Examples

Predistort Power Amplifier Input Signal

Apply digital predistortion (DPD) to a power amplifier input signal. The DPD coefficient estimator System object uses a captured signal containing power amplifier input and output signals to determine the predistortion coefficient matrix.

Load a file containing the input and output signals for the power amplifier.

```
load('commpowamp_dpd_data.mat','PA_input','PA_output')
```

Generate a DPD coefficient estimator System object and a raised cosine transmit filter System object.

```
estimator = comm.DPDCoefficientEstimator( ...
    'DesiredAmplitudeGaindB',10, ...
    'PolynomialType','Memory polynomial', ...
    'Degree',5,'MemoryDepth',3,'Algorithm','Least squares');

rctFilt = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',2);
```

Estimate the digital predistortion memory-polynomial coefficients.

```
coef = estimator(PA_input,PA_output);
```

Generate a DPD System object using `coef`, the estimated coefficients output from the DPD coefficient estimator, as for the coefficient matrix.

```
dpd = comm.DPD('PolynomialType','Memory polynomial', ...
    'Coefficients',coef);
```

Generate 2000 random symbols and apply 16-QAM modulation to the signal. Apply raised cosine transmit filtering to the modulated signal.

```
s = randi([0,15],2000,1);
u = qammod(s,16);
x = rctFilt(u);
```

Apply digital predistortion to the data. The DPD System object returns a predistorted signal to provide as input to the power amplifier.

```
y = dpd(x);
```

Format of Coefficient Matrix for Digital Predistortion Memory Polynomial

This examples shows the format of the coefficient matrix for the DPD memory polynomial by using a randomly generated coefficient matrix. The example:

- Creates a digital predistortion System object configured using a memory polynomial coefficient matrix with the memory depth set to 3 and the polynomial degree set to 5 consisting of random values.
- Predistorts a signal using the memory-polynomial coefficient matrix.
- Compares one predistorted output element to the corresponding input element that has been manually computed using the memory-polynomial coefficient matrix.

Create a coefficient matrix representing a predistorter with the output equal to the input by generating a 3-by-5 coefficient matrix of zeros and setting the `coef(1,1)` element to `1`. Add small random complex nonlinear terms to the coefficient matrix.

```
coef = zeros(3,5);
coef(1,1) = 1;
coef = coef + 0.01*(randn(3,5)+1j*randn(3,5));
```

Create a DPD System object using the memory polynomial coefficient matrix, `coef`.

```
dpd = comm.DPD('PolynomialType','Memory polynomial','Coefficients',coef);
```

Generate an input signal and predistort it using the `dpd` System object.

```
x = randn(20,1) + 1j*randn(20,1);
y = dpd(x);
```

Compare the manually distorted output for an input corresponding output element `y(18)` to show how the coefficient matrix is used to calculate that particular output value.

```
u = x(18:-1:(18-3+1));
isequal(y(18),sum(sum(coef.*[u u.*abs(u) u.*(abs(u).^2) u.*(abs(u).^3) u.*(abs(u).^4)])))
```

```
ans = logical
   1
```

Format of Cross-Term Coefficient Matrix for Digital Predistortion Memory Polynomial

This examples shows the format of the coefficient matrix for the DPD memory polynomial by using a randomly generated coefficient matrix. The example:

- Creates a digital predistorter System object configured using a cross-term memory polynomial coefficient matrix with the memory depth set to 3 and the polynomial degree set to 5 consisting of random values.
- Predistorts a signal using the cross-term memory polynomial coefficient matrix.
- Compares one predistorted output element to the corresponding input element that has been manually computed using the cross-term memory polynomial coefficient matrix.

Create a coefficient matrix representing a predistorter with the output equal to the input by generating a 3-by-5 coefficient matrix of zeros and setting the `coef(1,1)` element to `1`. Add small random complex nonlinear terms to the coefficient matrix.

```
coef = zeros(3,3*(5-1)+1);
coef(1,1) = 1;
coef = coef + 0.01*(randn(3,13) + 1j*randn(3,13));
```

Create a DPD System object using the cross-term memory polynomial coefficient matrix, `coef`.

```
dpd = comm.DPD('PolynomialType','Cross-term memory polynomial','Coefficients',coef);
```

Generate an input signal and predistort it using the `dpd` System object.

```
x = randn(20,1) + 1j*randn(20,1);
y = dpd(x);
```

Compare the manually distorted output for an input corresponding output element `y(18)` to show how the coefficient matrix is used to calculate that particular output value.

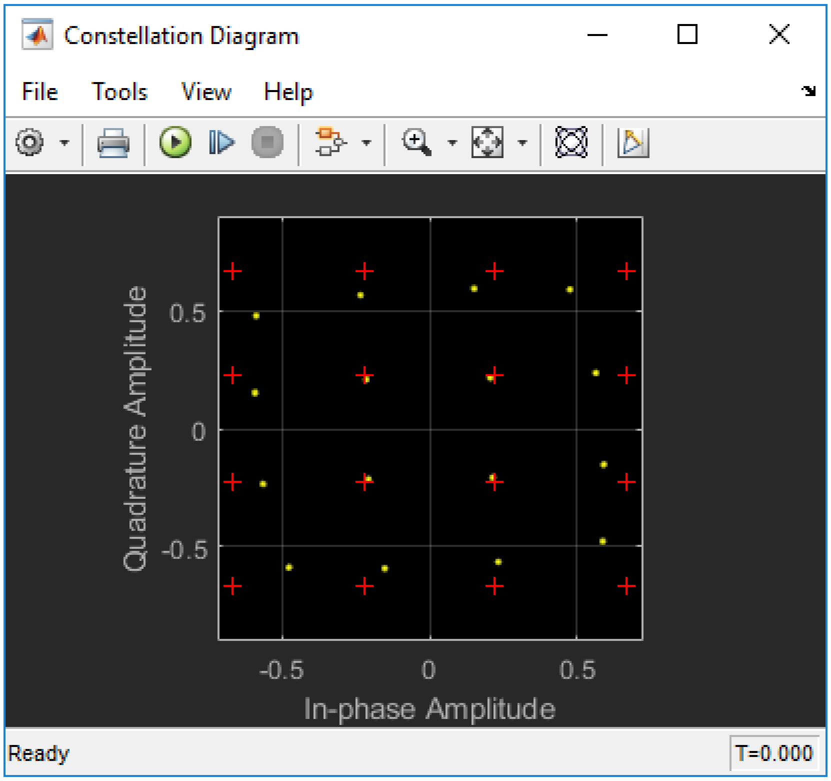
```
u = x(18:-1:(18-3+1));
isequal(y(18),sum(sum(coef.*[u u*abs(u.') u*(abs(u.').^2) u*(abs(u.').^3) u*(abs(u.').^4)])))
```

```
ans = logical
   1
```

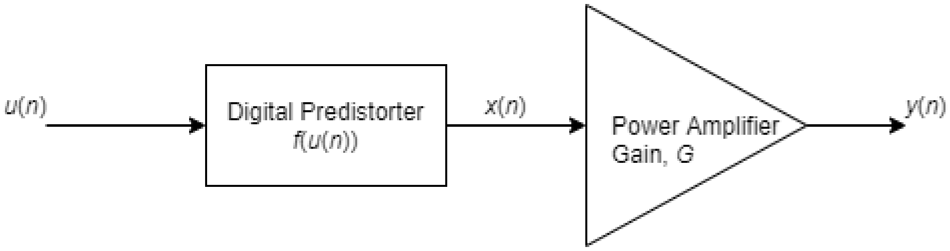
More About

Digital Predistortion

Wireless communication transmissions commonly require wide bandwidth signal transmission over a wide signal dynamic range. To transmit signals over a wide dynamic range and achieve high efficiency, RF power amplifiers (PAs) commonly operate in their nonlinear region. As this constellation diagram shows, the nonlinear behavior of a PA causes signal constellation distortions that pinch the amplitude (AM-AM distortion) and twist phase (AM-PM distortion) of constellation points proportional to the amplitude of the constellation point.



The goal of digital predistortion is to find a nonlinear function that linearizes the net effect of the PA nonlinear behavior at the PA output across the PA operating range. When the PA input is $x(n)$, and the predistortion function is $f(u(n))$, where $u(n)$ is the true signal to be amplified, the PA output is approximately equal to $G{\times}u(n)$, where G is the desired amplitude gain of the PA.



The digital predistorter can be configured to use a memory polynomial with or without cross terms.

- The memory polynomial with cross terms predistorts the input signal as

$$x(n) = f(u(n)) \triangleq \sum_{m=0}^{M-1} c_m \times u(n\text{-}m) + \sum_{m=0}^{M-1} \sum_{j=0}^{M-1} \sum_{k=0}^{K-1} a_{mjk} \times u(n\text{-}m) \times \left|u(n\text{-}j)\right|^k .$$

  The memory polynomial with cross terms has $(M{+}M{\times}M{\times}(K\text{-}1))$ coefficients for c_m and a_{mjk}.
- The memory polynomial without cross terms predistorts the input signal as

$$x(n) = f(u(n)) \triangleq \sum_{m=0}^{M-1} \sum_{k=0}^{K-1} a_{mk} \times u(n\text{-}m) \times \left|u(n\text{-}m)\right|^k .$$

The polynomial without cross terms has $M \times K$ coefficients for a_{mk}.

Estimating Predistortion Function and Coefficients

The DPD coefficient estimation uses an indirect learning architecture to find function $f(u(n))$ to predistort input signal $u(n)$ which precedes the PA input.

The DPD coefficient estimation algorithm models nonlinear PA memory effects based on the work in reference papers by Morgan, et al [1], and by Schetzen [2], using the theoretical foundation developed for Volterra systems.

Specifically, the inverse mapping from the PA output normalized by the PA gain, $\{y(n)/G\}$, to the PA input, $\{x(n)\}$, provides a good approximation to the function $f(u(n))$, needed to predistort $\{u(n)\}$ to produce $\{x(n)\}$.

Referring to the memory polynomial equations above, estimates are computed for the memory-polynomial coefficients:

- c_m and a_{mjk} for a memory polynomial with cross terms
- a_{mk} for a memory polynomial without cross terms

The memory-polynomial coefficients are estimated by using a least squares fit algorithm or a recursive least squares algorithm. The least squares fit algorithm or a recursive least squares algorithms use the memory polynomial equations above for a memory polynomial with or without cross terms, by replacing $\{u(n)\}$ with $\{y(n)/G\}$. The function order and dimension of the coefficient matrix are defined by the degree and depth of the memory polynomial.

For an example that details the process of accurately estimating memory-polynomial coefficients and predistorting a PA input signal, see “Digital Predistortion to Compensate for Power Amplifier Nonlinearities”.

For background reference material, see the works listed in [1] and [2].

comm.DPDCoefficientEstimator

Package: `comm`

Estimate memory-polynomial coefficients for digital predistortion

Description

The `comm.DPDCoefficientEstimator` System object estimates the coefficients of a memory polynomial for digital pre-distortion (DPD) of a nonlinear power amplifier, given the baseband equivalent input and baseband equivalent output of the power amplifier. For more information, see "Digital Predistortion" on page 3-444.

To compute predistortion coefficients:

1. Create the `comm.DPDCoefficientEstimator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
estimator = comm.DPDCoefficientEstimator
estimator = comm.DPDCoefficientEstimator(Name,Value)
```

Description

`estimator = comm.DPDCoefficientEstimator` creates a digital predistortion coefficient estimator System object to estimate the coefficients of a memory polynomial for digital predistortion (DPD) of a nonlinear power amplifier.

`estimator = comm.DPDCoefficientEstimator(Name,Value)` sets properties using one or more name-value pairs. For example, `comm.DPDCoefficientEstimator('PolynomialType','Cross-term memory polynomial')` configures the predistortion coefficient estimator System object to estimate the coefficients for a memory-polynomial with cross terms. Enclose each property name in quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

DesiredAmplitudeGaindB — Desired amplitude gain
10 (default) | scalar

Desired amplitude gain in dB, specified as a scalar. This property value expresses the desired signal gain at the compensated amplifier output.

Tunable: Yes

Data Types: double

PolynomialType — Polynomial type
'Memory polynomial' (default) | 'Cross-term memory polynomial'

Polynomial type used for predistortion, specified as one of these values:

- 'Memory polynomial' — Computes predistortion coefficients by using a memory polynomial without cross terms
- 'Cross-term memory polynomial' — Computes predistortion coefficients by using a memory polynomial with cross terms

For more information, see “Digital Predistortion” on page 3-444.

Degree — Memory-polynomial degree
5 (default) | positive integer

Memory-polynomial degree, specified as a positive integer.

Data Types: double

MemoryDepth — Memory-polynomial depth
3 (default) | positive integer

Memory-polynomial depth in samples, specified as a positive integer.

Data Types: double

Algorithm — Estimation algorithm
'Least squares' (default) | 'Recursive least squares'

Adaptive algorithm used for equalization, specified as one of these values:

- 'Least squares' — Estimate the memory polynomial coefficients by using a least squares algorithm
- 'Recursive least squares' — Estimate the memory polynomial coefficients by using a recursive least squares algorithm

For algorithm reference material, see the works listed in [1] and [2].

Data Types: char | string

ForgettingFactor — Forgetting factor
0.99 (default) | scalar in the range (0, 1]

Forgetting factor used by the recursive least squares algorithm, specified as a scalar in the range (0, 1]. Decreasing the forgetting factor reduces the convergence time but causes the output estimates to be less stable.

Tunable: Yes

Dependencies

To enable this property, set Algorithm to `'Recursive least squares'`.

Data Types: `double`

`InitialCoefficientEstimate` — Initial coefficient estimate

`[]` (default) | matrix

Initial coefficient estimate for the recursive least squares algorithm, specified as a matrix.

- If `InitialCoefficientEstimate` is an empty matrix, the initial coefficient estimate for the recursive least squares algorithm is chosen automatically to correspond to a memory polynomial that is an identity function, so that the output is equal to input.
- If `InitialCoefficientEstimate` is a nonempty matrix, the number of rows must be equal to `MemoryDepth`.

  - If `PolynomialType` is `'Memory polynomial'`, the number of columns is the degree of the memory polynomial.
  - If `PolynomialType` is `'Cross-term memory polynomial'`, the number of columns must equal $m(n\text{-}1)+1$. m is the memory depth of the polynomial, and n is the degree of the memory polynomial.

For more information, see “Digital Predistortion” on page 3-444.

Dependencies

To enable this property, set Algorithm to `'Recursive least squares'`.

Data Types: `double`
Complex Number Support: Yes

Usage

Syntax

```
coef = estimator(paIn,paOut)
```

Description

`coef = estimator(paIn,paOut)` estimates the coefficients of a memory polynomial for use by the `comm.DPD` System object to predistort a complex baseband signal by using a memory-polynomial to compensate for nonlinearities in a power amplifier.

Input Arguments

`paIn` — Power amplifier baseband equivalent input

column vector

Power amplifier baseband equivalent input, specified as a column vector.

Data Types: `double`
Complex Number Support: Yes

paOut — Power amplifier baseband equivalent output

column vector

Power amplifier baseband equivalent output, specified as a column vector of the same length as `paIn`.

Data Types: `double`
Complex Number Support: Yes

Output Arguments

coef — Memory-polynomial coefficients

matrix

Memory-polynomial coefficients, returned as a matrix. For more information, see “Digital Predistortion” on page 3-444.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Predistort Power Amplifier Input Signal

Apply digital predistortion (DPD) to a power amplifier input signal. The DPD coefficient estimator System object uses a captured signal containing power amplifier input and output signals to determine the predistortion coefficient matrix.

Load a file containing the input and output signals for the power amplifier.

```
load('commpowamp_dpd_data.mat','PA_input','PA_output')
```

Generate a DPD coefficient estimator System object and a raised cosine transmit filter System object.

```
estimator = comm.DPDCoefficientEstimator( ...
    'DesiredAmplitudeGaindB',10, ...
    'PolynomialType','Memory polynomial', ...
    'Degree',5,'MemoryDepth',3,'Algorithm','Least squares');

rctFilt = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',2);
```

Estimate the digital predistortion memory-polynomial coefficients.

```
coef = estimator(PA_input,PA_output);
```

Generate a DPD System object using `coef`, the estimated coefficients output from the DPD coefficient estimator, as for the coefficient matrix.

```
dpd = comm.DPD('PolynomialType','Memory polynomial', ...
    'Coefficients',coef);
```

Generate 2000 random symbols and apply 16-QAM modulation to the signal. Apply raised cosine transmit filtering to the modulated signal.

```
s = randi([0,15],2000,1);
u = qammod(s,16);
x = rctFilt(u);
```

Apply digital predistortion to the data. The DPD System object returns a predistorted signal to provide as input to the power amplifier.

```
y = dpd(x);
```

Format of Coefficient Matrix for Digital Predistortion Memory Polynomial

This examples shows the format of the coefficient matrix for the DPD memory polynomial by using a randomly generated coefficient matrix. The example:

- Creates a digital predistortion System object configured using a memory polynomial coefficient matrix with the memory depth set to `3` and the polynomial degree set to `5` consisting of random values.
- Predistorts a signal using the memory-polynomial coefficient matrix.
- Compares one predistorted output element to the corresponding input element that has been manually computed using the memory-polynomial coefficient matrix.

Create a coefficient matrix representing a predistorter with the output equal to the input by generating a 3-by-5 coefficient matrix of zeros and setting the `coef(1,1)` element to `1`. Add small random complex nonlinear terms to the coefficient matrix.

```
coef = zeros(3,5);
coef(1,1) = 1;
coef = coef + 0.01*(randn(3,5)+1j*randn(3,5));
```

Create a DPD System object using the memory polynomial coefficient matrix, `coef`.

```
dpd = comm.DPD('PolynomialType','Memory polynomial','Coefficients',coef);
```

Generate an input signal and predistort it using the `dpd` System object.

```
x = randn(20,1) + 1j*randn(20,1);
y = dpd(x);
```

Compare the manually distorted output for an input corresponding output element `y(18)` to show how the coefficient matrix is used to calculate that particular output value.

```
u = x(18:-1:(18-3+1));
isequal(y(18),sum(sum(coef.*[u u.*abs(u) u.*(abs(u).^2) u.*(abs(u).^3) u.*(abs(u).^4)])))
```

```
ans = logical
   1
```

Format of Cross-Term Coefficient Matrix for Digital Predistortion Memory Polynomial

This examples shows the format of the coefficient matrix for the DPD memory polynomial by using a randomly generated coefficient matrix. The example:

- Creates a digital predistorter System object configured using a cross-term memory polynomial coefficient matrix with the memory depth set to 3 and the polynomial degree set to 5 consisting of random values.
- Predistorts a signal using the cross-term memory polynomial coefficient matrix.
- Compares one predistorted output element to the corresponding input element that has been manually computed using the cross-term memory polynomial coefficient matrix.

Create a coefficient matrix representing a predistorter with the output equal to the input by generating a 3-by-5 coefficient matrix of zeros and setting the `coef(1,1)` element to 1. Add small random complex nonlinear terms to the coefficient matrix.

```
coef = zeros(3,3*(5-1)+1);
coef(1,1) = 1;
coef = coef + 0.01*(randn(3,13) + 1j*randn(3,13));
```

Create a DPD System object using the cross-term memory polynomial coefficient matrix, `coef`.

```
dpd = comm.DPD('PolynomialType','Cross-term memory polynomial','Coefficients',coef);
```

Generate an input signal and predistort it using the `dpd` System object.

```
x = randn(20,1) + 1j*randn(20,1);
y = dpd(x);
```

Compare the manually distorted output for an input corresponding output element `y(18)` to show how the coefficient matrix is used to calculate that particular output value.

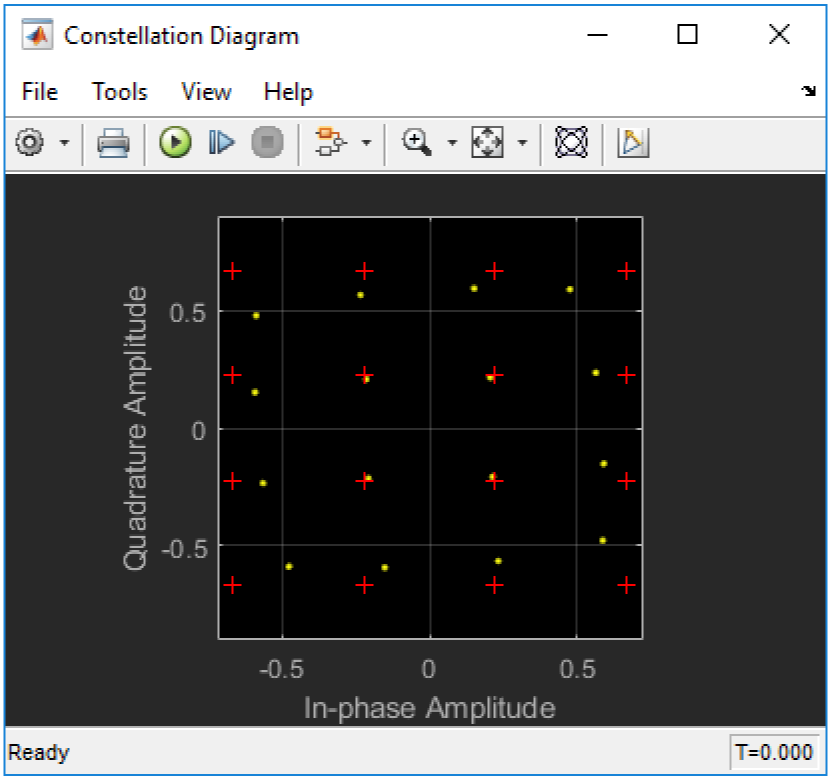
```
u = x(18:-1:(18-3+1));
isequal(y(18),sum(sum(coef.*[u u*abs(u.') u*(abs(u.').^2) u*(abs(u.').^3) u*(abs(u.').^4)])))
```

```
ans = logical
   1
```

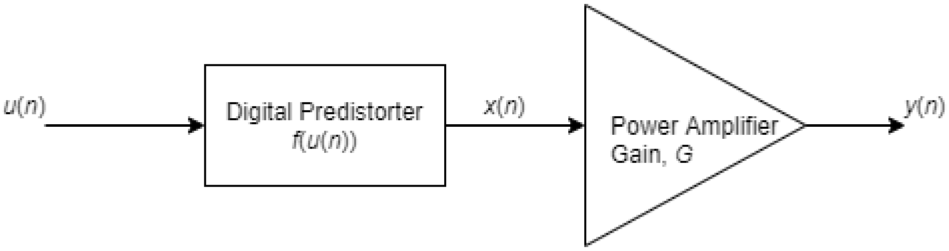
More About

Digital Predistortion

Wireless communication transmissions commonly require wide bandwidth signal transmission over a wide signal dynamic range. To transmit signals over a wide dynamic range and achieve high efficiency, RF power amplifiers (PAs) commonly operate in their nonlinear region. As this constellation diagram shows, the nonlinear behavior of a PA causes signal constellation distortions that pinch the amplitude (AM-AM distortion) and twist phase (AM-PM distortion) of constellation points proportional to the amplitude of the constellation point.



The goal of digital predistortion is to find a nonlinear function that linearizes the net effect of the PA nonlinear behavior at the PA output across the PA operating range. When the PA input is $x(n)$, and the predistortion function is $f(u(n))$, where $u(n)$ is the true signal to be amplified, the PA output is approximately equal to $G \times u(n)$, where G is the desired amplitude gain of the PA.



The digital predistorter can be configured to use a memory polynomial with or without cross terms.

- The memory polynomial with cross terms predistorts the input signal as

$$x(n) = f(u(n)) \triangleq \sum_{m=0}^{M-1} c_m \times u(n\text{-}m) + \sum_{m=0}^{M-1} \sum_{j=0}^{M-1} \sum_{k=0}^{K-1} a_{mjk} \times u(n\text{-}m) \times \left|u(n\text{-}j)\right|^{k}.$$

  The memory polynomial with cross terms has $(M{+}M{\times}M{\times}(K\text{-}1))$ coefficients for c_m and a_{mjk}.
- The memory polynomial without cross terms predistorts the input signal as

$$x(n) = f(u(n)) \triangleq \sum_{m=0}^{M-1}\sum_{k=0}^{K-1} a_{mk} \times u(n\text{-}m) \times |u(n\text{-}m)|^{k}.$$

The polynomial without cross terms has $M \times K$ coefficients for a_{mk}.

Estimating Predistortion Function and Coefficients

The DPD coefficient estimation uses an indirect learning architecture to find function *f*(u(n)) to predistort input signal $u(n)$ which precedes the PA input.

The DPD coefficient estimation algorithm models nonlinear PA memory effects based on the work in reference papers by Morgan, et al [1], and by Schetzen [2], using the theoretical foundation developed for Volterra systems.

Specifically, the inverse mapping from the PA output normalized by the PA gain, $\{y(n)/G\}$, to the PA input, $\{x(n)\}$, provides a good approximation to the function *f*(u(n)), needed to predistort $\{u(n)\}$ to produce $\{x(n)\}$.

Referring to the memory polynomial equations above, estimates are computed for the memory-polynomial coefficients:

- c_m and a_{mjk} for a memory polynomial with cross terms
- a_{mk} for a memory polynomial without cross terms

The memory-polynomial coefficients are estimated by using a least squares fit algorithm or a recursive least squares algorithm. The least squares fit algorithm or a recursive least squares algorithms use the memory polynomial equations above for a memory polynomial with or without cross terms, by replacing $\{u(n)\}$ with $\{y(n)/G\}$. The function order and dimension of the coefficient matrix are defined by the degree and depth of the memory polynomial.

For an example that details the process of accurately estimating memory-polynomial coefficients and predistorting a PA input signal, see “Digital Predistortion to Compensate for Power Amplifier Nonlinearities”.

For background reference material, see the works listed in [1] and [2].

comm.DPSKDemodulator

Package: `comm`

Demodulate using M-ary DPSK method

Description

The `DPSKDemodulator` object demodulates a signal that was modulated using the M-ary differential phase shift keying method. The input is a baseband representation of the modulated signal. The input and output for this object are discrete-time signals. This object accepts a scalar-valued or column vector input signal.

To demodulate a signal that was modulated using differential phase shift keying:

1. Define and set up your DPSK modulator object. See “Construction” on page 3-448.
2. Call `step` to demodulate a signal according to the properties of `DPSKDemodulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.DPSKDemodulator` creates a demodulator System object, `H`. This object demodulates the input signal using the *M*-ary differential phase shift keying (M-DPSK) method.

`H = comm.DPSKDemodulator(Name,Value)` creates an M-DPSK demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.DPSKDemodulator(M,PHASE,Name,Value)` creates an M-DPSK demodulator object, `H`. This object has the `ModulationOrder` property set to `M`, the `PhaseRotation` property set to `PHASE`, and the other specified properties set to the specified values.

Properties

`ModulationOrder`

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar value. The default is `8`.

`PhaseRotation`

Additional phase shift

Specify the additional phase difference between previous and current modulated symbols in radians as a real scalar value. The default is `pi/8`. This value corresponds to the phase difference between previous and current modulated symbols when the input is zero.

`BitOutput`

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. The default is `false`. When you set this property to `true` the `step` method outputs a column vector of bit values. The length of this column vector is equal to **log2**(`ModulationOrder` on page 3-0) times the number of demodulated symbols.

When you set this property to `false`, the `step` method outputs a column vector. The length of this column vector is equal to that of the input data vector. The output contains integer symbol values between `0` and `ModulationOrder-1`.

`SymbolMapping`

Constellation encoding

Specify how the object maps an integer or group of **log2**(`ModulationOrder` on page 3-0) bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-encoded signal constellation. When you set this property to `Binary`, the input integer *m*, between (0 ≤ *m* ≤ `ModulationOrder`–1) maps to the current symbol. This mapping uses **exp**(*j*×`PhaseRotation` + *j*×2 × *π* ×m/ModulationOrder)×(previously modulated symbol).

`OutputDataType`

Data type of output

Specify the output data type as one of `Full precision` | `Smallest unsigned integer` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`. The default is `Full precision`. When you set this property to `Full precision`, the input data type is single or double precision, the output data is the same as that of the input. When you set the `BitOutput` on page 3-0 property to true, `logical` data type becomes a valid option.

Methods

reset	Reset states of M-DPSK demodulator object
step	Demodulate using M-ary DPSK method

Common to All System Objects	
`release`	Allow System object property value changes

Examples

8-DPSK Signal in AWGN

Create a DPSK modulator and demodulator pair. Create an AWGN channel object having three bits per symbol.

```
dpskmod = comm.DPSKModulator(8,pi/8,'BitInput',true);
dpskdemod = comm.DPSKDemodulator(8,pi/8,'BitOutput',true);
channel = comm.AWGNChannel('EbNo',10,'BitsPerSymbol',3);
```

Create an error rate calculator. Set the `ComputationDelay` property to `1` to account for the one bit transient caused by the differential modulation

```
errorRate = comm.ErrorRate('ComputationDelay',1);
```

Main processing loop steps:

- Generate 50 3-bit frames
- 8-DPSK modulate
- Pass through AWGN channel
- 8-DPSK demodulate
- Collect error statistics

```
for counter = 1:100
    txData = randi([0 1],150,1);
    modSig = dpskmod(txData);
    rxSig = channel(modSig);
    rxData = dpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
```

```
ber = 0.0098
```

```
numErrors = errorStats(2)
```

```
numErrors = 147
```

```
numBits = errorStats(3)
```

```
numBits = 14999
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the M-DPSK Demodulator Baseband block reference page. The object properties correspond to the block parameters.

Extended Capabilities

System object: `comm.DPSKDemodulator`
Package: `comm`

Demodulate using M-ary DPSK method

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates input data, `X`, with the DPSK demodulator System object, `H`, and returns `Y`. Input `X` must be a double or single precision data type scalar or column vector. Depending on the `BitOutput` property value, output `Y` can be integer or bit valued.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.DPSKModulator

Package: comm

Modulate using M-ary DPSK method

Description

The DPSKModulator object modulates using the M-ary differential phase shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using differential phase shift keying:

1. Define and set up your DPSK modulator object. See “Construction” on page 3-454.
2. Call step to modulate a signal according to the properties of comm.DPSKModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.DPSKModulator creates a modulator System object, H. This object modulates the input signal using the M-ary differential phase shift keying (M-DPSK) method.

H = comm.DPSKModulator(Name,Value) creates an M-DPSK modulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.DPSKModulator(M,PHASE,Name,Value) creates an M-DPSK modulator object, H. This object has the ModulationOrder property set to M, the PhaseRotation property set to PHASE, and the other specified properties set to the specified values.

Properties

ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar value. The default is 8.

PhaseRotation

Additional phase shift

Specify the additional phase difference between previous and current modulated symbols in radians as a real scalar value. The default is pi/8. This value corresponds to the phase difference between previous and current modulated symbols when the input is zero.

BitInput

Assume bit inputs

Specify whether the input is bits or integers. The default is `false`. When you set this property to `true`, the `step` method input must be a column vector of bit values whose length is an integer multiple of **log2**(`ModulationOrder` on page 3-0). This vector contains bit representations of integers between `0` and `ModulationOrder–1`. When you set this property to `false`, the `step` method input requires a column vector of integer symbol values between `0` and `ModulationOrder–1`.

SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of **log2**(`ModulationOrder` on page 3-0) input bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-encoded signal constellation. When you set this property to `Binary`, the input integer *m*, between (0 ≤ *m* ≤ `ModulationOrder`–1) shifts the output phase. This shift is (`PhaseRotation` on page 3-0 + 2 × *π* ×*m*/`ModulationOrder`) radians from the previous output phase. The output symbol uses **exp**(*j*×`PhaseRotation` + *j*×2 × *π* ×m/ModulationOrder)× (previously modulated symbol).

OutputDataType

Data type of output

Specify output data type as one of `double` | `single`. The default is `double`.

Methods

reset	Reset states of M-DPSK modulator object
step	Modulate using M-ary DPSK method

Common to All System Objects	
`release`	Allow System object property value changes

Examples

8-DPSK Signal in AWGN

Create a DPSK modulator and demodulator pair. Create an AWGN channel object having three bits per symbol.

```
dpskmod = comm.DPSKModulator(8,pi/8,'BitInput',true);
dpskdemod = comm.DPSKDemodulator(8,pi/8,'BitOutput',true);
channel = comm.AWGNChannel('EbNo',10,'BitsPerSymbol',3);
```

Create an error rate calculator. Set the `ComputationDelay` property to `1` to account for the one bit transient caused by the differential modulation

```
errorRate = comm.ErrorRate('ComputationDelay',1);
```

Main processing loop steps:

- Generate 50 3-bit frames
- 8-DPSK modulate
- Pass through AWGN channel
- 8-DPSK demodulate
- Collect error statistics

```
for counter = 1:100
    txData = randi([0 1],150,1);
    modSig = dpskmod(txData);
    rxSig = channel(modSig);
    rxData = dpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
```

```
ber = 0.0098
```

```
numErrors = errorStats(2)
```

```
numErrors = 147
```

```
numBits = errorStats(3)
```

```
numBits = 14999
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the M-DPSK Modulator Baseband block reference page. The object properties correspond to the block parameters.

Extended Capabilities

reset

System object: `comm.DPSKModulator`
Package: `comm`

Reset states of M-DPSK modulator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `DPSKModulator` object, `H`.

step

System object: `comm.DPSKModulator`
Package: `comm`

Modulate using M-ary DPSK method

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` modulates input data, `X`, with the DPSK modulator System object, `H`. It returns the baseband modulated output, `Y`. Depending on the value of the `BitInput` property, input `X` can be an integer or bit valued column vector with numeric or logical data types.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.DQPSKDemodulator

Package: comm

Demodulate using DQPSK method

Description

The DQPSKDemodulator object demodulates a signal that was modulated using the differential quadrature phase shift keying method. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using differential quadrature phase shift keying:

1. Define and set up your DQPSK modulator object. See “Construction” on page 3-459.
2. Call step to demodulate a signal according to the properties of DQPSKDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.DQPSKDemodulator creates a demodulator System object, H. This object demodulates the input signal using the differential quadrature phase shift keying (DQPSK) method.

H = comm.DQPSKDemodulator(Name,Value) creates a DQPSK demodulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.DQPSKDemodulator(PHASE,Name,Value) creates a DQPSK demodulator object, H. This object has the PhaseRotation property set to PHASE and the other specified properties set to the specified values.

Properties

PhaseRotation

Additional phase shift

Specify the additional phase difference between previous and current modulated symbols in radians as a real scalar. The default is pi/4. This value corresponds to the phase difference between previous and current modulated symbols when the input is zero.

BitOutput

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. The default is false. When you set this property to true the step method outputs a column vector of bit values with length equal to twice the number of demodulated symbols. When you set this property to `false`, the `step` method outputs a column vector, of length equal to the input data vector, that contains integer symbol values between `0` and `3`.

`SymbolMapping`

Constellation encoding

Specify how the object maps an integer or group of 2 bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-encoded signal constellation. When you set this property to `Binary`, the integer *m*, between $0 \leq m \leq 3$ maps to the current symbol as $\mathbf{exp}(j \times$`PhaseRotation` on page 3-0 $+ j \times 2 \times \pi \times {}^{m}\!/_{4}) \times$ (previously modulated symbol).

`OutputDataType`

Data type of output

Specify the output data type as one of `Full precision` | `Smallest unsigned integer` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`. The default is `Full precision`. When you set this property to `Full precision` the output has the same data type as that of the input. In this case, the input data type is single- or double-precision value. When you set the `BitOutput` on page 3-0 property to `true`, `logical` data type becomes a valid option.

Methods

reset	Reset states of DQPSK demodulator object
step	Demodulate using DQPSK method

Common to All System Objects	
`release`	Allow System object property value changes

Examples

DQPSK Signal in AWGN

Create a DQPSK modulator and demodulator pair. Create an AWGN channel object having two bits per symbol.

```
dqpskmod = comm.DQPSKModulator('BitInput',true);
dqpskdemod = comm.DQPSKDemodulator('BitOutput',true);
channel = comm.AWGNChannel('EbNo',6,'BitsPerSymbol',2);
```

Create an error rate calculator. Set the `ComputationDelay` property to `1` to account for the one bit transient caused by the differential modulation

```
errorRate = comm.ErrorRate('ComputationDelay',1);
```

Main processing loop steps:

- Generate 50 2-bit frames

- 8-DPSK modulate
- Pass through AWGN channel
- 8-DPSK demodulate
- Collect error statistics

```
for counter = 1:100
    txData = randi([0 1],100,1);
    modSig = dqpskmod(txData);
    rxSig = channel(modSig);
    rxData = dqpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
```

```
ber = 0.0170
```

```
numErrors = errorStats(2)
```

```
numErrors = 170
```

```
numBits = errorStats(3)
```

```
numBits = 9999
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the DQPSK Demodulator Baseband block reference page. The object properties correspond to the block parameters.

Description

`reset(H)` resets the states of the `DQPSKDemodulator` object, `H`.

step

System object: `comm.DQPSKDemodulator`
Package: `comm`

Demodulate using DQPSK method

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates input data, `X`, with the DQPSK demodulator System object, `H`, and returns `Y`. Input `X` must be a single or double precision data type scalar or column vector. Depending on the `BitOutput` property value, output `Y` can be integer or bit valued.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.DQPSKModulator

Package: `comm`

Modulate using DQPSK method

Description

The `DQPSKModulator` object modulates using the differential quadrature phase shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using differential quadrature phase shift keying:

1. Define and set up your DQPSK modulator object. See “Construction” on page 3-464.
2. Call `step` to modulate a signal according to the properties of `comm.DQPSKModulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.DQPSKModulator` creates a modulator System object, `H`. This object modulates the input signal using the differential quadrature phase shift keying (DQPSK) method.

`H = comm.DQPSKModulator(Name,Value)` creates a DQPSK modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.DQPSKModulator(PHASE,Name,Value)` creates a DQPSK modulator object, `H`. This object has the `PhaseRotation` property set to `PHASE` and the other specified properties set to the specified values.

Properties

`PhaseRotation`

Additional phase shift

Specify the additional phase difference between previous and current modulated symbols in radians as a real scalar value. The default is `pi/4`. This value corresponds to the phase difference between previous and current modulated symbols when the input is zero.

`BitInput`

Assume bit inputs

Specify whether the input is bits or integers. The default is `false`. When you set this property to true, the step method input must be a column vector of bit values. The length of this vector is an integer multiple of two. This vector contains bit representations of integers between `0` and `3`. When you set this property to `false`, the `step` method input must be a column vector of integer symbol values between `0` and `3`.

SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of two input bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-encoded signal constellation. When you set this property to `Binary`, the input integer *m*, between $0 \leq m \leq 3$ shifts the output phase. This shift is (`PhaseRotation` on page 3-0 $+ 2 \times \pi \times {}^{m}\!/_{4}$) radians from the previous output phase. The output symbol is $\mathbf{exp}(j \times$`PhaseRotation`$+ j \times 2 \times \pi \times {}^{m}\!/_{4}) \times$(previously modulated symbol).

OutputDataType

Data type of output

Specify output data type as one of `double` | `single`. The default is `double`.

Methods

reset	Reset states of DQPSK modulator object
step	Modulate using DQPSK method

Common to All System Objects	
`release`	Allow System object property value changes

Examples

DQPSK Signal in AWGN

Create a DQPSK modulator and demodulator pair. Create an AWGN channel object having two bits per symbol.

```
dqpskmod = comm.DQPSKModulator('BitInput',true);
dqpskdemod = comm.DQPSKDemodulator('BitOutput',true);
channel = comm.AWGNChannel('EbNo',6,'BitsPerSymbol',2);
```

Create an error rate calculator. Set the `ComputationDelay` property to `1` to account for the one bit transient caused by the differential modulation

```
errorRate = comm.ErrorRate('ComputationDelay',1);
```

Main processing loop steps:

- Generate 50 2-bit frames
- 8-DPSK modulate
- Pass through AWGN channel

- 8-DPSK demodulate
- Collect error statistics

```
for counter = 1:100
    txData = randi([0 1],100,1);
    modSig = dqpskmod(txData);
    rxSig = channel(modSig);
    rxData = dqpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
```

```
ber = 0.0170
```

```
numErrors = errorStats(2)
```

```
numErrors = 170
```

```
numBits = errorStats(3)
```

```
numBits = 9999
```

Algorithms

Description

`reset(H)` resets the states of the `DQPSKModulator` object, `H`.

step

System object: `comm.DQPSKModulator`
Package: `comm`

Modulate using DQPSK method

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` modulates input data, `X`, with the DQPSK modulator System object, `H`. It returns the baseband modulated output, `Y`. Depending on the value of the `BitInput` property, input `X` can be an integer or bit valued column vector with numeric or logical data types.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.ErrorRate

Package: `comm`

Compute bit or symbol error rate of input data

Description

The `ErrorRate` object compares input data from a transmitter with input data from a receiver and calculates the error rate as a running statistic. To obtain the error rate, the object divides the total number of unequal pairs of data elements by the total number of input data elements from one source.

To obtain the error rate:

1. Define and set up your error rate object. See “Construction” on page 3-469.
2. Call `step` to compare input data from a transmitter with input data from a receiver and calculate the error rate according to the properties of `comm.ErrorRate`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.ErrorRate` creates an error rate calculator System object, `H`. This object computes the error rate of the received data by comparing it to the transmitted data.

`H = comm.ErrorRate(Name,Value)` creates an error rate calculator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`ReceiveDelay`

Number of samples to delay transmitted signal

Specify the number of samples by which the received data lags behind the transmitted data. This value must be a real, nonnegative, double-precision, integer scalar. Use this property to align the samples for comparison in the transmitted and received input data vectors. Specify the delay in number of samples, regardless of whether the input is a scalar or a vector. The default is `0`.

`ComputationDelay`

Computation delay

Specify the number of data samples that the object should ignore at the beginning of the comparison. This value must be a real, nonnegative, double-precision, integer scalar. Use this property to ignore the transient behavior of both input signals. The default is `0`.

`Samples`

Samples to consider

Specify samples to consider as one of `Entire frame` | `Custom` | `Input port`. The property defines whether the object should consider all or only part of the input frames when computing error statistics. The default is `Entire frame`. Select `Entire frame` to compare all the samples of the RX frame to those of the TX frame. Select `Custom` or `Input port` to list the indices of the RX frame elements that the object should consider when making comparisons. When you set this property to `Custom`, you can list the indices as a scalar or a column vector of double-precision integers through the `CustomSamples` on page 3-0 property. When you set this property to `Input port`, you can list the indices as an input to the `step` method.

`CustomSamples`

Selected samples from frame

Specify a scalar or a column vector of double-precision, real, positive integers. This value lists the indices of the elements of the RX frame vector that the object uses when making comparisons. This property applies when you set the `Samples` on page 3-0 property to `Custom`. The default is an empty vector, which specifies that all samples are used.

`ResetInputPort`

Enable error rate reset input

Set this property to `true` to reset the error statistics via an input to the `step` method. The default is `false`.

Methods

reset	Reset states of error rate calculator object
step	Compute bit or symbol error rate of input data

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Calculate Error Statistics

Create two binary vectors and determine the error statistics.

Create a bit error rate counter object.

```
errorRate = comm.ErrorRate;
```

Create an arbitrary binary data vector.

```
x = [1 0 1 0 1 0 1 0 1 0]';
```

Introduce errors to the first and last bits.

```
y = x;
y(1) = ~y(1);
y(end) = ~y(end);
```

Calculate the error statistics.

```
z = errorRate(x,y);
```

The first element of the vector z is the bit error rate.

```
z(1)
```

```
ans = 0.2000
```

The second element of z is the total error count.

```
z(2)
```

```
ans = 2
```

The third element of z is the total number of bits.

```
z(3)
```

```
ans = 10
```

Calculate BER between Transmitted and Received Signal

Create an 8-DPSK modulator and demodulator pair that work with binary data.

```
dpskModulator = comm.DPSKModulator('ModulationOrder',8,'BitInput',true);
dpskDemodulator = comm.DPSKDemodulator('ModulationOrder',8,'BitOutput',true);
```

Create an error rate calculator, accounting for the three bit (one symbol) transient caused by the differential modulation.

```
errorRate = comm.ErrorRate('ComputationDelay',3);
```

Calculate the BER for 10 frames.

```
BER = zeros(10,1);

for i= 1:10
    txData = randi([0 1],96,1);           % Generate binary data
    modData = dpskModulator(txData);      % Modulate
    rxSig = awgn(modData,7);              % Pass through AWGN channel
    rxData = dpskDemodulator(rxSig);      % Demodulate
    errors = errorRate(txData,rxData);    % Compute error statistics
    BER(i) = errors(1);                   % Save BER data
end
```

Display the BER.

```
BER
```

```
BER = 10×1

    0.1613
    0.1640
    0.1614
    0.1496
    0.1488
    0.1309
    0.1405
    0.1399
    0.1370
    0.1411
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Error Rate Calculation block reference page. The object properties correspond to the block parameters, except:

- The **Output data** and **Variable name** block parameters do not have a corresponding properties. The object always returns the result as an output.
- The **Stop simulation** block parameter does not have a corresponding property. To implement similar behavior, use the output of the `step` method in a while loop, to programmatically stop the simulation. .
- The **Computation mode** parameter corresponds to the `Samples` on page 3-0 and `CustomSamples` on page 3-0 properties.

Description

`reset(H)` resets the states of the `ErrorRate` object, `H`.

step

System object: comm.ErrorRate
Package: comm

Compute bit or symbol error rate of input data

Syntax

```
Y = step(H,TX,RX)
Y = step(H,TX,RX,SEL)
Y = step(H,TX,RX,RST)
```

Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Y = step(H,TX,RX) counts the number of differences between the transmitted data vector, TX, and received data vector, RX. The step method outputs a three-element vector consisting of the error rate, followed by the number of errors detected and the total number of samples compared. TX and RX inputs can be either scalars or column vectors of the same data type. Valid data types are single, double, integer or logical. If TX is a scalar and RX is a vector, or vice-versa, then the block compares the scalar with each element of the vector.

Y = step(H,TX,RX,SEL) calculates the errors based on selected samples from the input frame specified by the SEL input. SEL must be a real, double-precision integer-valued scalar or a column vector. The vector lists the indices of the elements of the RX input vector that the object should consider when making comparisons. This syntax applies when you set the Samples property to 'Input Port'.

Y = step(H,TX,RX,RST) resets the error count whenever the input RST is non-zero. RST must be a real, double, or logical scalar. When you set the RST input to a nonzero value, the object clears its error statistics and then recomputes them based on the current TX and RX inputs. This syntax applies when you set the ResetInputPort property to true. You can combine optional input arguments when their enabling properties are set. Optional inputs must be listed in the same order as the order of the enabling properties.

Note obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

comm.LinearEqualizer

Package: `comm`

Equalize modulated signals using linear filtering

Description

The `comm.LinearEqualizer` System object uses a linear filter tap delay line with a weighted sum to equalize modulated signals transmitted through a dispersive channel. The equalizer object adaptively adjusts tap weights based on the selected algorithm. For more information, see “Algorithms” on page 3-509.

To equalize modulated signals using a linear filter:

1. Create the `comm.LinearEqualizer` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
lineq = comm.LinearEqualizer
lineq = comm.LinearEqualizer(Name,Value)
```

Description

`lineq = comm.LinearEqualizer` creates a linear equalizer System object to adaptively equalize a signal.

`lineq = comm.LinearEqualizer(Name,Value)` sets properties using one or more name-value pairs. For example, `comm.LinearEqualizer('Algorithm','RLS')` configures the equalizer object to update tap weights using the recursive least squares (RLS) algorithm. Enclose each property name in quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Algorithm` — Adaptive algorithm
`'LMS'` (default) | `'RLS'` | `'CMA'`

Adaptive algorithm used for equalization, specified as one of these values:

- `'LMS'` — Update the equalizer tap weights using the “Least Mean Square (LMS) Algorithm” on page 3-510.
- `'RLS'` — Update the equalizer tap weights using the “Recursive Least Square (RLS) Algorithm” on page 3-511.
- `'CMA'` — Update the equalizer tap weights using the “Constant Modulus Algorithm (CMA)” on page 3-511.

Data Types: `char` | `string`

`NumTaps` — Number of equalizer taps

`5` (default) | positive integer

Number of equalizer taps, specified as a positive integer. The number of equalizer taps must be greater than or equal to the value of the `InputSamplesPerSymbol` property.

Data Types: `double`

`StepSize` — Step size

`0.01` (default) | positive scalar

Step size used by the adaptive algorithm, specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

Tip To determine the maximum step size allowed, use the `maxstep` object function.

Tunable: Yes

Dependencies

To enable this property, set Algorithm to `'LMS'` or `'CMA'`.

Data Types: `double`

`ForgettingFactor` — Forgetting factor

`0.99` (default) | scalar in the range (0, 1]

Forgetting factor used by the adaptive algorithm, specified as a scalar in the range (0, 1]. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

Tunable: Yes

Dependencies

To enable this property, set Algorithm to `'RLS'`.

Data Types: `double`

`InitialInverseCorrelationMatrix` — Initial inverse correlation matrix

`0.1` (default) | scalar | matrix

Initial inverse correlation matrix, specified as a scalar or an N_{Taps}-by-N_{Taps} matrix. N_{Taps} is equal to the NumTaps property value. If you specify `InitialInverseCorrelationMatrix` as a scalar, *a*, the equalizer sets the initial inverse correlation matrix to *a* times the identity matrix: a(`eye`(N_{Taps})).

Tunable: Yes

Dependencies

To enable this property, set Algorithm to `'RLS'`.

Data Types: `double`

`Constellation` — Signal constellation

`pskmod(0:3,4,pi/4)` (default) | vector

Signal constellation, specified as a vector. The default value is a QPSK constellation generated using this code: `pskmod(0:3,4,pi/4)`.

Tunable: Yes

Data Types: `double`

`ReferenceTap` — Reference tap

`3` (default) | positive integer

Reference tap, specified as a positive integer less than or equal to the NumTaps property value. The equalizer uses the reference tap location to track the main energy of the channel.

Data Types: `double`

`InputDelay` — Input signal delay

`0` (default) | nonnegative integer

Input signal delay in samples relative to the reset time of the equalizer, specified as a nonnegative integer. If the input signal is a vector of length greater than 1, then the input delay is relative to the start of the input vector. If the input signal is a scalar, then the input delay is relative to the first call of the System object and to the first call of the System object after calling the `release` or `reset` object function.

Data Types: `double`

`InputSamplesPerSymbol` — Number of input samples per symbol

`1` (default) | positive integer

Number of input samples per symbol, specified as a positive integer. Setting this property to any number greater than one effectively creates a fractionally spaced equalizer. For more information, see “Symbol Tap Spacing” on page 3-509.

Data Types: `double`

`TrainingFlagInputPort` — Enable training control input

`false` (default) | `true`

Enable training control input, specified as `false` or `true`. Setting this property to `true` enables the equalizer training flag input tf.

Tunable: Yes

Data Types: `logical`

`AdaptAfterTraining` — Update tap weights when not training

`true` (default) | `false`

Update tap weights when not training, specified as `true` or `false`. If this property is set to `true`, the System object uses decision directed mode to update equalizer tap weights. If this property is set to `false`, the System object keeps the equalizer tap weights unchanged after training.

Tunable: Yes

Data Types: `logical`

`AdaptWeightsSource` — Source of adapt tap weights request

`'Property'` (default) | `'Input port'`

Source of adapt tap weights request, specified as one of these values:

- `'Property'` — Specify this value to use the AdaptWeights property to control when the System object adapts tap weights.
- `'Input port'` — Specify this value to use the `aw` input to control when the System object adapts tap weights.

Dependencies

To enable this property, set Algorithm to `'CMA'`.

Data Types: `char` | `string`

`AdaptWeights` — Adapt tap weights

`true` (default) | `false`

Adapt tap weights, specified as `true` or `false`. If this property is set to `true`, the System object updates the equalizer tap weights. If this property is set to `false`, the System object keeps the equalizer tap weights unchanged.

Tunable: Yes

Dependencies

To enable this property, set AdaptWeightsSource to `'Property'` and set AdaptAfterTraining to `true`.

Data Types: `logical`

`InitialWeightsSource` — Source for initial tap weights

`'Auto'` (default) | `'Property'`

Source for initial tap weights, specified as

- `'Auto'` — Initialize the tap weights to the algorithm-specific default values, as described in the InitialWeights property.
- `'Property'` — Initialize the tap weights using the InitialWeights property value.

Data Types: `char` | `string`

`InitialWeights` — Initial tap weights

`0` or `[0;0;1;0;0]` (default) | scalar | column vector

Initial tap weights used by the adaptive algorithm, specified as a scalar or vector. The default is `0` when the Algorithm property is set to `'LMS'` or `'RLS'`. The default is `[0;0;1;0;0]` when the Algorithm property is set to `'CMA'`.

If you specify `InitialWeights` as a vector, the vector length must be equal to the NumTaps property value. If you specify `InitialWeights` as a scalar, the equalizer uses scalar expansion to create a vector of length NumTaps with all values set to `InitialWeights`.

Tunable: Yes

Dependencies

To enable this property, set InitialWeightsSource to `'Property'`.

Data Types: `double`

`WeightUpdatePeriod` — Tap weight update period

`1` (default) | positive integer

Tap weight update period in symbols, specified as a positive integer. The equalizer updates the tap weights after processing this number of symbols.

Data Types: `double`

Usage

Syntax

```
y = lineq(x,tsym)
y = lineq(x,tsym,tf)

y = lineq(x)
y = lineq(x,aw)
```

Description

`y = lineq(x,tsym)` equalizes input signal `x` by using training symbols `tsym`. The output is the equalized symbols. To enable this syntax, set the Algorithm property to `'LMS'` or `'RLS'`.

`y = lineq(x,tsym,tf)` also specifies training flag `tf`. The System object starts training when `tf` changes from `false` to `true` (at the rising edge). The System object trains until all symbols in `tsym` are processed. The input `tsym` is ignored when `tf` is `false`. To enable this syntax, set the Algorithm property to `'LMS'` or `'RLS'` and TrainingFlagInputPort property to `true`.

`y = lineq(x)` equalizes input signal `x`. To enable this syntax, set the Algorithm property to `'CMA'`.

`y = lineq(x,aw)` also specifies adapts weights flag `aw`. The System object adapts the equalizer tap weights when `aw` is `true`. If `aw` is `false`, the System object keeps the weights unchanged. To enable this syntax, set the Algorithm property to `'CMA'` and AdaptWeightsSource property to `'Input port'`.

`[y,err] = lineq( ___ )` also returns error signal `err` using input arguments from any of the previous syntaxes.

`[y,err,weights] = lineq( ___ )` also returns `weights`, the tap weights from the last tap weight update, using input arguments from any of the previous syntaxes.

Input Arguments

`x` — Input signal
column vector

Input signal, specified as a column vector. The input signal vector length must be equal to an integer multiple of the InputSamplesPerSymbol property value. For more information, see “Symbol Tap Spacing” on page 3-509.

Data Types: `double`
Complex Number Support: Yes

`tsym` — Training symbols
column vector

Training symbols, specified as a column vector of length less than or equal to the length of input `x`. The input `tsym` is ignored when `tf` is `false`.

Dependencies

To enable this argument, set the Algorithm property to `'LMS'` or `'RLS'`.

Data Types: `double`
Complex Number Support: Yes

`tf` — Training flag
`true` | `false`

Training flag, specified as `true` or `false`. The System object starts training when `tf` changes from `false` to `true` (at the rising edge). The System object trains until all symbols in `tsym` are processed. The input `tsym` is ignored when `tf` is `false`.

Dependencies

To enable this argument, set the Algorithm property to `'LMS'` or `'RLS'` and TrainingFlagInputPort property to `true`.

Data Types: `logical`

`aw` — Adapt weights flag
`true` | `false`

Adapt weights flag, specified as `true` or `false`. If `aw` is `true`, the System object adapts weights. If `aw` is `false`, the System object keeps the weights unchanged.

Dependencies

To enable this argument, set the Algorithm property to `'CMA'` and AdaptWeightsSource property to `'Input port'`.

Data Types: `logical`

Output Arguments

`y` — Equalized symbols
column vector

Equalized symbols, returned as a column vector that has the same length as input signal `x`.

`err` — Error signal
column vector

Error signal, returned as a column vector that has the same length as input signal `x`.

`weights` — Tap weights
column vector

Tap weights, returned as a column vector that has NumTaps elements. `weights` contains the tap weights from the last tap weight update.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.LinearEqualizer`

isLocked	Determine if System object is in use
clone	Create duplicate System object
info	Characteristic information about the equalizer object
maxstep	Maximum step size for LMS equalizer convergence
mmseweights	Linear equalizer MMSE tap weights

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Linearly Equalize BPSK-Modulated Signal

Create a BPSK modulator and an equalizer System object™, specifying a linear LMS equalizer having eight taps and a step size of 0.03.

```
bpsk = comm.BPSKModulator;
eqlms = comm.LinearEqualizer('Algorithm','LMS','NumTaps',8,'StepSize',0.03);
```

Change the reference tap index of the equalizer.

```
eqlms.ReferenceTap = 4;
```

Build a set of test data. Receive the data by convolving the signal.

```
x = bpsk(randi([0 1],1000,1));
rxsig = conv(x,[1 0.8 0.3]);
```

Use `maxstep` to find the maximum permitted step size.

```
mxStep = maxstep(eqlms,rxsig)
```

```
mxStep = 0.1384
```

Equalize the received signal. Use the first 200 symbols as the training sequence.

```
y = eqlms(rxsig,x(1:200));
```

Linearly Equalize QPSK-Modulated Signal

Apply linear equalization using the least mean squares (LMS) algorithm to recover QPSK symbols passed through a multipath AWGN channel.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
chtaps = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
```

Generate QPSK-modulated symbols. Apply multipath channel filtering and AWGN impairments to the symbols.

```
data = randi([0 M-1],numSymbols,1);
tx = pskmod(data,M,pi/4);
rx = awgn(filter(chtaps,1,tx),25,'measured');
```

Create a linear equalizer System object and display the default configuration. Adjust the reference tap to 1. Check the maximum permitted step size. Equalize the impaired symbols.

```
eq = comm.LinearEqualizer
```

```
eq = 
  comm.LinearEqualizer with properties:

                Algorithm: 'LMS'
                  NumTaps: 5
                 StepSize: 0.0100
            Constellation: [1x4 double]
             ReferenceTap: 3
               InputDelay: 0
    InputSamplesPerSymbol: 1
    TrainingFlagInputPort: false
       AdaptAfterTraining: true
     InitialWeightsSource: 'Auto'
       WeightUpdatePeriod: 1
```

```
eq.ReferenceTap = 1;
```

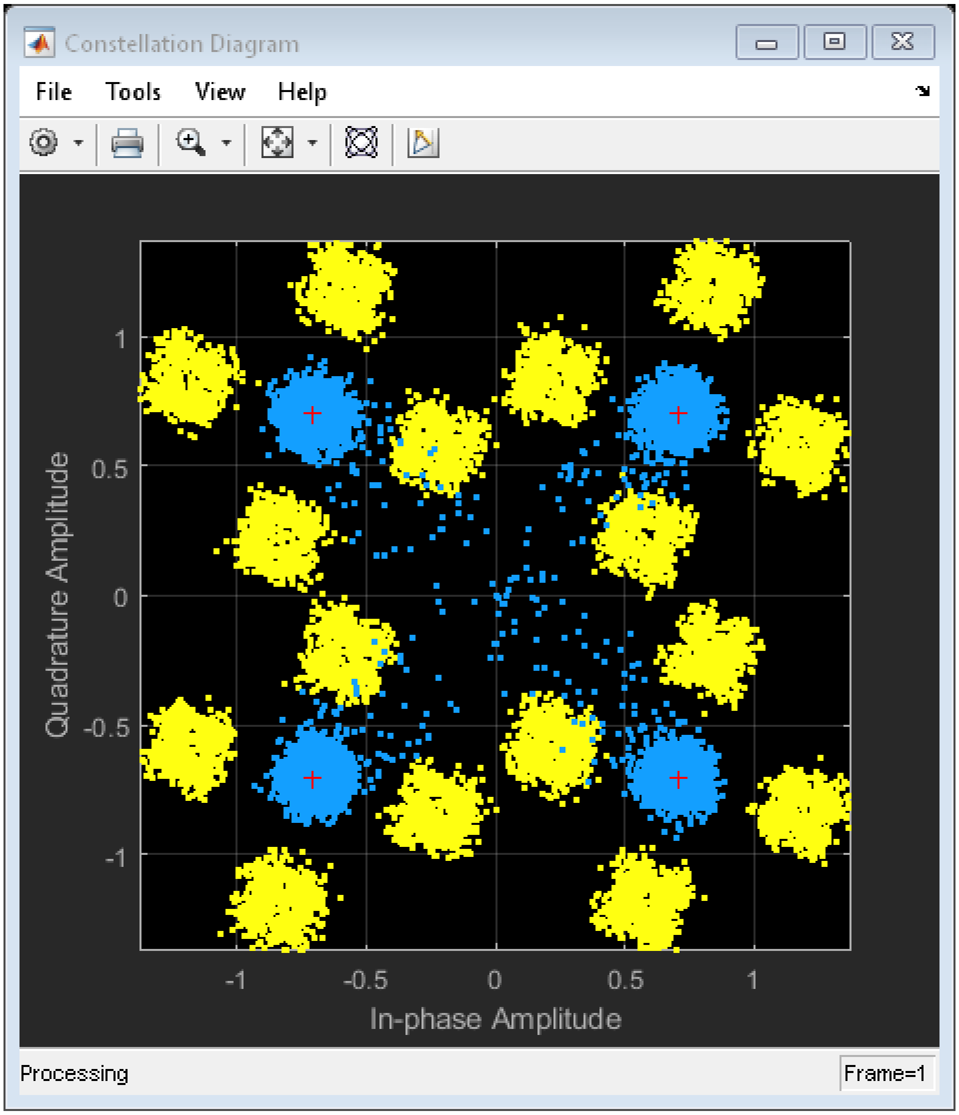
```
mxStep = maxstep(eq,rx)
```

```
mxStep = 0.3154
```

```
[y,err,weights] = eq(rx,tx(1:numTrainingSymbols));
```

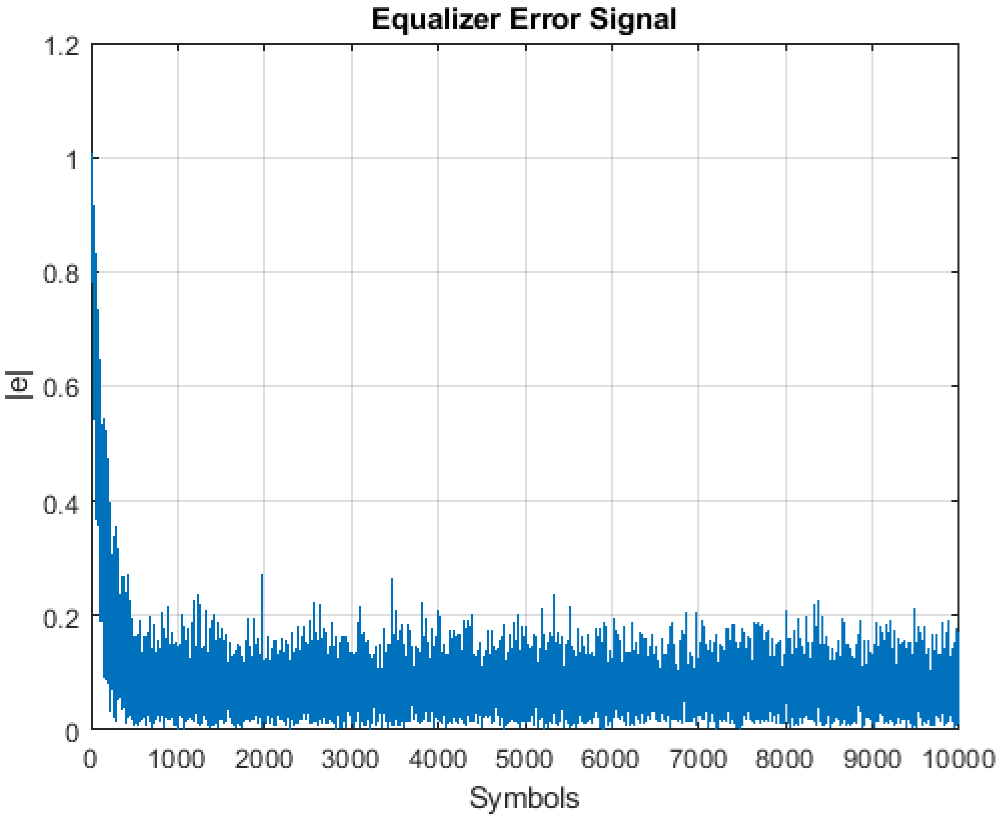
Plot the constellation of the impaired and equalized symbols.

```
constell = comm.ConstellationDiagram('NumInputPorts',2);
constell(rx,y)
```



Plot the equalizer error signal and compute the error vector magnitude (EVM) of the equalized symbols.

```
plot(abs(err))
grid on; xlabel('Symbols'); ylabel('|e|');title('Equalizer Error Signal')
```

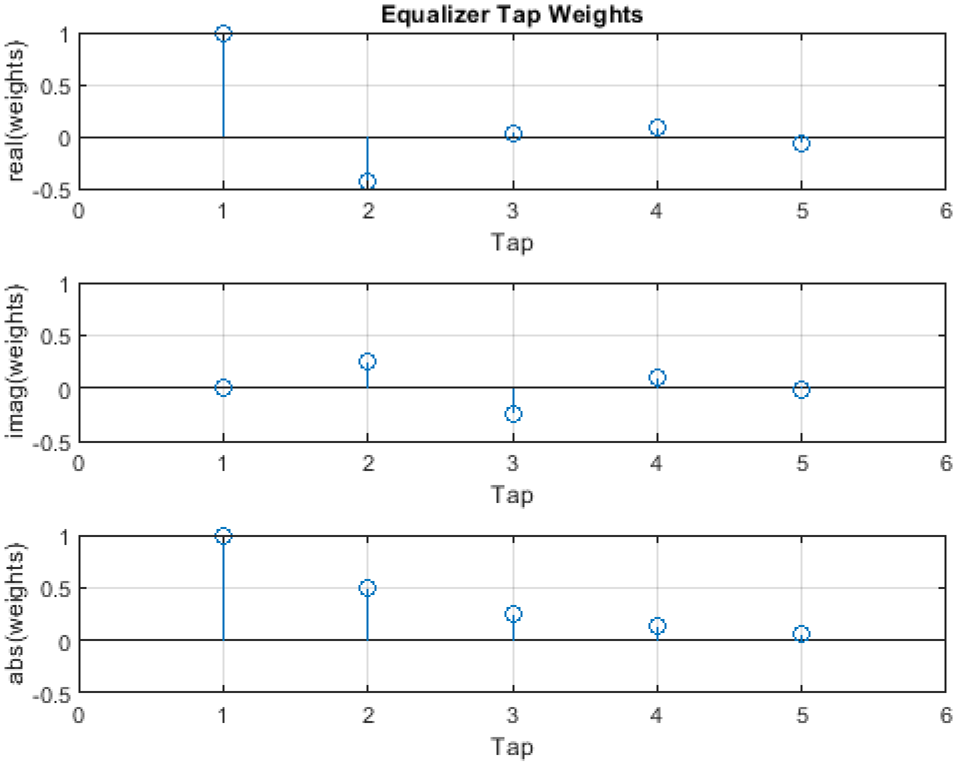


```
errevm = comm.EVM;
evm = errevm(tx,y)
```

```
evm = 11.7710
```

Plot the equalizer tap weights.

```
subplot(3,1,1);
stem(real(weights)); ylabel('real(weights)'); xlabel('Tap'); grid on; axis([0 6 -0.5 1])
title('Equalizer Tap Weights')
subplot(3,1,2);
stem(imag(weights)); ylabel('imag(weights)'); xlabel('Tap'); grid on; axis([0 6 -0.5 1])
subplot(3,1,3);
stem(abs(weights)); ylabel('abs(weights)'); xlabel('Tap'); grid on; axis([0 6 -0.5 1])
```



Linearly Equalize System By Using Different Training Schemes

Demonstrate linear equalization by using the least mean squares (LMS) algorithm to recover QPSK symbols passed through an AWGN channel. Apply different equalizer training schemes and show the symbol error magnitude.

System Setup

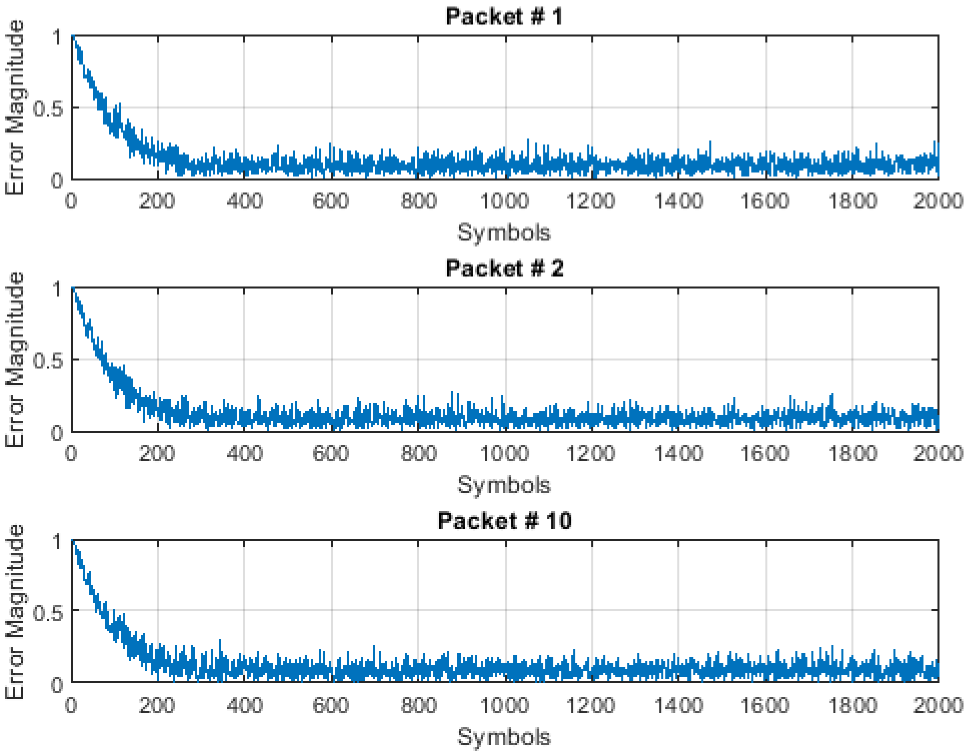
Simulate a QPSK-modulated system subject to AWGN. Transmit packets composed of 200 training symbols and 1800 random data symbols. Configure a linear LMS equalizer to recover the packet data.

```
M = 4;
numTrainSymbols = 200;
numDataSymbols = 1800;
SNR = 20;
trainingSymbols = pskmod(randi([0 M-1],numTrainSymbols,1),M,pi/4);
numPkts = 10;
lineq = comm.LinearEqualizer('Algorithm','LMS', ...
    'NumTaps',5,'ReferenceTap',3,'StepSize',0.01);
```

Train the Equalizer at the Beginning of Each Packet With Reset

Use prepended training symbols when processing each packet. After processing each packet, reset the equalizer. This reset forces the equalizer to train the taps with no previous knowledge. Equalizer error signal plots for the first, second, and last packet show higher symbol errors at the start of each packet.

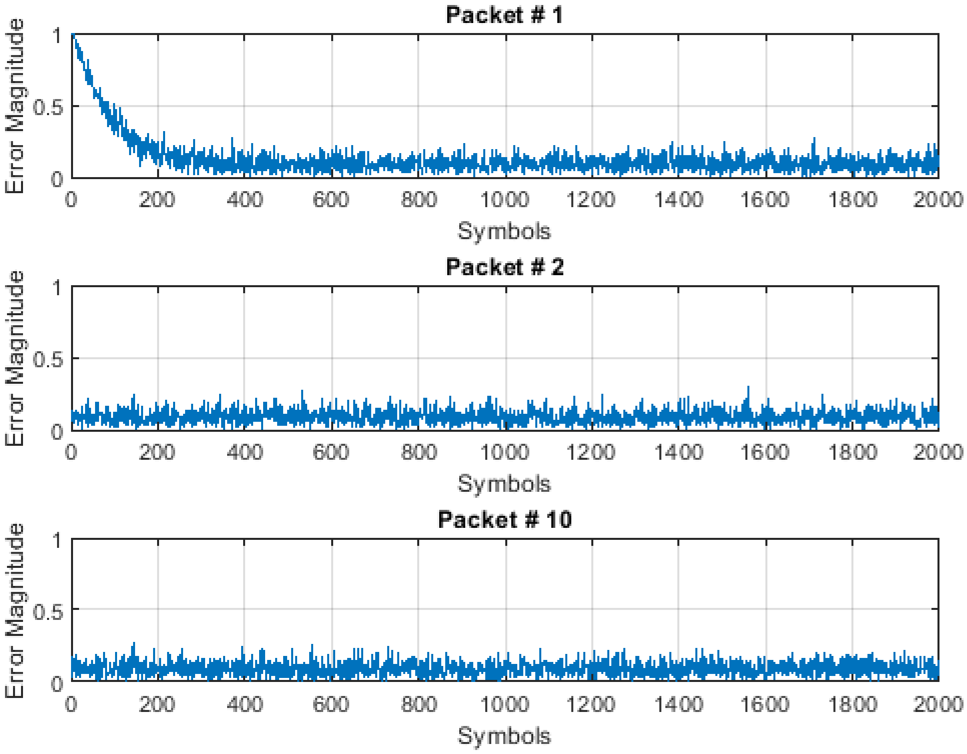
```
jj = 1;
figure
for ii = 1:numPkts
    b = randi([0 M-1],numDataSymbols,1);
    dataSym = pskmod(b,M,pi/4);
    packet = [trainingSymbols;dataSym];
    rx = awgn(packet,SNR);
    [~,err] = lineq(rx,trainingSymbols);
    reset(lineq)
    if (ii ==1 || ii == 2 ||ii == numPkts)
        subplot(3,1,jj)
        plot(abs(err))
        title(['Packet # ',num2str(ii)])
        xlabel('Symbols')
        ylabel('Error Magnitude')
        axis([0,length(packet),0,1])
        grid on;
        jj = jj+1;
    end
end
```



Train the Equalizer at the Beginning of Each Packet Without Reset

Process each packet using prepended training symbols. Do not reset the equalizer after each packet is processed. By not resetting after each packet, the equalizer retains tap weights from training prior packets. Equalizer error signal plots for the first, second, and last packet show that after the initial training on the first packet, subsequent packets have fewer symbol errors at the start of each packet.

```
release(lineq)
jj = 1;
figure
for ii = 1:numPkts
    b = randi([0 M-1],numDataSymbols,1);
    dataSym = pskmod(b,M,pi/4);
    packet = [trainingSymbols;dataSym];
    channel = 1;
    rx = awgn(packet*channel,SNR);
    [~,err] = lineq(rx,trainingSymbols);
    if (ii ==1 || ii == 2 ||ii == numPkts)
        subplot(3,1,jj)
        plot(abs(err))
        title(['Packet # ',num2str(ii)])
        xlabel('Symbols')
        ylabel('Error Magnitude')
        axis([0,length(packet),0,1])
        grid on;
        jj = jj+1;
    end
end
```



Train the Equalizer Periodically

Systems with signals subject to time-varying channels require periodic equalizer training to maintain lock on the channel variations. Specify a system that has 200 symbols of training for every 1800 data symbols. Between training, the equalizer does not update tap weights. The equalizer processes 200 symbols per packet.

```
Rs = 1e6;
fd = 20;
spp = 200; % Symbols per packet
b = randi([0 M-1],numDataSymbols,1);
dataSym = pskmod(b,M,pi/4);
packet = [trainingSymbols; dataSym];
stream = repmat(packet,10,1);
tx = (0:length(stream)-1)'/Rs;
channel = exp(1i*2*pi*fd*tx);
rx = awgn(stream.*channel,SNR);
```

Set the `AdaptAfterTraining` property to `false` to stop the equalizer tap weight updates after the training phase.

```
release(lineq)
lineq.AdaptAfterTraining = false
```

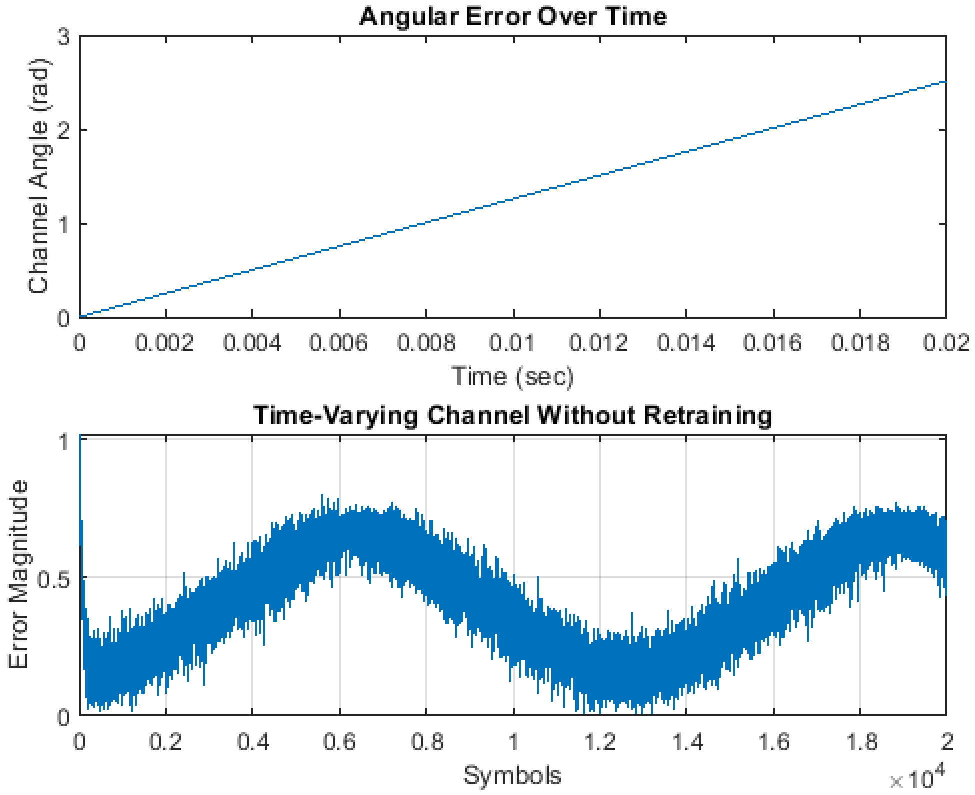
```
lineq = 
  comm.LinearEqualizer with properties:
```

```
                Algorithm: 'LMS'
                  NumTaps: 5
                 StepSize: 0.0100
            Constellation: [1x4 double]
             ReferenceTap: 3
               InputDelay: 0
    InputSamplesPerSymbol: 1
    TrainingFlagInputPort: false
       AdaptAfterTraining: false
     InitialWeightsSource: 'Auto'
       WeightUpdatePeriod: 1
```

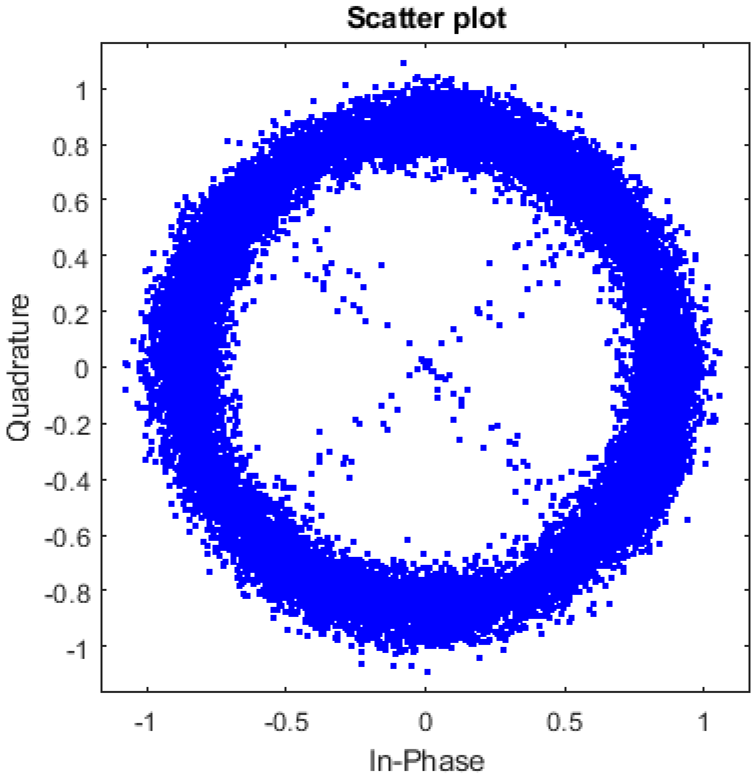
Equalize the impaired data. Plot the angular error from the channel, the equalizer error signal, and signal constellation. As the channel varies, the equalizer output does not remove the channel effects. The output constellation rotates out of sync, resulting in bit errors.

```
[y,err] = lineq(rx,trainingSymbols);

figure
subplot(2,1,1)
plot(tx, unwrap(angle(channel)))
xlabel('Time (sec)')
ylabel('Channel Angle (rad)')
title('Angular Error Over Time')
subplot(2,1,2)
plot(abs(err))
xlabel('Symbols')
ylabel('Error Magnitude')
grid on
title('Time-Varying Channel Without Retraining')
```



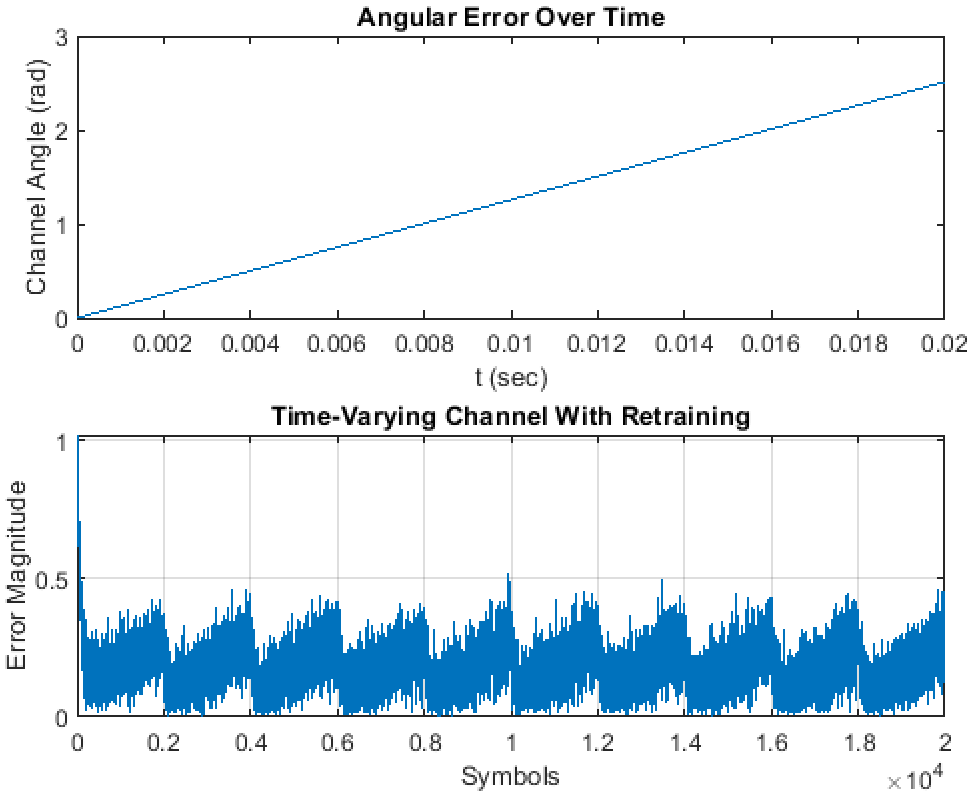
```
scatterplot(y)
```



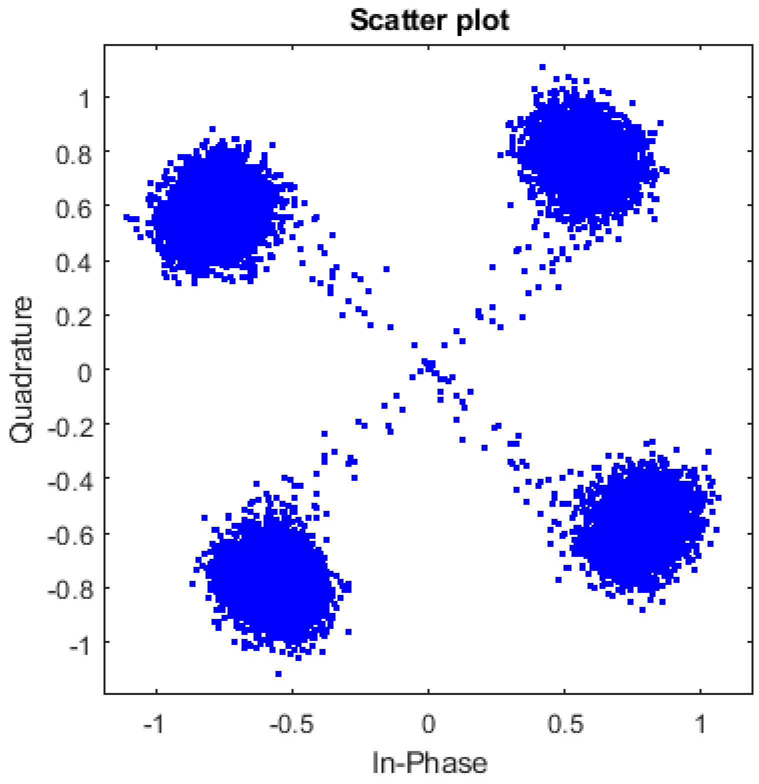
Set the `TrainingInputPort` property to `true` to configure the equalizer to retrain the taps when signaled by the `trainFlag` input. The equalizer trains only when `trainFlag` is `true`. After every 2000 symbols, the equalizer retrains the taps and keeps lock on variations of the channel. Plot the angular error from the channel, equalizer error signal, and signal constellation. As the channel varies, the equalizer output removes the channel effects. The output constellation does not rotate out of sync and bit errors are reduced.

```
release(lineq)
lineq.TrainingFlagInputPort = true;
symbolCnt = 0;
numPackets = length(rx)/spp;
trainFlag = true;
trainingPeriod = 2000;
eVec = zeros(size(rx));
yVec = zeros(size(rx));
for p=1:numPackets
    [yVec((p-1)*spp+1:p*spp,1),eVec((p-1)*spp+1:p*spp,1)] = ...
        lineq(rx((p-1)*spp+1:p*spp,1),trainingSymbols,trainFlag);
    symbolCnt = symbolCnt + spp;
    if symbolCnt >= trainingPeriod
        trainFlag = true;
        symbolCnt = 0;
    else
        trainFlag = false;
    end
end
figure
```

```
subplot(2,1,1)
plot(tx, unwrap(angle(channel)))
xlabel('t (sec)')
ylabel('Channel Angle (rad)')
title('Angular Error Over Time')
subplot(2,1,2)
plot(abs(eVec))
xlabel('Symbols')
ylabel('Error Magnitude')
grid on
title('Time-Varying Channel With Retraining')
```



```
scatterplot(yVec)
```



Linearly Equalize Delayed Signal

Simulate a system with delay between the transmitted symbols and received samples. Typical systems have transmitter and receiver filters that result in a delay. This delay must be accounted for to synchronize the system. In this example, the system delay is introduced without transmit and receive filters. Linear equalization, using the least mean squares (LMS) algorithm, recovers QPSK symbols.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
mpChan = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
systemDelay = dsp.Delay(20);
snr = 24;
```

Generate QPSK-modulated symbols. Apply multipath channel filtering, a system delay, and AWGN to the transmitted symbols.

```
data = randi([0 M-1],numSymbols,1);
tx = pskmod(data,M,pi/4); % OQPSK
delayedSym = systemDelay(filter(mpChan,1,tx));
rx = awgn(delayedSym,snr,'measured');
```

Create equalizer and EVM System objects. The equalizer System object specifies a linear equalizer that uses the LMS algorithm.

```
lineq = comm.LinearEqualizer('Algorithm','LMS', ...
    'NumTaps',9,'ReferenceTap',5);
evm = comm.EVM('ReferenceSignalSource', ...
    'Estimated from reference constellation');
```

Equalize Without Adjusting Input Delay

Equalize the received symbols.

```
[y1,err1,wts1] = lineq(rx,tx(1:numTrainingSymbols,1));
```

Find the delay between the received symbols and the transmitted symbols by using the `finddelay` function.

```
rxDelay = finddelay(tx,rx)
```

```
rxDelay = 20
```

Display the equalizer information. The latency value indicates the delay introduced by the equalizer. Calculate the total delay as the sum of `rxDelay` and the equalizer latency.

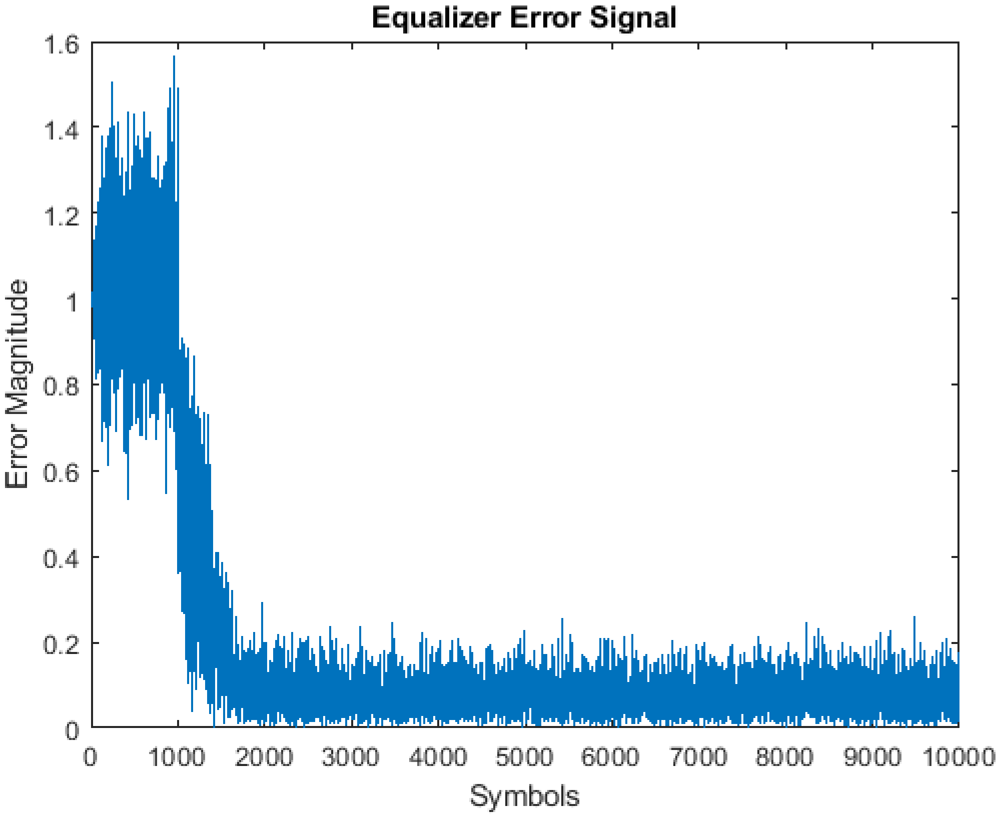
```
eqInfo = info(lineq)
```

```
eqInfo = struct with fields:
    Latency: 4
```

```
totalDelay = rxDelay + eqInfo.Latency;
```

Until the equalizer output converges, the symbol error rate is high. Plot the error output, `err1`, to determine when the equalized output converges.

```
plot(abs(err1))
xlabel('Symbols')
ylabel('Error Magnitude')
title('Equalizer Error Signal')
```



The plot shows excessive errors beyond the 1000 symbols training period. When demodulating symbols and computing symbol errors, to account for the unconverged output and the system delay between the equalizer output and transmitted symbols, skip the first 2000 symbols.

```
dataRec1 = pskdemod(y1(2000+totalDelay:end),M,pi/4);
symErrWithDelay = symerr(data(2000:end-totalDelay),dataRec1)
```

```
symErrWithDelay = 5999
```

```
evmWithDelay = evm(y1)
```

```
evmWithDelay = 29.5795
```

The error rate and EVM are high because the receive delay was not accounted for in the equalizer System object.

Adjust Input Delay in Equalizer

Equalize the received data by using the delay value to set the `InputDelay` property. Because `InputDelay` is a nontunable property, you must release the `lineq` System object to reconfigure the `InputDelay` property. Equalize the received symbols.

```
release(lineq)
lineq.InputDelay = rxDelay
```

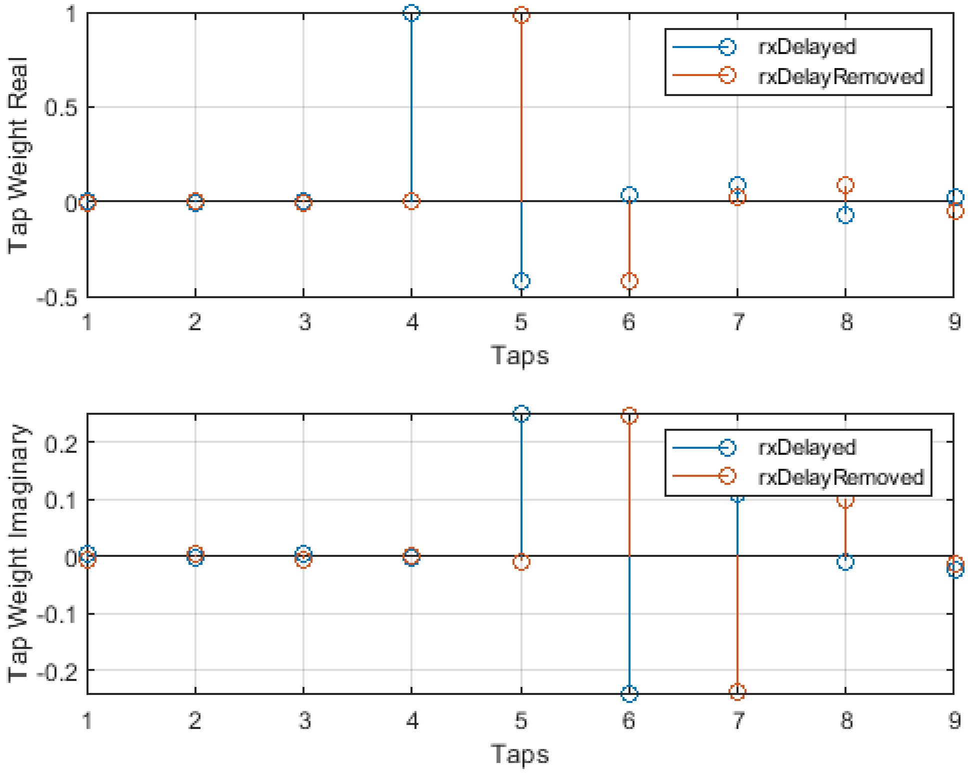
```
lineq = 
  comm.LinearEqualizer with properties:
```

```
                Algorithm: 'LMS'
                  NumTaps: 9
                 StepSize: 0.0100
            Constellation: [1x4 double]
             ReferenceTap: 5
               InputDelay: 20
    InputSamplesPerSymbol: 1
    TrainingFlagInputPort: false
       AdaptAfterTraining: true
     InitialWeightsSource: 'Auto'
       WeightUpdatePeriod: 1
```

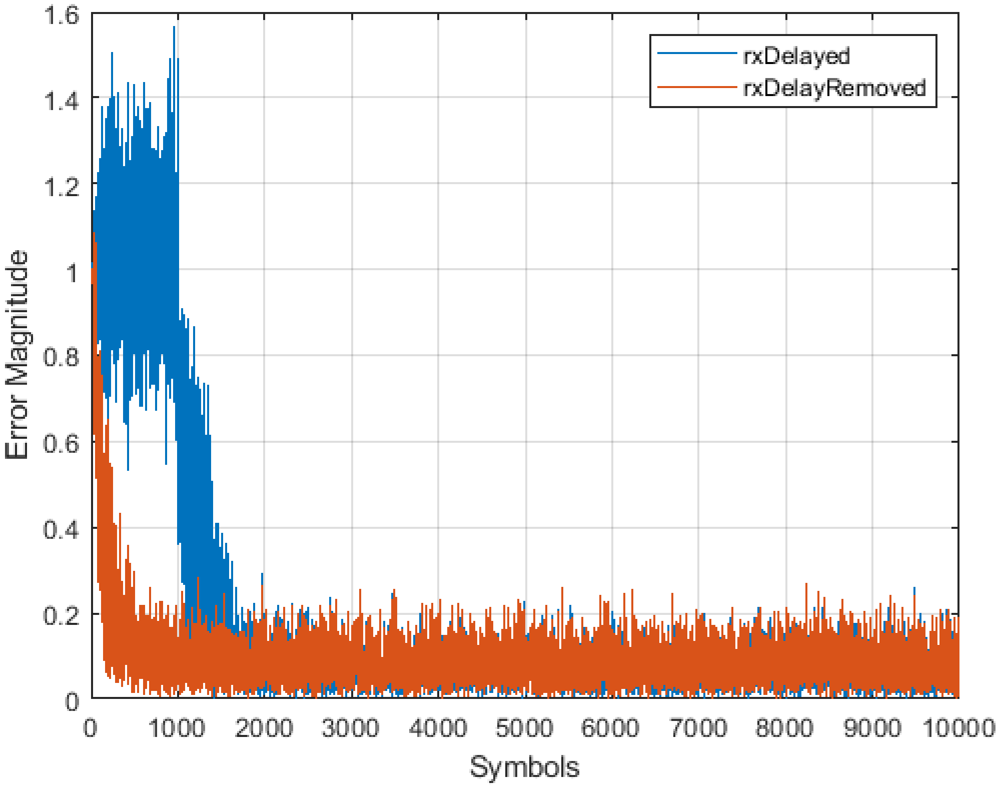
```
[y2,err2,wts2] = lineq(rx,tx(1:numTrainingSymbols,1));
```

Plot the tap weights and equalized error magnitude. A stem plot shows the equalizer tap weights before and after the system delay is removed. A 2-D line plot shows the slower equalizer convergence for the delayed signal as compared to the signal with the delay removed.

```
subplot(2,1,1)
stem([real(wts1),real(wts2)])
xlabel('Taps')
ylabel('Tap Weight Real')
legend('rxDelayed','rxDelayRemoved')
grid on
subplot(2,1,2)
stem([imag(wts1),imag(wts2)])
xlabel('Taps')
ylabel('Tap Weight Imaginary')
legend('rxDelayed','rxDelayRemoved')
grid on
```



```
figure
plot([abs(err1),abs(err2)])
xlabel('Symbols')
ylabel('Error Magnitude')
legend('rxDelayed','rxDelayRemoved')
grid on
```



Plot error output of the equalized signals, `rxDelayed` and `rxDelayRemoved`. For the signal that has the delay removed, the equalizer converges during the 1000 symbol training period. When demodulating symbols and computing symbol errors, to account for the unconverged output and the system delay between the equalizer output and transmitted symbols, skip the first 500 symbols. Reconfiguring the equalizer to account for the system delay enables better equalization of the signal, and reduces symbol errors and the EVM.

```
eqInfo = info(lineq)
```

```
eqInfo = struct with fields:
    Latency: 4
```

```
totalDelay = rxDelay + eqInfo.Latency;
dataRec2 = pskdemod(y2(500+totalDelay:end),M,pi/4);
symErrDelayRemoved = symerr(data(500:end-totalDelay),dataRec2)
```

```
symErrDelayRemoved = 0
```

```
evmDelayRemoved = evm(y2(500+totalDelay:end))
```

```
evmDelayRemoved = 9.4435
```

Linearly Equalize Symbols By Using EVM-Based Training

Recover QPSK symbols with a linear equalizer by using the constant modulus algorithm (CMA) and EVM-based taps training. When using blind equalizer algorithms, such as CMA, train the equalizer taps by using the AdaptWeights property to start and stop training. Helper functions are used to generate plots and apply phase correction.

Initialize system variables.

```
rng(123456);
M = 4; % QPSK
numSymbols = 100;
numPackets = 5000;
raylChan = comm.RayleighChannel('PathDelays',[0 1], ...
    'AveragePathGains',[0 -12],'MaximumDopplerShift',1e-5);
SNR = 50;
adaptWeights = true;
```

Create the equalizer and EVM System objects. The equalizer System object specifies a linear equalizer by using the CMA adaptive algorithm. Call the helper function to initialize figure plots.

```
lineq = comm.LinearEqualizer('Algorithm','CMA', ...
    'NumTaps',5,'ReferenceTap',3, ...
    'StepSize',0.03,'AdaptWeightsSource','Input port')
```

```
lineq = 
  comm.LinearEqualizer with properties:

                Algorithm: 'CMA'
                  NumTaps: 5
                 StepSize: 0.0300
            Constellation: [1x4 double]
             ReferenceTap: 3
    InputSamplesPerSymbol: 1
       AdaptWeightsSource: 'Input port'
     InitialWeightsSource: 'Auto'
       WeightUpdatePeriod: 1
```

```
info(lineq)
```

```
ans = struct with fields:
    Latency: 2
```

```
evm = comm.EVM('ReferenceSignalSource', ...
    'Estimated from reference constellation');
[errPlot,evmPlot,scatSym,adaptState] = initFigures(numPackets,lineq);
```

Equalization Loop

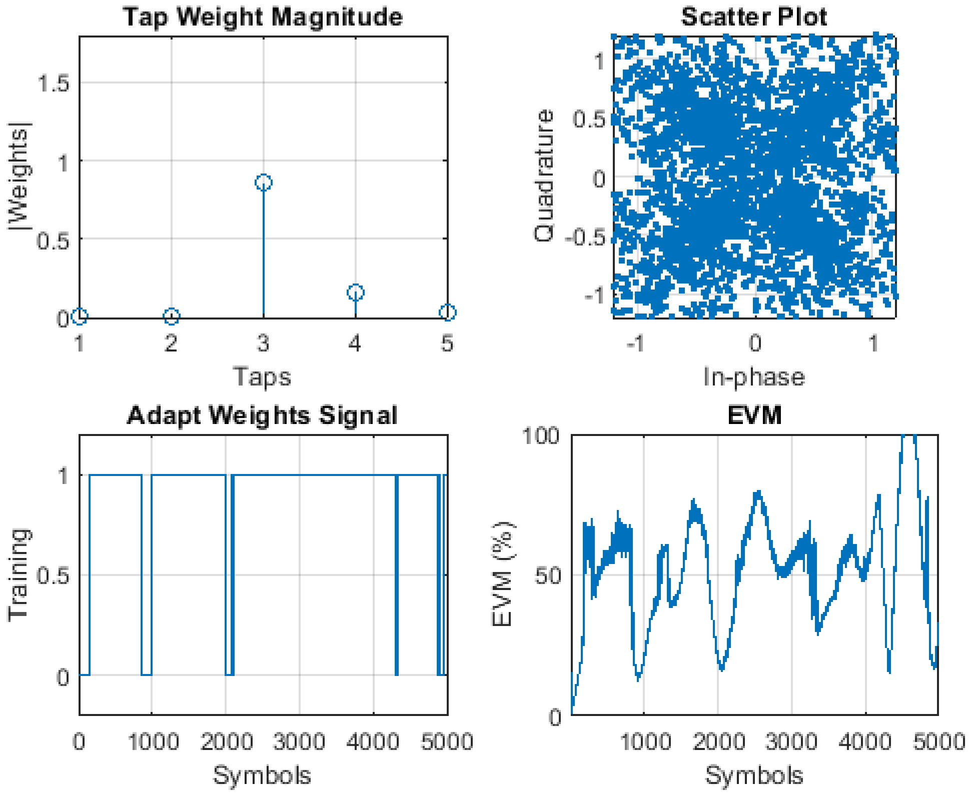
To implement the equalization loop:

1. Generate PSK data packets.
2. Apply Rayleigh fading and AWGN to the transmission data.
3. Apply equalization to the received data and phase correction to the equalizer output.
4. Estimate the EVM and toggle the adaptWeights flag to true or false based on the EVM level.
5. Update the figure plots.

```
for p=1:numPackets
```

```
    data = randi([0 M-1],numSymbols,1);
    tx = pskmod(data,M,pi/4);
    rx = awgn(raylChan(tx),SNR);
    rxDelay = finddelay(rx,tx);
    [y,err,wts] = lineq(rx,adaptWeights);
    y = phaseCorrection(y);
    evmEst = evm(y);
    adaptWeights = (evmEst > 20);

    updateFigures(errPlot,evmPlot,scatSym,adaptState, ...
        wts,y(end),evmEst,adaptWeights,p,numPackets)
end
```



```
rxDelay

rxDelay = 0
```

The figure plots show that, as the EVM varies, the equalizer toggles in and out of decision-directed weight adaptation mode.

Helper Functions

This helper function initializes figures that show a quad plot of simulation results.

```
function [errPlot,evmPlot,scatter,adaptState] = initFigures(numPkts,lineq)
yVec = nan(numPkts,1);
evmVec = nan(numPkts,1);
wVec = zeros(lineq.NumTaps,1);
```

```
adaptVec = nan(numPkts,1);

figure
subplot(2,2,1)
evmPlot = stem(wVec);
grid on; axis([1 lineq.NumTaps 0 1.8])
xlabel('Taps'); ylabel('|Weights|'); title('Tap Weight Magnitude')

subplot(2,2,2)
scatter = plot(yVec, '.');
axis square; axis([-1.2 1.2 -1.2 1.2]); grid on
xlabel('In-phase'); ylabel('Quadrature'); title('Scatter Plot');
subplot(2,2,3)
adaptState = plot(adaptVec);
grid on; axis([0 numPkts -0.2 1.2])
ylabel('Training'); xlabel('Symbols'); title('Adapt Weights Signal')
subplot(2,2,4)
errPlot = plot(evmVec);
grid on; axis([1 numPkts 0 100])
xlabel('Symbols'); ylabel('EVM (%)'); title('EVM')
end
```

This helper function updates figures.

```
function updateFigures(errPlot,evmPlot,scatSym, ...
    adaptState,w,y,evmEst,adaptWts,p,numFrames)
persistent yVec evmVec adaptVec

if p == 1
    yVec = nan(numFrames,1);
    evmVec = nan(numFrames,1);
    adaptVec = nan(numFrames,1);
end

yVec(p) = y;
evmVec(p) = evmEst;
adaptVec(p) = adaptWts;

errPlot.YData = abs(evmVec);
evmPlot.YData = abs(w);
scatSym.XData = real(yVec);
scatSym.YData = imag(yVec);
adaptState.YData = adaptVec;
drawnow limitrate
end
```

This helper function applies phase correction.

```
function y = phaseCorrection(y)
a = angle(y((real(y) > 0) & (imag(y) > 0)));
a(a < 0.1) = a(a < 0.1) + pi/2;
theta = mean(a) - pi/4;
y = y * exp(-1i*theta);
end
```

Linearly Equalize Packetized Signals in Fading Environments

Recover QPSK symbols in fading environments with a linear equalizer, using the least mean squares (LMS) algorithm. Use the `reset` object function to equalize independent packets. Use helper functions to generate plots. This example also shows symbol-based processing and frame-based processing.

Setup

Initialize system variables, create an equalizer System object, and initialize the plot figures.

```
M = 4; % QPSK
numSym = 1000;
numTrainingSym = 100;
numPackets = 5;
numTaps = 9;
ttlNumSym = numSym + numTrainingSym;
raylChan = comm.RayleighChannel('PathDelays',[0 1], ...
    'AveragePathGains',[0 -9], ...
    'MaximumDopplerShift',0, ...
    'PathGainsOutputPort',true);
SNR = 35;
rxVec = zeros(ttlNumSym,numPackets);
txVec = zeros(ttlNumSym,numPackets);
yVec = zeros(ttlNumSym,1);
eVec = zeros(ttlNumSym,1);

lineq1 = comm.LinearEqualizer('Algorithm','LMS', ...
    'NumTaps',numTaps,'ReferenceTap',5, ...
    'StepSize',0.01,'TrainingFlagInputPort',true);

[errPlot,wStem,hStem,scatPlot] = initFigures(ttlNumSym,lineq1, ...
    raylChan.AveragePathGains);
```

Symbol-Based Processing

For symbol-based processing, provide one symbol at the input of the equalizer. Reset the equalizer state and channel after processing each packet.

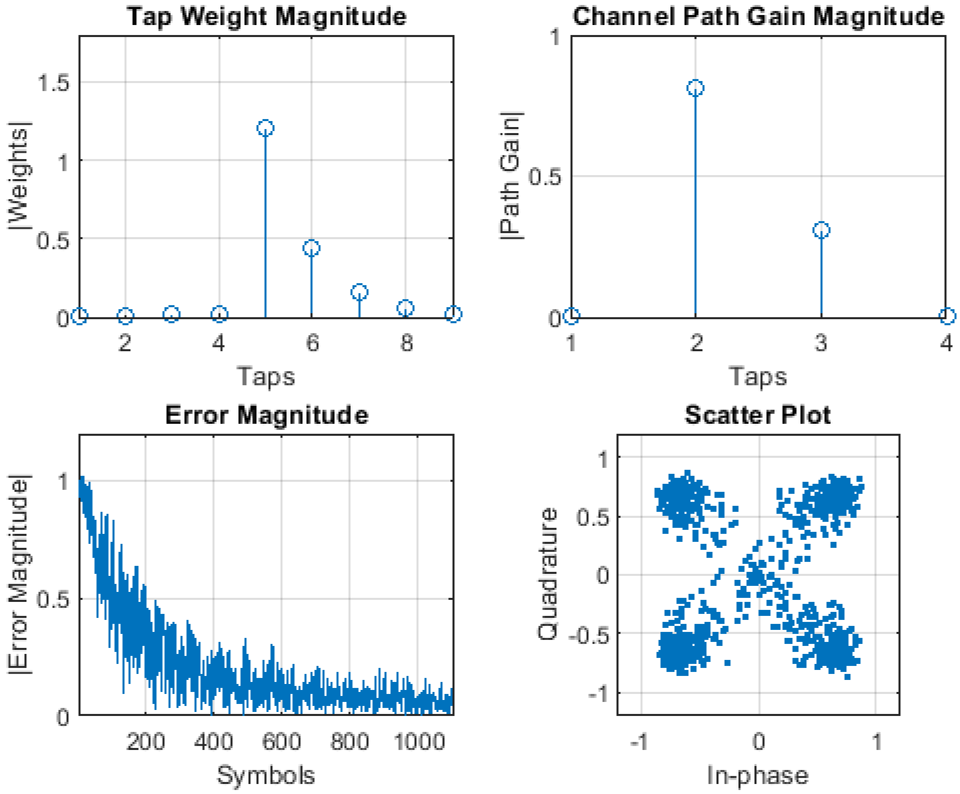
```
for p = 1:numPackets
    trainingFlag = true;
    for q=1:ttlNumSym
        data = randi([0 M-1],1,1);
        tx = pskmod(data,M,pi/4);
        [xc,pg] = raylChan(tx);
        rx = awgn(xc,25);
        [y,err,wts] = lineq1(rx,tx,trainingFlag);
```

Disable training after processing `numTrainingSym` training symbols.

```
        if q == numTrainingSym
            trainingFlag = false;
        end
        updateFigures(errPlot,wStem,hStem,scatPlot,err,wts,y,pg,q,ttlNumSym);
        txVec(q,p) = tx;
        rxVec(q,p) = rx;
    end
```

After processing each packet, reset the channel System object to get a new realization of channel taps and the equalizer System object to restore the default set of tap weights.

```
    reset(raylChan)
    reset(lineq1)
end
```



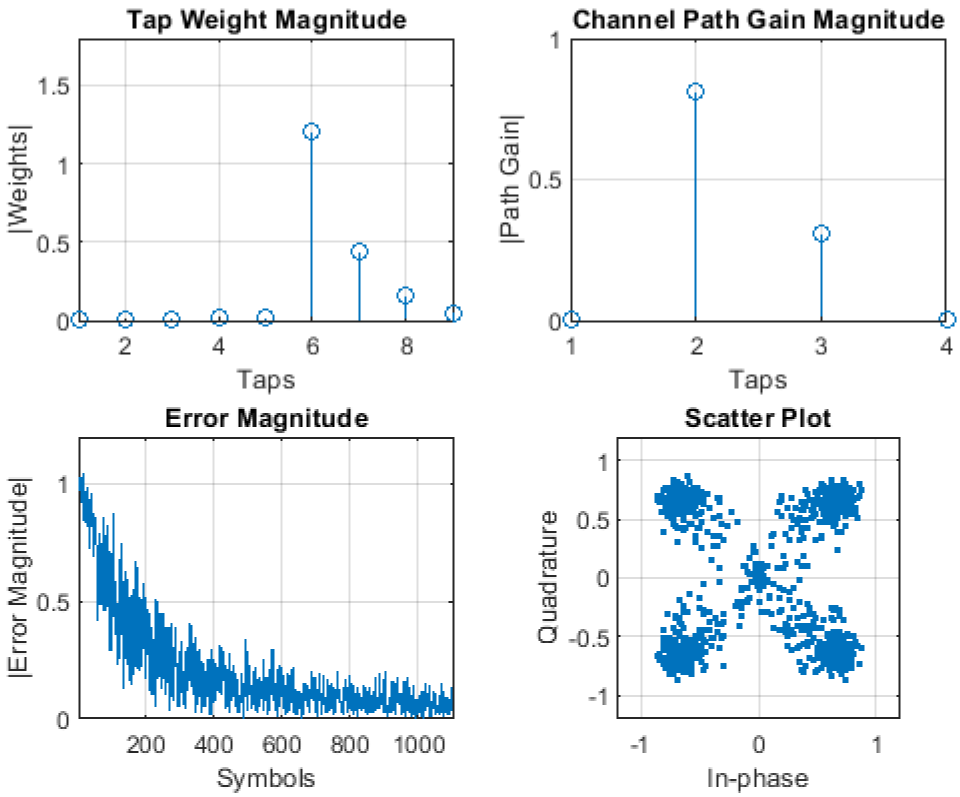
Packet-Based Processing

For packet-based processing, provide one packet at the input of the equalizer. Each packet contains `ttlNumSym` symbols. Because the training duration is less than the packet length, you do not need to specify the start-training input.

```
yVecPkt = zeros(ttlNumSym,numPackets);
errVecPkt = zeros(ttlNumSym,numPackets);
wgtVecPkt = zeros(numTaps,numPackets);
lineq2 = comm.LinearEqualizer('Algorithm','LMS', ...
    'NumTaps',9,'ReferenceTap',6,'StepSize',0.01);
for p = 1:numPackets
    [yVecPkt(:,p),errVecPkt(:,p),wgtVecPkt(:,p)] = ...
        lineq2(rxVec(:,p),txVec(1:numTrainingSym,p));
    for q=1:ttlNumSym
        updateFigures(errPlot,wStem,hStem,scatPlot, ...
            errVecPkt(q,p),wgtVecPkt(:,p),yVecPkt(q,p),pg,q,ttlNumSym);
    end
```

After processing each packet, reset the channel System object to get a new realization of channel taps and the equalizer System object to restore the default set of tap weights.

```
    reset(raylChan)
    reset(lineq2)
end
```



Helper Functions

The helper function initializes the figures.

```
function [errPlot,wStem,hStem,scatPlot] = initFigures(ttlNumSym,lineq,pg)
yVec = nan(ttlNumSym,1);
eVec = nan(ttlNumSym,1);
wVec = zeros(lineq.NumTaps,1);
figure;
subplot(2,2,1);
wStem = stem(wVec);
axis([1 lineq.NumTaps 0 1.8]); grid on
xlabel('Taps'); ylabel('|Weights|'); title('Tap Weight Magnitude')
subplot(2,2,2);
hStem = stem([0 abs(pg) 0]);
grid on;
xlabel('Taps'); ylabel('|Path Gain|'); title('Channel Path Gain Magnitude')
subplot(2,2,3);
errPlot = plot(eVec);
axis([1 ttlNumSym 0 1.2]); grid on
xlabel('Symbols'); ylabel('|Error Magnitude|'); title('Error Magnitude')
subplot(2,2,4);
scatPlot = plot(yVec,'.');
axis square; axis([-1.2 1.2 -1.2 1.2]); grid on;
```

```
xlabel('In-phase'); ylabel('Quadrature'); title(sprintf('Scatter Plot'));
end
```

This helper function updates the figures.

```
function updateFigures(errPlot,wStem,hStem,scatPlot, ...
    err,wts,y,pg,p,ttlNumSym)
persistent yVec eVec
if p == 1
    yVec = nan(ttlNumSym,1);
    eVec = nan(ttlNumSym,1);
end
yVec(p) = y;
eVec(p) = abs(err);
errPlot.YData = abs(eVec);
wStem.YData = abs(wts);
hStem.YData = [0 abs(pg) 0];
scatPlot.XData = real(yVec);
scatPlot.YData = imag(yVec);
drawnow limitrate
end
```

Nonadaptive Linear Equalization

Use the linear equalizer in nonadaptive mode. Use the `mmseweights` object function to calculate the minimum mean squared error (MMSE) solution and use the weights returned as the set of tap weights for the linear equalizer.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
chtaps = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
EbN0 = 20;
```

Generate QPSK modulated symbols. Apply delayed multipath channel filtering and AWGN impairments to the symbols.

```
data = randi([0 M-1], numSymbols, 1);
tx = pskmod(data, M, pi/4);
rx = awgn(filter(chtaps,1,tx),25,'measured');
```

Create a linear equalizer System object configured to use CMA algorithm, set the `AdaptWeights` property to `false`, and the `InitialWeightsSource` property to `Property`. Calculate the MMSE weights. Set the initial tap weights to the calculated MMSE weights. Equalize the impaired symbols.

```
eq = comm.LinearEqualizer('Algorithm','CMA','AdaptWeights',false,'InitialWeightsSource','Property
```

```
eq = 
  comm.LinearEqualizer with properties:

                Algorithm: 'CMA'
                  NumTaps: 5
                 StepSize: 0.0100
            Constellation: [1x4 double]
```

```
    InputSamplesPerSymbol: 1
       AdaptWeightsSource: 'Property'
             AdaptWeights: false
     InitialWeightsSource: 'Property'
           InitialWeights: [5x1 double]
       WeightUpdatePeriod: 1
```

```
wgts = mmseweights(eq,chtaps,EbN0)
```

```
wgts = 5×1 complex

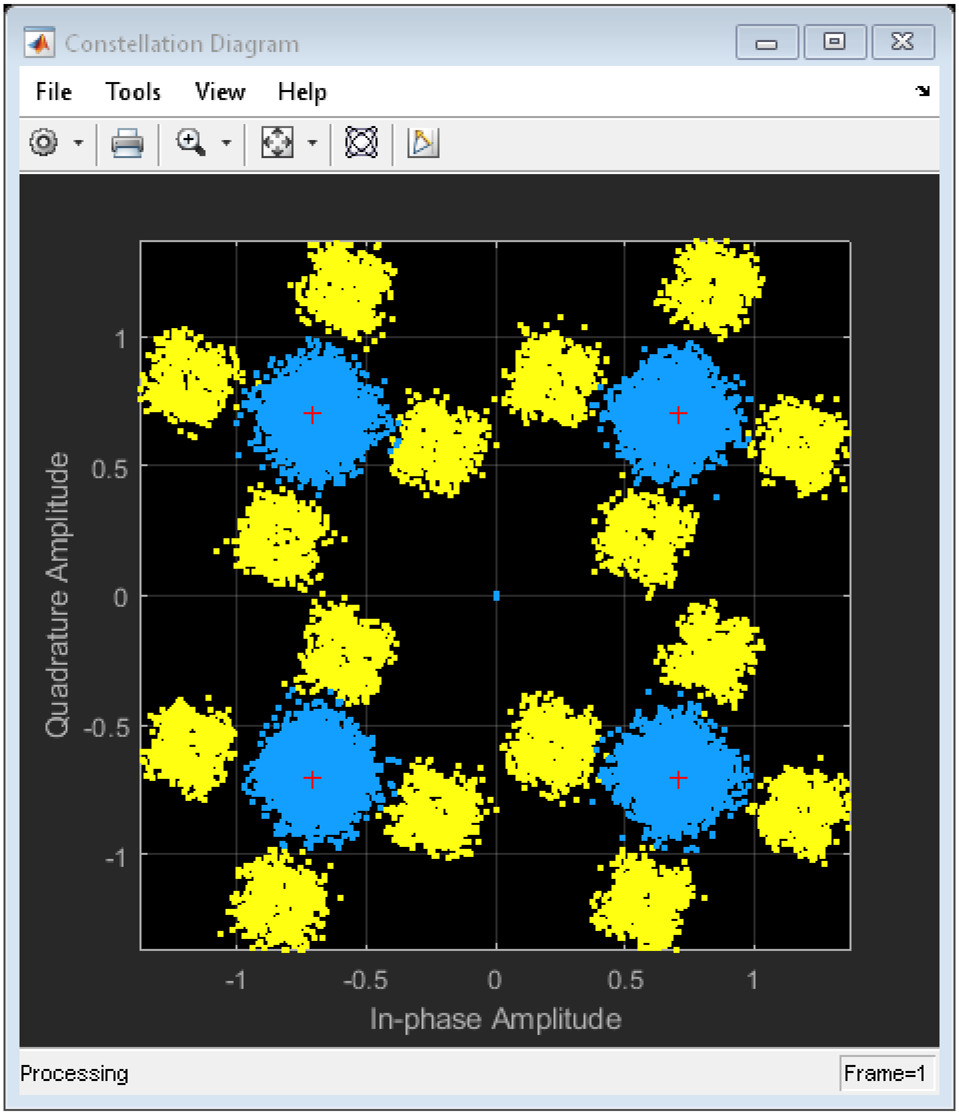
   0.0005 - 0.0068i
   0.0103 + 0.0117i
   0.9694 - 0.0019i
  -0.3987 + 0.2186i
   0.0389 - 0.1756i
```

```
eq.InitialWeights = wgts;
```

```
[y,err,weights] = eq(rx);
```

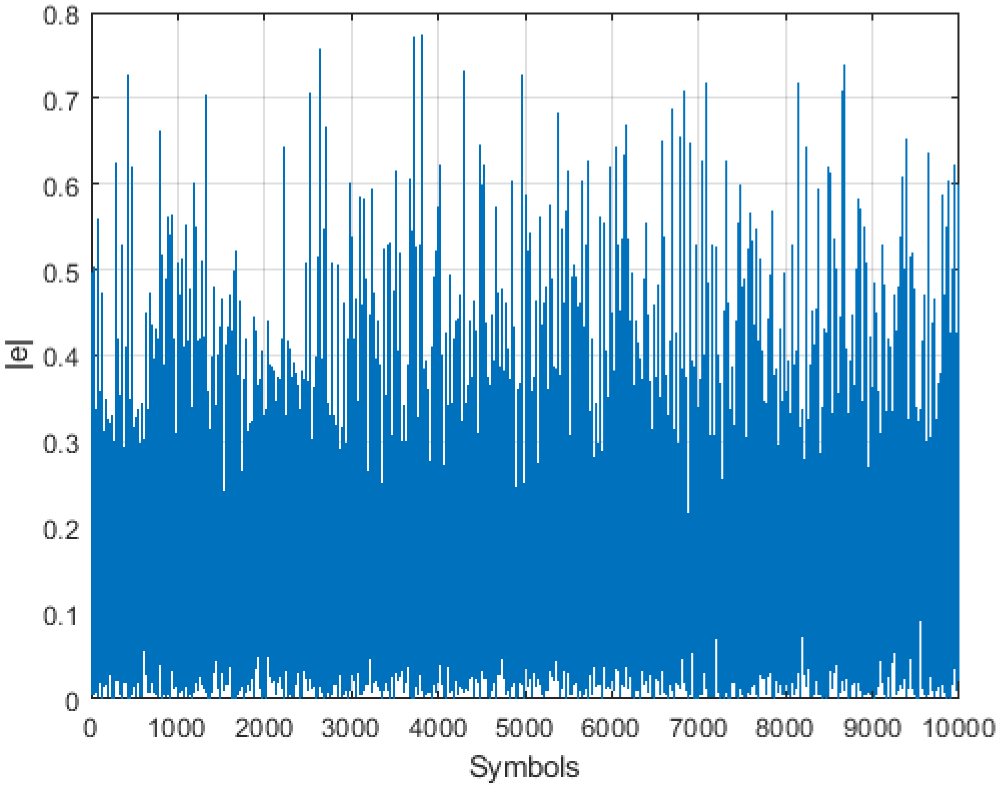
Plot constellation of impaired and equalized symbols.

```
constell = comm.ConstellationDiagram('NumInputPorts',2);
constell(rx,y)
```



Plot the equalizer error signal and compute the error vector magnitude of the equalized symbols.

```
plot(abs(err))
grid on; xlabel('Symbols'); ylabel('|e|')
```

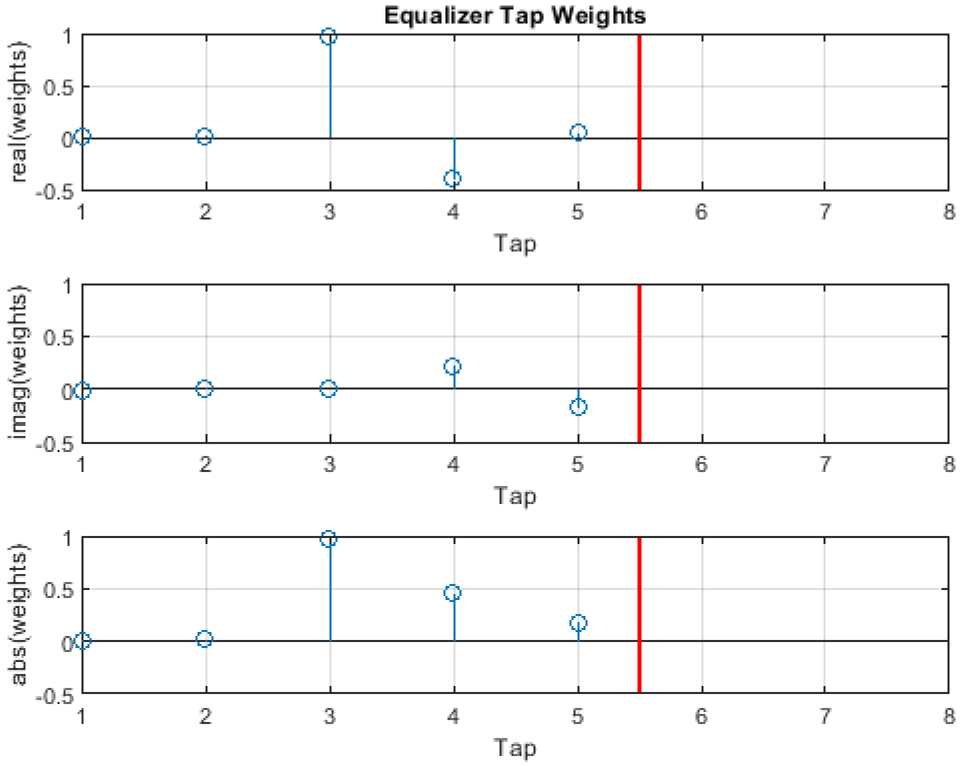


```
errevm = comm.EVM;
evm = errevm(tx,y)
```

```
evm = 140.6177
```

Plot equalizer tap weights.

```
subplot(3,1,1); stem(real(weights)); ylabel('real(weights)'); xlabel('Tap'); grid on; axis([1 8 -
line([eq.NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)
title('Equalizer Tap Weights')
subplot(3,1,2); stem(imag(weights)); ylabel('imag(weights)'); xlabel('Tap'); grid on; axis([1 8 -
line([eq.NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)
subplot(3,1,3); stem(abs(weights)); ylabel('abs(weights)'); xlabel('Tap'); grid on; axis([1 8 -0
line([eq.NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)
```



More About

Symbol Tap Spacing

You can configure the equalizer to operate as a symbol-spaced equalizer or as a fractional symbol-spaced equalizer.

- To operate the equalizer at a symbol-spaced rate, specify the number of samples per symbol as 1. Symbol-rate equalizers have taps spaced at the symbol duration. Symbol-rate equalizers are sensitive to timing phase.
- To operate the equalizer at a fractional symbol-spaced rate, specify the number of input samples per symbol as an integer greater than 1 and provide an input signal oversampled at that sampling rate. Fractional symbol-spaced equalizers have taps spaced at an integer fraction of the input symbol duration. Fractional symbol-spaced equalizers are not sensitive to timing phase.

Algorithms

Linear Equalizers

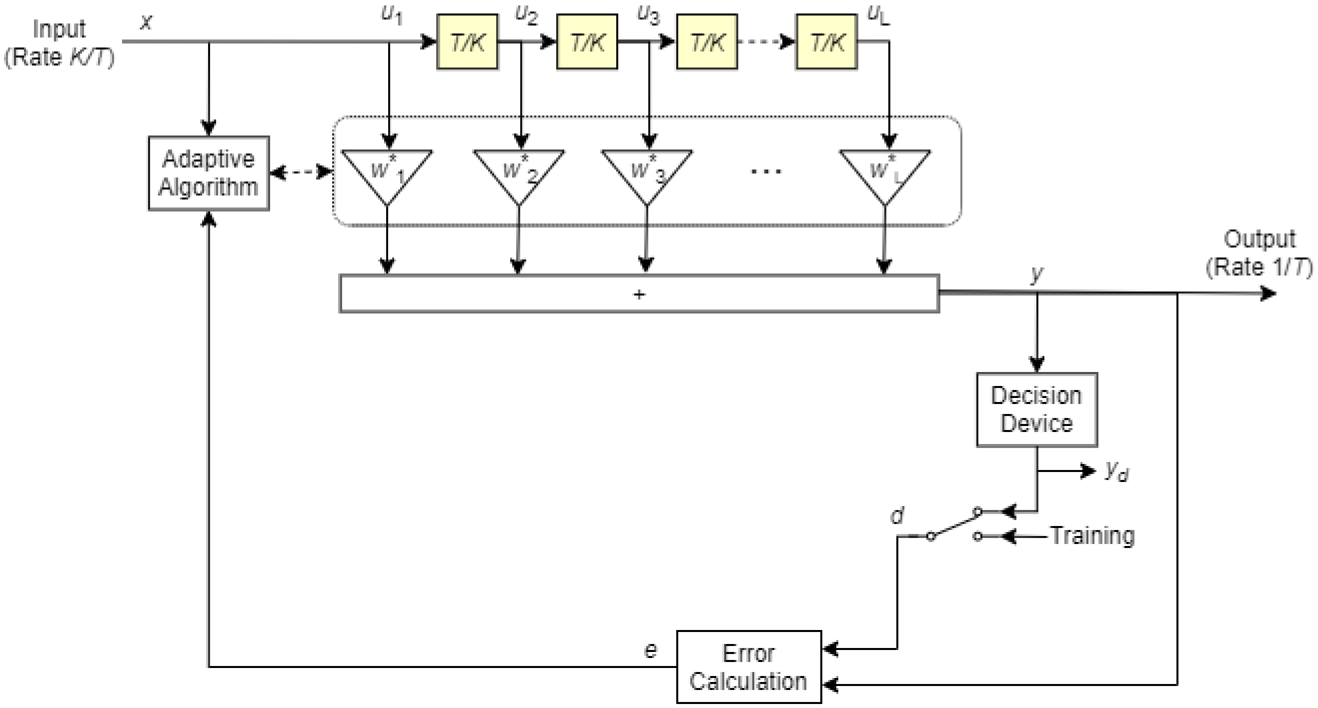
Linear equalizers can remove intersymbol interference (ISI) when the frequency response of a channel has no null. If a null exists in the frequency response of a channel, linear equalizers tend to enhance the noise. In this case, use decision feedback equalizers to avoid enhancing the noise.

A linear equalizer consists of a tapped delay line that stores samples from the input signal. Once per symbol period, the equalizer outputs a weighted sum of the values in the delay line and updates the weights to prepare for the next symbol period.

Linear equalizers can be symbol-spaced or fractional symbol-spaced.

- For a symbol-spaced equalizer, the number of samples per symbol, *K*, is 1. The output sample rate equals the input sample rate.
- For a fractional symbol-spaced equalizer, the number of samples per symbol, *K*, is an integer greater than 1. Typically, *K* is 4 for fractionally spaced equalizers. The output sample rate is 1/*T* and the input sample rate is *K/T*, where *T* is the symbol period. Tap-weight updating occurs at the output rate.

This schematic shows a linear equalizer with *L* weights, a symbol period of *T*, and *K* samples per symbol. If *K* is 1, the result is a symbol-spaced linear equalizer instead of a fractional symbol-spaced linear equalizer.



In each symbol period, the equalizer receives *K* input samples at the tapped delay line. The equalizer then outputs a weighted sum of the values in the tapped delay line and updates the weights to prepare for the next symbol period.

For more information, see “Equalization”.

Least Mean Square (LMS) Algorithm

For the LMS algorithm, in the previous schematic, *w* is a vector of all weights w_i, and *u* is a vector of all inputs u_i. Based on the current set of weights, the LMS algorithm creates the new set of weights as

$$w_{\text{new}} = w_{\text{current}} + (StepSize)\, ue^*.$$

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed when using the LMS adaptive algorithm, use the `maxstep` object function. The * operator denotes the complex conjugate and the error calculation $e = d - y$.

Recursive Least Square (RLS) Algorithm

For the RLS algorithm, in the previous schematic, w is the vector of all weights w_i, and u is the vector of all inputs u_i. Based on the current set of inputs, u, and the inverse correlation matrix, P, the RLS algorithm first computes the Kalman gain vector, K, as

$$K = \frac{Pu}{(ForgettingFactor) + u^H Pu}\,.$$

The forgetting factor used by the adaptive algorithm is specified as a scalar in the range (0, 1]. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalized output signal to be less stable. H denotes the Hermitian transpose. Based on the current inverse correlation matrix, the new inverse correlation matrix is

$$P_{\text{new}} = \frac{(1 - Ku^H)P_{\text{current}}}{ForgettingFactor}\,.$$

Based on the current set of weights, the RLS algorithm creates the new set of weights as

$$w_{\text{new}} = w_{\text{current}} + K^* e.$$

The * operator denotes the complex conjugate and the error calculation $e = d - y$.

Constant Modulus Algorithm (CMA)

For the CMA adaptive algorithm, in the previous schematic, w is the vector of all weights w_i, and u is the vector of all inputs u_i. Based on the current set of weights, the CMA adaptive algorithm creates the new set of weights as

$$w_{\text{new}} = w_{\text{current}} + (StepSize)\ u^* e.$$

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed by the CMA adaptive algorithm, use the `maxstep` object function. The * operator denotes the complex conjugate and the error calculation $e = y(R - |y|^2)$, where R is a constant related to the signal constellation.

comm.DecisionFeedbackEqualizer

Package: `comm`

Equalize modulated signals using decision feedback filtering

Description

The `comm.DecisionFeedbackEqualizer` System object uses a decision feedback filter tap delay line with a weighted sum to equalize modulated signals transmitted through a dispersive channel. The equalizer object adaptively adjusts tap weights based on the selected algorithm. For more information, see “Algorithms” on page 3-543.

To equalize modulated signals using a decision feedback filter:

1. Create the `comm.DecisionFeedbackEqualizer` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
dfe = comm.DecisionFeedbackEqualizer
dfe = comm.DecisionFeedbackEqualizer(Name,Value)
```

Description

`dfe = comm.DecisionFeedbackEqualizer` creates a decision feedback equalizer System object to adaptively equalize a signal.

`dfe = comm.DecisionFeedbackEqualizer(Name,Value)` sets properties using one or more name-value pairs. For example, `comm.DecisionFeedbackEqualizer('Algorithm','RLS')` configures the equalizer object to update tap weights using the recursive least squares (RLS) algorithm. Enclose each property name in quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Algorithm` — Adaptive algorithm
`'LMS'` (default) | `'RLS'` | `'CMA'`

Adaptive algorithm used for equalization, specified as one of these values:

- 'LMS' — Update the equalizer tap weights using the “Least Mean Square (LMS) Algorithm” on page 3-545.
- 'RLS' — Update the equalizer tap weights using the “Recursive Least Square (RLS) Algorithm” on page 3-545.
- 'CMA' — Update the equalizer tap weights using the “Constant Modulus Algorithm (CMA)” on page 3-545.

Data Types: char | string

NumForwardTaps — Number of forward equalizer taps

5 (default) | positive integer

Number of forward equalizer taps, specified as a positive integer. The number of forward equalizer taps must be greater than or equal to the value of the InputSamplesPerSymbol property.

Data Types: double

NumFeedbackTaps — Number of feedback equalizer taps

3 (default) | positive integer

Number of feedback equalizer taps, specified as a positive integer.

Data Types: double

StepSize — Step size

0.01 (default) | positive scalar

Step size used by the adaptive algorithm, specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

Tip To determine the maximum step size allowed, use the maxstep object function.

Tunable: Yes

Dependencies

To enable this property, set Algorithm to 'LMS' or 'CMA'.

Data Types: double

ForgettingFactor — Forgetting factor

0.99 (default) | scalar in the range (0, 1]

Forgetting factor used by the adaptive algorithm, specified as a scalar in the range (0, 1]. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

Tunable: Yes

Dependencies

To enable this property, set Algorithm to 'RLS'.

Data Types: double

`InitialInverseCorrelationMatrix` — Initial inverse correlation matrix

`0.1` (default) | scalar | matrix

Initial inverse correlation matrix, specified as a scalar or an N_{Taps}-by-N_{Taps} matrix. N_{Taps} is equal to the sum of the NumForwardTaps and NumFeedbackTaps property values. If you specify `InitialInverseCorrelationMatrix` as a scalar, *a*, the equalizer sets the initial inverse correlation matrix to *a* times the identity matrix: *a*(`eye`(N_{Taps})).

Tunable: Yes

Dependencies

To enable this property, set Algorithm to `'RLS'`.

Data Types: `double`

`Constellation` — Signal constellation

`pskmod(0:3,4,pi/4)` (default) | vector

Signal constellation, specified as a vector. The default value is a QPSK constellation generated using this code: `pskmod(0:3,4,pi/4)`.

Tunable: Yes

Data Types: `double`

`ReferenceTap` — Reference tap

`3` (default) | positive integer

Reference tap, specified as a positive integer less than or equal to the NumForwardTaps property value. The equalizer uses the reference tap location to track the main energy of the channel.

Data Types: `double`

`InputDelay` — Input signal delay

`0` (default) | nonnegative integer

Input signal delay in samples relative to the reset time of the equalizer, specified as a nonnegative integer. If the input signal is a vector of length greater than 1, then the input delay is relative to the start of the input vector. If the input signal is a scalar, then the input delay is relative to the first call of the System object and to the first call of the System object after calling the `release` or `reset` object function.

Data Types: `double`

`InputSamplesPerSymbol` — Number of input samples per symbol

`1` (default) | positive integer

Number of input samples per symbol, specified as a positive integer. Setting this property to any number greater than one effectively creates a fractionally spaced equalizer.

Data Types: `double`

`TrainingFlagInputPort` — Enable training control input

`false` (default) | `true`

Enable training control input, specified as `false` or `true`. Setting this property to `true` enables the equalizer training flag input `tf`.

Tunable: Yes

Data Types: `logical`

`AdaptAfterTraining` — Update tap weights when not training

`true` (default) | `false`

Update tap weights when not training, specified as `true` or `false`. If this property is set to `true`, the System object uses decision directed mode to update equalizer tap weights. If this property is set to `false`, the System object keeps the equalizer tap weights unchanged after training.

Tunable: Yes

Data Types: `logical`

`AdaptWeightsSource` — Source of adapt tap weights request

`'Property'` (default) | `'Input port'`

Source of adapt tap weights request, specified as one of these values:

- `'Property'` — Specify this value to use the AdaptWeights property to control when the System object adapts tap weights.
- `'Input port'` — Specify this value to use the `aw` input to control when the System object adapts tap weights.

Dependencies

To enable this property, set Algorithm to `'CMA'`.

Data Types: `char` | `string`

`AdaptWeights` — Adapt tap weights

`true` (default) | `false`

Adapt tap weights, specified as `true` or `false`. If this property is set to `true`, the System object updates the equalizer tap weights. If this property is set to `false`, the System object keeps the equalizer tap weights unchanged.

Tunable: Yes

Dependencies

To enable this property, set AdaptWeightsSource to `'Property'` and set AdaptAfterTraining to `true`.

Data Types: `logical`

`InitialWeightsSource` — Source for initial tap weights

`'Auto'` (default) | `'Property'`

Source for initial tap weights, specified as one of these values:

- `'Auto'` — Initialize the tap weights to the algorithm-specific default values, as described in the InitialWeights property.
- `'Property'` — Initialize the tap weights using the InitialWeights property value.

Data Types: `char` | `string`

`InitialWeights` — Initial weights
`0` or `[0;0;1;0;0]` (default) | scalar | vector

Initial weights used by the adaptive algorithm, specified as a scalar or vector. The default is `0` when the Algorithm property is set to `'LMS'` or `'RLS'`. The default is `[0;0;1;0;0]` when the Algorithm property is set to `'CMA'`.

If you specify `InitialWeights` as a scalar, the equalizer uses scalar expansion to create a vector of length N_{Taps} with all values set to `InitialWeights`. N_{Taps} is equal to the sum of the NumForwardTaps and NumFeedbackTaps property values. If you specify `InitialWeights` as a vector, the vector length must be N_{Taps}.

Tunable: Yes

Data Types: `double`

`WeightUpdatePeriod` — Tap weight update period
`1` (default) | positive integer

Tap weight update period in symbols, specified as a positive integer. The equalizer updates the tap weights after processing this number of symbols.

Data Types: `double`

Usage

Syntax

```
y = dfe(x,tsym)
y = dfe(x,tsym,tf)
y = dfe(x)
y = dfe(x,aw)
[y,err] = dfe( ___ )
[y,err,weights] = dfe( ___ )
```

Description

`y = dfe(x,tsym)` equalizes input signal `x` by using training symbols `tsym`. The output is the equalized symbols. To enable this syntax, set the Algorithm property to `'LMS'` or `'RLS'`.

`y = dfe(x,tsym,tf)` also specifies training flag `tf`. The System object starts training when `tf` changes from `false` to `true` (at the rising edge). The System object trains until all symbols in `tsym` are processed. The input `tsym` is ignored when `tf` is `false`. To enable this syntax, set the Algorithm property to `'LMS'` or `'RLS'` and TrainingFlagInputPort property to `true`.

`y = dfe(x)` equalizes input signal `x`. To enable this syntax, set the Algorithm property to `'CMA'`.

`y = dfe(x,aw)` also specifies adapts weights flag `aw`. The System object adapts the equalizer tap weights when `aw` is `true`. If `aw` is `false`, the System object keeps the weights unchanged. To enable this syntax, set the Algorithm property to `'CMA'` and AdaptWeightsSource property to `'Input port'`.

`[y,err] = dfe( ___ )` also returns error signal `err` using input arguments from any of the previous syntaxes.

[y,err,weights] = dfe(___) also returns weights, the tap weights from the last tap weight update, using input arguments from any of the previous syntaxes.

Input Arguments

x — Input signal

column vector

Input signal, specified as a column vector. The input signal vector length must be equal to an integer multiple of the InputSamplesPerSymbol property value. For more information, see “Symbol Tap Spacing” on page 3-543.

Data Types: double
Complex Number Support: Yes

tsym — Training symbols

column vector

Training symbols, specified as a column vector of length less than or equal to the length of input x. The input tsym is ignored when tf is false.

Dependencies

To enable this argument, set the Algorithm property to 'LMS' or 'RLS'.

Data Types: double

tf — Training flag

true | false

Training flag, specified as true or false. The System object starts training when tf changes from false to true (at the rising edge). The System object trains until all symbols in tsym are processed. The input tsym is ignored when tf is false.

Dependencies

To enable this argument, set the Algorithm property to 'LMS' or 'RLS' and TrainingFlagInputPort property to true.

Data Types: logical

aw — Adapt weights flag

true | false

Adapt weights flag, specified as true or false. If aw is true, the System object adapts weights. If aw is false, the System object keeps the weights unchanged.

Dependencies

To enable this argument, set the Algorithm property to 'CMA' and AdaptWeightsSource property to 'Input port'.

Data Types: logical

Output Arguments

y — Equalized symbols

column vector

Equalized symbols, returned as a column vector that has the same length as input signal `x`.

`err` — Error signal
column vector

Error signal, returned as a column vector that has the same length as input signal `x`.

`weights` — Tap weights
column vector

Tap weights, returned as a column vector that has N_{Taps} elements. N_{Taps} is equal to the sum of the NumForwardTaps and NumFeedbackTaps property values. `weights` contains the tap weights from the last tap weight update.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.DecisionFeedbackEqualizer`

isLocked	Determine if System object is in use
clone	Create duplicate System object
info	Characteristic information about the equalizer object
maxstep	Maximum step size for LMS equalizer convergence
mmseweights	Linear equalizer MMSE tap weights

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Decision Feedback Equalize BPSK-Modulated Signal

Create a BPSK modulator and an equalizer System object™, specifying a decision feedback LMS equalizer having eight forward taps, five feedback taps, and a step size of 0.03.

```
bpsk = comm.BPSKModulator;
eqdfe_lms = comm.DecisionFeedbackEqualizer('Algorithm','LMS', ...
    'NumForwardTaps',8,'NumFeedbackTaps',5,'StepSize',0.03);
```

Change the reference tap index of the equalizer.

```
eqdfe_lms.ReferenceTap = 4;
```

Build a set of test data. Receive the data by convolving the signal.

```
x = bpsk(randi([0 1],1000,1));
rxsig = conv(x,[1 0.8 0.3]);
```

Use `maxstep` to find the maximum permitted step size.

```
mxStep = maxstep(eqdfe_lms,rxsig)
```

```
mxStep = 0.1028
```

Equalize the received signal. Use the first 200 symbols as the training sequence.

```
y = eqdfe_lms(rxsig,x(1:200));
```

Decision Feedback Equalize QPSK-Modulated Signal

Apply decision feedback equalization using the least mean squares (LMS) algorithm to recover QPSK symbols passed through a delayed multipath AWGN channel.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
chtaps = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
```

Generate QPSK-modulated symbols. Apply delayed multipath channel filtering and AWGN impairments to the symbols.

```
data = randi([0 M-1], numSymbols, 1);
tx = pskmod(data, M, pi/4);
rx = awgn(filter(chtaps,1,tx),25,'measured');
```

Create a decision feedback equalizer System object and display the default configuration. Adjust the reference tap to 1. Check the maximum permitted step size. Equalize the impaired symbols.

```
eq = comm.DecisionFeedbackEqualizer
```

```
eq = 
  comm.DecisionFeedbackEqualizer with properties:

                Algorithm: 'LMS'
           NumForwardTaps: 5
          NumFeedbackTaps: 3
                 StepSize: 0.0100
            Constellation: [1x4 double]
             ReferenceTap: 3
               InputDelay: 0
    InputSamplesPerSymbol: 1
    TrainingFlagInputPort: false
       AdaptAfterTraining: true
     InitialWeightsSource: 'Auto'
       WeightUpdatePeriod: 1
```

```
eq.ReferenceTap = 1;

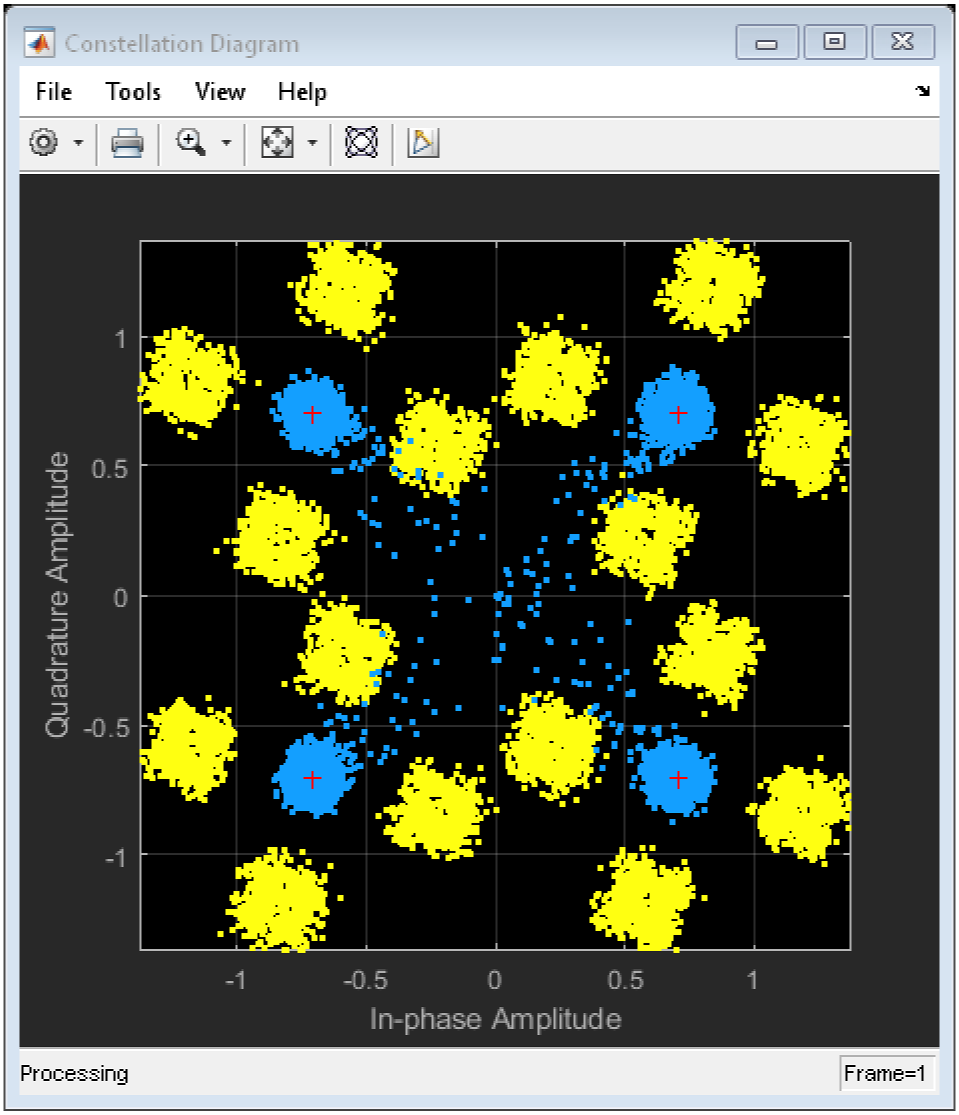
mxStep = maxstep(eq,rx)

mxStep = 0.2141
```

```
[y,err,weights] = eq(rx,tx(1:numTrainingSymbols));
```

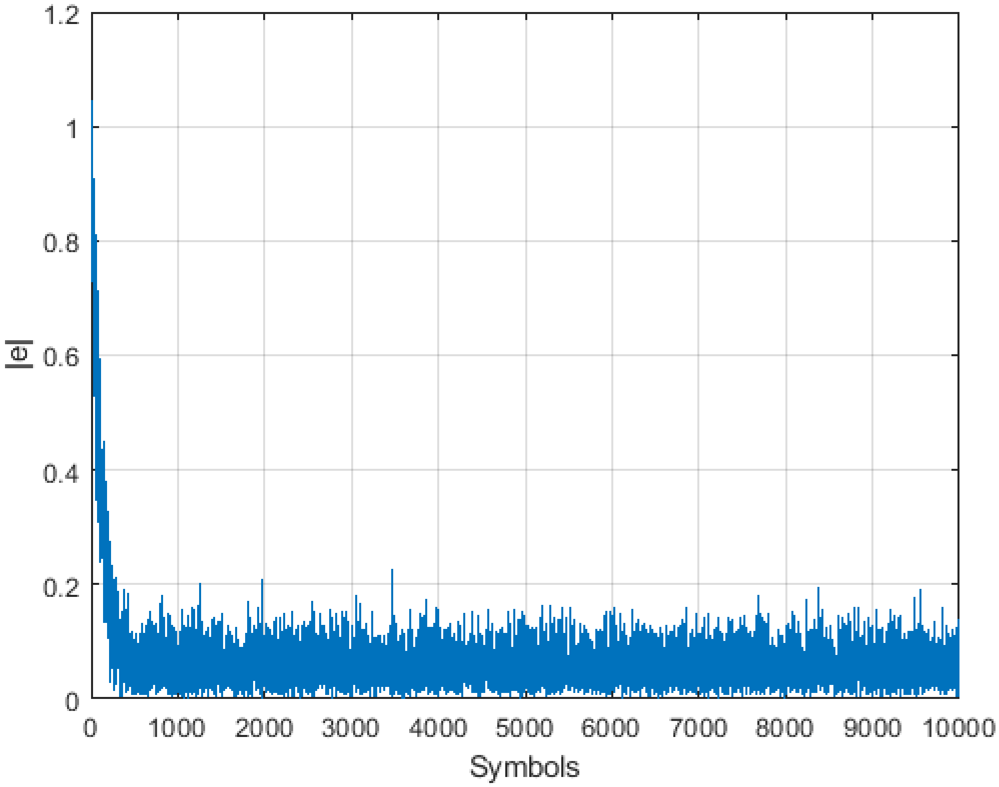
Plot the constellation of the impaired and equalized symbols.

```
constell = comm.ConstellationDiagram('NumInputPorts',2);
constell(rx,y)
```



Plot the equalizer error signal and compute the error vector magnitude of the equalized symbols.

```
plot(abs(err))
grid on; xlabel('Symbols'); ylabel('|e|')
```

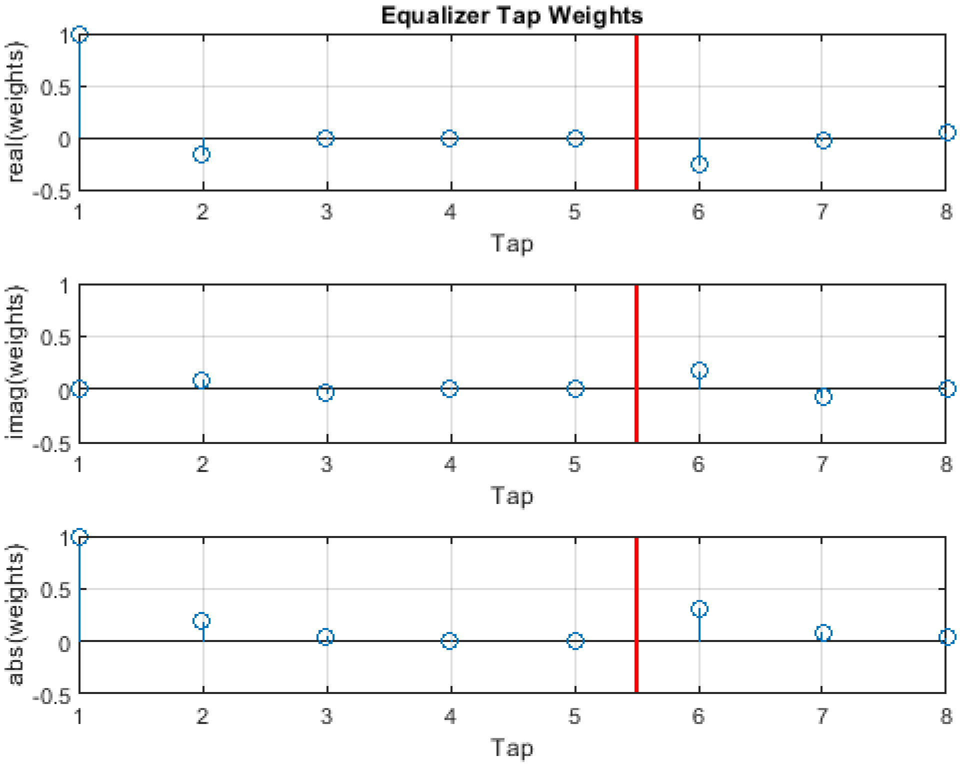


```
errevm = comm.EVM;
evm = errevm(tx,y)
```

```
evm = 10.1621
```

Plot the equalizer tap weights.

```
subplot(3,1,1); stem(real(weights)); ylabel('real(weights)'); xlabel('Tap'); grid on; axis([1 8 -
line([eq.NumForwardTaps+0.5 eq.NumForwardTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)
title('Equalizer Tap Weights')
subplot(3,1,2); stem(imag(weights)); ylabel('imag(weights)'); xlabel('Tap'); grid on; axis([1 8 -
line([eq.NumForwardTaps+0.5 eq.NumForwardTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)
subplot(3,1,3); stem(abs(weights)); ylabel('abs(weights)'); xlabel('Tap'); grid on; axis([1 8 -0
line([eq.NumForwardTaps+0.5 eq.NumForwardTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)
```



Decision Feedback Equalize System Using Different Training Schemes

Demonstrate decision feedback equalization using the least mean squares (LMS) algorithm to recover QPSK symbols passed through an AWGN channel. Apply different equalizer training schemes and show the symbol error magnitude.

System Setup

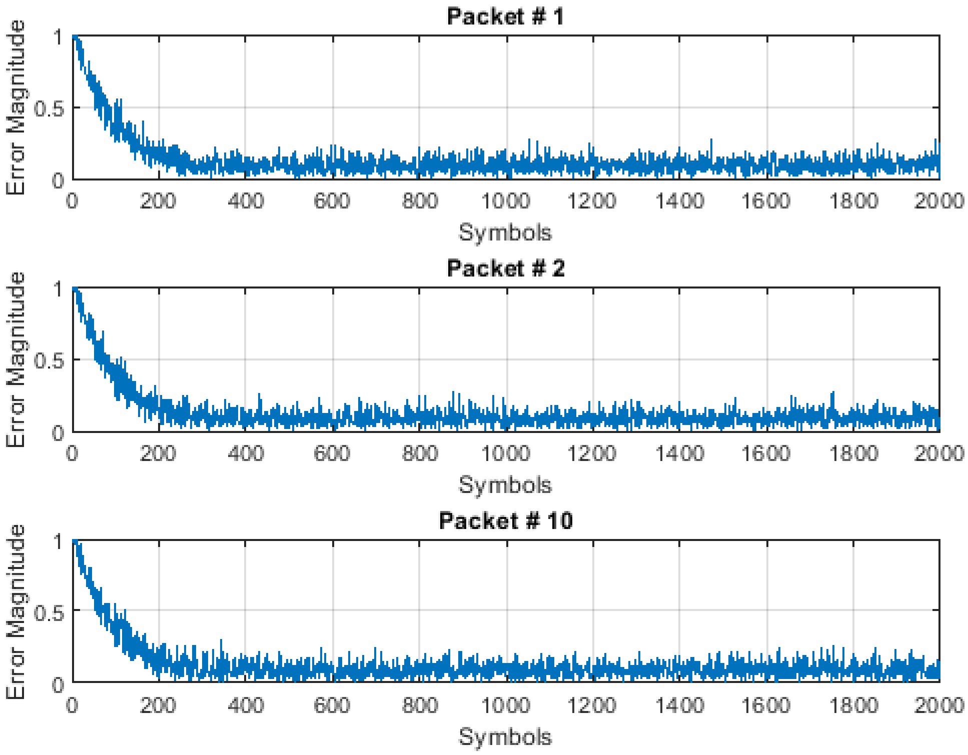
Simulate a QPSK-modulated system subject to AWGN. Transmit packets composed of 200 training symbols and 1800 random data symbols. Configure a decision feedback LMS equalizer to recover the packet data.

```
M = 4;
numTrainSymbols = 200;
numDataSymbols = 1800;
SNR = 20;
trainingSymbols = pskmod(randi([0 M-1],numTrainSymbols,1),M,pi/4);
numPkts = 10;
dfeq = comm.DecisionFeedbackEqualizer('Algorithm','LMS', ...
    'NumForwardTaps',5,'NumFeedbackTaps',4,'ReferenceTap',3,'StepSize',0.01);
```

Train the Equalizer at the Beginning of Each Packet With Reset

Process each packet using prepended training symbols. Reset the equalizer after processing each packet. Resetting the equalizer after each packet forces the equalizer to train taps with no a priori knowledge. Equalizer error signal plots for the first, second, and last packet show higher symbol errors at the start of each packet.

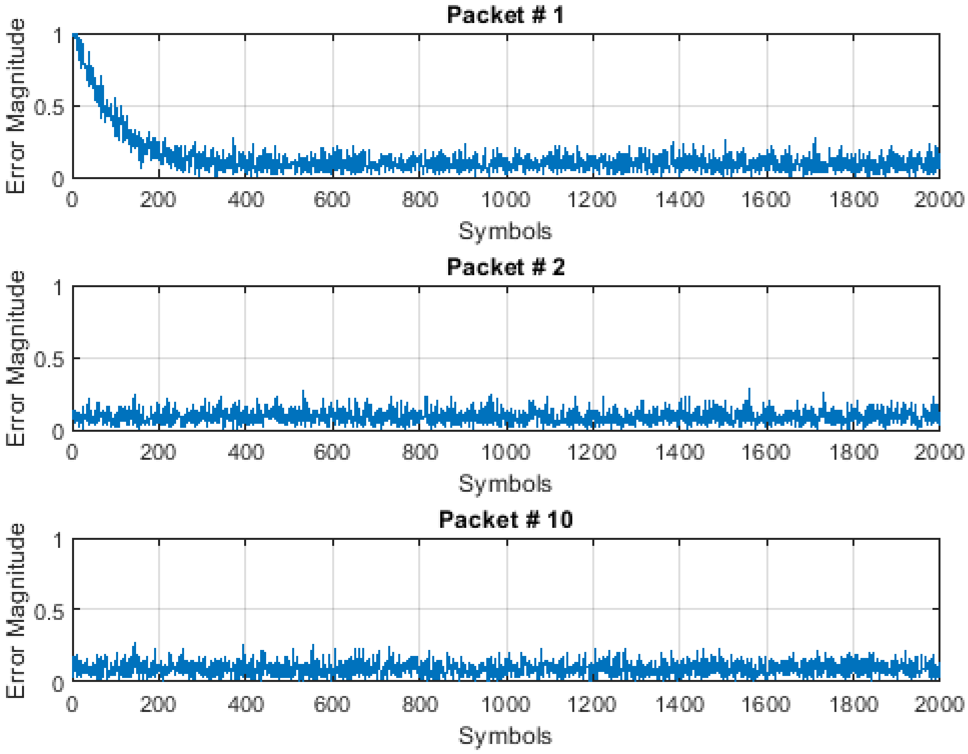
```
jj = 1;
figure
for ii = 1:numPkts
    b = randi([0 M-1],numDataSymbols,1);
    dataSym = pskmod(b,M,pi/4);
    packet = [trainingSymbols;dataSym];
    rx = awgn(packet,SNR);
    [~,err] = dfeq(rx,trainingSymbols);
    reset(dfeq)
    if (ii ==1 || ii == 2 ||ii == numPkts)
        subplot(3,1,jj)
        plot(abs(err))
        ylim([0 1])
        title(['Packet # ',num2str(ii)])
        xlabel('Symbols');
        ylabel('Error Magnitude');
        grid on;
        jj = jj+1;
    end
end
```



Train the Equalizer at the Beginning of Each Packet Without Reset

Process each packet using prepended training symbols. Do not reset the equalizer after each packet is processed. By not resetting after each packet, the equalizer retains tap weights from training prior packets. Equalizer error signal plots for the first, second, and last packet show that after the initial training on the first packet, subsequent packets have less symbol errors at the start of each packet.

```
release(dfeq)
jj = 1;
figure
for ii = 1:numPkts
    b = randi([0 M-1],numDataSymbols,1);
    dataSym = pskmod(b,M,pi/4);
    packet = [trainingSymbols;dataSym];
    channel = 1;
    rx = awgn(packet*channel,SNR);
    [~,err] = dfeq(rx,trainingSymbols);
    if (ii ==1 || ii == 2 ||ii == numPkts)
        subplot(3,1,jj)
        plot(abs(err))
        ylim([0 1])
        title(['Packet # ',num2str(ii)])
        xlabel('Symbols');
        ylabel('Error Magnitude');
        grid on;
        jj = jj+1;
    end
end
```



Train the Equalizer Periodically

Systems with signals subject to time-varying channels require periodic equalizer training to maintain lock on the channel variations. Specify a system that has 200 symbols of training for every 1800 data symbols. Between training, the equalizer does not update tap weights. The equalizer processes 200 symbols per packet.

```
Rs = 1e6;
fd = 20;
spp = 200; % Symbols per packet
b = randi([0 M-1],numDataSymbols,1);
dataSym = pskmod(b,M,pi/4);
packet = [trainingSymbols; dataSym];
stream = repmat(packet,10,1);
tx = (0:length(stream)-1)'/Rs;
channel = exp(1i*2*pi*fd*tx);
rx = awgn(stream.*channel,SNR);
```

Set the `AdaptAfterTraining` property to `false` to stop the equalizer tap weight updates after the training phase.

```
release(dfeq)
dfeq.AdaptAfterTraining = false
```

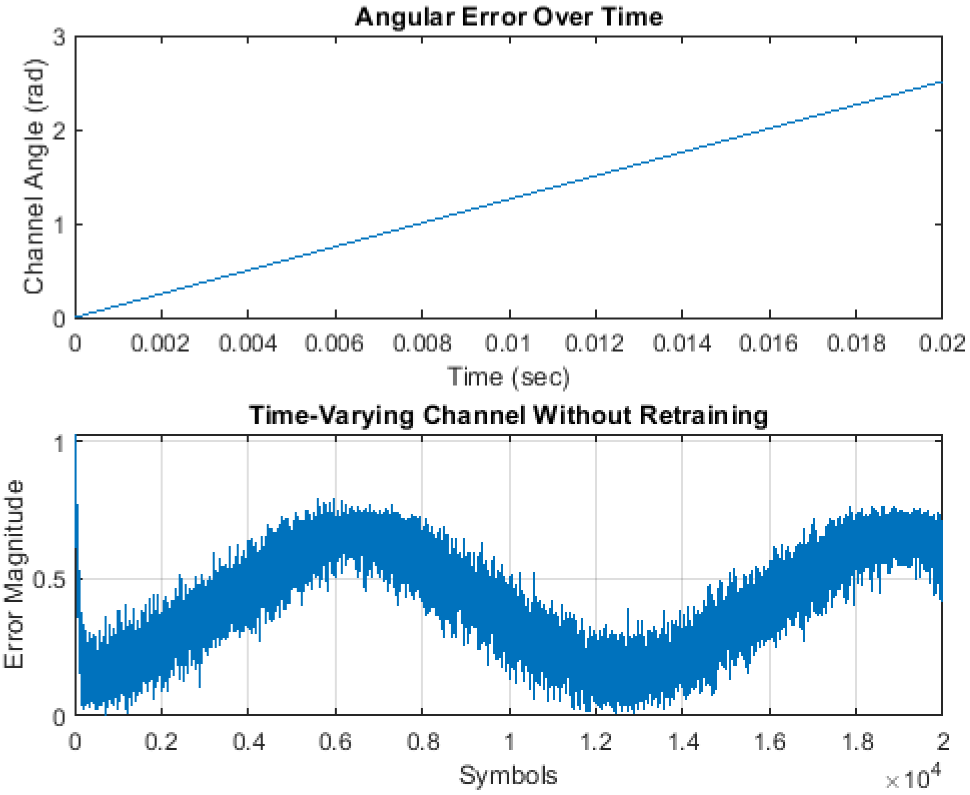
```
dfeq = 
  comm.DecisionFeedbackEqualizer with properties:
```

```
                Algorithm: 'LMS'
           NumForwardTaps: 5
          NumFeedbackTaps: 4
                 StepSize: 0.0100
            Constellation: [1x4 double]
             ReferenceTap: 3
               InputDelay: 0
    InputSamplesPerSymbol: 1
    TrainingFlagInputPort: false
       AdaptAfterTraining: false
     InitialWeightsSource: 'Auto'
       WeightUpdatePeriod: 1
```

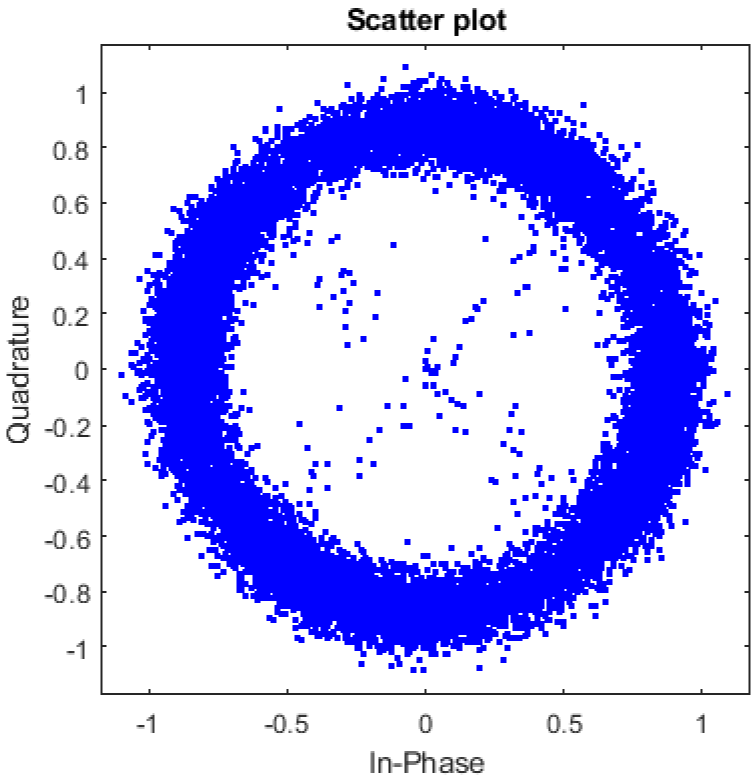
Equalize the impaired data. Plot the angular error from the channel, the equalizer error signal, and signal constellation. As the channel varies, the equalizer output does not remove the channel effects. Also, the output constellation rotates out of sync, resulting in bit errors.

```
[y,err] = dfeq(rx,trainingSymbols);

figure
subplot(2,1,1)
plot(tx, unwrap(angle(channel)))
xlabel('Time (sec)')
ylabel('Channel Angle (rad)')
title('Angular Error Over Time')
subplot(2,1,2)
plot(abs(err))
xlabel('Symbols')
ylabel('Error Magnitude')
grid on
title('Time-Varying Channel Without Retraining')
```



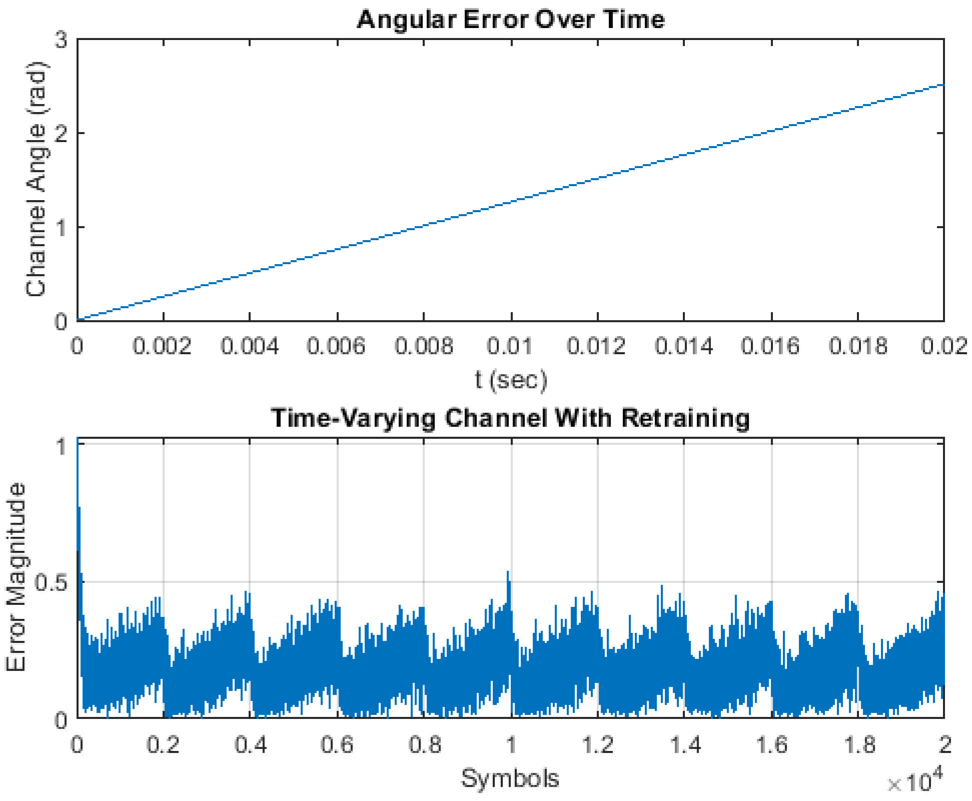
```
scatterplot(y)
```



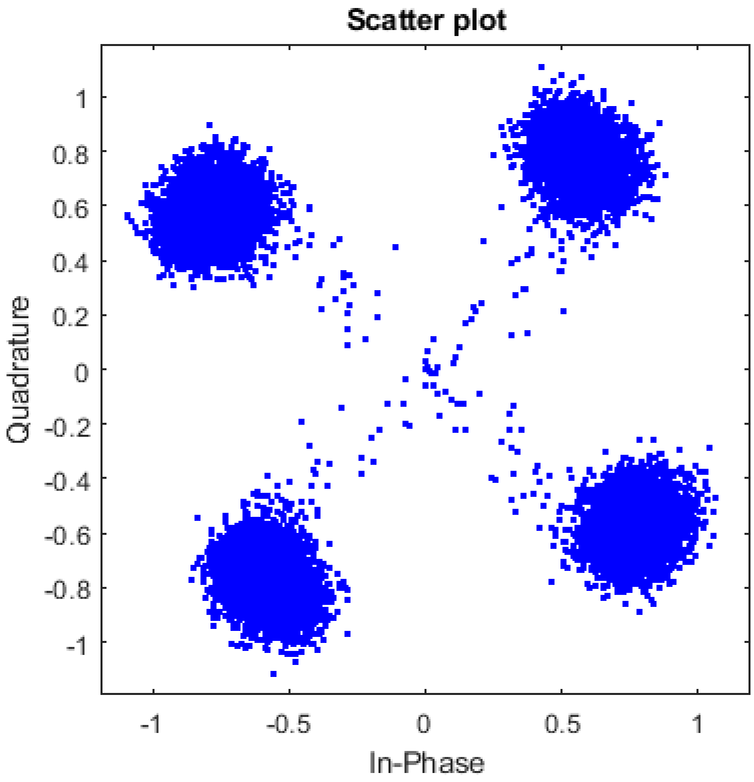
Set the `TrainingInputPort` property to `true` to configure the equalizer to retrain the taps when signaled by the `trainFlag` input. The equalizer trains only when `trainFlag` is `true`. After every 2000 symbols, the equalizer retrains the taps and keeps lock on variations of the channel. Plot the angular error from the channel, the equalizer error signal, and signal constellation. As the channel varies, the equalizer output removes the channel effects. Also, the output constellation does not rotate out of sync, and bit errors are reduced.

```
release(dfeq)
dfeq.TrainingFlagInputPort = true;
symbolCnt = 0;
numPackets = length(rx)/spp;
trainFlag = true;
trainingPeriod = 2000;
eVec = zeros(size(rx));
yVec = zeros(size(rx));
for p=1:numPackets
    [yVec((p-1)*spp+1:p*spp,1),eVec((p-1)*spp+1:p*spp,1)] = ...
        dfeq(rx((p-1)*spp+1:p*spp,1),trainingSymbols,trainFlag);
    symbolCnt = symbolCnt + spp;
    if symbolCnt >= trainingPeriod
        trainFlag = true;
        symbolCnt = 0;
    else
        trainFlag = false;
    end
end
figure
```

```
subplot(2,1,1)
plot(tx, unwrap(angle(channel)))
xlabel('t (sec)')
ylabel('Channel Angle (rad)')
title('Angular Error Over Time')
subplot(2,1,2)
plot(abs(eVec))
xlabel('Symbols')
ylabel('Error Magnitude')
grid on
title('Time-Varying Channel With Retraining')
```



```
scatterplot(yVec)
```



Decision Feedback Equalize Delayed Signal

Simulate a system with delay between the transmitted symbols and received samples. Typical systems have transmitter and receiver filters that result in a delay. This delay must be accounted for to synchronize the system. In this example, the system delay is introduced without transmit and receive filters. Decision feedback equalization, using the least mean squares (LMS) algorithm, recovers QPSK symbols.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
mpChan = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
systemDelay = dsp.Delay(20);
snr = 24;
```

Generate QPSK-modulated symbols. Apply multipath channel filtering, a system delay, and AWGN to the transmitted symbols.

```
data = randi([0 M-1],numSymbols,1);
tx = pskmod(data,M,pi/4); % OQPSK
delayedSym = systemDelay(filter(mpChan,1,tx));
rx = awgn(delayedSym,snr,'measured');
```

Create equalizer and EVM System objects. The equalizer System object specifies a decision feedback equalizer using the LMS algorithm.

```
dfeq = comm.DecisionFeedbackEqualizer('Algorithm','LMS', ...
    'NumForwardTaps',9,'NumFeedbackTaps',6,'ReferenceTap',5);
evm = comm.EVM('ReferenceSignalSource', ...
    'Estimated from reference constellation');
```

Equalize Without Adjusting Input Delay

Equalize the received symbols.

```
[y1,err1,wts1] = dfeq(rx,tx(1:numTrainingSymbols,1));
```

Find the delay between the received symbols and the transmitted symbols by using the `finddelay` function.

```
rxDelay = finddelay(tx,rx)
```

```
rxDelay = 20
```

Display the equalizer information. The latency value indicates the delay introduced by the equalizer. Calculate the total delay as the sum of `rxDelay` and the equalizer latency.

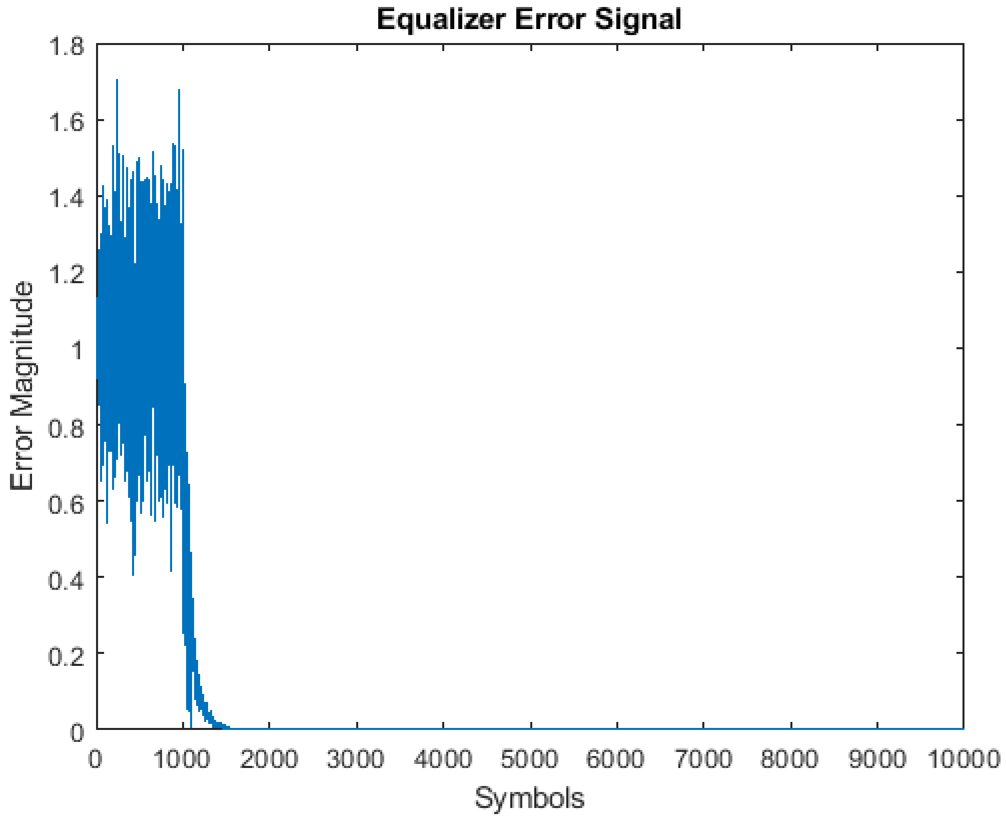
```
eqInfo = info(dfeq)
```

```
eqInfo = struct with fields:
    Latency: 4
```

```
totalDelay = rxDelay + eqInfo.Latency;
```

Until the equalizer output converges, the symbol error rate is high. Plot the error output, `err1`, to determine when the equalized output converges.

```
plot(abs(err1))
xlabel('Symbols')
ylabel('Error Magnitude')
title('Equalizer Error Signal')
```



The plot shows excessive errors for the first 2000 symbols. When demodulating symbols and computing symbol errors, account for the unconverged output and the system delay between the equalizer output and transmitted symbols.

```
dataRec1 = pskdemod(y1(2000+totalDelay:end),M,pi/4);
symErrWithDelay = symerr(data(2000:end-totalDelay),dataRec1)
```

```
symErrWithDelay = 6001
```

```
evmWithDelay = evm(y1)
```

```
evmWithDelay = 25.6868
```

The error rate and EVM are high because the receive delay was not accounted for in the equalizer System object.

Adjust Input Delay in Decision Feedback Equalizer

Equalize the received data by using the delay value to set the `InputDelay` property. Since `InputDelay` is a nontunable property, you must release the `dfeq` System object to reconfigure the `InputDelay` property. Equalize the received symbols.

```
release(dfeq)
dfeq.InputDelay = rxDelay
```

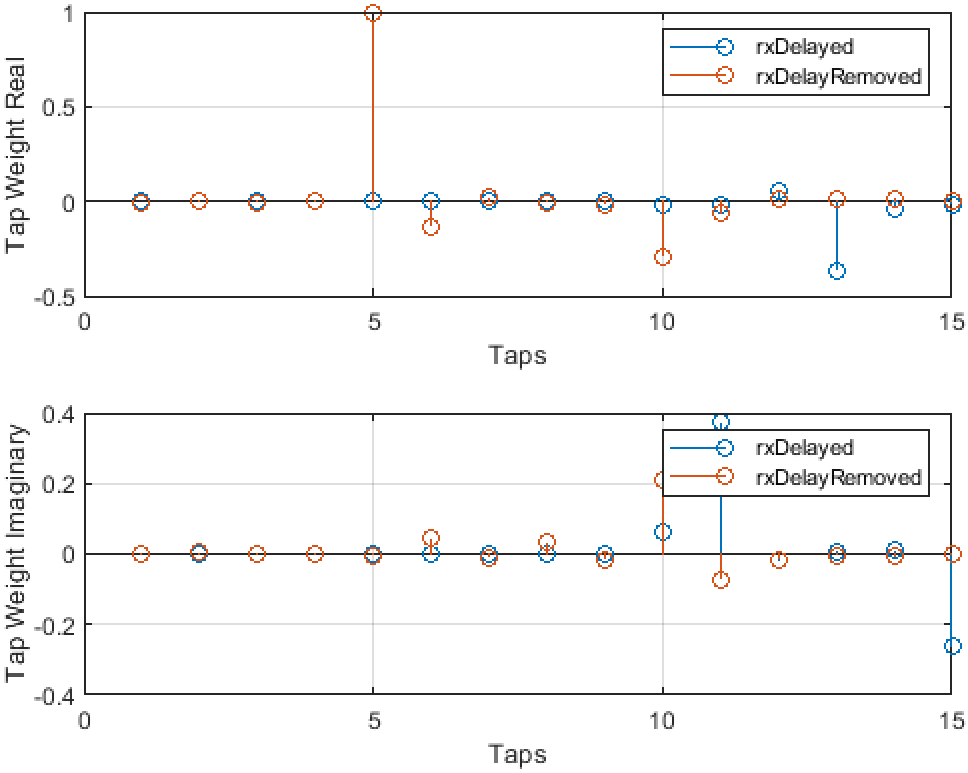
```
dfeq = 
  comm.DecisionFeedbackEqualizer with properties:
```

```
              Algorithm: 'LMS'
         NumForwardTaps: 9
        NumFeedbackTaps: 6
               StepSize: 0.0100
          Constellation: [1x4 double]
           ReferenceTap: 5
             InputDelay: 20
  InputSamplesPerSymbol: 1
  TrainingFlagInputPort: false
     AdaptAfterTraining: true
   InitialWeightsSource: 'Auto'
     WeightUpdatePeriod: 1
```

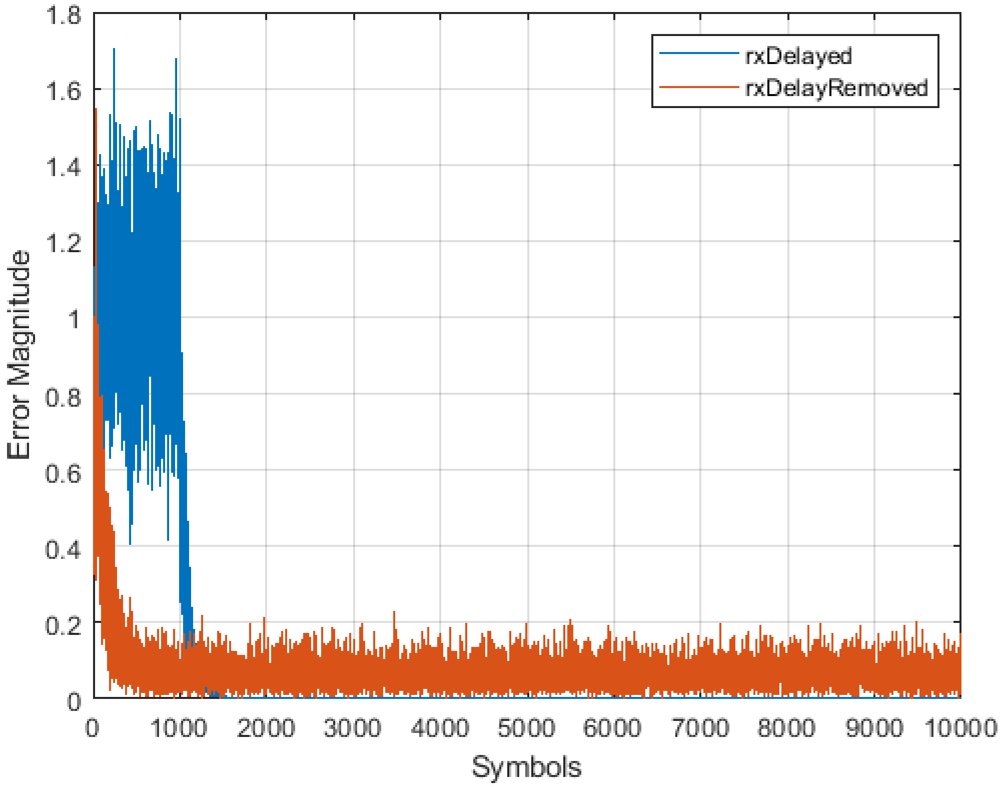
```
[y2,err2,wts2] = dfeq(rx,tx(1:numTrainingSymbols,1));
```

Plot the tap weights and equalized error magnitude. A stem plot shows the equalizer tap weights before and after the system delay is removed. A 2-D line plot shows the slower equalizer convergence for the delayed signal, as compared to the signal with the delay removed.

```
subplot(2,1,1)
stem([real(wts1),real(wts2)])
xlabel('Taps')
ylabel('Tap Weight Real')
legend('rxDelayed','rxDelayRemoved')
grid on
subplot(2,1,2)
stem([imag(wts1),imag(wts2)])
xlabel('Taps')
ylabel('Tap Weight Imaginary')
legend('rxDelayed','rxDelayRemoved')
grid on
```



```
figure
plot([abs(err1),abs(err2)])
xlabel('Symbols')
ylabel('Error Magnitude')
legend('rxDelayed','rxDelayRemoved')
grid on
```



Plot error output of the equalized signals, `rxDelayed` and `rxDelayRemoved`. For the signal that has the delay removed, the equalizer converges during the 1000 symbol training period. When demodulating symbols and computing symbol errors, to account for the unconverged output and the system delay between the equalizer output and transmitted symbols, skip the first 500 symbols. Reconfiguring the equalizer to account for the system delay enables better equalization of the signal, and reduces symbol errors and the EVM.

```
eqInfo = info(dfeq)
```

```
eqInfo = struct with fields:
    Latency: 4
```

```
totalDelay = rxDelay + eqInfo.Latency;
dataRec2 = pskdemod(y2(500+totalDelay:end),M,pi/4);
symErrDelayRemoved = symerr(data(500:end-totalDelay),dataRec2)
```

```
symErrDelayRemoved = 0
```

```
evmDelayRemoved = evm(y2(500+totalDelay:end))
```

```
evmDelayRemoved = 7.5147
```

Decision Feedback Equalize Symbols Using EVM-Based Training

Recover QPSK symbols with a decision equalizer, using the constant modulus algorithm (CMA) and EVM-based taps training. When using blind equalizer algorithms, such as CMA, you can train the equalizer taps using the `AdaptWeights` property to start and stop training. Use helper functions to generate plots and apply phase correction.

Initialize system variables.

```
rng(123456);
M = 4; % QPSK
numSymbols = 100;
numPackets = 5000;
refTap = 3;
nFwdTaps = 5;
nFdbkTaps = 4;
ttlTaps = nFwdTaps + nFdbkTaps;
raylChan = comm.RayleighChannel('PathDelays',[0 1], ...
    'AveragePathGains',[0 -12],'MaximumDopplerShift',1e-5);
SNR = 50;
adaptWeights = true;
```

Create the equalizer and EVM System objects. The equalizer System object specifies a decision feedback equalizer using the CMA adaptive algorithm. Call the helper function to initialize figure plots.

```
dfeq = comm.DecisionFeedbackEqualizer('Algorithm','CMA', ...
    'NumForwardTaps',nFwdTaps,'NumFeedbackTaps',nFdbkTaps,'ReferenceTap',refTap, ...
    'StepSize',0.03,'AdaptWeightsSource','Input port')
```

```
dfeq = 
  comm.DecisionFeedbackEqualizer with properties:

                Algorithm: 'CMA'
           NumForwardTaps: 5
          NumFeedbackTaps: 4
                 StepSize: 0.0300
            Constellation: [1x4 double]
             ReferenceTap: 3
    InputSamplesPerSymbol: 1
       AdaptWeightsSource: 'Input port'
     InitialWeightsSource: 'Auto'
       WeightUpdatePeriod: 1
```

```
info(dfeq)
```

```
ans = struct with fields:
    Latency: 2
```

```
evm = comm.EVM('ReferenceSignalSource', ...
    'Estimated from reference constellation');
[errPlot,evmPlot,scatSym,adaptState] = initFigures(numPackets,ttlTaps);
```

Equalization Loop

Follow these steps to implement the equalization loop.

1. Generate OQPSK data packets.
2. Apply Rayleigh fading and AWGN to the transmission data.

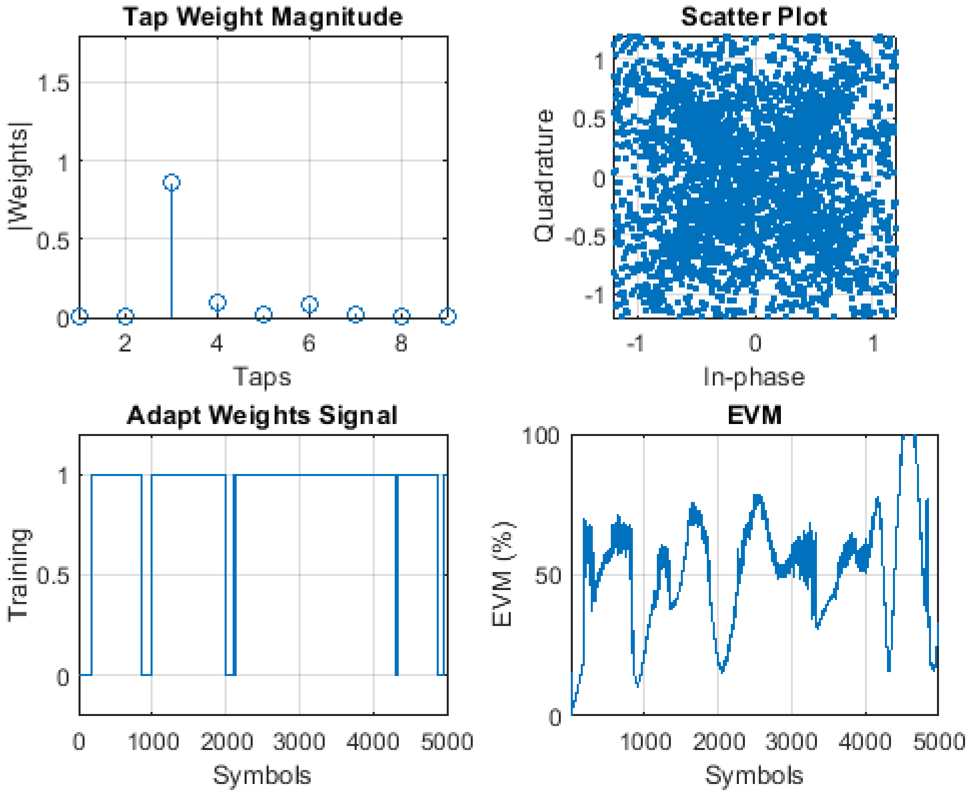
3 Apply equalization to the received data and phase correction to the equalizer output.

4 Estimate the EVM and toggle the `adaptWeights` flag to `true` or `false` based on the EVM level.

5 Update the figure plots.

```
for p=1:numPackets
    data = randi([0 M-1],numSymbols,1);
    tx = pskmod(data,M,pi/4);
    rx = awgn(raylChan(tx),SNR);
    rxDelay = finddelay(rx,tx);
    [y,err,wts] = dfeq(rx,adaptWeights);
    y = phaseCorrection(y);
    evmEst = evm(y);
    adaptWeights = (evmEst > 20);

    updateFigures(errPlot,evmPlot,scatSym,adaptState, ...
        wts,y(end),evmEst,adaptWeights,p,numPackets)
end
```



```
rxDelay
```

```
rxDelay = 0
```

The figure plots show that, as the EVM varies, the equalizer toggles in and out of decision-directed weight adaptation mode.

Helper Functions

This helper function initializes figures that show a quad plot of simulation results.

```
function [errPlot,evmPlot,scatter,adaptState] = initFigures(numPkts,ttlTaps)
yVec = nan(numPkts,1);
evmVec = nan(numPkts,1);
wVec = zeros(ttlTaps,1);
adaptVec = nan(numPkts,1);

figure
subplot(2,2,1)
evmPlot = stem(wVec);
grid on; axis([1 ttlTaps 0 1.8])
xlabel('Taps'); ylabel('|Weights|'); title('Tap Weight Magnitude')

subplot(2,2,2)
scatter = plot(yVec, '.');
axis square; axis([-1.2 1.2 -1.2 1.2]); grid on
xlabel('In-phase'); ylabel('Quadrature'); title('Scatter Plot');
subplot(2,2,3)
adaptState = plot(adaptVec);
grid on; axis([0 numPkts -0.2 1.2])
ylabel('Training'); xlabel('Symbols'); title('Adapt Weights Signal')
subplot(2,2,4)
errPlot = plot(evmVec);
grid on; axis([1 numPkts 0 100])
xlabel('Symbols'); ylabel('EVM (%)'); title('EVM')
end
```

This helper function updates the figures.

```
function updateFigures(errPlot,evmPlot,scatSym, ...
    adaptState,w,y,evmEst,adaptWts,p,numFrames)
persistent yVec evmVec adaptVec

if p == 1
    yVec = nan(numFrames,1);
    evmVec = nan(numFrames,1);
    adaptVec = nan(numFrames,1);
end

yVec(p) = y;
evmVec(p) = evmEst;
adaptVec(p) = adaptWts;

errPlot.YData = abs(evmVec);
evmPlot.YData = abs(w);
scatSym.XData = real(yVec);
scatSym.YData = imag(yVec);
adaptState.YData = adaptVec;
drawnow limitrate
end
```

This helper function applies phase correction.

```
function y = phaseCorrection(y)
a = angle(y((real(y) > 0) & (imag(y) > 0)));
```

```
a(a < 0.1) = a(a < 0.1) + pi/2;
theta = mean(a) - pi/4;
y = y * exp(-1i*theta);
end
```

Decision Feedback Equalize Packetized Signals in Fading Environments

Recover QPSK symbols in fading environments with a decision feedback equalizer, using the least mean squares (LMS) algorithm. Use the `reset` object function to equalize independent packets. Use helper functions to generate plots. This example also shows symbol-based processing and frame-based processing.

Setup

Initialize system variables, create the equalizer System object, and initialize the plot figures.

```
M = 4; % QPSK
numSym = 1000;
numTrainingSym = 100;
numPackets = 5;
refTap = 5;
nFwdTaps = 9;
nFdbkTaps = 4;
ttlTaps = nFwdTaps + nFdbkTaps;
stepsz = 0.01;
ttlNumSym = numSym + numTrainingSym;
raylChan = comm.RayleighChannel('PathDelays',[0 1], ...
    'AveragePathGains',[0 -9], ...
    'MaximumDopplerShift',0, ...
    'PathGainsOutputPort',true);
SNR = 35;
rxVec = zeros(ttlNumSym,numPackets);
txVec = zeros(ttlNumSym,numPackets);
yVec = zeros(ttlNumSym,1);
eVec = zeros(ttlNumSym,1);

dfeq1 = comm.DecisionFeedbackEqualizer('Algorithm','LMS', ...
    'NumForwardTaps',nFwdTaps,'NumFeedbackTaps',nFdbkTaps,'ReferenceTap',refTap, ...
    'StepSize',stepsz,'TrainingFlagInputPort',true);

[errPlot,wStem,hStem,scatPlot] = initFigures(ttlNumSym,ttlTaps, ...
    raylChan.AveragePathGains);
```

Symbol-Based Processing

For symbol-based processing, provide one symbol at the input of the equalizer. Reset the equalizer state and channel after processing each packet.

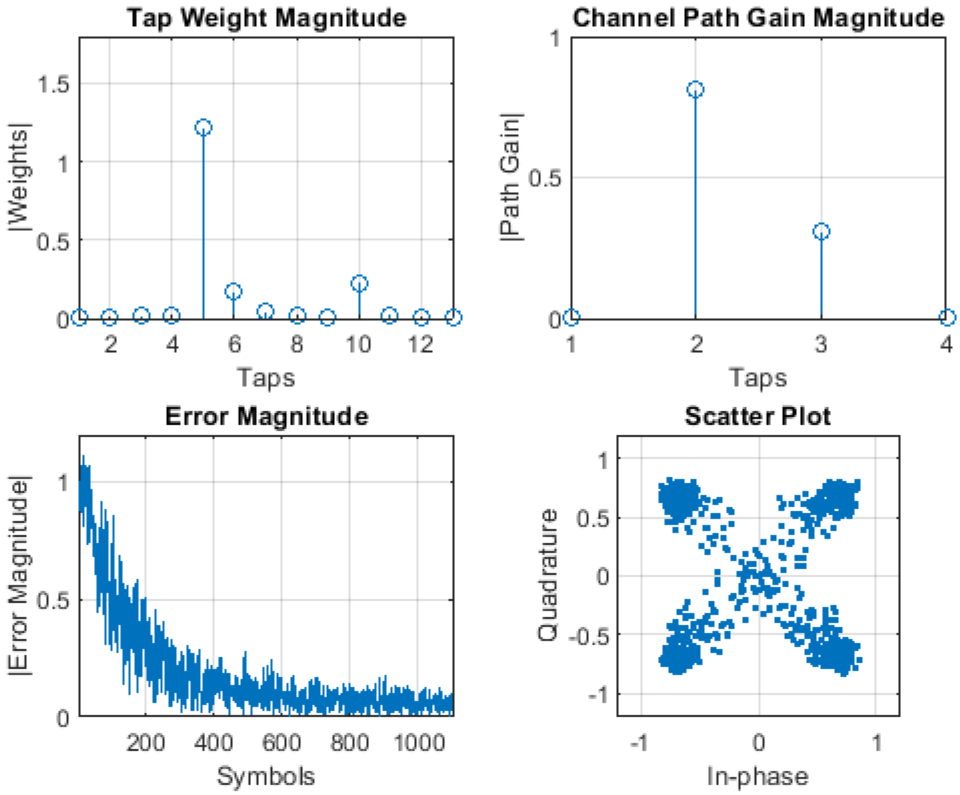
```
for p = 1:numPackets
    trainingFlag = true;
    for q=1:ttlNumSym
        data = randi([0 M-1],1,1);
        tx = pskmod(data,M,pi/4);
        [xc,pg] = raylChan(tx);
        rx = awgn(xc,25);
        [y,err,wts] = dfeq1(rx,tx,trainingFlag);
```

Disable training after processing `numTrainingSym` training symbols.

```
        if q == numTrainingSym
            trainingFlag = false;
        end
        updateFigures(errPlot,wStem,hStem,scatPlot,err,wts,y,pg,q,ttlNumSym);
        txVec(q,p) = tx;
        rxVec(q,p) = rx;
    end
```

After processing each packet, reset the channel System object to get a new realization of channel taps and the equalizer System object to restore the default taps weights.

```
    reset(raylChan)
    reset(dfeq1)
end
```



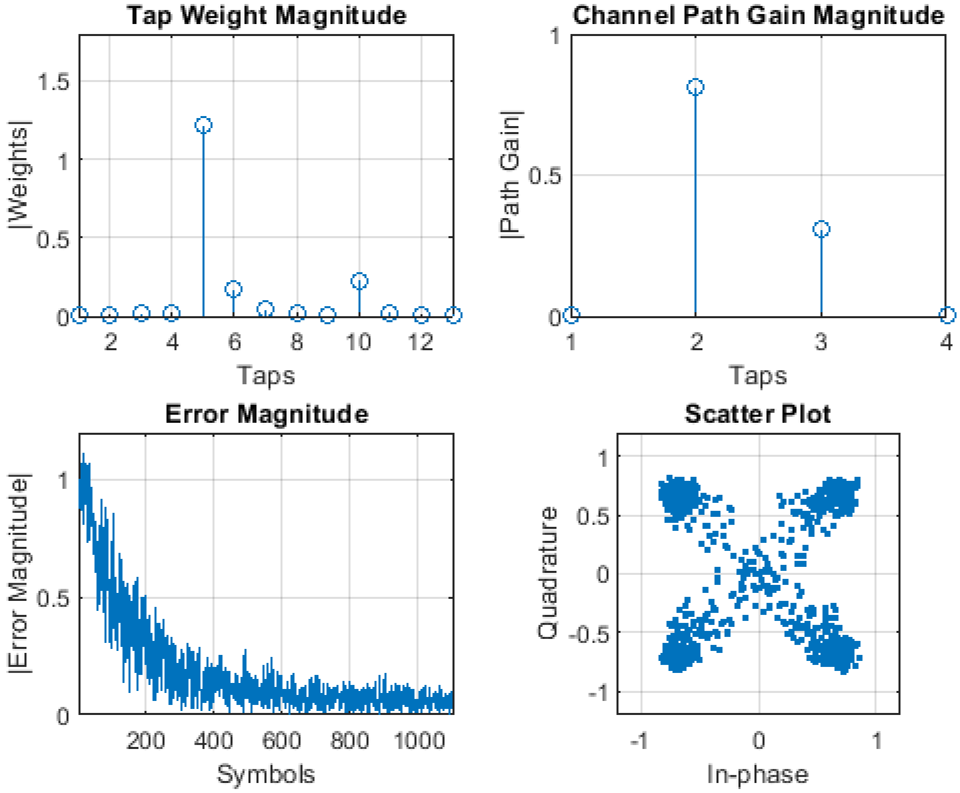
Packet-Based Processing

For packet-based processing, provide one packet at the input of the equalizer. Each packet contains `ttlNumSym` symbols. Because the training duration is less than the packet length, you do not need to specify the start-training input.

```
yVecPkt = zeros(ttlNumSym,numPackets);
errVecPkt = zeros(ttlNumSym,numPackets);
wgtVecPkt = zeros(ttlTaps,numPackets);
dfeq2 = comm.DecisionFeedbackEqualizer('Algorithm','LMS', ...
    'NumForwardTaps',nFwdTaps,'NumFeedbackTaps',nFdbkTaps,'ReferenceTap',refTap, ...
    'StepSize',stepsz);
for p = 1:numPackets
    [yVecPkt(:,p),errVecPkt(:,p),wgtVecPkt(:,p)] = ...
        dfeq2(rxVec(:,p),txVec(1:numTrainingSym,p));
    for q=1:ttlNumSym
        updateFigures(errPlot,wStem,hStem,scatPlot, ...
            errVecPkt(q,p),wgtVecPkt(:,p),yVecPkt(q,p),pg,q,ttlNumSym);
    end
```

After processing each packet, reset the channel System object to get a new realization of channel taps and the equalizer System object to restore the default taps weights.

```
    reset(raylChan)
    reset(dfeq2)
end
```



Helper Functions

This helper function initializes the figures.

```
function [errPlot,wStem,hStem,scatPlot] = initFigures(ttlNumSym,ttlTap,pg)
yVec = nan(ttlNumSym,1);
eVec = nan(ttlNumSym,1);
wVec = zeros(ttlTap,1);
figure;
subplot(2,2,1);
wStem = stem(wVec);
axis([1 ttlTap 0 1.8]); grid on
```

```
xlabel('Taps'); ylabel('|Weights|'); title('Tap Weight Magnitude')
subplot(2,2,2);
hStem = stem([0 abs(pg) 0]);
grid on;
xlabel('Taps'); ylabel('|Path Gain|'); title('Channel Path Gain Magnitude')
subplot(2,2,3);
errPlot = plot(eVec);
axis([1 ttlNumSym 0 1.2]); grid on
xlabel('Symbols'); ylabel('|Error Magnitude|'); title('Error Magnitude')
subplot(2,2,4);
scatPlot = plot(yVec,'.');
axis square; axis([-1.2 1.2 -1.2 1.2]); grid on;
xlabel('In-phase'); ylabel('Quadrature'); title(sprintf('Scatter Plot'));
end
```

This helper function updates the figures.

```
function updateFigures(errPlot,wStem,hStem,scatPlot, ...
    err,wts,y,pg,p,ttlNumSym)
persistent yVec eVec
if p == 1
    yVec = nan(ttlNumSym,1);
    eVec = nan(ttlNumSym,1);
end
yVec(p) = y;
eVec(p) = abs(err);
errPlot.YData = abs(eVec);
wStem.YData = abs(wts);
hStem.YData = [0 abs(pg) 0];
scatPlot.XData = real(yVec);
scatPlot.YData = imag(yVec);
drawnow limitrate
end
```

More About

Symbol Tap Spacing

You can configure the equalizer to operate as a symbol-spaced equalizer or as a fractional symbol-spaced equalizer.

- To operate the equalizer at a symbol-spaced rate, specify the number of samples per symbol as 1. Symbol-rate equalizers have taps spaced at the symbol duration. Symbol-rate equalizers are sensitive to timing phase.
- To operate the equalizer at a fractional symbol-spaced rate, specify the number of input samples per symbol as an integer greater than 1 and provide an input signal oversampled at that sampling rate. Fractional symbol-spaced equalizers have taps spaced at an integer fraction of the input symbol duration. Fractional symbol-spaced equalizers are not sensitive to timing phase.

Algorithms

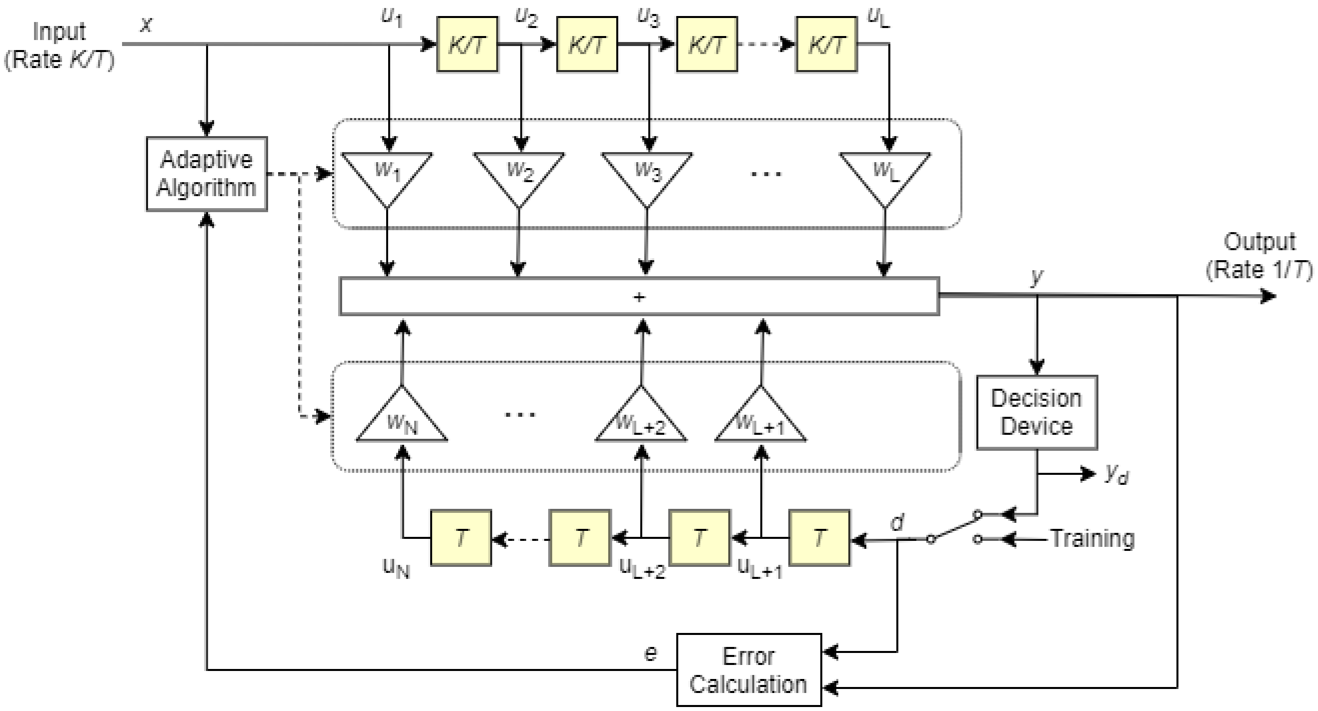
Decision Feedback Equalizers

A decision feedback equalizer (DFE) is a nonlinear equalizer that reduces intersymbol interference (ISI) in frequency-selective channels. If a null exists in the frequency response of a channel, DFEs do not enhance the noise. A DFE consists of a tapped delay line that stores samples from the input signal and contains a forward filter and a feedback filter. The forward filter is similar to a linear equalizer. The feedback filter contains a tapped delay line whose inputs are the decisions made on the equalized signal. Once per symbol period, the equalizer outputs a weighted sum of the values in the delay line and updates the weights to prepare for the next symbol period.

DFEs can be symbol-spaced or fractional symbol-spaced.

- For a symbol-spaced equalizer, the number of samples per symbol, *K*, is 1. The output sample rate equals the input sample rate.
- For a fractional symbol-spaced equalizer, the number of samples per symbol, *K*, is an integer greater than 1. Typically, *K* is 4 for fractional symbol-spaced equalizers. The output sample rate is 1/*T* and the input sample rate is *K/T*. Tap weight updating occurs at the output rate.

This schematic shows a fractional symbol-spaced DFE with a total of *N* weights, a symbol period of *T*, and *K* samples per symbol. The filter has *L* forward weights and *N-L* feedback weights. The forward filter is at the top, and the feedback filter is at the bottom. If *K* is 1, the result is a symbol-spaced DFE instead of a fractional symbol-spaced DFE.



In each symbol period, the equalizer receives *K* input samples at the forward filter and one decision or training sample at the feedback filter. The equalizer then outputs a weighted sum of the values in the forward and feedback delay lines and updates the weights to prepare for the next symbol period.

Note The algorithm for the Adaptive Algorithm block in the schematic jointly optimizes the forward and feedback weights. Joint optimization is especially important for convergence in the recursive least square (RLS) algorithm.

For more information, see “Equalization”.

Least Mean Square (LMS) Algorithm

For the LMS algorithm, in the previous schematic, *w* is a vector of all weights w_i, and *u* is a vector of all inputs u_i. Based on the current set of weights, the LMS algorithm creates the new set of weights as

$w_{\text{new}} = w_{\text{current}} + (StepSize)\ ue^*$.

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed when using the LMS adaptive algorithm, use the `maxstep` object function. The * operator denotes the complex conjugate and the error calculation $e = d - y$.

Recursive Least Square (RLS) Algorithm

For the RLS algorithm, in the previous schematic, *w* is the vector of all weights w_i, and *u* is the vector of all inputs u_i. Based on the current set of inputs, *u*, and the inverse correlation matrix, *P*, the RLS algorithm first computes the Kalman gain vector, *K*, as

$$K = \frac{Pu}{(ForgettingFactor) + u^H Pu}.$$

The forgetting factor used by the adaptive algorithm is specified as a scalar in the range (0, 1]. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalized output signal to be less stable. *H* denotes the Hermitian transpose. Based on the current inverse correlation matrix, the new inverse correlation matrix is

$$P_{\text{new}} = \frac{(1 - Ku^H)P_{\text{current}}}{ForgettingFactor}.$$

Based on the current set of weights, the RLS algorithm creates the new set of weights as

$w_{\text{new}} = w_{\text{current}} + K^*e$.

The * operator denotes the complex conjugate and the error calculation $e = d - y$.

Constant Modulus Algorithm (CMA)

For the CMA adaptive algorithm, in the previous schematic, *w* is the vector of all weights w_i, and *u* is the vector of all inputs u_i. Based on the current set of weights, the CMA adaptive algorithm creates the new set of weights as

$w_{\text{new}} = w_{\text{current}} + (StepSize)\ u^*e$.

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed by the CMA adaptive algorithm, use the `maxstep` object function. The * operator denotes the complex conjugate and the error calculation $e = y(R - |y|^2)$, where *R* is a constant related to the signal constellation.

comm.EVM

Package: `comm`

Measure error vector magnitude

Description

The `comm.EVM` (error vector magnitude) System object measures the modulator or demodulator performance of an impaired signal.

To measure error vector magnitude:

1. Define and set up your EVM object. See “Construction” on page 3-547.
2. Call `step` to measure the modulator or demodulator performance according to the properties of `comm.EVM`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`EVM = comm.EVM` creates an error vector magnitude object, `EVM`. This object measures the amount of impairment in a modulated signal.

`EVM = comm.EVM(Name,Value)` creates an `EVM` object with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Example: `EVM = comm.EVM('ReferenceSignalSource','Estimated from reference constellation')` creates an object, `EVM`, that measures the RMS EVM of a received signal by using a reference constellation.

Properties

`Normalization`

Normalization method

Normalization method used in EVM calculation, specified as one of the following: `'Average reference signal power'` (default), `'Average constellation power'`, or `'Peak constellation power'`.

`AverageConstellationPower`

Average constellation power

Average constellation power, specified in watts as a positive real scalar. This property is available when `Normalization` is `'Average constellation power'`. The default is `1`.

PeakConstellationPower

Peak constellation power

Peak constellation power, specified in watts as a positive real scalar. This property is available when `Normalization` is `'Peak constellation power'`. The default is `1`.

ReferenceSignalSource

Reference signal source

Reference signal source, specified as either `'Input port'` (default) or `'Estimated from reference constellation'`. To provide an explicit reference signal against which the input signal is measured, set this property to `'Input port'`. To measure the EVM of the input signal against a reference constellation, set this property to `'Estimated from reference constellation'`.

ReferenceConstellation

Reference constellation

Reference constellation, specified as a vector. This property is available when the `ReferenceSignalSource` property is `'Estimated from reference constellation'`.

The default is `[0.7071 - 0.7071i; -0.7071 - 0.7071i; -0.7071 + 0.7071i; 0.7071 + 0.7071i]`, which corresponds to a standard QPSK constellation. You can derive constellation points by using modulation functions or objects. For example, to derive the reference constellation for a 16-QAM signal, you can use `qammod(0:15,16)`.

MeasurementIntervalSource

Measurement interval source

Measurement interval source, specified as one of the following: `'Input length'` (default), `'Entire history'`, `'Custom'`, or `'Custom with periodic reset'`. This property affects the RMS and maximum EVM outputs only.

- To calculate EVM using only the current samples, set this property to `'Input length'`.
- To calculate EVM for all samples, set this property to `'Entire history'`.
- To calculate EVM over an interval you specify and to use a sliding window, set this property to `'Custom'`.
- To calculate EVM over an interval you specify and to reset the object each time the measurement interval is filled, set this property to `'Custom with periodic reset'`.

MeasurementInterval

Measurement interval

Measurement interval over which the EVM is calculated, specified in samples as a real positive integer. This property is available when `MeasurementIntervalSource` is `'Custom'` or `'Custom with periodic reset'`. The default is `100`.

AveragingDimensions

Averaging dimensions

Averaging dimensions over which to average the EVM measurements, specified as an integer or row vector of integers with element values in the range [1, 3]. For example, to average across the rows, set this property to `2`. The default is `1`.

The object supports variable-size inputs over the dimensions in which the averaging takes place. However, the input size for the nonaveraged dimensions must remain constant between calls of the object. For example, if the input has size `[4 3 2]` and `Averaging dimensions` is `[1 3]`, the output size is `[1 3 1]`, and the second dimension must remain fixed at `3`.

`MaximumEVMOutputPort`

Maximum EVM measurement output port

Maximum EVM measurement output port, specified as a logical scalar. To create an output port for maximum EVM measurements, set this property to `true`. The default is `false`.

`XPercentileEVMOutputPort`

X-percentile EVM measurement output port

X-percentile EVM measurement output port, specified as a logical scalar. To create an output port for *X*-percentile EVM measurements, set this property to `true`. The *X*-percentile EVM measurements persist until you reset the object. These measurements are calculated by using all of the input frames since the last reset. The default is `false`.

`XPercentileValue`

X-percentile value

X-percentile value below which *X*% of the EVM measurements fall, specified as a real scalar from `0` to `100`. This property is available when `XPercentileEVMOutputPort` is `true`. The default is `95`.

`SymbolCountOutputPort`

Symbol count output port

Symbol count output port, specified as a logical scalar. To output the number of accumulated symbols used to calculate the *X*-percentile EVM measurements, set this property to `true`. This property is available when `XPercentileEVMOutputPort` is `true`. The default is `false`.

Methods

reset	Reset states of EVM measurement object
step	Measure error vector magnitude

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Measure EVM of Noisy 16-QAM Modulated Signal

Create an EVM object. Configure it using name-value pairs to output maximum EVM, 90th percentile EVM, and the symbol count.

```
evm = comm.EVM('MaximumEVMOutputPort',true,...
    'XPercentileEVMOutputPort',true, 'XPercentileValue',90,...
    'SymbolCountOutputPort',true);
```

Generate random data symbols. Apply 16-QAM modulation. The modulated signal serves as the reference for the subsequent EVM measurements.

```
data = randi([0 15],1000,1);
refSym = qammod(data,16,'UnitAveragePower',true);
```

Pass the modulated signal through an AWGN channel.

```
rxSym = awgn(refSym,20);
```

Measure the EVM of the noisy signal.

```
[rmsEVM,maxEVM,pctEVM,numSym] = evm(refSym,rxSym)
```

```
rmsEVM = 9.8775

maxEVM = 26.8385

pctEVM = 14.9750

numSym = 1000
```

Estimate Received EVM

Generate filtered QAM data and pass it through an AWGN channel. Compute the symbol error rate, and estimate the EVM of the received signal.

Create channel and filter System objects™.

```
M = 16;
refConst = qammod(0:M-1,M);
channel = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (SNR)',...
    'SNR',15,'SignalPower',10);

txfilter = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',4);
rxfilter = comm.RaisedCosineReceiveFilter('InputSamplesPerSymbol',4, ...
    'DecimationFactor',4);
```

Create an EVM object to output RMS and maximum EVM measurements.

```
evm = comm.EVM('MaximumEVMOutputPort',true, ...
    'ReferenceSignalSource','Estimated from reference constellation', ...
    'ReferenceConstellation',refConst);
```

Create an error rate object and account for the signal delay through the transmit and receive filters. For a filter, the group delay is equal to 1/2 of the `FilterSpanInSymbols` property.

```
rxd = (txfilter.FilterSpanInSymbols + rxfilter.FilterSpanInSymbols)/2;
errorRate = comm.ErrorRate('ReceiveDelay',rxd);
```

Perform the following channel operations:

- Generate random data symbols.
- Apply 16-QAM modulation.
- Filter the modulated data through a raised cosine Tx filter.
- Pass the transmitted signal through an AWGN channel.
- Filter the received data through a raised cosine Rx filter.
- Demodulate the filtered data.

```
txData = randi([0 15],1000,1);
modData = qammod(txData,M);
txSig = txfilter(modData);
rxSig = channel(txSig);
filtSig = rxfilter(rxSig);
rxData = qamdemod(filtSig,M);
```

Calculate the error statistics and display the symbol error rate.

```
errStats = errorRate(txData,rxData);
symErrRate = errStats(1)
```

```
symErrRate = 0.0222
```

Measure and display the received RMS EVM and maximum EVM values. Take the filter delay into account by deleting the first `rxd+1` symbols. Because there are symbol errors, the EVM may not be totally accurate.

```
[rmsEVM,maxEVM] = evm(filtSig(rxd+1:end))
```

```
rmsEVM = 17.2966

maxEVM = 40.1595
```

Measure EVM Using Reference Constellation

Generate random data symbols, and apply 8-PSK modulation.

```
d = randi([0 7],2000,1);
txSig = pskmod(d,8,pi/8);
```

Pass the modulated signal through an AWGN channel.

```
rxSig = awgn(txSig,30);
```

Create an EVM object. Measure the RMS EVM using the transmitted signal as the reference.

```
evm = comm.EVM;
rmsEVM1 = evm(txSig,rxSig);
```

Release the EVM object. Configure the object to estimate the EVM of the received signal against a reference constellation.

```
release(evm)
evm.ReferenceSignalSource = 'Estimated from reference constellation';
evm.ReferenceConstellation = pskmod(0:7,8,pi/8);
```

Measure the RMS EVM using only the received signal as an input. Verify that it matches the result obtained when using a reference signal.

```
rmsEVM2 = evm(rxSig);
[rmsEVM1 rmsEVM2]
```

```
ans = 1×2

    3.1524    3.1524
```

Measure EVM Using Custom Measurement Interval

Measure the EVM of a noisy 8-PSK signal using two types of custom measurement intervals. Display the results.

Set the number of frames, M, and the number of subframes per frame, K.

```
M = 2;
K = 5;
```

Set the number of symbols in a subframe. Calculate the corresponding frame length.

```
sfLen = 100;
frmLen = K*sfLen
```

```
frmLen = 500
```

Create an EVM object. Configure the object to use a custom measurement interval equal to the frame length.

```
evm1 = comm.EVM('MeasurementIntervalSource','Custom', ...
    'MeasurementInterval',frmLen);
```

Configure the object to measure EVM using an 8-PSK reference constellation.

```
evm1.ReferenceSignalSource = 'Estimated from reference constellation';
evm1.ReferenceConstellation = pskmod(0:7,8,pi/8);
```

Create an EVM object, and configure it use a 500-symbol measurement interval with a periodic reset. Configure the object to measure EVM using an 8-PSK reference constellation.

```
evm2 = comm.EVM('MeasurementIntervalSource','Custom with periodic reset', ...
    'MeasurementInterval',frmLen);
evm2.ReferenceSignalSource = 'Estimated from reference constellation';
evm2.ReferenceConstellation = pskmod(0:7,8,pi/8);
```

Initialize the EVM and signal-to-noise arrays.

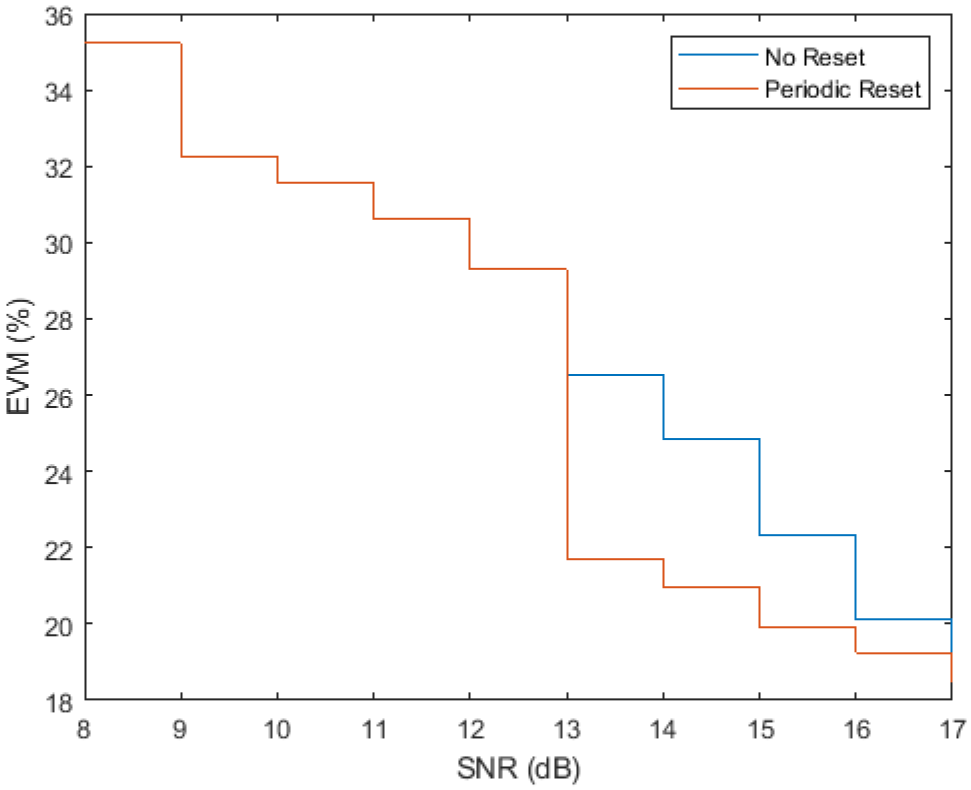
```
rmsEVM1 = zeros(K,M);
rmsEVM2 = zeros(K,M);
snrdB = zeros(K,M);
```

Measure the EVM for a noisy 8-PSK signal using both objects. The SNR increases by 1 dB from subframe to subframe. For `evm1`, the 500 most recent symbols are used to compute the estimate. In this case, a sliding window is used so that an entire frame of data is always processed. For `evm2`, the symbols are cleared each time a new frame is encountered.

```
for m = 1:M
    for k = 1:K
        data = randi([0 7],sfLen,1);
        txSig = pskmod(data,8,pi/8);
        snrdB(k,m) = k+(m-1)*K+7;
        rxSig = awgn(txSig,snrdB(k,m));
        rmsEVM1(k,m) = evm1(rxSig);
        rmsEVM2(k,m) = evm2(rxSig);
    end
end
```

Display the EVM measured using the two approaches. The windowing used in the first case provides an averaging across the subframes. In the second case, the EVM object resets after the first frame so that the calculated EVM values more accurately reflect the current SNR.

```
stairs(snrdB(:),[rmsEVM1(:) rmsEVM2(:)])
xlabel('SNR (dB)')
ylabel('EVM (%)')
legend('No Reset','Periodic Reset')
```



Measure EVM Across Different Dimensions

Create OFDM modulator and demodulator objects.

```
ofdmmod = comm.OFDMModulator('FFTLength',32,'NumSymbols',4);
ofdmdemod = comm.OFDMDemodulator('FFTLength',32,'NumSymbols',4);
```

Determine the number of subcarriers and symbols in the OFDM signal.

```
ofdmDims = info(ofdmmod);
numSC = ofdmDims.DataInputSize(1)
```

```
numSC = 21
```

```
numSym = ofdmDims.DataInputSize(2)
```

```
numSym = 4
```

Generate random symbols and apply QPSK modulation.

```
msg = randi([0 3],numSC,numSym);
modSig = pskmod(msg,4,pi/4);
```

OFDM modulate the QPSK signal. Pass the signal through an AWGN channel. Demodulate the noisy signal.

```
txSig = ofdmmod(modSig);
rxSig = awgn(txSig,10,'measured');
demodSig = ofdmdemod(rxSig);
```

Create an EVM object, where the result is averaged over the subcarriers. Measure the EVM. There are four entries corresponding to each of the 4 OFDM symbols.

```
evm = comm.EVM('AveragingDimensions',1);
rmsEVM = evm(demodSig,modSig)
```

```
rmsEVM = 1×4

   27.4354   23.6279   22.6772   23.1699
```

Overwrite the EVM object, where the result is averaged over the OFDM symbols. Measure the EVM. There are 21 entries corresponding to each of the 21 subcarriers.

```
evm = comm.EVM('AveragingDimensions',2);
rmsEVM = evm(demodSig,modSig)
```

```
rmsEVM = 21×1

   28.8225
   17.8536
   18.6809
   20.8872
   22.3532
   24.7197
   30.1954
   33.4899
   36.2847
   21.4230
```

```
      ⋮
```

Measure the EVM and average over both the subcarriers and the OFDM symbols.

```
evm = comm.EVM('AveragingDimensions',[1 2]);
rmsEVM = evm(demodSig,modSig)
```

```
rmsEVM = 24.2986
```

Plot Time-Varying EVM for OFDM Signal

Calculate and plot the EVM of an OFDM signal. The signal consists of two packets separated by an interval.

Create System objects to:

- OFDM modulate a signal
- Introduce phase noise
- Plot time-varying signals

```
ofdmmod = comm.OFDMModulator('FFTLength',256,'NumSymbols',2);

pnoise = comm.PhaseNoise('Level',-60,'FrequencyOffset',20,'SampleRate',1000);

tscope = timescope('YLabel','EVM (%)','YLimits',[0 40], ...
    'SampleRate',1000,'TimeSpanSource','Property','TimeSpan',1.2, ...
    'ShowGrid',true);
```

Create an EVM object. To generate a time-varying estimate of the EVM, set the `AveragingDimensions` property to `2`.

```
evm = comm.EVM('MaximumEVMOutputPort',false, ...
    'ReferenceSignalSource','Input port', ...
    'AveragingDimensions',2);
```

Determine the input data dimensions of the OFDM modulator.

```
modDims = info(ofdmmod)
```

```
modDims = 

  struct with fields:

    DataInputSize: [245 2]
       OutputSize: [544 1]
```

Create QPSK-modulated random data for the first packet. Apply OFDM modulation.

```
data = randi([0 3],modDims.DataInputSize);
qpskSig = pskmod(data,4,pi/4);
txSig1 = ofdmmod(qpskSig);
```

Create a second data packet.

```
data = randi([0 3],modDims.DataInputSize);
qpskSig = pskmod(data,4,pi/4);
txSig2 = ofdmmod(qpskSig);
```

Concatenate the two packets and include an interval in which nothing is transmitted.

```
txSig = [txSig1; zeros(112,1); txSig2];
```

Apply I/Q amplitude and phase imbalance to the transmitted signal.

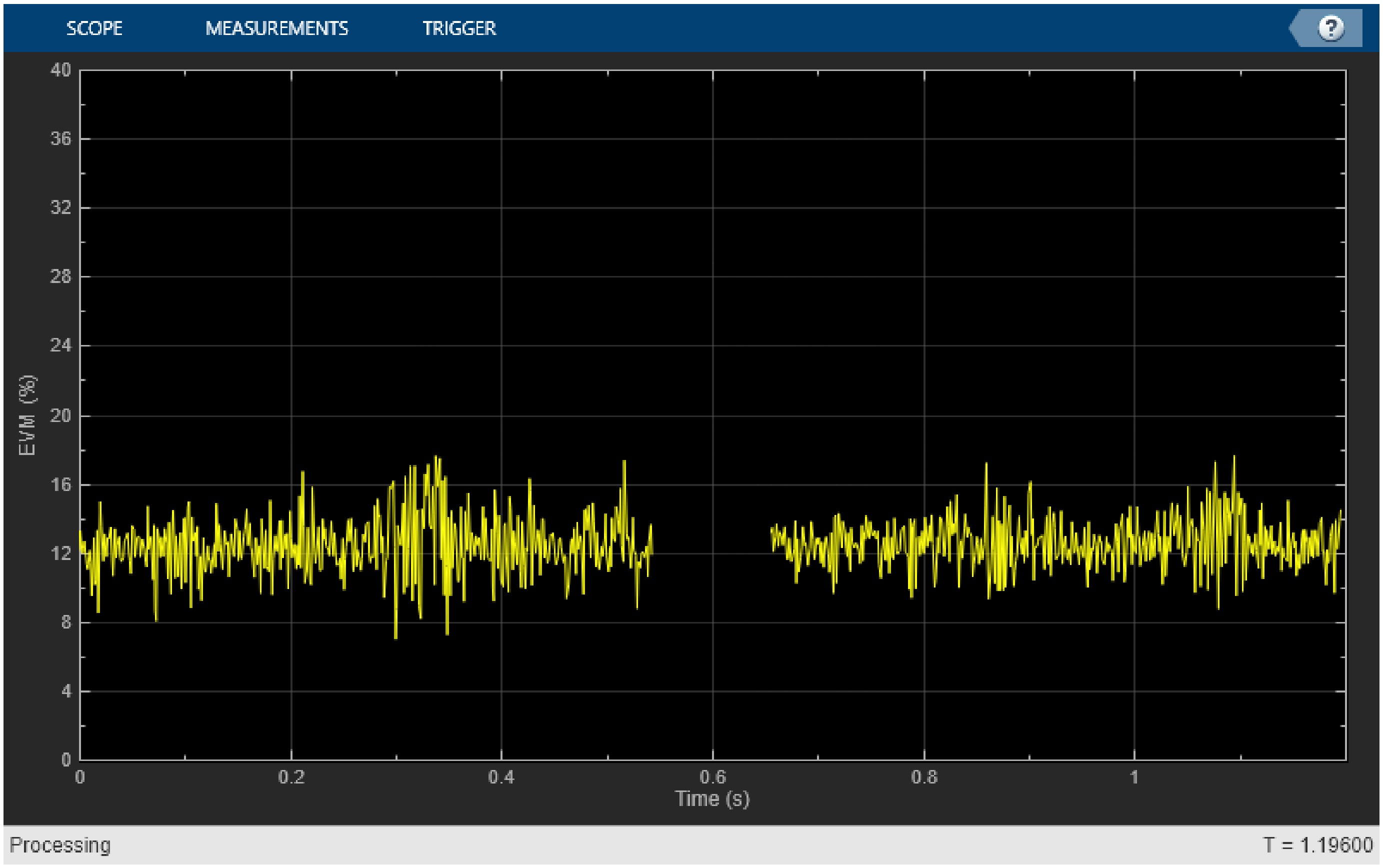
```
rxSigIQimb = iqimbal(txSig,2,5);
```

Apply phase noise.

```
rxSig = pnoise(rxSigIQimb);
```

Measure the EVM of the received signal, and plot its time-varying EVM.

```
e = evm(txSig,rxSig);
tscope(e)
```



Algorithms

Both the EVM block and the EVM object provide three normalization methods. You can normalize measurements according to the average power of the reference signal, average constellation power, or peak constellation power. Different industry standards follow one of these normalization methods.

The block or object calculates the RMS EVM value differently for each normalization method.

EVM Normalization Method	Algorithm
Reference signal	$EVM_{RMS} = \sqrt{\frac{\frac{1}{N}\sum_{k=1}^{N}(e_k)}{\frac{1}{N}\sum_{k=1}^{N}(I_k^2 + Q_k^2)}} * 100$
Average power	$\mathrm{EVM}_{\mathrm{RMS}}(\%) = 100\sqrt{\frac{\frac{1}{N}\sum_{k=1}^{N}(e_k)}{P_{\mathrm{avg}}}}$
Peak power	$\mathrm{EVM}_{\mathrm{RMS}}(\%) = 100\sqrt{\frac{\frac{1}{N}\sum_{k=1}^{N}(e_k)}{P_{\mathrm{max}}}}$

Where:

- $e_k = e_k = (I_k - \tilde{I}_k)^2 + (Q_k - \tilde{Q}_k)^2$
- I_k = In-phase measurement of the kth symbol in the burst
- Q_k = Quadrature phase measurement of the kth symbol in the burst
- N = Input vector length
- P_{avg} = The value for **Average constellation power**
- P_{max} = The value for **Peak constellation power**
- I_k and Q_k represent ideal (reference) values. $\tilde{I}_k$ and $\tilde{Q}_k$ represent measured (received) symbols.

The max EVM is the maximum EVM value in a frame or $\mathrm{EVM}_{\mathrm{max}} = \max_{k \in [1, \ldots, N]} \{\mathrm{EVM}_k\}$, where k is the kth symbol in a burst of length N.

The definition for EVM_k varies depending upon which normalization method you select for computing measurements. The block or object supports these algorithms.

EVM Normalization	Algorithm
Reference signal	$EVM_k = \sqrt{\frac{e_k}{\frac{1}{N}\sum_{k=1}^{N}(I_k^2 + Q_k^2)}} * 100$
Average power	$\mathrm{EVM}_k = 100\sqrt{\frac{e_k}{P_{\mathrm{avg}}}}$
Peak power	$\mathrm{EVM}_k = 100\sqrt{\frac{e_k}{P_{\mathrm{max}}}}$

The block or object computes the X-percentile EVM by creating a histogram of all the incoming EVM_k values. The output provides the EVM value below which X% of the EVM values fall.

`comm.ACPR` | `comm.CCDF` | `comm.MER`

Introduced in R2012a

reset

System object: `comm.EVM`
Package: `comm`

Reset states of EVM measurement object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `EVM` object, `H`.

step

System object: comm.EVM
Package: comm

Measure error vector magnitude

Syntax

```
RMSEVM = step(EVM,REFSYM,RXSYM)
RMSEVM = step(EVM,RXSYM)
[___,MAXEVM] = step(___)
[___,XEVM] = step(___)
[___,NUMSYM] = step(___)
```

Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

RMSEVM = step(EVM,REFSYM,RXSYM) returns the measured root-mean-square EVM, RMSEVM, of the received signal RXSYM, based on reference signal REFSYM. EVM values are measured as a percentage.

REFSYM and RXSYM inputs are complex column vectors of equal dimensions and data type. The data type can be double, single, signed integer, or signed fixed point with power-of-two slope and zero bias. All outputs of the object are of data type double. To set the interval over which the EVM is measured, use the MeasurementIntervalSource and MeasurementInterval properties.

RMSEVM = step(EVM,RXSYM) returns the measured EVM of received signal RXSYM based on a reference signal specified in the ReceivedConstellation property.

[___,MAXEVM] = step(___) returns the maximum EVM, MAXEVM, given either of the two previous syntaxes.

To return the maximum EVM value, set the MaximumEVMOutputPort property to true. To set the interval over which the maximum EVM is measured, use the MeasurementIntervalSource and MeasurementInterval properties.

[___,XEVM] = step(___) returns the *X*-percentile EVM, XEVM.

To return the X-percentile EVM, set the XPercentileEVMOutputPort property to true. XEVM is the EVM below which *X*% of the measurements fall, where *X* is set by the XPercentileValue property. XEVM is measured using all the input frames since the last reset.

[___,NUMSYM] = step(___) returns the number of symbols, NUMSYM, used to calculate the *X*-percentile EVM.

To return `NUMSYM`, set the `SymbolCountOutputPort` property to `true`. `NUMSYM` is measured using all the input frames since the last reset.

Note `EVM` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.EyeDiagram

Package: `comm`

(To be removed) Display eye diagram of time-domain signals

Note will be removed in a future release. To display the eye diagram of a signal, use the `eyediagram` function instead. For more details on the recommended workflow, see “Compatibility Considerations”.

Description

The `comm.EyeDiagram` System object displays multiple traces of a modulated signal to produce an eye diagram. You can use the object to reveal the modulation characteristics of the signal, such as the effects of pulse shaping or channel distortions. The eye diagram can measure signal characteristics and plot horizontal and vertical bathtub curves when the jitter and noise comply with the dual-Dirac model [1].

To display the eye diagram of an input signal:

1. Create the `comm.EyeDiagram` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
ed = comm.EyeDiagram
ed = comm.EyeDiagram(Name,Value)
```

Description

`ed = comm.EyeDiagram` creates an eye diagram System object with default property values.

`ed = comm.EyeDiagram(Name,Value)` sets properties using one or more name-value pair argument. Enclose each property name in single quotes. Unspecified properties have default values.

Example: `comm.EyeDiagram('SampleRate',2,'DisplayMode','2D color histogram')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Name — Title of eye diagram window
'Eye Diagram' (default) | character vector

Title of eye diagram window, specified as a character vector.

Tunable: Yes

Data Types: char

SampleRate — Sample rate of input signal
1 (default) | positive real-valued scalar

Sample rate of the input signal in hertz, specified as a positive real-valued scalar.

Data Types: double

SamplesPerSymbol — Number of samples per symbol
8 (default) | positive integer

Number of samples per symbol, specified as a positive integer.

Tunable: Yes

Data Types: double

SampleOffset — Number of samples to skip before plotting the first point
0 (default) | nonnegative integer

Number of samples to skip before plotting the first point, specified as a nonnegative integer. To avoid irregular behavior, specify the offset to be less than the product of the SamplesPerSymbol and SymbolsPerTrace properties.

Tunable: Yes

Data Types: double

SymbolsPerTrace — Number of symbols per trace
2 (default) | positive integer

Number of symbols per trace, specified as a positive integer. To obtain eye measurements and visualize bathtub curves, use the default value of 2.

Tunable: Yes

Data Types: double

TracesToDisplay — Number of traces to display
40 (default) | positive integer

Number of traces to display, specified as a positive integer.

Tunable: Yes

Dependencies

To enable this property, set DisplayMode property to 'Line plot'.

Data Types: `double`

`DisplayMode` — Eye diagram display mode

`'Line plot'` (default) | `'2D color histogram'`

Eye diagram display mode, specified as one of these values.

- `'Line plot'` — Overlay traces by plotting one line for each of the last TracesToDisplay traces.
- `'2D color histogram'` — Display a color gradient that shows how often the input matches different time and amplitude values.

Tunable: Yes

Data Types: `char`

`EnableMeasurements` — Option to enable eye diagram measurements

`false` (default) | `true`

Option to enable eye diagram measurements, specified as `true` or `false`. Set this property to `true` to display the measurement pane and calculations in the eye diagram.

Tunable: Yes

Data Types: `logical`

`ShowBathtub` — Option to enable visualization of bathtub curves

`'None'` (default) | `'Horizontal'` | `'Vertical'` | `'Both'`

Option to enable visualization of bathtub curves, specified as `'None'`, `'Horizontal'`, `'Vertical'`, or `'Both'`.

Tunable: Yes

Dependencies

To enable this property, set the EnableMeasurements property to `true`.

Data Types: `char`

`OverlayHistogram` — Histogram overlay

`'None'` (default) | `'Jitter'` | `'Noise'`

Histogram overlay, specified as `'None'`, `'Jitter'`, or `'Noise'`.

- To overlay a horizontal histogram on the eye diagram, set this property to `'Jitter'`.
- To overlay a vertical histogram on the eye diagram, set this property to `'Noise'`.
- To display no histogram overlay, set this property to `'None'`.

Tunable: Yes

Dependencies

To enable this property, set the DisplayMode property to `'2D color histogram'` and EnableMeasurements property to `true`.

Data Types: `char`

`DecisionBoundary` — Amplitude level threshold

`0` (default) | real-valued scalar

Amplitude level threshold in volts, specified as a real-valued scalar. This property separates the different signaling regions for horizontal (jitter) histograms. Jitter histograms reset when this property changes.

For non-return-to-zero (NRZ) signals, set `DecisionBoundary` to 0. For return-to-zero (RZ) signals, set `DecisionBoundary` to half the maximum amplitude.

Tunable: Yes

Dependencies

To enable this property, set the EnableMeasurements property to `true`.

Data Types: `double`

`EyeLevelBoundaries` — Time range for calculating eye levels

`[40 60]` (default) | two-element row vector

Time range for calculating eye levels, specified as a two-element row vector. Specify the vector values as percentages of the symbol duration.

Tunable: Yes

Dependencies

To enable this property, set the EnableMeasurements property to `true`.

Data Types: `double`

`RiseFallThresholds` — Amplitude levels of the rise and fall transitions

`[10 90]` (default) | two-element row vector

Amplitude levels of the rise and fall transitions, specified as a two-element row vector. Specify the vector values as percentages of the eye amplitude. The crossing histograms of the rise and fall thresholds reset when this property changes.

Tunable: Yes

Dependencies

To enable this property, set the EnableMeasurements property to `true`.

Data Types: `double`

`Hysteresis` — Amplitude tolerance of the horizontal crossings

`0` (default) | real-valued scalar

Amplitude tolerance of the horizontal crossings in volts, specified as a real-valued scalar. Increase this value to provide more tolerance to spurious crossings due to noise. Jitter and the rise and fall histograms reset when this property changes.

Tunable: Yes

Dependencies

To enable this property, set the EnableMeasurements property to `true`.

Data Types: `double`

`BERThreshold` — BER used for eye measurements

`1e-12` (default) | scalar in the range [0, 0.5]

Bit error rate (BER) used for eye measurements, specified as a scalar in the range [0, 0.5]. The System object uses this value to measure the random jitter, the total jitter, horizontal eye openings, and vertical eye openings.

Tunable: Yes

Dependencies

To enable this property, set the EnableMeasurements property to `true`.

Data Types: `double`

`BathtubBER` — BER values used to calculate openings of bathtub curves

`[0.5 10.^-(1:12)]` (default) | vector

BER values used to calculate the openings of bathtub curves, specified as a vector of elements in the range [0, 0.5]. Horizontal and vertical eye openings are calculated for each of the values specified by this property.

Tunable: Yes

Dependencies

To enable this property, set the EnableMeasurements property to `true` and ShowBathtub property to `'Both'`, `'Horizontal'`, or `'Vertical'`.

Data Types: `double`

`MeasurementDelay` — Duration of initial data discarded from measurements

`0` (default) | nonnegative scalar

Duration of initial data discarded from measurements in seconds, specified as a nonnegative scalar.

Dependencies

To enable this property, set the EnableMeasurements property to `true`.

Data Types: `double`

`OversamplingMethod` — Oversampling method

`'None'` (default) | `'Input interpolation'` | `'Histogram interpolation'`

Oversampling method, specified as `'None'`, `'Input interpolation'`, or `'Histogram interpolation'`.

To plot eye diagrams as quickly as possible, set `OversamplingMethod` to `'None'`. The drawback to not oversampling is that the plots look pixelated when the number of symbols per trace is small.

To create smoother, less-pixelated plots using a small number of symbols per trace, set `OversamplingMethod` to`'Input interpolation'` or `'Histogram interpolation'`. In this case, `'Input interpolation'` is the faster interpolation method and produces good results when the signal-to-noise ratio (SNR) is high. With a low SNR, this oversampling method is not recommended because it introduces a bias to the centers of the histogram ranges. `'Histogram` `interpolation'` is not as fast as the other techniques, but it provides good results even when the SNR is low.

Tunable: Yes

Dependencies

To enable this property, set the DisplayMode property to `'2D color histogram'`.

Data Types: `char`

`ColorScale` — Color scale of the histogram

`'Linear'` (default) | `'Logarithmic'`

Color scale of the histogram, specified as `'Linear'` or `'Logarithmic'`. Change this property if certain areas of the histogram include a disproportionate number of points. Use the `'Logarithmic'` option for eye diagrams with sharp peaks, where the signal repetitively matches specific time and amplitude values.

Tunable: Yes

Dependencies

To enable this property, set the DisplayMode property to `'2D color histogram'`.

Data Types: `char`

`ColorFading` — Color fading

`false` (default) | `true`

Color fading, specified as `true` or `false`. To fade the points in the display as the interval of time after they are first plotted increases, set this property to `true`. This animation resembles an oscilloscope.

Tunable: Yes

Dependencies

To enable this property, set the DisplayMode property to `'Line plot'`.

Data Types: `logical`

`ShowImaginaryEye` — Show imaginary signal component

`false` (default) | `true`

Show imaginary signal component, specified as `true` or `false`. To view the imaginary or quadrature component of the input signal, set this property to `true`.

Tunable: Yes

Dependencies

To enable this property, set the EnableMeasurements property to `false`.

Data Types: `logical`

`YLimits` — *Y*-axis limits

`[-1.1 1.1]` (default) | two-element row vector

Y-axis limits of the eye diagram in volts, specified as a two-element vector. The first element corresponds to *ymin* and the second to *ymax*. The second element must be greater than the first.

Tunable: Yes

Data Types: `double`

`ShowGrid` — Option to enable grid display

`false` (default) | `true`

Option to enable grid display on the eye diagram, specified as `true` or `false`. To display a grid on the eye diagram, set this property to `true`.

Tunable: Yes

Data Types: `logical`

`Position` — Scope window position

four-element row vector

Scope window position in pixels, specified as a four-element row vector of the form [*left bottom width height*].

Tunable: Yes

Data Types: `double`

Usage

Syntax

```
ed(x)
```

Description

`ed(x)` displays and analyzes input signal `x` in an eye diagram.

Input Arguments

`x` — Input signal

vector | matrix

Input signal to be analyzed and displayed in the eye diagram, specified as a vector or matrix. `x` can be either a real or complex vector, or a real two-column matrix.

Data Types: `double`
Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.EyeDiagram`

show	Show scope window
hide	Hide scope window
horizontalBathtub	Horizontal bathtub curve
verticalBathtub	Vertical bathtub curve
jitterHistogram	Jitter histogram
noiseHistogram	Noise histogram
measurements	Measure eye diagram parameters

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Eye Diagram of Filtered QPSK Signal

Specify the sample rate and the number of output samples per symbol parameters.

```
fs = 1000;
sps = 4;
```

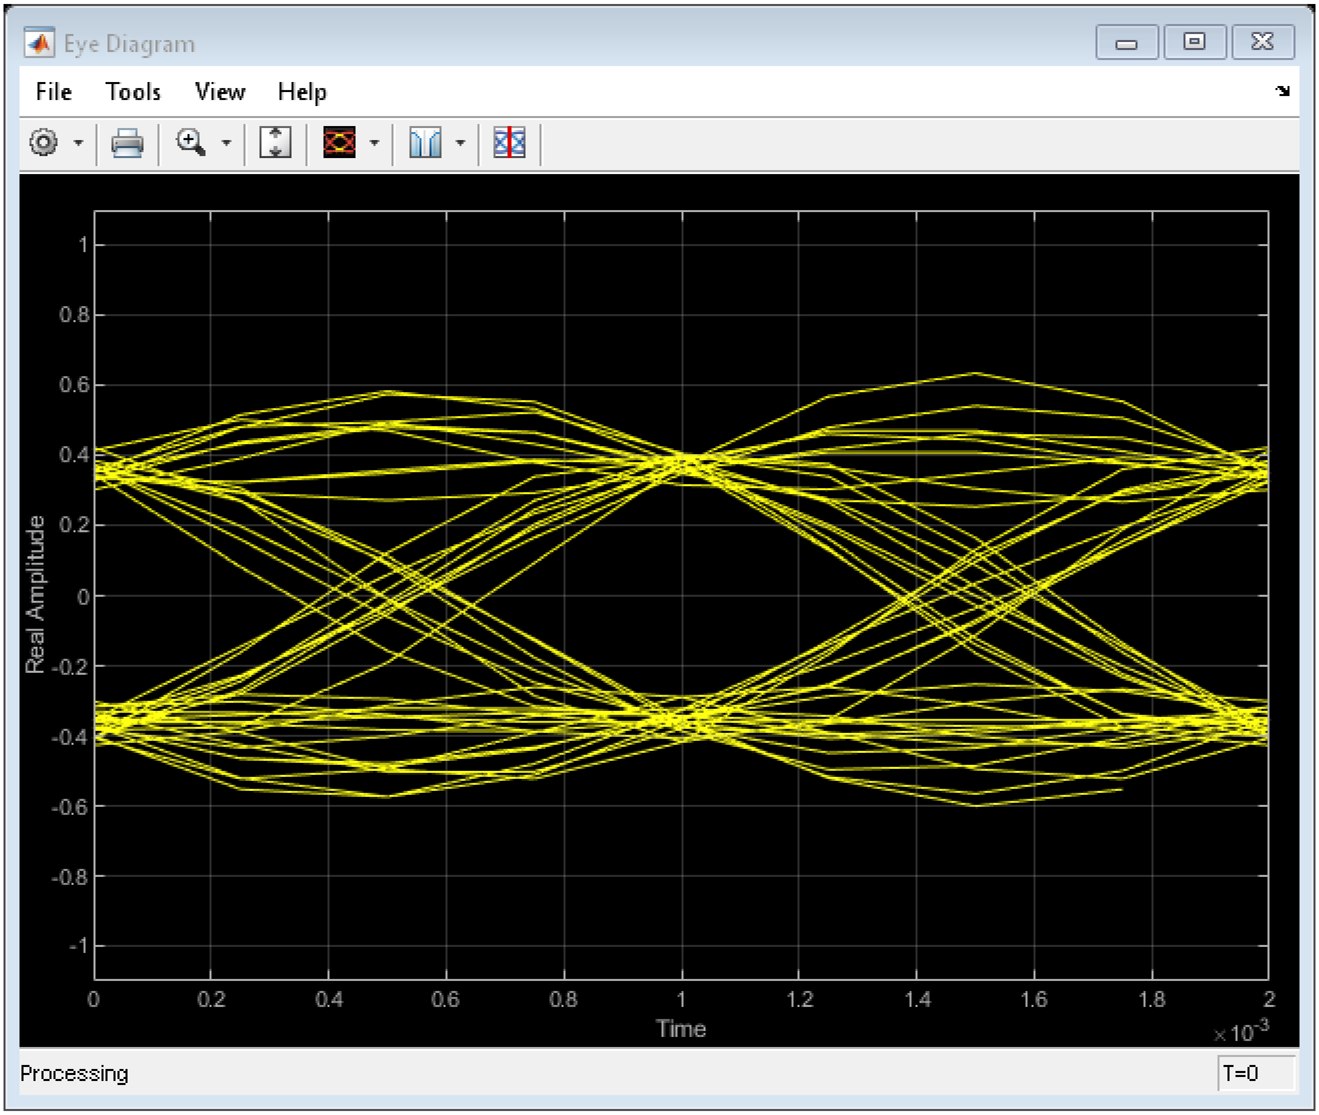
Create transmit filter and eye diagram objects.

```
txfilter = comm.RaisedCosineTransmitFilter(...
    'OutputSamplesPerSymbol',sps);
ed = comm.EyeDiagram('SampleRate',fs*sps,'SamplesPerSymbol',sps);
```

Generate random symbols and apply QPSK modulation. Then filter the modulated signal and display the eye diagram.

```
data = randi([0 3],1000,1);
modSig = pskmod(data,4,pi/4);

txSig = txfilter(modSig);
ed(txSig)
```



More About

Measurements

Measurements assume that the eye diagram object has valid data. A valid eye diagram has two distinct eye crossing points and two distinct eye levels.

To open the measurements pane, click on the **Eye Measurements** button or select **Tools > Measurements > Eye Measurements** from the toolbar menu.

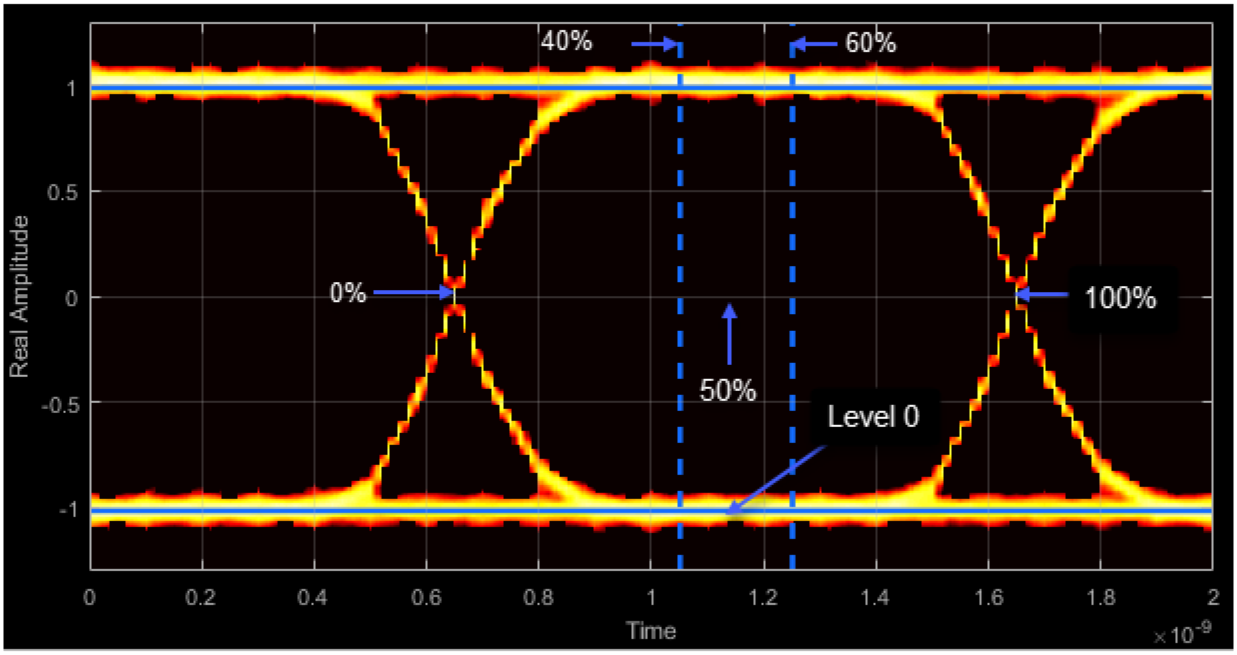
Note

- For amplitude measurements, at least one bin per vertical histogram must reach 10 hits before the measurement is taken, ensuring higher accuracy.
- For time measurements, at least one bin per horizontal histogram must reach 10 hits before the measurement is taken.

- When an eye crossing time measurement falls within the [-0.5/Fs, 0) seconds interval, the time measurement wraps to the end of the eye diagram, i.e., the measurement wraps by $2\times T_s$ seconds (where T_s is the symbol time). For a complex signal case, the analyze method issues a warning if the crossing time measurement of the in-phase branch wraps while that of the quadrature branch does not (or vice versa). To avoid time-wrapping or a warning, add a half-symbol duration delay to the current value in the `MeasurementDelay` property of the eye diagram object. This additional delay repositions the eye in the approximate center of the scope.

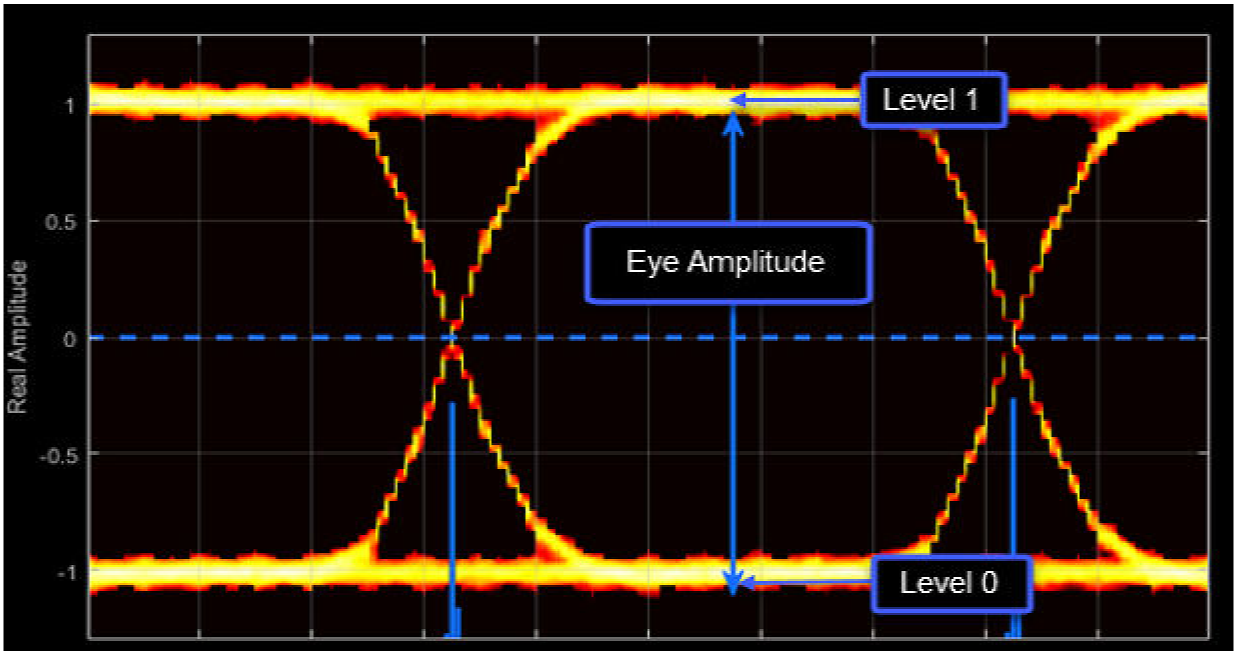
Eye Levels - Amplitude level used to represent data bits

Eye level is the amplitude level used to represent data bits. For the displayed NRZ signal, the levels are –1 V and +1 V. The eye levels are calculated by averaging the 2-D histogram within the eye level boundaries. For example, when the EyeLevelBoundaries property is set to `[40 60]`, that is, 40% and 60% of the symbol duration, the eye levels are calculated by estimating the mean value of the vertical histogram in this window marked by the eye level boundaries.



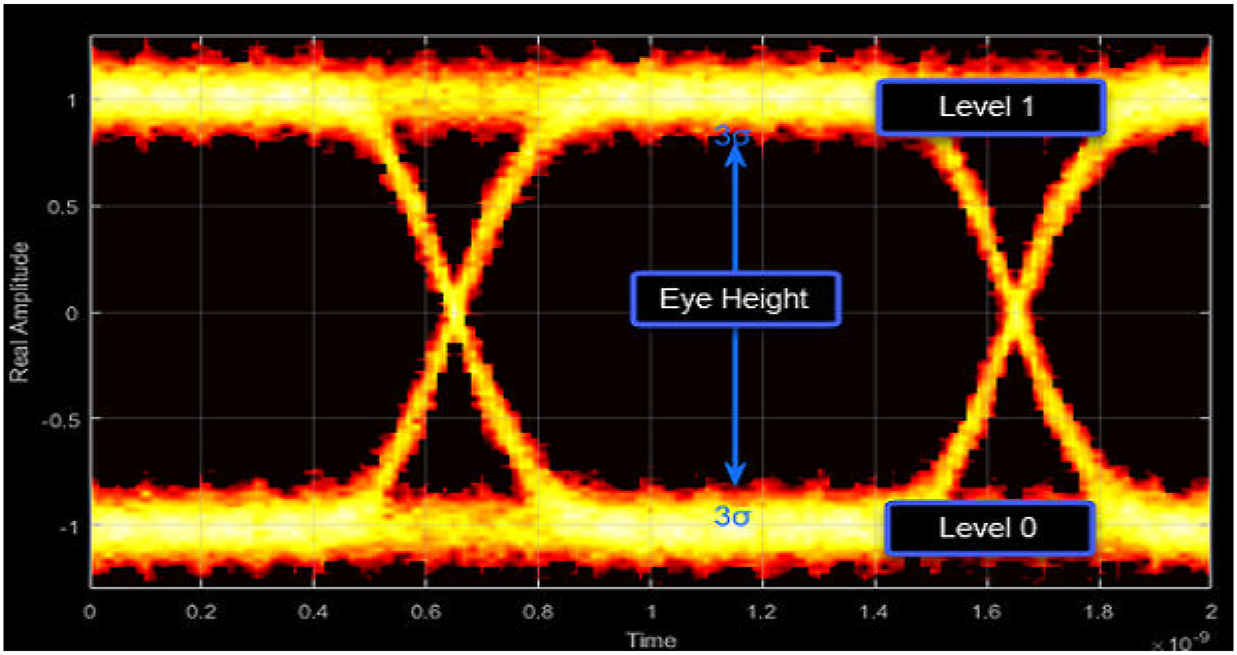
Eye Amplitude - Distance between eye levels

Eye amplitude is the distance in V between the mean value of two eye levels.



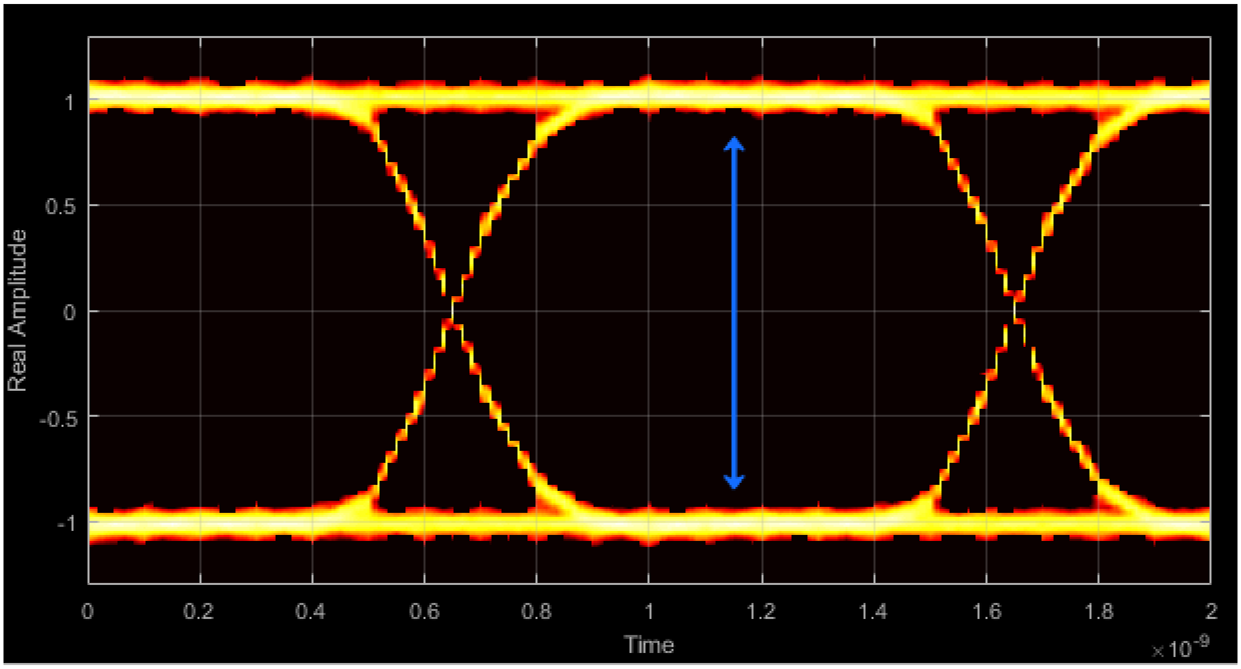
Eye Height - Statistical minimum distance between eye levels

Eye height is the distance between μ – 3σ of the upper eye level and μ + 3σ of the lower eye level. μ is the mean of the eye level, and σ is the standard deviation.



Vertical Opening - Distance between BER threshold points

The vertical opening is the distance between the two points that correspond to the BERThreshold property. For example, for a BER threshold of 10^{-12}, these points correspond to the 7σ distance from each eye level.



Eye SNR - Signal-to-noise ratio

The eye SNR is the ratio of the eye level difference to the difference of the vertical standard deviations corresponding to each eye level:

$$\mathrm{SNR} = \frac{L_1 - L_0}{\sigma_1 - \sigma_0},$$

where L_1 and L_0 represent the means of the upper and lower eye levels and σ_1 and σ_0 represent their standard deviations.

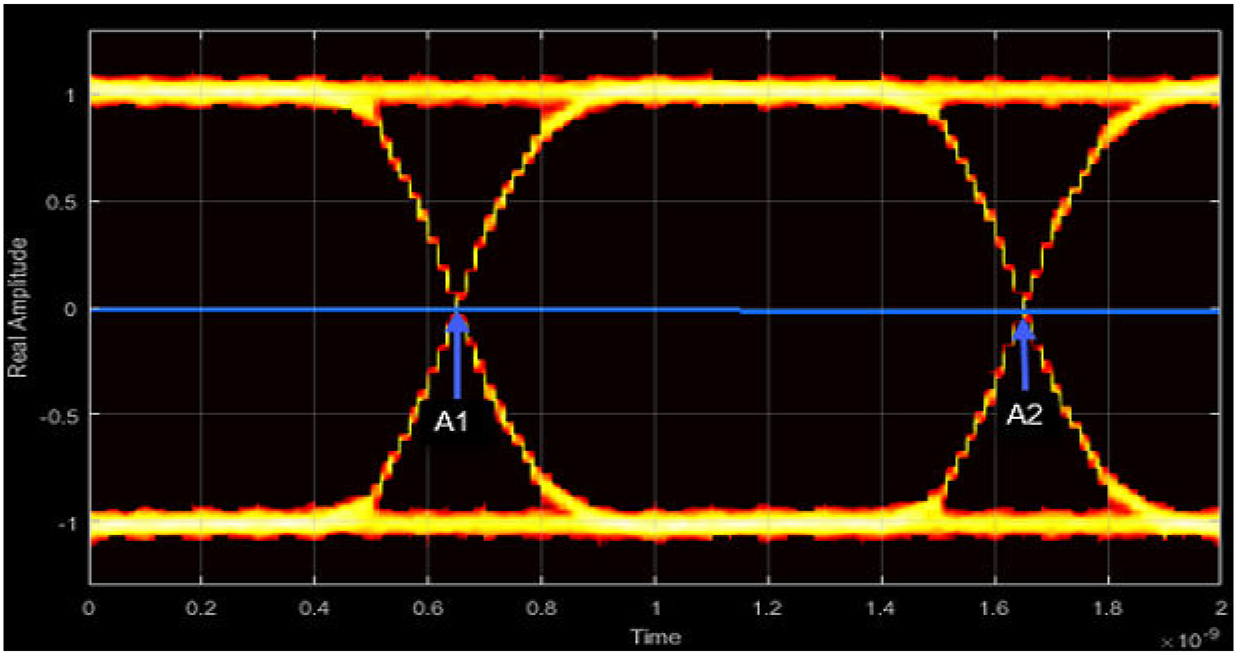
Q Factor - Quality factor

The Q factor is the quality factor and is calculated using the same formula as the eye SNR. However, the standard deviations of the vertical histograms are replaced with those computed with the dual-Dirac analysis.

Crossing Levels - Amplitude levels for eye crossings

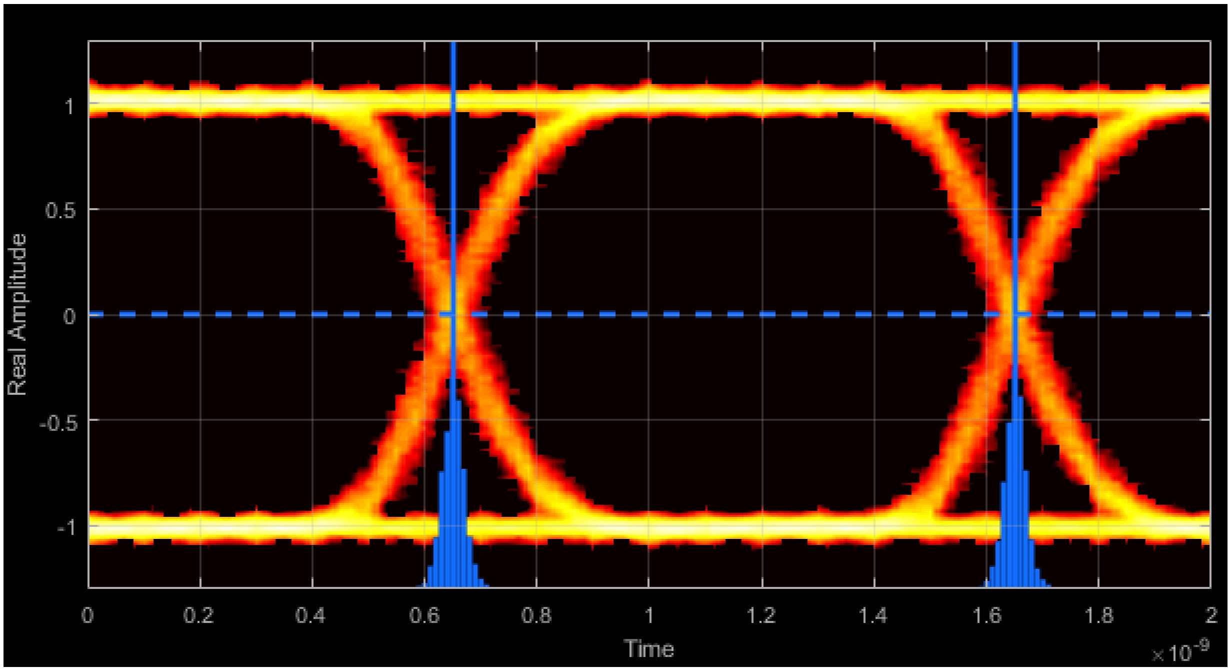
The crossing levels are the amplitude levels at which the eye crossings occur.

The level at which the input signal crosses the amplitude value is specified by the DecisionBoundary property.



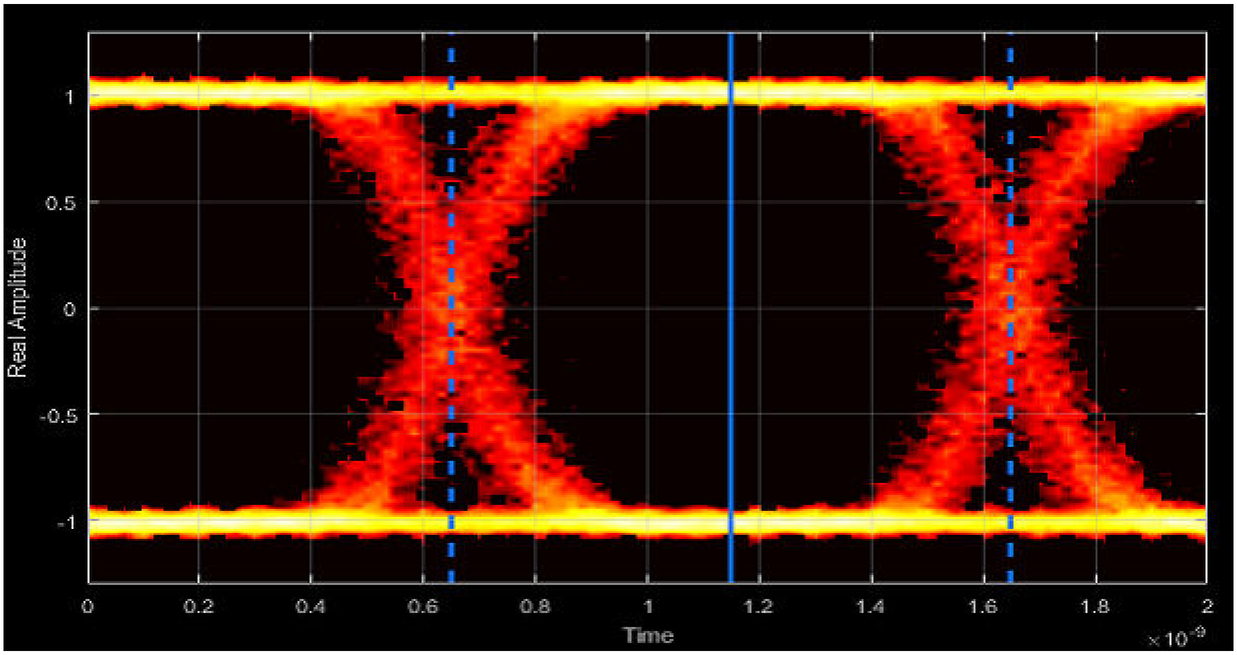
Crossing Times - Times for which crossings occur

The crossing times are the times at which the crossings occur. The times are computed as the mean values of the horizontal (jitter) histograms.



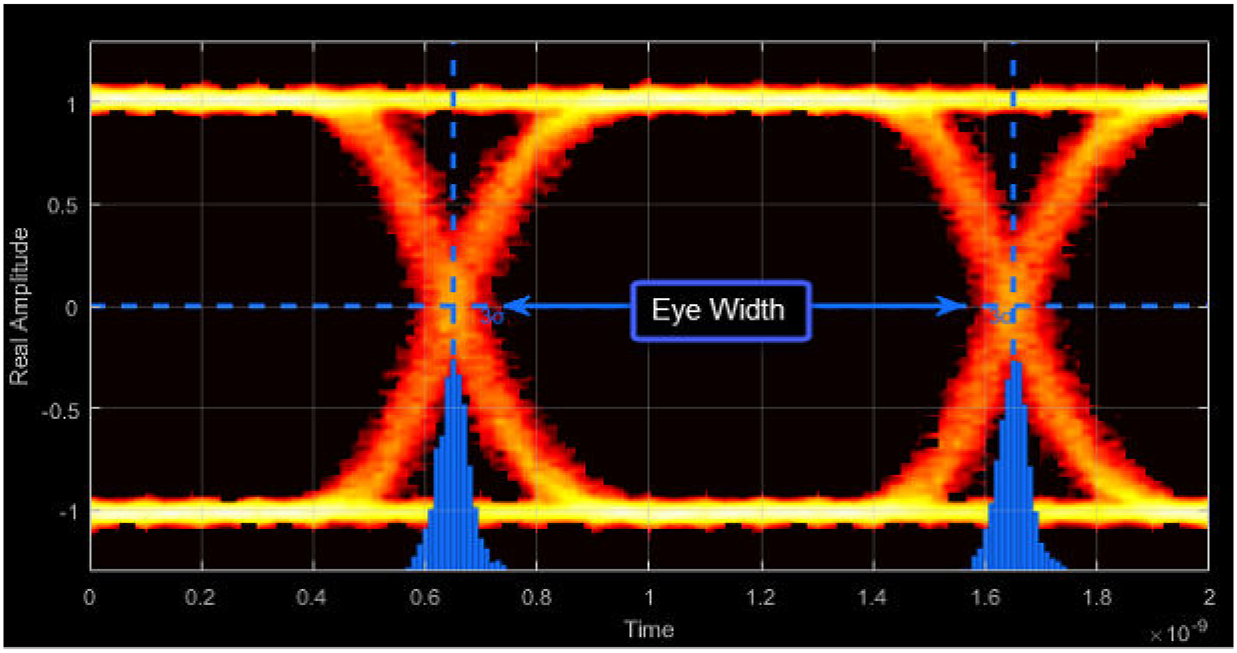
Eye Delay - Mean time between eye crossings

Eye delay is the midpoint between the two crossing times.



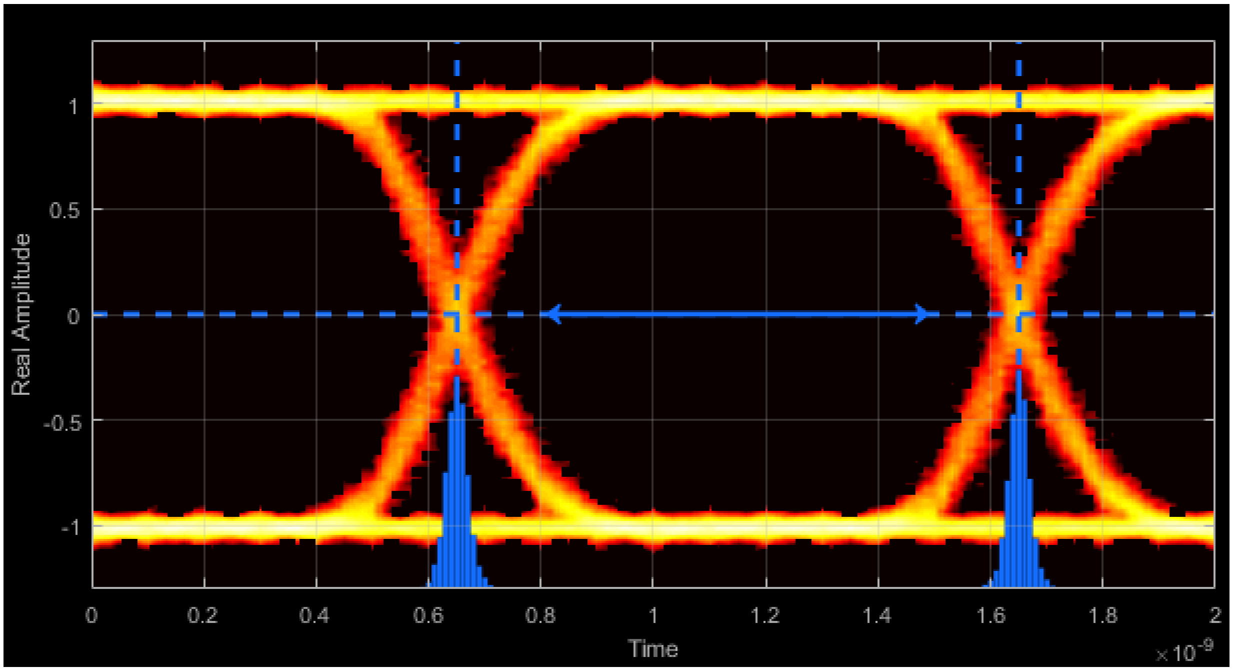
Eye Width - Statistical minimum time between eye crossings

Eye width is the horizontal distance between μ + 3σ of the left crossing time and μ – 3σ of the right crossing time. μ is the mean of the jitter histogram, and σ is the standard deviation.



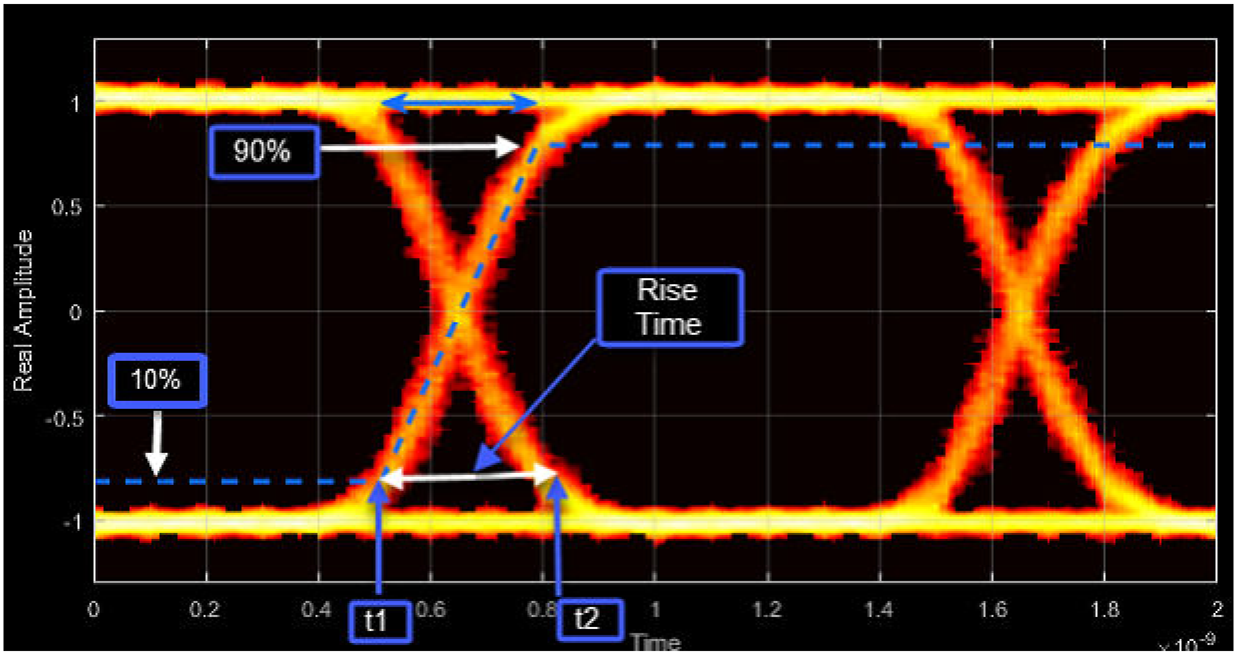
Horizontal Opening - Time between BER threshold points

The horizontal opening is the distance between the two points that correspond to the BERThreshold property. For example, for a 10^{-12} BER, these two points correspond to the 7σ distance from each crossing time.



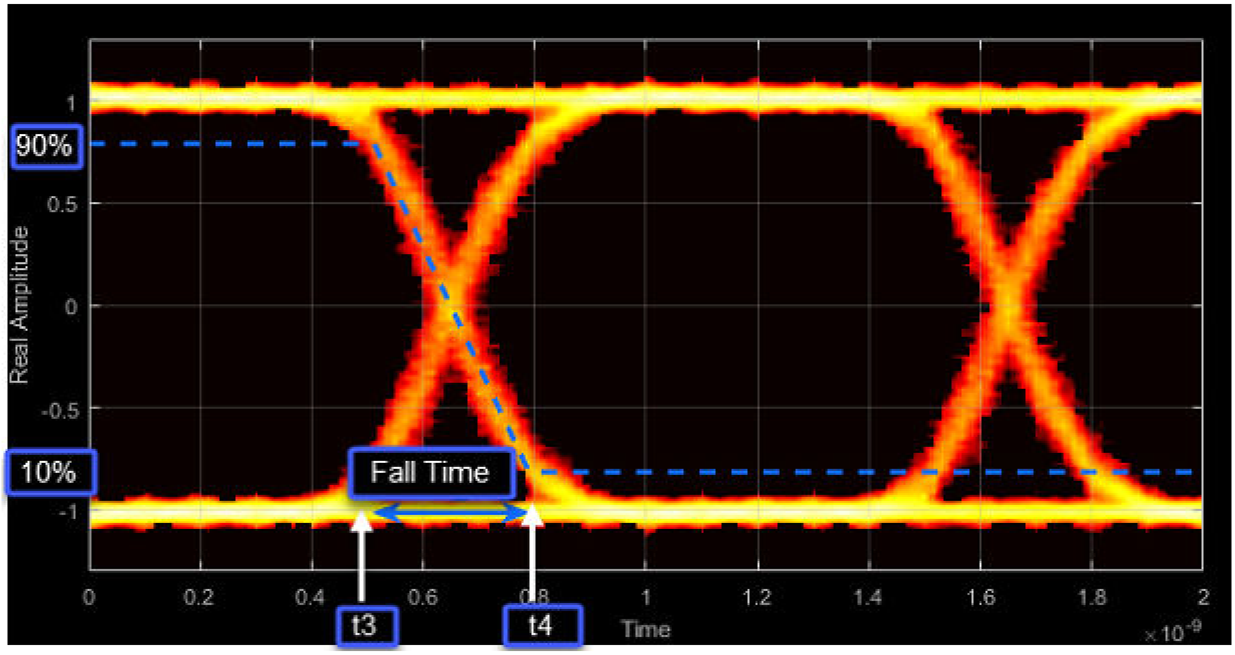
Rise Time - Time to transition from low to high

Rise time is the mean time between the low and high rise/fall thresholds defined in the eye diagram. The default thresholds are 10% and 90% of the eye amplitude.



Fall Time - Time to transition from high to low

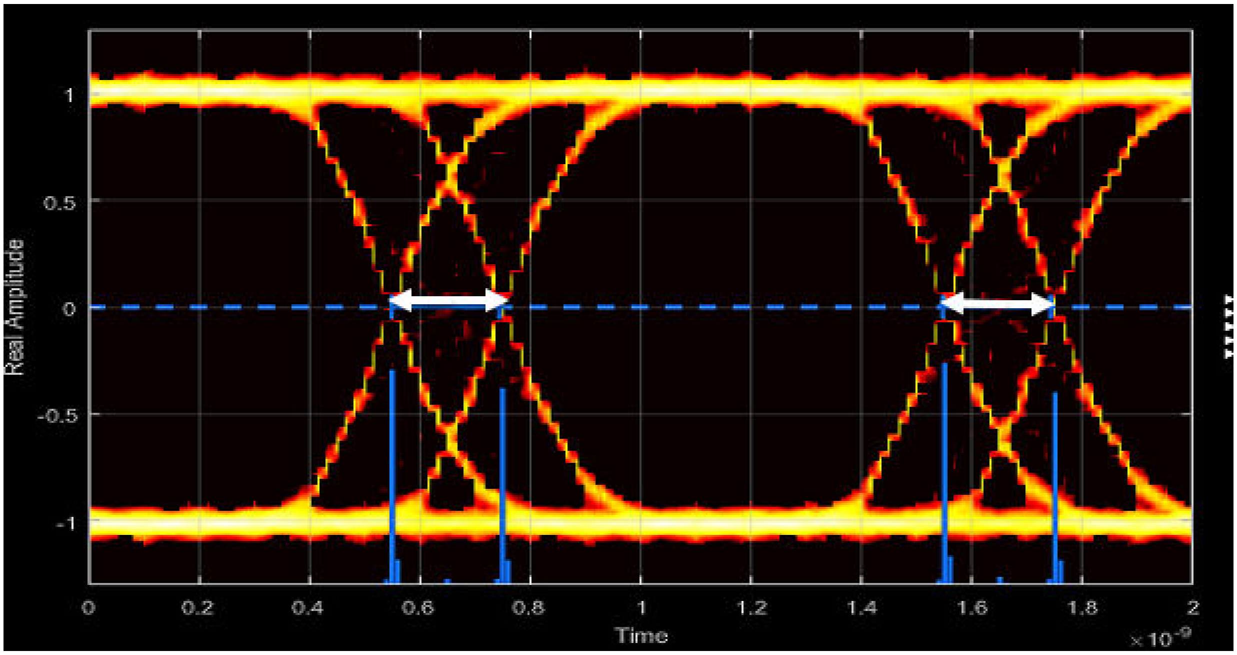
Fall time is the mean time between the high and low rise/fall thresholds defined in the eye diagram. The default thresholds are 10% and 90% of the eye amplitude.



Deterministic Jitter - Deterministic deviation from ideal signal timing

Jitter is the deviation of a signal's timing event from its intended (ideal) occurrence in time [2]. Jitter can be represented with a dual-Dirac model. A dual-Dirac model assumes that the jitter has two components: deterministic jitter (DJ) and random jitter (RJ).

DJ is the distance between the two peaks of the dual-Dirac histograms. The probability density function (PDF) of DJ is composed of two delta functions.



Random Jitter - Random deviation from ideal signal timing

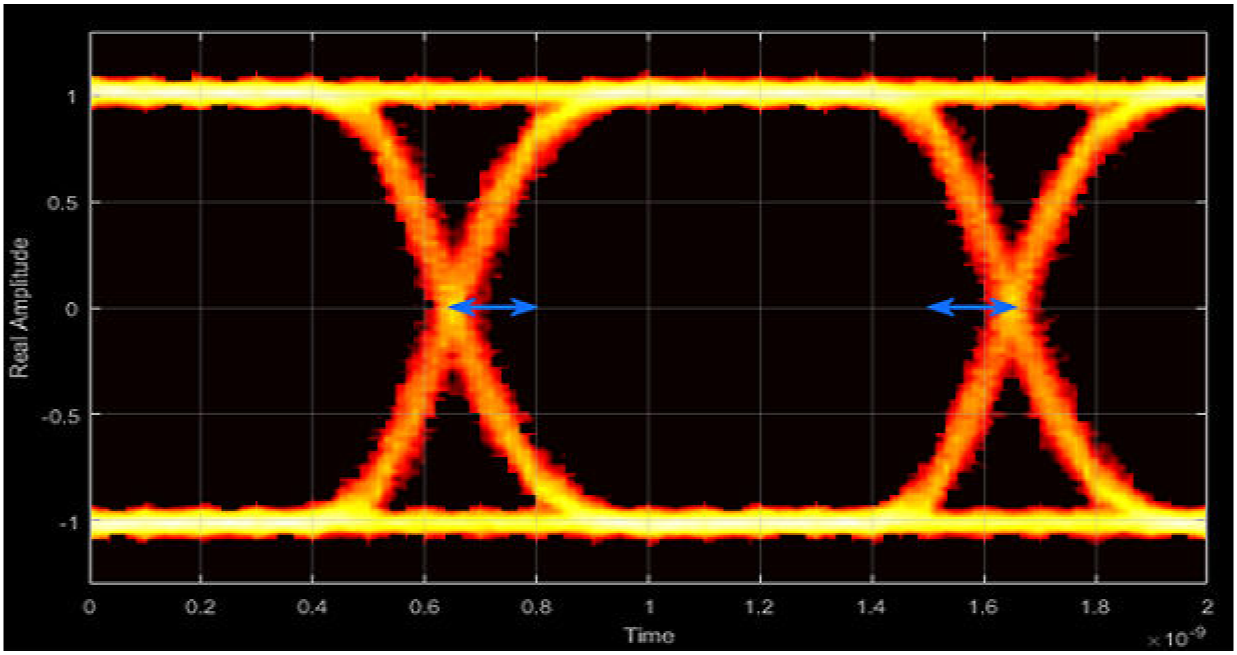
RJ is the Gaussian unbounded jitter component. The random component of jitter is modeled as a zero-mean Gaussian random variable with a specified standard-deviation of σ. The RJ is computed as:

$$\mathrm{RJ} = (Q_L + Q_R)\sigma\,,$$

where

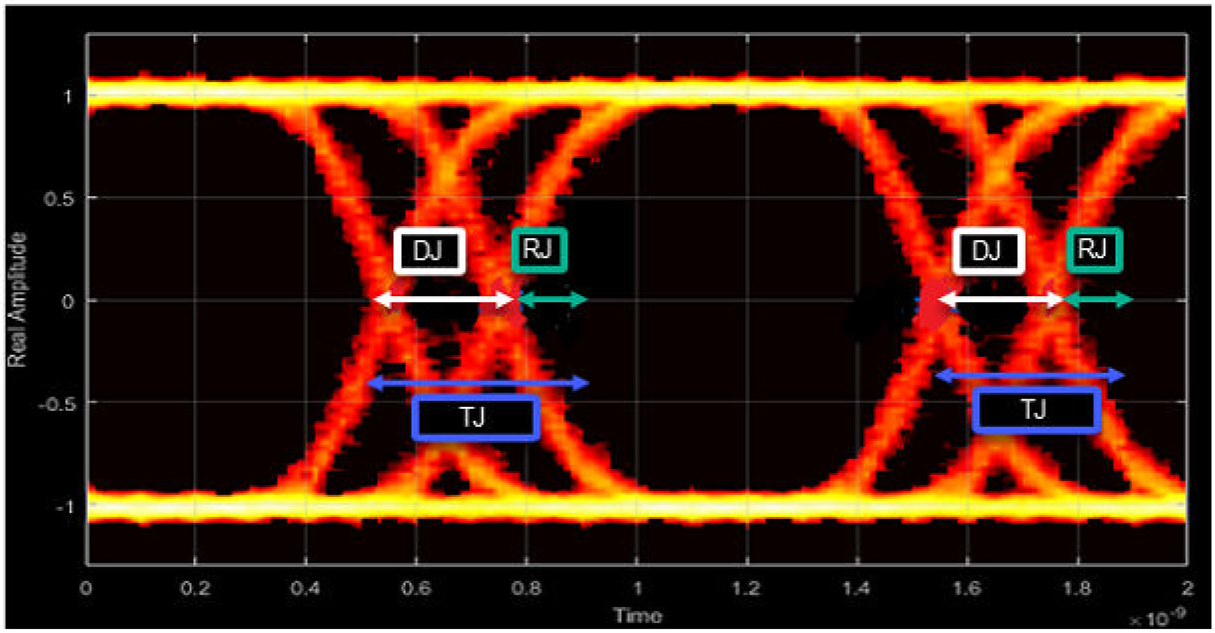
$$Q = \sqrt{2}\mathrm{erfc}^{-1}\left(2\frac{BER}{\rho}\right)\,.$$

BER is the specified BER threshold. ρ is the amplitude of the left and right Dirac function, which is determined from the bin counts of the jitter histograms.

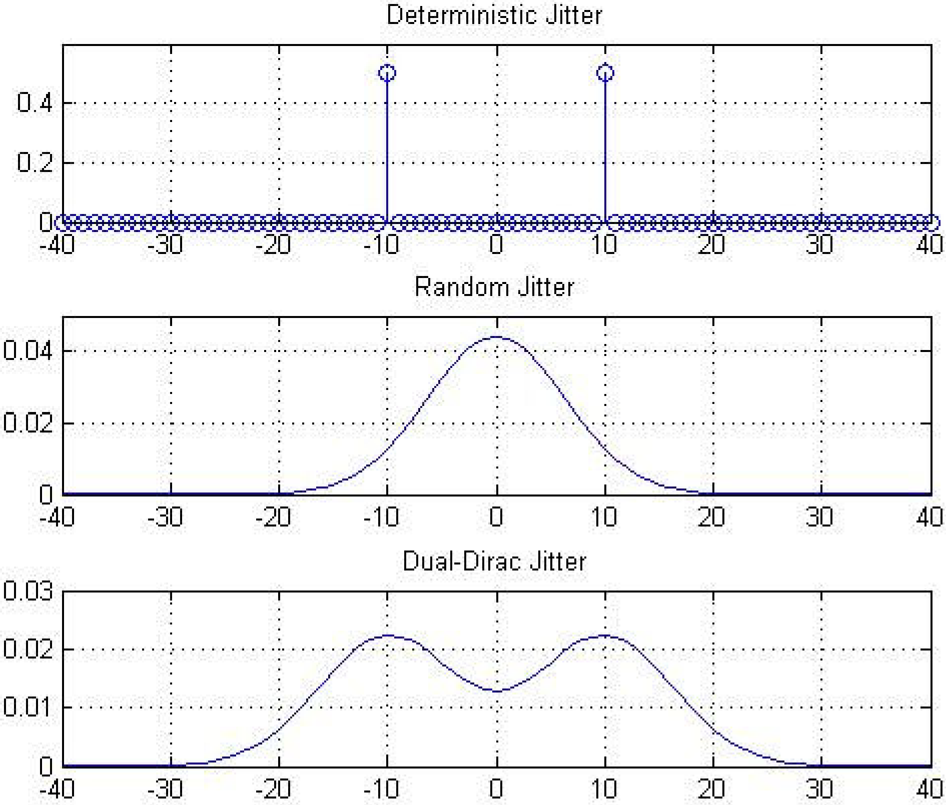


Total Jitter - Deviation from ideal signal timing

Total jitter (TJ) is the sum of the deterministic and random jitter, such that TJ = DJ + RJ.

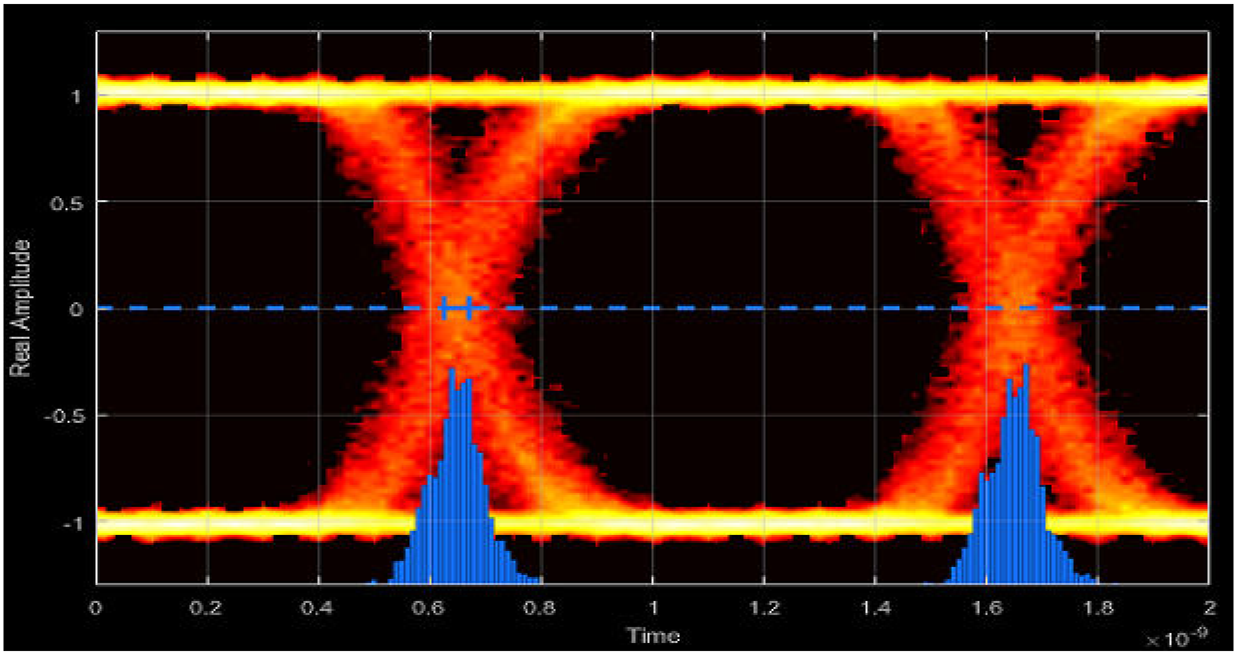


The total jitter PDF is the convolution of the DJ PDF and the RJ PDF.



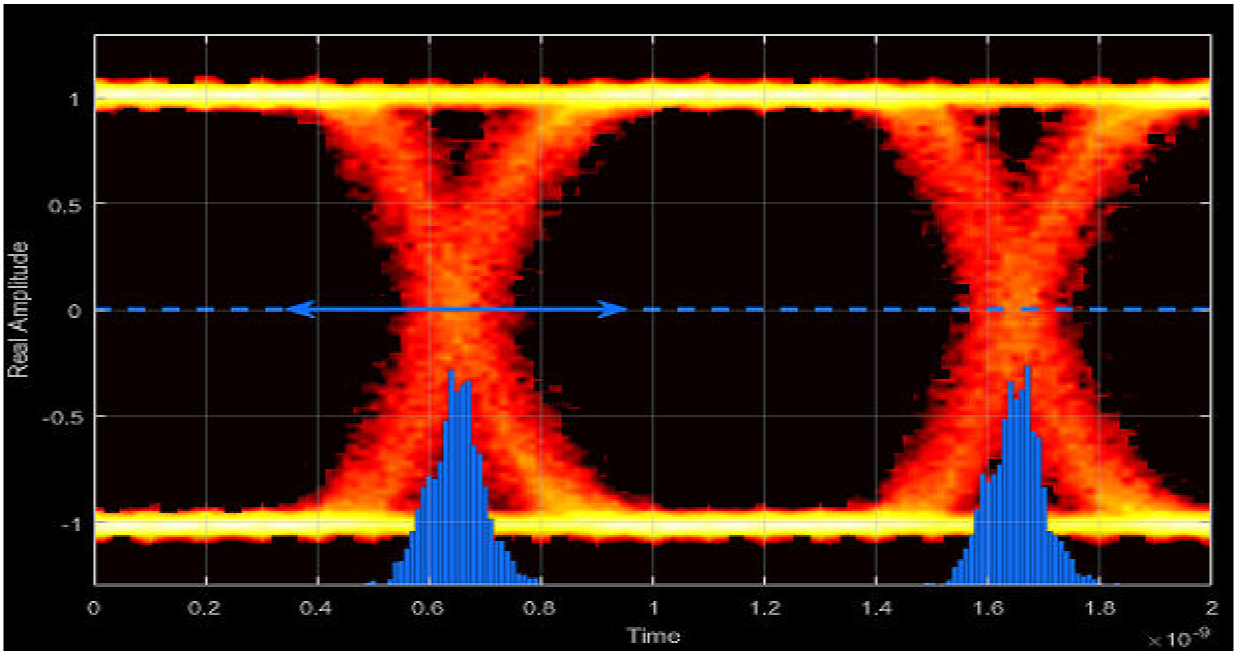
RMS Jitter - Standard deviation of jitter

RMS jitter is the standard deviation of the jitter calculated in the horizontal (jitter) histogram at the decision boundary.



Peak-to-Peak Jitter - Distance between extreme data points of histogram

Peak-to-peak jitter is the maximum horizontal distance between the left and right nonzero values in the horizontal histogram of each crossing time.



Compatibility Considerations

`comm.EyeDiagram` will be removed in a future release.
Not recommended starting in R2020b

comm.EyeDiagram will be removed in a future release. To display the eye diagram of a signal, use the `eyediagram` function instead.

horizontalBathtub

Package: comm

Horizontal bathtub curve

Syntax

```
s = horizontalBathtub(ed)
```

Description

`s = horizontalBathtub(ed)` returns a structure containing information of horizontalBathtub curve for the System object.

Note This method is available when both of these conditions apply:

- `EnableMeasurements` is `true`
- `ShowBathtub` is `'Horizontal'` or `'Both'`

Examples

Horizontal and Vertical Bathtub Curve Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Generate and plot the horizontal and vertical bathtub curves.

Specify the sample rate, the samples per symbol, and the number of traces parameters.

```
fs = 1000;
sps = 200;
numTraces = 1000;
```

Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps, ...
    'SampleOffset',sps/2,'DisplayMode','2D color histogram', ...
    'ColorScale','Logarithmic','EnableMeasurements',true, ...
    'ShowBathtub','Both','YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

```
src = commsrc.pattern('SamplesPerSymbol',sps, ...
    'RiseTime',3e-3,'FallTime', 3e-3);
src.Jitter = commsrc.combinedjitter('RandomJitter','on', ...
    'DiracJitter','on','DiracDelta',[-5e-04 5e-04],'RandomStd',2e-4);
```

Generate two symbols for each trace.

```
x = src.generate(numTraces*2);
```

Pass the signal through an AWGN channel with a fixed seed for repeatable results.

```
randStream = RandStream('mt19937ar','Seed',5489);
y = awgn(x,30,'measured',randStream);
```

Display the eye diagram.

```
ed(y)
```

    LowerThreshold
```

Input Arguments

ed — Eye Diagram System object
System object

Eye Diagram System object, where you get the bathtub curve information from.

Output Arguments

s — Structure containing information
struct

Structure containing information about the horizontal bathtub curve.

BER — Bit error rate values
scalar

Bit error rate values, mapped on the Y-axis of the horizontalBathtub plot against the corresponding `LeftThreshold` and `RightThreshold` values on the x-axis, specified as a scalar.

Data Types: `double`

`LeftThreshold` — Left threshold values
scalar

Left threshold values, mapped on the x-axis in the plot against corresponding BER values on the x-axis.

Data Types: `double`

`RightThreshold` — Right threshold values
scalar

Right threshold values, mapped on the x-axis in the plot against corresponding BER values on the x-axis.

Data Types: `double`

jitterHistogram

Package: comm

Jitter histogram

Syntax

```
jh = jitterHistogram(ed)
```

Description

`jh = jitterHistogram(ed)` returns the bin counts for decision boundary crossings set in eye diagram System object.

Note This method is available when `EnableMeasurements` is `true`.

Examples

Jitter and Noise Histogram Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Plot the jitter and noise histograms.

Specify the sample rate, the samples per symbol, and the number of traces parameters.

```
fs = 1000;
sps = 200;
numTraces = 1000;
```

Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps, ...
    'SampleOffset',sps/2, ...
    'DisplayMode','2D color histogram','ColorScale','Logarithmic', ...
    'EnableMeasurements',true,'YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

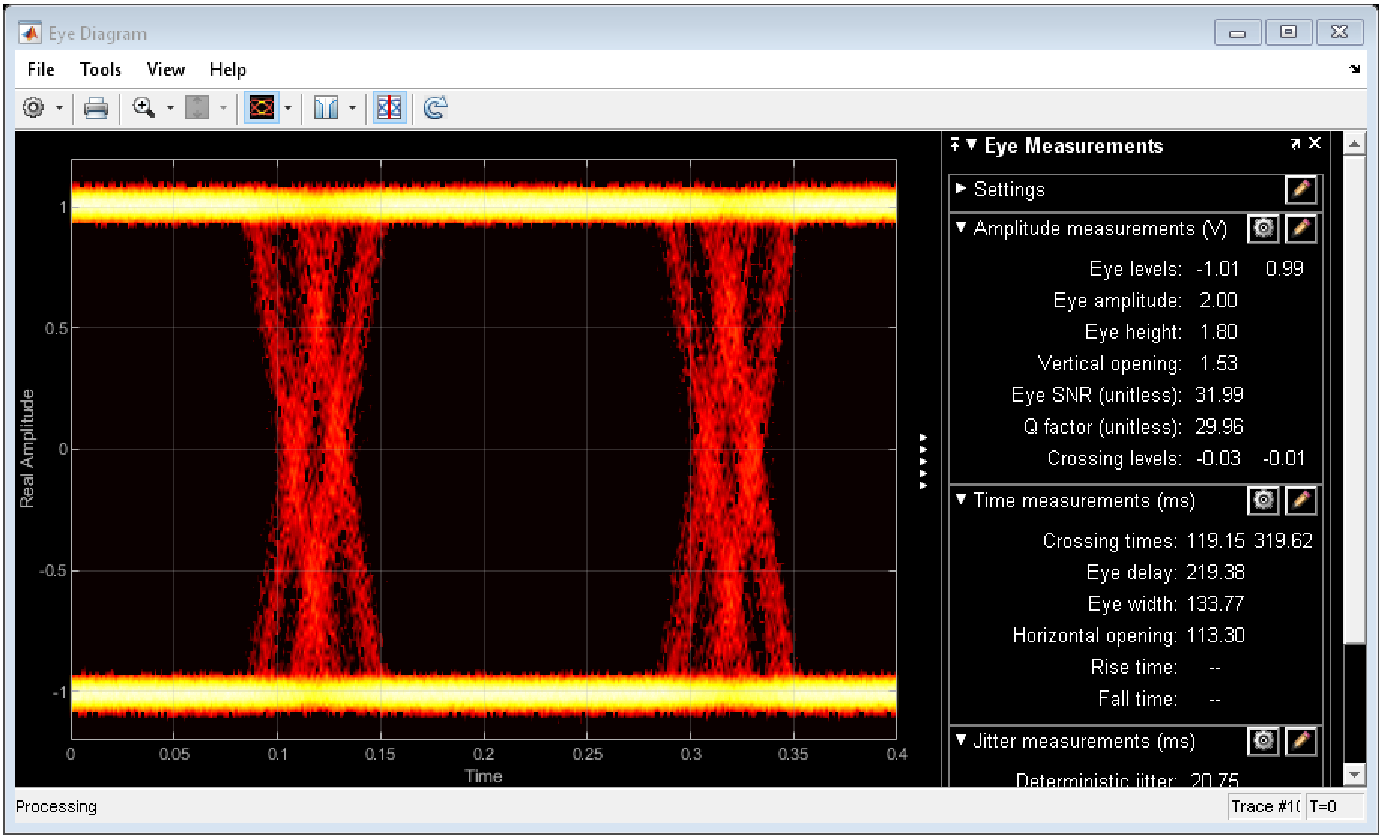
```
src = commsrc.pattern('SamplesPerSymbol',sps, ...
    'RiseTime',3e-3,'FallTime', 3e-3);
src.Jitter = commsrc.combinedjitter('RandomJitter','on', ...
    'DiracJitter','on','DiracDelta',[-10e-04 10e-04],'RandomStd',5e-4);
```

Generate two symbols for each trace.

```
x = src.generate(numTraces*2);
```

Pass the signal through an AWGN channel with a fixed seed for repeatable results.

```
randStream = RandStream('mt19937ar','Seed',5489);
y = awgn(x,30,'measured',randStream);
ed(y)
```



Amplitude measurements (V)

Eye levels: -1.01 0.99
Eye amplitude: 2.00
Eye height: 1.80
Vertical opening: 1.53
Eye SNR (unitless): 31.99
Q factor (unitless): 29.96
Crossing levels: -0.03 -0.01

Time measurements (ms)

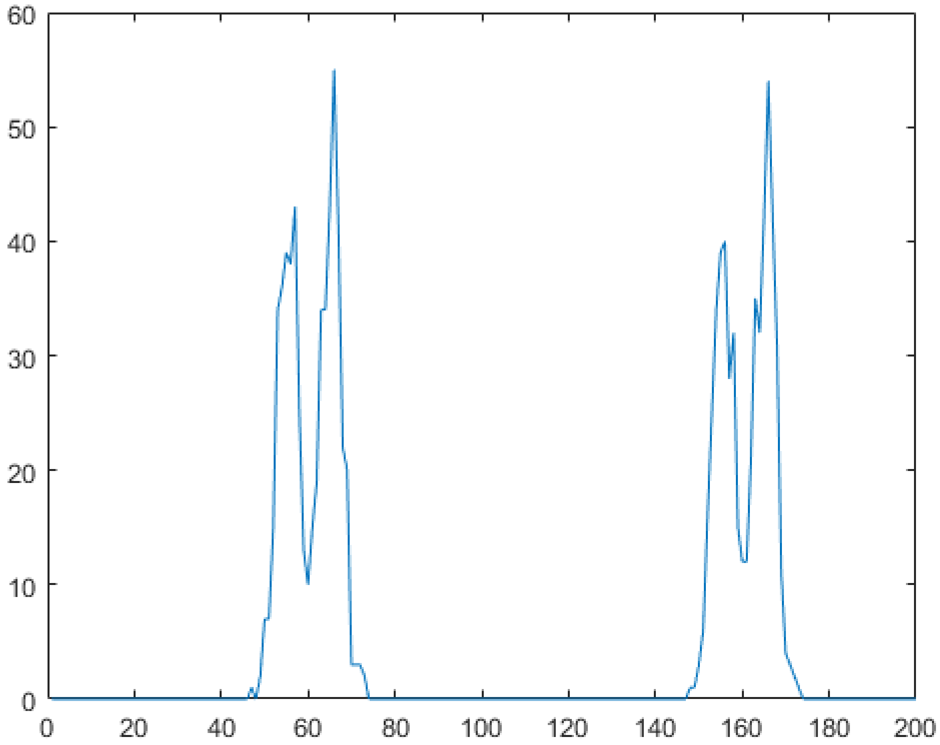
Crossing times: 119.15 319.62
Eye delay: 219.38
Eye width: 133.77
Horizontal opening: 113.30
Rise time: --
Fall time: --

Jitter measurements (ms)

Deterministic jitter: 20.75

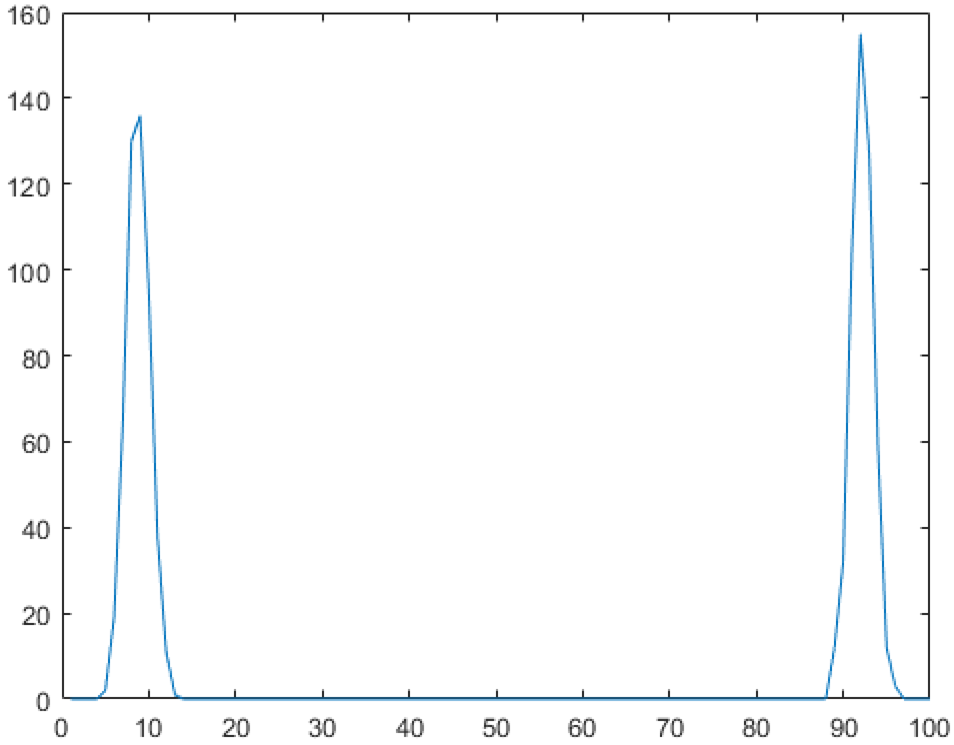
Calculate the jitter histogram count for each bin by using the `jitterHistogram` method. Plot the histogram.

```
jbins = jitterHistogram(ed);
plot(jbins)
```



Calculate the noise histogram count for each bin by using the `noiseHistogram` method. Plot the histogram.

```
nbins = noiseHistogram(ed);
plot(nbins)
```



Input Arguments

ed — Eye Diagram System object
System object

Eye Diagram System object, where the count for decision boundary crossings is set.

Output Arguments

`jh` — Jitter histogram
nonnegative integer

Jitter histogram, which represent the counts for decision boundary crossings, specified as a nonnegative integer.

Data Types: `double`

Introduced in R2016b

measurements

Package: comm

Measure eye diagram parameters

Syntax

```
m = measurements(ed)
```

Description

`m = measurements(ed)` returns the parameter measurements calculated by eye diagram System object.

Note This method is available when `EnableMeasurements` is `true`.

Examples

Rise and Fall Time of NRZ Signal

Create a combined jitter object having random jitter with a 2e-4 standard deviation.

```
jtr = commsrc.combinedjitter('RandomJitter','on','RandomStd',2e-4);
```

Generate an NRZ signal having random jitter and 3 ms rise and fall times.

```
genNRZ = commsrc.pattern('Jitter',jtr,'RiseTime',3e-3,'FallTime',3e-3);
x = generate(genNRZ,2000);
```

Pass the signal through an AWGN channel with fixed seed for repeatable results.

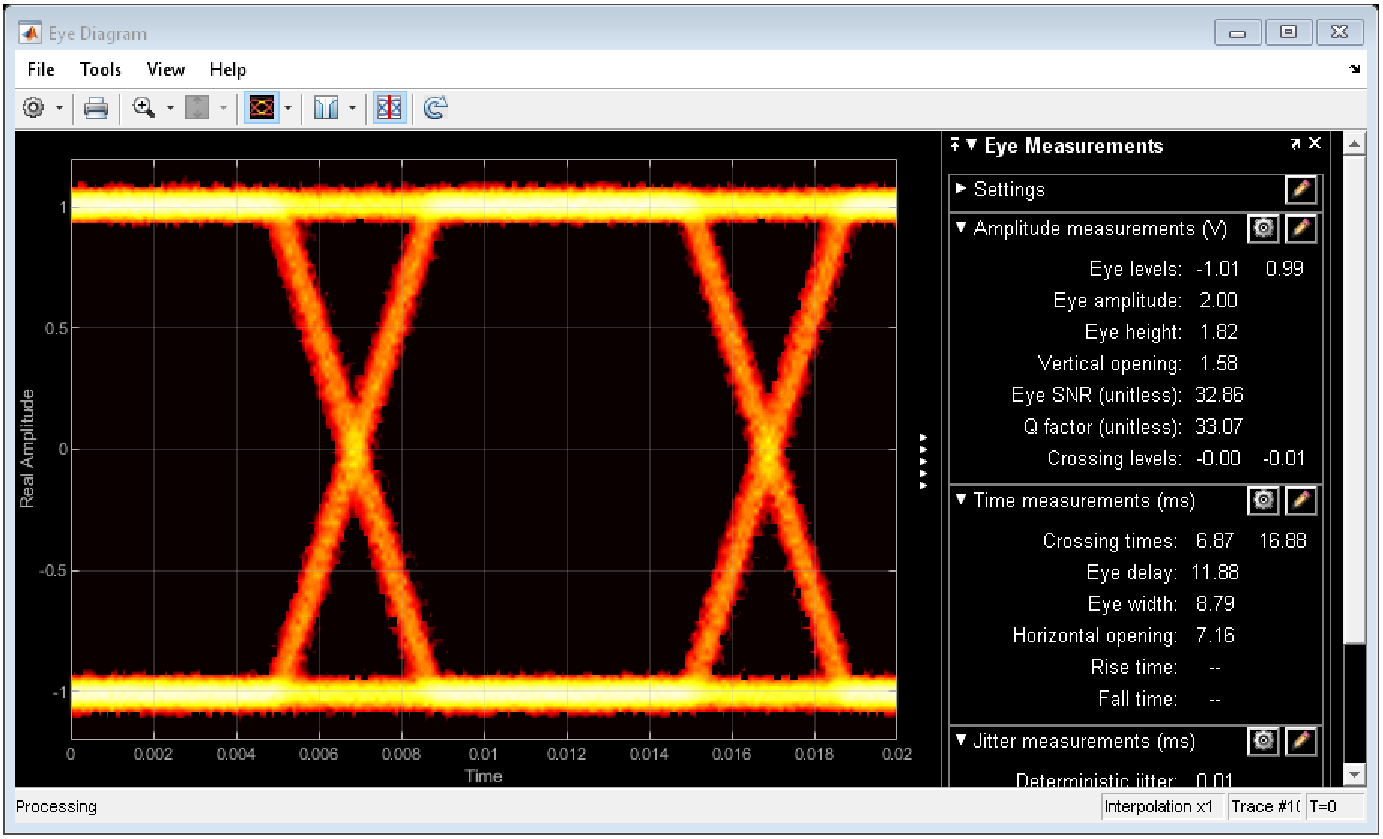
```
randStream = RandStream('mt19937ar','Seed',5489);
y = awgn(x,30,'measured',randStream);
```

Create an eye diagram object. Enable the measurements.

```
ed = comm.EyeDiagram('SamplesPerSymbol',genNRZ.SamplesPerSymbol, ...
    'SampleRate',genNRZ.SamplingFrequency, ...
    'SampleOffset',genNRZ.SamplesPerSymbol/2, ...
    'EnableMeasurements',true,'DisplayMode','2D color histogram', ...
    'OversamplingMethod','Input interpolation', ...
    'ColorScale','Logarithmic','YLimits',[-1.2 1.2]);
```

To compute the rise and fall times, determine the rise and fall thresholds from the eye level and eye amplitude measurements. Plot the eye diagram to calculate these parameters.

```
ed(y)
```



Eye Measurements

Settings

Amplitude measurements (V)

```
Eye levels:  -1.01    0.99
Eye amplitude:  2.00
Eye height:  1.82
Vertical opening:  1.58
Eye SNR (unitless):  32.86
Q factor (unitless):  33.07
Crossing levels:  -0.00    -0.01
```

Time measurements (ms)

```
Crossing times:  6.87    16.88
Eye delay:  11.88
Eye width:  8.79
Horizontal opening:  7.16
Rise time:  --
Fall time:  --
```

Jitter measurements (ms)

```
Deterministic jitter:  0.01
```

Processing | Interpolation x1 | Trace #1(| T=0

Pass the signal through the eye diagram object again to measure the rise and fall times.

```
ed(y)
hide(ed)
```

Display the data by using the measurements method.

```
eyestats = measurements(ed);
riseTime = eyestats.RiseTime
fallTime = eyestats.FallTime
```

```
riseTime =

    0.0030

fallTime =

    0.0030
```

The measured values match the 3 ms specification.

Input Arguments

ed — Eye Diagram System object

System object

Eye Diagram System object, where the parameter measurements are calculated.

Output Arguments

`m` — Eye Diagram parameters measurement

struct

Eye Diagram parameters measurement, returned as a structure containing all 18 parameters mentioned in “Measurements” on page 3-570, along with their values.

Data Types: `double`

See Also

noiseHistogram

Package: comm

Noise histogram

Syntax

```
nh = noiseHistogram(ed)
```

Description

nh = noiseHistogram(ed) returns the bin counts for the signal values at the vertical opening (eye delay) as set in eye diagram System object.

Note This method is available when both of these conditions apply:

- EnableMeasurements is true
- DisplayMode is '2D color histogram'

Examples

Jitter and Noise Histogram Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Plot the jitter and noise histograms.

Specify the sample rate, the samples per symbol, and the number of traces parameters.

```
fs = 1000;
sps = 200;
numTraces = 1000;
```

Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps, ...
    'SampleOffset',sps/2, ...
    'DisplayMode','2D color histogram','ColorScale','Logarithmic', ...
    'EnableMeasurements',true,'YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

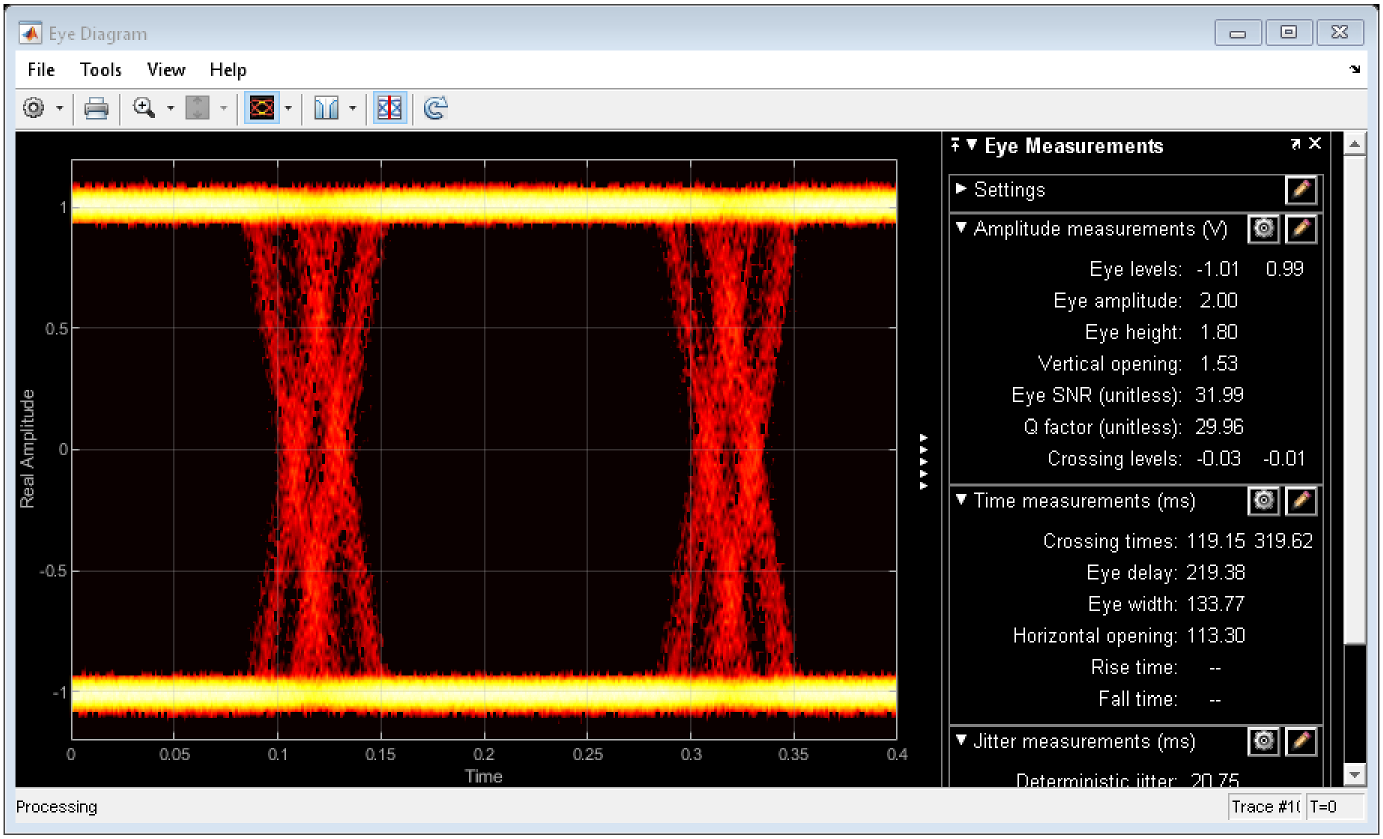
```
src = commsrc.pattern('SamplesPerSymbol',sps, ...
    'RiseTime',3e-3,'FallTime', 3e-3);
src.Jitter = commsrc.combinedjitter('RandomJitter','on', ...
    'DiracJitter','on','DiracDelta',[-10e-04 10e-04],'RandomStd',5e-4);
```

Generate two symbols for each trace.

```
x = src.generate(numTraces*2);
```

Pass the signal through an AWGN channel with a fixed seed for repeatable results.

```
randStream = RandStream('mt19937ar','Seed',5489);
y = awgn(x,30,'measured',randStream);
ed(y)
```



Amplitude measurements (V)

```
Eye levels:  -1.01   0.99
Eye amplitude:  2.00
Eye height:  1.80

```

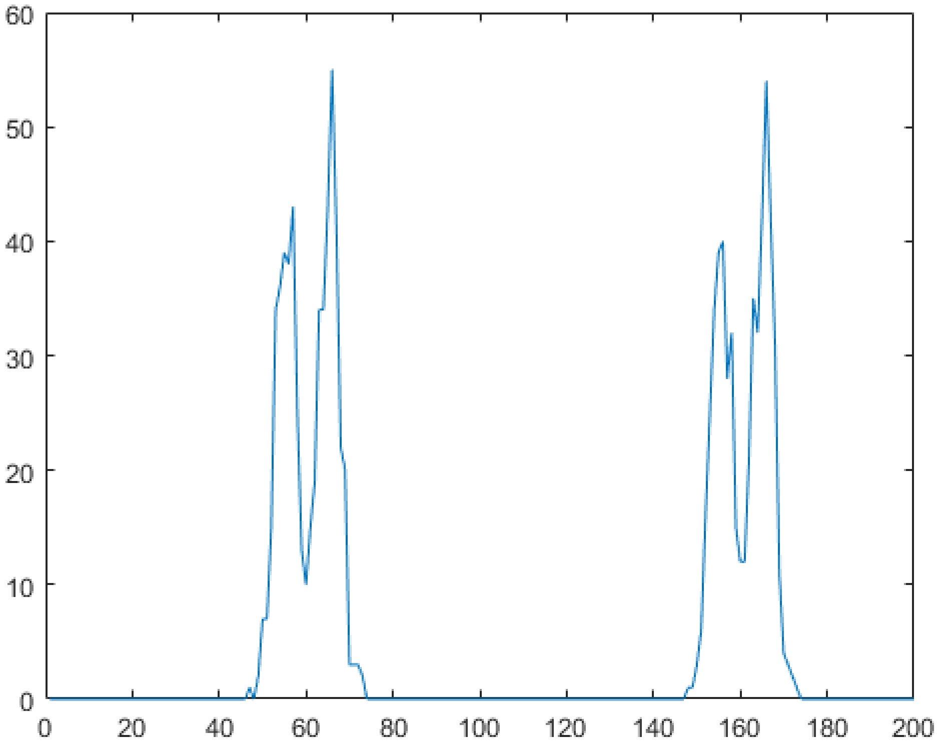
Jitter measurements (ms)

```
Deterministic jitter: 20.75
```

Processing   Trace #1(T=0

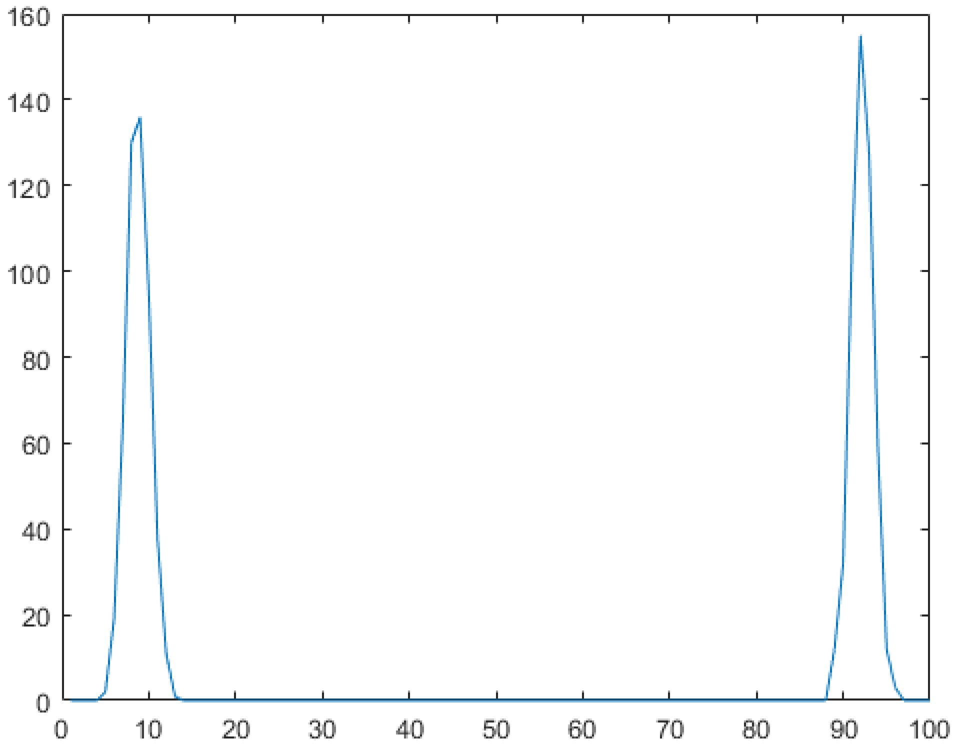
Calculate the jitter histogram count for each bin by using the `jitterHistogram` method. Plot the histogram.

```
jbins = jitterHistogram(ed);
plot(jbins)
```



Calculate the noise histogram count for each bin by using the `noiseHistogram` method. Plot the histogram.

```
nbins = noiseHistogram(ed);
plot(nbins)
```



Input Arguments

ed — Eye Diagram System object

System object

Eye Diagram System object, where the counts for signal values at the eye delay is set.

Output Arguments

nh — Noise histogram

nonnegative integer

Noise histogram, which represent the counts for the signal values at the vertical opening (eye delay), specified as a nonnegative integer.

Data Types: `double`

verticalBathtub

Package: comm

Vertical bathtub curve

Syntax

```
s = verticalBathtub(ed)
```

Description

`s = verticalBathtub(ed)` returns a structure containing information of verticalBathtub curve for the System object.

Note This method is available when both of these conditions apply:

- `EnableMeasurements` is `true`
- `ShowBathtub` is `'Vertical'` or `'Both'`

Examples

Horizontal and Vertical Bathtub Curve Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Generate and plot the horizontal and vertical bathtub curves.

Specify the sample rate, the samples per symbol, and the number of traces parameters.

```
fs = 1000;
sps = 200;
numTraces = 1000;
```

Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps, ...
    'SampleOffset',sps/2,'DisplayMode','2D color histogram', ...
    'ColorScale','Logarithmic','EnableMeasurements',true, ...
    'ShowBathtub','Both','YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

```
src = commsrc.pattern('SamplesPerSymbol',sps, ...
    'RiseTime',3e-3,'FallTime', 3e-3);
src.Jitter = commsrc.combinedjitter('RandomJitter','on', ...
    'DiracJitter','on','DiracDelta',[-5e-04 5e-04],'RandomStd',2e-4);
```

Generate two symbols for each trace.

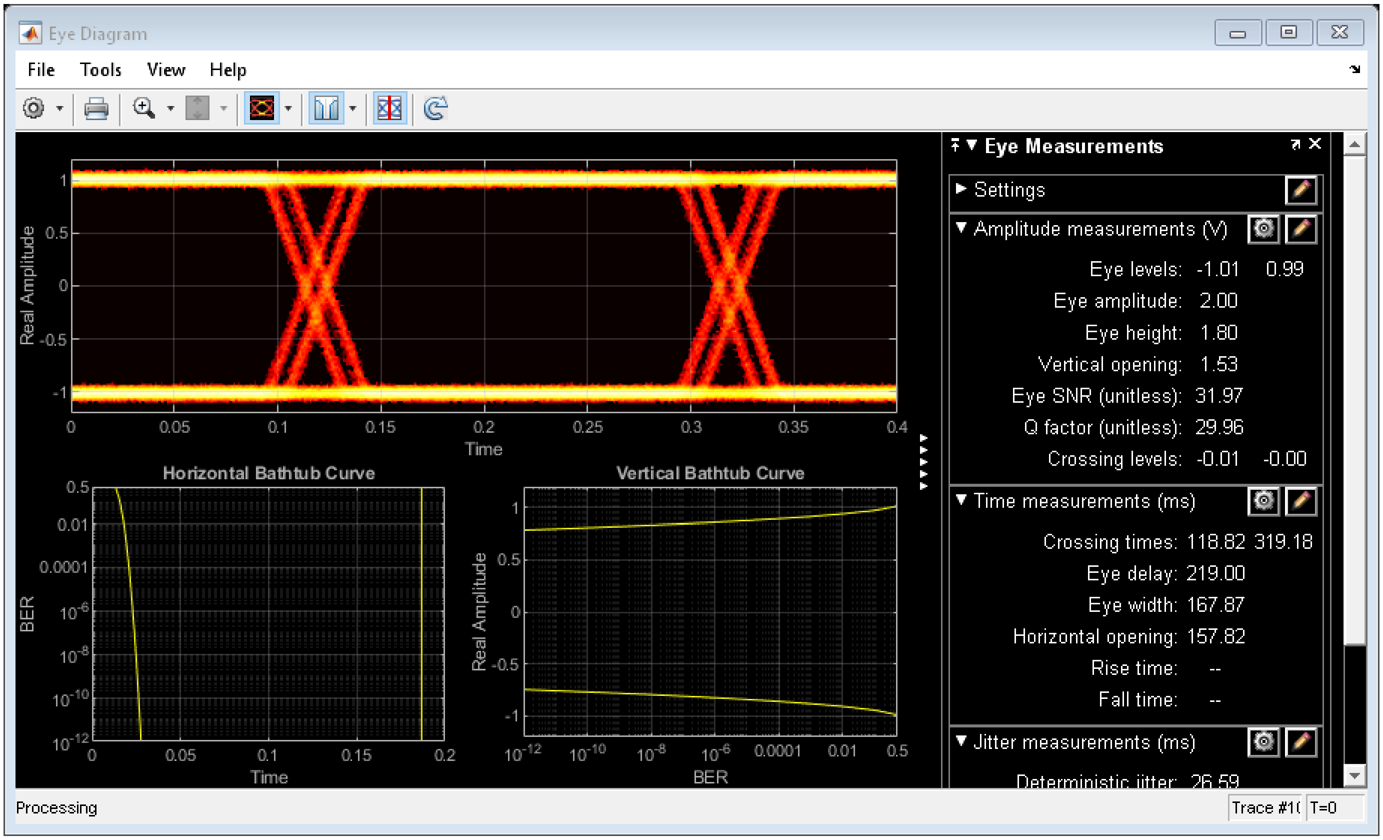
```
x = src.generate(numTraces*2);
```

Pass the signal through an AWGN channel with a fixed seed for repeatable results.

```
randStream = RandStream('mt19937ar','Seed',5489);
y = awgn(x,30,'measured',randStream);
```

Display the eye diagram.

```
ed(y)
```



Eye levels: -1.01 0.99
Eye amplitude: 2.00
Eye height: 1.80

Crossing times: 118.82 319.18
Eye delay: 219.00
Eye width: 167.87
Horizontal opening: 157.82
Rise time: --
Fall time: --

Deterministic jitter: 26.59

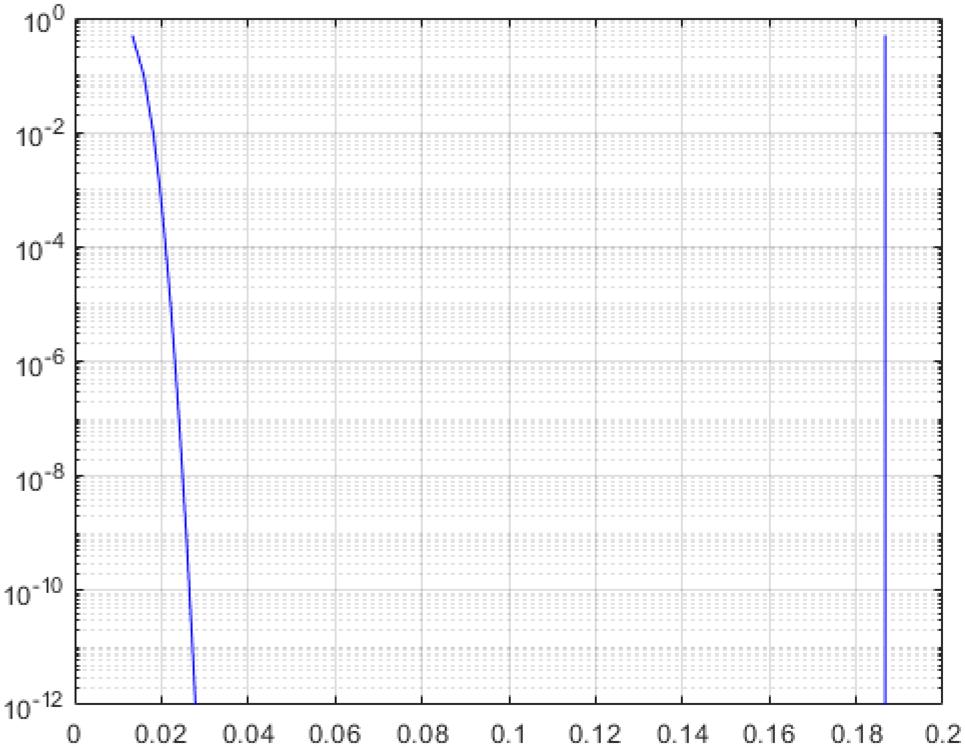
Generate the horizontal bathtub data for the eye diagram. Plot the curve.

```
hb = horizontalBathtub(ed)
semilogy([hb.LeftThreshold],[hb.BER],'b', ...
    [hb.RightThreshold],[hb.BER],'b')
grid
```

```
hb = 

  1x13 struct array with fields:

    BER
    LeftThreshold
    RightThreshold
```



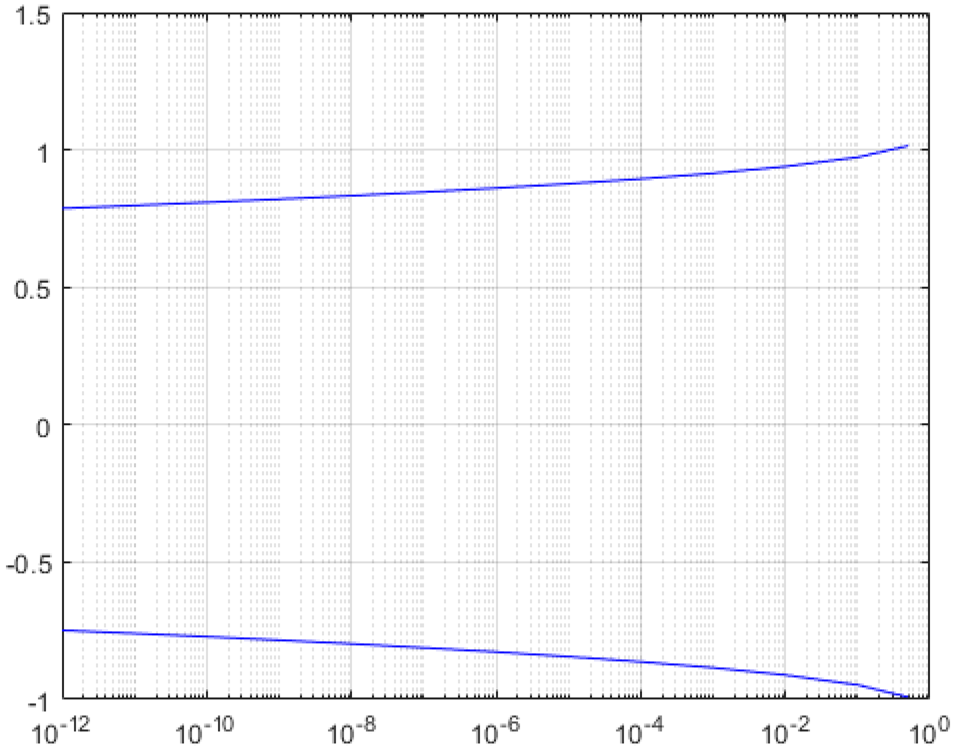
Generate the vertical bathtub data for the eye diagram. Plot the curve.

```
vb = verticalBathtub(ed)
semilogx([vb.BER],[vb.LowerThreshold],'b', ...
    [vb.BER],[vb.UpperThreshold],'b')
grid
```

```
vb = 

  1x13 struct array with fields:

    BER
    UpperThreshold
    LowerThreshold
```



Input Arguments

ed — Eye Diagram System object
System object

Eye Diagram System object, where you get the bathtub curve information from.

Output Arguments

s — Structure containing information
struct

Structure containing information about the vertical bathtub curve.

BER — Bit error rate values
scalar

Bit error rate values, mapped on the Y-axis of the verticalBathtub plot against the corresponding `UpperThreshold` and `LowerThreshold` values on the x-axis, specified as a scalar.

Data Types: `double`

`UpperThreshold` — Upper threshold value
scalar

Upper threshold value, mapped on the x-axis in the plot against its corresponding BER value on the x-axis.

Data Types: `double`

`LowerThreshold` — Lower threshold value

scalar

Lower threshold value, mapped on the x-axis in the plot against its corresponding BER value on the x-axis.

Data Types: `double`

comm.FMBroadcastDemodulator

Package: comm

Demodulate broadcast FM signal

Description

The comm.FMBroadcastDemodulator System object demodulates a complex baseband FM signal and filters the signal with a de-emphasis filter to produce an audio signal. If the Stereo property is set to true, the object performs stereo decoding. If the RBDS property is set to true, the object also demodulates the RDS/RBDS waveform. For more details, see "Algorithms" on page 3-609.

To demodulate a complex baseband FM signal:

1. Define and set up the comm.FMBroadcastDemodulator object. See "Construction" on page 3-605.
2. Call step to demodulate the complex baseband FM signal according to the properties of comm.FMBroadcastDemodulator.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

fmbDemod = comm.FMBroadcastDemodulator creates a demodulator System object, fmbDemod, that frequency demodulates an input signal.

fmbDemod = comm.FMBroadcastDemodulator(Name,Value) creates an FM demodulator object, fmbDemod, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

fmbDemod = comm.FMBroadcastDemodulator(MOD) creates an FM demodulator object, fmbDemod, whose properties are determined by the corresponding FM modulator object, MOD.

Properties

SampleRate

Input signal sample rate (Hz)

Specify the sample rate of the input signal in Hz as a positive real scalar. The default value is 240e3. This property is nontunable.

FrequencyDeviation

Peak deviation of the output signal frequency (Hz)

Specify the frequency deviation of the FM demodulator in Hz as a positive real scalar. The default value is 75e3. System bandwidth is equal to twice the sum of the frequency deviation and the message bandwidth. FM broadcast standards specify a value of 75 kHz in the United States and 50 kHz in Europe. This property is nontunable.

FilterTimeConstant

Time constant of the de-emphasis filter (s)

Specify the de-emphasis lowpass filter time constant as a positive real scalar. The default value is 7.5e-05. FM broadcast standards specify a value of 75 μs in the United States and 50 μs in Europe. This property is nontunable.

AudioSampleRate

Audio sample rate of the output signal (Hz)

Specify the output audio sample rate as a positive real scalar. The default value is 48000. This property is nontunable.

PlaySound

Flag to enable or disable audio playback

To playback the output signal on the default audio device, set this property to true. The default is false. This property is nontunable.

BufferSize

Buffer size of the audio device

Specify the size of the buffer (in samples) that the object uses to communicate with an audio device as a positive scalar integer. The default is 4096. This property is available only when PlaySound is true. This property is nontunable.

Stereo

Flag to enable or disable stereo audio

Set this property to true to demodulate a stereophonic audio signal. Set to false if the input signal is monophonic. The default is false. This property is nontunable.

RBDS

Flag to demodulate RDS/RBDS waveform

If RBDS is set to true, the second output of the step method is the baseband RDS/RBDS waveform. The default value is false. This property is nontunable.

RBDSSamplesPerSymbol

Oversampling factor of RDS/RBDS output

Specify the number of samples of the RDS/RBDS output as a positive integer. The RDS/RBDS sample rate is given by RBDSSamplesPerSymbol × 1187.5 Hz. According to the RDS/RBDS standard, the sample rate of each bit is 1187.5 Hz.

This property applies only when you set RBDS to true.

The default is 10.

RBDSCostasLoop

Option to recover phase of RDS/RBDS signal

Specify whether a Costas loop is used to recover the phase of the RDS/RBDS signal. Set this option to `true` for radio stations that do not lock the `57` kHz RDS/RBDS signal in phase with the third harmonic of the `19` kHz pilot tone.

This property applies only when you set `RBDS` to `true`.

The default value is `false`.

Methods

info	Filter information about FM broadcast demodulator
reset	Reset states of the FM broadcast demodulator object
step	Apply FM broadcast demodulation

Common to All System Objects	
`release`	Allow System object property value changes

Examples

FM Broadcast a Streaming Audio Signal

Modulate and demodulate a streaming audio signal with the FM broadcast modulator and demodulator objects. Play the audio signal using a default audio device.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Create an audio file reader System object™ and read the file `guitartune.wav`.

```
audio = dsp.AudioFileReader('guitartune.wav','SamplesPerFrame',4410);
```

Create FM broadcast modulator and demodulator objects. Set the `AudioSampleRate` property to match the sample rate of the input signal. Set the `SampleRate` property of the demodulator to match the specified sample rate of the modulator. Set the `PlaySound` property of the demodulator to `true` to enable audio playback.

```
fmbMod = comm.FMBroadcastModulator('AudioSampleRate',audio.SampleRate, ...
    'SampleRate',240e3);
fmbDemod = comm.FMBroadcastDemodulator( ...
    'AudioSampleRate',audio.SampleRate, ...
    'SampleRate',240e3,'PlaySound',true);
```

Read the audio data in frames of length 4410, apply FM broadcast modulation, demodulate the FM signal and playback the audio input.

```
while ~isDone(audio)
    audioData = audio();
    modData = fmbMod(audioData);
    demodData = fmbDemod(modData);
end
```

FM Modulate and Demodulate an RBDS Waveform

Generate a basic RBDS waveform, FM modulate it with an audio signal, and then demodulate it.

Note: This example runs only in R2017a or later.

Create a RBDS waveform with 19 groups per frame and 10 samples per symbol. The sample rate of the RBDS waveform is given by 1187.5 x 10. Set the audio sample rate to 1187.5 x 40.

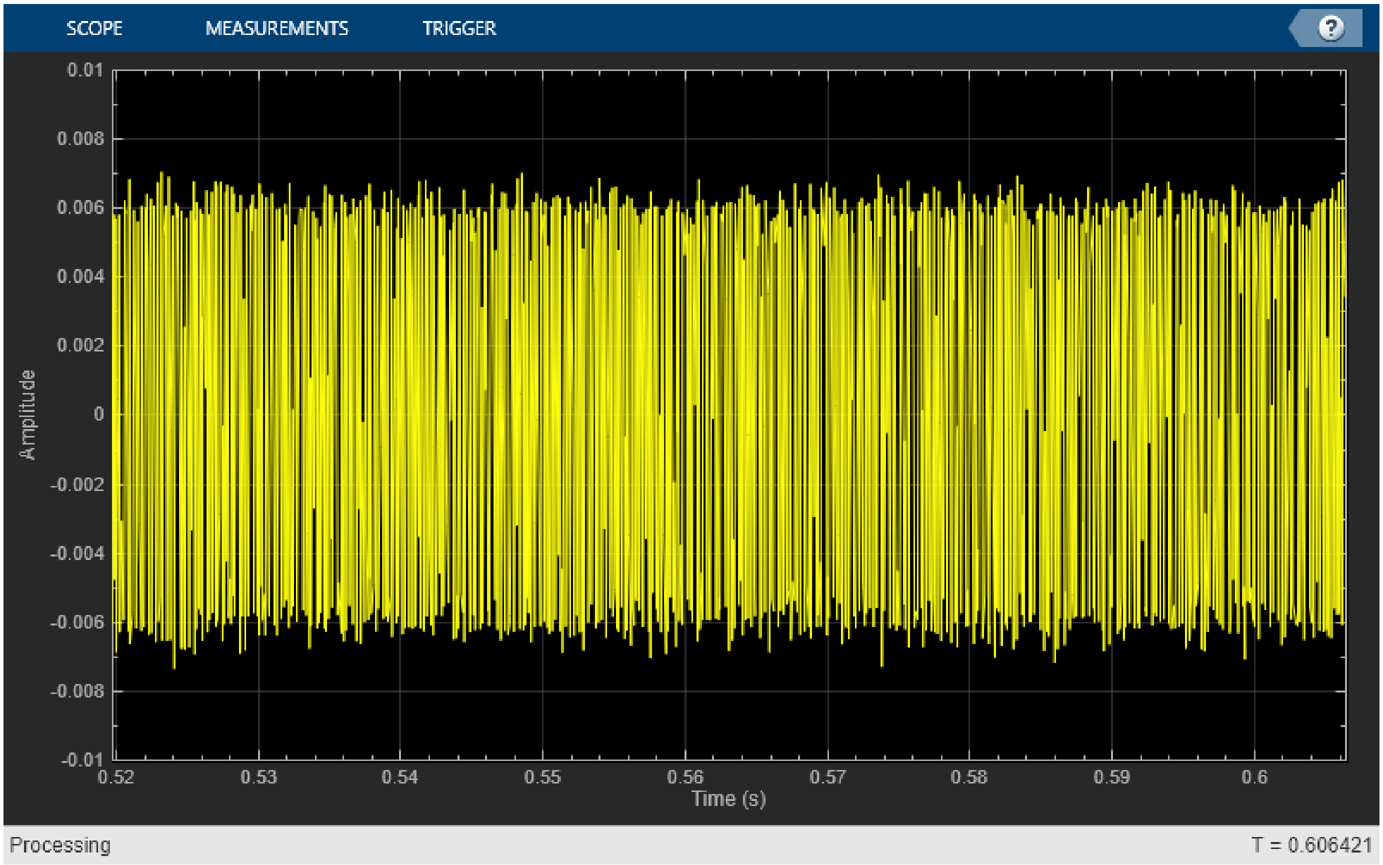
```
groupLen = 104;
sps = 10;
groupsPerFrame = 19;
rbdsFrameLen = groupLen*sps*groupsPerFrame;
afrRate = 40*1187.5;
rbdsRate = 1187.5*sps;
outRate = 4*57000;

afr = dsp.AudioFileReader('rbds_capture_47500.wav','SamplesPerFrame',rbdsFrameLen*afrRate/rbdsRat
rbds = comm.RBDSWaveformGenerator('GroupsPerFrame',groupsPerFrame,'SamplesPerSymbol',sps);

fmMod = comm.FMBroadcastModulator('AudioSampleRate',afr.SampleRate,'SampleRate',outRate,...
    'Stereo',true,'RBDS',true,'RBDSSamplesPerSymbol',sps);
fmDemod = comm.FMBroadcastDemodulator('SampleRate',outRate,...
    'Stereo',true,'RBDS',true,'PlaySound',true);
scope = timescope('SampleRate',outRate,'YLimits',10^-2*[-1 1]);
```

Get the current audio input. Generate RBDS information at the same configured rate as audio. FM modulate the stereo audio with RBDS information. Add additive white Gaussian noise. FM demodulate the audio and RBDS waveforms. View the waveforms in a time scope.

```
for idx = 1:7
    input = afr();
    rbdsWave = rbds();
    yFM = fmMod([input input], rbdsWave);
    rcv = awgn(yFM, 40);
    [audioRcv, rbdsRcv] = fmDemod(rcv);
    scope(rbdsRcv);
end
```

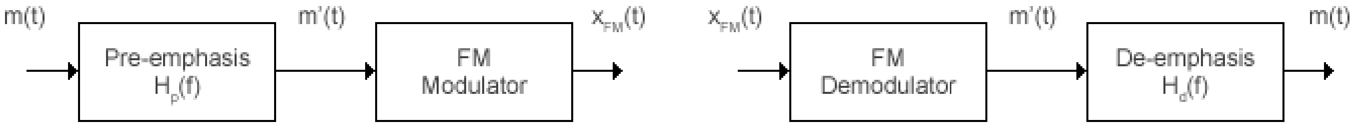


Algorithms

The FM Broadcast demodulator includes the functionality of the baseband FM demodulator, de-emphasis filtering, and the ability to receive stereophonic signals. The algorithms which govern basic FM modulation and demodulation are covered in `comm.FMDemodulator`.

Filtering

FM amplifies high-frequency noise and degrades the overall signal-to-noise ratio. To compensate, FM broadcasters insert a pre-emphasis filter prior to FM modulation to amplify the high-frequency content. The FM receiver has a reciprocal de-emphasis filter after the FM demodulator to attenuate high-frequency noise and restore a flat signal spectrum.



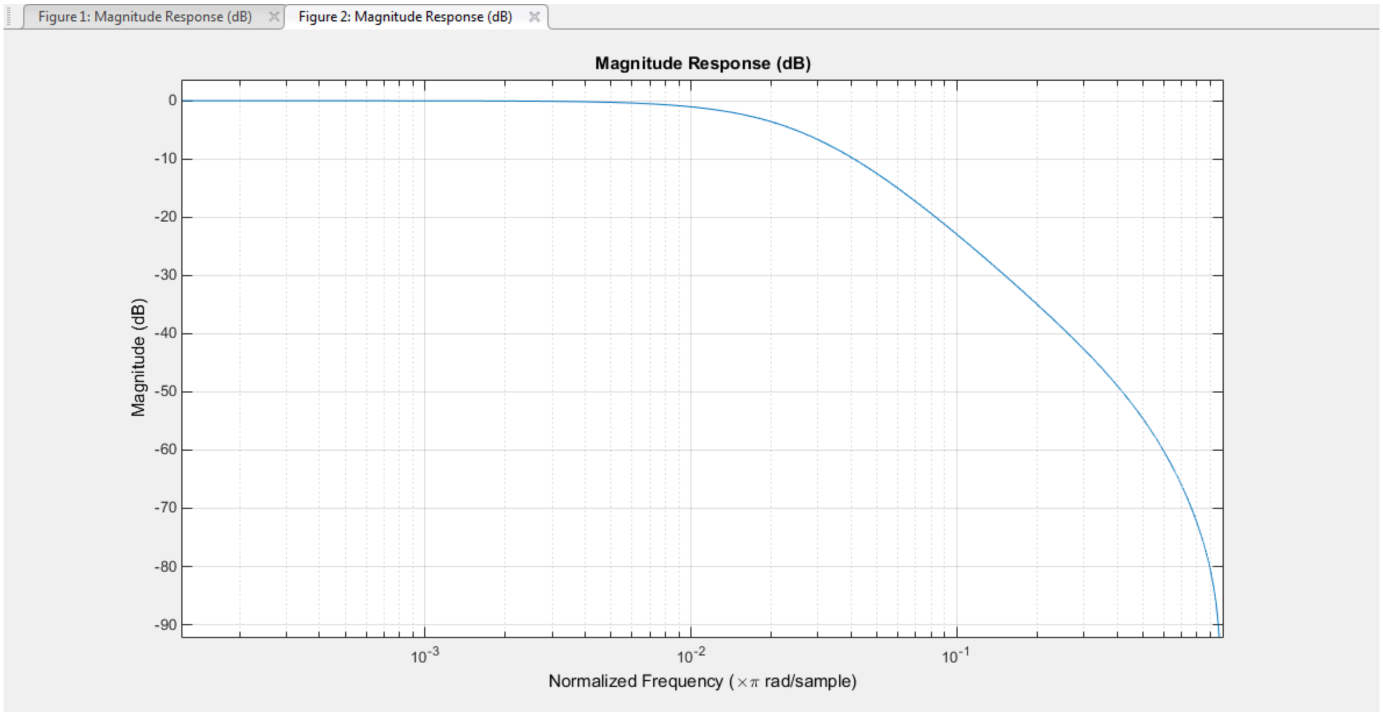
The pre-emphasis filter has a highpass characteristic transfer function given by

$$H_p(f) = 1 + j2\pi f\tau_s\,,$$

where τ_s is the filter time constant. The time constant is 50 µs in Europe and 75 µs in the United States. Similarly, the transfer function for the lowpass de-emphasis filter is given by

$$H_d(f) = \frac{1}{1 + j2\pi f\tau_s} .$$

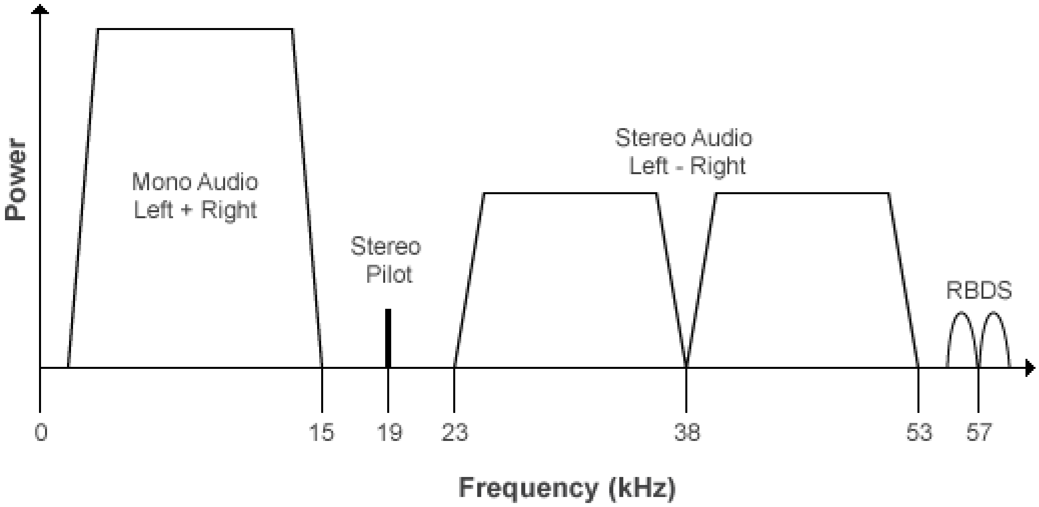
For an audio sample rate of 44.1 kHz, the de-emphasis filter has the following response.



Stereo and RDS/RBDS FM — Multiplex Signal

The FM broadcast demodulator supports stereophonic and monophonic operations. To support stereo transmission, the left (L) and right (R) channel information (L+R) is assigned to the mono portion of the spectrum (0 to 15 kHz). The (L-R) information is amplitude modulated onto the 23 to 53 kHz region of the baseband spectrum using a 38 kHz subcarrier signal. A pilot tone at 19 kHz in the multiplexed signal enables the FM receiver to coherently demodulate the stereo and RDS/RBDS signals.

Here is the spectrum of the multiplex baseband signal, *m(t)*.



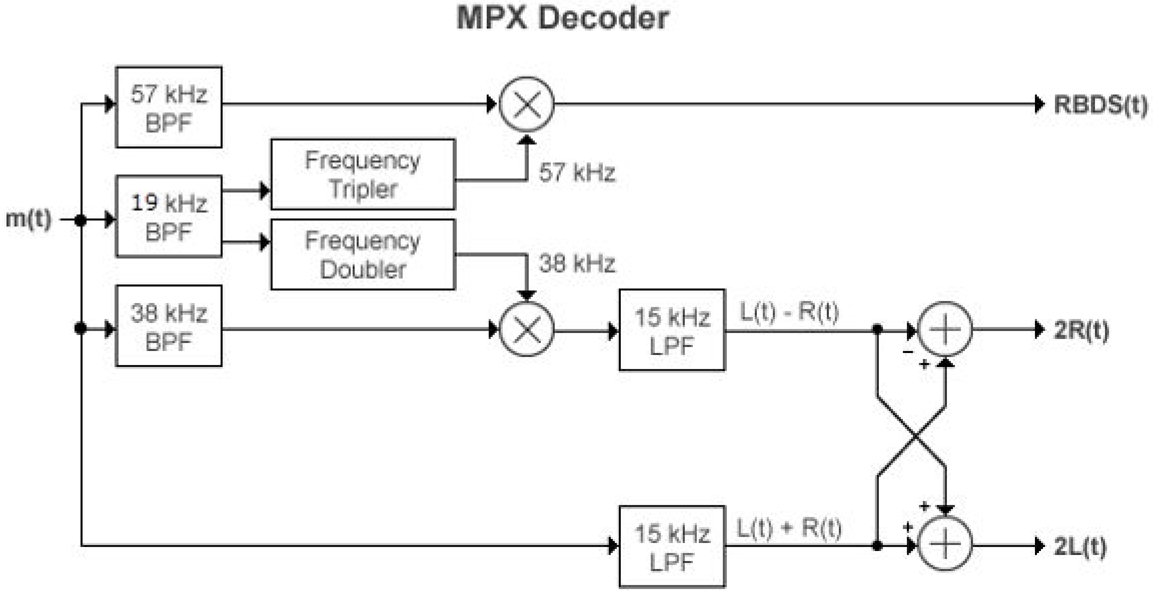
m(t) is given by

$$m(t) = C_0[L(t) + R(t)] + C_1\cos(2\pi \times 19kHz \times t) + C_0[L(t) - R(t)]\cos(2\pi \times 38kHz \times t) + C_2 RBDS(t)\cos(2\pi \times 57kHz \times t)\,,$$

where C_0, C_1, and C_2 are gains. To generate the appropriate modulation level, these gains scale the amplitudes of the (*L(t)*±*R(t)*) signals, the 19 kHz pilot tone, and the RDS/RBDS subcarrier, respectively.

The demodulator applies *m(t)* to three bandpass filters with center frequencies at 19, 38, and 57 kHz, and to a lowpass filter with a 3-dB cutoff frequency of 15 kHz. The 19 kHz bandpass filter extracts the pilot tone from the modulated signal. The recovered pilot tone is doubled and tripled in frequency to produce the 38 kHz and 57 kHz signals, which demodulate the (*L* – *R*) and RDS/RBDS signals, respectively. To generate a scaled version of the left and right channels that produce the stereo sound, the (*L* + *R*) and (*L* – *R*) signals are added and subtracted. The RDS/RBDS signal is recovered by mixing with the 57 kHz signal.

Here is the block diagram of the FM broadcast demodulator.



Limitations

The input length must be an integer multiple of the `AudioDecimationFactor` property. If `RBDS` is set to `true`, the input length in addition must be an integer multiple of `RBDSDecimationFactor`. For more information on these two properties, see the `info` method.

Introduced in R2015a

info

System object: comm.FMBroadcastDemodulator
Package: comm

Filter information about FM broadcast demodulator

Syntax

```
S = info(fmbDemod)
```

Description

S = info(fmbDemod) returns a structure, S, containing this information for the comm.FMBroadcastDemodulator System object, fmbDemod:

Field	Description
AudioDecimationFactor	Decimation factor of the audio demodulator filter.
AudioInterpolationFactor	Interpolation factor of the audio demodulator filter.
RBDSDecimationFactor	Decimation factor of the RDS/RBDS demodulator filter.
RBDSInterpolationFactor	Interpolation factor of the RDS/RBDS demodulator filter.

Note When RBDS is true, the demodulator input sequence length must be a multiple of AudioDecimationFactor and RBDSDecimationFactor.

When RBDS is false, the demodulator input sequence length must be a multiple of AudioDecimationFactor.

Introduced in R2015a

reset

System object: `comm.FMBroadcastDemodulator`
Package: `comm`

Reset states of the FM broadcast demodulator object

Syntax

```
reset(fmbDemod)
```

Description

`reset(fmbDemod)` resets the states of the `comm.FMBroadcastDemodulator` object, `fmbDemod`.

This method resets the windowed suffix from the last symbol in the previously processed frame.

Introduced in R2015a

step

System object: `comm.FMBroadcastDemodulator`
Package: `comm`

Apply FM broadcast demodulation

Syntax

```
audioSig = step(fmbDemod,X)
[audioSig,rbdsSig] = step(fmbDemod,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`audioSig = step(fmbDemod,X)` demodulates the complex baseband FM signal, `X`, and filters this signal with a de-emphasis filter to produce an audio signal, `audioSig`. If the `Stereo` property is set to `true`, stereo decoding is also performed. The output, `audioSig`, is a real vector with length equal to `(AudioSampleRate/SampleRate) × length(X)`.

`[audioSig,rbdsSig] = step(fmbDemod,X)` also demodulates the baseband RBDS signal, `rbdsSig`. The `step` method outputs the RBDS signal only if the `RBDS` property is set to `true`. The output, `rbdsSig`, is a real vector with length equal to `(RBDSSamplesPerSymbol × 1187.5/SampleRate) × length(X)`.

Note `fmbDemod` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Introduced in R2015a

comm.FMBroadcastModulator

Package: comm

Modulate broadcast FM signal

Description

The comm.FMBroadcastModulator System object pre-emphasizes an audio signal and modulates it onto a baseband FM signal. If the Stereo property is set to true, the object modulates the audio input (*L*–*R*) in the 38 kHz band, in addition to modulating it in the baseband (*L*+*R*). If the RBDS property is set to true, the object modulates a baseband RDS/RBDS signal at 57 kHz. For more details, see “Algorithms” on page 3-621.

To FM modulate an audio signal:

1. Define and set up the comm.FMBroadcastModulator object. See “Construction” on page 3-617.
2. Call step to apply broadcast FM modulation to an audio signal according to the properties of comm.FMBroadcastModulator.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

fmbMod = comm.FMBroadcastModulator creates a modulator System object, fmbMod, that frequency modulates an input signal.

fmbMod = comm.FMBroadcastModulator(demod) creates a broadcast FM modulator object whose properties are determined by the corresponding broadcast FM demodulator object, demod.

fmbMod = comm.FMBroadcastModulator(Name,Value) creates a broadcast FM modulator object with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

SampleRate

Output signal sample rate (Hz)

Specify the sample rate of the output signal in Hz as a positive real scalar. The default value is 240e3. This property is nontunable.

FrequencyDeviation

Peak deviation of the output signal frequency (Hz)

Specify the frequency deviation of the FM modulator in Hz as a positive real scalar. The default value is 75e3. The system bandwidth is equal to twice the sum of the frequency deviation and the message bandwidth. FM broadcast standards specify a value of 75 kHz in the United States and 50 kHz in Europe. This property is nontunable.

FilterTimeConstant

Filter time constant (s)

Specify the pre-emphasis highpass filter time constant as a positive real scalar. FM broadcast standards specify a value of 75 μs in the United States and 50 μs in Europe. The default value is 7.5e-05. The property is nontunable.

AudioSampleRate

Sample rate of the input audio signal (Hz)

Specify the audio sample rate as a positive real scalar. The default value is 48000. This property is nontunable.

Stereo

Flag to set stereo operations

Set this property to true if the input is a stereophonic audio signal. Set to false if the input signal is monophonic. The default is false. This property is nontunable.

RBDS

Flag to modulate RDS/RBDS waveform

If RBDS is set to true, the step method accepts the baseband RDS/RBDS waveform as its second input and the object modulates the signal at 57 kHz. The default value is false. This property is nontunable.

RBDSSamplesPerSymbol

Oversampling factor of RDS/RBDS input

Specify the number of samples per RDS/RBDS symbol as a positive integer. The RDS/RBDS sample rate is given by RBDSSamplesPerSymbol × 1187.5 Hz. According to the RDS/RBDS standard, the sample rate of each bit is 1187.5 Hz.

This property applies only when you set RBDS to true.

The default is 10.

Methods

info	Filter information about FM broadcast modulator
reset	Reset states of the FM broadcast modulator object
step	Apply FM broadcast modulation

Common to All System Objects	
release	Allow System object property value changes

Examples

FM Broadcast a Streaming Audio Signal

Modulate and demodulate a streaming audio signal with the FM broadcast modulator and demodulator objects. Play the audio signal using a default audio device.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Create an audio file reader System object™ and read the file `guitartune.wav`.

```
audio = dsp.AudioFileReader('guitartune.wav','SamplesPerFrame',4410);
```

Create FM broadcast modulator and demodulator objects. Set the `AudioSampleRate` property to match the sample rate of the input signal. Set the `SampleRate` property of the demodulator to match the specified sample rate of the modulator. Set the `PlaySound` property of the demodulator to `true` to enable audio playback.

```
fmbMod = comm.FMBroadcastModulator('AudioSampleRate',audio.SampleRate, ...
    'SampleRate',240e3);
fmbDemod = comm.FMBroadcastDemodulator( ...
    'AudioSampleRate',audio.SampleRate, ...
    'SampleRate',240e3,'PlaySound',true);
```

Read the audio data in frames of length 4410, apply FM broadcast modulation, demodulate the FM signal and playback the audio input.

```
while ~isDone(audio)
    audioData = audio();
    modData = fmbMod(audioData);
    demodData = fmbDemod(modData);
end
```

FM Modulate and Demodulate an RBDS Waveform

Generate a basic RBDS waveform, FM modulate it with an audio signal, and then demodulate it.

Note: This example runs only in R2017a or later.

Create a RBDS waveform with 19 groups per frame and 10 samples per symbol. The sample rate of the RBDS waveform is given by 1187.5 x 10. Set the audio sample rate to 1187.5 x 40.

```
groupLen = 104;
sps = 10;
groupsPerFrame = 19;
rbdsFrameLen = groupLen*sps*groupsPerFrame;
afrRate = 40*1187.5;
rbdsRate = 1187.5*sps;
```

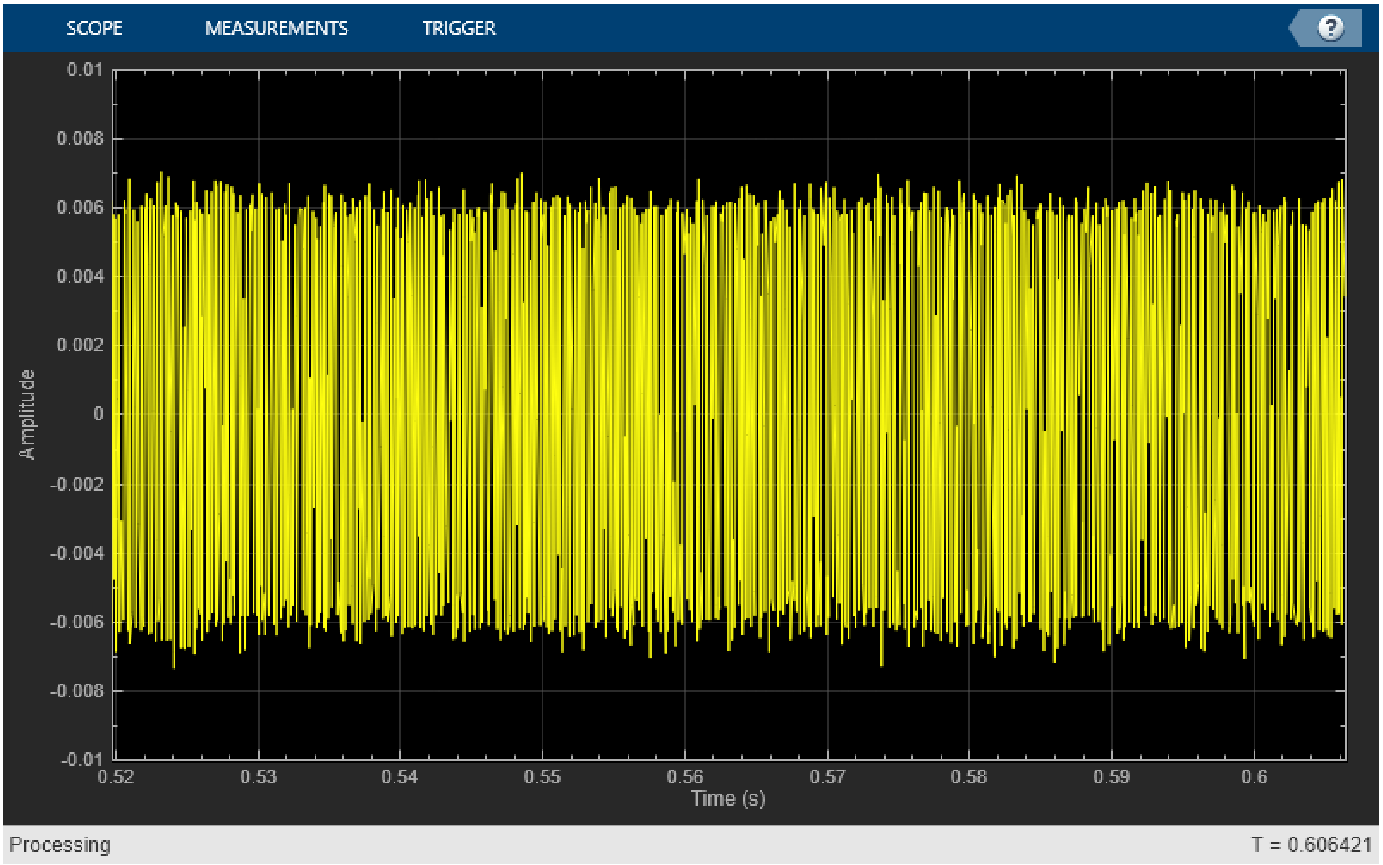
```
outRate = 4*57000;

afr = dsp.AudioFileReader('rbds_capture_47500.wav','SamplesPerFrame',rbdsFrameLen*afrRate/rbdsRa
rbds = comm.RBDSWaveformGenerator('GroupsPerFrame',groupsPerFrame,'SamplesPerSymbol',sps);

fmMod = comm.FMBroadcastModulator('AudioSampleRate',afr.SampleRate,'SampleRate',outRate,...
    'Stereo',true,'RBDS',true,'RBDSSamplesPerSymbol',sps);
fmDemod = comm.FMBroadcastDemodulator('SampleRate',outRate,...
    'Stereo',true,'RBDS',true,'PlaySound',true);
scope = timescope('SampleRate',outRate,'YLimits',10^-2*[-1 1]);
```

Get the current audio input. Generate RBDS information at the same configured rate as audio. FM modulate the stereo audio with RBDS information. Add additive white Gaussian noise. FM demodulate the audio and RBDS waveforms. View the waveforms in a time scope.

```
for idx = 1:7
    input = afr();
    rbdsWave = rbds();
    yFM = fmMod([input input], rbdsWave);
    rcv = awgn(yFM, 40);
    [audioRcv, rbdsRcv] = fmDemod(rcv);
    scope(rbdsRcv);
end
```

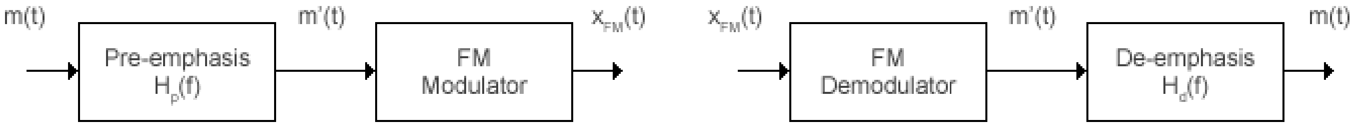


Algorithms

The FM Broadcast modulator includes the functionality of the baseband FM modulator, pre-emphasis filtering, and the ability to transmit stereophonic signals. The algorithms which govern basic FM modulation and demodulation are covered in `comm.FMModulator`.

Filtering

FM amplifies high-frequency noise and degrades the overall signal-to-noise ratio. To compensate, FM broadcasters insert a pre-emphasis filter prior to FM modulation to amplify the high-frequency content. The FM receiver has a reciprocal de-emphasis filter after the FM demodulator to attenuate high-frequency noise and restore a flat signal spectrum.



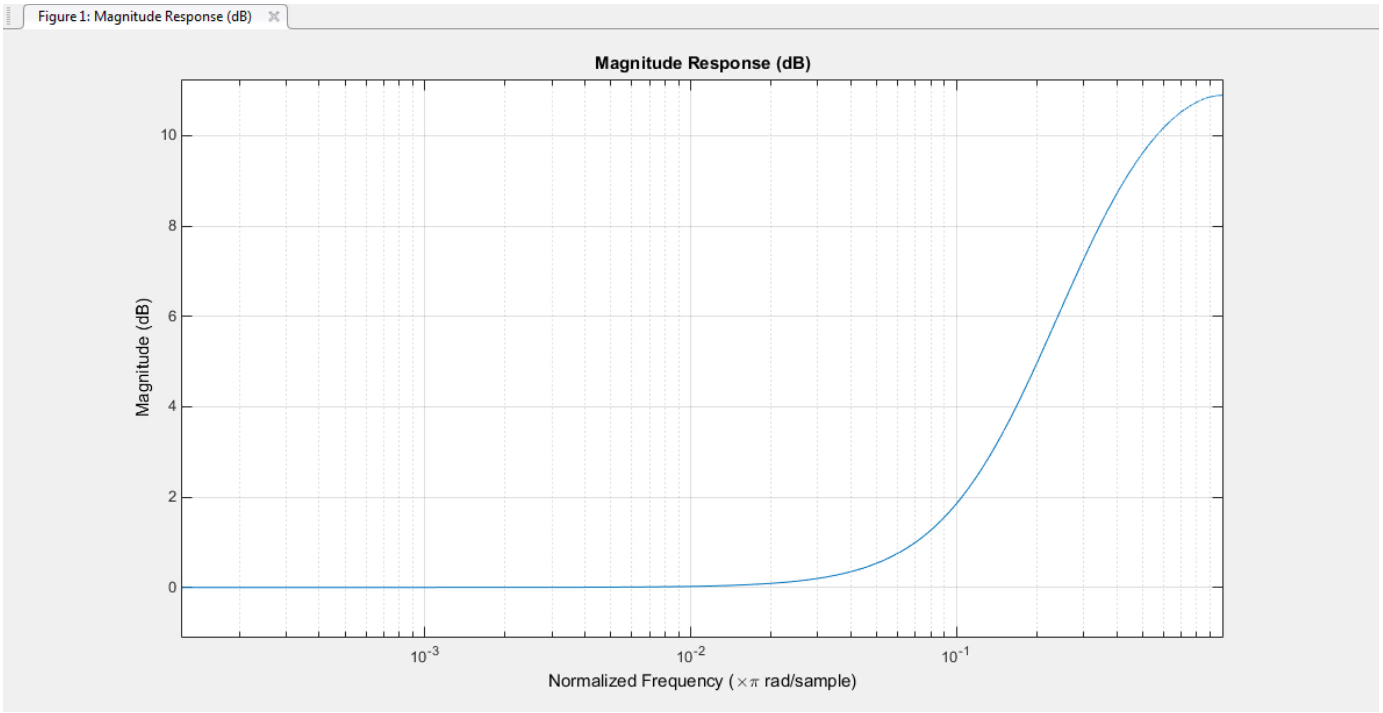
The pre-emphasis filter has a highpass characteristic transfer function given by

$$H_p(f) = 1 + j2\pi f\tau_s\,,$$

where τ_s is the filter time constant. The time constant is 50 µs in Europe and 75 µs in the United States. Similarly, the transfer function for the lowpass de-emphasis filter is given by

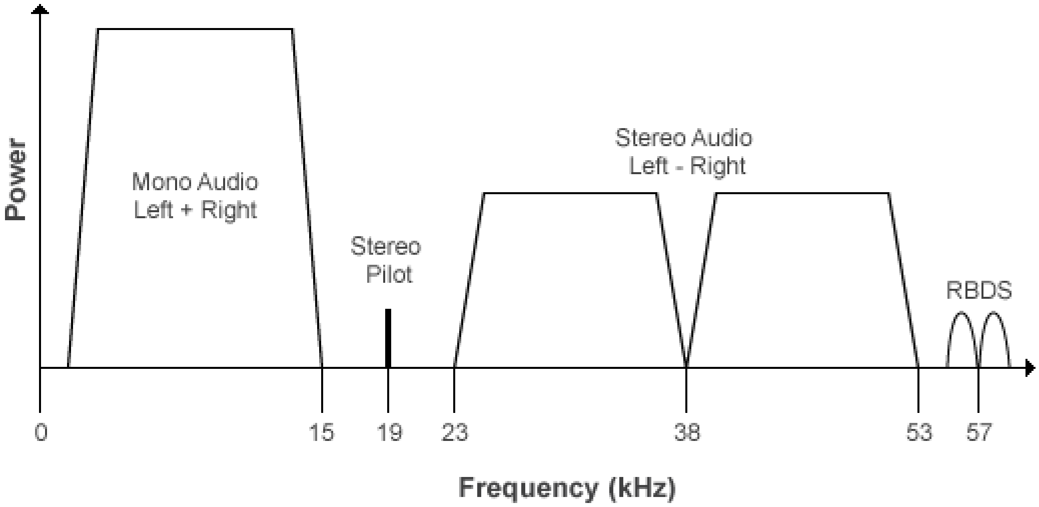
$$H_d(f) = \frac{1}{1 + j2\pi f\tau_s} .$$

Irrespective of the audio sampling rate, the signal is converted to a 152 kHz output sampling rate. For an audio sample rate of 44.1 kHz, the pre-emphasis filter has the following response.

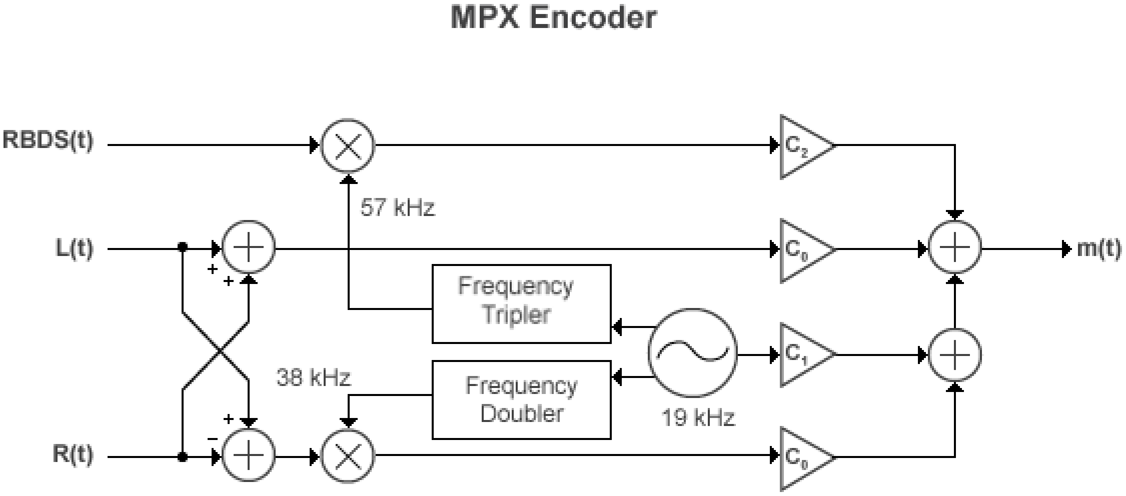


Stereo and RDS/RBDS FM – Multiplex Signal

The FM broadcast modulator supports stereophonic and monophonic operations. To support stereo transmission, the left (L) and right (R) channel information (L+R) is assigned to the mono portion of the spectrum (0 to 15 kHz). The (L-R) information is amplitude modulated onto the 23 to 53 kHz region of the baseband spectrum using a 38 kHz subcarrier signal. A pilot tone at 19 kHz in the multiplexed signal enables the FM receiver to coherently demodulate the stereo and RDS/RBDS signals. Here is the spectrum of the multiplex baseband signal.



Here is the block diagram of the FM broadcast modulator, which is used to generate the multiplex baseband signal. *L(t)* and *R(t)* denote the time-domain waveforms from the left and right channels. *RBDS(t)* denotes the time-domain waveform of the RDS/RBDS signal.



The multiplex message signal, *m(t)* is given by

$$m(t) = C_0[L(t) + R(t)] + C_1\cos(2\pi \times 19kHz \times t) + C_0[L(t) - R(t)]\cos(2\pi \times 38kHz \times t) + C_2RBDS(t)\cos(2\pi \times 57kHz \times t) ,$$

where C_0, C_1, and C_2 are gains. To generate the appropriate modulation level, these gains scale the amplitudes of the (*L(t)*±*R(t)*) signals, the 19 kHz pilot tone, and the RDS/RBDS subcarrier, respectively.

Limitations

- If `RBDS` is `true`, both the audio and RDS/RBDS inputs must satisfy the following equation:

$$\frac{audioLength}{audioSampleRate} = \frac{RBDSLength}{RBDSSampleRate}$$

- The input length of the audio signal must be an integer multiple of the `AudioDecimationFactor` property. The input length of the RDS/RBDS signal must be an integer multiple of the `RBDSDecimationFactor` property. For more information on these two properties, see the `info` method.

Blocks

FM Broadcast Demodulator Baseband | FM Broadcast Modulator Baseband

Introduced in R2015a

info

System object: `comm.FMBroadcastModulator`
Package: `comm`

Filter information about FM broadcast modulator

Syntax

```
S = info(fmbMod)
```

Description

`S = info(fmbMod)` returns a structure, `S`, containing this information for the `comm.FMBroadcastModulator` System object, `fmbMod`:

Field	Description
`AudioDecimationFactor`	Decimation factor of the audio modulator filter.
`AudioInterpolationFactor`	Interpolation factor of the audio modulator filter.
`RBDSDecimationFactor`	Decimation factor of the RDS/RBDS modulator filter.
`RBDSInterpolationFactor`	Interpolation factor of the RDS/RBDS modulator filter.

Note The modulator input sequence length for the audio input must be a multiple of `AudioDecimationFactor`.

The modulator input sequence length for the RDS/RBDS input must be a multiple of `RBDSDecimationFactor`.

Introduced in R2015a

reset

System object: `comm.FMBroadcastModulator`
Package: `comm`

Reset states of the FM broadcast modulator object

Syntax

```
reset(fmbMod)
```

Description

`reset(fmbMod)` resets the states of the `comm.FMBroadcastModulator` object, `fmbMod`.

This method resets the windowed suffix from the last symbol in the previously processed frame.

Introduced in R2015a

step

System object: `comm.FMBroadcastModulator`
Package: `comm`

Apply FM broadcast modulation

Syntax

```
modSig = step(fmbMod,audioSig)
modSig = step(fmbMod,audioSig,rbdsSig)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`modSig = step(fmbMod,audioSig)` pre-emphasizes the audio signal, `audioSig`, and modulates it onto a baseband FM signal. The audio signal can be real or complex with a single-precision or a double-precision data type. If the `Stereo` property of `fmbMod` is set to `true`, stereo encoding is performed after pre-emphasis and the audio signal must have at least two channels. If `Stereo` is `false`, the audio signal must be a column vector. The length of the modulated signal, `modSig`, is `(SampleRate/AudioSampleRate) × length(audioSig)`.

`modSig = step(fmbMod,audioSig,rbdsSig)` also modulates a baseband RBDS signal at 57 kHz. You can pass `rbdsSig` as an input only if you set the `RBDS` property to true. The length of output vector `modSig` is `(SampleRate/AudioSampleRate) × length(audioSig)`.

Note `fmbMod` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Introduced in R2015a

comm.FMDemodulator

Package: comm

Demodulate using FM method

Description

The FMDemodulator System object demodulates an FM modulated signal.

To FM demodulate a signal:

1. Define and set up the FMDemodulator object. See "Construction" on page 3-628.
2. Call step to FM demodulate a signal according to the properties of comm.FMDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.FMDemodulator creates a demodulator System object, H, that frequency demodulates an input signal.

H = comm.FMDemodulator(mod) creates an FM demodulator object whose properties are determined by the corresponding FM modulator object, mod.

H = comm.FMDemodulator(Name,Value) creates an FM demodulator object with each specified property Name set to the specified Value. Name must appear inside single quotes. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

FrequencyDeviation

Peak deviation of the output signal frequency (Hz)

Specify the frequency deviation of the FM demodulator in Hz as a positive real scalar. The default value is 75e3. The system bandwidth is equal to twice the sum of the frequency deviation and the message bandwidth. This property is nontunable.

SampleRate

Sample rate of input signal (Hz)

Specify the sample rate in Hz as a positive real scalar. The default value is 240e3. The output sample rate is equal to the input sample rate. This property is nontunable.

Methods

reset	Reset states of the FM demodulator object
step	Applies FM baseband demodulation

Common to All System Objects	
release	Allow System object property value changes

Examples

FM Modulate and Demodulate a Sinusoidal Signal

Modulate and demodulate a sinusoidal signal. Plot the demodulated signal and compare it to the original signal.

Set the example parameters.

```
fs = 100; % Sample rate (Hz)
ts = 1/fs; % Sample period (s)
fd = 25; % Frequency deviation (Hz)
```

Create a sinusoidal input signal with duration 0.5 s and frequency 4 Hz.

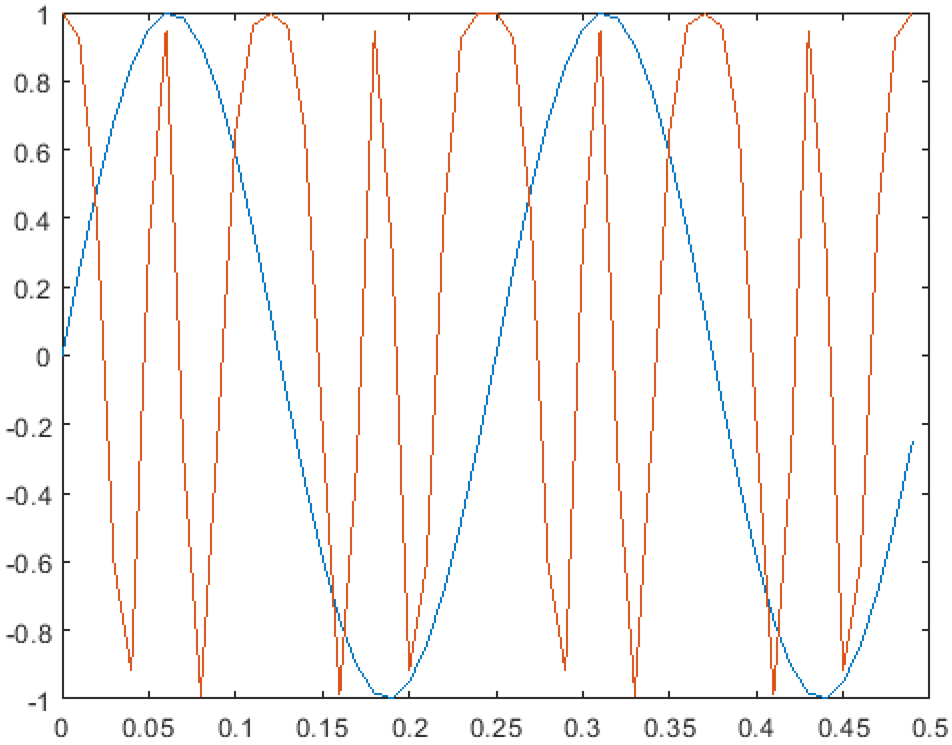
```
t = (0:ts:0.5-ts)';
x = sin(2*pi*4*t);
```

Create FM modulator and demodulator System objects.

```
fmmod = comm.FMModulator('SampleRate',fs,'FrequencyDeviation',fd);
fmdemod = comm.FMDemodulator('SampleRate',fs,'FrequencyDeviation',fd);
```

FM modulate the input signal and plot its real part. You can see that the frequency of the modulated signal changes with the amplitude of the input signal.

```
y = fmmod(x);
plot(t,[x real(y)])
```

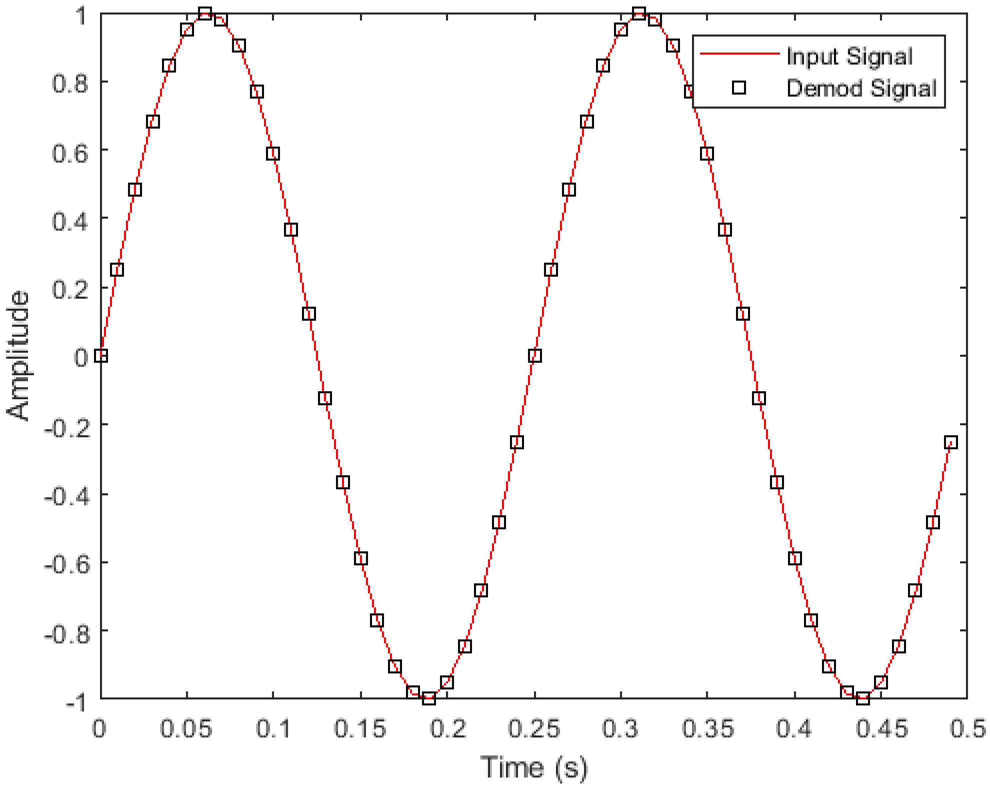


Demodulate the FM modulated signal.

```
z = fmdemod(y);
```

Plot the input and demodulated signals. The demodulator output signal exactly aligns with the input signal.

```
plot(t,x,'r',t,z,'ks')
legend('Input Signal','Demod Signal')
xlabel('Time (s)')
ylabel('Amplitude')
```



Create an FM Demodulator from an FM Modulator

Create an FM demodulator System object? from an FM modulator object. Modulate and demodulate audio data loaded from a file and compare its spectrum with that of the input data.

Set the example parameters.

```
fd = 50e3;                          % Frequency deviation (Hz)
fs = 300e3;                         % Sample rate (Hz)
```

Create an FM modulator System object.

```
MOD = comm.FMModulator('FrequencyDeviation',fd,'SampleRate',fs);
```

Create a companion demodulator object based on the modulator.

```
DEMOD = comm.FMDemodulator(MOD);
```

Verify that the properties are identical in the two System objects.

```
MOD
DEMOD
```

```
MOD =
  comm.FMModulator with properties:

             SampleRate: 300000
     FrequencyDeviation: 50000

DEMOD = 

  comm.FMDemodulator with properties:

             SampleRate: 300000
     FrequencyDeviation: 50000
```

Load audio data into structure variable, S.

```
S = load('handel.mat');
data = S.y;
fsamp = S.Fs;
```

Create a spectrum analyzer System object.

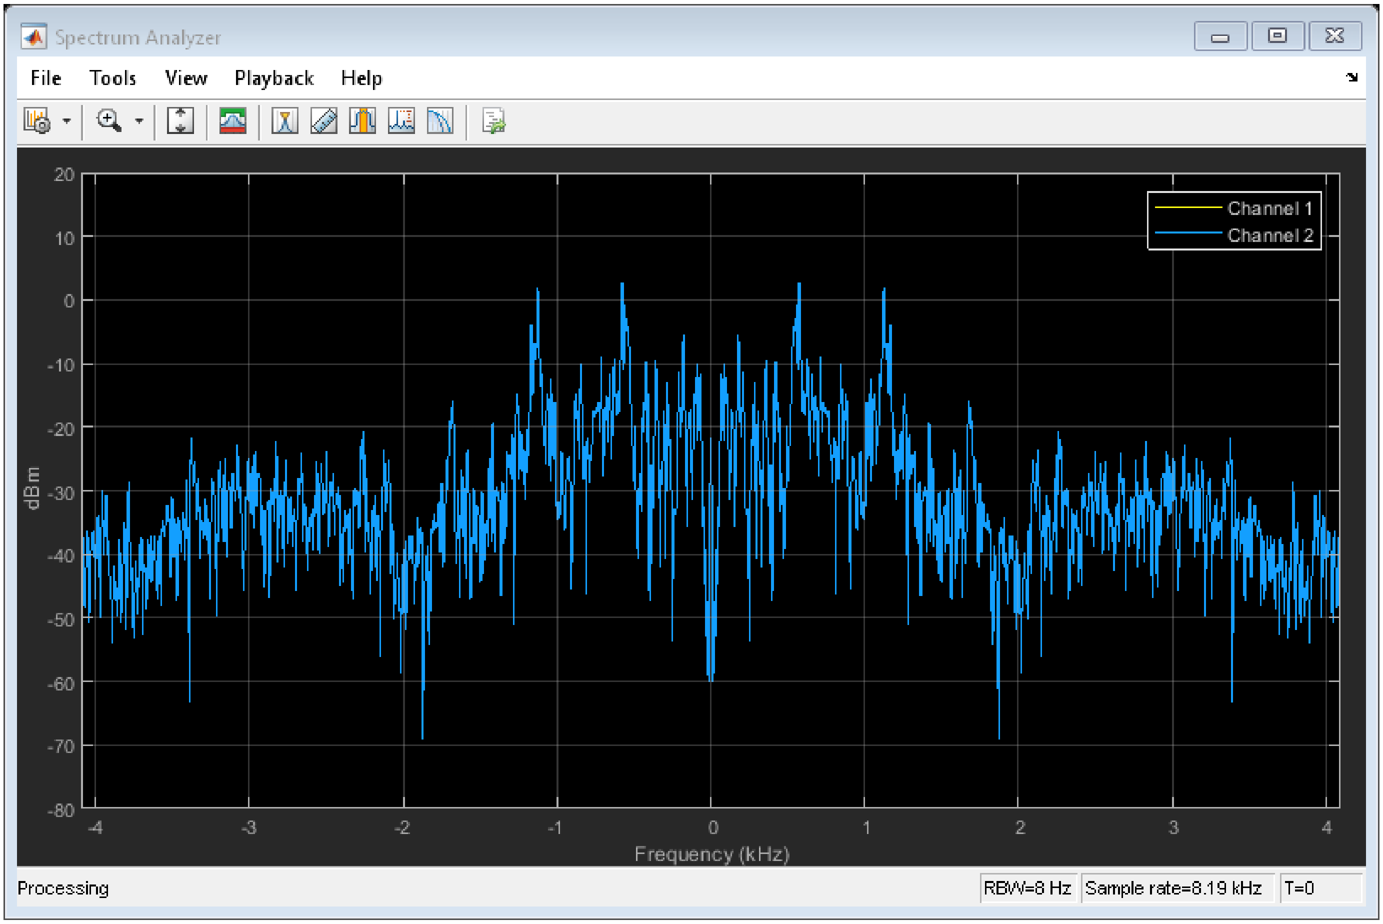
```
SA = dsp.SpectrumAnalyzer('SampleRate',fsamp,'ShowLegend',true);
```

FM modulate and demodulate the audio data.

```
modData = step(MOD,data);
demodData = step(DEMOD,modData);
```

Verify that the spectrum plot of the input data (Channel 1) is aligned with that of the demodulated data (Channel 2).

```
step(SA,[data demodData])
```



FM Modulate and Demodulate an Audio File

Playback an audio file after applying FM modulation and demodulation. The example takes advantage of the characteristics of System objects™ to process the data in streaming mode.

Load the audio file, `guitartune.wav`, using an audio file reader object.

```
AUDIO = dsp.AudioFileReader...
    ('guitartune.wav','SamplesPerFrame',4410);
```

Create an audio device writer object for audio playback.

```
AUDIOPLAYER = audioDeviceWriter;
```

Create modulator and demodulator objects having default properties.

```
MOD = comm.FMModulator;
DEMOD = comm.FMDemodulator;
```

Read audio data, FM modulate, FM demodulate, and playback the demodulated signal, `z`.

```
while ~isDone(AUDIO)
    x = step(AUDIO);                  % Read audio data
    y = step(MOD,x);                    % FM modulate
    z = step(DEMOD,y);                  % FM demodulate
    step(AUDIOPLAYER,z);                % Playback the demodulated signal
end
```

FM Modulate and Demodulate a Sinusoidal Signal

Modulate and demodulate a sinusoidal signal. Plot the demodulated signal and compare it to the original signal.

Set the example parameters.

```
fs = 100; % Sample rate (Hz)
ts = 1/fs; % Sample period (s)
fd = 25; % Frequency deviation (Hz)
```

Create a sinusoidal input signal with duration 0.5 s and frequency 4 Hz.

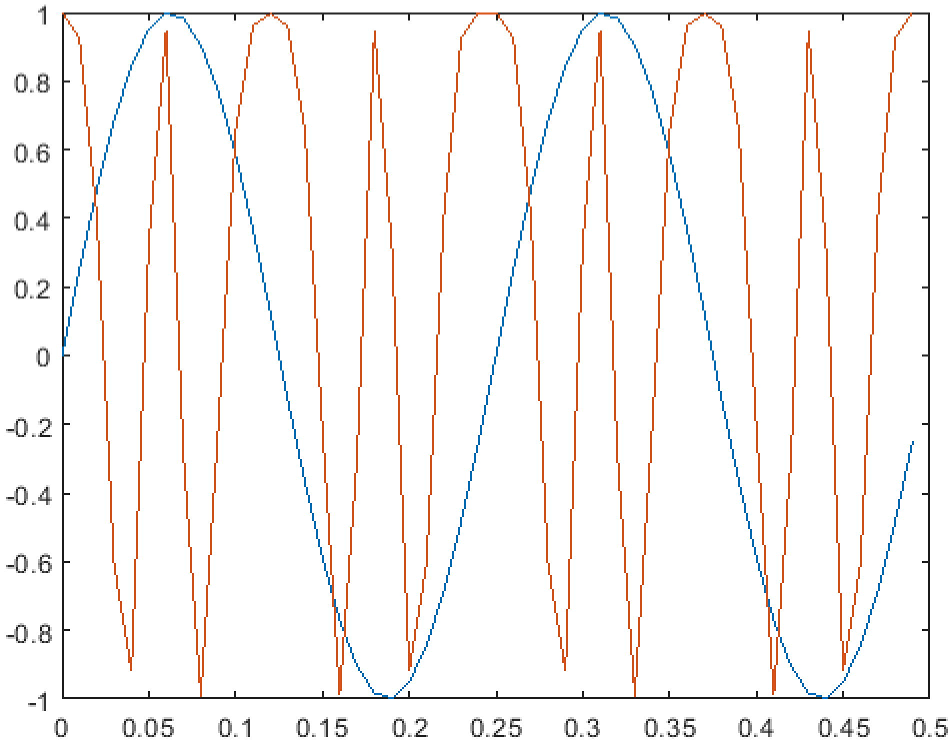
```
t = (0:ts:0.5-ts)';
x = sin(2*pi*4*t);
```

Create FM modulator and demodulator System objects.

```
fmmod = comm.FMModulator('SampleRate',fs,'FrequencyDeviation',fd);
fmdemod = comm.FMDemodulator('SampleRate',fs,'FrequencyDeviation',fd);
```

FM modulate the input signal and plot its real part. You can see that the frequency of the modulated signal changes with the amplitude of the input signal.

```
y = fmmod(x);
plot(t,[x real(y)])
```

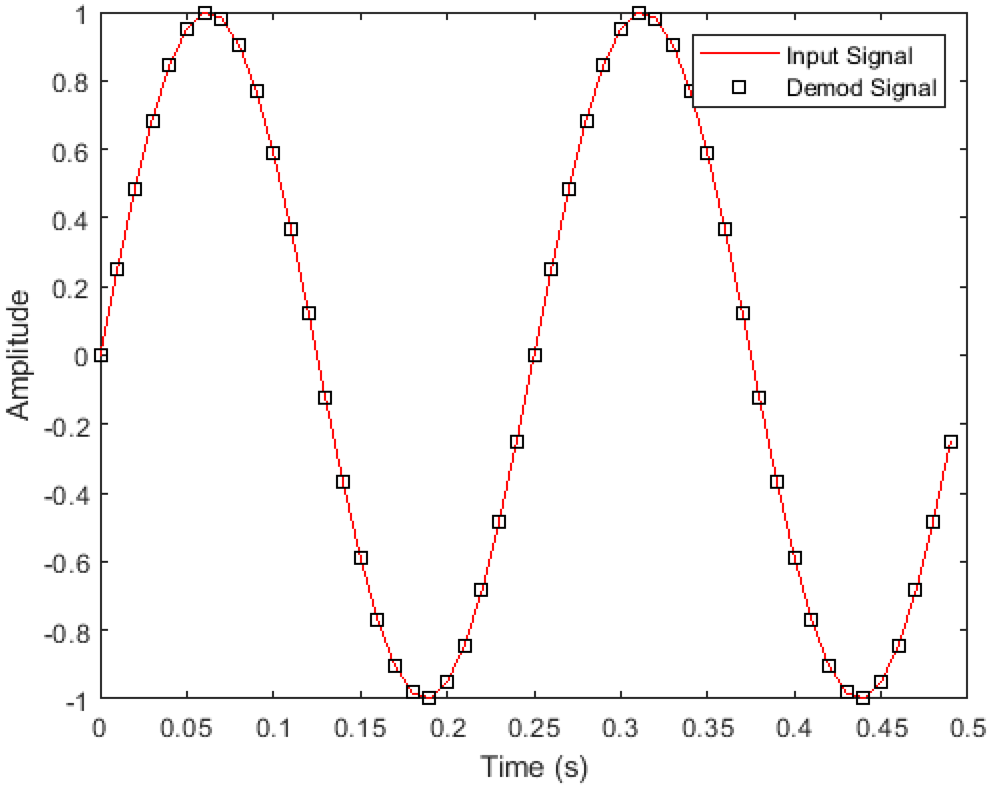


Demodulate the FM modulated signal.

```
z = fmdemod(y);
```

Plot the input and demodulated signals. The demodulator output signal exactly aligns with the input signal.

```
plot(t,x,'r',t,z,'ks')
legend('Input Signal','Demod Signal')
xlabel('Time (s)')
ylabel('Amplitude')
```



Selected Bibliography

[2] Taub, Herbert, and Donald L. Schilling. *Principles of Communication Systems*. New York: McGraw-Hill, 1971, pp. 142–155.

Algorithms

Represent a frequency modulated passband signal, *Y(t)*, as

$$Y(t) = A\cos\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau)d\tau\right),$$

where A is the carrier amplitude, f_c is the carrier frequency, $x(\tau)$ is the baseband input signal, and f_Δ is the frequency deviation in Hz. The frequency deviation is the maximum shift from f_c in one direction, assuming $|x(t)| \le 1$.

A baseband FM signal can be derived from the passband representation by downconverting it by f_c such that

$$y_s(t) = Y(t)e^{-j2\pi f_c t} = \frac{A}{2}\left[e^{j\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau)d\tau\right)} + e^{-j\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau)d\tau\right)}\right]e^{-j2\pi f_c t}$$
$$= \frac{A}{2}\left[e^{j2\pi f_\Delta \int_0^t x(\tau)d\tau} + e^{-j4\pi f_c t - j2\pi f_\Delta \int_0^t x(\tau)d\tau}\right].$$

Removing the component at -2f_c from $y_s(t)$ leaves the baseband signal representation, *y(t)*, which is expressed as

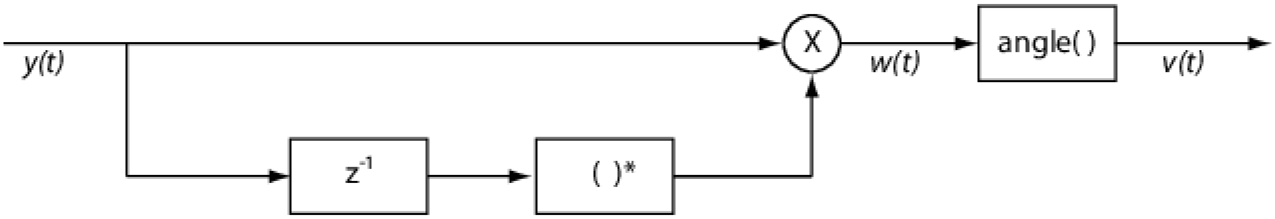
$$y(t) = \frac{A}{2}e^{j2\pi f_\Delta \int_0^t x(\tau)d\tau}.$$

The expression for *y(t)* is rewritten as

$$y(t) = \frac{A}{2}e^{j\phi(t)},$$

where $\phi(t) = 2\pi f_\Delta \int_0^t x(\tau)d\tau$, which implies that the input signal is a scaled version of the derivative of the phase, *ϕ(t)*.

A baseband delay demodulator is used to recover the input signal from *y(t)*.



A delayed and conjugated copy of the received signal is subtracted from the signal itself,

$$w(t) = \frac{A^2}{4}e^{j\phi(t)}e^{-j\phi(t-T)} = \frac{A^2}{4}e^{j[\phi(t) - \phi(t-T)]},$$

where *T* is the sample period. In discrete terms, w_n=*w(nT)*, and

$$w_n = \frac{A^2}{4}e^{j[\phi_n - \phi_{n-1}]},$$
$$v_n = \phi_n - \phi_{n-1}.$$

The signal v_n is the approximate derivative of ϕ_n, such that $v_n \approx x_n$.

`comm.FMBroadcastDemodulator` | `comm.FMBroadcastModulator` | `comm.FMModulator`

Introduced in R2015a

reset

System object: `comm.FMDemodulator`
Package: `comm`

Reset states of the FM demodulator object

Syntax

`reset(H)`

Description

`reset(H)` resets the states of the `FMDemodulator` object, `H`.

This method resets the windowed suffix from the last symbol in the previously processed frame.

step

System object: `comm.FMDemodulator`
Package: `comm`

Applies FM baseband demodulation

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` frequency demodulates an input signal, `X`, and returns an output signal, `Y`. The input `X` is real or complex and can be either a scalar or a column vector. Double- and single-precision data types are supported. The output `Y` is real and has the same data type and dimensions as `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.FMModulator

Package: `comm`

Modulate using FM method

Description

The `FMModulator` System object applies FM modulation to an input signal.

To FM modulate a signal:

1. Define and set up the `FMModulator` object. See "Construction" on page 3-641.
2. Call `step` to apply FM modulation to a signal according to the properties of `comm.FMModulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.FMModulator` creates a modulator System object, `H`, that frequency modulates an input signal.

`H = comm.FMModulator(demod)` creates an FM modulator object whose properties are determined by the corresponding FM demodulator object, `demod`.

`H = comm.FMModulator(Name,Value)` creates an FM modulator object with each specified property `Name` set to the specified `Value`. `Name` must appear inside single quotes. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`FrequencyDeviation`

Peak deviation of the output signal frequency (Hz)

Specify the frequency deviation of the FM modulator in Hz as a positive real scalar. The default value is `75e3`. The system bandwidth is equal to twice the sum of the frequency deviation and the message bandwidth. This property is nontunable.

`SampleRate`

Sample rate of the input signal (Hz)

Specify the sample rate in Hz as a positive real scalar. The default value is `240e3`. The output sample rate is equal to the input sample rate. This property is nontunable.

Methods

reset	Reset states of the FM modulator object
step	Applies FM baseband modulation

Common to All System Objects	
release	Allow System object property value changes

Examples

FM Modulate a Sinusoidal Signal

Apply baseband modulation to a sine wave input signal and plot its response.

Set the example parameters.

```
fs = 1e3;               % Sample rate (Hz)
ts = 1/fs;              % Sample period (s)
fd = 50;                % Frequency deviation (Hz)
```

Create a sinusoidal input signal with duration 0.5s and frequency 4 Hz.

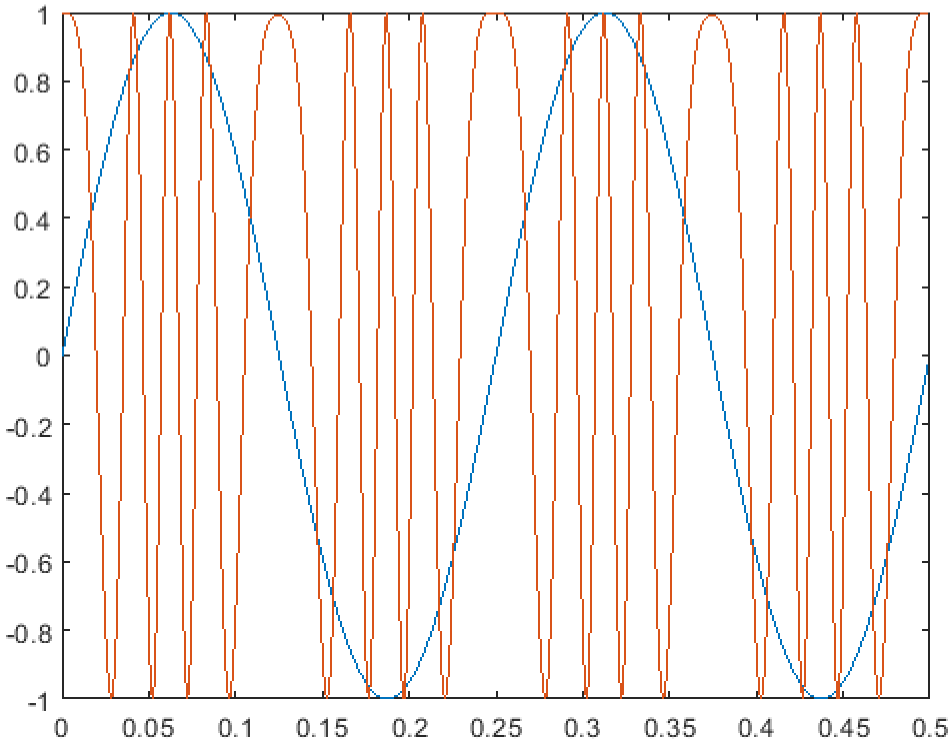
```
t = (0:ts:0.5-ts)';
x = sin(2*pi*4*t);
```

Create an FM modulator System object™.

```
MOD = comm.FMModulator('SampleRate',fs,'FrequencyDeviation',fd);
```

FM modulate the input signal and plot its real part. You can see that the frequency of the modulated signal changes with the amplitude of the input signal.

```
y = step(MOD,x);
plot(t,[x real(y)])
```



Plot Spectrum of FM Modulated Baseband Signal

Apply FM baseband modulation to a white Gaussian noise source and plot its spectrum.

Set the example parameters.

```
fs = 1e3;                % Sample rate (Hz)
ts = 1/fs;               % Sample period (s)
fd = 10;                 % Frequency deviation (Hz)
```

Create a white Gaussian noise source having a duration of 5s.

```
t = (0:ts:5-ts)';
x = wgn(length(t),1,0);
```

Create an FM modulator System object? and modulate the input signal.

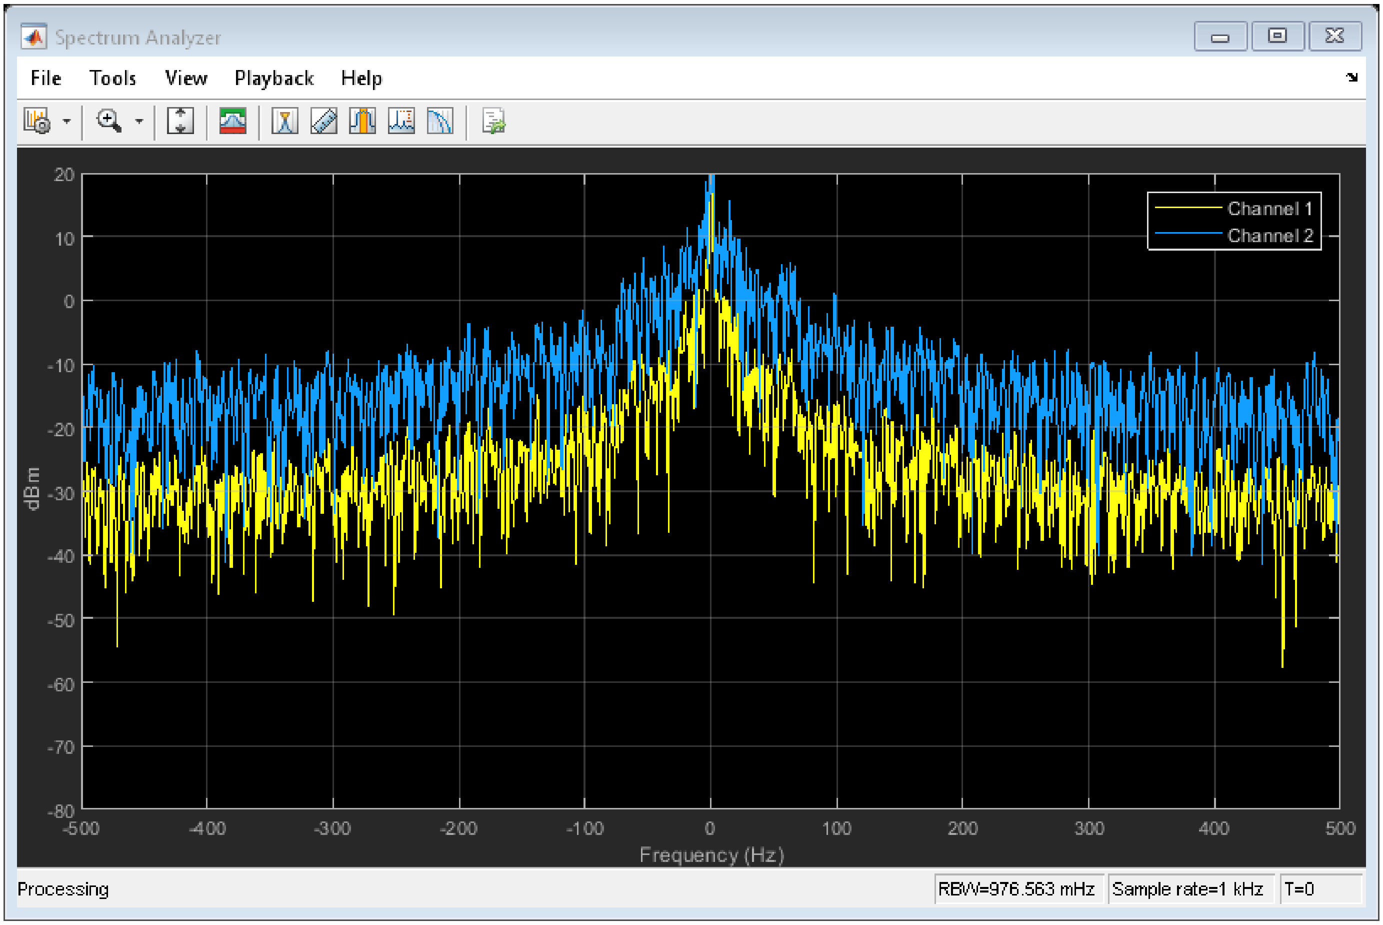
```
MOD1 = comm.FMModulator('SampleRate',fs,'FrequencyDeviation',fd);
y = step(MOD1,x);
```

Create another modulator object, `MOD2`, whose frequency deviation is five times larger and apply FM modulation.

```
MOD2 = comm.FMModulator('SampleRate',fs,'FrequencyDeviation',5*fd);
z = step(MOD2,x);
```

Plot the spectra of the two modulated signals. The larger frequency deviation associated with channel 2 results in a noise level that is 10 dB higher.

```
SA = dsp.SpectrumAnalyzer('SampleRate',fs,'ShowLegend',true);
step(SA,[y z])
```



FM Modulate and Demodulate a Sinusoidal Signal

Modulate and demodulate a sinusoidal signal. Plot the demodulated signal and compare it to the original signal.

Set the example parameters.

```
fs = 100; % Sample rate (Hz)
ts = 1/fs; % Sample period (s)
fd = 25; % Frequency deviation (Hz)
```

Create a sinusoidal input signal with duration 0.5 s and frequency 4 Hz.

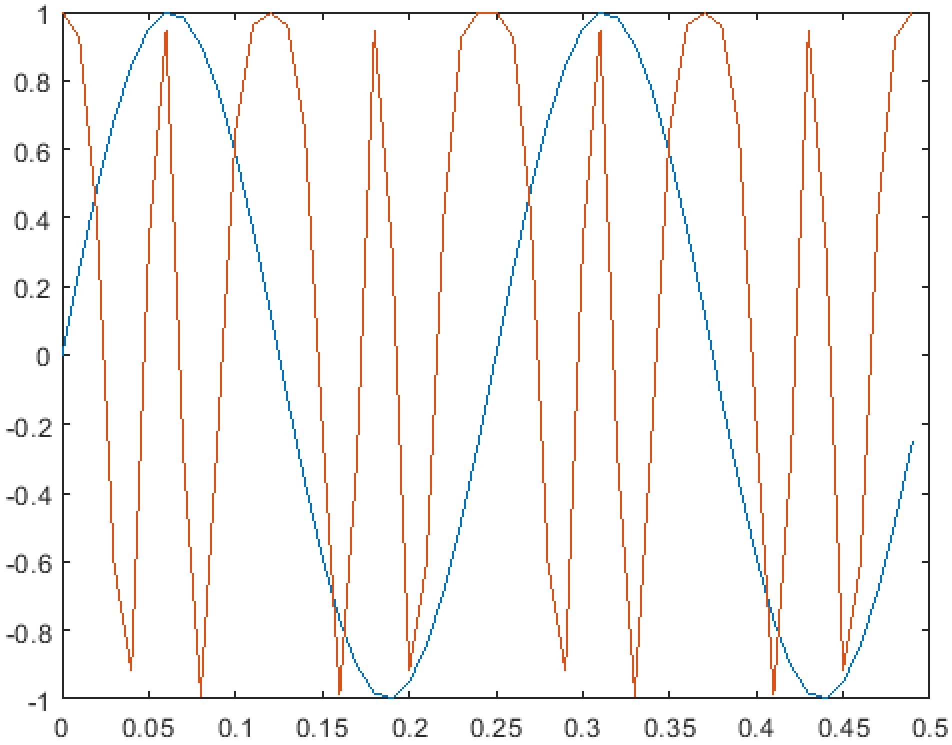
```
t = (0:ts:0.5-ts)';
x = sin(2*pi*4*t);
```

Create FM modulator and demodulator System objects.

```
fmmod = comm.FMModulator('SampleRate',fs,'FrequencyDeviation',fd);
fmdemod = comm.FMDemodulator('SampleRate',fs,'FrequencyDeviation',fd);
```

FM modulate the input signal and plot its real part. You can see that the frequency of the modulated signal changes with the amplitude of the input signal.

```
y = fmmod(x);
plot(t,[x real(y)])
```



Demodulate the FM modulated signal.

```
z = fmdemod(y);
```

Plot the input and demodulated signals. The demodulator output signal exactly aligns with the input signal.

```
plot(t,x,'r',t,z,'ks')
legend('Input Signal','Demod Signal')
xlabel('Time (s)')
ylabel('Amplitude')
```

Algorithms

Represent a frequency modulated passband signal, *Y(t)*, as

$$Y(t) = A\cos\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau)d\tau\right),$$

where A is the carrier amplitude, f_c is the carrier frequency, $x(\tau)$ is the baseband input signal, and f_Δ is the frequency deviation in Hz. The frequency deviation is the maximum shift from f_c in one direction, assuming $|x(t)| \leq 1$.

A baseband FM signal can be derived from the passband representation by downconverting it by f_c such that

$$y_s(t) = Y(t)e^{-j2\pi f_c t} = \frac{A}{2}\left[e^{j\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau)d\tau\right)} + e^{-j\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau)d\tau\right)}\right]e^{-j2\pi f_c t}$$
$$= \frac{A}{2}\left[e^{j2\pi f_\Delta \int_0^t x(\tau)d\tau} + e^{-j4\pi f_c t - j2\pi f_\Delta \int_0^t x(\tau)d\tau}\right].$$

Removing the component at -2f_c from *$y_s(t)$* leaves the baseband signal representation, *y(t)*, which is expressed as

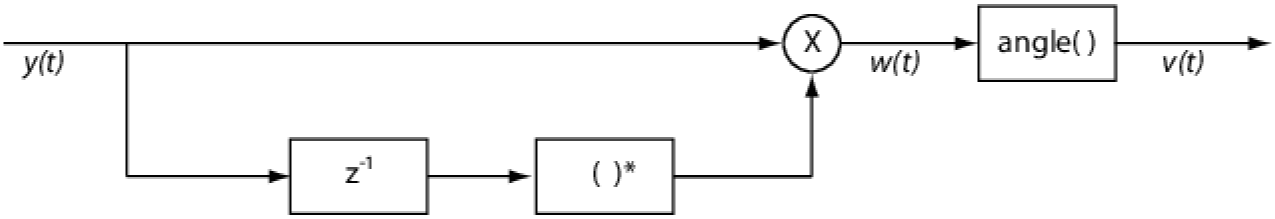
$$y(t) = \frac{A}{2}e^{j2\pi f_\Delta \int_0^t x(\tau)d\tau}.$$

The expression for *y(t)* is rewritten as

$$y(t) = \frac{A}{2}e^{j\phi(t)},$$

where $\phi(t) = 2\pi f_\Delta \int_0^t x(\tau)d\tau$, which implies that the input signal is a scaled version of the derivative of the phase, *ϕ(t)*.

A baseband delay demodulator is used to recover the input signal from *y(t)*.



A delayed and conjugated copy of the received signal is subtracted from the signal itself,

$$w(t) = \frac{A^2}{4}e^{j\phi(t)}e^{-j\phi(t-T)} = \frac{A^2}{4}e^{j[\phi(t) - \phi(t-T)]},$$

where *T* is the sample period. In discrete terms, *w_n=w(nT)*, and

$$w_n = \frac{A^2}{4}e^{j[\phi_n - \phi_{n-1}]},$$
$$v_n = \phi_n - \phi_{n-1}.$$

The signal v_n is the approximate derivative of ϕ_n, such that $v_n \approx x_n$.

`comm.FMBroadcastDemodulator` | `comm.FMBroadcastModulator` | `comm.FMDemodulator`

Introduced in R2015a

reset

System object: `comm.FMModulator`
Package: `comm`

Reset states of the FM modulator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `FMModulator` object, `H`.

This method resets the windowed suffix from the last symbol in the previously processed frame.

step

System object: `comm.FMModulator`
Package: `comm`

Applies FM baseband modulation

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` frequency modulates an input signal, `X`, and returns a modulated signal, `Y`. The input `X` is real or complex and can be either a scalar or a column vector. Double- and single-precision data types are supported. The output `Y` has the same data type and dimensions as `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

comm.FSKDemodulator

Package: comm

Demodulate using M-ary FSK method

Description

The FSKDemodulator object demodulates a signal that was modulated using the M-ary frequency shift keying method. The input is a baseband representation of the modulated signal. The input and output for this object are discrete-time signals.

To demodulate a signal that was modulated using frequency shift keying:

1. Define and set up your FSK demodulator object. See “Construction” on page 3-651.
2. Call step to demodulate a signal according to the properties of FSKDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.FSKDemodulator creates a demodulator System object, H. This object demodulates an M-ary frequency shift keying (M-FSK) signal using a noncoherent energy detector.

H = comm.FSKDemodulator(Name,Value) creates an M-FSK demodulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.FSKDemodulator(M,FREQSEP,RS,Name,Value) creates an M-FSK demodulator object, H. This object has the ModulationOrder property set to M, the FrequencySeparation property set to FREQSEP, the SymbolRate property set to RS, and the other specified properties set to the specified values.

Properties

ModulationOrder

Number of frequencies in modulated signal

Specify the number of frequencies in the modulated signal as a numeric, positive, integer scalar value that is a power of two. The default is 8.

BitOutput

Output data as bits

Specify whether the output is groups of bits or integer values. The default is false.

When you set this property to `false`, the `step` method outputs a column vector of length equal to *N*/ `SamplesPerSymbol` on page 3-0 . *N* is the length of the input data vector to the step method. The elements of the output vector are integers between `0` and `ModulationOrder` on page 3-0 –1. When you set this property to `true`, the `step` method outputs a column vector of length equal to **log2**(`ModulationOrder`)×(*N*/`SamplesPerSymbol`). The property's elements are bit representations of integers between `0` and `ModulationOrder`–1.

`SymbolMapping`

Symbol encoding

Specify how the object maps an integer or group of **log2**(`ModulationOrder` on page 3-0) bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`.

When you set this property to `Gray`, the object uses Gray-coded ordering.

When you set this property to `Binary`, the object uses natural binary-coded ordering.

For either type of mapping, the object maps the lowest frequency to the integer 0 and maps the highest frequency to the integer *M*–1. In baseband simulation, the lowest frequency is the negative frequency with the largest absolute value.

`FrequencySeparation`

Frequency separation between successive tones

Specify the frequency separation between successive symbols in the modulated signal in Hertz as a positive, real scalar value. The default is `6` Hz.

`SamplesPerSymbol`

Number of samples per input symbol

Specify the number of samples per input symbol as a positive, integer scalar value. The default is `17`.

`SymbolRate`

Symbol duration

Specify the symbol rate in symbols per second as a positive, double-precision, real scalar value. The default is `100`. To avoid output signal aliasing, specify an output sampling rate, *Fs* = `SamplesPerSymbol` on page 3-0 ×`SymbolRate`, which is greater than `ModulationOrder` on page 3-0 × `FrequencySeparation` on page 3-0 . The symbol duration remain the same, regardless of whether the input is bits or integers.

`OutputDataType`

Data type of output

Specify the output data type as one of `logical` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `double`. The default is `double`. The `logical` type is valid only when you set the `BitOutput` on page 3-0 property to false and the `ModulationOrder` on page 3-0 property to two. When you set the `BitOutput` property to true, the output data requires a type of `logical` | `double`.

Methods

reset	Reset states of M-FSK demodulator object
step	Demodulate using M-ary FSK method

Common to All System Objects	
`release`	Allow System object property value changes

Examples

FSK Modulation and Demodulation in AWGN

Modulate and demodulate a signal using 8-FSK modulation with a frequency separation of 100 Hz.

Set the modulation order and frequency separation parameters.

```
M = 8;
freqSep = 100;
```

Create FSK modulator and demodulator System objects™ with modulation order 8 and 100 Hz frequency separation.

```
fskMod = comm.FSKModulator(M,freqSep);
fskDemod = comm.FSKDemodulator(M,freqSep);
```

Create an additive white Gaussian noise channel, where the noise is specified as a signal-to-noise ratio.

```
ch = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)','SNR',-2);
```

Create an error rate calculator object.

```
err = comm.ErrorRate;
```

Transmit one hundred 50-symbol frames using 8-FSK in an AWGN channel.

```
for counter = 1:100
    data = randi([0 M-1],50,1);
    modSignal = step(fskMod,data);
    noisySignal = step(ch,modSignal);
    receivedData = step(fskDemod,noisySignal);
    errorStats = step(err,data,receivedData);
end
```

Display the error statistics.

```
es = 'Error rate = %4.2e\nNumber of errors = %d\nNumber of symbols = %d\n';
fprintf(es,errorStats)
```

```
Error rate = 1.40e-02
Number of errors = 70
Number of symbols = 5000
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the M-FSK Demodulator Baseband block reference page. The object properties correspond to the block parameters, except:

- The **Symbol set ordering** parameter corresponds to the `SymbolMapping` on page 3-0 property.
- The `SymbolRate` on page 3-0 property replaces the block sample rate capability.

Introduced in R2012a

reset

System object: `comm.FSKDemodulator`
Package: `comm`

Reset states of M-FSK demodulator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `FSKDemodulator` object, `H`.

step

System object: `comm.FSKDemodulator`
Package: `comm`

Demodulate using M-ary FSK method

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates input data, `X`, with the FSK demodulator System object, `H`, and returns `Y`. `X` must be a double or single precision data type column vector of length equal to an integer multiple of the number of samples per symbol that you specify in the `SamplesPerSymbol` property. Depending on the `BitOutput` property value, output `Y` can be integer or bit valued.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.FSKModulator

Package: `comm`

Modulate using M-ary FSK method

Description

The `FSKModulator` object modulates using the M-ary frequency shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using frequency shift keying:

1. Define and set up your FSK modulator object. See “Construction” on page 3-657.
2. Call `step` to modulate a signal according to the properties of `comm.FSKModulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.FSKModulator` creates a modulator System object, `H`. This object modulates the input signal using the M-ary frequency shift keying (M-FSK) method.

`H = comm.FSKModulator(Name,Value)` creates an M-FSK modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.FSKModulator(M,FREQSEP,RS,Name,Value)` creates an M-FSK modulator object, `H`. This object has the `ModulationOrder` property set to `M`, the `FrequencySeparation` property set to `FREQSEP`, the `SymbolRate` property set to `RS`, and the other specified properties set to the specified values.

Properties

`ModulationOrder`

Number of frequencies in modulated signal

Specify the number of frequencies in the modulated signal as a numeric positive integer scalar value that is a power of two. The default is `8`.

`BitInput`

Assume bit inputs

Specify whether the input is bits or integers. The default is `false`.

When you set this property to `false`, the `step` method input requires a numeric (except single precision data type) column vector of integer values between `0` and `ModulationOrder` on page 3-0 –1. In this case, the input vector can also be of data type logical if `ModulationOrder` equals `2`.

When you set this property to `true`, the `step` method input requires a double-precision or logical data type column vector of bit values. The length of this vector is an integer multiple of **log2**(`ModulationOrder`). This vector contains bit representations of integers between `0` and `ModulationOrder`–1.

SymbolMapping

Symbol encoding

Specify how the object maps an integer or group of **log2**(`ModulationOrder` on page 3-0) bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`.

When you set this property to `Gray`, the object uses Gray-coded ordering.

When you set this property to `Binary`, the object uses natural binary-coded ordering. For either type of mapping, the object maps the lowest frequency to the integer 0 and maps the highest frequency to the integer *M*–1. In baseband simulation, the lowest frequency is the negative frequency with the largest absolute value.

FrequencySeparation

Frequency separation between successive tones

Specify the frequency separation between successive tones in the modulated signal in Hertz as a positive, real scalar value. The default is `6` Hz. To avoid output signal aliasing, specify an output sampling rate, *Fs* = `SamplesPerSymbol` on page 3-0 ×`SymbolRate` on page 3-0 , which is greater than `ModulationOrder` on page 3-0 multiplied by `FrequencySeparation` on page 3-0 .

ContinuousPhase

Phase continuity

Specify if the phase of the output modulated signal is continuous or discontinuous. The default is `true`.

When you set this property to `true`, the modulated signal maintains continuous phase even when its frequency changes.

When you set this property to `false`, the modulated signal comprises portions of `ModulationOrder` on page 3-0 sinusoids of different frequencies. In this case, a change in the input value can cause a discontinuous change in the phase of the modulated signal.

SamplesPerSymbol

Number of samples per output symbol

Specify the number of output samples that the object produces for each integer or binary word in the input as a positive, integer scalar value. The default is `17`.

SymbolRate

Symbol duration

Specify the symbol rate in symbols per second as a positive, double-precision, real scalar. The default is `100`. To avoid output signal aliasing, specify an output sampling rate, *Fs* = `SamplesPerSymbol` on page 3-0 ×`SymbolRate`, which is greater than `ModulationOrder` on page 3-0 × `FrequencySeparation` on page 3-0 . The symbol duration remain the same, regardless of whether the input is bits or integers.

OutputDataType

Data type of output

Specify the output data type as one of `double` | `single`. The default is `double`.

Methods

reset	Reset states of M-FSK modulator object
step	Modulate using M-ary FSK method

Common to All System Objects	
`release`	Allow System object property value changes

Examples

FSK Modulation and Demodulation in AWGN

Modulate and demodulate a signal using 8-FSK modulation with a frequency separation of 100 Hz.

Set the modulation order and frequency separation parameters.

```
M = 8;
freqSep = 100;
```

Create FSK modulator and demodulator System objects™ with modulation order 8 and 100 Hz frequency separation.

```
fskMod = comm.FSKModulator(M,freqSep);
fskDemod = comm.FSKDemodulator(M,freqSep);
```

Create an additive white Gaussian noise channel, where the noise is specified as a signal-to-noise ratio.

```
ch = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)','SNR',-2);
```

Create an error rate calculator object.

```
err = comm.ErrorRate;
```

Transmit one hundred 50-symbol frames using 8-FSK in an AWGN channel.

```
for counter = 1:100
    data = randi([0 M-1],50,1);
    modSignal = step(fskMod,data);
    noisySignal = step(ch,modSignal);
    receivedData = step(fskDemod,noisySignal);
    errorStats = step(err,data,receivedData);
end
```

Display the error statistics.

```
es = 'Error rate = %4.2e\nNumber of errors = %d\nNumber of symbols = %d\n';
fprintf(es,errorStats)
```

```
Error rate = 1.40e-02
Number of errors = 70
Number of symbols = 5000
```

Visualize FSK Modulated Symbol Mapping

Visualize symbol mapping of an FSK modulated signal with a spectrogram.

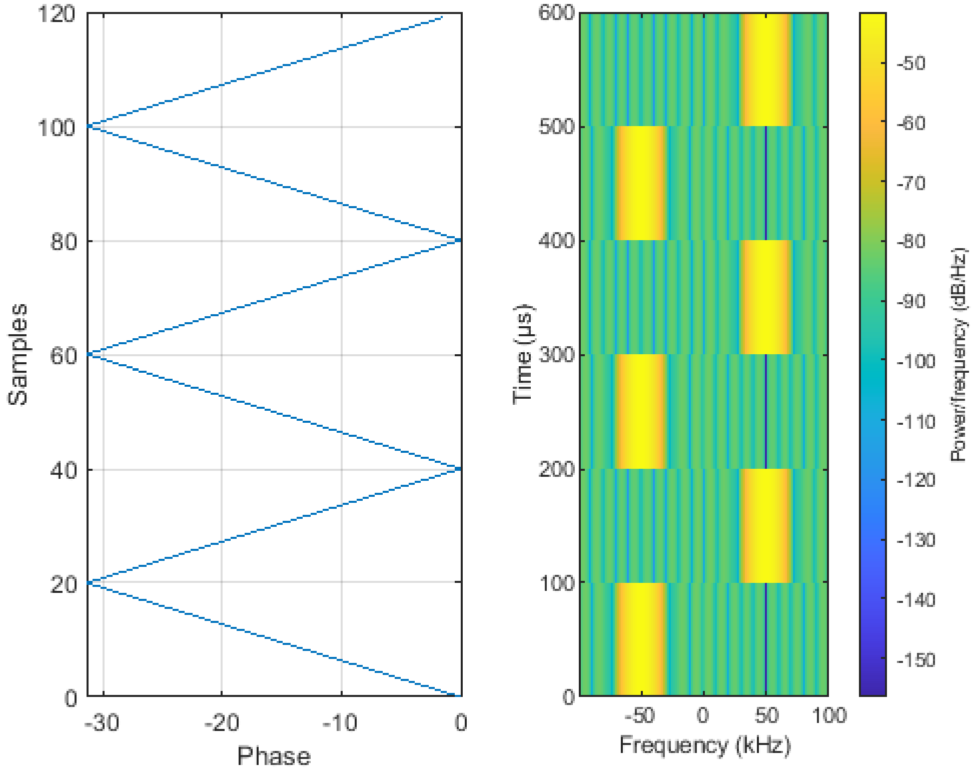
Specify 20 samples for each symbol. 0 maps to -50 kHz (negative phase slope) and 1 maps to +50 kHz (positive phase slope).

```
mod = comm.FSKModulator;
mod.ModulationOrder = 2;
mod.FrequencySeparation = 100000;
mod.SamplesPerSymbol = 20;
mod.SymbolMapping = 'Gray';
mod.SymbolRate = 1e4
```

```
mod = 
  comm.FSKModulator with properties:

        ModulationOrder: 2
               BitInput: false
          SymbolMapping: 'Gray'
    FrequencySeparation: 100000
        ContinuousPhase: true
       SamplesPerSymbol: 20
             SymbolRate: 10000
         OutputDataType: 'double'
```

```
x = mod([0 1 0 1 0 1]');
figure; subplot(1,2,1); plot(unwrap(angle(x)),0:length(x)-1);
grid on; xlabel('Phase'); ylabel('Samples')
subplot(1,2,2);
spectrogram(x,20,0,[],mod.SymbolRate*mod.SamplesPerSymbol,'centered')
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the M-FSK Modulator Baseband block reference page. The object properties correspond to the block parameters, except:

- The **Symbol set ordering** parameter corresponds to the `SymbolMapping` on page 3-0 property.
- The `SymbolRate` on page 3-0 property takes the place of the block sample rate capability.

`comm.CPFSKModulator` | `comm.FSKDemodulator`

Introduced in R2012a

reset

System object: `comm.FSKModulator`
Package: `comm`

Reset states of M-FSK modulator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `FSKModulator` object, `H`.

step

System object: `comm.FSKModulator`
Package: `comm`

Modulate using M-ary FSK method

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` modulates input data, `X`, with the FSK modulator System object, `H`. It returns the baseband modulated output, `Y`. Depending on the value of the `BitInput` property, input `X` can be an integer or bit- valued column vector with numeric or logical data types. The length of output vector, `Y`, is equal to the number of input samples times the number of samples per symbol you specify in the `SamplesPerSymbol` property.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.GeneralQAMDemodulator

Package: `comm`

Demodulate using arbitrary QAM constellation

Description

The `GeneralQAMDemodulator` object demodulates a signal that was modulated using quadrature amplitude modulation. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using quadrature amplitude modulation:

1. Define and set up your QAM demodulator object. See “Construction” on page 3-664.
2. Call `step` to demodulate a signal according to the properties of `comm.GeneralQAMModulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.GeneralQAMDemodulator` creates a demodulator System object, `H`. This object demodulates the input signal using a general quadrature amplitude modulation (QAM) method.

`H = comm.GeneralQAMDemodulator(Name,Value)` creates a general QAM demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.GeneralQAMDemodulator(CONST,Name,Value)` creates a general QAM demodulator object, `H`. This object has the `Constellation` property set to `CONST`, and the other specified properties set to the specified values.

Properties

`Constellation`

Signal constellation

Specify the constellation points as a real or complex, double-precision data type vector. The default is $\mathbf{exp}(2 \times \pi \times 1i \times {}^{(0:7)}\!/_{8})$. The length of the vector determines the modulation order.

When you set the `BitOutput` on page 3-0 property to `false`, the `step` method outputs a vector with integer values. These integers are between `0` and M–1, where M is the length of this property vector. The length of the output vector equals the length of the input signal.

When you set the `BitOutput` property to `true`, the output signal contains bits. For bit outputs, the size of the signal constellation requires an integer power of two and the output length is an integer multiple of the number of bits per symbol.

`BitOutput`

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. The default is `false`.

When you set this property to `true` the `step` method outputs a column vector of bit values with length equal to **log2**(*M*) times the number of demodulated symbols, where *M* is the length of the signal constellation specified in the `Constellation` on page 3-0 property. The length *M* determines the modulation order.

When you set this property to `false`, the `step` method outputs a column vector, of length equal to the input data vector. The vector contains integer symbol values between `0` and *M*–1.

`DecisionMethod`

Demodulation decision method

Specify the decision method the object uses as one of `Hard decision` | `Log-likelihood ratio` | `Approximate log-likelihood ratio`. The default is `Hard decision`. When you set the `BitOutput` on page 3-0 property to false the object always performs hard decision demodulation. This property applies when you set the `BitOutput` property to true.

`VarianceSource`

Source of noise variance

Specify the source of the noise variance as one of `Property` | `Input port`. The default is `Property`. This property applies when you set the `DecisionMethod` on page 3-0 property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`.

`Variance`

Noise variance

Specify the variance of the noise as a nonzero, real scalar value. The default is `1`. If this value is very small (i.e., SNR is very high), log-likelihood ratio (LLR) computations may yield Inf or -Inf. This result occurs because the LLR algorithm would compute the exponential of very large or very small numbers using finite-precision arithmetic. In such cases, using approximate LLR is recommended because its algorithm does not compute exponentials. This property applies when you set the `VarianceSource` on page 3-0 property to `Property`. This property is tunable.

`OutputDataType`

Data type of output

Specify the output data type as one of `Full precision` | `Smallest unsigned integer` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`. The default is `Full precision` .

This property applies only when you set the `BitOutput` on page 3-0 property to `false` or when you set the `BitOutput` property to `true` and the `DecisionMethod` on page 3-0 property to `Hard` decision or Approximate log-likelihood ratio. In this case, when you set the OutputDataType on page 3-0 property to Full precision, the output data type is the same as that of the input when the input data has a single or double-precision data type.

When the input data is of a fixed-point type, the output data type works as if you had set the OutputDataType property to Smallest unsigned integer.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in Smallest unsigned integer or Full precision mode.

When you set the BitOutput property to true, and the DecisionMethod property to Hard Decision the data type logical becomes a valid option.

When you set the BitOutput property to true and the DecisionMethod property to Approximate log-likelihood ratio you may only set this property to Full precision | Custom.

If you set the BitOutput property to true and the DecisionMethod property to Log-likelihood ratio, the output data has the same type as that of the input. In this case, that value can be only single or double precision.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set FullPrecisionOverride to true, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set FullPrecisionOverride to false, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects” on page 3-670.

RoundingMethod

Rounding of fixed-point numeric values

Specify the rounding method as one of Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero. The default is Floor. This property applies when the object is not in a full precision configuration. This property does not apply when you set BitOutput on page 3-0 to true and DecisionMethod on page 3-0 to Log-likelihood ratio.

OverflowAction

Action when fixed-point numeric values overflow

Specify the overflow action as one of Wrap | Saturate. The default is Wrap. This property applies when the object is not in a full precision configuration. This property does not apply when you set the BitOutput on page 3-0 property to true and the DecisionMethod on page 3-0 property to Log-likelihood ratio.

ConstellationDataType

Data type of signal constellation

Specify the constellation fixed-point data type as one of `Same word length as input` | `Custom`. The default is `Same word length as input`. This property does not apply when you set the `BitOutput` on page 3-0 property to true and the `DecisionMethod` on page 3-0 property to `Log-likelihood ratio`.

`CustomConstellationDataType`

Fixed-point data type of signal constellation

Specify the constellation fixed-point type as an unscaled `numerictype` object with a Signedness of Auto. The default is `numerictype([],16)`. This property applies when you set the `ConstellationDataType` on page 3-0 property to `Custom`.

`Accumulator1DataType`

Data type of accumulator 1

Specify the accumulator 1 fixed-point data type as one of `Full precision` | `Custom`. The default is `Full precision`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false. This property does not apply when you set the `BitOutput` on page 3-0 property to true and the `DecisionMethod` on page 3-0 property to `Log-likelihood ratio`.

`CustomAccumulator1DataType`

Fixed-point data type of accumulator 1

Specify the accumulator 1 fixed-point type as a scaled `numerictype` object with a Signedness of Auto. The default is `numerictype([],32,30)`. This property applies when you set the `Accumulator1DataType` on page 3-0 property to `Custom`.

`ProductInputDataType`

Data type of product

Specify the product input fixed-point data type as one of `Same as accumulator 1` | `Custom`. The default is `Same as accumulator 1`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false, the `BitOutput` on page 3-0 property to true and the `DecisionMethod` on page 3-0 property to `Log-likelihood ratio`.

`CustomProductInputDataType`

Fixed-point data type of product

Specify the product input fixed-point type as a scaled `numerictype` object with a Signedness of Auto. The default is `numerictype([],32,30)`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false and the `ProductInputDataType` on page 3-0 property to `Custom`.

`ProductOutputDataType`

Data type of product output

Specify the product output fixed-point data type as one of `Full precision` | `Custom`. The default is `Full precision` . This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false, the `BitOutput` on page 3-0 property to true and the `DecisionMethod` on page 3-0 property to `Log-likelihood ratio`.

CustomProductOutputDataType

Fixed-point data type of product output

Specify the product output fixed-point type as a scaled numerictype object with a Signedness of Auto. The default is numerictype([],32,30). This property applies when you set the FullPrecisionOverride on page 3-0 property to false and the ProductOutputDataType on page 3-0 property to Custom.

Accumulator2DataType

Data type of accumulator 2

Specify the accumulator 2 fixed-point data type as one of Full precision | Custom. The default is Full precision . This property applies when you set the FullPrecisionOverride on page 3-0 property to false, the BitOutput on page 3-0 property to true and the DecisionMethod on page 3-0 property to Log-likelihood ratio.

CustomAccumulator2DataType

Fixed-point data type accumulator 2

Specify the accumulator 2 fixed-point data type as a scaled numerictype object with a Signedness of Auto. The default is numerictype([],32,30). This property applies when you set the FullPrecisionOverride on page 3-0 property to false and the Accumulator2DataType on page 3-0 property to Custom.

Accumulator3DataType

Data type of accumulator 3

Specify the accumulator 3 fixed-point data type as one of Full precision | Custom. The default is Full precision . This property applies when you set the FullPrecisionOverride on page 3-0 property to false, the BitOutput on page 3-0 property to true and the DecisionMethod on page 3-0 property to Approximate log-likelihood ratio.

CustomAccumulator3DataType

Fixed-point data type of accumulator 3

Specify the accumulator 3 fixed-point type as a scaled numerictype object with a Signedness of Auto. The default is numerictype([],32,30). This property applies when you set the FullPrecisionOverride on page 3-0 property to false and the Accumulator3DataType on page 3-0 property to Custom.

NoiseScalingInputDataType

Data type of noise-scaling input

Specify the noise-scaling input fixed-point data type as one of Same as accumulator 3 | Custom. The default is Same as accumulator 3. This property applies when you set the FullPrecisionOverride on page 3-0 property to false, the BitOutput on page 3-0 property to true and the DecisionMethod on page 3-0 property to Approximate log-likelihood ratio.

CustomNoiseScalingInputDataType

Fixed-point data type of noise-scaling input

Specify the noise-scaling input fixed-point type as a scaled `numerictype` object with a Signedness of Auto. The default is `numerictype([],32,30)`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false and the `NoiseScalingInputDataType` on page 3-0 property to `Custom`.

InverseVarianceDataType

Data type of inverse noise variance

Specify the inverse noise variance fixed-point data type as one of `Same word length as input` | `Custom`. The default is `Same word length as input`. This property applies when you set the `BitOutput` on page 3-0 property to true, the `DecisionMethod` on page 3-0 property to `Approximate log-likelihood ratio`, and the `VarianceSource` on page 3-0 property to `Property`.

CustomInverseVarianceDataType

Fixed-point data type of inverse noise variance

Specify the inverse noise variance fixed-point type as a `numerictype` object with a Signedness of Auto. The default is `numerictype([],16,8)`. This property applies when you set the `InverseVarianceDataType` on page 3-0 property to `Custom`.

CustomOutputDataType

Data type of output

Specify the output fixed-point type as a scaled `numerictype` object with a Signedness of Auto. The default is `numerictype([],32,30)`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false and the `OutputDataType` on page 3-0 property to `Custom`.

Methods

step	Demodulate using arbitrary QAM constellation

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Modulate and demodulate data using an arbitrary three-point constellation.

```
% Setup a three point constellation
c = [1 1i -1];
hQAMMod = comm.GeneralQAMModulator(c);
hAWGN = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)','SNR',15,'SignalPower',0.89);
hQAMDemod = comm.GeneralQAMDemodulator(c);
```

```
%Create an error rate calculator
hError = comm.ErrorRate;
for counter = 1:100
    % Transmit a 50-symbol frame
    data = randi([0 2],50,1);
    modSignal = step(hQAMMod, data);
    noisySignal = step(hAWGN, modSignal);
    receivedData = step(hQAMDemod, noisySignal);
    errorStats = step(hError, data, receivedData);
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
     errorStats(1), errorStats(2))
```

More About

Full Precision for Fixed-Point System Objects

`FullPrecisionOverride` is a convenience property that, when you set to `true`, automatically sets the appropriate properties for an object to use full-precision to process fixed-point input.

For System objects, full precision, fixed-point operation refers to growing just enough additional bits to compute the ideal full precision result. This operation has no minimum or maximum range overflow nor any precision loss due to rounding or underflow. It is also independent of any hardware-specific settings. The data types chosen are based only on known data type ranges and not on actual numeric values. Full precision for System objects does not optimize coefficient values. When you set the `FullPrecisionOverride` property to `true`, the other fixed-point properties it controls no longer apply and any of their non-default values are ignored. These properties are also hidden. To specify individual fixed-point properties, first set `FullPrecisionOverride` to `false`.

Algorithms

This object implements the algorithm, inputs, and outputs described on the General QAM Demodulator Baseband block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Objects

`comm.GeneralQAMModulator` | `comm.RectangularQAMDemodulator`

Introduced in R2012a

step

System object: `comm.GeneralQAMDemodulator`
Package: `comm`

Demodulate using arbitrary QAM constellation

Syntax

```
Y = step(H,X)
Y = step(H,X,VAR)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates the input data, `X`, with the general QAM demodulator System object, `H`, and returns `Y`. Input `X` must be a scalar or a column vector with double or single precision data type. When you set the `BitOutput` property to true and the `DecisionMethod` property to 'Log-likelihood ratio' the input data type must be single or double precision. Depending on the `BitOutput` property value, output `Y` can be integer or bit valued.

`Y = step(H,X,VAR)` uses soft decision demodulation and noise variance `VAR`. This syntax applies when you set the `BitOutput` property to true, the `DecisionMethod` property to `Approximate log-likelihood ratio` or `Log-likelihood ratio`, and the `VarianceSource` property to 'Input port'.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.GeneralQAMModulator

Package: `comm`

Modulate using arbitrary QAM constellation

Description

The `GeneralQAMModulator` object modulates using quadrature amplitude modulation. The output is a baseband representation of the modulated signal.

To modulate a signal using quadrature amplitude modulation:

1. Define and set up your QAM modulator object. See "Construction" on page 3-673.
2. Call `step` to modulate a signal according to the properties of `comm.GeneralQAMModulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.GeneralQAMModulator` creates a modulator System object, `H`. This object modulates the input signal using a general quadrature amplitude modulation (QAM) method.

`H = comm.GeneralQAMModulator(Name,Value)` creates a QAM modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.GeneralQAMModulator(CONST,Name,Value)` creates a General QAM modulator object, `H`. This object has the `Constellation` property set to `CONST`, and the other specified properties set to the specified values.

Properties

`Constellation`

Signal constellation

Specify the constellation points as a vector of real or complex double-precision data type. The default is $\mathbf{exp}(2 \times \pi \times 1i \times {}^{(0:7)}\!/\!_{8})$. The length of the vector determines the modulation order. The `step` method inputs requires integers between 0 and M–1, where M indicates the length of this property vector. The object maps an input integer m to the $(m+1)^{st}$ value in the Constellation vector.

`OutputDataType`

Data type of output

Specify the output data type as one of `double` | `single` | `Custom`. The default is `double`.

Fixed-Point Properties

`CustomOutputDataType`

Fixed-point data type of output

Specify the output fixed-point type as a `numerictype` object with a signedness of Auto. The default is `numerictype([],16)`. This property applies when you set the `OutputDataType` on page 3-0 property to `Custom`.

Methods

step	Modulate using arbitrary QAM constellation

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Modulate data using an arbitrary 3-point constellation. Then, visualize the data in a scatter plot

```
     hQAMMod = comm.GeneralQAMModulator;
% Setup a three point constellation
     hQAMMod.Constellation = [1 1i -1];
     data = randi([0 2],100,1);
     modData = step(hQAMMod, data);
     scatterplot(modData)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the General QAM Modulator Baseband block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

comm.GeneralQAMTCMDemodulator

Package: comm

Demodulate convolutionally encoded data mapped to arbitrary QAM constellation

Description

The GeneralQAMTCMDemodulator object uses the Viterbi algorithm to decode a trellis-coded modulation (TCM) signal that was previously modulated using an arbitrary signal constellation.

To demodulate a signal that was modulated using a trellis-coded, general quadrature amplitude modulator:

1. Define and set up your general QAM TCM modulator object. See “Construction” on page 3-677.
2. Call step to demodulate a signal according to the properties of comm.GeneralQAMTCMDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.GeneralQAMTCMDemodulator creates a trellis-coded, general quadrature amplitude (QAM TCM) demodulator System object, H. This object demodulates convolutionally encoded data that has been mapped to an arbitrary QAM constellation.

H = comm.GeneralQAMTCMDemodulator(Name,Value) creates a general QAM TCM demodulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.GeneralQAMTCMDemodulator(TRELLIS,Name,Value) creates a general QAM TCM demodulator object, H. This object has the TrellisStructure property set to TRELLIS, and the other specified properties set to the specified values.

Properties

TrellisStructure

Trellis structure of convolutional code

Specify trellis as a MATLAB structure that contains the trellis description of the convolutional code. Use the istrellis function to check if a structure is a valid trellis structure. The default is the value that results from poly2trellis([1 3], [1 0 0; 0 5 2]).

TerminationMethod

Termination method of encoded frame

Specify the termination method as one of `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object saves the internal state metric at the end of each frame. The next frame uses the same state metric. The object treats each traceback path independently. If the input signal contains only one symbol, use `Continuous` mode.

When you set this property to `Truncated`, the object treats each input vector independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state.

When you set this property to `Terminated`, the object treats each input vector independently, and the traceback path always starts and ends in the all-zeros state.

`TracebackDepth`

Traceback depth for Viterbi decoder

Specify the scalar, integer number of trellis branches to construct each traceback path. The default is `21`. The Traceback depth parameter influences the decoding accuracy and delay. The decoding delay indicates the number of zero symbols that precede the first decoded symbol in the output.

When you set the `TerminationMethod` on page 3-0 property to `Continuous`, the decoding delay consists of `TracebackDepth` zero symbols or `TracebackDepth`×*K* zero bits for a rate *K*/*N* convolutional code.

When you set the `TerminationMethod` property to `Truncated` or `Terminated`, no output delay occurs and the traceback depth must be less than or equal to the number of symbols in each input vector.

`ResetInputPort`

Enable demodulator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this additional reset input is a nonzero value, the internal states of the encoder reset to their initial conditions. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous`.

`Constellation`

Signal constellation

Specify a double- or single-precision complex vector. This vector lists the points in the signal constellation that were used to map the convolutionally encoded data. The constellation must be specified in set-partitioned order. See documentation for the General TCM Encoder block for more information on set-partitioned order. The length of the constellation vector must equal the number of possible input symbols to the convolutional decoder of the general QAM TCM demodulator object. This corresponds to 2^N for a rate *K*/*N* convolutional code. The default corresponds to a set-partitioned order for the points of an 8-PSK signal constellation. This value is expressed as $\mathbf{exp}(2 \times \pi \times j \times [0\ 4\ 2\ 6\ 1\ 5\ 3\ 7]/8)$.

`OutputDataType`

Data type of output

Specify output data type as one of `logical` | `double`. The default is `double`.

Methods

reset	Reset states of the general QAM TCM demodulator object
step	Demodulate convolutionally encoded data mapped to arbitrary QAM constellation

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Modulate and Demodulate Data Using QAM TCM

Modulate and demodulate noisy data using QAM TCM modulation with an arbitrary 4-point constellation. Estimate the resultant BER.

Define a trellis structure with two input symbols and four output symbols using a [171 133] generator polynomial. Define an arbitrary four-point constellation.

```
qamTrellis = poly2trellis(7,[171 133]);
refConst = exp(pi*1i*[1 2 3 6]/4);
```

Create a QAM TCM modulator and demodulator System object™ pair using `qamTrellis` and `refConst`.

```
hMod = comm.GeneralQAMTCMModulator(qamTrellis,'Constellation', refConst);
hDemod = comm.GeneralQAMTCMDemodulator(qamTrellis,'Constellation',refConst);
```

Create an AWGN channel object in which the noise is set by using a signal-to-noise ratio.

```
hAWGN = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (SNR)', ...
    'SNR',4);
```

Create an error rate calculator with delay (in bits) equal to the product of `TracebackDepth` and the number of bits per symbol

```
hError = comm.ErrorRate(...
    'ReceiveDelay', hDemod.TracebackDepth*log2(qamTrellis.numInputSymbols));
```

Generate random binary data and apply QAM TCM modulation. Pass the signal through an AWGN channel and demodulate. Collect the error statistics.

```
for counter = 1:10
    % Generate binary data
    data = randi([0 1],500,1);
    % Modulate
    modSignal = step(hMod,data);
    % Pass through an AWGN channel
    noisySignal = step(hAWGN,modSignal);
    % Demodulate
    receivedData = step(hDemod,noisySignal);
    % Calculate the error statistics
    errorStats = step(hError,data,receivedData);
end
```

Display the BER and the number of bit errors.

```
fprintf('Error rate = %5.2e\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

```
Error rate = 1.16e-02
Number of errors = 58
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the General TCM Decoder block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Introduced in R2012a

reset

System object: `comm.GeneralQAMTCMDemodulator`
Package: `comm`

Reset states of the general QAM TCM demodulator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `GeneralQAMTCMDemodulator` object, `H`.

step

System object: `comm.GeneralQAMTCMDemodulator`
Package: `comm`

Demodulate convolutionally encoded data mapped to arbitrary QAM constellation

Syntax

```
Y = step(H,X)
Y = step(H,X,R)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates the general QAM modulated input data, `X`, and uses the Viterbi algorithm to decode the resulting demodulated convolutionally encoded bits. `X` must be a complex double or single precision column vector. The `step` method outputs a demodulated binary column data vector, `Y`. When the convolutional encoder represents a rate *K*/*N* code, the length of the output vector equals *K*×*L*, where *L* is the length of the input vector, `X`.

`Y = step(H,X,R)` resets the decoder states of the general QAM TCM demodulator System object to the all-zeros state when you input a non-zero reset signal, `R`. `R` must be a double precision or logical scalar integer. This syntax applies when you set the `ResetInputPort` property to `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.GeneralQAMTCMModulator

Package: `comm`

Convolutionally encode binary data and map using arbitrary QAM constellation

Description

The `GeneralQAMTCMModulator` object implements trellis-coded modulation (TCM) by convolutionally encoding the binary input signal. The object then maps the result to an arbitrary signal constellation. The Signal constellation property lists the signal constellation points in set-partitioned order.

To modulate a signal using a trellis-coded, general quadrature amplitude modulator:

1. Define and set up your general QAM TCM modulator object. See “Construction” on page 3-683.
2. Call `step` to modulate a signal according to the properties of `comm.GeneralQAMTCMModulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.GeneralQAMTCMModulator` creates a trellis-coded, general quadrature amplitude (QAM TCM) modulator System object, `H`. This object convolutionally encodes a binary input signal and maps the result using QAM modulation with a signal constellation specified in the Constellation property.

`H = comm.GeneralQAMTCMModulator(Name,Value)` creates a general QAM TCM modulator System object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.GeneralQAMTCMModulator(TRELLIS,Name,Value)` creates a general QAM TCM modulator System object, `H`. This object has the `TrellisStructure` property set to `TRELLIS`, and the other specified properties set to the specified values.

Properties

`TrellisStructure`

Trellis structure of convolutional code

Specify trellis as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check if a structure is a valid trellis structure. The default is the result of `poly2trellis([1 3], [1 0 0; 0 5 2])`.

TerminationMethod

Termination method of encoded frame

Specify the termination method as one of `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object retains the encoder states at the end of each input vector for use with the next input vector.

When you set this property to `Truncated`, the object treats each input vector independently. The encoder is reset to the all-zeros state at the start of each input vector.

When you set this property to `Terminated`, the object treats each input vector independently. For each input vector, the object uses extra bits to set the encoder to the all-zeros state at the end of the vector. For a rate K/N code, the `step` method outputs the vector with length $y = N \times {}^{(L + S)}\!/_{K}$, where $S = \mathit{constraintLength}–1$. In the case of multiple constraint lengths, $S = \mathbf{sum}(\mathit{constraintLength}(i)–1))$. L represents the length of the input to the `step` method.

ResetInputPort

Enable modulator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this additional reset input is a nonzero value, the internal states of the encoder reset to their initial conditions. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous`.

Constellation

Signal constellation

Specify a double- or single-precision complex vector that lists the points in the signal constellation that were used to map the convolutionally encoded data. You must specify the constellation in set-partitioned order. See documentation for the General TCM Encoder block for more information on set-partitioned order. The length of the constellation vector must equal the number of possible input symbols to the convolutional decoder of the general QAM TCM demodulator object. This corresponds to 2^N for a rate K/N convolutional code. The default corresponds to a set-partitioned order for the points of an 8-PSK signal constellation. This value is expressed $\mathbf{exp}(2 \times \pi \times j \times {}^{[0\ 4\ 2\ 6\ 1\ 5\ 3\ 7]}\!/_{8})$.

OutputDataType

Data type of output

Specify the output data type as one of `double` | `single`. The default is `double`.

Methods

reset	Reset states of the general QAM TCM modulator object
step	Convolutionally encode binary data and map using arbitrary QAM constellation

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Modulate Data using QAM TCM with an Arbitrary Constellation

Modulate data using QAM TCM modulation with an arbitrary 4-point constellation. Display a scatter plot of the modulated data.

Create binary data.

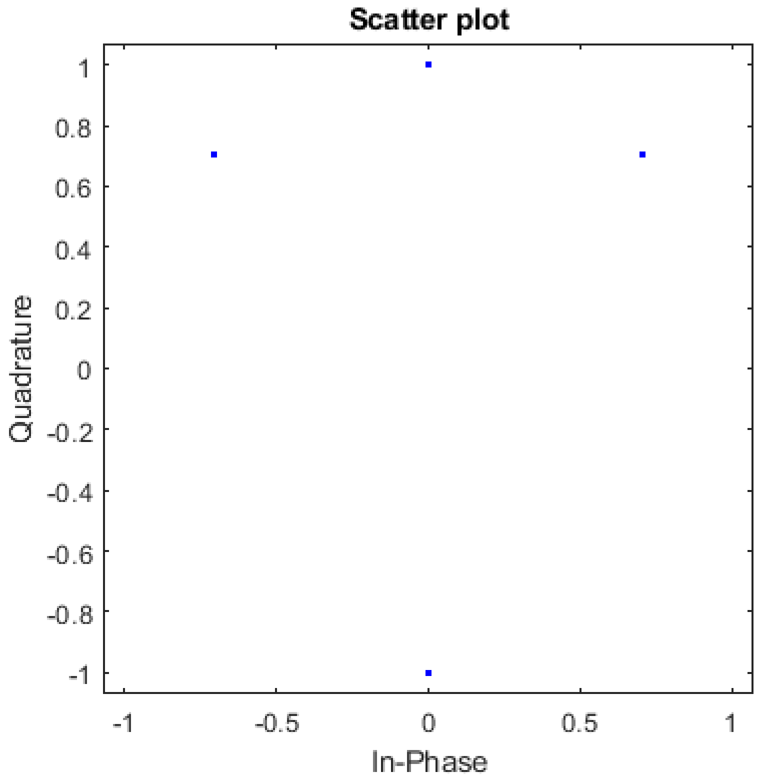
```
data = randi([0 1],1000,1);
```

Use the trellis structure with generating polynomial [171 133] and 4-point arbitrary constellation $\{ e^{j\pi/4}, e^{j\pi/2}, e^{j3\pi/4}, e^{j3\pi/2} \}$ to perform QAM TCM modulation.

```
t = poly2trellis(7,[171 133]);
hMod = comm.GeneralQAMTCMModulator(t,...
    'Constellation',exp(pi*1i*[1 2 3 6]/4));
```

Modulate and plot the data.

```
modData = step(hMod,data);
scatterplot(modData);
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the General TCM Encoder block reference page. The object properties correspond to the block parameters.

`comm.ConvolutionalEncoder` | `comm.GeneralQAMModulator` | `comm.GeneralQAMTCMDemodulator` | `comm.PSKTCMModulator`

Introduced in R2012a

reset

System object: `comm.GeneralQAMTCMModulator`
Package: `comm`

Reset states of the general QAM TCM modulator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `GeneralQAMTCMModulator` object, `H`.

step

System object: comm.GeneralQAMTCMModulator
Package: comm

Convolutionally encode binary data and map using arbitrary QAM constellation

Syntax

```
Y = step(H,X)
Y = step(H,X,R)
```

Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Y = step(H,X) convolutionally encodes and modulates the input data, X, and returns the encoded and modulated data, Y. X must be of data type numeric, logical, or unsigned fixed point of word length 1 (fi object). When the convolutional encoder represents a rate *K*/*N* code, the length of the input vector, X, must be *K*×*L*, for some positive integer *L*. The step method outputs a complex column vector, Y, of length *L*.

Y = step(H,X,R) resets the encoder of the general QAM TCM modulator object to the all-zeros state when you input a non-zero reset signal, R. R must be a double precision or logical scalar integer. This syntax applies when you set the ResetInputPort property to true.

Note obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

comm.GMSKDemodulator

Package: comm

Demodulate using GMSK method and the Viterbi algorithm

Description

The GMSKDemodulator object uses a Viterbi algorithm to demodulate a signal that was modulated using the Gaussian minimum shift keying method. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using Gaussian minimum shift keying:

1. Define and set up your GMSK demodulator object. See “Construction” on page 3-651.
2. Call step to demodulate a signal according to the properties of GMSKDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.GMSKDemodulator creates a demodulator System object, H. This object demodulates the input Gaussian minimum shift keying (GMSK) modulated data using the Viterbi algorithm.

H = comm.GMSKDemodulator(Name,Value) creates a GMSK demodulator object, H. This object has each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

BitOutput

Output data as bits

Specify whether the output is groups of bits or integer values. The default is false.

When you set the BitOutput on page 3-0 property to false, the step method outputs a column vector of length equal to *N*/SamplesPerSymbol on page 3-0 . *N* is the length of the input signal, which is the number of input baseband modulated symbols. The elements of the output vector are –1 or 1.

When you set the BitOutput property to true, the step method outputs a binary column vector of length equal to *N*/SamplesPerSymbol with bit values of 0 or 1.

BandwidthTimeProduct

Product of bandwidth and symbol time of Gaussian pulse

Specify the product of bandwidth and symbol time for the Gaussian pulse shape as a real, positive scalar. The default 0.3.

PulseLength

Pulse length

Specify the length of the Gaussian pulse shape in symbol intervals as a real positive integer. The default 4.

SymbolPrehistory

Symbol prehistory

Specify the data symbols used by the modulator prior to the first call to the step method. The default is 1. This property requires a scalar or vector with elements equal to -1 or 1. If the value is a vector, its length must be one less than the value you set in the PulseLength on page 3-0 property.

InitialPhaseOffset

Initial phase offset

Specify the initial phase offset of the input modulated waveform in radians as a real, numeric scalar value. The default is 0.

SamplesPerSymbol

Number of samples per input symbol

Specify the expected number of samples per input symbol as a positive, integer scalar value. The default is 8.

TracebackDepth

Traceback depth for Viterbi algorithm

Specify the number of trellis branches that the Viterbi algorithm uses to construct each traceback path as a positive, integer scalar value. The value of this property is also the output delay, and the number of zero symbols that precede the first meaningful demodulated symbol in the output. The default is 16.

OutputDataType

Data type of output

Specify the output data type as one of int8 | int16 | int32 | double, when you set the BitOutput on page 3-0 property to false.

When you set the BitOutput property to true, specify the output data type as one of logical | double. The default is double.

Methods

reset	Reset states of the GMSK demodulator object
step	Demodulate using GMSK method and the Viterbi algorithm

Common to All System Objects	
release	Allow System object property value changes

Examples

Demodulate a GMSK signal with bit inputs and phase offset

```
% Create a GMSK modulator, an AWGN channel, and a GMSK demodulator. Use a phase offset of pi/4.
    hMod = comm.GMSKModulator('BitInput', true, 'InitialPhaseOffset', pi/4);
    hAWGN = comm.AWGNChannel('NoiseMethod', ...
                    'Signal to noise ratio (SNR)','SNR',0);
    hDemod = comm.GMSKDemodulator('BitOutput', true, ...
                    'InitialPhaseOffset', pi/4);
% Create an error rate calculator, account for the delay caused by the Viterbi algorithm
    hError = comm.ErrorRate('ReceiveDelay', hDemod.TracebackDepth);
    for counter = 1:100
      % Transmit 100 3-bit words
      data = randi([0 1],300,1);
      modSignal = step(hMod, data);
      noisySignal = step(hAWGN, modSignal);
      receivedData = step(hDemod, noisySignal);
      errorStats = step(hError, data, receivedData);
    end
    fprintf('Error rate = %f\nNumber of errors = %d\n', ...
      errorStats(1), errorStats(2))
```

```
Error rate = 0.000133
Number of errors = 4
```

Map Binary Data to GMSK Signal

This example illustrates the mapping of binary sequences of zeros and ones to the output of a GMSK modulator. The relationship also applies for MSK modulation.

Create a GMSK modulator that accepts binary inputs. Specify the pulse length and samples per symbol to be 1.

```
gmsk = comm.GMSKModulator('BitInput',true,'PulseLength',1,'SamplesPerSymbol',1);
```

Create an input sequence of all zeros. Modulate the sequence.

```
x = zeros(5,1);
y = gmsk(x)
```

```
y = 5×1 complex
```

```
   1.0000 + 0.0000i
  -0.0000 - 1.0000i
  -1.0000 + 0.0000i
   0.0000 + 1.0000i
   1.0000 - 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to better show the trend.

```
theta = unwrap(angle(y))
```

```
theta = 5×1

         0
   -1.5708
   -3.1416
   -4.7124
   -6.2832
```

A sequence of zeros causes the phase to shift by -π/2 between samples.

Reset the modulator. Modulate an input sequence of all ones.

```
reset(gmsk)
x = ones(5,1);
y = gmsk(x)
```

```
y = 5×1 complex

   1.0000 + 0.0000i
  -0.0000 + 1.0000i
  -1.0000 - 0.0000i
   0.0000 - 1.0000i
   1.0000 + 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to better show the trend.

```
theta = unwrap(angle(y))
```

```
theta = 5×1

         0
    1.5708
    3.1416
    4.7124
    6.2832
```

A sequence of ones causes the phase to shift by +π/2 between samples.

Algorithms

This object implements the algorithm, inputs, and outputs described on the GMSK Demodulator Baseband block reference page. The object properties correspond to the block parameters. For GMSK the phase shift per symbol is π/2, which is a modulation index of 0.5.

Extended Capabilities

`comm.CPMDemodulator` | `comm.CPMModulator` | `comm.GMSKModulator`

Introduced in R2012a

reset

System object: `comm.GMSKDemodulator`
Package: `comm`

Reset states of the GMSK demodulator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `GMSKDemodulator` object, `H`.

step

System object: `comm.GMSKDemodulator`
Package: `comm`

Demodulate using GMSK method and the Viterbi algorithm

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates input data, `X`, with the GMSK demodulator object, `H`, and returns `Y`. `X` must be a double or single precision column vector with a length equal to an integer multiple of the number of samples per symbol you specify in the `SamplesPerSymbol` property.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.GMSKModulator

Package: comm

Modulate using GMSK method

Description

The GMSKModulator object modulates using the Gaussian minimum shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using Gaussian minimum shift keying:

1 Define and set up your GMSK modulator object. See “Construction” on page 3-696.
2 Call step to modulate a signal according to the properties of comm.GMSKModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.GMSKModulator creates a modulator System object, H. This object modulates the input signal using the Gaussian minimum shift keying (GMSK) modulation method.

H = comm.GMSKModulator(Name,Value) creates a GMSK modulator object, H. This object has each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

BitInput

Assume input is bits

Specify whether the input is bits or integers. The default is false.

When you set the BitInput on page 3-0 property to false, the step method input requires a double-precision or signed integer data type column vector with values of -1 or 1.

When you set the BitInput property to true, step method input requires a double-precision or logical data type column vector of 0s and 1s.

BandwidthTimeProduct

Product of bandwidth and symbol time of Gaussian pulse

Specify the product of the bandwidth and symbol time for the Gaussian pulse shape as a real, positive scalar value. The default is 0.3.

PulseLength

Pulse length

Specify the length of the Gaussian pulse shape in symbol intervals as a real, positive integer. The default is `4`.

SymbolPrehistory

Symbol prehistory

Specify the data symbols the modulator uses prior to the first call to the `step` method in reverse chronological order. The default is `1`. This property requires a scalar or vector with elements equal to `-1` or `1`. If the value is a vector, then its length must be one less than the value in the `PulseLength` on page 3-0 property.

InitialPhaseOffset

Initial phase offset

Specify the initial phase of the modulated waveform in radians as a real, numeric scalar value. The default is `0`.

SamplesPerSymbol

Number of samples per output symbol

Specify the upsampling factor at the output as a real, positive, integer scalar value. The default is `8`. The upsampling factor is the number of output samples that the `step` method produces for each input sample.

OutputDataType

Data type of output

Specify output data type as one of `double` | `single`. The default is `double`.

Methods

reset	Reset states of the GMSK modulator object
step	Modulate using GMSK method

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Modulate a GMSK signal with bit inputs and phase offset

```
% Create a GMSK modulator, an AWGN channel, and a GMSK demodulator. Use a phase offset of pi/4.
    hMod = comm.GMSKModulator('BitInput', true, 'InitialPhaseOffset', pi/4);
    hAWGN = comm.AWGNChannel('NoiseMethod', ...
                    'Signal to noise ratio (SNR)','SNR',0);
    hDemod = comm.GMSKDemodulator('BitOutput', true, ...
                    'InitialPhaseOffset', pi/4);
% Create an error rate calculator, account for the delay caused by the Viterbi algorithm
    hError = comm.ErrorRate('ReceiveDelay', hDemod.TracebackDepth);
    for counter = 1:100
      % Transmit 100 3-bit words
      data = randi([0 1],300,1);
      modSignal = step(hMod, data);
      noisySignal = step(hAWGN, modSignal);
      receivedData = step(hDemod, noisySignal);
      errorStats = step(hError, data, receivedData);
    end
    fprintf('Error rate = %f\nNumber of errors = %d\n', ...
      errorStats(1), errorStats(2))
```

```
Error rate = 0.000133
Number of errors = 4
```

Map Binary Data to GMSK Signal

This example illustrates the mapping of binary sequences of zeros and ones to the output of a GMSK modulator. The relationship also applies for MSK modulation.

Create a GMSK modulator that accepts binary inputs. Specify the pulse length and samples per symbol to be 1.

```
gmsk = comm.GMSKModulator('BitInput',true,'PulseLength',1,'SamplesPerSymbol',1);
```

Create an input sequence of all zeros. Modulate the sequence.

```
x = zeros(5,1);
y = gmsk(x)
```

```
y = 5×1 complex

   1.0000 + 0.0000i
  -0.0000 - 1.0000i
  -1.0000 + 0.0000i
   0.0000 + 1.0000i
   1.0000 - 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to better show the trend.

```
theta = unwrap(angle(y))
```

```
theta = 5×1

         0
   -1.5708
   -3.1416
   -4.7124
   -6.2832
```

A sequence of zeros causes the phase to shift by -π/2 between samples.

Reset the modulator. Modulate an input sequence of all ones.

```
reset(gmsk)
x = ones(5,1);
y = gmsk(x)
```

```
y = 5×1 complex

   1.0000 + 0.0000i
  -0.0000 + 1.0000i
  -1.0000 - 0.0000i
   0.0000 - 1.0000i
   1.0000 + 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to better show the trend.

```
theta = unwrap(angle(y))
```

```
theta = 5×1

         0
    1.5708
    3.1416
    4.7124
    6.2832
```

A sequence of ones causes the phase to shift by +π/2 between samples.

GMSK vs. MSK

Compare Gaussian minimum shift keying (GMSK) and minimum shift keying (MSK) modulation schemes by plotting the eye diagram for GMSK with different pulse lengths and for MSK.

Set the samples per symbol variable.

```
sps = 8;
```

Generate random binary data.

```
data = randi([0 1],1000,1);
```

Create GMSK and MSK modulators that accept binary inputs. Set the `PulseLength` property of the GMSK modulator to `1`.

```
gmskMod = comm.GMSKModulator('BitInput',true,'PulseLength',1, ...
    'SamplesPerSymbol',sps);
mskMod = comm.MSKModulator('BitInput',true,'SamplesPerSymbol',sps);
```

Modulate the data using the GMSK and MSK modulators.

```
modSigGMSK = gmskMod(data);
modSigMSK = mskMod(data);
```

Pass the modulated signals through an AWGN channel having an SNR of `30` dB.

```
rxSigGMSK = awgn(modSigGMSK,30);
rxSigMSK = awgn(modSigMSK,30);
```

Use the `eyediagram` function to plot the eye diagrams of the noisy signals. With the GMSK pulse length set to `1`, the eye diagrams are nearly identical.

```
eyediagram(rxSigGMSK,sps,1,sps/2)
```

```
eyediagram(rxSigMSK,sps,1,sps/2)
```

Set the `PulseLength` property for the GMSK modulator object to `3`. Because the property is nontunable, the object must be released first.

```
release(gmskMod)
gmskMod.PulseLength = 3;
```

Generate a modulated signal using the updated GMSK modulator object and pass it through the AWGN channel.

```
modSigGMSK = gmskMod(data);
rxSigGMSK = awgn(modSigGMSK,30);
```

With continuous phase modulation (CPM) waveforms, such as GSMK, the waveform depends on values of the previous symbols as well as the present symbol. Plot the eye diagram of the GMSK signal to see that the increased pulse length results in an increase in the number of paths in the eye diagram.

```
eyediagram(rxSigGMSK,sps,1,sps/2)
```

Experiment by changing the `PulseLength` parameter of the GMSK modulator object to other values. If you set the property to an even number, you should set `gmskMod.InitialPhaseOffset` to `pi/4` and update the offset argument of the `eyediagram` function from `sps/2` to `0` for a better view of the modulated signal. In order to more clearly view the Gaussian pulse shape, you must use scopes that display the phase of the signal, as described in the “CPM Phase Tree” example.

Algorithms

This object implements the algorithm, inputs, and outputs described on the GMSK Modulator Baseband block reference page. The object properties correspond to the block parameters. For GMSK the phase shift per symbol is π/2, which is a modulation index of 0.5.

`comm.CPMDemodulator` | `comm.CPMModulator` | `comm.GMSKDemodulator`

Introduced in R2012a

reset

System object: `comm.GMSKModulator`
Package: `comm`

Reset states of the GMSK modulator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `GMSKModulator` object, `H`.

step

System object: `comm.GMSKModulator`
Package: `comm`

Modulate using GMSK method

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` modulates input data, `X`, with the GMSK modulator object, `H`. It returns the baseband modulated output in `Y`. Depending on the `BitInput` property value, input `X` can be a double precision, signed integer, or logical column vector. The length of vector `Y` is equal to the number of input samples times the number of samples per symbol that you specify in the `SamplesPerSymbol` property.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.GMSKTimingSynchronizer

Package: `comm`

Recover symbol timing phase using fourth-order nonlinearity method

Description

The `GMSKTimingSynchronizer` object recovers the symbol timing phase of the input signal using a fourth-order nonlinearity method. This block implements a general non-data-aided feedback method. This timing synchronization is a non-data-aided feedback method that is independent of carrier phase recovery, but requires prior compensation for the carrier frequency offset. You can use this block for systems that use Gaussian minimum shift keying (GMSK) modulation.

To recover the symbol timing phase of the input signal:

1. Define and set up your GMSK timing synchronizer object. See “Construction” on page 3-706.
2. Call `step` to recover the symbol timing phase of the input signal according to the properties of `comm.GMSKTimingSynchronizer`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.GMSKTimingSynchronizer` creates a timing phase synchronizer System object, `H`. This object recovers the symbol timing phase of the GMSK input signal using a fourth-order nonlinearity method.

`H = comm.GMSKTimingSynchronizer(Name,Value)` creates a GMSK timing synchronizer object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SamplesPerSymbol`

Number of samples representing each symbol

Specify the number of samples that represent each symbol in the input signal as an integer-valued scalar value greater than `1`. The default is `4`.

`ErrorUpdateGain`

Error update step size

Specify the step size for updating successive timing phase estimates as a positive real scalar value. Typically, this number is less than 1/`SamplesPerSymbol` on page 3-0 , which corresponds to a slowly varying timing phase. The default is `0.05`. This property is tunable.

`ResetInputPort`

Enable synchronization reset input

Set this property to `true` to enable resetting the timing phase recovery process based on an input argument value. The default is `false`.

When you set this property to `true`, you must specify a reset input value to the `step` method.

When you specify a nonzero value as the reset input, the object restarts the timing phase recovery process. When you set this property to `false`, the object does not restart.

`ResetCondition`

Condition for timing phase recovery reset

Specify the conditions to reset the timing phase recovery process as one of `Never` | `Every frame`. The default is `Never`.

When you set this property to `Never`, the phase recovery process never restarts. The object operates continuously, retaining information from one symbol to the next.

When you set this property to `Every frame`, the timing phase recovery restarts at the start of each frame of data. In this case, the restart occurs at each `step` method call. This property applies when you set the `ResetInputPort` on page 3-0 property to `false`.

Methods

reset	Reset states of GMSK timing phase synchronizer object
step	Recover symbol timing phase using fourth-order nonlinearity method

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Recover Timing Phase of GMSK Signal

Create GMSK modulator, variable fractional delay, and GMSK timing synchronizer System objects.

```
gmskMod = comm.GMSKModulator('BitInput', true, ...
    'SamplesPerSymbol', 14);
timingOffset = 0.2;
varDelay = dsp.VariableFractionalDelay;
gmskTimingSync = comm.GMSKTimingSynchronizer('SamplesPerSymbol', 14, ...
    'ErrorUpdateGain', 0.05);
```

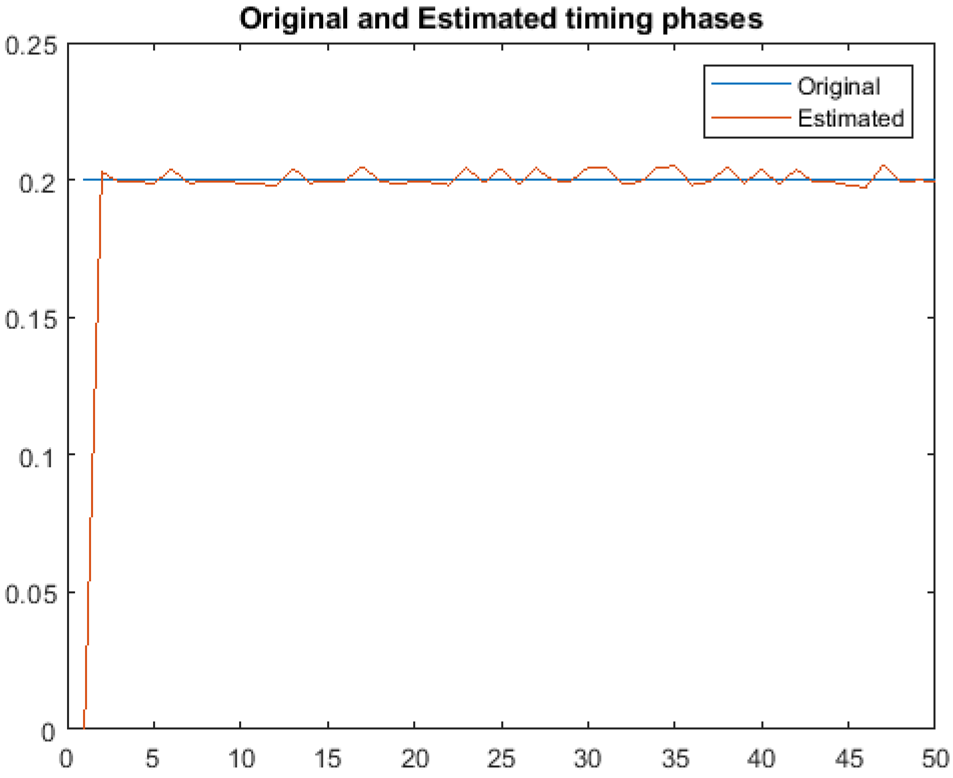
Main processing loop:

```
phEst = zeros(50,1);
for i = 1:50
    data = randi([0 1],100,1); % Generate data
    modData = gmskMod(data);   % Modulate data

    % Apply timing offset error
    impairedData = varDelay(modData,timingOffset*14);
    % Perform timing phase recovery
    [~,phase] = gmskTimingSync(impairedData);
    phEst(i) = phase(1)/14;
end
```

Plot the results.

```
plot(1:50,[0.2*ones(50,1) phEst])
legend( 'Original','Estimated')
title('Original and Estimated timing phases')
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the MSK-Type Signal Timing Recovery block reference page. The object properties correspond to the block parameters, except:

- The object corresponds to the MSK-Type Signal Timing Recovery block with the **Modulation type** parameter set to GMSK.

- The **Reset** parameter corresponds to the `ResetInputPort` on page 3-0 and `ResetCondition` on page 3-0 properties.

Extended Capabilities

`comm.SymbolSynchronizer`

Introduced in R2012a

reset

System object: `comm.GMSKTimingSynchronizer`
Package: `comm`

Reset states of GMSK timing phase synchronizer object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states for the `GMSKTimingSynchronizer` object `H`.

step

System object: `comm.GMSKTimingSynchronizer`
Package: `comm`

Recover symbol timing phase using fourth-order nonlinearity method

Syntax

```
[Y,PHASE] = step(H,X)
[Y,PHASE] = step(H,X,R)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[Y,PHASE] = step(H,X)` performs timing phase recovery and returns the time-synchronized signal, `Y`, and the estimated timing phase, `PHASE`, for input signal `X`. `X` must be a double or single precision complex column vector.

`[Y,PHASE] = step(H,X,R)` restarts the timing phase recovery process when you input a reset signal, `R`, that is non-zero. `R` must be a logical or double scalar. This syntax applies when you set the `ResetInputPort` property to true.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.GoldSequence

Package: `comm`

Generate Gold sequence

Description

The `GoldSequence` object generates a Gold sequence. Gold sequences form a large class of sequences that have good periodic cross-correlation properties.

To generate a Gold sequence:

1. Define and set up your Gold sequence object. See “Construction” on page 3-712.
2. Call `step` to generate the Gold sequence according to the properties of `comm.GoldSequence`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`H = comm.GoldSequence` creates a Gold sequence generator System object, `H`. This object generates a pseudo-random Gold sequence.

`H = comm.GoldSequence(Name,Value)` creates a Gold sequence generator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`FirstPolynomial`

Generator polynomial for first preferred PN sequence

Specify the polynomial that determines the feedback connections for the shift register of the first preferred PN sequence generator. The default is `'z^6 + z + 1'`. You can specify the polynomial as a character vector. You can also specify the generator polynomial as a numeric, binary vector that lists the coefficients of the polynomial in descending order of powers. The first and last elements must equal `1`, and the length of this vector requires a value of *n*+1, where *n* is the degree of the generator polynomial. Lastly, you can specify the generator polynomial as a numeric vector containing the exponents of *z* for the nonzero terms of the polynomial in descending order of powers. The last entry must be `0`. For example, `[1 0 0 0 0 0 1 0 1]` and `[8 2 0]` represent the same polynomial, $g(z) = z^8 + z^2 + 1$. The degree of the first generator polynomial must equal the degree of the second generator polynomial specified in the `SecondPolynomial` on page 3-0 property.

`FirstInitialConditions`

Initial conditions for first PN sequence generator

Specify the initial conditions for the shift register of the first preferred PN sequence generator. The default is `[0 0 0 0 0 1]`. The initial conditions require a numeric, binary scalar, or a numeric, binary vector with length equal to the degree of the first generator polynomial specified in the `FirstPolynomial` on page 3-0 property. If you set this property to a vector, each element of the vector corresponds to the initial value of the corresponding cell in the shift register. If you set this property to a scalar, the initial conditions of all shift register cells are the specified scalar value.

SecondPolynomial

Generator polynomial for second preferred PN sequence

Specify the polynomial that determines the feedback connections for the shift register of the second preferred PN sequence generator. The default is `'z^6 + z^5 + z^2 + z + 1'`. You can specify the polynomial as a character vector. You can also specify the generator polynomial as a binary, numeric vector that lists the coefficients of the polynomial in descending order of powers. The first and last elements must equal `1` and the length of this vector requires a value of *n*`+1`, where *n* is the degree of the generator polynomial. Lastly, you can specify the generator polynomial as a numeric vector containing the exponents of *z* for the nonzero terms of the polynomial in descending order of powers. The last entry must be `0`. For example, `[1 0 0 0 0 0 1 0 1]` and `[8 2 0]` represent the same polynomial, $g(z) = z^8 + z^2 + 1$. The degree of the second generator polynomial must equal the degree of the first generator polynomial specified in the `FirstPolynomial` on page 3-0 property.

SecondInitialConditionsSource

Source of initial conditions for second PN sequence

Specify the source of the initial conditions that determines the start of the second PN sequence as one of `Property` | `Input port`. The default is `Property`. When you set this property to `Property`, you can specify the initial conditions as a scalar or binary vector using the `SecondInitialConditions` property. When you set this property to `Input port`, you specify the initial conditions as an input to the `step`method. The object accepts a binary scalar or a binary vector input. The length of the input must equal the degree of the generator polynomial that the `SecondPolynomial` on page 3-0 property specifies.

SecondInitialConditions

Initial conditions for second PN sequence generator

Specify the initial conditions for the shift register of the second preferred PN sequence generator as a numeric, binary scalar, or as a numeric, binary vector. The length must equal the degree of the second generator polynomial. You set the second generator polynomial in the `SecondPolynomial` on page 3-0 property.

When you set this property to a vector, each element of the vector corresponds to the initial value of the corresponding cell in the shift register. The default is `[0 0 0 0 0 1]`.

When you set this property to a scalar, the initial conditions of all shift register cells are the specified scalar value.

Index

Index of output sequence of interest

Specify the index of the output sequence of interest from the set of available sequences as a scalar integer. The default is `0`. The scalar integer must be in the range [–2, 2^n–2], where *n* is the degree of the generator polynomials you specify in the `FirstPolynomial` on page 3-0 and `SecondPolynomial` on page 3-0 properties.

The index values `-2` and `-1` correspond to the first and second preferred PN sequences as generated by the `FirstPolynomial` and `SecondPolynomial`, respectively.

The set $G(u, v)$ of available Gold sequences is defined by $G(u,v) = \{u, v,$ $(u$ `xor` $T^{v})$, $(u$ `xor` $T^{2v})$, ..., $(u$ `xor` $T^{((N-1)v)})\}$.In this case, T represents the operator that shifts vectors cyclically to the left by one place, and u, v represent the two preferred PN sequences. Also, $G(u,v)$ contains N+2 Gold sequences of period N. You select the desired sequence from this set using the `Index` on page 3-0 property.

`Shift`

Sequence offset from initial time

Specify the offset of the Gold sequence from its starting point as a numeric, integer scalar value that can be positive or negative. The default is `0`. The Gold sequence has a period of $N = 2^{n} - 1$, where n is the degree of the generator polynomials specified in the `FirstPolynomial` on page 3-0 and `SecondPolynomial` on page 3-0 properties. The shift value is wrapped with respect to the sequence period.

`VariableSizeOutput`

Enable variable-size outputs

Set this property to true to enable an additional input to the step method. The default is false. When you set this property to true, the enabled input specifies the output size of the Gold sequence used for the step. The input value must be less than or equal to the value of the `MaximumOutputSize` property.

When you set this property to false, the `SamplesPerFrame` property specifies the number of output samples.

`MaximumOutputSize`

Maximum output size

Specify the maximum output size of the Gold sequence as a positive integer 2-element row vector. The second element of the vector must be 1. The default is [10 1].

This property applies when you set the `VariableSizeOutput` property to true.

`SamplesPerFrame`

Number of output samples per frame

Specify the number of Gold sequence samples that the `step` method outputs as a numeric, integer scalar value. The default is `1`. If you set this property to a value of M, then the `step` method outputs M samples of a Gold sequence with a period of $N = 2^{n} - 1$. The value of n represents the degree of the generator polynomials that you specify in the `FirstPolynomial` on page 3-0 and `SecondPolynomial` on page 3-0 properties.

`ResetInputPort`

Enable generator reset input

Set this property to `true` to enable an additional reset input to the `step` method. The default is `false`. This input resets the states of the two shift registers of the Gold sequence generator to the initial conditions specified in the `FirstInitialConditions` on page 3-0 and `SecondInitialConditions` on page 3-0 properties.

`OutputDataType`

Data type of output

Specify the output data type as one of `double` | `logical` | `Smallest unsigned integer`. The default is `double`.

You must have a Fixed-Point Designer user license to use this property in `Smallest unsigned integer` mode.

Methods

reset	Reset states of Gold sequence generator object
step	Generate a Gold sequence

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Generate Gold Sequence Samples

Generate 10 samples of a Gold sequence having period $2^5 - 1$.

```
goldseq = comm.GoldSequence('FirstPolynomial','x^5+x^2+1',...
    'SecondPolynomial','x^5+x^4+x^3+x^2+1',...
    'FirstInitialConditions',[0 0 0 0 1],...
    'SecondInitialConditions',[0 0 0 0 1],...
    'Index',4,'SamplesPerFrame',10);
x = goldseq()
```

```
x = 10×1

reset

System object: `comm.GoldSequence`
Package: `comm`

Reset states of Gold sequence generator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `GoldSequence` object, `H`.

step

System object: comm.GoldSequence
Package: comm

Generate a Gold sequence

Syntax

```
Y = step(H)
Y = step(H,RESET)
```

Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj) and y = obj() perform equivalent operations.

Y = step(H) outputs a frame of the Gold sequence in column vector Y. Specify the frame length with the SamplesPerFrame property. The object uses two PN sequence generators to generate a preferred pair of sequences with period N = 2^n-1. Then the object XORs these sequences to produce the output Gold sequence. The value in n is the degree of the generator polynomials that you specify in the FirstPolynomial and SecondPolynomial properties.

Y = step(H,RESET) uses RESET as the reset signal when you set the ResetInputPort property to true. The data type of the RESET input must be double precision or logical. RESET can be a scalar value or a column vector with length equal to the number of samples per frame specified in the SamplesPerFrame property. When the RESET input is a non-zero scalar, the object resets to the initial conditions that you specify in the FirstInitialConditions and SecondInitialConditions properties. It then generates a new output frame. A column vector RESET input allows multiple resets within an output frame. A non-zero value at the ith element of the vector causes a reset at the ith output sample time.

Note obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

comm.gpu.AWGNChannel

Package: `comm`

Add white Gaussian noise to input signal with GPU

Description

The `GPU AWGNChannel` object adds white Gaussian noise to an input signal using a graphics processing unit (GPU).

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see "GPU Computing" (Parallel Computing Toolbox).

To add white Gaussian noise to an input signal:

1. Define and set up your additive white Gaussian noise channel object. See "Construction" on page 3-719.
2. Call `step` to add white Gaussian noise to the input signal according to the properties of `comm.gpu.AWGNChannel`. The behavior of `step` is specific to each object in the toolbox.

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see "Establish Arrays on a GPU" (Parallel Computing Toolbox).

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.gpu.AWGNChannel` creates a GPU-based additive white Gaussian noise (AWGN) channel System object, `H`. This object adds white Gaussian noise to a real or complex input signal.

`H = comm.gpu.AWGNChannel(Name,Value)` creates a GPU-based AWGN channel object, `H`, with the specified property name set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

Properties

`NoiseMethod`

Method to specify noise level

Select the method to specify the noise level as one of `Signal to noise ratio (Eb/No)` | `Signal to noise ratio (Es/No)` | `Signal to noise ratio (SNR)` | `Variance`. The default is `Signal to noise ratio (Eb/No)`.

`EbNo`

Energy per bit to noise power spectral density ratio (Eb/No)

Specify the Eb/No ratio in decibels. Set this property to a numeric, real scalar or row vector with a length equal to the number of channels. This property applies when you set the NoiseMethod property to `Signal to noise ratio (Eb/No)`. The default is `10`. This property is tunable.

`EsNo`

Energy per symbol to noise power spectral density ratio (Es/No)

Specify the Es/No ratio in decibels. Set this property to a numeric, real scalar or row vector with a length equal to the number of channels. This property applies when you set the NoiseMethod property to `Signal to noise ratio (Es/No)`. The default is `10`. This property is tunable.

`SNR`

Signal to noise ratio (SNR)

Specify the SNR value in decibels. Set this property to a numeric, real scalar or row vector with a length equal to the number of channels. This property applies when you set the NoiseMethod property to `Signal to noise ratio (SNR)`. The default is `10`. This property is tunable.

`BitsPerSymbol`

Number of bits in one symbol

Specify the number of bits in each input symbol. You can set this property to a numeric, positive, integer scalar or row vector with a length equal to the number of channels. This property applies when you set the NoiseMethod property to `Signal to noise ratio (Eb/No)`. The default is `1` bit.

SignalPower

Input signal power in Watts

Specify the mean square power of the input signal in Watts. Set this property to a numeric, positive, real scalar or row vector with a length equal to the number of channels. This property applies when you set the NoiseMethod property to `Signal to noise ratio (Eb/No)`, `Signal to noise ratio (Es/No)` or `Signal to noise ratio (SNR)`. The default is `1` Watt. The object assumes a nominal impedance of `1` Ohm. This property is tunable.

SamplesPerSymbol

Number of samples per symbol

Specify the number of samples per symbol. Set this property to a numeric, positive, integer scalar or row vector with a length equal to the number of channels. This property applies when you set the NoiseMethod property to `Signal to noise ratio (Eb/No)` or `Signal to noise ratio (Es/No)`. The default is 1 sample.

VarianceSource

Source of noise variance

Specify the source of the noise variance as one of `Property` | `Input port`. The default is `Property`. Set `VarianceSource` to `Input port` to specify the noise variance value via an input to the step method. Set `VarianceSource` to `Property` to specify the noise variance value using the Variance property. This property applies when you set the NoiseMethod property to `Variance`.

Variance

Noise variance

Specify the variance of the white Gaussian noise. You can set this property to a numeric, positive, real scalar or row vector with a length equal to the number of channels. This property applies when you set the NoiseMethod property to `Variance` and the VarianceSource property to `Property`. The default is `1`. This property is tunable.

RandomStream

Source of random number stream

Specify the source of random number stream. The only valid setting for this property is `Global stream`. The object generates the normally distributed random numbers from the current global random number stream.

Seed

Initial seed of `mt19937ar` random number stream

The GPU version of the AWGN Channel System object does not use this property.

Methods

step	Add white Gaussian noise to input signal

Common to All System Objects	
release	Allow System object property value changes

Algorithm

This object uses the same algorithm as the comm.AWGNChannel System object. See the Algorithms section of the comm.AWGNChannel help page for more details. The object properties correspond to the related block parameters, except that:

- This object uses parallel.gpu.RandStream to provide an interface for controlling the properties of one or more random number streams that the GPU uses. Usage is the same as RandStream with the following restrictions:
  - Only the combRecursive (MRG32K3A) generator is supported.
  - Only the Inversion normal transform is supported.
  - Setting the substream property is not allowed.

Enter help parallel.gpu.RandStream at the MATLAB command line for more information.

Examples

GPU AWGN Channel

Specify the modulation order and generate PSK-modulated random data.

```
M = 8;
modData = pskmod(randi([0 M-1],1000,1),M,pi/M);
```

Create an AWGN channel object that uses a GPU. Pass the modulated data through the channel.

```
gpuChannel = comm.gpu.AWGNChannel('EbNo',15,'BitsPerSymbol', ...
                log2(M));
channelOutput = gpuChannel(modData);
```

Visualize the noiseless and noisy data in scatter plots.

`comm.AWGNChannel`

Introduced in R2012a

step

System object: `comm.gpu.AWGNChannel`
Package: `comm`

Add white Gaussian noise to input signal

Syntax

```
Y = step(H,X)
Y = step(H,X,VAR)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` adds white Gaussian noise to input `X` and returns the result in `Y`. The input `X` can be a double or single precision data type scalar, vector, or matrix with real or complex values. The dimensions of input `X` determine single or multichannel processing. For an `M`-by-`N` matrix input, `M` represents the number of time samples per channel and `N` represents the number of channels. `M` and `N` can be equal to `1`. The object adds frames of length `M` of Gaussian noise to each of the `N` channels independently.

`Y = step(H,X,VAR)` uses input `VAR` as the variance of the white Gaussian noise. This applies when you set the NoiseMethod property to `Variance` and the VarianceSource property to `Input port`. Input `VAR` can be a positive scalar or row vector with a length equal to the number of channels. `VAR` must be of the same data type as input `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.gpu.BlockDeinterleaver

Package: `comm`

Restore original ordering of block interleaved sequence with GPU

Description

The `BlockDeinterleaver` System object restores the original ordering of a sequence that was interleaved using the block interleaver System object.

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To deinterleave the input vector:

1. Define and set up your block deinterleaver object. See “Construction” on page 3-726.
2. Call `step` to rearrange the elements of the input vector according to the properties of `comm.gpu.BlockDeinterleaver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.gpu.BlockDeinterleaver` creates a GPU-based block deinterleaver System object, `H`. This object restores the original ordering of a sequence that was interleaved using the `BlockInterleaver` System object

`H = comm.gpu.BlockDeinterleaver(Name,Value)` creates a GPU-based block deinterleaver object, `H`, with the specified property name set to the specified value.

`H = comm.gpu.BlockDeinterleaver(PERMVEC)` creates a GPU-based block deinterleaver object, `H`, with the `PermutationVector` property set to `PERMVEC`.

Properties

`PermutationVector`

Permutation vector

Specify the mapping used to permute the input symbols as a column vector of integers. The default is `[5;4;3;2;1]`. The mapping is a vector where the number of elements is equal to the length, `N`, of the input to the step method. Each element must be an integer between `1` and `N`, with no repeated values.

Methods

step	Deinterleave input sequence

Common to All System Objects	
`release`	Allow System object property value changes

Algorithm

This object uses the same algorithm as the `comm.BlockDeinterleaver` System object. See Algorithms on the `comm.BlockDeinterleaver` help page for details.

Examples

Block Interleaving and Deinterleaving with GPU

Create interleaver and deinterleaver objects.

```
interleaver = comm.gpu.BlockInterleaver([3 4 1 2]');
deinterleaver = comm.gpu.BlockDeinterleaver([3 4 1 2]');
```

Pass random data through the interleaver and deinterleaver.

```
data = randi(7,4,1);
intData = interleaver(data);
deIntData = deinterleaver(intData);
```

Display the original sequence, interleaved sequence, and restored sequence.

```
[data intData deIntData]
```

```
ans =

     6     1     6
     7     7     7
     1     6     1
     7     7     7
```

Confirm the original and deinterleaved data are identical.

```
isequal(data,deIntData)
```

```
ans =

     1
```

Generate a random vector of unique integers as a permutation vector.

```
permVec = randperm(7)';
```

Specify `permVec` as the permutation vector for the interleaver and deinterleaver objects.

```
interleaver = comm.gpu.BlockInterleaver(permVec);
deinterleaver = comm.gpu.BlockDeinterleaver(permVec);
```

Pass random data through the interleaver and deinterleaver.

```
data = randi(10,7,1);
intData = interleaver(data);
deIntData = deinterleaver(intData);
```

Confirm the original and deinterleaved data are identical.

```
isequal(data,deIntData)
```

```
ans =

     1
```

Extended Capabilities

GPU Arrays

Deinterleave input sequence

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Y = step(H,X) restores the original ordering of the sequence, X, that was interleaved using a block interleaver. The step method forms the output, Y, based on the mapping specified by the PermutationVector property as Output(PermutationVector(k))=Input(k), for k = 1:N, where N is the length of the permutation vector. The input X must be a column vector of the same length, N. The data type of X can be numeric, logical, or fixed-point (fi objects). Y has the same data type as X.

Note obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

comm.gpu.BlockInterleaver

Package: `comm`

Create block interleaved sequence with GPU

Description

The `GPU BlockInterleaver` object permutes the symbols in the input signal using a graphics processing unit (GPU).

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To interleave the input signal:

1. Define and set up your block interleaver object. See “Construction” on page 3-730.
2. Call `step` to reorder the input symbols according to the properties of `comm.gpu.BlockInterleaver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.gpu.BlockInterleaver` creates a GPU-based block interleaver System object, `H`. This object permutes the symbols in the input signal based on a permutation vector.

`H = comm.gpu.BlockInterleaver(Name,Value)` creates a GPU-based block interleaver object, `H`, with the specified property `Name` set to the specified `Value`.

`H = comm.gpu.BlockInterleaver(PERMVEC)` creates a GPU-based block deinterleaver object, `H`, with the `PermutationVector` property set to `PERMVEC`.

Properties

`PermutationVector`

Permutation vector

Specify the mapping used to permute the input symbols as a column vector of integers. The default is `[5;4;3;2;1]`. The mapping is a vector where the number of elements is equal to the length, `N`, of the input to the step method. Each element must be an integer between `1` and `N`, with no repeated values.

Methods

step	Permute input symbols using a permutation vector

Common to All System Objects	
`release`	Allow System object property value changes

Algorithm

The `GPU Block Interleaver` System object uses the same algorithm as the `comm.BlockInterleaver` System object. See Algorithms on the `comm.BlockInterleaver` help page for details.

Examples

Block Interleaving and Deinterleaving with GPU

Create interleaver and deinterleaver objects.

```
interleaver = comm.gpu.BlockInterleaver([3 4 1 2]');
deinterleaver = comm.gpu.BlockDeinterleaver([3 4 1 2]');
```

Pass random data through the interleaver and deinterleaver.

```
data = randi(7,4,1);
intData = interleaver(data);
deIntData = deinterleaver(intData);
```

Display the original sequence, interleaved sequence, and restored sequence.

```
[data intData deIntData]
```

```
ans =

     6     1     6
     7     7     7
     1     6     1
     7     7     7
```

Confirm the original and deinterleaved data are identical.

```
isequal(data,deIntData)
```

```
ans =

     1
```

Generate a random vector of unique integers as a permutation vector.

```
permVec = randperm(7)';
```

Specify `permVec` as the permutation vector for the interleaver and deinterleaver objects.

```
interleaver = comm.gpu.BlockInterleaver(permVec);
deinterleaver = comm.gpu.BlockDeinterleaver(permVec);
```

Pass random data through the interleaver and deinterleaver.

```
data = randi(10,7,1);
intData = interleaver(data);
deIntData = deinterleaver(intData);
```

Confirm the original and deinterleaved data are identical.

```
isequal(data,deIntData)
```

```
ans =

     1
```

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This System object runs on a GPU, and also supports GPU array inputs. For more information, see “Simulation Acceleration Using GPUs”.

`comm.BlockInterleaver` | `comm.gpu.BlockDeinterleaver`

Introduced in R2012a

step

System object: `comm.gpu.BlockInterleaver`
Package: `comm`

Permute input symbols using a permutation vector

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` permutes input sequence, `X`, and returns interleaved sequence, `Y`. The step method forms the output `Y`, based on the mapping defined by the `PermutationVector` property as `Output(k)=Input(PermutationVector(k))`, for `k` = 1:`N`, where `N` is the length of the `PermutationVector` property. The input `X` must be a column vector of length `N`. The data type of `X` can be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.gpu.ConvolutionalEncoder

Package: `comm.gpu`

Convolutionally encode binary data with GPU

Description

The `GPU ConvolutionalEncoder` object encodes a sequence of binary input vectors to produce a sequence of binary output vectors.

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To convolutionally encode a binary signal:

1. Define and set up your convolutional encoder object. See “Construction” on page 3-734.
2. Call `step` to encode a sequence of binary input vectors to produce a sequence of binary output vectors according to the properties of `comm.gpu.ConvolutionalEncoder`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.gpu.ConvolutionalEncoder` creates a System object, `H`, that convolutionally encodes binary data.

`H = comm.gpu.ConvolutionalEncoder(Name,Value)` creates a convolutional encoder object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

H = comm.gpu.ConvolutionalEncoder(TRELLIS,Name,Value) creates a convolutional encoder object, H. This object has the TrellisStructure on page 3-0 property set to TRELLIS, and the other specified properties set to the specified values.

Properties

TrellisStructure

Trellis structure of convolutional code

Specify the trellis as a MATLAB structure that contains the trellis description of the convolutional code. The default is the result of poly2trellis(7, [171 133]). Use the istrellis function to check if a structure is a valid trellis structure.

TerminationMethod

Termination method of encoded frame

Specify how the encoded frame is terminated as one of Continuous | Truncated | Terminated. The default is Continuous.

When you set this property to Continuous, the object retains the encoder states at the end of each input vector for use with the next input vector.

When you set this property to Truncated, the object treats each input vector independently and resets its states to the all-zeros state.

When you set this property to Terminated, the object treats each input vector independently. For each input vector, the object uses extra bits to set the encoder states to the all-zeros state at the end of the vector. For a rate *K*/*N* code, the step method outputs a vector with length $N \times {}^{(L+S)}\!/_{K}$, where $S = constraintLength–1$. In the case of multiple constraint lengths, $S = \textbf{sum}(constraintLength(i)–1))$. L is the length of the input to the step method.

ResetInputPort

Enable encoder reset input

You cannot reset this encoder object using an input port. The only valid property setting is false.

DelayedResetAction

Delay output reset

You cannot reset this encoder object using an input port. The only valid property setting is false.

InitialStateInputPort

You cannot set the initial state of this encoder object. The only valid property setting is false.

FinalStateOutputPort

You cannot output the final state of this encoder object. The only valid property setting is false.

PuncturePatternSource

Source of puncture pattern

Specify the source of the puncture pattern as one of `None` | `Property`. The default is `None`. When you set this property to `None` the object does not apply puncturing. When you set this property to `Property`, the object punctures the code. This puncturing is based on the puncture pattern vector that you specify in the `PuncturePattern` on page 3-0 property. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous` or `Truncated`.

PuncturePattern

Puncture pattern vector

Specify the puncture pattern that the object uses to puncture the encoded data as a column vector. The default is `[1; 1; 0; 1; 0; 1]`. The vector contains `1`s and `0`s, where `0` indicates a punctured, or excluded, bit. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous` or `Truncated` and the `PuncturePatternSource` on page 3-0 property to `Property`.

NumFrames

Number of independent frames present in the input and output data vectors.

Specify the number of independent frames contained in a single data input/output vector. The default value of this property is `1`. The objects segments the input vector into `NumFrames` segments and encodes them independently. The output contains `NumFrames` encoded segments. This property is applicable when you set the `TerminationMethod` on page 3-0 to `Terminated` or `Truncated`.

Methods

reset	Reset states of the convolutional encoder object
step	Convolutionally encode binary data

Common to All System Objects	
`release`	Allow System object property value changes

Examples

8-PSK-Modulation With Convolutional Encoding

Transmit a Convolutionally Encoded, 8-PSK-Modulated Bit Stream Through an AWGN Channel.

Create a GPU-based Convolutional Encoder System object.

```
hConEnc = comm.gpu.ConvolutionalEncoder;
```

Create a GPU-based PSK Modulator System object that accepts a bit input signal.

```
hMod = comm.gpu.PSKModulator('BitInput',true);
```

Create a GPU-based AWGN Channel System object with a signal-to-noise ratio of seven.

```
hChan = comm.gpu.AWGNChannel('NoiseMethod', ...
         'Signal to noise ratio (SNR)',...
         'SNR',7);
```

Create a GPU-based PSK Demodulator System object that outputs a column vector of bit values.

```
hDemod = comm.gpu.PSKDemodulator('BitOutput',true);
```

Create a GPU-based Viterbi Decoder System object that accepts an input vector of hard decision values, which are zeros or ones.

```
hDec = comm.gpu.ViterbiDecoder('InputFormat','Hard');
```

Create an Error Rate System object that ignores 3 data samples before makings comparisons. The received data lags behind the transmitted data by 34 samples.

```
hError = comm.ErrorRate('ComputationDelay',3,'ReceiveDelay', 34);
```

Run the simulation by using the step method to process data.

```
for counter = 1:20
  data = randi([0 1],30,1);
  encodedData = step(hConEnc, gpuArray(data));
  modSignal = step(hMod, encodedData);
  receivedSignal = step(hChan, modSignal);
  demodSignal = step(hDemod, receivedSignal);
  receivedBits = step(hDec, demodSignal);
  errors = step(hError, data, gather(receivedBits));
end
```

Display the errors.

```
disp(errors)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Convolutional Encoder block reference page. The object properties correspond to the block parameters.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This System object runs on a GPU, and also supports GPU array inputs. For more information, see “Simulation Acceleration Using GPUs”.

See Also

`comm.ConvolutionalEncoder` | `comm.gpu.ConvolutionalDeinterleaver` | `comm.gpu.ConvolutionalInterleaver` | `comm.gpu.ViterbiDecoder`

Introduced in R2012a

reset

System object: `comm.gpu.ConvolutionalEncoder`
Package: `comm.gpu`

Reset states of the convolutional encoder object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `GPU ConvolutionalEncoder` object, `H`.

step

System object: `comm.gpu.ConvolutionalEncoder`
Package: `comm.gpu`

Convolutionally encode binary data

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` encodes the binary data, `X`, using the convolutional encoding that you specify in the TrellisStructure property. It returns the encoded data, `Y`. Both `X` and `Y` are column vectors of data type single, double, or logical. When the convolutional encoder represents a rate *K*/*N* code, the length of the input vector equals *K* × *L*, for a positive integer, *L*. The step method sets the length of the output vector, `Y`, to *L* × *N*.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.gpu.ConvolutionalInterleaver

Package: comm

Permute input symbols using shift registers with GPU

Description

The GPU ConvolutionalInterleaver object permutes the symbols in the input signal using a graphics processing unit (GPU). Internally, this class uses a set of shift registers.

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see "GPU Computing" (Parallel Computing Toolbox).

A GPU-based System object accepts typical MATLAB arrays or objects created using the gpuArray class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a gpuArray, the data remains on the GPU. The output signal is a gpuArray. When the object is given a gpuArray, calculations take place entirely on the GPU, and no data transfer occurs. Passing gpuArray arguments provides increased performance by reducing simulation time. For more information, see "Establish Arrays on a GPU" (Parallel Computing Toolbox).

To convolutionally interleave binary data:

1. Define and set up your convolutional interleaver object. See "Construction" on page 3-740.
2. Call step to convolutionally interleave according to the properties of comm.gpu.ConvolutionalInterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.gpu.ConvolutionalInterleaver creates a GPU-based convolutional interleaver System object, H. This object permutes the symbols in the input signal using a set of shift registers.

H = comm.gpu.ConvolutionalInterleaver(Name,Value) creates a GPU-based convolutional interleaver System object, H, with the specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.gpu.ConvolutionalInterleaver(M,B,IC) creates a GPU-based convolutional interleaver System object H, with the NumRegisters property set to M, the RegisterLengthStep property set to B, and the InitialConditions property set to IC. M, B, and IC are value-only arguments. To specify a value-only argument, you must also specify all preceding value-only arguments.

Properties

NumRegisters

Number of internal shift registers

Specify the number of internal shift registers as a scalar, positive integer. The default is 6.

RegisterLengthStep

Number of additional symbols that fit in each successive shift register

Specify the number of additional symbols that fit in each successive shift register as a positive, scalar integer. The default is 2. The first register holds zero symbols.

InitialConditions

Initial conditions of shift registers

Specify the values that are initially stored in each shift register as a numeric scalar or vector. You do not need to specify a value for the first shift register, which has zero delay. The default is 0. The value of the first element of this property is unimportant because the first shift register has zero delay. If you set this property to a scalar, then all shift registers, except the first one, store the same specified value. If you set it to a column vector with length equal to the value of the NumRegisters on page 3-0 property, then the *i*-th shift register stores the *i*-th element of the specified vector.

Methods

reset	Reset states of the convolutional interleaver object
step	Permute input symbols using shift registers

Common to All System Objects	
release	Allow System object property value changes

Examples

Convolutional Interleaving and Deinterleaving with GPU

Create convolutional interleaver and deinterleaver objects.

```
interleaver = comm.gpu.ConvolutionalInterleaver('NumRegisters',2, ...
    'RegisterLengthStep',3);
deinterleaver = comm.gpu.ConvolutionalDeinterleaver('NumRegisters',2, ...
    'RegisterLengthStep',3);
```

Generate data, and pass the data through the convolutional interleaver. Pass the interleaved data through the convolutional deinterleaver.

```
data = (0:20)';
intrlvData = interleaver(data);
deintrlvData = deinterleaver(intrlvData);
```

Display the original sequence, interleaved sequence and restored sequence.

```
[data intrlvData deintrlvData]
```

```
ans =

     0     0     0
     1     0     0
     2     2     0
     3     0     0
     4     4     0
     5     0     0
     6     6     0
     7     1     1
     8     8     2
     9     3     3
    10    10     4
    11     5     5
    12    12     6
    13     7     7
    14    14     8
    15     9     9
    16    16    10
    17    11    11
    18    18    12
    19    13    13
    20    20    14
```

The delay through the interleaver and deinterleaver pair is equal to the product of the `NumRegisters` and `RegisterLengthStep` properties. After accounting for this delay, confirm that the original and deinterleaved data are identical.

```
intrlvDelay = interleaver.NumRegisters * interleaver.RegisterLengthStep
numSymErrors = symerr(data(1:end-intrlvDelay),deintrlvData(1+intrlvDelay:end))
```

```
intrlvDelay =

     6

numSymErrors =

     0
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Convolutional Interleaver block reference page. The object properties correspond to the block parameters.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This System object runs on a GPU, and also supports GPU array inputs. For more information, see “Simulation Acceleration Using GPUs”.

See Also

`comm.ConvolutionalInterleaver` | `comm.gpu.ConvolutionalDeinterleaver`

Introduced in R2012a

reset

System object: `comm.gpu.ConvolutionalInterleaver`
Package: `comm`

Reset states of the convolutional interleaver object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `GPU ConvolutionalInterleaver` object, `H`.

step

System object: `comm.gpu.ConvolutionalInterleaver`
Package: `comm`

Permute input symbols using shift registers

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` permutes input sequence, `X`, and returns interleaved sequence, `Y`. The input X must be a column vector. The data type can be of type `double`, `single`, `uint32`, `int32`, or `logical`. `Y` has the same data type as `X`. The convolutional interleaver object uses a set of *N* shift registers, where *N* is the value specified by the `NumRegisters` property. The object sets the delay value of the k^{th} shift register to the product of (*k*-1) and the RegisterLengthStep property value. With each new input symbol, a commutator switches to a new register and the new symbol shifts in while the oldest symbol in that register shifts out. When the commutator reaches the N^{th} register and the next new input occurs, it returns to the first register.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.gpu.ConvolutionalDeinterleaver

Package: `comm`

Restore ordering of symbols using shift registers with GPU

Description

The `GPU ConvolutionalDeinterleaver` object recovers a signal that was interleaved using the GPU-based convolutional interleaver object. The parameters in the two blocks should have the same values.

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see "GPU Computing" (Parallel Computing Toolbox).

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see "Establish Arrays on a GPU" (Parallel Computing Toolbox).

To recover convolutionally interleaved binary data:

1. Define and set up your convolutional deinterleaver object. See "Construction" on page 3-746.
2. Call `step` to convolutionally deinterleave according to the properties of `comm.gpu.ConvolutionalDeinterleaver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.gpu.ConvolutionalDeinterleaver` creates a GPU-based convolutional deinterleaver System object, `H`. This object restores the original ordering of a sequence that was interleaved using a convolutional interleaver.

`H = comm.gpu.ConvolutionalDeinterleaver(Name,Value)` creates a GPU-based convolutional deinterleaver System object, `H`, with the specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

H = comm.gpu.ConvolutionalDeinterleaver(M,B,IC) creates a convolutional deinterleaver System object H, with the NumRegisters property set to M, the RegisterLengthStep property set to B, and the InitialConditions property set to IC. M, B, and IC are value-only arguments. To specify a value-only argument, you must also specify all preceding value-only arguments.

Properties

NumRegisters

Number of internal shift registers

Specify the number of internal shift registers as a scalar, positive integer. The default is 6.

RegisterLengthStep

Number of additional symbols that fit in each successive shift register

Specify the number of additional symbols that fit in each successive shift register as a positive, scalar integer. The default is 2. The first register holds zero symbols.

InitialConditions

Initial conditions of shift registers

Specify the values that are initially stored in each shift register (except the first shift register, which has zero delay) as a numeric scalar or vector. The default is 0. If you set this property to a scalar, then all shift registers, except the first one, store the same specified value. If you set it to a column vector with length equal to the value of the NumRegisters on page 3-0 property, then the *i*-th shift register stores the *i*-th element of the specified vector. The value of the first element of this property is unimportant, since the first shift register has zero delay.

Methods

step	Permute input symbols using shift registers
reset	Reset states of the convolutional deinterleaver object

Common to All System Objects	
release	Allow System object property value changes

Examples

Convolutional Interleaving and Deinterleaving with GPU

Create convolutional interleaver and deinterleaver objects.

```
interleaver = comm.gpu.ConvolutionalInterleaver('NumRegisters',2, ...
    'RegisterLengthStep',3);
deinterleaver = comm.gpu.ConvolutionalDeinterleaver('NumRegisters',2, ...
    'RegisterLengthStep',3);
```

Generate data, and pass the data through the convolutional interleaver. Pass the interleaved data through the convolutional deinterleaver.

```
data = (0:20)';
intrlvData = interleaver(data);
deintrlvData = deinterleaver(intrlvData);
```

Display the original sequence, interleaved sequence and restored sequence.

```
[data intrlvData deintrlvData]
```

```
ans =

     0     0     0
     1     0     0
     2     2     0
     3     0     0
     4     4     0
     5     0     0
     6     6     0
     7     1     1
     8     8     2
     9     3     3
    10    10     4
    11     5     5
    12    12     6
    13     7     7
    14    14     8
    15     9     9
    16    16    10
    17    11    11
    18    18    12
    19    13    13
    20    20    14
```

The delay through the interleaver and deinterleaver pair is equal to the product of the `NumRegisters` and `RegisterLengthStep` properties. After accounting for this delay, confirm that the original and deinterleaved data are identical.

```
intrlvDelay = interleaver.NumRegisters * interleaver.RegisterLengthStep
numSymErrors = symerr(data(1:end-intrlvDelay),deintrlvData(1+intrlvDelay:end))
```

```
intrlvDelay =

     6

numSymErrors =
     0
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Convolutional Deinterleaver block reference page. The object properties correspond to the block parameters.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This System object runs on a GPU, and also supports GPU array inputs. For more information, see "Simulation Acceleration Using GPUs".

See Also

`comm.ConvolutionalDeinterleaver` | `comm.gpu.ConvolutionalInterleaver`

Introduced in R2012a

step

System object: `comm.gpu.ConvolutionalDeinterleaver`
Package: `comm`

Permute input symbols using shift registers

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` restores the original ordering of the sequence, `X`, that was interleaved using a convolutional interleaver and returns `Y`. The input `X` must be a column vector. The data type can be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`. The convolutional deinterleaver object uses a set of `N` shift registers, where `N` represents the value specified by the `NumRegisters` property. The object sets the delay value of the k^{th} shift register to the product of (k-1) and the RegisterLengthStep property value. With each new input symbol, a commutator switches to a new register and the new symbol shifts in while the oldest symbol in that register shifts out. When the commutator reaches the *N*th register and the next new input occurs, it returns to the first register.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

reset

System object: `comm.gpu.ConvolutionalDeinterleaver`
Package: `comm`

Reset states of the convolutional deinterleaver object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `GPU ConvolutionalDeinterleaver` object, `H`.

comm.gpu.LDPCDecoder

Package: `comm`

Decode binary low-density parity-check (LDPC) code with GPU

Note To use this object, you must install Parallel Computing Toolbox™ and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

Description

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

The `comm.gpu.LDPCDecoder` System object uses the belief propagation algorithm to decode a binary LDPC code, which is input to the object as the soft-decision output (log-likelihood ratio of received bits) from demodulation. The object decodes generic binary LDPC codes where no patterns in the parity-check matrix are assumed. For more information, see “Belief Propagation Decoding” on page 3-758.

To decode an LDPC-encoded signal:

1. Create the `comm.gpu.LDPCDecoder` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
gpu_ldpcdecoder = comm.gpu.LDPCDecoder
gpu_ldpcdecoder = comm.gpu.LDPCDecoder(parity)
gpu_ldpcdecoder = comm.gpu.LDPCDecoder(___,Name,Value)
```

Description

`gpu_ldpcdecoder = comm.gpu.LDPCDecoder` creates a GPU-based binary LDPC decoder System object. This object performs LDPC decoding based on the specified parity-check matrix.

`gpu_ldpcdecoder = comm.gpu.LDPCDecoder(parity)` sets the `ParityCheckMatrix` property to `parity` and creates a GPU-based LDPC decoder System object. The `parity` input must be specified as described by the `ParityCheckMatrix` property.

`gpu_ldpcdecoder = comm.gpu.LDPCDecoder( ___ ,Name,Value)` sets properties using one or more name-value pairs, in addition to inputs from any of the prior syntaxes. For example, `comm.LDPCDecoder('DecisionMethod','Soft decision')` configures an LDPC decoder System object to decode data using the soft-decision method and output log-likelihood ratios of data type `double`. Enclose each property name in quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`ParityCheckMatrix` — Parity-check matrix

`dvbs2ldpc(1/2)` (default) | sparse binary matrix | nonsparse index matrix

Parity-check matrix, specified as a sparse (N – K)-by-N binary-valued matrix. N is the length of the received signal and must be in the range (0, 2^{31}). K is the length of the uncoded message and must be less than N. The last (N – K) columns in the parity-check matrix must be an invertible matrix in the Galois field of order 2, `gf`(2).

You can also specify the parity-check matrix as a two-column nonsparse index matrix, `I`, that defines the row and column indices of the `1`s in the parity-check matrix such that `sparse(I(:,1),I(:,2),1)`.

This property accepts numeric data types. When you set this property to a sparse binary matrix, this property also accepts the `logical` data type.

The default value uses the `dvbs2ldpc` function to configure a sparse parity-check matrix for half-rate LDPC coding, as specified in the DVB-S.2 standard.

Example: `dvbs2ldpc(R,'indices')` configures the index matrix for the DVB-S.2 standard, where `R` is the code rate, and `'indices'` specifies the output format of `dvbs2ldpc` as a two-column double-precision matrix that defines the row and column indices of the `1`s in the parity-check matrix.

Data Types: `double` | `logical`

`OutputValue` — Output value format

`'Information part'` (default) | `'Whole codeword'`

Output value format, specified as one of these values:

- `'Information part'` — The object outputs a K-by-1 column vector containing only the information-part of the received log-likelihood ratio vector. K is the length of the uncoded message.
- `'Whole codeword'` — The object outputs an N-by-1 column vector containing the whole log-likelihood ratio vector. N is the length of the received signal.

N and *K* must align with the dimension of the (*N*–*K*)-by-*K* parity-check matrix.

Data Types: `char`

`DecisionMethod` — Decision method
`'Hard decision'` (default) | `'Soft decision'`

Decision method used for decoding, specified as one of these values:

- `'Hard decision'` — The object outputs decoded data of data type `logical`.
- `'Soft decision'` — The object outputs log-likelihood ratios of data type `double`.

Data Types: `char`

`IterationTerminationCondition` — Condition for iteration termination
`'Maximum iteration count'` (default) | `'Parity check satisfied'`

Condition for iteration termination, specified as one of these values:

- `'Maximum iteration count'` — Decoding terminates after the number of iterations specified by the `MaximumIterationCount` property.
- `'Parity check satisfied'` — Decoding terminates after all parity checks are satisfied. If not all parity checks are satisfied, decoding terminates after the number of iterations specified by the `MaximumIterationCount` property.

Data Types: `char`

`MaximumIterationCount` — Maximum number of decoding iterations
`50` (default) | positive integer

Maximum number of decoding iterations, specified as a positive integer.

Data Types: `double`

`NumIterationsOutputPort` — Output number of iterations performed
`false` (default) | `true`

Output number of iterations executed, specified as `false` or `true`. To output the number of iterations executed, set this property to `true`.

Data Types: `logical`

`FinalParityChecksOutputPort` — Output final parity checks
`false` (default) | `true`

Output final parity checks, specified as `false` or `true`. To output the final calculated parity checks, set this property to `true`.

Data Types: `logical`

Usage

Syntax

```
y = gpu_ldpcdecoder(x)
```

```
[y,numiter] = gpu_ldpcdecoder(x)
[y,parity] = gpu_ldpcdecoder(x)
[y,numiter,parity] = gpu_ldpcdecoder(x)
```

Description

`y = gpu_ldpcdecoder(x)` decodes input data using an LDPC code based on the default parity-check matrix.

`[y,numiter] = gpu_ldpcdecoder(x)` returns the decoded data, `y`, and number of iterations performed, `numiter`. To use this syntax, set the `NumIterationsOutputPort` property to `true`.

`[y,parity] = gpu_ldpcdecoder(x)` returns the decoded data, `y`, and final parity checks, `parity`. To use this syntax, set the `FinalParityChecksOutputPort` property to `true`.

`[y,numiter,parity] = gpu_ldpcdecoder(x)` returns the decoded data, number of iterations performed, and final parity checks. To use this syntax, set the `NumIterationsOutputPort` and `FinalParityChecksOutputPort` properties to `true`.

Input Arguments

x — Log-likelihood ratios

column vector

Log-likelihood ratios, specified as an *N*-by-1 column vector containing the soft-decision output from demodulation. *N* is the number of bits in the LDPC codeword before modulation. Each element is the log-likelihood ratio for a received bit. Element values are more likely to be `0` if the log-likelihood ratio is positive. The first *K* elements correspond to the information-part of the input message.

Data Types: `double`

Output Arguments

y — Decoded data

column vector

Decoded data, returned as a column vector. The `DecisionMethod` property specifies whether the object outputs hard decisions or soft decisions (log-likelihood ratios).

- If the `OutputValue` property is set to `'Information part'`, the output includes only the information-part of the received log-likelihood ratio vector.
- If the `OutputValue` property is set to `'Whole codeword'`, the output includes the whole log-likelihood ratio vector.

Data Types: `double` | `logical`

`numiter` — Number of executed decoding iterations

positive integer

Number of executed decoding iterations, returned as a positive integer.

Dependencies

To enable this output, set the `NumIterationsOutputPort` property to `true`.

`parity` — Final parity checks

column vector

Final parity checks after decoding the input LDPC code, returned as an (*N*-*K*)-by-1 column vector. *N* is the number of bits in the LDPC codeword before modulation. *K* is the length of the uncoded message.

Dependencies

To enable this output, set the `FinalParityChecksOutputPort` property to `true`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

LDPC Encode and Decode QPSK-Modulated Signal Using GPU

Using a `comm.gpu.LDPCDecoder` System Object™ to decode the signal, transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. After adding AWGN, demodulate and decode the received signal. Compute the error statistics for the reception of uncoded and LDPC-coded signals. For more information, see “Simulation Acceleration Using GPUs”.

Define simulation variables. Create System objects for the LDPC encoder, LDPC decoder, QPSK modulator, and QPSK demodulators.

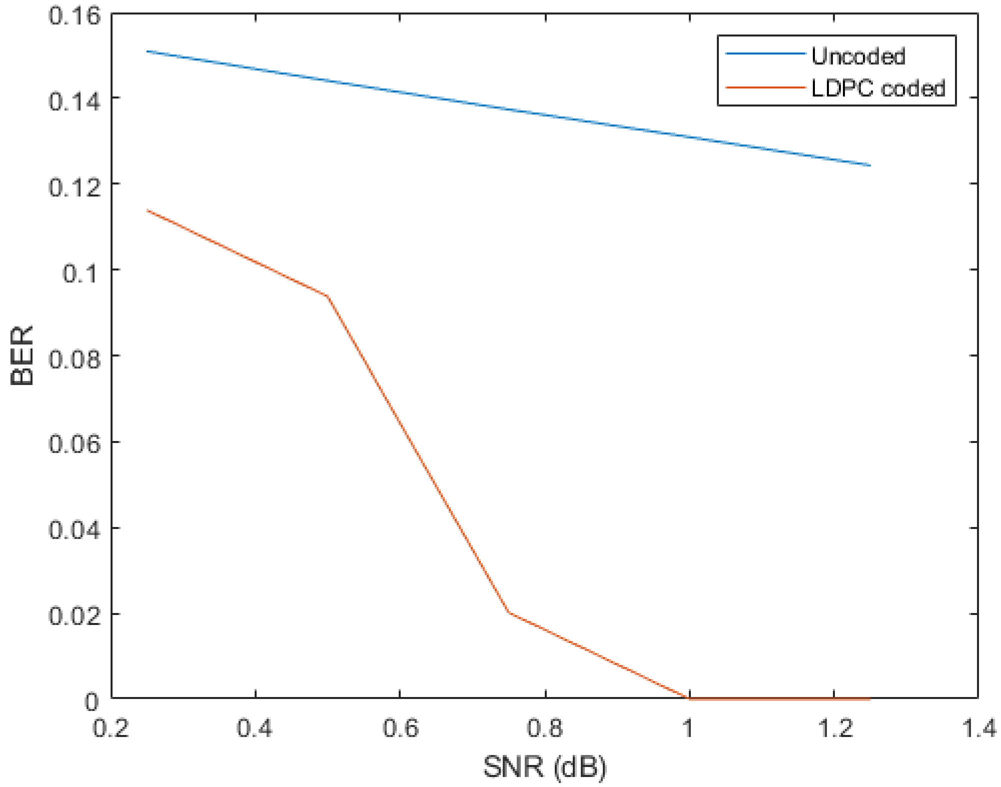
```
M = 4; % Modulation order (QPSK)
snr = [0.25,0.5,0.75,1.0,1.25];
numFrames = 10;
ldpcEncoder = comm.LDPCEncoder;
gpuldpcDecoder = comm.gpu.LDPCDecoder;
pskMod = comm.PSKModulator(M,'BitInput',true);
pskDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Approximate log-likelihood ratio');
pskuDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Hard decision');
errRate = zeros(1,length(snr));
uncErrRate = zeros(1,length(snr));
```

For each SNR setting and all frames, compute the error statistics for uncoded and LDPC-coded signals.

```
for ii = 1:length(snr)
    ttlErr = 0;
    ttlErrUnc = 0;
    pskDemod.Variance = 1/10^(snr(ii)/10); % Set variance using current SNR
    for counter = 1:numFrames
        data = logical(randi([0 1],32400,1));
        % Transmit and receiver uncoded signal data
        mod_uncSig = pskMod(data);
        rx_uncSig = awgn(mod_uncSig,snr(ii),'measured');
        demod_uncSig = pskuDemod(rx_uncSig);
        numErrUnc = biterr(data,demod_uncSig);
        ttlErrUnc = ttlErrUnc + numErrUnc;
        % Transmit and receive LDPC coded signal data
        encData = ldpcEncoder(data);
        modSig = pskMod(encData);
        rxSig = awgn(modSig,snr(ii),'measured');
        demodSig = pskDemod(rxSig);
        rxBits = gpuldpcDecoder(demodSig);
        numErr = biterr(data,rxBits);
        ttlErr = ttlErr + numErr;
    end
    ttlBits = numFrames*length(rxBits);
    uncErrRate(ii) = ttlErrUnc/ttlBits;
    errRate(ii) = ttlErr/ttlBits;
end
```

Plot the error statistics for uncoded and LDPC-coded data.

```
plot(snr,uncErrRate,snr,errRate)
legend('Uncoded','LDPC coded')
xlabel('SNR (dB)')
ylabel('BER')
```

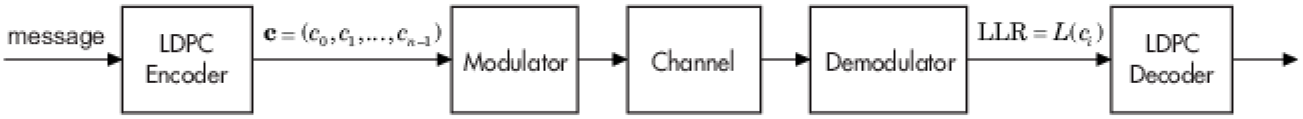


Algorithms

This object performs LDPC decoding using the belief propagation algorithm, also known as a message-passing algorithm.

Belief Propagation Decoding

The implementation of the belief propagation algorithm is based on the decoding algorithm presented by Gallager.



For transmitted LDPC-encoded codeword $c = c_0, c_1, \ldots, c_{n-1}$, the input to the LDPC decoder is the log-likelihood ratio (LLR) value $L(c_i) = \log\left(\frac{\Pr(c_i = 0 \mid \text{channel output for } c_i)}{\Pr(c_i = 1 \mid \text{channel output for } c_i)}\right)$.

In each iteration, the key components of the algorithm are updated based on these equations:

$$L(r_{ji}) = 2\,\mathrm{atanh}\left(\prod_{i' \in V_j \backslash i} \tanh\left(\frac{1}{2} L(q_{i'j})\right)\right),$$

$L(q_{ij}) = L(c_i) + \sum_{j' \in C_i \backslash j} L(r_{j'i})$, initialized as $L(q_{ij}) = L(c_i)$ before the first iteration, and

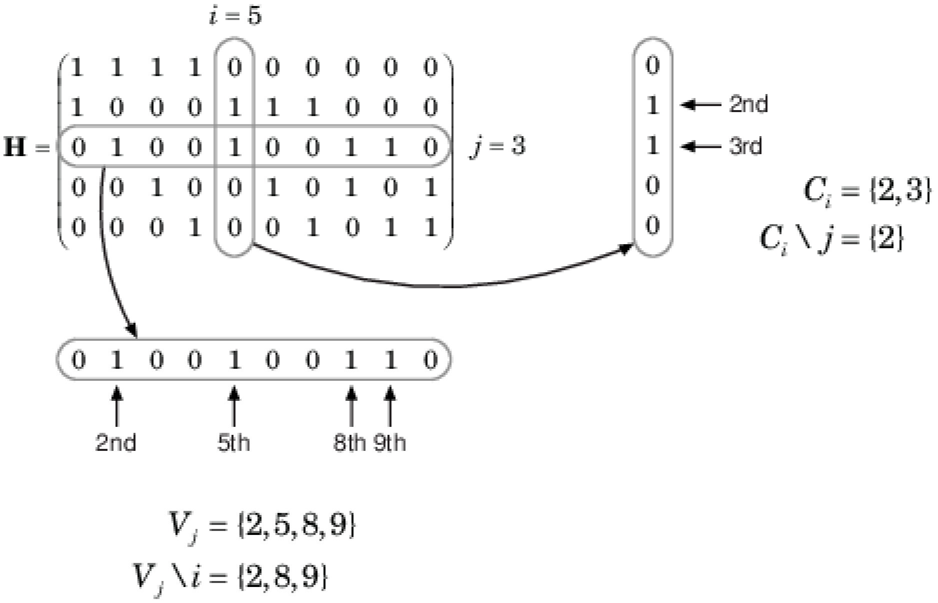
$L(Q_i) = L(c_i) + \sum_{j' \in C_i} L(r_{j'i})$.

At the end of each iteration, $L(Q_i)$ contains the updated estimate of the LLR value for transmitted bit c_i. The value $L(Q_i)$ is the soft-decision output for c_i. If $L(Q_i) < 0$, the hard-decision output for c_i is 1. Otherwise, the hard-decision output for c_i is 0.

If configured to stop when all parity checks are satisfied, the algorithm verifies the parity-check equation ($H\ c' = 0$) at the end of each iteration. When all parity checks are satisfied, or if the maximum number of iterations is reached, decoding stops.

Index sets $C_i \backslash j$ and $V_j \backslash i$ are based on the parity-check matrix (PCM). Index sets C_i and V_j correspond to all nonzero elements in column i and row j of the PCM, respectively.

This figure highlights the computation of these index sets in a given PCM for $i = 5$ and $j = 3$.



To avoid infinite numbers in the algorithm equations, atanh(1) and atanh(-1) are set to 19.07 and –19.07, respectively. Due to finite precision, MATLAB returns 1 for tanh(19.07) and –1 for tanh(-19.07).

comm.gpu.PSKDemodulator

Package: `comm`

Demodulate using M-ary PSK method with GPU

Description

The `GPU PSKDemodulator` object demodulates an input signal using the M-ary phase shift keying (M-PSK) method.

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To demodulate a signal that was modulated using phase shift keying:

1. Define and set up your PSK demodulator object. See “Construction” on page 3-761.
2. Call `step` to demodulate the signal according to the properties of `comm.gpu.PSKDemodulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.gpu.PSKDemodulator` returns a GPU-based demodulator System object, `H`. This object demodulates the input signal using the M-ary phase shift keying (M-PSK) method.

`H = comm.gpu.PSKDemodulator(Name,Value)` creates a GPU-based M-PSK demodulator object, `H,` with the specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN)

`H = comm.gpu.PSKDemodulator(M,PHASE,Name,Value)` creates a GPU-based M-PSK demodulator object, `H`, with the ModulationOrder property set to `M`, the PhaseOffset property set to `PHASE` and other specified property names set to the specified values. `M` and `PHASE` are value-only arguments. To specify a value-only argument, you must also specify all preceding value-only arguments. You can specify name-value pair arguments in any order.

Properties

ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar. The default is 8.

PhaseOffset

Phase of zeroth point of constellation

Specify the phase offset of the zeroth point of the constellation, in radians, as a real scalar. The default is π/8.

BitOutput

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. When you set this property to true, the step method outputs a column vector of bit values with length equal to log2(ModulationOrder) times the number of demodulated symbols. When you set this property to false, the step method outputs a column vector, with a length equal to the input data vector that contains integer symbol values between 0 and ModulationOrder-1. The default is false.

SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of log2(ModulationOrder) bits to the corresponding symbol as Binary | Gray | Custom. The default is Gray. When you set this property to Gray, the object uses a Gray-encoded signal constellation. When you set this property to Binary, the integer m (0 ≤ m ≤ModulationOrder-1) maps to the complex value. This value is represented as exp(j*PhaseOffset + j*2*pi*m/ModulationOrder). When you set this property to Custom, the object uses the signal constellation defined in the CustomSymbolMapping property.

CustomSymbolMapping

Custom constellation encoding

Specify a custom constellation symbol mapping vector. The default is 0:7. This property must be a row or column vector of size ModulationOrder with unique integer values in the range [0, ModulationOrder-1]. The values must be of data type double. The first element of this vector corresponds to the constellation point at an angle of 0 + PhaseOffset, with subsequent elements running counterclockwise. The last element corresponds to the constellation point at an angle of -π/ModulationOrder + PhaseOffset. This property applies when you set the SymbolMapping property to Custom.

DecisionMethod

Demodulation decision method

Specify the decision method that the object uses as one of `Hard decision` | `Log-likelihood ratio` | `Approximate log-likelihood ratio`. The default is `Hard decision`. When you set `DecisionMethod` to false, the object always performs hard decision demodulation. This property applies when you set the BitOutput property to true.

VarianceSource

Source of noise variance

Specify the source of the noise variance as one of `Property` | `Input port`. The default is `Property`. This property applies when you set the BitOutput property to `true` and the DecisionMethod property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`.

Variance

Specify the variance of the noise as a positive, real scalar. The default is `1`. If this value is very small (i.e., SNR is very high), then log-likelihood ratio (LLR) computations may yield Inf or -Inf. This occurs because the LLR algorithm computes the exponential value of very large or very small numbers using finite precision arithmetic. In such cases, use approximate LLR is recommended because its algorithm does not compute exponentials. This property applies when you set the BitOutput property to true, the DecisionMethod property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`, and the VarianceSource property to `Property`. This property is tunable.

OutputDataType

Data type of output

When you set this property to `Full precision`, the output signal inherits its data type from the input signal.

Methods

constellation	Calculate or plot ideal signal constellation
step	Demodulate using M-ary PSK method

Common to All System Objects	
`release`	Allow System object property value changes

Algorithm

The `GPU PSK Demodulator` System object uses the same algorithm as the `comm.PSKDemodulator` System object. See Decoding Algorithm for details.

Examples

Transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. Then demodulate, decode, and count errors.

16-PSK Modulation and Demodulation

Transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel.

Create a GPU-based PSK Modulator System object.

```
hMod = comm.gpu.PSKModulator(16, 'PhaseOffset',pi/16);
```

Create a GPU-based AWGN Channel System object with a signal-to-noise ratio of 15.

```
hAWGN = comm.gpu.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)','SNR',15);
```

Create a GPU-based PSK Demodulator System object.

```
 hDemod = comm.gpu.PSKDemodulator(16, 'PhaseOffset',pi/16);
```

Create an error rate calculator System object.

```
hError = comm.ErrorRate;
```

Transmit a frame of data containing 50 symbols.

```
for counter = 1:100
data = gpuArray.randi([0 hMod.ModulationOrder-1], 50, 1);
```

Run the simulation by using the step method to process data.

```
modSignal = step(hMod, data);
noisySignal = step(hAWGN, modSignal);
receivedData = step(hDemod, noisySignal);
errorStats = step(hError, gather(data), gather(receivedData));
end
```

Compute the error rate results.

```
fprintf('Error rate = %f\nNumber of errors = %d\n',...
    errorStats(1), errorStats(2))
```

GPU PSK Demodulator

Create GPU PSK modulator and demodulator pair.

```
gpuMod = comm.gpu.PSKModulator;
gpuDemod = comm.gpu.PSKDemodulator;
```

Generate random data symbols. Modulate the data.

```
txData = randi([0 7],1000,1);
txSig = gpuMod(txData);
```

Pass the signal through an AWGN channel.

```
rxSig = awgn(txSig,20);
```

Demodulate the received signal.

```
rxData = gpuDemod(rxSig);
```

Determine the number of symbol errors.

```
numSymErrors = symerr(txData,rxData)
```

```
numSymErrors =
```

736

`comm.PSKDemodulator` | `comm.gpu.PSKModulator`

Introduced in R2012a

constellation

Calculate or plot ideal signal constellation

Syntax

```
y = constellation(h)
constellation(h)
```

Description

`y = constellation(h)` returns the numerical values of the constellation.

`constellation(h)` generates a constellation plot for the object.

Examples

Calculate Ideal Signal Constellation for comm.gpu.PSKDemodulator

Create a `comm.gpu.PSKDemodulator` System object, and then calculate its ideal signal constellation.

Create a `comm.gpu.PSKDemodulator` System object by entering the following at the MATLAB command line:

```
h = comm.gpu.PSKDemodulator
```

Calculate and display the ideal signal constellation by calling the `constellation` method.

```
a = constellation(h)
```

Plot Ideal Signal Constellation for comm.gpu.PSKDemodulator

Create a `comm.gpu.PSKDemodulator` System object, and then plot the ideal signal constellation.

Create a `comm.gpu.PSKDemodulator` System object by entering the following at the MATLAB command line:

```
h = comm.gpu.PSKDemodulator
```

Plot the ideal signal constellation by calling the `constellation` method.

```
constellation(h)
```

step

Demodulate using M-ary PSK method

Syntax

```
Y = step(H,X)
Y = step(H,X,VAR)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates data, `X`, with the `GPU PSK Demodulator` System object, `H`, and returns `Y`. Input `X` must be a scalar or a column vector with double- or single- precision data type. Depending on the BitOutput property value, output `Y` can be integer or bit valued.

`Y = step(H,X,VAR)` uses soft decision demodulation and noise variance `VAR`. This syntax applies when you set the BitOutput property to true, the DecisionMethod property to `Approximate log-likelihood ratio` or `Log-likelihood ratio`, and the VarianceSource property to `Input port`. The data type of input `VAR` must be double or single precision.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.gpu.PSKModulator

Package: `comm`

Modulate using M-ary PSK method with GPU

Description

The `GPU PSKModulator` object modulates a signal using the M-ary phase shift keying method implemented on a graphics processing unit (GPU). The input is a baseband representation of the modulated signal. The input and output for this object are discrete-time signals. This object accepts a scalar-valued or column vector input signal.

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To modulate a signal using phase shift keying:

1. Define and set up your PSK modulator object. See “Construction” on page 3-768.
2. Call `step` to modulate the signal according to the properties of `comm.gpu.PSKModulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.gpu.PSKModulator` returns a GPU-based demodulator System object, `H`. This object modulates the input signal using the M-ary phase shift keying (M-PSK) method with soft decision using the approximate log-likelihood ratio algorithm.

`H = comm.gpu.PSKModulator(Name,Value)` creates a GPU-based M-PSK modulator object, `H`, with the specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN)

`H = comm.gpu.PSKModulator(M,PHASE,Name,Value)` creates a GPU-based M-PSK modulator object, `H`, with the ModulationOrder property set to `M`, the `PhaseOffset` property set to PHASE and other specified property Names set to the specified Values. `M` and PHASE are value-only arguments. To specify a value-only argument, you must also specify all preceding value-only arguments. You can specify name-value pair arguments in any order.

Properties

`ModulationOrder`

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar. The default is `8`.

`PhaseOffset`

Phase of zeroth point of constellation

Specify the phase offset of the zeroth point of the constellation, in radians, as a real scalar. The default is π/8.

`BitInput`

Assume bit inputs

Specify whether the input is bits or integers. The default is false. When you set this property to true, the step method input must be a column vector of bit values whose length is an integer multiple of log2(ModulationOrder). This vector contains bit representations of integers between 0 and ModulationOrder-1. The input data type can be numeric or logical. When you set the BitInput property to false, the step method input must be a column vector of integer symbol values between 0 and ModulationOrder-1. The data type of the input must be numeric.

`SymbolMapping`

Constellation encoding

Specify how the object maps an integer or group of log2(ModulationOrder) bits to the corresponding symbol as one of `Binary` | `Gray` | `Custom`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-encoded signal constellation. When you set this property to `Binary`, the integer m (0 ≤ m ≤ ModulationOrder-1) maps to the complex value exp(j*PhaseOffset + j*2*pi*m/ModulationOrder). When you set this property to `Custom`, the object uses the signal constellation defined in the CustomSymbolMapping property.

`CustomSymbolMapping`

Custom constellation encoding

Specify a custom constellation symbol mapping vector. This property must be a row or column vector of size `ModulationOrder` with unique integer values in the range [0, ModulationOrder-1]. The values must be of data type double. The first element of this vector corresponds to the constellation point at an angle of 0 + `PhaseOffset`, with subsequent elements running counterclockwise. The last element corresponds to the constellation point at an angle of -π/ModulationOrder + `PhaseOffset`. This property applies when you set the `SymbolMapping` property to Custom. The default is `0:7`.

OutputDataType

Data type of output

Specify the output data type as one of `double` | `single`. The default is `double`.

Methods

constellation	Calculate or plot ideal signal constellation
step	Modulate using M-ary PSK method with GPU

Common to All System Objects	
`release`	Allow System object property value changes

Algorithm

The `GPU PSK Modulator` System object supports floating-point and integer input data types. This object uses the same algorithm as the `comm.PSKModulator` System object. See the Algorithms section of the `comm.PSKModulator` help page for details.

Examples

GPU PSK Modulator

Create binary data for 100, 4-bit symbols

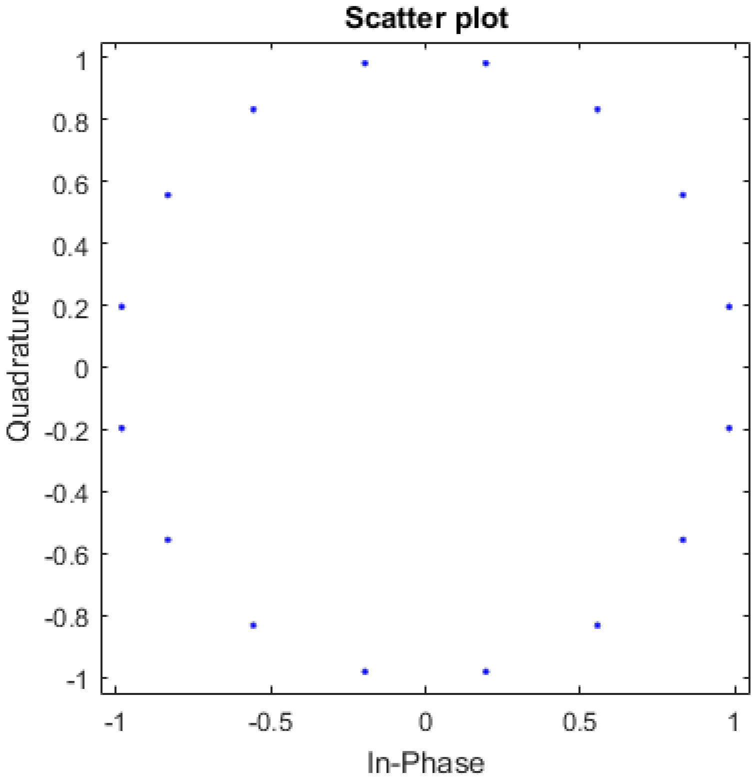
```
data = randi([0 1],400,1);
```

Create a 16-PSK modulator System object with bits as inputs and Gray-coded signal constellation. Change the phase offset to $\pi/16$.

```
gpuMod = comm.gpu.PSKModulator(16,'BitInput',true);
gpuMod.PhaseOffset = pi/16;
```

Modulate and plot the data

```
modData = gpuMod(data);
scatterplot(modData)
```



Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This System object runs on a GPU, and also supports GPU array inputs. For more information, see "Simulation Acceleration Using GPUs".

See Also

`comm.gpu.PSKDemodulator`

Introduced in R2012a

constellation

Calculate or plot ideal signal constellation

Syntax

```
y = constellation(h)
constellation(h)
```

Description

`y = constellation(h)` returns the numerical values of the constellation.

`constellation(h)` generates a constellation plot for the object.

Examples

Calculate Ideal Signal Constellation for comm.gpu.PSKModulator

Create a `comm.gpu.PSKModulator` System object, and then calculate its ideal signal constellation.

Create a `comm.gpu.PSKModulator` System object by entering the following at the MATLAB command line:

```
h = comm.gpu.PSKModulator
```

Calculate and display the ideal signal constellation by calling the `constellation` method.

```
a = constellation(h)
```

Plot Ideal Signal Constellation for comm.gpu.PSKModulator

Create a `comm.gpu.PSKModulator` System object, and then plot the ideal signal constellation.

Create a `comm.gpu.PSKModulator` System object by entering the following at the MATLAB command line:

```
h = comm.gpu.PSKModulator
```

Plot the ideal signal constellation by calling the `constellation` method.

```
constellation(h)
```

step

Modulate using M-ary PSK method with GPU

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` modulates the input data, `X`, using the GPU-based PSK modulator System object, `H`. The object returns the baseband modulated output `Y`. Depending upon the value of the BitInput property, input `X` can be an integer or bit-valued column vector with numeric or logical data types.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.gpu.TurboDecoder

Package: `comm.gpu`

Decode input signal using parallel concatenation decoding with GPU

Description

The `GPU Turbo Decoder` System object decodes the input signal using a parallel concatenated decoding scheme. This scheme uses the *a-posteriori* probability (APP) decoder as the constituent decoder. Both constituent decoders use the same trellis structure and algorithm.

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see "GPU Computing" (Parallel Computing Toolbox).

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see "Establish Arrays on a GPU" (Parallel Computing Toolbox).

To decode an input signal using a turbo decoding scheme:

1. Define and set up your turbo decoder object. See "Construction" on page 3-774.
2. Call `step` to decode a binary signal according to the properties of `comm.gpu.TurboDecoder`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.gpu.TurboDecoder` creates a GPU-based turbo decoder System object, `H`. This object uses the *a-posteriori* probability (APP) constituent decoder to iteratively decode the parallel-concatenated convolutionally encoded input data.

`H = comm.gpu.TurboDecoder(Name, Value)` creates a GPU-based turbo decoder object, `H`, with the specified property name set to the specified value. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

H = comm.gpu.TurboDecoder(TRELLIS, INTERLVRINDICES, NUMITER) creates a GPU-based turbo decoder object, H. In this object, the TrellisStructure property is set to TRELLIS, the InterleaverIndices property set to INTERLVRINDICES, and the NumIterations property set to NUMITER.

Properties

TrellisStructure

Trellis structure of constituent convolutional code

Specify the trellis as a MATLAB structure that contains the trellis description of the constituent convolutional code. The default is the result of poly2trellis(4, [13 15], 13). Use the istrellis function to check if a structure is a valid trellis structure.

InterleaverIndicesSource

Source of interleaver indices

Specify the source of the interleaver indices. The only valid setting for this property is Property.

InterleaverIndices

Interleaver indices

Specify the mapping used to permute the input bits at the encoder as a column vector of integers. The default is (64:-1:1).'. This mapping is a vector with the number of elements equal to the length, *L*, of the output of the step method. Each element must be an integer between 1 and *L*, with no repeated values.

Algorithm

Decoding algorithm

Specify the decoding algorithm. This object implements true *a posteriori* probability decoding. The only valid setting is True APP.

NumScalingBits

Number of scaling bits

The GPU version of the Turbo Decoder does not use this property.

NumIterations

Number of decoding iterations

Specify the number of decoding iterations used for each call to the step method. The default is 6. The object iterates and provides updates to the log-likelihood ratios (LLR) of the uncoded output bits. The output of the step method is the hard-decision output of the final LLR update.

NumFrames

Number of independent frames present in the input and output data vectors.

Specify the number of independent frames that a single data input/output vector contains. The default value of this property is `1`. This object segments the input vector into `NumFrames` segments and decodes the segments independently. The output contains `NumFrames` decoded segments.

Methods

reset	Reset states of the turbo decoder object
step	Decode input signal using parallel concatenated decoding scheme

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Transmit and decode using turbo coding

Transmit turbo-encoded blocks of data over a BPSK-modulated AWGN channel. Then, decode using an iterative turbo decoder and display errors.

Define a noise variable, establish a frame length of 256, and use the random stream property so that the results are repeatable.

```
noiseVar = 4; frmLen = 256;
s = RandStream('mt19937ar', 'Seed', 11);
intrlvrIndices = randperm(s, frmLen);
```

Create a Turbo Encoder System object. The trellis structure for the constituent convolutional code is poly2trellis(4, [13 15 17], 13). The `InterleaverIndices` property specifies the mapping the object uses to permute the input bits at the encoder as a column vector of integers.

```
turboEnc = comm.TurboEncoder('TrellisStructure', poly2trellis(4, ...
      [13 15 17], 13), 'InterleaverIndices', intrlvrIndices);
```

Create a BPSK Modulator System object.

```
bpsk = comm.BPSKModulator;
```

Create an AWGN Channel System object.

```
channel = comm.AWGNChannel('NoiseMethod', 'Variance', 'Variance', ...
      noiseVar);
```

Create a GPU-Based Turbo Decoder System object. The trellis structure for the constituent convolutional code is poly2trellis(4, [13 15 17], 13). The `InterleaverIndicies` property specifies the mapping the object uses to permute the input bits at the encoder as a column vector of integers.

```
turboDec = comm.gpu.TurboDecoder('TrellisStructure', poly2trellis(4, ...
      [13 15 17], 13), 'InterleaverIndices', intrlvrIndices, ...
      'NumIterations', 4);
```

Create an Error Rate System object.

```
errorRate = comm.ErrorRate;
```

Run the simulation.

```
for frmIdx = 1:8
 data = randi(s, [0 1], frmLen, 1);
 encodedData = turboEnc(data);
 modSignal = bpsk(encodedData);
 receivedSignal = channel(modSignal);
```

Convert the received signal to log-likelihood ratios for decoding.

```
receivedBits  = turboDec(-2/(noiseVar/2))*real(receivedSignal));
```

Compare original the data to the received data and then calculate the error rate results.

```
errorStats = errorRate(data,receivedBits);
end
fprintf('Error rate = %f\nNumber of errors = %d\nTotal bits = %d\n', ...
errorStats(1), errorStats(2), errorStats(3))
```

Algorithms

This object implements the inputs and outputs described on the Turbo Decoder block reference page. The object properties correspond to the block parameters.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This System object runs on a GPU, and also supports GPU array inputs. For more information, see “Simulation Acceleration Using GPUs”.

See Also

comm.TurboDecoder | comm.TurboEncoder

Introduced in R2012a

reset

System object: `comm.gpu.TurboDecoder`
Package: `comm.gpu`

Reset states of the turbo decoder object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `GPU TurboDecoder` object, `H`.

step

System object: `comm.gpu.TurboDecoder`
Package: `comm.gpu`

Decode input signal using parallel concatenated decoding scheme

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` decodes the input data, `X`, using the parallel concatenated convolutional coding scheme. You specify this scheme using the TrellisStructure and InterleaverIndices properties. It returns the binary decoded data, `Y`. Both `X` and `Y` are column vectors of double-precision data type. When the constituent convolutional code represents a rate 1/*N* code, the step method sets the length of the output vector, `Y`, to (M-2*N_{Tails})/(2*N-1). *M* represents the input vector length and N_{Tails} is given by log2(`TrellisStructure.numStates`)**N*. The output length, `L`, is the same as the length of the interleaver indices.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.gpu.ViterbiDecoder

Package: `comm`

Decode convolutionally encoded data using Viterbi algorithm with GPU

Description

The `GPU ViterbiDecoder` System object decodes input symbols to produce binary output symbols using a graphics processing unit (GPU). This object processes variable-size signals; however, variable-size signals cannot be applied for erasure inputs.

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see "GPU Computing" (Parallel Computing Toolbox).

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see "Establish Arrays on a GPU" (Parallel Computing Toolbox).

To decode input symbols and produce binary output symbols:

1. Define and set up your Viterbi decoder object. See "Construction" on page 3-780.
2. Call `step` to decode input symbols according to the properties of `comm.gpu.ViterbiDecoder`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.gpu.ViterbiDecoder` creates a Viterbi decoder System object, `H`. This object uses the Viterbi algorithm to decode convolutionally encoded input data.

`H = comm.gpu.ViterbiDecoder(Name,Value)` creates a Viterbi decoder object, `H`, with the specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`.

H = comm.gpu.ViterbiDecoder(TRELLIS,Name,Value) creates a Viterbi decoder object, H, with the TrellisStructure property set to TRELLIS, and other specified property Names set to the specified Values.

Properties

TrellisStructure

Trellis structure of convolutional code

Specify the trellis as a MATLAB structure that contains the trellis description of the convolutional code. Use the istrellis function to check if a structure is a valid trellis structure. This object supports rate 1/2, 1/3 and 1/4 trellises from simple feedforward encoders. The default value is the result of poly2trellis(7, [171 133]).

InputFormat

Input format

Specify the format of the input to the decoder as one of Unquantized | Hard | Soft. The default is Unquantized.

When you set this property to Unquantized, the input must be a real vector of double or single precision unquantized soft values. The object considers negative numbers to be ones and positive numbers to be zeros. When you set this property to Hard, the input must be a vector of hard decision values, which are zeros or ones. The data type of the inputs can be double precision or single precision. When you set this property to Soft, the input must be a vector of quantized soft values represented as integers between 0 and 2^SoftInputWordLength-1. The data type of the inputs can be double precision or single precision.

SoftInputWordLength

Soft input word length

Specify the number of bits used to represent each quantized soft input value as a positive, integer scalar. This property applies when you set the InputFormat property to Soft. The default is 4 bits.

InvalidQuantizedInputAction

Action when input values are out of range

The only valid setting is Ignore which ignores out of range inputs.

TracebackDepth

Traceback depth

Specify the number of trellis branches used to construct each traceback path as a positive, integer scalar less than or equal to 256. The traceback depth influences the decoding accuracy and delay. The number of zero symbols that precede the first decoded symbol in the output represent a decoding delay. When you set the TerminationMethod property to Continuous, the decoding delay consists of TracebackDepth zero symbols, or TracebackDepth zero bits for a rate 1/N convolutional code. When you set the TerminationMethod property to Truncated or Terminated, there is no output delay and TracebackDepth must be less than or equal to the number of symbols in each input. If the code rate is 1/2, a typical traceback depth value is about five times the constraint length of the code. The default is 34.

TerminationMethod

Termination method of encoded frame

Specify TerminationMethod as one of Continuous | Truncated | Terminated. The default is Continuous. In Continuous mode, the object saves its internal state metric at the end of each frame for use with the next frame. The object treats each traceback path independently. Select Continuous mode when the input signal contains only one symbol. In Truncated mode, the object treats each frame independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state. In Terminated mode, the object treats each frame independently, and the traceback path always starts and ends in the all-zeros state.

ResetInputPort

Enable decoder reset input

Set this property to true to enable an additional step method input. When the reset input is a non-zero value, the object resets the internal states of the decoder to initial conditions. This property applies when you set the TerminationMethod property to Continuous. The default is false.

DelayedResetAction

Delay output reset

Delaying the output reset is not supported. The only valid setting is false.

PuncturePatternSource

Source of puncture pattern

Specify the source of the puncture pattern as one of None | Property. The default is None. When you set this property to None the object assumes no puncturing. Set this property to Property to decode punctured codewords based on a puncture pattern vector specified via the PuncturePattern property.

PuncturePattern

Puncture pattern vector

Specify puncture pattern used to puncture the encoded data. The default is [1; 1; 0; 1; 0; 1]. The puncture pattern is a column vector of ones and zeros, where the zeros indicate where to insert dummy bits. The puncture pattern must match the puncture pattern used by the encoder. This property applies when you set the PuncturePatternSource property to Property.

ErasuresInputPort

Enable erasures input

Erasures are not supported. The only valid setting is false.

OutputDataType

Data type of output

The only valid setting is `Full precision` which makes the output data type match the input data type.

`NumFrames`

Number of independent frames present in the input and output data vectors.

Specify the number of independent frames contained in a single data input/output vector. The input vector will be segmented into `NumFrames` segments and decoded independently. The output will contain `NumFrames` decoded segments. The default value of this property is `1`. This property is applies when you set the TerminationMethod is set to `Terminated` or `Truncated`.

Methods

info	Display information about GPU-based Viterbi Decoder object
reset	Reset states of the GPU-based Viterbi Decoder modulator object
step	Decode convolutionally encoded data using Viterbi algorithm

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Transmit a convolutionally encoded 8-DPSK-modulated bit stream through an AWGN channel. Then, demodulate, decode using a Viterbi decoder, and count errors.

```
hConEnc = comm.ConvolutionalEncoder;
hMod = comm.DPSKModulator('BitInput',true);
hChan = comm.gpu.AWGNChannel('NoiseMethod', ...
            'Signal to noise ratio (SNR)', 'SNR',10);
hDemod = comm.DPSKDemodulator('BitOutput',true);
hDec = comm.gpu.ViterbiDecoder('InputFormat','Hard');
% Delay in bits is TracebackDepth times the number of
% bits per symbol
delay = hDec.TracebackDepth* ...
   log2(hDec.TrellisStructure.numInputSymbols);
hError = comm.ErrorRate( ...
   'ComputationDelay',3,'ReceiveDelay',delay);
for counter = 1:20
   data = randi([0 1],30,1);
   encodedData = step(hConEnc, data);
   modSignal = step(hMod, encodedData);
   receivedSignal = step(hChan, modSignal);
   demodSignal = step(hDemod, receivedSignal);
   receivedBits = step(hDec, demodSignal);
   errorStats = step(hError, data, receivedBits);
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
errorStats(1), errorStats(2))
```

`comm.ViterbiDecoder`

Introduced in R2012a

info

System object: comm.gpu.ViterbiDecoder
Package: comm

Display information about GPU-based Viterbi Decoder object

Syntax

```
S = info(OBJ)
```

Description

S = info(OBJ) returns a structure, S, containing characteristic information for the System object, OBJ. If OBJ has no characteristic information, S is empty. If OBJ has characteristic information, the fields of S vary depending on OBJ. For object specific details, refer to the help on the infoImpl method of that object.

reset

System object: `comm.gpu.ViterbiDecoder`
Package: `comm`

Reset states of the GPU-based Viterbi Decoder modulator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the GPU-based `ViterbiDecoder` object, `H`.

step

System object: `comm.gpu.ViterbiDecoder`
Package: `comm`

Decode convolutionally encoded data using Viterbi algorithm

Syntax

```
Y = step(H,X)
Y = step(H,X,R)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` decodes encoded data, `X`, using the Viterbi algorithm and returns `Y`. `X`, must be a column vector with data type and values that depend on how you set the `InputFormat` property. If the convolutional code uses an alphabet of 2^N possible symbols, the length of the input vector, `X`, must be `L*N` for some positive integer `L`. Similarly, if the decoded data uses an alphabet of 2^K possible output symbols, the length of the output vector, `Y`, is `L*K`.

`Y = step(H,X,R)` resets the internal states of the decoder when you input a non-zero reset signal, `R`. `R` must be a double precision, single precision or logical scalar. This syntax applies when you set the `TerminationMethod` property to `Continuous` and the `ResetInputPort` property to `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

gsmDownlinkConfig

Create GSM downlink TDMA frame configuration object

Description

The `gsmDownlinkConfig` object is a GSM downlink TDMA frame configuration object. Use `gsmDownlinkConfig` objects to create GSM downlink waveforms.

Creation

Syntax

```
cfggsmdl = gsmDownlinkConfig
cfggsmdl = gsmDownlinkConfig(sps)
cfggsmdl = gsmDownlinkConfig( ___ ,Name,Value)
```

Description

`cfggsmdl = gsmDownlinkConfig` creates a GSM downlink TDMA frame configuration object.

`cfggsmdl = gsmDownlinkConfig(sps)` sets the `SamplesPerSymbol` property to `sps`.

`cfggsmdl = gsmDownlinkConfig( ___ ,Name,Value)` sets one or more name-value pair arguments using any of the previous syntaxes. For example, `'RiseTime',4` sets the burst rise time to 4 symbols. Enclose each property in quotes. Specify name-value pair arguments after all other input arguments.

Properties

`SamplesPerSymbol` — Samples per symbol
`16` (default) | positive integer multiple of 4

Samples per symbol, specified as a positive integer multiple of 4.

Data Types: `double`

`BurstType` — Burst types
`["NB" "NB" "NB" "NB" "NB" "NB" "NB" "NB"]` (default) | string row vector with 8 elements | `"NB"` | `"FB"` | `"SB"` | `"Dummy"` | `"Off"`

Burst types for time slots 0–7 in the TDMA frame, specified as one of these options:

- Eight-element row vector where each value is `"NB"`, `"FB"`, `"SB"`, `"Dummy"`, or `"Off"` — Each element specifies the burst type for the corresponding time slot.
- `"NB"` — Transmit data using a normal burst for every time slot.
- `"FB"` — Transmit data using a frequency correction burst for every time slot.

- `"SB"` — Transmit data using a time synchronization burst for every time slot.
- `"Dummy"` — Transmit data using a dummy burst for every time slot.
- `"Off"` — All eight time slots contain no data.

For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-801.

Note The `BurstType` property is an enumeration. To perform code generation, see “Code Generation” on page 3-822 and the “MEX Generation for GSM Downlink Waveform” on page 3-796 example.

Example: `["NB" "AB" "AB" "NB" "Off" "NB" "AB" "Off"]` configures the frame to use normal bursts in time slots 0, 3, and 5, use access bursts in time slots 1, 2, and 6, and transmit no data in time slots 4 and 7.

TSC — Training sequence code

`[0 1 2 3 4 5 6 7]` (default) | eight-element row vector | integer in the range [0, 7]

Training sequence code (TSC) for normal bursts in time slots 0–7 in the TDMA frame, specified as one of these options:

- Eight-element row vector of integers in the range [0, 7] — Each element specifies the TSC value for the corresponding normal burst time slot.
- Integer in the range [0, 7] — Specifies the TSC value for every normal burst time slot.

For more information, see “Training Sequence Code (TSC)” on page 3-803.

Example: `[5 7 0 0 0 0 0 0]` configures the frame to use training sequence `5` in time slot 0, training sequence `7` in time slot 1, and training sequence `0` in time slots 2 through 7.

Dependencies

To enable this property for a time slot, set the corresponding element of `BurstType` to `"NB"`.

Data Types: `double`

`Attenuation` — Power attenuation

`[0 0 0 0 0 0 0 0]` (default) | eight-element row vector | nonnegative integer

Power attenuation in dB for time slots 0–7 in the TDMA frame, specified as one of these options:

- Eight-element row vector of nonnegative integers — Each element specifies the attenuation power value for the corresponding time slot.
- Nonnegative integer — Specifies the power attenuation value for every time slot.

Example: `[0 0 0 0 0 0 0 3]` configures the frame to apply 0 dB attenuation to the burst signal power in time slot 0 through 6 and 3 dB of attenuation to the burst signal power in time slot 7.

Data Types: `double`

`RiseTime` — Burst rise time

2 (default) | positive scalar

Burst rise time in symbols, specified as a positive scalar in the range [1/`SamplesPerSymbol`, 29], where the increment resolution is 1/`SamplesPerSymbol`. The total ramp-up and ramp-down duration

(RiseTime - RiseDelay + FallTime + FallDelay) must be less than 9.25 symbols. The characteristic shape of the rising edge of the burst is sinusoidal.

For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-801.

Data Types: double

RiseDelay — Burst rise delay
0 (default) | positive scalar

Burst rise delay in symbols, specified as a positive scalar in the range [–10, 10], where the increment resolution is 1/SamplesPerSymbol. The total ramp-up and ramp-down duration (RiseTime - RiseDelay + FallTime + FallDelay) must be less than 9.25 symbols. The burst rise delay is measured with respect to the start of the useful part of the burst. For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-801.

When the burst rise delay is 0, the burst reaches full amplitude at the start of the useful part of the burst. When the burst rise delay is positive, the burst reaches full amplitude RiseDelay symbols after the start of the useful part. When the burst rise delay is negative, the burst reaches full amplitude RiseDelay symbols before the start of the useful part.

Data Types: double

FallTime — Burst fall time
2 (default) | positive scalar

Burst fall time in symbols, specified as a positive scalar in the range [1/SamplesPerSymbol, 29], where the increment resolution is 1/SamplesPerSymbol. The total ramp-up and ramp-down duration (RiseTime - RiseDelay + FallTime + FallDelay) must be less than 9.25 symbols. The characteristic shape of the falling edge of the burst is sinusoidal.

For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-801.

Data Types: double

FallDelay — Burst fall delay
0 (default) | positive scalar

Burst fall delay in symbols, specified as a positive scalar in the range [–10, 10], where the increment resolution is 1/SamplesPerSymbol. The total ramp-up and ramp-down duration (RiseTime - RiseDelay + FallTime + FallDelay) must be less than 9.25 symbols. The burst fall delay is measured with respect to the end of the useful part of the burst. For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-801.

When the burst fall delay is 0, the burst begins decreasing from full amplitude at the end of the useful part of the burst. When the burst fall delay is positive, the burst begins decreasing from full amplitude FallDelay symbols after the end of the useful part. When the burst fall delay is negative, the burst begins decreasing from full amplitude FallDelay symbols before the end of the useful part.

Data Types: double

Examples

Create GSM Downlink Waveform

Create a GSM downlink TDMA frame configuration object with default settings, and then create a GSM waveform containing one TDMA frame. The GSM TDMA frame has eight time slots, each separated by a guard period of 8.25 symbols or about 30.46x10e-3 ms. Plot the GSM waveform.

Create a GSM downlink TDMA frame configuration object with default settings.

```
cfggsmdl = gsmDownlinkConfig
```

```
cfggsmdl = 
  gsmDownlinkConfig with properties:

           BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

Display information about the configured `gsmDownlinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmdl)
```

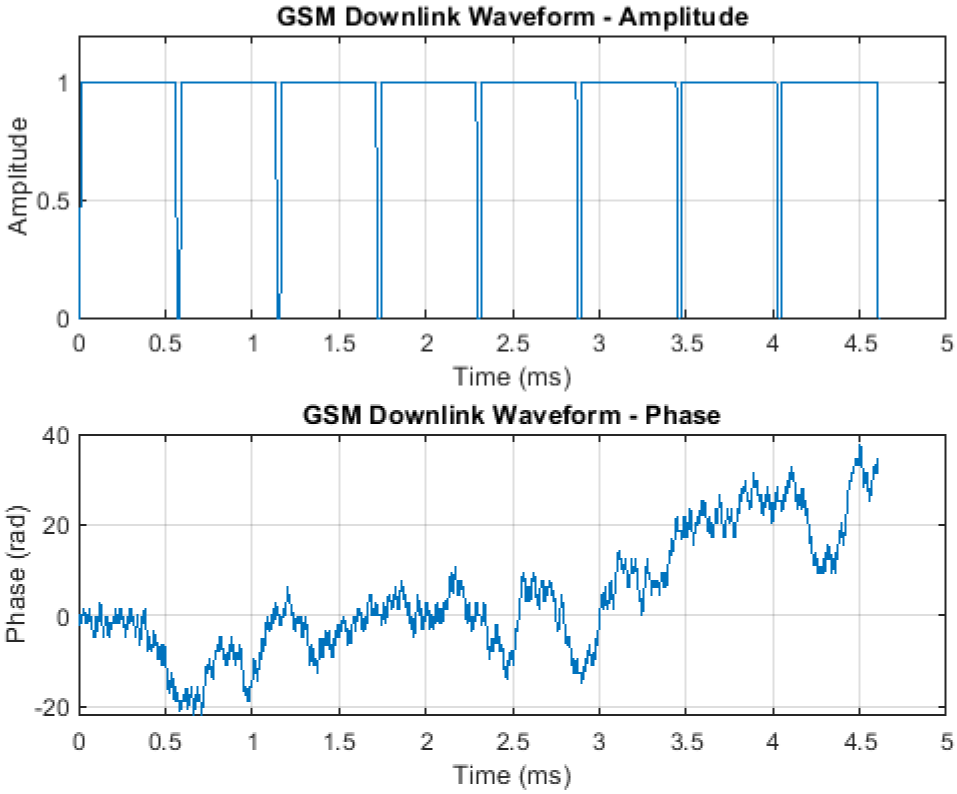
```
wfInfo = struct with fields:
              SymbolRate: 2.7083e+05
              SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
       NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmdl);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Downlink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Downlink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```



Create GSM Downlink Waveform with Specified Samples per Symbol

Create a GSM downlink TDMA frame configuration object that specifies 8 samples per symbol, and then create a GSM waveform containing one GSM downlink TDMA frame. The GSM TDMA frame are eight time slots, each separated by a guard period of 8.25 symbols or about 30.46x10e-3 ms separates each time slot. Plot the GSM waveform.

Create a GSM downlink TDMA frame configuration object, specifying 8 samples per symbols.

```
sps = 8;
cfggsmdl = gsmDownlinkConfig(sps)
```

```
cfggsmdl = 
  gsmDownlinkConfig with properties:

          BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 8
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

Display information about the configured `gsmDownlinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmdl)
```

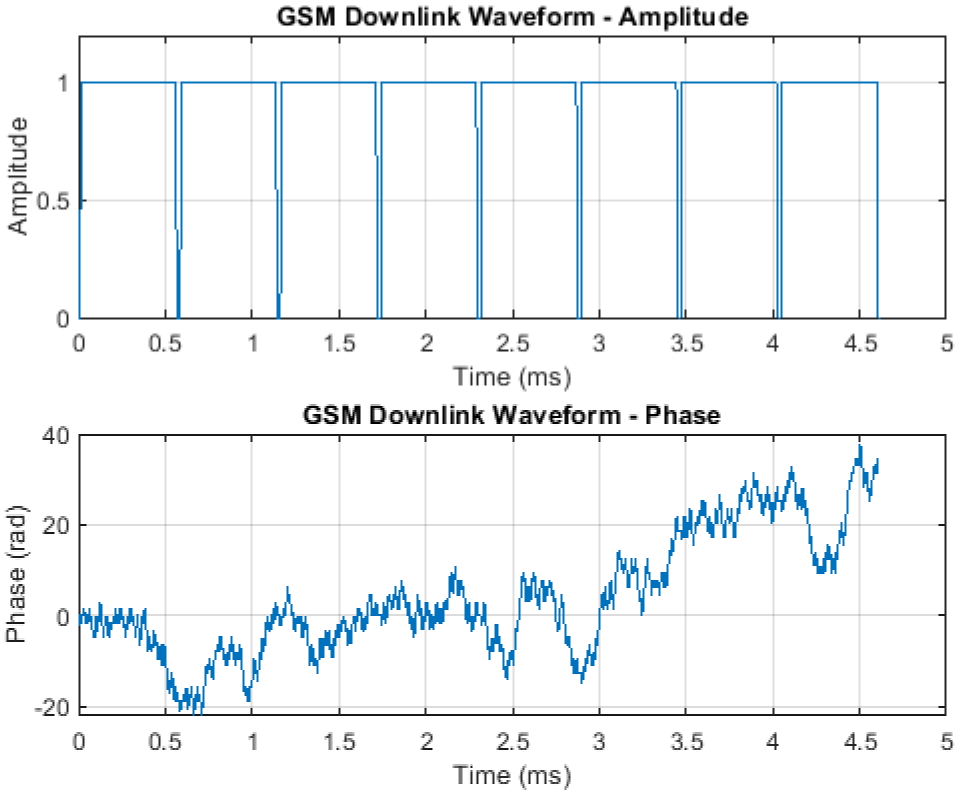
```
wfInfo = struct with fields:
              SymbolRate: 2.7083e+05
              SampleRate: 2.1667e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
       NumBurstsPerFrame: 8
    BurstLengthInSamples: 1250
    FrameLengthInSamples: 10000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmdl);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Downlink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Downlink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```



Create GSM Downlink Waveform with Specified Attenuation

Create two GSM downlink TDMA frame configuration objects. Specify default settings for the first `gsmDownlinkConfig` object and adjust the signal power per time slot for the second. Generate GSM waveforms for both configurations. Plot the waveforms to show the signal attenuation per time slot in the second waveform.

Create a GSM downlink TDMA frame configuration object with default settings.

```
cfggsmdl = gsmDownlinkConfig
```

```
cfggsmdl = 
  gsmDownlinkConfig with properties:

           BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

Create another GSM downlink TDMA frame configuration object, adjusting the signal attenuation settings per time slot.

```
cfggsmdl2 = gsmDownlinkConfig('Attenuation',[1 0 3 4 5 6 4 2])
```

```
cfggsmdl2 = 
  gsmDownlinkConfig with properties:

           BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [1 0 3 4 5 6 4 2]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

Display information about the configured `gsmDownlinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmdl)
```

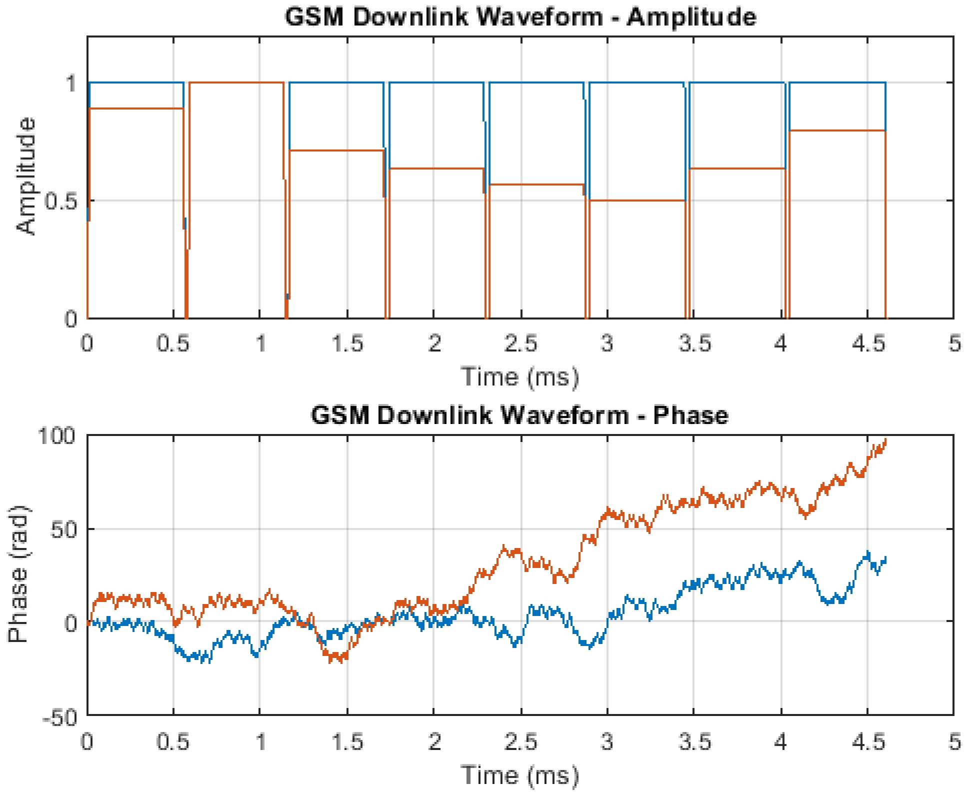
```
wfInfo = struct with fields:
              SymbolRate: 2.7083e+05
              SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
       NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveforms, containing one TDMA frame, by using the `gsmFrame` function. GSM TDMA frames have are eight time slots, each separated by a guard period of 8.25 symbols or about 30.46x10e-3 ms separates each time slot. Plot each GSM waveform.

```
waveform = gsmFrame(cfggsmdl);
waveform2 = gsmFrame(cfggsmdl2);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,[abs(waveform),abs(waveform2)])
grid on
axis([0 5 0 1.2])
title('GSM Downlink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,[unwrap(angle(waveform)),unwrap(angle(waveform2))])
grid on
title('GSM Downlink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```



MEX Generation for GSM Downlink Waveform

Generate and run a GSM waveform MEX function from the helper function `createDownlinkWaveform`. The `createDownlinkWaveform` helper function creates a GSM downlink waveform.

Write MATLAB Function

Open createDownlinkWaveform.m to see the code. The `createDownlinkWaveform` helper function generates a GSM downlink waveform by using the `gsmDownlinkConfig` object and the `gsmInfo` and `gsmFrame` functions.

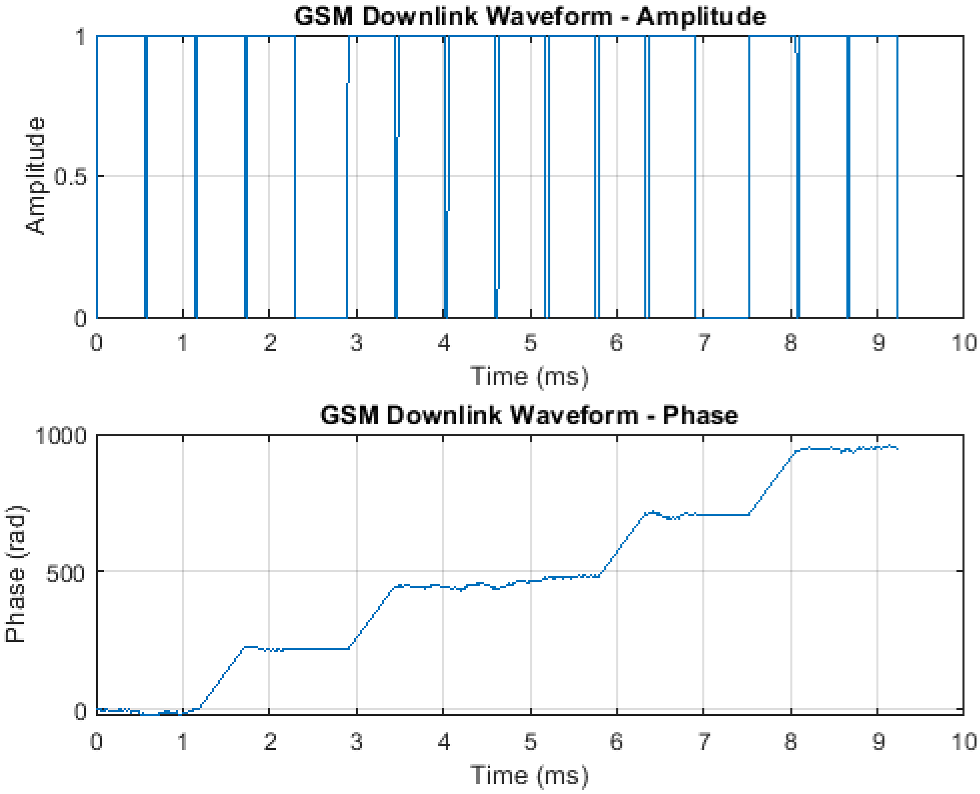
Generate GSM Waveform

Use the `createDownlinkWaveform` helper function to create a GSM waveform containing two TDMA frames, and then plot the waveform.

```
[x,t] = createDownlinkWaveform(2);

figure
subplot(2,1,1);
plot(t,abs(x));
grid on;
title('GSM Downlink Waveform - Amplitude');
```

```
xlabel('Time (ms)');
ylabel('Amplitude')
subplot(2,1,2);
plot(t,unwrap(angle(x)));
grid on;
title('GSM Downlink Waveform - Phase');
xlabel('Time (ms)');
ylabel('Phase (rad)')
```



Generate MEX Function

Code generation defaults to MEX code generation when you do not specify a build target. By default, `codegen` names the generated MEX function `createDownlinkWaveform_mex`. Generate a MEX function from the `createDownlinkWaveform` helper function, and then run the MEX function to create two TDMA frames.

```
codegen createDownlinkWaveform -args 3
```

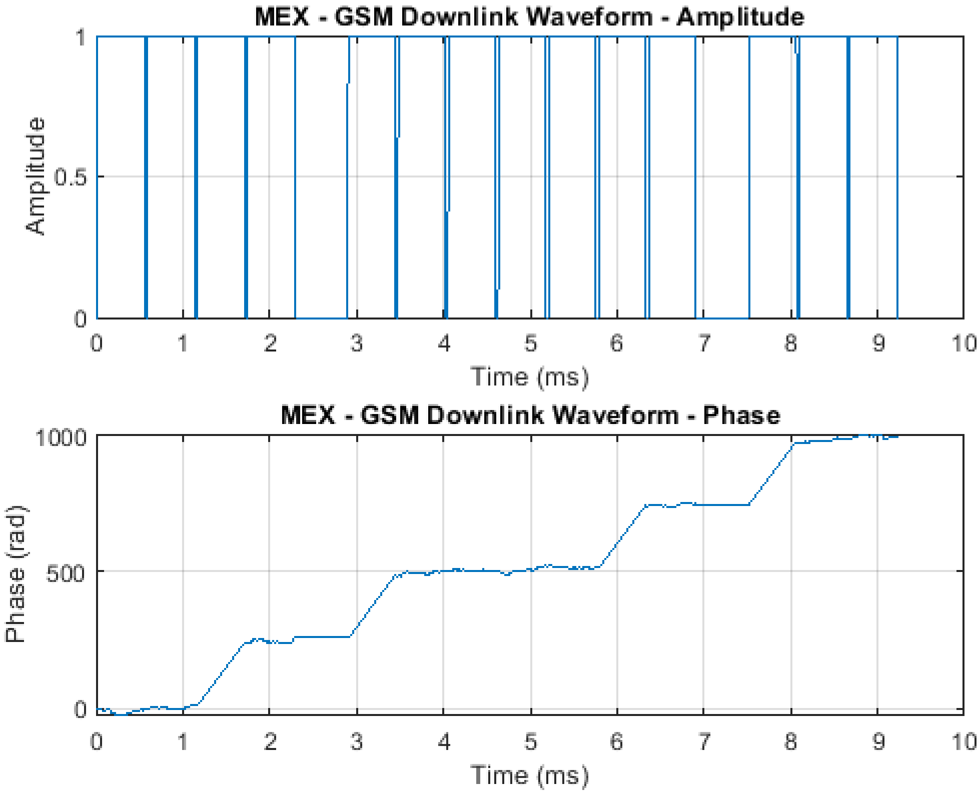
Generate Waveform Using MEX Function

Run the MEX function and plot the results. Since the waveform is created using random data, the phase plot changes each time you run the `generateDownlinkFrame` helper function or `createDownlinkWaveform_mex` function.

```
[x,t] = createDownlinkWaveform_mex(2);

figure
```

```
subplot(2,1,1);
plot(t,abs(x));
grid on;
title('MEX - GSM Downlink Waveform - Amplitude');
xlabel('Time (ms)');
ylabel('Amplitude')
subplot(2,1,2);
plot(t,unwrap(angle(x)));
grid on;
title('MEX - GSM Downlink Waveform - Phase');
xlabel('Time (ms)');
ylabel('Phase (rad)')
```

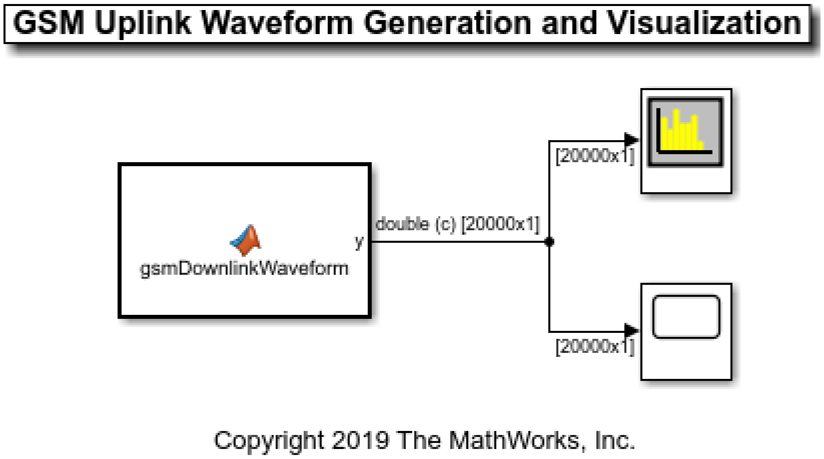


GSM Downlink Waveform Generation in Simulink

Model a GSM® waveform generator in Simulink® by using the MATLAB Function block and Communications Toolbox™ functions.

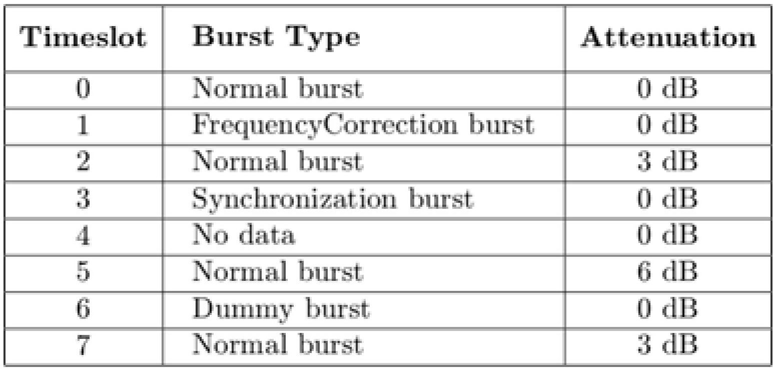
GSM Downlink Waveform Generation

The MATLAB Function (Simulink) block contains the `gsmDownlinkWaveform` function code. The code in the MATLAB Function block creates a GSM waveform by using the `gsmDownlinkConfig` object and the `gsmFrame` function.



GSM Uplink Waveform Generation and Visualization
gsmDownlinkWaveform
y
double (c) [20000x1]
[20000x1]
[20000x1]
Copyright 2019 The MathWorks, Inc.

The `gsmDownlinkConfig` object specifies 16 samples per symbol and the time slot configuration for the GSM downlink TDMA frame shown is this table.



Timeslot	Burst Type	Attenuation
0	Normal burst	0 dB
1	FrequencyCorrection burst	0 dB
2	Normal burst	3 dB
3	Synchronization burst	0 dB
4	No data	0 dB
5	Normal burst	6 dB
6	Dummy burst	0 dB
7	Normal burst	3 dB

The output waveform has 16 samples for each GMSK symbol. The `gsmFrame` function generates the samples of the waveform.

Explore the Model

In compliance with GSM standards 3GPP TS 45.001 and 3GPP TS 45.002, the sample time of the MATLAB Function block that contains the `gsmDownlinkWaveform` function code is set to the GSM symbol rate of 1625e3/6 symbols per second. Display the current `gsmDownlinkConfig` object settings by using the `gsmInfo` function.

```
wfInfo = 

  struct with fields:

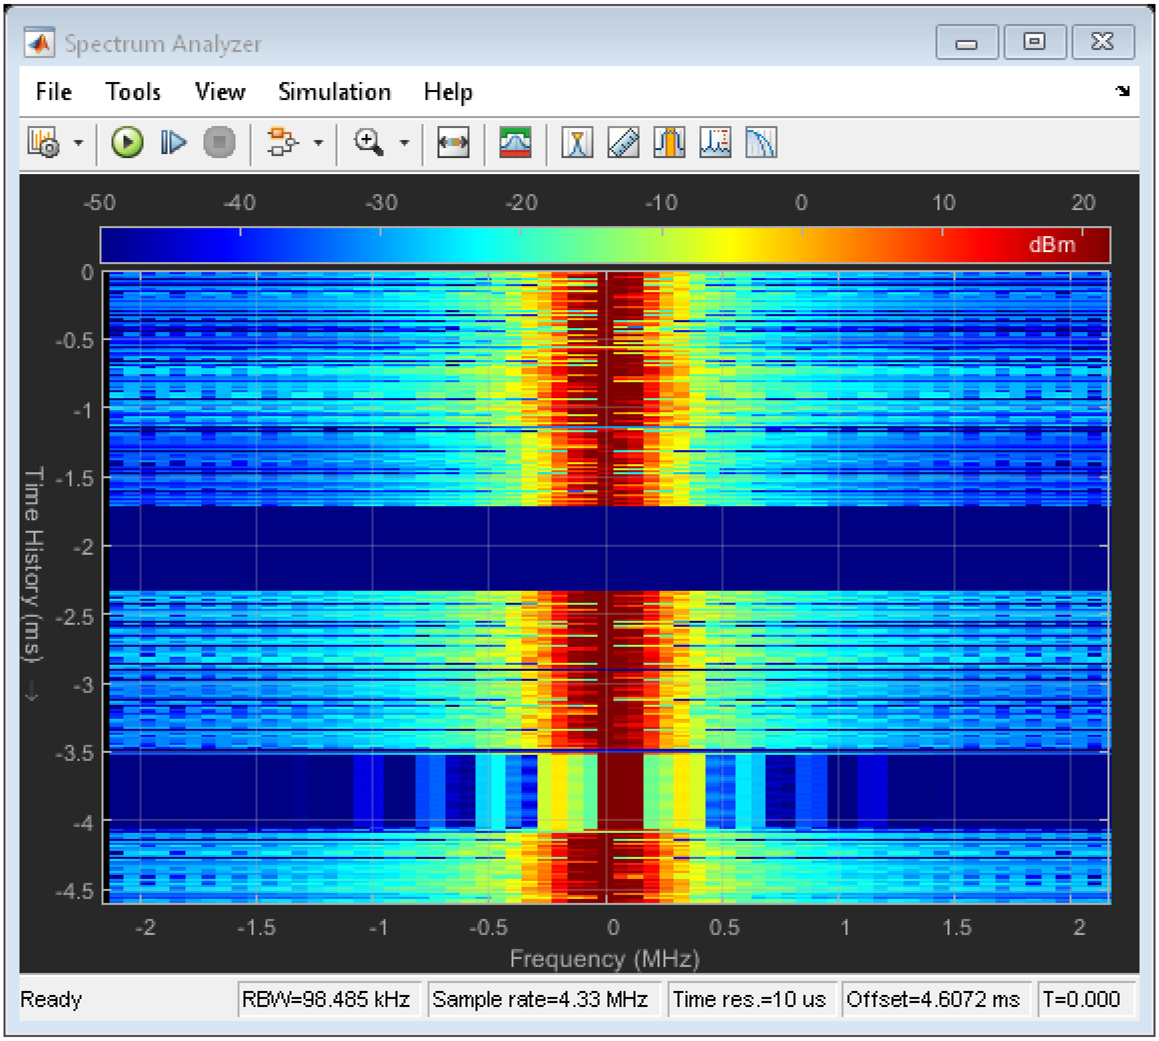
              SymbolRate: 2.7083e+05
              SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
       NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

The model sample time of the MATLAB Function (Simulink) block is set to `wfInfo.FrameLengthInSamples/wfInfo.SampleRate`. To view the **Sample time** parameter, open the Block Parameters dialog box by right-clicking the MATLAB Function block and selecting **Block Parameters (Subsystem)**.

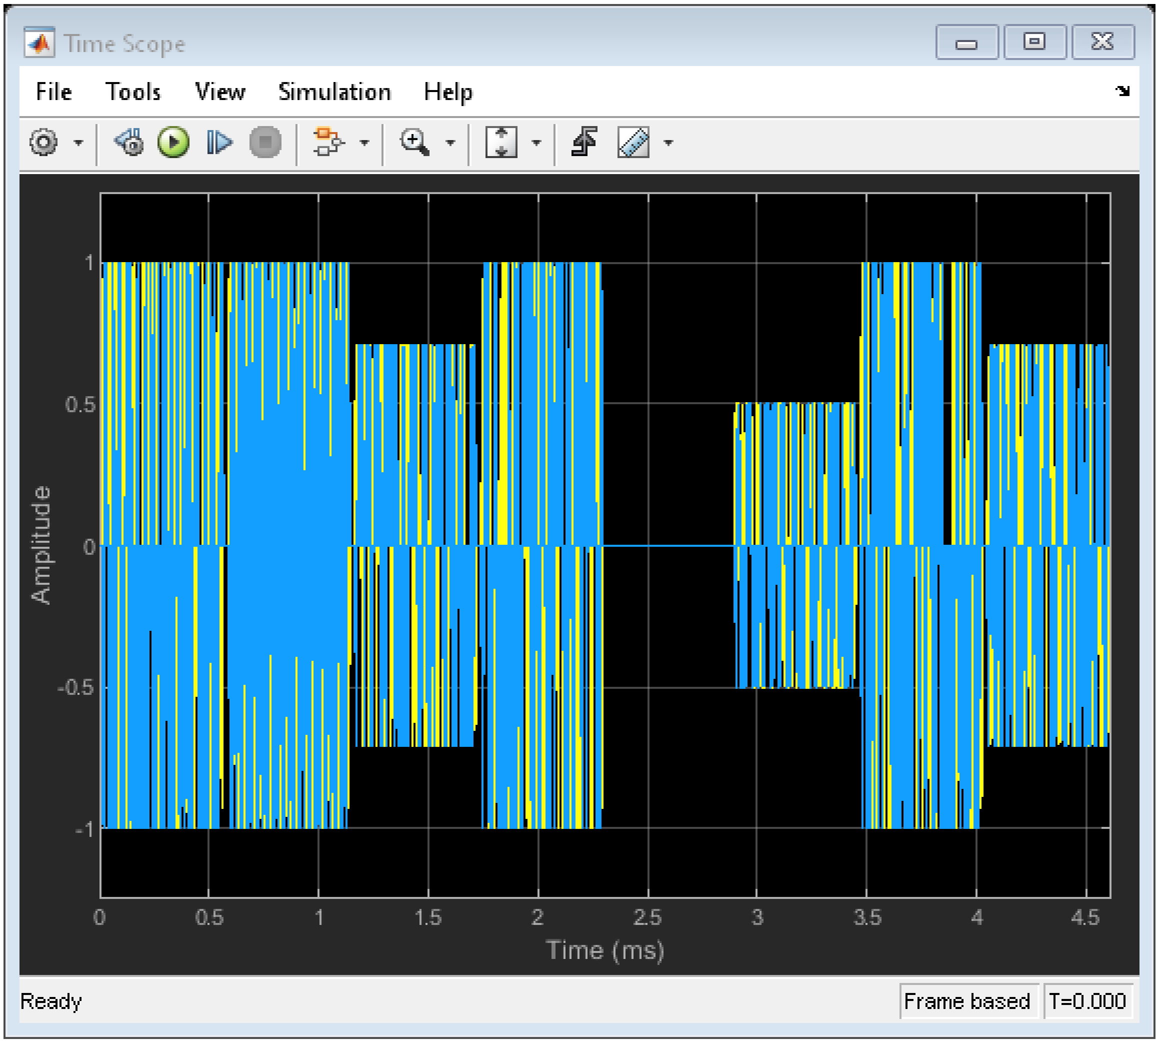
Before the simulation runs, you must configure the sample rate of the MATLAB Function block. The `PreLoadFcn` and `InitFcn` callback functions configure the MATLAB Function block by creating a `gsmDownlinkConfig` object and `wfInfo` structure. To view the callback functions, on the **Modeling** tab, in the **Setup** section, select **Model Settings** > **Model Properties**. Then, on the **Callbacks** tab, select the `PreLoadFcn` or `InitFcn` callback function in the **Model callbacks** pane.

Results

Display the time domain signal and the spectrogram by running the simulation.



RBW=98.485 kHz | Sample rate=4.33 MHz | Time res.=10 us | Offset=4.6072 ms | T=0.000



More About

GSM Frames, Time Slots, and Bursts

In GSM, transmissions consist of TDMA frames. Each GSM TDMA frame consists of eight time slots. The transmission data content of a time slot is called a burst. As described in Section 5.2 of 3GPP TS 45.011, a GSM time slot has a 156.25-symbol duration when using the normal symbol period, which is a time interval of 15/26 ms or about 576.9 microseconds. A guard period of 8.25 symbols or about 30.46 microseconds separates each time slot. The GSM standards describes a symbol as one bit period. Since GSM uses GMSK modulation, there is one bit per bit period. The transmission timing of a burst within a time slot is defined in terms of the bit number (BN). The BN refers to a particular bit period within a time slot. The bit with the lowest BN is transmitted first. BN0 is the first bit period, and BN156 is the last quarter-bit period.

This image from 3GPP TS 45.011 shows the relationship between different frame types and the relationship between different burst types.

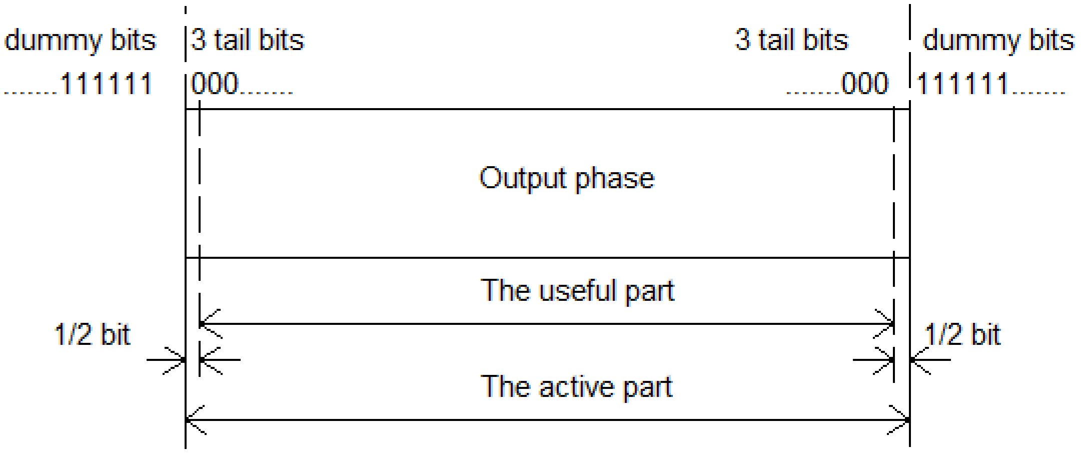
This table shows the supported burst types and their characteristics.

Burst Type	Description	Link Direction	Useful Duration
NB	Normal burst	Uplink/Downlink	147
FB	Frequency correction burst	Downlink	147
SB	Synchronization burst	Downlink	147
Dummy	Dummy burst	Downlink	147
AB	Access burst	Uplink	87
Off	No burst sent	Uplink/Downlink	0

Useful duration, described in Section 5.2.2 of 3GPP TS 45.002, is a characteristic of GSM bursts. The useful duration, or useful part, of a burst is defined as beginning halfway through BN0 and ending half a bit period before the start of the guard period. The guard period is the period between bursts in successive time slots. This figure, from Section 2.2 of 3GPP TS 45.004, shows the leading and trailing ½ bit difference between the useful and active parts of the burst.



For more information, see “GSM TDMA Frame Parameterization for Waveform Generation”.

Training Sequence Code (TSC)

Normal bursts include a training sequence bits field assigned a bit pattern based on the specified TSC. For GSM, you can select one of these eight training sequences for normal burst type time slots.

Training Sequence Code (TSC)	Training Sequence Bits (BN61, BN62, …, BN86)
0	(0,0,1,0,0,1,0,1,1,1,0,0,0,0,1,0,0,0,1,0,0,1,0,1,1,1)
1	(0,0,1,0,1,1,0,1,1,1,0,1,1,1,1,0,0,0,1,0,1,1,0,1,1,1)

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `SamplesPerSymbol`, `RiseTime`, `RiseDelay`, `FallTime`, and `FallDelay` properties must be set when creating the object, and their settings are static in the generated code.
- The `BurstType` [property must be set using the enumeration type instead of the string representation. Use these `gsmDownlinkBurstType` enumerations: `gsmDownlinkBurstType.NB`, `gsmDownlinkBurstType.FB`, `gsmDownlinkBurstType.SB`, `gsmDownlinkBurstType.Dummy`, and `gsmUplinkBurstType.Off`. For example, this code assigns a frequency correction burst in time slot 2 and 5.

```
cfg = gsmDownlinkConfig
```

```
cfg = 

  gsmDownlinkConfig with properties:

           BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

```
cfg.BurstType([2 5] +1) = gsmDownlinkBurstType.FB
```

```
cfg = 

  gsmDownlinkConfig with properties:

           BurstType: [NB    NB    FB    NB    NB    FB    NB    NB]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

Introduced in R2019b

gsmUplinkConfig

Create GSM uplink TDMA frame configuration object

Description

The `gsmUplinkConfig` object is a GSM uplink TDMA frame configuration object. Use `gsmUplinkConfig` objects to create GSM uplink waveforms.

Creation

Syntax

```
cfggsmul = gsmUplinkConfig
cfggsmul = gsmUplinkConfig(sps)
cfggsmul = gsmUplinkConfig(___,Name,Value)
```

Description

`cfggsmul = gsmUplinkConfig` creates a GSM uplink TDMA frame configuration object.

`cfggsmul = gsmUplinkConfig(sps)` sets the `SamplesPerSymbol` property to `sps`.

`cfggsmul = gsmUplinkConfig(___,Name,Value)` sets one or more name-value pair arguments using any of the previous syntaxes. For example, `'RiseTime',4` sets the burst rise time to `4` symbols. Enclose each property in quotes. Specify name-value pair arguments after all other input arguments.

Properties

`SamplesPerSymbol` — Samples per symbol
`16` (default) | positive integer multiple of 4

Samples per symbol, specified as a positive integer multiple of 4.

Data Types: `double`

`BurstType` — Burst types
`["NB" "NB" "NB" "NB" "NB" "NB" "NB" "NB"]` (default) | string row vector with 8 elements | `"NB"` | `"AB"` | `"Off"`

Burst types for time slots 0–7 in the TDMA frame, specified as one of these options:

- Eight-element row vector where each value is `"NB"`, `"AB"`, or `"Off"` — Each element specifies the burst type for the corresponding time slot.
- `"NB"` — Transmit data using a normal burst for every time slot.
- `"AB"` — Transmit data using an access burst for every time slot.

- "Off" — All eight time slots contain no data.

For more information, see "GSM Frames, Time Slots, and Bursts" on page 3-819

Note The BurstType property is an enumeration. To perform code generation, see "Code Generation" on page 3-822 and the "MEX Generation for GSM Uplink Waveform" on page 3-814 example.

Example: ["NB" "AB" "AB" "NB" "Off" "NB" "AB" "Off"] configures the frame to use normal bursts in time slots 0, 3, and 5, use access bursts in time slots 1, 2, and 6, and transmit no data in time slots 4 and 7.

TSC — Training sequence code

[0 1 2 3 4 5 6 7] (default) | eight-element row vector | integer in the range [0, 7]

Training sequence code (TSC) for normal bursts in time slots 0–7 in the TDMA frame, specified as one of these options:

- Eight-element row vector of integers in the range [0, 7] — Each element specifies the TSC value for the corresponding normal burst time slot.
- Integer in the range [0, 7] — Specifies the TSC value for every normal burst time slot.

For more information, see "Training Sequence Code (TSC)" on page 3-821.

Example: [5 7 0 0 0 0 0 0] configures the frame to use training sequence 5 in time slot 0, training sequence 7 in time slot 1, and training sequence 0 in time slots 2 through 7.

Dependencies

To enable this property for a time slot, set the corresponding element of BurstType to "NB".

Data Types: double

Attenuation — Power attenuation

[0 0 0 0 0 0 0 0] (default) | eight-element row vector | nonnegative integer

Power attenuation in dB for time slots 0–7 in the TDMA frame, specified as one of these options:

- Eight-element row vector of nonnegative integers — Each element specifies the attenuation power value for the corresponding time slot.
- Nonnegative integer — Specifies the power attenuation value for every time slot.

Example: [0 0 0 0 0 0 0 3] configures the frame to apply 0 dB of attenuation to the burst signal power in time slot 0 through 6 and 3 dB of attenuation to the burst signal power in time slot 7.

Data Types: double

RiseTime — Burst rise time

2 (default) | positive scalar

Burst rise time in symbols, specified as a positive scalar in the range [1/SamplesPerSymbol, 29], where the increment resolution is 1/SamplesPerSymbol. The total ramp-up and ramp-down duration (RiseTime - RiseDelay + FallTime + FallDelay) must be less than 9.25 symbols. The characteristic shape of the rising edge of the burst is sinusoidal.

For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-819.

Data Types: `double`

`RiseDelay` — Burst rise delay

`0` (default) | positive scalar

Burst rise delay in symbols, specified as a positive scalar in the range [–10, 10], where the increment resolution is 1/`SamplesPerSymbol`. The total ramp-up and ramp-down duration (`RiseTime` - `RiseDelay` + `FallTime` + `FallDelay`) must be less than 9.25 symbols. The burst rise delay is measured with respect to the start of the useful part of the burst. For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-819.

When the burst rise delay is `0`, the burst reaches full amplitude at the start of the useful part of the burst. When the burst rise delay is positive, the burst reaches full amplitude `RiseDelay` symbols after the start of the useful part. When the burst rise delay is negative, the burst reaches full amplitude `RiseDelay` symbols before the start of the useful part.

Data Types: `double`

`FallTime` — Burst fall time

`2` (default) | positive scalar

Burst fall time in symbols, specified as a positive scalar in the range [1/`SamplesPerSymbol`, 29], where the increment resolution is 1/`SamplesPerSymbol`. The total ramp-up and ramp-down duration (`RiseTime` - `RiseDelay` + `FallTime` + `FallDelay`) must be less than 9.25 symbols. The characteristic shape of the falling edge of the burst is sinusoidal.

For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-819.

Data Types: `double`

`FallDelay` — Burst fall delay

`0` (default) | positive scalar

Burst fall delay in symbols, specified as a positive scalar in the range [–10, 10], where the increment resolution is 1/`SamplesPerSymbol`. The total ramp-up and ramp-down duration (`RiseTime` - `RiseDelay` + `FallTime` + `FallDelay`) must be less than 9.25 symbols. The burst fall delay is measured with respect to the end of the useful part of the burst. For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-819.

When the burst fall delay is `0`, the burst begins decreasing from full amplitude at the end of the useful part of the burst. When the burst fall delay is positive, the burst begins decreasing from full amplitude `FallDelay` symbols after the end of the useful part. When the burst fall delay is negative, the burst begins decreasing from full amplitude `FallDelay` symbols before the end of the useful part.

Data Types: `double`

Examples

Create GSM Uplink Waveform

Create a GSM uplink TDMA frame configuration object with default settings, and then create a GSM waveform containing one TDMA frame. GSM TDMA frames have eight time slots, each separated by a guard period of 8.25 symbols or about 30.46x10e-3 ms. Plot the GSM waveform.

Create a GSM uplink TDMA frame configuration object with default settings.

```
cfggsmul = gsmUplinkConfig
```

```
cfggsmul = 
  gsmUplinkConfig with properties:

           BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

Display information about the configured `gsmUplinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)
```

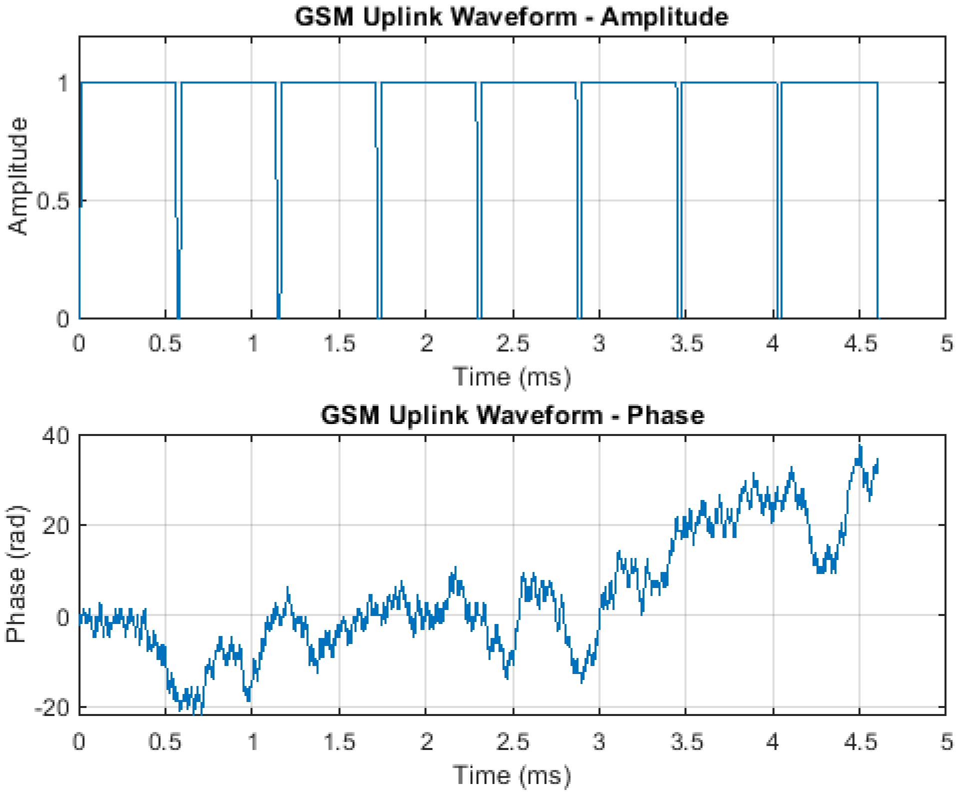
```
wfInfo = struct with fields:
              SymbolRate: 2.7083e+05
              SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
       NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmul);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```



Create GSM Uplink Waveform with Specified Samples per Symbol

Create a GSM uplink TDMA frame configuration object that specifies 4 samples per symbol, and then create a GSM waveform containing one GSM downlink TDMA frame. The GSM TDMA frame are eight time slots, each separated by a guard period of 8.25 symbols or about 30.46x10e-3 ms separates each time slot. Plot the GSM waveform.

Create a GSM uplink TDMA frame configuration object, specifying 4 samples per symbols.

```
sps = 4;
cfggsmul = gsmUplinkConfig(sps)
```

```
cfggsmul = 
  gsmUplinkConfig with properties:

           BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
      SamplesPerSymbol: 4
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

Display information about the configured `gsmUplinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)
```

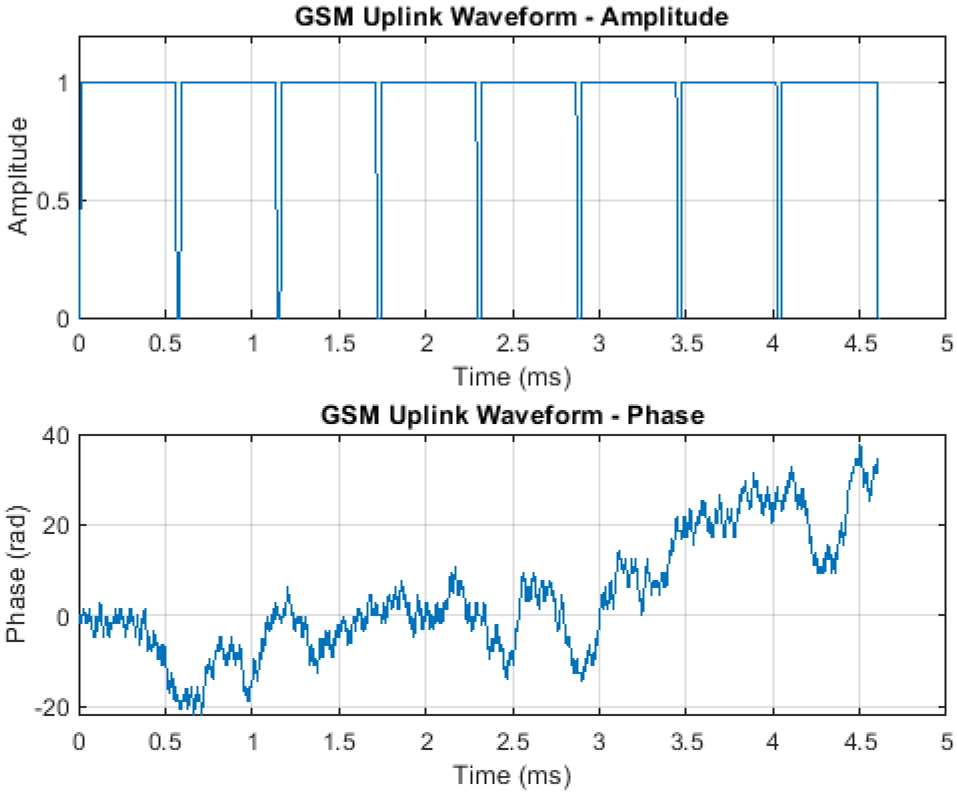
```
wfInfo = struct with fields:
              SymbolRate: 2.7083e+05
              SampleRate: 1.0833e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
       NumBurstsPerFrame: 8
    BurstLengthInSamples: 625
    FrameLengthInSamples: 5000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmul);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```



Create GSM Uplink Waveform with Specified Attenuation

Create two GSM uplink TDMA frame configuration objects. Specify default settings for the first `gsmUplinkConfig` object and adjust the signal power per time slot for the second. Generate GSM waveforms for both configurations. Plot the waveforms to show the signal attenuation per time slot in the second waveform.

Create a GSM uplink TDMA frame configuration object with default settings.

```
cfggsmul = gsmUplinkConfig
```

```
cfggsmul = 
  gsmUplinkConfig with properties:

           BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

Create another GSM uplink TDMA frame configuration object, adjusting the signal attenuation settings per time slot.

```
cfggsmul2 = gsmUplinkConfig('Attenuation',[1 2 3 4 5 4 3 2])
```

```
cfggsmul2 = 
  gsmUplinkConfig with properties:

           BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [1 2 3 4 5 4 3 2]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

Display information about the configured `gsmUplinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)
```

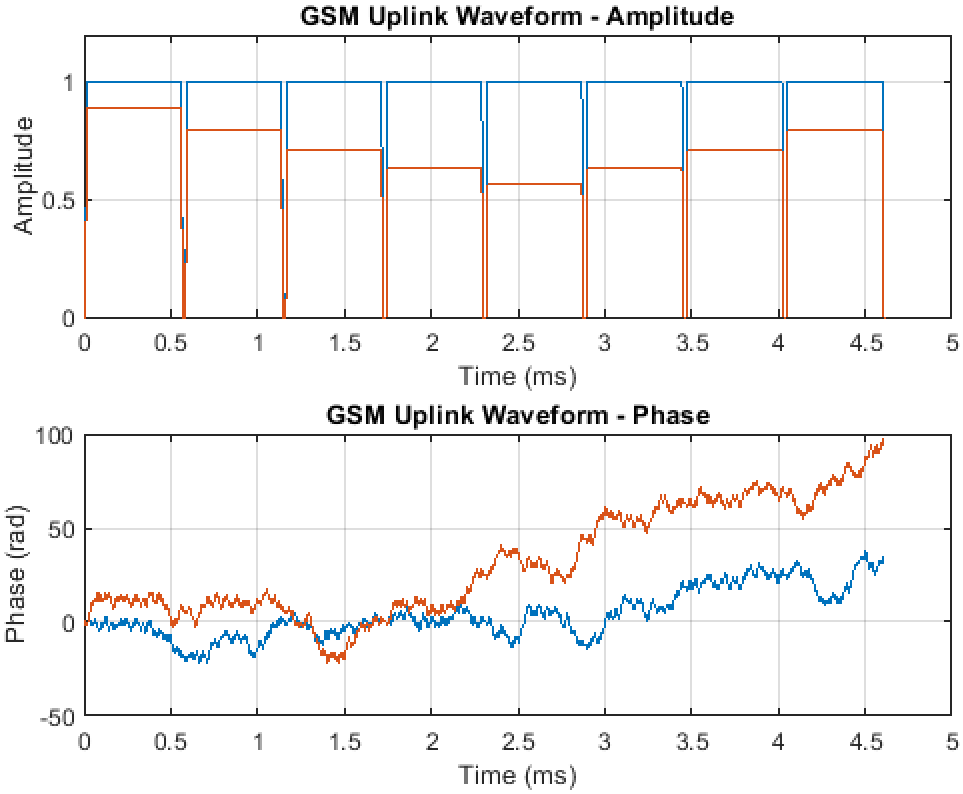
```
wfInfo = struct with fields:
              SymbolRate: 2.7083e+05
              SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
       NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveforms, containing one TDMA frame, by using the `gsmFrame` function. GSM TDMA frames are eight time slots, each separated by a guard period of 8.25 symbols or about 30.46x10e-3 ms. Plot each GSM waveform.

```
waveform = gsmFrame(cfggsmul);
waveform2 = gsmFrame(cfggsmul2);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,[abs(waveform),abs(waveform2)])
grid on
axis([0 5 0 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,[unwrap(angle(waveform)),unwrap(angle(waveform2))])
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```



MEX Generation for GSM Uplink Waveform

Generate and run a GSM waveform MEX function from the helper function `createUplinkWaveform`. The `createUplinkWaveform` helper function creates a GSM uplink waveform.

Write MATLAB Function

Open createUplinkWaveform.m to see the code. The `createUplinkWaveform` helper function generates a GSM uplink waveform by using the `gsmUplinkConfig` object and the `gsmInfo` and `gsmFrame` functions.

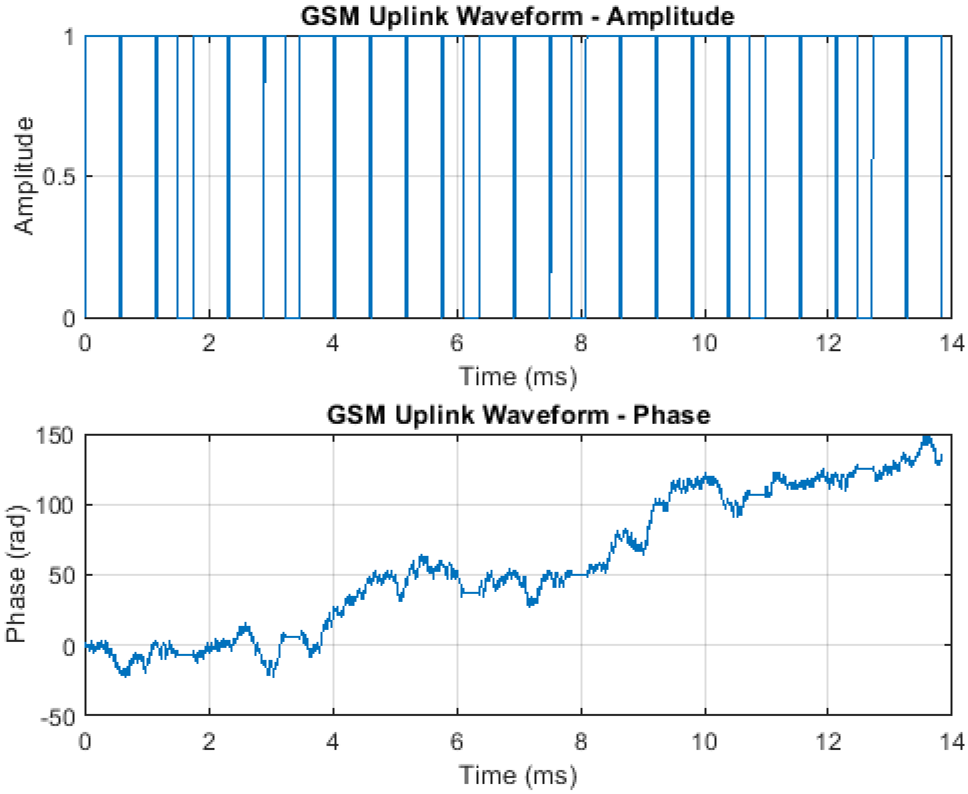
Generate GSM Waveform

Use the `createUplinkWaveform` helper function to create a GSM waveform containing three TDMA frames, and then plot the waveform.

```
[x,t] = createUplinkWaveform(3);

figure
subplot(2,1,1);
plot(t,abs(x));
grid on;
title('GSM Uplink Waveform - Amplitude');
```

```
xlabel('Time (ms)');
ylabel('Amplitude')
subplot(2,1,2);
plot(t,unwrap(angle(x)));
grid on;
title('GSM Uplink Waveform - Phase');
xlabel('Time (ms)');
ylabel('Phase (rad)')
```



Generate MEX Function

Code generation defaults to MEX code generation when you do not specify a build target. By default, `codegen` names the generated MEX function `createUplinkWaveform_mex`. Generate a MEX function from the `createUplinkWaveform` helper function, and then run the MEX function to create three TDMA frames.

```
codegen createUplinkWaveform -args 3
```

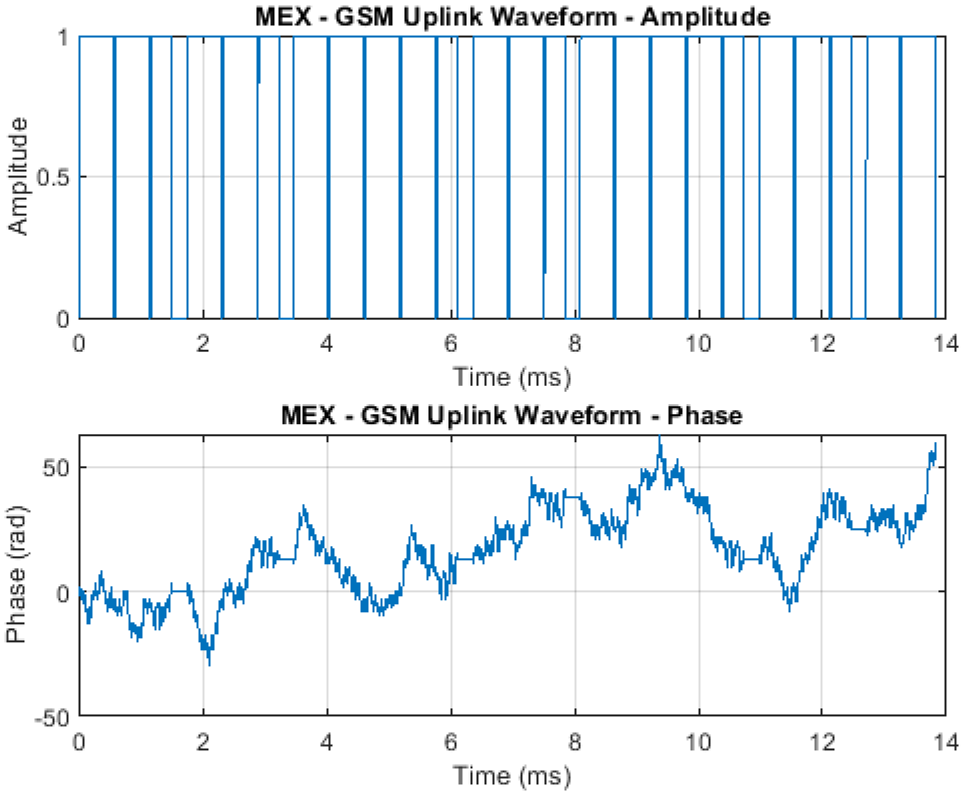
Generate Waveform Using MEX Function

Run the MEX function and plot the results. Since the waveform is created using random data, the phase plot changes each time you run the `generateUplinkFrame` helper function or `createUplinkWaveform_mex` function.

```
[x,t] = createUplinkWaveform_mex(3);
```

```
figure
```

```
subplot(2,1,1);
plot(t,abs(x));
grid on;
title('MEX - GSM Uplink Waveform - Amplitude');
xlabel('Time (ms)');
ylabel('Amplitude')
subplot(2,1,2);
plot(t,unwrap(angle(x)));
grid on;
title('MEX - GSM Uplink Waveform - Phase');
xlabel('Time (ms)');
ylabel('Phase (rad)')
```

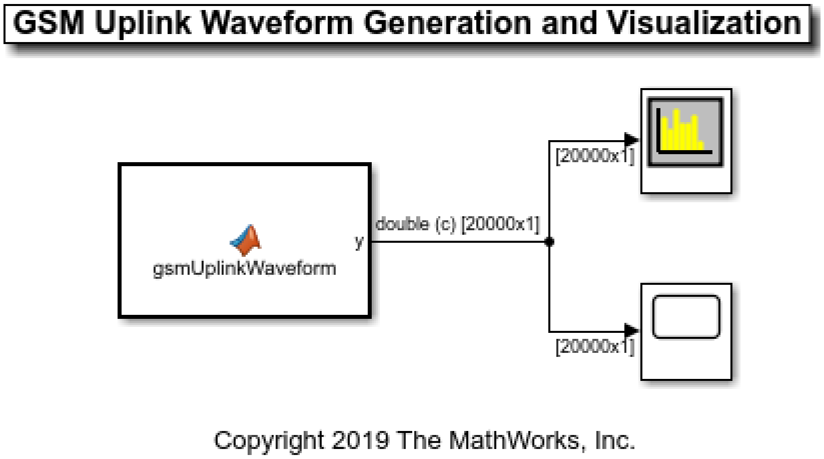


GSM Uplink Waveform Generation in Simulink

Model a GSM® waveform generator in Simulink® by using the MATLAB Function block and Communications Toolbox™ functions.

GSM Uplink Waveform Generation

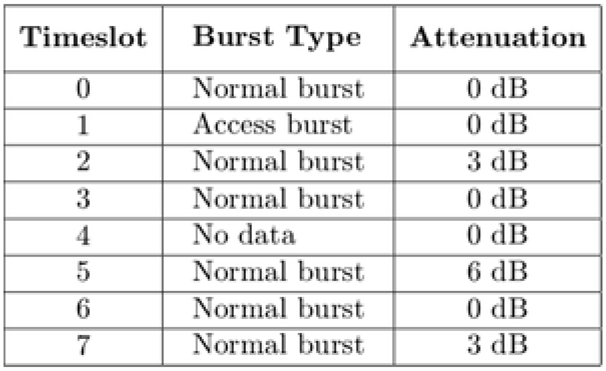
The MATLAB Function (Simulink) block contains the `gsmUplinkWaveform` function code. The code in the MATLAB Function block creates a GSM waveform by using the `gsmUplinkConfig` object and the `gsmFrame` function.



GSM Uplink Waveform Generation and Visualization

Copyright 2019 The MathWorks, Inc.

The `gsmUplinkConfig` object specifies 16 samples per symbol and the time slot configuration for the GSM uplink TDMA frame shown is this table.



Timeslot	Burst Type	Attenuation
0	Normal burst	0 dB
1	Access burst	0 dB
2	Normal burst	3 dB
3	Normal burst	0 dB
4	No data	0 dB
5	Normal burst	6 dB
6	Normal burst	0 dB
7	Normal burst	3 dB

The output waveform has 16 samples for each GMSK symbol. The `gsmFrame` function generates the samples of the waveform.

Explore the Model

In compliance with GSM standards 3GPP TS 45.001 and 3GPP TS 45.002, the sample time of the MATLAB Function block that contains the `gsmUplinkWaveform` function code is set to the GSM symbol rate of 1625e3/6 symbols per second. Display the current `gsmUplinkConfig` object settings by using the `gsmInfo` function.

```
wfInfo = 

  struct with fields:

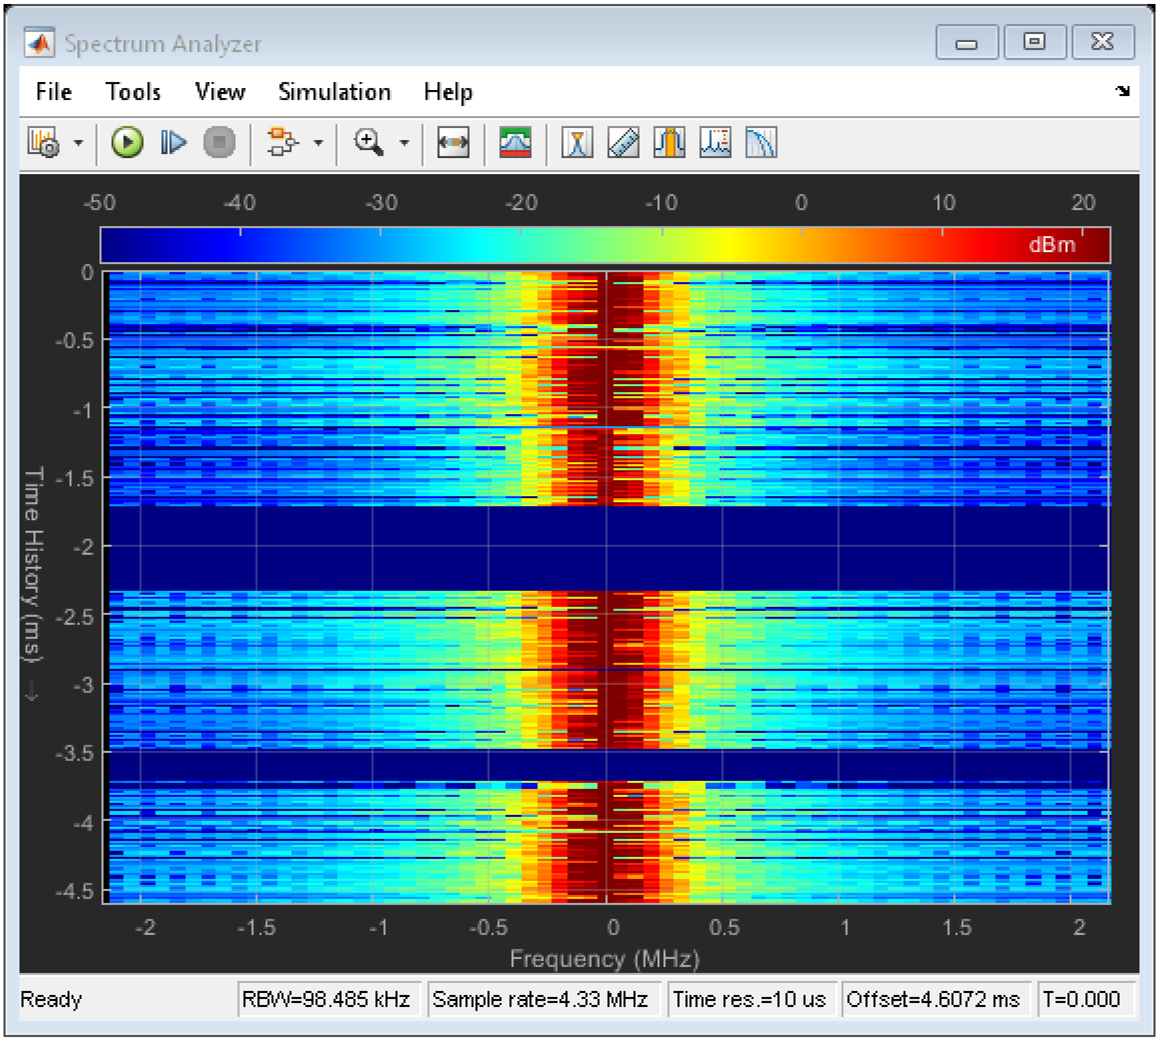
              SymbolRate: 2.7083e+05
              SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
       NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

The model sample time of the MATLAB Function (Simulink) block is set to `wfInfo.FrameLengthInSamples/wfInfo.SampleRate`. To view the **Sample time** parameter, open the Block Parameters dialog box by right-clicking the MATLAB Function block and selecting **Block Parameters (Subsystem)**.

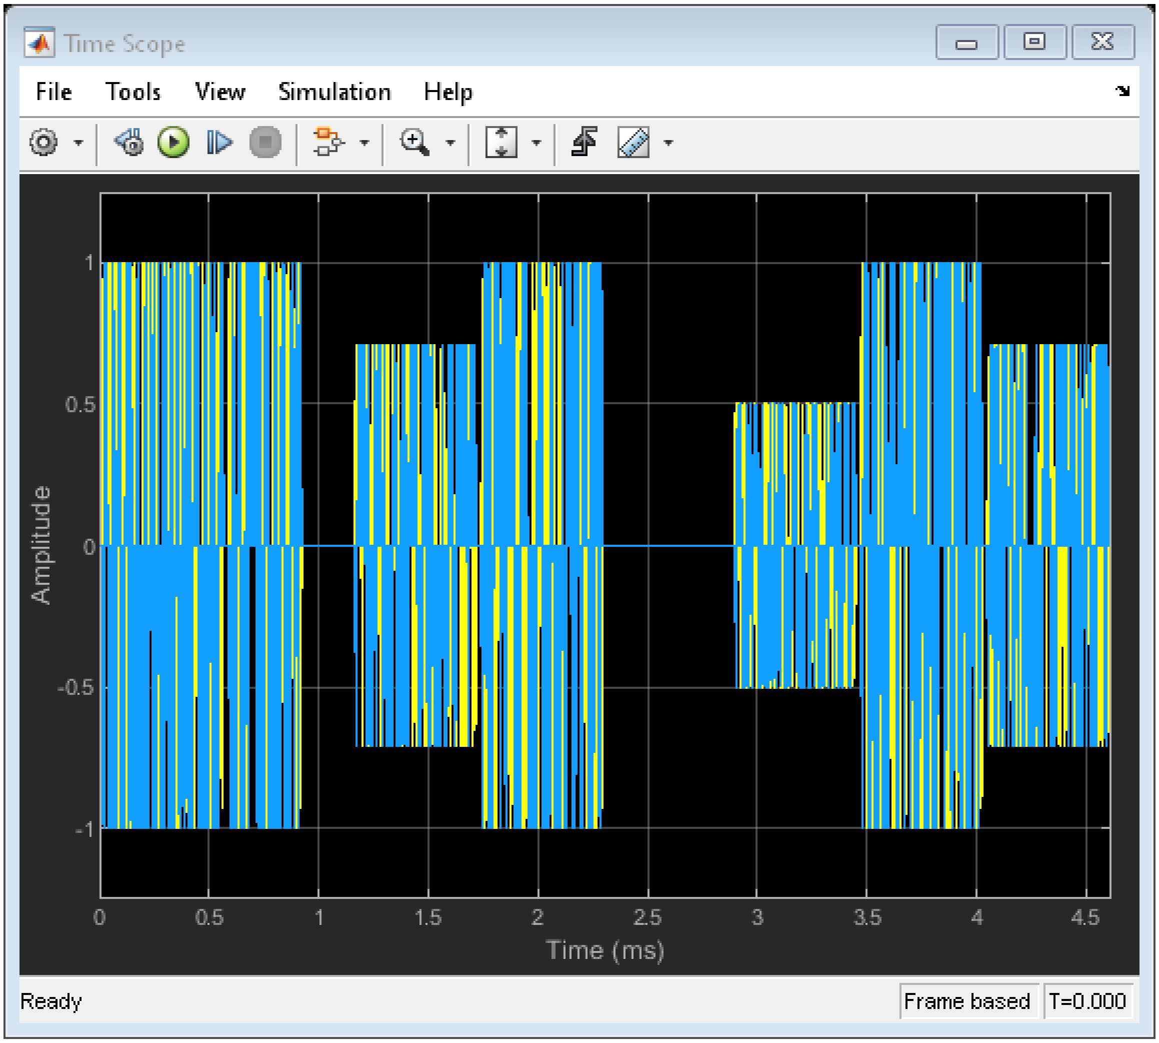
Before the simulation runs, you must configure the sample rate of the MATLAB Function block. The `PreLoadFcn` and `InitFcn` callback functions configure the MATLAB Function block by creating a `gsmUplinkConfig` object and `wfInfo` structure. To view the callback functions, on the **Modeling** tab, in the **Setup** section, select **Model Settings** > **Model Properties**. Then, on the **Callbacks** tab, select the `PreLoadFcn` or `InitFcn` callback function in the **Model callbacks** pane.

Results

Displays the time domain signal and the spectrogram by running the simulation.



Ready | RBW=98.485 kHz | Sample rate=4.33 MHz | Time res.=10 us | Offset=4.6072 ms | T=0.000



More About

GSM Frames, Time Slots, and Bursts

In GSM, transmissions consist of TDMA frames. Each GSM TDMA frame consists of eight time slots. The transmission data content of a time slot is called a burst. As described in Section 5.2 of 3GPP TS 45.011, a GSM time slot has a 156.25-symbol duration when using the normal symbol period, which is a time interval of 15/26 ms or about 576.9 microseconds. A guard period of 8.25 symbols or about 30.46 microseconds separates each time slot. The GSM standards describes a symbol as one bit period. Since GSM uses GMSK modulation, there is one bit per bit period. The transmission timing of a burst within a time slot is defined in terms of the bit number (BN). The BN refers to a particular bit period within a time slot. The bit with the lowest BN is transmitted first. BN0 is the first bit period, and BN156 is the last quarter-bit period.

This image from 3GPP TS 45.011 shows the relationship between different frame types and the relationship between different burst types.

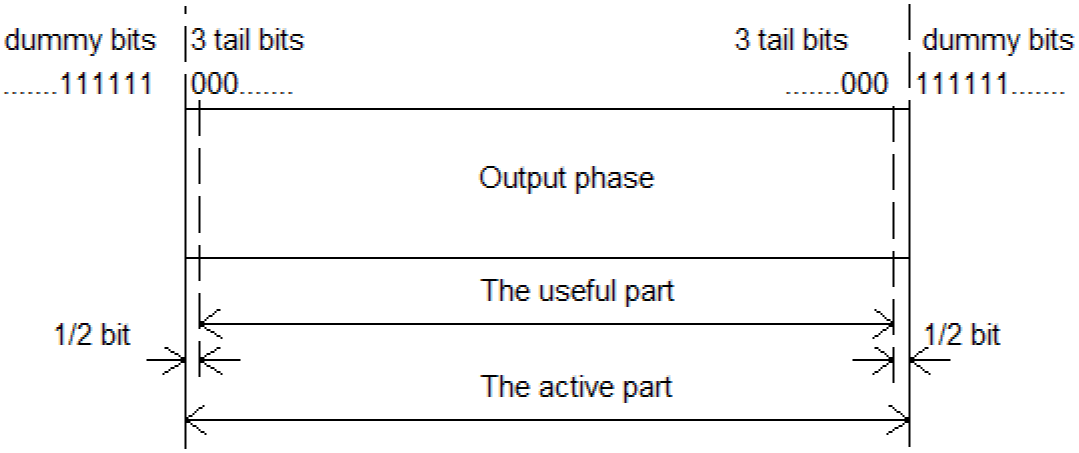
This table shows the supported burst types and their characteristics.

Burst Type	Description	Link Direction	Useful Duration
NB	Normal burst	Uplink/Downlink	147
FB	Frequency correction burst	Downlink	147
SB	Synchronization burst	Downlink	147
Dummy	Dummy burst	Downlink	147
AB	Access burst	Uplink	87
Off	No burst sent	Uplink/Downlink	0

Useful duration, described in Section 5.2.2 of 3GPP TS 45.002, is a characteristic of GSM bursts. The useful duration, or useful part, of a burst is defined as beginning halfway through BN0 and ending half a bit period before the start of the guard period. The guard period is the period between bursts in successive time slots. This figure, from Section 2.2 of 3GPP TS 45.004, shows the leading and trailing ½ bit difference between the useful and active parts of the burst.



For more information, see “GSM TDMA Frame Parameterization for Waveform Generation”.

Training Sequence Code (TSC)

Normal bursts include a training sequence bits field assigned a bit pattern based on the specified TSC. For GSM, you can select one of these eight training sequences for normal burst type time slots.

Training Sequence Code (TSC)	Training Sequence Bits (BN61, BN62, ..., BN86)
0	(0,0,1,0,0,1,0,1,1,1,0,0,0,0,1,0,0,0,1,0,0,1,0,1,1,1)
1	(0,0,1,0,1,1,0,1,1,1,0,1,1,1,1,0,0,0,1,0,1,1,0,1,1,1)

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The SamplesPerSymbol, RiseTime, RiseDelay, FallTime, and FallDelay properties must be set when creating the object, and their settings are static in the generated code.
- The BurstType property must be set using the enumeration type instead of the string representation. Use these gsmDownlinkBurstType enumerations: gsmDownlinkBurstType.NB, gsmDownlinkBurstType.AB, and gsmUplinkBurstType.Off. For example, this code assigns an access burst in time slot 2 and 5.

```
cfg = gsmUplinkConfig

cfg = 

  gsmUplinkConfig with properties:

           BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0

cfg.BurstType([2 5] +1) = gsmUplinkBurstType.AB

cfg = 

  gsmUplinkConfig with properties:

           BurstType: [NB    NB    AB    NB    NB    AB    NB    NB]
    SamplesPerSymbol: 16
                 TSC: [0 1 2 3 4 5 6 7]
         Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 2
           RiseDelay: 0
            FallTime: 2
           FallDelay: 0
```

Topics

"GSM TDMA Frame Parameterization for Waveform Generation"

Introduced in R2019b

comm.HadamardCode

Package: `comm`

Generate Hadamard code

Description

The `HadamardCode` object generates a Hadamard code from a Hadamard matrix, whose rows form an orthogonal set of codes. You can use orthogonal codes for spreading in communication systems in which the receiver is perfectly synchronized with the transmitter. In these systems, the despreading operation is ideal, because the codes decorrelate completely.

To generate a Hadamard code:

1. Define and set up your Hadamard code object. See “Construction” on page 3-824.
2. Call `step` to generate a Hadamard according to the properties of `comm.HadamardCode`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`H = comm.HadamardCode` creates a Hadamard code generator System object, `H`. This object generates Hadamard codes from a set of orthogonal codes.

`H = comm.HadamardCode(Name,Value)` creates a Hadamard code generator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`Length`

Length of generated code

Specify the length of the generated code as a numeric, integer scalar value with a power of two. The default is `64`.

`Index`

Row index of Hadamard matrix

Specify the row index of the Hadamard matrix as a numeric, integer scalar value in the range `[0, 1, ... , N-1]`. *N* is the value of the `Length` on page 3-0 property. The default is `60`. An *N*×*N* Hadamard matrix, denoted as *P*(*N*), is defined recursively as follows: *P*(1) = [1] *P*(2*N*) = [*P*(*N*) *P*(*N*); *P*(*N*) –*P*(*N*)] The *N*x*N* Hadamard matrix has the property that *P*(*N*)×*P*(*N*)' = *N*×`eye`(*N*). The `step` method outputs code samples from the row of the Hadamard matrix that you specify in this property.

When you set this property to an integer *k*, the output code has exactly *k* zero crossings, for *k* = 0, 1, ... , *N*–1.

`SamplesPerFrame`

Number of output samples per frame

Specify the number of Hadamard code samples that the `step` method outputs as a numeric, positive, integer scalar value. The default is `1`.

When you set this property to a value of *M*, the `step` method outputs *M* samples of a Hadamard code of length *N*. *N* equals the length of the code that you specify in the `Length` on page 3-0 property.

`OutputDataType`

Data type of output

Specify the output data type as one of `double` | `int8`. The default is `double`.

Methods

reset	Reset states of Hadamard code generator object
step	Generate Hadamard code

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Hadamard Code Sequence

Generate 10 samples of a Hadamard code sequence having a length of 128.

```
hadamard = comm.HadamardCode('Length',128,'SamplesPerFrame',10)
```

```
hadamard = 
  comm.HadamardCode with properties:

             Length: 128
              Index: 60
    SamplesPerFrame: 10
     OutputDataType: 'double'

```

```
seq = hadamard()
```

```
seq = 10×1

     1
     1
     1
     1
    -1
    -1
    -1
    -1
    -1
    -1
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Hadamard Code Generator block reference page. The object properties correspond to the block parameters, except:

- The object does not have a property to select frame based outputs.
- The object does not have a property that corresponds to the **Sample time** parameter.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

`comm.OVSFCode` | `comm.WalshCode`

Introduced in R2012a

reset

System object: `comm.HadamardCode`
Package: `comm`

Reset states of Hadamard code generator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `HadamardCode` object, `H`.

step

System object: `comm.HadamardCode`
Package: `comm`

Generate Hadamard code

Syntax

```
Y = step(H)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

`Y = step(H)` outputs a frame of the Hadamard code in column vector `Y`. Specify the frame length with the `SamplesPerFrame` property. The Hadamard code corresponds to one of the rows of an *N*x*N* Hadamard matrix, where *N* is a nonnegative power of 2, which you specify in the `Length` property. Use the `Index` property to choose the row of the Hadamard matrix. The `step` method outputs the code in a bi-polar format with `0` and `1` mapped to `1` and `-1`, respectively.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.HDLCRCDetector

Package: comm

Detect errors in input data using CRC

Description

This HDL-optimized cyclic redundancy code (CRC) detector System object computes a checksum on the input data and compares the result against the input checksum. Instead of frame processing, the HDLCRCDetector System object processes streaming data. The object has frame synchronization control signals for both input and output data streams.

To compute and compare checksums:

1. Create the comm.HDLCRCDetector object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
CRCDet = comm.HDLCRCDetector
CRCDet = comm.HDLCRCDetector(Name,Value)
CRCDet = comm.HDLCRCDetector(poly,Name,Value)
```

Description

CRCDet = comm.HDLCRCDetector creates an HDL-optimized CRC detector System object, CRCDet, that detects errors in the input data according to a specified generator polynomial.

CRCDet = comm.HDLCRCDetector(Name,Value)sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,

```
CRCDet = comm.HDLCRCDetector('Polynomial',[1 0 0 0 1 0 0 0 0], ...
'FinalXORValue',[1 1 0 0 0 0 0 0]);
```

specifies a CRC8 polynomial and an 8-bit value to XOR with the final checksum.

CRCDet = comm.HDLCRCDetector(poly,Name,Value) creates an HDL-optimized CRC detector System object, CRCDet, with the Polynomial property set to poly, and the other specified property names set to the specified values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Polynomial` — Generator polynomial
`[1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]` (default) | binary vector

Generator polynomial, specified as a binary vector, with coefficients in descending order of powers. The vector length must be equal to the degree of the polynomial plus 1.

`InitialState` — Initial conditions of shift register
`0` (default) | binary scalar | binary vector

Initial conditions of the shift register, specified as a binary, double-precision or single-precision scalar or vector. If you specify this property as a vector, the vector length is the degree of the generator polynomial that you specify in the `Polynomial` property. If you specify this property as a scalar, the object expands the value to a vector of length equal to the degree of the generator polynomial.

`DirectMethod` — Method of calculating checksum
`false` (default) | `true`

Method of calculating checksum, specified as a logical scalar. When this property is `true`, the object uses the direct algorithm for CRC checksum calculations.

To learn about direct and non-direct algorithms, see “Cyclic Redundancy Check Codes”.

`ReflectInput` — Input byte order
`false` (default) | `true`

Input byte order, specified as a logical scalar. When this property is `true`, the object flips the input data on a bytewise basis before it enters the shift register.

`ReflectCRCChecksum` — Checksum byte order
`false` (default) | `true`

Checksum byte order, specified as a logical scalar. When this property is `true`, the object flips the output CRC checksum around its center.

`FinalXORValue` — Checksum mask
`0` (default) | binary scalar | binary vector

Checksum mask, specified as a binary, double- or single-precision data type scalar or vector. The object XORs the checksum with this value before appending the checksum to the input data. If you specify this property as a vector, the vector length is the degree of the generator polynomial that you specify in the `Polynomial` property. If you specify this property as a scalar, the object expands the value to a vector of length equal to the degree of the generator polynomial.

Usage

Syntax

```
[Y,startOut,endOut,validOut,err] = CRCn(X,startIn,endIn,validIn)
```

Description

`[Y,startOut,endOut,validOut,err] = CRCn(X,startIn,endIn,validIn)` computes CRC checksums for an input message `X` based on the control signals and compares the computed checksum with input checksum. If the two checksums are not equal, the output `err` is set to 1 `true`).

Input Arguments

X — Input message and appended checksum
binary column vector | scalar integer

Input message and appended checksum, specified as a binary vector or a scalar integer representing several bits. For example, vector input `[0,0,0,1,0,0,1,1]` is equivalent to `uint8` input `19`.

If the input is a vector, the data type can be double or logical. If the input is a scalar, the data type can be unsigned integer or unsigned fixed-point with 0 fractional bits (`fi([],0,N,0)`).

`X` can be part or all of the message to be checked.

The length of `X` must be less than or equal to the CRC length, and the CRC length must be divisible by the length of `X`.

The CRC length is the order of the polynomial that you specify in the `Polynomial` property.

Data Types: `double` | `uint8` | `uint16` | `uint32` | `logical` | `unsigned fi`

`startIn` — Start of input message
logical scalar

Start of the input message, specified as a logical scalar.

`endIn` — End of input message
logical scalar

End of the input message, specified as a logical scalar.

`validIn` — Validity of input data
logical scalar

Validity of input data, specified as a logical scalar. When `validIn` is 1 (`true`), the object computes the CRC checksum for input `X`.

Output Arguments

Y — Message with checksum removed
binary column vector | scalar integer

Message with checksum removed, returned as a scalar integer or binary column vector with the same width and data type as input `X`.

`startOut` — Start of input message
logical scalar

Start of the input message, returned as a logical scalar.

`endOut` — End of input message
logical scalar

End of the input message, returned as a logical scalar.

`validOut` — Validity of input data
logical scalar

Validity of input data, returned as a logical scalar. When `validOut` is 1 (`true`), the output data `Y` is valid.

`err` — Checksum mismatch
logical scalar

Checksum mismatch, returned as a logical scalar. `err` is 1 (`true`) when the input checksum does not match the calculated checksum.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

CRC Encode and Decode for HDL

Encode and decode a signal using the HDL-optimized CRC generator and detector System objects. This example shows how to include each object in a function for HDL code generation.

Create a 32-bit message to be encoded, in two 16-bit columns.

```
msg = randi([0 1],16,2);
```

Run for 12 steps to accommodate the latency of both objects. Assign control signals for all steps. The first two samples are the valid data, and the remainder are processing latency.

```
numSteps = 12;
startIn = logical([1 0 0 0 0 0 0 0 0 0 0 0]);
endIn   = logical([0 1 0 0 0 0 0 0 0 0 0 0]);
validIn = logical([1 1 0 0 0 0 0 0 0 0 0 0]);
```

Pass random input to the `HDLCRCGenerator` System object™ while it is processing the input message. The random data is not encoded because the input valid signal is `0` for steps 3 to 10.

```
randIn = randi([0, 1],16,numSteps-2);
dataIn = [msg randIn];
```

Write a function that creates and calls each System object™. You can generate HDL from these functions. The generator and detector objects both have a CRC length of 16 and use the default polynomial.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function [dataOut,startOut,endOut,validOut] = HDLCRC16Gen(dataIn,startIn,endIn,validIn)
%HDLCRC16Gen
% Generates CRC checksum using the comm.HDLCRCGenerator System object(TM)
% dataIn is a binary column vector.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

  persistent crcg16;
  if isempty(crcg16)
    crcg16 = comm.HDLCRCGenerator()
  end
  [dataOut,startOut,endOut,validOut] = crcg16(dataIn,startIn,endIn,validIn);
end
```

```
function [dataOut,startOut,endOut,validOut,err] = HDLCRC16Det(dataIn,startIn,endIn,validIn)
%HDLCRC16Det
% Checks CRC checksum using the comm.HDLCRCDetector System object(TM)
% dataIn is a binary column vector.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

  persistent crcd16;
  if isempty(crcd16)
    crcd16 = comm.HDLCRCDetector()
  end
  [dataOut,startOut,endOut,validOut,err] = crcd16(dataIn,startIn,endIn,validIn);
end
```

Call the CRC generator function. The encoded message is the original message plus a 16 bit checksum.

```
 for i =  1:numSteps
 [dataOutGen(:,i),startOutGen(i),endOutGen(i),validOutGen(i)] = ...
     HDLCRC16Gen(logical(dataIn(:,i)),startIn(i),endIn(i),validIn(i));
 end
```

```
crcg16 = 

  comm.HDLCRCGenerator with properties:

           Polynomial: [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]
         InitialState: 0
         DirectMethod: false
```

```
          ReflectInput: false
    ReflectCRCChecksum: false
         FinalXORValue: 0
```

Add noise by flipping a bit in the message.

```
dataOutNoise = dataOutGen;
dataOutNoise(2,4) = ~dataOutNoise(2,4);
```

Call the CRC detector function. The output of the detector is the input message with the checksum removed. If the input checksum was not correct, the `err` flag is set with the last word of the output.

```
for i = 1:numSteps
[dataOut(:,i),startOut(i),endOut(i),validOut(i),err(i)] = ...
    HDLCRC16Det(logical(dataOutNoise(:,i)),startOutGen(i),endOutGen(i),validOutGen(i));
end
```

```
crcd16 =

  comm.HDLCRCDetector with properties:

            Polynomial: [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]
          InitialState: 0
          DirectMethod: false
          ReflectInput: false
    ReflectCRCChecksum: false
         FinalXORValue: 0
```

Use the **Logic Analyzer** to view the input and output signals.

```
channels = {'validIn','startIn','endIn',...
    {'dataIn','Radix','Hexadecimal'},...
    'validOutGen','startOutGen','endOutGen',...
    {'dataOutGen','Radix','Hexadecimal'},...
    {'dataOutNoise','Radix','Hexadecimal'},...
    'validOut','startOut','endOut','err',...
    {'dataOut','Radix','Hexadecimal'}};
la = dsp.LogicAnalyzer('Name','CRC Encode and Decode','NumInputPorts',length(channels),...
                      'BackgroundColor','Black','DisplayChannelHeight',8);

 for ii = 1:length(channels)
    if iscell(channels{ii})
        % Display data signals as hexadecimal integers
        c = channels{ii};
        modifyDisplayChannel(la,ii,'Name',c{1},c{2},c{3})
        % Convert binary column vector to integer
        dat2 = uint16(bi2de(eval(c{1})'));
        chanData{ii} = squeeze(dat2);
    else
        modifyDisplayChannel(la,ii,'Name',channels{ii})
        chanData{ii} = squeeze(eval(channels{ii})');
    end
 end
la(chanData{:})
```

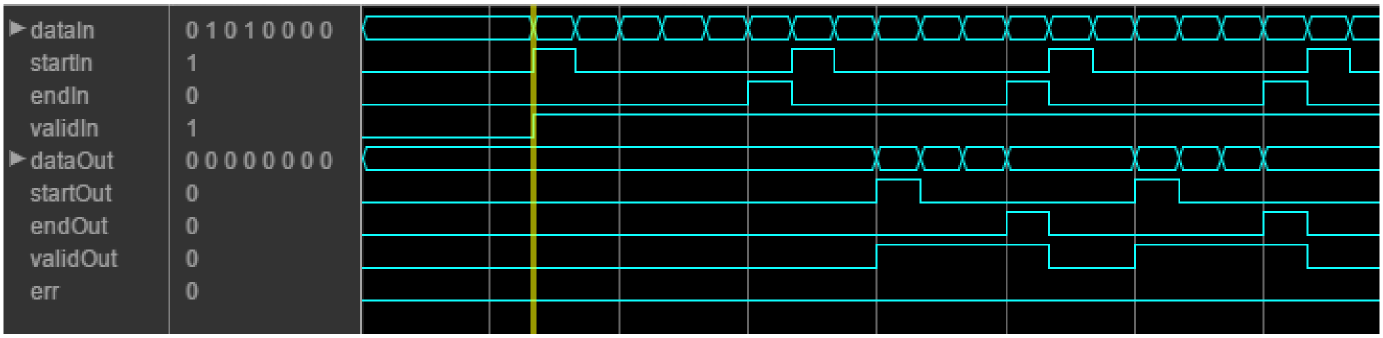
Algorithms

Timing Diagram

This waveform shows streaming data and the accompanying control signals for a CRC16 with 8-bit binary vector input. The input frames are contiguous. The output frames include space between them because the detector block removes the checksum word.



This waveform diagram shows continuous input data. Non-continuous data is also supported.

Initial Delay

The `HDLCRCDetector` System object introduces a latency on the output. You can compute the latency as follows, assuming the input data is continuous:

```
initialDelay =  3 * (CRCLength/inputDataWidth) + 2
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Objects

`comm.CRCDetector` | `comm.HDLCRCGenerator`

Blocks

General CRC Syndrome Detector HDL Optimized

Introduced in R2012b

comm.HDLCRCGenerator

Package: `comm`

Generate CRC code bits and append to input data

Description

This HDL-optimized cyclic redundancy code (CRC) generator System object generates cyclic redundancy code (CRC) bits. Instead of frame processing, the `HDLCRCGenerator` System object processes streaming data. The object has frame synchronization control signals for both input and output data streams.

To generate cyclic redundancy code bits:

1. Create the `comm.HDLCRCGenerator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
CRCGen = comm.HDLCRCGenerator
CRCGen = comm.HDLCRCGenerator(Name,Value)
CRCGen = comm.HDLCRCGenerator(poly,Name,Value)
```

Description

`CRCGen = comm.HDLCRCGenerator` creates an HDL-optimized CRC generator System object, `CRCGen`. This object generates CRC bits according to a specified generator polynomial and appends them to the input data.

`CRCGen = comm.HDLCRCGenerator(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,

```
CRCGen = comm.HDLCRCGenerator('Polynomial',[1 0 0 0 1 0 0 0 0], ...
'FinalXORValue',[1 1 0 0 0 0 0 0]);
```

specifies a CRC8 polynomial and an 8-bit value to XOR with the final checksum.

`CRCGen = comm.HDLCRCGenerator(poly,Name,Value)` sets the `Polynomial` property to `poly`, and the other specified property names to the specified values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Polynomial — Generator polynomial

[1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1] (default) | binary vector

Generator polynomial, specified as a binary vector, with coefficients in descending order of powers. The vector length must be equal to the degree of the polynomial plus 1.

InitialState — Initial conditions of shift register

0 (default) | binary scalar | binary vector

Initial conditions of the shift register, specified as a binary, double-precision or single-precision scalar or vector. If you specify this property as a vector, the vector length is the degree of the generator polynomial that you specify in the `Polynomial` property. If you specify this property as a scalar, the object expands the value to a vector of length equal to the degree of the generator polynomial.

DirectMethod — Method of calculating checksum

false (default) | true

Method of calculating checksum, specified as a logical scalar. When this property is `true`, the object uses the direct algorithm for CRC checksum calculations.

To learn about direct and non-direct algorithms, see “Cyclic Redundancy Check Codes”.

ReflectInput — Input byte order

false (default) | true

Input byte order, specified as a logical scalar. When this property is `true`, the object flips the input data on a bytewise basis before it enters the shift register.

ReflectCRCChecksum — Checksum byte order

false (default) | true

Checksum byte order, specified as a logical scalar. When this property is `true`, the object flips the output CRC checksum around its center.

FinalXORValue — Checksum mask

0 (default) | binary scalar | binary vector

Checksum mask, specified as a binary, double- or single-precision data type scalar or vector. The object XORs the checksum with this value before appending the checksum to the input data. If you specify this property as a vector, the vector length is the degree of the generator polynomial that you specify in the `Polynomial` property. If you specify this property as a scalar, the object expands the value to a vector of length equal to the degree of the generator polynomial.

Usage

Syntax

```
[Y,startOut,endOut,validOut] = CRCn(X,startIn,endIn, validIn)
```

Description

`[Y,startOut,endOut,validOut] = CRCn(X,startIn,endIn, validIn)` generates CRC checksums for input message X based on control signals and appends the checksums to X.

Input Arguments

X — Input message

binary column vector | scalar integer

Input message, specified as a binary vector or a scalar integer representing several bits. For example, vector input `[0,0,0,1,0,0,1,1]` is equivalent to `uint8` input `19`.

If the input is a vector, the data type can be double or logical. If the input is a scalar, the data type can be unsigned integer or unsigned fixed-point with 0 fractional bits (`fi([],0,N,0)`).

X can be part or all of the message to be encoded.

The length of X must be less than or equal to the CRC length, and the CRC length must be divisible by the length of X.

The CRC length is the order of the polynomial that you specify in the `Polynomial` property.

Data Types: `double` | `uint8` | `uint16` | `uint32` | `logical` | `unsigned fi`

`startIn` — Start of input message

logical scalar

Start of the input message, specified as a logical scalar.

`endIn` — End of input message

logical scalar

End of the input message, specified as a logical scalar.

`validIn` — Validity of input data

logical scalar

Validity of input data, specified as a logical scalar. When `validIn` is 1 (`true`), the object computes the CRC checksum for input X.

Output Arguments

Y — Output message with appended checksum

binary column vector | scalar integer

Output message, consisting of X with appended checksum, returned as a scalar integer or binary column vector with the same width and data type as input X.

`startOut` — Start of input message

logical scalar

Start of the input message, returned as a logical scalar.

`endOut` — End of input message

logical scalar

End of the input message, returned as a logical scalar.

validOut — Validity of input data
logical scalar

Validity of input data, returned as a logical scalar. When `validOut` is 1 (`true`), the output data `Y` is valid.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

CRC Encode and Decode for HDL

Encode and decode a signal using the HDL-optimized CRC generator and detector System objects. This example shows how to include each object in a function for HDL code generation.

Create a 32-bit message to be encoded, in two 16-bit columns.

```
msg = randi([0 1],16,2);
```

Run for 12 steps to accommodate the latency of both objects. Assign control signals for all steps. The first two samples are the valid data, and the remainder are processing latency.

```
numSteps = 12;
startIn = logical([1 0 0 0 0 0 0 0 0 0 0 0]);
endIn   = logical([0 1 0 0 0 0 0 0 0 0 0 0]);
validIn = logical([1 1 0 0 0 0 0 0 0 0 0 0]);
```

Pass random input to the `HDLCRCGenerator` System object™ while it is processing the input message. The random data is not encoded because the input valid signal is `0` for steps 3 to 10.

```
randIn = randi([0, 1],16,numSteps-2);
dataIn = [msg randIn];
```

Write a function that creates and calls each System object™. You can generate HDL from these functions. The generator and detector objects both have a CRC length of 16 and use the default polynomial.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function [dataOut,startOut,endOut,validOut] = HDLCRC16Gen(dataIn,startIn,endIn,validIn)
%HDLCRC16Gen
% Generates CRC checksum using the comm.HDLCRCGenerator System object(TM)
% dataIn is a binary column vector.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

  persistent crcg16;
  if isempty(crcg16)
    crcg16 = comm.HDLCRCGenerator()
  end
  [dataOut,startOut,endOut,validOut] = crcg16(dataIn,startIn,endIn,validIn);
end
```

```
function [dataOut,startOut,endOut,validOut,err] = HDLCRC16Det(dataIn,startIn,endIn,validIn)
%HDLCRC16Det
% Checks CRC checksum using the comm.HDLCRCDetector System object(TM)
% dataIn is a binary column vector.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

  persistent crcd16;
  if isempty(crcd16)
    crcd16 = comm.HDLCRCDetector()
  end
  [dataOut,startOut,endOut,validOut,err] = crcd16(dataIn,startIn,endIn,validIn);
end
```

Call the CRC generator function. The encoded message is the original message plus a 16 bit checksum.

```
 for i =  1:numSteps
 [dataOutGen(:,i),startOutGen(i),endOutGen(i),validOutGen(i)] = ...
     HDLCRC16Gen(logical(dataIn(:,i)),startIn(i),endIn(i),validIn(i));
 end
```

```
crcg16 = 

  comm.HDLCRCGenerator with properties:

            Polynomial: [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]
          InitialState: 0
          DirectMethod: false
          ReflectInput: false
    ReflectCRCChecksum: false
         FinalXORValue: 0
```

Add noise by flipping a bit in the message.

```
dataOutNoise = dataOutGen;
dataOutNoise(2,4) = ~dataOutNoise(2,4);
```

Call the CRC detector function. The output of the detector is the input message with the checksum removed. If the input checksum was not correct, the `err` flag is set with the last word of the output.

```
for i = 1:numSteps
[dataOut(:,i),startOut(i),endOut(i),validOut(i),err(i)] = ...
    HDLCRC16Det(logical(dataOutNoise(:,i)),startOutGen(i),endOutGen(i),validOutGen(i));
end
```

```
crcd16 = 

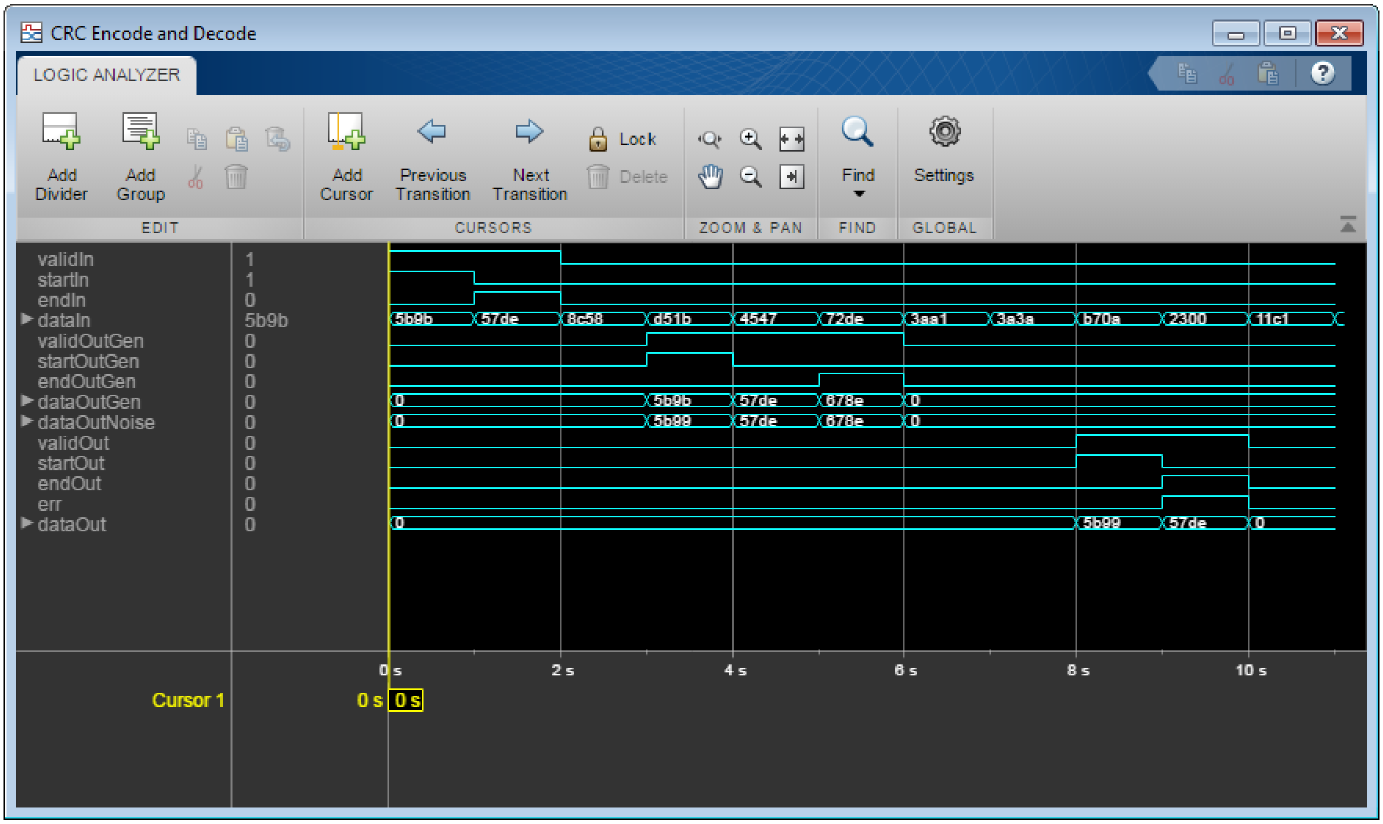
  comm.HDLCRCDetector with properties:

            Polynomial: [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]
          InitialState: 0
          DirectMethod: false
          ReflectInput: false
    ReflectCRCChecksum: false
         FinalXORValue: 0
```

Use the **Logic Analyzer** to view the input and output signals.

```
channels = {'validIn','startIn','endIn',...
    {'dataIn','Radix','Hexadecimal'},...
    'validOutGen','startOutGen','endOutGen',...
    {'dataOutGen','Radix','Hexadecimal'},...
    {'dataOutNoise','Radix','Hexadecimal'},...
    'validOut','startOut','endOut','err',...
    {'dataOut','Radix','Hexadecimal'}};
la = dsp.LogicAnalyzer('Name','CRC Encode and Decode','NumInputPorts',length(channels),...
                      'BackgroundColor','Black','DisplayChannelHeight',8);

 for ii = 1:length(channels)
    if iscell(channels{ii})
        % Display data signals as hexadecimal integers
        c = channels{ii};
        modifyDisplayChannel(la,ii,'Name',c{1},c{2},c{3})
        % Convert binary column vector to integer
        dat2 = uint16(bi2de(eval(c{1})'));
        chanData{ii} = squeeze(dat2);
    else
        modifyDisplayChannel(la,ii,'Name',channels{ii})
        chanData{ii} = squeeze(eval(channels{ii})');
    end
 end
la(chanData{:})
```

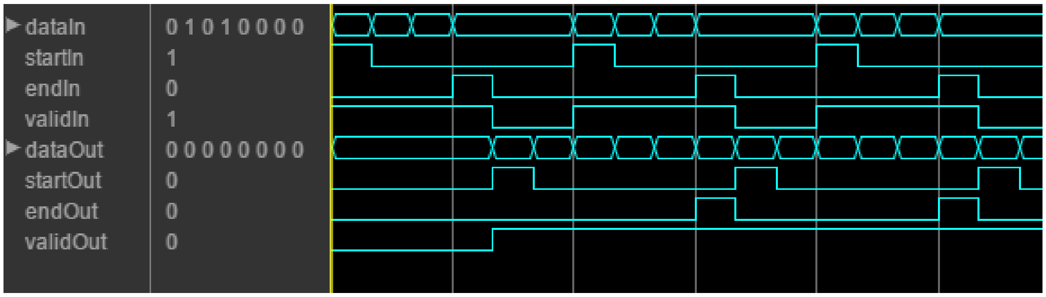


Algorithms

Timing Diagram

This waveform shows streaming data and the accompanying control signals for a CRC16 with an 8-bit binary vector input. To insert the checksum word, input frames must have enough space between the.

This waveform diagram shows continuous input data. The block also supports noncontinuous data. The output valid signal matches the input valid pattern.



Initial Delay

The `HDLCRCGenerator` System object introduces a latency on the output. You can compute the latency as follows, assuming the input data is continuous:

```
initialDelay = (CRCLength/inputDataWidth) + 2
```

Blocks

General CRC Generator HDL Optimized

Introduced in R2012a

comm.HDLRSDecoder

Package: `comm`

Decode message using Reed-Solomon decoder

Description

The HDL-optimized `HDLRSDecoder` System object recovers a message vector from a Reed-Solomon (RS) codeword vector. For proper decoding, the code and polynomial property values for this object must match those values in the corresponding encoder.

To recover a message vector from a Reed-Solomon codeword vector:

1. Create the `comm.HDLRSDecoder` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Troubleshooting

- Each input frame must contain more than `(N-K)*2` symbols and fewer than or exactly `N` symbols. The object infers a shortened code when the number of valid data samples between `startIn` and `endIn` is less than `N`. A shortened code still requires `N` cycles to perform the Chien search. If the input message is less than `N` symbols, leave a guard interval of at least `N - size` inactive cycles before starting the next frame, where `size`is the message length.
- The decoder can operate on up to four messages at a time. If the object receives the start of a fifth message before completely decoding the first message, the object drops data samples from the first message. To avoid this issue, increase the number of inactive cycles between input messages.
- The generator polynomial is not specified explicitly. However, it is defined by the codeword length, the message length, and the B value for the starting exponent of the roots. To get the value of B from a generator polynomial, use the `genpoly2b` function.

Creation

Syntax

```
RSDec = comm.HDLRSDecoder
RSDec = comm.HDLRSDecoder(Name,Value)
RSDec = comm.HDLRSDecoder(N,K,Name,Value)
```

Description

`RSDec = comm.HDLRSDecoder` creates an HDL-optimized RS decoder System object, `RSDec`, that performs Reed-Solomon decoding.

`RSDec = comm.HDLRSDecoder(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,

```
comm.HDLRSDecoder('BSource','Property','B',2)
```

sets a starting power of 2 for the roots of the primitive polynomial.

`RSDec = comm.HDLRSDecoder(N,K,Name,Value)` sets the `CodewordLength` property to `N`, the `MessageLength` property to `K`, and other specified property names to the specified values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

B — Starting power for roots of primitive polynomial
1 (default) | positive integer

Starting power for roots of the primitive polynomial, specified as a positive integer.

Dependencies

The object uses this value when you set `BSource` to `'Property'`.

`BSource` — Source of starting power for roots of primitive polynomial
`'Auto'` (default) | `'Property'`

Source of the starting power for roots of the primitive polynomial, specified as either `'Property'` or `'Auto'`. When you select `'Auto'`, the object uses `B = 1`.

`CodewordLength` — Number of symbols, N, in RS codeword
7 (default) | positive integer

Number of symbols, N, in the RS codeword, specified as a positive integer. This value is rounded up to 2^M–1. M is the degree of the primitive polynomial, as specified by the `PrimitivePolynomialSource` and `PrimitivePolynomial` properties. The difference of `CodewordLength` – `MessageLength` must be an even integer.

If the value of this property is less than 2^M–1, the object assumes a shortened RS code.

If you set `PrimitivePolynomialSource` to `'Auto'`, then `CodewordLength` must be in the range 3 < `CodewordLength` ≤ 2^{16} – 1.

If you set `PrimitivePolynomialSource` to `'Property'`, then `CodewordLength` must be in the range 3 ≤ `CodewordLength` ≤ 2^M– 1. M must be in the range $3 \leq M \leq 16$.

`MessageLength` — Message length, K
3 (default) | positive integer

Message length, K, specified as a positive integer. The difference of `CodewordLength` – `MessageLength` must be an even integer.

`NumErrorsOutputPort` — Enable number of errors output argument
`false` (default) | `true`

When you set this property to `true`, the object returns the number of corrected errors. The number of corrected errors is not valid when `errOut` is `true`, since there were more errors than could be corrected.

`PrimitivePolynomialSource` — Source of primitive polynomial

`'Auto'` (default) | `'Property'`

Source of the primitive polynomial, specified as either `'Property'` or `'Auto'`.

- When you set this property to `'Auto'`, the object uses a primitive polynomial of degree *M* = `ceil`(**log2**(`CodewordLength`+1)), which is the result of `fliplr`(`de2bi`(`primpoly`(*M*))).
- When you set this property to `'Property'`, you must specify a polynomial using the `PrimitivePolynomial` property.

`PrimitivePolynomial` — Primitive polynomial

`[1 0 1 1]` (default) | binary row vector

Primitive polynomial, specified as a binary row vector that represents a primitive polynomial over `gf`(2) of degree *M*, in descending order of powers. The polynomial defines the finite field `gf`(2^M) corresponding to the integers that form messages and codewords.

Dependencies

The object uses this value when you set `PrimitivePolynomialSource` to `'Property'`.

Usage

Syntax

```
[Y,startOut,endOut,validOut,errOut] = RSDec(X,startIn,endIn,validIn)
[Y,startOut,endOut,validOut,errOut,numErrors] = RSDec(X,startIn,endIn,
validIn)
```

Description

`[Y,startOut,endOut,validOut,errOut] = RSDec(X,startIn,endIn,validIn)` decodes one encoded message symbol, `X`, and returns the decoded symbol `Y`. The `start` and `end` signals indicate the message frame boundaries. If `errOut` is `1` (`true`), then the object detected uncorrectable errors in the input frame.

`[Y,startOut,endOut,validOut,errOut,numErrors] = RSDec(X,startIn,endIn, validIn)` decodes the input data, and also returns the number of errors detected and corrected. To use this syntax, set the `NumErrorsOutputPort` property to `true`. If `errOut` is `1` (`true`), then the object detected uncorrectable errors in the output frame, and `numErrors` is invalid.

Input Arguments

`X` — Input message data or parity symbols

integer

Input message data and parity symbols, one symbol at a time, specified as an unsigned integer or `fi()` with any binary point scaling.

`double` type is allowed for simulation but not supported for HDL code generation.

Data Types: `double` | `uint8` | `uint16` | `uint32` | `fi`

`startIn` — Start of input data frame
logical scalar

Start of input data frame, specified as a logical scalar.

Data Types: `logical`

`endIn` — End of input data frame
logical scalar

End of input data frame, specified as a logical scalar.

Data Types: `logical`

`validIn` — Validity of input data
logical scalar

Validity of input data, specified as a logical scalar.

Data Types: `logical`

Output Arguments

Y — Message data symbols
integer

Message data symbols, returned one symbol at a time, as an integer with the same data type as the input message, X.

Data Types: `double` | `uint8` | `uint16` | `uint32` | `fi`

`startOut` — Start of output data frame
logical scalar

Start of output data frame, returned as a logical scalar.

Data Types: `logical`

`endOut` — End of output data frame
logical scalar

End of output data frame, returned as a logical scalar.

Data Types: `logical`

`validOut` — Validity of output data
logical scalar

Validity of output data, returned as a logical scalar.

Data Types: `logical`

`errOut` — Uncorrectable error in output data frame
logical scalar

Uncorrectable error in output data frame, returned as a logical scalar. This signal is 1 (`true`) when the message frame contains uncorrectable errors. In this case, the output data symbols are corrupted. This value is valid when `endOut` is 1 (`true`).

Data Types: `logical`

`numErrors` — Number of errors detected and corrected
integer

Number of errors detected and corrected, returned as an integer. This value is valid when `endOut` is 1 (`true`) and `errOut` is 0 (`false`).

Data Types: `uint8`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Reed-Solomon Coding and Error Detection for HDL

Encode and decode a signal using Reed Solomon encoder and decoder System objects. This example shows how to include each object in a function for HDL code generation.

Create a random message to encode. This message is smaller than the codeword length to show how the objects support shortened codes. Pad the message with zeros to accommodate the latency of the decoder, including the Chien search.

```
messageLength = 188;
dataIn = [randi([0,255],1,messageLength,'uint8') zeros(1,1024-messageLength)];
```

Write a function that creates and calls a `HDLRSEncoder` System object™ with an RS(255,239) code. This code is used in the IEEE® 802.16 Broadband Wireless Access standard. `B` is the starting power of the roots of the primitive polynomial. You can generate HDL from this function.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function  [dataOut,startOut,endOut,validOut] = HDLRSEnc80216(dataIn,startIn,endIn,validIn)
%HDLRSEnc80216
% Processes one sample of data using the comm.HDLRSEncoder System object(TM)
% dataIn is a uint8 scalar, representing 8 bits of binary data.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

  persistent rsEnc80216;
  if isempty(rsEnc80216)
    rsEnc80216 = comm.HDLRSEncoder(255,239,'BSource','Property','B',0)
  end
  [dataOut,startOut,endOut,validOut] = rsEnc80216(dataIn,startIn,endIn,validIn);
end
```

Call the function to encode the message.

```
for ii = 1:1024
    messageStart = (ii==1);
    messageEnd = (ii==messageLength);
    validIn = (ii<=messageLength);
    [encOut(ii),startOut(ii),endOut(ii),validOut(ii)] = ...
        HDLRSEnc80216(dataIn(ii),messageStart,messageEnd,validIn);
end
```

```
rsEnc80216 = 

  comm.HDLRSEncoder with properties:

               CodewordLength: 255
                MessageLength: 239
    PrimitivePolynomialSource: 'Auto'
        PuncturePatternSource: 'None'
                      BSource: 'Property'
                            B: 0
```

Inject errors at random locations in the encoded message. Reed-Solomon can correct up to (*N* – *K*)/2 errors in each *N* symbols. So, in this example, the error correction capability is (255 – 239)/2=8 symbols.

```
numErrors = 8;
loc = randperm(messageLength,numErrors);
% encOut is qualified by validOut, use an offset for injecting errors
vi = find(validOut==true,1);
for i = 1:numErrors
   idx = loc(i)+vi;
   symbol = encOut(idx);
   encOut(idx) = randi([0 255],'uint8');
   fprintf('Symbol(%d): was 0x%x, now 0x%x\n',loc(i),symbol,encOut(idx))
end
```

```
Symbol(147): was 0x1f, now 0x82
Symbol(16): was 0x6b, now 0x82
Symbol(173): was 0x3, now 0xd1
Symbol(144): was 0x66, now 0xcb
Symbol(90): was 0x13, now 0xa4
Symbol(80): was 0x5a, now 0x60
Symbol(82): was 0x95, now 0xcf
Symbol(56): was 0xf5, now 0x88
```

Write a function that creates and calls a `HDLRSDecoder` System object™. This object must have the same code and polynomial as the encoder. You can generate HDL from this function.

```
function  [dataOut,startOut,endOut,validOut,err] = HDLRSDec80216(dataIn,startIn,endIn,validIn)
%HDLRSDec80216
% Processes one sample of data using the comm.HDLRSDecoder System object(TM)
% dataIn is a uint8 scalar, representing 8 bits of binary data.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

  persistent rsDec80216;
  if isempty(rsDec80216)
    rsDec80216 = comm.HDLRSDecoder(255,239,'BSource','Property','B',0)
  end
  [dataOut,startOut,endOut,validOut,err] = rsDec80216(dataIn,startIn,endIn,validIn);
end
```

Call the function to detect errors in the encoded message.

```
for ii = 1:1024
 [decOut(ii),decStartOut(ii),decEndOut(ii),decValidOut(ii),decErrOut(ii)] = ...
     HDLRSDec80216(encOut(ii),startOut(ii),endOut(ii),validOut(ii));
end
```

```
rsDec80216 = 

  comm.HDLRSDecoder with properties:

               CodewordLength: 255
                MessageLength: 239
    PrimitivePolynomialSource: 'Auto'
                      BSource: 'Property'
                            B: 0
          NumErrorsOutputPort: false
```

Select the valid decoder output and compare the decoded symbols to the original message.

```
decOut = decOut(decValidOut==1);
originalMessage = dataIn(1:messageLength);
if all(originalMessage==decOut)
    fprintf('All %d message symbols were correctly decoded.\n',messageLength)
else
   for jj = 1:messageLength
      if dataIn(jj)~=decOut(jj)
        fprintf('Error in decoded symbol(%d). Original 0x%x, Decoded 0x%x.\n',jj,dataIn(jj),decOu
      end
   end
end
```

```
All 188 message symbols were correctly decoded.
```

comm.HDLRSEncoder

Package: `comm`

Encode message using Reed-Solomon encoder

Description

The HDL-optimized `HDLRSEncoder` System object creates a Reed-Solomon (RS) code with message and codeword lengths that you specify.

To encode a message using a Reed-Solomon code:

1. Create the `comm.HDLRSEncoder` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
RSEnc = comm.HDLRSEncoder
RSEnc = comm.HDLRSEncoder(Name,Value)
RSEnc = comm.HDLRSEncoder(N,K,Name,Value)
```

Description

`RSEnc = comm.HDLRSEncoder` creates an HDL-optimized block encoder System object, `RSEnc`, that performs Reed-Solomon encoding in a streaming fashion for HDL.

`RSEnc = comm.HDLRSEncoder(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,

```
comm.HDLRSEncoder('BSource','Property','B',2)
```

sets a starting power of 2 for the roots of the primitive polynomial.

`RSEnc = comm.HDLRSEncoder(N,K,Name,Value)` sets the `CodewordLength` property to `N`, the `MessageLength` property to `K`, and other specified property names to the specified values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

B — Starting power for roots of primitive polynomial

1 (default) | positive integer

Starting power for roots of the primitive polynomial, specified as a positive integer.

Dependencies

The object uses this value when you set `BSource` to `'Property'`.

BSource — Source of starting power for roots of primitive polynomial

`'Auto'` (default) | `'Property'`

Source of the starting power for roots of the primitive polynomial, specified as either `'Property'` or `'Auto'`. When you select `'Auto'`, the object uses `B = 1`.

CodewordLength — Number of symbols, N, in RS codeword

7 (default) | positive integer

Number of symbols, *N*, in the RS codeword, specified as a positive integer. This value is rounded up to 2^M–1. *M* is the degree of the primitive polynomial, as specified by the `PrimitivePolynomialSource` and `PrimitivePolynomial` properties. The difference of `CodewordLength` – `MessageLength` must be an even integer.

If the value of this property is less than 2^M–1, the object assumes a shortened RS code.

If you set `PrimitivePolynomialSource` to `'Auto'`, then `CodewordLength` must be in the range 3 < `CodewordLength` ≤ 2^{16} – 1.

If you set `PrimitivePolynomialSource` to `'Property'`, then `CodewordLength` must be in the range 3 ≤ `CodewordLength` ≤ 2^M– 1. *M* must be in the range 3 ≤ *M* ≤ 16.

MessageLength — Message length, K

3 (default) | positive integer

Message length, *K*, specified as a positive integer. The difference of `CodewordLength` – `MessageLength` must be an even integer.

PrimitivePolynomialSource — Source of primitive polynomial

`'Auto'` (default) | `'Property'`

Source of the primitive polynomial, specified as either `'Property'` or `'Auto'`.

- When you set this property to `'Auto'`, the object uses a primitive polynomial of degree *M* = `ceil`(**log2**(`CodewordLength`+1)), which is the result of `fliplr`(`de2bi`(`primpoly`(*M*))).
- When you set this property to `'Property'`, you must specify a polynomial using the `PrimitivePolynomial` property.

PrimitivePolynomial — Primitive polynomial

`[1 0 1 1]` (default) | binary row vector

Primitive polynomial, specified as a binary row vector that represents a primitive polynomial over `gf`(2) of degree *M*, in descending order of powers. The polynomial defines the finite field `gf`(2^M) corresponding to the integers that form messages and codewords.

Dependencies

The object uses this value when you set PrimitivePolynomialSource to 'Property'.

PuncturePatternSource — Source of puncture pattern

'None' (default) | 'Property'

Source of the puncture pattern, specified as 'None' or 'Property'. If you set this property to 'None', then the object does not apply puncturing to the code. If you set this property to 'Property', then the object punctures the code based on a puncture pattern vector specified in the PuncturePattern property.

PuncturePattern — Pattern used to puncture encoded data

[ones(2,1); zeros(2,1)] (default) | binary column vector

Pattern used to puncture the encoded data, specified as a double-precision, binary column vector with a length of CodewordLength – MessageLength. The default is [ones(2,1); zeros(2,1)]. Zeros in the puncture pattern vector indicate the position of the parity symbols that are punctured or excluded from each codeword.

Dependencies

This property applies when you set the PuncturePatternSource property to 'Property'.

Usage

Syntax

```
[Y,startOut,endOut,validOut] = RSEnc(X,startIn,endIn,validIn)
```

Description

[Y,startOut,endOut,validOut] = RSEnc(X,startIn,endIn,validIn) encodes one input message symbol, X, and returns one symbol of encoded data, Y. The start and end signals indicate the message frame boundaries. The object returns associated parity symbols at the end of each message frame.

Input Arguments

X — Input message symbol

integer

Input message data, one symbol at a time, specified as an unsigned integer or fi() with any binary point scaling. The word length of each symbol must be ceil($\log_2$(CodewordLength+1)).

double type is allowed for simulation but not supported for HDL code generation.

Data Types: double | uint8 | uint16 | uint32 | fi

startIn — Start of input data frame

logical scalar

Start of input data frame, specified as a logical scalar.

Data Types: logical

`endIn` — End of input data frame

logical scalar

End of input data frame, specified as a logical scalar.

Data Types: `logical`

`validIn` — Validity of input data

logical scalar

Validity of input data, specified as a logical scalar.

Data Types: `logical`

Output Arguments

Y — Output message data and parity symbols

integer

Message data and parity symbols, returned one symbol at a time, as an integer with the same data type as the input message, X.

Data Types: `double` | `uint8` | `uint16` | `uint32` | `fi`

`startOut` — Start of output data frame

logical scalar

Start of output data frame, returned as a logical scalar.

Data Types: `logical`

`endOut` — End of output data frame

logical scalar

End of output data frame, returned as a logical scalar.

Data Types: `logical`

`validOut` — Validity of output data

logical scalar

Validity of output data, returned as a logical scalar.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics

reset	Reset internal states of System object

Examples

Reed-Solomon Coding and Error Detection for HDL

Encode and decode a signal using Reed Solomon encoder and decoder System objects. This example shows how to include each object in a function for HDL code generation.

Create a random message to encode. This message is smaller than the codeword length to show how the objects support shortened codes. Pad the message with zeros to accommodate the latency of the decoder, including the Chien search.

```
messageLength = 188;
dataIn = [randi([0,255],1,messageLength,'uint8') zeros(1,1024-messageLength)];
```

Write a function that creates and calls a `HDLRSEncoder` System object™ with an RS(255,239) code. This code is used in the IEEE® 802.16 Broadband Wireless Access standard. `B` is the starting power of the roots of the primitive polynomial. You can generate HDL from this function.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function  [dataOut,startOut,endOut,validOut] = HDLRSEnc80216(dataIn,startIn,endIn,validIn)
%HDLRSEnc80216
% Processes one sample of data using the comm.HDLRSEncoder System object(TM)
% dataIn is a uint8 scalar, representing 8 bits of binary data.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

  persistent rsEnc80216;
  if isempty(rsEnc80216)
    rsEnc80216 = comm.HDLRSEncoder(255,239,'BSource','Property','B',0)
  end
  [dataOut,startOut,endOut,validOut] = rsEnc80216(dataIn,startIn,endIn,validIn);
end
```

Call the function to encode the message.

```
for ii = 1:1024
    messageStart = (ii==1);
    messageEnd = (ii==messageLength);
    validIn = (ii<=messageLength);
    [encOut(ii),startOut(ii),endOut(ii),validOut(ii)] = ...
        HDLRSEnc80216(dataIn(ii),messageStart,messageEnd,validIn);
end
```

```
rsEnc80216 =

  comm.HDLRSEncoder with properties:
```

```
               CodewordLength: 255
                MessageLength: 239
    PrimitivePolynomialSource: 'Auto'
        PuncturePatternSource: 'None'
                      BSource: 'Property'
                            B: 0
```

Inject errors at random locations in the encoded message. Reed-Solomon can correct up to (*N* – *K*)/2 errors in each *N* symbols. So, in this example, the error correction capability is (255 – 239)/2=8 symbols.

```
numErrors = 8;
loc = randperm(messageLength,numErrors);
% encOut is qualified by validOut, use an offset for injecting errors
vi = find(validOut==true,1);
for i = 1:numErrors
   idx = loc(i)+vi;
   symbol = encOut(idx);
   encOut(idx) = randi([0 255],'uint8');
   fprintf('Symbol(%d): was 0x%x, now 0x%x\n',loc(i),symbol,encOut(idx))
end
```

```
Symbol(147): was 0x1f, now 0x82
Symbol(16): was 0x6b, now 0x82
Symbol(173): was 0x3, now 0xd1
Symbol(144): was 0x66, now 0xcb
Symbol(90): was 0x13, now 0xa4
Symbol(80): was 0x5a, now 0x60
Symbol(82): was 0x95, now 0xcf
Symbol(56): was 0xf5, now 0x88
```

Write a function that creates and calls a `HDLRSDecoder` System object™. This object must have the same code and polynomial as the encoder. You can generate HDL from this function.

```
function  [dataOut,startOut,endOut,validOut,err] = HDLRSDec80216(dataIn,startIn,endIn,validIn)
%HDLRSDec80216
% Processes one sample of data using the comm.HDLRSDecoder System object(TM)
% dataIn is a uint8 scalar, representing 8 bits of binary data.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

  persistent rsDec80216;
  if isempty(rsDec80216)
    rsDec80216 = comm.HDLRSDecoder(255,239,'BSource','Property','B',0)
  end
  [dataOut,startOut,endOut,validOut,err] = rsDec80216(dataIn,startIn,endIn,validIn);
end
```

Call the function to detect errors in the encoded message.

```
for ii = 1:1024
 [decOut(ii),decStartOut(ii),decEndOut(ii),decValidOut(ii),decErrOut(ii)] = ...
     HDLRSDec80216(encOut(ii),startOut(ii),endOut(ii),validOut(ii));
end
```

```
rsDec80216 = 

  comm.HDLRSDecoder with properties:

               CodewordLength: 255
                MessageLength: 239
    PrimitivePolynomialSource: 'Auto'
                      BSource: 'Property'
                            B: 0
          NumErrorsOutputPort: false
```

Select the valid decoder output and compare the decoded symbols to the original message.

```
decOut = decOut(decValidOut==1);
originalMessage = dataIn(1:messageLength);
if all(originalMessage==decOut)
    fprintf('All %d message symbols were correctly decoded.\n',messageLength)
else
   for jj = 1:messageLength
      if dataIn(jj)~=decOut(jj)
        fprintf('Error in decoded symbol(%d). Original 0x%x, Decoded 0x%x.\n',jj,dataIn(jj),decOu
      end
   end
end
```

```
All 188 message symbols were correctly decoded.
```

Integer-Input RS Encoder HDL Optimized

Introduced in R2012b

comm.HelicalDeinterleaver

Package: comm

Restore ordering of symbols using helical array

Description

The HelicalDeinterleaver object permutes the symbols in the input signal by placing them in a row-by-row array and then selecting groups helically to send to the output port.

To helically deinterleave input symbols:

1. Define and set up your helical deinterleaver object. See "Construction" on page 3-860.
2. Call step to deinterleave input symbols according to the properties of comm.HelicalDeinterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.HelicalDeinterleaver creates a helical deinterleaver System object, H. This object restores the original ordering of a sequence that was interleaved using the helical interleaver System object.

H = comm.HelicalDeinterleaver(Name,Value) creates a helical deinterleaver object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

NumColumns

Number of columns in helical array

Specify the number of columns in the helical array as a positive integer scalar value. The default is 6.

GroupSize

Size of each group of input symbols

Specify the size of each group of input symbols as a positive integer scalar value. The default is 4.

StepSize

Helical array step size

Specify number of rows of separation between consecutive input groups in their respective columns of the helical array. This property requires a positive integer scalar value. The default is `1`.

`InitialConditions`

Initial conditions of helical array

Specify the value that is initially stored in the helical array as a numeric scalar value. The default is `0`.

Methods

reset	Reset states of the helical deinterleaver object
step	Restore ordering of symbols using a helical array

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Helical Interleaving and Deinterleaving

Create helical interleaver and deinterleaver objects.

```
interleaver = comm.HelicalInterleaver('GroupSize',2,'NumColumns',3, ...
    'InitialConditions',-1);
deinterleaver = comm.HelicalDeinterleaver('GroupSize',2,'NumColumns',3, ...
    'InitialConditions',-1);
```

Generate random data. Interleave and then deinterleave the data.

```
[dataIn,dataOut] = deal([]);

for k = 1:10
    data = randi(7,6,1);
    intData = interleaver(data);
    deIntData = deinterleaver(intData);

    dataIn = cat(1,dataIn,data);
    dataOut = cat(1,dataOut,deIntData);
end
```

Determine the delay through the interleaver and deinterleaver pair.

```
intlvDelay = finddelay(dataIn,dataOut)
```

```
intlvDelay = 6
```

After taking the interleaving delay into account, confirm that the original and deinterleaved data are identical.

```
isequal(dataIn(1:end-intlvDelay),dataOut(1+intlvDelay:end))
```

```
ans = logical
   1
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Helical Deinterleaver block reference page. The object properties correspond to the block parameters.

`comm.HelicalInterleaver` | `comm.MultiplexedDeinterleaver`

Introduced in R2012a

reset

System object: `comm.HelicalDeinterleaver`
Package: `comm`

Reset states of the helical deinterleaver object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `HelicalDeinterleaver` object, `H`.

step

System object: `comm.HelicalDeinterleaver`
Package: `comm`

Restore ordering of symbols using a helical array

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` restores the original ordering of the sequence, `X`, that was interleaved using a helical interleaver and returns `Y`. The input `X` must be a column vector. The data type must be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`. The helical deinterleaver object uses an array for its computations. If you set the NumColumns property of the object to *C*, then the array has *C* columns and unlimited rows. If you set the GroupSize property to *N*, then the object accepts an input of length *C*×*N* and inserts it into the next *N* rows of the array. The object also places the value of the InitialConditions property into certain positions in the top few rows of the array. This accommodates the helical pattern and also preserves the vector indices of symbols that pass through the `HelicalInterleaver` and `HelicalDeinterleaver` objects. The output consists of consecutive groups of *N* symbols. The object selects the *k*-th output group in the array from column *k* mod *C*. This selection is of type helical because of the reduction modulo *C* and because the first symbol in the *k*-th group is in row 1+(*k*-1)×*s*, where *s* is the value for the StepSize property.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.HelicalInterleaver

Package: comm

Permute input symbols using helical array

Description

The HelicalInterleaver object permutes the symbols in the input signal by placing them in an array in a helical arrangement and then sending rows of the array to the output port.

To helically interleave input symbols:

1. Define and set up your helical interleaver object. See "Construction" on page 3-865.
2. Call step to interleave input symbols according to the properties of comm.HelicalInterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.HelicalInterleaver creates a helical interleaver System object, H. This object permutes the input symbols in the input signal by placing them in an array in a helical arrangement.

H = comm.HelicalInterleaver(Name,Value) creates a helical interleaver object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

NumColumns

Number of columns in helical array

Specify the number of columns in the helical array as a positive integer scalar value. The default is 6.

GroupSize

Size of each group of input symbols

Specify the size of each group of input symbols as a positive integer scalar value. The default is 4.

StepSize

Helical array step size

Specify the number of rows of separation between consecutive input groups in their respective columns of the helical array. This property requires as a positive integer scalar value . The default is 1.

`InitialConditions`

Initial conditions of helical array

Specify the value that is initially stored in the helical array as a numeric scalar value. The default is `0`.

Methods

reset	Reset states of the helical interleaver object
step	Permute input symbols using a helical array

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Helical Interleaving and Deinterleaving

Create helical interleaver and deinterleaver objects.

```
interleaver = comm.HelicalInterleaver('GroupSize',2,'NumColumns',3, ...
    'InitialConditions',-1);
deinterleaver = comm.HelicalDeinterleaver('GroupSize',2,'NumColumns',3, ...
    'InitialConditions',-1);
```

Generate random data. Interleave and then deinterleave the data.

```
[dataIn,dataOut] = deal([]);

for k = 1:10
    data = randi(7,6,1);
    intData = interleaver(data);
    deIntData = deinterleaver(intData);

    dataIn = cat(1,dataIn,data);
    dataOut = cat(1,dataOut,deIntData);
end
```

Determine the delay through the interleaver and deinterleaver pair.

```
intlvDelay = finddelay(dataIn,dataOut)
```

```
intlvDelay = 6
```

After taking the interleaving delay into account, confirm that the original and deinterleaved data are identical.

```
isequal(dataIn(1:end-intlvDelay),dataOut(1+intlvDelay:end))
```

```
ans = logical
   1
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Helical Interleaver block reference page. The object properties correspond to the block parameters.

Introduced in R2012a

reset

System object: `comm.HelicalInterleaver`
Package: `comm`

Reset states of the helical interleaver object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `HelicalInterleaver` object, `H`.

step

System object: `comm.HelicalInterleaver`
Package: `comm`

Permute input symbols using a helical array

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` permutes input sequence, `X`, and returns interleaved sequence, `Y`. The input `X` must be a column vector. The data type must be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`. The helical interleaver object places the elements of `X` in an array in a helical fashion. If you set the NumColumns property of the object to *C*, then the array has *C* columns and unlimited rows. If you set the GroupSize property to *N*, then the object accepts an input of length *C*×*N* and partitions the input into consecutive groups of *N* symbols. The object places the *k*-th group in the array along column *k* mod *C*. This placement is of type helical because of the reduction modulo C and because the first symbol in the *k*-th group is in the row 1+(*k*-1)×*s*, where *s* is the value for the StepSize property. Positions in the array that do not contain input symbols have default contents specified by the `InitialConditions` property. The object outputs *C*×*N* symbols from the array by reading the next *N* rows sequentially.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.IntegerToBit

Package: `comm`

(To be removed) Convert vector of integers to vector of bits

Note will be removed in a future release. Use `de2bi` instead. For more information, see "Compatibility Considerations".

Description

The `IntegerToBit` object maps each integer (or fixed-point value) in the input vector to a group of bits in the output vector.

To map integers to bits:

1 Define and set up your integer to bit object. See "Construction" on page 3-870.

2 Call `step` to map integers in the input vector to groups of bits in the output vector according to the properties of `comm.IntegerToBit`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.IntegerToBit` creates an integer-to-bit converter System object, `H`. This object maps a vector of integer-valued or fixed-point inputs to a vector of bits.

`H = comm.IntegerToBit(Name,Value)` creates an integer-to-bit converter object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.IntegerToBit(NUMBITS,Name,Value)` creates an integer-to-bit converter object, `H`. This object has the `BitsPerInteger` property set to `NUMBITS` and the other specified properties set to the specified values.

Properties

BitsPerInteger

Number of bits per integer

Specify the number of bits the System object uses to represent each input integer. You must set this property to a scalar integer between `1` and `32`. The default is `3`.

MSBFirst

Output bit words with first bit as most significant bit

Set this property to true to indicate that the first bit of the output bit words is the most significant bit (MSB). The default is `true`. Set this property to `false` to indicate that the first bit of the output bit words is the least significant bit (LSB).

SignedIntegerInput

Assume inputs are signed integers

Set this property to true if the integer inputs are signed. The default is `false`. Set this property to `false` if the integer inputs are unsigned. If the `SignedIntegerInput` on page 3-0 property is `false`, the input values must be between 0 and (2^N)–1. In this case, *N* is the value you specified in the `BitsPerInteger` on page 3-0 property. When you set this property to `true`, the input values must be between –($2^{(N-1)}$) and ($2^{(N-1)}$)–1.

OutputDataType

Data type of output

Specify output data type as one of `Full precision` | `Smallest unsigned integer` | `Same as input` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `logical`. The default is `Full precision`.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in `Smallest unsigned integer` or `Full precision` mode.

When you set this property to `Full precision`, the object determines the output data type based on the input data type. If the input data type is double- or single-precision, the output data has the same data type as the input data. Otherwise, the output data type is determined in the same way as when you set this property to `Smallest unsigned integer`.

When you set this property to `Same as input`, and the input data type is numeric or fixed-point integer (fi object), the output data has the same data type as the input data.

Methods

step	(To be removed) Convert vector of integers to vector of bits

Common to All System Objects	
`release`	Allow System object property value changes

Examples

```
hIntToBit = comm.IntegerToBit(4);
intData = randi([0 2^hIntToBit.BitsPerInteger-1],3,1);
bitData = step(hIntToBit,intData)
```

```
bitData = 12×1

     1
     1
     0
     1
     1
     1
     1
     0
     0
     0
       ⋮
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Integer to Bit Converter block reference page. The object properties correspond to the block parameters.

Compatibility Considerations

`comm.IntegerToBit` will be removed in a future release. Use `de2bi` instead.

Warns starting in R2020b

Use `de2bi` instead of comm.IntegerToBit. Data types as supported by comm.IntegerToBit are not inherently supported by functions. This code shows decimal to binary conversion for various data types using this function.

Examples Using de2bi for Various Data Types

```
function compde2bi

% Number of integers
n = randi([1 100]);

% Default
h1 = comm.IntegerToBit;
bpi = h1.BitsPerInteger;
x = randi([0,2^bpi-1],n,1);
y1 = h1(x);
y2 = reshape(de2bi(x,bpi,'left-msb')',[],1);
isequal(y1,y2)

% Right MSB, logical input
h2 = comm.IntegerToBit( ...
    'BitsPerInteger',5, ...
    'MSBFirst',false);
bpi = h2.BitsPerInteger;
x = randi([0,2^bpi-1],n,1);
y1 = h2(x);
y2 = reshape(de2bi(x,bpi,'right-msb')',[],1);
isequal(y1,y2)

% Right MSB, signed input, single input
h3 = comm.IntegerToBit( ...
    'BitsPerInteger',8, ...
    'MSBFirst',false, ...
    'SignedIntegerInput',true);
bpi = h3.BitsPerInteger;
N = 2^bpi;
x = randi([-N/2,N/2-1],n,1);
y1 = h3(x);
y2 = reshape(de2bi(x+(x<0)*N,bpi,'right-msb')',[],1);
isequal(y1,y2)
end
```

`bi2de` | `de2bi` | `dec2bin`

Introduced in R2012a

step

System object: `comm.IntegerToBit`
Package: `comm`

(To be removed) Convert vector of integers to vector of bits

Note `comm.IntegerToBit` will be removed in a future release. Use `de2bi` instead.

Syntax

`Y = step(H,X)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` converts integer input, `X`, to corresponding bits, `Y`. The input must be scalar or a column vector and the data type can be numeric or fixed-point (fi objects). The output is a column vector with length equal to length(`X`)×*N*, where *N* is the value of the `BitsPerInteger` property. If any input value is outside the range of *N*, the object issues an error. If the `SignedIntegerInput` property is `false`, the input values must be between `0` and (2^{N})-1. If you set the `SignedIntegerInput` property to `true`, the input values must be between -($2^{(N-1)}$) and ($2^{(N-1)}$)-1.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.IntegrateAndDumpFilter

Package: `comm`

Integrate discrete-time signal with periodic resets

Description

The `IntegrateAndDumpFilter` object creates a cumulative sum of the discrete-time input signal, while resetting the sum to zero according to a fixed schedule. When the simulation begins, the object discards the number of samples specified in the Offset property. After this initial period, the object sums the input signal along columns and resets the sum to zero every *N*input samples, set by the integration period property. The reset occurs after the object produces output at that time step.

To integrate discrete-time signals with periodic resets:

1. Define and set up your integrate and dump filter object. See “Construction” on page 3-875.
2. Call `step` to integrate discrete-time signals according to the properties of `comm.IntegrateAndDumpFilter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.IntegrateAndDumpFilter` creates an integrate and dump filter System object, `H`. this object integrates over a number of samples in an integration period, and then resets at the end of that period.

`H = comm.IntegrateAndDumpFilter(Name,Value)` creates an integrate and dump filter object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.IntegrateAndDumpFilter(PERIOD,Name,Value)` creates an integrate and dump filter object, `H`. This object has the `IntegrationPeriod` property set to `PERIOD` and the other specified properties set to the specified values.

Properties

`IntegrationPeriod`

Integration period

Specify the integration period, in samples, as a positive, integer scalar value greater than `1`. The integration period defines the length of the sample blocks that the object integrates between resets. The default is `8`.

`Offset`

Number of offset samples

Specify a nonnegative, integer vector or scalar specifying the number of input samples that the object discards from each column of input data at the beginning of data processing. Discarding begins when you call the `step` method for the first time. The default is `0`.

When you set the `Offset` on page 3-0 property to a nonzero value, the object outputs one or more zeros during the initial period while discarding input samples.

When you specify this property as a vector of length *L*, the *i*-th element of the vector corresponds to the offset for the *i*-th column of the input data matrix, which has *L* columns.

When you specify this property as a scalar value, the object applies the same offset to each column of the input data matrix. The offset creates a transient effect, rather than a persistent delay.

`DecimateOutput`

Decimate output

Specify whether the `step` method returns intermediate cumulative sum results or decimates intermediate results. The default is `true`.

When you set this property to `true`, the `step` method returns one output sample, consisting of the final integration value, for each block of `IntegrationPeriod` on page 3-0 input samples. If the inputs are (*K*×`IntegrationPeriod`)×*L* matrices, then the outputs are *K*×*L* matrices.

When you set this property to `false`, the `step` method returns `IntegrationPeriod` output samples, comprising the intermediate cumulative sum values, for each block of `IntegrationPeriod` input samples. In this case, inputs and outputs have the same dimensions.

Fixed-Point Properties

`FullPrecisionOverride`

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects” on page 3-879.

`RoundingMethod`

Rounding of fixed-point numeric values

Specify the rounding method as one of `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Action when fixed-point numeric values overflow

Specify the overflow action as one of `Wrap` | `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

AccumulatorDataType

Data type of accumulator

Specify the accumulator data type as one of `Full precision` | `Same as input` | `Custom`. The default is `Full precision`. When you set this property to `Full precision` the object automatically calculates the accumulator output word and fraction lengths. Set this property to `Custom` to specify the accumulator data type using the `CustomAccumulatorDataType` on page 3-0 property. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false.

CustomAccumulatorDataType

Fixed-point data type of accumulator

Specify the accumulator fixed-point type as a scaled `numerictype` object with a signedness of `Auto`. The default is `numerictype([],32,30)`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false and the `AccumulatorDataType` on page 3-0 property to `Custom`.

OutputDataType

Data type of output

Specify the output fixed-point type as one of `Same as accumulator` | `Same as input` | `Custom`. The default is `Same as accumulator`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false.

CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a scaled `numerictype` object with a signedness of `Auto`. The default is `numerictype([],32,30)`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false and the `OutputDataType` on page 3-0 property to `Custom`.

Methods

step	Integrate discrete-time signal with periodic resets

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Pass Noisy Pulses Through Integrate and Dump Filter

Create an integrate and dump filter having an integration period of 20 samples.

```
intdump = comm.IntegrateAndDumpFilter(20);
```

Generate binary data.

```
d = randi([0 1],50,1);
```

Upsample the data, and pass it through an AWGN channel.

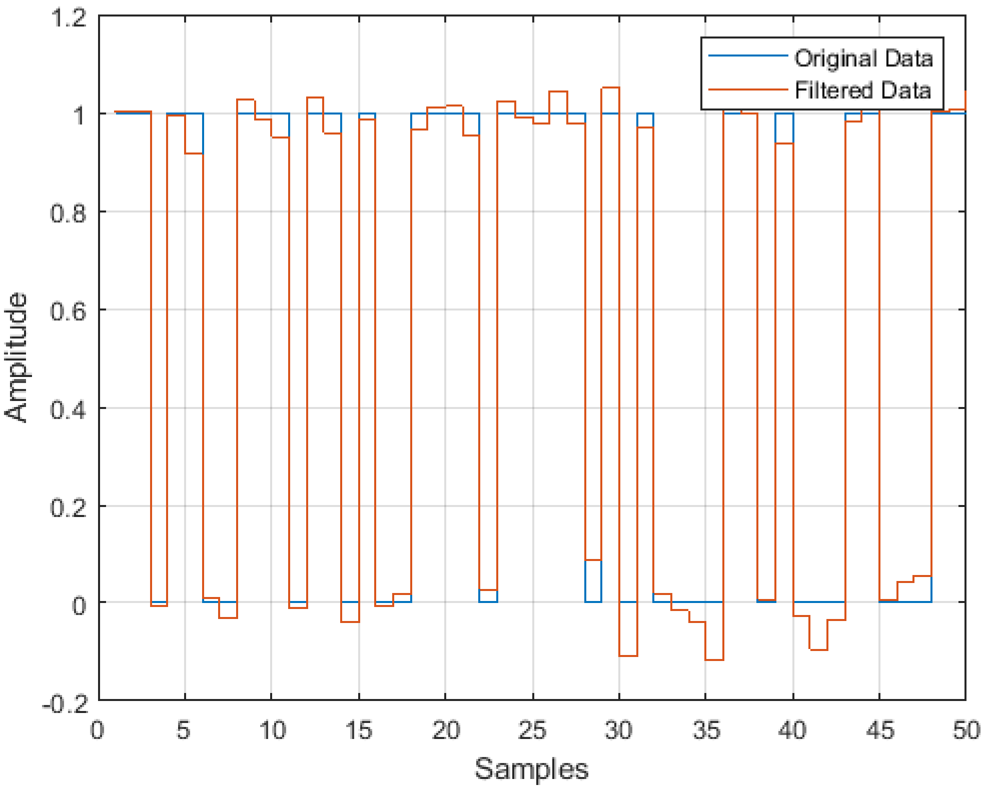
```
x = upsample(d,20);
y = awgn(x,25,'measured');
```

Pass the noisy data through the filter.

```
z = intdump(y);
```

Plot the original and filtered data. The integrate and dump filter removes most of the noise effects.

```
stairs([d z])
legend('Original Data','Filtered Data')
xlabel('Samples')
ylabel('Amplitude')
grid
```



More About

Full Precision for Fixed-Point System Objects

`FullPrecisionOverride` is a convenience property that, when you set to `true`, automatically sets the appropriate properties for an object to use full-precision to process fixed-point input.

For System objects, full precision, fixed-point operation refers to growing just enough additional bits to compute the ideal full precision result. This operation has no minimum or maximum range overflow nor any precision loss due to rounding or underflow. It is also independent of any hardware-specific settings. The data types chosen are based only on known data type ranges and not on actual numeric values. Full precision for System objects does not optimize coefficient values. When you set the `FullPrecisionOverride` property to `true`, the other fixed-point properties it controls no longer apply and any of their non-default values are ignored. These properties are also hidden. To specify individual fixed-point properties, first set `FullPrecisionOverride` to `false`.

Algorithms

This object implements the algorithm, inputs, and outputs described on the Integrate and Dump block reference page. The object properties correspond to the block parameters, except:
The **Output intermediate values** parameter corresponds to the `DecimateOutput` on page 3-0 property.

Extended Capabilities

C/C++ Code Generation

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Introduced in R2012a

step

System object: `comm.IntegrateAndDumpFilter`
Package: `comm`

Integrate discrete-time signal with periodic resets

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` periodically integrates blocks of N samples from the input data, `X`, and returns the result in `Y`. N is the number of samples that you specify in the `IntegrationPeriod` property. `X` is a column vector or a matrix and the data type is double, single or fixed-point (fi objects). `X` must have K*N rows for some positive integer K, with one or more columns. The object treats each column as an independent channel with integration occurring along every column. The dimensions of output `Y` depend on the value you set for the `DecimateOutput` property.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.KasamiSequence

Package: `comm`

Generate Kasami sequence

Description

The `KasamiSequence` object generates a sequence from the set of Kasami sequences. The Kasami sequences are a set of sequences that have good cross-correlation properties.

To generate a Kasami sequence:

1. Define and set up your Kasami sequence object. See “Construction” on page 3-881.
2. Call `step` to generate a Kasami sequence according to the properties of `comm.KasamiSequence`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`H = comm.KasamiSequence` creates a KasamiSequence System object, `H`. This object generates a Kasami sequence.

`H = comm.KasamiSequence(Name,Value)` creates a Kasami sequence generator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`Polynomial`

Generator polynomial

Specify the polynomial that determines the shift register's feedback connections. The default is `'z^6 + z + 1'`.

You can specify the generator polynomial as a character vector or as a binary numeric vector that lists the coefficients of the polynomial in descending order of powers. The first and last elements must equal `1`. Specify the length of this vector as n+1, where n is the degree of the generator polynomial and must be even.

Lastly, you can specify the generator polynomial as a vector containing the exponents of z for the nonzero terms of the polynomial in descending order of powers. The last entry must be `0`. For example, `[1 0 0 0 0 0 1 0 1]` and `[8 2 0]` represent the same polynomial, $g(z) = z^8 + z^2 + 1$.

InitialConditions

Initial conditions of shift register

Specify the initial values of the shift register as a binary numeric scalar or as binary numeric vector. The default is `[0 0 0 0 0 1]`. Set the vector length equal to the degree of the generator polynomial.

When you set this property to a vector value, each element of the vector corresponds to the initial value of the corresponding cell in the shift register.

When you set this property to a scalar value, that value specifies the initial conditions of all the cells of the shift register. The scalar, or at least one element of the specified vector, requires a nonzero value for the object to generate a nonzero sequence.

Index

Sequence index

Specify the index to select a Kasami sequence of interest from the set of possible sequences. The default is `0`. Kasami sequences have a period equal to $N = 2^n - 1$, where n indicates a nonnegative, even integer equal to the degree of the generator polynomial that you specify in the `Polynomial` on page 3-0 property.

There are two classes of Kasami sequences: those obtained from a small set and those obtained from a large set. You choose a Kasami sequence from the small set by setting this property to a numeric, scalar, integer value in the range $[0 \ldots 2^{n/2}-2]$. You choose a sequence from the large set by setting this property to a numeric 1×2 integer vector $[k\ m]$ for k in $[-2, \ldots, 2^n-2]$, and m in $[-1, \ldots, 2^{n/2}-2]$.

Shift

Sequence offset from initial time

Specify the offset of the Kasami sequence from its starting point as a numeric, integer scalar value that can be positive or negative. The default is `0`. The Kasami sequence has a period of $N = 2^n-1$, where n is the degree of the generator polynomial that you specify in the `Polynomial` on page 3-0 property. The shift value is wrapped with respect to the sequence period.

VariableSizeOutput

Enable variable-size outputs

Set this property to true to enable an additional input to the step method. The default is false. When you set this property to true, the enabled input specifies the output size of the Kasami sequence used for the step. The input value must be less than or equal to the value of the `MaximumOutputSize` property.

When you set this property to false, the `SamplesPerFrame` property specifies the number of output samples.

MaximumOutputSize

Maximum output size

Specify the maximum output size of the Kasami sequence as a positive integer 2-element row vector. The second element of the vector must be 1. The default is [10 1].

This property applies when you set the VariableSizeOutput property to true.

SamplesPerFrame

Number of output samples per frame

Specify the number of Kasami sequence samples that the step method outputs as a numeric, positive, integer scalar value . The default value is 1.

When you set this property to a value of *M*, then the step method outputs *M* samples of a Kasami sequence that has a period of $N = 2^n–1$. The value *n* equals the degree of the generator polynomial that you specify in the Polynomial on page 3-0 property.

ResetInputPort

Enable generator reset input

Set this property to true to enable an additional input to the step method. The default is false. The additional input resets the states of the Kasami sequence generator to the initial conditions that you specify in the InitialConditions on page 3-0 property.

OutputDataType

Data type of output

Specify the output data type as one of double | logical. The default is double.

Methods

reset	Reset states of Kasami sequence generator object
step	Generate a Kasami sequence

Common to All System Objects	
release	Allow System object property value changes

Examples

Spread BPSK Data with a Kasami Sequence

Spread BPSK data with a Kasami sequence of length 255 by using the Kasami sequence System object.

Generate binary data and apply BPSK modulation.

```
data = randi([0 1],10,1);
modData = pskmod(data,2);
```

Create a Kasami sequence object of length 255 using generator polynomial $x^8 + x^7 + x^4 + 1$.

```
kasamiSequence = comm.KasamiSequence('Polynomial',[8 7 4 0], ...
    'InitialConditions',[0 0 0 0 0 0 0 1],'SamplesPerFrame',255);
```

Generate the Kasami sequence and convert it to bipolar form.

```
kasSeq = kasamiSequence();
kasSeq = 2*kasSeq - 1;
```

Apply a gain of $1/\sqrt{255}$ to ensure that the spreading operation does not increase the overall signal power.

```
kasSeq = kasSeq/sqrt(255);
```

Spread the BPSK data using the Kasami sequence.

```
spreadData = modData*kasSeq';
spreadData = spreadData(:);
```

Verify that the spread data sequence is 255 times longer than the input data sequence.

```
spreadingFactor = length(spreadData)/length(data)
```

```
spreadingFactor = 255
```

Verify that the spreading operation did not increase the signal power.

```
spreadSigPwr = sum(abs(spreadData).^2)/length(data)
```

```
spreadSigPwr = 1.0000
```

Change the generator polynomial of the Kasami sequence generator to $x^8 + x^3 + 1$ after first releasing the object. Use the character representation of the polynomial.

```
release(kasamiSequence)
kasamiSequence.Polynomial = 'x^8 + x^3 + 1';
```

Generate a new sequence and convert it to bipolar form.

```
kasSeq = kasamiSequence();
kasSeq = 2*kasSeq - 1;
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Kasami Sequence Generator block reference page. The object properties correspond to the block parameters, except:

- The object does not have a property to select frame based outputs.
- The object does not have a property that corresponds to the **Sample time** parameter.

Extended Capabilities

See Also

`comm.GoldSequence` | `comm.PNSequence`

reset

System object: `comm.KasamiSequence`
Package: `comm`

Reset states of Kasami sequence generator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `KasamiSequence` object, `H`.

step

System object: `comm.KasamiSequence`
Package: `comm`

Generate a Kasami sequence

Syntax

```
Y = step(H)
Y = step(H,RESET)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

`Y = step(H)` outputs a frame of the Kasami sequence in column vector `Y`. Specify the frame length with the `SamplesPerFrame` property. The Kasami sequence has a period of $N = 2^n$-1, where n is the degree of the generator polynomial that you specify in the `Polynomial` property.

`Y = step(H,RESET)` uses `RESET` as the reset signal when you set the `ResetInputPort` property to `true`. The data type of the `RESET` input must be double precision or logical. `RESET` can be a scalar value or a column vector with a length equal to the number of samples per frame that you specify in the `SamplesPerFrame` property. When the `RESET` input is a non-zero scalar, the object resets to the initial conditions that you specify in the `InitialConditions` property. It then generates a new output frame. A column vector `RESET` input allows multiple resets within an output frame. A non-zero value at the *i*-th element of the vector causes a reset at the *i*-th output sample time.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.LDPCDecoder

Package: comm

Decode binary low-density parity-check (LDPC) code

Description

The comm.LDPCDecoder System object uses the belief propagation algorithm to decode a binary LDPC code, which is input to the object as the soft-decision output (log-likelihood ratio of received bits) from demodulation. The object decodes generic binary LDPC codes where no patterns in the parity-check matrix are assumed. For more information, see “Belief Propagation Decoding” on page 3-893.

To decode an LDPC-encoded signal:

1 Create the comm.LDPCDecoder object and set its properties.
2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
ldpcdecoder = comm.LDPCDecoder
ldpcdecoder = comm.LDPCDecoder(parity)
ldpcdecoder = comm.LDPCDecoder( ___ ,Name,Value)
```

Description

ldpcdecoder = comm.LDPCDecoder creates a binary LDPC decoder System object. This object performs LDPC decoding based on the specified parity-check matrix.

ldpcdecoder = comm.LDPCDecoder(parity) sets the ParityCheckMatrix property to parity and creates an LDPC decoder System object. The parity input must be specified as described by the ParityCheckMatrix property.

ldpcdecoder = comm.LDPCDecoder(___ ,Name,Value) sets properties using one or more name-value pairs, in addition to inputs from any of the prior syntaxes. For example, comm.LDPCDecoder('DecisionMethod','Soft decision') configures an LDPC decoder System object to decode data using the soft-decision method and output log-likelihood ratios of data type double. Enclose each property name in quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`ParityCheckMatrix` — Parity-check matrix
`dvbs2ldpc(1/2)` (default) | sparse binary matrix | nonsparse index matrix

Parity-check matrix, specified as a sparse (*N* – *K*)-by-*N* binary-valued matrix. *N* is the length of the received signal and must be in the range (0, 2^{31}). *K* is the length of the uncoded message and must be less than *N*. The last (*N* – *K*) columns in the parity-check matrix must be an invertible matrix in the Galois field of order 2, `gf`(2).

You can also specify the parity-check matrix as a two-column nonsparse index matrix, `I`, that defines the row and column indices of the `1`s in the parity-check matrix such that `sparse(I(:,1),I(:,2),1)`.

This property accepts numeric data types. When you set this property to a sparse binary matrix, this property also accepts the `logical` data type.

The default value uses the `dvbs2ldpc` function to configure a sparse parity-check matrix for half-rate LDPC coding, as specified in the DVB-S.2 standard.

Example: `dvbs2ldpc(R,'indices')` configures the index matrix for the DVB-S.2 standard, where `R` is the code rate, and `'indices'` specifies the output format of `dvbs2ldpc` as a two-column double-precision matrix that defines the row and column indices of the `1`s in the parity-check matrix.

Data Types: `double` | `logical`

`OutputValue` — Output value format
`'Information part'` (default) | `'Whole codeword'`

Output value format, specified as one of these values:

- `'Information part'` — The object outputs a *K*-by-1 column vector containing only the information-part of the received log-likelihood ratio vector. *K* is the length of the uncoded message.
- `'Whole codeword'` — The object outputs an *N*-by-1 column vector containing the whole log-likelihood ratio vector. *N* is the length of the received signal.

  N and *K* must align with the dimension of the (*N*–*K*)-by-*K* parity-check matrix.

Data Types: `char`

`DecisionMethod` — Decision method
`'Hard decision'` (default) | `'Soft decision'`

Decision method used for decoding, specified as one of these values:

- `'Hard decision'` — The object outputs decoded data of data type `logical`.
- `'Soft decision'` — The object outputs log-likelihood ratios of data type `double`.

Data Types: `char`

`IterationTerminationCondition` — Condition for iteration termination
`'Maximum iteration count'` (default) | `'Parity check satisfied'`

Condition for iteration termination, specified as one of these values:

- `'Maximum iteration count'` — Decoding terminates after the number of iterations specified by the `MaximumIterationCount` property.
- `'Parity check satisfied'` — Decoding terminates after all parity checks are satisfied. If not all parity checks are satisfied, decoding terminates after the number of iterations specified by the `MaximumIterationCount` property.

Data Types: `char`

`MaximumIterationCount` — Maximum number of decoding iterations
`50` (default) | positive integer

Maximum number of decoding iterations, specified as a positive integer.

Data Types: `double`

`NumIterationsOutputPort` — Output number of iterations executed
`false` (default) | `true`

Output number of iterations performed, specified as `false` or `true`. To output the number of iterations executed, set this property to `true`.

Data Types: `logical`

`FinalParityChecksOutputPort` — Output final parity checks
`false` (default) | `true`

Output final parity checks, specified as `false` or `true`. To output the final calculated parity checks, set this property to `true`.

Data Types: `logical`

Usage

Syntax

```
y = ldpcdecoder(x)
[y,numiter] = ldpcdecoder(x)
[y,parity] = ldpcdecoder(x)
[y,numiter,parity] = ldpcdecoder(x)
```

Description

`y = ldpcdecoder(x)` decodes input data using an LDPC code based on the default parity-check matrix.

`[y,numiter] = ldpcdecoder(x)` returns the decoded data, `y`, and number of iterations performed, `numiter`. To use this syntax, set the `NumIterationsOutputPort` property to `true`.

`[y,parity] = ldpcdecoder(x)` returns the decoded data, `y`, and final parity checks, `parity`. To use this syntax, set the `FinalParityChecksOutputPort` property to `true`.

`[y,numiter,parity] = ldpcdecoder(x)` returns the decoded data, number of iterations performed, and final parity checks. To use this syntax, set the `NumIterationsOutputPort` and `FinalParityChecksOutputPort` properties to `true`.

Input Arguments

x — Log-likelihood ratios

column vector

Log-likelihood ratios, specified as an *N*-by-1 column vector containing the soft-decision output from demodulation. *N* is the number of bits in the LDPC codeword before modulation. Each element is the log-likelihood ratio for a received bit. Element values are more likely to be `0` if the log-likelihood ratio is positive. The first *K* elements correspond to the information-part of the input message.

Data Types: `double`

Output Arguments

y — Decoded data

column vector

Decoded data, returned as a column vector. The `DecisionMethod` property specifies whether the object outputs hard decisions or soft decisions (log-likelihood ratios).

- If the `OutputValue` property is set to `'Information part'`, the output includes only the information-part of the received log-likelihood ratio vector.
- If the `OutputValue` property is set to `'Whole codeword'`, the output includes the whole log-likelihood ratio vector.

Data Types: `double` | `logical`

`numiter` — Number of executed decoding iterations

positive integer

Number of executed decoding iterations, returned as a positive integer.

Dependencies

To enable this output, set the `NumIterationsOutputPort` property to `true`.

`parity` — Final parity checks

column vector

Final parity checks after decoding the input LDPC code, returned as an (*N*-*K*)-by-1 column vector. *N* is the number of bits in the LDPC codeword before modulation. *K* is the length of the uncoded message.

Dependencies

To enable this output, set the `FinalParityChecksOutputPort` property to `true`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

LDPC Encode and Decode QPSK-Modulated Signal

Transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. Demodulate and decode the received signal. Compute the error statistics for the reception of uncoded and LDPC-coded signals.

Define simulation variables. Create System objects for the LDPC encoder, LDPC decoder, QPSK modulator, and QPSK demodulators.

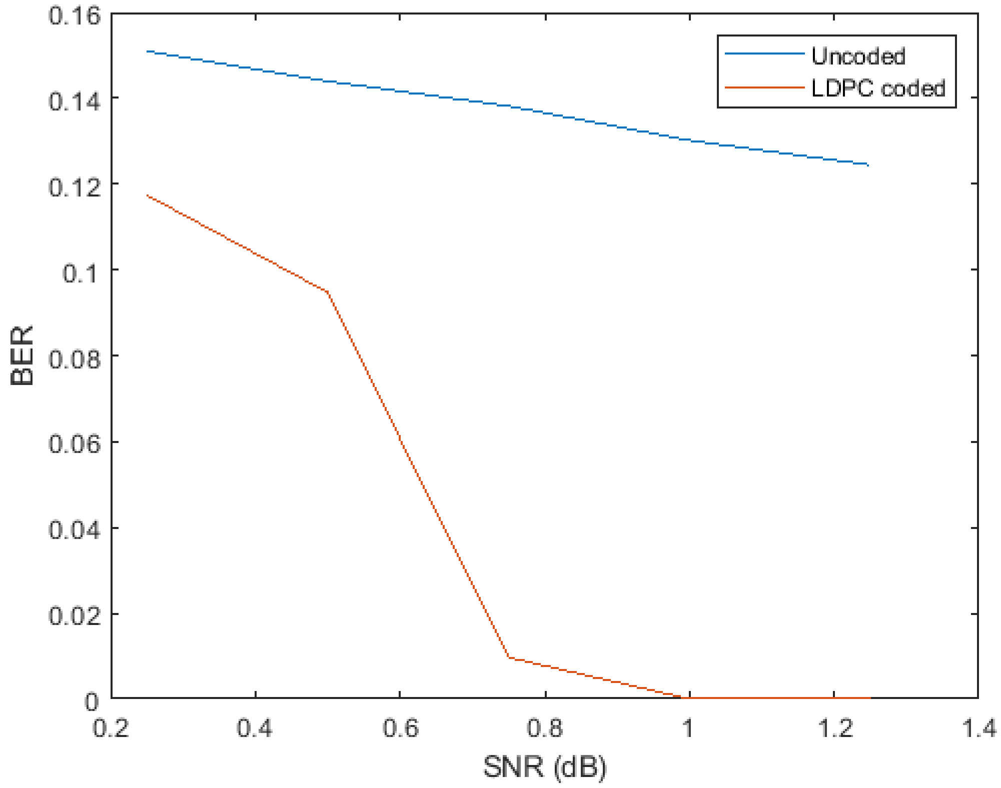
```
M = 4; % Modulation order (QPSK)
snr = [0.25,0.5,0.75,1.0,1.25];
numFrames = 10;
ldpcEncoder = comm.LDPCEncoder;
ldpcDecoder = comm.LDPCDecoder;
pskMod = comm.PSKModulator(M,'BitInput',true);
pskDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Approximate log-likelihood ratio');
pskuDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Hard decision');
errRate = zeros(1,length(snr));
uncErrRate = zeros(1,length(snr));
```

For each SNR setting and all frames, compute the error statistics for uncoded and LDPC-coded signals.

```
for ii = 1:length(snr)
    ttlErr = 0;
    ttlErrUnc = 0;
    pskDemod.Variance = 1/10^(snr(ii)/10); % Set variance using current SNR
    for counter = 1:numFrames
        data = logical(randi([0 1],32400,1));
        % Transmit and receiver uncoded signal data
        mod_uncSig = pskMod(data);
        rx_uncSig = awgn(mod_uncSig,snr(ii),'measured');
        demod_uncSig = pskuDemod(rx_uncSig);
        numErrUnc = biterr(data,demod_uncSig);
        ttlErrUnc = ttlErrUnc + numErrUnc;
        % Transmit and receive LDPC coded signal data
        encData = ldpcEncoder(data);
        modSig = pskMod(encData);
        rxSig = awgn(modSig,snr(ii),'measured');
        demodSig = pskDemod(rxSig);
        rxBits = ldpcDecoder(demodSig);
        numErr = biterr(data,rxBits);
        ttlErr = ttlErr + numErr;
    end
    ttlBits = numFrames*length(rxBits);
    uncErrRate(ii) = ttlErrUnc/ttlBits;
    errRate(ii) = ttlErr/ttlBits;
end
```

Plot the error statistics for uncoded and LDPC-coded data.

```
plot(snr,uncErrRate,snr,errRate)
legend('Uncoded', 'LDPC coded')
xlabel('SNR (dB)')
ylabel('BER')
```

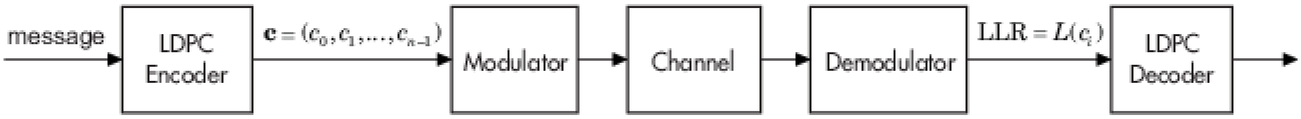


Algorithms

This object performs LDPC decoding using the belief propagation algorithm, also known as a message-passing algorithm.

Belief Propagation Decoding

The implementation of the belief propagation algorithm is based on the decoding algorithm presented by Gallager.



For transmitted LDPC-encoded codeword $c = c_0, c_1, \ldots, c_{n\text{-}1}$, the input to the LDPC decoder is the log-likelihood ratio (LLR) value $L(c_i) = \log\left(\frac{\Pr(c_i = 0 \mid \text{channel output for } c_i)}{\Pr(c_i = 1 \mid \text{channel output for } c_i)}\right)$.

In each iteration, the key components of the algorithm are updated based on these equations:

$$L(r_{ji}) = 2\,\text{atanh}\left(\prod_{i' \in V_j \backslash i} \tanh\left(\frac{1}{2} L(q_{i'j})\right)\right),$$

$L(q_{ij}) = L(c_i) + \sum_{j' \in C_i \backslash j} L(r_{j'i})$, initialized as $L(q_{ij}) = L(c_i)$ before the first iteration, and

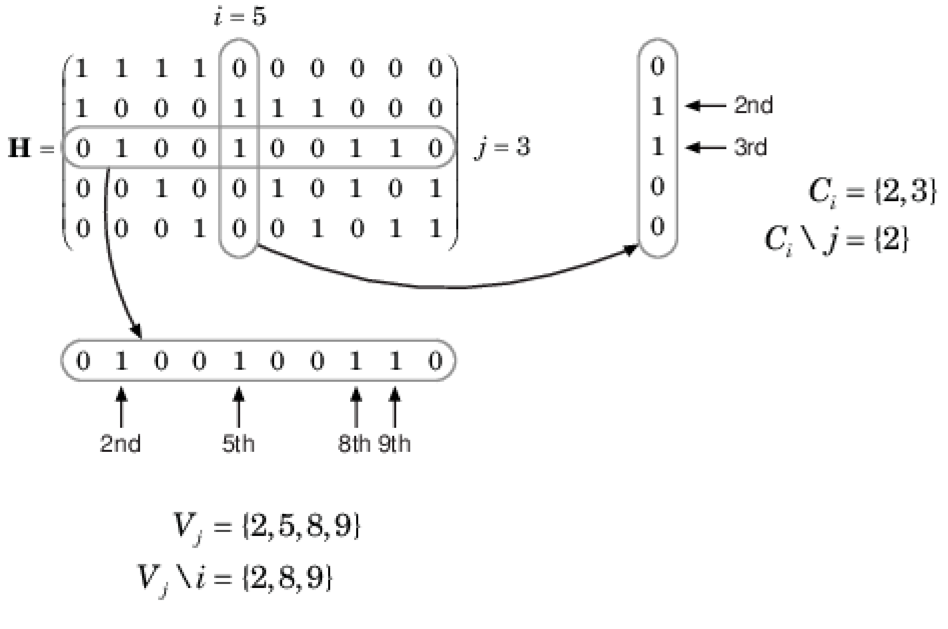
$$L(Q_i) = L(c_i) + \sum_{j' \in C_i} L(r_{j'i}).$$

At the end of each iteration, $L(Q_i)$ contains the updated estimate of the LLR value for transmitted bit c_i. The value $L(Q_i)$ is the soft-decision output for c_i. If $L(Q_i) < 0$, the hard-decision output for c_i is 1. Otherwise, the hard-decision output for c_i is 0.

If configured to stop when all parity checks are satisfied, the algorithm verifies the parity-check equation ($H\, c' = 0$) at the end of each iteration. When all parity checks are satisfied, or if the maximum number of iterations is reached, decoding stops.

Index sets $C_i \backslash j$ and $V_j \backslash i$ are based on the parity-check matrix (PCM). Index sets C_i and V_j correspond to all nonzero elements in column i and row j of the PCM, respectively.

This figure highlights the computation of these index sets in a given PCM for $i = 5$ and $j = 3$.



To avoid infinite numbers in the algorithm equations, atanh(1) and atanh(-1) are set to 19.07 and –19.07, respectively. Due to finite precision, MATLAB returns 1 for tanh(19.07) and –1 for tanh(-19.07).

Blocks
LDPC Decoder

Introduced in R2012a

comm.LDPCEncoder

Package: comm

Encode binary low-density parity-check (LDPC) code

Description

The comm.LDPCEncoder System object applies LDPC coding to a binary input message. LDPC codes are linear error control codes with sparse parity-check matrices and long block lengths that can attain performance near the Shannon limit.

To encode a binary LDPC code:

1. Create the comm.LDPCEncoder object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
ldpcencoder = comm.LDPCEncoder
ldpcencoder = comm.LDPCEncoder(parity)
ldpcencoder = comm.LDPCEncoder(___,Name,Value)
```

Description

ldpcencoder = comm.LDPCEncoder creates a binary LDPC encoder System object. This object performs LDPC encoding based on the default parity-check matrix.

ldpcencoder = comm.LDPCEncoder(parity) sets the ParityCheckMatrix property to parity and creates an LDPC encoder System object. The parity input must be specified as described by the ParityCheckMatrix property.

ldpcencoder = comm.LDPCEncoder(___,Name,Value) sets properties using one or more name-value pairs, in addition to inputs from any of the prior syntaxes. For example, comm.LDPCEncoder('ParityCheckMatrix',sparse(I(:,1),I(:,2),1)) configures an LDPC encoder System object to encode data using the parity matrix sparse(I(:,1),I(:,2),1). Enclose each property name in quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

ParityCheckMatrix — Parity-check matrix
dvbs2ldpc(1/2) (default) | sparse binary matrix | nonsparse index matrix

Parity-check matrix, specified as a sparse (*N* – *K*)-by-*N* binary-valued matrix. *N* is the length of the output codeword vector, and must be in the range (0, 2^{31}). *K* is the length of the uncoded message and must be less than *N*. The last (*N* – *K*) columns in the parity-check matrix must be an invertible matrix in the Galois field of order 2, gf(2).

You can also specify the parity-check matrix as a two-column nonsparse index matrix, I, that defines the row and column indices of the 1s in the parity-check matrix such that sparse(I(:,1),I(:,2),1).

This property accepts numeric data types. When you set this property to a sparse binary matrix, this property also accepts the logical data type.

The default value uses the dvbs2ldpc function to configure a sparse parity-check matrix for half-rate LDPC coding, as specified in the DVB-S.2 standard.

Note

- When the last (*N* – *K*) columns of the parity-check matrix form a triangular matrix, forward or backward substitution is performed to solve the parity-check equation.
- When the last (*N* – *K*) columns of the parity-check matrix do not form a triangular matrix, a matrix inversion is performed to solve the parity-check equation. If a large matrix needs to be inverted, initializations or updates take more time.

Example: dvbs2ldpc(R,'indices') configures the index matrix for the DVB-S.2 standard, where R is the code rate, and 'indices' specifies the output format of dvbs2ldpc as a two-column double-precision matrix that defines the row and column indices of the 1s in the parity-check matrix.

Data Types: double | logical

Usage

Syntax

```
codeword = ldpcencoder(message)
```

Description

codeword = ldpcencoder(message) codes the input message using an LDPC code based on a parity-check matrix. The LDPC codeword output is a solution to the parity-check equation.

Input Arguments

message — Input message
binary column vector

Input message, specified as a *K*-by-1 column vector containing binary-valued elements. *K* is the length of the uncoded message.

Data Types: `double` | `logical`

Output Arguments

`codeword` — LDPC codeword
column vector

LDPC codeword, returned as an *N*-by-1 column vector. *N* is the number of bits in the LDPC codeword. The output signal inherits its data type from the input signal. The LDPC codeword output is a solution to the parity-check equation. The input message comprises the first *K* bits of the LDPC codeword output, and the parity check comprises the remaining (*N* – *K*) bits.

Data Types: `double` | `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

LDPC Encode and Decode QPSK-Modulated Signal

Transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. Demodulate and decode the received signal. Compute the error statistics for the reception of uncoded and LDPC-coded signals.

Define simulation variables. Create System objects for the LDPC encoder, LDPC decoder, QPSK modulator, and QPSK demodulators.

```
M = 4; % Modulation order (QPSK)
snr = [0.25,0.5,0.75,1.0,1.25];
numFrames = 10;
ldpcEncoder = comm.LDPCEncoder;
ldpcDecoder = comm.LDPCDecoder;
pskMod = comm.PSKModulator(M,'BitInput',true);
pskDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Approximate log-likelihood ratio');
pskuDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Hard decision');
errRate = zeros(1,length(snr));
uncErrRate = zeros(1,length(snr));
```

For each SNR setting and all frames, compute the error statistics for uncoded and LDPC-coded signals.

```
for ii = 1:length(snr)
    ttlErr = 0;
    ttlErrUnc = 0;
    pskDemod.Variance = 1/10^(snr(ii)/10); % Set variance using current SNR
    for counter = 1:numFrames
        data = logical(randi([0 1],32400,1));
        % Transmit and receiver uncoded signal data
        mod_uncSig = pskMod(data);
        rx_uncSig = awgn(mod_uncSig,snr(ii),'measured');
        demod_uncSig = pskuDemod(rx_uncSig);
        numErrUnc = biterr(data,demod_uncSig);
        ttlErrUnc = ttlErrUnc + numErrUnc;
        % Transmit and receive LDPC coded signal data
        encData = ldpcEncoder(data);
        modSig = pskMod(encData);
        rxSig = awgn(modSig,snr(ii),'measured');
        demodSig = pskDemod(rxSig);
        rxBits = ldpcDecoder(demodSig);
        numErr = biterr(data,rxBits);
        ttlErr = ttlErr + numErr;
    end
    ttlBits = numFrames*length(rxBits);
    uncErrRate(ii) = ttlErrUnc/ttlBits;
    errRate(ii) = ttlErr/ttlBits;
end
```

Plot the error statistics for uncoded and LDPC-coded data.

```
plot(snr,uncErrRate,snr,errRate)
legend('Uncoded', 'LDPC coded')
xlabel('SNR (dB)')
ylabel('BER')
```

comm.LTEMIMOChannel

Package: `comm`

(To be removed) Filter input signal through LTE MIMO multipath fading channel

Note `comm.LTEMIMOChannel` will be removed in a future release. Use `comm.MIMOChannel` instead.

Description

The `comm.LTEMIMOChannel` System object filters an input signal through an LTE multiple-input multiple-output (MIMO) multipath fading channel.

A specialization of the `comm.MIMOChannel` System object, the `comm.LTEMIMOChannel` System objects offers pre-set configurations for use with LTE link level simulations. In addition to the `comm.MIMOChannel` System object, the `comm.LTEMIMOChannel` System object also corrects the correlation matrix to be positive semi-definite, after rounding to 4-digit precision. This System object models Rayleigh fading for each of its links.

To filter an input signal using an LTE MIMO multipath fading channel:

1. Define and set up your LTE MIMO multipath fading channel object. See “Construction” on page 3-901.
2. Call `step` to filter the input signal using an LTE MIMO multipath fading channel according to the properties of `comm.LTEMIMOChannel`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.LTEMIMOChannel` creates a 3GPP Long Term Evolution (LTE) Release 10 specified multiple-input multiple-output (MIMO) multipath fading channel System object, `H`. This object filters a real or complex input signal through the multipath LTE MIMO channel to obtain the channel impaired signal.

`H = comm.LTEMIMOChannel(Name,Value)` creates an LTE MIMO multipath fading channel object, `H`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SampleRate`

Input signal sample rate (Hertz)

Specify the sample rate of the input signal in hertz as a double-precision, real, positive scalar. The default value of this property is `30.72` MHz, as defined in the LTE specification.

`Profile`

Channel propagation profile

Specify the propagation conditions of the LTE multipath fading channel as one of `EPA 5Hz` | `EVA 5Hz` | `EVA 70Hz` | `ETU 70Hz` | `ETU 300Hz`, which are supported in the LTE specification Release 10. The default value of this property is `EPA 5Hz`.

This property defines the delay profile of the channel to be one of EPA, EVA, and ETU. This property also defines the maximum Doppler shift of the channel to be 5 Hz, 70 Hz, or 300 Hz. The Doppler spectrum always has a Jakes shape in the LTE specification. The EPA profile has seven paths. The EVA and ETU profiles have nine paths.

The following tables list the delay and relative power per path associated with each profile.

Extended Pedestrian A Model (EPA)

Excess tap delay [ns]	Relative power [db]
0	0.0
30	-1.0
70	-2.0
90	-3.0
110	-8.0
190	-17.2
410	-20.8

Extended Vehicular A Model (EVA)

Excess tap delay [ns]	Relative power [db]
0	0.0
30	-1.5
150	-1.4
310	-3.6
370	-0.6
710	-9.1
1090	-7.0
1730	-12.0
2510	-16.9

Extended Typical Urban Model (ETU)

Excess tap delay [ns]	Relative power [db]
0	-1.0

Excess tap delay [ns]	Relative power [db]
50	-1.0
120	-1.0
200	0.0
230	0.0
500	0.0
1600	-3.0
2300	-5.0
5000	-7.0

`AntennaConfiguration`

Antenna configuration

Specify the antenna configuration of the LTE MIMO channel as one of `1x2` | `2x2` | `4x2` | `4x4`. These configurations are supported in the LTE specification Release 10. The default value of this property is `2x2`.

The property value is in the format of N_t-by-N_r. N_t represents the number of transmit antennas and N_r represents the number of receive antennas.

`CorrelationLevel`

Spatial correlation strength

Specify the spatial correlation strength of the LTE MIMO channel as one of `Low` | `Medium` | `High`. The default value of this property is `Low`. When you set this property to `Low`, the MIMO channel is spatially uncorrelated.

The transmit and receive spatial correlation matrices are defined from this property according to the LTE specification Release 10. See the Algorithms section for more information.

`AntennaSelection`

Antenna selection

Specify the antenna selection scheme as one of `Off` | `Tx` | `Rx` | `Tx and Rx`, where `Tx` represents transmit antennas and `Rx` represents receive antennas. When you select `Tx` and/or `Rx`, additional input(s) are required to specify which antennas are selected for signal transmission. The default value of this property is `Off`.

`RandomStream`

Source of random number stream

Specify the source of random number stream as one of `Global stream` | `mt19937ar with seed`. The default value of this property is `Global stream`. When you set this property to `Global stream`, the current global random number stream is used for normally distributed random number generation. In this case, the `reset` method only resets the filters. If you set `RandomStream` to `mt19937ar with seed`, the object uses the mt19937ar algorithm for normally distributed random number generation. In this case, the `reset` method resets the filters and reinitializes the random number stream to the value of the Seed property.

Seed

Initial seed of mt19937ar random number stream

Specify the initial seed of an mt19937ar random number generator algorithm as a double-precision, real, nonnegative integer scalar. The default value of this property is `73`. This property applies when you set the RandomStream property to `mt19937ar with seed`. The `Seed` reinitializes the mt19937ar random number stream in the `reset` method.

NormalizePathGains

Normalize path gains (logical)

Set this property to `true` to normalize the fading processes so that the total power of the path gains, averaged over time, is `0` dB. The default value of this property is `true`. When you set this property to `false`, there is no normalization for path gains.

NormalizeChannelOutputs

Normalize channel outputs (logical)

Set this property to `true` to normalize the channel outputs by the number of receive antennas. The default value of this property is `true`. When you set this property to `false`, there is no normalization for channel outputs.

PathGainsOutputPort

Enable path gain output (logical)

Set this property to `true` to output the channel path gains of the underlying fading process. The default value of this property is `false`.

Methods

reset	(To be removed) Reset states of the `LTEMIMOChannel` object
step	(To be removed) Filter input signal through LTE MIMO multipath fading channel

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Configure MIMO Channel Object Using LTE MIMO Channel Object

Configure an equivalent `MIMOChannel` System Object using the `LTEMIMOChannel` System Object. Then, verify that the channel output and the path gain output from the two objects are the same.

Create a PSK Modulator System object™ to modulate randomly generated data.

```
pskModulator = comm.PSKModulator;
modData = pskModulator(randi([0 pskModulator.ModulationOrder-1],2e3,1));
```

Split modulated data into two spatial streams.

```
channelInput = reshape(modData,[2 1e3]).';
```

Create an `LTEMIMOChannel` System object with a 2-by-2 antenna configuration and a medium correlation level.

```
lteChan = comm.LTEMIMOChannel(...
    'Profile',              'EVA 5Hz',...
    'AntennaConfiguration', '2x2',...
    'CorrelationLevel',     'Medium',...
    'AntennaSelection',     'Off',...
    'RandomStream',         'mt19937ar with seed',...
    'Seed',                 99,...
    'PathGainsOutputPort',  true);
```

```
Warning: COMM.LTEMIMOCHANNEL will be removed in a future release. Use COMM.MIMOCHANNEL or LTEFADI
```

Filter the modulated data using the `LTEMIMOChannel` System object, `lteChan`.

```
[LTEChanOut,LTEPathGains] = lteChan(channelInput);
```

Create an equivalent `MIMOChannel` System object, `mimoChannel`, using the properties of the `LTEMIMOChannel` System object, `lteChan`.

The `KFactor`, `DirectPathDopplerShift` and `DirectPathInitialPhase` properties only exist for the `MIMOChannel` System object. All other `MIMOChannel` System object properties also exist for the `LTEMIMOChannel` System object; however, some properties are hidden and read-only.

```
mimoChannel = comm.MIMOChannel( ...
    'SampleRate',lteChan.SampleRate, ...
    'PathDelays',lteChan.PathDelays, ...
    'AveragePathGains',lteChan.AveragePathGains, ...
    'NormalizePathGains',lteChan.NormalizePathGains, ...
    'FadingDistribution',lteChan.FadingDistribution, ...
    'MaximumDopplerShift',lteChan.MaximumDopplerShift, ...
    'DopplerSpectrum',lteChan.DopplerSpectrum, ...
    'SpatialCorrelationSpecification', ...
         lteChan.SpatialCorrelationSpecification, ...
    'SpatialCorrelationMatrix',lteChan.SpatialCorrelationMatrix, ...
    'AntennaSelection',lteChan.AntennaSelection, ...
    'NormalizeChannelOutputs',lteChan.NormalizeChannelOutputs, ...
    'RandomStream',lteChan.RandomStream, ...
    'Seed',lteChan.Seed, ...
    'PathGainsOutputPort',lteChan.PathGainsOutputPort);
```

Filter the modulated data using the equivalent `mimoChannel` object.

```
[MIMOChanOut, MIMOPathGains] = mimoChannel(channelInput);
```

Verify that the channel output and the path gain output from the two objects are the same.

```
sameChOutput = isequal(LTEChanOut,MIMOChanOut)
```

```
sameChOutput = logical
   1
```

```
samePathGains = isequal(LTEPathGains,MIMOPathGains)
samePathGains = logical
   1
```

You can repeat the preceding process with `AntennaConfiguration` set to `4x2` or `4x4` and `CorrelationLevel` set to `Medium` or `High` for `lteChan`.

Algorithms

This System object is a specialized implementation of the `comm.MIMOChannel` System object. For additional algorithm information, see the `comm.MIMOChannel` System object help page.

Spatial Correlation Matrices

The following table defines the transmitter eNodeB correlation matrix.

	One Antenna	Two Antennas	Four Antennas
eNodeB Correlation	$R_{\mathrm{eNB}} = 1$	$R_{eNB} = \begin{pmatrix} 1 & \alpha \\ \alpha^* & 1 \end{pmatrix}$	$R_{eNB} =$ $\begin{pmatrix} 1 & \alpha^{1/9} & \alpha^{4/9} & \alpha \\ \alpha^{1/9*} & 1 & \alpha^{1/9} & \alpha^{4/9} \\ \alpha^{4/9*} & \alpha^{1/9*} & 1 & \alpha^{1/9} \\ \alpha^* & \alpha^{4/9*} & \alpha^{1/9*} & 1 \end{pmatrix}$

The following table defines the receiver UE correlation matrix.

	One Antenna	Two Antennas	Four Antennas
UE Correlation	$R_{\mathrm{UE}} = 1$	$R_{UE} = \begin{pmatrix} 1 & \beta \\ \beta^* & 1 \end{pmatrix}$	$R_{UE} =$ $\begin{pmatrix} 1 & \beta^{1/9} & \beta^{4/9} & \beta \\ \beta^{1/9}* & 1 & \beta^{1/9} & \beta^{4/9} \\ \beta^{4/9}* & \beta^{1/9}* & 1 & \beta^{1/9} \\ \beta* & \beta^{4/9}* & \beta^{1/9}* & 1 \end{pmatrix}$

The following table describes the R_{spat} channel spatial correlation matrix between the transmitter and receiver antennas.

Tx-by-Rx Configuration	Correlation Matrix
1-by-2	$R_{spat} = R_{UE} = \begin{bmatrix} 1 & \beta \\ \beta* & 1 \end{bmatrix}$
2-by-2	$R_{spat} = R_{eNB} \otimes R_{UE} = \begin{bmatrix} 1 & \alpha \\ \alpha* & 1 \end{bmatrix} \otimes \begin{bmatrix} 1 & \beta \\ \beta* & 1 \end{bmatrix}$ $= \begin{bmatrix} 1 & \beta & \alpha & \alpha\beta \\ \beta* & 1 & \alpha\beta* & \alpha \\ \alpha* & \alpha*\beta & 1 & \beta \\ \alpha*\beta* & \alpha* & \beta* & 1 \end{bmatrix}$
4-by-2	$R_{spat} = R_{eNB} \otimes R_{UE} = \begin{bmatrix} 1 & \alpha^{1/9} & \alpha^{4/9} & \alpha \\ \alpha^{1/9*} & 1 & \alpha^{1/9} & \alpha^{4/9} \\ \alpha^{4/9*} & \alpha^{1/9*} & 1 & \alpha^{1/9} \\ \alpha* & \alpha^{4/9*} & \alpha^{1/9*} & 1 \end{bmatrix}$ $\otimes \begin{bmatrix} 1 & \beta \\ \beta* & 1 \end{bmatrix}$

Tx-by-Rx Configuration	Correlation Matrix
4-by-4	$R_{spat} = R_{eNB} \otimes R_{UE} = \begin{bmatrix} 1 & \alpha^{1/9} & \alpha^{4/9} & \alpha \\ \alpha^{1/9*} & 1 & \alpha^{1/9} & \alpha^{4/9} \\ \alpha^{4/9*} & \alpha^{1/9*} & 1 & \alpha^{1/9} \\ \alpha^{*} & \alpha^{4/9*} & \alpha^{1/9*} & 1 \end{bmatrix} \otimes \begin{pmatrix} 1 & \beta^{1/9} & \beta^{4/9} & \beta \\ \beta^{1/9*} & 1 & \beta^{1/9} & \beta^{4/9} \\ \beta^{4/9*} & \beta^{1/9*} & 1 & \beta^{1/9} \\ \beta^{*} & \beta^{4/9*} & \beta^{1/9*} & 1 \end{pmatrix}$

Spatial Correlation Correction

Low Correlation		Medium Correlation		High Correlation	
α	β	α	β	α	β
0	0	0.3	0.9	0.9	0.9

To insure the correlation matrix is positive semi-definite after round-off to 4 digit precision, this System object uses the following equation:

$$R_{high} = \left[R_{spatial} + aI_n\right]/(1 + a)$$

Where

α represents the scaling factor such that the smallest value is used to obtain a positive semi-definite result.

For the 4-by-2 high correlation case, α=0.00010.

For the 4-by-4 high correlation case, α=0.00012.

The object uses the same method to adjust the 4-by-4 medium correlation matrix to insure the correlation matrix is positive semi-definite after rounding to 4 digit precision with α = 0.00012.

`comm.MIMOChannel`

Introduced in R2012a

reset

System object: `comm.LTEMIMOChannel`
Package: `comm`

(To be removed) Reset states of the `LTEMIMOChannel` object

Note `comm.LTEMIMOChannel` will be removed in a future release. Use `comm.MIMOChannel` instead.

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `LTEMIMOChannel` object, `H`.

If you set the RandomStream property of `H` to `Global stream`, the `reset` method only resets the filters. If you set `RandomStream` to `mt19937ar with seed`, the `reset` method not only resets the filters but also reinitializes the random number stream to the value of the Seed property.

step

System object: `comm.LTEMIMOChannel`
Package: `comm`

(To be removed) Filter input signal through LTE MIMO multipath fading channel

Note `comm.LTEMIMOChannel` will be removed in a future release. Use `comm.MIMOChannel` instead.

Syntax

```
Y = step(H,X)
[Y,PATHGAINS] = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` filters input signal `X` through an LTE MIMO multipath fading channel and returns the result in `Y`. The input `X` can be a double- or single-precision data type scalar, vector, or 2-D matrix with real or complex values. `X` is of size N_s-by-N_t. N_s represents the number of samples and N_t represents the number of transmit antennas that must match the AntennaConfiguration property setting of `H`. `Y` is the output signal of size N_s-by-N_r. N_r represents the number of receive antennas that is specified by the `AntennaConfiguration` property of `H`. `Y` contains complex values with same precision as input signal.

`[Y,PATHGAINS] = step(H,X)` returns the LTE MIMO channel path gains of the underlying fading process in PATHGAINS. This applies when you set the PathGainsOutputPort property to `true`. PATHGAINS is of size N_s-by-N_p-by-N_t-by-N_r. N_p represents the number of discrete paths of the channel implicitly defined by the Profile property of `H`. PATHGAINS contains complex values with same precision as input signal.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.MatrixDeinterleaver

Package: `comm`

(To be removed) Deinterleave input symbols using permutation matrix

Compatibility

comm.MatrixDeinterleaver will be removed in a future release. Use `matdeintrlv` instead. For more information, see “Compatibility Considerations” on page 3-913.

Description

The `MatrixDeinterleaver` object performs block deinterleaving by filling a matrix with the input symbols column by column and then sending the matrix contents to the output port row by row. The number of rows and number of columns properties set the dimensions of the matrix that the object uses internally for computations.

To deinterleave input symbols using a permutation vector:

1. Define and set up your matrix deinterleaver object. See “Construction” on page 3-912.
2. Call `step` to deinterleave the input signal according to the properties of `comm.MatrixDeinterleaver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.MatrixDeinterleaver` creates a matrix deinterleaver System object, `H`. This object restores the original ordering of a sequence that was interleaved using the matrix interleaver object.

`H = comm.MatrixDeinterleaver(Name,Value)` creates a matrix deinterleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.MatrixDeinterleaver(N,M)` creates a matrix deinterleaver object, `H`. This object has the `NumRows` property set to `N`, the `NumColumns` property set to `M`.

Properties

NumRows

Number of rows of permutation matrix

Specify the number of permutation matrix rows as a scalar, positive integer. The default is `3`.

`NumColumns`

Number of columns of permutation matrix

Specify the number of permutation matrix columns as a scalar, positive integer. The default is 4.

Methods

step	(To be removed) Deinterleave input symbols using permutation matrix

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Matrix Interleaving and Deinterleaving

Create matrix interleaver and deinterleaver objects.

```
interleaver = comm.MatrixInterleaver('NumRows',2,'NumColumns', 5);
```

```
Warning: COMM.MATRIXINTERLEAVER will be removed in a future release. Use MATINTRLV instead. See
```

```
deinterleaver = comm.MatrixDeinterleaver('NumRows',2,'NumColumns', 5);
```

```
Warning: COMM.MATRIXDEINTERLEAVER will be removed in a future release. Use MATDEINTRLV instead.
```

Generate random data, interleave, and then deinterleave the data.

```
data = randi(7,10,1);
intData = interleaver(data);
deIntData = deinterleaver(intData);
```

Confirm the original and deinterleaved data are identical.

```
isequal(data,deIntData)
```

```
ans = logical
   1
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Matrix Deinterleaver block reference page. The object properties correspond to the block parameters.

Compatibility Considerations

`comm.MatrixDeinterleaver` will be removed
Not recommended starting in R2019b

comm.MatrixDeinterleaver will be removed in a future release. Use `matdeintrlv` instead.

Extended Capabilities

C/C++ Code Generation

step

System object: `comm.MatrixDeinterleaver`
Package: `comm`

(To be removed) Deinterleave input symbols using permutation matrix

Compatibility

step will be removed in a future release. Use `matdeintrlv` instead.

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` restores the original ordering of the sequence, `X`, that was interleaved using a block interleaver. The object fills a permutation matrix with the input symbols column by column and outputs the matrix contents row by row in the output, `Y`. The input `X` must be a column vector of length equal to NumRows × NumColumns. The data type for `X` can be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.MatrixInterleaver

Package: comm

(To be removed) Permute input symbols using permutation matrix

Compatibility

comm.MatrixInterleaver will be removed in a future release. Use matintrlv instead. For more information, see “Compatibility Considerations” on page 3-917.

Description

The MatrixInterleaver object performs block interleaving by filling a matrix with the input symbols row by row and then outputs the matrix contents column-by-column.

To perform block interleaving using a permutation matrix:

1. Define and set up your matrix interleaver object. See “Construction” on page 3-916.
2. Call step to interleave the input symbols according to the properties of comm.MatrixInterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.MatrixInterleaver creates a matrix interleaver System object, H. This object permutes the input by filling a permutation matrix with the input symbols row by row. The object then outputs the matrix contents column by column.

H = comm.MatrixInterleaver(Name,Value) creates a matrix interleaver object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.MatrixInterleaver(N,M) creates a matrix interleaver object, H. This object has the NumRows property set to N, the NumColumns property set to M.

Properties

NumRows

Number of rows of permutation matrix

Specify the number of permutation matrix rows as a scalar, positive integer. The default is 3.

NumColumns

Number of columns of permutation matrix

Specify the number of permutation matrix columns as a scalar, positive integer. The default is 4.

Methods

step (To be removed) Permute input symbols using permutation matrix

Common to All System Objects	
release	Allow System object property value changes

Examples

Matrix Interleaving and Deinterleaving

Create matrix interleaver and deinterleaver objects.

```
interleaver = comm.MatrixInterleaver('NumRows',2,'NumColumns', 5);
```

```
Warning: COMM.MATRIXINTERLEAVER will be removed in a future release. Use MATINTRLV instead. See <
```

```
deinterleaver = comm.MatrixDeinterleaver('NumRows',2,'NumColumns', 5);
```

```
Warning: COMM.MATRIXDEINTERLEAVER will be removed in a future release. Use MATDEINTRLV instead. S
```

Generate random data, interleave, and then deinterleave the data.

```
data = randi(7,10,1);
intData = interleaver(data);
deIntData = deinterleaver(intData);
```

Confirm the original and deinterleaved data are identical.

```
isequal(data,deIntData)
```

```
ans = logical
   1
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Matrix Deinterleaver block reference page. The object properties correspond to the block parameters.

Compatibility Considerations

comm.MatrixInterleaver will be removed
Not recommended starting in R2019b

comm.MatrixInterleaver will be removed in a future release. Use matintrlv instead.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Introduced in R2012a

step

System object: `comm.MatrixInterleaver`
Package: `comm`

(To be removed) Permute input symbols using permutation matrix

Compatibility

step will be removed in a future release. Use `matintrlv` instead.

Syntax

`Y = step(H,X)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` permutes input sequence, `X`, and returns interleaved sequence, `Y`. The object fills a permutation matrix with the input symbols row by row and outputs the matrix contents column by column. The input `X` must be a column vector of length NumRows × NumColumns and the data type can be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.MatrixHelicalScanDeinterleaver

Package: `comm`

(To be removed) Deinterleave input symbols by filling a matrix along diagonals

Compatibility

comm.MatrixHelicalScanDeinterleaver will be removed in a future release. Use `helscandeintrlv` instead. For more information, see "Compatibility Considerations" on page 3-922.

Description

The `MatrixHelicalScanDeinterleaver` object performs block deinterleaving by filling a matrix with the input symbols helically and then outputs the matrix contents row by row. The number of rows and number of columns properties represent the dimensions of the matrix that the object uses internally for computations.

To deinterleave the input symbols by filling a matrix with the input symbols helically and then outputting the matrix contents row-by-row:

1. Define and set up your matrix helical scan deinterleaver object. See "Construction" on page 3-920.
2. Call `step` to deinterleave the input signal according to the properties of `comm.MatrixHelicalScanDeinterleaver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.MatrixHelicalScanDeinterleaver` creates a matrix helical scan deinterleaver object, `H`. This object restores the original ordering of a sequence that was interleaved using the matrix helical scan interleaver System object.

`H = comm.MatrixHelicalScanDeinterleaver(Name,Value)` creates a matrix helical scan deinterleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`NumRows`

Number of rows of permutation matrix

Specify the number of rows in the permutation matrix as a scalar, positive integer. The default is `64`.

NumColumns

Number of columns of permutation matrix

Specify the number of columns in the permutation matrix as a scalar, positive integer. The default is 64.

StepSize

Slope of diagonals

Specify slope as a scalar integer between 0 and the value you specify in the NumRows on page 3-0 property. The default is 1. The slope value indicates the amount by which the row index increases as the column index increases by 1. When you set the value of this property to 0, the object does not interleave and the output matches the input.

Methods

step (To be removed) Deinterleave input symbols by filling a matrix along diagonals

Common to All System Objects

Examples

Matrix Helical Scan Interleaving and Deinterleaving

Create matrix helical scan interleaver and deinterleaver objects.

```
interleaver = comm.MatrixHelicalScanInterleaver('NumRows',4,'NumColumns', 4);
```

```
Warning: COMM.MATRIXHELICALSCANINTERLEAVER will be removed in a future release. Use HELSCANINTRLV
```

```
deinterleaver = comm.MatrixHelicalScanDeinterleaver('NumRows',4,'NumColumns',4);
```

```
Warning: COMM.MATRIXHELICALSCANDEINTERLEAVER will be removed in a future release. Use HELSCANDEIN
```

Generate random symbols. Pass the data through the interleaver, and then pass that data through the deinterleaver.

```
data = randi(7,16,1);
intData = interleaver(data);
deIntData = deinterleaver(intData);
```

Display the original sequence, interleaved sequence and restored sequence.

```
[data intData deIntData]
```

```
ans = 16×3

     6     6     6
     7     1     7

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` restores the original ordering of the sequence, `X`. The object fills a permutation matrix with the input symbols in a helical fashion and output the contents row by row, and returns `Y`. The input `X` must be a NumRows × NumColumns long column vector and the data type can be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.MatrixHelicalScanInterleaver

Package: `comm`

(To be removed) Permute input symbols by selecting matrix elements along diagonals

Compatibility

comm.MatrixHelicalScanInterleaver will be removed in a future release. Use `helscanintrlv` instead. For more information, see “Compatibility Considerations” on page 3-926.

Description

The `MatrixHelicalScanInterleaver` object performs block interleaving by filling a matrix with the input symbols row by row and then outputs the matrix contents helically. The number of rows and number of columns properties are the dimensions of the matrix that the object uses internally for computations.

To interleave the input signal by filling a matrix row-by-row with the input symbols and then outputting the matrix contents helically:

1. Define and set up your matrix helical scan interleaver object. See “Construction” on page 3-924.
2. Call `step` to interleave the input signal according to the properties of `comm.MatrixHelicalScanInterleaver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.MatrixHelicalScanInterleaver` creates a matrix helical scan interleaver object, `H`. This object permutes the input by filling a permutation matrix with the input symbols row by row and then outputs the matrix contents helically.

`H = comm.MatrixHelicalScanInterleaver(Name,Value)` creates a matrix helical scan interleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

NumRows

Number of rows of permutation matrix

Specify the number of rows in the permutation matrix as a scalar, positive integer. The default is `64`.

NumColumns

Number of columns of permutation matrix

Specify the number of columns in the permutation matrix as a scalar, positive integer. The default is 64.

StepSize

Slope of diagonals

Specify slope as a scalar integer between 0 and the value you specify in the NumRows on page 3-0 property. The slope value represents the amount by which the row index increases as the column index increases by 1. When you set the value of this property to 0, the object does not interleave and the output matches the input. The default is 1.

Methods

comm.MemorylessNonlinearity

Package: `comm`

Apply memoryless nonlinearity to complex baseband signal

Description

The `comm.MemorylessNonlinearity` System object applies memoryless nonlinear impairments to a complex baseband signal. Use this System object to model memoryless nonlinear impairments caused by signal amplification in a radio frequency (RF) transmitter or receiver. For more information, see "Memoryless Nonlinear Impairments" on page 3-943.

Note All values of power assume a nominal impedance of 1 ohm.

To apply memoryless nonlinear impairments to a complex baseband signal:

1. Create the `comm.MemorylessNonlinearity` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
mnl = comm.MemorylessNonlinearity
mnl = comm.MemorylessNonlinearity(Name,Value)
```

Description

`mnl = comm.MemorylessNonlinearity` creates a memoryless nonlinearity System object that models RF nonlinear impairments.

`mnl = comm.MemorylessNonlinearity(Name,Value)` specifies properties using one or more name-value pair arguments. Enclose each property name in quotes. For example, `'Method','Saleh model'` sets the modeling method to the Saleh method.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Method` — Nonlinearity modeling method

`'Cubic polynomial'` (default) | `'Hyperbolic tangent'` | `'Saleh model'` | `'Ghorbani model'` | `'Rapp model'` | `'Lookup table'`

Nonlinearity modeling method, specified as `'Cubic polynomial'`, `'Hyperbolic tangent'`, `'Saleh model'`, `'Ghorbani model'`, `'Rapp model'`, or `'Lookup table'`. For more information, see “Memoryless Nonlinear Impairments” on page 3-943.

Data Types: `char` | `string`

`InputScaling` — Input signal scaling factor

`0` (default) | scalar

Input signal scaling factor in decibels, specified as a scalar. This property scales the power gain of the input signal.

Tunable: Yes

Dependencies

To enable this property, set the `Method` property to `'Saleh model'` or `'Ghorbani model'`.

Data Types: `double`

`LinearGain` — Linear gain

`0` (default) | scalar

Linear gain in decibels, specified as a scalar. This property scales the power gain of the output signal.

Tunable: Yes

Dependencies

To enable this property, set the `Method` property to `'Cubic polynomial'`, `'Hyperbolic tangent'`, or `'Rapp model'`.

Data Types: `double`

`IIP3` — Third-order input intercept point

`30` (default) | scalar

Third-order input intercept point in dBm, specified as a scalar.

Tunable: Yes

Dependencies

To enable this property, set the `Method` property to `'Cubic polynomial'` or `'Hyperbolic tangent'`.

Data Types: `double`

`AMPMConversion` — AM/PM conversion factor

`10` (default) | scalar

AM/PM conversion factor in degrees per decibel, specified as a scalar. For more information, see “Cubic Polynomial and Hyperbolic Tangent Model Methods” on page 3-945.

Tunable: Yes

Dependencies

To enable this property, set the `Method` property to `'Cubic polynomial'` or `'Hyperbolic tangent'`.

Data Types: `double`

`AMAMParameters` — AM/AM parameters

`[2.1587 1.1517]` | `[8.1081 1.5413 6.5202 -0.0718]` | row vector

AM/AM parameters used to compute the amplitude gain for an input signal, specified as a row vector.

- When the `Method` property is set to `'Saleh model'`, this property must be a two-element vector that specifies alpha and beta values. In this case, the default value is `[2.1587 1.1517]`.
- When the `Method` property is set to `'Ghorbani model'`, this property must be a four-element vector that specifies x_1, x_2, x_3, and x_4 values. In this case, the default value is `[8.1081 1.5413 6.5202 -0.0718]`.

For more information, see “Saleh Model Method” on page 3-945 and “Ghorbani Model Method” on page 3-946.

Tunable: Yes

Dependencies

To enable this property, set the `Method` property is set to `'Saleh model'` or `'Ghorbani model'`.

Data Types: `double`

`AMPMParameters` — AM/PM parameters

`[4.0033 9.1040]` | `[4.6645 2.0965 10.88 -0.003]` | row vector

AM/PM parameters used to compute the phase change for an input signal, specified as a row vector.

- When the `Method` property is set to `'Saleh model'`, this property must be a two-element vector that specifies alpha and beta values. In this case, the default value is `[4.0033 9.1040]`.
- When the `Method` property is set to `'Ghorbani model'`, this property must be a four-element vector that specifies y_1, y_2, y_3, and y_4 values. In this case, the default value is `[4.6645 2.0965 10.88 -0.003]`

For more information, see “Saleh Model Method” on page 3-945 and “Ghorbani Model Method” on page 3-946.

Tunable: Yes

Dependencies

To enable this property, set the `Method` property is set to `'Saleh model'` or `'Ghorbani model'`.

Data Types: `double`

`PowerLowerLimit` — Input power lower limit

`10` (default) | scalar

Input power lower limit in dBm, specified as a scalar less than the `PowerUpperLimit` property value. The AM/PM conversion scales linearly for input power values in the range [`PowerLowerLimit`, `PowerUpperLimit`]. If the input signal power is below the input power lower limit, the phase shift resulting from AM/PM conversion is zero. For more information, see “Cubic Polynomial and Hyperbolic Tangent Model Methods” on page 3-945.

Tunable: Yes

Dependencies

To enable this property, set the `Method` property is set to `'Cubic polynomial'` or `'Hyperbolic tangent'`.

Data Types: `double`

`PowerUpperLimit` — Input power upper limit

`inf` (default) | scalar

Input power upper limit in dBm, specified as a scalar greater than `PowerLowerLimit`. The AM/PM conversion scales linearly for input power values in the range [`PowerLowerLimit`, `PowerUpperLimit`]. If the input signal power is above the input power upper limit, the phase shift resulting from AM/PM conversion is constant. For more information, see “Cubic Polynomial and Hyperbolic Tangent Model Methods” on page 3-945.

Tunable: Yes

Dependencies

To enable this property, set the `Method` property is set to `'Cubic polynomial'` or `'Hyperbolic tangent'`.

Data Types: `double`

`OutputScaling` — Output signal scaling factor

`0` (default) | scalar

Output signal scaling factor in decibels, specified as a scalar. This property scales the power gain of the output signal.

Tunable: Yes

Dependencies

To enable this property, set the `Method` property is set to `'Saleh model'` or `'Ghorbani model'`.

Data Types: `double`

`Smoothness` — Smoothness factor

`0.5` (default) | scalar

Smoothness factor, specified as a scalar. For more information, see “Rapp Model Method” on page 3-947.

Tunable: Yes

Dependencies

To enable this property, set the `Method` property is set to `'Rapp model'`.

Data Types: `double`

`OutputSaturationLevel` — Output saturation level

1 (default) | scalar

Output saturation level, specified as a scalar. For more information, see "Rapp Model Method" on page 3-947.

Tunable: Yes

Dependencies

To enable this property, set the `Method` property is set to `'Rapp model'`.

Data Types: `double`

`Table` — Amplifier characteristics lookup table

N-by-[P_{in}, P_{out}, $\Delta\Phi$] matrix

Amplifier characteristics lookup table, specified as an N-by-3 matrix of measured power amplifier (PA) characteristics. Each row is of the form [P_{in}, P_{out}, $\Delta\Phi$]. P_{in} specifies the PA input signal in dBm, P_{out} specifies the PA output signal in dBm, and $\Delta\Phi$ specifies the output phase shift in degrees. The default value is `[-25, 5.16, -0.25; -20, 10.11, -0.47; -15, 15.11, -0.68; -10, 20.05, -0.89; -5, 24.79, -1.22; 0, 27.64, 5.59; 5, 28.49, 12.03]`.

The measured PA characteristics defined by this property are used to compute the AM/AM (in dBm/dBm) and AM/PM (in deg/dBm) nonlinear impairment characteristics. The System object distorts the input signal by the computed AM/AM (in dBm/dBm) and AM/PM (in deg/dBm) values.

Note To determine appropriate P_{out} and $\Delta\Phi$ for P_{in} values outside the range of values specified in the `Table` property, the System object applies linear extrapolation from the first two or last two [P_{in}, P_{out}, $\Delta\Phi$] rows of `Table`.

Tunable: Yes

Dependencies

To enable this property, set the `Method` property is set to `'Lookup table'`.

Data Types: `double`

Usage

Syntax

```
outsig = mnl(insig)
```

Description

`outsig = mnl(insig)` applies memoryless nonlinear impairments to the input RF baseband signal.

Input Arguments

`insig` — Input RF baseband signal

scalar | column vector

Input RF baseband signal, specified as a scalar or column vector. Values in this input must be complex.

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`outsig` — Output RF baseband signal
scalar | column vector

Output RF baseband signal, returned as a scalar or column vector. The output is of the same data type as the input.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Apply Saleh Model of Power Amplifier Nonlinearity to 16-QAM Signal

Generate 16-QAM data with an average power of 10 mW and pass the data through a nonlinear power amplifier (PA).

```
M = 16;
data = randi([0 (M - 1)]',1000,1);
avgPow = 1e-2;
minD = avgPow2MinD(avgPow,M);
```

Create a memoryless nonlinearity System object, specifying the Saleh model method.

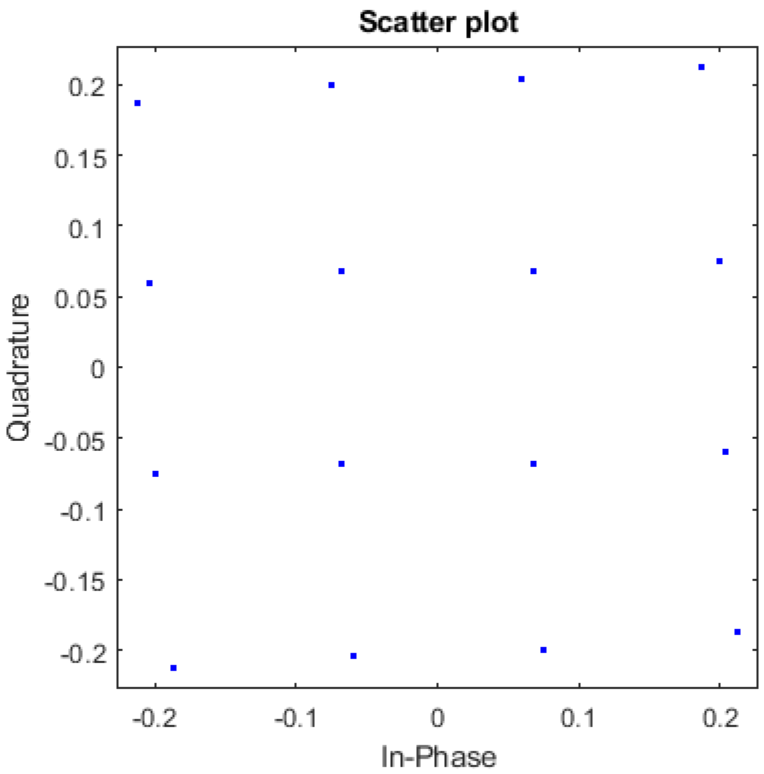
```
saleh = comm.MemorylessNonlinearity('Method','Saleh model');
```

Generate modulated symbols and pass them through the PA nonlinearity model.

```
modData = (minD/2).*qammod(data,M);
y = saleh(modData);
```

Generate a scatter plot of the results.

```
scatterplot(y)
```



Average power normalization of input signal.

```
function minD = avgPow2MinD(avgPow,M)
    % Average power to minimum distance
    nBits = log2(M);
    if (mod(nBits,2)==0)
        % Square QAM
        sf = (M - 1)/6;
    else
        % Cross QAM
        if (nBits>4)
            sf = ((31*M/32) - 1)/6;
        else
            sf = ((5*M/4) - 1)/6;
        end
    end
    minD = sqrt(avgPow/sf);
end
```

Nonlinear Amplifier Gain Compression

Plot the gain compression of a nonlinear amplifier for a 16-QAM signal.

Specify the modulation order and samples per symbol parameters.

```
M = 16;
sps = 4;
```

Model a nonlinear amplifier, by creating a memoryless nonlinearity System object with a 30 dB third-order input intercept point. Create a raised cosine transmit filter System object.

```
amplifier = comm.MemorylessNonlinearity('IIP3',30);

txfilter = comm.RaisedCosineTransmitFilter('RolloffFactor',0.3, ...
    'FilterSpanInSymbols',6, ...
    'OutputSamplesPerSymbol',sps, ...
    'Gain',sqrt(sps));
```

Specify the input power in dBm. Convert the input power to W and initialize the gain vector.

```
pindBm = -5:25;
pin = 10.^((pindBm-30)/10);
gain = zeros(length(pindBm),1);
```

Execute the main processing loop, which includes these steps.

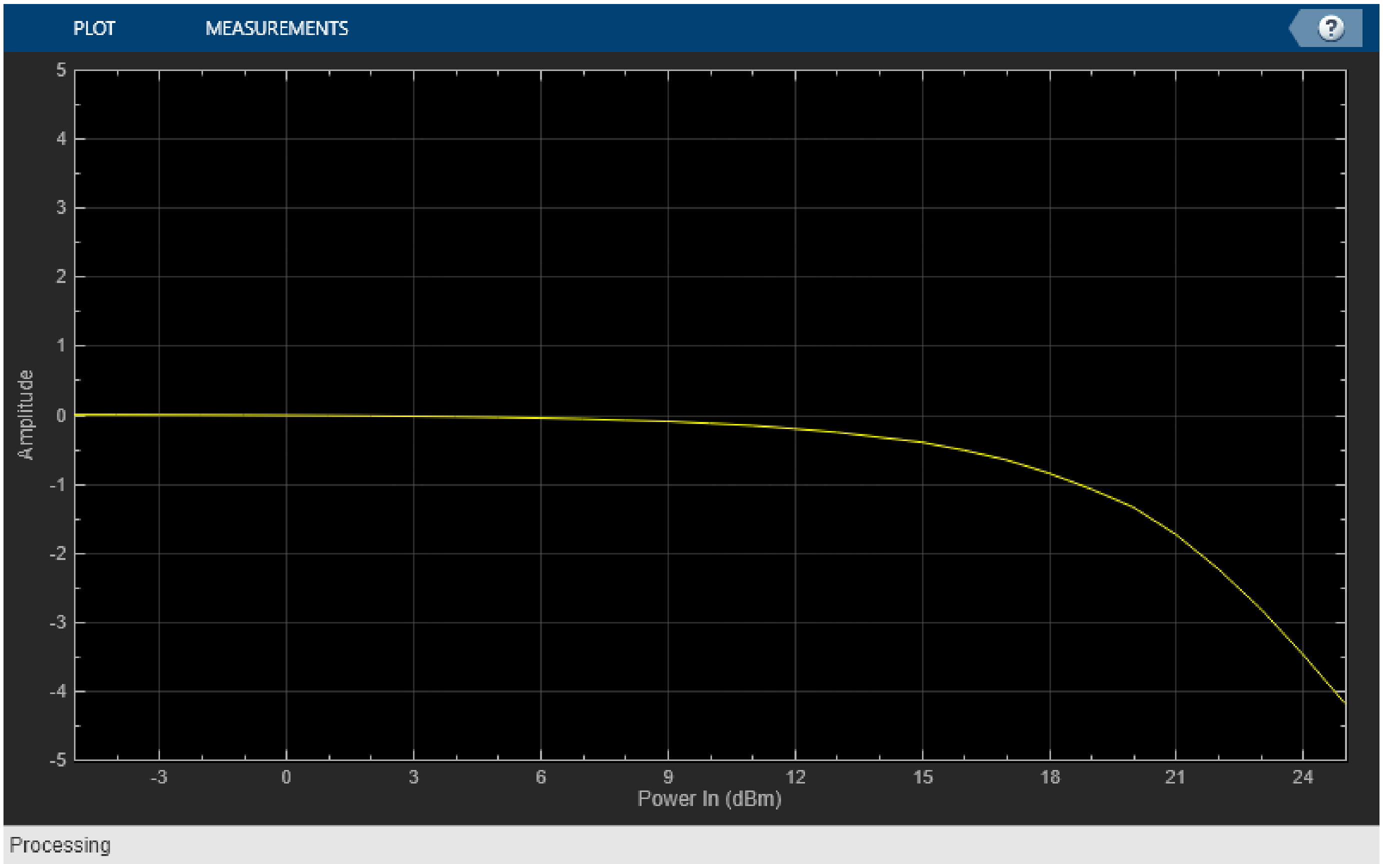
- Generate random data symbols.
- Modulate the data symbols and adjust the average power of the signal.
- Filter the modulated signal.
- Amplify the signal.
- Measure the gain.

```
for k = 1:length(pin)
    data = randi([0 (M - 1)],1000,1);
    modSig = qammod(data,M,'UnitAveragePower',true)*sqrt(pin(k));
    filtSig = txfilter(modSig);
    ampSig = amplifier(filtSig);
    gain(k) = 10*log10(var(ampSig)/var(filtSig));
end
```

Plot the amplifier gain as a function of the input signal power. The 1 dB gain compression point occurs for an input power of 18.5 dBm. To increase the point at which a 1 dB compression is observed, increase the third-order intercept point, `amplifier.IIP3`.

```
arrayplot = dsp.ArrayPlot('PlotType','Line','XLabel','Power In (dBm)', ...
    'XOffset',-5,'YLimits',[-5 5]);

arrayplot(gain)
```



Distort 16-QAM Signal with Custom Power Amplifier Nonlinearities

Apply nonlinear power amplifier (PA) characteristics to a 16-QAM signal by setting the `Method` property to `'Lookup table'`.

Define parameters for the modulation order, samples per symbol, and input power. Create random data.

```
M = 16; % Modulation order
sps = 4; % Samples per symbol
pindBm = -2; % Input power
pin = 10.^((pindBm-30)/10); % power in Watts
data = randi([0 (M - 1)],1000,1);
refdata = 0:M-1;
refconst = qammod(refdata,M,'UnitAveragePower',true);
```

Create a memoryless nonlinearity System object, a transmit filter System object, and a constellation diagram System object. The default lookup table values are used for the memoryless nonlinearity System object.

```
amplifier = comm.MemorylessNonlinearity('Method','Lookup table');
txfilter = comm.RaisedCosineTransmitFilter('RolloffFactor',0.3, ...
    'FilterSpanInSymbols',6,'OutputSamplesPerSymbol',sps,'Gain',sqrt(sps));
constellation = comm.ConstellationDiagram('SamplesPerSymbol',4,'ReferenceConstellation',refconst
    'Title','Amplified/Distorted Signal');
```

Modulate the random data. Filter and apply the nonlinear amplifier characteristics to the modulation symbols.

```
modSig = qammod(data,M,'UnitAveragePower',true)*sqrt(pin);
filtSig = txfilter(modSig);
ampSig = amplifier(filtSig);
```

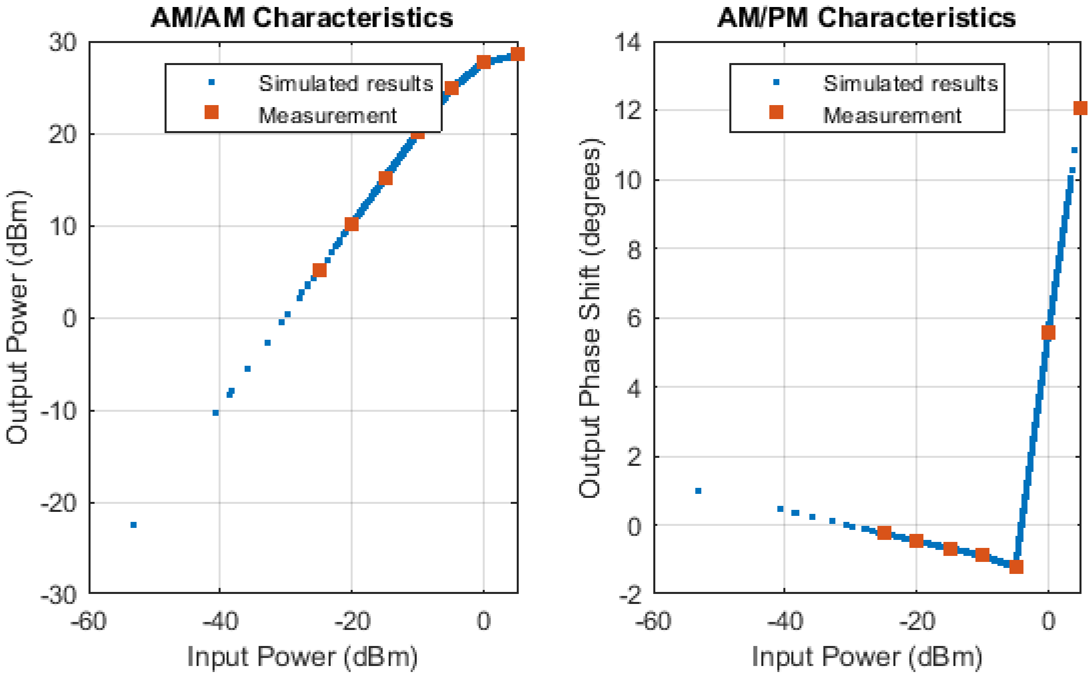
Compute input and output signal levels and the phase shift.

```
poutdBm = (20*log10(abs(ampSig))) + 30;
simulated_pindBm = (20*log10(abs(filtSig))) + 30;
phase = angle(ampSig.*conj(filtSig))*180/pi;
```

Plot AM/AM characteristics, AM/PM characteristics, and the constellation results.

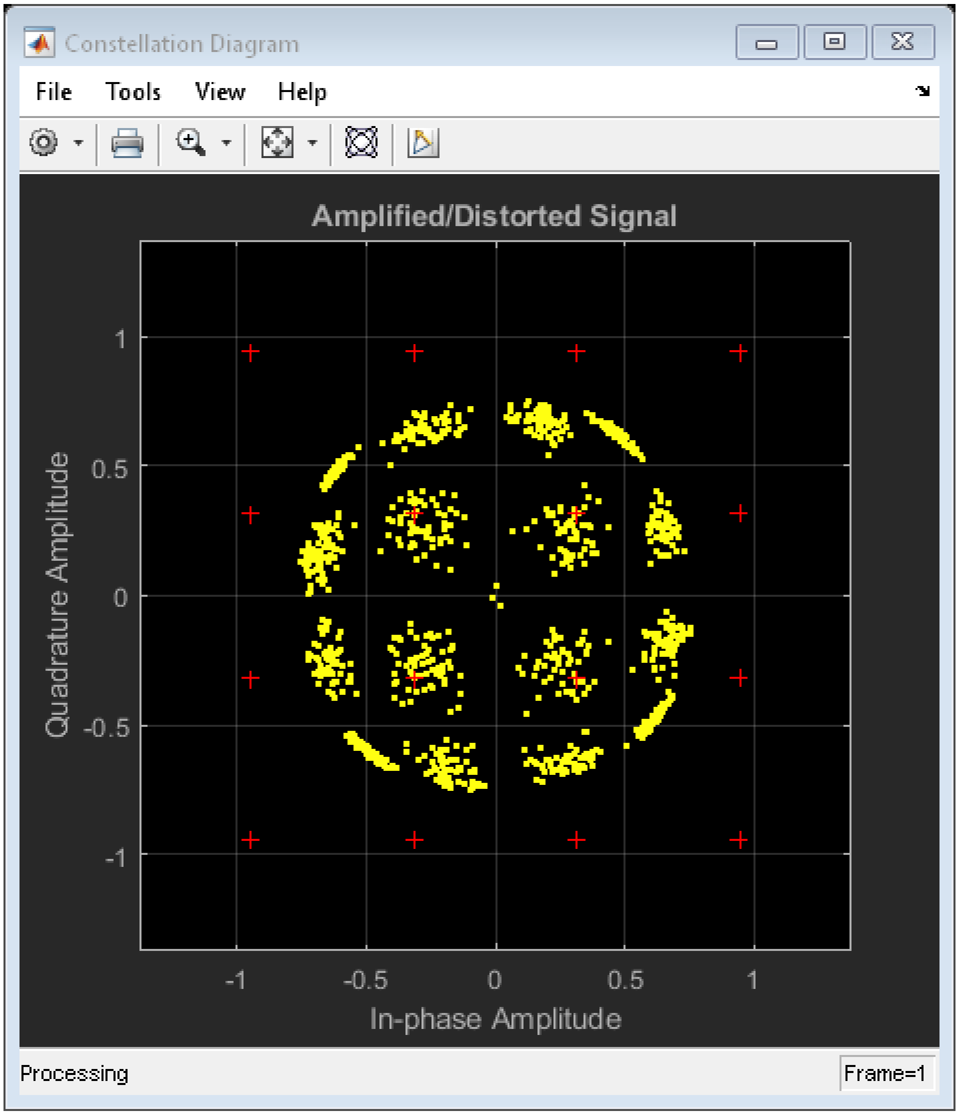
```
figure
set(gcf,'units','normalized','position',[.25 1/3 .5 1/3])
subplot(1,2,1)
plot(simulated_pindBm,poutdBm,'.');
hold on
plot(amplifier.Table(:,1),amplifier.Table(:,2),'.','Markersize',15);
xlabel('Input Power (dBm)')
ylabel('Output Power (dBm)');
grid on;
title('AM/AM Characteristics');
leglabels = {'Simulated results','Measurement'};
legend (leglabels,'Location','north');

subplot(1,2,2)
plot(simulated_pindBm,phase,'.');
hold on
plot(amplifier.Table(:,1),amplifier.Table(:,3),'.','Markersize',15);
legend (leglabels,'Location','north');
xlabel('Input Power (dBm)');
ylabel('Output Phase Shift (degrees)');
grid on; title('AM/PM Characteristics');
```



Generate a constellation diagram of the amplified signal and reference constellation. The nonlinear amplifier characteristics cause compression of the amplified signal constellation compared to the reference constellation.

```
constellation(ampSig)
```



Distort 16-QAM Signal with Measured Power Amplifier Nonlinearities

Apply nonlinear power amplifier (PA) characteristics to a 16-QAM signal by setting the `Method` property to `'Lookup table'`.

Define parameters for the modulation order, samples per symbol, and input power. Create random data.

```
M = 16; % Modulation order
sps = 4; % Samples per symbol
pindBm = -8; % Input power
pin = 10.^((pindBm-30)/10); % power in Watts
data = randi([0 (M - 1)],1000,1);
refdata = 0:M-1;
refconst = qammod(refdata,M,'UnitAveragePower',true);
paChar = pa_performance_characteristics();
```

Create a memoryless nonlinearity System object, a transmit filter System object, and a constellation diagram System object. The default lookup table values are used for the memoryless nonlinearity System object.

```
amplifier = comm.MemorylessNonlinearity('Method','Lookup table','Table',paChar);
txfilter = comm.RaisedCosineTransmitFilter('RolloffFactor',0.3, ...
    'FilterSpanInSymbols',6,'OutputSamplesPerSymbol',sps,'Gain',sqrt(sps));
constellation = comm.ConstellationDiagram('SamplesPerSymbol',4, ...
    'Title','Amplified/Distorted Signal','NumInputPorts',2, ...
    'ReferenceConstellation', refconst,'ShowLegend',true, ...
    'ChannelNames',{'Filtered signal','Amplified signal'});
```

Modulate the random data. Filter and apply the nonlinear amplifier characteristics to the modulation symbols.

```
modSig = qammod(data,M,'UnitAveragePower',true)*sqrt(pin);
filtSig = txfilter(modSig);
ampSig = amplifier(filtSig);
```

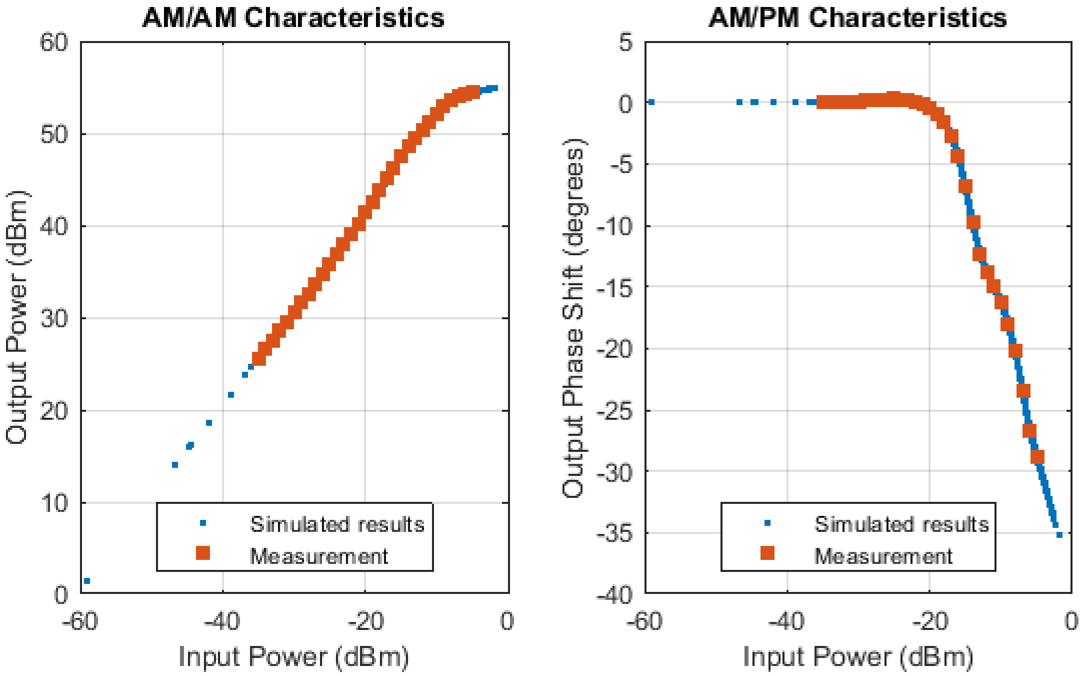
Compute input and output signal levels and the phase shift.

```
poutdBm = (20*log10(abs(ampSig))) + 30;
simulated_pindBm = (20*log10(abs(filtSig))) + 30;
phase = angle(ampSig.*conj(filtSig))*180/pi;
```

Plot AM/AM characteristics, AM/PM characteristics, and the constellation results.

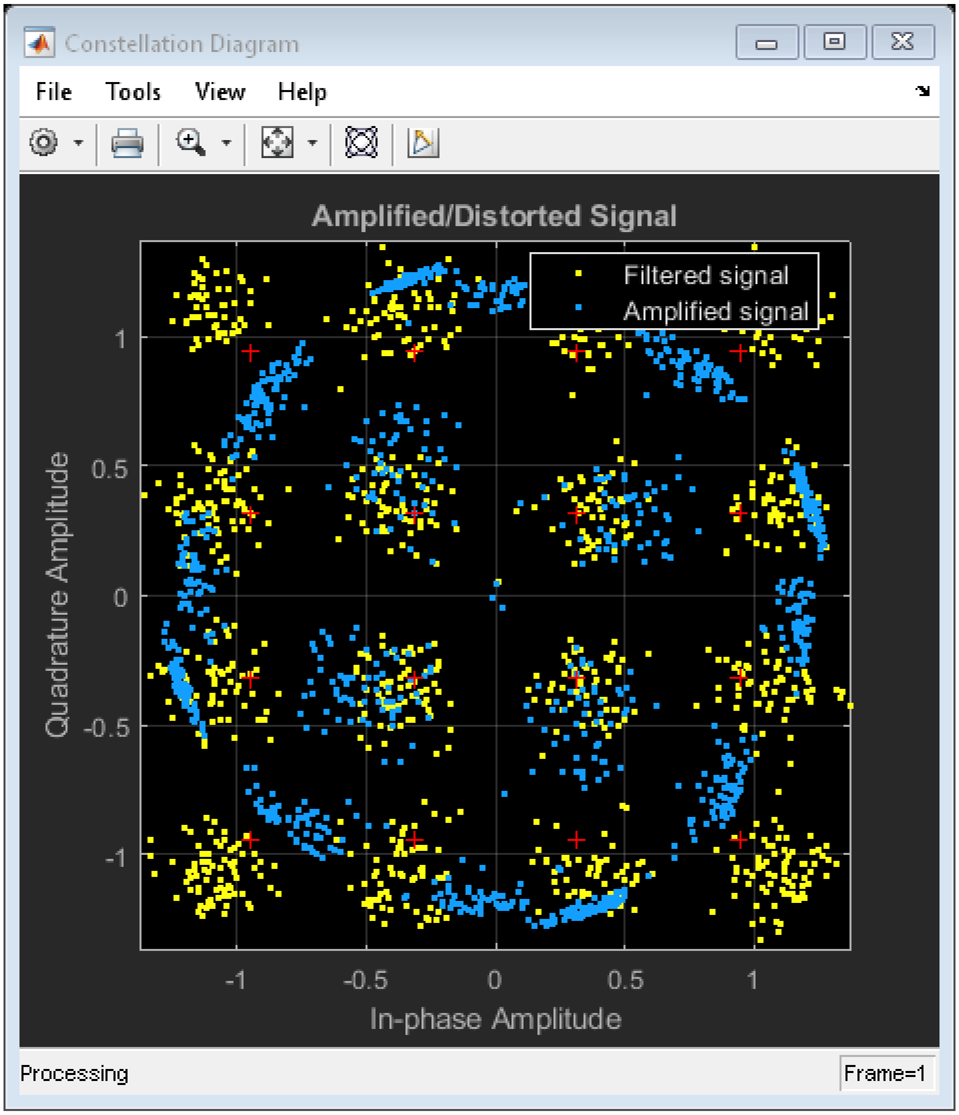
```
figure
set(gcf,'units','normalized','position',[.25 1/3 .5 1/3])
subplot(1,2,1)
plot(simulated_pindBm,poutdBm,'.');
hold on
plot(amplifier.Table(:,1),amplifier.Table(:,2),'.','Markersize',15);
xlabel('Input Power (dBm)')
ylabel('Output Power (dBm)');
grid on;
title('AM/AM Characteristics');
leglabel = {'Simulated results','Measurement'};
legend (leglabel,'Location','south');

subplot(1,2,2)
plot(simulated_pindBm,phase,'.');
hold on
plot(amplifier.Table(:,1),amplifier.Table(:,3),'.','Markersize',15);
legend (leglabel,'Location','south');
xlabel('Input Power (dBm)');
ylabel('Output Phase Shift (degrees)');
grid on;
title('AM/PM Characteristics');
```



For the purpose of constellation comparison, normalize the amplified signal and the filtered signal. Generate a constellation diagram of the filtered signal and amplified signal. The nonlinear amplifier characteristics cause compression of the amplified signal constellation compared to the filtered constellation.

```
filtSig = filtSig/mean(abs(filtSig)); % Normalized filtered signal
ampSig = ampSig/mean(abs(ampSig)); % Normalized amplified signal
constellation(filtSig,ampSig)
```



The `pa_performance_characteristics` helper function calculates the amplifier performance characteristics. The data is extracted from figure 4 of Hammi, Oualid, et al. "Power amplifiers' model assessment and memory effects intensity quantification using memoryless post-compensation technique." IEEE Transactions on Microwave Theory and Techniques 56.12 (2008): 3170-3179.

```
function paChar = pa_performance_characteristics()
```

The operating specification for the LDMOS-based Doherty amplifier are:

- A frequency of 2110 MHz
- A peak power of 300 W
- A small signal gain of 61 dB

Each row in `HAV08_Table` specifies Pin (dBm), gain (dB), phase shift (degrees).

```
HAV08_Table =...
    [-35,60.53,0.01;
    -34,60.53,0.01;
    -33,60.53,0.08;
    -32,60.54,0.08;
    -31,60.55,0.1;
    -30,60.56,0.08;
    -29,60.57,0.14;
    -28,60.59,0.19;
    -27,60.6,0.23;
    -26,60.64,0.21;
    -25,60.69,0.28;
    -24,60.76,0.21;
    -23,60.85,0.12;
    -22,60.97,0.08;
    -21,61.12,-0.13;
    -20,61.31,-0.44;
    -19,61.52,-0.94;
    -18,61.76,-1.59;
    -17,62.01,-2.73;
    -16,62.25,-4.31;
    -15,62.47,-6.85;
    -14,62.56,-9.82;
    -13,62.47,-12.29;
    -12,62.31,-13.82;
    -11,62.2,-15.03;
    -10,62.15,-16.27;
    -9,62,-18.05;
    -8,61.53,-20.21;
    -7,60.93,-23.38;
    -6,60.2,-26.64;
    -5,59.38,-28.75];
```

Convert the second column of the HAV08_Table from gain to Pout for use by the memoryless nonlinearity System object.

```
paChar = HAV08_Table;
paChar(:,2) = paChar(:,1) + paChar(:,2);
end
```

More About

Memoryless Nonlinear Impairments

Memoryless nonlinear impairments distort the input signal amplitude and phase. The amplitude distortion is amplitude-to-amplitude modulation (AM/AM) and the phase distortion is amplitude-to-phase modulation (AM/PM).

Model Method	Memoryless Nonlinear Impairment
Cubic polynomial	AM/AM and AM/PM
Hyperbolic tangent	
Saleh model	
Ghorbani model	
Rapp model	AM/AM only

Model Method	Memoryless Nonlinear Impairment
Lookup table	Applies impairment according to [P_{in}, P_{out}, ΔΦ] amplifier characteristics specified by the `Table` property

The modeled impairments apply the AM/AM and AM/PM distortions differently, according to the model method you specify. The models apply the memoryless nonlinear impairment to the input signal by following these steps.

1 Multiply the signal by an input gain factor.

Note You can normalize the signal to 1 by setting the input scaling gain to the inverse of the input signal amplitude.

2 Split the complex signal into its magnitude and angle components.

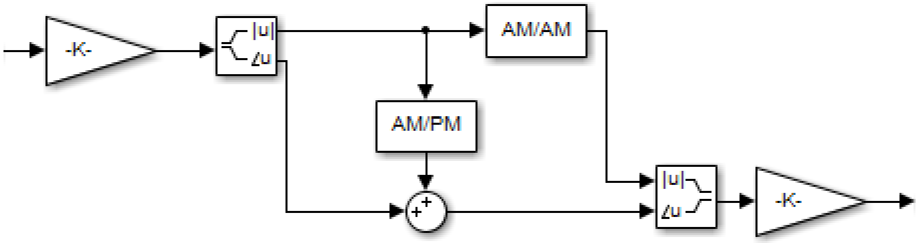
3 Apply an AM/AM distortion to the magnitude of the signal, according to the selected model method, to produce the magnitude of the output signal.

4 Apply an AM/PM distortion to the phase of the signal, according to the selected model method, to produce the angle of the output signal.

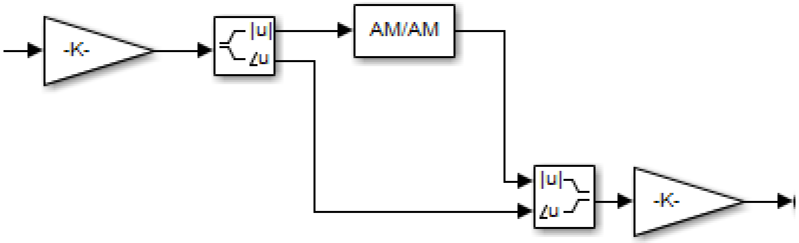
Note This step does not apply for the Rapp model.

5 Combine the new magnitude and angle components into a complex signal. Then, multiply the result by an output gain factor.

The first four model methods (cubic polynomial, hyperbolic tangent, Saleh model, and Ghorbani model) apply AM/AM and AM/PM impairments as shown in this figure.



The Rapp model method applies AM/AM distortion as shown in this figure.



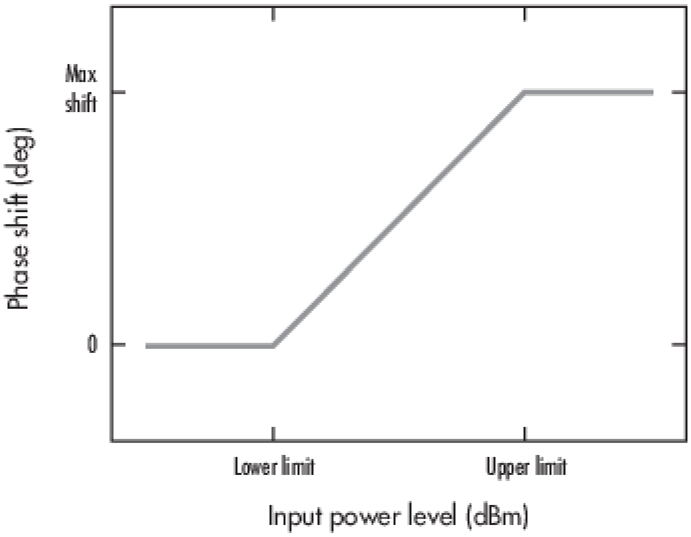
The lookup table method uses the power amplifier (PA) characteristics lookup table, specified as an *N*-by-3 matrix of measured power amplifier (PA) characteristics. Each row is of the form [P_{in}, P_{out},

$\Delta\Phi$]. P_{in} specifies the PA input signal in dBm, P_{out} specifies the PA output signal in dBm, and $\Delta\Phi$ specifies the output phase shift in degrees. The measured PA characteristics defined by the `Table` property are used to compute the AM/AM (in dBm/dBm) and AM/PM (in deg/dBm) nonlinear impairment characteristics. The System object distorts the input signal by the computed AM/AM (in dBm/dBm) and AM/PM (in deg/dBm) values.

Note To determine appropriate P_{out} and $\Delta\Phi$ for P_{in} values outside the range of values specified in the `Table` property, the System object applies linear extrapolation from the first two or last two [P_{in}, P_{out}, $\Delta\Phi$] rows of `Table`.

Cubic Polynomial and Hyperbolic Tangent Model Methods

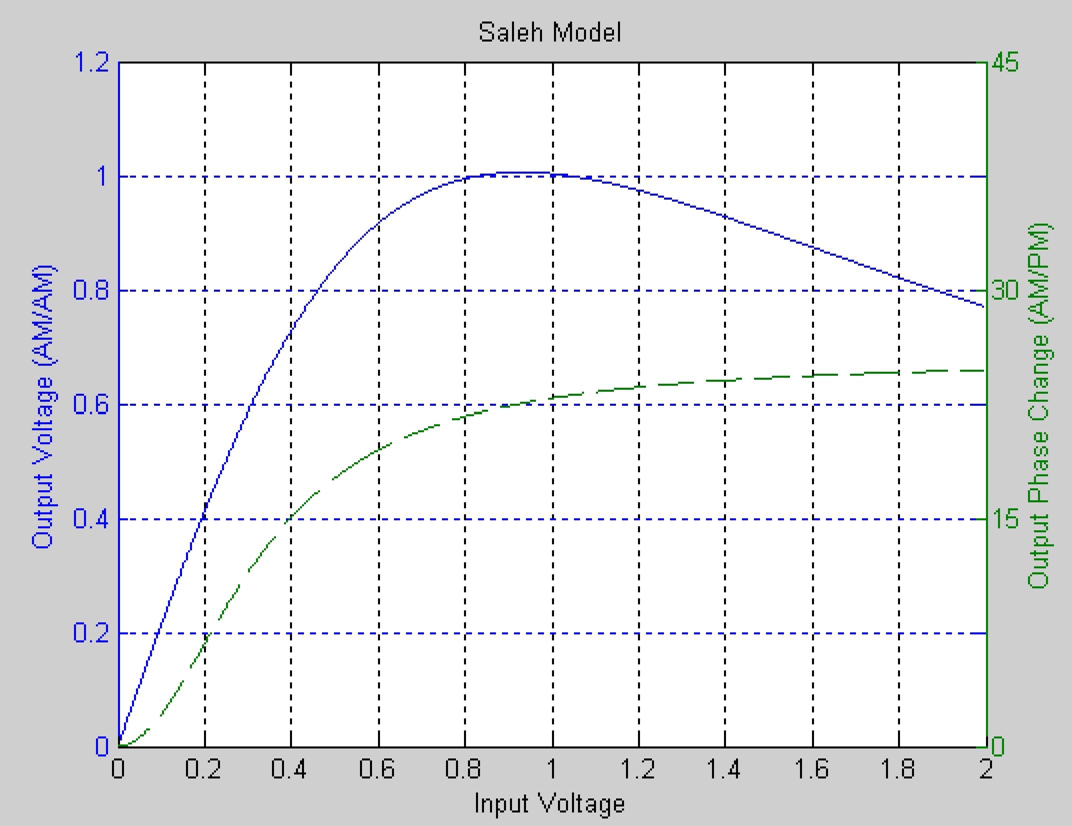
This figure shows the AM/PM conversion behavior for the cubic polynomial and hyperbolic tangent model methods.



The AM/PM conversion scales linearly with an input power value between the lower and upper limits of the input power level. Outside this range, the AM/PM conversion is constant at the values corresponding to the lower and upper input power limits, which are zero and (*AM/PM conversion*) × (*upper input power limit – lower input power limit*), respectively.

Saleh Model Method

This figure shows the AM/AM behavior (output voltage versus input voltage for the AM/AM distortion) and the AM/PM behavior (output phase versus input voltage for the AM/PM distortion) for the Saleh model method.



The AM/AM parameters, α_{AMAM} and β_{AMAM}, are used to compute the amplitude distortion of the input signal by using

$$F_{\mathrm{AMAM}}(u) = \frac{\alpha_{\mathrm{AMAM}} \times u}{1 + \beta_{\mathrm{AMAM}} \times u^2},$$

where u is the magnitude of the scaled signal.

The AM/PM parameters, α_{AMPM} and β_{AMPM}, are used to compute the phase distortion of the input signal by using

$$F_{\mathrm{AMPM}}(u) = \frac{\alpha_{\mathrm{AMPM}} \times u^2}{1 + \beta_{\mathrm{AMPM}} \times u^2},$$

where u is the magnitude of the scaled signal. The α and β parameters for AM/AM and AM/PM are similarly named but distinct.

Ghorbani Model Method

The Ghorbani model method applies AM/AM and AM/PM distortion as described in this section.

The AM/AM parameters (x_1, x_2, x_3, and x_4) are used to compute the amplitude distortion of the input signal by using

$$F_{\mathrm{AMAM}}(u) = \frac{x_1 u^{x_2}}{1 + x_3 u^{x_2}} + x_4 u,$$

where u is the magnitude of the scaled signal.

The AM/PM parameters (y_1, y_2, y_3, and y_4) are used to compute the phase distortion of the input signal by using

$$F_{\mathrm{AMPM}}(u) = \frac{y_1 u^{y_2}}{1 + y_3 u^{y_2}} + y_4 u,$$

where u is the magnitude of the scaled signal.

Rapp Model Method

The Rapp model method applies AM/AM distortion as described in this section. The Rapp model does not apply AM/PM distortion to the input signal.

The smoothness factor and output saturation level are used to compute the amplitude distortion of the input signal given by

$$F_{\mathrm{AMAM}}(u) = \frac{u}{\left(1 + \left(\frac{u}{O_{\mathrm{sat}}}\right)^{2\mathrm{S}}\right)^{1/2\mathrm{S}}},$$

where

- u is the magnitude of the scaled signal.
- S is the smoothness factor.
- O_{sat} is the output saturation level.

comm.MER

Package: comm

Measure modulation error ratio

Description

The comm.MER (modulation error ratio) object measures the signal-to-noise ratio (SNR) in digital modulation applications. You can use MER measurements to determine system performance in communications applications. For example, determining whether a DVB-T system conforms to applicable radio transmission standards requires accurate MER measurements. The block measures all outputs in dB.

To measure modulation error ratio:

1. Define and set up your MER object. See “Construction” on page 3-949.
2. Call step to measure the modulation error ratio according to the properties of comm.MER. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

MER = comm.MER creates a modulation error ratio (MER) System object, MER. This object measures the signal-to-noise ratio (SNR) in digital modulation applications.

MER = comm.MER(Name,Value) creates an MER object with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Example: MER = comm.MER('ReferenceSignalSource','Estimated from reference constellation') creates an object, MER, that measures the MER of a received signal by using a reference constellation.

Properties

ReferenceSignalSource

Reference signal source

Reference signal source, specified as either 'Input port' (default) or 'Estimated from reference constellation'. To provide an explicit reference signal against which the input signal is measured, set this property to 'Input port'. To measure the MER of the input signal against a reference constellation, set this property to 'Estimated from reference constellation'.

`ReferenceConstellation`

Reference constellation

Reference constellation, specified as a vector. This property is available when the `ReferenceSignalSource` property is `'Estimated from reference constellation'`.

The default is `[0.7071 - 0.7071i; -0.7071 - 0.7071i; -0.7071 + 0.7071i; 0.7071 + 0.7071i]`, which corresponds to a standard QPSK constellation. You can derive constellation points by using modulation functions or objects. For example, to derive the reference constellation for a 16-QAM signal, you can use `qammod(0:15,16)`.

`MeasurementIntervalSource`

Measurement interval source

Measurement interval source, specified as one of the following: `'Input length'` (default), `'Entire history'`, `'Custom'`, or `'Custom with periodic reset'`. This property affects the RMS and maximum MER outputs only.

- To calculate MER using only the current samples, set this property to `'Input length'`.
- To calculate MER for all samples, set this property to `'Entire history'`.
- To calculate MER over an interval you specify and to use a sliding window, set this property to `'Custom'`.
- To calculate MER over an interval you specify and to reset the object each time the measurement interval is filled, set this property to `'Custom with periodic reset'`.

`MeasurementInterval`

Measurement interval

Measurement interval over which the MER is calculated, specified in samples as a real positive integer. This property is available when `MeasurementIntervalSource` is `'Custom'` or `'Custom with periodic reset'`. The default is `100`.

`AveragingDimensions`

Averaging dimensions

Averaging dimensions, specified as a positive integer or row vector of positive integers. This property determines the dimensions over which the averaging is performed. For example, to average across the rows, set this property to `2`. The default is `1`.

The object supports variable-size inputs over the dimensions in which the averaging takes place. However, the input size for the nonaveraged dimensions must remain constant between `step` calls. For example, if the input has size `[4 3 2]` and `Averaging dimensions` is `[1 3]`, the output size is `[1 3 1]`, and the second dimension must remain fixed at `3`.

`MinimumMEROutputPort`

Minimum MER measurement output port

Minimum MER measurement output port, specified as a logical scalar. To create an output port for minimum MER measurements, set this property to `true`. The default is `false`.

`XPercentileMEROutputPort`

X-percentile MER measurement output port

X-percentile MER measurement output port, specified as a logical scalar. To create an output port for *X*-percentile MER measurements, set this property to `true`. The *X*-percentile MER measurements persist until you reset the object. These measurements are calculated by using all of the input frames since the last reset. The default is `false`.

`XPercentileValue`

X-percentile value

X-percentile value above which *X*% of the MER measurements fall, specified as a real scalar from `0` to `100`. This property applies when `XPercentileMEROutputPort` is `true`. The default is `95`.

`SymbolCountOutputPort`

Symbol count output port

Symbol count output port, specified as a logical scalar. To output the number of accumulated symbols used to calculate the *X*-percentile MER measurements, set this property to `true`. This property is available when `XPercentileMEROutputPort` property is `true`. The default is `false`.

Methods

reset	Reset states of MER measurement object
step	Measure modulation error ratio

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Measure MER of Noisy 16-QAM Modulated Signal

Create an MER object which outputs minimum MER, 90-percentile MER, and the number of symbols.

```
mer = comm.MER('MinimumMEROutputPort',true, ...
    'XPercentileMEROutputPort',true,'XPercentileValue',90,...
    'SymbolCountOutputPort',true);
```

Generate random data. Apply 16-QAM modulation having unit average power. Pass the signal through an AWGN channel.

```
data = randi([0 15],1000,1);
refsym = qammod(data,16,'UnitAveragePower',true);
rxsym = awgn(refsym,20);
```

Determine the RMS, minimum, and 90th percentile MER values.

```
[MERdB,MinMER,PercentileMER,NumSym] = mer(refsym,rxsym)
```

```
MERdB = 20.1071

MinMER = 11.4248

PercentileMER = 16.5850

NumSym = 1000
```

Measure MER Using Reference Constellation

Generate random data symbols, and apply 8-PSK modulation.

```
d = randi([0 7],2000,1);
txSig = pskmod(d,8,pi/8);
```

Pass the modulated signal through an AWGN channel.

```
rxSig = awgn(txSig,30);
```

Create an MER object. Measure the MER using the transmitted signal as the reference.

```
mer = comm.MER;
mer1 = mer(txSig,rxSig);
```

Release the MER object. Set the object to use a reference constellation for making MER measurements.

```
release(mer)
mer.ReferenceSignalSource = 'Estimated from reference constellation';
mer.ReferenceConstellation = pskmod(0:7,8,pi/8);
```

Measure the MER using only the received signal as an input. Verify that it matches the result obtained with a reference signal.

```
mer2 = mer(rxSig);
[mer1 mer2]
```

```
ans = 1×2

   30.0271   30.0271
```

Measure MER Using Custom Measurement Interval

Measure the MER of a noisy 8-PSK signal using two types of custom measurement intervals. Display the results.

Set the number of frames, M, and the number of subframes per frame, K.

```
M = 2;
K = 5;
```

Set the number of symbols in a subframe. Calculate the corresponding frame length.

```
sfLen = 100;
frmLen = K*sfLen

frmLen = 500
```

Create an MER object. Configure the object to use a custom measurement interval equal to the frame length.

```
mer1 = comm.MER('MeasurementIntervalSource','Custom', ...
    'MeasurementInterval',frmLen);
```

Configure the object to measure MER using an 8-PSK reference constellation.

```
mer1.ReferenceSignalSource = 'Estimated from reference constellation';
mer1.ReferenceConstellation = pskmod(0:7,8,pi/8);
```

Create an MER object, and configure it use a 500-symbol measurement interval with a periodic reset. Configure the object to measure MER using an 8-PSK reference constellation.

```
mer2 = comm.MER('MeasurementIntervalSource','Custom with periodic reset', ...
    'MeasurementInterval',frmLen);
mer2.ReferenceSignalSource = 'Estimated from reference constellation';
mer2.ReferenceConstellation = pskmod(0:7,8,pi/8);
```

Initialize the MER and signal-to-noise arrays.

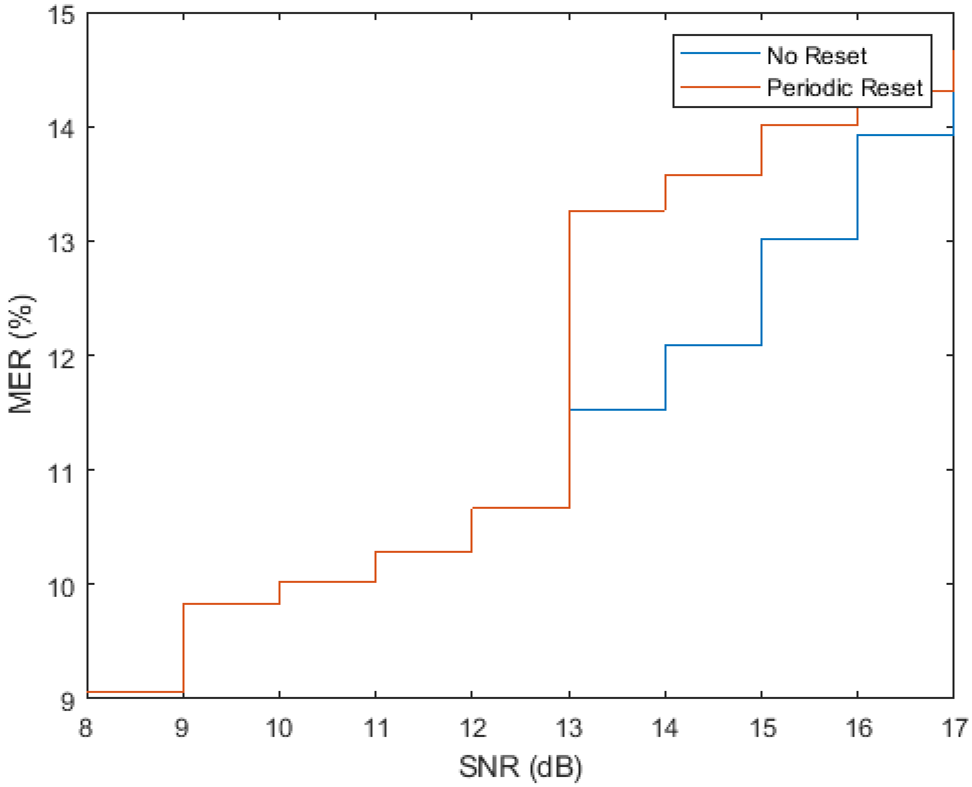
```
merNoReset = zeros(K,M);
merReset = zeros(K,M);
snrdB = zeros(K,M);
```

Measure the MER for a noisy 8-PSK signal using both objects. The SNR is increases by 1 dB from subframe to subframe. For `merNoReset`, the 500 most recent symbols are used to compute the estimate. In this case, a sliding window is used so that an entire data frame is used as the basis for the estimate. For `merReset`, the symbols are cleared each time a new frame is encountered.

```
for m = 1:M
    for k = 1:K
        data = randi([0 7],sfLen,1);
        txSig = pskmod(data,8,pi/8);
        snrdB(k,m) = k+(m-1)*K+7;
        rxSig = awgn(txSig,snrdB(k,m));
        merNoReset(k,m) = mer1(rxSig);
        merReset(k,m) = mer2(rxSig);
    end
end
```

Display the MER measured using the two approaches. The windowing used in the first case provides an averaging across the subframes. In the second case, the MER object resets after the first frame so that the calculated MER values more accurately reflect the current SNR.

```
stairs(snrdB(:),[merNoReset(:) merReset(:)])
xlabel('SNR (dB)')
ylabel('MER (%)')
legend('No Reset','Periodic Reset')
```



Measure MER Across Different Dimensions

Create OFDM modulator and demodulator objects.

```
ofdmmod = comm.OFDMModulator('FFTLength',32,'NumSymbols',4);
ofdmdemod = comm.OFDMDemodulator('FFTLength',32,'NumSymbols',4);
```

Determine the number of subcarriers and symbols in the OFDM signal.

```
ofdmDims = info(ofdmmod);
numSC = ofdmDims.DataInputSize(1)
```

```
numSC = 21
```

```
numSym = ofdmDims.DataInputSize(2)
```

```
numSym = 4
```

Generate random symbols and apply QPSK modulation.

```
msg = randi([0 3],numSC,numSym);
modSig = pskmod(msg,4,pi/4);
```

OFDM modulate the QPSK signal. Pass the signal through an AWGN channel. Demodulate the noisy signal.

```
txSig = ofdmmod(modSig);
rxSig = awgn(txSig,10,'measured');
demodSig = ofdmdemod(rxSig);
```

Create an MER object, where the result is averaged over the subcarriers. Measure the MER. There are four entries corresponding to each of the 4 OFDM symbols.

```
mer = comm.MER('AveragingDimensions',1);
modErrorRatio = mer(demodSig,modSig)
```

```
modErrorRatio = 1×4

   11.2338   12.5315   12.8882   12.7015
```

Overwrite the MER object, where the result is averaged over the OFDM symbols. Measure the MER. There are 21 entries corresponding to each of the 21 subcarriers.

```
mer = comm.MER('AveragingDimensions',2);
modErrorRatio = mer(demodSig,modSig)
```

```
modErrorRatio = 21×1

   10.8054
   14.9655
   14.5721
   13.6024
   13.0132
   12.1391
   10.4012
    9.5017
    8.8055
   13.3824
      ⋮
```

Measure the MER and average over both the subcarriers and the OFDM symbols.

```
mer = comm.MER('AveragingDimensions',[1 2]);
modErrorRatio = mer(demodSig,modSig)
```

```
modErrorRatio = 12.2884
```

Algorithms

MER is a measure of the SNR in a modulated signal calculated in dB. The MER over *N* symbols is

$$\mathrm{MER} = 10 \cdot \log_{10}\left(\frac{\sum_{n=1}^{N}\left(I_k^2 + Q_k^2\right)}{\sum_{n=1}^{N}(e_k)}\right) \mathrm{dB},$$

The MER for the *k*th symbol is

$$MER_k = 10 * \log_{10}\left(\frac{\frac{1}{N}\sum_{n=1}^{N}\left(I_k^2 + Q_k^2\right)}{e_k}\right) \text{dB}.$$

The minimum MER represents the minimum MER value in a burst, or

$$MER_{\min} = \min_{k \in [1, \ldots, N]} \{MER_k\} ,$$

where:

- $e_k = e_k = (I_k - \tilde{I}_k)^2 + (Q_k - \tilde{Q}_k)^2$
- I_k = In-phase measurement of the kth symbol in the burst
- Q_k = Quadrature phase measurement of the kth symbol in the burst
- I_k and Q_k represent ideal (reference) values. $\tilde{I}_k$ and $\tilde{Q}_k$ represent measured (received) symbols.

The block computes the X-percentile MER by creating a histogram of all the incoming MER_k values. The output provides the MER value above which X% of the MER values fall.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

`comm.ACPR` | `comm.CCDF` | `comm.EVM`

Introduced in R2012a

reset

System object: `comm.MER`
Package: `comm`

Reset states of MER measurement object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `MER` object, `H`.

step

System object: `comm.MER`
Package: `comm`

Measure modulation error ratio

Syntax

```
MERDB= step(MER,REFSYM,RXSYM)
MERDB = step(MER,RXSYM)
[ ___ ,MINMER] = step( ___ )
[ ___ ,XMER] = step( ___ )
[ ___ ,NUMSYM] = step( ___ )
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`MERDB= step(MER,REFSYM,RXSYM)` returns the measured MER, `MERDB`, of the received signal `RXSYM`, based on reference signal `REFSYM`. MER values are measured in dB.

`REFSYM`. `REFSYM` and `RXSYM` inputs are complex column vectors of equal dimensions and data type. The data type can be double, single, signed integer, or signed fixed point with power-of-two slope and zero bias. All outputs of the object are of data type `double`. To set the interval over which the MER is measured, use the `MeasurementIntervalSource` and `MeasurementInterval` properties.

`MERDB = step(MER,RXSYM)` returns the measured MER of received signal `RXSYM` based on a reference signal specified in the `ReceivedConstellation` property.

`[ ___ ,MINMER] = step( ___ )` returns the minimum MER, `MINMER`, given either of the two previous syntaxes.

To return minimum MER, set the `MinimumMEROutputPort` property to `true`. To set the interval over which `MINMER` is measured, use the `MeasurementIntervalSource` and `MeasurementInterval` properties.

`[ ___ ,XMER] = step( ___ )` returns the *X*-percentile MER, `XMER`.

To return the *X*-percentile MER, set the `XPercentileMEROutputPort` property to `true`. `XMER` is the MER above which *X*% of the measurements fall, where *X* is set by the `XPercentileValue` property. `XMER` is measured using all the input frames since the last reset.

`[ ___ ,NUMSYM] = step( ___ )` returns the number of symbols, `NUMSYM`, used to calculate the *X*-percentile MER.

To return `NUMSYM`, set the `SymbolCountOutputPort` to `true`. `NUMSYM` is measured using all the input frames since the last reset.

Note `MER` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.MIMOChannel

Package: `comm`

Filter input signal through MIMO multipath fading channel

Description

A comm.MIMOChannel object filters an input signal through a multiple-input/multiple-output (MIMO) multipath fading channel. This object models both Rayleigh and Rician fading and employs the Kronecker model for modeling the spatial correlation between the links. For processing details, see the Algorithms on page 3-983 section.

To filter an input signal through a MIMO multipath fading channel:

1. Create the `comm.MIMOChannel` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
mimochan = comm.MIMOChannel
mimochan = comm.MIMOChannel(Name,Value)
```

Description

`mimochan = comm.MIMOChannel` creates a multiple-input multiple-output (MIMO) frequency-selective or frequency-flat fading channel System object. This object filters a real or complex input signal through the multipath MIMO channel to obtain the channel-impaired signal.

`mimochan = comm.MIMOChannel(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Example: `comm.MIMOChannel('SampleRate',2)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`SampleRate` — Input signal sample rate
`1` (default) | positive scalar

Input signal sample rate in hertz, specified as a positive scalar.

Data Types: `double`

`PathDelays` — Discrete path delay

`0` (default) | scalar | row vector

Discrete path delay in seconds, specified as a scalar or row vector.

- When you set `PathDelays` to a scalar, the MIMO channel is frequency flat.
- When you set `PathDelays` to a vector, the MIMO channel is frequency selective.

Data Types: `double`

`AveragePathGains` — Average path gains (dB)

`0` (default) | scalar | row vector

Average path gains in decibels, specified as a scalar or row vector. `AveragePathGains` must have the same size as PathDelays.

Data Types: `double`

`NormalizePathGains` — Normalize path gains

`true` (default) | `false`

Normalize path gains, specified as `true` or `false`.

- When you set this property to `true`, the fading processes are normalized so that the total power of the path gains, averaged over time, is `0` dB.
- When you set this property to `false`, there is no normalization on path gains.

The average powers of the path gains are specified by the AveragePathGains property.

Data Types: `logical`

`FadingDistribution` — Fading distribution

`'Rayleigh'` (default) | `'Rician'`

Fading distribution to use for the channel, specified as `'Rayleigh'` or `'Rician'`.

Data Types: `char`

`KFactor` — K-factor of Rician fading channel

`3` (default) | positive scalar | row vector

K-factor of a Rician fading channel, specified as a positive scalar or a 1-by-N_P vector of positive-valued elements. N_P equals number of path delays specified by the PathDelays property.

- If you set `KFactor` to a scalar, the first discrete path is a Rician fading process with a Rician K-factor of `KFactor`. Any remaining discrete paths are independent Rayleigh fading processes.
- If you set `KFactor` to a row vector, the discrete path corresponding to a positive element of the `KFactor` vector is a Rician fading process with a Rician K-factor specified by that element. The discrete path corresponding to a zero-valued element of the `KFactor` vector is a Rayleigh fading process.

Dependencies

This property applies when FadingDistribution is `Rician`.

Data Types: `double`

`DirectPathDopplerShift` — Doppler shifts for line-of-sight components (Hz)

`0` (default) | scalar | row vector

Doppler shifts for the line-of-sight components of the Rician fading channel in hertz, specified as a scalar or row vector. This property must have the same size as KFactor.

- If you set `DirectPathDopplerShift` to a scalar, it represents the line-of-sight component Doppler shift of the first discrete path that is a Rician fading process.
- If you set `DirectPathDopplerShift` to a row vector, the discrete path that is a Rician fading process has its line-of-sight component Doppler shift specified by the elements of `DirectPathDopplerShift` that correspond to positive elements in the KFactor vector.

Dependencies

This property applies when FadingDistribution is `Rician`.

Data Types: `double`

`DirectPathInitialPhase` — Initial phases for line-of-sight components (Radians)

`0` (default) | scalar | row vector

Initial phases for the line-of-sight components of the Rician fading channel in radians, specified as a scalar or row vector. This property must have the same size as KFactor.

- If you set `DirectPathInitialPhase` to a scalar, it represents the line-of-sight component initial phase of the first discrete path that is a Rician fading process.
- If you set `DirectPathInitialPhase` to a row vector, the discrete path that is a Rician fading process has its line-of-sight component initial phase specified by the elements of `DirectPathInitialPhase` that correspond to positive elements in the KFactor vector.

Dependencies

This property applies when FadingDistribution is `Rician`.

Data Types: `double`

`MaximumDopplerShift` — Maximum Doppler shift for all channel paths (Hz)

`0.001` (default) | nonnegative scalar

Maximum Doppler shift for all channel paths in hertz, specified as a nonnegative scalar.

The Doppler shift applies to all channel paths. When you set this property to `0`, the channel remains static for the entire input. You can use the `reset` object function to generate a new channel realization.

`MaximumDopplerShift` must be smaller than (SampleRate/10)/f_c for each path, where f_c represents the cutoff frequency factor of the path. For more information on the cutoff frequency, see Cutoff Frequency Factor on page 3-984.

Data Types: `double`

`DopplerSpectrum` — Doppler spectrum shape for all channel paths

`doppler('Jakes')` (default) | `doppler('Flat')` | `doppler('Rounded', ...)` | `doppler('Bell', ...)` | `doppler('Asymmetric Jakes', ...)` | `doppler('Restricted Jakes', ...)` | `doppler('Gaussian', ...)` | `doppler('BiGaussian', ...)`

Doppler spectrum shape for all channel paths, specified as a single Doppler spectrum structure returned from the `doppler` function or a 1-by-N_P cell array of such structures. The default value of this property is the Jakes Doppler spectrum (`doppler('Jakes')`).

- If you assign a single call to `doppler`, all paths have the same specified Doppler spectrum.
- If you assign a 1-by-N_P cell array of calls to `doppler` using any of the specified syntaxes, each path has the Doppler spectrum specified by the corresponding Doppler spectrum structure in the array. In this case, N_P equals the value of the PathDelays property.

The maximum Doppler shift value necessary to specify the Doppler spectrum/spectra is given by the MaximumDopplerShift property.

Dependencies

This property applies when MaximumDopplerShift is greater than zero.

If you assign the FadingTechnique property to `'Sum of sinusoids'`, you must set `DopplerSpectrum` to `doppler('Jakes')`.

`SpatialCorrelationSpecification` — Spatial correlation specification

`'Separate Tx Rx'` (default) | `'None'` | `'Combined'`

Spatial correlation specification, specified as `'Separate Tx Rx'`, `'None'`, or `'Combined'`.

- Choose `'Spatial Tx Rx'` to separately specify the transmit and receive spatial correlation matrices from which the number of transmit antenna (N_T) and number of receive antennas (N_R) are derived.
- Choose `'None'` to specify the number of transmit and receive antennas.
- Choose `'Combined'` to specify a single correlation matrix for the whole channel, from which the product of N_T and N_R is derived.

Data Types: `char`

`NumTransmitAntennas` — Number of transmit antennas

2 (default) | positive integer

Number of transmit antennas, specified as a positive integer.

Dependencies

This property applies when SpatialCorrelationSpecification is `'None'` or `'Combined'`.

Data Types: `double`

`NumReceiveAntennas` — Number of receive antennas

2 (default) | positive integer

Number of receive antennas, specified as a positive integer.

Dependencies

This property applies when SpatialCorrelationSpecification is `'None'` or `'Combined'`.

Data Types: `double`

`TransmitCorrelationMatrix` — Spatial correlation of transmitter

`[1 0; 0 1]` (default) | matrix | 3-D array

Specify the spatial correlation of the transmitter as an N_T-by-N_T matrix or N_T-by-N_T-by-N_P array. N_T is the number of transmit antennas, and N_P equals the value of the PathDelays property.

- If `PathDelays` is a scalar, the channel is frequency-flat, and `TransmitCorrelationMatrix` is an N_T-by-N_T Hermitian matrix. The magnitude of any off-diagonal element must be no larger than the geometric mean of the two corresponding diagonal elements.
- If `PathDelays` is a vector, the channel is frequency selective, and you can specify `TransmitCorrelationMatrix` as a matrix. Each path has the same transmit spatial correlation matrix.
- Alternatively, you can specify `TransmitCorrelationMatrix` as an N_T-by-N_T-by-N_P array, where each path can have its own different transmit spatial correlation matrix.

Dependencies

This property applies when you set the SpatialCorrelationSpecification property to `'Separate Tx Rx'`.

Data Types: `double`
Complex Number Support: Yes

`ReceiveCorrelationMatrix` — Spatial correlation of receiver

`[1 0; 0 1]` (default) | matrix | 3-D array

Specify the spatial correlation of the receiver as an N_R-by-N_R matrix or N_R-by-N_R-by-N_P array. N_R is the number of receive antennas, and N_P equals the value of the PathDelays property.

- If PathDelays is a scalar, the channel is frequency flat, and `ReceiveCorrelationMatrix` is an N_R-by-N_R Hermitian matrix. The magnitude of any off-diagonal element must be no larger than the geometric mean of the two corresponding diagonal elements.
- If PathDelays is a vector, the channel is frequency selective, and you can specify `ReceiveCorrelationMatrix` as a matrix. Each path has the same receive spatial correlation matrix.
- Alternatively, you can specify `ReceiveCorrelationMatrix` as an N_R-by-N_R-by-N_P array, where each path can have its own different receive spatial correlation matrix.

Dependencies

This property applies when you set the SpatialCorrelationSpecification property to `'Separate Tx Rx'`.

Data Types: `double`
Complex Number Support: Yes

`SpatialCorrelationMatrix` — Combined spatial correlation matrix

`[1 0 0 0; 0 1 0 0; 0 0 1 0; 0 0 0 1]` (default) | matrix | 3-D array

Combined spatial correlation matrix, specified as an N_{TR}-by-N_{TR} matrix or N_{TR}-by-N_{TR}-by-N_P array, where $N_{TR} = (N_T \times N_R)$, and N_P equals the value of the PathDelays property.

- If PathDelays is a scalar, the channel is frequency flat, and `SpatialCorrelationMatrix` is an N_{TR}-by-N_{TR} Hermitian matrix. The magnitude of any off-diagonal element must be no larger than the geometric mean of the two corresponding diagonal elements.
- If PathDelays is a vector, the channel is frequency selective, and you can specify `SpatialCorrelationMatrix` as a matrix. Each path has the same spatial correlation matrix.
- Alternatively, you can specify `SpatialCorrelationMatrix` as an N_{TR}-by-N_{TR}-by-N_P array, where each path can have its own different combined spatial correlation matrix.

Dependencies

This property applies when you set the SpatialCorrelationSpecification property to `'Combined'`.

Data Types: `double`

`AntennaSelection` — Antenna selection scheme

`'Off'` (default) | `'Tx'` | `'Rx'` | `'Tx and Rx'`

Antenna selection scheme, specified as `'Off'`, `'Tx'`, `'Rx'`, or `'Tx and Rx'`.

`Tx` represents transmit antennas and `Rx` represents receive antennas. When you configure any antenna selection other than the default setting, the object requires one or more inputs to specify which antennas are selected for signal transmission. For more information, see Antenna Selection on page 3-984.

Data Types: `char`

`NormalizeChannelOutputs` — Normalize channel outputs

`true` (default) | `false`

Normalize channel outputs, specified as `true` or `false`.

- When you set this property to `true`, channel outputs are normalized by the number of receive antennas.
- When you set this property to `false`, channel outputs are not normalized.

Data Types: `logical`

FadingTechnique — Channel model fading technique

`'Filtered Gaussian noise'` (default) | `'Sum of sinusoids'`

Channel model fading technique, specified as `'Filtered Gaussian noise'` or `'Sum of sinusoids'`.

Data Types: `char`

`NumSinusoids` — Number of sinusoids used

48 (default) | positive integer

Number of sinusoids used to model the fading process, specified as a positive integer.

Dependencies

This property applies when FadingTechnique is `'Sum of sinusoids'`.

Data Types: `double`

`InitialTimeSource` — Source to control start time of fading process

`'Property'` (default) | `'Input port'`

Source to control the start time of the fading process, specified as `'Property'` or `'Input port'`.

- `'Property'` -- Use the InitialTime property to set the initial time offset.
- `'Input port'` -- Specify the start time of the fading process by using the `initialtime` input to the object. The input value can change in consecutive calls to the object.

Dependencies

This property applies when FadingTechnique is `'Sum of sinusoids'`.

`InitialTime` — Initial time offset

`0` (default) | nonnegative scalar

Initial time offset for the fading model in seconds, specified as a nonnegative scalar.

When `InitialTime` is not a multiple of 1/SampleRate, it is rounded up to the nearest sample position.

Dependencies

This property applies when the FadingTechnique property is set to `'Sum of sinusoids'` and the InitialTimeSource property is set to `'Property'`.

Data Types: `double`

`RandomStream` — Source of random number stream

`'Global stream'` (default) | `'mt19937ar with seed'`

Source of the random number stream, specified as `'Global stream'` or `'mt19937ar with seed'`.

- `'Global stream'` -- The current global random number stream is used for normally distributed random number generation. In this case, the `reset` object function resets the filters only.
- `'mt19937ar with seed'` -- The mt19937ar algorithm is used for normally distributed random number generation. In this case, the `reset` object function resets the filters and also reinitializes the random number stream to the value of the Seed property.

Data Types: `char`

Seed — Initial seed of mt19937ar random number stream

`73` (default) | nonnegative integer

Initial seed of the mt19937ar random number stream, specified as a nonnegative integer. When the `reset` object function is called, the mt19937ar random number stream is reinitialized to the `Seed` value.

Dependencies

This property applies when you set the RandomStream property to `'mt19937ar with seed'`.

Data Types: `double`

`PathGainsOutputPort` — Option to output path gains

`false` (default) | `true`

Option to output path gains, specified as `false` or `true`. Set this property to `true` to output the channel path gains of the underlying fading process.

Data Types: `logical`

`Visualization` — Channel visualization

`'Off'` (default) | `'Impulse response'` | `'Frequency response'` | `'Impulse and frequency responses'` | `'Doppler spectrum'`

Channel visualization preference, specified as `'Off'`, `'Impulse response'`, `'Frequency response'`, `'Impulse and frequency responses'`, or `'Doppler spectrum'`. When visualization is on, the selected channel characteristics, such as impulse response or Doppler spectrum, display in a separate window. For more information, see Channel Visualization.

Dependencies

Visualization applies only when the FadingTechnique property is set to `'Filtered Gaussian noise'`.

`AntennaPairsToDisplay` — Transmit-receive antenna pair to display

`[1 1]` (default) | row vector

Transmit-receive antenna pair to display, specified as a 1-by-2 vector, where the first element corresponds to the desired transmit antenna and the second element corresponds to the desired receive antenna. At this time, only a single pair can be displayed.

Dependencies

This property applies when Visualization is not `Off`.

`PathsForDopplerDisplay` — Path for which the Doppler spectrum is displayed

`1` (default) | positive integer

Path for which the Doppler spectrum is displayed, specified as a positive integer from 1 to N_P, where N_P equals the value of the PathDelays property.

Dependencies

This property applies when Visualization is set to `'Doppler spectrum'`.

`SamplesToDisplay` — Percentage of samples to display

`25%` (default) | `10%` | `50%` | `100%`

Percentage of samples to display, specified as `10%`, `25%`, `50%`, or `100%`. Increasing the percentage improves display accuracy at the expense of simulation speed.

Dependencies

This property applies when Visualization is `'Impulse response'`, `'Frequency response'`, or `'Impulse and frequency responses'`.

Usage

Syntax

```
outsignal = mimochan(insignal)
outsignal = mimochan(insignal,seltx)
outsignal = mimochan(insignal,selrx)
outsignal = mimochan(insignal,seltx,selrx)
outsignal = mimochan( ___ ,initialtime)
[outsignal,pathgains] = mimochan( ___ )
```

Description

`outsignal = mimochan(insignal)` filters the input signal through the MIMO fading channel specified by `mimochan` and returns the result in `outsignal`.

`outsignal = mimochan(insignal,seltx)` turns on the transmit antennas selected by `seltx` for channel processing.

This syntax applies when you set the AntennaSelection property of the object to `'Tx'`.

For example, to select the first and third transmit antenna index as active:

```
mimochan = comm.MIMOChannel('AntennaSelection','Tx');
seltx = [1 0 1];
...
outsignal = mimochan(insignal,seltx);
```

`outsignal = mimochan(insignal,selrx)` turns on receive antennas, selected by `selrx` for channel processing.

This syntax applies when you set the AntennaSelection property of the object to `'Rx'`.

For example, to select the second receive antenna index as active:

```
mimochan = comm.MIMOChannel('AntennaSelection','Rx');
selrx = [0 1];
...
outsignal = mimochan(insignal,selrx);
```

`outsignal = mimochan(insignal,seltx,selrx)` turns on transmit and receive antennas, selected by `seltx` and `selrx` for channel processing.

This syntax applies when you set the AntennaSelection property of the object to `'Tx and Rx'`.

For example:

```
mimochan = comm.MIMOChannel('AntennaSelection','Tx and Rx');
seltx = [1 1];
selrx = [0 1];
...
outsignal = mimochan(insignal,selrx);
```

`outsignal = mimochan( ___ ,initialtime)` specifies a start time for the fading process.

This syntax applies when you set the FadingTechnique property of the object to `'Sum of sinusoids'` and the InitialTimeSource property of the object to `'Input port'`. The syntax supports input options from prior syntaxes.

`[outsignal,pathgains] = mimochan( ___ )` also returns the MIMO channel path gains for antenna selection schemes. The syntax supports input options from prior syntaxes.

Input Arguments

`insignal` — Input signal
scalar | vector | matrix

Input signal, specified as a scalar, an N_S element column vector, an N_S-by-N_T matrix, or an N_S-by-N_{ST} matrix.

- N_S is the number of samples.
- N_T is the number of transmit antennas. N_T is determined by the TransmitCorrelationMatrix or NumTransmitAntennas property values of the object.
- N_{ST} is the number of selected transmit antennas, as determined by the number of elements set to `1` in the vector provided to the seltx input.

The number of transmit antennas is determined by the TransmitCorrelationMatrix or NumTransmitAntennas property values of the object.

Data Types: `double` | `single`
Complex Number Support: Yes

`seltx` — Select active transmit antennas
binary vector

Select active transmit antennas, specified as a 1-by-N_T binary vector. N_T represents the number of transmit antennas. Elements set to `1` identify selected antenna indices and `0` identify nonselected antenna indices.

Data Types: `double`

`selrx` — Select active receive antennas
binary vector

Select active receive antennas, specified as a 1-by-N_R binary vector. N_R represents the number of receive antennas. Elements set to `1` identify selected antenna indices and `0` identify nonselected antenna indices.

Data Types: `double`

`initialtime` — Initial time offset
`0` (default) | nonnegative scalar

Initial time offset for the fading model in seconds, specified as a nonnegative scalar.

The initial time offset must be greater than the last frame end time. When `initialtime` is not a multiple of 1/SampleRate, it is rounded up to the nearest sample position.

Data Types: `double`

Output Arguments

`outsignal` — Output signal
matrix

Output data signal, returned as an N_S-by-N_R or N_S-by-N_{SR} matrix.

- N_S is the number of samples.

- N_R is the number of receive antennas. N_R is determined by the ReceiveCorrelationMatrix or NumReceiveAntennas property values of the object.
- N_{SR} is the number of selected receive antennas, as determined by the number of elements set to `1` in the vector provided to the selrx input.

`pathgains` — Output path gains
4-D array

Output path gains, returned as an N_S-by-N_P-by-N_T-by-N_R array with `NaN` values for the unselected transmit-receive antenna pairs.

- N_S is the number of samples.
- N_P equals the value of the PathDelays property.
- N_T is the number of transmit antennas.
- N_R is the number of receive antennas.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to comm.MIMOChannel

info	Characteristic information about fading channel object

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Note

- If you set the `RandomStream` property of the object to `'Global stream'`, the `reset` object function resets the filters only.
- If you set `RandomStream` to `'mt19937ar with seed'`, the `reset` object function resets the filters and also reinitializes the random number stream to the value of the `Seed` property.

Examples

Pass QPSK Data Through 4-by-2 MIMO Channel

Create a 4-by-2 MIMO channel by using the MIMO channel System object. Pass modulated and spatially encoded data through the channel.

Generate QPSK-modulated data.

```
data = randi([0 3],1000,1);
modData = pskmod(data,4,pi/4);
```

Create an orthogonal space-time block encoder to encode the modulated data into four spatially separated streams. Encode the data.

```
ostbc = comm.OSTBCEncoder('NumTransmitAntennas',4,'SymbolRate',1/2);
txSig = ostbc(modData);
```

Create a MIMO channel object, using name-value pairs to set the properties. The channel consists of two paths with a maximum Doppler shift of 5 Hz. Set the `SpatialCorrelationSpecification` property to `'None'`, which requires that you specify the number of transmit and receive antennas. Set the number of transmit antennas to 4 and the number of receive antennas to 2.

```
mimochannel = comm.MIMOChannel(...
    'SampleRate',1000, ...
    'PathDelays',[0 2e-3], ...
    'AveragePathGains',[0 -5], ...
    'MaximumDopplerShift',5, ...
    'SpatialCorrelationSpecification','None', ...
    'NumTransmitAntennas',4, ...
    'NumReceiveAntennas',2);
```

Pass the modulated and encoded data through the MIMO channel.

```
rxSig = mimochannel(txSig);
```

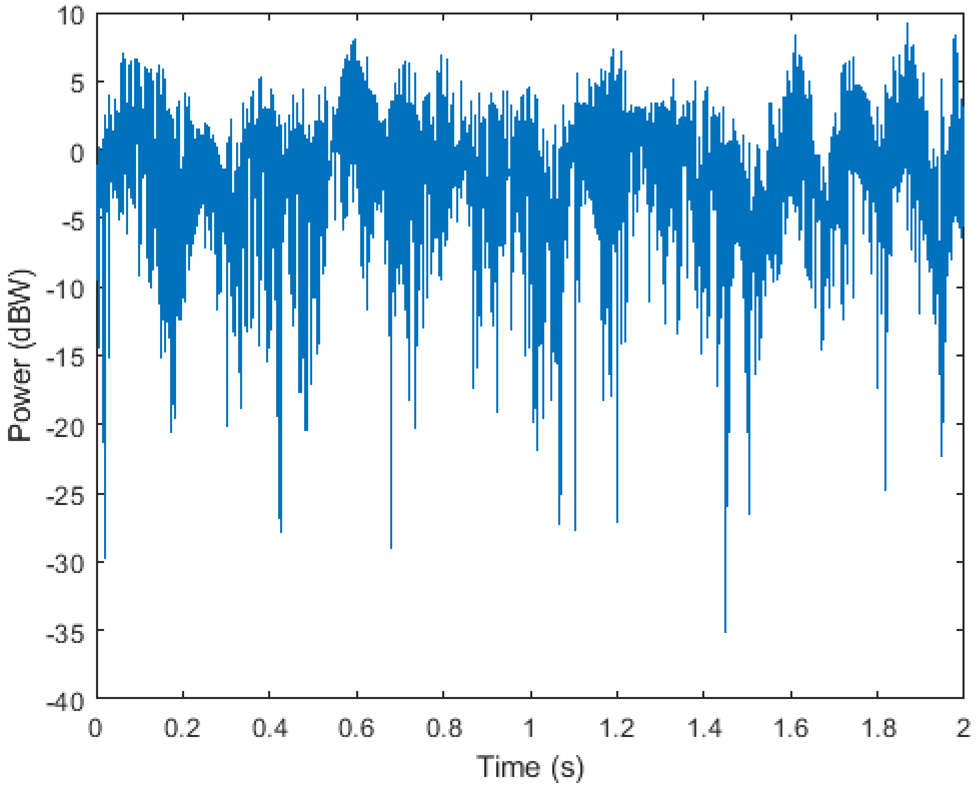
Create a time vector, `t`, to use for plotting the power of the received signal.

```
ts = 1/mimochannel.SampleRate;
t = (0:ts:(size(txSig,1)-1)*ts)';
```

Calculate and plot the power of the signal received by antenna 1.

```
pwrdB = 20*log10(abs(rxSig(:,1)));

plot(t,pwrdB)
xlabel('Time (s)')
ylabel('Power (dBW)')
```



Examine Spatial Correlation Characteristics of 2-by-2 Rayleigh Fading Channel

Without specifying antenna selection, filter PSK-modulated data through a 2-by-2 Rayleigh fading channel and examine the spatial correlation characteristics of the channel realization. Use the `release` object function to unlock the object to set the `AntennaSelection` property to `'Tx and Rx'` and then confirm the unselected transmit-receive antenna pairs.

Examine Spatial Correlation Characteristics Without Specifying Antenna Selection

Create a PSK modulator System object™ to modulate randomly generated data.

```
pskModulator = comm.PSKModulator;
modData = pskModulator(randi([0 pskModulator.ModulationOrder-1],1e5,1));
```

Split the modulated data into two spatial streams.

```
channelInput = reshape(modData,[2 5e4]).';
```

Create a 2-by-2 MIMO channel System object with two discrete paths. Each path has different transmit and receive correlation matrices, specified by the `TransmitCorrelationMatrix` and `ReceiveCorrelationMatrix` properties.

```
mimoChan = comm.MIMOChannel('SampleRate',1000, 'PathDelays',[0 1e-3], ...
    'AveragePathGains',[3 5], 'NormalizePathGains',false, 'MaximumDopplerShift',5, ...
    'TransmitCorrelationMatrix',cat(3,eye(2),[1 0.1;0.1 1]), ...
    'ReceiveCorrelationMatrix',cat(3,[1 0.2;0.2 1],eye(2)), ...
    'RandomStream','mt19937ar with seed', 'Seed',33, 'PathGainsOutputPort',true);
```

Filter the modulated data using the MIMO channel object.

```
[~,pathGains] = mimoChan(channelInput);
```

The transmit spatial correlation for the first discrete path at the first receive antenna is specified as an identity matrix in the `TransmitCorrelationMatrix` property. Confirm that the channel output `pathGains` exhibits the same statistical characteristics by using the `corrcoef` function.

```
disp('Tx spatial correlation, first path, first Rx:');
```

```
Tx spatial correlation, first path, first Rx:
```

```
disp(corrcoef(squeeze(pathGains(:,1,:,1))));
```

```
   1.0000 + 0.0000i   0.0357 - 0.0253i
   0.0357 + 0.0253i   1.0000 + 0.0000i
```

The transmit spatial correlation for the second discrete path at the second receive antenna is specified as `[1 0.1;0.1 1]` in the `TransmitCorrelationMatrix` property. Confirm that the channel output `pathGains` exhibits the same statistical characteristics.

```
disp('Tx spatial correlation, second path, second Rx:');
```

```
Tx spatial correlation, second path, second Rx:
```

```
disp(corrcoef(squeeze(pathGains(:,2,:,2))));
```

```
   1.0000 + 0.0000i   0.0863 + 0.0009i
   0.0863 - 0.0009i   1.0000 + 0.0000i
```

The receive spatial correlation for the first discrete path at the second transmit antenna is specified as `[1 0.2;0.2 1]` in the `ReceiveCorrelationMatrix` property. Confirm that the channel output `pathGains` exhibits the same statistical characteristics.

```
disp('Rx spatial correlation, first path, second Tx:');
```

```
Rx spatial correlation, first path, second Tx:
```

```
disp(corrcoef(squeeze(pathGains(:,1,2,:))));
```

```
   1.0000 + 0.0000i   0.2236 + 0.0550i
   0.2236 - 0.0550i   1.0000 + 0.0000i
```

The receive spatial correlation for the second discrete path at the first transmit antenna is specified as an identity matrix in the `ReceiveCorrelationMatrix` property. Confirm that the channel output `pathGains` exhibits the same statistical characteristics.

```
disp('Rx spatial correlation, second path, first Tx:');
```

```
Rx spatial correlation, second path, first Tx:
```

```
disp(corrcoef(squeeze(pathGains(:,2,1,:))));
```

```
   1.0000 + 0.0000i  -0.0088 - 0.0489i
  -0.0088 + 0.0489i   1.0000 + 0.0000i
```

Examine Spatial Correlation Characteristics Specifying Antenna Selection

Enable transmit and receive antenna selection for the mimoChan object. The input frame size is shortened to 100.

```
release(mimoChan);
mimoChan.AntennaSelection = 'Tx and Rx';
modData = pskModulator(randi([0 pskModulator.ModulationOrder-1],100,1));
```

Select the first transmit antenna and second receive antenna.

```
[channelOutput,pathGains] = mimoChan(modData,[1 0],[0 1]);
```

Confirm that the path gains that MATLAB® returns have NaN values for the unselected transmit-receive antenna pairs.

```
disp('Return 1 if the path gains for the second transmit antenna are NaN:');
```

```
Return 1 if the path gains for the second transmit antenna are NaN:
```

```
disp(isequal(isnan(squeeze(pathGains(:,:,2,:))), ones(100,2,2)));
```

```
   1
```

```
disp('Return 1 if the path gains for the first receive antenna are NaN:');
```

```
Return 1 if the path gains for the first receive antenna are NaN:
```

```
disp(isequal(isnan(squeeze(pathGains(:,:,:,1))), ones(100,2,2)));
```

```
   1
```

Display Impulse and Frequency Responses of Frequency Selective Channel

Create a frequency selective MIMO channel and display its impulse and frequency responses.

Set the sample rate to 10 MHz and specify path delays and gains using the extended vehicular A (EVA) channel parameters. Set the maximum Doppler shift to 70 Hz.

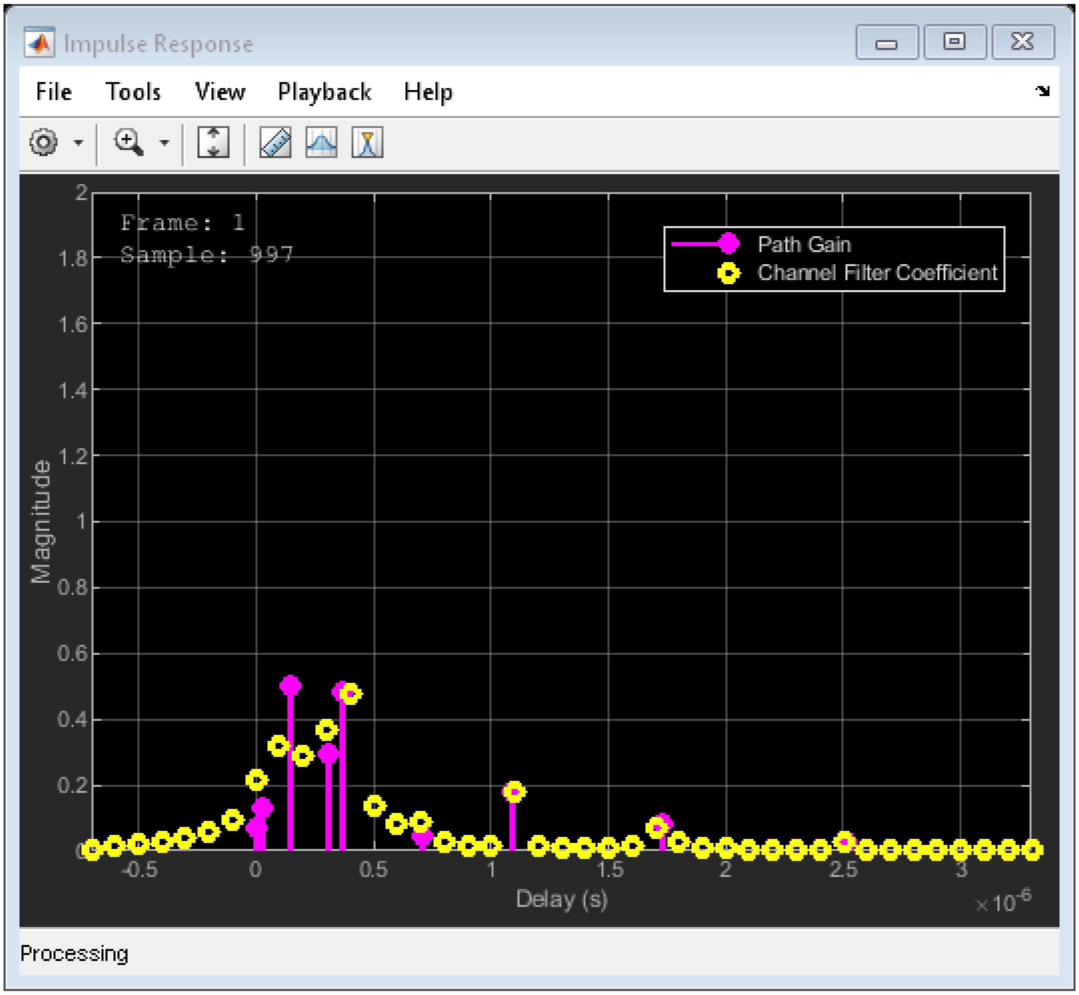
```
fs = 10e6;                                                  % Hz
pathDelays = [0 30 150 310 370 710 1090 1730 2510]*1e-9;    % sec
avgPathGains = [0 -1.5 -1.4 -3.6 -0.6 -9.1 -7 -12 -16.9];   % dB
fD = 70;                                                    % Hz
```

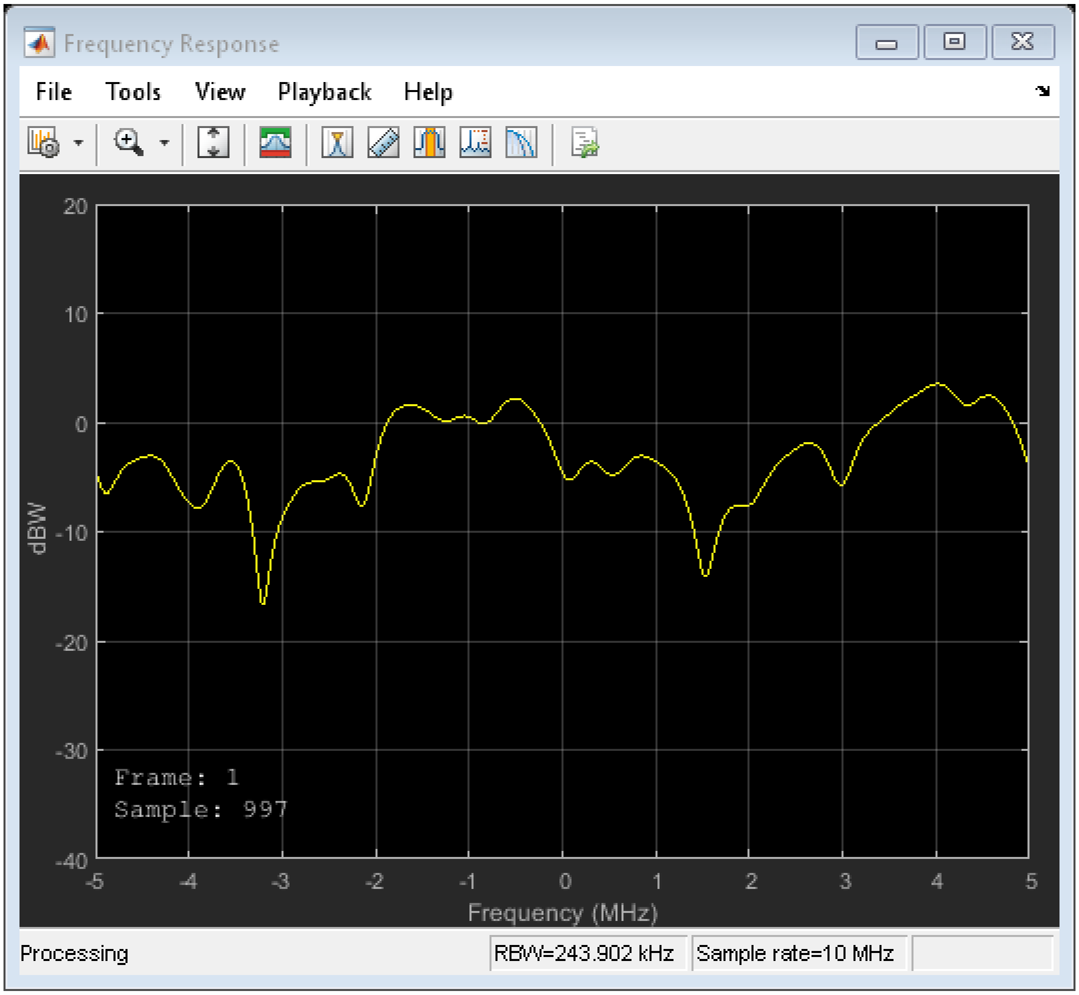
Create a 2x2 MIMO channel System object with the previously defined parameters and set the Visualization property to Impulse and frequency responses using name-value pairs. By default, the antenna pair corresponding to transmit antenna 1 and receive antenna 1 will be displayed.

```
mimoChan = comm.MIMOChannel('SampleRate',fs, ...
    'PathDelays',pathDelays, ...
    'AveragePathGains',avgPathGains, ...
    'MaximumDopplerShift',fD, ...
    'Visualization','Impulse and frequency responses');
```

Generate random binary data and pass it through the MIMO channel. The impulse response plot allows you to easily identify the individual paths and their corresponding filter coefficients. The frequency selective nature of the EVA channel is shown by the frequency response plot.

```
x = randi([0 1],1000,2);
y = mimoChan(x);
```





Release `mimoChan` and set the `AntennaPairsToDisplay` property to [2 1] to view the antenna pair corresponding to transmit antenna 2 and receive antenna 1. It is necessary to release the object as the property is non-tunable.

```
release(mimoChan)
mimoChan.AntennaPairsToDisplay = [2 1];
y = mimoChan(x);
```

Display Doppler for 2x2 MIMO Channel

Create and visualize the Doppler spectra of a MIMO channel having two paths.

Construct a cell array of Doppler structures to be used in creating the channel. The Doppler spectrum of the first path is set to have a bell shape while the second path is set to be flat.

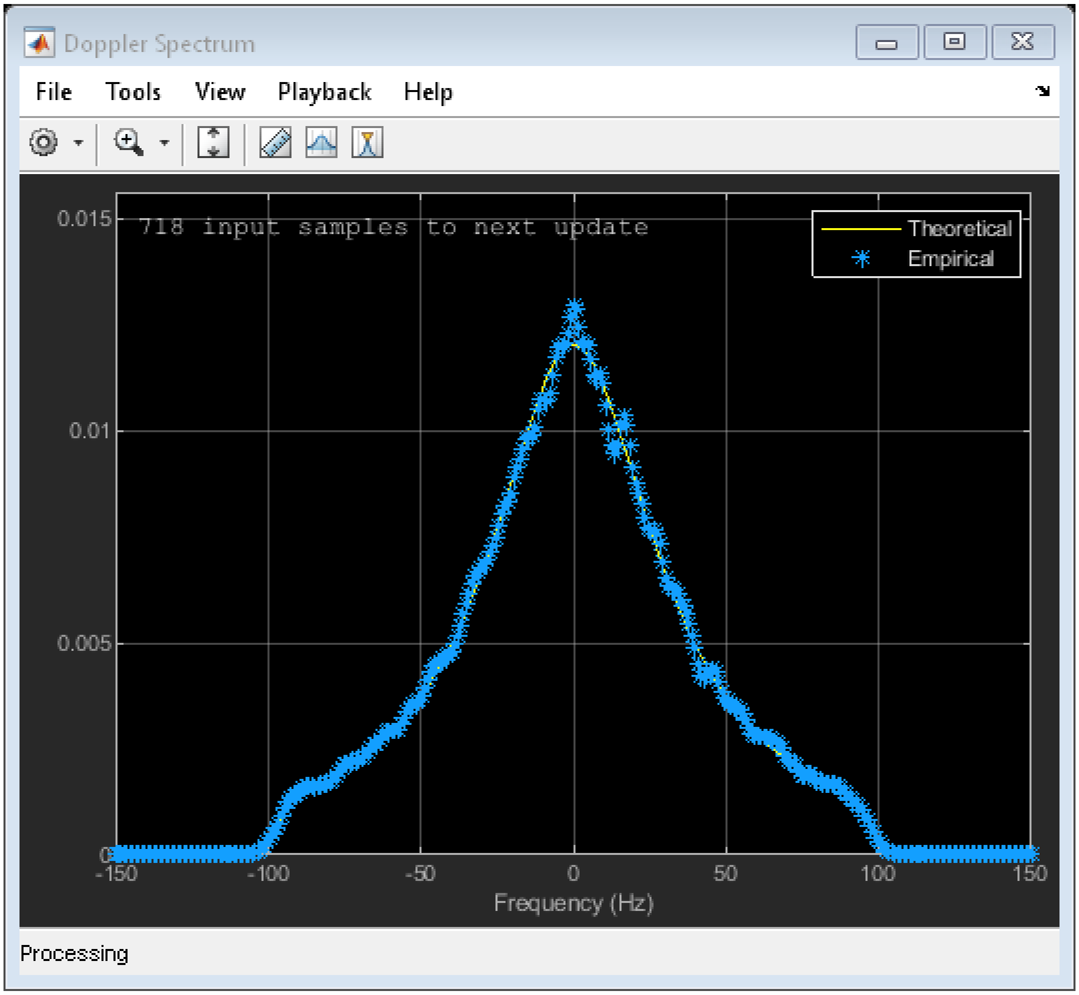
```
dp{1} = doppler('Bell');
dp{2} = doppler('Flat');
```

Create a default 2x2 MIMO channel with two paths and a 100 Hz maximum Doppler shift using name-value pairs. Set the `Visualization` property to `Doppler spectrum` and set `PathsForDopplerDisplay` to 1. The Doppler spectrum of the first path will be displayed.

```
mimoChan = comm.MIMOChannel('SampleRate',1000, ...
    'PathDelays',[0 0.002], ...
    'AveragePathGains',[0 -3], ...
    'MaximumDopplerShift',100, ...
    'DopplerSpectrum',dp, ...
    'Visualization','Doppler spectrum', ...
    'PathsForDopplerDisplay',1);
```

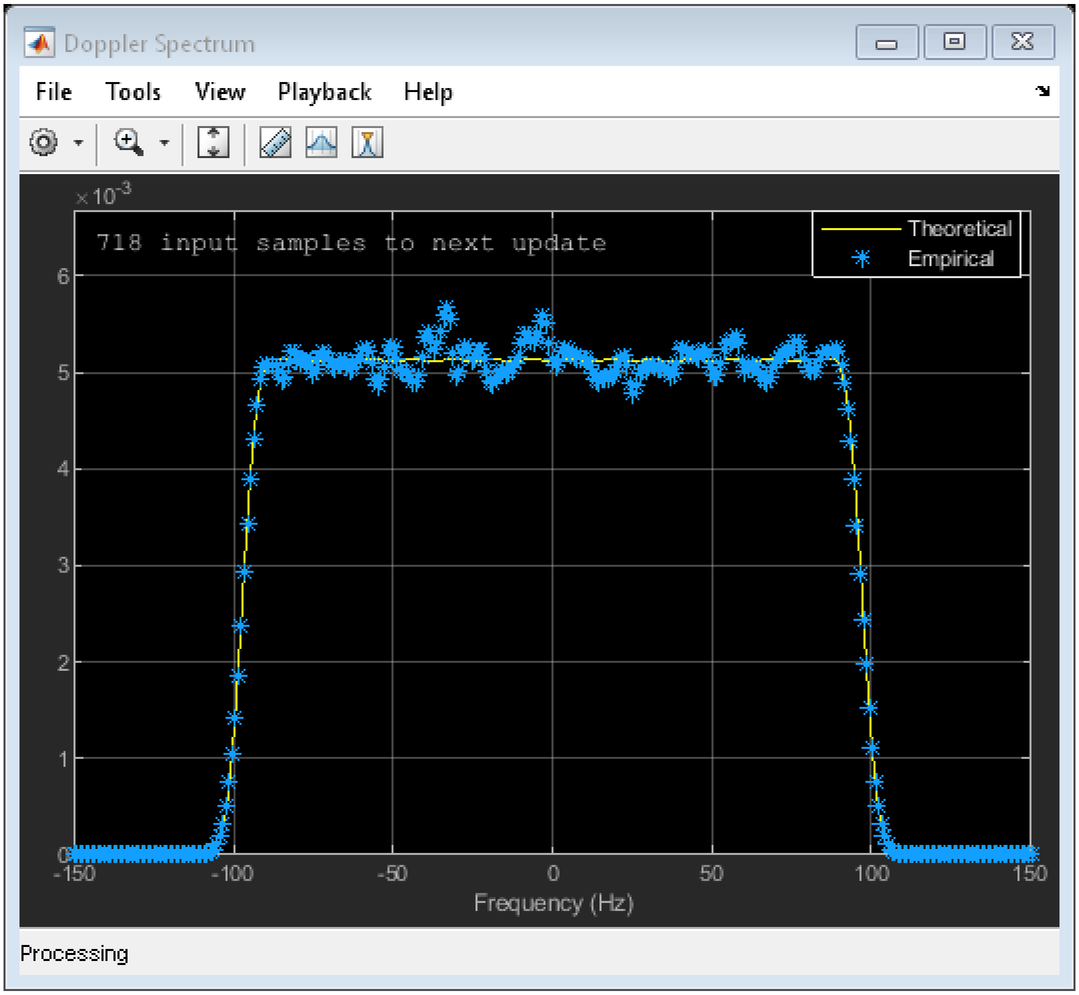
Pass random data through the MIMO channel to generate the Doppler spectrum of the first path. Since the Doppler spectrum plot only updates when its buffer is filled, the `mimoChan` function is invoked multiple times to improve the accuracy of the estimate. Observe that the spectrum has a bell shape and that its minimum and maximum frequencies fall within the limits set by `MaximumDopplerShift`.

```
for k = 1:25
    x = randi([0 1],10000,2);
    y = mimoChan(x);
end
```



Release `mimoChan` and set the `PathsForDopplerDisplay` property to 2. It is necessary to release the object as the property is non-tunable. Call the function multiple times to display the Doppler spectrum of the second path. Observe that the spectrum is flat.

```
release(mimoChan)
mimoChan.PathsForDopplerDisplay = 2;
for k = 1:25
    x = randi([0 1],10000,2);
    y = mimoChan(x);
end
```



Model MIMO Channel Using Sum-of-Sinusoids Technique

Create a MIMO channel object and pass data through it using the sum-of-sinusoids technique. The example demonstrates how the channel state is maintained in cases in which data is discontinuously transmitted.

Define the overall simulation time and three time segments for which data will be transmitted. In this case, the channel is simulated for 1 s with a 1000 Hz sampling rate. One 1000-sample, continuous data sequence is transmitted at time 0. Three 100-sample data packets are transmitted at time 0.1 s, 0.4 s, and 0.7 s.

```
t0 = 0:0.001:0.999;   % Transmission 0
t1 = 0.1:0.001:0.199; % Transmission 1
t2 = 0.4:0.001:0.499; % Transmission 2
t3 = 0.7:0.001:0.799; % Transmission 3
```

Generate random binary data corresponding to the previously defined time intervals.

```
d0 = randi([0 1],1000,2);  % 1000 samples
d1 = randi([0 1],100,2);   % 100 samples
```

```
d2 = randi([0 1],100,2);   % 100 samples
d3 = randi([0 1],100,2);   % 100 samples
```

Create a flat fading 2x2 MIMO channel System object with the `Sum of sinusoids` fading technique. So that results can be repeated, specify a seed using a name-value pair. As the `InitialTime` property is not specified, the fading channel will be simulated from time 0. Enable the path gains output port.

```
mimoChan1 = comm.MIMOChannel('SampleRate',1000, ...
    'MaximumDopplerShift',5, ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',17, ...
    'FadingTechnique','Sum of sinusoids', ...
    'PathGainsOutputPort',true);
```

Create a clone of the MIMO channel System object. Set the `InitialTimeSource` property to `Input port` so that the fading channel offset time can be specified as an input argument to the `mimoChan` function.

```
mimoChan2 = clone(mimoChan1);
mimoChan2.InitialTimeSource = 'Input port';
```

Pass random binary data through the first channel object, `mimoChan1`. Data is transmitted over all 1000 time samples. For this example, only the complex path gain is needed.

```
[~,pg0] = mimoChan1(d0);
```

Pass random data through the second channel object, `mimoChan2`, where the initial time offsets are provided as input arguments.

```
[~,pg1] = mimoChan2(d1,0.1);
[~,pg2] = mimoChan2(d2,0.4);
[~,pg3] = mimoChan2(d3,0.7);
```

Compare the number of samples processed by the two channels using the `info` method. You can see that 1000 samples were processed by `mimoChan1` while only 300 were processed by `mimoChan2`.

```
G = info(mimoChan1);
H = info(mimoChan2);
[G.NumSamplesProcessed H.NumSamplesProcessed]
```

```
ans = 1×2

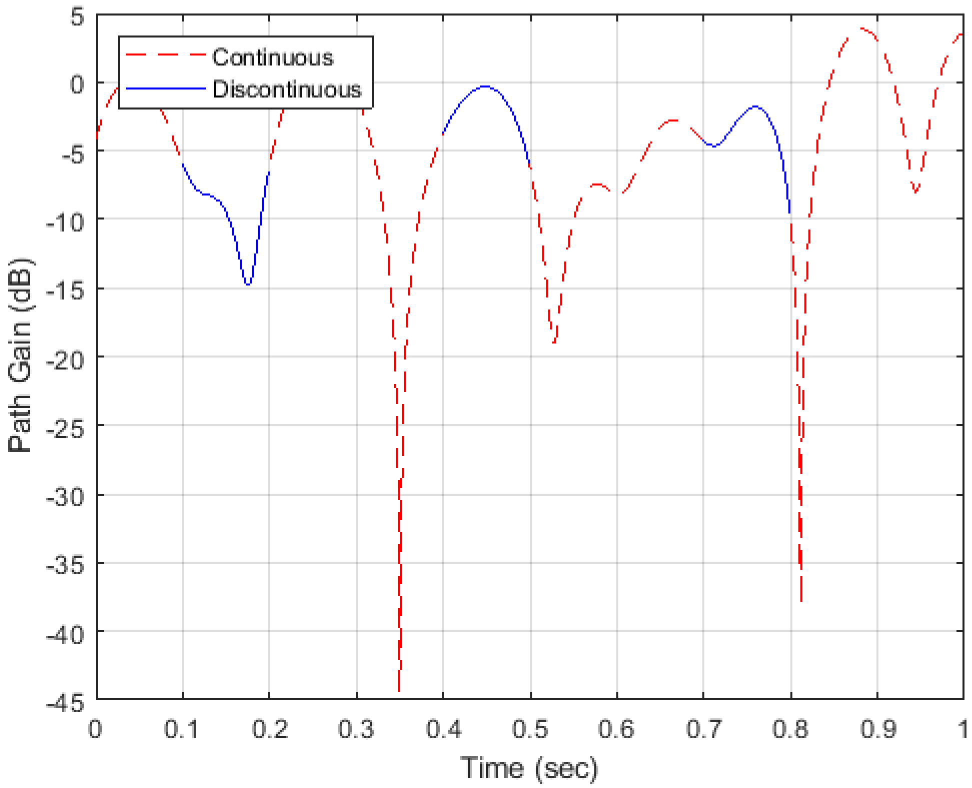
        1000         300
```

Convert the path gains into decibels for the path corresponding to the first transmit and first receive antenna.

```
pathGain0 = 20*log10(abs(pg0(:,1,1,1)));
pathGain1 = 20*log10(abs(pg1(:,1,1,1)));
pathGain2 = 20*log10(abs(pg2(:,1,1,1)));
pathGain3 = 20*log10(abs(pg3(:,1,1,1)));
```

Plot the path gains for the continuous and discontinuous cases. Observe that the gains for the three segments perfectly match the gain for the continuous case. The alignment of the two highlights that the sum-of-sinusoids technique is ideally suited to the simulation of packetized data as the channel characteristics are maintained even when data is not transmitted.

```
plot(t0,pathGain0,'r--')
hold on
plot(t1,pathGain1,'b')
plot(t2,pathGain2,'b')
plot(t3,pathGain3,'b')
grid
xlabel('Time (sec)')
ylabel('Path Gain (dB)')
legend('Continuous','Discontinuous','location','nw')
```



Calculate Execution Time Advantage Using Sum of Sinusoids

Demonstrate the advantage of using the sum of sinusoids fading technique when simulating a channel with burst data.

Set the simulation parameters such that the sampling rate is 100 kHz, the total simulation time is 100 seconds, and the duty cycle for the burst data is 25%.

```
fs = 1e5;            % Hz
tsim = 100;          % seconds
dutyCycle = 0.25;
```

Create a flat fading 2x2 MIMO channel object using the default `Filtered Gaussian noise` technique.

```
fgn = comm.MIMOChannel('SampleRate',fs);
```

Create a similar MIMO channel object using the `Sum of sinusoids` technique where the fading process start times are given as an input argument.

```
sos = comm.MIMOChannel('SampleRate',fs, ...
    'FadingTechnique','Sum of sinusoids', ...
    'NumSinusoids',48, ...
    'InitialTimeSource','Input port');
```

Run a continuous sequence of random bits through the filtered Gaussian noise MIMO channel object. Use the tic/toc stopwatch timer functions to measure the execution time of the function call.

```
tic
y = fgn(randi([0 1],fs*tsim,2));
tFGN = toc;
```

To transmit a data burst each second, pass random bits through the sum of sinusoids MIMO channel object by calling the `sos` function inside of a for loop. Use the tic/toc stopwatch timer to measure the execution time.

```
tic
for k = 1:tsim
    z = sos(randi([0 1],fs*dutyCycle,2),0.5+(k-1));
end
tSOS = toc;
```

Compare the ratio of the sum of sinusoids execution time to the filtered Gaussian noise execution time. The ratio is less than one, which indicates that the sum of sinusoids technique is faster.

```
tSOS/tFGN
```

```
ans = 0.2713
```

Algorithms

The fading processing per link is described in Methodology for Simulating Multipath Fading Channels and assumes the same parameters for all ($N_T \times N_R$) links of the MIMO channel. Each link comprises all multipaths for that link.

The Kronecker Model

The Kronecker model assumes that the spatial correlations at the transmit and receive sides are separable. Equivalently, the direction of departure (DoD) and directions of arrival (DoA) spectra are assumed to be separable. The full correlation matrix is:

$$R_H = E[R_t \otimes R_r]$$

- The ⊗ symbol represents the Kronecker product.
- R_t represents the correlation matrix at the transmit side: $R_t = E\left[H^H H\right]$, of size N_T-by-N_T.
- R_r represents the correlation matrix at the receive side: $R_r = E\left[H H^H\right]$, of size N_R-by-N_R.

You can obtain a realization of the MIMO channel matrix as:

$$H = R_r^{\frac{1}{2}} A R_t^{\frac{1}{2}}$$

A is an N_R-by-N_T matrix of independent identically distributed complex Gaussian variables with zero mean and unit variance.

Cutoff Frequency Factor

The cutoff frequency factor, f_c, is determined for different Doppler spectrum types.

- For any Doppler spectrum type other than Gaussian and biGaussian, f_c equals 1.
- For a `doppler('Gaussian')` spectrum type, f_c equals `NormalizedStandardDeviation` × $\sqrt{2\log 2}$.
- For a `doppler('BiGaussian')` spectrum type:
  - If the `PowerGains(1)` and `NormalizedCenterFrequencies(2)` field values are both `0`, then f_c equals `NormalizedStandardDeviation(1)` × $\sqrt{2\log 2}$.
  - If the `PowerGains(2)` and `NormalizedCenterFrequencies(1)` field values are both `0`, then f_c equals `NormalizedStandardDeviation(2)` × $\sqrt{2\log 2}$.
  - If the `NormalizedCenterFrequencies` field value is `[0,0]` and the `NormalizedStandardDeviation` field has two identical elements, then f_c equals `NormalizedStandardDeviation(1)` × $\sqrt{2\log 2}$.
  - In all other cases, f_c equals 1.

Antenna Selection

When the object is in antenna selection mode, it uses the following algorithms to process an input signal:

- All random path gains are always generated and keep evolving for each link, whether or not a given link is selected. The path gain values output for the non-selected links are populated with `NaN`.
- The spatial correlation only applies to the selected transmit and/or receive antennas, and the correlation coefficients are the corresponding entries in the transmit, receive, or combined correlation matrices. In other words, the spatial correlation matrix for the selected transmit or receive antennas is a submatrix of the transmit, receive, or combined spatial correlation matrix property value.
- For signal paths associated with nonactive antennas, a signal with zero power is transmitted to the channel filter.
- Channel output normalization happens over the number of selected receive antennas.

comm.MLSEEqualizer

Package: `comm`

Equalize using maximum likelihood sequence estimation

Description

The `MLSEEqualizer` object uses the Viterbi algorithm to equalize a linearly modulated signal through a dispersive channel. The object processes input frames and outputs the maximum likelihood sequence estimate (MLSE) of the signal. This processing uses an estimate of the channel modeled as a finite impulse response (FIR) filter.

To equalize a linearly modulated signal and output the maximum likelihood sequence estimate:

1. Define and set up your maximum likelihood sequence estimate equalizer object. See "Construction" on page 3-986.
2. Call `step` to equalize a linearly modulated signal and output the maximum likelihood sequence estimate according to the properties of `comm.MLSEEqualizer`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.MLSEEqualizer` creates a maximum likelihood sequence estimation equalizer (MLSEE) System object, `H`. This object uses the Viterbi algorithm and a channel estimate to equalize a linearly modulated signal that has been transmitted through a dispersive channel.

`H = comm.MLSEEqualizer(Name,Value)` creates an MLSEE object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.MLSEEqualizer(CHANNEL,Name,Value)` creates an MLSEE object, `H`. This object has the `Channel` property set to `CHANNEL`, and the other specified properties set to the specified values.

Properties

`ChannelSource`

Source of channel coefficients

Specify the source of the channel coefficients as one of `Input port` | `Property`. The default is `Property`.

`Channel`

Channel coefficients

Specify the channel as a numeric, column vector containing the coefficients of an FIR filter. The default is [1;0.7;0.5;0.3]. The length of this vector determines the memory length of the channel. This must be an integer multiple of the samples per symbol, that you specify in the SamplesPerSymbol on page 3-0 property. This property applies when you set the ChannelSource on page 3-0 property to Property.

Constellation

Input signal constellation

Specify the constellation of the input modulated signal as a complex vector. The default is [1+1i -1+1i -1-1i 1-1i].

TracebackDepth

Traceback depth of Viterbi algorithm

Specify the number of trellis branches (the number of symbols), the Viterbi algorithm uses to construct each traceback path. The default is 21. The traceback depth influences the decoding accuracy and delay. The decoding delay represents the number of zero symbols that precede the first decoded symbol in the output. When you set the TerminationMethod on page 3-0 property to Continuous, the decoding delay equals the number of zero symbols of this property. When you set the TerminationMethod property to Truncated, there is no output delay.

TerminationMethod

Termination method of Viterbi algorithm

Specify the termination method of the Viterbi algorithm as one of Continuous | Truncated. The default is Truncated. When you set this property to Continuous, the object initializes the Viterbi algorithm metrics of all the states to 0 in the first call to the step method. Then, the object saves its internal state metric at the end of each frame, for use with the next frame. When you set this property to Truncated, the object resets at every frame. The Viterbi algorithm processes each frame of data independently, resetting the state metric at the end of each frame. The traceback path always starts at the state with the minimum metric. The initialization of the state metrics depends on whether you specify a preamble or postamble. If you set the PreambleSource on page 3-0 property to None, the object initializes the metrics of all the states to 0 at the beginning of each data frame. If you set the PreambleSource property to Property, the object uses the preamble that you specify at the Preamble on page 3-0 property, to initialize the state metrics at the beginning of each data frame. When you specify a preamble, the traceback path ends at one of the states represented by that preamble. If you set the PostambleSource on page 3-0 property to None, the traceback path starts at the state with the smallest metric. If you set the PostambleSource property to Property, the traceback path begins at the state represented by the postamble that you specify at the Postamble on page 3-0 property. If the postamble does not decode to a unique state, the decoder identifies the smallest of all possible decoded states that are represented by the postamble. The decoder then begins traceback decoding at that state. When you set this property to Truncated, the step method input data signal must contain at least TracebackDepth on page 3-0 symbols, not including an optional preamble.

ResetInputPort

Enable equalizer reset input

Set this property to true to enable an additional input to the step method. The default is false. When this input is a nonzero, double-precision or logical scalar value, the object resets the states of the equalizer. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous`.

PreambleSource

Source of preamble

Specify the source of the preamble that is expected to precede the input signal. Choose from `None` | `Property`. The default is `None`. Set this property to `Property` to specify a preamble using the `Preamble` on page 3-0 property. This property applies when you set the `TerminationMethod` on page 3-0 property to `Truncated`.

Preamble

Preamble that precedes input signals

Specify a preamble that is expected to precede the data in the input signal as an integer, row vector. The default is `[0 3 2 1]`. The values of the preamble should be between `0` and *M*-`1`, where *M* is the length of the signal constellation that you specify in the `Constellation` on page 3-0 property. An integer value of *k*–`1` in the vector corresponds to the *k*-th entry in the vector stored in the `Constellation` property. This property applies when you set the `TerminationMethod` on page 3-0 property to `Truncated` and the `PreambleSource` on page 3-0 property to `Property`.

PostambleSource

Source of postamble

Specify the source of the postamble that is expected to follow the input signal. Choose from `None` | `Property`. The default is `None`. Set this property to `Property` to specify a postamble in the `Postamble` on page 3-0 property. This property applies when you set the `TerminationMethod` on page 3-0 property to `Truncated`.

Postamble

Postamble that follows input signals

Specify a postamble that is expected to follow the data in the input signal as an integer row vector. The default is `[0 2 3 1]`. The values of the postamble should be between `0` and *M*–`1`. In this case, *M* indicates the length of the `Constellation` on page 3-0 property. An integer value of *k*–`1` in the vector corresponds to the *k*-th entry in the vector specified in the `Constellation` property. This property applies when you set the `TerminationMethod` on page 3-0 property to `Truncated` and the `PostambleSource` on page 3-0 property to `Property`. The default is `[0 2 3 1]`.

SamplesPerSymbol

Number of samples per symbol

Specify the number of samples per symbol in the input signal as an integer scalar value. The default is `1`.

Methods

reset	Reset states of MLSEE object
step	Equalize using maximum likelihood sequence estimation

Common to All System Objects	
release	Allow System object property value changes

Examples

MLSE Equalize QPSK Signal Through Dispersive Channel

This example shows how to use an MLSE equalizer to remove the effects of a frequency-selective channel.

Specify static channel coefficients.

```
chCoeffs = [.986; .845; .237; .12345+.31i];
```

Create an MLSE equalizer object. Create an error rate calculator object.

```
mlse = comm.MLSEEqualizer('TracebackDepth',10,...
    'Channel',chCoeffs,'Constellation',pskmod(0:3,4,pi/4));
errorRate = comm.ErrorRate;
```

The main processing loop includes these steps:

- Data generation
- QPSK modulation
- Channel filtering
- Signal equalization
- QPSK demodulation
- Error computation

```
for n = 1:50
    data= randi([0 3],100,1);
    modSignal = pskmod(data,4,pi/4,'gray');

    % Introduce channel distortion.
    chanOutput = filter(chCoeffs,1,modSignal);

    % Equalize the channel output and demodulate.
    eqSignal = mlse(chanOutput);
    demodData = pskdemod(eqSignal,4,pi/4,'gray');

    % Compute BER.
    errorStats = errorRate(data,demodData);
end
```

Display the bit error rate and the number of errors.

```
ber = errorStats(1)
numErrors = errorStats(2)
```

```
ber =

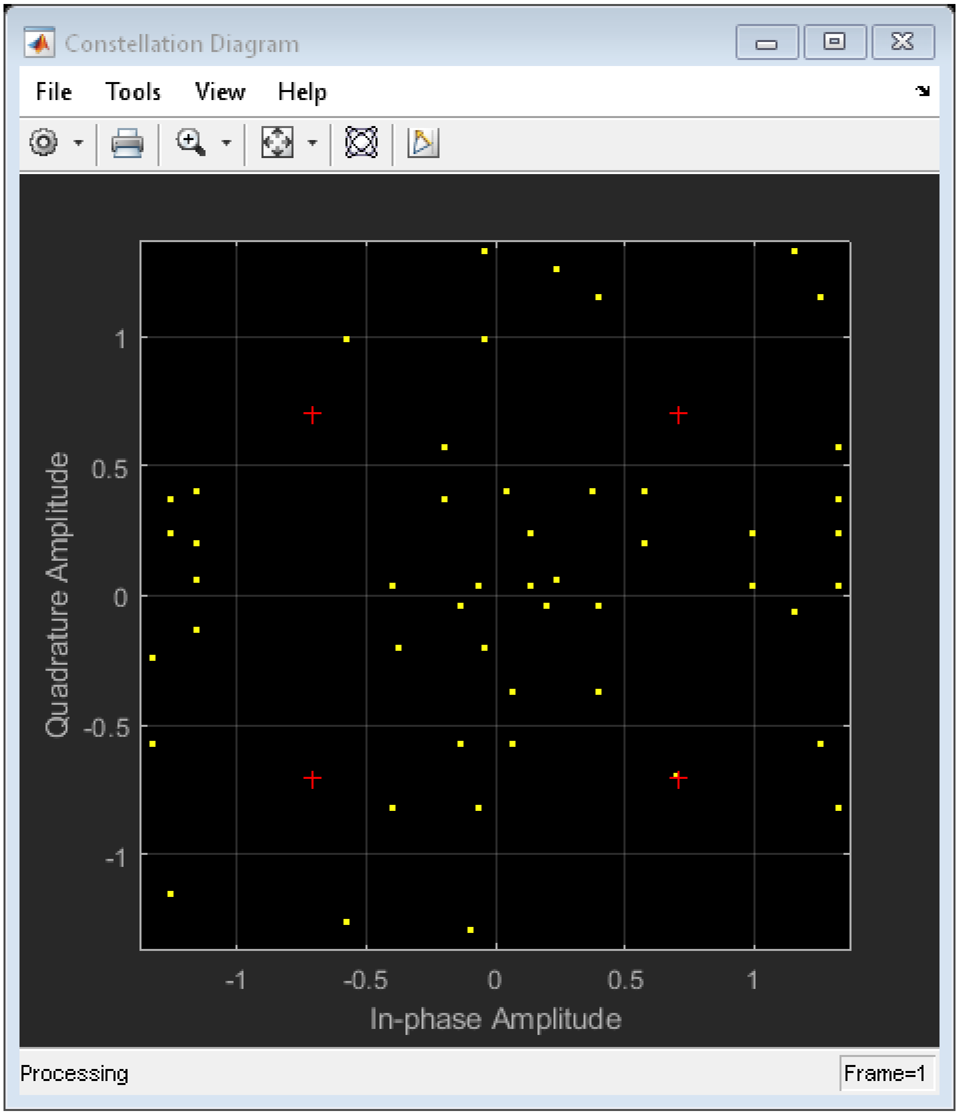
     0

numErrors =

     0
```

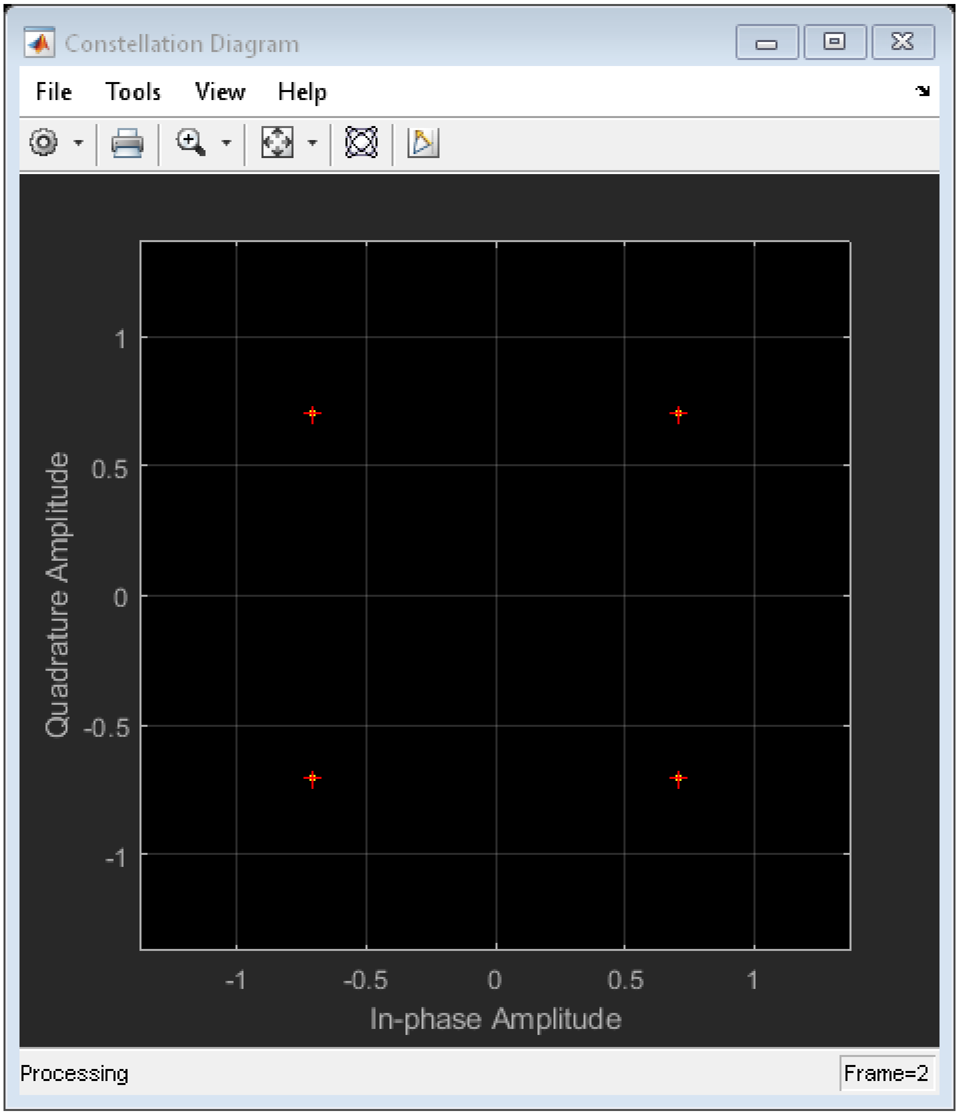
Plot the signal constellation prior to equalization.

```
constDiagram = comm.ConstellationDiagram;
constDiagram(chanOutput)
```



Plot the signal constellation after equalization.

```
constDiagram(eqSignal)
```



The equalized symbols align perfectly with the QPSK reference constellation.

Algorithms

This object implements the algorithm, inputs, and outputs described on the MLSE Equalizer block reference page. The object properties correspond to the block parameters.

```

Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Y = step(H,X) equalizes the linearly modulated data input, X, using the Viterbi algorithm. The step method outputs Y, the maximum likelihood sequence estimate of the signal. Input X must be a column vector of data type double or single.

Y = step(H,X,CHANNEL) uses CHANNEL as the channel coefficients when you set the ChannelSource property to 'Input port'. The channel coefficients input, CHANNEL, must be a numeric, column vector containing the coefficients of an FIR filter in descending order of powers of z. The length of this vector is the channel memory, which must be an integer multiple of the samples per input symbol specified in the SamplesPerSymbol property.

Y = step(H,X,RESET) uses RESET as the reset signal when you set the TerminationMethod property to 'Continuous' and the ResetInputPort property to true. The object resets when RESET has a non-zero value. RESET must be a double precision or logical scalar. You can combine optional input arguments when you set their enabling properties. Optional inputs must be listed in the same order as the order of the enabling properties. For example, Y = step(H,X,CHANNEL,RESET).

Note obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

comm.MSKDemodulator

Package: `comm`

Demodulate using MSK method and the Viterbi algorithm

Description

The comm.MSKDemodulator object demodulates a signal that was modulated using the minimum shift keying method. The object expects the input signal to be a baseband representation of a coherent modulated signal with no precoding. The initial phase offset property sets the initial phase of the modulated waveform.

To demodulate a signal that was modulated using minimum shift keying:

1. Define and set up your MSK demodulator object. See “Construction” on page 3-995.
2. Call `step` to demodulate the signal according to the properties of `comm.MSKDemodulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.MSKDemodulator` creates a demodulator System object, `H`. This object demodulates the input minimum shift keying (MSK) modulated data using the Viterbi algorithm.

`H = comm.MSKDemodulator(Name,Value)` creates an MSK demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`BitOutput`

Output data as bits

Specify whether the output consists of groups of bits or integer values. The default is `false`.

When you set this property to `false`, the `step` method outputs a column vector with a length equal to *N*/`SamplesPerSymbol` on page 3-0 . *N* represents the length of the input signal, which is the number of input baseband modulated symbols. The elements of the output vector are `-1` or `1`.

When you set the `BitOutput` on page 3-0 property to `true`, the `step` method outputs a binary column vector with a length equal to *N*/`SamplesPerSymbol`. The vector elements are bit values of `0` or `1`.

InitialPhaseOffset

Initial phase offset

Specify the initial phase offset of the input modulated waveform in radians as a real, numeric scalar value. The default is 0.

SamplesPerSymbol

Number of samples per input symbol

Specify the expected number of samples per input symbol as a positive, integer scalar value. The default is 8.

TracebackDepth

Traceback depth for Viterbi algorithm

Specify the number of trellis branches that the Viterbi algorithm uses to construct each traceback path as a positive, integer scalar value. The default is 16. The value of this property is also the output delay This value indicates number of zero symbols that precede the first meaningful demodulated symbol in the output.

OutputDataType

Data type of output

Specify the output data type as one of int8 | int16 | int32 | double, when you set the BitOutput on page 3-0 property to false. The default is double.

When you set the BitOutput property to true, specify the output data type as one of logical | double.

Methods

reset	Reset states of the MSK demodulator object
step	Demodulate using MSK method and the Viterbi algorithm

Common to All System Objects	
release	Allow System object property value changes

Examples

Demodulate an MSK signal with bit inputs and phase offset

```
% Create an MSK modulator, an AWGN channel, and an MSK demodulator.  Use a
% phase offset of pi/4.
 hMod = comm.MSKModulator('BitInput', true, ...
                    'InitialPhaseOffset', pi/4);
    hAWGN = comm.AWGNChannel('NoiseMethod', ...
                    'Signal to noise ratio (SNR)','SNR',0);
    hDemod = comm.MSKDemodulator('BitOutput', true, ...
                    'InitialPhaseOffset', pi/4);
 % Create an error rate calculator, account for the delay caused by the Viterbi algorithm
    hError = comm.ErrorRate('ReceiveDelay', hDemod.TracebackDepth);
    for counter = 1:100
      % Transmit 100 3-bit words
      data = randi([0 1],300,1);
      modSignal = step(hMod, data);
      noisySignal = step(hAWGN, modSignal);
      receivedData = step(hDemod, noisySignal);
      errorStats = step(hError, data, receivedData);
    end
    fprintf('Error rate = %f\nNumber of errors = %d\n', ...
      errorStats(1), errorStats(2))
```

```
Error rate = 0.000000
Number of errors = 0
```

Map Binary Data to GMSK Signal

This example illustrates the mapping of binary sequences of zeros and ones to the output of a GMSK modulator. The relationship also applies for MSK modulation.

Create a GMSK modulator that accepts binary inputs. Specify the pulse length and samples per symbol to be 1.

```
gmsk = comm.GMSKModulator('BitInput',true,'PulseLength',1,'SamplesPerSymbol',1);
```

Create an input sequence of all zeros. Modulate the sequence.

```
x = zeros(5,1);
y = gmsk(x)
```

```
y = 5×1 complex

   1.0000 + 0.0000i
  -0.0000 - 1.0000i
  -1.0000 + 0.0000i
   0.0000 + 1.0000i
   1.0000 - 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to better show the trend.

```
theta = unwrap(angle(y))
```

```
theta = 5×1

         0
   -1.5708
   -3.1416
   -4.7124
   -6.2832
```

A sequence of zeros causes the phase to shift by -π/2 between samples.

Reset the modulator. Modulate an input sequence of all ones.

```
reset(gmsk)
x = ones(5,1);
y = gmsk(x)
```

```
y = 5×1 complex

   1.0000 + 0.0000i
  -0.0000 + 1.0000i
  -1.0000 - 0.0000i
   0.0000 - 1.0000i
   1.0000 + 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to better show the trend.

```
theta = unwrap(angle(y))
```

```
theta = 5×1

         0
    1.5708
    3.1416
    4.7124
    6.2832
```

A sequence of ones causes the phase to shift by +π/2 between samples.

Algorithms

This object implements the algorithm, inputs, and outputs described on the MSK Demodulator Baseband block reference page. The object properties correspond to the block parameters. For MSK the phase shift per symbol is π/2, which is a modulation index of 0.5.

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `MSKDemodulator` object, `H`.

step

System object: comm.MSKDemodulator
Package: comm

Demodulate using MSK method and the Viterbi algorithm

Syntax

Y = step(H,X)

Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Y = step(H,X) demodulates input data, X, with the MSK demodulator System object, H, and returns Y. X must be a double or single precision column vector with a length equal to an integer multiple of the number of samples per symbol you specify in the SamplesPerSymbol property.

Note obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

comm.MSKModulator

Package: comm

Modulate using MSK method

Description

The MSKModulator object modulates using the minimum shift keying method. The output is a baseband representation of the modulated signal. The initial phase offset property sets the initial phase of the output waveform, measured in radians.

To modulate a signal using minimum shift keying:

1. Define and set up your MSK modulator object. See "Construction" on page 3-1001.
2. Call step to modulate the signal according to the properties of comm.MSKModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.MSKModulator creates a modulator System object, H. This object modulates the input signal using the minimum shift keying (MSK) modulation method.

H = comm.MSKModulator(Name,Value) creates an MSK modulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

BitInput

Assume bit inputs

Specify whether the input is bits or integers. The default is false.

When you set the BitInput on page 3-0 property to false, the step method input must be a column vector with a double-precision or signed integer data type and of values equal to -1 or 1.

When you set the BitInput property to true, the step method input requires double-precision or logical data type column vector of 0s and 1s.

InitialPhaseOffset

Initial phase offset

Specify the initial phase of the modulated waveform in radians as a real, numeric scalar value. The default is `0`.

`SamplesPerSymbol`

Number of samples per output symbol

Specify the upsampling factor at the output as a real, positive, integer scalar value. The default is `8`. The upsampling factor indicates the number of output samples that the step method produces for each input sample.

`OutputDataType`

Data type of output

Specify output data type as one of `double` | `single`. The default is `double`.

Methods

reset	Reset states of the MSK modulator object
step	Modulate using MSK method

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Modulate an MSK signal with bit inputs and phase offset

```
% Create an MSK modulator, an AWGN channel, and an MSK demodulator.  Use a
% phase offset of pi/4.
 hMod = comm.MSKModulator('BitInput', true, ...
                   'InitialPhaseOffset', pi/4);
    hAWGN = comm.AWGNChannel('NoiseMethod', ...
                   'Signal to noise ratio (SNR)','SNR',0);
    hDemod = comm.MSKDemodulator('BitOutput', true, ...
                   'InitialPhaseOffset', pi/4);
 % Create an error rate calculator, account for the delay caused by the Viterbi algorithm
    hError = comm.ErrorRate('ReceiveDelay', hDemod.TracebackDepth);
    for counter = 1:100
      % Transmit 100 3-bit words
      data = randi([0 1],300,1);
      modSignal = step(hMod, data);
      noisySignal = step(hAWGN, modSignal);
      receivedData = step(hDemod, noisySignal);
      errorStats = step(hError, data, receivedData);
    end
    fprintf('Error rate = %f\nNumber of errors = %d\n', ...
      errorStats(1), errorStats(2))
```

```
Error rate = 0.000000
Number of errors = 0
```

Map Binary Data to GMSK Signal

This example illustrates the mapping of binary sequences of zeros and ones to the output of a GMSK modulator. The relationship also applies for MSK modulation.

Create a GMSK modulator that accepts binary inputs. Specify the pulse length and samples per symbol to be 1.

```
gmsk = comm.GMSKModulator('BitInput',true,'PulseLength',1,'SamplesPerSymbol',1);
```

Create an input sequence of all zeros. Modulate the sequence.

```
x = zeros(5,1);
y = gmsk(x)
```

```
y = 5×1 complex

   1.0000 + 0.0000i
  -0.0000 - 1.0000i
  -1.0000 + 0.0000i
   0.0000 + 1.0000i
   1.0000 - 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to better show the trend.

```
theta = unwrap(angle(y))
```

```
theta = 5×1

         0
   -1.5708
   -3.1416
   -4.7124
   -6.2832
```

A sequence of zeros causes the phase to shift by -π/2 between samples.

Reset the modulator. Modulate an input sequence of all ones.

```
reset(gmsk)
x = ones(5,1);
y = gmsk(x)
```

```
y = 5×1 complex

   1.0000 + 0.0000i
  -0.0000 + 1.0000i
  -1.0000 - 0.0000i
   0.0000 - 1.0000i
   1.0000 + 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to better show the trend.

```
theta = unwrap(angle(y))
theta = 5×1

         0
    1.5708
    3.1416
    4.7124
    6.2832
```

A sequence of ones causes the phase to shift by +π/2 between samples.

GMSK vs. MSK

Compare Gaussian minimum shift keying (GMSK) and minimum shift keying (MSK) modulation schemes by plotting the eye diagram for GMSK with different pulse lengths and for MSK.

Set the samples per symbol variable.

```
sps = 8;
```

Generate random binary data.

```
data = randi([0 1],1000,1);
```

Create GMSK and MSK modulators that accept binary inputs. Set the `PulseLength` property of the GMSK modulator to `1`.

```
gmskMod = comm.GMSKModulator('BitInput',true,'PulseLength',1, ...
    'SamplesPerSymbol',sps);
mskMod = comm.MSKModulator('BitInput',true,'SamplesPerSymbol',sps);
```

Modulate the data using the GMSK and MSK modulators.

```
modSigGMSK = gmskMod(data);
modSigMSK = mskMod(data);
```

Pass the modulated signals through an AWGN channel having an SNR of `30` dB.

```
rxSigGMSK = awgn(modSigGMSK,30);
rxSigMSK = awgn(modSigMSK,30);
```

Use the `eyediagram` function to plot the eye diagrams of the noisy signals. With the GMSK pulse length set to `1`, the eye diagrams are nearly identical.

```
eyediagram(rxSigGMSK,sps,1,sps/2)
```

```
eyediagram(rxSigMSK,sps,1,sps/2)
```

Set the `PulseLength` property for the GMSK modulator object to `3`. Because the property is nontunable, the object must be released first.

```
release(gmskMod)
gmskMod.PulseLength = 3;
```

Generate a modulated signal using the updated GMSK modulator object and pass it through the AWGN channel.

```
modSigGMSK = gmskMod(data);
rxSigGMSK = awgn(modSigGMSK,30);
```

With continuous phase modulation (CPM) waveforms, such as GSMK, the waveform depends on values of the previous symbols as well as the present symbol. Plot the eye diagram of the GMSK signal to see that the increased pulse length results in an increase in the number of paths in the eye diagram.

```
eyediagram(rxSigGMSK,sps,1,sps/2)
```

Experiment by changing the `PulseLength` parameter of the GMSK modulator object to other values. If you set the property to an even number, you should set `gmskMod.InitialPhaseOffset` to `pi/4` and update the offset argument of the `eyediagram` function from `sps/2` to `0` for a better view of the modulated signal. In order to more clearly view the Gaussian pulse shape, you must use scopes that display the phase of the signal, as described in the “CPM Phase Tree” example.

Algorithms

This object implements the algorithm, inputs, and outputs described on the MSK Demodulator Baseband block reference page. The object properties correspond to the block parameters. For MSK the phase shift per symbol is π/2, which is a modulation index of 0.5.

`comm.CPMDemodulator` | `comm.CPMModulator` | `comm.MSKDemodulator`

Introduced in R2012a

reset

System object: `comm.MSKModulator`
Package: `comm`

Reset states of the MSK modulator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `MSKModulator` object, `H`.

step

System object: `comm.MSKModulator`
Package: `comm`

Modulate using MSK method

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` modulates input data, `X`, with the MSK modulator object, `H`. It returns the baseband modulated output, `Y`. Depending on the value of the `BitInput` property, input `X` can be a double precision, signed integer, or logical column vector. The length of output vector, `Y`, is equal to the number of input samples times the number of samples per symbol you specify in the `SamplesPerSymbol` property.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.MSKTimingSynchronizer

Package: comm

Recover symbol timing phase using fourth-order nonlinearity method

Description

The MSKTimingSynchronizer object recovers the symbol timing phase of the input signal using a fourth-order nonlinearity method. This object implements a general non-data-aided feedback method that is independent of carrier phase recovery. This method requires prior compensation for the carrier frequency offset. This object is suitable for systems that use baseband minimum shift keying (MSK) modulation.

To recover the symbol timing phase of the input signal:

1. Define and set up your MSK timing synchronizer object. See “Construction” on page 3-1011.
2. Call step to recover the symbol timing phase of the input signal according to the properties of comm.MSKTimingSynchronizer. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.MSKTimingSynchronizer creates a timing phase synchronizer System object, H. This object recovers the symbol timing phase of the input signal using a fourth-order nonlinearity method.

H = comm.MSKTimingSynchronizer(Name,Value) creates an MSK timing synchronizer object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

SamplesPerSymbol

Number of samples representing each symbol

Specify the number of samples that represent each symbol in the input signal as an integer-valued scalar greater than 1. The default is 4.

ErrorUpdateGain

Error update step size

Specify the step size for updating successive timing phase estimates as a positive, real scalar value. The default is 0.05. Typically, this number is less than 1/SamplesPerSymbol on page 3-0 , which corresponds to a slowly varying timing phase. This property is tunable.

ResetInputPort

Enable synchronization reset input

Set this property to `true` to enable resetting the timing phase recovery process based on an input argument value. The default is `false`.

When you set this property to `true`, you must specify a reset input value to the `step` method.

When the reset input is a nonzero value, the object restarts the timing phase recovery process. When you set this property to `false`, the object does not restart.

ResetCondition

Condition for timing phase recovery reset

Specify the conditions to reset the timing phase recovery process as one of `Never` | `Every frame`. The default is `Never`.

When you set this property to `Never`, the phase recovery process never restarts. The object operates continuously, retaining information from one symbol to the next.

When you set this property to `Every frame`, the timing phase recovery restarts at the start of each frame of data. Thus, each time the object calls the step method. This property applies when you set the `ResetInputPort` on page 3-0 property to `false`.

Methods

reset	Reset states of MSK timing phase synchronizer object
step	Recover symbol timing phase using fourth-order nonlinearity method

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Recover Timing Phase of MSK Signal

Create MSK modulator, variable fractional delay, and MSK timing synchronizer System objects.

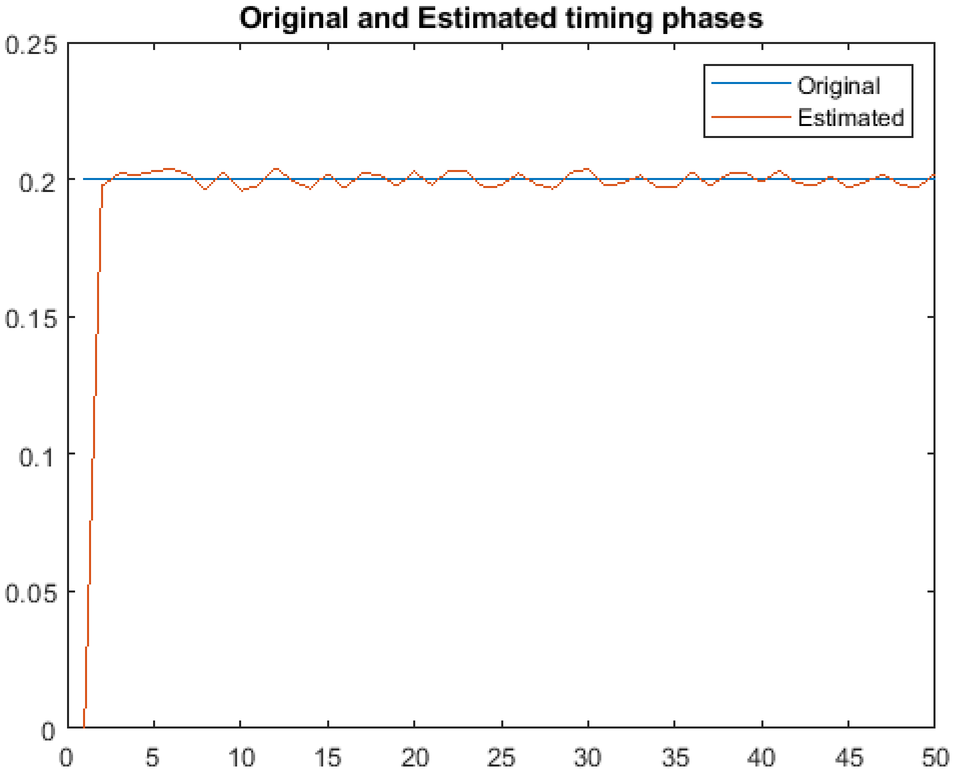
```
mskMod = comm.MSKModulator('BitInput',true,'SamplesPerSymbol',14);
timingOffset = 0.2;
varDelay = dsp.VariableFractionalDelay;
mskTimingSync = comm.MSKTimingSynchronizer('SamplesPerSymbol',14,'ErrorUpdateGain', 0.05);
```

Main processing loop.

```
phEst = zeros(50,1);
for i = 1:50
    data = randi([0 1],100,1);    % Generate data
    modData = mskMod(data);       % Modulate data
    % Apply timing offset error.
    impairedData = varDelay(modData,timingOffset*14);
    % Perform timing phase recovery.
    [~,phase] = mskTimingSync(impairedData);
    phEst(i) = phase(1)/14;
end
```

Plot the results.

```
plot(1:50,[0.2*ones(50,1) phEst]);
legend( 'Original','Estimated')
title('Original and Estimated timing phases');
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the MSK-Type Signal Timing Recovery block reference page. The object properties correspond to the block parameters, except:

- The object corresponds to the MSK-Type Signal Timing Recovery block with the **Modulation type** parameter set to MSK.
- The **Reset** parameter corresponds to the ResetInputPort on page 3-0 and ResetCondition on page 3-0 properties.

Extended Capabilities

`comm.SymbolSynchronizer`

Introduced in R2012a

reset

System object: `comm.MSKTimingSynchronizer`
Package: `comm`

Reset states of MSK timing phase synchronizer object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of `MSKTimingSynchronizer` object, `H`.

step

System object: `comm.MSKTimingSynchronizer`
Package: `comm`

Recover symbol timing phase using fourth-order nonlinearity method

Syntax

```
[Y,PHASE] = step(H,X)
[Y,PHASE] = step(H,X,R)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[Y,PHASE] = step(H,X)` recovers the timing phase and returns the time-synchronized signal, `Y`, and the estimated timing phase, `PHASE`, for input signal `X`. `X` must be a double or single precision complex column vector.

`[Y,PHASE] = step(H,X,R)` restarts the timing phase recovery process when you input a reset signal, `R`, that is non-zero. `R` must be a logical or double scalar. This syntax applies when you set the `ResetInputPort` property to true.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.MultiplexedDeinterleaver

Package: `comm`

Deinterleave input symbols using set of shift registers with specified delays

Description

The `MultiplexedDeinterleaver` object restores the original ordering of a sequence that was interleaved using the General Multiplexed Interleaver object.

To deinterleave the input symbols:

1. Define and set up your multiplexed deinterleaver object. See “Construction” on page 3-1017.
2. Call `step` to restore the original ordering of the input sequence according to the properties of `comm.MultiplexedDeinterleaver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.MultiplexedDeinterleaver` creates a multiplexed deinterleaver System object, `H`. This object restores the original ordering of a sequence that was interleaved using the multiplexed interleaver System object.

`H = comm.MultiplexedDeinterleaver(Name,Value)` creates a multiplexed deinterleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`Delay`

Interleaver delay

Specify the lengths of the shift registers as an integer column vector. The default is `[2;0;1;3;10]`.

`InitialConditions`

Initial conditions of shift registers

Specify the initial values in each shift register as a numeric scalar value or a column vector. The default is `0`. When you set this property to a column vector, the vector length must equal the value of the `Delay` on page 3-0 property. This vector contains initial conditions, where the *i*-th initial condition is stored in the *i*th shift register.

Methods

reset	Reset states of the multiplexed deinterleaver object
step	Deinterleave input symbols using a set of shift registers with specified delays

Common to All System Objects	
release	Allow System object property value changes

Examples

Multiplexed Interleaving and Deinterleaving

Create interleaver and deinterleaver objects.

```
interleaver = comm.MultiplexedInterleaver('Delay',[1; 0; 2; 1]);
deinterleaver = comm.MultiplexedDeinterleaver('Delay',[1; 0; 2; 1]);
```

Generate a random data sequence. Pass the data sequence through the interleaver and deinterleaver.

```
[dataIn,dataOut] = deal([]);            % Initialize data arrays

for k = 1:50
    data = randi([0 7],20,1);           % Generate data sequence
    intData = interleaver(data);        % Interleave sequence
    deIntData = deinterleaver(intData); % Deinterleave sequence

    dataIn = cat(1,dataIn,data);        % Save original data
    dataOut = cat(1,dataOut,deIntData); % Save deinterleaved data
end
```

Determine the delay through the interleaver and deinterleaver.

```
intlvrDelay = finddelay(dataIn,dataOut)
```

```
intlvrDelay = 8
```

After accounting for the delay, confirm that the original and deinterleaved sequences are identical.

```
isequal(dataIn(1:end-intlvrDelay),dataOut(intlvrDelay+1:end))
```

```
ans = logical
   1
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the General Multiplexed Deinterleaver block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

`comm.ConvolutionalDeinterleaver` | `comm.MultiplexedInterleaver`

Introduced in R2012a

reset

System object: `comm.MultiplexedDeinterleaver`
Package: `comm`

Reset states of the multiplexed deinterleaver object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `MultiplexedDeinterleaver` object, `H`.

step

System object: `comm.MultiplexedDeinterleaver`
Package: `comm`

Deinterleave input symbols using a set of shift registers with specified delays

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` restores the original ordering of the sequence, `X`, that was interleaved using a multiplexed interleaver and returns `Y`. The input `X` must be a column vector. The data type for `X` can be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`. The multiplexed deinterleaver object uses N shift registers, where N is the number of elements in the vector specified by the `Delay` property. When a new input symbol enters the deinterleaver, a commutator switches to a new register. The new symbol shifts in while the oldest symbol in that register is shifted out. When the commutator reaches the Nth register, upon the next new input, it returns to the first register. The multiplexed deinterleaver associated with a multiplexed interleaver has the same number of registers as the interleaver. The delay in a particular deinterleaver register depends on the largest interleaver delay minus the interleaver delay for the given register.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.MultiplexedInterleaver

Package: `comm`

Permute input symbols using set of shift registers with specified delays

Description

The `MultiplexedInterleaver` object permutes the symbols in the input signal. Internally, the object uses a set of shift registers, each with its own delay value.

To permute the symbols in the input signal:

1. Define and set up your multiplexed interleaver object. See “Construction” on page 3-1022.
2. Call `step` to interleave the input signal according to the properties of `comm.MultiplexedInterleaver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.MultiplexedInterleaver` creates a multiplexed interleaver System object, `H`. This object permutes the symbols in the input signal using a set of shift registers with specified delays.

`H = comm.MultiplexedInterleaver(Name,Value)` creates a multiplexed interleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`Delay`

Interleaver delay

Specify the lengths of the shift registers as an integer column vector. The default is `[2;0;1;3;10]`.

`InitialConditions`

Initial conditions of shift registers

Specify the initial values in each shift register as a numeric scalar value or a column vector. The default is `0`. When you set this property to a column vector, the length must equal the value of the `Delay` on page 3-0 property. This vector contains initial conditions, where the *i*-th initial condition is stored in the *i*-th shift register.

Methods

reset	Reset states of the multiplexed interleaver object
step	Permute input symbols using a set of shift registers with specified delays

Common to All System Objects	
release	Allow System object property value changes

Examples

Multiplexed Interleaving and Deinterleaving

Create interleaver and deinterleaver objects.

```
interleaver = comm.MultiplexedInterleaver('Delay',[1; 0; 2; 1]);
deinterleaver = comm.MultiplexedDeinterleaver('Delay',[1; 0; 2; 1]);
```

Generate a random data sequence. Pass the data sequence through the interleaver and deinterleaver.

```
[dataIn,dataOut] = deal([]);            % Initialize data arrays

for k = 1:50
    data = randi([0 7],20,1);           % Generate data sequence
    intData = interleaver(data);        % Interleave sequence
    deIntData = deinterleaver(intData); % Deinterleave sequence

    dataIn = cat(1,dataIn,data);        % Save original data
    dataOut = cat(1,dataOut,deIntData); % Save deinterleaved data
end
```

Determine the delay through the interleaver and deinterleaver.

```
intlvrDelay = finddelay(dataIn,dataOut)
```

```
intlvrDelay = 8
```

After accounting for the delay, confirm that the original and deinterleaved sequences are identical.

```
isequal(dataIn(1:end-intlvrDelay),dataOut(intlvrDelay+1:end))
```

```
ans = logical
   1
```

`comm.ConvolutionalInterleaver` | `comm.MultiplexedDeinterleaver`

Introduced in R2012a

reset

System object: `comm.MultiplexedInterleaver`
Package: `comm`

Reset states of the multiplexed interleaver object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `MultiplexedInterleaver` object, `H`.

step

System object: `comm.MultiplexedInterleaver`
Package: `comm`

Permute input symbols using a set of shift registers with specified delays

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` permutes input sequence, `X`, and returns interleaved sequence, `Y`. The input `X` must be a column vector and the data type can be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`. The multiplexed interleaver object consists of N registers, each with a specified delay. With each new input symbol, a commutator switches to a new register and the new symbol is shifted in while the oldest symbol in that register is shifted out. When the commutator reaches the Nth register, upon the next new input, it returns to the first register.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.OQPSKDemodulator

Package: `comm`

Demodulation using OQPSK method

Description

The comm.OQPSKDemodulator object applies pulse shape filtering to the input waveform and demodulates it using the offset quadrature phase shift keying (OQPSK) method. For more information, see “Pulse Shaping Filter” on page 3-1033. The input is a baseband representation of the modulated signal.

For information about delays incurred by modulator-demodulator pair processing, see “Modulation Delays” on page 3-1033.

To demodulate a signal that is OQPSK modulated:

1. Create the `comm.OQPSKDemodulator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
oqpskdemod = comm.OQPSKDemodulator
oqpskdemod = comm.OQPSKDemodulator(mod)
oqpskdemod = comm.OQPSKDemodulator(Name,Value)
oqpskdemod = comm.OQPSKDemodulator(phase,Name,Value)
```

Description

`oqpskdemod = comm.OQPSKDemodulator` creates a demodulator System object. This object can jointly match-filter and decimate a waveform, and demodulate it using the offset quadrature phase shift keying (OQPSK) method.

`oqpskdemod = comm.OQPSKDemodulator(mod)` creates a demodulator System object with symmetric configuration to the OQPSK modulator object, `mod`.

`oqpskdemod = comm.OQPSKDemodulator(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Example: `comm.OQPSKDemodulator('BitOutput',true)`

`oqpskdemod = comm.OQPSKDemodulator(phase,Name,Value)` sets the PhaseOffset property of the created object to `phase` and sets any other specified `Name`, `Value` pairs.

Example: `comm.OQPSKDemodulator(0.5*pi,'SamplesPerSymbol',2)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`PhaseOffset` — Phase of zeroth point of signal constellation

`0` (default) | scalar

Phase offset from π/4, specified as a scalar in radians. The phase offset is applied to the zeroth point of the signal constellation before delay of quadrature component. After the OQPSK imaginary-component delay the signal is normalized with unity power.

Example: `'PhaseOffset',pi/4` aligns the zeroth point of the QPSK signal constellation point on the axes, {(1,0), (0,j), (-1,0), (0,-j)}.

Data Types: `double`

`BitOutput` — Option to output data as bits

`false` (default) | `true`

Option to output data as bits, specified as `false` or `true`.

- When you set this property to `false`, the object outputs a column vector of integer values with a length equal to the number of demodulated symbols. The output values are integer representations of two bits and range from `0` to `3`.
- When you set this property to `true`, the object outputs a binary column vector of bit values. The output vector length is twice as long as the number of input symbols.

Data Types: `logical`

`SymbolMapping` — Signal constellation bit mapping

`'Gray'` (default) | `'Binary'` | custom 4-element numeric vector of integers with values from 0 to 3

Signal constellation bit mapping, specified as `'Gray'`, `'Binary'`, or a custom 4-element numeric vector of integers with values from 0 to 3.

Setting	Constellation Mapping for Integers	Constellation Mapping for Bits	Comment
`Gray`	 1 0 3 2	 01 00 11 10	The signal constellation mapping is Gray-encoded.

Setting	Constellation Mapping for Integers	Constellation Mapping for Bits	Comment
`Binary`			The signal constellation mapping for the input integer `m` (0 ≤ `m` ≤ 3) is the complex value $e^{(j*(PhaseOffset+\pi/4) + j*2*\pi*m/4)}$.
Custom 4-element numeric vector of integers with values from 0 to 3			Elements [a b c d] must be composed of the set of values [0, 1, 2, 3] in any order.

Data Types: `char` | `double`

`PulseShape` — Filtering pulse shape
`'Half sine'` (default) | `'Normal raised cosine'` | `'Root raised cosine'` | `'Custom'`

Filtering pulse shape, specified as `'Half sine'`, `'Normal raised cosine'` | `'Root raised cosine'`, or `'Custom'`.

Data Types: `char`

`RolloffFactor` — Raised cosine filter rolloff factor
`0.2` (default) | scalar

Raised cosine filter rolloff factor, specified as a scalar from `0` to `1`.

Dependencies

This property is enabled when PulseShape is `'Normal raised cosine'` or `'Root raised cosine'`.

Data Types: `double`

`FilterSpanInSymbols` — Filter length
`10` (default) | scalar

Filter length in symbols, specified as a scalar. An ideal raised cosine filter has an infinite impulse response. However, to realize a practical implementation of this filter, the object truncates the impulse response to `FilterSpanInSymbols` symbols.

Dependencies

This property is enabled when PulseShape is `'Normal raised cosine'` or `'Root raised cosine'`.

Data Types: `double`

`FilterNumerator` — Filter numerator
`[0.7071 0.7071]` (default) | row vector

Filter numerator, specified as a row vector.

Dependencies

This property is enabled when PulseShape is `'Custom'`.

Data Types: `double`

`SamplesPerSymbol` — Number of samples per symbol

4 (default) | positive even integer

Number of samples per symbol, specified as a positive even integer.

Data Types: `double`

`OutputDataType` — Data type assigned to output

`'double'` (default) | `'single'` | `'uint8'`

Data type assigned to output, specified as `'double'`, `'single'`, or `'uint8'`.

Data Types: `char`

Usage

Syntax

```
outsignal = oqpskdemod(waveform)
```

Description

`outsignal = oqpskdemod(waveform)` returns the demodulated output signal. The object produces one output symbol for each input pulse.

Input Arguments

`waveform` — Received waveform

scalar | column vector

Received waveform, specified as a complex scalar or column vector.

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`outsignal` — Demodulated signal

integer vector | bit vector

Demodulated signal, returned as an N_S-element integer vector or bit vector, where N_S is the number of samples.

The received waveform is pulse shaped according to the configuration properties PulseShape and SamplesPerSymbol. The setting of the BitOutput property determines the interpretation of the received waveform.

Data Types: `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

OQPSK Signal in AWGN

Create an OQPSK modulator and demodulator pair. Create an AWGN channel object having two bits per symbol.

```
oqpskmod = comm.OQPSKModulator('BitInput',true);
oqpskdemod = comm.OQPSKDemodulator('BitOutput',true);
channel = comm.AWGNChannel('EbNo',4,'BitsPerSymbol',2);
```

Create an error rate calculator. To account for the delay between the modulator and demodulator, set the `ReceiveDelay` property to `2`.

```
errorRate = comm.ErrorRate('ReceiveDelay',2);
```

Process 300 frames of data looping through these steps.

- Generate vectors with 100 elements of random binary data.
- OQPSK-modulate the data. The data frames are processed as 50 sample frames of 2-bit binary data.
- Pass the modulated data through the AWGN channel.
- OQPSK-demodulate the data.
- Collect error statistics on the frames of data.

```
for counter = 1:300
    txData = randi([0 1],100,1);
    modSig = oqpskmod(txData);
    rxSig = channel(modSig);
    rxData = oqpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
```

```
ber = 3.3336e-05
```

```
numErrors = errorStats(2)
numErrors = 1
```

```
numBits = errorStats(3)
```

```
numBits = 29998
```

OQPSK Signal with Root Raised Cosine Filtering

Perform OQPSK modulation and demodulation and apply root raised cosine filtering to a waveform.

System initialization

Define simulation parameters and create objects for OQPSK modulation and demodulation.

```
sps = 12; % samples per symbol
bits = randi([0, 1], 800, 1); % transmission data

modulator = comm.OQPSKModulator('BitInput',true,'SamplesPerSymbol',sps,'PulseShape','Root raised
demodulator = comm.OQPSKDemodulator(modulator);
```

Waveform transmission and reception

Use the `modulator` object to apply OQPSK modulation and transmit filtering to the input data.

```
oqpskWaveform = modulator(bits);
```

Pass the waveform through a channel.

```
snr = 0;
rxWaveform = awgn(oqpskWaveform, snr);
```

Use the `demodulator` object to apply receive filtering and OQPSK demodulation to the waveform.

```
demodData = demodulator(rxWaveform);
```

Compute the bit error rate to confirm the quality of the data recovery.

```
delay = (1+modulator.BitInput)*modulator.FilterSpanInSymbols;
[~, ber] = biterr(bits(1:end-delay), demodData(delay+1:end))
```

```
ber = 0
```

Soft-Decision OQPSK Modulation-Demodulation

Use the `qamdemod` function to simulate soft decision output for OQPSK-modulated signals.

Generate an OQPSK modulated signal.

```
sps = 4;
msg = randi([0 1],1000,1);
oqpskMod = comm.OQPSKModulator('SamplesPerSymbol',sps,'BitInput',true);
oqpskSig = oqpskMod(msg);
```

Add noise to the generated signal.

```
impairedSig = awgn(oqpskSig,15);
```

Perform Soft-Decision Demodulation

Create QPSK equivalent signal to align in-phase and quadrature.

```
impairedQPSK = complex(real(impairedSig(1+sps/2:end-sps/2)), imag(impairedSig(sps+1:end)));
```

Apply matched filtering to the received OQPSK signal.

```
halfSinePulse = sin(0:pi/sps:(sps)*pi/sps);
matchedFilter = dsp.FIRDecimator(sps,halfSinePulse,'DecimationOffset',sps/2);
filteredQPSK = matchedFilter(impairedQPSK);
```

To perform soft demodulation of the filtered OQPSK signal use the `qamdemod` function. Align symbol mapping of `qamdemod` with the symbol mapping used by the `comm.OQPSKModulator`, then demodulate the signal.

```
oqpskModSymbolMapping = [1 3 0 2];
demodulated = qamdemod(filteredQPSK,4,oqpskModSymbolMapping,'OutputType','llr');
```

More About

Modulation Delays

Digital modulation and demodulation objects incur delays between their inputs and outputs that result in an offset in the arrival sample of the received data. When comparing transmitted data with received data, such as when plotting or computing error statistics, you must take system delays into account. As shown here, the OQPSK modulation-demodulation delay varies depending on the pulse shaping filter and the input/output settings of the object pairs.

Pulse Shape	Input/Output Data (*)	End-to-End Delay Incurred by ay an OQPSK Modulator-Demodulator Object Pair (in samples)
`'Half sine'` or `'Custom'`	Integer	1
	Bit	2
`'Normal raised cosine'` or `'Root raised cosine'`	Integer	`FilterSpanInSymbols`
	Bit	2*`FilterSpanInSymbols`
(*) Set the data type property (`BitInput` for modulation or `BitOutput` for demodulation) to `false` for integer data and `true` for bit data.		

Pulse Shaping Filter

The OQPSK modulation scheme requires oversampling of two or greater in order to delay (or offset) the quadrature channel by 90 degrees. This oversampling is achieved through interpolation filtering implemented by pulse shaping.

Extended Capabilities

C/C++ Code Generation

comm.OQPSKModulator

Package: `comm`

Modulation using OQPSK method

Description

The comm.OQPSKModulator object modulates the input signal using the offset quadrature phase shift keying (OQPSK) method and applies pulse shape filtering to the output waveform. For more information, see “Pulse Shaping Filter” on page 3-1042. The output is a baseband representation of the modulated signal.

For information about delays incurred by modulator-demodulator pair processing, see “Modulation Delays” on page 3-1042.

To modulate a signal using offset quadrature phase shift keying:

1. Create the `comm.OQPSKModulator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
oqpskmod = comm.OQPSKModulator
oqpskmod = comm.OQPSKModulator(demod)
oqpskmod = comm.OQPSKModulator(Name,Value)
oqpskmod = comm.OQPSKModulator(phase,Name,Value)
```

Description

`oqpskmod = comm.OQPSKModulator` creates a modulator System object. This object applies offset quadrature phase shift keying (OQPSK) modulation and pulse shape filtering to the input signal.

`oqpskmod = comm.OQPSKModulator(demod)` creates a modulator System object with symmetric configuration to the OQPSK demodulator object, `demod`.

`oqpskmod = comm.OQPSKModulator(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Example: `comm.OQPSKModulator('BitInput',true)`

`oqpskmod = comm.OQPSKModulator(phase,Name,Value)` sets the PhaseOffset property of the created object to `phase` and sets any other specified `Name`, `Value` pairs.

Example: `comm.OQPSKModulator(0.5*pi,'SymbolMapping','Binary')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`PhaseOffset` — Phase of zeroth point of signal constellation

`0` (default) | scalar

Phase offset from π/4, specified as a scalar in radians. The phase offset is applied to the zeroth point of the signal constellation before delay of quadrature component. After the OQPSK imaginary-component delay, the signal is normalized with unity power.

Example: `'PhaseOffset',pi/4` aligns the zeroth point of the QPSK signal constellation point on the axes, {(1,0), (0,j), (-1,0), (0,-j)}.

Data Types: `double`

`BitInput` — Option to provide input in bits

`false` (default) | `true`

Option to provide input in bits, specified as `false` or `true`.

- When this property is set to `false`, the input values must be integer representations of two-bit input segments and range from 0 to 3.
- When this property is set to `true`, the input must be a binary vector of even length. Element pairs are binary representations of integers.

Data Types: `logical`

`SymbolMapping` — Signal constellation bit mapping

`'Gray'` (default) | `'Binary'` | custom 4-element numeric vector of integers with values from 0 to 3

Signal constellation bit mapping, specified as `'Gray'`, `'Binary'`, or a custom 4-element numeric vector of integers with values from 0 to 3.

Setting	Constellation Mapping for Integers	Constellation Mapping for Bits	Comment
`Gray`			The signal constellation mapping is Gray-encoded.

Setting	Constellation Mapping for Integers	Constellation Mapping for Bits	Comment
`Binary`			The signal constellation mapping for the input integer `m` (0 ≤ `m` ≤ 3) is the complex value $e^{(j*(PhaseOffset+\pi/4) + j*2*\pi*m/4)}$.
Custom 4-element numeric vector of integers with values from 0 to 3			Elements [a b c d] must be composed of the set of values [0, 1, 2, 3] in any order.

Data Types: `char` | `double`

`PulseShape` — Filtering pulse shape

`'Half sine'` (default) | `'Normal raised cosine'` | `'Root raised cosine'` | `'Custom'`

Filtering pulse shape, specified as `'Half sine'`, `'Normal raised cosine'`, `'Root raised cosine'`, or `'Custom'`.

Data Types: `char`

`RolloffFactor` — Raised cosine filter rolloff factor

`0.2` (default) | scalar

Raised cosine filter rolloff factor, specified as a scalar from `0` to `1`.

Dependencies

This property is enabled when PulseShape is `'Normal raised cosine'` or `'Root raised cosine'`.

Data Types: `double`

`FilterSpanInSymbols` — Filter length

`10` (default) | scalar

Filter length in symbols, specified as a scalar. An ideal raised cosine filter has an infinite impulse response. However, to realize a practical implementation of this filter, the object truncates the impulse response to `FilterSpanInSymbols` symbols.

Dependencies

This property is enabled when PulseShape is `'Normal raised cosine'` or `'Root raised cosine'`.

Data Types: `double`

`FilterNumerator` — Filter numerator

`[0.7071 0.7071]` (default) | row vector

Filter numerator, specified as a row vector.

Dependencies

This property is enabled when PulseShape is `'Custom'`.

Data Types: `double`

`SamplesPerSymbol` — Number of samples per symbol

4 (default) | positive even integer

Number of samples per symbol, specified as a positive even integer.

Data Types: `double`

`OutputDataType` — Data type assigned to output

`'double'` (default) | `'single'`

Data type assigned to output, specified as `'double'` or `'single'`.

Data Types: `char`

Usage

Syntax

`waveform = oqpskmod(insignal)`

Description

`waveform = oqpskmod(insignal)` returns baseband-modulated output. The output waveform is pulse shaped according to the configuration properties PulseShape and SamplesPerSymbol.

Input Arguments

`insignal` — Input signal

integer column vector | bit column vector

Input signal, specified as an N_S-element column vector of integers or bits, where N_S is the number of samples.

The setting of the BitInput property determines the interpretation of the input vector.

Data Types: `double`

Output Arguments

`waveform` — Output waveform

vector

Output waveform, returned as a vector. The output waveform is pulse-shaped according to the configuration properties PulseShape and SamplesPerSymbol.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

OQPSK Signal in AWGN

Create an OQPSK modulator and demodulator pair. Create an AWGN channel object having two bits per symbol.

```
oqpskmod = comm.OQPSKModulator('BitInput',true);
oqpskdemod = comm.OQPSKDemodulator('BitOutput',true);
channel = comm.AWGNChannel('EbNo',4,'BitsPerSymbol',2);
```

Create an error rate calculator. To account for the delay between the modulator and demodulator, set the `ReceiveDelay` property to `2`.

```
errorRate = comm.ErrorRate('ReceiveDelay',2);
```

Process 300 frames of data looping through these steps.

- Generate vectors with 100 elements of random binary data.
- OQPSK-modulate the data. The data frames are processed as 50 sample frames of 2-bit binary data.
- Pass the modulated data through the AWGN channel.
- OQPSK-demodulate the data.
- Collect error statistics on the frames of data.

```
for counter = 1:300
    txData = randi([0 1],100,1);
    modSig = oqpskmod(txData);
    rxSig = channel(modSig);
    rxData = oqpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
```

```
ber = 3.3336e-05
```

```
numErrors = errorStats(2)
```

```
numErrors = 1
```

```
numBits = errorStats(3)
```

```
numBits = 29998
```

Create OQPSK Modulator Using Demodulator

Use an OQPSK demodulator object to initialize an OQPSK modulator object while creating it.

Create an OQPSK demodulator, assigning it a phase offset of $\frac{1}{2}\pi$.

```
phase = 0.5*pi;
oqpskdemod = comm.OQPSKDemodulator(phase)
```

```
oqpskdemod = 
  comm.OQPSKDemodulator with properties:

   Modulation
         PhaseOffset: 1.5708
       SymbolMapping: 'Gray'
           BitOutput: false

   Filtering
          PulseShape: 'Half sine'
    SamplesPerSymbol: 4

      OutputDataType: 'double'
```

Use the demodulator object to initialize an OQPSK modulator while creating it.

```
oqpskmod = comm.OQPSKModulator(oqpskdemod)
```

```
oqpskmod = 
  comm.OQPSKModulator with properties:

   Modulation
         PhaseOffset: 1.5708
       SymbolMapping: 'Gray'
            BitInput: false

   Filtering
          PulseShape: 'Half sine'
    SamplesPerSymbol: 4

      OutputDataType: 'double'
```

OQPSK Signal with Root Raised Cosine Filtering

Perform OQPSK modulation and demodulation and apply root raised cosine filtering to a waveform.

System initialization

Define simulation parameters and create objects for OQPSK modulation and demodulation.

```
sps = 12; % samples per symbol
bits = randi([0, 1], 800, 1); % transmission data
```

```
modulator = comm.OQPSKModulator('BitInput',true,'SamplesPerSymbol',sps,'PulseShape','Root raised
demodulator = comm.OQPSKDemodulator(modulator);
```

Waveform transmission and reception

Use the `modulator` object to apply OQPSK modulation and transmit filtering to the input data.

```
oqpskWaveform = modulator(bits);
```

Pass the waveform through a channel.

```
snr = 0;
rxWaveform = awgn(oqpskWaveform, snr);
```

Use the `demodulator` object to apply receive filtering and OQPSK demodulation to the waveform.

```
demodData = demodulator(rxWaveform);
```

Compute the bit error rate to confirm the quality of the data recovery.

```
delay = (1+modulator.BitInput)*modulator.FilterSpanInSymbols;
[~, ber] = biterr(bits(1:end-delay), demodData(delay+1:end))
```

```
ber = 0
```

Soft-Decision OQPSK Modulation-Demodulation

Use the `qamdemod` function to simulate soft decision output for OQPSK-modulated signals.

Generate an OQPSK modulated signal.

```
sps = 4;
msg = randi([0 1],1000,1);
oqpskMod = comm.OQPSKModulator('SamplesPerSymbol',sps,'BitInput',true);
oqpskSig = oqpskMod(msg);
```

Add noise to the generated signal.

```
impairedSig = awgn(oqpskSig,15);
```

Perform Soft-Decision Demodulation

Create QPSK equivalent signal to align in-phase and quadrature.

```
impairedQPSK = complex(real(impairedSig(1+sps/2:end-sps/2)), imag(impairedSig(sps+1:end)));
```

Apply matched filtering to the received OQPSK signal.

```
halfSinePulse = sin(0:pi/sps:(sps)*pi/sps);
matchedFilter = dsp.FIRDecimator(sps,halfSinePulse,'DecimationOffset',sps/2);
filteredQPSK = matchedFilter(impairedQPSK);
```

To perform soft demodulation of the filtered OQPSK signal use the `qamdemod` function. Align symbol mapping of `qamdemod` with the symbol mapping used by the `comm.OQPSKModulator`, then demodulate the signal.

```
oqpskModSymbolMapping = [1 3 0 2];
demodulated = qamdemod(filteredQPSK,4,oqpskModSymbolMapping,'OutputType','llr');
```

More About

Modulation Delays

Digital modulation and demodulation objects incur delays between their inputs and outputs that result in an offset in the arrival sample of the received data. When comparing transmitted data with received data, such as when plotting or computing error statistics, you must take system delays into account. As shown here, the OQPSK modulation-demodulation delay varies depending on the pulse shaping filter and the input/output settings of the object pairs.

Pulse Shape	Input/Output Data (*)	End-to-End Delay Incurred by ay an OQPSK Modulator-Demodulator Object Pair (in samples)
`'Half sine'` or `'Custom'`	Integer	1
	Bit	2
`'Normal raised cosine'` or `'Root raised cosine'`	Integer	`FilterSpanInSymbols`
	Bit	`2*FilterSpanInSymbols`
(*) Set the data type property (`BitInput` for modulation or `BitOutput` for demodulation) to `false` for integer data and `true` for bit data.		

Pulse Shaping Filter

The OQPSK modulation scheme requires oversampling of two or greater in order to delay (or offset) the quadrature channel by 90 degrees. This oversampling is achieved through interpolation filtering implemented by pulse shaping.

comm.OSTBCCombiner

Package: comm

Combine inputs using orthogonal space-time block code

Description

The OSTBCCombiner object combines the input signal (from all of the receive antennas) and the channel estimate signal to extract the soft information of the symbols encoded by an OSTBC. The input channel estimate does not need to be constant and can vary at each call to the step method. The combining algorithm uses only the estimate for the first symbol period per codeword block. A symbol demodulator or decoder would follow the Combiner object in a MIMO communications system.

To combine input signals and extract the soft information of the symbols encoded by an OSTBC:

1. Define and set up your OSTBC combiner object. See "Construction" on page 3-1044.
2. Call step to Combine inputs using an orthogonal space-time block code according to the properties of comm.OSTBCCombiner. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.OSTBCCombiner creates an orthogonal space-time block code (OSTBC) combiner System object, H. This object combines the input signal (from all of the receive antennas) with the channel estimate signal to extract the soft information of the symbols encoded by an OSTBC.

H = comm.OSTBCCombiner(Name,Value) creates an OSTBC Combiner object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.OSTBCCombiner(N,M,Name,Value) creates an OSTBC Combiner object, H. This object has the NumTransmitAntennas property set to N, the NumReceiveAntennas property set to N, and the other specified properties set to the specified values.

Properties

NumTransmitAntennas

Number of transmit antennas

Specify the number of antennas at the transmitter as 2 | 3 | 4. The default is 2.

SymbolRate

Symbol rate of code

Specify the symbol rate of the code as 3/4 | 1/2. The default is 3/4. This property applies when the NumTransmitAntennas on page 3-0 property is greater than 2. For 2 transmit antennas, the symbol rate defaults to 1.

NumReceiveAntennas

Number of receive antennas

Specify the number of antennas at the receiver as a double-precision, real, scalar integer value from 1 to 8. The default is 1.

Fixed-Point Properties

RoundingMethod

Rounding of fixed-point numeric values

Specify the rounding method as Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero. The default is Floor.

OverflowAction

Action when fixed-point numeric values overflow

Specify the overflow action as one of Wrap | Saturate. The default is Wrap. This property specifies the action to be taken in case of overflow. Such overflow occurs if the magnitude of a fixed-point calculation result does not fit into the range of the data type and scaling that stores the result.

ProductDataType

Data type of product

Specify the product data type as one of Full precision | Custom. The default is Full precision.

CustomProductDataType

Fixed-point data type of product

Specify the product fixed-point type as a scaled numerictype object with a signedness of Auto. The default is numerictype([],32,16). This property applies when you set the ProductDataType property to Custom.

AccumulatorDataType

Data type of accumulator

Specify the accumulator data type as Full precision | Same as product | Custom. The default is Full precision.

CustomAccumulatorDataType

Fixed-point data type of accumulator

Specify the accumulator fixed-point type as a scaled `numerictype` object with a signedness of Auto. The default is `numerictype([],32,16)`. This property applies when you set the AccumulatorDataType property to `Custom`.

`EnergyProductDataType`

Data type of energy product

Specify the complex energy product data type as one of `Full precision` | `Same as product` | `Custom`. The default is `Full precision`. This property sets the data type of the complex product in the denominator to calculate the total energy in the MIMO channel.

`CustomEnergyProductDataType`

Fixed-point data type of energy product

Specify the energy product fixed-point type as a scaled `numerictype` object with a signedness of Auto. The default is `numerictype([],32,16)`. This property applies when you set the EnergyProductDataType property to `Custom`.

`EnergyAccumulatorDataType`

Data type of energy accumulator

Specify the energy accumulator data type as one of `Full precision` | `Same as energy product` | `Same as accumulator` | `Custom`. The default is `Full precision`. This property sets the data type of the summation in the denominator to calculate the total energy in the MIMO channel.

`CustomEnergyAccumulatorDataType`

Fixed-point data type of energy accumulator

Specify the energy accumulator fixed-point type as a scaled `numerictype` object with a signedness of Auto. The default is `numerictype([],32,16)`. This property applies when you set the EnergyAccumulatorDataType property to `Custom`.

`DivisionDataType`

Data type of division

Specify the division data type as one of `Same as accumulator` | `Custom`. The default is `Same as accumulator`. This property sets the data type at the output of the division operation. The setting normalizes diversity combining by the total energy in the MIMO channel.

`CustomDivisionDataType`

Fixed-point data type of division

Specify the division fixed-point type as a scaled `numerictype` object with a signedness of Auto. The default is `numerictype([],32,16)`. This property applies when you set the DivisionDataType property to `Custom`.

step	Combine inputs using orthogonal space-time block code

Common to All System Objects	
release	Allow System object property value changes

Examples

Encode with OSTBC and Calculate Errors

Determine the bit error rate for a QSPK signal employing OSTBC encoding when transmitted through a 4x2 MIMO channel. Perfect channel estimation is assumed to be used by the OSTBC combiner.

Define the system parameters.

```
numTx = 4;         % Number of transmit antennas
numRx = 2;         % Number of receive antennas
Rs = 1e6;          % Sampling rate (Hz)
tau = [0 2e-6];    % Path delays (sec)
pdb = [0 -10];     % Average path gains (dB)
maxDopp = 30;      % Maximum Doppler shift (Hz)
numBits = 12000;   % Number of bits
SNR = 6;           % Signal-to-noise ratio (dB)
```

Set the random number generator to its default state to ensure repeatable results.

```
rng default
```

Create a QPSK modulator System object™. Set the `BitInput` property to `true` and the `SymbolMapping` property to `Gray`.

```
hMod = comm.QPSKModulator(...
    'BitInput',true,...
    'SymbolMapping','Gray');
```

Create a corresponding QPSK demodulator System object. Set the `SymbolMapping` property to `Gray` and the `BitOutput` property to `true`.

```
hDemod = comm.QPSKDemodulator(...
    'SymbolMapping','Gray',...
    'BitOutput',true);
```

Create an OSTBC encoder and combiner pair, where the number of antennas is specified in the system parameters.

```
hOSTBCEnc = comm.OSTBCEncoder(...
    'NumTransmitAntennas',numTx);

hOSTBCComb = comm.OSTBCCombiner(...
    'NumTransmitAntennas',numTx,...
    'NumReceiveAntennas',numRx);
```

Create a flat 4x2 MIMO Channel System object, where the channel characteristics are set using name-value pairs. The path gains are made available to serve as a perfect channel estimate for the OSTBC combiner.

```
hChan = comm.MIMOChannel(...
    'SampleRate',Rs,...
    'PathDelays',tau,...
    'AveragePathGains',pdb,...
    'MaximumDopplerShift',maxDopp,...
    'SpatialCorrelationSpecification','None',...
    'NumTransmitAntennas',numTx,...
    'NumReceiveAntennas',numRx,...
    'PathGainsOutputPort',true);
```

Create an AWGN channel System object in which the noise method is specified as a signal-to-noise ratio.

```
hAWGN = comm.AWGNChannel(...
    'NoiseMethod','Signal to noise ratio (SNR)',...
    'SNR',SNR,...
    'SignalPower',1);
```

Generate a random sequence of bits.

```
data = randi([0 1],numBits,1);
```

Apply QPSK modulation.

```
modData = step(hMod,data);
```

Encode the modulated data using the OSTBC encoder object.

```
encData = step(hOSTBCEnc,modData);
```

Transmit the encoded data through the MIMO channel and add white noise by using the `step` functions of the MIMO and AWGN channel objects, respectively.

```
[chanOut,pathGains] = step(hChan,encData);
rxSignal = step(hAWGN,chanOut);
```

Sum the `pathGains` array along the number of paths (2nd dimension) to form the channel estimate. Apply the `squeeze` function to make its dimensions conform with those of `rxSignal`.

```
chEst = squeeze(sum(pathGains,2));
```

Combine the received MIMO signal and its channel estimate using the `step` function of the OSTBC combiner object. Demodulate the combined signal.

```
combinedData = step(hOSTBCComb,rxSignal,chEst);
receivedData = step(hDemod,combinedData);
```

Compute the number of bit errors and the bit error rate.

```
[numErrors,ber] = biterr(data,receivedData)
```

```
numErrors = 11
```

```
ber = 9.1667e-04
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the OSTBC Combiner block reference page. The object properties correspond to the block parameters.

`comm.OSTBCEncoder`

Introduced in R2012a

step

System object: comm.OSTBCCombiner
Package: comm

Combine inputs using orthogonal space-time block code

Syntax

```
Y = step(H,X,CEST)
```

Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Y = step(H,X,CEST) combines the received data, X, and the channel estimate, CEST, to extract the symbols encoded by an OSTBC. Both X and CEST are complex-valued and of the same data type, which can be double, single, or signed fixed point with power-of-two slope and zero bias. When the step method input X has double or single precision, the output, Y, has the same data type as the input. The input channel estimate can remain constant or can vary during each codeword block transmission. The combining algorithm uses the estimate only for the first symbol period per codeword block.

The time domain length, *T*/SymbolRate, must be a multiple of the codeword block length. *T* is the output symbol sequence length in the time domain. Specifically, when you set the NumTransmitAntennas property to 2, *T*/SymbolRate must be a multiple of two. When you set the NumTransmitAntennas property greater than 2, *T*/SymbolRate must be a multiple of four. For an input of *T*/SymbolRate rows by NumReceiveAntennas columns, the input channel estimate, CEST, must be a matrix of size *T*/SymbolRateby NumTransmitAntennas by NumReceiveAntennas. In this case, the extracted symbol data, Y, is a column vector with *T* elements. Input matrix size can be *F* by *T*/SymbolRate by NumReceiveAntennas, where *F* is an optional dimension (typically frequency domain) over which the combining calculation is independent. In this case, the input channel estimate, CEST, must be a matrix of size F by *T*/SymbolRate by NumTransmitAntennas by NumReceiveAntennas. The extracted symbol data, Y, is an *F* rows by *T* columns matrix.

Note obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

comm.OSTBCEncoder

Package: comm

Encode input using orthogonal space-time block code

Description

The OSTBCEncoder object encodes an input symbol sequence using orthogonal space-time block code (OSTBC). The block maps the input symbols block-wise and concatenates the output codeword matrices in the time domain.

To encode an input symbol sequence using an orthogonal space-time block code:

1. Define and set up your OSTBC encoder object. See "Construction" on page 3-1051.
2. Call step to encode an input symbol sequence according to the properties of comm.OSTBCEncoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.OSTBCEncoder creates an orthogonal space-time block code (OSTBC) encoder System object, H. This object maps the input symbols block-wise and concatenates the output codeword matrices in the time domain.

H = comm.OSTBCEncoder(Name,Value) creates an OSTBC encoder object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.OSTBCEncoder(N,Name,Value) creates an OSTBC encoder object, H. This object has the NumTransmitAntennas property set to N, and the other specified properties set to the specified values.

Properties

NumTransmitAntennas

Number of transmit antennas

Specify the number of antennas at the transmitter as 2 | 3 | 4. The default is 2.

SymbolRate

Symbol rate of code

Specify the symbol rate of the code as one of `3/4 | 1/2`. The default is `3/4`. This property applies when you set the `NumTransmitAntennas` on page 3-0 property to greater than `2`. For `2` transmit antennas, the symbol rate defaults to `1`.

Fixed-Point Properties

`OverflowAction`

Action when fixed-point numeric values overflow

Specify the overflow action as one of `Wrap | Saturate`. The default is `Wrap`. This property specifies the action to be taken in the case of an overflow. Such overflow occurs when the magnitude of a fixed-point calculation result does not fit into the range of the data type and scaling that stores the result.

Methods

step	Encode input using orthogonal space-time block code

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Encode BPSK Modulated Data with OSTBC

Generate random binary data, modulate using the BPSK modulation scheme, and encode the modulated data using OSTBC.

Generate an 8-by-1 vector of random binary data.

```
data = randi([0 1],8,1);
```

Create BPSK Modulator System object and modulated the data using the `step` function.

```
bpskMod = comm.BPSKModulator;
modData = bpskMod(data);
```

Create an OSTBC Encoder and encode the modulated signal. As the default number of transmit antennas is 2, you can see that `encData` is an 8-by-2 vector.

```
ostbcEnc = comm.OSTBCEncoder;
encData = ostbcEnc(modData)
```

```
encData = 8×2 complex

  -1.0000 + 0.0000i  -1.0000 + 0.0000i
   1.0000 + 0.0000i  -1.0000 - 0.0000i
   1.0000 + 0.0000i  -1.0000 + 0.0000i
   1.0000 + 0.0000i   1.0000 + 0.0000i
  -1.0000 + 0.0000i   1.0000 + 0.0000i
  -1.0000 + 0.0000i  -1.0000 - 0.0000i
   1.0000 + 0.0000i  -1.0000 + 0.0000i
   1.0000 + 0.0000i   1.0000 + 0.0000i
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the OSTBC Encoder block reference page. The object properties correspond to the block parameters.

When this object processes variable-size signals:

- If the input signal is a column vector, the first dimension can change, but the second dimension must remain fixed at `1`.
- If the input signal is a matrix, both dimensions can change.

Extended Capabilities

`comm.OSTBCCombiner`

Introduced in R2012a

step

System object: `comm.OSTBCEncoder`
Package: `comm`

Encode input using orthogonal space-time block code

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` encodes the input data, `X`, using OSTBC encoder object, `H`. The input is a complex-valued column vector or matrix of data type double, single, or signed fixed-point with power-of-two slope and zero bias. The step method output, `Y`, is the same data type as the input data. The time domain length, *T*, of `X` must be a multiple of the number of symbols in each codeword matrix. Specifically, when you set the NumTransmitAntennas property is `2` or the SymbolRate property is `1/2`, *T* must be a multiple of two and when the `SymbolRate` property to `3/4`, *T* must be a multiple of three. For a time or spatial domain input of *T* rows by one column, the encoded output data, `Y`, is a (*T*/`SymbolRate`)-by-`NumTransmitAntennas` matrix. The input matrix size can be *F* rows by *T* columns, where *F* is the additional dimension (typically the frequency domain) over which the encoding calculation is independent. In this case, the output is an *F*-by-(*T*/`SymbolRate`)-by-`NumTransmitAntennas` matrix.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.OVSFCode

Package: `comm`

Generate OVSF code

Description

The `OVSFCode` object generates an orthogonal variable spreading factor (OVSF) code from a set of orthogonal codes. OVSF codes were first introduced for 3G communication systems. They are primarily used to preserve orthogonality between different channels in a communication system.

To generate an OVSF code:

1. Define and set up your OVSF code object. See “Construction” on page 3-1055.
2. Call `step` to generate an OVSF code according to the properties of `comm.OVSFCode`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.OVSFCode` creates an orthogonal variable spreading factor (OVSF) code generator System object, `H`. This object generates an OVSF code.

`H = comm.OVSFCode(Name,Value)` creates an OVSF code generator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SpreadingFactor`

Length of generated code

Specify the length of the generated code as an integer scalar value with a power of two. The default is `64`.

`Index`

Index of code of interest

Specify the index of the desired code from the available set of codes that have the spreading factor specified in the `SpreadingFactor` on page 3-0 property. This property must be an integer scalar in the range `0` to `SpreadingFactor–1`. The default is `60`.

OVSF codes are defined as the rows of an *n*-by-*n* matrix, *Cn*, where *n* is the value specified in the `SpreadingFactor` property.

You can define the matrix *Cn* recursively as follows:
First, define *C*1 = [1].
Next, assume that *Cn* is defined and let *Cn*(*k*) denote the *k*-th row of *Cn*.
Then, *C*2*n* = [*Cn*(0) *Cn*(0); *Cn*(0) -*Cn*(0); ... ; *Cn*(*n*-1) *Cn*(*n*–1); *Cn*(*n*–1)–*Cn*(*n*–1)].
Cn is only defined for values of n that are a power of 2. Set this property to a value of *k* to choose the *k*-th row of the *C* matrix as the code of interest.

SamplesPerFrame

Number of output samples per frame

Specify the number of OVSF code samples that the `step` method outputs as a numeric, positive, integer scalar value. The default is `1`. If you set this property to a value of *M*, then the `step` method outputs *M* samples of an OVSF code of length *N*. *N* is the length of the OVSF code that you specify in the `SpreadingFactor` on page 3-0 property.

OutputDataType

Data type of output

Specify output data type as one of `double` | `int8`. The default is `double`.

Methods

reset	Reset states of OVSF code generator object
step	Generate OVSF code

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Generate 10 samples of an OVSF code with a spreading factor of 64.

```
    hOVSF = comm.OVSFCode('SamplesPerFrame', 10,'SpreadingFactor',64);
    seq = step(hOVSF)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the OVSF Code Generator block reference page. The object properties correspond to the block parameters, except:

- The object does not have a property to select frame based outputs.
- The object does not have a property that corresponds to the **Sample time** parameter.

step

System object: `comm.OVSFCode`
Package: `comm`

Generate OVSF code

Syntax

```
Y = step(H)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H)` outputs a frame of the OVSF code in column vector `Y`. Specify the frame length with the `SamplesPerFrame` property.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.PAMDemodulator

Package: `comm`

(Not recommended) Demodulate using M-ary PAM method

Note `comm.PAMDemodulator` is not recommended. Use `pamdemod` instead.

Description

The `PAMDemodulator` object demodulates a signal that was modulated using M-ary pulse amplitude modulation. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using M-ary pulse amplitude modulation:

1. Define and set up your PAM demodulator object. See “Construction” on page 3-1059.
2. Call `step` to demodulate the signal according to the properties of `comm.PAMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.PAMDemodulator` creates a demodulator System object, `H`. This object demodulates the input signal using the M-ary pulse amplitude modulation (M-PAM) method.

`H = comm.PAMDemodulator(Name,Value)` creates an M-PAM demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.PAMDemodulator(M,Name,Value)` creates an M-PAM demodulator object, `H`. This object has the `ModulationOrder` property set to `M`, and the other specified properties set to the specified values.

Properties

`ModulationOrder`

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar value. The default is `4`. When you set the `BitOutput` on page 3-0 property to `false`, this value must be even. When you set the `BitOutput` property to `true`, this value requires an integer power of two.

`BitOutput`

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. The default is `false`.

When you set this property to `true` the `step` method outputs a column vector of bit values with length equal to **log2**(`ModulationOrder` on page 3-0) times the number of demodulated symbols.

When you set this property to `false`, the `step` method outputs a column vector, with length equal to the input data vector. This value contains integer symbol values between `0` and `ModulationOrder`–1.

`SymbolMapping`

Constellation encoding

Specify how the object maps an integer or group of **log2**(`ModulationOrder` on page 3-0) bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`.

When you set this property to `Gray`, the object uses a Gray-encoded signal constellation.

When you set this property to `Binary`, the integer *m*, between 0 ≤ *m* ≤(`ModulationOrder`–1) maps to the complex value 2*m*-`ModulationOrder`+1.

`NormalizationMethod`

Constellation normalization method

Specify the method used to normalize the signal constellation as one of `Minimum distance between symbols` | `Average power` | `Peak power`. The default is `Minimum distance between symbols`.

`MinimumDistance`

Minimum distance between symbols

Specify the distance between two nearest constellation points as a positive, real, numeric scalar value. The default is `2`. This property applies when you set the `NormalizationMethod` on page 3-0 property to `Minimum distance between symbols`.

`AveragePower`

Average power of constellation

Specify the average power of the symbols in the constellation as a positive, real, numeric scalar value. The default is `1`. This property applies when you set the `NormalizationMethod` on page 3-0 property to `Average power`.

`PeakPower`

Peak power of constellation

Specify the maximum power of the symbols in the constellation as a positive, real, numeric scalar value. The default is `1`. This property applies when you set the `NormalizationMethod` on page 3-0 property to `Peak power`.

`OutputDataType`

Data type of output

Specify the output data type as one of `Full precision` | `Smallest unsigned integer` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`. The default is `Full precision`.

When you set this property to `Full precision`, and the input data type is single or double precision, the output data has the same data type that of the input.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in `Smallest unsigned integer` or `Full precision` mode.

When the input data is of a fixed-point type, the output data type behaves as if you had set the `OutputDataType` on page 3-0 property to `Smallest unsigned integer`.

When you set the `BitOutput` on page 3-0 property to `true`, then `logical` data type becomes a valid option.

Fixed-Point Properties

`FullPrecisionOverride`

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects” on page 3-1063.

`DenormalizationFactorDataType`

Data type of denormalization factor

Specify the denormalization factor data type as one of `Same word length as input` | `Custom`. The default is `Same word length as input`.

`CustomDenormalizationFactorDataType`

Fixed-point data type of denormalization factor

Specify the denormalization factor fixed-point type as an unscaled `numerictype` object with a signedness of Auto. The default is `numerictype([],16)`. This property applies when you set the `DenormalizationFactorDataType` on page 3-0 property to `Custom`.

`ProductDataType`

Data type of product

Specify the product data type as one of `Full precision` | `Custom`. The default is `Full precision`. When you set this property to `Full precision` the object calculates the full-precision product word and fraction lengths. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false.

CustomProductDataType

Fixed-point data type of product

Specify the product fixed-point type as an unscaled `numerictype` object with a signedness of Auto. The default is `numerictype([],32)`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false and the `ProductDataType` on page 3-0 property to `Custom`.

ProductRoundingMethod

Rounding of fixed-point numeric value of product

Specify the product rounding method as one of `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero`. The default is `Floor`. This property applies when the object is not in a full precision configuration

ProductOverflowAction

Action when fixed-point numeric value of product overflows

Specify the product overflow action as one of `Wrap` | `Saturate`. The default is `Wrap`. This property applies when the object is not in a full precision configuration.

SumDataType

Data type of sum

Specify the sum data type as one of `Full precision` | `Same as product` | `Custom`. The default is `Full precision`. When you set this property to `Full precision`, the object calculates the full-precision sum word and fraction lengths. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false

CustomSumDataType

Fixed-point data type of sum

Specify the sum fixed-point type as an unscaled `numerictype` object with a signedness of Auto. The default is `numerictype([],32)`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false and the `SumDataType` on page 3-0 property to `Custom`.

Methods

constellation	(Not recommended) Calculate or plot ideal signal constellation
step	(Not recommended) Demodulate using M-ary PAM method

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Modulate and demodulate a signal using 16-PAM modulation.

```
    hMod = comm.PAMModulator(16);
    hAWGN = comm.AWGNChannel('NoiseMethod', ...
                    'Signal to noise ratio (SNR)', ...
                    'SNR',20, 'SignalPower', 85);
    hDemod = comm.PAMDemodulator(16);
    %Create an error rate calculator
    hError = comm.ErrorRate;
    for counter = 1:100
      % Transmit a 50-symbol frame
      data = randi([0 hMod.ModulationOrder-1],50,1);
      modSignal = step(hMod, data);
      noisySignal = step(hAWGN, modSignal);
      receivedData = step(hDemod, noisySignal);
      errorStats = step(hError, data, receivedData);
    end
    fprintf('Error rate = %f\nNumber of errors = %d\n', ...
      errorStats(1), errorStats(2))
```

Compatibility Considerations

comm.PAMDemodulator is not recommended

comm.PAMDEmodulator is not recommended. Use pamdemod instead.

```
n = 10000; % Number of symbols to process
M = 8; % Modulation order
x = randi([0 M-1],n,1); % Create message signal.

%% Using PAM modulation and demodulation system objects
pammodObj = comm.PAMModulator(M);
pamdemodObj = comm.PAMDemodulator(M);
yOld = pammodObj(x); % Modulate.
% ... channel filtering ...
zOld = pamdemodObj(complex(y)); % Demodulate.

%% Using PAM modulation and demodulation functions
yNew = pammod(x,M); % Modulate.
% ... channel filtering ...
zNew = pamdemod(y,M); % Demodulate.
```

More About

Full Precision for Fixed-Point System Objects

FullPrecisionOverride is a convenience property that, when you set to true, automatically sets the appropriate properties for an object to use full-precision to process fixed-point input.

For System objects, full precision, fixed-point operation refers to growing just enough additional bits to compute the ideal full precision result. This operation has no minimum or maximum range overflow nor any precision loss due to rounding or underflow. It is also independent of any hardware-specific settings. The data types chosen are based only on known data type ranges and not on actual numeric values. Full precision for System objects does not optimize coefficient values. When you set the FullPrecisionOverride property to true, the other fixed-point properties it controls no longer apply and any of their non-default values are ignored. These properties are also hidden. To specify individual fixed-point properties, first set FullPrecisionOverride to false.

Algorithms

This object implements the algorithm, inputs, and outputs described on the M-PAM Demodulator Baseband block reference page. The object properties correspond to the block parameters.

step

System object: `comm.PAMDemodulator`
Package: `comm`

(Not recommended) Demodulate using M-ary PAM method

Note `comm.PAMDemodulator` is not recommended. Use `pamdemod` instead.

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates data, `X`, with the M-PAM demodulator System object, `H`, and returns `Y`. Input `X` must be a scalar or column vector. The data type of the input can be double or single precision, signed integer, or signed fixed point (fi objects). Depending on the `BitOutput` property value, output `Y` can be integer or bit valued.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.PAMModulator

Package: comm

(Not recommended) Modulate using M-ary PAM method

Note comm.PAMModulator is not recommended. Use pammod instead.

Description

The PAMModulator object modulates using M-ary pulse amplitude modulation. The output is a baseband representation of the modulated signal. The M-ary number parameter, M, represents the number of points in the signal constellation and requires an even integer.

To modulate a signal using M-ary pulse amplitude modulation:

1. Define and set up your PAM modulator object. See “Construction” on page 3-1068.
2. Call step to modulate the signal according to the properties of comm.PAMModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.PAMModulator creates a modulator System object, H. This object modulates the input signal using the M-ary pulse amplitude modulation (M-PAM) method.

H = comm.PAMModulator(Name,Value) creates an M-PAM modulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.PAMModulator(M,Name,Value) creates an M-PAM modulator object, H. This object has the ModulationOrder property set to M and the other specified properties set to the specified values.

Properties

ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar value. The default is 4. When you set the BitInput on page 3-0 property to false, ModulationOrder must be even. When you set the BitInput property to true, ModulationOrder must be an integer power of two.

BitInput

Assume bit inputs

Specify whether the input is in bits or integers. The default is false.

When you set this property to true, the step method input requires a column vector of bit values whose length is an integer multiple of **log2**(ModulationOrder on page 3-0). This vector contains bit representations of integers between 0 and ModulationOrder–1.

When you set this property to false, the step method input must be a column vector of integer symbol values between 0 and ModulationOrder–1.

SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of **log2**(ModulationOrder on page 3-0) input bits to the corresponding symbol as one of Binary | Gray. The default is Gray.

When you set this property to Gray, the object uses a Gray-encoded signal constellation.

When you set this property to Binary, the input integer *m*, between 0 ≤ *m* ≤ModulationOrder-1) maps to the complex value 2*m*– ModulationOrder + 1.

NormalizationMethod

Constellation normalization method

Specify the method used to normalize the signal constellation as one of Minimum distance between symbols | Average power | Peak power. The default is Minimum distance between symbols.

MinimumDistance

Minimum distance between symbols

Specify the distance between two nearest constellation points as a positive, real, numeric scalar value. The default is 2. This property applies when you set the NormalizationMethod on page 3-0 property to Minimum distance between symbols.

AveragePower

Average power of constellation

Specify the average power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the NormalizationMethod on page 3-0 property to Average power.

PeakPower

Peak power of constellation

Specify the maximum power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the NormalizationMethod on page 3-0 property to Peak power.

OutputDataType

Data type of output

Specify the output data type as one of double | single | Custom. The default is double.

Fixed-Point Properties

CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a numerictype object with a signedness of Auto. The default is numerictype([],16). This property applies when you set the OutputDataType on page 3-0 property to Custom.

Methods

constellation	(Not recommended) Calculate or plot ideal signal constellation
step	(Not recommended) Modulate using M-ary PAM method

Common to All System Objects	
release	Allow System object property value changes

Examples

Modulate data using 16-PAM modulation, and visualize the data in a scatter plot.

```
% Create binary data for 100, 4-bit symbols
data = randi([0 1],400,1);
% Create a 16-PAM modulator System object with bits as inputs and
% Gray-coded signal constellation
hModulator = comm.PAMModulator(16,'BitInput',true);
% Modulate and plot the data
modData = step(hModulator, data);
constellation(hModulator)
```

Compatibility Considerations

comm.PAMModulator is not recommended

comm.PAMModulator is not recommended. Use pammod instead.

```
n = 10000; % Number of symbols to process
M = 8; % Modulation order
x = randi([0 M-1],n,1); % Create message signal.

%% Using PAM modulation and demodulation system objects
pammodObj = comm.PAMModulator(M);
pamdemodObj = comm.PAMDemodulator(M);
yOld = pammodObj(x); % Modulate.
% ... channel filtering ...
zOld = pamdemodObj(complex(y)); % Demodulate.
```

```
%% Using PAM modulation and demodulation functions
yNew = pammod(x,M); % Modulate.
% ... channel filtering ...
zNew = pamdemod(y,M); % Demodulate.
```

step

System object: comm.PAMModulator
Package: comm

(Not recommended) Modulate using M-ary PAM method

Note comm.PAMModulator is not recommended. Use pammod instead.

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Y = step(H,X) modulates input data, X, with the M-PAM modulator System object, H. It returns the baseband modulated output, Y. Depending on the value of the BitInput property, input X can be an integer or bit valued column vector with numeric, logical, or fixed-point data types.

Note obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

comm.PhaseFrequencyOffset

Package: `comm`

Apply phase and frequency offsets to input signal

Description

The `PhaseFrequencyOffset` object applies phase and frequency offsets to an incoming signal.

To apply phase and frequency offsets to the input signal:

1. Define and set up your phase frequency offset object. See “Construction” on page 3-1075.
2. Call `step` to apply phase and frequency offsets to the input signal according to the properties of `comm.PhaseFrequencyOffset`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.PhaseFrequencyOffset` creates a phase and frequency offset System object, `H`. This object applies phase and frequency offsets to an input signal.

`H = comm.PhaseFrequencyOffset(Name,Value)` creates a phase and frequency offset object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`PhaseOffset`

Phase offset

Specify the phase offset in degrees. The default is `0`. If the `step` method input is an *M*-by-*N* matrix, the `PhaseOffset` on page 3-0 property can be set to a numeric scalar, an *M*-by-1, or 1-by-*N* numeric vector, or an *M*-by-*N* numeric matrix.

When you set the `PhaseOffset` property to a scalar value, the object applies the constant specified phase offset to each column of the input matrix.

When you set this property to an *M*-by-1 vector, the object applies time varying phase offsets, specified in the vector of this property, to each column of the input to the `step` method.

When you set this property to a 1-by-*N* vector, the object applies the *i*-th constant phase offset of this property to the *i*-th column of the input to the `step` method.

When you set this property to an *M*-by-*N* matrix, the object applies the *i*-th time varying phase offsets, specified in the *i*-th column of this property, to the *i*-th column of the input to the `step` method. This property is tunable.

`FrequencyOffsetSource`

Source of frequency offset

Specify the source of the frequency offset as one of `Property` | `Input port`. The default is `Property`. If you set this property to `Property`, you can specify the frequency offset using the `FrequencyOffset` on page 3-0 property. If you set this property to `Input port`, you specify the frequency offset as a step method input.

`FrequencyOffset`

Frequency offset

Specify the frequency offset in Hertz. The default is `0`. If the `step` method input is an *M*-by-*N* matrix, then the `FrequencyOffset` on page 3-0 property is a numeric scalar, an *M*-by-1, or 1-by-*N* numeric vector, or an *M*-by-*N* numeric matrix.

This property applies when you set the `FrequencyOffsetSource` on page 3-0 property to `Property`.

When you set this property to a scalar value, the object applies the constant specified frequency offset to each column of the input to the `step` method.

When you set this property to an *M*-by-1 vector, the object applies time-varying frequency offsets. These offsets are specified in the property, to each column of the input to the `step` method.

When you set this property to a 1-by-*N* vector, the object applies the *i*-th constant frequency offset in this property to the *i*-th column of the input to the `step` method.

When you set this property to an *M*-by-*N* matrix, the object applies the *i*-th time varying frequency offset. This offset is specified in the *i*-th column of this property and to the *i*-th column of input to the `step` method. This property is tunable.

`SampleRate`

Sample rate

Specify the sample rate of the input samples in seconds as a double-precision, real, positive scalar value. The default is `1`.

`SampleRate` = Input Vector Size / Simulink Sample Time

Methods

step	Apply phase and frequency offsets to input signal

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Introduce Phase Offset to 16-QAM Signal

Introduce a phase offset to a 16-QAM signal and view its effect on the constellation.

Create a phase frequency offset System object™. Set the phase offset to 30 degrees.

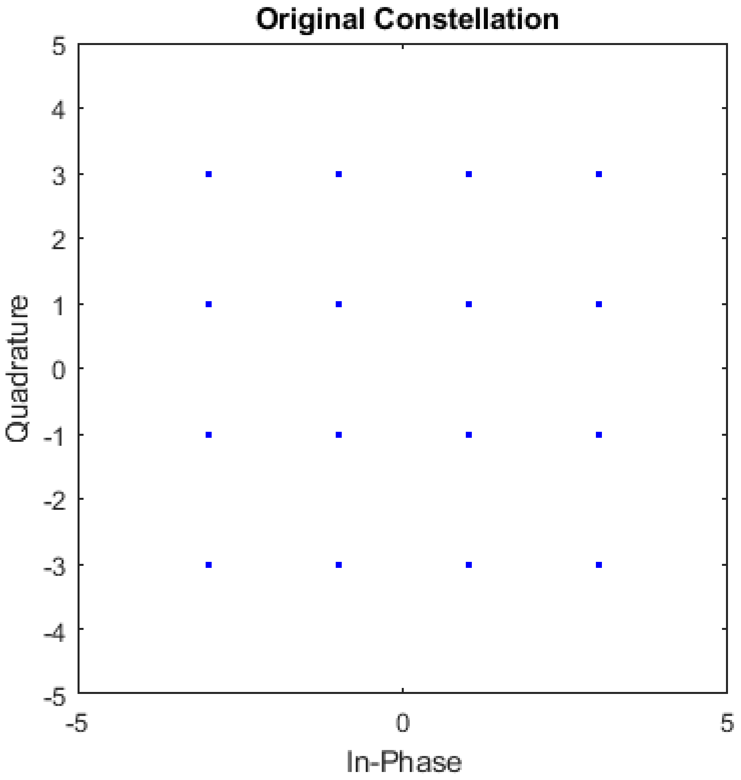
```
pfo = comm.PhaseFrequencyOffset('PhaseOffset',30);
```

Generate random symbols and apply 16-QAM modulation.

```
M = 16;
data = (0:M-1)';
modData = qammod(data,M);
```

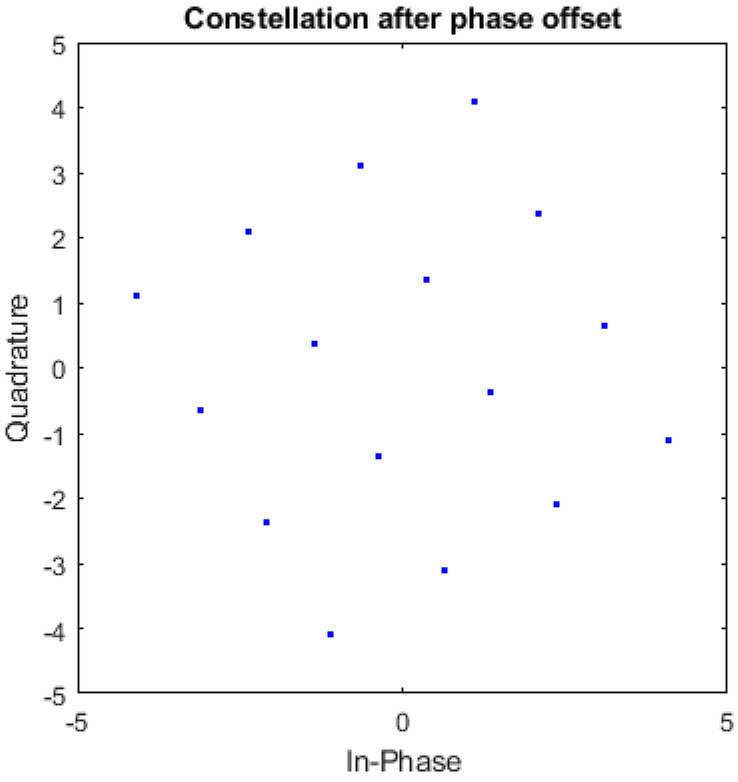
Plot the 16-QAM constellation.

```
scatterplot(modData);
title(' Original Constellation')
xlim([-5 5])
ylim([-5 5])
```



Introduce a phase offset using `pfo` and plot the offset constellation. Note that it has been shifted 30 degrees.

```
impairedData = pfo(modData);
scatterplot(impairedData);
title('Constellation after phase offset')
xlim([-5 5])
ylim([-5 5])
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the Phase/Frequency Offset block reference page. The object properties correspond to the block parameters, except: The object provides a `SampleRate` on page 3-0 property, which you must specify. The block senses the sample time of the signal and therefore does not have a corresponding parameter.

Extended Capabilities

`comm.MemorylessNonlinearity` | `comm.PhaseNoise` | `comm.ThermalNoise`

Introduced in R2012a

step

System object: comm.PhaseFrequencyOffset
Package: comm

Apply phase and frequency offsets to input signal

Syntax

```
Y = step(H,X)
Y = step(H,X,FRQ)
```

Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Y = step(H,X) applies phase and frequency offsets to input X, and returns Y. The input X is a double or single precision matrix X, of dimensions MxN. M is the number of time samples in the input signals and N is number of channels. Both M and N can be equal to 1. The object adds phase and frequency offsets independently to each column of X. The data type and dimensions of X and Y are the same.

Y = step(H,X,FRQ) uses FRQ as the frequency offset that the object applies to input X when you set the FrequencyOffsetSource property to 'Input port'. When the X input is an MxN matrix, the value for FRQ can be a numeric scalar, an Mx1 or 1xN numeric vector, or an MxN numeric matrix. When the FRQ input is a scalar, the object applies a constant frequency offset, FRQ, to each column of X. When the FRQ input is an Mx1 vector, the object applies time varying frequency offsets, which are specified in the FRQ vector, to each column of X. When the FRQ input is a 1xN vector, the object applies the ith constant frequency offset in FRQ to the ith column of X. When the FRQ input is an MxN matrix, the object applies the ith time varying frequency offsets, specified in the ith column of FRQ, to the ith column of X.

Note obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

comm.PhaseNoise

Package: `comm`

Apply phase noise to baseband signal

Description

The `comm.PhaseNoise` System object adds phase noise to a complex signal. This object emulates impairments introduced by the local oscillator of a wireless communication transmitter or receiver. The object generates filtered phase noise according to the specified spectral mask and adds it to the input signal. For a description of the phase noise modeling, see “Algorithms” on page 3-1087.

To add phase noise using a `comm.PhaseNoise` object:

1. Create the `comm.PhaseNoise` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
phznoise = comm.PhaseNoise
phznoise = comm.PhaseNoise(Name,Value)
phznoise = comm.PhaseNoise(level,offset,samplerate)
```

Description

`phznoise = comm.PhaseNoise` creates a phase noise System object with default property values.

`phznoise = comm.PhaseNoise(Name,Value)` creates a phase noise object with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`phznoise = comm.PhaseNoise(level,offset,samplerate)` creates a phase noise object with the phase noise level, frequency offset, and sample rate properties specified as value-only arguments. When specifying a value-only argument, you must specify all preceding value-only arguments.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Level` — Phase noise level

`[-60 -80]` (default) | vector of negative scalars

Phase noise level in decibels relative to carrier per hertz (dBc/Hz), specified as a vector of negative scalars. The `Level` and `FrequencyOffset` properties must have the same length.

Data Types: `double`

`FrequencyOffset` — Frequency offset

`[20 200]` (default) | vector of positive increasing values

Frequency offset in Hz, specified as a vector of positive increasing values. The `Level` and `FrequencyOffset` properties must have the same length.

Data Types: `double`

`SampleRate` — Sample rate

`1024` (default) | positive scalar

Sample rate in samples per second, specified as a positive scalar. To avoid aliasing, the sample rate must be greater than twice the largest value specified by `FrequencyOffset`.

Data Types: `double`

`RandomStream` — Source of random stream

`'Global stream'` (default) | `'mt19937ar with seed'`

Source of the random stream, specified as `'Global stream'` or `'mt19937ar with seed'`.If `RandomStream` is set to `'mt19937ar with seed'`, the mt19937ar algorithm is used for normally distributed random number generation, in which case the reset method reinitializes the random number stream to the value of the `Seed` property.

Data Types: `char` | `string`

`Seed` — Initial seed

`2137` (default) | positive scalar less than 2^{32}

Initial seed for `RandomStream`, specified as a positive scalar less than 2^{32}.

Dependencies

To enable this property, set `RandomStream` to `'mt19937ar with seed'`.

Data Types: `double`

Usage

Syntax

```
out = phznoise(in)
```

Description

`out = phznoise(in)` adds phase noise, specified by the `phznoise` System object, to the input signal. The result is returned in `out`.

Input Arguments

in — Input signal
complex column vector

Input signal, specified as an N_S-by-1 vector of complex values. N_S is the number of samples.

Data Types: `double`
Complex Number Support: Yes

Output Arguments

out — Output signal
column vector

Output signal, returned as an N_S-by-1 vector of complex values. N_S equals the number of samples in the input signal.

Data Types: `double`
Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to comm.PhaseNoise

visualize	Visualize spectrum mask of phase noise

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Phase Noise Effects on 16-QAM Signal

Add a phase noise vector and frequency offset vector to a 16-QAM signal. Then plot the signal.

Create a phase noise System object.

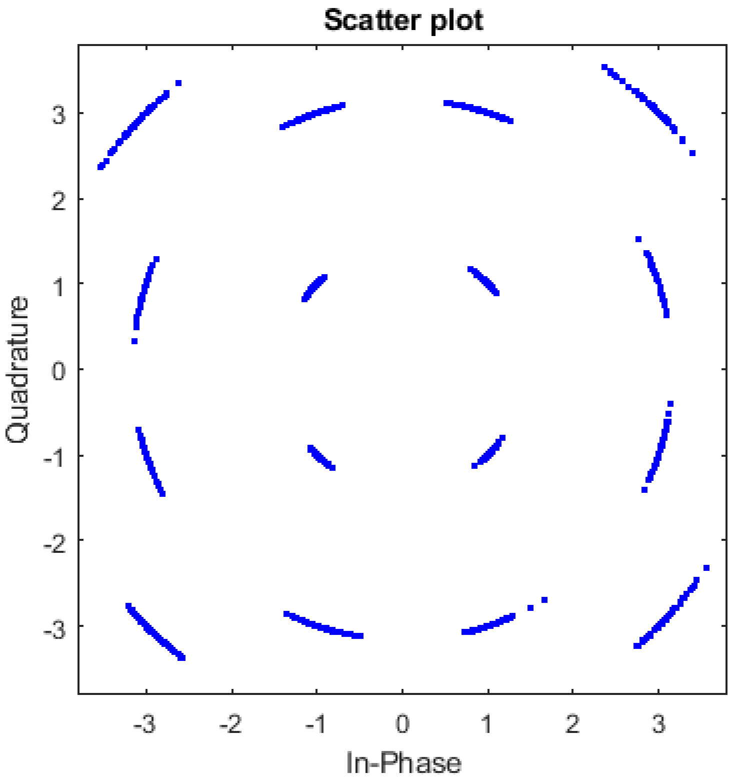
```
pnoise = comm.PhaseNoise('Level',-50,'FrequencyOffset',20);
```

Generate modulated symbols.

```
M = 16; % From 16-QAM
data = randi([0 M-1],1000,1);
modData = qammod(data,M);
```

Use `pnoise` to apply phase noise. Plot the impaired data.

```
y = pnoise(modData);
scatterplot(y)
```



View Phase Noise Effects on Signal Spectrum

View the effects of phase noise on a 10 MHz sine wave by using a spectrum analyzer. Adjust the resolution bandwidth of the spectrum analyzer to see its impact on the visualized spectral noise.

Initialize variables for the simulation.

```
fc = 1e6; % Carrier frequency in Hz
fs = 4e6; % Sample rate in Hz.
phNzLevel = [-85 -118 -125 -145]; % Phase noise level in dBc/Hz
phNzFreqOff = [1e3 9.5e3 19.5e3 195e3]; % Phase noise frequency offset in Hz
Nspf = 6e6; % Number of Samples per frame
freqSpan = 400e3; % Frequency span in Hz for spectrum computation
```

Create sine wave, phase noise, and spectrum analyzer objects.

```
sinewave = dsp.SineWave('Amplitude',1,'Frequency',fc,'SampleRate',fs, ...
    'SamplesPerFrame',Nspf,'ComplexOutput',true);
pnoise = comm.PhaseNoise('Level',phNzLevel, ...
    'FrequencyOffset',phNzFreqOff,'SampleRate',fs);
```

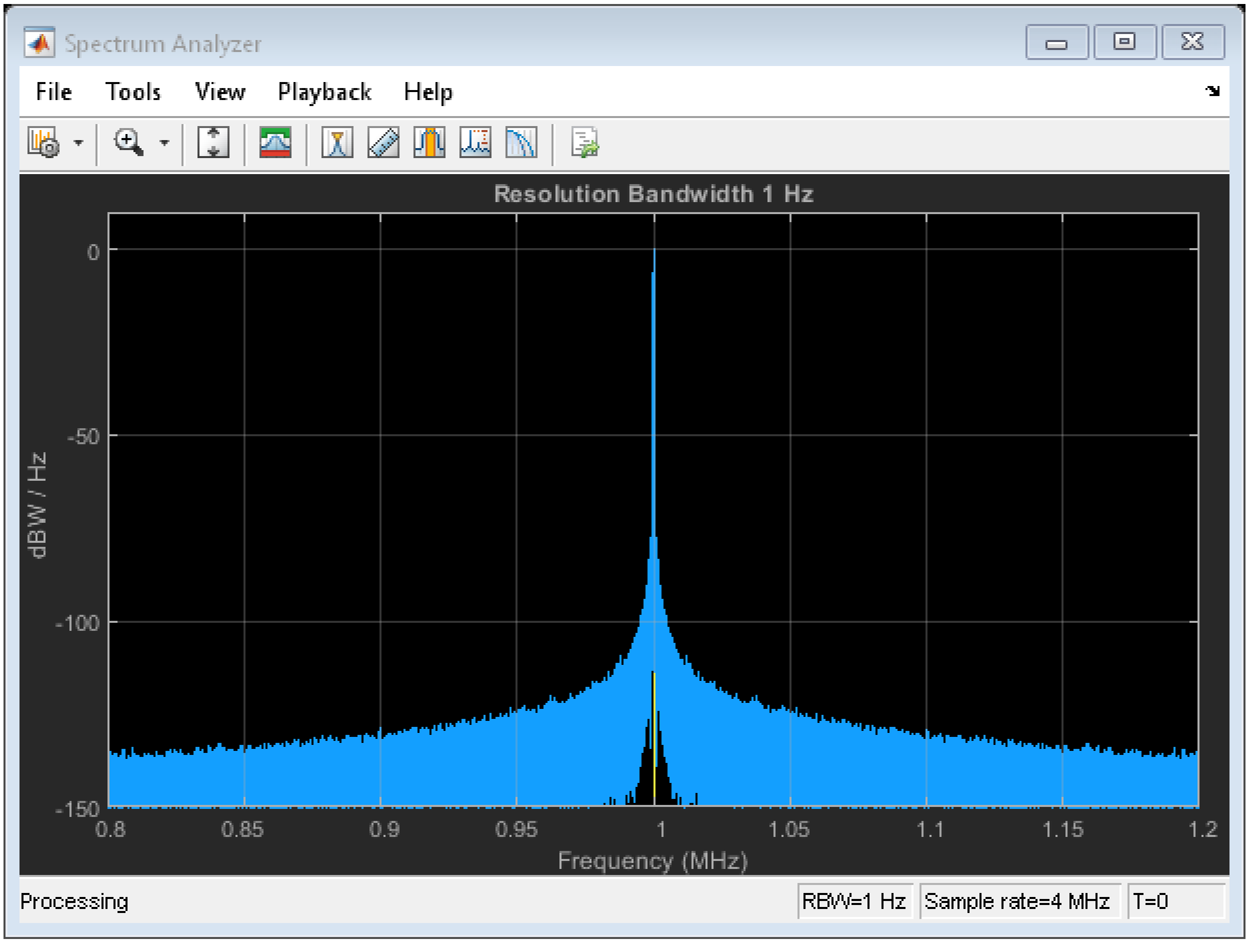
```
spectrumscopeRBW1 = dsp.SpectrumAnalyzer('NumInputPorts',2, ...
    'SampleRate',fs,'FrequencySpan','Span and center frequency', ...
    'CenterFrequency',fc,'Span',freqSpan,'RBWSource','Property', ...
    'RBW',1,'SpectrumType','Power density','SpectralAverages',10, ...
    'SpectrumUnits','dBW','YLimits',[-150 10], ...
    'Title','Resolution Bandwidth 1 Hz','Position',[79 147 605 374]);
spectrumscopeRBW10 = dsp.SpectrumAnalyzer('NumInputPorts',2, ...
    'SampleRate',fs,'FrequencySpan','Span and center frequency', ...
    'CenterFrequency',fc,'Span',freqSpan,'RBWSource','Property', ...
    'RBW',10,'SpectrumType','Power density','SpectralAverages',10, ...
    'SpectrumUnits','dBW','YLimits',[-150 10], ...
    'Title','Resolution Bandwidth 10 Hz','Position',[685 146 605 376]);
```

To analyze the spectrum and phase noise, the example includes two spectrum analyzer objects, with 1 Hz and 10 Hz resolution bandwidths, respectively. The spectrum analyzer objects use the default `Hann` windowing setting, the units are set to `dBW/Hz`, and the number of spectral averages is set to `10`.

```
x = sinewave();
y = pnoise(x);
```

When the resolution bandwidth is 1 Hz, the `dBW/Hz` view for the spectrum analyzer shows the tone at 0 dBW/Hz. The spectrum analyzer object corrects for the power spreading effect of the Hann windowing. Results show the visual average of the phase noise match the specified phase noise spectrum.

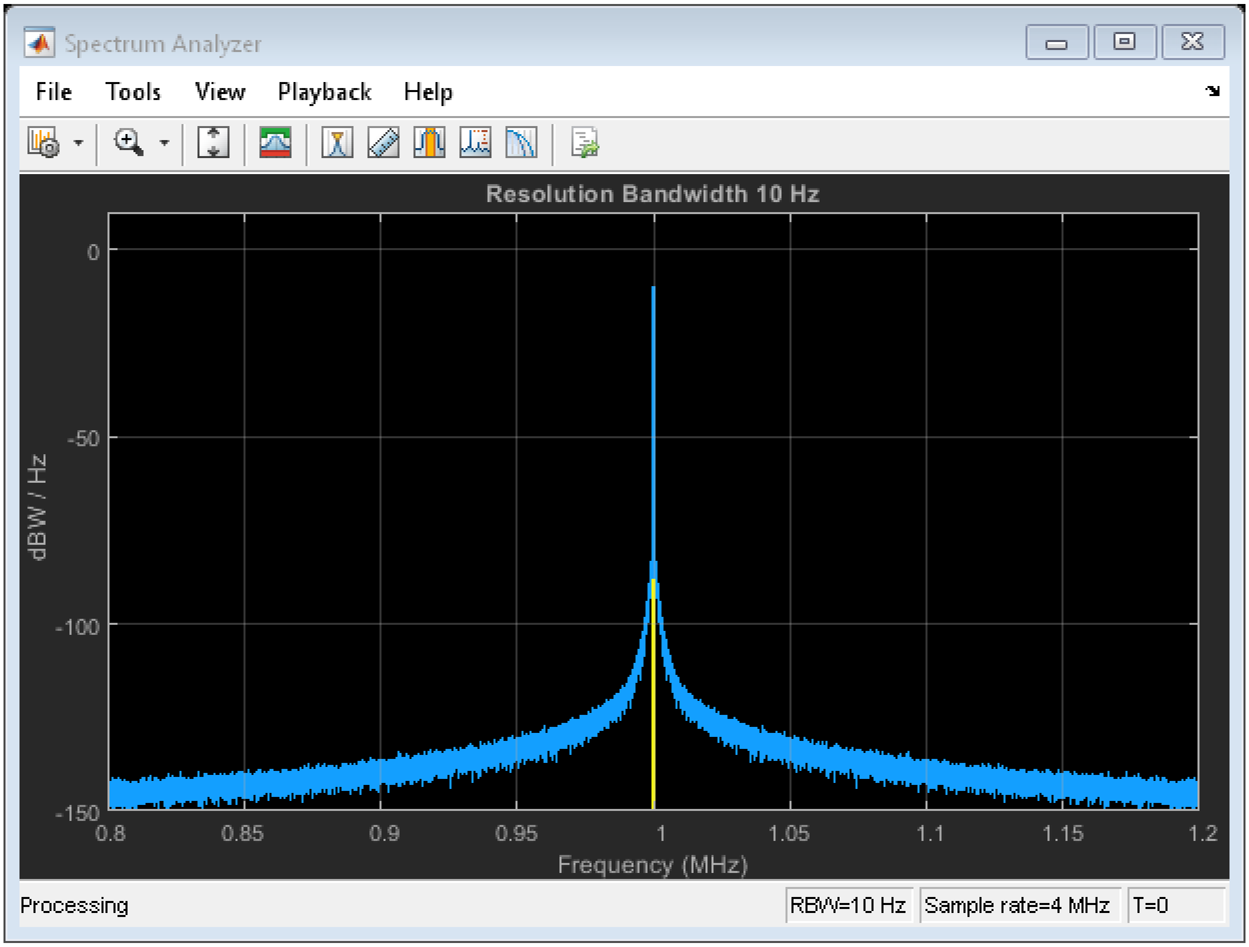
```
spectrumscopeRBW1(x,y)
```



When the resolution bandwidth is 10 Hz, the `dBW/Hz` view for the spectrum analyzer shows the tone at -10 dBW/Hz. The tone energy of the sine wave is now spread across 10 Hz instead of 1 Hz, so the sine wave PSD level reduces by 10 dB. With the resolution bandwidth at 10 Hz, the visual average of the phase noise still achieves the phase noise defined by the phase noise object.

With the resolution bandwidth increased from 1 Hz to 10 Hz, the spectrum analyzer object still corrects for the power spreading effect of the Hann window, and it achieves better spectral averaging with the wider resolution bandwidth. For more information, see “Why Use Windows?”.

```
spectrumscopeRBW10(x,y)
```



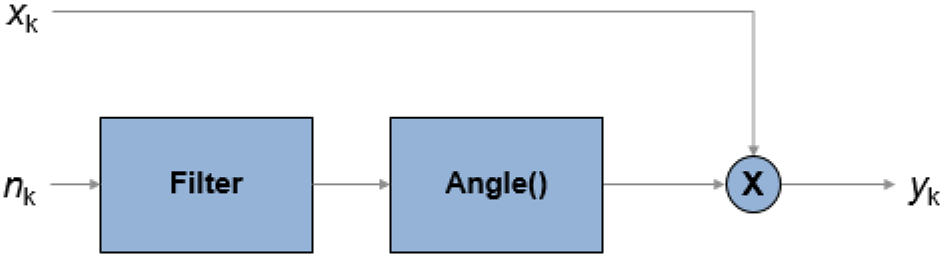
Calculate the RMS phase noise in degrees between the pure and noisy sine waves. In the general case, the pure signal must be time aligned with the noisy signal to accurately determine the phase error. However, in this case, the periodicity of the sine wave makes this step unnecessary.

```
ph_err = unwrap(angle(y) - angle(x));
rms_ph_nz_deg = rms(ph_err)*180/pi();
sprintf('The computed RMS phase noise is %3.2f degrees.\n',rms_ph_nz_deg)
```

```
ans = 
    'The computed RMS phase noise is 0.18 degrees.
     '
```

Algorithms

The output signal, y_k, is related to input sequence x_k by $y_k=x_k e^{j\varphi_k}$, where φ_k is the phase noise. The phase noise is filtered Gaussian noise such that $\varphi_k=f(n_k)$, where n_k is the noise sequence and f represents a filtering operation.



To model the phase noise, define the power spectrum density (PSD) mask characteristic by specifying scalar or vector values for the frequency offset and phase noise level.

- For a scalar frequency offset and phase noise level specification, an IIR digital filter computes the spectrum mask. The spectrum mask has a 1/*f* characteristic that passes through the specified point.
- For a vector frequency offset and phase noise level specification, an FIR filter computes the spectrum mask. The spectrum mask is interpolated across log10(*f*). It is flat from DC to the lowest frequency offset, and from the highest frequency offset to half the sample rate.

IIR Digital Filter

For the IIR digital filter, the numerator coefficient is

$$\lambda = \sqrt{2\pi f_{offset} 10^{L/10}}\,,$$

where f_{offset} is the frequency offset in Hz and L is the phase noise level in dBc/Hz. The denominator coefficients, γ_{i}, are recursively determined as

$$\gamma_i = (i - 2.5)\frac{\gamma_{i-1}}{i-1}\,,$$

where $\gamma_1 = 1$, $i = \{1, 2,..., N_{\text{t}}\}$, and N_{t} is the number of filter coefficients. N_{t} is a power of 2, from 2^7 to 2^{19}. The value of N_{t} grows as the phase noise offset decreases towards 0 Hz.

FIR Filter

For the FIR filter, the phase noise level is determined through log10(*f*) interpolation for frequency offsets over the range [df, f_{s} / 2], where df is the frequency resolution and f_{s} is the sample rate. The phase noise is flat from 0 Hz to the smallest frequency offset, and from the largest frequency offset to f_{s} / 2. The frequency resolution is equal to $\frac{f_s}{2}\left(\frac{1}{N_t}\right)$, where N_{t} is the number of coefficients, and is a power of 2 less than or equal to 2^{16}. If $N_{\text{t}} < 2^8$, a time domain FIR filter is used. Otherwise, a frequency domain FIR filter is used.

The algorithm increases N_{t} until these conditions are met:

- The frequency resolution is less than the minimum value of the frequency offset vector.
- The frequency resolution is less than the minimum difference between two consecutive frequencies in the frequency offset vector.

- The maximum number of FIR filter taps is 2^{16}.

Phase Noise

Introduced in R2012a

comm.PNSequence

Package: `comm`

Generate a pseudo-noise (PN) sequence

Description

The `PNSequence` object generates a sequence of pseudorandom binary numbers using a linear-feedback shift register (LFSR). This object implements LFSR using a simple shift register generator (SSRG, or Fibonacci) configuration. Pseudo-noise sequences are typically used for pseudorandom scrambling and in direct-sequence spread-spectrum systems.

To generate a PN sequence:

1. Create the `comm.PNSequence` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
pnSequence = comm.PNSequence
pnSequence = comm.PNSequence(Name,Value)
```

Description

`pnSequence = comm.PNSequence` creates a pseudo-noise (PN) sequence generator System object. This object generates a sequence of pseudorandom binary numbers using a linear-feedback shift register (LFSR).

`pnSequence = comm.PNSequence(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`Polynomial` — Generator polynomial
`'z^6 + z + 1'` (default) | polynomial character vector | binary row vector | integer vector

Generator polynomial that determines the feedback connections of the shift register , specified as one of these:

- A polynomial character vector that includes the number `1`.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power. The first and last entries must be `1`. The length of this vector is $N + 1$, where N is the degree of the generator polynomial.
- A vector containing the exponents of z for the nonzero terms of the polynomial in descending order of powers. The last entry must be `0`.

For more information, see "Character Representation of Polynomials".

Example: `'z^8 + z^2 + 1'`, `[1 0 0 0 0 0 1 0 1]`, and `[8 2 0]` represent the same polynomial, $p(z) = z^8 + z^2 + 1$.

Data Types: `double` | `char`

`InitialConditionsSource` — Source of initial conditions

`'Property'` (default) | `'Input port'`

Source of the initial conditions that determines the start of the PN sequence, specified as one of these:

- `'Property'` — Specify PN sequence generator initial conditions as a binary scalar or binary vector using the `InitialConditions` property.
- `'Input port'` — Specify PN sequence generator initial conditions by using an additional input argument, when calling the object. The object accepts a binary scalar or binary vector input. The length of the input must equal the degree of the generator polynomial that the `Polynomial` property specifies.

Data Types: `char`

`InitialConditions` — Initial conditions of shift register

`[0 0 0 0 0 1]` (default) | binary scalar | binary vector

Initial conditions of shift register when the simulation starts, specified as a binary scalar or binary vector.

If you set this property to a vector, each element of the vector corresponds to the initial value of the corresponding cell in the shift register. The length of the vector must equal the degree of the generator polynomial. If you set this property to a scalar, the initial conditions of all the cells of the shift register are the specified scalar value.

The scalar, or at least one element of the specified vector, must be nonzero for the object to generate a nonzero sequence.

Dependencies

This property is available when `InitialConditionsSource` is set to `'Property'`.

Data Types: `double`

`MaskSource` — Source of mask to shift PN sequence

`'Property'` (default) | `'Input port'`

Source of the mask that determines the shift of the PN sequence, specified as one of these:

- `'Property'` — Specify the mask as an integer scalar or binary vector using the `Mask` property.
- `'Input port'` — Specify the mask by using an additional input argument, when calling the object. The mask can only be specified as a binary vector, whose length must equal the degree of the generator polynomial that the `Polynomial` property specifies.

Data Types: `char`

`Mask` — Mask to shift PN sequence

`0` (default) | integer scalar | binary vector

Mask that determines how the PN sequence is shifted from its starting point, specified as an integer scalar or a binary vector.

When you set this property to an integer scalar, the value is the length of the shift. A scalar shift can be positive or negative. When the PN sequence has a period of $N = 2^n - 1$, where n is the degree of the generator polynomial that the `Polynomial` property specifies, the object wraps shift values that are negative or greater than N.

When you set this property to a binary vector, its length must equal the degree of the generator polynomial that the `Polynomial` specifies. For more information, see “Shifting PN Sequence Starting Point” on page 3-1100.

The mask vector can be calculated using the `shift2mask` function.

Dependencies

This property is available when `MaskSource` is set to `'Property'`.

`VariableSizeOutput` — Enable variable-size outputs

`false` (default) | `true`

Set this property to `true` to enable variable-size outputs by using an additional input argument when calling the object. The enabled input specifies the output size of the PN sequence. The input value must be less than or equal to the value of the `MaximumOutputSize` property.

When you set this property to `false`, the `SamplesPerFrame` property specifies the number of output samples.

`MaximumOutputSize` — Maximum output size

`[10 1]` (default) | two-element row vector

Maximum output size, specified as a positive integer two-element row vector that denotes the maximum output size of the PN sequence. The second element of the vector must be `1`.

Example: `[10 1]` gives a `10`-by-`1` maximum sized output signal.

Dependencies

This property is available when `VariableSizeOutput` is set to `true`.

`SamplesPerFrame` — Number of samples output per frame

`1` (default) | positive integer

Number of samples output per frame by the PN sequence object, specified as a positive integer. If you set this property to a value of M, then the object outputs M samples of a PN sequence that has a period of $N = 2^n - 1$, where n represents the degree of the generator polynomial that the `Polynomial` specifies.

If you set the `BitPackedOutput` property to `false`, the samples are bits from the PN sequence. If you set the `BitPackedOutput` property to `true`, then the output corresponds to `SamplesPerFrame` groups of bit-packed samples.

`ResetInputPort` — Enable generator reset input

`false` (default) | `true`

Set this property to `true` to enable PN sequence generator reset by using an additional input argument when calling the object. This input resets the states of the PN sequence generator to the initial conditions specified in the `InitialConditions` property. For more information, see "Resetting a Signal" on page 3-1100.

Dependencies

This property is available when `InitialConditionsSource` is set to `'Property'`.

`BitPackedOutput` — Output bit-packed words

`false` (default) | `true`

Option to output bit-packed words, specified as `false` or `true`. Set this property to `true` to enable bit-packed outputs.

When `BitPackedOutput` is `true`, the object outputs a column vector of length M, which contains most-significant-bit (MSB) first integer representations of bit words of length P. M is the number of samples per frame specified in the `SamplesPerFrame` property. P is the size of the bit-packed words specified in the `NumPackedBits` property.

Note The first bit from the left in the bit-packed word contains the most significant bit for the integer representation.

`NumPackedBits` — Number of bits per bit-packed word

8 (default) | integer in the range [1, 32]

Number of bits packed into each output data word, specified as an integer in the range [1, 32].

Dependencies

This property is available when `BitPackedOutput` is set to `true`.

`SignedOutput` — Output signed bit-packed words

`false` (default) | `true`

Set this property to `true` to obtain signed, bit-packed, output words. In this case, a `1` in the most significant bit (sign bit) indicates a negative value. The property indicates negative numbers in a two's complement format.

Dependencies

This property is available when `BitPackedOutput` is set to `true`.

`OutputDataType` — Data type of output

`'double'` (default) | `'logical'` | `'Smallest unsigned integer'` | `'Smallest integer'`

Output data type, specified as one of these:

- When BitPackedOutput is set to false, OutputDataType can be 'double', 'logical', or 'Smallest unsigned integer'.
- When BitPackedOutput is set to true, OutputDataType can be 'double' or 'Smallest integer'.

Note You must have a Fixed-Point Designer user license to use this property in 'Smallest unsigned integer' or 'Smallest integer' mode.

Dependencies

The valid settings for OutputDataType depends on the setting of BitPackedOutput.

Usage

Syntax

```
outSequence = pnSequence()
outSequence = pnSequence(initCond)
outSequence = pnSequence(maskVec)
outSequence = pnSequence(outputSize)
outSequence = pnSequence(reset)
outSequence = pnSequence(initCond,maskVec,outputSize)
outSequence = pnSequence(maskVec,outputSize,reset)
```

Description

outSequence = pnSequence() outputs a frame of the PN sequence. Specify the frame length with the SamplesPerFrame property. The PN sequence has a period of $N = 2^n - 1$, where n is the degree of the generator polynomial that you specify in the Polynomial property.

You can combine optional input arguments when you set their enabling properties. Optional inputs must be listed in the same order as the order of the enabling properties.

outSequence = pnSequence(initCond) provides an additional input with values specifying the initial conditions of the linear-feedback shift register.

This syntax applies when you set the InitialConditionsSource property of the object to 'Input port'.

outSequence = pnSequence(maskVec) provides an additional input specifying the mask vector that determines how the PN sequence is shifted from its starting point.

This syntax applies when you set the MaskSource property of the object to 'Input port'.

outSequence = pnSequence(outputSize) provides an additional input specifying the output size of the PN sequence.

This syntax applies when you set the VariableSizeOutput property of the object to true.

`outSequence = pnSequence(reset)` provides an additional input indicating whether to reset the PN sequence generator.

This syntax applies when you set `InitialConditionsSource` to `'Property'` and `ResetInputPort` to `true`.

`outSequence = pnSequence(initCond,maskVec,outputSize)`

`outSequence = pnSequence(maskVec,outputSize,reset)`

Using these syntaxes, you can combine optional input arguments when you set their enabling properties. Optional inputs must be listed in the same order as the order of the enabling properties.

Input Arguments

initCond — Initial register conditions

binary scalar | binary vector

Initial conditions of the shift register when the simulation starts, specified as a binary scalar or binary vector. When you set `initCond` to a binary vector, the length of the vector must equal the degree of the `Polynomial` property. The scalar, or at least one element of `initCond`, must be nonzero for the object to generate a nonzero sequence.

Example: `outSequence = pnSequence([1 1 0])` corresponds to possible initial register states for a PN sequence generator specified by a generator polynomial of degree 3.

Data Types: `double`

maskVec — Mask vector

binary vector

Mask that determines how the PN sequence is shifted from its starting point, specified as a binary vector. The length of the vector must equal the degree of the `Polynomial` property.

outputSize — Output size of the PN sequence

scalar | two-element row vector

Output size of the PN sequence, specified as a scalar or two-element row vector. When you set `outputSize` to a two-element row vector, the second element must be equal to `1`.

reset — Reset PN sequence generator

scalar | column vector

When you specify `reset` as a scalar, the object resets to the initial conditions specified in the `InitialConditions` property and generates a new output frame.

When you specify `reset` as a column vector, the length of the vector must equal the number of samples per frame specified in `SamplesPerFrame`. A column vector input allows multiple resets within an output frame. A non-zero value at the ith element of the vector will cause a reset at the ith element of the generated PN sequence.

Output Arguments

outSequence — PN Sequence

column vector

PN sequence generated by the object, returned as a column vector.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Generate Maximal Length PN Sequences

Generate a 14-sample frame of a maximal length PN sequence given generator polynomial, $x^3 + x^2 + 1$.

Generate PN sequence data by using the `comm.PNSequence` object. The sequence repeats itself as it contains 14 samples while the maximal sequence length is only 7 samples ($2^3 - 1$).

```
pnSequence = comm.PNSequence('Polynomial',[3 2 0], ...
    'SamplesPerFrame',14,'InitialConditions',[0 0 1]);
x1 = pnSequence();
[x1(1:7) x1(8:14)]
```

```
ans = 7×2

     1     1
     0     0
     0     0
     1     1
     1     1
     1     1
     0     0
```

Create another maximal length sequence based on the generator polynomial, $x^4 + x + 1$. As it is a fourth order polynomial, the sequence repeats itself after 15 samples ($2^4 - 1$).

```
pnSequence2 = comm.PNSequence('Polynomial','x^4+x+1', ...
    'InitialConditions',[0 0 0 1],'SamplesPerFrame',30);
x2 = pnSequence2();
[x2(1:15) x2(16:30)]
```

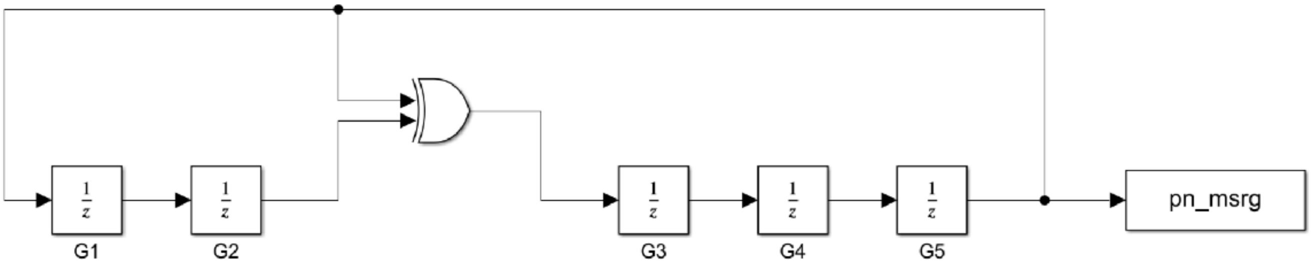
```
ans = 15×2

     1     1
     0     0
     0     0
     0     0
     1     1
     0     0
     0     0
     1     1
     1     1
     0     0
       ⋮
```

Generate Galois Linear-Feedback Shift Register Output

The `comm.PNSequence` system object implements a linear-feedback shift register (LFSR) using a simple shift register generator (SSRG, or Fibonacci configuration). This configuration differs from the modular shift register generator (MSRG, or Galois configuration) by a phase difference, that can be determined empirically from the system object.

This phase difference can be specified as the `Mask` parameter for the `comm.PNSequence` system object to generate the equivalent MSRG configuration output. The block diagram represents the implementation of a 5-bit LFSR in the Galois (MSRG) configuration.



Load the file `GaloisLFSR`. The file contains the following variables that define the properties and output PN sequence of the 5-bit Galois LFSR:

- `polyVec`: Generator polynomial
- `polySize`: Degree of the generator polynomial
- `initStates`: Initial conditions of the shift register
- `maskVar`: Mask to shift the PN sequence
- `pn_msrg`: Output PN sequence of maximal length, from the 5-bit Galois LFSR

```
load GaloisLFSR
```

Generate PN sequence data by using the `comm.PNSequence` object with the same set of properties used to implement the 5-bit Galois LFSR. Compare this PN sequence with the output of the 5-bit Galois LFSR. The two sequences differ by a phase shift.

```
pnSequence = comm.PNSequence('Polynomial',polyVec,'InitialConditions',initStates,...
    'Mask',maskVar,'SamplesPerFrame',2^polySize-1);
```

```
pn = pnSequence();

isequal(pn,pn_msrg)

ans = logical
   0
```

Compute the phase shift between the two configurations. Set the value of the `Mask` property based on this phase shift.

```
for i = 1:length(pn)
    exp_pn = [pn(i:end);pn(1:(i-1))];
    if isequal(exp_pn,pn_msrg)
        break
    end
end

maskVar = i-1;
```

Generate PN sequence data by using the `comm.PNSequence` system object with the modified `Mask` property value. Compare this sequence with the output of the 5-bit Galois LFSR. The two sequences are now equal.

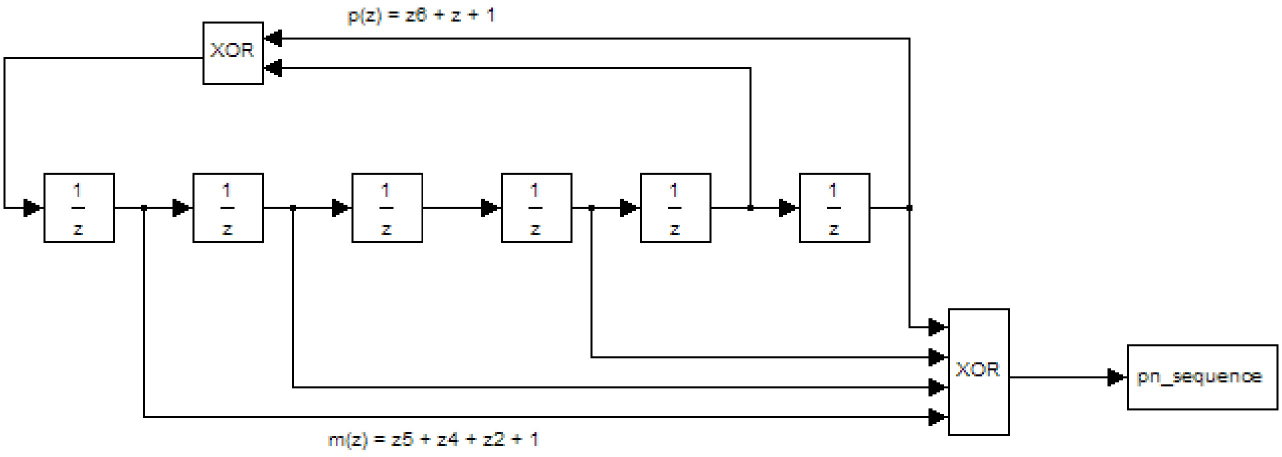
```
pnSequence_mod = comm.PNSequence('Polynomial',polyVec,'InitialConditions',initStates,...
    'Mask',maskVar,'SamplesPerFrame',2^polySize-1);

pn_mod = pnSequence_mod();

isequal(pn_mod,pn_msrg)

ans = logical
   1
```

Setting up the PN sequence generator



This figure defines a PN sequence generator with a generator polynomial $p(z) = z^6 + z + 1$. You can set up the PN sequence generator by typing the following at the MATLAB command line.

```
h1 = comm.PNSequence('Polynomial', [1 0 0 0 0 1 1], 'InitialConditions', [1 1 0 1 0 1]);
h2 = comm.PNSequence('Polynomial', [1 0 0 0 0 1 1], 'Mask', 22);
mask2shift ([1 0 0 0 0 1 1],[1 1 0 1 0 1])
```

```
ans = 22
```

Alternatively you can input the polynomial exponents of z for the nonzero terms of the polynomial in descending order of powers.

```
h = comm.PNSequence('Polynomial', [6 1 0], 'InitialConditions', [1 1 0 1 0 1])
```

```
h = 
  comm.PNSequence with properties:

                 Polynomial: [6 1 0]
    InitialConditionsSource: 'Property'
          InitialConditions: [1 1 0 1 0 1]
                 MaskSource: 'Property'
                       Mask: 0
         VariableSizeOutput: false
            SamplesPerFrame: 1

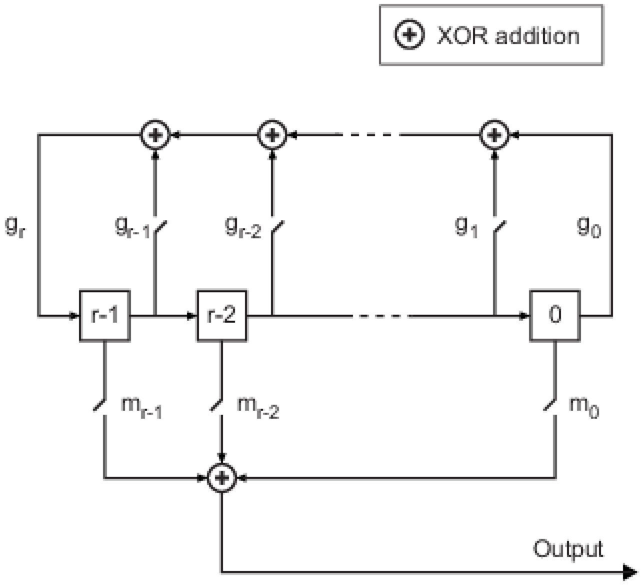
            BitPackedOutput: false
             OutputDataType: 'double'
```

Algorithms

Simple Shift Register Generator

A linear-feedback shift register (LFSR), implemented as a simple shift register generator (SSRG), is used to generate PN sequences. This type of shift register is also known as a Fibonacci implementation.



The `Polynomial` property determines the feedback connections of the shift register. It is a primitive binary polynomial in *z*, $g_r z^r + g_{r-1} z^{r-1} + g_{r-2} z^{r-2} + \ldots + g_0$. For the coefficient, $g_{k=0}$ to *r*, the coefficient g_k is 1 if there is a connection from the kth register to the adder. The leading term, g_r, and the constant term, g_0, of the `Polynomial` property must be `1` because the polynomial must be primitive. The `InitialConditions` property specifies the initial values of the registers. For example, the following table indicates two sets of parameter values that correspond to a generator polynomial of $p(z) = z^8 + z^2 + 1$.

Quantity	Example 1	Example 2
Polynomial	`g1 = [1 0 0 0 0 0 1 0 1]`	`g2 = [8 2 0]`
Degree of generator polynomial	8, which is `length(g1)-1`	8
InitialConditions	`[1 0 0 0 0 0 1 0]`	`[1 0 0 0 0 0 1 0]`

At each step, all *r* registers in the generator update their values according to the value of the incoming arrow to the shift register. The adders perform addition modulo 2. The output of the LFSR reflects the sum of all connections in the *m* mask vector.

The `Mask` property, *m*, determines the shift of the PN sequence starting point. For more information, see “Shifting PN Sequence Starting Point” on page 3-1100.

Shifting PN Sequence Starting Point

To shift the starting point of the PN sequence, specify the `Mask` property as:

- An integer representing the length of the shift.

  The default `Mask` setting of `0` corresponds to no shift. As illustrated in the LFSR shift register diagram in “Simple Shift Register Generator” on page 3-1099, there is no shift when the only connection is along the arrow labeled m_0.

  This table shows the shift that occurs when you set `Mask` to `0` versus a positive integer *d*.

	T = 0	T = 1	T = 2	…	T = *d*	T = *d*+1
Shift = 0	x_0	x_1	x_2	…	x_d	x_{d+1}
Shift = *d*	x_d	x_{d+1}	x_{d+2}	…	x_{2d}	x_{2d+1}

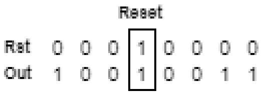
- A binary vector whose length is equal to the degree of the generator polynomial. The LFSR shift register diagram in “Simple Shift Register Generator” on page 3-1099 shows `Mask` specified as a mask vector, *m*. The binary vector must have *N* elements, where *N* is the degree of the generator polynomial. To calculate the mask vector, use the `shift2mask` function.

  The binary vector corresponds to a polynomial in *z*, $m_{r-1} z^{r-1} + m_{r-2} z^{r-2} + \ldots + m_1 z + m_0$, of degree at most $r - 1$. The mask vector that corresponds to a shift of *d* is the vector that represents $m(z) = z^d$ modulo $g(z)$, where $g(z)$ is the generator polynomial.

  For example, if the degree of the generator polynomial is 4, then the mask vector that corresponds to $d = 2$ is `[0 1 0 0]`, which represents the polynomial $m(z) = z^2$.

Resetting a Signal

To reset the PN generator sequence, you must first set the `ResetInputPort` property to `true`. Suppose that the system object generates a PN sequence of `[1 0 0 1 1 0 1 1]` when there is no reset. When the reset signal `[0 0 0 1]` is passed as an input argument to the object, the PN sequence is reset at the fourth bit, because the fourth bit of the reset signal is a `1`.



Rst	0	0	0	1	0	0	0	0
Out	1	0	0	1	0	0	1	1

Sequences of Maximum Length

To generate a maximum length sequence for a generator polynomial that has the degree *r*, set `Polynomial` to a value from the following table. The maximum sequence length is $2^r - 1$.

r	Generator Polynomial	r	Generator Polynomial	r	Generator Polynomial	r	Generator Polynomial
2	`[2 1 0]`	15	`[15 14 0]`	28	`[28 25 0]`	41	`[41 3 0]`
3	`[3 2 0]`	16	`[16 15 13 4 0]`	29	`[29 27 0]`	42	`[42 23 22 1 0]`
4	`[4 3 0]`	17	`[17 14 0]`	30	`[30 29 28 7 0]`	43	`[43 6 4 3 0]`
5	`[5 3 0]`	18	`[18 11 0]`	31	`[31 28 0]`	44	`[44 6 5 2 0]`
6	`[6 5 0]`	19	`[19 18 17 14 0]`	32	`[32 31 30 10 0]`	45	`[45 4 3 1 0]`
7	`[7 6 0]`	20	`[20 17 0]`	33	`[33 20 0]`	46	`[46 21 10 1 0]`
8	`[8 6 5 4 0]`	21	`[21 19 0]`	34	`[34 15 14 1 0]`	47	[47 14 0]

PN Sequence Generator

Introduced in R2012a

comm.PreambleDetector

Package: `comm`

Detect preamble in data

Description

The `comm.PreambleDetector` System object detects a preamble in an input data sequence. A preamble is a set of symbols or bits used in packet-based communication systems to indicate the start of a packet. The preamble detector object finds the location corresponding to the end of the preamble.

To detect a preamble in an input data sequence:

1. Create a `comm.PreambleDetector` object and set the properties of the object.
2. Call `step` to detect the presence of a preamble.

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`prbdet = comm.PreambleDetector` creates a preamble detector object, `prbdet`, using the default properties.

`prbdet = comm.PreambleDetector(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

`prbdet = comm.PreambleDetector(prb,Name,Value)` specifies the preamble, `prb` in addition to those properties specified by using `Name,Value` pairs.

Example:

```
prbdet = comm.PreambleDetector('Input','Bit','Detections','First');
```

Properties

`Input` — Type of input data

`'Symbol'` (default) | `'Bit'`

Type of input data, specified as `'Symbol'` or `'Bit'`. For binary inputs, set this parameter to `'Bit'`. For all other inputs, set this parameter to `'Symbol'`. Symbol data can be of data type `single` or `double` while bit data can, in addition, support the `Boolean`, `int8`, and `uint8` data types.

`Preamble` — Preamble sequence

`[1+1i; 1-1i]` (default) | column vector

Preamble sequence, specified as a real or complex column vector. The object uses this sequence to detect the presence of the preamble in the input data. If `Input` is `'Bit'`, the preamble must be a binary sequence. If `Input` is `'Symbol'`, the preamble can be any real or complex sequence.

Data Types: `double` | `single` | `logical` | `int8` | `uint8`

`Threshold` — Detection threshold

3 (default) | nonnegative scalar

Detection threshold, specified as a nonnegative scalar. When the computed detection metric is greater than or equal to `Threshold`, the preamble is detected. This property is available when `Input` is set to `'Symbol'`. Tunable.

`Detections` — Number of preambles to detect

`'All'` (default) | `'First'`

Number of preambles to detect, specified as `'All'` or `'First'`.

- `'All'` — Detects all the preambles in the input data sequence.
- `'First'` — Detect only the first preamble in the input data sequence.

Methods

reset	Reset states of preamble detector object
step	Detect preamble in data

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Detect Preamble from Binary Data Sequence

Specify a six-bit preamble.

```
prb = [1 0 0 1 0 1]';
```

Create a preamble detector object using preamble `prb` and taking bit inputs.

```
prbdet = comm.PreambleDetector(prb,'Input','Bit');
```

Generate a binary data sequence containing two preambles and using random bits to represent the data fields.

```
pkt = [prb; randi([0 1],10,1); prb; randi([0 1],10,1)];
```

Locate the indices of the two preambles. The indices correspond to the end of the preambles.

```
idx = prbdet(pkt)
```

```
idx = 2×1

     6
```

```
    22
```

The detector correctly identified indices 6 and 22 as the end of the two preambles inserted in the sequence.

Detect Preamble in Noisy QPSK Signal

Create a preamble and apply QPSK modulation.

```
p1 = [0 1 2 3 3 2 1 0]';
p = [p1; p1];
prb = pskmod(p,4,pi/4,'gray');
```

Create a `comm.PreambleDetector` object using preamble `prb`.

```
prbdet = comm.PreambleDetector(prb)
```

```
prbdet = 
  comm.PreambleDetector with properties:

         Input: 'Symbol'
      Preamble: [16x1 double]
     Threshold: 3
    Detections: 'All'
```

Generate a sequence of random symbols. The first sequence represents the last 20 symbols from a previous packet. The second sequence represents the symbols from the current packet.

```
d1 = randi([0 3],20,1);
d2 = randi([0 3],100,1);
```

Modulate the two sequences.

```
x1 = pskmod(d1,4,pi/4,'gray');
x2 = pskmod(d2,4,pi/4,'gray');
```

Create a sequence of modulated symbols consisting of the remnant of the previous packet, the preamble, and the current packet.

```
y = [x1; prb; x2];
```

Add white Gaussian noise.

```
z = awgn(y,10);
```

Determine the preamble index and the detection metric.

```
[idx,detmet] = prbdet(z);
```

Calculate the number of elements in `idx`. Because the number of elements is greater than one, the detection threshold is too low.

```
numel(idx)
```

```
ans = 80
```

Display the five largest detection metrics.

```
detmetSort = sort(detmet,'descend');
detmetSort(1:5)
```

```
ans = 5×1

   16.3115
   13.6900
   10.5698
    9.1920
    8.9706
```

Increase the threshold and determine the preamble index.

```
prbdet.Threshold = 15;
idx = prbdet(z)
```

```
idx = 36
```

The result of 36 corresponds to the sum of the preamble length (16) and the remaining samples in the previous packet (20). This indicates that the preamble has been successfully detected.

Algorithms

Bit Inputs

When the input data is composed of bits, the preamble detector uses an exact pattern match.

Symbol Inputs

When the input data is composed of symbols, the preamble detector uses a cross-correlation algorithm. A finite impulse response (FIR) filter, in which the coefficients are specified from the preamble, computes the cross-correlation between the input data and the preamble. When a sequence of input samples match the preamble, the filter output reaches its peak. The index of the peak corresponds to the end of the preamble sequence in the input data. See Discrete FIR Filter for further information on the FIR filter algorithm.

The cross-correlation values that are greater than or equal to the specified threshold are reported as peaks.

- If the detection threshold is too low, the algorithm will detect false peaks, or, in the extreme case, detect as many detected peaks as there are input samples.
- If the detection threshold is too high, the algorithm will miss detecting peaks, or, in the extreme case, detect no peaks.

Consequently, the selection of the detection threshold is critical.

Introduced in R2016b

reset

System object: `comm.PreambleDetector`
Package: `comm`

Reset states of preamble detector object

Syntax

```
reset(prbdet)
```

Description

`reset(prbdet)` resets the states of the `PreambleDetector` object, `prbdet`.

Introduced in R2016b

step

System object: `comm.PreambleDetector`
Package: `comm`

Detect preamble in data

Syntax

```
idx = step(prbdet,x)
[idx,detmet] = step(prbdet,x)
idx = prbdet(x)
[idx,detmet] = prbdet(x)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`idx = step(prbdet,x)` returns the location of the end of the preamble in data sequence `x`, using preamble detector `prbdet`. The index is of data type `double`.

`[idx,detmet] = step(prbdet,x)` also returns the detection metric, `detmet`. This syntax is available when the `Input` property is `'Symbol'`. `detmet` has the same dimensions and data type as `x`.

The output, `detmet`, is determined by one of these algorithms:

- If either the preamble or input data is complex, the detection metric is the absolute value of the cross-correlation of the preamble and the input signal.
- If both the preamble and input data are real, the detection metric is the cross-correlation of the preamble and the input signal.

`idx = prbdet(x)` is equivalent to the first syntax.

`[idx,detmet] = prbdet(x)` is equivalent to the second syntax.

Note `prbdet` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Introduced in R2016b

comm.PSKCoarseFrequencyEstimator

Package: `comm`

(To be removed) Estimate frequency offset for PSK signal

Note will be removed in a future release. Use `comm.CoarseFrequencyCompensator` instead.

Description

The `PSKCoarseFrequencyEstimator` System object estimates frequency offset for a PSK signal.

To estimate frequency offset for a PSK signal:

1. Define and set up your PSK coarse frequency estimator object. See “Construction” on page 3-1110.
2. Call `step` to estimate frequency offset for a PSK signal according to the properties of `comm.PSKCoarseFrequencyEstimator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.PSKCoarseFrequencyEstimator` creates a PSK coarse frequency offset estimator object, H. This object uses an open-loop technique to estimate the carrier frequency offset in a received PSK signal.

`H = comm.PSKCoarseFrequencyEstimator(Name,Value)` creates a PSK coarse frequency offset estimator object, H, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

`ModulationOrder`

Modulation order the object uses

Specify the modulation order of the PSK signal as a positive, real scalar of data type double. This value must be a positive power of 2. The default is `4`.

`Algorithm`

Estimation algorithm to object uses

Specify the estimation algorithm as one of `FFT-based` or `Correlation-based`. The default is `FFT-based`.

FrequencyResolution

Desired frequency resolution (Hz)

Specify the desired frequency resolution for offset frequency estimation as a positive, real scalar of data type double. This property establishes the FFT length used to perform spectral analysis, and must be less than or equal to half the SampleRate on page 3-0 property. This property applies only if the Algorithm property is FFT-based. The default is 0.001.

MaximumOffset

Maximum measurable frequency offset (Hz)

Specify the maximum measurable frequency offset as a positive, real scalar of data type double. The default is 0.05.

The value of this property must be less than SampleRate on page 3-0 / ModulationOrder on page 3-0 . It is recommended that MaximumOffset on page 3-0 be less than or equal to SampleRate on page 3-0 /(4*ModulationOrder on page 3-0). This property is active only if the Algorithm property is Correlation-based.

SampleRate

Sample rate (Hz)

Specify the sample rate in samples per second as a positive, real scalar of data type double. The default is 1.

Methods

reset	(To be removed) Reset states of the PSKCoarseFrequencyEstimator object
step	(To be removed) Estimate frequency offset for PSK signal

Common to All System Objects	
release	Allow System object property value changes

Examples

Compare Frequency Offset Estimation and Correction Methods for QPSK Signal

Estimate and correct for a frequency offset in a QPSK signal using the recommended comm.CoarseFrequencyCompensator System object. Compare frequency correction results to a workflow using the comm.PSKCoarseFrequencyEstimator System object.

Set example parameters.

```
nSym = 2048;     % Number of input symbols
M = 4;           % Modulation order
fs = 80000;      % Sampling frequency (Hz)
freqRez = 1;     % Frequency resolution (Hz)
freqOff = -2000; % Frequency offset
```

Create System objects for these operations:

```
% Square root raised cosine transmit filter
txfilter = comm.RaisedCosineTransmitFilter;
% Phase frequency offset - one to apply a frequency offset and a second
% that takes the frequency offset estimate as an input to correct the
% offset.
pfo = comm.PhaseFrequencyOffset('FrequencyOffset',freqOff, ...
    'SampleRate',fs);
pfoCorrect = comm.PhaseFrequencyOffset(...
    'FrequencyOffsetSource','Input port', ...
    'SampleRate',fs);
% PSK coarse frequency estimator
frequencyEst = comm.PSKCoarseFrequencyEstimator(...
    'SampleRate',fs,'FrequencyResolution',freqRez);
```

```
Warning: comm.PSKCoarseFrequencyEstimator will be removed in a future release.
Use comm.CoarseFrequencyCompensator instead.
```

```
% Coarse frequency compensatator
freqComp = comm.CoarseFrequencyCompensator('Modulation','QPSK', ...
    'SampleRate',fs,'FrequencyResolution',freqRez);
```

Generate a QPSK signal, filter the signal, apply the frequency offset, and pass the signal through the AWGN channel.

```
data = randi([0 M-1],nSym,1);
modData = pskmod(data,M,pi/4);  % Generate QPSK signal
txFiltData = txfilter(modData); % Apply Tx filter
offsetData = pfo(txFiltData);   % Apply frequency offset
rxData = awgn(offsetData,25);   % Pass through AWGN channel
```

This example does not apply receive filtering. In general, when the frequency offset is high, it is beneficial to apply coarse frequency compensation prior to receive filtering because filtering suppresses energy in the useful spectrum.

Compare the results for estimating and correcting the frequency offset by:

- Using the `frequencyEst` object to estimate the frequency offset and `pfoCorrect` to compensate for the frequency offset.
- Using the `freqComp` object estimate and apply compensation to the signal.

Observe the frequency offset estimate returned by both estimation methods.

```
estFreqOffset1
estFreqOffset2
```

```
estFreqOffset1 =
  -2.0000e+03
estFreqOffset2 =
  -2.0000e+03
```

Confirm the maximum resulting difference between the two compensation methods is negligible.

```
max(compensatedData1-compensatedData2)
```

```
ans =

  1.4710e-13 + 9.1149e-14i
```

Introduced in R2013b

reset

System object: comm.PSKCoarseFrequencyEstimator
Package: comm

(To be removed) Reset states of the PSKCoarseFrequencyEstimator object

Note comm.PSKCoarseFrequencyEstimator will be removed in a future release. Use comm.CoarseFrequencyCompensator instead.

Syntax

```
reset(H)
```

Description

reset(H) resets the internal states of the PSKCoarseFrequencyEstimator object, H.

step

System object: `comm.PSKCoarseFrequencyEstimator`
Package: `comm`

(To be removed) Estimate frequency offset for PSK signal

Note `comm.PSKCoarseFrequencyEstimator` will be removed in a future release. Use `comm.CoarseFrequencyCompensator` instead.

Syntax

`Y = step(H,X)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` estimates the carrier frequency offset of the input `X` and returns the result in `Y`. `X` must be a complex column vector of data type double. The step method outputs the estimate `Y` as a scalar of type double.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.PSKDemodulator

Package: comm

Demodulate using M-ary PSK method

Description

The PSKDemodulator object demodulates an input signal using the M-ary phase shift keying (M-PSK) method.

To demodulate a signal that was modulated using phase shift keying:

1. Define and set up your PSK demodulator object. See “Construction” on page 3-1116.
2. Call step to demodulate the signal according to the properties of comm.PSKDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.PSKDemodulator creates a demodulator System object, H. This object demodulates the input signal using the M-ary phase shift keying (M-PSK) method.

H = comm.PSKDemodulator(Name,Value) creates an M-PSK demodulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.PSKDemodulator(M,PHASE,Name,Value) creates an M-PSK demodulator object, H. This object has the ModulationOrder property set to M, the PhaseOffset property set to PHASE, and the other specified properties set to the specified values. M and PHASE are value-only arguments. To specify a value-only argument, you must also specify all preceding value-only arguments. You can specify name-value pair arguments in any order.

Properties

ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar value. The default is 8.

PhaseOffset

Phase of zeroth point of constellation

Specify the phase offset of the zeroth point of the constellation, in radians, as a real scalar value. The default is `pi/8`.

BitOutput

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. The default is `false`. When you set this property to `true`, the `step` method outputs a column vector of bit values. The length of this vector equals **log2**(`ModulationOrder` on page 3-0) times the number of demodulated symbols. When you set this property to `false`, the `step` method outputs a column vector with a length equal to the input data vector. This vector contains integer symbol values between `0` and `ModulationOrder-1`.

SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of **log2**(`ModulationOrder` on page 3-0) bits to the corresponding symbol. Choose from `Binary` | `Gray` | `Custom`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-encoded signal constellation. When you set this property to `Binary`, the integer *m* must be in the range [`0`, (`ModulationOrder–1`)] and maps to the complex value **exp**(*j*□`PhaseOffset` on page 3-0 + *j*2π*m*/`ModulationOrder`). When you set this property to `Custom`, the object uses the signal constellation defined in the `CustomSymbolMapping` on page 3-0 property.

CustomSymbolMapping

Custom constellation encoding

Specify a custom constellation symbol mapping vector. The default is `0:7`. This property requires a row or column vector with a size of `ModulationOrder` on page 3-0 . This vector must have unique integer values in the range [`0`, `ModulationOrder–1`]. The values must be of data type `double`. The first element of this vector corresponds to the constellation point at an angle of `0` + `PhaseOffset` on page 3-0 , with subsequent elements running counterclockwise. The last element corresponds to the constellation point at an angle of – 2π/`ModulationOrder` + `PhaseOffset`. This property applies when you set the `SymbolMapping` on page 3-0 property to `Custom`.

DecisionMethod

Demodulation decision method

Specify the decision method the object uses as `Hard decision` | `Log-likelihood ratio` | `Approximate log-likelihood ratio`. The default is `Hard decision`. When you set the `BitOutput` on page 3-0 property to `false`, the object always performs hard decision demodulation. This property applies when you set the `BitOutput` property to `true`.

VarianceSource

Source of noise variance

Specify the source of the noise variance as one of `Property` | `Input port`. The default is `Property`. This property applies when you set the `BitOutput` on page 3-0 property to true and the DecisionMethod on page 3-0 property to Log-likelihood ratio or Approximate log-likelihood ratio.

Variance

Noise variance

Specify the variance of the noise as a positive, real scalar value. The default is 1. If this value is very small (i.e., SNR is very high), log-likelihood ratio (LLR) computations may yield Inf or –Inf. This result occurs because the LLR algorithm computes the exponential of very large or very small numbers using finite-precision arithmetic. In such cases, use approximate LLR instead because the algorithm for that option does not compute exponentials. This property applies when you set the BitOutput on page 3-0 property to true, the DecisionMethod on page 3-0 property to Log-likelihood ratio, or Approximate log-likelihood ratio, and the VarianceSource on page 3-0 property to Property. This property is tunable.

OutputDataType

Data type of output

Specify the output data type as Full precision | Smallest unsigned integer | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32. The default is Full precision. This property applies when you set the BitOutput on page 3-0 property to false. It also applies when you set the BitOutput property to true and the DecisionMethod on page 3-0 property to Hard decision. In this second case, when the OutputDataType on page 3-0 property is set to Full precision, the input data type is single- or double-precision, the output data has the same data type as the input. . When the input data is of a fixed-point type, the output data type behaves as if you had set the OutputDataType property to Smallest unsigned integer.

When you set BitOutput to true and the DecisionMethod property to Hard Decision, then logical data type becomes a valid option. If you set the BitOutput property to true and the DecisionMethod property to Log-likelihood ratio or Approximate log-likelihood ratio, the output data has the same data type as the input. In this case, the data type must be single- or double-precision.

Fixed-Point Properties

DerotateFactorDataType

Data type of derotate factor

Specify the derotate factor data type as Same word length as input | Custom. The default is Same word length as input. This property applies when you set the BitOutput on page 3-0 property to false. It also applies when you set the BitOutput property to true and the DecisionMethod on page 3-0 property to Hard decision. The object uses the derotate factor in the computations only when the ModulationOrder on page 3-0 property is 2, 4, or 8. The step method input must also have a fixed-point type, and the PhaseOffset on page 3-0 property must have a nontrivial value. For ModulationOrder = 2, the phase offset is trivial if that value is a multiple of π/2. For ModulationOrder = 4, the phase offset is trivial if that value is an even multiple of π/4. For ModulationOrder = 8, there are no trivial phase offsets.

CustomDerotateFactorDataType

Fixed-point data type of derotate factor

Specify the derotate factor fixed-point type as an unscaled `numerictype` object with a signedness of Auto. The default is `numerictype([],16)`. This property applies when you set the `DerotateFactorDataType` on page 3-0 property to `Custom`. The word length must be a value between 2 and 128.

Methods

constellation	Calculate or plot ideal signal constellation
step	Demodulate using M-ary PSK method

Common to All System Objects	
`release`	Allow System object property value changes

Examples

16-PSK with Custom Symbol Mapping

Create 16-PSK modulator and demodulator System objects™ which use custom symbol mapping. Estimate the BER in an AWGN channel and compare the performance to a theoretical Gray-coded PSK system.

Create a custom symbol mapping for the 16-PSK modulation scheme. The 16 integer symbols must have values which fall between 0 and 15.

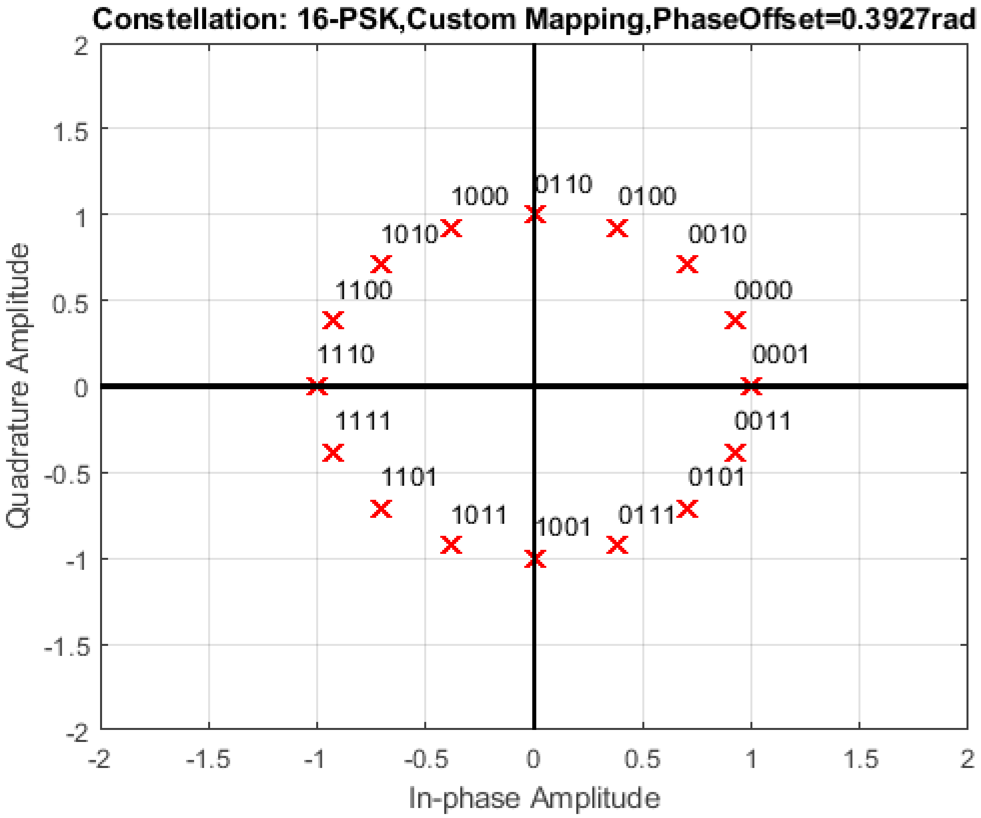
```
custMap = [0 2 4 6 8 10 12 14 15 13 11 9 7 5 3 1];
```

Create a 16-PSK modulator and demodulator pair having custom symbol mapping defined by the array, `custMap`.

```
pskModulator = comm.PSKModulator(16,'BitInput',true, ...
    'SymbolMapping','Custom','CustomSymbolMapping',custMap);
pskDemodulator = comm.PSKDemodulator(16,'BitOutput',true, ...
    'SymbolMapping','Custom','CustomSymbolMapping',custMap);
```

Display the modulator constellation.

```
constellation(pskModulator)
```



Create an AWGN channel System object for use with 16-ary data.

```
awgnChannel = comm.AWGNChannel('BitsPerSymbol',log2(16));
```

Create an error rate object to track the BER statistics.

```
errorRate = comm.ErrorRate;
```

Initialize the simulation vectors. The E_b/N_0 is varied from 6 to 18 dB in 1 dB steps.

```
ebnoVec = 6:18;
ber = zeros(size(ebnoVec));
```

Estimate the BER by modulating binary data, passing it through an AWGN channel, demodulating the received signal, and collecting the error statistics.

```
for k = 1:length(ebnoVec)

    % Reset the error counter for each Eb/No value
    reset(errorRate)
    % Reset the array used to collect the error statistics
    errVec = [0 0 0];
    % Set the channel Eb/No
    awgnChannel.EbNo = ebnoVec(k);

    while errVec(2) < 200 && errVec(3) < 1e7
        % Generate a 1000-symbol frame
        data = randi([0 1],4000,1);
        % Modulate the binary data
        modData = pskModulator(data);
        % Pass the modulated data through the AWGN channel
        rxSig = awgnChannel(modData);
        % Demodulate the received signal
        rxData = pskDemodulator(rxSig);
        % Collect the error statistics
        errVec = errorRate(data,rxData);
    end

    % Save the BER data
    ber(k) = errVec(1);
end
```

Generate theoretical BER data for an AWGN channel using the `berawgn` function.

```
berTheory = berawgn(ebnoVec,'psk',16,'nondiff');
```

Plot the simulated and theoretical results. The 16-PSK modulation BER performance of the simulated custom symbol mapping is not as good as the theoretical prediction curve for Gray codes.

```
figure
semilogy(ebnoVec,[ber; berTheory])
xlabel('Eb/No (dB)')
ylabel('BER')
grid
legend('Simulation','Theory','location','ne')
```

Hard-Decision M-PSK Demodulator (M > 8) Floating-Point Signal Diagram for Nontrivial Phase Offset

For $M > 8$, in order to improve speed and implementation costs, no derotation arithmetic is performed when `PhaseOffset` is 0, $\pi/2$, π, or $3\pi/2$ (i.e., when it is trivial).

Also, for $M > 8$, this block will only support inputs of type `double` and `single`.

Log-likelihood Ratio and Approximate Log-likelihood Ratio

The exact LLR and approximate LLR algorithms (soft-decision) are described in “Phase Modulation”.

step

System object: `comm.PSKDemodulator`
Package: `comm`

Demodulate using M-ary PSK method

Syntax

```
Y = step(H,X)
Y = step(H,X,VAR)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates data, `X`, with the PSK demodulator System object, `H`, and returns `Y`. Input `X` must be a scalar or a column vector with double or single precision data type. If the value of the `ModulationOrder` property is less than or equal to `8` and you set `BitOutput` to `false`, or when you set the `DecisionMethod` property to `Hard Decision` and `BitOutput` to `true`, the object accepts an input with a signed integer data type or signed fixed point (fi objects). Depending on the `BitOutput` property value, output `Y`, can be integer or bit valued.

`Y = step(H,X,VAR)` uses soft decision demodulation and noise variance `VAR`. This syntax applies when you set the `BitOutput` property to true, the `DecisionMethod` property to `Approximate log-likelihood ratio` or `Log-likelihood ratio`, and the `VarianceSource` property to `Input port`. The data type of input `VAR` must be double or single precision.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.PSKModulator

Package: `comm`

Modulate signal using M-PSK method

Description

The `PSKModulator` System object modulates using the M-ary phase shift keying (M-PSK) method. The output is a baseband representation of the modulated signal.

To modulate a signal by using the M-PSK method:

1. Create the `comm.PSKModulator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
mpskmod = comm.PSKModulator
mpskmod = comm.PSKModulator(Name,Value)
mpskmod = comm.PSKModulator(M,phase,Name,Value)
```

Description

`mpskmod = comm.PSKModulator` creates a modulator System object `mpskmod`, that modulates the input signal using the M-ary phase shift keying (M-PSK) method.

`mpskmod = comm.PSKModulator(Name,Value)` creates an M-PSK modulator object `mpskmod`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`mpskmod = comm.PSKModulator(M,phase,Name,Value)` creates a M-PSK modulator object `mpskmod` using the modulation order specified in `M`. The object's `PhaseOffset` property is set to `phase`, and the other specified properties are set to the specified values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`ModulationOrder` — Number of points in signal constellation

8 (default) | positive integer scalar

Number of points in the signal constellation, specified as a positive, integer scalar.

`PhaseOffset` — Phase of zeroth point of constellation

`pi/8` (default) | finite real-valued scalar

Phase of the zeroth point of the constellation in radians, specified as a finite real-valued scalar.

`BitInput` — Option to provide input in bits

`0` or `false` (default) | `1` or `true`

Option to provide input in bits, specified as a numeric or logical `0` (`false`) or `1` (`true`).

- If you set this property to `0` (`false`), the input values must be integer representations of two-bit input segments and range between 0 to 3.
- If you set this property to `1` (`true`), the input must be a binary vector of even length. Element pairs are binary representations of integers.

Data Types: `logical` | `char`

`SymbolMapping` — Signal constellation bit mapping

`'Gray'` (default) | `'Binary'` | `'Custom'`

Signal constellation bit mapping, specified as `'Gray'`, `'Binary'`, or `'Custom'`.

- `'Gray'` — Use this value to specify Gray-encoded signal constellation mapping.
- `'Binary'` — The integer *m* must be in the range [0, ModulationOrder – 1] and map to the complex value exp(*j*(PhaseOffset + 2π*m*/ModulationOrder))
- `'Custom'` — Use this value to specify the signal constellation mapping by using the CustomSymbolMapping property.

Data Types: `char` | `double`

`CustomSymbolMapping` — Custom constellation encoding

`[0 1 2 3 4 5 6 7]` (default) | row vector | column vector

Custom constellation encoding, specified as a row vector or column vector of values in the range [0, ModulationOrder – 1]. The length of this vector must be equal to the ModulationOrder property value. The first element of this vector corresponds to the constellation point at an angle of PhaseOffset, with subsequent elements running counterclockwise. The last element corresponds to the constellation point at an angle of – 2π/ModulationOrder + PhaseOffset.

Dependencies

To enable this property, set the SymbolMapping property to `'Custom'`.

Data Types: `double`

`OutputDataType` — Output datatype

`'double'` (default) | `'single'` | `'Custom'`

Output data type, specified as either `'double'`, `'single'` or `'Custom'`.

Fixed-Point Properties

`CustomOutputDataType` — Fixed-point data type of output
`numerictype([],16)` (default) | `numerictype` object

Fixed-point data type of the output signal, specified as a `numerictype` object with its `Signedness` property set to `Auto`. To create this type of object, use the `numerictype` function.

Dependencies

To enable this property, set the OutputDataType property to `'Custom'`.

Usage

Syntax

`mpsksignal = mpskmod(insignal)`

Description

`mpsksignal = mpskmod(insignal)` modulates the input signal by using the M-PSK method. The output is the modulated M-PSK baseband signal.

Input Arguments

`insignal` — Input signal
column vector

Input signal, specified as a column vector of integers or bits. The vector must be of length N_S, where N_S is the number of samples.

The setting of the BitInput property determines the interpretation of the input vector.

Data Types: `double`

Output Arguments

`mpsksignal` — M-PSK modulated baseband signal
vector

M-PSK modulated baseband signal, returned as a vector.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.PSKModulator`

constellation	Calculate or plot ideal signal constellation

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Add White Gaussian Noise to 8-PSK Signal

Modulate an 8-PSK signal, add white Gaussian noise, and plot the signal to visualize the effects of the noise.

Create a M-PSK modulator System object™. The default modulation order for the object is 8.

```
pskModulator = comm.PSKModulator;
```

Modulate the signal.

```
modData = pskModulator(randi([0 7],2000,1));
```

Add white Gaussian noise to the modulated signal by passing the signal through an additive white Gaussian noise (AWGN) channel.

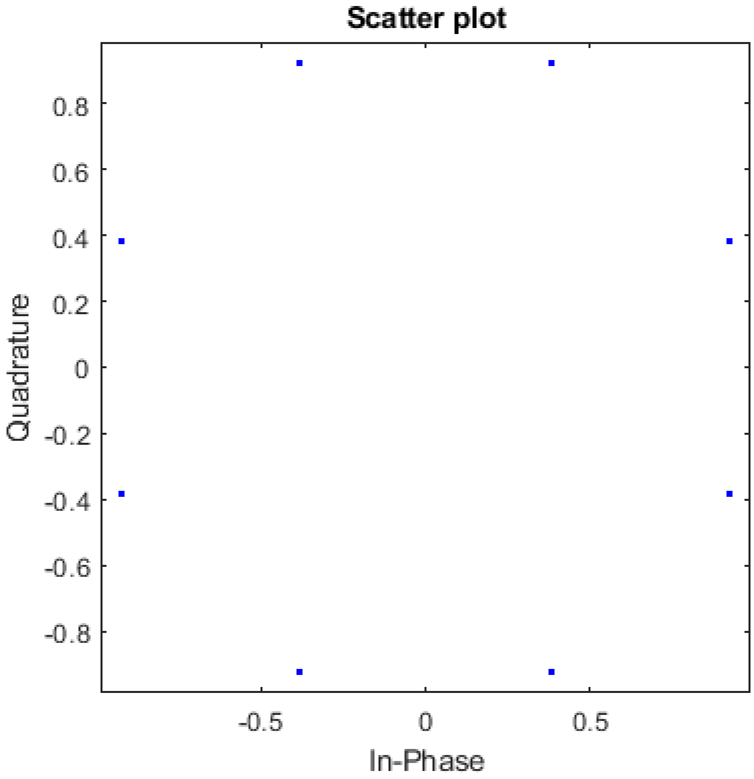
```
channel = comm.AWGNChannel('EbNo',20,'BitsPerSymbol',3);
```

Transmit the signal through the AWGN channel.

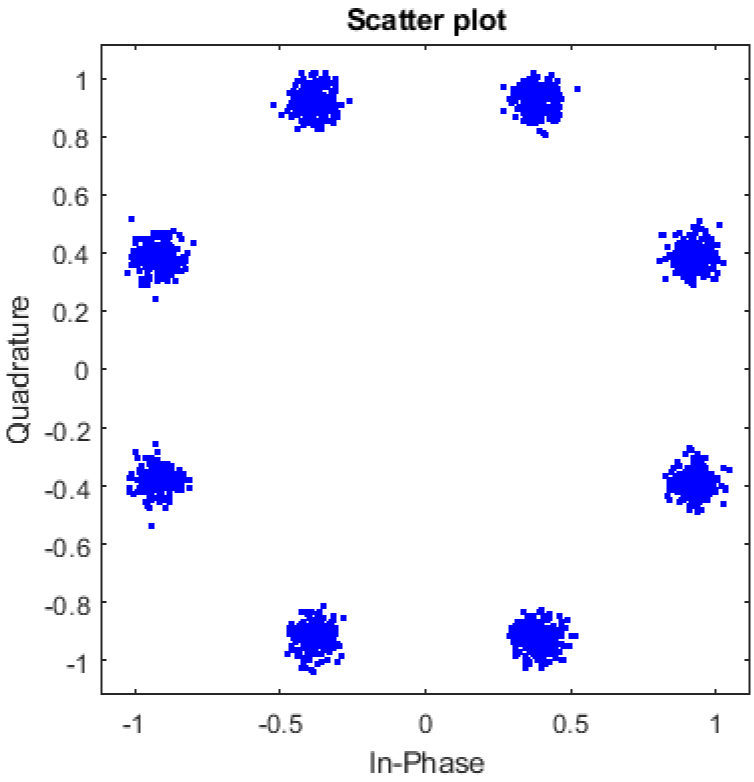
```
channelOutput = channel(modData);
```

Plot the noiseless and noisy data by using scatter plots to visualize the effects of the noise.

```
scatterplot(modData)
```



```
scatterplot(channelOutput)
```



Change the EbNo property to 10 dB to increase the noise.

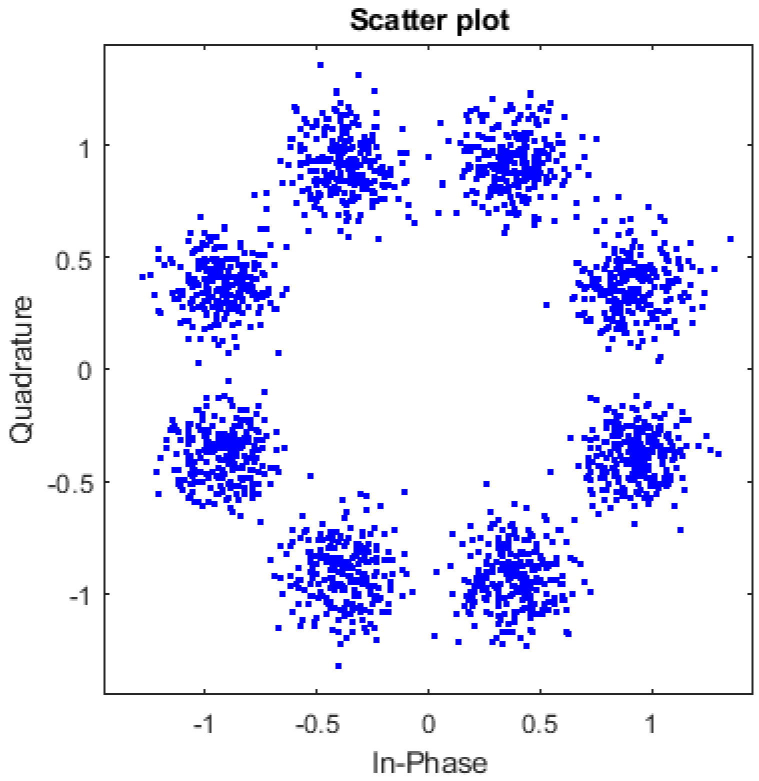
```
channel.EbNo = 10;
```

Pass the modulated data through the AWGN channel.

```
channelOutput = channel(modData);
```

Plot the channel output. You can see the effects of increased noise.

```
scatterplot(channelOutput)
```



16-PSK with Custom Symbol Mapping

Create 16-PSK modulator and demodulator System objects™ which use custom symbol mapping. Estimate the BER in an AWGN channel and compare the performance to a theoretical Gray-coded PSK system.

Create a custom symbol mapping for the 16-PSK modulation scheme. The 16 integer symbols must have values which fall between 0 and 15.

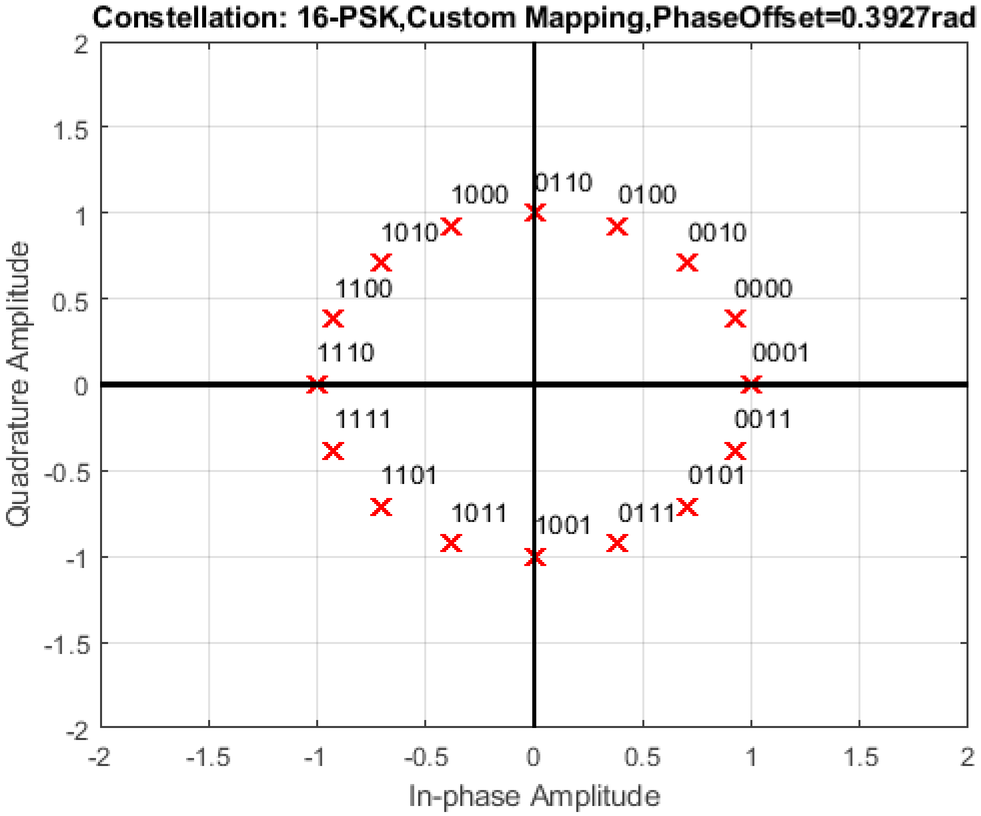
```
custMap = [0 2 4 6 8 10 12 14 15 13 11 9 7 5 3 1];
```

Create a 16-PSK modulator and demodulator pair having custom symbol mapping defined by the array, `custMap`.

```
pskModulator = comm.PSKModulator(16,'BitInput',true, ...
    'SymbolMapping','Custom','CustomSymbolMapping',custMap);
pskDemodulator = comm.PSKDemodulator(16,'BitOutput',true, ...
    'SymbolMapping','Custom','CustomSymbolMapping',custMap);
```

Display the modulator constellation.

```
constellation(pskModulator)
```



Create an AWGN channel System object for use with 16-ary data.

```
awgnChannel = comm.AWGNChannel('BitsPerSymbol',log2(16));
```

Create an error rate object to track the BER statistics.

```
errorRate = comm.ErrorRate;
```

Initialize the simulation vectors. The E_b/N_0 is varied from 6 to 18 dB in 1 dB steps.

```
ebnoVec = 6:18;
ber = zeros(size(ebnoVec));
```

Estimate the BER by modulating binary data, passing it through an AWGN channel, demodulating the received signal, and collecting the error statistics.

```
for k = 1:length(ebnoVec)

    % Reset the error counter for each Eb/No value
    reset(errorRate)
    % Reset the array used to collect the error statistics
    errVec = [0 0 0];
    % Set the channel Eb/No
    awgnChannel.EbNo = ebnoVec(k);

    while errVec(2) < 200 && errVec(3) < 1e7
        % Generate a 1000-symbol frame
        data = randi([0 1],4000,1);
        % Modulate the binary data
        modData = pskModulator(data);
        % Pass the modulated data through the AWGN channel
        rxSig = awgnChannel(modData);
        % Demodulate the received signal
        rxData = pskDemodulator(rxSig);
        % Collect the error statistics
        errVec = errorRate(data,rxData);
    end

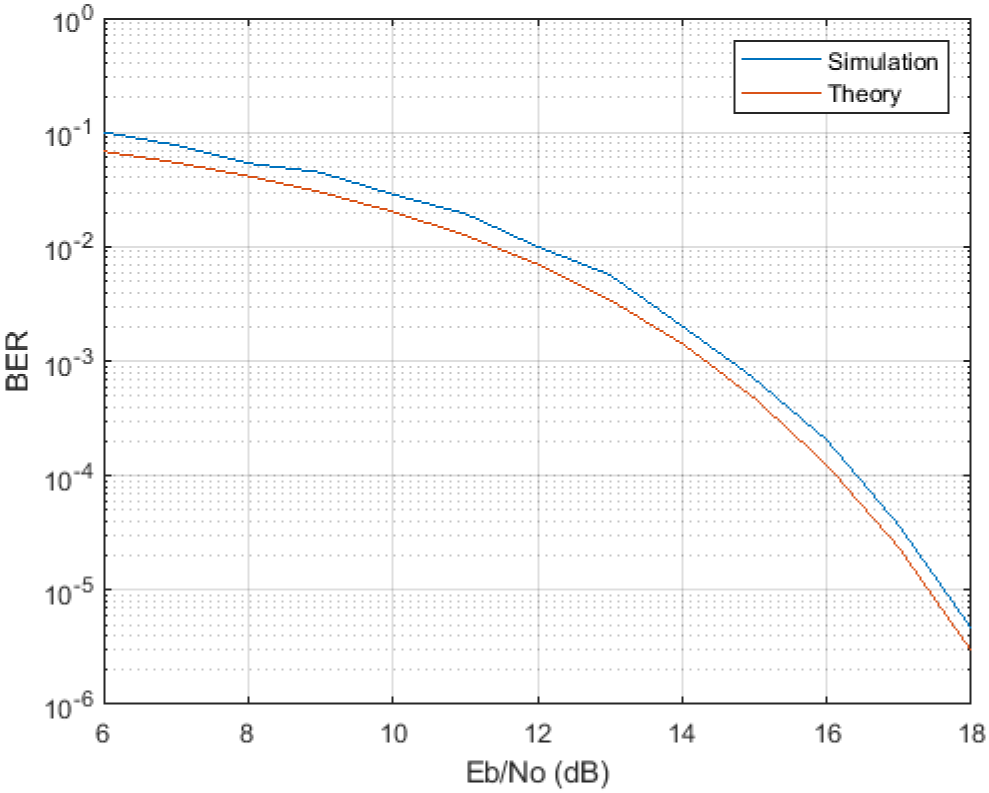
    % Save the BER data
    ber(k) = errVec(1);
end
```

Generate theoretical BER data for an AWGN channel using the `berawgn` function.

```
berTheory = berawgn(ebnoVec,'psk',16,'nondiff');
```

Plot the simulated and theoretical results. The 16-PSK modulation BER performance of the simulated custom symbol mapping is not as good as the theoretical prediction curve for Gray codes.

```
figure
semilogy(ebnoVec,[ber; berTheory])
xlabel('Eb/No (dB)')
ylabel('BER')
grid
legend('Simulation','Theory','location','ne')
```



Algorithms

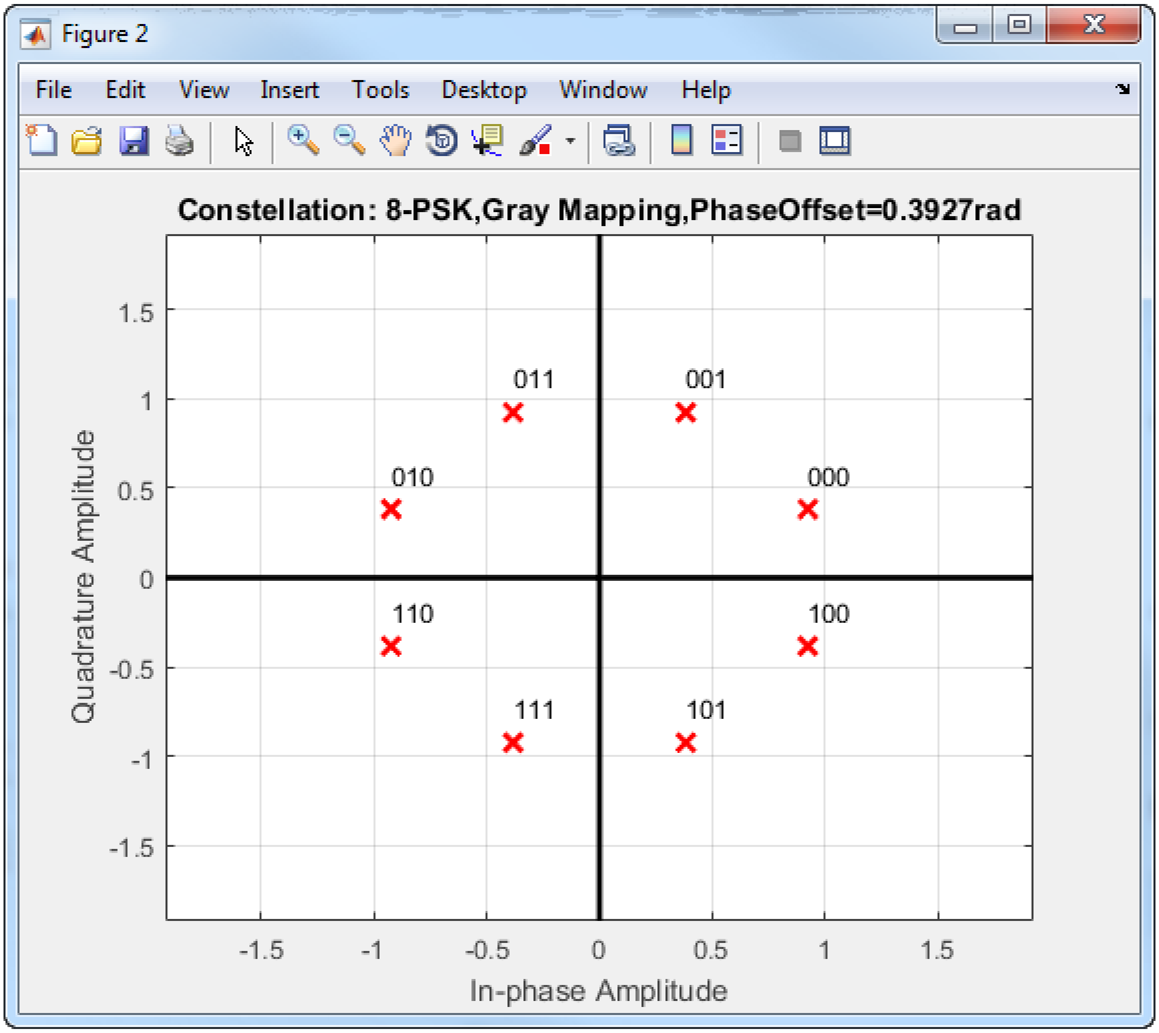
The block outputs a baseband signal by mapping input bits or integers to complex symbols according to the following:

$$s_n(t) = \exp\left(j\pi\left(\frac{2n+1}{M}\right)\right); \quad n \in \left\{0, 1, \ldots, M-1\right\}.$$

This applies when a natural binary ordering is used. Another common mapping is Gray coding, which has the advantage that only one bit changes between adjacent constellation points. This results in better bit error rate performance. For 8-PSK modulation with Gray coding, the mapping between the input and output symbols is shown.

Input	Output
0	0 *(000)*
1	1 *(001)*
2	3 *(011)*
3	2 *(010)*
4	6 *(110)*
5	7 *(111)*
6	5 *(101)*
7	4 *(100)*

The corresponding constellation diagram follows.



When the input signal is composed of bits, the block accepts binary-valued inputs that represent integers. The block collects binary-valued signals into groups of $\log_2(M)$ bits.

comm.PSKTCMDemodulator

Package: `comm`

Demodulate convolutionally encoded data mapped to M-ary PSK signal constellation

Description

The `PSKTCMDemodulator` object uses the Viterbi algorithm to decode a trellis-coded modulation (TCM) signal that was previously modulated using a PSK signal constellation.

To demodulate a signal that was modulated using trellis-coded modulation:

1. Define and set up your PSK TCM demodulator object. See “Construction” on page 3-1150.
2. Call `step` to demodulate the signal according to the properties of `comm.PSKTCMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.PSKTCMDemodulator` creates a trellis-coded, M-ary phase shift, keying (PSK TCM) demodulator System object, `H`. This object demodulates convolutionally encoded data that has been mapped to an M-PSK constellation.

`H = comm.PSKTCMDemodulator(Name,Value)` creates a PSK TCM demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.PSKTCMDemodulator(TRELLIS,Name,Value)` creates a PSK TCM demodulator System object, `H`. This object has the `TrellisStructure` property set to `TRELLIS` and the other specified properties set to the specified values.

Properties

`TrellisStructure`

Trellis structure of convolutional code

Specify trellis as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check whether the trellis structure is valid. The default is the result of `poly2trellis([1 3], [1 0 0; 0 5 2])`.

`TerminationMethod`

Termination method of encoded frame

Specify the termination method as one of `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object saves the internal state metric at the end of each frame. The next frame uses the same state metric. The object treats each traceback path independently. If the input signal contains only one symbol, use `Continuous` mode.

When you set this property to `Truncated`, the object treats each input vector independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state.

When you set property to `Terminated`, the object treats each input vector independently, and the traceback path always starts and ends in the all-zeros state.

`TracebackDepth`

Traceback depth for Viterbi decoder

Specify the scalar, integer number of trellis branches to construct each traceback path. The default is `21`. The traceback depth influences the decoding accuracy and delay. The decoding delay is the number of zero symbols that precede the first decoded symbol in the output.

When you set the `TerminationMethod` on page 3-0 property to `Continuous`, the decoding delay consists of TracebackDepth zero symbols or TracebackDepth×*K* zero bits for a rate *K*/*N* convolutional code.

When you set the `TerminationMethod` property to `Truncated` or `Terminated`, no output delay occurs and the traceback depth must be less than or equal to the number of symbols in each input vector.

`ResetInputPort`

Enable demodulator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this additional reset input is a nonzero value, the internal states of the encoder reset to initial conditions. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous`.

`ModulationOrder`

Number of points in signal constellation

Specify the number of points in the signal constellation used to map the convolutionally encoded data as a positive, integer scalar value. The number of points must be `4`, `8`, or `16`. The default is `8`. The `ModulationOrder` on page 3-0 property value must equal the number of possible input symbols to the convolutional decoder of the PSK TCM demodulator object. The `ModulationOrder` property must equal 2^N for a rate *K*/*N* convolutional code.

`OutputDataType`

Data type of output

Specify output data type as `logical` | `double`. The default is `double`.

Methods

reset	Reset states of the PSK TCM demodulator object
step	Demodulate convolutionally encoded data mapped to M-ary PSK constellation

Common to All System Objects	
release	Allow System object property value changes

Examples

Demodulate Noisy PSK QAM Data

Modulate and demodulate data using 8-PSK TCM modulation in an AWGN channel. Estimate the resulting error rate.

Define a trellis structure with four input symbols and eight output symbols.

```
t =  poly2trellis([5 4],[23 35 0; 0 5 13]);
```

Create modulator and demodulator System objects™ using trellis, `t`, having modulation order 8.

```
hMod = comm.PSKTCMModulator(t,'ModulationOrder',8);
hDemod = comm.PSKTCMDemodulator(t,'ModulationOrder',8, ...
    'TracebackDepth',16);
```

Create an AWGN channel object.

```
hAWGN = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (SNR)', ...
    'SNR',7);
```

Create an error rate calculator with delay in bits equal to `TracebackDepth` times the number of bits per symbol.

```
hError = comm.ErrorRate('ReceiveDelay',...
    hDemod.TracebackDepth*log2(t.numInputSymbols));
```

Generate random binary data and modulate with 8-PSK TCM. Pass the modulated signal through the AWGN channel and demodulate. Calculate the error statistics.

```
for counter = 1:10
    % Transmit frames of 250 2-bit symbols
    data = randi([0 1],500,1);
    % Modulate
    modSignal = step(hMod,data);
    % Pass through AWGN channel
    noisySignal = step(hAWGN,modSignal);
    % Demodulate
    receivedData = step(hDemod,noisySignal);
    % Calculate error statistics
    errorStats = step(hError,data,receivedData);
end
```

Display the BER and the number of bit errors.

```
fprintf('Error rate = %5.2e\nNumber of errors = %d\n', ...
    errorStats(1),errorStats(2))
```

```
Error rate = 2.17e-02
Number of errors = 108
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the M-PSK TCM Decoder block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See Also

`comm.GeneralQAMTCMDemodulator` | `comm.PSKTCMModulator` | `comm.RectangularQAMTCMDemodulator` | `comm.ViterbiDecoder`

Introduced in R2012a

reset

System object: `comm.PSKTCMDemodulator`
Package: `comm`

Reset states of the PSK TCM demodulator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `PSKTCMDemodulator` object, `H`.

step

System object: `comm.PSKTCMDemodulator`
Package: `comm`

Demodulate convolutionally encoded data mapped to M-ary PSK constellation

Syntax

```
Y = step(H,X)
Y = step(H,X,R)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates the PSK modulated input data, `X`, and uses the Viterbi algorithm to decode the resulting demodulated, convolutionally encoded bits. `X` must be a complex, double or single precision column vector. The `step` method outputs a demodulated, binary data column vector, `Y`. When the convolutional encoder represents a rate *K*/*N* code, the length of the output vector is *K*× *L*, where *L* is the length of the input vector, `X`.

`Y = step(H,X,R)` resets the decoder to the all-zeros state when you input a reset signal, `R` that is non-zero. `R` must be a double precision or logical, scalar integer. This syntax applies when you set the `ResetInputPort` property to true.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.PSKTCMModulator

Package: comm

Convolutionally encode binary data and map using M-ary PSK signal constellation

Description

The PSKTCMModulator object implements trellis-coded modulation (TCM) by convolutionally encoding the binary input signal and then mapping the result to a PSK signal constellation.

To modulate a signal using trellis-coded modulation:

1. Define and set up your PSK TCM modulator object. See “Construction” on page 3-1156.
2. Call step to modulate the signal according to the properties of comm.PSKTCMModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.PSKTCMModulator creates a trellis-coded M-ary phase shift keying (PSK TCM) modulator System object, H. This object convolutionally encodes a binary input signal and maps the result to an M-PSK constellation.

H = comm.PSKTCMModulator(Name,Value) creates a PSK TCM encoder object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.PSKTCMModulator(TRELLIS,Name,Value) creates a PSK TCM encoder object, H. This object has the TrellisStructure property set to TRELLIS and the other specified properties set to the specified values.

Properties

TrellisStructure

Trellis structure of convolutional code

Specify trellis as a MATLAB structure that contains the trellis description of the convolutional code. Use the istrellis function to check whether a trellis structure is valid. The default is the result of poly2trellis([1 3], [1 0 0; 0 5 2]).

TerminationMethod

Termination method of encoded frame

Specify the termination method as one of `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object retains the encoder states at the end of each input vector for use with the next input vector.

When you set this property to `Truncated`, the object treats each input vector independently. The encoder is reset to the all-zeros state at the start of each input vector.

When you set this property to `Terminated`, the object treats each input vector independently. However, for each input vector, the object uses extra bits to set the encoder to the all-zeros state at the end of the vector. For a rate *K/N* code, the `step` method outputs the vector with a length given by $y = N \times {}^{(L+S)}/_{K}$, where $S = constraintLength–1$ (or, in the case of multiple constraint lengths, $S =$ **sum**(*constraintLength*(*i*)–1)). *L* indicates the length of the input to the `step` method.

`ResetInputPort`

Enable modulator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this additional reset input is a nonzero value, the internal states of the encoder reset to initial conditions. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous`.

`ModulationOrder`

Number of points in signal constellation

Specify the number of points in the signal constellation used to map the convolutionally encoded data as a positive integer scalar value equal to `4`, `8`, or `16`. The default is `8`. The value of the `ModulationOrder` on page 3-0 property must equal the number of possible output symbols from the convolutional encoder of the PSK TCM modulator. Thus, the value for the `ModulationOrder` property must equal 2^N for a rate *K*/*N* convolutional code.

`OutputDataType`

Data type of output

Specify the output data type as one of `double` | `single`. The default is `double`.

Methods

reset	Reset states of the PSK TCM modulator object
step	Convolutionally encode binary data and map using M-ary PSK constellation

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Modulate Data Using 8-PSK TCM Modulation

Modulate random data using 8-PSK TCM modulation and display the constellation diagram.

Create binary data.

```
data = randi([0 1],1000,1);
```

Define a trellis structure with four input symbols and eight output symbols.

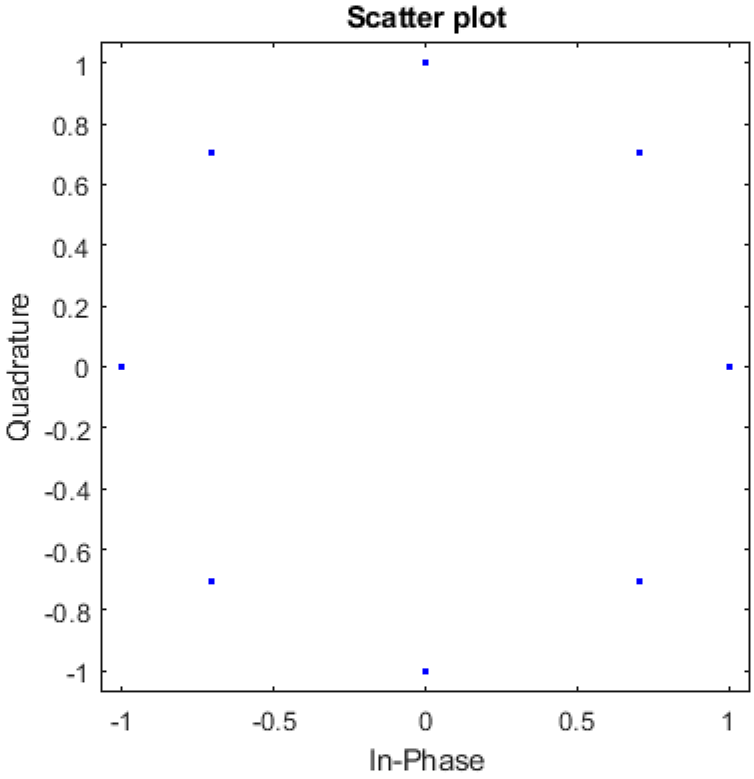
```
t =  poly2trellis([5 4],[23 35 0; 0 5 13]);
```

Create an 8-PSK TCM modulator object using the trellis structure variable, `t`.

```
hMod = comm.PSKTCMModulator(t,'ModulationOrder',8);
```

Modulate and plot the data.

```
modData = step(hMod,data);
scatterplot(modData);
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the M-PSK TCM Decoder block reference page. The object properties correspond to the block parameters.

Description

`reset(H)` resets the states of the `PSKTCMModulator` object, `H`.

step

System object: `comm.PSKTCMModulator`
Package: `comm`

Convolutionally encode binary data and map using M-ary PSK constellation

Syntax

```
Y = step(H,X)
Y = step(H,X,R)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` convolutionally encodes and modulates the input binary data column vector, `X`, and returns the encoded and modulated data, `Y`. `X` must be of data type numeric, logical, or unsigned fixed point of word length `1` (fi object). When the convolutional encoder represents a rate *K*/*N* code, the length of the input vector, `X`, must be *K*×*L*, for some positive integer *L*. The `step` method outputs a complex column vector, `Y`, of length *L*.

`Y = step(H,X,R)` resets the encoder of the PSK TCM modulator object to the all-zeros state when you input a reset signal, `R`, that is non-zero. `R` must be a double precision or logical scalar integer. This syntax applies when you set the `ResetInputPort` property to `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.QAMCoarseFrequencyEstimator

Package: `comm`

(To be removed) Estimate frequency offset for QAM signal

Note `comm.QAMCoarseFrequencyEstimator` will be removed in a future release. Use `comm.CoarseFrequencyCompensator` instead.

Description

The `QAMCoarseFrequencyEstimator` System object estimates frequency offset for a QAM signal.

To estimate frequency offset for a QAM signal:

1. Define and set up your QAM Coarse Frequency Estimator object. See "Construction" on page 3-1162.
2. Call `step` to estimate frequency offset for a QAM signal according to the properties of `comm.QAMCoarseFrequencyEstimator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.QAMCoarseFrequencyEstimator` creates a rectangular QAM coarse frequency offset estimator object, `H`. This object uses an open-loop, FFT-based technique to estimate the carrier frequency offset in a received rectangular QAM signal.

`H = comm.QAMCoarseFrequencyEstimator(Name,Value)` creates a rectangular QAM coarse frequency offset estimator object, `H`, with the specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

`FrequencyResolution`

Desired frequency resolution (Hz)

Specify the desired frequency resolution for offset frequency estimation as a positive, real scalar of data type double. This property establishes the FFT length that the object uses to perform spectral analysis. The value for this property must be less than or equal to half the `SampleRate` on page 3-0 property. The default is `0.001`.

`SampleRate`

Sample rate (Hz)

Specify the sample rate in samples per second as a positive, real scalar of data type double. The default is 1.

Methods

reset	(To be removed) Reset states of the `QAMCoarseFrequencyEstimator` object
step	(To be removed) Estimate frequency offset for QAM signal

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Compare Frequency Offset Estimation and Correction Methods for 16-QAM Signal

Estimate and correct for a frequency offset in a 16-QAM signal using the recommended `comm.CoarseFrequencyCompensator` System object. Compare frequency correction results to a workflow using the `comm.QAMCoarseFrequencyEstimator` System object.

Set example parameters.

```
nSym = 2048;     % Number of input symbols
M = 16;          % Modulation order
fs = 80000;      % Sampling frequency (Hz)
freqRez = 1;     % Frequency resolution (Hz)
freqOff = -3000; % Frequency offset
```

Create System objects for these operations:

```
% Square root raised cosine transmit filter
txfilter = comm.RaisedCosineTransmitFilter;
% Phase frequency offset - one to apply a frequency offset and a
% second that takes the frequency offset estimate as an input to correct
% the offset.
pfo = comm.PhaseFrequencyOffset('FrequencyOffset',freqOff, ...
    'SampleRate',fs);
pfoCorrect = comm.PhaseFrequencyOffset(...
    'FrequencyOffsetSource','Input port', ...
    'SampleRate',fs);
% QAM coarse frequency estimator
frequencyEst = comm.QAMCoarseFrequencyEstimator(...
    'SampleRate',fs, ...
    'FrequencyResolution',freqRez);
```

```
Warning: comm.QAMCoarseFrequencyEstimator will be removed in a future release.
Use comm.CoarseFrequencyCompensator instead.
```

```
% Coarse frequency compensatator
freqComp = comm.CoarseFrequencyCompensator('Modulation','QAM', ...
    'SampleRate',fs,'FrequencyResolution',freqRez);
```

Generate a 16-QAM signal, filter the signal, apply the frequency offset, and pass the signal through the AWGN channel.

```
data = randi([0 M-1],nSym,1);
modData = qammod(data,M,'UnitAveragePower',true); % Generate QAM signal
txFiltData = txfilter(modData);                   % Apply Tx filter
offsetData = pfo(txFiltData);                     % Apply frequency offset
rxData = awgn(offsetData,25,'measured');          % Pass through AWGN channel
```

This example does not apply receive filtering. In general, when the frequency offset is high, it is beneficial to apply coarse frequency compensation prior to receive filtering because filtering suppresses energy in the useful spectrum.

Compare the results for estimating and correcting the frequency offset by:

- Using the `frequencyEst` object to estimate the frequency offset and `pfoCorrect` to compensate for the frequency offset.
- Using the `freqComp` object estimate and apply compensation to the signal.

Observe the frequency offset estimate returned by both estimation methods.

```
estFreqOffset1
estFreqOffset2
```

```
estFreqOffset1 =
  -3.0000e+03
estFreqOffset2 =
  -3.0000e+03
```

Confirm the maximum resulting difference between the two compensation methods is negligible.

```
max(compensatedData1-compensatedData2)
```

```
ans =

  -1.3051e-13 - 1.7614e-13i
```

Description

`reset(H)` resets the internal states of the `QAMCoarseFrequencyEstimator` object, `H`.

step

System object: `comm.PSKCoarseFrequencyEstimator`
Package: `comm`

(To be removed) Estimate frequency offset for QAM signal

Note `comm.QAMCoarseFrequencyEstimator` will be removed in a future release. Use `comm.CoarseFrequencyCompensator` instead.

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` estimates the carrier frequency offset of the input `X` and returns the result in `Y`. `X` must be a complex column vector of data type double. The step method outputs the estimate `Y` as a scalar of type double.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.QPSKDemodulator

Package: `comm`

Demodulate using QPSK method

Description

The `QPSKDemodulator` object demodulates a signal that was modulated using the quadrature phase shift keying method. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using quadrature phase shift keying:

1. Define and set up your QPSK demodulator object. See “Construction” on page 3-1168.
2. Call `step` to demodulate the signal according to the properties of `comm.QPSKDemodulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.QPSKDemodulator` creates a demodulator System object, `H`. This object demodulates the input signal using the quadrature phase shift keying (QPSK) method.

`H = comm.QPSKDemodulator(Name,Value)` creates a QPSK demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.QPSKDemodulator(PHASE,Name,Value)` creates a QPSK demodulator object, `H`. This object has the `PhaseOffset` property set to `PHASE`, and the other specified properties set to the specified values.

Properties

`PhaseOffset`

Phase of zeroth point in constellation

Specify the phase offset of the zeroth point in the constellation, in radians, as a real scalar value. The default is `pi/4`.

`BitOutput`

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values.

When you set this property to true, the step method outputs a column vector of bit values with length equal to twice the number of demodulated symbols.

When you set this property to false, the step method outputs a column vector with length equal to the input data vector. This vector contains integer symbol values between 0 and 3. The default is false.

SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of 2 bits to the corresponding symbol as one of Binary | Gray. The default is Gray.

When you set this property to Gray, the object uses a Gray-encoded signal constellation.

When you set this property to Binary, the integer m, between $0 \leq m \leq 3$ maps to the complex value **exp**(j×PhaseOffset on page 3-0 $+ j \times 2\pi \times {}^{m}\!/_{4}$).

DecisionMethod

Demodulation decision method

Specify the decision method the object uses as Hard decision | Log-likelihood ratio | Approximate log-likelihood ratio. The default is Hard decision.

When you set the BitOutput on page 3-0 property to false, the object always performs hard decision demodulation. This property applies when you set the BitOutput property to true.

VarianceSource

Source of noise variance

Specify the source of the noise variance as one of Property | Input port. The default is Property. This property applies when you set the BitOutput on page 3-0 property to true and the DecisionMethod on page 3-0 property to Log-likelihood ratio or Approximate log-likelihood ratio.

Variance

Noise variance

Specify the variance of the noise as a positive, real scalar value. The default is 1. If this value is very small (i.e., SNR is very high), log-likelihood ratio (LLR) computations may yield Inf or -Inf. This result occurs because the LLR algorithm computes the exponential of very large or very small numbers using finite-precision arithmetic. In such cases, use approximate LLR is because that option's algorithm does not compute exponentials.

This property applies when you set the BitOutput on page 3-0 property to true, the DecisionMethod on page 3-0 property to Log-likelihood ratio or Approximate log-likelihood ratio, and the VarianceSource on page 3-0 property to Property.This property is tunable.

OutputDataType

Data type of output

Specify the output data type as Full precision | Smallest unsigned integer | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32. The default is Full precision.

This property applies when you set the BitOutput on page 3-0 property to false. The property also applies when you set the BitOutput property to true and the DecisionMethod on page 3-0 property to Hard decision. In this second case, when the OutputDataType on page 3-0 property is set to Full precision, and the input data type is single or double precision, the output data has the same as that of the input.

When the input data is of a fixed-point type, the output data type behaves as if you had set the OutputDataType property to Smallest unsigned integer.

When you set BitOutput to true and the DecisionMethod property to Hard Decision, then logical data type becomes a valid option.

When you set the BitOutput property to true and the DecisionMethod property to Log-likelihood ratio or Approximate log-likelihood ratio, the output data type is the same as that of the input. In this case, that data type can only be single or double precision.

Fixed-Point Properties

DerotateFactorDataType

Data type of derotate factor

Specify derotate factor data type as one of Same word length as input | Custom. The default is Same word length as input.

This property applies when you set the BitOutput on page 3-0 property to false. The property also applies when you set the BitOutput property to true and the DecisionMethod on page 3-0 property to Hard decision. The object uses the derotate factor in the computations only when the step method input is a fixed-point type and the PhaseOffset on page 3-0 property has a value that is not an even multiple of pi/4.

CustomDerotateFactorDataType

Fixed-point data type of derotate factor

Specify the derotate factor fixed-point type as an unscaled numerictype object with a signedness of Auto. The default is numerictype([],16). This property applies when you set the DerotateFactorDataType on page 3-0 property to Custom.

Methods

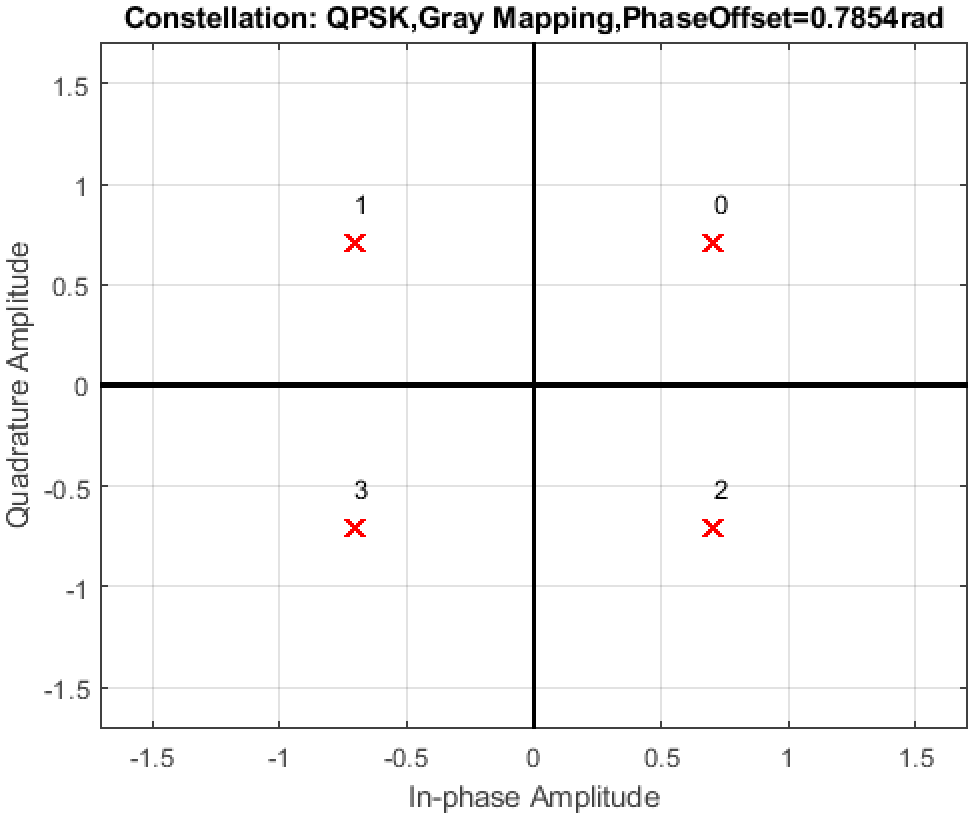
  -0.7071 - 0.7071i
   0.7071 - 0.7071i
```

Plot the constellation.

```
constellation(mod)
```

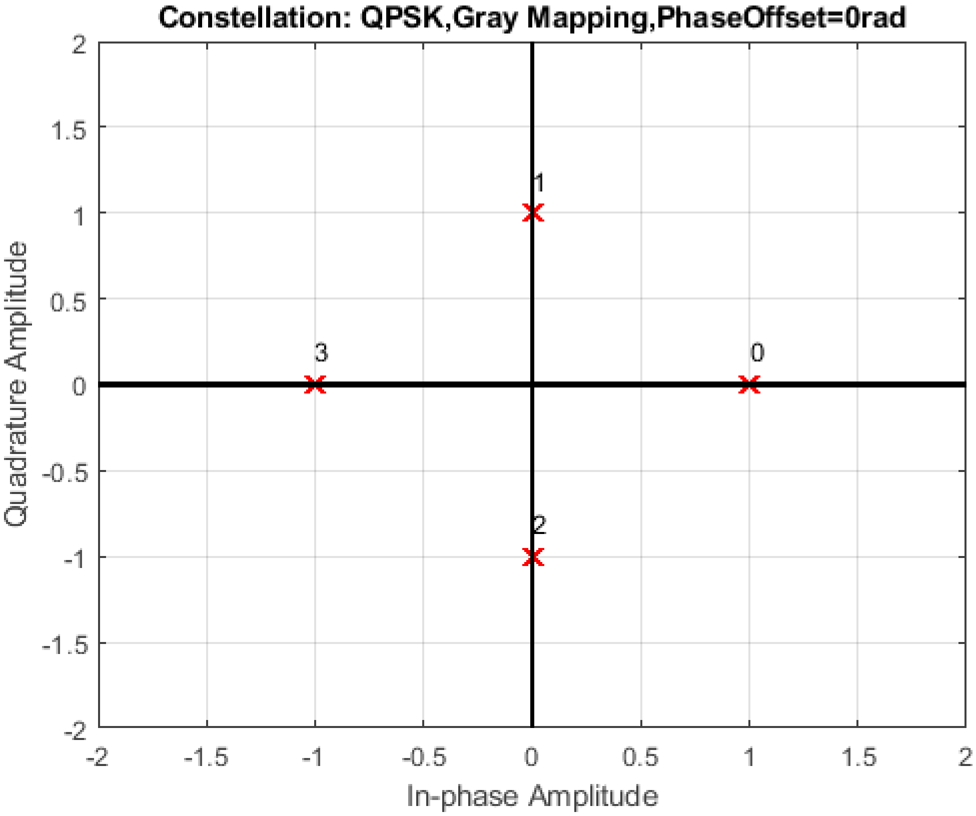


Create a PSK demodulator having 0 phase offset.

```
demod = comm.QPSKDemodulator('PhaseOffset',0);
```

Plot its reference constellation. The `constellation` method works for both modulator and demodulator objects.

```
constellation(demod)
```



BER Estimate of QPSK Signal

Create a QPSK modulator and demodulator pair that operate on bits.

```
qpskModulator = comm.QPSKModulator('BitInput',true);
qpskDemodulator = comm.QPSKDemodulator('BitOutput',true);
```

Create an AWGN channel object and an error rate counter.

```
channel = comm.AWGNChannel('EbNo',4,'BitsPerSymbol',2);
errorRate = comm.ErrorRate;
```

Generate random binary data and apply QPSK modulation.

```
data = randi([0 1],1000,1);
txSig = qpskModulator(data);
```

Pass the signal through the AWGN channel and demodulate it.

```
rxSig = channel(txSig);
rxData = qpskDemodulator(rxSig);
```

Calculate the error statistics. Display the BER.

```
errorStats = errorRate(data,rxData);
```

```
errorStats(1)
```

```
ans = 0.0100
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the QPSK Demodulator Baseband block reference page. The object properties correspond to the block parameters.

step

System object: `comm.QPSKDemodulator`
Package: `comm`

Demodulate using QPSK method

Syntax

```
Y = step(H,X)
Y = step(H,X,VAR)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates input data, `X`, with the QPSK demodulator System object, `H`, and returns `Y`. Input `X` must be a scalar or a column vector with double or single precision data type. When you set the `BitOutput` property to `false`, or when you set the `DecisionMethod` property to `Hard decision` and the `BitOutput` property to `true`, the data type of the input can also be signed integer, or signed fixed point (fi objects). Depending on the `BitOutput` property value, output `Y` can be integer or bit valued.

`Y = step(H,X,VAR)` uses soft decision demodulation and noise variance `VAR`. This syntax applies when you set the `BitOutput` property to `true`, the `DecisionMethod` property to `Approximate log-likelihood ratio`or `Log-likelihood ratio`, and the `VarianceSource` property to `Input port`. The data type of input `VAR` must be double or single precision.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.QPSKModulator

Package: comm

Modulate using QPSK method

Description

The comm.QPSKModulator object modulates using the quadrature phase shift keying method. The output is a baseband representation of the modulated signal.

To apply QPSK modulation:

1. Create the comm.QPSKModulator object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
qpskmod = comm.QPSKModulator
qpskmod = comm.QPSKModulator(Name,Value)
qpskmod = comm.QPSKModulator(phase,Name,Value)
```

Description

qpskmod = comm.QPSKModulator creates a modulator System object. Use this object to modulate the input signal using the quadrature phase shift keying (QPSK) method.

qpskmod = comm.QPSKModulator(Name,Value) creates a QPSK modulator object, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

qpskmod = comm.QPSKModulator(phase,Name,Value) creates a QPSK modulator object, qpskmod. This object has the PhaseOffset property set to phase and the other specified properties set to the specified values. Specify phase in radians.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

PhaseOffset — Phase offset of zeroth point in constellation

pi/4 (default) | scalar

Phase of zeroth point of the signal constellation in radians, specified as a scalar.

Example: 'PhaseOffset',0 aligns the QPSK signal constellation points on the axes, {(1,0), (0,j), (-1,0), (0,-j)}.

Data Types: double

BitInput — Option to provide input in bits

false (default) | true

Option to provide input in bits, specified as false or true.

- When this property is set to false, the input values must be integer representations of two-bit input segments and range from 0 to 3.
- When this property is set to true, the input must be a binary vector of even length. Element pairs are binary representations of integers.

Data Types: logical

SymbolMapping — Signal constellation bit mapping

'Gray' (default) | 'Binary'

Constellation encoding

Signal constellation bit mapping, specified as 'Gray' or 'Binary'.

Setting	Constellation Mapping for Integers	Constellation Mapping for Bits	Comment
Gray			The signal constellation mapping is Gray-encoded.
Binary			The signal constellation mapping for the input integer m (0 ≤ m ≤ 3) is the complex value $e^{(j*(PhaseOffset) + j*2*\pi*m/4)}$.

Data Types: char

OutputDataType — Data type assigned to output

'double' (default) | 'single' | 'Custom'

Data type assigned to output, specified as 'double', 'single', or 'Custom'.

Data Types: char

Fixed-Point Properties

`CustomOutputDataType` — Fixed-point data type of output
`numerictype([],16)` (default) | `numerictype` object

Fixed-point data type of output, specified as a `numerictype` object with a signedness of Auto. This property applies when you set the `OutputDataType` on page 3-0 property to `Custom`.

Dependencies

This property applies when you set the `OutputDataType` property to `'Custom'`.

Usage

Syntax

```
waveform = qpskmod(insignal)
```

Description

`waveform = qpskmod(insignal)` returns baseband-modulated output.

Input Arguments

`insignal` — Input signal
integer column vector | bit column vector

Input signal, specified as an N_S-element column vector of integers or bits, where N_S is the number of samples.

The setting of the BitInput property determines the interpretation of the input vector.

Data Types: `double` | `int8` | `logical` | `fi`

Output Arguments

`waveform` — Output waveform
vector

Output waveform, returned as a complex-valued vector.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.QPSKModulator`

constellation	Calculate or plot ideal signal constellation

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Plot QPSK Reference Constellation

Create a QPSK modulator.

```
mod = comm.QPSKModulator;
```

Determine the reference constellation points.

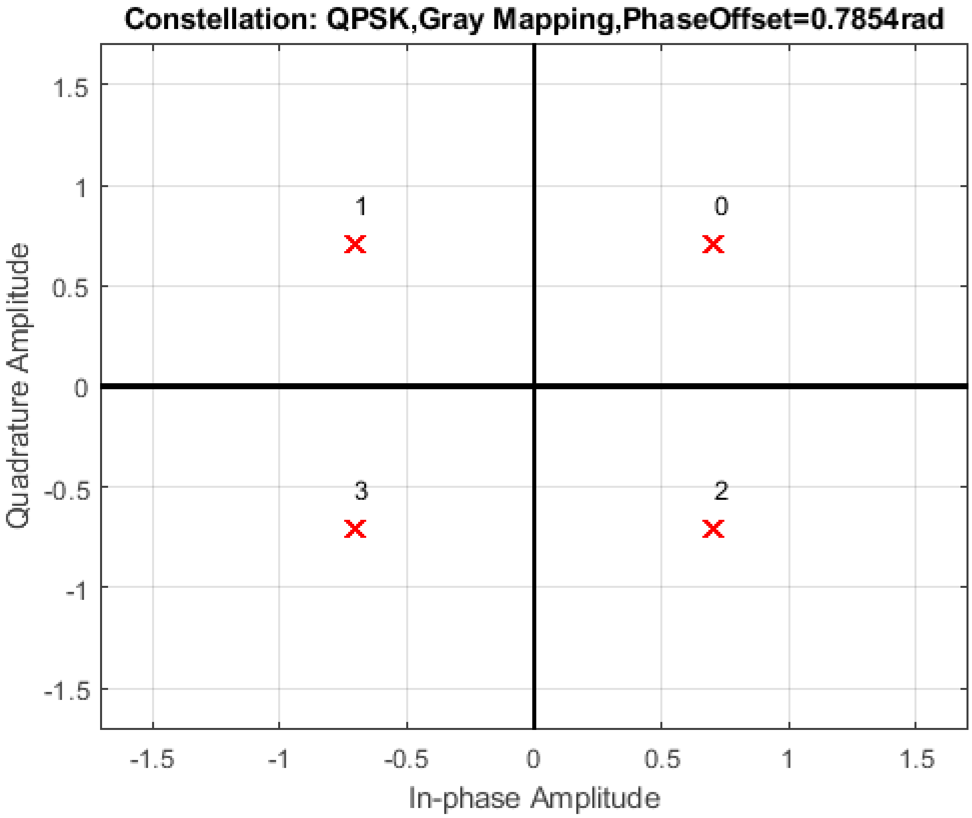
```
refC = constellation(mod)
```

```
refC = 4×1 complex

   0.7071 + 0.7071i
  -0.7071 + 0.7071i
  -0.7071 - 0.7071i
   0.7071 - 0.7071i
```

Plot the constellation.

```
constellation(mod)
```

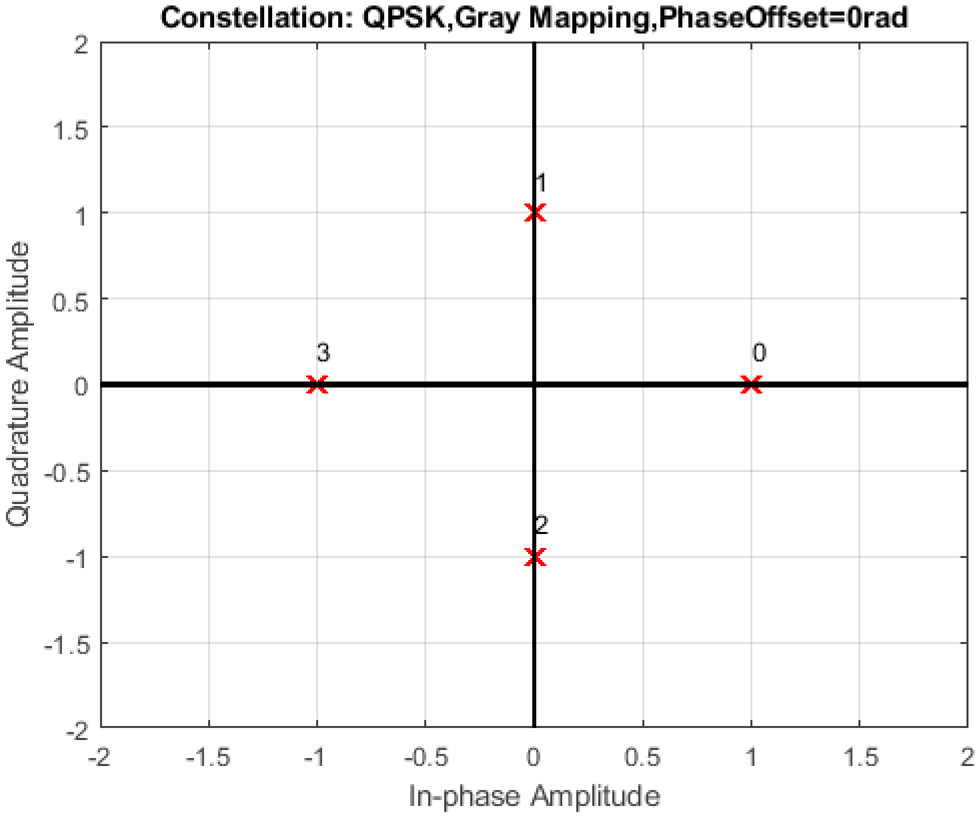


Create a PSK demodulator having 0 phase offset.

```
demod = comm.QPSKDemodulator('PhaseOffset',0);
```

Plot its reference constellation. The `constellation` method works for both modulator and demodulator objects.

```
constellation(demod)
```



Phase Noise on QPSK Signal

Create a QPSK modulator object and a phase noise object.

```
qpskModulator = comm.QPSKModulator;
phNoise = comm.PhaseNoise('Level',-55,'FrequencyOffset',20,'SampleRate',1000);
```

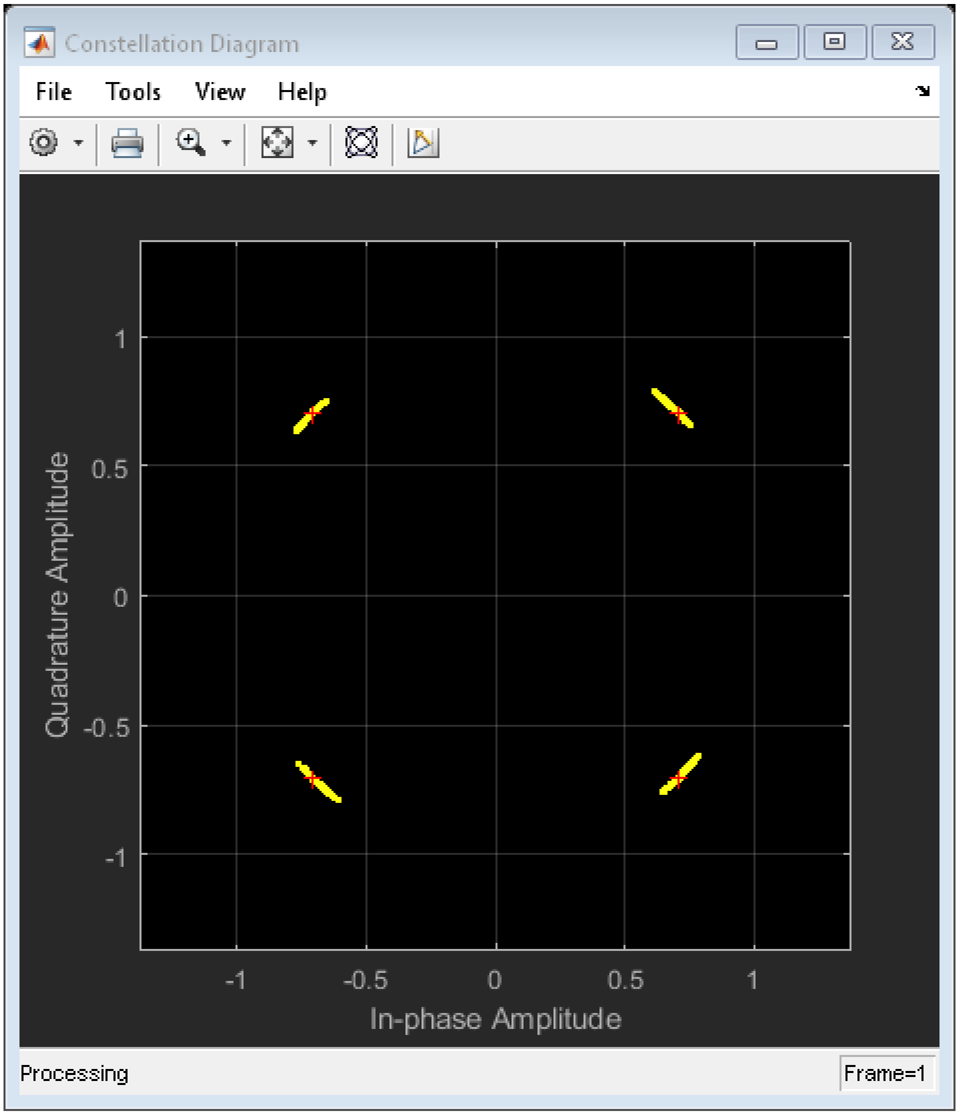
Generate random QPSK data. Pass the signal through the phase noise object.

```
d = randi([0 3],1000,1);
x = qpskModulator(d);
y = phNoise(x);
```

Display the constellation diagram of the QPSK signal. The phase noise has introduced a rotational distortion on the constellation diagram.

```
constDiagram = comm.ConstellationDiagram;

constDiagram(y)
```



Create QPSK Modulator Object with Bit Input

Create QPSK modulator object setting the `BitInput` property to `true`. Display the properties.

```
qpskmod = comm.QPSKModulator('BitInput',true)
```

```
qpskmod = 
  comm.QPSKModulator with properties:

        PhaseOffset: 0.7854
           BitInput: true
      SymbolMapping: 'Gray'
     OutputDataType: 'double'
```

Determine the reference constellation points.

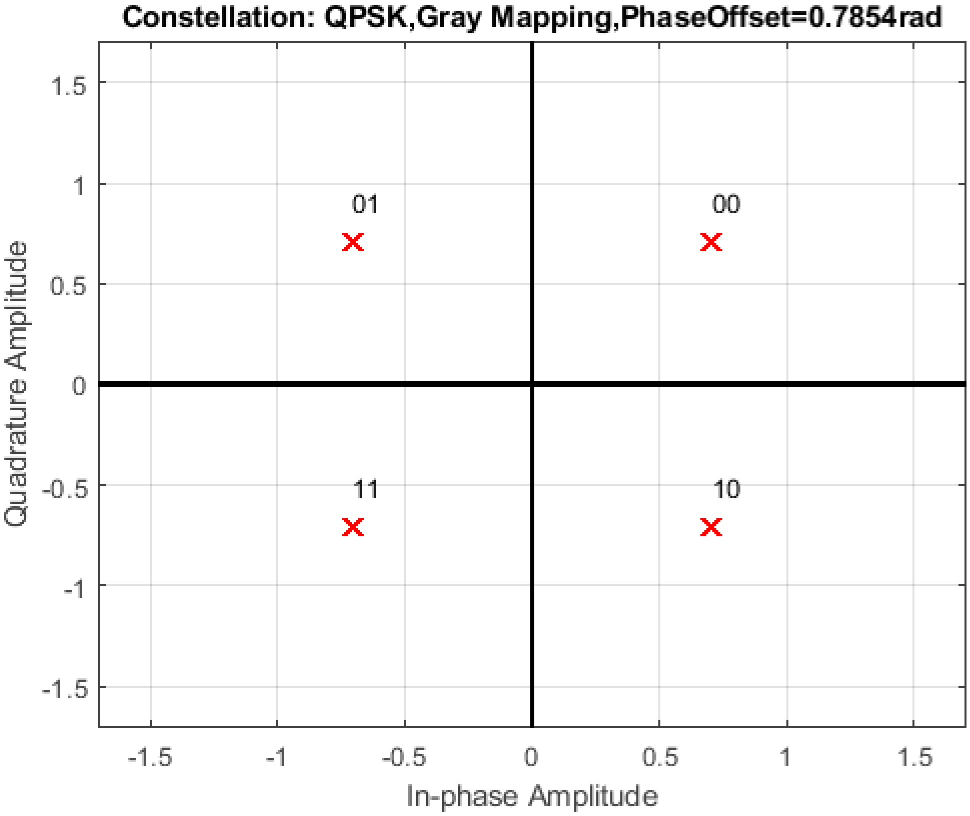
```
refC = constellation(qpskmod)
```

```
refC = 4×1 complex

   0.7071 + 0.7071i
  -0.7071 + 0.7071i
  -0.7071 - 0.7071i
   0.7071 - 0.7071i
```

Plot the constellation. Since `BitInput` is `true`, the constellation symbols are label with bit values.

```
constellation(qpskmod)
```



Create QPSK modulator object with default properties settings. Display the properties.

```
qpskmod2 = comm.QPSKModulator
```

```
qpskmod2 = 
  comm.QPSKModulator with properties:

        PhaseOffset: 0.7854
           BitInput: false
      SymbolMapping: 'Gray'
     OutputDataType: 'double'
```

Plot constellation with default settings. Since `BitInput` is `false`, the constellation symbols are label with integer values.

```
constellation(qpskmod2)
```

comm.RaisedCosineReceiveFilter

Package: `comm`

Apply pulse shaping by decimating signal using raised-cosine FIR filter

Description

The `comm.RaisedCosineReceiveFilter` System object applies pulse shaping by decimating an input signal using a raised-cosine finite impulse response (FIR) filter. The FIR filter has (`FilterSpanInSymbols` x `InputSamplesPerSymbol` + 1) tap coefficients.

To apply pulse shaping by decimating an input signal using a raised-cosine FIR filter:

1. Create the `comm.RaisedCosineReceiveFilter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
rxfilter = comm.RaisedCosineReceiveFilter
rxfilter = comm.RaisedCosineReceiveFilter(Name,Value)
```

Description

`rxfilter = comm.RaisedCosineReceiveFilter` returns a raised-cosine FIR receive filter System object, which decimates the input signal using a raised-cosine FIR filter. The filter uses an efficient polyphase FIR decimation structure and has unit energy.

`rxfilter = comm.RaisedCosineReceiveFilter(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `comm.RaisedCosineReceiveFilter('RolloffFactor',0.3)` configures a raised-cosine receive filter System object with the roll-off factor set to `0.3`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Shape — Filter shape
`Square root` (default) | `Normal`

Filter shape, specified as 'Square root' or 'Normal'.

Data Types: char | string

RolloffFactor — Roll-off factor
0.2 (default) | scalar in the range [0, 1]

Roll-off factor, specified as a scalar in the range [0, 1].

Data Types: double

FilterSpanInSymbols — Filter span in symbols
10 (default) | positive integer

Filter span in symbols, specified as a positive integer. The object truncates the infinite impulse response (IIR) of an ideal raised-cosine filter to an impulse response that spans the number of symbols specified by this property.

Data Types: double

InputSamplesPerSymbol — Input samples per symbol
8 (default) | positive integer

Input samples per symbol, specified as a positive integer.

Data Types: double

DecimationFactor — Decimation factor
8 (default) | integer

Decimation factor, specified as an integer in the range [1, InputSamplesPerSymbol]. This value must evenly divide into InputSamplesPerSymbol. The sampling rate of the output signal is reduced by the decimation factor such that length(y)/length(x) is equal to DecimationFactor. For a matrix input signal, the number of input rows must be a multiple of the decimation factor.

Data Types: double

DecimationOffset — Decimation offset
0 (default) | integer

Decimation offset, specified as an integer in the range [0, (DecimationFactor − 1)]. This property specifies the number of filtered samples the object discards before downsampling.

Data Types: double

Gain — Linear filter gain
1 (default) | positive scalar

Linear filter gain, specified as a positive scalar. The object designs a raised-cosine filter that has unit energy and then applies the linear filter gain to obtain final tap coefficient values.

Data Types: double

Usage

Syntax

```
y = rxfilter(x)
```

Description

`y = rxfilter(x)` applies pulse shaping by decimating an input signal using a raised cosine FIR filter. The output consists of decimated signal values.

Input Arguments

x — Input signal
column vector | matrix

Input signal, specified as a column vector or a K_i-by-N matrix. K_i is the number of input samples per signal channel, and N is the number of signal channels.

For a K_i-by-N matrix input, the object processes columns of the input matrix as N independent channels.

Data Types: `double` | `single`

Output Arguments

y — Output signal
column vector | matrix

Output signal, returned as a column vector or a K_o-by-N matrix. K_o is equal to K_i / `DecimationFactor`. K_i is the number of input samples per signal channel, and N is the number of signal channels.

The System object filters each channel over time and generates a K_o-by-N output matrix. The output signal is the same data type as the input signal.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.RaisedCosineReceiveFilter`

coeffs	Coefficients for filters
info	Information about filter System object
order	Order of discrete-time filter System object

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics

reset	Reset internal states of System object

Examples

Filter Signal Using Square-Root-Raised-Cosine Receive Filter

Filter the output of a square-root-raised-cosine (SRRC) transmit filter by using a matched SRRC receive filter. The input signal has eight samples per symbol.

Create an SRRC transmit filter object, setting the number of output samples per symbol to 8.

```
 txfilter = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',8);
```

Create an SRRC receive filter, setting the number of input samples per symbol to 8 and the decimation factor to 8.

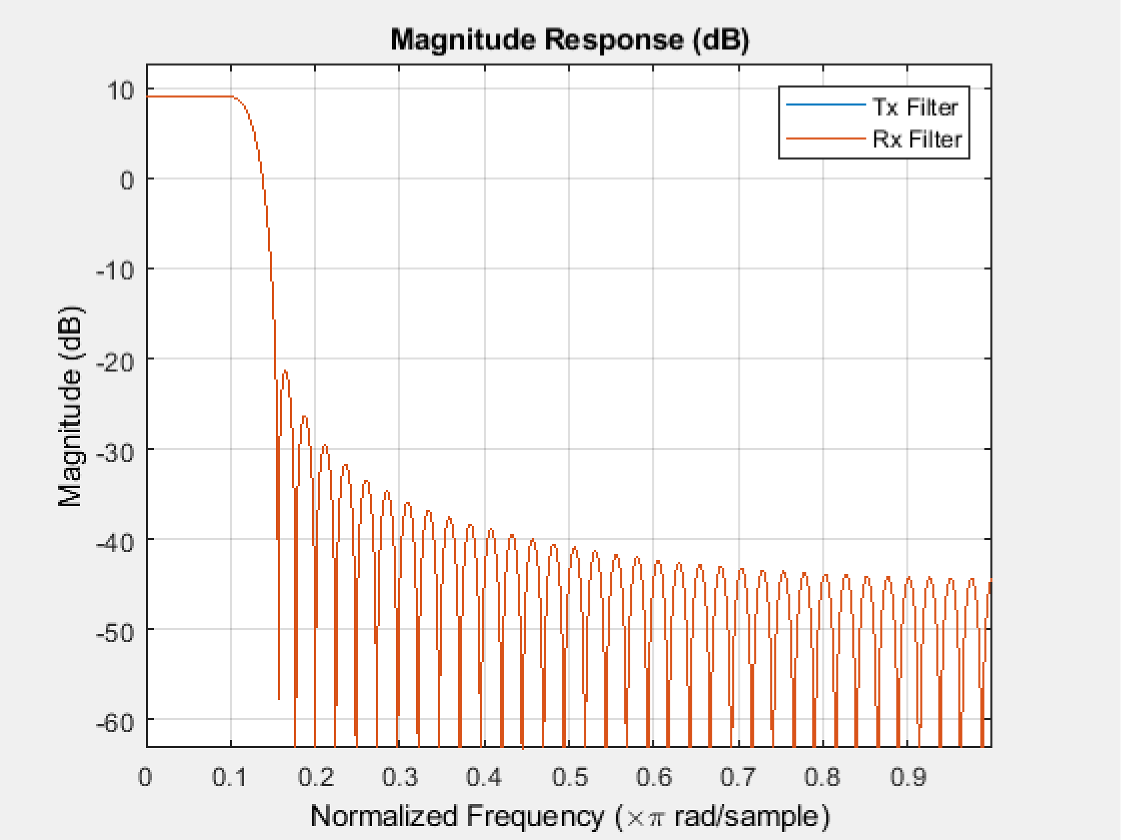
```
rxfilter = comm.RaisedCosineReceiveFilter('InputSamplesPerSymbol',8, ...
    'DecimationFactor',8);
```

Use the `coeffs` function to determine the filter coefficients for both filters.

```
txCoef = coeffs(txfilter);
rxCoef = coeffs(rxfilter);
```

Launch the filter visualization tool and display the magnitude responses of the two filters. The results show that the responses are the same.

```
 fvtool(txCoef.Numerator,1,rxCoef.Numerator,1);
 legend('Tx Filter','Rx Filter')
```



Generate a random bipolar signal. Interpolate the signal by using the SRRC transmit filter object.

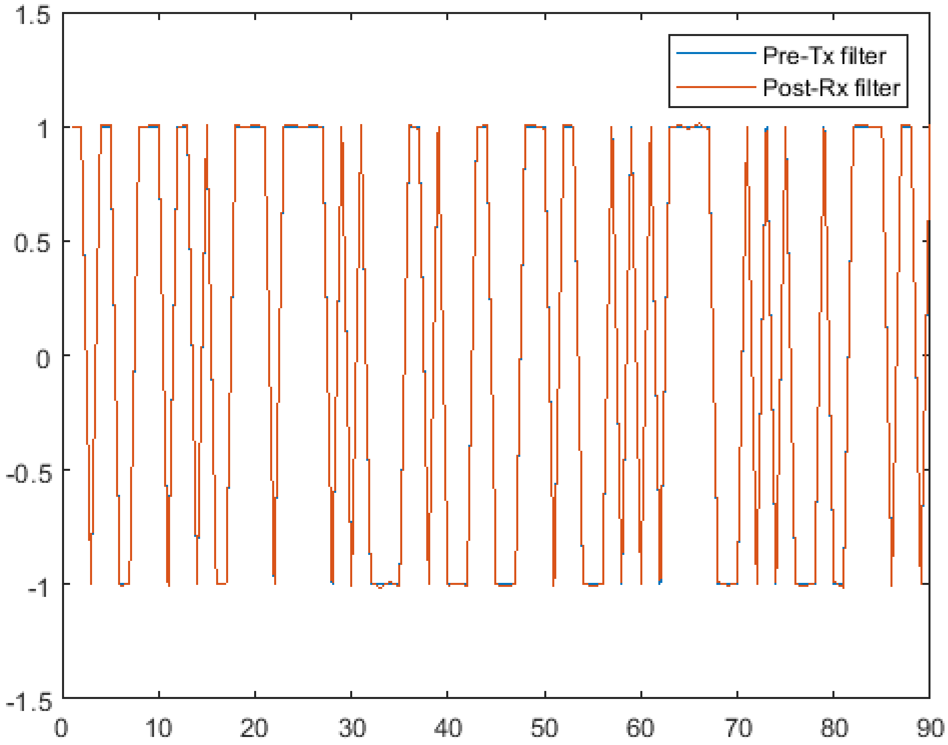
```
preTx = 2*randi([0 1],100,1) - 1;
y = txfilter(preTx);
```

Decimate the signal by using the SRRC receive filter object.

```
postRx = rxfilter(y);
```

The filter delay is equal to the filter span. Accounting for the filter delay, adjust the plotted samples to compare the pre-Tx filter signal with the post-Rx filter signal. Because the combined receive and the transmit RRC filters generate a matched filter pair, the two signals overlap one another.

```
delay = txfilter.FilterSpanInSymbols;
x = (1:(length(preTx)-delay));
plot(x,preTx(1:end-delay),x,postRx(delay+1:end))
legend('Pre-Tx filter','Post-Rx filter')
```



Specify Filter Span of Square-Root-Raised-Cosine Receive Filter

Decimate a bipolar signal using a square-root-raised-cosine (SRRC) filter whose impulse response is truncated to filter a span of six symbol durations.

Create a SRRC transmit FIR filter, setting the filter span to six symbols. The object truncates the impulse response to six symbols.

```
txfilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',6);
```

Generate a random bipolar signal . Filter the signal by using the SRRC transmit FIR filter object.

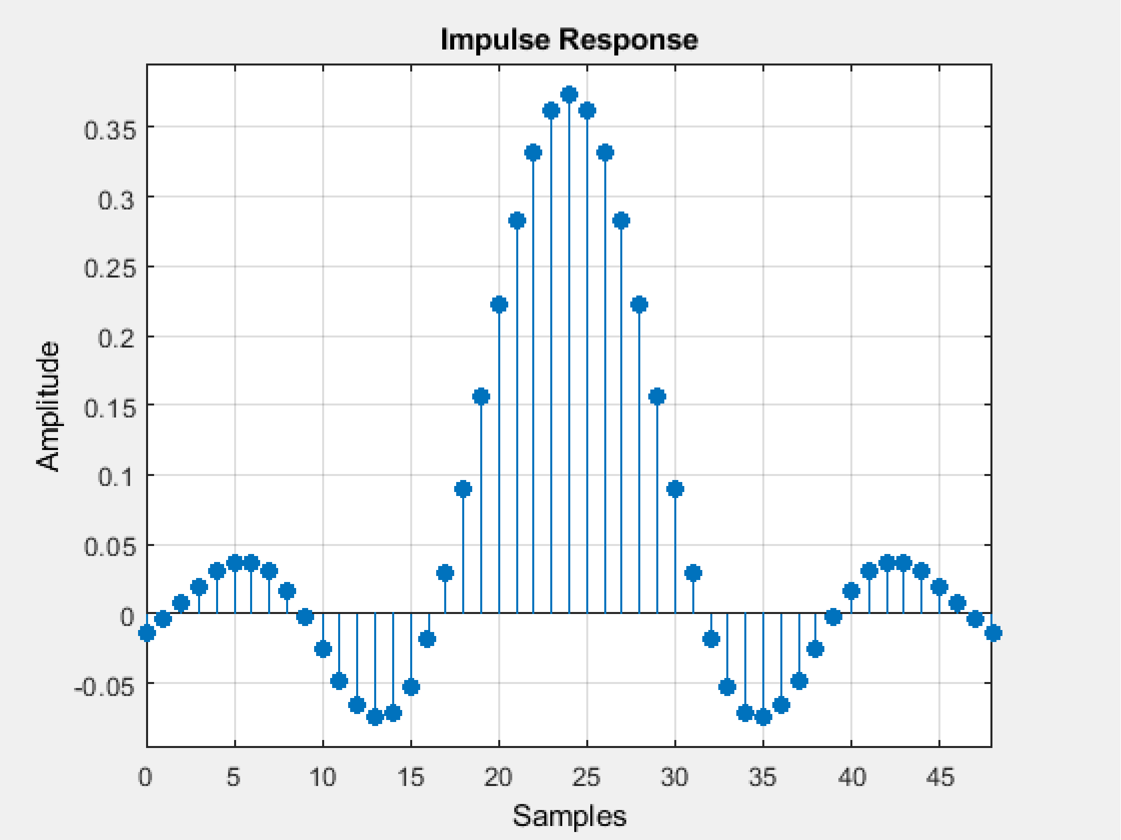
```
x = 2*randi([0 1],25,1) - 1;
y = txfilter(x);
```

Create a matched SRRC receive filter object.

```
rxfilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',6);
```

Launch the filter visualization tool to show the impulse response of the receive filter.

```
fvtool(rxfilter,'Analysis','impulse')
```

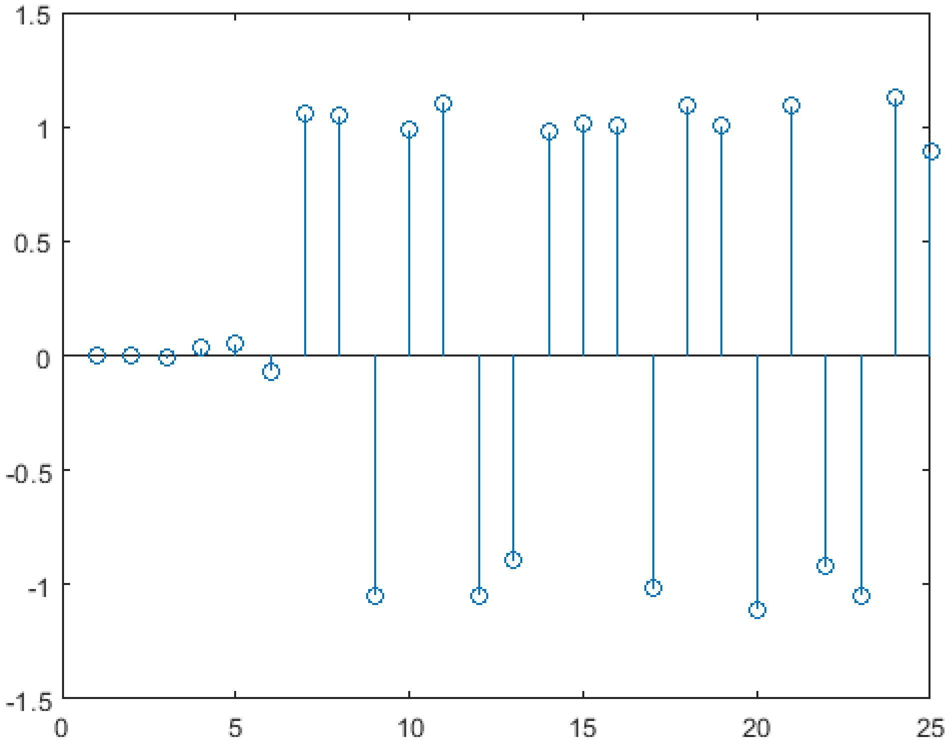


Filter the output signal from the transmit filter by using the matched SRRC receive filter object.

```
r = rxfilter(y);
```

Plot the interpolated signal. The results show a delay equal to the filter span (six symbols) before data passes through the filter.

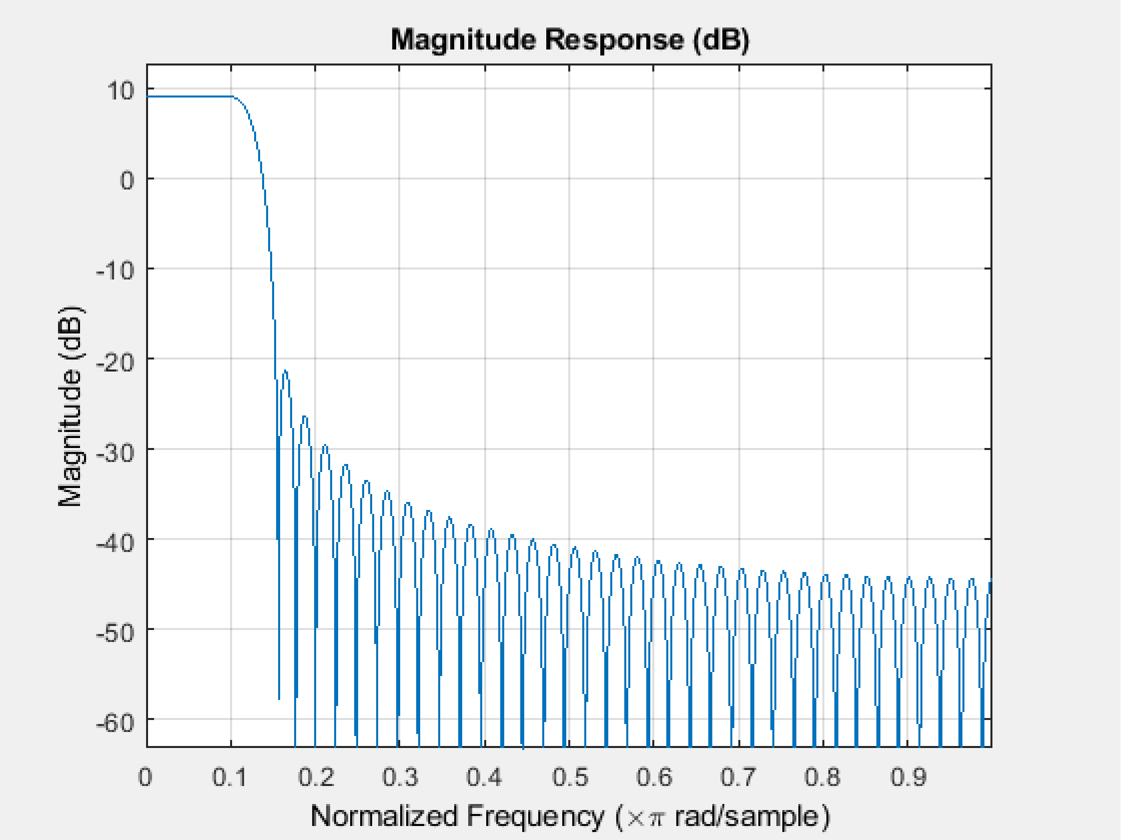
```
stem(r)
```



Create Square-Root-Raised-Cosine Receive Filter with Unity Passband Gain

Create a square-root-raised-cosine (SRRC) receive filter object. Use FVTool to plot the filter response. The results show that the linear filter gain is greater than unity. Specifically, the passband gain is more than 0 dB.

```
rxfilter = comm.RaisedCosineReceiveFilter;
fvtool(rxfilter)
```



Use the `coeffs` object function to obtain the filter coefficients and adjust the filter gain to unit energy.

```
b = coeffs(rxfilter);
```

Because a filter with unity passband gain must have filter coefficients that sum to 1, set the linear filter gain to the inverse of the sum of the filter tap coefficients, `b.Numerator`.

```
rxfilter.Gain = 1/sum(b.Numerator);
```

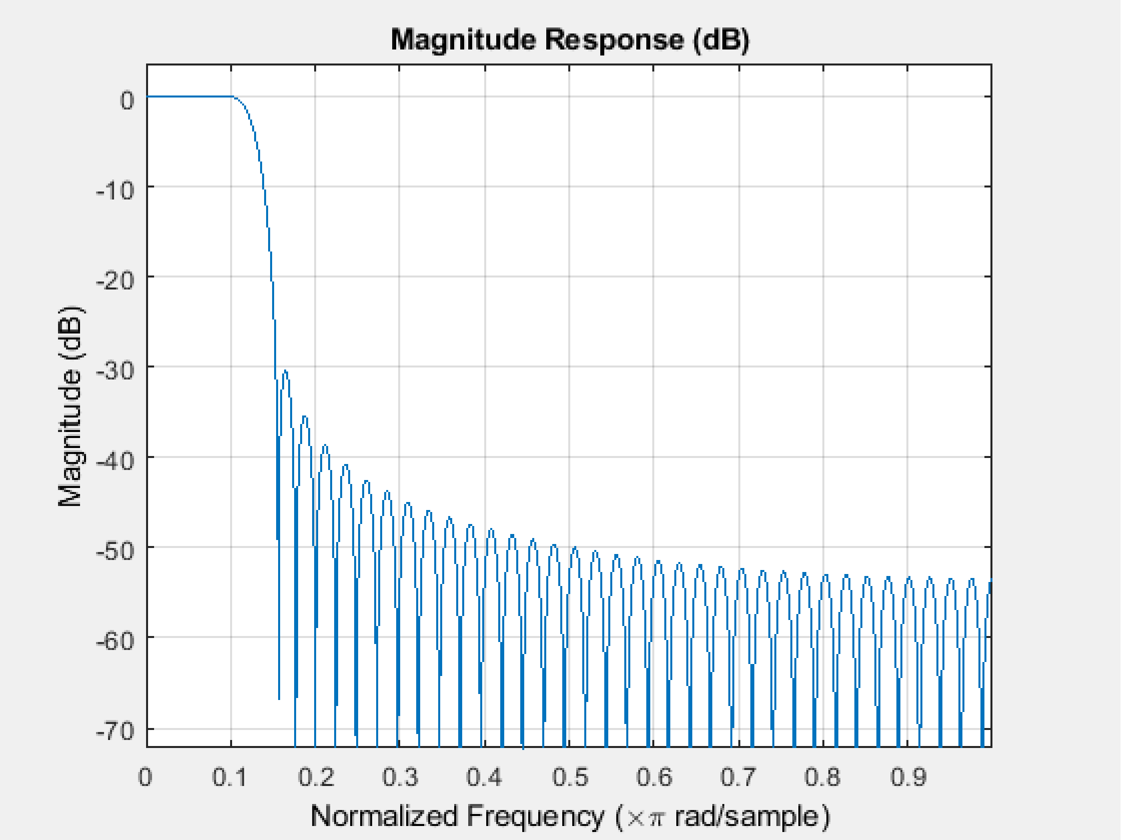
Verify that the resulting filter coefficients sum to 1.

```
bNorm = coeffs(rxfilter);
sum(bNorm.Numerator)
```

```
ans = 1.0000
```

Plot the filter frequency response. The results now show that the passband gain is 0 dB, which is unity gain.

```
fvtool(rxfilter)
```



Extended Capabilities

`comm.RaisedCosineTransmitFilter`

Functions

`rcosdesign`

Introduced in R2013b

comm.RaisedCosineTransmitFilter

Package: `comm`

Apply pulse shaping by interpolating signal using raised-cosine FIR filter

Description

The `comm.RaisedCosineTransmitFilter` System object applies pulse shaping by interpolating an input signal using a raised cosine finite impulse response (FIR) filter. The FIR filter has (`FilterSpanInSymbols` x `OutputSamplesPerSymbol` + 1) tap coefficients.

To apply pulse shaping by interpolating an input signal using a raised cosine FIR filter:

1. Create the `comm.RaisedCosineTransmitFilter` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
txfilter = comm.RaisedCosineTransmitFilter
txfilter = comm.RaisedCosineTransmitFilter(Name,Value)
```

Description

`txfilter = comm.RaisedCosineTransmitFilter` returns a raised cosine transmit FIR filter System object, which interpolates an input signal using a raised cosine FIR filter. The filter uses an efficient polyphase FIR interpolation structure and has unit energy.

`txfilter = comm.RaisedCosineTransmitFilter(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',15)` configures a raised cosine transmit filter System object with the filter span set to 15 symbols.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Shape — Filter shape
`'Square root'` (default) | `'Normal'`

Filter shape, specified as `'Square root'` or `'Normal'`.

Data Types: `char` | `string`

`RolloffFactor` — Roll-off factor

`0.2` (default) | scalar in the range [0, 1]

Roll-off factor, specified as a scalar in the range [0, 1].

Data Types: `double`

`FilterSpanInSymbols` — Filter span in symbols

`10` (default) | positive integer

Filter span in symbols, specified as a positive integer. The object truncates the infinite impulse response (IIR) of an ideal raised-cosine filter to an impulse response that spans the number of symbols specified by this property.

Data Types: `double`

`OutputSamplesPerSymbol` — Output samples per symbol

`8` (default) | positive integer

Output samples per symbol, specified as a positive integer.

Data Types: `double`

`Gain` — Linear filter gain

`1` (default) | positive scalar

Linear filter gain, specified as a positive scalar. The object designs a raised-cosine filter that has unit energy and then applies the linear filter gain to obtain final tap coefficient values.

Data Types: `double`

Usage

Syntax

```
y = txfilter(x)
```

Description

`y = txfilter(x)` applies pulse shaping by interpolating an input signal using a raised cosine FIR filter. The output consists of interpolated signal values.

Input Arguments

`x` — Input signal

column vector | matrix

Input signal, specified as a column vector or a K_i-by-N matrix. K_i is the number of input samples per signal channel, and N is the number of signal channels.

For a K_i-by-N matrix input, the object processes columns of the input matrix as N independent channels.

Data Types: `double` | `single`

Output Arguments

y — Output signal
column vector | matrix

Output signal, returned as a column vector or a K_o-by-N matrix. K_o is equal to K_i × `OutputSamplesPerSymbol`. K_i is the number of input samples per signal channel, and N is the number of signal channels.

The object interpolates and filters each channel over the first dimension and then generates a K_o-by-N output matrix. The output signal is the same data type as the input signal.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.RaisedCosineTransmitFilter`

coeffs	Coefficients for filters
info	Information about filter System object
order	Order of discrete-time filter System object

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Interpolate Signal Using Square-Root-Raised-Cosine Filter

Interpolate a signal using square-root-raised-cosine (SRRC) transmit filter object and display the spectrum of the filtered signal.

Create random bipolar symbols at a symbol rate of 1e6 symbols per second.

```
data = 2*randi([0 1],1e6,1) - 1;
```

Create a SRRC transmit filter object. The default sets the filter to a square-root shape and the number of samples per symbol to 8.

```
txfilter = comm.RaisedCosineTransmitFilter
```

```
txfilter = 
  comm.RaisedCosineTransmitFilter with properties:

                   Shape: 'Square root'
```

```
            RolloffFactor: 0.2000
        FilterSpanInSymbols: 10
      OutputSamplesPerSymbol: 8
                       Gain: 1
```

Filter the data by using the SRRC filter.

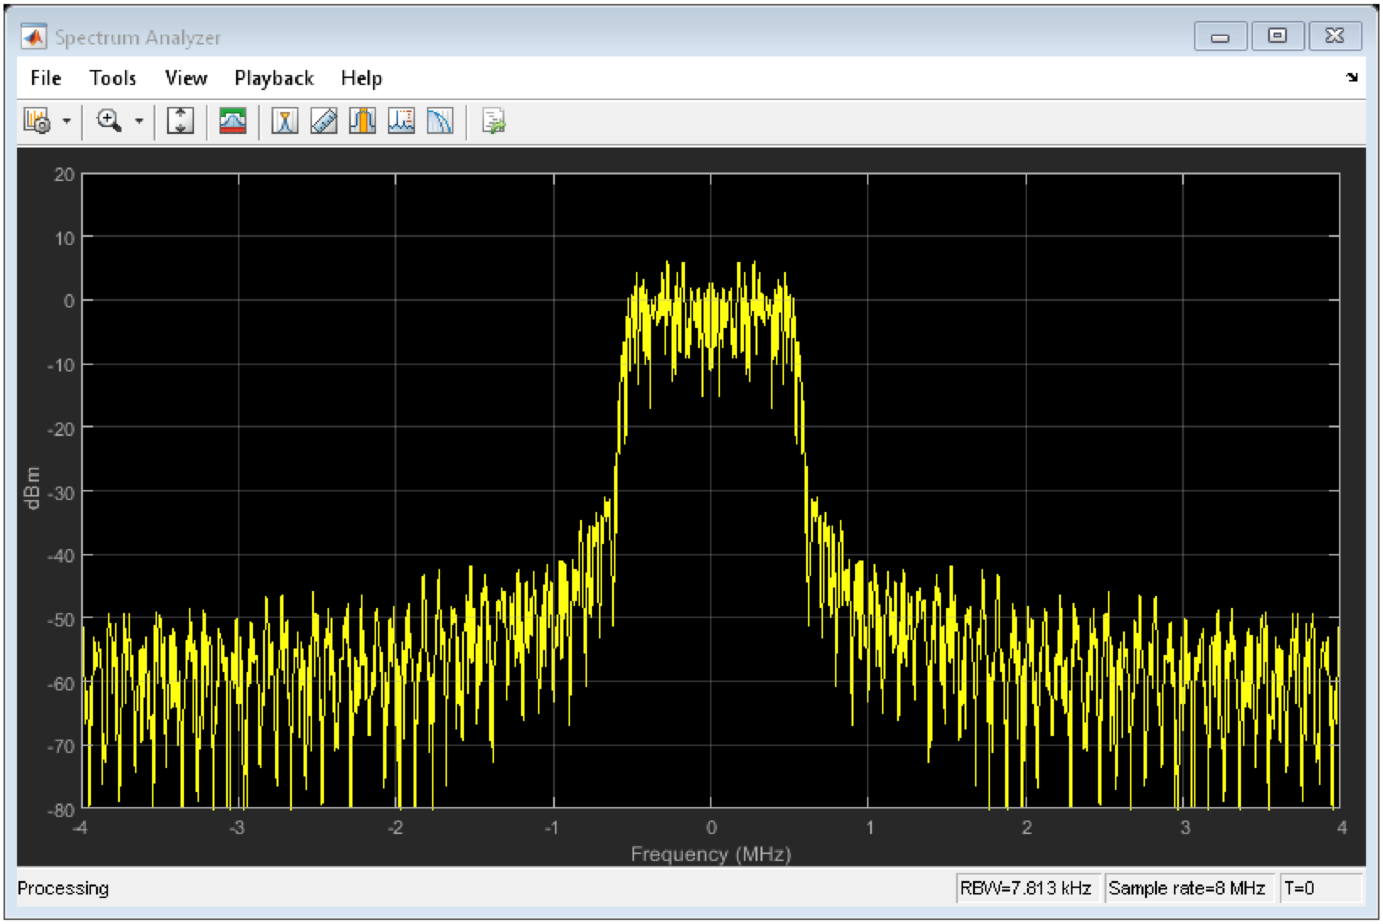
```
filteredData = txfilter(data);
```

Create a spectrum analyzer object with an 8e6 sampling rate. This sampling rate matches the sampling rate of the filtered signal.

```
spectrumAnalyzer = dsp.SpectrumAnalyzer('SampleRate',8e6);
```

View the spectrum of the filtered signal by using the spectrum analyzer object.

```
spectrumAnalyzer(filteredData)
```



Examine Effect of Filter Span on Magnitude Response

Create interpolated signals from a square-root-raised-cosine (SRRC) filter with various filter spans. Examine the magnitude response of the various filter designs.

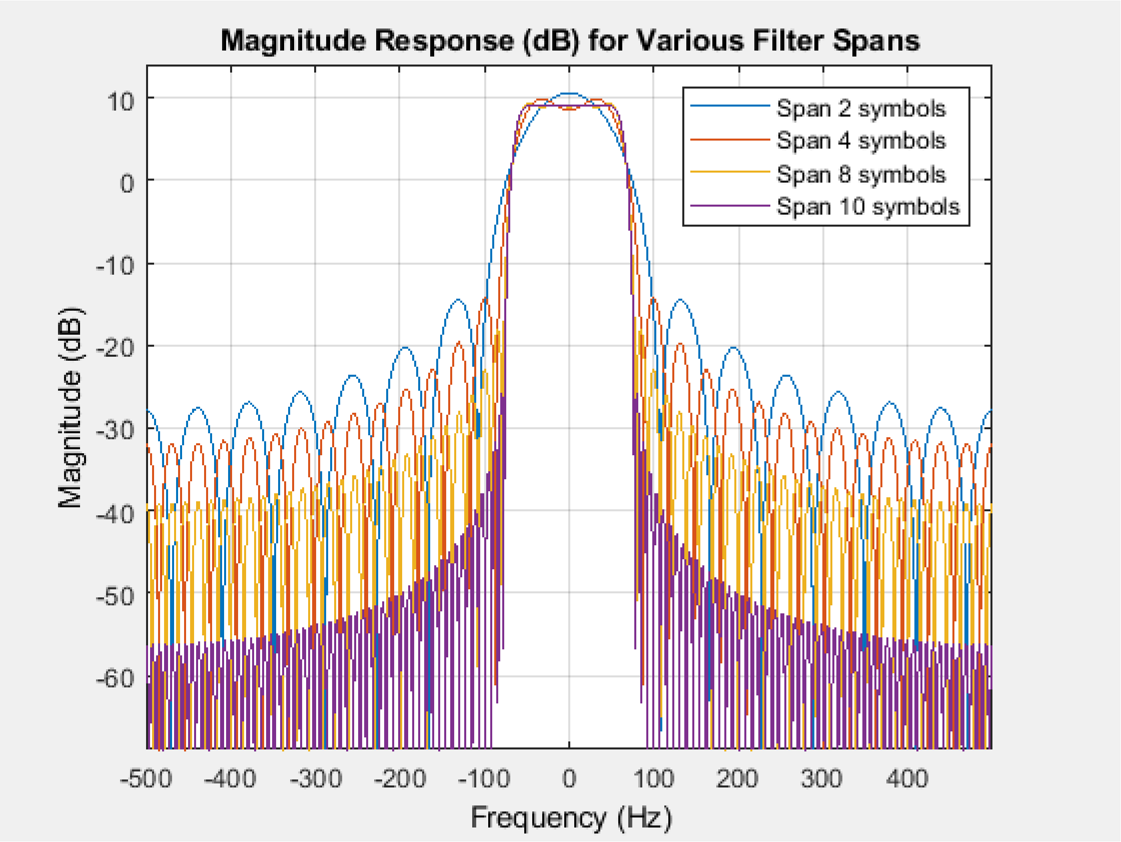
Create SRRC filter objects setting various filter spans. Use the `coeffs` object function to obtain the filter coefficients.

```
txfilt2 = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',2);
txfilt4 = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',4);
txfilt6 = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',6);
txfilt8 = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',8);
txfilt16 = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',16);

taps2 = coeffs(txfilt2).Numerator;
taps4 = coeffs(txfilt4).Numerator;
taps6 = coeffs(txfilt6).Numerator;
taps8 = coeffs(txfilt8).Numerator;
taps16 = coeffs(txfilt16).Numerator;
```

Launch the filter visualization tool to show the impulse response. Specify a sample rate of 1 kHz. Display the two-sided centered response.

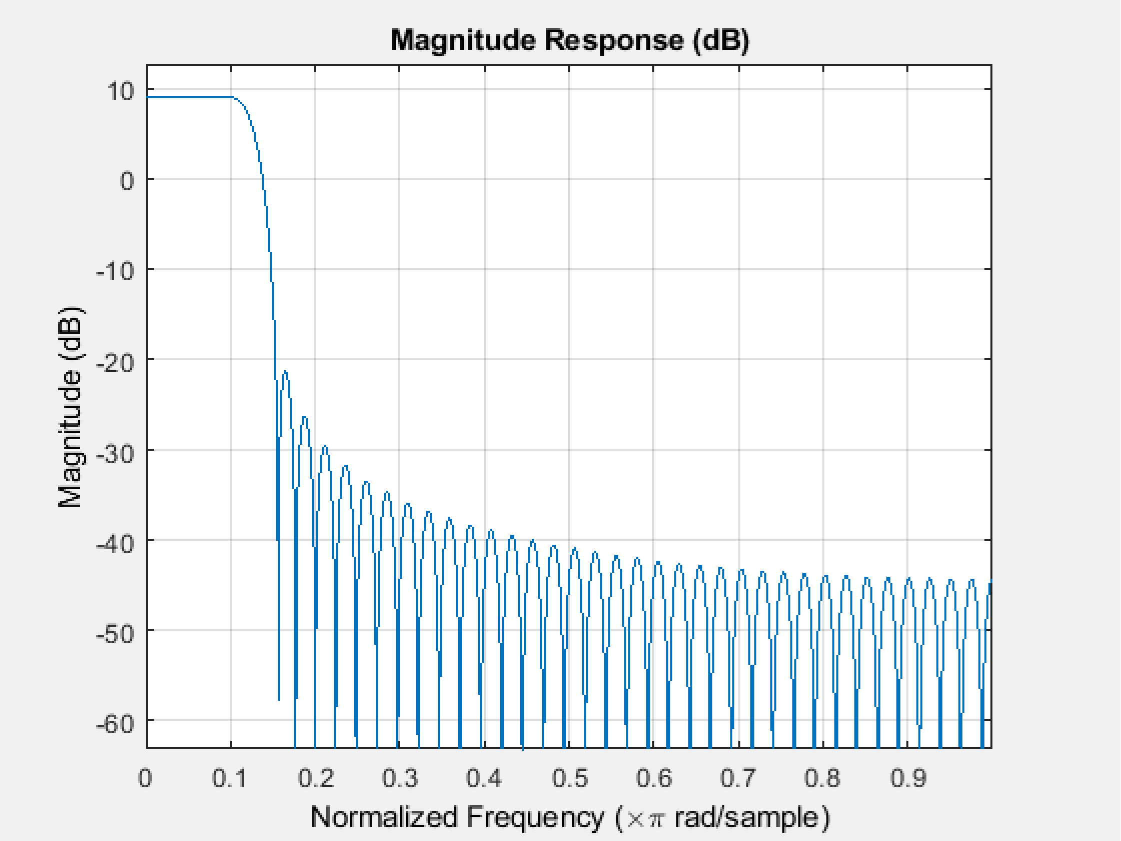
```
h = fvtool(taps2,1,taps4,1,taps8,1,taps16,1);
h.Fs = 1e3;
h.FrequencyRange = '[-Fs/2, Fs/2)';
legend('Span 2 symbols','Span 4 symbols','Span 8 symbols','Span 10 symbols')
title('Magnitude Response (dB) for Various Filter Spans')
```



Create Square-Root-Raised-Cosine Transmit Filter with Unity Passband Gain

Create a square-root-raised-cosine (SRRC) transmit filter object. Use FVTool to plot the filter response. The results show that the linear filter gain is greater than unity. Specifically, the passband gain is more than 0 dB.

```
txfilter = comm.RaisedCosineTransmitFilter;
fvtool(txfilter)
```



Use the `coeffs` object function to obtain the filter coefficients and adjust the filter gain to unit energy.

```
b = coeffs(txfilter);
```

Because a filter with unity passband gain must have filter coefficients that sum to 1, set the linear filter gain to the inverse of the sum of the filter tap coefficients, `b.Numerator`.

```
txfilter.Gain = 1/sum(b.Numerator);
```

Verify that the resulting filter coefficients sum to 1.

```
bNorm = coeffs(txfilter);
sum(bNorm.Numerator)
```

```
ans = 1.0000
```

Plot the filter frequency response. The results now show that the passband gain is 0 dB, which is unity gain.

```
fvtool(txfilter)
```

comm.RayleighChannel

Package: comm

Filter input signal through multipath Rayleigh fading channel

Description

The comm.RayleighChannel System object filters an input signal through a multipath Rayleigh fading channel. For more information on fading model processing, see Methodology for Simulating Multipath Fading Channels.

To filter an input signal using a multipath Rayleigh fading channel:

1. Create the comm.RayleighChannel object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
rayleighchan = comm.RayleighChannel
rayleighchan = comm.RayleighChannel(Name,Value)
```

Description

rayleighchan = comm.RayleighChannel creates a frequency-selective or frequency-flat multipath Rayleigh fading channel System object. This object filters a real or complex input signal through the multipath channel to obtain the channel-impaired signal.

rayleighchan = comm.RayleighChannel(Name,Value) sets properties using one or more name-value pair arguments. Enclose each property name in quotes. For example, comm.RayleighChannel('SampleRate',2) sets the input signal sample rate to 2.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

SampleRate — Input signal sample rate
1 (default) | positive scalar

Input signal sample rate in Hz, specified as a positive scalar.

Data Types: `double`

`PathDelays` — Discrete path delay

`0` (default) | scalar | row vector

Discrete path delay in seconds, specified as a scalar or row vector.

- When `PathDelays` is a scalar, the channel is frequency flat.
- When `PathDelays` is a vector, the channel is frequency selective.

Data Types: `double`

`AveragePathGains` — Average of the discrete paths

`0` (default) | scalar | row vector

Average gains of the discrete paths in decibels, specified as a scalar or row vector. `AveragePathGains` must be of the same size as the `PathDelays` property.

Data Types: `double`

`NormalizePathGains` — Normalize average path gains to 0 dB

`true` or `1` (default) | `false` or `0`

Normalize average path gains to 0 dB, specified as a logical `1` (`true`) or `0` (`false`).

- When `NormalizePathGains` is `true`, the fading processes are normalized so that the total power of the path gains, averaged over time, is 0 dB.
- When `NormalizePathGains` is `false`, the total power of the path gains is not normalized.

Data Types: `logical`

`MaximumDopplerShift` — Maximum Doppler shift for all channel paths

`0.001` (default) | nonnegative scalar

Maximum Doppler shift for all channel paths, specified as a nonnegative scalar. Units are in hertz.

The maximum Doppler shift limit applies to each channel path. When you set this property to `0`, the channel remains static for the entire input. You can use the `reset` object function to generate a new channel realization. The `MaximumDopplerShift` property value must be smaller than `SampleRate`/10/f_c for each path. f_c represents the cutoff frequency factor of the path. For most Doppler spectrum types, the value of f_c is 1. For Gaussian and biGaussian Doppler spectrum types, f_c is dependent on the Doppler spectrum structure fields. For more details about how f_c is defined, see “Cutoff Frequency Factor” on page 3-1218.

Data Types: `double`

`DopplerSpectrum` — Doppler spectrum shape for all channel paths

`doppler('Jakes')` (default) | Doppler spectrum structure | 1-by-N_P cell array of Doppler spectrum structures

Doppler spectrum shape for all channel paths, specified as a Doppler spectrum structure or a 1-by-N_P cell array of Doppler spectrum structures. These Doppler spectrum structures must be outputs of the form returned from the `doppler` function. N_P is the number of discrete delay paths, that is, the length of the `PathDelays` property.

- When DopplerSpectrum is defined by a single Doppler spectrum structure, all paths have the same specified Doppler spectrum.
- When DopplerSpectrum is defined by a cell array of Doppler spectrum structures, each path has the Doppler spectrum specified by the corresponding structure in the cell array.

Options for the spectrum type are specified by the specType input to the doppler function. If you set the FadingTechnique property to 'Sum of sinusoids', you must set DopplerSpectrum to doppler('Jakes').

Dependencies

To enable this property, set the MaximumDopplerShift property to a positive value. The MaximumDopplerShift property defines the maximum Doppler shift value permitted when specifying the Doppler spectrum.

Data Types: struct | cell

FadingTechnique — Channel model fading technique

'Filtered Gaussian noise' (default) | 'Sum of sinusoids'

Channel model fading technique, specified as 'Filtered Gaussian noise' or 'Sum of sinusoids'.

Data Types: char | string

NumSinusoids — Number of sinusoids used

48 (default) | positive integer

Number of sinusoids used to model the fading process, specified as a positive integer.

Dependencies

To enable this property, set the FadingTechnique property to 'Sum of sinusoids'.

Data Types: double

InitialTimeSource — Source to control start time of fading process

'Property' (default) | 'Input port'

Source to control the start time of the fading process, specified as 'Property' or 'Input port'.

- When InitialTimeSource is set to 'Property', use the InitialTime property to set the initial time offset.
- When InitialTimeSource is set to 'Input port', specify the start time of the fading process by using the itime input to the System object. The input value can change in consecutive calls to the System object.

Dependencies

To enable this property, set the FadingTechnique property to 'Sum of sinusoids'.

Data Types: string | char

InitialTime — Initial time offset

0 (default) | nonnegative scalar

Initial time offset, in seconds, for the fading model, specified as a nonnegative scalar. `InitialTime` must be greater than end time of the last frame. `InitialTime` is rounded up to the nearest sample position when it is not a multiple of 1/`SampleRate`.

Dependencies

To enable this property, set the `FadingTechnique` property to `'Sum of sinusoids'` and the `InitialTimeSource` property to `'Property'`.

Data Types: `double`

`RandomStream` — Source of random number stream

`'Global stream'` (default) | `'mt19937ar with seed'`

Source of random number stream, specified as `'Global stream'` or `'mt19937ar with seed'`.

- `'Global stream'` — The current global random number stream is used for normally distributed random number generation. In this case, the `reset` object function resets the channel filters only.
- `'mt19937ar with seed'` — The mt19937ar algorithm is used for normally distributed random number generation. In this case, the `reset` object function resets the channel filters and reinitializes the random number stream to the value of the `Seed` property.

Data Types: `string` | `char`

Seed — Initial seed of mt19937ar random number stream

`73` (default) | nonnegative integer

Initial seed of mt19937ar random number stream generator algorithm, specified as a nonnegative integer. When the `reset` object function is called, the mt19937ar random number stream is reinitialized to the `Seed` property value.

Dependencies

To enable this property, set the `RandomStream` property to `'mt19937ar with seed'`.

Data Types: `double`

`PathGainsOutputPort` — Option to output path gains

`false` or `0` (default) | `true` or `1`

Option to output path gains, specified as `0` (`false`) or `1` (`true`). Set this property to `1` (`true`) to output the channel path gains of the underlying fading process.

Data Types: `logical`

`Visualization` — Channel visualization

`'Off'` (default) | `'Impulse response'` | `'Frequency response'` | `'Impulse and frequency responses'` | `'Doppler spectrum'`

Channel visualization, specified as `'Off'`, `'Impulse response'`, `'Frequency response'`, `'Impulse and frequency responses'`, or `'Doppler spectrum'`. For more information, see “Channel Visualization” on page 3-1219.

Data Types: `string` | `char`

`SamplesToDisplay` — Percentage of samples to display

`'25%'` (default) | `'10%'` | `'50%'` | `'100%'`

Percentage of samples to display, specified as '25%', '10%', '50%', or '100%'. Displaying fewer samples improves (decreases) the display update rate at the expense of decreasing the visualized precision.

Dependencies

To enable this property, set the Visualization property to 'Impulse response', 'Frequency response', or 'Impulse and frequency responses'.

Data Types: string | char

PathsForDopplerDisplay — Path for Doppler display

1 (default) | positive integer

Path for Doppler display, specified as a positive integer. Use this property to select the discrete path used in constructing a Doppler spectrum plot. The specified path must be an element of {1, 2, ..., N_P}. In this set, N_P is the number of discrete delay paths, that is, the length of the PathDelays property value.

Dependencies

To enable this property, set the Visualization property to 'Doppler spectrum'.

Data Types: double

Usage

Syntax

```
y = rayleighchan(x)
[y,pathgains] = rayleighchan(x)
___ = rayleighchan(x,itime)
```

Description

y = rayleighchan(x) filters input signal x through a multipath Rayleigh fading channel and returns the output signal in y.

[y,pathgains] = rayleighchan(x) returns the channel path gains of the underlying multipath Rayleigh fading process in pathgains. To enable this syntax set the PathGainsOutputPort property set to 1 (true).

___ = rayleighchan(x,itime) passes data through the multipath Rayleigh fading channel beginning at the initial time specified by itime. To enable this syntax, set the FadingTechnique property to 'Sum of sinusoids' and the InitialTimeSource property to 'Input port'.

Input Arguments

x — Input signal

N_S-by-1 vector

Input signal, specified as an N_S-by-1 vector, where N_S is the number of samples.

Data Types: single | double
Complex Number Support: Yes

`itime` — Initial time

`0` | nonnegative scalar

Initial time in seconds, specified as a nonnegative scalar. The `itime` input must be greater than the end time of the last frame. When `itime` is not a multiple of 1/`SampleRate`, it is rounded up to the nearest sample position.

Data Types: `single` | `double`

Output Arguments

y — Output signal

N_S-by-1 vector

Output signal, returned as an N_S-by-1 vector of complex values with the same data precision as the input signal `x`. N_S is the number of samples.

`pathgains` — Path gains

N_S-by-N_P array

Path gains, returned as an N_S-by-N_P array. N_S is the number of samples. N_P is the number of discrete delay paths, that is, the length of the `PathDelays` property value. `pathgains` contains complex values with the same precision as the input signal `x`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.RayleighChannel`

info	Characteristic information about fading channel object

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Produce Same Rayleigh Channel Outputs Using Two Random Number Generation Methods

This example shows how to produce the same multipath Rayleigh fading channel response by using two different methods for random number generation. The multipath Rayleigh fading channel System object™ includes two methods for random number generation. You can use the current global stream or the mt19937ar algorithm with a specified seed. By interacting with the global stream, the System object can produce the same outputs from these two methods.

Create a PSK modulator System object to modulate randomly generated data.

```
pskModulator = comm.PSKModulator;
channelInput = pskModulator(randi([0 pskModulator.ModulationOrder-1],1024,1));
```

Create a multipath Rayleigh fading channel System object, specifying the random number generation method as the my19937ar algorithm and the random number seed as 22.

```
rayleighchan = comm.RayleighChannel(...
    'SampleRate',10e3, ...
    'PathDelays',[0 1.5e-4], ...
    'AveragePathGains',[2 3], ...
    'NormalizePathGains',true, ...
    'MaximumDopplerShift',30, ...
    'DopplerSpectrum',{doppler('Gaussian',0.6),doppler('Flat')}, ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',22, ...
    'PathGainsOutputPort',true);
```

Filter the modulated data by using the multipath Rayleigh fading channel System object.

```
[chanOut1,pathGains1] = rayleighchan(channelInput);
```

Set the System object to use the global stream for random number generation.

```
release(rayleighchan);
rayleighchan.RandomStream = 'Global stream';
```

Set the global stream to have the same seed that was specified when creating the multipath Rayleigh fading channel System object.

```
rng(22)
```

Filter the modulated data by using the multipath Rayleigh fading channel System object again.

```
[chanOut2,pathGains2] = rayleighchan(channelInput);
```

Verify that the channel and path gain outputs are the same for each of the two methods.

```
isequal(chanOut1,chanOut2)
```

```
ans = logical
   1
```

```
isequal(pathGains1,pathGains2)
```

```
ans = logical
   1
```

Display Impulse and Frequency Responses of Multipath Rayleigh Fading Channel

This example shows how to create a frequency-selective multipath Rayleigh fading channel System object and display its impulse and frequency responses.

Set the sample rate to 3.84 MHz. Specify path delays and gains by using the ITU pedestrian B channel configuration. Set the maximum Doppler shift to 50 Hz.

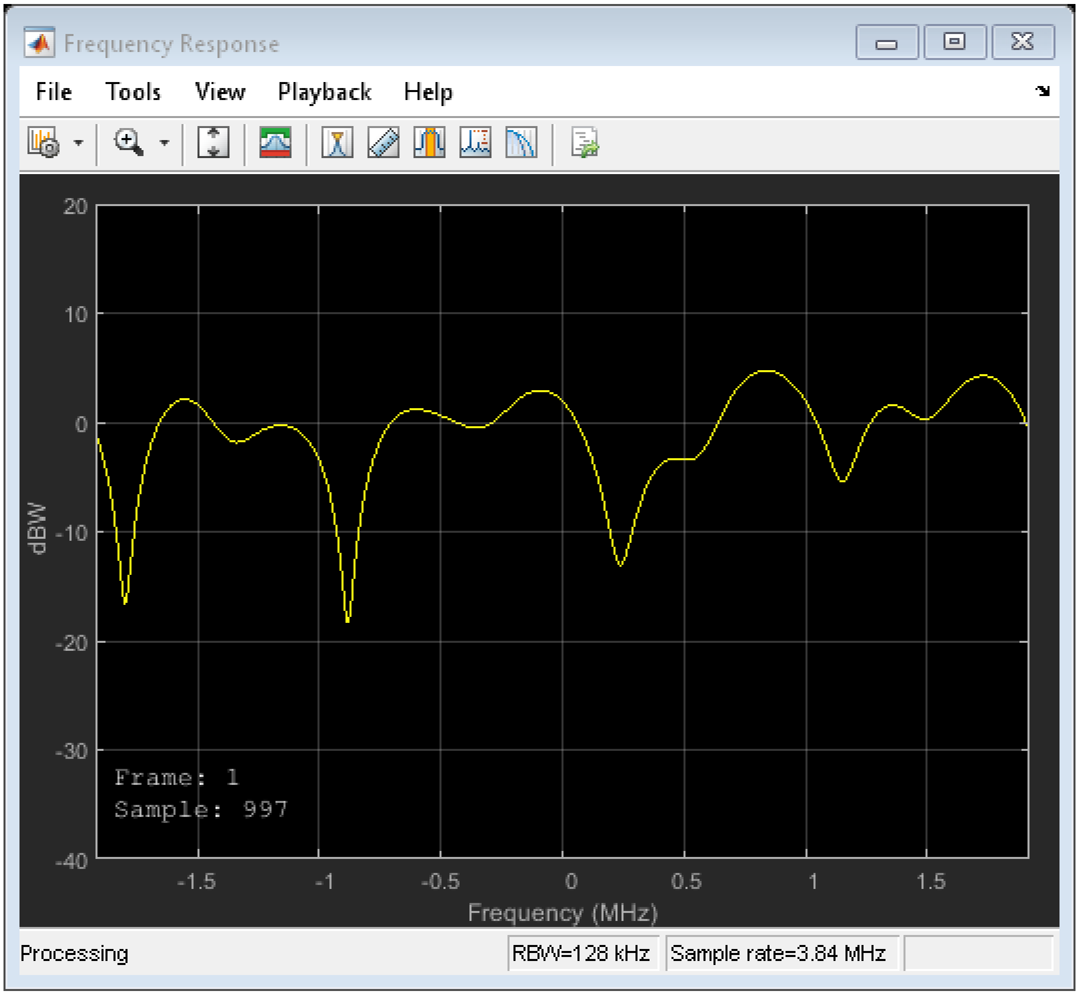
```
fs = 3.84e6; % Hz
pathDelays = [0 200 800 1200 2300 3700]*1e-9; % sec
avgPathGains = [0 -0.9 -4.9 -8 -7.8 -23.9]; % dB
fD = 50; % Hz
```

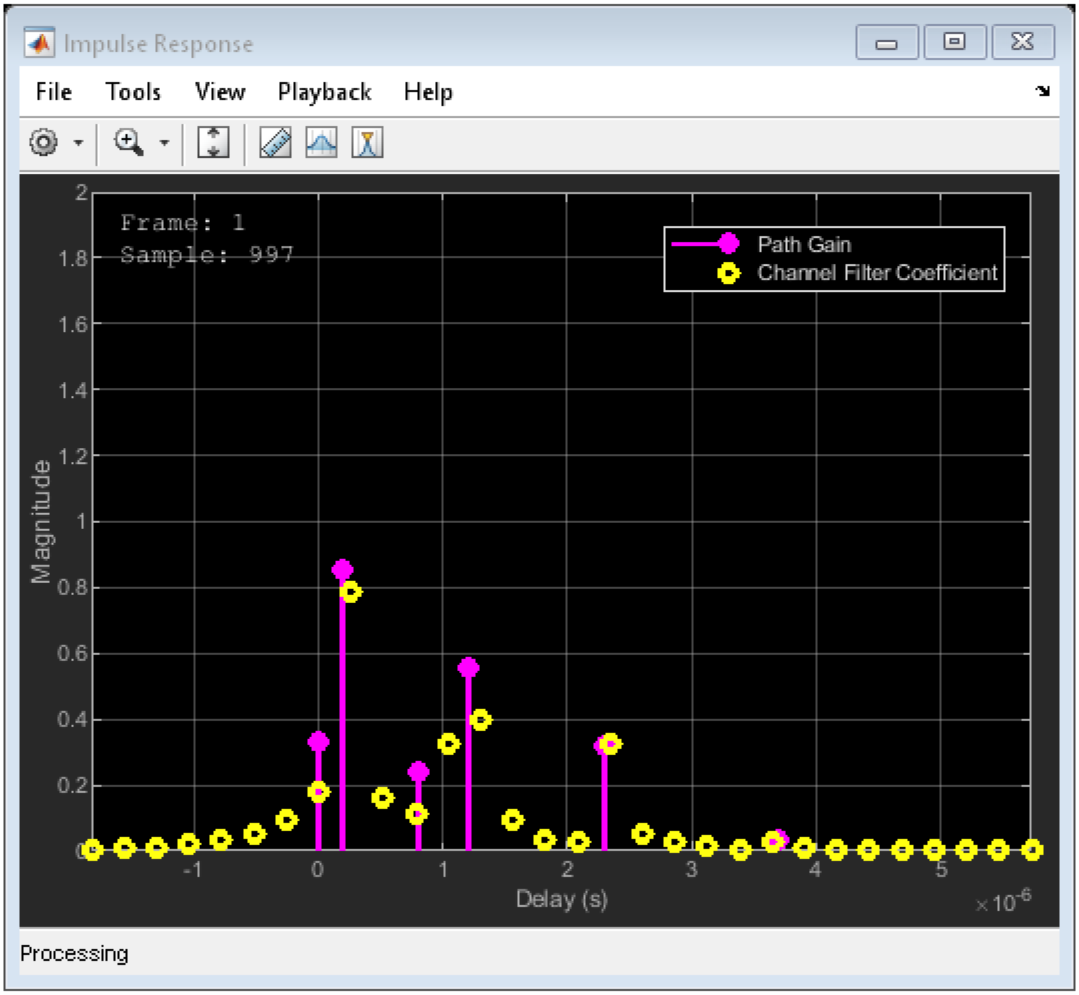
Create a multipath Rayleigh fading channel System object by using the previously defined properties and to visualize the impulse response and frequency response plots.

```
rayleighchan = comm.RayleighChannel('SampleRate',fs, ...
    'PathDelays',pathDelays, ...
    'AveragePathGains',avgPathGains, ...
    'MaximumDopplerShift',fD, ...
    'Visualization','Impulse and frequency responses');
```

Generate random binary data and pass it through the multipath Rayleigh fading channel. The impulse response plot enables you to identify the individual paths and their corresponding filter coefficients. The frequency response plot shows the frequency-selective nature of the ITU pedestrian B channel.

```
x = randi([0 1],1000,1);
y = rayleighchan(x);
```





Model Multipath Rayleigh Fading Channel by Using Sum-of-Sinusoids Technique

The example shows how the channel state is maintained in cases in which data is discontinuously transmitted. Create a multipath Rayleigh fading channel System object and pass data through it using the sum-of-sinusoids technique.

Set the channel properties.

```
fs = 1000; % Sample rate (Hz)
pathDelays = [0 2.5e-3]; % Path delays (s)
pathPower = [0 -6]; % Path power (dB)
fD = 5; % Maximum Doppler shift (Hz)
ns = 1000; % Number of samples
nsdel = 100; % Number of samples for delayed paths
```

Define the overall simulation time and three time segments for which data is to be transmitted. In this case, the channel is simulated for 1s with a 1000 Hz sampling rate. One 1000-sample continuous data sequence is transmitted at time 0. Three 100-sample data packets are transmitted at times 0.1 s, 0.4 s, and 0.7 s, respectively.

```
to0 = 0.0;
to1 = 0.1;
to2 = 0.4;
to3 = 0.7;
t0 = (to0:ns-1)/fs; % Transmission 0
t1 = to1+(0:nsdel-1)/fs; % Transmission 1
t2 = to2+(0:nsdel-1)/fs; % Transmission 2
t3 = to3+(0:nsdel-1)/fs; % Transmission 3
```

Generate random binary data corresponding to the previously defined time intervals.

```
d0 = randi([0 1],ns,1);
d1 = randi([0 1],nsdel,1);
d2 = randi([0 1],nsdel,1);
d3 = randi([0 1],nsdel,1);
```

Create a frequency-flat multipath Rayleigh fading System object, specifying the sum-of-sinusoids fading technique. So that results can be repeated, specify a seed value. Use the default `InitialTime` property setting so that the fading channel will be simulated from time 0. Enable the path gains output.

```
rayleighchan1 = comm.RayleighChannel('SampleRate',fs, ...
    'MaximumDopplerShift',5, ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',17, ...
    'FadingTechnique','Sum of sinusoids', ...
    'PathGainsOutputPort',true);
```

Create a clone of the multipath Rayleigh fading channel System object. Set the source for initial time so that the fading channel offset time can be specified as an input argument when using the System object.

```
rayleighchan2 = clone(rayleighchan1);
rayleighchan2.InitialTimeSource = 'Input port';
```

Pass random binary data through the first multipath Rayleigh fading channel System object, `rayleighchan1`. Data is transmitted over all 1000 time samples. For this example, only the complex path gain is needed.

```
[~,pg0] = rayleighchan1(d0);
```

Pass random data through the second multipath Rayleigh fading channel System object, `rayleighchan2`, where the initial time offsets are provided as input arguments.

```
[~,pg1] = rayleighchan2(d1,to1);
[~,pg2] = rayleighchan2(d2,to2);
[~,pg3] = rayleighchan2(d3,to3);
```

Compare the number of samples processed by the two channels by using the `info` object function. The `rayleighchan1` object processed 1000 samples, while the `rayleighchan2` object only processed 300 samples.

```
G = info(rayleighchan1);
H = info(rayleighchan2);
[G.NumSamplesProcessed H.NumSamplesProcessed]
```

```
ans = 1×2
```

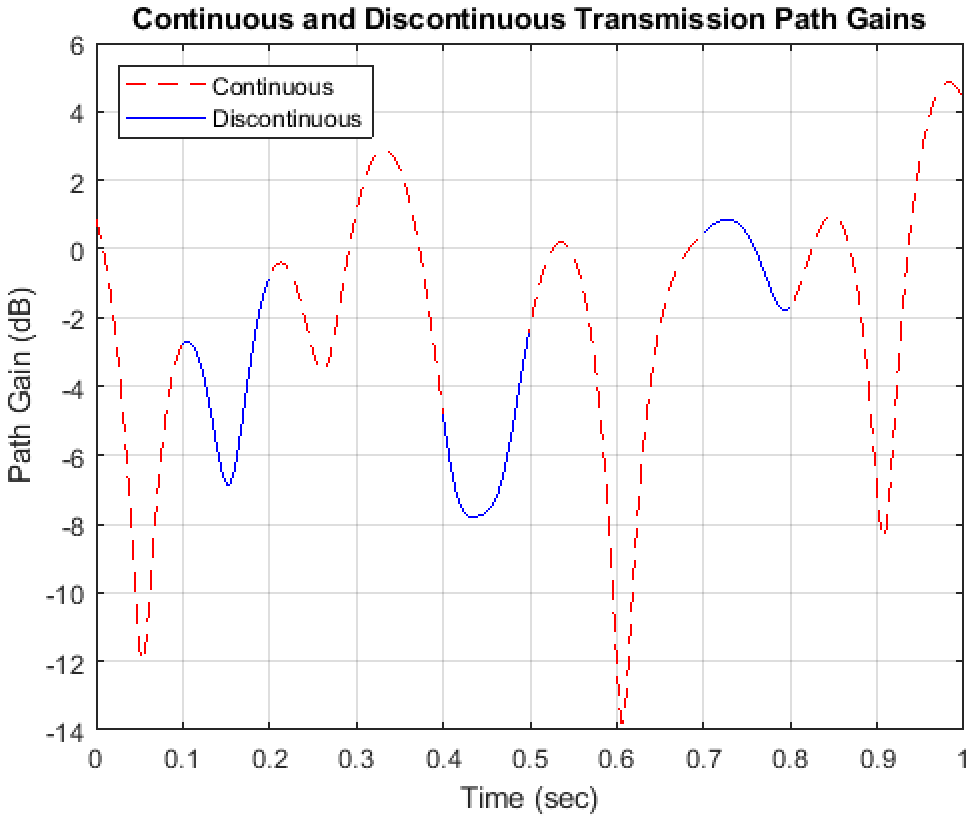
```
        1000         300
```

Convert the path gains into decibels.

```
pathGain0 = 20*log10(abs(pg0));
pathGain1 = 20*log10(abs(pg1));
pathGain2 = 20*log10(abs(pg2));
pathGain3 = 20*log10(abs(pg3));
```

Plot the path gains for the continuous and discontinuous cases. The gains for the three segments match the gain for the continuous case. The alignment of the two highlights that the sum-of-sinusoids technique is suited to the simulation of packetized data, as the channel characteristics are maintained even when data is not transmitted.

```
plot(t0,pathGain0,'r--')
hold on
plot(t1,pathGain1,'b')
plot(t2,pathGain2,'b')
plot(t3,pathGain3,'b')
grid
xlabel('Time (sec)')
ylabel('Path Gain (dB)')
legend('Continuous','Discontinuous','location','nw')
title('Continuous and Discontinuous Transmission Path Gains')
```



Use Info Method to Reproduce Multipath Rayleigh Fading Channel Response

The example show how to use the `ChannelFilterCoefficients` property returned by the `info` object function of the `comm.RayleighChannel` System object to reproduce the multipath Rayleigh fading channel output.

Create a multipath Rayleigh fading channel System object, defining two paths and specifying data to pass through the channel.

```
rayleighchan = comm.RayleighChannel('SampleRate',1000,'PathDelays',[0 1.5e-3], ...
    'AveragePathGains',[0 -3],'PathGainsOutputPort',true)
```

```
rayleighchan = 
  comm.RayleighChannel with properties:

             SampleRate: 1000
             PathDelays: [0 0.0015]
       AveragePathGains: [0 -3]
     NormalizePathGains: true
    MaximumDopplerShift: 1.0000e-03
        DopplerSpectrum: [1x1 struct]

  Show all properties
```

```
data = randi([0 1],600,1);
```

Pass data through the channel. Assign the `ChannelFilterCoefficients` property value to the variable `coeff`.

```
[chanout1,pg] = rayleighchan(data);
chaninfo = info(rayleighchan)
```

```
chaninfo = struct with fields:
           ChannelFilterDelay: 6
    ChannelFilterCoefficients: [2x16 double]
          NumSamplesProcessed: 600
```

```
coeff = chaninfo.ChannelFilterCoefficients;
```

Calculate the fractional delayed input signal at the path delay locations stored in `coeff`.

```
Np = length(rayleighchan.PathDelays);
fracdelaydata = zeros(size(data,1),Np);
for ii = 1:Np
    fracdelaydata(:,ii) = filter(coeff(ii,:),1,data);
end
```

Apply the path gains and sum the results for all paths.

```
chanout2 = sum(pg .* fracdelaydata,2);
```

Compare the output of the multipath Rayleigh fading channel System object to the output reproduced using the path gains and the `ChannelFilterCoefficients` property of the multipath Rayleigh fading channel System object.

```
isequal(chanout1,chanout2)
```

```
ans = logical
   1
```

Verify Autocorrelation of Rayleigh Channel Path Gains

Verify that the autocorrelation of the path gain output from the Rayleigh channel System object is a Bessel function. Based on the results in [1] and Appendix A of [2], we know that when the autocorrelation of the path gain outputs is a Bessel function, and the Doppler spectrum is Jakes-shaped.

Initialize simulation parameters.

```
Rsym = 9600; % Input signal symbol rate (symbols/sec)
sps = 10; % Number of samples per input symbol
Fs = sps*Rsym; % Input signal sampling frequency (samples/sec)
Ts = 1/Fs; % Input signal sampling period (sec)
numsym = 1e6; % Total number of input symbols to simulate
numsamp = numsym*sps; % Total number of channel samples to simulate
fd = 100; % Maximum Doppler frequency shift (Hz)
num_acsamp = 5000; % Number of samples of autocovariance of complex fading process calculated
numtx = 1; % Number of transmit antennas
numrx = 1; % Number of receive antennas
numsin = 48; % Number of sinusoids
frameLen = 10000;
numFrames = numsamp/frameLen;
```

Configure a Rayleigh channel System object.

```
chan = comm.RayleighChannel('FadingTechnique','Sum of sinusoids', ...
    'NumSinusoids',numsin,'RandomStream','mt19937ar with seed', ...
    'PathDelays',0,'AveragePathGains',0,'SampleRate',Fs, ...
    'MaximumDopplerShift',fd,'PathGainsOutputPort',true);
```

Apply DPSK modulation to a random bit stream.

```
tx = randi([0 1],numsamp,numtx); % Random bit stream
dpskSig = dpskmod(tx,2); % DPSK signal
```

Pass modulated signal through the channel.

```
outsig = zeros(numsamp,numrx);
pg_rx = zeros(numsamp,numrx,numtx);
for frmNum = 1:numFrames
    [outsig((1:frameLen)+(frmNum-1)*frameLen,:),pathGains] = chan(dpskSig((1:frameLen)+(frmNum-1
    for i = 1:numrx
        pg_rx((1:frameLen)+(frmNum-1)*frameLen,i,:) = pathGains(:,:,:,i);
    end
end
```

Using the channel path gains received per antenna, compute the autocovariance of the fading process for each transmit-receive path.

```
autocov = zeros(frameLen+1,numrx,numtx);
autocov_normalized_real = zeros(num_acsamp+1,numrx,numtx);
```

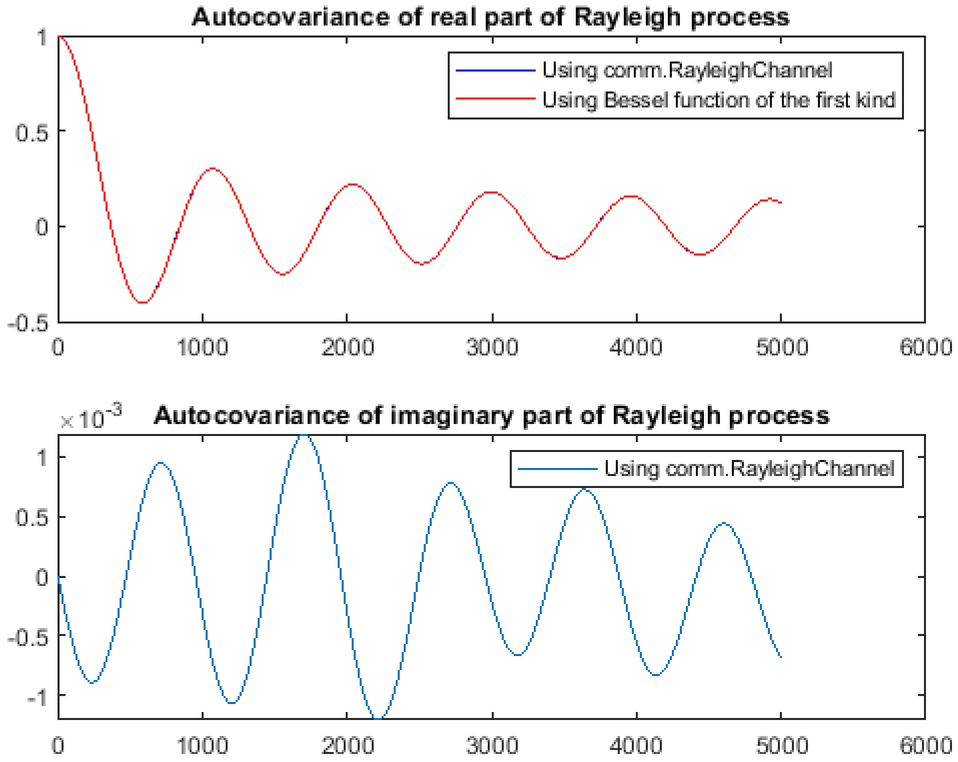
```
autocov_normalized_imag = zeros(num_acsamp+1,numrx,numtx);
for i = 1:numrx
    % Compute autocovariance of simulated complex fading process
    for j = 1:numtx
        autocov(:,i,j) = xcov(pg_rx(:,i,j),num_acsamp);
        % Real part of normalized autocovariance
        autocov_normalized_real(:,i,j) = real(autocov(num_acsamp+1:end,i,j)/autocov(num_acsamp+1
        % Imaginary part of normalized autocovariance
        autocov_normalized_imag(:,i,j) = imag(autocov(num_acsamp+1:end,i,j)/autocov(num_acsamp+1
    end
end
```

Using the `besselj` function compute the theoretical autocovariance of complex fading process.

```
Rrr = zeros(1,num_acsamp+1);
for n = 1:1:num_acsamp+1
    Rrr(n) = besselj(0,2*pi*fd*(n-1)*Ts);
end
Rrr_normalized = Rrr/Rrr(1);
```

Display the autocovariance comparing the results from the Rayleigh channel System object and the besselj function.

```
subplot(2,1,1)
plot(autocov_normalized_real,'b-')
hold on
plot(Rrr_normalized,'r-')
hold off
legend('Using comm.RayleighChannel','Using Bessel function of the first kind')
title('Autocovariance of real part of Rayleigh process')
subplot(2,1,2)
plot(autocov_normalized_imag)
legend('Using comm.RayleighChannel')
title('Autocovariance of imaginary part of Rayleigh process')
```



Compute mean square error.

```
act_mse_real = sum((autocov_normalized_real-repmat(Rrr_normalized.',1,numrx,numtx)).^2,1)/size(au
```

```
act_mse_real = 7.0043e-08
```

```
act_mse_imag = sum((autocov_normalized_imag-0).^2,1)/size(autocov_normalized_imag,1)
```

```
act_mse_imag = 4.1064e-07
```

More About

Cutoff Frequency Factor

The cutoff frequency factor, f_c, is determined for different Doppler spectrum types.

- For any Doppler spectrum type other than Gaussian and biGaussian, f_c equals 1.
- For a `doppler('Gaussian')` spectrum type, f_c equals `NormalizedStandardDeviation` × $\sqrt{2\log 2}$.

- For a `doppler('BiGaussian')` spectrum type:
  - If the `PowerGains(1)` and `NormalizedCenterFrequencies(2)` field values are both `0`, then f_c equals `NormalizedStandardDeviation(1) ×` $\sqrt{2\log 2}$.
  - If the `PowerGains(2)` and `NormalizedCenterFrequencies(1)` field values are both `0`, then f_c equals `NormalizedStandardDeviation(2) ×` $\sqrt{2\log 2}$.
  - If the `NormalizedCenterFrequencies` field value is `[0,0]` and the `NormalizedStandardDeviation` field has two identical elements, then f_c equals `NormalizedStandardDeviation(1) ×` $\sqrt{2\log 2}$.
  - In all other cases, f_c equals 1.

Channel Visualization

The `comm.RayleighChannel` System object enables visualization of the channel impulse response, frequency response, and Doppler spectrum.

Note

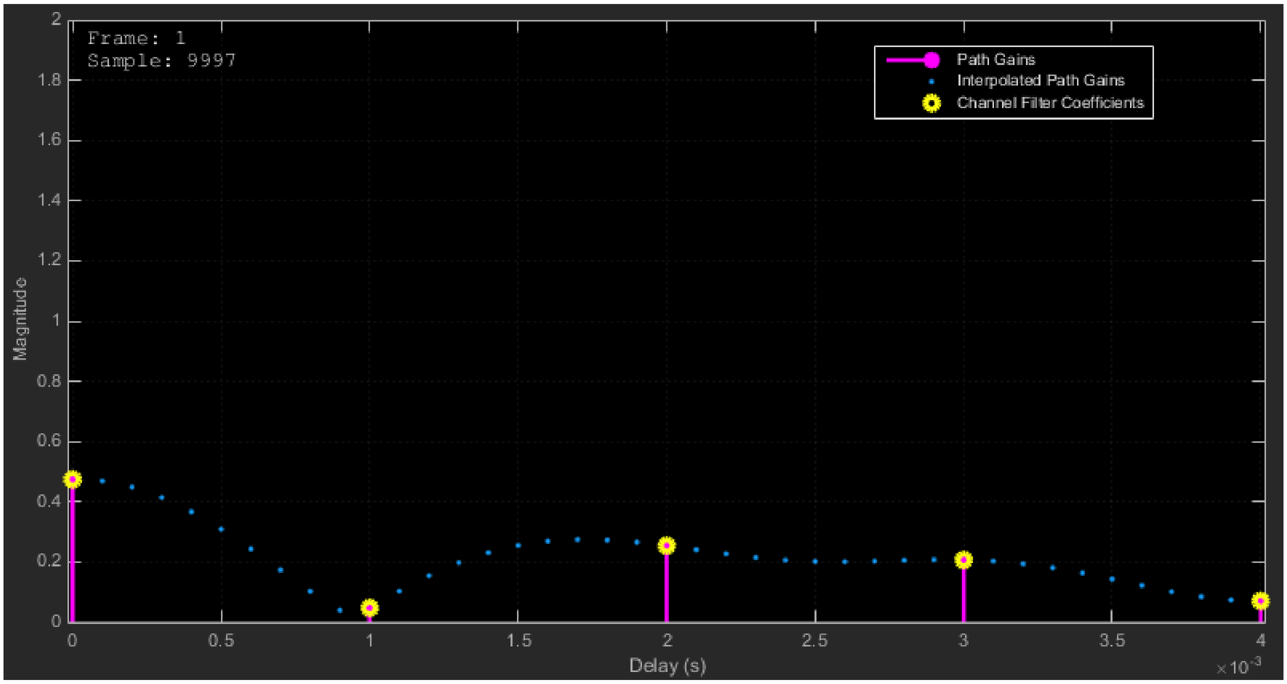
- The displayed and specified path gain locations can differ by as much as 5% of the input sample time.
- The visualization display speed is controlled by the combination of the `SamplesToDisplay` property and the **Playback > Reduce Updates to Improve Performance** scope menu item. Reducing the percentage of samples to display and enabling reduced updates can speed up the rendering of the visualization scope.
- After the visualization scopes are manually closed, calls to the System object are executed at its normal speed.
- Code generation is available only when the `Visualization` property is set to `'Off'`.

Impulse Response

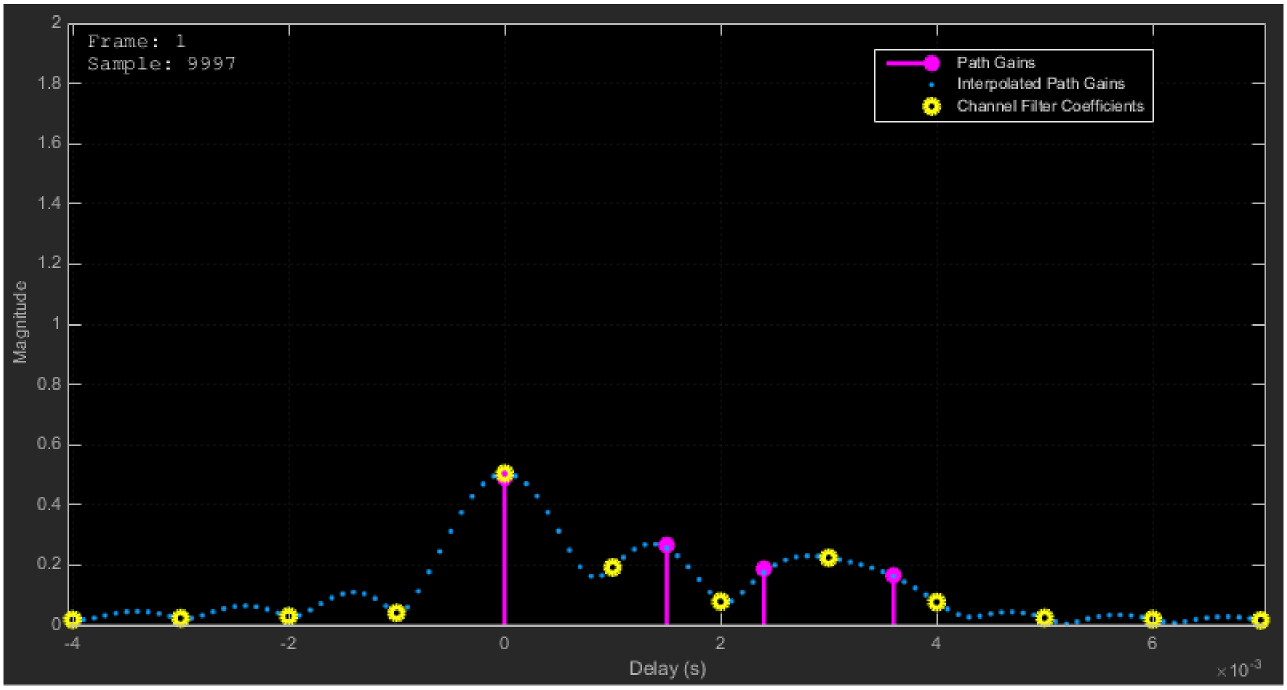
The impulse response scope displays the path gains, channel filter coefficients, and interpolated path gains. The path gains occur at time instances which correspond to the specified `PathDelays` property and might not be aligned with the input sampling time. The channel filter coefficients are used to model the channel. They are interpolated from the actual path gains and are aligned with the input sampling time. In cases in which the path gains are aligned with the sampling time, the path gains overlap the filter coefficients. Sinc interpolation is used to connect the channel filter coefficients and is shown as the interpolated path gains. These points are used solely for display purposes and not used in subsequent channel filtering. For a flat fading channel (one path), the sinc interpolation curve is not displayed. For all impulse response plots, the frame and sample numbers are shown in the upper-left corner of the scope.

The impulse response plot shares the same toolbar and menus as the `dsp.ArrayPlot` System object.

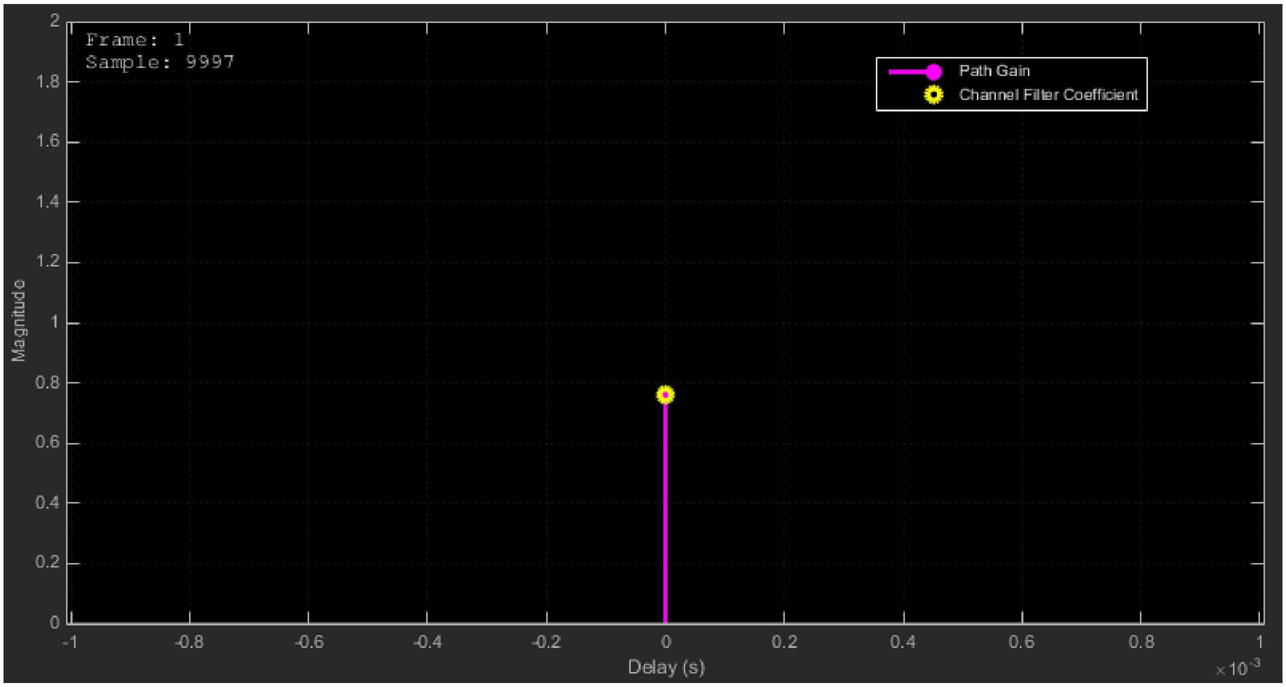
When the specified path gains align with the sample rate, the path gains and the channel filter coefficients overlap. In this figure the impulse response shows the path gains overlap the filter coefficients.



If the specified path gains are not aligned with the sample rate, the path gains and the channel filter coefficients do not overlap. In this figure, the filter coefficients are equally distributed. The path gains do not overlap with the channel filter coefficients because the path gains are not aligned with the sample rate.



This figure shows the impulse response for a frequency-flat channel. In this case, the interpolated path gains are not displayed.



Frequency response

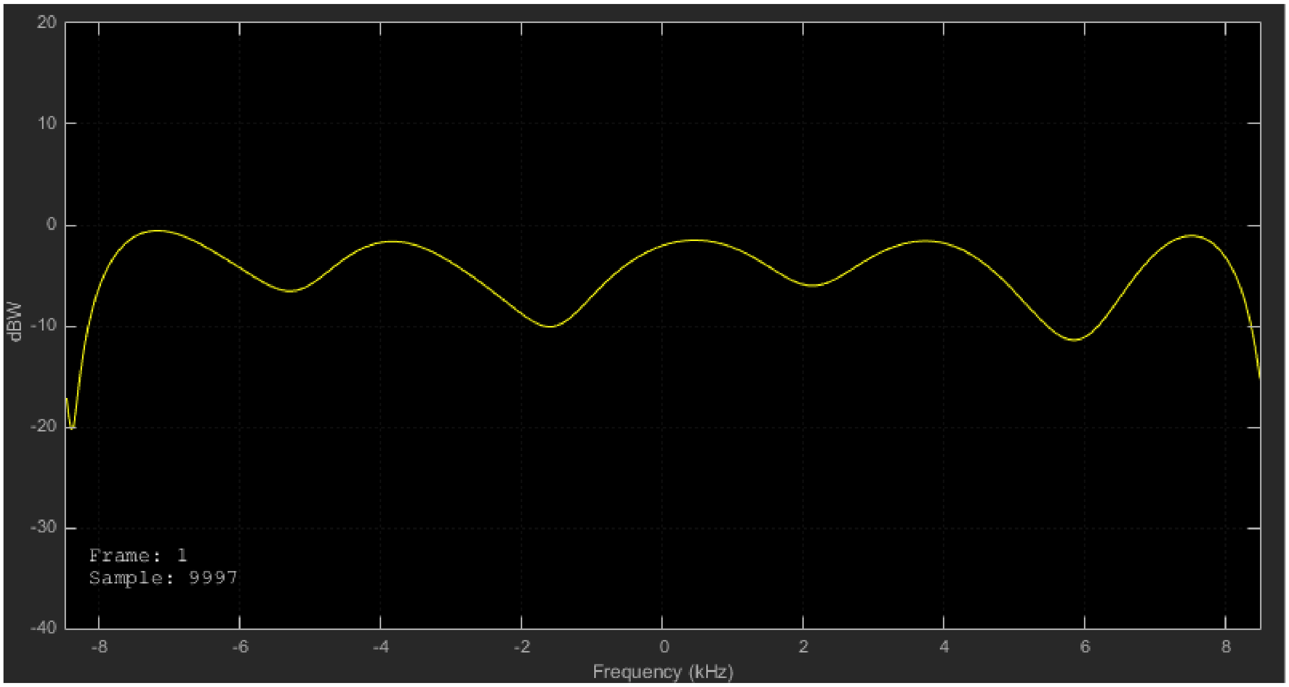
The frequency response scope displays the multipath Rayleigh fading channel spectrum by taking a discrete Fourier transform of the channel filter coefficients. The frequency response plot shares the same toolbar and menus as the `dsp.SpectrumAnalyzer` System object.

The y-axis limits of the plot are computed based on the `NormalizePathGains` and `AveragePathGains` properties of the `comm.RayleighChannel` System object.

This table shows other selected default spectrum settings. These settings can be changed from their default values by using the **View > Spectrum Settings** menu.

Spectrum Settings	Value
Main options>Type	`Power`
Main options>Window length	Channel filter length
Main options>NFFT	`512`
Window options>Window	`Rectangular`
Trace options>Units	`dBW`

This figure shows the frequency response plot for a frequency selective channel.



Doppler Spectrum

The Doppler spectrum plot displays the theoretical Doppler spectrum and the empirically determined data points. The theoretical data is displayed as a line for the case of nonstatic channels and as a point for static channels. The empirical data is shown as * symbols. Before the empirical plot is updated, the internal buffer must be completely filled with filtered Gaussian samples. The empirical plot is the running mean of the spectrum calculated from each full buffer. For nonstatic channels, the number of input samples needed before the next update is displayed in the upper-left corner of the plot. The number of samples needed is a function of the sample rate and the maximum Doppler shift. For static channels, the text "`Reset fading channel for next update`" is displayed.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- To generate C code, set the `DopplerSpectrum` property to a single Doppler spectrum structure.
- Code generation is available only when the `Visualization` property is `'Off'`.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

comm.RayTracingChannel

Package: comm

Filter signal through multipath fading channel defined by propagation rays

Description

The comm.RayTracingChannel System object filters a signal through a multipath fading channel that is defined by propagation rays.

To filter a signal through a fading channel defined by propagation rays:

1. Create the comm.RayTracingChannel object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
rtchan = comm.RayTracingChannel
rtchan = comm.RayTracingChannel(Name,Value)
rtchan = comm.RayTracingChannel(rays,tx,rx)
```

Description

rtchan = comm.RayTracingChannel creates a ray-tracing fading channel System object, which defines the multipath environment using a set of propagation rays.

rtchan = comm.RayTracingChannel(Name,Value) sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, 'SampleRate',1e6 sets the sample rate to 1 MHz.

rtchan = comm.RayTracingChannel(rays,tx,rx) creates a ray-tracing fading channel System object given inputs rays, tx, and rx.

- rays, specified as a set of comm.Ray objects, is used to set the PropagationRays property.
- tx, specified as a txsite object, is used to set the TransmitArray and TransmitArrayOrientationAxes properties.
- rx, specified as an rxsite, is used to set the ReceiveArray and ReceiveArrayOrientationAxes properties.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

SampleRate — Sample rate
10000000 (default) | positive scalar

Sample rate of the input signal in Hz, specified as a positive scalar.

Data Types: double

PropagationRays — Propagation rays
comm.Ray object (default) | row vector of comm.Ray objects | row cell array of comm.Ray objects

Propagation rays, specified as a comm.Ray object, a row vector of comm.Ray objects, or a row cell array of comm.Ray objects. This property specifies the propagation rays between the transmit and receive antenna arrays. All of the specified comm.Ray objects must have the same Frequency property setting. Any of the specified comm.Ray objects that have their PathSpecification property set to 'Locations', must have the same CoordinateSystem, TransmitterLocation, and ReceiverLocation property settings.

For code generation, the PropagationRays property must be a cell array of comm.Ray objects.

Data Types: comm.Ray object | cell

TransmitArray — Transmit antenna array
arrayConfig object (default) | phased.IsotropicAntennaElement | ...

Transmit antenna array, specified as one of these options.

- An arrayConfig object — You can adjust the Size property of the arrayConfig object to have it represent a uniform rectangular array (URA), uniform linear array (ULA), or single phased.IsotropicAntennaElement. The default configuration for an arrayConfig object is a 2-by-2 URA with an element spacing of 0.5 m.
- A phased array antenna System object — If you have the “Phased Array System Toolbox” software, you can specify phased array antenna System object configurations. For a list of these additional supported values, see “Phased Array Antenna Options” on page 3-1232.

TransmitArrayOrientationAxes — Orientation axes of transmit antenna array
eye(3) (default) | 3-by-3 unitary matrix

Orientation axes of the transmit antenna array, specified as a 3-by-3 unitary matrix indicating the rotation from the local coordinate system (LCS) to the global coordinate system (GCS). If the comm.Ray objects defined in the PropagationRays property set the CoordinateSystem property to 'Geographic', the GCS is the East-North-Up (ENU) coordinate system at the transmitter.

Data Types: double

ReceiveArray — Receive antenna array
arrayConfig object | phased.IsotropicAntennaElement | ...

Receive antenna array, specified as one of these options.

- An arrayConfig object — You can adjust the Size property of the arrayConfig object to have it represent a uniform rectangular array (URA), uniform linear array (ULA), or single phased.IsotropicAntennaElement. The default configuration for an arrayConfig object is a 2-by-2 URA with an element spacing of 0.5 m.

- A phased array antenna System object — If you have the “Phased Array System Toolbox” software, you can specify phased array antenna System object configurations. For a list of these additional supported values, see “Phased Array Antenna Options” on page 3-1232.

ReceiveArrayOrientationAxes — Orientation axes of receive antenna array

eye(3) (default) | 3-by-3 unitary matrix

Orientation axes of the receive antenna array, specified as a 3-by-3 unitary matrix indicating the rotation from the LCS to the GCS. If the comm.Ray objects defined in the PropagationRays property set the CoordinateSystem to 'Geographic', the GCS is the East-North-Up (ENU) coordinate system at the receiver.

Data Types: double

ReceiverVirtualVelocity — Receive antenna array instantaneous velocity

[1; 1; 0] (default) | three element column vector

Receive antenna array instantaneous velocity in the GCS in m/s, specified as a three element column vector of the form [*x*; *y*; *z*]. The elements of this vector specify *x*-, *y*-, and *z*-velocity, respectively. If the comm.Ray objects defined in the PropagationRays property set the CoordinateSystem to 'Geographic', the GCS is the East-North-Up (ENU) coordinate system at the receiver.

Data Types: double

NormalizeImpulseResponses — Option to normalize channel impulse responses

1 or true (default) | 0 or false

Option to normalize channel impulse responses (CIRs), specified as a logical 1 (true) or 0 (false). Set this property to 1 (true) to normalize the gains of CIRs to 0 dB from each transmit array element to each receive array element.

Data Types: logical

NormalizeChannelOutputs — Option to normalize channel outputs by number of receive elements

1 or true (default) | 0 or false

Option to normalize channel outputs by the number of receive elements, specified as a logical 1 (true) or 0 (false). Set this property to 1 (true) to normalize the channel output by the number of receive array elements.

Data Types: logical

Usage

Syntax

```
y = rtchan(x)
```

Description

`y = rtchan(x)` filters the input signal through a multipath fading channel defined by a set of propagation rays. When the channel filters the input signal, time zero is assigned to the ray with the minimum propagation delay. Arrival of other rays are delayed relative to time zero.

Input Arguments

x — Input signal
N_S-by-N_T matrix

Input signal, specified as an N_S-by-N_T matrix.

- N_S is the number of samples.
- N_T is the number of transmit array elements.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

y — Output signal
N_S-by-N_R matrix

Output signal, returned as an N_S-by-N_R matrix.

- N_S is the number of samples.
- N_R is the number of receive array elements.

`y` is the same data type as input `x`.

`cir` — Channel impulse response
N_S-by-N_P-by-N_T-by-N_R array

Channel impulse response (CIR), returned as an N_S-by-N_P-by-N_T-by-N_R array.

- N_S is the number of samples.
- N_P is the number of paths (specifically, the number of rays as indicated by the length of the `PropagationRays` property).
- N_T is the number of transmit array elements.
- N_R is the number of receive array elements.

`cir` is the same data type as input `x`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.RayTracingChannel`

info	Characteristic information about ray-tracing channel
showProfile	Plot temporal and spatial profiles of ray-tracing channel
clone	Create duplicate System object
isLocked	Determine if System object is in use

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

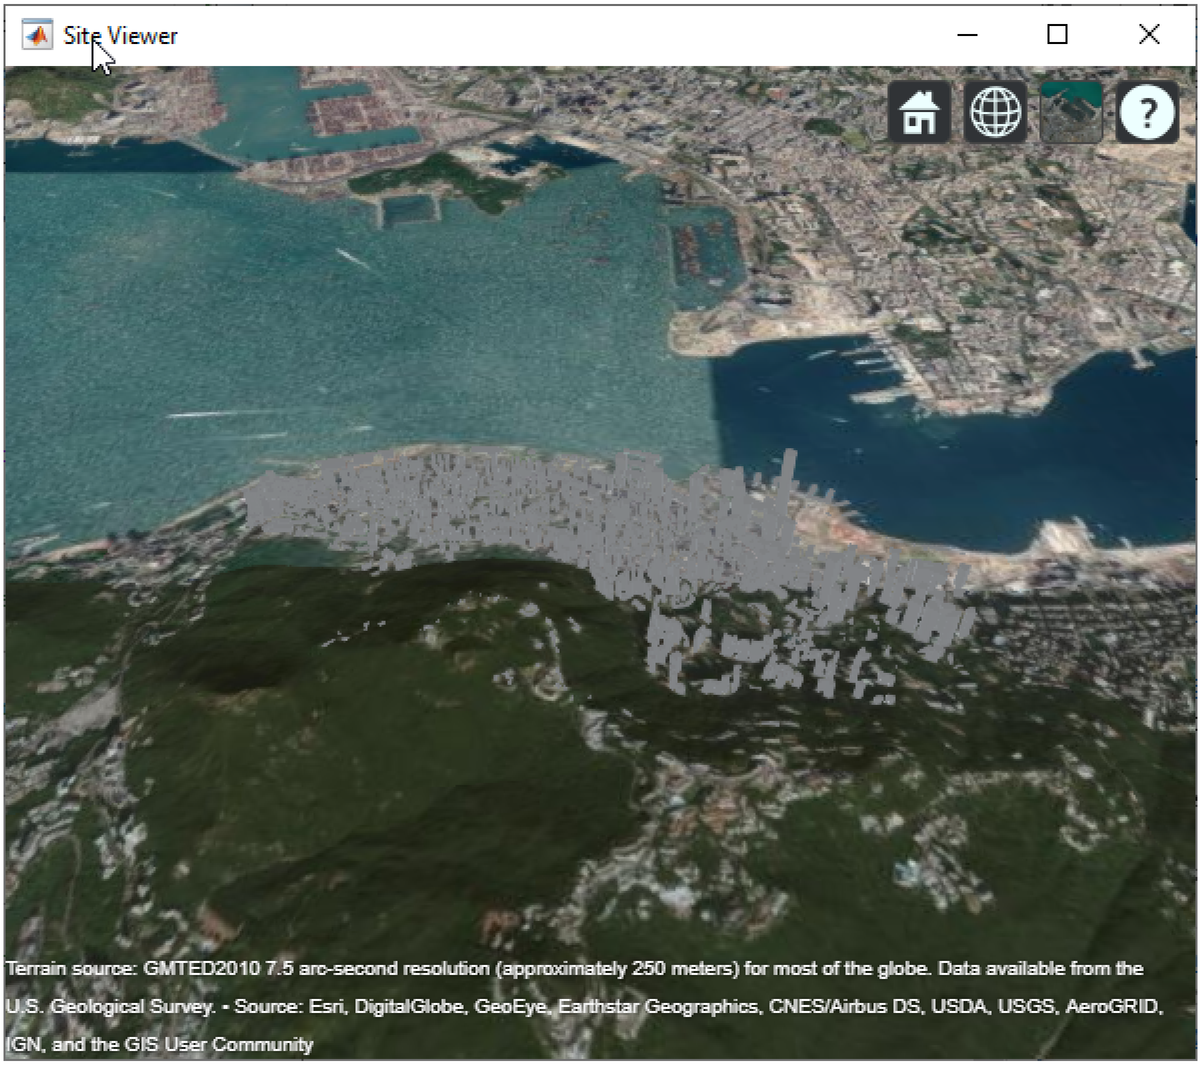
Examples

Apply Ray-Tracing Channel Between Two Sites in Hong Kong

Perform ray tracing between two sites in Hong Kong, China, build a multipath channel model using the ray-tracing result, and filter the signals through the channel.

Create a Site Viewer map display of buildings in Hong Kong. For more information about the osm file, see [1] on page 3-0   . Create transmitter and receiver sites.

```
sv = siteviewer("Buildings","hongkong.osm");
```



Site Viewer
Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

```
tx = txsite("Latitude",22.2789,"Longitude",114.1625, ...
    "AntennaAngle",30,"AntennaHeight",10,"TransmitterFrequency",28e9);
rx = rxsite("Latitude",22.2799,"Longitude",114.1617, ...
    "AntennaAngle",120,"AntennaHeight",1);
```

Perform ray tracing to find rays with up to 2 reflections.

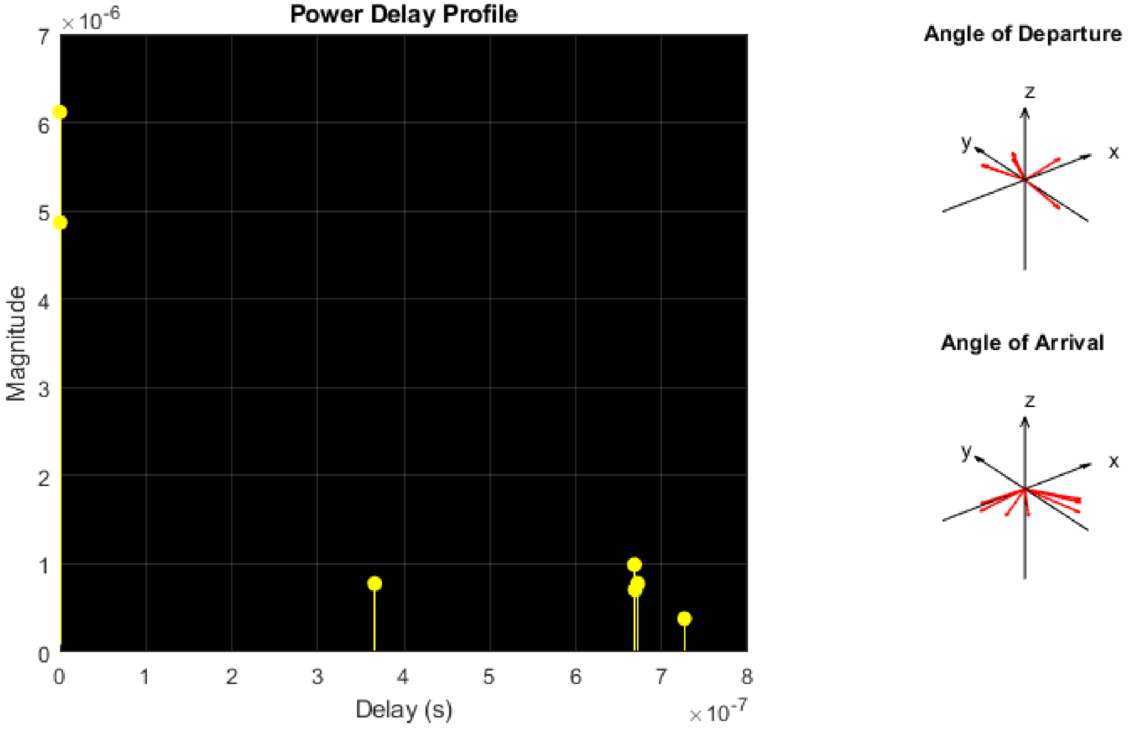
```
rays = raytrace(tx,rx,"NumReflections",[0 1 2]);
```

Create a channel model by using the transmitter site, receiver site, and calculated rays between the sites.

```
rtchan = comm.RayTracingChannel(rays{1},tx,rx);
```

Show temporal and spatial profiles of the ray-tracing channel.

```
showProfile(rtchan);
```

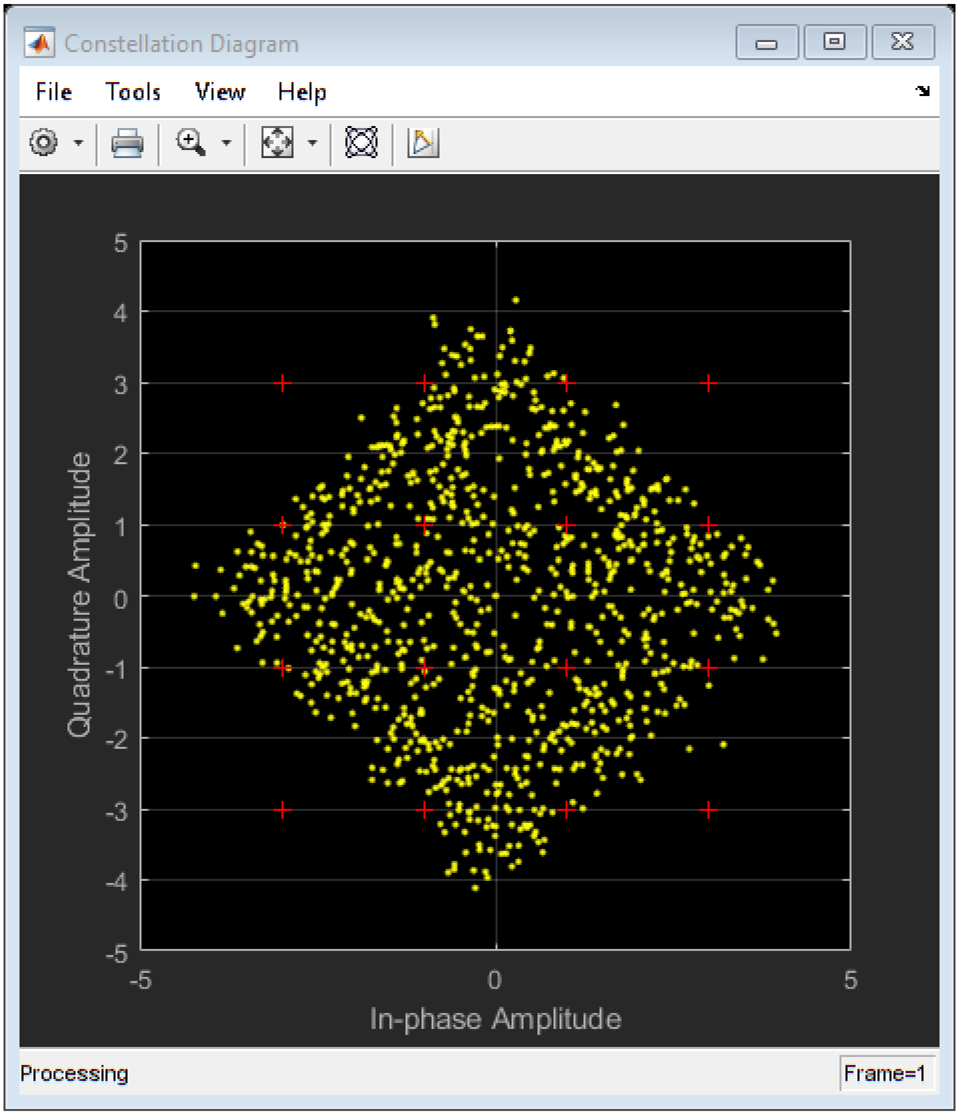


Filter a randomly generated 16-QAM signal through the channel.

```
modOrd = 16; % Modulation order
frmLen = 1e3; % Frame length
numTx = rtchan.info.NumTransmitElements;
x = qammod(randi([0,modOrd-1],frmLen,numTx),modOrd);
y = rtchan(x);
```

Show the filtered signal in a constellation diagram.

```
constdiag = comm.ConstellationDiagram("XLimits",[-5 5], ...
    "YLimits",[-5 5],"ReferenceConstellation", ...
    qammod(0:modOrd-1,modOrd));
constdiag(y);
```



Appendix

More About

Phased Array Antenna Options

If you have “Phased Array System Toolbox”, you can specify any of these phased antenna System object configurations for the `TransmitArray` and `ReceiveArray` properties.

- `phased.IsotropicAntennaElement`
- `phased.CustomAntennaElement`

- phased.URA with the Element property set to a phased.IsotropicAntennaElement or phased.CustomAntennaElement System object
- phased.ULA with the Element property set to a phased.IsotropicAntennaElement or phased.CustomAntennaElement System object
- phased.ConformalArray with the Element property set to a phased.IsotropicAntennaElement or phased.CustomAntennaElement System object

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

- For code generation, the PropagationRays property must be a cell array of comm.Ray objects.

Introduced in R2020b

comm.RBDSWaveformGenerator

Package: comm

Generate RDS/RBDS waveform

Description

The comm.RBDSWaveformGenerator System object generates configurable standard-compliant baseband RDS/RBDS waveforms in MATLAB. RDS/RBDS waveforms supplement FM radio stations with additional textual information, such as song title, artist name, and station description. The RDS/RBDS signal lies in the 57-kHz band of the baseband FM radio signal.

Use this object to generate a waveform containing RadioText Plus (RT+) information and register a custom encoding implementation for an Open Data Application (ODA). You can also specify the time, data, and the program type. The object supports short, scrolling 8-character text, and longer 32-character or 64-character text.

To generate baseband RDS/RBDS waveforms:

1. Create a comm.RBDSWaveformGenerator object and set the properties of the object.
2. Call step to generate the waveform.

Note Alternatively, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

rbdsgen = comm.RBDSWaveformGenerator creates an RDS/RBDS waveform generator object, rbdsgen, using the default properties.

rbdsgen = comm.RBDSWaveformGenerator(Name,Value) specifies additional properties using Name,Value pairs. Unspecified properties have default values.

Example:

```
rbdsgen = comm.RBDSWaveformGenerator( ...
     'GroupsPerFrame',20,'SamplesPerSymbol',10, ...
     'SendRadioTextPlus',true);
```

Properties

If a property is listed as tunable, then you can change its value even when the object is locked.

SamplesPerSymbol — Number of samples per symbol

10 (default) | positive even integer

Number of samples per symbol (bit), specified as a positive even integer. Half of the samples represent one amplitude level of Manchester coding. The other half of the samples represent the opposite level.

GroupsPerFrame — Number of groups per output frame
10 (default) | scalar integer

Number of groups per output frame, specified as a scalar integer. Each group is 104 symbols (bits) long.

RadioText — Long text conveyed with type 2A groups
'Long text' (default) | character vector

Radio text conveyed with type 2A groups, specified as a character vector that is up to 64 characters long. The object transmits the specified text four characters at a time, using type 2A groups.

Tunable: Yes

ProgramServiceName — Label of the program service
'ShortTxt' (default) | character vector

Label of the program service, specified as a character vector that is up to eight characters long. This information is conveyed as a short text with type 0A groups, two characters at a time.

Tunable: Yes

ProgramIdentificationCode — Program identification code
[0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0] (default) | 16-bit row vector

Program identification (PI) code, specified as a 16-bit row vector. In North America, the PI code conveys the call letters of the station. Example call letters include 'WABC' and 'KXYZ'.

To generate North American PI codes for a station's call letters, use the callLettersToPICode method.

ProgramType — Program type
'No program type or undefined' (default) | character vector

Program type, specified as a character vector containing one of the 31 values allowed by the RDS/RBDS standard. For a list of program types that the RDS/RBDS standard allows in North America, see [1].

Tunable: Yes

ProgramTypeName — Program type name
'' (default) | character vector

Program type name, specified as a character vector that is up to eight characters long. This text further characterizes the program type, such as 'Football' for the program type 'Sports'. The object conveys the program type name using type 10A groups. If this property is empty, then no 10A groups are generated.

Tunable: Yes

SendDateTime — Option to advertise date and time
false (default) | true

Option to advertise the date and time, specified as either `false` or `true`. When you set this property to `true`, one 4A group is periodically generated every 685 groups (once a minute).

`AlternativeFrequencies` — Alternative frequencies
`[]` (default) | row vector

Alternative frequencies, specified as a row vector in MHz. This information is conveyed with type 0A groups. It indicates other transmitters broadcasting the same program in the same or adjacent reception areas. With this information, receivers can switch to a different frequency with better reception.

`SendRadioTextPlus` — Option to send RT+ information
`false` (default) | `true`

Option to transmit RadioText Plus (RT+) information, specified as a scalar logical. When you set this property to `true`, the RT+ ODA information is advertised with type 3A groups. In addition, the RT+ content types, specified in `RadioTextType1`, `RadioTextType2`, and the two RT+ substrings indexed by `RadioTextIndices` are conveyed with the open-format type 11A group.

`RadioTextType1` — Content type of first RT+ substring
`'Item.Artist'` (default) | character vector

Content type of the first RT+ substring, specified as a character vector. Allowed values are the class names specified in the RT+ standard. For more details, see [2].

Tunable: Yes

`RadioTextType2` — Content type of second RT+ substring
`'Item.Title'` (default) | character vector

Content type of the second RT+ substring, specified as a character vector. Allowed values are the class names specified in the RT+ standard. For more details, see [2].

Tunable: Yes

`RadioTextIndices` — Start and end indices of RT+ substrings
`[1 2; 3 4]` (default) | 2-by-2 matrix of positive integers

Start and end indices of RT+ substrings, specified as a 2-by-2 matrix of positive integers. The first column indexes the beginning of each RT+ substring. The second column indexes the end of each substring.

Tunable: Yes

Methods

callLettersToPICode	Convert North-American call letters to binary PI code
registerODA	Register a custom encoding implementation for an ODA
reset	Reset states of RBDS waveform generator object
step	Generate RDS/RBDS waveform

Examples

Generate a Basic RBDS Waveform

Generate a basic RBDS waveform, FM modulate the waveform with an audio signal, and then demodulate the waveform.

Each frame of the RBDS waveform contains 19 groups, with a group length of 104 bits (symbols) each. Set the number of samples per RBDS symbol to 10. Therefore, the number of samples in each frame of RBDS waveform is 104 x 10 x 19 = 19,760. According to the RBDS standard, the bit rate is 1187.5 Hz. So, the RBDS sample rate = 1187.5 x samples per RBDS symbol. Set the audio frame rate to 40 x 1187.5 = 47,500.

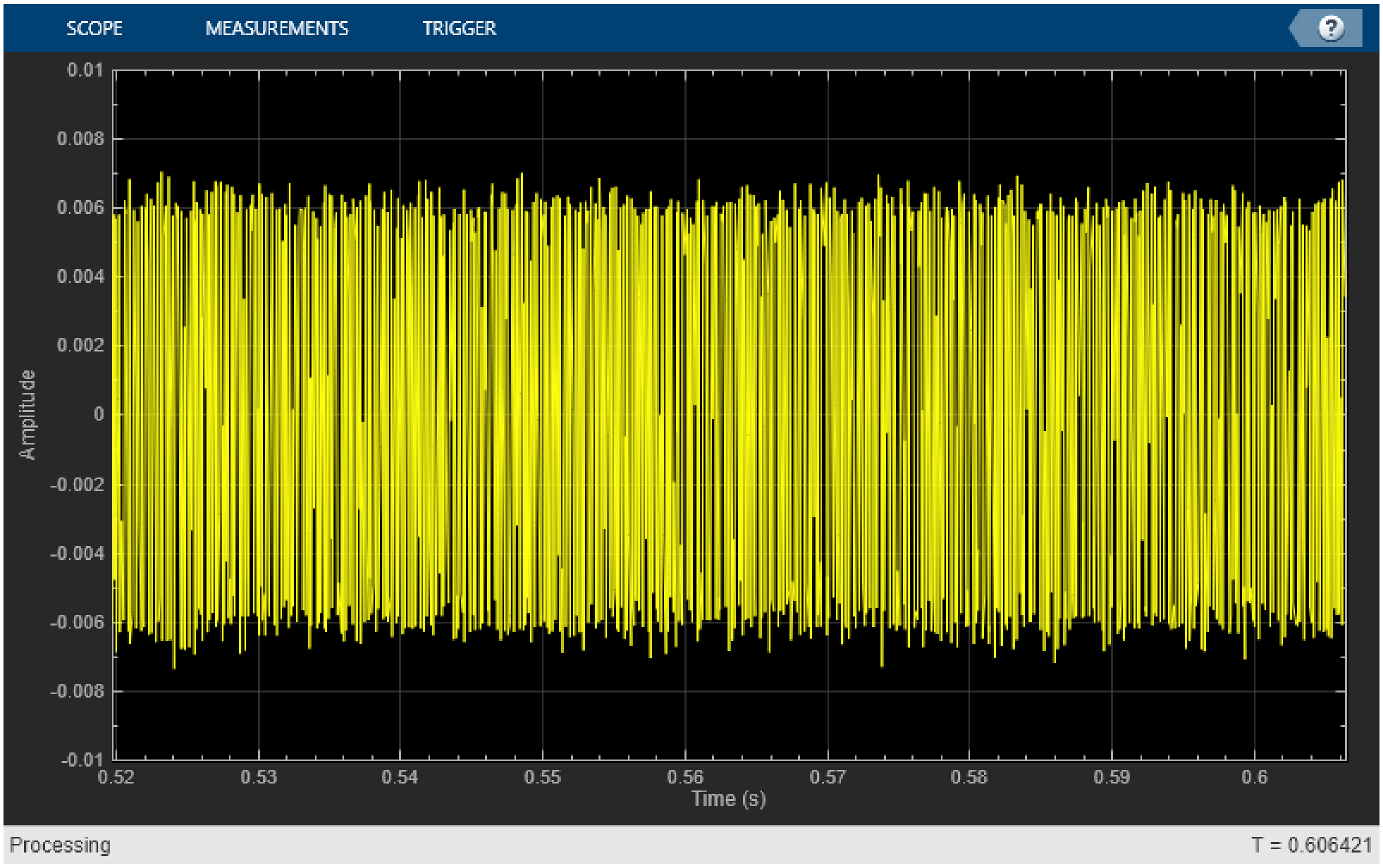
```
groupLen = 104;
sps = 10;
groupsPerFrame = 19;
rbdsFrameLen = groupLen*sps*groupsPerFrame;
afrRate = 40*1187.5;
rbdsRate = 1187.5*sps;
outRate = 4*57000;

afr = dsp.AudioFileReader('rbds_capture_47500.wav','SamplesPerFrame',rbdsFrameLen*afrRate/rbdsRat
rbds = comm.RBDSWaveformGenerator('GroupsPerFrame',groupsPerFrame,'SamplesPerSymbol',sps);

fmMod = comm.FMBroadcastModulator('AudioSampleRate',afr.SampleRate,'SampleRate',outRate,...
    'Stereo',true,'RBDS',true,'RBDSSamplesPerSymbol',sps);
fmDemod = comm.FMBroadcastDemodulator('SampleRate',outRate,...
    'Stereo',true,'RBDS',true,'PlaySound',true);
scope = timescope('SampleRate',outRate,'YLimits',10^-2*[-1 1]);
```

Get the audio input and generate the RBDS waveform. FM modulate the stereo audio with the RBDS waveform, add noise, and FM demodulate the audio and RBDS waveforms. View the demodulated RBDS waveform in the time scope.

```
for idx = 1:7
    input = afr();                        % get current audio input
    rbdsWave = rbds();                    % generate RBDS info at the same configured rate
    yFM = fmMod([input input], rbdsWave); % FM modulate stereo audio with RBDS info
    rcv = awgn(yFM, 40);                  % add noise
    [audioRcv, rbdsRcv] = fmDemod(rcv);   % FM demodulate the audio and RBDS waveforms
    scope(rbdsRcv);
end
```



Generate RBDS Waveform with RadioText Plus Information

Create a `comm.RBDSWaveformGenerator` System object™ with 20 groups per frame and 10 samples per symbol. Add the Radio Text plus (RT+) information, such as artist name and song, title, to the waveform. Indicate the start and end of the RT+ substrings by using the `RadioTextIndices` property.

```
rbds = comm.RBDSWaveformGenerator('GroupsPerFrame',20,'SamplesPerSymbol',10,...
    'SendRadioTextPlus', true);
rbds.RadioText = 'MyArtist - MySongTitle';
rbds.RadioTextType1 = 'Item.Artist';
rbds.RadioTextType2 = 'Item.Title';
rbds.RadioTextIndices = [1 8; 12 22];
for idx = 1:10
    rbds.step();
end
```

Register a Custom Encoding Implementation

Register a custom encoding implementation for an Open Data Application (ODA) by using the `registerODA` method of the `comm.RBDSWaveformGenerator` System object™. Set the ODA ID to `'CD46'`, which is the ID for the traffic message channel. The allocated group type is 8A.

```
rbds = comm.RBDSWaveformGenerator();
odaID = 'CD46';
allocatedGroupType = '8A';
```

This example uses the following templates as a starting point for custom encoding implementation.

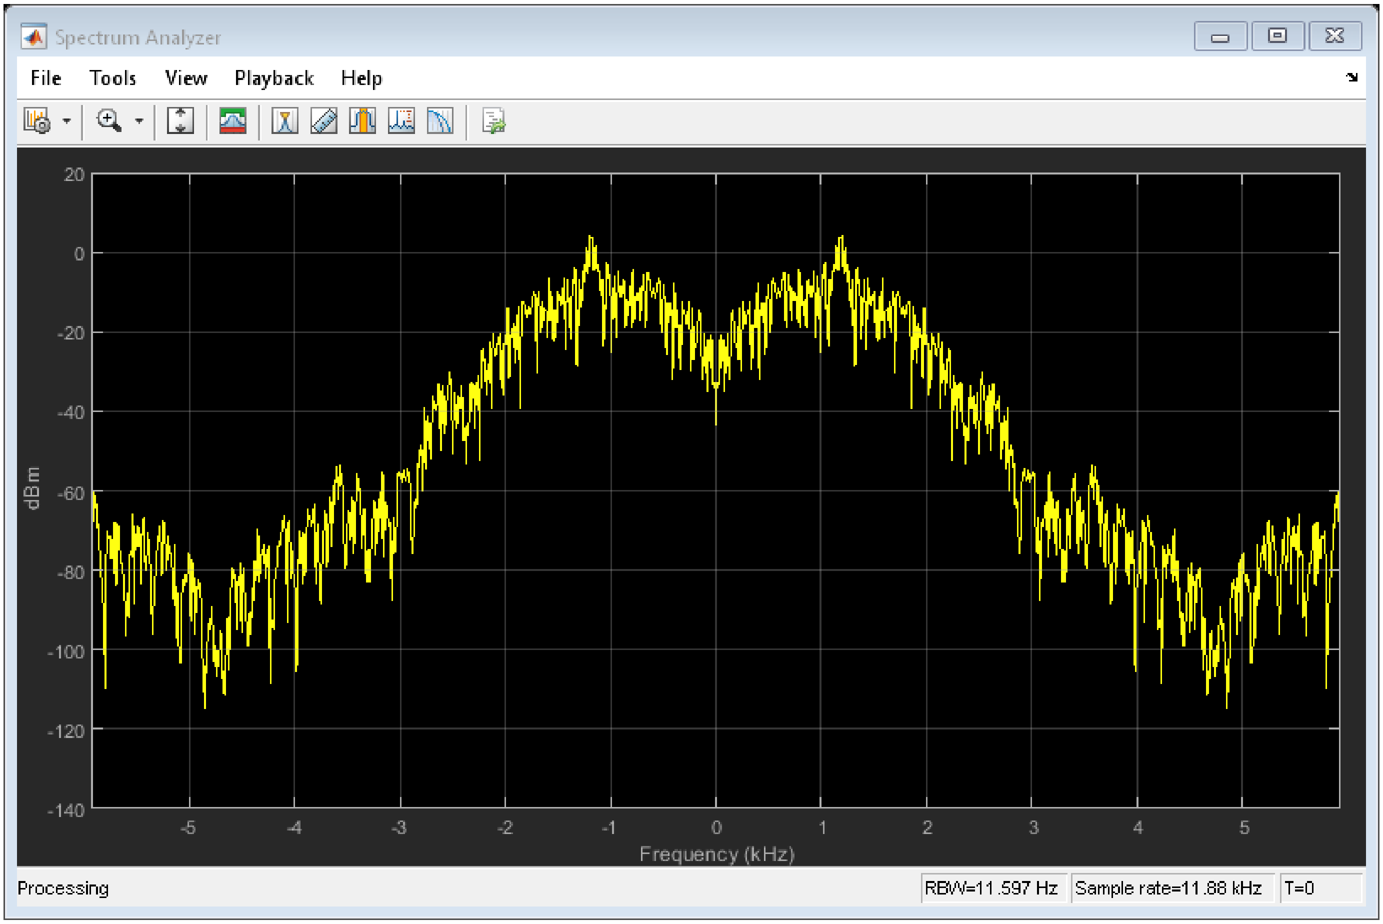
```
mainProcessingFcn = @CustomODAEncodingMain;
fcn3A             = @CustomODAEncoding3A;
registerODA(rbds,odaID,allocatedGroupType,mainProcessingFcn,fcn3A);
s = info(rbds);
s.ODAMap
```

```
ans=2×1 struct array with fields:
    ID
    GroupType
    FunctionMain
    Function3A
```

Configure RBDS Waveforms with Date and Time Information

Generate RBDS waveform with date and time information, the program type, and alternative frequencies. The `comm.RBDSWaveformGenerator` object uses type 4A groups for date and time information, type 10A groups for the program type information, and type 0A groups for alternative frequencies. View the waveform in a spectrum analyzer.

```
rbds = comm.RBDSWaveformGenerator('GroupsPerFrame',1000);
scope = dsp.SpectrumAnalyzer('SampleRate',1187.5*rbds.SamplesPerSymbol,'YLimits',[-140 20]);
rbds.SendDateTime = true;          % send type 4A groups
rbds.ProgramType = 'Sports';
rbds.ProgramTypeName = 'Football'; % send type 10A groups
rbds.AlternativeFrequencies = [99.1 102.5]; % info sent in type 0A groups
wave = rbds.step();
scope(wave)
```



Algorithms

`comm.RBDSWaveformGenerator` generates waveforms according to the RDS/RBDS standard [1]. The RDS/RBDS standard consists of three layers: physical layer, data-link layer, and session and application layer.

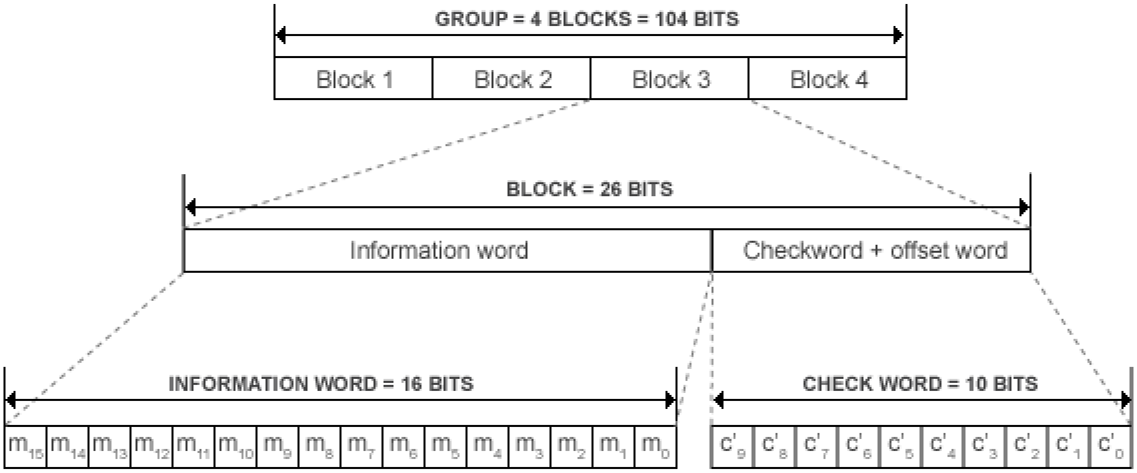
Physical Layer

The physical layer (first layer) converts the data-link bits to an analog waveform by conducting differential encoding and biphase symbol encoding (Manchester encoding) and pulse-shaping filtering.

Data-Link Layer

The data-link layer (second layer) performs (26,16) cyclic encoding shortened from (341,331) encoding [1]. The second layer is responsible for error detection, error correction, and the establishment of group-level synchronization. Each group of RDS/RBDS frames contains four blocks of 26 bits (that is 104 bits) each. Each block contains an information word and a check word. Each information word contains 16 bits, and each check word contains 10 bits.

Here is the baseband coding structure for the RDS/RBDS waveform. For more details, see [1].



GROUP = 4 BLOCKS = 104 BITS
Block 1
Block 2
Block 3
Block 4
BLOCK = 26 BITS
Information word
Checkword + offset word
INFORMATION WORD = 16 BITS
m15 m14 m13 m12 m11 m10 m9 m8 m7 m6 m5 m4 m3 m2 m1 m0
CHECK WORD = 10 BITS
c'9 c'8 c'7 c'6 c'5 c'4 c'3 c'2 c'1 c'0

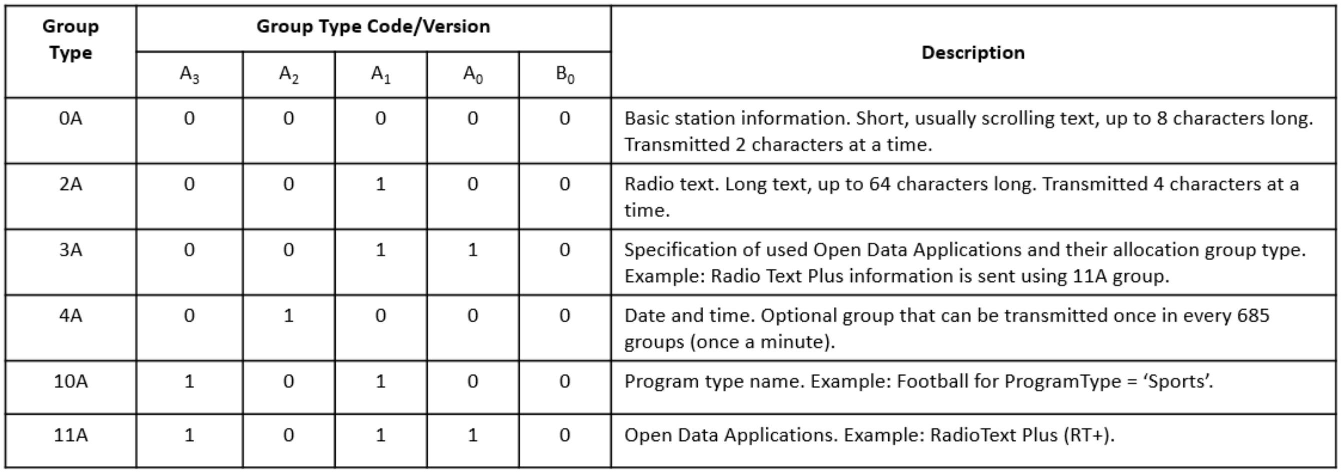
For each block, a unique offset word is modulo-2 added to the checkword bits. The added offset word provides a group and block synchronization system in the receiver (decoder). Because the addition of the offset is reversible in the decoder, the normal additive error-correcting and detecting properties of the basic code are unaffected.

Session and Application Layer

The first block in every group contains a program identification (PI) code. The first four bits of the second block of every group are allocated to a four-bit code. This code specifies the application of the group. Groups are referred to as types 0–15 according to the binary weighting A_3 = 8, A_2 = 4, A_1 = 2, A_0 = 1. The fifth bit of the second block, B_0, defines the version of the application. If B_0 = 0, the version of the group is A. The PI code in this version is inserted into block 1 only. Example group types include 0A, 1A, 2A, 3A, and 4A.

The Program Type code and Traffic Program Identification (PI) occupy fixed locations in block 2 of every group.

Group Types



Group Type	Group Type Code/Version					Description
	A_3	A_2	A_1	A_0	B_0	
0A	0	0	0	0	0	Basic station information. Short, usually scrolling text, up to 8 characters long. Transmitted 2 characters at a time.
2A	0	0	1	0	0	Radio text. Long text, up to 64 characters long. Transmitted 4 characters at a time.
3A	0	0	1	1	0	Specification of used Open Data Applications and their allocation group type. Example: Radio Text Plus information is sent using 11A group.
4A	0	1	0	0	0	Date and time. Optional group that can be transmitted once in every 685 groups (once a minute).
10A	1	0	1	0	0	Program type name. Example: Football for ProgramType = 'Sports'.
11A	1	0	1	1	0	Open Data Applications. Example: RadioText Plus (RT+).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See "System Objects in MATLAB Code Generation" (MATLAB Coder).

In addition, the following limitations apply when you generate code that contains this System object or when you use this object in a MATLAB function block.

- The group type 4A cannot be transmitted in the generated code.
- The `registerODA` method is not supported.
- The `ProgramType` property is not tunable.

See Also

Objects

`comm.FMBroadcastDemodulator` | `comm.FMBroadcastModulator`

Introduced in R2017a

callLettersToPICode

System object: `comm.RBDSWaveformGenerator`
Package: `comm`

Convert North-American call letters to binary PI code

Syntax

```
picode = callLettersToPICode(rbdsgen, callLetters)
```

Description

`picode = callLettersToPICode(rbdsgen, callLetters)` returns the 16-bit program identification (PI) code that corresponds to `callLetters`. Acceptable call letter formats are 3-character or 4-character vectors beginning with `'K'` or `'W'`.

Introduced in R2017a

registerODA

System object: `comm.RBDSWaveformGenerator`
Package: `comm`

Register a custom encoding implementation for an ODA

Syntax

```
registerODA(rbdsgen,odaID,group,handleMain,handle3A)
```

Description

`registerODA(rbdsgen,odaID,group,handleMain,handle3A)` associates the Open Data Application (ODA) specified by the hexadecimal ID `odaID`, with the type `group` groups generated by `rbdsgen`. The four 16-bit information words of these groups are generated by the function handle `handleMain`. The third information word of type 3A groups, which is ODA-specific, is generated by the function handle `handle3A`.

Introduced in R2017a

reset

System object: `comm.RBDSWaveformGenerator`
Package: `comm`

Reset states of RBDS waveform generator object

Syntax

```
reset(rbdsgen)
```

Description

`reset(rbdsgen)` resets the states of the `RBDSWaveformGenerator` object, `rbdsgen`.

Introduced in R2017a

step

System object: `comm.RBDSWaveformGenerator`
Package: `comm`

Generate RDS/RBDS waveform

Syntax

```
y = step(rbdsgen)
```

Description

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(rbdsgen)` outputs a frame of the baseband RDS/RBDS waveform in column vector `y`. The waveform contains the number of 104-bit groups, specified in the `GroupsPerFrame` property of the object. Each symbol is oversampled according to the `SamplesPerSymbol` property. Thus, the output length is `SamplesPerSymbol` × 104 × `GroupsPerFrame` samples. The object uses an internal scheduler to determine the order and frequency of the transmitted group types.

Note `rbdsgen` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Introduced in R2017a

comm.RectangularQAMDemodulator

Package: `comm`

(To be removed) Demodulate using rectangular QAM signal constellation

Note `comm.RectangularQAMDemodulator` will be removed in a future release. Use `qamdemod` instead. For more information, see “Compatibility Considerations”.

Description

The `RectangularQAMDemodulator` object demodulates a signal that was modulated using quadrature amplitude modulation with a constellation on a rectangular lattice.

To demodulate a signal that was modulated using quadrature amplitude modulation:

1. Define and set up your rectangular QAM demodulator object. See “Construction” on page 3-1247.
2. Call `step` to demodulate the signal according to the properties of `comm.RectangularQAMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.RectangularQAMDemodulator` creates a demodulator System object, `H`. This object demodulates the input signal using the rectangular quadrature amplitude modulation (QAM) method.

`H = comm.RectangularQAMDemodulator(Name,Value)` creates a rectangular QAM demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.RectangularQAMDemodulator(M,Name,Value)` creates a rectangular QAM demodulator object, `H`. This object has the `ModulationOrder` property set to `M`, and the other specified properties set to the specified values.

Properties

`ModulationOrder`

Number of points in signal constellation

Specify the number of points in the signal constellation as scalar value with a positive, integer power of two. The default is `16`.

`PhaseOffset`

Phase offset of constellation

Specify the phase offset of the signal constellation, in radians, as a real scalar value. The default is `0`.

`BitOutput`

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. When you set this property to true the step method outputs a column vector of bit values whose length equals **log2**(`ModulationOrder` on page 3-0) times the number of demodulated symbols. When you set this property to `false`, the `step` method outputs a column vector with a length equal to the input data vector. This vector contains integer symbol values between `0` and `ModulationOrder-1`. The default is `false`.

`SymbolMapping`

Constellation encoding

Specify how the object maps an integer or group of **log2**(`ModulationOrder` on page 3-0) bits to the corresponding symbol as one of `Binary` | `Gray` | `Custom`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-coded signal constellation. When you set this property to `Binary`, the object uses a natural binary-coded constellation. When you set this property to `Custom`, the object uses the signal constellation defined in the `CustomSymbolMapping` on page 3-0 property.

`CustomSymbolMapping`

Custom constellation encoding

Specify a custom constellation symbol mapping vector. The default is `0:15`. This property is a row or column vector with a size of `ModulationOrder` on page 3-0 and with unique integer values in the range [`0`, `ModulationOrder-1`]. The values must be of data type `double`. The first element of this vector corresponds to the top-leftmost point of the constellation, with subsequent elements running down column-wise, from left to right. The last element corresponds to the bottom-rightmost point. This property applies when you set the `SymbolMapping` on page 3-0 property to `Custom`.

`NormalizationMethod`

Constellation normalization method

Specify the method used to normalize the signal constellation as `Minimum distance between symbols` | `Average power` | `Peak power`. The default is `Minimum distance between symbols`.

`MinimumDistance`

Minimum distance between symbols

Specify the distance between two nearest constellation points as a positive, real, numeric scalar value. The default is `2`. This property applies when you set the `NormalizationMethod` on page 3-0 property to `Minimum distance between symbols`.

AveragePower

Average power of constellation

Specify the average power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the NormalizationMethod on page 3-0 property to Average power.

PeakPower

Peak power of constellation

Specify the maximum power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the NormalizationMethod on page 3-0 property to Peak power.

DecisionMethod

Demodulation decision method

Specify the decision method the object uses as Hard decision | Log-likelihood ratio | Approximate log-likelihood ratio. The default is Hard decision. When you set the BitOutput on page 3-0 property to false the object always performs hard-decision demodulation. This property applies when you set the BitOutput property to true.

VarianceSource

Source of noise variance

Specify the source of the noise variance as Property | Input port. The default is Property. This property applies when you set the BitOutput on page 3-0 property to true and the DecisionMethod on page 3-0 property to Log-likelihood ratio or Approximate log-likelihood ratio.

Variance

Noise variance

Specify the variance of the noise as a positive, real scalar value. The default is 1. If this value is very small (i.e., SNR is very high), log-likelihood ratio (LLR) computations may yield Inf or -Inf. This result occurs because the LLR algorithm computes the exponential of very large or very small numbers using finite-precision arithmetic. In such cases, using approximate LLR is recommended because its algorithm does not compute exponentials. This property applies when you set the BitOutput on page 3-0 property to true, the DecisionMethod on page 3-0 property to Log-likelihood ratio or Approximate log-likelihood ratio, and the VarianceSource on page 3-0 property to Property. This property is tunable.

OutputDataType

Data type of output

Specify the output data type as Full precision | Smallest unsigned integer | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32. The default is Full precision.

This property applies only when you set the BitOutput on page 3-0 property to false or when you set the BitOutput property to true and the DecisionMethod on page 3-0 property to Hard decision. In this case, when the OutputDataType on page 3-0 property is set to Full precision, and the input data type is single- or double-precision, the output data has the same data type as the input.

When the input data is of a fixed-point type, the output data type behaves as if you had set the OutputDataType property to Smallest unsigned integer.

When you set the BitOutput property to true and the DecisionMethod property to Hard Decision, then logical data type becomes a valid option.

When you set the BitOutput property to true and the DecisionMethod property to Log-likelihood ratio or Approximate log-likelihood ratio, the output data type is the same as that of the input. In this case, that data type can only be single- or double-precision.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set FullPrecisionOverride to true, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set FullPrecisionOverride to false, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects” on page 3-1252.

DerotateFactorDataType

Data type of derotate factor

Specify the derotate factor data type as Same word length as input | Custom. The default is Same word length as input. This property applies when you set the BitOutput on page 3-0 property to false, or when you set the BitOutput property to true and the DecisionMethod on page 3-0 property to Hard decision. The object uses the derotate factor in the computations only when the step method input is of a fixed-point type and the PhaseOffset on page 3-0 property has a value that is not a multiple of $\pi/2$.

CustomDerotateFactorDataType

Fixed-point data type of derotate factor

Specify the derotate factor fixed-point type as an unscaled numerictype object with a signedness of Auto. The default is numerictype([],16). This property applies when you set the DerotateFactorDataType on page 3-0 property to Custom.

DenormalizationFactorDataType

Data type of denormalization factor

Specify the denormalization factor data type as Same word length as input | Custom. The default is Same word length as input. This property applies when you set the BitOutput on page 3-0 property to false or when you set the BitOutput property to true and the DecisionMethod on page 3-0 property to Hard decision.

CustomDenormalizationFactorDataType

Fixed-point data type of denormalization factor

Specify the denormalization factor fixed-point type as an unscaled numerictype object with a signedness of Auto. The default is numerictype([],16). This property applies when you set the DenormalizationFactorDataType on page 3-0 property to Custom.

ProductDataType

Data type of product

Specify the product data type as Full precision | Custom. The default is Full precision. This property applies when you set the BitOutput on page 3-0 property to false or when you set the BitOutput property to true and the DecisionMethod on page 3-0 property to Hard decision.

CustomProductDataType

Fixed-point data type of product

Specify the product fixed-point type as an unscaled numerictype object with a signedness of Auto. The default is numerictype([],32). This property applies when you set the ProductDataType on page 3-0 property to Custom.

ProductRoundingMethod

Rounding of fixed-point numeric value of product

Specify the product rounding method as Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero. The default is Floor. This property applies when the object is not in a full precision configuration, when you set the BitOutput on page 3-0 property to false or when you set the BitOutput property to true and the DecisionMethod on page 3-0 property to Hard decision.

ProductOverflowAction

Action when fixed-point numeric value of product overflows

Specify the product overflow action as Wrap | Saturate. The default is Wrap. This property applies when the object is not in a full precision configuration, when you set the BitOutput on page 3-0 property to false or when you set the BitOutput property to true and the DecisionMethod on page 3-0 property to Hard decision.

SumDataType

Data type of sum

Specify the sum data type as Full precision | Same as product | Custom. The default is Full precision. This property applies when you set the FullPrecisionOverride on page 3-0 property to false, when you set the BitOutput on page 3-0 property to false or when you set the BitOutput property to true and the DecisionMethod on page 3-0 property to Hard decision.

CustomSumDataType

Fixed-point data type of sum

Specify the sum fixed-point type as an unscaled `numerictype` object with a signedness of Auto. The default is `numerictype([],32)`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false or when you set the `SumDataType` on page 3-0 property `Custom`.

Methods

constellation	(To be removed) Calculate or plot ideal signal constellation
step	(To be removed) Demodulate using rectangular QAM method

Common to All System Objects	
`release`	Allow System object property value changes

More About

Full Precision for Fixed-Point System Objects

`FullPrecisionOverride` is a convenience property that, when you set to `true`, automatically sets the appropriate properties for an object to use full-precision to process fixed-point input.

For System objects, full precision, fixed-point operation refers to growing just enough additional bits to compute the ideal full precision result. This operation has no minimum or maximum range overflow nor any precision loss due to rounding or underflow. It is also independent of any hardware-specific settings. The data types chosen are based only on known data type ranges and not on actual numeric values. Full precision for System objects does not optimize coefficient values. When you set the `FullPrecisionOverride` property to `true`, the other fixed-point properties it controls no longer apply and any of their non-default values are ignored. These properties are also hidden. To specify individual fixed-point properties, first set `FullPrecisionOverride` to `false`.

Algorithms

This object implements the algorithm, inputs, and outputs described on the Rectangular QAM Demodulator Baseband block reference page. The object properties correspond to the block parameters.

Compatibility Considerations

`comm.RectangularQAMDemodulator` will be removed in a future release. Use qamdemod instead.

Not recommended starting in R2018b

Constellation normalization by `PeakPower` and `AveragePower` (other than unit average power) as supported by `comm.RectangularQAMModulator` and `comm.RectangularQAMDemodulator` is not inherently provided by functions. This code shows you how to perform peak power and average power normalization using `qammod` and `qamdemod` functions.

Average Power Normalization for Hard Decision

Objects
`comm.GeneralQAMDemodulator`

Introduced in R2012a

constellation

System object: comm.RectangularQAMDemodulator
Package: comm

(To be removed) Calculate or plot ideal signal constellation

Note comm.RectangularQAMDemodulator will be removed in a future release. Use qamdemod instead.

Syntax

```
y = constellation(h)
constellation(h)
```

Description

y = constellation(h) returns the numerical values of the constellation.

constellation(h) generates a constellation plot for the object.

Examples

Plot QAM Reference Constellations

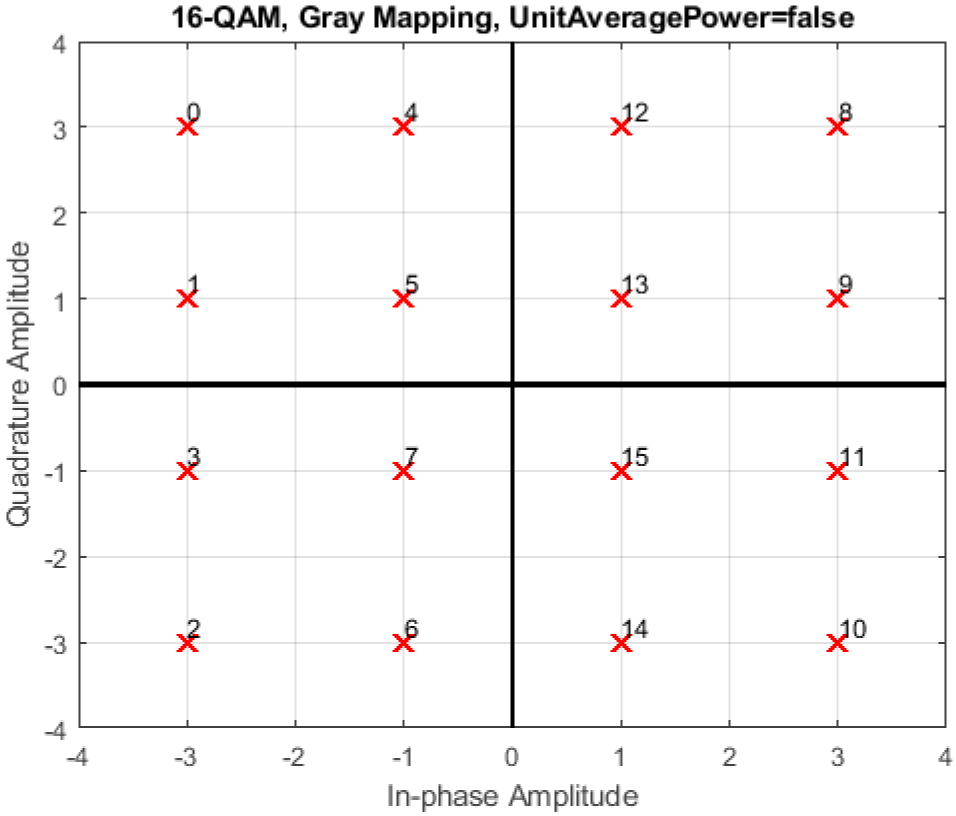
Plot QAM reference constellation using the qammod and qamdemod functions. Show that the 'PlotConstellation,true' Name,Value pair property works for both qammod and qamdemod functions. Also show the symbol ordering for Gray and binary code ordering by representing the data in binary format.

Create symbols for a 16-QAM modulator.

```
M = 16; % For 16-QAM
refSym = (0:M-1)';
```

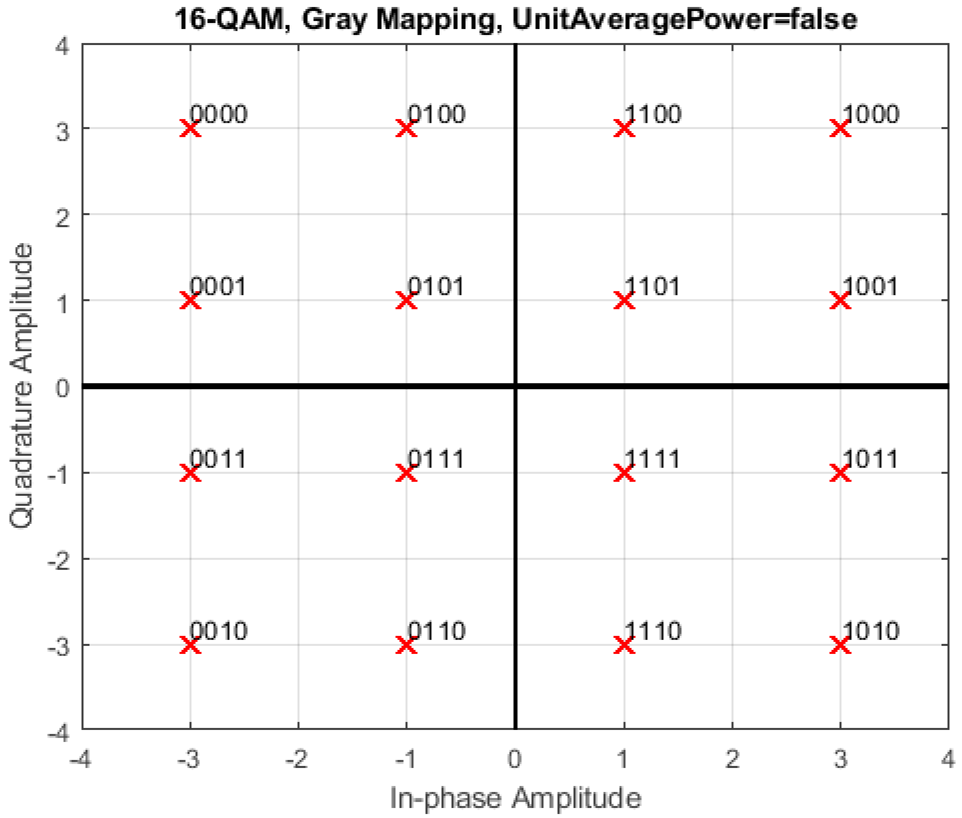
Plot the reference constellation using the qammod function.

```
qammod(refSym,M,'PlotConstellation',true);
```



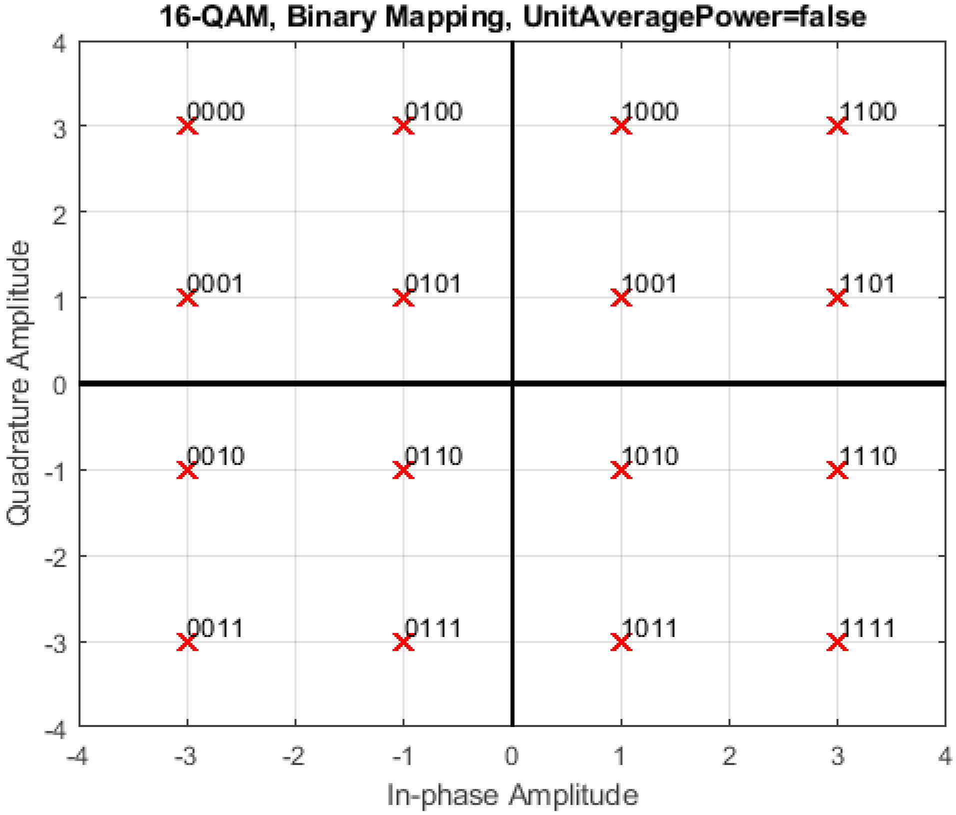
The default symbol order is Gray code ordering. To highlight the Gray symbol mapping, replot the reference constellation using binary input type. When you specify `'InputType','bit'`, the input signal must contain binary values, and the number of rows must be an integer multiple of `log2(M)`. Tranpose the input vector so that the input symbols map to the column vectors.

```
biRefSym = de2bi(refSym);
qammod(biRefSym',M,'PlotConstellation',true,'InputType','bit');
```



Replot the reference constellation using binary-coded symbol ordering.

```
biRefSym = de2bi(refSym);
qammod(biRefSym',M,'bin','PlotConstellation',true,'InputType','bit');
```



Create symbols for a 64-QAM modulator.

```
M = 64; % For 64-QAM
refSym = (0:M-1);
```

Plot the reference constellation using the `qamdemod` function.

```
qamdemod(refSym,M,'PlotConstellation',true);
```

step

System object: comm.RectangularQAMDemodulator
Package: comm

(To be removed) Demodulate using rectangular QAM method

Note comm.RectangularQAMDemodulator will be removed in a future release. Use qamdemod instead.

Syntax

```
Y = step(H,X)
Y = step(H,X,VAR)
```

Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Y = step(H,X) demodulates the input data, X, with the rectangular QAM demodulator System object, H, and returns, Y. Input X must be a scalar or a column vector with double or single precision data type. When ModulationOrder is an even power of two and you set the BitOutput property to false or, when you set the DecisionMethod to Hard decision and the BitOutput property to true, the data type of the input can also be signed integer, or signed fixed point (fi objects). Depending on the BitOutput property value, output Y can be integer or bit valued.

Y = step(H,X,VAR) uses soft decision demodulation and noise variance VAR. This syntax applies when you set the BitOutput property to true, the DecisionMethod property to Approximate log-likelihood ratioor Log-likelihood ratio, and the VarianceSource property to Input port. The data type of input VAR must be double or single precision.

Note obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

comm.RectangularQAMModulator

Package: comm

(To be removed) Modulate using rectangular QAM signal constellation

Note comm.RectangularQAMModulator will be removed in a future release. Use qammod instead. For more information, see “Compatibility Considerations”.

Description

The RectangularQAMModulator object modulates using M-ary quadrature amplitude modulation with a constellation on a rectangular lattice. The output is a baseband representation of the modulated signal. This block accepts a scalar or column vector input signal.

To modulate a signal using quadrature amplitude modulation:

1. Define and set up your rectangular QAM modulator object. See “Construction” on page 3-1269.
2. Call step to modulate the signal according to the properties of comm.RectangularQAMModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.RectangularQAMModulator creates a modulator object, H. This object modulates the input using the rectangular quadrature amplitude modulation (QAM) method.

H = comm.RectangularQAMModulator(Name,Value) creates a rectangular QAM modulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.RectangularQAMModulator(M,Name,Value) creates a rectangular QAM modulator object, H. This object has the ModulationOrder property set to M, and the other specified properties set to the specified values.

Properties

ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as scalar value that is a positive integer power of two. The default is 16.

PhaseOffset

Phase offset of constellation

Specify the phase offset of the signal constellation, in radians, as a real scalar value. The default is 0.

BitInput

Assume bit inputs

Specify whether the input is bits or integers. The default is false. When you set this property to true, the step method input requires a column vector of bit values. The length of this vector must be an integer multiple of **log2**(ModulationOrder on page 3-0). This vector contains bit representations of integers between 0 and ModulationOrder–1. When you set this property to false, the step method input must be a column vector of integer symbol values between 0 and ModulationOrder–1.

SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of **log2**(ModulationOrder on page 3-0) input bits to the corresponding symbol as Binary | Gray | Custom. The default is Gray. When you set this property to Gray, the System object uses a Gray-coded signal constellation. When you set this property to Binary, the object uses a natural binary-coded constellation. When you set this property to Custom, the object uses the signal constellation defined in the CustomSymbolMapping on page 3-0 property.

CustomSymbolMapping

Custom constellation encoding

Specify a custom constellation symbol mapping vector. The default is 0:15. This property is a row or column vector with a size of ModulationOrder on page 3-0 . This vector has unique integer values in the range [0, ModulationOrder–1]. These values must be of data type double. The first element of this vector corresponds to the top-leftmost point of the constellation, with subsequent elements running down column-wise, from left to right. The last element corresponds to the bottom-rightmost point. This property applies when you set the SymbolMapping on page 3-0 property to Custom.

NormalizationMethod

Constellation normalization method

Specify the method used to normalize the signal constellation as Minimum distance between symbols | Average power | Peak power. The default is Minimum distance between symbols.

MinimumDistance

Minimum distance between symbols

Specify the distance between two nearest constellation points as a positive, real, numeric scalar value. The default is 2. This property applies when you set the NormalizationMethod on page 3-0 property to Minimum distance between symbols.

`AveragePower`

Average power of constellation

Specify the average power of the symbols in the constellation as a positive, real, numeric scalar value. The default is `1`. This property applies when you set the `NormalizationMethod` on page 3-0 property to `Average power`.

`PeakPower`

Peak power of constellation

Specify the maximum power of the symbols in the constellation as a positive real, numeric scalar value. The default is `1`. This property applies when you set the `NormalizationMethod` on page 3-0 property to `Peak power`.

`OutputDataType`

Data type of output

Specify the output data type as `double` | `single` | `Custom`. The default is `double`.

Fixed-Point Properties

`CustomOutputDataType`

Fixed-point data type of output

Specify the output fixed-point type as a `numerictype` object with a signedness of Auto. The default is `numerictype([],16)`. This property applies when you set the `OutputDataType` on page 3-0 property to `Custom`.

Methods

constellation	(To be removed) Calculate or plot ideal signal constellation
step	(To be removed) Modulate using rectangular QAM method

Common to All System Objects	
`release`	Allow System object property value changes

Algorithms

This object implements the algorithm, inputs, and outputs described on the Rectangular QAM Modulator Baseband block reference page. The object properties correspond to the block parameters.

Compatibility Considerations

`comm.RectangularQAMModulator` will be removed in a future release. Use qammod instead.
Not recommended starting in R2018b

Constellation normalization by `PeakPower` and `AveragePower` (other than unit average power) as supported by `comm.RectangularQAMModulator` and `comm.RectangularQAMDemodulator` is not inherently provided by functions. This code shows you how to perform peak power and average power normalization using `qammod` and `qamdemod` functions.

Functions
`genqammod` | `qammod`

Objects
`comm.GeneralQAMModulator`

Introduced in R2012a

constellation

System object: `comm.RectangularQAMModulator`
Package: `comm`

(To be removed) Calculate or plot ideal signal constellation

Note `comm.RectangularQAMModulator` will be removed in a future release. Use `qammod` instead.

Syntax

```
y = constellation(h)
constellation(h)
```

Description

`y = constellation(h)` returns the numerical values of the constellation.

`constellation(h)` generates a constellation plot for the object.

Examples

Plot QAM Reference Constellations

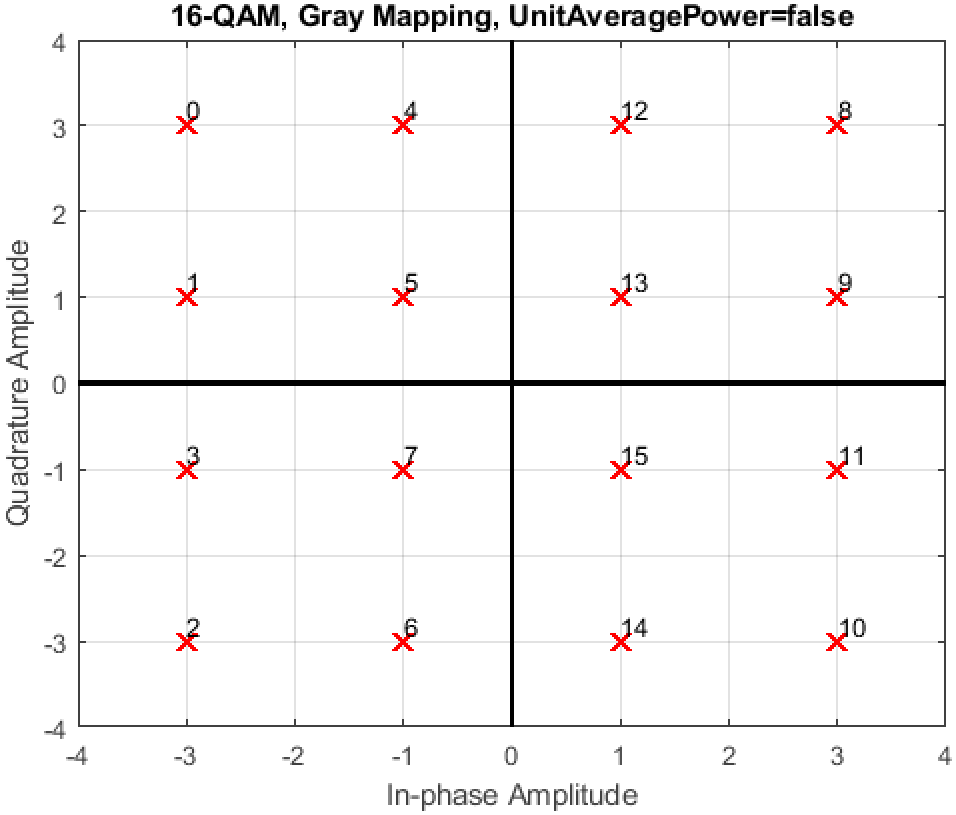
Plot QAM reference constellation using the `qammod` and `qamdemod` functions. Show that the `'PlotConstellation,true'` Name,Value pair property works for both `qammod` and `qamdemod` functions. Also show the symbol ordering for Gray and binary code ordering by representing the data in binary format.

Create symbols for a 16-QAM modulator.

```
M = 16; % For 16-QAM
refSym = (0:M-1)';
```

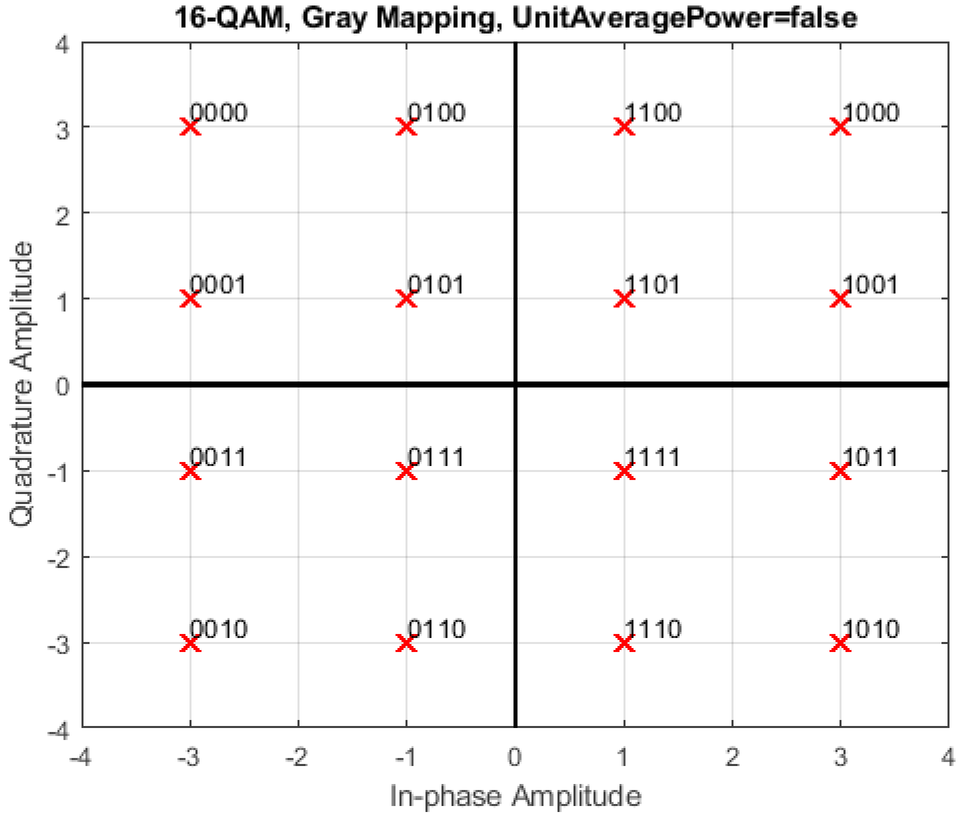
Plot the reference constellation using the `qammod` function.

```
qammod(refSym,M,'PlotConstellation',true);
```



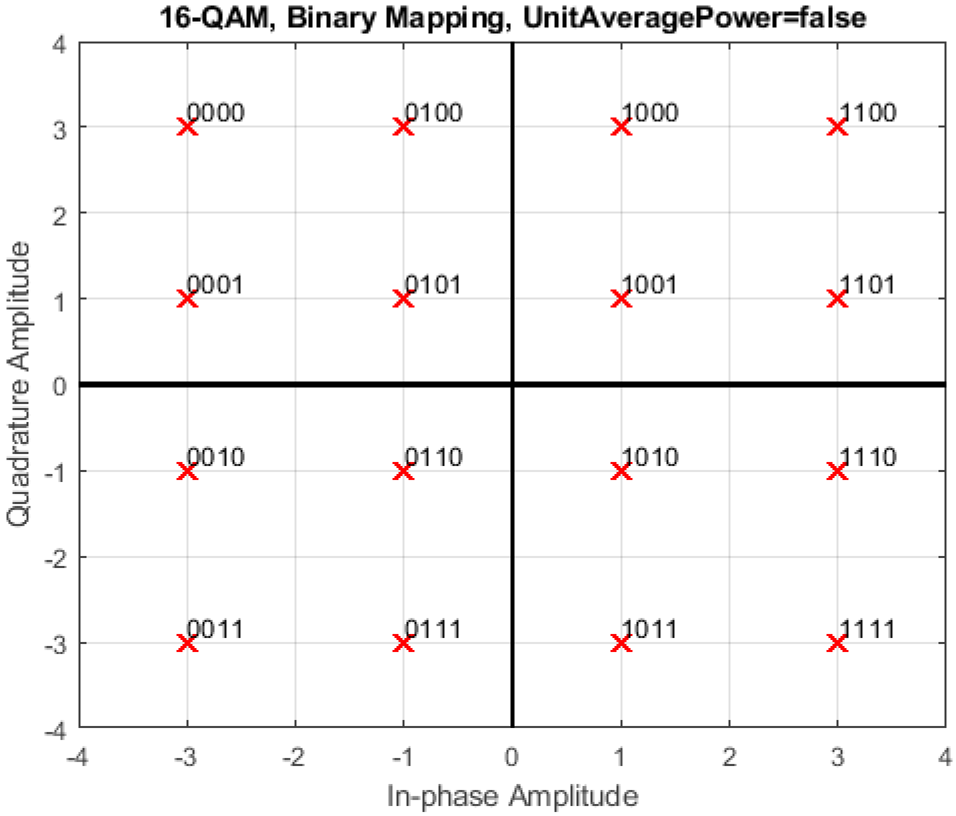
The default symbol order is Gray code ordering. To highlight the Gray symbol mapping, replot the reference constellation using binary input type. When you specify `'InputType','bit'`, the input signal must contain binary values, and the number of rows must be an integer multiple of `log2(M)`. Tranpose the input vector so that the input symbols map to the column vectors.

```
biRefSym = de2bi(refSym);
qammod(biRefSym',M,'PlotConstellation',true,'InputType','bit');
```



Replot the reference constellation using binary-coded symbol ordering.

```
biRefSym = de2bi(refSym);
qammod(biRefSym',M,'bin','PlotConstellation',true,'InputType','bit');
```



Create symbols for a 64-QAM modulator.

```
M = 64; % For 64-QAM
refSym = (0:M-1);
```

Plot the reference constellation using the `qamdemod` function.

```
qamdemod(refSym,M,'PlotConstellation',true);
```

step

System object: `comm.RectangularQAMModulator`
Package: `comm`

(To be removed) Modulate using rectangular QAM method

Note `comm.RectangularQAMModulator` will be removed in a future release. Use `qammod` instead.

Syntax

`Y = step(H,X)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` modulates input data, `X`, with the rectangular QAM modulator object, `H`. It returns the baseband modulated output, `Y`. Depending on the value of the `BitInput` property, input `X` can be an integer or bit valued column vector with numeric, logical, or fixed-point data types.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.RectangularQAMTCMDemodulator

Package: `comm`

Demodulate convolutionally encoded data mapped to rectangular QAM signal constellation

Description

The `RectangularQAMTCMDemodulator` object uses the Viterbi algorithm to decode a trellis-coded modulation (TCM) signal that was previously modulated using a rectangular QAM signal constellation.

To demodulate convolutionally encoded data mapped to a rectangular QAM signal constellation:

1. Define and set up your rectangular QAM TCM demodulator object. See "Construction" on page 3-1288.
2. Call `step` to demodulate the signal according to the properties of `comm.RectangularQAMTCMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.RectangularQAMTCMDemodulator` creates a trellis-coded, rectangular, quadrature amplitude (QAM TCM) demodulator System object, `H`. This object demodulates convolutionally encoded data that has been mapped to a rectangular QAM constellation.

`H = comm.RectangularQAMTCMDemodulator(Name,Value)` creates a rectangular, QAM TCM, demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.RectangularQAMTCMDemodulator(TRELLIS,Name,Value)` creates a rectangular QAM TCM demodulator object, `H`. This object has the TrellisStructure property set to `TRELLIS`, and the other specified properties set to the specified values.

Properties

`TrellisStructure`

Trellis structure of convolutional code

Specify trellis as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check whether a structure is a valid trellis. The default is the result of `poly2trellis([3 1 1], [ 5 2 0 0; 0 0 1 0; 0 0 0 1])`.

TerminationMethod

Termination method of encoded frame

Specify the termination method as `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object saves the internal state metric at the end of each frame. The next frame uses the same state metric. The object treats each traceback path independently. If the input signal contains only one symbol, you should use `Continuous` mode.

When you set this property to `Truncated`, the object treats each input vector independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state.

When you set this property to `Terminated`, the object treats each input vector independently, and the traceback path always starts and ends in the all-zeros state.

TracebackDepth

Traceback depth for Viterbi decoder

Specify the scalar, integer number of trellis branches to construct each traceback path. The default is `21`. The Traceback depth parameter influences the decoding accuracy and delay. The decoding delay is the number of zero symbols that precede the first decoded symbol in the output.

When you set the TerminationMethod property to `Continuous`, the decoding delay consists of TracebackDepth zero symbols or TracebackDepth×K zero bits for a rate K/N convolutional code.

When you set the TerminationMethod property to `Truncated` or `Terminated`, no output delay occurs and the traceback depth must be less than or equal to the number of symbols in each input vector.

ResetInputPort

Enable demodulator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this additional reset input is a nonzero value, the internal states of the encoder reset to initial conditions. This property applies when you set the TerminationMethod property to `Continuous`.

ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation used to map the convolutionally encoded data as a positive, integer scalar value. The number of points must be `4`, `8`, `16`, `32`, or `64`. The default is `16`. The ModulationOrder property value must equal the number of possible input symbols to the convolutional decoder of the rectangular QAM TCM demodulator object. The `ModulationOrder` must equal 2^N for a rate K/N convolutional code.

OutputDataType

Data type of output

Specify output data type as `logical` | `double`. The default is `double`.

Methods

reset	Reset states of the rectangular QAM TCM demodulator object
step	Demodulate convolutionally encoded data mapped to rectangular QAM constellation

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Modulate and Demodulate Using Rectangular 16-QAM TCM

Modulate and demodulate data using 16-QAM TCM in an AWGN channel. Estimate the BER.

Create QAM TCM modulator and demodulator System objects™.

```
hMod = comm.RectangularQAMTCMModulator;
hDemod = comm.RectangularQAMTCMDemodulator('TracebackDepth',16);
```

Create an AWGN channel object.

```
hAWGN = comm.AWGNChannel('EbNo',5);
```

Determine the delay through the QAM TCM demodulator. The demodulator uses the Viterbi algorithm to decode the TCM signal that was modulated using rectangular QAM. To accurately calculate the bit error rate, the delay through the decoder must be known.

```
bitsPerSymbol = log2(hDemod.TrellisStructure.numInputSymbols);
delay = hDemod.TracebackDepth*bitsPerSymbol;
```

Create an error rate calculator object with the `ReceiveDelay` property set to `delay`.

```
hErrorCalc = comm.ErrorRate('ReceiveDelay',delay);
```

Generate binary data and modulate with 16-QAM TCM. Pass the signal through an AWGN channel and demodulate. Calculate the error statistics. The loop runs until either 100 bit errors are encountered or 1e7 total bits are transmitted.

```
% Initialize the error results vector.
errStats = [0 0 0];

while errStats(2) < 100 && errStats(3) < 1e7
    % Transmit frames of 200 3-bit symbols
    txData = randi([0 1],600,1);
    % Modulate
    txSig = step(hMod,txData);
    % Pass through AWGN channel
    rxSig = step(hAWGN,txSig);
    % Demodulate
    rxData = step(hDemod,rxSig);
    % Collect error statistics
    errStats = step(hErrorCalc,txData,rxData);
end
```

Display the error data.

```
fprintf('Error rate = %4.2e\nNumber of errors = %d\n', ...
    errStats(1),errStats(2))
```

```
Error rate = 1.94e-03
Number of errors = 100
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Rectangular QAM TCM Decoder block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

`comm.GeneralQAMTCMDemodulator` | `comm.RectangularQAMTCMModulator` | `comm.ViterbiDecoder`

Introduced in R2012a

reset

System object: `comm.RectangularQAMTCMDemodulator`
Package: `comm`

Reset states of the rectangular QAM TCM demodulator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `RectangularQAMTCMDemodulator` object, `H`.

step

System object: `comm.RectangularQAMTCMDemodulator`
Package: `comm`

Demodulate convolutionally encoded data mapped to rectangular QAM constellation

Syntax

```
Y = step(H,X)
Y = step(H,X,R)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates the rectangular QAM modulated input data, `X`, and uses the Viterbi algorithm to decode the resulting demodulated, convolutionally encoded bits. `X` must be a complex, double or single precision column vector. The step method outputs a demodulated, binary data column vector, `Y`. When the convolutional encoder represents a rate K/N code, the length of the output vector is K*L, where L is the length of the input vector, `X`.

`Y = step(H,X,R)` resets the decoder to the all-zeros state when you input a reset signal, `R` that is non-zero. `R` must be a double precision or logical, scalar integer. This syntax applies when you set the `ResetInputPort` property to true.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.RectangularQAMTCMModulator

Package: comm

Convolutionally encode binary data and map using rectangular QAM signal constellation

Description

The RectangularQAMTCMModulator object implements trellis-coded modulation (TCM) by convolutionally encoding the binary input signal and mapping the result to a rectangular QAM signal constellation.

To convolutionally encode binary data and map the result using a rectangular QAM constellation:

1. Define and set up your rectangular QAM TCM modulator object. See “Construction” on page 3-1294.
2. Call step to modulate the signal according to the properties of comm.RectangularQAMTCMModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

H = comm.RectangularQAMTCMModulator creates a trellis-coded, rectangular, quadrature amplitude (QAM TCM) System object, H. This object convolutionally encodes a binary input signal and maps the result to a rectangular QAM constellation.

H = comm.RectangularQAMTCMModulator(Name,Value) creates a rectangular QAM TCM modulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.RectangularQAMTCMModulator(TRELLIS,Name,Value) creates a rectangular QAM TCM modulator object, H. This object has the TrellisStructure property set to TRELLIS and the other specified properties set to the specified values.

Properties

TrellisStructure

Trellis structure of convolutional code

Specify trellis as a MATLAB structure that contains the trellis description of the convolutional code. Use the istrellis function to check whether a structure is a valid trellis. The default is the result of poly2trellis([3 1 1], [5 2 0 0; 0 0 1 0; 0 0 0 1]).

`TerminationMethod`

Termination method of encoded frame

Specify the termination method as `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object retains the encoder states at the end of each input vector for use with the next input vector.

When you set this property to `Truncated`, the object treats each input vector independently. The encoder is reset to the all-zeros state at the start of each input vector.

When you set this property to `Terminated`, the object treats each input vector independently. For each input vector, the object uses extra bits to set the encoder to the all-zeros state at the end of the vector. For a rate *K*/*N* code, the `step` method outputs the vector with a length given by $y = N \times {}^{(L+S)}\!/_{K}$, where *S* = *constraintLength*–1 (or, in the case of multiple constraint lengths, *S* = **sum**(*constraintLength*(*i*)–1)). *L* is the length of the input to the `step` method.

`ResetInputPort`

Enable modulator reset input

Set this property to true to enable an additional input to the step method. The default is `false`. When you set the reset input to the step method to a nonzero value, the object resets the encoder to the all-zeros state. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous`.

`ModulationOrder`

Number of points in signal constellation

Specify the number of points in the signal constellation used to map the convolutionally encoded data as a positive integer scalar value equal to `4`, `8`, `16`, `32`, or `64`. The default is `16`. The value of the `ModulationOrder` on page 3-0 property must equal the number of possible output symbols from the convolutional encoder of the QAM TCM modulator. Thus, the value for the `ModulationOrder` property must equal 2^N for a rate *K*/*N* convolutional code.

`OutputDataType`

Data type of output

Specify the output data type as one of `double` | `single`. The default is `double`.

Methods

reset	Reset states of the rectangular QAM TCM modulator object
step	Convolutionally encode binary data and map using rectangular QAM constellation

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Modulate Data Using Rectangular QAM TCM

Modulate data using rectangular 16-QAM TCM modulation and display the scatter plot.

Generate random binary data. The length of the data vector must be an integer multiple of the number of input streams into the encoder, log2(8) = 3.

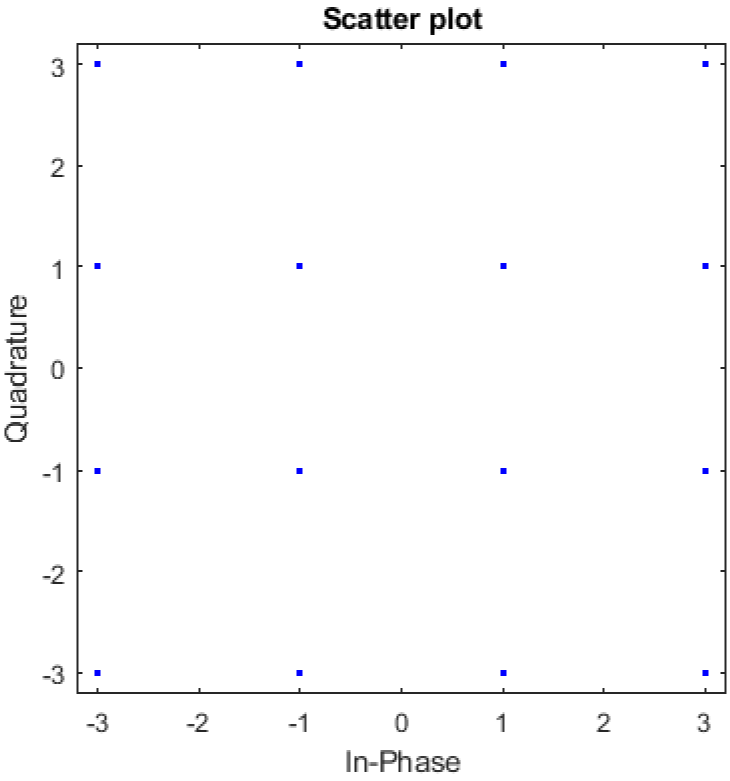
```
data = randi([0 1],3000,1);
```

Create a modulator System object™ and use its `step` function to modulate the data.

```
hMod = comm.RectangularQAMTCMModulator;
modData = step(hMod,data);
```

Plot the modulated data.

```
scatterplot(modData)
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the Rectangular QAM TCM Encoder block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Introduced in R2012a

reset

System object: `comm.RectangularQAMTCMModulator`
Package: `comm`

Reset states of the rectangular QAM TCM modulator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `RectangularQAMTCMModulator` object, `H`.

step

System object: comm.RectangularQAMTCMModulator
Package: comm

Convolutionally encode binary data and map using rectangular QAM constellation

Syntax

```
Y = step(H,X)
Y = step(H,X,R)
```

Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Y = step(H,X) convolutionally encodes and modulates the input data numeric or logical column vector X, and returns the encoded and modulated data, Y. X must be of data type numeric, logical, or unsigned fixed point of word length 1 (fi object). When the convolutional encoder represents a rate *K*/*N* code, the length of the input vector, X, must be *K*×*L*, for some positive integer *L*. The step method outputs a complex column vector, *Y*, of length *L*.

Y = step(H,X,R) resets the encoder of the rectangular QAM TCM modulator object to the all-zeros state when you input a non-zero reset signal, R. R must be a double precision or logical, scalar integer. This syntax applies when you set the ResetInputPort property to true.

Note obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

comm.RicianChannel

Package: `comm`

Filter input signal through multipath Rician fading channel

Description

The `comm.RicianChannel` System object filters an input signal through a multipath Rician fading channel. For more information on fading model processing, see Methodology for Simulating Multipath Fading Channels.

To filter an input signal using a multipath Rician fading channel:

1. Create the `comm.RicianChannel` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
ricianlchan = comm.RicianChannel
ricianlchan = comm.RicianChannel(Name,Value)
```

Description

`ricianlchan = comm.RicianChannel` creates a frequency-selective or frequency-flat multipath Rician fading channel System object. This object filters a real or complex input signal through the multipath channel to obtain the channel-impaired signal.

`ricianlchan = comm.RicianChannel(Name,Value)` sets properties using one or more name-value pair arguments. Enclose each property name in quotes. For example, `comm.RicianChannel('SampleRate',2)` sets the input signal sample rate to 2.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`SampleRate` — Input signal sample rate
`1` (default) | positive scalar

Input signal sample rate in Hz, specified as a positive scalar.

Data Types: `double`

`PathDelays` — Discrete path delay

`0` (default) | scalar | row vector

Discrete path delay in seconds, specified as a scalar or row vector.

- When `PathDelays` is a scalar, the channel is frequency flat.
- When `PathDelays` is a vector, the channel is frequency selective.

Data Types: `double`

`AveragePathGains` — Average of the discrete paths

`0` (default) | scalar | row vector

Average gains of the discrete paths in decibels, specified as a scalar or row vector. `AveragePathGains` must be of the same size as the `PathDelays` property.

Data Types: `double`

`NormalizePathGains` — Normalize average path gains to 0 dB

`true` or `1` (default) | `false` or `0`

Normalize average path gains to 0 dB, specified as a logical `1` (`true`) or `0` (`false`).

- When `NormalizePathGains` is `true`, the fading processes are normalized so that the total power of the path gains, averaged over time, is 0 dB.
- When `NormalizePathGains` is `false`, the total power of the path gains is not normalized.

Data Types: `logical`

`KFactor` — Rician *K*-factor

`3` (default) | positive scalar | row vector of nonnegative values

Rician *K*-factor, specified as a positive scalar or row vector of nonnegative values. The vector must be the same length as the `PathDelays` property value.

- When `KFactor` is a scalar, the first discrete path is a Rician fading process with a Rician *K*-factor of `KFactor`. Any remaining discrete paths are independent Rayleigh fading processes.
- When `KFactor` is a row vector, the discrete path corresponding to a positive element of the `KFactor` vector is a Rician fading process with a Rician *K*-factor specified by that element. The discrete path corresponding to any zero-valued elements of the `KFactor` vector are Rayleigh fading processes. At least one element value must be nonzero.

Data Types: `double`

`DirectPathDopplerShift` — Doppler shift

`0` (default) | scalar | row vector

Doppler shift of the line-of-sight components of a multipath Rician fading channel, specified as a scalar or row vector. Units are in hertz. The `DirectPathDopplerShift` property must be of the same size as the `KFactor` property.

- When `DirectPathDopplerShift` is a scalar, the value represents the line-of-sight component Doppler shift of the first discrete path. This path exhibits a Rician fading process.

- When `DirectPathDopplerShift` is a row vector, the discrete path corresponding to a positive element of the `KFactor` vector is a Rician fading process. The corresponding element of `DirectPathDopplerShift` specifies the line-of-sight component Doppler shift of that discrete path.

Data Types: `double`

`DirectPathInitialPhase` — Initial phase

`0` (default) | scalar | row vector

Initial phase of the line-of-sight components of a multipath Rician fading channel, specified as a scalar or row vector. Units are in radians. The `DirectPathInitialPhase` property must be of the same size as the `KFactor` property.

- When `DirectPathInitialPhase` is a scalar, the value represents the line-of-sight component initial phase of the first discrete path. This path exhibits a Rician fading process.
- When `DirectPathInitialPhase` is a row vector, the discrete path corresponding to a positive element of the `KFactor` vector is a Rician fading process. The corresponding element of `DirectPathInitialPhase` specifies the line-of-sight component initial phase of that discrete path.

Data Types: `double`

`MaximumDopplerShift` — Maximum Doppler shift for all channel paths

`0.001` (default) | nonnegative scalar

Maximum Doppler shift for all channel paths, specified as a nonnegative scalar. Units are in hertz.

The maximum Doppler shift limit applies to each channel path. When you set this property to `0`, the channel remains static for the entire input. You can use the `reset` object function to generate a new channel realization. The `MaximumDopplerShift` property value must be smaller than `SampleRate`/10/f_c for each path. f_c represents the cutoff frequency factor of the path. For most Doppler spectrum types, the value of f_c is 1. For Gaussian and biGaussian Doppler spectrum types, f_c is dependent on the Doppler spectrum structure fields. For more details about how f_c is defined, see “Cutoff Frequency Factor” on page 3-1313.

Data Types: `double`

`DopplerSpectrum` — Doppler spectrum shape for all channel paths

`doppler('Jakes')` (default) | Doppler spectrum structure | 1-by-N_P cell array of Doppler spectrum structures

Doppler spectrum shape for all channel paths, specified as a Doppler spectrum structure or a 1-by-N_P cell array of Doppler spectrum structures. These Doppler spectrum structures must be outputs of the form returned from the `doppler` function. N_P is the number of discrete delay paths, that is, the length of the `PathDelays` property.

- When `DopplerSpectrum` is defined by a single Doppler spectrum structure, all paths have the same specified Doppler spectrum.
- When `DopplerSpectrum` is defined by a cell array of Doppler spectrum structures, each path has the Doppler spectrum specified by the corresponding structure in the cell array.

Options for the spectrum type are specified by the `specType` input to the `doppler` function. If you set the `FadingTechnique` property to `'Sum of sinusoids'`, you must set `DopplerSpectrum` to `doppler('Jakes')`.

Dependencies

To enable this property, set the `MaximumDopplerShift` property to a positive value. The `MaximumDopplerShift` property defines the maximum Doppler shift value permitted when specifying the Doppler spectrum.

Data Types: `struct` | `cell`

`FadingTechnique` — Channel model fading technique

`'Filtered Gaussian noise'` (default) | `'Sum of sinusoids'`

Channel model fading technique, specified as `'Filtered Gaussian noise'` or `'Sum of sinusoids'`.

Data Types: `char` | `string`

`NumSinusoids` — Number of sinusoids used

`48` (default) | positive integer

Number of sinusoids used to model the fading process, specified as a positive integer.

Dependencies

To enable this property, set the `FadingTechnique` property to `'Sum of sinusoids'`.

Data Types: `double`

`InitialTimeSource` — Source to control start time of fading process

`'Property'` (default) | `'Input port'`

Source to control the start time of the fading process, specified as `'Property'` or `'Input port'`.

- When `InitialTimeSource` is set to `'Property'`, use the `InitialTime` property to set the initial time offset.
- When `InitialTimeSource` is set to `'Input port'`, specify the start time of the fading process by using the `itime` input to the System object. The input value can change in consecutive calls to the System object.

Dependencies

This property applies when the `FadingTechnique` property to `'Sum of sinusoids'`.

Data Types: `string` | `char`

`InitialTime` — Initial time offset

`0` (default) | nonnegative scalar

Initial time offset, in seconds, for the fading model, specified as a nonnegative scalar. `InitialTime` must be greater than end time of the last frame. `InitialTime` is rounded up to the nearest sample position when it is not a multiple of 1/`SampleRate`.

Dependencies

To enable this property, set the `FadingTechnique` property to `'Sum of sinusoids'` and the `InitialTimeSource` property to `'Property'`.

Data Types: `double`

RandomStream — Source of random number stream

'Global stream' (default) | 'mt19937ar with seed'

Source of random number stream, specified as 'Global stream' or 'mt19937ar with seed'.

- 'Global stream' — The current global random number stream is used for normally distributed random number generation. In this case, the reset object function resets the channel filters only.
- 'mt19937ar with seed' — The mt19937ar algorithm is used for normally distributed random number generation. In this case, the reset object function resets the channel filters and reinitializes the random number stream to the value of the Seed property.

Data Types: string | char

Seed — Initial seed of mt19937ar random number stream

73 (default) | nonnegative integer

Initial seed of mt19937ar random number stream generator algorithm, specified as a nonnegative integer. When the reset object function is called, the mt19937ar random number stream is reinitialized to the Seedproperty value.

Dependencies

This property applies when you set the RandomStream property to 'mt19937ar with seed'.

Data Types: double

PathGainsOutputPort — Option to output path gains

false or 0 (default) | true or 1

Option to output path gains, specified as 0 (false) or 1 (true). Set this property to 1 (true) to output the channel path gains of the underlying fading process.

Data Types: logical

Visualization — Channel visualization

'Off' (default) | 'Impulse response' | 'Frequency response' | 'Impulse and frequency responses' | 'Doppler spectrum'

Channel visualization, specified as 'Off', 'Impulse response', 'Frequency response', 'Impulse and frequency responses', or 'Doppler spectrum'. For more information, see “Channel Visualization” on page 3-1313.

Data Types: string | char

SamplesToDisplay — Percentage of samples to display

'25%' (default) | '10%' | '50%' | '100%'

Percentage of samples to display, specified as '25%', '10%', '50%', or '100%'. Displaying fewer samples improves (decreases) the display update rate at the expense of decreasing the visualized precision.

Dependencies

To enable this property, set the Visualization property to 'Impulse response', 'Frequency response', or 'Impulse and frequency responses'.

Data Types: string | char

PathsForDopplerDisplay — Path for Doppler display

1 (default) | positive integer

Path for Doppler display, specified as a positive integer. Use this property to select the discrete path used in constructing a Doppler spectrum plot. The specified path must be an element of {1, 2, ..., N_P}. In this set, N_P is the number of discrete delay paths, that is, the length of the PathDelays property value.

Dependencies

To enable this property, set the Visualization property to 'Doppler spectrum'.

Data Types: double

Usage

Syntax

```
y = rayleighchan(x)
[y,pathgains] = rayleighchan(x)
___ = rayleighchan(x,itime)
```

Description

y = rayleighchan(x) filters input signal x through a multipath Rician fading channel and returns the output signal in y.

[y,pathgains] = rayleighchan(x) returns the channel path gains of the underlying multipath Rician fading process in pathgains. To enable this syntax set the PathGainsOutputPort property set to 1 (true).

___ = rayleighchan(x,itime) passes data through the multipath Rician fading channel beginning at the initial time specified by itime. To enable this syntax, set the FadingTechnique property to 'Sum of sinusoids' and the InitialTimeSource property to 'Input port'.

Input Arguments

x — Input signal

N_S-by-1 vector

Input signal, specified as an N_S-by-1 vector, where N_S is the number of samples.

Data Types: single | double
Complex Number Support: Yes

itime — Initial time

0 | nonnegative scalar

Initial time in seconds, specified as a nonnegative scalar. The itime input must be greater than the end time of the last frame. When itime is not a multiple of 1/SampleRate, it is rounded up to the nearest sample position.

Data Types: single | double

Output Arguments

y — Output signal
N_S-by-1 vector

Output signal, returned as an N_S-by-1 vector of complex values with the same data precision as the input signal `x`. N_S is the number of samples.

`pathgains` — Path gains
N_S-by-N_P array

Path gains, returned as an N_S-by-N_P array. N_S is the number of samples. N_P is the number of discrete delay paths, that is, the length of the `PathDelays` property value. `pathgains` contains complex values with the same precision as the input signal `x`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.RicianChannel`

info	Characteristic information about fading channel object

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Produce Same Rician Channel Outputs Using two Random Number Generation Methods

This example shows how to produce the same multipath Rician fading channel response by using two different methods for random number generation. The multipath Rician fading channel System object™ includes two methods for random number generation. You can use the current global stream or the mt19937ar algorithm with a specified seed. By interacting with the global stream, the System object can produce the same outputs from the two methods.

Create a PSK modulator System object to modulate randomly generated data.

```
pskModulator = comm.PSKModulator;
channelInput = pskModulator(randi([0 pskModulator.ModulationOrder-1],1024,1));
```

Create a multipath Rician fading channel System object, specifying the random number generation method as the my19937ar algorithm and the random number seed as 73.

```
ricianchan = comm.RicianChannel(...
    'SampleRate',1e6,...
    'PathDelays',[0.0 0.5 1.2]*1e-6,...
    'AveragePathGains',[0.1 0.5 0.2],...
    'KFactor',2.8,...
    'DirectPathDopplerShift',5.0,...
    'DirectPathInitialPhase',0.5,...
    'MaximumDopplerShift',50,...
    'DopplerSpectrum',doppler('Bell', 8),...
    'RandomStream','mt19937ar with seed', ...
    'Seed',73, ...
    'PathGainsOutputPort',true);
```

Filter the modulated data by using the multipath Rician fading channel System object.

```
[RicianChanOut1, RicianPathGains1] = ricianchan(channelInput);
```

Set the System object to use the global stream for random number generation.

```
release(ricianchan);
ricianchan.RandomStream = 'Global stream';
```

Set the global stream to have the same seed that was specified when creating the multipath Rician fading channel System object.

```
rng(73)
```

Filter the modulated data by using the multipath Rician fading channel System object again.

```
[RicianChanOut2,RicianPathGains2] = ricianchan(channelInput);
```

Verify that the channel and path gain outputs are the same for each of the two methods.

```
isequal(RicianChanOut1,RicianChanOut2)
```

```
ans = logical
   1
```

```
isequal(RicianPathGains1,RicianPathGains2)
```

```
ans = logical
   1
```

Display Impulse and Frequency Responses of Multipath Rician Fading Channel

This example shows how to create a frequency-selective multipath Rician fading channel and display its impulse and frequency responses.

Set the sample rate to 3.84 MHz. Specify path delays and gains by using the ITU pedestrian B channel configuration. Set the Rician K-factor to 10 and the maximum Doppler shift to 50 Hz.

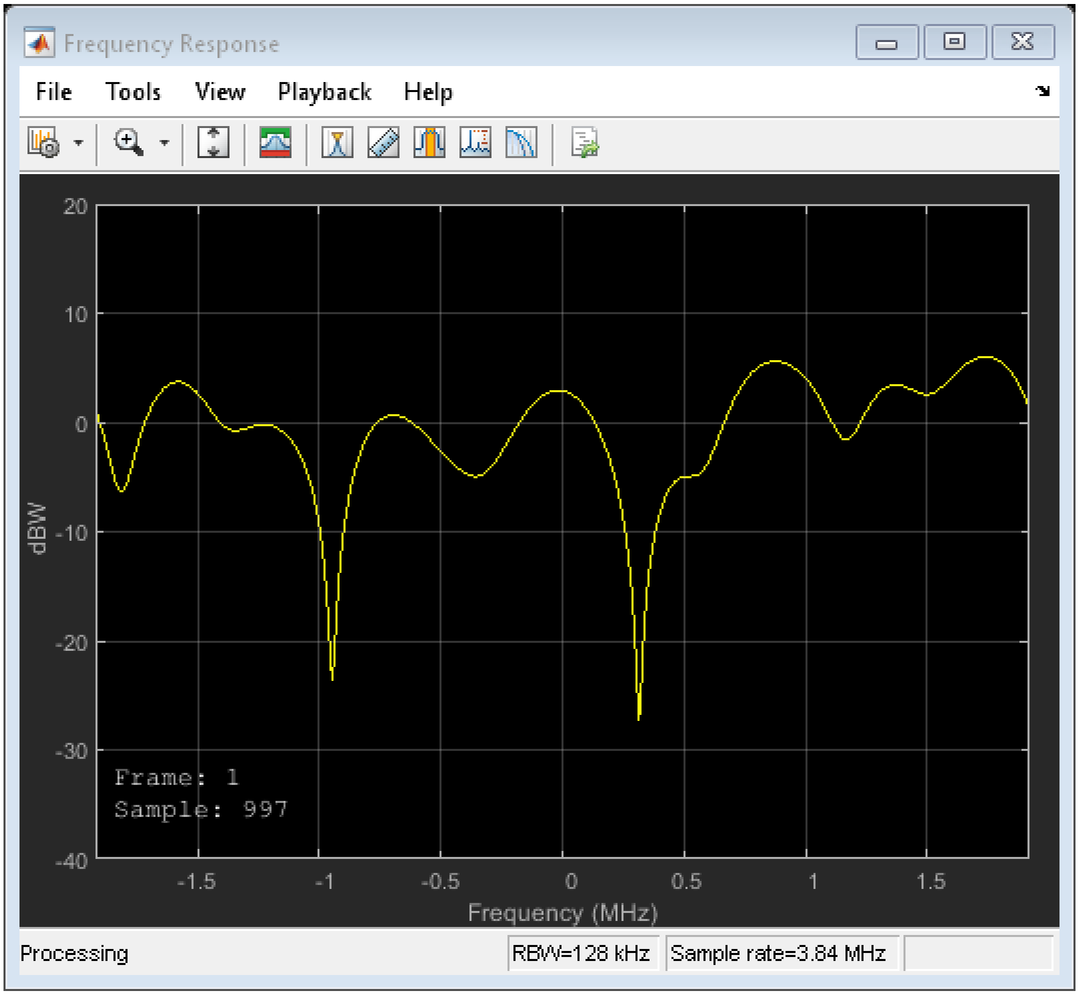
```
fs = 3.84e6; % Hz
pathDelays = [0 200 800 1200 2300 3700]*1e-9; % sec
avgPathGains = [0 -0.9 -4.9 -8 -7.8 -23.9]; % dB
fD = 50; % Hz
```

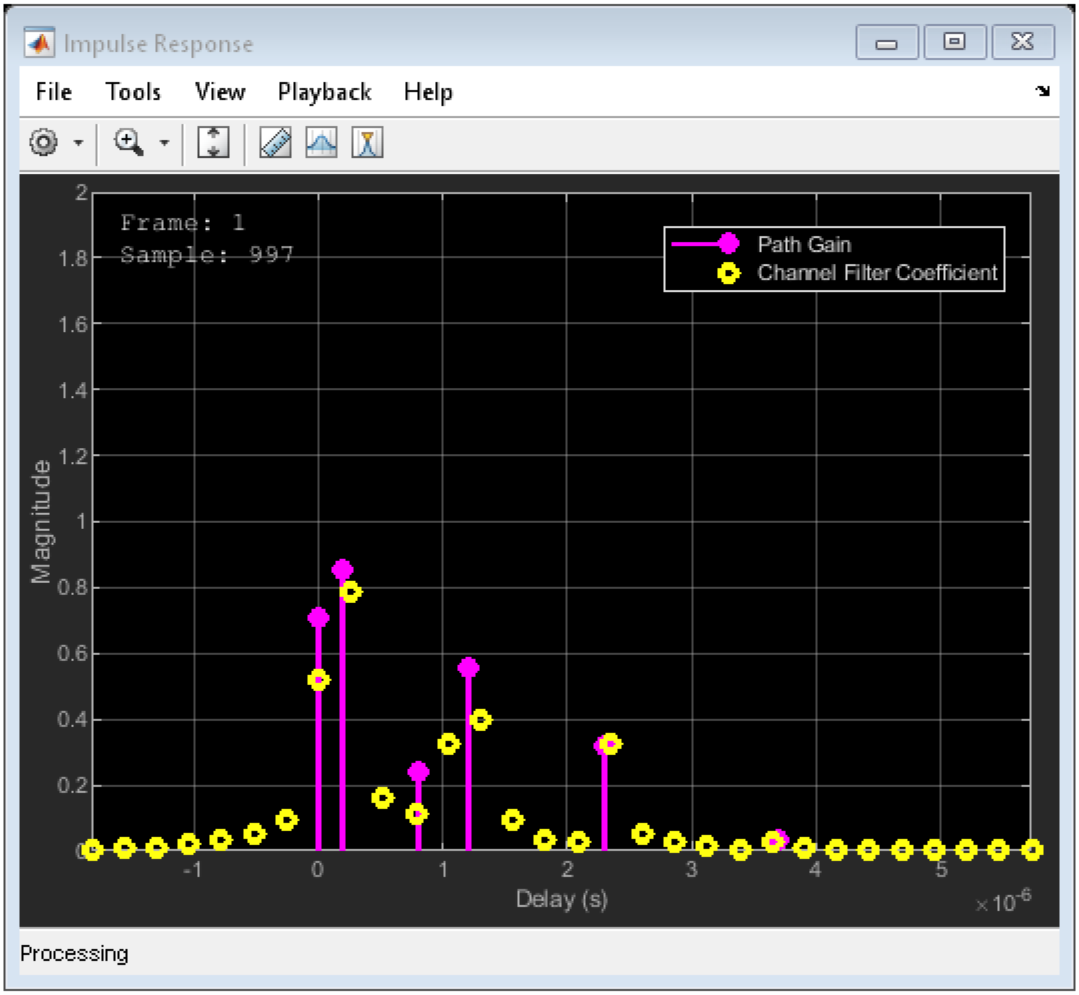
Create a multipath Rician fading channel System object by using the previously defined properties and to visualize the impulse response and frequency response plots.

```
ricianChan = comm.RicianChannel('SampleRate',fs, ...
    'PathDelays',pathDelays, ...
    'AveragePathGains',avgPathGains, ...
    'KFactor',10, ...
    'MaximumDopplerShift',fD, ...
    'Visualization','Impulse and frequency responses');
```

Generate random binary data and pass it through the multipath Rician fading channel. The impulse response plot enables you to identify the individual paths and their corresponding filter coefficients. The frequency response plot shows the frequency-selective nature of the ITU pedestrian B channel.

```
x = randi([0 1],1000,1);
y = ricianChan(x);
```





Model a Rician Channel Using Sum-of-Sinusoids Technique

The example shows how the channel state is maintained in cases in which data is discontinuously transmitted. Create a Rician channel object and pass data through it using the sum-of-sinusoids technique.

Set the channel properties.

```
fs = 1000; % Sample rate (Hz)
pathDelays = [0 2.5e-3]; % Path delays (s)
pathPower = [0 -6]; % Path power (dB)
fD = 5; % Maximum Doppler shift (Hz)
ns = 1000; % Number of samples
nsdel = 100; % Number of samples for delayed paths
```

Define the overall simulation time and three time segments for which data is to be transmitted. In this case, the channel is simulated for 1s with a 1000 Hz sampling rate. One 1000-sample continuous data sequence is transmitted at time 0. Three 100-sample data packets are transmitted at times 0.1 s, 0.5 s, and 0.8 s, respectively.

```
to0 = 0.0;
to1 = 0.1;
to2 = 0.5;
to3 = 0.8;
t0 = (to0:ns-1)/fs;      % Transmission 0
t1 = to1+(0:nsdel-1)/fs; % Transmission 1
t2 = to2+(0:nsdel-1)/fs; % Transmission 2
t3 = to3+(0:nsdel-1)/fs; % Transmission 3
```

Generate random binary data corresponding to the previously defined time intervals.

```
d0 = randi([0 1],ns,1);
d1 = randi([0 1],nsdel,1);
d2 = randi([0 1],nsdel,1);
d3 = randi([0 1],nsdel,1);
```

Create a frequency-flat multipath Rician fading System object, specifying the sum-of-sinusoids fading technique. So that results can be repeated, specify a seed value. Use the default `InitialTime` property setting so that the fading channel will be simulated from time 0. Enable the path gains output.

```
ricianchan1 = comm.RicianChannel('SampleRate',fs, ...
    'MaximumDopplerShift',5, ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',17, ...
    'FadingTechnique','Sum of sinusoids', ...
    'PathGainsOutputPort',true);
```

Create a clone of the multipath Rician fading channel System object. Set the source for initial time so that the fading channel offset time can be specified as an input argument when using the System object.

```
ricianchan2 = clone(ricianchan1);
ricianchan2.InitialTimeSource = 'Input port';
```

Pass random binary data through the first multipath Rician fading channel System object, `ricianchan1`. Data is transmitted over all 1000 time samples. For this example, only the complex path gain is needed.

```
[~,pg0] = ricianchan1(d0);
```

Pass random data through the second multipath Rician fading channel System object, `ricianchan2`, where the initial time offsets are provided as input arguments.

```
[~,pg1] = ricianchan2(d1,to1);
[~,pg2] = ricianchan2(d2,to2);
[~,pg3] = ricianchan2(d3,to3);
```

Compare the number of samples processed by the two channels by using the `info` object function. The `ricianchan1` object processed 1000 samples, while the `ricianhan2` object only processed 300 samples.

```
G = info(ricianchan1);
H = info(ricianchan2);
[G.NumSamplesProcessed H.NumSamplesProcessed]
```

```
ans = 1×2
```

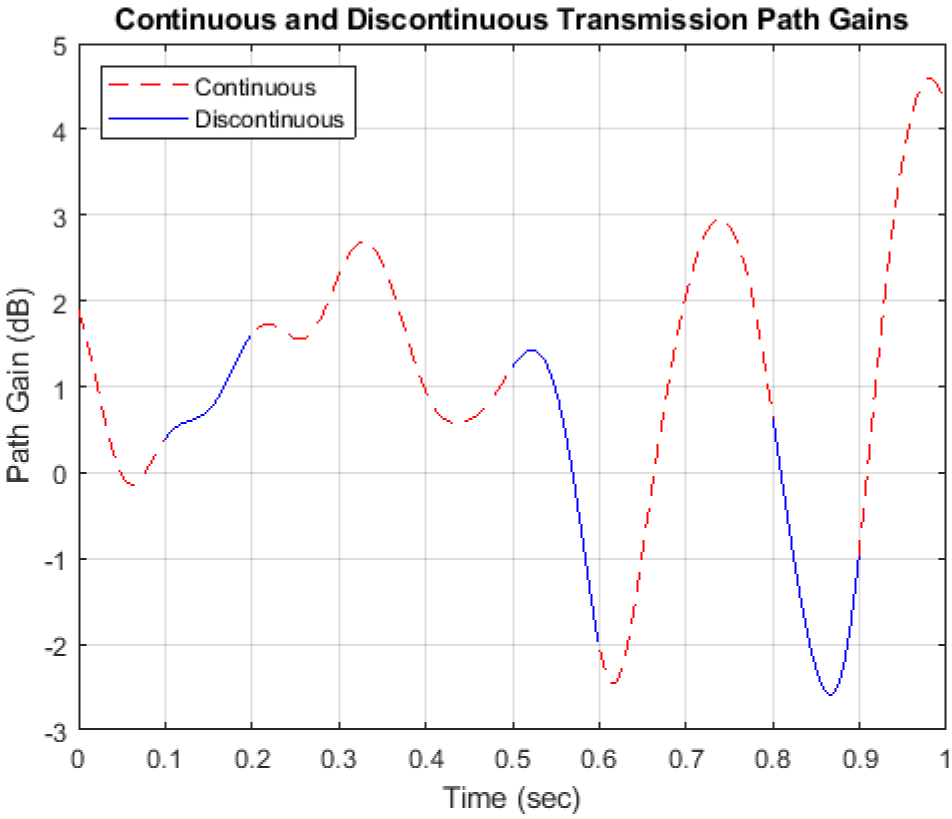
```
        1000         300
```

Convert the path gains into decibels.

```
pathGain0 = 20*log10(abs(pg0));
pathGain1 = 20*log10(abs(pg1));
pathGain2 = 20*log10(abs(pg2));
pathGain3 = 20*log10(abs(pg3));
```

Plot the path gains for the continuous and discontinuous cases. The gains for the three segments match the gain for the continuous case. The alignment of the two highlights that the sum-of-sinusoids technique is suited to the simulation of packetized data, as the channel characteristics are maintained even when data is not transmitted.

```
plot(t0,pathGain0,'r--')
hold on
plot(t1,pathGain1,'b')
plot(t2,pathGain2,'b')
plot(t3,pathGain3,'b')
grid
xlabel('Time (sec)')
ylabel('Path Gain (dB)')
legend('Continuous','Discontinuous','location','nw')
title('Continuous and Discontinuous Transmission Path Gains')
```



Use Info Method to Reproduce Multipath Rican Fading Channel Response

The example show how to use the `ChannelFilterCoefficients` property returned by the `info` object function of the `comm.RicianChannel` System object to reproduce the multipath Rician fading channel output.

Create a multipath Rician fading channel System object, defining two paths and specifying data to pass through the channel.

```
ricianchan = comm.RicianChannel('SampleRate',1000,'PathDelays',[0 1e-3], ...
    'AveragePathGains',[0 -2],'PathGainsOutputPort',true)
```

```
ricianchan = 
  comm.RicianChannel with properties:

                SampleRate: 1000
                PathDelays: [0 1.0000e-03]
          AveragePathGains: [0 -2]
        NormalizePathGains: true
                   KFactor: 3
    DirectPathDopplerShift: 0
    DirectPathInitialPhase: 0
       MaximumDopplerShift: 1.0000e-03
           DopplerSpectrum: [1x1 struct]

  Show all properties
```

```
data = randi([0 1],600,1);
```

Pass data through the channel. Assign the `ChannelFilterCoefficients` property value to the variable `coeff`.

```
[chanout1,pg] = ricianchan(data);
chaninfo = info(ricianchan)
```

```
chaninfo = struct with fields:
           ChannelFilterDelay: 0
    ChannelFilterCoefficients: [2x2 double]
          NumSamplesProcessed: 600
```

```
coeff = chaninfo.ChannelFilterCoefficients;
```

Calculate the fractional delayed input signal at the path delay locations stored in `coeff`.

```
Np = length(ricianchan.PathDelays);
fracdelaydata = zeros(size(data,1),Np);
for ii = 1:Np
    fracdelaydata(:,ii) = filter(coeff(ii,:),1,data);
end
```

Apply the path gains and sum the results for all paths.

```
chanout2 = sum(pg .* fracdelaydata,2);
```

Compare the output of the multipath Rician fading channel System object to the output reproduced using the path gains and the `ChannelFilterCoefficients` property of the multipath Rician fading channel System object.

```
isequal(chanout1,chanout2)

ans = logical
   1
```

More About

Cutoff Frequency Factor

The cutoff frequency factor, f_c, is determined for different Doppler spectrum types.

- For any Doppler spectrum type other than Gaussian and biGaussian, f_c equals 1.
- For a `doppler('Gaussian')` spectrum type, f_c equals `NormalizedStandardDeviation` × $\sqrt{2\log 2}$.
- For a `doppler('BiGaussian')` spectrum type:
  - If the `PowerGains(1)` and `NormalizedCenterFrequencies(2)` field values are both `0`, then f_c equals `NormalizedStandardDeviation(1)` × $\sqrt{2\log 2}$.
  - If the `PowerGains(2)` and `NormalizedCenterFrequencies(1)` field values are both `0`, then f_c equals `NormalizedStandardDeviation(2)` × $\sqrt{2\log 2}$.
  - If the `NormalizedCenterFrequencies` field value is `[0,0]` and the `NormalizedStandardDeviation` field has two identical elements, then f_c equals `NormalizedStandardDeviation(1)` × $\sqrt{2\log 2}$.
  - In all other cases, f_c equals 1.

Channel Visualization

The `comm.RicianChannel` System object enables visualization of the channel impulse response, frequency response, and Doppler spectrum.

Note

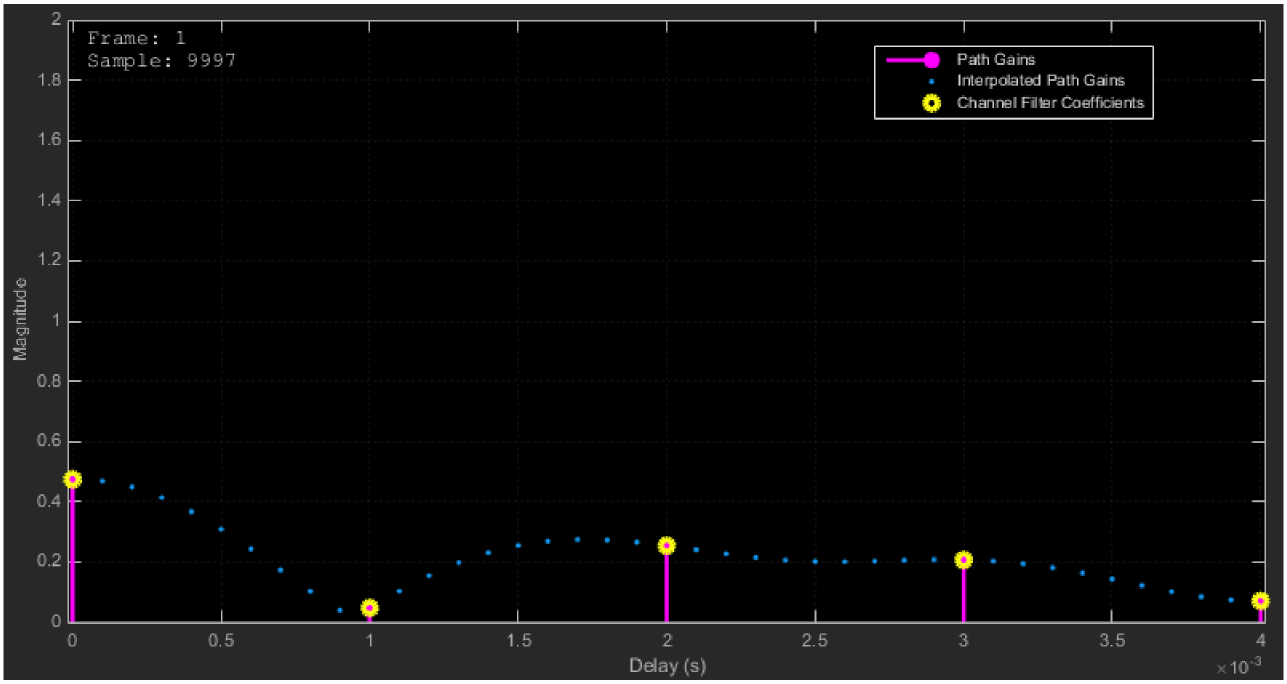
- The displayed and specified path gain locations can differ by as much as 5% of the input sample time.
- The visualization display speed is controlled by the combination of the `SamplesToDisplay` property and the **Playback > Reduce Updates to Improve Performance** scope menu item. Reducing the percentage of samples to display and enabling reduced updates can speed up the rendering of the visualization scope.
- After the visualization scopes are manually closed, calls to the System object are executed at its normal speed.
- Code generation is available only when the `Visualization` property is set to `'Off'`.

Impulse Response

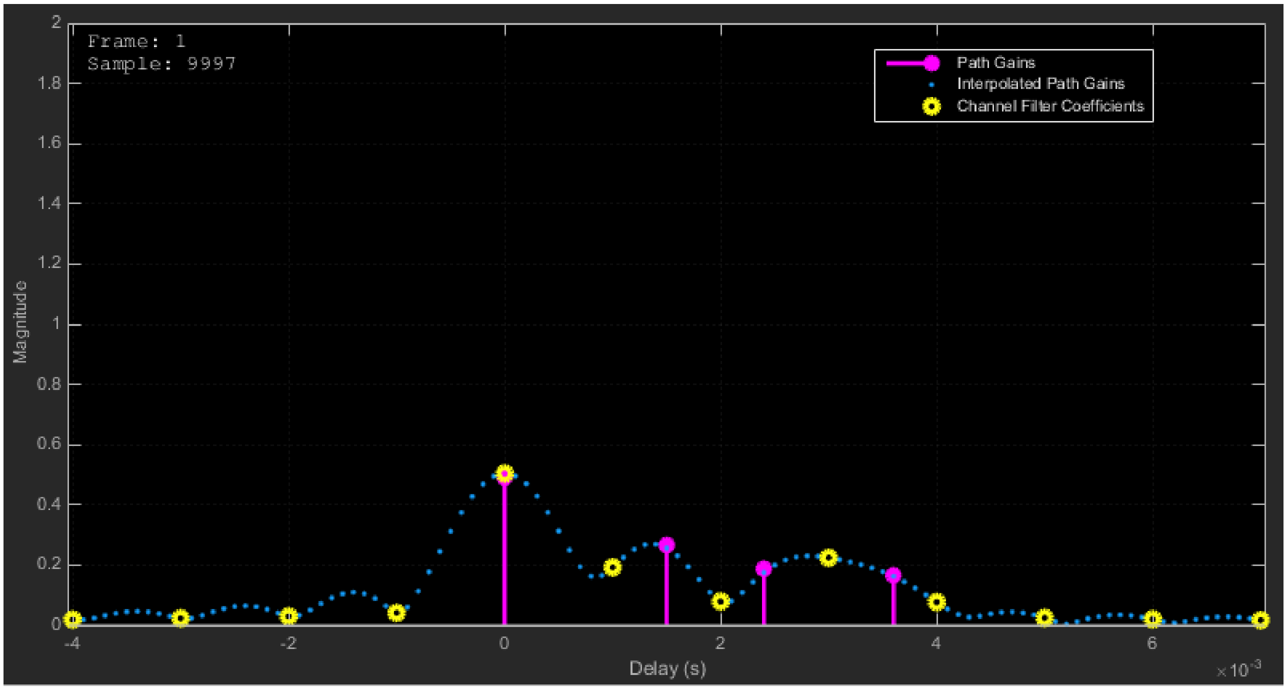
The impulse response scope displays the path gains, channel filter coefficients, and interpolated path gains. The path gains occur at time instances which correspond to the specified `PathDelays` property and might not be aligned with the input sampling time. The channel filter coefficients are used to model the channel. They are interpolated from the actual path gains and are aligned with the input sampling time. In cases in which the path gains are aligned with the sampling time, the path gains overlap the filter coefficients. Sinc interpolation is used to connect the channel filter coefficients and is shown as the interpolated path gains. These points are used solely for display purposes and not used in subsequent channel filtering. For a flat fading channel (one path), the sinc interpolation curve is not displayed. For all impulse response plots, the frame and sample numbers are shown in the upper-left corner of the scope.

The impulse response plot shares the same toolbar and menus as the `dsp.ArrayPlot` System object.

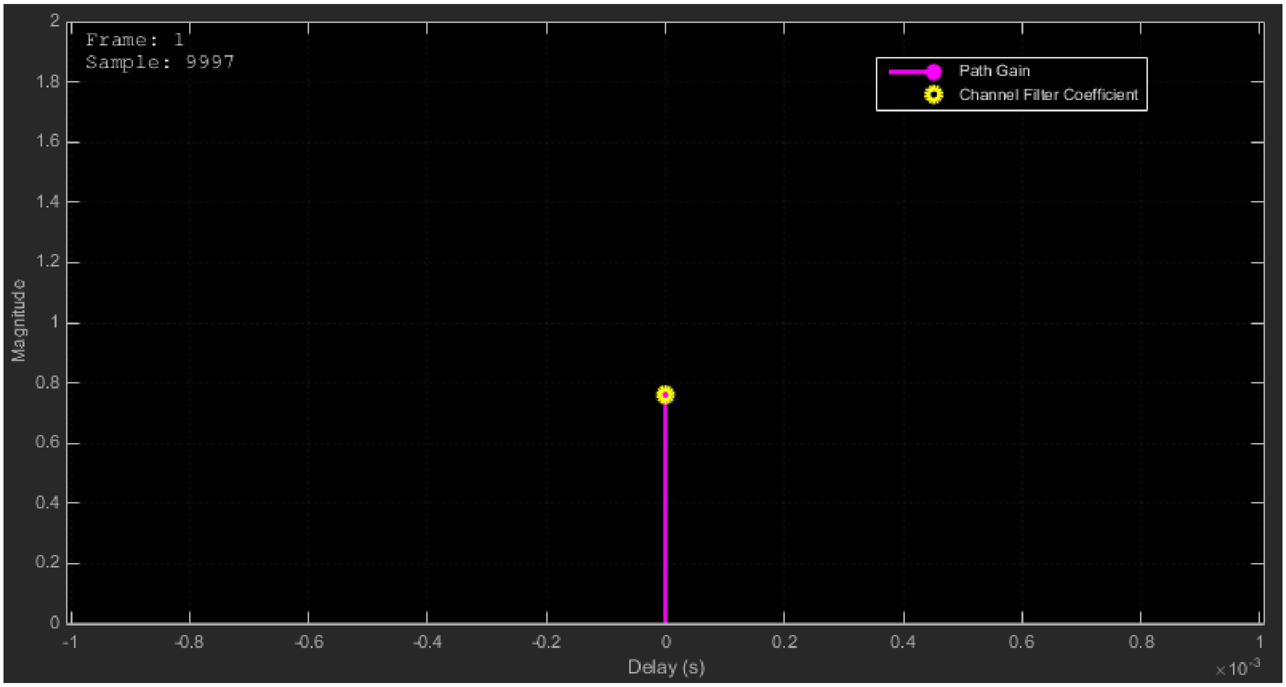
When the specified path gains align with the sample rate, the path gains and the channel filter coefficients overlap. In this figure the impulse response shows the path gains overlap the filter coefficients.



If the specified path gains are not aligned with the sample rate, the path gains and the channel filter coefficients do not overlap. In this figure, the filter coefficients are equally distributed. The path gains do not overlap with the channel filter coefficients because the path gains are not aligned with the sample rate.



This figure shows the impulse response for a frequency-flat channel. In this case, the interpolated path gains are not displayed.



Frequency response

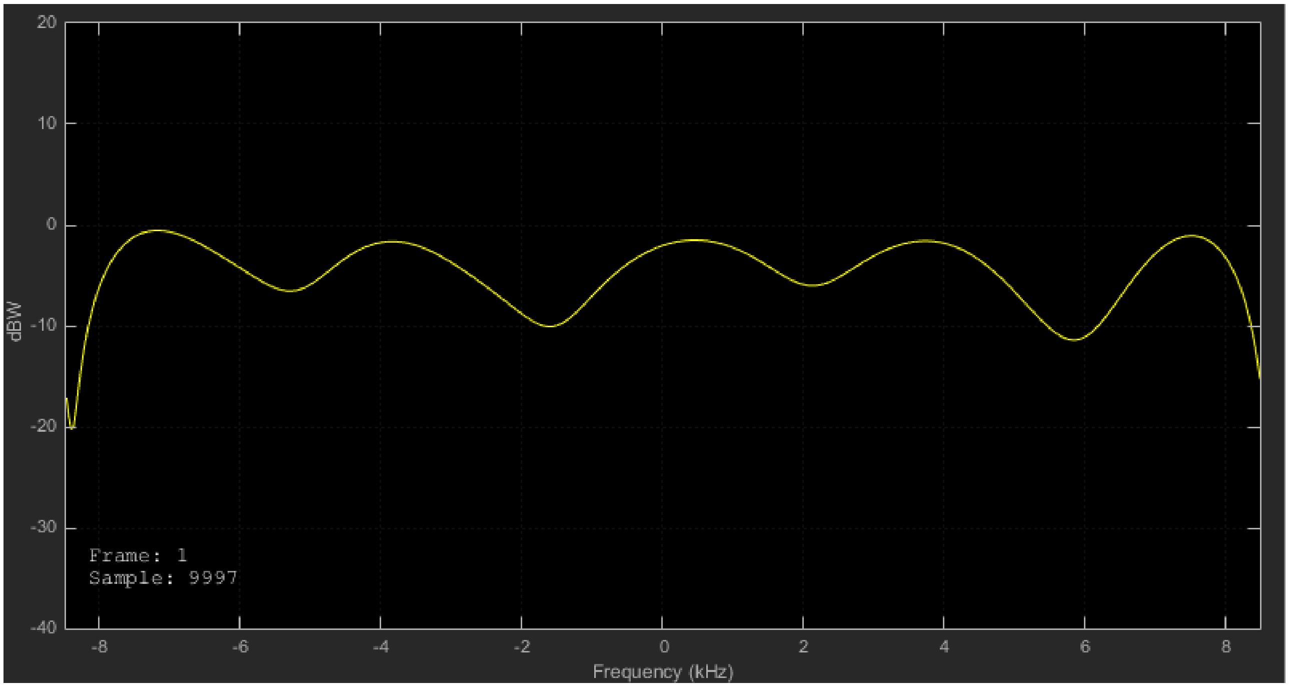
The frequency response scope displays the multipath Rayleigh fading channel spectrum by taking a discrete Fourier transform of the channel filter coefficients. The frequency response plot shares the same toolbar and menus as the `dsp.SpectrumAnalyzer` System object.

The y-axis limits of the plot are computed based on the `NormalizePathGains` and `AveragePathGains` properties of the `comm.RicianChannel` System object.

This table shows other selected default spectrum settings. These settings can be changed from their default values by using the **View > Spectrum Settings** menu.

Spectrum Settings	Value
Main options>Type	`Power`
Main options>Window length	Channel filter length
Main options>NFFT	`512`
Window options>Window	`Rectangular`
Trace options>Units	`dBW`

This figure shows the frequency response plot for a frequency selective channel.



Doppler Spectrum

The Doppler spectrum plot displays the theoretical Doppler spectrum and the empirically determined data points. The theoretical data is displayed as a line for the case of nonstatic channels and as a point for static channels. The empirical data is shown as * symbols. Before the empirical plot is updated, the internal buffer must be completely filled with filtered Gaussian samples. The empirical plot is the running mean of the spectrum calculated from each full buffer. For nonstatic channels, the number of input samples needed before the next update is displayed in the upper-left corner of the plot. The number of samples needed is a function of the sample rate and the maximum Doppler shift. For static channels, the text "`Reset fading channel for next update`" is displayed.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- To generate C code, set the `DopplerSpectrum` property to a single Doppler spectrum structure.
- Code generation is available only when the `Visualization` property is `'Off'`.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

comm.RSDecoder

Package: `comm`

Decode data using Reed-Solomon decoder

Description

The `RSDecoder` object recovers a message vector from a Reed-Solomon codeword vector. For proper decoding, the property values for this object should match the property values in the corresponding RS Encoder object.

To decode data using a Reed-Solomon decoding scheme:

1. Define and set up your Reed-Solomon decoder object. See “Construction” on page 3-1319.
2. Call `step` to decode data according to the properties of `comm.RSDecoder`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`dec = comm.RSDecoder` creates a block decoder System object, `dec`. This object performs Reed-Solomon (RS) decoding.

`dec = comm.RSDecoder(N,K)` creates an RS decoder object, `dec` with the `CodewordLength` property set to `N` and the `MessageLength` property set to `K`.

`dec = comm.RSDecoder(N,K,GP)` creates an RS decoder object, `dec` with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, and the `GeneratorPolynomial` property set to `GP`.

`dec = comm.RSDecoder(N,K,GP,S)` creates an RS decoder object, `dec` with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, the `GeneratorPolynomial` property set to `GP`, and the `ShortMessageLength` property set to `S`.

`dec = comm.RSDecoder(N,K,GP,S,Name,Value)` creates an RS decoder object, `dec` with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, the `GeneratorPolynomial` property set to `GP`, and each specified property `Name` set to the specified `Value`.

`dec = comm.RSDecoder(Name,Value)` creates an RS decoder object, `dec`, with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

Note The input and output signal lengths are listed in “Input and Output Signal Lengths in BCH and RS System Objects” on page 3-91 on the `comm.BCHDecoder` reference page.

`BitInput`

Assume that input is bits

Specify whether the input comprises bits or integers. The default is `false`.

When you set this property to `false`, the `step` method input data value must be a numeric, column vector of integers. The `step` method outputs an encoded data output vector. The output result is a column vector of integers. Each symbol that forms the input message and output codewords is an integer between 0 and $2^M - 1$. These integers correspond to an element of the finite Galois field `gf`(2^M). M is the degree of the primitive polynomial that you specify with the `PrimitivePolynomialSource` on page 3-0 and `PrimitivePolynomial` on page 3-0 properties.

When you set this property to `true`, the input value must be a numeric, column vector of bits. The encoded data output result is a column vector of bits.

`CodewordLength`

Codeword length

Specify the codeword length of the RS code in symbols as a double-precision, positive, integer scalar value. The default is `7`.

For a full-length RS code, the value of this property must be $2^M–1$, where M is an integer such that $3 \leq M \leq 16$.

`MessageLength`

Message length

Specify the message length in symbols as a double-precision positive integer scalar value. The default is `3`.

`ShortMessageLengthSource`

Short message length source

Specify the source of the shortened message as `Auto` or `Property`. When this property is set to `Auto`, the RS code is defined by the `CodewordLength` on page 3-0 , `MessageLength` on page 3-0 , `GeneratorPolynomial` on page 3-0 , and `PrimitivePolynomial` on page 3-0 properties.

When `ShortMessageLengthSource` is set to `Property`, you must specify the `ShortMessageLength` on page 3-0 property, which is used with the other properties to define the RS code. The default is `Auto`.

ShortMessageLength

Shortened message length

Specify the length of the shortened message in symbols as a double-precision positive integer scalar whose value must be less than or equal to `MessageLength` on page 3-0 .

When `ShortMessageLength` < `MessageLength`, the RS code is shortened. The default is `3`.

GeneratorPolynomialSource

Source of generator polynomial

Specify the source of the generator polynomial as `Auto` or `Property`. The default is `Auto`.

When you set this property to `Auto`, the object chooses the generator polynomial automatically. The object calculates the generator polynomial based on the value of the `PrimitivePolynomialSource` on page 3-0 property.

When you set this property to `Auto`, the object automatically chooses the generator polynomial. The object calculates the generator polynomial based on the value of the `PrimitivePolynomial` on page 3-0 property.

When you set this property to Property, you must specify a generator polynomial using the `GeneratorPolynomial` on page 3-0 property.

GeneratorPolynomial

Generator polynomial

Specify the generator polynomial for the RS code as a double-precision integer row vector or as a Galois field row vector whose entries are in the range from 0 to 2^M–1 and represent a generator polynomial in descending order of powers. The length of the generator polynomial must be `CodewordLength`-`MessageLength`+1. This property applies when you set `GeneratorPolynomialSource` on page 3-0 to `Property`.

The default is the result of `rsgenpoly(7,3,[],[],'double')`, which corresponds to `[1 3 1 2 3]`.

When you use this object to generate code, you must set the generator polynomial to a double-precision integer row vector.

CheckGeneratorPolynomial

Enable generator polynomial checking

Set this property to `true` to perform a generator polynomial check. The default is `true`. This check verifies that the specified generator polynomial is valid.

For larger codes, disabling the check accelerates processing time. As a best practice, perform the check at least once before setting this property to `false`. This property applies when you set `GeneratorPolynomialSource` on page 3-0 to `Property`.

PrimitivePolynomialSource

Source of primitive polynomial

Specify the source of the primitive polynomial as `Auto` or `Property`. The default is `Auto`.

When you set this property to `Auto`, the object uses a primitive polynomial of degree M = `ceil`(log2(`CodewordLength` on page 3-0 +1)).

When you set`PrimitivePolynomialSource` to `Property`, you must specify a polynomial using `PrimitivePolynomial` on page 3-0 .

`PrimitivePolynomial`

Primitive polynomial

Specify the primitive polynomial that defines the finite field `gf`(2^M) corresponding to the integers that form messages and codewords. The default is the result of `fliplr`(`de2bi`(`primpoly`(*3*))), which is `[1 0 1 1]` or the polynomial $x^3 + x + 1$. Specify this property as a double-precision, binary, row vector that represents a primitive polynomial over `gf`(2) of degree M in descending order of powers. This property applies when you set `PrimitivePolynomialSource` on page 3-0 to `Property`.

`PuncturePatternSource`

Source of puncture pattern

Specify the source of the puncture pattern as `None` or `Property`. The default is `None`.

If you set this property to `None`, the object does not apply puncturing to the code. If you set it to `Property`, the object punctures the code based on a puncture pattern vector specified in `PuncturePattern` on page 3-0 .

`PuncturePattern`

Puncture pattern vector

Specify the pattern used to puncture the encoded data as a double-precision, binary column vector of length (`CodewordLength` on page 3-0 -`MessageLength` on page 3-0). The default is `[ones(2,1); zeros(2,1)]`. Zeros in the puncture pattern vector indicate the position of the parity symbols that are punctured or excluded from each codeword. This property applies when you set `PuncturePatternSource` on page 3-0 to `Property`.

`ErasuresInputPort`

Enable erasures input

Set this property to `true` to specify a vector of erasures as an input to the `step` method. The default is `false`. The erasures input must be a double-precision or logical binary column vector that indicates which symbols of the input codewords to erase.

The length of the erasures vector is explained in “Input and Output Signal Lengths in BCH and RS System Objects” on page 3-91.

When this property is set to `false`, the object assumes no erasures.

`NumCorrectedErrorsOutputPort`

Enable number of corrected errors output

Set this property to `true` to obtain the number of corrected errors as an output to the `step` method. The default is `true`. A nonnegative value in the *i*-th element of the error output vector, denotes the number of corrected errors in the *i*-th input codeword. A value of `-1` in the *i*-th element of the error output vector indicates that a decoding error occurred for that codeword. A decoding error occurs when an input codeword has more errors than the error correction capability of the RS code.

`OutputDataType`

Data type of output

Specify the output data type as `Same as input`, `double`, or `logical`. The default is `Same as input`. This property applies when you set `BitInput` on page 3-0 to `true`.

Methods

step	Decode data using a Reed-Solomon decoder

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Transmit an RS-encoded, 8-DPSK-modulated symbol stream

Transmit an RS-encoded, 8-DPSK-modulated symbol stream through an AWGN channel. Then, demodulate, decode, and count errors.

```
    enc = comm.RSEncoder;
    mod = comm.DPSKModulator('BitInput',false);
    chan = comm.AWGNChannel(...
                'NoiseMethod','Signal to noise ratio (SNR)','SNR',10);
    demod = comm.DPSKDemodulator('BitOutput',false);
    hDdecec = comm.RSDecoder;
    errorRate = comm.ErrorRate('ComputationDelay',3);

    for counter = 1:20
      data = randi([0 7], 30, 1);
      encodedData = step(enc, data);
      modSignal = step(mod, encodedData);
      receivedSignal = step(chan, modSignal);
      demodSignal = step(demod, receivedSignal);
      receivedSymbols = step(hDdecec, demodSignal);
      errorStats = step(errorRate, data, receivedSymbols);
    end

  fprintf('Error rate = %f\nNumber of errors = %d\n', ...
      errorStats(1), errorStats(2))
```

```
Error rate = 0.115578
Number of errors = 69
```

Estimate BER of 8-PSK in AWGN with Reed-Solomon Coding

Transmit Reed-Solomon encoded data using 8-PSK over an AWGN channel. Demodulate and decode the received signal and collect error statistics. Plot the bit error rate estimate.

Define the example parameters.

```
M = 8;  % Modulation order
bps = log2(M); % Bits per symbol
N = 7; % RS codeword length
K = 5; % RS message length
```

Create modulator, demodulator, AWGN channel, and error rate objects.

```
pskModulator = comm.PSKModulator('ModulationOrder',M,'BitInput',true);
pskDemodulator = comm.PSKDemodulator('ModulationOrder',M,'BitOutput',true);
awgnChannel = comm.AWGNChannel('BitsPerSymbol',bps);
errorRate = comm.ErrorRate;
```

Create a (7,5) Reed-Solomon encoder and decoder pair which accepts bit inputs.

```
rsEncoder = comm.RSEncoder('BitInput',true,'CodewordLength',N,'MessageLength',K);
rsDecoder = comm.RSDecoder('BitInput',true,'CodewordLength',N,'MessageLength',K);
```

Set the range of E_b/N_0 values. Initialize the error statistics matrix.

```
ebnoVec = (3:0.5:8)';
errorStats = zeros(length(ebnoVec),3);
```

Estimate the bit error rate for each E_b/N_0 value. The simulation runs until either 100 errors or 10^7 bits is encountered. The main simulation loop processing includes encoding, modulation, demodulation, and decoding.

```
for i = 1:length(ebnoVec)
    awgnChannel.EbNo = ebnoVec(i);
    reset(errorRate)
    while errorStats(i,2) < 100 && errorStats(i,3) < 1e7
        data = randi([0 1],1500,1); % Generate binary data
        encData = rsEncoder(data); % RS encode
        modData = pskModulator(encData); % Modulate
        rxSig = awgnChannel(modData); % Pass signal through AWGN
        rxData = pskDemodulator(rxSig); % Demodulate
        decData = rsDecoder(rxData); % RS decode
        errorStats(i,:) = errorRate(data,decData); % Collect error statistics
    end
end
```

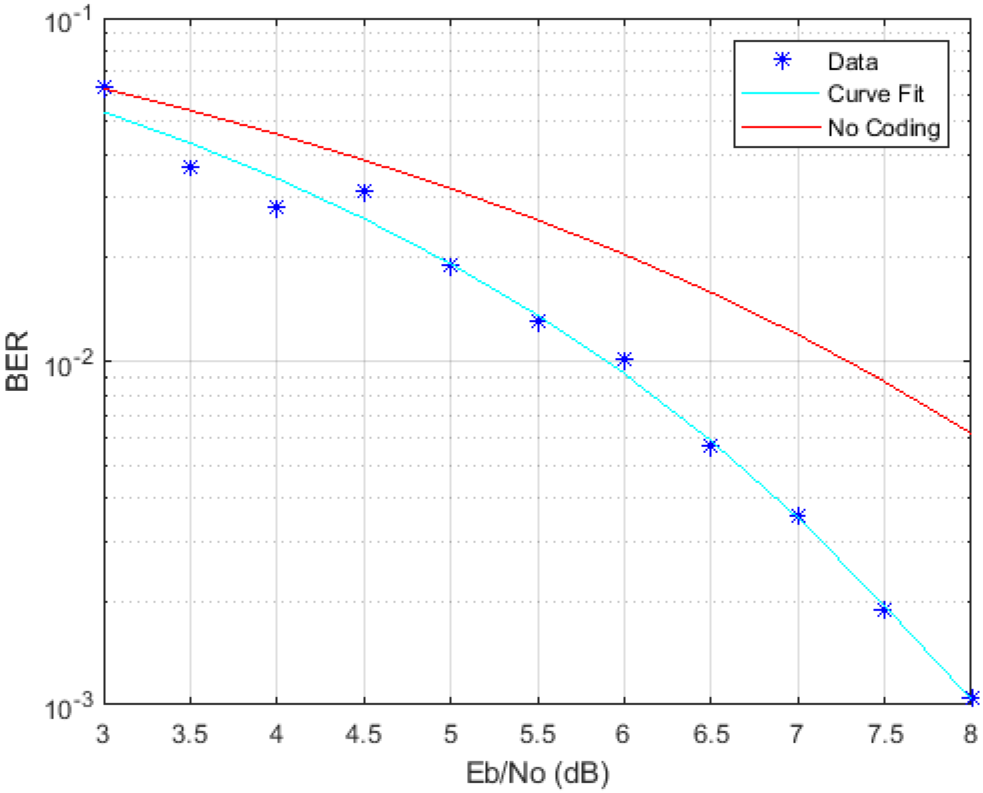
Fit a curve to the BER data using `berfit`. Generate an estimate of 8-PSK performance without coding using the `berawgn` function.

```
berCurveFit = berfit(ebnoVec,errorStats(:,1));
berNoCoding = berawgn(ebnoVec,'psk',8,'nondiff');
```

Plot the BER data, the BER curve fit, and the estimated performance without RS coding.

```
semilogy(ebnoVec,errorStats(:,1),'b*', ...
ebnoVec,berCurveFit,'c-',ebnoVec,berNoCoding,'r')
ylabel('BER')
```

```
xlabel('Eb/No (dB)')
legend('Data','Curve Fit','No Coding')
grid
```



The (7,5) RS code improves the E_b/N_0 required to achieve a 10^{-2} bit error rate by, approximately, 1.4 dB.

Transmit a Shortened RS-encoded, 256-QAM-modulated Symbol Stream

Transmit a shortened RS-encoded, 256-QAM-modulated symbol stream through an AWGN channel. Then demodulate, decode, and count errors.

Set the parameters for the Reed-Solomon code, where N is the codeword length, K is the nominal message length, and S is the shortened message length. Set the modulation order, M, and the number of frames, L.

```
N = 255;
K = 239;
S = 188;
M = 256;
L = 50;
```

Create an AWGN channel System object and an error rate System object.

```
awgnChan = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (Eb/No)', ...
    'EbNo',15,'BitsPerSymbol',log2(M));
errorRate = comm.ErrorRate('ComputationDelay',3);
```

Create the Reed-Solomon generator polynomial from the DVB-T standard.

```
gp = rsgenpoly(N,K,[],0);
```

Create a Reed-Solomon encoder and decoder pair using the shortened message length, `S`, and the DVB-T generator polynomial, `gp`.

```
enc = comm.RSEncoder(N,K,gp,S);
dec = comm.RSDecoder(N,K,gp,S);
```

Generate random symbol frames whose length equals one message block. Encode, modulate, apply AWGN, demodulate, decode, and collect statistics.

```
for counter = 1:L
    data = randi([0 1],S,log2(M));
    encodedData = step(enc,bi2de(data));
    modSignal = qammod(encodedData,M,'UnitAveragePower',true);
    rxSignal = awgnChan(modSignal);
    demodSignal = qamdemod(rxSignal,M,'UnitAveragePower',true);
    rxBits = dec(demodSignal);
    dataOut = de2bi(rxBits);
    errorStats = errorRate(data(:),dataOut(:));
end
```

Display the error rate and number of errors.

```
fprintf('Error rate = %5.2e\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

```
Error rate = 2.01e-02
Number of errors = 1509
```

Reed-Solomon Coding with Erasures

This example shows how to configure the `comm.RSEncoder` and `comm.RSDecoder` System objects to perform Reed-Solomon (RS) block coding with erasures when simulating a communications system. RS decoders can correct both errors and erasures. A receiver that identifies the most unreliable symbols in a given codeword can generate erasures. When a receiver erases a symbol, it replaces that symbol with a zero. The receiver then passes a flag to the decoder, indicating that the symbol is an erasure, not a valid code symbol. In addition, an encoder can generate punctures for which specific parity symbols are always removed from its output. The decoder, which knows the puncture pattern, inserts zeros in the puncture positions and treats those symbols as erasures. The decoder treats encoder-generated punctures and receiver-generated erasures the exact same way when it decodes a symbol. Puncturing also has the added benefit of making the code rate more flexible, at the expense of some error correction capability. Shortened codes achieve the same code rate flexibility without degrading the error correction performance, given the same demodulator input energy per bit to noise power spectral density ratio (Eb/N0). Note that puncturing is the removal of parity symbols from a codeword, and shortening is the removal of message symbols from a codeword.

This example shows the simulation of a communication system consisting of a random source, an RS encoder, a 64-QAM modulator, an AWGN channel, a 64-QAM demodulator, and an RS decoder. It includes analysis of RS coding with erasures by comparing the channel bit error rate (BER) performance versus the coded BER performance. This example obtains Channel BER by comparing inputs for the QAM modulator to outputs from the QAM demodulator and obtains Coded BER by comparing inputs for the RS encoder to outputs from the RS decoder.

Initialization

The helperRSCodingConfig.m helper function initializes simulation parameters, and configures the `comm.AWGNChannel` and `comm.ErrorRate` System objects used to simulate the communications system. The uncoded Eb/N0 ratio is set EbNoUncoded = 15 dB. Criteria to stop the simulation stop are defined to stop the simulation if 500 errors occur or a maximum 5e6 bits are transmitted.

```
helperRSCodingConfig;
```

Configure RS Encoder/Decoder

This example uses a (63,53) RS code operating with a 64-QAM modulation scheme. This code can correct (63-53)/2 = 5 errors, or it can alternatively correct (63-53) = 10 erasures. For each codeword at the output of the 64-QAM demodulator, the receiver determines the six least reliable symbols using the helperRSCodingGetErasures.m helper function. The indices that point to the location of these unreliable symbols are passed as an input to the RS decoder. The RS decoder treats these symbols as erasures resulting in an error correction capability of (10-6)/2 = 2 errors per codeword.

Create a `comm.RSEncoder` System object and set the `BitInput` property to false to specify that the encoder inputs and outputs are integer symbols.

```
N = 63;  % Codeword length
K = 53;  % Message length
rsEncoder = comm.RSEncoder(N,K,'BitInput',false);
numErasures = 6;
```

Create a `comm.RSDecoder` System object matching the configuration of the `comm.RSEncoder` object.

```
rsDecoder = comm.RSDecoder(N,K,'BitInput',false);
```

Set the `ErasuresInputPort` property to true to specify erasures as an input to the decoder object.

```
rsDecoder.ErasuresInputPort = true;
```

Set the `NumCorrectedErrorsOutputPort` property to true so that the decoder outputs the number of corrected errors. A non negative value in the error output denotes the number of corrected errors in the input codeword. A value of –1 in the error output indicates a decoding error. A decoding error occurs when the input codeword has more errors than the error correction capability of the RS code.

```
rsDecoder.NumCorrectedErrorsOutputPort = true;
```

Run Stream Processing Loop

Simulate the communications system for an uncoded Eb/N0 ratio of 15 dB. The uncoded Eb/N0 is the ratio that would be measured at the input of the channel if there was no coding in the system.

The signal going into the AWGN channel is the encoded signal, so you must convert the uncoded Eb/N0 values so that they correspond to the energy ratio at the encoder output. This ratio is the coded Eb/N0 ratio. If you input K symbols to the encoder and obtain N output symbols, then the energy relation is given by the K/N rate. Set the `EbNo` property of the AWGN channel object to the computed coded Eb/N0 value.

```
EbNoCoded = EbNoUncoded + 10*log10(K/N);
channel.EbNo = EbNoCoded;
```

Loop until the simulation reaches the target number of errors or the maximum number of transmissions.

```
chanErrorStats = zeros(3,1);
codedErrorStats = zeros(3,1);
correctedErrors = 0;
while (codedErrorStats(2) < targetErrors) && ...
        (codedErrorStats(3) < maxNumTransmissions)
```

The data symbols transmit one message word at a time. Each message word has K symbols in the [0 N] range.

```
    data = randi([0 N],K,1);
```

Encode the message word. The encoded word, `encData`, is `(N-numPunc)` symbols long.

```
    encData = rsEncoder(data);
```

Modulate encoded data and add noise. then demodulate channel output.

```
    modData = qammod(encData,M);
    chanOutput = channel(modData);
    demodData = qamdemod(chanOutput,M);
```

Use the helperRSCodingGetErasures.m helper function to find the 6 least reliable symbols and generate an erasures vector. The length of the erasures vector must be equal to the number of symbols in the demodulated codeword. A one in the ith element of the vector erases the ith symbol in the codeword. Zeros in the vector indicate no erasures.

```
    erasuresVec = helperRSCodingGetErasures(chanOutput,numErasures);
```

Decode the data. Accumulate the number of corrected errors using the cumulative sum object.

```
    [estData,errs] = rsDecoder(demodData,erasuresVec);
    if (errs >= 0)
        correctedErrors = cumulativeSum(errs);
    end
```

When computing the channel and coded BERs, convert integers to bits.

```
    chanErrorStats(:,1) = ...
        chanBERCalc(reshape(de2bi(encData,log2(M))',[],1),reshape(de2bi(demodData,log2(M))',[],1
    codedErrorStats(:,1) = ...
        codedBERCalc(reshape(de2bi(data,log2(M))',[],1),reshape(de2bi(estData,log2(M))',[],1));
end
```

The error rate measurement objects, `chanBERCalc` and `codedBERCalc`, output 3-by-1 vectors containing BER measurement updates, the number of errors, and the total number of bit transmissions. Display the channel BER, the coded BER and the total number of errors corrected by the RS decoder.

```
chanBitErrorRate = chanErrorStats(1)
```

```
chanBitErrorRate = 0.0017
```

```
codedBitErrorRate = codedErrorStats(1)
```

```
codedBitErrorRate = 0
```

```
totalCorrectedErrors = correctedErrors
```

```
totalCorrectedErrors = 882
```

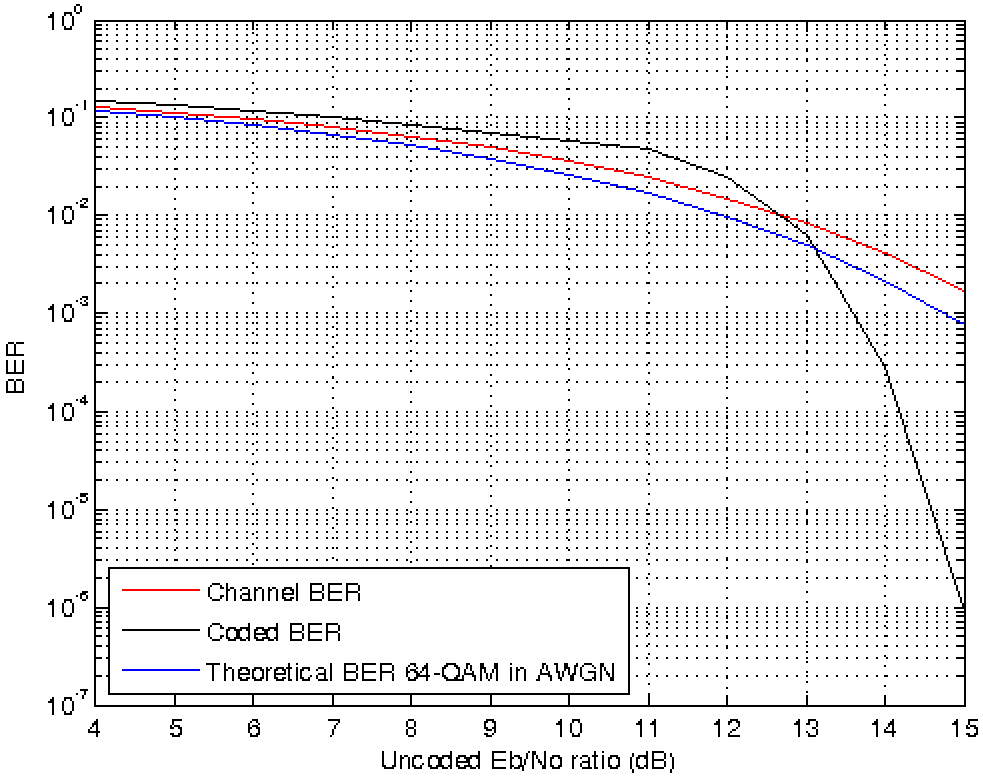
You can add a for loop around the processing loop above to run simulations for a set of Eb/N0 values. Simulations were run offline for uncoded Eb/N0 values in 4:15 dB, target number of errors equal to 5000, and maximum number of transmissions equal to 50e6. The results from the simulation are shown. The channel BER is worse than the theoretical 64-QAM BER because Eb/N0 is reduced by the code rate.



Summary

This example utilized several System objects to simulate a 64-QAM communications system over an AWGN channel with RS block coding. It showed how to configure the RS decoder to decode symbols with erasures. System performance was measured using channel and coded BER curves obtained using error rate measurement System objects.

Helper functions used in this example:

- helperRSCodingConfig.m
- helperRSCodingGetErasures.m

Reed-Solomon Coding with Erasures and Punctures

This example shows how to configure the `comm.RSEncoder` and `comm.RSDecoder` System objects to perform Reed-Solomon (RS) block coding with erasures and puncture codes when simulating a communications system. An encoder can generate punctures to remove specific parity symbols from its output. given the puncture pattern, the decoder inserts zeros in the puncture positions and treats those symbols as erasures. The decoder treats encoder-generated punctures and receiver-generated erasures in exactly the same way when it decodes. Puncturing has the added benefit of making the code rate more flexible, at the expense of some error correction capability.

This example shows the simulation of a communication system consisting of a random source, an RS encoder, a 64-QAM modulator, an AWGN channel, a 64-QAM demodulator, and an RS decoder. It includes analysis of RS coding with erasures and puncturing by comparing the channel bit error rate (BER) performance versus the coded BER performance. This example obtains Channel BER by comparing inputs for the QAM modulator to outputs from the QAM demodulator. This example obtains Coded BER by comparing inputs for the RS encoder to outputs from the RS decoder.

Initialization

The helperRSCodingConfig.m helper function initializes simulation parameters, and configures the `comm.AWGNChannel` and `comm.ErrorRate` System objects used to simulate the communications system. The uncoded E_b/N_0 ratio, `EbNoUncoded` is set to 15 dB. Criteria to stop the simulation stop are defined to stop the simulation if 500 errors occur or a maximum 5×10^6 bits are transmitted.

```
helperRSCodingConfig;
```

Configure RS Encoder/Decoder

This example uses the same (63,53) RS code operating with a 64-QAM modulation scheme that is configured for erasures and code puncturing. The RS algortihm decodes receiver-generated erasures and corrects encoder-generated punctures. For each codeword, the sum of the punctures and erasures cannot exceed twice the error-correcting capability of the code.

Create a `comm.RSEncoder` System object and set the `BitInput` property to false to specify that the encoder inputs and outputs are integer symbols.

```
N = 63;  % Codeword length
K = 53;  % Message length
rsEncoder = comm.RSEncoder(N,K,'BitInput',false);
numErasures = 6;
```

Create a `comm.RSDecoder` System object matching the configuration of the `comm.RSEncoder` object. Then set the `ErasuresInputPort` property to true to specify erasures as an input to the decoder object.

```
rsDecoder = comm.RSDecoder(N,K,'BitInput',false);
rsDecoder.ErasuresInputPort = true;
```

To enable code puncturing, set the `PuncturePatternSource` property to `'Property'` and set the `PuncturePattern` property to the desired puncture pattern vector. The same puncture vector must be specified in both the encoder and decoder. This example punctures two symbols from each codeword. Values of `1` in the puncture pattern vector indicate nonpunctured symbols, and values of `0` indicate punctured symbols.

```
numPuncs = 2;
rsEnc.PuncturePatternSource = 'Property';
rsEnc.PuncturePattern = [ones(N-K-numPuncs,1); zeros(numPuncs,1)];

rsDec.PuncturePatternSource = 'Property';
rsDec.PuncturePattern = rsEnc.PuncturePattern;
```

Run Stream Processing Loop

Simulate the communications system for an uncoded E_b/N_0 ratio of 15 dB. The uncoded E_b/N_0 is the ratio that would be measured at the input of the channel if there was no coding in the system.

The signal going into the AWGN channel is the encoded signal, so you must convert the uncoded E_b/N_0 values so that they correspond to the energy ratio at the encoder output. This ratio is the coded E_b/N_0 ratio. If you input K symbols to the encoder and obtain N output symbols, then the energy relation is given by the K/N rate. Since the length of the codewords generated by the RS encoder is reduced by the number of punctures specified in the puncture pattern vector, the value of the coded E_b/N_0 ratio needs to be adjusted to account for these punctures. In this example, The number of output symbols is (N - numPuncs) and the uncoded E_b/N_0 ratio relates to the coded E_b/N_0 as shown below. Set the EbNo property of the AWGN channel object to the computed coded E_b/N_0 value.

```
EbNoCoded = EbNoUncoded + 10*log10(K/(N - numPuncs));
channel.EbNo = EbNoCoded;
```

Loop until the simulation reaches the target number of errors or the maximum number of transmissions.

```
chanErrorStats = zeros(3,1);
codedErrorStats = zeros(3,1);
correctedErrors = 0;
while (codedErrorStats(2) < targetErrors) && ...
        (codedErrorStats(3) < maxNumTransmissions)
```

The data symbols transmit one message word at a time. Each message word has K symbols in the [0 N] range.

```
    data = randi([0 N],K,1);
```

Encode the message word. The encoded word, encData, is (N – numPunc) symbols long.

```
    encData = rsEncoder(data);
```

Modulate encoded data and add noise. then demodulate channel output.

```
    modData = qammod(encData,M);
    chanOutput = channel(modData);
    demodData = qamdemod(chanOutput,M);
```

Use the helperRSCodingGetErasures.m helper function to find the 6 least reliable symbols and generate an erasures vector. The length of the erasures vector must be equal to the number of symbols in the demodulated codeword. A one in the ith element of the vector erases the ith symbol in the codeword. Zeros in the vector indicate no erasures.

```
    erasuresVec = helperRSCodingGetErasures(chanOutput,numErasures);
```

Decode the data. Accumulate the number of corrected errors using the cumulative sum object.

```
    [estData,errs] = rsDecoder(demodData,erasuresVec);
    if (errs >= 0)
        correctedErrors = cumulativeSum(errs);
    end
```

When computing the channel and coded BERs, convert integers to bits.

```
    chanErrorStats(:,1) = ...
        chanBERCalc(reshape(de2bi(encData,log2(M))',[],1),reshape(de2bi(demodData,log2(M))',[],1
    codedErrorStats(:,1) = ...
        codedBERCalc(reshape(de2bi(data,log2(M))',[],1),reshape(de2bi(estData,log2(M))',[],1));
end
```

The error rate measurement objects, `chanBERCalc` and `codedBERCalc`, output 3-by-1 vectors containing BER measurement updates, the number of errors, and the total number of bit transmissions. Display the channel BER, the coded BER and the total number of errors corrected by the RS decoder.

```
chanBitErrorRate = chanErrorStats(1)
```

```
chanBitErrorRate = 0.0015
```

```
codedBitErrorRate = codedErrorStats(1)
```

```
codedBitErrorRate = 0
```

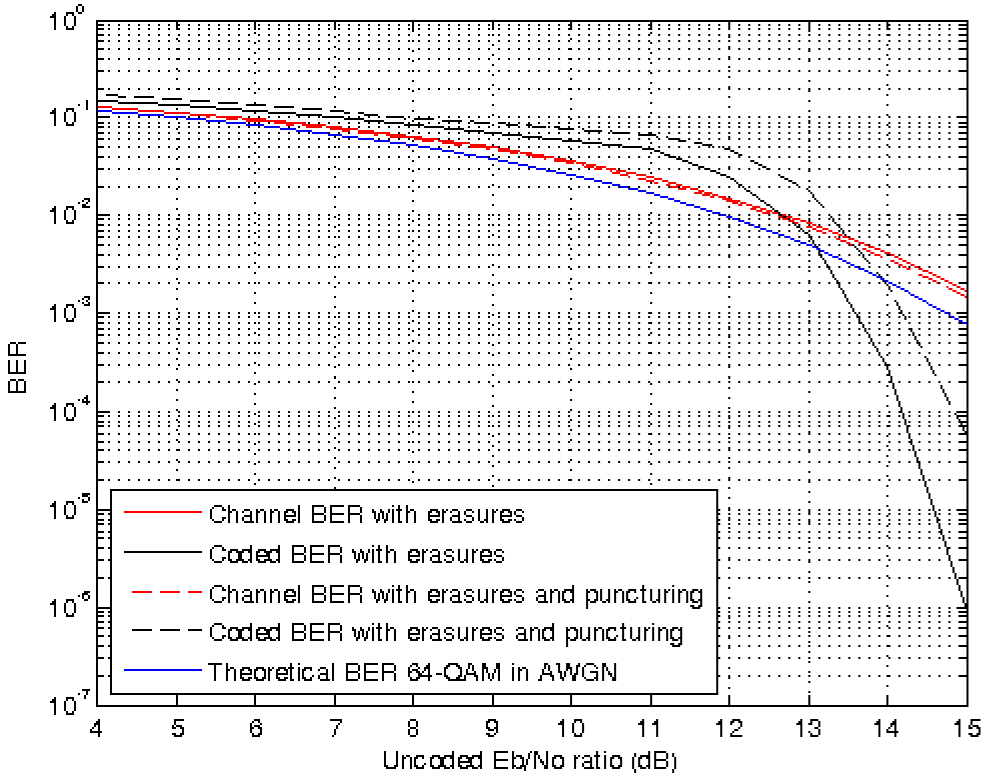
```
totalCorrectedErrors = correctedErrors
```

```
totalCorrectedErrors = 632
```

You can add a for loop around the processing loop above to run simulations for a set of E_b/N_0 values. Simulations were run offline for uncoded E_b/N_0 values in 4:15 dB, target number of errors equal to 5000, and maximum number of transmissions equal to 50×10^6. This figure compares results achieved for

- RS coding with only erasures
- RS coding with erasures and puncturing
- Theoretical BER for 64-QAM

The coded E_b/N_0 is slightly higher than the channel E_b/N_0, so the channel BER is slightly better in the punctured case. On the other hand, the coded BER is worse in the punctured case, because the two punctures reduce the error correcting capability of the code by one, leaving it able to correct only (10 – 6 – 2) / 2 = 1 error per codeword.



Summary

This example utilized functions and System objects to simulate a 64-QAM communications system over an AWGN channel with RS block coding. It showed how to configure the RS encoder/decoder System objects to obtain punctured codes. System performance was measured using channel and coded BER curves obtained using error rate measurement System objects.

Helper functions used in this example:

- helperRSCodingConfig.m
- helperRSCodingGetErasures.m

Reed-Solomon Coding with Erasures, Punctures, and Shortening

This example shows how to configure the `comm.RSEncoder` and `comm.RSDecoder` System objects to perform Reed-Solomon (RS) block coding to shorten the (63,53) code to a (28,18) code. The simulation of a communication system consisting of a random source, an RS encoder, a 64-QAM modulator, an AWGN channel, a 64-QAM demodulator, and an RS decoder is presented.

The effects of RS coding with erasures, puncturing, and shortening are analyzed by comparing the channel bit error rate (BER) performance versus the coded BER performance. This example obtains Channel BER by comparing inputs for the QAM modulator to outputs from the QAM demodulator and obtains Coded BER by comparing inputs for the RS encoder to outputs from the RS decoder. Puncturing is the removal of parity symbols from a codeword, and shortening is the removal of message symbols from a codeword. Puncturing has the benefit of making the code rate more flexible, at the expense of some error correction capability. Shortened codes achieve the same code rate flexibility without degrading the error correction performance for the same demodulator input E_b/N_0.

Initialization

The helperRSCodingConfig.m helper function initializes simulation parameters, and configures the `comm.AWGNChannel` and `comm.ErrorRate` System objects used to simulate the communications system. The uncodedE_b/N_0 ratio is set `EbNoUncoded` = 15 dB. Criteria to stop the simulation stop are defined to stop the simulation if 500 errors occur or a maximum 5×10^6 bits are transmitted.

```
helperRSCodingConfig;
```

Configure RS Encoder/Decoder

This example uses a (63,53) RS code operating with a 64-QAM modulation scheme. The RS coding operation includes erasures, puncturing, and code shortening. This example shows how to shorten the (63,53) code to a (28,18) code.

To shorten a (63,53) code by 10 symbols to a (53,43) code, you can simply enter 53 and 43 for the `CodewordLength` and `MessageLength` properties, respectively (since $2\lceil\log_2(53 + 1)\rceil - 1 = 63$). However, to shorten it by 35 symbols to a (28,18) code, you must explicitly specify that the symbols belong to the Galois field GF(26). Otherwise, the RS blocks will assume that the code is shortened from a (31,21) code (since $2\lceil\log_2(28 + 1)\rceil - 1 = 31$).

Create a pair of `comm.RSEncoder` and `comm.RSDecoder` System objects so that they perform block coding with a (28,18) code shortened from a (63,53) code that is configured to input and output integer symbols. Configure the decoder to accept an erasure input and two punctures. For each codeword at the output of the 64-QAM demodulator, the receiver determines the six least reliable symbols using the helperRSCodingGetErasures.m helper function. The indices that point to the location of these unreliable symbols are passed as an input to the RS decoder.

```
N = 63;  % Codeword length
K = 53;  % Message length
S = 18;  % Shortened message length
numErasures = 6;
numPuncs = 2;
rsEncoder = comm.RSEncoder(N, K, 'BitInput', false);
rsDecoder = comm.RSDecoder(N, K, 'BitInput', false, 'ErasuresInputPort', true);
rsEncoder.PuncturePatternSource = 'Property';
rsEncoder.PuncturePattern = [ones(N-K-numPuncs,1); zeros(numPuncs,1)];
rsDecoder.PuncturePatternSource = 'Property';
rsDecoder.PuncturePattern = rsEncoder.PuncturePattern;
```

Set the shortened codeword length and message length values.

```
rsEncoder.ShortMessageLength = S;
rsDecoder.ShortMessageLength = S;
```

Specify the field of $GF(2^6)$ in the RS encoder/decoder System objects, by setting the `PrimitivePolynomialSource` property to `'Property'` and the `PrimitivePolynomial` property to a 6th degree primitive polynomial.

```
primPolyDegree = 6;
rsEncoder.PrimitivePolynomialSource = 'Property';
rsEncoder.PrimitivePolynomial = de2bi(primpoly(primPolyDegree,'nodisplay'),'left-msb');

rsDecoder.PrimitivePolynomialSource = 'Property';
rsDecoder.PrimitivePolynomial = de2bi(primpoly(primPolyDegree,'nodisplay'),'left-msb');
```

Run Stream Processing Loop

Simulate the communications system for an uncoded E_b/N_0 ratio of 15 dB. The uncoded E_b/N_0 is the ratio that would be measured at the input of the channel if there was no coding in the system.

The signal going into the AWGN channel is the encoded signal, so you must convert the uncoded E_b/N_0 values so that they correspond to the energy ratio at the encoder output. This ratio is the coded E_b/N_0 ratio. If you input K symbols to the encoder and obtain N output symbols, then the energy relation is given by the K/N rate. he value of the coded E_b/N_0 ratio needs to be adjusted to account for shortened and punctured codewords. The number of output symbols is (N - numPuncs - S) and the uncoded E_b/N_0 ratio relates to the coded E_b/N_0 as shown below. Set the EbNo property of the AWGN channel object to the computed coded E_b/N_0 value.

```
EbNoCoded = EbNoUncoded + 10*log10(S/(N - numPuncs - K + S));
channel.EbNo = EbNoCoded;
```

Loop until the simulation reaches the target number of errors or the maximum number of transmissions.

```
chanErrorStats = zeros(3,1);
codedErrorStats = zeros(3,1);
correctedErrors = 0;
while (codedErrorStats(2) < targetErrors) && ...
        (codedErrorStats(3) < maxNumTransmissions)
```

The data symbols transmit one message word at a time. Each message word has K-S symbols in the [0 (2^primPolyDegree)-1] range.

```
    data = randi([0 2^primPolyDegree-1],S,1);
```

Encode the shortened message word. The encoded word encData is (N-numPuncs-S) symbols long.

```
    encData = rsEncoder(data);
```

Modulate encoded data and add noise. then demodulate channel output.

```
    modData = qammod(encData,M);
    chanOutput = channel(modData);
    demodData = qamdemod(chanOutput,M);
```

Use the helperRSCodingGetErasures.m helper function to find the 6 least reliable symbols and generate an erasures vector. The length of the erasures vector must be equal to the number of symbols in the demodulated codeword. A one in the ith element of the vector erases the ith symbol in the codeword. Zeros in the vector indicate no erasures.

```
    erasuresVec = helperRSCodingGetErasures(chanOutput,numErasures);
```

Decode the data. Accumulate the number of corrected errors using the cumulative sum object.

```
    [estData,errs] = rsDecoder(demodData,erasuresVec);
    if (errs >= 0)
```

```
        correctedErrors = cumulativeSum(errs);
    end
```

When computing the channel and coded BERs, convert integers to bits.

```
    chanErrorStats(:,1) = ...
        chanBERCalc(reshape(de2bi(encData,log2(M))',[],1), ...
        reshape(de2bi(demodData,log2(M))',[],1));
    codedErrorStats(:,1) = ...
        codedBERCalc(reshape(de2bi(data,log2(M))',[],1), ...
        reshape(de2bi(estData,log2(M))',[],1));
end
```

The error rate measurement objects, `chanBERCalc` and `codedBERCalc`, output 3-by-1 vectors containing BER measurement updates, the number of errors, and the total number of bit transmissions. Display the channel BER, the coded BER, and the total number of errors corrected by the RS decoder.

```
chanBitErrorRate = chanErrorStats(1)
```

```
chanBitErrorRate = 0.0036
```

```
codedBitErrorRate = codedErrorStats(1)
```

```
codedBitErrorRate = 9.6599e-05
```

```
totalCorrectedErrors = correctedErrors
```

```
totalCorrectedErrors = 1436
```

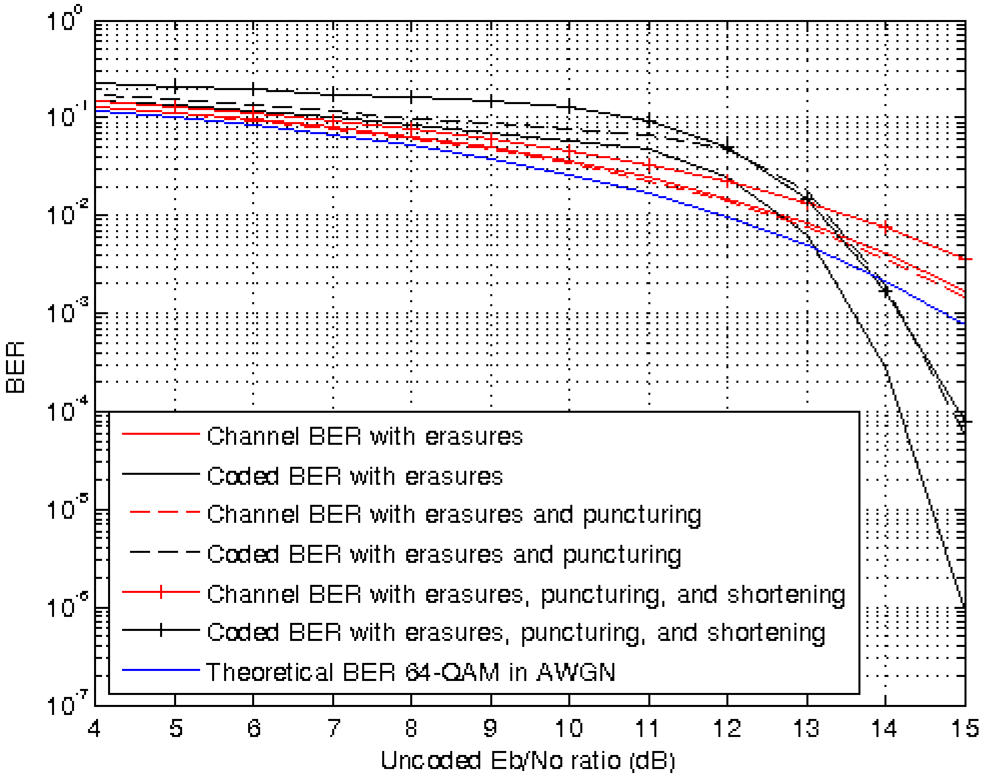
You can add a for loop around the processing loop above to run simulations for a set of E_b/N_0 values. Simulations were run offline for uncoded E_b/N_0 values in 4:15 dB, target number of errors equal to 5000, and maximum number of transmissions equal to 50×10^6. This figure compares results achieved for

- RS coding with only erasures
- RS coding with erasures and puncturing
- RS coding with erasures, puncturing, and shotening
- Theoretical BER for 64-QAM

The channel BER with shortening because the coded E_b/N_0 is ddegraded. This degraded coded E_b/N_0 occurs because the code rate of the shortened code is lower than that of the nonshortened code. Shortening also results in degraded coded BER, most noticably at lower E_b/N_0 values.



Summary

This example utilized several System objects to simulate a 64-QAM communications system over an AWGN channel with a shortened RS block code. It showed how to configure the RS decoder to shorten a (63,53) code to a (28,18) code. System performance was measured using channel and coded BER curves obtained using error rate measurement System objects.

Helper functions used in this example:

- helperRSCodingConfig.m
- helperRSCodingGetErasures.m

Algorithms

This object implements the algorithm, inputs, and outputs described in “Algorithms for BCH and RS Errors-only Decoding”.

Topics

“Reed-Solomon Codes”

Introduced in R2012a

step

System object: `comm.RSDecoder`
Package: `comm`

Decode data using a Reed-Solomon decoder

Syntax

```
[Y,ERR] = step(H,X)
Y = step(H,X)
Y = step(H,X,ERASURES)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[Y,ERR] = step(H,X)` decodes the encoded input data, `X`, into the output vector `Y` and returns the number of corrected symbols in output vector `ERR`. The value of the `BitInput` property determines whether `X` is a vector of integers or bits with a numeric, logical, or fixed-point data type. The input and output length of the step function equal the values listed in the table in “Input and Output Signal Lengths in BCH and RS System Objects” on page 3-91. This syntax applies when you set the `NumCorrectedErrorsOutputPort` property to `true`. A value of `-1` in the *i*-th element of the error output vector indicates that a decoding error occurred for that codeword.

`Y = step(H,X)` decodes the encoded data, `X`, into the output vector `Y`. This syntax applies when you set the `NumCorrectedErrorsOutputPort` property to `false`.

`Y = step(H,X,ERASURES)` uses the binary column input vector, `ERASURES`, to erase the symbols of the input codewords. The elements in `ERASURES` must be of data type double or logical. Values of 1 in the `ERASURES` vector correspond to erased symbols, and values of 0 correspond to non-erased symbols. This syntax applies when you set the ErasuresInputPort property to `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.RSEncoder

Package: comm

Encode data using Reed-Solomon encoder

Description

The RSEncoder object creates a Reed-Solomon code with message and codeword lengths you specify.

To encode data using a Reed-Solomon encoding scheme:

1. Define and set up your Reed-Solomon encoder object. See "Construction" on page 3-1340.
2. Call step to encode data according to the properties of comm.RSEncoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

enc = comm.RSEncoder creates a block encoder System object, enc. This object performs Reed-Solomon (RS) encoding.

enc = comm.RSEncoder(N,K) creates an RS encoder object, enc, with the CodewordLength property set to N and the MessageLength property set to K.

enc = comm.RSEncoder(N,K,GP) creates an RS encoder object, enc, with the CodewordLength property set to N, the MessageLength property set to K, and the GeneratorPolynomial property set to GP.

enc = comm.RSEncoder(N,K,GP,S) creates an RS encoder object, enc, with the CodewordLength property set to N, the MessageLength property set to K, the GeneratorPolynomial property set to GP, and the ShortMessageLength property set to S.

enc = comm.RSEncoder(N,K,GP,S,Name,Value) creates an RS encoder object, enc, with the CodewordLength property set to N, the MessageLength property set to K, the GeneratorPolynomial property set to GP, the ShortMessageLength property set to S, and each specified property Name set to the specified Value.

enc = comm.RSEncoder(Name,Value) creates an RS encoder object, enc, with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

Note The input and output signal lengths are listed in "Input and Output Signal Lengths in BCH and RS System Objects" on page 3-91 on the comm.BCHDecoder reference page.

BitInput

Assume that input is bits

Specify whether the input comprises bits or integers. The default is `false`.

When you set this property to `false`, the `step` method input data value must be a numeric, column vector of integers. Each symbol that forms the input message and output codewords is an integer between 0 and 2^M–1. These integers correspond to an element of the finite Galois field `gf`(2^M). M is the degree of the primitive polynomial that you specify with the `PrimitivePolynomialSource` on page 3-0 and `PrimitivePolynomial` on page 3-0 properties.

When you set this property to `true`, the input value must be a numeric, column vector of bits. The encoded data output result is a column vector of bits.

CodewordLength

Codeword length

Specify the codeword length of the RS code as a double-precision positive integer scalar value. The default is `7`.

For a full-length RS code, the value of this property must be 2^M–1, where M is an integer such that $3 \leq M \leq 16$.

MessageLength

Message length

Specify the message length as a double-precision positive integer scalar value. The default is `3`.

ShortMessageLengthSource

Short message length source

Specify the source of the shortened message as `Auto` or `Property`. When this property is set to `Auto`, the RS code is defined by the `CodewordLength` on page 3-0 , `MessageLength` on page 3-0 , `GeneratorPolynomial` on page 3-0 , and `PrimitivePolynomial` on page 3-0 properties. When `ShortMessageLengthSource` is set to `Property`, you must specify the `ShortMessageLength` on page 3-0 property, which is used with the other properties to define the RS code. The default is `Auto`.

ShortMessageLength

Shortened message length

Specify the length of the shortened message as a double-precision positive integer scalar whose value must be less than or equal to `MessageLength` on page 3-0 .
When `ShortMessageLength` < `MessageLength`, the RS code is shortened. The default is `3`.

GeneratorPolynomialSource

Source of generator polynomial

Specify the source of the generator polynomial as `Auto` or `Property`. The default is `Auto`.

When you set this property to Auto, the object chooses the generator polynomial automatically. The object calculates the generator polynomial based on the value of the PrimitivePolynomial on page 3-0 property.

When you set GeneratorPolynomialSource to Property, you must specify a generator polynomial using the GeneratorPolynomial on page 3-0 property.

GeneratorPolynomial

Generator polynomial

Specify the generator polynomial for the RS code as a double-precision integer row vector or as a Galois row vector. The Galois row vector entries must be in the range from 0 to 2^M-1. These entries must represent a generator polynomial in descending order of powers. Each coefficient is an element of the Galois field gf(2^M), represented in integer format. The length of the generator polynomial must be CodewordLength on page 3-0 – MessageLength on page 3-0 + 1.

The default is the result of rsgenpoly(7,3,[],[],'double'), which evaluates to a gf(2^3) array with elements [1 3 1 2 3]. This property applies when you set GeneratorPolynomialSource on page 3-0 to Property.

CheckGeneratorPolynomial

Enable generator polynomial checking

Set this property to true to perform a generator polynomial check. The default is true. This check verifies that the specified generator polynomial is valid. For larger codes, disabling the check speeds up processing. As a best practice, perform the check at least once before setting this property to false. This property applies when GeneratorPolynomialSource on page 3-0 is set to Property.

PrimitivePolynomialSource

Source of primitive polynomial

Specify the source of the primitive polynomial as Auto or Property. The default is Auto.

When you set this property to Auto, the object uses a primitive polynomial of degree M = ceil(log2(CodewordLength on page 3-0 +1)).

When you set this property to Property, you must specify a polynomial using the PrimitivePolynomial on page 3-0 property.

PrimitivePolynomial

Primitive polynomial

Specify the primitive polynomial that defines the finite field gf(2^M) corresponding to the integers that form messages and codewords. Specify this property as a double-precision, binary row vector that represents a primitive polynomial over gf(2) of degree M in descending order of powers.

If CodewordLength on page 3-0 is less than 2^M–1, the object uses a shortened RS code. The default is the result of fliplr(de2bi(primpoly(3))), which is [1 0 1 1] or the polynomial $x^3 + x + 1$.

This property applies when you set PrimitivePolynomialSource on page 3-0 to Property.

PuncturePatternSource

Source of puncture pattern

Specify the source of the puncture pattern as `None` or `Property`. The default is `None`.

If you set this property to `None`, the object does not apply puncturing to the code. If you set this property to `Property`, the object punctures the code based on a puncture pattern vector specified in the `PuncturePattern` on page 3-0 property.

PuncturePattern

Puncture pattern vector

Specify the pattern used to puncture the encoded data as a double-precision, binary column vector with a length of (`CodewordLength` on page 3-0 – `MessageLength` on page 3-0). The default is `[ones(2,1); zeros(2,1)]`. Zeros in the puncture pattern vector indicate the position of the parity symbols that are punctured or excluded from each codeword. This property applies when you set the `PuncturePatternSource` on page 3-0 property to `Property`.

OutputDataType

Data type of output

Specify the output data type as `Same as input`, `double`, or `logical`. The default is `Same as input`. This property applies when you set the `BitInput` on page 3-0 property to `true`.

Methods

step	Encode data using a Reed-Solomon encoder

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Transmit an RS-encoded, 8-DPSK-modulated symbol stream

Transmit an RS-encoded, 8-DPSK-modulated symbol stream through an AWGN channel. Then, demodulate, decode, and count errors.

```
enc = comm.RSEncoder;
mod = comm.DPSKModulator('BitInput',false);
chan = comm.AWGNChannel(...
            'NoiseMethod','Signal to noise ratio (SNR)','SNR',10);
demod = comm.DPSKDemodulator('BitOutput',false);
hDdecec = comm.RSDecoder;
errorRate = comm.ErrorRate('ComputationDelay',3);

for counter = 1:20
  data = randi([0 7], 30, 1);
  encodedData = step(enc, data);
```

```
        modSignal = step(mod, encodedData);
        receivedSignal = step(chan, modSignal);
        demodSignal = step(demod, receivedSignal);
        receivedSymbols = step(hDdecec, demodSignal);
        errorStats = step(errorRate, data, receivedSymbols);
    end

  fprintf('Error rate = %f\nNumber of errors = %d\n', ...
      errorStats(1), errorStats(2))
```

```
Error rate = 0.115578
Number of errors = 69
```

Estimate BER of 8-PSK in AWGN with Reed-Solomon Coding

Transmit Reed-Solomon encoded data using 8-PSK over an AWGN channel. Demodulate and decode the received signal and collect error statistics. Plot the bit error rate estimate.

Define the example parameters.

```
M = 8;  % Modulation order
bps = log2(M); % Bits per symbol
N = 7; % RS codeword length
K = 5; % RS message length
```

Create modulator, demodulator, AWGN channel, and error rate objects.

```
pskModulator = comm.PSKModulator('ModulationOrder',M,'BitInput',true);
pskDemodulator = comm.PSKDemodulator('ModulationOrder',M,'BitOutput',true);
awgnChannel = comm.AWGNChannel('BitsPerSymbol',bps);
errorRate = comm.ErrorRate;
```

Create a (7,5) Reed-Solomon encoder and decoder pair which accepts bit inputs.

```
rsEncoder = comm.RSEncoder('BitInput',true,'CodewordLength',N,'MessageLength',K);
rsDecoder = comm.RSDecoder('BitInput',true,'CodewordLength',N,'MessageLength',K);
```

Set the range of E_b/N_0 values. Initialize the error statistics matrix.

```
ebnoVec = (3:0.5:8)';
errorStats = zeros(length(ebnoVec),3);
```

Estimate the bit error rate for each E_b/N_0 value. The simulation runs until either 100 errors or 10^7 bits is encountered. The main simulation loop processing includes encoding, modulation, demodulation, and decoding.

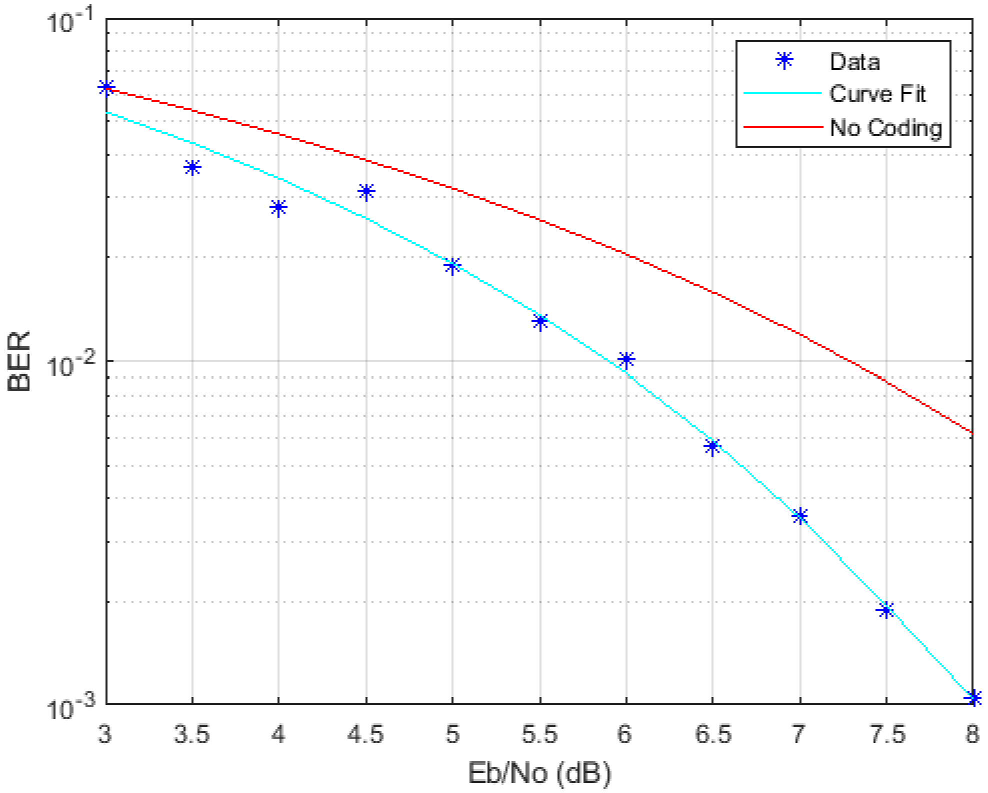
```
for i = 1:length(ebnoVec)
    awgnChannel.EbNo = ebnoVec(i);
    reset(errorRate)
    while errorStats(i,2) < 100 && errorStats(i,3) < 1e7
        data = randi([0 1],1500,1); % Generate binary data
        encData = rsEncoder(data); % RS encode
        modData = pskModulator(encData); % Modulate
        rxSig = awgnChannel(modData); % Pass signal through AWGN
        rxData = pskDemodulator(rxSig); % Demodulate
        decData = rsDecoder(rxData); % RS decode
        errorStats(i,:) = errorRate(data,decData); % Collect error statistics
    end
end
```

Fit a curve to the BER data using `berfit`. Generate an estimate of 8-PSK performance without coding using the `berawgn` function.

```
berCurveFit = berfit(ebnoVec,errorStats(:,1));
berNoCoding = berawgn(ebnoVec,'psk',8,'nondiff');
```

Plot the BER data, the BER curve fit, and the estimated performance without RS coding.

```
semilogy(ebnoVec,errorStats(:,1),'b*', ...
ebnoVec,berCurveFit,'c-',ebnoVec,berNoCoding,'r')
ylabel('BER')
xlabel('Eb/No (dB)')
legend('Data','Curve Fit','No Coding')
grid
```



The (7,5) RS code improves the E_b/N_0 required to achieve a 10^{-2} bit error rate by, approximately, 1.4 dB.

Transmit a Shortened RS-encoded, 256-QAM-modulated Symbol Stream

Transmit a shortened RS-encoded, 256-QAM-modulated symbol stream through an AWGN channel. Then demodulate, decode, and count errors.

Set the parameters for the Reed-Solomon code, where N is the codeword length, K is the nominal message length, and S is the shortened message length. Set the modulation order, M, and the number of frames, L.

```
N = 255;
K = 239;
S = 188;
M = 256;
L = 50;
```

Create an AWGN channel System object and an error rate System object.

```
awgnChan = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (Eb/No)', ...
    'EbNo',15,'BitsPerSymbol',log2(M));
errorRate = comm.ErrorRate('ComputationDelay',3);
```

Create the Reed-Solomon generator polynomial from the DVB-T standard.

```
gp = rsgenpoly(N,K,[],0);
```

Create a Reed-Solomon encoder and decoder pair using the shortened message length, S, and the DVB-T generator polynomial, gp.

```
enc = comm.RSEncoder(N,K,gp,S);
dec = comm.RSDecoder(N,K,gp,S);
```

Generate random symbol frames whose length equals one message block. Encode, modulate, apply AWGN, demodulate, decode, and collect statistics.

```
for counter = 1:L
    data = randi([0 1],S,log2(M));
    encodedData = step(enc,bi2de(data));
    modSignal = qammod(encodedData,M,'UnitAveragePower',true);
    rxSignal = awgnChan(modSignal);
    demodSignal = qamdemod(rxSignal,M,'UnitAveragePower',true);
    rxBits = dec(demodSignal);
    dataOut = de2bi(rxBits);
    errorStats = errorRate(data(:),dataOut(:));
end
```

Display the error rate and number of errors.

```
fprintf('Error rate = %5.2e\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

```
Error rate = 2.01e-02
Number of errors = 1509
```

Reed-Solomon Coding with Erasures

This example shows how to configure the comm.RSEncoder and comm.RSDecoder System objects to perform Reed-Solomon (RS) block coding with erasures when simulating a communications system.

RS decoders can correct both errors and erasures. A receiver that identifies the most unreliable symbols in a given codeword can generate erasures. When a receiver erases a symbol, it replaces that symbol with a zero. The receiver then passes a flag to the decoder, indicating that the symbol is an erasure, not a valid code symbol. In addition, an encoder can generate punctures for which specific parity symbols are always removed from its output. The decoder, which knows the puncture pattern, inserts zeros in the puncture positions and treats those symbols as erasures. The decoder treats encoder-generated punctures and receiver-generated erasures the exact same way when it decodes a symbol. Puncturing also has the added benefit of making the code rate more flexible, at the expense of some error correction capability. Shortened codes achieve the same code rate flexibility without degrading the error correction performance, given the same demodulator input energy per bit to noise power spectral density ratio (Eb/N0). Note that puncturing is the removal of parity symbols from a codeword, and shortening is the removal of message symbols from a codeword.

This example shows the simulation of a communication system consisting of a random source, an RS encoder, a 64-QAM modulator, an AWGN channel, a 64-QAM demodulator, and an RS decoder. It includes analysis of RS coding with erasures by comparing the channel bit error rate (BER) performance versus the coded BER performance. This example obtains Channel BER by comparing inputs for the QAM modulator to outputs from the QAM demodulator and obtains Coded BER by comparing inputs for the RS encoder to outputs from the RS decoder.

Initialization

The helperRSCodingConfig.m helper function initializes simulation parameters, and configures the `comm.AWGNChannel` and `comm.ErrorRate` System objects used to simulate the communications system. The uncoded Eb/N0 ratio is set EbNoUncoded = 15 dB. Criteria to stop the simulation stop are defined to stop the simulation if 500 errors occur or a maximum 5e6 bits are transmitted.

```
helperRSCodingConfig;
```

Configure RS Encoder/Decoder

This example uses a (63,53) RS code operating with a 64-QAM modulation scheme. This code can correct (63-53)/2 = 5 errors, or it can alternatively correct (63-53) = 10 erasures. For each codeword at the output of the 64-QAM demodulator, the receiver determines the six least reliable symbols using the helperRSCodingGetErasures.m helper function. The indices that point to the location of these unreliable symbols are passed as an input to the RS decoder. The RS decoder treats these symbols as erasures resulting in an error correction capability of (10-6)/2 = 2 errors per codeword.

Create a `comm.RSEncoder` System object and set the `BitInput` property to false to specify that the encoder inputs and outputs are integer symbols.

```
N = 63;  % Codeword length
K = 53;  % Message length
rsEncoder = comm.RSEncoder(N,K,'BitInput',false);
numErasures = 6;
```

Create a `comm.RSDecoder` System object matching the configuration of the `comm.RSEncoder` object.

```
rsDecoder = comm.RSDecoder(N,K,'BitInput',false);
```

Set the `ErasuresInputPort` property to true to specify erasures as an input to the decoder object.

```
rsDecoder.ErasuresInputPort = true;
```

Set the `NumCorrectedErrorsOutputPort` property to true so that the decoder outputs the number of corrected errors. A non negative value in the error output denotes the number of corrected errors in the input codeword. A value of –1 in the error output indicates a decoding error. A decoding error occurs when the input codeword has more errors than the error correction capability of the RS code.

```
rsDecoder.NumCorrectedErrorsOutputPort = true;
```

Run Stream Processing Loop

Simulate the communications system for an uncoded Eb/N0 ratio of 15 dB. The uncoded Eb/N0 is the ratio that would be measured at the input of the channel if there was no coding in the system.

The signal going into the AWGN channel is the encoded signal, so you must convert the uncoded Eb/N0 values so that they correspond to the energy ratio at the encoder output. This ratio is the coded Eb/N0 ratio. If you input K symbols to the encoder and obtain N output symbols, then the energy relation is given by the K/N rate. Set the `EbNo` property of the AWGN channel object to the computed coded Eb/N0 value.

```
EbNoCoded = EbNoUncoded + 10*log10(K/N);
channel.EbNo = EbNoCoded;
```

Loop until the simulation reaches the target number of errors or the maximum number of transmissions.

```
chanErrorStats = zeros(3,1);
codedErrorStats = zeros(3,1);
correctedErrors = 0;
while (codedErrorStats(2) < targetErrors) && ...
        (codedErrorStats(3) < maxNumTransmissions)
```

The data symbols transmit one message word at a time. Each message word has K symbols in the [0 N] range.

```
    data = randi([0 N],K,1);
```

Encode the message word. The encoded word, `encData`, is `(N-numPunc)` symbols long.

```
    encData = rsEncoder(data);
```

Modulate encoded data and add noise. then demodulate channel output.

```
    modData = qammod(encData,M);
    chanOutput = channel(modData);
    demodData = qamdemod(chanOutput,M);
```

Use the helperRSCodingGetErasures.m helper function to find the 6 least reliable symbols and generate an erasures vector. The length of the erasures vector must be equal to the number of symbols in the demodulated codeword. A one in the ith element of the vector erases the ith symbol in the codeword. Zeros in the vector indicate no erasures.

```
    erasuresVec = helperRSCodingGetErasures(chanOutput,numErasures);
```

Decode the data. Accumulate the number of corrected errors using the cumulative sum object.

```
    [estData,errs] = rsDecoder(demodData,erasuresVec);
    if (errs >= 0)
        correctedErrors = cumulativeSum(errs);
    end
```

When computing the channel and coded BERs, convert integers to bits.

```
    chanErrorStats(:,1) = ...
        chanBERCalc(reshape(de2bi(encData,log2(M))',[],1),reshape(de2bi(demodData,log2(M))',[],1
    codedErrorStats(:,1) = ...
        codedBERCalc(reshape(de2bi(data,log2(M))',[],1),reshape(de2bi(estData,log2(M))',[],1));
end
```

The error rate measurement objects, `chanBERCalc` and `codedBERCalc`, output 3-by-1 vectors containing BER measurement updates, the number of errors, and the total number of bit transmissions. Display the channel BER, the coded BER and the total number of errors corrected by the RS decoder.

```
chanBitErrorRate = chanErrorStats(1)
```

```
chanBitErrorRate = 0.0017
```

```
codedBitErrorRate = codedErrorStats(1)
```

```
codedBitErrorRate = 0
```

```
totalCorrectedErrors = correctedErrors
```

```
totalCorrectedErrors = 882
```

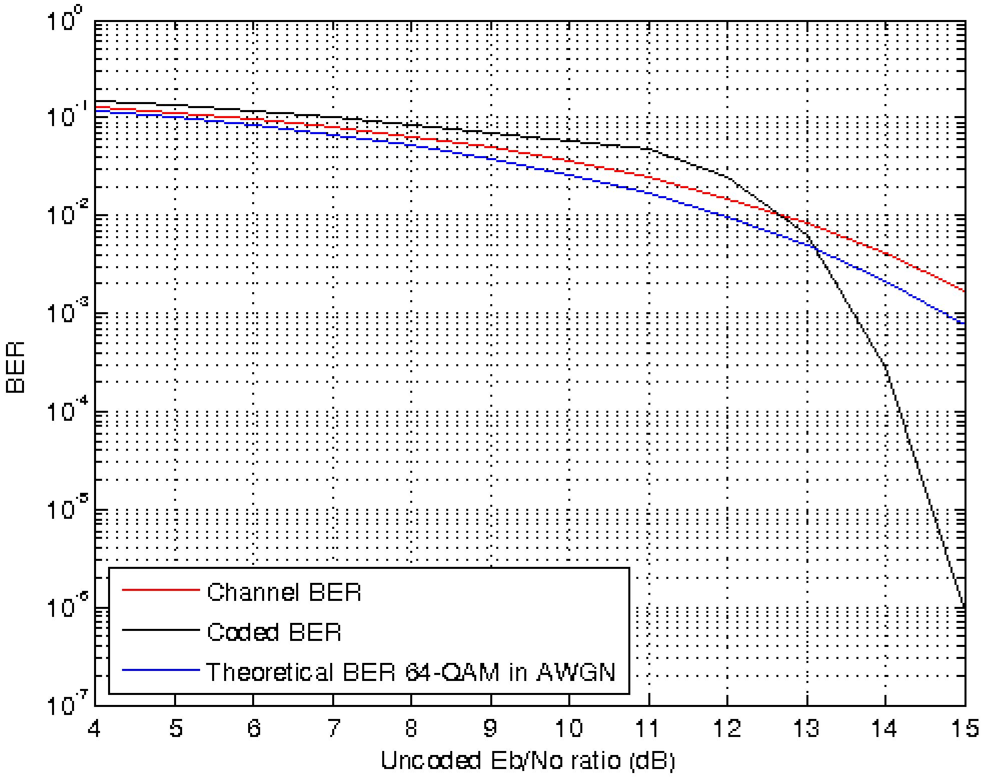
You can add a for loop around the processing loop above to run simulations for a set of Eb/N0 values. Simulations were run offline for uncoded Eb/N0 values in 4:15 dB, target number of errors equal to 5000, and maximum number of transmissions equal to 50e6. The results from the simulation are shown. The channel BER is worse than the theoretical 64-QAM BER because Eb/N0 is reduced by the code rate.



Summary

This example utilized several System objects to simulate a 64-QAM communications system over an AWGN channel with RS block coding. It showed how to configure the RS decoder to decode symbols with erasures. System performance was measured using channel and coded BER curves obtained using error rate measurement System objects.

Helper functions used in this example:

- helperRSCodingConfig.m
- helperRSCodingGetErasures.m

Reed-Solomon Coding with Erasures and Punctures

This example shows how to configure the `comm.RSEncoder` and `comm.RSDecoder` System objects to perform Reed-Solomon (RS) block coding with erasures and puncture codes when simulating a communications system. An encoder can generate punctures to remove specific parity symbols from its output. given the puncture pattern, the decoder inserts zeros in the puncture positions and treats those symbols as erasures. The decoder treats encoder-generated punctures and receiver-generated erasures in exactly the same way when it decodes. Puncturing has the added benefit of making the code rate more flexible, at the expense of some error correction capability.

This example shows the simulation of a communication system consisting of a random source, an RS encoder, a 64-QAM modulator, an AWGN channel, a 64-QAM demodulator, and an RS decoder. It includes analysis of RS coding with erasures and puncturing by comparing the channel bit error rate (BER) performance versus the coded BER performance. This example obtains Channel BER by comparing inputs for the QAM modulator to outputs from the QAM demodulator. This example obtains Coded BER by comparing inputs for the RS encoder to outputs from the RS decoder.

Initialization

The helperRSCodingConfig.m helper function initializes simulation parameters, and configures the `comm.AWGNChannel` and `comm.ErrorRate` System objects used to simulate the communications system. The uncoded E_b/N_0 ratio, `EbNoUncoded` is set to 15 dB. Criteria to stop the simulation stop are defined to stop the simulation if 500 errors occur or a maximum 5×10^6 bits are transmitted.

```
helperRSCodingConfig;
```

Configure RS Encoder/Decoder

This example uses the same (63,53) RS code operating with a 64-QAM modulation scheme that is configured for erasures and code puncturing. The RS algortihm decodes receiver-generated erasures and corrects encoder-generated punctures. For each codeword, the sum of the punctures and erasures cannot exceed twice the error-correcting capability of the code.

Create a `comm.RSEncoder` System object and set the `BitInput` property to false to specify that the encoder inputs and outputs are integer symbols.

```
N = 63;  % Codeword length
K = 53;  % Message length
rsEncoder = comm.RSEncoder(N,K,'BitInput',false);
numErasures = 6;
```

Create a `comm.RSDecoder` System object matching the configuration of the `comm.RSEncoder` object. Then set the `ErasuresInputPort` property to true to specify erasures as an input to the decoder object.

```
rsDecoder = comm.RSDecoder(N,K,'BitInput',false);
rsDecoder.ErasuresInputPort = true;
```

To enable code puncturing, set the `PuncturePatternSource` property to `'Property'` and set the `PuncturePattern` property to the desired puncture pattern vector. The same puncture vector must be specified in both the encoder and decoder. This example punctures two symbols from each codeword. Values of `1` in the puncture pattern vector indicate nonpunctured symbols, and values of `0` indicate punctured symbols.

```
numPuncs = 2;
rsEnc.PuncturePatternSource = 'Property';
rsEnc.PuncturePattern = [ones(N-K-numPuncs,1); zeros(numPuncs,1)];

rsDec.PuncturePatternSource = 'Property';
rsDec.PuncturePattern = rsEnc.PuncturePattern;
```

Run Stream Processing Loop

Simulate the communications system for an uncoded E_b/N_0 ratio of 15 dB. The uncoded E_b/N_0 is the ratio that would be measured at the input of the channel if there was no coding in the system.

The signal going into the AWGN channel is the encoded signal, so you must convert the uncoded E_b/N_0 values so that they correspond to the energy ratio at the encoder output. This ratio is the coded E_b/N_0 ratio. If you input `K` symbols to the encoder and obtain `N` output symbols, then the energy relation is given by the `K/N` rate. Since the length of the codewords generated by the RS encoder is reduced by the number of punctures specified in the puncture pattern vector, the value of the coded E_b/N_0 ratio needs to be adjusted to account for these punctures. In this example, The number of output symbols is (`N - numPuncs`) and the uncoded E_b/N_0 ratio relates to the coded E_b/N_0 as shown below. Set the `EbNo` property of the AWGN channel object to the computed coded E_b/N_0 value.

```
EbNoCoded = EbNoUncoded + 10*log10(K/(N - numPuncs));
channel.EbNo = EbNoCoded;
```

Loop until the simulation reaches the target number of errors or the maximum number of transmissions.

```
chanErrorStats = zeros(3,1);
codedErrorStats = zeros(3,1);
correctedErrors = 0;
while (codedErrorStats(2) < targetErrors) && ...
        (codedErrorStats(3) < maxNumTransmissions)
```

The data symbols transmit one message word at a time. Each message word has K symbols in the [0 `N`] range.

```
    data = randi([0 N],K,1);
```

Encode the message word. The encoded word, `encData`, is (`N – numPunc`) symbols long.

```
    encData = rsEncoder(data);
```

Modulate encoded data and add noise. then demodulate channel output.

```
    modData = qammod(encData,M);
    chanOutput = channel(modData);
    demodData = qamdemod(chanOutput,M);
```

Use the helperRSCodingGetErasures.m helper function to find the 6 least reliable symbols and generate an erasures vector. The length of the erasures vector must be equal to the number of symbols in the demodulated codeword. A one in the ith element of the vector erases the ith symbol in the codeword. Zeros in the vector indicate no erasures.

```
    erasuresVec = helperRSCodingGetErasures(chanOutput,numErasures);
```

Decode the data. Accumulate the number of corrected errors using the cumulative sum object.

```
    [estData,errs] = rsDecoder(demodData,erasuresVec);
    if (errs >= 0)
        correctedErrors = cumulativeSum(errs);
    end
```

When computing the channel and coded BERs, convert integers to bits.

```
    chanErrorStats(:,1) = ...
        chanBERCalc(reshape(de2bi(encData,log2(M))',[],1),reshape(de2bi(demodData,log2(M))',[],1
    codedErrorStats(:,1) = ...
        codedBERCalc(reshape(de2bi(data,log2(M))',[],1),reshape(de2bi(estData,log2(M))',[],1));
end
```

The error rate measurement objects, `chanBERCalc` and `codedBERCalc`, output 3-by-1 vectors containing BER measurement updates, the number of errors, and the total number of bit transmissions. Display the channel BER, the coded BER and the total number of errors corrected by the RS decoder.

```
chanBitErrorRate = chanErrorStats(1)
```

```
chanBitErrorRate = 0.0015
```

```
codedBitErrorRate = codedErrorStats(1)
```

```
codedBitErrorRate = 0
```

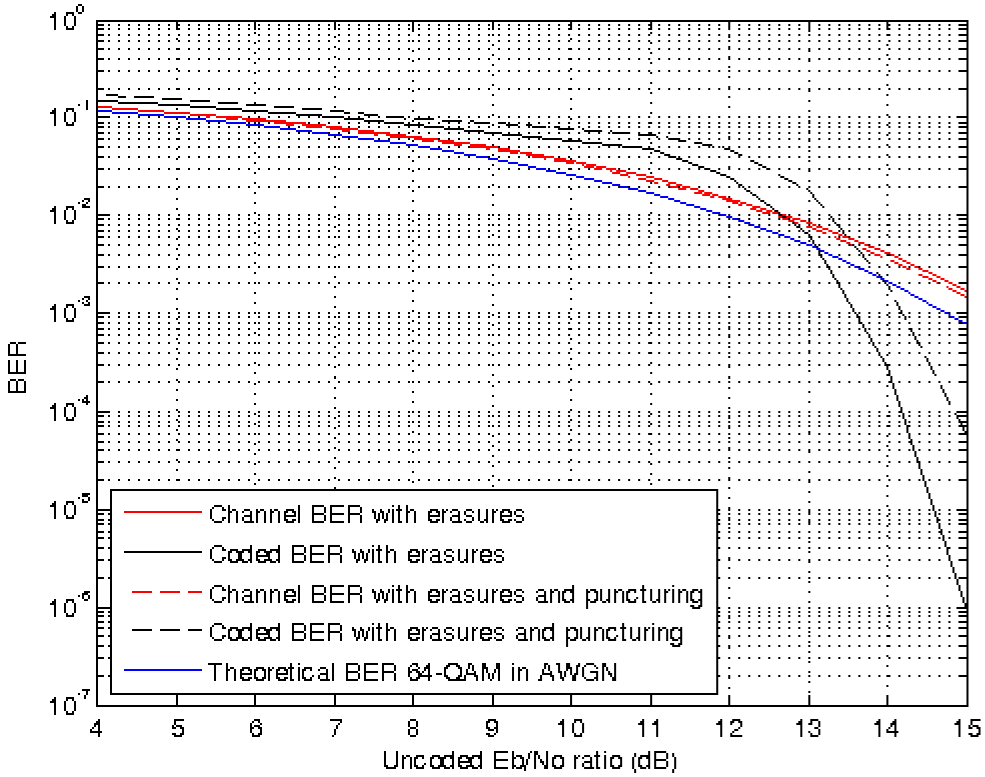
```
totalCorrectedErrors = correctedErrors
```

```
totalCorrectedErrors = 632
```

You can add a for loop around the processing loop above to run simulations for a set of E_b/N_0 values. Simulations were run offline for uncoded E_b/N_0 values in 4:15 dB, target number of errors equal to 5000, and maximum number of transmissions equal to 50×10^6. This figure compares results achieved for

- RS coding with only erasures
- RS coding with erasures and puncturing
- Theoretical BER for 64-QAM

The coded E_b/N_0 is slightly higher than the channel E_b/N_0, so the channel BER is slightly better in the punctured case. On the other hand, the coded BER is worse in the punctured case, because the two punctures reduce the error correcting capability of the code by one, leaving it able to correct only (10 – 6 – 2) / 2 = 1 error per codeword.



Summary

This example utilized functions and System objects to simulate a 64-QAM communications system over an AWGN channel with RS block coding. It showed how to configure the RS encoder/decoder System objects to obtain punctured codes. System performance was measured using channel and coded BER curves obtained using error rate measurement System objects.

Helper functions used in this example:

- helperRSCodingConfig.m
- helperRSCodingGetErasures.m

Reed-Solomon Coding with Erasures, Punctures, and Shortening

This example shows how to configure the `comm.RSEncoder` and `comm.RSDecoder` System objects to perform Reed-Solomon (RS) block coding to shorten the (63,53) code to a (28,18) code. The simulation of a communication system consisting of a random source, an RS encoder, a 64-QAM modulator, an AWGN channel, a 64-QAM demodulator, and an RS decoder is presented.

The effects of RS coding with erasures, puncturing, and shortening are analyzed by comparing the channel bit error rate (BER) performance versus the coded BER performance. This example obtains Channel BER by comparing inputs for the QAM modulator to outputs from the QAM demodulator and obtains Coded BER by comparing inputs for the RS encoder to outputs from the RS decoder. Puncturing is the removal of parity symbols from a codeword, and shortening is the removal of message symbols from a codeword. Puncturing has the benefit of making the code rate more flexible, at the expense of some error correction capability. Shortened codes achieve the same code rate flexibility without degrading the error correction performance for the same demodulator input E_b/N_0.

Initialization

The helperRSCodingConfig.m helper function initializes simulation parameters, and configures the `comm.AWGNChannel` and `comm.ErrorRate` System objects used to simulate the communications system. The uncodedE_b/N_0 ratio is set `EbNoUncoded` = 15 dB. Criteria to stop the simulation stop are defined to stop the simulation if 500 errors occur or a maximum 5×10^6 bits are transmitted.

```
helperRSCodingConfig;
```

Configure RS Encoder/Decoder

This example uses a (63,53) RS code operating with a 64-QAM modulation scheme. The RS coding operation includes erasures, puncturing, and code shortening. This example shows how to shorten the (63,53) code to a (28,18) code.

To shorten a (63,53) code by 10 symbols to a (53,43) code, you can simply enter 53 and 43 for the `CodewordLength` and `MessageLength` properties, respectively (since $2\lceil \log_2(53 + 1)\rceil - 1 = 63$). However, to shorten it by 35 symbols to a (28,18) code, you must explicitly specify that the symbols belong to the Galois field GF(26). Otherwise, the RS blocks will assume that the code is shortened from a (31,21) code (since $2\lceil \log_2(28 + 1)\rceil - 1 = 31$).

Create a pair of `comm.RSEncoder` and `comm.RSDecoder` System objects so that they perform block coding with a (28,18) code shortened from a (63,53) code that is configured to input and output integer symbols. Configure the decoder to accept an erasure input and two punctures. For each codeword at the output of the 64-QAM demodulator, the receiver determines the six least reliable symbols using the helperRSCodingGetErasures.m helper function. The indices that point to the location of these unreliable symbols are passed as an input to the RS decoder.

```
N = 63;  % Codeword length
K = 53;  % Message length
S = 18;  % Shortened message length
numErasures = 6;
numPuncs = 2;
rsEncoder = comm.RSEncoder(N, K, 'BitInput', false);
rsDecoder = comm.RSDecoder(N, K, 'BitInput', false, 'ErasuresInputPort', true);
rsEncoder.PuncturePatternSource = 'Property';
rsEncoder.PuncturePattern = [ones(N-K-numPuncs,1); zeros(numPuncs,1)];
rsDecoder.PuncturePatternSource = 'Property';
rsDecoder.PuncturePattern = rsEncoder.PuncturePattern;
```

Set the shortened codeword length and message length values.

```
rsEncoder.ShortMessageLength = S;
rsDecoder.ShortMessageLength = S;
```

Specify the field of GF(2^6) in the RS encoder/decoder System objects, by setting the `PrimitivePolynomialSource` property to `'Property'` and the `PrimitivePolynomial` property to a 6th degree primitive polynomial.

```
primPolyDegree = 6;
rsEncoder.PrimitivePolynomialSource = 'Property';
rsEncoder.PrimitivePolynomial = de2bi(primpoly(primPolyDegree,'nodisplay'),'left-msb');

rsDecoder.PrimitivePolynomialSource = 'Property';
rsDecoder.PrimitivePolynomial = de2bi(primpoly(primPolyDegree,'nodisplay'),'left-msb');
```

Run Stream Processing Loop

Simulate the communications system for an uncoded E_b/N_0 ratio of 15 dB. The uncoded E_b/N_0 is the ratio that would be measured at the input of the channel if there was no coding in the system.

The signal going into the AWGN channel is the encoded signal, so you must convert the uncoded E_b/N_0 values so that they correspond to the energy ratio at the encoder output. This ratio is the coded E_b/N_0 ratio. If you input K symbols to the encoder and obtain N output symbols, then the energy relation is given by the K/N rate. he value of the coded E_b/N_0 ratio needs to be adjusted to account for shortened and punctured codewords. The number of output symbols is (N - numPuncs - S) and the uncoded E_b/N_0 ratio relates to the coded E_b/N_0 as shown below. Set the EbNo property of the AWGN channel object to the computed coded E_b/N_0 value.

```
EbNoCoded = EbNoUncoded + 10*log10(S/(N - numPuncs - K + S));
channel.EbNo = EbNoCoded;
```

Loop until the simulation reaches the target number of errors or the maximum number of transmissions.

```
chanErrorStats = zeros(3,1);
codedErrorStats = zeros(3,1);
correctedErrors = 0;
while (codedErrorStats(2) < targetErrors) && ...
        (codedErrorStats(3) < maxNumTransmissions)
```

The data symbols transmit one message word at a time. Each message word has K-S symbols in the [0 (2^primPolyDegree)-1] range.

```
    data = randi([0 2^primPolyDegree-1],S,1);
```

Encode the shortened message word. The encoded word encData is (N-numPuncs-S) symbols long.

```
    encData = rsEncoder(data);
```

Modulate encoded data and add noise. then demodulate channel output.

```
    modData = qammod(encData,M);
    chanOutput = channel(modData);
    demodData = qamdemod(chanOutput,M);
```

Use the helperRSCodingGetErasures.m helper function to find the 6 least reliable symbols and generate an erasures vector. The length of the erasures vector must be equal to the number of symbols in the demodulated codeword. A one in the ith element of the vector erases the ith symbol in the codeword. Zeros in the vector indicate no erasures.

```
    erasuresVec = helperRSCodingGetErasures(chanOutput,numErasures);
```

Decode the data. Accumulate the number of corrected errors using the cumulative sum object.

```
    [estData,errs] = rsDecoder(demodData,erasuresVec);
    if (errs >= 0)
```

```
        correctedErrors = cumulativeSum(errs);
    end
```

When computing the channel and coded BERs, convert integers to bits.

```
    chanErrorStats(:,1) = ...
        chanBERCalc(reshape(de2bi(encData,log2(M))',[],1), ...
        reshape(de2bi(demodData,log2(M))',[],1));
    codedErrorStats(:,1) = ...
        codedBERCalc(reshape(de2bi(data,log2(M))',[],1), ...
        reshape(de2bi(estData,log2(M))',[],1));
end
```

The error rate measurement objects, `chanBERCalc` and `codedBERCalc`, output 3-by-1 vectors containing BER measurement updates, the number of errors, and the total number of bit transmissions. Display the channel BER, the coded BER, and the total number of errors corrected by the RS decoder.

```
chanBitErrorRate = chanErrorStats(1)
```

```
chanBitErrorRate = 0.0036
```

```
codedBitErrorRate = codedErrorStats(1)
```

```
codedBitErrorRate = 9.6599e-05
```

```
totalCorrectedErrors = correctedErrors
```

```
totalCorrectedErrors = 1436
```

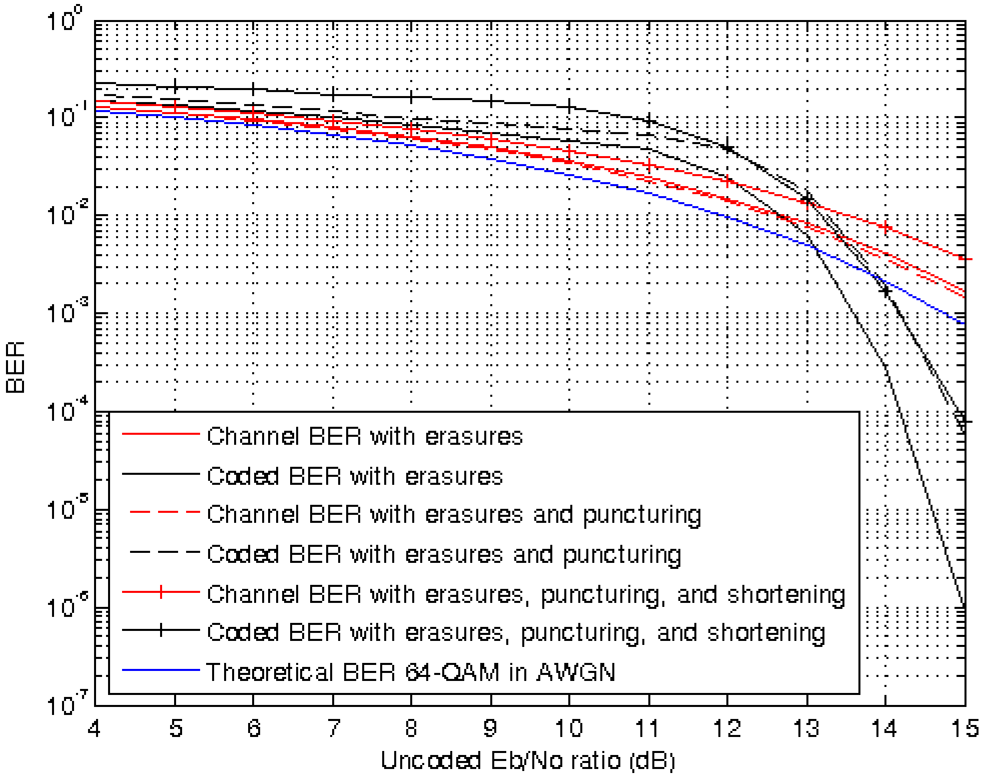
You can add a for loop around the processing loop above to run simulations for a set of E_{b}/N_0 values. Simulations were run offline for uncoded E_{b}/N_0 values in 4:15 dB, target number of errors equal to 5000, and maximum number of transmissions equal to 50×10^6. This figure compares results achieved for

- RS coding with only erasures
- RS coding with erasures and puncturing
- RS coding with erasures, puncturing, and shotening
- Theoretical BER for 64-QAM

The channel BER with shortening because the coded E_{b}/N_0 is ddegraded. This degraded coded E_{b}/N_0 occurs because the code rate of the shortened code is lower than that of the nonshortened code. Shortening also results in degraded coded BER, most noticably at lower E_{b}/N_0 values.



Summary

This example utilized several System objects to simulate a 64-QAM communications system over an AWGN channel with a shortened RS block code. It showed how to configure the RS decoder to shorten a (63,53) code to a (28,18) code. System performance was measured using channel and coded BER curves obtained using error rate measurement System objects.

Helper functions used in this example:

- helperRSCodingConfig.m
- helperRSCodingGetErasures.m

Algorithms

This object implements the algorithm, inputs, and outputs described in “Algorithms for BCH and RS Errors-only Decoding”.

Topics

“Reed-Solomon Codes”

Introduced in R2012a

step

System object: `comm.RSEncoder`
Package: `comm`

Encode data using a Reed-Solomon encoder

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` encodes the numeric column input data vector, `X`, and returns the encoded data, `Y`. The value of the `BitInput` property determines whether `X` is a vector of integers or bits with a numeric, logical, or fixed-point data type. The input and output length of the step function equal the values listed in the table in “Input and Output Signal Lengths in BCH and RS System Objects” on page 3-91.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.Scrambler

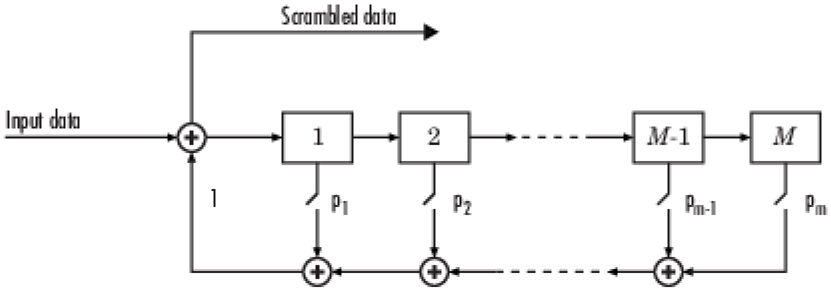
Package: `comm`

Scramble input signal

Description

The comm.Scrambler object scrambles a scalar or column vector input signal.

This schematic shows the scrambler operation. The adders operate modulo *N*, where *N* is the value specified by the Calculation base property.



At each time step, the input causes the contents of the registers to shift sequentially. Using the Polynomial property, you specify the on or off state for each switch in the scrambler.

To scramble an input signal:

1. Create the `comm.Scrambler` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
scrambler = comm.Scrambler
scrambler = comm.Scrambler(base,poly,cond)
scrambler = comm.Scrambler( ___ ,Name,Value)
```

Description

`scrambler = comm.Scrambler` creates a scrambler System object. This object scrambles the input data by using a linear feedback shift register that you specify with the Polynomial property.

`scrambler = comm.Scrambler(base,poly,cond)` creates the scrambler object with the CalculationBase property set to `base`, the Polynomial property set to `poly`, and the InitialConditions property set to `cond`.

Example: `comm.Scrambler(8,'1 + z^-2 + z^-3 + z^-5 + z^-7',[0 3 2 2 5 1 7])` sets the calculation base to 8, and the scrambler polynomial and initial conditions as specified.

`scrambler = comm.Scrambler( ___ ,Name,Value)` sets properties using one or more name-value pairs and either of the previous syntaxes. Enclose each property name in single quotes.

Example: `comm.Scrambler('CalculationBase',2)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`CalculationBase` — Range of input data
4 (default) | nonnegative integer

Range of input data used in the scrambler for modulo operations, specified as a nonnegative integer. The input and output of this object are integers from `0` to `CalculationBase` – `1`.

Data Types: `double`

`Polynomial` — Connections for linear feedback shift registers
`'1 + z^-1 + z^-2 + z^-4'` (default) | character vector | integer vector | binary vector

Connections for linear feedback shift registers in the scrambler, specified as a character vector, integer vector, or binary vector. The `Polynomial` property defines if each switch in the scrambler is on or off. Specify the polynomial as:

- A character vector, such as `'1 + z^-6 + z^-8'`. For more details on specifying polynomials in this way, see Character Representation of Polynomials.
- An integer vector, such as `[0 -6 -8]`, listing the scrambler coefficients in order of descending powers of z^{-1}, where $p(z^{-1}) = 1 + p_1 z^{-1} + p_2 z^{-2} + ...$
- A binary vector, such as `[1 0 0 0 0 0 1 0 1]`, listing the powers of z that appear in the polynomial that have a coefficient of 1. In this case, the order of the scramble polynomial is one less than the binary vector length.

Example: `'1 + z^-6 + z^-8'`, `[0 -6 -8]`, and `[1 0 0 0 0 0 1 0 1]` all represent this polynomial:

$p(z^{-1}) = 1 + z^{-6} + z^{-8}$

Data Types: `double` | `char`

`InitialConditionsSource` — Initial conditions source
`'Property'` (default) | `'Input port'`

- `'Property'` – Specify scrambler initial conditions by using the InitialConditions property.
- `'Input port'` – Specify scrambler initial conditions by using an additional input argument, initcond, when calling the object.

Data Types: `char`

`InitialConditions` — Initial conditions of scrambler registers
`[0 1 2 3]` (default) | nonnegative integer vector

Initial conditions of scrambler registers when the simulation starts, specified as a nonnegative integer vector. The length of `InitialConditions` must equal the order of the Polynomial property. The vector element values must be integers from `0` to CalculationBase – `1`.

Dependencies

This property is available when InitialConditionsSource is set to `'Property'`.

`ResetInputPort` — Scrambler state reset port
`false` (default) | `true`

Scrambler state reset port, specified as `false` or `true`. If `ResetInputPort` is `true`, you can reset the scrambler object by using an additional input argument, reset, when calling the object.

Dependencies

This property is available when InitialConditionsSource is set to `'Property'`.

Usage

Syntax

```
scrambledOut = scrambler(signal)
scrambledOut = scrambler(signal,initcond)
scrambledOut = scrambler(signal,reset)
```

Description

`scrambledOut = scrambler(signal)` scrambles the input signal. The output is the same data type and length as the input vector.

`scrambledOut = scrambler(signal,initcond)` provides an additional input with values specifying the initial conditions of the linear feedback shift register.

This syntax applies when you set the InitialConditionsSource property of the object to `'Input port'`.

`scrambledOut = scrambler(signal,reset)` provides an additional input indicating whether to reset the state of the scrambler.

This syntax applies when you set InitialConditionsSource to `'Property'` and ResetInputPort to `true`.

Input Arguments

`signal` — Input signal
column vector

Input signal, specified as a column vector.

Example: `scrambledOut = scrambler([0 1 1 0 1])`

Data Types: `double` | `logical`

`initcond` — Initial register conditions
nonnegative integer column vector

Initial scrambler register conditions when the simulation starts, specified as a nonnegative integer column vector. The length of `initcond` must equal the order of the Polynomial property. The vector element values must be integers from `0` to CalculationBase – `1`.

Example: `scrambledOut = scrambler(signal,[0 1 1 0])` corresponds to possible initial register states for a scrambler with a polynomial order of 4 and a calculation base of 2 or higher.

Data Types: `double`

`reset` — Reset initial state of scrambler
scalar

Reset the initial state of the scrambler when the simulation starts, specified as a scalar. When the value of `reset` is nonzero, the object is reset before it is called.

Example: `scrambledOut = scrambler(signal,0)` scrambles the input signal without resetting the scrambler states.

Data Types: `double`

Output Arguments

`out` — Scrambled output
column vector

Scrambled output, returned as a column vector with the same data type and length as signal.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Scramble and Descramble Data

Scramble and descramble 8-ary data using `comm.Scrambler` and `comm.Descrambler` System objects™ having a calculation base of 8.

Create scrambler and descrambler objects, specifying the calculation base, polynomial, and initial conditions using input arguments. The scrambler and descrambler polynomials are specified with different but equivalent data formats.

```
N = 8;
scrambler = comm.Scrambler(N,'1 + z^-2 + z^-3 + z^-5 + z^-7', ...
    [0 3 2 2 5 1 7]);
descrambler = comm.Descrambler(N,[1 0 1 1 0 1 0 1], ...
    [0 3 2 2 5 1 7]);
```

Scramble and descramble random integers. Display the original data, scrambled data, and descrambled data sequences.

```
data = randi([0 N-1],5,1);
scrData = scrambler(data);
deScrData = descrambler(scrData);
[data scrData deScrData]
```

```
ans = 5×3

     6     7     6
     7     5     7
     1     7     1
     7     0     7
     5     3     5
```

Verify that the descrambled data matches the original data.

```
isequal(data,deScrData)
```

```
ans = logical
   1
```

Scramble and Descramble Data with Changing Initial Conditions

Scramble and descramble quaternary data while changing the initial conditions between function calls.

Create scrambler and descrambler System objects having a calculation base of 4. Set the `InitialConditionsSource` property to `'Input port'` so you can set the initial conditions as an argument to the object.

```
N = 4;
scrambler = comm.Scrambler(N,'1 + z^-3','InitialConditionsSource','Input port');
descrambler = comm.Descrambler(N,'1 + z^-3','InitialConditionsSource','Input port');
```

Preallocate memory for the error vector which will be used to store errors output by the `symerr` function.

```
errVec = zeros(10,1);
```

Scramble and descramble random integers while changing the initial conditions, `initCond`, each time the loop executes. Use the `symerr` function to determine if the scrambling and descrambling operations result in symbol errors.

```
for k = 1:10
    initCond = randperm(3)';
    data = randi([0 N-1],5,1);
    scrData = scrambler(data,initCond);
    deScrData = descrambler(scrData,initCond);
    errVec(k) = symerr(data,deScrData);
end
```

Examine `errVec` to verify that the output from the descrambler matches the original data.

```
errVec
```

```
errVec = 10×1

     0
     0
     0
     0
     0
     0
     0
     0
     0
     0
```

Scrambler

Introduced in R2012a

comm.SphereDecoder

Package: `comm`

Decode input using sphere decoder

Description

The `Sphere Decoder` System object decodes the symbols sent over N_T antennas using the sphere decoding algorithm.

To decode input symbols using a sphere decoder:

1. Define and set up your sphere decoder object. See "Construction" on page 3-1367.
2. Call `step` to decode input symbols according to the properties of `comm.SphereDecoder`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.SphereDecoder` creates a System object, `H`. This object uses the sphere decoding algorithm to find the maximum-likelihood solution for a set of received symbols over a MIMO channel with N_T transmit antennas and N_R receive antennas.

`H = comm.SphereDecoder(Name,Value)` creates a sphere decoder object, `H`, with the specified property name set to the specified value. Name must appear inside single quotes (''). You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

`H = comm.SphereDecoder(CONSTELLATION,BITTABLE)` creates a sphere decoder object, `H`, with the Constellation property set to `CONSTELLATION`, and the `BitTable` property set to `BITTABLE`.

Properties

`Constellation`

Signal constellation per transmit antenna

Specify the constellation as a complex column vector containing the constellation points to which the transmitted bits are mapped. The default setting is a QPSK constellation with an average power of `1`. The length of the vector must be a power of two. The object assumes that each transmit antenna uses the same constellation.

`BitTable`

Bit mapping used for each constellation point.

Specify the bit mapping for the symbols that the `Constellation` property specifies as a numerical matrix. The default is `[0 0; 0 1; 1 0; 1 1]`, which matches the default `Constellation` property value.

The matrix size must be `[ConstellationLength bitsPerSymbol]`. `ConstellationLength` represents the length of the `Constellation` property. `bitsPerSymbol` represents the number of bits that each symbol encodes.

`InitialRadius`

Initial search radius of the decoding algorithm.

Specify the initial search radius for the decoding algorithm as either `Infinity` | `ZF Solution`. The default is `Infinity`.

When you set this property to `Infinity`, the object sets the initial search radius to `Inf`.

When you set this property to `ZF Solution`, the object sets the initial search radius to the zero-forcing solution. This calculation uses the pseudo-inverse of the input channel when decoding. Large constellations and/or antenna counts can benefit from the initial reduction in the search radius. In most cases, however, the extra computation of the `ZF Solution` will not provide a benefit.

`DecisionType`

Specify the decoding decision method as either `Soft` | `Hard`. The default is `Soft`.

When you set this property to `Soft`, the decoder outputs log-likelihood ratios (LLRs), or soft bits.

When you set this property to `Hard`, the decoder converts the soft LLRs to bits. The hard-decision output logical array follows the mapping of a zero for a negative LLR and one for all other values.

Methods

step	Decode received symbols using sphere decoding algorithm

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Decode Using a Sphere Decoder

Modulate a set of bits using 16-QAM constellation. Transmit the signal as two parallel streams over a MIMO channel. Decode using a sphere decoder with perfect channel knowledge.

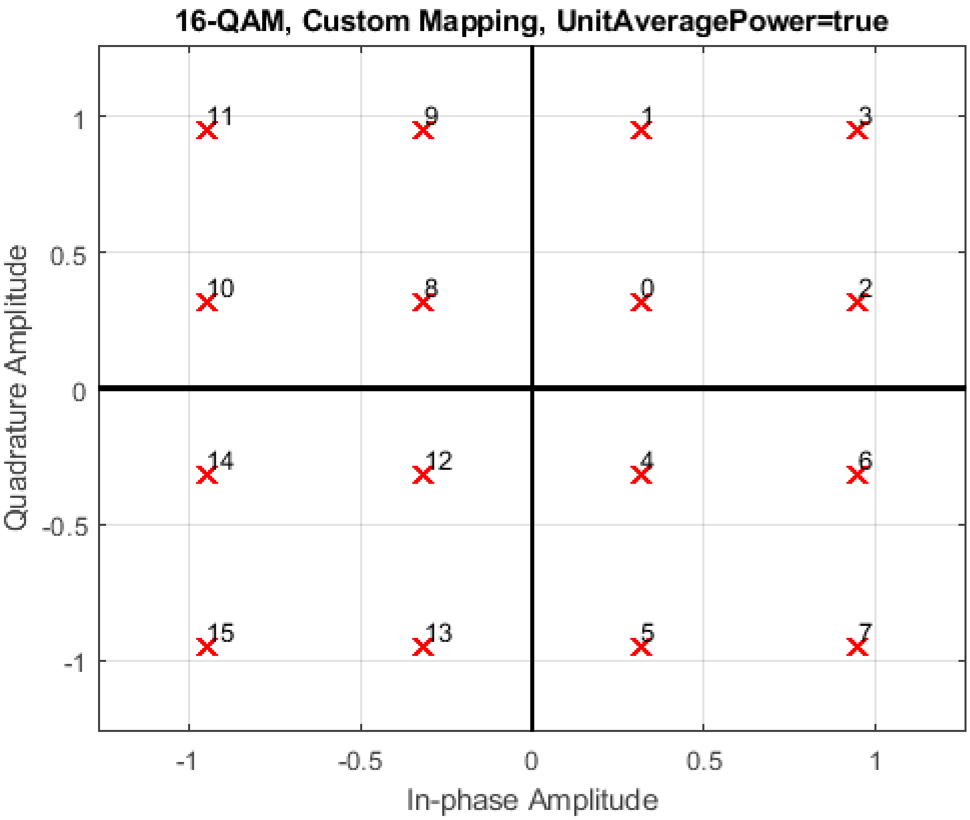
Specify the modulation order, the number of transmitted bits, the Eb/No ratio, and the symbol mapping.

```
bps = 4; % Bits per symbol
M = 2^bps; % Modulation order
nBits = 1e3*bps;
```

```
ebno = 10;
symMap = [11 10 14 15 9 8 12 13 1 0 4 5 3 2 6 7];
```

Generate and display the symbol mapping of the 16-QAM modulator by using the `qammod` function and the custom symbol map.

```
sym = qammod(symMap(1:M)',M,symMap,'UnitAveragePower',true,'PlotConstellation',true);
```



Convert the decimal value of the symbol map to binary bits using the left bit as the most significant bit (msb). The `M`-by-`bps` matrix `bitTable` is used by the sphere decoder.

```
bitTable = de2bi(symMap,bps,'left-msb');
```

Create a 2x2 MIMO Channel System object with `PathGainsOutputPort` set to `true` to use the path gains as a channel estimate. To ensure the repeatability of results, set the object to use the global random number stream.

```
mimo = comm.MIMOChannel( ...
    'PathGainsOutputPort',true, ...
    'RandomStream','Global stream');
```

Create an AWGN Channel System object.

```
awgnChan = comm.AWGNChannel('EbNo',ebno,'BitsPerSymbol',bps);
```

Create a Sphere Decoder System object that processes bits using hard-decision decoding. Configure using the custom bit table and symbol map.

```
sphDec = comm.SphereDecoder('Constellation',sym, ...
    'BitTable',bitTable,'DecisionType','Hard');
```

Create an error rate System object.

```
berRate = comm.ErrorRate;
```

Set the global random number generator seed.

```
rng(37)
```

Generate a random data stream.

```
data = randi([0 1],nBits,1);
```

Modulate the data and reshape it into two streams to be used with the 2x2 MIMO channel.

```
modData = qammod(data,M,symMap,'InputType','bit','UnitAveragePower',true);
modData = reshape(modData,[],2);
```

Pass the modulated data through the MIMO fading channel and add AWGN.

```
[fadedSig,pathGains] = mimo(modData);
rxSig = awgnChan(fadedSig);
```

Decode the received signal using `pathGains` as a perfect channel estimate.

```
decodedData = sphDec(rxSig,squeeze(pathGains));
```

Convert the decoded hard-decision data, which is a logical matrix, into a double column vector to enable the calculation of error statistics. Calculate and display the bit error rate and the number of errors.

```
dataOut = double(decodedData(:));
errorStats = berRate(data,dataOut);
errorStats(1:2)
```

```
ans = 2×1

    0.0380
  152.0000
```

Algorithm

This object implements a soft-output max-log a posteriori probability (APP) MIMO detector by means of a soft-output Schnorr-Euchner sphere decoder (SESD), implemented as single tree search (STS) tree traversal. The algorithm assumes the same constellation and bit table on all of the transmit antennas. Given as inputs, the received symbol vector and the estimated channel matrix, the algorithm outputs the log-likelihood ratios (LLRs) of the transmitted bits.

The algorithm assumes a MIMO system model with N_{T} transmit antennas and N_{R} receive antennas where N_{T} symbols are simultaneously sent, expressed as:

$y = Hs + n.$

where y is the received symbols, H is the MIMO channel matrix, s is the transmitted symbol vector, and n is the thermal noise.

The MIMO detector seeks the maximum-likelihood (ML) solution, $\widehat{s}_{ML}$, such that:

$$\widehat{s}_{ML} = \underset{s \in o}{\operatorname{argmin}} \|y - Hs\|^2$$

where O is the complex-valued constellation from which the N_{T} elements of s are chosen.

Soft detection also computes a log-likelihood ratio (LLR) for each bit that serves as a measure of the reliability of the estimate for each bit. The LLR is calculated as using the max-log approximation:

$$L(x_{j,b}) = \underbrace{\min_{s \in x_{j,b}^{(0)}} \|y - Hs\|^2}_{\lambda^{ML}} - \underbrace{\min_{s \in x_{j,b}^{(1)}} \|y - Hs\|^2}_{\lambda_{j,b}^{\overline{ML}}}$$

where

- $L(x_{j,b})$ is the LLR estimate for each bit.
- $x_{j,b}$ is each sent bit, the bth bit of the jth symbol.
- $x_{j,b}^{(0)}$ and $x_{j,b}^{(1)}$ are the disjoint sets of vector symbols that have the bth bit in the label of the jth scalar symbol equal to 0 and 1, respectively. The two λ symbols denotes the distance calculated as norm squared., specifically:
  - λ^{ML} is the distance $\widehat{s}_{ML}$.
  - $\lambda_{j,b}^{\overline{ML}}$ is the distance to the counter-hypothesis, which denotes the binary complement of the bth bit in the binary label of the jth entry of $\widehat{s}_{ML}$, specifically the minimum of the symbol set $x_{j,b}^{\left(x_{j,b}^{\overline{ML}}\right)}$, which contains all of the possible vectors for which the bth bit of the jth entry is flipped compared to the same entry of $\widehat{s}_{ML}$.

Based on whether $x_{j,b}^{\left(x_{j,b}^{ML}\right)}$ is `0` or `1`, the LLR estimate for bit $x_{j,b}$ is computed as follows:

$$L(x_{j,b}) = \begin{cases} \lambda^{ML} - \lambda_{j,b}^{\overline{ML}}, & x_{j,b}^{ML} = 0 \\ \lambda_{j,b}^{\overline{ML}} - \lambda^{ML}, & x_{j,b}^{ML} = 1 \end{cases}$$

The design of a decoder strives to efficiently find $\widehat{s}_{ML}$, λ^{ML}, and $\lambda_{j,b}^{\overline{ML}}$.

This search can be converted into a tree search by means of the sphere decoding algorithms. To this end, the channel matrix is decomposed into $H = QR$ by means of a QR decomposition. Left-multiplying y by Q^{H}, the problem can be reformulated as:

$$\lambda^{ML} = \underset{s \in o}{\arg\min} \|\bar{y} - Rs\|^2$$

$$\lambda_{j,b}^{\overline{ML}} = \underset{s \in x_{j,b}^{\left(x_{j,b}^{\overline{ML}}\right)}}{\text{argmin}} \|\bar{y} - Rs\|^2$$

Using this reformulated problem statement, the triangular structure of R can be exploited to arrange a tree structure such that each of the leaf nodes corresponds to a possible s vector and the partial distances to the nodes in the tree can be calculated cumulatively adding to the partial distance of the parent node.

In the STS algorithm, the λ^{ML} and $\lambda_{j,b}^{\overline{ML}}$ metrics are searched concurrently. The goal is to have a list containing the metric λ^{ML}, along with the corresponding bit sequence x^{ML} and the metrics $x_{j,b}^{\left(x_{j,b}^{\overline{ML}}\right)}$ of all counter-hypotheses. The sub-tree originating from a given node is searched only if the result can lead to an update of either λ^{ML} or $\lambda_{j,b}^{\overline{ML}}$.

The STS algorithm flow can be summarized as:

1. If when reaching a leaf node, a new ML hypothesis is found $\left(d(x) < \lambda^{ML}\right)$, all $\lambda_{j,b}^{\overline{ML}}$ for which $x_{j,b} = x_{j,b}^{\overline{ML}}$ are set to λ^{ML} which now turns into a valued counter-hypothesis. Then, λ^{ML} is set to the current distance, $d(x)$.
2. If $d(x) \geq \lambda^{ML}$, only the counter-hypotheses have to be checked. For all j and b for which $\left(d(x) < \lambda^{ML}\right)$ and $x_{j,b} = x_{j,b}^{\overline{ML}}$, the decoder updates $\lambda_{j,b}^{\overline{ML}}$ to be $d(x)$.
3. A sub-tree is pruned if the partial distance of the node is bigger than the current $\lambda_{j,b}^{\overline{ML}}$ which may be affected when traversing the subtree.
4. The STS concludes once all of the tree nodes have been visited once or pruned.

Limitations

- The output LLR values are not scaled by the noise variance. For coded links employing iterative coding (LDPC or turbo) or MIMO OFDM with Viterbi decoding, the output LLR values should be scaled by the channel state information to achieve better performance.

Sphere Decoder | `comm.LTEMIMOChannel` | `comm.MIMOChannel` | `comm.OSTBCCombiner`

Introduced in R2013a

step

System object: `comm.SphereDecoder`
Package: `comm`

Decode received symbols using sphere decoding algorithm

Syntax

```
Y = step(H, RXSYMBOLS, CHAN)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H, RXSYMBOLS, CHAN)` decodes the received symbols, RXSYMBOLS, using the sphere decoding algorithm. The algorithm can be employed to decode Ns channel realizations in one call, where in each channel realization, Nr symbols are received.

The inputs are:

`RXSYMBOLS`: a [Ns Nr] complex double matrix containing the received symbols.

`CHAN`: a [Ns Nt Nr] or [1 Nt Nr] complex double matrix representing the fading channel coefficients of the flat-fading MIMO channel. For the [Ns Nt Nr] case, the object applies each channel matrix to each Nr symbol set. For the block fading case, i.e., when the size of `CHAN` is [1 Nt Nr], the same channel is applied to all of the received symbols.

The output `Y`, which depends on the setting of the `DecisionType` property, is a double matrix containing the Log-Likelihood Ratios (LLRs) of the decoded bits or the bits themselves. For both cases, the size of the output is [Ns*bitsPerSymbol Nt], where `bitsPerSymbol` represents the number of bits per transmitted symbol, as determined by the `BitTable` property.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.SymbolSynchronizer

Package: `comm`

Correct symbol timing clock skew

Description

The `comm.SymbolSynchronizer` System object corrects symbol timing clock skew between a single-carrier transmitter and receiver for PAM, PSK, QAM, and OQPSK modulation schemes. For more information, see “Symbol Synchronization Overview” on page 3-1393.

Note The input signal operates on a sample-rate basis and the output signal operates on a symbol-rate basis.

To correct symbol timing clock skew:

1. Create the `comm.SymbolSynchronizer` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
symbolSync = comm.SymbolSynchronizer
symbolSync = comm.SymbolSynchronizer(Name,Value)
```

Description

`symbolSync = comm.SymbolSynchronizer` creates a symbol synchronizer System object for correcting the clock skew between a single-carrier transmitter and receiver.

`symbolSync = comm.SymbolSynchronizer(Name,Value)` sets properties using one or more name-value pairs. For example, `comm.SymbolSynchronizer('Modulation','OQPSK')` configures the symbol synchronizer System object for an OQPSK-modulated input signal. Enclose each property name in quotes.

Tunable `DampingFactor`, `NormalizedLoopBandwidth`, and `DetectorGain` properties enable you to optimize synchronizer performance in your simulation loop without releasing the object.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Name-Value Pair Arguments

`Modulation` — Modulation type

`'PAM/PSK/QAM'` (default) | `'OQPSK'`

Modulation type, specified as `'PAM/PSK/QAM'` or `'OQPSK'`.

Tunable: No

Data Types: `char` | `string`

`TimingErrorDetector` — Timing error detector method

`Zero-Crossing (decision-directed)` (default) | `Gardner (non-data-aided)` | `Early-Late (non-data-aided)` | `Mueller-Muller (decision-directed)`

Timing error detector method, specified as `Zero-Crossing (decision-directed)`, `Gardner (non-data-aided)`, `Early-Late (non-data-aided)`, or `Mueller-Muller (decision-directed)`. This property assigns the timing error detection scheme used in the synchronizer. For more information, see "Timing Error Detection (TED)" on page 3-1394.

Tunable: No

Data Types: `char` | `string`

`SamplesPerSymbol` — Samples per symbol

`2` (default) | integer greater than 1

Samples per symbol, specified as an integer greater than 1.

Tunable: No

Data Types: `double`

`DampingFactor` — Damping factor of loop filter

`1` (default) | positive scalar

Damping factor of the loop filter, specified as a positive scalar. For more information, see "Loop Filter" on page 3-1397.

Tunable: Yes

Data Types: `double` | `single`

`NormalizedLoopBandwidth` — Normalized bandwidth of loop filter

`0.01` (default) | scalar in the range (0, 1)

Normalized bandwidth of the loop filter, specified as a scalar in the range (0, 1). The loop bandwidth is normalized to the sample rate of the input signal. For more information, see "Loop Filter" on page 3-1397.

Note To ensure the symbol synchronizer locks, set the `NormalizedLoopBandwidth` property to a value less than `0.1`.

Tunable: Yes

Data Types: `double` | `single`

`DetectorGain` — Phase detector gain

`2.7` (default) | positive scalar

Phase detector gain, specified as a positive scalar.

Tunable: Yes

Data Types: `double` | `single`

Usage

Note For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Syntax

`symbols = symbolSync(samples)`

Description

`symbols = symbolSync(samples)` corrects symbol timing clock skew between a single-carrier transmitter and receiver based on the input samples and outputs synchronized symbols.

- The input operates on a sample-rate basis and the output signal operates on a symbol-rate basis.
- You can tune the `DampingFactor`, `NormalizedLoopBandwidth`, and `DetectorGain` properties to improve the synchronizer performance.

Input Arguments

`samples` — Input samples

scalar (default) | column vector

Input samples, specified as a scalar or column vector of a PAM-, PSK-, QAM-, or OQPSK-modulated single-carrier signal.

Data Types: `double` | `single`
Complex Number Support: Yes

Output Arguments

`symbols` — Synchronized symbols

column vector

Synchronized symbols, returned as a variable-sized column vector. The output symbols inherit the data type from the input samples. For an input with dimensions N_{samp}-by-1, this output has dimensions N_{sym}-by-1. N_{sym} is approximately equal to N_{samp} divided by N_{sps}, where N_{sps} is equal to the

`SamplesPerSymbol` property value. If the output exceeds the maximum output size of $\left\lceil \frac{N_{\text{samp}}}{N_{\text{sps}}} \times 1.1 \right\rceil$, it is truncated.

`timingErr` — Estimated timing error
scalar in the range [0, 1] | column vector of elements in the range [0, 1]

Estimated timing error for each input sample, returned as a scalar in the range [0, 1] or column vector of elements in the range [0, 1]. The estimated timing error is normalized to the input sample rate. `timingErr` has the same data type and size as input `samples`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.SymbolSynchronizer`

clone	Create duplicate System object
isLocked	Determine if System object is in use

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Correct Symbol Timing Error of QPSK-Modulated Signal

Correct a fixed symbol timing error on a noisy QPSK-modulated signal. Check the bit error rate (BER) of the synchronized received signal.

Initialize simulation parameters.

```
M = 4;          % Modulation order for QPSK
nSym = 5000;    % Number of symbols in a packet
sps = 4;        % Samples per symbol
timingErr = 2; % Samples of timing error
snr = 15;       % Signal-to-noise ratio (dB)
```

Create root raised cosine (RRC) transmit and receive filter System objects.

```
txfilter = comm.RaisedCosineTransmitFilter( ...
    'OutputSamplesPerSymbol',sps);
rxfilter = comm.RaisedCosineReceiveFilter( ...
    'InputSamplesPerSymbol',sps,'DecimationFactor',2);
```

Create a symbol synchronizer System object to correct the timing error.

```
symbolSync = comm.SymbolSynchronizer;
```

Generate random M-ary symbols and apply QPSK modulation.

```
data = randi([0 M-1],nSym,1);
modSig = pskmod(data,M,pi/4);
```

Create a delay object to introduce a fixed timing error of 2 samples. Because the transmit RRC filter outputs 4 samples per symbol, 1 sample is equivalent to a 1/4 symbol through the fixed delay and channel.

```
fixedDelay = dsp.Delay(timingErr);
fixedDelaySym = ceil(fixedDelay.Length/sps); % Round fixed delay to nearest integer in symbols
```

Filter the modulated signal through a transmit RRC filter by using the `txfilter` object. Apply a signal timing error by using the `fixedDelay` object.

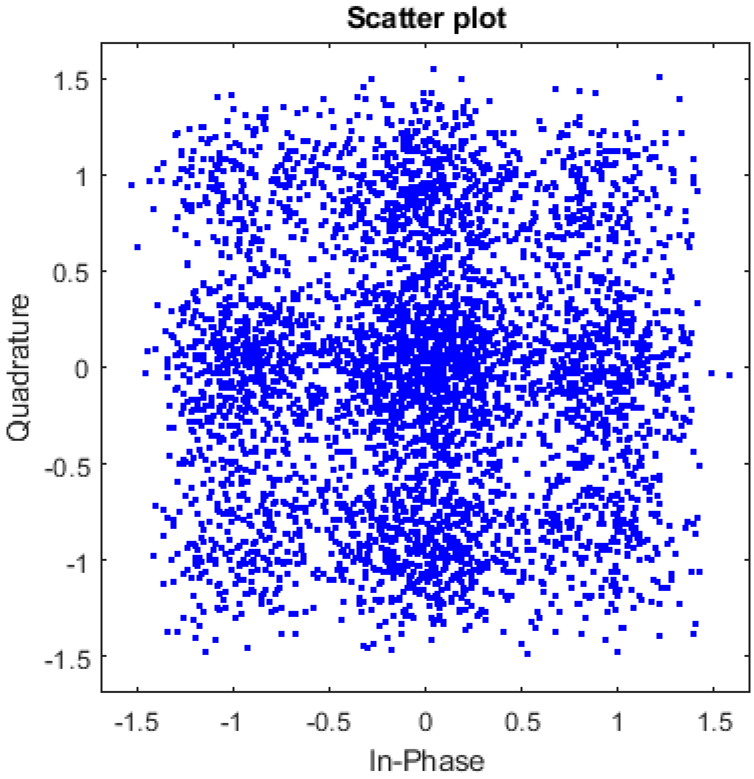
```
txSig = txfilter(modSig);
delaySig = fixedDelay(txSig);
```

Pass the delayed signal through an AWGN channel with a 15 dB signal-to-noise ratio.

```
rxSig = awgn(delaySig,snr,'measured');
```

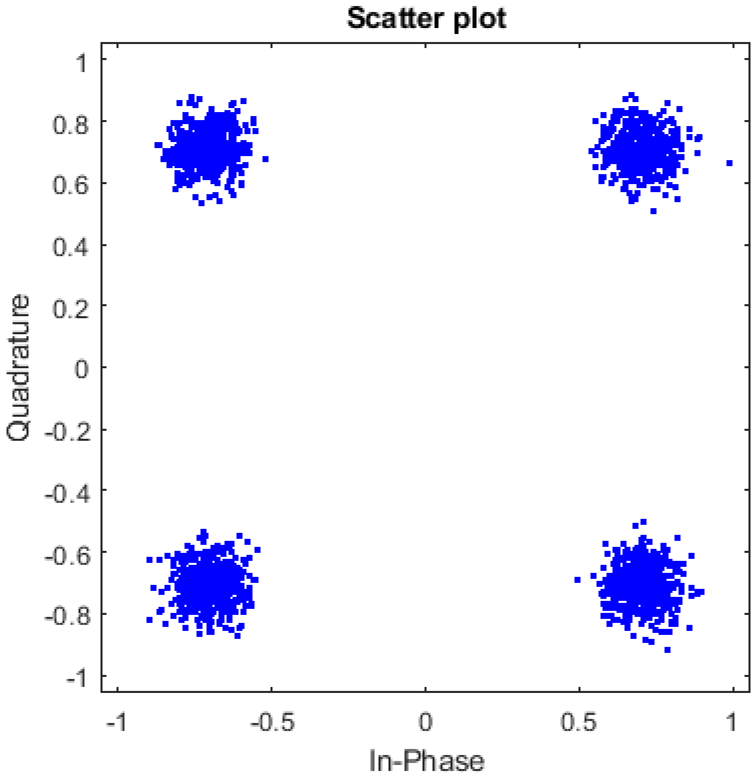
Filter the modulated signal through a receive RRC filter by using the `rxfilter` object. Display the scatter plot. Due to the timing error, the received signal does not align with the expected QPSK reference constellation.

```
rxSample = rxfilter(rxSig);
scatterplot(rxSample(1001:end),2)
```



Correct the symbol timing error by using the `symbolSync` object. Display the scatter plot. The synchronized signal now aligns with the expected QPSK constellation.

```
rxSync = symbolSync(rxSample);
scatterplot(rxSync(1001:end),2)
```



Demodulate the QPSK signal.

```
recData = pskdemod(rxSync,M,pi/4);
```

Compute, in symbols, the total system delay due to the fixed delay and the transmit and receive RRC filters.

```
sysDelay = dsp.Delay(fixedDelaySym + txfilter.FilterSpanInSymbols/2 + ...
    rxfilter.FilterSpanInSymbols/2);
```

Compute the BER, taking into account the system delay.

```
[numErr,ber] = biterr(sysDelay(data),recData)
```

```
numErr = 12
```

```
ber = 0.0012
```

Correct Symbol Timing Error of BPSK-Modulated Signal

Correct a fixed symbol timing error on a noisy BPSK transmission signal. Check the bit error rate (BER) of the synchronized received signal.

Initialize simulation parameters.

```
M = 2;          % Modulation order for BPSK
nSym = 20000;   % Number of symbols in a packet
sps = 4;        % Samples per symbol
timingErr = 2;  % Samples of timing error
snr = 15;       % Signal-to-noise ratio (dB)
```

Create root raised cosine (RRC) transmit and receive filter System objects.

```
txfilter = comm.RaisedCosineTransmitFilter(...
    'OutputSamplesPerSymbol',sps);
rxfilter = comm.RaisedCosineReceiveFilter(...
    'InputSamplesPerSymbol',sps,'DecimationFactor',1);
```

Create a symbol synchronizer System object™ to correct the timing error.

```
symbolSync = comm.SymbolSynchronizer(...
    'SamplesPerSymbol',sps, ...
    'NormalizedLoopBandwidth',0.01, ...
    'DampingFactor',1.0, ...
    'TimingErrorDetector','Early-Late (non-data-aided)');
```

Generate random data symbols and apply BPSK modulation.

```
data = randi([0 M-1],nSym,1);
modSig = pskmod(data,M);
```

Create a delay object to introduce a fixed timing error of 2 samples. Because the transmit RRC filter outputs 4 samples per symbol, 1 sample is equivalent to a 1/4 symbol through the fixed delay and channel.

```
fixedDelay = dsp.Delay(timingErr);
fixedDelaySym = ceil(fixedDelay.Length/sps); % Round fixed delay to nearest integer in symbols
```

Filter the modulated signal through a transmit RRC filter by using the `txfilter` object. Apply a signal timing error by using the `fixedDelay` object.

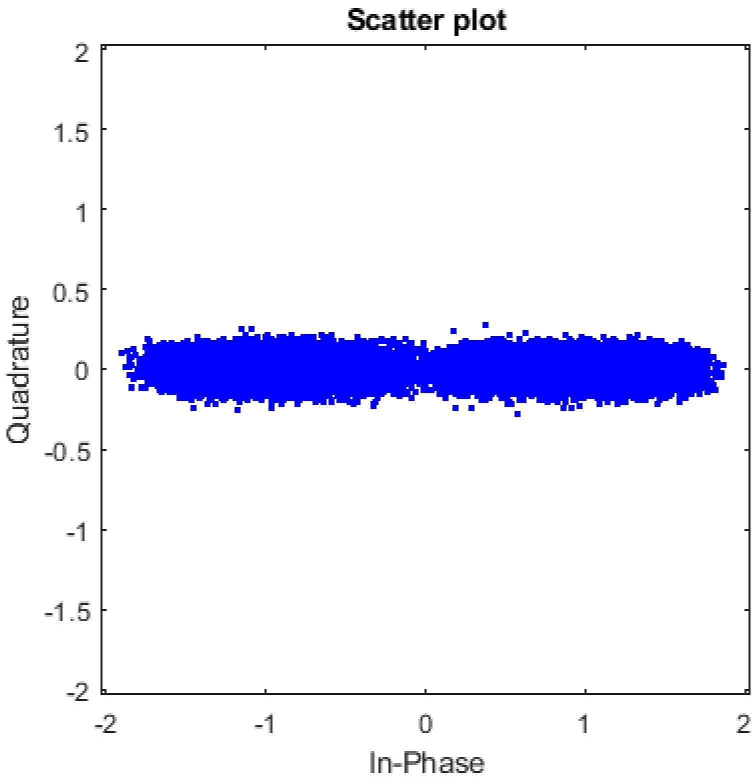
```
txSig = txfilter(modSig);
delayedSig = fixedDelay(txSig);
```

Pass the delayed signal through an AWGN channel.

```
rxSig = awgn(delayedSig,snr,'measured');
```

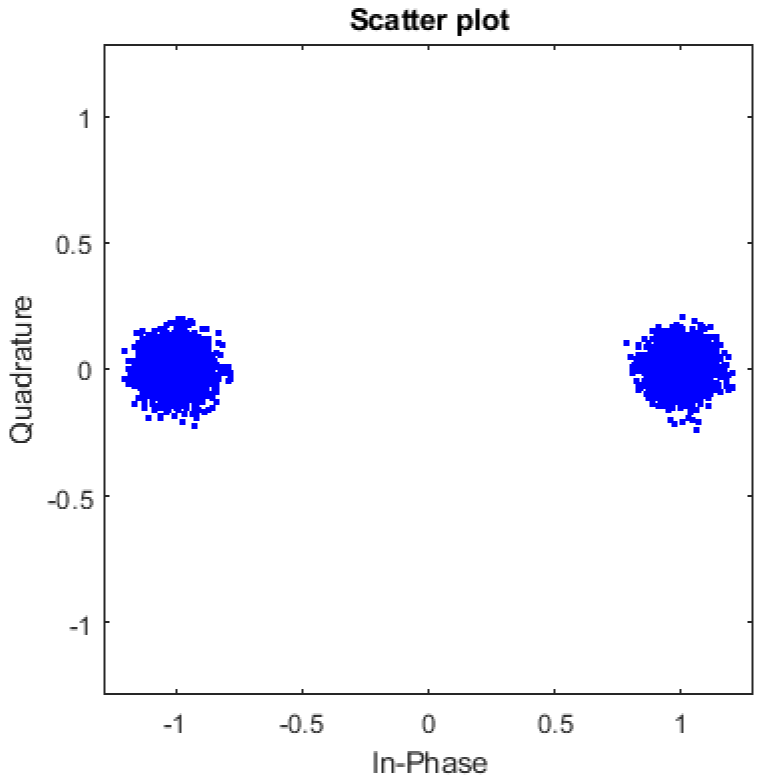
Filter the modulated signal through a receive RRC filter by using the `rxfilter` object. Display the scatter plot. Due to the timing error, the received signal does not align with the expected BPSK reference constellation.

```
rxSample = rxfilter(rxSig);
scatterplot(rxSample(10000:end),2)
```



Correct the symbol timing error by using the `symbolSync` object. Display the scatter plot. The synchronized signal now aligns with the expected BPSK constellation.

```
rxSync = symbolSync(rxSample);
scatterplot(rxSync(10000:end),2)
```



Demodulate the BPSK signal.

```
recData = pskdemod(rxSync,M);
```

Compute, in symbols, the total system delay due to the fixed delay and the transmit and receive RRC filters.

```
sysDelay = dsp.Delay(fixedDelaySym + txfilter.FilterSpanInSymbols/2 + ...
    rxfilter.FilterSpanInSymbols/2);
```

Compute the BER, taking into account the system delay.

```
[numErr1,ber1] = biterr(sysDelay(data),recData)
```

```
numErr1 = 8
```

```
ber1 = 4.0000e-04
```

Correct Symbol Timing and Doppler Offsets

Correct symbol timing and frequency offset errors by using the `comm.SymbolSynchronizer` and `comm.CarrierSynchronizer` System objects.

Configuration

Initialize simulation parameters.

```
M = 16;             % Modulation order
nSym = 2000;        % Number of symbols in a packet
sps = 2;            % Samples per symbol
spsFilt = 8;        % Samples per symbol for filters and channel
spsSync = 2;        % Samples per symbol for synchronizers
lenFilt = 10;       % RRC filter length
```

Create a matched pair of root raised cosine (RRC) filter System objects for transmitter and receiver.

```
txfilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',lenFilt, ...
    'OutputSamplesPerSymbol',spsFilt,'Gain',sqrt(spsFilt));
rxfilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',lenFilt, ...
    'InputSamplesPerSymbol',spsFilt,'DecimationFactor',spsFilt/2,'Gain',sqrt(1/spsFilt));
```

Create a phase-frequency offset System object to introduce a 100 Hz Doppler shift.

```
doppler = comm.PhaseFrequencyOffset('FrequencyOffset',100, ...
    'PhaseOffset',45,'SampleRate',1e6);
```

Create a variable delay System object to introduce timing offsets.

```
varDelay = dsp.VariableFractionalDelay;
```

Create carrier and symbol synchronizer System objects to correct for Doppler shift and timing offset, respectively.

```
carrierSync = comm.CarrierSynchronizer('SamplesPerSymbol',spsSync);
symbolSync = comm.SymbolSynchronizer( ...
    'TimingErrorDetector','Early-Late (non-data-aided)', ...
    'SamplesPerSymbol',spsSync);
```

Create constellation diagram System objects to view the results.

```
refConst = qammod(0:M-1,M,'UnitAveragePower',true);
cdReceive = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
    'SamplesPerSymbol',spsFilt,'Title','Received Signal');
cdDoppler = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
    'SamplesPerSymbol',spsSync,'Title','Frequency Corrected Signal');
cdTiming = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
    'SamplesPerSymbol',spsSync,'Title','Frequency and Timing Synchronized Signal');
```

Main Processing Loop

The main processing loop:

- Generates random symbols and apply QAM modulation.
- Filters the modulated signal.
- Applies frequency and timing offsets.
- Passes the transmitted signal through an AWGN channel.
- Filters the received signal.
- Corrects the Doppler shift.
- Corrects the timing offset.

```
for k = 1:15
    data = randi([0 M-1],nSym,1);
    modSig = qammod(data,M,'UnitAveragePower',true);
    txSig = txfilter(modSig);

    txDoppler = doppler(txSig);
    txDelay = varDelay(txDoppler,k/15);

    rxSig = awgn(txDelay,25);

    rxFiltSig = rxfilter(rxSig);
    rxCorr = carrierSync(rxFiltSig);
    rxData = symbolSync(rxCorr);
end
```

Visualization

Plot the constellation diagrams of the received signal, frequency corrected signal, and frequency and timing synchronized signal. Specific constellation points cannot be identified in the received signal and can be only partially identified in the frequency corrected signal. However, the timing and frequency synchronized signal aligns with the expected QAM constellation points.

```

Timing Error for Noisy 8-PSK Signal

Correct a monotonically increasing symbol timing error on a noisy 8-PSK signal. Display the normalized timing error.

Initialize simulation parameters.

```
M = 8;              % Modulation order
nSym = 5000;        % Number of symbol in a packet
sps = 2;            % Samples per symbol
nSamp = sps*nSym; % Number of samples in a packet
```

Create root raised cosine (RRC) transmit and receive filter System objects.

```
txfilter = comm.RaisedCosineTransmitFilter( ...
    'OutputSamplesPerSymbol',sps);
```

```
rxfilter = comm.RaisedCosineReceiveFilter( ...
    'InputSamplesPerSymbol',sps, ...
    'DecimationFactor',1);
```

Create a variable fractional delay System object™ to introduce a monotonically increasing timing error.

```
varDelay = dsp.VariableFractionalDelay;
```

Create a symbol synchronizer System object to correct the timing error.

```
symbolSync = comm.SymbolSynchronizer(...
    'TimingErrorDetector','Mueller-Muller (decision-directed)', ...
    'SamplesPerSymbol',sps);
```

Generate random 8-ary symbols and apply 8-PSK modulation.

```
data = randi([0 M-1],nSym,1);
modSig = pskmod(data,M,pi/8);
```

Filter the modulated signal through a raised cosine transmit filter and apply a monotonically increasing timing delay.

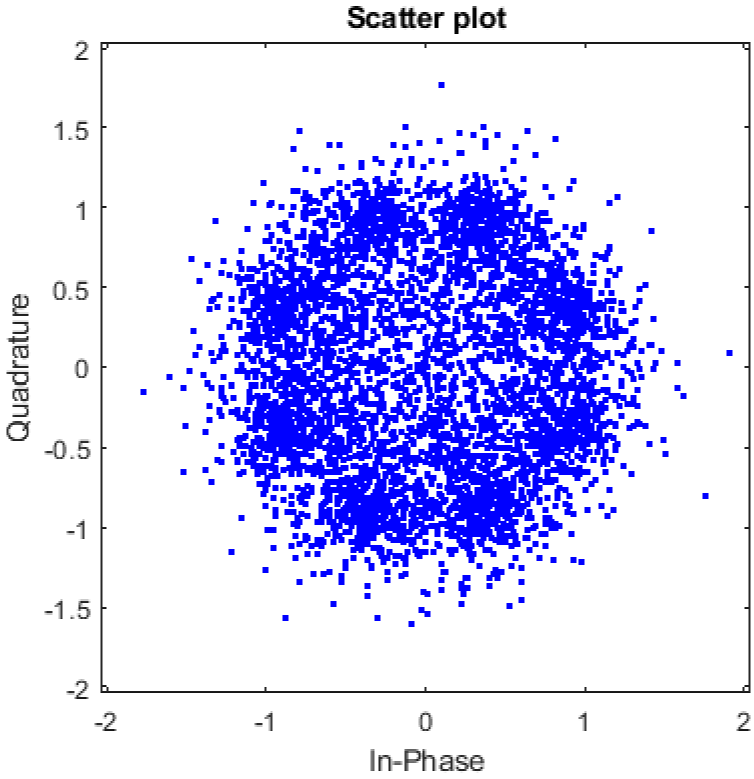
```
vdelay = (0:1/nSamp:1-1/nSamp)';
txSig = txfilter(modSig);
delaySig = varDelay(txSig,vdelay);
```

Pass the delayed signal through an AWGN channel with a 15 dB signal-to-noise ratio.

```
rxSig = awgn(delaySig,15,'measured');
```

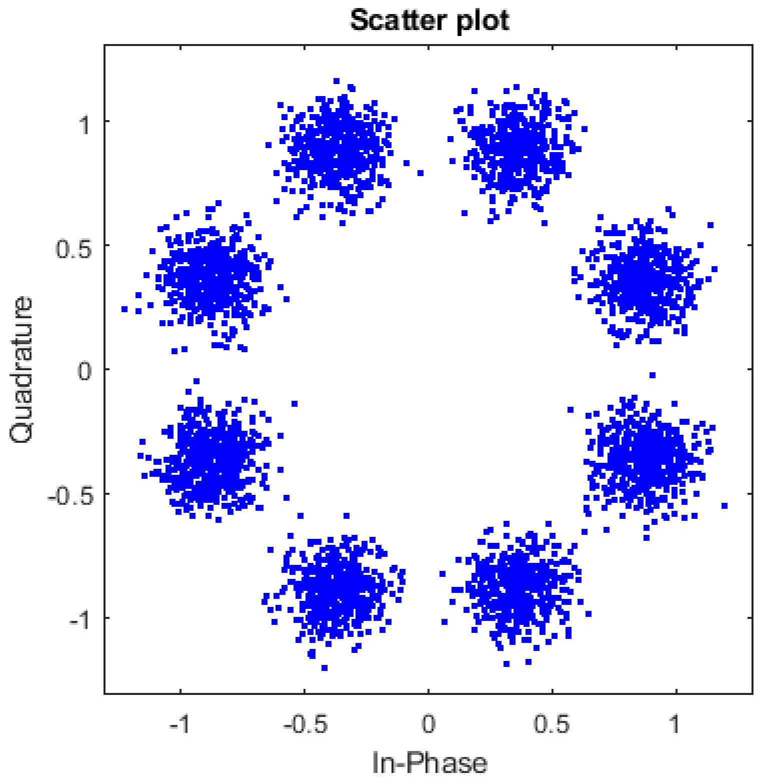
Filter the modulated signal through a receive RRC filter. Display the scatter plot. Due to the timing error, the received signal does not align with the expected 8-PSK reference constellation.

```
rxSample = rxfilter(rxSig);
scatterplot(rxSample,sps)
```



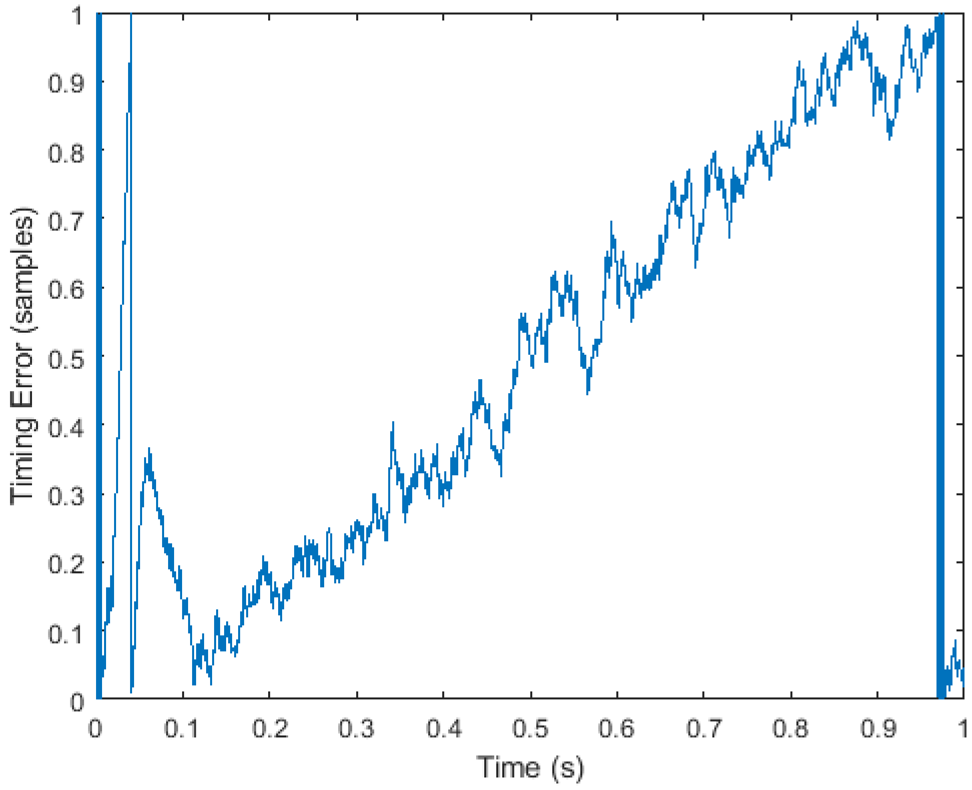
Correct the symbol timing error by using the `symbolSync` object. Display the scatter plot. The synchronized signal now aligns with the expected 8-PSK constellation.

```
[rxSym,tError] = symbolSync(rxSample);
scatterplot(rxSym(1001:end))
```



Plot the timing error estimate. Over time, the normalized timing error increases to 1 sample.

```
figure
plot(vdelay,tError)
xlabel('Time (s)')
ylabel('Timing Error (samples)')
```



More About

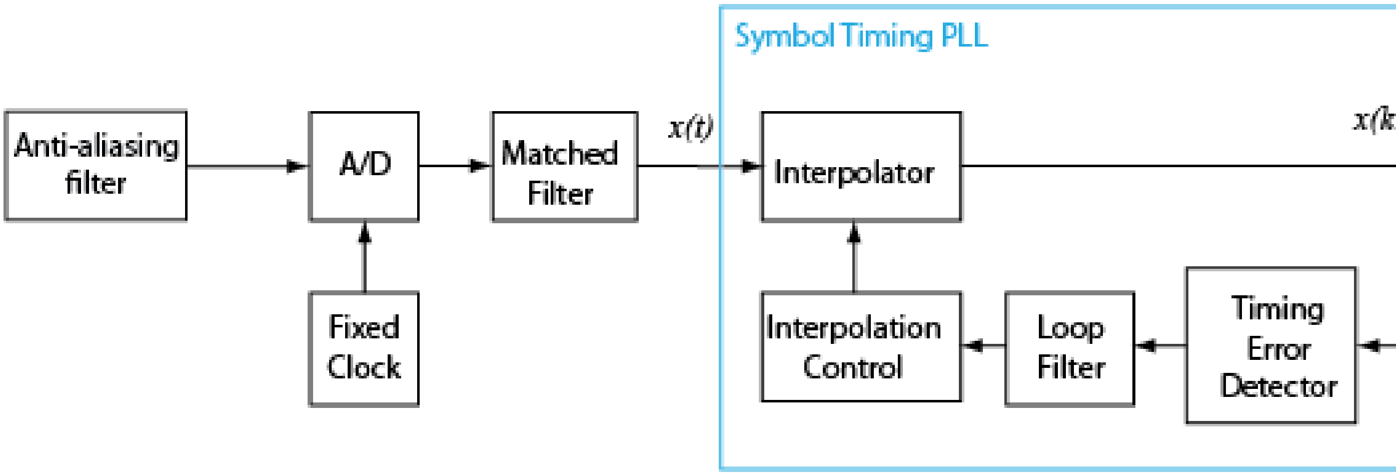
Symbol Synchronization Overview

The symbol timing synchronizer algorithm is based on a phased lock loop (PLL) algorithm that consists of four components:

- A timing error detector (TED)
- An interpolator
- An interpolation controller
- A loop filter

For OQPSK modulation, the in-phase and quadrature signal components are first aligned (as in QPSK modulation) using a state buffer to cache the last half symbol of the previous input. After initial alignment, the remaining synchronization process is the same as for QPSK modulation.

This block diagram shows an example of a timing synchronizer. In the figure, the symbol timing PLL operates on $x(t)$, the received sample signal after matched filtering. The symbol timing PLL outputs the symbol signal, $x(kT_s + \hat{\tau})$, after correcting for the clock skew between the transmitter and receiver.



Timing Error Detection (TED)

The symbol timing synchronizer supports non-data-aided TED and decision-directed TED methods. This table shows the timing estimate expressions for the TED method options.

TED Method	Expression
Zero-crossing (decision-directed)	$e(k) = x((k-1/2)T_s + \hat{\tau})[\hat{a}_0(k-1) - \hat{a}_0(k)] + y((k-1/2)T_s + \hat{\tau})[\hat{a}_1(k-1) - \hat{a}_1(k)]$
Gardner (non-data-aided)	$e(k) = x((k-1/2)T_s + \hat{\tau})[x((k-1)T_s + \hat{\tau}) - x(kT_s + \hat{\tau})] + y((k-1/2)T_s + \hat{\tau})[y((k-1)T_s + \hat{\tau}) - y(kT_s + \hat{\tau})]$
Early-late (non-data-aided)	$e(k) = x(kT_s + \hat{\tau})[x((k+1/2)T_s + \hat{\tau}) - x((k-1/2)T_s + \hat{\tau})] + y(kT_s + \hat{\tau})[y((k+1/2)T_s + \hat{\tau}) - y((k-1/2)T_s + \hat{\tau})]$
Mueller-Muller (decision-directed)	$e(k) = \hat{a}_0(k-1)x(kT_s + \hat{\tau}) - \hat{a}_0(k)x((k-1)T_s + \hat{\tau}) + \hat{a}_1(k-1)y(kT_s + \hat{\tau}) - \hat{a}_1(k)y((k-1)T_s + \hat{\tau})$

Non-data-aided TED uses received samples without any knowledge of the transmitted signal or the results of the channel estimation. Non-data-aided TED is used to estimate the timing error for signals with modulation schemes that have constellation points aligned with the in-phase or quadrature axis. Examples of signals suitable for the Gardner or early-late methods include QPSK-modulated signals with a zero phase offset that has points at {1+0*i*, 0+1*i*, -1+0*i*, 0−1*i*} and BPSK-modulated signals with a zero phase offset.

- **Gardner method** — The Gardner method is a non-data-aided feedback method that is independent of carrier phase recovery. It is used for baseband systems and modulated carrier systems. More specifically, this method is used for systems that use a linear modulation type with Nyquist pulses that have an excess bandwidth between approximately 40% and 100%. Examples include systems that use PAM, PSK, QAM, or OQPSK modulation and that shape the signal using raised cosine filters whose rolloff factor is between 0.4 and 1. In the presence of noise, the performance of this timing recovery method improves as the excess bandwidth increases (or rolloff factor increases in the case of a raised cosine filter). The Gardner method is similar to the early-late gate method.

- **Early-late method** — The early-late method is a non-data-aided feedback method. It is used for systems that use a linear modulation type such as PAM, PSK, QAM, or OQPSK modulation. For example, systems using a raised cosine filter with Nyquist pulses. In the presence of noise, the performance of this timing recovery method improves as the excess bandwidth of the pulse increases (or rolloff factor increases in the case of a raised cosine filter).

The early-late method is similar to the Gardner method. The Gardner method performs better in systems with high SNR values because it has lower self noise than the early-late method.

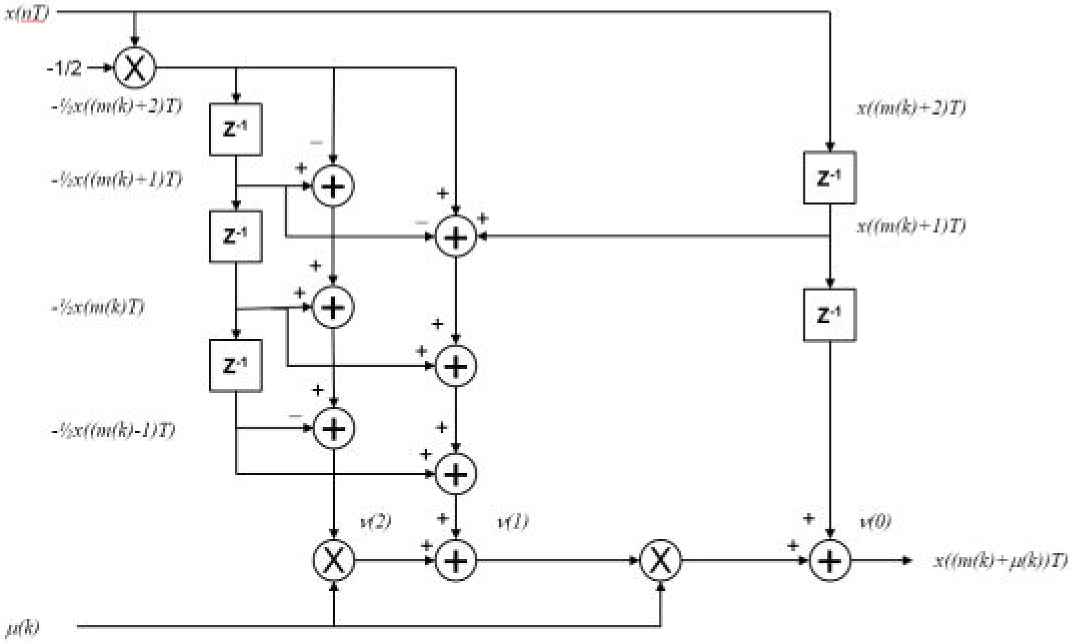
Decision-directed TED uses the `sign` function to estimate the in-phase and quadrature components of received samples, which result in lower computational complexity than non-data-aided TED.

- **Zero-crossing method** — The zero-crossing method is a decision-directed technique that requires 2 samples per symbol at the input to the synchronizer. It is used in low-SNR conditions for all values of excess bandwidth and in moderate-SNR conditions for moderate excess bandwidth factors in the approximate range [0.4, 0.6].
- **Mueller-Muller method** — The Mueller-Muller method is a decision-directed feedback method that requires prior recovery of the carrier phase. When the input signal has Nyquist pulses (for example, when using a raised cosine filter), the Mueller-Muller method has no self noise. For narrowband signaling in the presence of noise, the performance of the Mueller-Muller method improves as the excess bandwidth factor of the pulse decreases.

Because the decision-directed methods (zero-crossing and Mueller-Muller) estimate timing error based on the sign of the in-phase and quadrature components of signals passed to the synchronizer, they are not recommended for constellations that have points with either a zero in-phase or a quadrature component. $x(kT_S + \hat{\tau})$ and $y(kT_S + \hat{\tau})$ are the in-phase and quadrature components of the input signals to the timing error detector, where $\hat{\tau}$ is the estimated timing error. The Mueller-Muller method coefficients $\hat{a}_0(k)$ and $\hat{a}_1(k)$ are the estimates of $x(kT_S + \hat{\tau})$ and $y(kT_S + \hat{\tau})$. The timing estimates are made by applying the `sign` function to the in-phase and quadrature components and are used for only the decision-directed TED methods.

Interpolator

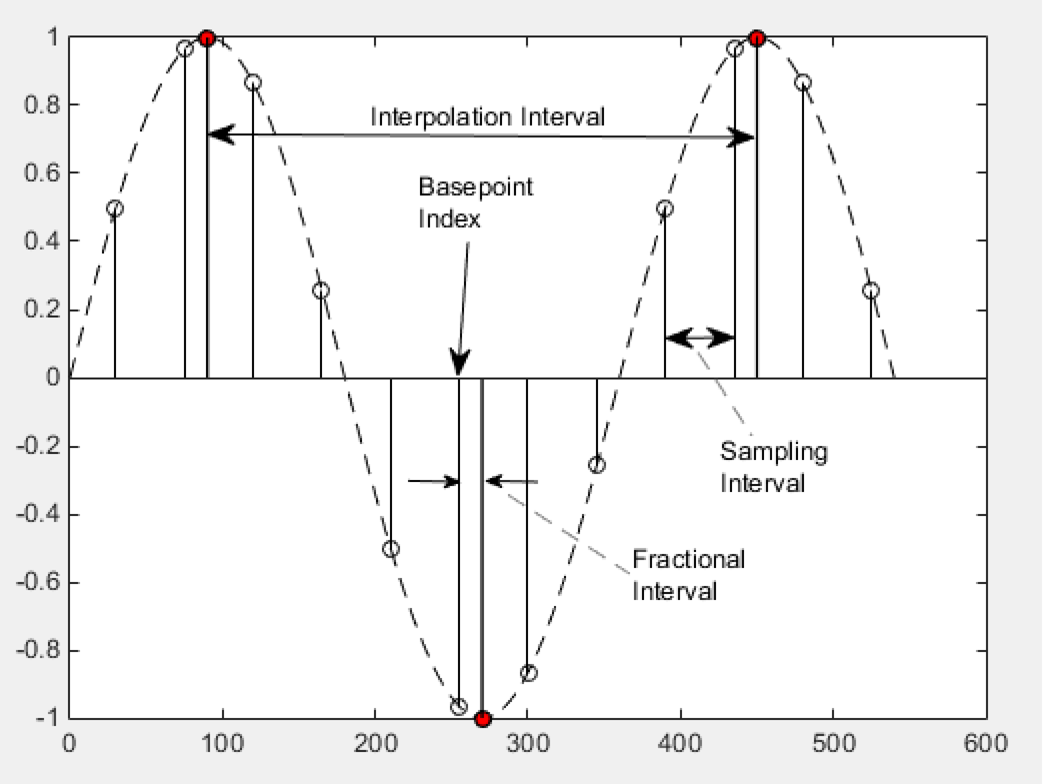
The time delay is estimated from the fixed-rate samples of the matched filter, which are asynchronous with the symbol rate. Because the resulting samples are not aligned with the symbol boundaries, an interpolator is used to "move" the samples. Because the time delay is unknown, the interpolator must be adaptive. Moreover, because the interpolant is a linear combination of the available samples, it can be thought of as the output of a filter.



The interpolator uses a piecewise parabolic interpolator with a Farrow structure and coefficient *α* set to 1/2 (see Rice, Michael, *Digital Communications: A Discrete-Time Approach*).

Interpolation Control

Interpolation control provides the interpolator with the basepoint index and fractional interval. The basepoint index is the sample index nearest to the interpolant. The fractional interval is the ratio of the time between the interpolant and its basepoint index and the interpolation interval.



Interpolation is performed for every sample, and a strobe signal is used to determine if the interpolant is output. The synchronizer uses a modulo-1 counter interpolation control to provide the strobe and the fractional interval for use with the interpolator.

Loop Filter

The synchronizer uses a proportional-plus integrator (PI) loop filter. The proportional gain, K_1, and the integrator gain, K_2, are calculated by

$$K_1 = \frac{-4\zeta\theta}{\left(1 + 2\zeta\theta + \theta^2\right)K_p}$$

and

$$K_2 = \frac{-4\theta^2}{\left(1 + 2\zeta\theta + \theta^2\right)K_p} .$$

The interim term, θ, is given by

$$\theta = \frac{\frac{B_n T_s}{N}}{\zeta + \frac{1}{4\zeta}} ,$$

where:

- N is the number of samples per symbol.

- ζ is the damping factor.
- B_nT_s is the normalized loop bandwidth.
- K_p is the detector gain.

Objects

`comm.CarrierSynchronizer`

Blocks

Symbol Synchronizer

Introduced in R2015a

comm.ThermalNoise

Package: `comm`

Add thermal noise to signal

Description

The `ThermalNoise` object simulates the effects of thermal noise on a complex, baseband signal.

To add thermal noise to a complex, baseband signal:

1. Define and set up your thermal noise object. See “Construction” on page 3-1399.
2. Call `step` to add thermal noise according to the properties of `comm.ThermalNoise`.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`tn = comm.ThermalNoise` creates a receiver thermal noise System object, `H`. This object adds thermal noise to the complex, baseband input signal.

`tn = comm.ThermalNoise(Name,Value)` creates a receiver thermal noise object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`NoiseMethod` — Method used to set noise power

`'Noise temperature'` (default) | `'Noise figure'` | `'Noise factor'`

Method used to set the noise power, specified as `'Noise temperature'`, `'Noise figure'`, or `'Noise factor'`.

`NoiseTemperature` — Receiver noise temperature

`290` (default) | nonnegative real scalar

Receiver noise temperature, specified in degrees K as a nonnegative real scalar. This property is available when `NoiseMethod` is equal to `'Noise temperature'`. Noise temperature is typically used to characterize satellite receivers because the input noise temperature can vary and is often less than 290 K. Tunable.

`NoiseFigure` — Noise figure

`3.01` (default) | nonnegative real scalar

Noise figure, specified in dB as a nonnegative real scalar. This property is available when `NoiseMethod` is equal to `'Noise figure'`. Noise figure describes the performance of a receiver and does not include the effect of the antenna. It is defined only for an input noise temperature of 290 K. The noise figure is the dB equivalent of the noise factor. Tunable.

`NoiseFactor` — Noise factor

2 (default) | real scalar ≥ 1

Noise factor, specified as a real scalar greater than or equal to 1. This property is available when `NoiseMethod` is equal to `'Noise factor'`. Noise factor describes the performance of a receiver and does not include the effect of the antenna. It is defined only for an input noise temperature of 290 K. The noise factor is the linear equivalent of the noise figure. Tunable.

`SampleRate` — Sample rate

1 (default) | positive real scalar

Sample rate, specified as in Hz as a positive real scalar. The object computes the variance of the noise added to the input signal as kT×`SampleRate`. The value k is Boltzmann's constant and T is the noise temperature specified explicitly or implicitly via one of the noise methods.

`Add290KAntennaNoise` — Add 290 K antenna noise

`false` (default) | `true`

Add 290 K antenna noise to the input signal, specified as a logical scalar. To add 290 K antenna noise, set this property to `true`. This property is available when `NoiseMethod` is equal to `'Noise factor'` or `'Noise figure'`.

The total noise applied to the input signal is the sum of the circuit noise and the antenna noise.

Methods

step	Add receiver thermal noise

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Add Thermal Noise to QPSK Signal

Create a thermal noise object having a noise temperature of 290 K and a sample rate of 5 MHz.

```
thNoise = comm.ThermalNoise('NoiseTemperature',290,'SampleRate',5e6);
```

Generate QPSK-modulated data having an output power of 20 dBm.

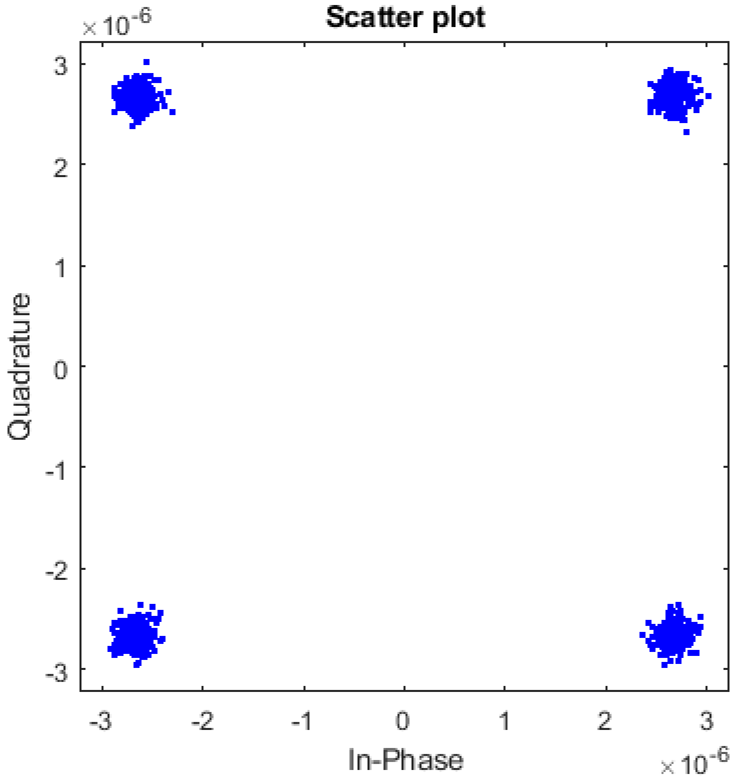
```
data = randi([0 3],1000,1);
modData = 0.3162*pskmod(data,4,pi/4);
```

Attenuate the signal by the free space path loss assuming a 1000 m link distance and a carrier frequency of 2 GHz.

```
fsl = (4*pi*1000*2e9/3e8)^2;
rxData = modData/sqrt(fsl);
```

Add thermal noise to the signal. Plot the noisy constellation.

```
noisyData = thNoise(rxData);
scatterplot(noisyData)
```



Add Antenna and Receiver Thermal Noise to 16-QAM Signal

Create a thermal noise object having a 5 dB noise figure and a 10 MHz sample rate. Specify that the 290 K antenna noise be included.

```
thermalNoise = comm.ThermalNoise('NoiseMethod','Noise figure', ...
    'NoiseFigure',5, ...
    'SampleRate',10e6, ...
    'Add290KAntennaNoise',true);
```

Generate QPSK-modulated data having a 1 W output power.

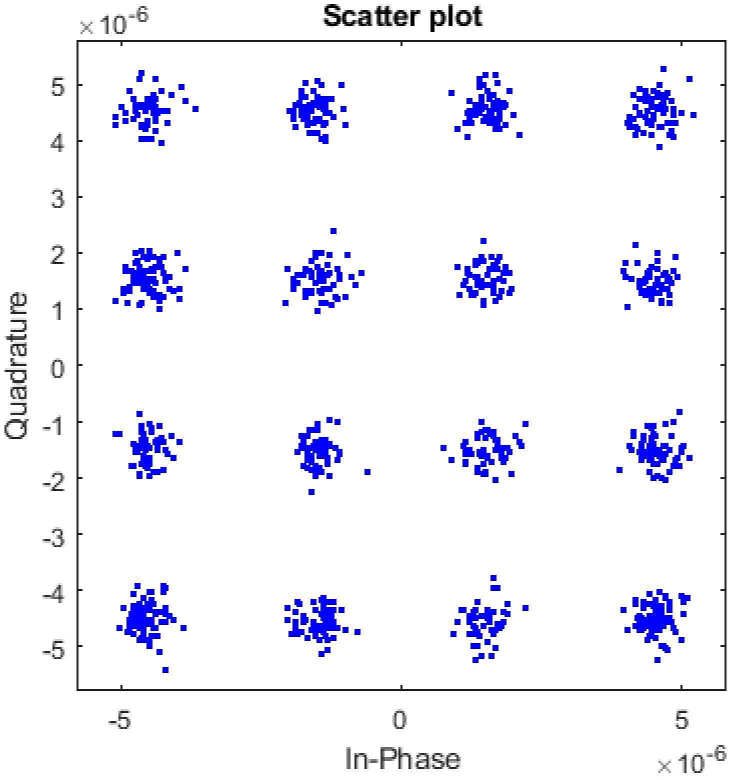
```
data = randi([0 15],1000,1);
modSig = qammod(data,16,'UnitAveragePower',true);
```

Attenuate the signal by the free space path loss assuming a 1 km link distance and a 5 GHz carrier frequency.

```
fsl = (4*pi*1000*5e9/3e8)^2;
rxSig = modSig/sqrt(fsl);
```

Add thermal noise to the signal and plot its constellation.

```
noisySig = thermalNoise(rxSig);
scatterplot(noisySig)
```



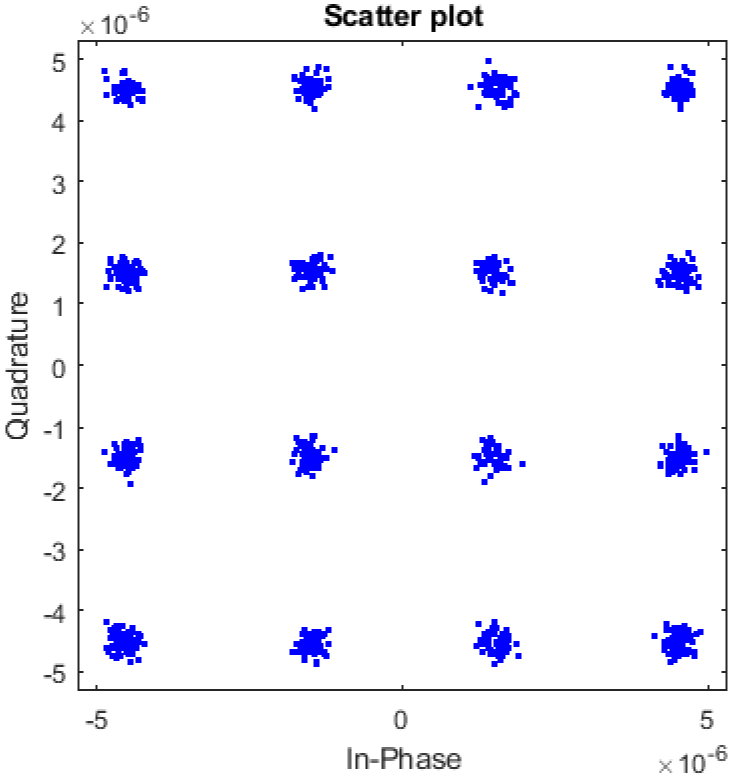
Estimate the SNR.

```
mer = comm.MER;
snrEst1 = mer(rxSig,noisySig)
```

```
snrEst1 = 22.6611
```

Decrease the noise figure to 0 dB, and plot the resultant received signal. Because antenna noise is included, the signal is not completely noiseless.

```
thermalNoise.NoiseFigure = 0;
noisySig = thermalNoise(rxSig);
scatterplot(noisySig)
```



Estimate the SNR. The SNR is 5 dB higher than in the first case, which is expected given the 5 dB decrease in the noise figure.

```
snrEst2 = mer(rxSig,noisySig)
```

```
snrEst2 = 27.8658
```

```
snrEst2 - snrEst1
```

```
ans = 5.2047
```

Algorithms

Wireless receiver performance is often expressed as a noise factor or figure. The noise factor is defined as the ratio of the input signal-to-noise ratio, S_i/N_i to the output signal-to-noise ratio, S_o/N_o, such that

$$F = \frac{S_i/N_i}{S_o/N_o} \; .$$

Given receiver gain G and receiver noise power N_{ckt}, the noise factor can be expressed as

$$\begin{aligned} F &= \frac{S_i/N_i}{GS_i/(N_{ckt} + GN_i)} \\ &= \frac{N_{ckt} + GN_i}{GN_i} \; . \end{aligned}$$

The IEEE defines the noise factor assuming that noise temperature at the input is T_0, where T_0 = 290 K. The noise factor is then

$$\begin{aligned} F &= \frac{N_{ckt} + GN_i}{GN_i} \\ &= \frac{GkBT_{ckt} + GkBT_0}{GkBT_0} \\ &= \frac{T_{ckt} + T_0}{T_0} \ . \end{aligned}$$

T_{ckt} is the equivalent input noise temperature of the receiver and is expressed as

$$T_{ckt} = T_0(F - 1) \ .$$

The overall noise temperature of an antenna and receiver, T_{sys}, is

$$T_{sys} = T_{ant} + T_{ckt} \, ,$$

where T_{ant} is the antenna noise temperature.

The noise figure, NF, is the dB equivalent of the noise factor and can be expressed as

$$NF = 10\log_{10}(F) \ .$$

`comm.AWGNChannel`

Introduced in R2012a

step

System object: `comm.ThermalNoise`
Package: `comm`

Add receiver thermal noise

Syntax

```
Y = step(H,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` adds thermal noise to the complex, baseband input signal, `X`, and outputs the result in `Y`. The input signal `X` must be a complex, double or single precision data type column vector or scalar.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.TurboDecoder

Package: `comm`

Decode input signal using parallel concatenated decoding scheme

Description

The `comm.TurboDecoder` System object uses a parallel concatenated decoding scheme to decode a coded input signal. The input signal is typically the soft-decision output from the baseband demodulation operation. For more information, see “Parallel Concatenated Convolutional Decoding Scheme” on page 3-1413.

To decode an input signal using a parallel concatenated decoding scheme:

1. Create the `comm.TurboDecoder` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
turbodec = comm.TurboDecoder
turbodec = comm.TurboDecoder(trellis,interlvrindices,numiter)
turbodec = comm.TurboDecoder(___,Name,Value)
```

Description

`turbodec = comm.TurboDecoder` creates a turbo decoder System object. This object uses the *a-posteriori* probability (APP) constituent decoder to iteratively decode the parallel-concatenated convolutionally encoded input data.

`turbodec = comm.TurboDecoder(trellis,interlvrindices,numiter)` creates a turbo decoder System object with the `TrellisStructure`, `InterleaverIndices`, and `numiter`, respectively. The `trellis` input must be specified as described by the `TrellisStructure` property. The `interlvrindices` input must be specified as described by the `InterleaverIndices` property. The `numiter` input must be specified as described by the `NumIterations` property.

`turbodec = comm.TurboDecoder(___,Name,Value)` sets properties using one or more name-value pairs in addition to any input argument combination from previous syntaxes. Enclose each property name in quotes. For example, `comm.TurboDecoder('InterleaverIndicesSource','Input port')` configures a turbo decoder System object with the interleaver indices to be supplied as an input argument to the System object when it is called.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`TrellisStructure` — Trellis description of constituent convolutional code

`poly2trellis(4,[13 15],13)` (default) | structure

Trellis description of the constituent convolutional code, specified as a structure that contains the trellis description for a rate K/N code. K is the number of input bit streams, and N is the number of output bit streams.

Note K must be 1 for the turbo coder. For more information, see “Coding Rate” on page 3-1414.

You can either use the `poly2trellis` function to create the trellis structure or create it manually. For more about this structure, see “Trellis Description of a Convolutional Code” and the `istrellis` function.

The trellis structure contains these fields.

`numInputSymbols` — Number of symbols input to encoder

2^K

Number of symbols input to the encoder, specified as an integer equal to 2^K, where K is the number of input bit streams.

Data Types: `double`

`numOutputSymbols` — Number of symbols output from encoder

2^N

Number of symbols output from the encoder, specified as an integer equal to 2^N, where N is the number of output bit streams.

Data Types: `double`

`numStates` — Number of states in encoder

power of 2

Number of states in the encoder, specified as a power of 2.

Data Types: `double`

`nextStates` — Next states

matrix of integers

Next states for all combinations of current states and current inputs, specified as a matrix of integers. The matrix size must be `numStates`-by-2^K.

Data Types: `double`

`outputs` — Outputs

matrix of octal numbers

Outputs for all combinations of current states and current inputs, specified as a matrix of octal numbers. The matrix size must be `numStates`-by-2^K.

Data Types: `double`

Data Types: `struct`

`InterleaverIndicesSource` — Source of interleaver indices

`'Property'` (default) | `'Input port'`

Source of interleaver indices, specified as `'Property'` or `'Input port'`.

- When you set this property to `'Input port'`, the object executes using the input interleaver indices, `interlvrindices`, set when you call the object. The vector length and values for the interleaver indices and coded input signal can change with each call to the object.
- When you set this property to `'Property'`, the object uses the interleaver indices that you specify for the `InterleaverIndices` property.

Data Types: `char` | `string`

`InterleaverIndices` — Interleaver indices

`(64:-1:1).'` (default) | column vector of integers

Interleaver indices, specified as a column vector of integers. The vector must be of length L, where L is the length of the decoded output message, `decmsg`. Each element of the vector must be an integer in the range [1, L] and must be unique. The interleaver indices define the mapping used to permute the input bits at the decoder.

Tunable: Yes

Dependencies

To enable this property, set the `InterleaverIndicesSource` property to `'Property'`.

Data Types: `double`

`Algorithm` — Decoding algorithm

`'True APP'` (default) | `'Max*'` | `'Max'`

Decoding algorithm, specified as `'True APP'`, `'Max*'`, or `'Max'`. When you set this property to `'True APP'`, the object implements true APP decoding. When you set this property to `'Max*'` or `'Max'`, the object uses approximations to increase the speed of the computations. For more information, see “APP Decoder” on page 3-1414.

Data Types: `char` | `string`

`NumScalingBits` — Number of scaling bits

3 (default) | integer in the range [0, 8]

Number of scaling bits, specified as an integer in the range [0, 8]. This property sets the number of bits the constituent decoders use to scale the input data to avoid losing precision during computations. The constituent decoders multiply the input by $2^{\texttt{NumScalingBits}}$ and divide the pre-output by the same factor. For more information, see “APP Decoder” on page 3-1414.

Dependencies

This enable this property, set the Algorithm property to `'Max*'`.

Data Types: `double`

`NumIterations` — Number of decoding iterations

`6` (default) | positive integer

Number of decoding iterations, specified as a positive integer. This property sets the number of decoding iterations used for each call to the object. The object iterates and provides updates to the log-likelihood ratios (LLR) of the uncoded output bits. The output of the object is the hard-decision output of the final LLR update.

Data Types: `double`

Usage

Syntax

```
decmsg = turbodec(codeword)
decmsg = turbodec(codeword,interlvrindices)
```

Description

`decmsg = turbodec(codeword)` decodes the input codeword using the parallel concatenated convolutional decoding scheme that is specified by the trellis structure and interleaver indices. `turbodec` returns the binary decoded data. For more information, see “Parallel Concatenated Convolutional Decoding Scheme” on page 3-1413.

`decmsg = turbodec(codeword,interlvrindices)` additionally specifies the interleaver indices. To enable this syntax, set the InterleaverIndicesSource property to `'Input port'`. The interleaver indices define the mapping used to permute the input at the decoder.

Input Arguments

`codeword` — Parallel concatenated codeword

column vector

Parallel concatenated codeword, specified as a column vector of length M, where M is the length of the parallel concatenated codeword.

Data Types: `double` | `single`

`interlvrindices` — Interleaver indices

column vector of integers

Interleaver indices, specified as a column vector of integers. The vector must be of length L, where L is the length of the decoded output message, `decmsg`. Each element of the vector must be an integer in the range [1, L] and must be unique. The interleaver indices define the mapping used to permute the input bits at the decoder.

Dependencies

To enable this property, set the `InterleaverIndicesSource` property to `'Input port'`.

Data Types: `double`

Output Arguments

`decmsg` — Decoded message
binary column vector

Decoded message, returned as a binary column vector of length *L*, where *L* is the length of the decoded output message. This output signal is the same as data type of the `codeword` input.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Transmit and Receive Turbo-Encoded Data over BPSK-Modulated AWGN Channel

Simulate the transmission and reception of BPSK data over an AWGN channel by using turbo encoding and decoding.

Specify simulation parameters, and then compute the effective coding rate and noise variance. For BPSK modulation, E_S/N_0 equals E_b/N_0 because the number of bits per symbol (bps) is 1. To ease reuse of this code for other modulation schemes, calculations in this example include the bps terms. Define the packet length, trellis structure, and number of iterations. Calculate the noise variance using E_S/N_0 and the code rate. Set the random number generator to its default state to ensure that the results are repeatable.

```
modOrd = 2; % Modulation order
bps = log2(modOrd); % Bits per symbol
EbNo = 1; % Energy per bit to noise power spectral density ratio in dB
EsNo = EbNo + 10*log10(bps); % Energy per symbol to noise power spectral density ratio in dB

L = 256; % Input packet length in bits
trellis = poly2trellis(4,[13 15 17],13);
numiter = 4;
n = log2(trellis.numOutputSymbols);
numTails = log2(trellis.numStates)*n;
M = L*(2*n - 1) + 2*numTails; % Output codeword packet length
rate = L/M; % Coding rate

snrdB = EsNo + 10*log10(rate); % Signal to noise ratio in dB
noiseVar = 1./(10.^(snrdB/10)); % Noise variance
```

```
rng default
```

Generate random interleaver indices.

```
intrlvrIndices = randperm(L);
```

Create a turbo encoder and decoder pair. Use the defined trellis structure and random interleaver indices. Configure the decoder to run a maximum of four iterations.

```
turboenc = comm.TurboEncoder(trellis,intrlvrIndices);
turbodec = comm.TurboDecoder(trellis,intrlvrIndices,numiter);
```

Create a BPSK modulator and demodulator pair, where the demodulator outputs soft bits determined using an LLR method.

```
bpskmod = comm.BPSKModulator;
bpskdemod = comm.BPSKDemodulator('DecisionMethod','Log-likelihood ratio', ...
    'Variance',noiseVar);
```

Create an AWGN channel object and an error rate object.

```
awgnchan = comm.AWGNChannel('NoiseMethod','Variance','Variance',noiseVar);
errrate = comm.ErrorRate;
```

The main processing loop performs these steps.

1. Generate binary data.
2. Turbo encode the data.
3. Modulate the encoded data.
4. Pass the modulated signal through an AWGN channel.
5. Demodulate the noisy signal by using LLR to output soft bits.
6. Turbo decode the demodulated data. Because the bit mapping from the demodulator is opposite of the mapping expected by the turbo decoder, the decoder input must use the inverse of the demodulated signal.
7. Calculate the error statistics.

```
for frmIdx = 1:100
    data = randi([0 1],L,1);
    encodedData = turboenc(data);
    modSignal = bpskmod(encodedData);
    receivedSignal = awgnchan(modSignal);
    demodSignal = bpskdemod(receivedSignal);
    receivedBits = turbodec(-demodSignal);
    errorStats = errrate(data,receivedBits);
end
```

Display the error data.

```
fprintf('Bit error rate = %5.2e\nNumber of errors = %d\nTotal bits = %d\n', errorStats)
```

```
Bit error rate = 2.34e-04
Number of errors = 6
Total bits = 25600
```

Perform Turbo Coding on 16-QAM Signal in AWGN Channel

Simulate an end-to-end communication link by using a 16-QAM signal and turbo codes in an AWGN channel. Inside a frame processing loop, packet sizes are randomly selected to be 500, 1000, or 1500 bits. Because the packet size varies, the interleaver indices are provided to the turbo encoder and decoder as an input argument of their associated System object.

Set the modulation order and E_b/N_0. Compute the number of bits per symbol and the energy per symbol to noise ratio (E_S/N_0) based on the modulation order and E_b/N_0. To get repeatable results, set the random number generator to its default state.

```
modOrder = 16;
bps = log2(modOrder); % Bits per symbol
EbNo = 2.8; % Energy per bit to noise power spectral density ratio in dB
EsNo = EbNo + 10*log10(bps); % Energy per symbol to noise power spectral density ratio in dB
rng default
```

Create a turbo encoder and decoder pair. Because the packet length varies for each frame, specify that the interleaver indices be supplied by an input argument of the System object when executed. Specify that the decoder perform four iterations.

```
turboEnc = comm.TurboEncoder('InterleaverIndicesSource','Input port');
turboDec = comm.TurboDecoder('InterleaverIndicesSource','Input port','NumIterations',4);
trellis = poly2trellis(4,[13 15 17],13);
n = log2(turboEnc.TrellisStructure.numOutputSymbols);
numTails = log2(turboEnc.TrellisStructure.numStates)*n;
```

Create an error rate object.

```
errRate = comm.ErrorRate;
```

The frame processing loop performs these steps.

1. Select a random packet length, and generate random binary data.
2. Compute the output codeword length and coding rate.
3. Compute the signal to noise ratio (SNR) and noise variance.
4. Generate interleaver indices.
5. Turbo encode the data.
6. Apply 16-QAM modulation, and normalize the average signal power.
7. Pass the modulated signal through an AWGN channel.
8. Demodulate the noisy signal by using an LLR method, output soft bits, and normalize the average signal power.
9. Turbo decode the data. Because the bit mapping order from the demodulator is opposite the mapping order expected by the turbo decoder, the decoder input must use the inverse of the demodulated signal.
10. Calculate the error statistics.

```
numFrames = 100;
for pktIdx = 1:numFrames
    L = 500*randi([1 3],1,1); % Packet length in bits
    data = randi([0 1],L,1);
    M = L*(2*n - 1) + 2*numTails; % Output codeword packet length
    rate = L/M; % Coding rate for current packet
    snrdB = EsNo + 10*log10(rate); % Signal to noise ratio in dB
    noiseVar = 1./(10.^(snrdB/10)); % Noise variance

    intrlvrIndices = randperm(L);
    encodedData = turboEnc(data,intrlvrIndices);
    modSignal = qammod(encodedData,modOrder,'InputType','bit','UnitAveragePower',true);
    receivedSignal = awgn(modSignal,snrdB);
    demodSignal = qamdemod(receivedSignal,modOrder,'OutputType','llr', ...
        'UnitAveragePower',true,'NoiseVariance',noiseVar);
    receivedBits = turboDec(-demodSignal,intrlvrIndices); % Demodulated signal is negated

    errorStats = errRate(data,receivedBits);
end
```

Display the error data.

```
fprintf('Bit error rate = %5.2e\nNumber of errors = %d\nTotal bits = %d\n',errorStats)
```

```
Bit error rate = 8.51e-04
Number of errors = 80
Total bits = 94000
```

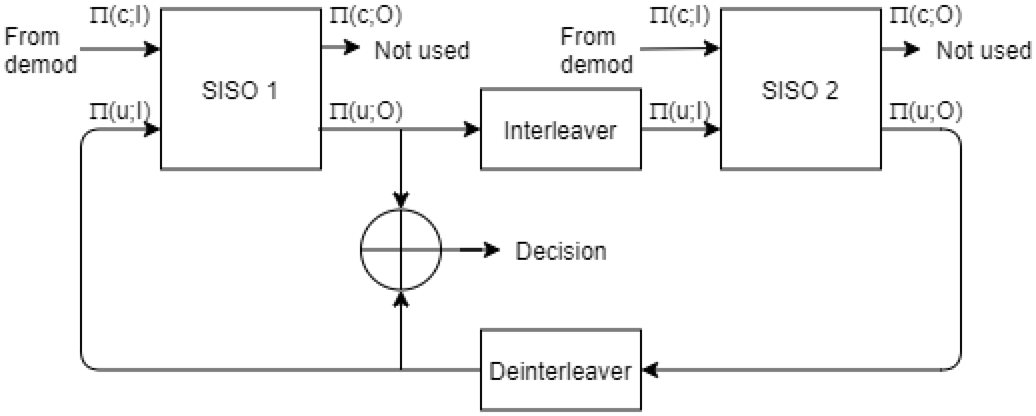
More About

Parallel Concatenated Convolutional Decoding Scheme

The turbo decoder uses a parallel concatenated convolutional decoding scheme to decode a coded input signal. The parallel concatenated decoding scheme uses an iterative “APP Decoder” on page 3-1414 with two constituent decoders, an interleaver, and a deinterleaver. This figure shows the decoding scheme.



The two constituent decoders use the same trellis structure and decoding algorithm. The soft-input soft-output APP decoders (SISO 1 and SISO 2) output an updated sequence of log-likelihoods of the encoder input bits, π(u;O).The sequence is based on the received sequence of log-likelihoods of the channel (coded) bits, π(c;I), and code parameters.

The decoder iteratively updates these likelihoods for a fixed number of decoding iterations and then outputs the decision bits. The interleaver used in the decoder is identical to the interleaver used in the encoder. The deinterleaver performs the inverse permutation with respect to the interleaver. The decoder does not assume knowledge of the tail bits and excludes these bits from the iterations.

For more information, see “Coding Rate” on page 3-1414.

APP Decoder

This System object implements the soft-input-soft-output APP decoding algorithm according to [1] and [2].

The `'True APP'` option of the `Algorithm` property implements APP decoding as per the equations 20–23 in section V of [1]. To gain speed, the `'Max*'` and `'Max'` values of the `Algorithm` property approximate expressions like $\log \sum_i \exp(a_i)$ by other quantities. The `'Max'` option uses $\max(a_i)$ as the approximation. The `'Max*'` option uses $\max(a_i)$ plus a correction term given by the expression $\ln(1 + \exp(-|a_{i-1} - a_i|))$.

Setting the `Algorithm` property to `'Max*'` enables the `NumScalingBits` property of this System object. This property denotes the number of bits by which this System object scales the data it processes internally (multiplies the input by $2^{\texttt{NumScalingBits}}$ and divides the pre-output by the same factor). Use this property to avoid losing precision during computations.

Coding Rate

Each constituent convolutional coder has a 1/*N* coding rate. The coding rate of the constituent convolutional code is represented as a rate *K*/*N* code. *K* is the number of input bit streams. *N* is the number of output bit streams.

Note *K* must be 1 for the turbo coder.

The decoder accepts an *M*-element column vector input signal and returns an *L*-element column vector output signal. The effective code rate of the turbo decoder is *L*/*M*. *L* is the length of the binary output message, and *M* is the length of the parallel concatenated codeword.

For a given trellis, *M* and *L* are related by $L = (M - 2 \times numTails) / (2 \times N - 1)$, where:

- $numTails = \log_2($`trellis.numStates`$) \times N$
- $N = \log_2($`trellis.numOutputSymbols`$)$. For a rate 1/2 trellis, $N = 2$.

For more information about trellis structures, see `poly2trellis` function.

comm.TurboEncoder

Package: `comm`

Encode input signal using parallel concatenated encoding scheme

Description

The `comm.TurboEncoder` System object applies a parallel concatenated encoding scheme to a binary input message. This coding scheme uses two identical convolutional encoders and appends the termination bits at the end of the encoded data bit stream. For more information, see “Parallel Concatenated Convolutional Encoding Scheme” on page 3-1424.

To encode a binary input message using a parallel concatenated encoding scheme:

1. Create the `comm.TurboEncoder` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?.

Creation

Syntax

```
turboenc = comm.TurboEncoder
turboenc = comm.TurboEncoder(Name,Value)
turboenc = comm.TurboEncoder(trellis,interlvrindices)
```

Description

`turboenc = comm.TurboEncoder` creates a turbo encoder System object. This object performs turbo encoding using the default object configuration.

`turboenc = comm.TurboEncoder(Name,Value)` sets properties using one or more name-value pairs. For example, `comm.TurboEncoder('InterleaverIndicesSource','Input port')` configures a turbo encoder System object with the interleaver indices to be supplied as an input argument to the System object when it is called. Enclose each property name in quotes.

`turboenc = comm.TurboEncoder(trellis,interlvrindices)` creates a turbo encoder System object with the `TrellisStructure` and `InterleaverIndices` properties set to `trellis` and `interlvrindices`, respectively. The `trellis` input must be specified as described by the `TrellisStructure` property. The `interlvrindices` input must be specified as described by the `InterleaverIndices` property.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

`TrellisStructure` — Trellis description of constituent convolutional code
`poly2trellis(4,[13 15],13)` (default) | structure

Trellis description of the constituent convolutional code, specified as a structure that contains the trellis description for a rate K/N code. K is the number of input bit streams, and N is the number of output bit streams.

Note K must be 1 for the turbo coder. For more information, see “Coding Rate” on page 3-1424.

You can either use the `poly2trellis` function to create the trellis structure or create it manually. For more about this structure, see “Trellis Description of a Convolutional Code” and the `istrellis` function.

The trellis structure contains these fields.

`numInputSymbols` — Number of symbols input to encoder
2^K

Number of symbols input to the encoder, specified as an integer equal to 2^K, where K is the number of input bit streams.

Data Types: `double`

`numOutputSymbols` — Number of symbols output from encoder
2^N

Number of symbols output from the encoder, specified as an integer equal to 2^N, where N is the number of output bit streams.

Data Types: `double`

`numStates` — Number of states in encoder
power of 2

Number of states in the encoder, specified as a power of 2.

Data Types: `double`

`nextStates` — Next states
matrix of integers

Next states for all combinations of current states and current inputs, specified as a matrix of integers. The matrix size must be `numStates`-by-2^K.

Data Types: `double`

`outputs` — Outputs
matrix of octal numbers

Outputs for all combinations of current states and current inputs, specified as a matrix of octal numbers. The matrix size must be `numStates`-by-2^K.

Data Types: double

Data Types: struct

InterleaverIndicesSource — Source of interleaver indices
'Property' (default) | 'Input port'

Source of interleaver indices, specified as 'Property' or 'Input port'.

- When you set this property to 'Input port', the object executes using the input interleaver indices, set when you call the object. The vector length and values for the interleaver indices and binary input message can change with each call to the object.
- When you set this property to 'Property', the object uses the interleaver indices that you specify for the InterleaverIndices property.

Data Types: char | string

InterleaverIndices — Interleaver indices
(64:-1:1).' (default) | column vector of integers

Interleaver indices, specified as a column vector of integers. The vector must be of length *L*, where *L* is the length of the binary input message. Each element of the vector must be an integer in the range [1, *L*] and must be unique. The interleaver indices define the mapping used to permute the input bits at the encoder.

Tunable: Yes

Dependencies

To enable this property, set the InterleaverIndicesSource property to 'Property'.

Data Types: double

Usage

Syntax

```
codeword = turboenc(message)
codeword = turboenc(message,interlvrindices)
```

Description

codeword = turboenc(message) encodes the input message using the parallel concatenated convolutional encoding scheme specified by the trellis structure and interleaver indices. turboenc returns the binary encoded codeword. message and codeword are column vectors of numeric, logical, or unsigned fixed-point values with word length 1 (fi object). For more information, see “Parallel Concatenated Convolutional Encoding Scheme” on page 3-1424.

codeword = turboenc(message,interlvrindices) additionally specifies the interleaver indices. interlvrindices must be a column vector containing integers in the range [1, *L*] with no repeated values. *L* is the length of the binary input message, message. This syntax applies when the InterleaverIndicesSource property is set to 'Input port'. The interleaver indices define the mapping used to permute the input bits at the encoder.

Input Arguments

`message` — Input message
binary column vector

Input message, specified as a binary column vector of length *L*, where *L* is the length of the uncoded input message.

Data Types: `double` | `int8` | `fi(data,0,1)`

Output Arguments

`codeword` — Parallel concatenated codeword
binary column vector

Parallel concatenated codeword, returned as a binary column vector of length *M*, where *M* is the number of bits in the parallel concatenated codeword. This output inherits its data type from the `message` input.

Data Types: `double` | `int8` | `fi(data,0,1)`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

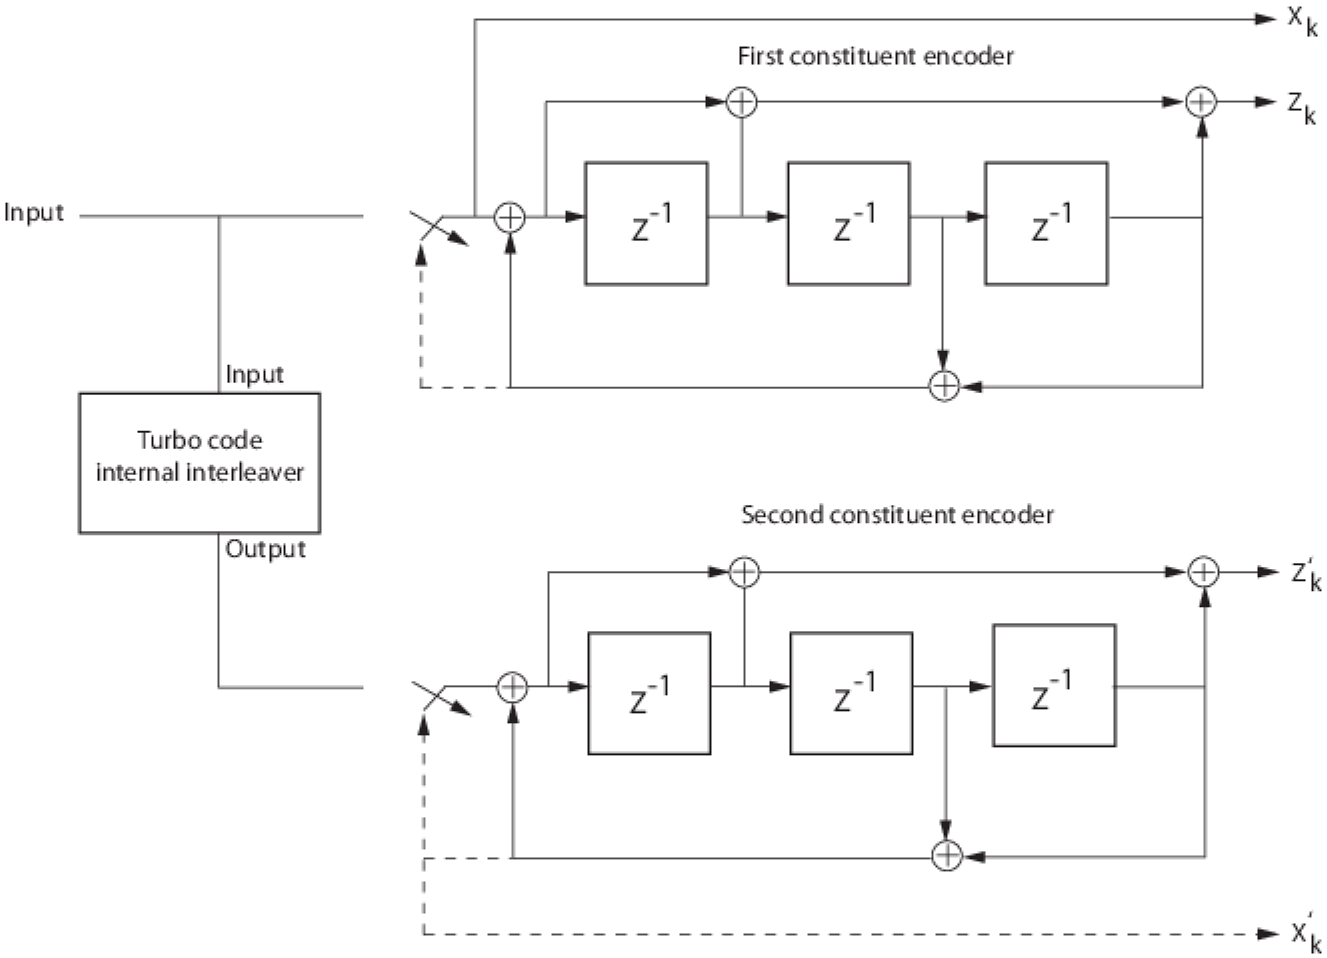
Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Perform Rate 1/3 Turbo Code Encoding

Encode an input message by using a rate 1/3 turbo encoder configuration with the default trellis structure, `poly2trellis(4,[13 15],13)`, as represented in this figure.



Input
Input
Turbo code internal interleaver
Output
First constituent encoder
Second constituent encoder
z^{-1}
X_k
Z_k
Z'_k
X'_k

For an input message with 64 bits, the codeword output from the encoder is 204 bits. The first 192 bits output correspond to the three 64 bit streams, interlaced as X_k, Z_k, and Z'_k. The systematic bit stream, X_k, and parity bit stream, Z_k, are from the first encoder and the parity bit stream, Z'_k, is from the second encoder. When the switches are in the lower position, signals follow the dashed lines and the last 12 bits correspond to the tail bits from the two encoders. The first group of six bits (three systematic bits and three parity bits) are the output tail bits from the first constituent encoder. The second group of six bits (three systematic bits and three parity bits) are the output tail bits from the second constituent encoder.

Create a turbo encoder using the default settings. Generate a frame of binary message data, and then encode the message data.

```
rng default
turboenc = comm.TurboEncoder;
frameLen = 64; % Frame length
data = randi([0 1],frameLen,1);
encData = turboenc(data);
codewordLen = length(encData);
```

Compute the coding rate. Due to the tail bits, the encoder output code rate is slightly less than 1/3.

```
codingrate = frameLen/codewordLen
codingrate = 0.3137
```

Transmit and Receive Turbo-Encoded Data over BPSK-Modulated AWGN Channel

Simulate the transmission and reception of BPSK data over an AWGN channel by using turbo encoding and decoding.

Specify simulation parameters, and then compute the effective coding rate and noise variance. For BPSK modulation, E_S/N_0 equals E_b/N_0 because the number of bits per symbol (bps) is 1. To ease reuse of this code for other modulation schemes, calculations in this example include the bps terms. Define the packet length, trellis structure, and number of iterations. Calculate the noise variance using E_S/N_0 and the code rate. Set the random number generator to its default state to ensure that the results are repeatable.

```
modOrd = 2; % Modulation order
bps = log2(modOrd); % Bits per symbol
EbNo = 1; % Energy per bit to noise power spectral density ratio in dB
EsNo = EbNo + 10*log10(bps); % Energy per symbol to noise power spectral density ratio in dB

L = 256; % Input packet length in bits
trellis = poly2trellis(4,[13 15 17],13);
numiter = 4;
n = log2(trellis.numOutputSymbols);
numTails = log2(trellis.numStates)*n;
M = L*(2*n - 1) + 2*numTails; % Output codeword packet length
rate = L/M; % Coding rate

snrdB = EsNo + 10*log10(rate); % Signal to noise ratio in dB
noiseVar = 1./(10.^(snrdB/10)); % Noise variance

rng default
```

Generate random interleaver indices.

```
intrlvrIndices = randperm(L);
```

Create a turbo encoder and decoder pair. Use the defined trellis structure and random interleaver indices. Configure the decoder to run a maximum of four iterations.

```
turboenc = comm.TurboEncoder(trellis,intrlvrIndices);
turbodec = comm.TurboDecoder(trellis,intrlvrIndices,numiter);
```

Create a BPSK modulator and demodulator pair, where the demodulator outputs soft bits determined using an LLR method.

```
bpskmod = comm.BPSKModulator;
bpskdemod = comm.BPSKDemodulator('DecisionMethod','Log-likelihood ratio', ...
    'Variance',noiseVar);
```

Create an AWGN channel object and an error rate object.

```
awgnchan = comm.AWGNChannel('NoiseMethod','Variance','Variance',noiseVar);
errrate = comm.ErrorRate;
```

The main processing loop performs these steps.

1. Generate binary data.
2. Turbo encode the data.
3. Modulate the encoded data.
4. Pass the modulated signal through an AWGN channel.
5. Demodulate the noisy signal by using LLR to output soft bits.
6. Turbo decode the demodulated data. Because the bit mapping from the demodulator is opposite of the mapping expected by the turbo decoder, the decoder input must use the inverse of the demodulated signal.
7. Calculate the error statistics.

```
for frmIdx = 1:100
    data = randi([0 1],L,1);
    encodedData = turboenc(data);
    modSignal = bpskmod(encodedData);
    receivedSignal = awgnchan(modSignal);
    demodSignal = bpskdemod(receivedSignal);
    receivedBits = turbodec(-demodSignal);
    errorStats = errrate(data,receivedBits);
end
```

Display the error data.

```
fprintf('Bit error rate = %5.2e\nNumber of errors = %d\nTotal bits = %d\n', errorStats)
```

```
Bit error rate = 2.34e-04
Number of errors = 6
Total bits = 25600
```

Perform Turbo Coding on 16-QAM Signal in AWGN Channel

Simulate an end-to-end communication link by using a 16-QAM signal and turbo codes in an AWGN channel. Inside a frame processing loop, packet sizes are randomly selected to be 500, 1000, or 1500 bits. Because the packet size varies, the interleaver indices are provided to the turbo encoder and decoder as an input argument of their associated System object.

Set the modulation order and E_b/N_0. Compute the number of bits per symbol and the energy per symbol to noise ratio (E_S/N_0) based on the modulation order and E_b/N_0. To get repeatable results, set the random number generator to its default state.

```
modOrder = 16;
bps = log2(modOrder); % Bits per symbol
EbNo = 2.8; % Energy per bit to noise power spectral density ratio in dB
EsNo = EbNo + 10*log10(bps); % Energy per symbol to noise power spectral density ratio in dB
rng default
```

Create a turbo encoder and decoder pair. Because the packet length varies for each frame, specify that the interleaver indices be supplied by an input argument of the System object when executed. Specify that the decoder perform four iterations.

```
turboEnc = comm.TurboEncoder('InterleaverIndicesSource','Input port');
turboDec = comm.TurboDecoder('InterleaverIndicesSource','Input port','NumIterations',4);
trellis = poly2trellis(4,[13 15 17],13);
```

```
n = log2(turboEnc.TrellisStructure.numOutputSymbols);
numTails = log2(turboEnc.TrellisStructure.numStates)*n;
```

Create an error rate object.

```
errRate = comm.ErrorRate;
```

The frame processing loop performs these steps.

1. Select a random packet length, and generate random binary data.
2. Compute the output codeword length and coding rate.
3. Compute the signal to noise ratio (SNR) and noise variance.
4. Generate interleaver indices.
5. Turbo encode the data.
6. Apply 16-QAM modulation, and normalize the average signal power.
7. Pass the modulated signal through an AWGN channel.
8. Demodulate the noisy signal by using an LLR method, output soft bits, and normalize the average signal power.
9. Turbo decode the data. Because the bit mapping order from the demodulator is opposite the mapping order expected by the turbo decoder, the decoder input must use the inverse of the demodulated signal.
10. Calculate the error statistics.

```
numFrames = 100;
for pktIdx = 1:numFrames
    L = 500*randi([1 3],1,1); % Packet length in bits
    data = randi([0 1],L,1);

    M = L*(2*n - 1) + 2*numTails; % Output codeword packet length
    rate = L/M; % Coding rate for current packet
    snrdB = EsNo + 10*log10(rate); % Signal to noise ratio in dB
    noiseVar = 1./(10.^(snrdB/10)); % Noise variance

    intrlvrIndices = randperm(L);
    encodedData = turboEnc(data,intrlvrIndices);
    modSignal = qammod(encodedData,modOrder,'InputType','bit','UnitAveragePower',true);
    receivedSignal = awgn(modSignal,snrdB);
    demodSignal = qamdemod(receivedSignal,modOrder,'OutputType','llr', ...
        'UnitAveragePower',true,'NoiseVariance',noiseVar);
    receivedBits = turboDec(-demodSignal,intrlvrIndices); % Demodulated signal is negated

    errorStats = errRate(data,receivedBits);
end
```

Display the error data.

```
fprintf('Bit error rate = %5.2e\nNumber of errors = %d\nTotal bits = %d\n',errorStats)
```

```
Bit error rate = 8.51e-04
Number of errors = 80
Total bits = 94000
```

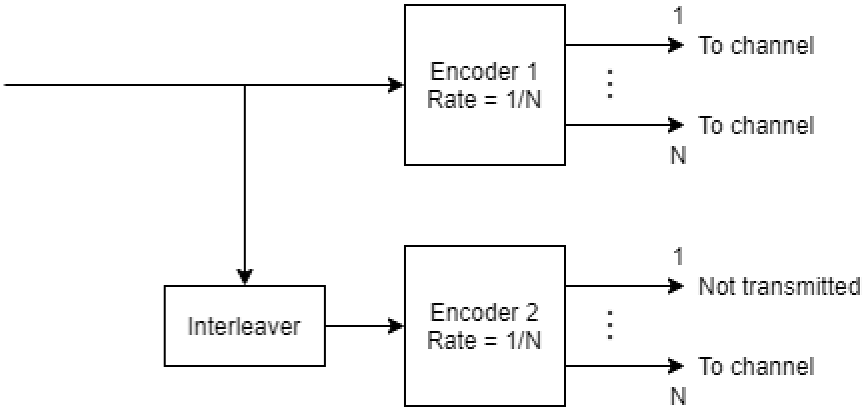
More About

Parallel Concatenated Convolutional Encoding Scheme

The turbo encoder uses a parallel concatenated convolutional encoding scheme to encode a binary input signal. This figure shows the two identical encoders and one internal interleaver used in the coding scheme. Each constituent encoder is terminated independently by tail bits. The output of the turbo encoder consists of the systematic and parity bit streams of the first encoder and only the parity bit streams of the second encoder.



For example, a rate 1/2 constituent encoder interlaces three streams and multiplexes the tail bits to the end of the encoded data streams.

For more information, see “Coding Rate” on page 3-1424 and “Tail bits” on page 3-1424.

Coding Rate

Each constituent convolutional coder has a 1/*N* coding rate. The coding rate of the constituent convolutional code is represented as a rate *K*/*N* code. *K* is the number of input bit streams. *N* is the number of output bit streams.

Note *K* must be 1 for the turbo coder.

The encoder accepts an *L*-by-1 column vector input signal and returns an *M*-by-1 column vector output signal. The effective code rate of the turbo encoder is *L*/*M*. *L* is the length of the binary input message and *M* is the number of bits in the parallel concatenated codeword.

For a given trellis, *M* and *L* are related by $M = L \times (2 \times N - 1) + 2 \times numTails$, where *numTails* is the number of tail bits. For more information, see “Tail bits” on page 3-1424.

Tail bits

The turbo encoder treats each input independently. For each input message, extra bits are used to set the encoder states to an all-zeros state. Each constituent encoder is terminated independently by tail bits. The turbo encoder output consists of the interlaced systematic and parity streams, with the tail bits multiplexed to the end of the encoded data streams.

The number of tail bits, *numTails*, output by each constituent encoder depends on values in the trellis structure.

- *numTails* = log_2(`trellis.numStates`) × *N*
- *N* = log_2(`trellis.numOutputSymbols`).

For a rate 1/2 trellis, *N* = 2.

For more information about trellis structures, see `poly2trellis`.

comm.ViterbiDecoder

Package: `comm`

Decode convolutionally encoded data using Viterbi algorithm

Description

The `ViterbiDecoder` object decodes input symbols to produce binary output symbols. This object can process several symbols at a time for faster performance. This object processes variable-size signals; however, variable-size signals cannot be applied for erasure inputs.

To decode input symbols and produce binary output symbols:

1. Define and set up your Viterbi decoder object. See “Construction” on page 3-1426.
2. Call `step` to decode input symbols according to the properties of `comm.ViterbiDecoder`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.ViterbiDecoder` creates a Viterbi decoder System object, `H`. This object uses the Viterbi algorithm to decode convolutionally encoded input data.

`H = comm.ViterbiDecoder(Name,Value)` creates a Viterbi decoder object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = comm.ViterbiDecoder(TRELLIS,Name,Value)` creates a Viterbi decoder object, `H`. This object has the `TrellisStructure` property set to `TRELLIS` and the other specified properties set to the specified values.

Properties

`TrellisStructure`

Trellis structure of convolutional code

Specify the trellis as a MATLAB structure that contains the trellis description of the convolutional code. The default is the result of `poly2trellis(7, [171 133])`. Use the `istrellis` function to verify whether a structure is a valid trellis.

`InputFormat`

Input format

Specify the format of the input to the decoder as `Unquantized` | `Hard` | `Soft`. The default is `Unquantized`.

When you set this property to `Unquantized`, the input must be a real vector of double- or single-precision soft values that are unquantized. The object considers negative numbers to be `1`s and positive numbers to be `0`s.

When you set this property to `Hard`, the input must be a vector of hard decision values, which are `0`s or `1`s. The data type of the inputs can be double-precision, single-precision, logical, 8-, 16-, and 32-bit signed integers. You can also use 8-, 16-, and 32-bit unsigned integers.

When you set this property to `Soft`, the input requires a vector of quantized soft values represented as integers between 0 and $2^{SoftInputWordLength} - 1$. The data type of the inputs can be double-precision, single-precision, logical, 8-, 16-, and 32-bit signed integers. You can also use 8-, 16-, and 32-bit unsigned integers. Alternately, you can specify the data type as an unsigned and unscaled fixed point object (fi) with a word length equal to the word length that you specify in the `SoftInputWordLength` property. The object considers negative numbers to be `0`s and positive numbers to be `1`s.

SoftInputWordLength

Soft input word length

Specify the number of bits to represent each quantized soft input value as a positive, integer scalar value. The default is `4` bits. This property applies when you set the `InputFormat` on page 3-0 property to `Soft`.

InvalidQuantizedInputAction

Action when input values are out of range

Specify the action the object takes when input values are out of range as `Ignore` | `Error`. The default is `Ignore`. Set this property to `Error` so that the object generates an error when the quantized input values are out of range. This property applies when you set the `InputFormat` on page 3-0 property to `Hard` or `Soft`.

TracebackDepth

Traceback depth

Specify the number of trellis branches to construct each traceback path as a numeric, integer scalar value. The default is `34`. The traceback depth influences the decoding accuracy and delay. The number of zero symbols that precede the first decoded symbol in the output represent a decoding delay.

When you set the `TerminationMethod` on page 3-0 property to `Continuous`, the decoding delay consists of `TracebackDepth`×*K* zero bits for a rate *K*/*N* convolutional code.

When you set the `TerminationMethod` property to `Truncated` or `Terminated`, there is no output delay.

For more information, see “Traceback and Decoding Delay” on page 3-1431 and “Traceback Depth Estimates” on page 3-1432.

TerminationMethod

Termination method of encoded frame

Specify the termination method as `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

In `Continuous` mode, the object saves the internal state metric at the end of each frame for use with the next frame. The object treats each traceback path independently.

In `Truncated` mode, the object treats each frame independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state. In `Terminated` mode, the object treats each frame independently, and the traceback path always starts and ends in the all-zeros state.

ResetInputPort

Enable decoder reset input

Set this property to true to enable an additional `step` method input. The default is `false`. When the reset input is a nonzero value, the object resets the internal states of the decoder to initial conditions. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous`.

DelayedResetAction

Reset on nonzero input via port

Set this property to true to delay resetting the object output. The default is false. When you set this property to true, the reset of the internal states of the decoder occurs after the object computes the decoded data. When you set this property to false, the reset of the internal states of the decoder occurs before the object computes the decoded data. This property applies when you set the `ResetInputPort` on page 3-0 property to true.

PuncturePatternSource

Source of puncture pattern

Specify the source of the puncture pattern as `None` | `Property`. The default is `None`.

When you set this property to `None`, the object assumes no puncturing. Set this property to `Property` to decode punctured codewords based on a puncture pattern vector specified via the `PuncturePattern` on page 3-0 property.

PuncturePattern

Puncture pattern vector

Specify puncture pattern to puncture the encoded data. The default is `[1; 1; 0; 1; 0; 1]`. The puncture pattern is a column vector of `1`s and `0`s. The `0`s indicate the position to insert dummy bits. The puncture pattern must match the puncture pattern used by the encoder. This property applies when you set the `PuncturePatternSource` on page 3-0 property to `Property`.

ErasuresInputPort

Enable erasures input

Set this property to true to specify a vector of erasures as a step method input. The default is false. The erasures input must be a double-precision or logical, binary, column vector. This vector indicates which symbols of the input codewords to erase. Values of 1 indicate erased bits. The decoder does not update the branch metric for the erasures in the incoming data stream.

The lengths of the step method erasure input and the step method data input must be the same. When you set this property to false, the object assumes no erasures.

OutputDataType

Data type of output

Specify the data type of the output as Full precision | Smallest unsigned integer | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | logical. The default is Full precision.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in Smallest unsigned integer or Full precision mode.

Fixed-Point Properties

StateMetricDataType

Data type of state metric

Specify the state metric data type as Full precision | Custom. The default is Full precision.

When you set this property to Full precision, the object sets the state metric fixed-point type to numerictype([],16). This property applies when you set the InputFormat on page 3-0 property to Hard or Soft.

When you set the InputFormat property to Hard, the step method data input must be a column vector. This vector comprises unsigned, fixed point numbers (fi objects) of word length 1 to enable fixed-point Viterbi decoding. Based on this input (either a 0 or a 1), the object calculates the internal branch metrics using an unsigned integer of word length *L*. In this case, *L* indicates the number of output bits as specified by the trellis structure.

When you set the InputFormat property to Soft, the step method data input must be a column vector. This vector comprises unsigned, fixed point numbers (fi objects) of word length N. N indicates the number of soft-decision bits specified in the SoftInputWordLength on page 3-0 property.

The step method data inputs must be integers in the range 0 to 2^N–1. The object calculates the internal branch metrics using an unsigned integer of word length $L = (N + Nout - 1)$. In this case, *Nout* represents the number of output bits as specified by the trellis structure.

CustomStateMetricDataType

Fixed-point data type of state metric

Specify the state metric fixed-point type as an unscaled, numerictype object with a signedness of Auto. The default is numerictype([],16). This property applies when you set the StateMetricDataType on page 3-0 property to Custom.

Methods

reset	Reset states of the Viterbi decoder object
step	Decode convolutionally encoded data using Viterbi algorithm

Common to All System Objects	
release	Allow System object property value changes

Examples

Encode and Decode 8-DPSK Modulated Data

Transmit a convolutionally encoded 8-DPSK modulated bit stream through an AWGN channel. Then, demodulate and decode using a Viterbi decoder.

Create the necessary System objects.

```
hConEnc = comm.ConvolutionalEncoder;
hMod = comm.DPSKModulator('BitInput',true);
hChan = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)',...
    'SNR',10);
hDemod = comm.DPSKDemodulator('BitOutput',true);
hDec = comm.ViterbiDecoder('InputFormat','Hard');
hError = comm.ErrorRate('ComputationDelay',3,'ReceiveDelay', 34);
```

Process the data using the following steps:

1 Generate random bits
2 Convolutionally encode the data
3 Apply DPSK modulation
4 Pass the modulated signal through AWGN
5 Demodulate the noisy signal
6 Decode the data using a Viterbi algorithm
7 Collect error statistics

```
for counter = 1:20
    data = randi([0 1],30,1);
    encodedData = step(hConEnc, data);
    modSignal = step(hMod, encodedData);
    receivedSignal = step(hChan, modSignal);
    demodSignal = step(hDemod, receivedSignal);
    receivedBits = step(hDec, demodSignal);
    errors = step(hError, data, receivedBits);
end
```

Display the number of errors.

```
errors(2)
```

```
ans = 3
```

Convolutional Encoding and Viterbi Decoding with a Puncture Pattern Matrix

Encode and decode a sequence of bits using a convolutional encoder and a Viterbi decoder with a defined puncture pattern. Verify that the input and output bits are identical

Define a puncture pattern matrix and reshape it into vector form for use with the Encoder and Decoder objects.

```
pPatternMat = [1 0 1;1 1 0];
pPatternVec = reshape(pPatternMat,6,1);
```

Create convolutional encoder and a Viterbi decoder in which the puncture pattern is defined by `pPatternVec`.

```
ENC = comm.ConvolutionalEncoder(...
    'PuncturePatternSource','Property', ...
    'PuncturePattern',pPatternVec);

DEC = comm.ViterbiDecoder('InputFormat','Hard', ...
    'PuncturePatternSource','Property',...
    'PuncturePattern',pPatternVec);
```

Create an error rate counter with the appropriate receive delay.

```
ERR = comm.ErrorRate('ReceiveDelay',DEC.TracebackDepth);
```

Encode and decode a sequence of random bits.

```
dataIn = randi([0 1],600,1);

dataEncoded = step(ENC,dataIn);

dataOut = step(DEC,dataEncoded);
```

Verify that there are no errors in the output data.

```
errStats = step(ERR,dataIn,dataOut);
errStats(2)
```

```
ans = 0
```

More About

Traceback and Decoding Delay

The traceback depth influences the decoding delay. The decoding delay is the number of zero symbols that precede the first decoded symbol in the output.

- For the continuous operating mode, the decoding delay is equal to the number of traceback depth symbols.
- For the truncated or terminated operating mode, the decoding delay is zero. In this case, the traceback depth must be less than or equal to the number of symbols in each input.

Traceback Depth Estimates

As a general estimate, a typical traceback depth value is approximately two to three times (*ConstraintLength* – 1) / (1 – *coderate*). The constraint length of the code, *ConstraintLength*, is equal to (log2(`trellis`.`numStates`) + 1). The *coderate* is equal to (*K* / *N*) × (length(*PuncturePattern*) / sum(*PuncturePattern*).

K is the number of input symbols, *N* is the number of output symbols, and *PuncturePattern* is the puncture pattern vector.

For example, applying this general estimate, results in these approximate traceback depths.

- A rate 1/2 code has a traceback depth of 5(*ConstraintLength* – 1).
- A rate 2/3 code has a traceback depth of 7.5(*ConstraintLength* – 1).
- A rate 3/4 code has a traceback depth of 10(*ConstraintLength* – 1).
- A rate 5/6 code has a traceback depth of 15(*ConstraintLength* – 1).

Algorithms

This object implements the algorithm, inputs, and outputs described on the Viterbi Decoder block reference page. The object properties correspond to the block parameters, except:

- The **Decision type** parameter corresponds to the `InputFormat` on page 3-0 property.
- The **Operation mode** parameter corresponds to the `TerminationMethod` on page 3-0 property.

reset

System object: `comm.ViterbiDecoder`
Package: `comm`

Reset states of the Viterbi decoder object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `ViterbiDecoder` object, `H`.

step

System object: `comm.ViterbiDecoder`
Package: `comm`

Decode convolutionally encoded data using Viterbi algorithm

Syntax

```
Y = step(H,X)
Y = step(H,X,ERASURES)
Y = step(H,X,R)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` decodes encoded data, `X`, using the Viterbi algorithm and returns `Y`. `X`, must be a column vector with data type and values that depend on how you set the `InputFormat` property. If the convolutional code uses an alphabet of 2^N possible symbols, the length of the input vector, `X`, must be $L \times N$ for some positive integer L. Similarly, if the decoded data uses an alphabet of 2^K possible output symbols, the length of the output vector, `Y`, is $L \times K$.

`Y = step(H,X,ERASURES)` uses the binary column input vector, `ERASURES`, to erase the symbols of the input codewords. The elements in `ERASURES` must be of data type double or logical. Values of `1` in the `ERASURES` vector correspond to erased symbols, and values of `0` correspond to non-erased symbols. The lengths of the `X` and `ERASURES` inputs must be the same. This syntax applies when you set the `ErasuresInputPort` property to true.

`Y = step(H,X,R)` resets the internal states of the decoder when you input a non-zero reset signal, `R`. `R` must be a double precision or logical scalar. This syntax applies when you set the `TerminationMethod` property to `Continuous` and the `ResetInputPort` property to `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.WalshCode

Package: comm

Generate Walsh code from orthogonal set of codes

Description

The WalshCode object generates a Walsh code from an orthogonal set of codes.

To generate a Walsh code:

1. Define and set up your Walsh code object. See “Construction” on page 3-1435.
2. Call step to encode the input signal according to the properties of comm.WalshCode. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj) and y = obj() perform equivalent operations.

Construction

H = comm.WalshCode creates a Walsh code generator System object, H. This object generates a Walsh code from a set of orthogonal codes.

H = comm.WalshCode(Name,Value) creates a Walsh code generator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

Length

Length of generated code

Specify the length of the generated code as a numeric, integer scalar value that is a power of two. The default is 64.

Index

Index of code of interest

Specify the index of the desired code from the available set of codes as a numeric, integer scalar value in the range [0, 1, ... , *N*-1]. *N* is the value of the Length on page 3-0 property. The default is 60. The number of zero crossings in the generated code equals the value of the specified index.

SamplesPerFrame

Number of output samples per frame

Specify the number of Walsh code samples that the step method outputs as a numeric, positive, integer scalar value . The default is `1`. If you set this property to a value of *M*, then the `step` method outputs *M* samples of a Walsh code of length *N*. *N* is the length of the code that you specify in the `Length` on page 3-0 property.

`OutputDataType`

Data type of output

Specify the output data type as `double` | `int8`. The default is `double`.

Methods

reset	Reset states of Walsh code generator object
step	Generate Walsh code from orthogonal set of codes

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Walsh Code Sequence

Generate 16 samples of a length-64 Walsh code sequence.

```
walsh = comm.WalshCode('SamplesPerFrame',16)
```

```
walsh = 
  comm.WalshCode with properties:

             Length: 64
              Index: 60
    SamplesPerFrame: 16
     OutputDataType: 'double'
```

```
seq = walsh()
```

```
seq = 16×1

     1
    -1
     1
    -1
     1
    -1
     1
    -1
     1
    -1
      ⋮
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Walsh Code Generator block reference page. The object properties correspond to the block parameters, except:

- The object does not have a property to select frame based outputs.
- The object does not have a property that corresponds to the **Sample time** parameter.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

```

Description

`reset(H)` resets the states of the `WalshCode` object, `H`.

step

System object: `comm.WalshCode`
Package: `comm`

Generate Walsh code from orthogonal set of codes

Syntax

```
Y = step(H)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

`Y = step(H)` outputs a frame of the Walsh code in column vector `Y`. Specify the frame length with the `SamplesPerFrame` property. The Walsh code corresponds to a row of an *N*x*N* Hadamard matrix, where *N* is a nonnegative power of 2 that you specify in the `Length` property. Use the `Index` property to choose the row of the Hadamard matrix. The output code is in a bi-polar format with `0` and `1` mapped to `1` and `-1` respectively.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.WINNER2Channel

Package: `comm`

Filter input signal through WINNER II fading channel

Download Required

To use `comm.WINNER2Channel`, first download the WINNER II Channel Model for Communications Toolbox from the Add-On Explorer. For more information on downloading add-ons, see “Get and Manage Add-Ons”.

Description

The `comm.WINNER2Channel` System object filters an input signal through a WINNER II fading channel. The object utilizes the basic model defined and provided by the WINNER II Channel Models [1].

To filter an input signal using a WINNER II fading channel:

1. Define and set up your WINNER II channel object. See “Construction” on page 3-1440.
2. Call `step` to filter the input signal through a WINNER II fading channel according to the properties of `comm.WINNER2Channel`.

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`chan = comm.WINNER2Channel` creates a WINNER II fading channel System object to model single or multiple links. `chan` generates channel coefficients using the WINNER II spatial channel model (SCM). It also filters a real or complex input signal through the fading channel for each link.

`chan = comm.WINNER2Channel(Name,Value)` creates a WINNER II fading channel object, `chan`, that overrides default values using one or more `Name,Value` pair arguments. You can specify additional name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`chan = comm.WINNER2Channel(cfgModel)` creates a WINNER II fading channel object with the `ModelConfig` property set to `cfgModel`.

`chan = comm.WINNER2Channel(cfgModel,cfgLayout)` creates a WINNER II fading channel object with the `ModelConfig` property set to `cfgModel` and the `LayoutConfig` property set to `cfgLayout`.

Properties

`ModelConfig`

WINNER II model parameter configuration

WINNER II model parameter configuration, specified as a structure containing these fields:

`NumTimeSamples`

Number of time samples. The default value is 100.

Note If the number of samples in the input signal (N_S) does not match `NumTimeSamples`, `NumTimeSamples` is updated to match N_S.

`FixedPdpUsed`

Set to `'yes'` to use predefined path delays and powers for specific scenarios. The default value is `'no'`.

`FixedAnglesUsed`

Set to `'yes'` to use predefined angles of departure (AoDs) and angles of arrival (AoAs) for specific scenarios. The default value is `'no'`.

`IntraClusterDsUsed`

Set to `'yes'` to divide each of the two strongest clusters per link into three subclusters. The default value is `'yes'`.

`PolarisedArrays`

Set to `'yes'` to use dual polarized arrays. The default value is `'yes'`.

`UseManualPropCondition`

Set to `'yes'` to use the manually defined propagation conditions (LOS or NLOS) in the `LayoutConfig.PropagConditionVector` field. Set to `'no'` to draw propagation conditions from predefined LOS probabilities. The default value is `'yes'`.

`UniformTimeSampling`

Set to `'yes'` to sample all links at the same time instants. The default value is `'no'`.

`SampleDensity`

Number of time samples per half wavelength. The default value is `2e6`.

`CenterFrequency`

Center frequency of carrier. The default value `5.25e9` Hz.

DelaySamplingInterval

Sampling grid to which the path delays are rounded. The default value of `0` seconds indicates no rounding on path delays.

- `DelaySamplingInterval` specifies the input signal sample time.
- When performing channel filtering, the object uses `DelaySamplingInterval = 0` to obtain the original path delays. Any non-zero value of `DelaySamplingInterval` is ignored, specifically the path delays used are not rounded to be multiples of `DelaySamplingInterval` values that are non-zero.

ShadowingModelUsed

Set to `'yes'` to include shadow fading in the model. The default value is `'no'`.

PathLossModelUsed

Set to `'yes'` to include path loss in the model. The default value is `'no'`.

PathLossModel

Path loss model function name, specified as `'pathloss'`, which uses the internal `pathloss` function from the “WINNER II Channel” Add-On to model the path loss. The `PathLossModel` property is applicable only when `PathLossModelUsed` is `'yes'`. The default value is `'pathloss'`.

PathLossOption

Path loss option indicating the wall material for the NLOS path loss calculation of scenario A1, specified as one of `{'CR_light', 'CR_heavy', 'RR_light', 'RR_heavy'}`. The default value is `'CR_light'`. The `PathLossOption` property is applicable only when `PathLossModelUsed` is `'yes'`.

See `LayoutConfig`.`ScenarioVector` for the scenario number mapping.

RandomSeed

Seed for random number generators. To use the global random stream, set `RandomSeed` to empty, `[]`. The default is `[]`.

LayoutConfig

WINNER II layout parameter configuration

WINNER II layout parameter configuration, specified as a structure containing these fields:

Stations

Row vector of structures to describe antenna arrays for active stations. The row ordering specifies BS sectors first, followed by the MS. The default assigns two structures, one for BS and one for MS.

NofSect

Vector of number of sectors in each BS. The default is `1`.

Pairing

A 2-by-N_L matrix, where N_L specifies the number links to be modeled. The default is `[1;2]`.

ScenarioVector

A 1-by-N_L vector of scenario numbers. The default is `1`, which specifies scenario A1.

The scenarios numbers map as {`1`=A1, `2`=A2, `3`=B1, `4`=B2, `5`=B3, `6`=B4, `10`=C1, `11`=C2, `12`=C3, `13`=C4, `14`=D1, `15`=D2a}.

For more information, see WINNER II Channel Models [1], Section 2.3.

PropagConditionVector

A 1-by-N_L vector of propagation conditions (LOS = 1 and NLOS = 0) for each link. The default is `1`.

StreetWidth

A 1-by-N_L vector of identical values that specify the average width (in meters) of the streets. `StreetWidth` is used for the path loss model of the B1 and B2 scenarios. The default is `20`. See `ScenarioVector` for the scenario number mapping. All elements must have the same value. The `StreetWidth` property is applicable only when the `ModelConfig.PathLossModelUsed` property is `'yes'`.

Dist1

A 1-by-N_L vector of distances from BS to the last LOS point. `Dist1` is used for the path loss model of the B1 and B2 scenarios. The default value is `NaN`, which means the distance is randomly determined in path loss function. See `ScenarioVector` for the scenario number mapping. `Dist1` is applicable only when the `ModelConfig.PathLossModelUsed` property is `'yes'`.

For more information, see WINNER II Channel Models [1], Figure 4-3.

NumFloors

A 1-by-N_L vector indicating the floor number where the indoor BS or MS is located. The default value is `1`. The `NumFloors` property is used for the path loss model of the A2 and B4 scenarios only. See `ScenarioVector` for the scenario number mapping. The `NumFloors` property is applicable only when `ModelConfig.PathLossModelUsed` is `'yes'`.

NumPenetratedFloors

A 1-by-N_L vector indicating the number of penetrated floors between BS and MS. The default value is `0`. The `NumPenetratedFloors` is used for the NLOS path loss model of the A1 scenario. See `ScenarioVector` for the scenario number mapping. The `NumPenetratedFloors` property is applicable only when `PathLossModelUsed` is `'yes'`.

For more information, see WINNER II Channel Models [1], Table 4-4.

NormalizeChannelOutputs

Normalize channel outputs, specified as `true` or `false`. Set this property to `true` to normalize the channel outputs by the number of receive antennas at the mobile station (MS) for each link. The default value is `true`.

For more information, see “Channel Power” on page 3-1447.

Methods

info	Display information about `WINNER2Channel` object
reset	Reset states of `WINNER2Channel` object
step	Filter input signal through WINNER II fading channel

Common to All System Objects	
`release`	Allow System object property value changes

Examples

WINNER II Channel with Two Mobile Stations

Simulate a system that has two MS connected to one BS. One MS is 8 meters away from the BS; the other is 20 meters away from the BS. Impulse signals are sent through the two links. The spectrum of the received signals at MS shows frequency selectivity. It also shows the MS that is closer the BS has a larger average received power than the other MS.

Specify random number generator seed for repeatability.

```
rng(100);
```

Initial frame length and sample rate.

```
frmLen   = 1024;
```

Configure layout parameters.

```
BSAA  = winner2.AntennaArray('UCA', 8, 0.02);  % UCA-8 antenna array for BS
MSAA1 = winner2.AntennaArray('ULA', 2, 0.01);  % ULA-2 antenna array for MS
MSAA2 = winner2.AntennaArray('ULA', 4, 0.005); % ULA-4 antenna array for MS
MSIdx = [2 3]; BSIdx = {1}; NL = 2; maxRange = 100; rndSeed = 101;
cfgLayout = winner2.layoutparset(MSIdx,BSIdx,NL, ...
   [BSAA,MSAA1,MSAA2],maxRange,rndSeed);
```

Adjust BS and MS positions.

```
cfgLayout.Stations(1).Pos(1:2) = [10, 10];
cfgLayout.Stations(2).Pos(1:2) = [18, 10];  % 8 meters away from BS
cfgLayout.Stations(3).Pos(1:2) = [22, 26];  % 20 meters away from BS
```

NLOS for both links

```
cfgLayout.Pairing = [1 1; 2 3];
cfgLayout.PropagConditionVector = [0 0];
```

Configure model parameters

```
cfgModel = winner2.wimparset;
cfgModel.NumTimeSamples     = frmLen; % Frame length
cfgModel.IntraClusterDsUsed = 'no';   % No cluster splitting
cfgModel.SampleDensity      = 2e5;    % For lower sample rate
cfgModel.PathLossModelUsed  = 'yes';  % Turn on path loss
cfgModel.ShadowingModelUsed = 'yes';  % Turn on shadowing
```

Create a WINNER II channel System object.

```
wimChan = comm.WINNER2Channel(cfgModel, cfgLayout);
```

Call the info method of the object to get some system information

```
chanInfo = info(wimChan)
```

```
chanInfo = struct with fields:
               NumLinks: 2
          NumBSElements: [8 8]
          NumMSElements: [2 4]
               NumPaths: [16 16]
             SampleRate: [1.0000e+07 1.0000e+07]
     ChannelFilterDelay: [7 7]
    NumSamplesProcessed: 0
```

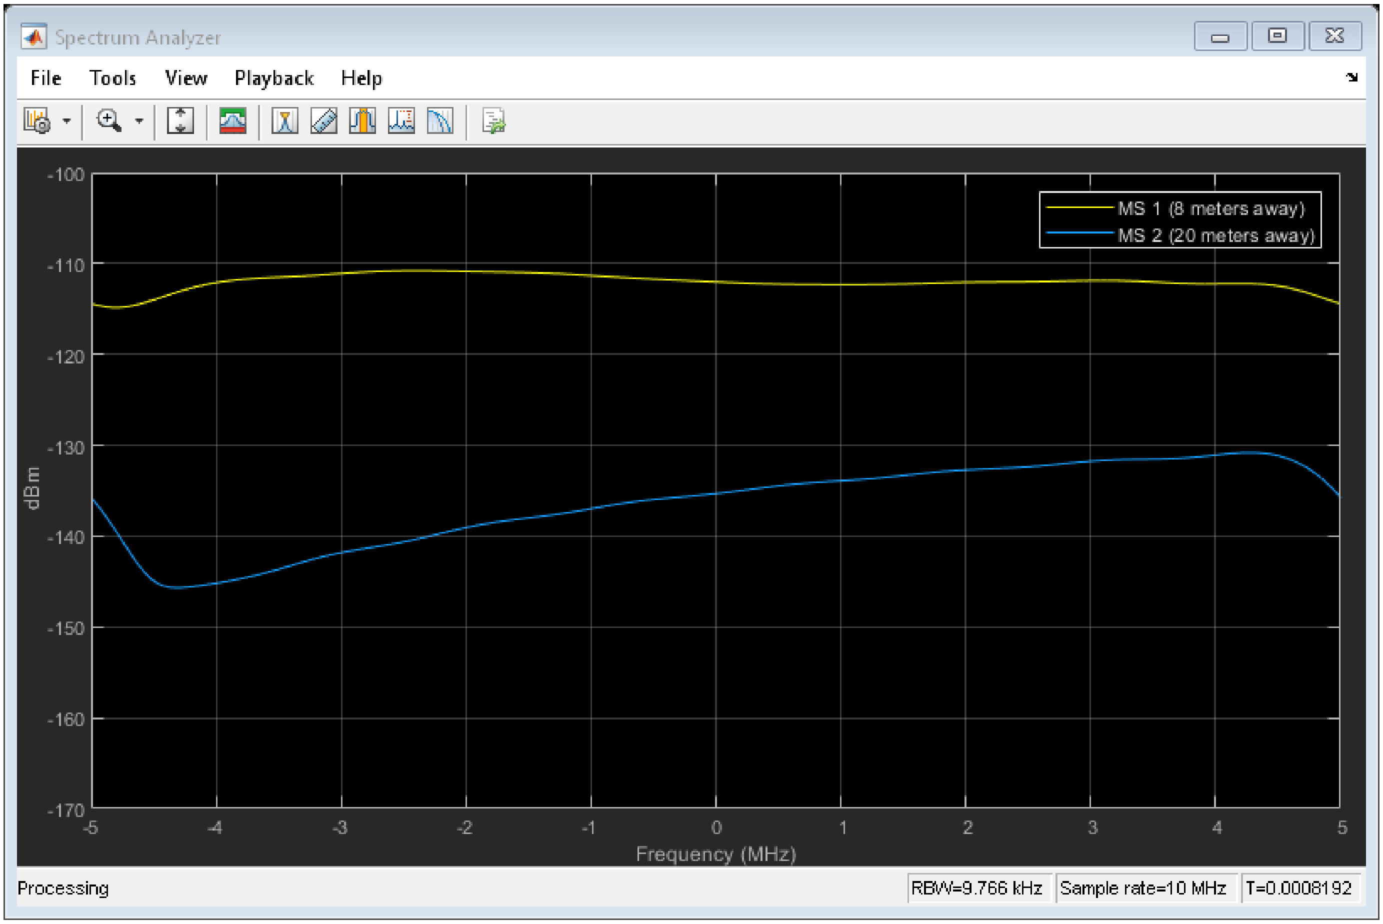
```
numTx    = chanInfo.NumBSElements(1);
Rs       = chanInfo.SampleRate(1);
```

Create a Spectrum Analyzer System object.

```
SA = dsp.SpectrumAnalyzer('SampleRate', Rs, ...
    'YLimits', [-170, -100], 'ShowLegend', true, ...
    'ChannelNames', {'MS 1 (8 meters away)','MS 2 (20 meters away)'});
```

Pass impulse signals through the two links and show spectra of the received signals at the two MS.

```
for i = 1:10
    x = [ones(1,numTx); zeros(frmLen-1, numTx)];
    y = wimChan(x);
    SA([y{1}(:,1), y{2}(:,1)]);
end
```



More About

WINNER II Sampling Rate

The signal sample rate (R_S) for generating channel coefficients and performing channel filtering is calculated per link using the mobile station speed (V_{MS}), half wavelength distance, and sample density. The sample rate for each link is available as a field in the info method return.

$R_S = V_{MS} / (C / F_{center} / 2 / N_{SD})$,

- For the MS speed,V_{MS},
  - When `ModelConfig.UniformTimeSampling` is set to `'no'`, V_{MS} is the speed of the MS for the corresponding link, derived from the `LayoutConfig.Stations(i).Velocity` field.
  - When `ModelConfig.UniformTimeSampling` is set to `'yes'`, V_{MS} is the maximum speed of the MS for all links.
- C is the speed of light (`2.99792458e8` m/s).
- F_{center} is `ModelConfig.CenterFrequency`.
- N_{SD} is `ModelConfig.SampleDensity`.

Channel Power

These conditions apply to the channel power of the `comm.WINNER2Channel` object:

- When path loss and shadowing are off, path gains are normalized. Specifically, path gains are normalized when the ModelConfig.`ShadowingModelUsed` and ModelConfig.`PathLossModelUsed` parameters are set to `'no'`.
- When the NormalizeChannelOutputs property is `true`, the average gain of the channel is 0 dB.

info

System object: `comm.WINNER2Channel`
Package: `comm`

Display information about `WINNER2Channel` object

Syntax

```
s = info(obj)
```

Description

`s = info(obj)` returns a structure containing information about the `Winner2Channel` System object characteristics. The information structure contains:

- `Numlinks` - Number of links in the system
- `NumBSElements` - Number of transmit antennas at the BS for each link
- `NumMSElements` - Number of receive antennas at the MS for each link
- `NumPaths` - Number of delay paths for each link
- `SampleRate` - Sample rate for each link
- `ChannelFilterDelay` - Channel filter delay per link, measured in samples
- `NumSamplesProcessed` - Number of samples the channel has processed since the last reset

Introduced in R2016b

reset

System object: `comm.WINNER2Channel`
Package: `comm`

Reset states of `WINNER2Channel` object

Syntax

```
reset(obj)
```

Description

`reset(obj)` resets the states of the `Winner2Channel` System object.

If the `ModelConfig.RandomSeed` property of `obj` is empty, the `reset` method resets the filters only. Otherwise, the `reset` method resets the filters and also reinitializes the random number stream to the value of the `ModelConfig.RandomSeed` property.

Introduced in R2016b

step

System object: `comm.WINNER2Channel`
Package: `comm`

Filter input signal through WINNER II fading channel

Syntax

```
y = step(obj,x)
[y,pathGains] = step(obj,x)
```

Description

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(obj,x)` filters input signal `x` through a WINNER II fading channel and returns the result in `y`. Both `x` and `y` are N_L-by-1 cell arrays, where N_L represents the number of links, as determined by the `LayoutConfig` property of `obj`. The `i`th element of `x` must be an N_S-by-N_T`(i)` matrix of doubles.

- N_S represents the number of samples to be generated and must be the same for all elements of `x`.
- N_T`(i)` is the number of transmit antennas at the base station (BS) for the `i`th link, determined by the `LayoutConfig` property of `obj`.

If the channel has only one link or if all links have the same number of transmit antennas, `x` can also be an N_S-by-N_T matrix of doubles. In this case, the same input signal is filtered through all the links. The `i`th element of `y` is an N_S-by-N_R`(i)` matrix of doubles. N_R`(i)` is the number of receive antennas at the mobile station (MS) for the `i`th link, as determined by the `LayoutConfig` property of `obj`.

`[y,pathGains] = step(obj,x)` also returns the channel coefficients of the underlying WINNER II fading process. `pathGains` is an N_L-by-1 cell array. The `i`th element of `pathGains` is an N_R`(i)`-by-N_T`(i)`-by-N_P`(i)`-by-N_S array of complex doubles. N_P`(i)` is the number of paths for the `i`th link, as determined by the `LayoutConfig` property of `obj`.

N_R, N_T, and N_P are link specific. N_S is the same for all the links.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Introduced in R2016b

rxsite

Create radio frequency receiver site

Description

Use the `rxsite` object to create a radio frequency receiver site.

Creation

Syntax

```
rx = rxsite
rx = rxsite(coordsys)
rx = rxsite(Name,Value)
```

Description

`rx = rxsite` creates a radio frequency receiver site.

`rx = rxsite(coordsys)` creates a receiver site with coordinate system set to `'geographic'` or `'cartesian'`.

`rx = rxsite(Name,Value)` sets properties using one or more name-value pairs. For example, `rx = rxsite('Name','RX Site')` creates a receiver site with name `RX Site`. Enclose each property name in quotes.

Create a 1-by-*N* array of receiver sites by specifying a property value as an array of *N* columns. Other property values must be specified with either 1 or *N* columns. The `Name`, `Latitude`, and `Longitude` properties may be specified as either a row vector or column vector with *N* elements. The `CoordinateSystem` property must be a string scalar or a character vector.

Properties

Name — Site name
character vector | string | row or column vector

Site name, specified as a character vector or as a row or column vector or as a string.

Example: `'Name','Site 3'`

Example: `rx.Name = 'Site 3'`

Example: If you want to assign multiple values then - `names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"]; rx = rxsite('Name',names)`

Data Types: `char` | `string`

`CoordinateSystem` — Coordinate system of site location
`'geographic'` (default) | `'cartesian'`

Coordinate system of the site location, specified as `'geographic'` or `'cartesian'`. If this property is `'geographic'`, the site location is defined using the properties `Latitude`, `Longitude`, and `AntennaHeight`. If this property is `'cartesian'`, the site location is defined using `AntennaPosition`.

Example: `'CoordinateSystem'`,`'cartesian'`

Example: `tx.CoordinateSystem = 'cartesian'`

Latitude — Site latitude coordinates
`42.3021` (default) | numeric scalar | row or column vector

Site latitude coordinates, specified as a numeric scalar or a row or column vector in the range of range `-90` to `90`. Coordinates are defined using Earth ellipsoid model WGS-84. Latitude is the north/south angle.

Example: `'Latitude'`,`45.098`

Example: `rx.Latitude = 45.098`

Example: If you want to assign multiple values then - `latitude = [42.3467,42.3598,42.3763]; rx = rxsite('Latitude',latitude)`

Dependencies

To use this property, `CoordinateSystem` must be set to `'geographic'`.

Longitude — Site longitude coordinates
`-71.3764` (default) | numeric scalar | row or column vector

Site longitude coordinates, specified as a numeric scalar or a row or column vector. Coordinates are defined using Earth ellipsoid model WGS-84. Longitude is the east/west angle.

Example: `'Longitude'`,`-68.890`

Example: `rx.Longitude = -68.890`

Example: If you want to assign multiple values then - `longitude = [-71.0972,-71.0545,-71.0611]; rx = rxsite('Longitude',longitude)`

Dependencies

To use this property, `CoordinateSystem` must be set to `'geographic'`.

Antenna — Antenna element or array
`'isotropic'` (default) | object | row vector

Antenna element or array specified as one of these:

- `'isotropic'` to model an antenna that radiates uniformly in all directions.
- An `arrayConfig` object.
- If you have Antenna Toolbox™, an antenna element from the “Antenna Catalog” (Antenna Toolbox).
- If you have Phased Array System Toolbox™, any antenna object in “Antennas, Microphones, and Sonar Transducers” (Phased Array System Toolbox) or any array object in “Array Geometries and Analysis” (Phased Array System Toolbox).

Example: `'Antenna'`,`cfgArray`, where `cfgArray` is an `arrayConfig` object

Example: `rx.Antenna = arrayConfig('Size',[8 1]);` specifies an 8-element ULA along z-axis

`AntennaAngle` — Angle of antenna local X-axis

`0` (default) | numeric scalar | 2-by-1 vector | 2-by-*N* matrix

Angle of antenna local Cartesian coordinate system X-axis, specified as a numeric scalar representing azimuth angle in degrees or a 2-by-1 vector representing both azimuth and elevation angles with each element unit in degrees.

The azimuth angle is measured counterclockwise to the antenna X-axis, either from the east (for geographical sites) or from the global X-axis around the global Z-axis (for Cartesian sites).

The elevation angle is measured from the horizontal plane or X-Y plane to the antenna X-axis in the range `-90` to `90` degrees.

Example: `'AntennaAngle'`,25

Example: `tx.AntennaAngle = [25,-80]`

`AntennaHeight` — Antenna height above surface

`1` (default) | non-negative numeric scalar | row vector

Antenna height from the ground or building surface, specified as a non-negative numeric scalar in meters. Maximum value for this property is 6,371,000 m.

If the site coincides with the building, the height is measured from the top of the building to the center of the antenna. Otherwise,the height is measured from ground elevation to the center of the antenna.

Example: `'AntennaHeight'`,25

Example: `rx.AntennaHeight = 15`

Dependencies

To use this property, `CoordinateSystem` must be set to `'geographic'`.

Data Types:

`AntennaPosition` — Position of antenna center

`[0;0;0]` (default) | 3-by-1 vector

Position of the antenna center, specified as a 3-by-1 vector representing [*x;y;z*] Cartesian coordinates with each element in meters.

Example: `'AntennaPosition'`,`[0;2;4]`

Example: `tx.AntennaPosition = [0;2;4]`

Dependencies

To use this property, choose `CoordinateSystem` must be set to `'cartesian'`.

Data Types:

`SystemLoss` — System loss

`0` (default) | nonnegative numeric scalar | row vector

System loss, specified as a non-negative numeric scalar or a row vector in dB.

System loss includes transmission line loss and any other miscellaneous system losses.

Example: `'SystemLoss'`,`10`

Example: `rx.SystemLoss = 10`

Data Types:

`ReceiverSensitivity` — Minimum received power to detect signal

`-100` (default) | numeric scalar | row vector

Minimum received power to detect the signal, specified as a numeric scalar or a row vector in dBm.

Example: `'ReceiverSensitivity'`,`-80`

Example: `rx.ReceiverSensitivity = -80`

Data Types: `double`

Object Functions

show	Show site location on map
hide	Hide site location on map
distance	Distance between sites
angle	Angle between sites
elevation	Elevation of site
location	Location coordinates at a given distance and angle from site
sigstrength	Signal strength due to transmitter
los	Plot or compute the line-of-sight (LOS) visibility between sites on a map
link	Display communication link on map
pattern	Plot antenna radiation pattern on map

Examples

Default Receiver Site

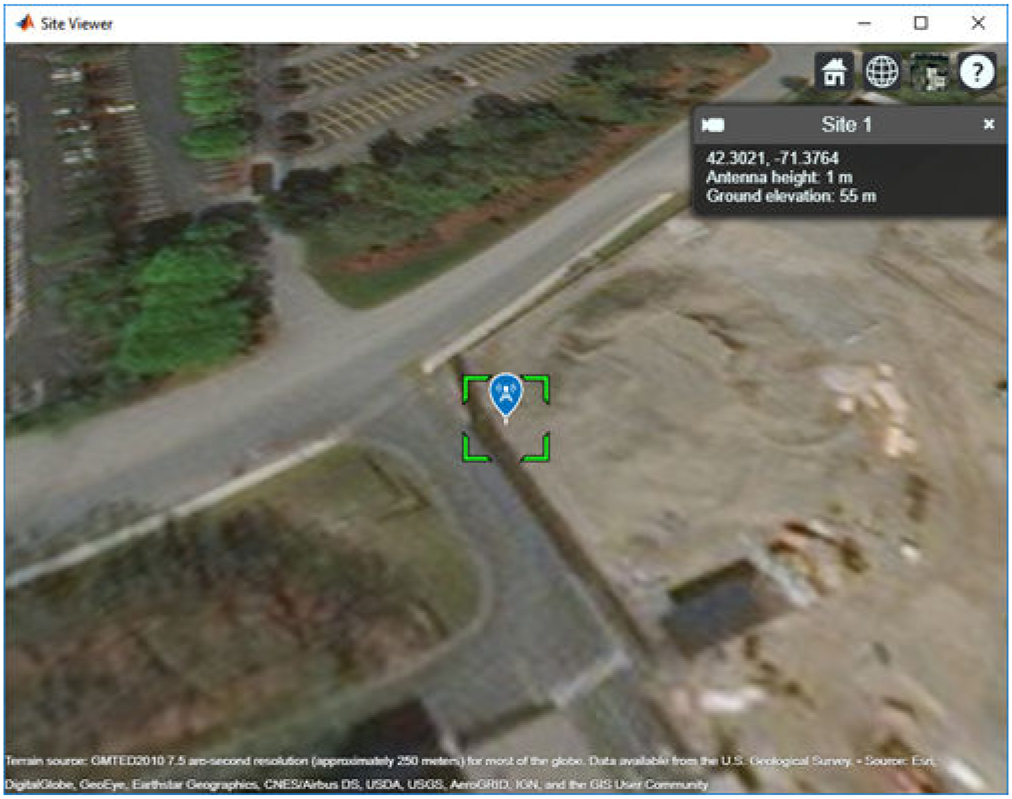
Create and show the default receiver site.

```
rx = rxsite
```

```
rx = 
  rxsite with properties:

                   Name: 'Site 2'
               Latitude: 42.3021
              Longitude: -71.3764
                Antenna: 'isotropic'
           AntennaAngle: 0
          AntennaHeight: 1
             SystemLoss: 0
    ReceiverSensitivity: -100
```

```
show(rx)
```



Site 1

42.3021, -71.3764
Antenna height: 1 m
Ground elevation: 55 m

Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

`arrayConfig` | `siteviewer` | `txsite`

Introduced in R2019b

siteviewer

Create Site Viewer map display for visualizing sites

Description

Use the `siteviewer` object to create a map viewer for visualizing transmitter and receiver sites.

Note

- Site Viewer is a 3-D map display and requires hardware graphics support for WebGL™.
- This object only supports antenna sites with `CoordinateSystem` property set to `'geographic'`.

Creation

Syntax

```
viewer = siteviewer
viewer = siteviewer(Name,Value)
```

Description

`viewer = siteviewer` creates a “Site Viewer” map display for visualizing transmitter or receiver sites.

`viewer = siteviewer(Name,Value)` creates a Site Viewer map display with properties specified by one or more name-value pairs. Properties you do not specify retain their default values.

Properties

`Name` — Caption to display on map viewer window
`'Site Viewer'` (default) | character vector | string scalar

Caption to display on map viewer window, specified as a character vector or a string scalar.

Data Types: `char` | `string`

`Position` — Size and location of map viewer window in pixels
four-element integer-valued vector

Size and location of map viewer window in pixels, specified as a four-element integer-valued vector in the form `[left bottom width height]`. The default value depends on the screen resolution such that the window lies in the center of the screen with a width of 800 pixels and a height of 600 pixels.

Data Types: `double`

Basemap — Map imagery used to visualize sites
'satellite' (default) | 'streets' | 'openstreetmap' | 'darkwater' | 'grayland' | 'bluegreen' | 'colorterrain' | 'grayterrain' | 'landcover'

Map imagery used to visualize sites, specified as a one of the following:

- 'satellite' - Satellite imagery provided by ESRI
- 'streets' - Street maps provided by ESRI.
- 'openstreetmap' - Street maps provided by OpenStreetMap.
- 'darkwater' - Two-tone map with light gray for land and dark gray for water.
- 'grayland' - Two-tone map with gray for land and white for water.
- 'bluegreen' - Two-tone map with green for land and blue for water.
- 'colorterrain' - Shaded relief map derived from elevation and climate.
- 'grayterrain' - Shaded relief map in shades of gray.
- 'landcover' - Shaded relief map derived from satellite data.

Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks®.

Data Types: char | string

Terrain — Data on which to visualize sites and perform terrain calculations
'gmted2010' (default) | 'none' | character vector | scalar

Data on which to visualize sites and perform terrain calculations, specified as a character vector or a scalar previously added using addCustomTerrain or one of the following options:

- 'none' - Terrain elevation is 0 everywhere.
- 'gmted2010' - USGS GMTED2010 terrain data. This option requires an internet connection.

This property is read-only once the Site Viewer is created.

For limitations, see “Limitations” (Antenna Toolbox).

Data Types: char | string

Buildings — Name of OpenStreetMap (.osm) file to use as buildings data
string scalar | character vector

Name of the OpenStreetMap (.osm) file to use as buildings data, specified as a string scalar or a character vector. The file must be in the current directory, in a directory on the MATLAB path. You can also use a full or relative path to the file to specify the data. By default, this value is empty.

This property is read-only once the Site Viewer is created.

For limitations, see “Limitations” (Antenna Toolbox).

Data Types: char | string

Object Functions

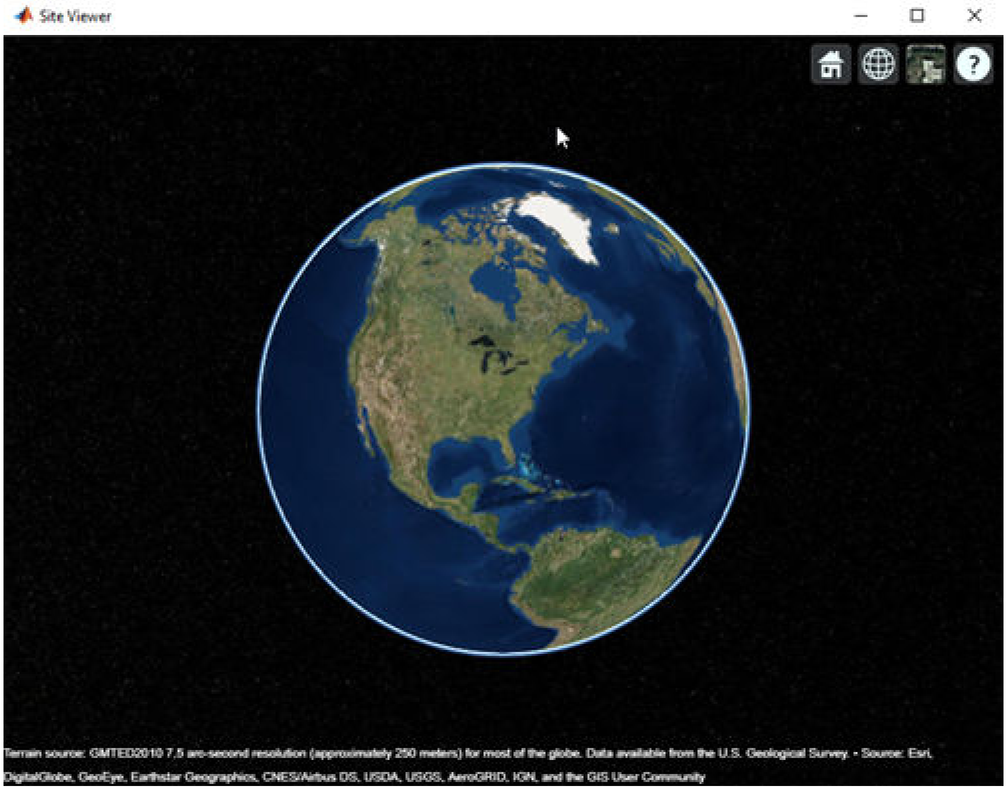
clearMap	Clear map visualizations
close	Close map viewer window

Examples

Default Site Viewer Map Display

Create a default Site Viewer map display.

```
viewer = siteviewer;
```

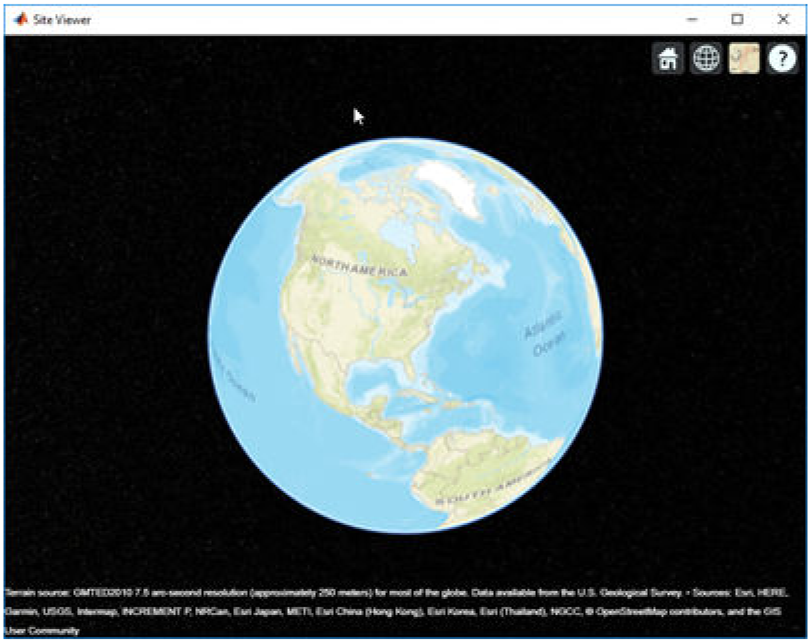


Terrain source: GMTED2010 7,5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

View Transmitter Site On Site Viewer

Launch a Site Viewer with `streets` basemap.

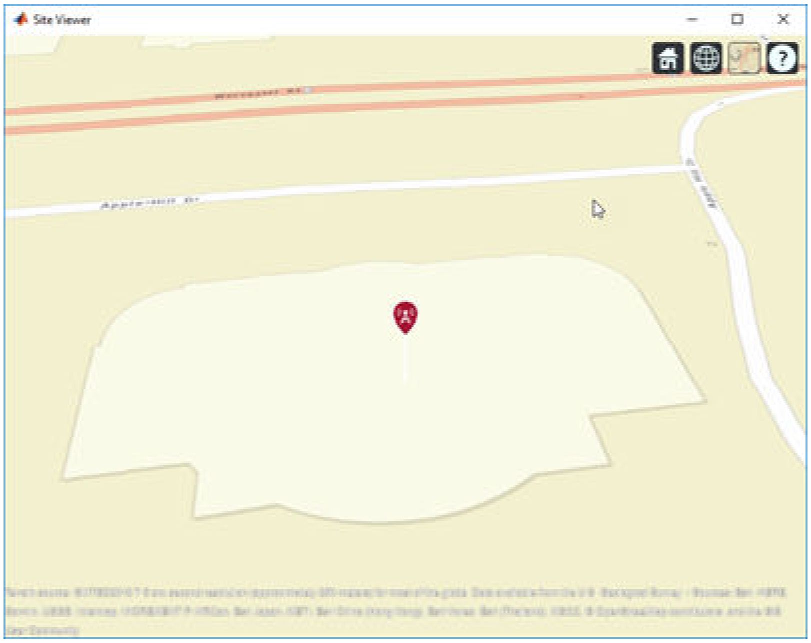
```
viewer = siteviewer("Basemap","streets");
```



Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Sources: Esri, HERE, Garmin, USGS, Intermap, INCREMENT P, NRCan, Esri Japan, METI, Esri China (Hong Kong), Esri Korea, Esri (Thailand), NGCC, © OpenStreetMap contributors, and the GIS User Community

View a transmitter site on this map.

```
tx = txsite;
show(tx)
```

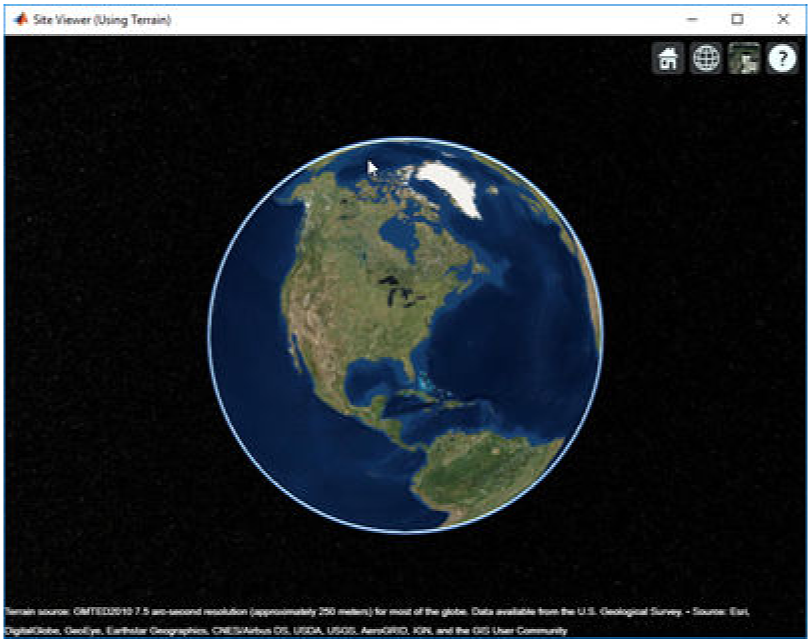


Compare Coverage Maps

Launch two Site Viewer windows.

One Site Viewer window uses the terrain model.

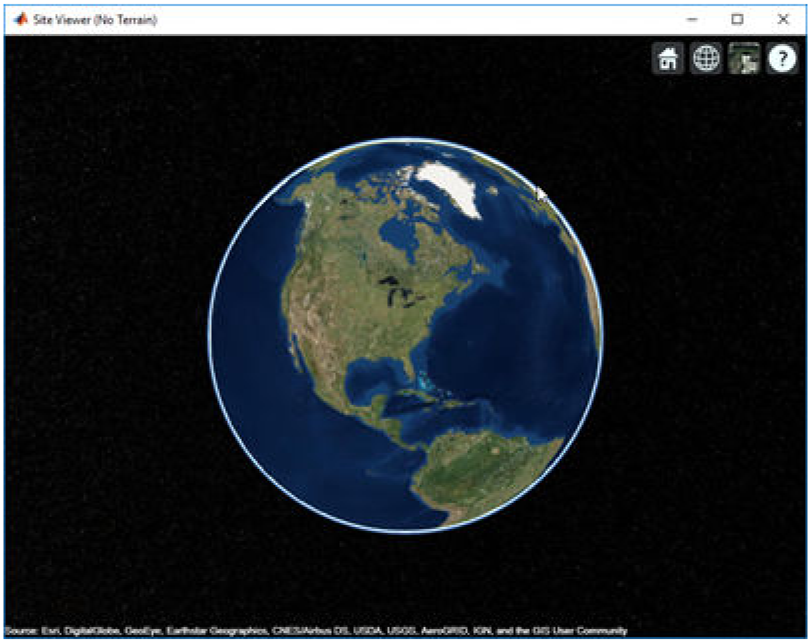
```
viewer1 = siteviewer("Terrain","gmted2010","Name","Site Viewer (Using Terrain)");
```



Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. - Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

The second Site Viewer window does not use the terrain model.

```
viewer2 = siteviewer("Terrain","none","Name","Site Viewer (No Terrain)");
```



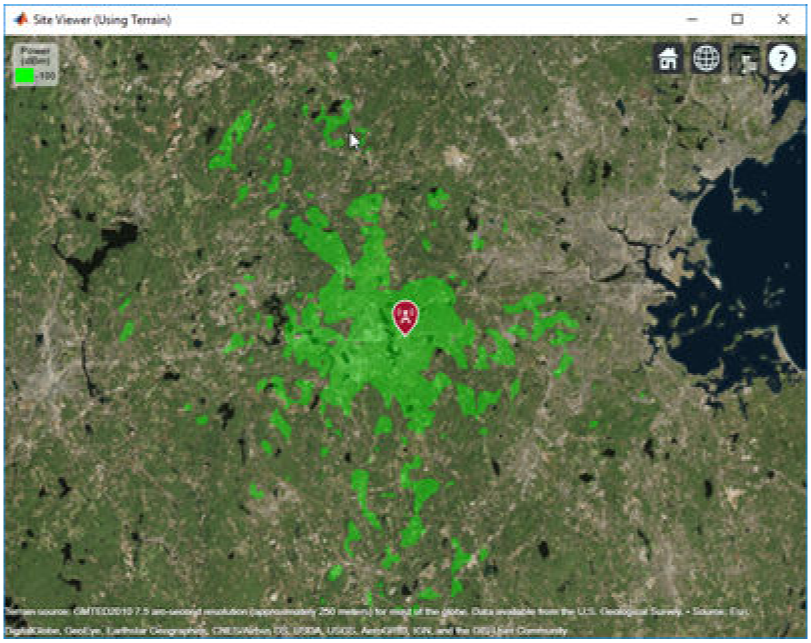
Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Create a transmitter site.

```
tx = txsite;
```

Generate a coverage map on each window. The map with terrain uses the Longley-Rice propagation model by default.

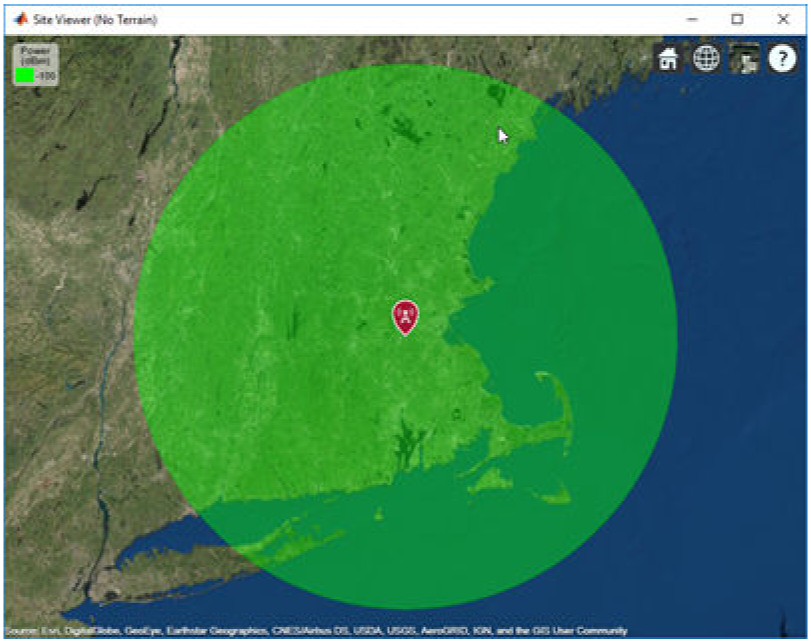
```
coverage(tx,"Map",viewer1)
```



Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

The map without terrain uses the free-space model by default.

```
coverage(tx,"Map",viewer2)
```



Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

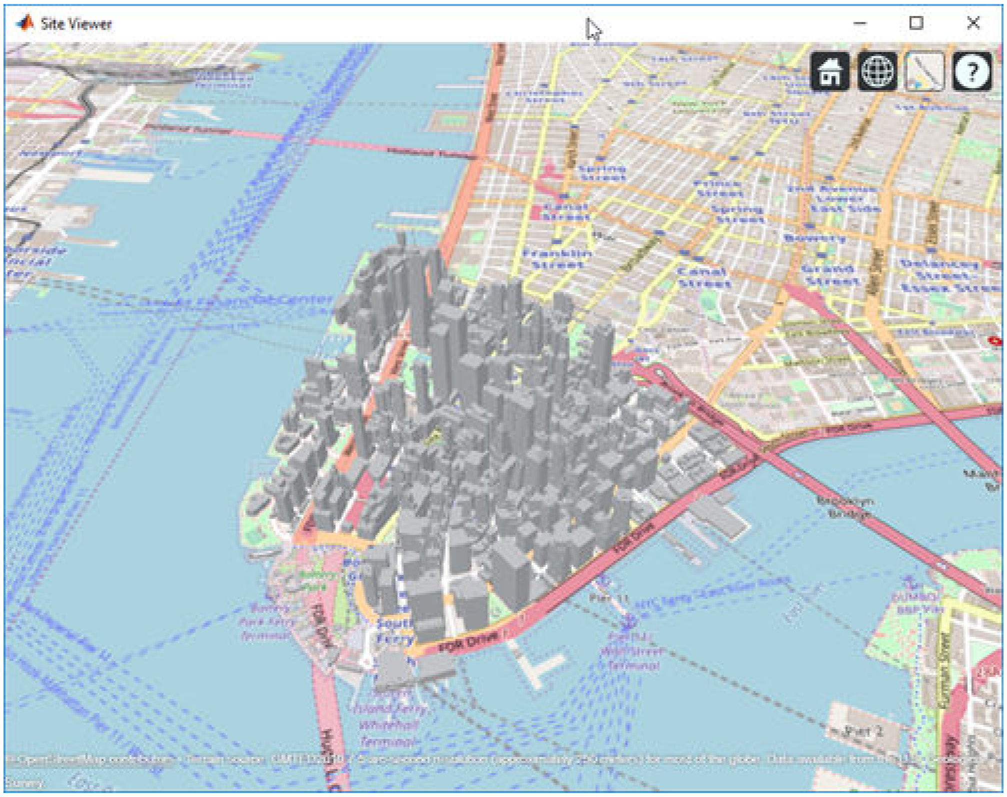
Close the maps.

```
close(viewer1)
close(viewer2)
```

Site Viewer with Buildings

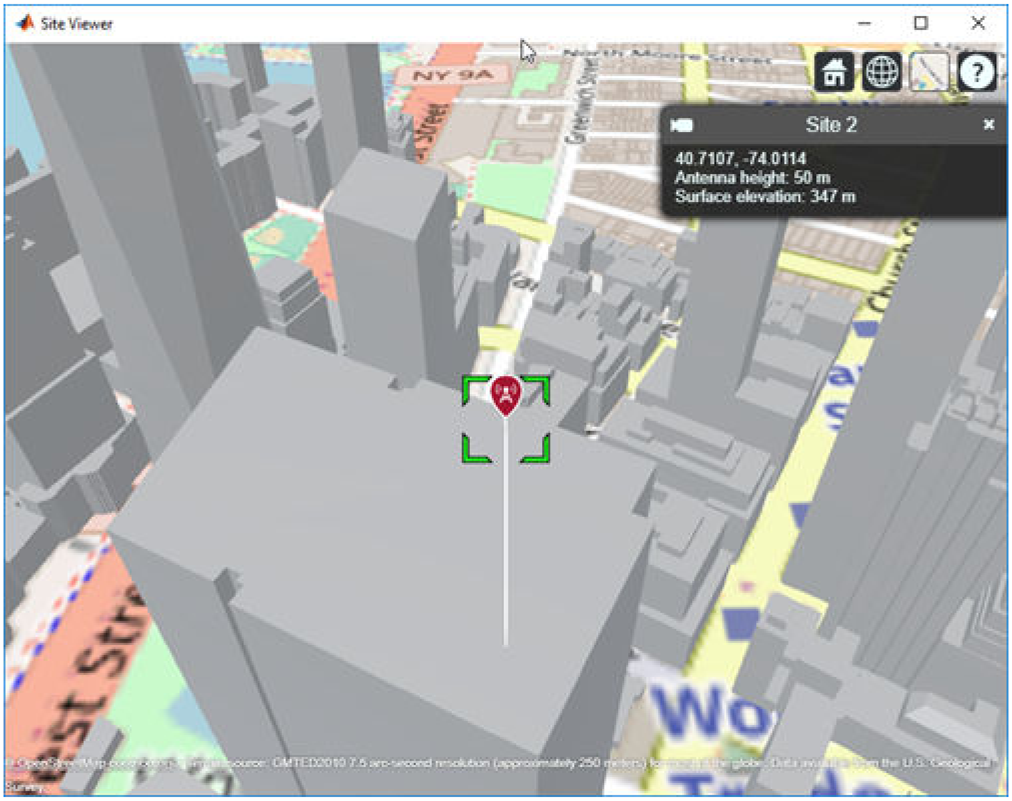
Launch siteviewer map window with basemap and buildings file for Manhattan. For more information about the osm file, see [1] on page 3-0 .

```
viewer = siteviewer("Basemap","openstreetmap",...
       "Buildings","manhattan.osm");
```



Show a transmitter site on a building.

```
tx = txsite("Latitude",40.7107,...
       "Longitude",-74.0114,...
       "AntennaHeight",50);
show(tx)
```



Site 2

40.7107, -74.0114
Antenna height: 50 m
Surface elevation: 347 m

© OpenStreetMap contributors, [illegible] source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) [illegible] the globe. Data available from the U.S. Geological Survey.

Appendix

[1] The osm file is downloaded from https://www.openstreetmap.org, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), https://opendatacommons.org/licenses/odbl/.

Add and Remove a Custom Basemap

Add a custom basemap to view locations on an OpenTopoMap® basemap, then remove the custom basemap from `siteviewer`.

Initialize simulation variables to:

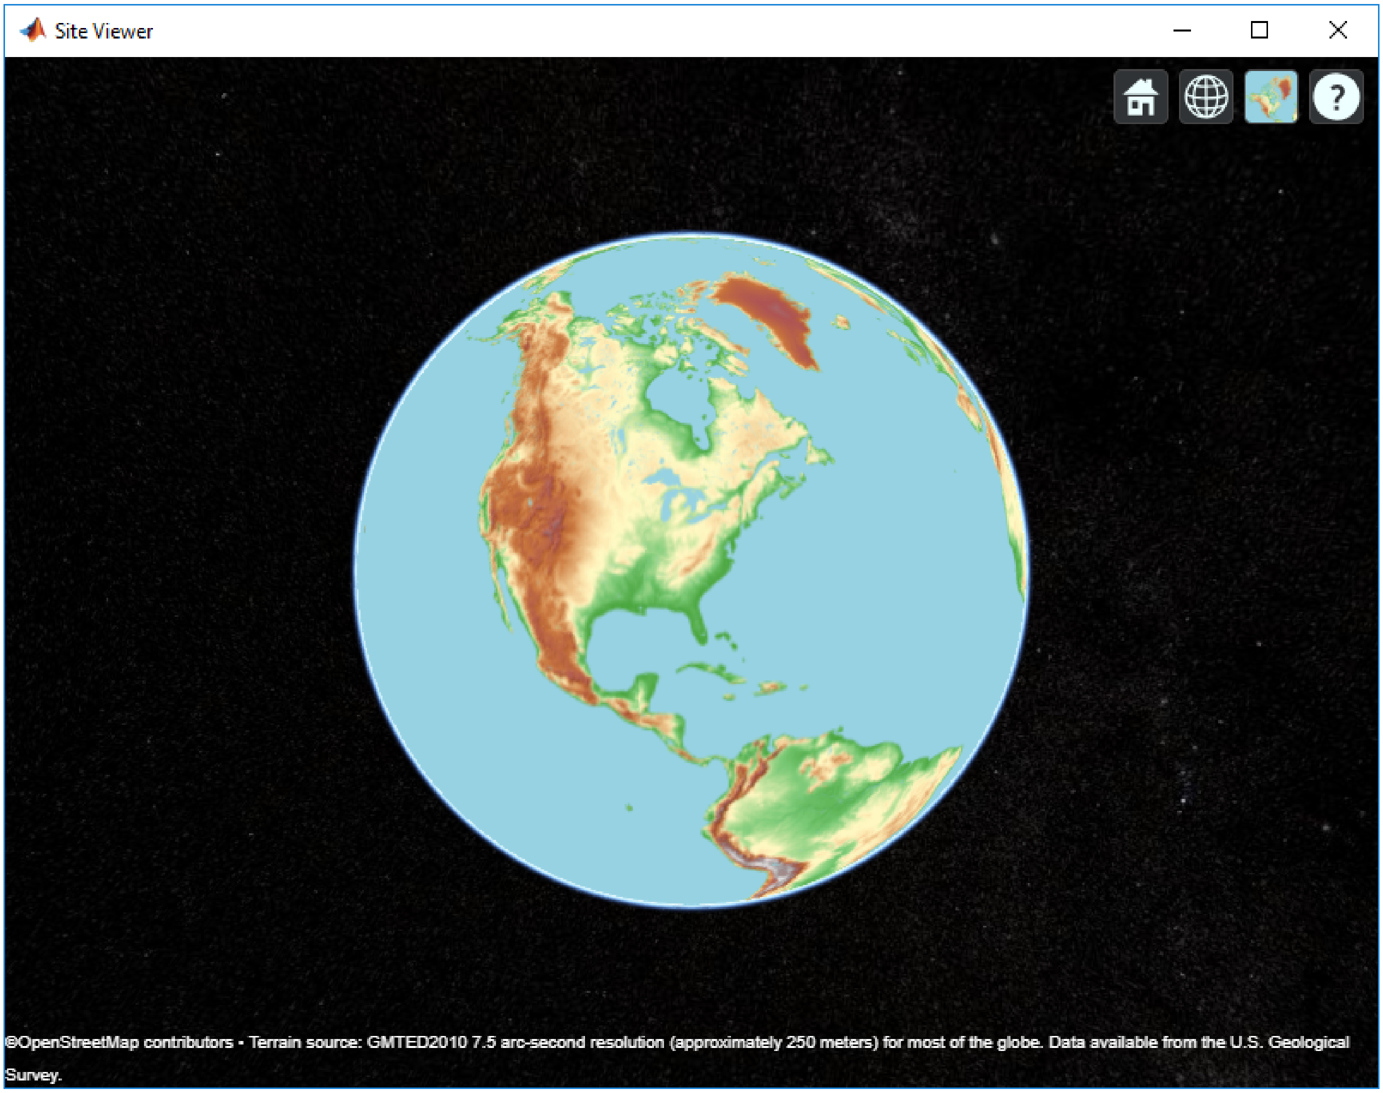
- Define the name that you will use to specify your custom basemap.
- Specify the website that provides the map data. The first character of the URL indicates which server to use to get the data. For load balancing, the provider has three servers that you can use: a, b, or c.
- Create an attribution to display on the map that gives credit to the provider of the map data. Web map providers might define specific requirements for the attribution.
- Define a display name for the custom map.

```
name = 'opentopomap';
url = 'a.tile.opentopomap.org';
copyright = char(uint8(169));
```

```
attribution = copyright + "OpenStreetMap contributors";
displayName = 'Open Topo Map';
```

Use `addCustomBasemap` to load the custom basemap, and then create a `siteviewer` object that loads the custom basemap.

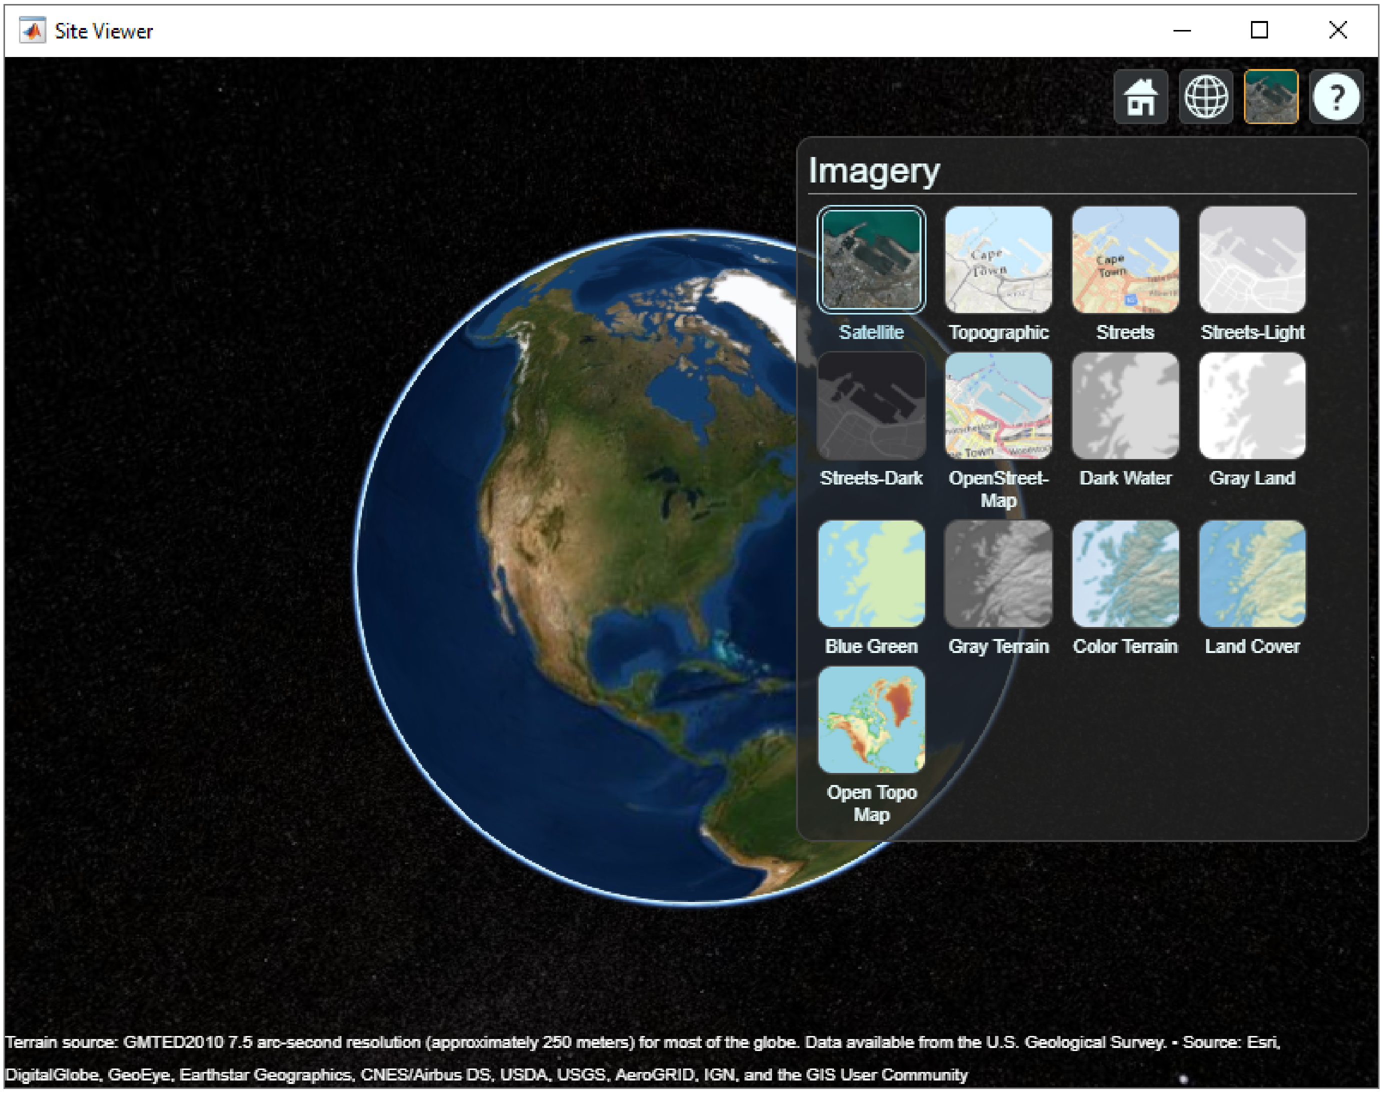
```
addCustomBasemap(name,url,'Attribution',attribution','DisplayName',displayName)
viewer = siteviewer('Basemap',name);
```



©OpenStreetMap contributors • Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey.

After a custom basemap is added to `siteviewer`, the custom map is available for future calls to `siteviewer`. Note the `'Open Topo Map'` icon in the `Imagery` tab.

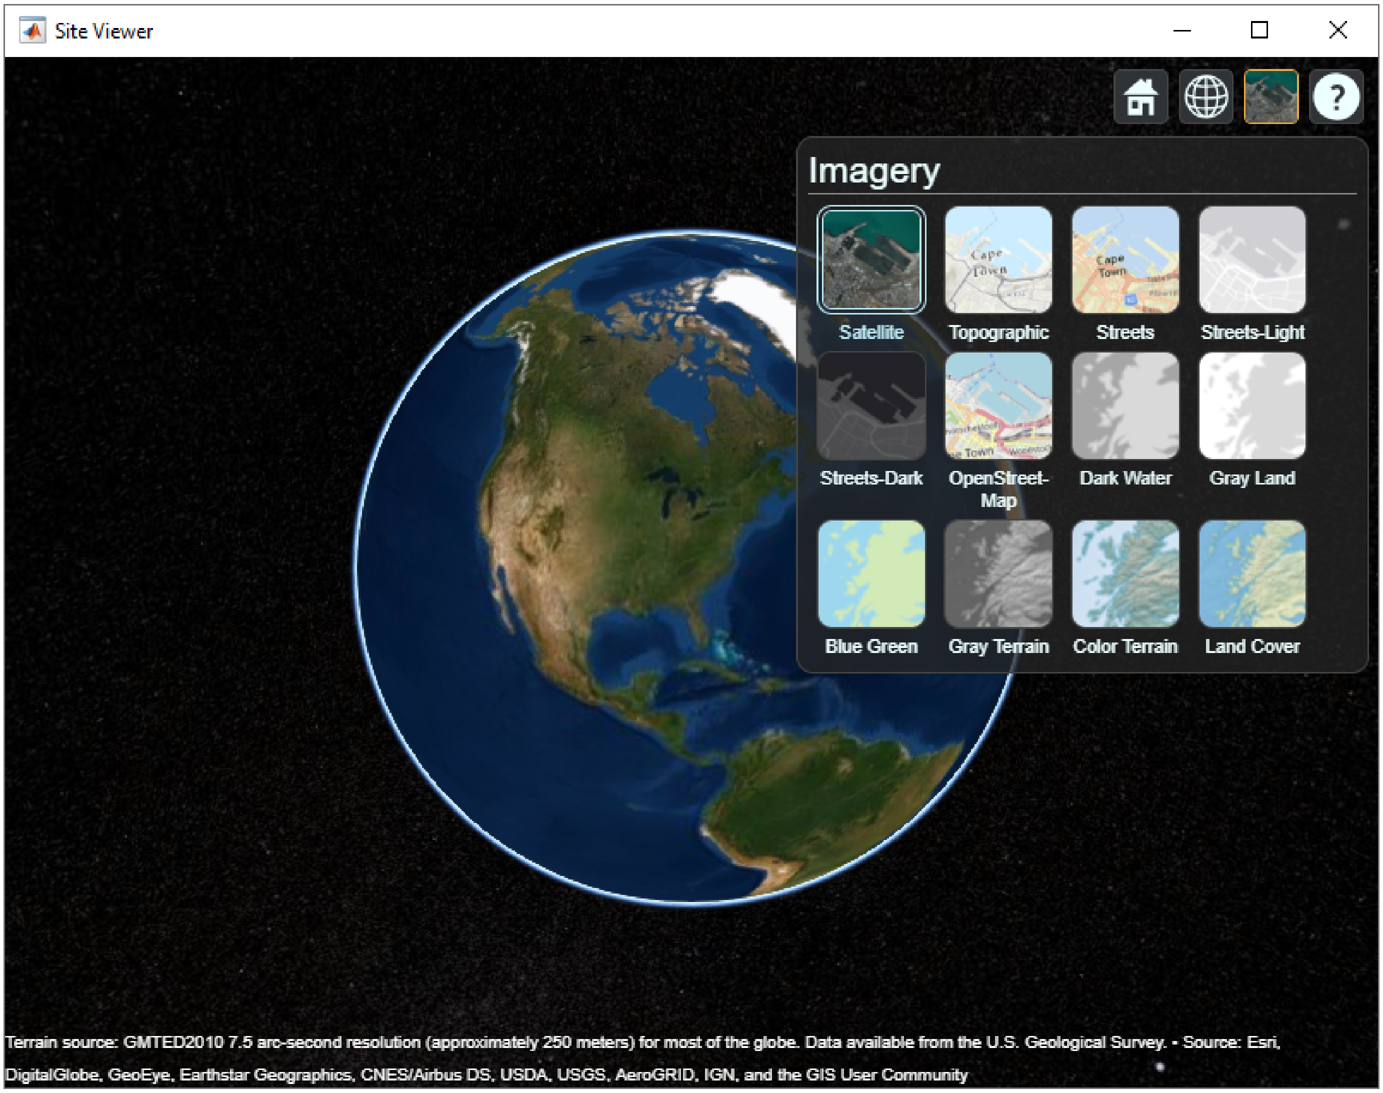
```
siteviewer;
```



Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Use `removeCustomBasemap` to remove the custom basemap from future calls to `siteviewer`. Note the `'Open Topo Map'` icon is no longer available in the `Imagery` tab.

```
removeCustomBasemap(name)
siteviewer;
```



Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Limitations

Terrain

- Default terrain access requires Internet connection. If no internet connection exists, then Site Viewer automatically uses `'none'` in the property `Terrain`.
- Custom DTED terrain files for use with `addCustomTerrain` must be acquired outside of MATLAB for example by using USGS EarthExplorer.
- When using custom terrain, analysis is restricted to the terrain region. For example, an error occurs if trying to show a txsite or rxsite outside of the region.

Buildings

- OpenStreetMap files obtained from https://www.openstreetmap.org represent crowd-sourced map data, and the completeness and accuracy of the buildings data may vary depending on the map location.

- When downloading data from https://www.openstreetmap.org, select an export area larger than the desired area to ensure that all expected building features are fully captured. Building features at the edge of the selected export area may be missing.
- Building geometry and features are interpreted from the file according to the recommendations of OpenStreetMap for 3D buildings.

Topics

"Site Viewer"

Introduced in R2019b

txsite

Create radio frequency transmitter site

Description

Use the `txsite` object to create a radio frequency transmitter site.

Creation

Syntax

```
tx = txsite
tx = txsite(coordsys)
tx = txsite( ___ ,Name,Value)
```

Description

`tx = txsite` creates a radio frequency transmitter site.

`tx = txsite(coordsys)` creates a transmitter site with the specified coordinate system. You can specify either `'geographic'` or `'cartesian'` coordinate system.

`tx = txsite( ___ ,Name,Value)` sets "Properties" (Antenna Toolbox) using one or more name-value pairs. For example, `tx = txsite('Name','TX Site')` creates a transmitter site with the name `TX Site`. Enclose each property name in quotes.

You can create multiple transmitter sites by using `Name`, `Latitude`, and `Longitude` properties. For example: `names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"]; lats = [42.3467,42.3598,42.3763]; lons = [-71.0972,-71.0545,-71.0611];`. The `CoordinateSystem` property must be a string scalar or a character vector.

Properties

`Name` — Site name
character vector | string | row or column vector

Site name, specified as a character vector or string or as a row or column vector of *N* elements. Specifying name as a row or column vector creates multiple sites.

Example: `'Name','Site 2'`

Example: `tx.Name = 'Fenway Park'`

Example: `names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"]; tx = txsite('Name',names)`

Data Types: `char` | `string`

`CoordinateSystem` — Coordinate system used to site location
`'geographic'` (default) | `'cartesian'`

Coordinate system used to the site location, specified as `'geographic'` or `'cartesian'`. If you specify `'geographic'`, the site location is defined using the `Latitude`, `Longitude`, and `AntennaHeight` properties. If you specify `'cartesian'`, the site location is defined using the `AntennaPosition` property.

Example: `'CoordinateSystem'`,`'cartesian'`

Example: `tx.CoordinateSystem = 'cartesian'`

Latitude — Site latitude coordinates

`42.3001` (default) | numeric scalar in the range `[-90 90]` | row or column vector

Site latitude coordinates, specified as a numeric scalar in the range of `-90` to `90`, or as a row or column vector of *N* elements in the range `[-90 90]`. Specifying latitude as a row or column vector creates multiple sites. The coordinates are defined using the world geodesic system of 1984 (WGS-84) reference ellipsoid. Latitude specifies north-south position.

Example: `'Latitude'`,`45.098`

Example: `tx.Latitude = 45.098`

Example: `latitude = [42.3467,42.3598,42.3763]; tx = txsite('Latitude',latitude)`

Dependencies

To enable this property, set `CoordinateSystem` to `'geographic'`.

Longitude — Site longitude coordinates

`-71.3504` (default) | numeric scalar in the range `[-180 180]` | row or column vector

Site longitude coordinates, specified as a numeric scalar in the range `[-180 180]`or as a row or column vector of *N* elements in the range `[-180 180]`. Specifying longitude as a row or column vector creates multiple sites. The coordinates are defined using the world geodesic system of 1984 (WGS-84) reference ellipsoid. Longitude specifies the east-west the position.

Example: `'Longitude'`,`-68.890`

Example: `tx.Longitude = -71.0972`

Example: `longitude = [-71.0972,-71.0545,-71.0611]; tx = txsite('Longitude',longitude)`

Dependencies

To enable this property, set the `CoordinateSystem` to `'geographic'`.

Antenna — Antenna element or array

`'isotropic'` (default) | object | row vector

Antenna element or array specified as one of these:

- `'isotropic'` to model an antenna that radiates uniformly in all directions
- An `arrayConfig` object
- An antenna element object from the “Antenna Catalog” (Antenna Toolbox)

Note When using the antenna element object, use the `design` function to design the antenna at the required transmit frequency. Then add this antenna element to the transmitter site.

- Any antenna object in “Antennas, Microphones, and Sonar Transducers” (Phased Array System Toolbox), if you have Phased Array System Toolbox
- Any array object in “Array Geometries and Analysis” (Phased Array System Toolbox), if you have Phased Array System Toolbox

Example: `'Antenna'`,`cfgArray`, where `cfgArray` is an `arrayConfig` object

Example: `tx.Antenna = arrayConfig('Size',[8 1]);` specifies an 8-element ULA along z-axis

`AntennaAngle` — Antenna X-axis angle

`0` (default) | numeric scalar | 2-by-1 vector | 2-by-*N* matrix

Antenna X-axis angle defined with reference to a local Cartesian coordinate system, specified as a numeric scalar representing an azimuth angle in degrees or as a 2-by-1 vector or a 2-by-*N* matrix representing both azimuth and elevation angles with each element unit in degrees.

The azimuth angle is measured counterclockwise from the east along the antenna X-axis (for geographical sites) or from the global X-axis around the global Z-axis (for Cartesian sites). Specify the azimuth angle between `-180` to `180`. degrees.

The elevation angle is measured from antenna X-axis along the horizontal or XY plane. Specify the elevation angle between`-90` to `90` degrees.

Example: `'AntennaAngle'`,25

Example: `tx.AntennaAngle = [25,-80]`

`AntennaHeight` — Antenna height above surface

`10` (default) | nonnegative numeric scalar | row vector

Antenna height from the ground or building surface, specified as a nonnegative numeric scalar in meters. Maximum value for this property is 6,371,000 m.

If the site location coincides with the building location, the antenna height is measured from the top of the building to the center of the antenna. Otherwise,the height is measured from ground elevation to the center of the antenna.

Example: `'AntennaHeight'`,25

Example: `tx.AntennaHeight = 15`

Dependencies

To enable this property, set `CoordinateSystem` to `'geographic'`.

Data Types:

`AntennaPosition` — Position of antenna center

`[0;0;0]` (default) | 3-by-1 vector

Position of the antenna center, specified as a 3-by-1 vector representing X-, Y-, and Z-axis Cartesian coordinates with each element in meters.

Example: `'AntennaPosition'`,`[0;2;4]`

Example: `tx.AntennaPosition = [0;2;4]`

Dependencies

To enable this property, set `CoordinateSystem` to `'cartesian'`.

Data Types:

`SystemLoss` — System loss

`0` (default) | nonnegative scalar | row vector

System loss, specified as a nonnegative scalar in dB.

System loss includes transmission line loss and any other miscellaneous system losses.

Example: `'SystemLoss',10`

Example: `txsite.SystemLoss = 10`

Data Types:

`TransmitterFrequency` — Transmitter operating frequency

`1.9000e+09` (default) | positive scalar | row vector

Transmitter operating frequency, specified as a positive scalar in Hz. in the range `[1e3 200e9`.

Example: `'TransmitterFrequency',30e9`

Example: `txsite.TransmitterFrequency = 30e9`

Data Types: `double`

`TransmitterPower` — Signal power at transmitter output

`10` (default) | positive scalar

Signal power at transmitter output, specified as a positive scalar in watts. The transmitter out is connected to the antenna.

Example: `'TransmitterPower',30`

Example: `txsite.TransmitterPower = 30`

Data Types: `double`

Object Functions

show	Show site location on map
hide	Hide site location on map
distance	Distance between sites
angle	Angle between sites
elevation	Elevation of site
location	Location coordinates at a given distance and angle from site

propagationData

Create RF propagation data container

Description

Use the `propagationData` object to import and visualize geolocated propagation data. The measurement data can be path loss data, signal strength measurements, signal-to-noise-ratio (SNR) data, or cellular information.

Creation

Syntax

```
pd = propagationData(filename)
pd = propagationData(table)

pd = propagationData(latitude,longitude,varname,varvalue)
pd = propagationData( ___ ,Name,Value)
```

Description

`pd = propagationData(filename)` creates a propagation data container object by reading data from a file specified by `filename`.

`pd = propagationData(table)` creates a propagation data container object from a table object specified by `table`.

`pd = propagationData(latitude,longitude,varname,varvalue)` creates a propagation data container object using `latitude` and `longitude` coordinates with data specified using `varname` and `varvalue`.

`pd = propagationData( ___ ,Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes.

Input Arguments

`filename` — Name of file containing propagation data
character vector | string scalar

Name of the file containing propagation data, specified as a character vector or a string scalar. The file must be in the current directory, in a directory on the MATLAB path, or be specified using a full or relative path. The file must be compatible with the `readtable` function. Call the `readtable` function if customized parameters are required to import the file and then pass the `table` object to the `propagationData` object.

Propagation data in the file must have one variable corresponding to the latitude values, one variable corresponding to longitude values, and at least one variable containing numeric data.

Data Types: `string` | `char`

`table` — Table containing propagation data
table object

Table containing propagation data, specified as a table object.

Propagation data in the file must have one variable corresponding to the latitude values, one variable corresponding to longitude values, and at least one variable containing numeric data.

Data Types: `table`

`latitude` — Latitude coordinate values
vector

Latitude coordinate values, specified as a vector in decimal degrees with reference to Earth's ellipsoid model WGS-84. The latitude coordinates must be in the range `[-90 90]`.

Data Types: `double`

`longitude` — Longitude coordinate values
vector

Longitude coordinate values, specified as a vector in decimal degrees with reference to earth's ellipsoid. model WGS-84.

Data Types: `double`

`varname` — Variable name
character vector | string scalar

Variable name, specified as a character vector or a string scalar. This variable name must correspond to the variable with numeric data other than latitude or longitude. The variable name and the corresponding values are stored as a column in the Data property table object.

Data Types: `string` | `char`

`varvalue` — Variable values
numeric vector

Variable values, specified as a numeric vector. The numeric vectors must be the same size as latitude and longitude. The variable name and corresponding values are stored as a column in the Data property table object.

Data Types: `double`

Output Arguments

pd — Propagation data
`propagationData` object

Propagation data, returned as a `propagationData` object.

Properties

Name — Propagation data name
`'Propagation Data'` (default) | character vector | string scalar

Propagation data name, specified as a character vector or string scalar.

Example: 'Name','propdata'

Example: pd.Name = 'propdata'

Data Types: char | string

Data — Propagation data table

scalar table object

This property is read-only.

Propagation data table, specified as a scalar table object containing a column corresponding to latitude coordinates, a column corresponding to longitude coordinates, and one or more columns corresponding to associated propagation data.

Data Types: table

DataVariableName — Name of data variable to plot

character vector | string scalar

Name of the data variable to plot, specified as a character vector or string scalar corresponding to a variable name in the Data table used to create propagation data container object. The variable name must correspond to a variable with numeric data and cannot correspond to the latitude or longitude variables. The default value for this property is the name of the first numeric data variable name in the Data table that is not a latitude or longitude variable.

Data Types: char | string

Object Functions

plot	Plot propagation data on map
contour	Display contour map
location	Data location coordinates
getDataVariable	Get data variable values of data points in propagation data object
interp	Geographic data interpolation

Examples

Compute Signal Strength Data in Urban Environment

Launch Site Viewer with basemaps and building files for Manhattan. For more information about the osm file, see [1] on page 3-0 .

```
viewer = siteviewer("Basemap","streets_dark",...

Introduced in R2020a

comm.Ray

Propagation ray container object

Description

The comm.Ray object is a container object for the properties of a propagation ray. The object contains the geometric and electromagnetic information of a radio wave propagating from one point to another point in the space.

Creation

Typically you create comm.Ray objects by using the raytrace function.

Syntax

```
ray = comm.Ray
ray = comm.Ray(Name,Value)
```

Description

ray = comm.Ray creates a container object that initializes properties for a propagation ray.

ray = comm.Ray(Name,Value) sets properties using one or more name-value pair arguments. Enclose each property name in quotes. For example, comm.Ray('CoordinateSystem','Geographic','TransmitterLocation',[40.730610,-73.935242,0]) specifies the geographic coordinate system and a transmitter located in New York City.

Properties

PathSpecification — Propagation path specification method
'Locations' (default) | 'Delay and angles'

Propagation path specification method, specified as one of these values.

- 'Locations' — The ray object path between waypoints are conveyed as (*x*, *y*, *z*) coordinate points by the TransmitterLocation, ReceiverLocation, and, if applicable, ReflectorLocations properties .
- 'Delay and angles' — The ray object path between waypoints are conveyed by the PropagationDelay, AngleOfDeparture, and AngleOfArrival properties.

Data Types: char | string

CoordinateSystem — Coordinate system
'Cartesian' (default) | 'Geographic'

Coordinate system, specified as 'Cartesian' or 'Geographic'. When you set the CoordinateSystem property to 'Geographic', the coordinate system is defined relative to the

WGS-84 Earth ellipsoid model and the object defines angles relative to the local East-North-Up (ENU) coordinate system at the transmitter and receiver.

Dependencies

To enable this property, set the `PathSpecification` property to `'Locations'`.

Data Types: `char` | `string`

`SystemScale` — Cartesian coordinate system scale

`1` (default) | positive scalar

Cartesian coordinate system scale in meters, specified as a positive scalar.

Dependencies

To enable this property, set the `PathSpecification` property to `'Locations'` and the `CoordinateSystem` property to `'Cartesian'`.

Data Types: `double`

`TransmitterLocation` — Transmitter location

`[0;0;0]` (default) | three-element numeric column vector

Transmitter location, specified as a three-element numeric column vector of coordinates in one of these forms.

- [*x*; *y*; *z*] — This form applies when you set the `CoordinateSystem` property to `'Cartesian'`. The object does not perform range validation for *x*, *y*, and *z*.
- [*latitude*; *longitude*; *height*] — This form applies when you set the `CoordinateSystem` property to `'Geographic'`. *latitude* must be in the range [–90, 90], and *height* must be nonnegative. The object does not perform range validation for *longitude*.

Dependencies

To enable this property, set the `PathSpecification` property to `'Locations'`.

Data Types: `double`

`ReceiverLocation` — Receiver location

`[10;10;10]` (default) | three-element numeric column vector

Receiver location, specified as a three-element numeric column vector of coordinates in one of these forms.

- [*x*; *y*; *z*] — This form applies when you set the `CoordinateSystem` property to `'Cartesian'`. The object does not perform range validation for *x*, *y*, and *z*.
- [*latitude*; *longitude*; *height*] — This form applies when you set the `CoordinateSystem` property to `'Geographic'`. *latitude* must be in the range [–90, 90], and *height* must be nonnegative. The object does not perform range validation for *longitude*.

Dependencies

To enable this property, set the `PathSpecification` property to `'Locations'`.

Data Types: `double`

LineOfSight — Line of sight

true or 1 (default) | false or 0

Line of sight, specified as a logical value of 1 (true) or 0 (false) to indicate whether the ray is a line-of-sight ray.

Dependencies

To enable this property, set the PathSpecification property to 'Locations'.

Data Types: logical

ReflectorLocations — Reflector locations

[10;10;0] (default) | 3-by-*N* numeric matrix

Reflector locations, specified as a 3-by-*N* numeric matrix containing the coordinates of the reflection points for the ray. *N* is the number of reflection points for the ray and is set by the NumReflections property. Each column represents the coordinate location of one reflection point along the propagation path from transmitter to receiver. The order of the columns is the same as the order of the points along the path. Columns (reflection point coordinates) are of one of these forms.

- [*x*; *y*; *z*] — when the CoordinateSystem property is set to 'Cartesian'. The object does not perform range validation for *x*, *y*, and *z*.
- [*latitude*; *longitude*; *height*] — when the CoordinateSystem property is set to 'Geographic'. *latitude* must be in the range [–90, 90], and *height* must be nonnegative. The object does not perform range validation for *longitude*.

Dependencies

To enable this property, set the PathSpecification property to 'Locations' and the LineOfSight property to 0 (false).

.

Data Types: double

PropagationDelay — Propagation delay

5.7775e-08 | nonnegative scalar

Propagation delay in seconds, specified as a nonnegative scalar. The default value is computed using the default values of the TransmitterLocation and ReceiverLocation properties for a line-of-sight ray.

- When you set the PathSpecification property to 'Locations', this property is read-only and the value is derived from TransmitterLocation, ReceiverLocation and, if applicable, the ReflectionLocations.
- When you set the PathSpecification property to 'Delay and angles', this property is configurable.

Data Types: double

PropagationDistance — Propagation distance

17.3205 | nonnegative scalar

This property is read-only.

Propagation distance in meters, specified as a nonnegative scalar. The default value is computed using the default values of the TransmitterLocation and ReceiverLocation properties for a line-of-sight ray.

- When you set the PathSpecification property to 'Locations', the value is derived from TransmitterLocation, ReceiverLocation and, if applicable, the ReflectionLocations.
- When you set the PathSpecification property to 'Delay and angles', the value is derived from PropagationDelay.

Data Types: double

AngleOfDeparture — Angle of departure
[45; 35.2644] | numeric vector of the form [*az*; *el*]

Angle of departure in degrees of the ray at the transmitter, specified as a numeric vector of the form [*az*; *el*]. The azimuth angle, *az*, is measured from the positive x-axis counterclockwise and must be in the range (–180, 180]. The elevation angle, *el*, is measured from the x-y plane and must be in the range [–90, 90]. The default value is computed using the default values of the TransmitterLocation and ReceiverLocation properties for a line-of-sight ray.

- When you set the PathSpecification property to 'Delay and angles', this property is configurable.
- When you set the PathSpecification property to 'Locations', this property is read-only and the value is derived from TransmitterLocation, ReceiverLocation and, if applicable, the ReflectionLocations.
- When CoordinateSystem is set to 'Geographic', the angles are defined with reference to the local East-North-Up (ENU) coordinate system at transmitter.

Data Types: double

AngleOfArrival — Angle of arrival
[-135; -35.2644] | numeric vector of the form [*az*; *el*]

Angle of arrival in degrees of the ray at the receiver, specified as a numeric vector of the form [*az*; *el*]. The azimuth angle, *az*, is measured from the positive x-axis counterclockwise and must be in the range (–180, 180]. The elevation angle, *el*, is measured from the x-y plane and must be in the range [–90, 90]. The default value is computed using the default values of the TransmitterLocation and ReceiverLocation properties for a line-of-sight ray.

- When you set the PathSpecification property to 'Delay and angles', this property is configurable.
- When you set the PathSpecification property to 'Locations', this property is read-only and the value is derived from TransmitterLocation, ReceiverLocation and, if applicable, the ReflectionLocations.
- When CoordinateSystem is set to 'Geographic', the angles are defined with reference to the local East-North-Up (ENU) coordinate system at receiver.

Data Types: double

NumReflections — Number of reflection points
0 (default) | nonnegative integer

This property is read-only.

Number of reflection points for the ray object from the transmitter to the receiver, specified as a nonnegative integer. The value is derived from `LineOfSight` and, if applicable, the `ReflectionLocations`.

Dependencies

To enable this property, set the `PathSpecification` property to `'Locations'`.

Data Types: `double`

`Frequency` — Signal frequency

`1.9e+09` (default) | positive scalar

Signal frequency in Hz, specified as a positive scalar.

Data Types: `double`

`PathLossSource` — Path loss source

`'Free space model'` (default) | `'Custom'`

Path loss source, specified as `'Free space model'` or `'Custom'`.

Data Types: `char` | `string`

`PathLoss` — Path loss

`62.7941` | nonnegative scalar

Path loss in dB, specified as a nonnegative scalar. The default value is computed using the default values of the `TransmitterLocation` and `ReceiverLocation` properties for a line-of-sight ray.

- When you set the `PathLossSource` property to `'Free space model'`, the `PathLoss` property is read-only and derived from the `PropagationDistance` and `Frequency` properties by using the free space propagation model.
- When you set the `PathLossSource` property to `'Custom'`, you can set the `PathLoss` property, independent of the geometric properties.

Data Types: `double`

`PhaseShift` — Phase shift

`4.8537` | numeric scalar

Phase shift in radians, specified as a numeric scalar. The default value is computed using the default values of the `TransmitterLocation` and `ReceiverLocation` properties for a line-of-sight ray.

- When you set the `PathLossSource` property to `'Free space model'`, the `PhaseShift` property is read-only and derived from the `PropagationDistance` and `Frequency` properties by using the free space propagation model.
- When you set the `PathLossSource` property to `'Custom'`, you can set the `PhaseShift` property, independent of the geometric properties.

Data Types: `double`

Object Functions

plot (rays)	Plot rays in Site Viewer map

Examples

Perform Ray Tracing Between Two Sites in Hong Kong

Perform ray tracing between two sites in Hong Kong, generating a cell array containing `comm.Ray` objects. The `comm.Ray` objects contain the geometric and electromagnetic information for the radio wave propagation paths from the transmitter site to the receiver site.

Create a Site Viewer map, loading building data for Hong Kong. For more information about the osm file, see [1] on page 3-0 .

```
viewer = siteviewer('Buildings','hongkong.osm');
```

Specify transmitter and receiver sites.

```
tx = txsite('Latitude',22.2789,'Longitude',114.1625, ...
    'AntennaHeight',10,'TransmitterPower',5, ...
    'TransmitterFrequency',28e9);
rx = rxsite('Latitude',22.2799,'Longitude',114.1617, ...
    'AntennaHeight',1);
```

Perform ray tracing between the sites, generating `comm.Ray` objects in a cell array. For the specified transmitter and receiver sites, performing ray tracing results in a 1-by-1 cell array containing three ray objects in a row vector.

```
rays = raytrace(tx,rx,'Type','pathloss','ColorLimits',[100 250])
```

```
rays = 1×1 cell array
    {1×3 comm.Ray}
```

Display the properties of the first `comm.Ray` object. The `LineOfSight` property value is `1`, and the `NumReflections` property value is `0`. This combination indicates that the ray defines a line-of-sight path.

```
rays{1}(1)
```

```
ans = 
  Ray with properties:

      PathSpecification: 'Locations'
       CoordinateSystem: 'Geographic'
    TransmitterLocation: [3×1 double]
       ReceiverLocation: [3×1 double]
            LineOfSight: 1
              Frequency: 2.8000e+10
         PathLossSource: 'Custom'
               PathLoss: 104.2656
             PhaseShift: 4.6390

   Read-only properties:
       PropagationDelay: 4.6442e-07
    PropagationDistance: 139.2294
       AngleOfDeparture: [2×1 double]
         AngleOfArrival: [2×1 double]
         NumReflections: 0
```

Display the properties of the second and third `comm.Ray` objects. The `LineOfSight` property values are `0`, and the `NumReflections` property values are greater than `0`. This combination indicates that the rays define reflected paths.

```
rays{1}(2)
```

```
ans = 
  Ray with properties:

      PathSpecification: 'Locations'
       CoordinateSystem: 'Geographic'
    TransmitterLocation: [3×1 double]
       ReceiverLocation: [3×1 double]
            LineOfSight: 0
    ReflectionLocations: [3×1 double]
              Frequency: 2.8000e+10
         PathLossSource: 'Custom'
               PathLoss: 106.2545
             PhaseShift: 0.3951

   Read-only properties:
       PropagationDelay: 4.6490e-07
    PropagationDistance: 139.3720
       AngleOfDeparture: [2×1 double]
         AngleOfArrival: [2×1 double]
         NumReflections: 1
```

```
rays{1}(3)
```

```
ans = 
  Ray with properties:

      PathSpecification: 'Locations'
       CoordinateSystem: 'Geographic'
    TransmitterLocation: [3×1 double]
       ReceiverLocation: [3×1 double]
            LineOfSight: 0
    ReflectionLocations: [3×1 double]
              Frequency: 2.8000e+10
         PathLossSource: 'Custom'
               PathLoss: 120.0733
             PhaseShift: 0.3965

   Read-only properties:
       PropagationDelay: 1.1327e-06
    PropagationDistance: 339.5692
       AngleOfDeparture: [2×1 double]
         AngleOfArrival: [2×1 double]
         NumReflections: 1
```

Visualize ray tracing results.

```
plot(rays{1});
```

Appendix

[1] The osm file is downloaded from https://www.openstreetmap.org, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), https://opendatacommons.org/licenses/odbl/.

Plot Propagation Rays Between Sites in Chicago

Return ray tracing results in `comm.Ray` objects and plot the ray propagation path after relaunching the Site Viewer map.

Create a Site Viewer map, loading building data for Chicago. For more information about the osm file, see [1] on page 3-0 .

```
viewer = siteviewer('Buildings','chicago.osm');
```

Create and show a transmitter site on one building and a receiver site on another building.

```
tx = txsite('Latitude',41.8800,'Longitude',-87.6295, ...
    'TransmitterFrequency',2.5e9);
show(tx);
rx = rxsite('Latitude',41.881352,'Longitude',-87.629771, ...
    'AntennaHeight',30);
show(rx);
```

Perform ray tracing, returning the ray object results. For the configuration defined, ray tracing returns a cell array containing one ray object. Display the ray object properties. Then, close the Site Viewer map.

```
rays = raytrace(tx,rx)
```

```
rays = 1×1 cell array
    {1×1 comm.Ray}
```

```
rays{1}
```

```
ans = 
  Ray with properties:

      PathSpecification: 'Locations'
       CoordinateSystem: 'Geographic'
    TransmitterLocation: [3×1 double]
       ReceiverLocation: [3×1 double]
            LineOfSight: 0
    ReflectionLocations: [3×1 double]
              Frequency: 2.5000e+09
         PathLossSource: 'Custom'
               PathLoss: 94.0915
             PhaseShift: 1.2939

   Read-only properties:
       PropagationDelay: 5.7088e-07
    PropagationDistance: 171.1462
       AngleOfDeparture: [2×1 double]
         AngleOfArrival: [2×1 double]
         NumReflections: 1
```

```
close(viewer);
```

You can plot the rays without performing ray tracing again. Create another Site Viewer map with the same buildings. Show the transmitter and receiver sites. Using the previously returned cell array of ray objects, plot the reflected rays between the transmitter site and the receiver site. The plot function can plot the path for one ray object at a time.

```
siteviewer('Buildings','chicago.osm');
show(tx);
show(rx);
plot(rays{1},'Type','power', ...
    'TransmitterSite',tx,'ReceiverSite',rx);
```

Appendix

[1] The osm file is downloaded from https://www.openstreetmap.org, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), https://opendatacommons.org/licenses/odbl/.

4

Object Functions

getElementPosition

Positions of the antenna array elements

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Syntax

```
pos = getElementPosition(cfg)
```

Description

`pos = getElementPosition(cfg)` returns the positions of the antenna array elements for the input BLE angle estimation configuration object. The object function uses the origin of the local coordinate system as the position of the first antenna of the antenna array.

Examples

Return Positions of Antenna Array Elements

Create a default BLE angle estimation configuration object.

```
cfg = bleAngleEstimateConfig
```

```
cfg = 
  bleAngleEstimateConfig with properties:

            ArraySize: 4
       ElementSpacing: 0.5000
         SlotDuration: 2
     SwitchingPattern: [1 2 3 4]
```

Return the positions of antenna array elements.

```
pos = getElementPosition(cfg)
```

```
pos = 3×4

         0         0         0         0
         0    0.5000    1.0000    1.5000
         0         0         0         0
```

Input Arguments

`cfg` — BLE angle estimation configuration object
`bleAngleEstimateConfig` object

BLE angle estimation configuration object, specified as a `bleAngleEstimateConfig` object.

Output Arguments

`pos` — Positions of the antenna array elements
3-by-*N* matrix

Positions of the antenna array elements, returned as a 3-by-*N* matrix, where *N* is the number of antenna array elements specified by the `cfg` input. Each column in `pos` defines the position of the antenna array element in the form [*x*; *y*; *z*] in the local coordinate system.

Data Types: `double`

getNumElements

Number of elements in antenna array

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Syntax

```
numElements = getNumElements(cfg)
```

Description

`numElements = getNumElements(cfg)` returns the number of elements in the antenna array for the input BLE angle estimation configuration object.

Examples

Return Number of Elements in Antenna Array

Create a BLE angle estimation configuration object, specifying a 2-by-3 URA.

```
cfg = bleAngleEstimateConfig('ArraySize',[2 3])
```

```
cfg = 
  bleAngleEstimateConfig with properties:

           ArraySize: [2 3]
      ElementSpacing: 0.5000
        SlotDuration: 2
    SwitchingPattern: [1 2 3 4]
```

Return the number of elements in the antenna array.

```
N = getNumElements(cfg)
```

```
N = 6
```

Input Arguments

`cfg` — BLE angle estimation configuration object
`bleAngleEstimateConfig` object

BLE angle estimation configuration object, specified as a `bleAngleEstimateConfig` object.

Output Arguments

`numElements` — Number of elements in antenna array
positive integer

Number of elements in the antenna array, returned as a positive integer. If the `SlotDuration` property of the `cfg` input is 2 µs, the value of this output is in the range [2, 38]. If the `SlotDuration` property is 1 µs, the value of this output is in the range [2, 75].

nextHop

Select Bluetooth BR/EDR channel index to hop for next frequency

Note Download Required: To use , first download Communications Toolbox™ Library for the Bluetooth® Protocol. For more information, see “Get and Manage Add-Ons”. Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

Syntax

```
[channelIndex,X] = nextHop(FH,Clock)
```

Description

`[channelIndex,X] = nextHop(FH,Clock)` selects a Bluetooth basic rate/enhanced data rate (BR/EDR) channel index, `channelIndex` to hop for next frequency. This selection is based on the Bluetooth BR/EDR frequency hopping object, `FH`, the clock, `Clock`, and the “SequenceType” on page 3-0 property of the “FH” on page 4-0 . The function also returns `X`, which is required for implementing whitening process in the physical layer (PHY).

Examples

Select Bluetooth BR/EDR Channel Index Using Default Values

Create a default Bluetooth BR/EDR channel index object for frequency hopping.

```
fh = bluetoothFrequencyHop
```

```
fh = 
  bluetoothFrequencyHop with properties:

      DeviceAddress: '9E8B33'
       SequenceType: 'Inquiry'
    InterlaceOffset: 16
             KNudge: 0
            KOffset: 24
            Counter: 0
       UsedChannels: [1x79 double]
```

Specify a clock value.

```
inputClock = '12C'; % 28-bit
```

Select a Bluetooth BR/EDR channel index to hop for the next frequency.

```
[channelIndex, X] = nextHop(fh,inputClock)
```

```
channelIndex = 41
```

```
X = 30
```

Input Arguments

FH — Bluetooth BR/EDR channel index for frequency hopping

bluetoothFrequencyHop object

Bluetooth BR/EDR channel index for frequency hopping, specified as a `bluetoothFrequencyHop` object.

`Clock` — Clock

character vector in hexadecimal format | string scalar in hexadecimal format | numeric scalar in the range [0, 2^{28}–1]

Clock, specified as one of these values:

- Character vector — This vector represents the `Clock` in hexadecimal format
- String scalar — This scalar represents the `Clock` in hexadecimal format
- Numeric scalar — This scalar represent the `Clock` in the range [0, 2^{28}–1]

This argument is a 28-bit value that computes the inputs to the hop selection kernel. This table shows the dependency of the `Clock` argument on the value of the `SequenceType` property of the `FH` input.

Value of SequenceType Property	`Clock` Input
`'Connection basic'` or `'Connection adaptive'`	Indicates native clock of the Master
`'Page'` or `'Inquiry'`	Indicates native clock of the Slave
`'Page scan'` or `'Inquiry scan'`	Indicates the estimated value of the clock for the Slave
`'Slave page response'`	Indicates the value when the access code of the recipient is detected
`'Master page response'`	Indicates the value that triggered a response from the paged device

Data Types: `char` | `string` | `double`

Output Arguments

`channelIndex` — Channel index

integer in the range [0, 78]

Channel index, returned as an integer in the range [0, 78].

Data Types: `double`

X — Control signal to be used in whitening process

nonnegative integer

Control signal to be used in whitening process, returned as a nonnegative integer.

Data Types: `double`

write

Write BLE LL protocol packet data to PCAP or PCAPNG file

Syntax

```
write(pcapObj,packet,timestamp)
write(pcapObj,packet,timestamp,Name,Value)
```

Description

`write(pcapObj,packet,timestamp)` writes Bluetooth low energy (BLE) link layer (link layer) protocol packet data to the PCAP or PCAPNG file specified in the BLE PCAP file writer object, `pcapObj`. Input `packet` specifies the BLE LL protocol packet, and input `timestamp` specifies the packet arrival time.

`write(pcapObj,packet,timestamp,Name,Value)` specifies options using one or more name-value pair arguments. For example, `'PacketFormat','bits'` sets the format of the BLE LL protocol packets to bits.

Examples

Write BLE LL Packet to PCAP File

Create a default BLE PCAP file writer object.

```
pcapObj = blePCAPWriter;
```

Generate a BLE LL packet.

```
cfgLLData = bleLLDataChannelPDUConfig('LLID', ...
    'Data (start fragment/complete)');
payload = '0E00050014010A001F004000170017000000';
llDataPDU = bleLLDataChannelPDU(cfgLLData, payload);
connAccessAddress = de2bi(hex2dec('E213BC42'), 32)';
llpacket = [connAccessAddress; llDataPDU];
```

Write the BLE LL packet to the PCAP file.

```
timestamp = 0; % Number of microseconds
write(pcapObj,llpacket,timestamp,'PacketFormat','bits');
```

Use BLE PCAP Writer to Write BLE LL Packet to PCAPNG File

Create a BLE PCAPNG file writer object, specifying the name and extension of the PCAPNG file.

```
pcapObj = blePCAPWriter('FileName','sampleBLELL', ...
    'FileExtension','pcapng');
```

Generate a BLE LL packet.

```
cfgLLData = bleLLDataChannelPDUConfig('LLID', ...
    'Data (start fragment/complete)');
payload = '0E00050014010A001F004000170017000000';
llDataPDU = bleLLDataChannelPDU(cfgLLData,payload);
connAccessAddress = de2bi(hex2dec('E213BC42'),32)';
llpacket = [connAccessAddress; llDataPDU];
```

Write the BLE LL packet to the PCAPNG file.

```
timestamp = 12800000; % Number of microseconds
write(pcapObj,llpacket,timestamp,'PacketFormat','bits');
```

Input Arguments

Note The `blePCAPWriter` object does not overwrite the existing PCAP or PCAPNG file. During each call of this object, specify a unique PCAP or PCAPNG file name.

`pcapObj` — BLE PCAP file writer object

`blePCAPWriter` object

BLE PCAP file writer object, specified as a `blePCAPWriter` object.

`packet` — BLE LL protocol packet

binary-valued vector | character vector | string scalar | numeric vector | *n*-by-2 character array

BLE LL protocol packet, specified as one of these values.

- Binary-valued vector – This value represents bits.
- Character vector – This value represents octets in hexadecimal format.
- String scalar – This value represents octets in hexadecimal format.
- Numeric vector with each element in the range [0, 255] – This value represents octets in decimal format.
- *n*-by-2 character array – In this value, each row represents an octet in hexadecimal format.

Data Types: `char` | `string` | `double`

`timestamp` — Packet arrival time

nonnegative integer

Packet arrival time since 1/1/1970, specified as a nonnegative integer. This value must be expressed in microseconds.

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: 'PacketFormat','bits' sets the format of the BLE LL protocol packets to bits.

PhyHeader — BLE LL protocol packet metadata
binary-valued vector | character vector | string scalar | numeric vector | *n*-by-2 character array

BLE LL protocol packet metadata, specified as the comma-separated pair consisting of PhyHeader and one of these values.

- Binary-valued vector – This value represents bits.
- Character vector – This value represents octets in hexadecimal format.
- String scalar – This value represents octets in hexadecimal format.
- Numeric vector with each element in the range [0, 255] – This value represents octets in decimal format.
- *n*-by-2 character array – In this value, each row represents an octet in hexadecimal format.

Data Types: char | string | double

PacketComment — Comment for the BLE LL protocol packet
'' (default) | character vector | string scalar

Comment for the BLE LL protocol packet, specified as the comma-separated pair consisting of PacketComment and a character vector or a string scalar.

Data Types: char | string

PacketFormat — Format of the BLE LL protocol packet
'octets' (default) | 'bits'

Format of the BLE LL protocol packet, specified as the comma-separated pair consisting of PacketFormat and 'octets' or 'bits'. If this value is specified as 'octets', packet is specified as one of these values.

- Binary-valued vector – This value represents bits.
- Character vector – This value represents octets in hexadecimal format.
- String scalar – This value represents octets in hexadecimal format.
- Numeric vector with each element in the range [0, 255] – This value represents octets in decimal format.
- *n*-by-2 character array – In this value, each row represents an octet in hexadecimal format.

Data Types: char | string | double

PhyHeaderFormat — Format of the PHY header
'octets' (default) | 'bits'

Format of the physical layer (PHY) header, specified as the comma-separated pair consisting of PhyHeaderFormat and 'octets' or 'bits'. If this value is specified as 'octets', PhyHeader can be specified as one of these values.

- Binary-valued vector – This value represents bits.
- Character vector – This value represents octets in hexadecimal format.
- String scalar – This value represents octets in hexadecimal format.

- Numeric vector with each element in the range [0, 255] – This value represents octets in decimal format.
- *n*-by-2 character array – In this value, each row represents an octet in hexadecimal format

Data Types: `char` | `string` | `double`

Objects
`blePCAPWriter`

Introduced in R2020b

write

Write protocol packet data to PCAP or PCAPNG file

Syntax

```
write(pcapObj,packet,timestamp)
write(pcapngObj,packet,timestamp,interfaceID)
write( ___ ,Name,Value)
```

Description

`write(pcapObj,packet,timestamp)` writes the protocol packet data to the PCAP file specified in the PCAP file writer object, `pcapObj`. Input `packet` specifies the protocol packet and input `timestamp` specifies the packet arrival time.

`write(pcapngObj,packet,timestamp,interfaceID)` writes protocol packet data to a PCAPNG file specified in the PCAPNG file writer object, `pcapngObj`. Input `packet`, `timestamp`, and `interfaceID` specifies the protocol packet, packet arrival time, and interface identifier, respectively.

`write( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input argument combinations from any of the previous syntaxes. For example, `'PacketFormat','bits'` sets the format of the protocol packets to bits.

Examples

Write BLE Packet Data to PCAP File

Create a PCAP file writer object, specifying the name of the PCAP file. Specify the Bluetooth low energy (BLE) link type.

```
pcapObj = pcapWriter('FileName','writeBLEpacket');
bleLinkType = 251;
```

Write a global header to the PCAP file.

```
writeGlobalHeader(pcapObj,bleLinkType);
```

Specify the BLE link layer (LL) packet.

```
llpacket = '42BC13E206120E00050014010A001F004000170017000007D47C0';
```

Write BLE LL packet to the PCAP file.

```
timestamp = 129100; % Number of microseconds
write(pcapObj,llpacket,timestamp);
```

Write BLE Packet Data to PCAPNG File

Create a PCAPNG file writer object, specifying the name of the PCAPNG file.

```
pcapngObj = pcapngWriter('FileName','writeBLEpacket');
```

Write an interface description block for BLE.

```
interfaceName = 'BLE interface';
bleLinkType = 251;
interfaceId = writeInterfaceDescriptionBlock(pcapngObj,bleLinkType, ...
    interfaceName);
```

Specify the BLE LL packet.

```
llpacket = '42BC13E206120E00050014010A001F004000170017000007D47C0';
```

Write BLE LL packet to the PCAPNG format file.

```
timestamp = 0; % Number of microseconds
packetComment = 'This is BLE packet';
write(pcapngObj, llpacket,timestamp,interfaceId,'PacketComment', ...
    packetComment);
```

Input Arguments

Note The `pcapWriter` and `pcapngWriter` objects do not overwrite the existing PCAP or PCAPNG files, respectively. During each call of these objects, specify a unique PCAP or PCAPNG file name.

`pcapObj` — PCAP file writer object

`pcapWriter` object

PCAP file writer object, specified as a `pcapWriter` object.

`packet` — Protocol packet

binary-valued vector | character vector | string scalar | numeric vector | *n*-by-2 character array

Protocol packet, specified as one of these values.

- Binary-valued vector – This value represents bits.
- Character vector – This value represents octets in hexadecimal format.
- String scalar – This value represents octets in hexadecimal format.
- Numeric vector with each element in the range [0, 255] – This value represents octets in decimal format.
- *n*-by-2 character array – In this value, each row represents an octet in hexadecimal format .

Data Types: `char` | `string` | `double`

`timestamp` — Packet arrival time

nonnegative integer

Packet arrival time since 1/1/1970, specified as a nonnegative integer. This value must be expressed in microseconds.

Data Types: `double`

`pcapngObj` — PCAPNG file writer object
`pcapngWriter` object

PCAPNG file writer object, specified as a `pcapngWriter` object.

`interfaceID` — Unique identifier for an interface
nonnegative scalar

Unique identifier for an interface, specified as a nonnegative scalar.

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'PacketFormat','bits'` sets the format of the protocol packets to bits.

`PacketFormat` — Format of the protocol packet
`'octets'` (default) | `'bits'`

Format of the protocol packet, specified as the comma-separated pair consisting of `PacketFormat` and `'octets'` or `'bits'`. If this value is specified as `'octets'`, `packet` is specified as one of these values.

- Binary-valued vector – This value represents bits.
- Character vector – This value represents octets in hexadecimal format.
- String scalar – This value represents octets in hexadecimal format.
- Numeric vector with each element in the range [0, 255] – This value represents octets in decimal format.
- *n*-by-2 character array – In this value, each row represents an octet in hexadecimal format .

Data Types: `char` | `string` | `double`

`PacketComment` — Comment for protocol packet
`''` (default) | character vector | string scalar

Comment for the protocol packet, specified as the comma-separated pair consisting of `PacketComment` and a character vector or a string scalar.

Dependencies

To enable this name-value pair argument, specify the `pcapngObj` input argument.

Data Types: `char` | `string`

Functions

`writeCustomBlock` | `writeGlobalHeader` | `writeInterfaceDescriptionBlock`

Objects

`pcapWriter` | `pcapngWriter`

Introduced in R2020b

writeCustomBlock

Write custom block to PCAPNG file

Syntax

```
writeCustomBlock(pcapngObj,customData)
```

Description

`writeCustomBlock(pcapngObj,customData)` writes the custom block data, `customData`, to a PCAPNG file specified in the PCAPNG file writer object.

Examples

Write BLE User-Defined Custom Block to PCAPNG File

Create a PCAPNG file writer object, specifying the name of the PCAPNG file.

```
pcapngObj = pcapngWriter('FileName','writeBLEcustomdata');
```

Write the interface description block for Bluetooth low energy (BLE).

```
interfaceName = 'BLE interface';
bleLinkType = 251;
interfaceId = writeInterfaceDescriptionBlock(pcapngObj,bleLinkType, ...
    interfaceName);
```

Write the custom block to specify user-defined data.

```
writeCustomBlock(pcapngObj,"This block writes user-defined data");
```

Input Arguments

Note The `pcapngWriter` object does not overwrite the existing PCAPNG file. During each call of this object, specify a unique PCAPNG file name.

pcapngObj — PCAPNG file writer object

`pcapngWriter` object

PCAPNG file writer object, specified as a `pcapngWriter` object.

customData — User-defined data

character vector | string scalar

User-defined data, specified as a character vector or a string scalar.

Data Types: `char` | `string`

Objects

`pcapWriter` | `pcapngWriter`

Introduced in R2020b

writeGlobalHeader

Write global header to PCAP file

Syntax

```
writeGlobalHeader(pcapObj,linkType)
```

Description

`writeGlobalHeader(pcapObj,linkType)` writes a global header to the PCAP file specified in the PCAP file writer object, `pcapObj`. Input `linkType` specifies the unique identifier for a protocol.

Examples

Write BLE Packet Global Header to PCAP File

Create a PCAP file writer object, specifying the name of the PCAP file.

```
pcapObj = pcapWriter('FileName','writeBLEheader');
```

Specify the Bluetooth low energy (BLE) link type.

```
bleLinkType = 251;
```

Write a global header to the PCAP file.

```
writeGlobalHeader(pcapObj,bleLinkType);
```

Input Arguments

Note The `pcapWriter` object does not overwrite the existing PCAP file. During each call of this object, specify a unique PCAP file name.

`pcapObj` — PCAP file writer object

`pcapWriter` object

PCAP file writer object, specified as a `pcapWriter` object.

`linkType` — Unique identifier for a protocol

integer in the range [0, 65,535].

Unique identifier for a protocol, specified as an integer in the range [0, 65535].

Data Types: `double`

writeInterfaceDescriptionBlock

Write interface description block to PCAPNG file

Syntax

```
interfaceID = writeInterfaceDescriptionBlock(pcapngObj,linkType,interface)
```

Description

`interfaceID = writeInterfaceDescriptionBlock(pcapngObj,linkType,interface)` writes an interface description block to the PCAPNG file specified in the PCAPNG file writer object, `pcapngObj`. Input `linkType` specifies the unique identifier for the protocol and input `interface` specifies the interface on which the protocol packets are captured. This object function returns the unique identifier for the interface.

Examples

Write BLE Interface Description Block to PCAPNG File

Create a PCAPNG file writer object, specifying the name of the PCAPNG file.

```
pcapngObj = pcapngWriter('FileName','writeBLEinterface');
```

Write the interface description block for BLE.

```
interfaceName = 'BLE interface';
bleLinkType = 251;
interfaceId = writeInterfaceDescriptionBlock(pcapngObj,bleLinkType, ...
    interfaceName);
```

Input Arguments

Note The `pcapngWriter` object does not overwrite the existing PCAPNG file. During each call of this object, specify a unique PCAPNG file name.

`pcapngObj` — PCAPNG file writer object

`pcapngWriter` object

PCAPNG file writer object, specified as a `pcapngWriter` object.

`linkType` — Unique identifier for protocol

integer in the range [0, 65,535].

Unique identifier for a protocol, specified as an integer in the range [0, 65,535].

Data Types: `double`

`interface` — Name of the interface on which protocol packets are captured
character vector | string scalar

Name of the interface on which protocol packets are captured, specified as a character vector or a string scalar in 8-bit unicode transformation format (UTF-8) format.

Data Types: `char` | `string`

Output Arguments

`interfaceID` — Unique identifier for an interface
nonnegative scalar

Unique identifier for an interface, specified as a nonnegative scalar.

Data Types: `double`

coeffs

Package: `comm`

Coefficients for filters

Syntax

```
coefInfo = coeffs(rcfilter)
coefInfo = coeffs(rcfilter,'Arithmetic',arithType)
```

Description

`coefInfo = coeffs(rcfilter)` obtain the coefficients for the specified filter System object.

`coefInfo = coeffs(rcfilter,'Arithmetic',arithType)` analyzes the filter System object based on the arithmetic specified in `arithType`.

Examples

Obtain Coefficients of Raised Cosine Filters

Create a receive raised cosine filter and obtain its numerator coefficients.

```
rxfilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',25);
srx = coeffs(rxfilter)
```

```
srx = struct with fields:
    Numerator: [1x201 double]
```

Calculate the expected number of numerator coefficients and confirm the value equals the length of `srx.Numerator`.

```
numcoefs = rxfilter.FilterSpanInSymbols * rxfilter.InputSamplesPerSymbol + 1
```

```
numcoefs = 201
```

```
isequal (numcoefs,length(srx.Numerator))
```

```
ans = logical
   1
```

Display the first ten coefficients.

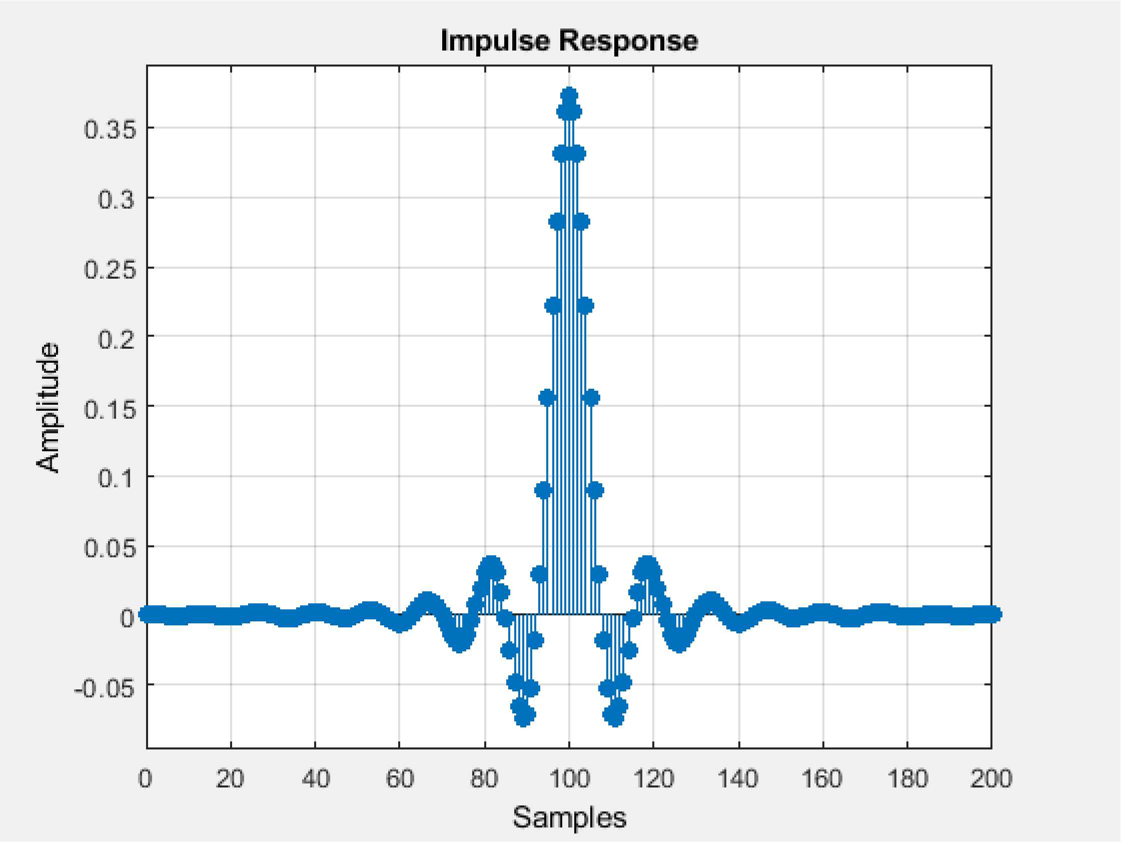
```
srx.Numerator(1:10)
```

```
ans = 1×10
10^-3 ×

    0.9094    0.8559    0.6136    0.2320   -0.2074   -0.6071   -0.8759   -0.9486   -0.8021   -0.4
```

Display the impulse response of the receive raised cosine filter.

```
fvtool(rxfilter,'impulse')
```



Create a transmit raised cosine filter and obtain its numerator coefficients.

```
txfilter = comm.RaisedCosineTransmitFilter('RolloffFactor',0.5);
stx = coeffs(txfilter);
```

Display the first ten filter coefficients.

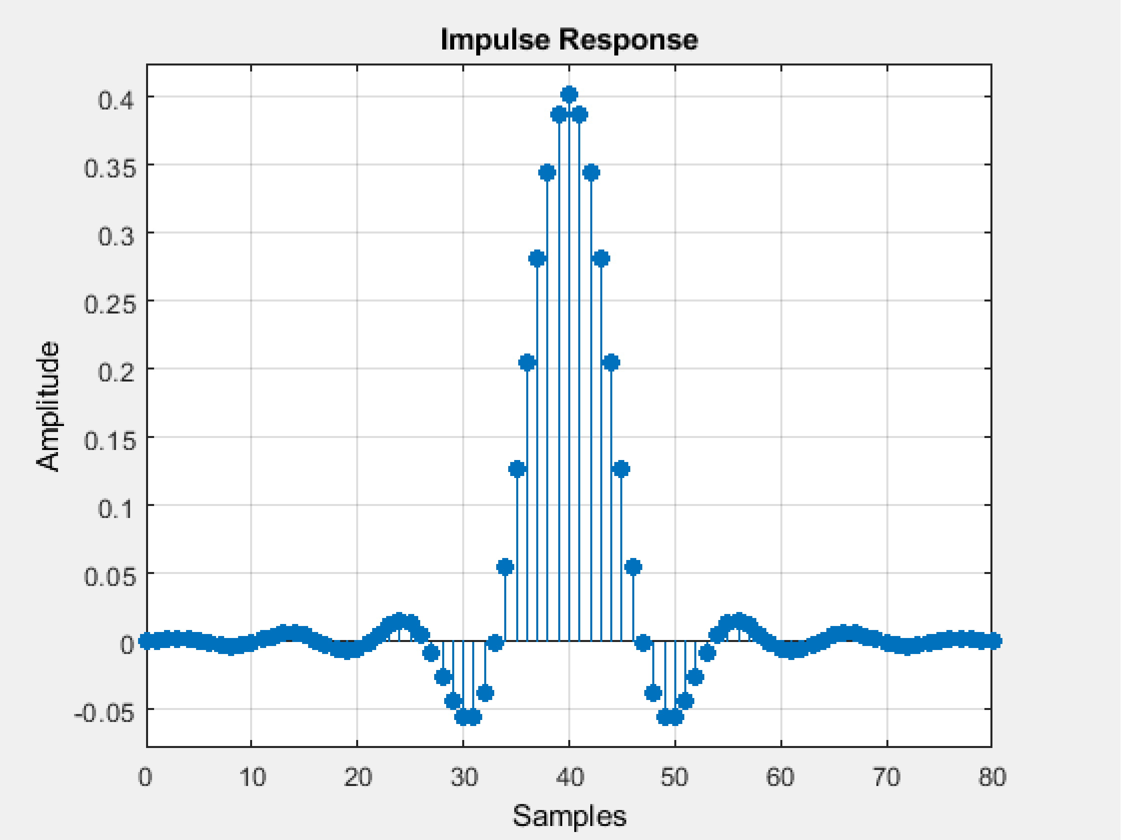
```
stx.Numerator(1:10)
```

```
ans = 1×10

   -0.0002    0.0011    0.0021    0.0024    0.0018    0.0004   -0.0014   -0.0029   -0.0036   -0.0
```

Display the impulse response of the transmit raised cosine filter.

```
fvtool(txfilter,'impulse')
```



Input Arguments

`rcfilter` — Input filter

`comm.RaisedCosineReceiveFilter` System object | `comm.RaisedCosineTransmitFilter` System object

Input filter, specified as one of these of filter System objects.

- `comm.RaisedCosineReceiveFilter`
- `comm.RaisedCosineTransmitFilter`

`arithType` — Arithmetic type

`'double'` (default) | `'single'` | `'Fixed'`

Specify the arithmetic used in the analysis. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The `'Arithmetic'` input argument specified as `'Fixed'` applies only to filter System objects with fixed-point properties.

When the `'Arithmetic'` input argument is specified as `'Fixed'` and the filter object has coefficients data type set to `'Same word length as input'`, the arithmetic analysis depends on whether the System object is:

- unlocked –– The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.
- locked –– When the input data type is 'double' or 'single', the analysis object function cannot determine the coefficients data type. The function assumes that the coefficient data type is signed, has 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the isLocked function.

When the arithmetic input is specified as 'Fixed' and the filter object has coefficients data type set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

Output Arguments

coefInfo — Filter coefficient info
structure

Filter coefficient info, returned as a structure containing the filter coefficients in the Numerator field. When the filter uses fixed-point arithmetic, the function returns additional information about the filter. This information includes the arithmetic setting and details about the filter internals.

info

Package: comm

Information about filter System object

Syntax

```
filtInfo = info(rcfilter)
filtInfo = info(rcfilter,infoType)
filtInfo = info(___,'Arithmetic',arithType)
```

Description

`filtInfo = info(rcfilter)` obtains information about the specified filter System object. The type of information returned by the function depends on the filter type and configuration.

`filtInfo = info(rcfilter,infoType)` obtains the amount of filter information as specified by `infoType`.

`filtInfo = info(___,'Arithmetic',arithType)` analyzes the filter System object based on the arithmetic specified in `arithType`. Specify this option with any of the input combinations from previous syntaxes.

For more input options, see `info` in Signal Processing Toolbox™.

Examples

Obtain Raised Cosine Filter Information

Obtain short-format and long-format information about a raised cosine filter.

```
txfilter = comm.RaisedCosineTransmitFilter;
info(txfilter)
```

```
ans = 10x62 char array
    'Discrete-Time FIR Multirate Filter (real)                     '
    '-----------------------------------------                     '
    'Filter Structure      : Direct-Form FIR Polyphase Interpolator'
    'Interpolation Factor  : 8                                     '
    'Polyphase Length      : 11                                    '
    'Filter Length         : 81                                    '
    'Stable                : Yes                                   '
    'Linear Phase          : Yes (Type 1)                          '
    '                                                              '
    'Arithmetic            : double                                '
```

```
info(txfilter,'long')
```

```
ans = 17x62 char array
    'Discrete-Time FIR Multirate Filter (real)                     '
```

```
'----------------------------------------                      '

'Number of Multipliers            : 81                         '
'Number of Adders                 : 73                         '
'Number of States                 : 10                         '
'Multiplications per Input Sample : 81                         '
'Additions per Input Sample       : 73                         '
```

Input Arguments

`rcfilter` — Input filter
`comm.RaisedCosineReceiveFilter` System object | `comm.RaisedCosineTransmitFilter` System object

Input filter, specified as one of these of filter System objects.

- `comm.RaisedCosineReceiveFilter`
- `comm.RaisedCosineTransmitFilter`

`infoType` — Amount of information to display
`'short'` (default) | `'long'`

Amount of filter information to display, specified as one of these values.

- `'short'` –– The function displays the basic filter information. This information is the same as the information output by `info(rcfilter)`.
- `'long'` –– The function returns this information about the filter.
  - Specifications such as the filter structure and filter order.
  - Information about the design method and options.
  - Performance measurements, such as the passband cutoff or stopband attenuation, for the filter response.
  - Cost of implementing the filter in terms of operations required to apply the filter to data.

  When the filter uses fixed-point arithmetic, the function returns additional information about the filter. This information includes the arithmetic setting and details about the filter internals.

Data Types: `char` | `string`

`arithType` — Arithmetic type
`'double'` (default) | `'single'` | `'Fixed'`

Specify the arithmetic used in the analysis. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The `'Arithmetic'` input argument specified as `'Fixed'` applies only to filter System objects with fixed-point properties.

When the `'Arithmetic'` input argument is specified as `'Fixed'` and the filter object has coefficients data type set to `'Same word length as input'`, the arithmetic analysis depends on whether the System object is:

- `unlocked` –– The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.
- `locked` –– When the input data type is `'double'` or `'single'`, the analysis object function cannot determine the coefficients data type. The function assumes that the coefficient data type is signed, has 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as `'Fixed'` and the filter object has coefficients data type set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

Output Arguments

`filtInfo` — Filter information
character array

Filter information, returned as a character array.

- When you set the `infoType` input to `'short'`, the function displays basic filter information.
- When you set the `infoType` input to `'long'`, the function displays this.
  - Specifications such as the filter structure and filter order.
  - Information about the design method and options.
  - Performance measurements, such as the passband cutoff or stopband attenuation, for the filter response.
  - Cost of implementing the filter in terms of operations required to apply the filter to data.

When the filter uses fixed-point arithmetic, the function returns additional information about the filter. The information includes the arithmetic setting and details about the filter internals.

Topics

"Analysis Methods for Filter System Objects"

Introduced in R2013b

hide

Package: `comm`

Hide scope window

Syntax

```
hide(scope)
```

Description

`hide(scope)` hides the window of the System object scope.

Examples

Hide and Show Scope

Create a `comm.ConstellationDiagram` object.

```
scope = comm.ConstellationDiagram;
```

Hide the constellation diagram scope window.

```
if(isVisible(scope))
    hide(scope)
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))
    show(scope)
end
```

Hide the constellation diagram scope window again.

```
if(isVisible(scope))
    hide(scope)
end
```

Hide and Show Constellation Diagram

Generate a 16-QAM reference constellation and a signal to display.

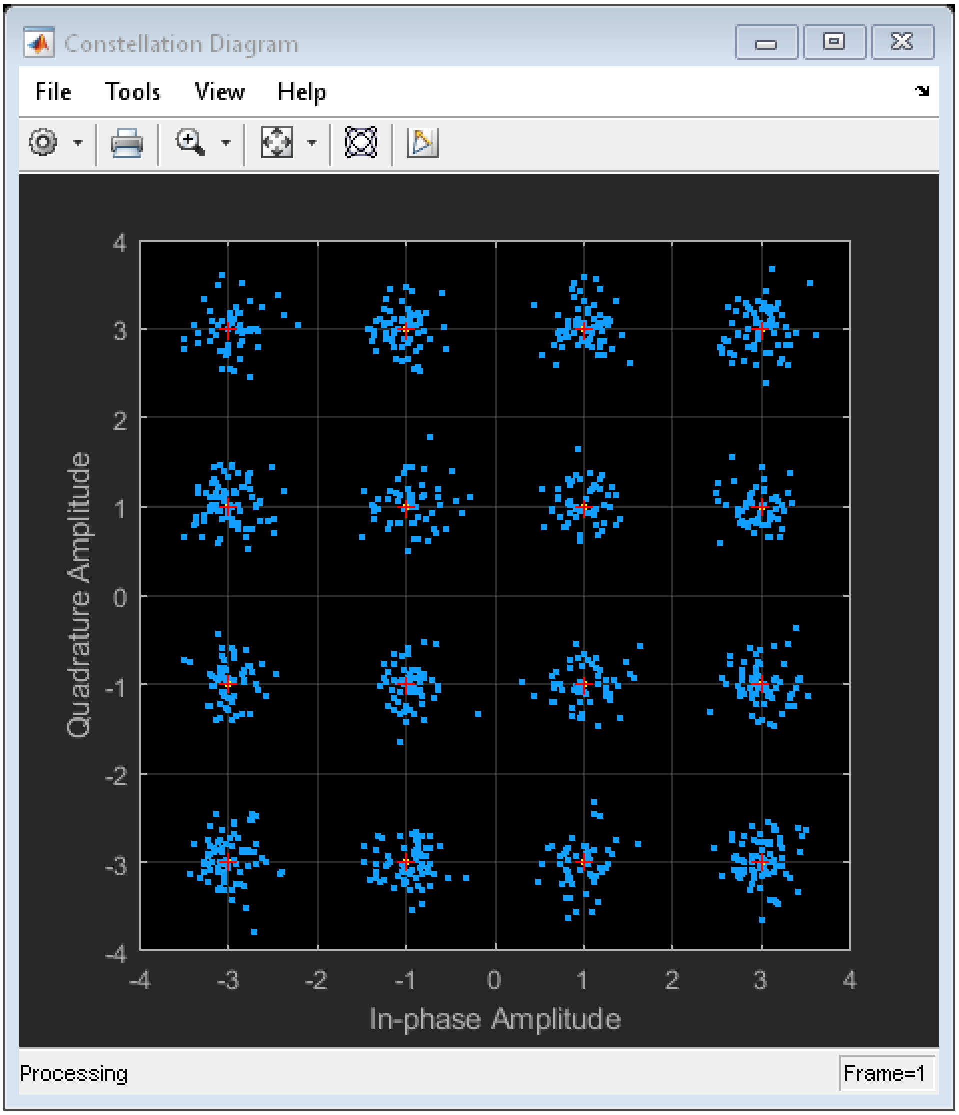
```
M = 16;
xRef = (0:M-1)';
refConst = qammod(xRef,M);
signal = randi([0 M-1],1000,1);
```

Create a constellation diagram System object™, specifying the constellation reference points and axes limits using name-value pairs.

```
scope = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
    'XLimits',[-4 4],'YLimits',[-4 4]);
```

Modulate the random data signal using QAM. Add Gaussian white noise to the QAM symbols. Display the QAM symbols and noisy symbols with the constellation diagram object.

```
sym = qammod(signal,M);
rcv = awgn(sym,20,'measured');
scope([sym rcv]);
```

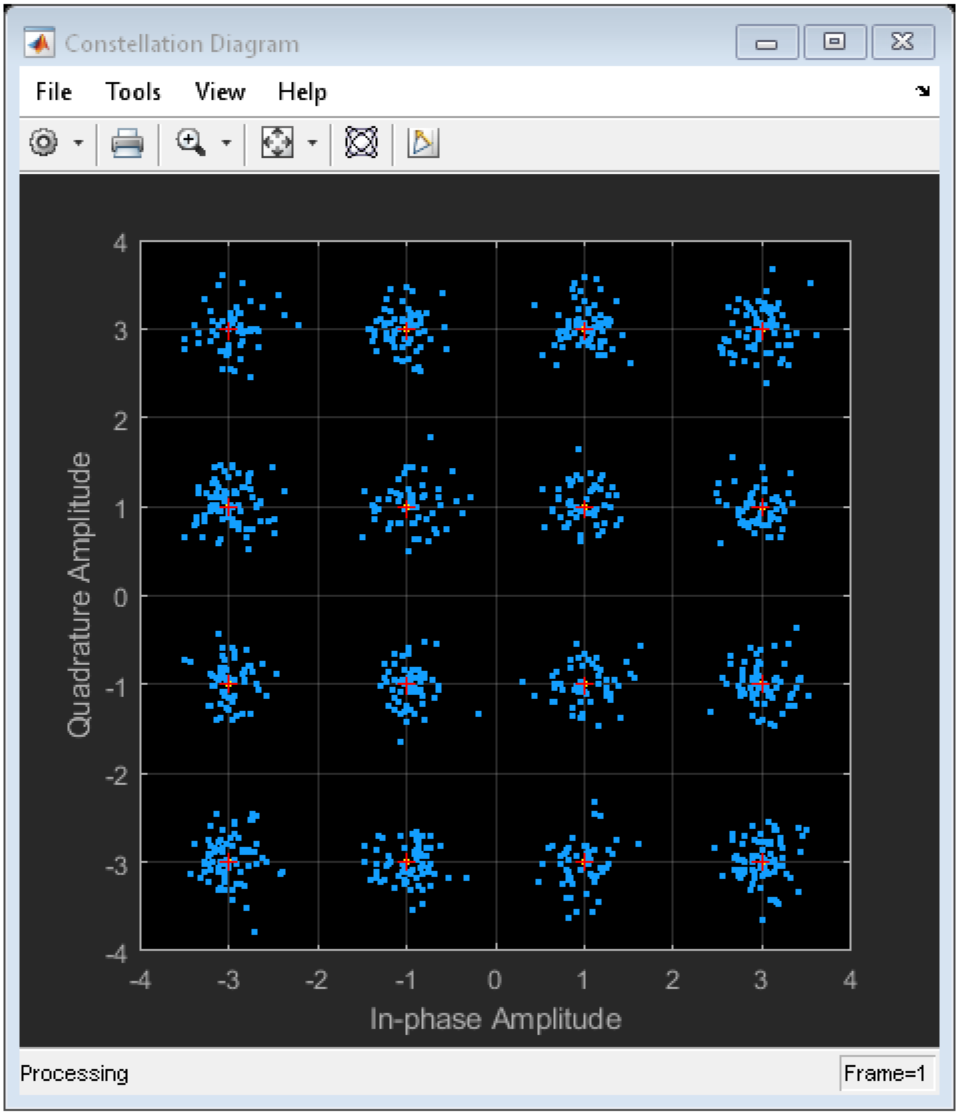


Hide the constellation diagram scope window.

```
if(isVisible(scope))
    hide(scope)
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))
    show(scope)
end
```



Clear the workspace variables.

```
clear scope sym rcv M refConst signal xRef
```

Input Arguments

scope — Scope System object

scope System object

Scope System object, specified as a `comm.ConstellationDiagram` System object.

Example: `scope = comm.ConstellationDiagram;`

See Also

Functions

`isVisible` | `show`

Objects

`comm.ConstellationDiagram`

Introduced in R2013a

isVisible

Package: comm

Determine visibility of scope window

Syntax

```
visibility = isVisible(scope)
```

Description

visibility = isVisible(scope) returns a logical to verify in the System object scope is open. visibility is 1 if the scope window is open and 0 otherwise.

Examples

Hide and Show Scope

Create a comm.ConstellationDiagram object.

```
scope = comm.ConstellationDiagram;
```

Hide the constellation diagram scope window.

```
if(isVisible(scope))
    hide(scope)
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))
    show(scope)
end
```

Hide the constellation diagram scope window again.

```
if(isVisible(scope))
    hide(scope)
end
```

Hide and Show Constellation Diagram

Generate a 16-QAM reference constellation and a signal to display.

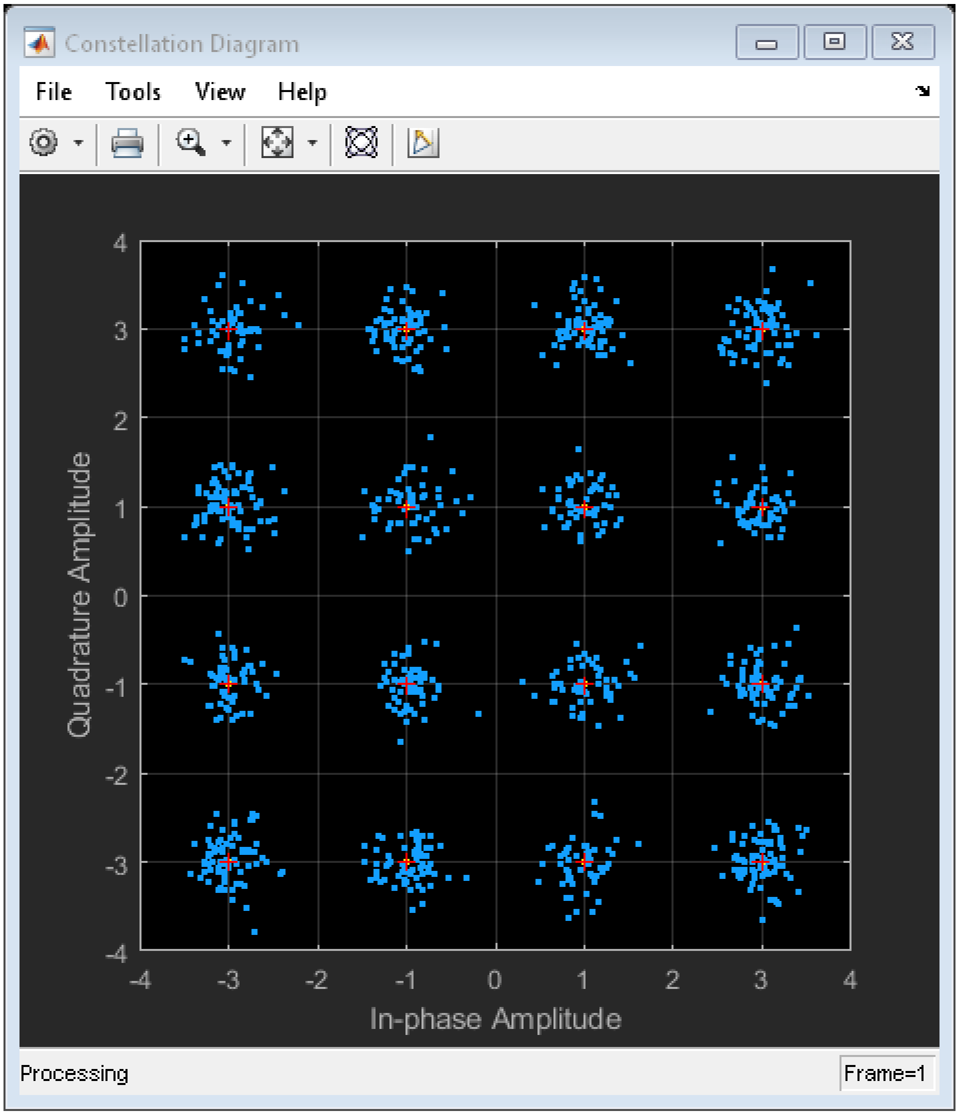
```
M = 16;
xRef = (0:M-1)';
refConst = qammod(xRef,M);
signal = randi([0 M-1],1000,1);
```

Create a constellation diagram System object™, specifying the constellation reference points and axes limits using name-value pairs.

```
scope = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
    'XLimits',[-4 4],'YLimits',[-4 4]);
```

Modulate the random data signal using QAM. Add Gaussian white noise to the QAM symbols. Display the QAM symbols and noisy symbols with the constellation diagram object.

```
sym = qammod(signal,M);
rcv = awgn(sym,20,'measured');
scope([sym rcv]);
```

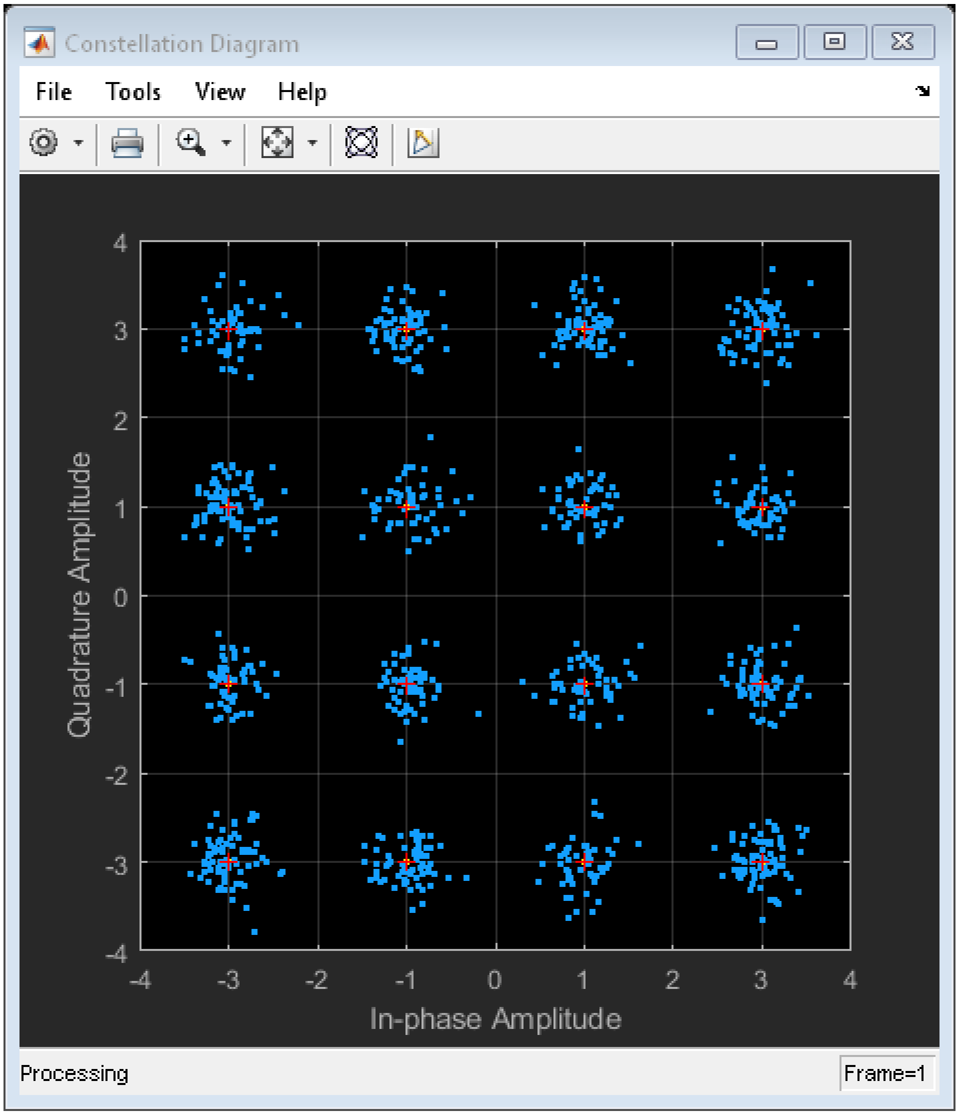


Hide the constellation diagram scope window.

```
if(isVisible(scope))
    hide(scope)
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))
    show(scope)
end
```



Clear the workspace variables.

```
clear scope sym rcv M refConst signal xRef
```

Input Arguments

scope — Scope System object

scope System object

Scope System object, specified as a `comm.ConstellationDiagram` or `comm.EyeDiagram` System object.

Example: `scope = comm.ConstellationDiagram;`

See Also

Functions
`hide` | `show`

Objects
`comm.ConstellationDiagram` | `comm.EyeDiagram`

order

Package: `comm`

Order of discrete-time filter System object

Syntax

```
filtOrder = order(rcfilter)
```

Description

`filtOrder = order(rcfilter)` returns the order of the filter System object. The order depends on the filter structure and the reference double-precision floating-point coefficients.

Examples

Determine Group Delay for RRC Filter Pair

Create a square root raised cosine (RRC) filter pair using the `comm.RaisedCosineTransmitFilter` and `comm.RaisedCosineReceiveFilter` System objects. Determine the group delay of the overall filter pair.

```
txrcfilt = comm.RaisedCosineTransmitFilter
```

```
txrcfilt = 
  comm.RaisedCosineTransmitFilter with properties:

                     Shape: 'Square root'
             RolloffFactor: 0.2000
       FilterSpanInSymbols: 10
    OutputSamplesPerSymbol: 8
                      Gain: 1
```

```
rxrcfilt = comm.RaisedCosineReceiveFilter
```

```
rxrcfilt = 
  comm.RaisedCosineReceiveFilter with properties:

                    Shape: 'Square root'
            RolloffFactor: 0.2000
      FilterSpanInSymbols: 10
    InputSamplesPerSymbol: 8
         DecimationFactor: 8
         DecimationOffset: 0
                     Gain: 1
```

```
groupDelay = order(txrcfilt)/2 + order(rxrcfilt)/2
```

```
groupDelay = 80
```

Input Arguments

`rcfilter` — Input filter

`comm.RaisedCosineReceiveFilter` System object | `comm.RaisedCosineTransmitFilter` System object

Input filter, specified as one of these of filter System objects.

- `comm.RaisedCosineReceiveFilter`
- `comm.RaisedCosineTransmitFilter`

Output Arguments

`filtOrder` — Filter order

scalar

Filter order, returned as a scalar. The order depends on the filter structure and the reference double-precision floating-point coefficients.

Data Types: `double`

show

Package: `comm`

Show scope window

Syntax

```
show(scope)
```

Description

`show(scope)` shows the window of the System object scope.

Examples

Hide and Show Scope

Create a `comm.ConstellationDiagram` object.

```
scope = comm.ConstellationDiagram;
```

Hide the constellation diagram scope window.

```
if(isVisible(scope))
    hide(scope)
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))
    show(scope)
end
```

Hide the constellation diagram scope window again.

```
if(isVisible(scope))
    hide(scope)
end
```

Hide and Show Constellation Diagram

Generate a 16-QAM reference constellation and a signal to display.

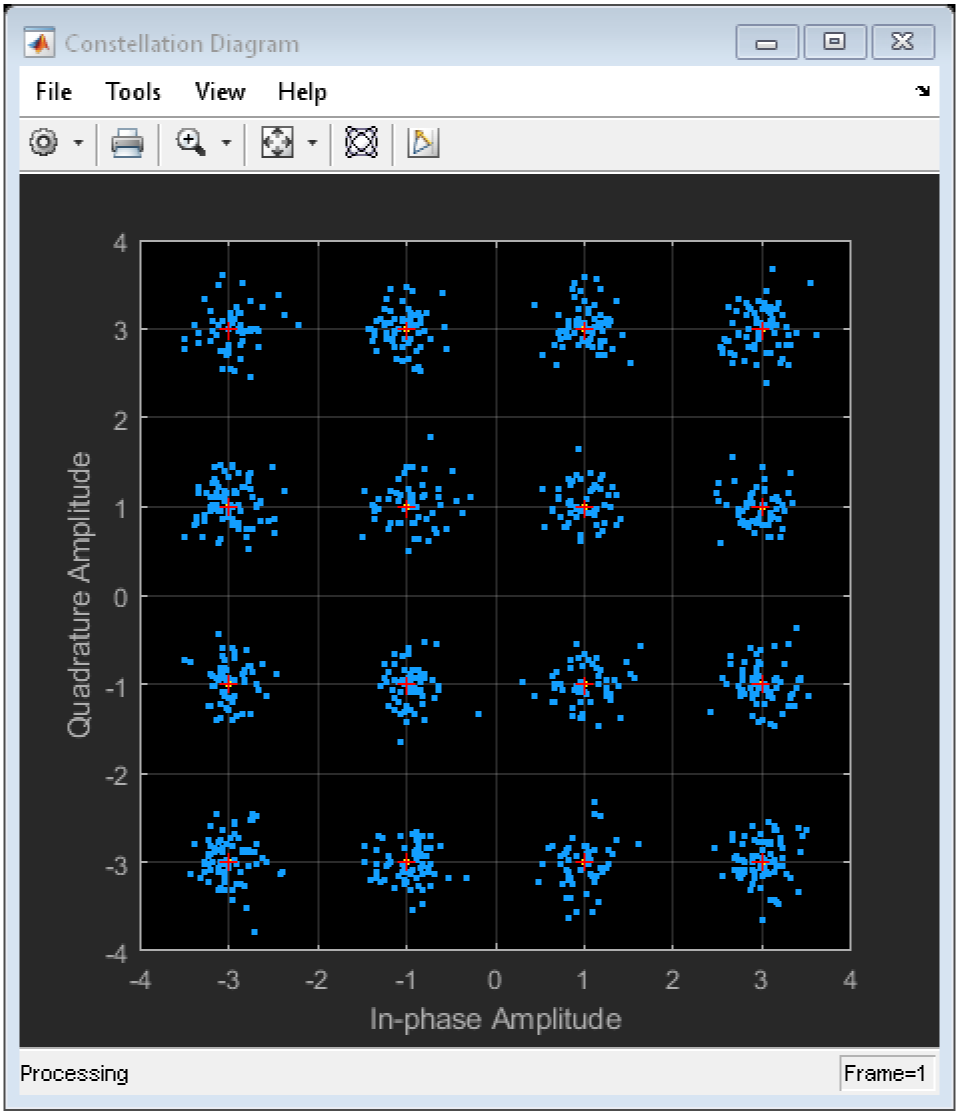
```
M = 16;
xRef = (0:M-1)';
refConst = qammod(xRef,M);
signal = randi([0 M-1],1000,1);
```

Create a constellation diagram System object™, specifying the constellation reference points and axes limits using name-value pairs.

```
scope = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
    'XLimits',[-4 4],'YLimits',[-4 4]);
```

Modulate the random data signal using QAM. Add Gaussian white noise to the QAM symbols. Display the QAM symbols and noisy symbols with the constellation diagram object.

```
sym = qammod(signal,M);
rcv = awgn(sym,20,'measured');
scope([sym rcv]);
```

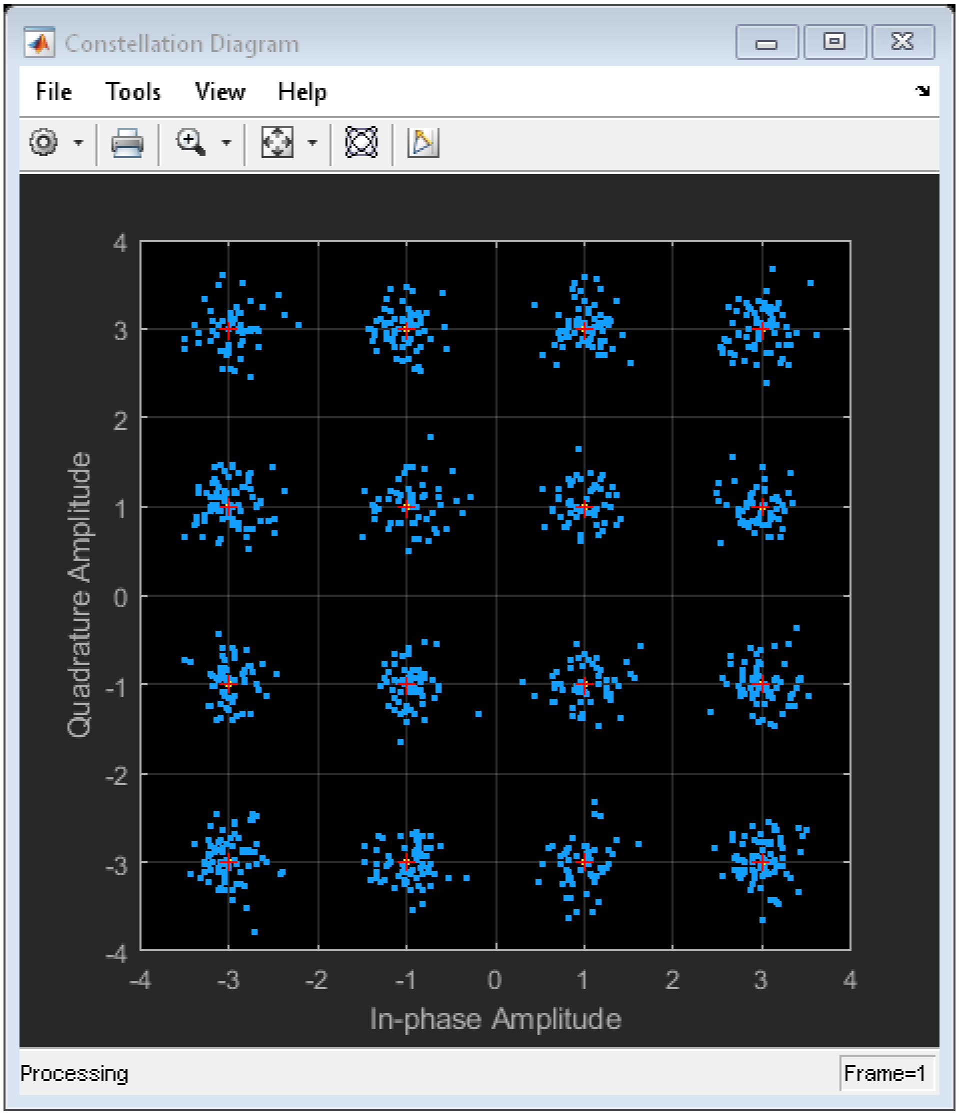


Hide the constellation diagram scope window.

```
if(isVisible(scope))
    hide(scope)
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))
    show(scope)
end
```



Clear the workspace variables.

```
clear scope sym rcv M refConst signal xRef
```

Input Arguments

scope — Scope System object

scope System object

Scope System object, specified as a `comm.ConstellationDiagram` System object.

Example: `scope = comm.ConstellationDiagram;`

info

Package: `comm`

Characteristic information about fading channel object

Syntax

```
infostruct = info(obj)
```

Description

`infostruct = info(obj)` returns a structure containing characteristic information about the fading channel System object.

Examples

Get comm.RayleighChannel Info

Use the `info` object function to get information from a `comm.RayleighChannel` object.

Create a Rayleigh channel object and some data to pass through the channel.

```
rayleighchan = comm.RayleighChannel('SampleRate',1000,'PathDelays',[0 0],'AveragePathGains',[0 0
```

```
rayleighchan = 
  comm.RayleighChannel with properties:

             SampleRate: 1000
             PathDelays: [0 0]
       AveragePathGains: [0 0]
     NormalizePathGains: true
    MaximumDopplerShift: 1.0000e-03
        DopplerSpectrum: [1x1 struct]

  Show all properties
```

```
data = randi([0 1],600,1);
```

Check the Rayleigh channel object information

```
info(rayleighchan)
```

```
ans = struct with fields:
           ChannelFilterDelay: 0
    ChannelFilterCoefficients: [2x1 double]
          NumSamplesProcessed: 0
```

Pass data through the channel and check the object information again.

```
rayleighchan(data);
info(rayleighchan)
```

```
ans = struct with fields:
           ChannelFilterDelay: 0
    ChannelFilterCoefficients: [2x1 double]
          NumSamplesProcessed: 600
```

Release the object so you can update attributes. Add a 1.5e-3 second path delay to the second delay path.

```
release(rayleighchan)
rayleighchan.PathDelays = [0 1.5e-3]
```

```
rayleighchan = 
  comm.RayleighChannel with properties:

             SampleRate: 1000
             PathDelays: [0 0.0015]
       AveragePathGains: [0 0]
     NormalizePathGains: true
    MaximumDopplerShift: 1.0000e-03
        DopplerSpectrum: [1x1 struct]

  Show all properties
```

Pass data through the channel and check the object information again.

```
rayleighchan(data);
info(rayleighchan)
```

```
ans = struct with fields:
           ChannelFilterDelay: 6
    ChannelFilterCoefficients: [2x16 double]
          NumSamplesProcessed: 600
```

Get comm.RicianChannel Info

Use the `info` object function to get information from a `comm.RicianChannel` object.

Create a Rician channel object and some data to pass through the channel.

```
ricianchan = comm.RicianChannel('SampleRate',500)
```

```
ricianchan = 
  comm.RicianChannel with properties:

                SampleRate: 500
                PathDelays: 0
          AveragePathGains: 0
        NormalizePathGains: true
                   KFactor: 3
    DirectPathDopplerShift: 0
    DirectPathInitialPhase: 0
       MaximumDopplerShift: 1.0000e-03
           DopplerSpectrum: [1x1 struct]

  Show all properties
```

```
data = randi([0 1],600,1);
```

Check the Rician channel object information

```
info(ricianchan)
```

```
ans = struct with fields:
           ChannelFilterDelay: 0
    ChannelFilterCoefficients: 1
          NumSamplesProcessed: 0
```

Pass data through the channel and check the object information again.

```
ricianchan(data);
info(ricianchan)
```

```
ans = struct with fields:
           ChannelFilterDelay: 0
    ChannelFilterCoefficients: 1
          NumSamplesProcessed: 600
```

Release the object so you can update attributes. Add a second path delay with a delay of 3.1e-3 second and an average path gain of -3 dB.

```
release(ricianchan)
ricianchan.PathDelays = [0 3.1e-3];
ricianchan.AveragePathGains = [0 -3]
```

```
ricianchan = 
  comm.RicianChannel with properties:

                SampleRate: 500
                PathDelays: [0 0.0031]
          AveragePathGains: [0 -3]
        NormalizePathGains: true
                   KFactor: 3
    DirectPathDopplerShift: 0
    DirectPathInitialPhase: 0
       MaximumDopplerShift: 1.0000e-03
           DopplerSpectrum: [1x1 struct]

  Show all properties
```

Pass data through the channel and check the object information again.

```
ricianchan(data);
info(ricianchan)
```

```
ans = struct with fields:
           ChannelFilterDelay: 6
```

```
    ChannelFilterCoefficients: [2x16 double]
          NumSamplesProcessed: 600
```

Get comm.MIMOChannel Info

Use the `info` object function to get information from a `comm.MIMOChannel` object.

Create a MIMO channel object and some data to pass through the channel.

```
mimo = comm.MIMOChannel('SampleRate',1000);
data = randi([0 1],600,2);
```

Check the MIMO channel object information

```
info(mimo)
```

```
ans = struct with fields:
           ChannelFilterDelay: 0
    ChannelFilterCoefficients: 1
          NumSamplesProcessed: 0
```

Pass data through the channel and check the object information again.

```
mimo(data);
info(mimo)
```

```
ans = struct with fields:
           ChannelFilterDelay: 0
    ChannelFilterCoefficients: 1
          NumSamplesProcessed: 600
```

Release the object so you can update attributes. Add a `2.5e-3` second path delay. Recheck the object information.

```
release(mimo)
mimo.PathDelays = 2.5e-3;
info(mimo)
```

```
ans = struct with fields:
           ChannelFilterDelay: 5
    ChannelFilterCoefficients: [1x16 double]
          NumSamplesProcessed: 0
```

Model MIMO Channel Using Sum-of-Sinusoids Technique

Create a MIMO channel object and pass data through it using the sum-of-sinusoids technique. The example demonstrates how the channel state is maintained in cases in which data is discontinuously transmitted.

Define the overall simulation time and three time segments for which data will be transmitted. In this case, the channel is simulated for 1 s with a 1000 Hz sampling rate. One 1000-sample, continuous data sequence is transmitted at time 0. Three 100-sample data packets are transmitted at time 0.1 s, 0.4 s, and 0.7 s.

```
t0 = 0:0.001:0.999;   % Transmission 0
t1 = 0.1:0.001:0.199; % Transmission 1
t2 = 0.4:0.001:0.499; % Transmission 2
t3 = 0.7:0.001:0.799; % Transmission 3
```

Generate random binary data corresponding to the previously defined time intervals.

```
d0 = randi([0 1],1000,2);  % 1000 samples
d1 = randi([0 1],100,2);   % 100 samples
d2 = randi([0 1],100,2);   % 100 samples
d3 = randi([0 1],100,2);   % 100 samples
```

Create a flat fading 2x2 MIMO channel System object with the `Sum of sinusoids` fading technique. So that results can be repeated, specify a seed using a name-value pair. As the `InitialTime` property is not specified, the fading channel will be simulated from time 0. Enable the path gains output port.

```
mimoChan1 = comm.MIMOChannel('SampleRate',1000, ...
    'MaximumDopplerShift',5, ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',17, ...
    'FadingTechnique','Sum of sinusoids', ...
    'PathGainsOutputPort',true);
```

Create a clone of the MIMO channel System object. Set the `InitialTimeSource` property to `Input port` so that the fading channel offset time can be specified as an input argument to the `mimoChan` function.

```
mimoChan2 = clone(mimoChan1);
mimoChan2.InitialTimeSource = 'Input port';
```

Pass random binary data through the first channel object, `mimoChan1`. Data is transmitted over all 1000 time samples. For this example, only the complex path gain is needed.

```
[~,pg0] = mimoChan1(d0);
```

Pass random data through the second channel object, `mimoChan2`, where the initial time offsets are provided as input arguments.

```
[~,pg1] = mimoChan2(d1,0.1);
[~,pg2] = mimoChan2(d2,0.4);
[~,pg3] = mimoChan2(d3,0.7);
```

Compare the number of samples processed by the two channels using the `info` method. You can see that 1000 samples were processed by `mimoChan1` while only 300 were processed by `mimoChan2`.

```
G = info(mimoChan1);
H = info(mimoChan2);
[G.NumSamplesProcessed H.NumSamplesProcessed]
```

```
ans = 1×2
```

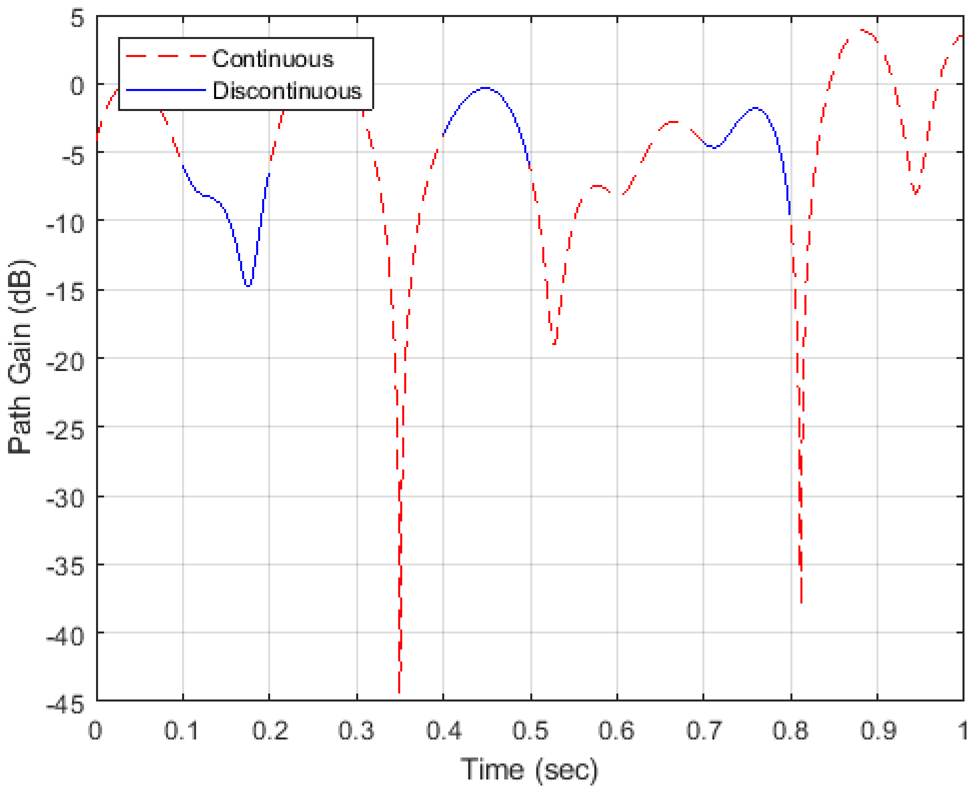
```
        1000         300
```

Convert the path gains into decibels for the path corresponding to the first transmit and first receive antenna.

```
pathGain0 = 20*log10(abs(pg0(:,1,1,1)));
pathGain1 = 20*log10(abs(pg1(:,1,1,1)));
pathGain2 = 20*log10(abs(pg2(:,1,1,1)));
pathGain3 = 20*log10(abs(pg3(:,1,1,1)));
```

Plot the path gains for the continuous and discontinuous cases. Observe that the gains for the three segments perfectly match the gain for the continuous case. The alignment of the two highlights that the sum-of-sinusoids technique is ideally suited to the simulation of packetized data as the channel characteristics are maintained even when data is not transmitted.

```
plot(t0,pathGain0,'r--')
hold on
plot(t1,pathGain1,'b')
plot(t2,pathGain2,'b')
plot(t3,pathGain3,'b')
grid
xlabel('Time (sec)')
ylabel('Path Gain (dB)')
legend('Continuous','Discontinuous','location','nw')
```



Input Arguments

`obj` — System object to get information from

System object

System object to get information from, specified as a `comm.MIMOChannel`, `comm.RayleighChannel`, or `comm.RicianChannel` System object.

Output Arguments

`infostruct` — Structure containing object information

structure

Structure containing these fields with information about the System object.

`ChannelFilterDelay` — Channel filter delay

positive integer

Channel filter delay in samples, returned as a positive integer.

`ChannelFilterCoefficients` — Channel filter coefficients

matrix

Channel filter coefficients, returned as a matrix. The coefficient matrix is used to convert path gains to channel filter tap gains for each sample and each pair of transmit and receive antennas.

`NumSamplesProcessed` — Number of samples processed by the channel object

positive integer

Number of samples processed by the channel object since the last reset, returned as a positive integer.

`LastFrameTime` — Last frame ending time

positive scalar

Last frame ending time in seconds, returned as a positive scalar. Use this value to confirm the simulation time.

Dependencies

This property applies when the `FadingTechnique` property is `'Sum of sinusoids'` and the `InitialTimeSource` property is `'Input port'`.

constellation

Package: `comm`

Calculate or plot ideal signal constellation

Syntax

```
symbols = constellation(obj)
constellation(obj)
```

Description

`symbols = constellation(obj)` returns the numerical values of the constellation.

`constellation(obj)` generates a constellation plot for the object.

Examples

Plot QPSK Reference Constellation

Create a QPSK modulator.

```
mod = comm.QPSKModulator;
```

Determine the reference constellation points.

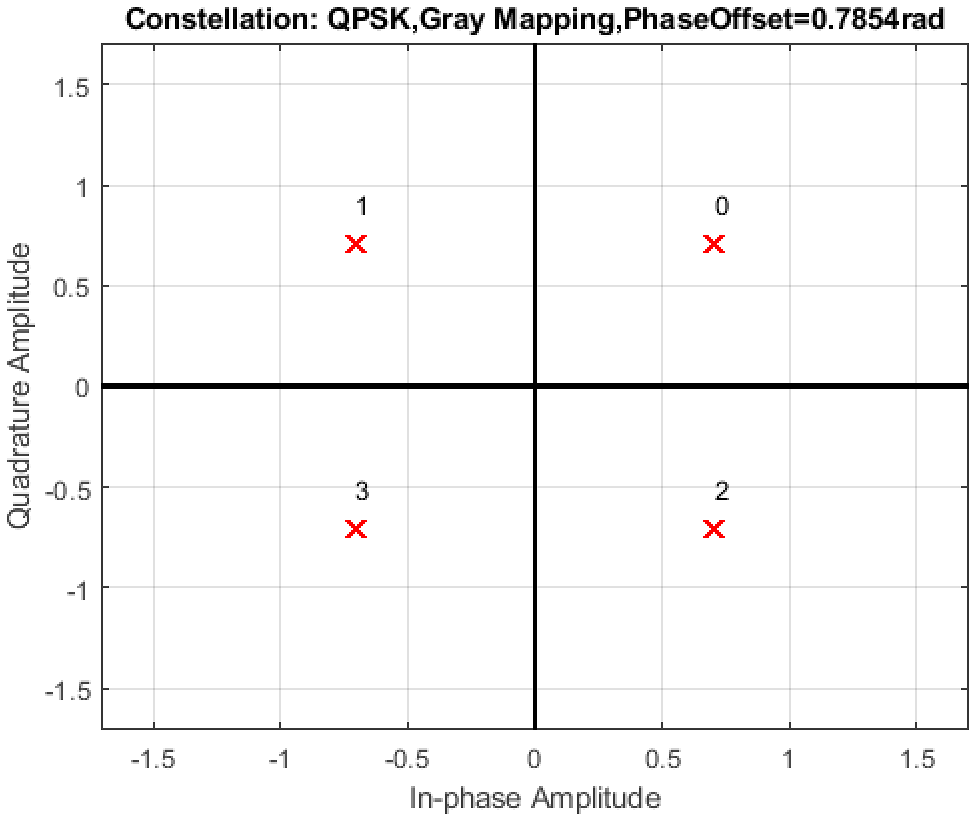
```
refC = constellation(mod)
```

```
refC = 4×1 complex

   0.7071 + 0.7071i
  -0.7071 + 0.7071i
  -0.7071 - 0.7071i
   0.7071 - 0.7071i
```

Plot the constellation.

```
constellation(mod)
```

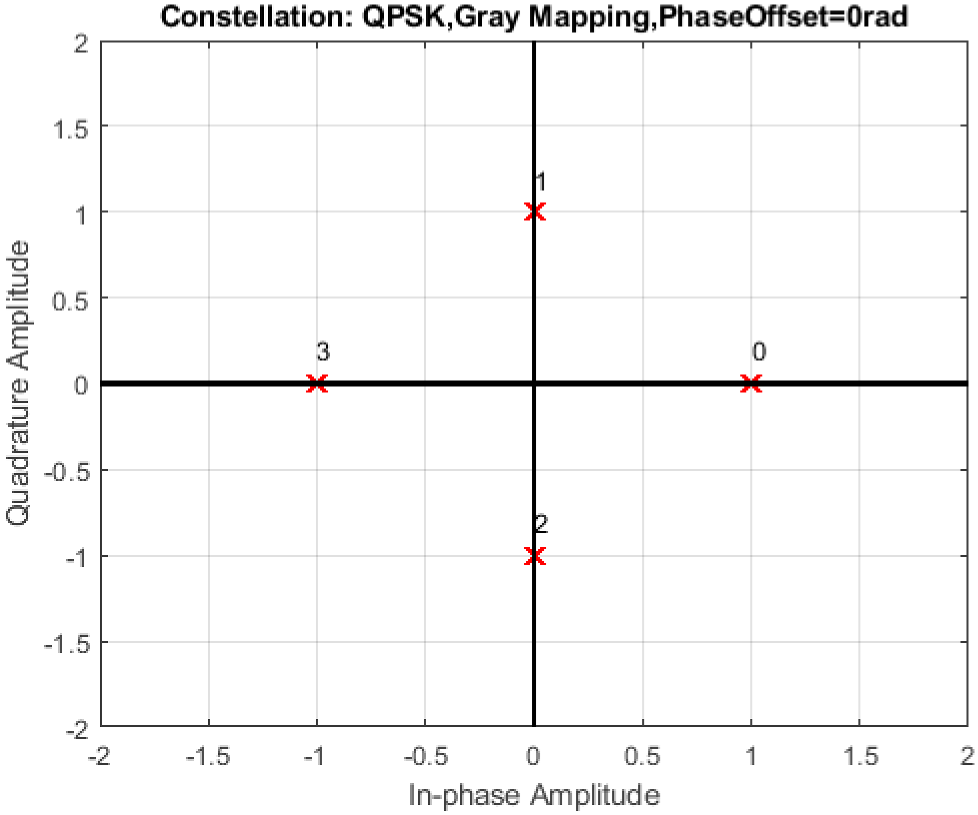


Create a PSK demodulator having 0 phase offset.

```
demod = comm.QPSKDemodulator('PhaseOffset',0);
```

Plot its reference constellation. The `constellation` method works for both modulator and demodulator objects.

```
constellation(demod)
```



Calculate BPSK Modulator Reference Constellation

Create a BPSK Modulator System object™ and calculate the reference constellation values.

Create a `comm.BPSKModulator` System object.

```
h = comm.BPSKModulator;
```

Calculate and display the reference constellation values by calling the `constellation` function.

```
refC = constellation(h)
```

```
refC = 2×1 complex

   1.0000 + 0.0000i
  -1.0000 + 0.0000i
```

Plot PSK Reference Constellation

Create a PSK modulator.

```
mod = comm.PSKModulator;
```

Determine the reference constellation points.

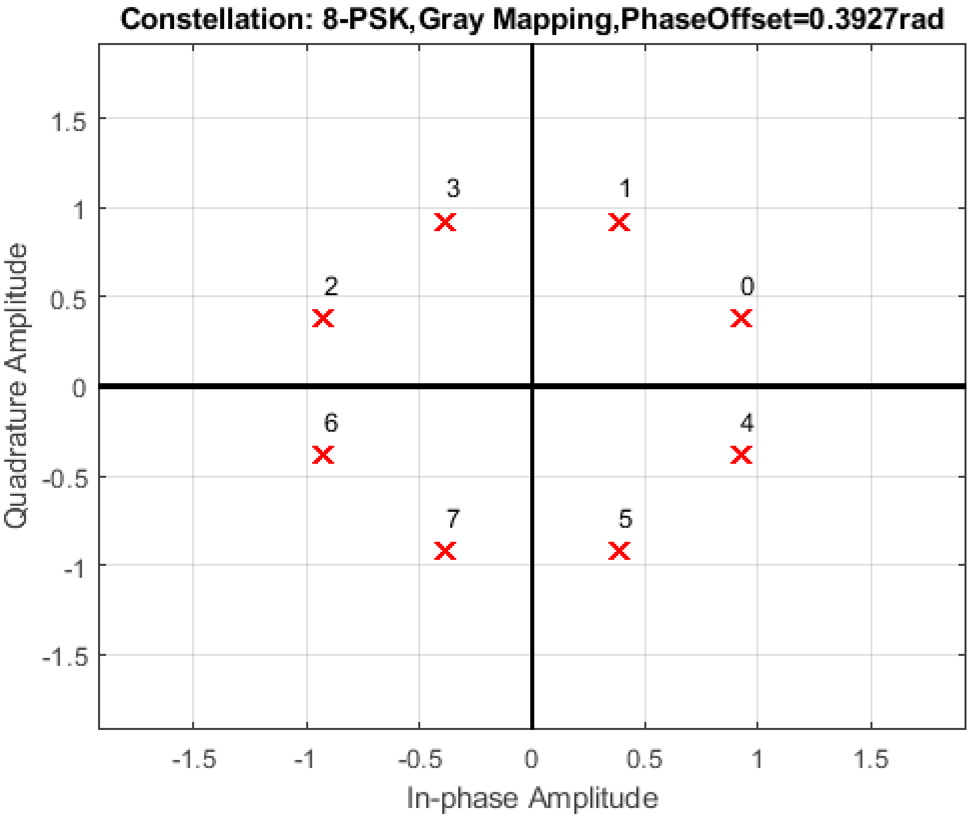
```
refC = constellation(mod)
```

```
refC = 8×1 complex

   0.9239 + 0.3827i
   0.3827 + 0.9239i
  -0.3827 + 0.9239i
  -0.9239 + 0.3827i
  -0.9239 - 0.3827i
  -0.3827 - 0.9239i
   0.3827 - 0.9239i
   0.9239 - 0.3827i
```

Plot the constellation.

```
constellation(mod)
```

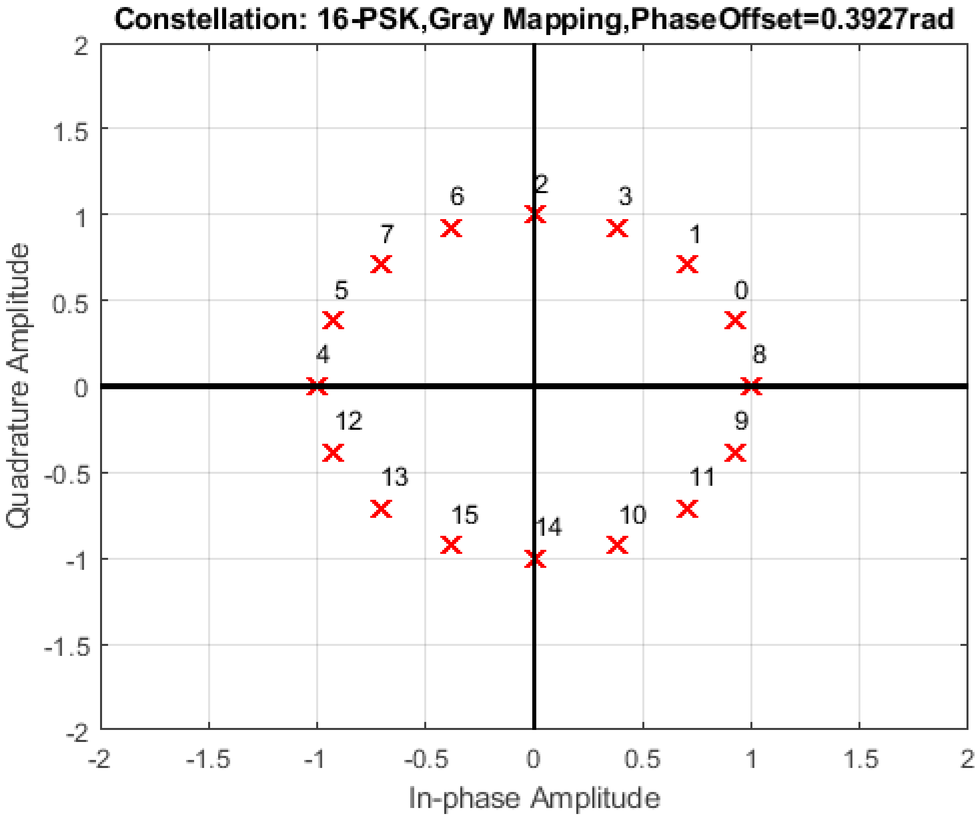


Create a PSK demodulator having modulation order 16.

```
demod = comm.PSKDemodulator(16);
```

Plot its reference constellation. The `constellation` method works for both modulator and demodulator objects.

```
constellation(demod)
```



Input Arguments

obj — System object to return constellation for
System object

System object to return constellation for, specified as a modulator System object.

Data Types: `object`

Output Arguments

symbols — Constellation points
complex vector (default)

Constellation points, returned as a complex vector.

Data Types: `double` | `single`
Complex Number Support: Yes

info

Package: comm

Provide dimensioning information for OFDM modulator

Syntax

```
infostruct = info(hMod)
```

Description

`infostruct = info(hMod)` returns the input, pilot, and output data dimensions for the specified OFDM modulator System object.

Examples

Determine OFDM Modulator Data Dimensions

Get the OFDM modulator data dimensions by using the `info` object function.

Construct an OFDM modulator System object™ with user-specified pilot indices, an inserted DC null, and specify two transmit antennas.

```
hMod = comm.OFDMModulator('NumGuardBandCarriers',[4;3], ...
    'PilotInputPort',true, ...
    'PilotCarrierIndices',cat(3,[12; 26; 40; 54], ...
    [11; 25; 39; 53]), ...
    'InsertDCNull',true, ...
    'NumTransmitAntennas',2);
```

Use the `info` object function to get the modulator input data, pilot input data, and output data sizes.

```
info(hMod)
```

```
ans = struct with fields:
     DataInputSize: [48 1 2]
    PilotInputSize: [4 1 2]
        OutputSize: [80 2]
```

Input Arguments

hMod — OFDM modulator

System object

OFDM modulator, specified as a `comm.OFDMModulator` System object.

Output Arguments

`infostruct` — Dimensions of structure for OFDM modulator

struct

Dimensions of structure for OFDM modulator, returned as a structure containing these fields.

`DataInputSize` — Dimensions of input data

3-D array

Dimensions of input data, returned as a 3-D array of numeric values. The dimensions of this field are N_{data}-by-N_{sym}-by-N_{t}, where N_{data} is the number of data subcarriers such that $N_{\text{data}} = N_{\text{FFT}} - N_{\text{leftG}} - N_{\text{rightG}} - N_{\text{DCNull}} - N_{\text{pilot}} - N_{\text{custNull}}$.

For variable definitions, see Variable Definitions.

`PilotInputSize` — Dimensions of the pilot input data

3-D array

Dimensions of the pilot input array, returned as a 3-D array of numeric values. The output dimensions of this field are N_{pilot}-by-N_{sym}-by-N_{t}.

`OutputSize` — Dimensions of modulator output data

3-D array

Dimensions of the modulator output data, returned as a 3-D array of numeric values. The dimensions of this field are $((N_{\text{FFT}} + N_{\text{CP}})\times N_{\text{sym}})$-by-$N_{\text{t}}$.

For variable definitions, see Variable Definitions.

Data Types: `struct`

More About

List of Variables

The variables mentioned in this table are defined in this table:

Variable Definitions

Variable	Description
N_{FFT}	Number of subcarriers
N_{leftG}	Number of subcarriers in the left guard band
N_{rightG}	Number of subcarriers in the right guard band
N_{DCNull}	Number of subcarriers in the DC null (either `0` or `1`)
N_{pilot}	Number of pilot subcarriers
N_{custNull}	Number of subcarriers used for custom nulls (applies only when the `PilotCarrierIndices` property of input `hMod` is a 3-D array)
N_{t}	Number of transmit antennas
N_{CP}	Length of cyclic prefix.

info

Package: `comm`

Return characteristic information about channel filter

Syntax

```
infostruct = info(chanFilt)
```

Description

`infostruct = info(chanFilt)` returns a structure containing characteristic information about the `comm.ChannelFilter` System object.

Examples

Determine Channel Filter Structure Dimensions

In a distributed MIMO system, send the same signal from two geographically separate transmitters (Tx) and combine the received signals at one single receiver (Rx) to explore spatial diversity. The two Txs are not co-located and they experience different multipath (path delays) to the Rx. Specify the path delays respectively.

```
delay1 = [0 1.5 2.3 5.2 6.6];
delay2 = [0 3.7 6.2];
```

Configure one channel filter object per Tx.

```
chanFilt1 = comm.ChannelFilter('PathDelays', delay1);
chanFilt2 = comm.ChannelFilter('PathDelays', delay2);
```

Use the `info` object function to get the ChannelFilterDelay and ChannelFilterCoefficients.

```
info(chanFilt1)
```

```
ans = struct with fields:
           ChannelFilterDelay: 6
    ChannelFilterCoefficients: [5x21 double]
```

```
info(chanFilt2)
```

```
ans = struct with fields:
           ChannelFilterDelay: 4
    ChannelFilterCoefficients: [3x19 double]
```

Input Arguments

`chanFilt` — Channel filter
System object

Channel filter, specified as a `comm.ChannelFilter` System object.

Output Arguments

`infostruct` — Characteristic information about channel filter
struct

Characteristic information about channel filter, returned as a structure containing these fields:

`ChannelFilterDelay` — Channel filter delay
positive real scalar

Channel filter delay, returned as a positive real scalar.

Data Types: `double`

`ChannelFilterCoefficients` — Channel filter coefficients
vector | matrix

Channel filter coefficients, returned as a vector or a matrix.

Data Types: `double`

showResourceMapping

Package: `comm`

Show the subcarrier mapping of the OFDM symbols created by the OFDM modulator System object

Syntax

```
showResourceMapping(hMod)
showResourceMapping(hMod,ci)
```

Description

`showResourceMapping(hMod)` shows a visualization of the subcarrier mapping for the OFDM symbols created by the OFDM modulator System object.

`showResourceMapping(hMod,ci)` uses the values in input `ci` to number the subcarrier indices that the function displays. The subcarrier indices are numbered from 1 to `ci`N_{FFT}, where N_{FFT} is the number of FFT points.

Examples

Create and Modify OFDM Modulator

Create and display an OFDM modulator System object™ with default property values.

```
hMod = comm.OFDMModulator
```

```
hMod = 
  comm.OFDMModulator with properties:

               FFTLength: 64
    NumGuardBandCarriers: [2x1 double]
             InsertDCNull: false
           PilotInputPort: false
      CyclicPrefixLength: 16
               Windowing: false
              NumSymbols: 1
     NumTransmitAntennas: 1
```

Modify the number of subcarriers and symbols.

```
hMod.FFTLength = 128;
hMod.NumSymbols = 2;
```

Verify that the number of subcarriers and the number of symbols changed.

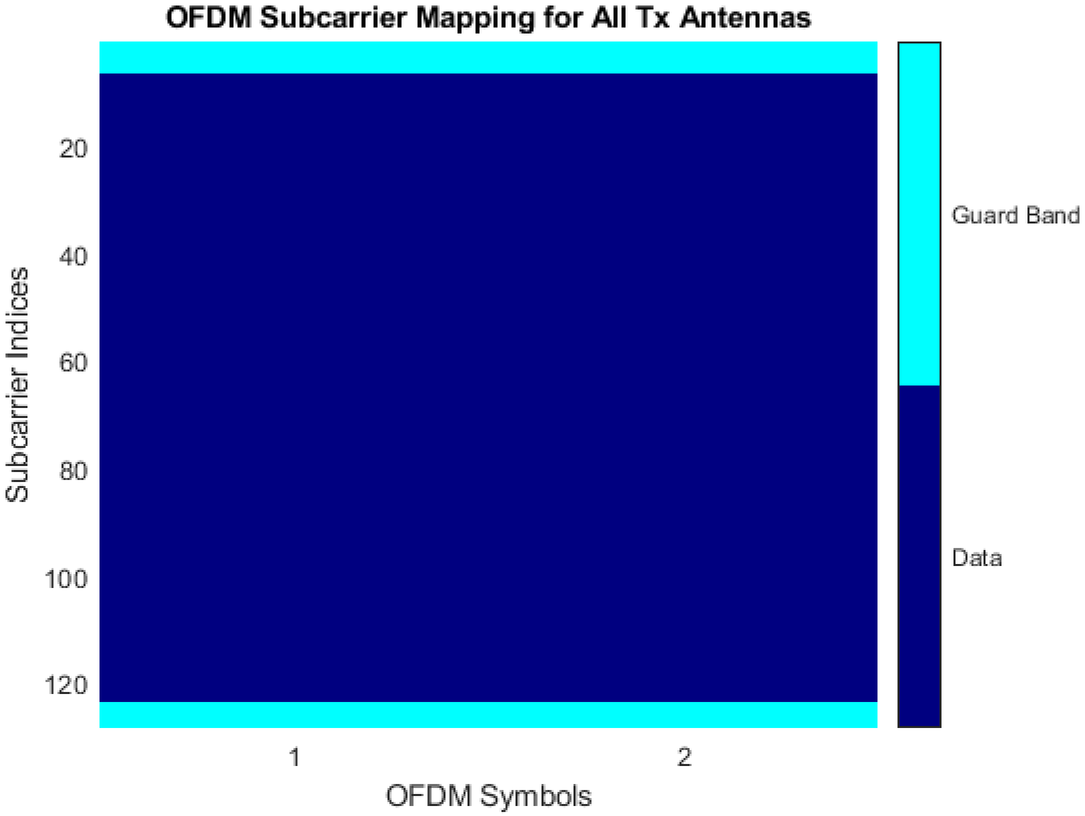
```
disp(hMod)
```

```
  comm.OFDMModulator with properties:
```

```
               FFTLength: 128
    NumGuardBandCarriers: [2x1 double]
            InsertDCNull: false
           PilotInputPort: false
      CyclicPrefixLength: 16
               Windowing: false
              NumSymbols: 2
     NumTransmitAntennas: 1
```

Use the `showResourceMapping` object function to show the mapping of data, pilot, and null subcarriers in the time-frequency space.

```
showResourceMapping(hMod)
```



Input Arguments

hMod — System object to visualize
`comm.OFDMModulator` System object

OFDM modulator, specified as a `comm.OFDMModulator` System object.

ci — Subcarrier indices to visualize
`[1,…,`N_{FFT}`]` (default) | two-element row vector of integers

Subcarrier indices to visualize, specified as a two-element row vector of integers. `ci` should satisfy diff(`ci`) = $N_{\text{FFT}} - 1$.

info

Package: `comm`

Characteristic information about ray-tracing channel

Syntax

`chanInfo = info(rtchan)`

Description

`chanInfo = info(rtchan)` returns a structure containing characteristic information about the input ray-tracing channel.

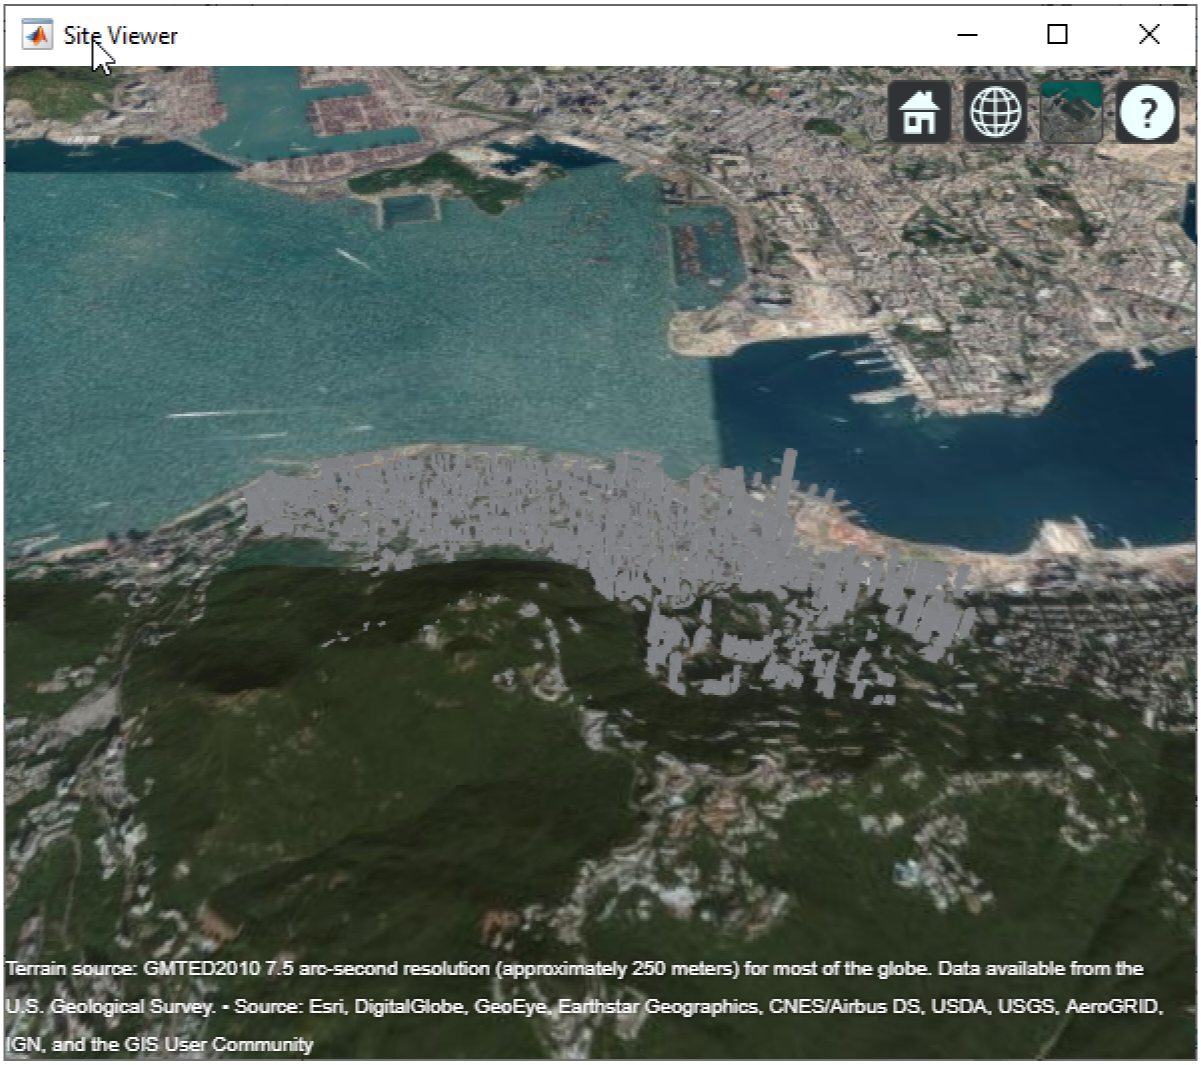
Examples

Return Information for Ray-Tracing Channel Between Two Sites in Hong Kong

Perform ray tracing between two sites in Hong Kong, China, build a multipath channel model using the ray-tracing result, and view the ray-tracing channel information.

Create a Site Viewer map display of buildings in Hong Kong. For more information about the osm file, see [1] on page 4-0   .

```
sv = siteviewer("Buildings","hongkong.osm");
```



Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Create transmitter and receiver sites.

```
tx = txsite("Latitude",22.2789,"Longitude",114.1625, ...
    "AntennaAngle",30, ... % azimuth
    "AntennaHeight",10,"TransmitterFrequency",28e9);
rx = rxsite("Latitude",22.2799,"Longitude",114.1617, ...
    "AntennaAngle",120, ... % azimuth
    "AntennaHeight",1);
```

Perform ray tracing to find rays with up to 2 reflections.

```
rays = raytrace(tx,rx,"NumReflections",[0 1 2]);
```

Create a channel model by using the transmitter site, receiver site, and calculated rays between the sites. Return information from the ray-tracing channel.

```
rtchan = comm.RayTracingChannel(rays{1},tx,rx);
info(rtchan)
```

```
ans = struct with fields:
             CarrierFrequency: 2.8000e+10
             CoordinateSystem: 'Geographic'
        TransmitArrayLocation: [3×1 double]
         ReceiveArrayLocation: [3×1 double]
          NumTransmitElements: 1
           NumReceiveElements: 1
           ChannelFilterDelay: 4
    ChannelFilterCoefficients: [7×20 double]
          NumSamplesProcessed: 0
```

Appendix

[1] The osm file is downloaded from https://www.openstreetmap.org, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), https://opendatacommons.org/licenses/odbl/.

Input Arguments

`rtchan` — Ray-tracing channel

`comm.RayTracingChannel` System object

Ray-tracing channel, specified as a `comm.RayTracingChannel` System object.

Output Arguments

`chanInfo` — Ray tracing channel characteristic information

structure

Ray tracing channel characteristic information, returned as a structure containing these fields. The ray tracing channel is specified by the input `rtchan`.

`CarrierFrequency` — Carrier frequency

positive scalar

Carrier frequency in Hz, returned as a positive scalar.

`CoordinateSystem` — Coordinate system

`'Cartesian'` | `'Geographic'`

Coordinate system, returned as `'Cartesian'` or `'Geographic'`. Any `comm.Ray` objects, specified by the `PropagationRays` property of the `rtchan` input, that have their `PathSpecification` property set to `'Locations'`, must have the same `CoordinateSystem` property setting.

Dependencies

This property applies when at least one `comm.Ray` object in the `PropagationRays` property of the `rtchan` input has `PathSpecification` set to `'Locations'`.

`TransmitArrayLocation` — Transmit array location

three element column vector

Transmit array location, returned as a three element column vector. Any `comm.Ray` objects, specified by the `PropagationRays` property of the `rtchan` input, that have their `PathSpecification` property set to `'Locations'`, must have the same `TransmitterLocation` property setting.

Dependencies

This property applies when at least one `comm.Ray` object in the `PropagationRays` property of the `rtchan` input has `PathSpecification` set to `'Locations'`.

`ReceiveArrayLocation` — Receive array location

three element column vector

Receive array location, returned as a three element column vector. Any `comm.Ray` objects, specified by the `PropagationRays` property of the `rtchan` input, that have their `PathSpecification` property set to `'Locations'`, must have the same `ReceiverLocation` property setting.

Dependencies

This property applies when at least one `comm.Ray` object in the `PropagationRays` property of the `rtchan` input has `PathSpecification` set to `'Locations'`.

`NumTransmitElements` — Number of elements in transmit array

positive integer

Number of elements in the transmit array, returned as a positive integer.

`NumReceiveElements` — Number of elements in receive array

positive integer

Number of elements in the receive array, returned as a positive integer.

`ChannelFilterDelay` — Channel filter delay

nonnegative integer

Channel filter delay in samples, returned as a nonnegative integer.

`ChannelFilterCoefficients` — Channel filter coefficients

N_P-by-N_H matrix

Channel filter coefficients, returned as an N_P-by-N_H matrix. This coefficient matrix is used to convert channel impulse responses to channel filter tap gains for each sample, and then for each pair of transmit and receive antenna elements. N_P is the number of paths (specifically, the number of rays as indicated by the length of the `PropagationRays` property of the `rtchan` input). N_H is the number of impulse response samples (specifically, the number of channel filter taps).

`NumSamplesProcessed` — Number of samples processed by channel object

nonnegative integer

Number of samples processed by the channel object since its last reset, returned as a nonnegative integer.

Functions
`showProfile`

Introduced in R2020b

showProfile

Package: `comm`

Plot temporal and spatial profiles of ray-tracing channel

Syntax

```
showProfile(rtchan)
showProfile(rtchan,'ArrayPattern',false)
```

Description

`showProfile(rtchan)` plots the power delay profile (PDP), angle of departure (AoD), and angle of arrival (AoA) information for the ray-tracing channels in a single figure with three subplots.

- The PDP subplot is derived from the propagation delay, path loss, phase shift, pattern gain at transmit array and pattern gain at receive array for each ray specified by the `PropagationRays` property of the `rtchan` input.
- The AoD and AoA subplots show the 3-D directions of the rays in the local coordinate system (LCS).
  - When the `TransmitArray` or `ReceiveArray` properties are objects from the “Phased Array System Toolbox” software, the AoD and AoA subplots also show the directivity pattern of the arrays.

`showProfile(rtchan,'ArrayPattern',false)` optionally turns off the directivity pattern in the AoD and AoA subplots. This option applies only when the `TransmitArray` or `ReceiveArray` property in the `comm.RayTracingChannel` System object are objects from the “Phased Array System Toolbox” software.

Examples

Show Temporal and Spatial Profiles of Ray-Tracing Channel

Perform ray-tracing between two sites, build a multipath channel model using the ray tracing result, and show the temporal and spatial profiles of the channel.

Create a transmitter site and a receiver site. Perform ray tracing to find rays with up to 2 reflections between the sites.

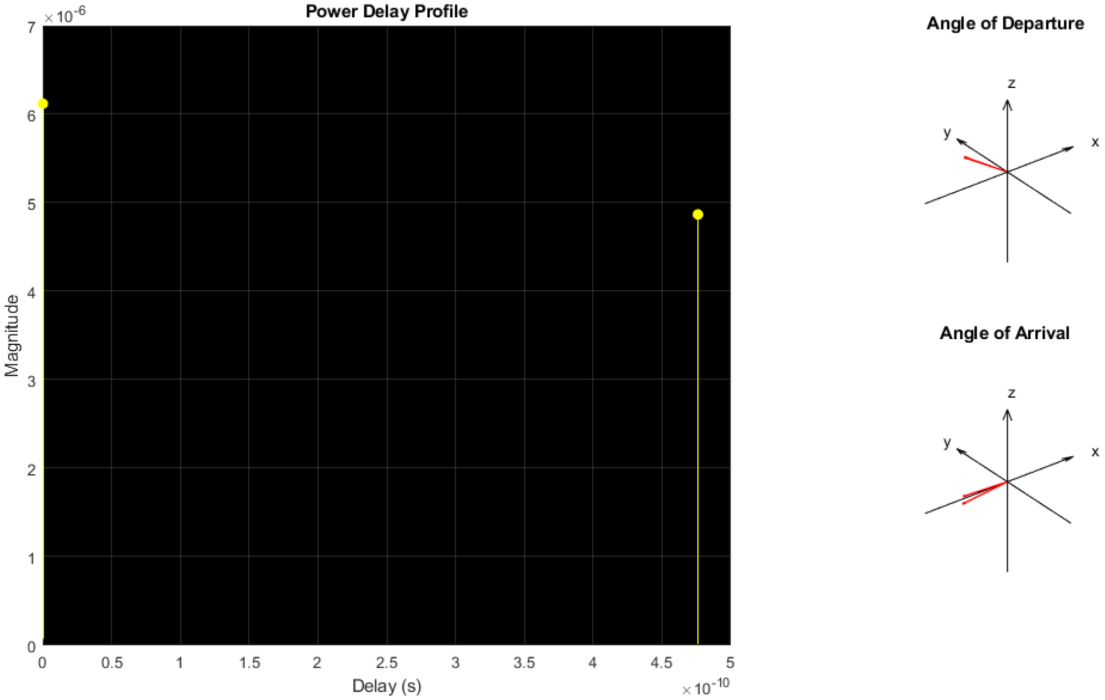
```
tx = txsite("Latitude",22.2789,"Longitude",114.1625, ...
    "AntennaAngle",30,"AntennaHeight",10,"TransmitterFrequency",28e9);
rx = rxsite("Latitude",22.2799,"Longitude",114.1617, ...
    "AntennaAngle",120,"AntennaHeight",1);
rays = raytrace(tx,rx,"NumReflections",[0 1 2]);
```

Create a channel model using transmitter site, receiver site, and calculated rays between the sites.

```
rtchan = comm.RayTracingChannel(rays{1},tx,rx);
```

Show temporal and spatial profiles of the channel.

```
showProfile(rtchan);
```



Input Arguments

`rtchan` — Ray-tracing channel

`comm.RayTracingChannel` System object

Ray-tracing channel, specified as a `comm.RayTracingChannel` System object.

See Also

Objects
`comm.Ray` | `comm.RayTracingChannel`

Functions
`info`

Introduced in R2020b

info

Package: `comm`

Characteristic information about carrier synchronizer

Syntax

```
infostruct = info(carrSynch)
```

Description

`infostruct = info(carrSynch)` returns a structure containing characteristic information for the `CarrierSynchronizer` System object.

Examples

Determine Carrier Synchronizer Loop Parameters

Create a carrier synchronizer object.

```
csync = comm.CarrierSynchronizer;
```

Determine the normalized pull-in range, the maximum frequency lock delay, and the maximum phase lock delay by using the `info` method.

```
syncInfo = info(csync)
```

```
syncInfo = struct with fields:
    NormalizedPullInRange: 0.0628
    MaxFrequencyLockDelay: 1.5787e+04
        MaxPhaseLockDelay: 130
```

The normalized pull-in range is 0.0628 rad/sec. Convert the pull-in range to Hz. This represents the maximum normalized frequency offset that can be corrected by the carrier synchronizer.

```
foffsetmax = syncInfo.NormalizedPullInRange/(2*pi)
```

```
foffsetmax = 0.0100
```

The time to acquire a frequency lock is 15787 s, and the time to acquire a phase lock is 130 s.

The overall acquisition time, `Tlock`, is well approximated by the sum of the frequency and phase lock terms.

```
Tlock = syncInfo.MaxFrequencyLockDelay + syncInfo.MaxPhaseLockDelay
```

```
Tlock = 1.5917e+04
```

Input Arguments

`carrSynch` — System object to get information from
System object

System object to get information from.

Output Arguments

`infostruct` — Structure containing object information
struct

Structure containing these fields with information about the System object.

`NormalizedPullInRange` — Normalized pull in range
scalar

Normalized pull in range in radians, returned as a scalar. `NormalizedPullInRange` is the largest frequency offset (rad), normalized by the loop bandwidth, for which the synchronizer can acquire lock.

`MaxFrequencyLockDelay` — Maximum frequency lock delay
positive integer

Maximum frequency lock delay, returned as a positive integer. `MaxFrequencyLockDelay` is the number of samples required for the synchronizer to acquire frequency lock.

`MaxPhaseLockDelay` — Maximum phase lock delay
positive integer

Maximum phase lock delay, returned as a positive integer. `MaxPhaseLockDelay` is the number of samples required for the synchronizer to acquire phase lock.

Data Types: `struct`

`comm.CarrierSynchronizer`

Introduced in R2015a

info

Package: `comm`

Characteristic information about the equalizer object

Syntax

`infostruct = info(obj)`

Description

`infostruct = info(obj)` returns a structure containing characteristic information for the System object.

Examples

Display Decision Feedback Equalizer Latency

Display latency value for a decision feedback equalizer object.

Create a decision feedback equalizer object.

```
dfe = comm.DecisionFeedbackEqualizer;
```

Display latency value for a decision feedback equalizer object by using the `info` object function.

```
info(dfe)
```

```
ans = struct with fields:
    Latency: 2
```

Input Arguments

`obj` — System object to get information from
System object

System object to get information from.

Output Arguments

`infostruct` — Structure containing object information
structure

Structure containing fields with information about the System object.

`Latency` — Equalizer latency
scalar

Equalizer latency, returned as a scalar.

`comm.DecisionFeedbackEqualizer` | `comm.LinearEqualizer`

Introduced in R2012a

maxstep

Package: comm

Maximum step size for LMS equalizer convergence

Syntax

```
mumax = maxstep(eq,x)
```

Description

mumax = maxstep(eq,x) predicts a bound on the step size to provide convergence of the mean values of the coefficients of the equalizer defined by the eq System object. The set input signal sequences in x are assumed to have zero mean or nearly so.

Examples

Decision Feedback Equalize BPSK-Modulated Signal

Create a BPSK modulator and an equalizer System object™, specifying a decision feedback LMS equalizer having eight forward taps, five feedback taps, and a step size of 0.03.

```
bpsk = comm.BPSKModulator;
eqdfe_lms = comm.DecisionFeedbackEqualizer('Algorithm','LMS', ...
    'NumForwardTaps',8,'NumFeedbackTaps',5,'StepSize',0.03);
```

Change the reference tap index of the equalizer.

```
eqdfe_lms.ReferenceTap = 4;
```

Build a set of test data. Receive the data by convolving the signal.

```
x = bpsk(randi([0 1],1000,1));
rxsig = conv(x,[1 0.8 0.3]);
```

Use maxstep to find the maximum permitted step size.

```
mxStep = maxstep(eqdfe_lms,rxsig)
```

```
mxStep = 0.1028
```

Equalize the received signal. Use the first 200 symbols as the training sequence.

```
y = eqdfe_lms(rxsig,x(1:200));
```

Input Arguments

eq — Equalizer object
System object

Equalizer object, specified as a `comm.LinearEqualizer` or `comm.DecisionFeedbackFEqualizer` System object.

x — Input signal
column vector

Input signal, specified as a column vector. The input signal vector length must be equal to an integer multiple of the InputSamplesPerSymbol property. For more information, see “Symbol Tap Spacing” on page 3-543.

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`mumax` — Prediction of maximum step size for LMS equalizer convergence
scalar

Prediction of maximum step size for LMS equalizer convergence, returned as a scalar.

mmseweights

Package: comm

Linear equalizer MMSE tap weights

Syntax

```
weights = mmseweights(eq,chTaps,EbN0)
```

Description

`weights = mmseweights(eq,chTaps,EbN0)` calculated minimum mean squared error (MMSE) solution for the linear equalizer, `eq` System object given the channel delay taps, `chTaps`, and signal to noise ratio, `EbN0`.

Examples

Calculate MMSE Weights for Linear Equalizer

Calculate the minimum mean squared error (MMSE) solution and use the weights for the linear equalizer taps weights.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
chtaps = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
EbN0 = 20;
```

Generate QPSK modulated symbols. Apply delayed multipath channel filtering and AWGN impairments to the symbols.

```
data = randi([0 M-1], numSymbols, 1);
tx = pskmod(data, M, pi/4);
rx = awgn(filter(chtaps,1,tx),25,'measured');
```

Create a linear equalizer System object configured to use CMA algorithm and input the taps weights. Calculate the MMSE weights. Set the initial tap weights to the calculated MMSE weights. Equalize the impaired symbols.

```
eq = comm.LinearEqualizer('Algorithm','CMA','AdaptWeights',false,'InitialWeightsSource','Property
```

```
eq = 
  comm.LinearEqualizer with properties:

                Algorithm: 'CMA'
                  NumTaps: 5
                 StepSize: 0.0100
            Constellation: [1x4 double]
    InputSamplesPerSymbol: 1
```

```
        AdaptWeightsSource: 'Property'
              AdaptWeights: false
      InitialWeightsSource: 'Property'
            InitialWeights: [5x1 double]
        WeightUpdatePeriod: 1
```

```
wgts = mmseweights(eq,chtaps,EbN0)
```

```
wgts = 5×1 complex

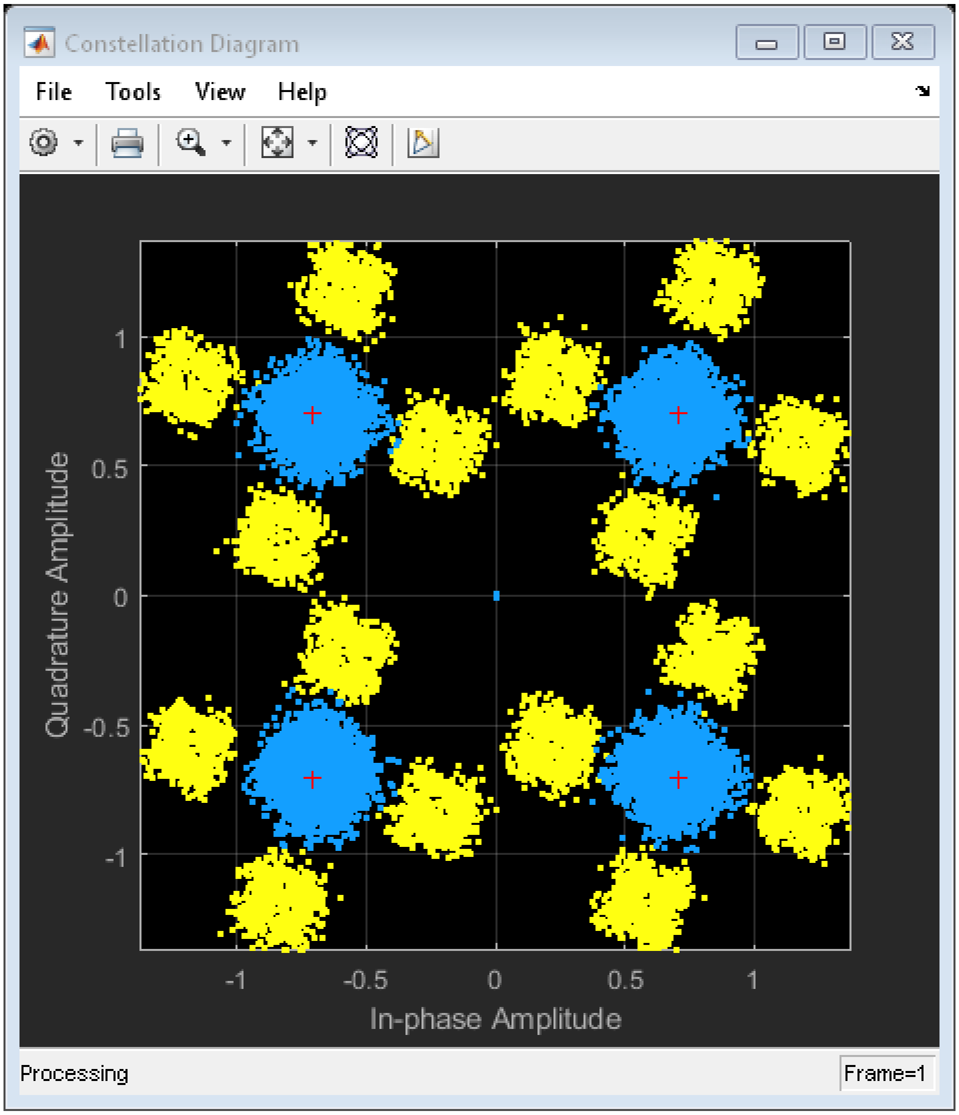
   0.0005 - 0.0068i
   0.0103 + 0.0117i
   0.9694 - 0.0019i
  -0.3987 + 0.2186i
   0.0389 - 0.1756i
```

```
eq.InitialWeights = wgts;
```

```
[y,err,weights] = eq(rx);
```

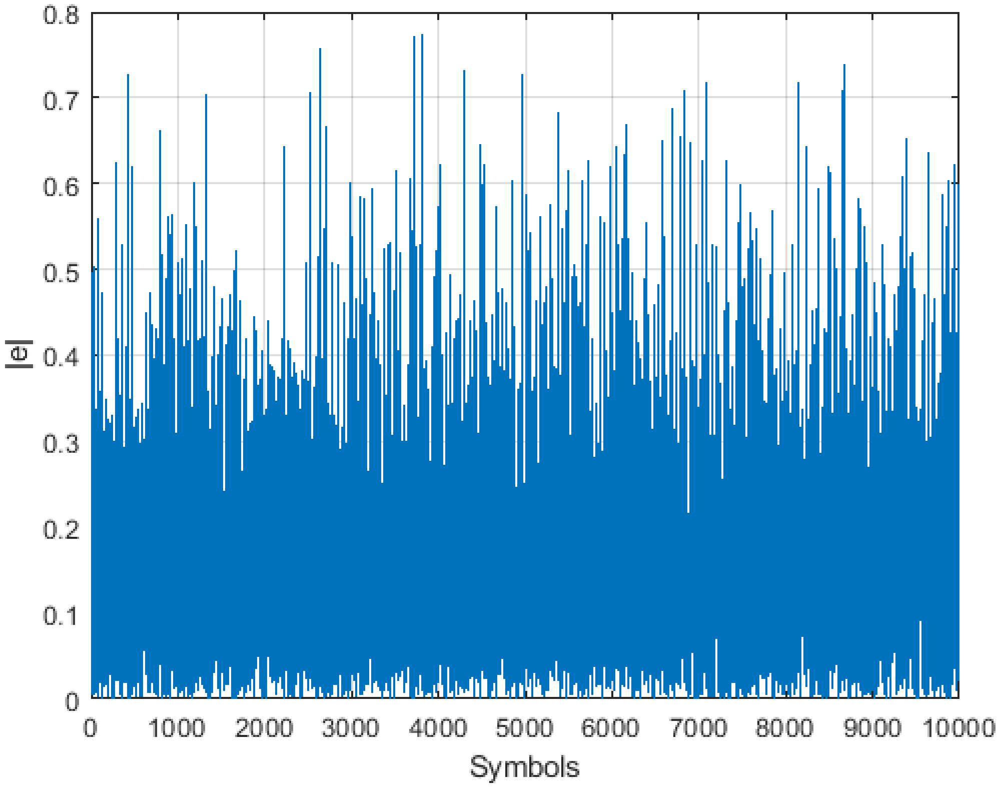
Plot constellation of impaired and equalized symbols.

```
constell = comm.ConstellationDiagram('NumInputPorts',2);
constell(rx,y)
```



Plot the equalizer error signal and compute the error vector magnitude of the equalized symbols.

```
plot(abs(err))
grid on; xlabel('Symbols'); ylabel('|e|')
```

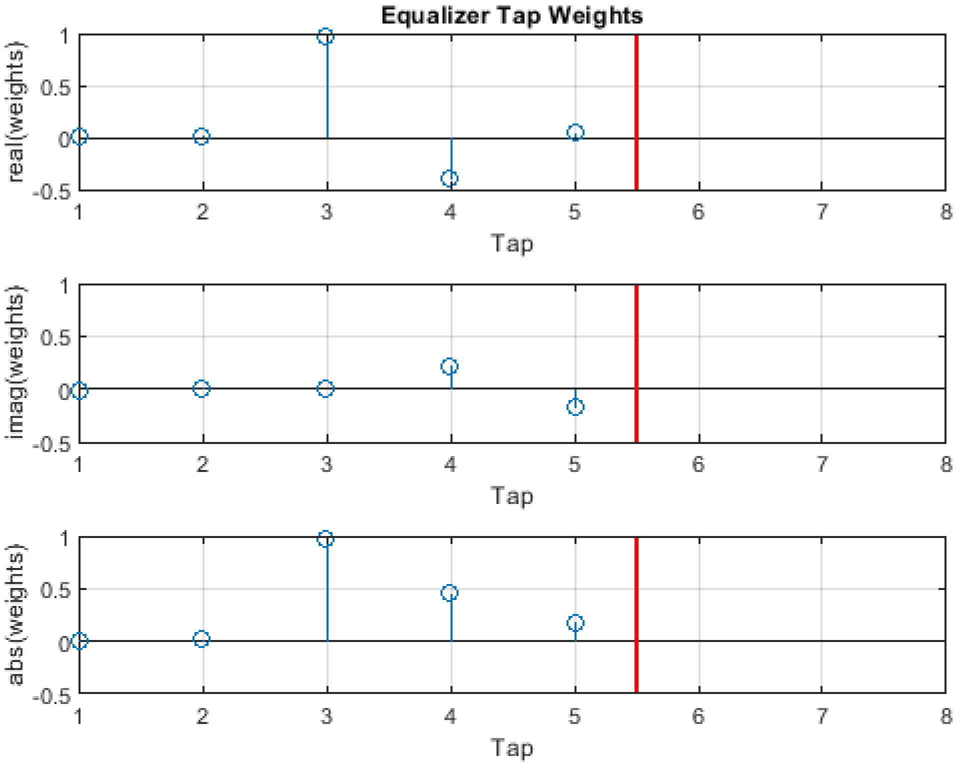


```
errevm = comm.EVM;
evm = errevm(tx,y)
```

```
evm = 140.6177
```

Plot equalizer tap weights.

```
subplot(3,1,1); stem(real(weights)); ylabel('real(weights)'); xlabel('Tap'); grid on; axis([1 8 
line([eq.NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)
title('Equalizer Tap Weights')
subplot(3,1,2); stem(imag(weights)); ylabel('imag(weights)'); xlabel('Tap'); grid on; axis([1 8 
line([eq.NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)
subplot(3,1,3); stem(abs(weights)); ylabel('abs(weights)'); xlabel('Tap'); grid on; axis([1 8 -0
line([eq.NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)
```



Input Arguments

eq — Equalizer object

System object

Equalizer object, specified as a `comm.LinearEqualizer` System object.

chTaps — Channel delay taps

vector

Channel delay taps, specified as a vector.

Data Types: `double`
Complex Number Support: Yes

EbN0 — Signal to noise ratio

scalar

Signal to noise ratio of the channel, specified as a scalar.

Data Types: `double`

Output Arguments

`weights` — Weights for linear equalizer
vector

Weights for linear equalizer, returned as a vector.

See Also

Objects
`comm.LinearEqualizer`

Introduced in R2019a

visualize

Package: comm

Visualize spectrum mask of phase noise

Syntax

```
visualize(phznoise)
```

Description

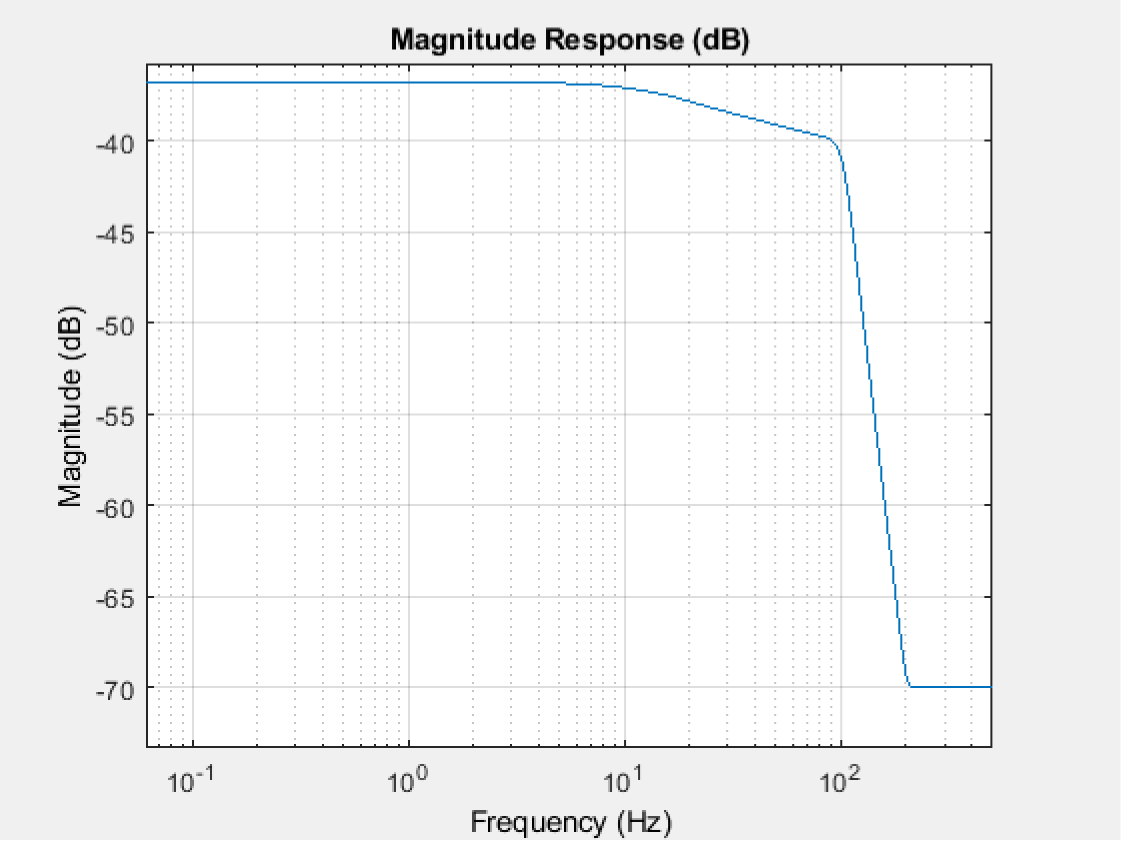
visualize(phznoise) displays the magnitude response of the filter defined by the comm.PhaseNoise System object. The function uses the fvtool function to display the magnitude response.

Examples

Visualize Spectrum Mask of Phase Noise

Create a phase noise object and display the spectral mask.

```
pnoise = comm.PhaseNoise('Level',[-40 -70],'FrequencyOffset',[100 200], ...
    'SampleRate',1000);
visualize(pnoise)
```



Input Arguments

`phznoise` — Phase noise

comm.PhaseNoise System object

Phase noise that defines the spectrum mask that is displayed, specified as a comm.PhaseNoise System object.

`fvtool`

Objects
`comm.PhaseNoise`

Introduced in R2012a

addCustomTerrain

Add custom terrain data

Syntax

```
addCustomTerrain(terrainName,files)
addCustomTerrain( ___ ,Name,Value)
```

Description

`addCustomTerrain(terrainName,files)` adds the terrain data specified with a user-defined `terrainName` and `files`. You can use this function to add custom terrain data in Site Viewer and other RF propagation functions. You can access the custom terrain data in the current and future sessions of MATLAB until you call `removeCustomTerrain`.

Note In Antenna Toolbox, `addCustomTerrain` function converts terrain elevation data from orthometric to ellipsoidal for visualization and when performing Euclidean distance or angle calculations between locations for example for free space path loss.

`addCustomTerrain( ___ ,Name,Value)` adds custom terrain data with additional options specified by one or more name-value pairs.

Examples

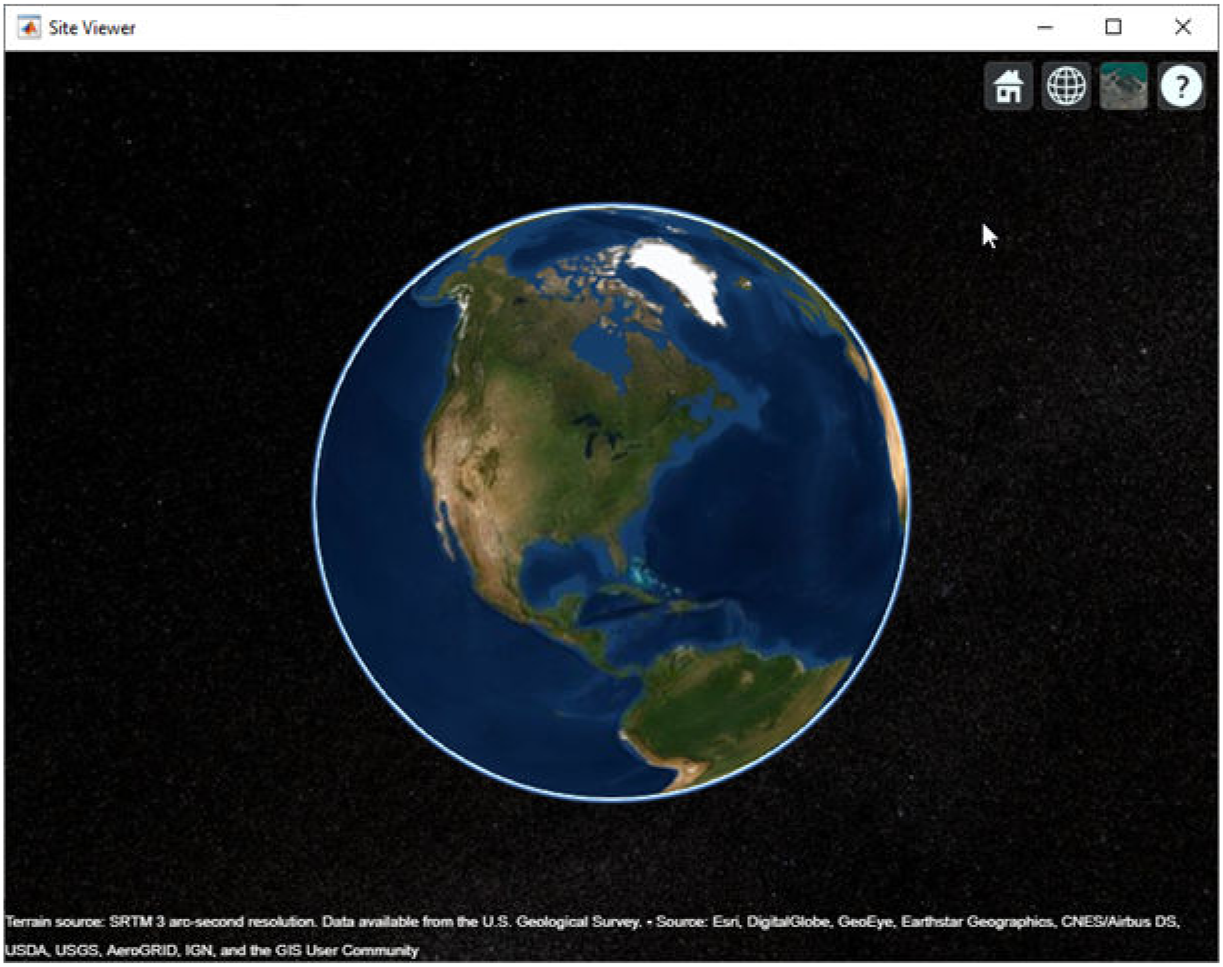
Site Viewer Maps Using Custom Terrain

Add terrain for a region around Boulder, CO. The DTED file was downloaded from the "SRTM Void Filled" data set available from the U.S. Geological Survey.

```
dtedfile = "n39_w106_3arc_v2.dt1";
attribution = "SRTM 3 arc-second resolution. Data available " + ...
   "from the U.S. Geological Survey.";
addCustomTerrain("southboulder",dtedfile,"Attribution",attribution)
```

Use the custom terrain name in Site Viewer.

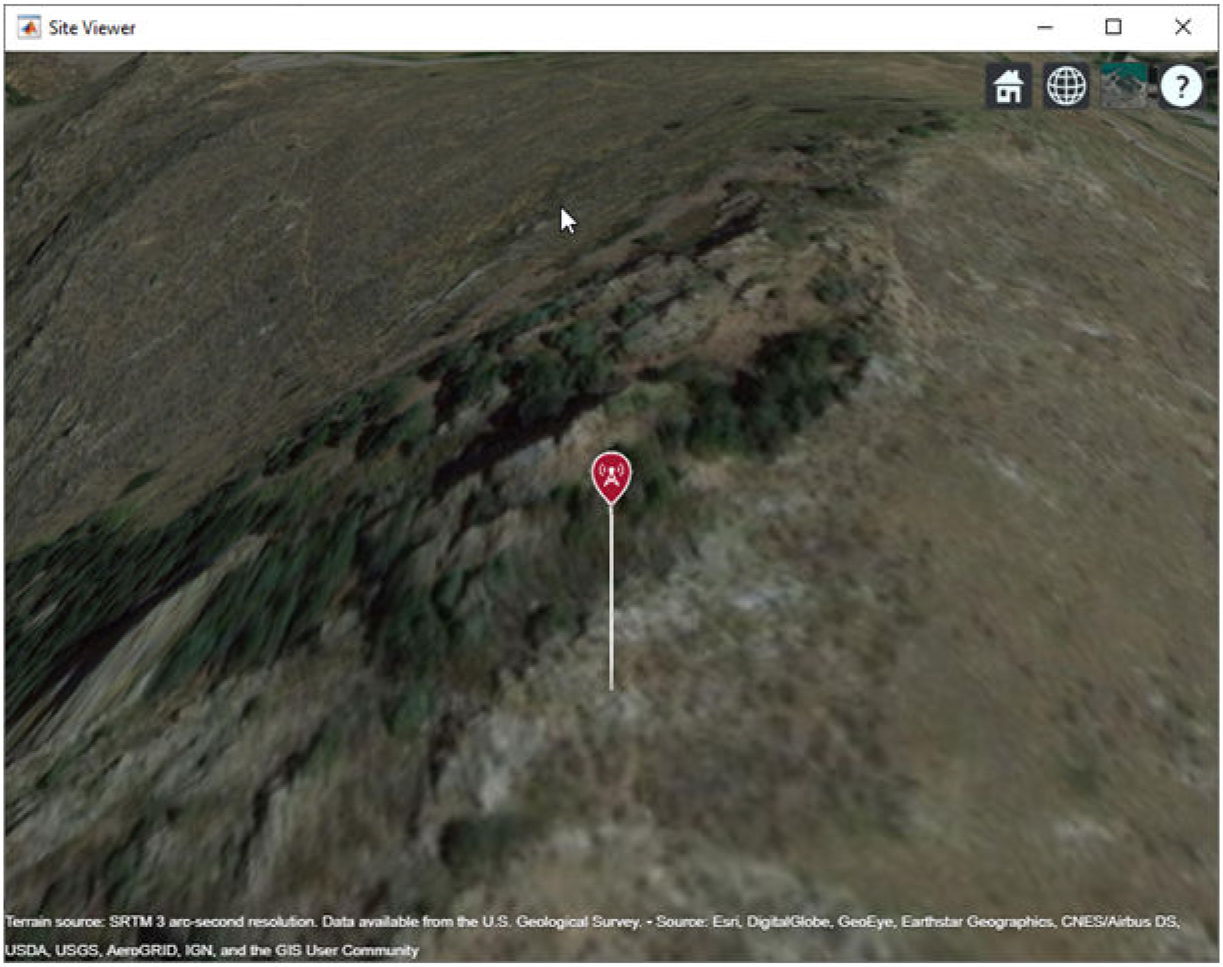
```
viewer = siteviewer("Terrain","southboulder");
```



Terrain source: SRTM 3 arc-second resolution. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Create a site with the terrain region.

```
mtzion = txsite("Name","Mount Zion", ...
   "Latitude",39.74356, ...
   "Longitude",-105.24193, ...
   "AntennaHeight", 30);
show(mtzion)
```



Terrain source: SRTM 3 arc-second resolution. Data available from the U.S. Geological Survey. - Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Create a coverage map of the area within 20 km of the transmitter site.

```
coverage(mtzion, ...
   "MaxRange",20000, ...
   "SignalStrengths",-100:-5)
```

Terrain source: SRTM 3 arc-second resolution. Data available from the U.S. Geological Survey. - Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Remove the custom terrain.

```
close(viewer)
removeCustomTerrain("southboulder")
```

Input Arguments

terrainName — User-defined identifier for terrain data

string scalar | character vector

User-defined identifier for terrain data, specified as a string scalar or a character vector.

Data Types: char | string

files — List of DTED files

string scalar | character vector | cell array of character vectors

List of DTED files, specified as a string scalar, a character vector or a cell array of character vectors.

Note If you specify multiple files, they must combine to define a complete rectangular geographic region. If not, you must set the name-value pair 'FillMissing' to 'true'.

Data Types: `char` | `string`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'FillMissing',true`

`Attribution` — Attribution of custom terrain data

character vector | string scalar

Attribution of custom terrain data, specified as a character vector or a string scalar. The attribution is displayed on the Site Viewer map. By default, the value is empty.

Data Types: `char` | `string`

`FillMissing` — Fill data of missing files with value 0

`false` (default) | `true`

Fill data of missing files with value 0, specified as `true` or `false`. Missing file values are required to complete a rectangular geographic region with the input `files`.

Data Types: `logical`

`WriteLocation` — Name of folder to write extracted terrain files to

character vector | string scalar

Name of folder to write extracted terrain files to, specified as a character vector or a string scalar. The folder must exist and have write permissions. By default, `addCustomTerrain` writes extracted terrain files to a temporary folder that it generates using the `tempname` function.

Data Types: `char` | `string`

See Also

`removeCustomTerrain` | `siteviewer`

Introduced in R2019b

angle

Angle between sites

Syntax

```
[az,el] = angle(site1,site2)
[az,el] = angle(site1,site2,path)
[az,el] = angle(___,Name,Value)
```

Description

`[az,el] = angle(site1,site2)` returns the azimuth and elevation angles between site 1 and site

`[az,el] = angle(site1,site2,path)` returns the angles using a specified path type, either Euclidean or great circle path.

`[az,el] = angle(___,Name,Value)` returns the azimuth and elevation angles with additional options specified by name-value pairs.

Examples

Angle Between Sites

Create transmitter and receiver sites.

```
tx = txsite('Name','MathWorks','Latitude',42.3001,'Longitude',-71.3504);
rx = rxsite('Name','Fenway Park','Latitude',42.3467,'Longitude',-71.0972);
```

Get the azimuth and elevation angles between the sites.

```
[az,el] = angle(tx,rx)
```

```
az = 14.0142
```

```
el = -0.2816
```

Get the azimuth angle between sites in degrees clockwise from north.

```
azFromEast = angle(tx,rx); % Unit: degrees counter-clockwise from east
azFromNorth = -azFromEast + 90 % Convert angle to clockwise from north
```

```
azFromNorth = 75.9858
```

Angle Between Sites When Path is Great Circle

Create transmitter and receiver sites.

```
tx = txsite('Name','MathWorks','Latitude',42.3001,'Longitude',-71.3504);
rx = rxsite('Name','Fenway Park','Latitude',42.3467,'Longitude',-71.0972);
```

Get the azimuth and elevation angles between the sites.

```
[az,el] = angle(tx,rx,'greatcircle')
```

```
az = 14.0635
```

```
el = 0
```

Input Arguments

site1,site2 — Transmitter or receiver site

txsite or rxsite object

Transmitter or receiver site, specified as a txsite or rxsite object. You can use array inputs to specify multiple sites.

path — Measurement path type

'euclidean' or 'greatcircle'

Measurement path type, specified as one of the following:

- 'euclidean': Uses the shortest path through space connecting the antenna center positions of the site 1 and site 2.
- 'greatcircle': Uses the shortest path on the surface of the earth connecting the latitude and longitude locations of site 1 and site 2. This path uses a spherical Earth model.

Data Types: char

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Map','siteviewer1'

Map — Map for visualization or surface data

siteviewer object | terrain name

Map for visualization or surface data, specified as the comma-separated pair consisting of 'Map and one of the following depending on the coordinate system:

Coordinate System	Valid map values	Default map value
'geographic'	• siteviewer[a] • A terrain name may be specified if the function is called with an output argument. Valid terrain names are 'none', 'gmted2010', or the name of the custom terrain data added using addCustomTerrain	• current siteviewer or new siteviewer if none are open. • 'gmted2010' if called with an output.

Coordinate System	Valid map values	Default map value
`'cartesian'`	`'none'`, triangulation object or name of an STL file.	`'none'`

a. Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: `char` | `string`

Output Arguments

`az` — Azimuth angle between site 1 and site 2

M-by-*N* arrays

Azimuth angle between site 1 and site 2, returned as *M*-by-*N* arrays in degrees. *M* is the number of sites in sites 2 and *N* is the number of sites in sites 1. The azimuth angle is expressed in degrees counter-clockwise from the east (for geographic sites), or from the global x-axis around the global z-axis (for Cartesian sites), ranging from -180 to 180

`el` — Elevation angle between site 1 and site 2

M-by-*N* arrays

Elevation angle between site 1 and site 2, returned as *M*-by-*N* arrays in degrees. *M* is the number of sites in sites 2 and *N* is the number of sites in sites 1 The elevation angle is expressed in degrees from the horizontal (or X-Y) plane, ranging from -90 to 90.

When the path type specified is `'greatcircle'`, elevation angle is always zero.

See Also

`distance`

Introduced in R2019b

clearMap

Clear map visualizations

Syntax

```
clearMap(viewer)
```

Description

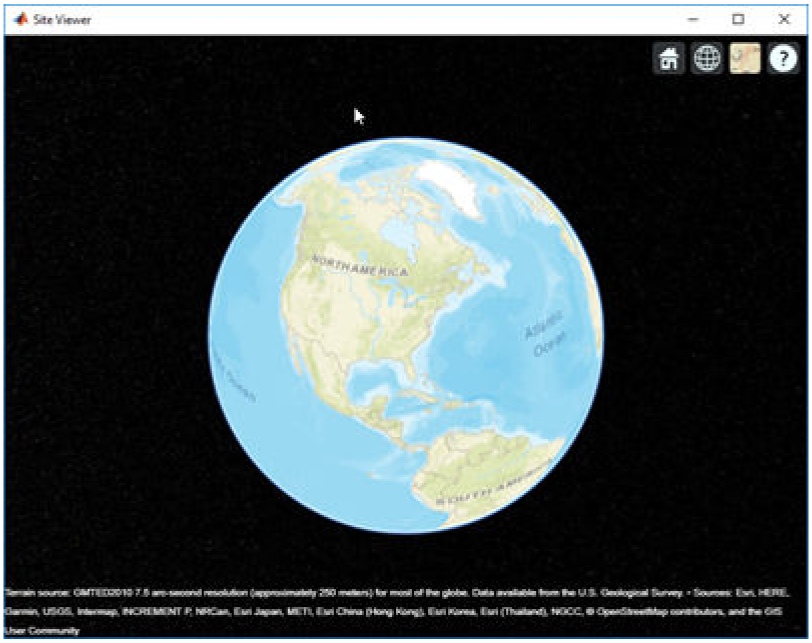
`clearMap(viewer)` removes all visualizations from the map.

Examples

View Transmitter Site On Site Viewer

1 Launch a Site Viewer with streets basemap.

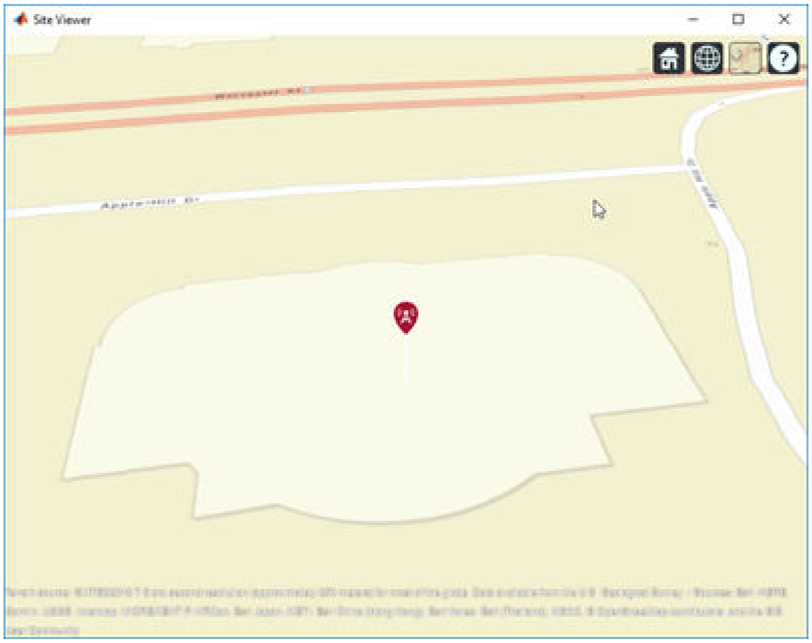
```
viewer = siteviewer("Basemap","streets");
```



Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Sources: Esri, HERE, Garmin, USGS, Intermap, INCREMENT P, NRCan, Esri Japan, METI, Esri China (Hong Kong), Esri Korea, Esri (Thailand), NGCC, © OpenStreetMap contributors, and the GIS User Community

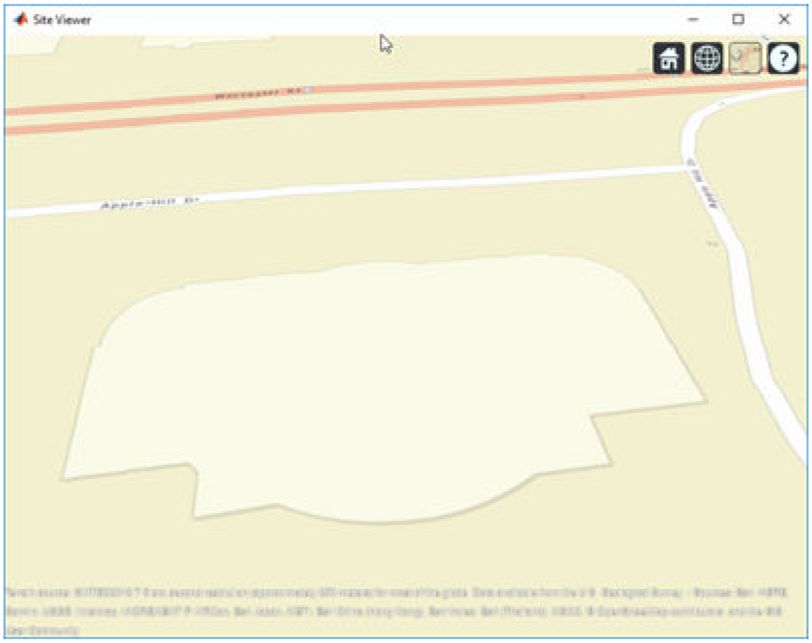
2 View a transmitter site on this map.

```
tx = txsite;
show(tx)
```



3 Clear the map.

```
t = timer('TimerFcn',@(~,~)disp('Fired.'),'StartDelay',3);
start(t)
wait(t)
clearMap(viewer)
```



Input Arguments

viewer — Map viewer for visualizing transmitter or receiver sites

siteviewer object

Map viewer for visualizing transmitter or receiver sites, specified as a `siteviewer` object.[1]

See Also

`close` | `siteviewer`

Introduced in R2019b

[1] Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

close

Close map viewer window

Syntax

```
close(viewer)
```

Description

`close(viewer)` closes the map viewer window and deletes the handle

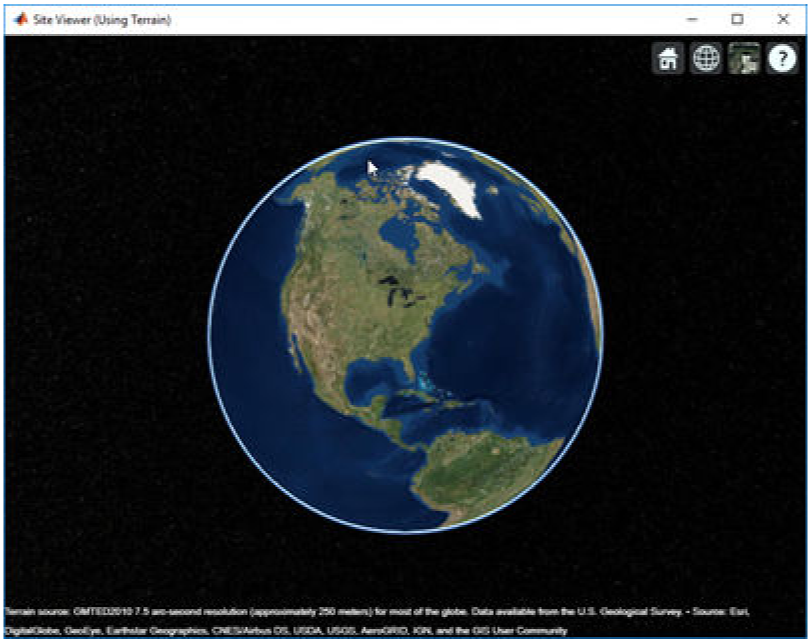
Examples

Compare Coverage Maps

Launch two Site Viewer windows.

One Site Viewer window uses the terrain model.

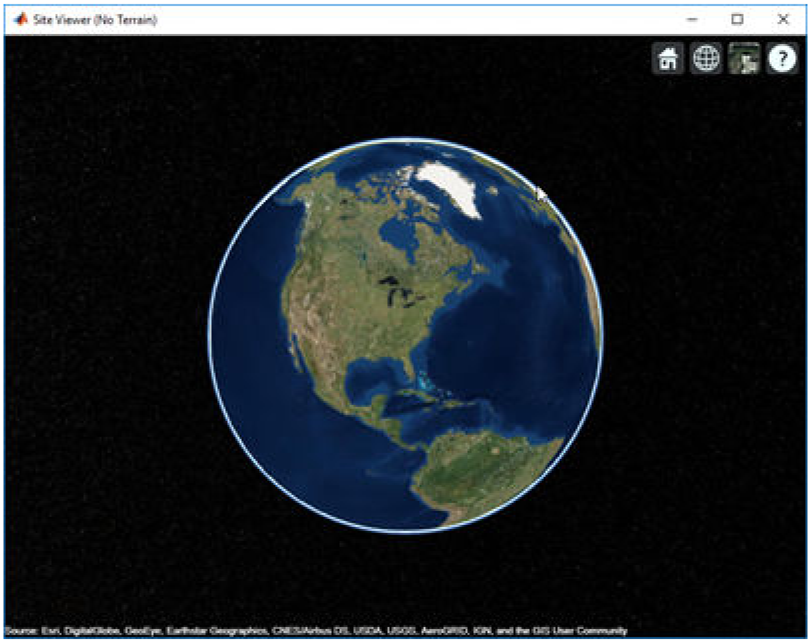
```
viewer1 = siteviewer("Terrain","gmted2010","Name","Site Viewer (Using Terrain)");
```



Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

The second Site Viewer window does not use the terrain model.

```
viewer2 = siteviewer("Terrain","none","Name","Site Viewer (No Terrain)");
```



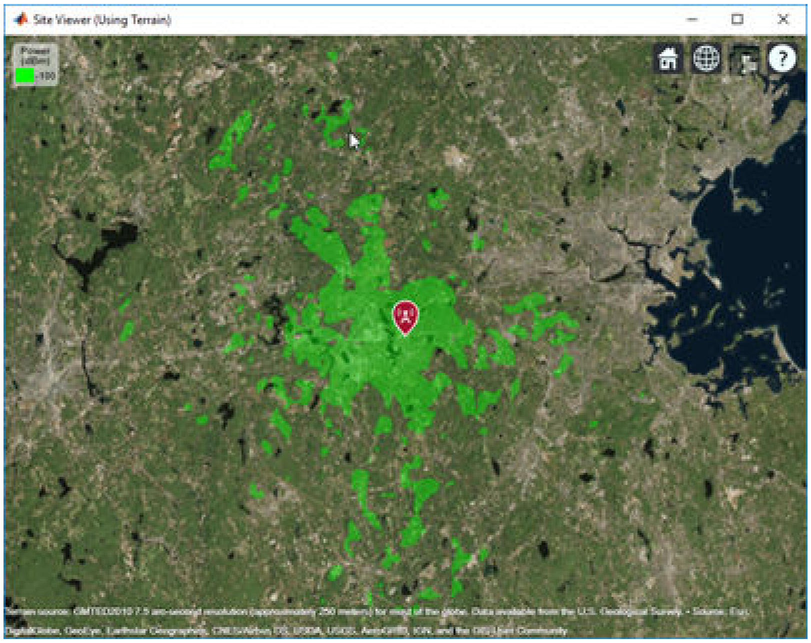
Site Viewer (No Terrain)
Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Create a transmitter site.

```
tx = txsite;
```

Generate a coverage map on each window. The map with terrain uses the Longley-Rice propagation model by default.

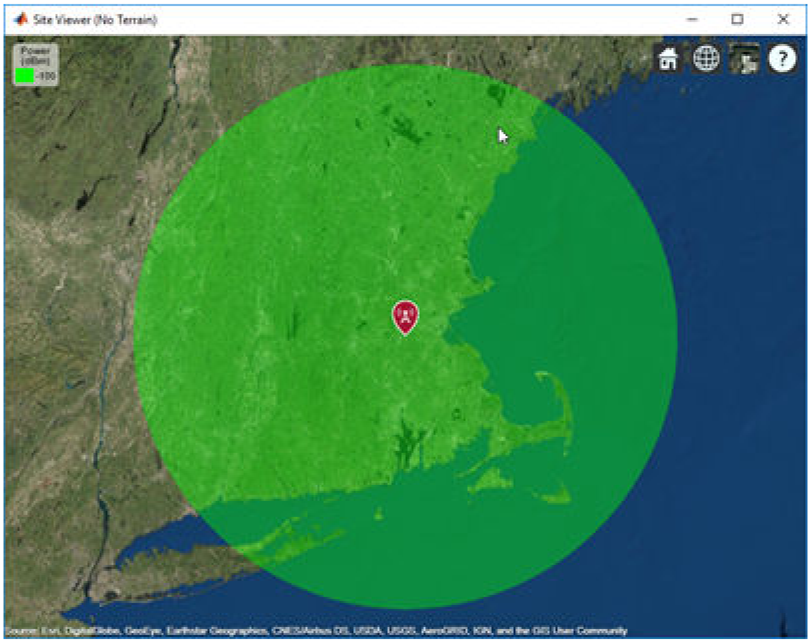
```
coverage(tx,"Map",viewer1)
```



Site Viewer (Using Terrain)
Power (dBm)
🟩 -100
Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

The map without terrain uses the free-space model by default.

```
coverage(tx,"Map",viewer2)
```



Site Viewer (No Terrain)
Power (dBm)
-100
Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Close the maps.

```
close(viewer1)
close(viewer2)
```

Input Arguments

`viewer` — Map viewer for visualizing transmitter or receiver sites

`siteviewer` object

Map viewer for visualizing transmitter or receiver sites, specified as a `siteviewer` object.[2]

See Also

`clearMap` | `siteviewer`

Introduced in R2019b

[2] Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

contour

Display contour map

Syntax

```
contour(pd)
contour( ___ ,Name,Value)
```

Description

`contour(pd)` creates a filled contour plot on a map. Contours are colored according to data values of corresponding locations.

`contour( ___ ,Name,Value)` creates a filled contour map with additional options specified by name-value pair arguments.

Examples

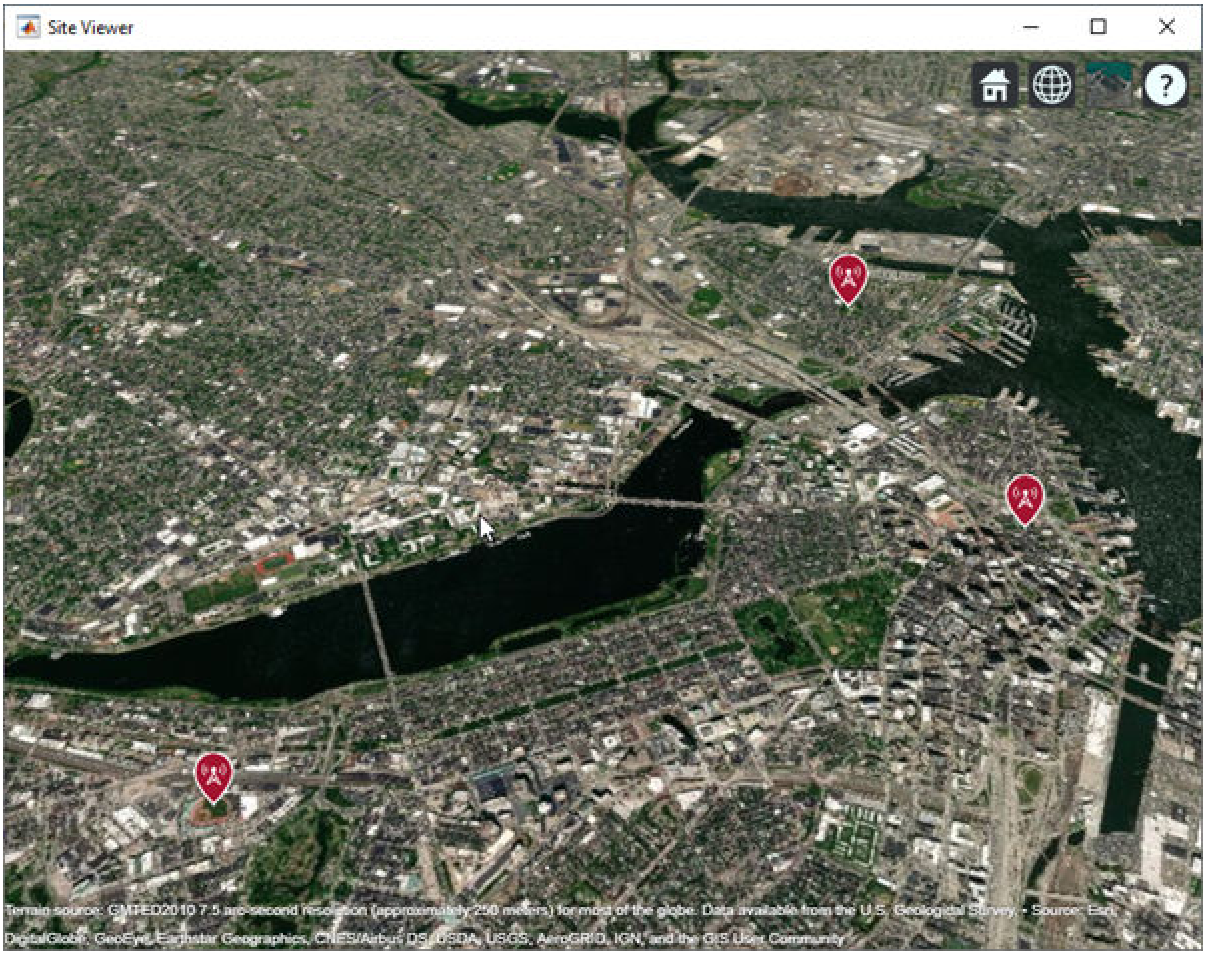
Capacity Map Using SINR Data

Define names and locations of sites around Boston.

```
names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"];
lats = [42.3467,42.3598,42.3763];
lons = [-71.0972,-71.0545,-71.0611];
```

Create an array of transmitter sites.

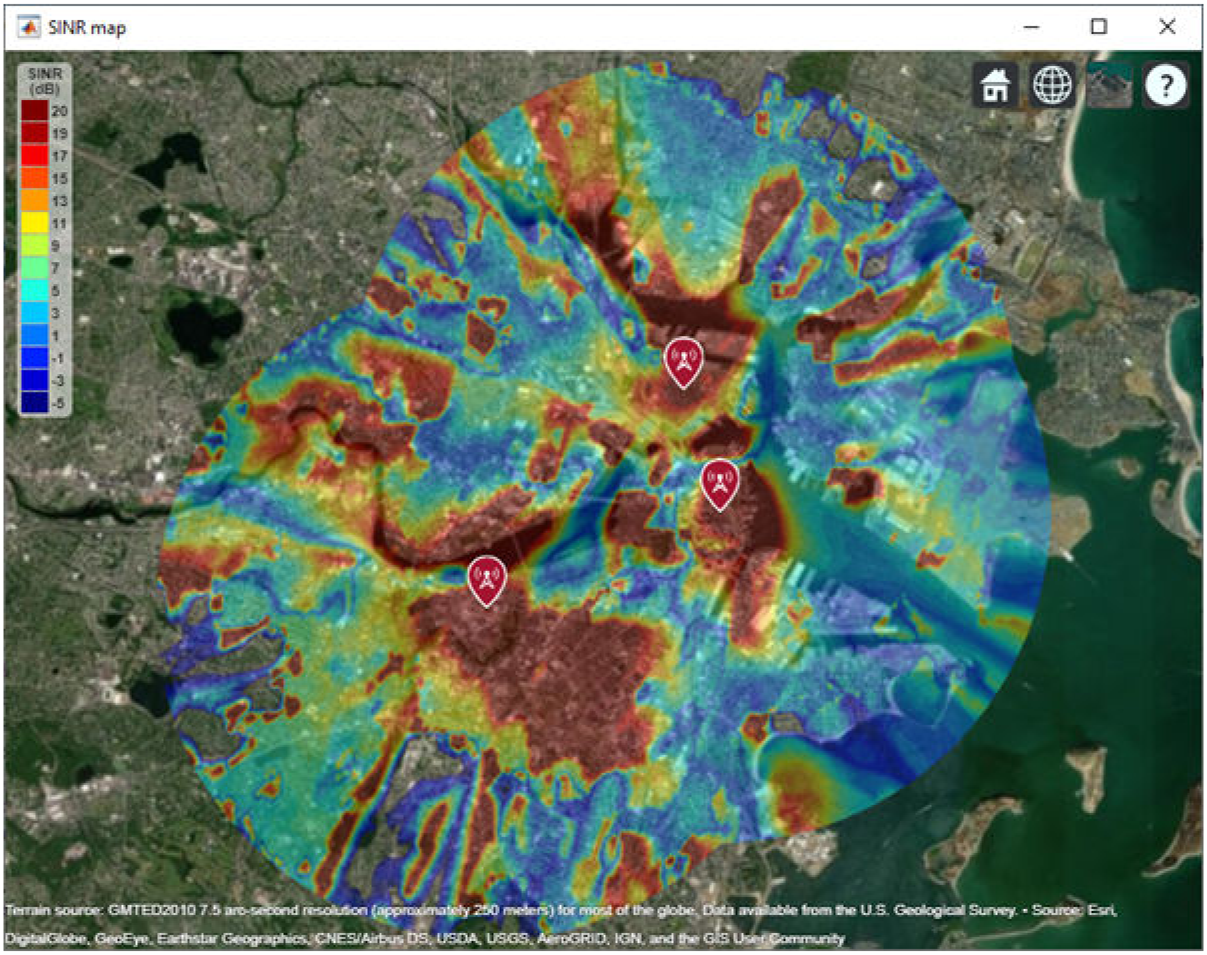
```
txs = txsite("Name",names,...
       "Latitude",lats,...
       "Longitude",lons, ...
       "TransmitterFrequency",2.5e9);
show(txs)
```



Site Viewer
Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. - Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Create a signal-to-interference-plus-noise-ratio (SINR) map, where signal source for each location is selected as the transmitter site with the strongest signal.

```
sv1 = siteviewer("Name","SINR map");
sinr(txs,"MaxRange",5000)
```



Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Return SINR propagation data.

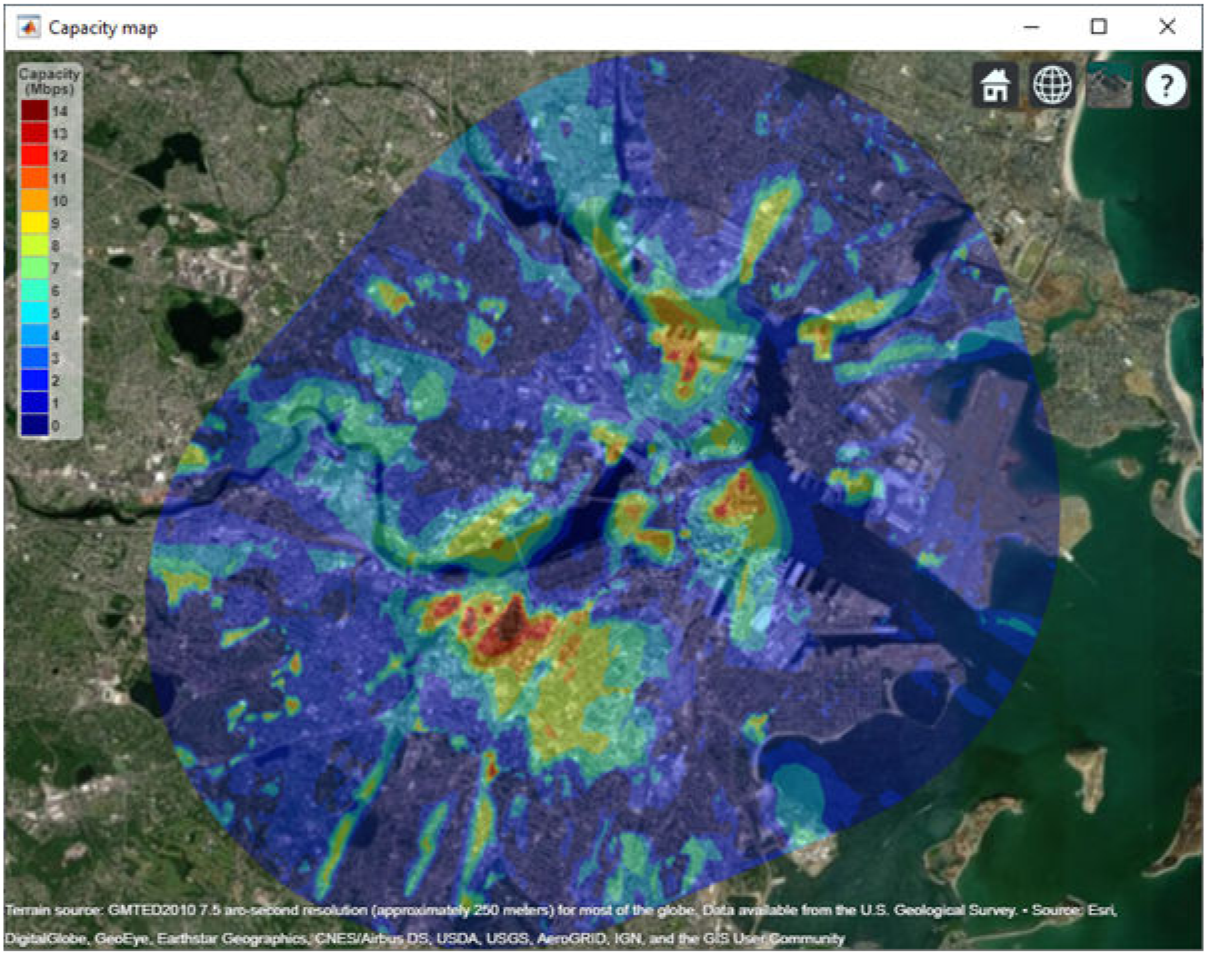
```
pd = sinr(txs,"MaxRange",5000);
[sinrDb,lats,lons] = getDataVariable(pd,"SINR");
```

Compute capacity using the Shannon-Hartley theorem.

```
bw = 1e6; % Bandwidth is 1 MHz
sinrRatio = 10.^(sinrDb./10); % Convert from dB to power ratio
capacity = bw*log2(1+sinrRatio)/1e6; % Unit: Mbps
```

Create new propagation data for the capacity map and display the contour plot.

```
pdCapacity = propagationData(lats,lons,"Capacity",capacity);
sv2 = siteviewer("Name","Capacity map");
legendTitle = "Capacity" + newline + "(Mbps)";
contour(pdCapacity,"LegendTitle",legendTitle);
```



Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Input Arguments

pd — Propagation data

`propagationData` object (default)

Propagation data, specified as a `propagationData` object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Type','power'`

DataVariableName — Data variable to contour map

`DataVariableName` (default) | character vector | string scalar

Data variable to contour map, specified as the comma-separated pair consisting of `'DataVariableName'` and a character vector or a string scalar corresponding to a variable name in the data table used to create the propagation data container object `pd`.

Data Types: char | string

Type — Type of value to plot
'custom' (default) | 'power' | 'efield' | 'sinr' | 'pathloss'

Type of value to plot, specified as the comma-separated pair consisting of 'Type' and one of the values in the 'Type' column:

Type	ColorLimits	LegendTitle
'custom'	[min(Data) max(Data)]	''
'power'	[-120 -5]	'Power (dBm)'
'efield'	[20 135]	'E-field (dBuV/m)'
'sinr'	[-5 20]	'SINR (dB)'
'pathloss'	[45 160]	'Path loss (dB)'

The default value for Levels is a linearly spaced vector bounded by ColorLimits.

Data Types: char | string

Levels — Data value levels to plot
numeric vector

Data value levels to plot, specified as the comma-separated pair consisting of 'Levels' and numeric vector. Each level is displayed as a different colored, filled contour on the map. The colors are selected using Colors if specified, or else Colormap and ColorLimits. Data points with values below the minimum level are not included in the plot.

The default value for Levels is a linearly spaced vector bounded by ColorLimits.

Data Types: double

Colors — Colors of data points
M-by-3 array of RGB | array of strings | cell array of character vectors

Colors of the filled contours, specified as the comma-separated pair consisting of 'Colors' and an M-by-3 array of RGB (red, blue, green) or an array of strings, or a cell array of character vectors. Colors are assigned element-wise to values in Levels for coloring the corresponding points. Colors cannot be used with Colormap and ColorLimits.

Data Types: double | char | string

Colormap — Color map for coloring points
'jet(256)' (default) | predefined colormap name | *M*-by-3 array of RGB triplets

Colormap for the coloring points, specified as the comma-separated pair consisting of 'Colormap' and a predefined colormap name or an *M*-by-3 array of RGB (red, blue, green) triplets that define *M* individual colors. Colormap cannot be used with Colors.

Data Types: double | char | string

ColorLimits — Color limits for color map
two-element vector

Color limits for the colormap, specified as the comma-separated pair consisting of `'ColorLimits'` and a two-element vector of the form [min max]. The color limits indicate the data level values that map to the first and last colors in the colormap. `ColorLimits` cannot be used with `Colors`.

Data Types: `double`

`Transparency` — Transparency of contour map
`0.4` (default) | numeric scalar in the range of [0,1]

Transparency of the contour plot, specified as a numeric scalar in the range [0,1], where `0` is completely transparent and `1` is completely opaque.

Data Types: `double`

`ShowLegend` — Show color legend on map
`true` (default) | `false`

Show color legend on map, specified as the comma-separated pair consisting of `'ShowLegend'` and `true` or `false`.

Data Types: `logical`

`LegendTitle` — Title of color legend
character vector | string scalar

Title of color legend, specified as the comma-separated pair consisting of `'LegendTitle'` and a character vector or a string scalar.

Data Types: `string` | `char`

`Map` — Map for surface data
`siteviewer` object

Map for surface data, specified as the comma-separated pair consisting of `'Map'` and a `siteviewer` object.[3] The default value is the current Site Viewer or a new Site Viewer, if none is open.

Data Types: `char` | `string`

coverage

Display coverage map

Syntax

```
coverage(txs)
coverage(txs,propmodel)
coverage(txs,rxs)
coverage(txs,rxs,propmodel)
coverage( ___ ,Name,Value, ___ )
pd = coverage(txs, ___ )
```

Description

`coverage(txs)` displays the coverage map for the transmitter site. Each colored contour of the map defines an area where the corresponding signal strength is transmitted to the mobile receiver.

Note This function only supports antenna sites with `CoordinateSystem` property set to `'geographic'`.

`coverage(txs,propmodel)` displays the coverage map based on the specified propagation model. The default propagation model is `'longley-rice'` when terrain is in use and `'freespace'` when terrain is not used.

`coverage(txs,rxs)` displays the coverage map based on the receiver site properties.

`coverage(txs,rxs,propmodel)` displays the coverage map based on the receiver site properties and specified propagation model.

`coverage( ___ ,Name,Value, ___ )` displays the coverage map using additional options specified by the `Name,Value` pairs.

`pd = coverage(txs, ___ )` returns computed coverage data in the propagation data object, `pd`. No plot is displayed and any graphical only name-value pairs are ignored.

Examples

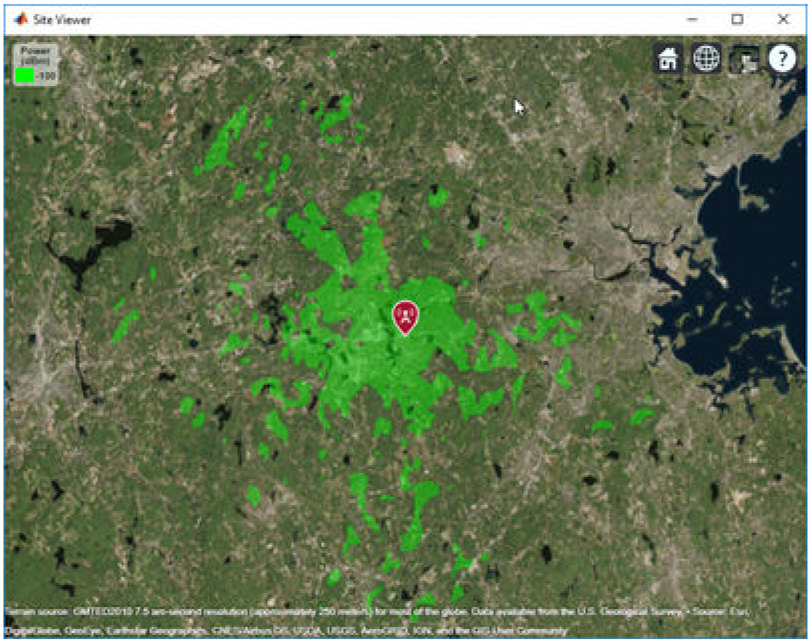
Coverage Map of Transmitter

Create a transmitter site at MathWorks headquarters.

```
tx = txsite('Name','MathWorks', ...
       'Latitude', 42.3001, ...
       'Longitude', -71.3503);
```

Show the coverage map.

```
coverage(tx)
```



Site Viewer

This coverage map shows new regions that are in service due to reflected propagation paths.

Appendix

[1] The osm file is downloaded from https://www.openstreetmap.org, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), https://opendatacommons.org/licenses/odbl/.

Input Arguments

txs — Transmitter sites

txsite object | array of txsite objects

Transmitter site, specified as a `txsite` object. Use array inputs to specify multiple sites.

This function only supports plotting antenna sites when `CoordinateSystem` property is set to `'geographic'`.

rxs — Receiver sites

rxsite object | array of rxsite objects

Receiver site, specified as a `rxsite` object. Use array inputs to specify multiple sites.

This function only supports plotting antenna sites when `CoordinateSystem` property is set to `'geographic'`.

`propmodel` — Propagation model

character vector | string

Propagation model, specified as a character vector or string. You can also use the name-value pair `'PropagationModel'` to specify this parameter. You can also use the `propagationModel` function to define this input. The default propagation model is `'longley-rice'` when terrain is enabled and `'freespace'` when terrain is disabled.

Data Types: `char` | `string`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Type','power'`

Type — Type of signal strength to compute

`'power'` (default) | `'efield'`

Type of signal strength to compute, specified as the comma-separated pair consisting of `'Type'` and `'power'` or `'efield'`.

When type is `'power'`, `SignalStrengths` is expressed in power units (dBm) of the signal at the mobile receiver input. When type is `'efield'`, `SignalStrengths` is expressed in electric field strength units (dBμV/m) of signal wave incident on the antenna.

Data Types: `char`

`SignalStrengths` — Signal strengths to display on coverage map

numeric vector

Signal strengths to display on coverage map, specified as the comma-separated pair consisting of `'SignalStrengths'` and a numeric vector.

Each strength uses different colored filled contour on the map. The default value is `-100` dBm if the `'Type'` name-value pair is `'power'` and `40` dBμV/m if `'Type'` is `'efield'`.

Data Types: `double`

`PropagationModel` — Propagation model to use for path loss calculations

`'longley-rice'` (default) | `'freespace'` | `'close-in'` | `'rain'` | `'gas'` | `'fog'` | `'raytracing-image-method'` | propagation model object

Propagation model to use for the path loss calculations, specified as the comma-separated pair consisting of `'PropagationModel'` and one of the following:

- `'freespace'` - Free space propagation model
- `'rain'` - Rain propagation model
- `'gas'` - Gas propagation model
- `'fog'` - Fog propagation model
- `'close-in'` - Close-in propagation model
- `'longley-rice'` - Longley-Rice propagation model

- 'tirem' - Tirem propagation model
- 'raytracing-image-method' - -Raytracing propagation model using method of images.

The default propagation model is 'longley-rice' when terrain is enabled and 'freespace' when terrain is disabled. If 'raytracing-image-method' is specified, the value of 'MaxNumReflections' property must be lesser than 1.

Data Types: char

MaxRange — Maximum range of coverage map from each transmitter site

numeric scalar

Maximum range of coverage map from each transmitter site, specified as a positive numeric scalar in meters representing great circle distance. MaxRange defines the region of interest on the map to plot. The default value is automatically computed based on the propagation model type as shown:

Propagation Model	MaxRange
Basic or urban	Range of minimum value in SignalStrengths.
Terrain	30 km or distance to the furthest building.
Multipath	500 m

Data Types: double

Resolution — Resolution of coverage map

'auto' (default) | numeric scalar

Resolution of coverage map, specified as the comma-separated pair consisting of 'Resolution' and a numeric scalar in meters.

The resolution of 'auto' computes the maximum value scaled to 'MaxRange'. Decreasing the resolution increases the quality of the coverage map and the time required to create it.

Data Types: char | double

ReceiverGain — Mobile receiver gain

2.1 (default) | numeric scalar

Mobile receiver gain, specified as the comma-separated pair consisting of 'ReceiverGain' and a numeric scalar in dB. The receiver gain value includes the mobile receiver antenna gain and system loss.

The receiver gain computes received signal strength when the 'Type' is 'power'.

If receiver site argument rx is passed to coverage, the default value is the maximum gain of the receiver antenna with the system loss subtracted. Otherwise the default value is 2.1.

Data Types: char | double

ReceiverAntennaHeight — Mobile receiver antenna height above ground elevation

1 (default) | numeric scalar

Mobile receiver antenna height above ground elevation, specified as the comma-separated pair consisting of 'ReceiverAntennaHeight' and a numeric scalar in meters.

If receiver site argument `rx` is passed to coverage, the default value is the `AntennaHeight` of the receiver. Otherwise the default value is 1.

Data Types: `double`

`Colors` — Colors of filled contours on coverage map
M-by-3 array of RGB triplets | array of strings | cell array of character vectors

Filled contours color of coverage map, specified as the comma-separated pair consisting of `'Colors'` and an *M*-by-3 array of RGB triplets, an array of strings, or a cell array of character vectors.

Colors are assigned element-wise to `'SignalStrengths'` values for coloring the corresponding filled contours.

`'Colors'` cannot be used with `'ColorLimits'` or `'ColorMap'`.

For more information, see `ColorSpec (Color Specification)`.

Data Types: `char` | `string` | `double`

`ColorLimits` — Color limits for colormap
two-element vector

Color limits for colormap, specified as the comma-separated pair consisting of `'ColorLimits'` and a two-element vector of type `[min max]`.

The color limits indicate the signal level values that map to the first and last colors on the colormap.

The default value is `[-120 -5]` if the `'Type'` name-value pair is `'power'` and `[20 135]` if `'Type'` is `'efields'`.

`'ColorLimits'` cannot be used with `'Color'`.

Data Types: `double`

`ColorMap` — Colormap filled contours for coverage map
`'jet'` (default) | predefined color map | *M*-by-3 array of RGB triplets

Colormap filled contours on coverage map, specified as the comma-separated pair consisting of `'ColorMap'` and a predefined colormap or *M*-by-3 array of RGB triplets, where *M* defines individual colors.

`'ColorMap'` cannot be used with `'Colors'`.

Data Types: `char` | `double`

`ShowLegend` — Show signal strength color legend on map
`true` (default) | `false`

Show signal strength color legend on map, specified as the comma-separated pair consisting of `'ShowLegend'` and `true` or `false`.

Data Types: `logical`

`Transparency` — Transparency of coverage map
`0.4` (default) | numeric scalar

Transparency of coverage map, specified as the comma-separated pair consisting of `'Transparency'` and a numeric scalar in the range `0` to `1`. `0` is transparent and `1` is opaque.

Data Types: `double`

`Map` — Map for visualization of surface data
`siteviewer` object

Map for visualization of surface data, specified as the comma-separated pair consisting of `'Map'` and a `siteviewer` object.[4]

Data Types: `char` | `string`

Output Arguments

pd — Coverage data
`propagationData` object

Coverage data, returned as a `propagationData` object consisting of *Latitude* and *Longitude*, and a signal strength variable corresponding to the plot type. Name of the `propagationData` is `"Coverage Data"`.

`link` | `propagationModel` | `sigstrength` | `sinr`

Topics
`ColorSpec (Color Specification)`

Introduced in R2019b

[4] Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

distance

Distance between sites

Syntax

```
d = distance(site1,site2)
d = distance(site1,site2,path)
d = distance( ___ ,Name,Value)
```

Description

`d = distance(site1,site2)` returns the distance in meters between site1 and site2.

`d = distance(site1,site2,path)` returns the distance using a specified path type, either Euclidean or great circle path.

`d = distance( ___ ,Name,Value)` returns the distance with additional options specified by name-value pairs.

Examples

Distance Between Transmitter and Receiver Site

Create transmitter and receiver sites.

```
tx = txsite('Name','MathWorks','Latitude',42.3001,'Longitude',-71.3504);
rx = rxsite('Name','Fenway Park','Latitude',42.3467,'Longitude',-71.0972);
```

Get the Euclidean distance in km between the sites.

```
dme = distance(tx,rx)
```

```
dme = 2.1504e+04
```

```
dkm = dme / 1000
```

```
dkm = 21.5037
```

Get the great circle distance between the two sites.

```
dmg = distance(tx,rx,'greatcircle')
```

```
dmg = 2.1451e+04
```

Input Arguments

site1,site2 — Transmitter or receiver site
txsite or rxsite object

Transmitter or receiver site, specified as a `txsite` or `rxsite`. You can use array inputs to specify multiple sites.

`path` — Measurement path type
`'euclidean'` | `'greatcircle'`

Measurement path type, specified as one of the following:

- `'euclidean'`: Uses the shortest path through space that connects the antenna center positions of the site 1 and site 2.
- `'greatcircle'`: Uses the shortest path on the surface of the earth that connects the latitude and longitude locations of site 1 and site 2. This path uses a spherical Earth model.

Data Types: `char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Map','siteviewer1'`

`Map` — Map for visualization or surface data
`siteviewer` object | terrain name

Map for visualization or surface data, specified as the comma-separated pair consisting of `'Map` and one of the following depending on the coordinate system:

Coordinate System	Valid map values	Default map value
`'geographic'`	• `siteviewer`[a] • A terrain name may be specified if the function is called with an output argument. Valid terrain names are `'none'`, `'gmted2010'`, or the name of the custom terrain data added using `addCustomTerrain`	• current siteviewer or new siteviewer if none are open. • `'gmted2010'` if called with an output.
`'cartesian'`	`'none'`, triangulation object or name of an STL file.	`'none'`

[a] Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: `char` | `string`

Output Arguments

d — Distance between sites
M-by-*N* numeric array

Distance between sites, returned as *M*-by-*N* arrays in degrees. *M* is the number of sites in site 2 and *N* is the number of sites in site 1.

See Also

`angle`

Introduced in R2019b

elevation

Elevation of site

Syntax

```
z = elevation(site)
z = elevation( ___ ,Name,Value)
```

Description

`z = elevation(site)` returns the ground or building surface elevation of antenna site in meters. Elevation is measured relative to mean sea level using earth gravitational model, EGM-96. If the site coincides with a building, elevation is measured at the top of the building. Otherwise, elevation is measured at the ground.

Note This function only supports antenna sites with `CoordinateSystem` property set to `'geographic'`.

`z = elevation( ___ ,Name,Value)` returns the ground elevation of the antenna in meters with additional options specified by name-value pairs.

Examples

Elevation at Mount Washington

Compute and display the elevation at Mount Washington in meters.

```
mtwash = txsite('Name','Mt Washington','Latitude',44.2706, ...
       'Longitude',-71.3033);
z = elevation(mtwash)
```

```
z = 1.8675e+03
```

Input Arguments

`site` — Transmitter or receiver site

`txsite` or `rxsite` object | array of `txsite` or `rxsite` objects

Transmitter or receiver site, specified as a `txsite` or `rxsite` object or an array of `txsite` or `rxsite` objects.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: 'Map','siteviewer1'

Map — Map for visualization or surface data
siteviewer object | terrain name

Map for visualization or surface data, specified as the comma-separated pair consisting of 'Map and one of the following depending on the coordinate system:

Coordinate System	Valid map values	Default map value
'geographic'	• siteviewer[a] • A terrain name may be specified if the function is called with an output argument. Valid terrain names are 'none', 'gmted2010', or the name of the custom terrain data added using addCustomTerrain	• current siteviewer or new siteviewer if none are open. • 'gmted2010' if called with an output.
'cartesian'	'none', triangulation object or name of an STL file.	'none'

[a] Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: char | string

Output Arguments

z — Ground or building surface elevation of antenna site
M-by-1 matrix

Ground or building surface elevation of the antenna site, returned as an *M*-by-1 matrix with each element unit in meters. *M* is the number of sites in site.

See Also

angle | distance | rxsite | txsite

Introduced in R2019b

getDataVariable

Get data variable values of data points in propagation data object

Syntax

```
datavariable = getDataVariable(pd)
[datavariable,lat,lon] = getDataVariable(pd)
[ ___ ] = getDataVariable(pd,varname)
```

Description

`datavariable = getDataVariable(pd)` returns the values of the data points in the propagation data object. The data is processed such that the missing values are removed and duplicate location data are replaced with mean values.

`[datavariable,lat,lon] = getDataVariable(pd)` returns the location coordinates of the data points in the propagation data object.

`[ ___ ] = getDataVariable(pd,varname)` returns the values of the data points corresponding to the `varname` variable.

Examples

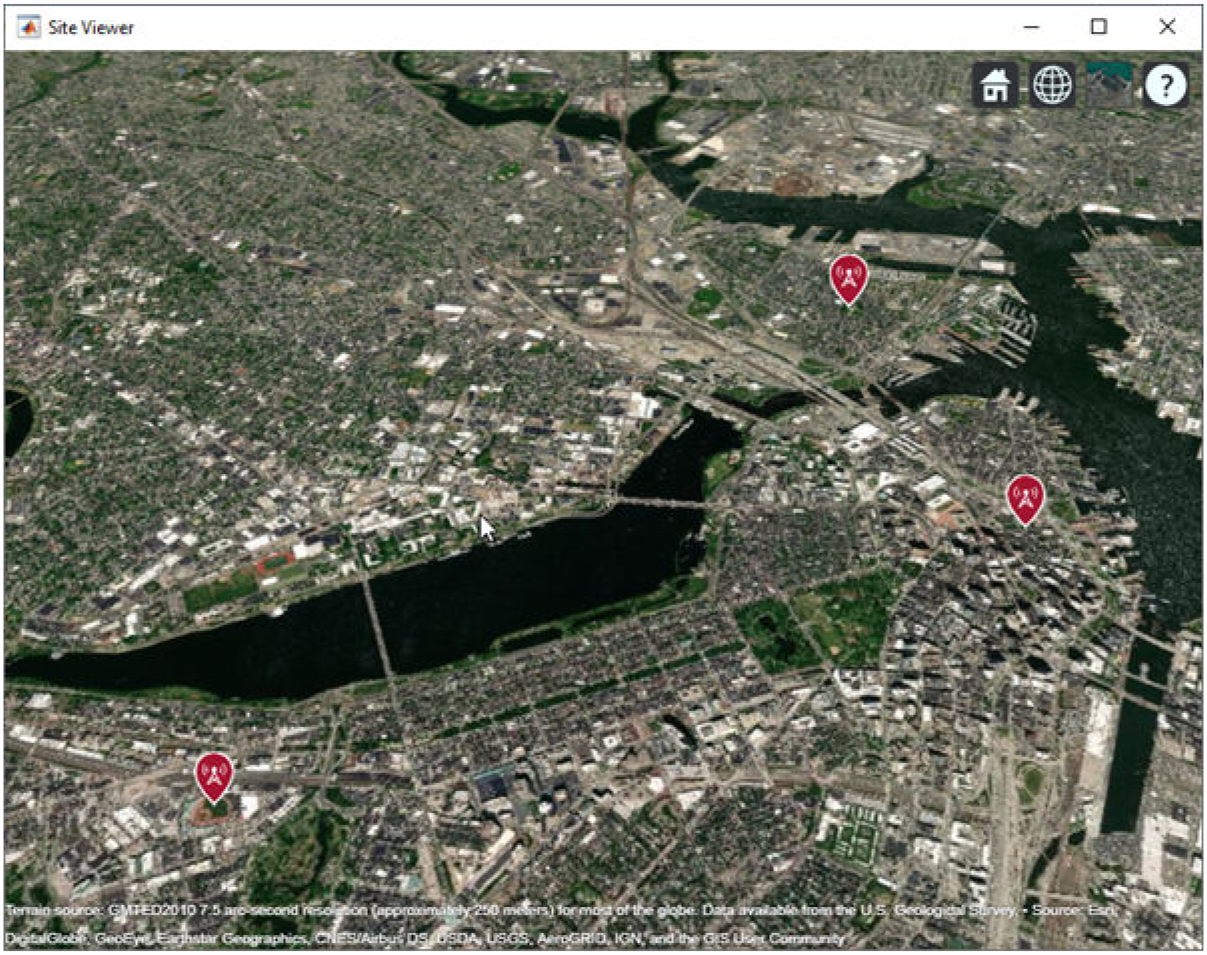
Capacity Map Using SINR Data

Define names and locations of sites around Boston.

```
names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"];
lats = [42.3467,42.3598,42.3763];
lons = [-71.0972,-71.0545,-71.0611];
```

Create an array of transmitter sites.

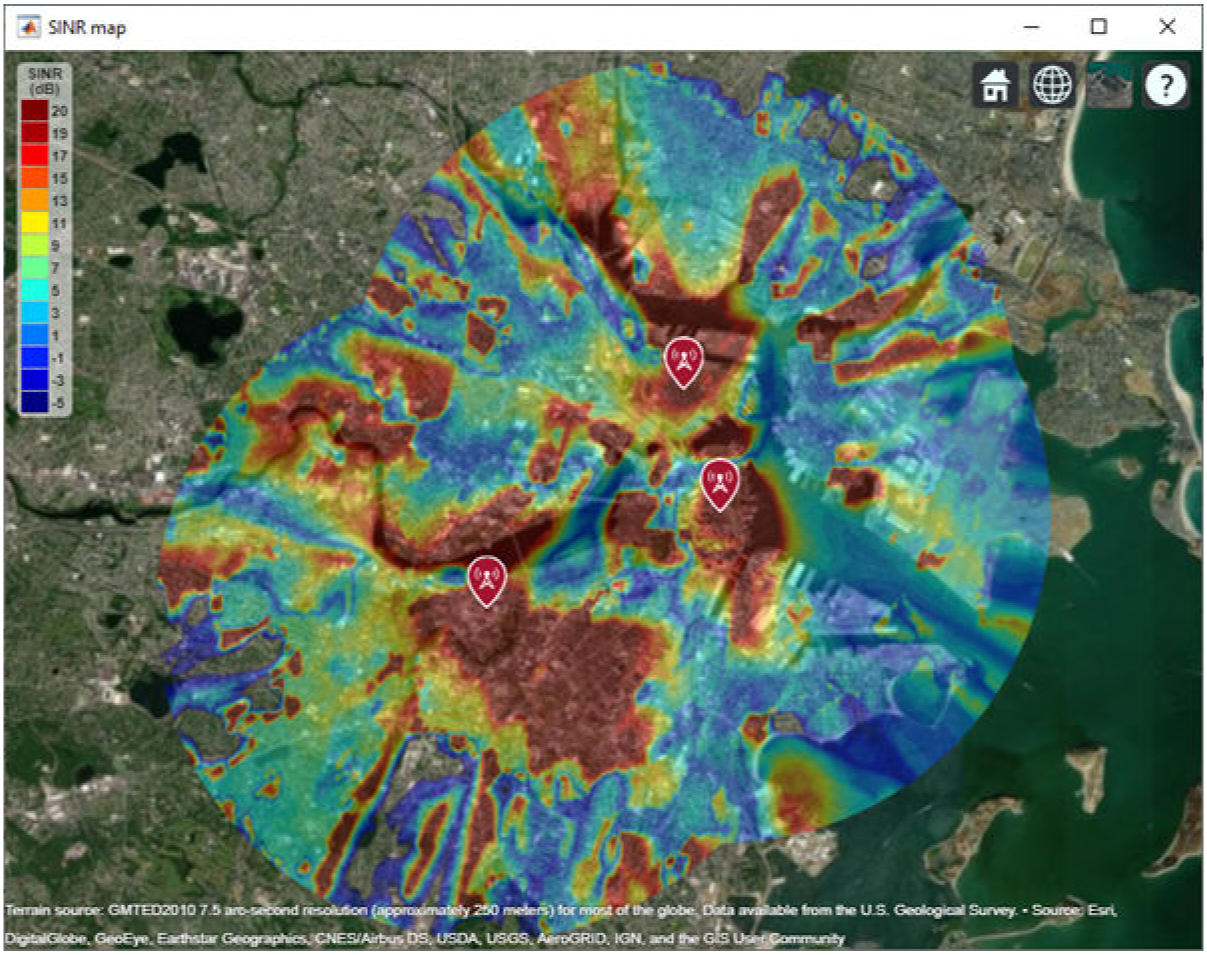
```
txs = txsite("Name",names,...
       "Latitude",lats,...
       "Longitude",lons, ...
       "TransmitterFrequency",2.5e9);
show(txs)
```



Site Viewer
Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. - Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Create a signal-to-interference-plus-noise-ratio (SINR) map, where signal source for each location is selected as the transmitter site with the strongest signal.

```
sv1 = siteviewer("Name","SINR map");
sinr(txs,"MaxRange",5000)
```



Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Return SINR propagation data.

```
pd = sinr(txs,"MaxRange",5000);
[sinrDb,lats,lons] = getDataVariable(pd,"SINR");
```

Compute capacity using the Shannon-Hartley theorem.

```
bw = 1e6; % Bandwidth is 1 MHz
sinrRatio = 10.^(sinrDb./10); % Convert from dB to power ratio
capacity = bw*log2(1+sinrRatio)/1e6; % Unit: Mbps
```

Create new propagation data for the capacity map and display the contour plot.

```
pdCapacity = propagationData(lats,lons,"Capacity",capacity);
sv2 = siteviewer("Name","Capacity map");
legendTitle = "Capacity" + newline + "(Mbps)";
contour(pdCapacity,"LegendTitle",legendTitle);
```

Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Input Arguments

pd — Propagation data

`propagationData` object (default)

Propagation data, specified as a `propagationData` object.

`varname` — Variable name in data table

character vector | string scalar

Variable name in the data table, specified as a character vector or a string scalar. This variable name must correspond to a variable with numeric data other than the latitude or longitude data.

Output Arguments

`datavariable` — Values of data points

column vector

Values of data points in the propagation data object, returned as a column vector.

`lat` — Latitude of data points
M-by-1 vector

Latitude of data points, returned as an *M*-by-`1` vector with each element unit in degrees.

`lon` — Longitude of data points
M-by-1 vector

Longitude of data points, returned as an *M*-by-`1` matrix with each element unit in degrees. The output is wrapped so that the values are in the range `[-180 180]`.

Introduced in R2020a

hide

Hide site location on map

Syntax

```
hide(site)
hide(___,Name,Value)
```

Description

`hide(site)` hides the site location of the antenna site on a map.

Note This function only supports antenna sites with `CoordinateSystem` property set to `'geographic'`.

`hide(___,Name,Value)` hides the site location with additional options specified by one or more name-value pairs.

Examples

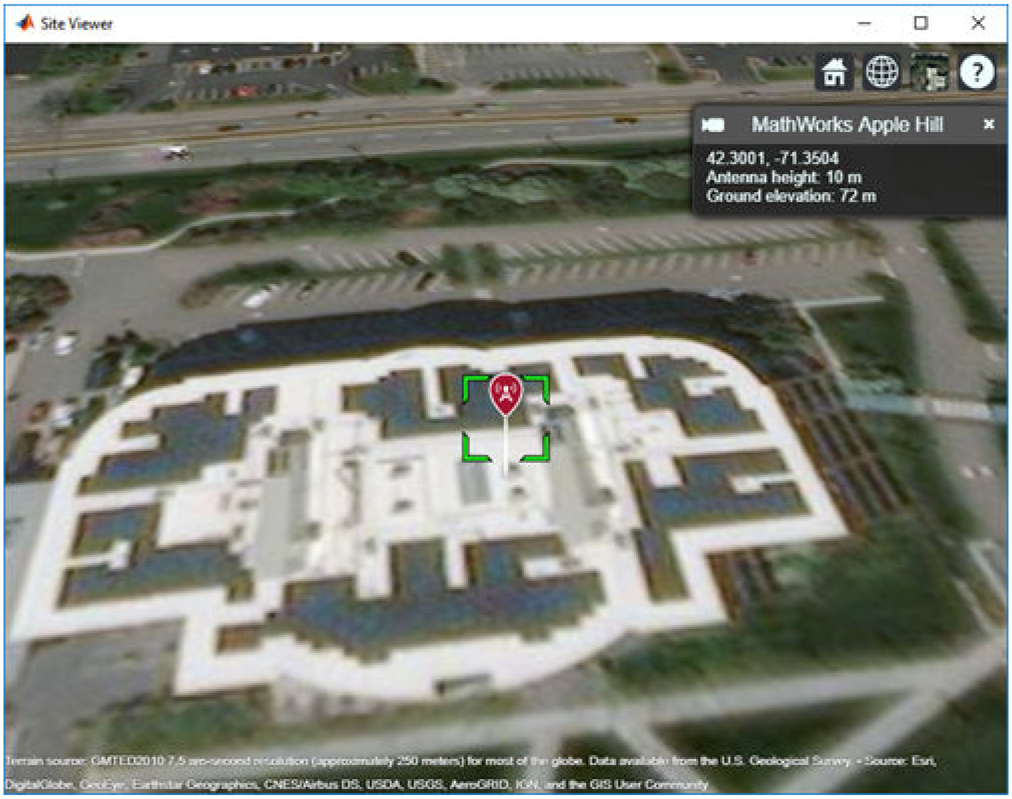
Show and Hide Transmitter Site

Create a transmitter site.

```
tx = txsite('Name','MathWorks Apple Hill',...
       'Latitude',42.3001, ...
       'Longitude',-71.3504);
```

Show the transmitter site.

```
show(tx)
```



Site Viewer

Input Arguments

`site` — Transmitter or receiver site
`txsite` or `rxsite` object | array of `txsite` or `rxsite` objects

Transmitter or receiver site, specified as a `txsite` or `rxsite` object or an array of `txsite` or `rxsite` objects.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Map','siteviewer1'`

`Map` — Map for visualization of surface data
`siteviewer` object

Map for visualization of surface data, specified as the comma-separated pair consisting of `'Map'` and a `siteviewer` object.[5]

Data Types: `char` | `string`

[5] Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

See Also

`show`

Introduced in R2019b

interp

Geographic data interpolation

Syntax

```
interpvalue = interp(pd,lat,lon)
interpvalue = interp(pd,Name,Value)
```

Description

`interpvalue = interp(pd,lat,lon)` returns interpolated values from the propagation data for each query point specified in latitude and longitude vectors. The interpolation is performed using a scattered data interpolation method. Values corresponding to query points outside the data region are assigned a `NaN`.

`interpvalue = interp(pd,Name,Value)` returns interpolated values with additional options specified by name-value pair arguments.

Examples

Transmitter Site Service Areas

Define names and locations of sites around Boston.

```
names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"];
lats = [42.3467,42.3598,42.3763];
lons = [-71.0972,-71.0545,-71.0611];
```

Create array of transmitter sites.

```
txs = txsite("Name", names,...
       "Latitude",lats,...
       "Longitude",lons, ...
       "TransmitterFrequency",2.5e9);
```

Compute received power data for each transmitter site.

```
maxr = 20000;
pd1 = coverage(txs(1),"MaxRange",maxr);
pd2 = coverage(txs(2),"MaxRange",maxr);
pd3 = coverage(txs(3),"MaxRange",maxr);
```

Compute rectangle containing locations of all data.

```
locs = [location(pd1); location(pd2); location(pd3)];
[minlatlon, maxlatlon] = bounds(locs);
```

Create grid of locations over rectangle.

```
gridlength = 300;
latv = linspace(minlatlon(1),maxlatlon(1),gridlength);
```

```
lonv = linspace(minlatlon(2),maxlatlon(2),gridlength);
[lons,lats] = meshgrid(lonv,latv);
lats = lats(:);
lons = lons(:);
```

Get data for each transmitter at grid locations using interpolation.

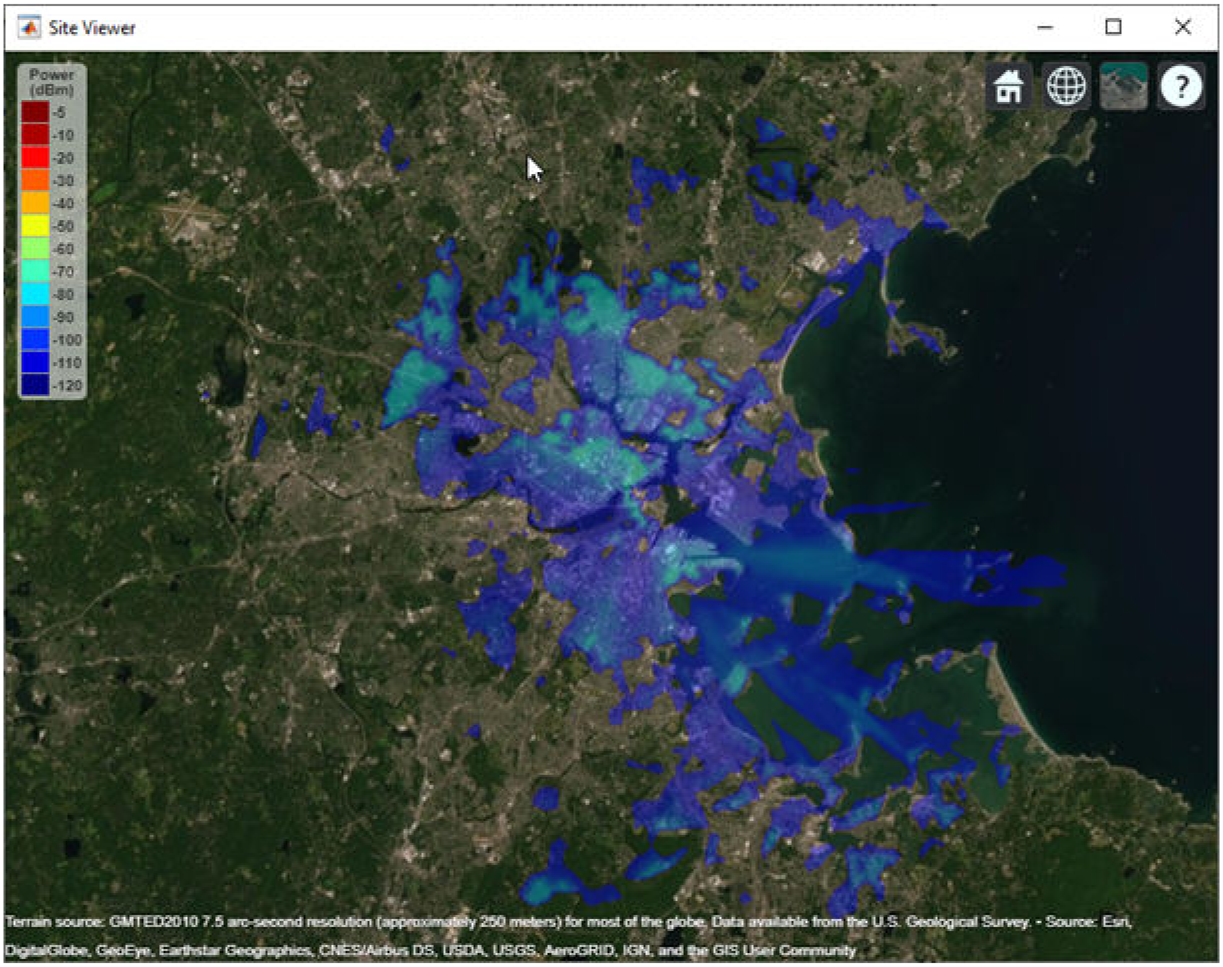
```
v1 = interp(pd1,lats,lons);
v2 = interp(pd2,lats,lons);
v3 = interp(pd3,lats,lons);
```

Create propagation data containing minimum received power values.

```
minReceivedPower = min([v1 v2 v3],[],2,"includenan");
pd = propagationData(lats,lons,"MinReceivedPower",minReceivedPower);
```

Plot minimum received power, which shows the weakest signal received from any transmitter site. The area shown may correspond to the service area of triangulation using the three transmitter sites.

```
sensitivity = -110;
contour(pd,"Levels",sensitivity:-5,"Type","power")
```



Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. - Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Input Arguments

pd — Propagation data
propagationData object (default)

Propagation data, specified as a propagationData object.

lat — Latitude coordinate values
vector

Latitude coordinate values, specified as a vector in decimal degrees with reference to Earth's ellipsoid. model WGS-84. The latitude coordinates must be in the range [-90 90].

lon — Longitude coordinate values
vector

Longitude coordinate values, specified as a vector in decimal degrees with reference to Earth's ellipsoid. model WGS-84.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Method','linear'

DataVariableName — Data variable to interpolate
character vector | string scalar

Data variable to interpolate, specified as the comma-separated pair consisting of 'DataVariableName' and a character vector or string scalar corresponding to a variable name in the data table used to create the propagationData container object. The default value is the DataVariableName property in the propagationData.

Data Types: char | string

Method — Method used to interpolate data
'natural' (default) | 'nearest' | 'linear'

Method used to interpolate data, specified as the comma separated-pair consisting 'Method' and one of the following:

- 'natural' - Natural neighbor interpolation
- 'linear' - Linear interpolation
- 'nearest' - Nearest neighbor interpolation

Data Types: char | string

Output Arguments

interpvalue — Interpolated values from propagation data
numeric vector

Interpolated values from the propagation data for each query point specified in latitude and longitude vectors, returned as a numeric vector.

Introduced in R2020a

link

Display communication link on map

Syntax

```
link(rx,tx)
link(rx,tx,propmodel)
link( ___ ,Name,Value)
status = link( ___ )
```

Description

`link(rx,tx)` plots a one-way point-to-point communication link between a receiver site and transmitter site. The plot is color coded to identify the link success status.

`link(rx,tx,propmodel)` plots the communication link based on the specified propagation model.

`link( ___ ,Name,Value)`plots a communication link using additional options specified by `Name,Value` pairs.

`status = link( ___ )` returns the success status of the communication link as `true` or `false`.

Examples

Communication Link Between Transmitter and Receiver

Create a transmitter site.

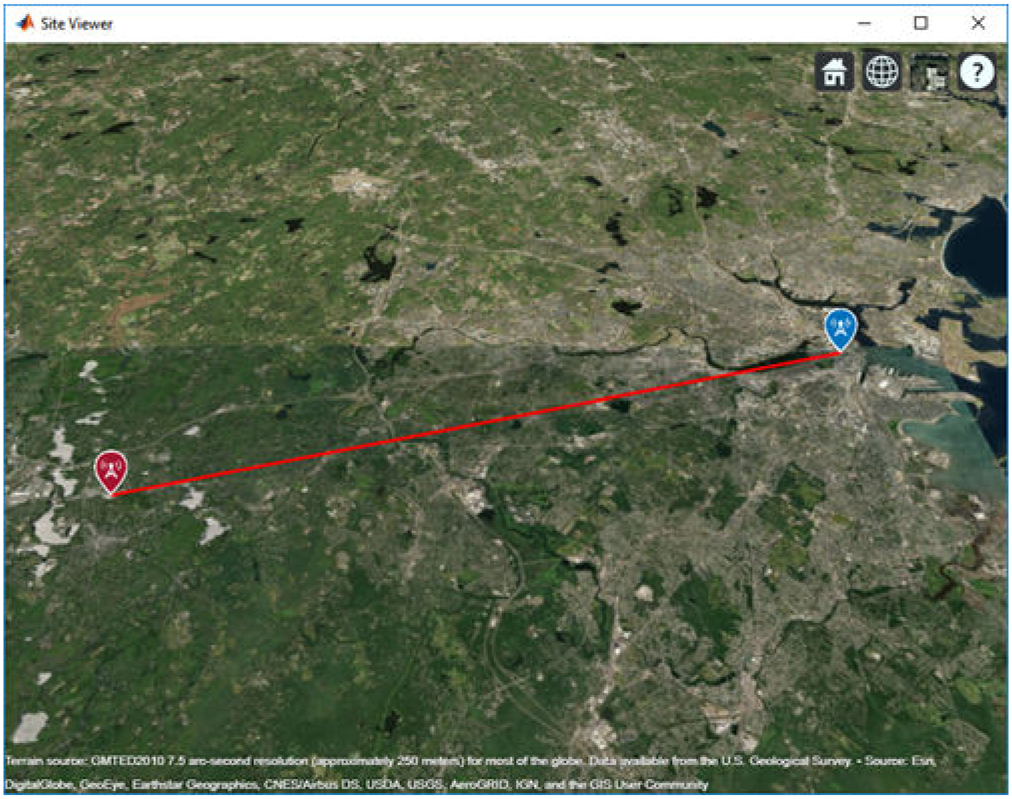
```
tx = txsite('Name','MathWorks', ...
        'Latitude', 42.3001, ...
        'Longitude', -71.3503);
```

Create a receiver site with sensitivity defined in dBm.

```
 rx = rxsite('Name','Boston', ...
        'Latitude', 42.3601, ...
        'Longitude', -71.0589, ...
        'ReceiverSensitivity', -90);
```

Plot the communication link between the transmitter and the receiver.

```
link(rx,tx)
```



Site Viewer
Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Input Arguments

rx — Receiver site

`rxsite` object | array of `rxsite` objects

Receiver site, specified as a `rxsite` object. You can use array inputs to specify multiple sites.

tx — Transmitter site

`txsite` object | array of `txsite` objects

Transmitter site, specified as a `txsite` object. You can use array inputs to specify multiple sites.

propmodel — Propagation model

character vector | string

Propagation model, specified as a character vector or string. You can use the `propagationModel` function to define this input. The default value depends on the coordinate system used by the input sites:

Coordinate System	Default propagation model value
`'geographic'`	• `'longley-rice'` when you use a terrain. • `'freespace'` when you do not use a terrain.

Coordinate System	Default propagation model value
'cartesian'	• 'freespace' when Map is set to none. • 'raytracing-image-method' when Map is set to the name of an STL file or a triangulation object.

You can also use the name-value pair 'PropagationModel' to specify this parameter.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Type','power'

PropagationModel — Propagation model to use for path loss calculations

'longley-rice' (default) | 'freespace' | 'close-in' | 'rain' | 'gas' | 'fog' | 'raytracing-image-method' | propagation model object

Propagation model to use for the path loss calculations, specified as the comma-separated pair consisting of 'PropagationModel' and one of the following:

- 'freespace' - Free space propagation model
- 'rain' - Rain propagation model
- 'gas' - Gas propagation model
- 'fog' - Fog propagation model
- 'close-in' - Close-in propagation model
- 'lonley-rice' - Longely-Rice propagation model
- 'tirem' - Tirem propagation model
- 'ray-tracing-image-method' - -Raytracing propagation model using method of images.

The default propagation model is 'longley-rice' when terrain is enabled and 'freespace' when terrain is disabled.

Terrain propagation models including 'longley-rice' and 'tirem' are only supported for sites with CoordinateSystem property set to 'geographic'.

Data Types: char

SuccessColor — Color of successful links

'green' (default) | RGB triplet | character vector

Color of successful links, specified as the comma-separated pair consisting of 'SuccessColor and an RGB triplet or character vector. For more information, see ColorSpec (Color Specification).

Data Types: char | double

FailColor — Color of unsuccessful links

'red' (default) | RGB triplet | character vector

Color of unsuccessful links, specified as the comma-separated pair consisting of `'FailColor` and RGB triplet or character vector. For more information, see `ColorSpec (Color Specification)`.

Data Types: `char` | `double`

`Map` — Map for visualization or surface data
`siteviewer` object | terrain name

Map for visualization or surface data, specified as the comma-separated pair consisting of `'Map` and one of the following depending on the coordinate system:

Coordinate System	Valid map values	Default map value
`'geographic'`	• `siteviewer`[a] • A terrain name may be specified if the function is called with an output argument. Valid terrain names are `'none'`, `'gmted2010'`, or the name of the custom terrain data added using `addCustomTerrain`	• current siteviewer or new siteviewer if none are open. • `'gmted2010'` if called with an output.
`'cartesian'`	`'none'`, triangulation object or name of an STL file.	`'none'`

[a] Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: `char` | `string`

Output Arguments

`status` — Success status of communication link
M-by-*N* array

Success status of communication links, returned as an *M*-by-*N* arrays. *M* is the number of transmitter sites and *N* is the number of receiver sites.

`ColorSpec (Color Specification)`

Introduced in R2019b

location

Location coordinates at a given distance and angle from site

Syntax

```
sitelocation = location(site)
[lat,lon] = location(site)
[ ___ ] = location(site,distance,azimuth)
```

Description

`sitelocation = location(site)` returns the site location of the antenna.

`[lat,lon] = location(site)` returns the latitude and longitude of the antenna site.

Note This syntax only supports antenna sites with `CoordinateSystem` property set to `'geographic'`.

`[ ___ ] = location(site,distance,azimuth)` returns the new location achieved by moving the antenna site by the distance specified in the direction of the azimuth angle. The location is calculated by moving along a great circle path using a spherical Earth model.

Note This syntax only supports antenna sites with `CoordinateSystem` property set to `'geographic'`.

Examples

Location of Antenna Site

Create a site 1 km north of a given site.

Create the first transmitter site.

```
tx = txsite('Name','MathWorks', ...
       'Latitude',42.3001, ...
       'Longitude',-71.3504);
```

Calculate the location 1 km north of the first site.

```
[lat,lon] = location(tx,1000,90)
```

```
lat = 42.3091
```

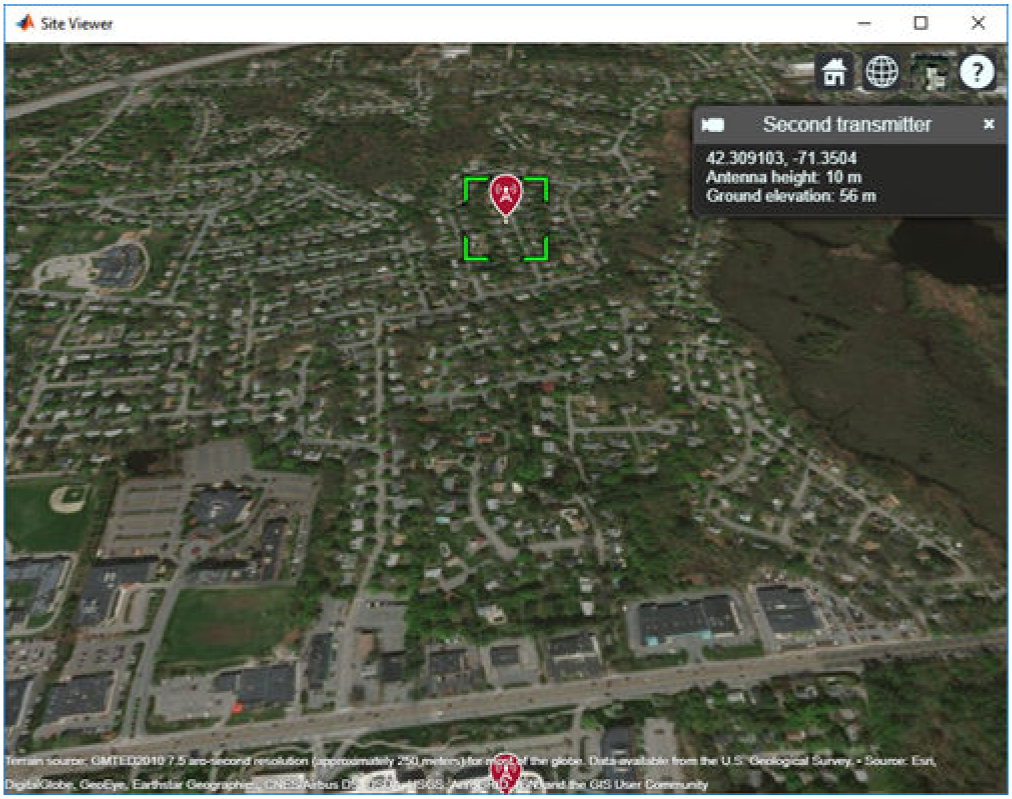
```
lon = -71.3504
```

Create a second transmitter site at the location specified by `lat` and `lon`.

```
tx2 = txsite('Name','Second transmitter', ...
       'Latitude',lat, ...
       'Longitude',lon);
```

Show the two transmitter sites.

```
show([tx,tx2])
```



Site Viewer
Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Second transmitter

42.309103, -71.3504
Antenna height: 10 m
Ground elevation: 56 m

Input Arguments

site — Antenna site

scalar | array

Antenna site, specified as a scalar or an array. It is either a txsite or a rxsite object. For more information, see `txsite`, and `rxsite`

Note If `distance` or `azimuth` is a vector, then site must be a scalar.

distance — Distance to move antenna site

scalar | vector

Distance to move antenna site, specified as a scalar or vector in meters.

azimuth — Azimuth angle

scalar | vector

Azimuth angle, specified as a scalar or vector in degrees. Azimuth angle is measured counterclockwise from due east.

Output Arguments

`sitelocation` — Location of antenna site

M-by-2 matrix

Location of antenna site, returned as an *M*-by-`2` matrix with each element unit in degrees. *M* is the number of sites in sites. The location value includes the latitude and longitude of the antenna site.

If the antenna site has the `CoordinateSystem` property set to `'geographic'`, *L* is a 1-by-2 vector in degrees latitude and longitude. The output longitude wrapped so that values are in the range `[-180 180]`. If SITE has `CoordinateSystem` set to `'cartesian'`, *L* is a 1-by-3 vector.

`lat` — Latitude of one or more antenna sites

M-by-1 vector

Latitude of one or more antenna sites, returned as an *M*-by-`1` vector with each element unit in degrees. *M* is the number of sites in `site`.

`lon` — Longitude of one or more antenna sites

M-by-1 matrix

Longitude of one or more antenna sites, returned as an *M*-by-`1` matrix with each element unit in degrees. *M* is the number of sites in `site`. The output is wrapped so that the values are in the range `[-180 180]`.

`angle` | `distance` | `rxsite` | `txsite`

Introduced in R2019b

los

Plot or compute the line-of-sight (LOS) visibility between sites on a map

Syntax

```
los(site1,site2)
los(site1,site2,Name,Value)
vis = los(site1,site2,Name,Value)
```

Description

`los(site1,site2)` plots the LOS from site 1 to site 2. The plot is color coded to identify the visibility of the points along the LOS.

`los(site1,site2,Name,Value)` sets properties using one or more name-value pairs. For example, `los(site1,site2,'ObstructedColor','red')` plots the LOS using red to show blocked visibility.

`vis = los(site1,site2,Name,Value)` returns the status of the LOS visibility.

Examples

LOS from a Transmitter Site to a Receiver Site

Plot the LOS from the MathWorks Apple Hill campus to the MathWorks Lakeside campus.

Create a transmitter site with an antenna of height 30 m.

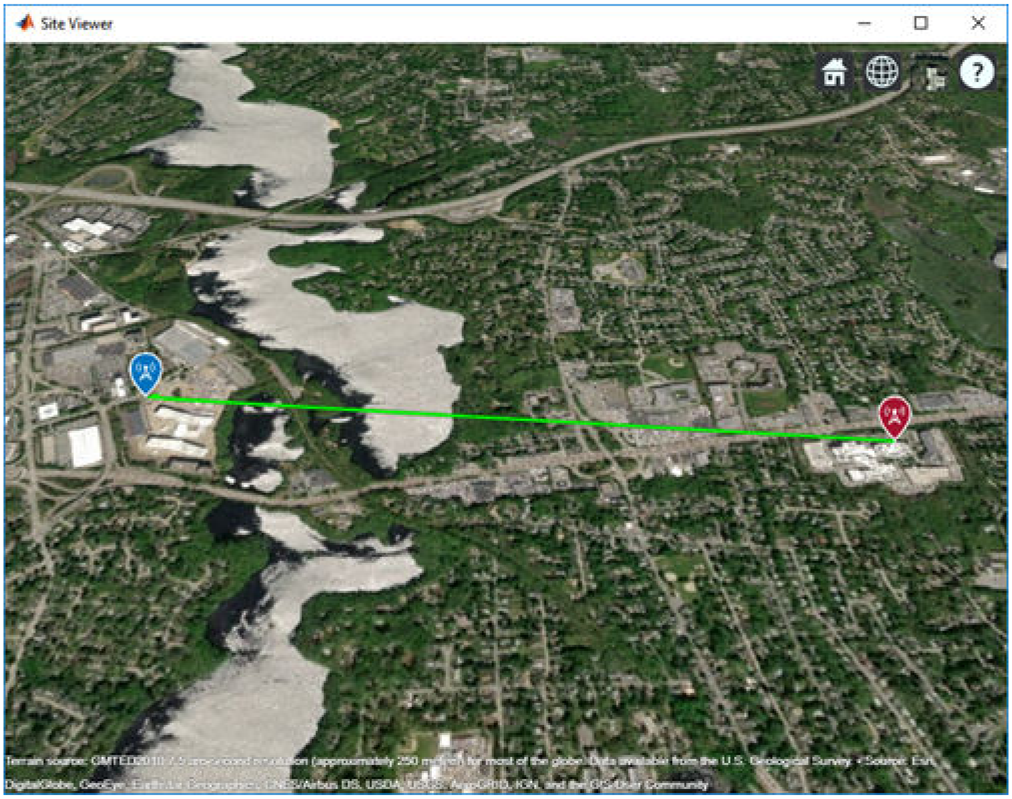
```
tx = txsite('Name','MathWorks Apple Hill',...
          'Latitude',42.3001,'Longitude',-71.3504,'AntennaHeight',30);
```

Create a receiver site with an antenna at ground level.

```
rx = rxsite('Name','MathWorks Lakeside', ...
           'Latitude',42.3021,'Longitude',-71.3764);
```

Plot the LOS between the two sites.

```
los(tx,rx);
```



Site Viewer
Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

LOS from a Transmitter Site to Two Receiver Sites

Create a transmitter site with an antenna of height 30 m.

```
tx = txsite('Name','MathWorks Apple Hill',...
          'Latitude',42.3001,'Longitude',-71.3504,'AntennaHeight',30);
```

Create two receiver sites with antennas at ground level.

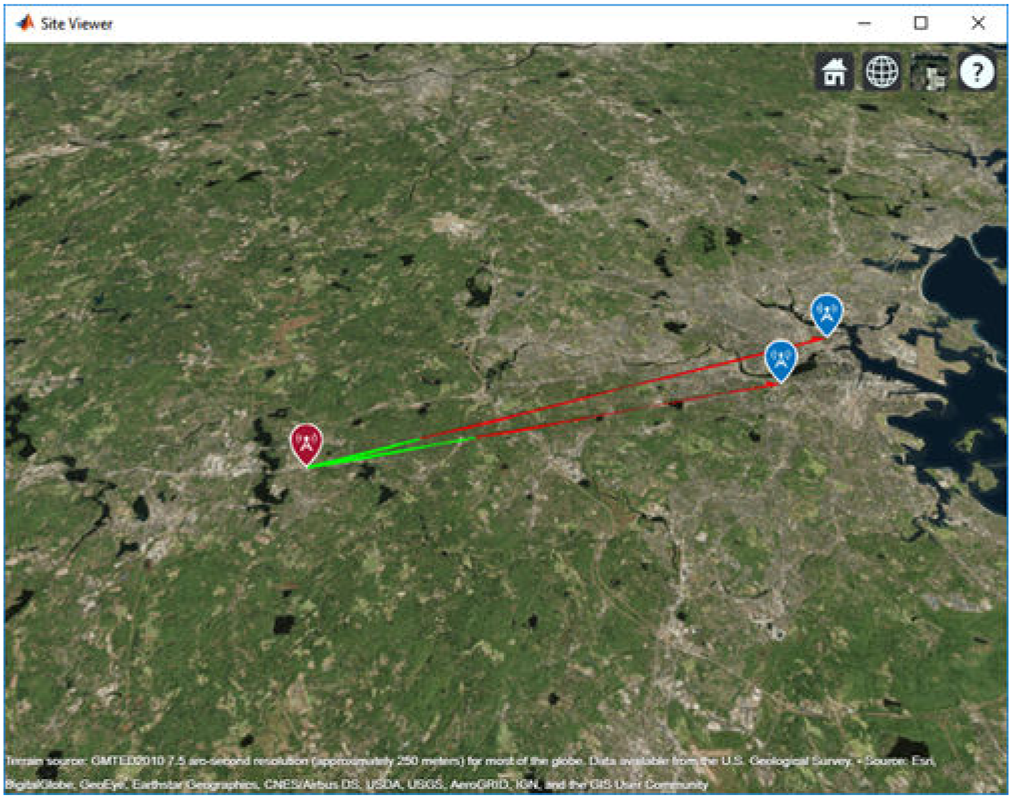
```
names = ["Fenway Park","Bunker Hill Monument"];
lats = [42.3467,42.3763];
lons = [-71.0972,-71.0611];
```

Create the receiver site array.

```
rxs = rxsite('Name', names,...
      'Latitude',lats,...
      'Longitude',lons);
```

Plot the lines of sight to the receiver sites. The red portion of the LOS represents obstructed visibility.

```
los(tx,rxs);
```



Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Input Arguments

`site1` — Source antenna site

`txsite` object | `rxsite` object

Source antenna site, specified as a `txsite` object or a `rxsite` object. Site 1 must be a single site object.

`site2` — Target antenna site

`txsite` object | `rxsite` object | vector of `txsite` or `rxsite` objects

Target antenna site, specified as a `txsite` object or a `rxsite` object. Site 2 can be a single site object or a vector of multiple site objects.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'ObstructedColor','blue'`

`VisibleColor` — Plot color for successful visibility

`'green'` (default) | RGB triplet | character vector | color name string

Plot color for successful visibility, specified as an RGB triplet, a character vector, or a color name specified as a string. For more information, see `ColorSpec (Color Specification)`.

`ObstructedColor` — Plot color for blocked visibility

`'red'` (default) | RGB triplet | character vector | color name string

Plot color for blocked visibility, specified as an RGB triplet, a character vector, or a color name specified as a string. For more information, see `ColorSpec (Color Specification)`.

`Resolution` — Sampling distance between two sites

`'auto'` (default) | numeric scalar

Resolution of sample locations used to compute line-of-sight visibility, specified as `'auto'` or a numeric scalar expressed in meters. `Resolution` defines the distance between samples on the great circle path using a spherical Earth model. If `Resolution` is `'auto'`, the function computes a value based on the distance between the sites.

`Map` — Map for visualization or surface data

`siteviewer` object | terrain name

Map for visualization or surface data, specified as the comma-separated pair consisting of `'Map` and one of the following depending on the coordinate system:

Coordinate System	Valid map values	Default map value
`'geographic'`	• `siteviewer`[a] • A terrain name may be specified if the function is called with an output argument. Valid terrain names are `'none'`, `'gmted2010'`, or the name of the custom terrain data added using `addCustomTerrain`	• current siteviewer or new siteviewer if none are open. • `'gmted2010'` if called with an output.
`'cartesian'`	`'none'`, triangulation object or name of an STL file.	`'none'`

[a] Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: `char` | `string`

Output Arguments

`vis` — Status of LOS visibility

`'true'` | `'false'` | *n*-by 1 logical array

Status of LOS visibility, returned as `'true'` or `'false'`. If there are multiple target sites, the function returns a logical array of *n*-by-1.

`ColorSpec (Color Specification)`

Introduced in R2019b

pathloss

Path loss of radio wave propagation

Syntax

```
pl = pathloss(propmodel,rx,tx)
pl = pathloss( ___ ,Name,Value)
[pl,info] = pathloss( ___ )
```

Description

`pl = pathloss(propmodel,rx,tx)` returns the path loss of radio wave propagation at the receiver site from the transmitter site.

`pl = pathloss( ___ ,Name,Value)` returns the path loss using additional options specified by `Name,Value` pairs.

`[pl,info] = pathloss( ___ )` returns the path loss and the information about the propagation paths.

Examples

Path Loss of Receiver In Heavy Rain

Specify the transmitter and the receiver sites.

```
tx = txsite('Name','MathWorks Apple Hill',...
       'Latitude',42.3001, ...
       'Longitude',-71.3504, ...
       'TransmitterFrequency', 2.5e9);

rx = rxsite('Name','Fenway Park',...
       'Latitude',42.3467, ...
       'Longitude',-71.0972);
```

Create the propagation model for heavy rainfall rate.

```
pm = propagationModel('rain','RainRate',50)
```

```
pm = 
  Rain with properties:

    RainRate: 50
        Tilt: 0
```

Calculate the pathloss at the receiver using the rain propagation model.

```
pl = pathloss(pm,rx,tx)
```

```
pl = 127.1559
```

Input Arguments

`propmodel` — Propagation model

character vector or string

Propagation model, specified as a character vector or string.

Data Types: `char`

`rx` — Receiver site

`rxsite` object

Receiver site, specified as a `rxsite` object. You can use array inputs to specify multiple sites.

Data Types: `char`

`tx` — Transmitter site

`txsite` object

Transmitter site, specified as a `txsite` object. You can use array inputs to specify multiple sites.

Data Types: `char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Map','none'`

`Map` — Map for visualization or surface data

`siteviewer` object | terrain name

Map for visualization or surface data, specified as the comma-separated pair consisting of `'Map` and one of the following depending on the coordinate system:

Coordinate System	Valid map values	Default map value
`'geographic'`	• `siteviewer`[a] • A terrain name may be specified if the function is called with an output argument. Valid terrain names are `'none'`, `'gmted2010'`, or the name of the custom terrain data added using `addCustomTerrain`	• current siteviewer or new siteviewer if none are open. • `'gmted2010'` if called with an output.
`'cartesian'`	`'none'`, triangulation object or name of an STL file.	`'none'`

[a] Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: `char` | `string`

Output Arguments

pl — Path loss
scalar | *M*-by-*N* arrays

Path loss, returned as a scalar or *M*-by-*N* cell arrays containing a row vector of path loss values in decibels. *M* is the number of TX sites and *N* is the number of RX sites.

Path loss is computed along the shortest path shortest path through space connecting the transmitter and receiver antenna centers.

For terrain propagation models, path loss is computed using terrain elevation profile that is computed at sample locations on the great circle path between the transmitter and the receiver. If `Map` is a `siteviewer` object with buildings specified, the terrain elevation is adjusted to include the height of the buildings.

`info` — Information corresponding to each propagation path
M-by-*N* struct array | *M*-by-*N* cell array containing vector of structs in each cell

Information corresponding to each propagation path, returned as a *M*-by-*N* cell array containing vector of structs in each cell for `ray-tracing-image-method` propagation model and *M*-by-*N* struct array fro all other propagation models. The field and values for the structures are:

- `PropagationDistance` - Total distance of propagation path returned as a double scalar in meters.
- `AngleOfDeparture` - Angle of departure of signal from transmitter site antenna returned as a 2-by-1 double vector of azimuth and elevation angles in degrees.
- `AngleOfArrival` - Angle of arrival of signal at receiver site antenna returned as a 2-by-1 double vector of azimuth and elevation angles in degrees.
- `NumReflections` - Number of reflections undergone by signal along propagation path, returned specified as `0`, `1`, or `2`. This field and value is only for `raytrtacing-image-method`.

Angle values in this structure are defined using the antenna's local East-North-Up coordinate system when `CoordinateSystem` is set to `geographic`. Angle values in this structure are defined using global Cartesian coordinate system when `CoordinateSystem` is set to `cartesian`. Azimuth angle is measured either from east (when `'geographic'`) or from the global x-axis around the global z-axis (when `'cartesian'`). Elevation angle is measured from the horizontal (or X-Y) plane to the antenna's x-axis in the range -90 to 90.

See Also

`propagationModel` | `range`

Introduced in R2019b

plot

Plot propagation data on map

Syntax

```
plot(pd)
plot(___,Name,Value)
```

Description

`plot(pd)` plots the propagation data on a map. Each data point is displayed as a circular marker that is colored according to the corresponding value.

`plot(___,Name,Value)` plots the propagation data with additional options specified by name-value pair arguments.

Examples

Compute Signal Strength Data in Urban Environment

Launch Site Viewer with basemaps and building files for Manhattan. For more information about the osm file, see [1] on page 4-0 .

```
viewer = siteviewer("Basemap","streets_dark",...
        "Buildings","manhattan.osm");
```

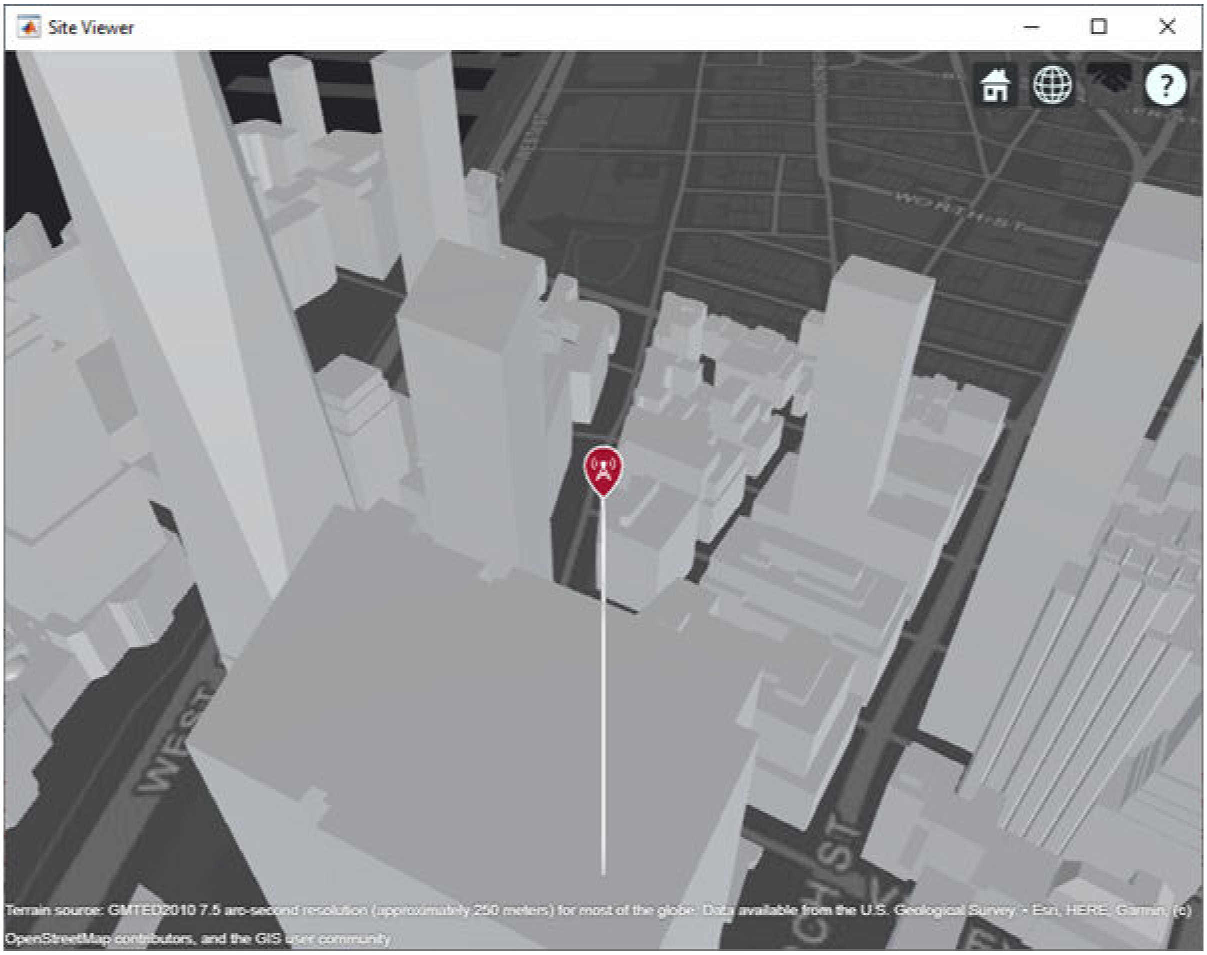
Show a transmitter site on a building.

```
tx = txsite("Latitude",40.7107,...
        "Longitude",-74.0114,...
        "AntennaHeight",80);
show(tx)
```



Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Esri, HERE, Garmin, (c) OpenStreetMap contributors, and the GIS user community

Create receiver sites along nearby streets.

```
latitude = [linspace(40.7088, 40.71416, 50), ...
        linspace(40.71416, 40.715505, 25), ...
        linspace(40.715505, 40.7133, 25), ...
        linspace(40.7133, 40.7143, 25)]';
longitude = [linspace(-74.0108, -74.00627, 50), ...
        linspace(-74.00627 ,-74.0092, 25), ...
        linspace(-74.0092, -74.0110, 25), ...
        linspace(-74.0110, -74.0132, 25)]';
rxs = rxsite("Latitude", latitude, "Longitude", longitude);
```

Compute signal strength at each receiver location.

```
signalStrength = sigstrength(rxs, tx)';
```

Create a `propagationData` object to hold computed signal strength data.

```
tbl = table(latitude, longitude, signalStrength);
pd = propagationData(tbl);
```

Plot the signal strength data on a map as colored points.

```
legendTitle = "Signal" + newline + "Strength" + newline + "(dB)";
plot(pd, "LegendTitle", legendTitle, "Colormap", parula);
```

Input Arguments

pd — Propagation data

`propagationData` object (default)

Propagation data, specified as a `propagationData` object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Type','power'`

DataVariableName — Data variable to plot

pd.DataVariableName (default) | character vector | string scalar

Data variable to plot, specified as the comma-separated pair consisting of 'DataVariableName' and a character vector or a string scalar corresponding to a variable name in the data table used to create the propagation data container object pd. The default value is dynamic and corresponds to the DataVariableName property of the propagationData object.

Data Types: char | string

Type — Type of value to plot

'custom' (default) | 'power' | 'efield' | 'sinr' | 'pathloss'

Type of value to plot, specified as the comma-separated pair consisting of 'Type' and one of the values in the Type column:

Type	ColorLimits	LegendTitle
'custom'	[min(Data) max(Data)]	''
'power'	[-120 -5]	'Power (dBm)'
'efield'	[20 135]	'E-field (dBuV/m)'
'sinr'	[-5 20]	'SINR (dB)'
'pathloss'	[45 160]	'Path loss (dB)'

The default value for Levels is a linearly spaced vector bounded by ColorLimits.

Data Types: char | string

Levels — Data value levels to plot

numeric vector

Data value levels to plot, specified as the comma-separated pair consisting of 'Levels' and a numeric vector. The propagation data is binned according to Levels. The data in each bin is color coded according to the corresponding level. The colors are selected using Colors if specified, or else Colormap and ColorLimits. Data points with values below the minimum level are not included in the plot.

The default value for Levels is a linearly spaced vector bounded by ColorLimits.

Data Types: double

Colors — Colors of data points

M-by-3 array of RGB | array of strings | cell array of character vectors

Colors of the data points, specified as the comma-separated pair consisting of 'Colors' and an *M*-by-3 array of RGB (red, blue, green) or an array of strings, or a cell array of character vectors. Colors are assigned element-wise to values in Levels for coloring the corresponding points. Colors cannot be used with Colormap and ColorLimits.

Data Types: double | char | string

Colormap — Color map for coloring points

'jet(256)' (default) | predefined colormap name | *M*-by-3 array of RGB triplets

Colormap for the coloring points, specified as the comma-separated pair consisting of `'Colormap'` and a predefined colormap name or an *M*-by-3 array of RGB (red, blue, green) triplets that define *M* individual colors. `Colormap` cannot be used with `Colors`.

Data Types: `double` | `char` | `string`

`ColorLimits` — Color limits for color map

two-element vector

Color limits for the colormap, specified as the comma-separated pair consisting of `'ColorLimits'` and a two-element vector of the form [min max]. The color limits indicate the data level values that map to the first and last colors in the colormap. `ColorLimits` cannot be used with `Colors`.

Data Types: `double`

`MarkerSize` — Size of data markers

`10` (default) | positive numeric scalar

Size of data markers plotted on the map, specified as the comma-separated pair consisting of `'MarkerSize'` and a positive numeric scalar in pixels.

Data Types: `double`

`ShowLegend` — Show color legend on map

`true` (default) | `false`

Show color legend on map, specified as the comma-separated pair consisting of `'ShowLegend'` and `true` or `false`.

Data Types: `logical`

`LegendTitle` — Title of color legend

character vector | string scalar

Title of color legend, specified as the comma-separated pair consisting of `'LegendTitle'` and a character vector or a string scalar.

Data Types: `string` | `char`

`Map` — Map for surface data

`siteviewer` object

Map for surface data, specified as the comma-separated pair consisting of `'Map'` and a `siteviewer` object.[6] The default value is the current Site Viewer or a new Site Viewer, if none is open.

Data Types: `char` | `string`

Introduced in R2020a

[6] Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

location

Data location coordinates

Syntax

```
datalocation = location(pd)
[lat,lon] = location(pd)
```

Description

`datalocation = location(pd)` returns the location coordinates of the data points in the propagation data object.

`[lat,lon] = location(pd)` returns the latitude and longitude of the propagation data object

Examples

Transmitter Site Service Areas

Define names and locations of sites around Boston.

```
names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"];
lats = [42.3467,42.3598,42.3763];
lons = [-71.0972,-71.0545,-71.0611];
```

Create array of transmitter sites.

```
txs = txsite("Name", names,...
       "Latitude",lats,...
       "Longitude",lons, ...
       "TransmitterFrequency",2.5e9);
```

Compute received power data for each transmitter site.

```
maxr = 20000;
pd1 = coverage(txs(1),"MaxRange",maxr);
pd2 = coverage(txs(2),"MaxRange",maxr);
pd3 = coverage(txs(3),"MaxRange",maxr);
```

Compute rectangle containing locations of all data.

```
locs = [location(pd1); location(pd2); location(pd3)];
[minlatlon, maxlatlon] = bounds(locs);
```

Create grid of locations over rectangle.

```
gridlength = 300;
latv = linspace(minlatlon(1),maxlatlon(1),gridlength);
lonv = linspace(minlatlon(2),maxlatlon(2),gridlength);
[lons,lats] = meshgrid(lonv,latv);
lats = lats(:);
lons = lons(:);
```

Get data for each transmitter at grid locations using interpolation.

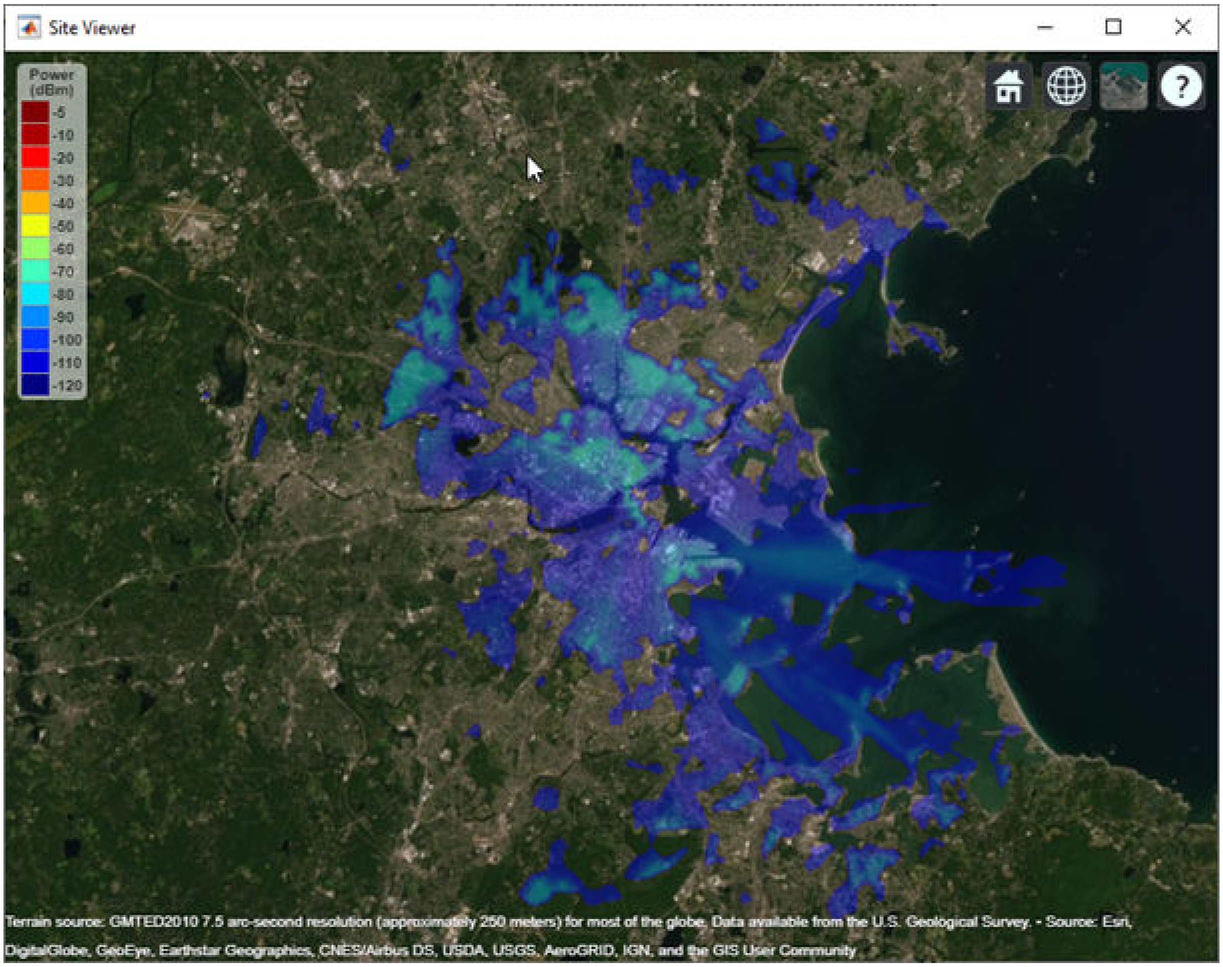
```
v1 = interp(pd1,lats,lons);
v2 = interp(pd2,lats,lons);
v3 = interp(pd3,lats,lons);
```

Create propagation data containing minimum received power values.

```
minReceivedPower = min([v1 v2 v3],[],2,"includenan");
pd = propagationData(lats,lons,"MinReceivedPower",minReceivedPower);
```

Plot minimum received power, which shows the weakest signal received from any transmitter site. The area shown may correspond to the service area of triangulation using the three transmitter sites.

```
sensitivity = -110;
contour(pd,"Levels",sensitivity:-5,"Type","power")
```



Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. - Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Input Arguments

pd — Propagation data
propagationData object (default)

Propagation data, specified as a `propagationData` object.

Output Arguments

`datalocation` — Location coordinates of data points

M-by-2 matrix

Location of antenna site, returned as an *M*-by-2 matrix with each element unit in degrees. *M* is the number of rows in the data table with valid latitude and longitude values. Duplicate locations are not removed.

`lat` — Latitude of data points

M-by-1 vector

Latitude of data points, returned as an *M*-by-`1` vector with each element unit in degrees.

`lon` — Longitude of data points

M-by-1 vector

Longitude of data points, returned as an *M*-by-`1` matrix with each element unit in degrees. The output is wrapped so that the values are in the range `[-180 180]`.

Introduced in R2020a

propagationModel

Create RF propagation model

Syntax

```
pm = propagationModel(modelname)
pm = propagationModel( ___ ,Name,Value)
```

Description

`pm = propagationModel(modelname)` creates an RF propagation model for the specified model.

`pm = propagationModel( ___ ,Name,Value)` updates the model using one or more name-value pairs. For example, `pm = propagationModel('rain','RainRate',96)` creates a rain propagation model with a rain rate of 96 mm/h. Enclose each property name in quotes.

Examples

Signal Strength of Receiver in Heavy Rain

Specify transmitter and receiver sites.

```
tx = txsite('Name','MathWorks Apple Hill',...
       'Latitude',42.3001, ...
       'Longitude',-71.3504, ...
       'TransmitterFrequency', 2.5e9);

rx = rxsite('Name','Fenway Park',...
       'Latitude',42.3467, ...
       'Longitude',-71.0972);
```

Create the propagation model for a heavy rainfall rate.

```
pm = propagationModel('rain','RainRate',50)
```

```
pm = 
  Rain with properties:

    RainRate: 50
        Tilt: 0
```

Calculate the signal strength at the receiver using the rain propagation model.

```
ss = sigstrength(rx,tx,pm)
```

```
ss = -87.1559
```

Longley-Rice Propagation Model

Create a transmitter site.

```
tx = txsite
```

```
tx = 
  txsite with properties:

                   Name: 'Site 1'
               Latitude: 42.3001
              Longitude: -71.3504
                Antenna: 'isotropic'
           AntennaAngle: 0
          AntennaHeight: 10
             SystemLoss: 0
    TransmitterFrequency: 1.9000e+09
        TransmitterPower: 10
```

Create a Longley-Rice propagation model using the `propagationModel` function.

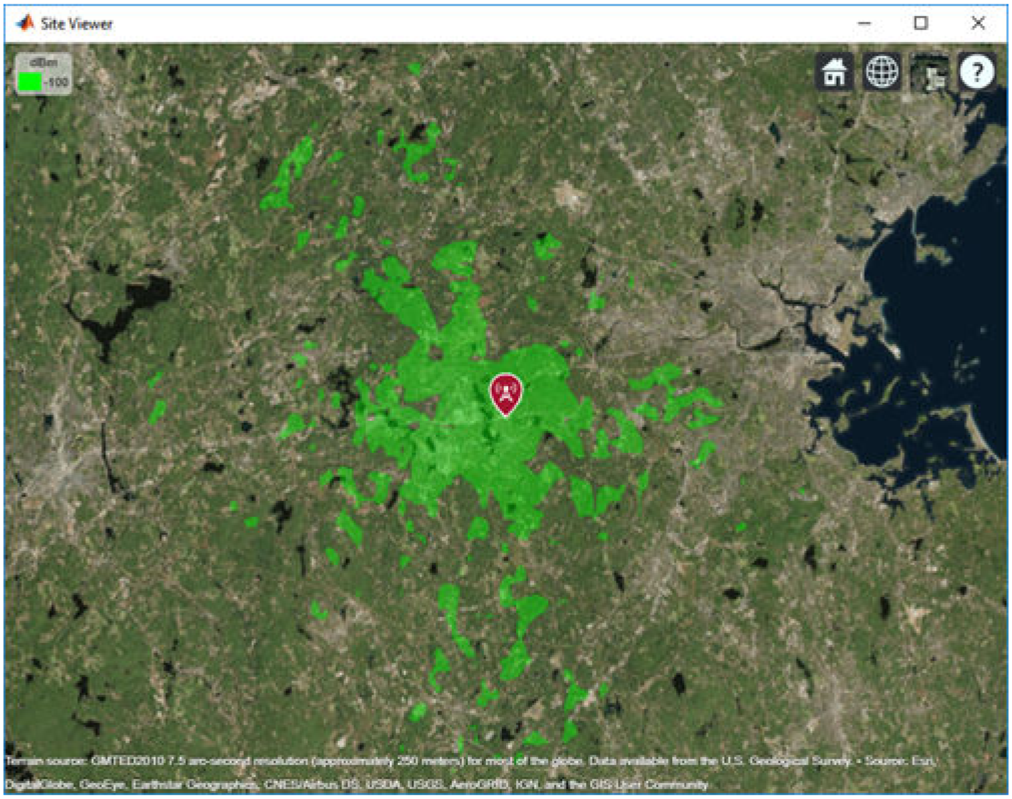
```
pm = propagationModel('longley-rice','TimeVariabilityTolerance',0.7)
```

```
pm = 
  LongleyRice with properties:

              AntennaPolarization: 'horizontal'
               GroundConductivity: 0.0050
               GroundPermittivity: 15
          AtmosphericRefractivity: 301
                      ClimateZone: 'continental-temperate'
         TimeVariabilityTolerance: 0.7000
    SituationVariabilityTolerance: 0.5000
```

Find the coverage of the transmitter site using the defined propagation model.

```
coverage(tx,'PropagationModel',pm)
```



Site Viewer

-100
Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Input Arguments

`modelname` — Type of propagation model
`'freespace'` | `'rain'` | `'gas'` | `'fog'` | `'close-in'` |`'longley-rice'` | `'tirem'` | `'raytracing-image-method'`

Type of propagation model specified as one of these:

- `'freespace'` — Free space propagation model.
- `'rain'` — Rain propagation model. For more information, see [3].
- `'gas'` — Gas propagation model.
- `'fog'` — Fog propagation model. For more information, see [2] (Antenna Toolbox).
- `'close-in'` — Close-in propagation model typically used in urban macro-cell scenarios. For more information, see [1].

  Note The close-in model implements a statistical path loss model and can be configured for different scenarios. The default values correspond to an urban macro-cell scenario in a non-line-of-sight (NLOS) environment.
- `'longley-rice'` — Longley-Rice propagation model. This model is also known as Irregular Terrain Model (ITM). You can use this model to calculate point-to-point path loss between sites over an irregular terrain, including buildings. Path loss is calculated from free-space loss, terrain diffraction, ground reflection, refraction through atmosphere, tropospheric scatter, and atmospheric absorption. For more information and list of limitations, see [4].

Note The Longley-Rice model implements the point-to-point mode of the model, which uses terrain data to predict the loss between two points.

- `'tirem'` — Terrain Integrated Rough Earth Model™ (TIREM™). You can use this model to calculate point-to-point path loss between sites over an irregular terrain, including buildings. Path loss is calculated from free-space loss, terrain diffraction, ground reflection, refraction through atmosphere, tropospheric scatter, and atmospheric absorption. This model needs access to an external TIREM library. The actual model is valid from 1 MHZ to 1000 GHz. But with Antenna Toolbox elements and arrays the frequency range is limited to 200 GHz.
- `'raytracing-image-method'` — The ray tracing propagation model is a multipath propagation model that uses ray tracing analysis to compute propagation paths and their corresponding path losses. Path loss is calculated from free-space loss, reflection loss due to material, and antenna polarization loss. The ray tracing analysis uses the method of images, which includes surface reflections but does not include effects from refraction, diffraction, or scattering. This model is valid for a frequency range of 100 MHz to 100 GHz.

You can use these functions on RF propagation models:

- `range` — Calculate the range of the radio wave under different propagation scenarios. The`range` function does not support Longley-Rice, TIREM or `'raytracing-image-method'` propagation models.
- `pathloss` — Calculate the path loss of radio wave propagation between the transmitter and receiver sites under different propagation scenarios.
- `add` — Add propagation models.

Dependencies

To specify `'tirem'`, requires the Antenna Toolbox.

Data Types: `char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'RainRate',50`. Sets the rate of rainfall in the rain propagation model to 40.

Rain

`RainRate` — Rain rate

`16` (default) | nonnegative scalar

Rain rate, specified as a nonnegative scalar in millimeters per hour (mm/h).

Dependencies

To specify `'RainRate'`, you must specify `'rain'` propagation model.

Data Types: `double`

`Tilt` — Polarization tilt angle of signal

`0` (default) | scalar

Polarization tilt angle of the signal, specified as a scalar in degrees.

Dependencies

To specify `'Tilt'`, you must specify `'rain'` propagation model.

Data Types: `double`

Gas

`Temperature` — Air temperature

`15` (default) | scalar

Air temperature, specified as a scalar in Celsius (C).

Dependencies

To specify `'Temperature'`, you must specify `'gas'` propagation model.

Data Types: `double`

`AirPressure` — Dry air pressure

`101300` (default) | scalar

Dry air pressure, specified as a scalar in pascals (Pa).

Dependencies

To specify `'AirPressure'`, you must specify `'gas'` propagation model.

Data Types: `double`

`WaterDensity` — Water vapor density

`7.5` (default) | scalar

Water vapor density, specified as a scalar in grams per cubic meter (g/m^3).

Dependencies

To specify `'WaterDensity'`, you must specify `'gas'` propagation model.

Data Types: `double`

Fog

`Temperature` — Air temperature

`15` (default) | scalar

Air temperature, specified as a scalar in Celsius (C).

Dependencies

To specify `'Temperature'`, you must specify `'fog'` propagation model.

Data Types: `double`

`WaterDensity` — Liquid water density

`0.5` (default) | scalar

Liquid water density, specified as a scalar in grams per cubic meter (g/m^3).

Dependencies

To specify `'WaterDensity'`, you must specify `'fog'` propagation model.

Data Types: `double`

Close-In

`ReferenceDistance` — Free-space reference distance

`1` (default) | scalar

Free-space reference distance, specified as a scalar in meters.

Dependencies

To specify `'ReferenceDistance'`, you must specify the `'close-in'` propagation model.

Data Types: `double`

`PathLossExponent` — Path loss exponent

`2.9` (default) | scalar

Path loss exponent, specified as a scalar.

Dependencies

To specify `'PathLossExponent'`, you must specify `'close-in'` propagation model.

Data Types: `double`

`Sigma` — Standard deviation

`5.7` (default) | scalar

Standard deviation of the zero-mean Gaussian random variable, specified as a scalar in decibels (dB).

Dependencies

To specify `'Sigma'`, you must specify `'close-in'` propagation model.

Data Types: `double`

`NumDataPoints` — Number of data points

`1869` (default) | integer

Number of data points of zero-mean Gaussian random variable, specified as an integer.

Dependencies

To specify `'NumDataPoints'`, you must specify `'close-in'` propagation model.

Data Types: `double`

Note The close-in model is valid for distances greater than or equal to the `'ReferenceDistance'` property. If a distance less than the `'ReferenceDistance'` is used, path loss is `0`.

Longley-Rice

`AntennaPolarization` — Polarization of transmitter and receiver antennas

`'horizontal'` (default) | `'vertical'`

Polarization of transmitter and receiver antennas, specified as `'horizontal'` or `'vertical'`. Both antennas are assumed to have the same polarization. This value is used to calculate path loss due to ground reflection.

Dependencies

To specify `'AntennaPolarization'`, you must specify `'longley-rice'` propagation model.

Data Types: `char` | `string`

`GroundConductivity` — Conductivity of ground

`0.005` (default) | scalar

Conductivity of the ground, specified as a scalar in Siemens per meter (S/m). This value is used to calculate path loss due to ground reflection. The default value corresponds to average ground.

Dependencies

To specify `'GroundConductivity'`, you must specify `'longley-rice'` propagation model.

Data Types: `double`

`GroundPermittivity` — Relative permittivity of ground

`15` (default) | scalar

Relative permittivity of the ground, specified as a scalar. Relative permittivity is expressed as a ratio of absolute material permittivity to the permittivity of vacuum. This value is used to calculate the path loss due to ground reflection. The default value corresponds to average ground.

Dependencies

To specify `'GroundPermittivity'`, you must specify `'longley-rice'` propagation model.

Data Types: `double`

`AtmosphericRefractivity` — Atmospheric refractivity near ground

`301` (default) | scalar

Atmospheric refractivity near the ground, specified as a scalar in N-units. This value is used to calculate the path loss due to refraction through the atmosphere and tropospheric scatter. The default value corresponds to average atmospheric conditions.

Dependencies

To specify `'AtmosphericRefractivity'`, you must specify `'longley-rice'` propagation model.

Data Types: `double`

`ClimateZone` — Radio climate zone

`'continental-temperate'` (default) | `'equatorial'` | `'continental-subtropical'` | `'maritime-subtropical'` | `'desert'` | `'maritime-over-land'` | `'maritime-over-sea'`

Radio climate zone. This value is used to calculate the variability due to changing atmospheric conditions. The default value corresponds to average atmospheric conditions in a particular climate zone.

Dependencies

To specify `'ClimateZone'`, you must specify `'longley-rice'` propagation model.

Data Types: `char` | `string`

`TimeVariabilityTolerance` — Time variability tolerance level

`0.5` (default) | scalar

Time variability tolerance level of the path loss, specified as a scalar between [0.001, 0.999]. Time variability occurs due to changing atmospheric conditions. This value gives the required system reliability or the fraction of time during which the actual path loss is expected to be less than or equal to model prediction. For more information, see [5].

Dependencies

To specify `'TimeVariabilityTolerance'`, you must specify `'longley-rice'` propagation model.

Data Types: `double`

`SituationVariabilityTolerance` — Situation variability tolerance level

`0.5` (default) | scalar

Situation variability tolerance level of the path loss, specified as a scalar in between [0.001, 0.999]. Situation variability occurs due to uncontrolled or hidden random variables. This value gives the required system confidence or the fraction of similar situations for which the actual path loss is expected to be less than or equal to the model prediction. For more information, see [5].

Dependencies

To specify `'SituationVariabilityTolerance'`, you must specify `'longley-rice'` propagation model.

Data Types: `double`

TIREM

`AntennaPolarization` — Polarization of transmitter and receiver antennas

`'horizontal'` (default) | `'vertical'`

Polarization of transmitter and receiver antennas, specified as `'horizontal'` or `'vertical'`. Both antennas are assumed to have the same polarization. This value is used to calculate path loss due to ground reflection.

Dependencies

To specify `'AntennaPolarization'`, you must specify `'tirem'` propagation model.

Data Types: `char` | `string`

`GroundConductivity` — Conductivity of ground

`0.005` (default) | numeric scalar

Conductivity of the ground, specified as a numeric scalar in Siemens per meter (S/m) in the range of 0.0005 to 100. This value is used to calculate path loss due to ground reflection. The default value corresponds to average ground.

Dependencies

To specify `'GroundConductivity'`, you must specify `'tirem'` propagation model.

Data Types: `double`

`GroundPermittivity` — Relative permittivity of ground
`15` (default) | numeric scalar

Relative permittivity of the ground, specified as a numeric scalar in the range of 1 to 100. Relative permittivity is expressed as a ratio of absolute material permittivity to the permittivity of vacuum. This value is used to calculate the path loss due to ground reflection. The default value corresponds to average ground.

Dependencies

To specify `'GroundPermittivity'`, you must specify `'tirem'` propagation model.

Data Types: `double`

`AtmosphericRefractivity` — Atmospheric refractivity near ground
`301` (default) | scalar

Atmospheric refractivity near the ground, specified as a numeric scalar in N-units in the range of 250 to 400. This value is used to calculate the path loss due to refraction through the atmosphere and tropospheric scatter. The default value corresponds to average atmospheric conditions.

Dependencies

To specify `'AtmosphericRefractivity'`, you must specify `'tirem'` propagation model.

Data Types: `double`

`Humidity` — Absolute air humidity near ground
`'9'` (default) | numeric scalar

Absolute air humidity near ground,specified as a numeric scalar in `g/m^3` units in the range of 0 to 110. You can use this value to calculate path loss due to atmospheric absorption. The default value corresponds to the absolute humidity of air at 15 degrees Celsius and 70 percent relative humidity.

Dependencies

To specify `'Humidity'`, you must specify `'tirem'` propagation model.

Data Types: `double`

raytracing-image-method

`MaxNumReflections` — Maximum number of path reflections
`1` (default) | `0` | `2`

Maximum number of reflections in the propagation paths to search for using ray tracing, specified as `0`, `1`, or `2`. The default value results in a search for a line-of-sight propagation path along with propagation paths that each contain a single reflection.

Dependencies

To specify `'MaxNumReflections'`, you must specify `'raytracing-image-method'` propagation model.

Data Types: `double`

`CoordinateSystem` — Coordinate system of map and site location
`'geographic'` (default) | `'cartesian'`

Coordinate system of the site location, specified as `'geographic'` or `'cartesian'`. If you specify `'geographic'`, material types are defined using `'BuildingMaterial'` or `'TerrainMaterial'` properties. If you specify `'cartesian'`, material types are defined using the `'SurfaceMaterial'` properties.

Data Types: `string` | `char`

`BuildingsMaterial` — Surface material of geographic buildings

`'concrete'` (default) | `'perfect-reflector'` | `'brick'` | `'wood'` | `'glass'` | `'metal'` | `'custom'`

Surface material of geographic buildings, specified as one of these: `'perfect-reflector'`, `'concrete'`, `'brick'`, `'wood'`, `'glass'`, `'metal'`, or `'custom'`. The material type is used to calculate reflection loss where propagation paths reflect off of building surfaces. For more information, see “ITU Permittivity and Conductivity Values for Common Materials” on page 4-173.

When `'BuildingsMaterial'` is set to `'custom'`, the material permittivity and conductivity are specified in the `BuildingsMaterialPermittivity` and `BuildingsMaterialConductivity` properties.

Dependencies

To specify `'BuildingsMaterials'`, you must set `'CoordinateSystem'` to `'geographic'`.

Data Types: `char` | `string`

`BuildingsMaterialPermittivity` — Relative permittivity of buildings surface materials

`5.31` (default) | nonnegative scalar

Relative permittivity of the buildings surface material, specified as a nonnegative scalar. Relative permittivity is expressed as a ratio of absolute material permittivity to the permittivity of vacuum. This value is used to calculate path loss due to reflection. The default value corresponds to concrete at 1.9 GHz.

Dependencies

To specify `'BuildingsMaterialPermittivity'`, you must set `'CoordinateSystem'` to `'geographic'` and `'BuildingsMaterial'` to `'custom'`.

Data Types: `double`

`BuildingsMaterialConductivity` — Conductivity of buildings surface materials

`0.0548` (default) | nonnegative scalar

Conductivity of the buildings surface material, specified as a nonnegative scalar in Siemens per meter (S/m). This value is used to calculate path loss due to reflection. The default value corresponds to concrete at 1.9 GHz.

Dependencies

To specify `'BuildingsMaterialConductivity'`, you must set `'CoordinateSystem'` to `'geographic'` and `'BuildingsMaterial'` to `'custom'`.

Data Types: `double`

`TerrainMaterial` — Surface material of geographic terrain

`'concrete'` (default) | `'perfect-reflector'` | `'brick'` | `'water'` | `'vegetation'` | `'loam'` | `'custom'`

Surface material of terrain, specified as one of these: `'perfect-reflector'`, `'concrete'`, `'brick'`, `'water'`, `'vegetation'`, `'loam'`, or `'custom'`. The material type is used to calculate reflection loss where propagation paths reflect off of terrain surfaces. For more information, see “ITU Permittivity and Conductivity Values for Common Materials” on page 4-173.

When `'TerrainMaterial'` is set to `'custom'`, the material permittivity and conductivity are specified in the `'TerrainMaterialPermittivity'` and `'TerrainMaterialConductivity'` properties.

Dependencies

To specify `'TerrainMaterial'`, you must set `'CoordinateSystem'` to `'geographic'`.

Data Types: `char` | `string`

`TerrainMaterialPermittivity` — Relative permittivity of terrain materials

`5.31` (default) | nonnegative scalar

Relative permittivity of the terrain material, specified as a nonnegative scalar. Relative permittivity is expressed as a ratio of absolute material permittivity to the permittivity of vacuum. This value is used to calculate path loss due to reflection. The default value corresponds to concrete at 1.9 GHz.

Dependencies

To specify `'TerrainMaterialPermittivity'`, you must set `'CoordinateSystem'` to `'geographic'` and `'TerrainMaterial'` to `'custom'`.

Data Types: `double`

`TerrainMaterialConductivity` — Conductivity of terrain materials

`0.0548` (default) | nonnegative scalar

Conductivity of the terrain material, specified as a nonnegative scalar in Siemens per meter (S/m). This value is used to calculate path loss due to reflection. The default value corresponds to concrete at 1.9 GHz.

Dependencies

To specify `'TerrainMaterialConductivity '`, you must set `'CoordinateSystem'` to `'geographic'` and set `'TerrainMaterial'` to `'custom'`.

Data Types: `double`

`SurfaceMaterial` — Surface material of Cartesian map surface

`'plasterboard'` (default) | `'perfect-reflector'` | `'ceilingboard'` | `'chipboard'` | `'floorboard'` | `'concrete'` | `'brick'` | `'wood'` | `'glass'` | `'metal'` | `'water'` | `'vegetation'` | `'loam'` | `'custom'`

Surface material of Cartesian map surface, specified as one of these: `'plasterboard'`,`'perfect-reflector'`, `'ceilingboard'`, `'chipboard'`, `'floorboard'`, `'concrete'`, `'brick'`, wood, `'glass'`, `'metal'`, `'water'`, `'vegetation'`, `'loam'`, or `'custom'`. The material type is used to calculate reflection loss where propagation paths reflect off of surfaces. For more information, see “ITU Permittivity and Conductivity Values for Common Materials” on page 4-173.

When `'SurfaceMaterial'` is set to `'custom'`, the material permittivity and conductivity are specified in the `'SurfaceMaterialPermittivity'` and `'SurfaceMaterialConductivity'` properties.

Dependencies

To specify `'SurfaceMaterial'`, you must set `'CoordinateSystem'` to `'cartesian'`.

Data Types: `char` | `string`

`SurfaceMaterialPermittivity` — Relative permittivity of surface materials

`2.94` (default) | nonnegative scalar

Relative permittivity of the surface material, specified as a nonnegative scalar. Relative permittivity is expressed as a ratio of absolute material permittivity to the permittivity of vacuum. This value is used to calculate path loss due to reflection. The default value corresponds to plaster board at 1.9 GHz.

Dependencies

To specify `'SurfaceMaterialPermittivity'`, you must set `'CoordinateSystem'` to `'cartesian'` and `'SurfaceMaterial'` to `'custom'`.

Data Types: `double`

`SurfaceMaterialConductivity` — Conductivity of surface materials

`0.0183` (default) | nonnegative scalar

Conductivity of the surface material, specified as a nonnegative scalar in Siemens per meter (S/m). This value is used to calculate path loss due to reflection. The default value corresponds to plaster board at 1.9 GHz.

Dependencies

To specify `'SurfaceMaterialConductivity '`, you must set `'CoordinateSystem'` to `'cartesian'` and set `'SurfaceMaterial'` to `'custom'`.

Data Types: `double`

More About

N-Units

The refractive index of air *n* is related to the dielectric constants of the gas constituents of an air mixture. The numerical value of *n* is only slightly larger than one. To make the calculation more convenient, you can use *N* units, which are given by the formula: $N = (n - 1) \times 10^6$

ITU Permittivity and Conductivity Values for Common Materials

ITU-R P.2040-1 [8] and ITU-R P.527-5 [9] present methods, equations, and values used to calculate real relative permittivity, conductivity, and complex relative permittivity for the common materials.

- For information about the values computed for building materials specified in ITU-R P.2040-1, see `buildingMaterialPermittivity`.
- For information about the values computed for terrain materials specified in ITU-R P.527-5, see `earthSurfacePermittivity`.

Topics

“Access TIREM Software” (Antenna Toolbox)

Introduced in R2019b

range

Range of radio wave propagation

Syntax

```
r = range(propmodel,tx,pl)
```

Description

`r = range(propmodel,tx,pl)`returns the range of radio wave propagation from the transmitter site.

Examples

Range of Transmitter In Heavy Rain

Specify transmitter and receiver sites.

```
tx = txsite('Name','MathWorks Apple Hill',...
       'Latitude',42.3001, ...
       'Longitude',-71.3504, ...
       'TransmitterFrequency', 2.5e9);

rx = rxsite('Name','Fenway Park',...
       'Latitude',42.3467, ...
       'Longitude',-71.0972);
```

Create the propagation model for heavy rainfall rate.

```
pm = propagationModel('rain','RainRate',50)
```

```
pm = 
  Rain with properties:

    RainRate: 50
        Tilt: 0
```

Calculate the range of transmitter using the rain propagation model and a path loss of 127 dB.

```
r = range(pm,tx,127)
```

```
r = 2.0747e+04
```

Input Arguments

`propmodel` — Propagation model

character vector or string

Propagation model, specified as a character vector or string.

Data Types: `char`

`tx` — Transmitter site
`txsite` object

Transmitter site, specified as a `txsite` object. You can use array inputs to specify multiple sites.

Data Types: `char`

`pl` — Path loss
scalar

Path loss, specified as a scalar in decibels.

Data Types: `double`

Output Arguments

`r` — range
scalar | *M*-by-1 arrays

Range, returned as a scalar or *M*-by-1 array with each element in meters. *M* is the number of TX sites.

Range is the maximum distance for which the path loss does not exceed the value of specified `pl`.

See Also

`pathloss` | `propagationModel`

Introduced in R2019b

raytrace

Plot propagation paths between sites

Syntax

```
raytrace(tx,rx)
raytrace(tx,rx,propmodel)
raytrace( ___ ,Name,Value)
rays = raytrace( ___ )
```

Description

`raytrace(tx,rx)` plots the propagation paths from the transmitter site (`tx`) to the receiver site (`rx`). The propagation paths are found using ray tracing with surface geometry defined by the `Map` property. Each propagation path is color-coded according to the received power (dBm) or path loss (dB) along the path, assuming unpolarized rays.

Note

- The ray tracing analysis includes surface reflections but does not include effects from refraction, diffraction, or scattering.
- Operational frequency for this function is from 100 MHz to 100 GHz.

`raytrace(tx,rx,propmodel)` plots the propagation paths from the transmitter site (`tx`) to the receiver site (`rx`) based on the specified propagation model. To input building and terrain materials to calculate path loss, please use the `'raytracing-image-method'` propagation model and set the properties to specify building materials.

`raytrace( ___ ,Name,Value)` plots propagation paths with additional options specified by one or more name-value pairs.

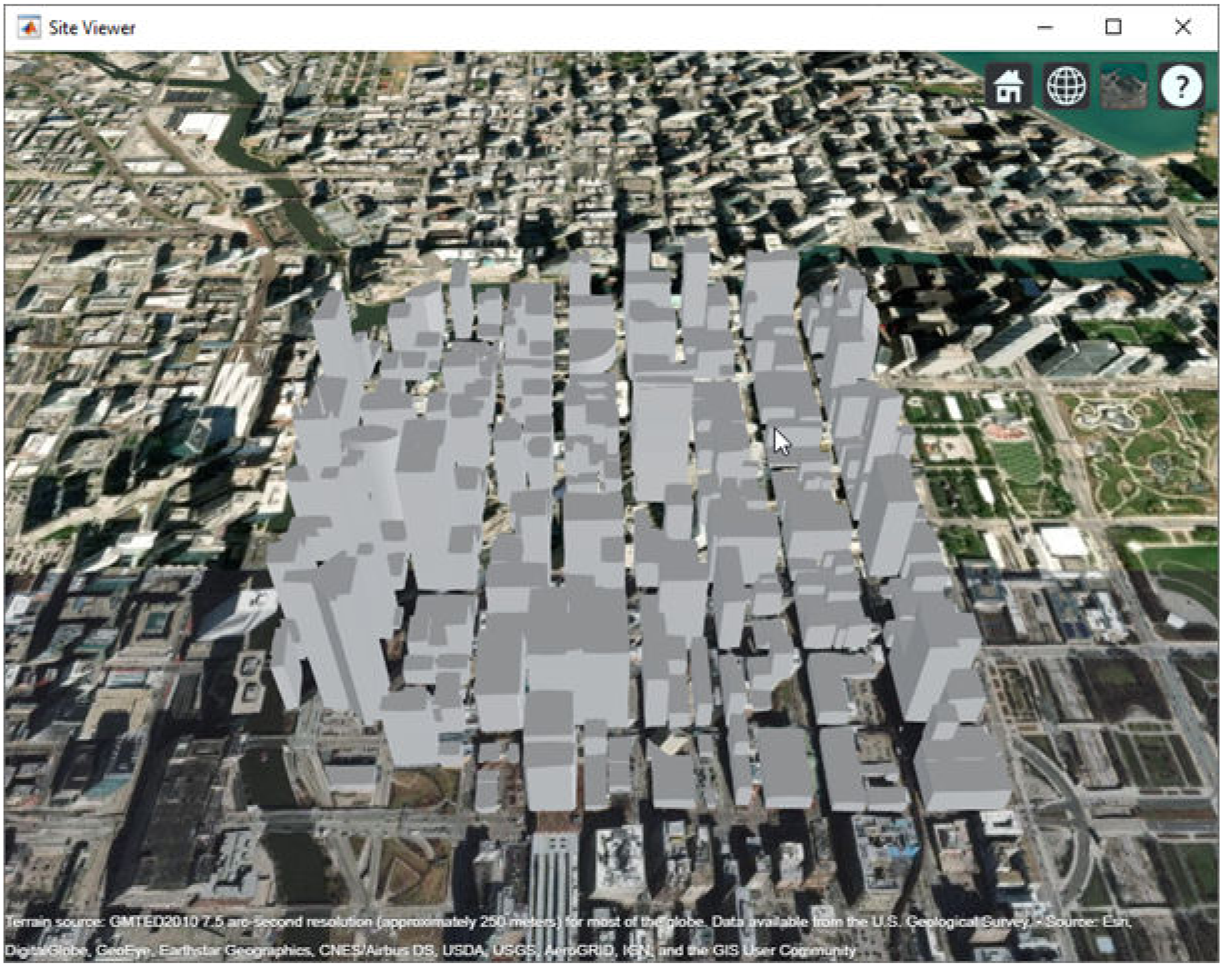
`rays = raytrace( ___ )` returns the propagation paths in `rays`.

Examples

Signal Strength Using Ray Tracing Image Method Propagation Model

Launch Site Viewer with buildings in Chicago. For more information about the osm file, see [1] on page 4-0 .

```
viewer = siteviewer("Buildings","chicago.osm");
```



Site Viewer
Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Create transmitter site on a building.

```
tx = txsite('Latitude',41.8800, ...
    'Longitude',-87.6295, ...
    'TransmitterFrequency',2.5e9);
```

Create receiver site near another building.

```
rx = rxsite('Latitude',41.881352, ...
    'Longitude',-87.629771, ...
    'AntennaHeight',30);
```

Compute signal strength using ray tracing propagation model and default single-reflection analysis.

```
pm = propagationModel("raytracing-image-method");
ssOneReflection = sigstrength(rx,tx,pm)
```

```
ssOneReflection = -54.0915
```

Compute signal strength with analysis up to two reflections, where total received power is the cumulative power of all propagation paths

```
pm.MaxNumReflections = 2;
ssTwoReflections = sigstrength(rx,tx,pm)
ssTwoReflections = -52.3890
```

Observe effect of material by replacing default concrete material with perfect reflector.

```
pm.BuildingsMaterial = 'perfect-reflector';
ssPerfect = sigstrength(rx,tx,pm)
```

```
ssPerfect = -41.9927
```

Plot propagation paths.

```
raytrace(tx, rx, pm)
```

Ray Tracing In Conference Room

Define a 3-D map for a conference room with one table and four chairs.

```
mapFileName = "conferenceroom.stl";
```

Visualize the 3-D map.

```
figure; view(3);
trisurf(stlread(mapFileName), 'FaceAlpha', 0.3, 'EdgeColor', 'none');
```

```
hold on; axis equal; grid off;
xlabel('x'); ylabel('y'); zlabel('z');
```

Define a transmitter site close to the wall and a receiver site under the table.

```
    tx = txsite("cartesian",  "AntennaPosition", [-1.45; -1.45; 1.5],"TransmitterFrequency", 2.8e
    rx = rxsite("cartesian","AntennaPosition", [.3; .2; .5]);
```

Plot the transmitter site in red and receiver site in blue.

```
scatter3(tx.AntennaPosition(1,:), tx.AntennaPosition(2,:), tx.AntennaPosition(3,:), 'sr', 'filled
scatter3(rx.AntennaPosition(1,:), rx.AntennaPosition(2,:),rx.AntennaPosition(3,:), 'sb', 'filled
```

Create a ray tracing propagation model for Cartesian coordinates and set the surface material to wood.

```
pm = propagationModel("raytracing-image-method", "CoordinateSystem", "cartesian", ...
        "SurfaceMaterial", "wood", "MaxNumReflections", 2);
```

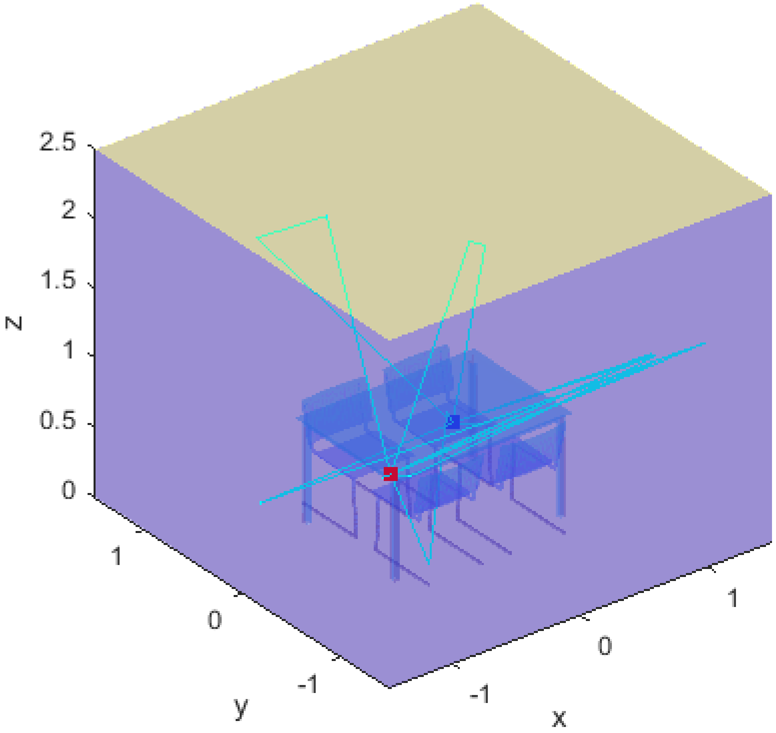
Perform ray tracing and save the computed rays using comm.Ray object

```
rays = raytrace(tx, rx, pm, 'Map', mapFileName);
rays = rays{1};
```

Visualize rays in the 3D map.

```
    for i = 1:length(rays)
        if rays(i).LineOfSight
            propPath = [rays(i).TransmitterLocation, ...
                        rays(i).ReceiverLocation];
        else
            propPath = [rays(i).TransmitterLocation, ...
                    rays(i).ReflectionLocations, ...
                        rays(i).ReceiverLocation];
        end

        line(propPath(1,:), propPath(2,:), propPath(3,:), 'Color', 'cyan');
    end
```



Input Arguments

rx — Receiver site

rxsite object | array of rxsite objects

Receiver site, specified as a rxsite object or an array of rxsite objects. If the transmitter sites are specified as arrays, then the propagation paths are plotted from each transmitter to each receiver site.

tx — Transmitter site

txsite object | array of txsite objects

Transmitter site, specified as a txsite object or an array of txsite objects. If the receiver sites are specified as arrays, then the propagation paths are plotted from each transmitter to each receiver site.

propmodel — Propagation model

character vector | string

Propagation model, specified as a character vector or string. You can use the propagationModel function to define this input. The default propagation model is 'raytracing-image-method'.

You can also use the name-value pair 'PropagationModel' to specify this parameter.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Type','power'`

Type — Type of quantity to plot

`'power'` (default) | `'pathloss'`

Type of quantity to plot, specified as the comma-separated pair consisting of `'Type'` and `'power'` in dBm or `'pathloss'` in dB.

When you specify `'power'`, each path is color-coded according to the received power along the path. When you specify `'pathloss'`, each path is color-coded according to the path loss along the path.

Friis equation is used to calculate the received power:

$$P_{rx} = P_{tx} + G_{tx} + G_{rx} - L - L_{tx} - L_{rx}$$

where:

- P_{rx} is the received power along the path.
- P_{tx} is the transmit power defined in tx.TransmitterPower.
- G_{tx} is the antenna gain of tx in the direction of the angle-of-departure (AoD).
- G_{rx} is the antenna gain of rx in the direction of the angle-of-arrival (AoA).
- L is the path loss calculated along the path.
- L_{tx} is the system loss of the transmitter defined in tx.SystemLoss.
- L_{rx} is the system loss of the receiver defined in rx.SystemLoss.

Data Types: `char`

`PropagationModel` — Type of propagation model for ray tracing analysis

`'raytracing-image-method'` (default) | ray tracing propagation model object

Type of propagation model for ray tracing analysis, specified as the comma-separated pair consisting of `'PropagationModel'` and `'raytracing-image-method'` or a ray tracing propagation model object created using `propagationModel`.

Data Types: `char`

`NumReflections` — Number of reflections to search for in propagation paths

`[0 1]` (default) | numeric row vector

Number of reflections to search for in propagation paths using ray tracing, specified as the comma-separated pair consisting of `'NumReflections'` and a numeric row vector whose elements are `0`, `1`, or `2`.

The default value results in the search for a line-of-sight propagation path along with propagation paths that each contain a single reflection.

Data Types: `double`

`Colormap` — Color map for coloring propagation paths

`'jet'` (default) | predefined color map name | *M*-by-3 array of RGB

Color map for coloring propagation paths, specified as the comma-separated pair consisting of `'Colormap'` and a predefined color map name or an *M*-by-3 array of RGB (red, blue, green) triplets that define *M* individual colors.

Data Types: `char` | `double`

`ColorLimits` — Color limits for colormap

two-element numeric row vector

Color limits for colormap, specified as the comma-separated pair consisting of `'ColorLimits'` and a two-element numeric row vector of the form [min max]. The units and default values of the color limits depend on the value of the `'Type'` parameter:

- `'power'`– Units are in dBm, and the default value is `[-120 -5]`.
- `'pathloss'`– Units are in dB, and the default value is `[45 160]`.

The color limits indicate the values that map to the first and last colors in the colormap. Propagation paths with values below the minimum color limit are not plotted.

Data Types: `double`

`ShowLegend` — Show color legend on map

`true` (default) | `false`

Show color legend on map, specified as the comma-separated pair consisting of `'ShowLegend'` and `true` or `false`.

Data Types: `logical`

`Map` — Map for visualization or surface data

`siteviewer` object | terrain name

Map for visualization or surface data, specified as the comma-separated pair consisting of `'Map` and one of the following depending on the coordinate system:

Coordinate System	Valid map values	Default map value
`'geographic'`	• `siteviewer`[a] • A terrain name may be specified if the function is called with an output argument. Valid terrain names are `'none'`, `'gmted2010'`, or the name of the custom terrain data added using `addCustomTerrain`	• current siteviewer or new siteviewer if none are open. • `'gmted2010'` if called with an output.
`'cartesian'`	`'none'`, triangulation object or name of an STL file.	`'none'`

[a] Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: `char` | `string`

Output Arguments

`rays` — Ray configuration object

M-by-*N* cell array

Ray configuration, returned as a *M*-by-*N* cell array where *M* is the number of transmitter sites and *N* is the number of receiver sites. Each cell element is a row vector of objects representing all the rays found between the corresponding transmitter site and receiver site. array. Within each row vector, the `comm.Ray` objects are ordered by increasing number of reflections, and where number of reflections are equal they are ordered by increasing propagation distance.

`los` | `siteviewer`

Introduced in R2019b

removeCustomTerrain

Remove custom terrain data

Syntax

```
removeCustomTerrain(terrainName)
```

Description

`removeCustomTerrain(terrainName)` removes the custom terrain data specified by the user-defined `terrainName`. You can use this function to remove terrain data that is no longer needed. The terrain data to be removed must have been previously added using `addCustomTerrain`.

Examples

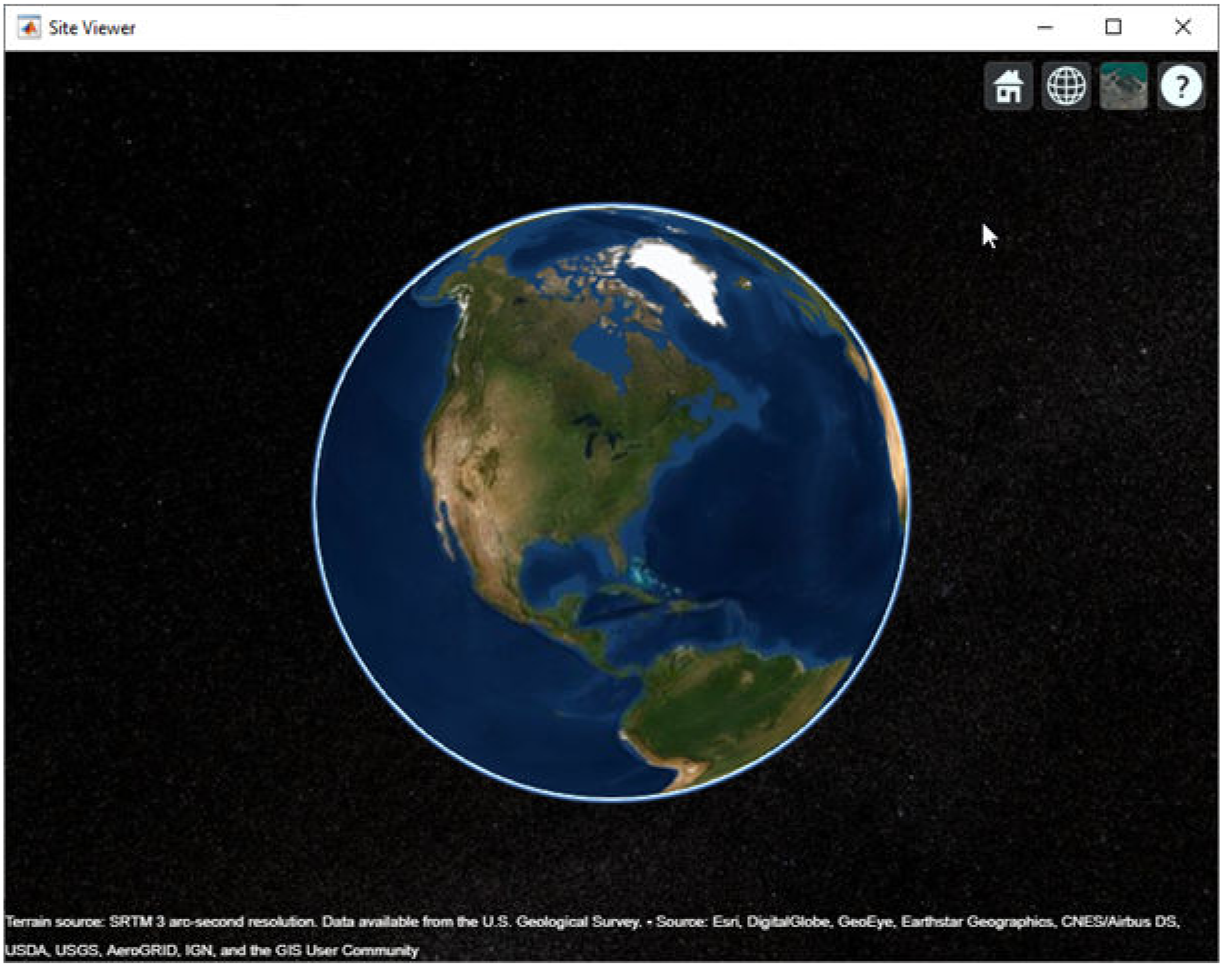
Site Viewer Maps Using Custom Terrain

Add terrain for a region around Boulder, CO. The DTED file was downloaded from the "SRTM Void Filled" data set available from the U.S. Geological Survey.

```
dtedfile = "n39_w106_3arc_v2.dt1";
attribution = "SRTM 3 arc-second resolution. Data available " + ...
   "from the U.S. Geological Survey.";
addCustomTerrain("southboulder",dtedfile,"Attribution",attribution)
```

Use the custom terrain name in Site Viewer.

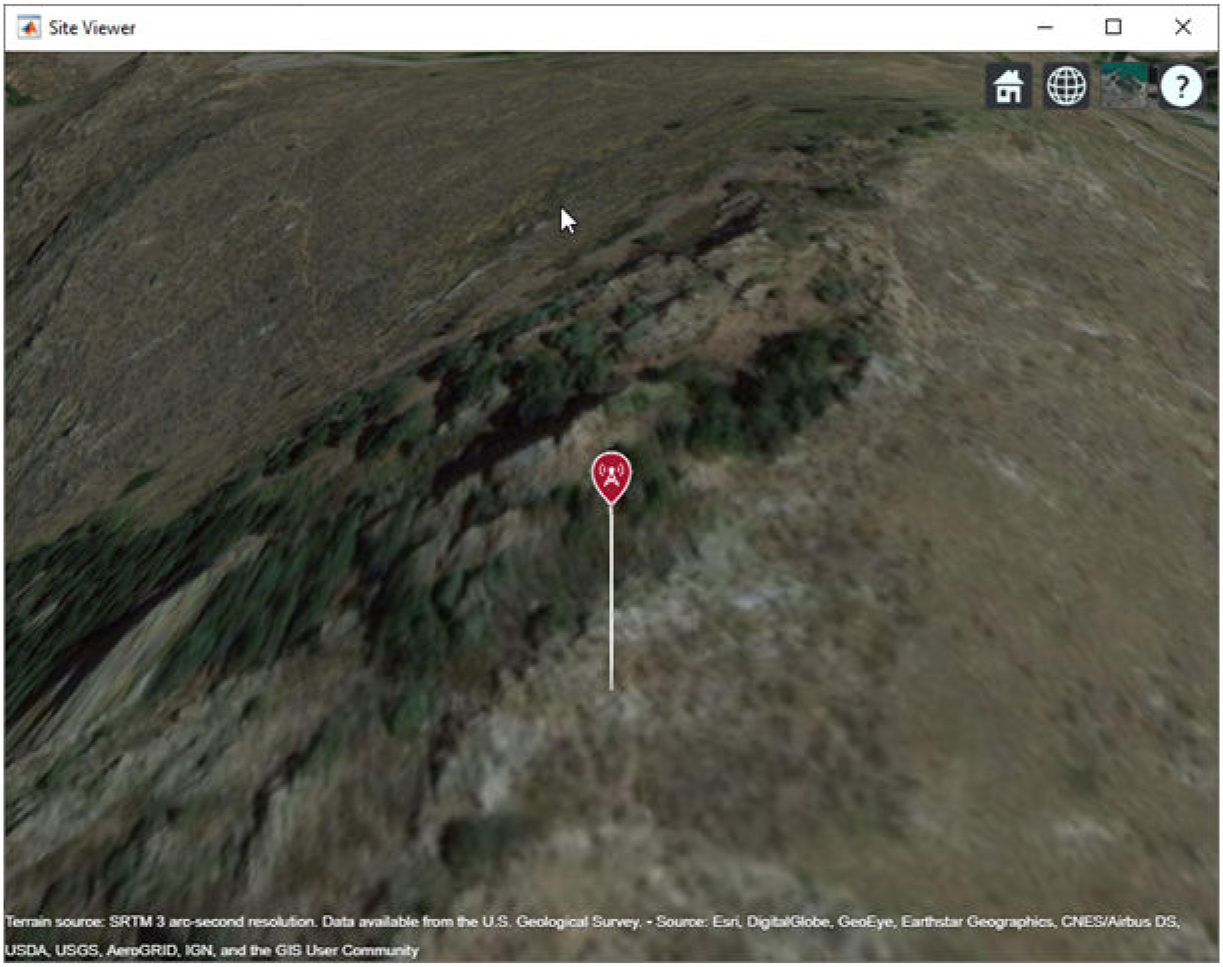
```
viewer = siteviewer("Terrain","southboulder");
```



Terrain source: SRTM 3 arc-second resolution. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Create a site with the terrain region.

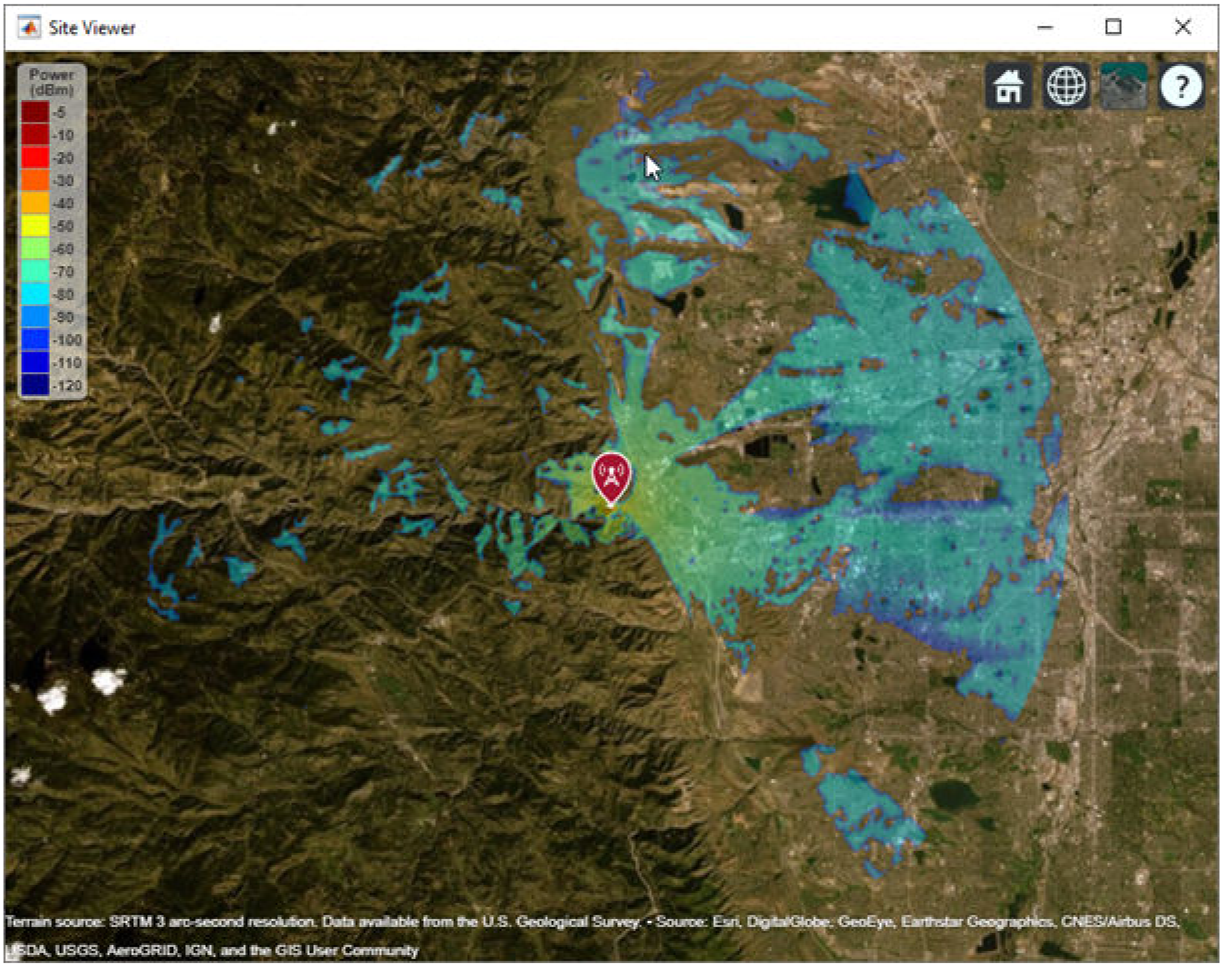
```
mtzion = txsite("Name","Mount Zion", ...
   "Latitude",39.74356, ...
   "Longitude",-105.24193, ...
   "AntennaHeight", 30);
show(mtzion)
```



Site Viewer
Terrain source: SRTM 3 arc-second resolution. Data available from the U.S. Geological Survey. - Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Create a coverage map of the area within 20 km of the transmitter site.

```
coverage(mtzion, ...
   "MaxRange",20000, ...
   "SignalStrengths",-100:-5)
```



Terrain source: SRTM 3 arc-second resolution. Data available from the U.S. Geological Survey. - Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Remove the custom terrain.

```
close(viewer)
removeCustomTerrain("southboulder")
```

Input Arguments

terrainName — User-defined identifier for terrain data

string scalar | character vector

User-defined identifier for terrain data previously added using `addCustomTerrain`, specified as a string scalar or a character vector.

Data Types: `char` | `string`

See Also

`addCustomTerrain` | `siteviewer`

Introduced in R2019b

add

Add propagation models

Syntax

`pmc = add(propmodel1,propmodel2)`

Description

`pmc = add(propmodel1,propmodel2)` adds propagation model objects `propmodel1` and `propmodel2` and returns a composite propagation model object `pmc` which contains `propmodel1` and `propmodel2`.

Note

- The syntax `propmodel1+propmodel2` can be used in place of add.
- A composite propagation model cannot contain more than one propagation model object of the same class.
- A composite propagation model cannot contain more than one propagation model object which includes effects of free-space loss.

Examples

Signal Strength Over Terrain Using Composite Propagation Model

Specify the transmitter and the receiver sites.

```
tx = txsite("Name","Fenway Park", ...
      "Latitude",42.3467, ...
        "Longitude",-71.0972, ...
        "TransmitterFrequency",6e9);
rx = rxsite("Name","Bunker Hill Monument", ...
        "Latitude",42.3763, ...
        "Longitude",-71.0611);
```

Calculate signal strength using default Longley-Rice model.

```
 ss1 = sigstrength(rx,tx)
```

```
ss1 = -80.9353
```

Create composite propagation model with Longley-Rice and specific atmospheric propagation models.

```
pm = propagationModel("longley-rice") + ...
       propagationModel("gas") + propagationModel("rain");
```

Calculate signal strength using composite propagation model.

```
ss2 = sigstrength(rx,tx,pm)
```

```
ss2 = -81.2259
```

Input Arguments

`propmodel1` — Propagation model

character vector | string

Propagation model, specified as a character vector or string. You can also use the `propagationModel` function to define this input.

Data Types: `char` | `string`

`propmodel2` — Propagation model

character vector | string

Propagation model, specified as a character vector or string. You can also use the `propagationModel` function to define this input.

Data Types: `char` | `string`

Output Arguments

`pmc` — Composite propagation model

composite `propagationModel` function object

Composite propagation model, composite `propagationModel` function object

The path loss computed by `pmc` is the sum of path losses computed by `propmodel1` and `propmodel2`. If either `propmodel1` or `propmodel2` is a multipath propagation model, then `pmc` is also a multipath propagation model where path losses from rain, gas, or fog models in the composite are added to the path loss computed for each propagation path.

See Also

`propagationModel` | `range`

Introduced in R2020a

pattern

Plot antenna radiation pattern on map

Syntax

```
pattern(tx)
pattern(rx,frequency)
pattern(___,Name,Value)
```

Description

`pattern(tx)` plots the 3-D antenna radiation pattern for the transmitter site, `txsite`. Signal gain value (dBi) in a particular direction determines the color of the pattern.

Note This function only supports antenna sites with `CoordinateSystem` property set to `'geographic'`.

`pattern(rx,frequency)` plots the 3-D radiation pattern for the receiver site, `rxsite` for the specified `frequency`.

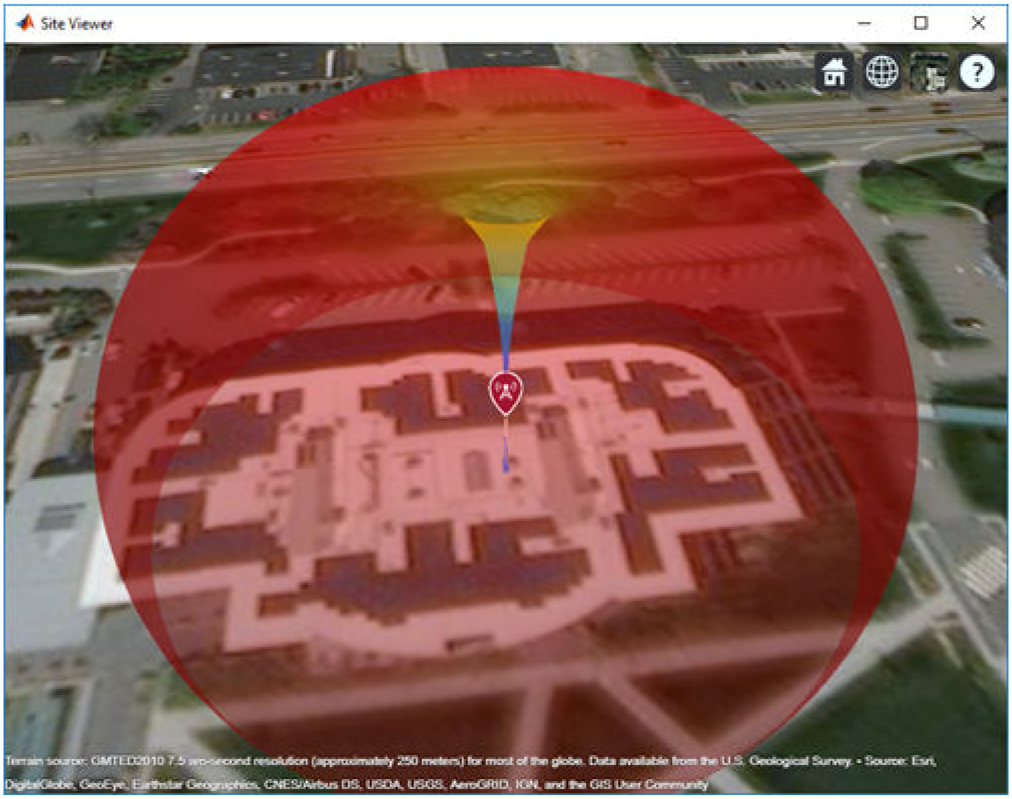
`pattern(___,Name,Value)` plots the 3-D radiation pattern with additional options specified by name-value pair arguments.

Examples

Single Transmitter Site Pattern

Define and visualize the radiation pattern of a single transmitter site.

```
tx = txsite;
pattern(tx)
```



Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Input Arguments

tx — Transmitter site

txsite object

Transmitter site, specified as a txsite object.

rx — Receiver site

rxsite object

Receiver site, specified as a rxsite object.

frequency — Frequency to calculate radiation pattern

positive scalar

Frequency to calculate radiation pattern, specified as a positive scalar.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Size',2

Size — Size of pattern plot

50 (default) | numerical scalar

Size of the pattern plot, specified as the comma-separated pair consisting of `'Size'` and a numerical scalar in meters. This parameter represents the distance between the antenna position and the point on the plot with the highest gain.

Data Types: `double`

`Transparency` — Transparency of pattern plot
`0.4` (default) | real number in the range of [0,1]

Transparency of the pattern plot, specified as the comma-separated pair consisting of `'Transparency'` and a real number in the range of [0,1], where `0` is completely transparent and `1` is completely opaque.

Data Types: `double`

`Colormap` — Colormap for coloring of pattern plot
`'jet(256)'` (default) | predefined colormap name | *M*-by-3 array of RGB triplets

Colormap for coloring of the pattern plot, specified as the comma-separated pair consisting of `'Colormap'` and predefined colormap name or an *M*-by-3 array of RGB (red, blue, green) triplets that define *M* individual colors.

Data Types: `double`

`Resolution` — Resolution of 3-D pattern
`'high'` (default) | `'low'` | `'`

Resolution of 3-D map, specified as the comma-separated pair consisting of `'Resolution'` and `'low'`, `'medium'`, or `'high'`. This property controls the visual quality and the time taken to plot the pattern where the value of `'low'` corresponds to the fastest and the least detailed pattern.

Data Types: `double`

`Map` — Map for visualization of surface data
`siteviewer` object

Map for visualization of surface data, specified as the comma-separated pair consisting of `'Map'` and a `siteviewer` object.[7]

Data Types: `char` | `string`

See Also

`coverage`

Introduced in R2019b

[7] Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

show

Show site location on map

Syntax

```
show(site)
show(site,Name,Value)
```

Description

`show(site)` displays the location of transmitter or receiver site on a map using a marker.

Note This function only supports antenna sites with `CoordinateSystem` property set to `'geographic'`.

`show(site,Name,Value)` displays `site` on a map with additional options specified by one or more Name-Value pairs.

Examples

Default Receiver Site

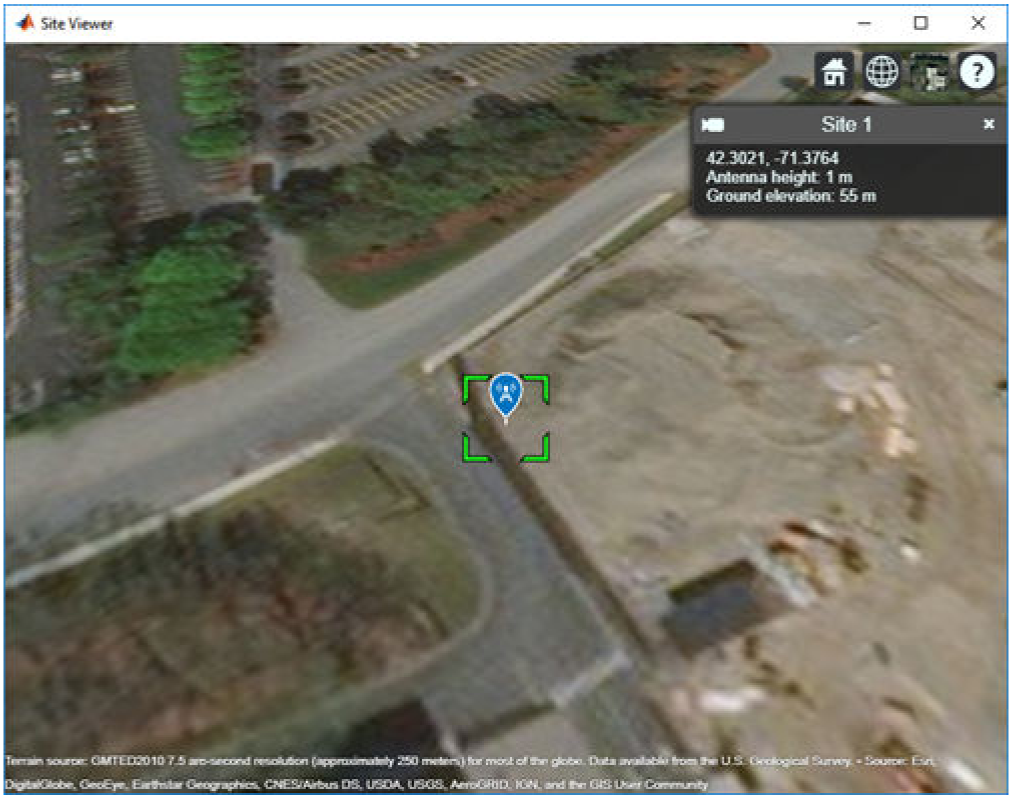
Create and show the default receiver site.

```
rx = rxsite
```

```
rx = 
  rxsite with properties:

                   Name: 'Site 2'
               Latitude: 42.3021
              Longitude: -71.3764
                Antenna: 'isotropic'
           AntennaAngle: 0
          AntennaHeight: 1
             SystemLoss: 0
    ReceiverSensitivity: -100
```

```
show(rx)
```



Site 1

42.3021, -71.3764
Antenna height: 1 m
Ground elevation: 55 m

Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

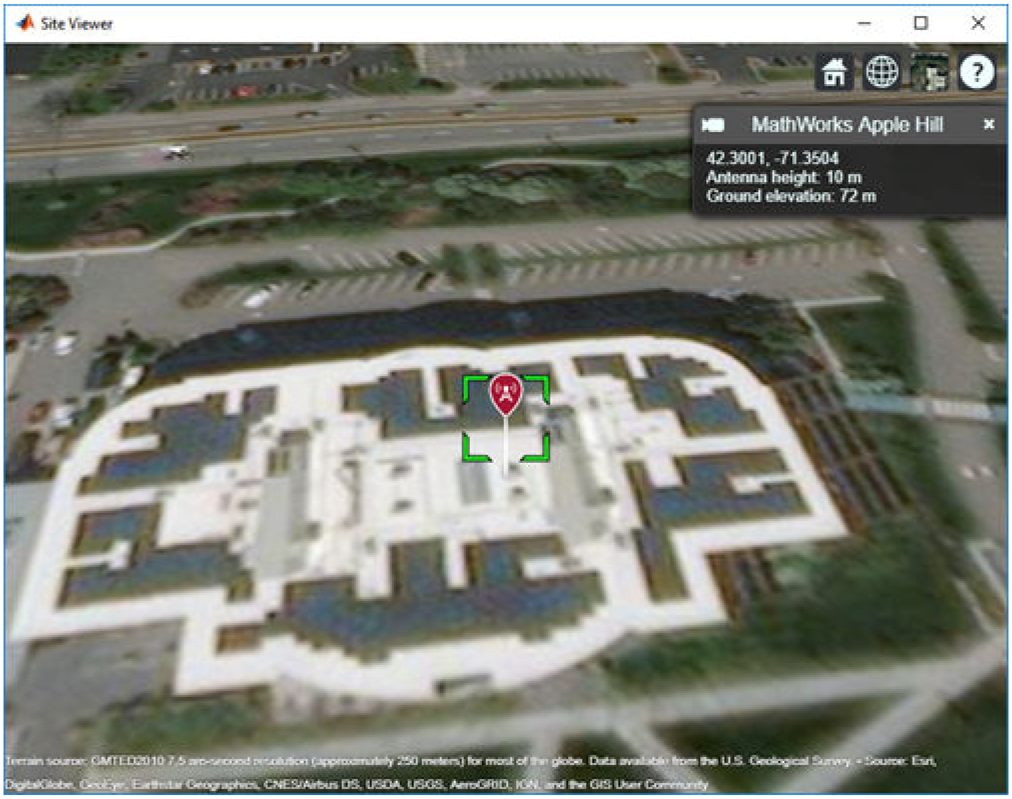
Show and Hide Transmitter Site

Create a transmitter site.

```
tx = txsite('Name','MathWorks Apple Hill',...
       'Latitude',42.3001, ...
       'Longitude',-71.3504);
```

Show the transmitter site.

```
show(tx)
```



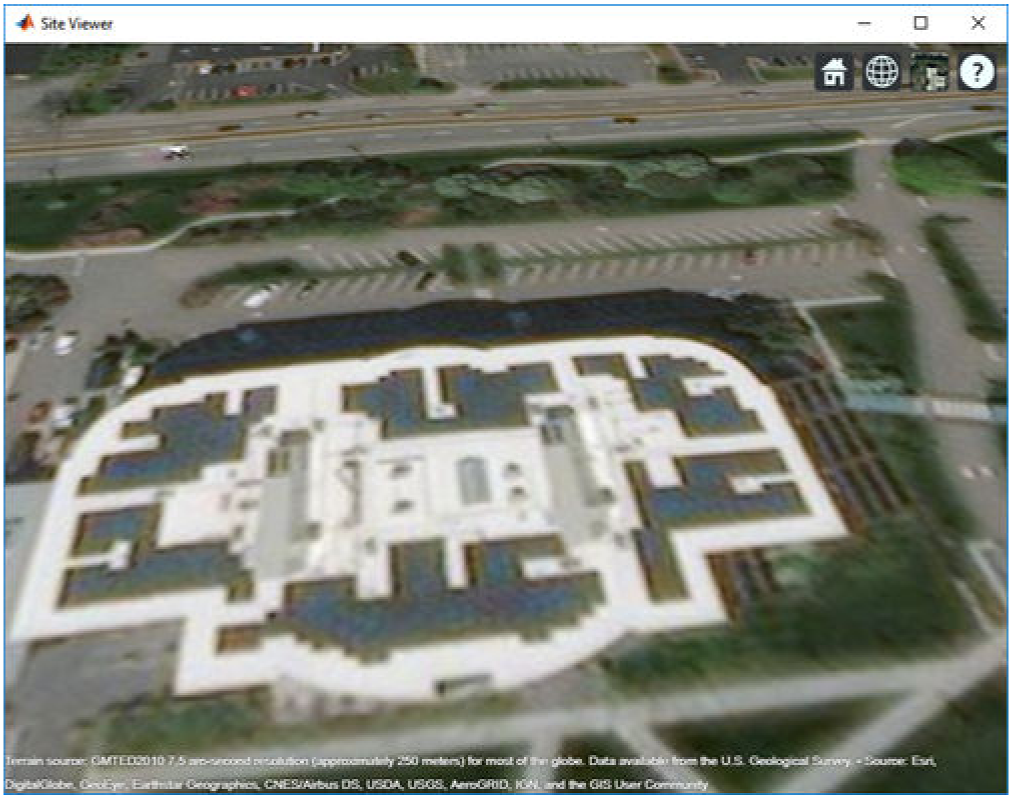
MathWorks Apple Hill

42.3001, -71.3504
Antenna height: 10 m
Ground elevation: 72 m

Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Hide the transmitter site.

```
hide(tx)
```



Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Input Arguments

`site` — Transmitter or receiver site
`txsite` or `rxsite` object | array of `txsite` or `rxsite` objects

Transmitter or receiver site, specified as a `txsite` or `rxsite` object or an array of `txsite` or `rxsite` objects.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'ClusterMarkers',true`

`Icon` — Image file
character vector

Image file, specified as a character vector.

Data Types: `char`

`IconSize` — Width and height of icon
`36-by-36` (default) | 1-by-2 vector of positive numeric values

Width and height of the icon, specified as a 1-by-2 vector of positive numeric values in pixels.

`IconAlignment` — Vertical position of icon relative to site

'top' (default) | `'center'` | `'bottom'`

Vertical position of icon relative to site, specified as:

- `'bottom` - Aligns the icon below the site antenna position.
- `'center'` - Aligns the center of the icon to the site antenna position.
- `'top'` - Aligns the icon above the site antenna position.

`ClusterMarkers` — Combine nearby markers into groups or clusters

true | false

Combine nearby markers into groups or clusters, specified as true or false.

Data Types: `char`

`Map` — Map for visualization of surface data

`siteviewer` object

Map for visualization of surface data, specified as the comma-separated pair consisting of `'Map'` and a `siteviewer` object.[8]

Data Types: `char` | `string`

See Also

`hide`

Introduced in R2019b

[8] Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

sigstrength

Signal strength due to transmitter

Syntax

```
ss = sigstrength(rx,tx)
ss = sigstrength(rx,tx,propmodel)
ss = sigstrength( ___ ,Name,Value)
```

Description

`ss = sigstrength(rx,tx)` returns the signal strength at the receiver site due to the transmitter site.

`ss = sigstrength(rx,tx,propmodel)` returns the signal strength at the receiver site using the specified propagation model. Specifying propagation model is same as specifying the `'PropagationModel'` name-value pair.

`ss = sigstrength( ___ ,Name,Value)` returns the signal strength using additional options specified by `Name,Value` pairs and either of the previous syntaxes.

Examples

Received Power and Link Margin at Receiver

Create a transmitter site.

```
tx = txsite('Name','Fenway Park', ...
        'Latitude', 42.3467, ...
        'Longitude', -71.0972);
```

Create a receiver site with sensitivity defined (in dBm).

```
 rx = rxsite('Name','Bunker Hill Monument', ...
        'Latitude', 42.3763, ...
        'Longitude', -71.0611, ...
        'ReceiverSensitivity', -90);
```

Calculate the received power and link margin. Link margin is the difference between the receiver's sensitivity and the received power.

```
ss = sigstrength(rx,tx)
```

```
ss = -71.1414
```

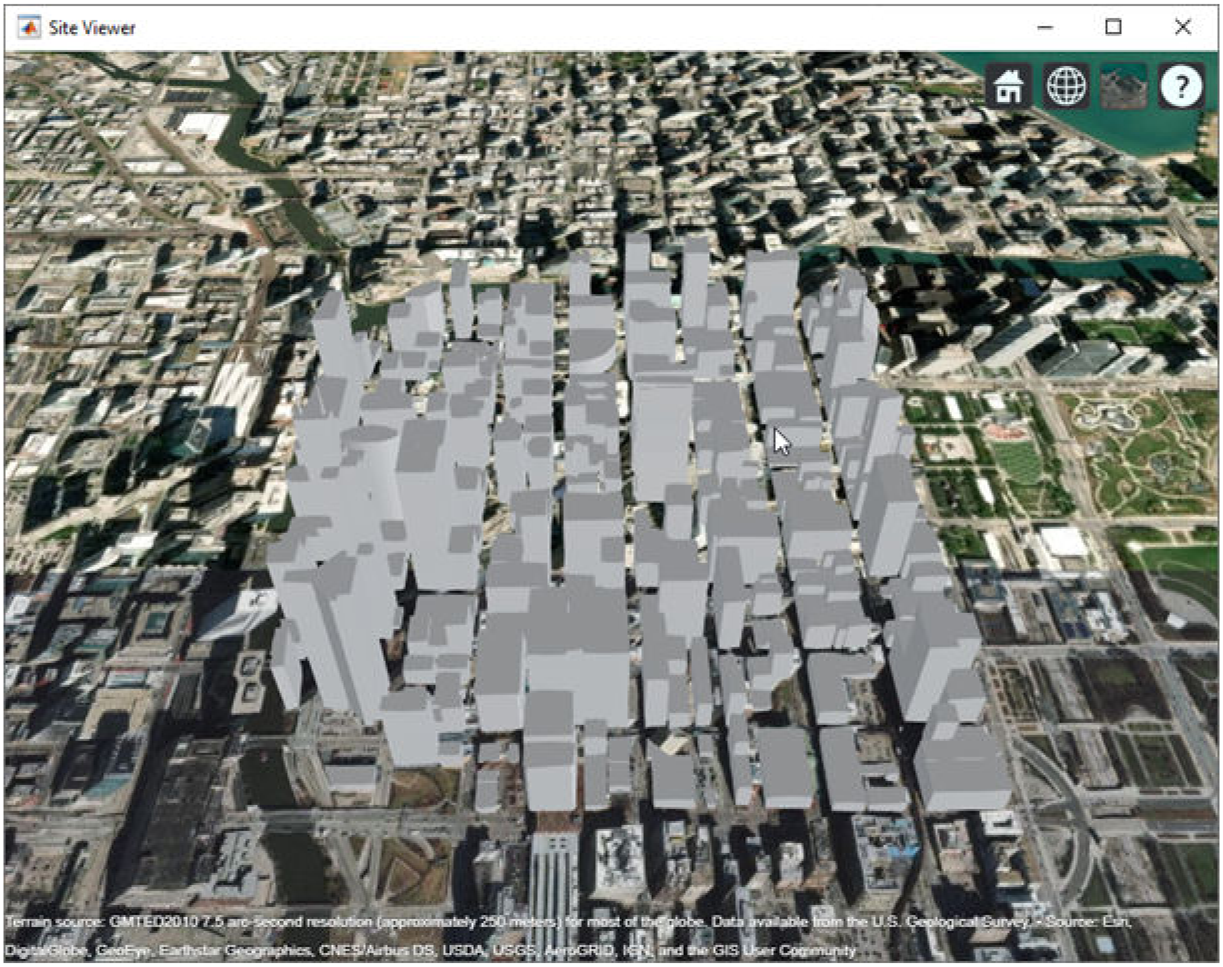
```
margin = abs(rx.ReceiverSensitivity - ss)
```

```
margin = 18.8586
```

Signal Strength Using Ray Tracing Image Method Propagation Model

Launch Site Viewer with buildings in Chicago. For more information about the osm file, see [1] on page 4-0 .

```
viewer = siteviewer("Buildings","chicago.osm");
```



Site Viewer
Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. • Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Create transmitter site on a building.

```
tx = txsite('Latitude',41.8800, ...
    'Longitude',-87.6295, ...
    'TransmitterFrequency',2.5e9);
```

Create receiver site near another building.

```
rx = rxsite('Latitude',41.881352, ...
    'Longitude',-87.629771, ...
    'AntennaHeight',30);
```

Compute signal strength using ray tracing propagation model and default single-reflection analysis.

```
pm = propagationModel("raytracing-image-method");
ssOneReflection = sigstrength(rx,tx,pm)
ssOneReflection = -54.0915
```

Compute signal strength with analysis up to two reflections, where total received power is the cumulative power of all propagation paths

```
pm.MaxNumReflections = 2;
ssTwoReflections = sigstrength(rx,tx,pm)
```

```
ssTwoReflections = -52.3890
```

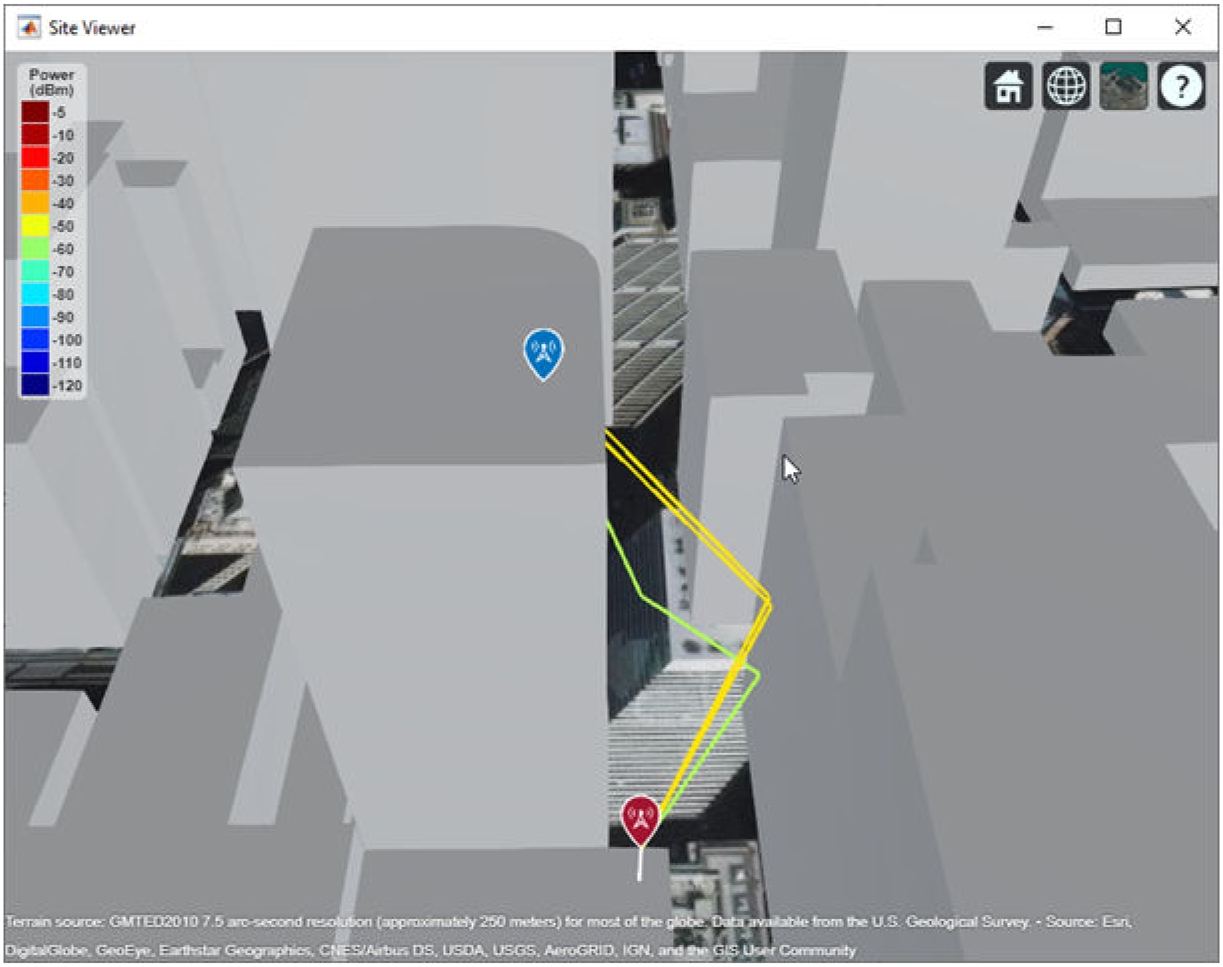
Observe effect of material by replacing default concrete material with perfect reflector.

```
pm.BuildingsMaterial = 'perfect-reflector';
ssPerfect = sigstrength(rx,tx,pm)
```

```
ssPerfect = -41.9927
```

Plot propagation paths.

```
raytrace(tx, rx, pm)
```



Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. - Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Appendix

[1] The osm file is downloaded from https://www.openstreetmap.org, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), https://opendatacommons.org/licenses/odbl/.

Input Arguments

rx — Receiver site

rxsite object | array of rxsite objects

Receiver site, specified as a rxsite object. You can use array inputs to specify multiple sites.

tx — Transmitter site

txsite object | array of txsite objects

Transmitter site, specified as a txsite object. You can use array inputs to specify multiple sites.

propmodel — Propagation model

character vector | string

Propagation model, specified as a character vector or string. You can use the propagationModel function to define this input. The default value depends on the coordinate system used by the input sites:

Coordinate System	Default propagation model value
'geographic'	• 'longley-rice' when you use a terrain. • 'freespace' when you do not use a terrain.
'cartesian'	• 'freespace' when Map is set to none. • 'raytracing-image-method' when Map is set to the name of an STL file or a triangulation object.

You can also use the name-value pair 'PropagationModel' to specify this parameter.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Type','power'

Type — Type of signal strength to compute

'power' (default) | 'efield'

Type of signal strength to compute, specified as the comma-separated pair consisting of 'Type and 'power' or 'efield'.

When type is 'power', signal strength is expressed in power units (dBm) of the signal at the mobile receiver input. When type is 'efield', signal strength is expressed in electric field strength units (dBµV/m) of signal wave incident on the antenna.

Data Types: char | string

PropagationModel — Propagation model to use for path loss calculations

'longley-rice' (default) | 'freespace' | 'close-in' | 'rain' | 'gas' | 'fog' | 'raytracing-image-method' | propagation model object

Propagation model to use for the path loss calculations, specified as the comma-separated pair consisting of 'PropagationModel' and one of the following:

- 'freespace' - Free space propagation model
- 'rain' - Rain propagation model
- 'gas' - Gas propagation model
- 'fog' - Fog propagation model
- 'close-in' - Close-in propagation model
- 'longley-rice' - Longley-Rice propagation model
- 'tirem' - Tirem propagation model
- 'raytracing-image-method' - -Raytracing propagation model using method of images.

The default propagation model is 'longley-rice' when terrain is enabled and 'freespace' when terrain is disabled.

Terrain propagation models including 'longley-rice' and 'tirem' are only supported for sites with CoordinateSystem property set to 'geographic'.

Data Types: char

Map — Map for visualization or surface data

siteviewer object | terrain name

Map for visualization or surface data, specified as the comma-separated pair consisting of 'Map and one of the following depending on the coordinate system:

Coordinate System	Valid map values	Default map value
'geographic'	• siteviewer[a] • A terrain name may be specified if the function is called with an output argument. Valid terrain names are 'none', 'gmted2010', or the name of the custom terrain data added using addCustomTerrain	• current siteviewer or new siteviewer if none are open. • 'gmted2010' if called with an output.
'cartesian'	'none', triangulation object or name of an STL file.	'none'

[a] Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: char | string

Output Arguments

`ss` — Signal strength

M-by-*N* array

Signal strength, returned as *M*-by-*N* array in dBm. *M* is the number of TX sites and *N* is the number of RX sites.

See Also

`link` | `propagationModel` | `sinr`

Introduced in R2019b

sinr

Display signal-to-interference-plus-noise ratio (SINR) map

Syntax

```
sinr(txs)
sinr(txs,propmodel)
sinr( ___ ,Name,Value)
pd = sinr(txs, ___ )
r = sinr(rxs,txs, ___ )
```

Description

`sinr(txs)` displays the signal-to-interference-plus-noise ratio (SINR) for transmitter sites, `txs`. The map contours are generated using SINR values computed for receiver site locations on the map. For each location, the signal source is the transmitter site in TXS with the greatest signal strength. The remaining transmitter sites in `txs` with the same transmitter frequency act as sources of interference. If `txs` is scalar or there are no sources of interference the resultant map displays signal-to-noise ratio (SNR).

`sinr(txs,propmodel)` displays the SINR map with the propagation model set to the value in `propmodel`.

`sinr( ___ ,Name,Value)` sets properties using one or more name-value pairs, in addition to the input arguments in previous syntaxes. For example, `sinr(txs,'MaxRange',8000)` sets the range from the site location at 8000 meters to include in the SINR map region.

`pd = sinr(txs, ___ )` returns computed SINR data in the propagation data object, `pd`. No plot is displayed and any graphical only name-value pairs are ignored.

`r = sinr(rxs,txs, ___ )` returns the `sinr` in dB computed at the receiver sites due to the transmitter sites.

Examples

SINR Map for Multiple Transmitters

Define names and location of sites in Boston.

```
names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"];
lats = [42.3467,42.3598,42.3763];
lons = [-71.0972,-71.0545,-71.0611];
```

Create a transmitter site array.

```
txs = txsite('Name', names,...
       'Latitude',lats,...
       'Longitude',lons, ...
       'TransmitterFrequency',2.5e9);
```

Display the SINR map, where signal source for each location is selected as the transmitter site with the strongest signal.

```
sinr(txs)
```

Terrain source: GMTED2010 7.5 arc-second resolution (approximately 250 meters) for most of the globe. Data available from the U.S. Geological Survey. - Source: Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AeroGRID, IGN, and the GIS User Community

Input Arguments

txs — Transmitter sites

`txsite` object | array of `txsite` objects

Transmitter site, specified as a `txsite` object. Use array inputs to specify multiple sites.

This function only supports plotting antenna sites when `CoordinateSystem` property is set to `'geographic'`.

rxs — Receiver sites

`rxsite` object | array of `rxsite` objects

Receiver site, specified as a `rxsite` object. Use array inputs to specify multiple sites.

This function only supports plotting antenna sites when `CoordinateSystem` property is set to `'geographic'`.

propmodel — Propagation model
character vector | string

Propagation model, specified as a character vector or string. You can use the propagationModel function to define this input. The default value depends on the coordinate system used by the input sites:

Coordinate System	Default propagation model value
'geographic'	• 'longley-rice' when you use a terrain. • 'freespace' when you do not use a terrain.
'cartesian'	• 'freespace' when Map is set to none. • 'raytracing-image-method' when Map is set to the name of an STL file or a triangulation object.

You can also use the name-value pair 'PropagationModel' to specify this parameter.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'MaxRange',8000

General

SignalSource — Signal source of interest
'strongest' (default) | transmitter site object

Signal source of interest, specified as the comma-separated pair consisting of SignalSource and 'strongest' or as a transmitter site object. When the signal source of interest is 'strongest', the transmitter with the greatest signal strength is chosen as the signal source of interest for that location. When computing sinr, SignalSource can be a txsite array with equal number of elements rxs where each transmitter site element defines the signal source for the corresponding receiver site.

PropagationModel — Propagation model to use for path loss calculations
'longley-rice' (default) | 'freespace' | 'close-in' | 'rain' | 'gas' | 'fog' | 'raytracing-image-method' | propagation model object

Propagation model to use for the path loss calculations, specified as the comma-separated pair consisting of 'PropagationModel' and one of the following:

- 'freespace' - Free space propagation model
- 'rain' - Rain propagation model
- 'gas' - Gas propagation model
- 'fog' - Fog propagation model
- 'close-in' - Close-in propagation model
- 'longley-rice' - Longley-Rice propagation model
- 'tirem' - Tirem propagation model

- `'raytracing-image-method'`--Raytracing propagation model using method of images.

The default propagation model is `'longley-rice'` when terrain is enabled and `'freespace'` when terrain is disabled. If `'raytracing-image-method'` is specified, the value of `'MaxNumReflections'` property must be lesser than 1.

Terrain propagation models including `'longley-rice'` and `'tirem'` are only supported for sites with `CoordinateSystem` property set to `'geographic'`.

Data Types: `char`

`ReceiverNoisePower` — Total noise power at receiver

`-107` (default) | scalar

Total noise power at receiver, specified as the comma-separated pair consisting of `'ReceiverNoisePower'` and a scalar in dBm. The default value assumes that the receiver bandwidth is 1 MHz and receiver noise figure is 7 dB.

$$N = -174 + 10 * \log(B) + F$$

where,

- N = Receiver noise in dBm
- B = Receiver bandwidth in Hz
- F = Noise figure in dB

`ReceiverGain` — Receiver gain

`2.1` (default) | scalar

Mobile receiver gain, specified as the comma-separated pair consisting of `'ReceiverGain'` and a scalar in dB. The receiver gain values include the antenna gain and the system loss. If you call the function using an output argument, the default value is computed using `rxs`.

`ReceiverAntennaHeight` — Receiver antenna height

`1` (default) | scalar

Receiver antenna height above the ground, specified as the comma-separated pair consisting of `'ReceiverAntennaHeight'` and a scalar in meters. If you call the function using an output argument, the default value is computed using `rxs`.

`Map` — Map for visualization or surface data

`siteviewer` object | terrain name

Map for visualization or surface data, specified as the comma-separated pair consisting of `'Map` and one of the following depending on the coordinate system:

Coordinate System	Valid map values	Default map value
'geographic'	- siteviewer[a] - A terrain name may be specified if the function is called with an output argument. Valid terrain names are 'none', 'gmted2010', or the name of the custom terrain data added using addCustomTerrain	- current siteviewer or new siteviewer if none are open. - 'gmted2010' if called with an output.
'cartesian'	'none', triangulation object or name of an STL file.	'none'

[a] Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: char | string

For Plotting SINR

Values — Values of SINR for display

[-5:20] (default) | numeric vector

Values of SINR for display, specified as the comma-separated pair consisting of 'Values' and a numeric vector. Each value is displayed as a different colored, filled on the contour map. The contour colors are derived using Colormap and ColorLimits.

MaxRange — Maximum range of coverage map from each transmitter site

numeric scalar

Maximum range of coverage map from each transmitter site, specified as a positive numeric scalar in meters representing great circle distance. MaxRange defines the region of interest on the map to plot. The default value is automatically computed based on the propagation model type as shown:

Propagation Model	MaxRange
Basic or urban	30 km
Terrain	30 km or distance to the furthest building.
Multipath	500 m

Data Types: double

Resolution — Resolution of receiver site locations used to compute SINR values

'auto' (default) | numeric scalar

Resolution of receiver site locations used to compute SINR values, specified as the comma-separated pair consisting of 'Resolution' and 'auto' or a numeric scalar in meters. The resolution defines the maximum distance between the locations. If the resolution is 'auto', sinr computes a value scaled to MaxRange. Decreasing the resolution increases the quality of the SINR map and the time required to create it.

Colormap — Colormap for coloring filled contours

'jet' (default) | *M*-by-3 array of RGB triplets

Colormap for coloring filled contours, specified as the comma-separated pair consisting of `'ColorMap'` and an *M*-by-3 array of RGB triplets, where *M* is the number of individual colors.

`ColorLimits` — Color limits for color maps
`[-5 20]` (default) | two-element vector

Color limits for color maps, specified as the comma-separated pair consisting of `'ColorLimits'` and a two-element vector of the form [min max]. The color limits indicate the SINR values that map to the first and last colors in the colormap.

`ShowLegend` — Show signal strength color legend on map
`'true'` (default) | `'false'`

Show signal strength color legend on map, specified as the comma-separated pair consisting of `'ShowLegend'` and `'true'` or `'false'`.

`Transparency` — Transparency of SINR map
`0.4` (default) | numeric scalar

Transparency of SINR map, specified as the comma-separated pair consisting of `'Transparency'` and a numeric scalar in the range 0–1. If the value is zero, the map is completely transparent. If the value is one, the map is completely opaque.

Output Arguments

r — Signal to interference plus noise ratio at the receiver
numeric vector (default)

Signal to interference plus noise ratio at the receiver due to the transmitter sites, returned as a numeric vector. The vector length is equal to the number of receiver sites.

Data Types: `double`

pd — SINR data
`propagationData` object

SINR data, returned as a `propagationData` object consisting of *Latitude* and *Longitude*, and a signal strength variable corresponding to the plot type. Name of the `propagationData` is `"SINR Data"`.

Note This function only supports plotting for antenna sites with `CoordinateSystem` property set to `'geographic'`.

See Also

`coverage` | `propagationModel`

Introduced in R2019b

plot (rays), plot

Package: comm

Plot rays in Site Viewer map

Syntax

```
plot(rays)
plot(rays,Name,Value)
```

Description

plot(rays) plots the propagation paths for ray objects in the Site Viewer map.

plot(rays,Name,Value) plots the propagation paths for ray objects in the Site Viewer map with additional options specified by one or more name-value pair arguments.

Examples

Plot Propagation Rays Between Sites in Chicago

Return ray tracing results in comm.Ray objects and plot the ray propagation path after relaunching the Site Viewer map.

Create a Site Viewer map, loading building data for Chicago. For more information about the osm file, see [1] on page 4-0 .

```
viewer = siteviewer('Buildings','chicago.osm');
```

Create and show a transmitter site on one building and a receiver site on another building.

```
tx = txsite('Latitude',41.8800,'Longitude',-87.6295, ...
    'TransmitterFrequency',2.5e9);
show(tx);
rx = rxsite('Latitude',41.881352,'Longitude',-87.629771, ...
    'AntennaHeight',30);
show(rx);
```

Perform ray tracing, returning the ray object results. For the configuration defined, ray tracing returns a cell array containing one ray object. Display the ray object properties. Then, close the Site Viewer map.

```
rays = raytrace(tx,rx)
```

```
rays = 1×1 cell array
    {1×1 comm.Ray}
```

```
rays{1}
```

```
ans = 
  Ray with properties:
      PathSpecification: 'Locations'
       CoordinateSystem: 'Geographic'
    TransmitterLocation: [3×1 double]
       ReceiverLocation: [3×1 double]
            LineOfSight: 0
    ReflectionLocations: [3×1 double]
              Frequency: 2.5000e+09
         PathLossSource: 'Custom'
               PathLoss: 94.0915
             PhaseShift: 1.2939

   Read-only properties:
       PropagationDelay: 5.7088e-07
    PropagationDistance: 171.1462
       AngleOfDeparture: [2×1 double]
         AngleOfArrival: [2×1 double]
         NumReflections: 1
```

```
close(viewer);
```

You can plot the rays without performing ray tracing again. Create another Site Viewer map with the same buildings. Show the transmitter and receiver sites. Using the previously returned cell array of ray objects, plot the reflected rays between the transmitter site and the receiver site. The plot function can plot the path for one ray object at a time.

```
siteviewer('Buildings','chicago.osm');
show(tx);
show(rx);
plot(rays{1},'Type','power', ...
    'TransmitterSite',tx,'ReceiverSite',rx);
```

Appendix

[1] The osm file is downloaded from https://www.openstreetmap.org, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), https://opendatacommons.org/licenses/odbl/.

Input Arguments

rays — Ray configuration object

comm.Ray object

Ray configuration, specified as one `comm.Ray` object or a vector of `comm.Ray` objects. Each object must have the `PathSpecification` property set to `"Locations"` and the `CoordinateSystem` property set to `"Geographic"`.

Data Types: `comm.Ray`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `plot(rays,"Type","pathloss","ColorLimits",[-100 0])` adds the propagation path specified in `rays` to the current Site Viewer and adjusts the default color limits.

Type — Quantity type to plot
`"pathloss"` (default) | `"power"`

Quantity type to plot, specified as `"pathloss"` or `"power"`. Based on the value specified for `Type`, the color applied along the path maps to the path loss in dB or the power in dBm of the signal along the path.

Data Types: `char` | `string`

`TransmitterSite` — Transmitter site
`txsite` object

Transmitter site, specified as a `txsite` object.

Dependencies

Applies only when `Type` is set to `"power"`.

Data Types: `char`

`ReceiverSite` — Receiver site
`rxsite` object

Receiver site, specified as an `rxsite` object.

Dependencies

Applies only when `Type` is set to `"power"`.

Data Types: `char`

`ColorLimits` — Colormap color limits
[-120 -5] or [45 160] (default) | 1-by-2 numeric vector

Color limits for colormap, specified as a 1-by-2 numeric vector, [*min*, *max*], where *min* represents the lower saturation limit and *max* represents the upper saturation limit. The default is [-120 -5] when `Type` is set to `'power'` and [45 160] when `Type` is set to `'pathloss'`.

Data Types: `double`

`Colormap` — Colormap applied to propagation path
`'jet'` (default) | *M*-by-3 numeric array

Colormap applied to propagation path, specified as an *M*-by-3 numeric array of RGB (red,green,blue) triplets that define *M* individual colors.

Data Types: `double` | `char` | `string`

`ShowLegend` — Show color legend on map
`true` (default) | `false`

Show color legend on map, specified as `true` or `false`.

Data Types: `logical`

Map — Map for visualization and surface data
siteviewer object

Map for visualization and surface data, specified as a siteviewer object.[9] The default is the current siteviewer object, or if no Site Viewer is open a new siteviewer object opens.

Data Types: siteviewer object

Blocks

A-Law Compressor

Implement A-law compressor for source coding

Library

Source Coding

Description

The A-Law Compressor block implements an A-law compressor for the input signal. The formula for the A-law compressor is

$$y = \begin{cases} \dfrac{A|x|}{1 + \log A}\mathrm{sgn}(x) & \text{for } 0 \le |x| \le \dfrac{V}{A} \\ \dfrac{V(1 + \log(A|x|/V))}{1 + \log A}\mathrm{sgn}(x) & \text{for } \dfrac{V}{A} < |x| \le V \end{cases}$$

where A is the A-law parameter of the compressor, V is the peak signal magnitude for x, log is the natural logarithm, and *sgn* is the `sign` function.

The most commonly used A value is 87.6.

The input can have any shape or frame status. This block processes each vector element independently.

Parameters

A value

The A-law parameter of the compressor.

Peak signal magnitude

The peak value of the input signal. This is also the peak value of the output signal.

Supported Data Type

Port	Supported Data Types
In	• double
Out	• double

A-Law Expander

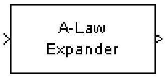
Implement A-law expander for source coding



Library

Source Coding

Description

The A-Law Expander block recovers data that the A-Law Compressor block compressed. The formula for the A-law expander, shown below, is the inverse of the compressor function.

$$x = \begin{cases} \dfrac{y(1 + \log A)}{\mathrm{A}} & \text{for } 0 \le |y| \le \dfrac{\mathrm{V}}{1+\log\mathrm{A}} \\ \exp(|\mathrm{y}|(1 + \log A)/V - 1)\dfrac{V}{A}\mathrm{sgn}(y) & \text{for } \dfrac{\mathrm{V}}{1+\log\mathrm{A}} < |y| \le V \end{cases}$$

The input can have any shape or frame status. This block processes each vector element independently.

Parameters

A value

The A-law parameter of the compressor.

Peak signal magnitude

The peak value of the input signal. This is also the peak value of the output signal.

Match these parameters to the ones in the corresponding A-Law Compressor block.

Algebraic Deinterleaver

Restore ordering of input symbols using algebraically derived permutation

Library

Block sublibrary of Interleaving

Description

The Algebraic Deinterleaver block restores the original ordering of a sequence that was interleaved using the Algebraic Interleaver block. In typical usage, the parameters in the two blocks have the same values.

The **Number of elements** parameter, *N*, indicates how many numbers are in the input vector. This block accepts a column vector input signal.

The block accepts the following data types: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point. The output signal inherits its data type from the input signal.

The **Type** parameter indicates the algebraic method that the block uses to generate the appropriate permutation table. Choices are `Takeshita-Costello` and `Welch-Costas`. Each of these methods has parameters and restrictions that are specific to it; these are described on the reference page for the Algebraic Interleaver block.

Parameters

Type

The type of permutation table that the block uses for deinterleaving. Choices are `Takeshita-Costello` and `Welch-Costas`.

Number of elements

The number of elements, *N*, in the input vector.

Multiplicative factor

The factor the block uses to compute the corresponding interleaver's cycle vector. This field appears only when you set **Type** to `Takeshita-Costello`.

Cyclic shift

The amount by which the block shifts indices when creating the corresponding interleaver's permutation table. This field appears only when you set **Type** to `Takeshita-Costello`.

Primitive element

An element of order *N* in the finite field GF(N+1). This field appears only if **Type** is set to `Welch-Costas`.

Blocks

Algebraic Interleaver | General Block Deinterleaver

Introduced before R2006a

Algebraic Interleaver

Reorder input symbols using algebraically derived permutation table

Library

Block sublibrary of Interleaving

Description

The Algebraic Interleaver block rearranges the elements of its input vector using a permutation that is algebraically derived. The **Number of elements** parameter, *N*, indicates how many numbers are in the input vector. This block accepts a column vector input signal.

The block accepts the following data types: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point. The output signal inherits its data type from the input signal.

The **Type** parameter indicates the algebraic method that the block uses to generate the appropriate permutation table. Choices are `Takeshita-Costello` and `Welch-Costas`. Each of these methods has parameters and restrictions that are specific to it:

- If you set **Type** to `Welch-Costas`, then $N + 1$ must be prime. The **Primitive element** parameter is an integer, *A*, between 1 and *N* that represents a primitive element of the finite field GF($N + 1$). This means that every nonzero element of GF($N + 1$) can be expressed as *A* raised to some integer power.

  In a Welch-Costas interleaver, the permutation maps the integer *k* to mod(A^k,$N + 1$) - 1.
- If you set **Type** to `Takeshita-Costello`, then *N* must be 2^m for some integer *m*. The **Multiplicative factor** parameter, *k*, must be an odd integer less than *N*. The **Cyclic shift** parameter, *h*, must be a nonnegative integer less than *N*.

  A Takeshita-Costello interleaver uses a length-*N* *cycle vector* whose *n*th element is

  $$c(n) = \mathrm{mod}\left(k \cdot \frac{n \cdot (n-1)}{2}, N\right) + 1,\ n$$

  for integers n between 1 and N. The intermediate permutation function is obtained by using the following relationship:

  $$\Pi(c(n)) = c(n+1)$$

  where

  $$n = 1{:}N$$

  The interleaver's actual permutation vector is the result of cyclically shifting the elements of the permutation vector, π, by the **Cyclic shift** parameter, *h*.

Parameters

Type

The type of permutation table that the block uses for interleaving.

Number of elements

The number of elements, *N*, in the input vector.

Multiplicative factor

The factor used to compute the interleaver's cycle vector. This field appears only if **Type** is set to `Takeshita-Costello`.

Cyclic shift

The amount by which the block shifts indices when creating the permutation table. This field appears only if **Type** is set to `Takeshita-Costello`.

Primitive element

An element of order *N* in the finite field GF(N+1). This field appears only if **Type** is set to `Welch-Costas`.

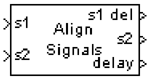
Align Signals

(To be removed) Align two signals by finding delay between them



Align Signals

Compatibility

Align Signals Block will be removed in a future release. Use the Find Delay block to find delays and the Delay block to apply delays instead. For more information, see “Compatibility Considerations” on page 5-11.

Library

Utility Blocks

Description

The Align Signals block aligns two signals by finding the delay between them. This is useful when you want to compare a transmitted and received signal to determine the bit error rate, but do not know the delay in the received signal. This block accepts a column vector or matrix input signal. For a matrix input, the block aligns each channel independently.

The `s1` input port receives the original signal, while the `s2` input port receives a delayed version. The two input signals must have the same dimensions and sample times. The block calculates the delay between the two signals, and then

- Delays the first signal, `s1`, by the calculated value, and outputs it through the port labeled `s1 del`.
- Outputs the second signal `s2` without change through the port labeled `s2`.
- Outputs the delay value through the port labeled `delay`.

See “Delays” for more information about signal delays.

The block's **Correlation window length** parameter specifies how many samples of the signals the block uses to calculate the cross-correlation. The delay output is a nonnegative integer less than the **Correlation window length**.

As the **Correlation window length** is increased, the reliability of the computed delay also increases. However, the processing time to compute the delay increases as well.

You can make the Align Signals block stop updating the delay after it computes the same delay value for a specified number of samples. To do so, select **Disable recurring updates**, and enter a positive integer in the **Number of constant delay outputs to disable updates** field. For example, if you set **Number of constant delay outputs to disable updates** to `20`, the block will stop recalculating and updating the delay after it calculates the same value 20 times in succession. Disabling recurring updates causes the simulation to run faster after the target number of constant delays occurs.

Tips for Using the Block Effectively

- Set the **Correlation window length** parameter sufficiently large so that the computed delay eventually stabilizes at a constant value. If the computed delay is not constant, you should increase **Correlation window length**. If the increased value of **Correlation window length** exceeds the duration of the simulation, then you should also increase the duration of the simulation accordingly.
- If the cross-correlation between the two signals is broad, then **Correlation window length** should be much larger than the expected delay, or else the algorithm might stabilize at an incorrect value. For example, a CPM signal has a broad autocorrelation, so it has a broad cross-correlation with a delayed version of itself. In this case, the **Correlation window length** value should be much larger than the expected delay.
- If the block calculates a delay that is greater than 75 percent of **Correlation window length**, the signal `s1` is probably delayed relative to the signal `s2`. In this case, you should switch the signal lines leading into the two input ports.
- If you use the Align Signals block with the Error Rate Calculation block, you should set the **Receive delay** parameter of the Error Rate Calculation block to `0` because the Align Signals block compensates for the delay. Also, you might want to set the Error Rate Calculation block's **Computation delay** parameter to a nonzero value to account for the possibility that the Align Signals block takes a nonzero amount of time to stabilize on the correct amount by which to delay one of the signals.

Parameters

Correlation window length

The number of samples the block uses to calculate the cross-correlations of the two signals.

Disable recurring updates

Selecting this option causes the block to stop computing the delay after it computes the same delay value for a specified number of samples.

Number of constant delay outputs to disable updates

A positive integer specifying how many times the block must compute the same delay before ceasing to update. This field appears only if **Disable recurring updates** is selected.

Algorithm

The Align Signals block finds the delay by calculating the cross-correlations of the first signal with time-shifted versions of the second signal, and then finding the index at which the cross-correlation is maximized.

Compatibility Considerations

Align Signals Block will be removed

Warns starting in R2019b

Align Signals Block will be removed in a future release. Use the Find Delay block to find delays and the Delay block to apply delays instead.

See “Delays” for an example that uses the Find Delay block in conjunction with the Error Rate Calculation block.

For an example that illustrates how to set the correlation window length properly, see the section **Setting the Correlation Window Length** on the Find Delay block reference page.

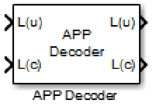
APP Decoder

Decode convolutional code using a posteriori probability (APP) method



Library

Convolutional sublibrary of Error Detection and Correction

Description

The APP Decoder block performs a posteriori probability (APP) decoding of a convolutional code.

Input Signals and Output Signals

The input $L(u)$ represents the sequence of log-likelihoods of encoder input bits, while the input $L(c)$ represents the sequence of log-likelihoods of code bits. The outputs $L(u)$ and $L(c)$ are updated versions of these sequences, based on information about the encoder.

If the convolutional code uses an alphabet of 2^n possible symbols, this block's $L(c)$ vectors have length $Q*n$ for some positive integer Q. Similarly, if the decoded data uses an alphabet of 2^k possible output symbols, then this block's L(u) vectors have length $Q*k$.

This block accepts a column vector input signal with any positive integer for Q.

If you only need the input $L(c)$ and output $L(u)$, you can attach a Simulink Ground block to the input $L(u)$ and a Simulink Terminator block to the output $L(c)$.

This block accepts `single` and `double` data types. Both inputs, however, must be of the same type. The output data type is the same as the input data type.

Specifying the Encoder

To define the convolutional encoder that produced the coded input, use the **Trellis structure** parameter. This parameter is a MATLAB structure whose format is described in “Trellis Description of a Convolutional Code”. You can use this parameter field in two ways:

- If you have a variable in the MATLAB workspace that contains the trellis structure, enter its name as the **Trellis structure** parameter. This way is preferable because it causes Simulink to spend less time updating the diagram at the beginning of each simulation, compared to the usage described next.
- If you want to specify the encoder using its constraint length, generator polynomials, and possibly feedback connection polynomials, use a `poly2trellis` command within the **Trellis structure** field. For example, to use an encoder with a constraint length of 7, code generator polynomials of 171 and 133 (in octal numbers), and a feedback connection of 171 (in octal), set the **Trellis structure** parameter to

  ```
  poly2trellis(7,[171 133],171)
  ```

To indicate how the encoder treats the trellis at the beginning and end of each frame, set the **Termination method** parameter to either `Truncated` or `Terminated`. The `Truncated` option indicates that the encoder resets to the all-zeros state at the beginning of each frame. The `Terminated` option indicates that the encoder forces the trellis to end each frame in the all-zeros state. If you use the Convolutional Encoder block with the **Operation mode** parameter set to `Truncated (reset every frame)`, use the `Truncated` option in this block. If you use the Convolutional Encoder block with the **Operation mode** parameter set to `Terminate trellis by appending bits`, use the `Terminated` option in this block.

Specifying Details of the Algorithm

You can control part of the decoding algorithm using the **Algorithm** parameter. The `True APP` option implements a posteriori probability decoding as per equations 20–23 in section V of [1]. To gain speed, both the `Max*` and `Max` options approximate expressions like

$$\log\sum_i \exp(a_i)$$

by other quantities. The `Max` option uses $\max(a_\mathrm{i})$ as the approximation, while the `Max*` option uses $\max(a_\mathrm{i})$ plus a correction term given by $\ln(1 + \exp(-|a_{i-1} - a_i|))$ [3].

The `Max*` option enables the **Scaling bits** parameter in the dialog box. This parameter is the number of bits by which the block scales the data it processes internally (multiplies the input by (2^`numScalingBits`) and divides the pre-output by the same factor). Use this parameter to avoid losing precision during the computations.

Parameters

Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder.

Termination method

Either `Truncated` or `Terminated`. This parameter indicates how the convolutional encoder treats the trellis at the beginning and end of frames.

Algorithm

Either `True APP`, `Max*`, or `Max`.

Number of scaling bits

An integer between 0 and 8 that indicates by how many bits the decoder scales data in order to avoid losing precision. This field is active only when **Algorithm** is set to `Max*`.

Disable L(c) output port

Select this check box to disable the secondary block output, L(c).

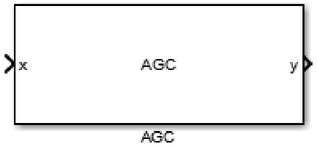
AGC Block

Adaptively adjust gain for constant signal-level output



Library

RF Impairments Correction

Description

The automatic gain controller (AGC) block adaptively adjusts its gain to achieve a constant signal level at the output.

Parameters

Step size

Specify the step size for gain updates as a double-precision or single-precision real positive scalar. The default is `0.01`.

If you increase **Step size**, the AGC responds faster to changes in the input signal level. However, gain pumping also increases.

Desired output power (W)

Specify the desired output power level as a real positive scalar. The power level is specified in Watts referenced to 1 ohm. The default is `1`.

Averaging length

Specify the length of the averaging window in samples as a positive integer scalar. The default is `100`.

Note If you use the AGC with higher order QAM signals, you might need to reduce the variation in the gain during steady-state operation. Inspect the constellation diagram at the output of the AGC and increase the averaging length as needed. An increase in **Averaging length** reduces execution speed.

Maximum power gain (dB)

Specify the maximum gain of the AGC in decibels as a positive scalar. The default is `60`.

If the AGC input signal power is very small, the AGC gain will be very large. This can cause problems when the input signal power suddenly increases. Use **Maximum power gain (dB)** to avoid this by limiting the gain that the AGC applies to the input signal.

Enable output of estimated input power

Select this check box to provide an input signal power estimate to an output port. By default, the check box is not selected.

Simulate using

Select the simulation mode.

`Code generation`

On the first model run, simulate and generate code. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is `Code generation`, System objects corresponding to the blocks accept a maximum of nine inputs.

`Interpreted execution`

Simulate model without generating code. This option results in faster start times but can slow subsequent simulation performance.

Algorithms

This block implements the algorithm, inputs, and outputs described on the `comm.AGC` reference page. The object properties correspond to the block parameters.

Examples

To open these examples, enter the example names at the MATLAB command prompt:

- doc_agc_received_signal_amplitude — Adaptively adjusts the received signal power to approximately 1 Watt.
- doc_agc_plot_step_size — Plots the effect of step size on AGC performance.
- doc_agc_plot_max_gain — Shows how the maximum gain affects the ability of the AGC to reach its target output power.

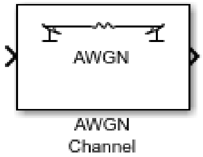
AWGN Channel

Add white Gaussian noise to input signal
Library: Communications Toolbox / Channels



Description

The AWGN Channel block adds white Gaussian noise to the input signal. It inherits the sample time from the input signal.

Ports

Input

`In` — Input data signal
vector | matrix

Input data signal, specified as an N_S-by-1 vector or an N_S-by-N_C matrix.

N_S represents the number of samples in the input signal. N_C represents the number of channels, as determined by the number of columns in the input signal matrix. Both N_S and N_C can be equal to `1`.

The block adds frames of length-N_S Gaussian noise to each of the N_C channels, using a distinct random distribution per channel.

Data Types: `double` | `single`
Complex Number Support: Yes

`Var` — Variance of additive white Gaussian noise
positive scalar | vector

Variance of additive white Gaussian noise, specified as a positive scalar or a 1-by-N_C vector. N_C represents the number of channels, as determined by the number of columns in the input signal matrix. For more information, see “Specifying the Variance Directly or Indirectly” on page 5-22.

Dependencies

To enable this port, set Mode to `Variance from port`.

Data Types: `double`

Output

`Out` — Output data signal
vector | matrix

Output data signal for the AWGN channel, returned as a vector or matrix. The datatype and dimensions of `Out` match those of the input signal, In.

Parameters

`Initial seed` — Noise generator initial seed

`67` (default) | positive scalar | vector

Noise generator initial seed, specified as a positive scalar or a 1-by-N_C vector.

This block uses the Random Source block to generate noise. Random numbers are generated using the Ziggurat method (V5 RANDN algorithm). The block reuses the same initial seeds every time you rerun the simulation, so that this block outputs the same signal each time you run a simulation.

When the input signal is complex, the block creates random data as:

```
randData = randn(2*NS,NC)
noise = randData(1:2:end) + 1i(randData(2:2:end))
```

N_S is the number of samples and N_C is the number of channels.

You can specify different seed values for each DLL build.

Tunable: Yes

`Mode` — Variance mode

`Signal to noise ratio (Eb/No)` (default) | `Signal to noise ratio (Es/No)` | `Signal to noise ratio (SNR)` | `Variance from mask` | `Variance from port`

Variance mode, specified as `Signal to noise ratio (Eb/No)`, `Signal to noise ratio (Es/No)`, `Signal to noise ratio (SNR)`, `Variance from mask`, or `Variance from port`. For more information, see "Relationship Among Eb/No, Es/No, and SNR Modes" on page 5-21 and "Specifying the Variance Directly or Indirectly" on page 5-22.

`Eb/No (dB)` — Ratio of information bit energy per symbol to noise power spectral density

`10` (default) | scalar | vector

Ratio of information bit energy per symbol to noise power spectral density in decibels, specified as a scalar or vector. The information bit energy is the magnitude without channel coding.

Tunable: Yes

Dependencies

To enable this parameter, set Mode to `Eb/No`.

`Es/No (dB)` — Ratio of information symbol energy per symbol to noise power spectral density

`10` (default) | scalar | vector

Ratio of information symbol energy per symbol to noise power spectral density in decibels, specified as a scalar or vector. The information bit energy is the magnitude without channel coding.

Tunable: Yes

Dependencies

To enable this parameter, set Mode to `Es/No`.

`SNR (dB)` — Ratio of signal power to noise power

`10` (default) | scalar | vector

Ratio of signal power to noise power in decibels, specified as a scalar or vector.

Tunable: Yes

Dependencies

To enable this parameter, set Mode to `SNR`.

`Number of bits per symbol` — Number of bits in each input symbol

1 (default) | scalar | vector

Number of bits in each input symbol, specified as a scalar or vector.

Dependencies

To enable this parameter, set Mode to `Eb/No`.

`Input signal power, referenced to 1 ohm (watts)` — Mean square power of input

`1` (default) | scalar | vector

Mean square power of the input in watts, specified as a scalar or vector.

- When Mode is `Eb/No` or `Es/No`, the parameter is the mean square power of the input symbols.
- When `Mode` is `SNR`, this parameter is the mean square power of the input samples.

Tunable: Yes

Dependencies

To enable this parameter, set `Mode` to `Eb/No`, `Es/No`, or `SNR`.

`Symbol period (s)` — Duration of an information channel

`1` (default) | positive scalar | vector

Duration of an information channel symbol in seconds, specified as a positive scalar or vector. The duration of the information channel is measured without channel coding.

Dependencies

To enable this parameter, set Mode to `Eb/No` or `Es/No`.

`Variance` — Variance of white Gaussian noise

`1` (default) | scalar | vector

Variance of the white Gaussian noise, specified as a scalar or vector. For more information, see “Specifying the Variance Directly or Indirectly” on page 5-22.

Tunable: Yes

Dependencies

To enable this parameter, set Mode to `Variance from mask`.

Block Characteristics

Data Types	`double` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`no`

Tips

- You can tune parameters in normal mode, accelerator mode, or rapid accelerator mode.
- Unless otherwise indicated, parameters are *nontunable*.
  - For nontunable parameters, when you use the Simulink Coder™ rapid simulation (RSIM) target to build an RSIM executable, you cannot change their values without recompiling the model.
  - If a parameter is *tunable*, you can change its value at any time. This is useful for Monte Carlo simulations in which you run the simulation multiple times (such as on multiple computers) with different amounts of noise.

Algorithms

Relationship Among Eb/No, Es/No, and SNR Modes

For uncoded complex input signals, the AWGN Channel block relates $E_b/N_{0,}$ E_s/N_0, and SNR according to these equations:

$$E_s/N_0 = (T_{sym}/T_{samp}) \cdot SNR$$

$$E_s/N_0 = E_b/N_0 + 10\log_{10}(k) \text{ in dB}$$

- E_s represents the signal energy in joules.
- E_b represents the bit energy in joules.
- N_0 represents the noise power spectral density in watts/Hz.
- T_{sym} represents the Symbol period (s) parameter of the block in `Es/No` mode.
- k represents the number of information bits per input symbol, Number of bits per symbol.
- T_{samp} represents the inherited sample time of the block, in seconds.

For real signal inputs, the AWGN Channel block relates E_s/N_0 and SNR according to this equation:

$$E_s/N_0 = 0.5\ (T_{sym}/T_{samp}) \cdot SNR$$

Note

- All values of power assume a nominal impedance of 1 ohm.
- The equation for the real case differs from the corresponding equation for the complex case by a factor of 2. Specifically, the object uses a noise power spectral density of $N_0/2$ watts/Hz for real input signals, versus N_0 watts/Hz for complex signals.

For more information, see “AWGN Channel Noise Level”.

Specifying the Variance Directly or Indirectly

To directly specify the variance of the noise generated by AWGN Channel, specify the Mode as:

- `Variance from mask`, where you specify the variance in the dialog box. The value must be positive.
- `Variance from port`, where you provide the variance as an input to the block. The variance input must be positive, and its sampling rate must equal that of the input signal.

For `Variance from mask` and `Variance from port` mode:

- If the variance is a scalar, then all signal channels are uncorrelated but share the same variance.
- If the variance is a vector whose length is the number of channels in the input signal, then each element represents the variance of the corresponding signal channel.

> **Note** If you apply complex input signals to the AWGN Channel block, then it adds complex zero-mean Gaussian noise with the calculated or specified variance. The variance for each quadrature component of the complex noise is half of the calculated or specified value.

To specify the variance indirectly, that is, to have the block calculate the variance, specify the Mode as:

- `Signal to noise ratio (Eb/No)`, where the block calculates the variance from these quantities that you specify in the dialog box:
  - Eb/No (dB), the ratio of bit energy to noise power spectral density
  - Number of bits per symbol
  - Input signal power, referenced to 1 ohm (watts), the actual power of the symbols at the input of the block
  - Symbol period (s)
- `Signal to noise ratio (Es/No)`, where the block calculates the variance from these quantities that you specify in the dialog box:
  - Es/No (dB), the ratio of signal energy to noise power spectral density
  - Input signal power, referenced to 1 ohm (watts), the actual power of the symbols at the input of the block
  - Symbol period (s)
- `Signal to noise ratio (SNR)`, where the block calculates the variance from these quantities that you specify in the dialog box:
  - SNR (dB), the ratio of signal power to noise power
  - Input signal power, referenced to 1 ohm (watts), the actual power of the samples at the input of the block

Changing the symbol period in the AWGN Channel block affects the variance of the noise added per sample, which also causes a change in the final error rate.

$$NoiseVariance = \frac{SignalPower \times SymbolPeriod}{SampleTime \times 10^{\frac{Es/No}{10}}}$$

Tip Select the symbol period equal to the symbol period of the model. The value depends on what constitutes a symbol and what the oversampling applied to it is. For example, a symbol could have 3 bits and be oversampled by 4. For more information, see “AWGN Channel Noise Level”.

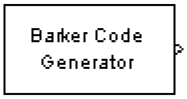
Barker Code Generator

Generate bipolar Barker Code

Library: Communications Toolbox
Communications Toolbox / Comm Sources / Sequence Generators



Description

The Barker Code Generator block generates a bipolar Barker code. The short length and low correlation sidelobes make Barker codes useful for frame synchronization in digital communications systems. For more information, see “Barker Codes” on page 5-25.

Ports

Output

`output` — Barker code frame
column vector

Barker code frame, returned as a column vector. If the frame length exceeds the Barker code length, the block fills the frame by repeating the Barker code.

Dependencies

Set the data type of the output with the **Output data type** parameter.

Parameters

`Code length` — Length of generated code
7 (default) | 1 | 2 | 3 | 4 | 5 | 11 | 13

Length of the generated code, specified as 1, 2, 3, 4, 5, 7, 11, or 13. For more information, see “Barker Codes” on page 3-73.

Example: 2 outputs the Barker code [–1;1].

Data Types: `double`

`Sample time` — Output sample time
1 (default) | -1 | positive scalar

Output sample time, specified as `-1` or a positive scalar that represents the time between each sample of the output signal. If **Sample time** is set to `-1`, the sample time is inherited from downstream. For information on the relationship between **Sample time** and **Samples per frame**, see “Sample Timing” on page 5-26.

`Samples per frame` — Samples per output frame
1 (default) | positive integer

Samples per output frame, specified as a positive integer. If **Samples per frame** is *M*, the block outputs a frame containing *M* samples comprised of length *N* Barker code sequences. *N* is the length of the generated code, which is set by the **Code length** parameter. When *M* is not an integer multiple of *N*, consecutive frames maintain continuity of the Barker code across frame boundaries.

For information on the relationship between **Sample time** and **Samples per frame**, see “Sample Timing” on page 5-26.

Data Types: `double`

`Output data type` — Output data type

`double` (default) | `int8`

Output data type, specified as `double` or `int8`.

Data Types: `char` | `string`

`Simulate using` — Type of simulation to run

`Code generation` (default) | `Interpreted execution`

Type of simulation to run, specified as `Code generation` or `Interpreted execution`.

- `Code generation` –– Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than `Interpreted execution`.
- `Interpreted execution` –– Simulate the model by using the MATLAB interpreter. This option requires less startup time than the `Code generation` method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

Block Characteristics

Data Types	`double` | `integer`
Multidimensional Signals	`no`
Variable-Size Signals	`no`

More About

Barker Codes

Barker codes have a maximum autocorrelation sequence, which has off-peak autocorrelations no larger than 1.

A correlation sidelobe is the correlation of a codeword with a time-shifted version of itself. The correlation sidelobe, C_k, for a *k*-symbol shift of an *N*-bit code sequence, $\{X_j\}$, is

$$C_k = \sum_{j=1}^{N-k} X_j X_{j+k}$$

For j=1, 2, 3,..., N, X_j is an individual code symbol that is equal to +1 or –1. The adjacent symbols are assumed to be 0.

The output code is in a bipolar format with 0 and 1 mapped to 1 and –1. The maximum known Barker code length is 13. The short length and low correlation sidelobes make Barker codes useful for frame synchronization in digital communications systems. The Barker code generator outputs the Barker codes listed in this table.

Barker Code Length	Barker Code	Sidelobe Level
1	[–1]	0 dB
2	[–1; 1]	–6 dB
3	[–1; –1; 1]	–9.5 dB
4	[–1; –1; 1; –1]	–12 dB
5	[–1; –1; –1; 1; –1]	–14 dB
7	[–1; –1; –1; 1; 1; –1; 1]	–16.9 dB
11	[–1; –1; –1; 1; 1; 1; –1; 1; 1; –1; 1]	–20.8 dB
13	[–1; –1; –1; –1; –1; 1; 1; –1; –1; 1; –1; 1; –1]	–22.3 dB

Sample Timing

The time between output updates is equal to the product of **Samples per frame** and **Sample time**. For example, if **Sample time** and **Samples per frame** equal one, the block outputs a sample every second. If **Samples per frame** is increased to 10, then a 10-by-1 vector is output every 10 seconds. This ensures that the equivalent output rate is not dependent on the **Samples per frame** parameter.

Compatibility Considerations

Existing models automatically update this block to current version

Behavior changed in R2020a

Starting in R2020a, Simulink no longer allows you to use the Barker Code Generator block version available before R2015b.

Existing models automatically update to load the Barker Code Generator block version announced in “Source blocks output frames of contiguous time samples but do not use the frame attribute” in the R2015b Release Notes. For more information on block forwarding, see “Forwarding Tables” (Simulink).

Extended Capabilities

Objects

`comm.BarkerCode`

Introduced before R2006a

Baseband File Reader

Read baseband signals from file
Library: Communications Toolbox / Comm Sources

Description

The Baseband File Reader block reads a signal from a baseband file. A baseband file is a specific type of binary file written by the Baseband File Writer block. Baseband signals are typically downconverted from a nonzero center frequency to 0 Hz. The block automatically reads the sample rate, center frequency, number of channels, and any descriptive data.

Input/Output Ports

Output

`Data` — Baseband signal
scalar | vector | matrix

Baseband signal, returned as a scalar, vector, or matrix. The signal is read from the file specified by the **Baseband file name** parameter. The sample time is either inherited from the file or can be set by the **Sample Time (s)** parameter.

Data Types: `double`

`EOF` — End-of-file indicator
logical scalar

End-of-file indicator, returned as a logical scalar. The output is `true` when the **Repeatedly read the file** parameter is `false` and the entire file has been read. To enable this port, select the **Output end-of-file indicator** parameter.

Parameters

`Baseband file name` — Name of file from which data is read
`example.bb` (default) | character vector

Specify the name of the baseband file as a character vector.

Click **Browse** to locate the baseband file you want to read. Click **File Info** to display this information:

- File name
- Sample rate
- Center frequency
- Number of samples

- Number of channels
- Data type
- Any metadata fields

Data Types: `char`

`Inherit sample time from file` — Select source of sample time

`on` (default) | `off`

Select this check box to inherit the sample time from the file specified by **Baseband file name**.

`Sample time (s)` — Block sample time

`1` (default) | positive scalar

Specify the block sample time in seconds as a positive scalar. To enable this parameter, clear the **Inherit sample time from file** check box.

`Samples per frame` — Number of samples in one frame

`100` (default) | positive integer scalar

Specify the samples per frame as a positive integer scalar.

`Repeatedly read the file` — Continuously loop data from file

`off` (default) | `on`

Select this check box to repeatedly read the contents of the baseband file. When the end of the file is reached:

- The block outputs zeros, if the **Repeatedly read the file** parameter is not selected (`off`).
- The block outputs samples from the beginning of the file, if the **Repeatedly read the file** parameter is selected (`on`).

`Simulate using` — Type of simulation to run

`Code generation` (default) | `Interpreted execution`

Type of simulation to run, specified as `Code generation` or `Interpreted execution`.

- `Code generation` –– Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than `Interpreted execution`.
- `Interpreted execution` –– Simulate the model by using the MATLAB interpreter. This option requires less startup time than the `Code generation` method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

Block Characteristics

Data Types	`double` | `integer` | `single`

Blocks

Baseband File Writer

Introduced in R2016b

Baseband File Writer

Write baseband signals to file
Library: Communications Toolbox / Comm Sinks

Description

The Baseband File Writer block writes a baseband signal to a specific type of binary file. Baseband signals are typically down-converted from a nonzero center frequency to 0 Hz. Sample rate, which is determined by the input signal sample time and frame size, and center frequency are saved when the signal is written to a file.

Input/Output Ports

Input

`Port_1` — Baseband signal

scalar | vector | matrix

This port accepts a baseband signal to be saved under the filename specified by the **Baseband file name** parameter. The saved signal is always complex.

Data Types: `single` | `double`

Parameters

`Baseband file name` — Name of file in which data is saved

`untitled.bb` (default) | character vector

Specify the name of the baseband file as a character vector.

To specify the location where the file is saved, click **Browse**.

`Center frequency (Hz)` — Center frequency of the baseband signal

`1e8` (default) | nonnegative scalar

Specify the center frequency in Hz as a nonnegative scalar.

`Metadata in a structure` — Data describing the baseband signal

`struct()` (default) | structure

Specify data describing the baseband signal as a structure. If the signal has no descriptive data, this parameter is an empty structure. The structure can contain any number of fields. Field names have no restrictions, but the field values must be numeric, logical, or character data types having any dimension.

`Number of latest samples to write` — Number of samples to write
`inf` (default) | positive scalar

Specify the number to write. If this parameter is `inf`, all samples are saved. Otherwise, only the last *N* samples are saved, where *N* is specified by this parameter.

`Simulate using` — Select simulation mode
`Code generation` (default) | `Interpreted execution`

`Code generation`

> On the first model run, simulate and generate code for the block using only MATLAB functions supported for code generation. If the structure of the block does not change, subsequent model runs do not regenerate the code.

`Interpreted execution`

> Simulate model using all supported MATLAB functions. Choosing this option can slow simulation performance.

Block Characteristics

Data Types	`double` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`no`

Tips

- The Baseband File Writer block writes baseband signals to uncompressed binary files. To share these files, you can compress them to a zip file using the `zip` function. For more information, see “Create and Extract from Zip Archives”.

Baseband PLL

Implement baseband phase-locked loop

Library

Components sublibrary of Synchronization

Description

The Baseband PLL (phase-locked loop) block is a feedback control system that automatically adjusts the phase of a locally generated signal to match the phase of an input signal. Unlike the Phase-Locked Loop block, this block uses a baseband method and does not depend on a carrier frequency.

This PLL has these three components:

- An integrator used as a phase detector.
- A filter. You specify the filter's transfer function using the **Lowpass filter numerator** and **Lowpass filter denominator** parameters. Each is a vector that gives the respective polynomial's coefficients in order of descending powers of *s*.

  To design a filter, you can use the Signal Processing Toolbox functions `cheby1`, and `cheby2`. The default filter is a Chebyshev type II filter whose transfer function arises from the command below.

  ```
  [num, den] = cheby2(3,40,100,'s')
  ```
- A voltage-controlled oscillator (VCO). You specify the sensitivity of the VCO signal to its input using the **VCO input sensitivity** parameter. This parameter, measured in Hertz per volt, is a scale factor that determines how much the VCO shifts from its quiescent frequency.

This block accepts a sample-based scalar signal. The input signal represents the received signal. The three output ports produce:

- The output of the filter
- The output of the phase detector
- The output of the VCO

This model is nonlinear; for a linearized version, use the Linearized Baseband PLL block.

Parameters

Lowpass filter numerator

The numerator of the lowpass filter's transfer function, represented as a vector that lists the coefficients in order of descending powers of *s*.

Lowpass filter denominator

The denominator of the lowpass filter's transfer function, represented as a vector that lists the coefficients in order of descending powers of *s*.

VCO input sensitivity (Hz/V)

This value scales the input to the VCO and, consequently, the shift from the VCO's quiescent frequency.

References

For more information about phase-locked loops, see the works listed in “Selected Bibliography for Synchronization” in *Communications Toolbox User*'*s Guide*.

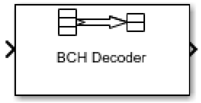
BCH Decoder

Decode BCH code to recover binary vector data

Library: Communications Toolbox / Error Detection and Correction / Block



Description

The BCH Decoder block recovers a binary message vector from a binary BCH codeword vector. For proper decoding, the **Codeword length, N** and **Message length, K** parameter values in this block must match the parameters in the corresponding BCH Encoder block. The full-length values of *N* and *K* must produce a valid narrow-sense BCH code.

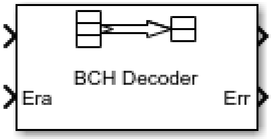
If the encoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords. The input and output signal lengths are listed in “Input and Output Signal Length in BCH Blocks” on page 5-38.

See “Tips” on page 5-40 for information about valid *N* values, valid (*N*,*K*) pairs, and error-correcting capabilities for a given BCH code.

If decoding fails, the message portion of the decoder input is returned unchanged as the decoder output.

The sample times of all input and output signals are equal.

This icon shows optional ports.



Ports

Input

In — Encoded message
binary column vector

Encoded message, specified as a binary column vector. The encoded message is a BCH code with message length *K* and codeword length (*N* – number of punctures).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Era — Erasure vector
binary column vector

Erasure vector, specified as a binary column vector that is the same length as `In`. Erasure values of 1 correspond to erased bits in the same position in the codeword. Values of 0 correspond to bits that are not erased.

Dependencies

To enable this port, select **Enable erasures input port**.

Data Types: `double` | `Boolean`

Output

`Out` — Decoded message

binary column vector

Decoded message, returned as a binary column vector input signal with an integer multiple of **Message length, K** elements or **Shortened message length, S** elements if the code is shortened. Each group of input elements represents one codeword to decode. The input and output signal lengths are listed in the "Input and Output Signal Length in BCH Blocks" on page 5-38 table.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

`Err` — Decoding errors

integer vector

Decoding errors, returned as an integer vector that indicates the number of errors detected during decoding of the codeword. A negative integer indicates that the block detected more errors than it could correct by using the coding scheme.

Dependencies

To enable this port, select **Output number of corrected errors**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

For more information, see "Supported Data Types" on page 5-40.

Parameters

`Codeword length, N` — Codeword length

15 (default) | integer

Codeword length, specified as an integer of the form $N = 2^M–1$, where M is an integer from 3 through 16. For more information, see "Tips" on page 5-40.

`Message length, K` — Message length

5 (default) | integer

Message length, specified as an integer. The (`N`, `K`) pair must produce a narrow-sense BCH code.

`Shortened message length, S` — Shortened message length

5 (default) | integer

Shortened message length, specified as an integer. When you specify this parameter, provide full-length N and K values to specify the (N, K) code that is shortened to an ($N–K+S$, S) code.

Dependencies

To enable this parameter, select **Specify shortened message length**.

`Generator polynomial` — Generator polynomial

`'X^10 + X^8 + X^5 + X^4 + X^2 + X + 1'` (default) | polynomial character vector | binary row vector | binary Galois row vector

Generator polynomial, specified as one of the following:

- A polynomial character vector — For more information, see “Character Representation of Polynomials”.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power.
- A binary Galois row vector that represents the coefficients of the generator polynomial in order of descending power.

Example: `'X^10 + X^8 + X^5 + X^4 + X^2 + X + 1'`, which is equivalent to `bchgenpoly(15,5)`

Dependencies

To enable this parameter, select **Specify generator polynomial**.

`Primitive polynomial` — Primitive polynomial

`'X^4 + X + 1'` (default) | polynomial character vector | binary row vector

Primitive polynomial in order of descending power. It is a polynomial of order *M* that defines the finite Galois field GF(2), specified as one of the following:

- A polynomial character vector — For more information, see “Character Representation of Polynomials”.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power.

Example: `'X^4 + X + 1'`, which is the primitive polynomial used for a (15,5) code, `de2bi(primpoly(4,'nodisplay'),'left-msb')`

Dependencies

To enable this parameter, select **Specify primitive polynomial**.

`Disable generator polynomial checking` — Option to disable generator polynomial checking

on (default) | off

Select this parameter to disable generator polynomial check.

Each time a model initializes, the block performs a polynomial check. This check verifies that $X^N + 1$ is divisible by the specified generator polynomial, where *N* represents the full codeword length. For larger codes, disabling the check speeds up the simulation process.

Tip Always run the check at least once before disabling this feature.

Dependencies

To enable this parameter, select **Specify generator polynomial**.

`Puncture vector` — Puncture vector

`[ones(8,1); zeros(2,1)]` (default) | column vector

Puncture vector, specified as a binary column vector of length *N*–*K*. Element indices with `1`s represent data symbol indices that pass through the block unaltered. Element indices with `0`s represent data symbol indices that get punctured, or removed, from the data stream. For more information, see “Puncturing and Erasures” on page 5-39.

Dependencies

To enable this parameter, select **Puncture code**.

`Enable erasures input port` — Option to enable erasures input port

off (default) | on

Selecting this check box enables the erasures port, `Era`.

Through the port, you can input a binary column vector that is 1/*M* times as long as the codeword input.

Erasure values of `1` correspond to erased symbols in the same position in the bit-packed codeword. Values of `0` correspond to nonerased symbols. For more information, see “Puncturing and Erasures” on page 5-39.

`Output number of corrected errors` — Option to enable port to output number of corrected errors

off (default) | on

Selecting this check box enables an additional output port, `Err`, which indicates the number of errors the block corrected in the input codeword.

Block Characteristics

Data Types	`Boolean` | `double` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`no`

More About

Input and Output Signal Length in BCH Blocks

This table shows how to compute the input and output signal lengths for the BCH encoder and decoder blocks.

The notation `y = c * x` denotes that `y` is an integer multiple of `x`.

Specify Shortened Message Length, S	BCH Encoder	BCH Decoder
off	**Input Length:** *c * K* **Output Length:** *c * (N – P)*	**Input Length:** *c * (N – P)* **Output Length:** *c * K* **Erasures Length:** *c * (N – P)*
on	**Input Length:** *c * S* **Output Length:** *c * (N - K + S - P)*	**Input Length:** *c * (N - K + S - P)* **Output Length:** *c * S* **Erasures Length:** *c * (N - K + S - P)*

- *N* is the codeword length
- *K* is the message length
- *S* is the shortened message length
- *P* is the number of punctures value, and is equal to the number of zeros in the puncture vector.

Puncturing and Erasures

1s and 0s have precisely opposite meanings for the puncture and erasure vectors.

In a puncture vector,

- 1 means that the data symbol is passed through the block unaltered.
- 0 means that the data symbol is to be punctured, or removed, from the data stream.

In an erasure vector,

- 1 means that the data symbol is to be replaced with an erasure symbol.
- 0 means that the data symbol is passed through the block unaltered.

These conventions apply to both the encoder and the decoder. For more information, see “Shortening, Puncturing, and Erasures”.

Supported Data Types

Port	Supported Data Types
In	• Double-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Out	• Double-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Era	• Double-precision floating point • Boolean
Err	• Double-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Pair Block

BCH Encoder — Encodes data using BCH algorithm.

Tips

- To generate the list of valid (`N`,`K`) pairs along with the corresponding values of the error-correction capability, run `bchnumerr(N)`.
- Valid values for `N` = 2^M–1, where M is an integer from 3 through 16. The maximum allowable value of `N` is 65,535.

Algorithms

This block implements the algorithm, inputs, and outputs described in “Algorithms for BCH and RS Errors-only Decoding”.

BCH Encoder

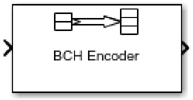
Create BCH code from binary vector data

Library: Communications Toolbox / Error Detection and Correction / Block



Description

The BCH Encoder block creates a BCH code with message length *K* and codeword length (*N* – number of punctures).

If the encoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords. The input and output signal lengths are listed in “Input and Output Signal Length in BCH Blocks” on page 5-44.

See “Tips” on page 5-45 for information about valid *N* values, valid (*N,K*) pairs, and error-correcting capabilities for a given BCH code.

Ports

Input

`In` — Message to encode
binary column vector

Message to encode, specified as a binary column vector input signal with an integer multiple of **Message length, K** elements or **Shortened message length, S** elements if the code is shortened. Each group of input elements represents one message word to encode. The input and output signal lengths are listed in “Input and Output Signal Length in BCH Blocks” on page 5-44.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Output

`Out` — Encoded message
binary column vector

Encoded message, returned as a binary column vector. The encoded message is a BCH code with message length *K* and codeword length (*N* – number of punctures).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

For more information, see “Supported Data Types” on page 5-45.

Parameters

`Codeword length, N` — Codeword length
15 (default) | integer

Codeword length, specified as an integer of the form $N = 2^M–1$, where M is an integer from 3 through 16. For more information, see “Tips” on page 5-45.

`Message length, K` — Message length

5 (default) | integer

Message length, specified as an integer. The (`N`, `K`) pair must produce a narrow-sense BCH code.

`Shortened message length, S` — Shortened message length

5 (default) | integer

Shortened message length, specified as an integer. When you specify this parameter, provide full-length N and K values to specify the (N, K) code that is shortened to an ($N–K+S$, S) code.

Dependencies

To enable this parameter, select **Specify shortened message length**.

`Generator polynomial` — Generator polynomial

`'X^10 + X^8 + X^5 + X^4 + X^2 + X + 1'` (default) | polynomial character vector | binary row vector | binary Galois row vector

Generator polynomial, specified as one of the following:

- A polynomial character vector — For more information, see “Character Representation of Polynomials”.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power.
- A binary Galois row vector that represents the coefficients of the generator polynomial in order of descending power.

Example: `'X^10 + X^8 + X^5 + X^4 + X^2 + X + 1'`, which is equivalent to `bchgenpoly(15,5)`

Dependencies

To enable this parameter, select **Specify generator polynomial**.

`Primitive polynomial` — Primitive polynomial

`'X^4 + X + 1'` (default) | polynomial character vector | binary row vector

Primitive polynomial in order of descending power. It is a polynomial of order M that defines the finite Galois field GF(2), specified as one of the following:

- A polynomial character vector — For more information, see “Character Representation of Polynomials”.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power.

Example: `'X^4 + X + 1'`, which is the primitive polynomial used for a (15,5) code, `de2bi(primpoly(4,'nodisplay'),'left-msb')`

Dependencies

To enable this parameter, select **Specify primitive polynomial**.

`Disable generator polynomial checking` — Option to disable generator polynomial checking

on (default) | off

Select this parameter to disable generator polynomial check.

Each time a model initializes, the block performs a polynomial check. This check verifies that $X^N + 1$ is divisible by the specified generator polynomial, where N represents the full codeword length. For larger codes, disabling the check speeds up the simulation process.

Tip Always run the check at least once before disabling this feature.

Dependencies

To enable this parameter, select **Specify generator polynomial**.

`Puncture vector` — Puncture vector

`[ones(8,1); zeros(2,1)]` (default) | binary column vector

Puncture vector, specified as a binary column vector of length $N–K$. Element indices with `1`s represent data symbol indices that pass through the block unaltered. Element indices with `0`s represent data symbol indices that get punctured, or removed, from the data stream. For more information, see “Shortening, Puncturing, and Erasures”.

Note `1`s and `0`s have precisely opposite meanings for the puncture and erasure vectors. For an erasure vector, `1` means that the data symbol is to be replaced with an erasure symbol, and `0` means that the data symbol is passed through the block unaltered. This convention applies to both the encoder and the decoder.

Dependencies

To enable this parameter, select **Puncture code**.

Block Characteristics

Data Types	`Boolean` | `double` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`no`

More About

Input and Output Signal Length in BCH Blocks

This table shows how to compute the input and output signal lengths for the BCH encoder and decoder blocks.

The notation `y = c * x` denotes that `y` is an integer multiple of `x`.

Specify Shortened Message Length, S	BCH Encoder	BCH Decoder
off	**Input Length:** *c * K* **Output Length:** *c * (N – P)*	**Input Length:** *c * (N – P)* **Output Length:** *c * K* **Erasures Length:** *c * (N – P)*
on	**Input Length:** *c * S* **Output Length:** *c * (N - K + S - P)*	**Input Length:** *c * (N - K + S - P)* **Output Length:** *c * S* **`Erasures Length:`** *c * (N - K + S - P)*

- *N* is the codeword length
- *K* is the message length
- *S* is the shortened message length
- *P* is the number of punctures value, and is equal to the number of zeros in the puncture vector.

Supported Data Types

Port	Supported Data Types
In	• Double-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Out	• Double-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Pair Block

BCH Decoder — Decodes BCH encoded data.

Tips

- To generate the list of valid (`N`,`K`) pairs along with the corresponding values of the error-correction capability, run `bchnumerr(N)`.

- Valid values for `N` = 2^M–1, where *M* is an integer from 3 through 16. The maximum allowable value of `N` is 65,535.

Algorithms

This block implements the algorithm, inputs, and outputs described in “Algorithms for BCH and RS Errors-only Decoding”.

Bernoulli Binary Generator

Generate Bernoulli-distributed random binary numbers

Library: Communications Toolbox / Comm Sources / Random Data Sources

Description

The Bernoulli Binary Generator block generates random binary numbers using a Bernoulli distribution. Use this block to generate random data bits to simulate digital communication systems and obtain performance metrics such as bit error rate. The Bernoulli distribution with parameter *p* produces zero with probability *p* and one with probability *1-p*. The Bernoulli distribution has mean value *1-p* and variance *p*(*1-p*). The **Probability of zero** parameter specifies *p* and can be any real number in range [0, 1].

The output signal can be a column or row vector, two-dimensional matrix, or scalar. The number of rows in the output signal corresponds to the number of samples in one frame and is set by the **Samples per frame** parameter. The number of columns in the output signal corresponds to the number of channels and is set by the number of elements in the **Probability of zero** parameter. For more details, see "Sources and Sinks" in *Communications Toolbox User's Guide*

Ports

Output

`Out` — Output data signal
scalar | vector | matrix

Output data signal, returned as a scalar, vector, or matrix.

Data Types: `double`

Parameters

`Probability of zero` — Probability of generating zero at output
`0.5` (default) | integer in the range [0, 1] | vector of integers in the range [0, 1]

Probability of zero must be in the range of [0, 1]. The number of elements in the **Probability of zero** parameter corresponds to the number of independent channels output from the block. The Bernoulli distribution with parameter *p* produces zero with probability *p* and one with probability *1-p*.

`Source of initial seed` — Source of initial seed for random number generator
`Auto` (default) | `Parameter`

Select `Parameter` to use the **Initial seed** parameter to specify the initial seed for the random number generator.

Note When the **Source of initial seed** parameter is set to `Auto` and the **Simulate using** parameter is set to `Code generation`, the random number generator uses an initial seed of zero. In this case, the block generates the same random numbers each time it is started. To ensure that the model uses different initial seeds, set **Simulate using** parameter to `Interpreted execution`. If you run `Interpreted execution` in `Rapid accelerator` mode, then the model behaves the same as `Code generation` mode.

Dependencies

Select `Auto` for the block to use the global random number stream as the initial seed. For more information, see “Managing the Global Stream Using RandStream” and “Random Number Generators”.

`Initial seed` — Initial seed for random number generator

nonnegative scalar

If you set the **Initial seed** parameter to a constant value, then the resulting sequence is repeatable.

Dependencies

To enable this parameter, set the **Source of initial seed** to `Parameter`.

`Sample time` — Sample time of output signal

1 (default) | -1 | positive scalar

Output sample time, specified as `-1` or a positive scalar that represents the time between each sample of the output signal. If **Sample time** is set to `-1`, the sample time is inherited from downstream. For information on the relationship between **Sample time** and **Samples per frame**, see “Sample Timing” on page 5-49.

`Samples per frame` — Samples per frame of output signal

1 (default) | positive scalar

Samples per frame in one channel of the output signal, specified as a positive integer. For information on the relationship between **Sample time** and **Samples per frame**, see “Sample Timing” on page 5-49.

`Output data type` — Data type of output signal

`double` (default) | `boolean`

Select the data type for the output signal.

`Simulate using` — Type of simulation to run

`Code generation` (default) | `Interpreted execution`

Type of simulation to run, specified as `Code generation` or `Interpreted execution`.

- `Code generation` –– Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than `Interpreted execution`.
- `Interpreted execution` –– Simulate the model by using the MATLAB interpreter. This option requires less startup time than the `Code generation` method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

Block Characteristics

Data Types	`Boolean` | `double` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`no`

More About

Sample Timing

The time between output updates is equal to the product of **Samples per frame** and **Sample time**. For example, if **Sample time** and **Samples per frame** equal one, the block outputs a sample every second. If **Samples per frame** is increased to 10, then a 10-by-1 vector is output every 10 seconds. This ensures that the equivalent output rate is not dependent on the **Samples per frame** parameter.

Compatibility Considerations

Bernoulli Binary Generator block update supported in Upgrade Advisor

Behavior changed in R2020a

Starting in R2020a, Bernoulli Binary Generator block allows you to use the Upgrade Advisor. You can update to the block version announced in R2015b or keep the block version available before R2015b.

- Use the Upgrade Advisor to update existing models that include the Bernoulli Binary Generator block.
- Behavior of the random number generator is changed. The statistics are improved. For more information, see "Source blocks output frames of contiguous time samples but do not use the frame attribute" in the R2015b Release Notes.

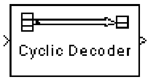
Binary Cyclic Decoder

Decode systematic cyclic code to recover binary vector data



Library

Block sublibrary of Error Detection and Correction

Description

The Binary Cyclic Decoder block recovers a message vector from a codeword vector of a binary systematic cyclic code. For proper decoding, the parameter values in this block should match those in the corresponding Binary Cyclic Encoder block.

This block accepts a column vector input signal containing *N* elements, where *N* is the codeword length. The output signal is a column vector containing *K* elements, where *K* is the message length of the cyclic code.

You can determine the systematic cyclic coding scheme in one of two ways:

- To create an [N,K] code, enter *N* and *K* as the first and second dialog parameters, respectively. The block computes an appropriate generator polynomial, namely, `cyclpoly(N,K,'min')`.
- To create a code with codeword length N and a particular degree-(N-K) binary *generator polynomial*, enter *N* as the first parameter and a polynomial character vector or a binary vector as the second parameter. The vector represents the generator polynomial by listing its coefficients in order of ascending exponents. You can create cyclic generator polynomials using the Communications Toolbox `cyclpoly` function.

For information about the data types each block port supports, see the “Supported Data Type” on page 5-51 table on this page.

Parameters

Codeword length N

The codeword length *N*, which is also the input vector length.

Message length K, or generator polynomial

Either the message length, which is also the input vector length, a polynomial character vector, or a binary vector that represents the generator polynomial for the code.

Supported Data Type

Port	Supported Data Types
In	- Double-precision floating point - Single-precision floating point - Boolean - 8-, 16-, and 32-bit signed integers - 8-, 16-, and 32-bit unsigned integers - Fixed-point
Out	- Double-precision floating point - Single-precision floating point - Boolean - 8-, 16-, and 32-bit signed integers - 8-, 16-, and 32-bit unsigned integers - Fixed-point

Binary Cyclic Encoder

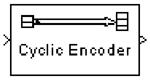
Create systematic cyclic code from binary vector data



Library

Block sublibrary of Error Detection and Correction

Description

The Binary Cyclic Encoder block creates a systematic cyclic code with message length *K* and codeword length *N*.

This block accepts a column vector input signal containing *K* elements. The output signal is a column vector containing *N* elements.

You can determine the systematic cyclic coding scheme in one of two ways:

- To create an [N,K] code, enter N and K as the first and second dialog parameters, respectively. The block computes an appropriate generator polynomial, namely, `cyclpoly(N,K,'min')`.
- To create a code with codeword length *N* and a particular degree-(N-K) binary *generator polynomial*, enter *N* as the first parameter and a polynomial character vector or a binary vector as the second parameter. The vector represents the generator polynomial by listing its coefficients in order of ascending exponents. You can create cyclic generator polynomials using the Communications Toolbox `cyclpoly` function.

For information about the data types each block port supports, see the “Supported Data Type” on page 5-53 table on this page.

Parameters

Codeword length N

The codeword length, which is also the output vector length.

Message length K, or generator polynomial

Either the message length, which is also the input vector length, a polynomial character vector, or a binary vector that represents the generator polynomial for the code.

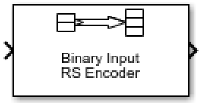
Binary-Input RS Encoder

Create Reed-Solomon code from binary vector data

Library: Communications Toolbox / Error Detection and Correction / Block

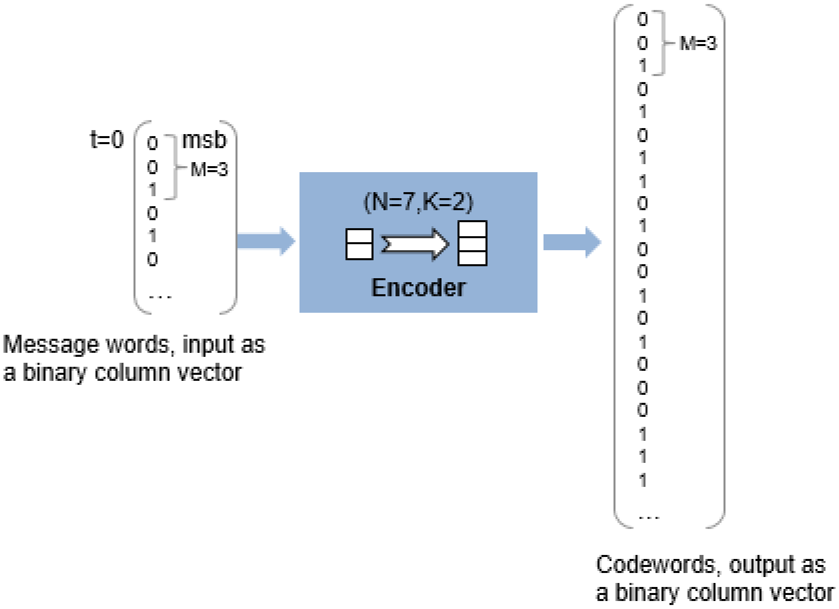


Description

The Binary-Input RS Encoder block creates a Reed-Solomon code.

The symbols for the code are binary sequences of length *M*, corresponding to elements of the Galois field *GF*(2^M). The first bit in each symbol is the most significant bit.

Suppose M = 3, N = 2^3-1 = 7, and K = 2. Then a message is a vector of length 2 whose entries are integers between 0 and 7. A corresponding codeword is a vector of length 7 whose entries are integers between 0 and 7. The following figure illustrates possible input and output signals to this block when codeword length *N*=7 and message word length *K*=2. Since *N*=2^M–1, when *N*=7, the symbol length, *M*=3.



Each input message word is a binary vector of length 6, that represents 2 three-bit integers. Each corresponding output codeword is a binary vector of length 21 that represents 7 three-bit integers. For more information, see “Input and Output Signal Length in RS Blocks” on page 5-57.

Ports

Input

`In` — Message
binary column vector

Message in bits, specified as one of the following:

- When there is no message shortening, a (N_C×K×M)-by-1 binary column vector.
- When there is message shortening, a (N_C×S×M)-by-1 binary column vector.

N_C is the number of message words, K is the **Message length K (symbols)**, M is the number of bits per symbol, and S is the **Shortened message length S (symbols)**.

Note The number of decoded message words equals the number of codewords.

For more information, see “Input and Output Signal Length in RS Blocks” on page 5-57.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `ufix(1)`

Output

`Out` — Reed-Solomon codeword
binary column vector

Reed-Solomon codeword in bits, returned as an (N_C×(N – K + S – P)×M)-by-1 binary column vector. N_C is the number of codewords, N is the **Codeword length N (symbols)**, K is the **Message length K (symbols)**, S is the **Shortened message length S (symbols)**, P is the number of punctures per codeword, and M is the number of bits per symbol.

For more information, see “Input and Output Signal Length in RS Blocks” on page 5-57.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `ufix(1)`

For more information, see “Supported Data Types” on page 5-59.

Parameters

`Codeword length N (symbols)` — Codeword length
7 (default) | integer

Codeword length in symbols, specified as an integer.

For more information, see “Restrictions on the M and the Codeword Length N” on page 5-58 and “Input and Output Signal Length in RS Blocks” on page 5-57.

`Message length K (symbols)` — Message word length
3 (default) | integer

Message word length in symbols, specified as an integer in the range [1, N–2], where N is the codeword length.

`Shortened message length S (symbols)` — Shortened message word length

3 (default) | integer

Shortened message word length in symbols, specified as an integer, such that $S \leq K$. When **Shortened message length S (symbols) < Message length K (symbols)**, the Reed-Solomon code is shortened.

You still specify *N* and *K* values for the full-length (*N*, *K*) code but the decoding is shortened to an (*N*–*K*+*S*, *S*) code.

Dependencies

To enable this parameter, select **Specify shortened message length**.

`Generator polynomial` — Generator polynomial

`rsgenpoly(7, 3, [], [], 'double')` (default) | polynomial character vector | binary row vector | binary Galois row vector

Generator polynomial with values from 0 to 2^M–1, in order of descending power, specified as one of the following:

- A polynomial character vector. For more information, see "Character Representation of Polynomials".
- An integer row vector that represents the coefficients of the generator polynomial in order of descending power.
- An integer Galois row vector that represents the coefficients of the generator polynomial in order of descending power.

Each coefficient is an element of the Galois field defined by the primitive polynomial. For more information, see "Specify the Generator Polynomial" on page 5-58.

Example: `[1 3 1 2 3]`, which is equivalent to `rsgenpoly(7,3)`

Dependencies

To enable this parameter, select **Specify generator polynomial**.

`Primitive polynomial` — Primitive polynomial

`'X^3 + X + 1'` (default) | polynomial character vector | binary row vector

Primitive polynomial in order of descending power. This polynomial is of order *M* and defines the finite Galois field GF(2^M) corresponding to the integers that form message words and codewords. Specify the primitive polynomial as one of the following:

- A polynomial character vector. For more information, see "Character Representation of Polynomials".
- A binary row vector that represents the coefficients of the generator polynomial.

For more information, see "Restrictions on the M and the Codeword Length N" on page 5-58.

Example: `'X^3 + X + 1'`, which is the primitive polynomial used for a (7,3) code, `de2bi(primpoly(3,'nodisplay'),'left-msb')`

Dependencies

To enable this parameter, select **Specify primitive polynomial**.

`Puncture vector` — Puncture vector
`[ones(2,1); zeros(2,1)]` (default) | binary column vector

Puncture vector, specified as an (*N*–*K*)-by-1 binary column vector. Element indices with `1`s represent data symbol indices that pass through the block unaltered. Element indices with `0`s represent data symbol indices that get punctured, or removed, from the data stream. For more information, see “Puncturing and Erasures” on page 5-59.

Dependencies

To enable this parameter, select **Puncture code**.

`Output data type` — Output type of the block
`Same as input` (default) | `boolean` | `double`

Output type of the block, specified as `Same as input`, `boolean`, or `double`.

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point`[a] | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`no`

[a] ufix(1) only.

More About

Input and Output Signal Length in RS Blocks

The Reed-Solomon code has a message word length, *K*, or shortened message word length, *S*. The codeword length is $N - K + S - P$, where *N* is the full codeword length and *P* is the number of punctures per codeword. When there is no message shortening, the codeword length expression reduces to $N - P$, because $K = S$. If the decoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords.

This table provides expressions for the input and output signal lengths for the Reed-Solomon encoder and decoder.

The notation $y = N_C \times x$ denotes that *y* is an integer multiple of *x*.

	Input, Erasure, and Output Vector Lengths	
RS Block Coder	**No Message Shortening Used**	**Message Shortening Used**

Binary-Input RS Encoder	**Input Length (bits):**
	$N_C \times K \times M$
	Output Length (bits):
	$N_C \times (N–P) \times M$
		Input Length (bits):
		$N_C \times S \times M$
		Output Length (bits):
		$N_C \times (N–K+S–P) \times M$

	Input, Erasure, and Output Vector Lengths	
RS Block Coder	**No Message Shortening Used**	**Message Shortening Used**

Binary-Output RS Decoder	**Input Length (bits):**
	$N_C \times (N–P) \times M$
	Erasures Length (symbols):
	$N_C \times (N–P)$
	Output Length (bits):
	$N_C \times K \times M$
		Input Length (bits):
		$N_C \times (N–K+S–P) \times M$
		Erasures Length (symbols):
		$N_C \times (N–K+S–P)$
		Output Length (bits):
		$N_C \times S \times M$

- N is the codeword length.
- K is the message word length.
- S is the shortened message word length.
- N_C is the number of codewords (and message words).
- P is the number of punctures per codeword, and is equal to the number of zeros in the puncture vector.
- M is the degree of the primitive polynomial. Each group of M bits represents an integer between `0` and `2`^{M}`–1` that belongs to the finite Galois field `GF(2`^{M}`)`.

For more information on representing data for Reed-Solomon codes, see “Integer Format (Reed-Solomon Only)”.

Also, see “Restrictions on the M and the Codeword Length N” on page 5-58.

Restrictions on the M and the Codeword Length N

- If you do not select **Specify primitive polynomial**, valid values for the codeword length, N, are from 7 to 65535. In this case, the block uses the default primitive polynomial of degree `M = ceil(log2(N+1))`. You can display the default primitive polynomial by running `primpoly(ceil(log2(N+1)))`.
- If you select **Specify primitive polynomial**, valid values for the primitive polynomial degree, M, are from 3 to 16. The valid values for N in this case are from 7 to 2^M–1. Selecting **Specify primitive polynomial** enables you to specify the primitive polynomial that defines the finite field $GF(2^M)$, which corresponds to the values that form message words and codewords.

Specify the Generator Polynomial

Select **Specify generator polynomial** to enable the **Generator polynomial** parameter for specifying the generator polynomial of the Reed-Solomon code. Enter an integer row vector with element values from 0 to 2^M-1. The vector represents a polynomial, in descending order of powers, whose coefficients are elements of $GF(2^M)$ represented in integer format. For more information about integer and binary format, see “Integer Format (Reed-Solomon Only)”. The generator polynomial must be equal to a polynomial with this factored form:

$$g(x) = (x+\alpha^{b})(x+\alpha^{b+1})(x+\alpha^{b+2})\ldots(x+\alpha^{b+N-K-1})$$

α is the primitive element of the Galois field over which the input message is defined, and b is an integer.

If you do not select **Specify generator polynomial**, the block uses the default generator polynomial, corresponding to *b*=1, for Reed-Solomon encoding. You can display the default generator polynomial by running `rsgenpoly`.

- If you are using the default primitive polynomial (**Specify primitive polynomial** is not selected), the default generator polynomial is `rsgenpoly(N,K)`, where `N = 2`^{M}`-1`.
- If you are not using the default primitive polynomial (**Specify primitive polynomial** is selected) and you specify the primitive polynomial as `poly`, the generator polynomial is `rsgenpoly(N,K,poly)`.

Note The degree of the generator polynomial is $N - K$, where N is the codeword length and K is the message word length.

Puncturing and Erasures

`1`s and `0`s have precisely opposite meanings for the puncture and erasure vectors.

In a puncture vector,

- `1` means that the data symbol is passed through the block unaltered.
- `0` means that the data symbol is to be punctured, or removed, from the data stream.

In an erasure vector,

- `1` means that the data symbol is to be replaced with an erasure symbol.
- `0` means that the data symbol is passed through the block unaltered.

These conventions apply to both the encoder and the decoder. For more information, see “Shortening, Puncturing, and Erasures”.

Supported Data Types

Port	Supported Data Types
In	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • 1-bit unsigned integer (ufix(1))

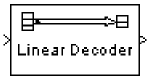
Binary Linear Decoder

Decode linear block code to recover binary vector data



Library

Block sublibrary of Error Detection and Correction

Description

The Binary Linear Decoder block recovers a binary message vector from a binary codeword vector of a linear block code.

The **Generator matrix** parameter is the generator matrix for the block code. For proper decoding, this should match the **Generator matrix** parameter in the corresponding Binary Linear Encoder block. If *N* is the codeword length of the code, then **Generator matrix** must have *N* columns. If *K* is the message length of the code, then the **Generator matrix** parameter must have *K* rows.

This block accepts a column vector input signal containing *N* elements. This block outputs a column vector with a length of *K* elements.

The decoder tries to correct errors, using the **Decoding table** parameter. If **Decoding table** is the scalar 0, then the block defaults to the table produced by the Communications Toolbox function `syndtable`. Otherwise, **Decoding table** must be a 2^{N-K}-by-N binary matrix. The *r*th row of this matrix is the correction vector for a received binary codeword whose syndrome has decimal integer value *r*-1. The syndrome of a received codeword is its product with the transpose of the parity-check matrix.

For information about the data types each block port supports, see the “Supported Data Type” on page 5-62 table on this page.

Parameters

Generator matrix

Generator matrix for the code; same as in Binary Linear Encoder block.

Decoding table

Either a 2^{N-K}-by-N matrix that lists correction vectors for each codeword's syndrome; or the scalar 0, in which case the block defaults to the table corresponding to the **Generator matrix** parameter.

Binary Linear Encoder

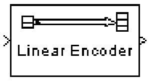
Create linear block code from binary vector data



Library

Block sublibrary of Error Detection and Correction

Description

The Binary Linear Encoder block creates a binary linear block code using a generator matrix that you specify. If *K* is the message length of the code, then the **Generator matrix** parameter must have *K* rows. If *N* is the codeword length of the code, then **Generator matrix** must have *N* columns.

This block accepts a column vector input signal containing *K* elements. This block outputs a column vector with a length of *N* elements. For information about the data types each block port supports, see "Supported Data Type" on page 5-63.

Parameters

Generator matrix

A *K*-by-*N* matrix, where *K* is the message length and *N* is the codeword length.

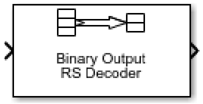
Binary-Output RS Decoder

Decode Reed-Solomon code to recover binary vector data

Library: Communications Toolbox / Error Detection and Correction / Block

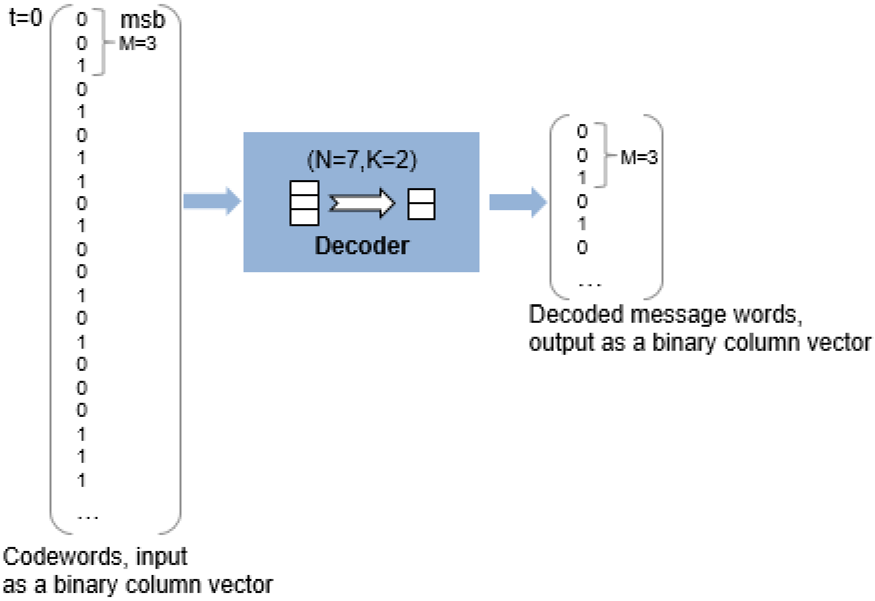


Description

The Binary-Output RS Decoder block recovers a binary message vector from a binary Reed-Solomon codeword vector. For proper decoding, the parameter values in this block must match parameter values in the corresponding Binary-Input RS Encoder block.

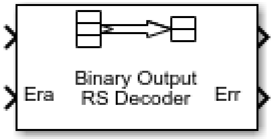
The symbols for the code are binary sequences of length *M*, corresponding to elements of the Galois field $GF(2^M)$. The first bit in each symbol is the most significant bit.

This figure shows the decoder input-output word length for codeword length $N=7$ and message word length $K=2$. Since $N=2^M-1$, when $N=7$, the symbol length, $M=3$.



Each input codeword is a binary vector of length 21 that represents 7 three-bit integers. Each corresponding output message word is a binary vector of length 6, that represents 2 three-bit integers. For more information, see “Input and Output Signal Length in RS Blocks” on page 5-69.

This icon shows all ports, including optional ones:



Ports

Input

`In` — Reed-Solomon codeword
binary column vector

Reed-Solomon codeword in bits, specified as an (N_C×(N – K + S – P)×M)-by-1 binary column vector. N_C is the number of codewords, N is the **Codeword length N (symbols)**, K is the **Message length K (symbols)**, S is the **Shortened message length S (symbols)**, P is the number of punctures per codeword, and M is the number of bits per symbol.

For more information, see "Input and Output Signal Length in RS Blocks" on page 5-69.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `ufix(1)`

`Era` — Erasure vector
binary column vector

Erasure vector in symbols, specified as an (N_C×(N – K + S – P))-by-1 binary column vector. N_C is the number of codewords, N is the **Codeword length N (symbols)**, K is the **Message length K (symbols)**, S is the **Shortened message length S (symbols)**, P is the number of punctures per codeword, and M is the number of bits per symbol.

Erasure values of 1 correspond to erased bits in the same position in the codeword. Values of 0 correspond to bits that are not erased. For more information, see "Puncturing and Erasures" on page 5-71.

Dependencies

To enable this port, select **Enable erasures input port**.

Data Types: `double` | `Boolean`

Output

`Out` — Decoded message
binary column vector

Decoded message in bits, returned as one of the following:

- When there is no message shortening, a (N_C×K×M)-by-1 binary column vector.
- When there is message shortening, a (N_C×S×M)-by-1 binary column vector.

N_C is the number of message words, K is the **Message length K (symbols)**, M is the number of bits per symbol, and S is the **Shortened message length S (symbols)**.

Note The number of decoded message words equals the number of codewords.

For more information, see "Input and Output Signal Length in RS Blocks" on page 5-69.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `ufix(1)`

`Err` — Decoding errors

integer vector

Symbol decoding errors, returned as an integer vector with N_C elements, where N_C is the number of codewords. This port indicates the number of symbol errors detected during decoding of each codeword. A negative integer indicates that the block detected more errors than it could correct by using the specified coding scheme.

Note An (*N*,*K*) Reed-Solomon code can correct up to `floor((N-K)/2)` symbol errors (not bit errors) in each codeword. When a received codeword contains more than (*N*-*K*)/2 symbol errors, a decoding failure occurs.

Dependencies

To enable this port, select **Output number of corrected symbol errors**.

Data Types: `double`

For more information, see "Supported Data Types" on page 5-71.

Parameters

`Codeword length N (symbols)` — Codeword length

7 (default) | integer

Codeword length in symbols, specified as an integer.

For more information, see "Restrictions on M and Codeword Length N" on page 5-70 and "Input and Output Signal Length in RS Blocks" on page 5-69.

`Message length K (symbols)` — Message word length

3 (default) | integer

Message word length in symbols, specified as an integer in the range [1, *N*–2], where *N* is the codeword length.

`Shortened message length S (symbols)` — Shortened message word length

3 (default) | integer

Shortened message word length in symbols, specified as an integer, such that $S \leq K$. When **Shortened message length S (symbols) < Message length K (symbols)**, the Reed-Solomon code is shortened.

You still specify *N* and *K* values for the full-length (*N*, *K*) code but the decoding is shortened to an (*N*–*K*+*S*, *S*) code.

Dependencies

To enable this parameter, select **Specify shortened message length**.

`Generator polynomial` — Generator polynomial

`rsgenpoly(7, 3, [], [], 'double')` (default) | polynomial character vector | binary row vector | binary Galois row vector

Generator polynomial with values from 0 to 2^M–1, in order of descending power, specified as one of the following:

- A polynomial character vector. For more information, see “Character Representation of Polynomials”.
- An integer row vector that represents the coefficients of the generator polynomial in order of descending power.
- An integer Galois row vector that represents the coefficients of the generator polynomial in order of descending power.

Each coefficient is an element of the Galois field defined by the primitive polynomial. For more information, see “Specify the Generator Polynomial” on page 5-70.

Example: `[1 3 1 2 3]`, which is equivalent to `rsgenpoly(7,3)`

Dependencies

To enable this parameter, select **Specify generator polynomial**.

`Primitive polynomial` — Primitive polynomial

`'X^3 + X + 1'` (default) | polynomial character vector | binary row vector

Primitive polynomial in order of descending power. This polynomial is of order *M* and defines the finite Galois field GF(2^M) corresponding to the integers that form message words and codewords. Specify the primitive polynomial as one of the following:

- A polynomial character vector. For more information, see “Character Representation of Polynomials”.
- A binary row vector that represents the coefficients of the generator polynomial.

For more information, see “Restrictions on M and Codeword Length N” on page 5-70.

Example: `'X^3 + X + 1'`, which is the primitive polynomial used for a (7,3) code, `de2bi(primpoly(3,'nodisplay'),'left-msb')`

Dependencies

To enable this parameter, select **Specify primitive polynomial**.

`Puncture vector` — Puncture vector

`[ones(2,1); zeros(2,1)]` (default) | binary column vector

Puncture vector, specified as an (*N*–*K*)-by-1 binary column vector. Element indices with `1`s represent data symbol indices that pass through the block unaltered. Element indices with `0`s represent data symbol indices that get punctured, or removed, from the data stream. For more information, see “Puncturing and Erasures” on page 5-71.

Dependencies

To enable this parameter, select **Punctured code**.

`Enable erasures input port` — Enable erasures input port

off (default) | on

Selecting this check box enables the erasures port, **Era**. For more information, see “Puncturing and Erasures” on page 5-71.

`Output number of corrected symbol errors` — Enable port to output number of corrected symbol errors

off (default) | on

Selecting this check box enables an additional output port, **Err**, which indicates the number of symbol errors the block corrected in the input codeword.

`Output data type` — Output type of the block

`Same as input` (default) | `boolean` | `double`

Output type of the block, specified as `Same as input`, `boolean`, or `double`.

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point`[a] | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`no`

[a] ufix(1) only.

More About

Input and Output Signal Length in RS Blocks

The Reed-Solomon code has a message word length, *K*, or shortened message word length, *S*. The codeword length is $N – K + S – P$, where *N* is the full codeword length and *P* is the number of punctures per codeword. When there is no message shortening, the codeword length expression reduces to $N – P$, because $K = S$. If the decoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords.

This table provides expressions for the input and output signal lengths for the Reed-Solomon encoder and decoder.

The notation $y = N_C \times x$ denotes that *y* is an integer multiple of *x*.

	Input, Erasure, and Output Vector Lengths	
RS Block Coder	**No Message Shortening Used**	**Message Shortening Used**

Binary-Input RS Encoder	**Input Length (bits):**
	$N_C \times K \times M$
	Output Length (bits):
	$N_C \times (N-P) \times M$
		Input Length (bits):
		$N_C \times S \times M$
		Output Length (bits):
		$N_C \times (N-K+S-P) \times M$

Binary-Output RS Decoder	**Input Length (bits):**
	$N_C \times (N-P) \times M$
	Erasures Length (symbols):
	$N_C \times (N-P)$
	Output Length (bits):
	$N_C \times K \times M$
		Input Length (bits):
		$N_C \times (N-K+S-P) \times M$
		Erasures Length (symbols):
		$N_C \times (N-K+S-P)$
		Output Length (bits):
		$N_C \times S \times M$

- N is the codeword length.
- K is the message word length.
- S is the shortened message word length.
- N_C is the number of codewords (and message words).
- P is the number of punctures per codeword, and is equal to the number of zeros in the puncture vector.
- M is the degree of the primitive polynomial. Each group of M bits represents an integer between `0` and 2^M–`1` that belongs to the finite Galois field `GF(`2^M`)`.

For more information on representing data for Reed-Solomon codes, see “Integer Format (Reed-Solomon Only)”.

Also, see “Restrictions on M and Codeword Length N” on page 5-70.

Restrictions on M and Codeword Length N

- If you do not select **Specify primitive polynomial**, valid values for the codeword length, N, are from 7 to 65535. In this case, the block uses the default primitive polynomial of degree `M = ceil(log2(N+1))`. You can display the default primitive polynomial by running `primpoly(ceil(log2(N+1)))`.
- If you select **Specify primitive polynomial**, valid values for the primitive polynomial degree, M, are from 3 to 16. The valid values for N in this case are from 7 to 2^M–1. Selecting **Specify primitive polynomial** enables you to specify the primitive polynomial that defines the finite field $GF(2^M)$, which corresponds to the values that form message words and codewords.

Specify the Generator Polynomial

Select **Specify generator polynomial** to enable the **Generator polynomial** parameter for specifying the generator polynomial of the Reed-Solomon code. Enter an integer row vector with element values from 0 to 2^M-1. The vector represents a polynomial, in descending order of powers, whose coefficients are elements of $GF(2^M)$ represented in integer format. For more information about integer and binary format, see “Integer Format (Reed-Solomon Only)”. The generator polynomial must be equal to a polynomial with this factored form:

$$g(x) = (x+\alpha^{b})(x+\alpha^{b+1})(x+\alpha^{b+2})\ldots(x+\alpha^{b+N-K-1})$$

α is the primitive element of the Galois field over which the input message is defined, and b is an integer.

If you do not select **Specify generator polynomial**, the block uses the default generator polynomial, corresponding to b=1, for Reed-Solomon encoding. You can display the default generator polynomial by running `rsgenpoly`.

- If you are using the default primitive polynomial (**Specify primitive polynomial** is not selected), the default generator polynomial is `rsgenpoly(N,K)`, where `N = 2`^{M}`-1`.
- If you are not using the default primitive polynomial (**Specify primitive polynomial** is selected) and you specify the primitive polynomial as `poly`, the generator polynomial is `rsgenpoly(N,K,poly)`.

Note The degree of the generator polynomial is $N - K$, where N is the codeword length and K is the message word length.

Puncturing and Erasures

`1`s and `0`s have precisely opposite meanings for the puncture and erasure vectors.

In a puncture vector,

- `1` means that the data symbol is passed through the block unaltered.
- `0` means that the data symbol is to be punctured, or removed, from the data stream.

In an erasure vector,

- `1` means that the data symbol is to be replaced with an erasure symbol.
- `0` means that the data symbol is passed through the block unaltered.

These conventions apply to both the encoder and the decoder. For more information, see “Shortening, Puncturing, and Erasures”.

Supported Data Types

Port	Supported Data Types
In	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • 1-bit unsigned integer (ufix(1))

Port	Supported Data Types
Out	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • 1-bit unsigned integer (ufix(1))
Era	• Double-precision floating point • Boolean
Err	• Double-precision floating point

Pair Block

Binary-Input RS Encoder

Algorithms

This block uses the Berlekamp-Massey decoding algorithm. For information about this algorithm, see "Algorithms for BCH and RS Errors-only Decoding".

Objects

`comm.RSDecoder`

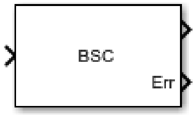
Functions

`primpoly` | `rsdec` | `rsgenpoly`

Introduced before R2006a

Binary Symmetric Channel

Introduce binary errors
Library: Communications Toolbox / Channels



Description

The Binary Symmetric Channel block introduces errors to the input signal transmitted through a binary symmetric channel. The errors are introduced based on the specified Error probability. For more information, see “Tips” on page 5-74.

Ports

Input

`Input` — Input signal
column vector | matrix

Input signal, specified as a column vector or an N_S-by-N_C matrix of `Boolean` values. N_S is the number of samples per channel. N_C is the number of independent data channels. For more information, see “Tips” on page 5-74.

Output

`Output` — Binary output signal
column vector | matrix

Binary output signal, returned as a column vector or matrix with the same dimensions as `Input`. The output signal is a version of the input signal that has been modified by introducing random errors based on the specified Error probability. To set the output data type, use Output data type.

`Err` — Error locations
column vector | matrix

Error locations, returned as a column vector or matrix with the same dimensions as `Input`. Element values in `Err` are `1` or `0`, where:

- `1` indicates that the corresponding element in `Output` has an error.
- `0` indicates that the corresponding element in `Output` does not have an error.

The data type of `Err` is the same as Output, as set by Output data type.

Dependencies

To enable this port, select Output error vector.

Parameters

Error probability — Probability of error occurrence

0.05 (default) | scalar

Probability of error occurrence for the input signal elements, specified as a scalar in the range [0,1]. The probability of error applies independently for each element.

Output error vector — Option to output error locations

on (default) | off

To enable the Err output port to the block, select this parameter.

Output data type — Output data type

double (default) | single | boolean

Select the output data type as double, single, or boolean. This parameter sets the output data type for both the **Output** and **Err** ports.

Initial seed — Initial seed

71 (default) | integer

Initial seed value for the random number generator used by the block, specified as an integer. The block uses the mt19937ar algorithm to generate uniformly distributed random numbers. For details about the mt19937ar algorithm, see “Choosing a Random Number Generator”.

Simulate using — Type of simulation to run

Code generation (default) | Interpreted execution

Type of simulation to run, specified as:

- Code generation –– Simulate the model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time.
- Interpreted execution –– Simulate the model using the MATLAB interpreter. This option shortens startup time. In Interpreted execution mode, you can debug the source code of the block.

Block Characteristics

Data Types	Boolean | double | fixed point | integer | single
Multidimensional Signals	no
Variable-Size Signals	no

Tips

- When the input consists of not Boolean values, Binary Symmetric Channel converts zero-valued elements to 0 and converts nonzero-valued elements to 1.
- The Binary Symmetric Channel block creates and uses an independent RandStream to provide a random number stream for probability determination.

- To generate repeatable results, use the same Initial seed value.
- To generate independent probability statistics, set different Initial seed values for multichannel signals, multiple processing chains, or simulation runs.

Compatibility Considerations

Random Number Generation

Behavior changed in R2018b

To improve statistical properties, the Binary Symmetric Channel block uses the `mt19937ar` algorithm with `RandStream`. The Binary Symmetric Channel block accepts a single scalar value for the Initial seed parameter.

Introduced before R2006a

Bipolar to Unipolar Converter

Map bipolar signal into unipolar signal in range [0, M-1]

Library

Utility Blocks

Description

The Bipolar to Unipolar Converter block maps the bipolar input signal to a unipolar output signal. If the input consists of integers in the set {-*M*+1, -*M*+3, -*M*+5,..., *M*-1}, where *M* is the **M-ary number** parameter, then the output consists of integers between 0 and M-1. This block is only designed to work when the input value is within the set {-*M*+1, -*M*+3, -*M*+5,..., *M*-1}, where M is the **M-ary number** parameter. If the input value is outside of this set of integers the output may not be valid.

The table below shows how the block's mapping depends on the **Polarity** parameter.

Polarity Parameter Value	Output Corresponding to Input Value of k
`Positive`	(M-1+k)/2
`Negative`	(M-1-k)/2

Parameters

M-ary number

The number of symbols in the bipolar or unipolar alphabet.

Polarity

A value of `Positive` causes the block to maintain the relative ordering of symbols in the alphabets. A value of `Negative` causes the block to reverse the relative ordering of symbols in the alphabets.

Output Data Type

The type of bipolar signal produced at the block's output.

The block supports the following output data types:

- `Inherit via internal rule`
- `Same as input`
- `double`
- `int8`
- `uint8`
- `int16`

- `uint16`
- `int32`
- `uint32`
- `boolean`

When the parameter is set to its default setting, `Inherit via internal rule`, the block determines the output data type based on the input data type.

- If the input signal is floating-point (either `single` or `double`), the output data type is the same as the input data type.
- If the input data type is not floating-point:
  - Based on the **M-ary number** parameter, the output data type is the ideal unsigned integer output word length required to contain the range [0 M-1] and is computed as follows:

    ideal word length = ceil(log2(*M*))
  - The block sets the output data type to be an unsigned integer, based on the smallest word length (in bits) that can fit best the computed ideal word length.

Note The selections in the “Hardware Implementation Pane” (Simulink) pane pertaining to word length constraints do not affect how this block determines output data types.

Examples

If the input is [-3; -1; 1; 3], the **M-ary number** parameter is `4`, and the **Polarity** parameter is `Positive`, then the output is [0; 1; 2; 3]. Changing the **Polarity** parameter to `Negative` changes the output to [3; 2; 1; 0].

If the value for the **M-ary number** is 2^8 the block gives an output of uint8.

If the value for the **M-ary number** is 2^8+1 the block gives an output of uint16.

Pair Block

Unipolar to Bipolar Converter

Extended Capabilities

Introduced before R2006a

Bit to Integer Converter

Map vector of bits to corresponding vector of integers
Library: Communications Toolbox / Utility Blocks

Description

The Bit to Integer Converter block maps groups of bits in the input vector to integers in the output vector.

If *M* is specified by the **Number of bits per integer(M)** parameter:

- For unsigned integers, the block maps each group of *M* bits to an integer in the range [0, (2^M – 1)]. As a result, the output vector length is 1/*M* times the input vector length.
- For signed integers, the block maps each group of *M* bits to an integer in the range [(–2^{M-1}), ($2^{M - 1}$ – 1)].

Ports

Input

`In` — Input signal

bit scalar | column vector of bits

Input signal, specified as a scalar or column vector of bits with a length that is a multiple of the value specified in the **Number of bits per integer(M)** parameter. The input must be bits with values of 0 or 1.

Data Types: `double`

Output

`Out` — Output signal

integer | integer column vector of integers

Output signal, returned as an integer or column vector of integers. The **After bit packing, treat resulting integer values as** parameter specifies whether input bits are treated as unsigned or signed.

- When the input bits are treated as unsigned, each integer output is in the range [0, (2^M – 1)].
- When the input bits are treated as signed, each integer output is in the range [(–2^{M-1}), ($2^{M - 1}$ – 1)].

Parameters

`Number of bits per integer(M)` — Number of bits per integer

3 (default) | integer in the range [1, 32]

Number of input bits mapped to each integer in the output, specified as an integer in the range [1, 32].

`Input bit order` — Input bit order

`MSB first` (default) | `LSB first`

Input bit order, specified as `'MSB first'` or `'LSB first'`.

- `'MSB first'` –– First bit of the input signal is the most significant bit (MSB).
- `'LSB first'` –– First bit of the input signal is the least significant bit (LSB).

`After bit packing, treat resulting integer values as` — Flag for signed integer values after bit packing

`Unsigned` (default) | `Signed`

Specify whether the resulting integer values are treated as signed or unsigned after bit packing. This parameter setting determines which **Output data type** selections are available.

`Output data type` — Output data type

`Inherit via internal rule` (default) | `Smallest integer` | `Same as input` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`

The **Output data type** options change depending on the desired signedness of the output.

If the output integers are `Signed`, you can choose from the following **Output data type** options:

- `Inherit via internal rule`
- `Smallest integer`
- `double`
- `single`
- `int8`
- `int16`
- `int32`

If the output integers are `Unsigned`, you can choose from the following options in addition to the `Signed` options:

- `Same as input`
- `uint8`
- `uint16`
- `uint32`

When you set the parameter to `Inherit via internal rule`, the block determines the output data type based on the input data type.

- If the input signal is floating-point (either `double` or `single`), the output data type is the same as the input data type.
- If the input data type is not floating-point, the output data type is determined as if the parameter is set to `Smallest integer`.

When you set the parameter to `Smallest integer`, the block selects the output data type based on the settings used in the “Hardware Implementation Pane” (Simulink) of the Configuration Parameters dialog box.

- If you select `ASIC/FPGA` for the device vendor, the output data type is the smallest ideal integer or fixed-point data type, based on the setting for the **Number of bits per integer(M)** parameter.
- For all other device vendor selections, the output data type is the smallest available (signed or unsigned) integer word length that is large enough to fit the ideal minimum bit size.

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point`[ab] | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

[a] Fixed-point inputs must be ufix(1).

[b] ufix(N) or sfix(N) when ASIC/FPGA is selected in the Hardware Implementation Pane and output data-type is set to either (a) Smallest integer or, (b) Inherit via internal rule and at the same time input is non floating-point.

Introduced before R2006a

BPSK Demodulator Baseband

Demodulate BPSK-modulated data

Library: Communications Toolbox / Modulation / Digital Baseband Modulation / PM
Communications Toolbox HDL Support / Modulation / PM

Description

The BPSK Demodulator Baseband block demodulates a signal that was modulated using the binary phase shift keying method. The input is a baseband representation of the modulated signal. This block accepts a scalar or column vector input signal. The input signal must be a discrete-time complex signal. The block maps the points exp(jθ) and -exp(jθ) to 0 and 1, respectively, where θ is the **Phase offset** parameter.

Ports

Input

`In` — BPSK-modulated signal
scalar | vector | matrix

BPSK-modulated signal, specified as a scalar, vector, or matrix. When this input is a matrix, each column is treated as an independent channel.

Data Types: `double` | `single` | `fixed point`
Complex Number Support: Yes

Output

`Out` — Demodulated signal
scalar | vector

Demodulated signal, returned as a scalar or vector. If the output is a scalar, the value is an integer. If the output is a vector, it is an integer-valued or binary-valued vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Parameters

`Output type` — Output type
`Inherit via internal rule` (default) | `Smallest unsigned integer` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `boolean`

When you set the **Decision type** parameter to `Hard decision`, you can set this parameter to `Inherit via internal rule`, `Smallest unsigned integer`, `double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, or `boolean`.

When you set this parameter to `Inherit via internal rule`, the block inherits the output data type from the input port. If the input is a floating-point type (`single` or `double`) the output data type is the same as the input data type. If the input data type is fixed-point, the output data type will work as if this parameter is set to `Smallest unsigned integer`.

When you set this parameter to `Smallest unsigned integer`, the block selects the output data type based on the settings used in the **Hardware Implementation** pane of the Configuration Parameters dialog box of the model. If you select `ASIC/FPGA` is selected in the **Hardware Implementation** pane, the output data type is the ideal minimum one-bit size, that is., `ufix(1)`. For all other selections, the output data type is an unsigned integer with the smallest available word length large enough to fit one bit. This value usually corresponds to the size of a character (for example, `uint8`).

`Derotate factor` — Derotate factor

`Same word length as input` (default) | `Specify word length`

Derotate factor, specified as `Same word length as input` or `Specify word length`. This parameter applies only when the input is fixed-point and the **Phase offset** (rad) parameter is not a multiple of π/2.

`Decision type` — Decision type

`Hard decision` (default) | `Log-likelihood ratio` | `Approximate log-likelihood ratio`

Decision type used during demodulation, specified as `Hard decision`, `Log-likelihood ratio` or `Approximate log-likelihood ratio`. The output values when you select `Log-likelihood ratio` and `Approximate log-likelihood ratio` are of the same data type as the input values. For algorithm details, see “Exact LLR Algorithm” and “Approximate LLR Algorithm” in the Communications Toolbox User's Guide for algorithm details.

`Noise variance source` — Noise variance source

`Dialog` (default) | `Port`

Noise variance source, specified as `Dialog` or `Port`.

Select `Dialog` to specify the noise variance using the **Noise variance** parameter. Select `Port`to enable the port to input the noise variance.

`Noise variance` — Noise Variance

`1` (default)

This parameter specifies the noise variance in the input signal. This parameter is tunable in normal mode, accelerator mode and rapid accelerator mode.

If you use the Simulink Coder rapid simulation (RSIM) target to build an RSIM executable, then you can tune the parameter without recompiling the model. This is useful for Monte Carlo simulations, in which you run the simulation multiple times (perhaps on multiple computers) with different amounts of noise.

The LLR algorithm involves computing exponentials of very large or very small numbers using finite precision arithmetic and yields:

- `Inf` to `-Inf` if **Noise variance** is very high
- `NaN` if **Noise variance** and the signal power are both very small

In such cases, use approximate LLR, as its algorithm does not involve computing exponentials.

Dependencies

To enable this parameter, set the **Noise variance source** parameter to `Dialog`.

`Phase offset (rad)` — Phase of zeroth point

`0` (default) | real-valued scalar

Phase of the zeroth point, specified as a real-valued scalar. Units are in radians.

Example: `pi/4`

`Output data type` — Data type of output

`Inherit via internal rule` (default) | `Smallest unsigned integer` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `boolean`

Datatype of output, specified as one of these options.

- `Inherit via internal rule`
- `Smallest unsigned integer`
- `double`
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`
- `boolean`

When you set the **Decision type** parameter to

- `Hard decision`, you can set this parameter to `Inherit via internal rule`, `Smallest unsigned integer`, `double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, or `boolean`
- `Inherit via internal rule` (default), the block inherits the output data type from the input port. If the input is a floating-point type (`single` or `double`), the output data type is the same as the input data type. If the input data type is fixed-point, the output data type works as if you set this parameter to `Smallest unsigned integer`.
- `Smallest unsigned integer`, the block selects the output data type based on the settings used in the **Hardware Implementation** pane of the Configuration Parameters dialog box of the model. If you select `ASIC/FPGA` in the **Hardware Implementation** pane, the output data type is the ideal minimum one-bit size, that is, `ufix(1)`. For all other selections, the output data type is an unsigned integer with the smallest available word length large enough to fit one bit, usually corresponding to the size of a character (for example, `uint8`).
- `Log-likelihood ratio` or `Approximate log-likelihood ratio`, the block inherits the output data type from the input (for example, if the input is of data type `double`, the output is also of data type `double`).

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point`[a][b] | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

[a] Fixed-point inputs must be signed.

[b] ufix(1) only at the output when ASIC/FPGA is selected in the Hardware Implementation Pane.

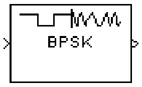
BPSK Modulator Baseband

Modulate signal by using BPSK method

Library: Communications Toolbox / Modulation / Digital Baseband Modulation / PM
Communications Toolbox HDL Support / Modulation / PM



Description

The BPSK Modulator Baseband block modulates a signal by using the binary phase shift keying (BPSK) method. The output is a baseband representation of the modulated signal.

The input signal must be a discrete-time binary-valued signal. If the input bit is 0 or 1, then the modulated symbol is *exp(jθ)* or *-exp(jθ)*, respectively, where *θ* represents the **Phase offset (rad)** parameter.

Ports

Input

`Port_1` — Input data
scalar | vector

Input signal, specified as a scalar or vector.

- If you specify a scalar, it must be an integer from 0 to M – 1, where M is the modulation order.
- If you specify a vector, the elements must be either integers from 0 to M-1 or binary values. If you specify a binary vector, the number of elements must be an integer multiple of the number of bits per symbol. The number of bits per symbol is equal to $\log_2(M)$.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Output

`Port_1` — BPSK-modulated baseband signal
scalar | vector

BPSK-modulated baseband signal, returned as a complex scalar or vector of complex values.

Data Types: `single` | `double` | `fixed point`

Parameters

`Phase offset (rad)` — Phase of zeroth point
`0` (default) | finite real-valued scalar

Specify a finite real-valued scalar for the phase of the zeroth point of the constellation in radians.

Example: `pi/4`

`Output data type` — Output data type

`double` (default) | `single` | `Inherit via back propagation` | `fixdt(1,16)` | `fixdt(1,16,0)` | `<data type expression>`

Data type of output,. Set this parameter to one of the fixed point options or `<data type expression>` to enable parameters in which you specify additional details. Set this parameter to `Inherit via back propagation`, to match the output data type and scaling to the following block in the model.

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point`[ab] | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`

a. ufix(ceil(log2(M))) only at the input for M-ary modulation.

b. Fixed-point outputs must be signed.

Tips

The BPSK Modulator Baseband block provides the capability to visualize a signal constellation from the block mask. This constellation visualization feature allows you to visualize a signal constellation for the specified block parameters. For more information, see the “Constellation Visualization” section of the *Communications Toolbox User's Guide*.

Algorithms

Phase modulation is a linear baseband modulation technique in which the message modulates the phase of a constant amplitude signal. Binary Phase Shift Keying (BPSK) is a two phase modulation scheme, where the 0’s and 1’s in a binary message are represented by two different phase states in the carrier signal

$$s_n(t) = \sqrt{\frac{2E_b}{T_b}}\cos(2\pi f_c t + \pi(1 - n));\ n \in \left\{0, 1\right\},$$

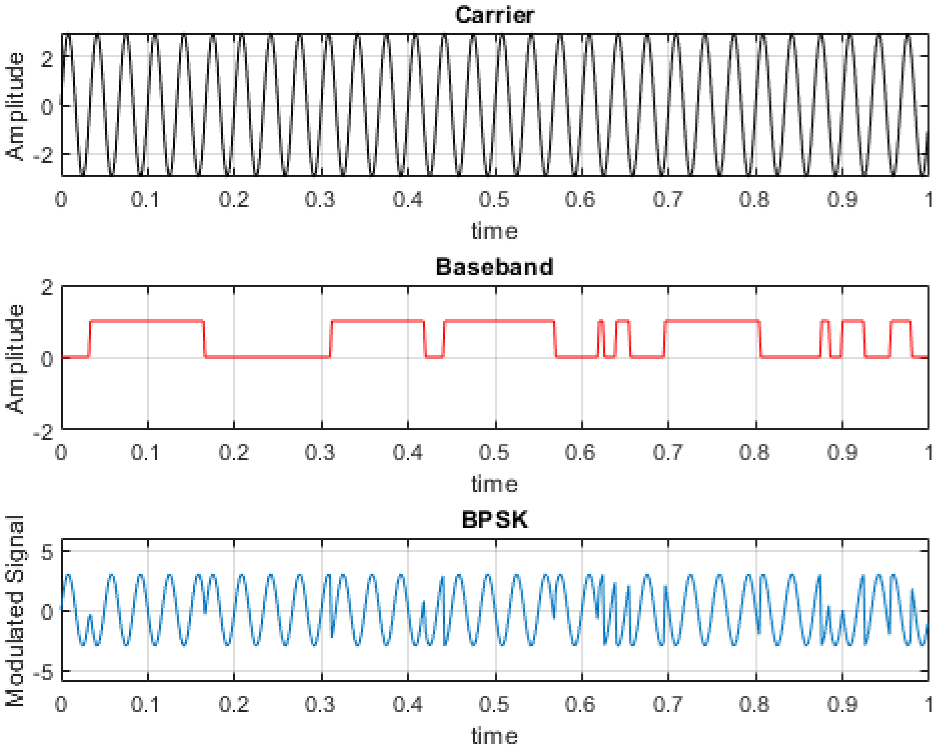
where:

- E_b is the energy per bit.
- T_b is the bit duration.
- f_c is the carrier frequency.

In MATLAB, the baseband representation of a BPSK signal is

$$s_n(t) = \cos(\pi n);\ n \in \{0, 1\}\ .$$

The BPSK signal has two phases: 0 and π.



The probability of a bit error in an AWGN channel is

$$P_b = Q\left(\sqrt{\frac{2E_b}{N_0}}\right),$$

where N_0 is the noise power spectral density.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is `0`. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is `0`. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is `0`. For more details, see “OutputPipeline” (HDL Coder).

Carrier Synchronizer

Compensate for carrier frequency offset

Out
Carrier
Synchronizer
PhEst
Carrier Synchronizer

Library

Synchronization

Description

The Carrier Synchronizer block compensates for carrier frequency and phase offsets using a closed-loop approach for BPSK, QPSK, OQPSK, 8-PSK, QAM, and PAM modulation schemes. The block accepts a single input port. To obtain an estimate of the phase error in radians, select the **Estimated phase error output port** check box. The block accepts a sample- or frame-based complex input signal and returns a complex output signal and a an real phase estimate. The block outputs have the same dimensions as the input.

Note

- This block does not resolve phase ambiguities created by the synchronization algorithm. As indicated in this table, the potential phase ambiguity introduced by the synchronizer depends on the modulation type:

Modulation	Phase Ambiguity (degrees)
`'BPSK'` or `'PAM'`	0, 180
`'OQPSK'`, `'QPSK'`, or `'QAM'`	0, 90, 180, 270
`'8PSK'`	0, 45, 90, 135, 180, 225, 270, 315

- For best results, apply carrier synchronization to non-oversampled signals.

Parameters

Modulation

Specify the modulation type as `BPSK`, `QPSK`, `OQPSK`, `8PSK`, `QAM`, or `PAM`.

Modulation phase offset

Specify the method used to calculate the modulation phase offset as either `Auto` or `Custom`.

- `Auto` applies the traditional offset for the specified modulation type.

Modulation	Phase Offset (radians)
BPSK, QAM, or PAM	0
QPSK or OQPSK	$\pi/4$
8PSK	$\pi/8$

- Custom enables the **Custom phase offset (radians)** parameter.

Custom phase offset (radians)

Specify the phase offset in radians as a real scalar. This parameter is available only when **Modulation phase offset** is set to Custom.

Samples per symbol

Specify the number of samples per symbol as a positive integer scalar.

Damping factor

Specify the damping factor of the loop as a positive real finite scalar.

Normalized loop bandwidth

Specify the normalized loop bandwidth as a real scalar between 0 and 1. The bandwidth is normalized by the sample rate of the carrier synchronizer block.

Estimated phase error output port

Select this check box to provide the estimated phase error to an output port.

Simulate using

Select the simulation mode.

`Code generation`

On the first model run, simulate and generate code for the block using only MATLAB functions supported for code generation. If the structure of the block does not change, subsequent model runs do not regenerate the code.

`Interpreted execution`

Simulate model using all supported MATLAB functions. Choosing this option can slow simulation performance.

Algorithms

This block implements the algorithm, inputs, and outputs described on the `comm.CarrierSynchronizer` reference page. The object properties correspond to the block parameters.

Examples

Correct for Frequency and Phase Offset

Correct for a phase and frequency offset imposed on a noisy 16-QAM channel using the Carrier Synchronizer block.

Open the doc_qamcarriersync model.

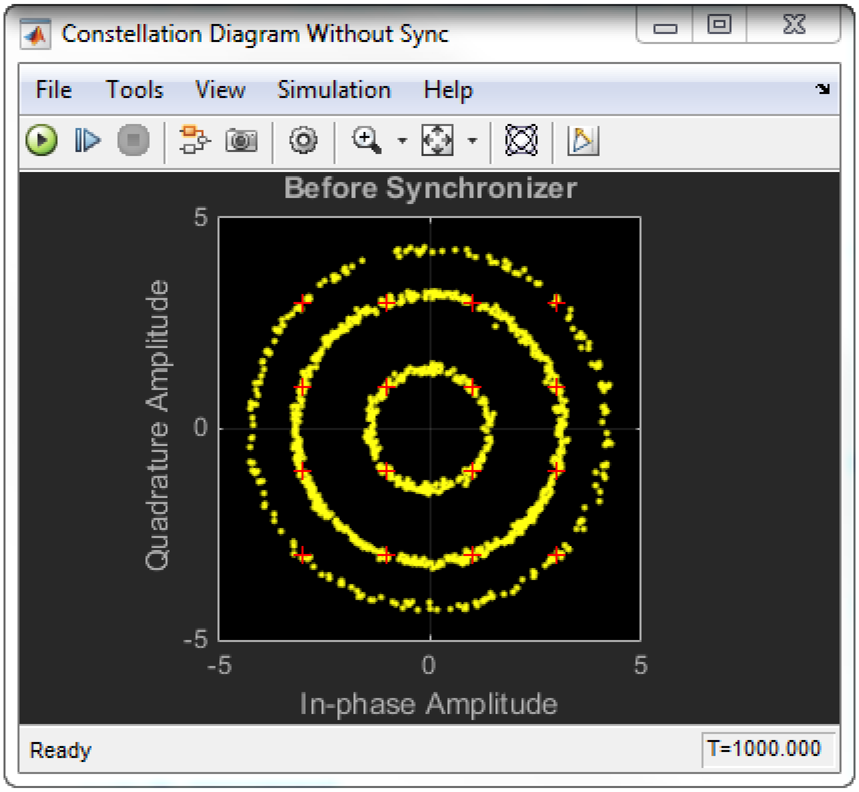
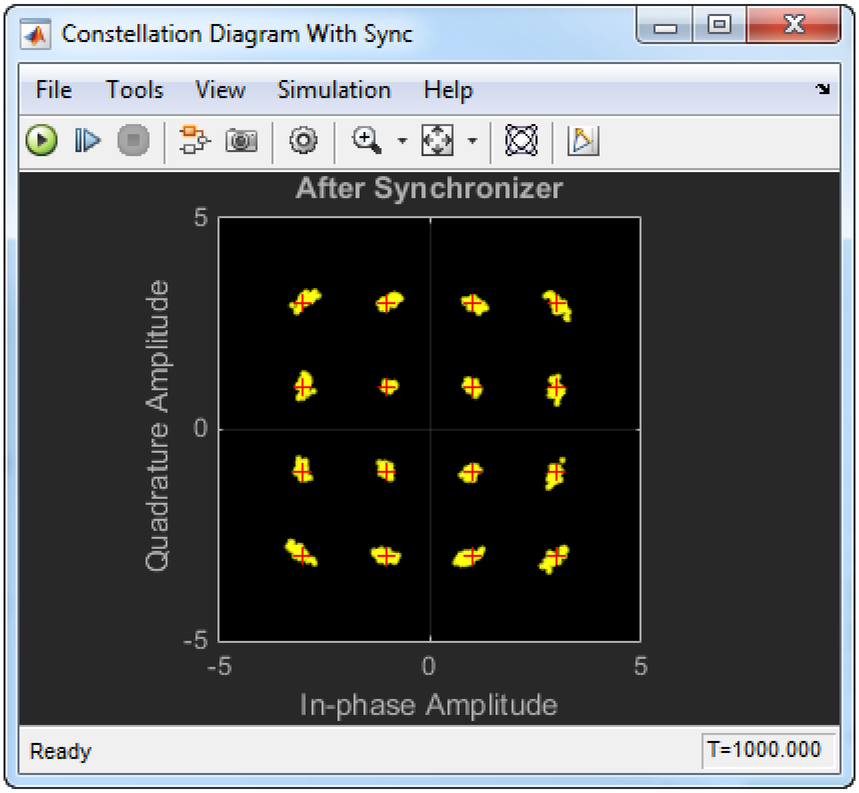
Random Integer
Rectangular 16-QAM
AWGN
Phase/ Frequency Offset
Carrier Synchronizer
Constellation Diagram With Sync
Constellation Diagram Without Sync
Ready
100%
ode45

Run the model. The Constellation Diagram Without Sync block shows a spiral pattern that indicates a phase and frequency offset. After the carrier synchronizer converges to a solution, the data displayed on the Constellation Diagram With Sync block are grouped around the reference constellation.





Experiment with the parameters in the Phase/Frequency Offset and Carrier Synchronizer blocks. By varying these parameters, you can change how quickly the output conforms to an ideal 16-QAM constellation.

If the signal does not converge to the expected constellation, additional measures can be taken to achieve successful recovery. For more information, see the “Correct Phase and Frequency Offset for 16-QAM Using Coarse and Fine Synchronization” on page 3-275 example.

Supported Data Types

Port	Supported Data Types
Signal Input	• Double-precision floating point • Single-precision floating point
Signal Output	• Double-precision floating point • Single-precision floating point
Phase Error Estimate	• Double-precision floating point • Single-precision floating point

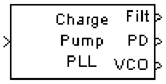
Charge Pump PLL

Implement charge pump phase-locked loop using digital phase detector



Library

Components sublibrary of Synchronization

Description

The Charge Pump PLL (phase-locked loop) block automatically adjusts the phase of a locally generated signal to match the phase of an input signal. It is suitable for use with digital signals.

This PLL has these three components:

- A sequential logic phase detector, also called a digital phase detector or a phase/frequency detector.
- A filter. You specify the filter transfer function using the **Lowpass filter numerator** and **Lowpass filter denominator** parameters. Each is a vector that gives the respective polynomial's coefficients in order of descending powers of *s*.

  To design a filter, use functions such as `butter`, `cheby1`, and `cheby2` in Signal Processing Toolbox software. The default filter is a Chebyshev type II filter whose transfer function arises from the command below.

  ```
  [num, den] = cheby2(3,40,100,'s')
  ```
- A voltage-controlled oscillator (VCO). You specify characteristics of the VCO using the **VCO input sensitivity**, **VCO quiescent frequency**, **VCO initial phase**, and **VCO output amplitude** parameters.

This block accepts a sample-based scalar input signal. The input signal represents the received signal. The three output ports produce:

- The output of the filter
- The output of the phase detector
- The output of the VCO

A sequential logic phase detector operates on the zero crossings of the signal waveform. The equilibrium point of the phase difference between the input signal and the VCO signal equals π. The sequential logic detector can compensate for any frequency difference that might exist between a VCO and an incoming signal frequency. Hence, the sequential logic phase detector acts as a frequency detector.

Parameters

Lowpass filter numerator

The numerator of the lowpass filter transfer function, represented as a vector that lists the coefficients in order of descending powers of *s*.

Lowpass filter denominator

The denominator of the lowpass filter transfer function, represented as a vector that lists the coefficients in order of descending powers of *s*.

VCO input sensitivity (Hz/V)

This value scales the input to the VCO and, consequently, the shift from the **VCO quiescent frequency** value. The units of **VCO input sensitivity** are Hertz per volt.

VCO quiescent frequency (Hz)

The frequency of the VCO signal when the voltage applied to it is zero. This should match the frequency of the input signal.

VCO initial phase (rad)

The initial phase of the VCO signal.

VCO output amplitude

The amplitude of the VCO signal.

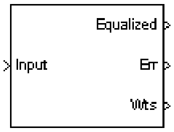
CMA Equalizer

(To be removed) Equalize using constant modulus algorithm

Note will be removed in a future release. Use Linear Equalizer instead.



Library

Equalizers

Description

The CMA Equalizer block uses a linear equalizer and the constant modulus algorithm (CMA) to equalize a linearly modulated baseband signal through a dispersive channel. During the simulation, the block uses the CMA to update the weights, once per symbol. If the **Number of samples per symbol** parameter is `1`, then the block implements a symbol-spaced equalizer; otherwise, the block implements a fractionally spaced equalizer.

When using this block, you should initialize the equalizer weights with a nonzero vector. Typically, CMA is used with differential modulation; otherwise, the initial weights are very important. A typical vector of initial weights has a 1 corresponding to the center tap and zeros elsewhere.

Input and Output Signals

The `Input` port accepts a scalar-valued or column vector input signal. The `Desired` port receives a training sequence with a length that is less than or equal to the number of symbols in the `Input` signal.

You can configure the block to have one or more of the extra ports listed in the table below.

Port	Meaning	How to Enable
`Err` output	y(R -|y|^2), where y is the equalized signal and R is a constant related to the signal constellation	Select **Output error**.
`Wts` output	A vector listing the weights after the block has processed either the current input frame or sample.	Select **Output weights**.

Algorithms

Referring to the schematics in “Adaptive Equalizers”, define *w* as the vector of all weights w_i and define *u* as the vector of all inputs u_i. Based on the current set of weights, *w*, this adaptive algorithm creates the new set of weights given by

(`LeakageFactor`) w + (`StepSize`) u^*e

where the * operator denotes the complex conjugate.

Equalizer Delay

The delay between the transmitter's modulator output and the CMA equalizer output is typically unknown (unlike the delay for other adaptive equalizers in this product). If you need to determine the delay, you can use the Find Delay block.

Parameters

Number of taps

The number of taps in the filter of the equalizer.

Number of samples per symbol

The number of input samples for each symbol.

When you set this parameter to 1, the filter weights are updated once for each symbol, for a symbol spaced (i.e. T-spaced) equalizer. When you set this parameter to a value greater than one, the weights are updated once every N^{th} sample, for a fractionally spaced (i.e. T/N-spaced) equalizer.

Signal constellation

A vector of complex numbers that specifies the constellation for the modulation.

Step size

The step size of the CMA.

Leakage factor

The leakage factor of the CMA, a number between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, and a value of 0 corresponds to a memoryless update algorithm.

Initial weights

A vector that lists the initial weights for the taps.

Output error

If you check this box, the block outputs the error signal described in the table above.

Output weights

If you check this box, the block outputs the current weights.

References

Compatibility Considerations

CMA Equalizer will be removed

Warns starting in R2020a

- CMA Equalizer will be removed in a future release. Use Linear Equalizer instead with the adaptive algorithm set to CMA.
- The Linear Equalizer block does not have a leakage factor parameter. This is equivalent to setting the **Leakage factor** parameter to 1 in the CMA Equalizer block.

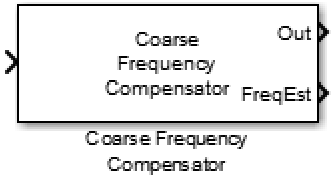
Coarse Frequency Compensator

Compensate for carrier frequency offset for PAM, PSK, or QAM



Library

Synchronization

Description

The Coarse Frequency Compensator block compensates for a carrier frequency offset for BPSK, QPSK, OQPSK, 8-PSK, PAM, and QAM modulation schemes. The block accepts a single input signal. To obtain an estimate of the frequency offset in Hz, select the **Estimated frequency offset output port** check box. The block accepts a sample- or frame-based complex input signal and returns a complex output signal and a real frequency offset estimate. The output signal has the same dimensions as the input signal. The frequency offset estimate is a scalar.

Parameters

Modulation type of input signal

Specify the modulation type as `BPSK`, `QPSK`, `OQPSK`, `8PSK`, `PAM`, or `QAM`.

The default setting is `QAM`.

Estimation algorithm

Specify the frequency offset estimation algorithm as `FFT-based` or `Correlation-based`. This parameter appears when **Modulation type of input signal** is `BPSK`, `QPSK`, `8PSK`, or `PAM`.

The table shows the allowable combinations of the modulation type and the estimation algorithm.

Modulation	FFT-Based Algorithm	Correlation-Based Algorithm
BPSK, QPSK, 8PSK, PAM	✓	✓
OQPSK, QAM	✓	

Frequency resolution (Hz)

Specify the frequency resolution in Hz as a positive real scalar. This option is available when the `FFT-based` algorithm is used. The default setting is `0.001` Hz.

Samples per symbol

Specify the number of samples per symbol as a positive integer scalar greater than or equal to 4. The default setting is 4.

Maximum frequency offset (Hz)

Specify the maximum frequency offset in Hz as a positive real scalar. This option is appears when you set **Estimation algorithm** to `Correlation-based`. The default setting is `0.05` Hz.

Estimated frequency offset output port

Select this check box to provide the estimated frequency offset to an output port. The default for this parameter is selected.

Simulate using

Select the simulation mode.

`Code generation`

On the first model run, simulate and generate code for the block using only MATLAB functions supported for code generation. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is `Code generation`, System objects accept a maximum of nine inputs.

`Interpreted execution`

Simulate your model using all supported MATLAB functions. Choosing this option can slow simulation performance.

The default setting is `Code generation`.

Algorithms

This block implements the algorithm, inputs, and outputs described on the `comm.CoarseFrequencyCompensator` reference page. The object properties correspond to the block parameters.

Examples

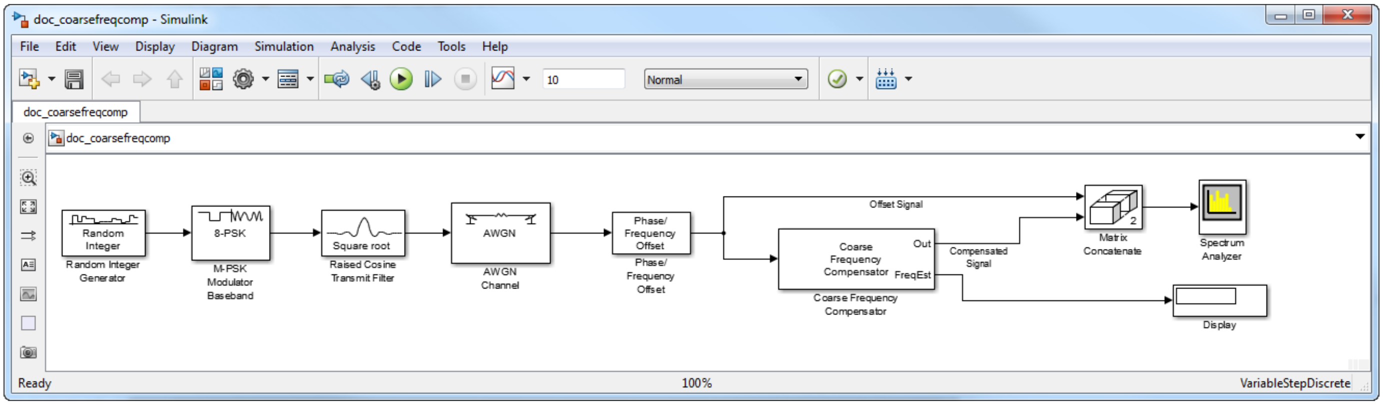
Correct for Frequency and Phase Offset

Correct for a frequency offset imposed on a noisy 8-PSK channel by using the Coarse Frequency Compensator block.

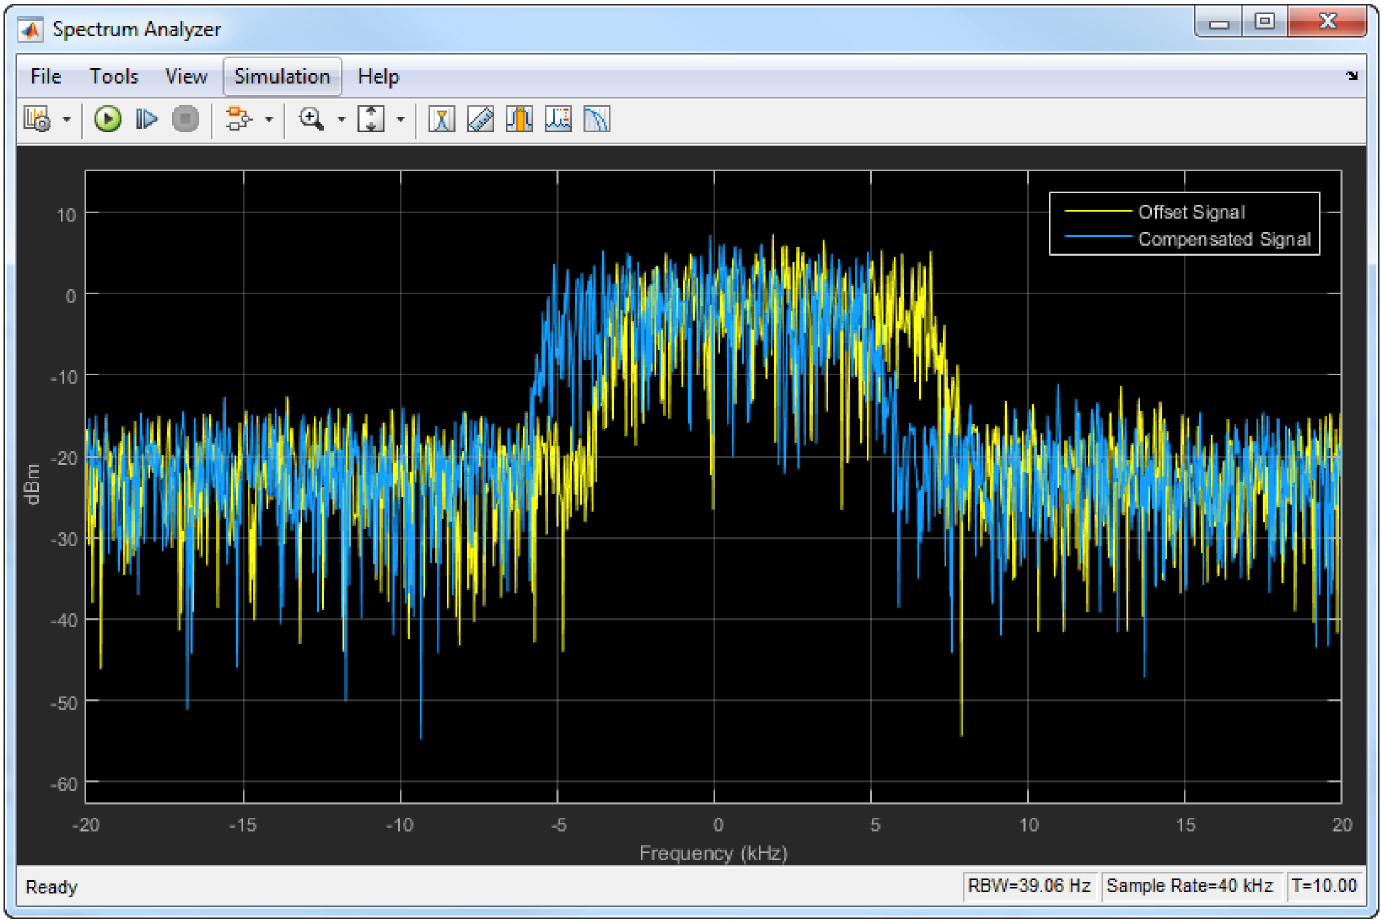
Open the doc_coarsefreqcomp model.

Open the dialog boxes to verify these parameter values:

- Random Integer Generator — **Sample time** is `1e-4`, which is equivalent to a 10 ksym/sec symbol rate.
- Raised Cosine Transmit Filter — **Output samples per symbol** is `4`.
- AWGN Channel — **Mode** is `Signal to noise ratio (SNR)` and **SNR (dB)** is `20`.
- Phase/Frequency Offset — **Frequency offset (Hz)** is `2000`.
- Coarse Frequency Compensator — **Estimation algorithm** is `FFT-based` and **Frequency resolution (Hz)** is `1`.



Run the model. The Spectrum Analyzer block shows both the frequency offset signal and the compensated signal. In addition, the Display block shows the estimate of the frequency offset. Observe that the spectrum plot shows that the Coarse Frequency Compensator correctly centers the signal around 0 Hz. Additionally, the display shows that the estimated frequency offset is 2000 Hz.



Adjust the parameters in the Phase/Frequency Offset and Coarse Frequency Compensator blocks and see their effect on frequency compensation performance.

Supported Data Types

Port	Supported Data Types
Signal Input	• Double-precision floating point • Single-precision floating point
Signal Output	• Double-precision floating point • Single-precision floating point
Frequency Estimate	• Double-precision floating point • Single-precision floating point

Complex Phase Difference

Phase difference between two complex signals
Library: Communications Toolbox / Utility Blocks

Description

The Complex Phase Difference block computes the phase difference in radians between the second input signal and the first input signal. The elements of the output are between -π and π. This block independently processes each pair of corresponding elements.

Ports

Input

`In1` — First input signal
scalar | column vector | matrix

First input signal, specified as a scalar, column vector, or matrix. If both input signals are nonscalar, they must be the same dimension.

Note This block processes complex signals. Real values at the input ports are type cast to complex values with `+j0` complex components.

Data Types: `double` | `single`
Complex Number Support: Yes

`In2` — Second input signal
scalar | column vector | matrix

Second input signal, specified as a scalar, column vector, or matrix. If both input signals are nonscalar, they must be the same dimension. **In2** must be the same data type as **In1**.

Note This block processes complex signals. Real values at the input ports are type cast to complex values with `+j0` complex components.

Data Types: `double` | `single`

Output

`Out1` — Phase shift difference
scalar | column vector | matrix

Phase shift difference in radians, returned as a scalar, column vector, or matrix. If either input signal is nonscalar, the output signal dimension matches the dimension of the nonscalar input signal. The output is the phase difference between the second input signal and the first input signal. The elements of the output signal are between -π and π and are the same data type as the input signals.

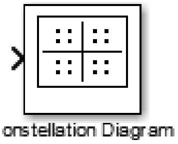
Constellation Diagram

Display constellation diagram for input signals

Library: Communications Toolbox / Comm Sinks
Communications Toolbox HDL Support / Comm Sinks

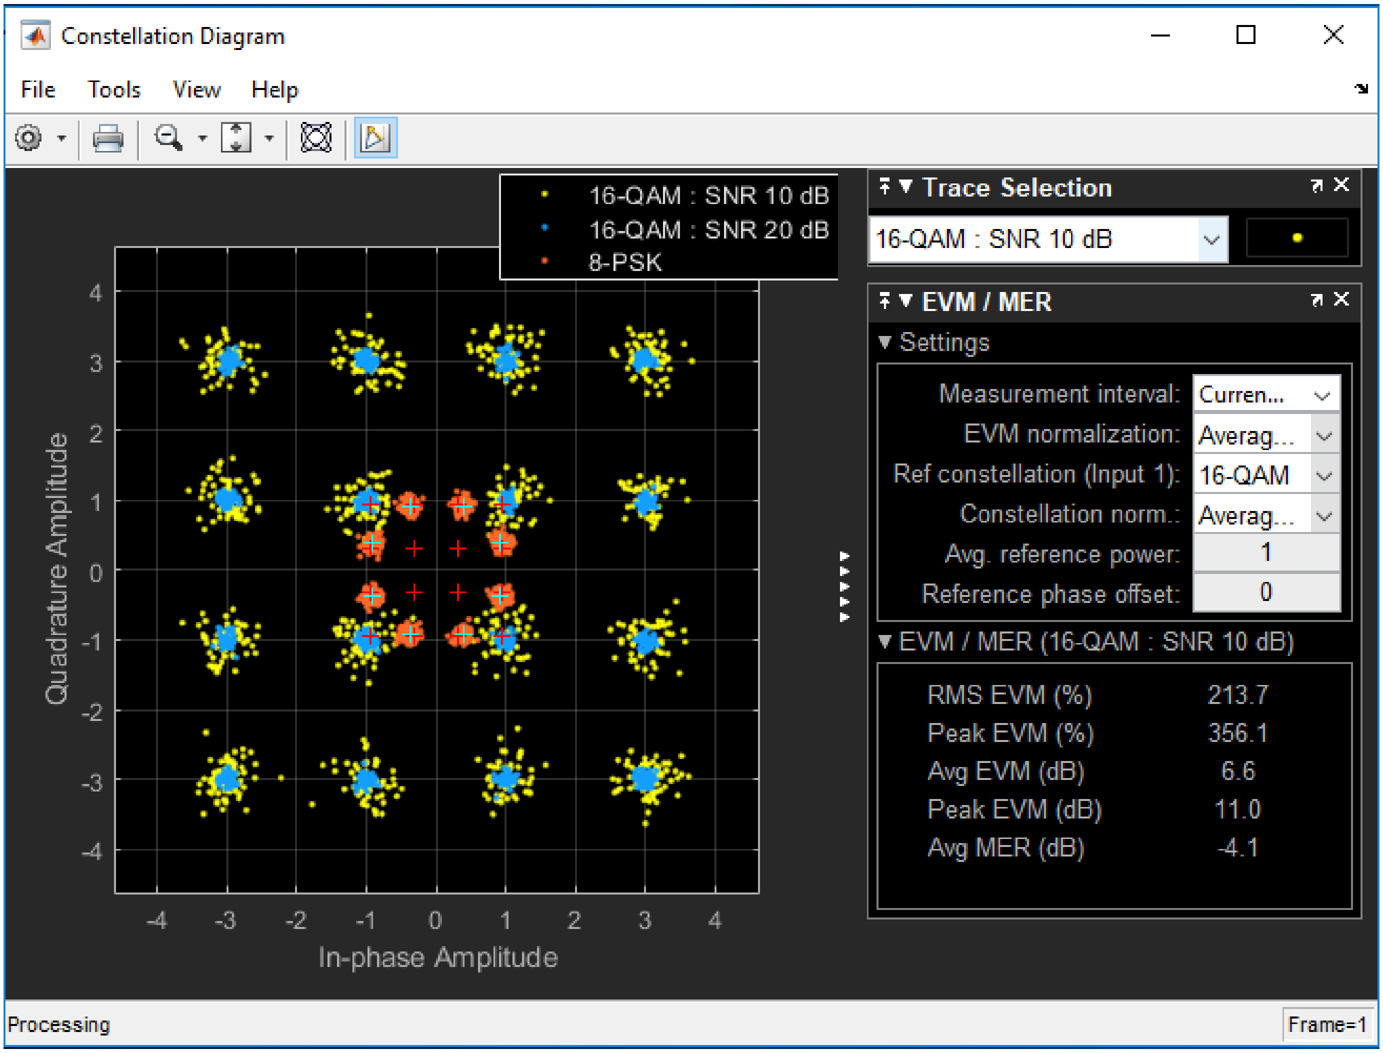


Description

The Constellation Diagram block displays real and complex-valued floating and fixed-point signals in the I/Q plane. Use this block to perform qualitative and quantitative analysis on modulated single-carrier signals.

In the constellation diagram window you can:

- Input and plot multiple signals on a single constellation diagram. You can define one reference constellation for each input signal. For more information, see **Reference constellation**.
- Choose which channels are displayed by selecting signals in the legend. Use the Show legend parameter to display the legend.
- Display the “EVM / MER Measurements” on page 5-120 panel, which displays calculated error vector magnitude (EVM) and modulation error ratio (MER) measurements. When a multichannel signal is input, use Trace Selection to choose the signal being measured.



Trace Selection: 16-QAM : SNR 10 dB

Measurement interval: Curren...
EVM normalization: Averag...
Ref constellation (Input 1): 16-QAM
Constellation norm.: Averag...
Avg. reference power: 1
Reference phase offset: 0

EVM / MER (16-QAM : SNR 10 dB)

```
RMS EVM (%)     213.7
Peak EVM (%)    356.1
Avg EVM (dB)      6.6
Peak EVM (dB)    11.0
Avg MER (dB)     -4.1
```

Ports

Input

`Port_1` — Signal or signals to visualize

column vector | matrix

Connect to the signal or signals you want to visualize as an N_{sym}-by-1 column vector or N_{sym}-by-N_{sig} matrix. N_{sym} is the number of symbols and N_{sig} is the number of input signals.

You can specify up to 20 input signals. Specifically, the maximum number of channels through all the ports is 20. For example, if you create a two-channel signal for every input port, then you can define up 10 number of input ports.

Example: `[-1 + 1i; -1 - 1i; 1 + 1i; 1 - 1i]` specifies a 4-symbol input signal.

Parameters

File

From the Constellation Diagram window, select **File** to view the options available.

`Open at Start of Simulation` — Open constellation diagram at start of simulation
on (default) | off

Select to open constellation diagram window at start of simulation. Deselect to prevent constellation diagram window from opening at start of simulation.

`Number of input ports` — Number of input ports on scope block
`1` (default) | positive integer in the range [1, 20]

Specify the number of input ports on the Scope block, specified as an integer in the range [1, 20].

When multichannel input signals are specified, the maximum number of input ports is limited by the total number of input signals defined. The total number of input signal cannot exceed 20.

Tools > Axes Scaling Properties

From the Constellation Diagram window, under **Tools**, select **Axes Scaling Properties** to open the Axes Scaling Properties: Constellation Diagram dialog box. In this dialog box, you can customize the graphical properties of the axes.

Properties

`Axes scaling` — Axes scaling options
`Manual` (default) | `Auto` | `After N Updates`

Axes scaling options, specified as:

- `Manual` — Applies the *x* and *y* axes limits specified in the Visuals – Constellation Properties: Constellation Diagram dialog box.
- `Auto` — Scales the axes limits as needed during and after simulation.
- `After N Updates` — Scales the axes limits after the specified **Number of updates**.

Tunable: Yes

`Number of updates` — Number of updates after which to scale the axes
`10` (default) | positive integer

Number of updates after which to scale the axes, specified as a positive integer.

Tunable: Yes

Dependencies

This parameter appears when **Axes scaling** is set to `After N Updates`.

`Scale axes limits at stop` — Option to scale axes at end of simulation
`off` (default) | `on`

Select to scale axes at end of the simulation to the data range percentage limits specified by **X-axis Data range (%)** and **Y-axis Data range (%)**.

`X-axis Data range (%)` — Percentage of *x*-axis used to display data

`80` (default) | scalar from 1 to 100

Percentage of *x*-axis used to display data.

Example: `100` scales the x-axis range to the maximum value of the in-phase amplitude component of the input signal.

Tunable: Yes

`X-axis Align` — Align data along *x*-axis

`Center` (default) | `Left` | `Right`

Align data along *x*-axis, specified as `Center`, `Left`, or `Right`.

Example: `Right` aligns the maximum value of the in-phase amplitude component of the input signal toward the upper x-axis limit.

Tunable: Yes

`Y-axis Data range (%)` — Percentage of *y*-axis used to display data

`80` (default) | scalar from 1 to 100

Percentage of *y*-axis used to display data.

Example: `30` scales the y-axis range so that the maximum value of the quadrature amplitude component of the signal occupies 30% of the y-axis range.

Tunable: Yes

`Y-axis Align` — Align data along *y*-axis

`Center` (default) | `Top` | `Bottom`

Align data along *y*-axis, specified as `Center`, `Top`, or `Bottom`.

Example: `Bottom` aligns the maximum value of the quadrature amplitude component of the signal toward the lower y-axis limit.

Tunable: Yes

Tools > Measurements

From the Constellation Diagram window, under **Tools**, select **Measurements** for options to display the **Trace Selection** and **Signal Quality** panes. By default these panes are docked in the Constellation Diagram window when displayed.

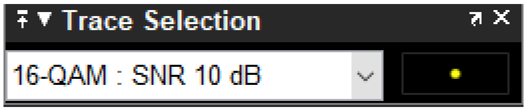
The **Signal Quality** pane contains the **Settings** and **EVM / MER** subpanes. Both subpanes can be independently expanded or collapsed.

For more information about the signal quality measurements, see “EVM / MER Measurements” on page 5-120.

`Trace Selection` — Signal trace used to compute measurements

list of signals

Select the signal trace used to compute measurements from the list of available signals. This parameter lists the signals input to the block.



Tunable: Yes

Dependencies

To set this parameter, the **Trace Selection** pane must be visible. The **Trace Selection** pane automatically appears when you plot multiple signals on the Constellation Diagram window. To hide or display the **Trace Selection** pane from the Constellation Diagram window, under **Tools**, select **Measurements** > **Trace Selection** to toggle the visibility of the traceback selection measurement.

EVM / MER Settings Pane

`Measurement interval` — Duration of EVM or MER measurement

`Current Display` (default) | `All displays` | positive integer

Duration of the EVM or MER measurement in symbols, specified as `Current Display`, `All displays`, or a positive integer. To specify a positive integer, select and then replace `<user-defined>` with your desired value. The value must be positive and less than or equal to **Symbols to display**. The measurement is computed after the number of input data samples exceeds the measurement interval.

Tunable: Yes

`EVM normalization` — Normalization method used for EVM calculation

`Average constellation power` (default) | `Peak constellation power`

Normalization method used for EVM calculation, specified as `Average constellation power` or `Peak constellation power`. The `comm.EVM` System object computes the EVM.

Tunable: Yes

`Reference constellation` — Reference constellation

`QPSK` (default) | `BPSK` | `8-PSK` | `16-QAM` | `64-QAM` | `256-QAM` | vector

Reference constellation, specified as `BPSK`, `QPSK`, `8-PSK`, `16-QAM`, `64-QAM`, `256-QAM`, or a <user-defined> vector. To specify a custom value, select `<user-defined>`, then in the **Custom value** property replace the entry with your desired value.

Each input port can have its own reference constellation. For a multichannel input signal, a single reference constellation is applied for all signals in that input port.

To obtain the EVM/MER measurements, you must set **Reference constellation** to a valid value corresponding to the modulation of the input signal.

Tunable: Yes

`Custom value` — Input reference constellation

vector

Input the reference constellation, specified as a vector.

Dependencies

To enable this parameter, set **Reference constellation** to <user-defined>.

Data Types: `double`
Complex Number Support: Yes

`Average reference power` — Average power of reference constellation

`1` (default) | positive scalar

Average power of the reference constellation in watts, specified as a positive scalar and referenced to a one-ohm load.

Tunable: Yes

`Reference phase offset (rad)` — Phase offset of reference constellation

`pi/4` (default) | scalar

Phase offset of the reference constellation in radians, specified as a scalar.

Tunable: Yes

View > Configuration Properties

From the Constellation Diagram window, select **View** > **Configuration Properties** to open the Visuals – Constellation Properties: Constellation Diagram dialog box. In this dialog box, you can customize the graphical properties of the plotted signals.

Main

`Number of input ports` — Number of input ports on scope block

1 (default) | positive integer in the range [1, 20]

Specify the number of input ports on the Scope block, specified as an integer in the range [1, 20].

`Samples per symbol` — Number of samples used to represent each symbol

`1` (default) | positive integer

Number of samples used to represent each symbol, specified as a positive integer. When **Samples per symbol** is greater than 1, the signal is downsampled before it is plotted.

Tunable: Yes

`Offset (samples)` — Number of samples to skip before plotting points

`0` (default) | nonnegative integer

Number of samples to skip before plotting points, specified as a nonnegative integer less than Samples per symbol. This parameter specifies the number of samples to skip when downsampling the input signal.

Tunable: Yes

`Symbols to display` — Maximum number of symbols to display

`Input frame length` (default) | positive integer

Maximum number of symbols to display, specified as `Input frame length` or a positive integer. To specify a positive integer, select and then replace `<user-defined>` with your desired value.

Use **Symbols to display** to limit the maximum number of symbols displayed when long signals are input. Symbols plotted are the most recent symbols received.

Tunable: Yes

Display

`Show grid` — Display plot grid lines

`on` (default) | `off`

Select to display plot grid lines.

Tunable: Yes

`Show legend` — Display plot legend

`off` (default) | `on`

Select to display plot legend. The names listed in the legend are the signal names from the model.

From the legend, you can control which signals are plotted. This control is equivalent to changing the visibility in the **View** > **Style** dialog box. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal and hide all other signals, right-click the signal name. To show all signals, press **Esc**.

Tunable: Yes

`Show signal trajectory` — Display signal trajectory

`off` (default) | `on`

Select to display the trajectory between constellation points for the plotted signals.

Tunable: Yes

`Color fading` — Option to add color fading effect

`off` (default) | `on`

When you select **Color fading**, the points in the display fade as the interval of time after they are first plotted increases. **Color fading** is for animation that resembles an oscilloscope.

Tunable: Yes

`X-limits (Minimum)` — Minimum *x*-axis value

`-1.375` (default) | scalar

Minimum *x*-axis value, specified as a scalar.

Tunable: Yes

`X-limits (Maximum)` — Maximum *x*-axis value

`1.375` (default) | scalar

Maximum *x*-axis value, specified as a scalar.

Tunable: Yes

`Y-limits (Minimum)` — Minimum *y*-axis value

`-1.375` (default) | scalar

Minimum *y*-axis value, specified as a scalar.

Tunable: Yes

`Y-limits (Maximum)` — Maximum *y*-axis value

`1.375` (default) | scalar

Maximum *y*-axis value, specified as a scalar.

Tunable: Yes

`Title` — Title on plot

blank (default) | character vector | string

Title on plot, specified as a character vector or string.

Tunable: Yes

`X-axis label` — *x*-axis label

`'In-phase Amplitude'` (default) | character vector | string

x-axis label, specified as a character vector or string.

Tunable: Yes

`Y-axis label` — *y*-axis label

`'Quadrature Amplitude'` (default) | character vector | string

y-axis label, specified as a character vector or string.

Tunable: Yes

Reference constellation

`Show reference constellation` — Select to display reference constellation

on (default) | off

Select to display the reference constellation.

Tunable: Yes

`Input` — Input port number

`1` (default) | integer

Select the input port number for which you want to view/change the reference constellation and the associated attributes.

Dependencies

To enable this parameter, set the **Number of input ports** parameter to a value greater than 1.

`Reference constellation` — Reference constellation

`QPSK` (default) | `BPSK` | `8-PSK` | `16-QAM` | `64-QAM` | `256-QAM` | vector

Reference constellation, specified as `BPSK`, `QPSK`, `8-PSK`, `16-QAM`, `64-QAM`, `256-QAM`, or a <user-defined> vector. To specify the value, select and then replace `<user-defined>` with your desired value. When defined by the user, the reference constellation values can be specified as a vector.

Each input port can have its own reference constellation. For a multichannel input signal, a single reference constellation is applied for all signals in that input port.

To obtain the EVM/MER measurements, you must set **Reference constellation** to a valid value corresponding to the modulation of the input signal.

Tunable: Yes

Data Types: `double`
Complex Number Support: Yes

`Average reference power` — Average power of reference constellation

`1` (default) | positive scalar

Average power of the reference constellation in watts, specified as a positive scalar and referenced to a one-ohm load.

Tunable: Yes

`Reference phase offset (rad)` — Phase offset of reference constellation

`pi/4` (default) | scalar

Phase offset of the reference constellation in radians, specified as a scalar.

Tunable: Yes

View > Style

From the Constellation Diagram window, select **View** > **Style** to open the Constellation Diagram - Style dialog box. In this dialog box, you can customize the graphical properties of the components in the Constellation Diagram window.

`Figure color` — Select background color

gray (default)

Select the background color within the Constellation Diagram window and outside the scope axes.

`Axes colors` — Select colors of plot and measurement panes

black (default for background) | gray (default for axes)

Select colors of plot and measurement panes. The first color option specifies the background color of the plot figure and the measurement panes. The second option specifies the color of the plot figure axes (ticks, labels, and grid lines) and the text. For more a description of the measurement panes, see in the “Tools > Measurements” on page 5-113.

Tunable: Yes

`Properties for channel` — View or change graphical properties of each channel

`Channel 1` (default)

Select a channel to view or change its graphical properties.

`Bring To Front` — Bring channel to front

button

Bring the active channel, as indicated by **Properties for channel**, to the front.

`Show signal and reference constellation` — Option to hide channel

`on` (default) | `off`

Clear to hide the active channel and its associated reference constellation. Use **Properties for channel** to select the active channel. The setting is synchronized with actions in the interactive legend, see Show legend.

`Symbols` — Set properties of symbols

symbol properties

Set graphical properties of the symbols for the active channel. Adjust style, size, line width, and color of the marker. Use **Properties for channel** to select the active channel.

Dependencies

To set marker shape to `none`, **Show signal trajectory** must be selected.

`Signal trajectory` — Select properties of signal trajectory

no line (default) | trajectory properties

Set graphical properties for the signal trajectory of the active channel. Adjust style, width, and color of the line. Use **Properties for channel** to select the active channel.

Dependencies

To adjust signal trajectory properties, **Show signal trajectory** must be selected. When **Show signal trajectory** is selected, the **Signal trajectory** line style cannot be set to `no line`.

Reference Constellation

`Input` — Input port number

`1` (default) | integer

View or change the graphical properties for the symbol of the reference constellation for each port individually.

If none of the input are multichannel signals, then the graphical properties of the reference constellation can be adjusted by selecting the channel from the **Properties for channel** parameter.

Dependencies

To enable this parameter, set the **Number of input ports** parameter to a value greater than 1 and specify at least one multichannel input signal.

`Properties` — Select properties of reference constellation symbols

symbol properties

Select the graphical properties for the symbols of the reference constellation. Adjust the style, size, line width, and color of the marker.

Dependencies

To adjust reference constellation graphical properties, **Show reference constellation** must be selected.

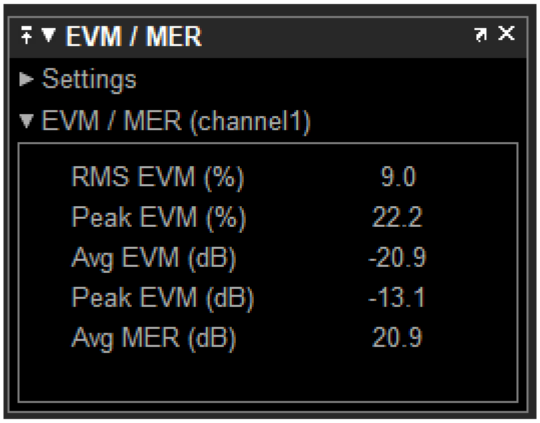
Block Characteristics

Data Types	`Boolean` | `double` | `enumerated` | `fixed point` | `integer` | `single`
Direct Feedthrough	`no`
Multidimensional Signals	`no`
Variable-Size Signals	`yes`
Zero-Crossing Detection	`no`

More About

EVM / MER Measurements

The **EVM / MER** signal quality pane displays the measurement settings, and error vector magnitude (EVM) and modulation error ratio (MER) measurement calculation results for the specified trace selection.



RMS EVM (%)	9.0
Peak EVM (%)	22.2
Avg EVM (dB)	-20.9
Peak EVM (dB)	-13.1
Avg MER (dB)	20.9

- **EVM** — An error vector is a vector in the IQ plane from the ideal constellation point to the actual point at the receiver. The root mean square error vector magnitude, EVM_{RMS}, is measured for the average and peak constellation power.

  On the constellation diagram, you can display the EVM_{RMS} measurements normalized by either the `Average constellation power` or `Peak constellation power` method as computed using these algorithms.

EVM Normalization Method	Algorithm
`Average constellation power`	Average constellation power normalization: $$\text{EVM}_k = 100\sqrt{\frac{e_k}{P_{\text{avg}}}}$$ EVM_{RMS}, in percent, for average constellation power normalization: $$\text{EVM}_{\text{RMS}}(\%) = 100\sqrt{\frac{\frac{1}{N}\sum_{k=1}^{N}(e_k)}{P_{\text{avg}}}}$$
`Peak constellation power`	Peak constellation power normalization $$\text{EVM}_k = 100\sqrt{\frac{e_k}{P_{\text{max}}}}$$ EVM_{RMS}, in percent, for peak constellation power normalization $$\text{EVM}_{\text{RMS}}(\%) = 100\sqrt{\frac{\frac{1}{N}\sum_{k=1}^{N}(e_k)}{P_{\text{max}}}}$$

The **EVM / MER** pane shows the average and peak EVM_{RMS} in both percent and decibels for the selected trace. The EVM reported in decibels is computed as EVM (dB) = 10-log10(EVM_{MS}) = 20-log10(EVM_{RMS}), where:

- $e_k = (I_k - \tilde{I}_k)^2 + (Q_k - \tilde{Q}_k)^2$
- I_k is the in-phase value of the kth symbol in the input vector.
- Q_k is the quadrature phase value of the kth symbol in the input vector.
- I_k and Q_k represent ideal (reference) symbol values. $\tilde{I}_k$ and $\tilde{Q}_k$ represent measured (received) symbol values.
- N is the input vector length.
- P_{avg} is the value for `Average constellation power`.
- P_{max} is the value for `Peak constellation power`.
- $\text{EVM}_{\text{RMS}} = \sqrt{\text{EVM}_{\text{MS}}}$

The maximum EVM value in a vector is $\text{EVM}_{\text{max}} = \max\limits_{k \in [1, \ldots, N]} \{\text{EVM}_k\}$, where k is the kth symbol in a vector of length N.

For more information, see `comm.EVM`.

- **MER** — MER is the ratio of the average power of the transmitted signal to the average power of the error vector. The **EVM / MER** pane indicates average MER measurement result in decibels for the selected trace.

  MER is a measure of the SNR in a modulated signal, calculated in dB. The MER over N symbols is

$$\mathrm{MER} = 10 \cdot \log_{10}\left(\frac{\sum_{n=1}^{N}\left(I_k^2 + Q_k^2\right)}{\sum_{n=1}^{N}\left(e_k\right)}\right)\mathrm{dB},$$

where:

- $e_k = (I_k - \tilde{I}_k)^2 + (Q_k - \tilde{Q}_k)^2$
- I_k is the in-phase value of the kth symbol in the input vector.
- Q_k is the quadrature phase value of the kth symbol in the input vector.
- I_k and Q_k represent ideal (reference) values. $\tilde{I}_k$ and $\tilde{Q}_k$ represent measured (received) symbols.

For more information, see `comm.MER`.

Programmatic Configuration

You can programmatically configure the scope properties with callbacks or within scripts using a scope configuration object as, described in “Control Scope Blocks Programmatically” (Simulink).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

This block is excluded from the generated code when code generation is performed on a system containing this block.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

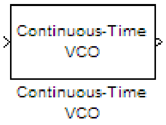
Continuous-Time VCO

Implement voltage-controlled oscillator



Library

Components sublibrary of Synchronization

Description

The Continuous-Time VCO (voltage-controlled oscillator) block generates a signal with a frequency shift from the **Quiescent frequency** parameter that is proportional to the input signal. The input signal is interpreted as a voltage. If the input signal is $u(t)$, then the output signal is

$$y(t) = A_c\cos\left(2\pi f_c t + 2\pi k_c\int_0^t u(\tau)d\tau + \varphi\right)$$

where A_c is the **Output amplitude** parameter, f_c is the **Quiescent frequency** parameter, k_c is the **Input sensitivity** parameter, and φ is the **Initial phase** parameter.

This block uses a continuous-time integrator to interpret the equation above.

The input and output are both sample-based scalar signals.

Parameters

Output amplitude

The amplitude of the output.

Quiescent frequency

The frequency of the oscillator output when the input signal is zero.

Input sensitivity

This value scales the input voltage and, consequently, the shift from the **Quiescent frequency** value. The units of **Input sensitivity** are Hertz per volt.

Initial phase

The initial phase of the oscillator in radians.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code.

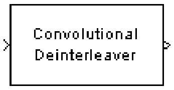
Discrete-Time VCO

Introduced before R2006a

Convolutional Deinterleaver

Restore ordering of symbols that were permuted using shift registers



Library

Convolutional sublibrary of Interleaving

Description

The Convolutional Deinterleaver block recovers a signal that was interleaved using the Convolutional Interleaver block. Internally, this block uses a set of shift registers. The delay value of the k^{th} shift register is (N-k) times the **Register length step** parameter. The number of shift registers, N, is the value of the **Rows of shift registers** parameter. The parameters in the two blocks must have the same values.

This block accepts a scalar or column vector input signal, which can be real or complex. The output signal has the same sample time as the input signal.

This block accepts the following data types: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point.

Parameters

Rows of shift registers

The number of shift registers that the block uses internally.

Register length step

The difference in symbol capacity of each successive shift register, where the last register holds zero symbols.

Initial conditions

Indicates the values that fill each shift register at the beginning of the simulation (except for the last shift register, which has zero delay).

- When you select a scalar value for **Initial conditions**, the value fills all shift registers (except for the last one)
- When you select a column vector with a length equal to the **Rows of shift registers** parameter, each entry fills the corresponding shift register.

The value of the first element of the **Initial conditions** parameter is unimportant, since the last shift register has zero delay.

Examples

For an example that uses this block, see “Convolutional Interleaving”.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

You can generate HDL code for the Convolutional Deinterleaver block using a shift-register-based implementation, or a RAM-based implementation.

The default implementation for the Convolutional Deinterleaver block is shift register-based. To suppress generation of reset logic, set the implementation parameter `ResetType` to`'none'`. When you set `ResetType` to`'none'`, reset is not applied to the shift registers.

When registers are not fully loaded, mismatches between Simulink and the generated code occur for some number of samples during the initial phase. To avoid spurious test bench errors, determine the number of samples required to fill the shift registers. Set the **Ignore output data checking (number of samples)** option accordingly. (If you are using the command-line interface, you can use the `IgnoreDataChecking` property for this purpose.)

When you select the `RAM` implementation for a Convolutional Deinterleaver block, HDL Coder uses RAM resources instead of shift registers.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is `0`. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is `0`. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is `0`. For more details, see "OutputPipeline" (HDL Coder).
ResetType	Suppress reset logic generation. The default is `default`, which generates reset logic. See also "ResetType" (HDL Coder).

Restrictions

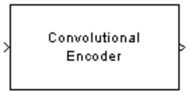
When you select the `RAM` implementation:

- Double or single data types are not supported for either input or output signals.
- You must set **Initial conditions** for the block to zero.
- At least two rows of interleaving are required.

Introduced before R2006a

Convolutional Encoder

Create convolutional code from binary data



Library

Convolutional sublibrary of Error Detection and Correction

Description

The Convolutional Encoder block encodes a sequence of binary input vectors to produce a sequence of binary output vectors. This block can process multiple symbols at a time.

This block can accept inputs that vary in length during simulation. For more information about variable-size signals, see “Variable-Size Signal Basics” (Simulink).

Input and Output Sizes

If the encoder takes *k* input bit streams (that is, it can receive 2^k possible input symbols), the block input vector length is L*k for some positive integer L. Similarly, if the encoder produces *n* output bit streams (that is, it can produce 2^n possible output symbols), the block output vector length is L*n.

This block accepts a column vector input signal with any positive integer for L. For variable-size inputs, the L can vary during simulation. The operation of the block is governed by the **Operation mode** parameter.

For both its inputs and outputs for the data ports, the block supports `double`, `single`, `boolean`, `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, and `ufix1`. The port data types are inherited from the signals that drive the block. The input reset port supports `double` and `boolean` typed signals.

Specifying the Encoder

To define the convolutional encoder, use the **Trellis structure** parameter. This parameter is a MATLAB structure whose format is described in “Trellis Description of a Convolutional Code”. You can use this parameter field in two ways:

- If you have a variable in the MATLAB workspace that contains the trellis structure, enter its name in the **Trellis structure** parameter. This way is preferable because it causes Simulink to spend less time updating the diagram at the beginning of each simulation, compared to the usage described next.
- If you want to specify the encoder using its constraint length, generator polynomials, and possibly feedback connection polynomials, use a `poly2trellis` command in the **Trellis structure** parameter. For example, to use an encoder with a constraint length of 7, code generator polynomials of 171 and 133 (in octal numbers), and a feedback connection of 171 (in octal), set the **Trellis structure** parameter to

```
poly2trellis(7,[171 133],171)
```

The encoder registers begin in the all-zeros state. Set the **Operation mode** parameter to `Reset on nonzero input via port` to reset all encoder registers to the all-zeros state during the simulation. This selection opens a second input port, labeled `Rst`, which accepts a scalar-valued input signal. When the input signal is nonzero, the block resets before processing the data at the first input port. To reset the block after it processes the data at the first input port, select **Delay reset action to next time step**.

Parameters

Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder.

Operation mode

In `Continuous` mode, the block retains the encoder states at the end of each input, for use with the next frame.

In `Truncated (reset every frame)` mode, the block treats each input independently. The encoder states are reset to all-zeros state at the start of each input.

Note When this block outputs sequences that vary in length during simulation and you set the **Operation mode** to `Truncated (reset every frame)` or `Terminate trellis by appending bits`, the block's state resets at every input time step.

In `Terminate trellis by appending bits` mode, the block treats each input independently. For each input frame, extra bits are used to set the encoder states to all-zeros state at the end of the frame. The output length is given by $y = n \cdot (x + s)/k$, where x is the number of input bits, and s = constraint length – 1 (or, in the case of multiple constraint lengths, s =`sum(ConstraintLength(i)-1)`).

Note This block works for cases $k \geq 1$, where it has the same values for constraint lengths in each input stream (e.g., constraint lengths of [2 2] or [7 7] will work, but [5 4] will not).

In `Reset on nonzero input via port` mode, the block has an additional input port, labeled `Rst`. When the `Rst` input is nonzero, the encoder resets to the all-zeros state.

Delay reset action to next time step

When you select **Delay reset action to next time step**, the Convolutional Encoder block resets after computing the encoded data. This check box only appears when you set the **Operation mode** parameter to `Reset on nonzero input via port`.

The delay in the reset action allows the block to support HDL code generation. In order to generate HDL code, you must have an HDL Coder license.

Output final state

When you select **Output final state**, the second output port signal specifies the output state for the block. The output signal is a scalar, integer value. You can select **Output final state** for all operation modes except `Terminate trellis by appending bits` .

Specify initial state via input port

When you select **Specify initial state via input port** the second input port signal specifies the starting state for every frame in the block. The input signal must be a scalar, integer value. **Specify initial state via input port** appears only in `Truncated` operation mode.

Puncture code

Selecting this option opens the field **Puncture vector**.

Puncture vector

Vector used to puncture the encoded data. The puncture vector is a pattern of `1`s and `0`s where the `0`s indicate the punctured bits. This field appears when you select **Punctured code**.

Puncture Pattern Examples

For some commonly used puncture patterns for specific rates and polynomials, see the last three references listed on this page.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is `0`. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is `0`. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is `0`. For more details, see “OutputPipeline” (HDL Coder).

Restrictions

- Input data requirements:
  - Must be sample-based,
  - Must have a `boolean` or `ufix1` data type.
- HDL Coder supports only the following coding rates:
  - ½ to 1/7
  - 2/3
- The coder supports only constraint lengths for 3 to 9.
- Specify **Trellis structure** by the `poly2trellis` function.
- The coder supports the following **Operation mode** settings:
  - `Continuous`
  - `Reset on nonzero input via port`

    If you select this mode, you must select the **Delay reset action to next time step** option. When you select this option, the Convolutional Encoder block finishes its current computation before executing a reset.
- You cannot generate HDL for this block inside a Resettable Synchronous Subsystem.

Introduced before R2006a

Convolutional Interleaver

Permute input symbols using set of shift registers

Library

Convolutional sublibrary of Interleaving

Description

The Convolutional Interleaver block permutes the symbols in the input signal. Internally, it uses a set of shift registers. The delay value of the kth shift register is (k-1) times the **Register length step** parameter. The number of shift registers is the value of the **Rows of shift registers** parameter.

The **Initial conditions** parameter indicates the values that fill each shift register at the beginning of the simulation (except for the first shift register, which has zero delay). If **Initial conditions** is a scalar, then its value fills all shift registers except the first; if **Initial conditions** is a column vector whose length is the **Rows of shift registers** parameter, then each entry fills the corresponding shift register. The value of the first element of the **Initial conditions** parameter is unimportant, since the first shift register has zero delay.

This block accepts a scalar or column vector input signal, which can be real or complex. The output signal has the same sample time as the input signal.

The block can accept the data types `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point. The data type of this output will be the same as that of the input signal.

Parameters

Rows of shift registers

The number of shift registers that the block uses internally.

Register length step

The number of additional symbols that fit in each successive shift register, where the first register holds zero symbols.

Initial conditions

The values that fill each shift register when the simulation begins.

Examples

For an example that uses this block, see “Convolutional Interleaving”.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

You can generate HDL code for the Convolutional Interleaver block using a shift-register-based implementation, or a RAM-based implementation.

The default implementation for the Convolutional Interleaver block is shift register-based. To suppress generation of reset logic, set the implementation parameter `ResetType` to`'none'`. When you set `ResetType` to`'none'`, reset is not applied to the shift registers.

When registers are not fully loaded, mismatches between Simulink and the generated code occur for some number of samples during the initial phase. To avoid spurious test bench errors, determine the number of samples required to fill the shift registers. Set the **Ignore output data checking (number of samples)** option accordingly. (If you are using the command-line interface, you can use the `IgnoreDataChecking` property for this purpose.)

When you select the `RAM` implementation for a Convolutional Interleaver block, HDL Coder uses RAM resources instead of shift registers.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is `0`. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is `0`. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is `0`. For more details, see "OutputPipeline" (HDL Coder).
ResetType	Suppress reset logic generation. The default is `default`, which generates reset logic. See also "ResetType" (HDL Coder).

Restrictions

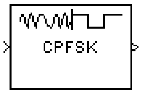
When you select the `RAM` implementation:

- Double or single data types are not supported for either input or output signals.
- You must set **Initial conditions** for the block to zero.
- At least two rows of interleaving are required.

Introduced before R2006a

CPFSK Demodulator Baseband

Demodulate CPFSK-modulated data



Library

CPM, in Digital Baseband sublibrary of Modulation

Description

The CPFSK Demodulator Baseband block demodulates a signal that was modulated using the continuous phase frequency shift keying method. The input to this block is a baseband representation of the modulated signal. The **M-ary number** parameter, *M*, is the size of the input alphabet. *M* must have the form 2^K for some positive integer *K*.

This block supports multi-h **Modulation index**. See CPM Modulator Baseband for details.

Integer-Valued Signals and Binary-Valued Signals

When you set the **Output type** parameter to `Integer`, then the block produces odd integers between -(M-1) and M-1.

When you set the **Output type** parameter to `Bit`, then the block produces groupings of *K* bits. Each grouping is called a binary *word*.

In binary output mode, the block first maps each input symbol to an intermediate value as in the integer output mode. The block then maps the odd integer k to the nonnegative integer (k+M-1)/2. Finally, the block maps each nonnegative integer to a binary word, using a mapping that depends on whether the **Symbol set ordering** parameter is set to `Binary` or `Gray`.

This block accepts a scalar-valued or column vector input signal with a data type of `single` or `double`.

Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. The input width must be an integer multiple of the **Samples per symbol** parameter value, and the input can be a column vector.

- When you set **Output type** to `Bit`, the output width is *K* times the number of input symbols.
- When you set **Output type** to `Integer`, the output width is the number of input symbols.

Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. The input must be a scalar. The output symbol time is the product of the input sample time and the **Samples per symbol** parameter value.

- When you set **Output type** to `Bit`, the output width equals the number of bits per symbol.
- When you set **Output type** to `Integer`, the output is a scalar.

Traceback Depth and Output Delays

Internally, this block creates a trellis description of the modulation scheme and uses the Viterbi algorithm. The **Traceback depth** parameter, *D*, in this block is the number of trellis branches that the algorithm uses to construct each traceback path. *D* influences the output delay, which is the number of zero symbols that precede the first meaningful demodulated value in the output.

- When you set the **Rate options** parameter to `Allow multirate processing`, and the model uses a variable-step solver or a fixed-step solver with the **Tasking Mode** parameter set to `SingleTasking`, then the delay consists of D+1 zero symbols.
- When you set the **Rate options** parameter to `Enforce single-rate processing`, then the delay consists of D zero symbols.

The optimal **Traceback depth** parameter value is dependent on minimum squared Euclidean distance calculations. Alternatively, a typical value, dependent on the number of states, can be chosen using the “five-times-the-constraint-length” rule, which corresponds to 5·log2(*numStates*).

For the definition of the number of states, see CPM Demodulator Baseband Help page.

Parameters

M-ary number

The size of the alphabet.

Output type

Determines whether the output consists of integers or groups of bits.

Symbol set ordering

Determines how the block maps each integer to a group of output bits. This field is active only when **Output type** is set to `Bit`.

Modulation index

Specify the modulation index {h_i}. The default is `0.5`. The value of this property must be a real, nonnegative scalar or column vector.

This block supports multi-h **Modulation index**. See CPM Modulator Baseband for details.

Phase offset (rad)

The initial phase of the modulated waveform.

Samples per symbol

The number of input samples that represent each modulated symbol, which must be a positive integer. For more information, see “Upsample Signals and Rate Changes” in *Communications Toolbox User*'s *Guide*.

Rate options

Select the rate processing method for the block.

- `Enforce single-rate processing` — When you select this option, the input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width is the number of symbols (which is given by dividing the input length by the **Samples per symbol** parameter value when the **Output type** parameter is set to `Integer`).
- `Allow multirate processing` — When you select this option, the input and output signals have different port sample times. The output period is the same as the symbol period and equals the product of the input period and the **Samples per symbol** parameter value.

For more information, see Single-Rate Processing and Multirate Processing in the Description section of this page.

Traceback depth

The number of trellis branches that the CPFSK Demodulator Baseband block uses to construct each traceback path.

Output datatype

The output data type can be `boolean`, `int8`, `int16`, `int32`, or `double`.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Boolean (When **Output type** set to `Bit`) • 8-, 16-, and 32-bit signed integers (When **Output type** set to `Integer`)

CPFSK Modulator Baseband

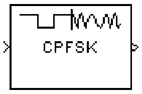
Modulate using continuous phase frequency shift keying method



Library

CPM, in Digital Baseband sublibrary of Modulation

Description

The CPFSK Modulator Baseband block modulates a signal using the continuous phase frequency shift keying method. The output is a baseband representation of the modulated signal. The **M-ary number** parameter, *M*, represents the size of the input alphabet. *M* must have the form 2^K for some positive integer *K*.

This block supports multi-h **Modulation index**. See CPM Modulator Baseband for details.

Integer-Valued Signals and Binary-Valued Signals

When you set the **Input type** parameter to `Integer`, the block accepts odd integers between -(M-1) and M-1.

When you set the **Input type** parameter to `Bit`, the block accepts groupings of *K* bits. Each grouping is called a binary *word*. The input vector length must be an integer multiple of *K*.

In binary input mode, the block maps each binary word to an integer between 0 and M-1, using a mapping scheme that depends on whether you set the **Symbol set ordering** parameter to `Binary` or `Gray`. The block then maps the integer *k* to the intermediate value 2k-(M-1) and proceeds as if it operates in the integer input mode. For more information, see “Integer-Valued Signals and Binary-Valued Signals”.

This block accepts a scalar-valued or column vector input signal. If you set **Input type** to `Bit`, then the input signal can also be a vector of length *K*.

Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. In this mode, the input to the block can be multiple symbols.

- When you set **Input type** to `Integer`, the input can be a column vector, the length of which is the number of input symbols.
- When you set **Input type** to `Bit`, the input must be a column vector with a width that is an integer multiple of *K*, the number of bits per symbol.

The output width equals the product of the number of input symbols and the **Samples per symbol** parameter value.

Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. In this mode, the input to the block must be one symbol.

- When you set **Input type** to `Integer`, the input must be a scalar.
- When you set **Input type** to `Bit`, the input width must equal the number of bits per symbol.

The output sample time equals the symbol period divided by the **Samples per symbol** parameter value.

Parameters

M-ary number

The size of the alphabet.

Input type

Indicates whether the input consists of integers or groups of bits.

Symbol set ordering

Determines how the block maps each group of input bits to a corresponding integer. This field is active only when **Input type** is set to `Bit`.

Modulation index

Specify the modulation index {h_i}. The default is `0.5`. The value of this property must be a real, nonnegative scalar or column vector.

This block supports multi-h **Modulation index**. See CPM Modulator Baseband for details.

Phase offset (rad)

The initial phase of the output waveform, measured in radians.

Samples per symbol

The number of output samples that the block produces for each integer or binary word in the input, which must be a positive integer. For all non-binary schemes, as defined by the pulse shapes, this value must be greater than 1.

For more information, see “Upsample Signals and Rate Changes”.

Rate options

Select the rate processing option for the block.

- `Enforce single-rate processing` — When you select this option, the input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width equals the product of the number of symbols and the **Samples per symbol** parameter value.
- `Allow multirate processing` — When you select this option, the input and output signals have different port sample times. The output sample time equals the symbol period divided by the **Samples per symbol** parameter value.

Output data type

Select the data type of the output signal. The output data type can be `single` or `double`.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Boolean (When **Input type** set to `Bit`) • 8-, 16-, and 32-bit signed integers (When **Input type** set to `Integer`)
Output	• Double-precision floating point • Single-precision floating point

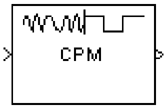
CPM Demodulator Baseband

Demodulate CPM-modulated data

Library: Communications Toolbox / Modulation / Digital Baseband Modulation / CPM



Description

The CPM Demodulator Baseband block demodulates a signal that was modulated using continuous phase modulation (CPM).

CPM is a modulation method with memory. The block processing includes a correlator followed by a maximum-likelihood sequence detector (MLSD) that searches the paths through the state trellis for the minimum Euclidean distance path. The block uses the Viterbi algorithm to perform MLSD.

For more information about this demodulation and the filtering applied, see “CPM Demodulation” on page 5-146 and “Pulse Shape Filtering” on page 5-147.

Ports

Input

`In` — Input signal
scalar | column vector

Input signal, specified as a scalar or column vector. The length of the input signal must be an integer multiple of the number of samples per symbol specified in the **Samples per symbol** parameter. For more information, see “Integer-Valued and Binary-Valued Output Signals” on page 5-148.

Data Types: `double` | `single`

Output

`Out` — Output signal
scalar | column vector

Output signal, returned as a scalar or column vector. For more information, see “Integer-Valued and Binary-Valued Output Signals” on page 5-148.

Supported Data Types

- Double-precision floating point
- Boolean (when **Output type** is set to `Bit`)
- 8-, 16-, and 32-bit signed integers (when **Output type** is set to `Integer`)

Data Types: `double` | `Boolean` | `int8` | `int16` | `int32`

For more information on the processing rates, see “Single-Rate Processing” on page 5-148, and “Multirate Processing” on page 5-149.

Parameters

`M-ary number` — Modulation order

4 (default) | positive integer

Modulation order indicating the alphabet size, specified as a positive integer that is a nonzero power of two. M must have the form 2^K for some positive integer K, where K is the number of bits per symbol.

`Output type` — Determines whether output consists of integers or groups of bits

`Integer` (default) | `Bit`

Determines whether the output consists of integers or groups of bits, specified as `Integer` or `Bit`.

`Symbol set ordering` — Bit mapping

`Binary` (default) | `Gray`

Bit mapping, specified as `Binary` or `Gray`.

This parameter determines how the block maps each integer to a group of output bits. For more information, see “Integer-Valued and Binary-Valued Output Signals” on page 5-148.

Dependencies

To enable this parameter, set **Output type** to `Bit`.

`Modulation index` — Modulation index {h_i}

`0.5` (default) | nonnegative scalar | column vector

Modulation index {h_i}, specified as a nonnegative scalar or column vector.

{h} represents a sequence of modulation indices. For more information, see “CPM Demodulation” on page 5-146.

`Frequency pulse shape` — Type of pulse shaping

`Rectangular` (default) | `Raised Cosine` | `Spectral Raised Cosine` | `Gaussian` | `Tamed FM`

Type of pulse shaping used to smooth the phase transitions of the modulated signal, specified as `Rectangular`, `Raised Cosine`, `Spectral Raised Cosine`, `Gaussian`, or `Tamed FM`. For more information on the filtering options, see “Pulse Shape Filtering” on page 5-147.

`Main lobe pulse duration (symbol intervals)` — Number of symbol intervals of largest lobe of the spectral raised cosine pulse

1 (default) | positive scalar

Number of symbol intervals of the largest lobe of the spectral raised cosine pulse, specified as a positive scalar.

Dependencies

To enable this parameter, set **Frequency pulse shape** to `Spectral Raised Cosine`.

`Rolloff` — Rolloff factor of spectral raised cosine pulse shape

`0.2` (default) | nonnegative scalar

Rolloff factor of the spectral raised cosine pulse shape, specified as a scalar from 0 to 1.

Dependencies

To enable this parameter, set **Frequency pulse shape** to `Spectral Raised Cosine`.

`BT product` — Product of bandwidth and time

`0.3` (default) | nonnegative scalar

Product of bandwidth and time, specified as a nonnegative scalar. Use **BT product** to reduce the bandwidth, at the expense of increased intersymbol interference.

Dependencies

To enable this parameter, set **Frequency pulse shape** to `Gaussian`.

`Pulse length (symbol intervals)` — Frequency pulse length

`1` (default) | positive scalar

Frequency pulse shape length, specified as a positive scalar. Refer to *LT* in “Pulse Shape Filtering” on page 5-147 for more information on the frequency pulse length.

`Symbol prehistory` — Data symbols used before the start of simulation

`1` (default) | scalar | vector

Data symbols used before the start of simulation in reverse chronological order. If **Symbol prehistory** is a vector, then its length must be one less than the **Pulse length** parameter value.

`Phase offset (rad)` — Initial phase offset

`0` (default) | scalar

Initial phase offset of output in radians, specified as a scalar.

`Samples per symbol` — Symbol sampling rate

`8` (default) | positive scalar

Symbol sampling rate, specified as a positive scalar. This parameter represents the number of samples output for each integer or binary word input. For all nonbinary schemes, as defined by the pulse shapes, this value must be greater than 1.

For more information, see “Upsample Signals and Rate Changes”.

`Rate options` — Block processing rate

`Enforce single-rate processing` (default) | `Allow multirate processing`

Block processing rate, specified as one of these options:

- `Enforce single-rate processing` — The input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width is the number of symbols (which is given by dividing the input length by the **Samples per symbol** parameter value when the **Output type** parameter is set to `Integer`).

- `Allow multirate processing` — The input and output signals have different port sample times. The output period is the same as the symbol period and equals the product of the input period and the **Samples per symbol** parameter value.

`Traceback depth` — Number of trellis branches

16 (default) | positive integer

Number of trellis branches used to construct each traceback path, specified as a positive integer. For more information, see "Traceback Depth and Output Delays" on page 5-149.

`Output data type` — Output data type

`double` (default) | `boolean` | `int8` | `int16` | `int32`

Output data type, specified as `double`, `boolean`, `int8`, `int16`, or `int32`. For more information, see **Supported Data Types** in `Out`.

Block Characteristics

Data Types	`Boolean` | `double` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`no`

More About

CPM Demodulation

The CPM demodulation processing consists of a correlator followed by a maximum-likelihood sequence detector (MLSD) that searches the paths through the state trellis for the minimum Euclidean distance path. When the modulation index is rational ($h = m/p$), there are a finite number of phase states in the symbol. The block uses the Viterbi algorithm to perform MLSD.

$\{h_\mathrm{i}\}$ represents a sequence of modulation indices that moves cyclically through a set of indices $\{h_0, h_1, h_2, \ldots, h_{H\text{-}1}\}$.

- $h_\mathrm{i} = m_\mathrm{i}/p_\mathrm{i}$ represents the modulation index in proper rational form.
- m_i represents the numerator of the modulation index.
- p_i represents the denominator of the modulation index.
- m_i and p_i are relatively prime positive numbers.
- The least common multiple (LCM) of $\{p_0, p_1, p_2, \ldots, p_{H\text{-}1}\}$ is denoted as p.
- $h_\mathrm{i} = m'_\mathrm{i} / p$

$\{h_\mathrm{i}\}$ determines the number of phase states:

$$numPhaseStates = \begin{Bmatrix} p,\ for\ all\ even\ m'_i \\ 2p,\ for\ any\ odd\ m'_i \end{Bmatrix}$$

and affects the number of trellis states:

$numStates = numPhaseStates{*}M^{(L\text{-}1)}$

- L represents the **Pulse length**.
- M represents the **M-ary number**.

CPM Modulation

The input to the demodulator is a baseband representation of the modulated signal:

$$s(t) \ = \ \exp\left[j\,2\pi \sum_{i\ =\ 0}^{n} \alpha_i h_i q(t - iT)\right],$$
$$nT < \ t < (n+1)T$$

where:

- $\{\alpha_\mathrm{i}\}$ represents a sequence of M-ary data symbols selected from the alphabet ±1, ±3, $\pm(M–1)$.
- M must have the form 2^K for some positive integer K, where M is the modulation order and specifies the size of the symbol alphabet.
- $\{h_\mathrm{i}\}$ represents a sequence of modulation indices and h_i moves cyclically through a set of indices $\{h_0, h_1, h_2, ..., h_{H\text{-}1}\}$. When H=1, there is only one modulation index, h_0, which is denoted as h.

Pulse Shape Filtering

Continuous phase modulation uses pulse shaping to smooth the phase transitions of the modulated signal. The function $q(t)$ is the phase response obtained from the frequency pulse, $g(t)$, through this relation: $q(t) = \int_{-\infty}^{t} g(t)dt$

The specified frequency pulse shape corresponds to these pulse shape expressions, $g(t)$.

Pulse Shape	Expression
`Rectangular`	$g(t) = \begin{cases} \dfrac{1}{2LT}, & 0 \le t \le LT \\ 0 & \text{otherwise} \end{cases}$
`Raised Cosine`	$g(t) = \begin{cases} \dfrac{1}{2LT}\left[1-\cos\left(\dfrac{2\pi t}{LT}\right)\right], & 0 \le t \le LT \\ 0 & \text{otherwise} \end{cases}$
`Spectral Raised Cosine`	$g(t) = \dfrac{1}{L_{main}T} \dfrac{\sin\left(\dfrac{2\pi t}{L_{main}T}\right)}{\dfrac{2\pi t}{L_{main}T}} \dfrac{\cos\left(\beta \dfrac{2\pi t}{L_{main}T}\right)}{1-\left(\dfrac{4\beta}{L_{main}T}t\right)^2}, \quad 0 \le \beta \le 1$

Pulse Shape	Expression
`Gaussian`	$g(t)=\frac{1}{2T}\left\{Q\left[2\pi B_b\frac{t-\frac{T}{2}}{\sqrt{\ln 2}}\right]-Q\left[2\pi B_b\frac{t+\frac{T}{2}}{\sqrt{\ln 2}}\right]\right\}$, where $Q(t)=\int_t^{\infty}\frac{1}{\sqrt{2\pi}}e^{-\tau^2/2}d\tau$
`Tamed FM` (tamed frequency modulation)	$g(t)=\frac{1}{8}\left[g_0(t-T)+2g_0(t)+g_0(t+T)\right]$, where $g_0(t)\approx\frac{1}{T}\Bigg[\frac{\sin(\frac{\pi t}{T})}{\frac{\pi t}{T}}-\frac{\pi^2}{24}\frac{2\sin\left(\frac{\pi t}{T}\right)-\frac{2\pi t}{T}\cos\left(\frac{\pi t}{T}\right)-\left(\frac{\pi t}{T}\right)^2\sin\left(\frac{\pi t}{T}\right)}{\left(\frac{\pi t}{T}\right)^3}$

- L_{main} is the main lobe pulse duration in symbol intervals.
- β is the rolloff factor of the spectral raised cosine.
- $B_{\text{b}}$is the product of the bandwidth and the Gaussian pulse.
- The duration of the pulse, *LT*, is the pulse length in symbol intervals. As defined by the expressions, the `Spectral Raised Cosine`, `Gaussian`, and `Tamed FM` pulse shapes have infinite length. For all practical purposes, *LT* specifies the truncated finite length.

For more information on pulse shape filtering, see [1]

Integer-Valued and Binary-Valued Output Signals

When the **Output type** parameter is set to `Integer`:

- The block produces odd integers between –(*M*–1) and *M*–1. The modulation order, *M*, is specified by the **M-ary number** parameter.
- The **Output datatype** parameter cannot be set to `boolean`.

When the **Output type** parameter is set to `Bit`:

- The block produces groupings of *K* bits. Each grouping is called a binary word.
- The **Output datatype** can only be `double` or `boolean`.
- In binary output mode, the block processing follows this procedure:

  1. Maps each input symbol to an intermediate value, as in the integer output mode.
  2. Maps the odd integer *k* to the nonnegative integer (*k*+*M*–1)/2.
  3. Maps each nonnegative integer to a binary word, using `Binary` or `Gray` mapping, as specified by the **Symbol set ordering** parameter.

Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. The input width must be an integer multiple of the **Samples per symbol** parameter value, and the input can be a column vector.

- When you set **Output type** to `Bit`, the output width is *K* times the number of input symbols.

- When you set **Output type** to `Integer`, the output width is the number of input symbols.

Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. The input must be a scalar. The output symbol time is the product of the input sample time and the **Samples per symbol** parameter value.

- When you set **Output type** to `Bit`, the output width equals the number of bits per symbol.
- When you set **Output type** to `Integer`, the output is a scalar.

Traceback Depth and Output Delays

The **Traceback depth** parameter, *D*, is the number of trellis branches used to construct each traceback path. *D* influences the output delay, which is the number of zero symbols that precede the first meaningful demodulated value in the output.

- When the **Rate options** parameter is set to `Allow multirate processing`, and the model uses a variable-step solver or a fixed-step solver with the **Tasking Mode** parameter set to `SingleTasking`, then the delay vector consists of D+1 zero-value symbols.
- When the **Rate options** parameter is set to `Enforce single-rate processing`, the delay vector consists of *D* zero-value symbols.

The optimal **Traceback depth** parameter value depends on minimum squared Euclidean distance calculations. Alternatively, a typical value, dependent on the number of states, can be chosen using the five-times-the-constraint-length rule, which corresponds to 5 · log2(*numStates*).

For a binary raised cosine pulse shape with a pulse length of 3 and h=2/3, applying this rule ($5*\log2(3*2^2)$ = 18) gives a result that is close to the optimum value of 20.

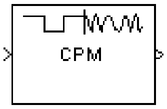
CPM Modulator Baseband

Modulate using continuous phase modulation

Library: Communications Toolbox / Modulation / Digital Baseband Modulation / CPM



Description

The CPM Modulator Baseband block modulates an input signal using continuous phase modulation (CPM). The output of the modulator is a baseband representation of the modulated signal:

$$s(t) = \exp\left[j2\pi \sum_{i=0}^{n} \alpha_i h_i q(t - iT)\right],$$
$$nT < t < (n+1)T$$

where:

- $\{\alpha_\mathrm{i}\}$ represents a sequence of M-ary data symbols selected from the alphabet ±1, ±3, ±(M–1).
- M must have the form 2^K for some positive integer K, where M is the modulation order and specifies the size of the symbol alphabet.
- $\{h_\mathrm{i}\}$ represents a sequence of modulation indices and h_i moves cyclically through a set of indices $\{h_0, h_1, h_2, ..., h_{H\text{-}1}\}$. When H=1, there is only one modulation index, h_0, which is denoted as h.

For more information about this modulation and the filtering applied, see “CPM Modulation” on page 5-154 and “Pulse Shape Filtering” on page 5-155.

Ports

Input

In — Input signal
scalar | column vector

Input signal, specified as a scalar or column vector.

When the **Input type** parameter is set to `Integer`, the block accepts odd integers between –(M–1) and M–1. M represents the **M-ary number** parameter.

When the **Input type** parameter is set to `Bit`, the block accepts binary-valued inputs that represent integers. The block collects binary-valued signals into groups of $K = \log_2(M)$ bits. K is the number of bits per symbol and M is the modulation order. The input vector length must be an integer multiple of K. The block maps each group of K bits onto a symbol, as specified by the **Symbol set ordering** parameter. For each group of K bits, the block outputs one modulated symbol, oversampled by the **Samples per symbol** parameter value.

Supported Data Types

- Double-precision floating point
- Boolean (when **Input type** is set to `Bit`)
- 8-, 16-, and 32-bit signed integers (when **Input type** is set to `Integer`)

Data Types: `double` | `Boolean` | `int8` | `int16` | `int32`

Output

`Out` — Output signal

scalar | column vector

Output signal, returned as a scalar or column vector.

- When the **Input type** parameter is set to `Integer`, the block outputs one modulated symbol for each input symbol.
- When the **Input type** parameter is set to `Bit`, the block outputs one modulated symbol for each group of *K* bits.

In both cases, the modulated symbols are oversampled by the **Samples per symbol** parameter value.

Data Types: `double` | `single`

For more information on the processing rates, see “Single-Rate Processing” on page 5-156, and “Multirate Processing” on page 5-156.

Parameters

`M-ary number` — Modulation order

4 (default) | positive integer

Modulation order indicating the alphabet size, specified as a positive integer that is a nonzero power of two. M must have the form 2^K for some positive integer K, where K is the number of bits per symbol.

`Input type` — Integer or group of bits input indicator

`Integer` (default) | `Bit`

Indicates whether the input consists of integers or groups of bits, specified as `Integer` or `Bit`.

`Symbol set ordering` — Bit mapping

`Binary` (default) | `Gray`

Bit mapping, specified as `Binary` or `Gray`. For more information, see “Symbol Sets” on page 5-156.

Dependencies

To enable this parameter, set **Input type** to `Bit`.

`Modulation index` — Modulation index $\{h_i\}$

`0.5` (default) | nonnegative scalar | column vector

Modulation index $\{h_i\}$, specified as a nonnegative scalar or column vector.

$\{h\}$ represents a sequence of modulation indices. For more information, see “CPM Modulation” on page 5-154.

`Frequency pulse shape` — Type of pulse shaping

`Rectangular` (default) | `Raised Cosine` | `Spectral Raised Cosine` | `Gaussian` | `Tamed FM`

Type of pulse shaping used to smooth the phase transitions of the modulated signal, specified as `Rectangular`, `Raised Cosine`, `Spectral Raised Cosine`, `Gaussian`, or `Tamed FM`. For more information on the filtering options, see “Pulse Shape Filtering” on page 5-155.

`Main lobe pulse duration (symbol intervals)` — Number of symbol intervals of largest lobe of spectral raised cosine pulse

`1` (default) | positive scalar

Number of symbol intervals of the largest lobe of the spectral raised cosine pulse, specified as a positive scalar.

Dependencies

To enable this parameter, set **Frequency pulse shape** to `Spectral Raised Cosine`.

`Rolloff` — Rolloff factor of spectral raised cosine pulse shape

`0.2` (default) | nonnegative scalar

Rolloff factor of the spectral raised cosine pulse, specified as a scalar from 0 to 1.

Dependencies

To enable this parameter, set **Frequency pulse shape** to `Spectral Raised Cosine`.

`BT product` — Product of bandwidth and time

`0.3` (default) | nonnegative scalar

Product of bandwidth and time, specified as a nonnegative scalar. Use **BT product** to reduce the bandwidth, at the expense of increased intersymbol interference.

Dependencies

To enable this parameter, set **Frequency pulse shape** to `Gaussian`.

`Pulse length (symbol intervals)` — Frequency pulse length

`1` (default) | positive scalar

Frequency pulse length, specified as a positive scalar. Refer to *LT* in “Pulse Shape Filtering” on page 5-155 for more information on the frequency pulse length.

`Symbol prehistory` — Data symbols used before the start of simulation

`1` (default) | scalar | vector

Data symbols used before the start of simulation, specified as a scalar or vector in reverse chronological order. If **Symbol prehistory** is a vector, then its length must be one less than the **Pulse length (symbol intervals)** parameter value.

`Phase offset (rad)` — Initial phase offset

`0` (default) | scalar

Initial phase offset of output in radians, specified as a scalar.

`Samples per symbol` — Symbol sampling rate
8 (default) | positive scalar

Symbol sampling rate, specified as a positive scalar. This parameter represents the number of samples output for each integer or binary word input. For all nonbinary schemes, as defined by the pulse shapes, this value must be greater than 1.

For more information, see “Upsample Signals and Rate Changes”.

`Rate options` — Block processing rate
`Enforce single-rate processing` (default) | `Allow multirate processing`

Block processing rate, specified as one of these options:

- `Enforce single-rate processing` — The input and output signals have the same sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width equals the product of the number of symbols and the **Samples per symbol** parameter value.
- `Allow multirate processing` — The input and output signals have different sample times. The output sample time equals the symbol period divided by the **Samples per symbol** parameter value.

`Output data type` — Output data type
`double` (default) | `single`

Output data type, specified as `double` or `single`.

Block Characteristics

Data Types	`Boolean` | `double` | `integer` | `single`
Multidimensional Signals	`no`
Variable-Size Signals	`no`

More About

CPM Modulation

The output of the modulator is a baseband representation of the modulated signal:

$$s(t) = \exp\left[j2\pi\sum_{i=0}^{n}\alpha_i h_i q(t - iT)\right],$$
$$nT < t < (n+1)T$$

where:

- $\{\alpha_i\}$ represents a sequence of M-ary data symbols selected from the alphabet ±1, ±3, $\pm(M–1)$.
- M must have the form 2^K for some positive integer K, where M is the modulation order and specifies the size of the symbol alphabet.
- $\{h_i\}$ represents a sequence of modulation indices and h_i moves cyclically through a set of indices $\{h_0, h_1, h_2, ..., h_{H\text{-}1}\}$. When H=1, there is only one modulation index, h_0, which is denoted as h.

h_i specifies the modulation index. When h_i varies from interval to interval, the block operates in multi-h. To ensure a finite number of phase states, h_i must be a rational number.

Pulse Shape Filtering

Continuous phase modulation uses pulse shaping to smooth the phase transitions of the modulated signal. The function $q(t)$ is the phase response obtained from the frequency pulse, $g(t)$, through this relation: $q(t) = \int_{-\infty}^{t} g(t)dt$

The specified frequency pulse shape corresponds to these pulse shape expressions, $g(t)$.

Pulse Shape	**Expression**
`Rectangular`	$g(t) = \begin{cases} \dfrac{1}{2LT}, & 0 \le t \le LT \\ 0 & \text{otherwise} \end{cases}$
`Raised Cosine`	$g(t) = \begin{cases} \dfrac{1}{2LT}\left[1-\cos\left(\dfrac{2\pi t}{LT}\right)\right], & 0 \le t \le LT \\ 0 & \text{otherwise} \end{cases}$
`Spectral Raised Cosine`	$g(t) = \dfrac{1}{L_{main}T} \dfrac{\sin\left(\dfrac{2\pi t}{L_{main}T}\right)}{\dfrac{2\pi t}{L_{main}T}} \dfrac{\cos\left(\beta \dfrac{2\pi t}{L_{main}T}\right)}{1-\left(\dfrac{4\beta}{L_{main}T}t\right)^2}, \quad 0 \le \beta \le 1$
`Gaussian`	$g(t) = \dfrac{1}{2T}\left\{Q\left[2\pi B_b \dfrac{t-\frac{T}{2}}{\sqrt{\ln 2}}\right] - Q\left[2\pi B_b \dfrac{t+\frac{T}{2}}{\sqrt{\ln 2}}\right]\right\}$, where $Q(t) = \int_t^{\infty} \dfrac{1}{\sqrt{2\pi}} e^{-\tau^2/2} d\tau$
`Tamed FM` (tamed frequency modulation)	$g(t) = \frac{1}{8}\left[g_0(t-T) + 2g_0(t) + g_0(t+T)\right]$, where $g_0(t) \approx \dfrac{1}{T}\left[\dfrac{\sin(\frac{\pi t}{T})}{\frac{\pi t}{T}} - \dfrac{\pi^2}{24} \dfrac{2\sin\left(\frac{\pi t}{T}\right) - \frac{2\pi t}{T}\cos\left(\frac{\pi t}{T}\right) - \left(\frac{\pi t}{T}\right)^2 \sin\left(\frac{\pi t}{T}\right)}{\left(\frac{\pi t}{T}\right)^3}\right.$

- L_{main} is the main lobe pulse duration in symbol intervals.
- β is the rolloff factor of the spectral raised cosine.
- $B_b$is the product of the bandwidth and the Gaussian pulse.
- The duration of the pulse, LT, is the pulse length in symbol intervals. As defined by the expressions, the `Spectral Raised Cosine`, `Gaussian`, and `Tamed FM` pulse shapes have infinite length. For all practical purposes, LT specifies the truncated finite length.

For more information on pulse shape filtering, see [1].

Symbol Sets

In binary input mode, the block processing follows this procedure:

1. Maps each binary word to k, an integer from 0 to M–1. The binary word mapping options are `Binary` or `Gray`, as specified by the **Symbol set ordering** parameter.
2. Maps k to the intermediate value $2k–(M–1)$
3. Proceeds with block processing as in the integer input mode.

Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. In this mode, the input to the block can be multiple symbols. The block implicitly implements the rate change by making a size change at the output when compared to the input.

- When you set **Input type** to `Integer`, the input can be a scalar or a column vector with the length equal to the number of input symbols.
- When you set **Input type** to `Bit`, the input width must be an integer multiple of the number of bits per symbol.

The output width equals $N_{\text{Sym}} \times N_{\text{SPS}}$, where N_{Sym} is the number of symbols in the frame and N_{SPS} is the number of samples per symbol.

Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. In this mode, the input to the block must be one symbol.

- When you set **Input type** to `Integer`, the input must be a scalar.
- When you set **Input type** to `Bit`, the input width must equal the number of bits per symbol.

The output sample time equals T_{Sym} / N_{SPS}, where T_{Sym} is the symbol period and N_{SPS} is the number of samples per symbol.
