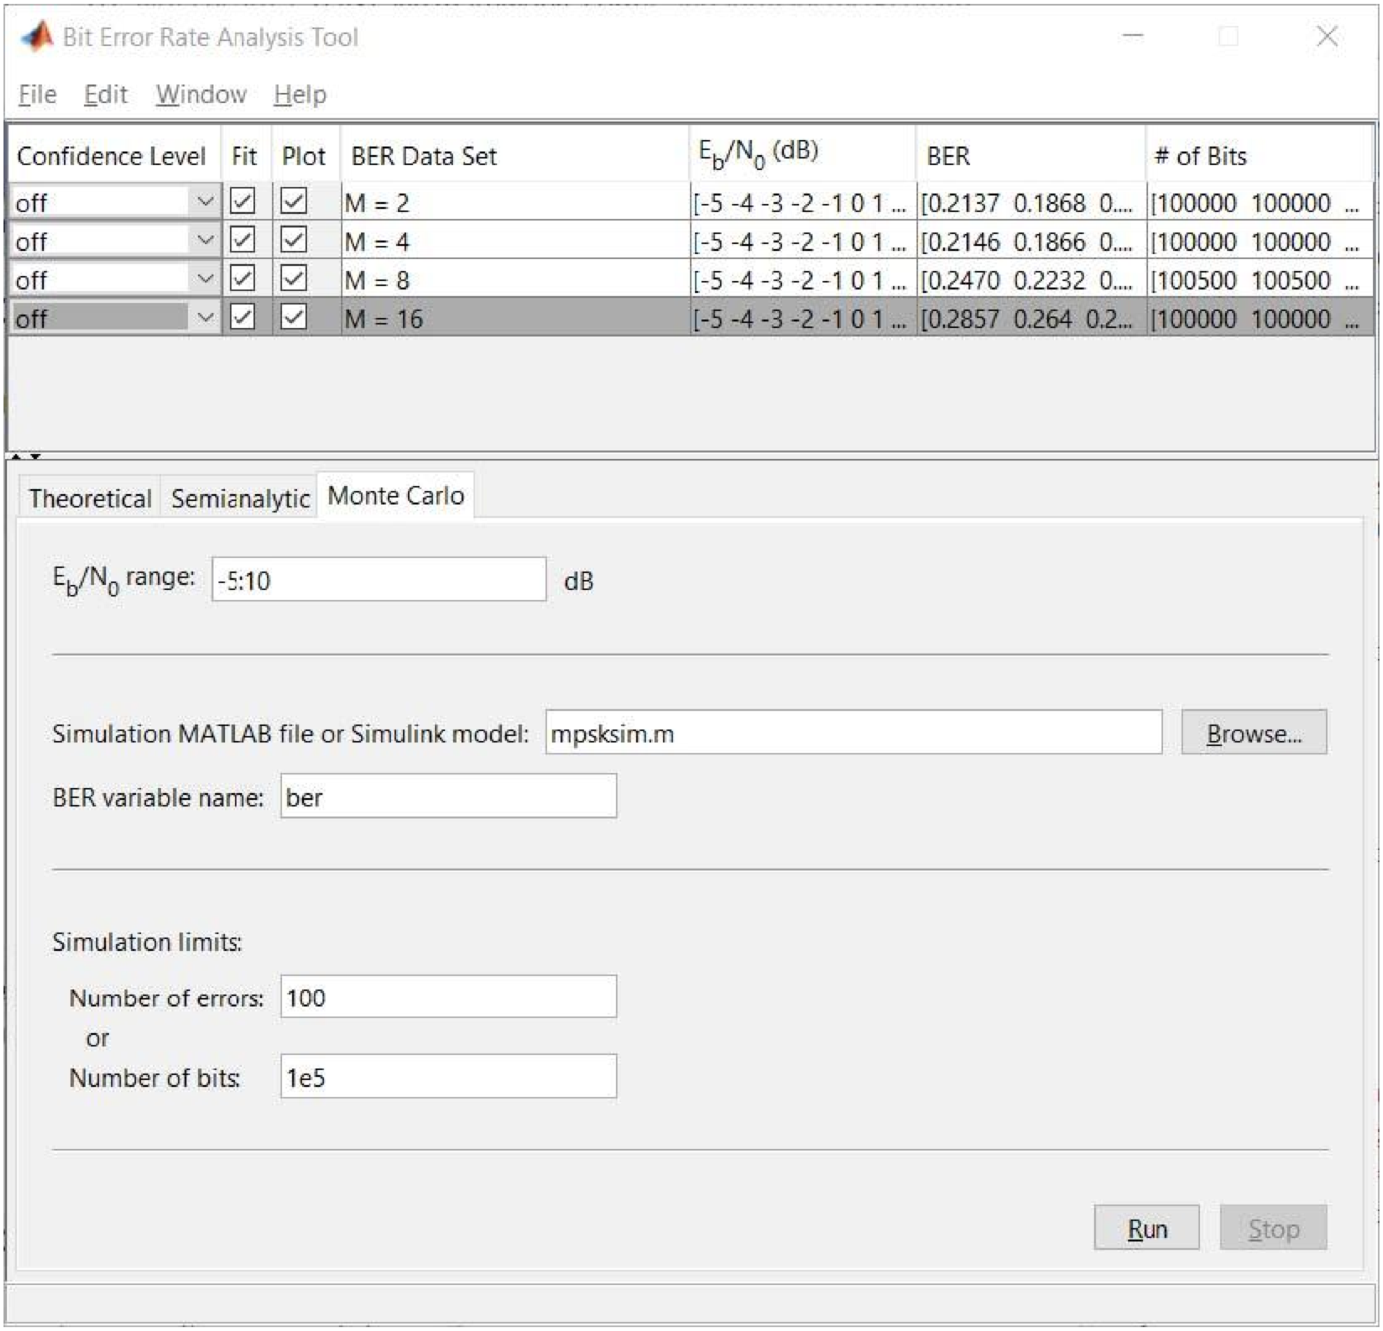
or

Number of bits: 1e5

Display the BER curve for M=2.



Update the value for `M` in the `mpsksim` function, repeating this process for `M = 4`, `8`, `16`. You will see results similar to those below in the **Bit Error Rate Analysis Tool** window and the **BER** figure.



Confidence Level	Fit	Plot	BER Data Set	E_b/N_0 (dB)	BER	# of Bits
off	☑	☑	M = 2	[-5 -4 -3 -2 -1 0 1 ...	[0.2137 0.1868 0....	[100000 100000 ...
off	☑	☑	M = 4	[-5 -4 -3 -2 -1 0 1 ...	[0.2146 0.1866 0....	[100000 100000 ...
off	☑	☑	M = 8	[-5 -4 -3 -2 -1 0 1 ...	[0.2470 0.2232 0....	[100500 100500 ...
off	☑	☑	M = 16	[-5 -4 -3 -2 -1 0 1 ...	[0.2857 0.264 0.2...	[100000 100000 ...

E_b/N_0 range: -5:10 dB

Simulation MATLAB file or Simulink model: mpsksim.m

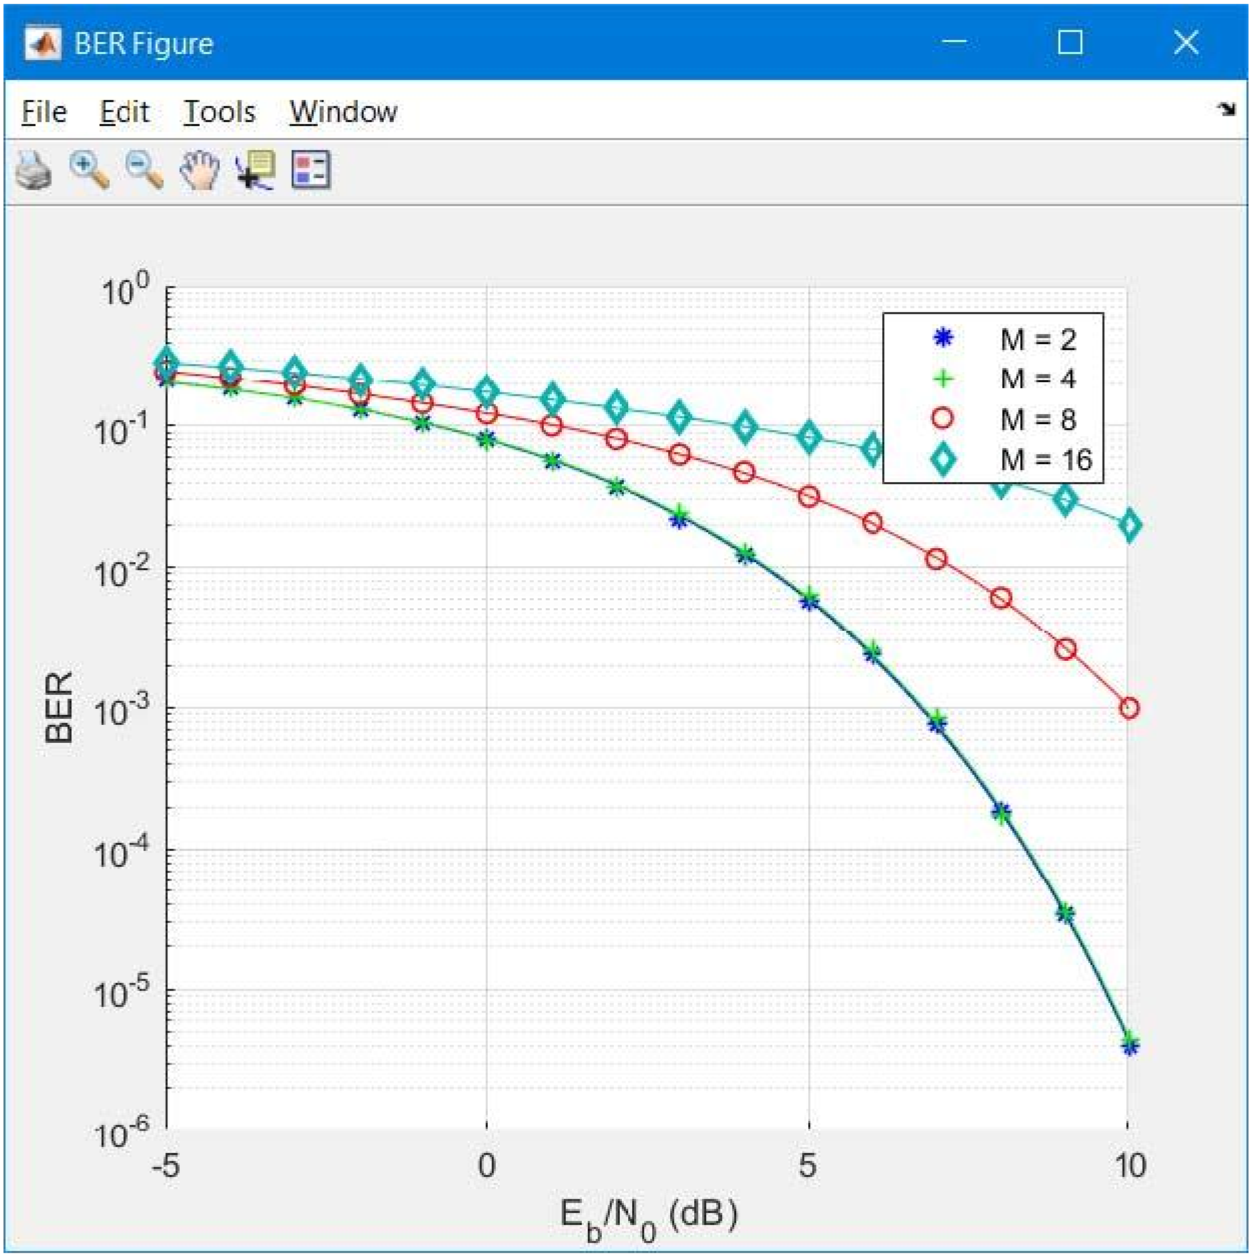
BER variable name: ber

Simulation limits:

Number of errors: 100

or

Number of bits: 1e5



Parallel SNR Sweep using BERTool

Using `parfor`, run each simulation point in parallel by configuring your simulation function similar to the `mpsksim_parfor` function included below. Since `parfor` cannot work with the Java class for `BERTool`, you will not be able to stop the simulation using the **Stop** button.

```
function [ber,numBits] = mpsksim_parfor(EbNo,minNumErrs,maxNumBits)

% Find out if there is a parallel pool and how many workers are available
if license('test','Distrib_Computing_Toolbox')
  p = gcp;
  if isempty(p)
    numWorkers = 1;
  else
    numWorkers = p.NumWorkers;
  end
else
  numWorkers = 1;
end

M = 2;
bitsPerSymbol = log2(M);

maxNumSymbols = maxNumBits/bitsPerSymbol;

minNumErrorsPerWorker = minNumErrs/numWorkers;
maxNumSymbolsPerWorker = maxNumSymbols/numWorkers;
frameLength = 500;

SNR = EbNo + 10*log10(bitsPerSymbol);

% Initialize variables related to exit criteria.
numBitErrors = zeros(numWorkers,1);
numSymbols = zeros(numWorkers,1);

parfor worker = 1:numWorkers
  while (numBitErrors(worker) < minNumErrorsPerWorker) ...
      || (numSymbols(worker) < maxNumSymbolsPerWorker)

    % Generate frameLength source outputs
    txMsg = randi([0 M-1],frameLength,1);
    numSymbols(worker) = numSymbols(worker)+frameLength;

    % Modulate the data
    txOutput = pskmod(txMsg, M, 0, 'gray');
    % Pass data through an AWGN channel with current SNR value
    chnlOutput  = awgn(txOutput,SNR,'measured',[],'dB');
    % Demodulate the data
    rxOutput = pskdemod(chnlOutput,M,0,'gray');

    % Convert symbol streams to bit streams
    bTx = de2bi(txMsg,bitsPerSymbol,'left-msb')';
    bTx = bTx(:);
    bRx = de2bi(rxOutput,bitsPerSymbol,'left-msb')';
    bRx = bRx(:);

    % Calculate number of bit errors
    numBitErrors(worker) = numBitErrors(worker)+sum(bTx~=bRx);
  end
end

% Assign values to the output variables.
ber = sum(numBitErrors)/sum(numSymbols);
numBits = sum(numSymbols)*bitsPerSymbol;
```

Compatibility Considerations

`testconsole.Results` will be removed

Warns starting in R2019b

testconsole.Results will be removed in a future release. Use `comm.ErrorRate` or `bertool` instead. The “Error Rate Simulation Sweeps” on page 2-800 example demonstrates alternate workflows using `comm.ErrorRate` and `bertool`.

tpcdec

Turbo product code (TPC) decoder

Syntax

```
decoded = tpcdec(llr,N,K)
decoded = tpcdec(llr,N,K,S)
decoded = tpcdec(llr,N,K,S,maxnumiter)
decoded = tpcdec(llr,N,K,S,maxnumiter,earlyterm)
[decoded,actualnumiter] = tpcdec(___)
```

Description

`decoded = tpcdec(llr,N,K)` performs 2-D TPC decoding on input log likelihood ratios, `llr`, using two linear block codes specified by codeword length `N` and message length `K`. For a description of 2-D TPC decoding, see “Turbo Product Code Decoding” on page 2-819.

`decoded = tpcdec(llr,N,K,S)` performs 2-D TPC decoding on the shortened `llr` using a 2-D TPC decoder specified by codeword length (`N`–`K`+`S`) and message length `S`.

`decoded = tpcdec(llr,N,K,S,maxnumiter)` performs 2-D TPC decoding for `maxnumiter` iterations. To use `maxnumiter` with full-length messages, specify `S` as empty, [ ].

`decoded = tpcdec(llr,N,K,S,maxnumiter,earlyterm)` performs 2-D TPC decoding and terminates early if the calculated syndrome or parity-check of the component code evaluates to zero before `maxnumiter` decoding iterations. To use `maxnumiter` and `earlyterm` with full-length messages, specify `S` as empty, [ ].

`[decoded,actualnumiter] = tpcdec(___)`also returns the actual number of decoding iterations after performing 2-D TPC decoding using any of the prior syntaxes.

Examples

Decode Using Full-Length TPC Codes

Decode an approximate log-likelihood ratio output signal from 16-QAM demodulation.

Begin by encoding a random bit vector using 2-D turbo product coding (TPC) with extended Hamming codes and extended BCH codes.

Specify the (N,K) code pairs to use for TPC encoding.

```
N = [32;16];
K = [21;11];
```

Generate a column vector of random message bits and TPC-encode the message. Specify the message bits as a vector with length equal to the product of the elements in `K`.

```
msg = randi([0 1],prod(K),1);
code = tpcenc(msg,N,K);
```

Apply 16-QAM modulation. Add AWGN to the signal. Demodulate the signal, outputting approximate LLRs.

```
M = 16;
snr = 10;

txsig = qammod(code,M,'InputType','bit', ...
    'UnitAveragePower',true);

rxsig = awgn(txsig,snr,'measured');

llr = qamdemod(rxsig,M,'OutputType','approxllr', ...
    'UnitAveragePower',true,'NoiseVariance',10.^(-snr/10));
```

Perform TPC decoding using three iterations. Because the demodulator output is negative bipolar mapped and TPC decoder expects positive bipolar mapped input, the demodulated signal output must be negated at the decoder input. Check the number of bit errors in the decoded signal.

```
iterations = 3;
decoded = tpcdec(-llr,N,K,[],iterations);

numerr = biterr(msg,decoded)
```

```
numerr = 0
```

Decode Using Shortened TPC Codes

Decode a shortened TPC code. Apply QPSK modulation and output the approximate log-likelihood ratio signal obtained from QPSK demodulation.

Begin by encoding a random bit vector using 2-D turbo product coding (TPC) with extended Hamming codes and extended BCH codes.

Specify (N,K) code pairs and S for TPC encoding.

```
N = [32;32];
K = [21;26];
S = [19;24];
```

Generate a column vector of random message bits and TPC-encode the message. Specify the shortened message bits as a vector with length equal to the product of the elements in S.

```
msg = randi([0 1],prod(S),1);
code = tpcenc(msg,N,K,S);
```

Apply QPSK modulation. Add AWGN to the signal. Demodulate the signal and output approximate LLRs.

```
M = 4;
snr = 3;

txsig = qammod(code,M,'InputType','bit', ...
    'UnitAveragePower',true);

rxsig = awgn(txsig,snr,'measured');
```

```
llr = qamdemod(rxsig,M,'OutputType','approxllr', ...
    'UnitAveragePower',true,'NoiseVariance',10.^(-snr/10));
```

Perform TPC decoding using two iterations. Because the demodulator output is negative bipolar mapped and TPC decoder expects positive bipolar mapped input, the demodulated signal output must be negated at the decoder input. Check the bit error rate of the decoded signal.

```
iterations = 2;
decoded = tpcdec(-llr,N,K,S,iterations);

[~,ber] = biterr(msg,decoded)
```

```
ber = 0.0066
```

TPC Decoding with Shortening and Early Termination

Decode a shortened TPC code and specify early termination of decoding. Apply QPSK modulation and output the approximate log-likelihood ratio signal obtained from QPSK demodulation.

Begin by encoding a random bit vector using 2-D turbo product coding (TPC) with extended Hamming codes and extended BCH codes. Specify (N,K) code pairs and S for TPC encoding, and a maximum of 10 decoding iterations. Perform QPSK modulation on the signal.

```
n = [64; 32];
k = [51; 26];
s = [49; 24];
maxnumiter = 10;
M = 4;

msg = randi([0 1],prod(s),1);  % Random bits
code = tpcenc(msg,n,k,s);

txsig = qammod(code,M,'InputType','bit', ...
    'UnitAveragePower',true);
```

Add noise to the transmitted signal.

```
snr = 5;
rxsig = awgn(txsig,snr,'measured');
```

Demodulate the received signal using approximate LLR demapping.

```
llr = qamdemod(rxsig,M,'OutputType', ...
    'approxllr','UnitAveragePower',true, ...
    'NoiseVariance',10.^(-snr/10));
```

Specify the maximum number of TPC decoding iterations and return the actual number of iterations performed. Early termination of the TPC decoding is on by default. Display the number of errors and the number of iterations performed.

```
[decoded,actualNumIter] = tpcdec(-llr,n,k,s,maxnumiter);
numErr = biterr(msg,decoded);
disp(['Terminated after ' num2str(actualNumIter) ' iterations.' ...
    ' Number of errors = ' num2str(numErr) '.']);
```

```
Terminated after 4 iterations. Number of errors = 0.
```

Input Arguments

`llr` — Log likelihood ratios

column vector

Log likelihood ratios, specified as a column vector.

- For full-length codes, the length of the input column vector is the product of the elements in `N`.
- For shortened codes, the length of the input column vector is the product of the elements in (`N`–`K`+`S`).

Data Types: `double` | `single`

`N` — Codeword length

two-element integer vector

Codeword length, specified as a two-element integer vector, [N_R; N_C]. N_R represents the number of rows in the product code matrix. N_C represents the number of columns in the product code matrix. For more information about N_R and N_C, see “Turbo Product Code Decoding” on page 2-819. For a list of valid ($N(i)$, $K(i)$) code pairs, see “More About” on page 2-818.

Data Types: `double`

`K` — Message length

two-element integer vector

Message length, specified as a two-element integer vector, [K_R; K_C]. For a full-length message, the input column vector containing the input LLRs is arranged into a K_R-by-K_C matrix. K_R represents the number of rows in the message matrix. K_C represents the number of columns in the message matrix. For more information about K_R and K_C, see “Turbo Product Code Decoding” on page 2-819. For a list of valid ($N(i)$, $K(i)$) code pairs, see “More About” on page 2-818.

Data Types: `double`

`S` — Shortened message length

two-element integer vector

Shortened message length, specified as a two-element integer vector, [S_R; S_C]. For a shortened message, the input column vector containing the input LLRs is arranged into an S_R-by-S_C matrix. S_R represents the number of rows in the matrix. S_C represents the number of columns in the matrix. For more information about S_R and S_C, see “Turbo Product Code Decoding” on page 2-819.

When you specify this parameter, specify N and K vectors for the full-length TPC codes that are shortened to ($N(i)$ – $K(i)$ + $S(i)$, $S(i)$) codes.

Data Types: `double`

`maxnumiter` — Maximum number of decoding iterations

4 (default) | positive integer

Maximum number of decoding iterations, specified as a positive integer.

Data Types: `double`

`earlyterm` — Enable early termination

`true` (default) | `false`

Enable early termination of decoding, specified as a logical. When `earlyterm` is `true` the decoding terminates early if the calculated syndrome or parity-check of the component code evaluates to zero before `maxnumiter` decoding iterations.

Data Types: `double`

Output Arguments

decoded — TPC decoded message

column vector

TPC decoded message, returned as a column vector.

- For full-length codes, the length of the returned column vector is the product of the elements in `K`.
- For shortened codes, the length of the returned column vector is the product of the elements in `S`.

Data Types: `logical`

`actualnumiter` — Actual number of decoding iterations

positive integer

Actual number of decoding iterations performed, returned as a positive integer.

Data Types: `double`

More About

Component Codes

This table lists the supported component code pairs for the row (N_R,K_R) and column (N_C,K_C) parameters.

- N_R and K_R represent the number of rows in the product code matrix and message matrix, respectively.
- N_C and K_C represent the number of columns in the product code matrix and message matrix, respectively.

Within each code type, any two component code pairs can form a 2-D TPC code. The table also includes the error-correction capability for each code pair.

Code type	**Component Code Pairs**(N_R,K_R) and (N_C,K_C)	**Error-Correction Capability (*T*)**
Hamming code	(255,247)	1
	(127,120)	1

Turbo Product Code Decoding

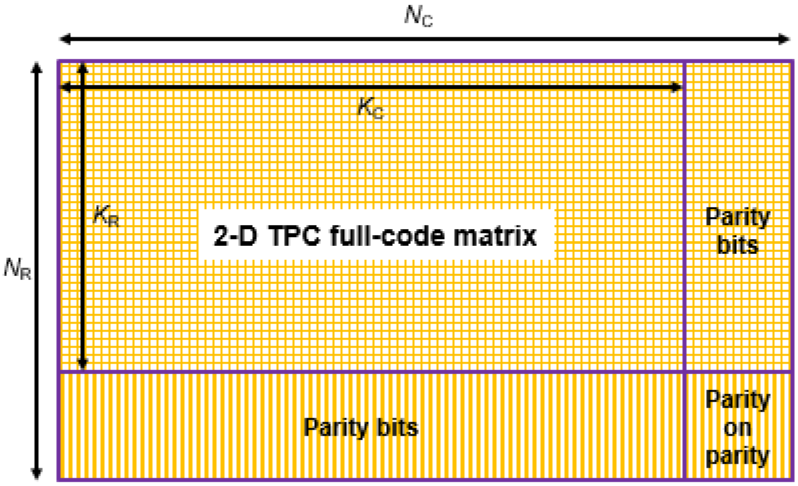
Turbo product codes (TPC) are a form of concatenated codes used as forward error correcting (FEC) codes. Two or more component block codes, such as systematic linear block codes, are used to construct TPCs. The TPC decoder achieves near-optimum decoding of product codes using Chase decoding and the Pyndiah algorithm to perform iterative soft input, soft output decoding. For a detailed description, see [1] and [2]. This decoder implements an iterative soft input, soft output 2-D product code decoding, as described in [2], using two “Linear Block Codes”. The decoder expects the soft bit log likelihood ratios (LLRs) obtained from digital demodulation as the input signal.

Note The TPC decoder expects a positive bipolar mapped input, specifically –1 mapped to 0 and +1 mapped to 1. The output from demodulators in the Communications Toolbox is negative bipolar mapping, specifically +1 mapped to 0 and –1 mapped to +1. Therefore, the LLR output from demodulators must be negated to provide the positive bipolar mapped input expected by the TPC decoder.

The TPC decoder decodes either full-length or shortened codes.

TPC Decoding Full-Length Messages

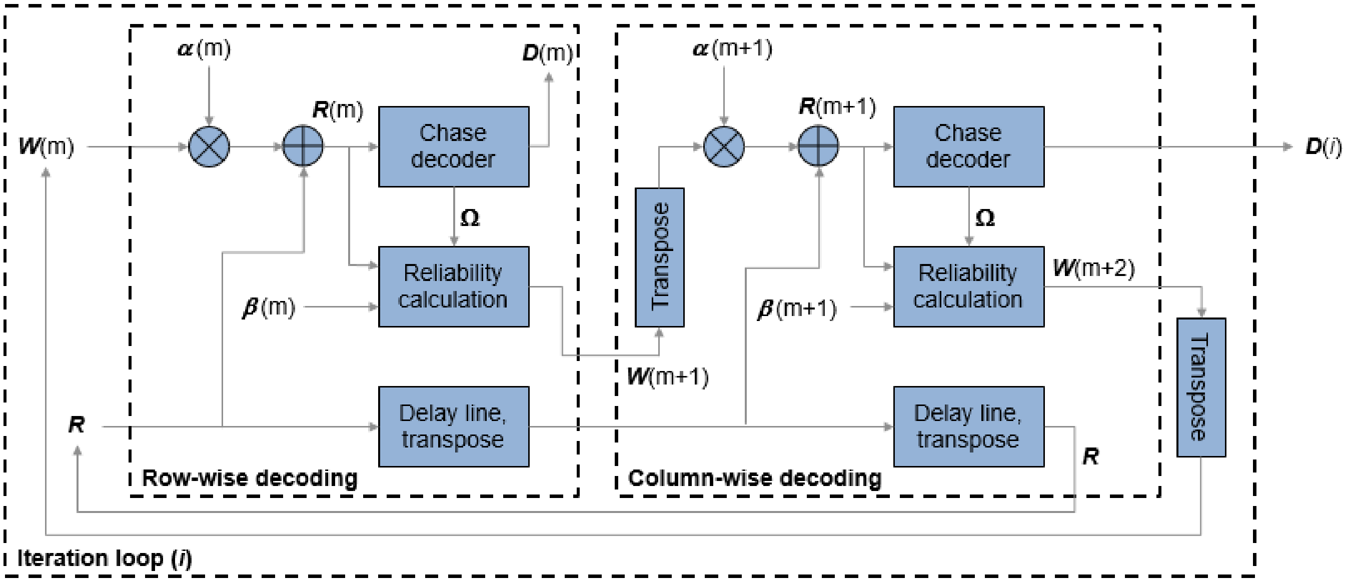
TPC encoded full-length input messages are decoded using specified 2-D TPC code pairs. Row-wise decoding uses the (N_C,K_C) code pair and column-wise decoding uses the (N_R,K_R) code pair. The input vector length must be $N_R \times N_C$. To perform the 2-D TPC decoding, the column vector of the input LLRs, composed of the message and parity bits, is arranged into an N_R-by-N_C matrix.



The TPC decoder achieves near-optimum decoding of product codes using Chase decoding and the Pyndiah algorithm to perform iterative soft input, soft output decoding. Chase decoding forms a set of possible codewords for each row or column. The Pyndiah algorithm calculates soft information required for the next decoding step.

Iterative Soft Input, Soft Output Decoder

The iterative soft input, soft output decoding, as shown in the block diagram, carries out two decoding steps for each iteration.



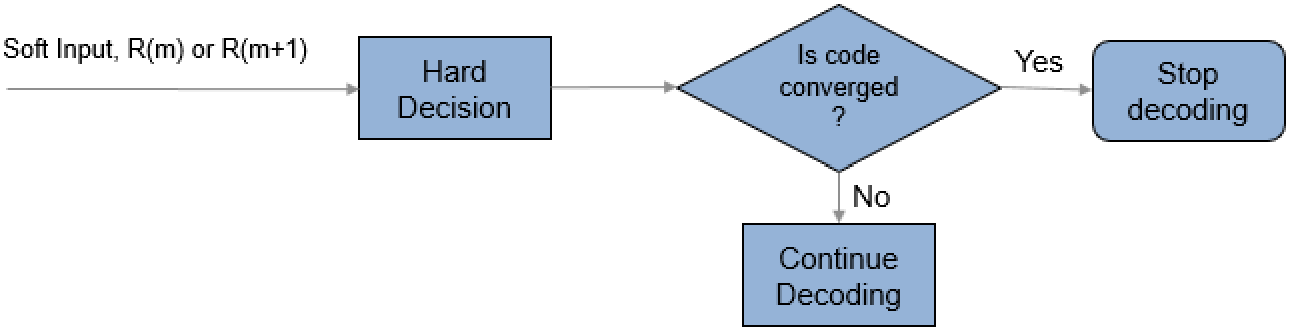
The soft inputs for decoding are $\boldsymbol{R}(m) = \boldsymbol{R} + \alpha(m)\boldsymbol{W}(m)$.

- Iteration loop counter i increments from $i = 1$ to the specified number of iterations.
- $m = 2i - 1$ is the decoding step index.
- $\boldsymbol{R}$ is the received LLR matrix.
- $\boldsymbol{R}(m)$ is the soft input for the mth decoding step.
- $\boldsymbol{W}(m)$ is the input extrinsic information for the mth decoding step.
- $\alpha(m) = [0,0.2,0.3,0.5,0.7,0.9,1,1, \ldots]$, where α is a weighting factor applied based on the decoding step index. For higher decoding steps, $\alpha = 1$.
- $\beta(m) = [0.2,0.4,0.6,0.8,1,1, \ldots]$, where β is a reliability factor applied based on the decoding step index. For higher decoding steps, $\beta = 1$.
- $\boldsymbol{D}$ contains the decoded message bits. The output message bits are formed from $\boldsymbol{D}$ by mapping –1 to 0 and +1 to 1, then reshaping the message block into a column vector.

The output message bits are formed after iterating through the specified number of iterations, or, if early termination is enabled, after code convergence.

Early Termination of TPC Decoding

If early termination is enabled, a code convergence check is performed on the hard decision of the soft input in each row-wise and column-wise decoding step. Early termination can be triggered after either the row-wise decoding or column-wise decoding converges.



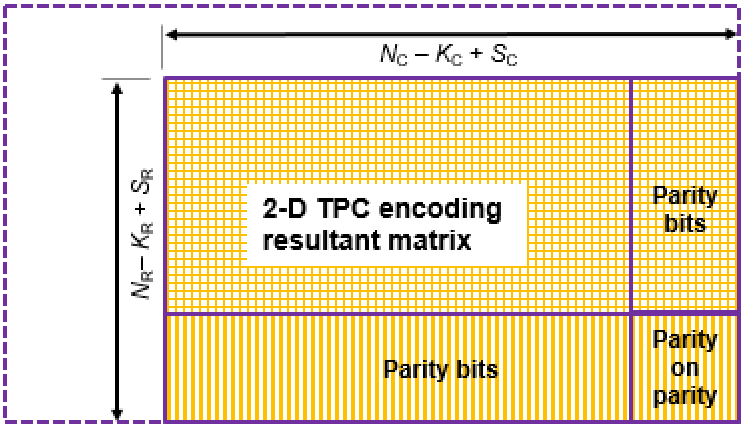
The code is converged if, for all rows or all columns,

- The syndrome evaluates to zero in the codes (Hamming codes, Extended Hamming codes, BCH codes, or Extended BCH codes).
- The parity check is evaluated to zero in parity check codes.

The reported number of iterations evaluates to the iteration value that is currently in progress. For example, if the code convergence check is satisfied after row-wise decoding in the third iteration (after 2.5 decoding steps), then the number of iteration returned is 3.

TPC Decoding Shortened Messages

TPC encoded shortened input messages are decoded using specified 2-D TPC code pairs. Row-wise decoding uses the $(N_C - K_C + S_C, S_C)$ code pair and column-wise decoding uses the $(N_R - K_R + S_R, S_R)$ code pair. The input vector length must be $(N_R - K_R + S_R) \times (N_C- K_C + S_C)$. To perform the 2-D TPC decoding of shortened messages, the column vector of the input LLRs, composed of the shortened message and parity bits, is arranged into an (N_R – K_R + S_R)-by-(N_C – K_C + S_C) matrix.



The TPC decoder processes the received shortened message LLRs similar to full length codes, with these exceptions:

- The shortened bit positions in the received codeword are set to –1.
- The Chase algorithm does not consider the shortened bit positions while choosing the least reliable bits.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- TPC parameters `N`, `K`, and `S` must be constant values. If the value used for each of these parameters does not change, then you can assign them by expression or variable.

Blocks

TPC Decoder

Introduced in R2018a

tpcenc

Turbo product code (TPC) encoder

Syntax

```
code = tpcenc(msg,N,K)
code = tpcenc(msg,N,K,S)
```

Description

`code = tpcenc(msg,N,K)` performs 2-D TPC encoding of the input message, `msg`, using two linear block codes specified by codeword length `N` and message length `K`. For a description of 2-D TPC encoding, see “Turbo Product Code Construction” on page 2-827.

`code = tpcenc(msg,N,K,S)` performs 2-D TPC encoding on the shortened input message of length `S`, using a 2-D TPC encoder specified by codeword length (`N`–`K`+`S`) and message length `S`.

Examples

Encode Using Full-Length TPC Codes

Encode a random bit vector using 2-D turbo product coding (TPC) with extended Hamming codes and extended BCH codes.

Specify (N,K) code pairs for TPC encoding.

```
N = [32;64];
K = [21;57];
```

Generate a column vector of random message bits. The desired length for the message bits is the product of elements in `K`.

```
msg = randi([0 1],prod(K),1);
```

TPC-encode the message.

```
code = tpcenc(msg,N,K);
```

Verify that the length of the encoded codeword is the product of elements in `N`.

```
size(code)
```

```
ans = 1×2

        2048           1
```

```
prod(N)
```

```
ans = 2048
```

Encode Shortened Message Using Turbo Product Coding

Encode a random bit vector using 2-D turbo product coding (TPC), applying message shortening.

Specify (N,K) code pairs and S for TPC encoding.

```
N = [32;64];
K = [21;57];
S = [19;24];
```

Generate a column vector of random message bits. The desired length for the shortened message bits is the product of the elements in S.

```
msg = randi([0 1],prod(S),1);
```

TPC-encode the shortened message.

```
code = tpcenc(msg,N,K,S);
```

Verify that the length of the encoded codeword is the product of elements in (N-K+S).

```
size(code)
```

```
ans = 1×2

   930     1

```

```
prod(N-K+S)
```

```
ans = 930
```

Input Arguments

msg — Input message bits to encode

column vector

Input message bits to encode, specified as a column vector.

- For a full-length input messages, the length of the column vector must be the product of the elements in K.
- For a shortened input messages, the length of the column vector must be the product of the elements in S.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | logical

N — Codeword length

two-element integer vector

Codeword length, specified as a two-element integer vector, [N_R; N_C]. N_R represents the number of rows in the product code matrix. N_C represents the number of columns in the product code matrix. For more information about N_R and N_C, see “Turbo Product Code Construction” on page 2-827. For a list of valid ($N(i)$,$K(i)$) code pairs, see “Component Codes” on page 2-826.

Data Types: `double`

K — Message length

two-element integer vector

Message length, specified as a two-element integer vector, [K_R; K_C]. For a full-length message, the input column vector containing the message bits to encode is arranged into a K_R-by-K_C matrix. K_R represents the number of rows in the message matrix. K_C represents the number of columns in the message matrix. For more information about K_R and K_C, see "Turbo Product Code Construction" on page 2-827. For a list of valid ($N(i)$,$K(i)$) code pairs, see "Component Codes" on page 2-826.

Data Types: `double`

S — Shortened message length

two-element integer vector

Shortened message length, specified as a two-element integer vector, [S_R; S_C]. For a shortened message, the input column vector containing the message bits to encode is arranged into an S_R-by-S_C matrix. S_R represents the number of rows in the matrix. S_C represents the number of columns in the matrix. For more information about S_R and S_C, see "Turbo Product Code Construction" on page 2-827.

When you specify this parameter, specify N and K vectors for the full-length TPC codes that are shortened to ($N(i)$–$K(i)$+$S(i)$, $S(i)$) codes.

Data Types: `double`

Output Arguments

code — TPC-encoded message

column vector

TPC-encoded message, returned as a column vector with the same data type as the input message bits.

- For full-length input messages, the length of the returned column vector is the product of the elements in `N`.
- For shortened input messages, the length of the returned column vector is the product of the elements in (`N–K+S`).

More About

Component Codes

This table lists the supported component code pairs for the row (N_R,K_R) and column (N_C,K_C) parameters.

- N_R and K_R represent the number of rows in the product code matrix and message matrix, respectively.
- N_C and K_C represent the number of columns in the product code matrix and message matrix, respectively.

Within each code type, any two component code pairs can form a 2-D TPC code. The table also includes the error-correction capability for each code pair.

Code type	**Component Code Pairs**(N_R,K_R) and (N_C,K_C)	**Error-Correction Capability (*T*)**

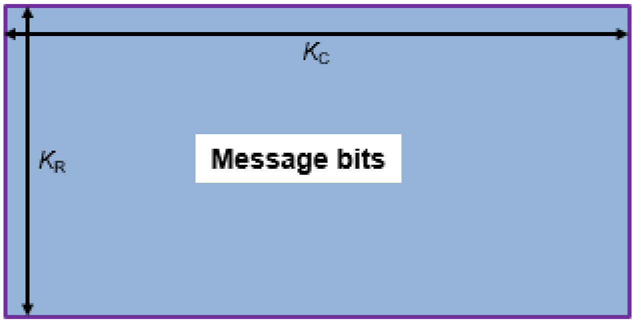
Turbo Product Code Construction

Turbo product codes (TPC) are a form of concatenated codes used as forward error-correcting (FEC) codes. Two or more component block codes, such as systematic linear block codes, are used to construct TPCs. This encoder implements 2-D product code encoding, as described in [1], using two “Linear Block Codes”.

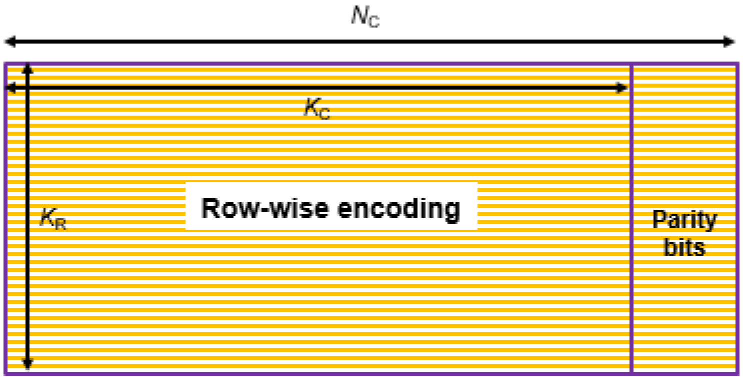
The TPC encoder accepts either full-length or shortened messages.

Construction of Full-Length Message Product Codes

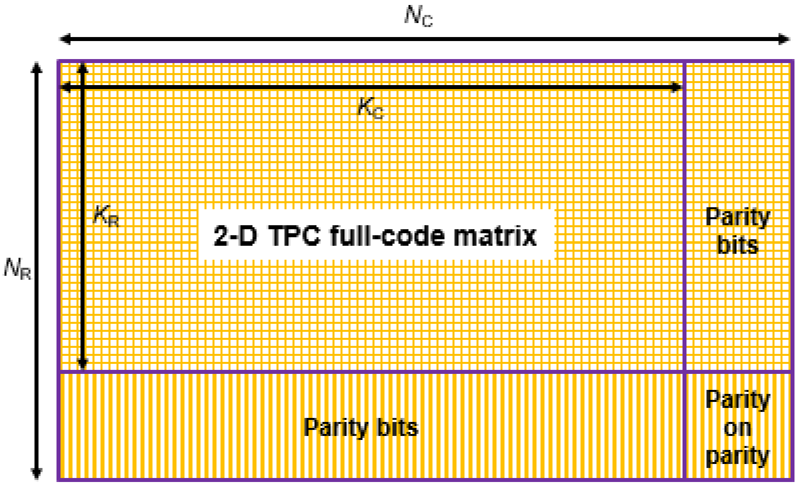
Full-length input messages are encoded using specified 2-D TPC code pairs. Row-wise encoding uses the (N_C,K_C) code pair and column-wise encoding uses the (N_R,K_R) code pair. The input vector length must be $K_R \cdot K_C$. The input message bits vector is arranged into a K_R-by-K_C matrix.



Row-wise encoding uses an (N_C,K_C) systematic linear block encoder with K_C bits per row. The row-wise encoding results in a K_R-by-N_C matrix that includes parity bits added to each row.



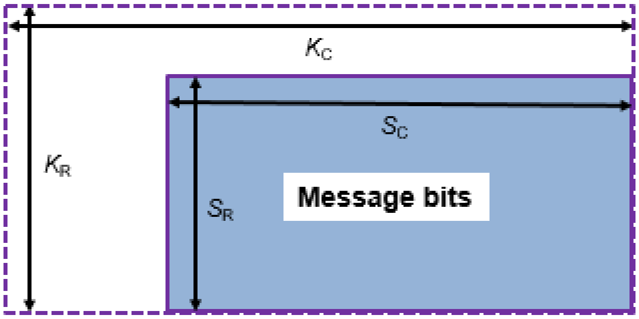
Next, column-wise encoding uses an (N_R,K_R) systematic linear block encoder on each of the N_C columns. Applying this 2-D TPC encoding to the initial K_R-by-K_C matrix results in an N_R-by-N_C matrix that includes parity bits added to each row and column.



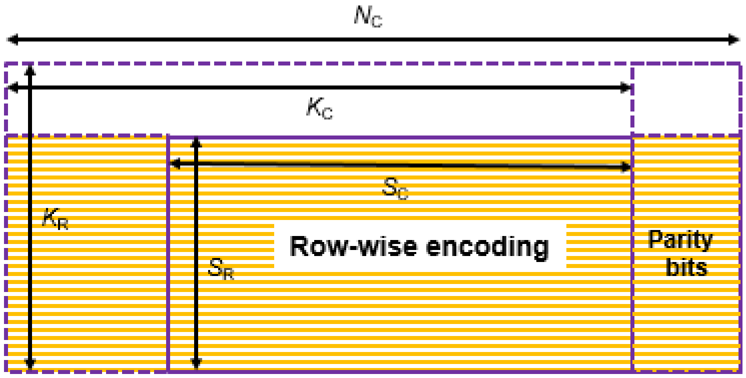
The 2-D TPC full-code matrix is reshaped into a column vector of length $N_R \cdot N_C$ and returned as the TPC-encoded output.

Construction of Shortened Message Product Codes

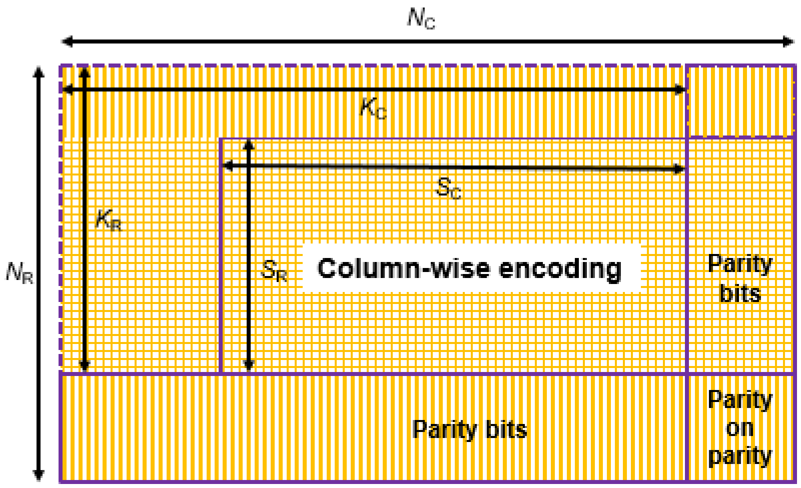
Shortened input messages are encoded using specified 2-D TPC code pairs. Row-wise encoding uses the (N_C,K_C) code pair and column-wise encoding uses an (N_R,K_R) code pair. The input vector length must be $S_R \cdot S_C$. The input shortened message bits vector is arranged into an S_R-by-S_C matrix. The shortened message matrix prepends two dimensions by padding the beginning of the message matrix with zeros. The resulting matrix is a K_R-by-K_C matrix.



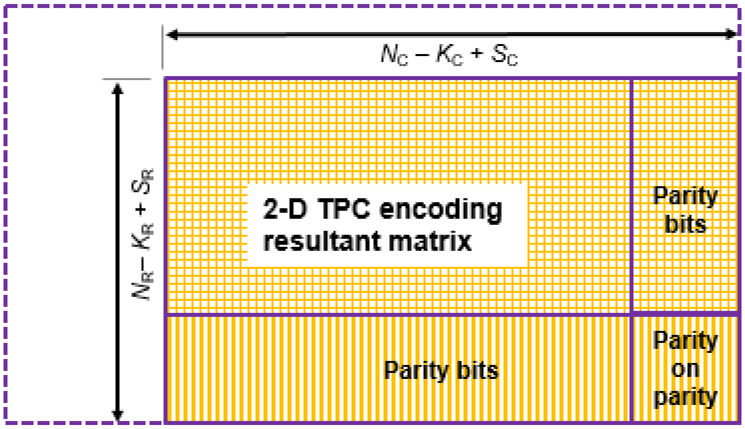
Row-wise encoding uses an (N_C,K_C) systematic linear block encoder with K_C bits per row. The row-wise encoding results in a K_R-by-N_C matrix that includes parity bits added to each row.



Next, the column-wise encoding uses an (N_R,K_R) systematic linear block encoder on each of the N_C columns.



Applying this 2-D TPC encoding to the initial K_R-by-K_C matrix and excluding the zero-padded bits from the output results in an (N_R-K_R+S_R)-by-(N_C-K_C+S_C) matrix. This matrix includes parity bits added to each row and column.



The 2-D TPC shortened-code matrix is reshaped into a column vector of length (N_R–K_R+S_R) · (N_C–K_C +S_C) and returned as the TPC-encoded output.

TPC Encoder

Introduced in R2018a

varlms

(To be removed) Construct variable-step-size least mean square (LMS) adaptive algorithm object

Note will be removed in a future release. Use `comm.LinearEqualizer` or `comm.DecisionFeedback` instead.

Syntax

```
alg = varlms(initstep,incstep,minstep,maxstep)
```

Description

The `varlms` function creates an adaptive algorithm object that you can use with the `lineareq` function or `dfe` function to create an equalizer object. You can then use the equalizer object with the `equalize` function to equalize a signal. To learn more about the process for equalizing a signal, see “Equalization”.

`alg = varlms(initstep,incstep,minstep,maxstep)` constructs an adaptive algorithm object based on the variable-step-size least mean square (LMS) algorithm. `initstep` is the initial value of the step size parameter. `incstep` is the increment by which the step size changes from iteration to iteration. `minstep` and `maxstep` are the limits between which the step size can vary.

Properties

The table below describes the properties of the variable-step-size LMS adaptive algorithm object. To learn how to view or change the values of an adaptive algorithm object, see “Equalization”.

Property	Description
`AlgType`	Fixed value, `'Variable Step Size LMS'`
`LeakageFactor`	LMS leakage factor, a real number between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, while a value of 0 corresponds to a memoryless update algorithm.
`InitStep`	Initial value of step size when the algorithm starts
`IncStep`	Increment by which the step size changes from iteration to iteration
`MinStep`	Minimum value of step size
`MaxStep`	Maximum value of step size

Also, when you use this adaptive algorithm object to create an equalizer object (via the `lineareq` or `dfe` function), the equalizer object has a `StepSize` property. The property value is a vector that lists the current step size for each weight in the equalizer.

Examples

Configuring Linear Equalizers

This example configures the recommended `comm.LinearEqualizer` System object™ and the legacy `lineareq` feature with comparable settings.

Initialize Variables and Supporting Objects

```
d = randi([0 3],1000,1);
x = pskmod(d,4,pi/4);
r = awgn(x,25);
sps = 2; %samples per symbol for oversampled cases
nTaps = 6;
txFilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',nTaps, ...
    'OutputSamplesPerSymbol',4);
rxFilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',nTaps, ...
    'InputSamplesPerSymbol',4,'DecimationFactor',2);
x2 = txFilter(x);
r2 = rxFilter(awgn(x2,25,0.5));
filterDelay = txFilter.FilterSpanInSymbols/2 + ...
    rxFilter.FilterSpanInSymbols/2; % Total filter delay in symbols
```

To compare the equalized output, plot the constellations using code such as:

```
% plot(yNew,'*')
% hold on
% plot(yOld,'o')
% hold off; legend('New Eq','Old Eq'); grid on
```

Use LMS Algorithm with Linear Equalizer

Configure `lineareq` and `comm.LinearEqualizer` objects with comparable settings. The `LeakageFactor` property has been removed from LMS algorithm. The `comm.LinearEqualizer` System object™ assumes that leakage factor is always 1.

```
eqOld = lineareq(5,lms(0.05),pskmod(0:3,4,pi/4))
```

```
eqOld =
  EqType: 'Linear Equalizer'
  AlgType: 'LMS'
  nWeights: 5
  nSampPerSym: 1
  RefTap: 1
  SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  StepSize: 0.0500
  LeakageFactor: 1
  Weights: [0 0 0 0 0]
  WeightInputs: [0 0 0 0 0]
  ResetBeforeFiltering: 1
  NumSamplesProcessed: 0
```

```
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','LMS','StepSize',0.05, ...
    'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'LMS'
  NumTaps: 5
  StepSize: 0.0500
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 1
  InputDelay: 0
  InputSamplesPerSymbol: 1
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers.

```
yOld = equalize(eqOld,r);
yNew = eqNew(r);
```

Use Linear Equalizers Considering Signal Delays

Configure `lineareq` and `comm.LinearEqualizer` objects with comparable settings. The transmit and receive filters result in a signal delay between the transit and receive signals. Account for this delay by setting the `RefTap` property of the `lineareq` to a value close to the delay value in samples. Additionally, `nWeights` must be set to a value greater than `RefTap`.

```
eqOld = lineareq(filterDelay*sps+4,lms(0.01),pskmod(0:3,4,pi/4),sps);
eqOld.RefTap = filterDelay*sps+1 % Adjust to synchronize with delayed signal
```

```
eqOld =
  EqType: 'Linear Equalizer'
  AlgType: 'LMS'
  nWeights: 16
  nSampPerSym: 2
  RefTap: 13
  SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  StepSize: 0.0100
  LeakageFactor: 1
  Weights: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
  WeightInputs: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
  ResetBeforeFiltering: 1
  NumSamplesProcessed: 0
```

```
eqNew = comm.LinearEqualizer('NumTaps',16,'Algorithm','LMS','StepSize',0.01, ...
    'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    'ReferenceTap',filterDelay*sps+1,'InputDelay',0)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'LMS'
  NumTaps: 16
  StepSize: 0.0100
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 13
  InputDelay: 0
  InputSamplesPerSymbol: 2
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

Call the equalizers. When `ResetBeforeFiltering` is set to `true`, each call of the `equalize` object resets the equalizer. To get the equivalent behavior call `reset` after each call of the `comm.LinearEqualizer` object.

```
yOld1 = equalize(eqOld,r,x(1:100));
yOld2 = equalize(eqOld,r,x(1:100));

yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

In the `comm.LinearEqualizer` object, `InputDelay` is used to synchronize with the delayed signal. `NumTaps` and `ReferenceTap` are independent of delay value. We can reduce the number of taps by utilizing the `InputDelay` to synchronize instead of reference tap. Reducing the number of taps also reduces equalizer self noise.

```
eqNew = comm.LinearEqualizer('NumTaps',11,'Algorithm','LMS','StepSize',0.01, ...
    'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    'ReferenceTap',6,'InputDelay',filterDelay*sps)
```

```
eqNew = comm.LinearEqualizer with properties:
  Algorithm: 'LMS'
  NumTaps: 11
  StepSize: 0.0100
  Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
  ReferenceTap: 6
  InputDelay: 12
  InputSamplesPerSymbol: 2
  TrainingFlagInputPort: false
  AdaptAfterTraining: true
  InitialWeightsSource: 'Auto'
  WeightUpdatePeriod: 1
```

```
yNew1 = eqNew(r2,x(1:100));
reset(eqNew)
yNew2 = eqNew(r2,x(1:100));
```

Algorithms

Referring to the schematics presented in “Equalization”, define *w* as the vector of all current weights w_i and define *u* as the vector of all inputs u_i. Based on the current step size, μ, this adaptive algorithm first computes the quantity

$\mu_0 = \mu + (\texttt{IncStep})\ \mathrm{Re}(gg_{\mathrm{prev}})$

where $g = ue^*$, g_{prev} is the analogous expression from the previous iteration, and the * operator denotes the complex conjugate.

Then the new step size is given by

- μ_0, if it is between `MinStep` and `MaxStep`
- `MinStep`, if $\mu_0 <$ `MinStep`
- `MaxStep`, if $\mu_0 >$ `MaxStep`

The new set of weights is given by

$(\texttt{LeakageFactor})\ w + 2\ \mu\ g^*$

Compatibility Considerations

`varlms` will be removed

Warns starting in R2020a

- varlms will be removed in a future release. Consider using `comm.LinearEqualizer` or `comm.DecisionFeedback` instead with the adaptive algorithm set to LMS.
- The `comm.LinearEqualizer` or `comm.DecisionFeedback` System objects do not have a leakage factor property. This is equivalent to setting `LeakageFactor` to `1` in the varlms function.
- For examples comparing setup of `comm.LinearEqualizer` to `lineareq`, see “Configuring Linear Equalizers” on page 2-832.

vec2mat

(Not recommended) Change dimension

Note is not recommended. Use reshape instead. For more information, see “Compatibility Considerations”.

Syntax

```
mat = vec2mat(vec,matcol)
mat = vec2mat(vec,matcol,padding)
[mat,padded] = vec2mat( ___ )
```

Description

mat = vec2mat(vec,matcol) converts vector vec to matrix mat with matcol columns. The function creates the matrix one row at a time, filling the rows with elements from vec in order. If the length of vec is not a multiple of matcol, then the function pads the last row of mat with zeros until the row contains matcol elements.

mat = vec2mat(vec,matcol,padding) specifies values for the function to use to pad the last row of mat. The function uses the value from padding in order.

[mat,padded] = vec2mat(___) also returns padded, the number of padded elements in the last row of mat. You can specify any of the input argument combinations from previous syntaxes.

Examples

Reshape Vector and Add Padding

This example uses shows you how to add padding, as needed, when converting a vector to matrix.

Create a vector that will be converted to a matrix and a vector to provide padding values.

```
vec = [10;20;30;40;50];
padding = [1,2;3,4;5,6];
n = 4;
```

When using vec2mat to convert the vector to a matrix, the function determines needed padding.

```
[mat4,numPadded4] = vec2mat(vec,n,padding)
```

```
mat4 =
    10    20    30    40
    50     1     3     5
numPadded4 =
     3
```

When using reshape to convert the vector to a matrix, the needed padding must be computed and appended to the vector before converting the vector to a matrix.

```
numPadded = mod(numel(vec),n);
if numPadded > 0
    numPadded = n - numPadded
    mat = reshape([vec.' padding(1:numPadded)], n, []).'
else
    numPadded % No padding required
    mat = reshape(vec.', n, []).'
end

numPadded =
     3
mat =
    10    20    30    40
    50     1     3     5
```

Input Arguments

vec — Input array

vector

Input array, specified as a vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`
Complex Number Support: Yes

`matcol` — Number of columns

positive integer

Number of columns for the output matrix `mat`, specified as a positive integer. If the length of `vec` is not a multiple of `matcol`, then the function pads the last row of `mat` with zeros until the row contains `matcol` elements.

Data Types: `double`

padding — Padding values

vector | matrix

Padding values for the last row of `mat`, specified as a vector or matrix. The `padding` input inherits the data type of the `vec` input. The function uses the values from `padding` in order. If `padding` has fewer elements than what the function needs to complete the last row of `mat`, then the function repeats the last element of `padding` until `mat` is full.

Output Arguments

mat — Output array

matrix

Output array, returned as a matrix with elements from `vec` and having `matcol` columns. The output inherits the data type of the input. The number of rows is equal to `ceil(length(vec)/matcol)`.

padded — Number of padded elements

positive integer

Number of padded elements in the last row of `mat`, returned as a positive integer.

Compatibility Considerations

`vec2mat` is not recommended

Not recommended starting in R2020a

- vec2mat is not recommended. Use `reshape` instead.
- Given a vector input, `reshape` creates its corresponding matrix one column at a time (instead of one row at a time).
- `reshape` requires its input and output arrays to have the same number of elements, whereas `vec2mat` pads its output matrix if necessary.
- For an example comparing use of `reshape` to `vec2mat`, see “Reshape Vector and Add Padding” on page 2-837.

Introduced before R2006a

vitdec

Convolutionally decode binary data by using Viterbi algorithm

Syntax

```
decodedout = vitdec(codedin,trellis,tbdepth,opmode,dectype)
decodedout = vitdec(codedin,trellis,tbdepth,opmode,'soft',nsdec)
decodedout = vitdec(codedin,trellis,tbdepth,opmode,dectype,puncpat)
decodedout = vitdec(codedin,trellis,tbdepth,opmode,dectype,puncpat,eraspat)
decodedout = vitdec(codedin,trellis,tbdepth,'cont',dectype, ___ ,imetric,
istate,iinput)
[decodedout,fmetric,fstate,finput] = vitdec(codedin,trellis,tbdepth,'cont',
___ )
```

Description

`decodedout = vitdec(codedin,trellis,tbdepth,opmode,dectype)` decodes each symbol of the `codedin` input by using the Viterbi algorithm. All other inputs specify the convolutional coding trellis, traceback depth, operating mode, and decision type, respectively and collectively configure the Viterbi algorithm at runtime.

`decodedout = vitdec(codedin,trellis,tbdepth,opmode,'soft',nsdec)` configures the Viterbi algorithm for soft-decision decoding for `dectype` and with `nsdec` bits of quantization.

`decodedout = vitdec(codedin,trellis,tbdepth,opmode,dectype,puncpat)` decodes each symbol of the punctured `codedin` input, where `puncpat` is the puncture pattern.

`decodedout = vitdec(codedin,trellis,tbdepth,opmode,dectype,puncpat,eraspat)` specifies an erasure pattern, `eraspat`. To not use puncturing, specify `puncpat` as `[]`.

`decodedout = vitdec(codedin,trellis,tbdepth,'cont',dectype, ___ ,imetric, istate,iinput)` specifies a continuous operation mode for `opmode` for any of the preceding syntaxes. The decoder starts with its initial state metrics, traceback states, and traceback inputs specified by `imetric`, `istate`, and `iinput`, respectively.

Continuous operation mode enables you to save the internal state information of the decoder for use in subsequent calls to this function. Repeated calls to this function can be useful if your data is partitioned into a series of vectors that you process within a loop. For workflows that require repeated calls to the Viterbi decoding algorithm, see “Tips” on page 2-849.

`[decodedout,fmetric,fstate,finput] = vitdec(codedin,trellis,tbdepth,'cont', ___ )` also returns the final state metrics, traceback states, and traceback inputs at the end of the decoding process when using a continuous operation mode for any of the preceding syntaxes. Use `fmetric`, `fstate`, and `finput` as the initial settings of `imetric`, `istate`, and `iinput`, respectively, in subsequent calls to this function. For workflows that require repeated calls to the Viterbi decoding algorithm, see “Tips” on page 2-849.

Examples

Decode Convolutional Code by Using Viterbi Decoder

Convolutionally encode a vector of 1s by using the `convenc` function, and decode it by using the `vitdec` function.

Define a trellis structure, by using the `poly2trellis` function. Use the trellis structure to configure the `convenc` function when encoding a vector of ones.

```
trellis = poly2trellis([4 3],[4 5 17;7 4 2]);
x = ones(100,1);
code = convenc(x,trellis);
```

When decoding the encoded message, configure the Viterbi decoder to use the trellis structure defined previously, a traceback depth of 2, the truncated operating mode, and hard decisions.

```
tb = 2;
decoded = vitdec(code,trellis,tb,'trunc','hard');
```

Verify that the decoded message is a vector of 100 1s.

```
isequal(decoded,ones(100,1))
```

```
ans = logical
   1
```

Decode Punctured Signal Using Viterbi Algorithm

Apply Viterbi decoding to a punctured signal. The puncturing changes the code rate from 1/2 to 3/4.

Initialize parameters for the encoding and decoding operations.

```
trellis = poly2trellis(7,[171 133])
```

```
trellis = struct with fields:
     numInputSymbols: 2
    numOutputSymbols: 4
           numStates: 64
          nextStates: [64x2 double]
             outputs: [64x2 double]
```

```
puncpat = [1;1;0;1;1;0];
tbdepth = 96;
opmode = 'trunc';
dectype = 'hard';
```

Calculate the unpunctured and punctured code rates.

```
K = log2(trellis.numInputSymbols); % Number of input streams
N = log2(trellis.numOutputSymbols); % Number of output streams
unpunc_coderate = K/N % Unpunctured code rate
```

```
unpunc_coderate = 0.5000
```

```
punc_coderate = (K/N)*(length(puncpat)/sum(puncpat)) % Punctured code rate
punc_coderate = 0.7500
```

Convolutionally encode an all 1s bit message with puncturing applied to the coded output.

```
msg = ones(100*length(puncpat),1);
puncturedcode = convenc(msg,trellis,puncpat);
```

Show the lengths of the message, the punctured code, and the puncture pattern.

```
length(msg)
```

```
ans = 600
```

```
length(puncturedcode)
```

```
ans = 800
```

```
length(puncpat)
```

```
ans = 6
```

Apply Viterbi decoding to the punctured coded message. Compare the decoded output to the original message. Even with puncturing applied to the coded message, the Viterbi decoding recovered the message with zero error.

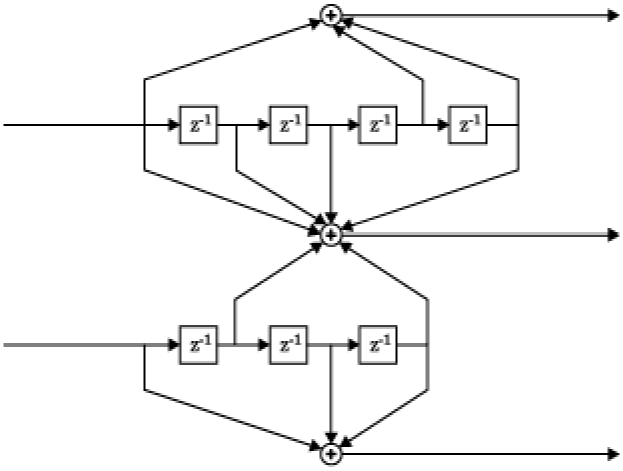
```
codedin = puncturedcode;
decodedout = vitdec(codedin,trellis,tbdepth,opmode,dectype,puncpat);
```

```
isequal(msg,decodedout)
```

```
ans = logical
   1
```

Estimate BER for Rate 2/3 Convolutional Code

Estimate the bit error rate (BER) simulation for a link that uses a rate 2/3 convolutional code, applies 16-QAM modulation, and transmits data through an AWGN channel. This diagram shows a rate 2/3 encoder with two input streams, three output streams, and seven shift registers.



Define the convolutional coding trellis represented by the diagram.

```
trellis = poly2trellis([5 4],[23 35 0; 0 5 13])
```

```
trellis = struct with fields:
     numInputSymbols: 4
    numOutputSymbols: 8
           numStates: 128
          nextStates: [128x4 double]
             outputs: [128x4 double]
```

```
K = log2(trellis.numInputSymbols); % Number of input bit streams
N = log2(trellis.numOutputSymbols); % Number of output bit streams
coderate = K/N;

fprintf('K is %d and N is %d. The code rate is %3.2f.\n', ...
    K,N,coderate)
```

```
K is 2 and N is 3. The code rate is 0.67.
```

Set the modulation order, and compute the number of bits per modulation symbol. Generate random binary data. The input bit stream must be a multiple of number of the input bit streams (K) for the coding operation and must be a multiple of the number of bits per modulation symbol (bps) for the modulation operation.

```
M = 16; % Modulation order
bps = log2(M); % Bits per modulation symbol
numSymPerFrame = 5000;
dataIn = randi([0 1],K*bps*numSymPerFrame,1);
```

Convolutionally encode the input data.

```
codedout = convenc(dataIn,trellis);
```

Apply 16-QAM modulation to the encoded symbols.

```
txSig = qammod(codedout,M,'InputType','bit');
```

Using the number of bits per symbol (bps) and the code rate (coderate), convert the ratio of energy per bit to noise power spectral density (EbNo) to an signal-to-noise (snr) value for use by the awgn function. Convert a 10 dB Eb/No to an equivalent SNR ratio. Pass the signal through an AWGN channel.

```
EbNo = 9;
snr = EbNo + 10*log10(bps*coderate);
rxSig = awgn(txSig,snr,'measured');
```

Demodulate the received signal.

```
demodSig = qamdemod(rxSig,M,'OutputType','bit');
```

Specify the traceback depth of the Viterbi decoder.

```
tbdepth = 16;
```

Decode the binary demodulated signal by using a Viterbi decoder operating in a continuous termination mode.

```
dataOut = vitdec(demodSig,trellis,tbdepth,'cont','hard');
```

Calculate the delay through the decoder, and account for the decoding delay when computing the BER. Compare the coded BER with the theoretical uncoded BER to see the improved BER for the coded data.

```
decDelay = K*tbdepth;
berCoded = biterr(dataIn(1:end-decDelay),dataOut(decDelay+1:end))/length(dataOut(decDelay+1:end)
berUncoded = berawgn(EbNo,'qam',M);
fprintf('  The coded BER is %6.5f.\nThe uncoded BER is %6.5f.\n', ...
    berCoded,berUncoded)
```

```
  The coded BER is 0.00060.
The uncoded BER is 0.00439.
```

Input Arguments

codedin — Convolutionally encoded message

vector of binary values | vector of numeric values

Convolutionally encoded message, specified as a vector of binary or numeric values. Each symbol in `codedin` consists of log2(`trellis`.`numOutputSymbols`) bits.

Data Types: `double` | `logical`

trellis — Trellis description

structure

Trellis description, specified as a MATLAB structure that contains the trellis description for a rate *K*/*N* code. *K* represents the number of input bit streams, and *N* represents the number of output bit streams.

The trellis structure contains these fields. You can either use the `poly2trellis` function to create the trellis structure or create it manually. For more about this structure, see “Trellis Description of a Convolutional Code” and the `istrellis` function.

numInputSymbols — Number of symbols input to encoder

2^K

Number of symbols input to the encoder, specified as an integer equal to 2^K, where *K* is the number of input bit streams.

Data Types: `double`

numOutputSymbols — Number of symbols output from encoder

2^N

Number of symbols output from the encoder, specified as an integer equal to 2^N, where *N* is the number of output bit streams.

Data Types: `double`

numStates — Number of states in encoder

power of 2

Number of states in the encoder, specified as a power of 2.

Data Types: double

nextStates — Next states
matrix of integers

Next states for all combinations of current states and current inputs, specified as a matrix of integers. The matrix size must be numStates-by-2^K.

Data Types: double

outputs — Outputs
matrix of octal numbers

Outputs for all combinations of current states and current inputs, specified as a matrix of octal numbers. The matrix size must be numStates-by-2^K.

Data Types: double

Data Types: struct

tbdepth — Traceback depth
positive integer

Traceback depth, specified as a positive integer. For more information, see "Traceback Depth Estimates" on page 2-849.

Data Types: double

opmode — Operating mode
'cont' | 'term' | 'trunc'

Operating mode, specified as 'cont', 'term', or 'trunc'. This input indicates the operating mode of the decoder and these assumptions made about the operation of the corresponding encoder.

- 'cont' — Specifies continuous operating mode. In continuous operating mode, the encoder is assumed to have started at the all-zeros state. The decoder traces back from the state with the best metric. A delay equal to input tbdepth symbols elapses before the first decoded symbol appears in the output. This mode is appropriate when you call this function repeatedly and want to preserve continuity between successive calls. For workflows that require repeated calls to the Viterbi decoding algorithm, see "Tips" on page 2-849.
- 'term' — Specifies terminated operating mode. In terminated operating mode, the encoder is assumed to have started and ended at the all-zeros state, which is true for the default syntax of the convenc function. The decoder traces back from the all-zeros state. This mode incurs zero delay.

  This mode is appropriate when the message input to the convenc function has enough zeros at its end to fill all memory registers of the encoder. The zero-valued tail bits flush all message data bits out of the encoder. Using the polynomial description of the encoder, for an encoder with K input bits and the constraint length vector ConstraintLength, the number of zeros required to flush the encoder is K × max(ConstraintLength – 1) . The constraint length vector is the first input argument to the poly2trellis function.
- 'trunc' — Specifies truncated operating mode. In truncated operating mode, the encoder is assumed to have started at the all-zeros state. The decoder traces back from the state with the best metric. This mode incurs zero delay. This mode is appropriate when you cannot assume the encoder ended at the all-zeros state and when you do not want to preserve continuity between successive calls to this function.

For the `'term'` and `'trunc'` modes, the traceback depth, `tbdepth`, must be a positive integer, less than or equal to the number of input symbols in input `codedin`.

For more information, see “Traceback and Decoding Delay” on page 2-848 and “Traceback Depth Estimates” on page 2-849.

Data Types: `char` | `string`

`dectype` — Decoding type
`'unquant'` | `'hard'` | `'soft'`

Decoding type, specified as `'unquant'`, `'hard'`, or `'soft'`. This parameter indicates the type of decoding decision that the decoder makes and influences the type of data the decoder expects as input in `codedin`.

- `'unquant'` — The decoder expects signed numeric input values, where positive values map to a logical `0` and negative values map to a logical `1`.
- `'hard'` — The decoder expects binary input values of `0` or `1`.
- `'soft'` — The decoder expects integer input values in the range [0, (2^{nsdec} – 1)]. The Viterbi algorithm decision criteria regards 0 as the most confident 0 and 2^{nsdec} – 1 as the most confident 1.

Data Types: `char` | `string`

`nsdec` — Number of soft decision quantization bits
integer in the range [1, 13]

Number of soft decision quantization bits, specified as a integer in the range [1, 13]. For reference, soft decision decoding with 3 bits of quantization improves error decoding recovery by approximately 2 dB as compared to hard decision decoding.

Dependencies

To enable this input argument set the `dectype` input argument to `'soft'`.

Data Types: `double`

`puncpat` — Puncture pattern
vector of binary values

Puncture pattern, specified as a vector of binary values. Indicate punctured bits with `0`s and unpunctured bits with `1`s. The input code length divided by the number of 1s in the puncture pattern times the length of the puncture pattern must be an integer multiple of the number of bits in an input symbol.

Data Types: `double`

`eraspat` — Erasure pattern
vector of binary values

Erasure pattern, specified as a vector of binary values. Indicate erased bits with `1`s and nonerased bits with `0`s. The length of the erasures pattern must be the same as the input code length.

Data Types: `double`

`imetric` — Decoder state metrics
integer | vector of integer values

Decoder state metrics, specified as an integer or a vector of integer values. Each value in `imetric` represents the starting state metric of the corresponding decoder state. When you set `imetric` to a vector, the length must be `trellis.numStates`. To use the default decoder state metrics, specify `imetric` as `[]`.

Dependencies

To enable this input argument set the `opmode` input argument to `'cont'`.

Data Types: `double`

`istate` — Decoder initial traceback states

matrix of integer values

Decoder initial traceback states, specified as a `trellis.numStates`-by-`tbdepth` matrix of integer values in the range [0, (`trellis.numStates` – 1)]. To use the default decoder initial traceback states, specify `istate` as `[]`.

Inputs `istate` and `iinput` jointly specify the initial traceback memory of the decoder. If the encoder schematic has more than one input stream, the shift register that receives the first input stream provides the least significant bits in `istate`, and the shift register that receives the last input stream provides the most significant bits in `istate`.

Dependencies

To enable this input argument set the `opmode` input argument to `'cont'`.

Data Types: `double`

`iinput` — Decoder initial traceback inputs

matrix of integer values

Decoder initial traceback inputs, specified as a `trellis.numStates`-by-`tbdepth` matrix of integer values in the range [0, (`trellis.numStates` – 1)]. To use the default decoder initial traceback inputs, specify `iinput` as `[]`.

Inputs `istate` and `iinput` jointly specify the initial traceback memory of the decoder.

Dependencies

To enable this input argument set the `opmode` input argument to `'cont'`.

Data Types: `double`

Output Arguments

`decodedout` — Decoded message

vector of binary values

Decoded message, returned as a vector of binary values. Each symbol in the vector `decodedout` consists of log2(`trellis.numInputSymbols`) bits.

`fmetric` — Decoder final state metrics

vector of integer values

Decoder final state metrics, returned as an vector of integer values with `trellis.numStates` elements. Each value in `fmetric` represents the final state metric of the corresponding decoder state.

When calling `vitdec` in continuous mode, `fmetric` is typically used to set `imetric` for subsequent calls to the `vitdec` function.

Dependencies

This output applies when the `opmode` parameter is set to `'cont'`.

Data Types: `double`

`fstate` — Decoder final traceback states

matrix of integer values

Decoder final traceback states, returned as a `trellis.numStates`-by-`tbdepth` matrix of integer values in the range [0, (`trellis.numStates` – 1)].

Outputs `fstate` and `finput` jointly describe the final traceback memory of the decoder. If the encoder schematic has more than one input stream, the shift register that receives the first input stream provides the least significant bits in `fstate`, and the shift register that receives the last input stream provides the most significant bits in `fstate`.

When calling `vitdec` in continuous mode, `fstate` is typically used to set `istate` for subsequent calls to the `vitdec` function.

Dependencies

This output applies when the `opmode` parameter is set to `'cont'`.

Data Types: `double`

`finput` — Decoder final traceback inputs

matrix of integer values

Decoder final traceback inputs, returned as a `trellis.numStates`-by-`tbdepth` matrix of integer values in the range [0, (`trellis.numStates` – 1)].

Outputs `fstate` and `finput` jointly specify the final traceback memory of the decoder.

When calling `vitdec` in continuous mode, `finput` is typically used to set `iinput` for subsequent calls to the `vitdec` function.

Dependencies

This output applies when the `opmode` parameter is set to `'cont'`.

Data Types: `double`

More About

Traceback and Decoding Delay

The traceback depth influences the decoding delay. The decoding delay is the number of zero symbols that precede the first decoded symbol in the output.

- For the continuous operating mode, the decoding delay is equal to the number of traceback depth symbols.
- For the truncated or terminated operating mode, the decoding delay is zero. In this case, the traceback depth must be less than or equal to the number of symbols in each input.

Traceback Depth Estimates

As a general estimate, a typical traceback depth value is approximately two to three times (*ConstraintLength* – 1) / (1 – *coderate*). The constraint length of the code, *ConstraintLength*, is equal to (log2(`trellis.numStates`) + 1). The *coderate* is equal to (*K* / *N*) × (length(*PuncturePattern*) / sum(*PuncturePattern*).

K is the number of input symbols, *N* is the number of output symbols, and *PuncturePattern* is the puncture pattern vector.

For example, applying this general estimate, results in these approximate traceback depths.

- A rate 1/2 code has a traceback depth of 5(*ConstraintLength* – 1).
- A rate 2/3 code has a traceback depth of 7.5(*ConstraintLength* – 1).
- A rate 3/4 code has a traceback depth of 10(*ConstraintLength* – 1).
- A rate 5/6 code has a traceback depth of 15(*ConstraintLength* – 1).

For more information, see [7].

Tips

- Consider using the `comm.ViterbiDecoder` System object when successive calls to the Viterbi algorithm are needed. The System object simplifies the required state retention operation by inherently retaining state metrics, traceback states, and inputs between calls.

wgn

Generate white Gaussian noise samples

Syntax

```
noise = wgn(m,n,power)
noise = wgn(m,n,power,imp)
noise = wgn(m,n,power,imp,randobject)
noise = wgn(m,n,power,imp,seed)

noise = wgn( ___ ,powertype)
noise = wgn( ___ ,outputtype)
```

Description

`noise = wgn(m,n,power)` generates an `m`-by-`n` matrix of white Gaussian noise samples in volts. `power` specifies the power of `noise` in dBW.

`noise = wgn(m,n,power,imp)` specifies the load impedance in ohms.

`noise = wgn(m,n,power,imp,randobject)` specifies a random number stream object to use when generating the matrix of white Gaussian noise samples. For information about producing repeatable noise samples, see “Tips” on page 2-853.

`noise = wgn(m,n,power,imp,seed)` specifies a seed value for initializing the normal random number generator that is used when generating the matrix of white Gaussian noise samples. For information about producing repeatable noise samples, see “Tips” on page 2-853.

`noise = wgn( ___ ,powertype)` specifies the units of `power` as `'dBW'`, `'dBm'`, or `'linear'` in addition to the input arguments in any of the previous syntaxes.

`noise = wgn( ___ ,outputtype)` specifies the output type as `'real'` or `'complex'` in addition to the input arguments in any of the previous syntaxes.

Examples

Generate White Gaussian Noise

Generate real and complex white Gaussian noise (WGN) samples. Check the power of output WGN matrices.

Generate a 1000-element column vector of real WGN samples and confirm that the power is approximately 1 watt, which is 0 dBW.

```
y1 = wgn(1000,1,0);
var(y1)
```

```
ans = 0.9979
```

Generate a 1000-element column vector of complex WGN samples and confirm that the power is approximately 0.25 watts, which is –6 dBW.

```
y2 = wgn(1000,1,-6,'complex');
var(y2)
```

```
ans = 0.2522
```

Input Arguments

m — Number of white Gaussian noise samples

positive integer

Number of white Gaussian noise samples desired per channel, specified as a positive integer.

Data Types: double

n — Number of channels

positive integer

Number of channels of white Gaussian noise samples desired, specified as a positive integer.

Data Types: double

power — Power of noise samples

scalar

Power of noise samples, specified as a scalar. The default units for power is dBW. Use powertype to change the units of power.

Data Types: double

imp — Load impedance

1 (default) | scalar

Load impedance in ohms, specified as a scalar.

Data Types: double

randobject — Random number stream object

RandStream object

Random number stream object, specified as a RandStream object. The state of the random stream object determines the sequence of numbers produced by the randn function. Configure the random stream object using the reset (RandStream) function and its properties.

wgn generates normal random noise samples using randn. The randn function uses one or more uniform values from the RandStream object to generate each normal value.

For information about producing repeatable noise samples, see “Tips” on page 2-853.

seed — Random number generator seed

nonnegative integer

Random number generator seed, specified as a nonnegative integer. For more information on the random number generator, see randn.

powertype — Signal power unit
'dBW' (default) | 'dBm' | 'linear'

Signal power unit, specified as 'dBW', 'dBm', or 'linear'. Linear power is in watts.

outputtype — Output type
'real' (default) | 'complex'

Output type, specified as 'real' or 'complex'. If outputtype is 'complex', then the real and imaginary parts of noise each have a noise power of (power / 2).

Output Arguments

noise — Output white Gaussian noise samples
scalar | vector | array

Output white Gaussian noise samples in volts, returned as an m-by-n matrix.

Note Unless the default impedance for imp is changed, a load of 1 ohm is used for power calculations.

Tips

- To generate repeatable white Gaussian noise samples, use one of these tips:
  - Provide a static seed value as an input to wgn.
  - Use the reset (RandStream) function on the randobject before passing it as an input to wgn.
  - Provide randobject in a known state as an input to wgn. For more information, see RandStream.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Code generation supported, except for syntaxes that include a RandStream object.

RandStream | awgn | randn

Topics
"Sources and Sinks"

Introduced before R2006a

winner2.AntennaArray

Create antenna array

Syntax

```
antArray = winner2.AntennaArray
antArray = winner2.AntennaArray(Name,Value)
```

Description

Download Required: To use this function, first download the WINNER II Channel Model for Communications Toolbox from the Add-On Explorer. For more information on downloading add-ons, see “Get and Manage Add-Ons”.

`antArray = winner2.AntennaArray` returns a structure representing an antenna array with one isotropic antenna element. Both the antenna array and the single element have no rotation and are located at the origin, [0;0;0].

`antArray = winner2.AntennaArray(Name,Value)` returns a structure representing an antenna array defined using one or more `Name,Value` pair arguments.

For more information, see “Antenna Array Model” on page 2-858.

Examples

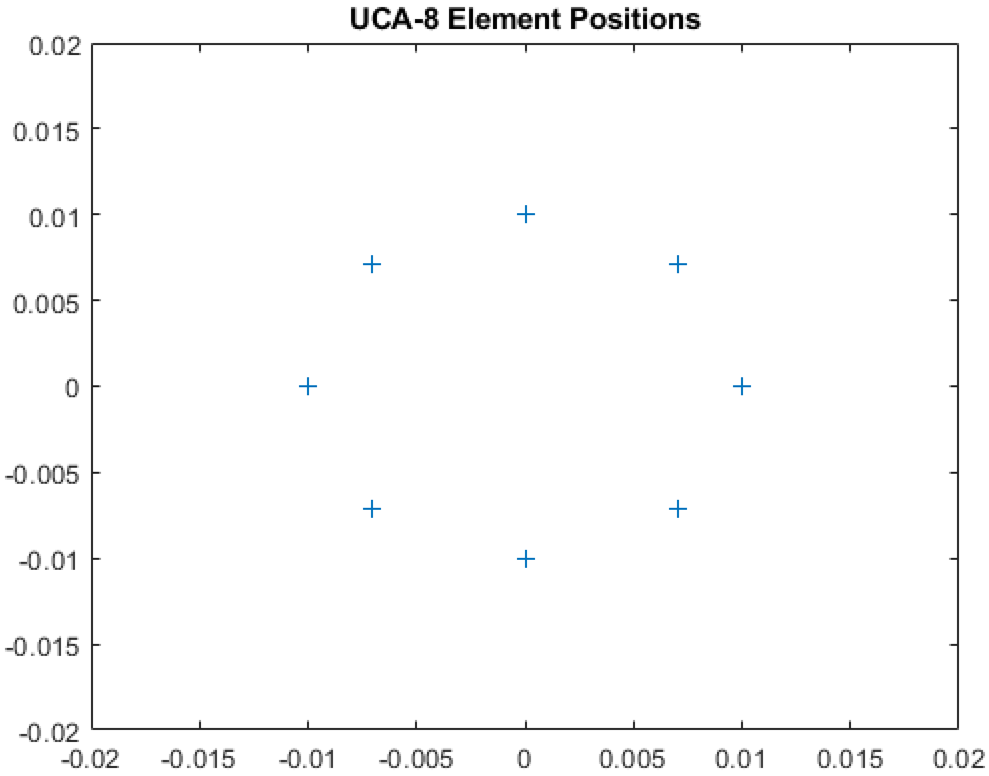
Create WINNER II Eight Element Uniform Circular Array

Use the `winner2.AntennaArray` function to create an eight element uniform circular array (UCA-8) with a 1 cm radius.

```
UCA8 = winner2.AntennaArray('UCA',8,0.01);
```

Plot element positions.

```
pos = {UCA8.Element(:).Pos};
plot(cellfun(@(x) x(1),pos),cellfun(@(x) x(2),pos),'+');
xlim([-0.02 0.02]);
ylim([-0.02 0.02]);
title('UCA-8 Element Positions');
```



Create WINNER II Two Element Uniform Linear Array

Use the `winner2.AntennaArray` function to create a two element uniform linear array (ULA-2) with 50 cm spacing and the dipole elements slanted at +45 and -45 degrees.

```
az = -180:179; % 1-degree spacing
pattern = cat(1,shiftdim(winner2.dipole(az,45),-1), ...
    shiftdim(winner2.dipole(az,-45),-1));
ULA2 = winner2.AntennaArray('ULA',2,0.5, ...
    'FP-ECS',pattern,'Azimuth',az);
```

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Pos',[1 0 0; 0 1 0],'Rot',[0 0 0; 0 pi() 0]` indicates the coordinates and rotation angles for two antenna elements.

Pos — Position of each antenna element

0 (default) | column vector | matrix

Position of each antenna element, specified as the comma-separated pair consisting of 'Pos' and a column vector or an N_E-by-3 matrix. The three columns represent the x-, y-, and z-coordinates in meters from the origin. N_E indicates the number of elements in the antenna array. The elements have no rotation. When there is more than one element, the 'Element' field of antArray is a row vector of structures representing all the elements.

Example: 'Pos',[63.1 10.2 11.5; 62 11 12] indicates the coordinates for two antenna elements.

Data Types: double

Rot — Rotation angle of each antenna element

0 (default) | column vector | matrix | optional

Rotation angle of each antenna element, specified as the comma-separated pair consisting of 'Rot' and a column vector or an N_E-by-3 matrix. The three columns represent the Rot_X, Rot_Y, and Rot_Z rotation angles of each antenna element in radians. N_E indicates the number of elements in the antenna array. Rot only applies when Pos is specified. If not specified with Pos, the rotation angle is 0.

Example: 'Rot',[2 1.5 0; 0 pi() 0] indicates the rotation angles for two antenna elements.

Data Types: double

UCA — Uniform circular antenna array

N,1 (default) | N,Rad

Uniform circular antenna array, specified as the comma-separated pair consisting of 'UCA' and N,Rad. In this argument, N indicates the number of elements (N_E) and Rad indicates the radius in meters. If Rad is not specified, the default radius is 1 meter.

Example: 'UCA',8,0.5 indicates an eight element uniform circular array with 0.5 meter radius.

Data Types: double

ULA — Uniform linear antenna array

N,1/N (default) | N,Spacing

Uniform linear antenna array, specified as the comma-separated pair consisting of 'ULA' and N,Spacing. In this argument, N indicates the number of elements (N_E) and Spacing indicates the separation between adjacent elements in meters. If Spacing is not specified, the default separation is 1/N meters.

ULA elements are placed along *x-axis* with the center of the array at [0;0;0]. For an even number of elements, there is no antenna element at [0;0;0].

Example: 'ULA',3,0.25 indicates a three element uniform linear array with 0.25 meter spacing between adjacent elements.

Data Types: double

FP-ECS — Field pattern of element coordinate system

4-D array

Field pattern of element coordinate system, specified as the comma-separated pair consisting of `'FP-ECS'` and a P-by-2-by1-by-N_{AZ} array.

- The first dimension, P, can be either 1 or any number greater than or equal to the number of elements in the antenna array (N_E). When $P = 1$, the same pattern applies to all elements. When $P > N_E$, the first N_E rows apply.
- The second dimension, `2`, indicates that two polarizations characterize the field pattern. The first dimension in the field pattern stores vertical polarization, and the second one stores horizontal polarization.
- The third dimension, `1`, indicates that one elevation angle characterizes the field pattern.
- The fourth dimension, N_{AZ}, is the number of field pattern samples taken between –180 and 180 degrees. N_{AZ} equals the number of elements specified in `Azimuth` or when `Azimuth` is not present it equals the number of equidistant field pattern samples taken over azimuth angle.

Data Types: `double`

`FP-ACS` — Field pattern array coordinate system

4-D array

Field pattern array coordinate system, specified as the comma-separated pair consisting of `'FP-ACS'` and a P-by-2-by1-by-N_{AZ} array. Array format is the same as the `FP-ECS` syntax, except that the field pattern is specified in the array-coordinate-system (ACS).

- The first dimension, P, can be either 1 or any number greater than or equal to the number of elements in the antenna array (N_E). When $P = 1$, the same pattern applies to all elements. When $P > N_E$, the first N_E rows apply.
- The second dimension, `2`, indicates that two polarizations characterize the field pattern. The first dimension in the field pattern stores vertical polarization, and the second one stores horizontal polarization. Missing polarization dimensions of the field pattern are substituted with zeros.
- The third dimension, `1`, indicates that one elevation angle characterizes the field pattern.
- The fourth dimension, N_{AZ}, is the number of field pattern samples taken between –180 and 180 degrees. N_{AZ} equals the number of elements specified in `Azimuth` or when `Azimuth` is not present it equals the number of equidistant field pattern samples taken over azimuth angle.

Data Types: `double`

`Azimuth` — Azimuth angles for 'FP-ACS' or 'FP-ECS' field patterns

row vector

Azimuth angles for `FP-ACS` or `FP-ECS` field patterns in degrees , specified as the comma-separated pair consisting of `'Azimuth'` and an 1-by-N_{AZ} row vector. The values in the row vector indicate azimuth angles for elements in the field patterns.

Note `Azimuth` applies only when `FP-ACS` or `FP-ECS` are defined. If `Azimuth` is not specified, uniform spacing is used for elements in the field pattern.

Example: `'Azimuth',[0 10 20 90 180 270 340 350]`

Data Types: `double`

Output Arguments

`antArray` — Antenna array definition
structure

Antenna array definition, returned as a structure containing these fields.

`Name` — Antenna array name
character vector

Antenna array name, returned as a character vector.

`Pos` — Antenna array position
vector

Antenna array position, returned as a 3-by-1 vector, representing the x-, y-, and z-coordinates in meters from the origin.

`Rot` — Antenna array rotation
vector

Antenna array rotation, returned as a 3-by-1 vector, representing the Rot_X, Rot_Y, and Rot_Z rotation angles of each antenna element in radians.

`Element` — Element definition
row vector of structures

Element definition, returned as a row vector of structures, with each structure representing one element and containing these fields.

`Pos` — Antenna array position
vector

Antenna array position, returned as a 3-by-1 vector, representing the x-, y-, and z-coordinates in meters from the origin.

`Rot` — Antenna array rotation
vector

Antenna array rotation, returned as a 3-by-1 vector, representing the Rot_X, Rot_Y, and Rot_Z rotation angles of each antenna element in radians.

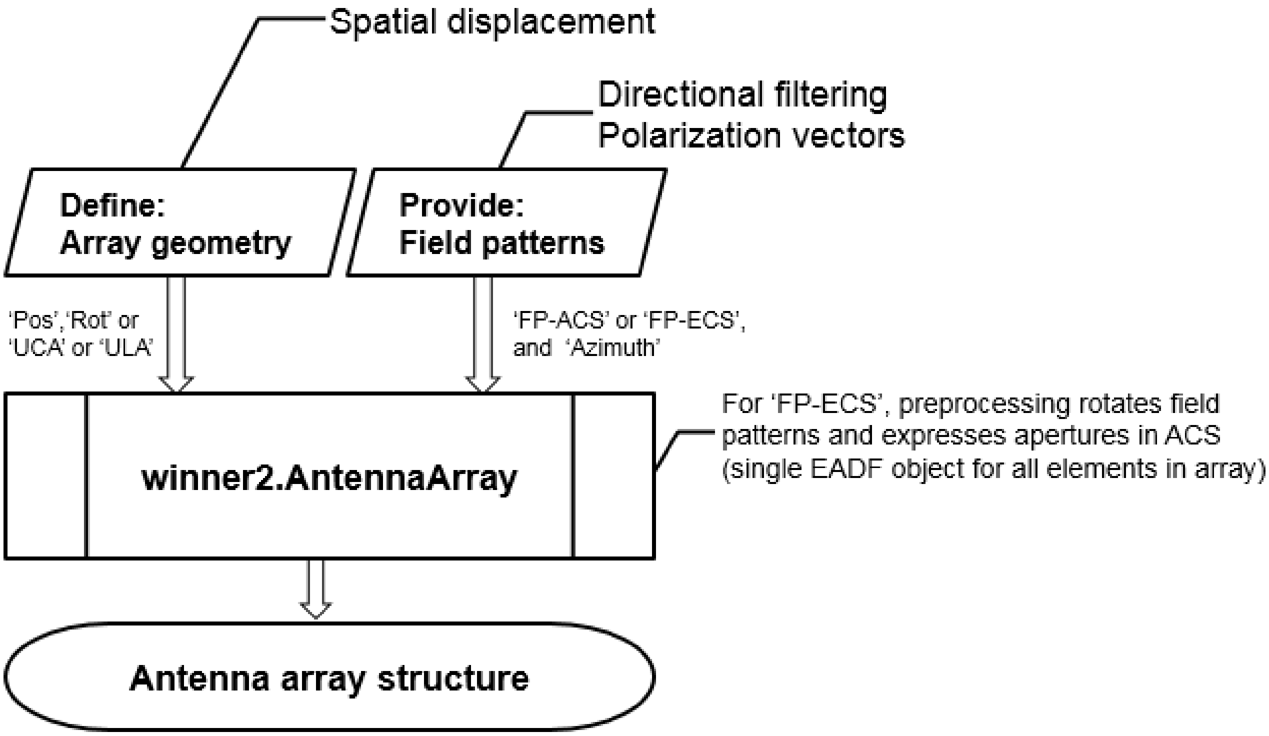
`Aperture` — Aperture definition
structure

Aperture definition, returned as a structure representing the antenna aperture.

More About

Antenna Array Model

To create an antenna array model, you must define the geometry of array elements (positions and rotation) and the element field patterns. The arguments provided to `winner2.AntennaArray` are always processed such that the array geometry is created first, and then the field patterns are assigned.



For a detailed description of the antenna array specification for the WINNER channel model, see WINNER II Channel Models [1], Section 4.1.

See Also

`winner2.dipole` | `winner2.layoutparset`

Introduced in R2017a

winner2.dipole

Calculate field pattern of half-wavelength dipole

Syntax

```
pat = winner2.dipole(az)
pat = winner2.dipole(az,slant)
```

Description

Download Required: To use this function, first download the WINNER II Channel Model for Communications Toolbox from the Add-On Explorer. For more information on downloading add-ons, see “Get and Manage Add-Ons”.

`pat = winner2.dipole(az)` returns the azimuth field pattern of a 0-degree slanted dipole at the azimuth angles specified in `az`.

`pat = winner2.dipole(az,slant)` returns the azimuth field pattern of a slanted dipole at the azimuth angles specified in `az`.

Examples

Create 45 and 90 Degree Slanted Dipoles

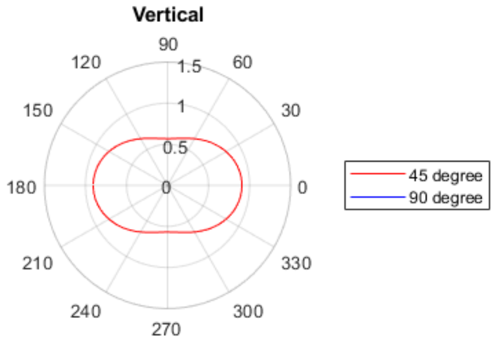
Create 45 and 90 degree slanted dipoles by using the `winner2.dipole` function.

```
az = -180:179; % 1 degree spacing
pattern45 = squeeze(winner2.dipole(az,45));
pattern90 = squeeze(winner2.dipole(az,90));
```

Display the antenna pattern by using the `polarplot` function.

```
fh = figure;
set(fh, 'Position', [100 100 1000 500]);
fh.Name = 'Dipole Pattern Plots';
subplot(1,2,1);
polarplot(az/180*pi,pattern45(1,:),'r');
hold on;
polarplot(az/180*pi,pattern90(1,:),'b');
rlim([0 1.5]);
legend('45 degree','90 degree');
title('Vertical');

subplot(1,2,2);
polarplot(az/180*pi,pattern45(2,:),'r');
hold on;
polarplot(az/180*pi,pattern90(2,:),'b');
rlim([0 1.5]);
legend('45 degree','90 degree');
title('Horizontal');
```



Input Arguments

az — Azimuth angles

vector

Azimuth angles, specified as a vector indicating the azimuth angles to compute the field pattern gain. Units are in degrees.

Data Types: `double`

`slant` — Slant angle

scalar

Slant angle, specified as a scalar representing the counterclockwise angle seen from the front of the dipole. Units are in degrees.

Data Types: `double`

Output Arguments

pat — Field pattern

3-D array

Field pattern, returned as a 2-by-1-by-N_{AZ} array representing the vertical and horizontal field pattern, where N_{AZ} is the number of elements in the `az` input vector.

See Also

`winner2.AntennaArray` | `winner2.layoutparset`

Introduced in R2017a

winner2.layoutparset

WINNER II layout parameter configuration

Syntax

```
cfgLayout = winner2.layoutparset(msIdx,bsIdx,K,arrays)
cfgLayout = winner2.layoutparset(msIdx,bsIdx,K,arrays,rmax)
cfgLayout = winner2.layoutparset(msIdx,bsIdx,K,arrays,rmax,seed)
```

Description

Download Required: To use this function, first download the WINNER II Channel Model for Communications Toolbox from the Add-On Explorer. For more information on downloading add-ons, see “Get and Manage Add-Ons”.

`cfgLayout = winner2.layoutparset(msIdx,bsIdx,K,arrays)` returns a structure of randomly generated WINNER II network layout parameters given mobile station (MS) indices, base station (BS) indices, BS to MS links, and antenna array configurations.

`cfgLayout = winner2.layoutparset(msIdx,bsIdx,K,arrays,rmax)` additionally specifies the maximum layout range used when generating MS and BS positions.

`cfgLayout = winner2.layoutparset(msIdx,bsIdx,K,arrays,rmax,seed)` additionally specifies a seed value for repeatability. To assign `seed` when not assigning `rmax`, specify `rmax` as [ ].

Examples

Create Two MS to One BS WINNER II System Layout

Create a WINNER II system layout with two mobile stations (MS) connecting to the same base station (BS).

Define antenna arrays for one BS and two MS.

```
BSAA  = winner2.AntennaArray('UCA', 8, 0.02);  % UCA-8 array for BS
MSAA1 = winner2.AntennaArray('ULA', 2, 0.01);  % ULA-2 array for MS
MSAA2 = winner2.AntennaArray('ULA', 4, 0.005); % ULA-4 array for MS
```

Create system layout by using the `winner2.layoutparset` function.

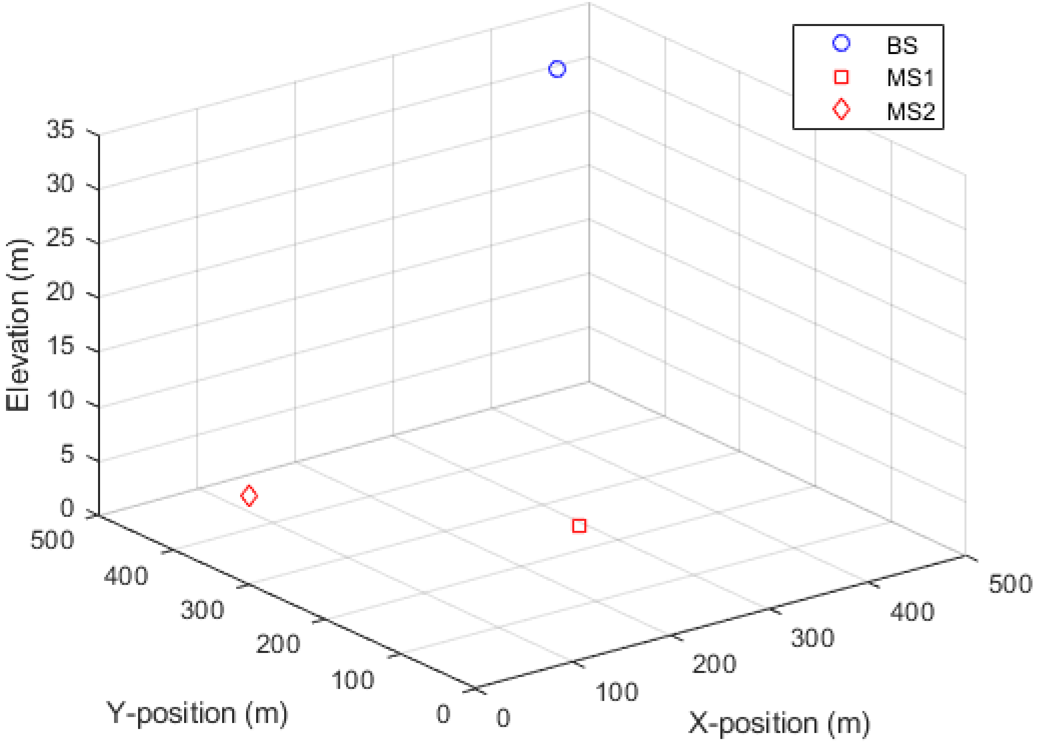
```
MSIdx = [2 3];
BSIdx = {1};
K = 2;
rndSeed = 5;
cfgLayout = winner2.layoutparset(MSIdx,BSIdx, ...
    K,[BSAA,MSAA1,MSAA2],[],rndSeed);
```

Visualize BS and MS positions.

```
BSPos  = cfgLayout.Stations(cfgLayout.Pairing(1,1)).Pos;
MS1Pos = cfgLayout.Stations(cfgLayout.Pairing(2,1)).Pos;
```

```
MS2Pos = cfgLayout.Stations(cfgLayout.Pairing(2,2)).Pos;

plot3(BSPos(1),BSPos(2),BSPos(3),'bo', ...
    MS1Pos(1),MS1Pos(2),MS1Pos(3),'rs', ...
    MS2Pos(1),MS2Pos(2),MS2Pos(3),'rd');
grid on;
xlim([0 500]);
ylim([0 500]);
zlim([0 35]);
xlabel('X-position (m)');
ylabel('Y-position (m)');
zlabel('Elevation (m)');
legend('BS','MS1','MS2','Location','northeast');
```



Input Arguments

msIdx — Mobile station index

row vector

Mobile station index, specified as a row vector indicating the indices in `arrays` to serve as mobile stations.

Data Types: `double`

bsIdx — Base station index

column cell array

Base station index, specified as a column cell array, with each element representing one base station. Each cell element is an integer-valued row vector to indicate the indices in `arrays` to serve as different sectors of that base station.

Data Types: `double`

`K` — Number of links
scalar

Number of links, specified as a scalar representing the number of BS-MS links to be formulated.

Data Types: `double`

`arrays` — Antenna array configurations
vector of structures

Antenna array configurations, specified as a vector of structures defining all available arrays. All MS and BS sectors are chosen from this vector. The array of elements is typically created using the `winner2.AntennaArray` function.

Data Types: `double`

`rmax` — Maximum layout range
`500` (default) | scalar

Maximum layout range, specified as a scalar representing the maximum layout range in meters used to randomly generate the MS and BS positions.

Data Types: `double`

`seed` — Seed value
integer

Seed value used to provide repeatability, specified as an integer. When `seed` is not specified, the global random number generator is used. To assign `seed` when not assigning `rmax`, specify `rmax` as `[]`.

Data Types: `double`

Output Arguments

`cfgLayout` — Configuration layout
structure

Configuration layout, returned as a structure containing these fields, which represent the location and orientation parameters for all simulated stations.

`Stations` — Active stations
row vector of structures

Active stations, returned as a row vector of structures describing the antenna arrays for active stations. `Stations` is created from the `arrays` input and adds an additional `Velocity` field. The row ordering specifies base station (BS) sectors first, followed by the mobile stations (MS). The BS sector and MS positions are randomly assigned. The BS sectors have no velocity. Each MS has a velocity of about 1.42 m/s with a randomly assigned direction.

NofSect — Number of sectors
vector

Number of sectors, returned as a vector indicating the number of sectors in each BS.

Pairing — BS to MS pairing
matrix

BS to MS pairing, returned as a 2-by-N_L matrix, where N_L specifies the number of links to be modeled. See Stations for BS and MS row ordering.

ScenarioVector — Spatial scenario
1 (default) | vector

Spatial scenario, returned as a 1-by-N_L vector of scenario numbers. The default is 1, which specifies scenario A1.

The scenarios numbers map as {1=A1, 2=A2, 3=B1, 4=B2, 5=B3, 6=B4, 10=C1, 11=C2, 12=C3, 13=C4, 14=D1, 15=D2a}.

For more information, see WINNER II Channel Models [1], Section 2.3.

PropagConditionVector — Propagation condition
1 (default) | vector

Propagation condition, returned as a 1-by-N_L vector of propagation conditions (LOS = 1 and NLOS = 0) for each link. The default is 1.

StreetWidth — Street width
20 (default) | vector

Street width, returned as a 1-by-N_L vector of identical values that specify the average width (in meters) of the streets. StreetWidth is used for the path loss model of the B1 and B2 scenarios. See ScenarioVector for the scenario number mapping. All elements must have the same value. StreetWidth applies only when the PathLossModelUsed field from winner2.wimparset is set to 'yes'.

Dist1 — Distances from BS to the last LOS point
NaN (default) | vector

Distances from BS to the last LOS point, returned as a 1-by-N_L vector. Dist1 is used for the path loss model of the B1 and B2 scenarios. The default value of NaN indicates that the distance is randomly determined in path loss function. See ScenarioVector for the scenario number mapping. Dist1 applies only when the PathLossModelUsed field from winner2.wimparset is set to 'yes'.

For more information, see WINNER II Channel Models [1], Figure 4-3.

NumFloors — Floor numbers
1 (default) | vector

Floor numbers, returned as a 1-by-N_L vector indicating the floor number where the indoor BS or MS is located. The NumFloors property is used for the path loss model of the A2 and B4 scenarios only. See ScenarioVector for the scenario number mapping. NumFloors applies only when the PathLossModelUsed field from winner2.wimparset is set to 'yes'.

`NumPenetratedFloors` — Number of floors penetrated

`0` (default) | vector

Number of floors penetrated, returned as a 1-by-N_L vector indicating the number of penetrated floors between BS and MS. The `NumPenetratedFloors` property is used for the NLOS path loss model of the A1 scenario. See `ScenarioVector` for the scenario number mapping. `NumPenetratedFloors` applies only when the `PathLossModelUsed` field from `winner2.wimparset` is set to `'yes'`.

For more information, see WINNER II Channel Models [1], Table 4-4.

See Also

Objects
`comm.WINNER2Channel`

Functions
`winner2.AntennaArray` | `winner2.wim` | `winner2.wimparset`

Introduced in R2017a

winner2.wim

Generate channel coefficients using WINNER II channel model

Syntax

```
chanCoef = winner2.wim(cfgWim,cfgLayout)
[chanCoef,pathDelays] = winner2.wim(cfgWim,cfgLayout)
[chanCoef,pathDelays,finalCond] = winner2.wim(cfgWim,cfgLayout)
[chanCoef,pathDelays,finalCond] = winner2.wim(cfgWim,cfgLayout,initCond)
```

Description

Download Required: To use this function, first download the WINNER II Channel Model for Communications Toolbox from the Add-On Explorer. For more information on downloading add-ons, see “Get and Manage Add-Ons”.

`chanCoef = winner2.wim(cfgWim,cfgLayout)` returns channel coefficients based on the WINNER II model parameters for all links defined in the WINNER II network layout.

`[chanCoef,pathDelays] = winner2.wim(cfgWim,cfgLayout)` also returns the path delays for all links.

`[chanCoef,pathDelays,finalCond] = winner2.wim(cfgWim,cfgLayout)` also returns the final condition of the system after generating the channel coefficients.

`[chanCoef,pathDelays,finalCond] = winner2.wim(cfgWim,cfgLayout,initCond)` generates the channel coefficients by using the initial system conditions rather than of performing random initialization. `initCond` is of the same form as `finalCond` and is typically the `finalCond` output from the prior call of this function. Use this syntax to repeatedly generate channel coefficients for continuous time samples.

Examples

Continuously Generate WINNER II Channel Coefficients

Continuously generate channel coefficients for each link in a two-link system layout.

Configure model parameters.

```
cfgWim = winner2.wimparset;
cfgWim.SampleDensity = 20;
cfgWim.RandomSeed = 10; % For repeatability
```

Configure layout parameters.

```
BSAA  = winner2.AntennaArray('UCA',8,0.02);  % UCA-8 array for BS
MSAA1 = winner2.AntennaArray('ULA',2,0.01);  % ULA-2 array for MS1
MSAA2 = winner2.AntennaArray('ULA',4,0.005); % ULA-4 array for MS2
MSIdx = [2,3];
```

```
BSIdx = {1};
NL = 2;
rndSeed = 5;
cfgLayout = winner2.layoutparset(MSIdx,BSIdx,NL,[BSAA,MSAA1,MSAA2],[],rndSeed);
```

Generate channel coefficients for the first time.

```
[H1,~,finalCond] = winner2.wim(cfgWim,cfgLayout);
```

Generate a second set of channel coefficients.

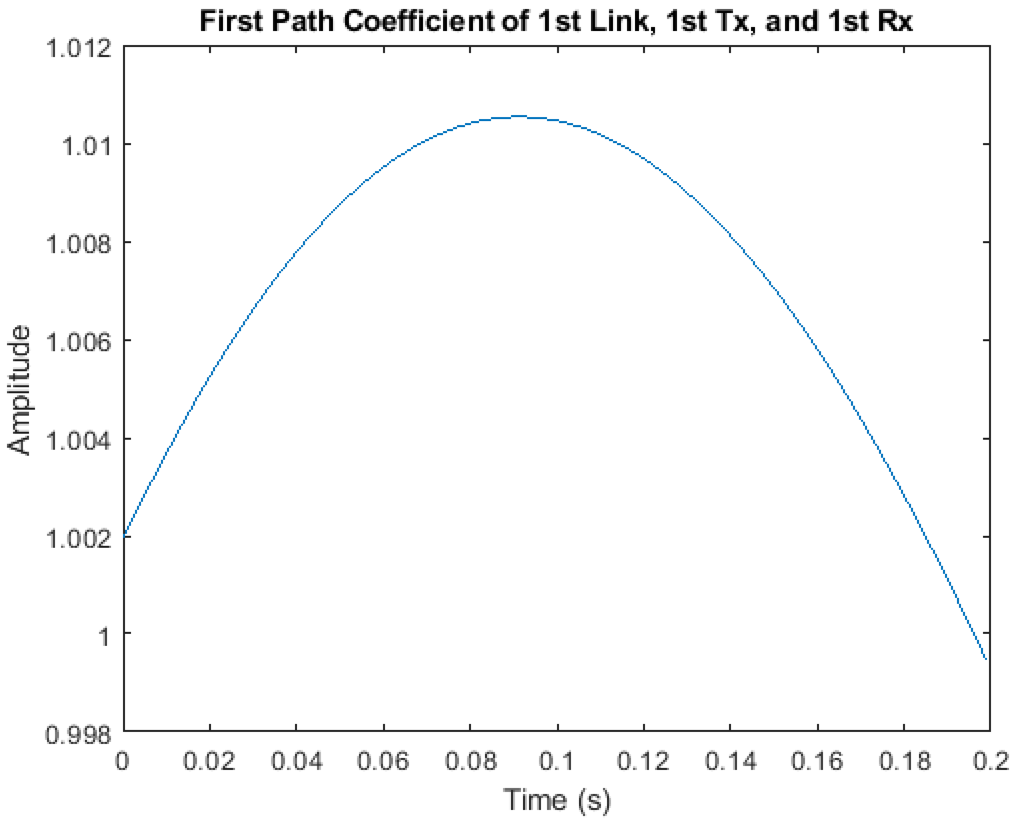
```
[H2,~,finalCond] = winner2.wim(cfgWim,cfgLayout,finalCond);
```

Concatenate H1 and H2 in time domain.

```
H = cellfun(@(x,y) cat(4,x,y),H1,H2,'UniformOutput',false);
```

Plot H for the first link, 1st Tx, 1st Rx, and 1st path. The plot shows the channel continuity over the two outputs from the `winner2.wim` function.

```
figure;
Ts = finalCond.delta_t(1);  % Sample time for the 1st link
plot(Ts*(0:2*cfgWim.NumTimeSamples-1)', ...
    abs(squeeze(H{1}(1,1,1,:))));
xlabel('Time (s)');
ylabel('Amplitude');
title('First Path Coefficient of 1st Link, 1st Tx, and 1st Rx');
```



Input Arguments

`cfgWim` — Configuration layout

structure

Configuration model, specified as a structure containing these fields. `cfgWim` is typically created using the `winner2.wimparset` function.

`NumTimeSamples` — Number of time samples

`100` (default) | scalar

Number of time samples, specified as a scalar.

`FixedPdpUsed` — Use predefined path delays and powers for specific scenarios

`'no'` (default) | `'yes'`

Use predefined path delays and powers for specific scenarios, specified as `'no'` or `'yes'`.

`FixedAnglesUsed` — Use predefined path angles of departure (AoDs) and angles of arrival (AoAs) for specific scenarios

`'no'` (default) | `'yes'`

Use predefined path angles of departure (AoDs) and angles of arrival (AoAs) for specific scenarios, specified as `'yes'` or `'no'`.

`IntraClusterDsUsed` — Divide each of the two strongest clusters into three subclusters per link

`'yes'` (default) | `'no'`

Divide each of the two strongest clusters into three subclusters per link, specified as `'yes'` or `'no'`.

`PolarisedArrays` — Use dual-polarized arrays

`'yes'` (default) | `'no'`

Use dual-polarized arrays, specified as `'yes'` or `'no'`.

`UseManualPropCondition` — Use manually defined propagation conditions

`'yes'` (default) | `'no'`

Use manually defined propagation conditions, specified as `'yes'` or `'no'`. Set to `'yes'` to enforce the use of manually defined propagation conditions (LOS/NLOS) in the `PropagConditionVector` structure field returned by `winner2.layoutparset`. Set to `'no'` to draw propagation conditions from pre-defined LOS probabilities.

`CenterFrequency` — Carrier frequency

`5.25e9` (default) | scalar

Carrier frequency in Hz, specified as a scalar.

`UniformTimeSampling` — Enforce uniform time sampling

`'no'` (default) | `'yes'`

Enforce all links to be sampled at the same time instants, specified as `'no'` or `'yes'`.

`SampleDensity` — Number of time samples per half wavelength

`2e6` (default) | scalar

Number of time samples per half wavelength, specified as a scalar.

`DelaySamplingInterval` — Sampling interval

`5e-9` (default) | scalar

Sampling interval, specified as an scalar indicating the input signal sample time in seconds. `DelaySamplingInterval` defines the sampling grid to which the path delays are rounded. A value of `0` seconds indicates no rounding on path delays.

`ShadowingModelUsed` — Use shadow fading

`'no'` (default) | `'yes'`

Use shadow fading, specified as `'no'` or `'yes'`.

`PathLossModelUsed` — Use path loss model

`'no'` (default) | `'yes'`

Use path loss model, specified as `'no'` or `'yes'`.

`PathLossModel` — Path loss model

`'pathloss'` (default) | character vector

Path loss model, specified as a character vector representing a valid function name. `PathLossModel` applies only when `PathLossModelUsed` is set to `'yes'`.

`PathLossOption` — Wall material

`'CR_light'` (default) | `'CR_heavy'` | `'RR_light'` | `'RR_heavy'`

Wall material, specified as `'CR_light'`, `'CR_heavy'`, `'RR_light'`, or `'RR_heavy'`, indicating the wall material for the *A1* scenario NLOS path loss calculation. `PathLossOption` applies only when `PathLossModelUsed` is set to `'yes'`.

`RandomSeed` — Seed for random number generators

`[]` (default) | scalar

Seed for random number generators, specified as a scalar or empty brackets. Empty brackets, `[]`, indicate that the global random stream is used.

`cfgLayout` — Configuration layout

structure

Configuration layout, specified as a structure containing these fields, which represent the location and orientation parameters for all simulated stations. `cfgLayout` is typically created using the `winner2.layoutparset` function.

`Stations` — Active stations

row vector of structures

Active stations, specified as a row vector of structures describing the antenna arrays for active stations. `Stations` is created from the `arrays` input of `winner2.layoutparset` and adds an additional `Velocity` field. The row ordering specifies base station (BS) sectors first, followed by the mobile stations (MS). The BS sector and MS positions are randomly assigned. The BS sectors have no velocity. Each MS has a velocity of about 1.42 m/s with a randomly assigned direction.

`NofSect` — Number of sectors

vector

Number of sectors, specified as a vector indicating the number of sectors in each BS.

`Pairing` — BS to MS pairing

matrix

BS to MS pairing, specified as a 2-by-N_L matrix, where N_L specifies the number of links to be modeled. See `Stations` for BS and MS row ordering.

`ScenarioVector` — Spatial scenario

`1` (default) | vector

Spatial scenario, specified as a 1-by-N_L vector of scenario numbers. The default is `1`, which specifies scenario A1.

The scenarios numbers map as `{1=`A1, `2=`A2, `3=`B1, `4=`B2, `5=`B3, `6=`B4, `10=`C1, `11=`C2, `12=`C3, `13=`C4, `14=`D1, `15=`D2a`}`.

For more information, see WINNER II Channel Models [1], Section 2.3.

`PropagConditionVector` — Propagation condition

`1` (default) | vector

Propagation condition, specified as a 1-by-N_L vector of propagation conditions (LOS = 1 and NLOS = 0) for each link.

`StreetWidth` — Street width

`20` (default) | vector

Street width, specified as a 1-by-N_L vector of identical values that specify the average width (in meters) of the streets. `StreetWidth` is used for the path loss model of the B1 and B2 scenarios. See `ScenarioVector` for the scenario number mapping. All elements must have the same value. `StreetWidth` applies only when `cfgWim.PathLossModelUsed` is set to `'yes'`.

`Dist1` — Distances from BS to the last LOS point

`NaN` (default) | vector

Distances from BS to the last LOS point, specified as a 1-by-N_L vector. `Dist1` is used for the path loss model of the B1 and B2 scenarios. The default value of `NaN` indicates that the distance is randomly determined in path loss function. See `ScenarioVector` for the scenario number mapping. `Dist1` applies only when `cfgWim.PathLossModelUsed` is set to `'yes'`.

For more information, see WINNER II Channel Models [1], Figure 4-3.

`NumFloors` — Floor numbers

`1` (default) | vector

Floor numbers, specified as a 1-by-N_L vector indicating the floor number where the indoor BS or MS is located. The default value is `1`. The `NumFloors` field is used for the path loss model of the A2 and B4 scenarios only. See `ScenarioVector` for the scenario number mapping. `NumFloors` applies only when `cfgWim.PathLossModelUsed` is set to `'yes'`.

`NumPenetratedFloors` — Number of floors penetrated

0 (default) | vector

Number of floors penetrated, specified as a 1-by-N_L vector indicating the number of penetrated floors between BS and MS. The default value is `0`. The `NumPenetratedFloors` is used for the NLOS path loss model of the A1 scenario. See ScenarioVector for the scenario number mapping. NumPenetratedFloors field applies only when cfgWim.PathLossModelUsed is set to 'yes'.

For more information, see WINNER II Channel Models [1], Table 4-4.

initCond — Initial system condition
structure | optional

Initial system condition, specified as a structure. initCond is of the same form as finalCond and is typically the finalCond output from the prior call of winner2.wim.

Data Types: struct

Output Arguments

chanCoef — Channel coefficients
cell array containing 4-D arrays of complex values

Channel coefficients, returned as an N_L-by-1 cell array. N_L is the number of links in the system. The ith element of chanCoef is an $N_R(i)$-by-$N_T(i)$-by-$N_P(i)$-by-N_S array. N_R, N_T, and N_P are link specific. N_S is the same for all the links.

- $N_R(i)$ is the number of receive antenna elements at MS for the ith link.
- $N_T(i)$ is the number of transmit antenna elements at BS for the ith link.
- $N_P(i)$ is the number of paths for the ith link.
- N_S is the number of time samples given by cfgWim.NumTimeSamples.

For more information , see “Channel Power” on page 2-874.

Data Types: cell

pathDelays — Path delays
matrix

Path delays, returned as an N_L-by-$maxN_P$ matrix. N_L is the number of links in the system and $maxN_P$ is the maximum number of paths among all links. Each row of the matrix applies to each link. When a link has fewer than $maxN_P$ paths, the corresponding row in pathDelays is NaN padded.

Data Types: double

finalCond — Final system condition
structure

Final system condition, returned as a structure. When generating channel coefficients for continuous time samples, use finalCond as the initCond input for the next call to winner2.wim.

For more information, see WINNER II Channel Models [1], Section 5.2.

Data Types: struct

More About

Channel Power

When path loss and shadowing are off, path gains of the computed WINNER channel are normalized. Specifically, path gains are normalized when the `ShadowingModelUsed` and `PathLossModelUsed` parameters are set to `'no'`.

Functions
`winner2.AntennaArray` | `winner2.layoutparset` | `winner2.wimparset`

Introduced in R2017a

winner2.wimparset

WINNER II model parameter configuration

Syntax

```
cfgWim = winner2.wimparset
```

Description

Download Required: To use this function, first download the WINNER II Channel Model for Communications Toolbox from the Add-On Explorer. For more information on downloading add-ons, see “Get and Manage Add-Ons”.

`cfgWim = winner2.wimparset` returns a structure of WINNER II model parameters with their default values.

Examples

Create a WINNER II model parameter set

Use the `winner2.wimparset` function to create a WINNER II model parameter set.

```
cfgwim = winner2.wimparset;
```

Adjust default settings.

```
cfgwim.RandomSeed = 31; % Set the rng seed for repeatability
cfgwim.NumTimeSamples = 250;
cfgwim.CenterFrequency = 4e9;
```

Display the WINNER II model parameter settings.

```
cfgwim
```

```
cfgwim = struct with fields:
            NumTimeSamples: 250
              FixedPdpUsed: 'no'
           FixedAnglesUsed: 'no'
        IntraClusterDsUsed: 'yes'
           PolarisedArrays: 'yes'
    UseManualPropCondition: 'yes'
           CenterFrequency: 4.0000e+09
        UniformTimeSampling: 'no'
             SampleDensity: 2000000
     DelaySamplingInterval: 5.0000e-09
        ShadowingModelUsed: 'no'
         PathLossModelUsed: 'no'
             PathLossModel: 'pathloss'
            PathLossOption: 'CR_light'
                RandomSeed: 31
```

Output Arguments

`cfgWim` — Configuration layout

structure

Configuration model, returned as a structure containing these fields.

`NumTimeSamples` — Number of time samples

`100` (default) | scalar

Number of time samples, specified as a scalar.

`FixedPdpUsed` — Use predefined path delays and powers for specific scenarios

`'no'` (default) | `'yes'`

Use predefined path delays and powers for specific scenarios, specified as `'no'` or `'yes'`.

`FixedAnglesUsed` — Use predefined path angles of departure (AoDs) and angles of arrival (AoAs) for specific scenarios

`'no'` (default) | `'yes'`

Use predefined path angles of departure (AoDs) and angles of arrival (AoAs) for specific scenarios, specified as `'yes'` or `'no'`.

`IntraClusterDsUsed` — Divide each of the two strongest clusters into three subclusters per link

`'yes'` (default) | `'no'`

Divide each of the two strongest clusters into three subclusters per link, specified as `'yes'` or `'no'`.

`PolarisedArrays` — Use dual-polarized arrays

`'yes'` (default) | `'no'`

Use dual-polarized arrays, specified as `'yes'` or `'no'`.

`UseManualPropCondition` — Use manually defined propagation conditions

`'yes'` (default) | `'no'`

Use manually defined propagation conditions, specified as `'yes'` or `'no'`. Set to `'yes'` to enforce the use of manually defined propagation conditions (LOS/NLOS) in the `PropagConditionVector` structure field returned by `winner2.layoutparset`. Set to `'no'` to draw propagation conditions from pre-defined LOS probabilities.

`CenterFrequency` — Carrier frequency

`5.25e9` (default) | scalar

Carrier frequency in Hz, specified as a scalar.

`UniformTimeSampling` — Enforce uniform time sampling

`'no'` (default) | `'yes'`

Enforce all links to be sampled at the same time instants, specified as `'no'` or `'yes'`.

SampleDensity — Number of time samples per half wavelength

2e6 (default) | scalar

Number of time samples per half wavelength, specified as a scalar.

DelaySamplingInterval — Sampling interval

5e-9 (default) | scalar

Sampling interval, specified as an scalar indicating the input signal sample time in seconds. DelaySamplingInterval defines the sampling grid to which the path delays are rounded. A value of 0 seconds indicates no rounding on path delays.

ShadowingModelUsed — Use shadow fading

'no' (default) | 'yes'

Use shadow fading, specified as 'no' or 'yes'.

PathLossModelUsed — Use path loss model

'no' (default) | 'yes'

Use path loss model, specified as 'no' or 'yes'.

PathLossModel — Path loss model

'pathloss' (default) | character vector

Path loss model, specified as a character vector representing a valid function name. PathLossModel applies only when PathLossModelUsed is set to 'yes'.

PathLossOption — Wall material

'CR_light' (default) | 'CR_heavy' | 'RR_light' | 'RR_heavy'

Wall material, specified as 'CR_light', 'CR_heavy', 'RR_light', or 'RR_heavy', indicating the wall material for the *A1* scenario NLOS path loss calculation. PathLossOption applies only when PathLossModelUsed is set to 'yes'.

RandomSeed — Seed for random number generators

[] (default) | scalar

Seed for random number generators, specified as a scalar or empty brackets. Empty brackets, [], indicate that the global random stream is used.

Introduced in R2017a

zadoffChuSeq

Generate root Zadoff-Chu sequence

Syntax

```
seq = zadoffChuSeq(R,N)
```

Description

`seq = zadoffChuSeq(R,N)` generates the `R`th root Zadoff-Chu sequence with length `N`, as defined in 3GPP TS 36.211.

The function generates the sequence using the algorithm given by

seq(m+1) = exp(-j·π·R·m·(m+1)/N), for *m = 0, ..., N-1*.

The function uses a negative polarity on the argument of the exponent, that is, a clockwise sequence of phases.

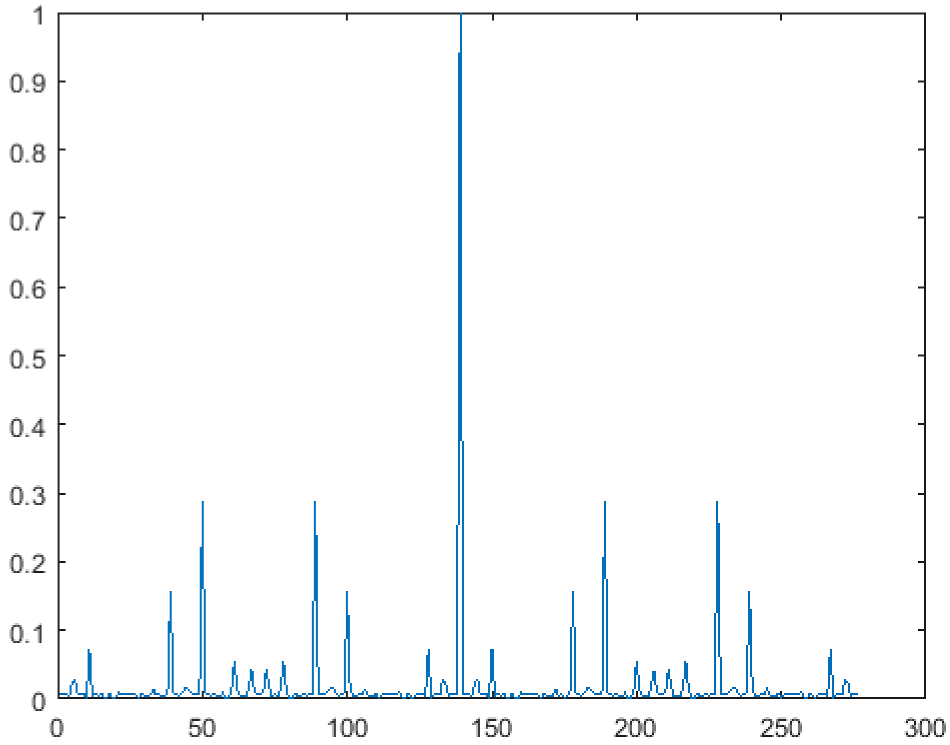
Examples

Examine Correlation Properties of Root Zadoff-Chu Sequence

Generate the 25th root Zadoff-Chu sequence with a length of 139.

Plot the absolute values of the output sequence.

```
seq = zadoffChuSeq(25,139);
plot(abs(xcorr(seq)./length(seq)))
```



Input Arguments

R — Root of Zadoff-Chu sequence

positive integer

Root of the Zadoff-Chu sequence, specified as a positive integer.

Example: 25

Data Types: double

N — Length of Zadoff-Chu sequence

odd positive integer

Length of the Zadoff-Chu sequence, specified as an odd positive integer.

Example: 139

Data Types: double

Output Arguments

seq — Rth root Zadoff-Chu sequence

column vector of complex values

Rth root Zadoff-Chu sequence, returned as an N-by-1 vector of complex values.

Compatibility Considerations

`lteZadoffChuSeq` was renamed to `zadoffChuSeq`

Behavior changed in R2019a

In release R2019a, the `lteZadoffChuSeq` function was renamed to `zadoffChuSeq`.

Introduced in R2012b

bleAngleEstimate

Estimate AoA or AoD of BLE Signal

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Syntax

`angle = bleAngleEstimate(IQsamples,cfg)`

Description

`angle = bleAngleEstimate(IQsamples,cfg)` estimates the angle of arrival (AoA) or angle of departure (AoD), `angle`, for the given in-phase and quadrature (IQ) samples, `IQsamples`, and Bluetooth low energy (BLE) angle estimation configuration object, `cfg`.

Examples

Estimate AoA of the BLE Signal

Create a BLE angle estimation configuration object, specifying the values of antenna array size, slot duration, and antenna switching pattern.

```
cfg = bleAngleEstimateConfig('ArraySize',2,'SlotDuration',2,...
    'SwitchingPattern',[1 2])
```

```
cfg = 
  bleAngleEstimateConfig with properties:

           ArraySize: 2
      ElementSpacing: 0.5000
        SlotDuration: 2
    SwitchingPattern: [1 2]
```

Set the IQ samples such that they define a connection data channel protocol data unit (PDU) with an AoA constant tone extension (CTE) of 2 *μs* slots, CTE time of 16 *μs*, and azimuth rotation of 70 degrees.

```
IQsamples = [0.8507+0.5257i;-0.5257 + 0.8507i;-0.8507 - 0.5257i;...
    0.5257 - 0.8507i;0.8507+0.5257i;-0.5257 + 0.8507i;...
    -0.8507 - 0.5257i;0.5257 - 0.8507i;-0.3561 + 0.9345i];
```

Estimate the AoA of the BLE signal.

```
angle = bleAngleEstimate(IQsamples,cfg)
```

```
angle = 70
```

Input Arguments

`IQsamples` — IQ samples

complex-valued column vector

IQ samples, specified as a complex-valued column vector. This argument corresponds to the 8 µs value of the reference period and slot duration.

Data Types: `single` | `double`

`cfg` — BLE angle estimation configuration object

`bleAngleEstimateConfig` object

BLE angle estimation configuration object, specified as a `bleAngleEstimateConfig` object.

Output Arguments

`angle` — AoA or AoD

real number | two-element row vector of real numbers

AoA or AoD, returned as one of these values.

- Real number – This value is the estimated broadside angle. If *elevation* is 0, the estimated broadside angle represents the azimuth angle.
- Two-element row vector of real numbers in the form [*azimuth elevation*] – *azimuth* and *elevation* are the estimated azimuth angle and elevation angle in degrees, respectively.

The size of this output argument is equal to the size of the “ArraySize” on page 3-0 property of the `bleAngleEstimateConfig` object.

Data Types: `double`

bleATTPDU

Generate BLE ATT PDU

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Syntax

```
attPDU = bleATTPDU(cfgATT)
```

Description

`attPDU = bleATTPDU(cfgATT)` generates a Bluetooth low energy (BLE) attribute protocol data unit (ATT PDU) corresponding to the BLE ATT PDU configuration object `cfgATT`.

Examples

Generate BLE ATT PDUs

Generate two unique BLE ATT PDUs of type `'Read by type request'` and `'Error response'`.

Create a BLE ATT PDU configuration object with default settings.

```
cfgATT = bleATTPDUConfig;
```

Change the BLE ATT PDU opcode as `'Read by type request'`. View the applicable properties of the opcode `'Read by type request'`.

```
cfgATT.Opcode = 'Read by type request'
```

```
cfgATT = 
  bleATTPDUConfig with properties:

           Opcode: 'Read by type request'
      StartHandle: '0001'
        EndHandle: 'FFFF'
    AttributeType: '2800'
```

Generate a BLE ATT PDU using the corresponding configuration object.

```
attPDU = bleATTPDU(cfgATT)
```

```
attPDU = 7x2 char array
    '08'
    '01'
    '00'
    'FF'
    'FF'
    '00'
    '28'
```

Create another BLE ATT PDU configuration object, this time using the name-value pairs. Change the BLE ATT PDU opcode to `'Error response'`. View the applicable properties of the opcode `'Error response'`.

```
cfgATT = bleATTPDUConfig('Opcode','Error response')
```

```
cfgATT = 
  bleATTPDUConfig with properties:

             Opcode: 'Error response'
    RequestedOpcode: 'Read request'
    AttributeHandle: '0001'
       ErrorMessage: 'Invalid handle'
```

Generate a BLE ATT PDU corresponding to this configuration object.

```
attPDU = bleATTPDU(cfgATT)
```

```
attPDU = 5x2 char array
    '01'
    '0A'
    '01'
    '00'
    '01'
```

Input Arguments

`cfgATT` — BLE ATT PDU configuration object

`bleATTPDUConfig` object

BLE ATT PDU configuration object, specified as a `bleATTPDUConfig` object. This value defines the type of BLE ATT PDU and its applicable properties.

Output Arguments

`attPDU` — Generated BLE ATT PDU

character array

Generated BLE ATT PDU, returned as a character array. Each row in this array is the hexadecimal representation of an octet.

Introduced in R2019b

bleATTPDUDecode

Decode BLE ATT PDU

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Syntax

```
[status,cfgATT] = bleATTPDUDecode(attPDU)
```

Description

`[status,cfgATT] = bleATTPDUDecode(attPDU)` decodes the specified Bluetooth low energy (BLE) attribute protocol data unit (ATT PDU), returning the corresponding BLE ATT PDU configuration object, `cfgATT`, and the decoding status, `status`.

Examples

Decode BLE ATT PDUs

Decode two unique BLE ATT PDUs of type `'Read by type request'` and `'Error response'`.

Create a BLE ATT PDU configuration object with default settings.

```
cfgATT = bleATTPDUConfig;
```

Change the BLE ATT PDU opcode as `'Read by type request'`. View the applicable properties of the opcode `'Read by type request'`.

```
cfgATT.Opcode = 'Read by type request'
```

```
cfgATT = 
  bleATTPDUConfig with properties:

           Opcode: 'Read by type request'
      StartHandle: '0001'
        EndHandle: 'FFFF'
    AttributeType: '2800'
```

Generate a BLE ATT PDU using the corresponding configuration object.

```
attPDU = bleATTPDU(cfgATT)
```

```
attPDU = 7x2 char array
    '08'
    '01'
    '00'
    'FF'
    'FF'
    '00'
    '28'
```

Decode the generated BLE ATT PDU. The returned status indicates decoding is successful. View the applicable properties of the opcode `'Read by type request'`.

```
[status, cfg] = bleATTPDUDecode(attPDU)
```

```
status = 
Success

cfg = 
  bleATTPDUConfig with properties:

           Opcode: 'Read by type request'
      StartHandle: '0001'
        EndHandle: 'FFFF'
    AttributeType: '2800'
```

Create another BLE ATT PDU configuration object, this time using the name-value pairs. Change the BLE ATT PDU opcode as `'Error response'`. View the applicable properties of the opcode `'Error response'`.

```
cfgATT = bleATTPDUConfig('Opcode','Error response')
```

```
cfgATT = 
  bleATTPDUConfig with properties:

             Opcode: 'Error response'
    RequestedOpcode: 'Read request'
    AttributeHandle: '0001'
       ErrorMessage: 'Invalid handle'
```

Generate a BLE ATT PDU using the corresponding configuration object.

```
attPDU = bleATTPDU(cfgATT)
```

```
attPDU = 5x2 char array
    '01'
    '0A'
    '01'
    '00'
    '01'
```

Decode the generated BLE ATT PDU. The returned status indicates decoding is successful. View the applicable properties of the opcode `'Error response'`.

```
[status, cfg] = bleATTPDUDecode(attPDU)
```

```
status = 
Success

cfg = 
  bleATTPDUConfig with properties:
```

```
             Opcode: 'Error response'
    RequestedOpcode: 'Read request'
    AttributeHandle: '0001'
       ErrorMessage: 'Invalid handle'
```

Decode Corrupted BLE ATT PDU

Specify a BLE ATT PDU containing corrupted data values.

```
attPDU = ['09'; '03'; '01'; '00'; '18'; '0D']; % Sample corrupted BLE ATT PDU
```

Decode the specified BLE ATT PDU. The returned status indicates that the decoding failed due to mismatched attribute data lengths. In case of failed decoding, BLE ATT PDU configuration object, `'cfgATT'`, displays no properties.

```
[status, cfgATT] = bleATTPDUDecode(attPDU)
```

```
status = 
MismatchAttributeDataLength

cfgATT = 
  bleATTPDUConfig with properties:
```

Input Arguments

`attPDU` — BLE ATT PDU

character vector | string scalar | numeric vector | character array

BLE ATT PDU, specified as one of these values:

- Character vector — This vector represent octets in hexadecimal format.
- String scalar — This scalar represent octets in hexadecimal format.
- Numeric vector of elements in the range [0,255] — This vector represent octets in decimal format.
- n-by-2 character array — Each row represent an octet in hexadecimal format.

Data Types: `char` | `uint8` | `uint16` | `uint32` | `double` | `string`

Output Arguments

`cfgATT` — BLE ATT PDU configuration object

`bleATTPDUConfig` object

BLE ATT PDU configuration object, returned as a `bleATTPDUConfig` object. This value denotes the decoded BLE ATT PDU configuration.

`status` — Packet decoding status

nonpositive integer

Packet decoding status, returned as a nonpositive number of type `blePacketDecodeStatus`. This value represents the result of an ATT PDU decoding. Each value of `status` corresponds to a member of the `blePacketDecodeStatus` enumeration class, which indicates the packet decoding status according to this table.

Enumeration Value	Member of Enumeration Class	Decoding Status
0	`Success`	Packet decoding succeeded
–401	`UnsupportedATTOpcode`	Invalid ATT opcode
–402	`IncompleteATTPDU`	Incomplete ATT PDU
–403	`InvalidATTReqOpcodeInErrorResp`	Invalid requested opcode in "Error Response" PDUs
–404	`InvalidATTErrorCode`	Invalid error code
–405	`InvalidATTRxMTU`	Invalid received MTU
–406	`InvalidAttributeHandleRange`	Invalid attribute handle range
–407	`InvalidAttributeType`	Invalid attribute type flag
–408	`InvalidATTExecuteWriteFlag`	Invalid execute write flag
–409	`MismatchAttributeDataLength`	Length mismatches with actual length
–410	`InvalidATTDataFormat`	Invalid Data Format

An enumeration value other than `0` means that the BLE ATT PDU decoding failed. If the decoding fails, object `cfgATT` displays no output.

bleGAPDataBlock

Generate BLE GAP data block

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Syntax

```
dataBlock = bleGAPDataBlock(cfgGAP)
```

Description

`dataBlock = bleGAPDataBlock(cfgGAP)` generates a Bluetooth low energy (BLE) generic access profile (GAP) data block of type advertising data (AD) or scan response data (SRD) corresponding to the BLE GAP data block configuration object `cfgGAP`.

Examples

Generate BLE GAP AD Blocks

Generate three unique BLE GAP AD blocks: first one with AD types `'Flags'` and `'Tx power level'`, the second one with AD types `'Advertising interval'` and `'Local name'` and the third one with AD type `'Flags'` and having simultaneous support for low energy (LE) and basic rate/enhanced data rate (BR/EDR) at the host.

Create a configuration object for a BLE GAP AD block and specify the AD types as `'Flags'` and `'Tx power level'`. Assign the values of LED discoverability as `'Limited'` and Tx power level as `45`.

```
cfgGAP = bleGAPDataBlockConfig;
cfgGAP.AdvertisingDataTypes   = {'Flags';'Tx power level'};
cfgGAP.LEDiscoverability      = 'Limited';
cfgGAP.TxPowerLevel           = 45;
```

Generate the BLE GAP AD block from the corresponding configuration object.

```
dataBlock = bleGAPDataBlock(cfgGAP)
```

```
dataBlock = 6x2 char array
    '02'
    '01'
    '05'
    '02'
    '0A'
    '2D'
```

Create a configuration object for a BLE GAP AD block, this time with advertising data types as `'Advertising interval'` and `'Local name'`. Specify the values of the advertising interval as `48`, the local name as `'MathWorks'` and the local name shortening as `true`.

```
cfgGAP = bleGAPDataBlockConfig('AdvertisingDataTypes', ...
    {'Advertising interval', ...
    'Local name'});
cfgGAP.AdvertisingInterval  = 48;
cfgGAP.LocalName            = 'MathWorks';
cfgGAP.LocalNameShortening  = true;
```

Generate the BLE GAP AD block from the corresponding configuration object.

```
dataBlock = bleGAPDataBlock(cfgGAP)
```

```
dataBlock = 15x2 char array
    '03'
    '1A'
    '30'
    '00'
    '0A'
    '08'
    '4D'
    '61'
    '74'
    '68'
    '57'
    '6F'
    '72'
    '6B'
    '73'
```

Create a configuration object for a BLE GAP AD block with type `'Flags'`. Specify the values of LE discoverability as `'Limited'`, BR/EDR support as `true`, and simultaneous support for LE and BR/EDR as `'Host'`.

```
cfgGAP = bleGAPDataBlockConfig;
cfgGAP.LEDiscoverability      = 'Limited';
cfgGAP.BREDR                  = true;
cfgGAP.LE                     = 'Host';
```

Generate the BLE GAP AD block from the corresponding configuration object.

```
dataBlock = bleGAPDataBlock(cfgGAP)
```

```
dataBlock = 3x2 char array
    '02'
    '01'
    '11'
```

Input Arguments

`cfgGAP` — BLE GAP data block configuration object

`bleGAPDataBlockConfig` (default) | object

BLE GAP data block configuration object, specified as a `bleGAPDataBlockConfig` object. This value defines the type of BLE GAP data block and its applicable properties.

Output Arguments

`dataBlock` — Generated BLE GAP data block

character array

Generated BLE GAP data block, returned as a character array. Each row in this array is the hexadecimal representation of an octet.

bleGAPDataBlockDecode

Decode BLE GAP data block

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Syntax

```
[status,cfgGAP] = bleGAPDataBlockDecode(dataBlock)
```

Description

`[status,cfgGAP] = bleGAPDataBlockDecode(dataBlock)` decodes a Bluetooth low energy (BLE) generic access profile (GAP) data block, `dataBlock`, of the type advertising data (AD) or scan response data (SRD), returning the decoding status, `status`, and the BLE GAP data block configuration object, `cfgGAP`.

Examples

Decode BLE GAP AD Blocks

Decode two unique BLE GAP AD blocks: one with AD types `'Flags'` and `'Tx power level'` and the other with AD types `'Advertising interval'` and `'Local name'`.

Create a configuration object for a BLE GAP AD block. Specify the AD types as `'Flags'` and `'Tx power level'`. Set the values of LE discoverability as `'Limited'` and Tx power level to `45`. View the properties of the configuration object `'cfgGAP'`.

```
cfgGAP = bleGAPDataBlockConfig;
cfgGAP.AdvertisingDataTypes = {'Flags'; 'Tx power level'};
cfgGAP.LEDiscoverability = 'Limited';
cfgGAP.TxPowerLevel = 45
```

```
cfgGAP = 
  bleGAPDataBlockConfig with properties:

    AdvertisingDataTypes: {2x1 cell}
       LEDiscoverability: 'Limited'
                   BREDR: 0
            TxPowerLevel: 45
```

Generate a BLE GAP AD block from the corresponding configuration object.

```
dataBlock = bleGAPDataBlock(cfgGAP);
```

Decode the generated BLE GAP AD block. The returned status indicates decoding was successful. View the output of `'status'` and `'cfgGAP'`.

```
[status, cfgGAP] = bleGAPDataBlockDecode(dataBlock)
```

```
status = 
Success

cfgGAP = 
  bleGAPDataBlockConfig with properties:

    AdvertisingDataTypes: {2x1 cell}
          LEDiscoverability: 'Limited'
                      BREDR: 0
               TxPowerLevel: 45
```

Create another BLE GAP AD block configuration object, this time specifying AD types `'Advertising interval'` and `'Local name'`. Set the values of advertising interval as `48`, local name as `'MathWorks'`, and local name shortening as `true`. View the properties of the configuration object `'cfgGAP'`.

```
cfgGAP = bleGAPDataBlockConfig('AdvertisingDataTypes', ...
    {'Advertising interval','Local name'});
cfgGAP.AdvertisingInterval = 48;
cfgGAP.LocalName = 'MathWorks';
cfgGAP.LocalNameShortening = true
```

```
cfgGAP = 
  bleGAPDataBlockConfig with properties:

    AdvertisingDataTypes: {2x1 cell}
               LocalName: 'MathWorks'
     LocalNameShortening: 1
     AdvertisingInterval: 48
```

Generate the BLE GAP AD block from the corresponding configuration object.

```
dataBlock = bleGAPDataBlock(cfgGAP);
```

Decode the generated BLE GAP AD block. The returned status indicates decoding was successful. View the output of `'status'` and `'cfgGAP'`.

```
[status, cfgGAP] = bleGAPDataBlockDecode(dataBlock)
```

```
status = 
Success

cfgGAP = 
  bleGAPDataBlockConfig with properties:

    AdvertisingDataTypes: {2x1 cell}
               LocalName: 'MathWorks'
     LocalNameShortening: 1
     AdvertisingInterval: 48
```

Decode Corrupted BLE GAP AD Block

Specify a BLE GAP AD block containing corrupted data values.

```
dataBlock = ['010106010202']; % Sample BLE GAP AD block with corrupted data values
```

Decode the specified BLE GAP AD block. The returned status indicates that the decoding failed due to the corrupted input BLE GAP AD block. In this case, when decoding fails, the BLE GAP AD block configuration object, `'cfgGAP'`, displays no properties.

```
[status, cfgGAP] = bleGAPDataBlockDecode(dataBlock)
```

```
status = 
MismatchGAPADLength

cfgGAP = 
  bleGAPDataBlockConfig with properties:
```

Input Arguments

`dataBlock` — BLE GAP data block

character vector | string scalar | numeric vector | character array

BLE GAP data block, specified as one of these values:

- Character vector — This vector represents octets in hexadecimal format.
- String scalar — This scalar represents octets in hexadecimal format.
- Numeric vector of elements in the range [0, 255] — This vector represents octets in decimal format.
- *n*-by-2 character array — Each row represents an octet in hexadecimal format.

Data Types: `char` | `string` | `double`

Output Arguments

`status` — BLE GAP data block decoding status

nonpositive integer

BLE GAP data block decoding status, returned as a nonpositive integer of type `blePacketDecodeStatus`. This value represents the result of an BLE GAP data block decoding. Each value of `status` corresponds to a member of the `blePacketDecodeStatus` enumeration class, which indicates the packet decoding status according to this table.

Enumeration Value	Member of Enumeration Class	Decoding Status
0	`Success`	Packet decoding succeeded
-201	`InvalidGAPADLength`	GAP AD length is not valid
-202	`MismatchGAPADLength`	Received AD length does not match with actual length

-203	UnsupportedGAPADType	Advertising data type is not valid or not supported
-204	InvalidGAPAdvertisingInterval	Advertising interval is not valid
-205	InvalidGAPConnectionIntervalRange	Invalid connection interval
-206	InvalidGAPConnectionIntervalMinimum	Invalid interval minimum
-207	InvalidGAPConnectionIntervalMaximum	Invalid interval maximum

An enumeration value other than 0 means that the BLE GAP data block decoding failed. If the decoding fails, object cfgGAP displays no output.

cfgGAP — BLE GAP data block configuration object
bleGAPDataBlockConfig | object

BLE GAP data block configuration object, returned as a bleGAPDataBlockConfig object. This value defines the type of BLE GAP data block and its applicable properties.

bleIdealReceiver

Ideal receiver for BLE PHY waveform

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Syntax

```
[bits,accessAddr] = bleIdealReceiver(waveform)
[bits,accessAddr] = bleIdealReceiver(waveform,Name,Value)
[ ___ ,IQsamples] = bleIdealReceiver( ___ )
```

Description

`[bits,accessAddr] = bleIdealReceiver(waveform)` decodes the Bluetooth low energy (BLE) `waveform`, generated by `bleWaveformGenerator` , and returns the received bits, `bits`, and the access address information, `accesAddr`.

`[bits,accessAddr] = bleIdealReceiver(waveform,Name,Value)` also specifies options using one or more name-value pair arguments. For example, `'Mode','LE2M'` specifies the physical (PHY) layer transmission mode of the desired BLE waveform.

`[ ___ ,IQsamples] = bleIdealReceiver( ___ )` also returns the in-phase and quadrature (IQ) samples, `IQsamples`, corresponding to constant tone extension (CTE).

Examples

Decode BLE Waveform Using Default Settings

Create an input message column vector of length 1000 containing random binary values. Generate a BLE transmit waveform from the transmission bits by using the `bleWaveformGenerator` function.

```
txBits = randi([0 1],1000,1);
txWaveform = bleWaveformGenerator(txBits);
```

Pass the transmit waveform through a noisy channel and obtain the received waveform.

```
snr = 30; % specified in dB
rxWaveform = awgn(txWaveform,snr);
```

Recover data bits from the received BLE waveform using `bleIdealReceiver`. Check for the number of bit errors in the recovered bits. The returned value indicates that the BLE waveform was successfully decoded.

```
[rxBits,accessAddr] = bleIdealReceiver(rxWaveform);
numErr = biterr(txBits,rxBits)
```

```
numErr = 0
```

Decode BLE Waveform Using Specified Name-Value Pairs

Specify the values of PHY generating mode, channel index and samples per symbol (sps).

```
phyMode = 'LE125K';
chanIndex = 2;
sps = 4;
```

Generate transmission bits containing random binary values. Obtain the BLE transmit waveform from the transmission bits and the specified name-value pairs using the `bleWaveformGenerator` function.

```
txBits = randi([0 1],100,1);
txWaveform = bleWaveformGenerator(txBits,'Mode',phyMode,...
    'SamplesPerSymbol',sps,'ChannelIndex',chanIndex);
```

Recover the data bits, and then compare them with the transmission bits. The recovered data bits match the transmission bits, indicating there are no errors in the decoded BLE waveform.

```
rxBits = bleIdealReceiver(txWaveform,'Mode',phyMode,...
    'SamplesPerSymbol',sps,'ChannelIndex',chanIndex);
isequal(txBits,rxBits)
```

```
ans = logical
   1
```

Decode BLE Waveform With CTE For Connectionless Scenario

Specify a connectionless advertising channel protocol data unit (PDU) for angle of arrival (AoA) CTE.

```
pduHex = '02049B0327';
pdu = de2bi(hex2dec(pduHex),40)';
```

Generate and append cyclic redundancy check (CRC) to the PDU.

```
crcGen = comm.CRCGenerator('z^24+z^10+z^9+z^6+z^4+z^3+z+1',...
    'InitialConditions',de2bi(hex2dec('555551'),'left-msb',24),...
    'DirectMethod',true);
pduCRC = crcGen(pdu);
```

Generate the BLE transmit waveform using specified name-value pair arguments.

```
txWaveform = bleWaveformGenerator(pduCRC,'ChannelIndex',36,...
    'DFPacketType','ConnectionlessCTE');
```

Recover the data bits by demodulating, dewhitening, and IQ sampling for a slot duration of 2 μs.

```
[bits,accAddr,iqSamples] = bleIdealReceiver(txWaveform,...
    'ChannelIndex',36,'DFPacketType','ConnectionlessCTE');
```

Input Arguments

`waveform` — Received time-domain signal

complex-valued vector

Received time-domain signal, specified as a complex-valued signal with size N_s-by-1, where N_s represents the number of received samples. The values of N_s depend on the `'Mode'` and `'SamplesPerSymbol'` (sps) name-value pairs, according to the constraints specified in this table. For example, if the value of `'Mode'` is `'LE1M'` and the value of `'SamplesPerSymbol'` is 4 then the value of N_s must be greater than or equal to 160 and a multiple of `'SamplesPerSymbol'`.

Value of `'Mode'`	Value of N_s	Multiple of
`'LE1M'`	≥40×*sps*	*sps*
`'LE2M'`	≥48×*sps*	*sps*
`'LE500K'`	≥376×*sps*	2×*sps*
`'LE125K'`	≥376×*sps*	8×*sps*

Data Types: `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `bleIdealReceiver(waveform,'Mode','LE2M','ChannelIndex',36)`

`Mode` — PHY transmission mode

`'LE1M'` (default) | `'LE2M'` | `'LE500K'` | `'LE125K'`

PHY transmission mode, specified as the comma-separated pair consisting of `'Mode'` and `'LE1M'`, `'LE2M'`, `'LE500K'`, or `'LE125K'`. This value indicates the type of PHY used to decode the received BLE waveform.

Data Types: `string` | `char`

`ChannelIndex` — Channel Index

`37` (default) | integer in the range [0, 39]

Channel index, specified as the comma-separated pair consisting of `'ChannelIndex'` and an integer in the range [0, 39]. For data channels, this value must be in the range [0, 36]. This value is used by the data-dewhitening block.

Data Types: `single` | `double`

`SamplesPerSymbol` — Samples per symbol

`8` (default) | positive integer

Samples per symbol, specified as the comma-separated pair consisting of `'SamplesPerSymbol'` and a positive integer. The object uses this value for Gaussian frequency shift keying (GFSK) modulation.

Data Types: `single` | `double`

`DFPacketType` — Type of direction finding packet

`'Disabled'` (default) | `'ConnectionlessCTE'` | `'ConnectionCTE'`

Type of direction finding packet, specified as the comma-separated pair consisting of `'DFPacketType'` and `'ConnectionlessCTE'`, `'ConnectionCTE'`, or `'Disabled'`.

Data Types: `string` | `char`

`SlotDuration` — Switch and sample slot duration
2 (default) | 1

Switch and sample slot duration, specified as the comma-separated pair consisting of `'SlotDuration'` and `1` or `2`. This value must be expressed in microseconds.

Data Types: `double`

Output Arguments

`bits` — Payload bits
column vector

Payload bits, returned as a column vector of maximum length 260 bytes. This output represents the recovered information bits.

Data Types: `int8`

`accessAddr` — Access address information
32-bit column vector

Access address information, returned as a 32-bit column vector. This output is used by the higher layers for validating a packet.

Data Types: `int8`

`IQsamples` — IQ samples
complex-valued column vector

IQ samples, specified as a complex-valued column vector. This argument corresponds to the 8 µs value of the reference period and slot duration. If the value of “'DFPacketType'” on page 2-0 argument is `'ConnectionlessCTE'` or `'ConnectionCTE'`, then the function returns this argument.

Data Types: `double`

bleL2CAPFrame

Generate BLE L2CAP frame

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Syntax

```
L2CAPFrame = bleL2CAPFrame(cfgL2CAP)
L2CAPFrame = bleL2CAPFrame(cfgL2CAP,SDU)
```

Description

`L2CAPFrame = bleL2CAPFrame(cfgL2CAP)` generates a Bluetooth low energy (BLE) logical link control and adaptation protocol (L2CAP) frame, `L2CAPFrame`, for a given BLE L2CAP configuration object, `cfgL2CAP`. Use this syntax to generate the signaling frames.

`L2CAPFrame = bleL2CAPFrame(cfgL2CAP,SDU)` generates a BLE L2CAP frame, `L2CAPFrame`, for a given BLE L2CAP configuration object `cfgL2CAP` and the upper-layer payload service data unit (SDU), `SDU`. Use this syntax to generate the data frames.

Examples

Generate BLE L2CAP Signaling Command Frame

Create a BLE L2CAP configuration object, `'cfgL2CAP'`, and view the corresponding default properties.

```
cfgL2CAP = bleL2CAPFrameConfig
```

```
cfgL2CAP = 
  bleL2CAPFrameConfig with properties:

          ChannelIdentifier: '0005'
                CommandType: 'Credit based connection request'
           SignalIdentifier: '01'
    SourceChannelIdentifier: '0040'
                      LEPSM: '001F'
        MaxTransmissionUnit: 23
          MaxPDUPayloadSize: 23
                    Credits: 1
```

Change the value of credits to `10`.

```
cfgL2CAP.Credits            = 10;
```

Generate a BLE L2CAP signaling command frame from the corresponding configuration object.

```
l2capFrame = bleL2CAPFrame(cfgL2CAP)
```

```
l2capFrame = 18x2 char array
    '0E'
    '00'
    '05'
    '00'
    '14'
    '01'
    '0A'
    '00'
    '1F'
    '00'
    '40'
    '00'
    '17'
    '00'
    '17'
    '00'
    '0A'
    '00'
```

Generate BLE L2CAP Data Frames

Generate two unique BLE L2CAP data frames: one with SDU from the attribute protocol (ATT) layer as `'0A0100'` and the other with an upper-layer payload SDU,`'0A01E2D3'`.

Create a BLE L2CAP configuration object, `'cfgL2CAP'`, and view the default properties.

```
cfgL2CAP = bleL2CAPFrameConfig
```

```
cfgL2CAP = 
  bleL2CAPFrameConfig with properties:

          ChannelIdentifier: '0005'
                CommandType: 'Credit based connection request'
           SignalIdentifier: '01'
    SourceChannelIdentifier: '0040'
                      LEPSM: '001F'
        MaxTransmissionUnit: 23
          MaxPDUPayloadSize: 23
                    Credits: 1
```

Change the value of channel identifier to `'0004'`.

```
cfgL2CAP.ChannelIdentifier = '0004'; % Channel identifier for ATT
```

Generate a BLE L2CAP data frame from `'cfgL2CAP'`, specifying the upper-layer payload SDU from the ATT layer as `'0A0100'`.

```
l2capFrame = bleL2CAPFrame(cfgL2CAP,"0A0100")
```

```
l2capFrame = 7x2 char array
    '03'
    '00'
    '04'
    '00'
    '0A'
    '01'
    '00'
```

Create another BLE L2CAP configuration object, `'cfgL2CAP'`, with default properties. Set the value of channel identifier to `'007A'`.

```
cfgL2CAP = bleL2CAPFrameConfig;
cfgL2CAP.ChannelIdentifier = '007A'; % Dynamic channel identifier
```

Generate a BLE L2CAP data frame from `'cfgL2CAP'`, specifying the upper-layer payload SDU as `'0A01E2D3'`.

```
l2capFrame = bleL2CAPFrame(cfgL2CAP,['0A'; '01'; 'E2'; 'D3'])
```

```
l2capFrame = 10x2 char array
    '06'
    '00'
    '7A'
    '00'
    '04'
    '00'
    '0A'
    '01'
    'E2'
    'D3'
```

Input Arguments

`cfgL2CAP` — BLE L2CAP configuration object

`bleL2CAPFrameConfig` object

BLE L2CAP configuration object, specified as a `bleL2CAPFrameConfig` object. The function uses this object to configure the BLE L2CAP frame and its applicable properties.

SDU — Upper-layer payload

character vector | string scalar | numeric vector | character array

Upper-layer payload, specified as one of these types:

- Character vector — This vector represents octets in hexadecimal format.
- String scalar — This scalar represents octets in hexadecimal format.
- Numeric vector of elements in the range [0, 255] — This vector represents octets in decimal format.
- *n*-by-2 character array — Each row represents an octet in hexadecimal format.

Data Types: `char` | `double` | `string`

Output Arguments

`L2CAPFrame` — Generated BLE L2CAP frame

character array

Generated BLE L2CAP frame, returned as a character array. Each row of the array represents an octet in hexadecimal format. This value represents the output BLE L2CAP frame.

bleL2CAPFrameDecode

Decode BLE L2CAP frame

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Syntax

```
[status,cfgL2CAP,SDU] = bleL2CAPFrameDecode(L2CAPFrame)
```

Description

`[status,cfgL2CAP,SDU] = bleL2CAPFrameDecode(L2CAPFrame)` decodes the specified Bluetooth low energy (BLE) logical link control and adaptation protocol (L2CAP) frame, `L2CAPFrame`. The function returns the decoding status, `status`, the corresponding BLE L2CAP configuration object, `cfgL2CAP`, and the upper-layer payload service data unit (SDU), `SDU`.

Examples

Decode BLE L2CAP Data Frame with SDU

Create a BLE L2CAP configuration object, `'cfgL2CAP'`, with default properties and view the applicable properties. Change the value of channel identifier to `'0004'`.

```
cfgL2CAP = bleL2CAPFrameConfig
```

```
cfgL2CAP = 
  bleL2CAPFrameConfig with properties:

          ChannelIdentifier: '0005'
                CommandType: 'Credit based connection request'
           SignalIdentifier: '01'
    SourceChannelIdentifier: '0040'
                      LEPSM: '001F'
        MaxTransmissionUnit: 23
          MaxPDUPayloadSize: 23
                    Credits: 1
```

```
cfgL2CAP.ChannelIdentifier = '0004'; % Channel identifier for ATT
```

Generate a BLE L2CAP data frame from `'cfgL2CAP'`, specifying the upper-layer payload SDU from attribute protocol (ATT) layer as `'0A0100'`.

```
L2CAPFrame = bleL2CAPFrame(cfgL2CAP, "0A0100");
```

Decode the generated BLE L2CAP data frame. The returned status indicates decoding was successful. View the output of `'status'`, `'cfgL2CAP'` and the `'SDU'`.

```
[status, cfgL2CAP, SDU] = bleL2CAPFrameDecode(L2CAPFrame)
```

```
status = 
Success

cfgL2CAP = 
  bleL2CAPFrameConfig with properties:

    ChannelIdentifier: '0004'

SDU = 3x2 char array
    '0A'
    '01'
    '00'
```

Decode Corrupted BLE L2CAP Frame

Specify a BLE L2CAP frame containing corrupted data values.

```
l2capFrame = ['090005000107040060005000']; % Sample frame
```

Decode the specified BLE L2CAP frame. The returned status indicates that the decoding failed due to the corrupted input L2CAP frame. In this case, when decoding fails, the output displays the reason of failure and the BLE L2CAP frame configuration object, `'cfgL2CAP'`, displays no properties.

```
[status, cfgL2CAP, SDU] = bleL2CAPFrameDecode(l2capFrame)
```

```
status = 
MismatchL2CAPHeaderLength

cfgL2CAP = 
  bleL2CAPFrameConfig with properties:

SDU =

  1x0 empty char array
```

Input Arguments

L2CAPFrame — BLE L2CAP frame

character vector | string scalar | numeric vector | character array

BLE L2CAP frame, specified as one of these values:

- Character vector — This vector represents octets in hexadecimal format.
- String scalar — This scalar represents octets in hexadecimal format.
- Numeric vector of elements in the range [0, 255] — This vector represents octets in decimal format.
- *n*-by-2 character array — Each row represents an octet in hexadecimal format.

Data Types: `char` | `double` | `string`

Output Arguments

`status` — Packet decoding status

nonpositive integer

Packet decoding status, returned as a nonpositive integer of type `blePacketDecodeStatus`. This value represents the result of decoding a BLE L2CAP frame. Each value of `status` corresponds to a member of the `blePacketDecodeStatus` enumeration class, which indicates the packet decoding status according to this table.

Enumeration Value	Member of Enumeration Class	Decoding Status
0	`Success`	Packet decoding succeeded
–301	`InvalidL2CAPConnectionIntervalRange`	Invalid connection intervals
–302	`InvalidL2CAPSlaveLatency`	Invalid slave latency
–303	`InvalidLECredits`	Invalid low energy (LE) credits
–304	`L2CAPSegmentationUnsupported`	Segmentation is not supported
–305	`MismatchL2CAPHeaderLength`	Length mismatches with actual length
–306	`IncompleteL2CAPDataFrame`	L2CAP data frame is not sufficient to decode
–307	`InvalidL2CAPChannelIdentifier`	Invalid L2CAP channel identifier
–308	`InvalidL2CAPCommand`	Invalid L2CAP command code
–309	`InvalidL2CAPCommandRejectReason`	Invalid command reject reason code
–310	`InvalidL2CAPParameterUpdateResult`	Invalid parameters update result
-311	`InvalidL2CAPConnectionResult`	Invalid connection result code
-312	`IllegalL2CAPSignalIdentifier`	Illegal signal identifier in L2CAP
-313	`InvalidL2CAPConnectionIntervalMinimum`	Invalid interval minimum
-314	`InvalidL2CAPConnectionIntervalMaximum`	Invalid interval maximum
-315	`InvalidL2CAPConnectionTimeout`	Invalid connection timeout
-316	`InvalidLEPSM`	Invalid LE protocol/service multiplexer

-317	`InvalidL2CAPChannelMTU`	Invalid maximum transmission unit
-318	`InvalidL2CAPChannelMPS`	Invalid maximum PDU payload size
-319	`InvalidL2CAPSDULength`	Invalid SDU length
-320	`MismatchL2CAPSignalFrameLength`	Length mismatches with actual length
-321	`IncompleteL2CAPSignalFrame`	L2CAP signal frame is not valid or not sufficient

An enumeration value other than `0` means that the BLE ATT PDU decoding failed. If the decoding fails, object `cfgATT` displays no output.

`cfgL2CAP` — BLE L2CAP frame configuration object
`bleL2CAPFrameConfig` object

BLE L2CAP frame configuration object, returned as a `bleL2CAPFrameConfig` object. This value denotes the decoded BLE L2CAP frame configuration.

`SDU` — Upper-layer payload
character array

Upper-layer payload, returned as a character array. Each row represents an octet in hexadecimal format.

Data Types: `char` | `string`

bleLLAdvertisingChannelPDU

Generate BLE LL advertising channel PDU

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see "Get and Manage Add-Ons". Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Syntax

pdu = bleLLAdvertisingChannelPDU(cfgLLAdv)

Description

pdu = bleLLAdvertisingChannelPDU(cfgLLAdv) generates a Bluetooth low energy (BLE) link layer (LL) advertising channel protocol data unit (PDU) corresponding to the BLE LL advertising channel PDU configuration object cfgLLAdv.

Examples

Generate BLE LL Advertising Channel PDUs

Generate two unique BLE LL advertising channel PDUs: first one of the type 'Advertising indication' using advertising data '020106' and the other of type 'Connection indication' using a set of data channels to be used.

Create a BLE LL advertising channel PDU configuration object, 'cfgLLAdv', with the opcode as 'Advertising indication' by using advertising data '020106'. View the configured properties corresponding to the opcode.

```
cfgLLAdv = bleLLAdvertisingChannelPDUConfig;
cfgLLAdv.AdvertisingData = '020106'
```

```
cfgLLAdv = 
  bleLLAdvertisingChannelPDUConfig with properties:

                  PDUType: 'Advertising indication'
         ChannelSelection: 'Algorithm1'
    AdvertiserAddressType: 'Random'
        AdvertiserAddress: '0123456789AB'
          AdvertisingData: [3x2 char]
```

Generate the BLE LL advertising channel PDU by using the corresponding configuration object. Display the PDU length in octets.

```
pdu = bleLLAdvertisingChannelPDU(cfgLLAdv);
numel(pdu)/8
```

```
ans = 14
```

Display the first octet of the generated BLE LL advertising channel PDU.

```
pdu(1:8)
```

```
ans = 8×1

     0
     0
     0
     0
     0
     0
     1
     0
```

Create another BLE LL advertising channel PDU configuration object, this time using the name-value pairs. Change the BLE LL advertising channel PDU opcode to `'Connection indication'`. View the active configured properties of the specified opcode.

```
cfgLLAdv = bleLLAdvertisingChannelPDUConfig('PDUType', ...
    'Connection indication')
```

```
cfgLLAdv = 
  bleLLAdvertisingChannelPDUConfig with properties:

                  PDUType: 'Connection indication'
         ChannelSelection: 'Algorithm1'
    AdvertiserAddressType: 'Random'
        AdvertiserAddress: '0123456789AB'
     InitiatorAddressType: 'Random'
         InitiatorAddress: '0123456789CD'
            AccessAddress: '01234567'
        CRCInitialization: '012345'
               WindowSize: 1
             WindowOffset: 0
       ConnectionInterval: 6
             SlaveLatency: 0
        ConnectionTimeout: 10
             UsedChannels: [1x37 double]
             HopIncrement: 5
       SleepClockAccuracy: '251 to 500 ppm'
```

Specify the value of connection interval as `8` and the set of data channels as `[0 4 12 16 18 24 25]`. View the configured properties.

```
cfgLLAdv.ConnectionInterval = 8; % in milliseconds
cfgLLAdv.UsedChannels       = [0 4 12 16 18 24 25]
```

```
cfgLLAdv = 
  bleLLAdvertisingChannelPDUConfig with properties:

                  PDUType: 'Connection indication'
         ChannelSelection: 'Algorithm1'
    AdvertiserAddressType: 'Random'
        AdvertiserAddress: '0123456789AB'
     InitiatorAddressType: 'Random'
```

```
         InitiatorAddress: '0123456789CD'
            AccessAddress: '01234567'
        CRCInitialization: '012345'
               WindowSize: 1
             WindowOffset: 0
       ConnectionInterval: 8
             SlaveLatency: 0
        ConnectionTimeout: 10
             UsedChannels: [0 4 12 16 18 24 25]
             HopIncrement: 5
       SleepClockAccuracy: '251 to 500 ppm'
```

Generate the BLE LL advertising channel PDU from the corresponding configuration object. Display the PDU length in octets.

```
pdu = bleLLAdvertisingChannelPDU(cfgLLAdv);
numel(pdu)/8
```

```
ans = 39
```

Display the first octet of the generated BLE LL advertising channel PDU.

```
pdu(1:8)
```

```
ans = 8×1

     1
     0
     1
     0
     0
     0
     1
     1
```

Input Arguments

cfgLLAdv — BLE LL advertising channel PDU configuration object
bleLLAdvertisingChannelPDUConfig object

BLE LL advertising channel PDU configuration object, specified as a bleLLAdvertisingChannelPDUConfig object. This value defines the type of generated BLE LL advertising channel PDU and its applicable properties.

Output Arguments

pdu — Generated BLE LL advertising channel PDU
binary column vector

Generated BLE LL advertising channel PDU, returned as a binary column vector. This value represents the output BLE LL advertising channel PDU.

bleLLAdvertisingChannelPDUDecode

Decode BLE LL advertising channel PDU

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Syntax

```
[status,cfgLLAdv] = bleLLAdvertisingChannelPDUDecode(pdu)
[status,cfgLLAdv] = bleLLAdvertisingChannelPDUDecode(pdu,Name,Value)
```

Description

`[status,cfgLLAdv] = bleLLAdvertisingChannelPDUDecode(pdu)`decodes the specified Bluetooth low energy (BLE) link layer (LL) advertising channel protocol data unit (PDU), returning the decoding status, `status`, and the corresponding BLE LL advertising channel PDU configuration object, `cfgLLAdv`.

`[status,cfgLLAdv] = bleLLAdvertisingChannelPDUDecode(pdu,Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `'InputFormat','octets'` specifies the input BLE LL advertising channel PDU in the form of octets.

Examples

Decode BLE LL Advertising Channel PDU Given in Bits

Create a BLE LL advertising channel PDU configuration object, `'cfgLLAdv'`, with default settings and view the corresponding applicable properties.

```
cfgLLAdv = bleLLAdvertisingChannelPDUConfig
```

```
cfgLLAdv = 
  bleLLAdvertisingChannelPDUConfig with properties:

                  PDUType: 'Advertising indication'
         ChannelSelection: 'Algorithm1'
    AdvertiserAddressType: 'Random'
        AdvertiserAddress: '0123456789AB'
          AdvertisingData: [3x2 char]
```

Generate the BLE LL advertising channel PDU from the corresponding configuration object.

```
pdu = bleLLAdvertisingChannelPDU(cfgLLAdv);
```

Decode the generated BLE LL advertising channel PDU. The returned status indicates decoding is successful. View the output of `'status'`and `'cfgLLAdv'`.

```
[status, cfgLLAdv] = bleLLAdvertisingChannelPDUDecode(pdu)
```

```
status = 
Success

cfgLLAdv = 
  bleLLAdvertisingChannelPDUConfig with properties:

                PDUType: 'Advertising indication'
       ChannelSelection: 'Algorithm1'
  AdvertiserAddressType: 'Random'
      AdvertiserAddress: '0123456789AB'
        AdvertisingData: [3x2 char]
```

Decode BLE LL Advertising Channel PDU Given in Octets

Specify a sample BLE LL advertising channel PDU in octets.

```
pdu = 'C409AB8967452301020106A8F1DF'; % Sample PDU in octets
```

Decode the specified BLE LL advertising channel PDU by specifying `'InputFormat'` to `'octets'`. The returned status indicates decoding is successful. View the output of `'status'` and `'cfgLLData'`.

```
[status, cfgLLAdv] = bleLLAdvertisingChannelPDUDecode(pdu, ...
    'InputFormat','octets')
```

```
status = 
Success

cfgLLAdv = 
  bleLLAdvertisingChannelPDUConfig with properties:

                PDUType: 'Scan response'
       ChannelSelection: 'Algorithm1'
  AdvertiserAddressType: 'Random'
      AdvertiserAddress: '0123456789AB'
       ScanResponseData: [3x2 char]
```

Decode Corrupted BLE LL Advertising Channel PDU

Specify a BLE LL advertising channel PDU containing corrupted data values.

```
pdu = 'D409AB89674523010201'; % Sample corrupted PDU
```

Decode the specified BLE LL advertising channel PDU. The returned status indicates that the decoding failed due to corrupted input BLE LL advertising channel PDU. In case of failed decoding, the reason of failure is indicated and the BLE LL advertising channel PDU configuration object, `'cfgLLAdv'`, displays no properties.

```
[status, cfgLLAdv] = bleLLAdvertisingChannelPDUDecode(pdu, ...
    'InputFormat','octets')
```

```
status = 
CRCFailed

cfgLLAdv = 
  bleLLAdvertisingChannelPDUConfig with properties:
```

Input Arguments

pdu — BLE LL advertising channel PDU

character vector | string scalar | numeric vector | character array | binary vector

BLE LL advertising channel PDU, specified as one of these types:

- Character vector — This vector represents octets in hexadecimal format.
- String scalar — This scalar represents octets in hexadecimal format.
- Numeric vector of elements in the range [0,255] — This vector represents octets in decimal format.
- `n-by-2` character array — Each row represents an octet in hexadecimal format.
- Binary vector — This vector represents the BLE LL advertising channel PDU bits.

Data Types: `char` | `double` | `string`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `[status,cfgLLAdv] = bleLLAdvertisingChannelPDUDecode('pdu','InputFormat','octets')`

`InputFormat` — BLE LL advertising channel PDU format

`'bits'` (default) | `'octets'`

BLE LL advertising channel PDU format, specified as `'bits'` or`'octets'`. When specified as `'bits'`, the `InputFormat` is a binary vector. When specified as `'octets'`, `InputFormat` is a numeric vector representing octets in decimal format or a character array or a string scalar representing octets in hexadecimal format.

Data Types: `char` | `string`

Output Arguments

`status` — BLE LL advertising channel PDU decoding status

nonpositive integer

BLE LL advertising channel PDU decoding status, returned as a nonpositive number of type `blePacketDecodeStatus`. This value represents the result of BLE LL advertising channel PDU decoding. Each value of `status` corresponds to a member of the `blePacketDecodeStatus` enumeration class, which indicates the packet decoding status listed in this table.

Enumeration Value	Member of Enumeration Class	Decoding Status
0	`Success`	Packet decoding succeeded
-1	`CRCFailed`	Link Layer PDU is corrupted
-2	`LLPDULengthMismatch`	Length field does not match with actual PDU length
-3	`InvalidLLSlaveLatency`	Invalid slave latency
-4	`InvalidLLConnectionTimeout`	Invalid connection timeout
-5	`InvalidLLWindowSize`	Invalid window size
-6	`InvalidLLWindowOffset`	Invalid window offset
-7	`InvalidLLConnectionInterval`	Invalid connection interval
-8	`InvalidLLChannelMap`	Invalid channel map
-51	`IncompleteLLAdvertisingChannelPDU`	Insufficient octets in advertising channel PDU
-52	`InvalidLLHopIncrement`	Invalid hop increment value
-53	`InvalidLLAdvertisingDataLength`	Invalid advertising data
-54	`InvalidLLScanResponseDataLength`	Invalid scan response data
-55	`UnsupportedLLAdvertisingPDUType`	Unsupported advertising channel PDU

An enumeration value other than `0` means that the BLE LL advertising channel PDU decoding failed. If the decoding fails, object `cfgLLAdv` displays no output.

`cfgLLAdv` — BLE LL advertising channel PDU configuration object
`bleLLAdvertisingChannelPDUConfig` object

BLE LL advertising channel configuration object, returned as a `bleLLAdvertisingChannelPDUConfig` object. This value represents the decoded BLE LL advertising channel PDU configuration.

bleLLDataChannelPDU

Generate BLE LL data channel PDU

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Syntax

```
pdu = bleLLDataChannelPDU(cfgLLData)
pdu = bleLLDataChannelPDU(cfgLLData,LLPayload)
```

Description

`pdu = bleLLDataChannelPDU(cfgLLData)` generates a Bluetooth low energy (BLE) link layer (LL) data channel protocol data unit (PDU), `pdu`, for a given BLE LL data channel configuration object `cfgLLData`. This syntax is used for generating BLE LL control PDUs.

`pdu = bleLLDataChannelPDU(cfgLLData,LLPayload)` generates a BLE LL data channel PDU, `pdu`, containing the upper-layer payload `LLPayload` for a given BLE LL data channel configuration object `cfgLLData`. This syntax is used for generating BLE LL data PDUs.

Examples

Generate BLE LL Control PDU of Type Connection Update Indication

Create a BLE LL control PDU configuration object for a control PDU using the default configuration. View the corresponding default properties.

```
cfgControl = bleLLControlPDUConfig
```

```
cfgControl = 
  bleLLControlPDUConfig with properties:

                Opcode: 'Connection update indication'
            WindowSize: 1
          WindowOffset: 0
    ConnectionInterval: 6
          SlaveLatency: 0
     ConnectionTimeout: 10
               Instant: 0
```

Create a BLE LL data channel PDU configuration object for a control PDU of type `'Connection update indication'` by configuring the values of link layer identifier (LLID) as `'Control'` and ControlConfig as `'cfgControl'`. View the corresponding properties.

```
cfgLLData = bleLLDataChannelPDUConfig('LLID', 'Control', ...
    'ControlConfig', cfgControl)
```

```
cfgLLData = 
  bleLLDataChannelPDUConfig with properties:

                 LLID: 'Control'
                 NESN: 0
       SequenceNumber: 0
             MoreData: 0
    CRCInitialization: '012345'
        ControlConfig: [1x1 bleLLControlPDUConfig]
```

Generate a BLE LL data channel PDU of type `'Connection update indication'` by using the configuration object `'cfgLLData'`. Display the PDU length in octets.

```
pdu = bleLLDataChannelPDU(cfgLLData);
numel(pdu)/8
```

```
ans = 17
```

Display the first octet of the generated BLE LL data channel PDU.

```
pdu(1:8)
```

```
ans = 8×1

     0
     0
```

Generate BLE LL Data PDU Using Upper-Layer Payload

Create a BLE LL data channel PDU configuration object, `'cfgLLData'`, for a data PDU by using the default configuration. View the corresponding default properties.

```
cfgLLData = bleLLDataChannelPDUConfig
```

```
cfgLLData = 
  bleLLDataChannelPDUConfig with properties:

                 LLID: 'Data (continuation fragment/empty)'
                 NESN: 0
       SequenceNumber: 0
             MoreData: 0
    CRCInitialization: '012345'
```

Generate a BLE LL data PDU by using the corresponding configuration object, `'cgLLData'` and the upper-layer payload `'030004000A0100'`. Display the PDU length in octets.

```
pdu = bleLLDataChannelPDU(cfgLLData,'030004000A0100');
numel(pdu)/8

ans = 12
```

Display the first octet of the generated BLE LL data PDU.

```
pdu(1:8)

ans = 8×1

     1
     0
     0
     0
     0
     0
     0
     0
```

Input Arguments

`cfgLLData` — BLE LL data channel configuration object

`bleLLDataChannelPDUConfig` object

BLE LL data channel configuration object, specified as a `bleLLDataChannelPDUConfig` object. This object is used to configure the BLE LL data channel PDU and its applicable properties.

LLPayload — Upper-layer payload

character vector | string scalar | numeric vector | character array

Upper-layer payload, specified as one of these types:

- Character vector — This vector represents octets in hexadecimal format.
- String scalar — This scalar represents octets in hexadecimal format.
- Numeric vector of elements in the range [0,255] — This vector represents octets in decimal format.
- `n-by-2` character array — Each row represents an octet in hexadecimal format.

Data Types: `char` | `double` | `string`

Output Arguments

pdu — Generated BLE LL data channel PDU

binary vector

Generated BLE LL data channel PDU, returned as a binary column vector. This value represents the output BLE LL data channel PDU.

bleLLDataChannelPDUDecode

Decode BLE LL data channel PDU

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Syntax

```
[status,cfgLLData,LLPayload] = bleLLDataChannelPDUDecode(pdu,CRCinit)
[status,cfgLLData,LLPayload] = bleLLDataChannelPDUDecode(pdu,CRCinit
Name,Value)
```

Description

`[status,cfgLLData,LLPayload] = bleLLDataChannelPDUDecode(pdu,CRCinit)` decodes a Bluetooth low energy (BLE) link layer (LL) data channel protocol data unit (PDU), returning the decoding status, `status`, the BLE LL data channel PDU configuration object, `cfgLLData`, and the upper-layer payload, `LLPayload`. The `CRCinit` denotes the initialization value of cyclic redundancy check (CRC).

`[status,cfgLLData,LLPayload] = bleLLDataChannelPDUDecode(pdu,CRCinit Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `'InputFormat','bits'` specifies the format of input BLE LL data channel PDU in bits.

Examples

Decode BLE LL Data Channel PDU Given in Bits

Create a BLE LL data channel PDU configuration object by using default settings and view the corresponding applicable properties.

```
cfgLLData = bleLLDataChannelPDUConfig
```

```
cfgLLData = 
  bleLLDataChannelPDUConfig with properties:

                 LLID: 'Data (continuation fragment/empty)'
                 NESN: 0
       SequenceNumber: 0
             MoreData: 0
    CRCInitialization: '012345'
```

Initialize and set the LLID value to `'start fragment/complete'` indicating the BLE LL data channel PDU with the upper-layer payload. Initialize the cyclic redundancy check (CRC) value to `'ED321C'`.

```
cfgLLData.LLID = 'Data (start fragment/complete)';
cfgLLData.CRCInitialization = 'ED321C';
crcInit = 'ED321C'; % CRC initialization value
```

Generate the BLE LL data channel PDU with upper-layer payload given in hexadecimal octets.

```
pdu = bleLLDataChannelPDU(cfgLLData,'030004000A0100');
```

Decode the generated BLE LL data channel PDU. The returned status indicates decoding is successful. View the output of `'status'`, `'cfgLLData'` and `'llPayload'`.

```
[status, cfgLLData, llPayload] = bleLLDataChannelPDUDecode(pdu,crcInit)
```

```
status =
Success

cfgLLData =
  bleLLDataChannelPDUConfig with properties:

               LLID: 'Data (start fragment/complete)'
               NESN: 0
     SequenceNumber: 0
           MoreData: 0
  CRCInitialization: '012345'

llPayload = 7x2 char array
    '03'
    '00'
    '04'
    '00'
    '0A'
    '01'
    '00'
```

Decode BLE LL Data Channel PDU Given in Octets

Specify a sample BLE LL data channel PDU in octets.

```
pdu = '030C00010000060000000A000000FCD2A6'; % Sample PDU in octets
```

Initialize the CRC value.

```
crcInit = 'ED323C'; % CRC initialization value
```

Decode the specified BLE LL data channel PDU by specifying `'InputFormat'` to `'octets'`. The specified PDU is a control PDU. The returned status indicates decoding is successful. View the output of `'status'`, `'cfgLLData'` and `'llPayload'`. You can see the decoded configuration of the specified PDU in the `'ControlConfig'` property of `'cfgLLData'`.

```
[status, cfgLLData, llPayload] = bleLLDataChannelPDUDecode(...
    pdu, crcInit, ...
    'InputFormat', ...
    'octets')
```

```
status = 
Success

cfgLLData = 
  bleLLDataChannelPDUConfig with properties:

                LLID: 'Control'
                NESN: 0
      SequenceNumber: 0
            MoreData: 0
    CRCInitialization: '012345'
       ControlConfig: [1x1 bleLLControlPDUConfig]

llPayload =

  1x0 empty char array
```

Decode Corrupted BLE LL Data Channel PDU

Specify a BLE LL data channel PDU containing corrupted data values. Initialize the CRC value.

```
pdu = '040C00010000060000000A00'; % Sample corrupted PDU
crcInit = 'CD3234'; % CRC initialization value
```

Decode the specified BLE LL data channel PDU. The returned status indicates that the decoding failed due to the corrupted BLE LL data channel PDU. If the decoding fails, the reason is indicated and the BLE LL data channel PDU configuration object, `'cfgLLData'`, displays no properties.

```
[status, cfgLLData, llPayload] = bleLLDataChannelPDUDecode(...
    pdu, crcInit, ...
    'InputFormat', ...
    'octets')
```

```
status = 
CRCFailed

cfgLLData = 
  bleLLDataChannelPDUConfig with properties:

llPayload =

  1x0 empty char array
```

Input Arguments

pdu — BLE LL data channel PDU

character vector | string scalar | numeric vector | character array | binary vector

BLE LL data channel PDU, specified as one of these values:

- Character vector — This vector represents octets in hexadecimal format.

- String scalar — This scalar represents octets in hexadecimal format.
- Numeric vector of elements in the range [0,255] — This vector represents octets in decimal format.
- `n-by-2` character array — Each row represents an octet in hexadecimal format.
- Binary vector — This vector represents BLE LL data channel PDU bits.

Data Types: `char` | `string` | `double`

`CRCinit` — CRC initialization value

character vector | string scalar

CRC initialization value, specified as a 6-element character vector or a string scalar representing 3-octet hexadecimal value.

Data Types: `char` | `string`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `[status,cfgLLData,LLPayload] = bleLLDecodeDataChannelPDU('pdu','CRCInit','InputFormat','octets')`

`InputFormat` — BLE LL data channel PDU format

`'bits'` (default) | `'octets'`

BLE LL data channel PDU format, specified as `'bits'` or`'octets'`. When specified as `'bits'`, `InputFormat` is a binary vector. When specified as `'octets'`, `InputFormat` is a numeric vector representing octets in decimal format or a character array or a string scalar representing octets in hexadecimal format.

Data Types: `char` | `string` | `double`

Output Arguments

`status` — BLE LL data channel PDU decoding status

nonpositive integer

BLE LL data channel PDU decoding status, returned as a nonpositive number of type `blePacketDecodeStatus`. This value represents the result of a BLE LL data channel PDU decoding. Each value of `status` corresponds to a member of the `blePacketDecodeStatus` enumeration class, which indicates the packet decoding status as listed in this table.

Enumeration Value	Member of Enumeration Class	Decoding Status
0	`Success`	Packet decoding succeeded
-1	`CRCFailed`	Link Layer PDU is corrupted
–2	`LLPDULengthMismatch`	Length field does not match with actual PDU length
–3	`InvalidLLSlaveLatency`	Invalid slave latency

–4	`InvalidLLConnectionTimeout`	Invalid connection timeout
–5	`InvalidLLWindowSize`	Invalid window size
–6	`InvalidLLWindowOffset`	Invalid window offset
–7	`InvalidLLConnectionInterval`	Invalid connection interval
–8	`InvalidLLChannelMap`	Invalid channel map
-101	`IncompleteLLDataChannelPDU`	Insufficient octets in data channel PDU
-102	`InvalidLLID`	Invalid LLID
-103	`UnsupportedLLOpCode`	Unsupported opcode
-104	`InvalidLLErrorCode`	Invalid error code
-105	`InvalidBluetoothVersion`	Invalid version
-106	`ExpectedNonZeroPayload`	Nonzero payload expected
-107	`MICNotSupported`	Payload contains MIC

An enumeration value other than `0` means that the BLE LL data channel PDU decoding failed. If decoding fails, object `cfgLLData` displays no output.

`cfgLLData` — BLE LL data channel configuration object
`bleLLDataChannelPDUConfig` object

BLE LL data channel configuration object, returned as a `bleLLDataChannelPDUConfig` object. This value represents the decoded BLE LL data channel PDU configuration.

`LLPayload` — Upper-layer payload
array

Upper-layer payload, returned as a character array where each row is the hexadecimal representation of an octet.

Introduced in R2019b

bluetoothIdealReceiver

Ideal receiver for Bluetooth BR/EDR PHY waveform

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Syntax

```
[bits,decodedInfo] = bluetoothIdealReceiver(waveform,rxConfig)
[ ___ ,pktValidStatus,decodedCRC] = bluetoothIdealReceiver( ___ )
```

Description

`[bits,decodedInfo] = bluetoothIdealReceiver(waveform,rxConfig)` demodulates and decodes a synchronized time-domain Bluetooth waveform, `waveform`, generated by the `bluetoothWaveformGenerator` function for a given system configuration object, `rxConfig`. The function returns the decoded payload bits, `bits`, and decoded information, `decodedInfo`.

`[ ___ ,pktValidStatus,decodedCRC] = bluetoothIdealReceiver( ___ )` returns a flag, `pktValidStatus`, to indicate the validity of the received Bluetooth BR/EDR packet. The function also returns the decoded cyclic redundancy check (CRC), `decodedCRC`, of the received Bluetooth packet.

Examples

Demodulate and Decode Time-Domain Bluetooth BR/EDR Waveform

Demodulate and decode time-domain Bluetooth BR/EDR waveform using two different ways to get physical layer (PHY) information. The `bluetoothIdealReceiver` function uses `bluetoothPhyConfig` object or `bluetoothWaveformConfig` object to extract PHY information and decode the Bluetooth BR/EDR waveform.

Use the `bluetoothPhyConfig` object to get PHY information

Create a Bluetooth BR/EDR waveform configuration object with default settings.

```
txconfig = bluetoothWaveformConfig;
```

Create a random input bit vector to generate the payload. Generate the time-domain Bluetooth BR/EDR waveform using the payload.

```
dataBits = randi([0 1],getPayloadLength(txconfig)*8,1);
waveform = bluetoothWaveformGenerator(dataBits,txconfig);
```

Create a configuration object for Bluetooth BR/EDR PHY with default settings. This object sends the PHY information to the ideal receiver.

```
rxConfig = bluetoothPhyConfig;
```

Demodulate and decode the Bluetooth BR/EDR waveform. The generated output displays the decoded bits and a structure containing the decoded information.

```
[bits,decodedInfo] = bluetoothIdealReceiver(waveform,rxConfig)
```

```
bits = 144×1

decodedInfo = struct with fields:
                       LAP: [24x1 double]
                PacketType: 'FHS'
    LogicalTransportAddress: [3x1 double]
          HeaderControlBits: [3x1 double]
              PayloadLength: 18
                       LLID: [2x1 double]
              FlowIndicator: 0
```

Use the bluetoothWaveformConfig object to get PHY information

Create a Bluetooth BR/EDR waveform configuration object with default settings. Set the packet type to 'DM1'and payload length to 10.

```
cfg = bluetoothWaveformConfig;
cfg.PacketType = 'DM1';
cfg.PayloadLength = 10;
```

Create a random input bit vector to generate the payload.

```
numBits = getPayloadLength(cfg)*8;
dataBits = randi([0 1],numBits,1);
```

Generate the time-domain Bluetooth BR/EDR waveform using the payload.

```
waveform = bluetoothWaveformGenerator(dataBits,cfg);
```

Get PHY information from the `bluetoothWaveformConfig` object function, `getPhyConfigProperties`.

```
rxConfig = getPhyConfigProperties(cfg);
```

Demodulate and decode the Bluetooth BR/EDR waveform. The generated output displays the decoded bits, a structure containing the decoded information, the packet status, and the decoded CRC.

```
[bits,decodedInfo,pktStatus,crc] = bluetoothIdealReceiver(waveform,rxConfig)

Input Arguments

`waveform` — Synchronized time-domain Bluetooth waveform
complex-valued column vector

Synchronized time-domain Bluetooth waveform, specified as a complex-valued column vector.

Data Types: `double`
Complex Number Support: Yes

`rxConfig` — System configuration object
`bluetoothPHYConfig` object

System configuration object, specified as a `bluetoothPhyConfig` object. The function uses this value to set its configuration parameters.

Output Arguments

bits — Decoded payload bits

binary-valued column vector

Decoded payload bits, returned as a binary-valued column vector.

Data Types: double

decodedInfo — Decoded information

structure

Decoded information, returned as a structure containing these fields:

Field	Value	Description
PacketType	'ID', 'NULL', 'POLL', 'FHS', 'HV1', 'HV2', 'HV3', 'DV', 'EV3', 'EV4', 'EV5', 'AUX1', 'DM3', 'DM1', 'DH1', 'DM5', 'DH3', 'DH5', '2-DH1', '2-DH3', '2-DH5', '2-DH1', '2-DH3', '2-DH5', '2-EV3', '2-EV5', '3-EV3', or '3-EV5'	Type of received Bluetooth BR/EDR packet
LAP	24-bit column vector of type double.	Decoded lower address part (LAP) of the Bluetooth device address
PayloadLength	Scalar of type double	Number of payload bytes in the received Bluetooth BR/EDR packet
LogicalTransportAddress	3-bit vector of type double	Active destination slave for a Bluetooth BR/EDR packet in a master-to-slave transmission slot
HeaderControlBits	3-bit vector of type double	Link control information containing flow control information (FLOW), acknowledgement for successfully receiving a Bluetooth BR/EDR packet payload (ARQN), and sequencing scheme for received packets (SEQN) bits
LLID	2-bit binary vector of type double	Logical link identifier. This field is applicable only if the value of PacketType field is one of these: 'DM1', 'DH1', 'DM3', 'DH3', 'DM5', 'DH5', 'AUX1', 'DV', '2-DH1', '2-DH3', '2-DH5', '3-DH1', '3-DH3', or '3-DH5'.

Field	Value	Description
FlowIndicator	Scalar of type double	Control data flow indicator over logical channels. This field is applicable only if the value of PacketType field is one of these: 'DM1', 'DH1', 'DM3', 'DH3', 'DM5', 'DH5', 'AUX1', 'DV', '2-DH1', '2-DH3', '2-DH5', '3-DH1', '3-DH3', or '3-DH5'

Data Types: struct

pktValidStatus — Flag indicating validity of received Bluetooth BR/EDR packet
1 | 0

Flag indicating validity of received Bluetooth BR/EDR packet, returned as 1 or 0 of data type logical. Validity is based on the Bluetooth BR/EDR packet header error check (HEC) and cyclic redundancy check (CRC). The value of this argument is true only when both, HEC and CRC are true.

Dependencies

To enable this output argument, set the PacketType field value of the “decodedInfo” on page 2-0 output argument to any one of these: 'NULL', 'POLL', 'FHS', 'HV1', 'HV2', 'HV3', 'DV', 'EV3', 'EV4', 'EV5', 'AUX1', 'DM3', 'DM1', 'DH1', 'DM5', 'DH3', 'DH5', '2-DH1', '2-DH3', '2-DH5', '2-DH1', '2-DH3', '2-DH5', '2-EV3', '2-EV5', '3-EV3', or '3-EV5'.

Data Types: logical

decodedCRC — Decoded CRC
16-bit binary-valued column vector

Decoded CRC, specified as the CRC of the received Bluetooth BR/EDR packet.

Dependencies

To enable this output argument, set the packet type field value of the decoded information output argument to any one of these: 'FHS', 'DV', 'EV3', 'EV4', 'EV5', 'DM3', 'DM1', 'DH1', 'DM5', 'DH3', 'DH5', '2-DH1', '2-DH3', '2-DH5', '2-DH1', '2-DH3', '2-DH5', '2-EV3', '2-EV5', '3-EV3', or '3-EV5'.

Data Types: double

bluetoothWaveformGenerator

Waveform generator for Bluetooth BR/EDR PHY

Note **Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Syntax

```
waveform = bluetoothWaveformGenerator(data,cfgFormat)
```

Description

`waveform = bluetoothWaveformGenerator(data,cfgFormat)` generates `waveform`, a multipacket time-domain Bluetooth BR/EDR waveform, for input information bits `data` and a given format configuration `cfgFormat`.

Examples

Generate Multipacket Bluetooth BR/EDR Waveform with HV1 Packets

Specify the number of HV1 packets.

```
numPackets = 10;
```

Create a Bluetooth BR/EDR waveform configuration object. Specify the packet type as HV1.

```
cfg = bluetoothWaveformConfig;
cfg.PacketType = 'HV1';
```

Create a random input bit vector containing concatenated payloads.

```
numBits = getPayloadLength(cfg)*8*numPackets; % Byte to bit conversion
dataBits = randi([0 1],numBits,1);
```

Set the symbol rate.

```
symbolRate = 1e6; % In MHz
```

Generate the Bluetooth waveform.

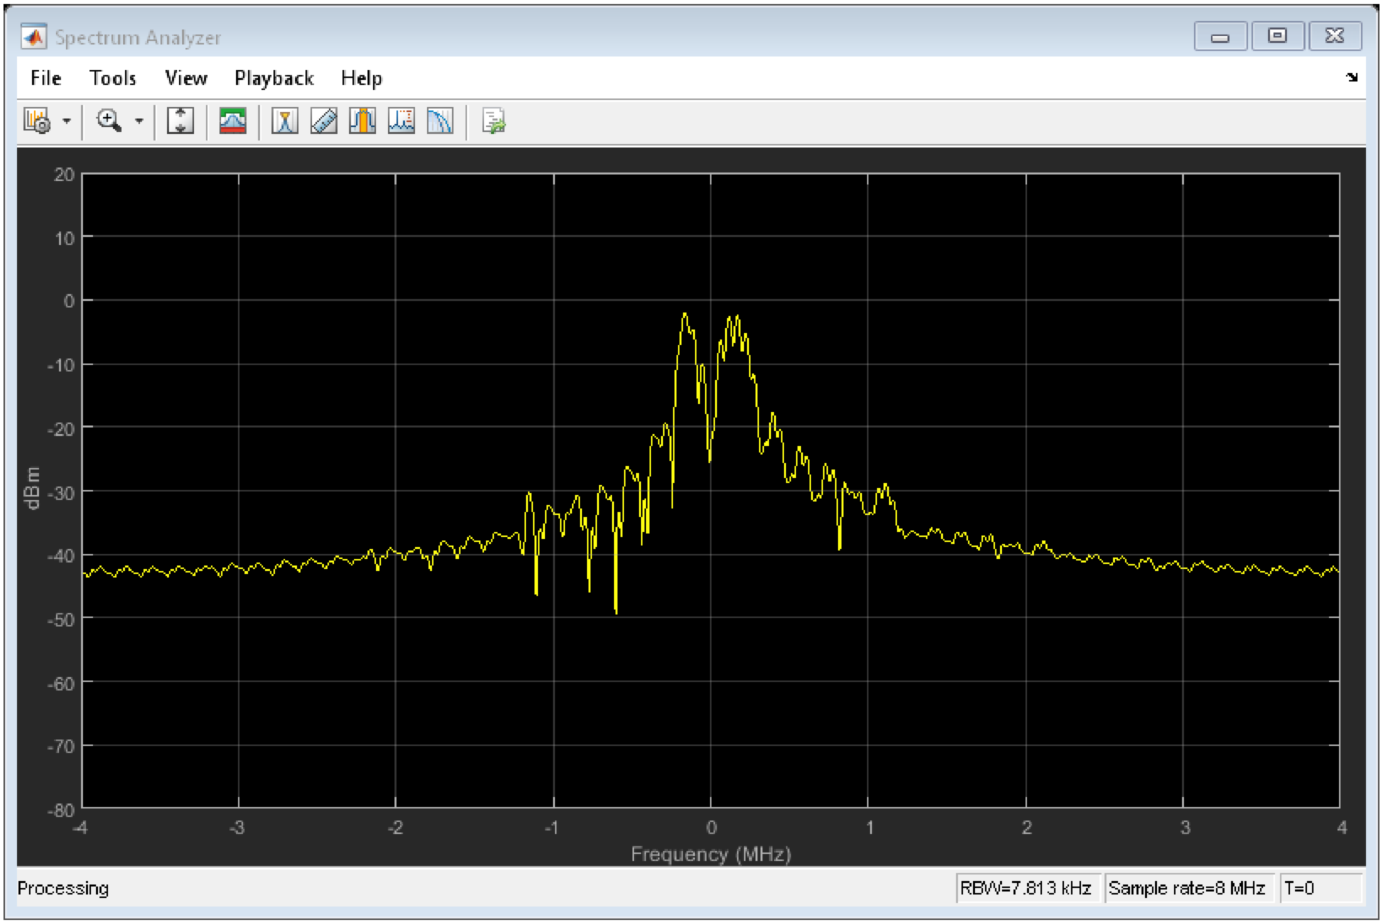
```
waveform = bluetoothWaveformGenerator(dataBits,cfg);
```

Create a `dsp.SpectrumAnalyzer` System object to display the frequency spectrum of the generated Bluetooth BR/EDR waveform. Set the sample rate of the frequency spectrum.

```
scope = dsp.SpectrumAnalyzer;
scope.SampleRate = cfg.SamplesPerSymbol*symbolRate;
```

Plot the Bluetooth BR/EDR waveform.

```
scope(waveform);
```



Generate Bluetooth BR/EDR Waveform for Single Enhanced Data Rate Packet

Create a Bluetooth BR/EDR waveform configuration object.

```
cfg = bluetoothWaveformConfig;
```

To generate enhanced data rate packet 2-EV3, specify the packet type as EV3 and the transmission mode as EDRM2.

```
cfg.PacketType = 'EV3';
cfg.Mode = 'EDR2M';
```

Create a random input bit vector to generate the payload for a single packet.

```
numBits = getPayloadLength(cfg)*8; % Byte to bit conversion
dataBits = randi([0 1],numBits,1);
```

Generate the Bluetooth BR/EDR waveform.

```
txWaveform = bluetoothWaveformGenerator(dataBits,cfg);
```

Input Arguments

`data` — Input information bits

binary-valued column vector

Input information bits, specified as a binary-valued column vector with data type `double`. This value represents multiple concatenated payloads. The length of `data` must be an exact multiple of the payload length derived from the `getPayloadLength` object function for the `bluetoothWaveformConfig` object.

Data Types: `double`

`cfgFormat` — Format configuration object

`bluetoothWaveformConfig` object

Format configuration object, specified as a `bluetoothWaveformConfig` object. The function uses this value to set its configuration parameters.

Output Arguments

`waveform` — Generated time-domain Bluetooth BR/EDR waveform

complex-valued column vector

Generated time-domain Bluetooth BR/EDR waveform, returned as a complex-valued column vector containing the generated Bluetooth BR/EDR waveform. The function appends this value with zero samples to accommodate a packet-specific slot duration.

Data Types: `double`

bleWaveformGenerator

Waveform generator for BLE PHY

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Syntax

```
waveform = bleWaveformGenerator(message)
waveform = bleWaveformGenerator(message,Name,Value)
```

Description

`waveform = bleWaveformGenerator(message)` generates `waveform`, a time-domain Bluetooth low energy (BLE) physical layer (PHY) waveform by using the input information bits `message`.

`waveform = bleWaveformGenerator(message,Name,Value)` also specifies options using one or more name-value pair arguments. For example, `'Mode','LE2M'` specifies the generating mode value of the desired BLE waveform.

Examples

Generate BLE Waveform Using Default Settings

Create an input message column vector of length 2056 containing random binary values. Set the symbol rate to default value.

```
message = randi([0 1],2056,1);
symbolRate = 1e6;
```

Generate the BLE waveform.

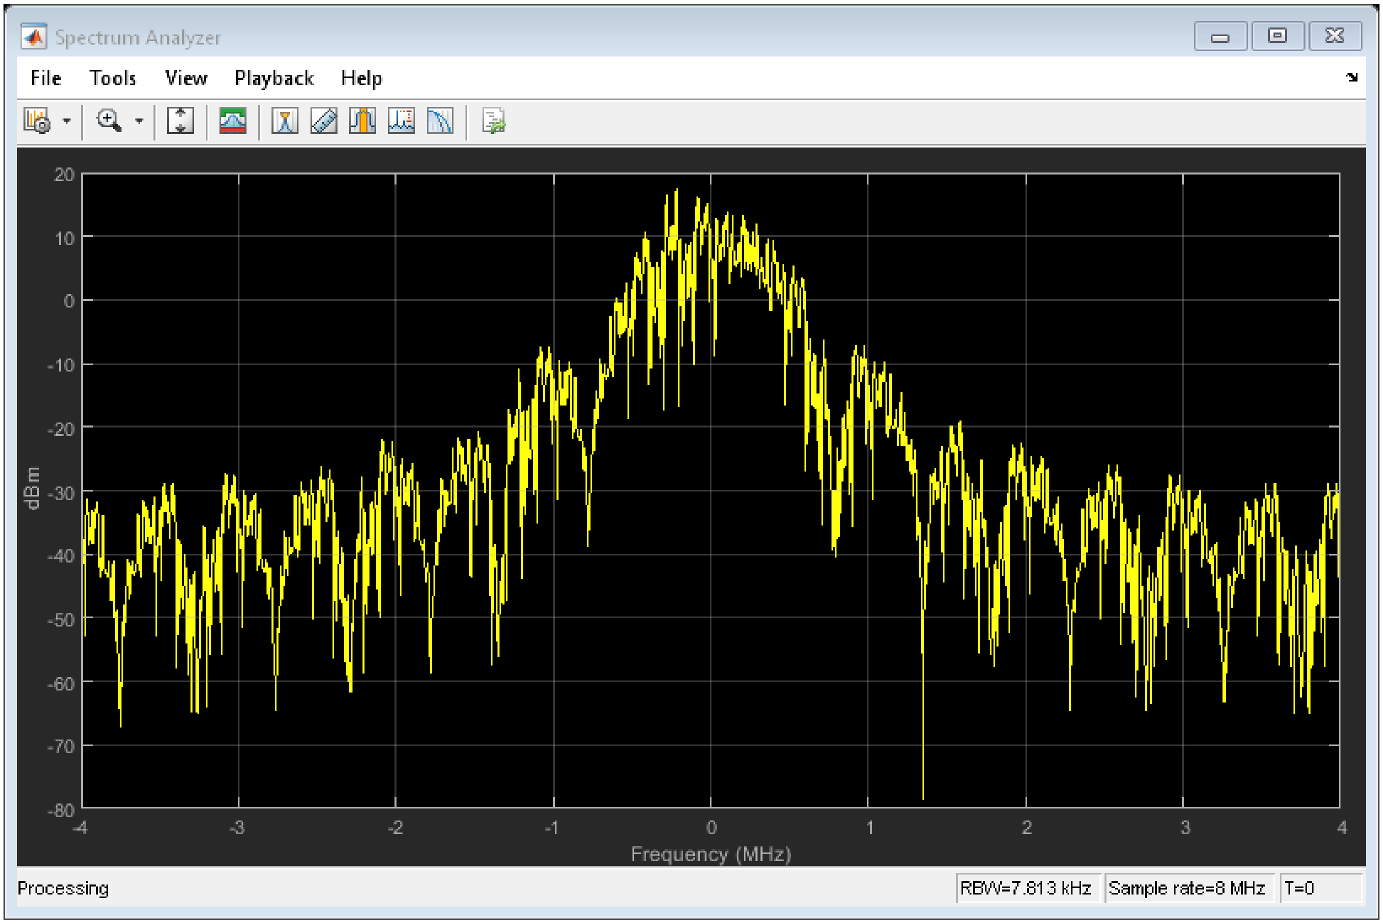
```
waveform = bleWaveformGenerator(message);
```

Create a `dsp.SpectrumAnalyzer` System object to display the frequency spectrum of the generated BLE waveform. Set the sample rate of the frequency spectrum.

```
scope = dsp.SpectrumAnalyzer;
scope.SampleRate = 8*symbolRate;
```

Plot the BLE waveform.

```
scope(waveform);
```



Generate BLE Waveform Using Specified Name-Value Pairs

Create an input message column vector of length 640 containing random binary values.

```
message = randi([0 1],640,1);
```

Specify the values of generating mode, channel index, samples per symbol and access address. Set symbol rate to default value.

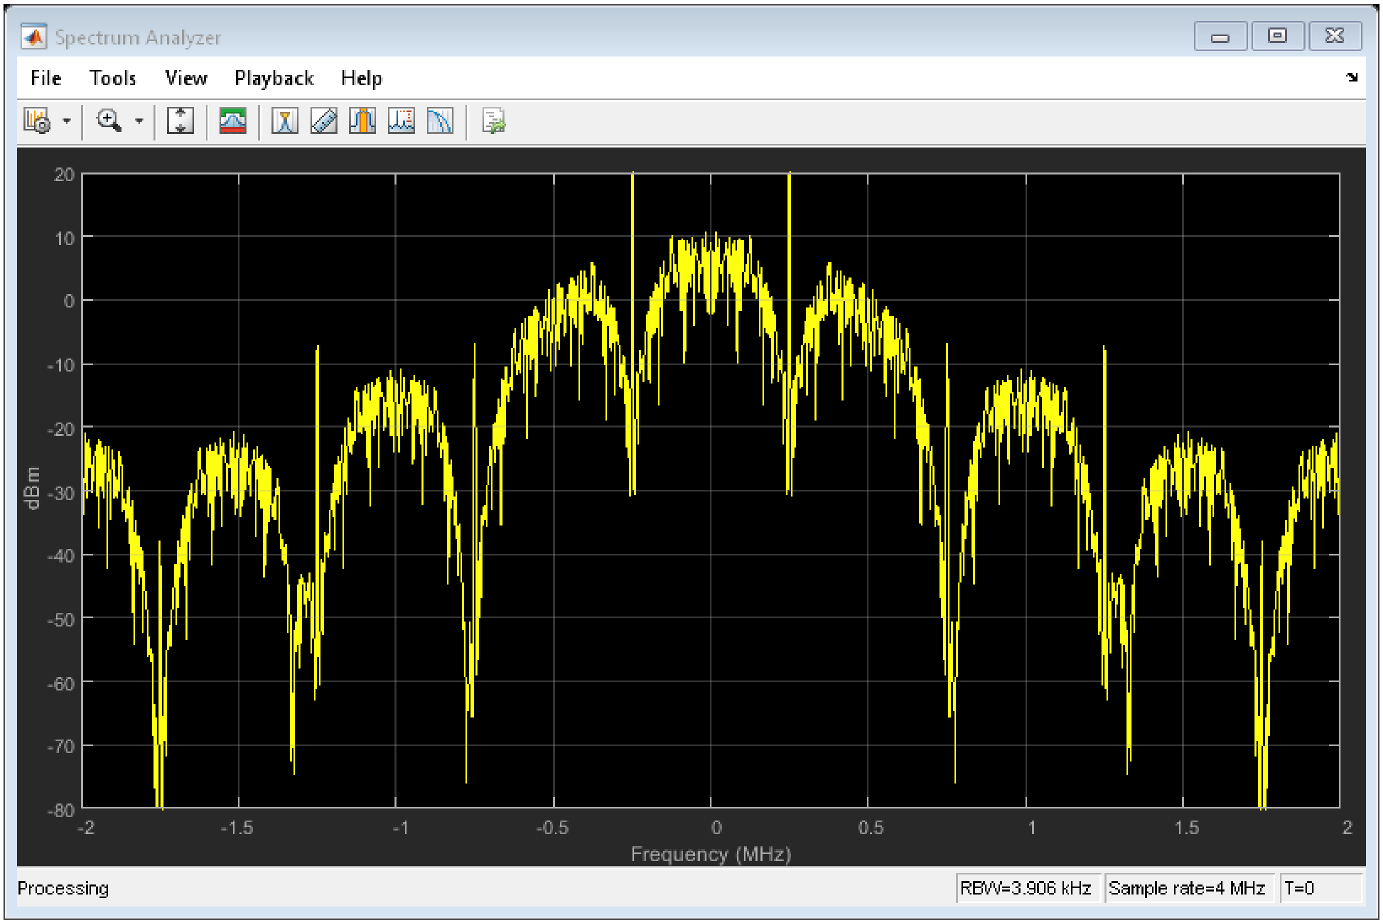
```
phyMode = 'LE125K';
chanIdx = 2;
sps = 4;
accAdd = [1 1 1 1 0 1 0 0 1 1 0 1 0 0 1 0 0 1 1 0 1 1 1 0 1 ...
    0 1 0 1 1 0 0].';
symbolRate = 1e6;
```

Create a `dsp.SpectrumAnalyzer` System object to display the frequency spectrum of the generated BLE waveform. Set the sample rate of the frequency spectrum.

```
scope = dsp.SpectrumAnalyzer;
scope.SampleRate = sps*symbolRate;
```

Generate the BLE waveform using specified name-value pair arguments. Plot the BLE waveform.

```
waveform = bleWaveformGenerator(message,'Mode',phyMode, ...
    'SamplesPerSymbol',sps,'ChannelIndex',chanIdx,'AccessAddress',accAdd);
scope(waveform);
```



Generate BLE Waveform With Constant Tone Extension For Connection-Oriented Scenario

Specify a connection data channel protocol data unit (PDU) for angle of departure (AoD) constant tone extension (CTE).

```
pduHex = '1B820127'; % Valid PDU in hexadecimal
pdu = de2bi(hex2dec(pduHex), 32)';
```

Generate and append cyclic redundancy check (CRC) to the PDU.

```
crcGen = comm.CRCGenerator('z^24+z^10+z^9+z^6+z^4+z^3+z+1',...
    'InitialConditions',de2bi(hex2dec('555551'),'left-msb',24),...
    'DirectMethod',true);
pduCRC = crcGen(pdu);
```

Generate the BLE waveform using specified name-value pair arguments.

```
waveform = bleWaveformGenerator(pduCRC,'ChannelIndex',36,...
    'DFPacketType','ConnectionCTE')
```

```
waveform = 896×1 complex

   1.0000 + 0.0000i
   0.9892 + 0.1469i

   0.0000 + 1.0000i
   0.1469 + 0.9892i
      ⋮
```

Input Arguments

`message` — Input message bits

binary-valued column vector

Input message bits, specified as a binary-valued column vector of numerical or logical values. This message contains the protocol data unit (PDU) and cyclic redundancy check (CRC) data. The maximum length of this value is 2080 bits.

Data Types: `double` | `logical`

Name-Value Pair Arguments

Note For information about connection CTE and connectionless CTE direction finding packet generation, see “Bluetooth Packet Structure”.

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `bleWaveformGenerator(message,'Mode','LE2M','ChannelIndex',36)`

`Mode` — Generating mode

`'LE1M'` (default) | `'LE2M'` | `'LE500K'` | `'LE125K'`

Generating mode, specified as the comma-separated pair consisting of `'Mode'` and `'LE1M'`, `'LE2M'`, `'LE500K'`, or `'LE125K'`. This value indicates the type of BLE waveform.

Data Types: `string` | `char`

`ChannelIndex` — Channel Index

`37` (default) | integer in the range [0, 39]

Channel index, specified as the comma-separated pair consisting of `'ChannelIndex'`and an integer in the range [0, 39]. For data channels, this value must be in the range [0, 36]. This value is used by the data-whitening block to randomize the bits.

Data Types: `single` | `double`

`SamplesPerSymbol` — Samples per symbol

8 (default) | positive integer

Samples per symbol, specified as the comma-separated pair consisting of `'SamplesPerSymbol'` and a positive integer. This value is used for the Gaussian frequency-shift keying (GFSK) modulation.

Data Types: `single` | `double`

`AccessAddress` — Access address

`[0 1 1 0 1 0 1 1 0 1 1 1 1 1 0 1 1 0 0 1 0 0 0 1 0 1 1 1 0 0 0 1]'` (default) | 32-bit column vector

Access address, specified as the comma-separated pair consisting of `'AccessAddress'` and a 32-bit column vector of numerical or logical values.

Data Types: `logical` | `single` | `double`

`DFPacketType` — Type of direction finding packet

`'Disabled'` (default) | `'ConnectionlessCTE'` | `'ConnectionCTE'`

Type of direction finding packet, specified as the comma-separated pair consisting of `'DFPacketType'` and `'ConnectionlessCTE'`, `'ConnectionCTE'`, or `'Disabled'`.

Data Types: `string` | `char`

Output Arguments

`waveform` — Output time-domain waveform

complex-valued column vector

Output time-domain waveform, returned as a complex-valued column vector of size *Ns*-by-1, where *Ns* represents the number of time-domain samples. The `waveform` is generated in the form of complex in-phase quadrature (IQ) samples.

Data Types: `double`

Introduced in R2019b

getPayloadLength

Payload length in bytes for Bluetooth BR/EDR format configuration

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Syntax

```
payloadLength = getPayloadLength(cfg)
```

Description

`payloadLength = getPayloadLength(cfg)` returns the payload length, in bytes, for the Bluetooth BR/EDR format configuration, `cfg`.

Examples

Get Payload Length for Bluetooth BR/EDR Format Configuration

Create a Bluetooth BR/EDR waveform configuration object with default properties.

```
cfg = bluetoothWaveformConfig
```

```
cfg = 
  bluetoothWaveformConfig with properties:

                      Mode: 'BR'
                PacketType: 'FHS'
             DeviceAddress: '0123456789AB'
   LogicalTransportAddress: [3x1 double]
         HeaderControlBits: [3x1 double]
           ModulationIndex: 0.3200
          SamplesPerSymbol: 8
              WhitenStatus: 'On'
      WhitenInitialization: [7x1 double]
```

Get the payload length of the default `'FHS'` packet.

```
payloadLength = getPayloadLength(cfg)
```

```
payloadLength = 18
```

Create another Bluetooth BR/EDR waveform configuration object. Set the packet type as `'HV1'`.

```
cfgHV1 = bluetoothWaveformConfig('PacketType','HV1');
```

Get the payload length of the specified `'HV1'` packet.

```
payloadLength = getPayloadLength(cfgHV1)
```

```
payloadLength = 10
```

Input Arguments

`cfg` — Bluetooth BR/EDR format configuration
`bluetoothWaveformConfig` object

Bluetooth BR/EDR format configuration, specified as `bluetoothWaveformConfig` object.

Output Arguments

`payloadLength` — Payload length of packet
18 (default) | nonnegative integer

Payload length of packet, returned as a nonnegative integer. This value indicates the number of bytes to be processed in a packet.

Data Types: `double`

getPhyConfigProperties

Updated configuration properties of Bluetooth BR/EDR PHY configuration object

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Syntax

```
cfgPHY = getPhyConfigProperties(cfg)
```

Description

`cfgPHY = getPhyConfigProperties(cfg)` returns updated Bluetooth BR/EDR PHY configuration properties, `cfgPHY` for the Bluetooth BR/EDR waveform format configuration object, `cfg`.

Examples

Get PHY Configuration Properties of Bluetooth BR/EDR PHY Configuration Object

Create a Bluetooth BR/EDR waveform configuration object with default properties.

```
cfg = bluetoothWaveformConfig
```

```
cfg = 
  bluetoothWaveformConfig with properties:

                     Mode: 'BR'
               PacketType: 'FHS'
            DeviceAddress: '0123456789AB'
    LogicalTransportAddress: [3x1 double]
          HeaderControlBits: [3x1 double]
            ModulationIndex: 0.3200
           SamplesPerSymbol: 8
               WhitenStatus: 'On'
       WhitenInitialization: [7x1 double]
```

Get the PHY configuration properties for the created Bluetooth BR/EDR waveform configuration object.

```
cfgPHY = getPhyConfigProperties (cfg)
```

```
cfgPHY = 
  bluetoothPhyConfig with properties:

                 Mode: 'BR'
        DeviceAddress: '0123456789AB'
      ModulationIndex: 0.3200
     SamplesPerSymbol: 8
```

```
            WhitenStatus: 'On'
    WhitenInitialization: [7x1 double]
```

Create another Bluetooth BR/EDR waveform configuration object and specify the PHY transmission mode as `'EDR2M'`.

```
cfgEDR = bluetoothWaveformConfig('Mode','EDR2M');
```

Get the PHY configuration properties for this Bluetooth BR/EDR waveform configuration object.

```
cfgPHY = getPhyConfigProperties (cfgEDR)
```

```
cfgPHY = 
  bluetoothPhyConfig with properties:

                    Mode: 'EDR2M'
           DeviceAddress: '0123456789AB'
         ModulationIndex: 0.3200
        SamplesPerSymbol: 8
            WhitenStatus: 'On'
    WhitenInitialization: [7x1 double]
```

Input Arguments

`cfg` — Bluetooth BR/EDR format configuration

`bluetoothWaveformConfig` object

Bluetooth BR/EDR Format configuration, specified as `bluetoothWaveformConfig` object.

Output Arguments

`cfgPHY` — Configuration object for Bluetooth BR/EDR PHY

`bluetoothPHYConfig` object

Configuration object for Bluetooth BR/EDR PHY, returned as a `bluetoothPhyConfig` object.

addCustomBasemap

Add custom basemap

Syntax

```
addCustomBasemap(basemapName,URL)
addCustomBasemap( ___ ,Name,Value)
```

Description

`addCustomBasemap(basemapName,URL)` adds the custom basemap specified by `URL` to the list of basemaps available for use with mapping functions. `basemapName` is the name you choose to call the custom basemap. Added basemaps remain available for use in future MATLAB sessions.

`addCustomBasemap( ___ ,Name,Value)` specifies name-value pairs that set additional parameters of the basemap.

Examples

Add and Remove a Custom Basemap

Add a custom basemap to view locations on an OpenTopoMap® basemap, then remove the custom basemap from `siteviewer`.

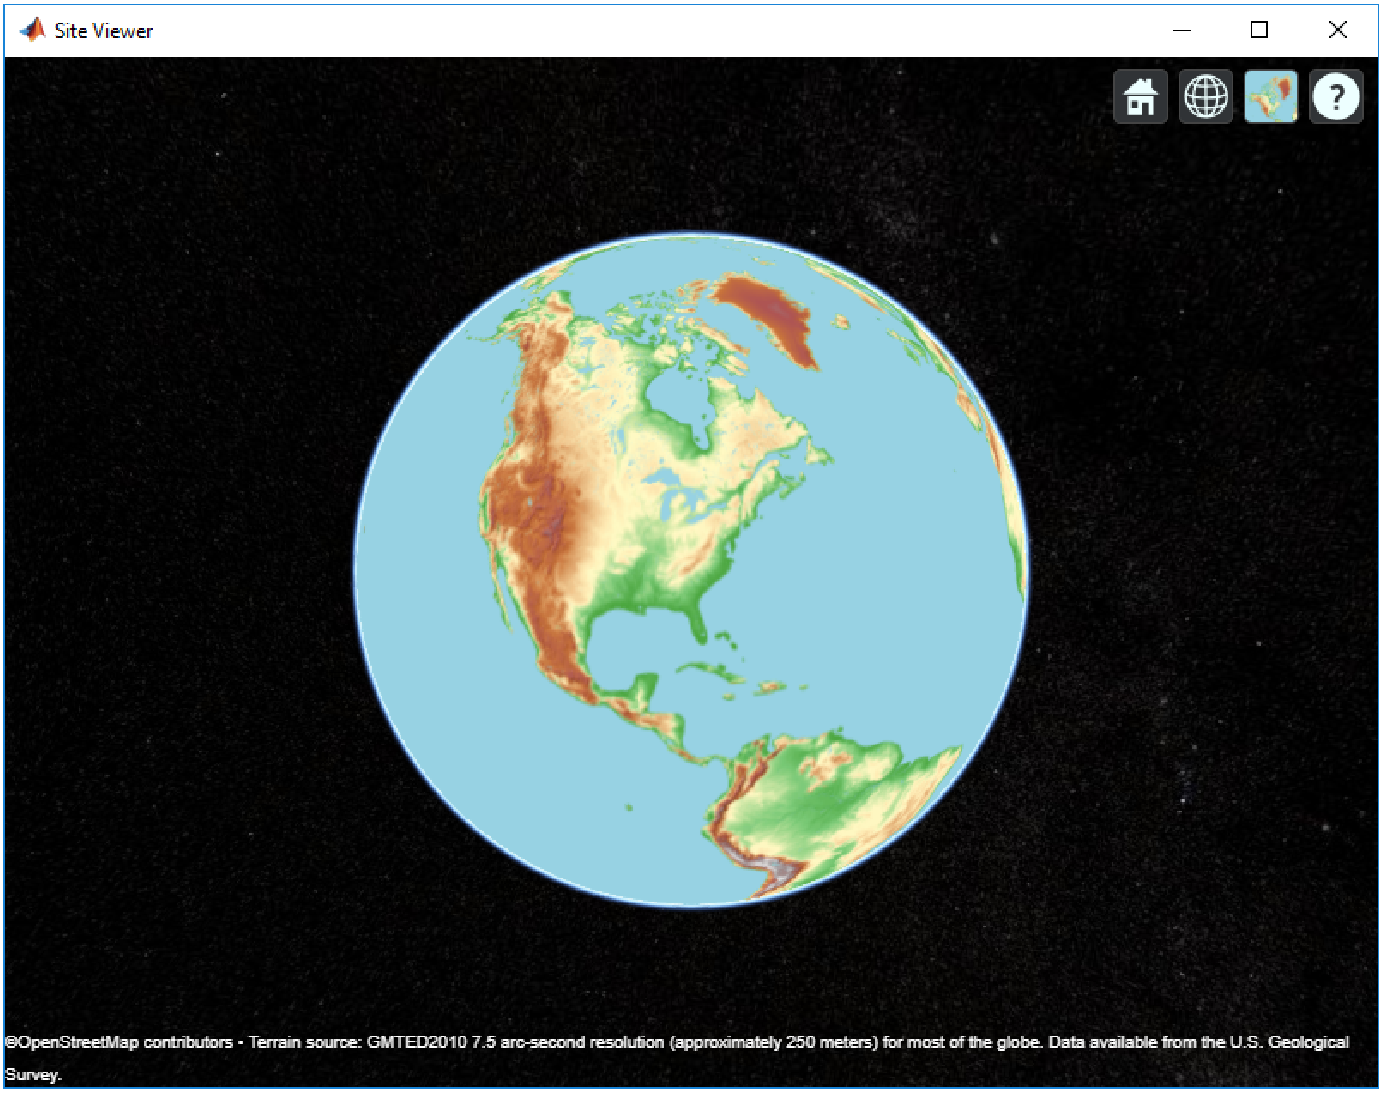
Initialize simulation variables to:

- Define the name that you will use to specify your custom basemap.
- Specify the website that provides the map data. The first character of the URL indicates which server to use to get the data. For load balancing, the provider has three servers that you can use: a, b, or c.
- Create an attribution to display on the map that gives credit to the provider of the map data. Web map providers might define specific requirements for the attribution.
- Define a display name for the custom map.

```
name = 'opentopomap';
url = 'a.tile.opentopomap.org';
copyright = char(uint8(169));
attribution = copyright + "OpenStreetMap contributors";
displayName = 'Open Topo Map';
```

Use `addCustomBasemap` to load the custom basemap, and then create a `siteviewer` object that loads the custom basemap.

```
addCustomBasemap(name,url,'Attribution',attribution','DisplayName',displayName)
viewer = siteviewer('Basemap',name);
```



©OpenStreetMap contributors • Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey.

After a custom basemap is added to `siteviewer`, the custom map is available for future calls to `siteviewer`. Note the `'Open Topo Map'` icon in the `Imagery` tab.

```

Input Arguments

basemapName — Name used to identify basemap programmatically

string scalar | character vector

Name used to identify basemap programmatically, specified as a string scalar or character vector.

Example: `'openstreetmap'`

Data Types: `string` | `char`

URL — Parameterized map URL

string scalar | character vector

Parameterized map URL, specified as a string scalar or character vector. A parameterized URL is an index of the map tiles, formatted as `${z}/${x}/${y}.png` or `{z}/{x}/{y}.png`, where:

- `${z}` or `{z}` is the tile zoom level.
- `${x}` or `{x}` is the tile column index.
- `${y}` or `{y}` is the tile row index.

Example: `'https://hostname/${z}/${x}/${y}.png'`

Data Types: `string` | `char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `addCustomBasemap(basemapName,URL,'Attribution',attribution)`

`Attribution` — Attribution of custom basemap

`'Tiles courtesy of` *`DOMAIN_NAME_OF_URL`*`'` (default) | string scalar | string array | character vector | cell array of character vectors

Attribution of custom basemap, specified as the comma-separated pair consisting of `'Attribution'` and a string scalar, string array, character vector, or cell array of character vectors. If the host is `'localhost'`, or if `URL` contains only IP numbers, specify an empty value (`''`). To create a multiline attribution, specify a string array or nonscalar cell array of character vectors.

If you do not specify an attribution, the default attribution is `'Tiles courtesy of` *`DOMAIN_NAME_OF_URL`*`'`, where the `addCustomBasemap` function obtains the domain name from the `URL` input argument.

Example: `'Credit: U.S. Geological Survey'`

Data Types: `string` | `char` | `cell`

`DisplayName` — Display name of custom basemap

string scalar | character vector

Display name of the custom basemap, specified as the comma-separated pair consisting of `'DisplayName'` and a string scalar or character vector.

Example: `'OpenStreetMap'`

Data Types: `string` | `char`

`MaxZoomLevel` — Maximum zoom level of basemap

`18` (default) | integer in the range [0, 25]

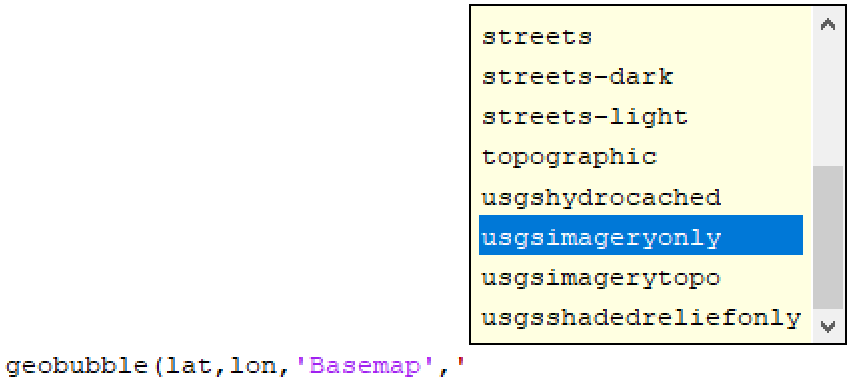
Maximum zoom level of the basemap, specified as the comma-separated pair consisting of `'MaxZoomLevel'` and an integer in the range [0, 25].

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Tips

- You can find tiled web maps from various vendors, such as OpenStreetMap®, the USGS National Map, Mapbox, DigitalGlobe, Esri® ArcGIS Online, the Geospatial Information Authority of Japan (GSI), and HERE Technologies. Abide by the map vendors terms-of-service agreement and include accurate attribution with the maps you use.

- To access a list of available basemaps, press **Tab** before specifying the basemap in your plotting function.



```
geobubble(lat,lon,'Basemap','
```

See Also

geoaxes | geobasemap | geobubble | removeCustomBasemap

removeCustomBasemap

Remove custom basemap

Syntax

```
removeCustomBasemap(basemapName)
```

Description

`removeCustomBasemap(basemapName)` removes the custom basemap specified by `basemapName` from the list of available basemaps.

Examples

Add and Remove a Custom Basemap

Add a custom basemap to view locations on an OpenTopoMap® basemap, then remove the custom basemap from `siteviewer`.

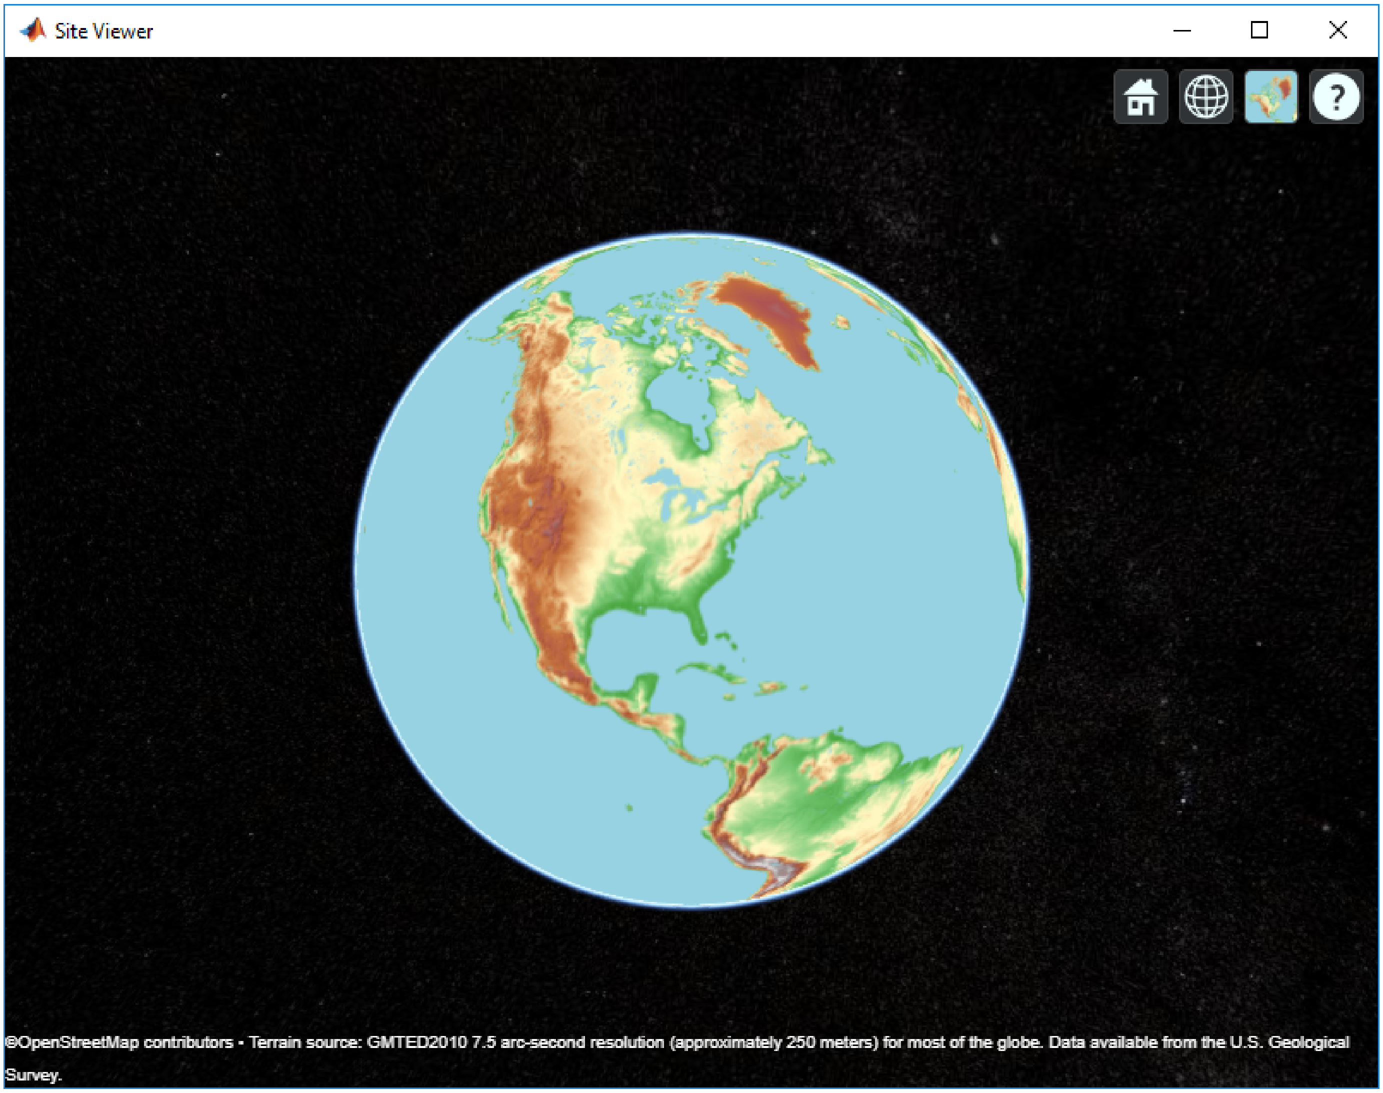
Initialize simulation variables to:

- Define the name that you will use to specify your custom basemap.
- Specify the website that provides the map data. The first character of the URL indicates which server to use to get the data. For load balancing, the provider has three servers that you can use: a, b, or c.
- Create an attribution to display on the map that gives credit to the provider of the map data. Web map providers might define specific requirements for the attribution.
- Define a display name for the custom map.

```
name = 'opentopomap';
url = 'a.tile.opentopomap.org';
copyright = char(uint8(169));
attribution = copyright + "OpenStreetMap contributors";
displayName = 'Open Topo Map';
```

Use `addCustomBasemap` to load the custom basemap, and then create a `siteviewer` object that loads the custom basemap.

```
addCustomBasemap(name,url,'Attribution',attribution','DisplayName',displayName)
viewer = siteviewer('Basemap',name);
```



©OpenStreetMap contributors • Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey.

After a custom basemap is added to `siteviewer`, the custom map is available for future calls to `siteviewer`. Note the `'Open Topo Map'` icon in the `Imagery` tab.

```
siteviewer;

buildingMaterialPermittivity

Permittivity and conductivity of building materials

Syntax

```
[epsilon,sigma,complexepsilon] = buildingMaterialPermittivity(material,fc)
```

Description

`[epsilon,sigma,complexepsilon] = buildingMaterialPermittivity(material,fc)` calculates the relative permittivity, conductivity, and complex relative permittivity for the specified material at the specified frequency. The methods and equations modeled in the `buildingMaterialPermittivity` function are presented in Recommendation ITU-R P.2040 [1].

Examples

Calculate Permittivity of Various Building Materials

Calculate relative permittivity and conductivity at 9 GHz for various building materials as defined by textual classifications in ITU-R P.2040, Table 3.

```
material = ["vacuum";"concrete";"brick";"plasterboard";"wood"; ...
    "glass";"ceiling-board";"chipboard";"floorboard";"metal"];
fc = repmat(9e9,size(material)); % Frequency in Hz
[permittivity,conductivity] = ...
    arrayfun(@(x,y)buildingMaterialPermittivity(x,y),material,fc);
```

Display the results in a table.

```
varNames = ["Material";"Permittivity";"Conductivity"];
table(material,permittivity,conductivity,'VariableNames',varNames)
```

```
ans=10×3 table
       Material        Permittivity    Conductivity
    _______________    ____________    ____________

    "vacuum"                  1                   0
    "concrete"             5.31             0.19305
    "brick"                3.75               0.038
    "plasterboard"         2.94            0.054914
    "wood"                 1.99            0.049528
    "glass"                6.27            0.059075
    "ceiling-board"         1.5           0.0064437
    "chipboard"            2.58             0.12044
    "floorboard"           3.66            0.085726
    "metal"                   1               1e+07
```

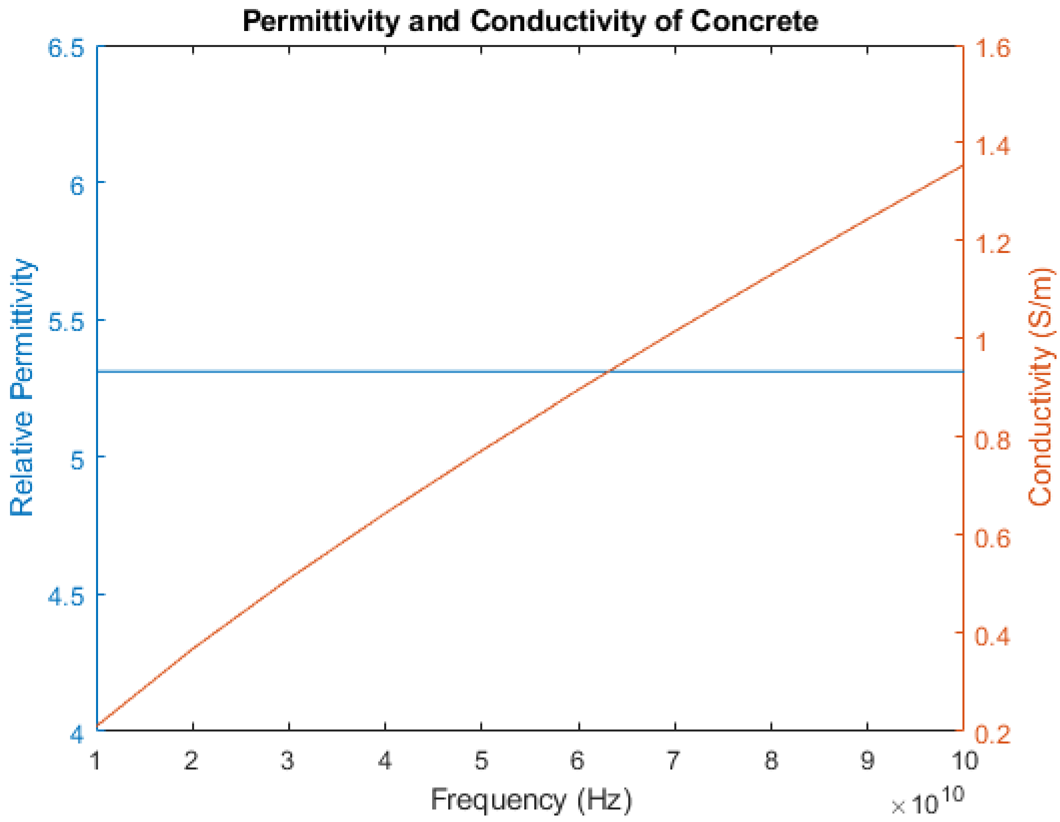
Plot Permittivity and Conductivity of Concrete at Various Frequencies

Calculate the relative permittivity and conductivity for concrete at frequencies specified.

```
fc = ((1:1:10)*10e9); % Frequency in Hz
[permittivity,conductivity] = ...
    arrayfun(@(y)buildingMaterialPermittivity("concrete",y),fc);
```

Plot the relative permittivity and conductivity of concrete across the range of frequencies.

```
figure
yyaxis left
plot(fc,permittivity)
ylabel('Relative Permittivity')
yyaxis right
plot(fc,conductivity)
ylabel('Conductivity (S/m)')
xlabel('Frequency (Hz)')
title('Permittivity and Conductivity of Concrete')
```



Input Arguments

`material` — Building material
`"vacuum"` | `"concrete"` | `"brick"` | `"plasterboard"` | ...

Building material, specified as vector of strings including one or more of these options:

`"vacuum"`	`"glass"`	`"very-dry-ground"`
`"concrete"`	`"ceiling-board"`	`"medium-dry-ground"`
`"brick"`	`"floorboard"`	`"wet-ground"`
`"plasterboard"`	`"chipboard"`	
`"wood"`	`"metal"`	

Example: `["vacuum" "brick"]`

Data Types: `char` | `string`

`fc` — Carrier frequency
positive scalar

Carrier frequency in Hz, specified as a positive scalar.

Note `fc` must be in the range [1e6, 10e6] when the `material` is `"very-dry-ground"`, `"medium-dry-ground"` or `"wet-ground"`.

Data Types: `double`

Output Arguments

`epsilon` — Relative permittivity
nonnegative scalar | nonnegative row vector

Relative permittivity of the building material, returned as a nonnegative scalar or row vector. The output dimension of `epsilon` matches that of the input argument `material`. For more information about the computation for the relative permittivity, see “ITU Building Materials” on page 2-967.

`sigma` — Conductivity
nonnegative scalar | nonnegative row vector

Conductivity, in Siemens/m, of the building material, returned as a nonnegative scalar or row vector. The output dimension of `sigma` matches that of the input argument `material`. For more information about the computation for the conductivity, see “ITU Building Materials” on page 2-967.

`complexepsilon` — Complex relative permittivity
complex scalar | row vector of complex values

Complex relative permittivity of the building material, returned as a complex scalar or row vector of complex values.

The output dimension of `complexepsilon` matches that of the input argument `material`. For more information about the computation for the complex relative permittivity, see “ITU Building Materials” on page 2-967.

More About

ITU Building Materials

Section 3 of ITU-R P.2040-1 [1] presents methods, equations, and values used to calculate real relative permittivity, conductivity, and complex relative permittivity at carrier frequencies up to 100 GHz for common building materials.

The `buildingMaterialPermittivity` function uses equations from ITU-R P.2040-1 to compute these values.

- The real part of the relative permittivity is calculated as
  `epsilon` = af^b.
  The computation of `epsilon` is based on equation (58). f is the frequency in GHz. Values for a and b are specified in Table 3 from ITU-R P.2040-1.
- The conductivity in Siemens/m is calculated as
  `sigma` = cf^d.
  The computation of `sigma` is based on equation (59). f is the frequency in GHz. Values for c and d are specified in Table 3 from ITU-R P.2040-1.
- The complex permittivity is calculated as
  `complexepsilon` = `epsilon` – 1*i* `sigma` / $(2\pi f c \varepsilon_0)$.
  The computation of `complexepsilon` is based on Equations (59) and (9b). f is the frequency in GHz. c is the velocity of light in free space. ε_0 = 8.854187817e-12 Farads/m, where ε_0 is the electric constant for the permittivity of free space.

For cases where the value of b or d is zero, the corresponding value of `epsilon` or `sigma` is a or c, respectively and independent of frequency.

The contents of Table 3 from ITU-R P.2040-1 are repeated in this table. The values a, b, c, and d are used to calculate relative permittivity and conductivity. Except as noted for the three ground types, the frequency ranges given in the table are not hard limits but are indicative of the measurements used to derive the models. The `buildingMaterialPermittivity` function interpolates or extrapolates relative permittivity and conductivity values for frequencies that fall outside of the noted limits. To compute relative permittivity and conductivity for different types of ground as a function carrier frequencies up to 1000 GHz, see the `earthSurfacePermittivity` function.

Material Class	**Real Part of Relative Permittivity**		**Conductivity (S/m)**		**Frequency Range (GHz)**
	a	***b***	***c***	***d***	
Vacuum (~ air)	1	0	0	0	[0.001, 100]
Concrete	5.31	0	0.0326	0.8095	[1, 100]
Brick	3.75	0	0.038	0	[1, 10]
Plasterboard	2.94	0	0.0116	0.7076	[1, 100]
Wood	1.99	0	0.0047	1.0718	[0.001, 100]
Glass	6.27	0	0.0043	1.1925	[0.1, 100]
Ceiling board	1.50	0	0.0005	1.1634	[1, 100]
Chipboard	2.58	0	0.0217	0.78	[1, 100]
Floorboard	3.66	0	0.0044	1.3515	[50, 100]

Material Class	**Real Part of Relative Permittivity**		**Conductivity (S/m)**		**Frequency Range (GHz)**
	a	***b***	***c***	***d***	
Metal	1	0	10^7	0	[1, 100]
Very dry ground	3	0	0.00015	2.52	[1, 10] only[(a)]
Medium dry ground	15	– 0.1	0.035	1.63	[1, 10] only[(a)]
Wet ground	30	– 0.4	0.15	1.30	[1, 10] only[(a)]
Note (a): For the three ground types (very dry, medium dry, and wet), the noted frequency limits cannot be exceeded.

Objects

`comm.Ray`

Introduced in R2020a

earthSurfacePermittivity

Permittivity and conductivity of earth surface materials

Syntax

```
[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('pure-water',fc,
temp)
[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('dry-ice',fc,temp)
[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('sea-water',fc,
temp,salinity)
[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('wet-ice',fc,
liqfrac)
```

```
[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('soil',fc,temp,
sandpercent,claypercent,specificgravity,vwc)
[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('soil',___,
bulkdensity)
```

```
[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('vegetation',fc,
temp,gwc)
```

Description

The `earthSurfacePermittivity` function computes electrical characteristics (relative permittivity, conductivity, and complex relative permittivity) of earth surface materials based on the methods and equations presented in ITU-R P.527 [1]. The `earthSurfacePermittivity` function provides various syntaxes to account for characteristics germane to the specified surface material.

`[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('pure-water',fc,temp)` calculates the electrical characteristics for pure water at the specified frequency and temperature. For pure-water, the temperature setting must be greater than 0 ℃.

`[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('dry-ice',fc,temp)` calculates the electrical characteristics for dry-ice at the specified frequency and temperature. For dry-ice, the temperature must be less than or equal to 0 ℃.

`[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('sea-water',fc,temp,salinity)` calculates the electrical characteristics for sea water at the specified frequency, temperature, and salinity. For sea-water, the temperature must be greater than –2 ℃.

`[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('wet-ice',fc,liqfrac)` calculates the electrical characteristics for wet ice at the specified frequency, and liquid water volume fraction. For wet-ice, the temperature is 0 ℃.

`[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('soil',fc,temp,sandpercent,claypercent,specificgravity,vwc)` calculates the electrical characteristics for soil at the specified frequency, temperature, sand percentage, clay percentage, specific gravity, and volumetric water content.

`[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('soil',___,bulkdensity)` sets the soil bulk density in addition to input arguments from the previous syntax.

`[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('vegetation',fc,temp,gwc)` calculates the electrical characteristics for vegetation at the specified frequency, temperature, and gravimetric water content. For vegetation, the temperature must be greater than or equal to –20 ℃.

Examples

Compare Permittivity and Conductivity of Salt-free Sea Water to Pure Water

Compare the relative permittivity and conductivity for salt-free (zero-salinity) sea water to pure water.

Specify a carrier frequency of 9 GHz, temperature of 30℃, and salinity of zero.

```
fc = 9e9; % Carrier frequency in Hz.
temp = 30;
salinity = 0;
```

Compute the relative permittivity and conductivity.

```
[epsilon_pure_water,sigma_pure_water] = earthSurfacePermittivity('pure-water',fc,temp);
[epsilon_sea_water,sigma_sea_water] = earthSurfacePermittivity('sea-water',fc,temp,salinity);
```

Confirm that salt-free sea water and pure water have equal relative permittivity and conductivity.

```
isequal(epsilon_pure_water,epsilon_sea_water)
```

```
ans = logical
   1
```

```
isequal(sigma_pure_water,sigma_sea_water)
```

```
ans = logical
   1
```

Compare Permittivity and Conductivity of Wet Ice to Dry Ice

Compare the relative permittivity and conductivity for wet ice with no liquid water to dry ice at 0℃. Confirm the results differ by a negligible amount.

Specify a carrier frequency of 12 GHz.

```
fc = 12e9; % Carrier frequency in Hz.
```

Calculate the relative permittivity and conductivity for wet ice with zero liquid water by volume.

```
liqfrac = 0;
[epsilon_wet_ice_0,sigma_wet_ice_0] = earthSurfacePermittivity('wet-ice',fc,liqfrac); % Set liqu
```

Calculate the relative permittivity and conductivity for dry ice at 0 ℃.

```
temp = 0;
[epsilon_dry_ice_0,sigma_dry_ice_0] = earthSurfacePermittivity('dry-ice',fc,temp); % Set tempera
```

Compare the relative permittivity and conductivity for wet ice with no liquid to dry ice at 0℃. Confirm that wet ice with no liquid and dry ice at 0℃ have essentially equal relative permittivity and conductivity.

```
epsilon_wet_ice_0-epsilon_dry_ice_0
```

```
ans = 8.8818e-16
```

```
sigma_wet_ice_0-sigma_dry_ice_0
```

```
ans = -9.2179e-16
```

Plot permittivity and conductivity versus frequency for dry ice and for wet ice. For dry ice, vary the temperature. For wet ice, vary the liquid water volume fraction. Calculate the permittivity and conductivity values by using `arrayfun` to apply the `earthSurfacePermittivity` function to the elements of the arrayed inputs.

```
freq = repmat([0.1,10,20,40,60]*1e9,6,1);
temp = repmat((-100:20:0)',1,5);
liqfrac = repmat((0:0.2:1)',1,5);
[epsilon_dry_ice, sigma_dry_ice] = arrayfun(@(x,y)earthSurfacePermittivity('dry-ice',x,y),freq,te
[epsilon_wet_ice, sigma_wet_ice] = arrayfun(@(x,y)earthSurfacePermittivity('wet-ice',x,y),freq,li
```

Display tiled surface plots across specified ranges.

```
figure
tiledlayout(2,2)

Calculate Permittivity and Conductivity of Various Soil Mixtures

Calculate relative permittivity and conductivity for various soil mixtures as defined by textual classifications in ITU-R P.527, Table 1.

Initialize computation variables for constant values and arrayed values.

```
fc = 28e9; % Frequency in Hz
temp = 23; % Temperature in °C
vwc = 0.5; % Volumetric water content
pSand = [51.52; 41.96; 30.63; 5.02]; % Sand percentage
pClay = [13.42; 8.53; 13.48; 47.38]; % Clay percentage
sg = [2.66; 2.70; 2.59; 2.56]; % Specific gravity
bd = [1.6006; 1.5781; 1.5750; 1.4758]; % Bulk density (g/cm^3)
```

Calculate the relative permittivity and conductivity for these textual classifications: sandy loam, loam, silty loam, and silty clay. Use `arrayfun` to apply the `earthSurfacePermittivity` function to the elements of the arrayed inputs. Tabulate the results.

```
[Permittivity,Conductivity] = arrayfun(@(w,x,y,z)earthSurfacePermittivity( ...
    'soil',fc,temp,w,x,y,vwc,z),pSand,pClay,sg,bd);

pSilt = 100 - (pSand + pClay); % Silt percentage
soilType = ["Sandy Loam";"Loam";"Silty Loam";"Silty Clay"];
```

```
varNames1 = ["Soil Textual Classification";"Sand";"Clay";"Silt";"Specific Gravity";"Bulk Density"
varNames2 = ["Soil Textual Classification";"Permittivity";"Conductivity"];
```

ITU-R P.527, Table 1 specifies the sand percentage, clay percentage, specific gravity, and bulk density for soil mixtures with these soil textual classifications.

```
table(soilType,pSand,pClay,pSilt,sg,bd,'VariableNames',varNames1)

Calculate Permittivity and Conductivity of Vegetation

Calculate relative permittivity and conductivity versus frequency for vegetation, varying gravimetric water content and temperature.

Calculate relative permittivity and conductivity for vegetation at specified settings.

```
fc = 10e9; % Frequency in Hz
temp  = 23; % Temperature in °C
gwc = 0.68; % Gravimetric water content
[epsilon_veg,sigma_veg] = ...
    earthSurfacePermittivity('vegetation',fc,temp,gwc)
```

```
epsilon_veg = 20.5757

sigma_veg = 4.9320
```

Calculate values necessary to plot permittivity and conductivity by using `arrayfun` to apply the `earthSurfacePermittivity` function to the elements of the arrayed inputs.

For a range of temperatures, calculate values to plot permittivity and conductivity versus frequency for vegetation at a 0.68 gravimetric water content.

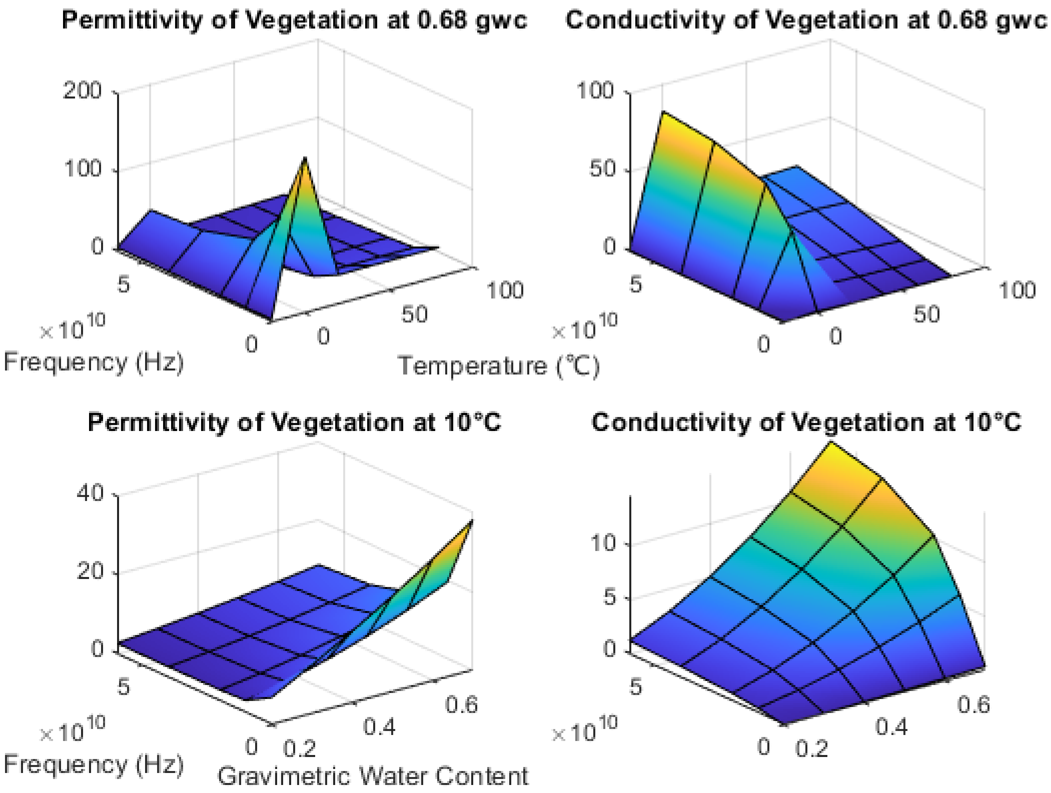
```
fc = repmat([0.1,10,20,40,60]*1e9,6,1);
gwc1 = 0.68;
temp1 = repmat((-20:20:80)',1,5);
[epsilon_veg_gwc,sigma_veg_gwc] = ...
    arrayfun(@(x,y)earthSurfacePermittivity('vegetation',x,y,gwc1),fc,temp1);
```

For a range of gravimetric water contents, calculate values to plot permittivity and conductivity versus frequency for vegetation at 10°C.

```
temp2 = 10;
gwc2 = repmat((0.2:0.1:0.7)',1,5);
[epsilon_veg_tmp, sigma_veg_tmp] = ...
    arrayfun(@(x,z)earthSurfacePermittivity('vegetation',x,temp2,z),fc,gwc2);
```

Display tiled surface plots across specified ranges.

```
figure
tiledlayout(2,2)
nexttile
surf(temp1,fc,epsilon_veg_gwc,'FaceColor','interp')
title('Permittivity of Vegetation at 0.68 gwc')
xlabel('Temperature (℃)')
ylabel('Frequency (Hz)')
nexttile
surf(temp1,fc,sigma_veg_gwc,'FaceColor','interp')
title('Conductivity of Vegetation at 0.68 gwc')
nexttile
surf(gwc2,fc,epsilon_veg_tmp,'FaceColor','interp')
title('Permittivity of Vegetation at 10°C')
xlabel('Gravimetric Water Content')
ylabel('Frequency (Hz)')
nexttile
surf(gwc2,fc,sigma_veg_tmp,'FaceColor','interp')
title('Conductivity of Vegetation at 10°C')
```



Input Arguments

`fc` — Carrier frequency

scalar in the range (0, 1e12]

Carrier frequency in Hz, specified as a scalar in the range (0, 1e12].

Data Types: `double`

`temp` — Temperature

numeric scalar

Temperature in °C, specified as a numeric scalar. Valid surfaces and associated temperature limits are indicated in this table.

Surface	Valid Temperature (°C)
pure-water	greater than 0
dry-ice	less than or equal to 0
sea-water	greater than or equal to –2
soil	any numeric
vegetation	≥ –20

Note When the surface is wet-ice, the temperature is 0 ℃.

Data Types: `double`

`salinity` — Salinity of sea water
nonnegative scalar

Salinity of the sea water in g/Kg, specified as a nonnegative scalar.

Data Types: `double`

`liqfrac` — Liquid water volume fraction of wet ice
numeric scalar in the range [0, 1]

Liquid water volume fraction of the wet ice, specified as a numeric scalar in the range [0, 1].

Data Types: `double`

`sandpercent` — Sand percentage of soil
numeric scalar in the range [0, 100]

Sand percentage of the soil, specified as a numeric scalar in the range [0, 100]. The sum of `sandpercent` and `claypercent` must be less than or equal to 100.

Data Types: `double`

`claypercent` — Clay percentage of soil
numeric scalar in the range [0, 100]

Clay percentage of the soil, specified as a numeric scalar in the range [0, 100]. The sum of `sandpercent` and `claypercent` must be less than or equal to 100.

Data Types: `double`

`specificgravity` — Specific gravity of soil
nonnegative scalar

Specific gravity of the soil, specified as a nonnegative scalar. The specific gravity is the mass density of the soil sample divided by the mass density of the amount of water in the soil sample.

Data Types: `double`

`vwc` — Volumetric water content of soil
numeric scalar in the range [0, 1]

Volumetric water content of the soil, specified as a numeric scalar in the range [0, 1]. For more information, see “Soil Water Content” on page 2-978.

Data Types: `double`

`bulkdensity` — Bulk density of soil
nonnegative scalar

Bulk density, in g/cm^3, of the soil, specified as a nonnegative scalar. For more information, see “Soil Water Content” on page 2-978.

Data Types: `double`

`gwc` — Gravimetric water content of vegetation
numeric scalar in the range [0, 0.7]

Gravimetric water content of the vegetation, specified as a numeric scalar in the range [0, 0.7]. For more information, see "Soil Water Content" on page 2-978.

Data Types: `double`

Output Arguments

`epsilon` — Relative permittivity
nonnegative scalar

Relative permittivity of the earth surface, returned as a nonnegative scalar.

`sigma` — Conductivity
nonnegative scalar

Conductivity of the earth surface in Siemens per meter (S/m), returned as a nonnegative scalar.

`complexepsilon` — Complex relative permittivity
complex scalar

Complex relative permittivity of the earth surface, returned as a complex scalar calculated as
`complexepsilon` = `epsilon` – 1*i* `sigma` / ($2\pi fc\varepsilon_0$).
The computation of `complexepsilon` is based on Equations (59) and (9b) in ITU-R P.527 [1]. *f* is the frequency in GHz. *c* is the velocity of light in free space. ε_0 = 8.854187817e-12 Farads/m, where ε_0 is the electric constant for the permittivity of free space.

More About

ITU Terrain Materials

ITU-R P.527 [1] presents methods and equations to calculate complex relative permittivity at carrier frequencies up to 1,000 GHz for these common earth surface materials.

- Water
- Sea Water
- Dry or Wet Ice
- Dry or Wet Soil (combination of sand, clay, and silt)
- Vegetation (above and below freezing)

As described in ITU-R P.527, specific textural classification applies to these mixtures of sand, clay, and silt in soil with associated specific gravities and bulk densities.

Soil Designation Textural Class	Sandy Loam	Loam	Silty Loam	Silty Clay
% Sand	51.52	41.96	30.63	5.02
% Clay	13.42	8.53	13.48	47.38
% Silt	35.06	49.51	55.89	47.60

Soil Designation Textural Class	**Sandy Loam**	**Loam**	**Silty Loam**	**Silty Clay**
Specific gravity (ρ_s)	2.66	2.70	2.59	2.56
Bulk Density (ρ_b) in g/cm^3	1.6006	1.5781	1.5750	1.4758

Soil Water Content

Soil water content is expressed on a gravimetric or volumetric basis. Gravimetric water content, `gwc`, is the mass of water per mass of dry soil. Volumetric water content, `vwc`, is the volume of liquid water per volume of soil. The bulk density, `bulkdensity`, is the ratio of the dry soil weight to the volume of the soil sample. The relationship between `gwc` and `vwc` is `vwc` = `gwc` □ `bulkdensity`. When bulk density is not specified, the value of `bulkdensity` is computed by using ITU-R P.527, Equation 36:

`bulkdensity` = 1.07256 + 0.078886 ln(*pSand*) + 0.038753 ln(*pClay*) + 0.032732 ln(*pSilt*),

where

- *pSand* = `sandpercent`
- *pClay* = `claypercent`
- *pSilt* = 100 – (`sandpercent` + `claypercent`)

Functions
`buildingMaterialPermittivity` | `propagationModel` | `raypl` | `raytrace`

Objects
`comm.Ray`

Introduced in R2020a

raypl

Calculate path loss and phase shift for ray

Syntax

```
[pl,phase] = raypl (ray)
[pl,phase] = raypl (ray,Name,Value)
```

Description

`[pl,phase] = raypl (ray)` returns the path loss in dB and phase shift in radians based on the properties specified by `ray`. The path loss and path shift computations consider the free space loss and reflection loss derived from the propagation path, reflection materials, and polarizations. The function accounts for geometric coupling between horizontal and vertical polarizations only when both transmit and receive antennas are polarized. For more information, see “Path Loss Computation” on page 2-984.

`[pl,phase] = raypl (ray,Name,Value)` calculates the path loss and phase shift with additional options specified by one or more name-value pair arguments.

Examples

Reevaluate Path Loss Changing Reflection Materials and Frequency

Change the reflection materials and frequency for a ray and reevaluate the path loss and phase shift.

Launch Site Viewer with buildings in Hong Kong. For more information about the osm file, see [1] on page 2-0 . Specify transmitter and receiver sites.

```
viewer = siteviewer("Buildings","hongkong.osm");

tx = txsite("Latitude",22.2789,"Longitude",114.1625, ...
    "AntennaHeight",10,"TransmitterPower",5, ...
    "TransmitterFrequency",28e9);
rx = rxsite("Latitude",22.2799,"Longitude",114.1617, ...
    "AntennaHeight",1);
```

Perform ray tracing between the sites.

```
rays = raytrace(tx,rx,"NumReflections",0:2);
```

Find the first ray with 2-order reflections from the result. Display the ray characteristics. Plot the ray to see the ray reflect off two buildings.

```
ray = rays{1}(find([rays{1}.NumReflections] == 2,1))
```

```
ray = 
  Ray with properties:

      PathSpecification: 'Locations'
```

```
       CoordinateSystem: 'Geographic'
    TransmitterLocation: [3×1 double]
       ReceiverLocation: [3×1 double]
            LineOfSight: 0
    ReflectionLocations: [3×2 double]
              Frequency: 2.8000e+10
         PathLossSource: 'Custom'
               PathLoss: 122.1825
             PhaseShift: 4.5977

   Read-only properties:
       PropagationDelay: 8.3060e-07
    PropagationDistance: 249.0069
       AngleOfDeparture: [2×1 double]
         AngleOfArrival: [2×1 double]
          NumReflections: 2
```

```
plot(ray);
```

By default, all buildings have concrete building material electrical characteristics. Change the material to metal for the second reflection and re-evaluate path loss. Use the `raypl` function to reevaluate the pathloss for the ray. Display the ray path to compare the change in path loss. Replot to show the slight change in color due to the path loss change of the ray.

```
[ray.PathLoss,ray.PhaseShift] = raypl(ray, ...
    "ReflectionMaterials",["concrete","metal"])
```

```
ray = 
  Ray with properties:

      PathSpecification: 'Locations'
       CoordinateSystem: 'Geographic'
    TransmitterLocation: [3×1 double]
       ReceiverLocation: [3×1 double]
            LineOfSight: 0
    ReflectionLocations: [3×2 double]
              Frequency: 2.8000e+10
         PathLossSource: 'Custom'
               PathLoss: 117.4814
             PhaseShift: 4.5977

   Read-only properties:
       PropagationDelay: 8.3060e-07
    PropagationDistance: 249.0069
       AngleOfDeparture: [2×1 double]
         AngleOfArrival: [2×1 double]
         NumReflections: 2

ray = 
  Ray with properties:

      PathSpecification: 'Locations'
       CoordinateSystem: 'Geographic'
    TransmitterLocation: [3×1 double]
       ReceiverLocation: [3×1 double]
            LineOfSight: 0
    ReflectionLocations: [3×2 double]
              Frequency: 2.8000e+10
         PathLossSource: 'Custom'
               PathLoss: 117.4814
             PhaseShift: 4.5977

   Read-only properties:
       PropagationDelay: 8.3060e-07
    PropagationDistance: 249.0069

Input Arguments

ray — Ray configuration

`comm.Ray` object

Ray configuration, specified as one `comm.Ray` object. The object must have the `PathSpecification` property set to `"Locations"`.

Data Types: `comm.Ray`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `raypl(ray,'TransmitterPolarization','H','ReceiverPolarization','H')`, specifies the horizontal polarizations for the transmit and receive antennas for `ray`.

ReflectionMaterials — Reflection materials

`"concrete"` (default) | string scalar | 1-by-*NR* string vector | 2-by-1 numeric vector | 2-by-*NR* numeric matrix

Reflection materials for a non-line-of-sight (NLOS) ray, specified as a string scalar, 1-by-*NR* string vector, 2-by-1 numeric vector, or 2-by-*NR* numeric matrix. *NR* represents the number of reflections as specified by the `comm.Ray.NumReflections` property.

- When `ReflectionMaterials` is specified as a string scalar or string vector, the reflection material must be one of `"concrete"`, `"brick"`, `"wood"`, `"glass"`, `"metal"`, `"water"`, `"vegetation"`, `"loam"`, or `"perfect-reflector"`. When specified as a string scalar, the setting applies to all the reflections.
- When `ReflectionMaterials` is specified as a 2-by-1 numeric vector, the [relative permittivity; conductivity] value pair applies to all the reflections.
- When `ReflectionMaterials` is specified as a 2-by-*NR* numeric matrix, the [relative permittivity; conductivity] value pair in each column applies for each of the *NR* reflection points, respectively.

Example: `"ReflectionMaterials",["concrete","water"]`, specifies that a ray with two reflections will use electrical characteristics of concrete at the first reflection point and water at the second reflection point.

Data Types: `string` | `char` | `double`

`TransmitterPolarization` — Transmit antenna polarization type
`"none"` (default) | `"H"` | `"V"` | `"RHCP"` | `"LHCP"` | normalized 2-by-1 Jones vector

Transmit antenna polarization type, specified as `"none"`, `"H"`, `"V"`, `"RHCP"`, `"LHCP"`, or a normalized [H; V] Jones vector. For more information, see “Jones Vector Notation” on page 2-985.

Example: `'TransmitterPolarization','RHCP'`, specifies right-hand circular polarization for the transmit antenna.

Data Types: `double` | `char` | `string`

`ReceiverPolarization` — Receive antenna polarization type
`"none"` (default) | `"H"` | `"V"` | `"RHCP"` | `"LHCP"` | normalized 2-by-1 Jones vector

Receive antenna polarization type, specified as `"none"`, `"H"`, `"V"`, `"RHCP"`, `"LHCP"`, or a normalized [H; V] Jones vector. For more information, see “Jones Vector Notation” on page 2-985.

Example: `'ReceiverPolarization',[1;0]`, specifies horizontal polarization for the receive antenna by using Jones vector notation.

Data Types: `double` | `char` | `string`

`TransmitterAxes` — Orientation of transmit antenna axes
3-by-3 identity matrix (default) | 3-by-3 unitary matrix

Orientation of the transmit antenna axes, specified as a 3-by-3 unitary matrix indicating the rotation from the transmitter local coordinate system (LCS) into the global coordinate system (GCS). When the `CoordinateSystem` property of the `comm.Ray` is set to `"Geographic"`, the GCS orientation is the local East-North-Up (ENU) coordinate system at transmitter. For more information, see “Coordinate System Orientation” on page 2-983.

Example: `'TransmitterAxes',eye(3)`, specifies that the local coordinate system for the transmitter axes is aligned with the global coordinate system. This is the default orientation.

Data Types: `double`

`ReceiverAxes` — Orientation of receive antenna axes
3-by-3 identity matrix (default) | 3-by-3 unitary matrix

Orientation of the receive antenna axes, specified as a 3-by-3 unitary matrix indicating the rotation from the receiver local coordinate system (LCS) into the global coordinate system (GCS). The GCS orientation is the local East-North-Up (ENU) coordinate system at receiver when the .`CoordinateSystem` property of the `comm.Ray` is set to `"Geographic"`. For more information, see “Coordinate System Orientation” on page 2-983.

Example: `'ReceiverAxes',[0 -1 0; 1 0 0; 0 0 1]`, specifies a 90° rotation around the z-axis of the local receiver coordinate system with respect to the global coordinate system.

Data Types: `double`

Output Arguments

`pl` — Path loss

scalar

Path loss in dB, returns the path loss calculated for the input ray object, accounting for any modifications specified by `Name,Value` pairs.

`phase` — Phase shift

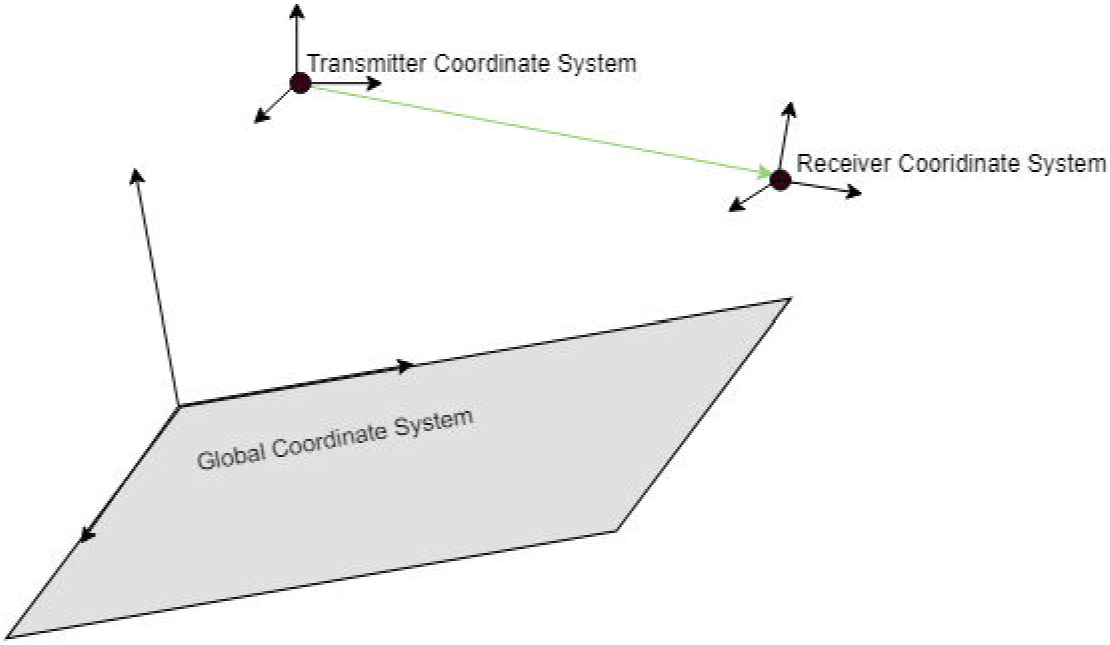
scalar

Phase shift in radians, returns the phase shift calculated for the input ray object, accounting for any modifications specified by `Name,Value` pairs.

More About

Coordinate System Orientation

This image shows the orientation of the electromagnetic fields in the global coordinate system (GCS) and the local coordinate systems of the transmitter and receiver.



When the `CoordinateSystem` property of the `comm.Ray` is set to `"Geographic"`, the GCS orientation is the local East-North-Up (ENU) coordinate system at observer. The path loss computation accounts for the round-earth differences between ENU coordinates at the transmitter and receiver.

Path Loss Computation

The path loss computations in raypl follow the path loss and reflection matrix computations as described in IEEE Document 802.11-09/0334r8 [1]. The function accounts for geometric coupling between horizontal and vertical polarizations only when both transmit and receive antennas are polarized.

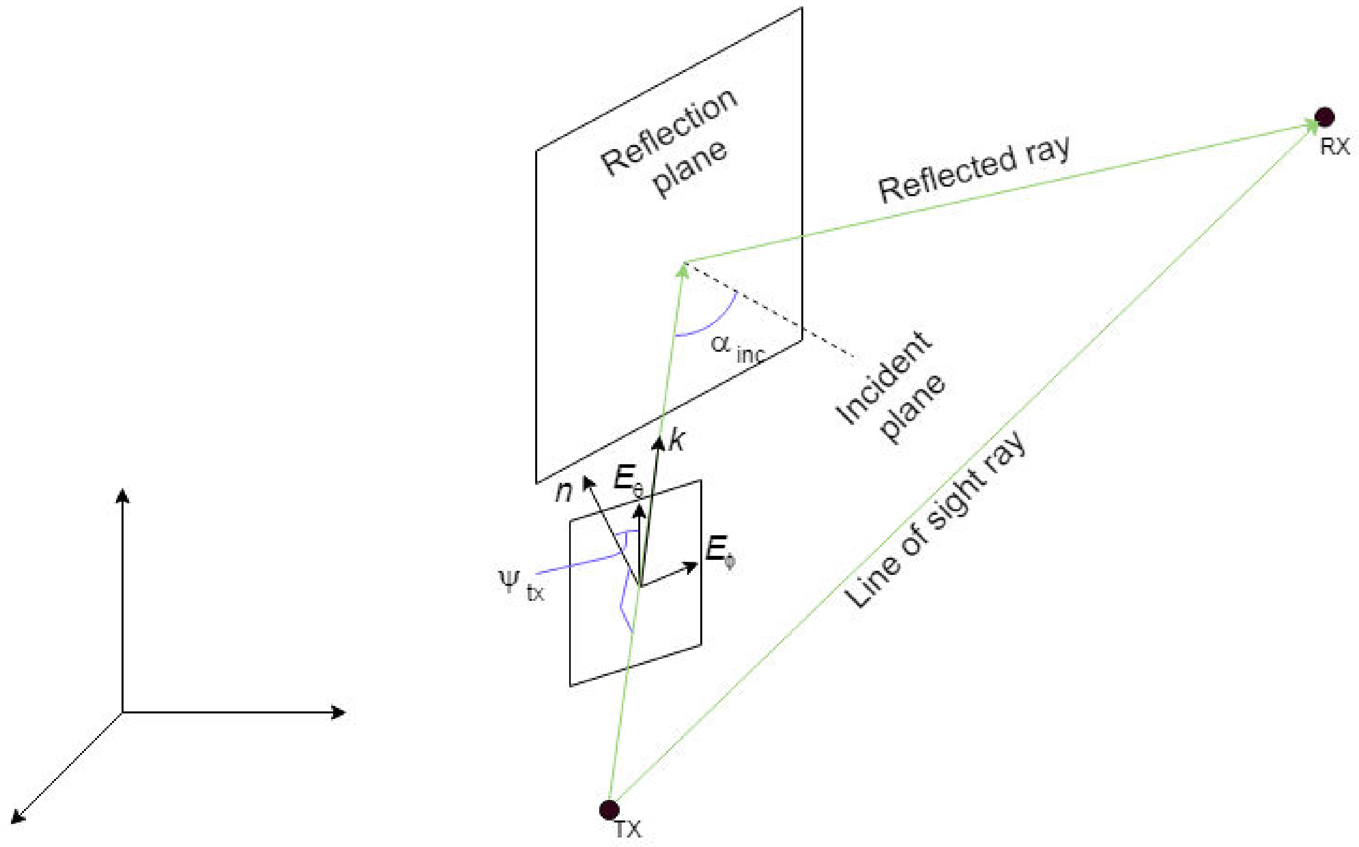
For a first order signal reflection, the reflection matrix, H_{ref1}, is computed as

$$H_{ref1} = \begin{bmatrix} \cos(\psi_{rx}) & \sin(\psi_{rx}) \\ -\sin(\psi_{rx}) & \cos(\psi_{rx}) \end{bmatrix} \times \begin{bmatrix} R_{\perp}(\alpha_{inc}) & 0 \\ 0 & R_{\parallel}(\alpha_{inc}) \end{bmatrix} \times \begin{bmatrix} \cos(\psi_{tx}) & \sin(\psi_{tx}) \\ -\sin(\psi_{tx}) & \cos(\psi_{tx}) \end{bmatrix}$$

The terms in the channel propagation matrix computation represent

- RX geometric coupling matrix — Recalculation of the polarization vector from the plane of incidence basis to RX coordinates.
- Polarization matrix — Matrix includes the reflection coefficients *R*▯ and *R*‖ for the perpendicular and parallel components of the electric field *E* ▯ and *E* ‖ respectively.
- TX geometric coupling matrix — Recalculation of the polarization vector from the TX coordinates basis to the plane of incidence.

This figure illustrates a first order reflected signal path.



Where

- The reflection plane is offset from the global coordinate system origin.
- k represents the waveform propagation vector.
- n represents the vector normal to the incident plane.
- E_θ and E_φ represent the vertical and horizontal electromagnetic field vectors.
- α_{inc} represents the incident angle of k.
- ψ_{tx} represents the angle between E_θ and a normal to the incident plane.
- TX represents the transmit antenna.
- RX represents the receive antenna.

The reflection matrix computations for second order signal reflections extend from the first order signal reflection computations. For more information, see IEEE Document 802.11-09/0334r8 [1].

Jones Vector Notation

For Jones vector notation, the raypl function describes signal polarization using Jones calculus.

The orthogonal components of Jones vectors are defined for E_θ and E_φ. This table shows the Jones vector corresponding to various antenna polarizations.

Antenna Polarization Type	Corresponding Jones Vector
Linear polarized in the θ direction	$\begin{pmatrix} H \\ V \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$
Linear polarized in the φ direction	$\begin{pmatrix} H \\ V \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$
Left-hand circular polarized (LHCP)	$\begin{pmatrix} H \\ V \end{pmatrix} = \frac{1}{\sqrt{2}}\begin{pmatrix} j \\ 1 \end{pmatrix}$
Right-hand circular polarized (RHCP)	$\begin{pmatrix} H \\ V \end{pmatrix} = \frac{1}{\sqrt{2}}\begin{pmatrix} -j \\ 1 \end{pmatrix}$

blkdiagbfweights

MIMO channel block diagonalized weights

Syntax

```
[wp,wc] = blkdiagbfweights(chanmat,ns)
[wp,wc] = blkdiagbfweights(chanmat,ns,pt)
```

Description

`[wp,wc] = blkdiagbfweights(chanmat,ns)` returns precoding weights, `wp`, and combining weights, `wc`, derived from the channel response matrices contained in a MATLAB cell array `chanmat`.

- You can specify multiple user channels by putting each channel in a `chanmat` cell. `chanmat{k}` represents the k^{th}channel from the transmitter to the user.
- - For a single frequency, specify the channel cell as a matrix.
  - For multiply frequencies, specify the channel cell as a three-dimensional array where the rows represent different subcarriers.
- Specify multiple subchannels per channel using the `ns` argument. Subchannels represent different data streams. `ns` specifies the number of subchannels for each user channel. Multiply the data streams by the precoding weights, `wp`.

The precoding and combining weights diagonalize the channel into independent subchannels so that for the k^{th}user, the matrix `wp*chanmat{k}*wc{k}` is diagonal for each subcarrier.

`[wp,wc] = blkdiagbfweights(chanmat,ns,pt)` also specifies the total transmitted power, `pt`, per subcarrier.

Examples

Spatial Multiplexing with Block Diagonal Weights

Start with a base station consisting of a uniform linear array (ULA) with 16 antennas, and two users having receiver ULA arrays with 8 and 4 antennas, respectively. Show that using block diagonalization-based precoding and combining weights achieves spatial multiplexing, where the received signal at each user can be decoded without interference from the other user. Specify two data streams for each user.

Specify the transmitter location in `txpos` and two user receiver locations in `rxpos1` and `rxpos2`. Array elements are spaced one-half wavelength apart.

```
txpos = (0:15)*0.5;
rxpos1 = (0:7)*0.5;
rxpos2 = (0:3)*0.5;
```

Create the channel matrix cell array using `scatteringchanmtx` and then compute the beamforming weights `wp` and `wc`. Each channel corresponds to a user. Assume that the channels have 10 scatterers. Each channel has two subchannels specified by the vector `ns`.

```
chanmat = {scatteringchanmtx(txpos,rxpos1,10), ...
    scatteringchanmtx(txpos,rxpos2,10)};
ns = [2 2];
[wp,wc] = blkdiagbfweights(chanmat,ns);
```

The weights diagonalize the channel matrices for each user.

For channel 1:

```
disp(wp*chanmat{1}*wc{1})
```

```
   8.2269 - 0.0000i   0.0000 - 0.0000i
   0.0000 + 0.0000i   6.1371 - 0.0000i
   0.0000 - 0.0000i  -0.0000 + 0.0000i
   0.0000 - 0.0000i   0.0000 + 0.0000i
```

For channel 2:

```
disp(wp*chanmat{2}*wc{2})
```

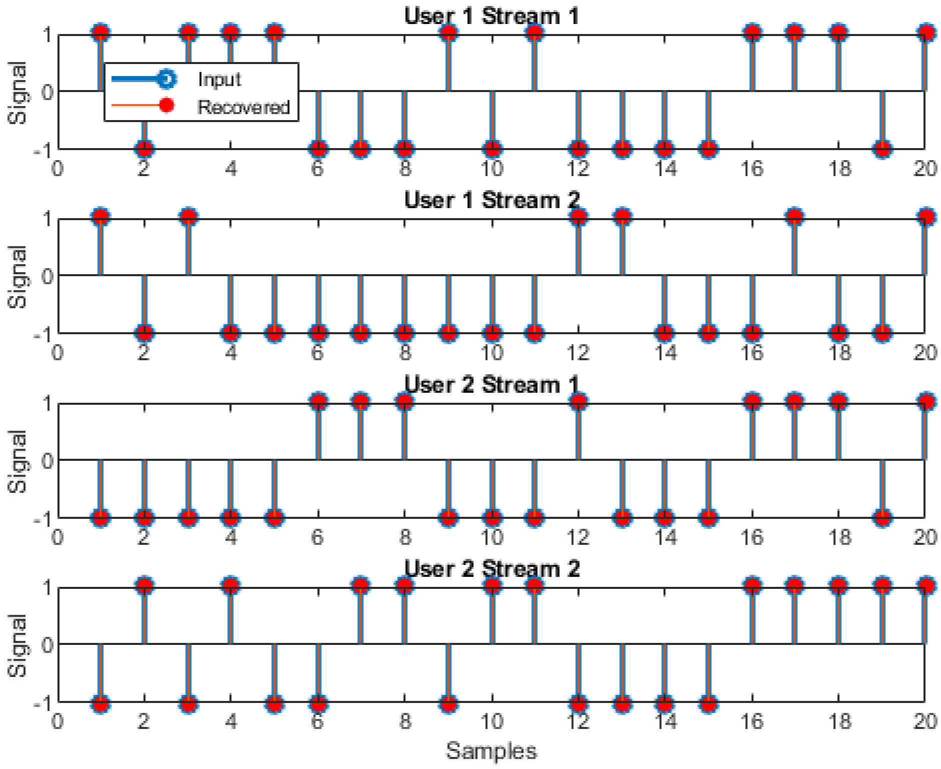
```
  -0.0000 + 0.0000i  -0.0000 + 0.0000i
  -0.0000 + 0.0000i  -0.0000 + 0.0000i
   8.7543 - 0.0000i   0.0000 - 0.0000i
   0.0000 + 0.0000i   4.4372 + 0.0000i
```

First create four subchannels to carry the data streams: two subchannels per channel. Each data stream contains 20 samples of ±1. Precode the input streams and combine the streams to produce the recovered signals.

```
x = 2*round(rand([20,4])) - 1;
xp = x*wp;
y1 = xp*chanmat{1} + 0.1*randn(20,8);
y2 = xp*chanmat{2} + 0.1*randn(20,4);
y = [y1*wc{1},y2*wc{2}];
```

Overlay stem plots of the input and recovered signals to show that the received user signals are the same as the transmitted signals.

```
for m = 1:4
    subplot(4,1,m)
    s = stem([x(:,m) 2*((real(y(:,m)) > 0) - 0.5)]);
    s(1).LineWidth = 2;
    s(2).MarkerEdgeColor = 'none';
    s(2).MarkerFaceColor = 'r';
    ylabel('Signal')
    title(sprintf('User %d Stream %d',ceil(m/2),rem(m-1,2) + 1))
    if m==1
        legend('Input','Recovered','Location','best')
    end
end
xlabel('Samples')
```



Spatial Multiplexing with Specified Power

Start with a base station consisting of a uniform linear array (ULA) with 16 antennas, and two users having receiver ULA arrays with 8 and 5 antennas, respectively. Show how to use three-dimensional arrays of channel matrices to handle two subcarriers. Then, the channel matrix for the first user takes the form 2-by-16-by-8 and the channel matrix for the second users takes the form 2-by-16-by-5. Also assume that there are two data streams for each user.

Specify the transmitter location in `txpos` and two user receiver locations in `rxpos1` and `rxpos2`. Array elements are spaced one-half wavelength apart.

```
nr1 = 8;
nr2 = 5;
txpos = (0:15)*0.5;
rxpos1 = (0:(nr1-1))*0.5;
rxpos2 = (0:(nr2-1))*0.5;
```

Create the channel matrices using `scatteringchanmtx` and put them in a cell array. To create a second subchannel for each receiver, duplicate each channel matrix. Assume 10 point scatterers in computing the channel matrix.

```
smtmp1 = scatteringchanmtx(txpos,rxpos1,10);
smtmp2 = scatteringchanmtx(txpos,rxpos2,10);
sm1 = zeros(2,16,8);
```

```
sm2 = zeros(2,16,5);
sm1(1,:,:) = smtmp1;
sm1(2,:,:) = smtmp1;
sm2(1,:,:) = smtmp2;
sm2(2,:,:) = smtmp2;
chanmat = {sm1,sm2};
```

Specify that there are two data streams for each user.

```
ns = [2 2];
```

Specify the transmitted powers for each subcarrier.

```
pt = [1.0 1.5];
```

Compute the beamforming weights.

```
[wp,wc] = blkdiagbfweights(chanmat,ns,pt);
```

Show that the channels are diagonalized for the first subcarrier.

```
ksubcr = 1;
wpx = squeeze(wp(ksubcr,:,:));
chanmat1 = squeeze(chanmat{1}(ksubcr,:,:));
chanmat2 = squeeze(chanmat{2}(ksubcr,:,:));
wc1 = squeeze(wc{1}(ksubcr,:,:));
wc2 = squeeze(wc{2}(ksubcr,:,:));
wpx*chanmat1*wc1
```

```
ans = 4×2 complex

   8.2104 + 0.0000i  -0.0000 - 0.0000i
   0.0000 - 0.0000i   5.9732 - 0.0000i
   0.0000 - 0.0000i  -0.0000 - 0.0000i
   0.0000 - 0.0000i   0.0000 - 0.0000i
```

```
wpx*chanmat2*wc2
```

```
ans = 4×2 complex

  -0.0000 + 0.0000i   0.0000 + 0.0000i
  -0.0000 + 0.0000i   0.0000 + 0.0000i
   8.8122 + 0.0000i  -0.0000 + 0.0000i
   0.0000 + 0.0000i   4.8186 - 0.0000i
```

Propagate the signals to each user and then decode. Generate four streams of random data containing -1's and +1's and having two columns for each user. Each stream is a subchannel.

```
x = 2*(round(rand([20 4]))) - 1;
```

Precode the data streams.

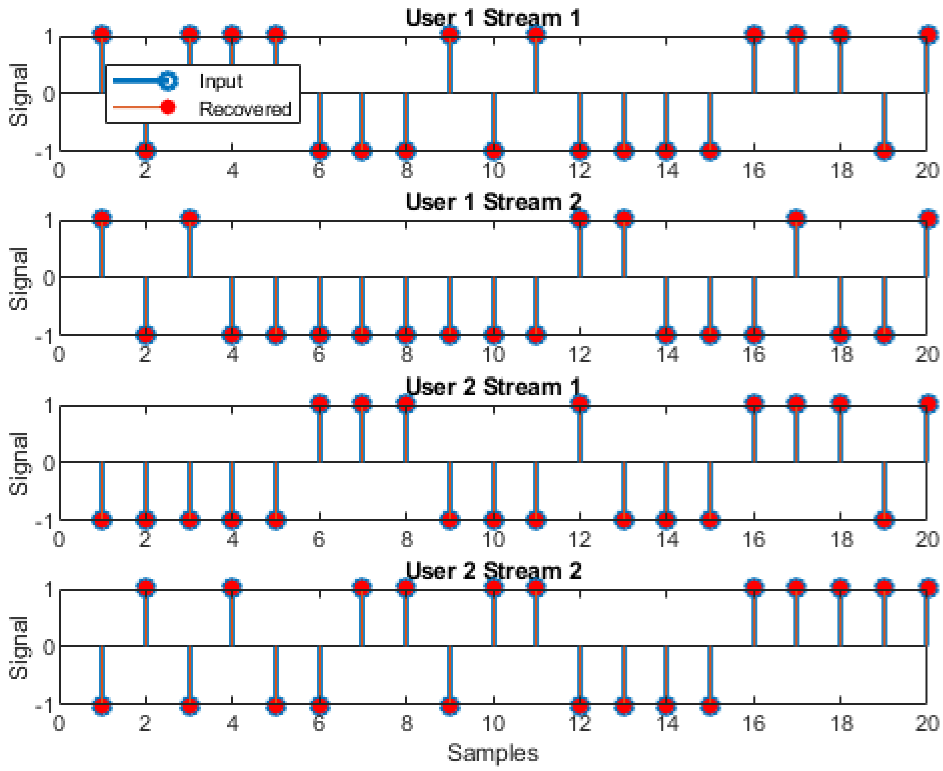
```
xp = x*wpx;
y1 = xp*chanmat1 + 0.1*randn(20,8);
y2 = xp*chanmat2 + 0.1*randn(20,5);
```

Decode the data streams.

```
y = [y1*wc1,y2*wc2];
```

Overlay stem plots of the input and recovered signals to show that the received user signals are the same as the transmitted signals.

```
for m = 1:4
    subplot(4,1,m)
    s = stem([x(:,m) 2*((real(y(:,m)) > 0) - 0.5)]);
    s(1).LineWidth = 2;
    s(2).MarkerEdgeColor = 'none';
    s(2).MarkerFaceColor = 'r';
    ylabel('Signal')
    title(sprintf('User %d Stream %d',ceil(m/2),rem(m-1,2) + 1))
    if m==1
        legend('Input','Recovered','Location','best')
    end
end
xlabel('Samples')
```



Input Arguments

chanmat — Channel response matrices

N_u-element cell array

Channel response matrices, specified as an N_u-element cell array. N_u is the number of receive arrays. Each cell corresponds to a different channel and contains a channel response matrix or a three dimensional MATLAB array. The cell array must contain either all matrices or all arrays. For matrices, the number of rows for all matrices must be the same. For three-dimensional arrays, the number of rows and columns must be the same.

- If the k^{th} cell is a matrix, the matrix has the size N_t-by-$N_r(k)$. N_t is the number of elements in the transmitting array and $N_r(k)$ is the number of elements in the k^{th} receiving array.
- If the k^{th} cell is an array, the array has the size L-by-N_t-by-$N_r(k)$. L is the number of subcarriers. N_t is the number of elements in the transmit array and $N_r(k)$ is the number of elements in the k^{th} receive array.

Data Types: `double`
Complex Number Support: Yes

`ns` — Number of data streams per receive array
N_u-element row vector of positive integers

Number of data streams per receive array, specified as an N_u-element row vector of positive integers. N_u is the number of receive arrays.

Data Types: `double`

`pt` — Total transmitted power per subcarrier
`1` (default) | positive scalar | L-element vector of positive values

Total transmitted power per subcarrier, specified as a positive scalar or an L-element vector of positive values. L is the number of subcarriers. If `pt` is a scalar, all subcarriers have the same transmitted power. If `pt` is a vector, each vector element specifies the transmitted power for the corresponding subcarrier. Power is in linear units.

Data Types: `double`

Output Arguments

`wp` — Precoding weights
complex-valued N_{st}-by-N_t matrix | complex-valued L-by-N_{st}-by-N_t MATLAB array

Precoding weights, returned as a complex-valued N_{st}-by-N_t matrix or a complex-valued L-by-N_{st}-by-N_t MATLAB array.

- If `chanmat` contains matrices, `wp` is a complex-valued N_{st}-by-N_t matrix where N_{st} is the total number of data channels (`sum(ns)`).
- If `chanmat` contains three-dimensional MATLAB arrays, `wp` is a complex-valued L-by-N_{st}-by-N_t MATLAB array where N_{st} is the total number of data channels (`sum(ns)`).

Units are dimensionless.

Data Types: `double`

`wc` — Combining weights
N_u-element cell array

Combining weights, returned as an N_u-element cell array. Units are dimensionless.

- If `chanmat` contains matrices, the k^{th} cell in `wc` contains a complex valued $N_r(k)$-by-$N_s(k)$ matrix. $N_s(k)$ is the value of the argument `ns` for the k^{th} receive array.

- If chanmat contains three-dimensional MATLAB arrays, the k^{th} cell of wc contains a complex-valued L-by-$N_r(k)$-by-$N_s(k)$ MATLAB array. $N_s(k)$ is the value of the k^{th} entry of the ns vector.

Data Types: double

cart2sphvec

Convert vector from Cartesian components to spherical representation

Syntax

```
vs = cart2sphvec(vr,az,el)
```

Description

`vs = cart2sphvec(vr,az,el)` converts the components of a vector or set of vectors, `vr`, from their representation in a local Cartesian coordinate system to a spherical basis representation contained in `vs`. A spherical basis representation is the set of components of a vector projected into a basis given by $(\hat{\mathbf{e}}_{az}, \hat{\mathbf{e}}_{el}, \hat{\mathbf{e}}_{R})$. The orientation of a spherical basis depends upon its location on the sphere as determined by azimuth, `az`, and elevation, `el`.

Examples

Spherical Representation of Unit Z-Vector

Start with a vector in Cartesian coordinates pointing along the *z*-direction and located at 45° azimuth, 45° elevation. Compute its components with respect to the spherical basis at that point.

```
vr = [0;0;1];
vs = cart2sphvec(vr,45,45)
```

```
vs = 3×1

         0
    0.7071
    0.7071
```

Input Arguments

`vr` — Vector in Cartesian basis representation
3-by-1 column vector | 3-by-N matrix

Vector in Cartesian basis representation specified as a 3-by-1 column vector or 3-by-N matrix. Each column of `vr` contains the three components of a vector in the right-handed Cartesian basis *x,y,x*.

Example: `[4.0; -3.5; 6.3]`

Data Types: `double`
Complex Number Support: Yes

az — Azimuth angle
scalar in range [–180,180]

Azimuth angle specified as a scalar in the closed range [–180,180]. Angle units are in degrees. To define the azimuth angle of a point on a sphere, construct a vector from the origin to the point. The azimuth angle is the angle in the *xy*-plane from the positive *x*-axis to the vector's orthogonal projection into the *xy*-plane. As examples, zero azimuth angle and zero elevation angle specify a point on the *x*-axis while an azimuth angle of 90° and an elevation angle of zero specify a point on the *y*-axis.

Example: `45`

Data Types: `double`

`el` — Elevation angle
scalar in range [–90,90]

Elevation angle specified as a scalar in the closed range [–90,90]. Angle units are in degrees. To define the elevation of a point on the sphere, construct a vector from the origin to the point. The elevation angle is the angle from its orthogonal projection into the *xy*-plane to the vector itself. As examples, zero elevation angle defines the equator of the sphere and ±90° elevation define the north and south poles, respectively.

Example: `30`

Data Types: `double`

Output Arguments

`vs` — Vector in spherical basis
3-by-1 column vector | 3-by-N matrix

Spherical representation of a vector returned as a 3-by-1 column vector or 3-by-N matrix having the same dimensions as `vs`. Each column of `vs` contains the three components of the vector in the right-handed ($\hat{\mathbf{e}}_{az}$, $\hat{\mathbf{e}}_{el}$, $\hat{\mathbf{e}}_{R}$) basis.

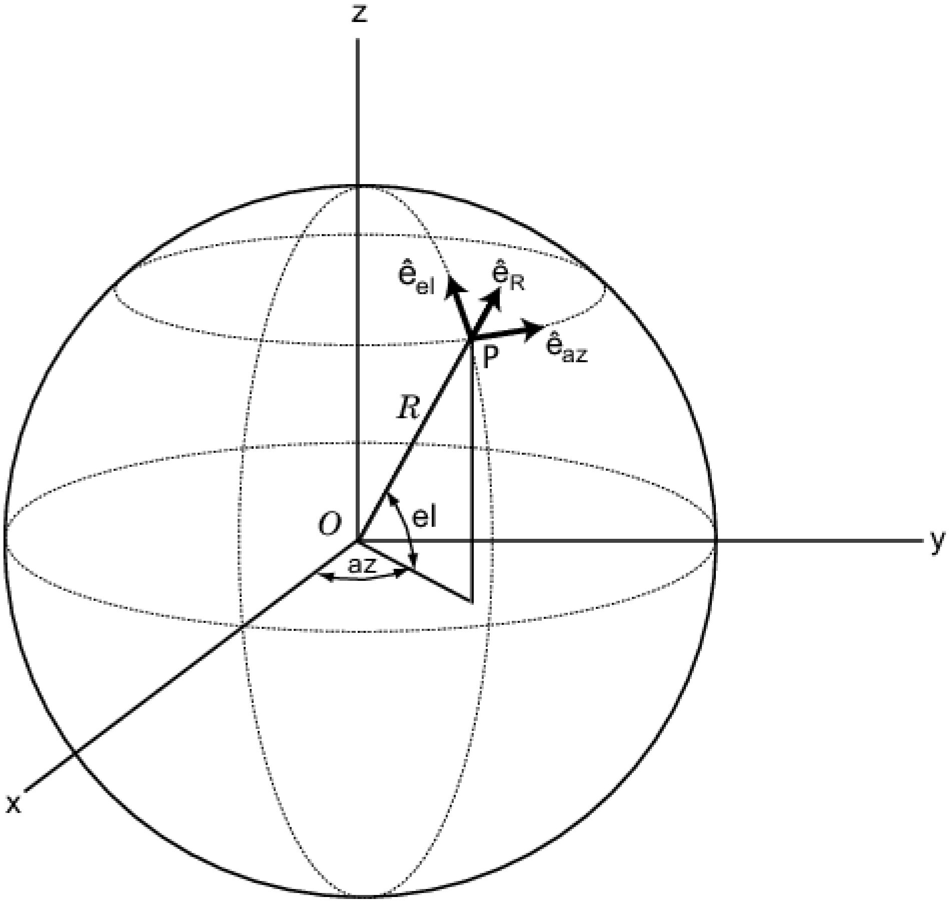
More About

Spherical basis representation of vectors

Spherical basis vectors are a local set of basis vectors which point along the radial and angular directions at any point in space.

The spherical basis is a set of three mutually orthogonal unit vectors ($\hat{\mathbf{e}}_{az}$, $\hat{\mathbf{e}}_{el}$, $\hat{\mathbf{e}}_{R}$) defined at a point on the sphere. The first unit vector points along lines of azimuth at constant radius and elevation. The second points along the lines of elevation at constant azimuth and radius. Both are tangent to the surface of the sphere. The third unit vector points radially outward.

The orientation of the basis changes from point to point on the sphere but is independent of *R* so as you move out along the radius, the basis orientation stays the same. The following figure illustrates the orientation of the spherical basis vectors as a function of azimuth and elevation:



For any point on the sphere specified by *az* and *el*, the basis vectors are given by:

$$\begin{aligned}
\widehat{\mathbf{e}}_{\mathbf{az}} &= -\sin(az)\widehat{\mathbf{i}} + \cos(az)\widehat{\mathbf{j}} \\
\widehat{\mathbf{e}}_{\mathbf{el}} &= -\sin(el)\cos(az)\widehat{\mathbf{i}} - \sin(el)\sin(az)\widehat{\mathbf{j}} + \cos(el)\widehat{\mathbf{k}} \\
\widehat{\mathbf{e}}_{\mathbf{R}} &= \cos(el)\cos(az)\widehat{\mathbf{i}} + \cos(el)\sin(az)\widehat{\mathbf{j}} + \sin(el)\widehat{\mathbf{k}} \quad .
\end{aligned}$$

Any vector can be written in terms of components in this basis as $\mathbf{v} = v_{az}\widehat{\mathbf{e}}_{\mathbf{az}} + v_{el}\widehat{\mathbf{e}}_{\mathbf{el}} + v_R\widehat{\mathbf{e}}_{\mathbf{R}}$. The transformations between spherical basis components and Cartesian components take the form

$$\begin{bmatrix} v_x \\ v_y \\ v_z \end{bmatrix} = \begin{bmatrix} -\sin(az) & -\sin(el)\cos(az) & \cos(el)\cos(az) \\ \cos(az) & -\sin(el)\sin(az) & \cos(el)\sin(az) \\ 0 & \cos(el) & \sin(el) \end{bmatrix} \begin{bmatrix} v_{az} \\ v_{el} \\ v_R \end{bmatrix}$$

.

and

$$\begin{bmatrix} v_{az} \\ v_{el} \\ v_R \end{bmatrix} = \begin{bmatrix} -\sin(az) & \cos(az) & 0 \\ -\sin(el)\cos(az) & -\sin(el)\sin(az) & \cos(el) \\ \cos(el)\cos(az) & \cos(el)\sin(az) & \sin(el) \end{bmatrix} \begin{bmatrix} v_x \\ v_y \\ v_z \end{bmatrix}.$$

cranerainpl

RF signal attenuation due to rainfall using Crane model

Syntax

```
L = cranerainpl(range,freq,rainrate)
L = cranerainpl(range,freq,rainrate,elev)
L = cranerainpl(range,freq,rainrate,elev,tau)
```

Description

`L = cranerainpl(range,freq,rainrate)` returns the signal attenuation, `L`, due to rain based on the Crane rain model [1]. Signal attenuation is a function of the signal path length, `range`, the signal frequency, `freq`, and the rain rate, `rainrate`. The rain rate is defined as the long-term statistical rain rate. The attenuation model applies only for frequencies from 1 GHz to 1000 GHz and is valid for ranges up to 22.5 km. The Crane model accounts for the cellular nature of rainstorms.

`L = cranerainpl(range,freq,rainrate,elev)` also specifies the elevation angle, `elev`, of the signal path.

`L = cranerainpl(range,freq,rainrate,elev,tau)` also specifies the polarization tilt angle, `tau`, of the signal.

Examples

Compare Attenuation for Two Rain Rates Using Crane Model

Use the Crane rain model to compute the signal attenuation caused by rain for a 20 GHz signal sent over a distance of 10 km. Use rain rates of 10.0 and 100.0 mm/hr.

First, set the rain rate to 10 mm/hr.

```
rr = 10.0;
L = cranerainpl(10e3,20.0e9,rr)
```

```
L = 12.5988
```

Repeat the computation using a rain rate of 100.0 mm/hr.

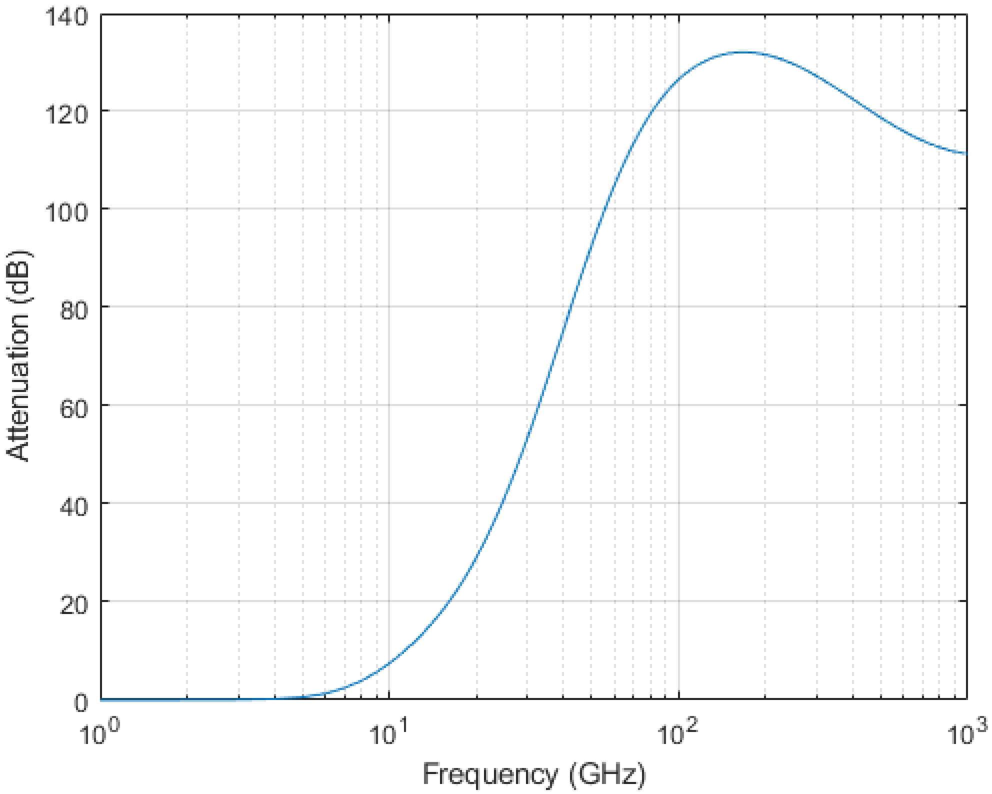
```
rr = 100.0;
L = cranerainpl(10e3,20.0e9,rr)
```

```
L = 73.1912
```

Rain Attenuation as a Function of Frequency Using Crane Model

Plot the signal attenuation due to rain for signals in the frequency range from 1 to 1000 GHz. Use the Crane model to compute the attenuation for a rain rate of 30.0 mm/hr and a signal path distance of 10 km.

```
rr = 30.0;
freq = [1:1000]*1e9;
L = cranerainpl(10e3,freq,rr);
semilogx(freq/1e9,L)
grid
xlabel('Frequency (GHz)')
ylabel('Attenuation (dB)')
```



Rain Attenuation as a Function of Elevation Using Crane Model

Plot the signal attenuation due to rain as a function of elevation angle. Elevation angles vary from 0 to 90 degrees. Assume a path distance of 10 km and a signal frequency of 10 GHz. The rain rate is 100 mm/hr.

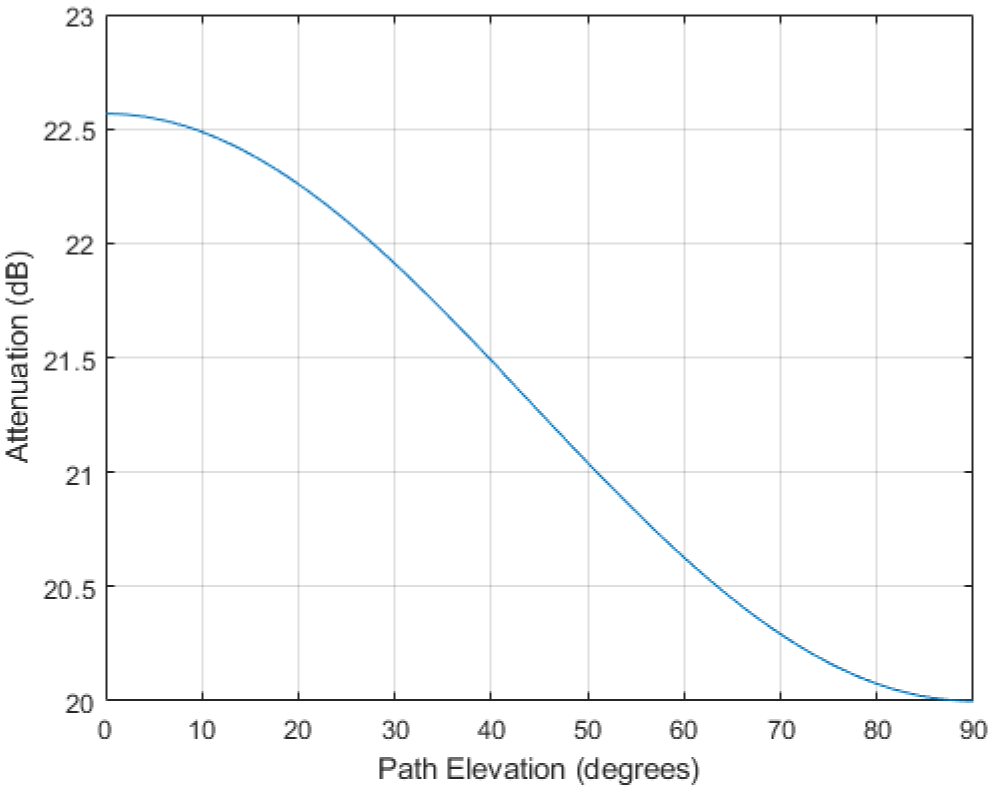
```
rr = 100.0;
```

Set the elevation angles, frequency, and path length.

```
elev = [0:1:90];
freq = 10.0e9;
rng = 10e3*ones(size(elev));
```

Compute and plot the loss.

```
L = cranerainpl(rng,freq,rr,elev);
plot(elev,L)
grid
xlabel('Path Elevation (degrees)')
ylabel('Attenuation (dB)')
```



Rain Attenuation as a Function of Polarization Using Crane Model

Plot the signal attenuation due to rainfall as a function of the polarization tilt angle. Assume a path distance of 10 km, a signal frequency of 10 GHz, and a path elevation angle of 0 degrees. Set the rainfall rate to 70 mm/hour. Plot the signal attenuation against polarization tilt angle.

Set the polarization tilt angle to vary from -90 to 90 degrees.

```
tau = -90:90;
```

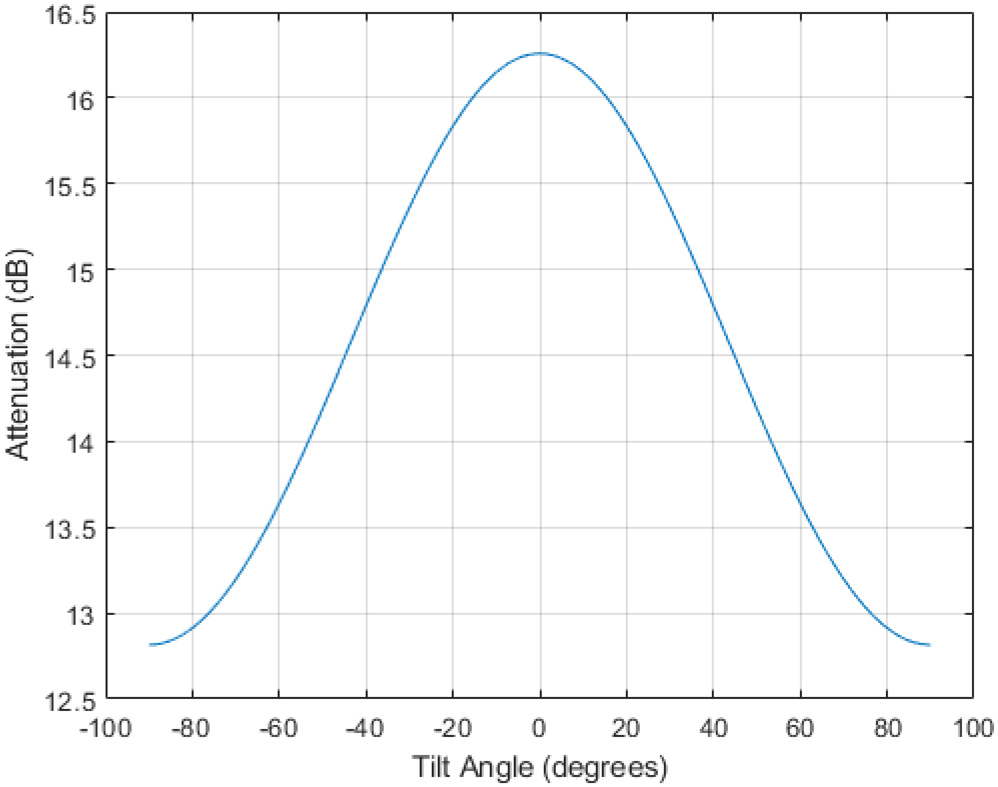
Set the elevation angle, frequency, path distance, and rain rate.

```
elev = 0;
freq = 10.0e9;
```

```
rng = 10e3*ones(size(tau));
rr = 70.0;
```

Compute and plot the attenuation.

```
L = cranerainpl(rng,freq,rr,elev,tau);
plot(tau,L)
grid
xlabel('Tilt Angle (degrees)')
ylabel('Attenuation (dB)')
```



Input Arguments

range — Signal path length

positive scalar | real-valued 1-by-*M* vector of positive values | real-valued *M*-by-1 vector of positive values

Signal path length, specified as a positive scalar, a real-valued 1-by-*M* vector of positive values, or real-valued *M*-by-1 vector of positive values. Units are in meters.

Example: `[13000.0,14000.0]`

freq — Signal frequency

positive scalar | real-valued 1-by-*N* vector of positive values | real-valued *N*-by-1 vector of positive values

Signal frequency, specified as a positive scalar, a real-valued 1-by-*N* vector of positive values, or a real-valued *N*-by-1 vector of positive values. Units are in Hz. Frequencies must lie in the range 1–1000 GHz.

Example: `[2.0:2:10.0]*1e9]`

`rainrate` — Rain rate

nonnegative scalar

Rain rate, specified as a nonnegative scalar. Rain rate represents the long-term statistical rainfall rate provided by Crane (see [1]). Units are in mm/hr.

Example: `100.5`

`elev` — Signal path elevation angle

0.0 (default) | scalar | real-valued 1-by-*M* vector | real-valued *M*-by-1 vector

Signal path elevation angle, specified as a real-valued scalar, or real-valued *M*-by-1 or real-valued 1-by-*M* vector. Units are in degrees between –90° and 90°.

- If `elev` is a scalar, all propagation paths have the same elevation angle.
- If `elev` is a vector, its length must match the length of `range` and each element in `elev` corresponds to a propagation range.

Example: `[0,45]`

`tau` — Tilt angle of signal polarization ellipse

0.0 (default) | scalar | real-valued 1-by-*M* vector | real-valued *M*-by-1 vector

Tilt angle of the signal polarization ellipse, specified as a scalar, a real-valued 1-by-*M* vector, or a real-valued *M*-by-1 vector. Tilt angle values are in the range –90° and 90°, inclusive. Units are in degrees.

- If `tau` is a scalar, all signals have the same tilt angle.
- If `tau` is a vector, its length must match the length of `range`. In that case, each element in `tau` corresponds to a propagation path in `range`.

The tilt angle is defined as the angle between the semimajor axis of the polarization ellipse and the *x*-axis. Because the ellipse is symmetrical, a tilt angle of 10° corresponds to the same polarization state as a tilt angle of -80°. Thus, the tilt angle need only be specified between ±90°.

Example: `[45,30]`

Output Arguments

`L` — Signal attenuation

real-valued *M*-by-*N* matrix

Signal attenuation, returned as a real-valued *M*-by-*N* matrix. Each matrix row represents a different path where *M* is the number of paths. Each column represents a different frequency where *N* is the number of frequencies. Units are in dB.

More About

Crane Rainfall Attenuation Model

The Crane model calculates the attenuation of signals that propagate through regions of rainfall. The model was developed for use on Earth–space or terrestrial propagation paths and is a commonly-used method for the calculation of rain attenuation. The model is based on observations of rain rate, rain structure, and the vertical variation of temperature in the atmosphere. The Crane model (see *Electromagnetic Wave Propagation through Rain*) is primarily applicable to North America. The Crane model generally predicts losses greater than those of the ITU rain attenuation model used in the `rainpl` function. However, the uncertainty of both models and the short-term variation of fade can be large.

The ITU and Crane models are very similar but have some differences. The ITU and Crane rain attenuation models both require statistical annual rainfall rates and utilize an effective path length reduction factor to account for the cellular nature of storms. The 0.01% rainfall rate tables provided by Crane and the ITU are different. The Crane rainfall zones are similar to the ITU zones but more zones are defined in the US than in the ITU model. The ITU rainfall zones are discussed in *ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*. The Crane model is more complex consisting of a piecewise combination of path profiles composed of exponential functions.

The Crane model utilizes two exponential functions to span the distance from 0 to 22.5 km.

- For $\delta < D < 22.5$,

  $$L = \gamma\left(\frac{e^{y\delta} - 1}{y} - \frac{b^{\alpha}e^{z\delta}}{z} + \frac{b^{\alpha}e^{zD}}{z}\right)$$

- For $0 < D < \delta$,

  $$L = \gamma\left(\frac{e^{yD} - 1}{y}\right)$$

where

- L = path attenuation (dB)
- □□= propagation distance (km)
- R = statistical 0.01% rain rate (mm/hr)
- γ = specific attenuation identical to that calculated in `rainpl`.

  $$\gamma_R = kR^{\alpha},$$

  The parameters k and α depend on the frequency, the polarization state, and the elevation angle of the signal path. These coefficients, given by both Crane *Electromagnetic Wave Propagation through Rain* and the *ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*, are identical and are valid from 1 GHz to 1000 GHz. The specific attenuation model is valid for frequencies from 1–1000 GHz. Rainfall specific attenuation is computed according to the ITU rainfall model in *ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*.

The remaining parameters are empirical constants defined as:

- $b = 2.3R^{-0.17}$

- c = 0.026 - 0.03ln R
- δ = 3.8 - 0.6 ln R
- u = ln $(be^{c\delta})/\delta$
- $y = \alpha u$
- $z = \alpha c$

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the propagation distance.

You can also apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

Introduced in R2020a

fogpl

RF signal attenuation due to fog and clouds

Syntax

```
L = fogpl(R,freq,T,den)
```

Description

`L = fogpl(R,freq,T,den)` returns attenuation, `L`, when signals propagate in fog or clouds. `R` represents the signal path length. `freq` represents the signal carrier frequency, `T` is the ambient temperature, and `den` specifies the liquid water density in the fog or cloud.

The `fogpl` function applies the International Telecommunication Union (ITU) cloud and fog attenuation model to calculate path loss of signals propagating through clouds and fog. See [1] (Phased Array System Toolbox). Fog and clouds are the same atmospheric phenomenon, differing only by height above ground. Both environments are parametrized by their liquid water density. Other model parameters include signal frequency and temperature. This function applies to cases when the signal path is contained entirely in a uniform fog or cloud environment. The liquid water density does not vary along the signal path. The attenuation model applies only for frequencies at 10–1000 GHz.

Examples

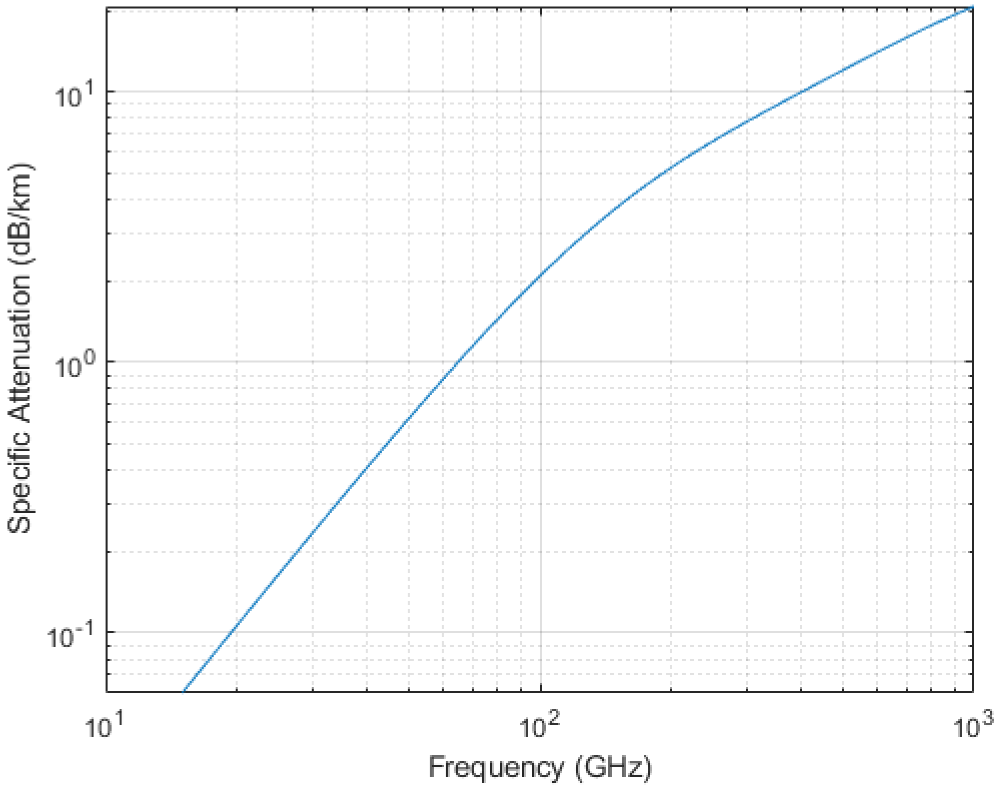
Attenuation in Cumulus Clouds

Compute the attenuation of signals propagating through a cloud that is 1 km long at 1000 meters altitude. Compute the attenuation for frequencies from 15 to 1000 GHz. A typical value for the cloud liquid water density is 0.5 g/m^3. Assume the atmospheric temperature at 1000 meters is 20˚C.

```
R = 1000.0;
freq = [15:5:1000]*1e9;
T = 20.0;
lwd = 0.5;
L = fogpl(R,freq,T,lwd);
```

Plot the specific attenuation as a function of frequency. Specific attenuation is the attenuation or loss per kilometer.

```
loglog(freq/1e9,L)
grid
xlabel('Frequency (GHz)')
ylabel('Specific Attenuation (dB/km)')
```



Input Arguments

R — Signal path length

positive real-valued scalar | *M*-by-1 nonnegative real-valued vector | 1-by-*M* nonnegative real-valued vector

Signal path length, specified as a scalar or as an *M*-by-1 or 1-by-*M* vector of nonnegative real-values. Total attenuation is the specific attenuation multiplied by the path length. Units are meters.

Example: `[1300.0,1400.0]`

`freq` — Signal frequency

positive real-valued scalar | *N*-by-1 nonnegative real-valued column vector | 1-by-*N* nonnegative real-valued row vector

Signal frequency, specified as a positive real-valued scalar or as an *N*-by-1 nonnegative real-valued vector or 1-by-*N* nonnegative real-valued vector. Frequencies must lie in the range 10–1000 GHz.

Example: `[14.0e9,15.0e9]`

T — Ambient temperature

real-valued scalar

Ambient temperature in fog or cloud, specified as a real-valued scalar. Units are in degrees Celsius.

Example: `-10.0`

den — Liquid water density
nonnegative real-valued scalar

Liquid water density, specified as a nonnegative real-valued scalar. Units are g/m^3. Typical values for liquid water density in fog range from approximately 0.05 g/m^3 for medium fog to approximately 0.5 g/m^3 for thick fog. For medium fog, visibility is about 300 meters. For heavy fog, visibility is about 50 meters. Cumulus cloud liquid water density is typically 0.5 g/m^3.

Example: `0.01`

Output Arguments

L — Signal attenuation
real-valued *M*-by-*N* matrix

Signal attenuation, returned as a real-valued *M*-by-*N* matrix. Each matrix row represents a different path where *M* is the number of paths. Each column represents a different frequency where *N* is the number of frequencies. Units are in dB.

More About

Fog and Cloud Attenuation Model

This model calculates the attenuation of signals that propagate through fog or clouds.

Fog and cloud attenuation are the same atmospheric phenomenon. The ITU model, *Recommendation ITU-R P.840-6: Attenuation due to clouds and fog* is used. The model computes the specific attenuation (attenuation per kilometer), of a signal as a function of liquid water density, signal frequency, and temperature. The model applies to polarized and nonpolarized fields. The formula for specific attenuation at each frequency is

$$\gamma_c = K_l(f)M,$$

where *M* is the liquid water density in gm/m^3. The quantity $K_l(f)$ is the specific attenuation coefficient and depends on frequency. The cloud and fog attenuation model is valid for frequencies 10–1000 GHz. Units for the specific attenuation coefficient are (dB/km)/(g/m^3).

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length *R*. Total attenuation is $L_c = R\gamma_c$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply narrowband attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

`fspl` | `gaspl` | `rainpl`

Introduced in R2017b

fspl

Free space path loss

Syntax

```
L = fspl(R,lambda)
```

Description

`L = fspl(R,lambda)` returns the free space path loss in decibels for a waveform with wavelength `lambda` propagated over a distance of `R` meters. The minimum value of `L` is zero, indicating no path loss.

Examples

Calculate Free-Space Path Loss

Calculate the free-space path loss (in dB) of a 10 GHz radar signal over a distance of 10 km.

```
fc = 10.0e9;
lambda = physconst('LightSpeed')/fc;
R = 10e3;
L = fspl(R,lambda)
```

```
L = 132.4478
```

Input Arguments

R — Propagation distance of signal
real-valued 1-by-*M* or *M*-by-1 vector

Units are in meters.

lambda — Speed of propagation divided by the signal frequency
real-valued 1-by-*N* or *N*-by-1 vector

Wavelength units are meters.

Output Arguments

L — Path loss in decibels
M-by-*N* non-negative matrix. A value of zero signifies no path loss.

When `lambda` is a scalar, `L` has the same dimensions as `R`.

More About

Free Space Path Loss

The free-space path loss, *L*, in decibels is:

$$L = 20\log_{10}(\frac{4\pi R}{\lambda})$$

This formula assumes that the target is in the far-field of the transmitting element or array. In the near-field, the free-space path loss formula is not valid and can result in a loss smaller than 0 dB, equivalent to a signal gain. For this reason, the loss is set to 0 dB for range values $R \le \lambda/4\pi$.

gaspl

RF signal attenuation due to atmospheric gases

Syntax

```
L = gaspl(range,freq,T,P,den)
```

Description

`L = gaspl(range,freq,T,P,den)` returns the attenuation, `L`, when signals propagate through the atmosphere. `range` represents the signal path length, and `freq` represents the signal carrier frequency. `T` represents the ambient temperature, `P` represents the atmospheric pressure, and `den` represents the atmospheric water vapor density.

The `gaspl` function applies the International Telecommunication Union (ITU) atmospheric gas attenuation model [1] to calculate path loss for signals primarily due to oxygen and water vapor. The model computes attenuation as a function of ambient temperature, pressure, water vapor density, and signal frequency. The function requires that the signal path is contained entirely in a uniform environment. Atmospheric parameters do not vary along the signal path. The attenuation model applies only for frequencies at 1–1000 GHz.

Examples

Atmospheric Gas Attenuation Spectrum

Compute the attenuation spectrum from 1 to 1000 GHz for an atmospheric pressure of 101.300 kPa and a temperature of 15˚C. Plot the spectrum for a water vapor density of 7.5 g/m^3 and then plot the spectrum for dry air (zero water vapor density).

Set the attenuation frequencies.

```
freq = [1:1000]*1e9;
```

Assume a 1 km path distance.

```
R = 1000.0;
```

Compute the attenuation for air containing water vapor.

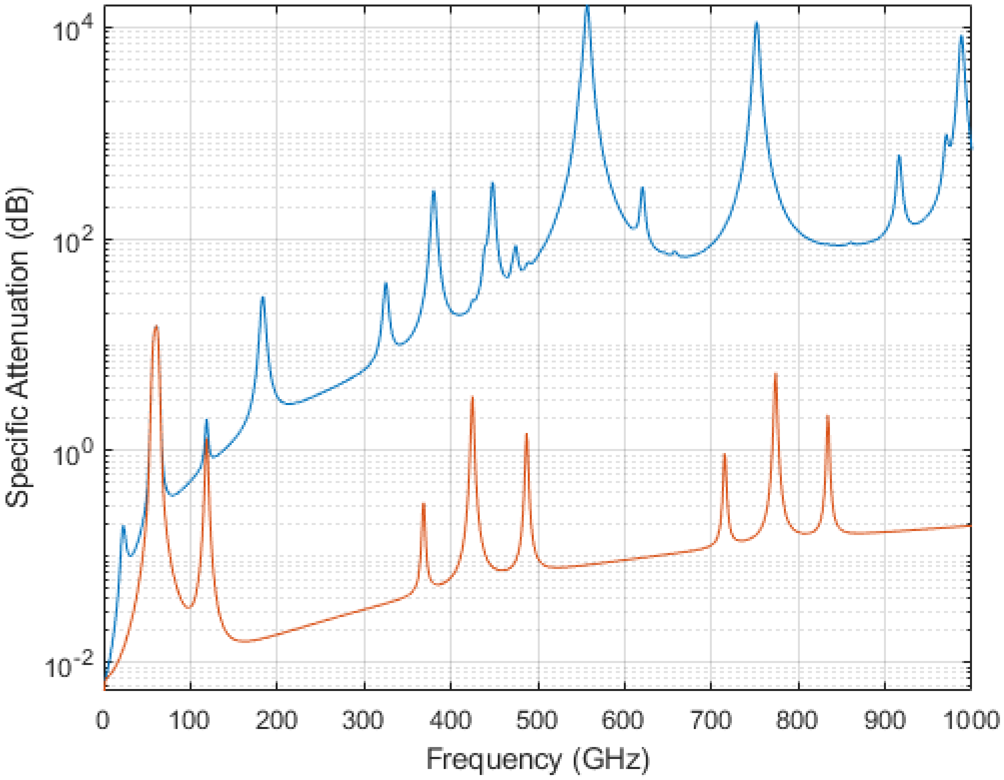
```
T = 15;
P = 101300.0;
W = 7.5;
L = gaspl(R,freq,T,P,W);
```

Compute the attenuation for dry air.

```
L0 = gaspl(R,freq,T,P,0.0);
```

Plot the attenuations.

```
semilogy(freq/1e9,L)
hold on
semilogy(freq/1e9,L0)
grid
xlabel('Frequency (GHz)')
ylabel('Specific Attenuation (dB)')
hold off
```



Plot Attenuation Due to Atmospheric Gases and Free Space

First, plot the specific attenuation of atmospheric gases for frequencies from 1 GHz to 1000 GHz. Assume a sea-level dry air pressure of 101.325e5 kPa and a water vapor density of 7.5 g/m^3. The air temperature is 20˚C. Specific attenuation is defined as dB loss per kilometer. Then, plot the actual attenuation at 10 GHz for a span of ranges.

Plot Specific Atmospheric Gas Attenuation

Set the atmosphere temperature, pressure, water vapor density.

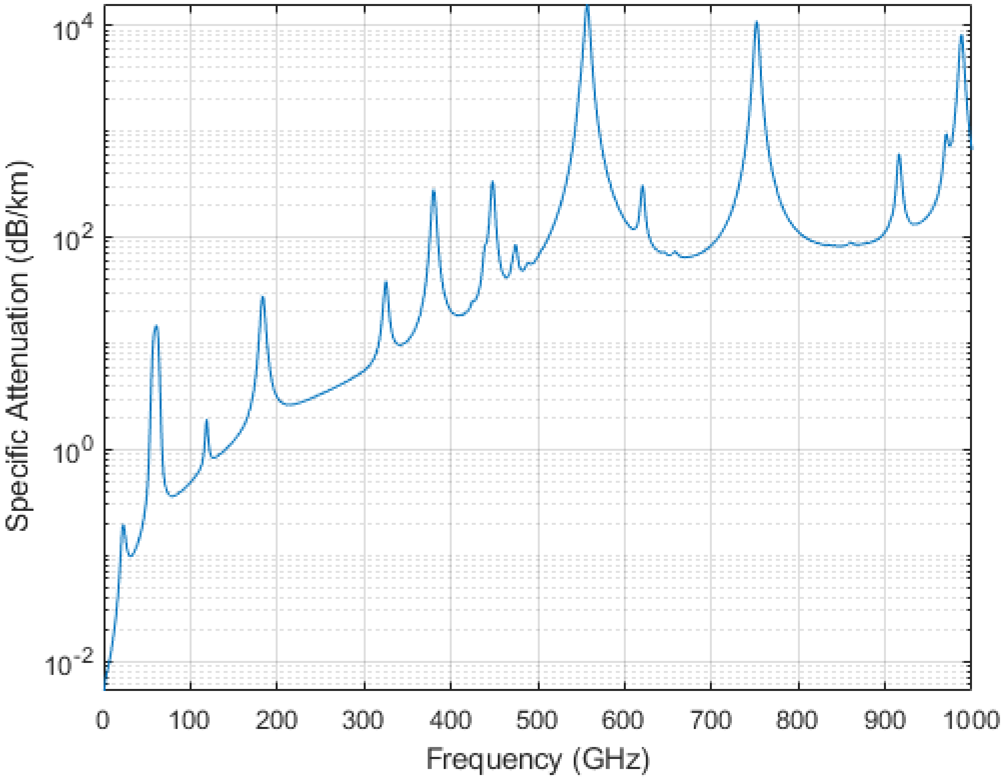
```
T = 20.0;
Patm = 101.325e3;
rho_wv = 7.5;
```

Set the propagation distance, speed of light, and frequencies.

```
km = 1000.0;
c = physconst('LightSpeed');
freqs = [1:1000]*1e9;
```

Compute and plot the atmospheric gas loss.

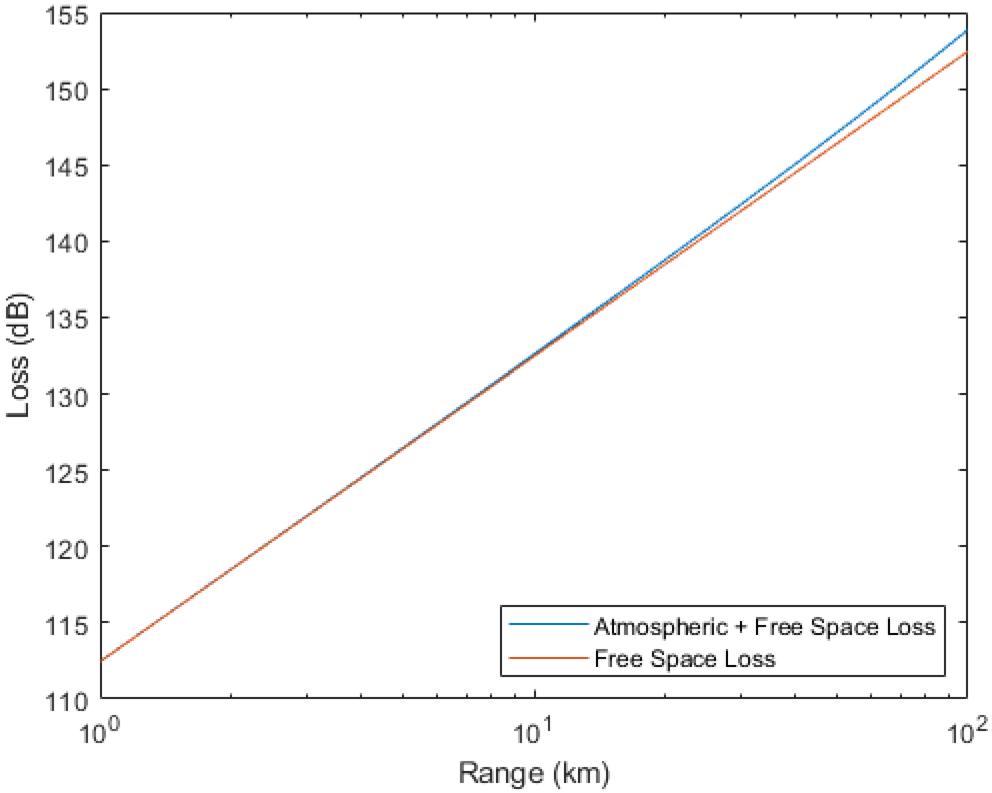
```
loss = gaspl(km,freqs,T,Patm,rho_wv);
semilogy(freqs/1e9,loss)
grid on
xlabel('Frequency (GHz)')
ylabel('Specific Attenuation (dB/km)')
```



Plot Actual Atmospheric and Free Space Attenuation

Compute both free space loss and atmospheric gas loss at 10 GHz for ranges from 1 to 100 km. The frequency corresponds to an *X*-band radar. Then, plot the free space loss and the total (atmospheric + free space) loss.

```
ranges = [1:100]*1000;
freq_xband = 10e9;
loss_gas = gaspl(ranges,freq_xband,T,Patm,rho_wv);
lambda = c/freq_xband;
loss_fsp = fspl(ranges,lambda);
semilogx(ranges/1000,loss_gas + loss_fsp.',ranges/1000,loss_fsp)
legend('Atmospheric + Free Space Loss','Free Space Loss','Location','SouthEast')
xlabel('Range (km)')
ylabel('Loss (dB)')
```



Input Arguments

`range` — Signal path length

nonnegative real-valued scalar | *M*-by-1 nonnegative real-valued column vector | 1-by-*M* nonnegative real-valued row vector

Signal path length used to compute attenuation, specified as a nonnegative real-valued scalar or vector. You can specify multiple path lengths simultaneously. Units are in meters.

Example: `[13000.0,14000.0]`

`freq` — Signal frequency

positive real-valued scalar | *N*-by-1 nonnegative real-valued column vector | 1-by-*N* nonnegative real-valued row vector

Signal frequency, specified as a positive real-valued scalar, or as an *N*-by-1 nonnegative real-valued vector or 1-by-*N* nonnegative real-valued vector. You can specify multiple frequencies simultaneously. Frequencies must lie in the range 1–1000 GHz. Units are in hertz.

Example: `[1.4e9,2.0e9]`

`T` — Ambient temperature

real-valued scalar

Ambient temperature, specified as a real-valued scalar. Units are in degrees Celsius.

Example: `-10.0`

P — Dry air pressure
positive real-valued scalar

Dry air pressure, specified as a positive real-valued scalar. Units are in Pa. One standard atmosphere at sea level is 101325 Pa.

Example: `101300.0`

den — Water vapor density
nonnegative real-valued scalar

Water vapor density or absolute humidity, specified as a nonnegative real-valued scalar. Units are g/m^3. The maximum water vapor density of air at 30° C is approximately 30.0 g/m^3. The maximum water vapor density of air at 0°C is approximately 5.0 g/m^3.

Example: `4.0`

Output Arguments

L — Signal attenuation
real-valued *M*-by-*N* matrix

Signal attenuation, returned as a real-valued *M*-by-*N* matrix. Each matrix row represents a different path where *M* is the number of paths. Each column represents a different frequency where *N* is the number of frequencies. Units are in dB.

More About

Atmospheric Gas Attenuation Model

This model calculates the attenuation of signals that propagate through atmospheric gases.

Electromagnetic signals attenuate when they propagate through the atmosphere. This effect is due primarily to the absorption resonance lines of oxygen and water vapor, with smaller contributions coming from nitrogen gas. The model also includes a continuous absorption spectrum below 10 GHz. The ITU model *Recommendation ITU-R P.676-10: Attenuation by atmospheric gases* is used. The model computes the specific attenuation (attenuation per kilometer) as a function of temperature, pressure, water vapor density, and signal frequency. The atmospheric gas model is valid for frequencies from 1–1000 GHz and applies to polarized and nonpolarized fields.

The formula for specific attenuation at each frequency is

$$\gamma = \gamma_o(f) + \gamma_w(f) = 0.1820 f N''(f)\,.$$

The quantity *N"()* is the imaginary part of the complex atmospheric refractivity and consists of a spectral line component and a continuous component:

$$N''(f) = \sum_i S_i F_i + N''_D(f)$$

The spectral component consists of a sum of discrete spectrum terms composed of a localized frequency bandwidth function, $F(f)_{\mathrm{i}}$, multiplied by a spectral line strength, S_{i}. For atmospheric oxygen, each spectral line strength is

$$S_i = a_1 \times 10^{-7}\left(\frac{300}{T}\right)^3 \exp\left[a_2(1 - \left(\frac{300}{T}\right)\right]P\,.$$

For atmospheric water vapor, each spectral line strength is

$$S_i = b_1 \times 10^{-1}\left(\frac{300}{T}\right)^{3.5}\exp\left[b_2(1 - \left(\frac{300}{T}\right)\right]W\,.$$

P is the dry air pressure, W is the water vapor partial pressure, and T is the ambient temperature. Pressure units are in hectoPascals (hPa) and temperature is in degrees Kelvin. The water vapor partial pressure, W, is related to the water vapor density, ρ, by

$$W = \frac{\rho T}{216.7}\,.$$

The total atmospheric pressure is $P + W$.

For each oxygen line, S_i depends on two parameters, a_1 and a_2. Similarly, each water vapor line depends on two parameters, b_1 and b_2. The ITU documentation cited at the end of this section contains tabulations of these parameters as functions of frequency.

The localized frequency bandwidth functions $F_i(f)$ are complicated functions of frequency described in the ITU references cited below. The functions depend on empirical model parameters that are also tabulated in the reference.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length, R. Then, the total attenuation is $L_g= R(\gamma_o + \gamma_w)$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

Introduced in R2017b

global2localcoord

Convert global to local coordinates

Syntax

```
lclCoord = global2localcoord(gCoord, OPTION)
gCoord = global2localcoord( ___ ,localOrigin)
gCoord = global2localcoord( ___ ,localAxes)
```

Description

`lclCoord = global2localcoord(gCoord, OPTION)` converts global coordinates `gCoord` to local coordinates `lclCoord`. `OPTION` determines the type of global-to-local coordinate transformation. In this syntax, the global coordinate origin is located at (0,0,0) and the coordinate axes are the unit vectors in the *x*, *y*, and *z* directions.

`gCoord = global2localcoord( ___ ,localOrigin)` specifies the origin of the local coordinate system, `localOrigin`.

`gCoord = global2localcoord( ___ ,localAxes)` specifies the axes of the local coordinate system, `localAxes`.

Input Arguments

gCoord

Global coordinates in rectangular or spherical coordinate, specified as a 3-by-*N* matrix. Each column represents one set of global coordinates.

If the coordinates are in rectangular form, each column contains the (*x*,*y*,*z*) components. Units are in meters.

If the coordinates are in spherical form, each column contains (*az*,*el*,*r*) components. *az* is the azimuth angle on page 2-1018 in degrees, *el* is the elevation angle on page 2-1018 in degrees, and *r* is the radius in meters.

The origin of the global coordinate system is assumed to be located at (0, 0, 0). The global system axes are the standard unit basis vectors in three-dimensional space, (1, 0, 0), (0, 1, 0), and (0, 0, 1).

OPTION

Type of coordinate transformation, specified as a character vector. Valid types are

OPTION	Transformation
`'rr'`	Global rectangular to local rectangular
`'rs'`	Global rectangular to local spherical
`'sr'`	Global spherical to local rectangular

OPTION	Transformation
'ss'	Global spherical to local spherical

localOrigin

Origin of local coordinate system, specified as a 3-by-*N* matrix containing the rectangular coordinates of the local coordinate system origin with respect to the global coordinate system. *N* must match the number of columns of `gCoord`. Each column represents a separate origin. However, you can specify `localOrigin` as a 3-by-*1* vector. In this case, `localOrigin` is expanded into a 3-by-*N* matrix with identical columns.

Default: `[0;0;0]`

localAxes

Axes of local coordinate system, specified as a 3-by-3-by-*N* array. Each page contains a 3-by-3 matrix representing a different local coordinate system axes. The columns of the 3-by-3 matrices specify the local *x*, *y*, and *z* axes in rectangular form with respect to the global coordinate system. However, you can specify `localAxes` as a single 3-by-3 matrix. In this case, `localAxes` is expanded into a 3-by-3-by-*N* array with identical 3-by-3 matrices. The default is the identity matrix.

Default: `[1 0 0;0 1 0;0 0 1]`

Output Arguments

lclCoord

Local coordinates in rectangular or spherical coordinate form, returned as a 3-by-*N* matrix. The dimensions of `lclCoord` match the dimensions of `gCoord`.

Examples

Convert Global Coordinates to Local Coordinates

Convert global rectangular coordinates, *(0,1,0)*, to local rectangular coordinates. The local coordinate origin is *(1,1,1)*.

```
lclCoord = global2localcoord([0;1;0],'rr',[1;1;1])
```

```
lclCoord = 3×1

    -1
     0
    -1
```

Convert global spherical coordinates to local rectangular coordinates.

```
lclCoord = global2localcoord([45;45;50],'sr',[50;50;50])
```

```
lclCoord = 3×1

  -25.0000
  -25.0000
  -14.6447
```

More About

Azimuth and Elevation Angles

The azimuth angle of a vector is the angle between the *x*-axis and the orthogonal projection of the vector onto the *xy* plane. The angle is positive in going from the *x* axis toward the *y* axis. Azimuth angles lie between –180 and 180 degrees. The elevation angle is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy* plane. By default, the boresight direction of an element or array is aligned with the positive *x*-axis. The boresight direction is the direction of the main lobe of an element or array.

Note The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive *z*-axis. The MATLAB and Communications Toolbox products do not use this definition.

This figure illustrates the azimuth and elevation angles of a direction vector.

Introduced in R2020a

local2globalcoord

Convert local to global coordinates

Syntax

```
gCoord = local2globalcoord(lclCoord,OPTION)
gCoord = local2globalcoord( ___ ,localOrigin)
gCoord = local2globalcoord( ___ ,localAxes)
```

Description

`gCoord = local2globalcoord(lclCoord,OPTION)` converts local coordinates `lclCoord` to global coordinates `gCoord`. `OPTION` determines the type of local-to-global coordinate transformation.

`gCoord = local2globalcoord( ___ ,localOrigin)` specifies the origin of the local coordinate system, `localOrigin`.

`gCoord = local2globalcoord( ___ ,localAxes)` specifies the axes of the local coordinate system, `localAxes`.

Input Arguments

`lclCoord`

Local coordinates in rectangular or spherical coordinate form, specified as a 3-by-*N* matrix. Each column represents one set of local coordinates.

If the coordinates are in rectangular form, each column contains the (*x*,*y*,*z*) components. Units are in meters.

If the coordinates are in spherical form, each column contains (*az*,*el*,*r*) components. *az* is the azimuth angle on page 2-1018 in degrees, *el* is the elevation angle on page 2-1018 in degrees, and *r* is the radius in meters.

`OPTION`

Types of coordinate transformations, specified as a character vector. Valid values are

OPTION	Transformation
`'rr'`	Local rectangular to global rectangular
`'rs'`	Local rectangular to global spherical
`'sr'`	Local spherical to global rectangular
`'ss'`	Local spherical to global spherical

`localOrigin`

Origin of local coordinate system, specified as a 3-by-*N* matrix containing the rectangular coordinates of the local coordinate system origin with respect to the global coordinate system. *N* must match the number of columns of `gCoord`. Each column represents a separate origin. However, you can specify `localOrigin` as a 3-by-*1* vector. In this case, `localOrigin` is expanded into a 3-by-*N* matrix with identical columns.

Default: `[0;0;0]`

`localAxes`

Axes of local coordinate system, specified as a 3-by-3-by-*N* array. Each page contains a 3-by-3 matrix representing a different local coordinate system axes. The columns of the 3-by-3 matrices specify the local *x*, *y*, and *z* axes in rectangular form with respect to the global coordinate system. However, you can specify `localAxes` as a single 3-by-3 matrix. In this case, `localAxes` is expanded into a 3-by-3-by-*N* array with identical 3-by-3 matrices. The default is the identity matrix.

Default: `[1 0 0;0 1 0;0 0 1]`

Output Arguments

`gCoord`

Glabal coordinates in rectangular or spherical coordinate form, returned as a 3-by-*N* matrix. The dimensions of `gCoord` match the dimensions of `lclCoord`. The origin of the global coordinate system is assumed to be located at (0, 0, 0). The global system axes are the standard unit basis vectors in three-dimensional space, (1, 0, 0), (0, 1, 0), and (0, 0, 1).

Examples

Convert Local Rectangular Coordinates to Global Rectangular Coordinates

Convert from local rectangular coordinates to global rectangular coordinates. The local coordinate origin is a *(1,1,1)*

```
globalcoord = local2globalcoord([0;1;0], 'rr',[1;1;1])
```

```
globalcoord = 3×1

     1
     2
     1
```

Convert Local Spherical Coordinates to Global Rectangular Coordinates

Convert local spherical coordinate to global rectangular coordinate.

```
globalcoord = local2globalcoord([30;45;4],'sr')
```

```
globalcoord = 3×1

    2.4495
    1.4142
    2.8284
```

Convert Two Vectors Between Local and Global Coordinates

Convert two vectors in global coordinates into two vectors in global coordinates using the `global2local` function. Then convert them back to local coordinates using the `local2global` function.

Start with two vectors in global coordinates, *(0,1,0)* and *(1,1,1)*. The local coordinate origins are *(1,5,2)* and *(-4,5,7)*.

```
gCoord = [0 1; 1 1; 0 1]
```

```
gCoord = 3×2

     0     1
     1     1
     0     1
```

```
lclOrig = [1 -4; 5 5; 2 7];
```

Construct two rotation matrices using the rotation functions.

```
lclAxes(:,:,1) = rotz(45)*roty(-15);
lclAxes(:,:,2) = roty(45)*rotx(35);
```

Convert the vectors in global coordinates into local coordinates.

```
lclCoord = global2localcoord(gCoord,'rr',lclOrig,lclAxes)
```

```
lclCoord = 3×2

   -3.9327    7.7782
   -2.1213   -3.6822
   -1.0168    1.7151
```

Convert the vectors in local coordinates back into global coordinates.

```
gCoord1 = local2globalcoord(lclCoord,'rr',lclOrig,lclAxes)
```

```
gCoord1 = 3×2

   -0.0000    1.0000

         0    1.0000
```

More About

Azimuth Angle, Elevation Angle

The azimuth angle of a vector is the angle between the *x*-axis and the orthogonal projection of the vector onto the *xy* plane. The angle is positive in going from the *x* axis toward the *y* axis. Azimuth angles lie between –180 and 180 degrees. The elevation angle is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy* plane. By default, the boresight direction of an element or array is aligned with the positive *x*-axis. The boresight direction is the direction of the main lobe of an element or array.

Note The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive *z*-axis. The MATLAB and Communications Toolbox products do not use this definition.

This figure illustrates the azimuth and elevation angles of a direction vector.

rainpl

RF signal attenuation due to rainfall

Syntax

```
L = rainpl(range,freq,rainrate)
L = rainpl(range,freq,rainrate,elev)
L = rainpl(range,freq,rainrate,elev,tau)
L = rainpl(range,freq,rainrate,elev,tau,pct)
```

Description

`L = rainpl(range,freq,rainrate)` returns the signal attenuation, `L`, due to rainfall. In this syntax, attenuation is a function of signal path length, `range`, signal frequency, `freq`, and rain rate, `rainrate`. The path elevation angle and polarization tilt angles are assumed to zero.

The `rainpl` function applies the International Telecommunication Union (ITU) rainfall attenuation model to calculate path loss of signals propagating in a region of rainfall [1]. The function applies when the signal path is contained entirely in a uniform rainfall environment. Rain rate does not vary along the signal path. The attenuation model applies only for frequencies at 1–1000 GHz.

`L = rainpl(range,freq,rainrate,elev)` also specifies the elevation angle, `elev`, of the propagation path.

`L = rainpl(range,freq,rainrate,elev,tau)` also specifies the polarization tilt angle, `tau`, of the signal.

`L = rainpl(range,freq,rainrate,elev,tau,pct)` also specifies the specified percentage of time, `pct`. `pct` is a scalar in the range of 0.001–1, inclusive. The attenuation, `L`, is computed from a power law using the long-term statistical 0.01% rain rate (in mm/h).

Examples

Signal Attenuation Due to Rainfall

Compute the signal attenuation due to rainfall for a 20 GHz signal over a distance of 10 km in light and heavy rain.

Propagate the signal in a light rainfall of 1 mm/hr.

```
rr = 1.0;
L = rainpl(10000,20.0e9,rr)
```

```
L = 1.3009
```

Propagate the signal in a heavy rainfall of 10 mm/hr.

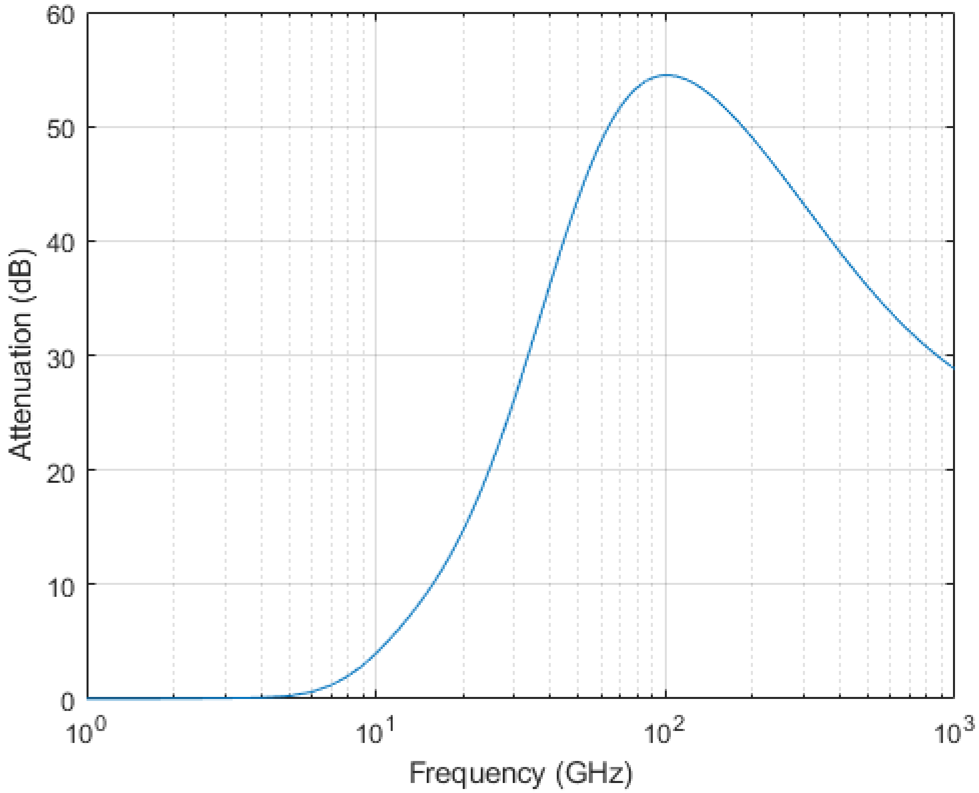
```
rr = 10.0;
L = rainpl(10000,20.0e9,rr)
```

```
L = 8.1584
```

Signal Attenuation Due to Rainfall as Function of Frequency

Plot the signal attenuation due to a 20 mm/hr statistical rainfall for signals in the frequency range from 1 to 1000 GHz. The path distance is 10 km.

```
rr = 20.0;
freq = [1:1000]*1e9;
L = rainpl(10000,freq,rr);
semilogx(freq/1e9,L)
grid
xlabel('Frequency (GHz)')
ylabel('Attenuation (dB)')
```



Signal Attenuation Due to Rainfall as Function of Elevation Angle

Compute the signal attenuation due to heavy rain as a function of elevation angle. Elevation angles vary from 0 to 90 degrees. Assume a path distance of 100 km and a signal frequency of 100 GHz.

Set the rain rate to 10 mm/hr.

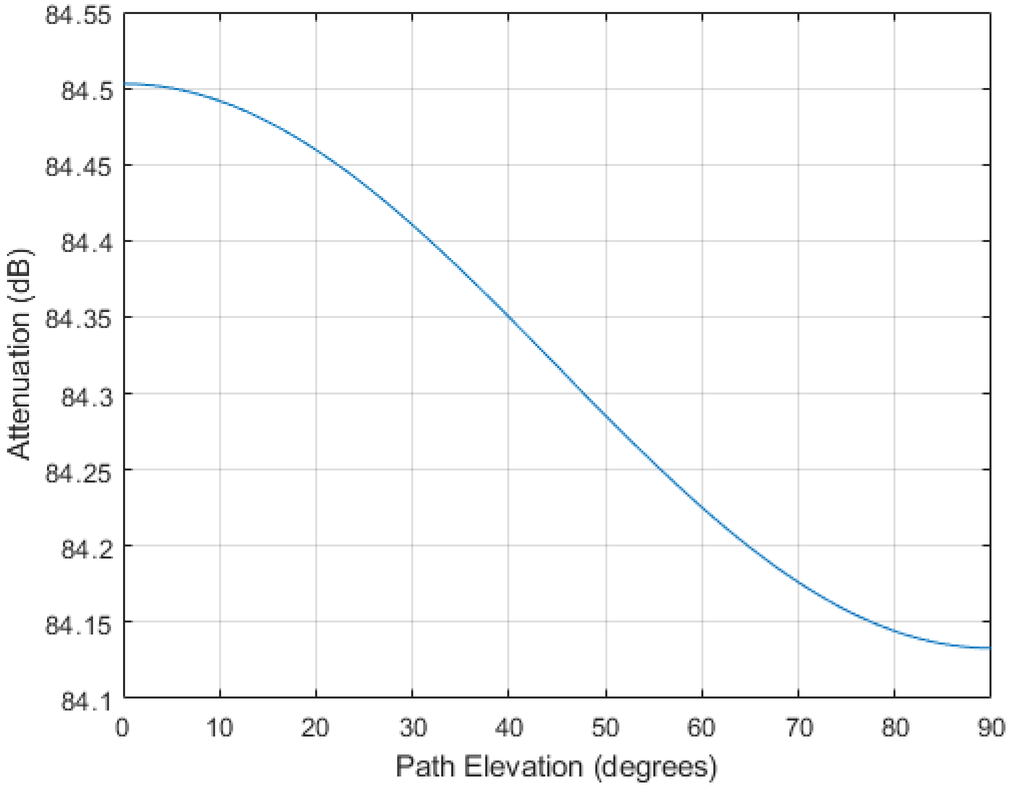
```
rr = 10.0;
```

Set the elevation angles, frequency, range.

```
elev = [0:1:90];
freq = 100.0e9;
rng = 100000.0*ones(size(elev));
```

Compute and plot the loss.

```
L = rainpl(rng,freq,rr,elev);
plot(elev,L)
grid
xlabel('Path Elevation (degrees)')
ylabel('Attenuation (dB)')
```



Signal Attenuation Due to Rainfall as Function of Polarization

Compute the signal attenuation due to heavy rainfall as a function of the polarization tilt angle. Assume a path distance of 100 km, a signal frequency of 100 GHz, and a path elevation angle of 0 degrees. Set the rainfall rate to 10 mm/hour. Plot the signal attenuation versus polarization tilt angle.

Set the polarization tilt angle to vary from -90 to 90 degrees.

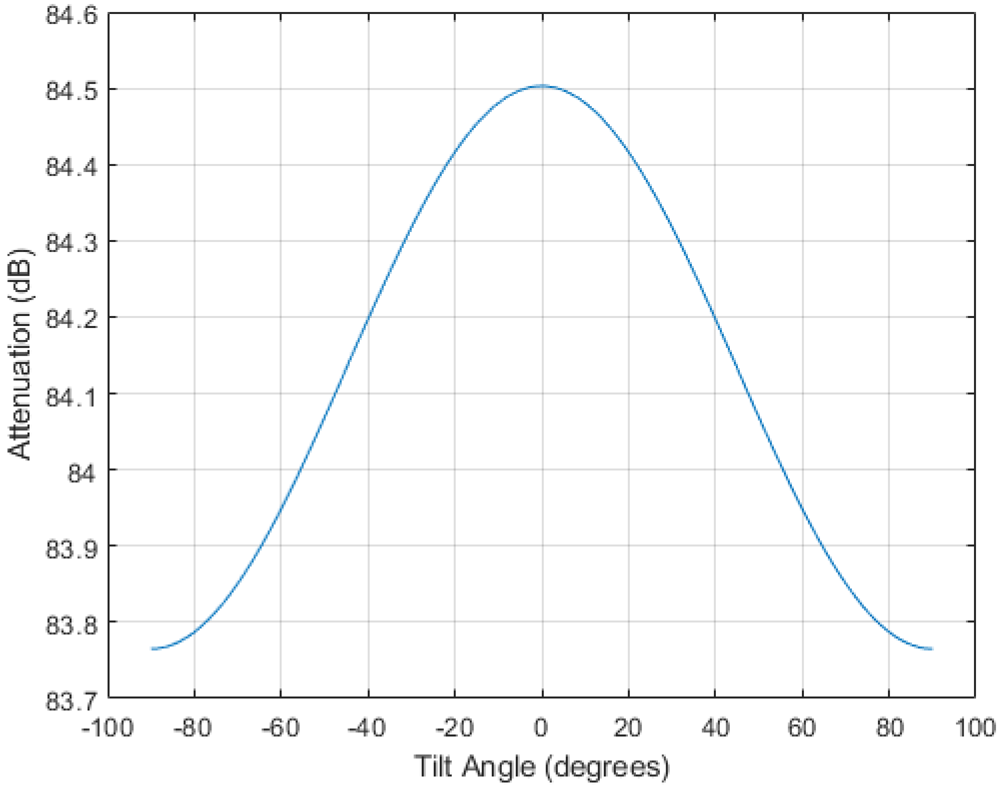
```
tau = -90:90;
```

Set the elevation angle, frequency, path distance, and rain rate.

```
elev = 0;
freq = 100.0e9;
rng = 100e3*ones(size(tau));
rr = 10.0;
```

Compute and plot the attenuation.

```
L = rainpl(rng,freq,rr,elev,tau);
plot(tau,L)
grid
xlabel('Tilt Angle (degrees)')
ylabel('Attenuation (dB)')
```



Input Arguments

range — Signal path length

nonnegative real-valued scalar | nonnegative real-valued *M*-by-1 column vector | nonnegative real-valued 1-by-*M* row vector

Signal path length, specified as a nonnegative real-valued scalar, or as a *M*-by-1 or 1-by-*M* vector. Units are in meters.

Example: `[13000.0,14000.0]`

freq — Signal frequency
positive real-valued scalar | nonnegative real-valued *N*-by-1 column vector | nonnegative real-valued 1-by-*N* row vector

Signal frequency, specified as a positive real-valued scalar, or as a nonnegative *N*-by-1 or 1-by-*N* vector. Frequencies must lie in the range 1–1000 GHz.

Example: `[1400.0e6,2.0e9]`

rainrate — Long-term statistical rain rate
nonnegative real-valued scalar

Long-term statistical rain rate, specified as a nonnegative real-valued scalar. The long-term statistical rain rate is the rain rate that is exceeded 0.01% of the time. You can adjust the percent of time using the `pct` argument. Units are in mm/hr.

Example: `1.5`

elev — Signal path elevation angle
0.0 (default) | real-valued scalar | real-valued *M*-by-1 column vector | real-valued 1-by-*M* row vector

Signal path elevation angle, specified as a real-valued scalar, or as an *M*-by-1 or 1-by- *M* vector. Units are in degrees between –90° and 90°. If `elev` is a scalar, all propagation paths have the same elevation angle. If `elev` is a vector, its length must match the dimension of `range` and each element in `elev` corresponds to a propagation range in `range`.

Example: `[0,45]`

tau — Tilt angle of polarization ellipse
0.0 (default) | real-valued scalar | real-valued *M*-by-1 column vector | real-valued 1-by-*M* row vector

Tilt angle of the signal polarization ellipse, specified as a real-valued scalar, or as an *M*-by-1 or 1-by-*M* vector. Units are in degrees between –90° and 90°. If `tau` is a scalar, all signals have the same tilt angle. If `tau` is a vector, its length must match the dimension of `range`. In that case, each element in `tau` corresponds to a propagation path in `range`.

The tilt angle is defined as the angle between the semi-major axis of the polarization ellipse and the *x*-axis. Because the ellipse is symmetrical, a tilt angle of 100° corresponds to the same polarization state as a tilt angle of -80°. Thus, the tilt angle need only be specified between ±90°.

Example: `[45,30]`

pct — Exceedance percentage of rainfall
`0.01` (default) | positive scalar between 0.001 and 1

Exceedance percentage of rainfall, specified as a positive scalar between 0.001 and 1. The long-term statistical rain rate is the rain rate that is exceeded `pct` of the time. Units are dimensionless.

Data Types: `double`

Output Arguments

L — Signal attenuation
real-valued *M*-by-*N* matrix

Signal attenuation, returned as a real-valued *M*-by-*N* matrix. Each matrix row represents a different path where *M* is the number of paths. Each column represents a different frequency where *N* is the number of frequencies. Units are in dB.

More About

Rainfall Attenuation Model

This model calculates the attenuation of signals that propagate through regions of rainfall. Rain attenuation is a dominant fading mechanism and can vary from location-to-location and from year-to-year.

Electromagnetic signals are attenuated when propagating through a region of rainfall. Rainfall attenuation is computed according to the ITU rainfall model *Recommendation ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*. The model computes the specific attenuation (attenuation per kilometer) of a signal as a function of rainfall rate, signal frequency, polarization, and path elevation angle. The specific attenuation, γ_{R}, is modeled as a power law with respect to rain rate

$$\gamma_R = kR^{\alpha},$$

where *R* is rain rate. Units are in mm/hr. The parameter *k* and exponent *α* depend on the frequency, the polarization state, and the elevation angle of the signal path. The specific attenuation model is valid for frequencies from 1–1000 GHz.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the an effective propagation distance, d_{eff}. Then, the total attenuation is $L = d_{\mathrm{eff}}\gamma_{\mathrm{R}}$.

The effective distance is the geometric distance, *d*, multiplied by a scale factor

$$r = \frac{1}{0.477d^{0.633}R_{0.01}^{0.073\alpha}f^{0.123} - 10.579(1 - \exp(-0.024d))}$$

where *f* is the frequency. The article *Recommendation ITU-R P.530-17 (12/2017): Propagation data and prediction methods required for the design of terrestrial line-of-sight systems* presents a complete discussion for computing attenuation.

The rain rate, *R*, used in these computations is the long-term statistical rain rate, $R_{0.01}$. This is the rain rate that is exceeded 0.01% of the time. The calculation of the statistical rain rate is discussed in *Recommendation ITU-R P.837-7 (06/2017): Characteristics of precipitation for propagation modelling*. This article also explains how to compute the attenuation for other percentages from the 0.01% value.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

rangeangle

Range and angle calculation

Syntax

```
[rng,ang] = rangeangle(pos)
[rng,ang] = rangeangle(pos,refpos)
[rng,ang] = rangeangle(pos,refpos,refaxes)
[rng,ang] = rangeangle( ___ ,model)
```

Description

The function `rangeangle` determines the propagation path length and path direction of a signal from a source point or set of source points to a reference point. The function supports two propagation models – the *free space* model and the *two-ray* model. The *free space* model is a single line-of-sight path from a source point to a reference point. The *two-ray* multipath model generates two paths. The first path follows the free-space path. The second path is a reflected path off a boundary plane at $z = 0$. Path directions are defined with respect to either the global coordinate system at the reference point or a local coordinate system at the reference point. Distances and angles at the reference point do not depend upon which direction the signal is travelling along the path.

`[rng,ang] = rangeangle(pos)` returns the propagation path length, `rng`, and direction angles, `ang`, of a signal path from a source point or set of source points, `pos`, to the origin of the global coordinate system. The direction angles are the azimuth and elevation with respect to the global coordinate axes at the origin. Signals follow a line-of-sight path from the source point to the origin. The line-of-sight path corresponds to the geometric straight line between the points.

`[rng,ang] = rangeangle(pos,refpos)` also specifies a reference point or set of reference points, `refpos`. `rng` now contains the propagation path length from the source points to the reference points. The direction angles are the azimuth and elevation with respect to the global coordinate axes at the reference points. You can specify multiple points and multiple reference points.

`[rng,ang] = rangeangle(pos,refpos,refaxes)` also specifies local coordinate system axes, `refaxes`, at the reference points. Direction angles are the azimuth and elevation with respect to the local coordinate axes centered at `refpos`.

`[rng,ang] = rangeangle( ___ ,model)`, also specifies a propagation model. When `model` is set to `'freespace'`, the signal propagates along a line-of-sight path from source point to reception point. When `model` is set to `'two-ray'`, the signal propagates along two paths from source point to reception point. The first path is the line-of-sight path. The second path is the reflecting path. In this case, the function returns the distances and angles for two paths for each source point and corresponding reference point.

Input Arguments

pos

Source point position, specified as a real-valued 3-by-1 vector or a real-valued 3-by-*N* matrix. A matrix represents multiple source points. The columns contain the Cartesian coordinates of *N* points in the form `[x;y;z]`.

When `pos` is a 3-by-*N* matrix, you must specify `refpos` as a 3-by-*N* matrix for *N* reference positions. If all the reference points are identical, you can specify `refpos` by a single 3-by-1 vector.

Position units are meters.

`refpos`

Reference point position, specified as a real-valued 3-by-1 vector or a real-valued 3-by-*N* matrix. A matrix represents multiple reference points. The columns contain the Cartesian coordinates of *N* points ins the form `[x;y;z]`.

When `refpos` is a 3-by-*N* matrix, you must specify `pos` as a 3-by-*N* matrix for *N* source positions. If all the source points are identical, you can specify `pos` by a single 3-by-1 vector.

Position units are meters.

Default: `[0;0;0]`

`refaxes`

Local coordinate system axes, specified as a real-valued 3-by-3 matrix or a 3-by-3-by-*N* array. For an array, each page corresponds to a local coordinate axes at each reference point. The columns in `refaxes` specify the direction of the coordinate axes for the local coordinate system in Cartesian coordinates. *N* must match the number of columns in `pos` or `refpos` when these dimensions are greater than one.

Default: `[1 0 0;0 1 0;0 0 1]`

`model`

Propagation model, specified as `'freespace'` or `'two-ray'`. Choosing `'freespace'` invokes the free space propagation model. Choosing `'two-ray'` invokes the two-ray propagation model.

Default: `'freespace'`

Output Arguments

`rng`

Propagation range, returned as a real-valued 1-by-*N* vector or real-valued 1-by-*2N* vector.

When `model` is set to `'freespace'`, the size of `rng` is 1-by-*N*. The propagation range is the length of the direct path from the position defined in `pos` to the corresponding reference position defined in `refpos`.

When `model` is set to `'two-ray'`, `rng` contains the ranges for the direct path and the reflected path. Alternate columns of `rng` refer to the line-of-sight path and reflected path, respectively for the same source-reference point pair. Position units are meters.

`ang`

Azimuth and elevation angles, returned as a 2-by-*N* matrix or 2-by-*2N* matrix. Each column represents a direction angle in the form `[azimuth;elevation]`.

When `model` is set to `'freespace'`, `ang` is a 2-by-*N* matrix and represents the angle of the path from a source point to a reference point.

When `model` is set to `'two-ray'`, `ang` is a 2-by-*2N* matrix. Alternate columns of `ang` refer to the line-of-sight path and reflected path, respectively.

Angle units are in degrees.

Examples

Range and Angle Computation

Compute the range and angle of a target located at *(1000,2000,50)* meters from the origin.

```
TargetLoc = [1000;2000;50];
[tgtrng,tgtang] = rangeangle(TargetLoc)
```

```
tgtrng = 2.2366e+03
```

```
tgtang = 2×1

   63.4349
    1.2810
```

Range and Angle With Respect to Local Origin

Compute the range and angle of a target located at *(1000,2000,50)* meters with respect to a local origin at *(100,100,10)* meters.

```
TargetLoc = [1000;2000;50];
Origin = [100;100;10];
[tgtrng,tgtang] = rangeangle(TargetLoc,Origin)
```

```
tgtrng = 2.1028e+03
```

```
tgtang = 2×1

   64.6538
    1.0900
```

Range and Angle With Respect to Local Coordinates

Compute the range and angle of a target located at *(1000,2000,50)* meters but with respect to a local coordinate system origin at *(100,100,10)* meters. Choose a local coordinate reference frame that is rotated about the z-axis by 45° from the global coordinate axes.

```
targetpos = [1000;2000;50];
origin = [100;100;10];
```

```
refaxes = [1/sqrt(2) -1/sqrt(2) 0; 1/sqrt(2) 1/sqrt(2) 0; 0 0 1];
[tgtrng,tgtang] = rangeangle(targetpos,origin,refaxes)
```

```
tgtrng = 2.1028e+03

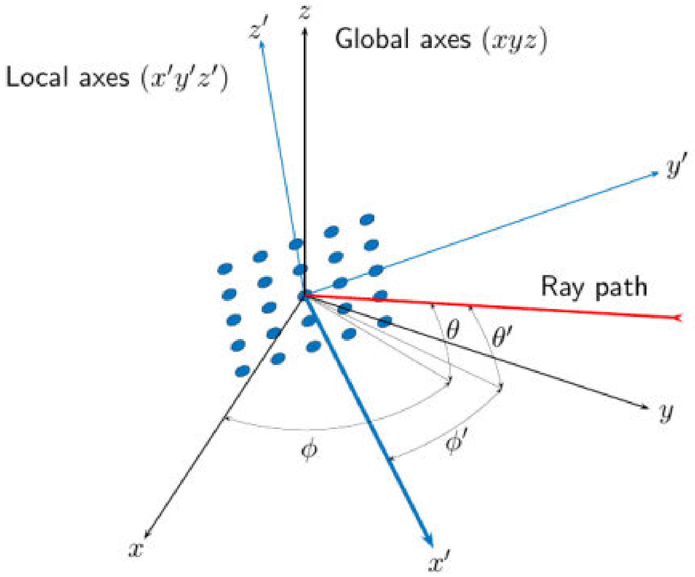
tgtang = 2×1

   19.6538
    1.0900
```

More About

Angles in Local and Global Coordinate Systems

The `rangeangle` function returns the path distance and path angles in either the global or local coordinate systems. By default, the `rangeangle` function determines the angle a signal path makes with respect to global coordinates. If you add the `refaxes` argument, you can compute the angles with respect to local coordinates. As an illustration, this figure shows a 5-by-5 uniform rectangular array (URA) rotated from the global coordinates *(xyz)* using `refaxes`. The *x*' axis of the local coordinate system *(x'y'z')* is aligned with the main axis of the array and moves as the array moves. The path length is independent of orientation. The global coordinate system defines the azimuth and elevations angles *(Φ,θ)* and the local coordinate system defines the azimuth and elevations angles *(Φ',θ')*.



Local and Global Coordinate Axes

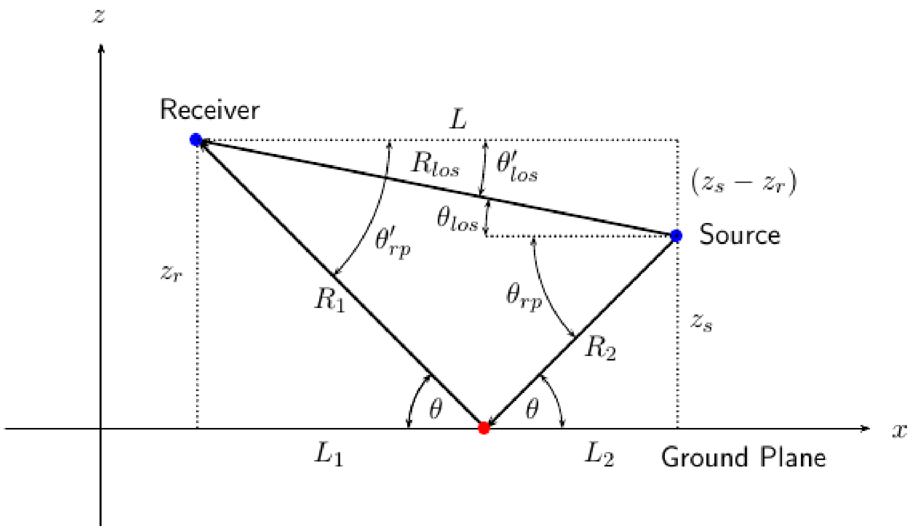
Free Space Propagation Model

The free-space signal propagation model states that a signal propagating from one point to another in a homogeneous, isotropic medium travels in a straight line, called the *line-of-sight* or *direct path*. The straight line is defined by the geometric vector from the radiation source to the destination.

Two-Ray Propagation Model

A two-ray propagation channel is the next step up in complexity from a free-space channel and is the simplest case of a multipath propagation environment. The free-space channel models a straight-line *line-of-sight* path from point 1 to point 2. In a two-ray channel, the medium is specified as a homogeneous, isotropic medium with a reflecting planar boundary. The boundary is always set at *z = 0*. There are at most two rays propagating from point 1 to point 2. The first ray path propagates along the same line-of-sight path as in the free-space channel. The line-of-sight path is often called the *direct path*. The second ray reflects off the boundary before propagating to point 2. According to the Law of Reflection , the angle of reflection equals the angle of incidence. In short-range simulations such as cellular communications systems and automotive radars, you can assume that the reflecting surface, the ground or ocean surface, is flat.

The figure illustrates two propagation paths. From the source position, s_s, and the receiver position, s_r, you can compute the arrival angles of both paths, θ'_{los} and θ'_{rp}. The arrival angles are the elevation and azimuth angles of the arriving radiation with respect to a local coordinate system. In this case, the local coordinate system coincides with the global coordinate system. You can also compute the transmitting angles, θ_{los} and θ_{rp}. In the global coordinates, the angle of reflection at the boundary is the same as the angles θ_{rp} and θ'_{rp}. The reflection angle is important to know when you use angle-dependent reflection-loss data. You can determine the reflection angle by using the `rangeangle` function and setting the reference axes to the global coordinate system. The total path length for the line-of-sight path is shown in the figure by R_{los} which is equal to the geometric distance between source and receiver. The total path length for the reflected path is $R_{rp}= R_1 + R_2$. The quantity L is the ground range between source and receiver.



You can easily derive exact formulas for path lengths and angles in terms of the ground range and object heights in the global coordinate system.

$$\vec{R} = \vec{x}_s - \vec{x}_r$$

$$R_{los} = \left|\vec{R}\right| = \sqrt{(z_r - z_s)^2 + L^2}$$

$$R_1 = \frac{z_r}{z_r + z_z}\sqrt{(z_r + z_s)^2 + L^2}$$

$$R_2 = \frac{z_s}{z_s + z_r}\sqrt{(z_r + z_s)^2 + L^2}$$

$$R_{rp} = R_1 + R_2 = \sqrt{(z_r + z_s)^2 + L^2}$$

$$\tan\theta_{los} = \frac{(z_s - z_r)}{L}$$

$$\tan\theta_{rp} = -\frac{(z_s + z_r)}{L}$$

$$\theta'_{los} = -\theta_{los}$$

$$\theta'_{rp} = \theta_{rp}$$

sph2cartvec

Convert vector from spherical basis components to Cartesian components

Syntax

```
vr = sph2cartvec(vs,az,el)
```

Description

`vr = sph2cartvec(vs,az,el)` converts the components of a vector or set of vectors, `vs`, from their spherical basis representation to their representation in a local Cartesian coordinate system. A spherical basis representation is the set of components of a vector projected into the right-handed spherical basis given by $(\hat{\mathbf{e}}_{az}, \hat{\mathbf{e}}_{el}, \hat{\mathbf{e}}_{R})$. The orientation of a spherical basis depends upon its location on the sphere as determined by azimuth, `az`, and elevation, `el`.

Examples

Cartesian Representation of Azimuthal Vector

Start with a vector in a spherical basis located at 45° azimuth, 45° elevation. The vector points along the azimuth direction. Compute the vector components with respect to Cartesian coordinates.

```
vs = [1;0;0];
vr = sph2cartvec(vs,45,45)
```

```
vr = 3×1

   -0.7071
    0.7071
         0
```

Input Arguments

vs — Vector in spherical basis representation

3-by-1 column vector | 3-by-*N* matrix

Vector in spherical basis representation specified as a 3-by-1 column vector or 3-by-*N* matrix. Each column of `vs` contains the three components of a vector in the right-handed spherical basis $(\hat{\mathbf{e}}_{az}, \hat{\mathbf{e}}_{el}, \hat{\mathbf{e}}_{R})$.

Example: `[4.0; -3.5; 6.3]`

Data Types: `double`
Complex Number Support: Yes

az — Azimuth angle

scalar in range [–180,180]

Azimuth angle specified as a scalar in the closed range [–180,180]. Angle units are in degrees. To define the azimuth angle of a point on a sphere, construct a vector from the origin to the point. The azimuth angle is the angle in the *xy*-plane from the positive *x*-axis to the vector's orthogonal projection into the *xy*-plane. As examples, zero azimuth angle and zero elevation angle specify a point on the *x*-axis while an azimuth angle of 90° and an elevation angle of zero specify a point on the *y*-axis.

Example: `45`

Data Types: `double`

`el` — Elevation angle
scalar in range [–90,90]

Elevation angle specified as a scalar in the closed range [–90,90]. Angle units are in degrees. To define the elevation of a point on the sphere, construct a vector from the origin to the point. The elevation angle is the angle from its orthogonal projection into the *xy*-plane to the vector itself. As examples, zero elevation angle defines the equator of the sphere and ±90° elevation define the north and south poles, respectively.

Example: `30`

Data Types: `double`

Output Arguments

`vr` — Vector in Cartesian representation
3-by-1 column vector | 3-by-*N* matrix

Cartesian vector returned as a 3-by-1 column vector or 3-by-*N* matrix having the same dimensions as `vs`. Each column of `vr` contains the three components of the vector in the right-handed *x*,*y*,*z* basis.

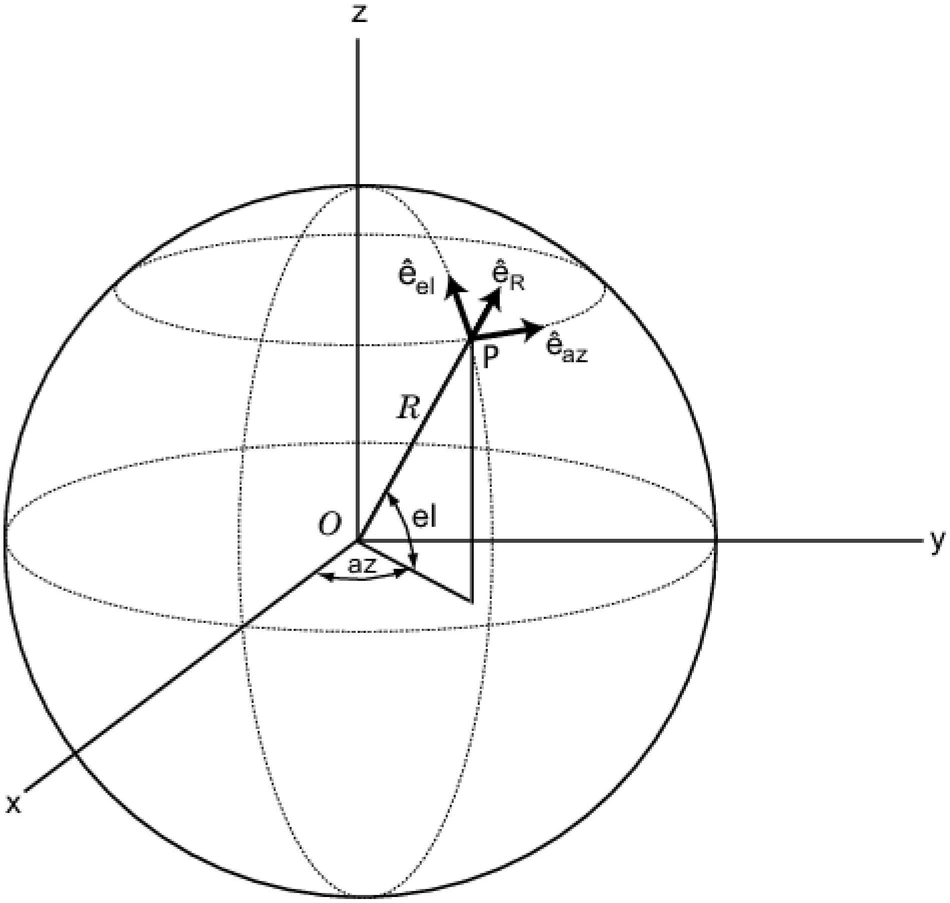
More About

Spherical basis representation of vectors

Spherical basis vectors are a local set of basis vectors which point along the radial and angular directions at any point in space.

The spherical basis is a set of three mutually orthogonal unit vectors ($\hat{\mathbf{e}}_{az}, \hat{\mathbf{e}}_{el}, \hat{\mathbf{e}}_{R}$) defined at a point on the sphere. The first unit vector points along lines of azimuth at constant radius and elevation. The second points along the lines of elevation at constant azimuth and radius. Both are tangent to the surface of the sphere. The third unit vector points radially outward.

The orientation of the basis changes from point to point on the sphere but is independent of *R* so as you move out along the radius, the basis orientation stays the same. The following figure illustrates the orientation of the spherical basis vectors as a function of azimuth and elevation:



For any point on the sphere specified by *az* and *el*, the basis vectors are given by:

$$\begin{aligned}\widehat{\mathbf{e}}_{\mathbf{az}} &= -\sin(az)\,\widehat{\mathbf{i}} + \cos(az)\,\widehat{\mathbf{j}}\\ \widehat{\mathbf{e}}_{\mathbf{el}} &= -\sin(el)\cos(az)\,\widehat{\mathbf{i}} - \sin(el)\sin(az)\,\widehat{\mathbf{j}} + \cos(el)\widehat{\mathbf{k}}\\ \widehat{\mathbf{e}}_{\mathbf{R}} &= \cos(el)\cos(az)\,\widehat{\mathbf{i}} + \cos(el)\sin(az)\,\widehat{\mathbf{j}} + \sin(el)\widehat{\mathbf{k}}\quad .\end{aligned}$$

Any vector can be written in terms of components in this basis as $\mathbf{v} = v_{az}\widehat{\mathbf{e}}_{\mathbf{az}} + v_{el}\widehat{\mathbf{e}}_{\mathbf{el}} + v_R\widehat{\mathbf{e}}_{\mathbf{R}}$. The transformations between spherical basis components and Cartesian components take the form

$$\begin{bmatrix} v_x \\ v_y \\ v_z \end{bmatrix} = \begin{bmatrix} -\sin(az) & -\sin(el)\cos(az) & \cos(el)\cos(az) \\ \cos(az) & -\sin(el)\sin(az) & \cos(el)\sin(az) \\ 0 & \cos(el) & \sin(el) \end{bmatrix} \begin{bmatrix} v_{az} \\ v_{el} \\ v_R \end{bmatrix}$$

.

and

$$\begin{bmatrix} v_{az} \\ v_{el} \\ v_R \end{bmatrix} = \begin{bmatrix} -\sin(az) & \cos(az) & 0 \\ -\sin(el)\cos(az) & -\sin(el)\sin(az) & \cos(el) \\ \cos(el)\cos(az) & \cos(el)\sin(az) & \sin(el) \end{bmatrix} \begin{bmatrix} v_x \\ v_y \\ v_z \end{bmatrix}.$$

comm.ACPR

Package: comm

Adjacent Channel Power Ratio measurements

Description

The ACPR System object measures adjacent channel power ratio (ACPR) of an input signal.

To measure adjacent channel power:

1. Define and set up your adjacent channel power object. See “Construction” on page 3-2.
2. Call step to measure the adjacent channel power ratio according to the properties of comm.ACPR. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.ACPR` creates a System object, H, that measures adjacent channel power ratio (ACPR) of an input signal.

`H = comm.ACPR(Name,Value)` creates object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

NormalizedFrequency

Assume normalized frequency values

Specify whether the frequency values are normalized. If you set this property to true, the object assumes that frequency values are normalized (in the [-1 1] range). The default is false. If you set this property to false, the object assumes that frequency values are measured in Hertz.

SampleRate

Sample rate of input signal

Specify the sample rate of the input signal, in samples per second, as a double-precision, positive scalar. The default is 1e6 samples per second. This property applies when you set the NormalizedFrequency property to false.

MainChannelFrequency

Main channel center frequency

Specify the main channel center frequency as a double-precision scalar. The default is `0` Hz.

When you set the NormalizedFrequency property to `true`, you must specify the center frequency as a normalized value between `-1` and `1`.

When you set the NormalizedFrequency property to `false`, you must specify the center frequency in Hertz. The object measures the main channel power in the bandwidth that you specify in the MainMeasurementBandwidth property. This measurement is taken at the center of the frequency that you specify in the `MainMeasurementBandwidth` property.

MainMeasurementBandwidth

Main channel measurement bandwidth

Specify the main channel measurement bandwidth as a double-precision, positive scalar. The default is `50e3` Hz.

When you set the NormalizedFrequency property to `true`, you must specify the measurement bandwidth as a normalized value between `0` and `1`.

When you set the NormalizedFrequency property to `false`, you must specify the measurement bandwidth in Hertz. The object measures the main channel power in the bandwidth that you specify in the `MainMeasurementBandwidth` property. This measurement is taken at the center of the frequency that you specify in the MainChannelFrequency property.

AdjacentChannelOffset

Adjacent channel frequency offsets

Specify the adjacent channel offsets as a double-precision scalar or as a row vector comprising frequencies that define the location of adjacent channels of interest. The default is `[-100e3 100e3]` Hz.

When you set the NormalizedFrequency property to `true`, you must specify normalized frequency offset values between `-1` and `1`. When you set the `NormalizedFrequency` property to `false`, you must specify frequency offset values in Hertz. The offset values indicate the distance between the main channel center frequency and adjacent channel center frequencies. Positive offsets indicate adjacent channels to the right of the main channel center frequency. Negative offsets indicate adjacent channels to the left of the main channel center frequency.

AdjacentMeasurementBandwidth

Adjacent channel measurement bandwidths

Specify the measurement bandwidth for each adjacent channel. The default is the scalar, `50e3`. The object assumes that each adjacent bandwidth is centered at the frequency defined by the corresponding frequency offset. You define this offset in the AdjacentChannelOffset property. Set this property to a double-precision scalar or row vector of length equal to the number of specified offsets in the AdjacentChannelOffset property.

When you set this property to a scalar, the object obtains all adjacent channel power measurements within equal measurement bandwidths. When you set the NormalizedFrequency property to `true`, you must specify normalized bandwidth values between `0` and `1`. When you set the NormalizedFrequency property to `false`, you must specify the adjacent channel bandwidth values in Hertz.

MeasurementFilterSource

Source of the measurement filter

Specify the measurement filter source as one of `None` | `Property`. The default is `None`. When you set this property to `None` the object does not apply filtering to obtain ACPR measurements. When you set this property to `Property`, the object applies a measurement filter to the main channel before measuring the average power. Each of the adjacent channel bands also receives a measurement filter . In this case, you specify the measurement filter coefficients in the MeasurementFilter property.

MeasurementFilter

Measurement filter coefficients

Specify the measurement filter coefficients as a double-precision row vector containing the coefficients of an FIR filter in descending order of powers of z. Center the response of the filter at DC. The ACPR object automatically shifts and applies the filter response at each of the main and adjacent channel center frequencies before obtaining the average power measurements. The internal filter states persist and clear only when you call the reset method. This property applies when you set the MeasurementFilterSource property to `Property`. The default is `1`, which is an all-pass filter that has no effect on the measurements.

SpectralEstimation

Spectral estimation control

Specify the spectral estimation control as one of `Auto` | `Specify frequency resolution` | `Specify window parameters`. The default is `Auto`.

When you set this property to `Auto`, the object obtains power measurements with a Welch spectral estimator with zero-percent overlap, a Hamming window, and a segment length equal to the length of the input data vector. In this setting, the spectral estimator set should achieve the maximum frequency resolution attainable with the input data length.

When you set this property to `Specify frequency resolution`, you specify the desired spectral frequency resolution, in normalized units or in Hertz, using the FrequencyResolution property. In this setting, the object uses the value in the `FrequencyResolution` property to automatically compute the size of the spectral estimator data window.

When you set this property to `Specify window parameters`, several spectral estimator properties become available so that you can control the Welch spectral estimation settings. These properties are: `SegmentLength`, `OverlapPercentage`, Window, and SidelobeAttenuation. Sidelobe attenuation applies only when you set the Window property to `Chebyshev`.

When you set this property to `Specify window parameters`, the `FrequencyResolution` property does not apply, and you control the resolution using the above properties.

SegmentLength

Segment length

Specify the segment length, in samples, for the spectral estimator as a numeric, positive, integer scalar. The default is `64`. The length of the segment allows you to make tradeoffs between frequency resolution and variance in the spectral estimates. A long segment length results in better resolution.

A short segment length results in more averaging and a decrease in variance. This property applies when you set the SpectralEstimation property to `Specify window parameters`.

OverlapPercentage

Overlap percentage

Specify the percentage of overlap between each segment in the spectral estimator as a double-precision scalar in the `[0 100]` interval. This property applies when you set the SpectralEstimation property to `Specify window parameters`. The default is `0` percent.

Window

Window function

Specify a window function for the spectral estimator as one of `Bartlett` | `Bartlett-Hanning` | `Blackman` | `Blackman-Harris` | `Bohman` | `Chebyshev` | `Flat Top` | `Hamming` | `Hann` | `Nuttall` | `Parzen` | `Rectangular` | `Triangular`. The default is `Hamming`. A Hamming window has `42.5`dB of sidelobe attenuation. This attenuation may mask spectral content below this value, relative to the peak spectral content. Choosing different windows allows you to make tradeoffs between resolution and sidelobe attenuation. This property applies when you set the SpectralEstimation property to `Specify window parameters`.

SidelobeAttenuation

Sidelobe attenuation for Chebyshev window

Specify the sidelobe attenuation, in decibels, for the Chebyshev window function as a double-precision, nonnegative scalar. The default is `100` dB. This property applies when you set the SpectralEstimation property to `Specify window parameters` and the Window property to `Chebyshev`.

FrequencyResolution

Frequency resolution

Specify the frequency resolution of the spectral estimator as a double-precision scalar. The default is `10625` Hz.

When you set the NormalizedFrequency property to `true`, you must specify the frequency resolution as a normalized value between `0` and `1`. When you set the NormalizedFrequency property to `false`, you must specify the frequency resolution in Hertz. The object uses the value in the FrequencyResolution property to calculate the size of the data window used by the spectral estimator. This property applies when you set the SpectralEstimation property to `Specify frequency resolution`.

FFTLength

FFT length

Specify the FFT length that the Welch spectral estimator uses as one of `Next power of 2` | `Same as segment length` | `Custom`. The default is `Next power of 2`.

When you set this property to `Custom`, the CustomFFTLength property becomes available to specify the desired FFT length.

When you set this property to `Next power of 2`, the object sets the length of the FFT to the next power of 2. This length is greater than the spectral estimator segment length or `256`, whichever is greater.

When you set this property to `Same as segment length`, the object sets the length of the FFT. This length equals the spectral estimator segment length or `256`, whichever is greater.

`CustomFFTLength`

Custom FFT length

Specify the number of FFT points that the spectral estimator uses as a numeric, positive, integer scalar. This property applies when you set the FFTLength property to `Custom`. The default is `256`.

`MaxHold`

Max-hold setting control

Specify the maximum hold setting. The default is `false`.

When you set this property to `true`, the object compares two vectors. One vector compared is the current estimated power spectral density vector (obtained with the current input data frame). The object checks this vector against the previous maximum-hold accumulated power spectral density vector, (obtained at the previous call to the `step` method). The object stores the maximum values at each frequency bin and uses them to compute average power measurements. You clear the maximum-hold spectrum by calling the `reset` method on the object. When you set this property to `false`, the object obtains power measurements using instantaneous power spectral density estimates. This property is tunable.

`PowerUnits`

Power units

Specify power measurement units as one of `dBm` | `dBW` | `Watts`. The default is `dBm`.

When you set this property to `dBm`, or `dBW`, the `step` method outputs ACPR measurements in a dBc scale (adjacent channel power referenced to main channels power). If you set this property to `Watts`, the `step` method outputs ACPR measurements in a linear scale.

`MainChannelPowerOutputPort`

Enable main channel power measurement output

When you set this property to `true`, the `step` method outputs the main channel power measurement. The default is `false`. The main channel power is the power of the input signal measured in the band that you define with the MainChannelFrequency and MainMeasurementBandwidth properties. The `step` method returns power measurements in the units that you specify in the PowerUnits property.

`AdjacentChannelPowerOutputPort`

Enable adjacent channel power measurements output

When you set this property to `true`, the `step` method outputs a vector of adjacent channel power measurements. The default is `false`. The adjacent channel powers correspond to the input signal's power measured in the bands that you define with the AdjacentChannelOffset and

AdjacentMeasurementBandwidth properties. The `step` method returns power measurements in the units that you specify in the PowerUnits property.

Methods

reset	Reset states of ACPR measurement object
step	Adjacent Channel Power Ratio measurements

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Measure ACPR of a 16-QAM signal with symbol rate of 3.84 Msps

Generate data with an alphabet size of 16 and modulate the data

```
x  = randi([0 15],5000,1);
y = qammod(x,16);
```

Upsample the data by L = 8 using a rectangular pulse shape

```
L = 8;
yPulse = rectpulse(y,L);
```

Create an ACPR measurement object and measure the modulated signal

```
acpr = comm.ACPR(...
    'SampleRate', 3.84e6*8,...
    'MainChannelFrequency', 0,...
    'MainMeasurementBandwidth', 3.84e6,...
    'AdjacentChannelOffset', [-5e6 5e6],...
    'AdjacentMeasurementBandwidth', 3.84e6,...
    'MainChannelPowerOutputPort', true,...
    'AdjacentChannelPowerOutputPort', true);
[ACPR,mainChnlPwr,adjChnlPwr] = acpr(yPulse)
```

```
ACPR = 1×2

  -14.3659  -14.3681

mainChnlPwr = 38.8668

adjChnlPwr = 1×2

   24.5010   24.4988
```

Algorithms

Note The following conditions must be true, otherwise power measurements fall out of the Nyquist interval.

$$\left| MainChannelFreq \pm \frac{MainChannelMeasBW}{2} \right| < F\text{max}$$

$$\left| (MainChannelFreq + AdjChannelOffset) \pm \frac{AdjChannelMeasBW}{2} \right| < F\text{max}$$

F_{max} = Fs/2 if NormalizedFrequency = false

F_{max} = 1 if NormalizedFrequency = true

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supports MEX code generation. Does not support code generation for standalone applications.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

`comm.CCDF` | `comm.EVM` | `comm.MER`

Introduced in R2012a

reset

System object: `comm.ACPR`
Package: `comm`

Reset states of ACPR measurement object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `ACPR` object, `H`.

step

System object: `comm.ACPR`
Package: `comm`

Adjacent Channel Power Ratio measurements

Syntax

```
A = step(H,X)
[A,MAINPOW] = step(H,X)
[A,ADJPOW] = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`A = step(H,X)` returns a vector of the adjacent channel power ratio, `A`, measured in the input data, `X`. The measurements are at the frequency bands that you specify with the `MainChannelFrequency`, `MainMeasurementBandwidth`, `AdjacentChannelOffset`, and `AdjacentMeasurementBandwidth` properties. Input `X` must be a double precision column vector. The length of the output vector, `A`, equals the number of adjacent channels that you specify in the `AdjacentChannelOffset` property.

`[A,MAINPOW] = step(H,X)` returns the measured main channel power, `MAINPOW`, when you set the `MainChannelPowerOutputPort` property to true. The step method outputs the main channel power measured within the main channel frequency band of interest that you specify with the `MainChannelFrequency` and `MainMeasurementBandwidth` properties.

`[A,ADJPOW] = step(H,X)` returns a vector of the measured adjacent channel powers, `ADJPOW`, when you set the `AdjacentChannelPowerOutputPort` property to true. The adjacent channel powers are measured at the adjacent frequency bands of interest that you specify with the `AdjacentChannelOffset` and `AdjacentMeasurementBandwidth` properties. The length of the output vector, `ADJPOW`, equals the length of the vector that you specify in the `AdjacentChannelOffset` property. You can combine optional output arguments when you set their enabling properties. Optional outputs must be listed in the same order as the order of the enabling properties. For example,

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.AGC

Package: `comm`

Adaptively adjust gain for constant signal level output

Description

The `comm.AGC` System object creates an automatic gain controller (AGC) that adaptively adjusts its gain to achieve a constant signal level at the output. For more information, see “Logarithmic-Loop AGC” on page 3-26. This object is designed for streaming applications. For more information, see “Tips” on page 3-28.

To adaptively adjust gain for a constant signal level at the output:

1. Create the `comm.AGC` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
agc = comm.AGC
agc = comm.AGC(Name,Value)
```

Description

`agc = comm.AGC` creates an AGC System object that adaptively adjusts its gain to achieve a constant signal level at the output.

`agc = comm.AGC(Name,Value)` set properties using one or more name-value pairs. Enclose each name in quotes. For example, '`AdaptationStepSize`',0.05 sets the step size for gain updates to 0.05.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`AdaptationStepSize` — Step size for gain updates
`0.01` (default) | positive scalar

Step size for gain updates, specified as a positive scalar. Increasing the step size enables the AGC to respond more quickly to changes in the input signal level but increases variation in the output signal level after reaching steady-state operation. For more information, see “AGC Performance Criteria” on page 3-28, and the “Vary AGC Step Size” on page 3-18, and “Plot Effect of Step Size on AGC Performance” on page 3-21 examples.

Tunable: Yes

Data Types: `double`

`DesiredOutputPower` — Target output power level

`1` W (default) | positive scalar

Target output power level, specified as a positive scalar. The power is measured in Watts referenced to 1 ohm. For more information, see the “Adaptively Adjust Received Signal Amplitude Using AGC” on page 3-20 example.

Data Types: `double`

`AveragingLength` — Length of averaging window

`100` samples (default) | positive integer

Length of the averaging window in samples, specified as a positive integer. For more information on how the averaging length influences the variance of the AGC output signal in steady-state operation and the execution speed, see “Tips” on page 3-28 and the “Vary AGC Averaging Length” on page 3-13 example.

Data Types: `double`

`MaxPowerGain` — Maximum power gain

`60` dB (default) | positive scalar

Maximum power gain in decibels, specified as a positive scalar. Large gain adjustments can cause clipping when a small input signal power suddenly increases. Use this property to avoid large gain adjustments by limiting the gain that the AGC applies to the input signal. For more information, see the “Vary AGC Maximum Gain” on page 3-15 and “Demonstrate Effect of Maximum AGC Gain on Packet Data” on page 3-24 examples.

Data Types: `double`

Usage

Syntax

```
y = agc(x)
[y,powerlevel] = agc(x)
```

Description

`y = agc(x)` adaptively adjusts the gain to the input signal to achieve a reference signal level at the output. The AGC System object uses a square law detector to determine the output signal level. For more information, see “AGC Detector” on page 3-27.

`[y,powerlevel] = agc(x)` returns `powerlevel`, the power level estimate of the input signal. You can use `powerlevel` as an energy detector output.

Input Arguments

x — Input signal
column vector

Input signal, specified as a column vector.

Data Types: `single` | `double`

Output Arguments

y — Output signal
column vector

Output signal, returned as a column vector. The output signal is the same data type as the input signal, `x`.

`powerlevel` — Power level estimate
N_S-element column vector

Power level estimate, returned as an N_S-element column vector. N_S is the length of the input signal, `x`. You can use `powerlevel` as an energy detector output.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Vary AGC Averaging Length

Apply different AGC averaging lengths to QAM-modulated signals. Compare the variance and plot of the signals after AGC is applied.

Create three AGC System objects with their average window lengths set to 10, 100, and 1000 samples, respectively.

```
agc1 = comm.AGC('AveragingLength',10);
agc2 = comm.AGC('AveragingLength',100);
agc3 = comm.AGC('AveragingLength',1000);
```

Generate 16-QAM modulated and raised cosine pulse shaped packetized data.

```
M = 16;
d = randi([0 M-1],1000,1);
```

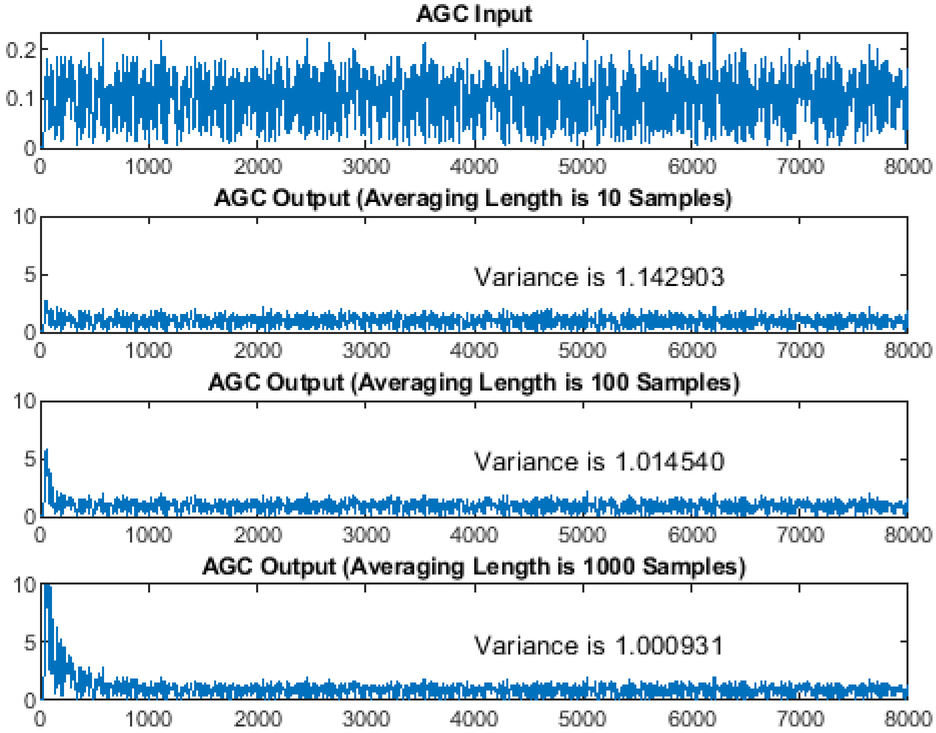
```
s = qammod(d,M);
x = 0.1*s;
pulseShaper = comm.RaisedCosineTransmitFilter;
y = awgn(pulseShaper(x),inf);
```

Apply AGC to the data capturing separate outputs for each AGC object.

```
r1 = agc1(y);
r2 = agc2(y);
r3 = agc3(y);
```

Plot and compare the signals. As the averaging length increases, the variance at the output of AGC decreases.

```
figure(1)
subplot(4,1,1)
plot(abs(y))
title('AGC Input')
subplot(4,1,2)
plot(abs(r1))
axis([0 8000 0 10])
title('AGC Output (Averaging Length is 10 Samples)')
text(4000,5,sprintf('Variance is %f',var(r1(3000:end))))
subplot(4,1,3)
plot(abs(r2))
axis([0 8000 0 10])
title('AGC Output (Averaging Length is 100 Samples)')
text(4000,5,sprintf('Variance is %f',var(r2(3000:end))))
subplot(4,1,4)
plot(abs(r3))
axis([0 8000 0 10])
title('AGC Output (Averaging Length is 1000 Samples)')
text(4000,5,sprintf('Variance is %f',var(r3(3000:end))))
```



Vary AGC Maximum Gain

Apply different AGC maximum gain levels to QPSK-modulated signals. Compare the plot of the signals after AGC is applied.

Create three AGC System objects with their maximum gain values set to 10, 20, and 30 dB, respectively.

```
agc1 = comm.AGC('MaxPowerGain',10);
agc2 = comm.AGC('MaxPowerGain',20);
agc3 = comm.AGC('MaxPowerGain',30);
```

Generate QPSK-modulated data. Pass the data through raised cosine pulse shaped filtering and an AWGN channel.

```
M = 4;
pktLen = 10000;
d = randi([0 M-1],pktLen,1);
s = pskmod(d,M,pi/4);
x = repmat([zeros(pktLen,1); 0.3*s],3,1);
pulseShaper = comm.RaisedCosineTransmitFilter;
y = awgn(pulseShaper(x),50);
```

Apply AGC to the data capturing separate outputs for each AGC object.

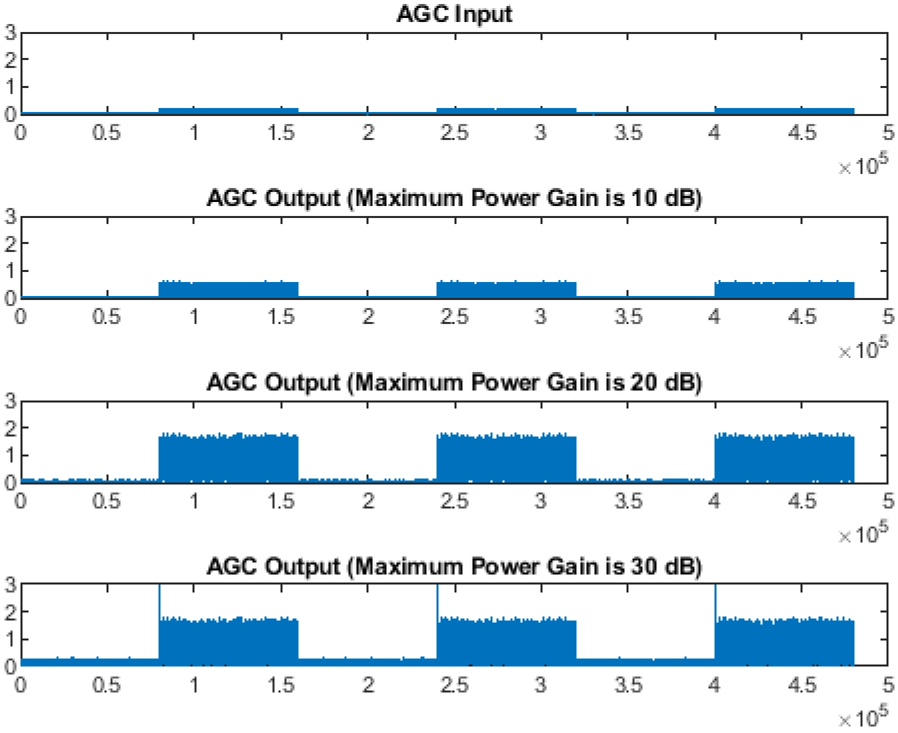
```
r1 = agc1(y);
r2 = agc2(y);
r3 = agc3(y);
```

Plot the input signal and the AGC-adjusted signal with various maximum gain levels. Compare the results for the conditions in this example.

- A maximum gain setting of 10 dB is too small, and the AGC output does not reach the desired output signal level risking data loss due to decreased signal dynamic range.
- A maximum gain setting of 20 dB is optimal, and the AGC output reaches the desired level without signal loss due to saturation.
- A maximum gain setting of 30 dB is too large, and the AGC output overshoots the desired signal level risking signal saturation and data loss at the start of received packets.
- Between packets the input signal contains only noise.

As shown in the plots, the packet transmissions have extended periods when no data is received. The extended periods with no data received results in AGC increasing to the maximum gain setting. If a packet arrives when the AGC gain is too high, the output power overshoots the desired signal level until the AGC can respond to the change in the input power level and reduce its gain.

```
limits = [0 3];
figure(1)
subplot(4,1,1)
plot(abs(y))
ylim(limits)
title('AGC Input')
subplot(4,1,2)
plot(abs(r1))
ylim(limits)
title('AGC Output (Maximum Power Gain is 10 dB)')
subplot(4,1,3)
plot(abs(r2))
ylim(limits)
title('AGC Output (Maximum Power Gain is 20 dB)')
subplot(4,1,4)
plot(abs(r3))
ylim(limits)
title('AGC Output (Maximum Power Gain is 30 dB)')
```



Show Power Level Estimate Output from AGC

Plot a signal and the power level estimate. Compare the results. The power level estimate can serve as a power detector, indicating exactly when the received packet has arrived.

Create an AGC System object with its maximum gain value set to 20 dB.

```
agc20 = comm.AGC('MaxPowerGain',20);
```

Generate QPSK-modulated data. Pass the data through raised cosine pulse shaped filtering and an AWGN channel.

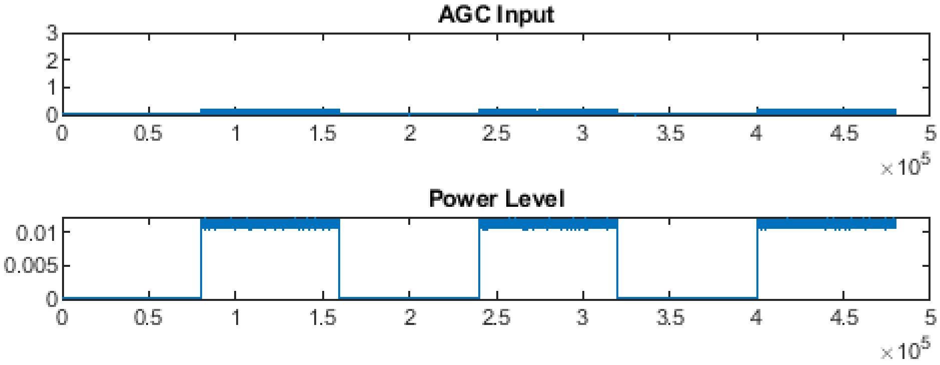
```
modOrd = 4; % Modulation order
pktLen = 10000; % Packet length
d = randi([0 modOrd-1],pktLen,1);
s = pskmod(d,modOrd,pi/4);
x = repmat([zeros(pktLen,1); 0.3*s],3,1);
pulseShaper = comm.RaisedCosineTransmitFilter;
y = awgn(pulseShaper(x),50);
```

Apply AGC to the data capturing separate outputs for each AGC object.

```
[r2,p2] = agc20(y);
```

Plot the input signal and the received signal power level estimate. Compare the results. Reception of packetized data with extended periods when no data is received results in the detected power level estimate decreasing to nearly zero. While an input signal is detected, the output power level estimate, p2, serves as a power detector, indicating exactly when the received packet has arrived.

```
limits = [0 3];
figure(1)
subplot(4,1,1)
plot(abs(y))
ylim(limits)
title('AGC Input')
subplot(4,1,2)
plot(abs(p2))
title('Power Level')
```



Vary AGC Step Size

Apply different AGC step sizes to QPSK-modulated signals. Compare the signals after applying AGC.

Create three AGC System objects with their step sizes set to 1e-1, 1e-3, and 1e-4, respectively.

```
agc1 = comm.AGC('AdaptationStepSize',1e-1);
agc2 = comm.AGC('AdaptationStepSize',1e-3);
agc3 = comm.AGC('AdaptationStepSize',1e-4);
```

Generate QPSK-modulated data with raised cosine pulse shaping.

```
d = randi([0 3],500,1);
s = pskmod(d,4,pi/4);
x = 0.1*s;
pulseShaper = comm.RaisedCosineTransmitFilter;
y = pulseShaper(x);
```

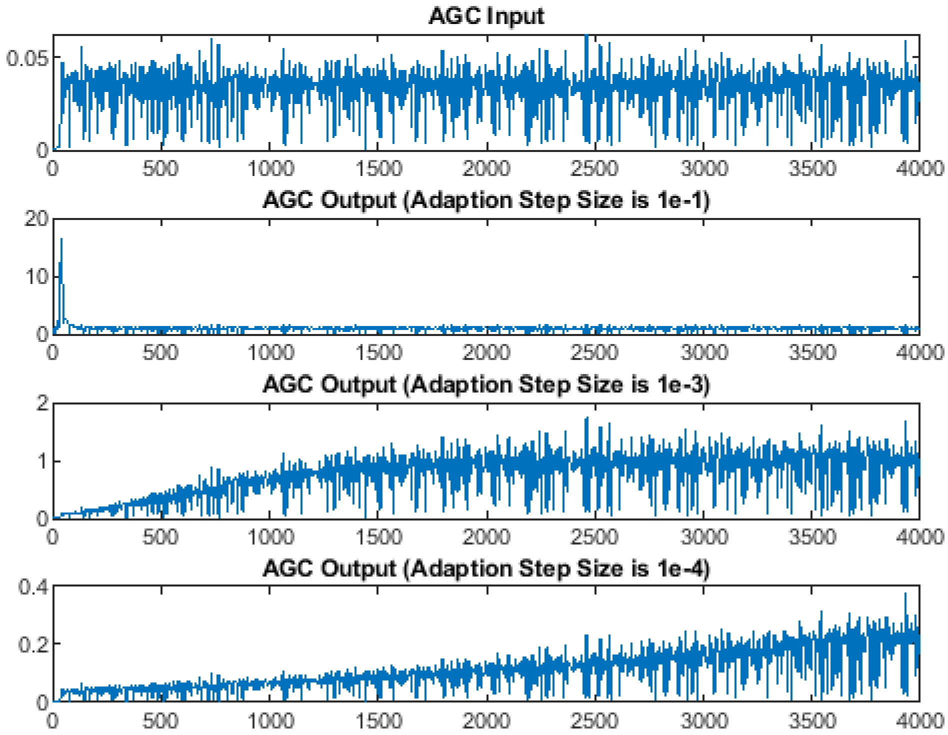
Apply AGC to the data capturing separate outputs for each AGC object.

```
r1 = agc1(y);
r2 = agc2(y);
r3 = agc3(y);
```

Plot the input and output signal after the various AGC step sizes.

- With the step size set to 1e-1, the AGC output signal overshoot is evident. The output signal converges very quickly.
- With the step size set to 1e-3, the AGC output signal overshoot disappears. The output signal gradually converges.
- With the step size set to 1e-4, the AGC output signal takes 2 to 3 times longer to converge than a step size of 1e-3.

```
figure
subplot(4,1,1)
plot(abs(y))
title('AGC Input')
subplot(4,1,2)
plot(abs(r1))
title('AGC Output (Adaption Step Size is 1e-1)')
subplot(4,1,3)
plot(abs(r2))
title('AGC Output (Adaption Step Size is 1e-3)')
subplot(4,1,4)
plot(abs(r3))
title('AGC Output (Adaption Step Size is 1e-4)')
```



Adaptively Adjust Received Signal Amplitude Using AGC

Modulate and amplify a QPSK signal. Set the received signal amplitude to approximately 1 volt by using an AGC. Plot the output.

Create a QPSK-modulated signal by using the QPSK System object.

```
data = randi([0 3],1000,1);
qpsk = comm.QPSKModulator;
modData = qpsk(data);
```

Attenuate the modulated signal.

```
txSig = 0.1*modData;
```

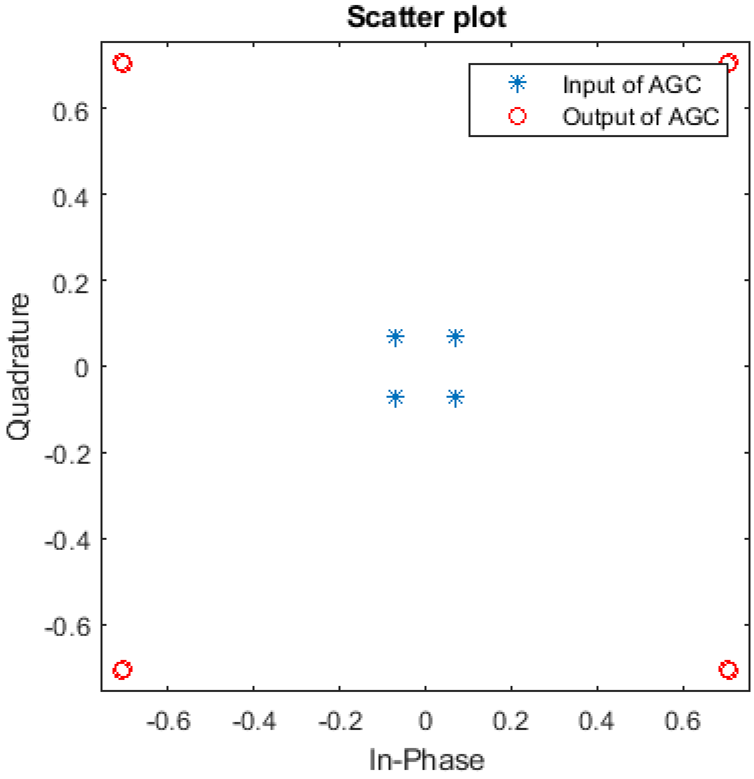
Create an AGC System object and pass the transmitted signal through it. The AGC adjusts the received signal power to approximately 1 W.

```
agc = comm.AGC;
rxSig = agc(txSig);
```

Plot the signal constellations of the transmit and received signals after the AGC reaches steady-state.

```
h = scatterplot(txSig(200:end),1,0,'*');
hold on
```

```
scatterplot(rxSig(200:end),1,0,'or',h);
legend('Input of AGC','Output of AGC')
```



Measure and compare the power of the transmitted and received signals after the AGC reaches a steady state. The power of the transmitted signal is 100 times smaller than the power of the received signal.

```
txPower = var(txSig(200:end));
rxPower = var(rxSig(200:end));
[txPower rxPower]
```

```
ans = 1×2

    0.0100    0.9970
```

Plot Effect of Step Size on AGC Performance

Create two AGC System objects™ to adjust the level of the received signal using two different step sizes with identical update periods.

Generate an 8-PSK signal such that its power is 10 W.

```
data = randi([0 7],200,1);
modData = sqrt(10)*pskmod(data,8,pi/8,'gray');
```

Create a pair of raised cosine matched filters with their `Gain` property set so that they have unity output power.

```
txfilter = comm.RaisedCosineTransmitFilter('Gain',sqrt(8));
rxfilter = comm.RaisedCosineReceiveFilter('Gain',sqrt(1/8));
```

Filter the modulated signal through the raised cosine transmit filter.

```
txSig = txfilter(modData);
```

Create two AGC System objects to adjust the received signal level. Set a step size of 0.01 and 0.1, respectively.

```
agc1 = comm.AGC('AdaptationStepSize',0.01);
agc2 = comm.AGC('AdaptationStepSize',0.1);
```

Apply AGC to the modulated signal capturing separate outputs for each AGC object.

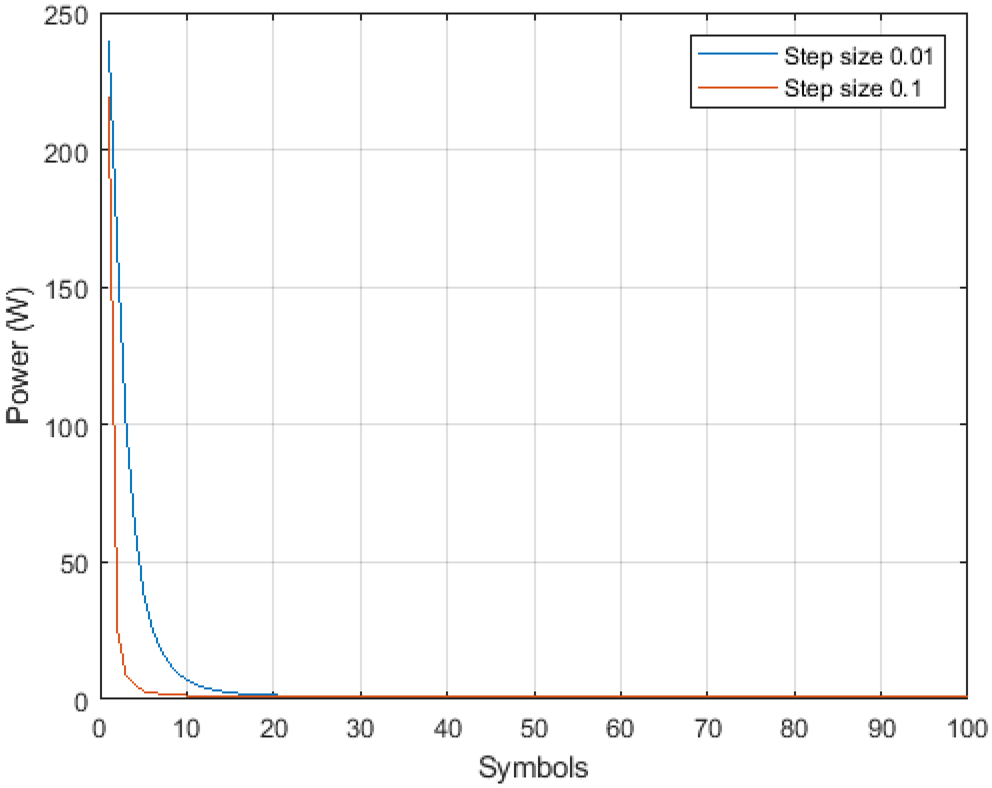
```
agcOut1 = agc1(txSig);
agcOut2 = agc2(txSig);
```

Filter the AGC output signals by using the raised cosine receive filter.

```
rxSig1 = rxfilter(agcOut1);
rxSig2 = rxfilter(agcOut2);
```

Plot the power of the filtered AGC responses while accounting for the 10 symbol delay through the transmit-receive filter pair.

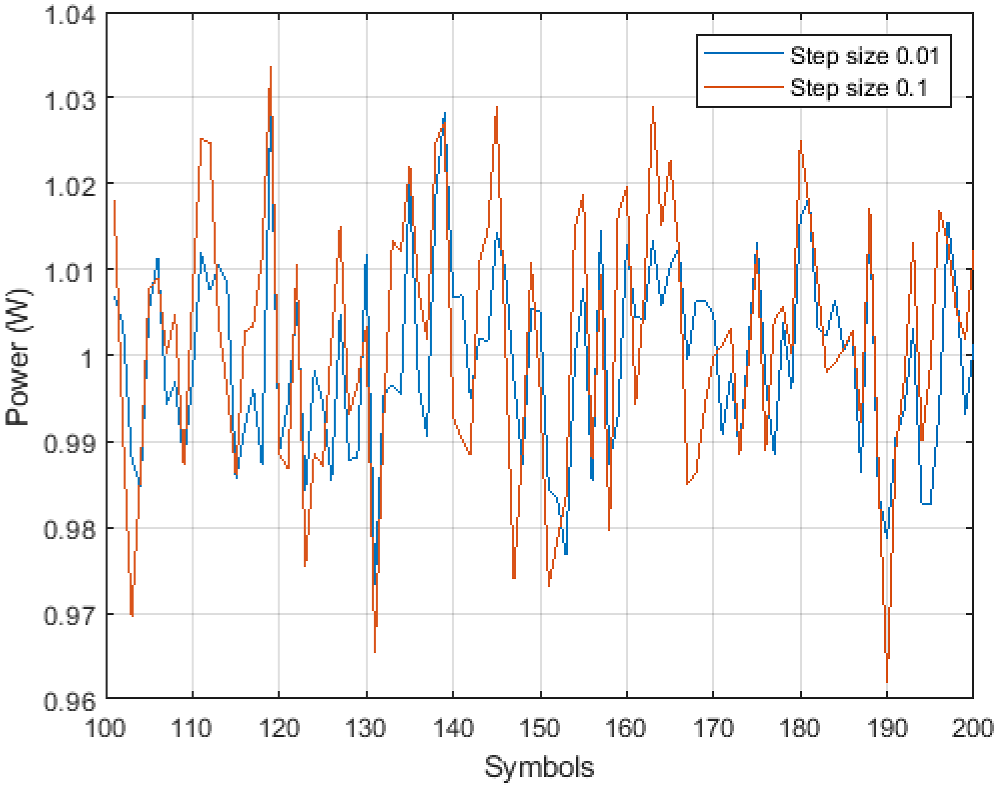
```
plot([abs(rxSig1(11:110)).^2 abs(rxSig2(11:110)).^2])
grid on
xlabel('Symbols')
ylabel('Power (W)')
legend('Step size 0.01','Step size 0.1')
```



The signal with the larger step size converges faster to the AGC target power level of 1 W.

Plot the power of the steady-state filtered AGC signals by including only the last 100 symbols. The larger AGC step size results in less accurate gain correction. Larger AGC step size values result in faster convergence at the expense of less accurate gain control.

```
plot((101:200),[abs(rxSig1(101:200)).^2 abs(rxSig2(101:200)).^2])
grid on
xlabel('Symbols')
ylabel('Power (W)')
legend('Step size 0.01','Step size 0.1')
```



Demonstrate Effect of Maximum AGC Gain on Packet Data

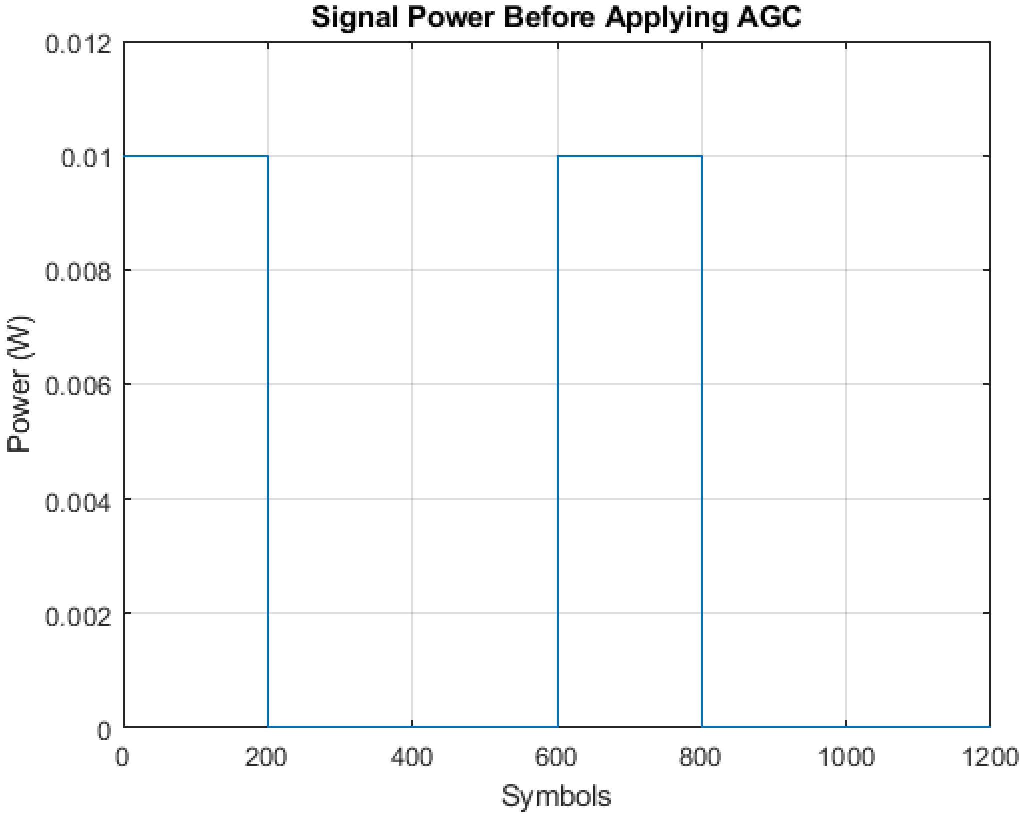
Pass attenuated QPSK packet data to two AGCs with different maximum gains. Plot the results.

Create two, 200-symbol QSPK data packets. Transmit the packets over a 1200-symbol frame.

```
modData1 = pskmod(randi([0 3],200,1),4,pi/4);
modData2 = pskmod(randi([0 3],200,1),4,pi/4);
txSig = [modData1; zeros(400,1); modData2; zeros(400,1)];
```

Attenuate the transmitted burst signal by 20 dB and plot its power.

```
rxSig = 0.1*txSig;
rxSigPwr = abs(rxSig).^2;
plot(rxSigPwr)
grid
xlabel('Symbols')
ylabel('Power (W)')
title('Signal Power Before Applying AGC')
```



Create two AGCs with maximum power gains of 30 dB and 24 dB, respectively.

```
agc1 = comm.AGC('MaxPowerGain',30,'AdaptationStepSize',0.02);
```

```
agc2 = comm.AGC('MaxPowerGain',24,'AdaptationStepSize',0.02);
```

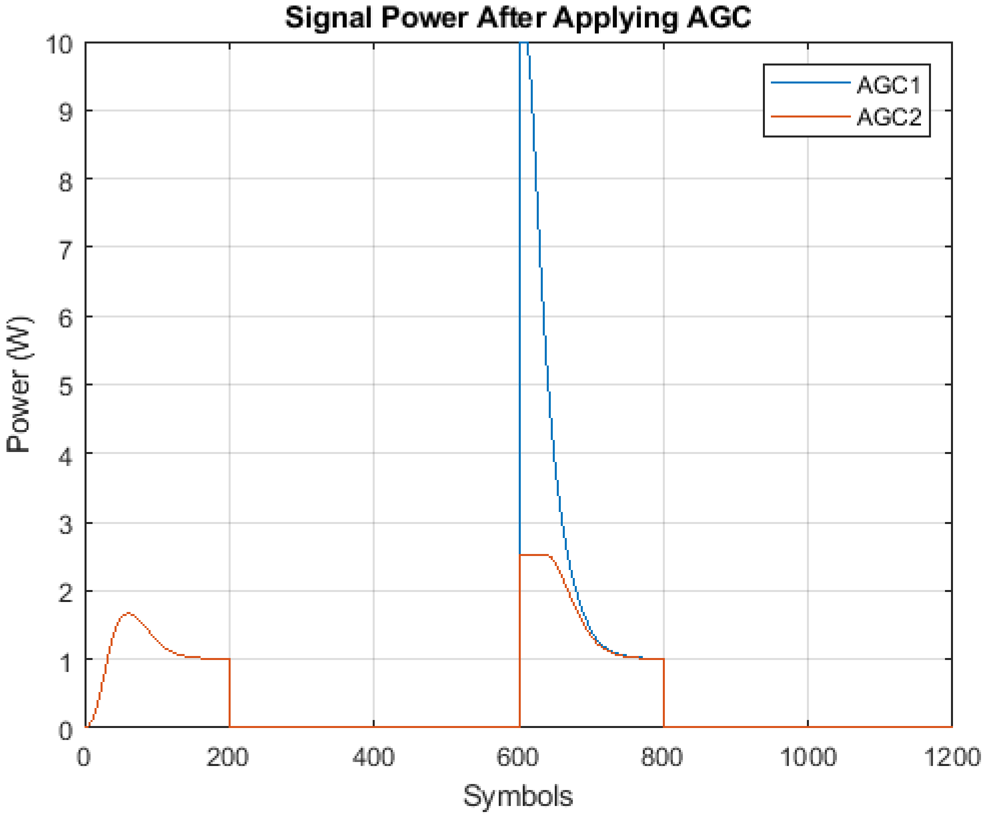
Apply AGC to the attenuated signal capturing separate outputs for each AGC object. Calculate the output power for each case.

```
rxAGC1 = agc1(rxSig);
rxAGC2 = agc2(rxSig);

pwrAGC1 = abs(rxAGC1).^2;
pwrAGC2 = abs(rxAGC2).^2;
```

Plot the output powers. Initially, for the second packet, the `agc1` output signal power is too high because the AGC applied its maximum gain during the period when no data was transmitted. The corresponding `agc2` output signal power (2.5 W) overshoots the target power level of 1 W by significantly less than the `agc1` output signal power (10 W). The convergence time for `agc2` is shorter than the convergence time for `agc1`, because the signal input to `agc2` applies a smaller maximum gain than `agc1`.

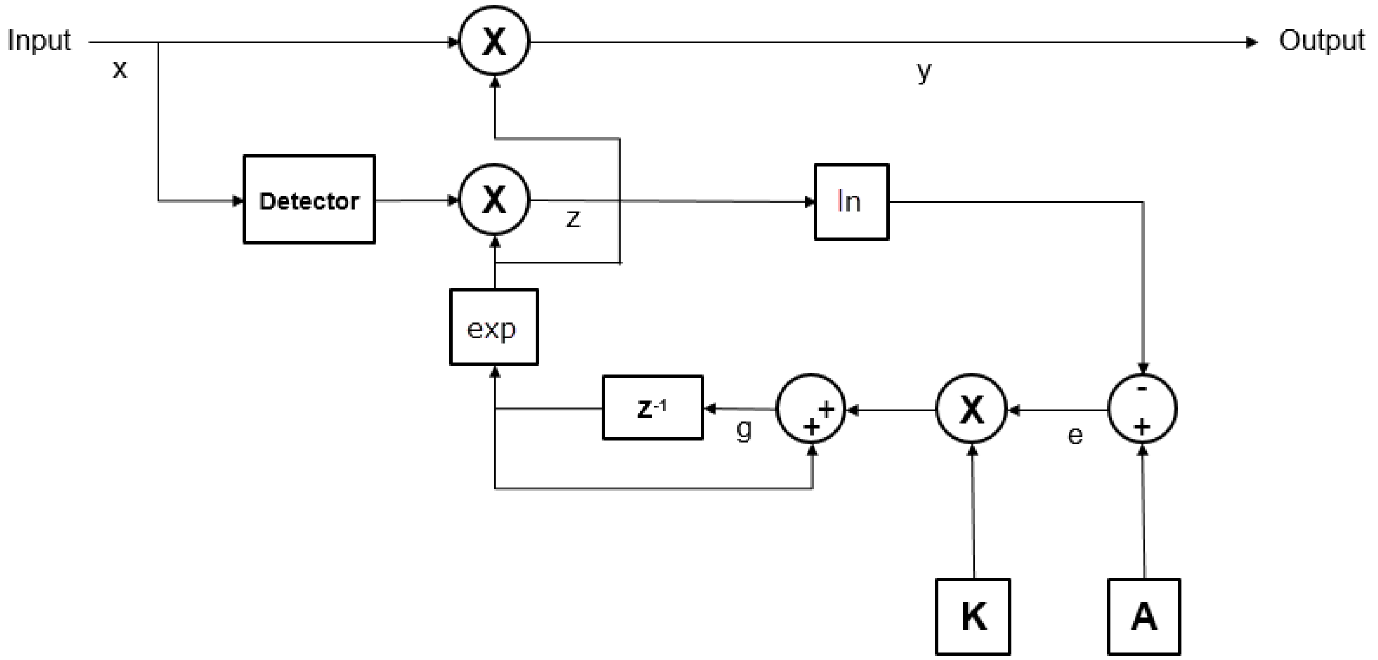
```
plot([pwrAGC1 pwrAGC2])
legend('AGC1','AGC2')
grid
xlabel('Symbols')
ylabel('Power (W)')
title('Signal Power After Applying AGC')
```



More About

Logarithmic-Loop AGC

The AGC implementation uses a logarithmic feedback loop. As this figure of the logarithmic-loop AGC algorithm shows, the output signal is the product of the input signal and the exponential of the loop gain. The error signal is the difference between the reference level and the product of the logarithm of the detector output and the exponential of the loop gain. After multiplying by the step size, the AGC passes the error signal to an integrator.



The logarithmic-loop AGC performs well for a variety of signal types, including amplitude modulation. The “AGC Detector” on page 3-27 is applied to the input signal, which improves convergence times, but increases signal power variation at the detector input. Large signal variation at the detector input is acceptable for floating-point systems.

Mathematically, the algorithm is summarized as

$$y(n) = x(n) \cdot \exp(g(n-1)),$$
$$z(n) = D(x(n)) \cdot \exp(2g(n-1)),$$
$$e(n) = A - \ln(z(n)), \text{ and}$$
$$g(n) = g(n-1) + K \cdot e(n),$$

where:

- *x* is the input signal.
- *y* is the output signal.
- *g* is the loop gain.
- *D(•)* is the detector function.
- *z* is the detector output.
- *A* is the reference value.
- *e* is the error signal.
- *K* is the step size.

AGC Detector

The AGC detector output, *z*, computes a square law detector given by

$$z(m) = \frac{1}{N}\sum_{n = mN}^{(m+1)N-1} |y(n)|^2 ,$$

where *N* is the update period. The square law detector produces an output proportional to the square of the input signal *y*.

AGC Performance Criteria

Increasing the step size decreases the attack time and decay times, but it also increases gain pumping.

- Attack time — The duration taken for the AGC to respond to an increase in the input amplitude
- Decay time — The duration taken for the AGC to respond to a decrease in the input amplitude
- Gain pumping — The variation in the gain value during steady-state operation

Tips

- This System object is designed for streaming applications.
- If the signal amplitude does not change within the frame, you can simulate an ideal AGC by calculating the average gain desired for a frame of samples. Then, apply the gain to each sample in the frame.
- If you use the AGC with higher order QAM signals, you might need to reduce the variation in the gain during steady-state operation. Inspect the constellation diagram at the output of the AGC during steady-state operation. You can increase the averaging length to avoid frequent gain adjustments. An increase in averaging length reduces execution speed.

AGC

Introduced in R2013a

comm.AlgebraicDeinterleaver

Package: comm

(To be removed) Deinterleave input symbols using algebraically derived permutation vector

Compatibility

comm.AlgebraicDeinterleaver will be removed in a future release. Use algdeintrlv instead. For more information, see “Compatibility Considerations” on page 3-32.

Description

The AlgebraicDeinterleaver object restores the original ordering of a sequence that was interleaved using the AlgebraicInterleaver object. In typical usage, the properties of the two objects have the same values.

To deinterleave input symbols using an algebraically derived permutation vector:

1. Define and set up your algebraic deinterleaver object. See “Construction” on page 3-29.
2. Call step to deinterleave the input symbols according to the properties of comm.AlgebraicDeinterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.AlgebraicDeinterleaver creates a deinterleaver System object, H. This object restores the original ordering of a sequence from the corresponding algebraic interleaver object.

H = comm.AlgebraicDeinterleaver(Name,Value) creates an Algebraic deinterleaver System object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

Method

Algebraic method to generate permutation vector

Specify the algebraic method as one of Takeshita-Costello| Welch-Costas. The default is Takeshita-Costello. The algebraic interleaver performs all computations in modulo *N*, where *N* equals the length you set in the Length property.

For the Welch-Costas method, the value of (N+1) must be a prime number, where N equals the value you specify in the Length property. You must set the PrimitiveElement property to an integer, A, between 1 and N. This integer represents a primitive element of the finite field $GF(N+1)$.

For the Takeshita-Costello method, you must set the Length property to a value equal to 2^m, for any integer m. You must also set the MultiplicativeFactor property to an odd integer that is less than the value of the Length property. The CyclicShift property requires a nonnegative integer which is less than the value of the Length property. The Takeshita-Costello interleaver method uses a cycle vector of length N, which you specify in the Length property. The cycle vector calculation uses the equation, $\mathrm{mod}(k \times (n - 1) \times \frac{n}{2}, N)+1$, for any integer n, between 1 and N. The object creates an intermediate permutation function using the relationship, $P(c(n)) = c(n+1)$. You can shift the elements of the intermediate permutation vector to the left by the amount specified by the CyclicShift property. Doing so produces the interleaver's actual permutation vector.

Length

Number of elements in input vector

Specify the number of elements in the input as a positive, integer, scalar. When you set the Method property to Welch-Costas, then the value of Length+1 must equal a prime number. When you set the Method property to Takeshita-Costello, then the value of the Length property requires a power of two. The default is 256.

MultiplicativeFactor

Cycle vector computation factor

Specify the factor the object uses to compute the interleaver's cycle vector as a positive, integer, scalar. This property applies when you set the Method property to Takeshita-Costello. The default is 13.

CyclicShift

Amount of cyclic shift

Specify the amount by which the object shifts indices, when the object creates the final permutation vector, as a nonnegative, integer, scalar. The default is 0. This property applies when you set the Method property to Takeshita-Costello.

PrimitiveElement

Primitive element

Specify the primitive element as an element of order N in the finite field $GF(N+1)$. N is the value you specify in the Length on page 3-0 property. You can express every nonzero element of $GF(N+1)$ as the value of the PrimitiveElement property raised to some integer power. In a Welch-Costas interleaver, the permutation maps the integer k to mod(A^k,N+1)-1, where A represents the value of the PrimitiveElement property. This property applies when you set the Method property to Welch-Costas. The default is 6.

step

System object: `comm.AlgebraicDeinterleaver`
Package: `comm`

(To be removed) Deinterleave input symbols using algebraically derived permutation vector

Compatibility

step will be removed in a future release. Use `algdeintrlv` instead.

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` restores the original ordering of the sequence, `X`, that was interleaved using an algebraic interleaver. An algebraically derived permutation vector based on the algebraic method you specify in the Method property forms the base of the output, `Y`. `X` must be a column vector of length specified by the Length property. `X` can be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.AlgebraicInterleaver

Package: `comm`

(To be removed) Permute input symbols using algebraically derived permutation vector

Compatibility

comm.AlgebraicInterleaver will be removed in a future release. Use `algintrlv` instead. For more information, see "Compatibility Considerations" on page 3-37.

Description

The `AlgebraicInterleaver` object rearranges the elements of its input vector using an algebraically derived permutation.

To interleave input symbols using an algebraically derived permutation vector:

1. Define and set up your algebraic interleaver object. See "Construction" on page 3-34.
2. Call `step` to interleave the input symbols according to the properties of `comm.AlgebraicInterleaver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.AlgebraicInterleaver` creates an interleaver System object, `H`, that permutes the symbols in the input signal. This permutation is based on an algebraically derived permutation vector.

`H = comm.AlgebraicInterleaver(Name,Value)` creates an algebraic interleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`Method`

Algebraic method to generate permutation vector

Algebraic method to generate permutation vector

Specify the algebraic method as one of `Takeshita-Costello`| `Welch-Costas`. The default is `Takeshita-Costello`. The algebraic interleaver performs all computations in modulo *N*, where *N* is the length you set in the Length property.

For the Welch-Costas method, the value of (N+1) must be a prime number, where N is the value you specify in the Length property. You must set the PrimitiveElement property to an integer, A, between 1 and N. This integer represents a primitive element of the finite field $GF(N+1)$.

For the Takeshita-Costello method, you must set the Length property to a value equal to 2^m, for any integer m. You must also set the MultiplicativeFactor property to an odd integer which is less than the value of the Length property. In addition, you must set the CyclicShift property to a nonnegative integer which is less than the value of the Length property. The Takeshita-Costello interleaver method uses a cycle vector of length N, which you specify in the Length property. The cycle vector calculation uses the equation, $\mathrm{mod}(k \times (n-1) \times \frac{n}{2}, N)+1$, for any integer n, between 1 and N. The object creates an intermediate permutation function using the relationship, $P(c(n)) = c(n+1)$. You can shift the elements of the intermediate permutation vector to the left by the amount specified by the CyclicShift property. Doing so produces the actual permutation vector of the interleaver.

Length

Number of elements in input vector

Specify the number of elements in the input as a positive, integer, scalar. When you set the Method property to Welch-Costas, then the value of Length+1 must equal a prime number. When you set the Method property to Takeshita-Costello, then the value of the Length property requires a power of two. The default is 256.

MultiplicativeFactor

Cycle vector computation method

Specify the factor the object uses to compute the cycle vector for the interleaver as a positive, integer, scalar. This property applies when you set the Method on page 3-0 property to Takeshita-Costello. The default is 13.

CyclicShift

Amount of cyclic shift

Specify the amount by which the object shifts indices, when it creates the final permutation vector, as a nonnegative, integer, scalar. This property applies when you set the Method on page 3-0 property to Takeshita-Costello. The default is 0.

PrimitiveElement

Primitive element

Specify the primitive element as an element of order N in the finite field $GF(N+1)$. N is the value you specify in the Length property. You can express every nonzero element of $GF(N+1)$ as the value of the PrimitiveElement property raised to an integer power. In a Welch-Costas interleaver, the permutation maps the integer k to $\mathrm{mod}(A^k,N+1)-1$, where A represents the value of the PrimitiveElement property. This property applies when you set the Method property to Welch-Costas. The default is 6.

(To be removed) Permute input symbols using an algebraically derived permutation vector

Compatibility

step will be removed in a future release. Use `algintrlv` instead.

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` permutes input sequence, `X`, and returns interleaved sequence, `Y`. The object uses an algebraically derived permutation vector, based on the algebraic method you specify in the Method property, to form the output. The input `X` must be a column vector of length specified by the Length property. `X` can be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.APPDecoder

Decode convolutional code by using APP method

Description

The `APPDecoder` system object performs a posteriori probability (APP) decoding of a convolutional code.

To decode convolutional code by using APP method:

1. Create the `comm.APPDecoder` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
appDec = comm.APPDecoder
appDec = comm.APPDecoder(Name,Value)
appDec = comm.APPDecoder(trellis,Name,Value)
```

Description

`appDec = comm.APPDecoder` creates an APP decoder System object, `appDec`, that decodes a convolutional code using the APP method.

`appDec = comm.APPDecoder(Name,Value)` sets properties using one or more name-value pairs. For example, `comm.APPDecoder('Algorithm','True APP')` configures the System object, `appDec`, to implement true a posteriori probability decoding. Enclose each property name in quotes.

`appDec = comm.APPDecoder(trellis,Name,Value)` creates an APP decoder object, `appDec`, with the TrellisStructure property set to `trellis`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`TrellisStructure` — Trellis description of constituent convolutional code
`poly2trellis(7,[171 133],171)` (default) | structure

Trellis description, specified as a MATLAB structure that contains the trellis description for a rate *K*/*N* code. *K* represents the number of input bit streams, and *N* represents the number of output bit streams.

You can either use the `poly2trellis` function to create the trellis structure or create it manually. For more about this structure, see “Trellis Description of a Convolutional Code” and the `istrellis` function.

The trellis structure contains these fields.

`numInputSymbols` — Number of symbols input to encoder
2^K

Number of symbols input to the encoder, specified as an integer equal to 2^K, where *K* is the number of input bit streams.

Data Types: `double`

`numOutputSymbols` — Number of symbols output from encoder
2^N

Number of symbols output from the encoder, specified as an integer equal to 2^N, where *N* is the number of output bit streams.

Data Types: `double`

`numStates` — Number of states in encoder
power of 2

Number of states in the encoder, specified as a power of 2.

Data Types: `double`

`nextStates` — Next states
matrix of integers

Next states for all combinations of current states and current inputs, specified as a matrix of integers. The matrix size must be `numStates`-by-2^K.

Data Types: `double`

`outputs` — Outputs
matrix of octal numbers

Outputs for all combinations of current states and current inputs, specified as a matrix of octal numbers. The matrix size must be `numStates`-by-2^K.

Data Types: `double`

Data Types: `struct`

`TerminationMethod` — Termination method of encoded frame
`'Truncated'` (default) | `'Terminated'`

Termination method of encoded frame, specified as `'Truncated'` or `'Terminated'`. When you set this property to `'Truncated'`, this System object assumes that the encoder stops after encoding the last symbol in the input frame. When you set this property to `'Terminated'`, this System object assumes that the encoder forces the trellis to end each frame in the all-zeros state by encoding additional symbols. If you use the `comm.ConvolutionalEncoder` System object to generate the encoded frame, this property value must match the property value of the convolutional encoder and this System object.

Data Types: `char` | `string`

`Algorithm` — Decoding algorithm
`'Max*'` (default) | `'True APP'` | `'Max'`

Decoding algorithm, specified as `'Max*'`, `'True APP'`, or `'Max'`. When you set this property to `'True APP'`, this System object implements true APP decoding. When you set this property to any other value, this System object uses approximations to increase the speed of the computations. For more information, see "Algorithms" on page 3-43.

Data Types: `char` | `string`

`NumScalingBits` — Number of scaling bits
`3` (default) | integer in the range [0, 8]

Number of scaling bits, specified as an integer in the range [0, 8]. This property specifies the number of bits the decoder uses to scale the input data to avoid losing precision during the computations.

Dependencies

To enable this property, set the "Algorithm" on page 3-0 property to `'Max*'`.

Data Types: `double`

`CodedBitLLROutputPort` — Option to enable coded-bit log-likelihood ratio output
`true or 1` (default) | `false or 0`

Option to enable coded-bit log-likelihood ratio (LLR) output, specified as a numeric or logical `1` (`true`) or `0` (`false`). To disable the second output when you call this System object, set this property to `0` (`false`).

Data Types: `logical`

Usage

Syntax

```
[LUD,LCD] = appDec(LU,LC)
LUD = appDec(LU,LC)
```

Description

`[LUD,LCD] = appDec(LU,LC)` performs APP decoding on the sequence of LLRs of encoder input bits, `LU`, and the sequence of LLRs of encoded bits, `LC`. The System object returns `LUD` and `LCD`. These output values are the updated versions of `LU` and `LC`, respectively, and are obtained based on the encoder information.

`LUD = appDec(LU,LC)` performs APP decoding with the `LCD` output disabled. To disable the `LCD` output, set the "CodedBitLLROutputPort" on page 3-0 property to `0` (`false`).

Input Arguments

LU — Sequence of LLRs of encoder input data

real-valued column vector

Sequence of LLRs of encoder input data, specified as a real-valued column vector. A positive soft input is interpreted as a logical `1`, and a negative soft input is interpreted as a logical `0`.

Data Types: `single` | `double`

LC — Sequence of LLRs of encoded data

real-valued column vector

Sequence of LLRs of encoded data, specified as a real-valued column vector of. A positive soft input is interpreted as a logical `1`, and a negative soft input is interpreted as a logical `0`.

Data Types: `single` | `double`

Output Arguments

LUD — Updated value of LU

real-valued column vector

Updated value of LU, returned as a real-valued column vector.

Data Types: `single` | `double`

LCD — Updated value of LC

real-valued column vector

Updated value of LC, returned as a real-valued column vector.

Data Types: `single` | `double`

Note If the convolutional code uses an alphabet of 2^n possible symbols, where n is the number of bits per input symbol, then the `LC` and `LCD` vector lengths are $L \times n$ for some positive integer L. Similarly, if the decoded data uses an alphabet of 2^k output symbols, where k is the number of bits per output symbol, then the `LU` and `LUD` vector lengths are $L \times k$.

This System object accepts a column vector input signal with any positive integer value for L. For variable-sized inputs, L can vary during multiple calls.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Decode Convolutional Code Using the APP Decoder

Specify noise variance and the frame length in bits. Create convolutional encoder, PSK modulator, and AWGN channel System objects.

```
noiseVar = 2e-1;
frameLength = 300;
convEncoder = comm.ConvolutionalEncoder('TerminationMethod','Truncated');
pskMod = comm.PSKModulator('BitInput',true,'PhaseOffset',0);
awgnChan = comm.AWGNChannel('NoiseMethod','Variance', ...
    'Variance',noiseVar);
```

Create convolutional APP decoder, PSK demodulator, and error rate System objects.

```
appDecoder = comm.APPDecoder(...
    'TrellisStructure',poly2trellis(7,[171 133]), ...
    'Algorithm','True APP','CodedBitLLROutputPort',false);
pskDemod = comm.PSKDemodulator('BitOutput',true,'PhaseOffset',0, ...
    'DecisionMethod','Approximate log-likelihood ratio', ...
    'Variance',noiseVar);
errRate = comm.ErrorRate;
```

Transmit a convolutionally encoded 8-PSK-modulated bit stream through an AWGN channel. Demodulate the received signal using soft-decision. Decode the demodulated signal using the APP decoder.

```
for counter = 1:5
     data = randi([0 1],frameLength,1);
     encodedData = convEncoder(data);
     modSignal = pskMod(encodedData);
     receivedSignal = awgnChan(modSignal);
     demodSignal = pskDemod(receivedSignal);
     % The APP decoder assumes a polarization of the soft inputs that is
     % inverse to that of the demodulator soft outputs. Change the sign of
     % demodulated signal.
     receivedSoftBits = appDecoder(zeros(frameLength,1),-demodSignal);
     % Convert from soft-decision to hard-decision.
     receivedBits = double(receivedSoftBits > 0);
     % Count errors
     errorStats = errRate(data,receivedBits);
end
```

Display the error rate information.

```
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
     errorStats(1), errorStats(2))
```

```
Error rate = 0.000000
Number of errors = 0
```

Algorithms

This System object implements the soft-input-soft-output APP decoding algorithm according to [1] and [2].

The `'True APP'` option of the `Algorithm` property implements APP decoding as per the equations 20–23 in section V of [1]. To gain speed, the `'Max*'` and `'Max'` values of the `Algorithm` property approximate expressions like $\log\sum_i \exp(a_i)$ by other quantities. The `'Max'` option uses $\max(a_i)$ as the approximation. The `'Max*'` option uses $\max(a_i)$ plus a correction term given by the expression $\ln(1 + \exp(-|a_{i-1} - a_i|))$.

Setting the `Algorithm` property to `'Max*'` enables the `NumScalingBits` property of this System object. This property denotes the number of bits by which this System object scales the data it processes internally (multiplies the input by $2^{\texttt{NumScalingBits}}$ and divides the pre-output by the same factor). Use this property to avoid losing precision during computations.

arrayConfig

Phased array configuration object

Description

The `arrayConfig` object sets phased array configuration properties. Use an `arrayConfig` object to configure a uniform rectangular array (URA) with isotropic antenna elements, a uniform linear array (ULA) with isotropic antenna elements, or a single isotropic antenna element.

Creation

Syntax

```
cfgArray = arrayConfig
cfgArray = arrayConfig(Name,Value)
```

Description

`cfgArray = arrayConfig` creates a configuration object with default property values. The *x*-axis is normal to the plane on which the elements are placed. The default array is a 2-by-2 URA with an element spacing of 0.5 meter.

`cfgArray = arrayConfig(Name,Value)` sets properties using one or more name-value pair arguments. Enclose each property name in quotes. For example, `arrayConfig('Size',[8 1],'ElementSpacing',0.1)` specifies an eight-element ULA along the *z*-axis with an element spacing of 0.1 meter.

Properties

`Element` — Array element
`'isotropic'` (default)

This property is read-only.

Array element, returned as `'isotropic'`. Array elements are isotropic radiators.

Data Types: `char` | `string`

`Size` — Antenna array size
`[2 2]` (default) | two-element row vector of positive integers

Antenna array size, specified as a two-element row vector of positive integers. The first element specifies the number of rows of the antenna array and the second element specifies the number of columns of the antenna array. The rows of the array are along the *z*-axis. The columns of the array are along the *y*-axis.

- When both elements of this vector are greater than 1, the array is a URA.

- When one element of this vector is 1, the array is a ULA.
- When both elements of this vector are 1, the array is a single isotropic element.

Array elements are indexed from top to bottom along a column, continuing to the next column from left to right. For more information, see “Array Alignment” on page 3-47.

Data Types: `double`

`ElementSpacing` — Antenna array element spacing
`0.5` (default) | positive scalar | two-element row vector

Antenna array element spacing in meters, specified as one of these values.

- A positive scalar — This value specifies the spacing between rows and the spacing between columns of the antenna array.
- A two-element vector of positive values — The first element of the vector specifies the spacing between rows of the antenna array. The second element specifies the spacing between columns of the antenna array.

The rows of the array are along the *z*-axis, and the columns of the array are along the *y*-axis. For more information, see “Array Alignment” on page 3-47.

Dependencies

To enable this property, set at least one element in the `Size` property vector to a value greater than `1`.

Data Types: `double`

Examples

Configure 4-by-4 URA

Configure a 4-by-4 URA with an element spacing of 0.1 meter along rows and 0.2 meter along columns.

```
cfgArray = arrayConfig("Size",[4 4],"ElementSpacing",[0.1 0.2])
```

```
cfgArray = 
  arrayConfig with properties:

           Element: 'isotropic'
              Size: [4 4]
    ElementSpacing: [0.1000 0.2000]
```

Configure Eight-Element ULA for Transmitter Site

Configure an eight-element ULA along the *z*-axis with an element spacing of 0.1 meter.

```
cfgArray = arrayConfig("Size",[8 1],"ElementSpacing",0.1);
```

Assign the array to a transmitter site and display the antenna pattern.

```
tx = txsite("Antenna",cfgArray);
pattern(tx,'Size',6);
```

More About

Array Alignment

Array elements are indexed from top to bottom along a column, continuing to the next column from left to right. The spacing between columns is the distance between adjacent elements in the same row. The spacing between rows is the distance between elements in the same column.

This illustration shows orientation and spacing between rows and columns for a URA of size 3-by-2. The array has three rows and two columns.

comm.AWGNChannel

Package: `comm`

Add white Gaussian noise to input signal

Description

comm.AWGNChannel adds white Gaussian noise to the input signal.

When applicable, if inputs to the object have a variable number of channels, the EbNo, EsNo, SNR, BitsPerSymbol, SignalPower, SamplesPerSymbol, and Variance properties must be scalars.

To add white Gaussian noise to an input signal:

1. Create the `comm.AWGNChannel` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
awgnchan = comm.AWGNChannel
awgnchan = comm.AWGNChannel(Name,Value)
```

Description

`awgnchan = comm.AWGNChannel` creates an additive white Gaussian noise (AWGN) channel System object, `awgnchan`. This object then adds white Gaussian noise to a real or complex input signal.

`awgnchan = comm.AWGNChannel(Name,Value)` creates a AWGN channel object, `awgnchan`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`NoiseMethod` — Noise level method
`'Signal to noise ratio (Eb/No)'` (default) | `'Signal to noise ratio (Es/No)'` | `'Signal to noise ratio (SNR)'` | `'Variance'`

Noise level method, specified as `'Signal to noise ratio (Eb/No)'`, `'Signal to noise ratio (Es/No)'`, `'Signal to noise ratio (SNR)'`, or `'Variance'`. For more information, see Specifying the Variance Directly or Indirectly on page 3-68.

Data Types: `char`

`EbNo` — Ratio of energy per bit to noise power spectral density
`10` (default) | scalar | row vector

Ratio of energy per bit to noise power spectral density (Eb/No) in decibels, specified as a scalar or 1-by-N_C vector. N_C is the number of channels.

Tunable: Yes

Dependencies

This property applies when NoiseMethod is set to `'Signal to noise ratio (Eb/No)'`.

Data Types: `double`

`EsNo` — Ratio of energy per symbol to noise power spectral density
`10` (default) | scalar | row vector

Ratio of energy per symbol to noise power spectral density (Es/No) in decibels, specified as a scalar or 1-by-N_C vector. N_C is the number of channels.

Tunable: Yes

Dependencies

This property applies when NoiseMethod is set to `'Signal to noise ratio (Es/No)'`.

Data Types: `double`

`SNR` — Ratio of signal power to noise power
`10` (default) | scalar | row vector

Ratio of signal power to noise power in decibels, specified as a scalar or 1-by-N_C vector. N_C is the number of channels.

Tunable: Yes

Dependencies

This property applies when NoiseMethod is set to `'Signal to noise ratio (SNR)'`.

Data Types: `double`

`BitsPerSymbol` — Number of bits per symbol
`1` (default) | positive integer

Number of bits per symbol, specified as a positive integer.

Dependencies

This property applies when NoiseMethod is set to `'Signal to noise ratio (Eb/No)'`.

Data Types: `double`

`SignalPower` — Input signal power

1 (default) | positive scalar | row vector

Input signal power in watts, specified as a positive scalar or 1-by-N_C vector. N_C is the number of channels. The object assumes a nominal impedance of 1 Ω.

Tunable: Yes

Dependencies

This property applies when NoiseMethod is set to `'Signal to noise ratio (Eb/No)'`, `'Signal to noise ratio (Es/No)'`, or `'Signal to noise ratio (SNR)'`.

Data Types: `double`

`SamplesPerSymbol` — Number of samples per symbol

1 (default) | positive integer | row vector

Number of samples per symbol, specified as a positive integer or 1-by-N_C vector. N_C is the number of channels.

Dependencies

This property applies when NoiseMethod is set to `'Signal to noise ratio (Eb/No)'` or `'Signal to noise ratio (Es/No)'`.

Data Types: `double`

`VarianceSource` — Source of noise variance

`'Property'` (default) | `'Input port'`

Source of noise variance, specified as `'Property'` or `'Input port'`.

- Set `VarianceSource` to `'Property'` to specify the noise variance value using the Variance property.
- Set `VarianceSource` to `'Input port'` to specify the noise variance value using an input to the object, when you call it as a function.

For more information, see Specifying the Variance Directly or Indirectly on page 3-68.

Dependencies

This property applies when NoiseMethod is `'Variance'`.

Data Types: `char`

`Variance` — White Gaussian noise variance

1 (default) | positive scalar | row vector

White Gaussian noise variance, specified as a positive scalar or 1-by-N_C vector. N_C is the number of channels.

Tunable: Yes

Dependencies

This property applies when NoiseMethod is set to `'Variance'` and VarianceSource is set to `'Property'`.

Data Types: double

RandomStream — Source of random number stream
'Global stream' (default) | 'mt19937ar with seed'

Source of random number stream, specified as 'Global stream' or 'mt19937ar with seed'.

- When you set RandomStream to 'Global stream', the object uses the MATLAB default random stream to generate random numbers. To generate reproducible numbers using this object, you can reset the MATLAB default random stream. For example reset(RandStream.getGlobalStream). For more information, see RandStream.
- When you set RandomStream to 'mt19937ar with seed', the object uses the mt19937ar algorithm for normally distributed random number generation. In this scenario, when you call the reset function, the object reinitializes the random number stream to the value of the Seed property. You can generate reproducible numbers by resetting the object.

For a complex input signal, the object creates the random data as follows:

noise = randn(N_S,N_C)+1i(randn(N_S,N_C))

N_S is the number of samples and N_C is the number of channels.

Dependencies

This property applies when NoiseMethod is set to 'Variance'.

Data Types: char

Seed — Initial seed
67 (default) | nonnegative integer

Initial seed of the mt19937ar random number stream, specified as a nonnegative integer. For each call to the reset function, the object reinitializes the mt19937ar random number stream to the Seed value.

Dependencies

This property applies when RandomStream is set to 'mt19937ar with seed'.

Data Types: double

Usage

Syntax

```
outsignal = awgnchan(insignal)
outsignal = awgnchan(insignal,var)
```

Description

outsignal = awgnchan(insignal) adds white Gaussian noise, as specified by awgnchan, to the input signal. The result is returned in outsignal.

outsignal = awgnchan(insignal,var) specifies the variance of the white Gaussian noise. This syntax applies when you set the NoiseMethod to 'Variance' and VarianceSource to 'Input port'.

For example:

```
awgnchan = comm.AWGNChannel('NoiseMethod','Variance', ...
     'VarianceSource','Input port');
var = 12;
...
outsignal = awgnchan(insignal,var);
```

Input Arguments

`insignal` — Input signal
scalar | vector | matrix

Input signal, specified as a scalar, an N_S-element vector, or an N_S-by-N_C matrix. N_S is the number of samples and N_C is the number of channels.

Data Types: `double`
Complex Number Support: Yes

`var` — Variance of additive white Gaussian noise
positive scalar | row vector

Variance of additive white Gaussian noise, specified as a positive scalar or 1-by-N_C vector. N_C is the number of channels, as determined by the number of columns in the input signal matrix.

Output Arguments

`outsignal` — Output signal
matrix

Output signal, returned with the same dimensions as `insignal`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Create Default AWGN Channel System Object

Create an AWGN channel System object with the default configuration. Pass signal data through this channel.

Create an AWGN channel object and signal data.

```
awgnchan = comm.AWGNChannel;
insignal = randi([0 1],100,1);
```

Send the input signal through the channel.

```
outsignal = awgnchan(insignal);
```

Add White Gaussian Noise to 8-PSK Signal

Modulate an 8-PSK signal, add white Gaussian noise, and plot the signal to visualize the effects of the noise.

Create a M-PSK modulator System object™. The default modulation order for the object is 8.

```
pskModulator = comm.PSKModulator;
```

Modulate the signal.

```
modData = pskModulator(randi([0 7],2000,1));
```

Add white Gaussian noise to the modulated signal by passing the signal through an additive white Gaussian noise (AWGN) channel.

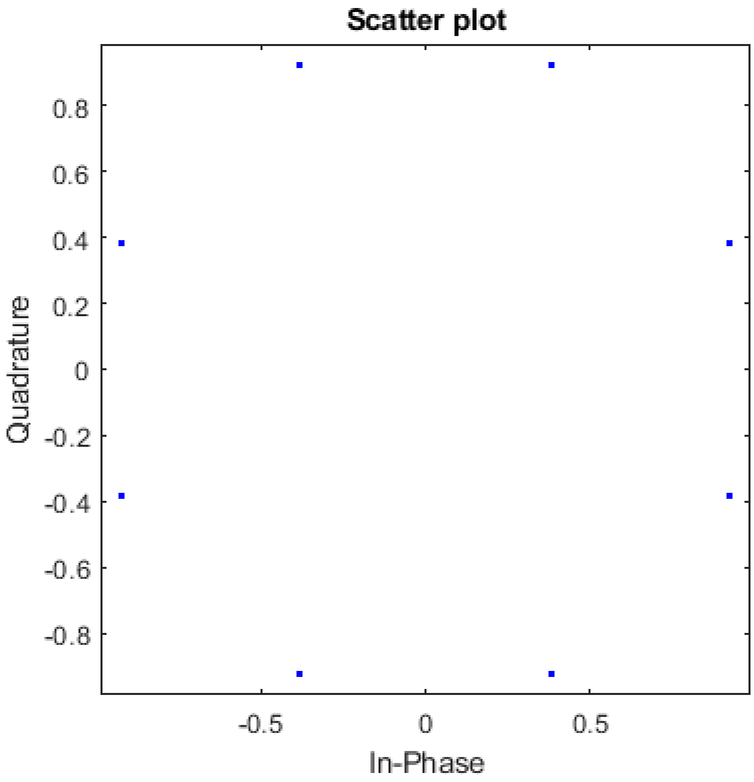
```
channel = comm.AWGNChannel('EbNo',20,'BitsPerSymbol',3);
```

Transmit the signal through the AWGN channel.

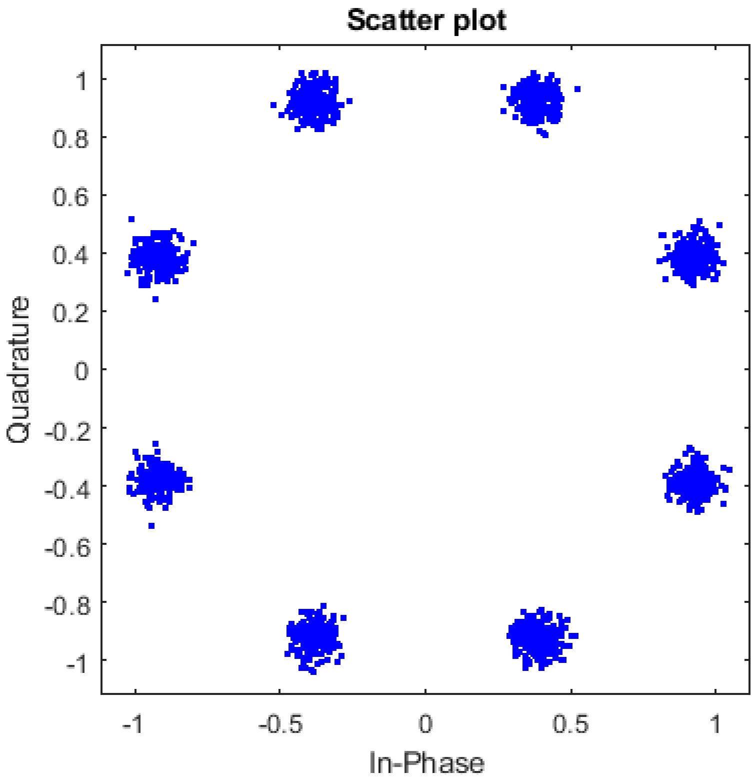
```
channelOutput = channel(modData);
```

Plot the noiseless and noisy data by using scatter plots to visualize the effects of the noise.

```
scatterplot(modData)
```



```
scatterplot(channelOutput)
```



Change the `EbNo` property to 10 dB to increase the noise.

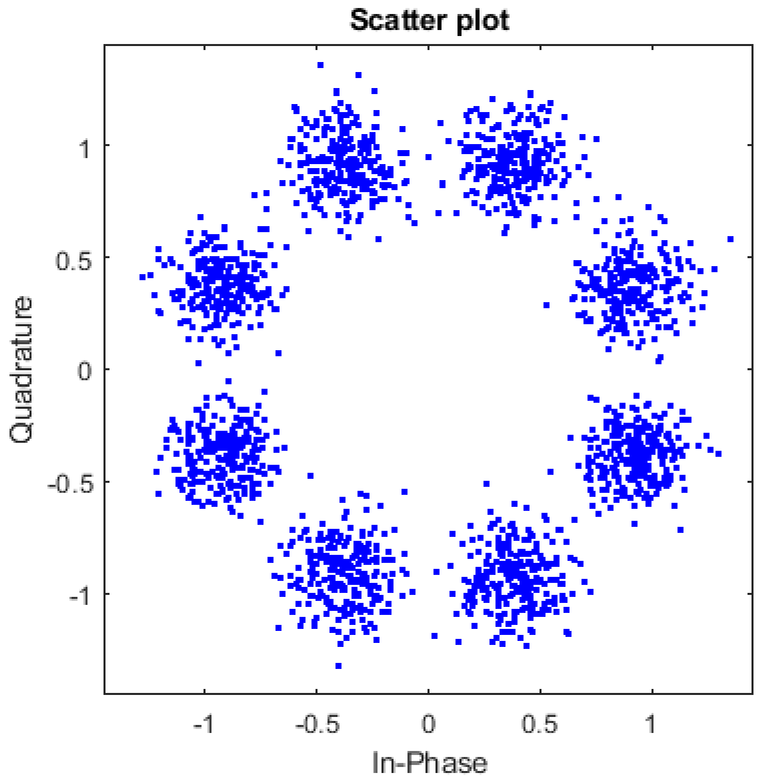
```
channel.EbNo = 10;
```

Pass the modulated data through the AWGN channel.

```
channelOutput = channel(modData);
```

Plot the channel output. You can see the effects of increased noise.

```
scatterplot(channelOutput)
```



Process Signals When Number of Channels Changes

Pass a single-channel and multichannel signal through an AWGN channel System object™.

Create an AWGN channel System object with the Eb/No ratio set for a single channel input. In this case, the EbNo property is a scalar.

```
channel = comm.AWGNChannel('EbNo',15);
```

Generate random data and apply QPSK modulation.

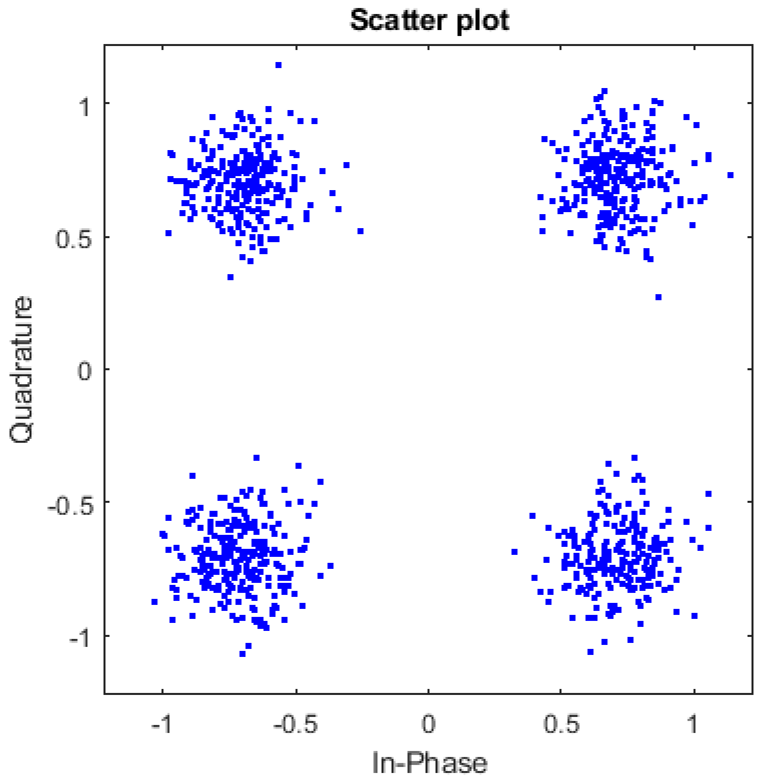
```
data = randi([0 3],1000,1);
modData = pskmod(data,4,pi/4);
```

Pass the modulated data through the AWGN channel.

```
rxSig = channel(modData);
```

Plot the noisy constellation.

```
scatterplot(rxSig)
```



Generate two-channel input data and apply QPSK modulation.

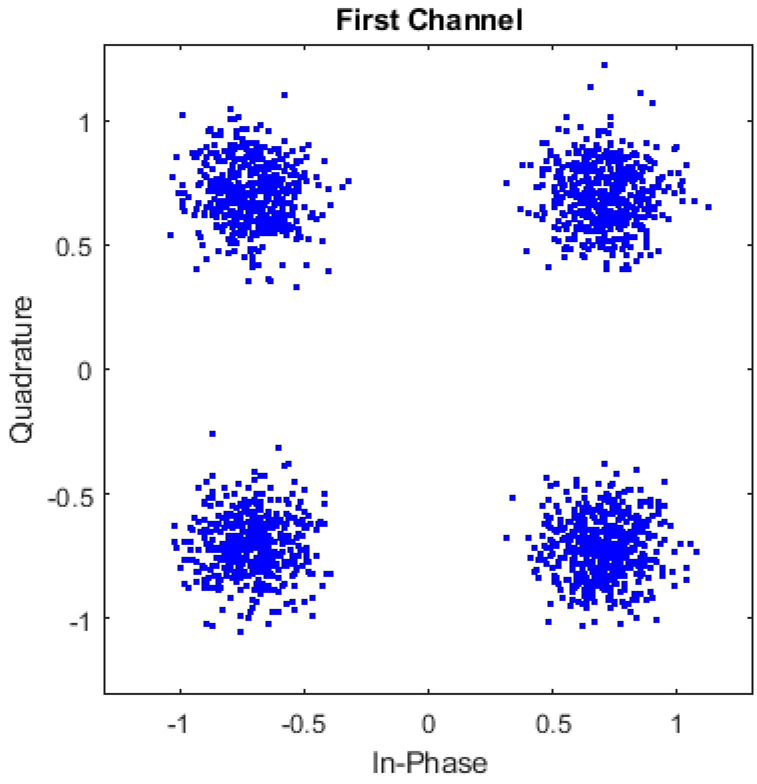
```
data = randi([0 3],2000,2);
modData = pskmod(data,4,pi/4);
```

Pass the modulated data through the AWGN channel.

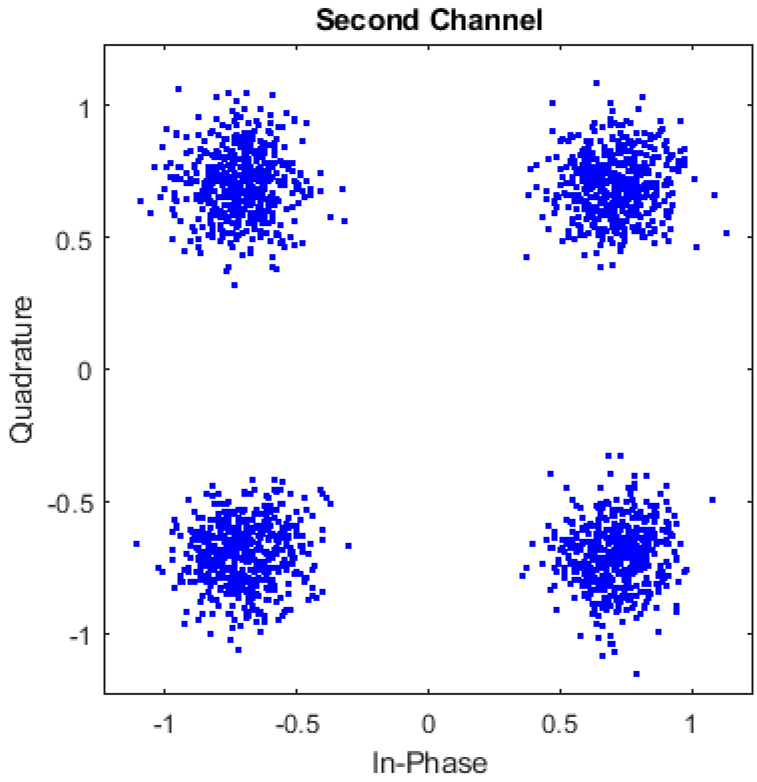
```
rxSig = channel(modData);
```

Plot the noisy constellations. Each channel is represented as a single column in `rxSig`. The plots are nearly identical, because the same Eb/No value is applied to both channels.

```
scatterplot(rxSig(:,1))
title('First Channel')
```



```
scatterplot(rxSig(:,2))
title('Second Channel')
```



Modify the AWGN channel object to apply a different Eb/No value to each channel. To apply different values, set the `EbNo` property to a 1-by-2 vector. When changing the dimension of the `EbNo` property, you must release the AWGN channel object.

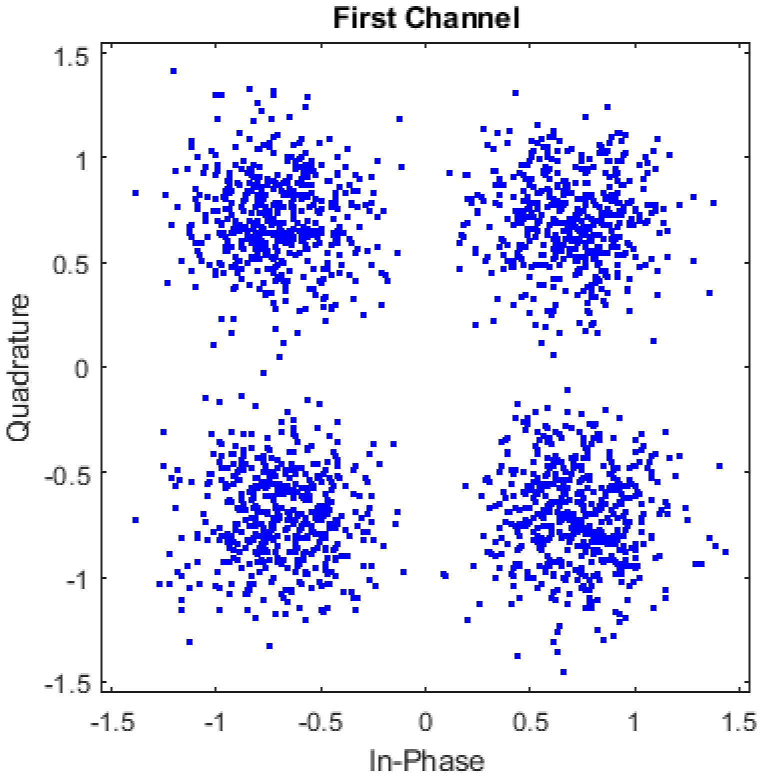
```
release(channel)
channel.EbNo = [10 20];
```

Pass the data through the AWGN channel.

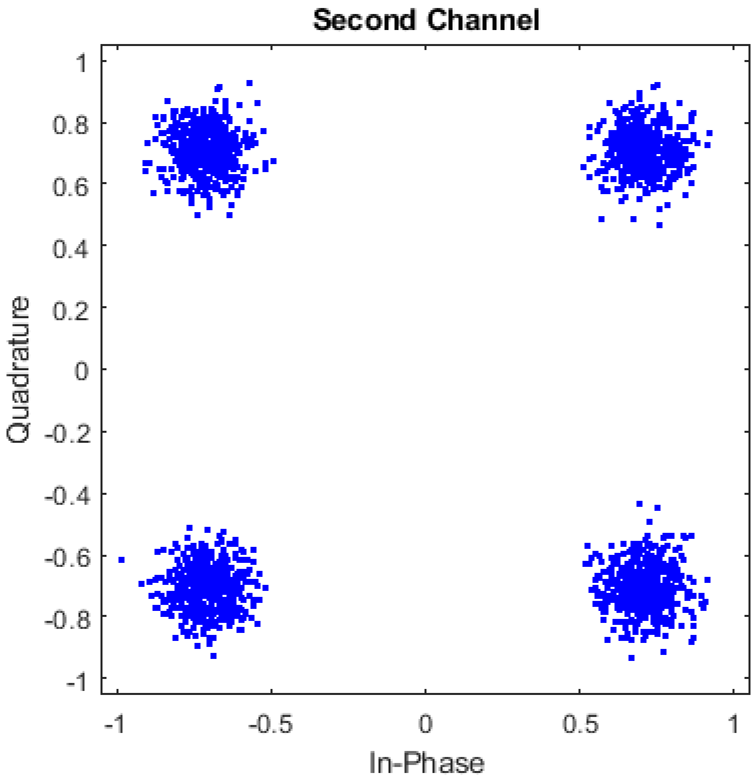
```
rxSig = channel(modData);
```

Plot the noisy constellations. The first channel has significantly more noise due to its lower Eb/No value.

```
scatterplot(rxSig(:,1))
title('First Channel')
```



```
scatterplot(rxSig(:,2))
title('Second Channel')
```



Add AWGN Using Noise Variance Input Port

Apply the noise variance input as a scalar or a row vector, with a length equal to the number of channels of the current signal input.

Create an AWGN channel System object™ with the `NoiseMethod` property set to '`Variance`' and the `VarianceSource` property set to '`Input port`'.

```
channel = comm.AWGNChannel('NoiseMethod','Variance', ...
'VarianceSource','Input port');
```

Generate random data for two channels and apply 16-QAM modulation.

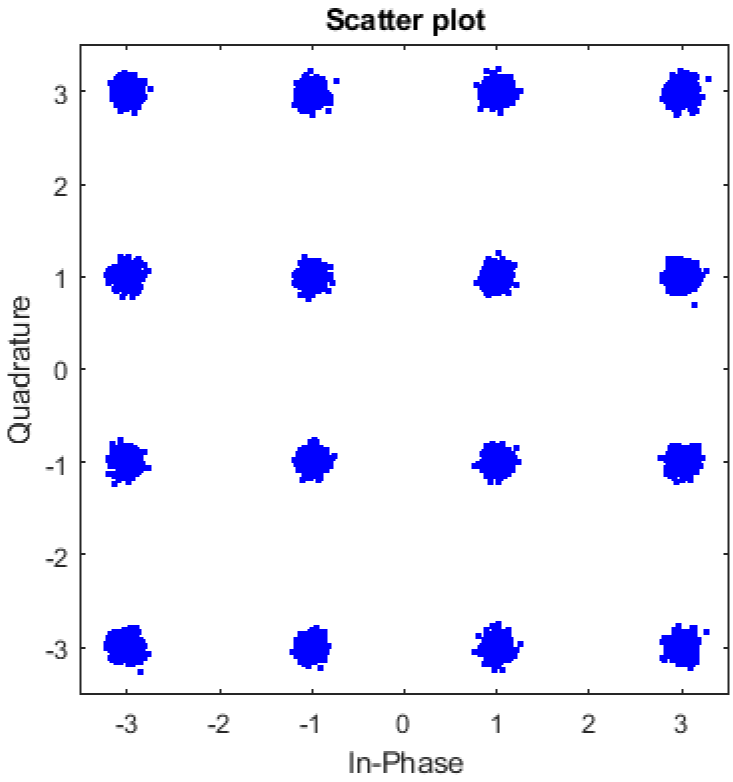
```
data = randi([0 15],10000,2);
txSig = qammod(data,16);
```

Pass the modulated data through the AWGN channel. The AWGN channel object processes data from two channels. The variance input is a 1-by-2 vector.

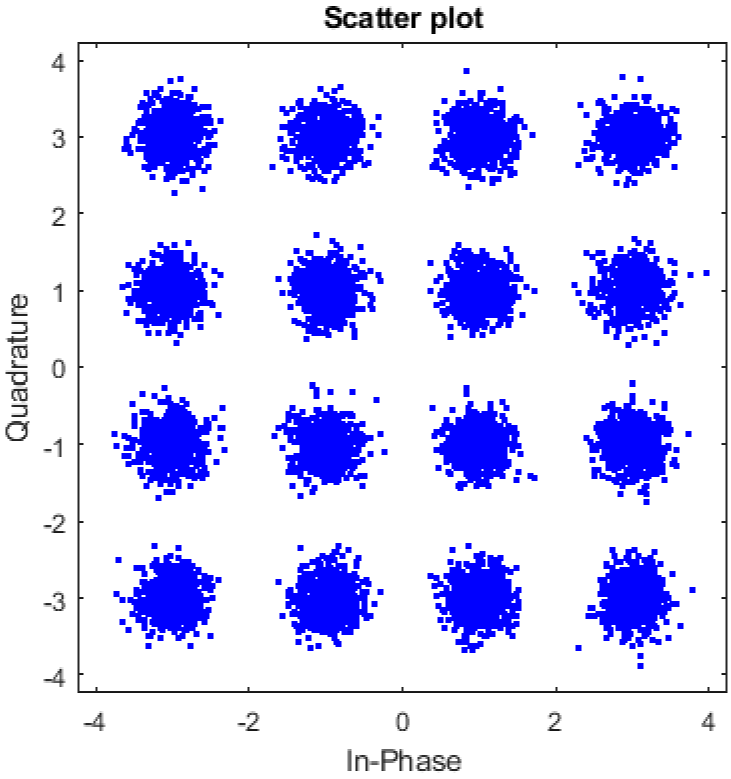
```
rxSig = channel(txSig,[0.01 0.1]);
```

Plot the constellation diagrams for the two channels. The second signal is noisier because its variance is ten times larger.

```
scatterplot(rxSig(:,1))
```

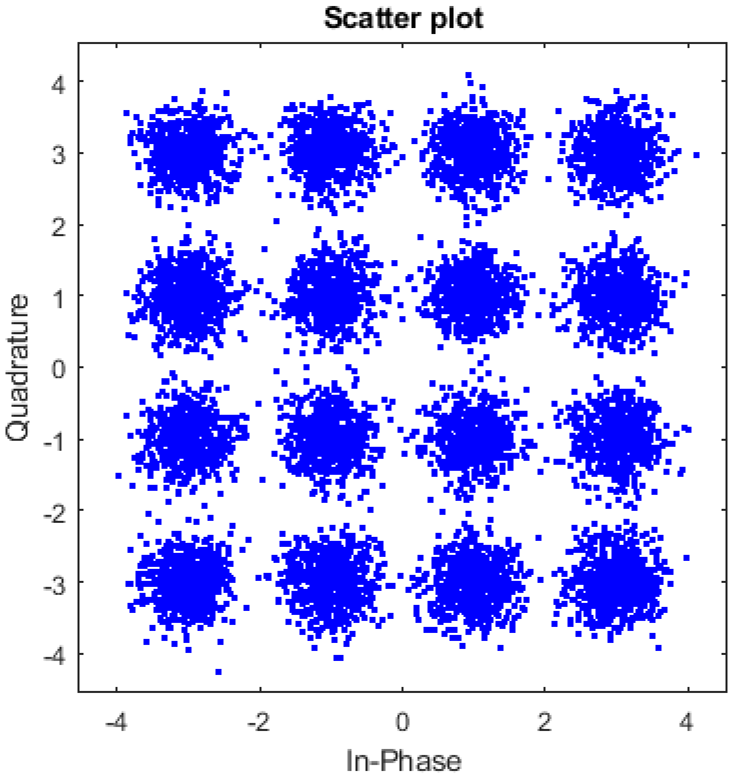


```
scatterplot(rxSig(:,2))
```

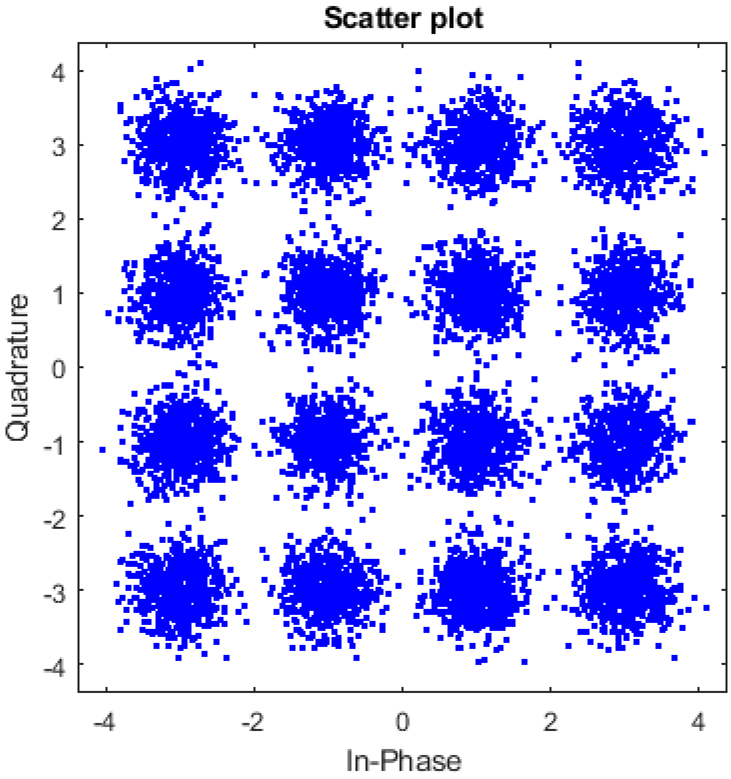


Repeat the process where the noise variance input is a scalar. The same variance is applied to both channels. The constellation diagrams are nearly identical.

```
rxSig = channel(txSig,0.2);
scatterplot(rxSig(:,1))
```



```
scatterplot(rxSig(:,2))
```



Set Random Number Seed for Repeatability

Specify a seed to produce the same outputs when using a random stream in which you specify the seed.

Create an AWGN channel System object™. Set the `NoiseMethod` property to `'Variance'`, the `RandomStream` property to `'mt19937ar with seed'`, and the `Seed` property to `99`.

```
channel = comm.AWGNChannel( ...
    'NoiseMethod','Variance', ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',99);
```

Pass data through the AWGN channel.

```
y1 = channel(zeros(8,1));
```

Pass another all-zeros vector through the channel.

```
y2 = channel(zeros(8,1));
```

Because the seed changes between function calls, the output is different.

```
isequal(y1,y2)
```

```
ans = logical
   0
```

Reset the AWGN channel object by calling the `reset` function. The random data stream is reset to the initial seed of `99`.

```
reset(channel);
```

Pass the all-zeros vector through the AWGN channel.

```
y3 = channel(zeros(8,1));
```

Confirm that the two signals are identical.

```
isequal(y1,y3)
```

```
ans = logical
   1
```

Algorithms

Relationship Among Eb/No, Es/No, and SNR Modes

For uncoded complex input signals, comm.AWGNChannel relates $E_b/N_{0,}$ E_s/N_0, and SNR according to these equations:

$E_s/N_0 = N_{sps} \times SNR$

$E_s/N_0 = E_b/N_0 + 10\log_{10}(k)$ in dB

where

- E_s represents the signal energy in joules.
- E_b represents the bit energy in joules.
- N_0 represents the noise power spectral density in watts/Hz.
- N_{sps} represents the number of samples per symbol, SamplesPerSymbol.
- k represents the number of information bits per input symbol, BitsPerSymbol.

For real signal inputs, the comm.AWGNChannel relates E_s/N_0 and SNR according to this equation:

$E_s/N_0 = 0.5\ (N_{sps}) \times SNR$

Note

- All values of power assume a nominal impedance of 1 ohm.
- The equation for the real case differs from the corresponding equation for the complex case by a factor of 2. Specifically, the object uses a noise power spectral density of $N_0/2$ watts/Hz for real input signals, versus N_0 watts/Hz for complex signals.

For more information, see AWGN Channel Noise Level.

Specifying the Variance Directly or Indirectly

To directly specify the variance of the noise generated by comm.AWGNChannel, specify VarianceSource as:

- `'Property'`, then set NoiseMethod to `'Variance'` and specify the variance with the Variance property.
- `'Input port'` then specify the variance level for the object as an input with an input argument, var.

To specify variance indirectly, that is, to have it calculated by comm.AWGNChannel, specify VarianceSource as `'Property'` and the NoiseMethod as:

- `'Signal to noise ratio (Eb/No)'`, where the object uses these properties to calculate the variance:
  - EbNo, the ratio of bit energy to noise power spectral density
  - BitsPerSymbol
  - SignalPower, the actual power of the input signal samples
  - SamplesPerSymbol
- `'Signal to noise ratio (Es/No)'`, where the object uses these properties to calculate the variance:
  - EsNo, the ratio of signal energy to noise power spectral density
  - SignalPower, the actual power of the input signal samples
  - SamplesPerSymbol
- `'Signal to noise ratio (SNR)'`, where the object uses these properties to calculate the variance:
  - SNR, the ratio of signal power to noise power
  - SignalPower, the actual power of the input signal samples

Changing the number of samples per symbol (SamplesPerSymbol) affects the variance of the noise added per sample, which also causes a change in the final error rate.

$$NoiseVariance = \text{SignalPower} \times \text{SamplesPerSymbol} / 10^{(\text{EsNo})/10}$$

Tip Select the number of samples per symbol based on what constitutes a symbol and the oversampling applied to it. For example, a symbol could have 3 bits and be oversampled by 4. For more information, see AWGN Channel Noise Level.

comm.BarkerCode

Package: `comm`

Generate bipolar Barker code

Description

The `comm.BarkerCode` System object generates a bipolar Barker code. Barker codes have low autocorrelation properties. The short length and low correlation sidelobes make Barker codes useful for frame synchronization in digital communications systems. For more information, see "Barker Codes" on page 3-73.

To generate a Barker code:

1. Create the `comm.BarkerCode` object and set its properties.
2. Call the object, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
barkerCode = comm.BarkerCode
barkerCode = comm.BarkerCode(Name,Value)
```

Description

`barkerCode = comm.BarkerCode` creates a bipolar Barker code generator System object to generate a Barker code.

`barkerCode = comm.BarkerCode(Name,Value)` sets properties using one or more name-value pairs. For example, `comm.BarkerCode('Length',11,'SamplesPerFrame','11')` configures a bipolar Barker code generator System object to output a length 11 Barker code in an 11-sample frame. Enclose each property name in quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Length` — Length of generated code
7 (default) | 1 | 2 | 3 | 4 | 5 | 11 | 13

Length of the generated code, specified as `1`, `2`, `3`, `4`, `5`, `7`, `11`, or `13`. For more information, see "Barker Codes" on page 3-73.

Example: `'Length',2` outputs the Barker code [–1;1].

Data Types: `double`

`SamplesPerFrame` — Samples per output frame
`1` (default) | positive integer

Samples per output frame, specified as a positive integer. If `SamplesPerFrame` is *M*, the object outputs a frame containing *M* samples comprised of length *N* Barker code sequences. If necessary, the object repeats the code sequence to reach *M* samples. *N* is the length of the generated code, which is set by the `Length` property.

Data Types: `double`

`OutputDataType` — Output data type
`double` (default) | `int8`

Output data type, specified as `double` or `int8`.

Data Types: `char` | `string`

Usage

Note For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Syntax

```
y = barkerCode
```

Description

`y = barkerCode` outputs a Barker code frame, as a column vector. If the frame length exceeds the Barker code length, the object fills the frame by repeating the Barker code.

Set the data type of the output with the `OutputDataType` property.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.BarkerCode`

clone	Create duplicate System object
isLocked	Determine if System object is in use

Common to All System Objects

step Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics

reset Reset internal states of System object

Examples

Generate Barker Code Sequence

Create a Barker code System object with 10 samples per frame.

```
barker = comm.BarkerCode('SamplesPerFrame',10)
```

```
barker = 
  comm.BarkerCode with properties:

              Length: 7
     SamplesPerFrame: 10
      OutputDataType: 'double'
```

Generate multiple frames by using the default Barker code sequence of length 7. The code wraps within the frame and continues in the next frame.

```
for ii = 1:2
    seq = barker()
end
```

```
seq = 10×1

    -1
    -1
    -1
     1
     1
    -1
     1
    -1
    -1
    -1

seq = 10×1

     1
     1
    -1
     1
    -1
    -1
    -1
     1
     1
    -1
```

Compute Barker Code Sidelobe Level

Compute the peak sidelobe level for each Barker code.

```
CodeLength = [1 2 3 4 5 7 11 13]';
psl = zeros(length(CodeLength),1);
ac = dsp.Autocorrelator;
barker = comm.BarkerCode;
for ii=1:length(CodeLength)
    spf = CodeLength(ii);
    barker.Length = CodeLength(ii);
    barker.SamplesPerFrame = spf;
    seq = barker();
    sll_dB = 20*log10(abs(ac(seq)));
    psl(ii) = -(max(sll_dB));
    release(barker);
    release(ac);
end
Sidelobe_dB = psl;
T = table(CodeLength,Sidelobe_dB)
```

```
T=8×2 table
    CodeLength    Sidelobe_dB
    __________    ___________

         1              0
         2        -6.0206
         3        -9.5424
         4        -12.041
         5        -13.979
         7        -16.902
        11        -20.828
        13        -22.279
```

More About

Barker Codes

Barker codes have a maximum autocorrelation sequence, which has off-peak autocorrelations no larger than 1.

A correlation sidelobe is the correlation of a codeword with a time-shifted version of itself. The correlation sidelobe, C_k, for a k-symbol shift of an N-bit code sequence, $\{X_j\}$, is

$$C_k = \sum_{j=1}^{N-k} X_j X_{j+k}$$

For j=1, 2, 3,..., N, X_j is an individual code symbol that is equal to +1 or –1. The adjacent symbols are assumed to be 0.

The output code is in a bipolar format with 0 and 1 mapped to 1 and –1. The maximum known Barker code length is 13. The short length and low correlation sidelobes make Barker codes useful for frame synchronization in digital communications systems. The Barker code generator outputs the Barker codes listed in this table.

Barker Code Length	Barker Code	Sidelobe Level
1	[–1]	0 dB
2	[–1; 1]	–6 dB
3	[–1; –1; 1]	–9.5 dB
4	[–1; –1; 1; –1]	–12 dB
5	[–1; –1; –1; 1; –1]	–14 dB
7	[–1; –1; –1; 1; 1; –1; 1]	–16.9 dB
11	[–1; –1; –1; 1; 1; 1; –1; 1; 1; –1; 1]	–20.8 dB
13	[–1; –1; –1; –1; –1; 1; 1; –1; –1; 1; –1; 1; –1]	–22.3 dB

comm.BasebandFileReader

Package: `comm`

Read baseband signals from file

Description

The `comm.BasebandFileReader` object reads a baseband signal from a specific type of binary file written by `comm.BasebandFileWriter`. Baseband signals are typically downconverted from a nonzero center frequency to 0 Hz. The `SampleRate` and `CenterFrequency` properties are saved when the file is created. The `comm.BasebandFileReader` object automatically reads the sample rate, center frequency, number of channels, and any descriptive data and saves them to its read-only properties.

To create an input signal from a saved baseband file:

1. Create a `comm.BasebandFileReader` object and set the properties of the object.
2. Call `step` to generate a baseband signal from saved data.
3. Call `release` to close the file.

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`bbr = comm.BasebandFileReader` returns a baseband reader object, `bbr`, using the default properties.

`bbr = comm.BasebandFileReader(fname)` returns a baseband reader object and sets `fname` as the `Filename` property.

`bbr = comm.BasebandFileReader(fname,spf)` also sets `spf` as the `SamplesPerFrame` property.

`bbr = comm.BasebandFileReader(___,Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

Example:

```
bbr = comm.BasebandFileReader('recorded_data',100);
```

Properties

Filename — Name of the baseband file to read

`'example.bb'` (default) | character vector

Name of the baseband file to read, specified as a character vector. Specify the absolute path only if the file is not on the MATLAB path. Only the absolute path is saved and displayed.

`SampleRate` — Sample rate of the saved baseband signal
`1` (default) | positive scalar

This property is read-only.

Sample rate of the saved baseband signal in Hz.

`CenterFrequency` — Center frequency of the saved baseband signal
`100000000` (default) | positive scalar | row vector

This property is read-only.

Center frequency of the saved baseband signal in Hz. When this property is a row vector, each element represents the center frequency of a channel in a multichannel signal.

`NumChannels` — Number of channels of the saved baseband signal
`1` (default) | positive integer

This property is read-only.

Number of channels of the saved baseband signal.

`Metadata` — Data describing the baseband signal
`struct()` (default) | structure

This property is read-only.

Data describing the baseband signal. If the file has no descriptive data, this property is an empty structure.

`SamplesPerFrame` — Number of samples per output frame
`100` (default) | positive integer

Number of samples per output frame, specified as a positive integer.

Data Types: `double`

`CyclicRepetition` — Flag to repeatedly read baseband file
`false` (default) | `true`

Flag to repeatedly read baseband file, specified as a logical scalar. To repeatedly read the baseband file specified by `Filename`, set this property to `true`.

Methods

info	Characteristic information about baseband file reader

Common to All System Objects	
`release`	Allow System object property value changes
`step`	Generate baseband signal from file
`reset`	Reset states of baseband file reader object
`isDone`	Read status of baseband file samples

Examples

Read Baseband Data from File

Read a baseband signal from file using the `comm.BasebandFileReader` System object.

Create a baseband file reader object.

```
bbr = comm.BasebandFileReader('example.bb')
```

```
bbr = 
  comm.BasebandFileReader with properties:

            Filename: 'C:\TEMP\Bdoc20b_1465442_5924\ib8F4264\10\tpa899180b\comm-ex87872352\exampl
          SampleRate: 1
     CenterFrequency: 100000000
         NumChannels: 1
            Metadata: [1x1 struct]
     SamplesPerFrame: 100
    CyclicRepetition: false
```

Use the `info` method to gain additional information about `bbr`. The file contains 10000 samples of type `'double'`. No samples have been read.

```
info(bbr)
```

```
ans = struct with fields:
    NumSamplesInData: 10000
            DataType: 'double'
      NumSamplesRead: 0
```

Reading Data with Multiple Calls to Baseband File Reader Object

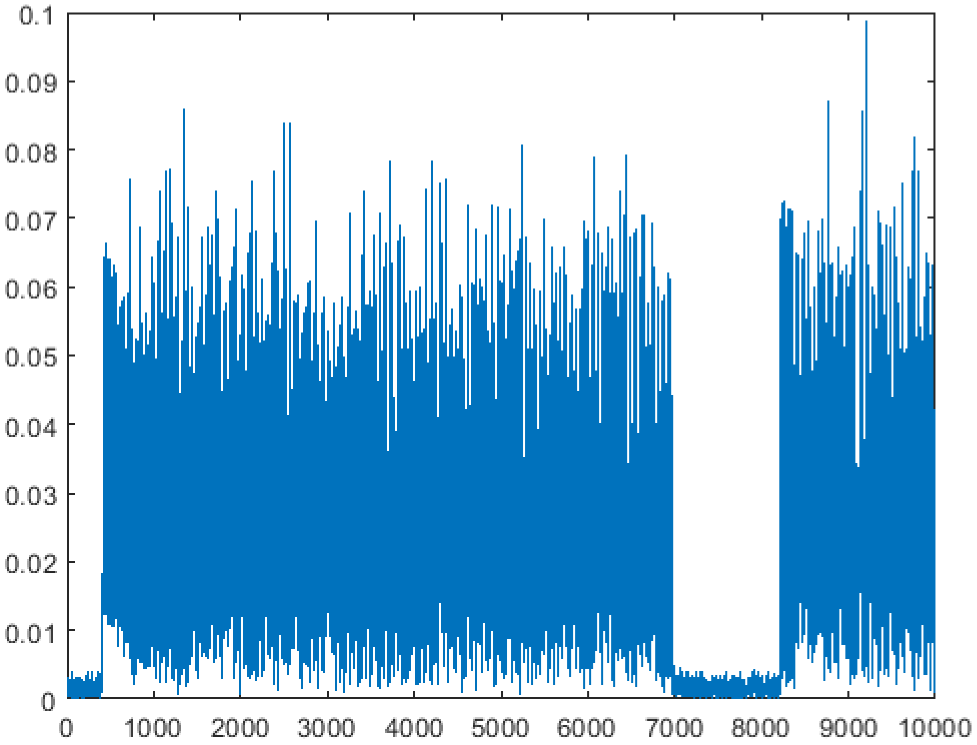
Since the `NumSamplesPerFrame` is 100, and `NumSamplesInData` is 10000, reading the entire contents of the `example.bb` file will require multiple calls to the `bbr` object. This can be achieved by using the `isDone` method to terminate a `while` loop.

```
y = [];

while ~isDone(bbr)
    x = bbr();
    y = cat(1,y,x);
end
```

Plot the absolute magnitude of the baseband data.

```
plot(abs(y))
```



Confirm that all the samples have been read.

```
info(bbr)
```

```
ans = struct with fields:
    NumSamplesInData: 10000
            DataType: 'double'
      NumSamplesRead: 10000
```

The total number of samples and the number of samples read are the same.

Release the baseband file reader resources.

```
release(bbr)
```

Reading Data with Single Call to Baseband File Reader Object

Alternatively, to read all samples from the file in one call to the object, you can set the samples per frame equal to the number of samples in the data file.

```
bbrinfo = bbr.info
```

```
bbrinfo = struct with fields:
    NumSamplesInData: 10000
            DataType: 'double'
      NumSamplesRead: 10000
```

```
bbr.SamplesPerFrame = bbrinfo.NumSamplesInData
```

```
bbr = 
  comm.BasebandFileReader with properties:

            Filename: 'C:\TEMP\Bdoc20b_1465442_5924\ib8F4264\10\tpa899180b\comm-ex87872352\examp
          SampleRate: 1
     CenterFrequency: 100000000
         NumChannels: 1
            Metadata: [1x1 struct]
     SamplesPerFrame: 10000
    CyclicRepetition: false
```

Now read the entire contents of the `example.bb` file with a single call to the `bbr` object. Confirm that all the samples have been read.

```
xx = bbr();
isequal(y,xx)
```

```
ans = logical
   1
```

```
info(bbr)
```

```
ans = struct with fields:
    NumSamplesInData: 10000
            DataType: 'double'
      NumSamplesRead: 10000
```

`comm.BasebandFileWriter`

Introduced in R2016b

info

System object: `comm.BasebandFileReader`
Package: `comm`

Characteristic information about baseband file reader

Syntax

```
s = info(bbr)
```

Description

`s = info(bbr)` returns a structure, `s`, containing characteristic information for the `BasebandFileReader` System object, `bbr`. `s` has these fields:

- `NumSamplesInData` is the total number of baseband data samples in the file, returned as a positive integer.
- `DataType` is the data type of the baseband signal in the file.
- `NumSamplesRead` is the number of samples that have been read from the file, returned as a positive integer. It cannot exceed the `NumSamplesInData` property when `CyclicRepetition` is `false`.

Introduced in R2016b

comm.BasebandFileWriter

Package: comm

Write baseband signals to file

Description

A baseband file is a specific type of binary file written by the comm.BasebandFileWriter System object. Baseband signals are typically down-converted from a nonzero center frequency to 0 Hz. The SampleRate and CenterFrequency properties are saved when the file is created.

To save a baseband signal to a file:

1. Create a comm.BasebandFileWriter object and set the properties of the object.
2. Call step to save a baseband signal to a file.
3. Call release to save the baseband signal to a file and to close the file.

Note Alternatively, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

bbw = comm.BasebandFileWriter returns a baseband writer object, bbw, using the default properties.

bbw = comm.BasebandFileWriter(fname) returns bbw and sets fname as the Filename property.

bbw = comm.BasebandFileWriter(fname,fs) also sets fs as the SampleRate property.

bbw = comm.BasebandFileWriter(fname,fs,fc) also sets fc as the CenterFrequency property.

bbw = comm.BasebandFileWriter(fname,fs,fc,md) also sets structure md as the MetaData property.

bbw = comm.BasebandFileWriter(___ ,Name,Value) specifies additional properties using Name,Value pairs. Unspecified properties have default values.

Example:

```
bbw = comm.BasebandFileWriter('qpsk_data.bb',10e6,2e9);
```

Properties

Filename — Name of saved file

'untitled.bb' (default) | character vector

Name of saved file, specified as a character vector. The filename can include a relative or an absolute path.

SampleRate — Sample rate of output signal

1 (default) | positive scalar

Sample rate of the output signal, specified in Hz as a positive scalar.

CenterFrequency — Center frequency of the baseband signal

100000000 (default) | positive integer scalar | row vector

Center frequency of the baseband signal, specified in Hz as a positive integer scalar or row vector. If CenterFrequency is a row vector, each element corresponds to a channel.

Metadata — Data describing the baseband signal

empty structure (default) | structure

Data describing the baseband signal, specified as a structure. The structure can have any number of fields and any field name. The field values can be of any numeric, logical, or character data type and have any number of dimensions.

NumSamplesToWrite — Number of samples to save

Inf (default) | positive integer

Number of samples to save, specified as a positive integer.

- To write all the baseband signal samples to a file, set NumSamplesToWrite to Inf.
- To write only the last NumSamplesToWrite samples to a file, set NumSamplesToWrite to a finite number.

Data Types: double

Methods

info	Characteristic information about baseband file writer
reset	Reset states of baseband file writer object
step	Write baseband signal to file

Common to All System Objects	
release	Allow System object property value changes

Examples

Write Baseband Signal to File

Create a baseband file writer object having a sample rate of 1 kHz and a 0 Hz center frequency.

```
bbw = comm.BasebandFileWriter('baseband_data.bb',1000,0);
```

Save today's date in the Metadata structure.

```
bbw.Metadata = struct('Date',date);
```

Generate two channels of QPSK-modulated data.

```
d = randi([0 3],1000,2);
x = pskmod(d,4,pi/4,'gray');
```

Write the baseband data to file `'baseband_data.bb'`.

```
bbw(x)
```

Display information about `bbw`. Release the object.

```
info(bbw)
```

```
ans = struct with fields:
              Filename: 'C:\TEMP\Bdoc20b_1465442_5924\ib8F4264\6\tp07b81c5a\comm-ex66490302\baseba
      SamplesPerFrame: 1000
          NumChannels: 2
             DataType: 'double'
    NumSamplesWritten: 1000
```

```
release(bbw)
```

Create a baseband file reader object to read the saved data. Read the metadata from the file.

```
bbr = comm.BasebandFileReader('baseband_data.bb','SamplesPerFrame',100);
bbr.Metadata
```

```
ans = struct with fields:
    Date: '25-Aug-2020'
```

Read the data from the file.

```
z = [];

while ~isDone(bbr)
    y = bbr();
    z = cat(1,z,y);
end
```

Display information about `bbr`. Release `bbr`.

```
info(bbr)
```

```
ans = struct with fields:
    NumSamplesInData: 1000
            DataType: 'double'
      NumSamplesRead: 1000
```

```
release(bbr)
```

Confirm the original modulated data, `x`, matches the data read from file `'baseband_data.bb'`, `z`.

```
isequal(x,z)
```

```
ans = logical
   1
```

Tips

- `comm.BasebandFileWriter` writes baseband signals to uncompressed binary files. To share these files, you can compress them to a zip file using the `zip` function. For more information, see “Create and Extract from Zip Archives”.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

`comm.BasebandFileReader`

Introduced in R2016b

info

Characteristic information about baseband file writer

Syntax

```
s = info(bbw)
```

Description

`s = info(bbw)` returns a structure, `s`, containing characteristic information for the `BasebandFileWriter` System object, `bbw`. `s` has these fields:

- `Filename` is the name of the baseband data file, returned as a character vector. The filename shows the absolute path.
- `SamplesPerFrame` is the number of samples in each frame, returned as a positive integer.
- `NumChannels` is the number of channels, returned as a positive integer greater than or equal to 1.
- `DataType` is the input data type.
- `NumSamplesWritten` is the number of samples written to the file, returned as a positive integer. This field returns the smaller of the total number of samples processed by the object and the `NumSamplesWritten` property.

Note All fields are available when the object is locked. When the object is unlocked, only the `Filename` and `NumSamplesWritten` fields are available.

reset

System object: `comm.BasebandFileWriter`
Package: `comm`

Reset states of baseband file writer object

Syntax

```
reset(bbw)
```

Description

`reset(bbw)` resets the states of the `BasebandFileWriter` object, `bbw`.

Introduced in R2016b

step

System object: `comm.BasebandFileWriter`
Package: `comm`

Write baseband signal to file

Syntax

```
step(bbw,x)
bbw(x)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`step(bbw,x)` writes a baseband signal, `x`, to the file specified by the `Filename` property of the `BasebandFileWriter` object, `bbw`. The number of samples written to the file is determined by the `NumSamplesToWrite` property of `bbw`.

`bbw(x)` is equivalent to the first syntax.

Note `bbw` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Introduced in R2016b

comm.BCHDecoder

Package: comm

Decode data using BCH decoder

Description

The BCHDecoder object recovers a binary message vector from a binary BCH codeword vector. For proper decoding, the codeword and message length values in this object must match the properties in the corresponding comm.BCHEncoder System object.

To decode a binary message from a BCH codeword:

1. Define and set up your BCH decoder object. See “Construction” on page 3-88.
2. Call step to recover a binary message vector from a binary BCH codeword vector according to the properties of comm.BCHDecoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

dec = comm.BCHDecoder creates a BCH decoder System object, dec, that performs BCH decoding.

dec = comm.BCHDecoder(N,K) creates a BCH decoder object, dec, with the CodewordLength property set to N and the MessageLength property set to K.

dec = comm.BCHDecoder(N,K,GP) creates a BCH decoder object, dec, with the CodewordLength property set to N, the MessageLength property set to K, and the GeneratorPolynomial property set to GP.

dec = comm.BCHDecoder(N,K,GP,S) creates a BCH decoder object, dec, with the CodewordLength property set to N, the MessageLength property set to K, the GeneratorPolynomial property set to GP, and the ShortMessageLength property set to S.

dec = comm.BCHDecoder(N,K,GP,S,Name,Value) creates a BCH decoder object, dec, with the CodewordLength property set to N, the MessageLength property set to K, the GeneratorPolynomial property set to GP, the ShortMessageLength property set to S, and each specified property Name set to the specified Value.

dec = comm.BCHDecoder(Name,Value) creates a BCH decoder object, dec, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

CodewordLength

Codeword length

Specify the codeword length of the BCH code as a double-precision positive integer scalar. The default is 15. The values of the CodewordLength and MessageLength on page 3-0 properties must produce a valid narrow-sense BCH code. For a full-length BCH code, the value of this property must take the form $2^M - 1$, where M is an integer such that $3 \le M \le 16$. The default is 15.

MessageLength

Message length

Specify the message length as a double-precision positive integer scalar. The values of the CodewordLength on page 3-0 and MessageLength properties must produce a valid narrow-sense BCH code. The default is 5.

ShortMessageLengthSource

Short message length source

Specify the source of the shortened message as either Auto or Property. When this property is set to Auto, the BCH code is defined by the CodewordLength on page 3-0 , MessageLength on page 3-0 , GeneratorPolynomial on page 3-0 , and PrimitivePolynomial on page 3-0 properties. When ShortMessageLengthSource is set to Property, you must specify the ShortMessageLength on page 3-0 property, which is used with the other properties to define the BCH code. The default is Auto.

ShortMessageLength

Shortened message length

Specify the length of the shortened message as a double-precision positive integer scalar whose value must be less than or equal to MessageLength on page 3-0 . When ShortMessageLength < MessageLength, the BCH code is shortened. The default is 5.

GeneratorPolynomialSource

Source of generator polynomial

Specify the source of the generator polynomial as either Auto or Property. Set this property to Auto to create the generator polynomial automatically. Set GeneratorPolynomialSource to Property to specify a generator polynomial using the GeneratorPolynomial on page 3-0 property. The default is Auto.

GeneratorPolynomial

Generator polynomial

Specify the generator polynomial as a binary double-precision row vector, a binary Galois field row vector that represents the coefficients of the generator polynomial in order of descending powers, or as a polynomial character vector. The length of the generator polynomial requires a value of CodewordLength on page 3-0 –MessageLength on page 3-0 +1. This property applies when you set GeneratorPolynomialSource on page 3-0 to Property. The default is 'X^10 + X^8 + X^5 + X^4 + X^2 + X + 1', which is the result of bchgenpoly(15,5,[],'double') and corresponds to a 15,5 code.

CheckGeneratorPolynomial

Enable generator polynomial checking

Set this property to true to perform a generator polynomial check the first time you call the step method. The default is true. This check verifies that the specified generator polynomial is valid. For larger codes, disabling the check reduces processing time. As a best practice, perform the check at least once before setting this property to false. This property applies when you set GeneratorPolynomialSource on page 3-0 to Property. The default is true.

PrimitivePolynomialSource

Source of primitive polynomial

Specify the source of the primitive polynomial as Auto or Property. Set this property to Auto to create a primitive polynomial of degree *M*=ceil(log2(CodewordLength on page 3-0 +1)). Set PrimitivePolynomialSource to Property to specify a polynomial using the PrimitivePolynomial on page 3-0 property. The default is Auto.

PrimitivePolynomial

Primitive polynomial

Specify the primitive polynomial of order M, that defines the finite Galois field GF(2). Use a double-precision, binary row vector with the coefficients of the polynomial in order of descending powers or a polynomial character vector. This property applies when you set the PrimitivePolynomialSource on page 3-0 property to Property. The default is 'X^4 + X + 1', which is the result of fliplr(de2bi(primpoly(4))).

PuncturePatternSource

Source of puncture pattern

Specify the source of the puncture pattern as None or Property. Set this property to None to disable puncturing. Set it to Property to decode punctured codewords. This decoding is based on a puncture pattern vector you specify in the PuncturePattern on page 3-0 property. The default is None.

PuncturePattern

Puncture pattern vector

Specify the pattern that the object uses to puncture the encoded data. Use a double-precision binary column vector of length CodewordLength on page 3-0 –MessageLength on page 3-0 . Zeros in the puncture pattern vector indicate the position of the parity bits that the object punctures or excludes from each codeword. This property applies when you set PuncturePatternSource on page 3-0 to Property. The default is [ones(8,1); zeros(2,1)].

ErasuresInputPort

Enable erasures input

Set this property to true to specify a vector of erasures as a step method input. The erasures vector is a double-precision or logical binary column vector that indicates which bits of the input codewords to erase or ignore. Values of 1 in the erasures vector correspond to erased bits in the same position of the (possibly punctured) input codewords. Set this property to false to disable erasures. The default is false.

NumCorrectedErrorsOutputPort

Output number of corrected errors

Set this property to true so that the step method outputs the number of corrected errors. The default is true.

Input and Output Signal Lengths in BCH and RS System Objects

The notation y = c * x denotes that y is an integer multiple of x.

The number of punctures equals the number of zeros in the puncture vector.

M is the degree of the primitive polynomial. Each group of *M* bits represents an integer between 0 and 2^M–1 that belongs to the finite Galois field GF(2^M).

Methods

step	Decode data using a BCH decoder

Common to All System Objects	
release	Allow System object property value changes

Examples

Transmit and decode an 8-DPSK-modulated signal, then count errors

```
% The following code transmits a BCH-encoded, 8-DPSK-modulated bit stream
% through an AWGN channel.  Then, the example demodulates, decodes, and counts errors.
```

```
enc = comm.BCHEncoder;
mod = comm.DPSKModulator('BitInput',true);
chan = comm.AWGNChannel(...
         'NoiseMethod','Signal to noise ratio (SNR)','SNR',10);
demod = comm.DPSKDemodulator('BitOutput',true);
dec = comm.BCHDecoder;
errorRate = comm.ErrorRate('ComputationDelay',3);

for counter = 1:20
  data = randi([0 1], 30, 1);
  encodedData = step(enc, data);
  modSignal = step(mod, encodedData);
  receivedSignal = step(chan, modSignal);
  demodSignal = step(demod, receivedSignal);
  receivedBits = step(dec, demodSignal);
  errorStats = step(errorRate, data, receivedBits);
end

fprintf('Error rate = %f\nNumber of errors = %d\n', ...
  errorStats(1), errorStats(2))
```

```
Error rate = 0.015075
Number of errors = 9
```

Transmit and receive a BPSK-modulated signal

Transmit and receive a BPSK-modulated signal encoded with a shortened BCH code, then count errors.

Specify the codeword, message, and shortened message lengths.

```
N = 255;
K = 239;
S = 63;
```

Create a BCH (255,239) generator polynomial. Use the generator polynomial to create a BCH encoder and decoder pair. The BCH code is based on the AMR standard.

```
gp = bchgenpoly(255,239);
bchEncoder = comm.BCHEncoder(N,K,gp,S);
bchDecoder = comm.BCHDecoder(N,K,gp,S);
```

Create an error rate counter.

```
errorRate = comm.ErrorRate('ComputationDelay',3);
```

Main processing loop.

```
for counter = 1:20
  data = randi([0 1],630,1);                % Generate binary data
  encodedData = bchEncoder(data);           % BCH encode data
  modSignal = pskmod(encodedData,2);        % BPSK modulate
  receivedSignal = awgn(modSignal,5);       % Pass through AWGN channel
  demodSignal = pskdemod(receivedSignal,2); % BSPK demodulate
  receivedBits = bchDecoder(demodSignal);   % BCH decode data
  errorStats = errorRate(data,receivedBits); % Compute error statistics
end
```

Display the error statistics.

```
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
  errorStats(1), errorStats(2))
```

```
Error rate = 0.000318
Number of errors = 4
```

Shorten a BCH Code

Shorten a (31,26) BCH code to an (11,6) BCH code and use it to encode and decode random binary data.

Create a BCH encoder and decoder pair for a (31,26) code. Specify the generator polynomial, $x^5 + x^2 + 1$, and a shortened message length of 6.

```
enc = comm.BCHEncoder(31,26,'x5+x2+1',6);
dec = comm.BCHDecoder(31,26,'x5+x2+1',6);
```

Encode and decode random binary data and verify that the decoded bit stream matches the original data.

```
x = randi([0 1],60,1);
y = step(enc,x);
z = step(dec,y);
isequal(x,z)
```

```
ans = logical
   1
```

step

System object: `comm.BCHDecoder`
Package: `comm`

Decode data using a BCH decoder

Syntax

```
Y = step(H,X)
[Y,ERR] = step(H,X)
Y = step(H,X,ERASURES)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` decodes input binary codewords in `X` using a (`CodewordLength`,`MessageLength`) BCH decoder with the corresponding narrow-sense generator polynomial. The step method returns the estimated message in `Y`. This syntax applies when you set the `NumCorrectedErrorsOutputPort` property to false. The input and output length of the step function equal the values listed in the table in “Input and Output Signal Lengths in BCH and RS System Objects” on page 3-91.

`[Y,ERR] = step(H,X)` returns the number of corrected errors in output `ERR` when you set the `NumCorrectedErrorsOutputPort` property to `true`. A non- negative value in the *i*-th element of the `ERR` output vector denotes the number of corrected errors in the *i*-th input codeword. A value of `-1` in the *i*-th element of the `ERR` output indicates that a decoding error occurred for the *i*-th input codeword. A decoding error occurs when an input codeword has more errors than the error correction capability of the BCH code.

`Y = step(H,X,ERASURES)` uses `ERASURES` as the erasures pattern input when you set the `ErasuresInputPort` property to `true`. The object decodes the binary encoded data input, `X`, and treats as erasures the bits of the input codewords specified by the binary column vector, `ERASURES`. The length of `ERASURES` must equal the length of `X`, and its elements must be of data type double or logical. Values of `1` in the erasures vector correspond to erased bits in the same position of the (possibly punctured) input codewords.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.BCHEncoder

Package: `comm`

Encode data using BCH encoder

Description

The `BCHEncoder` object creates a BCH code with specified message and codeword lengths.

To encode data using a BCH coding scheme:

1. Define and set up your BCH encoder object. See "Construction" on page 3-97.
2. Call `step` to create a BCH code with message and codeword lengths specified according to the properties of `comm.BCHEncoder`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`enc = comm.BCHEncoder` creates a BCH encoder System object, `enc`, that performs BCH encoding.

`enc = comm.BCHEncoder(N,K)` creates a BCH encoder object, `enc`, with the `CodewordLength` property set to `N` and the `MessageLength` property set to `K`.

`enc = comm.BCHEncoder(N,K,GP)` creates a BCH encoder object, `enc`, with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K` and the `GeneratorPolynomial` property set to `GP`.

`enc = comm.BCHEncoder(N,K,GP,S)` creates a BCH encoder object, `enc`, with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, the `GeneratorPolynomial` property set to `GP` and the `ShortMessageLength` property set to `S`.

`enc = comm.BCHEncoder(N,K,GP,S,Name,Value)` creates a BCH encoder object, `enc`, with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, the `GeneratorPolynomial` property set to `GP`, the `ShortMessageLength` property set to `S`, and each specified property `Name` set to the specified `Value`.

`enc = comm.BCHEncoder(Name,Value)` creates a BCH encoder object, `enc`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

Note The input and output signal lengths are listed in "Input and Output Signal Lengths in BCH and RS System Objects" on page 3-91 on the `comm.BCHDecoder` reference page.

CodewordLength

Codeword length

Specify the codeword length of the BCH code as a double-precision positive integer scalar. The default is 15. The values of the CodewordLength and MessageLength on page 3-0 properties must produce a valid narrow-sense BCH code. For a full-length BCH code, the value of the property must use the form $2^M - 1$, where M is an integer such that $3 \leq M \leq 16$. The default is 15.

MessageLength

Message length

Specify the message length as a double-precision positive integer scalar. The values of the CodewordLength on page 3-0 and MessageLength properties must produce a valid narrow-sense BCH code. The default is 5.

ShortMessageLengthSource

Short message length source

Specify the source of the shortened message as either Auto or Property. When this property is set to Auto, the BCH code is defined by the CodewordLength on page 3-0 , MessageLength on page 3-0 , GeneratorPolynomial on page 3-0 , and PrimitivePolynomial on page 3-0 properties. When ShortMessageLengthSource is set to Property, you must specify the ShortMessageLength on page 3-0 property that is used with the other properties to define the RS code. The default is Auto.

ShortMessageLength

Shortened message length

Specify the length of the shortened message as a double-precision positive integer scalar whose value must be less than or equal to MessageLength on page 3-0 . When ShortMessageLength < MessageLength, the BCH code is shortened. The default is 5.

GeneratorPolynomialSource

Source of generator polynomial

Specify the source of the generator polynomial as either Auto or Property. Set this property to Auto to create the generator polynomial automatically. Set it to Property to specify a generator polynomial using the GeneratorPolynomial on page 3-0 property. The default is Auto.

GeneratorPolynomial

Generator polynomial

Specify the generator polynomial as a binary double-precision row vector, a binary Galois row vector that represents the coefficients of the generator polynomial in order of descending powers, or as a polynomial character vector. The length of the generator polynomial requires a value of CodewordLength on page 3-0 -MessageLength on page 3-0 +1. This property applies when you set GeneratorPolynomialSource on page 3-0 to Property. The default is 'X^10 + X^8 + X^5 + X^4 + X^2 + X + 1', which is the result of bchgenpoly(15,5,[],'double') and corresponds to a (15,5) code.

CheckGeneratorPolynomial

Enable generator polynomial checking

Set this property to `true` to perform a generator polynomial check the first time you call the `step` method. This check verifies that the specified generator polynomial is valid. For larger codes, disabling the check reduces processing time. As a best practice, perform the check at least once before setting this property to false. This property applies when you set `GeneratorPolynomialSource` on page 3-0 to `Property`. The default is `true`.

PrimitivePolynomialSource

Source of primitive polynomial

Specify the source of the primitive polynomial as one of `Auto` or `Property`. Set this property to `Auto` to create a primitive polynomial of degree *M*`=ceil(log2(CodewordLength on page 3-0 +1))`. Set it to `Property` to specify a polynomial using the `PrimitivePolynomial` on page 3-0 property. The default is `Auto`

PrimitivePolynomial

Primitive polynomial

Specify the primitive polynomial of order M, that defines the finite Galois field GF(2). Use a double-precision, binary row vector with the coefficients of the polynomial in order of descending powers or as a polynomial character vector. This property applies when you set the `PrimitivePolynomialSource` on page 3-0 property to `Property`. The default is `'X^4 + X + 1'`, which is the result of `fliplr(de2bi(primpoly(4)))`.

PuncturePatternSource

Source of puncture pattern

Specify the source of the puncture pattern as one of `None` or `Property`. Set this property to `None` to disable puncturing. Set it to `Property` to decode punctured codewords. This decoding is based on a puncture pattern vector you specify in the `PuncturePattern` on page 3-0 property. The default is `None`.

PuncturePattern

Puncture pattern vector

Specify the pattern that the object uses to puncture the encoded data. Use a double-precision binary column vector of length `CodewordLength` on page 3-0 `-MessageLength` on page 3-0 . Zeros in the puncture pattern vector indicate the position of the parity bits that the object punctures or excludes from each codeword. This property applies when you set `PuncturePatternSource` on page 3-0 to `Property`. The default is `[ones(8,1); zeros(2,1)]`.

Methods

step	Encode data using a BCH encoder

Common to All System Objects	
release	Allow System object property value changes

Examples

Transmit and decode an 8-DPSK-modulated signal, then count errors

```
% The following code transmits a BCH-encoded, 8-DPSK-modulated bit stream
% through an AWGN channel.  Then, the example demodulates, decodes, and counts errors.

enc = comm.BCHEncoder;
mod = comm.DPSKModulator('BitInput',true);
chan = comm.AWGNChannel(...
         'NoiseMethod','Signal to noise ratio (SNR)','SNR',10);
demod = comm.DPSKDemodulator('BitOutput',true);
dec = comm.BCHDecoder;
errorRate = comm.ErrorRate('ComputationDelay',3);

for counter = 1:20
  data = randi([0 1], 30, 1);
  encodedData = step(enc, data);
  modSignal = step(mod, encodedData);
  receivedSignal = step(chan, modSignal);
  demodSignal = step(demod, receivedSignal);
  receivedBits = step(dec, demodSignal);
  errorStats = step(errorRate, data, receivedBits);
end

fprintf('Error rate = %f\nNumber of errors = %d\n', ...
  errorStats(1), errorStats(2))
```

```
Error rate = 0.015075
Number of errors = 9
```

Transmit and receive a BPSK-modulated signal

Transmit and receive a BPSK-modulated signal encoded with a shortened BCH code, then count errors.

Specify the codeword, message, and shortened message lengths.

```
N = 255;
K = 239;
S = 63;
```

Create a BCH (255,239) generator polynomial. Use the generator polynomial to create a BCH encoder and decoder pair. The BCH code is based on the AMR standard.

```
gp = bchgenpoly(255,239);
bchEncoder = comm.BCHEncoder(N,K,gp,S);
bchDecoder = comm.BCHDecoder(N,K,gp,S);
```

Create an error rate counter.

```
errorRate = comm.ErrorRate('ComputationDelay',3);
```

Main processing loop.

```
for counter = 1:20
  data = randi([0 1],630,1);                 % Generate binary data
  encodedData = bchEncoder(data);            % BCH encode data
  modSignal = pskmod(encodedData,2);         % BPSK modulate
  receivedSignal = awgn(modSignal,5);        % Pass through AWGN channel
  demodSignal = pskdemod(receivedSignal,2);  % BSPK demodulate
  receivedBits = bchDecoder(demodSignal);    % BCH decode data
  errorStats = errorRate(data,receivedBits); % Compute error statistics
end
```

Display the error statistics.

```
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
  errorStats(1), errorStats(2))
```

```
Error rate = 0.000318
Number of errors = 4
```

Shorten a BCH Code

Shorten a (31,26) BCH code to an (11,6) BCH code and use it to encode and decode random binary data.

Create a BCH encoder and decoder pair for a (31,26) code. Specify the generator polynomial, $x^5 + x^2 + 1$, and a shortened message length of 6.

```
enc = comm.BCHEncoder(31,26,'x5+x2+1',6);
dec = comm.BCHDecoder(31,26,'x5+x2+1',6);
```

Encode and decode random binary data and verify that the decoded bit stream matches the original data.

```
x = randi([0 1],60,1);
y = step(enc,x);
z = step(dec,y);
isequal(x,z)
```

```
ans = logical
   1
```

step

System object: `comm.BCHEncoder`
Package: `comm`

Encode data using a BCH encoder

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` encodes input binary data, `X`, using a (`CodewordLength`,`MessageLength`) BCH encoder with the corresponding narrow-sense generator polynomial and returns the result in vector `Y`. The input and output length of the step function equal the values listed in the table in “Input and Output Signal Lengths in BCH and RS System Objects” on page 3-91.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.BitToInteger

Package: comm

(To be removed) Convert vector of bits to vector of integers

Note will be removed in a future release. Use bi2de instead. For more information, see “Compatibility Considerations”.

Description

The BitToInteger object maps groups of bits in the input vector to integers in the output vector.

To map bits to integers:

1. Define and set up your bit to integer object. See “Construction” on page 3-104.
2. Call step to map groups of bits in the input vector to integers in the output vector according to the properties of comm.BitToInteger. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.BitToInteger creates a bit-to-integer converter System object, H, that maps a vector of bits to a corresponding vector of integer values.

H = comm.BitToInteger(Name,Value) creates a bit-to-integer converter object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.BitToInteger(NUMBITS,Name,Value) creates a bit-to-integer converter System object, H This object has the BitsPerInteger on page 3-0 property set to NUMBITS and the other specified properties set to the specified values.

Properties

BitsPerInteger

Number of bits per integer

Specify the number of input bits that the object maps to each output integer. You can set this property to a scalar integer between 1 and 32. The default is 3.

MSBFirst

Assume first bit of input bit words is most significant bit

Set this property to true to indicate that the first bit of the input bit words is the most significant bit (MSB). The default is `true`. You can set this property to `false` to indicate that the first bit of the input bit words is the least significant bit (LSB).

SignedIntegerOutput

Output signed integers

Set this property to true to generate signed integer outputs. The default is `false`. You can set this property to `false` to generate unsigned integer outputs.

When you set this property to `false`, the output values are integers between `0` and (2^{N}) –1. In this case, *N* is the value you specified in the `BitsPerInteger` on page 3-0 property.

When you set this property to `true`, the output values are integers between -($2^{(N-1)}$) and ($2^{(N -1)}$) –1.

OutputDataType

Data type of output

Specify the output data type. The default is `Full precision`.

When you set the `SignedIntegerOutput` on page 3-0 property to `false`, set this property as one of `Full precision` | `Smallest integer` | `Same as input` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`.

When you set this property to `Same as input`, and the input data type is numeric or fixed-point (fi object), the output data has the same type as the input data.

When the input signal is an integer data type, you must have a Fixed-Point Designer™ user license to use this property in `Smallest unsigned integer` or `Full precision` mode.

When you set the `SignedIntegerOutput` property to `true`, specify the output data type as one of `Full precision` | `Smallest integer` | `double` | `single` | `int8` | `int16` | `int32`.

When you set this property to `Full precision`, the object determines the output data type based on the input data type. If the input data type is double or single precision, the output data has the same type as the input data. Otherwise, the property determines the output data type in the same way as when you set this property to `Smallest unsigned integer`.

Methods

step	(To be removed) Convert vector of bits to vector of integers

Common to All System Objects	
`release`	Allow System object property value changes

Examples

```
hBitToInt = comm.BitToInteger(4);
```

Generate three 4 bit words.

```
bitData = randi([0 1],3*hBitToInt.BitsPerInteger,1);
intData = step(hBitToInt,bitData)

intData = 3×1

    13
     9
    13
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Bit To Integer Converter block reference page. The object properties correspond to the block parameters.

Compatibility Considerations

`comm.BitToInteger` will be removed in a future release. Use `bi2de` instead.

Warns starting in R2020b

Use `bi2de` instead of comm.BitToInteger. Data types as supported by comm.BitToInteger are not inherently supported by functions. This code shows binary to decimal conversion for various data types using this function.

Examples Using bi2de for Various Data Types

```
function compbi2de

% Number of integers
n = randi([1 100]);

% Default
h1 = comm.BitToInteger;
bpi = h1.BitsPerInteger;
x = randi([0,1],n*bpi,1);
y1 = h1(x);
y2 = bi2de(reshape(x,bpi,[])','left-msb');
isequal(y1,y2)

% Right MSB, logical input
h2 = comm.BitToInteger( ...
    'BitsPerInteger',5, ...
    'MSBFirst',false);
bpi = h2.BitsPerInteger;
x = logical(randi([0,1],n*bpi,1));
y1 = h2(x);
y2 = bi2de(reshape(x,bpi,[])','right-msb');
isequal(y1,y2)

% Right MSB, signed output, single input
h3 = comm.BitToInteger( ...
    'BitsPerInteger',8, ...
    'MSBFirst',false, ...
    'SignedIntegerOutput',true);
bpi = h3.BitsPerInteger;
x = randi([0,1],n*bpi,1,'single');
y1 = h3(x);
y2 = bi2de(reshape(x,bpi,[])','right-msb');
N = 2^bpi;
y2 = y2 - (y2>=N/2)*N;
isequal(y1,y2)
end
```

step

System object: `comm.BitToInteger`
Package: `comm`

(To be removed) Convert vector of bits to vector of integers

Note `comm.BitToInteger` will be removed in a future release. Use `bi2de` instead.

Syntax

`Y = step(H,X)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` converts binary input, `X`, to corresponding integers, `Y`. The input must be a scalar or a column vector and the data type can be numeric, `numerictype(0,1)`, or logical. The length of input `X` must be an integer multiple of the value you specify in the BitsPerInteger property. The object outputs a column vector with a length equal to length(`X`)/`BitsPerInteger`. When you set the SignedIntegerOutput property to `false`, the object maps each group of bits to an integer between `0` and ($2^{\text{BitsPerInteger}}$)-1. A group of bits contains *N* bits, where *N* is the value of the `BitsPerInteger` property. If you set the `SignedIntegerOutput` property to true, the object maps each group of BitsPerInteger bits to an integer between -($2^{(\text{BitsPerInteger-1})}$) and ($2^{(\text{BitsPerInteger-1})}$)-1.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.BinarySymmetricChannel

Package: `comm`

(Removed) Introduce binary errors

Note has been removed. Use `bsc` instead. For more information, see “Compatibility Considerations”.

Description

The `BinarySymmetricChannel` object introduces binary errors to the signal transmitted through this channel.

To introduce binary errors into the transmitted signal:

1. Define and set up your binary symmetric channel object. See “Construction” on page 3-109.
2. Call `step` to introduce binary errors into the signal transmitted through this channel according to the properties of `comm.ACPR`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.BinarySymmetricChannel` creates a binary symmetric channel System object, `H`, that introduces binary errors to the input signal with a prescribed probability.

`H = comm.BinarySymmetricChannel(Name,Value)` creates a binary symmetric channel object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`ErrorProbability`

Probability of binary error

Specify the probability of a binary error as a scalar with a value between `0` and `1`. The default is `0.05`.

`ErrorVectorOutputPort`

Enable error vector output

When you set this property to `true`, the `step` method outputs an error signal, `ERR`. This error signal, in vector form, indicates where errors were introduced in the input signal, `X`. A value of `1` at the *i*-th element of ERR indicates that an error was introduced at the *i*-th element of X. Set the property to `false` if you do not want the ERR vector at the output of the `step` method. The default is `true`.

`OutputDataType`

Data type of output

Specify output data type as one of `double` | `logical`. The default is `double`.

Methods

step	(Removed) Introduce binary errors

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Add Errors to Binary Input Signal

```
% Add binary errors with a probability of 0.2 to a binary input signal.
p = 0.2;
binSymChan = comm.BinarySymmetricChannel('ErrorProbability',p);
data = randi([0 1],1000,1);
[~,err1] = binSymChan(data);

% Confirm that the number errors is approximately
% equal to the probability value multiplied by the number of symbols.
[sum(err1) p*length(data)];

% Perform using the bsc function
[~,err2] = bsc(data,p);
[sum(err2) p*length(data)];
```

```
ans =

   192   200
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Binary Symmetric Channel block reference page. The object properties correspond to the block parameters, except:This object uses the MATLAB default random stream to generate random numbers. The block uses a random number generator based on the V5 RANDN (Ziggurat) algorithm. An initial seed, set with the **Initial seed** parameter initializes the random number generator. For every system run that contains the block, the block generates the same sequence of random numbers. To generate reproducible numbers using this object, you can reset the MATLAB default random stream using the following code.

```
reset(RandStream.getGlobalStream)
```

For more information, see help for `RandStream`.

Compatibility Considerations

`comm.BinarySymmetricChannel` will be removed

Errors starting in R2020b

comm.BinarySymmetricChannel will be removed in a future release. Use bsc instead.

```
% This code provides examples using various syntaxes
% for the comm.BinarySymmetricChannel object versus the |bsc| function.

%% Simulate BSC with default comm.BinarySymmetricChannel object
data = randi([0 1],1000,2); % generate binary data
% Using comm.BinarySymmetricChannel object
bscObj = comm.BinarySymmetricChannel;
s = rng; % Save default MATLAB random number generator state
outOld = bscObj(data);
% Using bsc function
rng(s)  % Restore saved random number generator state
outNew = bsc(data,0.05);

%% Simulate BSC with object and set ErrorProbability property
data = randi([0 1],1000,2); % generate binary data
p = 0.3; % probability
% Using comm.BinarySymmetricChannel object
bscObj = comm.BinarySymmetricChannel('ErrorProbability',p);
s = rng; % Save default MATLAB random number generator state
outOld = bscObj(data);
% Using bsc function
rng(s)  % Restore saved random number generator state
outNew = bsc(data,p);

%% Simulate BSC with object and set ErrorVectorOutputPort property
data = randi([0 1],1000,2); % generate binary data
% Using comm.BinarySymmetricChannel object
bscObj = comm.BinarySymmetricChannel('ErrorVectorOutputPort', true)
s = rng; % Save default MATLAB random number generator state
[outOld,errOld] = bscObj(data);
% Using bsc function
rng(s)  % Restore saved random number generator state
[outNew,errNew] = bsc(data,0.05);

%% Simulate BSC with object and set OutputDataType property to logical
data = randi([0 1],1000,2); % generate binary data
% Using comm.BinarySymmetricChannel object
bscObj = comm.BinarySymmetricChannel('OutputDataType','logical');
s = rng; % Save default MATLAB random number generator state
outOld = bscObj(data);
% Using bsc function
rng(s)  % Restore saved random number generator state
outNew = logical(bsc(data,0.05));

%% Simulate BSC with object and input is logical
data = logical(randi([0 1],1000,2)); % generate logical data
% Using comm.BinarySymmetricChannel object
bscObj = comm.BinarySymmetricChannel;
s = rng; % Save default MATLAB random number generator state.
outOld = bscObj(data);
% Using bsc function
rng(s)  % Restore saved random number generator state
outNew = bsc(double(data),0.05);

%% Simulate BSC with object and input is integer, 'int8'
% Integer datatype options: int8, uint8, int16, uint16, int32, uint32
```

```
data = randi([0 1],1000,2,'int8'); % generate integer data
% Using comm.BinarySymmetricChannel object
bscObj = comm.BinarySymmetricChannel;
s = rng; % Save default MATLAB random number generator state
outOld = bscObj(int8(data));
% Using bsc function
rng(s) % Restore saved random number generator state
outNew = bsc(double(data),0.05);
```

step

System object: `comm.BinarySymmetricChannel`
Package: `comm`

(Removed) Introduce binary errors

Note `comm.BinarySymmetricChannel` has been removed. Use `bsc` instead. For more information, see “Compatibility Considerations”.

Syntax

```
Y = step(H,X)
[Y,ERR] = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` adds binary errors to the input signal `X` and returns the modified signal, `Y`. The input signal can be a vector or matrix with numeric, logical, or fixed-point (fi objects) data type elements. The step method output, `Y`, has the same dimensions as the input, `X`. If `X` input contains a non-binary value, *V*, the object considers it to be 1 when **abs**(*V*) > 0. This syntax applies when you set the `ErrorVectorOutputPort` property to false.

`[Y,ERR] = step(H,X)` returns the error signal vector, `ERR`. A value of `1` at the *i*-th element of `ERR` indicates that an error was introduced at the *i*-th element of `X`. The outputs, `Y` and `ERR`, have the same dimensions as the input, `X`. This syntax applies when you set the `ErrorVectorOutputPort` property to `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

blePCAPWriter

PCAP or PCAPNG file writer of BLE LL packets

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Description

The `blePCAPWriter` object writes generated and recovered Bluetooth low energy (BLE) link layer (LL) packets to a packet capture (PCAP) or packet capture next generation (PCAPNG) file (`.pcap` or `.pcapng`, respectively).

Creation

Syntax

```
obj = blePCAPWriter
obj = blePCAPWriter(Name,Value)
```

Description

`obj = blePCAPWriter` creates a default BLE PCAP or PCAPNG file writer object that writes BLE LL packets to a PCAP or PCAPNG file, respectively.

`obj = blePCAPWriter(Name,Value)` sets “Properties” on page 3-114 using one or more name-value pairs. Enclose each property name in quotes. For example, `('FileExtension','pcapng')` sets the extension of the file as `.pcapng`.

Properties

Note The `blePCAPWriter` object does not overwrite the existing PCAP or PCAPNG file. During each call of this object, specify a unique PCAP or PCAPNG file name.

`FileName` — Name of the PCAP or PCAPNG file
`'bleCapture'` (default) | character row vector | string scalar

Name of the PCAP or PCAPNG file, specified as a character row vector or a string scalar.

Data Types: `char` | `string`

`ByteOrder` — Byte order
`'little-endian'` (default) | `'big-endian'`

Byte order, specified as `'little-endian'` or `'big-endian'`.

Data Types: char | string

FileExtension — Type of file
'pcap' (default) | 'pcapng'

Type of file, specified as 'pcap' or 'pcapng'.

Data Types: char | string

FileComment — Comment for PCAPNG file
'' (default) | character vector | string scalar

Comment for the PCAPNG file, specified as a character vector or a string scalar.

Data Types: char | string

Interface — Name of interface on which BLE packets are captured
'BLE' (default) | character vector | string scalar

Name of the interface on which BLE packets are captured, specified as a character vector or a string scalar.

Data Types: char | string

PhyHeaderPresent — Flag to indicate presence of PHY header
false or 0 (default) | true or 1

Flag to indicate the presence of physical layer (PHY) header, specified as a logical 1 (true) or 0 (false).

Data Types: logical

PCAPWriter — PCAP or PCAPNG file writer object
pcapWriter object | pcapngWriter object

PCAP or PCAPNG file writer object, specified as pcapWriter or pcapngWriter object.

Object Functions

Specific to This Object

write	Write BLE LL protocol packet data to PCAP or PCAPNG file

Examples

Use BLE PCAP Writer to Write LL Packet to PCAP File

Create a BLE PCAP file writer object, specifying the name of the PCAP file.

```
pcapObj = blePCAPWriter('FileName','writeblepacket');
```

Generate a BLE LL packet.

```
cfgLLData = bleLLDataChannelPDUConfig('LLID', ...
    'Data (start fragment/complete)');
```

```
payload = '0E00050014010A001F004000170017000000';
llDataPDU = bleLLDataChannelPDU(cfgLLData,payload);
connAccessAddress = de2bi(hex2dec('E213BC42'),32)';
llpacket = [connAccessAddress; llDataPDU];
```

Write the BLE LL packet to the PCAP file.

```
timestamp = 0; % Number of microseconds
write(pcapObj,llpacket,timestamp,'PacketFormat','bits');
```

Use BLE PCAP Writer to Write BLE LL Packet to PCAPNG File

Create a BLE PCAPNG file writer object, specifying the name and extension of the PCAPNG file.

```
pcapObj = blePCAPWriter('FileName','sampleBLELL', ...
    'FileExtension','pcapng');
```

Generate a BLE LL packet.

```
cfgLLData = bleLLDataChannelPDUConfig('LLID', ...
    'Data (start fragment/complete)');
payload = '0E00050014010A001F004000170017000000';
llDataPDU = bleLLDataChannelPDU(cfgLLData,payload);
connAccessAddress = de2bi(hex2dec('E213BC42'),32)';
llpacket = [connAccessAddress; llDataPDU];
```

Write the BLE LL packet to the PCAPNG file.

```
timestamp = 12800000; % Number of microseconds
write(pcapObj,llpacket,timestamp,'PacketFormat','bits');
```

Write BLE LL Packet to PCAPNG File from PCAPNG File Writer

Create a PCAPNG file writer object, specifying the name of the PCAPNG file.

```
pcapObj = pcapngWriter('FileName','sampleBLELL',  ...
    'FileComment','This is a sample file');
```

Create a BLE PCAP file writer object, specifying the PCAPNG file writer and the presence of PHY header.

```
blePCAP = blePCAPWriter('PCAPWriter',pcapObj,'PhyHeaderPresent',true);
```

Generate a BLE LL packet.

```
cfgLLAdv = bleLLAdvertisingChannelPDUConfig;
cfgLLAdv.PDUType = 'Advertising indication';
cfgLLAdv.AdvertisingData = '020106';
llDataPDU = bleLLAdvertisingChannelPDU(cfgLLAdv);
connAccessAddress = de2bi(hex2dec('E213BC42'),32)';
llpacket = [connAccessAddress;llDataPDU];
```

Write the BLE LL packet to the PCAPNG file.

```
PhyHeaderBytes = [39 10 8 1 10 10 10 10 15 00];
timestamp = 18912345; % Number of microseconds
write(blePCAP,llpacket,timestamp,'PacketFormat','bits', ...
    'PhyHeader',PhyHeaderBytes,'PacketComment','This is the first packet');
```

bleAngleEstimateConfig

Configuration object for BLE angle estimation

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Description

The `bleAngleEstimateConfig` object creates a configuration object for Bluetooth low energy (BLE) angle estimation. You can estimate the angle of arrival (AoA) and angle of departure (AoD) by configuring the properties of this object.

Creation

Syntax

```
cfg = bleAngleEstimateConfig
cfg = bleAngleEstimateConfig(Name,Value)
```

Description

`cfg = bleAngleEstimateConfig` creates a default BLE angle estimation configuration object.

`cfg = bleAngleEstimateConfig(Name,Value)` sets “Properties” on page 3-118 by using one or more name-value pairs. Enclose each property name in quotes. For example, `bleAngleEstimateConfig('SlotDuration',1)` sets the switch and sample slot duration to 1 µs.

Properties

`ArraySize` — Size of an antenna array
4 (default) | positive integer | two-element row vector of positive integers

Size of an antenna array, specified as a positive integer or a two-element row vector of positive integers. Setting this property to a positive integer, specifies a uniform linear array (ULA) antenna array design with array elements on the *y*-axis. Setting this property to a vector, specifies a uniform rectangular array (URA) antenna array design. The vector must be of the form [*r c*], where *r* and *c* denote the number of row elements and column elements in the antenna array, respectively. In this case, the row elements and column elements are present along *y*-axis and *z*-axis, respectively.

Data Types: `double`

`ElementSpacing` — Normalized element spacing with respect to signal wavelength
`0.5` (default) | positive real number less than or equal to 0.5 | two-element row vector of positive real numbers less than or equal to 0.5

Normalized element spacing with respect to signal wavelength, specified as a positive real number less than or equal to 0.5 or a two-element row vector of positive real numbers less than or equal to

0.5. Setting this property to a positive real number, specifies a ULA antenna array design with array elements on the *y*-axis. Setting this property to a vector, specifies a URA antenna array design. The vector must be of the form [*sr sc*], where *sr* and *sc* denote the spacing between row and column elements of the antenna array, respectively. In this case, the rows and columns are present along *y*-axis and *z*-axis, respectively.

Data Types: `double`

`SlotDuration` — Switch and sample slot duration

`2` (default) | `1`

Switch and sample slot duration, specified as `1` or `2`. This value must be expressed in microseconds.

Data Types: `double`

`SwitchingPattern` — Antenna switching pattern

`[1 2 3 4]` (default) | *M*-element row vector

Antenna switching pattern, specified as an *M*-element row vector, where *M* must be in the range [2, 74/“SlotDuration” on page 3-0 +1].

Data Types: `double`

Object Functions

Specific to This Object

getElementPosition	Positions of the antenna array elements
getNumElements	Number of elements in antenna array

Examples

Estimate Single Angle Using Four-Element ULA

Create a default BLE angle estimation configuration object.

```
cfg = bleAngleEstimateConfig;
```

Specify a ULA antenna array design by setting the antenna array size of the configuration object to 4.

```
cfg.ArraySize = 4
```

```
cfg = 
  bleAngleEstimateConfig with properties:

            ArraySize: 4
       ElementSpacing: 0.5000
         SlotDuration: 2
     SwitchingPattern: [1 2 3 4]
```

Estimate Two Angles Using 4-by-4 URA

Create a default BLE angle estimation configuration object.

```
cfg = bleAngleEstimateConfig
```

```
cfg = 
  bleAngleEstimateConfig with properties:

           ArraySize: 4
      ElementSpacing: 0.5000
        SlotDuration: 2
    SwitchingPattern: [1 2 3 4]
```

Specify a URA antenna array design by setting the antenna array size of the configuration object to [4 4].

```
cfg.ArraySize = [4 4];
```

Set the row element spacing and column element spacing to `0.4` and `0.3`, respectively.

```
cfg.ElementSpacing = [0.4 0.3];
```

Set the value of antenna switching pattern.

```
cfg.SwitchingPattern = 1:16
```

```
cfg = 
  bleAngleEstimateConfig with properties:

           ArraySize: [4 4]
      ElementSpacing: [0.4000 0.3000]
        SlotDuration: 2
    SwitchingPattern: [1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16]
```

bleATTPDUConfig

Configuration object for BLE ATT PDU

Note **Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Description

The `bleATTPDUConfig` creates a configuration object for a Bluetooth low energy (BLE) attribute protocol data unit (ATT PDU). You can configure a BLE ATT PDU using the applicable properties of `bleATTPDUConfig`.

Creation

Syntax

```
cfgATT = bleATTPDUConfig
cfgATT = bleATTPDUConfig(Name,Value)
```

Description

`cfgATT = bleATTPDUConfig` creates a `bleATTPDUConfig` configuration object, `cfgATT`, for a BLE ATT PDU with default values.

`cfgATT = bleATTPDUConfig(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `bleATTPDUConfig('Opcode','Error response')` sets the `Opcode` property of `cfgATT` to `'Error response'`.

Properties

Note For more information about BLE ATT PDU properties and their respective values, see volume 3, part F, sections 3.3 and 3.4 of the Bluetooth Core Specification [2].

`Opcode` — BLE ATT PDU operation code

`'Read request'` (default) | `'MTU request'` | `'Information request'` | `...`

BLE ATT PDU operation code, specified as one of the values in this list. Each valid value describes a BLE ATT PDU operation code.

- `'MTU request'`
- `'Error response'`
- `'Information request'`

- 'Find by type value request'
- 'Read by type request'
- 'Read request'
- 'Read response'
- 'Read blob request'
- 'Read blob response'
- 'Read by group type request'
- 'Write request'
- 'Write response'
- 'Write command'
- 'Prepare write request'
- 'Prepare write response'
- 'Execute write request'
- 'Execute write response'
- 'Handle value notification'
- 'Handle value indication'
- 'Handle value confirmation'
- 'Information response'
- 'Find by type value response'
- 'Read by type response'
- 'Read by group type response'

Data Types: char | string

RequestedOpcode — Opcode of request BLE ATT PDU
'Read request' (default) | character vector | string scalar

Opcode of request BLE ATT PDU, specified as one of the values in this list. Each valid value describes a request BLE ATT PDU (from a peer device) that caused an error.

- 'MTU request'
- 'Information request'
- 'Find by type value request'
- 'Read by type request'
- 'Read request'
- 'Read blob request'
- 'Read by group type request'
- 'Write request'
- 'Prepare to write request'
- 'Execute write request'

Data Types: char | string

Format — Format of information data field

'16 bit' (default) | '128 bit'

Format of information data field, specified as '16 bit' or '128 bit'. This value specifies the format of information data element in the PDU with opcode 'Information Response'.

Data Types: char | string

AttributeHandle — Handle value of attribute

'0001' (default) | character vector of two-octet hexadecimal

Handle value of attribute, specified as the character vector of a two-octet hexadecimal value in the range [0x0001, 0xFFFF]. This value is a unique identifier. The server dynamically assigns this value.

Data Types: char | string

ErrorMessage — Error message corresponding to request BLE ATT PDU

'Invalid handle' (default) | 'Invalid handle' | 'Read not permitted' | ...

Error message corresponding to request BLE ATT PDU, specified as one of the values in this list. Each value indicates the cause of an error corresponding to the request PDU from a peer device.

- 'Invalid handle'
- 'Read not permitted'
- 'Write not permitted'
- 'Invalid PDU'
- 'Insufficient authentication'
- 'Request not supported'
- 'Invalid offset'
- 'Insufficient authorization'
- 'Prepare queue full'
- 'Attribute not found'
- 'Attribute not long'
- 'Insufficient encryption key size'
- 'Invalid attribute value length'
- 'Unlikely error'
- 'Insufficient encryption'
- 'Unsupported group type'
- 'Insufficient resources'

Data Types: char | string

MaxTransmissionUnit — Maximum size of BLE ATT PDU

23 (default) | positive integer

Maximum size of BLE ATT PDU, specified as a positive integer in the range [23,65535]. This value sets the maximum size of the BLE ATT PDU in bytes that a client or server can receive.

Data Types: double

`StartHandle` — Starting handle of handle range

`'0001'` (default) | character vector of two-octet hexadecimal value

Starting handle of handle range, specified as a two-octet hexadecimal value in the range [0x0001,0xFFFF]. This value indicates the handle value of a service or characteristic declaration or the starting handle of a handle range. This value must be less than the `EndHandle`.

Data Types: `char` | `string`

`EndHandle` — Ending handle of handle range

`'FFFF'` (default) | character vector of two-octet hexadecimal value

Ending handle of handle range, specified as a two-octet hexadecimal value in the range [0x0001,0xFFFF]. This value sets the end handle value of a service declaration or a characteristic declaration or the ending handle of a handle range. This value must be greater than the `StartHandle`.

Data Types: `char` | `string`

`AttributeType` — Type of attribute

`'2800' (Primary service)` (default) | four-element or 32-element character vector | 2-octet or 16-octet string scalar

Type of attribute, specified as a four-element or 32-element character vector or a string scalar denoting a two-octet or16-octet hexadecimal value.

Data Types: `char` | `string`

`AttributeValue` — Value of attribute

`' '` (default) | character vector | string scalar | numeric vector of elements in the range [0,255] | `n`-by-2 character array of maximum length `131068`

Value of attribute, specified as one of these values:

- Character vector — This vector represent octets in hexadecimal format.
- String scalar — This scalar represent octets in hexadecimal format.
- Numeric vector of elements in the range [0,255] — This vector represent octets in decimal format. The maximum length of the numeric vector is `65534`.
- `n`-by-2 character array — Each row represent an octet in hexadecimal format. The maximum length of the character array is `131068`.

`AttributeValue` indicates the value of an attribute to be stored in or read from the attribute database. Specify this value in LSB first format.

Data Types: `char` | `string` | `double`

`Offset` — Offset of next octet to be read

`0` (default) | integer in the range [0, 65565]

Offset of next octet to be read, specified as an integer in the range `[0, 65535]`. You can use this value in the BLE ATT PDUs with opcodes `'Read blob request'`, `'Prepare write request'`, and `'Prepare write response'` to identify an attribute value offset in the attribute database.

Data Types: `double`

ExecuteWrite — Execute write flag

'Cancel all prepared writes' (default) | 'Write all pending requests'

Execute write flag, specified as 'Cancel all prepared writes' or 'Write all pending requests'. You can determine the action (discard or write) to be performed when this property is used.

Data Types: char | string

Object Functions

Specific to This Object

bleATTPDU	Generate BLE ATT PDU
bleATTPDUDecode	Decode BLE ATT PDU

Examples

Create BLE ATT PDU Configuration Objects

Create two unique BLE ATT PDU configuration objects: one of type 'Read by type request' and the other of type 'Error response' using default settings and name-value pairs respectively.

Create a BLE ATT PDU configuration object with default settings.

```
cfgATT = bleATTPDUConfig;
```

Set the BLE ATT PDU opcode as 'Read by type request'. View the applicable properties of the opcode 'Read by type request'.

```
cfgATT.Opcode = 'Read by type request'
```

```
cfgATT = 
  bleATTPDUConfig with properties:

           Opcode: 'Read by type request'
      StartHandle: '0001'
        EndHandle: 'FFFF'
    AttributeType: '2800'
```

Create another BLE ATT PDU configuration object, this time using the name-value pairs. Change the BLE ATT PDU opcode to 'Error response'. View the applicable properties of the opcode 'Error response'.

```
cfgATT = bleATTPDUConfig('Opcode','Error response')
```

```
cfgATT = 
  bleATTPDUConfig with properties:

             Opcode: 'Error response'
    RequestedOpcode: 'Read request'
    AttributeHandle: '0001'
       ErrorMessage: 'Invalid handle'
```

End-to-End Workflow of BLE ATT PDU

Create a BLE ATT PDU configuration object. Change the value of opcode to `'Read by type request'`. View the applicable properties of the specified value of opcode.

```
cfgTx = bleATTPDUConfig;
cfgTx.Opcode = 'Read by type request'
```

```
cfgTx = 
  bleATTPDUConfig with properties:

           Opcode: 'Read by type request'
      StartHandle: '0001'
        EndHandle: 'FFFF'
    AttributeType: '2800'
```

Generate a BLE ATT PDU from the corresponding configuration object.

```
attPDU = bleATTPDU(cfgTx);
```

Decode the generated BLE ATT PDU. The returned status indicates decoding is successful. View the applicable properties of the opcode `'Error response'`.

```
[status, cfgRx] = bleATTPDUDecode(attPDU)
```

```
status = 
Success

cfgRx = 
  bleATTPDUConfig with properties:

           Opcode: 'Read by type request'
      StartHandle: '0001'
        EndHandle: 'FFFF'
    AttributeType: '2800'
```

bleChannelSelection

BLE channel index for connection events

Note **Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Description

The `bleChannelSelection` System object selects a Bluetooth low energy (BLE) channel index based on the selected algorithm. For more information, see `Algorithm` in property.

To select a BLE channel index:

1. Create the `bleChannelSelection` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
csa = bleChannelSelection
csa = bleChannelSelection(Name,Value)
```

Description

`csa = bleChannelSelection` creates a `blechannelselection` System object, `csa`, to select a BLE channel index for connection events or periodic advertising events.

`csa = bleChannelSelection(Name,Value)`sets properties using one or more name-value pairs. For example, `bleChannelSelection('Algorithm','2')` configures the System object, `csa`, to select a BLE channel index based on `'Algorithm #2'`. Enclose each property name in quotes.

Properties

Note For more information about BLE channel selection properties and their respective values, see volume 6, part B, section 4.5.8 of the Bluetooth Core Specification [2].

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Algorithm` — Type of BLE channel selection algorithm

`1` (default) | `2`

Type of BLE channel selection algorithm, specified as `1` or `2` representing `'Algorithm #1'` or `'Algorithm #2'` respectively. The property uses this algorithm to select the channel index.

Data Types: `double`

`HopIncrement` — Hop increment count

`5` (default) | integer in the range [5, 16]

Hop increment count, specified as an integer in the range [5,16]. This property indicates the hop increment count to be used for hopping between data channels. `'Algorithm #1'` uses this value as an input.

Data Types: `double`

`AccessAddress` — Unique connection address

`'8E89BED6'` (default) | eight-element character vector | string scalar denoting a four-octet hexadecimal value

Unique connection address, specified as an eight-element character vector or a string scalar denoting a four-octet hexadecimal value. This value indicates a unique 32-bit address for the link layer connection between two devices. `'Algorithm #2'` uses this value as an input.

Data Types: `char` | `string`

`UsedChannels` — List of used (good) data channels

row vector containing all the channel indices [0, 36] (default) | vector of integers in the range [0, 36]

List of used (good) data channels, specified as an integer vector with element values in the range [0, 36]. The vector length must be greater than 1. At least two channels must be set as used (good) channels. This value indicates the set of good channels classified by the master.

Data Types: `double`

Usage

Syntax

```
channelIndex = csa()
```

Description

`channelIndex = csa()` selects a channel index based on the algorithm specified by the `Algorithm` property, the list of used data channels specified by the `UsedChannels` property, and other applicable properties dependent on the selected algorithm. The returned channel index, `channelIndex`, is of data type double.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `bleChannelSelection`

clone	Create duplicate System object
isLocked	Determine if System object is in use

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Select BLE Channel Indices Based on Type of Channel Selection Algorithm

Create a `blechannelselection` System object, `'csa'`, to select a BLE channel index based on the channel selection algorithm, `'Algorithm #1'`. View the corresponding applicable properties.

```
csa = bleChannelSelection
```

```
csa = 
  bleChannelSelection with properties:

       Algorithm: 1
    HopIncrement: 5
    UsedChannels: [1x37 double]
    ChannelIndex: 0
    EventCounter: 0
```

Set the values of `'HopIncrement'` to `7` and `'UsedChannels'` to `[0,2,24,6,10,14,26,30,34,36]`. View the corresponding properties.

```
csa.HopIncrement = 7;
csa.UsedChannels = [0, 2, 24, 6, 10, 14, 26, 30, 34, 36]
```

```
csa = 
  bleChannelSelection with properties:

       Algorithm: 1
    HopIncrement: 7
    UsedChannels: [0 2 6 10 14 24 26 30 34 36]
    ChannelIndex: 0
    EventCounter: 0
```

Select a BLE channel index from the corresponding system object using `'Algorithm #1'`.

```
channelIndex = csa()
```

```
channelIndex = 30
```

Create another blechannelselection System object, 'csa', this time to select a BLE channel index by specifying the type of channel selection algorithm as 'Algorithm #2'. View the corresponding applicable properties.

```
csa2 = bleChannelSelection("Algorithm",2);
```

Change the values of 'AccessAddress' to '8E89BED6' and 'UsedChannels' to [9,10,21,22,23,33,34,35,36]. View the corresponding properties.

```
csa2.AccessAddress = '8E89BED6';
csa2.UsedChannels = [9, 10, 21, 22, 23, 33, 34, 35, 36]
```

```
csa2 = 
  bleChannelSelection with properties:

        Algorithm: 2
    AccessAddress: '8E89BED6'
     UsedChannels: [9 10 21 22 23 33 34 35 36]
     ChannelIndex: 0
     EventCounter: 0
```

Select a BLE channel index from the corresponding system object using 'Algorithm #2'.

```
channelIndex2 = csa2()
```

```
channelIndex2 = 9
```

bleLLControlPDUConfig

Configuration object for BLE LL control PDU payload configuration

Note **Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Description

The `bleLLControlPDUConfig` creates a configuration object for Bluetooth low energy (BLE) link layer (LL) control protocol data unit (PDU) payload configuration by using the default and specified values. You can configure a BLE LL control PDU payload configuration using the applicable properties of `bleLLControlPDUConfig`.

Creation

Syntax

```
cfgControl = bleLLControlPDUConfig
cfgControl = bleLLControlPDUConfig(Name,Value)
```

Description

`cfgControl = bleLLControlPDUConfig` creates a configuration object, `cfgControl`, for a BLE LL control PDU payload configuration using default values.

`cfgControl = bleLLControlPDUConfig(Name,Value)`sets the properties using one or more name-value pairs. Enclose each property name in quotes. For example, `bleLLControlPDUConfig('Opcode','Version indication')` configures `cfgControl` with the operation code as `'Version indication'`

Properties

Note For more information about BLE LL control PDU properties and their respective values, see volume 6, part B, section 2.4 of the Bluetooth Core Specification [2].

Opcode — BLE LL control PDU payload configuration operation code
`'Connection update indication'` (default) | `'Channel map indication'` | `'Terminate indication'` | `'Unknown response'` | `'Version indication'` | `'Reject indication'`

BLE LL control PDU payload configuration operation code, specified as one of the values in this list. Each valid value describes a BLE LL control PDU operation code.

- `'Connection update indication'`

- 'Channel map indication'
- 'Terminate indication'
- 'Unknown response'
- 'Version indication'
- 'Reject indication'

Data Types: char | string

WindowSize — Transmit window size
1 (default) | nonnegative integer

Transmit window size, specified as a nonnegative integer in the range [1, Mws], where Mws is the lesser of 8 and (ConnectionInterval-1). This property indicates the window size within which the master transmits a data packet and the slave listens for a data packet after the connection is established. Each unit is taken as 1.25 ms so that the window size (WindowSize×1.25) is in the range of 1.25 ms to the minimum of (10 ms, ((ConnectionInterval×1.25) - 1.25) ms).

Data Types: double

ConnectionInterval — Connection interval
6 (7.5 ms) (default) | integer in the range [6, 3200]

Connection interval, specified as an integer in the range [6, 3200]. This property indicates the interval between the start of two consecutive connection events. Each unit is taken as 1.25 ms so that the connection interval (ConnectionInterval×1.25) is in the range of 7.5 ms to 4.0 s.

Data Types: double

SlaveLatency — Slave latency
0 (default) | nonnegative integer

Slave latency, specified as a nonnegative integer in the range [0, Msl], where Msl is the lesser of 499 and ((ConnectionTimeout×10)/((ConnectionInterval×1.25)×2))-1. This property indicates the number of connection events that a slave can ignore.

Data Types: double

ConnectionTimeout — Connection supervision timeout
10 (default) | nonnegative integer

Connection supervision timeout, specified as a nonnegative integer in the range [Mct, 3200], where Mct is the larger of 10 and ((1+SlaveLatency)*(ConnectionInterval×1.25)×2)/10. If the slave does not receive a valid packet within this time, this property indicates the connection timeout. Each unit is taken as 10 ms so that the connection timeout (ConnectionInterval×10) is in the range of 100 ms to 32.0 s.

Data Types: double

Instant — Connection event instant
0 (default) | integer in the range [0, 65535]

Connection event instant, specified as an integer in the range [0, 65535]. This property indicates the event count at which specific action must occur, for instance, using updated connection parameters.

Data Types: double

`UsedChannels` — List of used data channels

`row vector containing the channel indices between [0:36]` (default) | integer vector with element values in the range [0, 36]

List of used data channels, specified as an integer vector with element values in the range [0, 36]. The vector length must be greater than 1. At least two channels must be set as used (good) channels. This property indicates the set of good channels classified by the master.

Data Types: `double`

`ErrorCode` — Connection termination error code

`'Success'` (default) | `'Unknown connection identifier'` | `'Hardware failure'` | `...`

Connection termination error code, specified as one of the values in this list. Each valid value describes the error description informing the remote device why the connection is about to be terminated.

- `'Success'`
- `'Unknown connection identifier'`
- `'Hardware failure'`
- `'Memory capacity exceeded'`
- `'Connection timeout'`
- `'Connection limit exceeded'`
- `'Connection already exists'`
- `'Command disallowed'`
- `'Connection accept timeout exceeded'`
- `'Connection rejected due to limited resources'`
- `'Invalid LL parameters'`
- `'Connection rejected due to unacceptable BD_ADDR'`
- `'Unspecified error'`
- `'Unsupported LL parameter value'`
- `'Role change not allowed'`
- `'LL response timeout'`
- `'LL procedure collision'`
- `'Instant passed'`
- `'Channel classification not supported'`
- `'Extended inquiry response too large'`
- `'Connection rejected due to no suitable channel found'`
- `'Advertising timeout'`
- `'Controller busy'`
- `'Unacceptable connection parameters'`
- `'Connection failed to be established'`
- `'Unknown advertising identifier'`
- `'Limit reached'`

- `'Operation cancelled by host'`

Data Types: `char` | `string`

`UnknownOpcode` — Unrecognized or unsupported operation code
`'00'` (default) | two-element character vector | string scalar denoting one-octet hexadecimal value

Unrecognized or unsupported operation code, specified as the comma-separated pair consisting of `'UnknownOpcode'` and a two-element character vector or string scalar denoting a one-octet hexadecimal value. This property indicates the type of BLE LL control PDU that is not recognized or supported.

Data Types: `char` | `string`

`VersionNumber` — Version number of Bluetooth Core Specification
`'5.0'` (default) | `'4.0'` | `'4.1'` | `'4.2'`

Version number of Bluetooth Core Specification, specified as `'4.0'`, `'4.1'`, `'4.2'` or `'5.0'`. This property indicates the version number of the Bluetooth Core Specification.

Data Types: `string`

`CompanyIdentifier` — Manufacturer ID of Bluetooth controller
`'FFFF'` (default) | four-element character vector | string scalar denoting a two-octet hexadecimal value

Manufacturer ID of Bluetooth controller, specified as a four-element character vector or a string scalar denoting a two-octet hexadecimal value. This property indicates the unique identifier assigned to your organization by Bluetooth Special Interest Group (SIG) [2].

Data Types: `char` | `string`

`SubVersionNumber` — Subversion number of the Bluetooth controller
`'0000'` (default) | four-element character vector | string scalar denoting a two-octet hexadecimal value

Subversion number of the Bluetooth controller, specified as a four-element character vector or string scalar denoting a two-octet hexadecimal value. This property indicates the unique value for each implementation or revision of a Bluetooth controller implementation.

Data Types: `char` | `string`

Object Functions

Specific to This Object

bleLLDataChannelPDU	Generate BLE LL data channel PDU
bleLLDataChannelPDUDecode	Decode BLE LL data channel PDU
bleLLDataChannelPDUConfig	Configuration object for BLE LL data channel PDU

Examples

Create BLE LL Control PDU Configuration Object Using Default Settings

Create a BLE LL control PDU configuration object, `'cfgControl'`, using default settings. View the corresponding applicable properties.

```
cfgControl = bleLLControlPDUConfig
```

```
cfgControl = 
  bleLLControlPDUConfig with properties:

                Opcode: 'Connection update indication'
            WindowSize: 1
          WindowOffset: 0
    ConnectionInterval: 6
          SlaveLatency: 0
     ConnectionTimeout: 10
               Instant: 0
```

Change the value of the connection interval to `64`. View the configured properties.

```
cfgControl.ConnectionInterval = 64
```

```
cfgControl = 
  bleLLControlPDUConfig with properties:

                Opcode: 'Connection update indication'
            WindowSize: 1
          WindowOffset: 0
    ConnectionInterval: 64
          SlaveLatency: 0
     ConnectionTimeout: 10
               Instant: 0
```

Create BLE LL Control PDU Configuration Object Using Name-Value Pairs

Create two unique BLE LL control PDU configuration objects using name-value pairs: first one of the type `'Terminate indication'` and error code `'Connection timeout'` and second one of the type `'Channel map indication'` with used set of data channels.

Create a BLE LL control PDU configuration object, `'cfgControl'`, by specifying opcode as `'Terminate indication'` and the error code as `'Connection timeout'`. View the applicable properties corresponding to the specified opcode.

```
cfgControl = bleLLControlPDUConfig('Opcode','Terminate indication', ...
    'ErrorCode','Connection Timeout')
```

```
cfgControl = 
  bleLLControlPDUConfig with properties:

       Opcode: 'Terminate indication'
    ErrorCode: 'Connection timeout'
```

Create another BLE LL control PDU payload configuration object, `'cfgControl'`, this time by setting the value of opcode as `'Channel map indication'`. Specify the list of used data channels. View the configured properties corresponding to the specified opcode.

```
cfgControl = bleLLControlPDUConfig('Opcode','Channel map indication');
cfgControl.UsedChannels = [0 3 12 16 18 24]
```

```
cfgControl = 
  bleLLControlPDUConfig with properties:

          Opcode: 'Channel map indication'
         Instant: 0
    UsedChannels: [0 3 12 16 18 24]
```

Create a BLE LL data channel configuration object, `'cfgLLData'`, by specifying the values of `'LLID'` as `'Control'` and `'ControlConfig'` as `'cfgControl'`. View the properties of the configuration object `'cfgLLData'`.

```
cfgLLData = bleLLDataChannelPDUConfig('LLID','Control');
cfgLLData.ControlConfig = cfgControl
```

```
cfgLLData = 
  bleLLDataChannelPDUConfig with properties:

                 LLID: 'Control'
                 NESN: 0
       SequenceNumber: 0
             MoreData: 0
    CRCInitialization: '012345'
        ControlConfig: [1x1 bleLLControlPDUConfig]
```

End-to-End Workflow of BLE LL Control PDU

Create a BLE LL data channel PDU configuration object for a control PDU by using default configuration. View the corresponding default properties.

```
cfgControl = bleLLControlPDUConfig
```

```
cfgControl = 
  bleLLControlPDUConfig with properties:

               Opcode: 'Connection update indication'
           WindowSize: 1
         WindowOffset: 0
   ConnectionInterval: 6
         SlaveLatency: 0
    ConnectionTimeout: 10
              Instant: 0
```

Generate a BLE LL data channel PDU using `'cfgTx'` by specifying the value of link layer identifier, `'LLID'`, as `'Control'` and `'ControlConfig'` as `'cfgControl'`. Specify the cyclic redundancy check (CRC) value for the configuration object `'cfgTx'`. View the properties of `'cfgTx'`.

```
cfgTx = bleLLDataChannelPDUConfig('LLID', 'Control', ...
    'ControlConfig',cfgControl);
cfgTx.CRCInitialization = 'E23456'

cfgTx = 
  bleLLDataChannelPDUConfig with properties:

                 LLID: 'Control'
                 NESN: 0
       SequenceNumber: 0
             MoreData: 0
    CRCInitialization: 'E23456'
        ControlConfig: [1x1 bleLLControlPDUConfig]
```

Generate a BLE LL control PDU from `'cfgTx'`.

```
pdu = bleLLDataChannelPDU(cfgTx);
```

Decode the generated BLE LL control PDU by initializing the CRC value. The returned status indicates decoding is successful. View the values of `'status'`, `'cfgRx'` and `'llPayload'`.

```
crcInit = 'E23456'; % Received during associaton
[status, cfgRx, llPayload] = bleLLDataChannelPDUDecode(pdu, crcInit)

status = 
Success

cfgRx = 
  bleLLDataChannelPDUConfig with properties:

                 LLID: 'Control'
                 NESN: 0
       SequenceNumber: 0
             MoreData: 0
    CRCInitialization: '012345'
        ControlConfig: [1x1 bleLLControlPDUConfig]

llPayload =

  1x0 empty char array
```

bleL2CAPFrameConfig

Configuration object for BLE L2CAP frame

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Description

The `bleL2CAPFrameConfig` creates a configuration object for Bluetooth low energy (BLE) logical link control and adaptation protocol (L2CAP) signaling frame or data frame using the default and specified values. You can configure a BLE L2CAP signaling frame or data frame using the applicable properties of `bleL2CAPFrameConfig`.

Creation

Syntax

```
cfgL2CAP = bleL2CAPFrameConfig
cfgL2CAP = bleL2CAPFrameConfig(Name,Value)
```

Description

`cfgL2CAP = bleL2CAPFrameConfig` creates a configuration object, `cfgL2CAP`, for a BLE L2CAP signaling command frame or data frame with default values.

`cfgL2CAP = bleL2CAPFrameConfig(Name,Value)` specifies properties using one or more name-value pairs. Enclose each property name in quotes. For example, `bleL2CAPFrameConfig('CommandType','Command reject')` configures `cfgL2CAP` with the type of signaling command frame as `'Command reject'`.

Properties

Note For more information about BLE L2CAP frame properties and their respective values, see volume 3, part A, section 3 of the Bluetooth Core Specification [2].

`ChannelIdentifier` — Identifier for logical channel endpoint
`'0005'` (default) | four-element character vector | string scalar denoting a two-octet hexadecimal value

Identifier for a logical channel endpoint, specified as a four-element character vector or a string scalar denoting a two-octet hexadecimal value. The `'ChannelIdentifier'` denotes the local name representing a logical channel endpoint. This property is used to identify the command and data frames. Command frames use `'0005'` as the `'ChannelIdentifier'`. L2CAP B-frames use fixed

'ChannelIdentifier', '0004' for attribute protocol (ATT) and '0006' for security manager protocol (SMP).

Data Types: char | string

CommandType — Signaling command type
'Credit Based Connection request' (default) | 'Command reject' | 'Disconnection request' | ...

Signaling command type, specified as a character vector or a string scalar. You can specify CommandType as one of these values:

- 'Command reject'
- 'Disconnection request'
- 'Disconnection response'
- 'Connection Parameter Update request'
- 'Connection Parameter Update response'
- 'Credit Based Connection request'
- 'Credit Based Connection response'
- 'Flow Control Credit'

This property is applicable only when the value of ChannelIdentifier is set to '0005' (signaling channel identifier).

Data Types: char | string

SignalIdentifier — Identifier for request-response frame exchange
'01' (default) | two-element character vector | string scalar denoting one-octet hexadecimal value

Identifier for a request-response frame exchange, specified as a two-element character vector or string scalar denoting a one-octet hexadecimal value. The requesting device sets the value of this property and the responding device uses the same value in its response. The value of this property cannot be set to '00'.

Data Types: char | string

CommandRejectReason — Reason for rejecting received signaling command frame
'Command not understood' (default) | 'Signaling MTU exceeded' | 'Invalid CID in request'

Reason for rejecting the received signaling command frame, specified as a character vector or a string scalar. You can specify CommandRejectReason as one of these values:

- 'Command not understood'
- 'Signaling MTU exceeded'
- 'Invalid CID in request'

This property specifies the reason for rejecting a signaling command frame.

Data Types: char | string

SourceChannelIdentifier — Source logical channel endpoint
'0040' (default) | four-element character vector | string scalar denoting two-octet hexadecimal value

Source logical channel endpoint, specified as a four-element character vector or string scalar denoting a two-octet hexadecimal value. This property specifies the source channel endpoint from which the request is sent or a response is received. When the channel is created using credit-based connection procedure, data packets flowing to the sender of the request are sent to the `SourceChannelIdentifier`.

Data Types: `char` | `string`

`DestinationChannelIdentifier` — Destination logical channel endpoint

`'0040'` (default) | four-element character vector | string scalar denoting two-octet hexadecimal value

Destination logical channel endpoint, specified as a four-element character vector or string scalar denoting a two-octet hexadecimal value. This property specifies the destination channel endpoint from which the request is sent or a response is received. When the channel is created using credit-based connection procedure, data packets flowing to the destination of the request are sent to the `DestinationChannelIdentifier`.

Data Types: `char` | `string`

`ConnectionIntervalRange` — Connection interval range

`[6,3200]` (default) | two-element numeric vector specified as [*MIN*, *MAX*]

Connection interval range, specified as a two-element numeric vector in the form of [*MIN*, *MAX*]. *MIN* and *MAX* specify the minimum and the maximum value of the `ConnectionIntervalRange` respectively. You can specify the value of *MIN* and *MAX* in the range [6, 3200]. *MIN* must be less than or equal to *MAX*. Each unit for *MIN* or *MAX* is taken as 1.25 ms so the resultant value is in the range [7.5 ms, 4.0 s].

Data Types: `double`

`ConnectionTimeout` — Connection supervision timeout

`10 (100 ms)` (default) | integer in the range [*Mct*, 3200]

Connection supervision timeout, specified as an integer in the range [*Mct*, 3200], where *Mct* is the larger of 10 and ((1+`SlaveLatency`)×(`ConnectionInterval`×1.25)×2)/10. This property indicates the timeout for a connection if no valid packet is received within this time. Each unit is taken as 10 ms so that the resultant connection timeout, (`ConnectionInterval`×10), is in the range [100 ms, 32.0s].

Data Types: `double`

`SlaveLatency` — Number of link layer connection events a slave can ignore

`0` (default) | integer in the range [0, *Msl*]

Number of link layer connection events a slave can ignore, specified as an integer in the range [0, *Msl*], where *Msl* is the lesser of 499 and ((`ConnectionTimeout`×10)/((`ConnectionInterval`×1.25) ×2))-1. This property indicates the number of connection events that a slave can ignore.

Data Types: `double`

`ParameterUpdateResult` — Result of connection parameters update

`'Accepted'` (default) | `'Rejected'`

Result of the connection parameters update, specified as `'Accepted'` or `'Rejected'`. This property indicates the response to the `'Connection Parameter Update Request'` value of the property `CommandType` and specifies the result after updating the connection parameters.

Data Types: `char` | `string`

`LEPSM` — LE protocol or service multiplexer

`'001F'` (default) | four-element character vector | string scalar denoting two-octet hexadecimal value

LE protocol or service multiplexer, specified as a four-element character vector or a string scalar denoting a two-octet hexadecimal value. The value of this property is a unique number specified by the Special Interest Group (SIG) for each protocol. The SIG assigns the value of this property within the range [0x0001, 0x007F] for a set of existing protocols. The SIG dynamically assigns the value of this property in the range [0x0080, 0x00FF] to the implemented protocols.

Data Types: `char` | `string`

`MaxTransmissionUnit` — Maximum service data unit (SDU) size

`23` (default) | integer in the range of [23, 65,535]

Maximum service data unit (SDU) size, specified as an integer in the range of [23, 65,535] octets. This property specifies the maximum acceptable SDU size for the upper-layer entity.

Data Types: `double`

`MaxPDUPayloadSize` — Maximum protocol data unit (PDU) payload size

`23` (default) | integer in the range of [23, 65,535]

Maximum protocol data unit (PDU) payload size, specified as an integer in the range of [23, 65,535] octets. This property specifies the maximum acceptable payload data for the L2CAP layer entity.

Data Types: `double`

`Credits` — Number of LE-frames peer device can send or receive

`1` (default) | integer in the range of [0, 65,535]

Number of LE-frames peer device can send or receive, specified as an integer in the range of [0, 65,535] octets. This property indicates the number of LE-frames that the peer device can send or receive. If the value of `CommandType` property is set to `'Flow control credit'`, then this property cannot be set to `0`.

Data Types: `double`

`ConnectionResult` — Result of credit-based connection procedure

`'Successful'` (default) | `'LEPSM not supported'` | `'No resources available'` | `...`

Result of the credit-based connection procedure, specified as a character vector or a string scalar. You can specify `ConnectionResult` as one of these values:

- `'Successful'`
- `'LEPSM not supported'`
- `'No resources available'`
- `'Insufficient authentication'`
- `'Insufficient authorization'`
- `'Insufficient encryption key size'`
- `'Insufficient encryption'`
- `'Invalid Source CID'`

- `'Source CID already allocated'`
- `'Unacceptable parameters'`

This property indicates the outcome of the connection request.

Data Types: `char` | `string`

Object Functions

Specific to This Object

bleL2CAPFrame	Generate BLE L2CAP frame
bleL2CAPFrameDecode	Decode BLE L2CAP frame

Examples

Create BLE L2CAP Frame Configuration Object Using Default Settings

Create a BLE L2CAP frame configuration object, `'cfgL2CAP'`, using default properties. View the corresponding applicable properties. This configuration object generates a BLE L2CAP signaling frame of type `'Credit based connection request'`.

```
cfgL2CAP = bleL2CAPFrameConfig
```

```
cfgL2CAP = 
  bleL2CAPFrameConfig with properties:

          ChannelIdentifier: '0005'
                CommandType: 'Credit based connection request'
           SignalIdentifier: '01'
    SourceChannelIdentifier: '0040'
                      LEPSM: '001F'
        MaxTransmissionUnit: 23
          MaxPDUPayloadSize: 23
                    Credits: 1
```

Set the value of credits to `10`. View the corresponding properties of `'cfgL2CAP'`.

```
cfgL2CAP.Credits            = 10
```

```
cfgL2CAP = 
  bleL2CAPFrameConfig with properties:

          ChannelIdentifier: '0005'
                CommandType: 'Credit based connection request'
           SignalIdentifier: '01'
    SourceChannelIdentifier: '0040'
                      LEPSM: '001F'
        MaxTransmissionUnit: 23
          MaxPDUPayloadSize: 23
                    Credits: 10
```

Create BLE L2CAP Configuration Object Using Name-Value pairs

Create a BLE L2CAP frame configuration object, `'cfgL2CAP'`, by setting the value of channel identifier as `'0004'`using name-value pairs. View the corresponding applicable properties. This configuration object generates a BLE L2CAP data frame (B-frame).

```
cfgL2CAP = bleL2CAPFrameConfig('ChannelIdentifier','0004')
```

```
cfgL2CAP = 
  bleL2CAPFrameConfig with properties:

    ChannelIdentifier: '0004'
```

End-to-End Workflow of BLE L2CAP Frames

Create a BLE L2CAP configuration object, `'bleL2CAPFrameConfig'`, to generate a BLE L2CAP data frame (B-frame). Set the value of channel identifier as`'0004'` and view the corresponding applicable properties.

```
cfgTx = bleL2CAPFrameConfig('ChannelIdentifier','0004')
```

```
cfgTx = 
  bleL2CAPFrameConfig with properties:

    ChannelIdentifier: '0004'
```

Generate a BLE L2CAP data frame (B-frame) with service data unit (SDU) from ATT specified as `'0A0100'`.

```
l2capFrame = bleL2CAPFrame(cfgTx,"0A0100")
```

```
l2capFrame = 7x2 char array
    '03'
    '00'
    '04'
    '00'
    '0A'
    '01'
    '00'
```

Decode the generated BLE L2CAP data frame (B-frame). The returned status indicates decoding was successful. View the output of `'status'`, `'cfgRx'` and `'SDU'`.

```
[status, cfgRx, SDU] = bleL2CAPFrameDecode(l2capFrame)
```

```
status = 
Success

cfgRx = 
  bleL2CAPFrameConfig with properties:

    ChannelIdentifier: '0004'
```

```
SDU = 3x2 char array
    '0A'
    '01'
    '00'
```

bleLLDataChannelPDUConfig

Configuration object for BLE LL data channel PDU

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Description

The `bleLLDataChannelPDUConfig` creates a configuration object for a Bluetooth low energy (BLE) link layer (LL) data channel protocol data unit (PDU) using the default and specified values. You can configure a BLE LL data PDU and a BLE LL control PDU using the applicable properties of `bleLLDataChannelPDUConfig`.

Creation

Syntax

```
cfgLLData = bleLLDataChannelPDUConfig
cfgLLData = bleLLDataChannelPDUConfig(Name,Value)
```

Description

`cfgLLData = bleLLDataChannelPDUConfig` creates a configuration object, `cfgLLData`, for a BLE LL data channel PDU with default values.

`cfgLLData = bleLLDataChannelPDUConfig(Name,Value)` sets properties by using one or more name-value pairs. Enclose each property name in quotes. For example, `bleLLDataChannelPDUConfig('LLID','Data (start fragment/complete)')` configures `cfgLLData` with the type of BLE LL data channel PDU as a data PDU.

Properties

Note For more information about BLE LL data channel PDU properties and their respective values, see volume 6, part B, section 2.4 of the Bluetooth Core Specification [2].

`LLID` — Link layer identifier

`'Data (continuation fragment/empty)'` (default) | `'Data (continuation fragment/empty)'` | `'Control'`

Link layer identifier, specified as a character vector or a string scalar to describe the type of a BLE LL data channel PDU. You can specify `'LLID'` as one of these values:

- `'Data (continuation fragment/empty)'`

- `'Data (start fragment/complete)'`
- `'Control'`

Data Types: `char` | `string`

`NESN` — Next expected sequence number
`0` (default) | `1`

Next expected sequence number, specified as `0` or `1`. This property indicates either an acknowledgment for the last received packet or a request for resending the last transmitted packet from the peer.

Data Types: `logical` | `double`

`SequenceNumber` — Transmitting packet sequence number
`0` (default) | `1`

Transmitting packet sequence number, specified as `0` or `1`. This property indicates the sequence number of the packet being transmitted.

Data Types: `logical` | `double`

`MoreData` — Indication for more data
`false` or `0` (default) | `true` or `1`

Indication for more data, specified as a numeric or a logical value of `1` (`true`) or `0` (`false`). A `true` or `1` value indicates that the sender has more data to send.

Data Types: `logical`

`CRCInitialization` — Cyclic redundancy check initialization value
`'012345'` (default) | six-element character vector | string scalar denoting three-octet hexadecimal value

Cyclic redundancy check initialization value, specified as a six-element character vector or a string scalar denoting a three-octet hexadecimal value.

Data Types: `char` | `string`

`ControlConfig` — BLE LL control PDU payload configuration object
`bleLLControlPDUConfig` object

BLE LL control PDU payload configuration object, specified as a `bleLLControlPDUConfig` object. The different fields of this value are configured using the settings of `bleLLControlPDUConfig`. The default value of this property is an object of type `bleLLControlPDUConfig` with all properties set to their default values. This property is applicable for generating and decoding a BLE LL control PDU.

Object Functions

Specific to This Object

bleLLDataChannelPDU	Generate BLE LL data channel PDU
bleLLDataChannelPDUDecode	Decode BLE LL data channel PDU
bleLLControlPDUConfig	Configuration object for BLE LL control PDU payload configuration

Examples

Create BLE LL Data Channel PDU Configuration Object for Data PDU

Create a BLE LL data channel PDU configuration object for a data PDU and view the corresponding default properties.

```
cfgLLData = bleLLDataChannelPDUConfig
```

```
cfgLLData = 
  bleLLDataChannelPDUConfig with properties:

                LLID: 'Data (continuation fragment/empty)'
                NESN: 0
      SequenceNumber: 0
            MoreData: 0
   CRCInitialization: '012345'
```

Specify the value of LLID as `'Data (start fragment/complete)'` and view the corresponding properties.

```
cfgLLData.LLID = 'Data (start fragment/complete)'
```

```
cfgLLData = 
  bleLLDataChannelPDUConfig with properties:

                LLID: 'Data (start fragment/complete)'
                NESN: 0
      SequenceNumber: 0
            MoreData: 0
   CRCInitialization: '012345'
```

Create BLE LL Data Channel PDU Configuration Object for Control PDU

Create two unique BLE LL data channel PDU configuration objects for a control PDU of type `'Channel map indication'` and `'Version indication'` using name-value pairs.

Create a BLE LL control PDU payload configuration object, `'cfgControl'`, for a control PDU with opcode `'Channel map indication'`. View the applicable properties corresponding to the specified opcode.

```
cfgControl = bleLLControlPDUConfig('Opcode','Channel map indication')
```

```
cfgControl = 
  bleLLControlPDUConfig with properties:

          Opcode: 'Channel map indication'
         Instant: 0
    UsedChannels: [1x37 double]
```

Create a BLE LL data channel configuration object by specifying the values of `'LLID'` as `'Control'` and `'ControlConfig'` as `'cfgControl'`. View the properties of `'cfgLLData'`.

```
 cfgLLData = bleLLDataChannelPDUConfig('LLID','Control', ...
    'ControlConfig',cfgControl)
```

```
cfgLLData = 
  bleLLDataChannelPDUConfig with properties:

               LLID: 'Control'
               NESN: 0
     SequenceNumber: 0
           MoreData: 0
  CRCInitialization: '012345'
      ControlConfig: [1x1 bleLLControlPDUConfig]
```

Create another BLE LL data channel configuration object, `'cfgControl'` for a control PDU, this time specifying the opcode as `'Version indication'`. View the applicable properties of `'cfgControl'` corresponding to the specified opcode.

```
cfgControl.Opcode = 'Version indication';
cfgControl.SubVersionNumber = '008E'
```

```
cfgControl = 
  bleLLControlPDUConfig with properties:

             Opcode: 'Version indication'
      VersionNumber: '5.0'
  CompanyIdentifier: 'FFFF'
   SubVersionNumber: '008E'
```

Create a BLE LL data channel configuration object, `'cfgLLData'`, by specifying the values of `'ControlConfig'` as `'cfgControl'` and view the applicable properties.

```
cfgLLData.ControlConfig = cfgControl
```

```
cfgLLData = 
  bleLLDataChannelPDUConfig with properties:

               LLID: 'Control'
               NESN: 0
     SequenceNumber: 0
           MoreData: 0
  CRCInitialization: '012345'
      ControlConfig: [1x1 bleLLControlPDUConfig]
```

End-to-End Workflow of BLE LL Data Channel PDU

Create a BLE LL data channel PDU configuration object, `'cfgTx'`, for a data PDU using default configuration. View the corresponding default properties.

```
cfgTx = bleLLDataChannelPDUConfig
cfgTx =
  bleLLDataChannelPDUConfig with properties:

                LLID: 'Data (continuation fragment/empty)'
                NESN: 0
      SequenceNumber: 0
            MoreData: 0
   CRCInitialization: '012345'
```

Initialize the CRC value corresponding to the configuration object `'cfgTx'`.

```
cfgTx.CRCInitialization = '123456';
```

Generate a BLE LL data channel PDU by using the data PDU configuration object, `'cfgTx'` and the upper-layer payload `'030004000A0100'`.

```
pdu = bleLLDataChannelPDU(cfgTx,'030004000A0100');
```

Decode the generated BLE LL data channel PDU by initializing the CRC value. The returned status indicates decoding is successful. View the values of `'status'`, `'cfgRx'` and `'llPayload'`.

```
crcInit = '123456';
[status, cfgRx, llPayload] = bleLLDataChannelPDUDecode(pdu, crcInit)
```

```
status =
Success

cfgRx =
  bleLLDataChannelPDUConfig with properties:

                LLID: 'Data (continuation fragment/empty)'
                NESN: 0
      SequenceNumber: 0
            MoreData: 0
   CRCInitialization: '012345'

llPayload = 7x2 char array
    '03'
    '00'
    '04'
    '00'
    '0A'
    '01'
    '00'
```

bleLLAdvertisingChannelPDUConfig

Configuration object for BLE LL advertising channel PDU

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Description

The `bleLLAdvertisingChannelPDUConfig` creates a configuration object for Bluetooth low energy (BLE) link layer (LL) advertising channel protocol data unit (PDU) using the default and specified values. You can configure a BLE LL advertising channel PDU using the applicable properties of `bleLLAdvertisingChannelPDUConfig`.

Creation

Syntax

```
cfgLLAdv = bleLLAdvertisingChannelPDUConfig
cfgLLAdv = bleLLAdvertisingChannelPDUConfig(Name,Value)
```

Description

`cfgLLAdv = bleLLAdvertisingChannelPDUConfig` creates a configuration object, `cfgLLAdv`, for a BLE LL advertising channel PDU with default values.

`cfgLLAdv = bleLLAdvertisingChannelPDUConfig(Name,Value)` creates a BLE LL advertising channel PDU configuration object by specifying properties using one or more name-value pairs. Enclose each property name in quotation marks. For example, `bleLLAdvertisingChannelPDUConfig('PDUType','Scan response')` configures `cfgLLAdv` with the type of BLE LL advertising channel PDU as `'Scan response'`.

Properties

Note For more information about BLE LL advertising channel PDU properties and their respective values, see volume 6, part B, section 2.3 of the Bluetooth Core Specification [2].

PDUType — BLE LL advertising channel PDU type
`'Advertising indication'` (default) | `'Advertising direct indication'` | `'Advertising non connectable indication'` | ...

BLE LL advertising channel PDU type, specified as a character vector or a string scalar to describe the type of a BLE LL advertising channel PDU. You can specify `'PDUType'` as one of these values:

- `'Advertising indication'`
- `'Advertising direct indication'`
- `'Advertising non connectable indication'`
- `'Scan request'`
- `'Scan response'`
- `'Connection indication'`
- `'Advertising scannable indication'`

Data Types: `char` | `string`

`ChannelSelection` — Channel selection algorithm
`'Algorithm1'` (default) | `'Algorithm2'`

Channel selection algorithm, specified as `'Algorithm1'` or `'Algorithm2'` to indicate the type of algorithm used for hopping between channels.

Data Types: `char` | `string`

`AdvertiserAddressType` — Advertiser device address type
`'Random'` (default) | `'Public'`

Advertiser device address type, specified as `'Random'` or `'Public'` to indicate the type of advertiser address in the packet.

Data Types: `char` | `string`

`AdvertiserAddress` — Advertiser device address
`'0123456789AB'` (default) | 12-element character vector | string scalar denoting a six-octet hexadecimal value

Advertiser device address, specified as a 12-element character vector or a string scalar denoting a six-octet hexadecimal value to indicate the advertiser device address.

Data Types: `char` | `string`

`TargetAddressType` — Target device address type
`'Random'` (default) | `'Public'`

Target device address type, specified as `'Random'` or `'Public'` to indicate the type of target device address when a directed advertisement packet is transmitted.

Data Types: `char` | `string`

`TargetAddress` — Target device address
`'0123456789CD'` (default) | 12-element character vector | string scalar denoting a six-octet hexadecimal value

Target device address, specified as a 12-element character vector or a string scalar denoting a six-octet hexadecimal value to indicate the target device address when a directed advertisement packet is transmitted.

Data Types: `char` | `string`

`ScannerAddressType` — Scanner device address type
`'Random'` (default) | `'Public'`

Scanner device address type, specified as `'Random'` or `'Public'` to indicate the type of scanner device address when a scan request packet is transmitted.

Data Types: `char` | `string`

`ScannerAddress` — Scanner device address

`'0123456789CD'` (default) | 12-element character vector | string scalar denoting a six-octet hexadecimal value

Scanner device address, specified as a 12-element character vector or a string scalar denoting a six-octet hexadecimal value to indicate the scanner device address when a scan request packet is transmitted.

Data Types: `char` | `string`

`InitiatorAddressType` — Initiator device address type

`'Random'` (default) | `'Public'`

Initiator device address type, specified as `'Random'` or `'Public'` to indicate the type of initiator device address when a connection indication packet is transmitted.

Data Types: `char` | `string`

`InitiatorAddress` — Initiator device address

`'0123456789CD'` (default) | 12-element character vector | string scalar denoting a six-octet hexadecimal value

Initiator device address, specified as a 12-element character vector or a string scalar denoting a six-octet hexadecimal value to indicate the initiator device address when a connection indication packet is transmitted.

Data Types: `char` | `string`

`AdvertisingData` — Advertising data

`'020106'` (default) | character vector | string scalar | numeric vector of elements in the range [0,31] | `n`-by-2 character array

Advertising data, specified as one of these values:

- Character vector — This vector represent octets in hexadecimal format.
- String scalar — This scalar represent octets in hexadecimal format.
- Numeric vector of elements in the range [0,31] — This vector represent octets in decimal format.
- `n`-by-2 character array — Each row represent an octet in hexadecimal format.

This property indicates the advertising data that the device sends out in an advertisement packet.

Data Types: `char` | `string` | `double`

`ScanResponseData` — Scan response data

`'020106'` (default) | character vector | string scalar | numeric vector of elements in the range [0,31] | `n`-by-2 character array

Scan response data, specified as one of these values:

- Character vector — This vector represent octets in hexadecimal format.

- String scalar — This scalar represent octets in hexadecimal format.
- Numeric vector of elements in the range [0,31] — This vector represent octets in decimal format.
- n-by-2 character array — Each row represent an octet in hexadecimal format.

This property indicates the scan response data that the device sends out in a scan response packet (when scan request is received).

Data Types: `char` | `string` | `double`

`AccessAddress` — Unique connection address
`'01234567'` (default) | eight-element character vector or a string scalar

Unique connection address, specified as an eight-element character vector or a string scalar. This property indicates a unique 32-bit address generated by the LL for the new connection or for a periodic advertisement between two devices.

Data Types: `char` | `string`

`CRCInitialization` — CRC initialization value
`'012345'` (default) | six-element character vector | three-octet hexadecimal value

CRC initialization value, specified as a six-element character vector or a string scalar denoting a three-octet hexadecimal value. This property is used as initialization value for the CRC calculation.

Data Types: `char` | `string`

`WindowSize` — Transmit window size
`1` (default) | nonnegative integer

Transmit window size, specified as a nonnegative integer in the range [1, Mws], where Mws is the lesser of 8 and `ConnectionInterval`-1. This property indicates the window size within which the master transmits the data packet and slave listens for the data packet after connection establishment. Each unit is taken as 1.25 ms so that the window size (`WindowSize`×1.25) is in the range of 1.25 ms to the minimum of (10 ms, ((`ConnectionInterval`×1.25) - 1.25) ms).

Data Types: `double`

`WindowOffset` — Transmit window offset
`0` (default) | nonnegative integer

Transmit window offset, specified as a nonnegative integer in the range [0, Mwo], where Mwo is the lesser of 3200 and `ConnectionInterval`. This property indicates the window offset after which the transmit window starts. Each unit is taken as 1.25 ms so that the resultant window offset (`WindowOffset`×1.25) is in the range of 0 ms to (`ConnectionInterval`×1.25) ms.

Data Types: `double`

`ConnectionInterval` — Connection interval
`6 (7.5 ms)` (default) | positive integer

Connection interval, specified as a positive integer in the range [6, 3200]. This property indicates the interval between the start of two consecutive connection events. Each unit is taken as 1.25 ms so that the resultant connection interval (`ConnectionInterval`×1.25) is in the range of 7.5 ms to 4.0 s.

Data Types: `double`

`SlaveLatency` — Slave latency

`0` (default) | nonnegative integer

Slave latency, specified as a nonnegative integer in the range [0, Msl], where Msl is the lesser of 499 and ((`ConnectionInterval`×10)/((`ConnectionInterval`×1.25)×2))-1. This property indicates the number of connection events that a slave can skip listening for packets from the master.

Data Types: `double`

`ConnectionTimeout` — Connection supervision timeout

`10` (default) | positive integer

Connection supervision timeout, specified as a positive integer in the range [Mct, 3200], where Mct is the larger of 10 and ((1+`SlaveLatency`)×(`ConnectionInterval`×1.25)×2)/10. This property indicates the timeout for a connection if no valid packet is received within this time. Each unit is taken as 10 ms so that the resultant connection timeout (`ConnectionInterval`×10) is in the range of 100 ms to 32.0 s.

Data Types: `double`

`UsedChannels` — List of used data channels

`row vector containing the channel indices between [0:36]` (default) | integer vector with element values in the range [0, 36]

List of used data channels, specified as an integer vector with element values in the range [0, 36]. The vector length must be greater than 1. At least two channels must be set as used (good) channels. This property indicates the set of good channels classified by the master.

Data Types: `double`

`HopIncrement` — Hop increment count

`5` (default) | positive integer

Hop increment count, specified as an integer in the range [5, 16]. This property indicates the hop increment count to be used for hopping between data channels.

Data Types: `double`

`SleepClockAccuracy` — Master sleep clock accuracy

`'251 to 500 ppm'` (default) | `'151 to 250 ppm'` | `'101 to 150 ppm'` | `...`

Master sleep clock accuracy, specified as a character vector or a string scalar indicating the worst case master sleep clock accuracy. You can specify `SleepClockAccuracy` as one of these values:

- `'251 to 500 ppm'`
- `'151 to 250 ppm'`
- `'101 to 150 ppm'`
- `'76 to 100 ppm'`
- `'51 to 75 ppm'`
- `'31 to 50 ppm'`
- `'21 to 30 ppm'`
- `'0 to 20 ppm'`

Data Types: `char` | `string`

Object Functions

Specific to This Object

bleLLAdvertisingChannelPDU	Generate BLE LL advertising channel PDU
bleLLAdvertisingChannelPDUDecode	Decode BLE LL advertising channel PDU

Examples

Create BLE LL Advertising Channel PDU Configuration Object Using Default Settings

Create a BLE LL advertising channel configuration object and view the corresponding default properties.

```
cfgLLAdv = bleLLAdvertisingChannelPDUConfig
```

```
cfgLLAdv = 
  bleLLAdvertisingChannelPDUConfig with properties:

                 PDUType: 'Advertising indication'
        ChannelSelection: 'Algorithm1'
   AdvertiserAddressType: 'Random'
       AdvertiserAddress: '0123456789AB'
         AdvertisingData: [3x2 char]
```

Create BLE LL Advertising Channel PDU Configuration Object Using Name-Value Pairs

Create two unique BLE LL advertising channel configuration objects of type `'Scan response'` and `'Connection indication'` using name-value pairs.

Create a BLE LL advertising channel PDU configuration object, `'cfgLLAdv'`, by setting the values of PDU type as `'Scan response'`, advertiser address as `'1234567890AB'`, and scan response data as `'020106020AD3'` using name-value pairs. View the corresponding properties.

```
cfgLLAdv = bleLLAdvertisingChannelPDUConfig(...
    'PDUType','Scan response', ...
    'AdvertiserAddress','1234567890AB', ...
    'ScanResponseData','020106020AD3')
```

```
cfgLLAdv = 
  bleLLAdvertisingChannelPDUConfig with properties:

                 PDUType: 'Scan response'
        ChannelSelection: 'Algorithm1'
   AdvertiserAddressType: 'Random'
       AdvertiserAddress: '1234567890AB'
        ScanResponseData: [6x2 char]
```

Create another BLE LL advertising channel PDU configuration object, `'cfgLLAdv'`, and change the type of PDU to `'Connection indication'`. Set the values of the connection interval as `64` and the set of data channels as `[0 4 12 16 18 24 25]`. View the corresponding properties.

```
cfgLLAdv = bleLLAdvertisingChannelPDUConfig('PDUType', ...
    'Connection indication');
cfgLLAdv.ConnectionInterval = 64;
cfgLLAdv.UsedChannels       = [0 4 12 16 18 24 25]
```

```
cfgLLAdv = 
  bleLLAdvertisingChannelPDUConfig with properties:

                  PDUType: 'Connection indication'
         ChannelSelection: 'Algorithm1'
    AdvertiserAddressType: 'Random'
        AdvertiserAddress: '0123456789AB'
     InitiatorAddressType: 'Random'
         InitiatorAddress: '0123456789CD'
            AccessAddress: '01234567'
        CRCInitialization: '012345'
               WindowSize: 1
             WindowOffset: 0
       ConnectionInterval: 64
             SlaveLatency: 0
        ConnectionTimeout: 10
             UsedChannels: [0 4 12 16 18 24 25]
             HopIncrement: 5
       SleepClockAccuracy: '251 to 500 ppm'
```

End-to-End Workflow of BLE LL Advertising Channel PDU

Create a BLE LL advertising channel PDU configuration object, `'cfgTx'`. Set the values of PDU type as `'Connection indication'`, the connection interval as `8`, and the set of data channels as `[0 4 12 16 18 24 25]`.

```
cfgTx = bleLLAdvertisingChannelPDUConfig('PDUType', ...
    'Connection indication');
cfgTx.ConnectionInterval = 8;
cfgTx.UsedChannels       = [0 4 12 16 18 24 25]
```

```
cfgTx = 
  bleLLAdvertisingChannelPDUConfig with properties:

                  PDUType: 'Connection indication'
         ChannelSelection: 'Algorithm1'
    AdvertiserAddressType: 'Random'
        AdvertiserAddress: '0123456789AB'
     InitiatorAddressType: 'Random'
         InitiatorAddress: '0123456789CD'
            AccessAddress: '01234567'
        CRCInitialization: '012345'
               WindowSize: 1
             WindowOffset: 0
       ConnectionInterval: 8
             SlaveLatency: 0
        ConnectionTimeout: 10
             UsedChannels: [0 4 12 16 18 24 25]
             HopIncrement: 5
       SleepClockAccuracy: '251 to 500 ppm'
```

Generate a BLE LL advertising channel PDU by using the corresponding configuration object.

```
pdu = bleLLAdvertisingChannelPDU(cfgTx);
```

Decode the generated BLE LL advertising channel PDU. The returned status indicates decoding is successful. View the output of `'status'` and `'cfgRx'`.

```
[status, cfgRx] = bleLLAdvertisingChannelPDUDecode(pdu)
```

```
status = 
Success

cfgRx = 
  bleLLAdvertisingChannelPDUConfig with properties:

                PDUType: 'Connection indication'
       ChannelSelection: 'Algorithm1'
   AdvertiserAddressType: 'Random'
       AdvertiserAddress: '0123456789AB'
    InitiatorAddressType: 'Random'
        InitiatorAddress: '0123456789CD'
           AccessAddress: '01234567'
        CRCInitialization: '012345'
              WindowSize: 1
            WindowOffset: 0
      ConnectionInterval: 8
            SlaveLatency: 0
       ConnectionTimeout: 10
            UsedChannels: [0 4 12 16 18 24 25]
            HopIncrement: 5
      SleepClockAccuracy: '251 to 500 ppm'
```

bleGAPDataBlockConfig

Configuration object for BLE GAP data block

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Description

The `bleGAPDataBlockConfig` creates a configuration object for a Bluetooth low energy (BLE) generic access profile (GAP) data block of the type advertising data (AD) or scan response data (SRD). You can configure a BLE GAP data block using the applicable properties of `bleGAPDataBlockConfig`.

Creation

Syntax

```
cfgGAP = bleGAPDataBlockConfig
cfgGAP = bleGAPDataBlockConfig(Name,Value)
```

Description

`cfgGAP = bleGAPDataBlockConfig` creates a configuration object, `cfgGAP`, for a BLE GAP data block of the type AD or SRD with default values.

`cfgGAP = bleGAPDataBlockConfig(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `bleGAPDataBlockConfig('AdvertisingDataTypes','Tx power level')` configures `cfgGAP` with block data advertising data type as `'Tx power level'`.

Properties

Note For more information about BLE GAP data block properties and their respective values, see vol 3, part C, section 4 of the Bluetooth Core Specification [2].

`AdvertisingDataTypes` — Block data advertising data types
`'Flags'` (default) | `'UUIDs'` | `'Local name'` | `'Tx power level'` | `'Connection interval range'` | `'Advertising interval'`

Block data advertising data types, specified as a character vector or a string scalar or a cell array, containing the list of advertising data types for BLE GAP data block. You can specify `AdvertisingDataTypes` as one of these values:

- 'Flags'
- 'UUIDs'
- 'Local name'
- 'Tx power level'
- 'Connection interval range'
- 'Advertising interval'

Data Types: char | string | cell

LEDiscoverability — LE discoverable mode
'General' (default) | 'None' | 'Limited' | 'Limited and general'

LE discoverable mode, specified as a character vector or a string scalar, describing the LE discoverable mode of the device. You can specify LEDiscoverability as one of these values:

- 'None'
- 'General'
- 'Limited'
- 'Limited and general'

Data Types: char | string

BREDR — Basic rate (BR) or enhanced data rate (EDR) support
false (default) | true

Basic rate (BR) or enhanced data rate (EDR) support, specified as true or false. A true value indicates that BR or EDR is supported. This is used when AdvertisingDataTypes is set to 'Flags'.

Data Types: logical

LE — Simultaneous LE and BR or EDR support
'None' (default) | 'Host' | 'Controller' | 'Host and controller'

Simultaneous LE and BR/EDR support, specified as a character vector or a string scalar. You can specify 'LE' as one of these values:

- 'None'
- 'Host'
- 'Controller'
- 'Host and controller'

This property is applicable only when BREDR is set to true. Set this property to 'Host' or 'Controller' to specify simultaneous LE and BR or EDR support at the host or the controller respectively. Set this property to 'Host and Controller' for simultaneous LE and BR or EDR support at the host and the controller.

Data Types: char | string

LocalNameShortening — Enable shortening of local name
false (default) | true

Local name shortened used, specified as a scalar logical value of `false` or `true`. Set this value to `true` value indicates that the name of the device is shortened.

Data Types: `logical`

`LocalName` — UTF-8 encoded user-friendly descriptive name
`'Bluetooth'` (default) | character vector or a string scalar consisting of UTF-8 characters

UTF-8 encoded user-friendly descriptive name, specified as a character vector or a string scalar consisting of UTF-8 characters. This property specifies the local name assigned to the device.

Data Types: `char` | `string`

`IdentifierType` — Type of 16-bit service or service class identifiers
`'Incomplete'` (default) | `'Complete'`

Type of 16-bit service or service class identifiers, specified as `'Incomplete'` or `'Complete'`. If this value is `'Incomplete'`, then the list of 16-bit service or service class identifiers list is incomplete.

Data Types: `char` | `string`

`Identifiers` — List of 16-bit service or service class identifiers
`'' (empty)` (default) | *n*-by-4 character array

List of 16-bit service or service class identifiers, specified as an *n*-by-4 character array. The value of *n* must be in the range [0, 127]. Each row in the *n*-by-4 character array is represented as a four-element character vector or string scalar denoting a two-octet (16-bit) hexadecimal value of a service or service class universally unique identifier (UUID). These UUIDs are assigned by the Bluetooth Special Interest Group (SIG).

Data Types: `char`

`AdvertisingInterval` — Advertising interval
`32` (default) | integer in the range [32, 65,535]

Advertising interval, specified as an integer in the range [32, 65,535]. This property denotes the interval between the start of two consecutive advertising events. Incremental units are 0.625 ms steps, so the resultant range for [32, 65,535] is [20, 40.959375].

Data Types: `double`

`TxPowerLevel` — Packet transmit power level
`0 (dBm)` (default) | integer in the range [–127, 127]

Packet transmit power level, in dBm, specified as an integer in the range [–127, 127]. This property calculates the pathloss as *pathloss = Tx Power Level – RSSI*, where *RSSI* is the received signal strength indicator.

Data Types: `double`

`ConnectionIntervalRange` — Connection interval range
`[6,3200]` (default) | two-element numeric vector [MIN, MAX]

Connection interval range, specified as a two-element numeric vector [*MIN*, *MAX*], where *MIN* and *MAX* must be in the range [6,3200]. *MIN* and *MAX* specify the minimum and maximum value for the connection interval respectively. *MIN* must be less than or equal to *MAX*. Incremental units are 1.25 ms steps, so that the resultant range for [6, 3200] is [7.5, 4.0].

Data Types: double

Object Functions

Specific to This Object

bleGAPDataBlock	Generate BLE GAP data block
bleGAPDataBlockDecode	Decode BLE GAP data block

Examples

Create BLE GAP AD Block Configuration Object Using Default Settings

Create two unique BLE GAP AD configuration objects: one with AD types 'Flags' and 'Tx power level' and the other with AD type 'Flags' and simultaneous LE and BR or EDR support at the host.

Create a BLE GAP AD block configuration object using default settings. Set the values of AD types as 'Flags' and 'Tx power level', LE discoverability as 'Limited' and Tx power level as 45. View the properties of the corresponding configuration object.

```
cfgGAP = bleGAPDataBlockConfig;
cfgGAP.AdvertisingDataTypes = {'Flags';'Tx power level'};
cfgGAP.LEDiscoverability = 'Limited';
cfgGAP.TxPowerLevel = 45
```

```
cfgGAP = 
  bleGAPDataBlockConfig with properties:

    AdvertisingDataTypes: {2x1 cell}
       LEDiscoverability: 'Limited'
                   BREDR: 0
            TxPowerLevel: 45
```

Create another BLE GAP AD block configuration object using default settings, this time with AD type 'Flags' and having simultaneous support for LE and BR/EDR. Set the values of LE discoverability as 'Limited', enable BR or EDR support as true and enable simultaneous support for LE and BR or EDR as 'Host'. View the properties of the corresponding configuration object.

```
cfgGAP = bleGAPDataBlockConfig;
cfgGAP.LEDiscoverability = 'Limited and general';
cfgGAP.BREDR = true;
cfgGAP.LE = 'Host'
```

```
cfgGAP = 
  bleGAPDataBlockConfig with properties:

    AdvertisingDataTypes: {'Flags'}
       LEDiscoverability: 'Limited and general'
                   BREDR: 1
                      LE: 'Host'
```

Create BLE GAP AD Block Configuration Object Using Name-Value Pairs

Create a configuration object for a BLE GAP AD block using name-value pairs. Set the values of AD types as `'Advertising interval'` and `'Local name'`, advertising interval as `48`, local name as `'MathWorks'` and local name shortening as `true`. View the properties of the corresponding configuration object.

```
cfgGAP = bleGAPDataBlockConfig('AdvertisingDataTypes', ...
    {'Advertising interval', ...
    'Local name'});
cfgGAP.AdvertisingInterval = 48;
cfgGAP.LocalName = 'MathWorks';
cfgGAP.LocalNameShortening = true
```

```
cfgGAP = 
  bleGAPDataBlockConfig with properties:

    AdvertisingDataTypes: {2x1 cell}
               LocalName: 'MathWorks'
     LocalNameShortening: 1
     AdvertisingInterval: 48
```

End-to-End Workflow of BLE GAP AD Blocks

Create a configuration object for a BLE GAP AD block using name-value pairs. Set the values of AD types as `'Advertising interval'` and `'Local name'`, advertising interval as `48`, local name as `'MathWorks'`, and local name shortening as `true`. View the properties of the corresponding configuration object.

```
cfgTx = bleGAPDataBlockConfig('AdvertisingDataTypes',{'Advertising interval','Local name'});
cfgTx.AdvertisingInterval = 48;
cfgTx.LocalName = 'MathWorks';
cfgTx.LocalNameShortening = true
```

```
cfgTx = 
  bleGAPDataBlockConfig with properties:

    AdvertisingDataTypes: {2x1 cell}
               LocalName: 'MathWorks'
     LocalNameShortening: 1
     AdvertisingInterval: 48
```

Create a BLE GAP AD block using the configuration object `'cfgTx'`.

```
dataBlock = bleGAPDataBlock(cfgTx);
```

Decode the generated BLE GAP AD block. The returned status indicates decoding was successful. View the output of `'status'` and `'cfgRx'`.

```
[status, cfgRx] = bleGAPDataBlockDecode(dataBlock)
```

```
status = 
Success

cfgRx = 
  bleGAPDataBlockConfig with properties:

    AdvertisingDataTypes: {2x1 cell}
               LocalName: 'MathWorks'
     LocalNameShortening: 1
     AdvertisingInterval: 48
```

bluetoothFrequencyHop

Bluetooth BR/EDR channel index for frequency hopping

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Description

The `bluetoothFrequencyHop` object creates a Bluetooth basic rate/enhanced data rate (BR/EDR) channel index for frequency hopping. This object generates the hopping sequence used in inquiry, paging, and connection procedures.

Creation

Syntax

```
FH = bluetoothFrequencyHop
FH = bluetoothFrequencyHop(Name,Value)
```

Description

`FH = bluetoothFrequencyHop` creates a default Bluetooth BR/EDR channel index object for frequency hopping.

`FH = bluetoothFrequencyHop(Name,Value)` sets “Properties” on page 3-170 by using one or more name-value pairs. Enclose each property name in quotes. For example, `bluetoothFrequencyHop('SequenceType','Page')` sets the frequency hopping sequence type to `Page`.

Properties

`DeviceAddress` — Bluetooth BR/EDR device address
`'9E8B33'` (default) | 12-element character vector | string scalar denoting a 6-octet hexadecimal value

Bluetooth BR/EDR device address, specified as a 12-element character vector or a string scalar denoting a 6-octet hexadecimal value. This property indicates the Bluetooth BR/EDR device address given as an input to the hop selection kernel. This property ignores all consecutive 0s starting from the most significant bit (MSB). This table maps the value of this property to different physical channels.

Type of Physical Channel	Value of `DeviceAddress` Property
Basic	Address of Master

Type of Physical Channel	Value of DeviceAddress Property
Page scan	Address of the scanning device
Inquiry	General inquiry access code (GIAC)

The default value of this property denotes the lower address part (LAP) of GIAC.

Data Types: char | string

SequenceType — Frequency hopping sequence type

'Inquiry' (default) | 'Page scan' | 'Inquiry scan' | 'Page' | ...

Frequency hopping sequence type, specified as one of these values:

- 'Page scan'
- 'Inquiry scan'
- 'Page'
- 'Inquiry'
- 'Master page response'
- 'Slave page response'
- 'Inquiry response'
- 'Connection basic'
- 'Connection adaptive'
- 'Interlaced page scan'
- 'Interlaced inquiry scan'

Data Types: char | string

InterlaceOffset — Offset for available frequencies in inquiry and paging procedures

16 (default) | integer in the range [0, 31]

Offset for available frequencies in inquiry and paging procedures, specified as an integer in the range [0, 31].

Dependencies

To enable this property, set the “SequenceType” on page 3-0 property to 'Interlaced page scan' or 'Interlaced inquiry scan'.

Data Types: double

KNudge — Offset to compute control signal (X)

0 (default) | even integer

Offset to compute control signal (X), specified as an even integer. This property specifies the additional offset added to the clock bits.

Dependencies

To enable this property, set the SequencyType property to 'Page' or 'Inquiry'.

Data Types: double

`KOffset` — Offset to switch between A-train and B-train

24 (default) | 8

Offset to switch between A-train and B-train, specified as 24 (for A-train) or 8 (for B-train). To switch between the trains, this property specifies the offset added to the clock bits.

Dependencies

To enable this property, set the `SequencyType` property to `'Page'` or `'Inquiry'`.

Data Types: `double`

`Counter` — Counter for Master or Slave page response sequence

`0` (default) | nonnegative integer

Counter for Master or Slave page response sequence, specified as a nonnegative integer. This property is incremented at every Master transmission slot.

Dependencies

To enable this property, set the `SequencyType` property to `'Slave page response'`, `'Master page response'`, or `'Inquiry response'`.

Data Types: `double`

`UsedChannels` — List of used channels

row vector containing all 79 channel indices (default) | vector of integers in the range [0, 78]

List of used channels, specified as a vector of integers in the range [0, 78]. The vector must contain at least 20 elements.

Dependencies

To enable this property, set the `SequencyType` property to `'Connection adaptive'`.

Data Types: `double`

Object Functions

Specific to This Object

nextHop Select Bluetooth BR/EDR channel index to hop for next frequency

Examples

Select Bluetooth BR/EDR Channel Index for Connection Basic Frequency Hopping Sequence

Create a Bluetooth BR/EDR channel index object for frequency hopping.

```
fh = bluetoothFrequencyHop;
```

Specify the frequency hopping sequence type as connection basic.

```
fh.SequenceType = 'Connection basic';
```

Specify a clock value and Bluetooth BR/EDR device address.

```
inputClock = '2C'; % 28-bit
fh.DeviceAddress = '2A96EF25'
```

```
fh = 
  bluetoothFrequencyHop with properties:

      DeviceAddress: '2A96EF25'
       SequenceType: 'Connection basic'
    InterlaceOffset: 16
             KNudge: 0
            KOffset: 24
            Counter: 0
       UsedChannels: [1x79 double]
```

Select a Bluetooth BR/EDR channel index to hop for next frequency.

```
[channelIndex, X] = nextHop(fh,inputClock)
```

```
channelIndex = 27
```

```
X = 11
```

Select Bluetooth BR/EDR Channel Index for Connection Adaptive Frequency Hopping Sequence

Create a Bluetooth BR/EDR channel index object for frequency hopping, specifying frequency hopping sequence type, Bluetooth BR/EDR device address, and used channels.

```
fh = bluetoothFrequencyHop('SequenceType','Connection adaptive', ...
    'DeviceAddress','2A96EF25','UsedChannels',22:78)
```

```
fh = 
  bluetoothFrequencyHop with properties:

      DeviceAddress: '2A96EF25'
       SequenceType: 'Connection adaptive'
    InterlaceOffset: 16
             KNudge: 0
            KOffset: 24
            Counter: 0
       UsedChannels: [1x57 double]
```

Specify a clock value.

```
inputClock = '12C'; % 28-bit
```

Select a Bluetooth BR/EDR channel index to hop for next frequency.

```
[channelIndex, X] = nextHop(fh, inputClock)
```

```
channelIndex = 65
```

```
X = 11
```

Select Bluetooth BR/EDR Channel Index for Page Frequency Hopping Sequence

Create a Bluetooth BR/EDR channel index object for frequency hopping.

```
fh = bluetoothFrequencyHop;
```

Specify the frequency hopping sequence type as page.

```
fh.SequenceType = 'Page';
```

Specify a clock value, offset to select frequencies in A-train, and Bluetooth BR/EDR device address.

```
inputClock = 44; % 28-bit
fh.KOffset = 24;
fh.DeviceAddress = '2A96EF25'
```

```
fh = 
  bluetoothFrequencyHop with properties:

      DeviceAddress: '2A96EF25'
       SequenceType: 'Page'
    InterlaceOffset: 16
             KNudge: 0
            KOffset: 24
            Counter: 0
       UsedChannels: [1x79 double]
```

Select a Bluetooth BR/EDR channel index to hop for next frequency.

```
[channelIndex, X] = nextHop(fh, inputClock)
```

```
channelIndex = 15
```

```
X = 30
```

Select Bluetooth BR/EDR Channel Index for Slave Page Response Frequency Hopping Sequence

Create a Bluetooth BR/EDR channel index object for frequency hopping.

```
fh = bluetoothFrequencyHop;
```

Specify the frequency hopping sequence type as Slave page response.

```
fh.SequenceType = 'Slave page response';
```

Specify a clock value, counter for Slave page response, and Bluetooth BR/EDR device address.

```
frozenClock = '2A'; % 28-bit
fh.Counter = 1;
fh.DeviceAddress = '2A96EF25'
```

```
fh = 
  bluetoothFrequencyHop with properties:
      DeviceAddress: '2A96EF25'
       SequenceType: 'Slave page response'
    InterlaceOffset: 16
             KNudge: 0
            KOffset: 24
            Counter: 1
       UsedChannels: [1x79 double]
```

Select a Bluetooth BR/EDR channel index to hop for next frequency.

```
[channelIndex, X] = nextHop(fh, frozenClock)
```

```
channelIndex = 28
```

```
X = 1
```

“Bluetooth Packet Structure”

Introduced in R2020b

pcapWriter

PCAP file writer of protocol packets

Description

The `pcapWriter` object writes generated and recovered protocol packets to a packet capture (PCAP) file (`.pcap`).

You can write these packet types to a PCAP file:

- Generated and recovered Bluetooth low energy (BLE) link layer (LL) packets (requires Communications Toolbox Library for the Bluetooth Protocol)
- Generated and recovered 5G NR protocol packets (requires 5G Toolbox™)
- Generated and recovered WLAN protocol packets (requires WLAN Toolbox)

Creation

Syntax

```
pcapObj = pcapWriter
pcapObj = pcapWriter(Name,Value)
```

Description

`pcapObj = pcapWriter` creates a default PCAP file writer object.

`pcapObj = pcapWriter(Name,Value)` sets properties using one or more name-value pair arguments. Enclose each property name in quotes. For example, `'ByteOrder','big-endian'` specifies the byte order as big-endian.

Properties

Note The `pcapWriter` object does not overwrite the existing PCAP file. During each call of this object, specify a unique PCAP file name.

`FileName` — Name of the PCAP file
`'capture'` (default) | character row vector | string scalar

Name of the PCAP file, specified as a character row vector or a string scalar.

Data Types: `char` | `string`

`ByteOrder` — Byte order
`'little-endian'` (default) | `'big-endian'`

Byte order, specified as `'little-endian'` or `'big-endian'`.

Data Types: `char` | `string`

Object Functions

Specific to This Object

write	Write protocol packet data to PCAP or PCAPNG file
writeGlobalHeader	Write global header to PCAP file

Examples

Write BLE Link Layer Packet to PCAP File

Create a PCAP file writer object, specifying the name of the PCAP file. Specify the BLE link type.

```
pcapObj = pcapWriter('FileName','writeBLE');
bleLinkType = 251;
```

Write a global header to the PCAP file.

```
writeGlobalHeader(pcapObj,bleLinkType);
```

Specify a BLE LL packet.

```
llpacket = '42BC13E206120E00050014010A001F0040001700170000007D47C0';
```

Write the BLE LL packet to the PCAP file.

```
timestamp = 129100; % Number of microseconds
write(pcapObj,llpacket,timestamp);
```

`pcapngWriter`

Introduced in R2020b

pcapngWriter

PCAPNG file writer of protocol packets

Description

The `pcapngWriter` object writes generated and recovered protocol packets to a packet capture next generation (PCAPNG) file (`.pcapng`).

You can write these packet types to a PCAPNG file:

- Generated and recovered Bluetooth low energy (BLE) link layer (LL) packets (requires Communications Toolbox Library for the Bluetooth Protocol)
- Generated and recovered 5G NR protocol packets (requires 5G Toolbox)
- Generated and recovered WLAN protocol packets (requires WLAN Toolbox)

Creation

Syntax

```
pcapngObj = pcapngWriter
pcapngObj = pcapngWriter(Name,Value)
```

Description

`pcapngObj = pcapngWriter` creates a default PCAPNG file writer object.

`pcapngObj = pcapngWriter(Name,Value)` sets properties using one or more name-value pair arguments. Enclose each property name in quotes. For example, `'ByteOrder','big-endian'` specifies the byte order as big-endian.

Properties

Note The `pcapngWriter` object does not overwrite the existing PCAPNG file. During each call of this object, specify a unique PCAPNG file name.

`FileName` — Name of the PCAPNG file
`'capture'` (default) | character row vector | string scalar

Name of the PCAPNG file, specified as a character row vector or a string scalar.

Data Types: `char` | `string`

`ByteOrder` — Byte order
`'little-endian'` (default) | `'big-endian'`

Byte order, specified as `'little-endian'` or `'big-endian'`.

Data Types: `char` | `string`

`FileComment` — Comment for PCAPNG file

`' '` (default) | character vector | string scalar

Comment for the PCAPNG file, specified as a character vector or a string scalar.

Data Types: `char` | `string`

Object Functions

Specific to This Object

write	Write protocol packet data to PCAP or PCAPNG file
writeCustomBlock	Write custom block to PCAPNG file
writeInterfaceDescriptionBlock	Write interface description block to PCAPNG file

Examples

Write BLE Link Layer Packet to PCAPNG File

Create a PCAPNG file writer object, specifying the name of the PCAPNG file. Specify the BLE link type.

```
pcapngObj = pcapngWriter('FileName','BLELLCapture');
```

Write an interface description block for BLE.

```
interfaceName = 'BLE interface';
bleLinkType = 251;
interfaceId = writeInterfaceDescriptionBlock(pcapngObj,bleLinkType, ...
    interfaceName);
```

Specify a BLE LL packet.

```
llpacket = '42BC13E206120E00050014010A001F0040001700170000007D47C0';
```

Write the BLE LL packet to the PCAPNG format file.

```
timestamp = 0; % Number of microseconds
packetComment = 'This is a BLE packet';
write(pcapngObj,llpacket,timestamp,interfaceId,'PacketComment', ...
    packetComment);
```

Objects

`pcapWriter`

Introduced in R2020b

comm.BlockDeinterleaver

Package: `comm`

(To be removed) Deinterleave input symbols using permutation vector

Compatibility

comm.BlockDeinterleaver will be removed in a future release. Use `deintrlv` instead. For more information, see "Compatibility Considerations" on page 3-183.

Description

The `BlockDeinterleaver` object, which can process variable-sized signals, rearranges the elements of its input vector without repeating or omitting any elements. The input can be real or complex.

To deinterleave the input vector:

1. Define and set up your block deinterleaver object. See "Construction" on page 3-181.
2. Call `step` to rearrange the elements of the input vector according to the properties of `comm.BlockDeinterleaver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.BlockDeinterleaver` creates a block deinterleaver System object, `H`. This object restores the original ordering of a sequence that was interleaved using the block interleaver System object.

`H = comm.BlockDeinterleaver(Name,Value)` creates object, `H`, with the specified property set to the specified value.

Properties

`PermutationVectorSource`

Permutation vector source

Specify the source of the permutation vector as either `Property` or `Input port`. The default value is `Property`.

`PermutationVector`

Permutation vector

Specify the mapping used to permute the input symbol as a column vector of integers. The default is `[5;4;3;2;1]`. The mapping is a column vector of integers where the number of elements is equal to the length, *N*, of the input to the step method. Each element must be an integer, between 1 and *N*, with no repeated values. The `PermutationVector` property is available only when the `PermutationVectorSource` property is set to `Property`.

Methods

step (To be removed) Deinterleave input symbols using permutation vector

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Block Interleaving and Deinterleaving

Create interleaver and deinterleaver objects.

```
interleaver = comm.BlockInterleaver([3 4 1 2]');
```

```
Warning: COMM.BLOCKINTERLEAVER will be removed in a future release. Use INTRLV instead. See <a hr
```

```
deinterleaver = comm.BlockDeinterleaver([3 4 1 2]');
```

```
Warning: COMM.BLOCKDEINTERLEAVER will be removed in a future release. Use DEINTRLV instead. See <
```

Pass random data through the interleaver and deinterleaver.

```
data = randi(7,4,1);
intData = interleaver(data);
deIntData = deinterleaver(intData);
```

Display the original sequence, interleaved sequence, and restored sequence.

```
[data, intData, deIntData]
```

```
ans = 4×3

     6     1     6
     7     7     7
     1     6     1
     7     7     7
```

Confirm the original and deinterleaved data are identical.

```
isequal(data,deIntData)
```

```
ans = logical
   1
```

Generate a random vector of unique integers as a permutation vector.

```
permVec = randperm(7)';
```

Specify `permVec` as the permutation vector for the interleaver and deinterleaver objects.

```
interleaver = comm.BlockInterleaver(permVec);
```

```
Warning: COMM.BLOCKINTERLEAVER will be removed in a future release. Use INTRLV instead. See <a h
```

```
deinterleaver = comm.BlockDeinterleaver(permVec);
```

```
Warning: COMM.BLOCKDEINTERLEAVER will be removed in a future release. Use DEINTRLV instead. See <
```

Pass random data through the interleaver and deinterleaver.

```
data = randi(10,7,1);
intData = interleaver(data);
deIntData = deinterleaver(intData);
```

Confirm the original and deinterleaved data are identical.

```
isequal(data,deIntData)
```

```
ans = logical
   1
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the General Block Deinterleaver block reference page. The object properties correspond to the block parameters.

Compatibility Considerations

`comm.BlockDeinterleaver` will be removed

Not recommended starting in R2019b

comm.BlockDeinterleaver will be removed in a future release. Use `deintrlv` instead.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Functions

`deintrlv` | `intrlv`

Introduced in R2012a

step

System object: `comm.BlockDeinterleaver`
Package: `comm`

(To be removed) Deinterleave input symbols using permutation vector

Compatibility

step will be removed in a future release. Use `deintrlv` instead.

Syntax

`Y = step(H,X)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` restores the original ordering of the sequence, `X`, that was interleaved using a block interleaver. The step method forms the output, `Y`, based on the mapping specified by the PermutationVector property as **Output**(`PermutationVector`(*k*))=**Input**(*k*), for *k* = `1`:*N*, where *N* is the length of the permutation vector. The input `X` must be a column vector of the same length, *N*. The data type of `X` can be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.BlockInterleaver

Package: `comm`

(To be removed) Permute input symbols using permutation vector

Compatibility

comm.BlockInterleaver will be removed in a future release. Use `intrlv` instead. For more information, see “Compatibility Considerations” on page 3-187.

Description

The `BlockInterleaver` object permutes the symbols in the input signal. Internally, it uses a set of shift registers, each with its own delay value. This object processes variable-size signals.

To interleave the input signal:

1. Define and set up your block interleaver object. See “Construction” on page 3-185.
2. Call `step` to reorder the input symbols according to the properties of `comm.BlockInterleaver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.BlockInterleaver` creates a block interleaver System object, `H` This object permutes the symbols in the input signal based on a permutation vector.

`H = comm.BlockInterleaver(Name,Value)` creates object, `H`, with specified property set to the specified value.

Properties

`PermutationVectorSource`

Permutation vector source

Specify the source of the permutation vector as either `Property` or `Input port`. The default value is `Property`.

`PermutationVector`

Permutation vector

Specify the mapping used to permute the input symbols as an integer column vector. The default is `[5;4;3;2;1]`. The number of elements of the permutation vector property must equal the length of the input vector. The `PermutationVector` property indicates the indices, in order, of the input elements that form the output vector. The relationship **Output**(*k*)=**Input**(`PermutationVector`(*k*)) describes this order. Each integer, *k*, must be between `1` and *N*, where *N* is the number of elements in the permutation vector. The elements in the `PermutationVector` property must be integers between `1` and *N* with no repetitions. The `PermutationVector` property is available only when the `PermutationVectorSource` property is set to `Property`.

Methods

step	(To be removed) Permute input symbols using a permutation vector

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` permutes input sequence, `X`, and returns interleaved sequence, `Y`. The step method forms the output `Y`, based on the mapping defined by the PermutationVector property as **Output**(*k*)=**Input**(`PermutationVector`(*k*)), for *k* = `1`:*N*, where *N* is the length of the `PermutationVector` property. The input `X` must be a column vector of length *N*. The data type of `X` can be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.BPSKDemodulator

Package: `comm`

Demodulate using BPSK method

Description

The `BPSKDemodulator` object demodulates a signal that was modulated using the binary phase shift keying method. The input is a baseband representation of the modulated signal.

To demodulate a binary phase shift signal:

1. Define and set up your BPSK demodulator object. See “Construction” on page 3-189.
2. Call `step` to demodulate a signal according to the properties of `comm.BPSKDemodulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.BPSKDemodulator` creates a demodulator System object, `H`, that demodulates the input signal using the binary phase shift keying (BPSK) method.

`H = comm.BPSKDemodulator(Name,Value)` creates a BPSK demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.BPSKDemodulator(PHASE,Name,Value)` creates a BPSK demodulator object, `H`, with the `PhaseOffset` property set to `PHASE`, and the other specified properties set to the specified values.

Properties

`PhaseOffset`

Phase of zeroth point of constellation

Specify the phase offset of the zeroth point of the constellation, in radians, as a finite, real scalar. The default is `0`.

`DecisionMethod`

Demodulation decision method

Specify the decision method the object uses as one of `Hard decision` | `Log-likelihood ratio` | `Approximate log-likelihood ratio`. The default is `Hard decision`.

VarianceSource

Source of noise variance

Specify the source of the noise variance as one of Property | Input port. The default is Property. This property applies when you set the DecisionMethod on page 3-0 property to Log-likelihood ratio or Approximate log-likelihood ratio.

Variance

Noise variance

Specify the variance of the noise as a nonzero, real scalar. The default is 1. If this value is very small (i.e., SNR is very high), log-likelihood ratio (LLR) computations can yield Inf or -Inf. This variance occurs because the LLR algorithm computes the exponential of very large or very small numbers using finite precision arithmetic. As a best practice in such cases, use approximate LLR because this option's algorithm does not compute exponentials. This property applies when you set the VarianceSource on page 3-0 property to Property. This property is tunable.

OutputDataType

Data type of output

Specify the output data type as one of Full precision | Smallest unsigned integer | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | logical. The default is Full precision. This property applies only when you set the DecisionMethod on page 3-0 property to Hard decision. Thus, when you set the OutputDataType on page 3-0 property to Full precision, and the input data type is single or double precision, the output data has the same data type as the input. If the input data is of a fixed-point type, then the output data type behaves as if you had set the OutputDataType property to Smallest unsigned integer. If you set the DecisionMethod property to Log-likelihood ratio or Approximate log-likelihood ratio, the output data type is the same as that of the input. In this case, that data type can only be single or double precision.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in Smallest unsigned integer or Full precision mode.

Fixed-Point Properties

DerotateFactorDataType

Data type of derotate factor

Specify the derotate factor data type as one of Same word length as input | Custom. The default is Same word length as input. This property applies when you set the DecisionMethod on page 3-0 property to Hard decision. The object uses the derotate factor in the computations only when certain conditions exist. The step method input must be of a fixed-point type, and the PhaseOffset on page 3-0 property must have a value that is not a multiple of π/2.

CustomDerotateFactorDataType

Fixed-point data type of derotate factor

Specify the derotate factor fixed-point type as an unscaled, numerictype object with a Signedness of Auto. The default is numerictype([],16). This property applies when you set the

DecisionMethod on page 3-0 property to Hard decision and the DerotateFactorDataType on page 3-0 property to Custom.

Methods

constellation	Calculate or plot ideal signal constellation
step	Demodulate using BPSK method

Common to All System Objects	
release	Allow System object property value changes

Examples

Demodulate BPSK Signal and Calculate Errors

Generate a BPSK signal, pass it through an AWGN channel, demodulate the signal, and compute the error statistics.

Create BPSK modulator and demodulator System objects.

```
bpskModulator = comm.BPSKModulator;
bpskDemodulator = comm.BPSKDemodulator;
```

Create an error rate calculator System object.

```
errorRate = comm.ErrorRate;
```

Generate 50-bit random data frames, apply BPSK modulation, pass the signal through an AWGN channel, demodulate the received data, and compile the error statistics.

```
for counter = 1:100
    % Transmit a 50-symbol frame
    txData = randi([0 1],50,1);            % Generate data
    modSig = bpskModulator(txData);        % Modulate
    rxSig = awgn(modSig,5);                % Pass through AWGN
    rxData = bpskDemodulator(rxSig);       % Demodulate
    errorStats = errorRate(txData,rxData); % Collect error stats
end
```

Display the cumulative error statistics.

```
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

```
Error rate = 0.005600
Number of errors = 28
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the BPSK Demodulator Baseband block reference page. The object properties correspond to the block parameters.

constellation

System object: `comm.BPSKDemodulator`
Package: `comm`

Calculate or plot ideal signal constellation

Syntax

```
y = constellation(h)
constellation(h)
```

Description

`y = constellation(h)` returns the numerical values of the constellation.

`constellation(h)` generates a constellation plot for the object.

Examples

Calculate Reference Signal Constellation for BPSK Demodulator

Create BPSK Demodulator System object™ and calculate its reference constellation.

Create a `comm.BPSKDemodulator` System object.

```
h = comm.BPSKDemodulator;
```

Calculate and display the reference signal constellation by calling the `constellation` function.

```
refC = constellation(h)
```

```
refC = 2×1 complex

   1.0000 + 0.0000i
  -1.0000 + 0.0000i
```

Plot BPSK Demodulator Reference Signal Constellation

Create a BPSK Demodulator System object™ and then plot the reference signal constellation.

Create a `comm.BPSKDemodulator` System object.

```
h = comm.BPSKDemodulator;
```

Plot the reference constellation by calling the `constellation` function.

```
constellation(h)

step

System object: `comm.BPSKDemodulator`
Package: `comm`

Demodulate using BPSK method

Syntax

```
Y = step(H,X)
Y = step(H,X,VAR)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates input data, `X`, with the BPSK demodulator System object, `H`, and returns `Y`. Input `X` must be a scalar or a column vector with double or single precision data type. When you set the `DecisionMethod` property to `Hard decision`, the data type of the input can also be signed integer, or signed fixed point (fi objects).

`Y = step(H,X,VAR)` uses soft decision demodulation and noise variance `VAR`. This syntax applies when you set the `DecisionMethod` property to `Log-likelihood ratio` or `Approximate log-likelihood ratio` and the `VarianceSource` property to `Input port`. The data type of input `VAR` must be double or single precision.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

bluetoothPhyConfig

Configuration object for Bluetooth BR/EDR PHY

Note **Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Description

The `bluetoothPhyConfig` object creates a configuration object for the Bluetooth physical layer (PHY) using default and specified values. You can configure the Bluetooth PHY by using the applicable properties of the `bluetoothPhyConfig` object.

Creation

Syntax

```
cfg = bluetoothPhyConfig
cfg = bluetoothPhyConfig(Name,Value)
```

Description

`cfg = bluetoothPhyConfig` creates a configuration object, `cfg`, for Bluetooth PHY with default property values.

`cfg = bluetoothPhyConfig(Name,Value)` sets “Properties” on page 3-196 by using one or more name-value pairs. Enclose each property name in quotes. For example, `bluetoothPhyConfig('Mode','EDR3M')` sets the physical layer transmission mode to 3 Mbps.

Properties

Note For more information about Bluetooth BR/EDR waveform generator properties and their respective values, see volume 2, part B, sections 6 and 7 of the Bluetooth Core Specification [2].

`Mode` — PHY transmission mode
`'BR'` (default) | `'EDR2M'` | `'EDR3M'`

PHY transmission mode, specified as `'BR'`, `'EDR2M'` or `'EDR3M'`. This value indicates the type of Bluetooth BR/EDR waveform.

Data Types: `char` | `string`

`DeviceAddress` — Bluetooth device address
`'0123456789AB'` (default) | 12-element character vector | string scalar denoting 6-octet hexadecimal value

Bluetooth device address, specified as a 12-element character vector or a string scalar denoting a 6-octet hexadecimal value.

Data Types: `char` | `string`

`ModulationIndex` — Modulation Index
`0.32` (default) | scalar in the range [0.28, 0.35]

Modulation index, specified as a scalar in the range [0.28, 0.35]. This property is the modulation index that the object uses when performing Gaussian frequency shift keying (GFSK) modulation or demodulation.

Data Types: `double`

`SamplesPerSymbol` — Samples per symbol
8 (default) | positive integer

Samples per symbol, specified as a positive integer. This value is used for GFSK modulation and demodulation.

Data Types: `double`

`WhitenStatus` — Data whiten status
`'On'` (default) | `'Off'`

Data whiten status, specified as `'On'` or `'Off'`. Set this value to `'On'` for the object to perform whitening on header and payload bits.

Data Types: `char` | `string`

`WhitenInitialization` — Whiten initialization
`[1; 1; 1; 1; 1; 1; 1]` (default) | 7-bit binary column vector

Whiten initialization, specified as a 7-bit binary column vector.

Dependencies

To enable this property, set the “WhitenStatus” on page 3-0 property to `'On'`.

Data Types: `double`

Object Functions

Specific to This Object

bluetoothIdealReceiver	Ideal receiver for Bluetooth BR/EDR PHY waveform

Examples

Create Bluetooth BR/EDR PHY Configuration Objects

Create two unique Bluetooth BR/EDR PHY configuration objects: one for synchronous connection oriented (SCO) logical transport and the other for connectionless slave broadcast (CSB) logical transport.

Create a Bluetooth BR/EDR PHY configuration object for an SCO logical transport. For SCO logical transport, the PHY transmission mode must be set to basic rate (BR).

```
cfg = bluetoothPhyConfig
```

```
cfg = 
  bluetoothPhyConfig with properties:

                  Mode: 'BR'
         DeviceAddress: '0123456789AB'
       ModulationIndex: 0.3200
      SamplesPerSymbol: 8
          WhitenStatus: 'On'
    WhitenInitialization: [7x1 double]
```

Create another Bluetooth BR/EDR PHY configuration object for a CSB logical transport by disabling the whiten status.

```
cfg = bluetoothPhyConfig('WhitenStatus','Off')
```

```
cfg = 
  bluetoothPhyConfig with properties:

              Mode: 'BR'
     DeviceAddress: '0123456789AB'
   ModulationIndex: 0.3200
  SamplesPerSymbol: 8
      WhitenStatus: 'Off'
```

bluetoothWaveformConfig

Configuration object for Bluetooth BR/EDR waveform generator

Note **Download Required:** To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Description

The `bluetoothWaveformConfig` object creates a configuration object for the Bluetooth BR/EDR waveform generator using default and specified values. You can configure the Bluetooth waveform generator by using the applicable properties of the `bluetoothWaveformConfig` object.

Creation

Syntax

```
cfg = bluetoothWaveformConfig
cfg = bluetoothWaveformConfig(Name,Value)
```

Description

`cfg = bluetoothWaveformConfig` creates a configuration object, `cfg`, for a Bluetooth BR/EDR waveform generator with default property values.

`cfg = bluetoothWaveformConfig(Name,Value)` sets “Properties” on page 3-200 by using one or more name-value pairs. Enclose each property name in quotes. For example, `bluetoothWaveformConfig('Mode','EDR3M')` sets the physical layer transmission mode to 3 Mbps.

Properties

Note For more information about Bluetooth BR/EDR waveform generator properties and their respective values, see volume 2, part B, sections 6 and 7 of the Bluetooth Core Specification [2].

`Mode` — PHY transmission mode
`'BR'` (default) | `'EDR2M'` | `'EDR3M'`

PHY transmission mode, specified as `'BR'`, `'EDR2M'` or `'EDR3M'`. This value indicates the type of Bluetooth BR/EDR waveform.

Data Types: `char` | `string`

`PacketType` — Packet type
`'FHS'` (default) | `'ID'` | `'NULL'` | `'POLL'` | `...`

Packet type, specified as one of these values:

- `'ID'`
- `'NULL'`
- `'POLL'`
- `'FHS'`
- `'DM1'`
- `'HV1'`
- `'HV2'`
- `'HV3'`
- `'DV'`
- `'EV3'`
- `'EV4'`
- `'EV5'`
- `'DH1'`
- `'AUX1'`
- `'DM3'`
- `'DH3'`
- `'DM5'`
- `'DH5'`
- `'2-EV3'`
- `'3-EV3'`
- `'2-EV5'`
- `'3-EV5'`
- `'2-DH1'`
- `'3-DH1'`
- `'2-DH3'`
- `'3-DH3'`
- `'2-DH5'`
- `'3-DH5'`

Data Types: `char` | `string`

`PayloadLength` — Payload length of packet
18 (default) | integer in the range [0, *X*]

Payload length of packet, specified as an integer in the range [0, *X*], where *X* depends on the "PacketType" on page 3-0 property. This value sets the number of bytes to be processed in a packet.

Dependencies

To enable this property, set the value of packet type to `'DM1'`, `'DH1'`, `'DM3'`, `'DH3'`, `'DM5'`, `'DH5'`, `'AUX1'`, or `'DV'`.

Data Types: `double`

`DeviceAddress` — Bluetooth device address

`'0123456789AB'` (default) | 12-element character vector | string scalar denoting 6-octet hexadecimal value

Bluetooth device address, specified as a 12-element character vector or string scalar denoting a 6-octet hexadecimal value.

Data Types: `char` | `string`

`LogicalTransportAddress` — Logical transport address for packet

`[0; 0; 1]` (default) | 3-bit binary column vector

Logical transport address for the packet, specified as a 3-bit binary column vector. This property indicates the active destination slave for a packet in the master-to-slave transmission slot.

Data Types: `double`

`HeaderControlBits` — Header control information

`[1; 1; 1]` (default) | 3-bit binary column vector

Header control information, specified as a 3-bit binary column vector. This property indicates the header control information consisting of these three fields:

Field	Size of Field	Field Information Indicates
FLOW	1 bit	Flow control information
ARQN	1 bit	Acknowledgment for successful reception of a CRC packet
SEQN	1 bit	Sequencing scheme to order the packet stream

Data Types: `double`

`ModulationIndex` — Modulation Index

`0.32` (default) | scalar in the range [0.28, 0.35]

Modulation index, specified as a scalar in the range [0.28, 0.35]. This property is the modulation index that the object uses when performing Gaussian frequency shift keying (GFSK) modulation or demodulation.

Data Types: `double`

`SamplesPerSymbol` — Samples per symbol

`8` (default) | positive integer

Samples per symbol, specified as a positive integer. This value is used for GFSK modulation and demodulation.

Data Types: `double`

`WhitenStatus` — Data whiten status

`'On'` (default) | `'Off'`

Data whiten status, specified as `'On'` or `'Off'`. Set this value to `'On'` for the object to perform whitening on the header and payload bits.

Data Types: `char` | `string`

`WhitenInitialization` — Whiten initialization
`[1; 1; 1; 1; 1; 1; 1]` (default) | 7-bit binary column vector

Whiten initialization, specified as a 7-bit binary column vector.

Dependencies

To enable this property, set the "WhitenStatus" on page 3-0 property to `'On'`.

Data Types: `double`

`LLID` — Logical link identifier
`[1; 1]` (default) | 2-bit binary column vector

Logical link identifier, specified as a 2-bit binary column vector.

Dependencies

To enable this property, set the value of "PacketType" on page 3-0 to `'DM1'`, `'DH1'`, `'DM3'`, `'DH3'`, `'DM5'`, `'DH5'`, `'AUX1'`, and `'DV'`.

Data Types: `double`

`FlowIndicator` — Logical channel flow control indicator
`true` (default) | `false`

Logical channel flow control indicator, specified as `true` or `false`.

Dependencies

To enable this property, set the value of packet type to `'DM1'`, `'DH1'`, `'DM3'`, `'DH3'`, `'DM5'`, `'DH5'`, `'AUX1'`, and `'DV'`.

Data Types: `logical`

Object Functions

Specific to This Object

getPayloadLength	Payload length in bytes for Bluetooth BR/EDR format configuration
getPhyConfigProperties	Updated configuration properties of Bluetooth BR/EDR PHY configuration object
bluetoothWaveformGenerator	Waveform generator for Bluetooth BR/EDR PHY
bluetoothIdealReceiver	Ideal receiver for Bluetooth BR/EDR PHY waveform

Examples

Create Bluetooth BR/EDR Waveform Configuration Objects

Create three unique Bluetooth BR/EDR waveform configuration objects for synchronous connection oriented (SCO), connectionless slave broadcast (CSB), and asynchronous connectionless (ACL) logical transports.

Create a Bluetooth BR/EDR waveform configuration object for an SCO logical transport by specifying packet type as HV1. For SCO logical transport, the PHY transmission mode must be basic rate (BR).

```
cfg = bluetoothWaveformConfig;
cfg.PacketType = 'HV1'
```

```
cfg = 
  bluetoothWaveformConfig with properties:

                       Mode: 'BR'
                 PacketType: 'HV1'
              DeviceAddress: '0123456789AB'
    LogicalTransportAddress: [3x1 double]
          HeaderControlBits: [3x1 double]
            ModulationIndex: 0.3200
           SamplesPerSymbol: 8
               WhitenStatus: 'On'
       WhitenInitialization: [7x1 double]
```

Create a second Bluetooth BR/EDR waveform configuration object for a CSB logical transport by specifying the packet type as DH1 and disabling the whiten status.

```
cfg = bluetoothWaveformConfig('PacketType','DH1','WhitenStatus','Off')
```

```
cfg = 
  bluetoothWaveformConfig with properties:

                       Mode: 'BR'
                 PacketType: 'DH1'
              PayloadLength: 18
              DeviceAddress: '0123456789AB'
    LogicalTransportAddress: [3x1 double]
          HeaderControlBits: [3x1 double]
            ModulationIndex: 0.3200
           SamplesPerSymbol: 8
               WhitenStatus: 'Off'
                       LLID: [2x1 double]
              FlowIndicator: 1
```

Create a third Bluetooth BR/EDR waveform configuration object for an ACL logical transport with enhanced data rate mode. Set the value of packet type to DH3, and payload length to 184 bytes.

```
cfg = bluetoothWaveformConfig;
cfg.Mode = 'EDR2M';
cfg.PacketType = 'DH3';
cfg.PayloadLength = 184  % in bytes
```

```
cfg = 
  bluetoothWaveformConfig with properties:

                       Mode: 'EDR2M'
                 PacketType: 'DH3'
              PayloadLength: 184
              DeviceAddress: '0123456789AB'
    LogicalTransportAddress: [3x1 double]
          HeaderControlBits: [3x1 double]
```

```
         ModulationIndex: 0.3200
        SamplesPerSymbol: 8
            WhitenStatus: 'On'
    WhitenInitialization: [7x1 double]
                    LLID: [2x1 double]
           FlowIndicator: 1
```

comm.IQImbalanceCompensator

Package: `comm`

Compensate for I/Q imbalance

Description

The `IQImbalanceCompensator` System object compensates for the imbalance between the in-phase and quadrature components of a modulated signal.

To compensate for I/Q imbalance:

1. Define and set up the `IQImbalanceCompensator` object. See “Construction” on page 3-206.
2. Call `step` to compensate for the I/Q imbalance according to the properties of `comm.IQImbalanceCompensator`. The behavior of `step` is specific to each object in the toolbox.

The adaptive algorithm inherent to the I/Q imbalance compensator is compatible with M-PSK, M-QAM, and OFDM modulation schemes, where *M>2*.

Note The output of the compensator might be scaled and rotated, that is, multiplied by a complex number, relative to the reference constellation. In practice, this is not an issue as receivers correct for this prior to demodulation through the use of channel estimation.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.IQImbalanceCompensator` creates a compensator System object, `H`, that compensates for the imbalance between the in-phase and quadrature components of the input signal.

`H = comm.IQImbalanceCompensator(Name,Value)` creates an I/Q imbalance compensator object, `H`, with each specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`CoefficientSource`

Source of compensator coefficients

Specify either `Estimated from input signal` or `Input port`. If the `CoefficientSource` property is set to `Estimated from input signal`, the compensator uses an adaptive algorithm to estimate the compensator coefficient from the input signal. If the `CoefficientSource` property is set to `Input port`, all other properties are disabled and the compensator coefficients must be provided to the `step` function as an input argument. The default value is `Estimated from input signal`. This property is nontunable.

InitialCoefficent

Initial coefficient used to compensate for I/Q imbalance

The initial coefficient is a complex scalar that can be either single or double precision. The default value is `0+0i`. This property is nontunable.

StepSizeSource

Source of step size for coefficient adaptation

Specify either `Property` or `Input port`. If `StepSizeSource` is set to `Property`, you specify the step size through the `StepSize` property. Otherwise, the step size is provided to the `step` function as an input argument. The default value is `Property`. This property is nontunable.

StepSize

Adaptation step size

Specifies the step size used by the algorithm in estimating the I/Q imbalance. This property is accessible only when `StepSizeSource` is set to `Property`. The default value is `1e-5`. This property is tunable.

AdaptInputPort

Creates input port to control compensator coefficient adaptation

When this logical property is `true`, an input port is created to enable or disable coefficient adaptation. If `AdaptInputPort` is `false`, the coefficients update after each output sample. The default value is `false`. This property is nontunable.

CoefficientOutputPort

Create port to output compensator coefficients

When this logical property is `true`, the I/Q imbalance compensator coefficients are made available through an output argument of the `step` function. The default value is `false`. This property is nontunable.

Methods

step	Compensate I/Q Imbalance
reset	Reset states of the `IQImbalanceCompensator` System object

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Remove I/Q Imbalance from a QPSK Signal

Mitigate the impacts of amplitude and phase imbalance on a QPSK modulated signal by using the comm.IQImbalanceCompensator System object?.

Create a constellation diagram object. Specify name-value pairs to ensure that the constellation diagram displays only the last 100 data symbols.

```
constDiagram = comm.ConstellationDiagram(...
    'SymbolsToDisplaySource','Property', ...
    'SymbolsToDisplay',100);
```

Create an I/Q imbalance compensator.

```
iqImbComp = comm.IQImbalanceCompensator;
```

Generate random data symbols and apply QPSK modulation.

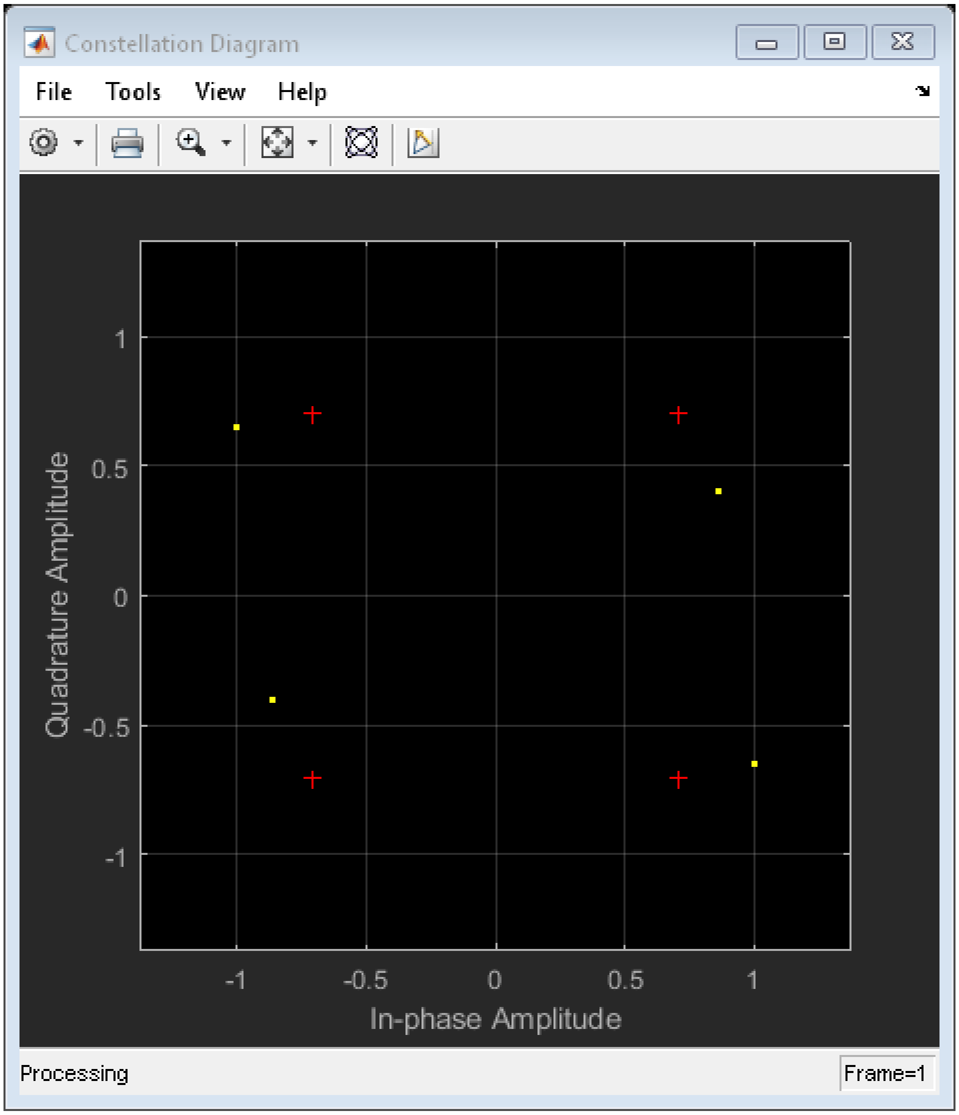
```
data = randi([0 3],1e7,1);
txSig = pskmod(data,4,pi/4);
```

Apply amplitude and phase imbalance to the transmitted signal.

```
ampImb = 5; % dB
phImb = 15; % deg
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(txSig)*gainI*exp(-0.5i*phImb*pi/180);
imbQ = imag(txSig)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));
rxSig = imbI + imbQ;
```

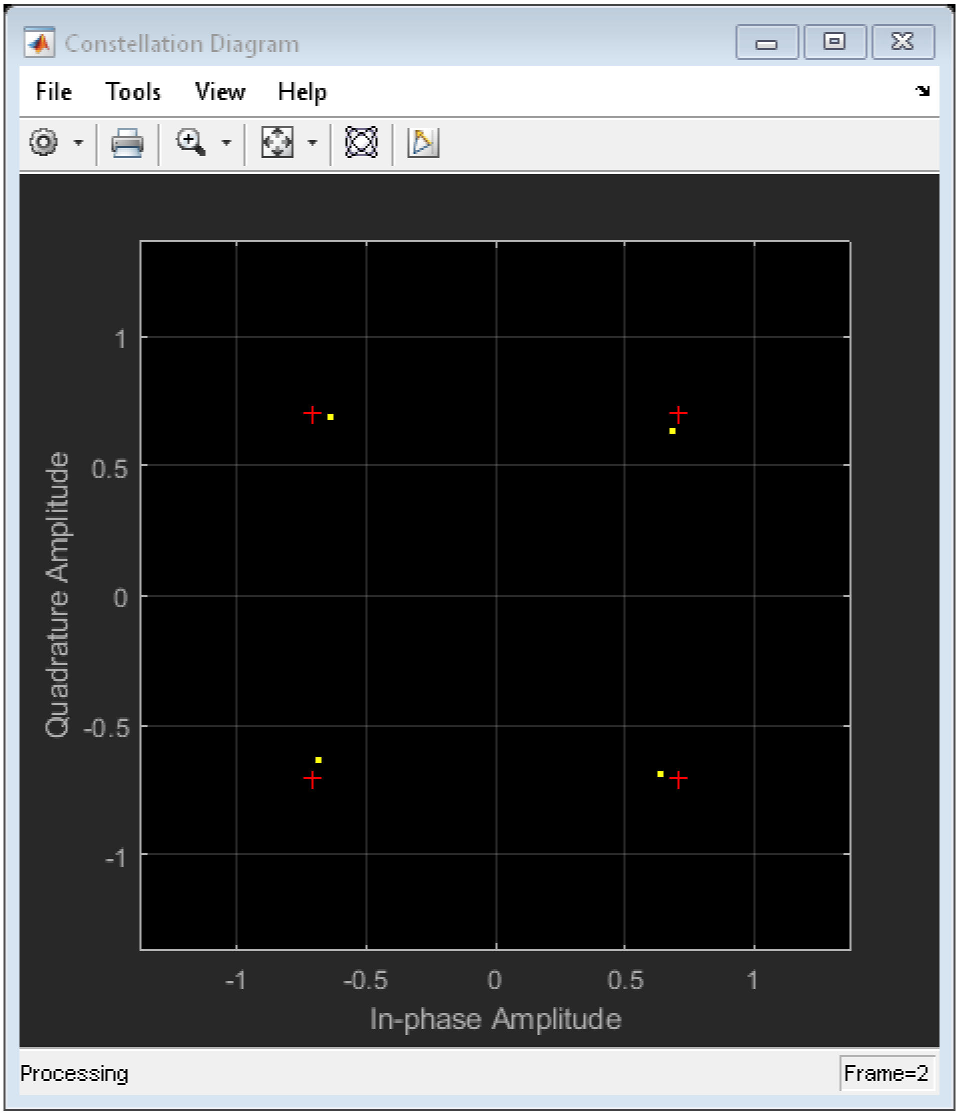
Plot the constellation diagram of the received signal. Observe that the received signal experienced an amplitude and phase shift.

```
constDiagram(rxSig)
```



Apply the I/Q compensation algorithm and view the constellation. The compensated signal constellation is nearly aligned with the reference constellation.

```
compSig = iqImbComp(rxSig);
constDiagram(compSig)
```



Remove I/Q Imbalance from an 8-PSK Signal using External Coefficients

Compensate for an amplitude and phase imbalance on an 8-PSK signal by using the `comm.IQImbalanceCompensator` System object™ with external coefficients.

Create 8-PSK modulator and constellation diagram System objects. Use name-value pairs to ensure that the constellation diagram displays only the last 100 data symbols and to provide the reference constellation.

```
hMod = comm.PSKModulator(8);
refC = constellation(hMod);
hScope = comm.ConstellationDiagram(...
    'SymbolsToDisplaySource','Property', ...
    'SymbolsToDisplay',100, ...
    'ReferenceConstellation',refC);
```

Create an I/Q imbalance compensator object with an input port for the algorithm coefficients.

```
hIQComp = comm.IQImbalanceCompensator('CoefficientSource','Input port');
```

Generate random data symbols and apply 8-PSK modulation.

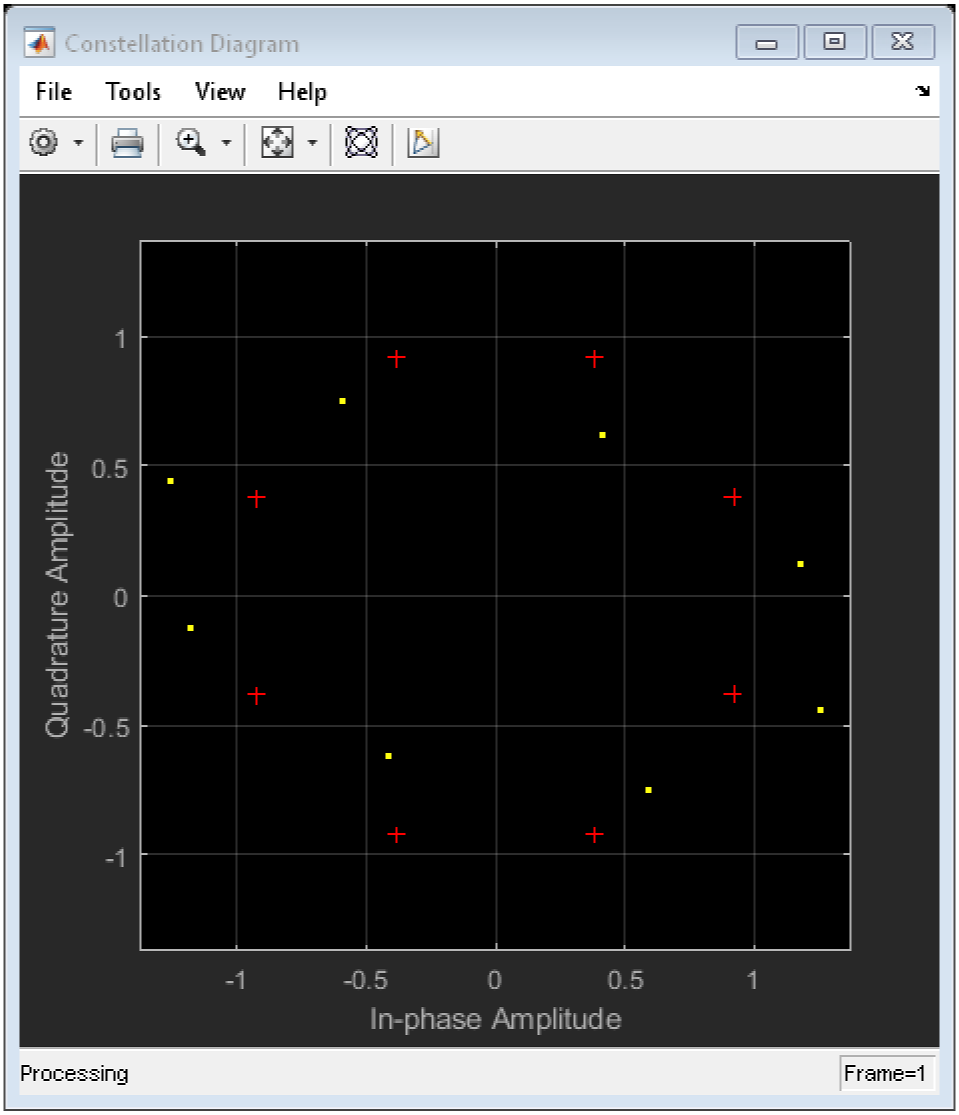
```
data = randi([0 7],1000,1);
txSig = step(hMod,data);
```

Apply amplitude and phase imbalance to the transmitted signal.

```
ampImb = 5; % dB
phImb = 15; % deg
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(txSig)*gainI*exp(-0.5i*phImb*pi/180);
imbQ = imag(txSig)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));
rxSig = imbI + imbQ;
```

Plot the constellation diagram of the received signal. Observe that the received signal experienced an amplitude and phase shift.

```
step(hScope,rxSig);
```

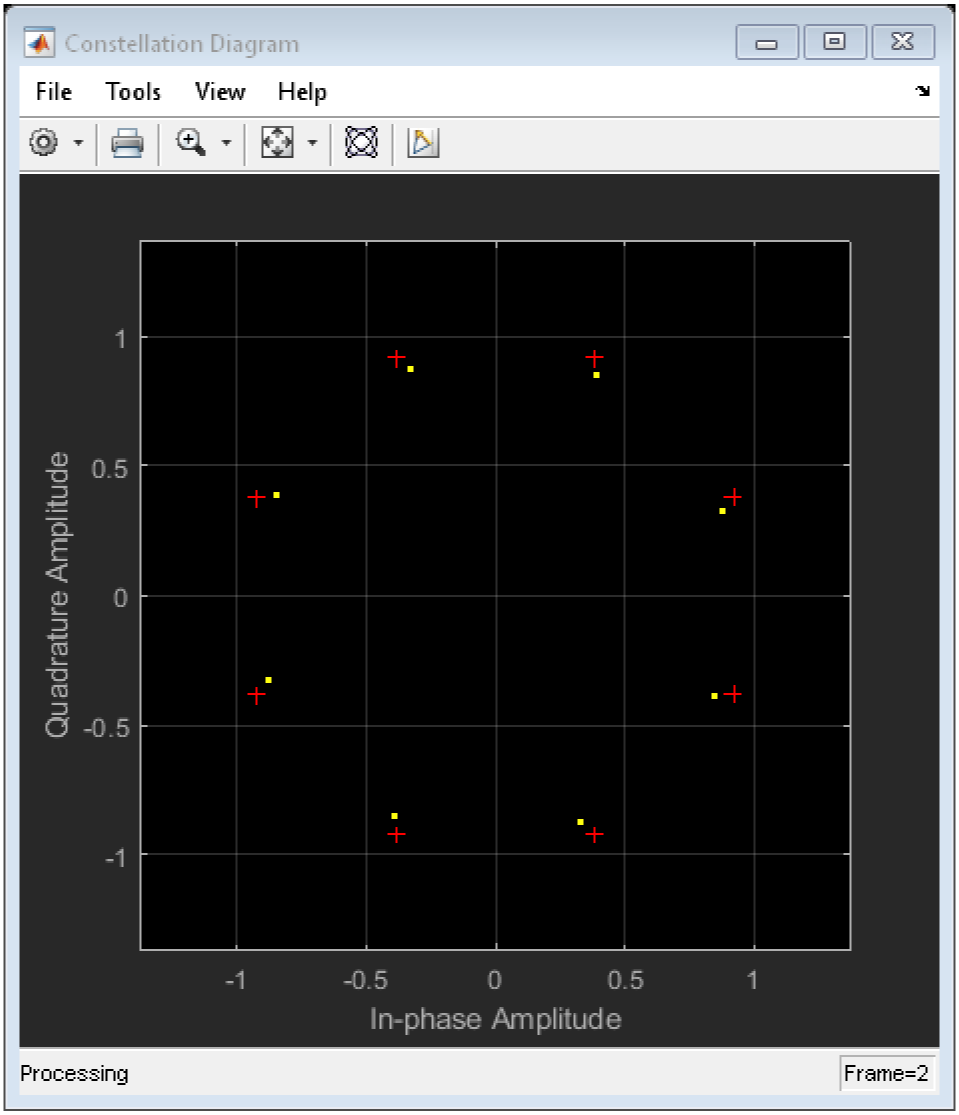


Use the `iqimbal2coef` function to determine the compensation coefficient given the amplitude and phase imbalance.

```
compCoef = iqimbal2coef(ampImb,phImb);
```

Apply the compensation coefficient to the received signal using the `step` function of the `comm.IQImbalanceCompensator` object and view the resultant constellation. You can see that the compensated signal constellation is now nearly aligned with the reference constellation.

```
compSig = step(hIQComp,rxSig,compCoef);
step(hScope,compSig)
```



Remove I/Q Imbalance from a QAM Signal

Remove an I/Q imbalance from a 64-QAM signal and to make the estimated coefficients externally available while setting the algorithm step size from an input port.

Create a constellation diagram object. Use name-value pairs to ensure that the constellation diagram displays only the last 256 data symbols, set the axes limits, and specify the reference constellation.

```
M = 64;
refC = qammod(0:M-1,M);
constDiagram = comm.ConstellationDiagram(...
    'SymbolsToDisplaySource','Property', ...
    'SymbolsToDisplay',256, ...
    'XLimits',[-10 10],'YLimits',[-10 10], ...
    'ReferenceConstellation',refC);
```

Create an I/Q imbalance compensator System object in which the step size is specified as an input argument and the estimated coefficients are made available through an output port.

```
iqImbComp = comm.IQImbalanceCompensator('StepSizeSource','Input port', ...
    'CoefficientOutputPort',true);
```

Generate random data symbols and apply 64-QAM modulation.

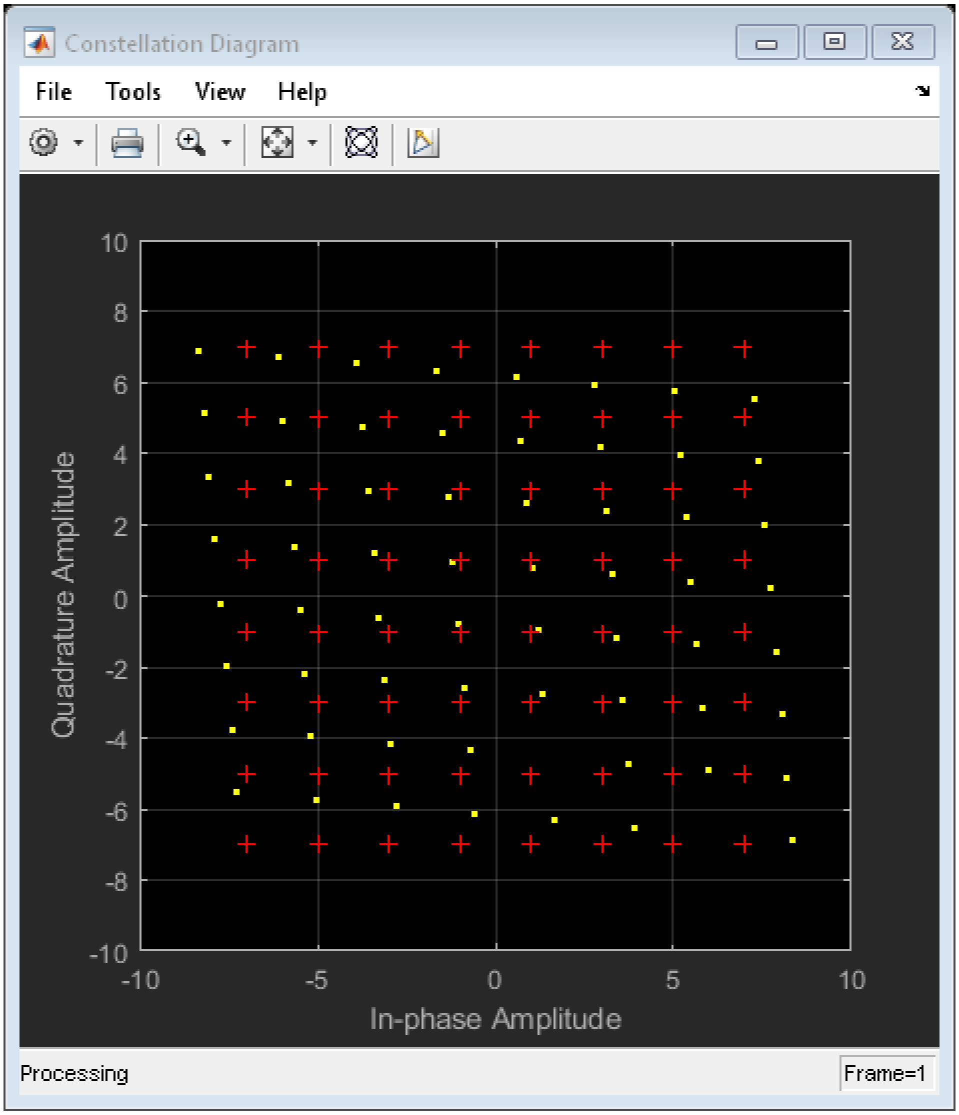
```
nSym = 25000;
data = randi([0 M-1],nSym,1);
txSig = qammod(data,M);
```

Apply amplitude and phase imbalance to the transmitted signal.

```
ampImb = 2; % dB
phImb = 10; % deg
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(txSig)*gainI*exp(-0.5i*phImb*pi/180);
imbQ = imag(txSig)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));
rxSig = imbI + imbQ;
```

Plot the constellation diagram of the received signal.

```
constDiagram(rxSig);
```

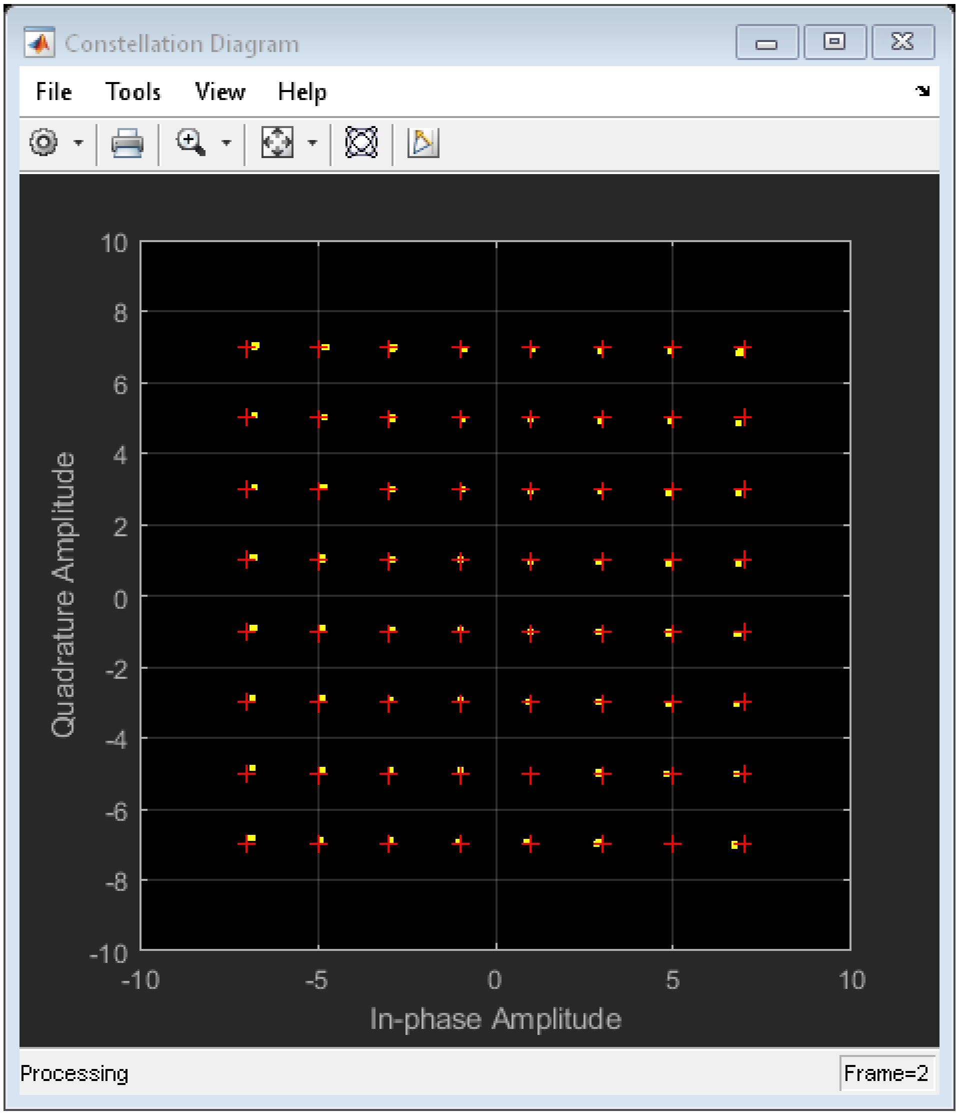


Specify the step size parameter for the I/Q imbalance compensator.

```
stepSize = 1e-5;
```

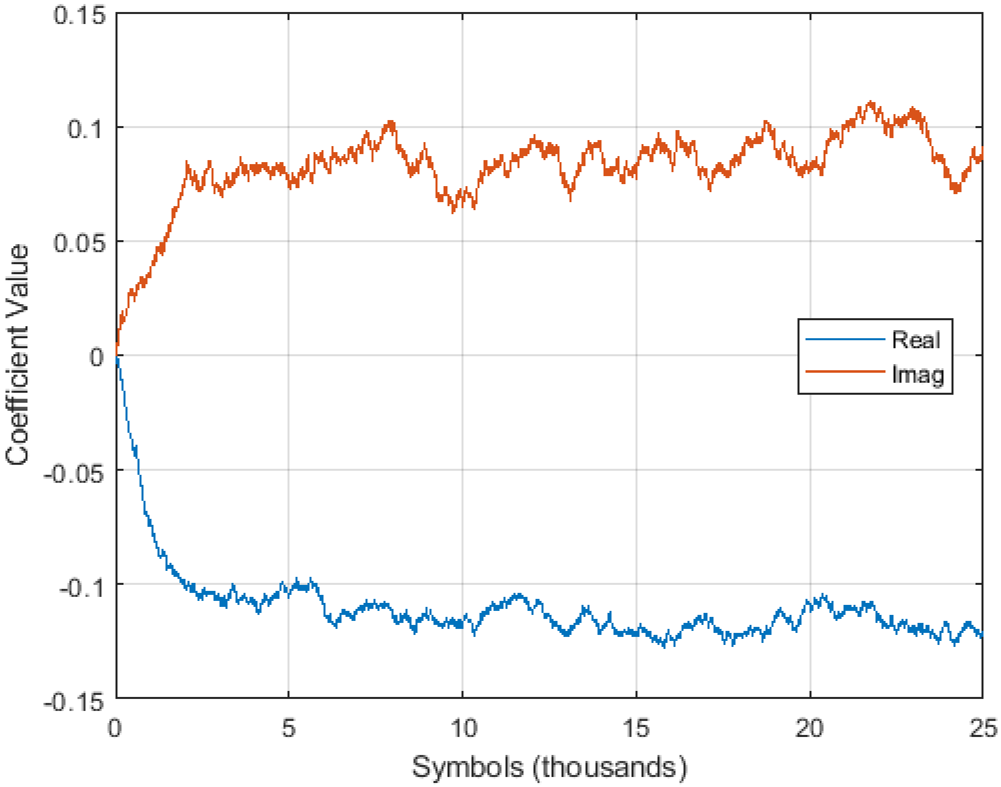
Compensate for the I/Q imbalance while setting the step size via an input argument. You can see that the compensated signal constellation is now nearly aligned with the reference constellation.

```
[compSig,estCoef] = iqImbComp(rxSig,stepSize);
constDiagram(compSig)
```



Plot the real and imaginary values of the estimated coefficients. You can see that they reach a steady-state solution.

```
plot((1:nSym)'/1000,[real(estCoef),imag(estCoef)])
grid
xlabel('Symbols (thousands)')
ylabel('Coefficient Value')
legend('Real','Imag','location','best')
```



Control Adaptation Algorithm for I/Q Imbalance Compensator

Control the adaptation algorithm of the I/Q imbalance compensator using an external argument.

Apply QPSK modulation to random data symbols.

```
data = randi([0 3],600,1);
txSig = pskmod(data,4,pi/4,'gray');
```

Create an I/Q imbalance compensator in which the adaptation algorithm is controlled through an input port, the step size is specified through the `StepSize` property, and the estimated coefficients are made available through an output port.

```
iqImbComp = comm.IQImbalanceCompensator('AdaptInputPort',true, ...
    'StepSize',0.001,'CoefficientOutputPort',true);
```

Apply amplitude and phase imbalance to the transmitted signal.

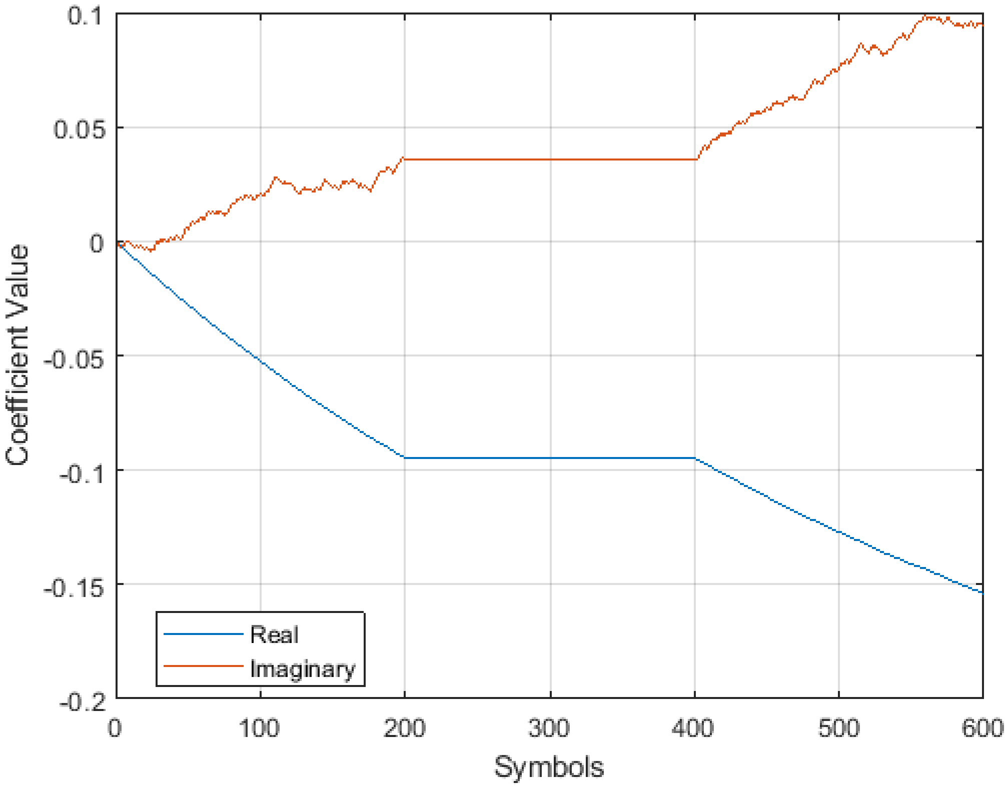
```
ampImb = 5; % dB
phImb = 15; % deg
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(txSig)*gainI*exp(-0.5i*phImb*pi/180);
imbQ = imag(txSig)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));
rxSig = imbI + imbQ;
```

Break the compensation operation into three segments in which the compensator is enabled for the first 200 symbols, disabled for the next 200 symbols, and enabled for the last 200 symbols. Save the coefficient data in three vectors.

```
[~,estCoef1] = iqImbComp(rxSig(1:200),true);
[~,estCoef2] = iqImbComp(rxSig(201:400),false);
[~,estCoef3] = iqImbComp(rxSig(401:600),true);
```

Concatenate the complex algorithm coefficients and plot their real and imaginary parts.

```
estCoef = [estCoef1; estCoef2; estCoef3];
plot((1:600)',[real(estCoef) imag(estCoef)])
grid
xlabel('Symbols')
ylabel('Coefficient Value')
legend('Real','Imaginary','location','best')
```

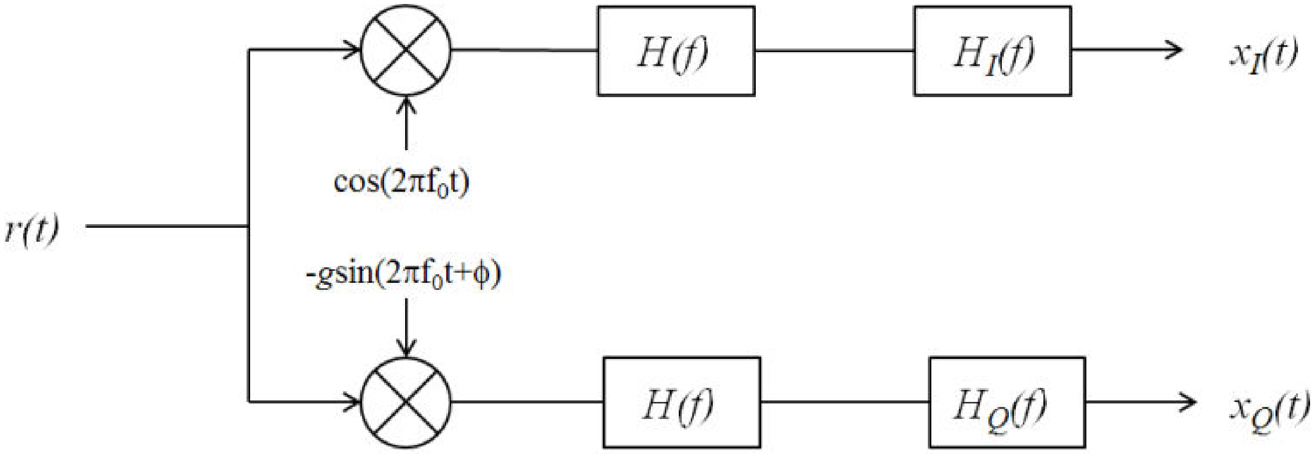


Observe that the coefficients do not adapt during the time in which the compensator is disabled.

Algorithms

One of the major impairments affecting direct conversion receivers is the imbalance between the received signal’s in-phase and quadrature components. Rather than improving the front-end, analog hardware, it is more cost effective to tolerate a certain level of I/Q imbalance and then implement compensation methods. A circularity-based blind compensation algorithm is used as the basis for the I/Q Imbalance Compensator.

A generalized I/Q imbalance model is shown, where g is the amplitude imbalance and ϕ is the phase imbalance (ideally, $g = 1$ and $\phi = 0$). In the figure, $H(f)$ is the nominal frequency response of the branches due to, for example, lowpass filters. $H_I(f)$ and $H_Q(f)$ represent the portions of the in-phase and quadrature amplitude and phase responses that differ from the nominal response. With perfect matching, $H_I(f) = H_Q(f) = 1$.



Let $z(t)$ be the ideal baseband equivalent signal of the received signal, $r(t)$, where its Fourier transform is denoted as $Z(f)$. Given the generalized I/Q imbalance model, the Fourier transform of the imbalanced signal, $x(t) = x_I(t) + x_Q(t)$, is

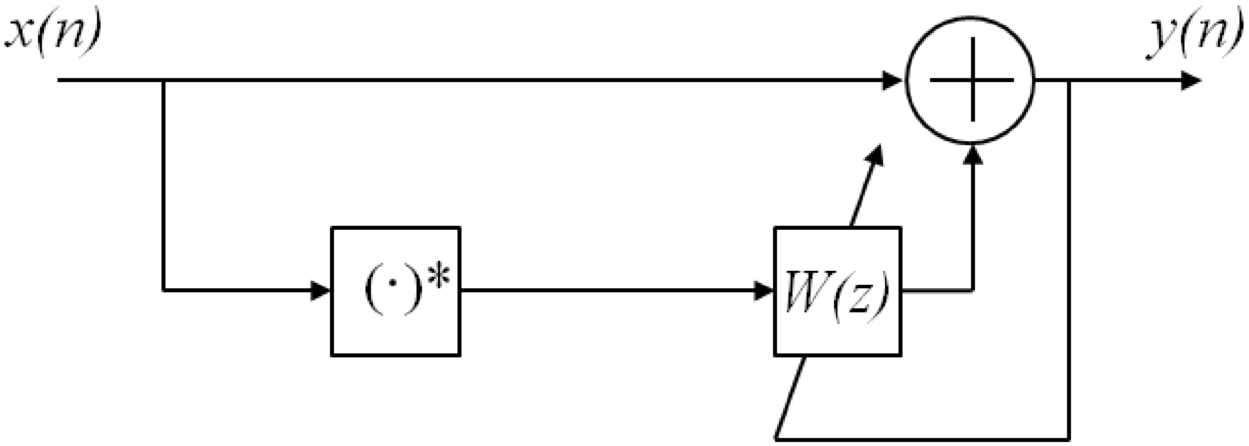
$$X(f) = G_1(f)Z(f) + G_2(f)Z^*(-f)$$

where $G_1(f)$ and $G_2(f)$ are the direct and conjugate components of the I/Q imbalance. These components are defined as

$$G_1(f) = \left[H_I(f) + H_Q(f)g\exp(-j\phi)\right]/2$$
$$G_2(f) = \left[H_I(f) + H_Q(f)g\exp(j\phi)\right]/2$$

Applying the inverse Fourier transform to $X(f)$, the signal model becomes $x(t) = g_1(t) * z(t) + g_2(t) * z^*(t)$.

This suggests the compensator structure as shown in which discrete-time notation is used to express the variables. The compensated signal is expressed as y(n) = $x(n) + wx^*(n)$.



A simple algorithm of the form

$$\begin{cases} y(n) = x(n) + w(n)x^*(n) \\ w(n+1) = w(n) - My^2(n) \end{cases}$$

is used to determine the weights, because it ensures that the output is “proper”, that is, $E[y^2(n)] = 0$ [1]. The initial value of w is determined by the `InitialCoefficient` property, which has a default value of `0 + 0i`. M is the step size, as specified in the `StepSize` property.

[Y,ESTCOEF] = step(H,X)
[Y,ESTCOEF] = step(H,X,STEPSIZE)
[Y,ESTCOEF] = step(H,X,STEPSIZE,ADAPT)
[Y,ESTCOEF] = step(H,X,ADAPT)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` estimates the I/Q imbalance in the input signal, `X`, and returns a compensated signal, `Y`. The input `X` can take real or complex values and can be either a scalar or a column vector. Double- and single-precision data types are supported. The output `Y` has the same properties as `X`.

`Y = step(H,X,COEF)` accepts input coefficients, `COEF`, instead of generating them internally. This syntax applies when the CoefficientSource property of `H` is set to `Input port`. The input coefficients, `COEF`, are complex and can be either double or single precision. `COEF` has the same dimensions as `X`. At each time instant, `COEF` is a complex scalar.

`Y = step(H,X,STEPSIZE)` accepts a step size input, `STEPSIZE`. This syntax applies when the StepSizeSource property of `H` is set to `Input port`. The step size is a real scalar supporting either double or single precision.

`Y = step(H,...,ADAPT)` accepts a control signal, `ADAPT`, to enable or disable coefficient updates. This syntax applies when the AdaptInputPort property of `H` is `true`. The adaptation control signal is a logical scalar.

`[Y,ESTCOEF] = step(H,X)` outputs the estimated coefficients, `ESTCOEF`, when the CoefficientOutputPort property of `H` is `true`. `ESTCOEF` has the same data properties and dimensionality as the input signal, `X`.

`[Y,ESTCOEF] = step(H,X,STEPSIZE)` outputs the estimated coefficients, `ESTCOEF`, and accepts a step size input, `STEPSIZE`. This syntax applies when the properties of `H` are set so that CoefficientOutputPort is `true` and StepSizeSource is `Input port`.

[Y,ESTCOEF] = step(H,X,STEPSIZE,ADAPT) outputs the estimated coefficients, ESTCOEF, and accepts a step size input,STEPSIZE, and a control signal input, ADAPT. This syntax applies when the properties of H are set so that CoefficientOutputPort is true, StepSizeSource is Input port, and AdaptInputPort is true.

[Y,ESTCOEF] = step(H,X,ADAPT) outputs the estimated coefficients, ESTCOEF, and accepts a control signal input, ADAPT. This syntax applies when the properties of H are set so that CoefficientOutputPort is true and AdaptInputPort is true.

Note obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

reset

System object: `comm.IQImbalanceCompensator`
Package: `comm`

Reset states of the `IQImbalanceCompensator` System object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `IQImbalanceCompensator` object, `H`.

This method resets the windowed suffix from the last symbol in the previously processed frame.

comm.BPSKModulator

Package: `comm`

Modulate using BPSK method

Description

The `BPSKModulator` object modulates using the binary phase shift keying method. The output is a baseband representation of the modulated signal.

To modulate a binary phase shift signal:

1. Create the `comm.BPSKModulator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
bpskmod = comm.BPSKModulator
bpskmod = comm.BPSKModulator(Name,Value)
bpskmod = comm.BPSKModulator(phase,Name,Value)
```

Description

`bpskmod = comm.BPSKModulator` creates a modulator System object `bpskmod`, that modulates the input signal using the binary phase shift keying (BPSK) method.

`bpskmod = comm.BPSKModulator(Name,Value)` creates a BPSK modulator object `bpskmod`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`bpskmod = comm.BPSKModulator(phase,Name,Value)` creates a BPSK modulator object `bpskmod`. The object's `PhaseOffset` property is set to `phase`, and the other specified properties are set to the specified values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`PhaseOffset` — Phase of zeroth point of constellation
`0` (default) | finite real scalar

Phase of zeroth point of constellation in radians, specified as a finite real scalar.

`OutputDataType` — Output datatype
`double` (default) | `single` | `Custom`

Output datatype, specified as either `double`, `single` or `Custom`.

Fixed-Point Properties

`CustomOutputDataType` — Fixed-point data type of output
`numerictype([],16)` (default) | `numerictype` object

Fixed-point data type of output, specified as a `numerictype` object with a signedness of Auto.

Dependencies

This property applies when you set the `OutputDataType` property to `'Custom'`.

Usage

Syntax

```
waveform = bpskmod(data)
```

Description

`waveform = bpskmod(data)` applies BPSK modulation to the input data and returns the modulated BPSK baseband signal.

Input Arguments

`data` — Input data
column vector | matrix

Input data, specified as a column vector or matrix.

Data Types: `double`

Output Arguments

`waveform` — BPSK Modulated baseband signal
column vector | matrix

BPSK Modulated baseband signal, returned as a column vector or matrix of the same size as the input signal.

Data Types: `double`
Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.BPSKModulator`

constellation	Calculate or plot ideal signal constellation

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

BPSK Data Scatter Plot

This example creates binary data, modulates it, and then displays the data using a scatter plot.

Create binary data symbols

```
data = randi([0 1],100,1);
```

Create a BPSK modulator System object

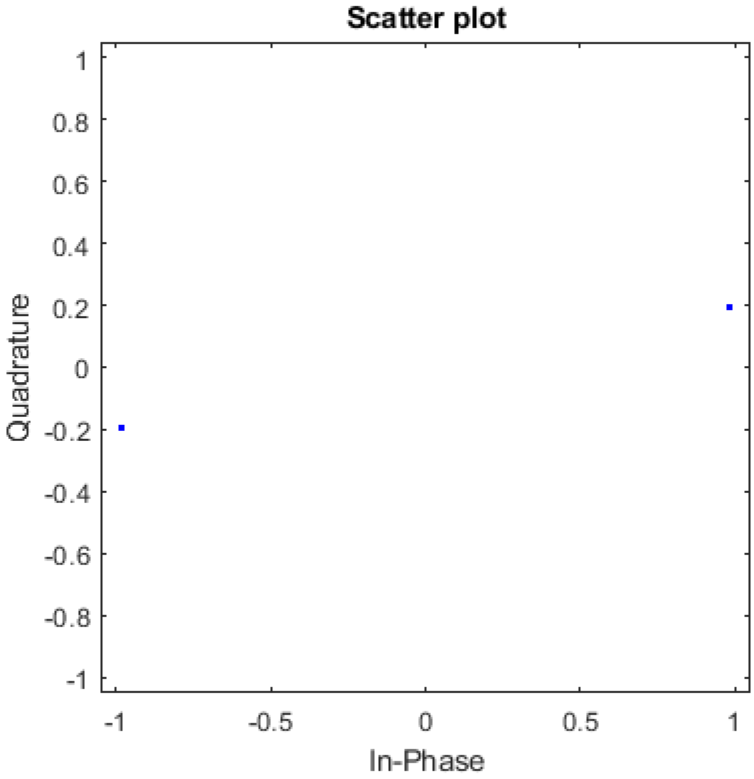
```
bpskModulator = comm.BPSKModulator;
```

Change the phase offset to pi/16

```
bpskModulator.PhaseOffset = pi/16;
```

Modulate and plot the data

```
modData = bpskModulator(data);
scatterplot(modData)
```



Algorithms

Phase modulation is a linear baseband modulation technique in which the message modulates the phase of a constant amplitude signal. Binary Phase Shift Keying (BPSK) is a two phase modulation scheme, where the 0’s and 1’s in a binary message are represented by two different phase states in the carrier signal

$$s_n(t) = \sqrt{\frac{2E_b}{T_b}}\cos(2\pi f_c t + \pi(1 - n));\ n \in \left\{0, 1\right\},$$

for $(n - 1)T_b \le t \le nT_b,\ \text{n} = 1, 2,\ 3, \ldots$ where:

- $\phi_n = \pi m,\ m\in\{0,1\}$.
- E_b is the energy per bit.
- T_b is the bit duration.
- f_c is the carrier frequency.

In MATLAB, the baseband representation of a BPSK signal is

$$s_n(t) = \cos(\pi n);\ n \in \{0, 1\}\ .$$

The BPSK signal has two phases: 0 and π. The probability of a bit error in an AWGN channel is

$$P_b = Q\left(\sqrt{\frac{2E_b}{N_0}}\right),$$

where N_0 is the noise power spectral density.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Objects

`comm.BPSKDemodulator` | `comm.PSKModulator`

Blocks

BPSK Modulator Baseband

Introduced in R2012a

constellation

Package: `comm`

Calculate or plot ideal signal constellation

Syntax

```
y = constellation(bpskmod)
constellation(bpskmod)
```

Description

`y = constellation(bpskmod)` returns the numerical values of the constellation.

`constellation(bpskmod)` generates a constellation plot for the object.

Examples

Calculate BPSK Modulator Reference Constellation

Create a BPSK Modulator System object™ and calculate the reference constellation values.

Create a `comm.BPSKModulator` System object.

```
h = comm.BPSKModulator;
```

Calculate and display the reference constellation values by calling the `constellation` function.

```
refC = constellation(h)
```

```
refC = 2×1 complex

   1.0000 + 0.0000i
  -1.0000 + 0.0000i
```

Plot BPSK Modulator Reference Constellation

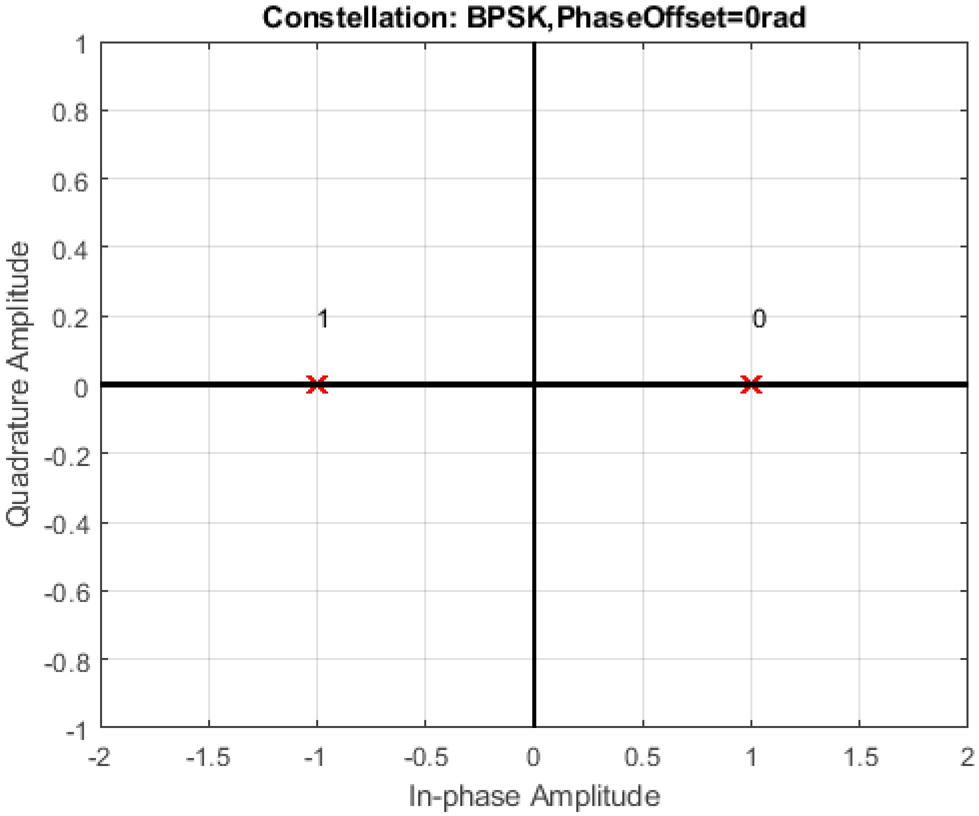
Create a BPSK Modulator System object™ and plot the reference constellation.

Create a `comm.BPSKModulator` System object.

```
bpsk = comm.BPSKModulator;
```

Plot the reference constellation by calling the `constellation` function.

```
constellation(bpsk)
```



Input Arguments

bpskmod — BPSK Modulator
System object

BPSK Modulator, specified as a `comm.BPSKModulator` System object.

Objects
`comm.BPSKModulator`

Introduced in R2012a

step

System object: `comm.BPSKModulator`
Package: `comm`

Modulate using BPSK method

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` modulates input data, `X`, with the BPSK modulator System object, `H`. It returns the baseband modulated output, `Y`. The input must be a column vector of bits. The data type of the input can be numeric, logical, or unsigned fixed point of word length `1` (fi object).

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

comm.OFDMModulator

Package: `comm`

Modulate signal using OFDM method

Description

The `OFDMModulator` object modulates a signal using the orthogonal frequency division modulation method. The output is a baseband representation of the modulated signal.

To modulate a signal using OFDM:

1. Create the `comm.OFDMModulator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
hMod = comm.OFDMModulator
hMod = comm.OFDMModulator(Name,Value)
hMod = comm.OFDMModulator(hDemod)
```

Description

`hMod = comm.OFDMModulator` creates an OFDM modulator System object.

`hMod = comm.OFDMModulator(Name,Value)` specifies “Properties” on page 3-233 using one of more name-value pair arguments. Enclose each property name in quotes. For example, `comm.OFDMModulator('NumSymbols',8)` specifies eight OFDM symbols in the time-frequency grid.

`hMod = comm.OFDMModulator(hDemod)` sets the OFDM modulator system object properties based on the specified OFDM demodulator system object `comm.OFDMDemodulator`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`FFTLength` — Number of FFT points
`64` (default) | positive integer

Number of Fast Fourier Transform (FFT) points, specified as a positive integer. The length of the FFT, N_{FFT}, must be greater than or equal to 8 and is equivalent to the number of subcarriers.

Data Types: `double`

`NumGuardBandCarriers` — Number of subcarriers to the left and right guard bands

`[6;5]` (default) | two-element column vector of integers

Number of subcarriers allocated to the left and right guard bands, specified as a two-element column vector of integers. The number of subcarriers must fall within $[0, \lfloor N_{\mathrm{FFT}}/2\rfloor - 1]$. This vector has the form $[N_{\mathrm{leftG}}, N_{\mathrm{rightG}}]$, where N_{leftG} and N_{rightG} specify the left and right guard bands, respectively.

Data Types: `double`

`InsertDCNull` — Option to insert DC null

`false` or `0` (default) | `true` or `1`

Option to insert DC null, specified as a numeric or logical `0` (`false`) or `1` (`true`). The DC subcarrier is the center of the frequency band and has the index value:

- (`FFTLength` / 2) + 1 when `FFTLength` is even
- (`FFTLength` + 1) / 2 when `FFTLength` is odd

`PilotInputPort` — Option to specify pilot input

`false` or `0` (default) | `true` or `1`

Option to specify pilot input, specified as a numeric or logical `0` (`false`) or `1` (`true`). If this property is `1` (`true`), you can assign individual subcarriers for pilot transmission. If this property is `0` (`false`), pilot information is assumed to be embedded in the input data.

`PilotCarrierIndices` — Pilot subcarrier indices

`[12; 26; 40; 54]` (default) | column vector

Pilot subcarrier indices, specified as a column vector. If the PilotCarrierIndices property is set to `1` (`true`), you can specify the indices of the pilot subcarriers. You can assign the indices to the same or different subcarriers for each symbol. Similarly, the pilot carrier indices can differ across multiple transmit antennas. Depending on the desired level of control for index assignments, the dimensions of the property vary. Valid pilot indices fall in the range

$$[N_{\mathrm{leftG}} + 1,\ N_{\mathrm{FFT}}/2] \cup \left[N_{\mathrm{FFT}}/2 + 2,\ N_{\mathrm{FFT}} - N_{\mathrm{rightG}}\right],$$

where the index value cannot exceed the number of subcarriers. When the pilot indices are the same for every symbol and transmit antenna, the property has dimensions N_{pilot}-by-1. When the pilot indices vary across symbols, the property has dimensions N_{pilot}-by-N_{sym}. If you transmit only one symbol but multiple transmit antennas, the property has dimensions N_{pilot}-by-1-by-N_{t}., where N_{t}. is the number of transmit antennas. If the indices vary across the number of symbols and transmit antennas, the property has dimensions N_{pilot}-by-N_{sym}-by-N_{t}. If the number of transmit antennas is greater than one, ensure that the indices per symbol must be mutually distinct across antennas to minimize interference.

To enable this property, set the `PilotInputPort` property to `1` (`true`).

`CyclicPrefixLength` — Length of cyclic prefix

`16` (default) | positive integer | row vector

Length of cyclic prefix, specified as a positive integer. If you specify a scalar, the prefix length is the same for all symbols through all antennas. If you specify a row vector of length N_{sym}, the prefix length can vary across symbols but remains the same through all antennas.

Data Types: `double`

`Windowing` — Option to apply raised cosine window between OFDM symbols

`false` or `0` (default) | `true` or `1`

Option to apply raised cosine window between OFDM symbols, specified as `true` or `false`. Windowing is the process in which the OFDM symbol is multiplied by a raised cosine window before transmission to more quickly reduce the power of out-of-band subcarriers. Windowing reduces spectral regrowth.

`WindowLength` — Length of raised cosine window

`1` (default) | positive scalar

Length of raised cosine window, specified as a positive scalar. This value must be less than or equal to the minimum cyclic prefix length. For example, in a configuration of four symbols with cyclic prefix lengths 12, 14, 16, and 18, the window length must be less than or equal to 12.

To enable this property, set the `Windowing` property to `1` (`true`).

`NumSymbols` — Number of OFDM symbols

`1` (default) | positive integer

Number of OFDM symbols in the time-frequency grid, specified as a positive integer.

`NumTransmitAntennnas` — Number of transmit antennas

`1` (default) | positive integer

Number of transmit antennas, used to transmit the OFDM modulated signal, specified as a positive integer.

Usage

Syntax

```
waveform = hMod(insignal)
waveform = hMod(data,pilot)
```

Description

`waveform = hMod(insignal)` applies OFDM modulation the specified baseband signal and returns the modulated OFDM baseband signal.

`waveform = hMod(data,pilot)` assigns the pilot signal, `pilot`, into the frequency subcarriers specified by the PilotCarrierIndices property value of the `hMod` system object. To enable this syntax set the PilotCarrierIndices property to `true`.

Input Arguments

`insignal` — Input baseband signal

matrix | 3-D array

Input baseband signal, specified as a matrix or 3-D array of numeric values. The input baseband signal must be of size N_f-by-N_{sym}-by-N_t. where N_f is the number of frequency subcarriers excluding guard bands and DC null.

Data Types: `double`
Complex Number Support: Yes

`data` — Input data
matrix | 3-D array

Input data, specified as a matrix or 3-D array. The input must be a numeric of size N_d-by-N_{sym}-by-N_t. where N_d is the number of data subcarriers in each symbol. For more information on how N_d is calculated, see the PilotCarrierIndices property.

Data Types: `double`
Complex Number Support: Yes

`pilot` — Pilot signal
3-D array

Pilot signal, specified as a 3-D array of numeric values. The pilot signal must be of size N_{pilot}-by-N_{sym}-by-$\mathrm{N_t}$.

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`waveform` — OFDM Modulated baseband signal
2-D array

OFDM Modulated baseband signal, returned as a 2-D array. If the `CyclicPrefixLength` property is a scalar, the output `waveform` is of size $((\mathrm{N_{FFT}}+\mathrm{CP_{len}})*\mathrm{N_{sym}})$-by-$\mathrm{N_t}$. Otherwise, the size is $(\mathrm{N_{FFT}}*\mathrm{N_{sym}}+\sum(\mathrm{CP_{len}}))$-by-$\mathrm{N_t}$.

Data Types: `double`
Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.OFDMModulator`

info	Provide dimensioning information for OFDM modulator
showResourceMapping	Show the subcarrier mapping of the OFDM symbols created by the OFDM modulator System object

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics

reset	Reset internal states of System object

Examples

Create and Modify OFDM Modulator

Create and display an OFDM modulator System object™ with default property values.

```
hMod = comm.OFDMModulator
```

```
hMod = 
  comm.OFDMModulator with properties:

               FFTLength: 64
    NumGuardBandCarriers: [2x1 double]
            InsertDCNull: false
          PilotInputPort: false
      CyclicPrefixLength: 16
               Windowing: false
              NumSymbols: 1
     NumTransmitAntennas: 1
```

Modify the number of subcarriers and symbols.

```
hMod.FFTLength = 128;
hMod.NumSymbols = 2;
```

Verify that the number of subcarriers and the number of symbols changed.

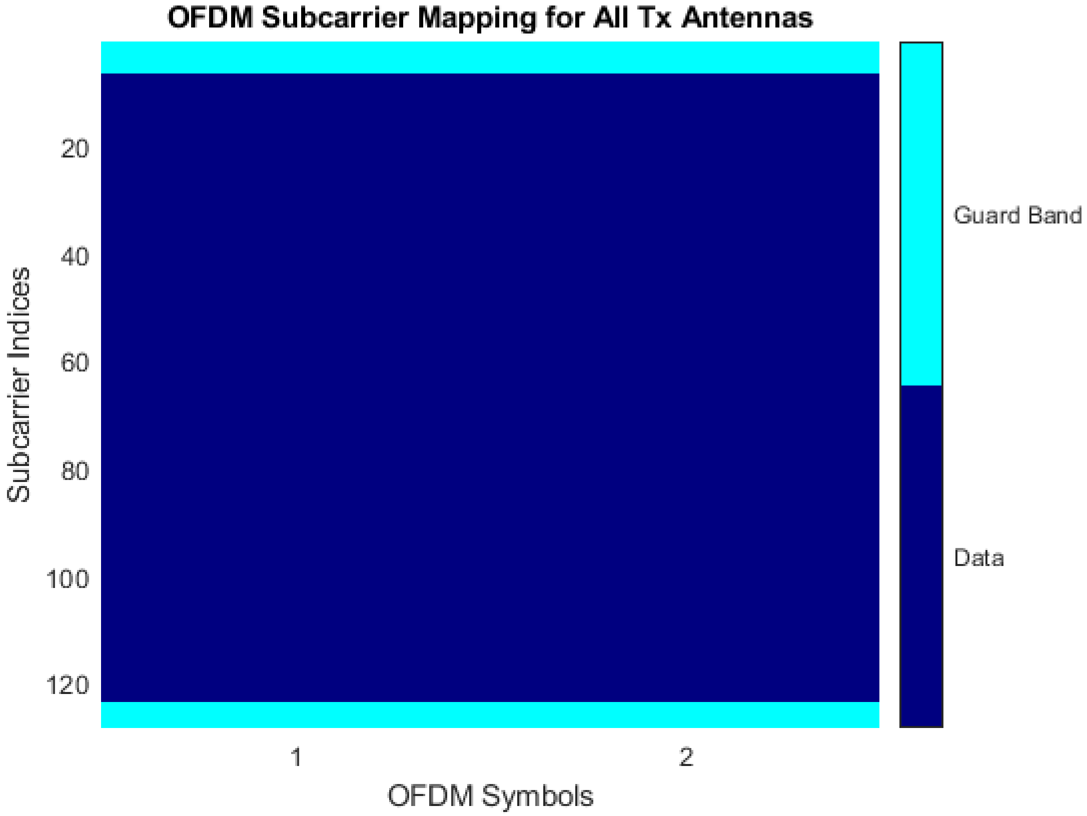
```
disp(hMod)
```

```
  comm.OFDMModulator with properties:

               FFTLength: 128
    NumGuardBandCarriers: [2x1 double]
            InsertDCNull: false
          PilotInputPort: false
      CyclicPrefixLength: 16
               Windowing: false
              NumSymbols: 2
     NumTransmitAntennas: 1
```

Use the `showResourceMapping` object function to show the mapping of data, pilot, and null subcarriers in the time-frequency space.

```
showResourceMapping(hMod)
```



Create OFDM Modulator from OFDM Demodulator

Create an OFDM demodulator System object™ with default property values. Then, specify pilot indices for a single symbol and two transmit antennas.

Setting the `PilotCarrierIndices` property of the demodulator affects the number of transmit antennas in the OFDM modulator when you use the demodulator in the creation of the modulator. The number of receive antennas in the demodulator is uncorrelated with the number of transmit antennas.

```
ofdmDemod = comm.OFDMDemodulator;
ofdmDemod.PilotOutputPort = true;
ofdmDemod.PilotCarrierIndices = cat(3,[12; 26; 40; 54],[13; 27; 41; 55]);
```

Use the OFDM demodulator to construct the OFDM modulator.

```
ofdmMod = comm.OFDMModulator(ofdmDemod);
```

Display the properties of the OFDM modulatorand demodulator, verifying that the applicable properties match.

```
disp(ofdmMod)
```

```
  comm.OFDMModulator with properties:
```

```
               FFTLength: 64
    NumGuardBandCarriers: [2x1 double]
            InsertDCNull: false
          PilotInputPort: true
     PilotCarrierIndices: [4x1x2 double]
      CyclicPrefixLength: 16
               Windowing: false
              NumSymbols: 1
     NumTransmitAntennas: 2
```

```
disp(ofdmDemod)
```

```
  comm.OFDMDemodulator with properties:

               FFTLength: 64
    NumGuardBandCarriers: [2x1 double]
         RemoveDCCarrier: false
         PilotOutputPort: true
     PilotCarrierIndices: [4x1x2 double]
      CyclicPrefixLength: 16
              NumSymbols: 1
      NumReceiveAntennas: 1
```

Visualize Time-Frequency Resource Assignments for OFDM Modulator

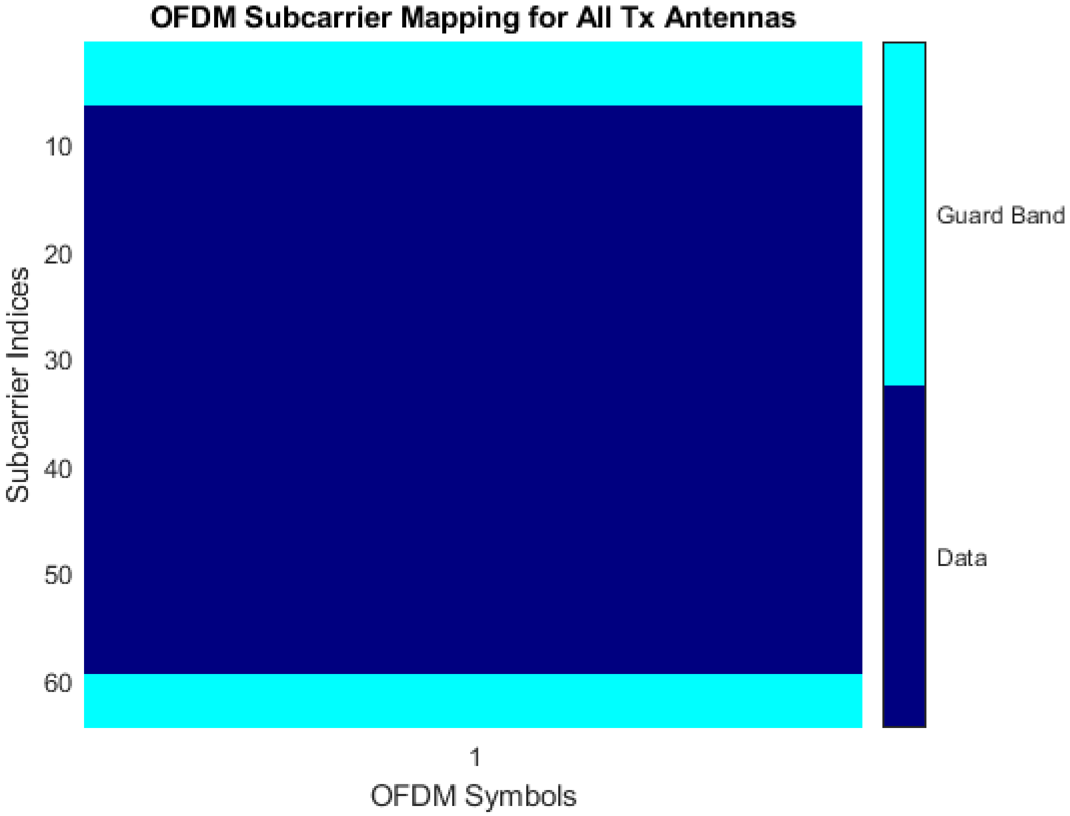
The `showResourceMapping` method displays the time-frequency resource mapping for each transmit antenna.

Construct an OFDM modulator.

```
mod = comm.OFDMModulator;
```

Apply the `showResourceMapping` method.

```
showResourceMapping(mod)
```

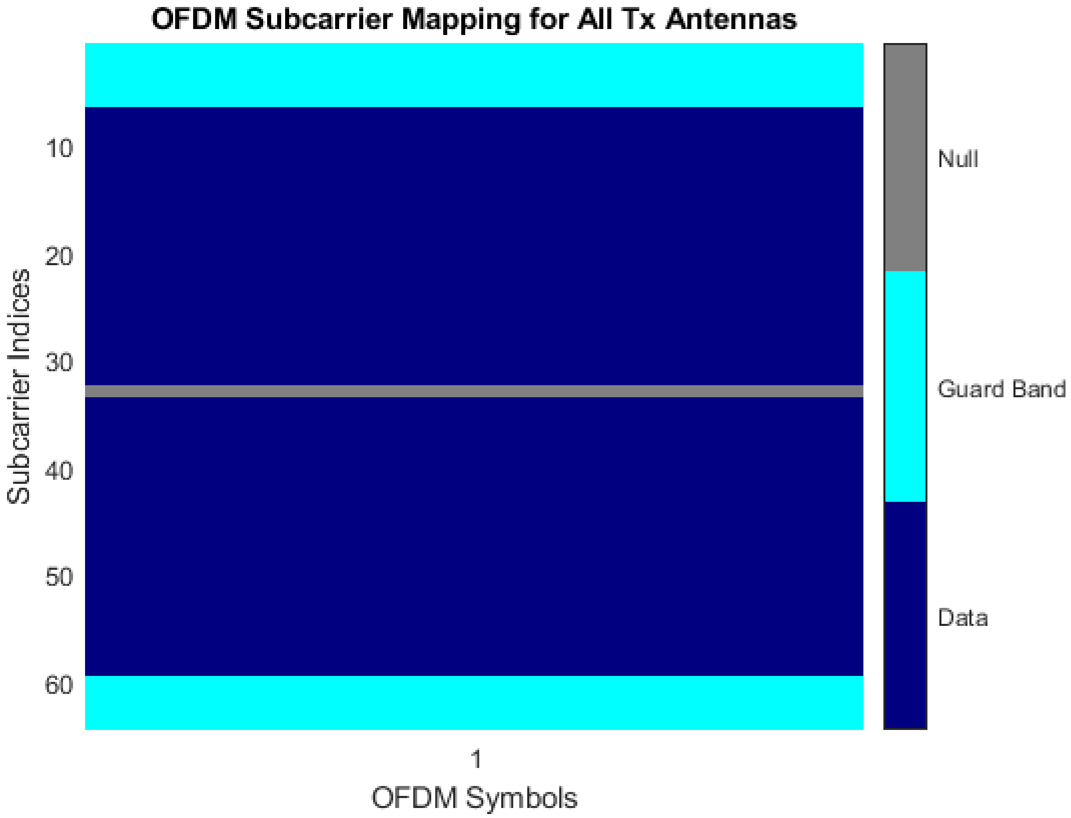


Insert a DC null.

```
mod.InsertDCNull = true;
```

Show the resource mapping after adding the DC null.

```
showResourceMapping(mod)
```



Create OFDM Modulator and Specify Pilots

Create an OFDM modulator and specify the subcarrier indices for the pilot signals. Specify the indices for each symbol and transmit antenna. When the number of transmit antennas is greater than one, set different pilot indices for each symbol between antennas.

Create an OFDM modulator System object, specifying two symbols and inserting a DC null.

```
mod = comm.OFDMModulator('FFTLength',128,'NumSymbols',2,...
    'InsertDCNull',true);
```

Enable the pilot input port so you can specify the pilot indices.

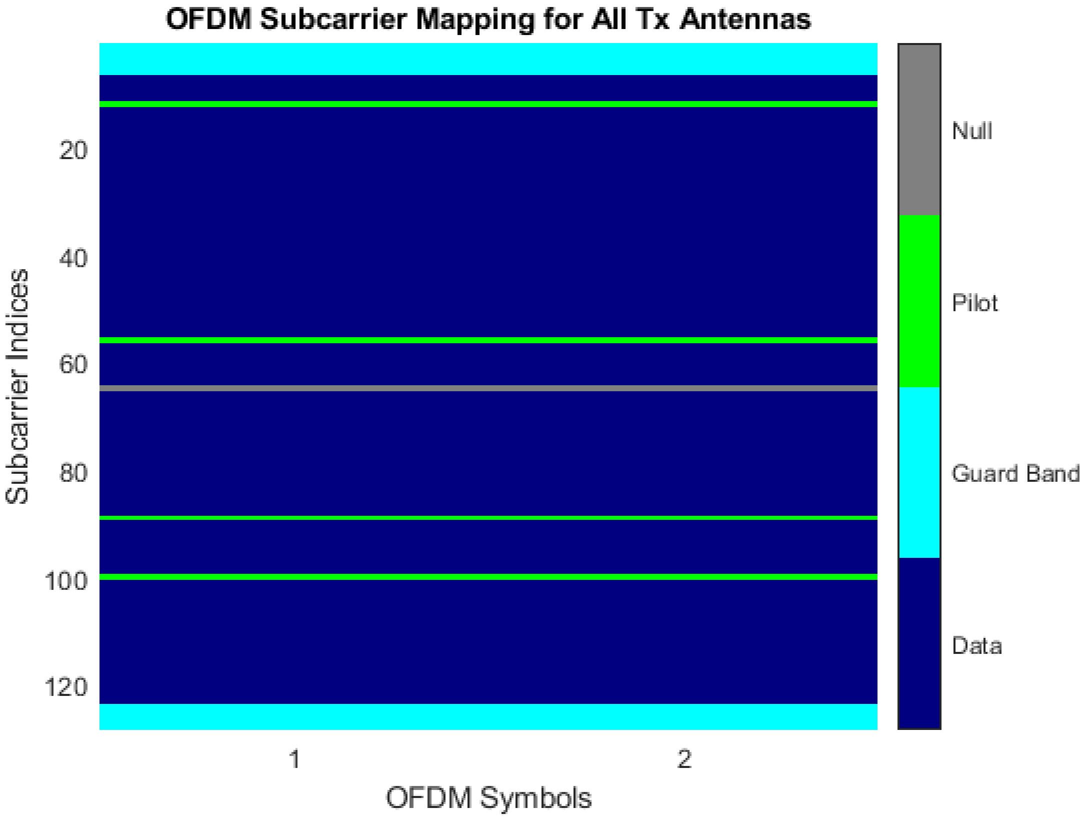
```
mod.PilotInputPort = true;
```

Specify the same pilot indices for both symbols.

```
mod.PilotCarrierIndices = [12; 56; 89; 100];
```

Visualize the placement of the pilot signals and nulls in the OFDM time-frequency grid by using the `showResourceMapping` object function.

```
showResourceMapping(mod)
```

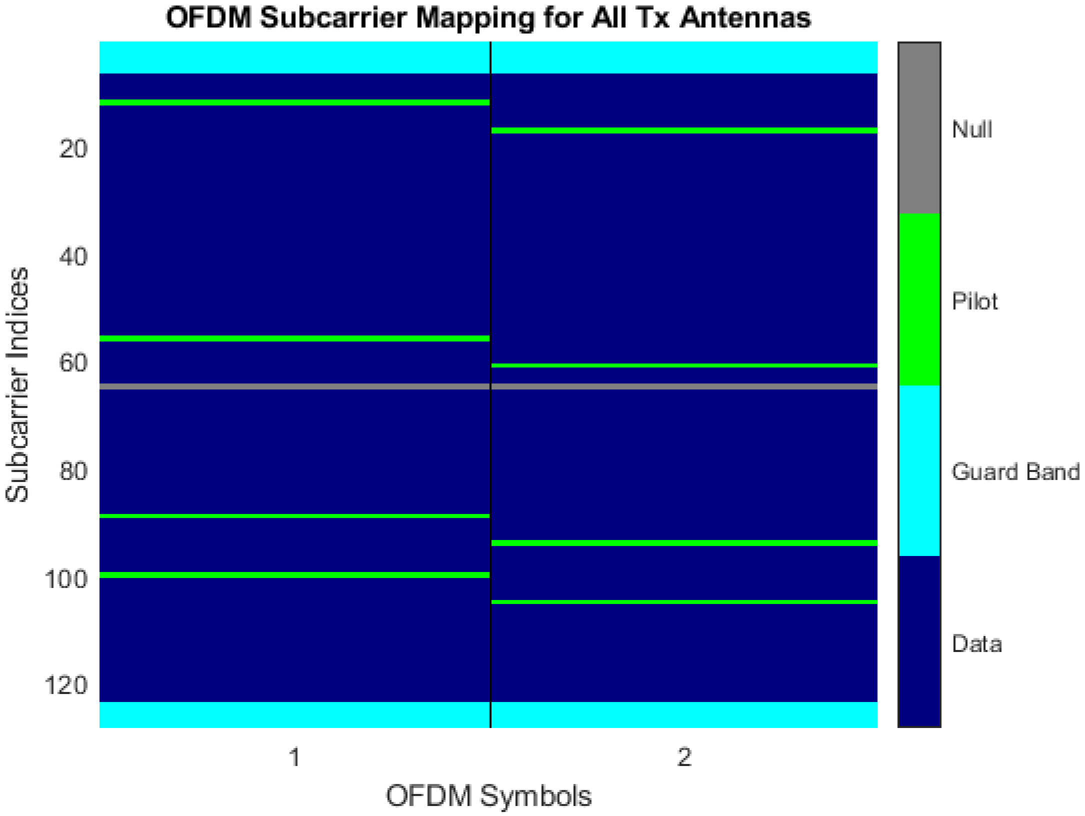


Specify different indices for the second symbol by concatenating a second column of pilot indices to the `PilotCarrierIndices` property.

```
mod.PilotCarrierIndices = cat(2,mod.PilotCarrierIndices, ...
    [17; 61; 94; 105]);
```

Verify that the pilot subcarrier indices differ between the two symbols.

```
showResourceMapping(mod)
```



Increase the number of transmit antennas to two.

```
mod.NumTransmitAntennas = 2;
```

Specify the pilot indices for each of the two transmit antennas. To provide indices for multiple antennas while minimizing interference among the antennas, set the `PilotCarrierIndices` property as a 3-D array such that the indices for each symbol differ among antennas.

```
mod.PilotCarrierIndices = cat(3,[20; 50; 70; 110], [15; 60; 75; 105]);
```

Display the resource mapping for the two transmit antennas. The gray lines denote the insertion of custom nulls. The nulls are created by the object to minimize interference among the pilot symbols from different antennas.

```
showResourceMapping(mod)
```

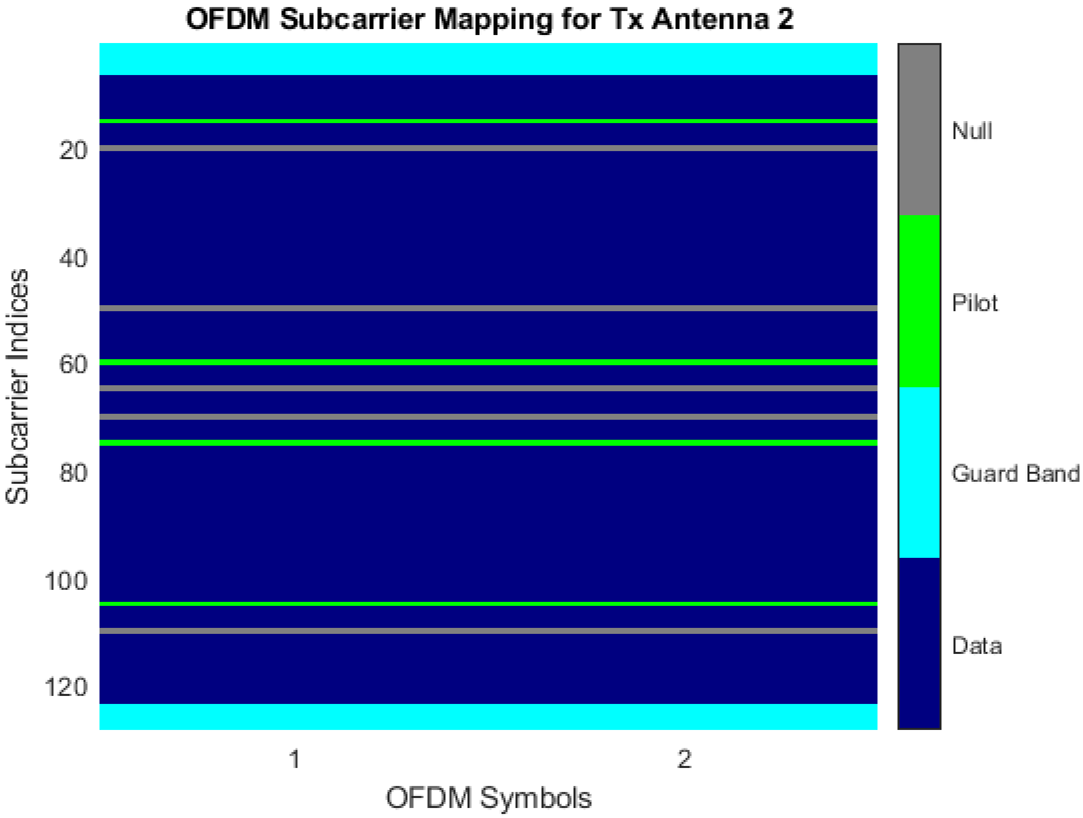
Data



Create OFDM Modulator with Varying Cyclic Prefix Lengths

Specify the length of the cyclic prefix for each OFDM symbol.

Create an OFDM modulator, specifying five symbols, four left and three right guard-band subcarriers, and the cyclic prefix length for each OFDM symbol.

```
mod = comm.OFDMModulator('NumGuardBandCarriers',[4;3],...
    'NumSymbols',5,...
    'CyclicPrefixLength',[12 10 14 11 13]);
```

Display the properties of the OFDM modulator, verifyING that the cyclic prefix length changes across symbols.

```
disp(mod)
```

```
  comm.OFDMModulator with properties:

               FFTLength: 64
    NumGuardBandCarriers: [2x1 double]
            InsertDCNull: false
           PilotInputPort: false
      CyclicPrefixLength: [12 10 14 11 13]
               Windowing: false
```

```
             NumSymbols: 5
    NumTransmitAntennas: 1
```

Determine OFDM Modulator Data Dimensions

Get the OFDM modulator data dimensions by using the `info` object function.

Construct an OFDM modulator System object™ with user-specified pilot indices, an inserted DC null, and specify two transmit antennas.

```
hMod = comm.OFDMModulator('NumGuardBandCarriers',[4;3], ...
    'PilotInputPort',true, ...
    'PilotCarrierIndices',cat(3,[12; 26; 40; 54], ...
    [11; 25; 39; 53]), ...
    'InsertDCNull',true, ...
    'NumTransmitAntennas',2);
```

Use the `info` object function to get the modulator input data, pilot input data, and output data sizes.

```
info(hMod)
```

```
ans = struct with fields:
     DataInputSize: [48 1 2]
    PilotInputSize: [4 1 2]
        OutputSize: [80 2]
```

Create OFDM Modulated Data

Generate OFDM modulated symbols for use in link-level simulations.

Construct an OFDM modulator with an inserted DC null, seven guard-band subcarriers, and two symbols having different pilot indices for each symbol.

```
mod = comm.OFDMModulator('NumGuardBandCarriers',[4;3],...
'PilotInputPort',true, ...
'PilotCarrierIndices',[12 11; 26 27; 40 39; 54 55], ...
'NumSymbols',2, ...
'InsertDCNull',true);
```

Determine input data, pilot, and output data dimensions.

```
modDim = info(mod);
```

Generate random data symbols for the OFDM modulator. The structure variable, `modDim`, determines the number of data symbols.

```
dataIn = complex(randn(modDim.DataInputSize),randn(modDim.DataInputSize));
```

Create a pilot signal that has the correct dimensions.

```
pilotIn = complex(rand(modDim.PilotInputSize),rand(modDim.PilotInputSize));
```

Apply OFDM modulation to the data and pilot signals.

```
modData = step(mod,dataIn,pilotIn);
```

Use the OFDM modulator object to create the corresponding OFDM demodulator.

```
demod = comm.OFDMDemodulator(mod);
```

Demodulate the OFDM signal and output the data and pilot signals.

```
[dataOut, pilotOut] = step(demod,modData);
```

Verify that, within a tight tolerance, the input data and pilot symbols match the output data and pilot symbols.

```
isSame = (max(abs([dataIn(:) - dataOut(:); ...
    pilotIn(:) - pilotOut(:)])) < 1e-10)
```

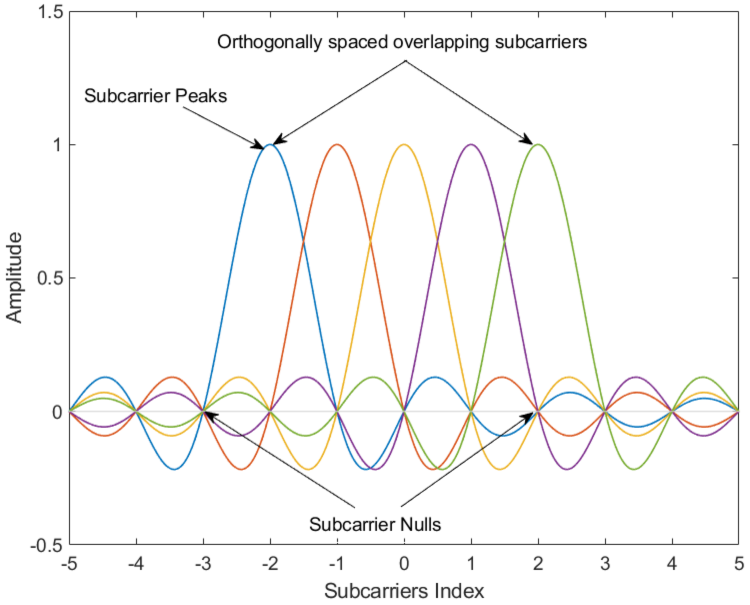
```
isSame = logical
   1
```

More About

Orthogonal Frequency Division Modulation

OFDM operation divides a high-rate data stream into lower data rate substreams by decomposing the transmission frequency band into *N* contiguous individually modulated subcarriers. Multiple parallel and orthogonal subcarriers carry the samples with almost the same bandwidth as a wideband channel. By using narrow orthogonal subcarriers, the OFDM signal gains robustness over a frequency-selective fading channel and eliminates adjacent subcarrier interference. Intersymbol interference (ISI) is reduced because the lower data rate substreams have symbol durations larger than the channel delay spread.

The Frequency domain representation of orthogonal subcarriers in an OFDM waveform looks as follows:



The transmitter applies inverse fast Fourier transform (IFFT) to N symbols at a time. The output of the IFFT is the sum of the N orthogonal sinusoids:

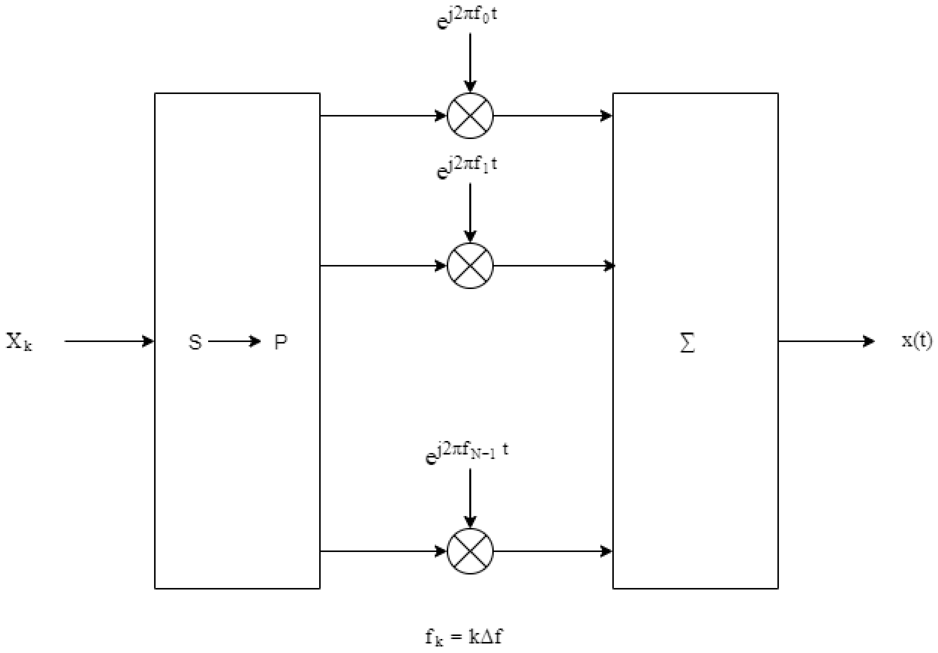
$$x(t) = \sum_{k=0}^{N-1} X_k e^{j2\pi k\Delta f t}, \quad 0 \le t \le T,$$

where $\{X_\mathrm{k}\}$ are data symbols, and T is the OFDM symbol time. The data symbols X_k are typically complex and can be from any digital modulation alphabet (for example, QPSK, 16-QAM, 64-QAM).

The subcarrier spacing is $\Delta f = 1/T$; ensuring that the subcarriers are orthogonal over each symbol period, as shown below:

$$\frac{1}{T}\int_0^T \left(e^{j2\pi m\Delta f t}\right)^* \left(e^{j2\pi n\Delta f t}\right) dt = \frac{1}{T}\int_0^T e^{j2\pi(m-n)\Delta f t}\, dt = 0 \quad \text{for } m \ne n\,.$$

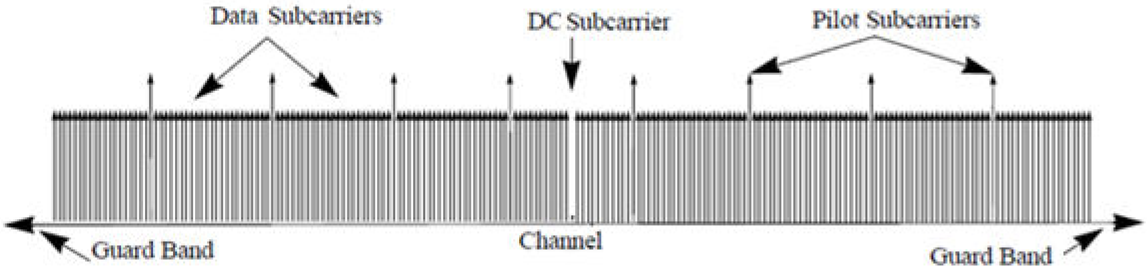
An OFDM modulator consists of a serial-to-parallel conversion followed by a bank of N complex modulators, individually corresponding to each OFDM subcarrier.



Subcarrier Allocation, Guard Bands and Guard Intervals

Individual OFDM subcarriers are allocated as data, pilot, or null subcarriers.

As shown here, subcarriers are designated as data, DC, pilot, or guard band subcarriers.

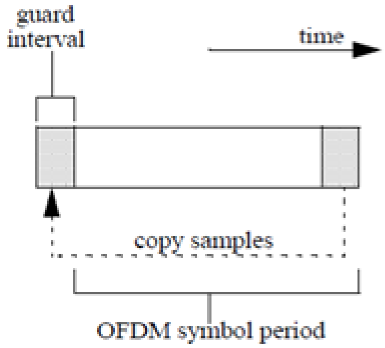


- Data subcarriers transmit user data.
- Pilot subcarriers are used for channel estimation.
- Null subcarriers transmit no data. Subcarriers with no data are used to provide a DC null and serve as buffers between OFDM resource blocks.
  - The null DC subcarrier is the center of the frequency band with an index value of (`nfft`/2 + 1) if `nfft` is even, or ((`nfft` + 1) / 2) if `nfft` is odd.
  - The guard bands provide buffers between consecutive OFDM symbols to protect the integrity of transmitted signals by reducing intersymbol interference.

Null subcarriers enable you to model guard bands and DC subcarrier locations for specific standards, such as the various 802.11 formats, LTE, WiMAX, or for custom allocations. You can allocate the location of nulls by assigning a vector of null subcarrier indices.

Similar to guard bands, guard intervals are used in OFDM to protect the integrity of transmitted signals by reducing intersymbol interference.

Assignment of guard intervals is analogous to the assignment of guard bands. You can model guard intervals to provide temporal separation between OFDM symbols. The guard intervals help preserve intersymbol orthogonality after the signal passes through time-dispersive channels. Guard intervals are created by using cyclic prefixes. Cyclic prefix insertion copies the last part of an OFDM symbol as the first part of the OFDM symbol.



As long as the span of the time dispersion does not exceed the duration of the cyclic prefix, the benefit of cyclic prefix insertion is maintained.

Inserting a cyclic prefix results in a fractional reduction of user data throughput because the cyclic prefix occupies bandwidth that could be used for data transmission.

Raised Cosine Windowing

While the cyclic prefix creates a guard period in time domain to preserve orthogonality, an OFDM symbol rarely begins with the same amplitude and phase exhibited at the end of the prior OFDM symbol causing spectral regrowth and therefore, spreading of signal bandwidth due to intermodulation distortion. To limit this spectral regrowth, it is desired to create a smooth transition between the last sample of a symbol and the first sample of the next symbol. This can be done by using a cyclic suffix and raised cosine windowing.

To create the cyclic suffix, the first N_{WIN} samples of a given symbol are appended to the end of that symbol. However, in order to comply with the 802.11g standard, for example, the length of a symbol cannot be arbitrarily lengthened. Instead, the cyclic suffix must overlap in time and is effectively summed with the cyclic prefix of the following symbol. This overlapped segment is where windowing is applied. Two windows are applied, one of which is the mathematical inverse of the other. The first raised cosine window is applied to the cyclic suffix of symbol k and decreases from 1 to 0 over its duration. The second raised cosine window is applied to the cyclic prefix of symbol k+1 and increases from 0 to 1 over its duration. This process provides a smooth transition from one symbol to the next.

The raised cosine window, $w(t)$, in the time domain can be expressed as:

$$w(t) = \begin{cases} 1,\ 0 \le |t| < \dfrac{T - T_W}{2} \\ \dfrac{1}{2}\left\{1 + \cos\left[\dfrac{\pi}{T_W}\left(|t| - \dfrac{T - T_W}{2}\right)\right]\right\}, \dfrac{T - T_W}{2} \le |t| \le \dfrac{T + T_W}{2} \\ 0, \text{otherwise} \end{cases}$$

where:

- T is the OFDM symbol duration including the guard interval.
- T_W is the duration of the window.

Adjust the length of the cyclic suffix via the window length setting property, with suffix lengths set between 1 and the minimum cyclic prefix length. While windowing improves spectral regrowth, it does so at the expense of multipath fading immunity. This occurs because redundancy in the guard band is reduced because the guard band sample values are compromised by the smoothing.

The following figures display the application of raised cosine windowing.

Blocks

OFDM Modulator Baseband

Introduced in R2014a

comm.OFDMDemodulator

Package: `comm`

Demodulate using OFDM method

Description

The `OFDMDemodulator` object demodulates using the orthogonal frequency division demodulation method. The output is a baseband representation of the modulated signal, which was input into the `OFDMModulator` companion object.

To demodulate an OFDM signal:

1. Define and set up the OFDM demodulator object. See "Construction" on page 3-253.
2. Call `step` to demodulate a signal according to the properties of `comm.OFDMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.OFDMDemodulator` creates a demodulator System object, `H`, that demodulates an input signal by using the orthogonal frequency division demodulation method.

`H = comm.OFDMDemodulator(Name,Value)` creates an OFDM demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.OFDMDemodulator(hMod)` creates an OFDM demodulator object, `H`, whose properties are determined by the corresponding OFDM modulator object, `hMod`.

Properties

FFTLength

The length of the FFT, N_{FFT}, is equivalent to the number of subcarriers used in the modulation process. `FFTLength` must be ≥ 8.

Specify the number of subcarriers. The default is `64`.

NumGuardBandCarriers

The number of guard band subcarriers allocated to the left and right guard bands.

Specify the number of left and right subcarriers as nonnegative integers in $[0, N_{FFT}/2 - 1]$ where you specify the left, N_{leftG}, and right, N_{rightG}, guard bands independently in a 2-by-1 column vector. The default values are `[6; 5]`.

RemoveDCCarrier

A `logical` variable that when `true`, mandates removal of a DC subcarrier. The default value is `false`.

PilotOutputPort

A `logical` property that controls whether to separate the pilot signals and make them available at an additional output port. The location of each pilot output symbol is determined by the pilot subcarrier indices specified in the `PilotCarrierIndices` property. When false, pilot symbols may be present but embedded in the data. The default value is `false`.

PilotCarrierIndices

If the `PilotOutputPort` property is `true`, output separate pilot signals located at the indices specified by the `PilotCarrierIndices` property. If the indices are a 2-D array, the pilot carriers across all the transmit antennas per symbol are the same. If there is more than one transmit antenna (this information is not known by the demodulator), the pilots from different transmit antennas may interfere with each other. To avoid this, specify the pilot carrier indices as a 3-D array with different pilot indices for each symbol across the antennas. This avoids interference between pilots from different transmit antennas, since, on a per-symbol basis, each transmit antenna has different pilot carriers and the OFDM modulator creates custom nulls at the appropriate locations. The size of the third dimension of the `PilotCarrierIndices` property gives the number of transmit antennas.

CyclicPrefixLength

The cyclic prefix length property specifies the length of the OFDM cyclic prefix. If you specify a scalar, the prefix length is the same for all symbols through all antennas. If you specify a row vector of length N_{sym}, the prefix length can vary across symbols but remains the same length through all antennas. The default value is `16`.

NumSymbols

This property specifies the number of symbols, N_{sym}. Specify N_{sym} as a positive integer. The default value is `1`.

NumReceiveAntennnas

This property determines the number of antennas, N_{R}, used to receive the OFDM modulated signal. Specify N_{R} as a positive integer. The default value is `1`.

Methods

info	Provide dimensioning information for the OFDM method
reset	Reset states of the `OFDMDemodulator` System object
showResourceMapping	Show the subcarrier mapping of the OFDM symbols created by the OFDM demodulator System object
step	Demodulate using OFDM method

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Create and Modify OFDM Demodulator

Construct an OFDM demodulator System object™ with default properties. Modify some of the properties.

Construct the OFDM demodulator.

```
demod = comm.OFDMDemodulator
```

```
demod = 
  comm.OFDMDemodulator with properties:

               FFTLength: 64
    NumGuardBandCarriers: [2x1 double]
         RemoveDCCarrier: false
         PilotOutputPort: false
      CyclicPrefixLength: 16
              NumSymbols: 1
      NumReceiveAntennas: 1
```

Modify the number of subcarriers and symbols.

```
demod.FFTLength = 128;
demod.NumSymbols = 2;
```

Verify that the number of subcarriers and the number of symbols changed.

```
demod
```

```
demod = 
  comm.OFDMDemodulator with properties:

               FFTLength: 128
    NumGuardBandCarriers: [2x1 double]
         RemoveDCCarrier: false
         PilotOutputPort: false
      CyclicPrefixLength: 16
              NumSymbols: 2
      NumReceiveAntennas: 1
```

Create OFDM Demodulator from OFDM Modulator

Create an OFDM demodulator System object™ from an existing OFDM modulator System object.

Construct an OFDM modulator using default parameters.

```
mod = comm.OFDMModulator('NumTransmitAntennas',4);
```

Construct the corresponding OFDM demodulator from the modulator, `mod`.

```
demod = comm.OFDMDemodulator(mod);
```

Display the properties of the modulator and verify that they match those of the demodulator.

```
mod
```

```
mod = 
  comm.OFDMModulator with properties:

                FFTLength: 64
     NumGuardBandCarriers: [2x1 double]
             InsertDCNull: false
           PilotInputPort: false
       CyclicPrefixLength: 16
                Windowing: false
               NumSymbols: 1
      NumTransmitAntennas: 4
```

```
demod
```

```
demod = 
  comm.OFDMDemodulator with properties:

                FFTLength: 64
     NumGuardBandCarriers: [2x1 double]
          RemoveDCCarrier: false
          PilotOutputPort: false
       CyclicPrefixLength: 16
               NumSymbols: 1
       NumReceiveAntennas: 1
```

Note that the number of transmit antennas is independent of the number of receive antennas.

Visualize Time-Frequency Resource Assignments

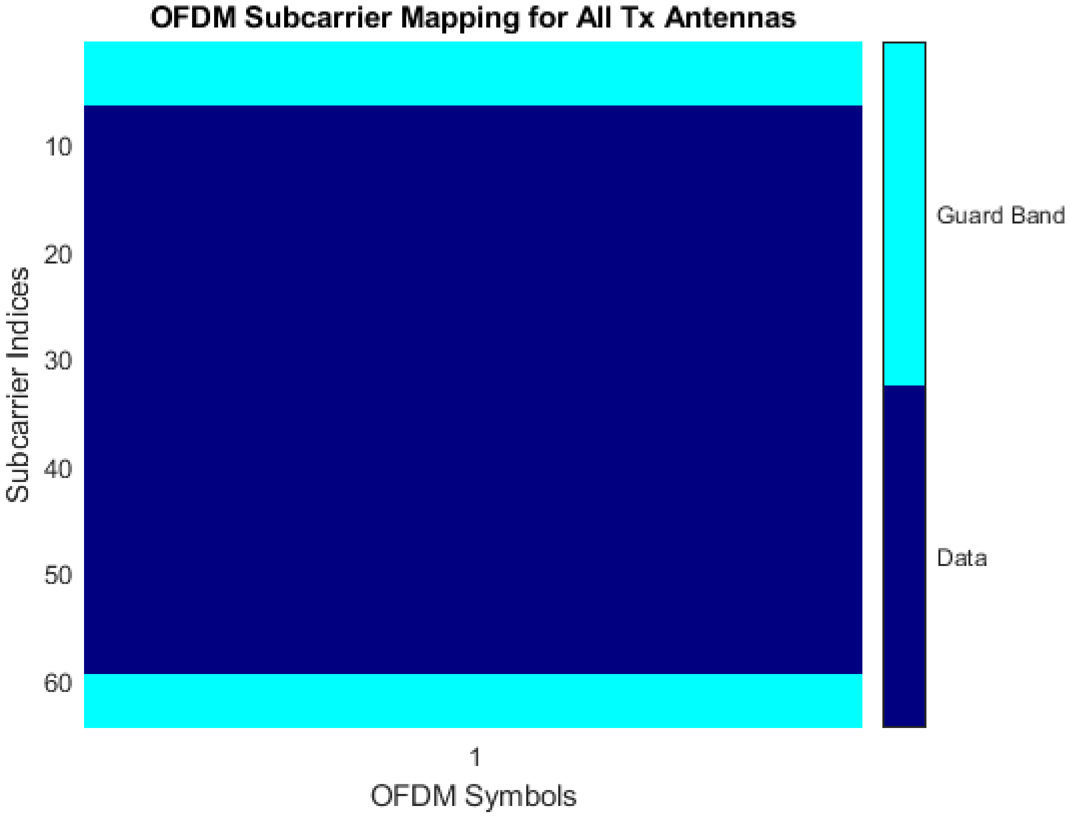
The `showResourceMapping` method shows the time-frequency resource mapping for each transmit antenna.

Construct an OFDM demodulator.

```
demod = comm.OFDMDemodulator;
```

Apply the `showResourceMapping` method.

```
showResourceMapping(demod)
```

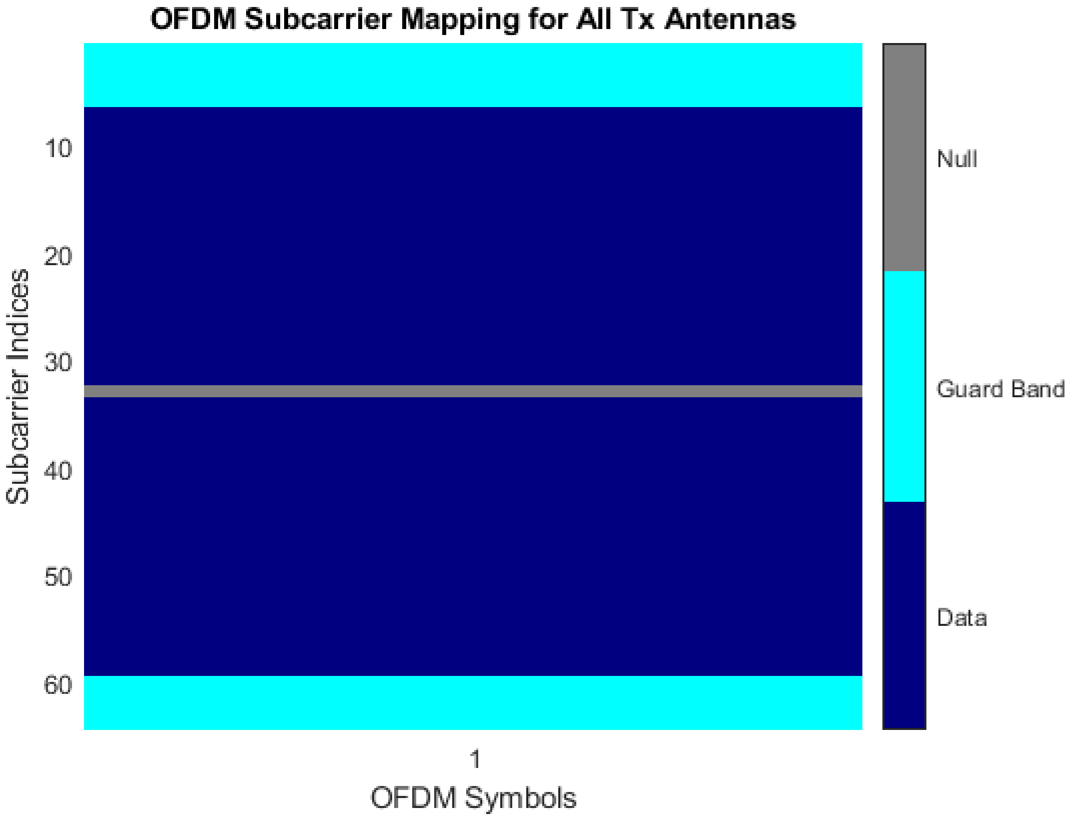


Remove the DC subcarrier.

```
demod.RemoveDCCarrier = true;
```

Show the resource mapping after removing the DC subcarrier.

```
showResourceMapping(demod)
```



Demodulate OFDM Data

Construct an OFDM modulator with an inserted DC null, seven guard-band subcarriers, and two symbols that have different pilot indices for each symbol.

```
mod = comm.OFDMModulator('NumGuardBandCarriers',[4;3],...
'PilotInputPort',true,'PilotCarrierIndices',cat(2,[12; 26; 40; 54],...
[11; 27; 39; 55]),'NumSymbols',2,'InsertDCNull',true);
```

Determine input data, pilot, and output data dimensions.

```
modDim = info(mod)
```

```
modDim = struct with fields:
     DataInputSize: [52 2]
    PilotInputSize: [4 2]
        OutputSize: [160 1]
```

Generate random data symbols for the OFDM modulator. Determine the number of data symbols by using the structure variable, `modDim`.

```
dataIn = complex(randn(modDim.DataInputSize),randn(modDim.DataInputSize));
```

Create a pilot signal that has the correct dimensions.

```
pilotIn = complex(rand(modDim.PilotInputSize),rand(modDim.PilotInputSize));
```

Apply OFDM modulation to the data and pilot signals.

```
modSig = step(mod,dataIn,pilotIn);
```

Use the OFDM modulator object to create the corresponding OFDM demodulator.

```
demod = comm.OFDMDemodulator(mod);
```

Demodulate the OFDM signal and output the data and pilot signals.

```
[dataOut,pilotOut] = step(demod,modSig);
```

Verify that the input data and pilot symbols match the output data and pilot symbols.

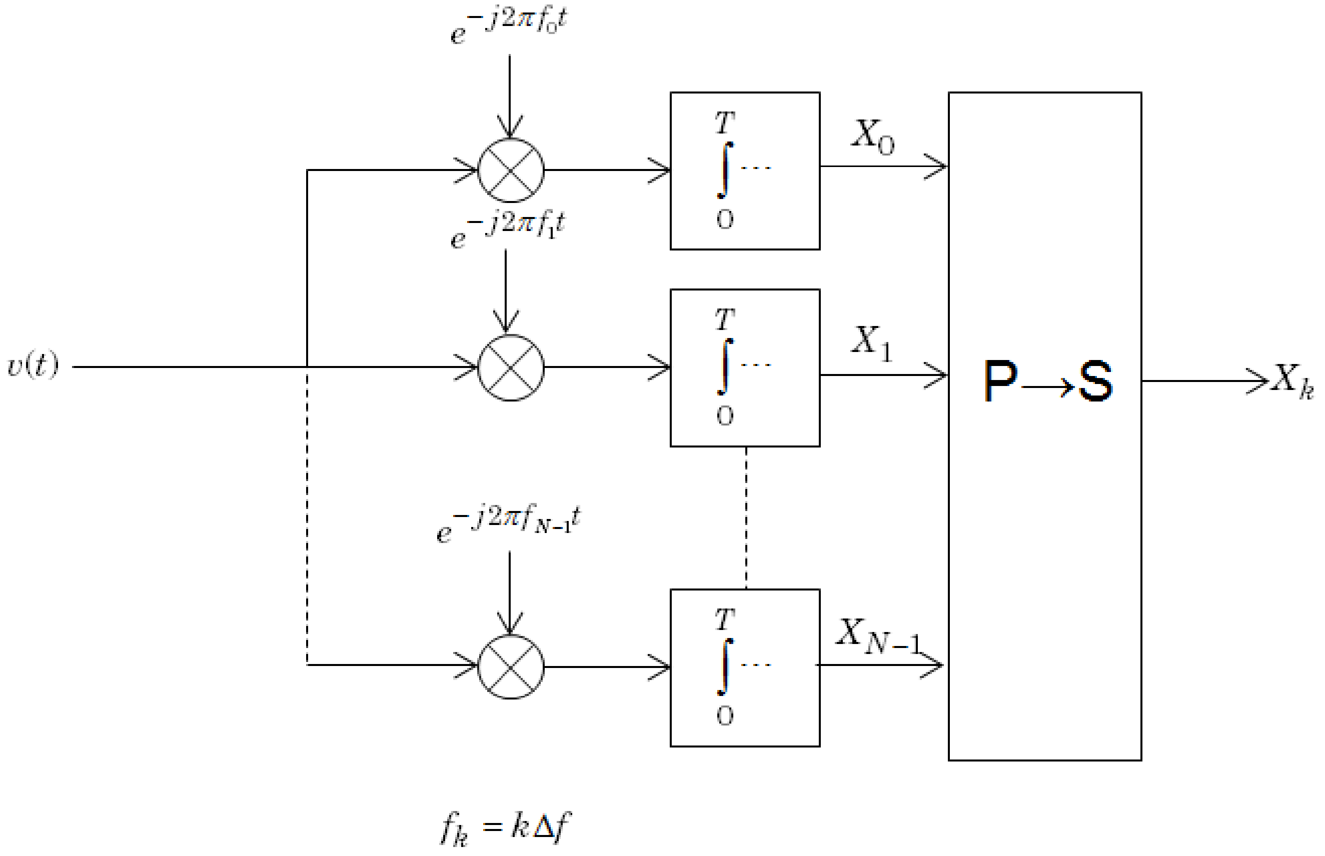
```
isSame = (max(abs([dataIn(:) - dataOut(:); ...
    pilotIn(:) - pilotOut(:)])) < 1e-10)
```

```
isSame = logical
   1
```

Algorithms

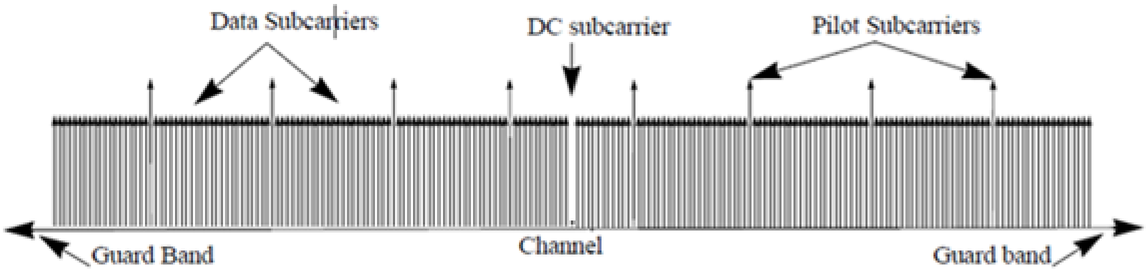
The Orthogonal Frequency Division Modulation (OFDM) Demodulator System object demodulates an OFDM input signal by using an FFT operation that results in *N* parallel data streams.

The figure shows an OFDM demodulator. It consists of a bank of *N* correlators with one assigned to each OFDM subcarrier followed by a parallel-to-serial conversion.



Guard Bands and Intervals

There are three types of OFDM subcarriers: data, pilot, and null. Data subcarriers are used for transmitting data while pilot subcarriers are used for channel estimation. There is no transmission on null subcarriers, which are used to provide a DC null as well as to provide buffers between OFDM resource blocks. These buffers are referred to as guard bands whose purpose is to prevent inter-symbol interference. The allocation of nulls and guard bands varies depending upon the standard, e.g., 802.11n differs from LTE. Consequently, the OFDM modulator object allows the user to assign subcarrier indices as required.



Analogous to the concept of guard bands, the OFDM modulator object supports guard intervals that provide temporal separation between OFDM symbols so that the signal does not lose orthogonality due to time-dispersive channels. As long as the guard interval is longer than the delay spread, each symbol does not interfere with other symbols. Guard intervals are created by using cyclic prefixes in which the last part of an OFDM symbol is copied and inserted as the first part of the OFDM symbol. The benefit of cyclic prefix insertion is maintained as long as the span of the time dispersion does not exceed the duration of the cyclic prefix. The OFDM modulator object enables the cyclic prefix length to be set. The drawback in using a cyclic prefix is increased overhead.

Blocks

OFDM Demodulator Baseband

Functions

`ofdmdemod`

Introduced in R2014a

info

System object: `comm.OFDMDemodulator`
Package: `comm`

Provide dimensioning information for the OFDM method

Syntax

```
Y = info(H)
```

Description

`Y = info(H)` provides data dimensioning information for the OFDM demodulator System object, `H`. It returns the expected dimensions for data input into the OFDM demodulator, for the pilot output, and for the data output from the demodulator. The output, `Y`, is a structure containing three fields: `InputSize`, `DataOutputSize`, and `PilotOutputSize`.

Y.InputSize

Gives the dimensions of the demodulator input data, [(N_{FFT} + N_{CP}) × N_{sym}]-by-N_r, where N_{FFT} is the number of subcarriers, N_{CP} is the length of the cyclic prefix, N_{sym} is the number of symbols, and N_r is the number of receive antennas.

Y.DataOutputSize

Shows the dimensions of the demodulator output data, N_{data}-by-N_{sym}-by-N_r, where N_{data} is the number of data subcarriers such that $N_{data} = N_{FFT} - N_{leftG} - N_{rightG} - N_{DCNull} - N_{pilot} - N_{custNull}$. The variables are defined as follows:

N_{FFT}	Number of subcarriers
N_{leftG}	Number of subcarriers in the left guard band
N_{rightG}	Number of subcarriers in the right guard band
N_{DCNull}	Number of subcarriers in the DC null (either 0 or 1)
N_{pilot}	Number of pilot subcarriers
$N_{custNull}$	Number of subcarriers used for custom nulls

Y.PilotOutputSize

Provides the dimensions of the pilot signal output array, N_{pilot}-by-N_{sym}-by-N_r or N_{pilot}-by-N_{sym}-by-N_t-by-N_r, depending on the number of transmit antennas.

reset

System object: `comm.OFDMDemodulator`
Package: `comm`

Reset states of the `OFDMDemodulator` System object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `OFDMDemodulator` object, `H`.

This method resets the windowed suffix from the last symbol in the previously processed frame.

showResourceMapping

System object: `comm.OFDMDemodulator`
Package: `comm`

Show the subcarrier mapping of the OFDM symbols created by the OFDM demodulator System object

Syntax

```
showResourceMapping(H)
showResourceMapping(H,CI)
```

Description

`showResourceMapping(H)` shows a visualization of the subcarrier mapping for the OFDM symbols used by the OFDM demodulator System object, `H`. The subcarrier indices are numbered from 1 to N_{FFT}.

`showResourceMapping(H,CI)` shows the resource mapping where the optional argument, `CI`, is used to number the subcarrier indices that will be displayed. `CI` is a 1x2 integer row vector such that `diff(CI)`$= N_{FFT} - 1$.

step

System object: `comm.OFDMDemodulator`
Package: `comm`

Demodulate using OFDM method

Syntax

```
Y = step(H,X)
[Y,PILOT] = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates input data, `X`, with the OFDM demodulator System object, `H`, and returns the baseband demodulated output, `Y`. The input is a double-precision, real or complex, 2-D matrix of symbols whose dimensions are a function of the number of subcarriers, the cyclic prefix length, and the number of receive antennas. You can determine the dimensions by using the `info` method. The output, `Y`, is a double-precision, complex, 3-D array.

`[Y,PILOT] = step(H,X)` separates the `PILOT` signal on the subcarriers specified by the PilotCarrierIndices property value of `H`. This syntax applies when the PilotOutputPort property of `H` is true. `PILOT` is a double-precision, complex, 3-D array.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.CarrierSynchronizer

Package: `comm`

Compensate for carrier frequency offset

Description

The `comm.CarrierSynchronizer` System object compensates for carrier frequency and phase offsets in signals that use single-carrier modulation schemes. The carrier synchronizer algorithm is compatible with BPSK, QPSK, OQPSK, 8-PSK, PAM, and rectangular QAM modulation schemes.

Note

- This System object does not resolve phase ambiguities created by the synchronization algorithm. As indicated in this table, the potential phase ambiguity introduced by the synchronizer depends on the modulation type:

Modulation	Phase Ambiguity (degrees)
`'BPSK'` or `'PAM'`	0, 180
`'OQPSK'`, `'QPSK'`, or `'QAM'`	0, 90, 180, 270
`'8PSK'`	0, 45, 90, 135, 180, 225, 270, 315

  The “Examples” on page 3-0 demonstrate carrier synchronization and resolution of phase ambiguity.
- For best results, apply carrier synchronization to non-oversampled signals, as demonstrated in “Correct Phase and Frequency Offset for 16-QAM Using Coarse and Fine Synchronization” on page 3-275.

To compensate for frequency and phase offsets in signals that use single-carrier modulation schemes:

1. Create the `comm.CarrierSynchronizer` object and set its properties.
2. Call the object, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
carrSynch = comm.CarrierSynchronizer
carrSynch = comm.CarrierSynchronizer(Name,Value)
```

Description

`carrSynch = comm.CarrierSynchronizer` creates a System object that compensates for carrier frequency offset and phase offset in signals that use single-carrier modulation schemes.

`carrSynch = comm.CarrierSynchronizer(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Modulation` — Modulation type

`'QAM'` (default) | `'8PSK'` | `'BPSK'` | `'OQPSK'` | `'PAM'` | `'QPSK'`

Modulation type, specified as `'QAM'`, `'8PSK'`, `'BPSK'`, `'OQPSK'`, `'PAM'`, or `'QPSK'`.

Example: `comm.CarrierSynchronizer('Modulation','QPSK')` creates a carrier synchronizer System object to use with a QPSK modulated signal.

Tunable: No

`ModulationPhaseOffset` — Modulation phase offset method

`'Auto'` (default) | `'Custom'`

Modulation phase offset method, specified as `'Auto'` or `'Custom'`.

- `'Auto'` — Apply the traditional offset for the specified modulation type.

Modulation	Phase Offset (radians)
`'BPSK'`, `'QAM'`, or `'PAM'`	0
`'OQPSK'` or `'QPSK'`	$\pi/4$
`'8PSK'`	$\pi/8$

- `'Custom'` — Specify a user-defined phase offset with the CustomPhaseOffset property.

Tunable: Yes

`CustomPhaseOffset` — Custom phase offset

`0` (default) | scalar

Custom phase offset in radians, specified as a scalar.

Dependencies

This property applies when the ModulationPhaseOffset property is set to `'Custom'`.

Data Types: `double`

`SamplesPerSymbol` — Number of samples per symbol

2 (default) | positive integer

Number of samples per symbol, specified as a positive integer.

Tunable: Yes

Data Types: `double`

`DampingFactor` — Damping factor of loop

`0.707` (default) | positive scalar

Damping factor of the loop, specified as a positive scalar.

Tunable: Yes

Data Types: `double`

`NormalizedLoopBandwidth` — Normalized bandwidth of loop

`0.01` (default) | scalar

Normalized bandwidth of the loop, specified as a scalar in the range (0,1]. The loop bandwidth is normalized by the sample rate of the synchronizer.

Decreasing the loop bandwidth reduces the synchronizer convergence time but also reduces the pull-in range of the synchronizer.

Tunable: Yes

Data Types: `double`

Usage

Syntax

```
[outSig,phErr] = carrSynch(inSig)
```

Description

`[outSig,phErr] = carrSynch(inSig)` compensates for frequency offset and phase offset in the input signal. This System object returns a compensated output signal and an estimate of the phase error.

Input Arguments

`inSig` — Input signal

scalar | column vector

Input signal, specified as a complex scalar or a column vector of complex values.

Data Types: `double` | `single`
Complex Number Support: Yes

Output Arguments

`outSig` — Output signal

scalar (default) | column vector

Output signal, returned as a scalar or column vector with the same data type and length as `inSig`. The output signal adjusts the input signal compensating for carrier frequency and phase offsets in signals that use single-carrier modulation schemes.

`phErr` — Phase error estimate

scalar (default) | column vector

Phase error estimate in radians, returned as a scalar or column vector with the same length as `inSig`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.CarrierSynchronizer`

info	Characteristic information about carrier synchronizer
clone	Create duplicate System object
isLocked	Determine if System object is in use

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Correct Phase and Frequency Offset in QPSK Link

Correct phase and frequency offsets of a QPSK signal passed through an AWGN channel. Using preambles, resolve phase ambiguity.

Define the simulation parameters.

```
M = 4; % Modulation order
rng(1993) % For repeatable results
barker = comm.BarkerCode(...
    'Length',13,'SamplesPerFrame',13);  % For preamble
msgLen = 1e4;
numFrames = 10;
frameLen = msgLen/numFrames;
```

Add preambles to each frame, which are used later when performing phase ambiguity resolution. Generate random data symbols, and apply QPSK modulation.

```
preamble = (1+barker())/2;  % Length 13, unipolar
data = zeros(msgLen,1);
for idx = 1 : numFrames
    payload = randi([0 M-1],frameLen-barker.Length,1);
    data((idx-1)*frameLen + (1:frameLen)) = [preamble; payload];
end

modSig = pskmod(data,4,pi/4);
```

Create a `comm.PhaseFrequencyOffset` System object™ to introduce phase and frequency offsets to the modulated input signal. Set the phase offset to 45 degrees, frequency offset to 1 kHz, and sample rate to 10 kHz. The frequency offset is set to 1% of the sample rate.

```
pfo = comm.PhaseFrequencyOffset('PhaseOffset',45, ...
    'FrequencyOffset',1e4,'SampleRate',1e6);
```

Create a carrier synchronizer System object to use for correcting the phase and frequency offsets with samples per symbol set to 1.

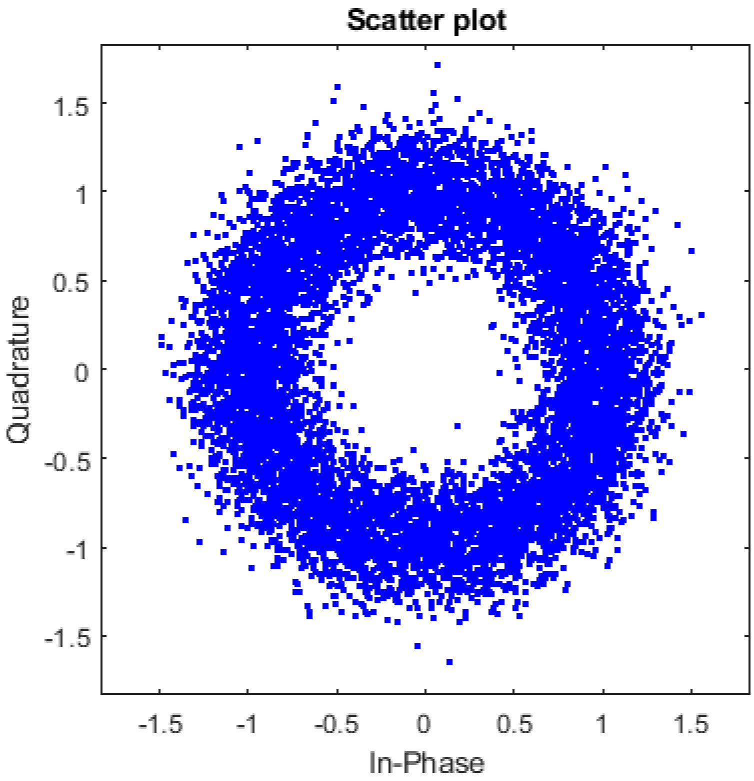
```
carrierSync = comm.CarrierSynchronizer( ...
    'SamplesPerSymbol',1,'Modulation','QPSK');
```

Apply phase and frequency offsets using the `pfo` System object, and then pass the signal through an AWGN channel to add white Gaussian noise.

```
modSigOffset = pfo(modSig);
rxSig = awgn(modSigOffset,12);
```

Display the scatter plot of the received signal. The data appear in a circle instead of being grouped around the reference constellation points due to the frequency offset.

```
scatterplot(rxSig)
```



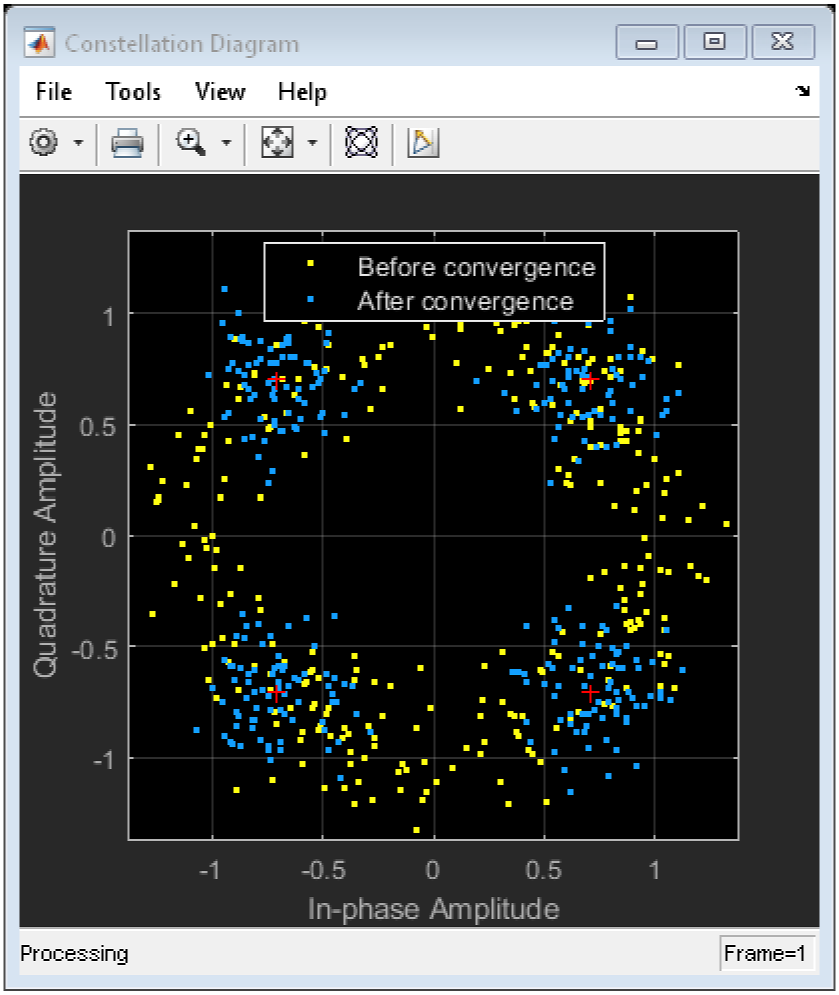
Use the `carrierSync` System object to correct the phase and frequency offset in the received signal.

```
syncSignal = carrierSync(rxSig);
```

Use a constellation diagram to display the first and last 1000 symbols of the synchronized signal. Before convergence of the synchronizer loop, the plotted symbols are not grouped around the reference constellation points. After convergence, the plotted symbols are grouped around the reference constellation points.

```
constDiag = comm.ConstellationDiagram( ...
'SymbolsToDisplaySource','Property','SymbolsToDisplay',300, ...
'ChannelNames',{'Before convergence','After convergence'},'ShowLegend',true, ...
'Position',[400 400 400 400]);

constDiag([syncSignal(1:1000) syncSignal(9001:10000)]);
```



Demodulate the synchronized signal. Compute and display the total bit errors and BER.

```
syncData = pskdemod(syncSignal,4,pi/4);
[syncDataTtlErr,syncDataBER] = biterr(data(6000:end),syncData(6000:end))
```

```
syncDataTtlErr = 3990

syncDataBER = 0.4986
```

Phase ambiguity in the received signal might cause bit errors. Using the preamble, determine phase ambiguity. Remove this phase ambiguity from the synchronized signal to reduce bit errors.

```
idx = 9000 + (1:barker.Length);
phOffset = angle(modSig(idx) .* conj(syncSignal(idx)));
phOffset = round((2/pi) * phOffset); % -1, 0, 1, +/-2
phOffset(phOffset==-2) = 2; % Prep for mean operation
phOffset = mean((pi/2) * phOffset); % -pi/2, 0, pi/2, or pi
disp(['Estimated mean phase offset = ',num2str(phOffset*180/pi),' degrees'])
```

```
Estimated mean phase offset = 180 degrees
```

```
resPhzSig = exp(1i*phOffset) * syncSignal;
```

Demodulate the signal after resolving the phase ambiguity. Recompute and display the updated total bit errors and BER. Removing the phase ambiguity reduces the BER dramatically.

```
resPhzData = pskdemod(resPhzSig,4,pi/4);
[resPhzTtlErr, resPhzBER] = biterr(data(6000:end),resPhzData(6000:end))
```

```
resPhzTtlErr = 403

resPhzBER = 0.0504
```

Estimate Frequency Offset in an 8-PSK Link

Estimate the frequency offset introduced into a noisy 8-PSK signal using a carrier synchronizer System object™.

Define the simulation parameters.

```
M = 8;                  % Modulation order
fs = 1e6;               % Sample rate (Hz)
foffset = 1000;         % Frequency offset (Hz)
phaseoffset = 15;       % Phase offset (deg)
snrdb = 20;             % Signal-to-noise ratio (dB)
```

Create a `comm.PhaseFrequencyOffset` System object to introduce phase and frequency offsets to a modulated signal.

```
pfo = comm.PhaseFrequencyOffset('PhaseOffset',phaseoffset, ...
    'FrequencyOffset',foffset,'SampleRate',fs);
```

Create a carrier synchronizer System object to use for correcting the phase and frequency offsets. Set the `Modulation` property to `8PSK`.

```
carrierSync = comm.CarrierSynchronizer('Modulation','8PSK');
```

Generate random data and apply 8-PSK modulation.

```
data = randi([0 M-1],5000,1);
modSig = pskmod(data,M,pi/M);
```

Apply phase and frequency offsets using the pfo System object, and pass the signal through an AWGN channel to add Gaussian white noise.

```
modSigOffset = pfo(modSig);
rxSig = awgn(modSigOffset,snrdb);
```

Use the carrier synchronizer to estimate the phase offset of the received signal.

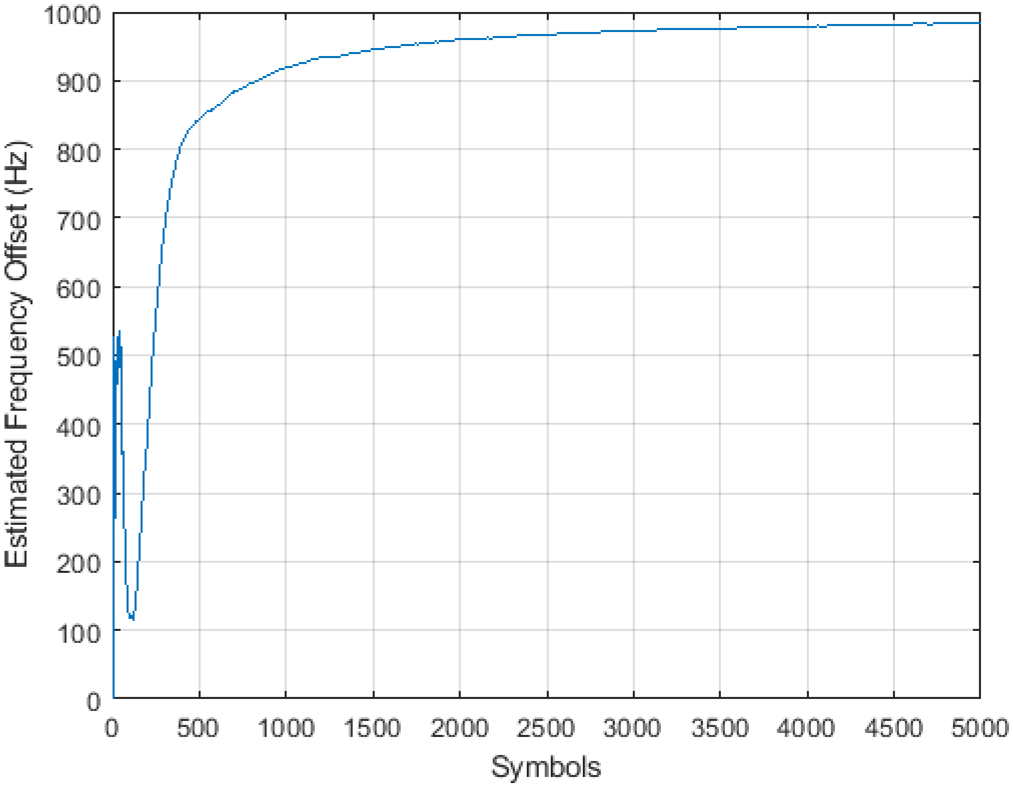
```
[~,phError] = carrierSync(rxSig);
```

Determine the frequency offset by using the `diff` function to compute an approximate derivative of the phase error. The derivative must be scaled by 2π because the phase error is measured in radians.

```
estFreqOffset = diff(phError)*fs/(2*pi);
```

Plot the running mean of the estimated frequency offset. After the synchronizer converges to a solution, the mean value of the estimate is approximately equal to the input frequency offset value of 1000 Hz.

```
rmean = cumsum(estFreqOffset)./(1:length(estFreqOffset))';
plot(rmean)
xlabel('Symbols')
ylabel('Estimated Frequency Offset (Hz)')
grid
```



Correct Phase and Frequency Offset for 16-QAM Using Coarse and Fine Synchronization

Compensation of significant phase and frequency offsets for a 16-QAM signal in an AWGN channel is accomplished in two steps. First, correct the coarse frequency offset using the estimate provided by the coarse frequency compensator, and then fine-tune the correction using carrier synchronization. Because of the coarse frequency correction, the carrier synchronizer converges quickly even though the normalized bandwidth is set to a low value. Lower normalized bandwidth values enable better correction for small residual carrier offsets. After applying phase and frequency offset corrections to the received signal, resolve phase ambiguity using the preambles.

Define the simulation parameters.

```
fs = 10000;       % Sample rate (Hz)
sps = 4;          % Samples per symbol
```

```
M = 16;          % Modulation order
k = log2(M);     % Bits per symbol
rng(1996)        % Set seed for repeatable results
barker = comm.BarkerCode(...
    'Length',13,'SamplesPerFrame',13);  % For preamble
msgLen = 1e4;
numFrames = 10;
frameLen = msgLen/numFrames;
```

Generate data payloads and add the preamble to each frame. The preamble is later used for phase ambiguity resolution.

```
preamble = (1+barker())/2;  % Length 13, unipolar
data = zeros(msgLen, 1);
for idx = 1 : numFrames
    payload = randi([0 M-1],frameLen-barker.Length,1);
    data((idx-1)*frameLen + (1:frameLen)) = [preamble; payload];
end
```

Create a System object for the transmit pulse shape filtering, the receive pulse shape filtering, the QAM coarse frequency compensation, the carrier synchronization, and a constellation diagram.

```
txFilter = comm.RaisedCosineTransmitFilter( ...
    'OutputSamplesPerSymbol',sps);
rxFilter = comm.RaisedCosineReceiveFilter(...
    'InputSamplesPerSymbol',sps,'DecimationFactor',sps);
coarse = comm.CoarseFrequencyCompensator('SampleRate',fs, ...
    'FrequencyResolution',10);
fine = comm.CarrierSynchronizer( ...
    'DampingFactor',0.4,'NormalizedLoopBandwidth',0.001, ...
    'SamplesPerSymbol',1,'Modulation','QAM');
axislimits = [-6 6];
constDiagram = comm.ConstellationDiagram('ReferenceConstellation',qammod(0:M-1,M), ...
    'ChannelNames',{'Before convergence','After convergence'}, ...
    'ShowLegend',true,'XLimits',axislimits,'YLimits',axislimits);
```

Also create a System object for the AWGN channel, and the phase and frequency offset to add impairments to the signal. A phase offset greater than 90 degrees is added to induce a phase ambiguity that results in a constellation quadrant shift.

```
ebn0 = 8;
freqoffset = 110;
phaseoffset = 110;
awgnChannel = comm.AWGNChannel('EbNo',ebn0, ...
    'BitsPerSymbol',k,'SamplesPerSymbol',sps);
pfo = comm.PhaseFrequencyOffset('FrequencyOffset',freqoffset, ...
    'PhaseOffset',phaseoffset,'SampleRate',fs);
```

Generate random data symbols, apply 16-QAM modulation, and pass the modulated signal through the transmit pulse shaping filter.

```
txMod = qammod(data,M);
txSig = txFilter(txMod);
```

Apply phase and frequency offsets using the `pfo` System object, and then pass the signal through an AWGN channel to add white Gaussian noise.

```
txSigOffset = pfo(txSig);
rxSig = awgnChannel(txSigOffset);
```

The coarse frequency compensator System object provides a rough correction for the frequency offset. For the conditions in this example, correcting the frequency offset of the received signal correction to within 10 Hz of the transmitted signal is sufficient.

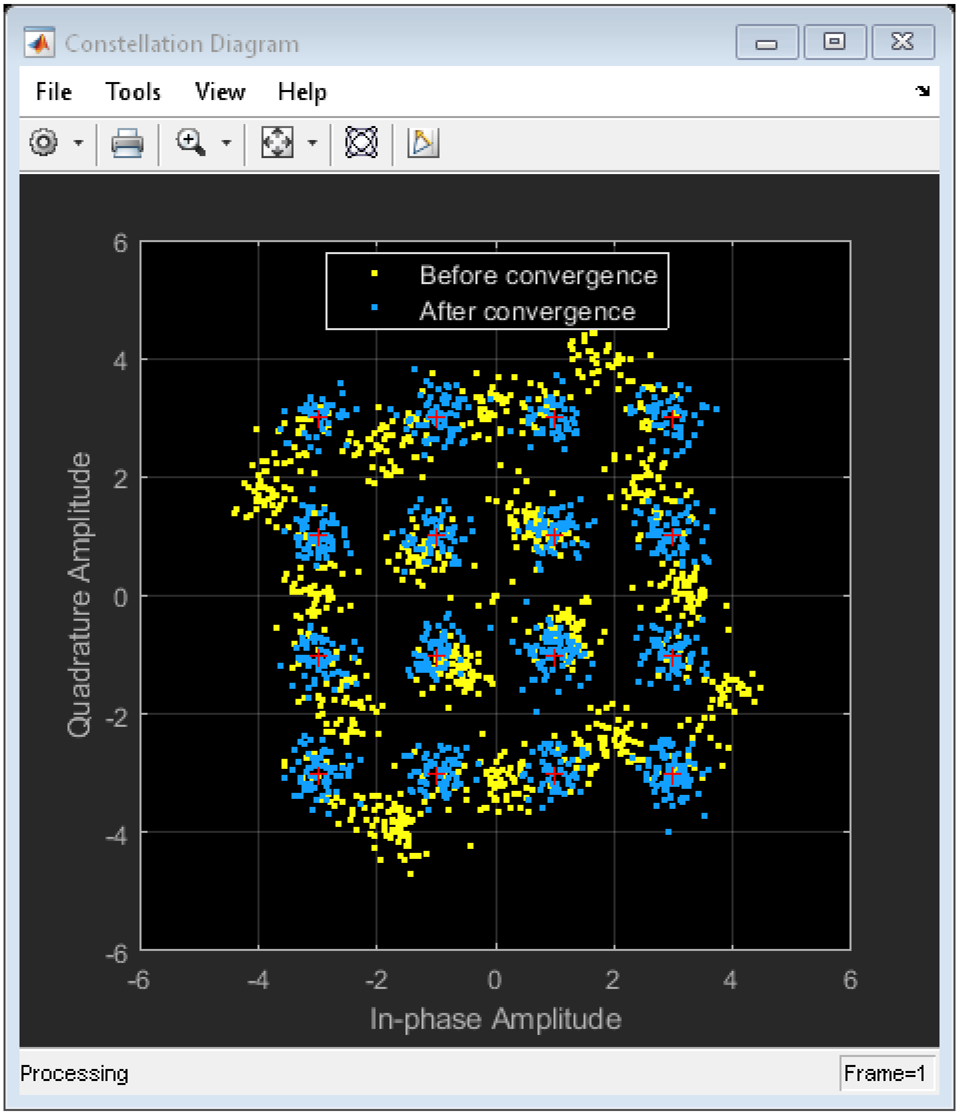
```
syncCoarse = coarse(rxSig);
```

Pass the signal through the receive pulse shaping filter, and apply fine frequency correction.

```
rxFiltSig = fine(rxFilter(syncCoarse));
```

Display the constellation diagram of the first and last 1000 symbols in the signal. Before convergence of the synchronization loop, the spiral nature of the diagram indicates that the frequency offset is not corrected. After the carrier synchronizer has converged to a solution, the symbols are aligned with the reference constellation.

```
constDiagram([rxFiltSig(1:1000) rxFiltSig(9001:end)])
```



Demodulate the signal. Account for the signal delay caused by the transmit and receive filters to align the received data with the transmitted data. Compute and display the total bit errors and BER. When checking the bit errors, use the later portion of the received signal to be sure the synchronization loop has converged.

```
rxData = qamdemod(rxFiltSig,M);
delay = (txFilter.FilterSpanInSymbols + rxFilter.FilterSpanInSymbols) / 2;
idxSync = 2000; % Check BER for the received signal after the synchronization loop has converged
[syncDataTtlErr,syncDataBER] = biterr(data(idxSync:end-delay),rxData(idxSync+delay:end))
```

```
syncDataTtlErr = 16116

syncDataBER = 0.5042
```

Depending on the random data used, there may be bit errors resulting from phase ambiguity in the received signal after the synchronization loop converges and locks. In this case, you can use the preamble to determine and then remove the phase ambiguity from the synchronized signal to reduce bit errors. If phase ambiguity is minimal, the number of bit errors may be unchanged.

```
idx = 9000 + (1:barker.Length);
phOffset = angle(txMod(idx) .* conj(rxFiltSig(idx+delay)));

phOffsetEst = mean(phOffset);
disp(['Phase offset = ',num2str(rad2deg(phOffsetEst)),' degrees'])
```

```
Phase offset = -90.1401 degrees
```

```
resPhzSig = exp(1i*phOffsetEst) * rxFiltSig;
```

Demodulate the signal after resolving the phase ambiguity. Recompute the total bit errors and BER.

```
resPhzData = qamdemod(resPhzSig,M);
[resPhzTtlErr,resPhzBER] = biterr(data(idxSync:end-delay),resPhzData(idxSync+delay:end))
```

```
resPhzTtlErr = 5

resPhzBER = 1.5643e-04
```

MSK Signal Recovery

Model channel impairments such as timing phase offset, carrier frequency offset, and carrier phase offset for a minimum shift keying (MSK) signal. Use `comm.MSKTimingSynchronizer` and `comm.CarrierSynchronizer` System objects to synchronize such signals at the receiver. The MSK timing synchronizer recovers the timing offset, while a carrier synchronizer recovers the carrier frequency and phase offsets.

Initialize system variables by running the MATLAB script `configureMSKSignalRecoveryEx`. Define the logical control variable `recoverTimingPhase` to enable timing phase recovery, and `recoverCarrier` to enable carrier frequency and phase recovery.

```
configureMSKSignalRecoveryEx;
recoverTimingPhase = true;
recoverCarrier = true;
```

Modeling Channel Impairments

Specify the sample delay, `timingOffset`, that the channel model applies. Create a variable fractional delay object to introduce the timing delay to the transmitted signal.

```
timingOffset = 0.2;
varDelay = dsp.VariableFractionalDelay;
```

Create a `comm.PhaseFrequencyOffset` System object to introduce carrier phase and frequency offsets to a modulated signal. Because the MSK modulator upsamples the transmitted symbols, set the `SampleRate` property to the ratio of the `samplesPerSymbol` and the sample time, `Ts`.

```
freqOffset = 50;
phaseOffset = 30;
pfo = comm.PhaseFrequencyOffset(...
    'FrequencyOffset',freqOffset, ...
    'PhaseOffset',phaseOffset, ...
    'SampleRate',samplesPerSymbol/Ts);
```

Create a `comm.AWGNChannel` System object to add white Gaussian noise to the modulated signal. The noise power is determined by the `EbNo` property, that is the bit energy to noise power spectral density ratio. Because the MSK modulator generates symbols with 1 Watt of power, set the signal power property of the AWGN channel System object to 1.

```
EbNo = 20 + 10*log10(samplesPerSymbol);
chAWGN = comm.AWGNChannel(...
    'NoiseMethod','Signal to noise ratio (Eb/No)', ...
    'EbNo',EbNo,...
    'SignalPower',1, ...
    'SamplesPerSymbol',samplesPerSymbol);
```

Timing Phase, Carrier Frequency, and Carrier Phase Synchronization

Create an MSK timing synchronizer to recover symbol timing phase using a fourth-order nonlinearity method.

```
timeSync = comm.MSKTimingSynchronizer(...
    'SamplesPerSymbol',samplesPerSymbol, ...
    'ErrorUpdateGain',0.02);
```

Create a carrier synchronizer to recover both carrier frequency and phase. Because the MSK constellation is QPSK with a 0-degree phase offset, set the `comm.CarrierSynchronizer` accordingly.

```
phaseSync = comm.CarrierSynchronizer(...
    'Modulation','QPSK', ...
    'ModulationPhaseOffset','Custom', ...
    'CustomPhaseOffset',0, ...
    'SamplesPerSymbol',1);
```

Stream Processing Loop

The simulation modulates data using MSK modulation. The modulated symbols pass through the channel model, which applies timing delay, carrier frequency and phase shift, and additive white Gaussian noise. The receiver performs timing phase and carrier frequency and phase recovery. Finally, the signal symbols are demodulated and the bit error rate is calculated. The `plotResultsMSKSignalRecoveryEx` script generates scatter plots in this order to show these effects:

1. Channel impairments
2. Timing synchronization
3. Carrier synchronization

At the end of the simulation, the example displays the timing phase, frequency, and phase estimates as a function of simulation time.

```
for p = 1:numFrames
    %------------------------------------------------------------------------
    % Generate and modulate data
    %------------------------------------------------------------------------
    txBits = randi([0 1],samplesPerFrame,1);

Conclusion and Further Experimentation

The recovery algorithms are demonstrated by using constellation plots taken after timing, carrier frequency, and carrier phase synchronization.

Open the script to create a writable copy of this example and its supporting files. Then, to show the effects of the recovery algorithms, you can enable and disable the logical control variables `recoverTimingPhase` and `recoverCarrier` and rerun the simulation.

Appendix

This example uses these scripts:

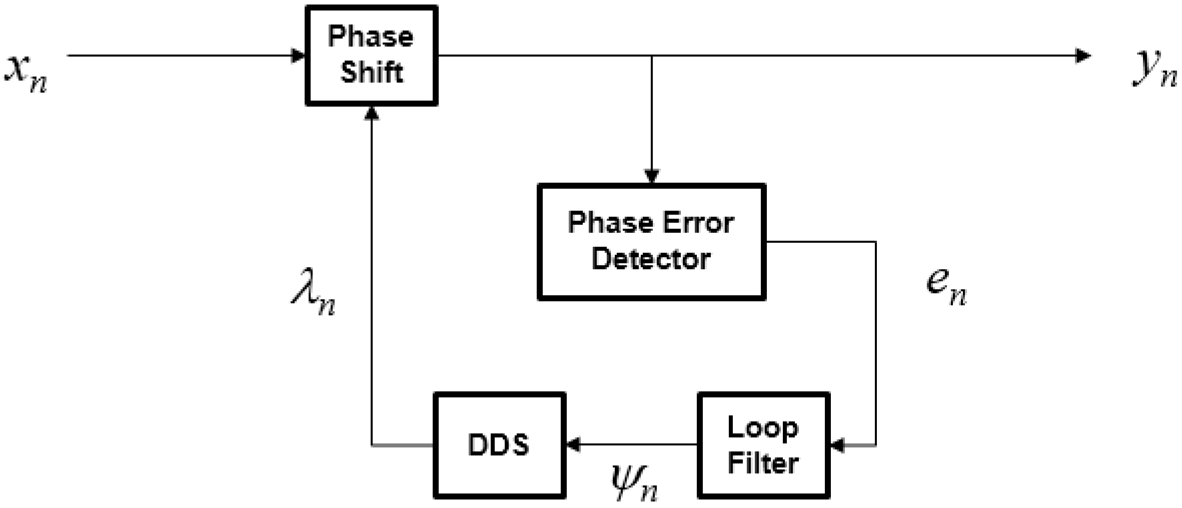
- `configureMSKSignalRecoveryEx`
- `plotResultsMSKSignalRecoveryEx`
- `removePhaseAmbiguityMSKSignalRecoveryEx`

Algorithms

The `comm.CarrierSynchronizer` System object is a closed-loop compensator that uses the PLL-based algorithm described in [1]. The output of the synchronizer, y_n, is a frequency-shifted version of the complex input signal, x_n, for the nth sample. The synchronizer output is

$$y_n = x_n e^{i\lambda_n},$$

where λ_n is the output of the direct digital synthesizer (DDS). The DDS is the discrete-time version of a voltage-controlled oscillator and is a core component of discrete-time phase locked loops. In the context of this System object, the DDS works as an integration filter.



To correct for the frequency offset, first the algorithm determines the phase error, e_n. The value of the phase error depends on the modulation scheme.

Modulation	Phase Error
QAM or QPSK	$e_n = \text{sgn}(\text{Re}\{x_n\}) \times \text{Im}\{x_n\} - \text{sgn}(\text{Im}\{x_n\}) \times \text{Re}\{x_n\}$ For a detailed description of this equation, see [1].
BPSK or PAM	$e_n = \text{sgn}(\text{Re}\{x_n\}) \times \text{Im}\{x_n\}$ For a detailed description of this equation, see [1].

Modulation	Phase Error
8-PSK	$e_{\text{n}} =$ $\begin{cases} \text{sgn}(\text{Re}\{x_{\text{n}}\}) \times \text{Im}\{x_{\text{n}}\} - (\sqrt{2}-1)\text{sgn}(\text{Im}\{x_{\text{n}}\}) \times \text{Re}\{x_{\text{n}}\}, & \text{for} \\ (\sqrt{2}-1)\text{sgn}(\text{Re}\{x_{\text{n}}\}) \times \text{Im}\{x_{\text{n}}\} - \text{sgn}(\text{Im}\{x_{\text{n}}\}) \times \text{Re}\{x_{\text{n}}\}, & \text{for} \end{cases}$ For a detailed description of this equation, see [2].
OQPSK	$e_{\text{n}} = \text{sgn}\left(\text{Re}\left\{x_{\text{n-SamplePerSymbol/2}}\right\}\right)$ $\times \text{Im}\left\{x_{\text{n-SamplePerSymbol/2}}\right\} - \text{sgn}(\text{Im}\{x_{\text{n}}\})$ $\times \text{Re}\{x_{\text{n}}\}$

To ensure system stability, the phase error passes through a biquadratic loop filter governed by

$$\psi_{\text{n}} = g_{\text{I}} e_{\text{n}} + \psi_{\text{n}-1} \,,$$

where ψ_{n} is the output of the loop filter at sample n, and g_{I} is the integrator gain. The integrator gain is determined from the equation

$$g_{\text{I}} = \frac{4\left(\theta^2/d\right)}{K_{\text{p}}K_0} \quad ,$$

where θ, d, K_0, and K_{p} are determined from the System object properties. Specifically,

$$\theta = \frac{B_{\text{n}}}{\left(\zeta + \frac{1}{4\zeta}\right)} \text{ and } d \;=\; 1 + 2\zeta\theta + \theta^2,$$

where B_{n} is the normalized loop bandwidth, and ζ is the damping factor. The phase recovery gain, K_0, is equal to the number of samples per symbol. The modulation type determines the phase error detector gain, K_{p}.

Modulation	K_{p}
BPSK, PAM, QAM, QPSK, or OQPSK	2
8-PSK	1

The output of the loop filter is then passed to the DDS. The DDS is another biquadratic loop filter whose expression is based on the forward Euler integration rule

$$\lambda_{\text{n}} = (g_{\text{P}} e_{\text{n-1}} + \psi_{\text{n-1}}) + \lambda_{\text{n-1}} \,,$$

where g_{P} is the proportional gain that is expressed as

$$g_{\text{P}} = \frac{4\zeta(\theta/d)}{K_{\text{p}}K_0} \;.$$

The `info` object function of this System object returns estimates of the normalized pull-in range, the maximum frequency lock delay, and the maximum phase lock delay. The normalized pull-in range, $(\Delta f)_{\text{pull-in}}$, is expressed in radians and estimated as

$$(\Delta f)_{\text{pull-in}} \approx \min(1, 2\pi\sqrt{2}\zeta B_{\text{n}}) \;.$$

The expression for $(\Delta f)_{\text{pull-in}}$ becomes less accurate as $2\pi\sqrt{2}\zeta B_{\text{n}}$ approaches 1.

The maximum frequency lock delay, T_{FL}, and phase lock delay, T_{PL}, are expressed in samples and estimated as

$$T_{\text{FL}} \approx 4\frac{(\Delta f)^2_{\text{pull-in}}}{B_{\text{n}}^3} \text{ and } T_{\text{PL}} \approx \frac{1.3}{B_{\text{n}}} .$$

Introduced in R2015a

comm.CCDF

Package: `comm`

Measure complementary cumulative distribution function

Description

The `comm.CCDF` object measures the probability that the instantaneous power of the input signal being a specified level above its average power.

To measure complementary cumulative distribution of a signal:

1. Define and set up your CCDF object. See "Construction" on page 3-287 .
2. Call `step` to measure complementary cumulative distribution according to the properties of `comm.CCDF`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ccdf = comm.CCDF` creates a complementary cumulative distribution function measurement (CCDF) System object, `ccdf`, that measures the probability of a signal's instantaneous power to be a specified level above its average power.

`ccdf = comm.CCDF(Name,Value)` creates a CCDF object, `ccdf`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`NumPoints`

Number of CCDF points

Specify the number of CCDF points that the object calculates. This property requires a numeric, positive, integer scalar. The default is `1000`. Use this property with the `MaximumPowerLimit` on page 3-0 property to control the size of the histogram bins. The object uses these bins to estimate CCDF curves. This controls the resolution of the curves. All input channels must have the same number of CCDF points.

`MaximumPowerLimit`

Maximum expected input signal power

Maximum expected input signal power limit for each input channel, specified as a scalar or row vector with length equal to the number of input channels. The default is `50`. This property is expected to have the same units as the PowerUnits property. When you set this property to a scalar, the object assumes that the signals in all input channels have the same expected maximum power. When you set this property to a row vector, the object assumes that the *i*-th element of the vector is the maximum expected power for the signal at the *i*-th input channel. For each input channel, the object obtains CCDF results by integrating a histogram of instantaneous input signal powers. The object sets the bins of the histogram so that the last bin collects all power occurrences that are equal to, or greater than the power that you specify in this property. The object issues a warning if any input signal exceeds its specified maximum power limit. Use this property with the NumPoints property to control the size of the histogram bins that the object uses to estimate CCDF curves (such as control the resolution of the curves).

PowerUnits

Power units

Specify the power measurement units as one of dBm | dBW | Watts. The default is dBm. The step method outputs power measurements in the units specified in the PowerUnits property. When you set this property to dBm or dBW, the step method outputs relative power values in a dB scale. When you set this property to Watts, the step method outputs relative power values in a linear scale. When you call the step method, the object assumes that the units of MaximumPowerLimit have the same value you specified in the PowerUnits property.

AveragePowerOutputPort

Enable average power measurement output

When you set this property to true, running the object returns the running average power measurements. The default is false.

PeakPowerOutputPort

Enable peak power measurement output

When you set this property to true, running the object returns the peak power measurements. The default is false.

PAPROutputPort

Enable PAPR measurement output

When you set this property to true, running the object returns the peak-to-average-power measurements. The default is false.

Methods

getPercentileRelativePower	Get relative power value for a given probability
getProbability	Get the probability for a given relative power value
plot	Plot CCDF curves
reset	Reset states of CCDF measurement object
step	Measure complementary cumulative distribution function

Common to All System Objects	
release	Allow System object property value changes

Examples

Obtain CCDF curves for 16-QAM and QPSK signals

Create a CCDF System object and specify that it output average power and peak power measurements.

```
ccdf = comm.CCDF('AveragePowerOutputPort',true, ...
    'PeakPowerOutputPort',true);
```

Generate 16-QAM and QPSK modulated signals.

```
qamTxSig = qammod(randi([0 15],20e3,1),16,'UnitAveragePower',true);
qpskTxSig = pskmod(randi([0 3],20e3,1),4,pi/4);
```

Pass the signals through an AWGN channel.

```
qamRxSig = awgn(qamTxSig,15);
qpskRxSig = awgn(qpskTxSig,15);
```

Measure the CCDF of the two waveforms. Plot the CCDF using the `plot` method of `comm.CCDF`.

```
[CCDFy,CCDFx,AvgPwr,PeakPwr] = ccdf([qamRxSig qpskRxSig]);

plot(ccdf)
legend('16-QAM','QPSK')
```

`comm.ACPR` | `comm.EVM` | `comm.MER`

Introduced in R2012a

getPercentileRelativePower

System object: `comm.CCDF`
Package: `comm`

Get relative power value for a given probability

Syntax

```
R = getPercentileRelativePower(H,P)
```

Description

`R = getPercentileRelativePower(H,P)` finds the relative power values, `R`. The power of the signal of interest is above its average power by `R` dB (if PowerUnits equals 'dBW', or 'dBm') or by a factor of `R` (in linear scale if PowerUnits equals 'Watts') with a probability `P`.

The method output `R`, is a column vector with the *i*-th element corresponding to the relative power for the *i*-th input channel. The method input `P` can be a double precision scalar, or a vector with a number of elements equal to the number of input channels. If `P` is a scalar, then all the relative powers in `R` correspond to the same probability value specified in `P`. If `P` is a vector, then the *i*-th element of `R` corresponds to a power value that occurs in the *i*-th input channel, with a probability specified in the *i*-th element of `P`.

For the *i*-th input channel, this method evaluates the inverse CCDF curve at probability value $P(i)$.

Examples

Obtain CCDF curves for a unit variance AWGN signal and a dual- one signal. The AWGN signal is RPW1 dB above its average power one percent of the time, and the dual-tone signal is RPW2 dB above its average power 10 percent of the time. This example finds the values of RPW1 and RPW2.

```
n = [0:5e3-1].';
s1 = randn(5e3,1);                     % AWGN signal
s2 = sin(0.01*pi*n)+sin(0.03*pi*n);   % dual-tone signal
hCCDF = comm.CCDF;                     % create a CCDF object
step(hCCDF,[s1 s2]);                   % step the CCDF measurements
plot(hCCDF)                            % plot CCDF curves
legend('AWGN','Dual-tone')
RPW = getPercentileRelativePower(hCCDF,[1 10]);
RPW1 = RPW(1)
RPW2 = RPW(2)
```

getProbability

System object: comm.CCDF
Package: comm

Get the probability for a given relative power value

Syntax

P = getProbability(H,R)

Description

P = getProbability(H,R) finds the probability, P, of the power level of the signal of interest being R dBs (if PowerUnits equals 'dBW', or 'dBm') or Watts (if PowerUnits equals 'Watts') above its average power. P is a column vector with the *i*-th element corresponding to the probability value for the *i*-th input channel. Input R can be a double precision scalar or a vector with a number of elements equal to the number of input channels. If R is a scalar, then all the probability values in P correspond to the same relative power specified in R. If R is a vector, then the ith element of P contains a probability value for the *i*-th channel and for the relative power specified in the *i*-th element of R.

For the *i*-th input channel, this method evaluates the CCDF curve at relative power value R(*i*)

Examples

Obtain CCDF curves for a unit variance AWGN signal and a dual- tone signal. Find the probability that the AWGN signal power is 5 dB above its average power and that the dual-tone signal power is 3 dB above its average power.

```
n = [0:5e3-1].';
s1 = randn(5e3,1);                   % AWGN signal
s2 = sin(0.01*pi*n)+sin(0.03*pi*n);  % dual-tone signal
hCCDF = comm.CCDF;
step(hCCDF,[s1 s2]);
plot(hCCDF)                          % plot CCDF curves
legend('AWGN','Dual-tone')
P = getProbability(hCCDF,[5 3])      % get probabilities
```

plot

System object: `comm.CCDF`
Package: `comm`

Plot CCDF curves

Syntax

`D = plot(H)`

Description

`D = plot(H)` plots CCDF measurements in the CCDF System object, `H`. The `plot` method returns the plot handles as an output, `D`. This method plots the same number of curves as there are input channels. The `H` input can be followed by parameter-value pairs to specify additional properties of the curves. For example, `plot`(`H`,`LineWidth`,`2`) will create curves with line widths of 2 points.

The `comm.CCDF` System object does not support C code generation for this method.

reset

System object: `comm.CCDF`
Package: `comm`

Reset states of CCDF measurement object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `CCDF` object, `H`.

step

System object: `comm.CCDF`
Package: `comm`

Measure complementary cumulative distribution function

Syntax

```
[CCDFY,CCDFX] = step(H,X)
[CCDFY,CCDFX,AVG] = step(H,X)
[CCDFY,CCDFX,PEAK] = step(H,X)
[CCDFY,CCDFX,PAPR] = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[CCDFY,CCDFX] = step(H,X)` updates CCDF, average power, and peak power measurements for input `X` using the CCDF System object, `H`. It outputs the y-axis, `CCDFY`, and x-axis, `CCDFX`, CCDF points. `X` must be a double precision, *M*-by-*N* matrix, where *M* is the number of time samples and *N* is the number of input channels. The `step` method outputs `CCDFY` as a matrix whose *i*-th column contains updated probability values measured from the *i*-th column of input matrix `X`. `CCDFY` contains the *y*-axis points of the CCDF curves of each channel. The `step` method outputs `CCDFX` as a matrix containing, in its *i*-th column, the corresponding updated instantaneous-to-average power ratios for the ith column of input matrix `X`. `CCDFX` contains the *x*-axis points of the CCDF curves of each channel. The object sets the number of rows in `CCDFY` and `CCDFX` equal to `NumPoints` property + 1. The probability values are percentages in the `[0 100]` interval. When you set the `PowerUnits` property to `dBW` or `dBm`, the relative powers are in dB scale. When you set the `PowerUnits` property to `Watts`, the relative powers are in linear scale. Measurements are updated each time you call the step method until you reset the object. You call the plot method to plot CCDF curves for each channel.

`[CCDFY,CCDFX,AVG] = step(H,X)` returns updated average power measurements, `AVG`, when you set the `AveragePowerOutputPort` property to true. The step method outputs `AVG` as a column vector with the ith element corresponding to an updated average power measurement for the signal available in the ith column of input matrix `X`. You specify the units for `AVG` in the `PowerUnits` property.

`[CCDFY,CCDFX,PEAK] = step(H,X)` returns updated peak power measurements, `PEAK`, when you set the `PeakPowerOutputPort` property to true. The step method outputs `PEAK` as a column vector with the ith element corresponding to an updated peak power measurement for the signal available in the ith column of input matrix `X`. You specify the units for `PEAK` in the `PowerUnits` property.

`[CCDFY,CCDFX,PAPR] = step(H,X)` returns updated peak-to-average power ratio measurements, `PAPR`, when you set the `PAPROutputPort` property to true. The step methods outputs `PAPR` as a column vector with the ith element corresponding to an updated peak-to-average power ratio measurement for the signal available in the ith column of input matrix `X`. When you set the

PowerUnits property to dBW or dBm, the method outputs PAPR in a dB scale. When you set the PowerUnits property to Watts, the method outputs PAPR in a linear scale. You can combine optional output arguments when you set their enabling properties. Optional outputs must be listed in the same order as the order of the enabling properties. For example,

Note obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

comm.CoarseFrequencyCompensator

Package: `comm`

Compensate for frequency offset for PAM, PSK, or QAM

Description

The `CoarseFrequencyCompensator` System object compensates for the frequency offset of received signals.

To compensate for the frequency offset of a PAM, PSK, or QAM signal:

1. Define and set up your coarse frequency compensator object. See "Construction" on page 3-297.
2. Call `step` to compensate for the frequency offset of a PAM, PSK, or QAM signal according to the properties of `comm.CoarseFrequencyCompensator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`CFC = comm.CoarseFrequencyCompensator` creates a coarse frequency offset compensator object, `CFC`. This object uses an open-loop technique to estimate and compensate for the carrier frequency offset in a received signal.

`CFC = comm.CoarseFrequencyCompensator(Name,Value)` creates a coarse frequency offset compensator object, `CFC`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Properties

`Modulation`

Modulation type

Specify the signal modulation type as `BPSK`, `QPSK`, `OQPSK`, `8PSK`, `PAM`, or `QAM`. The default is `QAM`. This property is nontunable.

`Algorithm`

Algorithm used to estimate frequency offset

Specify the estimation algorithm as one of `FFT-based` or `Correlation-based`. The default is `FFT-based`. This property is nontunable.

The table shows the allowable combinations of the modulation type and the estimation algorithm.

Modulation	FFT-Based Algorithm	Correlation-Based Algorithm
BPSK, QPSK, 8PSK, PAM	✓	✓
OQPSK, QAM	✓	

Use the correlation-based algorithm for HDL implementations and for other situations in which you want to avoid using an FFT.

This property appears when `Modulation` is `'BPSK'`, `'QPSK'`, `'8PSK'`, or `'PAM'`.

`FrequencyResolution`

Frequency resolution (Hz)

Specify the frequency resolution for the offset frequency estimation as a positive, real scalar of data type `double`. This property establishes the FFT length used to perform spectral analysis and must be less than the sample rate. The default is `0.001`. This property is nontunable.

`MaximumFrequencyOffset`

Maximum measurable frequency offset (Hz)

Specify the maximum measurable frequency offset as a positive, real scalar of data type `double`.

The value of this property must be less than f_{samp} / M, where f_{samp} is the sample rate and M is the modulation order. As a best practice, set `MaximumOffset` to less than $r / (4M)$. This property applies only if `Algorithm` is `Correlation-based`. The default is `0.05`. This property is nontunable.

`SampleRate`

Sample rate (Hz)

Specify the sample rate in samples per second as a positive, real scalar of data type `double`. The default is `1`. This property is nontunable.

`SamplesPerSymbol`

Samples per symbol

Specify the number of samples per symbol, s, as a real positive finite integer scalar, such that $s \geq 2$. The default value is `4`. This property is nontunable.

This property appears when `Modulation` is `'OQPSK'`.

Methods

info	Characteristic information about coarse frequency compensator
reset	Reset states of the `CoarseFrequencyCompensator` object
step	Compensate for frequency offset

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Compensate for Frequency Offset in a QPSK Signal

Compensate for a 4 kHz frequency offset imposed on a noisy QPSK signal.

Set the example parameters.

```
nSym = 2048;       % Number of input symbols
sps = 4;           % Samples per symbol
nSamp = nSym*sps;  % Number of samples
fs = 80000;        % Sampling frequency (Hz)
```

Create a square root raised cosine transmit filter.

```
txfilter = comm.RaisedCosineTransmitFilter(...
    'RolloffFactor',0.2, ...
    'FilterSpanInSymbols',8,   ...
    'OutputSamplesPerSymbol',sps);
```

Create a phase frequency offset object to introduce the 4 kHz frequency offset.

```
freqOffset = comm.PhaseFrequencyOffset(...
    'FrequencyOffset',-4000, ...
    'SampleRate',fs);
```

Create a coarse frequency compensator object to compensate for the offset.

```
freqComp = comm.CoarseFrequencyCompensator(...
    'Modulation','QPSK', ...
    'SampleRate',fs, ...
    'FrequencyResolution',1);
```

Generate QPSK symbols, filter the modulated data, pass the signal through an AWGN channel, and apply the frequency offset.

```
data = randi([0 3],nSym,1);
modData = pskmod(data,4,pi/4);
txSig = txfilter(modData);
rxSig = awgn(txSig,20,'measured');
offsetData = freqOffset(rxSig);
```

Compensate for the frequency offset using `freqComp`. When the frequency offset is high, it is beneficial to do coarse frequency compensation prior to receive filtering because filtering suppresses energy in the useful spectrum.

```
[compensatedData,estFreqOffset] = freqComp(offsetData);
```

Display the estimate of the frequency offset.

```
estFreqOffset
```

```
estFreqOffset =

  -3.9999e+03
```

Return information about the `freqComp` object. To obtain the FFT length, you must call `freqComp` prior to calling the `info` method.

```
freqCompInfo = info(freqComp)
```

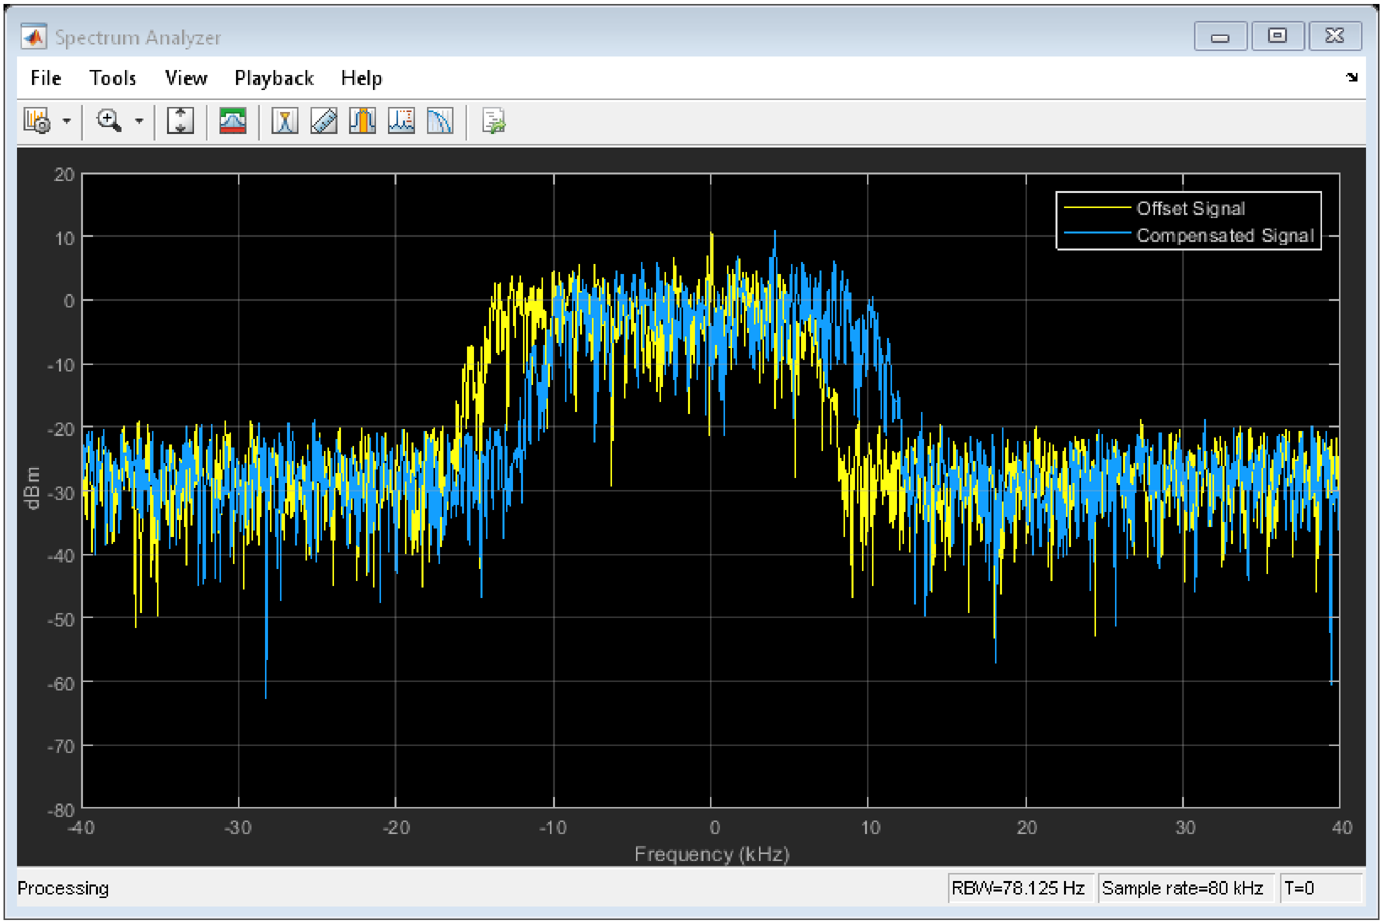
```
freqCompInfo = 

  struct with fields:

    FFTLength: 131072
    Algorithm: 'FFT-based'
```

Create a spectrum analyzer object and plot the offset and compensated spectra. Verify that the compensated signal has a center frequency at 0 Hz and that the offset signal has a center frequency at -4 kHz.

```
specAnal = dsp.SpectrumAnalyzer('SampleRate',fs,'ShowLegend',true, ...
    'ChannelNames',{'Offset Signal' 'Compensated Signal'});
specAnal([offsetData compensatedData])
```



Compensate for Frequency Offset Using Coarse and Fine Compensation

Correct for a phase and frequency offset in a noisy QAM signal using a carrier synchronizer. Then correct for the offsets using both a carrier synchronizer and a coarse frequency compensator.

Set the example parameters.

```
fs = 10000;           % Symbol rate (Hz)
sps = 4;              % Samples per symbol
M = 16;               % Modulation order
k = log2(M);          % Bits per symbol
```

Create a QAM modulator and an AWGN channel.

```
channel = comm.AWGNChannel('EbNo',20,'BitsPerSymbol',k,'SamplesPerSymbol',sps);
```

Create a constellation diagram object to visualize the effects of the offset compensation techniques. Specify the constellation diagram to display only the last 4000 samples.

```
constdiagram = comm.ConstellationDiagram(...
    'ReferenceConstellation',qammod(0:M-1,M), ...
    'SamplesPerSymbol',sps, ...
    'SymbolsToDisplaySource','Property','SymbolsToDisplay',4000, ...
    'XLimits',[-5 5],'YLimits',[-5 5]);
```

Introduce a frequency offset of 400 Hz and a phase offset of 30 degrees.

```
phaseFreqOffset = comm.PhaseFrequencyOffset(...
    'FrequencyOffset',400,...
    'PhaseOffset',30,...
    'SampleRate',fs);
```

Generate random data symbols and apply 16-QAM modulation.

```
data = randi([0 M-1],10000,1);
modSig = qammod(data,M);
```

Create a raised cosine filter object and filter the modulated signal.

```
txfilter = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',sps, ...
    'Gain',sqrt(sps));
txSig = txfilter(modSig);
```

Apply the phase and frequency offset, and then pass the signal through the AWGN channel.

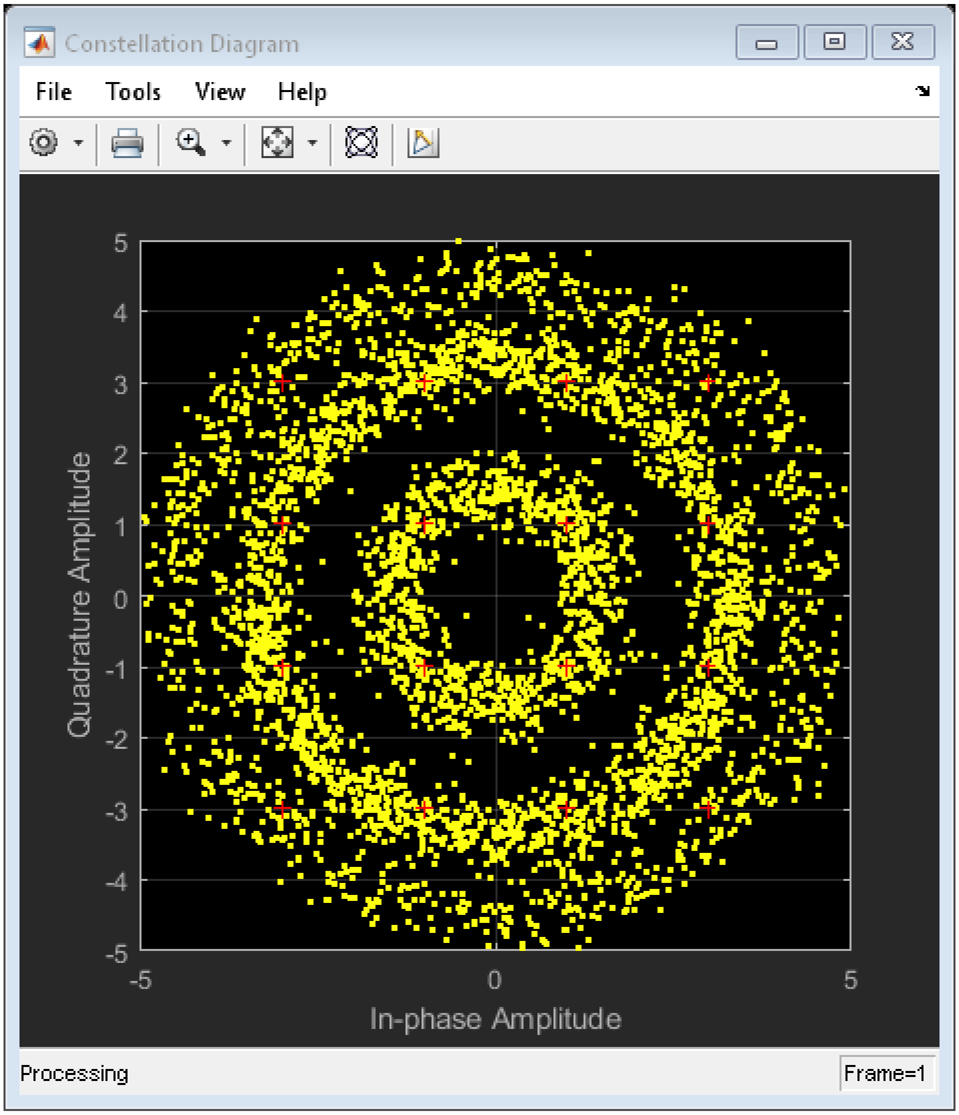
```
freqOffsetSig = phaseFreqOffset(txSig);
rxSig = channel(freqOffsetSig);
```

Apply fine frequency correction to the signal by using the carrier synchronizer.

```
fineSync = comm.CarrierSynchronizer('DampingFactor',0.7, ...
    'NormalizedLoopBandwidth',0.005, ...
    'SamplesPerSymbol',sps, ...
    'Modulation','QAM');
rxData = fineSync(rxSig);
```

Display the constellation diagram of the last 4000 symbols.

```
constdiagram(rxData)
```



Even with time to converge, the spiral nature of the plot shows that the carrier synchronizer has not yet compensated for the large frequency offset. The 400 Hz offset is 1% of the sample rate.

Repeat the process with a coarse frequency compensator inserted before the carrier synchronizer.

Create a coarse frequency compensator to reduce the frequency offset to a manageable level.

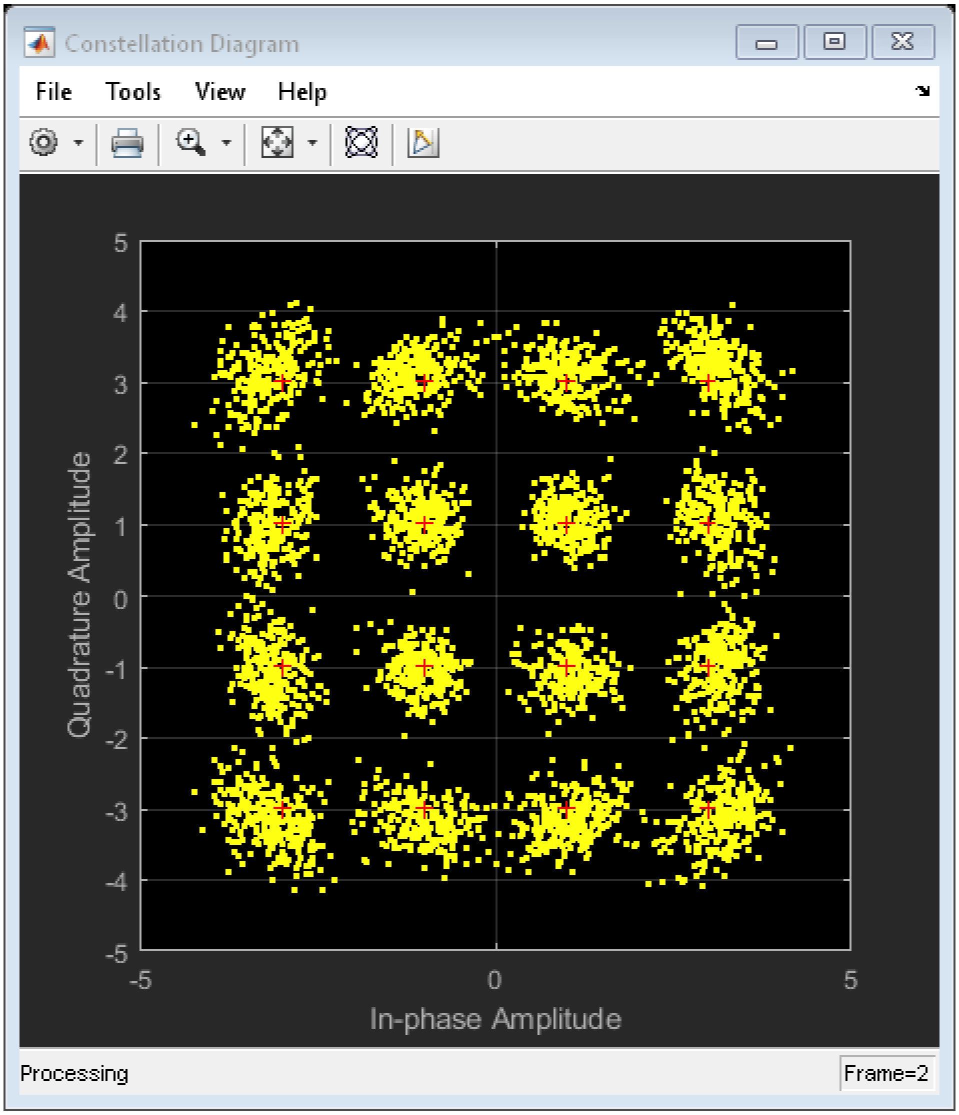
```
coarseSync = comm.CoarseFrequencyCompensator('Modulation','QAM','FrequencyResolution',1,'SampleRa
```

Pass the received signal to the coarse frequency compensator and then to the carrier synchronizer.

```
syncCoarse = coarseSync(rxSig);
rxData = fineSync(syncCoarse);
```

Plot the constellation diagram of the signal after coarse and fine frequency compensation.

```
constdiagram(rxData)
```



The received data now aligns with the reference constellation.

Algorithms

Correlation-Based

The correlation-based estimation algorithm, which can be used to estimate the frequency offset for PSK and PAM signals, is described in [1]. To determine the frequency offset, *Δf*, the algorithm performs a maximum likelihood (ML) estimation of the complex-valued oscillation exp(*j2πΔft*). The observed signal, r_k, is represented as

$$r_k = e^{j(2\pi\Delta f k \mathrm{T}_S + \theta)},\ 1 \le k \le N\,,$$

where T_s is the sampling interval, θ is an unknown random phase, and N is the number of samples. The maximum likelihood estimation of the frequency offset is equivalent to seeking the maximum of the likelihood function, *Λ(Δf)*,

$$\Lambda(\Delta f) \approx \left|\sum_{i=1}^{N} r_i e^{-j2\pi\Delta f i T_s}\right|^2 = \sum_{k=1}^{N}\sum_{m=1}^{N} r_k r_m^* e^{-j2\pi\Delta f T_s(k-m)} .$$

After simplifying, the problem is expressed as a discrete Fourier transform, weighted by a parabolic windowing function. It is expressed as

$$\mathrm{Im}\left\{\sum_{k=1}^{N-1} k(N-k)R(k)e^{j2\pi\widehat{\Delta f}T_s}\right\} = 0 ,$$

where *R(k)* denotes the estimated autocorrelation of the sequence r_k and is represented as

$$R(k) \triangleq \frac{1}{N-k}\sum_{i=k+1}^{N} r_i r_{i-k}^*,\ 0 \le k \le N-1 .$$

The term *k(N–k)* is the parabolic windowing function. In [1], it is shown that *R(k)* is a poor estimate of the autocorrelation of r_k when k = 0 or when k is close to N. Consequently, the windowing function can be expressed as a rectangular sequence of 1s for k = 1, 2, ..., L, where $L \le N$ – 1. The results is a modified ML estimation strategy in which

$$\mathrm{Im}\left\{\sum_{k=1}^{L} R(k)e^{-j2\pi\widehat{\Delta f}kT_s}\right\} = 0 .$$

This results in an estimate of $\widehat{\Delta f}$ in which

$$\widehat{\Delta f} \cong \frac{f_{samp}}{\pi(L+1)}\arg\left\{\sum_{k=1}^{L} R(k)\right\} .$$

The sampling frequency, f_{samp}, is the reciprocal of T_s. The number of elements used to compute the autocorrelation sequence, L, are determined as

$$L = \mathrm{round}\left(\frac{f_{samp}}{f_{max}}\right) - 1,$$

where f_{max} is the maximum expected frequency offset and `round` is the nearest integer function. The frequency offset estimate improves when $L \ge 7$ and leads to the recommendation that $f_{max} \le f_{samp}$ / (4M).

FFT-Based

FFT-based algorithms can be used to estimate the frequency offset for all modulation types. Two variations are used in comm.CoarseFrequencyCompensator.

- For `BPSK`, `QPSK`, `8PSK`, `PAM`, or `QAM` modulations the FFT-based algorithm used is described in [2]. The algorithm estimates $\widehat{\Delta f}$ by using a periodogram of the m^{th} power of the received signal and is given as

  $$\widehat{\Delta f} = \frac{f_{samp}}{N \cdot m}\underset{f}{\mathrm{argmax}}\left|\sum_{k=0}^{N-1} r^m(k)e^{-j2\pi kt/N}\right|, \quad \left(-\frac{R_{sym}}{2} \le f \le \frac{R_{sym}}{2}\right),$$

  where m is the modulation order, *r(k)* is the received sequence, R_{sym} is the symbol rate, and N is the number of samples. The algorithm searches for a frequency that maximizes the time average of the m^{th} power of the received signal multiplied by various frequencies in the range of [–R_{sym}/2, R_{sym}/2]. As the form of the algorithm is the definition of the discrete Fourier transform of $r^m(t)$, searching for a frequency that maximizes the time average is equivalent to searching for a peak line in the spectrum of $r^m(t)$. The number of points required by the FFT is

$$N = 2^{\left\lceil \log_2\left(\frac{f_{samp}}{f_r}\right)\right\rceil},$$

where f_r is the desired frequency resolution.

- For OQPSK modulation the FFT-based algorithm used is described in [4]. The algorithm searches for spectral peaks at +/- 200 kHz around the symbol rate. This technique locates desired peaks in the presence of interference from spectral content around baseband frequencies due to filtering.

`comm.CarrierSynchronizer` | `comm.PhaseFrequencyOffset` | `dsp.FFT`

Introduced in R2015b

info

System object: `comm.CoarseFrequencyCompensator`
Package: `comm`

Characteristic information about coarse frequency compensator

Syntax

```
S = info(CFC)
```

Description

`S = info(CFC)` returns a structure, `S`, containing characteristic information for the `CoarseFrequencyCompensator` System object, `CFC`. `S` has fields `FFTLength`, `Algorithm`, and `MaxLag`. `Algorithm` is the type of algorithm used in estimating the frequency offset. `FFTLength` is the number of samples used in the FFT and is provided when the algorithm is `FFT-based`. `MaxLag` is the number of samples used in estimating the autocorrelation and is provided when the algorithm is `Correlation-based`.

Note The `step` method must be run once to determine the `FFTLength`.

reset

System object: `comm.CoarseFrequencyCompensator`
Package: `comm`

Reset states of the `CoarseFrequencyCompensator` object

Syntax

```
reset(CFC)
```

Description

`reset(CFC)` resets the internal states of the `CoarseFrequencyCompensator` object, `CFC`.

step

System object: `comm.CoarseFrequencyCompensator`
Package: `comm`

Compensate for frequency offset

Syntax

```
Y = step(CFC,X)
[Y,EST] = step(CFC,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(CFC,X)` compensates for the carrier frequency offset of the input `X` and returns the result in `Y`. `X` must be a column vector. The step method outputs the compensated signal `Y` as a complex column vector having the same dimensions and data type as `X`.

`[Y,EST] = step(CFC,X)` returns a scalar estimate of the frequency offset, `EST`.

Note `CFC` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.ChannelFilter

Package: `comm`

Filter signal using multipath gains at specified path delays

Description

Use the `comm.ChannelFilter` System object to filter a signal using multipath gains at specified path delays.

To filter a signal using multipath gains:

1. Create the `comm.ChannelFilter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
chanFilt = comm.ChannelFilter
chanFilt = comm.ChannelFilter(Name,Value)
```

Description

`chanFilt = comm.ChannelFilter` creates a multipath channel filter System object to filter an input signal with path gains at the specified path delays

`chanFilt = comm.ChannelFilter(Name,Value)` sets properties using one or more name-value pairs. For example, `'SampleRate',1e6` sets the sampling rate to 1 MHz. Enclose each property name in quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`SampleRate` — Sample rate
1 Hz (default) | real positive scalar

Sample rate of the input signal, specified as a real, positive scalar.

Data Types: `double`

`PathDelays` — Discrete path delays
`0` (default) | real scalar | real vector

Delays of the discrete paths in seconds, specified as a real scalar or vector.

Data Types: `double`

`FilterDelaySource` — Channel filter delay source
`'Auto'` (default) | `'Custom'`

Channel filter delay source, specified as either `'Auto'` or `'Custom'`.

- Set `FilterDelaySource` to `'Auto'` to specify the channel filter delay as the minimum possible value.
- Set `FilterDelaySource` to `'Custom'` to specify the channel filter delay as a custom value. The custom value cannot be smaller than the minimum possible value.

Data Types: `char`

`FilterDelay` — Channel filter delay
7 (default) | real non-negative integer scalar

Channel filter delay in samples, specified as a real, non-negative, integer scalar.

Dependencies

To enable this property, set the `FilterDelaySource` property to `'Custom'`. The specified value must be no smaller than the automatically determined channel filter delay when you set `FilterDelaySource` to `'Auto'`.

Data Types: `double`

`NormalizeChannelOutputs` — Normalize outputs by number of receive antennas
`'true'` or `1` (default) | `'false'` or `0`

Normalize outputs by number of receive antennas, specified as either `'true'` (`1`) or `'false'` (`0`).

Data Types: `logical`

Usage

Syntax

```
y = chanFilt(x,g)
```

Description

`y = chanFilt(x,g)` filters input signal `x`, through a multipath channel with path gains `g`, at the path delay locations specified by the PathDelays property.

Input Arguments

`x` — Input signal
matrix

Input signal, specified as a matrix. The argument `x` must be a N_s-by-N_t matrix, where N_s is the number of samples and N_t is the number of transmit antennas.

Data Types: `double`

g — Path gain
array

Path gain, specified as an array. The input G must be a N_s-by-N_p-by-N_t-by-N_r or 1-by-N_p-by-N_t-by-N_r array, where N_r is the number of receive antennas and N_p is the number of paths, i.e., the length of the PathDelays property.

Data Types: `double`

Output Arguments

y — Channel output
matrix

Channel output, returned as a N_s-by-N_r matrix.

Data Types: `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.ChannelFilter`

info	Return characteristic information about channel filter

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Explore Spatial Diversity of Channel in Distributed MIMO System

In a distributed MIMO system, send the same signal from two geographically separate transmitters (Tx) and combine the received signals at one single receiver (Rx) to explore spatial diversity. The two Txs are not co-located and they experience different multipath (path delays) to the Rx. Specify the path delays respectively.

```
delay1 = [0 1.5 2.3 5.2 6.6];
delay2 = [0 3.7 6.2];
```

Configure one channel filter object per Tx.

```
chanFilt1 = comm.ChannelFilter('PathDelays', delay1);
chanFilt2 = comm.ChannelFilter('PathDelays', delay2);
```

The two channel filters get different filter delays.

```
fd1 = chanFilt1.info.ChannelFilterDelay
```

```
fd1 = 6
```

```
fd2 = chanFilt2.info.ChannelFilterDelay
```

```
fd2 = 4
```

In order to combine the two channel outputs at Rx, the two channel filters must have the same filter delay. Customize the filter delay for each object.

```
set(chanFilt1, ...
    "FilterDelaySource", 'Custom', ...
    "FilterDelay", max(fd1, fd2));
set(chanFilt2, ...
    "FilterDelaySource", 'Custom', ...
    "FilterDelay", max(fd1, fd2));
```

Set up system parameters. It is assumed one antenna at each Tx and Rx.

```
[Nt, Nr] = deal(1);
Ns  = 30720;
Np1 = length(chanFilt1.PathDelays);
Np2 = length(chanFilt2.PathDelays);
M   = 64;
```

Generate random 64-QAM signal and complex path gains for the two channels.

```
x  = qammod(randi([0, M-1], Ns, Nt), M);
g1 = complex(rand(Ns, Np1, Nt, Nr), rand(Ns, Np1, Nt, Nr));
g2 = complex(rand(Ns, Np2, Nt, Nr), rand(Ns, Np2, Nt, Nr));
```

Perform channel filtering and Rx combining. The combined 2x1 MIMO channel has a filter delay of max(`fd1`, `fd2`).

```
y = chanFilt1(x, g1) + chanFilt2(x, g2);
```

Perform Channel Filtering for an LTE 2x2 EVA Profile

Construct a channel filter object with the LTE Extended Vehicular A model (EVA) delay profile.

```
chanFilt = comm.ChannelFilter( ...
    'SampleRate', 30.72e6, ...
    'PathDelays', [0 30 150 310 370 710 1090 1730 2510]*1e-9);
```

Set up system parameters. There are two transmit and receive antennas.

```
[Nt, Nr] = deal(2);
Ns = 30720;
Np = length(chanFilt.PathDelays);
M  = 256;
```

Generate random 256-QAM signal and complex path gains.

```
x = qammod(randi([0, M-1], Ns, Nt), M);
g = complex(rand(Ns, Np, Nt, Nr), rand(Ns, Np, Nt, Nr));
```

Filter the signal with path gains for the EVA delay profile.

```
y = chanFilt(x, g);
```

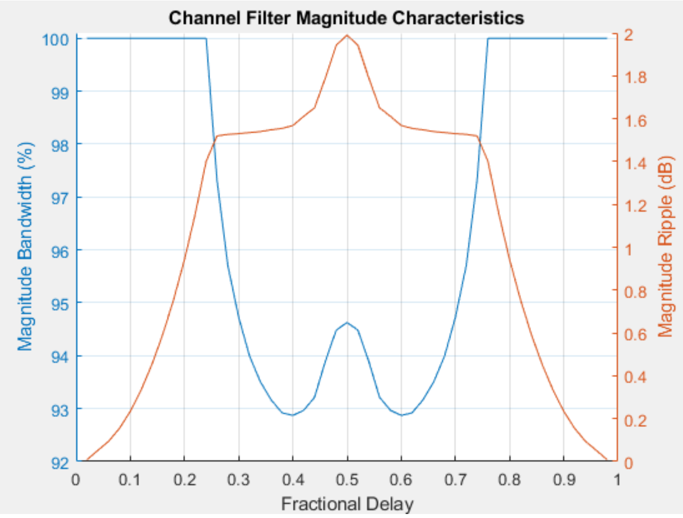
Algorithms

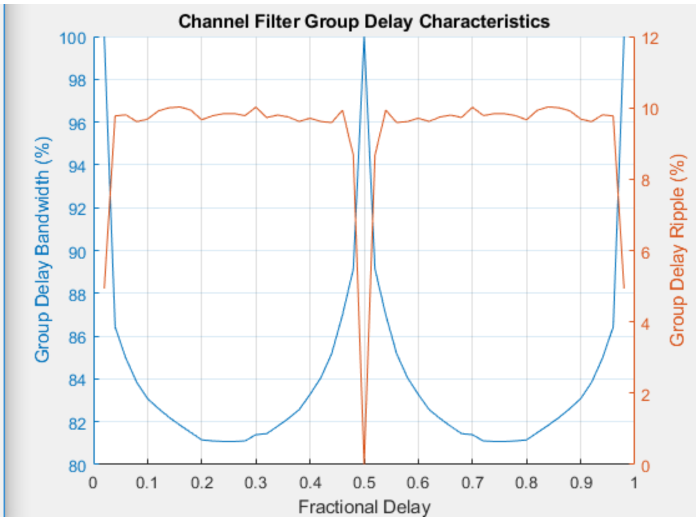
The channel filter implements a fractional delay (FD) finite impulse response (FIR) bandpass filter with a length of 16 coefficients for each candidate fractional delay at 0, 0.02, 0.04, ..., 0.98.

Each discrete path is rounded to its nearest candidate fractional delay, so the delay error limit is 1% of the sample time. To achieve a group delay bandwidth exceeding 80% and a magnitude bandwidth exceeding 90%, the algorithm selects the optimal FIR coefficient values for each fractional delay, while satisfying the following criteria:

- Group delay ripple ≤ 10%
- Magnitude ripple ≤ 2 dB
- Magnitude bandedge attenuation = 3 dB

The plots show bandwidths that satisfy the design criteria for group delay ripple, magnitude ripple, and magnitude bandedge attenuation.





For additional information, see the article *A Matlab-based Object-Oriented Approach to Multipath Fading Channel Simulation* at MATLAB Central.

comm.ConstellationDiagram

Package: comm

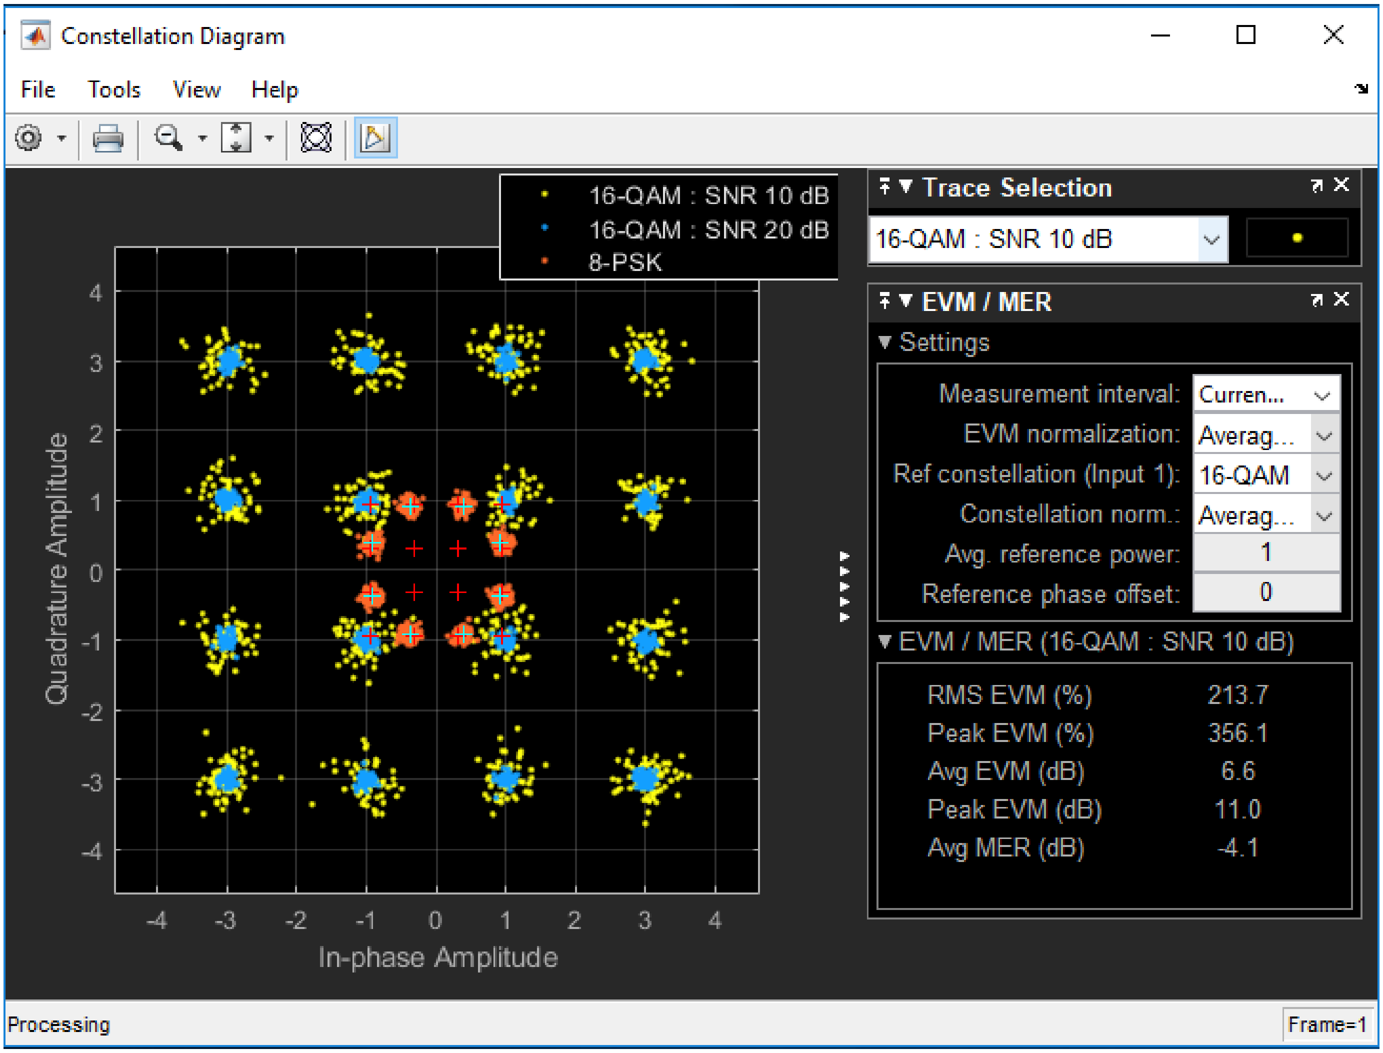
Display constellation diagram for input signals

Description

The comm.ConstellationDiagram System object displays real and complex-valued floating and fixed-point signals in the IQ plane. Use this System object to perform qualitative and quantitative analysis on modulated single-carrier signals.

In the constellation diagram window you can:

- Input and plot multiple signals on a single constellation diagram. You can define one reference constellation for each input signal. For more information, see ReferenceConstellation.
- Choose which channels are displayed by selecting signals in the legend. Use the ShowLegend property to display the legend. For a multichannel signal, specify the input as a matrix with individual signals defined in the columns of the matrix.
- Display the "EVM / MER Measurements" on page 3-328 panel, which displays calculated error vector magnitude (EVM) and modulation error ratio (MER) measurements. When multiple signals are input to a comm.ConstellationDiagram System object, use the **Trace Selection** pane to choose the signal being measured.



Trace Selection: 16-QAM : SNR 10 dB

EVM / MER

Settings

Measurement interval: Curren...

RMS EVM (%)	213.7
Peak EVM (%)	356.1
Avg EVM (dB)	6.6
Peak EVM (dB)	11.0
Avg MER (dB)	-4.1

Processing

Frame=1

To display constellation diagrams:

1 Create the `comm.ConstellationDiagram` object and set its properties.
2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
constdiag = comm.ConstellationDiagram
constdiag = comm.ConstellationDiagram(Name,Value)
```

Description

`constdiag = comm.ConstellationDiagram` returns a `comm.ConstellationDiagram` System object that displays real and complex-valued floating and fixed-point signals in the IQ plane.

`constdiag = comm.ConstellationDiagram(Name,Value)` set the properties of the System object using one or more name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Example: `constdiag = comm.ConstellationDiagram('SampleOffset',1e3)` specifies that the first `1000` samples received will not be displayed.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Name — Title of Constellation Diagram window

`'Constellation Diagram'` (default) | character vector

Title of the Constellation Diagram window, specified as a character vector.

`SamplesPerSymbol` — Number of samples used to represent each symbol

`1` (default) | positive integer

Number of samples used to represent each symbol, specified as a positive integer. When the `SamplesPerSymbol` property is greater than 1, the signal is downsampled before it is plotted.

Tunable: Yes

`SampleOffset` — Number of samples to skip before plotting points

`0` (default) | nonnegative integer

Number of samples to skip before plotting points, specified as a nonnegative integer less than SamplesPerSymbol. This property specifies the number of samples to skip when downsampling the input signal.

Tunable: Yes

`SymbolsToDisplaySource` — Source of symbols to display

`'Input frame length'` (default) | `'Property'`

Source of symbols to display, specified as:

- `'Input frame length'` — The number of symbols to display is equal to the input frame length divided by SamplesPerSymbol.
- `'Property'` — SymbolsToDisplay specifies the maximum number of symbols to display.

Tunable: Yes

SymbolsToDisplay — Maximum number of symbols to display

256 (default) | positive integer

Maximum number of symbols to display, specified as a positive integer. Use SymbolsToDisplay to limit the maximum number of symbols displayed when long signals are input. Symbols plotted are the most recent symbols received.

Tunable: Yes

Dependencies

This property applies when SymbolsToDisplaySource is set to 'Property'.

ReferenceConstellation — Reference constellations

[0.7071+0.7071i -0.7071+0.7071i -0.7071-0.7071i 0.7070-0.7071i] (default) | row vector | cell array

Reference constellations for the input signals, specified as a row vector or cell array of vectors defining the ideal constellation points for each input signal. Input signals can be single channel or multichannel. You can define one reference constellation for each input signal. For multichannel input signals, one reference constellation specification applies to all the individual signals in that input signal. To obtain the "EVM / MER Measurements" on page 3-328, you must set the **ReferenceConstellation** property.

Tunable: Yes

Data Types: double
Complex Number Support: Yes

ReferenceMarker — Marker for reference display

'+' (default) | string | cell array

Specify the marker for the reference display as a string or cell array of strings. Select the marker symbol as one of the markers in this table.

Value	Description
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'_'	Horizontal line
'|'	Vertical line
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle

Value	Description
`'pentagram'` or `'p'`	Five-pointed star (pentagram)
`'hexagram'` or `'h'`	Six-pointed star (hexagram)
`'none'`	No markers

Tunable: Yes

Data Types: `string`

`ReferenceColor` — Color for reference display constellation

`[1 0 0]` (red) (default) | row vector | cell array

Color for reference display constellation, specified as a three-element row vector indicating RGB component colors or as a cell array containing RGB component colors for each input signal.

Data Types: `double`

`ShowReferenceConstellation` — Display the reference constellation

`true` (default) | `false`

Display the reference constellation, specified as `true` or `false`.

Tunable: Yes

Data Types: `logical`

`ShowTrajectory` — Turn on signal trajectory plot

`false` (default) | `true`

Turn on signal trajectory plot, specified as `false` or `true`. The signal trajectory is a plot of the in-phase component versus the quadrature component of a modulated signal. See the **Show Signal Trajectory** button on the toolbar in the “Signal Display” on page 3-327.

Tunable: Yes

Data Types: `logical`

`Position` — Scope window position and size

410-by-300 pixel window at center of screen (default) | four-element vector

Scope window position and size in pixels, specified as a four-element vector of the form [*left bottom width height*]. The first two elements in the vector indicate the location of the lower left corner and the last two specify the size of the window. The default value for the location depends on the screen resolution. By default, the window is positioned in the center of the screen with a width and height of 410 and 300 pixels, respectively.

Tunable: Yes

Data Types: `double`

`NumInputPorts` — Number of input ports

`1` (default) | integer in the range [1, 20]

Specify the number of input ports, as an integer in the range [1, 20]. Each input signal, whether it is a multichannel signal or a single channel signal, becomes a separate input port in the scope.

When multichannel input signals are specified, the maximum number of input ports is limited by the total number of input signals defined. The total number of input signals cannot exceed 20.

ShowGrid — Turn on grid

true (default) | false

Turn on the grid, specified as true or false.

Tunable: Yes

Data Types: logical

ChannelNames — Names for input channels

empty cell (default) | cell array of strings or character vectors

Names for input channels, specified as a cell array of strings or character vectors. If you do not specify names, the channels are labeled as Channel 1, Channel 2, etc.

The names assigned to input channels appear in the legend and the **Measurements** > **Trace Selection** pane.

To show the legend, set ShowLegend to true. The legend displays after you provide an input signal to the comm.ConstellationDiagram System object.

To show the **Trace Selection** pane, select **Measurements** > **Trace Selection**. To enable the **Trace Selection** pane, you must first provide an input signal to the comm.ConstellationDiagram System object.

Example: constDiag = comm.ConstellationDiagram('ChannelNames',{'8-QAM','8-PSK'}) assigns names for two input channels to 8-QAM and 8-PSK.

Tunable: Yes

ShowLegend — Display legend

false (default) | true

Display the legend, specified as false or true. The names listed in the legend are the signal names specified by the ChannelNames property.

From the legend, you can control which signals to plot. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal and hide all other signals, right-click the signal name. To show all signals, press **Esc**.

Tunable: Yes

Data Types: logical

ColorFading — Add color fading effect

false (default) | true

Add color fading effect, specified as false or true. When you set this property to true, the points in the display fade as the interval of time after they are first plotted increases. This animation resembles an oscilloscope display.

Data Types: logical

`Title` — Plot title

blank (default) | character vector | string

Plot title, specified as a character vector or string.

Tunable: Yes

`XLimits` — *x*-axis limits

`[-1.375 1.375]` (default) | two-element numeric vector

x-axis limits, specified as a two-element numeric vector of the form [*xmin xmax*].

Tunable: Yes

`YLimits` — *y*-axis limits

`[-1.375 1.375]` (default) | two-element numeric vector

y-axis limits, specified as a two-element numeric vector of the form [*ymin ymax*].

Tunable: Yes

`XLabel` — *x*-axis label

`'In-phase Amplitude'` (default) | character vector | string

x-axis label, specified as a character vector or string.

Tunable: Yes

`YLabel` — *y*-axis label

`'Quadrature Amplitude'` (default) | character vector | string

y-axis label, specified as a character vector or string.

Tunable: Yes

`EnableMeasurements` — Display measurements pane

`false` (default) | `true`

Display measurements pane, specified as `false` or `true`. To compute and display EVM or MER measurements, activate this pane.

Tunable: Yes

Data Types: `logical`

`MeasurementInterval` — Measurement interval

`'Current Display'` (default) | `'All displays'` | positive integer

Measurement interval, specified as `'Current Display'`, `'All displays'`, or a positive integer in the range [2 SymbolsToDisplay]. This property specifies the window length for the EVM and MER measurements.

When the input signal contains one sample per symbol and the reference constellation is provided, the constellation diagram display can measure the signal quality in terms of EVM and MER. The “EVM / MER Measurements” on page 3-328 pane can be displayed by clicking the **Signal Quality** button. See the toolbar in the “Signal Display” on page 3-327. After the number of input data samples is greater than MeasurementInterval, the EVM and MER measurements are computed.

Tunable: Yes

`EVMNormalization` — EVM normalization method

`'Average constellation power'` (default) | `'Peak constellation power'`

EVM normalization method, specified as `'Average constellation power'` or `'Peak constellation power'`. For more information, see "EVM / MER Measurements" on page 3-328.

Tunable: Yes

Usage

Syntax

`constdiag(signal1,signal2,...,signalN)`

Description

`constdiag(signal1,signal2,...,signalN)` displays up to `NumInputPorts` signals in one constellation diagram.

Input Arguments

`signal` — Input signal or signals to plot

column vector | matrix

Specify one or more signals to be plotted in the `comm.ConstellationDiagram`. Signals can have different data types and dimensions. To create a multichannel signal, specify a matrix with individual signals defined in the columns of the matrix.

Example: `constDiag([siganl1_1,signal1_2],signal2)` displays the multichannel and multi-input constellation diagram. First input is two concatenated column vectors of length N to make an N-by-2 matrix input signal and the second input is a single channel signal.

Data Types: `double`
Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to Scopes

show	Show scope window
hide	Hide scope window
isVisible	Determine visibility of scope window

Common to All System Objects

step	Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics

reset Reset internal states of System object

Examples

Plot Amplitude-Imbalanced QPSK Constellation

QPSK modulate random data symbols and apply an amplitude imbalance to the signal. Pass the signal through a noisy channel. Plot the resultant constellation.

Create a constellation diagram object. Because the default reference constellation for the `comm.ConstellationDiagram` System object is QPSK, it is not necessary to set additional properties.

```
constDiagram = comm.ConstellationDiagram;
```

Generate random data symbols and apply QPSK modulation.

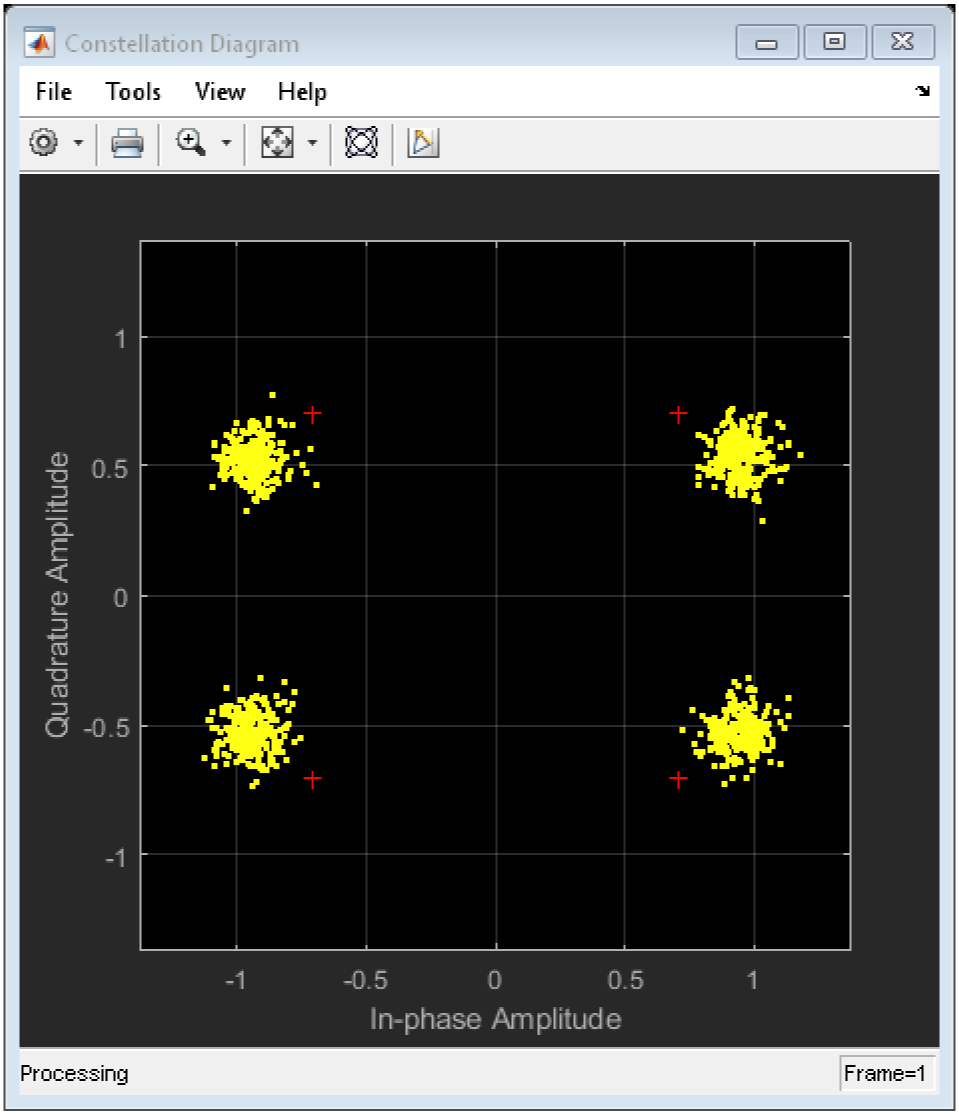
```
data = randi([0 3],1000,1);
modData = pskmod(data,4,pi/4);
```

Apply an amplitude imbalance to the modulated signal.

```
txSig = iqimbal(modData,5);
```

Pass the transmitted signal through an AWGN channel and display the constellation diagram. Observe that the data points have shifted from their ideal locations.

```
rxSig = awgn(txSig,20);
constDiagram(rxSig)
```



Plot 16-QAM Constellation

Apply 16-QAM modulation, transmit data using an AWGN channel, and plot the signal constellation.

Create a 16-QAM reference constellation.

```
M = 16;
refC = qammod(0:M-1,M);
```

Create a `comm.ConstellationDiagram` System object. Specify the constellation reference points and axes limits using name-value pairs.

```
constDiagram = comm.ConstellationDiagram('ReferenceConstellation',refC, ...
    'XLimits',[-4 4],'YLimits',[-4 4]);
```

Generate random, 16-ary data symbols.

```
data = randi([0 M-1],1000,1);
```

Apply 16-QAM modulation.

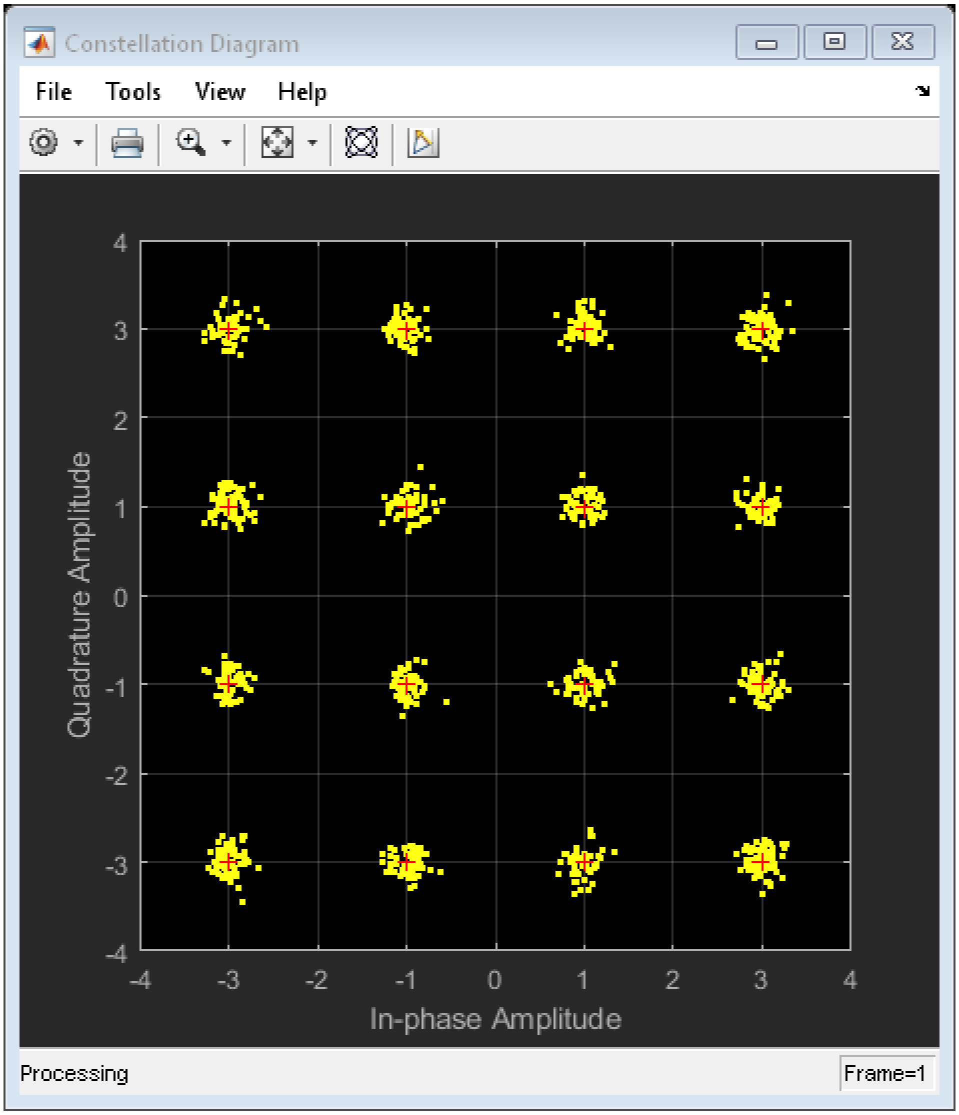
```
sym = qammod(data,M);
```

Pass the modulated signal through an AWGN channel.

```
rcv = awgn(sym,15);
```

Display the constellation diagram.

```
constDiagram(rcv)
```



View Multi-Input Signals Constellation

Use the `comm.ConstellationDiagram` System object to visualize the constellation of multi-input and multichannel modulated signals. Plot a multichannel signal with two 16-QAM signals with SNR 10 and 20 for the first input, and one 8-PSK signal for the second input.

Create a 16-QAM and a 8-PSK reference constellation.

```
M = 16;
refQAM = qammod(0:M-1,M);
S = 8;
refPSK = pskmod(0:S-1,S,pi/8);
```

Create a comm.ConstellationDiagram object™.

```
constDiag = comm.ConstellationDiagram(2,...
      'ReferenceConstellation',{refQAM,refPSK},'ShowLegend',true,...
      'XLimits',[-6 6],'YLimits',[-6 6], ...
      'ChannelNames',{'16-QAM , SNR 10 dB','16-QAM , SNR 20 dB','8-PSK'});
```

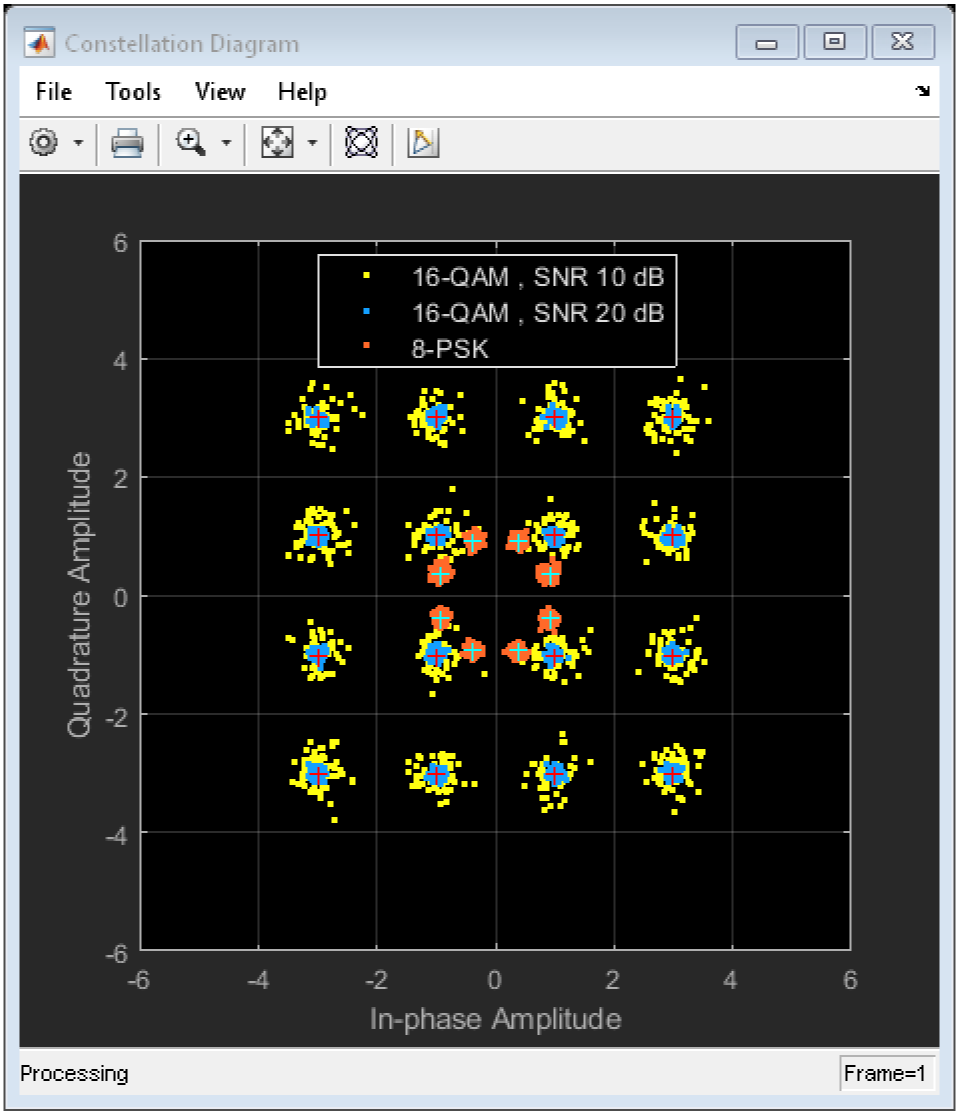
Generate random data symbols, modulate the symbols, and add AWGN with two different SNRs to yield two received signals.

```
d = randi([0 M-1],1000,1);
dQAM = qammod(d,M);
rcv1_1 = awgn(dQAM,10);
rcv1_2 = awgn(dQAM,20);
d = randi([0 S-1],1000,1);
dPSK = pskmod(d,S,pi/8);
rcv2 = awgn(dPSK,20);
```

For the first input, create a multichannel signal by concatenating the two received 16-QAM signals. A single reference constellation is applied for all the multichannel signals of one input. Second input uses a single channel 8-PSK signal. This input has a separate reference constellation.

View the multi-input and multichannel signals .

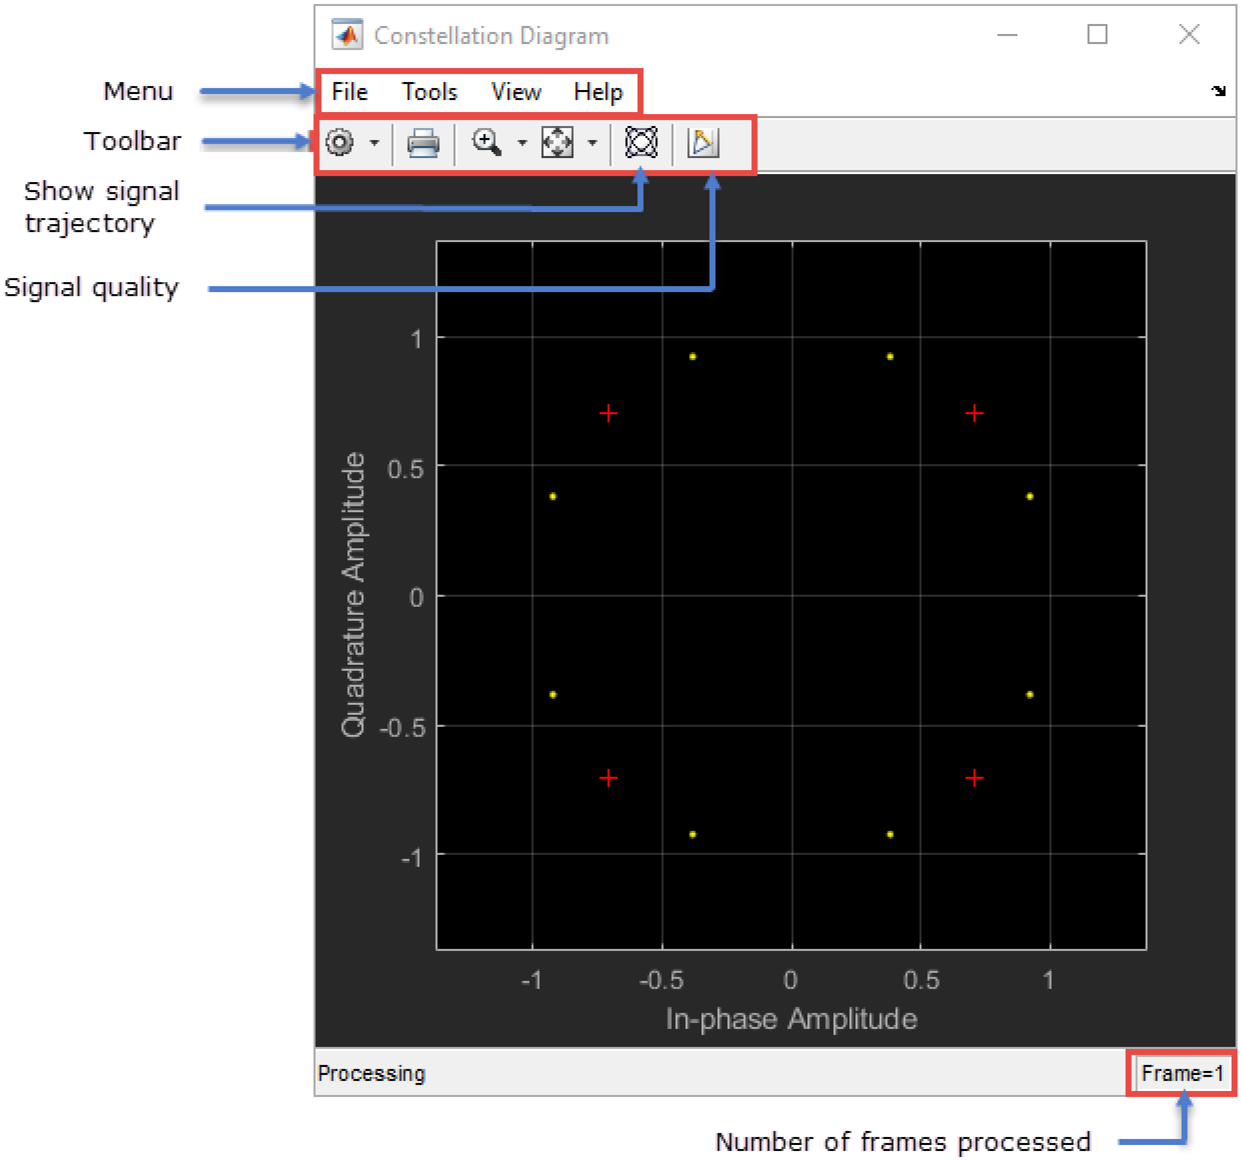
```
constDiag([rcv1_1,rcv1_2],rcv2);
```



More About

Signal Display

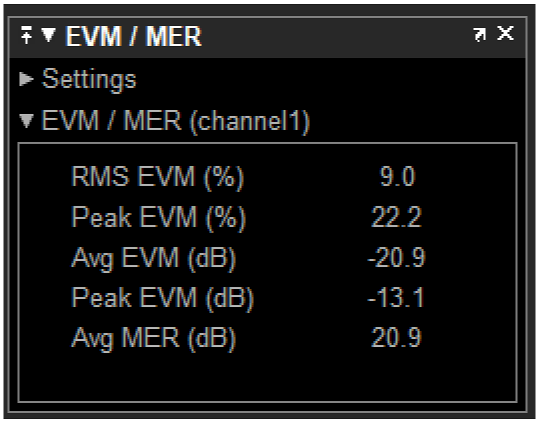
To communicate simulation data that corresponds to the current display, the scope uses the **Frames** indicator on the scope window. This figure highlights important aspects of the Constellation Diagram window.



To change the Constellation Diagram window settings, select menu options under **File**, **Tools**, and **View**. Changes made via menu options adjust the property settings of the System object accordingly.

EVM / MER Measurements

The **EVM / MER** signal quality pane displays the measurement settings, and error vector magnitude (EVM) and modulation error ratio (MER) measurement calculation results for the specified trace selection.



```
RMS EVM (%)      9.0
Peak EVM (%)     22.2
Avg EVM (dB)     -20.9
Peak EVM (dB)    -13.1
Avg MER (dB)     20.9
```

- **EVM** — An error vector is a vector in the IQ plane from the ideal constellation point to the actual point at the receiver. The root mean square error vector magnitude, EVM_{RMS}, is measured for the average and peak constellation power.

  On the constellation diagram, you can display the EVM_{RMS} measurements normalized by either the `Average constellation power` or `Peak constellation power` method as computed using these algorithms.

EVM Normalization Method	Algorithm
`Average constellation power`	Average constellation power normalization: $$\mathrm{EVM}_k = 100\sqrt{\frac{e_k}{P_{\mathrm{avg}}}}$$ $\mathrm{EVM}_{\mathrm{RMS}}$, in percent, for average constellation power normalization: $$\mathrm{EVM}_{\mathrm{RMS}}(\%) = 100\sqrt{\frac{\frac{1}{N}\sum_{k=1}^{N}(e_k)}{P_{\mathrm{avg}}}}$$
`Peak constellation power`	Peak constellation power normalization $$\mathrm{EVM}_k = 100\sqrt{\frac{e_k}{P_{\mathrm{max}}}}$$ EVM_{RMS}, in percent, for peak constellation power normalization $$\mathrm{EVM}_{\mathrm{RMS}}(\%) = 100\sqrt{\frac{\frac{1}{N}\sum_{k=1}^{N}(e_k)}{P_{\mathrm{max}}}}$$

  The **EVM / MER** pane shows the average and peak $\mathrm{EVM}_{\mathrm{RMS}}$ in both percent and decibels for the selected trace. The EVM reported in decibels is computed as EVM (dB) = 10-log10($\mathrm{EVM}_{\mathrm{MS}}$) = 20-log10($\mathrm{EVM}_{\mathrm{RMS}}$), where:

  - $e_k = (I_k - \tilde{I}_k)^2 + (Q_k - \tilde{Q}_k)^2$
  - I_k is the in-phase value of the kth symbol in the input vector.
  - Q_k is the quadrature phase value of the kth symbol in the input vector.
  - I_k and Q_k represent ideal (reference) symbol values. $\tilde{I}_k$ and $\tilde{Q}_k$ represent measured (received) symbol values.
  - N is the input vector length.
  - P_{avg} is the value for `Average constellation power`.
  - P_{max} is the value for `Peak constellation power`.
  - $\text{EVM}_{\text{RMS}} = \sqrt{\text{EVM}_{\text{MS}}}$

  The maximum EVM value in a vector is $\text{EVM}_{\text{max}} = \max_{k \in [1,\ldots,N]} \{\text{EVM}_k\}$, where k is the kth symbol in a vector of length N.

  For more information, see `comm.EVM`.

- **MER** — MER is the ratio of the average power of the transmitted signal to the average power of the error vector. The **EVM / MER** pane indicates average MER measurement result in decibels for the selected trace.

  MER is a measure of the SNR in a modulated signal, calculated in dB. The MER over N symbols is

$$\text{MER} = 10 \cdot \log_{10}\left(\frac{\sum_{n=1}^{N}\left(I_k^2 + Q_k^2\right)}{\sum_{n=1}^{N}(e_k)}\right)\text{dB},$$

  where:

  - $e_k = (I_k - \tilde{I}_k)^2 + (Q_k - \tilde{Q}_k)^2$
  - I_k is the in-phase value of the kth symbol in the input vector.
  - Q_k is the quadrature phase value of the kth symbol in the input vector.
  - I_k and Q_k represent ideal (reference) values. $\tilde{I}_k$ and $\tilde{Q}_k$ represent measured (received) symbols.

  For more information, see `comm.MER`.

Tips

- If you want any of these features, use a `comm.ConstellationDiagram` System object.
  - Measurements
  - Basic reference constellations
  - Signal trajectory plots
  - Maintaining state between calls
- If you want a simple signal constellation snapshot, use the `scatterplot` function.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supports MEX code generation by treating the calls to the object as extrinsic. Does not support code generation for standalone applications.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Functions
`eyediagram` | `scatterplot`

Introduced in R2013a

comm.ConvolutionalDeinterleaver

Package: comm

Restore ordering of symbols using shift registers

Description

The ConvolutionalDeinterleaver object recovers a signal that was interleaved using the convolutional Interleaver object. The parameters in the two blocks should have the same values.

To recover convolutionally interleaved binary data:

1. Define and set up your convolutional deinterleaver object. See "Construction" on page 3-332.
2. Call step to convolutionally deinterleave according to the properties of comm.ConvolutionalDeinterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.ConvolutionalDeinterleaver creates a convolutional deinterleaver System object, H. This object restores the original ordering of a sequence that was interleaved using the convolutional interleaver System object.

H = comm.ConvolutionalDeinterleaver(Name,Value) creates a convolutional deinterleaver System object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

NumRegisters

Number of internal shift registers

Specify the number of internal shift registers as a scalar, positive integer. The default is 6.

RegisterLengthStep

Symbol capacity difference of each successive shift register

Specify the difference in symbol capacity of each successive shift register, where the last register holds zero symbols as a positive, scalar integer. The default is 2.

InitialConditions

Initial conditions of shift registers

Specify the values that are initially stored in each shift register as a numeric scalar or vector, except the last shift register, which has zero delay. If you set this property to a scalar, then all shift registers, except the last one, store the same specified value. You can also set this property to a column vector with length equal to the value of the `NumRegisters` property. With this setting, the *i*-th shift register stores the *(N–i+1)*-th element of the specified vector. The value of the first element of this property is unimportant because the last shift register has zero delay. The default is `0`.

Methods

reset	Reset states of the convolutional deinterleaver object
step	Restore ordering of symbols using shift registers

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Convolutional Interleaving and Deinterleaving

Create convolutional interleaver and deinterleaver objects.

```
interleaver = comm.ConvolutionalInterleaver('NumRegisters',2, ...
    'RegisterLengthStep',3);
deinterleaver = comm.ConvolutionalDeinterleaver('NumRegisters',2, ...
    'RegisterLengthStep',3);
```

Generate data, and pass the data through the convolutional interleaver. Pass the interleaved data through the convolutional deinterleaver.

```
data = (0:20)';
intrlvData = interleaver(data);
deintrlvData = deinterleaver(intrlvData);
```

Display the original sequence, interleaved sequence and restored sequence.

```
[data intrlvData deintrlvData]
```

```
ans = 21×3

     0     0     0
     1     0     0
     2     2     0
     3     0     0
     4     4     0
     5     0     0
     6     6     0
     7     1     1
     8     8     2
     9     3     3
      ⋮
```

The delay through the interleaver and deinterleaver pair is equal to the product of the `NumRegisters` and `RegisterLengthStep` properties. After accounting for this delay, confirm that the original and deinterleaved data are identical.

```
intrlvDelay = interleaver.NumRegisters * interleaver.RegisterLengthStep
```

```
intrlvDelay = 6
```

```
numSymErrors = symerr(data(1:end-intrlvDelay),deintrlvData(1+intrlvDelay:end))
```

```
numSymErrors = 0
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Convolutional Deinterleaver block reference page. The object properties correspond to the block parameters.

Extended Capabilities

`comm.ConvolutionalInterleaver` | `comm.MultiplexedInterleaver`

Introduced in R2012a

reset

System object: `comm.ConvolutionalDeinterleaver`
Package: `comm`

Reset states of the convolutional deinterleaver object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `ConvolutionalDeinterleaver` object, `H`.

step

System object: `comm.ConvolutionalDeinterleaver`
Package: `comm`

Restore ordering of symbols using shift registers

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` restores the original ordering of the sequence, `X`, that was interleaved using a convolutional interleaver and returns `Y`. The input `X` must be a column vector. The data type can be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`. The convolutional deinterleaver object uses a set of *N* shift registers, where *N* is the value specified by the NumRegisters property. The object sets the delay value of the *k*-th shift register to the product of (*k*-1) and RegisterLengthStep property value. With each new input symbol, a commutator switches to a new register and the new symbol shifts in while the oldest symbol in that register shifts out. When the commutator reaches the *N*-th register and the next new input occurs, it returns to the first register.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.ConvolutionalEncoder

Package: comm

Convolutionally encode binary data

Description

The ConvolutionalEncoder object encodes a sequence of binary input vectors to produce a sequence of binary output vectors.

To convolutionally encode a binary signal:

1. Define and set up your convolutional encoder object. See "Construction" on page 3-337.
2. Call step to encode a sequence of binary input vectors to produce a sequence of binary output vectors according to the properties of comm.ConvolutionalEncoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.ConvolutionalEncoder creates a System object, H, that convolutionally encodes binary data.

H = comm.ConvolutionalEncoder(Name,Value) creates a convolutional encoder object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.ConvolutionalEncoder(TRELLIS,Name,Value) creates a convolutional encoder object, H This object has the TrellisStructure on page 3-0 property set to TRELLIS, and the other specified properties set to the specified values.

Properties

TrellisStructure

Trellis structure of convolutional code

Specify the trellis as a MATLAB structure that contains the trellis description of the convolutional code. Use the istrellis function to check if a structure is a valid trellis structure. The default is the result of poly2trellis(7, [171 133]).

TerminationMethod

Termination method of encoded frame

Specify how the encoded frame is terminated as one of Continuous | Truncated | Terminated. The default is Continuous. When you set this property to Continuous, the object retains the encoder states at the end of each input vector for use with the next input vector. When you set this property to `Truncated`, the object treats each input vector independently. The encoder states are reset at the start of each input vector. If you set the `InitialStateInputPort` on page 3-0 property to `false`, the object resets its states to the all-zeros state. If you set the `InitialStateInputPort` property to `true`, the object resets the states to the values you specify in the initial states `step` method input. When you set this property to `Terminated`, the object treats each input vector independently. For each input vector, the object uses extra bits to set the encoder states to all-zeros states at the end of the vector. For a rate *K*/*N* code, the *step* method outputs a vector with length $N \times {}^{(L + S)}\!/\!{}_{K}$, where S = *constraintLength*–1 (or, in the case of multiple constraint lengths, S = **sum**(*constraintLength*(*i*)–1)). *L* is the length of the input to the `step` method.

`ResetInputPort`

Enable encoder reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this additional reset input is a nonzero value, the internal states of the encoder reset to their initial conditions. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous`.

`DelayedResetAction`

Delay output reset

Set this property to `true` to delay resetting the object output. The default is `false`. When you set this property to `true`, the reset of the internal states of the encoder occurs after the object computes the encoded data. When you set this property to `false`, the reset of the internal states of the encoder occurs before the object computes the encoded data. This property applies when you set the `ResetInputPort` on page 3-0 property to `true`.

`InitialStateInputPort`

Enable initial state input

Set this property to `true` to enable a `step` method input that allows the specification of the initial state of the encoder for each input vector. The default is `false`. This property applies when you set the `TerminationMethod` on page 3-0 property to `Truncated`.

`FinalStateOutputPort`

Enable final state output

Set this property to true to obtain the final state of the encoder via a `step` method output. The default is `false`. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous` or `Truncated`.

`PuncturePatternSource`

Source of puncture pattern

Specify the source of the puncture pattern as one of `None | Property`. The default is `None`. When you set this property to `None` the object does not apply puncturing. When you set this property to `Property`, the object punctures the code. This puncturing is based on the puncture pattern vector that you specify in the `PuncturePattern` on page 3-0 property. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous` or `Truncated`.

PuncturePattern

Puncture pattern vector

Specify the puncture pattern used to puncture the encoded data as a column vector. The default is `[1; 1; 0; 1; 0; 1]`. The vector contains `1`s and `0`s, where the `0` indicates the punctured, or excluded, bits. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous` or `Truncated` and the `PuncturePatternSource` on page 3-0 property to `Property`.

Methods

reset	Reset states of the convolutional encoder object
step	Convolutionally encode binary data

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Encode and Decode 8-DPSK Modulated Data

Transmit a convolutionally encoded 8-DPSK modulated bit stream through an AWGN channel. Then, demodulate and decode using a Viterbi decoder.

Create the necessary System objects.

```
hConEnc = comm.ConvolutionalEncoder;
hMod = comm.DPSKModulator('BitInput',true);
hChan = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)',...
    'SNR',10);
hDemod = comm.DPSKDemodulator('BitOutput',true);
hDec = comm.ViterbiDecoder('InputFormat','Hard');
hError = comm.ErrorRate('ComputationDelay',3,'ReceiveDelay', 34);
```

Process the data using the following steps:

1. Generate random bits
2. Convolutionally encode the data
3. Apply DPSK modulation
4. Pass the modulated signal through AWGN
5. Demodulate the noisy signal
6. Decode the data using a Viterbi algorithm
7. Collect error statistics

```
for counter = 1:20
    data = randi([0 1],30,1);
    encodedData = step(hConEnc, data);
    modSignal = step(hMod, encodedData);
    receivedSignal = step(hChan, modSignal);
    demodSignal = step(hDemod, receivedSignal);
    receivedBits = step(hDec, demodSignal);
    errors = step(hError, data, receivedBits);
end
```

Display the number of errors.

```
errors(2)
```

```
ans = 3
```

Convolutional Encoding and Viterbi Decoding with a Puncture Pattern Matrix

Encode and decode a sequence of bits using a convolutional encoder and a Viterbi decoder with a defined puncture pattern. Verify that the input and output bits are identical

Define a puncture pattern matrix and reshape it into vector form for use with the Encoder and Decoder objects.

```
pPatternMat = [1 0 1;1 1 0];
pPatternVec = reshape(pPatternMat,6,1);
```

Create convolutional encoder and a Viterbi decoder in which the puncture pattern is defined by `pPatternVec`.

```
ENC = comm.ConvolutionalEncoder(...
    'PuncturePatternSource','Property', ...
    'PuncturePattern',pPatternVec);

DEC = comm.ViterbiDecoder('InputFormat','Hard', ...
    'PuncturePatternSource','Property',...
    'PuncturePattern',pPatternVec);
```

Create an error rate counter with the appropriate receive delay.

```
ERR = comm.ErrorRate('ReceiveDelay',DEC.TracebackDepth);
```

Encode and decode a sequence of random bits.

```
dataIn = randi([0 1],600,1);

dataEncoded = step(ENC,dataIn);

dataOut = step(DEC,dataEncoded);
```

Verify that there are no errors in the output data.

```
errStats = step(ERR,dataIn,dataOut);
errStats(2)
```

```
ans = 0
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Convolutional Encoder block reference page. The object properties correspond to the block parameters, except:
The operation mode **Reset on nonzero input via port** block parameter corresponds to the `ResetInputPort` on page 3-0 property.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

`comm.APPDecoder` | `comm.ViterbiDecoder`

Introduced in R2012a

reset

System object: `comm.ConvolutionalEncoder`
Package: `comm`

Reset states of the convolutional encoder object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `ConvolutionalEncoder` object, `H`.

step

System object: `comm.ConvolutionalEncoder`
Package: `comm`

Convolutionally encode binary data

Syntax

```
Y = step(H,X)
Y = step(H,X,INITSTATE)
Y = step(H,X,R)
[Y,FSTATE] = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` encodes the binary data, `X`, using the convolutional encoding that you specify in the TrellisStructure property. It returns the encoded data, `Y`. Both `X` and `Y` are column vectors of data type numeric, logical, or unsigned fixed point of word length `1` (fi object). When the convolutional encoder represents a rate *K*/*N* code, the length of the input vector equals *K*×*L*, for some positive integer, *L*. The step method sets the length of the output vector, `Y`, to *L*×*N*.

`Y = step(H,X,INITSTATE)` uses the initial state specified in the `INITSTATE` input when you set the `TerminationMethod` property to 'Truncated' and the InitialStateInputPort property to `true`. `INITSTATE` must be an integer scalar.

`Y = step(H,X,R)` resets the internal states of the encoder when you input a non-zero reset signal, `R`. `R` must be a double precision or logical scalar. This syntax applies when you set the TerminationMethod property to `Continuous` and the ResetInputPort property to true.

`[Y,FSTATE] = step(H,X)` returns the final state of the encoder in the integer scalar output `FSTATE` when you set the `FinalStateOutputPort` property to `true`. This syntax applies when you set the `TerminationMethod` property to `Continuous` or `Truncated`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.ConvolutionalInterleaver

Package: comm

Permute input symbols using shift registers with same property values

Description

The ConvolutionalInterleaver object permutes the symbols in the input signal. Internally, this class uses a set of shift registers.

To convolutionally interleave binary data:

1. Define and set up your convolutional interleaver object. See “Construction” on page 3-344.
2. Call step to convolutionally interleave according to the properties of comm.ConvolutionalInterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.ConvolutionalInterleaver creates a convolutional interleaver System object, H, that permutes the symbols in the input signal using a set of shift registers.

H = comm.ConvolutionalInterleaver(Name,Value) creates a convolutional interleaver System object, H. This object has each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

NumRegisters

Number of internal shift registers

Specify the number of internal shift registers as a scalar, positive integer. The default is 6.

RegisterLengthStep

Number of additional symbols that fit in each successive shift register

Specify the number of additional symbols that fit in each successive shift register as a positive, scalar integer. The default is 2. The first register holds zero symbols.

InitialConditions

Initial conditions of shift registers

Specify the values that are initially stored in each shift register as a numeric scalar or vector. You do not need to specify a value for the first shift register, which has zero delay. The default is `0`. The value of the first element of this property is unimportant because the first shift register has zero delay. If you set this property to a scalar, then all shift registers, except the first one, store the same specified value. If you set it to a column vector with length equal to the value of the `NumRegisters` on page 3-0 property, then the *i*-th shift register stores the *i*-th element of the specified vector.

Methods

reset	Reset states of the convolutional interleaver object
step	Permute input symbols using shift registers

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Convolutional Interleaving and Deinterleaving

Create convolutional interleaver and deinterleaver objects.

```
interleaver = comm.ConvolutionalInterleaver('NumRegisters',2, ...
    'RegisterLengthStep',3);
deinterleaver = comm.ConvolutionalDeinterleaver('NumRegisters',2, ...
    'RegisterLengthStep',3);
```

Generate data, and pass the data through the convolutional interleaver. Pass the interleaved data through the convolutional deinterleaver.

```
data = (0:20)';
intrlvData = interleaver(data);
deintrlvData = deinterleaver(intrlvData);
```

Display the original sequence, interleaved sequence and restored sequence.

```
[data intrlvData deintrlvData]
```

```
ans = 21×3

     0     0     0
     1     0     0
     2     2     0
     3     0     0
     4     4     0
     5     0     0
     6     6     0
     7     1     1
     8     8     2
     9     3     3
      ⋮
```

The delay through the interleaver and deinterleaver pair is equal to the product of the `NumRegisters` and `RegisterLengthStep` properties. After accounting for this delay, confirm that the original and deinterleaved data are identical.

```
intrlvDelay = interleaver.NumRegisters * interleaver.RegisterLengthStep
```

```
intrlvDelay = 6
```

```
numSymErrors = symerr(data(1:end-intrlvDelay),deintrlvData(1+intrlvDelay:end))
```

```
numSymErrors = 0
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Convolutional Interleaver block reference page. The object properties correspond to the block parameters.

To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.CPFSKDemodulator

Package: `comm`

Demodulate using CPFSK method and Viterbi algorithm

Description

The `CPFSKDemodulator` object demodulates a signal that was modulated using the continuous phase frequency shift keying method. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using the continuous phase frequency shift keying method:

1. Define and set up your CPFSK demodulator object. See "Construction" on page 3-349 .
2. Call `step` to demodulate the signal according to the properties of `comm.CPFSKDemodulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.CPFSKDemodulator` creates a demodulator System object, `H`. This object demodulates the input continuous phase frequency shift keying (CPFSK) modulated data using the Viterbi algorithm.

`H = comm.CPFSKDemodulator(Name,Value)` creates a CPFSK demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.CPFSKDemodulator(M,Name,Value)` creates a CPFSK demodulator object, `H`. This object has the `ModulationOrder` property set to `M`, and the other specified properties set to the specified values.

Properties

`ModulationOrder`

Size of symbol alphabet

Specify the size of the symbol alphabet. The value of this property requires a power of two, real, integer scalar. The default is `4`.

`BitOutput`

Output data as bits

Specify whether the output consists of groups of bits or integer values. The default is `false`.

When you set this property to `false`, the `step` method outputs a column vector of length equal to *N*/`SamplesPerSymbol` on page 3-0 and with elements that are integers between –(`ModulationOrder` on page 3-0 –1) and `ModulationOrder`–1. In this case, *N*, is the length of the input signal, which indicates the number of input baseband modulated symbols.

When you set this property to `true`, the `step` method outputs a binary column vector of length equal to *P*×(*N*/`SamplesPerSymbol`), where *P* = **log2**(`ModulationOrder`). The output contains length-*P* bit words. In this scenario, the object first maps each demodulated symbol to an odd integer value, *K*, between –(`ModulationOrder`-1) and `ModulationOrder`–1. The object then maps *K* to the nonnegative integer (*K*+`ModulationOrder`–1)/2. Finally, the object maps each nonnegative integer to a length-*P* binary word, using the mapping specified in the `SymbolMapping` on page 3-0 property.

SymbolMapping

Symbol encoding

Specify the mapping of the modulated symbols as one of `Binary` | `Gray`. The default is `Binary`. This property determines how the object maps each demodulated integer symbol value (in the range 0 and `ModulationOrder` on page 3-0 –1) to a *P*-length bit word, where *P* = `ModulationOrder` on page 3-0 (`ModulationOrder`).

When you set this property to `Binary`, the object uses a natural binary-coded ordering.

When you set this property to `Gray`, the object uses a Gray-coded ordering.

This property applies when you set the `BitOutput` on page 3-0 property to `true`.

ModulationIndex

Modulation index

Specify the modulation index. The default is `0.5`. The value of this property can be a scalar, *h*, or a column vector, [h_0, h_1, ... $h_{\text{H-1}}$]

where H-1 represents the length of the column vector.

When h_{i} varies from interval to interval, the object operates in multi-h. When the object operates in multi-h, h_{i} must be a rational number.

InitialPhaseOffset

Initial phase offset

Specify the initial phase offset of the input modulated waveform in radians as a real, numeric scalar. The default is `0`.

SamplesPerSymbol

Number of samples per input symbol

Specify the expected number of samples per input symbol as a positive, integer scalar. The default is `8`.

TracebackDepth

Traceback depth for Viterbi algorithm

Specify the number of trellis branches that the Viterbi algorithm uses to construct each traceback path as a positive, integer scalar. The default is 16. The value of this property is also the value of the output delay. That value is the number of zero symbols that precede the first meaningful demodulated symbol in the output.

OutputDataType

Data type of output

Specify the output data type as one of `int8` | `int16` | `int32` | `double`, when you set the `BitOutput` on page 3-0 property to false. The default is `double`.

When you set the `BitOutput` property to `true`, specify the output data type as one of `logical` | `double`.

Methods

reset	Reset states of CPFSK demodulator object
step	Demodulate using CPFSK method and Viterbi algorithm

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Demodulate a signal using CPFSK modulation with Gray mapping

```
% Create a CPFSK modulator, an AWGN channel, and a CPFSK demodulator
    hMod = comm.CPFSKModulator(8, 'BitInput', true, ...
                         'SymbolMapping', 'Gray');
    hAWGN = comm.AWGNChannel('NoiseMethod', ...
                         'Signal to noise ratio (SNR)','SNR',0);
    hDemod = comm.CPFSKDemodulator(8, 'BitOutput', true, ...
                         'SymbolMapping', 'Gray');

 % Create an error rate calculator, account for the delay caused by the Viterbi algorithm.
    delay = log2(hDemod.ModulationOrder)*hDemod.TracebackDepth;
    hError = comm.ErrorRate('ReceiveDelay', delay);
    for counter = 1:100
        % Transmit 100 3-bit words
        data = randi([0 1],300,1);
        modSignal = step(hMod, data);
        noisySignal = step(hAWGN, modSignal);
        receivedData = step(hDemod, noisySignal);
        errorStats = step(hError, data, receivedData);
    end

    fprintf('Error rate = %f\nNumber of errors = %d\n', ...
      errorStats(1), errorStats(2))
```

```
Error rate = 0.004006
Number of errors = 120
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the CPFSK Demodulator Baseband block reference page. The object properties correspond to the block parameters. For CPFSK the phase shift per symbol is π × *h*, where *h* is the modulation index.

```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates input data, `X`, with the CPFSK demodulator System object, `H`, and returns `Y`. Input `X` must be a double or single precision, column vector with a length equal to an integer multiple of the number of samples per symbol specified in the `SamplesPerSymbol` property. Depending on the `BitOutput` property value, output `Y` can be integer or bit valued.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.CPFSKModulator

Package: `comm`

Modulate using CPFSK method

Description

The `CPFSKModulator` object modulates using the continuous phase frequency shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using the continuous phase frequency shift keying method:

1. Define and set up your CPFSK modulator object. See "Construction" on page 3-355.
2. Call `step` to modulate the signal according to the properties of `comm.CPFSKModulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.CPFSKModulator` creates a modulator System object, `H`. This object modulates the input signal using the continuous phase frequency shift keying (CPFSK) modulation method.

`H = comm.CPFSKModulator(Name,Value)` creates a CPFSK modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.CPFSKModulator(M,Name,Value)` creates a CPFSK modulator object, `H`. This object has the `ModulationOrder` property set to `M`, and the other specified properties set to the specified values.

Properties

`ModulationOrder`

Size of symbol alphabet

Specify the size of the symbol alphabet. The value of this property requires a power of two, real, integer scalar. The default is `4`.

`BitInput`

Assume bit inputs

Specify whether the input is bits or integers. The default is `false`. When you set this property to `false`, the `step` method input must be a double-precision or signed integer data type column vector.

This vector comprises odd integer values between –(ModulationOrder on page 3-0 –1) and ModulationOrder–1.

When you set this property to true, the step method input must be a column vector of *P*-length bit words, where *P* = **log2**(ModulationOrder). The input data must be double precision or logical data type. The object maps each bit word to an integer K between 0 and ModulationOrder–1, using the mapping specified in the SymbolMapping on page 3-0 property. The object then maps the integer *K* to the intermediate value 2*K*–(ModulationOrder–1) and proceeds as in the case when you set the BitInput on page 3-0 property to false.

SymbolMapping

Symbol encoding

Specify the mapping of bit inputs as one of Binary | Gray. The default is Binary. This property determines how the object maps each input *P*-length bit word, where *P* = **log2**(ModulationOrder on page 3-0), to an integer between 0 and ModulationOrder–1.

When you set this property to Binary, the object uses a natural binary-coded ordering.

When you set this property to Gray, the object uses a Gray-coded ordering.

This property applies when you set the BitInput on page 3-0 property to true.

ModulationIndex

Modulation index

Specify the modulation index. The default is 0.5. The value of this property can be a scalar, *h*, or a column vector, [h_0, h_1, ... $h_{\text{H-1}}$]

where H-1 represents the length of the column vector. The phase shift over a symbol is π × *h*.

When h_{i} varies from interval to interval, the object operates in multi-h. When the object operates in multi-h, h_{i} must be a rational number.

InitialPhaseOffset

Initial phase offset

Specify the initial phase of the modulated waveform in radians as a real, numeric scalar. The default is 0.

SamplesPerSymbol

Number of samples per output symbol

Specify the upsampling factor at the output as a real, positive, integer scalar. The default is 8. The upsampling factor is the number of output samples that the step method produces for each input sample.

OutputDataType

Data type of output

Specify output data type as one of double | single. The default is double.

Methods

reset	Reset states of CPFSK modulator object
step	Modulate using CPFSK method

Common to All System Objects	
release	Allow System object property value changes

Examples

Demodulate a signal using CPFSK modulation with Gray mapping

```
% Create a CPFSK modulator, an AWGN channel, and a CPFSK demodulator
    hMod = comm.CPFSKModulator(8, 'BitInput', true, ...
                         'SymbolMapping', 'Gray');
    hAWGN = comm.AWGNChannel('NoiseMethod', ...
                         'Signal to noise ratio (SNR)','SNR',0);
    hDemod = comm.CPFSKDemodulator(8, 'BitOutput', true, ...
                         'SymbolMapping', 'Gray');

 % Create an error rate calculator, account for the delay caused by the Viterbi algorithm.
    delay = log2(hDemod.ModulationOrder)*hDemod.TracebackDepth;
    hError = comm.ErrorRate('ReceiveDelay', delay);
    for counter = 1:100
        % Transmit 100 3-bit words
        data = randi([0 1],300,1);
        modSignal = step(hMod, data);
        noisySignal = step(hAWGN, modSignal);
        receivedData = step(hDemod, noisySignal);
        errorStats = step(hError, data, receivedData);
    end

    fprintf('Error rate = %f\nNumber of errors = %d\n', ...
      errorStats(1), errorStats(2))
```

```
Error rate = 0.004006
Number of errors = 120
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the CPFSK Modulator Baseband block reference page. The object properties correspond to the block parameters. For CPFSK the phase shift per symbol is π × *h*, where *h* is the modulation index.

`comm.CPFSKDemodulator` | `comm.CPMDemodulator` | `comm.CPMModulator`

Introduced in R2012a

reset

System object: `comm.CPFSKModulator`
Package: `comm`

Reset states of CPFSK modulator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `CPFSKModulator` object, `H`.

step

System object: `comm.CPFSKModulator`
Package: `comm`

Modulate using CPFSK method

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` modulates input data, `X`, with the CPFSK modulator System object, `H`. It returns the baseband modulated output, `Y`. Depending on the value of the `BitInput` property, input `X` can be an integer or bit valued column vector with data types double, signed integer, or logical. The length of output vector, `Y`, is equal to the number of input samples times the number of samples per symbol specified in the `SamplesPerSymbol` property.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.CPMCarrierPhaseSynchronizer

Package: `comm`

(Removed) Recover carrier phase of baseband CPM signal

Note `comm.CPMCarrierPhaseSynchronizer` has been removed. Use `comm.CarrierSynchronizer` instead.

Description

The `CPMCarrierPhaseSynchronizer` object recovers the carrier phase of the input signal using the 2*P*-Power method. This feedforward method is clock aided, but not data aided. The method is suitable for systems that use certain types of baseband modulation. These types include: continuous phase modulation (CPM), minimum shift keying (MSK), continuous phase frequency shift keying (CPFSK), and Gaussian minimum shift keying (GMSK).

To recover the carrier phase of the input signal:

1. Define and set up your CPM carrier phase synchronizer object. See “Construction” on page 3-361.
2. Call `step` to recover the carrier phase of the input signal using the 2*P*-Power method according to the properties of `comm.CPMCarrierPhaseSynchronizer`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.CPMCarrierPhaseSynchronizer` creates a CPM carrier phase synchronizer System object, `H`. This object recovers the carrier phase of a baseband continuous phase modulation (CPM), minimum shift keying (MSK), continuous phase frequency shift keying (CPFSK), or Gaussian minimum shift keying (GMSK) modulated signal using the 2P-power method.

`H = comm.CPMCarrierPhaseSynchronizer(Name,Value)` creates a CPM carrier phase synchronizer object, `H` This object has each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.CPMCarrierPhaseSynchronizer(HALFPOW,Name,Value)` creates a CPM carrier phase synchronizer object, `H`. This object has the `P` on page 3-0 property set to `HALFPOW`, and the other specified properties set to the specified values.

Properties

P

Denominator of CPM modulation index

Specify the denominator of the CPM modulation index of the input signal as a real positive scalar integer value of data type single or double. The default is `2`. This property is tunable.

ObservationInterval

Number of symbols where carrier phase assumed constant

Specify the observation interval as a real positive scalar integer value of data type single or double. The default is `100`.

Methods

reset	Reset states of the CPM carrier phase synchronizer object
step	(Removed) Recover carrier phase of baseband CPM signal

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Recover carrier phase of a GMSK signal.

```
% Initialize random seed for repeatability
rng(123)

% Create a GMSK modulator, an AWGN channel, and a GMSK demodulator.
% Use a phase offset of pi/4.
samplesPerSymbol = 4;
modulator = comm.GMSKModulator('BitInput',true,'InitialPhaseOffset',pi/4, ...
    'SamplesPerSymbol',samplesPerSymbol);
awgnChannel = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (SNR)', ...
    'SNR',40);
demodulator = comm.GMSKDemodulator('BitOutput',true, ...
    'InitialPhaseOffset',pi/4,'SamplesPerSymbol',samplesPerSymbol);

% Create a System object for frequency offset
frequencyOffset = 1e4;
sampleRate = 1e6;
pfo = comm.PhaseFrequencyOffset('FrequencyOffset',frequencyOffset, ...
    'SampleRate',sampleRate);

% Create a carrier synchronizer
carrierSync = comm.CarrierSynchronizer('SamplesPerSymbol', samplesPerSymbol, ...
    'Modulation','OQPSK');

% Create a preamble for resolving phase ambiguity
preambleLength = 13;
barker = comm.BarkerCode('Length',preambleLength,'SamplesPerFrame', ...
    preambleLength); % For preamble
preamble = (1+barker())/2; % Length 13, unipolar

% Create an error rate calculator, account for the delay caused by
% the Viterbi algorithm used by the GMSK demodulator.
errorCalculator = comm.ErrorRate('ReceiveDelay',demodulator.TracebackDepth);

numFrames = 4000;
symbolsPerFrame = 300;
estimatedPhaseOffset = zeros(symbolsPerFrame*samplesPerSymbol,numFrames);
```

```
errorHistory = zeros(numFrames,1);

for counter = 1:numFrames
    % Transmit 300 bits
    payload = randi([0 1],symbolsPerFrame - preambleLength,1);
    data = [preamble; payload];
    modulatedSignal = modulator(data);
    noisySignal = awgnChannel(modulatedSignal);
    rxSignal = pfo(noisySignal); % with carrier frequency offset

    [syncSignal, phOffset] = carrierSync(rxSignal);
    estimatedPhaseOffset(:, counter) = phOffset;

    phaseCorrection = round((2/pi)*angle(...
        modulatedSignal(1:preambleLength*samplesPerSymbol).* ...
        conj(syncSignal(1:preambleLength*samplesPerSymbol))));
    phaseCorrection(phaseCorrection==-2)=2;
    phaseCorrection = mode(phaseCorrection)*pi/2;

    receivedData = demodulator(exp(1j*phaseCorrection)*syncSignal);
    errorStats = errorCalculator(data,receivedData);
    errorHistory(counter) = errorStats(2);
end

estimatedFreqOffset = estimatedPhaseOffset(:);
% plot((estimatedFreqOffset(2:end)-estimatedFreqOffset(1:end-1))*sampleRate/(2*pi))
% xlabel('Sample')
% ylabel('Estimated Frequency Offset (Hz)');

% Number of bit errors (ignoring those in the first half of the simulation,
% before frequency and phase offset are corrected)
numErrors = errorHistory(end) - errorHistory(0.5*end)
```

```
numErrors =

     0
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the CPM Phase Recovery block reference page. The object properties correspond to the block parameters.

Compatibility Considerations

`comm.CPMCarrierPhaseSynchronizer` has been removed

Errors starting in R2020a

`comm.CPMCarrierPhaseSynchronizer` has been removed. Use `comm.CarrierSynchronizer` instead.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

reset(H)
```

Description

`reset(H)` resets the states of the `CPMCarrierPhaseSynchronizer` object, `H`.

step

System object: comm.CPMCarrierPhaseSynchronizer
Package: comm

(Removed) Recover carrier phase of baseband CPM signal

Note comm.CPMCarrierPhaseSynchronizer has been removed. Use comm.CarrierSynchronizer instead.

Syntax

```
[Y,PH] = step(H,X)
```

Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

[Y,PH] = step(H,X) recovers the carrier phase of the input signal, X, and returns the phase corrected signal, Y, and the carrier phase estimate (in degrees), PH. X must be a complex scalar or column vector input signal of data type single or double.

Note obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

comm.CPMDemodulator

Package: `comm`

Demodulate using CPM method and Viterbi algorithm

Description

The `CPMDemodulator` object demodulates a signal that was modulated using continuous phase modulation. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using continuous phase modulation:

1. Define and set up your CPM demodulator object. See “Construction” on page 3-367.
2. Call `step` to demodulate a signal according to the properties of `comm.CPMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.CPMDemodulator` creates a demodulator System object, `H`. This object demodulates the input continuous phase modulated (CPM) data using the Viterbi algorithm.

`H = comm.CPMDemodulator(Name,Value)` creates a CPM demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.CPMDemodulator(M,Name,Value)` creates a CPM demodulator object, `H`, with the `ModulationOrder` property set to `M`, and the other specified properties set to the specified values.

Properties

`ModulationOrder`

Size of symbol alphabet

Specify the size of the symbol alphabet. The value of this property requires a power of two, real, integer scalar. The default is `4`.

`BitOutput`

Output data as bits

Specify whether the output consists of groups of bits or integer values. The default is `false`.

When you set this property to `false`, the `step` method outputs a column vector of length equal to *N*/ `SamplesPerSymbol` on page 3-0 and with elements that are integers between -

(`ModulationOrder` on page 3-0 -1) and `ModulationOrder`–1. Here, *N*, is the length of the input signal which indicates the number of input baseband modulated symbols.

When you set this property to `true`, the `step` method outputs a binary column vector of length equal to *P*×(*N*/`SamplesPerSymbol`), where *P* = **log2**(`ModulationOrder`). The output contains length-*P* bit words. In this scenario, the object first maps each demodulated symbol to an odd integer value, *K*, between –(`ModulationOrder`–1) and `ModulationOrder`–1. The object then maps *K* to the nonnegative integer (*K*+`ModulationOrder`–1)/2. Finally, the object maps each nonnegative integer to a length-*P* binary word, using the mapping specified in the `SymbolMapping` on page 3-0 property.

SymbolMapping

Symbol encoding

Specify the mapping of the demodulated symbols as one of `Binary` | `Gray`. The default is `Binary`. This property determines how the object maps each demodulated integer symbol value (in the range `0` and `ModulationOrder` on page 3-0 –1) to a *P*-length bit word, where *P* = **log2**(`ModulationOrder`).

When you set this property to `Binary`, the object uses a natural binary-coded ordering.

When you set this property to `Gray`, the object uses a Gray-coded ordering.

This property applies when you set the `BitOutput` on page 3-0 property to true.

ModulationIndex

Modulation index

Specify the modulation index. The default is `0.5`. The value of this property can be a scalar, *h*, or a column vector, [h_0, h_1, …. $h_{\text{H-1}}$]

where H-1 represents the length of the column vector.

When h_i varies from interval to interval, the object operates in multi-h. When the object operates in multi-h, h_i must be a rational number.

FrequencyPulse

Frequency pulse shape

Specify the type of pulse shaping that the modulator has used to smooth the phase transitions of the input modulated signal as one of `Rectangular` | `Raised Cosine` | `Spectral Raised Cosine` | `Gaussian` | `Tamed FM`. The default is `Rectangular`.

MainLobeDuration

Main lobe duration of spectral raised cosine pulse

Specify, in number of symbol intervals, the duration of the largest lobe of the spectral raised cosine pulse. This value is the value that the modulator used to pulse-shape the input modulated signal. The default is `1`. This property requires a real, positive, integer scalar. This property applies when you set the `FrequencyPulse` on page 3-0 property to `Spectral Raised Cosine`.

RolloffFactor

Rolloff factor of spectral raised cosine pulse

Specify the roll off factor of the spectral raised cosine pulse. This value is the value that the modulator used to pulse-shape the input modulated signal. The default is `0.2`. This property requires a real scalar between `0` and `1`. This property applies when you set the `FrequencyPulse` on page 3-0 property to `Spectral Raised Cosine`.

BandwidthTimeProduct

Product of bandwidth and symbol time of Gaussian pulse

Specify the product of bandwidth and symbol time for the Gaussian pulse shape. This value is the value that the modulator used to pulse-shape the input modulated signal. The default is `0.3`. This property requires a real, positive scalar. This property applies when you set the `FrequencyPulse` on page 3-0 property to `Gaussian`.

PulseLength

Pulse length

Specify the length of the frequency pulse shape in symbol intervals. The value of this property requires a real positive integer. The default is `1`.

SymbolPrehistory

Symbol prehistory

Specify the data symbols used by the modulator prior to the first call to the `step` method. The default is `1`. This property requires a scalar or vector with odd integer elements between –(`ModulationOrder` on page 3-0 –1) and (`ModulationOrder`–1). If the value is a vector, then its length must be one less than the value in the `PulseLength` on page 3-0 property.

InitialPhaseOffset

Initial phase offset

Specify the initial phase offset of the input modulated waveform in radians as a real, numeric scalar. The default is `0`.

SamplesPerSymbol

Number of samples per input symbol

Specify the expected number of samples per input symbol as a positive, integer scalar. The default is `8`.

TracebackDepth

Traceback depth for Viterbi algorithm

Specify the number of trellis branches that the Viterbi algorithm uses to construct each traceback path as a positive, integer scalar. The default is `16`. The value of this property is also the output delay, which is the number of zero symbols that precede the first meaningful demodulated symbol in the output.

OutputDataType

Data type of output

Specify the output data type as one of `int8` | `int16` | `int32` | `double`, when you set the `BitOutput` on page 3-0 property to false. When you set the `BitOutput` property to `true`, specify the output data type as one of `logical` | `double`. The default is `double`.

Methods

reset	Reset states of CPM demodulator object
step	Demodulate using CPM method and Viterbi algorithm

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Demodulate a CPM signal with Gray mapping and bit inputs

```
% Create a CPM modulator, an AWGN channel, and a CPM demodulator.
    hMod = comm.CPMModulator(8, 'BitInput', true, ...
                         'SymbolMapping', 'Gray');
    hAWGN = comm.AWGNChannel('NoiseMethod', ...
                         'Signal to noise ratio (SNR)','SNR',0);
    hDemod = comm.CPMDemodulator(8, 'BitOutput', true, ...
                         'SymbolMapping', 'Gray');
% Create an error rate calculator, account for the delay caused by the Viterbi algorithm.
    delay = log2(hDemod.ModulationOrder)*hDemod.TracebackDepth;
    hError = comm.ErrorRate('ReceiveDelay', delay);
    for counter = 1:100
        % Transmit 100 3-bit words
        data = randi([0 1],300,1);
        modSignal = step(hMod, data);
        noisySignal = step(hAWGN, modSignal);
        receivedData = step(hDemod, noisySignal);
        errorStats = step(hError, data, receivedData);
    end
    fprintf('Error rate = %f\nNumber of errors = %d\n', ...
      errorStats(1), errorStats(2))
```

```
Error rate = 0.004006
Number of errors = 120
```

Apply GFSK Modulation and Demodulation

Using the `comm.CPMModulator` and `comm.CPMDemodulator` System objects apply GFSK modulation and demodulation to random bit data.

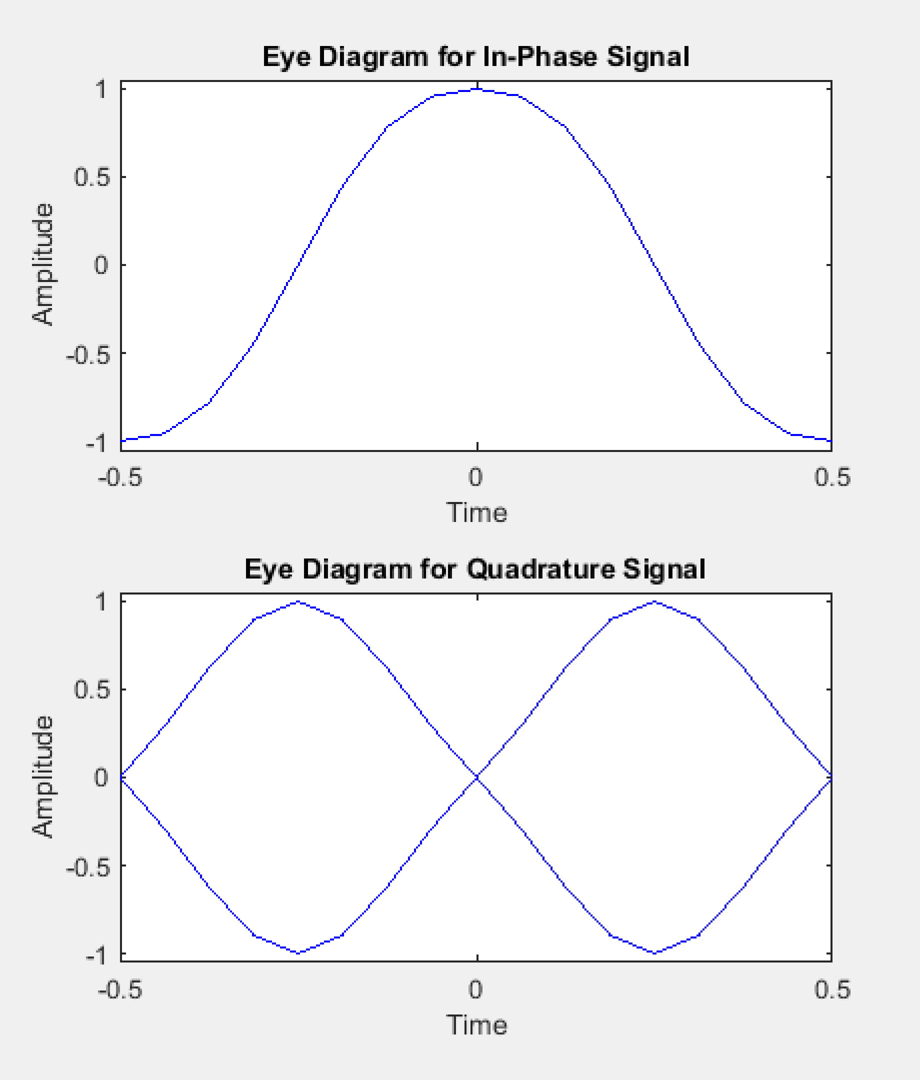
Create a GFSK modulator and demodulator object pair.

```
gfskMod = comm.CPMModulator('ModulationOrder', 2, 'FrequencyPulse', 'Gaussian', ...
               'BandwidthTimeProduct', 0.5, 'ModulationIndex', 1, ...
```

```
                  'BitInput', true);
gfskDemod = comm.CPMDemodulator('ModulationOrder', 2, 'FrequencyPulse', 'Gaussian', ...
                  'BandwidthTimeProduct', 0.5, 'ModulationIndex', 1, ...
                  'BitOutput', true);
```

Generate random bit data and apply GFSK modulation. Use a scatter plot to view the constellation.

```
numSym = 100;
x = randi([0 1],numSym*gfskMod.SamplesPerSymbol,1);
y = gfskMod(x);
eyediagram(y,16)
```



Demodulate the GFSK modulated data. To verify that the demodulated signal data is equal to the original data, you must account for the delay introduced by the Gaussian filtering in the GFSK modulation and demodulation processing.

```
z = gfskDemod(y);
delay = finddelay(x,z);
isequal(x(1:end-delay),z(delay+1:end))
```

```
ans = logical
   1
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the CPM Demodulator Baseband block reference page. The object properties correspond to the block parameters. For CPM the phase shift per symbol is π × *h*, where *h* is the modulation index.

Extended Capabilities

System object: `comm.CPMDemodulator`
Package: `comm`

Reset states of CPM demodulator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `CPMDemodulator` object, `H`.

step

System object: `comm.CPMDemodulator`
Package: `comm`

Demodulate using CPM method and Viterbi algorithm

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates input data, `X`, with the CPM demodulator System object, `H`, and returns `Y`. `X` must be a double or single precision, column vector with a length equal to an integer multiple of the number of samples per symbol specified in the `SamplesPerSymbol` property. Depending on the `BitOutput` property value, output `Y` can be integer or bit valued.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.CPMModulator

Package: `comm`

Modulate using CPM method

Description

The `CPMModulator` object modulates using continuous phase modulation. The output is a baseband representation of the modulated signal.

To modulate a signal using continuous phase modulation:

1. Define and set up your CPM modulator object. See “Construction” on page 3-375.
2. Call `step` to modulate a signal according to the properties of `comm.CPMModulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.CPMModulator` creates a modulator System object, `H`. This object modulates the input signal using the continuous phase modulation (CPM) method.

`H = comm.CPMModulator(Name,Value)` creates a CPM modulator object, `H`. This object has each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.CPMModulator(M,Name,Value)` creates a CPM modulator object, `H`, with the `ModulationOrder` property set to `M` and the other specified properties set to the specified values.

Properties

`ModulationOrder`

Size of symbol alphabet

Specify the size of the symbol alphabet. The value of this property must be a power of two, real, integer scalar. The default is `4`.

`BitInput`

Assume bit inputs

Specify whether the input is bits or integers. The default is `false`.

When you set this property to `false`, the `step` method input requires double-precision or signed integer data type column vector. This vector must comprise odd integer values between –(`ModulationOrder` on page 3-0 –1) and `ModulationOrder`–1.

When you set this property to `true`, the `step` method input requires a column vector of *P*-length bit words, where *P* = **log2**(`ModulationOrder`). The input data must have a double-precision or logical data type. The object maps each bit word to an integer *K* between `0` and `ModulationOrder`–1, using the mapping specified in the `SymbolMapping` on page 3-0 property. The object then maps the integer *K* to the intermediate value 2*K*-(`ModulationOrder`–1) and proceeds as in the case when BitInput is false.

SymbolMapping

Symbol encoding

Specify the mapping of bit inputs as one of `Binary` | `Gray`. The default is `Binary`. This property determines how the object maps each input *P*-length bit word, where *P* = **log2**(`ModulationOrder` on page 3-0), to an integer between 0 and `ModulationOrder`–1.

When you set this property to `Binary`, the object uses a natural binary-coded ordering.

When you set this property to `Gray`, the object uses a Gray-coded ordering.

This property applies when you set the `BitInput` on page 3-0 property to true.

ModulationIndex

Modulation index

Specify the modulation index. The default is `0.5`. The value of this property can be a scalar, h, or a column vector, [h_0, h_1, …. $h_{\mathrm{H-1}}$]

where H-1 represents the length of the column vector. The phase shift over a symbol is π × h.

When h_i varies from interval to interval, the object operates in multi-h. When the object operates in multi-h, h_i must be a rational number.

FrequencyPulse

Frequency pulse shape

Specify the type of pulse shaping that the modulator uses to smooth the phase transitions of the modulated signal. Choose from `Rectangular` | `Raised Cosine` | `Spectral Raised Cosine` | `Gaussian` | `Tamed FM`. The default is `Rectangular`.

MainLobeDuration

Main lobe duration of spectral raised cosine pulse

Specify, in number of symbol intervals, the duration of the largest lobe of the spectral raised cosine pulse. The default is `1`. This property requires a real, positive, integer scalar. This property applies when you set the `FrequencyPulse` on page 3-0 property to `Spectral Raised Cosine`.

RolloffFactor

Rolloff factor of spectral raised cosine pulse

Specify the rolloff factor of the spectral raised cosine pulse. The default is `0.2`. This property requires a real scalar between `0` and `1`. This property applies when you set the `FrequencyPulse` on page 3-0 property to `Spectral Raised Cosine`.

`BandwidthTimeProduct`

Product of bandwidth and symbol time of Gaussian pulse

Specify the product of bandwidth and symbol time for the Gaussian pulse shape. The default is `0.3`. This property requires a real, positive scalar. This property applies when you set the `FrequencyPulse` on page 3-0 property to `Gaussian`.

`PulseLength`

Pulse length

Specify the length of the frequency pulse shape in symbol intervals. The value of this property requires a real, positive integer. The default is `1`.

`SymbolPrehistory`

Symbol prehistory

Specify the data symbols used by the modulator prior to the first call to the `step` method in reverse chronological order. The default is `1`. This property requires a scalar or vector with odd integer elements between –(`ModulationOrder` on page 3-0 –1) and (`ModulationOrder`–1). If the value is a vector, then its length must be one less than the value in the `PulseLength` on page 3-0 property.

`InitialPhaseOffset`

Initial phase offset

Specify the initial phase of the modulated waveform in radians as a real, numeric scalar. The default is `0`.

`SamplesPerSymbol`

Number of samples per output symbol

Specify the upsampling factor at the output as a real, positive, integer scalar. The default is `8`. The upsampling factor is the number of output samples that the `step` method produces for each input sample.

`OutputDataType`

Data type of output

Specify output data type as one of `double` | `single`. The default is `double`.

Methods

reset	Reset states of CPM modulator object
step	Modulate using CPM method

Common to All System Objects	
release	Allow System object property value changes

Examples

Modulate a CPM signal with Gray mapping and bit inputs

```
% Create a CPM modulator, an AWGN channel, and a CPM demodulator.
    hMod = comm.CPMModulator(8, 'BitInput', true, ...
                            'SymbolMapping', 'Gray');
    hAWGN = comm.AWGNChannel('NoiseMethod', ...
                            'Signal to noise ratio (SNR)','SNR',0);
    hDemod = comm.CPMDemodulator(8, 'BitOutput', true, ...
                            'SymbolMapping', 'Gray');
% Create an error rate calculator, account for the delay caused by the Viterbi algorithm.
    delay = log2(hDemod.ModulationOrder)*hDemod.TracebackDepth;
    hError = comm.ErrorRate('ReceiveDelay', delay);
    for counter = 1:100
        % Transmit 100 3-bit words
        data = randi([0 1],300,1);
        modSignal = step(hMod, data);
        noisySignal = step(hAWGN, modSignal);
        receivedData = step(hDemod, noisySignal);
        errorStats = step(hError, data, receivedData);
    end
    fprintf('Error rate = %f\nNumber of errors = %d\n', ...
      errorStats(1), errorStats(2))
```

```
Error rate = 0.004006
Number of errors = 120
```

Apply GFSK Modulation and Demodulation

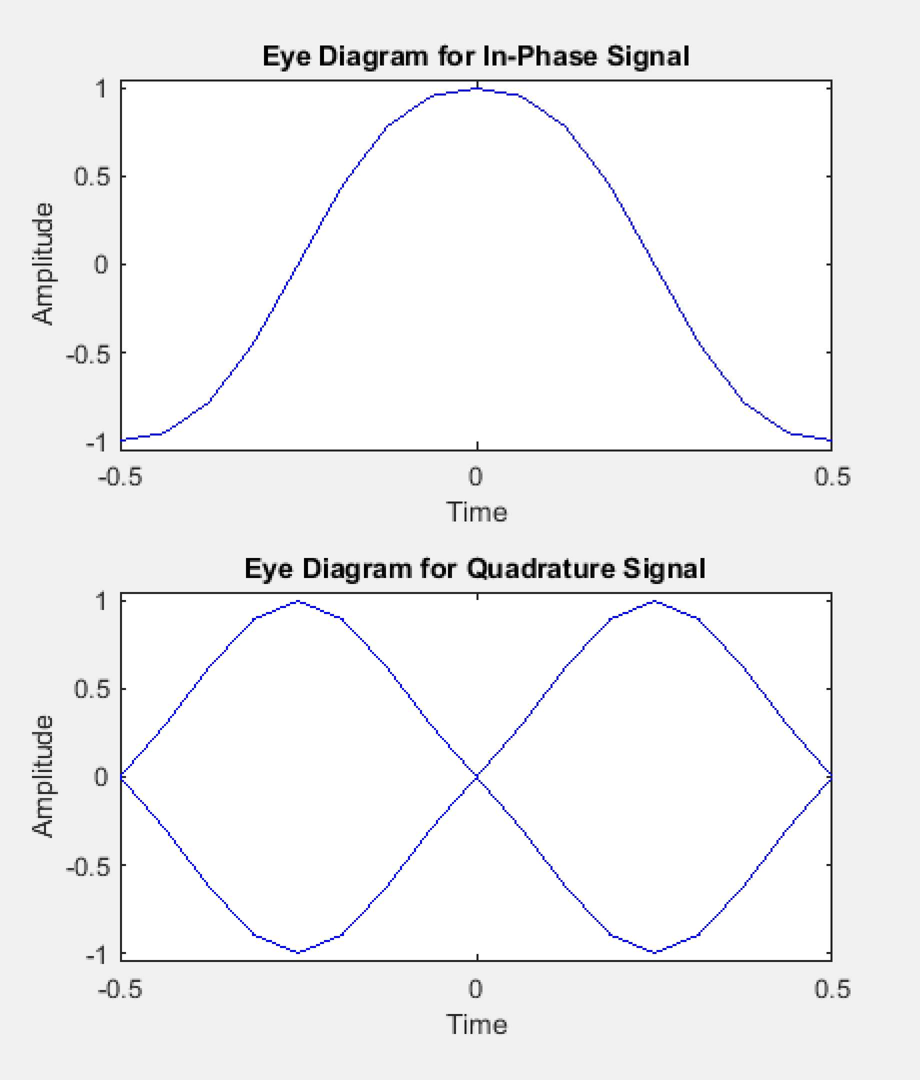
Using the comm.CPMModulator and comm.CPMDemodulator System objects apply GFSK modulation and demodulation to random bit data.

Create a GFSK modulator and demodulator object pair.

```
gfskMod = comm.CPMModulator('ModulationOrder', 2, 'FrequencyPulse', 'Gaussian', ...
               'BandwidthTimeProduct', 0.5, 'ModulationIndex', 1, ...
               'BitInput', true);
gfskDemod = comm.CPMDemodulator('ModulationOrder', 2, 'FrequencyPulse', 'Gaussian', ...
               'BandwidthTimeProduct', 0.5, 'ModulationIndex', 1, ...
               'BitOutput', true);
```

Generate random bit data and apply GFSK modulation. Use a scatter plot to view the constellation.

```
numSym = 100;
x = randi([0 1],numSym*gfskMod.SamplesPerSymbol,1);
y = gfskMod(x);
eyediagram(y,16)
```



Demodulate the GFSK modulated data. To verify that the demodulated signal data is equal to the original data, you must account for the delay introduced by the Gaussian filtering in the GFSK modulation and demodulation processing.

```
z = gfskDemod(y);
delay = finddelay(x,z);
isequal(x(1:end-delay),z(delay+1:end))
```

```
ans = logical
   1
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the CPM Modulator Baseband block reference page. The object properties correspond to the block parameters. For CPM the phase shift per symbol is π × *h*, where *h* is the modulation index.

`comm.CPFSKModulator` | `comm.CPMDemodulator` | `comm.GMSKModulator` | `comm.MSKModulator`

Introduced in R2012a

reset

System object: `comm.CPMModulator`
Package: `comm`

Reset states of CPM modulator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `CPMModulator` object, `H`.

step

System object: `comm.CPMModulator`
Package: `comm`

Modulate using CPM method

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` modulates input data, `X`, with the CPM modulator System object, `H`. It returns the baseband modulated output, `Y`. Depending on the value of the `BitInput` property, input `X` can be an integer or bit valued column vector with data types double, signed integer, or logical. The length of output vector, `Y`, is equal to the number of input samples times the number of samples per symbol specified in the `SamplesPerSymbol` property.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.CRCDetector

Package: comm

Detect errors in input data using CRC

Description

The comm.CRCDetector System object computes cyclic redundancy check (CRC) checksums for an entire received codeword. For successful CRC detection in a communications system link, you must align the property settings of the comm.CRCDetector System object with the paired comm.CRCGenerator System object. For more information, see “CRC Syndrome Detector Operation” on page 3-388.

To detect errors in the received codeword containing CRC sequence bits:

1. Create the comm.CRCDetector object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
crcdetector = comm.CRCDetector
crcdetector = comm.CRCDetector(Name,Value)
crcdetector = comm.CRCDetector(poly,Name,Value)
```

Description

`crcdetector = comm.CRCDetector` creates a CRC code detector System object. This object detects errors in the received codewords according to a specified generator polynomial.

`crcdetector = comm.CRCDetector(Name,Value)` sets properties using one or more name-value pairs. For example, `comm.CRCDetector('Polynomial','z^16 + z^14 + z + 1')` configures the CRC code detector System object to use the CRC-16 cyclic redundancy check bits when checking for CRC code errors in the received codewords. Enclose each property name in quotes.

`crcdetector = comm.CRCDetector(poly,Name,Value)` creates a CRC code detector System object. This object has the `Polynomial` property set to `poly`, and the other specified properties set to the specified values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Polynomial` — Generator polynomial
`'z^16 + z^12 + z^5 + 1'` (default) | polynomial character vector | binary row vector | integer row vector

Generator polynomial for the CRC algorithm, specified as one of the following:

- A polynomial character vector such as `'z^3 + z^2 + 1'`.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power. The length of this vector is (N+1), where N is the degree of the generator polynomial. For example, `[1 1 0 1]` represents the polynomial x^3+ z^2+ 1.
- An integer row vector containing the exponents of z for the nonzero terms in the polynomial in descending order. For example, `[3 2 0]` represents the polynomial $z^3 + z^2 + 1$.

For more information, see “Character Representation of Polynomials”.

Some commonly used generator polynomials include:

CRC method	Generator polynomial
CRC-32	`'z^32 + z^26 + z^23 + z^22 + z^16 + z^12 + z^11 + z^10 + z^8 + z^7 + z^5 + z^4 + z^2 + z + 1'`
CRC-24	`'z^24 + z^23 + z^14 + z^12 + z^8 + 1'`
CRC-16	`'z^16 + z^15 + z^2 + 1'`
Reversed CRC-16	`'z^16 + z^14 + z + 1'`
CRC-8	`'z^8 + z^7 + z^6 + z^4 + z^2 + 1'`
CRC-4	`'z^4 + z^3 + z^2 + z + 1'`

Example: `'z^7 + z^2 + 1'`, `[1 0 0 0 0 1 0 1]`, and `[7 2 0]` represent the same polynomial, $p(z) = z^7 + z^2 + 1$.

Data Types: `double` | `char`

`InitialConditions` — Initial states of internal shift register
`0` (default) | `1` | binary row vector

Initial states of the internal shift register, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial.

Data Types: `logical`

`DirectMethod` — Use direct algorithm for CRC checksum calculations
`false` (default) | `true`

Use direct algorithm for CRC checksum calculations, specified as `false` or `true`.

When you set this property to `true`, the object uses the direct algorithm for CRC checksum calculations. When you set this property to `false`, the object uses the non-direct algorithm for CRC checksum calculations.

For more information on direct and non-direct algorithms, see “Error Detection and Correction”.

Data Types: `logical`

`ReflectInputBytes` — Reflect input bytes

`false` (default) | `true`

Reflect input bytes, specified as `false` or `true`. Set this property to `true` to flip the received codeword on a bytewise basis before entering the data into the shift register.

When you set this property to `true`, the received codeword length divided by the value of the `ChecksumsPerFrame` property must be an integer and a multiple of `8`.

Data Types: `logical`

`ReflectChecksums` — Reflect checksums before final XOR

`false` (default) | `true`

Reflect checksums before final XOR, specified as `false` or `true`. Set this property to `true` to flip the CRC checksums around their centers after the received codeword is completely through the shift register.

When you set this property to `true`, the object flips the CRC checksums around their centers before the final XOR.

Data Types: `logical`

`FinalXOR` — Final XOR

0 (default) | binary scalar | binary vector

Final XOR, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. The XOR operation runs using the value of the `FinalXOR` property and the CRC checksum before comparing with the input checksum. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial. A setting of `0` is equivalent to no XOR operation.

Data Types: `logical`

`ChecksumsPerFrame` — Number of checksums calculated

1 (default) | positive integer

Number of checksums calculated for each received codeword frame, specified as a positive integer. for more information, see “CRC Syndrome Detector Operation” on page 3-388.

Data Types: `double`

Usage

Syntax

```
out = crcdetector(codeword)
[msg,err] = crcdetector(codeword)
```

Description

`out = crcdetector(codeword)` checks CRC code bits for each received codeword frame, removes the checksums, and then concatenates subframes to the output frame.

`[msg,err] = crcdetector(codeword)` also returns the checksum error signal computed when checking CRC code bits for each codeword subframe.

Input Arguments

`codeword` — Received codeword
binary column vector

Received codeword, specified as a binary column vector.

Data Types: `double` | `logical`

Output Arguments

`out` — Output frame
binary column vector

Output frame, returned as a binary column vector that inherits the data type of the input signal. The message word output contains the received codeword with the checksums removed.

The length of the output frame is *n* - *k* * *r* bits, where *n* is the size of the received codeword, *k* is the number of checksums per frame, and *r* is the degree of the generator polynomial.

`err` — Checksum error signal
binary column vector

Checksum error signal, returned as a binary column vector that inherits the data type of the input signal. The length of `Err` equals the value of `ChecksumsPerFrame`. For each checksum computation, an element value of 0 in `err` indicates no checksum error, and an element value of 1 in `err` indicates a checksum error.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

CRC Detection of Errors in a Random Message

Pass binary data through a CRC generator, introduce a bit error, and detect the error using a CRC detector.

Create a random binary vector.

```
x = randi([0 1],12,1);
```

Encode the input message frame using a CRC generator with the `ChecksumsPerFrame` property set to 2. This subdivides the incoming frame into two equal-length subframes.

```
crcgenerator = comm.CRCGenerator([1 0 0 1],'ChecksumsPerFrame',2);
codeword = crcgenerator(x);
```

Decode the codeword and verify that there are no errors in either subframe.

```
crcdetector = comm.CRCDetector([1 0 0 1],'ChecksumsPerFrame',2);
[~, err] = crcdetector(codeword)
```

```
err = 2×1

     0
     0
```

Introduce an error in the second subframe by inverting the last element of subframe 2. Pass the corrupted codeword through the CRC detector and verify that the error is detected in the second subframe.

```
codeword(end) = not(codeword(end));
[~,err] = crcdetector(codeword)
```

```
err = 2×1

     0
     1
```

Cyclic Redundancy Check of Noisy BPSK Data Frames

Use a CRC code to detect frame errors in a noisy BPSK signal.

Create a CRC generator and detector pair using a standard CRC-4 polynomial, $z^4 + z^3 + z^2 + z + 1$.

```
poly = 'z4+z3+z2+z+1';
crcgenerator = comm.CRCGenerator(poly);
crcdetector = comm.CRCDetector(poly);
```

Generate 12-bit frames of binary data and append the CRC bits. Based on the degree of the polynomial, 4 bits are appended to each frame. Apply BPSK modulation and pass the signal through an AWGN channel. Demodulate and use the CRC detector to determine if the frame is in error.

```
numFrames = 20;
frmError = zeros(numFrames,1);
```

```
for k = 1:numFrames
    data = randi([0 1],12,1);                 % Generate binary data
    encData = crcgenerator(data);                   % Append CRC bits
    modData = pskmod(encData,2);              % BPSK modulate
    rxSig = awgn(modData,5);                  % AWGN channel, SNR = 5 dB
    demodData = pskdemod(rxSig,2);            % BPSK demodulate
    [~,frmError(k)] = crcdetector(demodData); % Detect CRC errors
end
```

Identify the frames in which CRC code bit errors are detected.

```
find(frmError)
```

```
ans = 6
```

More About

Cyclic Redundancy Check Coding

Cyclic redundancy check (CRC) coding is an error-control coding technique for detecting errors that occur when a data frame is transmitted. Unlike block or convolutional codes, CRC codes do not have a built-in error-correction capability. Instead, when a communications system detects an error in a received codeword, the receiver requests the sender to retransmit the codeword.

In CRC coding, the transmitter applies a rule to each data frame to create extra CRC bits, called the *checksum* or *syndrome*, and then appends the checksum to the data frame. After receiving a transmitted codeword, the receiver applies the same rule to the received codeword. If the resulting checksum is nonzero, an error has occurred and the transmitter should resend the data frame.

When the number of checksums per frame is greater than 1, the input data frame is divided into subframes, the rule is applied to each data subframe, and individual checksums are appended to each subframe. The subframe codewords are concatenated to output one frame.

For a discussion of the supported CRC algorithms, see “Cyclic Redundancy Check Codes”.

CRC Syndrome Detector Operation

The CRC syndrome detector outputs the received message frame and a checksum error vector according to the specified generator polynomial and number of checksums per frame.

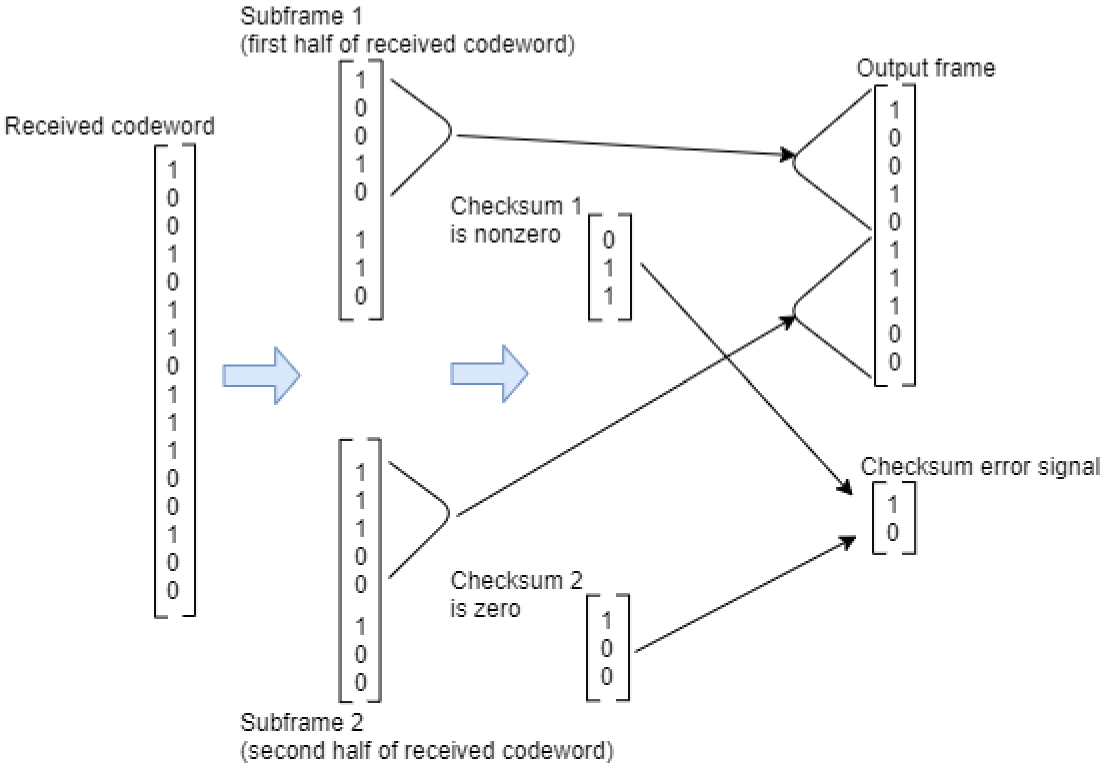
The checksum bits are removed from each subframe, so that the resulting the output frame length is $n - k \times r$, where n is the size of the received codeword, k is the number of checksums per frame, and r is the degree of the generator polynomial. The input frame must be evenly divisible by k.

For a specific initial state of the internal shift register:

1. The received codeword is divided into k equal sized subframes.
2. The CRC is removed from each of the k subframes and compared to the checksum calculated on the received codeword subframes.
3. The output frame is assembled by concatenating the subframe bits of the k subframes and then output as a column vector.

4 The checksum error is output as a binary column vector of length *k*. An element value of 0 indicates an error-free received subframe, and an element value of 1 indicates an error occurred in the received subframe.

For the scenario shown here, a 16-bit codeword is received, a third degree generator polynomial computes the CRC checksum, the initial state is 0, and the number of checksums per frame is 2.



Since the number of checksums per frame is 2 and the generator polynomial degree is 3, the received codeword is split in half and two checksums of size 3 are computed, one for each half of the received codeword. The initial states are not shown, because an initial state of `[0]` does not affect the output of the CRC algorithm. The output frame contains the concatenation of the two halves of the received codeword as a single vector of size 10. The checksum error signal output contains a 2-by-1 binary frame vector whose entries depend on whether the computed checksums are zero. As shown in the figure, the first checksum is nonzero and the second checksum is zero, indicating an error occurred in reception of the first half of the codeword.

comm.CRCGenerator

Package: `comm`

Generate CRC code bits and append to input data

Description

The `comm.CRCGenerator` System object generates cyclic redundancy check (CRC) code bits for each input frame and appends them to the frame. For more information, see "CRC Generator Operation" on page 3-399.

To generate CRC code bits for each input frame and append them to the frame:

1. Create the `comm.CRCGenerator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
crcgenerator = comm.CRCGenerator
crcgenerator = comm.CRCGenerator(Name,Value)
crcgenerator = comm.CRCGenerator(poly,Name,Value)
```

Description

`crcgenerator = comm.CRCGenerator` creates a CRC code generator System object. This object generates CRC bits according to a specified generator polynomial and appends them to the input frame.

`crcgenerator = comm.CRCGenerator(Name,Value)` sets properties using one or more name-value pairs. For example, `comm.CRCGenerator('Polynomial','z^16 + z^14 + z + 1')` configures the CRC generator System object to append CRC-16 cyclic redundancy check bits to the input frame. Enclose each property name in quotes.

`crcgenerator = comm.CRCGenerator(poly,Name,Value)` creates a CRC code generator System object. This object has the `Polynomial` property set to `poly`, and the other specified properties set to the specified values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Polynomial` — Generator polynomial
`'z^16 + z^12 + z^5 + 1'` (default) | polynomial character vector | binary row vector | integer row vector

Generator polynomial for the CRC algorithm, specified as one of the following:

- A polynomial character vector such as `'z^3 + z^2 + 1'`.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power. The length of this vector is (N+1), where N is the degree of the generator polynomial. For example, `[1 1 0 1]` represents the polynomial x^3+ z^2+ 1.
- An integer row vector containing the exponents of z for the nonzero terms in the polynomial in descending order. For example, `[3 2 0]` represents the polynomial $z^3 + z^2 + 1$.

For more information, see "Character Representation of Polynomials".

Some commonly used generator polynomials include:

CRC method	Generator polynomial
CRC-32	`'z^32 + z^26 + z^23 + z^22 + z^16 + z^12 + z^11 + z^10 + z^8 + z^7 + z^5 + z^4 + z^2 + z + 1'`
CRC-24	`'z^24 + z^23 + z^14 + z^12 + z^8 + 1'`
CRC-16	`'z^16 + z^15 + z^2 + 1'`
Reversed CRC-16	`'z^16 + z^14 + z + 1'`
CRC-8	`'z^8 + z^7 + z^6 + z^4 + z^2 + 1'`
CRC-4	`'z^4 + z^3 + z^2 + z + 1'`

Example: `'z^7 + z^2 + 1'`, `[1 0 0 0 0 1 0 1]`, and `[7 2 0]` represent the same polynomial, $p(z) = z^7 + z^2 + 1$.

Data Types: `double` | `char`

`InitialConditions` — Initial states of internal shift register
`0` (default) | `1` | binary row vector

Initial states of the internal shift register, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial.

Data Types: `logical`

`DirectMethod` — Use direct algorithm for CRC checksum calculations
`false` (default) | `true`

Use direct algorithm for CRC checksum calculations, specified as `false` or `true`.

When you set this property to `true`, the object uses the direct algorithm for CRC checksum calculations. When you set this property to `false`, the object uses the non-direct algorithm for CRC checksum calculations.

For more information on direct and non-direct algorithms, see "Error Detection and Correction".

Data Types: `logical`

`ReflectInputBytes` — Reflect input bytes

`false` (default) | `true`

Reflect input bytes, specified as `false` or `true`. Set this property to `true` to flip the input frame on a bytewise basis before entering the data into the shift register.

When you set this property to `true`, the input frame length divided by the value of the `ChecksumsPerFrame` property must be an integer and a multiple of `8`.

Data Types: `logical`

`ReflectChecksums` — Reflect checksums before final XOR

`false` (default) | `true`

Reflect checksums before final XOR, specified as `false` or `true`. Set this property to `true` to flip the CRC checksums around their centers after the input data are completely through the shift register.

Data Types: `logical`

`FinalXOR` — Final XOR

0 (default) | binary scalar | binary vector

Final XOR, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. The XOR operation runs using the value of the `FinalXOR` property and the CRC checksum before comparing with the input checksum. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial. A setting of `0` is equivalent to no XOR operation.

Data Types: `logical`

`ChecksumsPerFrame` — Number of checksums calculated for each frame

1 (default) | positive integer

Number of checksums calculated for each frame, specified as a positive integer. For more information, see "CRC Generator Operation" on page 3-399.

Data Types: `double`

Usage

Syntax

```
codeword = crcgenerator(x)
```

Description

`codeword = crcgenerator(x)` generates CRC code bits for each input frame and appends them to the frame.

Input Arguments

x — Input signal
binary column vector

Input signal, specified as a binary column vector. The length of the input frame must be a multiple of the value of the `ChecksumsPerFrame` property. If the input data type is double, the least significant bit is used as the binary value. For more information, see “CRC Generator Operation” on page 3-399.

Data Types: `double` | `logical`

Output Arguments

`codeword` — Output codeword frame
binary column vector

Output codeword frame, returned as a binary column vector that inherits the data type of the input signal. The output contains the input frames with the CRC code sequence bits appended.

The length of the output codeword frame is $m + k * r$, where m is the size of the input message, k is the number of checksums per input frame, and r is the degree of the generator polynomial. For more information, see “CRC Generator Operation” on page 3-399.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Generate CRC-8 Checksum

Generate a CRC-8 checksum for the example shown in 802.11™-2016[1] on page 3-0 , section 21.3.10.3 and compare with the expected CRC.

Create a CRC Generator System object™. To align with the CRC calculation in 802.11-20016, the System object™ sets the generator polynomial as $z^8 + z^2 + z + 1$, initial states to 1, direct method, and final XOR to 1.

```
crc8 = comm.CRCGenerator('Polynomial','z^8 + z^2 + z + 1', ...
    'InitialConditions',1,'DirectMethod',true,'FinalXOR',1)
```

```
crc8 = 
  comm.CRCGenerator with properties:
```

```
           Polynomial: 'z^8 + z^2 + z + 1'
    InitialConditions: 1
         DirectMethod: true
    ReflectInputBytes: false
     ReflectChecksums: false
             FinalXOR: 1
    ChecksumsPerFrame: 1
```

Process one input frame according to the example from the 802.11-2016 standard in section 21.3.10.3. In the example, the input bit stream {m0, … m22} is {1 0 0 1 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 1} and the expected CRC checksum {c7, … c0} is {0 0 0 1 1 1 0 0}.

```
x = [1 0 0 1 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 1]';
expectedChecksum = [0 0 0 1 1 1 0 0]';
checksumLength = length(expectedChecksum);
```

The generated CRC checksum is compared to the expected checksum.

```
codeword = crc8(x);
checksum = codeword(end-checksumLength+1:end);
isequal(checksum,expectedChecksum)
```

```
ans = logical
   1
```

CRC Detection of Errors in a Random Message

Pass binary data through a CRC generator, introduce a bit error, and detect the error using a CRC detector.

Create a random binary vector.

```
x = randi([0 1],12,1);
```

Encode the input message frame using a CRC generator with the `ChecksumsPerFrame` property set to `2`. This subdivides the incoming frame into two equal-length subframes.

```
crcgenerator = comm.CRCGenerator([1 0 0 1],'ChecksumsPerFrame',2);
codeword = crcgenerator(x);
```

Decode the codeword and verify that there are no errors in either subframe.

```
crcdetector = comm.CRCDetector([1 0 0 1],'ChecksumsPerFrame',2);
[~, err] = crcdetector(codeword)
```

```
err = 2×1

     0
     0
```

Introduce an error in the second subframe by inverting the last element of subframe 2. Pass the corrupted codeword through the CRC detector and verify that the error is detected in the second subframe.

```
codeword(end) = not(codeword(end));
[~,err] = crcdetector(codeword)
```

```
err = 2×1

     0
     1
```

Cyclic Redundancy Check of Noisy BPSK Data Frames

Use a CRC code to detect frame errors in a noisy BPSK signal.

Create a CRC generator and detector pair using a standard CRC-4 polynomial, $z^4 + z^3 + z^2 + z + 1$.

```
poly = 'z4+z3+z2+z+1';
crcgenerator = comm.CRCGenerator(poly);
crcdetector = comm.CRCDetector(poly);
```

Generate 12-bit frames of binary data and append the CRC bits. Based on the degree of the polynomial, 4 bits are appended to each frame. Apply BPSK modulation and pass the signal through an AWGN channel. Demodulate and use the CRC detector to determine if the frame is in error.

```
numFrames = 20;
frmError = zeros(numFrames,1);

for k = 1:numFrames
    data = randi([0 1],12,1);                 % Generate binary data
    encData = crcgenerator(data);                   % Append CRC bits
    modData = pskmod(encData,2);              % BPSK modulate
    rxSig = awgn(modData,5);                  % AWGN channel, SNR = 5 dB
    demodData = pskdemod(rxSig,2);            % BPSK demodulate
    [~,frmError(k)] = crcdetector(demodData); % Detect CRC errors
end
```

Identify the frames in which CRC code bit errors are detected.

```
find(frmError)
```

```
ans = 6
```

CRC-16-CCITT Generator for X.25

Create a CRC-16-CCITT generator as described in Section 2.2.7.4 of ITU-T Recommendation X-25[1] on page 3-0 using the input data and expected frame check sequence (FCS) from Example 2 in Appendix I, I.1.

Create an unnumbered acknowledgement (UA) response frame where address = B and F = 1.

```
Address = [1 0 0 0 0 0 0 0];
UA = [1 1 0 0 1 1 1 0];
input = [Address UA]';
expectedChecksum = [1 1 0 0 0 0 0 1 1 1 1 0 1 0 1 0]'; % Expected FCS
checksumLength = 16;

crcGen = comm.CRCGenerator(...
    'Polynomial','X^16 + X^12 + X^5 + 1',...
    'InitialConditions',1,...
    'DirectMethod',true,...
    'FinalXOR',1);
crcSeq = crcGen(input);
checkSum =  crcSeq(end-checksumLength+1:end);
```

Compare calculated checksum with the expected checksum.

```
isequal(expectedChecksum,checkSum)
```

```
ans = logical
   1
```

CRC-32 Generator for Ethernet

Create a CRC-32 code for the frame check sequence (FCS) field for Ethernet as described in Section 3.2.9 of the IEEE Standard for Ethernet[1] on page 3-0   .

```
rng(1865);  % Seed the random number generator for repeatable results
```

Initialize a message with random data to represent the protected fields of the MAC frame, specifically the destination address, source address, length or type field, MAC client data, and padding.

```
data = randi([0,1],100,1);
```

Specify the CRC-32 generating polynomial used for encoding Ethernet messages.

```
poly = [32,26,23,22,16,12,11,10,8,7,5,4,2,1,0];
```

Calculate the CRC by following the steps specified in the standard and using the nondirect method to generate the CRC code.

```
dataN = [not(data(1:32));data(33:end)];    % Section 3.2.9 step a) and b)
crcGen1 = comm.CRCGenerator(...
    'Polynomial', poly, ...
    'InitialConditions', 0, ...
    'DirectMethod', false, ...
    'FinalXOR', 1);
seq = crcGen1(dataN);                      % Section 3.2.9 step c), d) and e)
csNondirect = seq(end-31:end);
```

Calculate the CRC by following the steps specified in the standard and using the direct method to generate the CRC code.

```
crcGen2 = comm.CRCGenerator(...
    'Polynomial', poly, ...
    'InitialConditions', 1, ...
    'DirectMethod', true, ...
    'FinalXOR', 1);
txSeq = crcGen2(data);
csDirect = txSeq(end-31:end);
```

Compare the generated CRC codes by using the nondirect and direct methods.

```
disp([csNondirect';csDirect']);
```

```
  Columns 1 through 13

     1     1     1     0     1     1     0     0     1     0     0     1     0
     1     1     1     0     1     1     0     0     1     0     0     1     0

More About

Cyclic Redundancy Check Coding

Cyclic redundancy check (CRC) coding is an error-control coding technique for detecting errors that occur when a data frame is transmitted. Unlike block or convolutional codes, CRC codes do not have a built-in error-correction capability. Instead, when a communications system detects an error in a received codeword, the receiver requests the sender to retransmit the codeword.

In CRC coding, the transmitter applies a rule to each data frame to create extra CRC bits, called the *checksum* or *syndrome*, and then appends the checksum to the data frame. After receiving a transmitted codeword, the receiver applies the same rule to the received codeword. If the resulting checksum is nonzero, an error has occurred and the transmitter should resend the data frame.

When the number of checksums per frame is greater than 1, the input data frame is divided into subframes, the rule is applied to each data subframe, and individual checksums are appended to each subframe. The subframe codewords are concatenated to output one frame.

For a discussion of the supported CRC algorithms, see “Cyclic Redundancy Check Codes”.

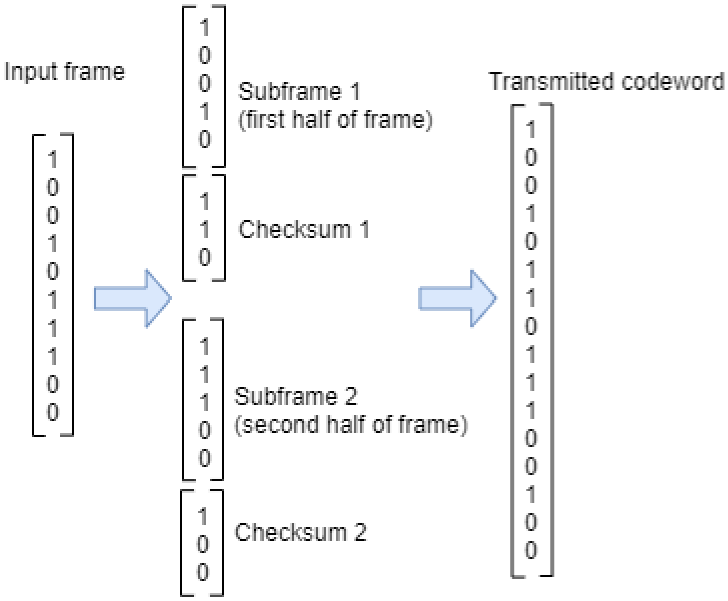
CRC Generator Operation

The CRC generator appends CRC checksums to the input frame according to the specified generator polynomial and number of checksums per frame.

For a specific initial state of the internal shift register and *k* checksums per input frame:

1. The input signal is divided into *k* subframes of equal size.
2. Each of the *k* subframes are prefixed with the initial states vector.
3. The CRC algorithm is applied to each subframe.
4. The resulting checksums are appended to the end of each subframe.
5. The subframes are concatenated and output as a column vector.

For the scenario shown here, a 10-bit frame is input, a third degree generator polynomial computes the CRC checksum, the initial state is 0, and the number of checksums per frame is 2.



The input frame is divided into two subframes of size 5 and checksums of size 3 are computed and appended to each subframe. The initial states are not shown, because an initial state of `[0]` does not affect the output of the CRC algorithm. The output transmitted codeword frame has the size 5 + 3 + 5 + 3 = 16.

comm.DBPSKDemodulator

Package: comm

Demodulate using DBPSK method

Description

The DBPSKDemodulator object demodulates a signal that was modulated using the differential binary phase shift keying method. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using differential binary phase shift keying:

1. Define and set up your DBPSK demodulator object. See “Construction” on page 3-401.
2. Call step to demodulate a signal according to the properties of comm.DBPSKDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.DBPSKDemodulator creates a demodulator System object, H. This object demodulates the input signal using the differential binary phase shift keying (DBPSK) method.

H = comm.DBPSKDemodulator(Name,Value) creates a DBPSK demodulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.DBPSKDemodulator(PHASE,Name,Value) creates a DBPSK demodulator object, H. This object has the PhaseRotation property set to PHASE and the other specified properties set to the specified values.

Properties

PhaseRotation

Additional phase shift

Specify the additional phase difference between previous and current modulated bits in radians as a real scalar. The default is 0. This value corresponds to the phase difference between previous and current modulated bits when the input is zero.

OutputDataType

Data type of output

Specify output data type as one of Full precision | Smallest unsigned integer | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | logical. The default is Full precision. When you set this property to Full precision, the output data type has the same data type as the input. In this case, that value must be a double- or single-precision data type.

Methods

reset	Reset states of DBPSK demodulator object
step	Demodulate using DBPSK method

Common to All System Objects	
release	Allow System object property value changes

Examples

DBPSK Signal in AWGN

Create a DBPSK modulator and demodulator pair.

```
dbpskmod = comm.DBPSKModulator(pi/4);
dpbpskdemod = comm.DBPSKDemodulator(pi/4);
```

Create an error rate calculator. Set the ComputationDelay property to 1 to account for the one bit transient caused by the differential modulation

```
errorRate = comm.ErrorRate('ComputationDelay',1);
```

Main processing loop steps:

- Generate 50-bit frames
- DBPSK modulate
- Pass through AWGN channel
- DBPSK demodulate
- Collect error statistics

```
for counter = 1:100
    txData = randi([0 1],50,1);
    modSig = dbpskmod(txData);
    rxSig = awgn(modSig,7);
    rxData = dpbpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
```

```
ber = 0.0040
```

```
numErrors = errorStats(2)
```

```
numErrors = 20
```

```
numBits = errorStats(3)
numBits = 4999
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the DBPSK Demodulator Baseband block reference page. The object properties correspond to the block parameters.

`comm.DBPSKModulator` | `comm.DQPSKModulator`

Introduced in R2012a

reset

System object: `comm.DBPSKDemodulator`
Package: `comm`

Reset states of DBPSK demodulator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `DBPSKDemodulator` object, `H`.

step

System object: `comm.DBPSKDemodulator`
Package: `comm`

Demodulate using DBPSK method

Syntax

`Y = step(H,X)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates input data, `X`, with the DBPSK demodulator System object, `H`, and returns `Y`. Input `X` must be a double or single precision data type scalar or column vector.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.DBPSKModulator

Package: `comm`

Modulate using DBPSK method

Description

The `DBPSKModulator` object modulates using the differential binary phase shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using differential binary phase shift keying:

1. Define and set up your DBPSK modulator object. See "Construction" on page 3-406.
2. Call `step` to modulate a signal according to the properties of `comm.DBPSKModulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.DBPSKModulator` creates a modulator System object, `H`. This object modulates the input signal using the differential binary phase shift keying (DBPSK) method.

`H = comm.DBPSKModulator(Name,Value)` creates a DBPSK modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.DBPSKModulator(PHASE,Name,Value)` creates a DBPSK modulator object, `H`. This object has the `PhaseRotation` property set to `PHASE`, and the other specified properties set to the specified values.

Properties

`PhaseRotation`

Additional phase shift

Specify the additional phase difference between previous and current modulated bits in radians as a real scalar value. The default is `0`. This value corresponds to the phase difference between previous and current modulated bits when the input is zero.

`OutputDataType`

Data type of output

Specify output data type as one of `double` | `single`. The default is `double`.

Methods

reset	Reset states of DBPSK modulator object
step	Modulate using DBPSK method

Common to All System Objects	
release	Allow System object property value changes

Examples

DBPSK Signal in AWGN

Create a DBPSK modulator and demodulator pair.

```
dbpskmod = comm.DBPSKModulator(pi/4);
dpbpskdemod = comm.DBPSKDemodulator(pi/4);
```

Create an error rate calculator. Set the `ComputationDelay` property to `1` to account for the one bit transient caused by the differential modulation

```
errorRate = comm.ErrorRate('ComputationDelay',1);
```

Main processing loop steps:

- Generate 50-bit frames
- DBPSK modulate
- Pass through AWGN channel
- DBPSK demodulate
- Collect error statistics

```
for counter = 1:100
    txData = randi([0 1],50,1);
    modSig = dbpskmod(txData);
    rxSig = awgn(modSig,7);
    rxData = dpbpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
```

```
ber = 0.0040
```

```
numErrors = errorStats(2)
```

```
numErrors = 20
```

```
numBits = errorStats(3)
```

```
numBits = 4999
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the DBPSK Modulator Baseband block reference page. The object properties correspond to the block parameters.

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `DBPSKModulator` object, `H`.

step

System object: `comm.DBPSKModulator`
Package: `comm`

Modulate using DBPSK method

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` modulates input data, `X`, with the DBPSK modulator System object, `H`. It returns the baseband modulated output, `Y`. The input must be a numeric or logical data type column vector of bits.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.Descrambler

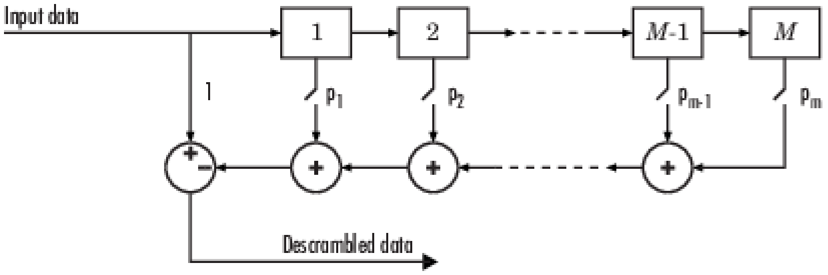
Package: `comm`

Descramble input signal

Description

The comm.Descrambler object descrambles a scalar or column vector input signal. The comm.Descrambler object is the inverse of the `comm.Scrambler` object. If you use the `comm.Scrambler` object in a transmitter, then you use the comm.Descrambler object in the related receiver.

This schematic shows the descrambler operation. The adders and subtracter operate modulo *N*, where *N* is the value specified by the Calculation base property.



At each time step, the input causes the contents of the registers to shift sequentially. Using the Polynomial property, you specify the on or off state for each switch in the descrambler. To make the `comm.Descrambler` object reverse the operation of the `comm.Scrambler` object, use the same property settings in both objects. If there is no signal delay between the scrambler and the descrambler, then the InitialConditions in the two objects must be the same.

To descramble an input signal:

1. Create the `comm.Descrambler` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
descrambler = comm.Descrambler
descrambler = comm.Descrambler(base,poly,cond)
descrambler = comm.Descrambler(___,Name,Value)
```

Description

`descrambler = comm.Descrambler` creates a descrambler System object. This object descrambles the input data by using a linear feedback shift register that you specify with the Polynomial property.

`descrambler = comm.Descrambler(base,poly,cond)` creates the descrambler object with the CalculationBase property set to `base`, the Polynomial property set to `poly`, and the InitialConditions property set to `cond`.

Example: `comm.Descrambler(8,'1 + z^-2 + z^-3 + z^-5 + z^-7',[0 3 2 2 5 1 7])` sets the calculation base to `8`, and the descrambler polynomial and initial conditions as specified.

`descrambler = comm.Descrambler(___,Name,Value)` sets properties using one or more name-value pairs and either of the previous syntaxes. Enclose each property name in single quotes.

Example: `comm.Descrambler('CalculationBase',2)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`CalculationBase` — Range of input data

4 (default) | nonnegative integer

Range of input data used in the descrambler for modulo operations, specified as a nonnegative integer. The input and output of this object are integers from `0` to `CalculationBase – 1`.

Data Types: `double`

`Polynomial` — Connections for linear feedback shift registers

`'1 + z^-1 + z^-2 + z^-4'` (default) | character vector | integer vector | binary vector

Connections for linear feedback shift registers in the descrambler, specified as a character vector, integer vector, or binary vector. The `Polynomial` property defines if each switch in the descrambler is on or off. Specify the polynomial as:

- A character vector, such as `'1 + z^-6 + z^-8'`. For more details on specifying polynomials in this way, see Character Representation of Polynomials.
- An integer vector, such as `[0 -6 -8]`, listing the descrambler coefficients in order of descending powers of z^{-1}, where $p(z^{-1}) = 1 + p_1z^{-1} + p_2z^{-2} + ...$
- A binary vector, such as `[1 0 0 0 0 0 1 0 1]`, listing the powers of z that appear in the polynomial that have a coefficient of 1. In this case, the order of the descramble polynomial is one less than the binary vector length.

Example: `'1 + z^-6 + z^-8'`, `[0 -6 -8]`, and `[1 0 0 0 0 0 1 0 1]` all represent this polynomial:

$p(z^{-1}) = 1 + z^{-6} + z^{-8}$

Data Types: `double` | `char`

`InitialConditionsSource` — Initial conditions source

`'Property'` (default) | `'Input port'`

- `'Property'` – Specify descrambler initial conditions by using the InitialConditions property.
- `'Input port'` – Specify descrambler initial conditions by using an additional input argument, initcond, when calling the object.

Data Types: `char`

`InitialConditions` — Initial conditions of descrambler registers

`[0 1 2 3]` (default) | nonnegative integer vector

Initial conditions of descrambler registers when the simulation starts, specified as a nonnegative integer vector. The length of `InitialConditions` must equal the order of the Polynomial property. The vector element values must be integers from `0` to CalculationBase – `1`.

Dependencies

This property is available when InitialConditionsSource is set to `'Property'`.

`ResetInputPort` — Descrambler state reset port

`false` (default) | `true`

Descrambler state reset port, specified as `false` or `true`. If `ResetInputPort` is `true`, you can reset the descrambler object by using an additional input argument, reset, when calling the object.

Dependencies

This property is available when InitialConditionsSource is set to `'Property'`.

Usage

Syntax

```
descrambledOut = descrambler(signal)
descrambledOut = descrambler(signal,initcond)
descrambledOut = descrambler(signal,reset)
```

Description

`descrambledOut = descrambler(signal)` descrambles the input signal. The output is the same data type and length as the input vector.

`descrambledOut = descrambler(signal,initcond)`provides an additional input with values specifying the initial conditions of the linear feedback shift register.

This syntax applies when you set the InitialConditionsSource property of the object to `'Input port'`.

`descrambledOut = descrambler(signal,reset)` provides an additional input indicating whether to reset the state of the descrambler.

This syntax applies when you set the InitialConditionsSource property of the object to `'Property'` and the ResetInputPort to `true`.

Input Arguments

`signal` — Input signal
column vector

Input signal, specified as a column vector.

Example: `descrambledOut = descrambler([0 1 1 0 1 0])`

Data Types: `double` | `logical`

`initcond` — Initial register condition
nonnegative integer column vector

Initial descrambler register conditions when the simulation starts, specified as a nonnegative integer column vector. The length of `initcond` must equal the order of the Polynomial property. The vector element values must be integers from `0` to CalculationBase – `1`.

Example: `descrambledOut = descrambler(signal,[0 1 1 0])` corresponds to possible initial register states for a descrambler with a polynomial order of 4 and a calculation base of 2 or higher.

Data Types: `double`

`reset` — Reset initial state of descrambler
scalar

Reset initial state of the descrambler when the simulation starts, specified as a scalar. When the value of `reset` is nonzero, the object is reset before it is called.

Example: `descrambledOut = descrambler(signal,0)` descrambles the input signal without resetting the descrambler states.

Data Types: `double`

Output Arguments

`out` — Descrambled output
column vector

Descrambled output, returned as a column vector with the same data type and length as signal.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Scramble and Descramble Data

Scramble and descramble 8-ary data using `comm.Scrambler` and `comm.Descrambler` System objects™ having a calculation base of 8.

Create scrambler and descrambler objects, specifying the calculation base, polynomial, and initial conditions using input arguments. The scrambler and descrambler polynomials are specified with different but equivalent data formats.

```
N = 8;
scrambler = comm.Scrambler(N,'1 + z^-2 + z^-3 + z^-5 + z^-7', ...
    [0 3 2 2 5 1 7]);
descrambler = comm.Descrambler(N,[1 0 1 1 0 1 0 1], ...
    [0 3 2 2 5 1 7]);
```

Scramble and descramble random integers. Display the original data, scrambled data, and descrambled data sequences.

```
data = randi([0 N-1],5,1);
scrData = scrambler(data);
deScrData = descrambler(scrData);
[data scrData deScrData]
```

```
ans = 5×3

     6     7     6
     7     5     7
     1     7     1
     7     0     7
     5     3     5
```

Verify that the descrambled data matches the original data.

```
isequal(data,deScrData)
```

```
ans = logical
   1
```

Scramble and Descramble Data with Changing Initial Conditions

Scramble and descramble quaternary data while changing the initial conditions between function calls.

Create scrambler and descrambler System objects having a calculation base of 4. Set the `InitialConditionsSource` property to `'Input port'` so you can set the initial conditions as an argument to the object.

```
N = 4;
scrambler = comm.Scrambler(N,'1 + z^-3','InitialConditionsSource','Input port');
descrambler = comm.Descrambler(N,'1 + z^-3','InitialConditionsSource','Input port');
```

Preallocate memory for the error vector which will be used to store errors output by the `symerr` function.

```
errVec = zeros(10,1);
```

Scramble and descramble random integers while changing the initial conditions, `initCond`, each time the loop executes. Use the `symerr` function to determine if the scrambling and descrambling operations result in symbol errors.

```
for k = 1:10
    initCond = randperm(3)';
    data = randi([0 N-1],5,1);
    scrData = scrambler(data,initCond);
    deScrData = descrambler(scrData,initCond);
    errVec(k) = symerr(data,deScrData);
end
```

Examine `errVec` to verify that the output from the descrambler matches the original data.

```
errVec
```

```
errVec = 10×1

Blocks

Descrambler

Introduced in R2012a

comm.DifferentialDecoder

Package: `comm`

Decode binary signal using differential decoding

Description

The `DifferentialDecoder` object decodes the binary input signal. The output is the logical difference between the consecutive input element within a channel.

To decode a binary signal using differential decoding:

1. Define and set up your differential decoder object. See “Construction” on page 3-417.
2. Call `step` to decode a binary signal according to the properties of `comm.DifferentialDecoder`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.DifferentialDecoder` creates a differential decoder System object, `H`. This object decodes a binary input signal that was previously encoded using a differential encoder.

`H = comm.DifferentialDecoder(Name,Value)` creates object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`InitialCondition`

Initial value used to generate initial output

Specify the initial condition as a real scalar. This property can have a logical, numeric, or fixed-point (embedded.fi object) data type. The default is `0`. The object treats nonbinary values as binary signals.

Methods

reset	Reset states of differential decoder object
step	Decode binary signal using differential decoding

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Decode Differentially Encoded Signal

Create a differential encoder and decoder pair.

```
diffEnc = comm.DifferentialEncoder;
diffDec = comm.DifferentialDecoder;
```

Generate random binary data. Differentially encode and decode the data.

```
data = randi([0 1],100,1);
encData = diffEnc(data);
decData = diffDec(encData);
```

Determine the number of errors between the original data and the decoded data.

```
numErrors = biterr(data,decData)
```

```
numErrors = 0
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Differential Decoder block reference page. The object properties correspond to the block parameters, except:
The object only supports single channel, column vector inputs.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

`comm.DifferentialEncoder`

Introduced in R2012a

reset

System object: `comm.DifferentialDecoder`
Package: `comm`

Reset states of differential decoder object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `DifferentialDecoder` object, `H`.

step

System object: `comm.DifferentialDecoder`
Package: `comm`

Decode binary signal using differential decoding

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` decodes the differentially encoded input data, `X`, and returns the decoded data, `Y`. The input `X` must be a column vector of data type logical, numeric, or fixed-point (embedded.fi objects). `Y` has the same data type as `X`. The object treats non-binary inputs as binary signals. The object computes the initial output value by performing an Xor operation of the value in the `InitialCondition` property and the first element of the vector you input the first time you call the step method.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.DifferentialEncoder

Package: comm

Encode binary signal using differential coding

Description

The DifferentialEncoder object encodes the binary input signal within a channel. The output is the logical difference between the current input element and the previous output element.

To encode a binary signal using differential coding:

1. Define and set up your differential encoder object. See "Construction" on page 3-421.
2. Call step to encode a binary signal according to the properties of comm.DifferentialEncoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.DifferentialEncoder creates a differential encoder System object, H. This object encodes a binary input signal by calculating its logical difference with the previously encoded data.

H = comm.DifferentialEncoder(Name,Value) creates object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

InitialCondition

Initial value used to generate initial output

Specify the initial condition as a real scalar. This property can have a logical, numeric, or fixed-point (embedded.fi object) data type. The default is 0. The object treats nonbinary values as binary signals.

Methods

reset	Reset states of differential encoder object
step	Encode binary signal using differential coding

Common to All System Objects

step

System object: comm.DifferentialEncoder
Package: comm

Encode binary signal using differential coding

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Y = step(H,X) encodes the binary input data, X, and returns the differentially encoded data, Y. The input X must be a column vector of data type logical, numeric, or fixed-point (embedded.fi objects). Y has the same data type as X. The object treats non-binary inputs as binary signals. The object computes the initial output value by performing an Xor operation of the value in the InitialCondition property and the first element of the vector you input the first time you call the step method.

Note obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

comm.DiscreteTimeVCO

Package: `comm`

Generate variable frequency sinusoid

Description

The `DiscreteTimeVCO` (voltage-controlled oscillator) object generates a signal whose frequency shift from the quiescent frequency property is proportional to the input signal. The input signal is interpreted as a voltage.

To generate a variable frequency sinusoid:

1. Define and set up your discrete time voltage-controlled oscillator object. See "Construction" on page 3-425 .
2. Call `step` to generate a variable frequency sinusoid according to the properties of `comm.DiscreteTimeVCO`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.DiscreteTimeVCO` creates a discrete-time voltage-controlled oscillator (VCO) System object, `H`. This object generates a sinusoidal signal with the frequency shifted from the specified quiescent frequency to a value proportional to the input signal.

`H = comm.DiscreteTimeVCO(Name,Value)` creates a discrete-time VCO object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`OutputAmplitude`

Amplitude of output signal

Specify the amplitude of the output signal as a double- or single-precision, scalar value. The default is `1`. This property is tunable.

`QuiescentFrequency`

Frequency of output signal when input is zero

Specify the quiescent frequency of the output signal in Hertz, as a double- or single-precision, real, scalar value. The default is `10`. This property is tunable.

`Sensitivity`

Sensitivity of frequency shift of output signal

Specify the sensitivity of the output signal frequency shift to the input as a double- or single-precision, real, scalar value. The default is `1`. This value scales the input voltage and, consequently, the shift from the quiescent frequency value. The property measures Sensitivity in Hertz per volt. This property is tunable.

`InitialPhase`

Initial phase of output signal

Specify the initial phase of the output signal, in radians, as a double or single precision, real, scalar value. The default is `0`.

`SampleRate`

Sample rate of input

Specify the sample rate of the input, in Hertz, as a double- or single-precision, positive, scalar value. The default is `100`.

Methods

reset	Reset states of discrete-time VCO object
step	Generate variable frequency sinusoid

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Generate FSK Signal Using Discrete Time VCO

Create a signal source System object™.

```
reader = dsp.SignalSource;
```

Generate random data and apply rectangular pulse shaping.

```
reader.Signal = randi([0 7],10,1);
reader.Signal = rectpulse(reader.Signal,100);
```

Create a signal logger and discrete time VCO System objects.

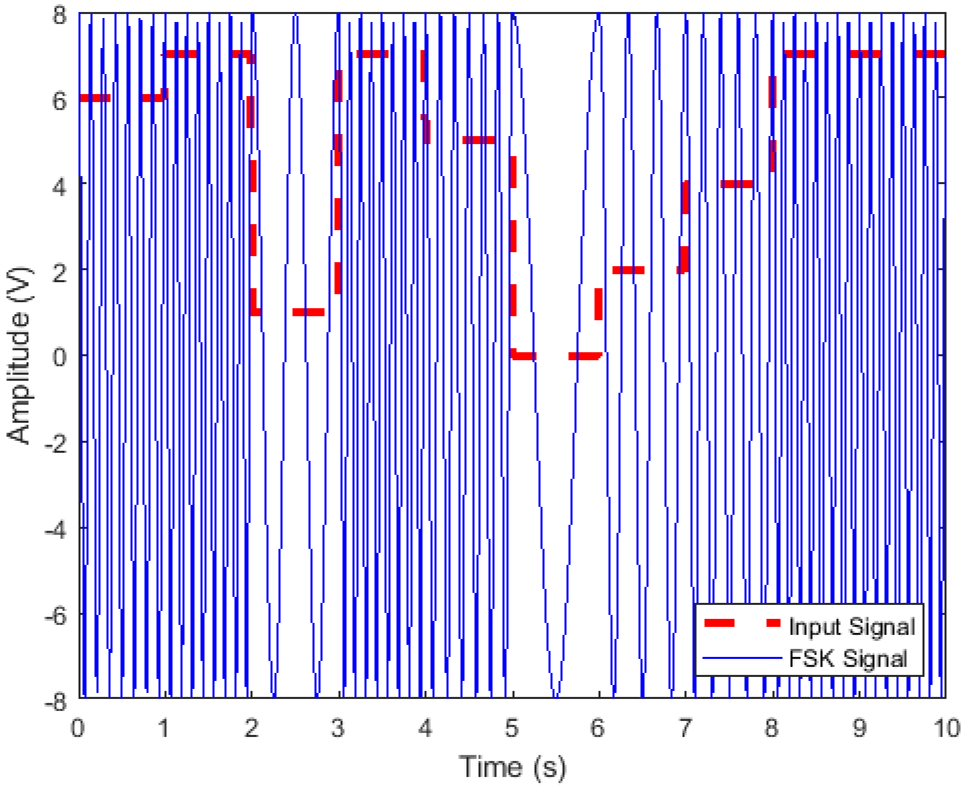
```
logger = dsp.SignalSink;
discreteVCO = comm.DiscreteTimeVCO('OutputAmplitude',8,'QuiescentFrequency',1);
```

Generate an FSK signal.

```
while(~isDone(reader))
    sig = reader();
    y = discreteVCO(sig);
    logger(y);
end
oscsig = logger.Buffer;
```

Plot the generated FSK signal.

```
t = (0:length(oscsig)-1)'/discreteVCO.SampleRate;
plot(t,reader.Signal,'--r', 'LineWidth',3)
hold on
plot(t,oscsig,'-b');
hold off
xlabel('Time (s)')
ylabel('Amplitude (V)')
legend('Input Signal','FSK Signal','location','se')
```



Algorithms

This object implements the algorithm, inputs, and outputs as described on the Discrete-Time VCO block reference page. However, this object and the corresponding block may not generate the exact same outputs for single-precision inputs or property values due to the following differences in casting strategies and arithmetic precision issues:

- The block always casts the result of intermediate mathematical operations to the input data type. The object does not cast intermediate results and MATLAB decides the data type. The object casts the final output to the input data type.

- You can specify the `SampleRate` object property in single-precision or double-precision. The block does not allow this.
- In arithmetic operations with more than two operands with mixed data types, the result may differ depending on the order of operation. Thus, the following calculation may also contribute to the difference in the output of the block and the object:

  input * sensitivity * `sampleTime`
- The block performs this calculation from left to right. However, since sensitivity * `sampleTime` is a one-time calculation, the object calculates this in the following manner:

  input * (sensitivity * `sampleTime`)

Extended Capabilities

`comm.CarrierSynchronizer`

Introduced in R2012a

reset

System object: `comm.DiscreteTimeVCO`
Package: `comm`

Reset states of discrete-time VCO object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `DiscreteTimeVCO` object, `H`.

step

System object: `comm.DiscreteTimeVCO`
Package: `comm`

Generate variable frequency sinusoid

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` generates a sinusoidal signal, `Y`, with frequency shifted, from the value you specify in the `QuiescentFrequency` property, to a value proportional to the input signal, `X`. The input, `X`, must be a double or single precision, real, scalar value. The output, `Y`, has the same data type and size as the input, `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.DPD

Package: `comm`

Digital predistorter

Description

The `comm.DPD` System object applies digital predistortion (DPD) to a complex baseband signal by using a memory polynomial to compensate for nonlinearities in a power amplifier. For more information, see “Digital Predistortion” on page 3-435.

To predistort signals:

1. Create the `comm.DPD` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
dpd = comm.DPD
dpd = comm.DPD(Name,Value)
```

Description

`dpd = comm.DPD` creates a digital predistorter System object to predistort a signal.

`dpd = comm.DPD(Name,Value)` sets properties using one or more name-value pairs. For example, `comm.DPD('PolynomialType','Cross-term memory polynomial')` configures the predistorter System object to predistort the input signal by using a memory polynomial with cross terms. Enclose each property name in quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`PolynomialType` — Polynomial type
`'Memory polynomial'` (default) | `'Cross-term memory polynomial'`

Polynomial type used for predistortion, specified as one of these values:

- `'Memory polynomial'` — Predistorts the input signal by using a memory polynomial without cross terms.
- `'Cross-term memory polynomial'` — Predistorts the input signal by using a memory polynomial with cross terms.

For more information, see “Digital Predistortion” on page 3-435.

`Coefficients` — Memory-polynomial coefficients
`complex([1 0 0 0 0; 0 0 0 0 0; 0 0 0 0 0])` (default) | matrix

Memory-polynomial coefficients, specified as a matrix. The number of rows in the matrix must equal the memory depth of the memory polynomial.

- If `PolynomialType` is `'Memory polynomial'`, the number of columns in the matrix is the degree of the memory polynomial.
- If `PolynomialType` is `'Cross-term memory polynomial'`, the number of columns in the matrix must equal $m(n\text{-}1)+1$. m is the memory depth of the polynomial, and n is the degree of the memory polynomial.

For more information, see “Digital Predistortion” on page 3-435.

Data Types: `double`
Complex Number Support: Yes

Usage

Syntax

`out = dpd(in)`

Description

`out = dpd(in)` predistorts a complex baseband signal by using a memory polynomial to compensate for nonlinearities in a power amplifier.

Input Arguments

`in` — Input baseband signal
column vector

Input baseband signal, specified as a column vector.

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`out` — Predistorted baseband signal
column vector

Predistorted baseband signal, returned as a column vector of the same length as the input signal.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```
